RESULTS: **Large morphometric variations were found along the small intestine. The wall thickness was highest in the proximal duodenum and decreased in distal direction along the axis of the small intestine (P<0.001). The circumferential length of the inner and outer surfaces decreased rapidly along the length of duodenum by 30-50% (P<0.001). The wall area and lumen area showed a similar pattern (P<0.001). In zero-stress state the rings always opened up after making the cut. The experiments resulted in larger inner circumferential length and smaller outer circumferential length when compared to the no-load state. The wall thickness and wall area did not differ between the no-load and zero-stress state. The opening angle and tangent rotation angle increased along the length of the duodenum and had its highest value 30% down the intestine. Further down the intestine it decreased again (P<0.001). The serosal residual strain was tensile with the highest value close to the ligament of Treitz (P<0.001). The mucosal residual strain was compressive in all segments of the small intestine with average values between -0.25 and -0.4 and with the lowest values close to the ligament of Treitz (P<0.001).**

CONCLUSION: **Axial variation in morphometric properties and residual strains were found in the small intestine. Existence of large residual strains indicates that the zero-stress state must be considered in future biomechanical studies in the gastrointestinal tract.**

INTRODUCTION

The gastrointestinal (GI) tract is a hollow muscular tube serving as a digestive organ. The small intestine transports, digests and absorbs nutrients. It extends from the pylorus to the caecum and comprises the duodenum, jejunum and ileum which merges into the large intestine at the ileocaecal valve. Our knowledge of GI motility has increased considerably during the last decades. Most data dealt with motility patterns, flow rates, peristaltic reflexes, and tone in sphincter regions[1-5]. The GI tract, like other hollow organs such as the heart, blood vessels, urinary bladder and the urethra, is functionally subjected to dimensional changes. Hence, biomechanical properties are of particularly functional importance. Data in the literature pertaining to the passive mechanical properties of small intestine were concerned with the length-tension relationship in circular and longitudinal tissue strips[6-8], the compliance[9], and the stress-strain relationship of the intact wall[10, 11]. However, a complete biomechanical analysis of GI physiology requires a full set of data describing the geometric properties and a valid reference state.

The zero-stress state of an organ is the state at which the organ is stress-free, meaning that all external and internal forces are removed. Thus, the morphometric properties are best described at the zero-stress state where no internal or external forces deform the tissue. Furthermore, knowing the zero-stress configuration is essential in any mechanical analysis since it serves as the reference state for computing stress and strain under physiological or pathophysiological conditions. Until 1983, it was believed that biological organs were free of stress when all external loads were removed (now known as the no-load state). Vaishnav and Vossoughi[12] and Fung[13] independently reported in 1983 that the no-load state of a blood vessel was not the zero-stress state. This was shown by an experiment where tissue rings that were cut radially opened up into sectors. The difference in stress and strain between the no-load and zero-stress state was called residual stress and strain, respectively, and it was found that the opening angle of the sector was a convenient way to quantitate the residual stress (Figure 1). Since then, a large number of studies have been published on the zero-stress state of different organ systems. The majority of these studies focused on the zero-stress state of systemic and pulmonary arteries, the heart and veins in normal animals and in various disease models such as experimental hypertension and diabetes and in venous grafts. Studies were also presented on the airway[14] and ureter[15].

The first data on residual strains and stresses in the gastrointestinal tract appeared in 1996[16]. Now we realize that the zero-stress configuration of the gastrointestinal tract is very different from that of the no-load condition and that the zero-stress state is sensitive to growth and remodeling by surgical resection (Dou *et al*, unpublished data). Gregersen *et al*[17] made an attempt to describe the geometry of the duodenum at the zero-stress state, and studied the strain distribution with reference to the zero-stress state in guinea pig duodenum using an elastomer casting method. It was found that the duodenum had very large opening angles and circumferential residual strains with axial variation. These studies opened up a whole new field of investigation in relation to gastrointestinal physiology and pathophysiology. The aims of the current study were to provide morphometric data at the no-load and zero-stress states of the entire

small intestine in rats and the axial distribution of residual circumferential strains.

MATERIALS AND METHODS

Eleven three-month-old male SD rats weighing 293±18g were included in this study. The rats were anaesthetised with pentobarbital sodium (100mg·kg^{-1}, ip). Following laparatomy, the calcium antagonist, papaverine (60mg·kg^{-1}) was injected into the lower thoracic aorta through a cannula (22G/25mm) in order to abolish contractile activity in the GI tract. After obtaining smooth muscle relaxation, the whole small intestine was harvested and 12 segments from various parts of the intestine were isolated. The most proximal segment was close to the pylorus whereas the most distal segment was close to the ileo-cacal valve. Within a short time, the residual contents in the lumen were gently cleared using saline. Then the segments were placed immediately into cold aerated Krebs solution containing 60g·L^{-1} dextran. Three rings, 1-2mm in length, were cut from each segment for no-load and zero-stress state tests. The rings were photographed in the no-load state using a video camera (SONY CCD Camera, Japan) and then cut radially on the anti-mesenteric side to obtain their zero-stress state (Figure 1). A60-min-period was allowed for equilibration and the specimens were photographed again. The selection of this time period was based on pilot experiments.

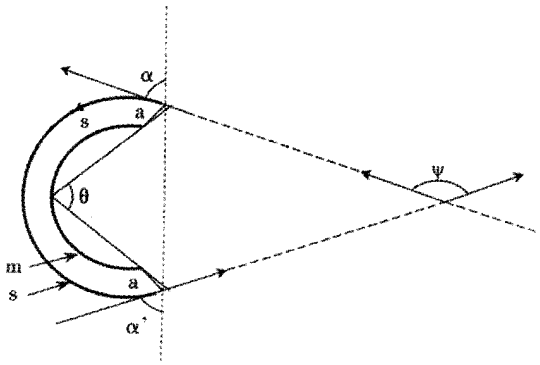

Figure 1 Definition of the zero-stress state. Traditionally, the zero-stress state is characterized by an opening angle defined as the angle subtended by two radii drawn from the mid-point of the inner wall to the inner tips of two ends of the sector in the zero-stress state. The opening angle is denoted by θ. The labels m and s denote the mucosal and serosal surfaces and a is the line cutting. The angle between the tip tangents, which is described in the text, is denoted by ψ. The angles between the tangents at the tip of the sector and the line joining the tips are designated as α and α', respectively. The mean value (α+α')/2 is referred to as the mean tangential angle.

Data Analysis

The morphometric data were obtained from the digitised images of the photographs of segments in the zero-stress and no-load states (Figure 2). Measurements were done using SigmaScan software (Jandel Scientific, Germany). The following data were measured from each specimen: the circumferential length (C), the wall thickness (h), the wall and lumen area, and the opening angle (α) at the zero-stress state. The subscripts i, o, n and z referred to the inner (mucosal) surface, outer (serosal) surface, no-load state and zero-stress state condition. The data from triplet of rings were averaged before further analysis.

Figure 2 shows a schematic of a tissue sector in the zero-stress state. The subtended angle is called the opening angle, θ, and is defined as the subtended angle between the two radii from the midpoint of the arc of the inner wall of the specimen to the inner tips of the sector.

The opening angle was a convenient measure but might not always be useful in practice. First, it required that both the no-load and the zero-stress state to be circular. However, neither configuration might be exactly circular. The opening angle is a measure of the angle between the two radii and does not account for the shape of the curve. It provides no information on the curvature of the wall. The angles between the tangents at the tip of the sector and the line joining the tips are designated as α and α', respectively (Figure 1). The mean value (α+α')/2 was referred to as the mean tangential angle. If the sector is exactly circular, then θ=(α+α')/2. The second difficulty with the opening angle is when its value exceeds 360°(i.e., the sector inverts inside out). Some organs such as the guinea-pig duodenum often have θ greater than 360°[17]. The geometry of the duodenum at the zero-stress state can also be characterized by the angle between the two tangents of the tip, ψ, as shown in Figure 1. ψ refers to the angle between the tip tangents. The value of ψ is relatively independent on where the cuts are made in the ring and does not require the no-load or zero-stress shape to be circular (see reference 18).

The measured data was used for computation of residual strains defined as:

Residual Green's strain at the mucosal surface: $\varepsilon_i=(C_{i\text{-}n}/C_{i\text{-}z})-1/2$

Residual Green's strain at the serosal surface:$\varepsilon_o=(C_{o\text{-}n}/C_{o\text{-}z})-1/2$

Thus, from the circumferential lengths at the no-load and zero-stress state, we can compute the circumferential residual strain, at the mucosal and serosal surfaces in the sense of green. Green strain is used when large deformations are encountered as in this study. Negative strain implies that the tissue is in compression whereas positive strain implies extension.

Statistical Analysis

The data were representative of a normal distribution and accordingly the results were expressed as mean±SD unless otherwise stated. Analysis of variance was used to detect possible variations in axial direction of the small intestine and between no-load and zero-stress state (Sigmastat 2.0™). In case of significance, data were evaluated in pairs by a multiple comparison procedure Student-Newman-Keuls method. If the normality test or the equal variance test failed, Kruskal-Wallis one-way analysis of variance on ranks was used. The results were regarded as significant when $P<0.05$.

RESULTS

Representative images of rings in the no-load state and after cutting into the zero-stress state are illustrated in Figure 2. Figure 3 presented the morphometric data measured from the photographs of the segments in the no-load state and zero-stress state. In the no-load state (Figure 3A), the wall thickness was highest in the proximal duodenum (average value approximately 1.2mm) and decreased in distal direction along the axis of the small intestine to a value close to 0.6mm (f=66.48, $P<0.001$). The circumferential length and the inner and outer surfaces decreased rapidly along the length of duodenum by 30-50% in both no-load state and zero-stress state (Figure 3B, inner, f=22.46 and $P<0.001$; outer, f=37.68 and $P<0.001$). The wall area and lumen area showed a similar pattern (Figure 3C, wall area, f=43.43 and $P<0.001$; Lumen area, f=12.50 and $P<0.001$). The wall thickness-to-inner circumferential length ratio increased along the length of duodenum after it decreased continuously towards the distal ileum (Figure 3D. f=38.52 and $P<0.001$). The highest average value was found close to the ligament of Treitz (0.21) and the lowest value of 0.08 was found close to the ileo-caecal valve.

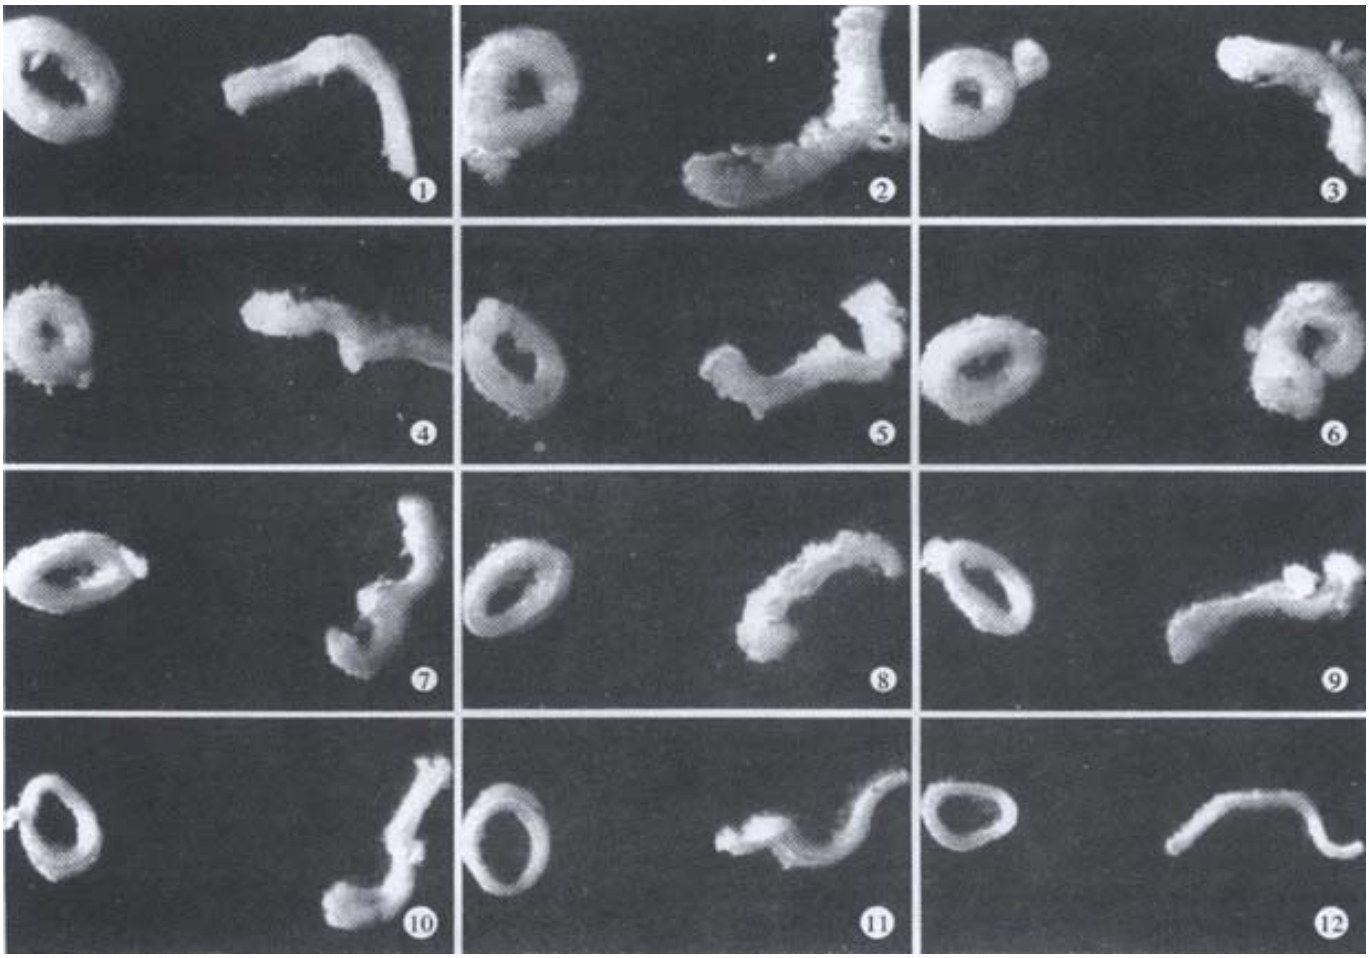

Figure 2 Photographs showing specimens obtained from different locations in the intestine in the no-load state (left, closed rings) and the zero-stress state (right, open sectors). The rings of jejunum (site 5 to site 8) turned inside out when cut open.

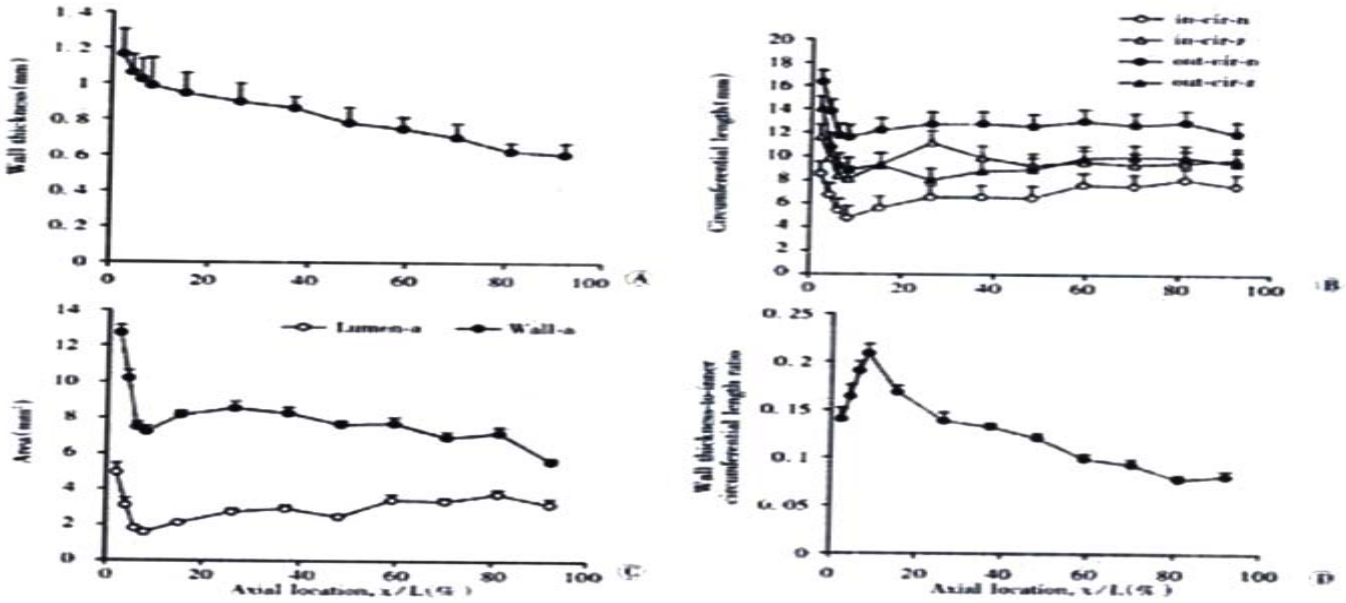

Figure 3 Photographs showing morphometry of rat small intestine including wall thickness in the no-load state (A), inner and outer circuferential length in the no-load state and zero-stress state (B), the wall and lumen area in the no-load state (C) and wall thickness-to-inner circumferential length ratio (D). Values are (S. Variation of all morphometric parameters related to location along the axis of the small intestine was found (P<0.001).

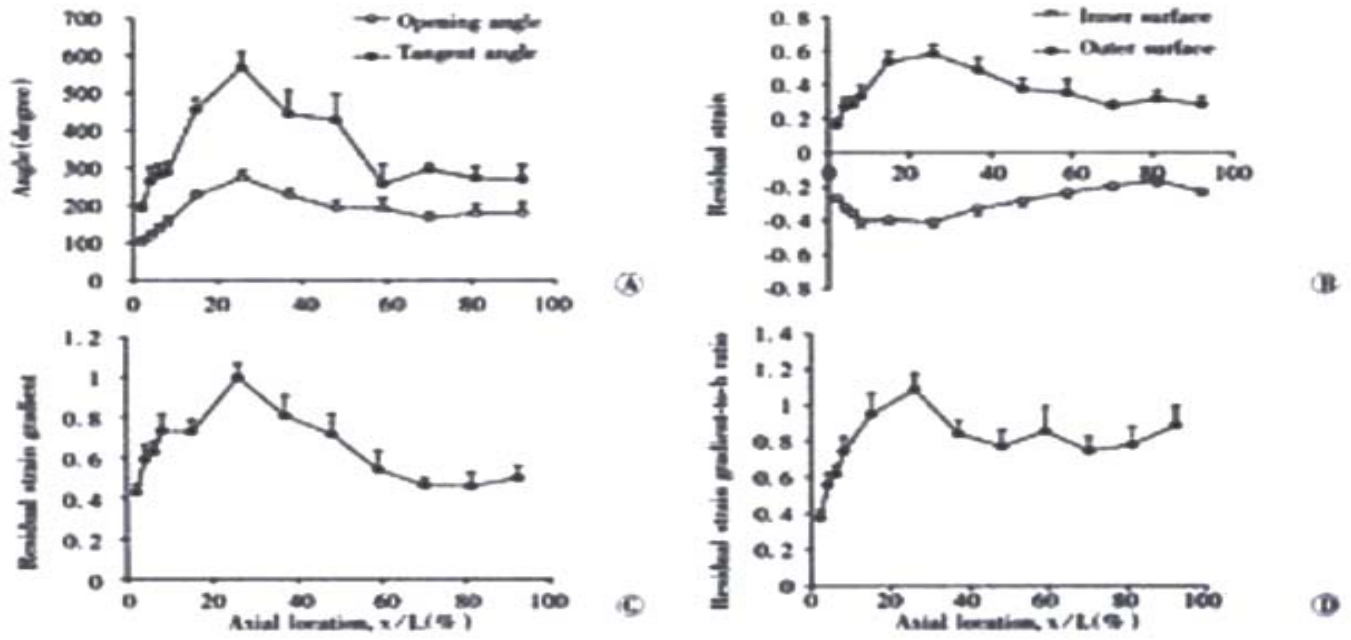

Figure 4 Photographs showing (A) the distributions of the opening angle and tangent rotation angle, (B) residual strains at the mucosal and serosal surfaces, (C) the residual strain gradient and (D) residual strain gradient normalised with respect to the wall thickness (h). Values are $x \pm s$. A significant variation was found along the small intestine for all variables ($P<0.001$).

In the zero-stress state, the rings always opened up after making the cut. This resulted in larger inner circumferential length and smaller outer circumferential length when compared to the no-load state. Otherwise, the wall thickness and wall area did not differ between the no-load and zero-stress state ($P>0.5$). The distributions of the opening angle and residual strains at the mucosal and serosal surfaces are shown in Figure 4. The opening angle and tangent rotation angle increased along the length of the duodenum and had its highest value 30% down the intestine. They decreased again further down the intestine (opening angle, f=9.07 and $P<0.001$; tangent rotation angle, f=11.95 and $P<0.001$). The opening angle attained values higher than 180 degrees in the jejunum and ileum, meaning that the rings turned themselves inside-out (Figure 4A). The serosal residual strain was tensile with the highest value close to the ligament of Treitz (approximately 0.6) and decreased to approximately 0.3 in the distal ileum (Figure 4B, f=5.20 and $P<0.001$). The mucosal residual strain was compressive in all segments of the small intestine with average values between -0.25 and -0.4. A significant variation was found along the small intestine with the lowest values close to the ligament of Treitz (f=8.17 and $P<0.001$). The curve for the residual strain gradient (i.e. the difference between mucosal and serosal residual strains) showed a pattern similar to that for the tangent rotation angle (Figure 4C, f=7.11 and $P<0.001$). Furthermore, the residual strain gradient normalised as the wall thickness increased rapidly along the length of the duodenum from average values of 0.4 to 1.1 and dropped to a constant level of approximately 0.8 in more distal parts of the small intestine (Figure 4D, f=4.43 and $P<0.001$).

DISCUSSION

Mechanical properties are important for cardiovascular[18,19] and urogenital function[15,20]. The GI tract is similar to these organs in which it is functionally subjected to changes in wall stresses and strains. Therefore, during the last decade, acquiring biomechanical information in the digestive tract has increasingly called attention. Some studies have provided data on the small intestine[9-11, 17]. However, many aspects are still left largely unexplored. With respect to biomechanics of the small intestine, we still lack a database on its geometry to fulfil a detailed biomechanical analysis of small intestinal physiology. Moreover, our knowledge about the small intestine at the zero-stress state is very limited. Gregersen H *et al*[17] provided the first data on the zero-stress state of the guinea pig duodenum. The current study aimed to describe the morphometry at the no-load and zero-stress states of the small intestine and to analyse the residual strain in the small intestine. The duodenal residual strains obtained in pigs[21] and rats in this study are less than that in the guinea-pig. In general, the opening angle in pigs and rats is not larger than 360 degrees.

Our results demonstrated large axial variations of all the morphometric parameters. The outer circumferential length and the luminal area increased whereas the wall thickness decreased in distal direction. A decrease in wall thickness is in line with findings in prior studies[22, 23]. When radial cuts were made, the rings from the proximal small intestine were more likely to turn inside out resulting in a larger opening angle and larger residual strains than those in the jejunal and ileal rings. In accordance with observations in other hollow organs, the circumferential residual strain in the small intestine was compressive at the inner wall and tensile at the outer wall. From the mechanical point of view, a large residual strain may be nature's way to resist luminal pressures. The present study showed that the small intestinal mucosa at the no-load state was under compression and with axial variation from duodenum to ileum. This variation seems to correlate to morphometric variation along the small intestine[22]. In this sense we hypothesise that the compressed duodenal mucosa might be better protected against injury from frequent pressure changes produced by frequent contractions and the rush of luminal contents ejected at intervals from the stomach. By contrast, the less compressed ileal mucosa fulfils the protection in a region under relatively lower and stable pressure. From our studies, it is evident that a gradient in residual stress and strain exists and that the mucosal and submucosal layers are in compression. It still remains to be investigated whether mucosal growth is determined by the compression induced by residual

stresses or whether the residual stress largely is a result of mucosal growth. It is of interest to notice that Rodriguez *et al*[24] predicted how volumetric tissue growth altered residual stress. Particularly, it was predicted that concentric hypertrophy (increase in wall thickness-to-radius ratio) increased residual stress and strain. The prediction is in accordance with the data in this study (comparison of Figure 3D with Figure 4).

Our previous data showed that the duodenal wall was stiffer than the jejunal and the ileal wall in circumferential direction. That is, the elastic properties differed among the small intestinal segments. The differences in stiffness may be associated with the specialised functions of the proximal and distal segments of the small intestine. The duodenum has a large influence on gastric emptying and has been proposed to act as a capacitative resistor[25], whereas the distal ileum acts as a reservoir[4]. The transit time is slower distally[1], which may be partly explained by the difference in the viscosity of the chyme. However, the passive elastic properties may also contribute to differences in intestinal flow patterns: a passing bolus will be slowed to a lesser degree in the duodenum where the wall stiffness is high whereas the compliant ileal walls bulges lead to pooling of luminal contents and decreased flow. Though we find the highest residual strains in the proximal small intestine, the association between the stiffness[9] and the residual strains found in this study does not seem that the mechanism is clear cut and further investigation is needed.

There are several important implications of the zero-stress state, some of which are, as yet, hypothetical. It is clear from the above discussion that using any state other than the zero-stress state will lead to error in the computed stresses and strains. Analysis of strain must refer to the zero-stress state in order to compare the specimens obtained from different locations of the GI tract in different species, and in remodeling induced by diseases, growth or degeneration. Furthermore, since the zero-stress state is not influenced by external or internal forces, it provides a standard state for describing tissue morphology.

All GI studies done thus far show that the rings open into sectors when cut radially. This implies that the mucosa is under compression in the no-load state (and at physiological conditions in the low pressure range) whereas the muscle layers are in tension. The residual tension in the muscle may provide a more optimum length for muscle contraction. It has been demonstrated that residual stress reduces the stress concentration at the inner wall of the GI tract at no-load and homeostatic states[17, 21, 26, 27]. Thus, the compressed mucosa may be better protected against injury from the flow of luminal contents than uncompressed mucosa. These protection mechanisms could be important when unphysiologically high pressures are reached, such as in mechanical obstruction. Since peristaltic bolus transport bulges out the intestinal wall in the vicinity of the bolus[28,29], the residual strain would likely influence the resistance to bolus flow under normal conditions. Since residual strains exist, the mucosa will inevitably be under compressive stress and strain in the no-load condition, for instance, where the transmural pressure is zero. The GI muscles are usually passive since phasic contractions occur infrequently[30]. We may also ask if there are any other functions of the mucosa compression than those mentioned above It is well known that the mucosa is one of the tissues with the fastest turnover rate. The fast growth of the mucosal surface could easily cause mucosal compression and hence explain the presence of large residual strains. Likewise the large compressive stresses may affect mucosal growth. Studies on the intestine and other organs have shown that mechanical stresses are important factors in regulating gene expression and growth[31] (Gregersen *et al*., unpublished data). Well-known examples are cardiac hypertrophy caused by hypertension and muscle atrophy in space flight. Theoretically, absorption of luminal contents may also be affected by the residual compression. It is well known that a gradient in the height of the mucosal villi exists along the small intestine, with the highest villi found in the proximal duodenum[23], and that small intestinal absorption depends on the luminal pressure[32]. Thus, there may exist a correlation between the residual strain gradient and the gradient in the height of villi. These interesting aspects of small intestinal function should be the focus of future studies.

Other important issues pertain to the function of the mechanoreceptors (endings of the sensory afferent nerves) in the gastrointestinal wall. Such receptors include noci-sensitive receptors and receptors in the peristaltic reflex pathway. It is well known that the receptors are located both in the submucosa and in the muscle layers. We have shown that a strain gradient exists from the mucosa to the serosa of the wall under physiological conditions. This suggests that the population of receptors from different locations in the wall may have different zero-settings and respond differently to the same stimuli. A difference in the responses of mucosal and muscle receptors to stimuli has in fact been observed[33]. The present results emphasize the importance of studying the receptor kinematics by using experimental models on the intact organ approximating the *in vivo* conditions. Data on receptor kinematics obtained from tissue strips or otherwise cut-open segments would likely give erroneous results.

Differences in morphometric properties and residual strains were found between rat duodenum, jejunum and ileum. Existence of a large residual circumferential strain indicates that the zero-stress state must be considered in future biomechanical studies. Residual stress may affect the tissue remodeling in response to disease and interventions by varying the stress distribution in the organ. The data on residual strains in the GI tract and the non-uniform remodeling may be used to improve surgery (for example, the procedures may be designed to prestress the tissue to make it more resistant to injury).

Abstract

AIM: **Using bacterial, yeast, or mammalian cell expressing a human drug metabolism enzyme would seem good way to study drug metabolism-related problems. Human cytochrome P-450 2C9(*CYP2C9*) is a polymorphic enzyme responsible for the metabolism of a large number of clinically important drugs. It ranks among the most important drug metabolizing enzymes in humans. In order to provide a sufficient amount of the enzyme for drug metabolic research, the *CYP2C9* cDNA was cloned and expressed stably in CHL cells.**

METHODS: **After extraction of total RNA from human liver tissue, the human *CYP2C9* cDNA was amplified with reverse transcription-polymerase chain reaction (RT-PCR), and cloned into cloning vector pGEM-T. The cDNA fragment was identified by DNA sequencing and subcloned into a mammalian expression vector pREP9. A transgenic cell line was established by transfecting the recombinant vector of pREP9-*CYP2C9* into CHL cells. The enzyme activity of *CYP2C9* catalyzing oxidation of tolbutamide to hydroxy tolbutamide in S9 fraction of the cell was determined by high performance liquid chromatography(HPLC).**

RESULTS: **The amino acid sequence predicted from the cDNA segment was identical to that of *CYP2C9**1, the wild type *CYP2C9*. However, there were two base differences, i.e. 21T>C, 1146C>T, but the encoding amino acid sequence was the same, L7, P382. The S9 fraction of the established cell line metabolizes tolbutamide to hydroxy tolbutamide; tolbutamide hydroxylase activity was found to be 0.465±0.109 μmol·min^{-1}·g^{-1} S9 protein or 8.62±2.02mol·min^{-1}·mol^{-1} CYP, but was undetectable in parental CHL cell.**

CONCLUSION: **The cDNA of human *CYP2C9* was successfully cloned and a cell line of CHL-*CYP2C9*, efficiently expressing the protein of *CYP2C9*, was established.**

Zhu GJ, Yu YN, Li X, Qian YL. Cloning of cytochrome P-450 2C9 cDNA from human liver and its expression in CHL cells. *World J Gastroenterol* 2002; 8(2) :318-322

INTRODUCTION

Cytochrome P-450 (CYP) is a heme-containing enzyme widely distributed from bacteria to mammals, which catalyzes oxidative or reductive metabolism of a wide variety of substances including endogenous as well as exogenous compounds. Mammalian CYP present in liver microsomes is one of the key enzymatic mechanisms for the matabolism of drugs, pesticides, environmental pollutants, and carcinogens[1]. Mammals possess at least 17 distinct CYP gene families that together code for an estimated 50-60 individual CYP genes in any given species[2]. The human CYP2C subfamily comprises four members, *CYP2C8*, *CYP2C9*, *CYP2C18* and *CYP2C19*[3], accounting for 20% of the total CYP in human liver. *CYP2C9* is a polymorphic enzyme responsible for the metabolism of a large number of clinically important drugs such as S-warfarin, phenytoin, tolbutamide, torsemide, losartan, fluoxetine, dapsone[4], cyclooxygenase-2 inhibitor: celecoxib[5,6], nonpeptide angiotensin II receptor antagonist: irbesartan[7] and numerous nonsteroidal anti-inflammatory drugs. It ranks among the most important drug metabolizing enzymes in humans[8].

The combination of gene technology and cell culture technology has provided new opportunities for studying proteins because any gene from any species encoding an protein may be cloned and expressed in bacterial, yeast, or mammalian cells in a defined way[9-18]. This approach to drug metabolism is of particular importance because some of the enzymes are difficult to purify and prepare in sufficient quantities, or expression levels are low, expression is organ-specificity, or the enzyme-product organs are very scarce. These restrictions apply especially for human enzymes. The heterologous expression of the cDNA allows to bypass these restrictions[19]. Human *CYP2C9* previously has been expressed in E. *coli*[20], Salmonella typhimurium[21], yeast[22] COS-1[3], human liver epithelial cell THLE[23], and human hepatic cell line HepG2[24]. Several cell lines stably expressing human CYP1A1[25], CYP2B6[25], CYP2A6[26], CYP3A4[27], *CYP2C18*(in press) and a phase II metabolism enzyme UDP-glucuronosyltransferase, UGT1A9[28] have been established in our laboratory. In this study human *CYP2C9* cDNA was amplified with reverse transcription-polymerase chain reaction (RT-PCR), and a transgenic cell line stably expressing *CYP2C9* was established.

MATERIALS AND METHODS

Materials

Restriction endonucleases, Moloney murine leukemia virus (M-MuLV) reverse transcriptase were purchased from MBI Fermentas AB, Lithuania. Taq plus I DNA polymerase, dNTPs, PCR primers, DNA sequence primers and random hexamer primer were supplied or synthesized by Shanghai Sangon Biotechnology Corp. DNA sequencing kit was supplied by Perkin-Elmer Corp. The TRIzol reagent, G418, minimum essential media(MEM) and newborn bovine calf sera from Gibco. NADPH from Roche Molecular Biochemicals. Diethyl pyrocarbonate (DEPC), tolbutamide and hydroxytolbutamide were obtaineded from Sigma Chemical Company. T4 DNA ligase and pGEM-T vector system were supplied by

Promega. Other chemical reagents used were all of analytical purity from commercial sources.

Methods

Cloning of human CYP2C9 cDNA from a Chinese human liver

The total RNA was extracted from a surgical specimen of human liver with TRIzol reagent according to the manufacture's instructions, and then the first strand of cDNA was reverse transcripted from mRNA. Procedure: 5μg of the total RNA and 2μg of random hexamer primer in deionized DEPC-treated water were denatured at 65℃ for 15min, then 4μL 5×reverse transcription buffer, 3μL 10mmol·L^{-1} dNTP, 1μL M-MuLV reverse transcriptase (200u) and essential deionized DEPC treated water was added to a total volume of 20μL. The reaction was performed at 25℃ for 10min, then at 42℃ for 1h, and finally at 70℃ for 10min to inactivate reverse transcriptase. The reactant then was stored at 4℃. To amplify the human *CYP2C9* cDNA by PCR, 2μL of the reactant were mixed with 2μL of 10mmol·L^{-1} each of dNTPs, 20pmol of PCR primers and 4u of Taq plus I DNA polymerase in 1×PCR buffer containing 1.5mmol·L^{-1} $MgCl_2$. A total volume of 100μL was reached by adding deionized water. Two specific 32 mer and 28 mer oligonucleotide PCR primers were designed according to the cDNA sequence of *CYP2C9* clone 25 reported by Romkes *et al*[3] (GenBank accession no. M61855, J05326). The sense primer corresponding to base position 1 to 32 was 5'-GAGAAGGTACCAATGGATTCTCTTGTGGTCCT- 3', with a restriction site of *Kpn* I, and the anti-sense one, corresponding to the base position from 1513 to 1540, was 5'-AGAGGAAAGAGAGCTCGAGGGACTGCAC-3' with a restriction site of *Xho* I. The PCR was performed at 94℃ 2min, then 35 cycles of 94℃ 60s, 60℃ 60s, 72℃ 2min, and lastly 72℃ 10min. The product was stored at 4℃. An aliquot of 10μL from the PCR was subjected to electrophoresis in a 10g·L^{-1} agarose gel stained with ethidium bromide.

Construction of recombinant pGEM-CYP2C9 and sequencing of CYP2C9 cDNA[29]

The PCR product of about 1.5 kb in length, recovered and purified by electroelution into dialysis bag was ligated with a clone vector, pGEM-T (Promega), by T4 DNA ligase. E.coli DH5α was transformed with the resulted recombinant pGEM-*CYP2C9* and the replicated plasmid was harvested from the bacteria screened by ampicillin resistant and blue-white selection with X-gal and IPTG. The cDNA of *YP2C9* cloned in pGEM-T was sequenced on both strands by dideoxy chain-termination method marked with BigDye with primers of T7 and SP6 promoters and two specific primers of 5'-TGCCTTGTGGAGTTG-AGA-3'(463-483),and 5'-ACAGAGACGACAAGCACAAC -3' (907-926). The termination products were resolved and detected using an automated DNA sequencer (Perkin-Elmer-ABI Prism 310).

Construction of the pREP9 based expression plasmid for CYP2C9

The *Kpn* I/ *Xho* I fragment of the human *CYP2C9* cDNA cleaved from the recombinant pGEM-*CYP2C9* recovered and purificated by electroelution into dialysis bag was cloned directly into a unique site *Kpn* I/ *Xho* I within the multiple cloning sites of the mammalian expression vector pREP9 (Invitrogen) with T4 DNA ligase. The recombinant was transformed to *E. coli* Top 10, and screened by ampicillin resistant. The recombinant was identified by restriction mapping.

Transfection and selection[29]

Chinese hamster lung(CHL) cells were transfected with the resultant recombinant, pREP9-*CYP2C9*, using a modified calcium phosphate method. After 24h incubation in MEM containing 10% newborn bovine calf sera at 37℃, the culture was rinsed and re-fed with fresh growth medium. After 72h post-transfection, the culture were split and then selected in the culture medium containing the neomycin analogue G418 (400mg·L^{-1}). The selective medium was changed every 3-4d to remove dead cells and to allow the growth of resistant colonies. After 1mo, surviving colonies (termed CHL-*CYP2C9*) were harvested as a pool and propagated in medium containing G418.

Preparation of S9 of CHL-CYP2C9

CHL-*CYP2C9* cells grown in the culture medium containing G418 (400mg·L^{-1}) were rinsed with phosphate balanced solution (PBS), scraped and collected from the bottle with 11.5g·L^{-1} KCl aqua solution and then sonicated in 200W, 5 s for 10 times with 10s of interval break. The resulted homogenate was centrifuged at 9000g at 4℃ for 20min and the postmitochondrial supernatant (S9) was transferred carefully to a clean tube for assay or storage under -70℃. The protein in S9 was determined by the method described by Lowry *et al*, with bovine serum albumin as standard. CYP was measured spectrally using the method of Johannesen *et al*[30].

Tolbutamide hydroxylase assay[22,31]

The *CYP2C9* tolbutamide hydroxylase activity of S9 fraction was determined by high performance liquid chromatography (HPLC). The assay was performed in a total volume of 500μL containing final concentrations of 5mmol·L^{-1} HEPES (pH 7.4), 1.5mmol·L^{-1} $MgCl_2$, 0.1mmol·L^{-1} EDTA, 0.25mg S9 and 1mmol·L^{-1} sodium tolbutamide. The reaction was initiated with 0.5mmol·L^{-1} NADPH and terminated after 60min at 37℃ by the addition of 50μL of 4mmol·L^{-1} HCl. Reaction product was extracted by vortex-mixing of 3mL of water-saturated ethyl acetate with the mixture for 2min. The organic layer was collected after centrifugation in a table top centrifuge at 1000g for 5min. After most of the ethyl acetate extract had air-dried, the rest was removed in a heating block at 75℃. The residue was resolubilized in 200μL of methanol, and reaction product, hydroxytolbutamide was then assayed using HPLC by injecting 20μL of the solubilized extract on to a reversed phase column (Shim-pack CLC-ODS 15cm×0.6cm id, 10μm particle size), using 0.5g·L^{-1} phosphoric acid, pH 2.6, acetonitrile (6:4/V:V) as the mobile phase with a flow rate of 1mL·min^{-1}. The column elution was monitored at 230nm, and rates of product formation were determined from standard curves prepared by adding varying amounts of hydroxytolbutamide to incubations conducted without NADPH.

RESULTS

Construction of recombinants

The recombinant of pGEM-*CYP2C9* (Figure 1) was constructed with the human *CYP2C9* cDNA inserted into the cloning site of vector pGEM-T between the promoters of T7 and SP6. Selection and identification of the recombinant was carried out by *Kpn* I/*Xho* I endonuclease digestion and agarose gel electorphoresis (Figure1). The cloned cDNA segment was sequenced. In comparison with the CYP2C9 clone 65 cDNA sequence reported by Romkes *et al*[3] (GenBank accession no. M61857, J05326), our preparation showed two base differences, i.e. 21T>C, 1146C>T, but the encoding amino acid sequence was the same, *i.e.* L7, P382 respectively.

The *Kpn* I/*Xho* I fragment (1.5 kb) containing the complete *CYP2C9* cDNA was subcloned into the *Kpn* I/*Xho* I site of mammalian expression vector pREP9 (Figure 2). Selection and identification of the recombinants were carried out by *Kpn* I/*Xho* I endonuclease digestion and agarose gel electrophoresis (Figure 2). The resulting plasmid was designated as pREP9-*CYP2C9* and

contained the entire coding region, along with 2 bp of the 5'end and 41 bp of the 3'end untranslated region of the *CYP2C9* cDNA, respectively.

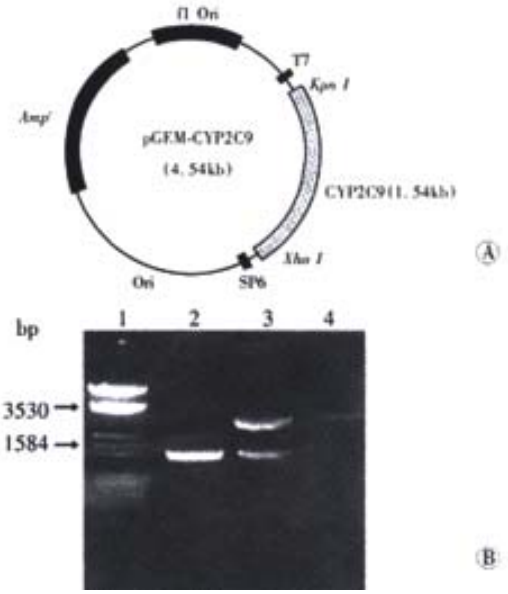

Figure 1 Scheme and electrophoresis identification of recombinant pGEM-*CYP2C9*. Establishment of transgenic cell lines with CYP2C9 enzyme activity

CHL cells were transfected with pREP9-*CYP2C9*, and selected with G418 (400mg·L^{-1}). The surviving colonies were propagated and a cell line termed CHL-*CYP2C9* was established. The tolbutamide hydroxylase activity of *CYP2C9* in S9 fraction of CHL-*CYP2C9* cells was assayed by HPLC.A typical elution profile of hydroxytolbutamide in extracts is shown (Figure 3). *CYP2C9* enzyme activity with tolbutamide was found to be 0.465±0.109μmol·min^{-1}·g^{1} S9 protein or 8.62±2.02mol·min^{-1}·mol^{-1} CYP (n=3), but none was detectable in parental CHL cells. The CYP content was 57.7nmol·g^{1} S9 protein from CHL-*CYP2C9* but no detectable CYP was present in CHL cell.

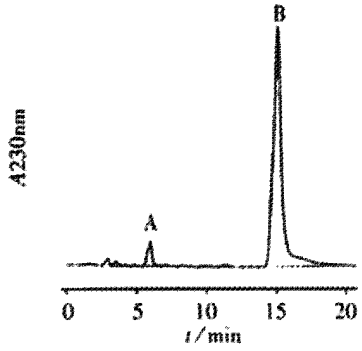

Figure 3 Representative chromatogram of extractsA Shim-pack CLC-ODS column (15cm×0.6cm i.d.) was used. The mobile phase was constituted with phosphoric acid (pH 2.6), acetonitrile (6:4/V:V) with the flow rate at 1mL·min^{-1}. Hydroxytolbutamide was monitored at 230nm. A: hydroxytolbutamide; B: tolbutamide

DISCUSSION

Direct cloning of human *CYP* cDNAs from cDNA libraries generally has been successful using anti-rodent or anti-human *CYP* antibodies and rodent *CYP*cDNA probes. But these cloning procedures are applicable only for the most abundantly expressed *CYP* mRNAs. Using the RT-PCR to clone low abundance *CYP*cDNA is a simple and direct method. *CYP2C9* mRNA was present in human liver[32], HepG2 cells[33], kidney, testes, adrenal gland, prostate, ovary, duodenum[34], and brain tumors[35]. The pGEM-T vector system possesing single 3'-T overhangs at the insertion site greatly improves the efficiency of ligation of a PCR product into the plasmid by preventing recircularization of the vector and providing a compatible overhang for PCR products generateed by Taq Plus I DNA polymerases.

The human *CYP2C9* gene is located on chromosome 10q24. Up to date, 12 *CYP2C9* alleles have been identified (see: Table 1 and *CYP2C9* alleles nomenclature http://www.imm.ki.se/CYPalleles/cyp2c9.htm). *CYP2C9**1 is the wild type of human *CYP2C9*. *CYP2C9**2 exhibit a base substitute 430C>T, resulting in a R144C substitution which has been suggested to affect the interaction between the CYP enzyme molecule and the cytochrome P450 reductase[36]; this may explain the slower metabolism of some *CYP2C9* substrates such as S-warfarin and tolbutamide[8, 37]. *CYP2C9**3 has a base substitute 1075A>C, which leads to an I359L substitute. Takanashi *et al*[38] expressed the *CYP2C9**1 and *CYP2C9**3 cDNA in yeast and examined the kinetics of seven individual metabolic reactions by wild-type *CYP2C9**1 and its *CYP2C9**3 variant. Their results indicated that the I359L exchange significantly reduces the catalytic activity with all *CYP2C9*-mediated substrates studied, although the extent of the reduction in activity and kinetic parameters varied between different substrates. Interestingly Kidd *et al*[39] reported a male Caucasian, homozygous for *CYP2C9**3, who poorly metabolized phenytoin and glipizide/tolbutamide. This study establishes that the I359L mutation is responsible for the poor metabolizer phenotype. The *CYP2C9**2 and *CYP2C9**3 are responsible for the poor metabolizing celecoxib[5], losartan[40], torsemide[41]. *CYP2C9**4[42] has a base substitute of 1076T>C,

leading to a I359T substitution. Ieiri *et al*[43] evaluated the catalytic activity of three variants (I, L, and T) at codon 359 of *CYP2C9* enzymes expressed in a yeast cDNA expression system. The specific catalytic activities were assessed by diclofenac-4'-hydroxylation. The *in vitro* study revealed that recombinant I359, L359, and T359 (2 batches) exhibited a mean Km of 2.0, 16.5 and (3.8 and 2.9) μmol and Vmax of 12.4, 17.9 and (4.4 and 5.1) nmol·min^{-1}·nmol^{-1}*CYP*, respectively. The *CYP2C9**5 variant is derived from a 1080C>G transversion in exon 7 of *CYP2C9* that leads to a D360E substitution in the encoded protein[44]. The *CYP2C9**5 variant was found to be expressed in African-Americans with a frequency of approximately 3% in this population group. This variant was expressed in, and purified from, insect cells infected with a recombinant baculovirus. The *in vitro* data suggest that carriers of the *CYP2C9**5 allele would eliminate *CYP2C9* substrates at slower rates compared to individuals expressing the wild-type protein[44]. Kidd *et al*[45] reported a new *CYP2C9* allele (*CYP2C9**6) with the deletion of an adenine at base pair 818 of the cDNA. The clearance of phenytoin in this individual is estimated to be approximately 17% of that observed in normal patients. The frequency of this allele was 0.6% in 79 African-Americans and 0% in 172 Caucasians. Shintani *et al*[46] reported that mutations in the 5'-flanking region of the human *CYP2C9* gene appear to contribute to the large interindividual variability in drug metabolism activity. Compared with *CYP2C9**1 cDNA, there are two base differences in the *CYP2C9* cDNA cloned by us, but the encoded amino acid sequence remains unchanged. This obviously is the molecular basis for full enzymatic activity.

Table 1 Nomenclature and characteristics of CYP2C9 alleles

Allele	Protein	Nucleotide changes	Effect	Enzyme activity		References
				In Vivo	*In vitro*

*CYP2C9*7-*12*						*In press*

To express the functional activity of a CYP, a cell evidently must have adequate heme supply, either by intracellular biosynthesis or extracellular provision[47]. CYPs also require other enzymatic components for full activity, including the flavoprotein NADPH-P450 oxidoreductase (OR) and, in some cases, cytochrome b_5. The OR must interact directly with the CYP to transfer the required two electrons from NADPH. Cytochrome b5 is necessary for increasing electron transfer for certain CYP forms and specific substrates. The CHL is the cell line originally derived from the lung of a newborn female Chinese hamster and has no or very limited activities of CYP enzymes, but has adequate OR and cytochrome b5 levels to support CYP activities.

To achieve high expression levels of *CYP2C9*, the *CYP2C9* cDNA was cloned into the eukaryotic expression vector pREP9, which had previously been used in this laboratory for the expression of human CYP1A1, CYP2B6, CYP2A6, CYP3A4 and UGT1A9 in CHL cells[25-28]. The salient feature of this vector has an Epstein Barr Virus origin of replication and nuclear antigen (EBNA-1) to allow high-copy episomal replication in mammal cell lines. The Rous sarcoma virus long terminal repeat (RSV LTR) early promoter controls the expression of the *CYP2C9* cDNA.

Tolbutamide (1-butyl-3-p-tolylsulfonylurea) is an oral hypoglycemic agent which is being used in the treatment of diabetes. In humans it undergoes CYP-catalyzed hydroxylation of the tolyl methyl group which is the initial and rate-limiting reaction followed by further oxidation by cytosolic dehydrogenases yielding carboxytolbutamide. Overall this pathway accounts for up to 85% of tolbutamide clearance in humans. Evidence that *CYP2C9* is solely responsible for tolbutamide hydroxylation is convincing and tolbutamide is widely accepted as a prototypic substrate for the assessment of hepatic *CYP2C9* activity, both *in vitro* and *in vivo*[8].

We used tolbutamide as a substrate for evaluating the expressing of human CYP2C9 activity in CHL-*CYP2C9* cell. The tolbutamide hydroxylase activity was 0.465±0.109μmol·min^{-1}·g^{-1} S9 protein or 8.62±2.02mol·min^{-1}·mol^{-1} *CYP*. These value, were somewhat higher than these obtained with recombinant *CYP2C9* purified from *E. coli*: 4.67-4.96nmol·min^{-1}·nmol^{-1} *CYP*[48] or human liver microsomes: 0.189±0.0083nmol·min^{-1}·mg^{-1} microsome[49] and 2.29-4.33nmol·min^{-1} ·nmol^{-1} CYP[48]. This clearly stated that CHL-*CYP2C9* expressed the *CYP2C9* efficiently and this may be a useful tool for further studies of its enzymatic function and mechanism.

Abstract

AIM: **To display the thermoimages of the body surface in experimental cholecystitis, to observe the body surface temperature reaction in visceral disorders, and to study if the theory of body surface-viscera correlation is true and the mechanism of temperature changes along the meridians.**

METHODS: **By injecting bacteria suspension into the stricture bile duct and gallbladder, 21 rabbits were prepared as acute pyogenic cholangiocholecystitis models, with another 8 rabbits prepared by the same process except without injection of bacteria suspension as control. The body surface infrared thermoimages were continuously observed on the hair shaven rabbit skin with AGA-782 thermovision 24h before, 1-11d after and (2,3wk) 4wk after the operation with a total of over 10 records of thermoimages.**

RESULTS: **Twelve cases out of 21 rabbits with cholecystitis revealed bi-lateral longitudinal high temperature lines in its trunk; with negative findings in the control group. The high-temperature line appeared on d1-d2, first in the right trunk, after the preparation of the model, about 7d after the model preparation, the lines appeared at the left side too, persisting for 4wk. The hyper-temperature line revealed 1.1-2.7℃ higher than before the model preparation, 0.7-2.5℃ higher than the surrounding skin. The length of the high temperature line might reach a half length of the body trunk, or as long as the whole body itself.**

CONCLUSION: **The appearance of the longitudinal high temperature lines at the lateral aspects of the trunk in the experimental group is directly bound up with the experimental animals pyogenic cholecystitis, with its running course quite similar to that of the Gallbladder Channel of Foot Shaoyang, but different to the zones of hyperalgesia and site of referred pain in cholecystitis.**

INTRODUCTION

The reactions on body surface due to visceral lesion have long aroused the interest of investigators. As early as 1889, the Head's zone was observed and the referred pain was interpreted by the two concepts of pre-spinal and intra-spinal viscero-somatic association neurons several decades later. The above-mentioned zones of hyperalgesia were mainly based on the complaint of the patients themselves, and the accompanying reaction of nerve-blood vessel-muscle-sclerotic zone-dermatomere is again a kind of pathological changes with indefinite boundary, still short of objective examination. Formerly, some scholars have explored the relation between the visceral lesion and temperature of the body surface, which was limited only to the region around the lesion, like observation, for instance, around cholecystitis. The theory of meridian in Traditional Chinese Medicine(TCM) maintains that, the meridians connect the viscera internally and the body surface externally. Physiologically, it serves for the flowing of blood-qi, and pathologically, reflects disease changes. Acupuncture is a therapy of entrails by stimulating acupoints along channels on the body surface[1-6]. However, exactly how the temperature changes induced by visceral disorders, whether it occurs at the meridians and acupoints through TCM theory or appears at the special regions of Head's zone or referred pain on the basis of Western medicine, or even only appears around the lesions, is still a question attracting investigators' interests. Infrared thermography, a modern measuring temperature method, could be used for diagnosing some diseases and medical basic researches, such as the displaying of temperature imaging of cerebral cortex[7,8], effect of acupuncture on brain[9,10] and study of principle of acupuncture[11,12], etc. Based on past work[13], we have studied this topic by the above-mentioned animal models for continuous follow-up examinations so as to investigate whether cholecystitis can lead to body surface temperature reactions and their locations in this paper.

MATERIALS AND METHODS

Experimental animal

Adult healthy rabbits, 21 in the experimental group, and 8 in the control group in both sexes, weighing 3.0±0.35kg, supplied by Department of Experimental Animals from our Academy.

Animal model

The models were made based on the method reported by Xu *et al*[14]. The animals were anesthetized with sodium phenobarbital through auricular marginal vessel (45mg·kg^{-1}) with abdominal hairs shaved. After routine anesthesia, an incision was made at the mid-abdominal line from the xyphoid process to the umbilicus and the abdomen was opened. We isolated a small segment of the common bile duct 1cm from the duodenum, inserted a hard plastic tube 0.5cm long opened longitudinally with a caliber just a little more slender than the common bile duct, and then put outside the bile duct. The lower end of the tube was penetrated with a thread and ligated to close its open end. Thus, the duct was strictured in an incomplete blocked manner. 1mL suspension prepared by mixing a piece of rabbit dung with 10mL was injecued with saline into the gallbladder to create a pyogenic cholecystitis. We sutured the wound and applied some antibiotics locally and continued to feed the animal. After the animals resumed its consciousness, there were manifestations including loss of appetite, icteric jaundice in the sclera, auricles, and skin to different degrees, with deep-colored urine. By anatomy, when the experiment was over, the gallbladder could be seen enlarged, dilated, with thickened wall and fibrosis, indicating a chronic inflammation. By the same process, the common bile ducts of the animals in the control group were isolated but with no bacterial suspension administered. After we sutured the wounds the feeding was continued.

Observation process

Before every thermoinage was taken and the model operations were porformed in the two groups, the hairs at the back and both sides of the trunk were cut. The infrared thermoimages were taken 24h before the operation and 1-11d, and (2, 3wk) 4wk after the operations at the hairless areas to investigate the temperature changes and its evolution before and!after the models were formed.

Experimental instrument and surroundings

Swedish AGA-782 Infrared thermovision was applied for observation of thermoimages with the thermosensitivity being 0.1 (0.025℃ available after computerized processing). The images of temperature distribution of the observed parts were taken with the infrared camera of the instrument, and continuous images were taken by the black-white demonstrator and color monitor. The infrared thermoimage was processed, reserved and analyzed by equipment system TC-800 computer and DISCO3.1 thermoimage program, while the absolute values of temperature were checked by the DH-1 Model Thermal Calibration Source (Figure 1). The room temperatures were 25.5-29.6℃, and relative humidities 33-60%.

Method for observation and recording of thermoimages of body surface

The camera of the thermovision was placed 1 meter above the observed parts, while the Thermal Calibration Source within the visual field of the camera so as to indicate the absolute temperature. The thermoimages were recorded at the hairless areas (for fixation of the animal, Figure 2), more than 10 follow-up continuous observations were made 1d before and 4 wk after the operation.

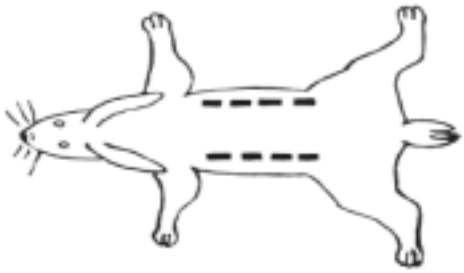

Figure 2 The method for recording the thermoimage of the rabbit's trunk

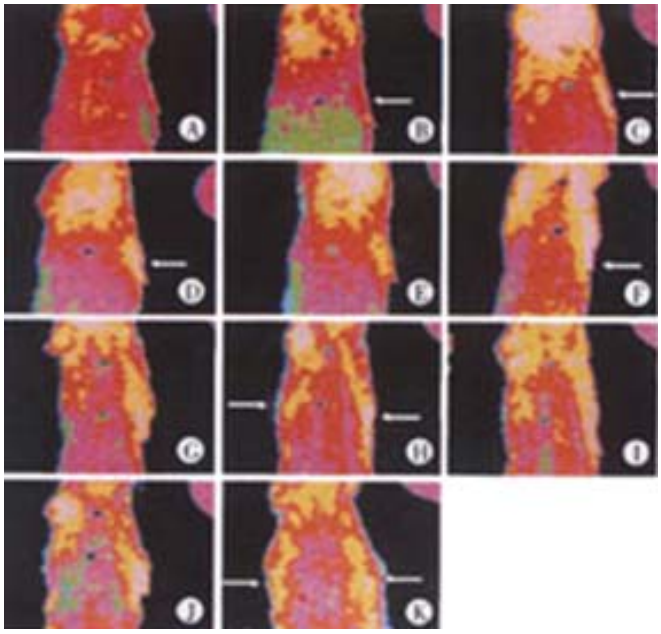
RESULTS

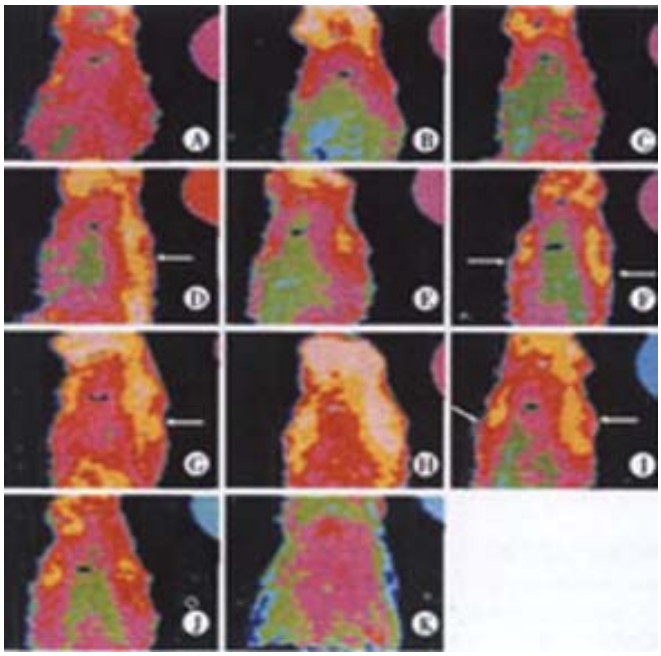
Symptoms of the animal models

The operation process went smoothly, with the animals resuming its consciousness 4-5h after the operation. All conditions but food taking remained normal, without any inflammatory reactions in the wound. In three cases, the sclera and auricle became icteric 1d after operation, another 16 cases showed such jaundice 2-5d after operation. Generally, general jaundice of the skin appeard 3-5d after operation. All 21 animals had deep-colored urine and fever to certain degree.One week later, the animal returned to normal temperature without jaundice, but the appetite was still abnormal, with emaciation ,indicating chronic inflammation.In our series, 5 cases died 7d later, 1 died 9d later, and another 1 died 18d later. The remaining animals survived, and 12 revealed longitudinal high temperature lines along the lateral aspects of the trunk, which was similar to the running course of Gallbladder Channel of Foot Shaoyang. The lines elongated as time went on (Figure 3).

Figure 3 Continuous display of the infrared thermoimages of rabbit trunk with cholecystitis in 2 rabbits.



I. The distribution and evolution of high temperature line on the infrared thermoimage of No.11 rabbit's trunk (back and axillary aspect) A: before cholecystitis model; B:1d after cholecystitis,high temperature line appeared in the lateral aspect; C:on d2; D:on d3; E:on d4; F:on d7, high temperature line began to appear at the left side; G:on d8; H:on d9,marked bilateral high temperature lines; I:on d10; J:on d11; K:on d30, high temperature line remained.



Ⅱ. The distribution and evolution of high temperature line on the infrared thermoimage of No.8 rabbit's trunk (back and axillary aspect) A: before

cholecystitis model; B:1d after cholecystitis; C:on d2, right high temperature line; D:on d3, marked right high temperature line appeared; E:on d4; F: on d7, left high temperature line appeared; G:on d8; H:on d9, marked bilateral high temperature lines; I:on d10; J:on d11; K:on d30, bilateral high temperature lines disappeared.

The distribution is shown by the dotted line in Figure 1. The other 9 rabbits didn't show such lines. Only some spotted high temperature areas could be seen. There might even be lower temperature of the body surface.

Features of high temperature lines in the trunk in acute cholecystitis

The features included: (1)9 out of the 12 animals with longitudinal high temperature line in the trunk were bilateral, and the other 3 unilateral; (2)Most of the high temperature lines first appeared in the right side, among them, 3 cases appeared 1d after operation; 5 cases after d2. The lines in the left side appeared rather late. All left high temperature lines appeared 7d after operation except 1 case appeared only 2d after; (3)The lines were thread (band) shaped, first rather short and elongated as time elapsed, the longest being as long as the trunk itself; (4)The duration of the existing lines lasted, with over 30d as the longest; (5)The temperature of the lines was about 0.7-2.5℃ higher than that of the surrounding region, about 1.1-2.7℃ higher than that before the lesion appeared in the same region.

The thermoimages of body surface and symptoms of the control animals after operation

All 8 cases resumed consciousness 4-5h after the operation, with normal activities, without swelling or infection in the wound, without icteric sclera, auricles or deep-colored urine. Body temperatures rose in different degree, with normal appetite and better survival condition. No longitudinal high temperature lines appeared in the trunk 1mo after the operation except that 1 case had some high temperature areas that appeared remittently (Figure 4).

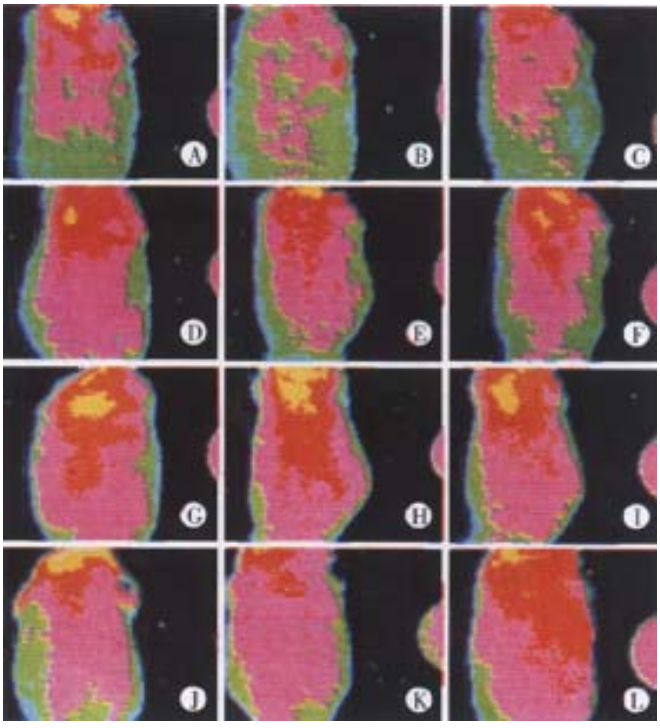


Figure 4 The distribution and evolution on infrared thermoimage of control rabbit's trunk (back and axillary aspect) A: before operation; B: 1d after operation; C: on d2; D: on d3; E: on d4; F: on d7; G: on d8; H: on d9; I: on d10; J: on d11; K: on d22; L: on d30. It can be seen here that there was no longitudinal high temperature line 1 month after the operation.

DISCUSSION

Reaction on the body surface due to visceral disorders, a phenomenon recognized in both traditional Chinese medicine and western medicine, is called "correlation of body surface and viscera" in modern medicine and "correlation of meridian and viscera" in TCM theory. Though not exactly identical in the description of both systems, yet, they bear the common idea that viscera lesions might be reflected on the body surface. As the largest organ of the body, skin receives all stimulations from outside, preserves body fluid and maintains body heat balance, with a comprehensive function of sensation, secretion, excretion, temperature regulation, and metabolism. There is a close relationship between the body surface and internal viscera. The former always reflects the disorders of the latter. Visible changes can be seen on the skin in diseases such as scleroderma, lupus erythematosus, and iatrogenic dermatitis, therefore, visceral diseases can sometimes be diagnosed by changes in the skin, and conversely, abnormal cutaneous sensation also reflects visceral ailments. The left shoulder pain, for instance, can be seen in myocardial ischemia; inter-scapular pain, in stomach and pancreas diseases; referred pain in the right shoulder, and scapular pain in liver and gallbladder disorders (Figure 5A), as well as the Head's zone with clear distribution (pain hypersensitivity) (Figure 5B), and so on.

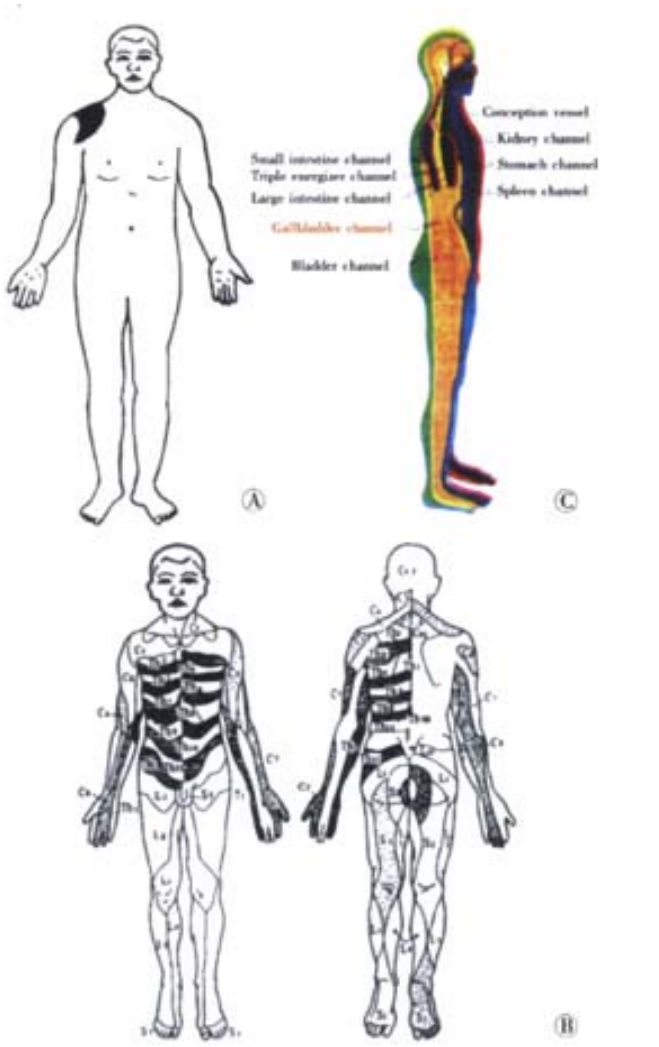

Figure 5 Diagram showing referred pain in cholecystitis, Head's zone and "cutaneous portion" of gallbladder channel.
A: Referred pain in cholecystitis; B: Head's zone; C: "Cutaneous portion" of gallbladder channel on the lateral aspect of the body

For the Head's zone, it is interpreted that the nerve impulse comes from the stimulus in the internal organ which, through the posterior root of the spinal cord, arrives at a specific spinal segment and forms an excitation focus in the cord and then reaches the efferent nerve fibers of the same segment via the intermediary association neurons, resulting in the sensory hypersensitivity of the correlative body surface part. This is a visceral-sensory reflection related to a kind of pain sensitive phenomenon that appeared on a certain part of the body surface due to disorders of the internal organs whereas referred pain may be due to the fact that the afferent nerve of the body surface and affected organ share the same spinal posterior nerve root entering the spinal cord, whose never endings project to the sane viscero-somatic association neuron. Abundant clinical facts and basic research reveal that there are minute description and summary for the specificities and law of distribution of Head's zone and referred pain. Though the mechanism of body surface reaction for visceral disorders is still unclear, yet, it is of clinical significance to judge the disorders of the organs by these reaction areas on the body surface. However, the subjective complaints of sensation are not to be used as objective basis for diagnosis. This is why someone observed the relations between the temperature and pain sensation, attempting to apply temperature in the place of subjective complaints. Unfortunately, the correlative relations are still indefinite[5]. Objective phenomena and records for the external manifestations of disorders of internal organ are still rare. The goal of our study is to record the longitudinal zone of high temperature on the lateral trunk by infrared thermography. We noticed that there are significant differences between the recorded longitudinal and the distribution of the 2 pain hypersensitive areas on the body surface.

The past studies show that there are high temperature lines running longitudinally on the human surface whose course is related to the meridians, hence, the title "high temperature lines along meridian" (HTLM). The study of these phenomena with infrared thermography is a great advance on the basis of biophysical studies on acupoints. Acupuncture-moxibustion can raise the skin temperature[15,16]. Although observation on HTLM reveals that the rate of their appearance is rather low under natural condition, it can be raised by acupuncturing-moxibusting[17], indicating that the appearance of HTLM might need certain inducing factors, inside or outside the body. For the outside inducing factor, such as acu-moxibusting stimuli, there have been a lot of reports; but there are no reports concerning inside stimuli (such as visceral disorders) so far. In the theory of traditional Chinese medicine, it is the meridian system that connects the interior with the exterior, provides the passage for the flowing of blood and Qi, communicates the superficies with the interior, and regulates Yin and Yang. All internal viscerae connect them through corresponding meridian and collaterals. Once a viscera is ill, it can be manifested on the body surface through their corresponding meridian. The above description in traditional Chinese medicine is rather identical with the observation and study of Head's zone and referred pain in modern medicine. In the modern studies of meridian phenomena, the dematosis, capillary dilatation in the skin, cutaneous and subcutaneous nodules, depressions, elevation, tenderness, acupoints electric measurement and acupoints temperature examination, etc. along the meridian were all focused on the search for the correlation between the viscera and its corresponding meridian, so as to prove the scientific theory of meridian. Unfortunately, the conclusion is still unclear. Compared with the above theories between traditional Chinese medicine and western medicine, there are both similarities and dissimilarities. The idea that body surface can reflect the diseases of the viscera is the same between the two medical systems, while their locations reflecting the affected viscera are different. Head's zone is distributed on the basis of neural segments, viz. being transversely distributed in the trunk, while referred pain is distributed in regions or in patches; whereas meridians are distributed longitudinally and in bands. The satisfactory results of Chinese herbal medicine[18-20] and acupunctura-moxibustion[21-28] on digestive diseases demonstrate that it is feasible to apply traditional Chinese medical therapies for diseases in western medicine, acupuncture plays also an impotent role on the research of pathogeny and treatment[29-32], and the difference in the theories of the two medical systems can be unified and verified with objective indices. The acute pyogenic cholecystitis falls under the category of gallbladder disorders in traditional Chinese medicine. In the thermoimage of body surface recorded by infra-red thermography, we observed, for the first time, the longitudinal distribution of high temperature lines on the body trunk, which is different to the zones of hyperalgesia and referred pain area on the body surface in gallbladder disease, but similar to the distribution of "cutaneous portion" of Gallbladder Channel of Foot Shaoyang (Figure 5C), indicating that there is a tendency of temperature reaction on the body surface along the meridian in visceral diseases.

Gallbladder diseases could be diagnosed by modern instrument[33]. The rise of body temperature is an index of infection[34,35]. Due to the inflammatory reaction in experimental pyogenic cholecystitis, body temperature is raised, which is a systematic phenomenon. However, in our experiment, the temperature of the longitudinal high temperature lines on the lateral trunk was higher than the surrounding skin, indicating that the existence of the lines was not due to the rise of temperature, or rather, a specific mechanism. Physiologically, high body temperature indicates the degree of energy metabolism and the flowing blood volume in the local part[36-39]. In addition to the interpretation that the distribution of high temperature lines on body surface in cholecystitis can be made by the running course of Gallbladder channel and theory of traditional Chinese medicine, it can also be preliminarily interpreted by blood circulation, metabolism and nervous function. After the gallbladder is affected, the nervous reflex on the body surface reactive area is increased, leading to the increase of metabolism of the skin tissue and blood circulation to meet the needs of recovery of the viscera, hence, the high temperature lines. Formerly, we observed many phenomena of high temperature lines along the meridians, their depths[40,41] and the relationship between autonomic nervous system and the lines[42]. We now further understand, through our present experiment, the mechanism of its appearance, viz. visceral disease being one of the factors responsible for the appearance of the high temperature lines, and the lines along the meridians being a kind of manifestation reflecting visceral pathology. Here, we offer a pictorial basis for the objective verification of meridian-visceral correlation in traditional Chinese medicine, and a supplement to the theory of zones of hyperalgesia and referred pain in modern medicine.

Abstract

AIM: **To investigate the effect of L-NAME on nitric oxide and gastrointestinal motility alterations in cirrhotic rats.**

METHODS: **Rats with cirrhosis induced by carbon tetrachloride were randomly divided into two groups, one(*n*=13) receiving 0.5mg·kg^{-1} per day of N-G-nitro-L-arginine methyl ester (L-NAME), a nitric oxide synthase inhibitor, for 10 days, whereas the other group (*n*=13) and control (*n*=10) rats were administrated the same volume of 9g·L^{-1} saline. Half gastric emptying time and 2h residual rate were measured by SPECT, using ^{99m}Tc-DTPA-labeled barium sulfate as test meal. Gastrointestinal transition time was recorded simultaneously. Serum concentration of nitric oxide (NO) was determined by the kinetic cadmium reduction and colorimetric methods. Immunohistochemical SABC method was used to observe the expression and distribution of three types of nitric oxide synthase (NOS) isoforms in the rat gastrointestinal tract. Western blot was used to detect expression of gastrointestinal NOS isoforms.**

RESULTS: **Half gastric emptying time and trans-gastrointestinal time were significantly prolonged (124.0±26.4min; 33.7±8.9min;72.1±15.3min; *P*<0.01), (12.4±0.5h; 9.5±0.3h; 8.2±0.8h; *P*<0.01), 2h residual rate was raised in cirrhotic rats than in controls and cirrhotic rats treated with L-NAME(54.9±7.6%,13.7±3.2%, 34.9±10.3%, *P*<0.01). Serum concentration of NO was significantly increased in cirrhotic rats than in the other groups (8.20±2.48)μmol·L^{-1}, (5.94±1.07) μmol·L^{-1},and control (5.66±1.60)μmol·L^{-1}, *P*<0.01. NOS staining intensities which were mainly located in the gastrointestinal tissues were markedly lower in cirrhotic rats than in the controls and cirrhotic rats after treated with L-NAME.**

CONCLUSION: **Gastrointestinal motility was remarkably inhibited in cirrhotic rats, which could be alleviated by L-NAME.Nitric oxide may play an important role in the inhibition of gastrointestinal motility in cirrhotic rats.**

INTRODUCTION

Investigation in gastrointestinal motility has promoted the interest of researchers in the functional changes in gastrointestinal motility of cirrhotic patients[1-8]. It is validated that nitric oxide (NO) plays a pivotal role in neural transduction and gastrointestinal motility regulation as a neurotransmitter and messenger molecule with various physiological functions[9-19]. However, the relationship between NO and functional changes in cirrhotic gastrointestinal motility is not yet clear[20-27]. We used nitric oxide synthase (NOS) -specific inhibitor to treat cirrhosis model rats and observe changes in their gastrointestinal motility so as to disclose the role of NO in such changes and to provide experimental basis for diagnosis of cirrhotic gastrointestinal motility abnormalities.

MATERIALS AND METHODS

Preparation of animal model

Male SD rats were provided by the Experimental Animal Center, the Fourth Military Medical University, weighting (250±50)g, fed with standard granule food, and randomly divided into model group(26 rats) and normal control group (10 rats). CCl_4 toxic cirrhosis model preparation: rats in the model group received subcutaneous injection of CCl_4 (3mL·kg^{-1}) twice a week for 12 weeks; and rats in the control group received olive oil (3mL·kg^{-1}) twice a week for 12 weeks. At the end of 12 weeks, cirrhosis model group was randomly subdivided into treated group and untreated group. Normal SD rats were served as controls, each group having 10 rats. Rats in the treated group were given 0.5mg·kg^{-1}d^{-1} N_G-nitro-L-arginine methyl ester (L-NAME, Sigma product, USA), a NOS inhibitor, through intragastric administration for 10 days, and the untreated group and control group received gastric delivery of 9g·L^{-1} NaCl once a day for 10 days. Hepatic tissue samples were normally fixed with 40g·L^{-1} polyformaldehyde, prepared into paraffin wrapped sections, stained with HE and observed under light microscope.

Analysis of gstrointestinal motility

Examination of gastric emptying Experimental animals were fast for over 12h without receiving drugs or food that might influence gastric motility during the previous 2 weeks.!Each rat received 2mL $BaSO_4$ mixed with 3.7GBq·L^{-199m}Tc-DTPA through the esophagus into the stomach in 2min, and was placed lying on the back. SPECT (Type CT, Sophycamera Co, France) detector was focused on the abdomen of the animals with the whole stomach as the Region of Interest (ROI); radioactivity was recorded and images were displayed for 60s as the total radioactivity. Gastric images were then taken at 15, 30, 45, 60, 90 and 120min, delineating the ROI; the curve of time-half gastric emptying was drawn and gastric residual radioactivity rates at different time points were calculated by computer.

Total gastrointestinal transition time (TGIT) After isotopic scanning, the time of $BaSO_4$ excretion through anus was recorded.

Alterations of NO and NOS

Assay of serum NO_2-/NO_3-content Rats were decapitated and the blood was collected and quietly placed for 60min. After 4000r·min^{-1} centrifugation for 15min, the supernatant was used for NO_2-/NO_3-measurement. Operation was performed following the instructions of the reagent kit (purchased from Institute of Nuclear Medicine, General Hospital of Chinese PLA).

Expression of NOS in gastrointestinal tract Immunohistochemical method was used with immunohistochemical reagents from Wuhan Boshide Biotech Co Ltd. Five rats were randomly selected from each of the three groups. Each rat was anesthetized with 10g·L^{-1} sodium pentabarbitol (50mL·kg^{-1}) through abdominal cavity injection and perfused with 40g·L^{-1} polyformaldehyde for 1.5h. Gastric, small intestinal and colonic tissues were immediately taken out and immersed in 200g·L^{-1} sucrose solution at 4℃ for 24h until the tissues sank to the bottom. Then the tissues were cryotomized at -20℃ into slices 14-16μm thick. The tissues were rinsed three times with 0.01mmol·L^{-1} PBS for 5min; treated with peroxide and methanol for 15min; vibrated and washed with PBS for 5min three times; and blocked with normal bovine serum for 30min. Rabbit anti-NOS_1 (1∶100 rabbit polyclonal antibody), anti-NOS_2 (1∶50 rabbit polyclonal antibody), anti-NOS_3 (100 rabbit polyclonal antibody) were added and the solution was incubated at 4℃ overnight. Then it was vibrated and washed with PBS three times for 5min. Biotinized sheep-anti-rabbit lgG was added and the solution was let react at 37℃ for 30min. The system was washed again with 0.01mmol·L^{-1}PBS for 5min×3; SABC was added and let react at 37℃ for 30min; and washed with 0.01mmol·L^{-1}PBS for 5min×4. The stain was developed with DAB and stained with lignin. The sample was normally dehydratized till transparent and sealed with neutral resin. Microscopic observation was done and photo taken under microscope.

Determination of NOS in gastrointestinal tract with Western blot Animals fasted 12h before experiment without water deprivation. Three rats each from treated group, untreated group and control group were randomly chosen, decapitated, and eviscerated immediately to obtain the stomach, small intestine and colon, which were rinsed in ice-water containing 0.1mmol·L^{-1}PMSF, frozen in liquid nitrogen and moved into -70℃ refrigerator for preservation. The whole process should be finished within 5min. Tissue lysis liquid was prepared with ion-free water containing 0.1mmol·L^{-1}PMSF. The gastrointestinal tissues were weighed and homogenized (3500r·min^{-1}, 5s×5) in ice-bathing, the mass/volume ratio of tissue to tissue lysis liquid being 1∶5. Centrifugation was then performed at 12500r·min^{-1} for 10min; the supernatant was separated and preserved at -70℃; the protein concentration in the extract was measured by the Bradford method.

Eighty g·L^{-1} PAGE gel was prepared and 2×SDS loading buffer was added to the protein samples, followed by heating at 100℃ for 3min. Centrifugation was performed again and protein samples of the same amount were added. Electrophoresis was done with 20mA current; and the gel was stained with Coomassie brilliant blue. Separation of protein extracts of the stomach, small intestines and colons of the rats was accomplished with 80g·L^{-1} SDS-PAGE. After electrophoresis, electric transfer of the proteins onto NC membrane was done with a constant current of 0.8mA·cm^{-2} for 1h using semi-dry electric transfer device (Beijing 61 Factory). Transfer buffer ingredients (25mmol·L^{-1}Tris-Hcl, 192mmol·L^{-1} glycine, 10g·L^{-1}SDS, 200g·L^{-1} methanol, pH8.3. TBS pH7.5+50g·L^{-1} non-fat milk+0.5g·L^{-1} NP-40) were used for blocking the sample for 2h at RT. Primary antibody NOS_1, NOS_2 and NOS^a-3 (1∶100 rabbit multiclonal antibody) was diluted with TBS buffer containing 1g·L^{-1}BSA and added. The sample was incubated at 4℃ for 16-18h and rinsed in TBS three times for 10min. HRP linked sheep-anti-rabbit secondary antibody (1∶400, Boshide Co.) was diluted with TBS, added to the sample and let react for 2h at RT. The sample was then rinsed in TBS+1 g·L^{-1}NP-40 10min×5 and developed with DAB.

Statistical analysis

Analysis of variance was conducted using NOSA statistics program (Fourth Military Medical University), and the results were presented in form of $\bar{x}\pm s$.

RESULTS

Establishment of rat model with cirrohosis

Model rats had hepatomegaly and splenomegaly, the liver became hard, the edge turned blunt, and the surface was not smooth, with nodules of varied sizes. Light microscopy showed hepatocyte regeneration, fat degeneration, proliferation of collagen fibers, and pseudo-lobulation.

Gastrointestinal motility

Gastrointestinal motility for barium Gastric semi-solid emptying: after intragastric administration of $BaSO_4$ containing ^{99m}Tc-DTPA, abdominal radioactivity images were taken in 8 rats in normal group (Figure 1A), untreated group (Figure 1B) and treated group (Figure 1C) each at 5, 30, 90 and 120min. The images showed that gastric emptying of cirrhotic rats was slowed down, and after treatment it was accelerated. The residual rate of gastric semi-solid substance of rats was observed dynamically.

Gastric emptying of cirrhotic rats was slowed down, the 2h residual rate being increased significantly. After L-NAME treatment, the gastric emptying was accelerated, the 2h residual rate decreased significantly (Figure 2 and Table 1).

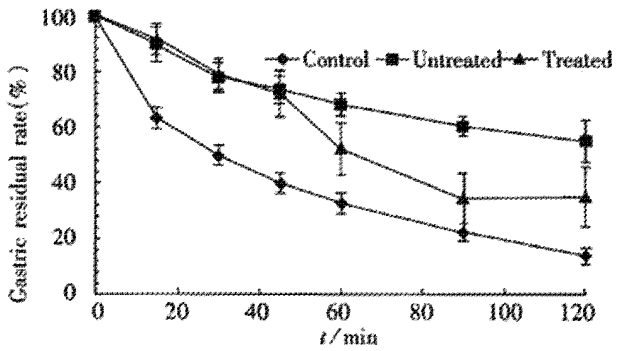

Figure 2 Residual rate curves of gastric semi-solid substance of rats

Table 1 Half-emptying time and 2h residual rate (n=8)

Groups	$GET_{1/2}$(min)	RR2h(%)
Control	33.7	13.7
Untreated	124.0	54.9[b]
Treated	72.1	34.9

[b]P<0.01, *vs* control and treated. $GET_{1/2}$: half-emptying time; RR2h: 2h residual rate

Gastrointestinal transition time TGIT of rats in untreated group (12.4±0.5)h was significantly longer (P<0.01) than that in the control group (9.5±0.3)h, whereas TGIT of rats in treated group (8.2±0.8)h was significantly shorter (P<0.01). Figure 3 shows that gastrointestinal transition of barium sulfate apparently slowed down in cirrhotic rats, and was significantly accelerated after L-NAME treatment; and barium sulfate was excreted in 6h after delivery.

A, B: Control rats at 5min and 6h; C, D: Untreated rats at 5min and 6h; E, F: Treated rats 5min and 6h

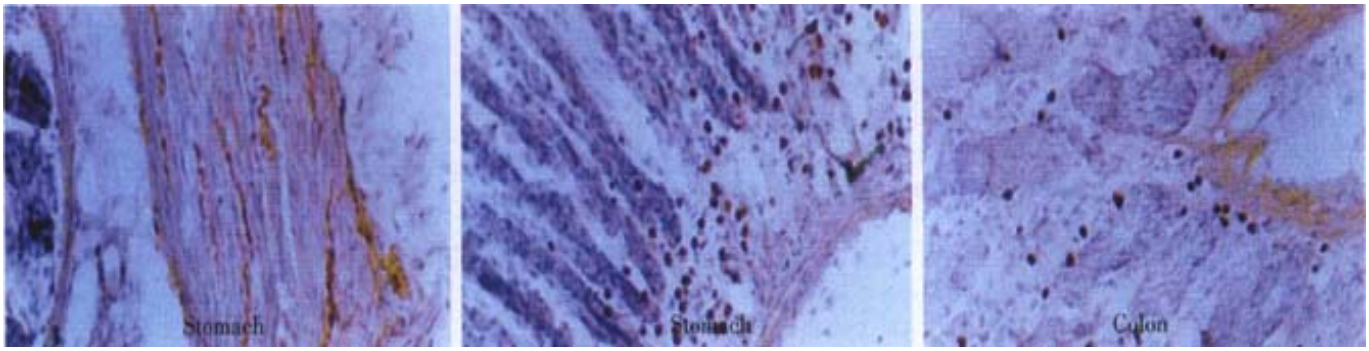

Figure 4 Expression and distribution of NOS in rat gastrointestinal tract with cirrhosis.

Alterations of NO and NOS

Serum concentration of NO The serum NO_2-/NO_3- concentrations were (8.20±2.48)μmol·L^{-1}, (5.94±1.07)μmol·L^{-1}, and (5.66±1.60)μmol·L^{-1} in the rats of untreated group, normal control group, and treated group, respectively. It was apparent that NO concentration in the untreated group was significantly higher than in other groups (P<0.01).

Expression of NOS in rat gastrointestinal tract NOS immunohistochemical staining showed that NOS_1, NOS_2 and NOS_3 had similar distribution in gastrointestinal mucosal lamina propria layer, principally in neutrophiles, monocytes, macrophages and some lymphocytes of gastrointestinal mucosal lamina propria layer

interstitial. NOS_1 existed mainly in intermuscular nerve bundles in the gastrointestinal wall, endocrine cells in the mucosal layer, macrophages in gastrointestinal mucosal lamina propria layer interstitial, and some lymphocytes. In normal rats, NOS positive cells were mainly located in the lower third part of the gastric mucosal layer, in the intermuscular nerve bundles and villus interstitial of small intestine, and pervasively in colonic mucosal villus interstitial (Figure 4). In cirrhotic rats, NOS positive cells decreased significantly in the whole gastrointestinal tract and intermuscular nerve bundle.These two indexes in cirrhotic rats treated with L-NAME were significantly higher than those in untreated rats.

Western blot analysis Protein electrophoresis showed that the sampling amounts of gastric, small intestinal and colonic proteins of rats in the three groups were the same, and that the protein composition in the small intestine was quite different from that in the stomach and the colon. Western blot showed that NOS expression decreased significantly in the gastric and colonic tissues of cirrhotic rats, and it returned to normal after treated with L-NAME. NOS was not detected in the small intestine in either groups.

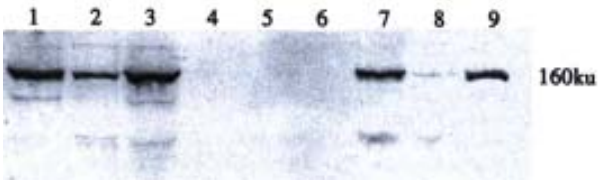

Figure 5 Expression of NOS_1 in stomach(1,2,3), intestine(4,5,6) and colon(7, 8,9) of rats 1,4,7: Control; 2,5,8: Cirrhotic; 3,7,9: Treated

DISCUSSION

NO plays an important role in gastrointestinal physiological activities as well as in the pathogenesis and progress of many severe diseases[27-31]. It is involved in the regulation of gastrointestinal smooth muscle contraction and secretion of water and salt of intestinal epithelial cells[32,33]. It mediates endotoxin-induced inhibition of gastric acid secretion, protects gastrointestinal mucosa, sustains mucosal blood flow, inhibits neutrophile adhesion to vascular endothelium and blocks platelet adhesion; prevents macrophage activation. NOS is the rate-limiting enzyme of NO synthesis, which exists pervasively in gastrointestinal tissues, including epithelia, fibroblasts, macrophages, inherent and infiltrating lymphocytes, neutrophiles, monocytes, smooth muscle cells, endocrine cells, and intramuscular ganglia. The kinds and densities of NOS positive cells diverse at different regions [34-40]. NOS can be classified into 3 types according to biological characters and encoding genes: neuronal type nNOS (NOS_1), endothelial type eNOS (NOS_3) and induced type iNOS (NOS_2). There are 50% homology between them. NOS_1 primarily exists in neural and epithelial cells. NOS NOS_2 was firstly separated from macrophages and later discovered to exist in other kinds of cells such as vascular smooth muscle cells. NOS_3 mainly exists in vascular endothelial cells. According to the activity dependence on Ca^{2+}/CaM, NOS has two subtypes: constructive NOS (cNOS), including NOS_1 and NOS_3 whose activity is regulated by Ca^{2+}/CaM, and induced NOS, including NOS_2 whose enzymatic activity is not dependent on Ca^{2+}/CaM but needs inducing factors. The cNOS primarily exists in normal vascular endothelial cells, and is also found in adrenal gland cells, platelets, fibroblasts, PMNs, brain cells and certain non-cholinergenic, non-adrenalergenic synapses[41,42].

NOS expression in gastrointestinal tissues differs in certain pathological situations. In abdominal inflammation, positive cells on the small intestinal wall mainly exist in the mucosal lamina propria layer, over 80% of the positive cells are CD45 positive inflammatory cells, about 15% are CD3 positive T lymphocytes, and epithelial cells are all negative. In ulcerative *coli*tis, iNOS positive cells are mainly intesitinal epithelial cells, while mucosal inherent cells are all negative. The status in cirrhosis is not known yet[43-45]. NO is the major inhibitory neurotransmitter released by non-adrenaline, non-cholergenic neurons, which is closely related to gastrointestinal motility and pathology. Gastric physiological expansion and intestinal peristalsis are regulated by NO, which can directly inhibit gastrointestinal smooth muscle contraction and retard gastrointestinal motility. NOS inhibitor can promote ascites re-absorption and urinary sodium excretion of cirrhotic rats, and the rats' colonic motility recovery after abdominal operations. We prepared a toxic cirrhotic rat model, used radioactive isotopic method to determine gastric emptying functions of the rats, and recorded the total gastrointestinal transition time (TGIT). The results showed that TGIT of the rats in untreated group was significantly longer than that of the rats in the control group and the treated group, while gastric emptying was significantly slower in the former. It suggested the dysfunction of gastrointestinal motility in cirrhosis.

Cirrhotic patients are prone to develop endotoxemia due to floratranslocation, enhanced absorption of endotoxins and reduced hepatic detoxification. Endotoxins stimulate vascular endothelial cells, activate NOS, and consequently increasing NO synthesis. The serum NO concentration in cirrhotic patients rose significantly[46-48], and the same findings were observed in cirrhotic rat's model in our experiment. However, immunohistochemical staining revealed the different distribution of NOS_1, NOS_2 and NOS_3 as described above. The quantity of NOS positive cells in cirrhotic rat gastrointestinal tissues was significantly lower than that in rats treated with L-NAME and normal control, so was NOS staining intensity in nerve bundles. Western blot was used to examine the expression of the three types of NOS in gastric, small intestinal and colonic tissues of rats and the same results were obtained as we did through NOS immunohistochemistry. These results indicate that local synthesis of NO is regulated by many factors in cirrhotic rat gastrointestinal tissues[49].

NOS-specific competitive inhibitor L-NAME was used to treat cirrhotic rats and the results were as follows: TGIT of untreated cirrhotic rats was significantly longer than that of normal or treated cirrhotic rats, and gastric emptying in the former group was significantly slower. L-NAME treatment significantly accelerated gastric emptying and reduced TGIT. The sreum NO concentration in cirrhotic rats was elevated, and L-NAME treatment reduced the serum NO concentration and gastrointestinal NO synthesis as well. These results indicate that NO contributes greatly to cirrhotic gastrointestinal motility dysfunction. NOS inhibitor L-NMMA can reduce the duration of small intestinal digestive interval MMC I phase as well as the total duration of MMC, whereas the occurrence frequency of MMC was raised and small intestinal motility was enhanced. This might be one of the mechanisms of L-NAME enhancing cirrhotic rat gastrointestinal motility[50].

Disorder of cirrhotic gastrointestinal motility is a multi-factor disease. Our research showed that the gastrointestinal motility of cirrhotic rats was significantly inhibited, which was demonstrated by slowed gastric emptying and prolonged gastrointestinal transition time. As NO activity in the serum and tissues of cirrhotic rats was comparatively high, we used NOS-specific inhibitor to treat the rats and removed such inhibition, and found that NO played an important role in cirrhotic gastrointestinal motility dysfunction. Thus, we conclude that drugs inhibiting NO synthesis would be clinically conducive to alleviate the gastrointestinal motility dysfunction of cirrhotic patients and could consequently reduce the occurrence of cirrhosis-related complications.

Abstract

AIM: **To observe the regulatory effect of Chinese herbal medicine on peritoneal lymphatic stomata and its significance in treating ascites in liver fibrosis model mice.**

METHODS: **Two Chinese herbal composite prescriptions were used separately to treat the carbon tetrachloride-induced mouse model of liver fibrosis. The histo-pathologic changes of the liver sections (HE and VG stainings) were observed. The peritoneal lymphatic stomata was detected by scanning electron microscopy and computer image processing. The changes of urinary volume and sodium ion concentration were measured.**

RESULTS: **In the model group, lots of fibrous tissue formed in liver and extended into the hepatic lobules to separate them incompletely. In the treated and prevention groups, the histo-pathologic changes of liver was rather milder, only showed much less fibrous tissue proliferation in the hepatic lobules. The peritoneal lymphatic stomata enlarged with increased density in the experimental groups (diameter: PA, 3.07±0.69μm; PB, 2.82±0.37μm; TA, 3.25±0.82μm and TB, 2.82±0.56μm; density: PA, 7.11±1.90 stomata·1000μm^{-2}; PB, 8.76±1.45 stomata·1000μm^{-1}; TA, 6.55±1.44 stomata·1000μm^{-2} and TB, 8.76±1.79 stomata·1000μm^{-2}), as compared with the model group (diameter: 2.00±0.52μm; density: 4.45±1.05 stomata·1000μm^{-2}). After treatment, the urinary volume and sodium ion excretion increased in the experimental groups (PA, 231.28±41.09mmol·L^{-1}; PB, 171.69±27.48mmol·L^{-1} and TA, 231.44±34.12mmol·L^{-1}), which were significantly different with those in the model group (129.33±36.75mmol·L^{-1}).**

CONCLUSION: **Chinese herbal medicine has marked effects in alleviating liver fibrosis, regulating peritoneal lymphatic stomata, improving the drainage of ascites from peritoneal cavity and causing increase of urinary volume and sodium ion excretion to reduce the water and sodium retention, and thus have favorable therapeutic effect in treating ascites.**

INTRODUCTION

Since von Recklinghausen first reported the peritoneal lymphatic stomata, numerous investigators demonstrated that these are small openings of the subperitoneal lymphatic vessels in animals and in humans[1]. It has also been observed that particles, cells and solutions containing vital dyes are absorbed rapidly by the peritoneal lymphatic stomata. Subsequent researchers suggested that the peritoneal cavity is an integral part of the lymphatic system with enormous absorption powers, functioning primarily by means of the subperitoneal lymphatics via the peritoneal stomata[2-4]. Thus it has played an extremely important role in pathological conditions such as ascites absorption[2-4], peritoneal dialysis[3], intrauterine fetal hemolytic hemorrhage, and neoplastic metastasis of the peritoneal cavity[5].

Liver cirrhosis is a common progressive pathological lesion of chronic liver diseases in response to various liver-damaging factors[6-38]. Among liver cirrhosis of various causes, one common feature is the increased hepatic deposition of extracellular matrix, which consists mainly of collagen, leading to portal hypertension, esophageal varices and ascites. In the treatment of the ascites, the methods such as catharsis, diuresis, diaphoresis were used, but these methods would have side-effects which limit their clinical use[32-35]. In recent years, attention has been paid to the therapeutic effect of Chinese medicine on the ascites[36-41]. With the discovery of the human lymphatic stomata and the study of the lymphatic drainage system in the peritoneal cavity, Li *et al* confirmed that Chinese medicine can regulate the lymphatic stomata and promote the excretion of substance from the peritoneal cavity, and provided a new approach to the management of liver cirrhosis with ascites[4].

In the present case, based on the previous study of peritoneal lymphatic stomata (PLS) regulation, mouse liver fibrosis model induced by carbon tetrachloride gastrogavage was used for studying the effect of two kinds of Chinese herbal medicine in anti-fibrosis, regulating PLS and promoting urine output and urinary ion excretion, so as to provide an experimental basis for clinical trial in cirrhosis with ascites.

MATERIALS AND METHODS

Animal and grouping

One hundred and two male ICR mice, weighing 18.2-25.4g, provided by Experimental Animal Center of Zhejiang Academy of Medical Sciences, were randomly divided into six groups: 17 in the prevention A group (PA group), 17 in the prevention B group (PB group), 20 in the treatment A group (TA group), 20 in the treatment B group (TB group), 20 in the model group aod 8 in the control group.

Drugs

Chinese composite prescription I and II (CP I and II) were supplied by Zhejiang Academy of Traditional Chinese Medicine. The former consisted of radix Salviae Miltiorrhizae, *Radix Codonopsitis*

Pilosulae, Rhizoma Atractylodis Alba and Rhizoma Alismatis, and the latter consisted of rhizoma Ligustici Wallichii, Semen Persicae and radix Salviae Miltiorrhizae. The herbal drugs were steeped in 75% alcohol for 24h, then purified with rotatory evaporator (ZFQ85A type, produced by Shanghai 11th Factory of Electron Tube). The crude drug content in CP I was 9Kg·L^{-1} and in CP II 6Kg·L^{-1}.

Establishment of mouse liver fibrosis model

All the experimental animals were fed freely with 380mg·L^{-1} pentobarbital solution instead of water for 10d. Excepting the control group, the mice were given 10% CCl_4 in rape-seed oil solution (100ml/900ml) 0.2ml/mouse by gastro-gavage every 4 days for 10 weeks to induce liver fibrosis. CP I or CP II (0.2ml/mouse) was given to the PA and PB groups respectively at tqsfhe same time of CCl_4 administration. For the TA and TB groups, equal volumes of CP I and CP II were given respectively beginning from wk 7 of the experiment, after liver fibrosis formation was confirmed by pathological examination. The model group was untreated and the control group was given 0.2ml/mouse of normal saline per day.The experiment was lasted to wk10.

Preparation of pathological samples

The livers were taken out after the mice were killed, fixed with Bouin liquid, embedded in paraffin, sectioned, and stained with HE and VG methods for observation under light microscopy.

Preparation of sample for transmission electron microscopic examination

The tissue blocks of about 1-2mm in diameter were fixed with 25mL·L^{-1} glutaraldehyde solution in 0.1 M phosphate buffer. Then they were postfixed in 10g·L^{-1} O_sO_4 in 0.1mol·L^{-1} phosphate buffer for 1h at 4℃. After dehydration in a graded series of ethanol and steeping in propylene oxide, they were embedded in Epon 812. Semi-thin serial sections were made for orientation and identification of the mesothelium, and then fine sections of the mesothelium were cut with Leica Ultracut UCT ultramicrotome and stained with uranyl acetate and lead citrate. The sections were examined with a Philips EM 410 TEM operated at 60 kV.

Preparation of sample for scanning electron microscopic examination

The diaphragmatic peritoneum of mice was cut into pieces 3×3mm in size, double fixed with 25mL·L^{-1} glutaraldehyde solution and 10g·L^{-1} O_sO_4, gradiently dehydrated with ethanol, managed by 20g·L^{-1} tannic acid electric conduction, CO_2 dried under critical point by HCP-2 type apparatus, Hitachi, and examined with Hitachi S-570 scanning electron microscope after metallizing with 20kV of accelerating voltage.

Computer image processing

Computerized digital processor of electronic microscopic image was used. The whole set of instruments consisted of camera, A/D, IBMP II computer, high resolution color display monitor of 64 grey level / 256 false color (including VGA adapter) and application software.

Urinary volume and ionic concentration determination

Urine in 2 hrs was collected with a filter and ionic concentration of Na^+, K^+ and Cl^- were determined using auto-biochemical analyzer (Beckman CX△7 type).

Statistic analysis

Student's *t*-test was adopted.

RESULTS

Body weight and death of CCl_4-treated mice

After intake of CCl_4, the mice generally manifested sluggish motion, loose skin with lusterless hairs, obvious lowering of body weight 24h afterward but recovered gradually in the later 3d until the next CCl_4 medication, and these formed a cyclic change. The lowest number of deaths due to CCl_4 intake occurred in the PA group (3 mice), and then the TA group (7 mice), PB group (11 mice), TB group (13 mice) and the model group (13 mice) in the order. The mortalities in PA and TA group were significantly lower than that in the model group (P<0.05).

Pathological changes of liver

In the model group, the margin of liver was uneven; lots of fibrous tissue formed in pertal areas and extended into the hepatic lobules to separate them incompletely; a large amount of inflammatory cells infiltrated in the intralobular and the interlobular regions; the liver structure was disordered with some displacement of central veins, and there were more necrotic and degenerated liver cells compared with the control (Figure 1, 2). Under transmission electron microscopy, there were numerous collagenous fibers around the liver cells (Figure 3). In the two preventive and two treated groups, the pathological changes of liver was rather milder, showing less fibrous tissue proliferation and inflammatory cell infiltration in the interlobular space; the hepatic cell cords arranged radially with less displacement of central veins and less degenerated or necrosis hepatic cells (Figure 4). The pathologic changes in the PA and TA groups were milder than those in the PB and TB groups.

Changes of peritoneal lymphatic stomata

Many microvilli on the mesothelial surface of diaphragmatic peritoneum of mice could be seen with electron microscopy. The microvilli seemed to be less at the place where the mesothelial cell with its nucleus protruding to peritoneal cavity and to be more at the junctions neighboring mesothelial cells. Such uneven distribution of the villi drew out the rhomboid or polygonal outlines of mesothelial cells, which were ordinarily of the flat form and the cubical form. Peritoneal lymphatic stomata (PLS) could be found only between the neighboring cubical mesothelial cells, distributed in cluster distribution and were round or elliptical shaped. In physiological condition, only a part of PLS are opened, most are in the locked manner (Figure 5).

Observations in this study showed that the diameters of PLS in the PA and PB groups increased significantly with more stomata opened, and thus resulted in an increase in their density (Table 1, Figure 6). Similar changes also occurred in the TA and TB groups (Table 1, Figure 7). Through PLS, one could see the lymphatic drainage units (LDU) formed by endothelial cytoplasmic protrusions and connective tissue fibers at the bottom of PLS (Figure 8). Intraperitoneal substances could enter through PLS into the subperitoneal lymphatic vessels so as to accelerate the absorption of ascites from the peritoneal cavity.

Table 1 Comparison of Diameter and Density of PLS between Groups ($\bar{x}\pm s$)

Group	*n*	Diameter / μm	Density / (stomata·1000μm^{-2})
Control	8	2.11±0.78	5.70±1.25
Model	20	2.00±0.52	4.45±1.05
PA	17	3.07±0.69^{bd}	7.11±1.90^{ad}
TA	20	3.25±0.82^{bd}	6.55±1.44^{ad}
PB	17	2.82±0.37^{bd}	8.76±1.45^{bd}
TB	20	2.82±0.56^{bd}	8.76±1.79^{bd}

$^{a}P<0.05$, $^{b}P<0.01$, *vs* control group; $^{d}P<0.01$, *vs* model group.

Comparison of urinary ionic concentration

The excretions of Na^+, K^+ and Cl^- in the PA and PB group were significantly increased than those in the control group and the model group respectively ($P<0.05$ or $P<0.01$) (Table 2). The excretion of these ions in the TA group was also increased, but in the TB group, increase in ionic excretion was only limited to K^+ and Cl^-, whereas the Na^+ excretion was not significantly different from that in the model or the control group (Table 2).

Table 2 Comparison of urinary ionic concentration between groups (mmol·L^{-1}, $\bar{x}\pm s$)

Group	*n*	Na^+	K^+	Cl^-
Control	8	117.98±42.29	100.16±31.32^{c}	93.43±36.20
Model	20	129.33±36.75	162.21±39.42^{a}	120.49±42.34
PA	17	231.28±41.09^{ac}	241.63±59.43^{ac}	212.17±44.01^{ac}
TA	20	231.44±34.12^{ac}	306.45±79.53^{ac}	240.66±31.37^{ac}
PB	17	171.69±27.48^{ac}	185.97±54.92^{ac}	158.10±32.79^{ac}
TB	20	135.33±34.59	188.17±73.91^{ac}	149.50±45.79^{a}

$^{a}P<0.05$, *vs* control group; $^{c}P<0.05$, *vs* model group

Comparison of urine volume between groups

The urine volumes 2h after CP I and CP II gastrogavage in the prevention or treatment groups (average 1250μL) were more than that in the control group (average 550μL), and that in the model group was the least one (average 150μL).

DISCUSSION

It is considered currently that liver fibrosis is the basic pathologic change of chronic liver diseases. No matter what the pathogenic mechanism of different liver diseases is, the ultimate consequence of progressive pathologic processes is the development of cirrhosis, portal hypertension and ascites[42-46]. CCl_4 is a super-hepatotoxin, with which the CCl_3 free radical is produced during metabolic processes and acts on liver cells to covalently conjugate with the cyto-membranous unsaturated lipid to cause lipid peroxidation and necrosis of hepatocytes[16,47,48].

CP I and CP II are made up according to the traditional Chinese medicinal therapeutic principle in treating "hypochondriac pain", "lump" and "tympanites". The former has the effects of activating blood circulation to relieve stasis, strengthening "Spleen", supplementing Qi, and smoothening Qi to eliminate fullness, The latter is mainly used to activate blood circulation and remove stasis. Salviae miltiorrhizae in the prescriptions could preserve the integrity of hepatocytes, eliminate toxic free radicals, inhibit lipid peroxidation of cytomembrane and relieve necrosis of hepatocytes[49]. The two composite Chinese herbal prescriptions contain equal dosage of Salviae miltiorrhizae, aiming at antagonizing the CCl_3 free radical, preserving the integrity of hepatocytes and decreasing the toxic action of CCl_4 on hepatocytes. However, view from the mortality of hepato-fibrosis mice, the mortality in the PA group was the lowest, and that in the PB and TB groups was not significantly different from that in the model group, the results suggested that the effect of CP I in protecting against acute damage of hepatocytes was superior to that of CP II. Wang held that the main mechanisms of Chinese herbal medicine in antagonizing liver fibrosis were: (1) To protect liver cells from degeneration, necrosis and immunological damage so as to eliminate the inducing factors of liver fibrosis; (2) to inhibit the activation and proliferation of hepatic stellate cells; (3) to decrease the expression of the genes responsible for ECM secretion; (4) to promote the activity and production of collagenase[14,50].

According to traditional Chinese medical theory, cirrhotic ascites, one of the serious complications of liver cirrhosis, is caused by insufficiency of Yuan-Qi (vigour) and ferociousness of evil Water in the late decompensatory stage. Radix Codonopsis Pilosulae used in the prescriptions may strengthen "Spleen" and promote its function, activate Yuan-Qi of Middle-Jiao; Rhizoma Atractylodis Alba may strengthen "Spleen" and promote urination, and supplement "Spleen" to remove ascites; and Rhizoma Alismatis has special function in inducing duresis. The collocation of the four drugs has effects not only in strengthening Spleen, supplementing Qi, activating blood circulation to relieve stasis, and inducing diuresis to relieve abdominal distension, but also in antagonizing liver fibrosis and protecting liver.

In the previous study, it was shown that PLS are opening of subperitoneal lymphatic capillary vessels on the surface of peritoneum, possessing an active absorptive function for liquid and granular substances in the peritoneal cavity, and the drugs for treating ascites can accelerate the absorption of peritoneal lymph by PLS. This experiment touched preliminarily upon the function of PLS regulation and changes of urinary volume and ions excretion during prevention and treatment of liver fibrosis with traditional Chinese drugs. It was shown in the experiment that the diameter and density of PLS in the CPIor CP Ⅱ prevention or treatment groups were all higher than those in the control or the model groups respectively. Our previous study also revealed that when the diameter and density of PLS were increased by drugs, the quantity of absorption through PLS was increased significantly[4]. It was further proved that the urinary volume and ionic excretion in the CP I and CP II prevention groups were increased significantly and also increased in the two treatment groups except Na^+ in CP Ⅱ group. These results coincide with the regulatory effects of PLS, and indicate that both the two composite prescriptions have the effects in promoting the absorption through PLS on intraperitoneal substances of PLS, so as to accelerate liquid and ion excretion in cirrohotic patients with ascites.

Abstract

AIM: **To study the dose-dependent of progesterone (P) effect and the interaction between the oxytocin (OT) and P on gastrointestinal motility.**

METHODS: **In order to monitor the gastric emptying and intestinal transit, the SD male rats were intubated via a catheter with normal saline (3ml/kg) containing $Na_2{}^{51}CrO_4$ (0.5μCi/ml) and 10% charcoal. OT was dissolved into normal saline and P was dissolved into 75% alcohol.**

RESULTS: **Low does of P (1mg/kg, i.p.) enhanced the gastric emptying (75±3%, *P*<0.05) and high dose of P (5mg/kg, i.p.) inhibit it (42±11.2%, *P*<0.01). P (1mg/kg) increased the intestinal transit (4.2±0.3, *P*<0.05) while the higher dose (10-20mg/kg) had no effect. OT (0.8mg/kg, i.p.) inhibited the gastric emptying (23.5± 9.8%, *P*<0.01). The inhibitory effects of P(20mg/kg) (32±9.7%, *P*<0.05) and OT (0.8mg/kg) on gastric emptying enhanced each other when the two chemicals were administrated simultaneously (17±9.4%, *P*<0.01).**

CONCLUSION: **Low dose of P increased GI motility while high dose of P decreased it. During the later period of pregnancy, elevated plasma level of OT may also participate in the gastrointestinal inhibition.**

INTRODUCTION

Gastrointestinal motility is disturbed in pregnant women because of the changes of some hormone levels in the plasma, such as estrogen (E), progesterone (P), and other gastrointestinal hormones[1,2]. Steroids, especially P and E, participate the regulation of gastrointestinal motility[3-5] and are involved in the pathogenesis of some functional disorders in the gut[6]. We reported that administration of estrogen inhibited the rat gastric emptying and intestinal transit while P enhanced the gut motility[7]. The effects of E were testified by other scholars while the inhibitory effect of P was observed[8]. Oxytocin (OT) is also a hormone related to pregnancy, and its plasma concentration is higher during the late phase[9, 10]. It is reported that OT inhibited gastric motility and secretion[11 - 13]. We recently found that administration of OT inhibited the rat gastrointestinal motility through inducing the release of cholecystokinin (CCK) (unpublished data). Progesterone affects the OT effect on uterine smooth muscle[14], but it is unknown if P and OT interact with each other on the effect of gut motility. In this study, three experiments were conducted to investigate the dose-dependent effect of P and the interaction between P and OT on gastric emptying and intestinal transit in male rats.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats weighing 250-350g were housed at 22℃ and light-controlled environment (6a.m.-8p. m.) and fed with rat chow. Tap water was given *ad libitum*.

Experiment protocol

Experiment 1. The male rats were randomly divided into four groups (*n*=6each). They were fasted but with access to water for 24h before use. On the day of experiment, the four groups of animals were injected intraperitoneally (i. p.) with 0, 0.3, 1.0 and 3.0mg/kg of P, respectively 15min before gastric intubation of a non-nutrient liquid meal. Fifteen min after the administration of the liquid meal, the rats were decapitated and the gastric emptying and intestinal transit were measured.

Experiment 2. The procedure was identical to that in experiment 1, except the dose of *P* was 0, 5, 10 and 20mg/kg, respectively in the four groups of animals (*n*=7).

Experiment 3. Male rats were divided into four groups with 7 animals each and fasted for 24h before use. Fifteen min before gastric intubation of a non-nutrient liquid meal, the animals were injected i.p. with the normal saline and 75% alcohol (1ml/kg) in group 1, OT (0. 8mg/kg) and 75% alcohol (1ml/kg) in group 2, normal saline (1ml/kg) and P (20mg/kg) in group 3, and OT (0.8mg/kg) and *P* (20mg/kg) in group 4. OT was dissolved in the normal saline and *P* was dissolved in the alcohol (75%).

Measurement of gastric emptying and GI transit

Gastric emptying and GI transit were measured as described by Doong *et al*[15]. Rats were intubated via a catheter (PE-205, ID 1. 67mm, OD 2.42mm, Clay-Adam, Parsippany, NJ, USA) with normal saline (3mL/kg) containing $Na_2{}^{51}CrO_4$ (0.5μCi/mL) and 10% charcoal. The test meal was continuously stirred before intubation. Air (0.5mL) was used to flush the residual charcoal suspension in the catheter into the rats. Fifteen min later, the rats were decapitated and the stomach and attached small intestine immediately exposed by laparotomy. After ligation of the esophagogastric, gastroduodenal, and ileocecal junctions, the whole stomach and small intestine were carefully removed and placed on a wooden board to observe the leading edge of the charcoal in the intestine. The small intestine was then divided into 10 equal segments and the radioactivity in the stomach and each segment of small intestine was measured in an automatic gamma counter (1470 Vizard, Pharmacia, Turku, Finland). Gastric emptying was measured by determining the amount of labeled chromium contained in the small intestine 15min after

intubation, expressed as a percentage of the amount given. Intestinal transit was assessed by calculating the geometric center of distribution of the radioactivity with the 10 segments by summation of the radioactivity in each segment multiplied by the segment number.

Statistical analysis

The data were expressed as the mean value ± S. E. M. The treatment means were tested for homogeneity using one-way analysis of variance, and the significance of any difference between means was tested using Duncan's multiple range test. A difference between two means was considered to be statistically significant when P was less than 0.05.

RESULTS

Low dose of P on gastric emptying and intestinal transit

Gastric emptying was enhanced slightly after P (0.3mg/kg) was injected i. p., and was elevated significantly by administration of P (1mg/kg) in the same way (P<0.05, n=6). P (3mg/kg) inhibited the gastric emptying, although the difference was not significant (Figure 1-1). Administration of P, 1mg/kg or 3mg/kg, increased the intestinal transit significantly (P<0.05, n=6), but the dose of 0.3mg/kg did not influence it (Figure 1-2).

High dose of P on gastric emptying and intestinal transit

Administration of P (5-20mg/kg, i.p.) dose dependently decreased the gastric emptying (Figure 2-1). In this experiment, only the lowest dose of P (5mg/kg, i.p.) significantly increased the intestinal transit, P with much higher dose (10 and 20mg/kg) did not influence the intestinal transit (Figure 2-2).

Interaction of OT and P on gastric emptying and intestinal transit

Compared with control, both OT (0.8mg/kg, i.p.) and P (20mg/kg i.p.) significantly inhibited the gastric emptying. When both OT and P were administrated, the gastric emptying was further inhibited (Figure 3). Administration of OT (0.8mg/kg) and/or P (20mg/kg) did not influence the intestinal transit.

DISCUSSION

It is known that the liquid emptying slows as the calorie content increases. For nutrient liquid that stimulates intestinal feedback inhibition, there is an initial rapid emptying phase followed by a linear phase. In this study, we used non-nutrient liquid meal, and therefore the emptying rate was rapid, representing the initial rapid emptying of nutrient liquid. Because the volume in the initial rapid emptying contributes greatly to the nutrient liquid being half emptied, it is reasonable to assume that the changes of liquid emptying caused by the hormones from our study could influence the half-emptying time of nutrient liquid.

The result in this study indicated that the lower dose of P enhanced the gastrointestinal motility while the higher dose inhibited it. This data could explain why different effects of P on gastric emptying and intestinal transit were observed. Different routes of administration could make the chemicals absorbed at different velocity, thus making the plasma level of this hormone different. Besides the central nervous system, other organs such as the uterus also secrete OT into blood[16, 17]. In the pregnant women with or without pain, the OT concentration in plasma is much higher than that in the cerebrospinal fluid, so the higher level of OT during the late period of pregnancy may mainly come from the peripheral organs[18].

Although there is no direct evidence that there exists OT receptor in the gut, our data indicated that OT could inhibit the gastric emptying.

Disturbed gastrointestinal motility was observed in the pregnant women. In the early period, the high level of estrogen and progesterone may contribute to this pathophysiological phenomenon. During the late period, the OT level in plasma was elevated[9, 10]. In the present study, when administrated simultaneously, the inhibitory effects of P and OT on gastrointestinal were strengthened each other. Thus, OT may also participate in the inhibition of gastrointestinal motility during the late period of pregnancy.

In the uterus, The OT receptor is upregulated in the secretary phase during the oestrous cycle and downregulated during the early pregnancy[19-21]. Two levels of interaction between OT and steroid hormones were reported, the genomic and non - genomic mechanisms[22]. Estrogen induces the OT receptor (OTR) mRNA expression, and then increases the OTR density on the membrane of the uterus smooth muscle[22-35]. This effect of estrogen was also observed in the central nervous system[36]. The effect of P on OTR expression is controversial. It has been suggested that, through the nuclear receptors, P inhibits the OTR mRNA expression, and makes the target cell less sensitive to OT stimulation[25, 26, 37-43]. Giacalone also reported that, RU-486, a P receptor antagonist, increases the incidences of tachysystole, hypertonia and fetal heart rat abnormality[44]. However, Al-Matubsi reported that pretreatment with P enhanced the OTR mRNA expression in the ovine corpus luteum[45]. OT excites the uterus smooth muscle mainly through two mechanisms: binding the membrane receptor directly and increasing the secretion of prostaglandin (PG)[46-48]. P enhanced uterine PGF 2á secretion in response to OT in ovaritctomized sows[49].

Direct interaction, but not through the regulation of RNA expression, between P and OT was also reported. Grazzini *et al* found that P specially binded to the OTR and inhibited its ligand binding and signal functions[14, 50]. Burger also reported that P inhibited the calcium signaling evoked by ligand stimulation of G protein-coupled receptor. This kind of P effect was fast, reversible and was not prevented by cycloheximide, indicating a non-genomic nature[51].

In this experiment, administration of P (20mg/kg) and OT (0.8mg/kg) in combination inhibited the gastric emptying, and the gastric motility was further attenuated. Because this effect was found within 30min after the chemical treatment, it is clear that the nature of the potentiation between P and OT is non - genomic.

In conclusion, the data indicated that high dose of P inhibited the GI motility while low dose of P enhanced it. During pregnancy, especially during the later period, high levels of P and OT enhance each other to disturb the gastrointestinal motility.

Abstract

AIM: **The objective of this study is to elucidate the potential role of poly-morphonuclear neutrophils (PMN) in the development of such a sinusoidal endothelial cell (SEC) injury during early acute obstructive cholangitis (AOC) in rats.**

METHODS: **Twenty one Wistar rats were divided into three groups: the AOC group, the bile duct ligated group (BDL group), and the sham operation group (SO group). The common bile duct (CBD) of rats in AOC group was dually ligated and 0.2ml of the *E. coli* O_{111} B_4 (5×10^9cfu/ml) suspension was injected into the upper segment, in BDL group, only the CBD was ligated and in SO group, neither injection of E. *coli* suspension nor CBD ligation was done, but the same operative procedure. Such group consisted of seven rats, all animals were killed 6h after the operation. Morphological changes of the liver were observed under light and electron microscope. Expression of intercellular adhesion molecule-1 (ICAM-1) mRNA in hepatic tissue was determined with reverse transcription polymerase chain reaction (RT-PCR). The serum levels of alanine aminotransferase (ALT) were determined with anutoanalyger and cytokine-induced neutrophil chemoattractant (CINC) was determined by enzyme-linked immunosorbent assay (ELISA).**

RESULTS: **Neutrophils was accumulated in the hepatic sinusoids and sinusoidal endothelial cell injury existed in AOC group. In contrast, in rats of BDL group, all the features of SEC damage were greatly reduced. Expression of ICAM-1 mRNA in hepatic tissue in three groups were 7.54±0.82, 2.87±0.34, and 1.01±0.12, respectively. There were significant differences among three groups ($P<0.05$). The serum CINC levels in the three groups were 188±21ng·L^{-1}, 94±11ng·L^{-1}, and 57±8ng·L^{-1}, respectively. There were also significant differences among the three groups ($P<0.05$). Activity of the serum ALT was 917±167nkat·L^{-1}, 901±171nkat·L^{-1}, and 908±164nkat·L^{-1}, respectively, ($P>0.05$).**

CONCLUSION: **Hepatic SEC injury occurs earlier than hepatic parenchymal cells during AOC. Recruitments of circulating neutrophils in the hepatic sinusoidal space might mediate the SEC injury, and ICAM-1 in the liver may modulate the PMN of accumulation.**

Gong JP, Wu CX, Liu CA, Li SW, Shi YJ, Li XH, Peng Y. Liver sinusoidal endothelial cell injury by neutrophils in rats with acute obstructive cholangitis. *World J Gastroenterol* 2002;8(2):342-345

INTRODUCTION

Biliary tract infection, especially acute obstructive cholangitis (AOC) is common[1,2]. Despite a multitude of advances in treatment of surgical infection, this remains a significant cause of morbidity and mortality[3,4], where sepsis and endotoxemia from AOC are important causes of multiple organ failure (MOF) and deaths[5-9]. Ohtsuka *et al*[10] reported that polymorphonuclear neutrophils (PMN) accumulated in the hepatic sinusoidal space increased obviously in rats with obstructive jaundice and there were interaction between PMN and sinusoidal endothelial cells (SEC) causing injury during AOC. This study was study the potential role of PMN in the development of SEC injury and the mechanism of accumulation of PMN during early period of AOC.

MATERIALS AND METHODS

Animal Experiment

Male Wistar rats weighing 200-230g were purchased from Laboratory Animal Center of Chongqing University of Medical Science. These animals were divided into three groups: the AOC group, bile duct ligated group of (BDL group), and sham operation group (SO group). All the animals were killed 6 hour after operation, the surgical procedures were carried out under light diethyl ether anesthesia. The animal models were performed as follows. In AOC group, a 1. 5cm medium incision was made over the upper abdomen, the common bile duct (CBD) was mobilized and dually ligated, and 0.2mL of the *E. coli* O_{111} B_4 (5×10^{12}cfu·L^{-1}) (Sigma, USA) suspension was injected into the upper segment. In BDL group, the CBD was doubly ligated but without injection of *E. coli* O_{111} B_4 suspension. In SO group, neither *E. coli* injection of suspention nor CBD ligation was done, but only routine operative procedure was performed. Seven rats constituted each group.

Serum ALT & CINC

Hepatic injury was assessed by measuring the serum alanine aminotransferase (ALT) which was performed with autoanalyger. The serum cytokine-induced neutrophil chemoattractant (CINC) concentration was measured by enzyme-linked immunosorbent assay (ELISA) according to the manufacturer's direction with a lower limit of 10ng·L^{-1}. For CINC, microtitre plates were coated with anti CINC mAb overnight at room temperature on a plate shaker, after the blockage, samples were then added. The detected antibody was biotinylated anti-CINC. Standard curves were made with a natural CINC calibrated against the WHO interim International Standard.

Expression of ICAM-1 mRNA in Hepatic Tissue

Total RNA was isolated from rat liver tissue by using the Trizol Reagent (Life Technologies, USA). The quality of RNA was controlled by the intactness of ribosomal RNA bands. A total of 0.5mg of each intact total RNA sample was reverse-transcribed to complementary DNA (cDNA) by using reverse transcription polymerase chain reaction (RT-PCR) kit (Roche, USA). cDNA was stored at -70℃ until PCR analysis. The PCR primers used were ICAM-1: sense (5'-CTTCTCCTGCTCTGCAACCC-3'), antisense (5'-GGGAGAGCACATTCAGGTC-3'); β-actin: sense (5'-ACCACAGCTGAGAGGGAAATCG-3'), antisense(5'-AGAGGTCTTTACGGATGTCAACG-3'). The sizes of the amplified PCR products were 326 bp for ICAM-1 and 281 bp for β-actin. The procedure was as follows: denaturation at 95℃ for 30sec, annealing at 55℃ for 1min, and extension at 71℃ for 1min for 28 cycles. The PCR products were electrophoresed in 20g·L^{-1} agarose gels, and the gels were ethidium bromide stained and video photographed on an ultraviolet transilluminator. The bands representing reactive product were scanned by densitometer of a Bio-Image Analysis System (Doc Gel 2000). The relative optical density (ROD) values were expressed as the level of ICAM-1 mRNA in hepatic tissue.

Morphologic Observations of Hepatic Tissue

Liver samples from different liver lobes were fixed with 100mL·L^{-1} buffered formalin or 25g·L^{-1} glutaraldehyde immediately. For light microscopy, the tissue blocks were embedded in paraffin, and the sections were stained with hematoxylin and eosin(H&E). For transmission electron microscopy (TEM), the tissue blocks were embedded in Epon 618 resin and ultrathin sections were stained with uranyl acetate and lead citrate. A H-2000 transmission electron microscope was used.

Statistical Analysis

Results were presented as $x \pm s$. Statistical difference was analysed by means of the analysis of Variance (ANOVA). $P<0.05$ is considered significant.

RESULTS

Accumulation of PMN in hepatic sinusoidal space

Accumulation of PMN in the hepatic sinusoidal space was found, under light microscopy, PMN counts in hepatic sinusoidal space increased significantly after 6h in AOC group in comparison with BDL group or SO group. Under electron microscopy, PMN were seen easily in hepatic sinusoidal space in AOC group (Figure 1A).

Sinusoidal endothelial cell injury

Under light microscopy, no distinct change in SEC could be shown in any of the above groups. Electron microscopically, however, focal detachment, decreased electron density of cytoplasm, and swollen or even vacuolated mitochondria in SEC could often be observed in the AOC group (Figure 1B). In this group, the Kupffer cells were enlarged, but normal surface structures were retained and no degenerative changes of the nucleus or cytoplasm were shown (Figure 1-C). In contrast such changes could be occasionally seen in the SEC of BDL group. No evident morphological changes of SEC could be observed in SO group.

Expression of ICAM-1 mRNA in hepatic tissue

Expression of ICAM-1 mRNA in hepatic tissues was distinctly enhanced after 6h in AOC group when compared to other two groups ($P<0.05$). There was less expression of ICAM-1 gene in BDL group and no expression of ICAM-1 gene in SO group (Figure 2).

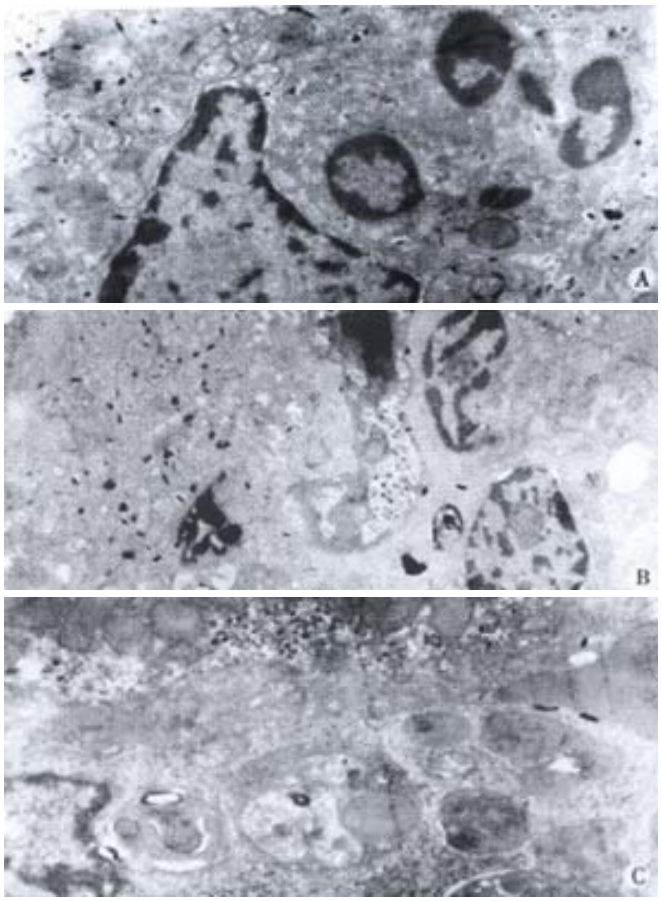

Figure 1 A: In AOC group, PMN was seen easily in hepatic sinusoidal. TEM×4000; B: In AOC group, two PMNs were seen in hepatic sinusoid with decreased electronic density of cytoplasm, and swollen or even vacuolated mitochondria in SEC. TEM×3000; C: In AOC group, KC was also seen easily in hepatic sinusoid with active phagocytosis. TEM×4000

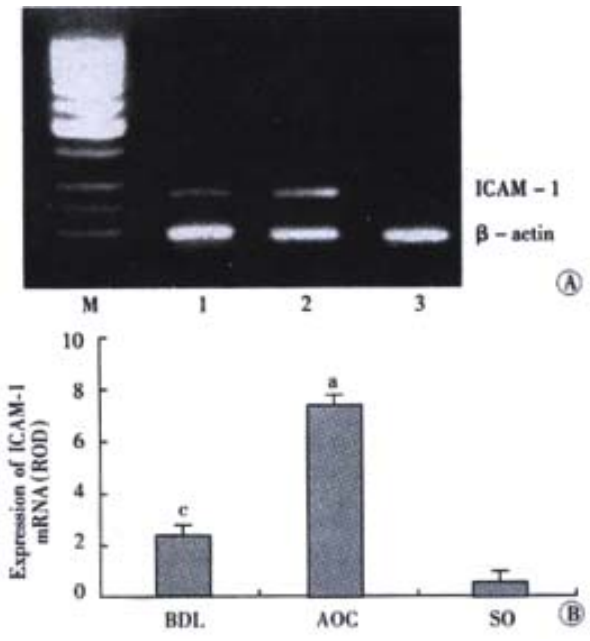

Figure 2 A: Expression of ICAM-1 mRNA. M, Marker. Lane 1: BDL; Lane 2: AOC; Lane 3: SO;B: Expression ofICAM-1 mRNA. $^{a}P<0.05$, vs other two groups, $^{c}P<0.05$, *vs* control group

The serum ALT level and CINC concentration

The serum ALT level and CINC concentration were shown in Table 1. The serum ALT activity in the three groups was evidently unchanged in the same period (P>0.05). but, the serum CINC concentration in the AOC group was significantly higher than that in the BDL group or the SO group (P<0.05).

Table 1 The changes of serum ALT level and CINC concentration in the three groups ($\bar{x}\pm s$, n=7)

Serum parameters	AOC	BDL	SO
ALT (nkat·L^{-1})	917±167	901±171	908±164
CINC (ng·L^{-1})	188±21[a]	94±11[c]	57±8

[a]P<0.05, *vs* other two groups. [c]P<0.05, *vs* SO group.

DISCUSSION

Neutrophils and macrophages play a central role in the host defence against microbial infections. However, they also produce damage to normal tissue by releasing oxygen free radicals, elastase, and various cytokines[11,12]. The hepatic sinusoidal endothelia are fenestrated allowing exchange of substance between the circulating blood and hepatocytes[13]. The Kupffer cells are located at the luminal side of the SEC and is able to phagocytize pathogens and release cytokines, such as tumor necrosis factor-α(TNF-α), interleukin (IL)-1, IL-6, IL-8, and adhesion molecules ICAM-1 (CD54), etc[14-16], these inflammatory cytokines and chemokines can be upregulated in inflammatory processes within the liver[17-20]. Recent reports have revealed the interaction between neutrophils and SEC in sepsis, and neutrophils have the potential to cause endothelial cell injury by producting protease and superoxides[13,16,21]. Overreaction of neutrophils may be responsible for organ failure in cholestatic rats[10,12,22]. We found that accumulation of PMNs in the hepatic sinusoidal space was accompanied by SEC injury with decreased electron density of cytoplasm, and swollen or even vacuolated mitochondria in the early period of AOC. Our results indicated that damage of SEC ocurred earlier than that of hepatic parenchymal cells and the vascular endothelium which was a critical and initial event in AOC and organ failure processes. SEC injury might develop microcirculatory disturbance in the liver, resulted in hepatocytic damage and hepatic dysfunction.

Although obvious parenchymal cell necrosis was not observed in our study, it is likely that the microcirculatory disturbance could provoke liver dysfunction during AOC. CINC, a member of IL-8 family and a major neutrophil chemotactic factor in rats, increased in the liver during sepsis[23]. Substantial neutrophil accumulation in the liver and the role of these cells in the pathophysiology of liver injury was found in models of endotoxin shock and hepatic ischemia-reperfusion injury[24-32]. But, the relationship between PMN accumulation, ICAM-1 expression and SEC injury during AOC is unclear. The injury to SECs was induced by the interaction of the activated PMNs and SECs via ICAM-1 and CD18[33-37]. Ohtsuka *et al* reported ICAM-1 expression on SEC started to rise 6-12h after partial hepatectomy, reaching a peak after 24-48h. ICAM-1 is particularly expressed on Kupffer cells, endothelial cells, and leukocytes and it promotes accumulation of PMN in the hepatic sinusoids and is linked to endothelial cell injury[38-52]. The mechanisms of upregulated ICAM-1 gene expression during AOC may included (1) inflammatory cytokines upregulate ICAM-1 expression in endotoxemia[28]; (2)synthesis of ICAM-1 is increased and /or its elimination is decreased through the bile in bile duct ligated animals.

In conclusion, hepatic SEC injury occurs earlier than hepatic parenchymal cells damage during AOC. Recruitment of circulating neutrophils in the hepatic sinusoidal space enhance the SEC injury, and ICAM-1 in the liver can modulate the accumulation of PMN.

Abstract

AIM: **To determine the NF-kB activity in peripheral blood mononuclear cells (PBMC) in patients with acute cholangitis of severe type (ACST) and correlate the degree of NF-kB activation with severity of biliary tract infection and clinical outcome.**

METHODS: **Twenty patients with ACST were divided into survivor group (13 cases) and nonsurvivor group (7 cases). Other ten patients undergoing elective gastrectomy or inguinal hernia repair were selected as control group. Peripheral blood samples were taken 24 hours postoperatively. PBMC were separated by density gradient centrifugation, then nuclear proteins were isolated from PBMC, and Electrophoretic Mobility Shift Assay (EMSA) used determined. The results were quantified by scanning densitometer of a Bio-Image Analysis System and expressed as relative optical density (ROD). The levels of TNF-α, IL-6, and IL-10 in the plasma of patients with ACST and healthy control subjects were determined by using an enzyme-linked immunoassay (ELISA).**

RESULTS: **The NF-kB activity was 5.02±1.03 in nonsurvivor group, 2.98±0.51 in survivor group and 1.06±0.34 in control group. There were statistical differences in three groups ($P<0.05$). The levels of TNF-a and IL-6 in plasma were (498±53)ng·L^{-1} and (587±64)ng·L^{-1} in nonsurvivor group, (284±32)ng·L^{-1} and (318±49)ng·L^{-1} in survivor group and (89±11)ng·L^{-1} and (102±13) ng·L^{-1} in control group. All patients with ACST had increased levels of TNF-α and IL-6, which were many-fold greater than those of control group, and there was an evidence of significantly higher levels in those of nonsurvivor group than that in survivor group ($P<0.05$). The levels of IL-10 in plasma were (378±32)ng·L^{-1}, (384±37)ng·L^{-1} and (68±11)ng·L^{-1} in three groups, respectively. All patients had also increased levels of IL-10 when compared with control group ($P<0.05$), but the IL-10 levels were not significantly higher in nonsurvivors than in survivors ($P>0.05$).**

CONCLUSION: **NF-kB activity in PBMC in patients with ACST increases markedly and the degree of NF-kB activation is correlated with severity of biliary tract infection and clinical outcome.**

Gong JP, Liu CA, Wu CX, Li SW, Shi YJ, Li XH. Nuclear factor kB activity in patients with acute severe cholangitis. *World J Gastroenterol* 2002; 8(2):346-349

INTRODUCTION

Acute cholangitis of severe type (ACST) is a common problem facing today's surgeons[1-3]. Despite a multitude of advances in the area of surgical infection and surgical or nonsurgical interventions to treat biliary tract diseases, ACST and biliary sepsis remain a significant cause of morbidity and mortality[4-9]. Many reports have focused on aspects of the proinflammatory cytokines which are believed to be central to the pathophysiology of the sepsis syndrome[10-11]. Recent investigations have shown that expression of many cytokines is closely linked to the activation of transcriptional factors[12-13]. Among several transcriptional regulatory factors involved in immuno-regulatory genes expression, nuclear factor kappa B (NF-kB) acts as a critical step for directing the transcription of many proinflammatory cytokine genes in animal models of sepsis or endotoxemia[14-16]. Investigations regarding the role of NF-kB in human inflammatory diseases are scarce[17-20]. So far, no study has aimed to examine in patients with ACST the relationship among NF-kB activity in peripheral blood mononuclear cells (PBMC), the concentrations of the pro-inflammatory cytokines in plasma, and clinical outcome. The purpose of this study was to determine the NF-kB DNA binding activity in circulating blood cells and the cytokines tumor necrosis factor alpha (TNF-α), interleukin (IL)-6, and IL-10 profile in patients with ACST. Attempts were made also to correlate degree of NF-kB activation with severity of biliary tract infection and clinical outcome.

MATERIALS AND METHODS

Patients

The study population was recruited from a series of 20 patients with a clinical diagnosis of ACST. Among them, 13 were male, and 7 female, ranging in age from 27 to 78 yr. All patients had manifestations of fever, chill, jaundice, and right upper quadrant pain. Other manifestations included two or more of the following clinical conditions: Blood cultures were positive; Core body temperature >39℃ or <36℃; Heart rate >120 beats/min; Hypotension: A systolic blood pressure of <12.0 kPa or a reduction of >5.33 kPa from baseline in the absence of other causes of hypotension; White blood cell count >1.5×10^{9}L^{-1}. These patients were divided into nonsurvivor group (7 cases) and survivor group (13 cases). Ten patients undergoing elective gastrectomy or inguinal hernia repair were selected as control group. Peripheral blood samples were taken 24h postoperatively.

Isolation of PBMC

PBMC were separated by density gradient centrifugation, as previously described[18]. In brief, PBMC were isolated grom blood

freshly collected on sodium citrate by centrifugation on Ficoll-Hypaue. Before Ficoll, a fraction of the blood was centrifuged 5min at 1500r ·min^{-1} and 1mL of plasma was collected and put immediately at -20℃ for further cytokine measurements.

Isolation of nuclear proteins

Nuclear proteins were isolated from PBMC extract by placing the sample in 0.8mL of ice-cold hypotonic buffer [10mmol·L^{-1} HEPES (pH7.9), 10mL KCL, 0.1mmol·L^{-1} EDTA, 0.1mmol·L^{-1} ethylene glycol tetraacetic acid, 1mmol·L^{-1} DTT; Protease inhibitors (aprotinin, pepstatin, and leupeptin, 10mg·L^{-1} each)]. The homogenates were incubated on ice for 20min, vortexed for 20s after adding 50μL of 10 per cent Nonidet P-40, and then centrifuged for 1 minute at 4℃ in an Eppendorf centrifuge. Supernatants were decanted, the nuclear pellets after a single wash with hypotonic buffer without Nonidet P-40 were suspended in an ice-cold hypertonic buffer [20mmol·L^{-1} HEPES (pH7.9), 0.4mol·L^{-1} NaCL, 1mmol·L^{-1} EDTA, 1mmol·L^{-1} DTT; Protease inhibitors], incubated on ice for 30min at 4℃, mixed frequently, and centrifuged for 15min at 4℃. The supernatants were collected as nuclear extracts and stored at -70℃. Concentrations of total proteins in the samples were determined according to the method of Bradford.

Electrophoretic Mobility Shift Assay (EMSA)

NF-kB binding activity was performed in a 10-uL binding reaction mixture containing 1×binding buffer [50mg·L^{-1} of double-stranded poly(dI-dC), 10mmmol·L^{-1} Tris-HCl (pH 7.5), 50mmmol·L^{-1} NaCl, 0.5mmmol·L^{-1} EDTA, 0.5mmmol·L^{-1} DTT, 1mmmol·L^{-1} $MgCl_2$, and 100mL·L^{-1} glycerol], 5μg of nuclear protein, and 35 fmol of double-stranded NF-kB consensus oligonucleotide (5'-AGT TGA GGG GAC TTT CCC AGG-3') that was endly labeled with γ-32P(111TBq mmol^{-1} at 370GBq L^{-1}) using T4 polynucleotide kinase. The binding reaction mixture was incubated at room temperature for 20min and analyzed by electrophoresis on 7 per cent nondenaturing polyacrylamide gels. After electrophoresis the gels were dried by Gel-Drier (Bio-Rad Laboratories, Hercules, CA) and exposed to Kodak X-ray films at -70℃.

Quantifying with the Phosphor Imager

The binding bands were quantified by scanning densitometer of a Bio-Image Analysis System. The results were expressed as relative optical density (ROD).

Measurement of cytokines in plasma

TNF-α, IL-6, and IL-10 levels in the plasma of patients with ACST and healthy control subjects were determined with using an enzyme-linked immunoassay (ELISA). The detection limits of the assays were 50ng·L^{-1} (TNF-α), 49ng·L^{-1} (IL-6), and 49ng·L^{-1} (IL-10). All cytokines assays were performed in duplicate and had intra- and interassay variations lower than 8% and 11%, respectively.

Statistical Analysis

Data were analyzed with using Microsoft Excel with Astute statistical add-in and were expressed as median ± standard error. *A* value of $P \leqslant 0.05$ was considered statistically significant.

RESULTS

Methods

The patients of nonsurvivor group died within 35d, all from complications of SIRS, sepsis or MOF. The patients of survivor group were well discharged from hospital postoperatively in 28 days. The median age in nonsurvivor group was 54 yr, which was not significantly different from that of survivor group (53yr) (P>0.05). An admission APACHE II score in nonsurvivor group was 25, which was also not different from that of survivor group (24) (P>0.05).

The NF-kB activity was 5.02±1.03 in nonsurvivor group, 2.98±0.51 in survivor group and 1.06±0.34 in control group. There were statistical differences in three groups (P<0.05). The NF-kB activity increased in all patients with ACST, versus the control group (P<0.05), and the patients of nonsurvivor group had higher levels of NF-kB activation than those of survivor group (P<0.05, Figure 1).

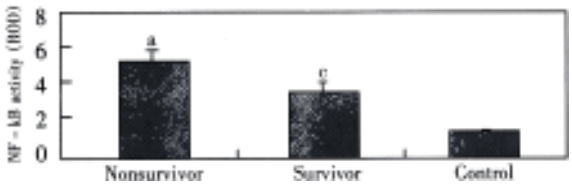

Figure 1 The activity of NF-kB in three groups. [a]P<0.05, *vs* other groups, [c]P<0.05, *vs* control.

The levels of TNF-a and IL-6 in plasma were (498±53)ng·L^{-1} and (587±64)ng·L^{-1} in nonsurvivor group, (284±32)ng·L^{-1} and (318±49) ng·L^{-1} in survivor group and (89±11)ng·L^{-1} and (102±13)ng·L^{-1} in control group. All patients with ACST had increased levels of TNF-α and IL-6, which were many-fold greater than those of control group, and there was an evidence of significantly higher levels in those of nonsurvivor group than that in survivor group (P<0.05). The levels of IL-10 in plasma were (378±32)ng·L^{-1}, (384±37)ng·L^{-1} and (68±11) ng·L^{-1} in three groups, respectively. All patients had also increased levels of IL-10 when compared with control group (P<0.05), but the IL-10 levels were not significantly higher in nonsurvivors than in survivors (P>0.05). (Figure 2).

DISCUSSION

The overwhelming inflammatory response in patients with ACST is a major cause which induces systemic inflammatory response syndrome (SIRS) and MOF[1-4]. Mortality in patients with ACST reflects a multifactorial pathology, and neither cytokine concentrations in plasma nor even the APACHE II score can be expected to accurately predict patients' outcomes[5-9]. NF-kB is a protein found in inflammatory cells such as lymphocytes, monocytes, and macrophages. NF-kB activation is stimulated by LPS, TNF-α, and IL-1, the very early mediators or factors in the inflammatory cascade[21,22]. Once stimulated NF-kB activates various parts of the inflammatory resposes: TNF-α, IL-6 and IL-10, and adhesion molecules such as selectins and integrin[23-25]. These mediators and factors then promote further activity of the inflammatory cascade and "off" goes the SIRS and MOF[2,8,9,24]. Therefore, we chose to focus on NF-kB as an important regulatory factor to regulate the expression of multiple cytokine genes. NF-kB is a ubiquitous transcription factor involved in the signal transduction pathway of many inducers of the inflammatory response and is therefore a potentially attractive target for

immunomodulatiom to reduce sepsis and organ dysfunction[26], but we are not yet clear about changes of NF-kB and relation between NF-kB and cytokines in patients with ACST. Foulds *et al*[20] reported that levels of nuclear-bound NF-kB (activated NF-kB) were greater in patients who developed organ dysfunction after surgery, and patients with lower levels of nuclear NF-kB who recovered from surgery without organ dysfunction. Bohrer *et al* investigated activity of NF-kB in nuclear extracts from PBMC of 15 patients with sepsis, of whom 10 survived. NF-kB activity was measured on days 1, 2, 3, 4, 5, 6, 8, 10, and 14 after admission where available. All patients with NF-kB binding activty exceeding 200% of day 1 died. This small study concluded that NF-kB activation might be an important event in clinical sepsis. But, Adib-Conquy *et al*[27] found the expression of NF-kB was signifcantly reduced for all patients with sepsis and trauma as compared with control subjects. In our study, by comparing the predictive value of measuring NF-kB activity in PBMC and the concentrations of some pro- and anti-inflammatory mediators in plasma in patients with ACST, we found that the NF-kB activity measured in the PBMC was a better overall predictor of mortality than the balance and time course of pro- and anti-inflammatory cytokines released in plasma. On the basis of these results NF-kB would seem to be a more sensitive molecular marker assay when compared with cytokines used as an indicator of sepsis.The expressions of many genes involved in the inflammatory and immune processes are regulated by NF-kB, TNF-α, IL-6, and IL-10, and they possess NF-kB binding sites in the promoter region, enabling messenger ribonucleic acid to express in response to extracellular stimuli[28-31]. TNF-α,IL-6, and IL-10 have all been implicated in the pathogenesis of SIRS and MOF that results from trauma, injury, infection, and sepsis[32-43]. In the present study, we found that TNF-α and IL-6 were elevated in the patients with ACST and there were higher levels of TNF-α and IL-6 in patients who survived than in patients who died, which is in agreement with previous reports. These previous studies also showed that levels were higher in patients with sepsis when compared with trauma patients. We found significant relationship between NF-kB activation and circulating concentrations of TNF-α and IL-6. IL-10, as an anti-inflammtory mediator, was elevated in the patients with ACST but reduced in patients who died. There might be other transcription factor as AP-1 involved in the signal transduction pathway of the inflammatory response[16,21,23,44-48] and its mechanism is going on.

In conclusion, we have shown NF-kB activation in PBMCs in patients with ACST increased markedly before death and was related to plasma TNF-α and IL-6 concentrations. These findings have important implications for the development of future therapeutic interventions in the critically ill and support the need for further study of the role of NF-kB activation in mortality from ACST and MOF.

Abstract

AIM: **To investigate the effects of areca on the contractile activity of isolated colonic muscle strips in rats and mechanism involved.**

METHODS: **Each strip (LMPC, longitudinal muscle of proximal colon; CMPC, circular muscle of proximal colon; LMDC, longitudinal muscle of distal colon; CMDC, circular muscle of distal colon.) was suspended in a tissue chamber containing 5mL Krebs solution (37℃), bubbled continuously with 950mL·L^{-1} O_2 and 50mL·L^{-1} CO_2. The mean contractile amplitude (A), the resting tension (T), and the contractile frequency (F) were simultaneously recorded on recorders.**

RESULTS: **Areca dose dependently increased the mean contractile amplitude, the resting tension of proximal and distal colonic smooth muscle strips in rats (P<0.05). It also partly increased the contractile frequency of colonic smooth muscle strips in rats (P<0.05). The effects were partly inhibited by atropine (the resting tension of LMPC decreased from 0.44±0.12 to 0.17±0.03; the resting tension of LMDC decreased from 0.71±0.14 to 0.03±0.01; the mean contractile amplitude of LMPC increased from -45.8±7.2 to -30.5±2.9; the motility index of CMDC decreased from 86.6±17.3 to 32.8±9.3; P<0.05 vs areca), but the effects were not inhibited by hexamethonium (P>0.05).**

CONCLUSION: **Areca stimulated the motility of isolated colonic smooth muscle strips in rats. The stimulation of areca might be relevant with M receptor partly.**

INTRODUCTION

Areca (*Areca catechu L.*) had already been shown to relieve indigestion, unblocked stagnation of the circulation of vital energy. It had been used to treat abdominal distention and constipation, which were caused by stagnation of the circulation of vital energy in taste. But the actions and mechanisms of areca on the colonic smooth muscle motility are not reported. In this study, we observed the effect of areca on the different colonic smooth muscle strips in rats and investigated the mechanism involved.

MATERIALS AND METHODS

Animal preparation

Wistar rats of either sex (gradeI, purchased from Animal Center of Lanzhou Medical College), weighing 200-250g, were sacrificed, and the proximal colon and distal colon were removed[1]. The segments of the colon were opened along the mesentery. Muscle strips (8×3mm) were cut, parallel to either the circular or the longitudinal fibers, and named circular muscle of proximal colon (CMPC), longitudinal muscle of proximal colon (LMPC), circular muscle of distal colon (CMDC), and longitudinal muscle of distal colon (LMDC). The mucosa on each strip was carefully removed.

Experiments

The muscle strip was suspended in a tissue chamber containing 5mL Krebs solution (37℃) and bubbled continuously with 950mL·L^{-1} O_2 and 50mL·L^{-1} CO_2[2]. One end of the strip was fixed to a hook on the bottom of the chamber. The other end was connected to an external isometric force transducer (JZ-BK,BK). Motility of colonic strips (under an initial tension of 1g) in 4 tissue chambers were simultaneously recorded on ink-writing recorders (LMS-ZB, Cheng-Du). After 1h equilibration, areca(10,100,1000g·L^{-1}) was added in the tissue chamber to observe their effects on colon; atropine(0.01μmol·L^{-1}) or hexamethonium(10μmol·L^{-1}), given 3min before the administration of areca(100g·L^{-1}), was added separately to investigate whether the actions of areca were relevant with M receptor or N receptor. The resting tension, the frequency, and the mean contractile amplitude of LMPC, CMPC and LMDC, as well as the motility index of CMDC were measured. Motility index= Σ(amplitude×duration).

Drugs preparation

Areca was broken into pieces, boiled, filtrated, and diluted to 1000g·L^{-1} (the drug was appraised and prepared by Drug Control Institute of Gansu Province). The following agents were used: atropine (Pharmaceutical Factory in Yancheng, Jiangsu Province), hexamethonium (Sigma Chemical Company).

Data analysis

The results were presented as $x\pm s$, and statistically analyzed by paired t test, P<0.05 was considered to be significant.

RESULTS

Effect of areca on the spontaneous contraction of colonic smooth muscle strips

Areca (10,100,1000g·L^{-1}) dose dependently increased the mean contractile amplitude of CMPC and LMDC, the motility index of CMDC, and the resting tension of LMPC, LMDC and CMDC; but it

decreased the mean contractile amplitude of LMPC (Figure 1). It increased the contractile frequency of CMPC and LMDC (Table 1). It had no significant effects on the resting tension of CMPC and the contractile frequency of LMPC and CMDC.

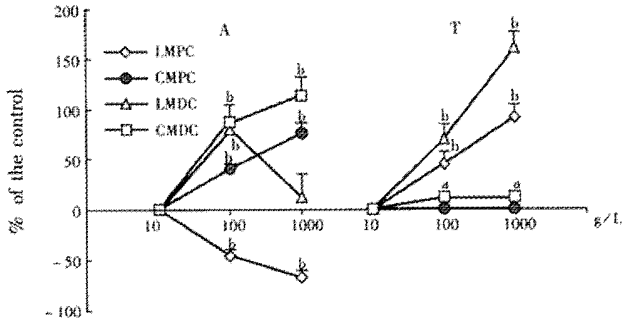

Figure 1 Effect of areca on the mean contractile (the motility index of CMDC) and the resting tension ($\bar{x}\pm s$, n=12)
LMPC: longitudinal muscle of proximal colon; CMPC: circular muscle of proximal colon; LMDC: longitudinal muscle of distal colon; CMDC: circular muscle of distal colon. A, the mean contractile amplitude; T, the resting tension. $^aP<0.05$, $^bP<0.01$ *vs* control.

Effect of atropine on the responses caused by areca

Atropine (0.01μmol·L^{-1}) itself had no significant effects on rat colon. But when given 3min before the administration of areca (100g·L^{-1}), it reduced the increasing action of areca on the resting tension of LMPC and LMDC, the motility index of CMDC, and the mean contractile amplitude of LMPC. It had no significant effects on the other action of areca (Table 2).

Table 2 Effect of areca on the mean contractile amplitude and the resting tension of colon, and the motilityindex of distal colon after atropine pretreatment in rats ($\bar{x}\pm s$, n=12)

	LMPC		CMPC		LMDC		CMDC

T, the resting tension; A, the mean contractile amplitude; MI, the motility index. $^aP<0.05$, $^bP<0.001$ *vs* control. $^cP<0.05$, $^dP<0.001$ *vs* areca.

Effect of hexamethonium on the responses caused by areca

Hexamethonium (10μmol·L^{-1}) had no significant effect on the contractile activity of each colonic smooth muscle strip. Hexamethonium given 3 minute before administration of areca (100g·L^{-1}) had no significant effects on the action of areca.

DISCUSSION

There are many diseases which are caused by colonic motility disorder or accompany with colonic motility abnormality, such as constipation, diarrhea, irritable bowel syndrome and so on[3-11]. There are some reports on the study of normal colonic motility and intestinal diseases that are connected with colonic motility[12-25]. The studies on how to treat the diseases that are caused by colonic motility disorder have also been reported[26-35]. But it still needs a long time for us to recognize the colonic motility completely.

Recently, the effects of Chinese herbals on the gastrointestinal motility have been reported[36-46]. Areca had been used to treat abdominal distention,constipation, abdominal pain and non-ulcer dyspepsia,which were considered to be connected with intestinal motility disorder[47-49]. Whether the clinical use is connected with its effects on colonic motility The present study revealed that areca dose dependently stimulated the contractions of proximal and distal colonic smooth muscle strips of rats. The exciting actions suggested that areca might caused the colonic contents to be mixed, stirred, promoted, and even excreted. These results can partly explained why areca was used to treat intestinal motility disorder.

Areca has been showed to stimulate both cholinergic M and N receptors. Our results showed that the stimulating effects of areca were partly blocked by atropine but not by hexamethonium. Our results suggested that the stimulating effects of areca on rat colonic smooth muscle strips were relevant with M receptor but irrelevant with N receptor. When M receptor was stimulated,the potential sensitive Ca^{2+} channel was opened, which will cause the influx of extracellular Ca^{2+} and then cause the contraction of smooth muscle[50]. Areca might stimulate M receptor and then cause the concentration of intracellular Ca^{2+} increased, areca might also act on the Ca^{2+} channel receptor directly, which still need to be further studied. In conclusion, areca stimulates the contractile activity of colonic smooth muscle of rats *in vitro*. The effect of areca is partly relevant with M receptor, but irrelevant with N receptor.

Abstract

AIM: **To isolate a novel isoform of human HPO (HPO-205) from human fetal liver Marathon-ready cDNA and characterize its primary biological function.**

METHODS: **5'-RACE (rapid amplification of cDNA 5' ends) was used to isolate a novel isoform of hHPO in this paper. The constructed pcDNA$^{HPO-205}$, pcDNA^{HPO} and pcDNA eukaryotic expression vectors were respectively transfected by lipofectamine method and the stimulation of DNA synthesis was observed by ^{3}H-TdR incorporation assay. Proteins extracted from different cells were analyzed by Western blot.**

RESULTS: **A novel isoform of hHPO (HPO-205) encoding a 205 amino acid ORF corresponding to a translated production of 23 kDa was isolated and distinguished from the previous HPO that lacked the N-terminal 80 amino acids. The dose-dependent stimulation of DNA synthesis of HepG2 hepatoma cells by HPO-205 demonstrated its similar biological activity with HPO *in vitro*. The level of MAPK (Mitogen-activated protein kinase) phosphorylation by Western blot analysis revealed that HPO-205 might have the stronger activity of stimulating hepatic cell proliferation than that of HPO.**

CONCLUSION: **A novel isoform of hHPO (HPO-205) was isolated from hepatic-derived cells. The comparison of HPO-205 and HPO will lead to a new insight into the structure and function of hHPO, and provide the new way of thinking to deeply elucidate the biological roles of HPO/ALR.**

INTRODUCTION

Hepatic stimulatory activity was identified from human fetal liver lysate, which was named as hepatopoietin (HPO)[1]. Later we proved that HPO was encoded by mRNA of human fetal liver[2]. Recombinant human hepatopoietin (rhHPO) showed its activity of specifically stimulating DNA synthesis of hepatic cells and promoting healing after liver injury *in vitro* and *in vivo*[3-6]. Recently, HPO/ALR/EVR1 homologous cDNAs (including EST sequences) have been isolated in many laboratories[7,8]. Sequence analysis of these homologous cDNAs revealed that the same 3' sequence was presented in all reported sequences, however, the 5' sequence varied in these cDNAs[9]. Furthermore, The analysis of genomic sequences of HPO/ALR also suggested there might exist different transcripts in nature. In this paper, we reported the identification and characterization of a novel isoform of human HPO in hepatic-derived cells. This cDNA with a 205 amino acid ORF was named HPO-205 to distinguish it from the previous HPO that lacked the N-terminal 80 amino acids.

MATERIALS AND METHODS

Sequence analysis and RNA extraction

HPO sequences and their proteins were analyzed by using DNA tools, Biosoft software and GenBank blast program. The primer for 5'RACE was: 5'-GGT CTT CAG GTT CAG ACA CAT GTT GGC-3'. The human fetal liver Marathon-ready cDNA Clontech) served as template to amplify 5' end of HPO by using a kit (Clontech). The PCR products were ligated to pGEM-T vector and sequenced using T7 and SP6 primers by PE (ABI PRISM) DNA Sequencer. Cos7 (African green monkey kidney cell line), HepG2 and HLE (human hepatoma cell line) were purchased from the American Type Culture Collection. BEL-7402 (epithelial hepatoma cell lines, derived from male, 75 years) and SMMC-7721 (epithelial hepatoma cell lines, derived from male, 50 years) were purchased from the Cell Institute of Chinese Academy of Science. All cell lines were cultured in Dulbecco's Modified Eagle Media (DMEM) (GiBco BRL, Life Technologies.) supplemented with antibiotics and 100mL·L^{-1} heat-inactivated fetal bovine serum in a humidified atmosphere of 50mL·L^{-1} CO_2.Total RNA was isolation from the cells using TRIzol™ reagent (GiBco).

RT-PCR

Forward and reverse primers for human HPO-250 and G3PDH genes were designed and applied to amplify transcripts. Briefly, Total RNAs were extracted with Trizol (GIbco) reagent. Reverse-transcribed and amplified for 30 cycles, using RT and PCR kit (TaKaRa LA Taq with GC buffer, TaKaRa Biotech, Dalian,China), according to the manufacturer's instructions. The expression of G3PDH mRNA was detected as an internal control. Primer pairs for RT-PCR were: HPO-250 sense: 5'- ATG GCG GCG CCC GGC GAG CGG GGC CGC TT-3'; antisense:5'- CTA GTC ACA GGA GCC ATC CTT CCA-3'; G3PDH sense:5'-ACC ACA GTC CAT GCC ATC AC-3'; antisense: 5'-TCC ACC ACC CTG TTG CTG TA-3'. The expected size of the amplified DNA fragments for HPO-250 and G3PDH were 618 and 1000 bp respectively. The PCR products were separated on 10g·L^{-1} agarose gel with ethidium bromide staining and photographed under UV. The photographs of the gels were analysed using Bio-Print (M&S Instruments Trading Inc, Tokyo). The values of these DNA fragments were calculated as relative intensity against G3PDH mRNA.

Construction of HPO expression vectors and Transfection

Both *Eco*R I and *Bam*H I sites were introduced by PCR *in vitro* mutagenesis, and the full length cDNA encoding human HPO and HPO-250 were inserted into pcDNA 3.1(+) vector downstream of CMV promoter. The recombinant pCDNA 3.1 plasmids were isolated and used for transfection. Cos-7 or Bel-7402 cells were subsequently harvested and reseeded at a density of 1×10^{6}cells/100-mm plate.

The cells were transfected the next day with different plasmids (2μg) using lipofectamine reagent (Gibco). For transient expression, the conditional medium of Cos-7 cells transfected with pcDNA$^{HPO-250}$ or pcDNA plasmid was harvested 48h after transfection. For stable expression, the Bel-7402 cells after being transfected with pcDNA$^{HPO-250}$ or pcDNA^{HPO} or pcDNA plasmid by 72h were selected in DMEM medium containing 400mg·L^{-1} G418 for 14d. G418-resistant clones were isolated and grown in DMEM medium containing G418 to maintain the phenotype.

Western blot analysis

Protein was extracted from different cells, and the protein concentration was determined by Coomassie Brilliant Blue G-250 staining. Samples containing equivalent amounts (50ìg) were separated on a 100g·L^{-1} SDS polycocrylamide gel under reducing conditions and transferred to a Hybond-N nitrocellulose membrane (Amersham, Arlington Heights, Illinois). The membrane was incubated respectively with rabbit polyclonal anti-human HPO antibody or rabbit polyclonal anti-pERK or ERK antibody (Santa Cruz) and developed with an ECL western blotting detection system (Santa Cruz) using horseradish peroxidase-conjugated second antibody (Santa Cruz).

^{3}H-TdR incorporation assay

HepG2 hepatoma cells were counted and adjusted to 1×10^{8}cells·L^{-1}, then 100μL of cell suspension was inoculated into 96-well plates and incubated at 37℃, 50mL·L^{-1} CO_2 for 12h. Then the fresh medium containing prepared samples was added. After 48h of culture in presence of various medium supplements, 37kBq/well ^{3}H-TdR was added and incubated for 3h. The cells were collected to filters, and radioactivity was determined in an LKB liquid scintillation counter,and results were expressed as median counts per minute from triplicate cultures.

RESULTS

Sequence analysis of HPO

Searching against GenBank with human HPO sequence, this sequence showed homology with 11 human cDNAs encoding HPO-like proteins, Protein sequence alignment showed that all of these encoding proteins were highly conserved in the 125 amino acid of C terminal but varied in the N terminal. Further analysis of their nucleotide sequences demonstrated no stop codon was found before the same open reading frame (ORF). This result indicated that deposited 125 amino acid HPO might be incomplete.

Isolation of HPO-205 cDNA and sequence analysis

To investigate whether a novel isoform of HPO exists in nature, a Marathon-ready cDNA from human fetal liver served as the template to amplify 5' ends of hHPO. The PCR products containing different sizes of 375, 500, 750 and 1200 bp bands were cloned into pMD18-Tvectors and transformed *Ecoli*. DH5α. Then the clones were screened by hybridization with ^{32}P-HPO cDNA as a probe, and more than 50 positive clones were obtained. After we sequenced 10 positive clones, we obtained the novel isoform HPO cDNA that encoded a 205 amino acid ORF. This cDNA with a 205 amino acid ORF was named HPO-205 (GenBank CI 11559825) to distinguish it from the previous HPO that lacked the N-terminal 80 amino acids (Figure 1).

Figure 1 Amino acid sequence alignment of HPO-205 and HPO(GenBank CI 11559825)

Expression of HPO-205 in hepatoma cell lines

The expression of HPO-205 was determined by semi-quantitive RT-PCR and Western blotting. As shown in Figure 2 and Figure 3, the cell lines showed interesting and revealing differences in the levels of HPO-205. The levels of hHPO-205 mRNA in HepG2 and HLE cell lines were significantly higher (4-5 folds) than in BEL-7402 and 7721 cell lines (Figure 2). Similarly, we also observed HPO-205 protein in HepG2 and HLE cell lines were significantly higher (4-5 folds) than in BEL-7402 and 7721 cell lines (Figure 3) by Western blot analysis. The M_r of HPO-205 in these four hepatoma cell lines is 23000 identical to the predicted molecular weight (Figure 3).

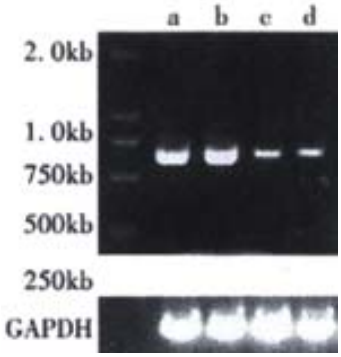

Figure 2 The mRNA expression of HPO-205 was determined by RT-PCR in hepatoma cell lines. a: HepG2 cell line; b: HLE cell line; c: SMMC-7721 cell line; d: Bel-7402cell line; GAPDH as a control.

HPO-205 stimulated HepG2 cells proliferation in vitro

We demonstrated that biological activity of HPO-205 could be expressed from its cDNA in transient expression experiment in Cos7 cells. As shown in Figures 4A and 4B, the conditional medium from transfected cells with the pcDNA$^{HPO-205}$ revealed the dose-dependent stimulation of DNA synthesis of HepG2 hepatoma cells. However, as a negative control, the conditional medium from mock-transfected did not show any activity.

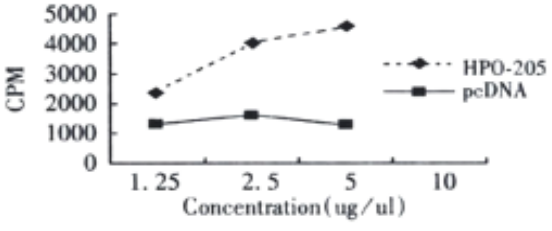

Figure 4B The effect of DNA synthesis of HepG2 cells stimulated by the different expressed protein.

Activition of Mitogen-activated protein kinase (MAPK) by expression of HPO-205 in Bel-7402 hepatoma cells

MAPK could be activated by a number of growth factors and cytokines. To assess whether HPO-205 activated the MAPK pathway, the pcDNA$^{HPO-205}$, pcDNA^{HPO} and pcDNA plasmids were transfected into Bel-7402 cells with low level expression of HPO. Expression of HPO-205 and HPO protein were analyzed by western blotting using antibody against HPO protein. As shown in Figure 5A, a protein band with an apparent M_r of 23000 only was detected in the HPO-205 transfected Bel-7402 cells, and a protein band with an apparent M_r of 15000 only was detected in the HPO transfected Bel-7402 cells. As shown in Figure 5B, the level of MAPK phosphorylation in BEL-7402 cells could be elevated by HPO and HPO-205 (P<0.01), and the level of MAPK phosphorylation activated by HPO-205 was higher than that by HPO (P<0.01).

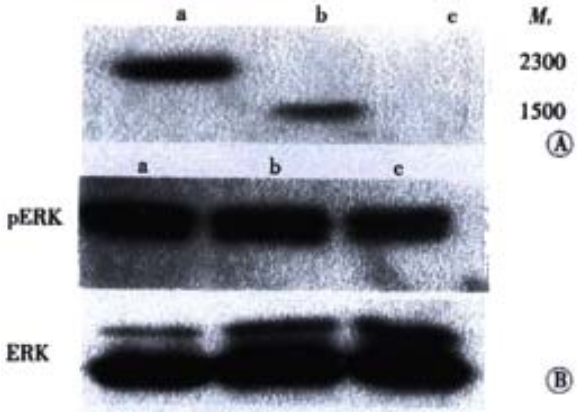

Figure 5 The stably transfected cell lines were confirmed and MAPK activation was examined by Western Blot.

DISCUSSION

We isolated and characterized a novel isoform of HPO (HPO-205) cDNA that encoded a 205 amino acid ORF. This cDNA with a 205 amino acid ORF was named HPO-205 (GenBank CI 11559825) to distinguish it from the previous HPO that lacked the N-terminal 80 amino acids. The molecular weight of HPO-205 was 23 kDa identified in four human hepatoma cell lines by Western blot, and the HPO-205 mRNA expressions were detectable in human hepatoma cell lines including HepG2, HLE, 7402 and 7721 by RT-PCR method. Our sequence analysis of HPO-205 shows presence of very rich GC bases in 5' end of HPO mRNA (more than 75%). Such high amount of GC bases will affect the efficiency of mRNA transcription. Therefore, it will lead to obtaining different kinds of incompleted HPO mRNA under different conditions in many laboratories[10].

As we know, human HPO is a specific growth factor and plays an important role in liver regeneration *in vivo*[11-14]. Many experiments demonstrated that HPO could stimulate the proliferation of hepatic cells *in vitro* and *in vivo*[1,2,15]. Therefore, identification and characterization of the biological function of HPO-205 and the relationship between HPO-205 and HPO are very important. Some data have shown they are different in intracellular location, tissue distribution and mRNA expression under different pathological conditions, which have suggested their different biological functions[16]. In this paper, we find, as human HPO, HPO-205 also stimulated the DNA synthesis of HepG2 cells. However, whether HPO-205 can specifically stimulate DNA synthesis of hepatic cells and promote healing after liver injury *in vitro* and *in vivo*, just like HPO, remain to be under investigation.

Our previous study demonstrated that HPO stimulated the hepatic cell proliferation through its specific receptor[4]. Recently, another report indicates that HPO/ALR assigns a FAD-linked sulfhydryl oxidase activity, which plays a role in modifying some molecules *in vivo*[17], and regulates the expression of some mitochondrial genes[18-21]. These data suggest that there are many different mechanisms of HPO/ALR involved in stimulating cell proliferation and improving hepatic repair. Recently, Li *et al*[22] have reported that HPO promotes the proliferation of hepatic cells through activating MAPK signal pathway. Here we have also found that both of HPO-205 and HPO could increase the activation of MAPK phosphorylation compared with the control. Moreover, the result also showed that the level of MAPK phosphorylation in HPO-205 transfected cells was significantly higher than that in HPO transfected cells by Western blot. These data indicate that HPO-205 might have the stronger activity of stimulating hepatic cell proliferation than that of HPO.

Abstract

AIM: **To search for the biomarker of cellular immortalization, the telomere length, telomerase activity and its subunits in cultured epithelial cells of human fetal esophagus in the process of immortalization.**

METHODS: **The transgenic cell line of human fetal esophageal epithelium (SHEE) was established with E_6E_7 genes of human papillomavirus (HPV) type 18 in our laboratory. Morphological phenotype of cultured SHEE cells from the 6th to 30th passages, was examined by phase contrast microscopy, the telomere length was assayed by Southern blot method, and the activity of telomerase was analyzed by telomeric repeat amplification protocol (TRAP). Expressions of subunits of telomerase, hTR and hTERT, were assessed by RT-PCR. DNA content in cell cycle was detected by flow cytometry. The cell apoptosis was examined by electron microscopy (EM) and TUNEL label.**

RESULTS: **SHEE cells from the 6th to 10th passages showed cellular proliferation with a good differentiation. From the 12th to the 16th passages, many senescent and apoptotic cells appeared, and the telomere length sharply shortened from 23kb to 17kb without expression of hTERT and telomerase activity. At the 20th passage, SHEE cells overcame the senescence and apoptosis and restored their proliferative activity with expression of telomerase and hTERT at low levels, but the telomere length shortened continuously to the lowest of 3kb. After the 30th passage cells proliferation was restored by increment of cells at S and G2M phase in the cell cycle and telomerase activity expressed at high levels and with maintenance of telomere length.**

CONCLUSION: **At the early stage of SHEE cells, telomeres are shortened without expression of telomerase and hTERT causing cellular senescence and cell death. From the 20th to the 30th passages, the activation of telomerase and maintenance of telomere length show a progressive process for immortalization of esophageal epithelial cells. The expression of telomerase may constitute a biomarker for detection of immortalization of cells.**

INTRODUCTION

Telomerase activity was demonstrated in cancer of digestive tract[1-3], such as gastric[4-7], hepatic[8-10] colorectal[11-13] and esophageal cancers[14-19]. Inhibition of telomerase activity will be a new therapeutic for cancer[20-26]. Telomerase activity can be used as a diagnostic marker for cancer[27-30]. Normal mammalian cells grow in cultural medium with a limited number of passages before entering senescence and death[31], which are associated with shortening of telomere. Telomeres are specialized structures at chromosomal ends that are composed of TTAGGG DNA repeats[32]. Telomerase is a ribonuclear protein complex, which contains human telomerase reverse transcriptase (hTERT) as a catalytic domain, and human telomerase RNA component (hTR)[33]. Telemetries cap chromosomal ends perform the function of preventing abnormal chromosomal fusions and rearrangement[34]. However, each time a cell divides, the most distal part of the chromosome is incompletely duplicated and the telomere becomes shorter. Critically short telomeres enable the formation of aberrant chromosomal structures resulting in growth arrest or senescence[35]. With expression of telomerase or hTR and hTERT, the length of telomere extends to maintain the life span of the cells. There are other roles of telomerase in immortal and malignant lesion, such as proliferative potential[36], delaying senescence[37, 38], promoting cell cycle, cell immortalization and carcinogenesis[39].

Recently, many papers have indicated that human papillomavirus (HPV) are the important etiological factor in esophageal carcinoma[40-42]. Induced by HPV 18 E_6E_7 genes, we established an immortalized cell line (SHEE) from the esophageal epithelium which underwent[43-46] malignant transformation[47,48]. Changes of telomere length and telomerase activity in the cell line are not clear at this early stage, nor is which criteria to use to detect immortalization of cells and what the relationship between telomerase and cell phenotype in SHEE cells is. The goal of this study is to explore when telomerase activity appears in the immortalized progressive process and study the relationship between telomerase and cellular phenotype.

MATERIALS AND METHODS

Cell culture and EM examination

The SHEE cell line was a kind of immortal embryonic esophageal epithelium induced by E_6E_7genes of human papillomavirus (HPV) type 18 in our laboratory[43]. The continual growth cells from the 6th to 30th passages were routinely cultivated in flasks and the 24-well plates (Corning Co.) with culture medium 199 (Gibco), 100mL·L^{-1} bovine serum, 100u penicillin and streptomycin in a humidified atmosphere of 50mL·L^{-1} CO_2 and 950mL·L^{-1} air. The cell shape and size, anchorage-dependent growth and contact-inhibited growth were examined by phase contrast microscopy. For electron microscopic assessment, cells were spun to form a pellet and fixed with 25g·L^{-1} glutaraldehyde. They were dehydrated in graded ethanol and

embedded in Araldite. Ultra-thin sections were cut with glass knifes and mounted on copper grids. They were contrasted for 15 min with uranyl acetate and for 3 min with lead citrate. The sections were examined by electron microscope (Hitachi, H-300).

Cell proliferative Cycle and apoptosis

Cells cultured in the flask were digested, washed twice with PBS, fixed by 70% alcohol, prepared as single-cell suspension and stored at 4℃. Cells were stained with propidium iodide (Sigma) and analyzed with flow cytometry (FACSort, B-D Co.). The percentage of cells in various stages of the cell cycle, the apoptotic cell rate (AI) and proliferation index ($PI=S+G_2M/G_0G_1+S+G_2M$) were calculated. These cells on the glass coverslips within the 24-well plate were incubated with 10mg·L^{-1} proteinase K for 15 min at room temperature. After the quenching of endogenous peroxidase, labeled nuclei with TUNEL (*In-Situ* Death Detection kit, Boehringer Mannhein Co.) were detected according to the instructions of the manufacturer. The brownish nucleus was considered positive apoptotic nucleus.

Telomere length analysis[49]

The genomic DNA of 10^6-10^8 cells was extracted. The telomeric restriction fragment (TRF) was measured by Southern blot. Briefly, 20μg of genomic DNA was digested with *Hinf* I and run on 7g·L^{-1} agarose gel with marker DNA/*Hind* III. After electrophoresis the gel was blotted to nylon membrane (Hybond™ N^+, Amersham, Life Science) and hybridized to the Dig-labeled probes$(CCCTAA)^3$ at 50℃ in 5×SSC, 1g·L^{-1} Sod. n-Lauroylsarcosine (SLS), 0.2g·L^{-1}SDS for 12-16h and washed twice at room temperature in 2×SSC, 1g·L^{-1}SDS for 5min, once at 50℃ in 1×SSC, 1g·L^{-1}SDS for 10min, twice at 50℃ in 1×SSC, 1g·L^{-1}SDS for 10min, twice at 50℃ in 0.1×SSC, 1g·L^{-1}SDS for 5min, stained with NBT/BCIP and the median points were measured to obtain the mean telomere length[50].

Telomerase activity assay

Telomerase activity was measured using the telomeric repeat amplification protocol (TRAP). Frozen samples were homogenized in 10~50μL of ice-cold lyses buffer (10mmol·L^{-1} Tris-HCl, pH7.5, 1mmol·L^{-1} EGTA, 0.1mmol·L^{-1} Benzamidine, 5mmol·L^{-1} β-mercaptothanol, 5g·L^{-1} CHAPS, 100mL·L^{-1} glycerol). After 30min of incubation on ice, the lysate was centrifuged at 12000g for 20min at 4℃. TRAP-eze Telomerase Detection Kit (Oncor Inc.) reaction was performed using 1μL lysate or 1/10 diluted lysate, 2.5μL 10×TRAP buffer (200mmol·L^{-1} Tris-HCl, pH8.3, 15mmol·L^{-1} $MgCl_2$, 630mmol·L^{-1} KCl, 0.5% Tween 20, 10mmol·L^{-1} EGTA, 1g·L^{-1} BSA), 0.5μL 2.5mmol·L^{-1} dNTP, 0.5μL Ts primer, 0.5μL TRAP primer mix, 19.5μL water, 0.5μL taq (2×10^6u·L^{-1}). After incubation at 30℃ for 30min, the reaction mix was immediately transferred to 94℃ and performed PCR (GeneAmp PCR System 2400, PE, USA) at 94℃ for 30s, 55℃ for 30s, for 30 cycles. PCR products were separated in a non-denaturing 120g·L^{-1} PAGE in 1×TBE at 5V·cm^{-1}. The gel was stained using $AgNO^3$ and was photographed.

Subunits of telomerase analysis

The activities of telomerase were performed by hTERT and hTR analysis. Analysis of expression of hTR and hTERT was determined by reverse transcription-PCR (RT-PCR) amplification in contrast with house-keeping gene GAPDH. Total RNA was isolated from the cell using Gstract™ RNA Isolation Kit (Maxim Biotech, Inc.). cDNA was synthesized from 10μg of total RNA using Ready-to-use First Strand cDNA Synthesis Kit(Maxim Biotech, Inc.). PCR reaction was performed using 2μL aliquots of the reverse-transcribed cDNA, 2.5μL 10×PCR buffer, 1.5μL 25mmol·L^{-1} $MgCl_2$, 2.5μL 1.0mmol·L^{-1} dNTP, 2.0μL specific primers, 14μL water, 0.5μL taq (2×10^6u·L^{-1}). hTERT mRNA was amplified using the primer pair:5'-CGGAAGAGTGTCTG-GAGCAA-3' and 5'-GGATGAAGCGGAGTCTGGA-3' for 31 cycles (94℃ for 45s, 55℃ for 45s, 72℃ for 90s). hTR was amplified using the primer pair: 5'-TCTAACCCTAACTGAGAAGGGCGTAG-3' and 5'-GTTTGCTCTAGAATGAACGGTGGAAG-3'. GAPDH was amplified using the primer pair:5'-GAAGGTGAAGGTCGGAGTC-3' and 5'-GAAGATGGTGATGGGATTTC-3' for 33 cycles (94℃ for 60s, 55℃ for 60s, 72℃ for 60s). PCR products of each sample were subjected to electrophoresis in a 15g·L^{-1} agarose gel containing 0.5mg·L^{-1} ethidium bromide.

RESULTS

In the initiated passages, the cells in the 6th to the 10th passages were uniform in size and shape (Figure 1A), and grew as an even monolayer with characteristics of anchorage-dependent and attachment-inhibited growth. Cells continuously cultured in the 12th to the 16th passages exhibited morphologic changes in which cells were enlarged and flattened and exhibited differentiation and senescence. When many cells had shrunk, were round and floated freely, the majority underwent apoptosis and cell death with a few cells surviving (Figure 1B). Over coming senescence and apoptosis, the cells of the 20th passage restored their proliferation capacity (Figure 1C). After 30 passage the cells proliferated again and exhibited diphasic differentiation,a portion of cells displayed the undifferentiated basal epithelium and the other portion displayed differentiated squamous epithelium (Figure 1D).

Proliferative index (PI) and apoptosis

The PI of cell in 10, 16, 20, 30 the passage were 25.5%, 17.3%, 43.3%, and 43.0% respectively (Figure 2, A, B, C, D). Apoptotic cells index (AI) was in 10th passage, 7.3%; 16th, 57.5%; 20th, 5.7% and 30th, 7.5%. The cells in the 16th passage were at the stage of senescence and death, and the 10th, 20th and 30th were at their proliferated stages at various levels. Cells in G_0G_1 phase were identified as the differentiated cells containing some senescent cells.

The TUNEL assay was also used to characterize the biological features of cells apoptosis. Many TUNEL-positive nuclei were observed in cells of passage 16th (Figure 3), and in a few cells in other passages. By EM examination, many apoptotic cells revealed rounded and shrunken nuclei with condensed chromatin stuck closely to the nuclear membrane (Figure 4).

Telomere length

Following continuous growth of the cells, the telomere length of the cells in the 6th to 10th passages exhibited shortening from a mean size of 23kb in the normal esophageal mucosa to 17kb at passage 10. At 20th passage telomere length was shortened continually to the shortest 3kb, but maintained till the 30th passage (Figure 5).

Telomerase activity, expression of hTR and hTERT

Expression of hTR and hTERT in SHEE cells was determined by RT-PCR. The hTERT expression was positive in the 20th and 30th passages, but negative in the 10th passage (Figure 6A). Cells of the 10th, 20th and 30th passage showed positive expression of hTR (Figure 6B). House-keeping protein GAPDH was used as a control (Figure 6C). Comparing the variation of telomerase activity in SHEE from the 10th to the 30th passage,cells of the 10th passage were negative, while the 20th was weak and the 30th was apparent. The positive control of human esophageal squamous cell carcinoma expressed the highest telomerase activity (Figure 7).

The relationship between telomerase activity and cellular proliferation

At an early stage in the immortalization process, SHEE cells could be divided into three stages. At the primary stage, telomerase activity and expression of hTERT was absent and the telomere length shortened. The cells of SHEE were proliferated and differentiated and then their were senescent and apoptotic cells in the culture. At the early immortal stage, cells exhibited telomerase activity and its subunits hTERT at low levels with telomere length being continually shortened and proliferation restored. At the immortal stage, telomerase and hTERT were expressed in high level and telomere length maintained, accompanied by cell proliferation. From 6th to 30th passages the cells expressed hTR.

DISCUSSION

After transferring the HPV18E_6E_7 genes to the fetal esophageal epithelial cells, we established an immortal cell line designated SHEE. In order to focus on the process of immortalization, we monitored the dynamic changes of telomere length and telomerase activity of SHEE cells for extended periods of time (from the 6th passage to the 30th passage). At the primary stage the cells of passages 6-10 appeared as differentiated squamous epithelial cells with telomere length shortened without telomerase expression, after which the cells of passages 12-16 became senescent and underwent cell death. After overcoming the senescence and cell death, cells of the 20th passage expressed telomerase activity at low levels, where the length of shortened telomere was not maintained, but the proliferation of cells was restored. At the 30th passage, the cells exhibited a higher level of telomerase activity, hTR and hTERT, with maintained telomere length and continual proliferation of cells (immortalization). Therefore, one can suggest that telomerase activity and maintenance of telomere length might be necessary for immortalization of human esophageal epithelium *in vitro*.

To investigate the immortalization process, we used the SHEE cell model to define steps in aging of cells. After transduction of E_6E_7 genes from HPV type 18 normal cultured cells proliferate until they reach a discrete point (passage 12 times) in which the population growth ceases and develops to senescence. This period is termed the M1 stage of aging[51]. After M1, a large amount of cells dead to reach a "crisis" point with a few cells survival. This period is termed the M2 stage of aging[52]. Both M1 and M2 are therefore potential suppression pathways for tumorigenesis. The telomerase activity is sufficient to allow the cultured cells to escape from crisis[53]. In our experiment cells transfected with HPV, cell proliferated for an extended period of time, after that cells encountered senescence (M1) and apoptosis (M2). Overcome the M1 and M2, cells exhibited accelerant hyperplasia with telomerase activity.

Recent evidence suggests that viral oncogenes might directly up-regulate telomerase activity[54], such as HCV core protein, EBV-, HPV- and SV40 T antigen-expressing cell clones[55-58]. In our data the increase of hTR in the primary cells of SHEE might be directly or indirectly affected by the HPV viral oncogenes. Previous reports also have shown that telomerase activity can be achieved by the E_6 and E_7 protein of HPV[59]. HPV 16 E6 oncoprotein was capable of inducing telomerase activity in monolayer cultures of proliferating keratinocyte[60]. It was more likely that HPV E6/E7 transcription or other additional alterations, as chromosome instability[61,62] was prerequisite for induction of telomerase activity in proliferating cells. This hypothesis fits very well with our data on HPV-mediated immortalization of cells *in vitro*.

In summary, immortal cell line of the SHEE, up to 30th passage, may be divided into three stages. At the primary stage, telomerase activity and hTERT of cells were absent but hTR is positive with telomere length shortening and the cells became senescent and apoptotic. At the early-immortalized stage, the telomerase activity and hTERT expressed at low level and telomere length shortened continuously, but underwent cell hyperplasia occurred. At the immortalized stage, the telomerase activity and its two subunits expressed at a high level, telomere length was maintained and cell proliferation continued, in which the cells reached the stage of immortalization. The shortened telomere length and the activated telomerase activity display in a dynamic process. Our results prove that shortening of telomeres and absence of telomerase activity contribute to cellular senescence and cell death, and the activation of telomerase to maintain telomere length is necessary for immortalization. Therefore, the telomerase activity is the biomarker of immortalization of cell.

Abstract

AIM: **To examine the protective effect of estradiol on the cultured hepatocytes under oxidative stress.**

METHODS: **Hepatocytes of rat were isolated by using perfusion method, and oxidative stress was induced by a serum-free medium and FeNTA. MDA level was determined with TBA method. Cell damage was assessed by LDH assay. Apoptosis of hepatocytes was assessed with cytoflowmetric analysis. Expression of Bcl-xl in cultured hepatocytes was detected by Western blot. The radical-scavenging activity of estradiol was valued by its ability to scavenge the stable free radical of DDPH.**

RESULTS: **Oxidative stress increased LDH (from $168\pm25\times10^{-6}$IU.cell^{-1} to $780\pm62\times10^{-6}$IU.cell^{-1}) and MDA (from $0.28\pm0.07\times10^{-6}$nmol.cell^{-1} to $1.35\pm0.12\times10^{-6}$ nmol.cell^{-1}) levels in cultured hepatocyte, and estradiol inhibited both LDH and MDA production in a dose dependent manner. In the presence of estradiol 10^{-6} mol.L^{-1},10^{-7}mol.L^{-1} and 10^{-8}mol.L^{-1},the LDH levels are $410\pm53\times10^{-6}$IU.cell^{-1}($P<0.01$ *vs* oxidative group), $530\pm37\times10^{-6}$IU.cell^{-1} ($P<0.01$ *vs* oxidative group), $687\pm42\times10^{-6}$IU.cell^{-1}($P<0.05$ *vs* oxidative group) respectively, and the MDA level are $0.71\pm0.12\times10^{-6}$ nmol.cell^{-1}($P<0.01$ *vs* oxidative group),$0.97\pm0.11\times10^{-6}$ nmol.cell^{-1}($P<0.01$ *vs* oxidative group) and $1.27\pm0.19\times10^{-6}$nmol.cell^{-1} respectively. Estradiol suppressed apoptosis of hepatocytes induced by oxidative stress, administration of estradiol(10^{-6}mol/L)decreased the apoptotic rate of hepatocytes under oxidative stress from 18.6±1.2% to 6.5±2.5%, $P<0.01$. Bcl-xl expression was related to the degree of liver cell damage due to oxidative stress, and estradiol showed a protective action.**

CONCLUSION: **Estradiol protects hepatocytes from oxidative damage by means of its antioxidant activity.**

INTRODUCTION

Hepatic fibrosis is a common consequence of chronic liver injury from many causes[1-7], and the critical event in hepatic fibrosis is the activation of lipocyte (also known as the stellate, fat-storing or Ito cell) which is the main source of extracelluar matrix in fibrosis formation [8-20]. The putative impetus to lipocyte activation came from cytokines released from Kupffer cells or leukocytes in liver injury[21]. An alternative way is that parenchymal-cell necrosis itself may activate lipocyte; such activation could be mediated by the lipid peroxides formed after the membrane of parenchymal cells is injured[22-28]. Therefore, preventing hepatocyte from injury is a matter of primary importance in blocking the fibrogenic pathway. We have reported the inhibitory effect of estradiol on activation of rat lipocytes[29,30] and the suppressive effect on fibrogenesis in rat model[31]. The present study is initiated to investigate the role of estradiol on the hepatocyte under oxidative stress, and to elucidate the mechanism of its inhibitory effect on hepatic fibrogenesis.

MATERIALS AND METHODS

Hepatocyte isolation and induction of lipid peroxidation

Hepatocytes were isolated from the liver of male Wistar rats(500-600g) with *in situ* perfusion method as previously described. Inocula of 2×10^5 cells per well were introduced into 12-well plate, (Nunc). The cells were cultured in 1ml Williams medium E supplemented with 50ml·L^{-1} FBS, 105U·L^{-1} penicillin,100mg·L^{-1} strptomycin, and 10g·L^{-1} L-glutamine at 37℃ in 50ml·L^{-1} CO_2 atmosphere and 100% humidity. After 4h, the cell medium was removed and lipid peroxidation was induced by incubating hepatocytes in serum-free Williams medium E with 100μmol·L^{-1} FeNTA(ferric nitrilotriacetate). Three groups of hepatocyte were analysed in parallel in each experiment including the hepatocytes cultured under normal condition and the hepatocyte cultured under oxidative stress in the presence or absence of 17-β-estradiol(Sigma).

Detection of (MDA) and lactate dehydrogenase (LDH) level in culture medium

Lipid peroxidation in cultured hepatocyte was determined by detecting the level of malondialdehyde (MDA), end product of lipid peroxidation in culture medium. The cell medium was collected, centrifuged at 450g to remove cell debris, and the MDA contents was determined by using a colorimetic reaction with thiobarbituric acid. A calibration curve was constructed from the conversion of tetraethoxypropane to MDA. The degree of cell damage was assessed by detecting the lactate dehydrogenase (LDH) activity released from the cytosol of damaged cells into the supernatant. The LDH activity was determined by using LDH detection Kit(Sigma). The time course of the MDA and LDH levels in culture medium was constructed to examine the lipid peroxidation and cell damage of hepatocyte during cultivation.

Flowcytometric analysis for apoptosis in hepatocytes

Rat hepatocytes were isolated and inoculated in 24-well plate as described, After oxidative stress was induced for 24h, apoptotic hepatocytes were detected by flowcytometry. Apoptotic cells expose their phosphatidylserine (PS) in the outer leaflet of cell membrane.

The exposed PS can be revealed by FITC-conjugated annexin V. Annexin V Kits(BD pharmingen) was used ,and the samples were treated according to the instruction enclosed in the kit as mannul described and analysed on the flowcytometer(Coulter Epics).

Western blot analysis of Bcl-xl

Rat hepatocytes were cultured in 35mm diameter dishes(Nunc) which were divided into 3 groups: the normal group, the oxygen stress and the oxygen stress plus estradiol group. In the presence or absence of 10^{-6}mol·L^{-1} estradiol for the indicated time period,the dishes were then washed twice with ice cold PBS and lysed directly in 1ml SDS loading buffer(50mmol·L^{-1} Tris, pH6.7, 20g·L^{-1}SDS, 100g·L^{-1} glycerol, 0.6g·L^{-1}bromophenol blue, 100mmol·L^{-1} dithiothreitol). The samples were boiled for 5 min and applied to a standard 120g·L^{-1} SDS polyacrylamide protein gel. After electrophoresis, protein transfer was performed onto Hybond-ECL(Amersham Pharmacia Biotech) using a semi-dry blotting apparatus. The membrane was treated first with 100ml·L^{-1} non-fat milk in PBS at room temperature for 2h and next with the Bcl-xl or Bcl-2 monoclonal antibody (Tanslab; diluted 1:500)for two hours at room temperature. After washing, the membrane was then incubated with HRP conjugated goat antimouse IgG(Amersham Pharmacia Biotech; diluted 1:1000)for one hour at room temperature. Immunoreactive bands were visualized using the ECL western blotting detection system kit (Amersham Pharmacia Biotech) according to the manufacturer's recommended protocol. The membranes used for Bcl-xl or Bcl-2 detection were reprobed with actin polyantibody and the corresponding secondary antibody to normalize the signal strength of Bcl-xl and Bcl-2.

Radical-scavenging activity of estradiol

The radical-scavenging activity of estradiol was determined from its ability to scavenge the stable free radical of 1,1-diphenyl-2-picrylhydrazyl (DPPH,Wako) and was compared with that of the well-known antioxidant, α-tocopherol. 5μl of estradiol or α-tocopherol (2,4,6,8, 10μmol·L^{-1}) was added to 2.5ml 100μmo·L^{-1}l DPPH, in 20mmol·L^{-1} 2-(N-morpholino) ethanesulfonic acid (MES) (pH 5.5) and the change in optical absorbance at 517nm was measured 30min thereafter.

Statistical analysis

Experimental results were analyzed by Student's *t* test for multiple comparisons. *P* values less than 0.05 were considered to be statistically significant.

RESULTS

Effect of estradiol on MDA and LDH level in hepatocytes under oxidative stress

The MDA and LDH levels in the medium of hepatocytes cultured under normal condition and oxidative stress were shown respectively in Figure 1 and Figure 2. The MDA level increased rapidly 5h after the oxidative stress and was maintained at a considerably high concentration during the period of continued cultivation. In normal control, MDA was kept at a low concentration in the incubating time, indicating a low level of lipid peroxidation in the normal condition. LDH level increased steadily after oxidative stress, whereas the LDH level in normal control increased slightly during culture. These data revealed that oxidative stress initiate lipid peroxidation and cause cell membrane damage in hepatocytes under stress. Twenty-four' oxidative stress was selected as the time point to examine the effect of estradiol administration on the MDA and LDH level in hepatocytes under oxidative stress. As the data showed in Table 1,estradiol decreased the MDA and LDH level in the culture medium in a dose dependent manner.That means estradiol could inhibit the lipid peroxidation and subsequent hepatocytic membrane damage under oxidative stress.

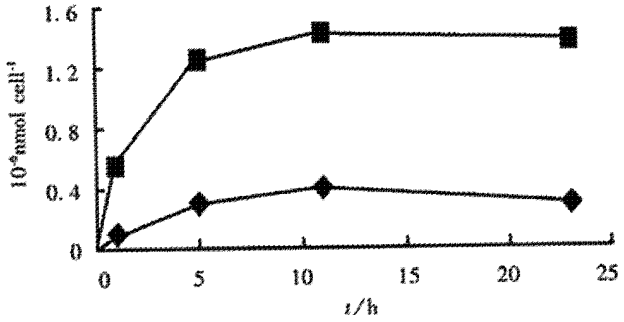

Figure 1 Effect of estradiol on MDA level in hepatocytes cultured under normal condition (◆) and oxidative stress (■)

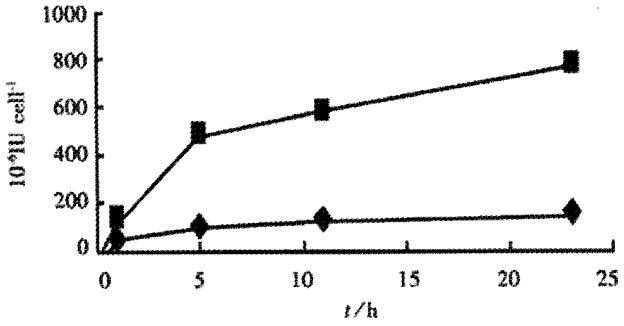

Figure 2 Effect of estradiol on LDH level in hepatocytes cultured under normal contion (◆) and oxidative stress (■)

Table 1 Effect of estradiol on MDA and LDH level in culture medium of hepatocytes under oxidative stress

Stress	MDA(10^{-6}nmol·cell^{-1})	LDH (10^{-6}IU·cell^{-1})
780±62		1.35±0.12
10^{-8}mol·L^{-1}estradiol	1.27±0.19	687±42[a]
10^{-7}mol·L^{-1}estradiol	0.97±0.11[b]	530±37[b]
10^{-6}mol·L^{-1}estradiol	0.71±0.12[b]	410±53[b]
Normal control	0.28±0.07[b]	168±25[b]

[a]$P<0.05$, [b]$P<0.01$ *vs* stress group.

Flowcyto-metric analysis for apoptotic hepatocytes

The aim of this investigation was to ascertain whether oxidative stress could induce apoptosis of hepatocytes, and whether estradiol could protect hepatocytes from such damage. The apoptotic rate of hepatocyte under normal culture condition was 5.9±1.7%, but in hepatocytes under oxidative stress it was 18.6±1.2%. With the administration of 10^{-6}mol·L^{-1} estradiol,the apoptotic rate of hepatocytes under oxidative stress decreased to 6.5±2.5%. These data suggest that estradiol inhibit hepatocytic apoptosis induced by oxidative stress (results obtained from three distinct experiments).

Western blot analysis of Bcl-xl

Bcl-2 family has been investigated extensively for its proapoptotic or antiapoptotic property; Bcl-xl and Bcl-2 are well-known negative regulator of apoptosis[32-36]. Western blot was used to examine the relationship between Bcl-xl and Bcl-2 level and estradiol administration. Estradiol applied in this experiment was 10^{-6}mol·L^{-1}. The result was depicted in Figure 3 (showing one representative result

from three independent experiments). Bcl-xl level was upregulated in hepatocytes under oxidative stress for 24h as compared with the normal control, while estradiol administration attenuated the increased expression of Bcl-xl induced by oxidative stress. After culturing for 48h, Bcl-xl expression was increased in hepatocytes both in the absence or presence of estradiol under oxidative stress. Bcl-xl level in hepatocytes was increased under oxidative stress.Bcl-2 expression was not detectable even though two antibodies from two different companies were used, indicating its low level in hepatocyte.

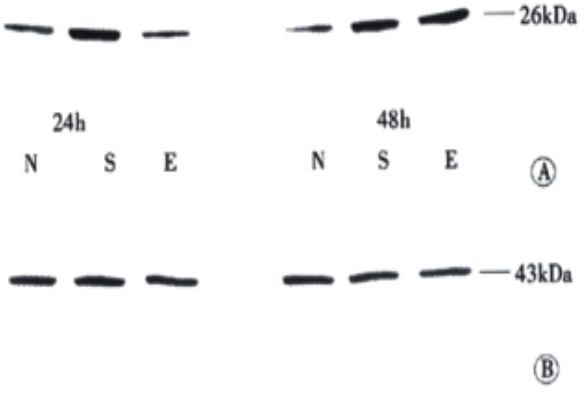

Figure 3 (A) Effect of estradiol on Bcl-xl expression in cultured hepatocytes for 24h and 48h.
(B) Actin expression in cultured hepatocytes for 24h and 48h. N: Normal condition. S: Oxidative stress. E: Oxidative stress supplemented with 10^{-6}mol $\cdot L^{-1}$ estradiol.

Radical-scavenging activity of estradiol

Radical-scavenging activity of estradiol was determined by monitoring the decrease in absorbance at 517nm. Estradiol caused an immediate decrease in DPPH absorbance in a dose dependent manner(Figure 4). Its radical scavenging activity potency was approximately half that of α-tocopherol.

DISCUSSION

Hepatic fibrosis and cirrhosis occur more frequently in men than in women. The ratio of male:female has been reported to range from 2.3:1 to 2.6:1 which indicates that sex hormones may play a role in the development of hepatic fibrosis and subsequent cirrhosis. We have found that estradiol treatment resulted in reduced hepatic fibrosis in male rat in which hepatic fibrosis had been induced by dimethylnitrosamine(DMN), and this phenomenon had been proven to be associated with the inhibitory effect of estradiol on the activation of lipocyte which is essential for hepatic fibrogenesis. Lipocyte can be activated by inflammatory factors realeased from Kupffer cells or free radicals and lipid peroxides formed in injuried liver. Therefore, we examined the effect of estradiol on the cultured hepatocytes to evaluate its protective activity against oxidative damage of the liver. Estradiol is a steroidal compound that binds to specific intracellular receptors which act as transcription factors. Although the liver is not the classical sex hormone target ,but livers in both men and women contain high affinity, low capacity estadiol receptors, and they are believed to respond to estradiol regulation. Another transcription independent activity of the molecule estradiol is its intrinsic antioxidant activity which makes it a potential chemical shield for cells[37,38]. The neuroprotective effect of estradiol from oxidative damage has been extensively investigated in recent years[39,40]. It is also noteworthy that oxygen-derived free radicals and lipid peroxidation have been implicated in hepatic injury[41]. Our data also demonstrated that estradiol could inhibit the lipid peroxidation in hepatocyte and the free radicals induced-hepatocytic injury,and thus exerted its suppressive effect on liver fibrosis.

Hepatocytic damages induced by oxidative stress include two forms: cell necrosis and apoptosis. We also found that estradiol could inhibit the apoptosis of hepatocytes in the face of oxidative challenges. To elucidate the mechanism of its antiapoptotic effect, we examined the relationship between estradiol administration and the Bcl-2 and Bcl-x expression level by Western blotting. Figure 3 showed that Bcl-xl level in hepatocytes was increased under oxidative stress, while administration of estradiol attenuated the increased expression of Bcl-x induced by oxidative stress.These data suggested that Bcl-x expression responsed directly to oxidative stress as a protective reaction, and estradiol could counteract the oxidative stress and stabilized the Bcl-xl expression before its antioxidant activity was depleted. In this study, Bcl-2 expression was not detectable even though two antibodies from different companies were used because of its low level in hepatocytes. But in another investigation we found that estradiol administration dramatically increased the Bcl-2 level in fibrotic liver tissue of rat induced by DMN injection(data not presented). Therefore, the mechanism of the antiapoptotic effect of estradiol is still elusive. The regulators, which participate in this pathway need further investigation. In conclusion, our findings suggested that estradiol could protect hepatocytes from oxidative stress , and the transcription-independent antioxidant activity of estradiol molecule may play a major role in this pathway.

Abstract

AIM: **Artificial β-cell lines may offer an abundant source of cells for the treatment of type I diabetes, but insulin secretion in β-cells is tightly regulated in physiological conditions. The Tet-On system is a "gene switch" system, which can induce gene expression by administration of tetracycline (Tet) derivatives such as doxcycline (Dox). Using this system, we established 293 cells to an artificial cell line secreting insulin in response to stimulation by Dox.**

METHODS: **The mutated proinsulin cDNA was obtained from plasmid pcDNA3.1/C-mINS by the polymerase chain reaction (PCR), and was inserted downstream from the promoter on the expression vector pTRE2, to construct a recombined expression vector pTRE2mINS. The promoter on pTRE2 consists of the tetracycline-response element and the CMV minimal promoter and is thus activated by the reverse tetracycline-controlled transactivator (rtTA) when Dox is administrated. pTRE2mINS and plasmid pTK-Hyg encoding hygromycin were co-transfected in the tet293 cells, which express rtTA stably. Following hygromycin screening, the survived cells expressing insulin were selected and enriched. Dox was used to control the expression of insulin in these cells. At the levels of mRNA and protein, the regulating effect of Dox in culture medium on the expression of proinsulin gene was estimated respectively with Northern blot, RT-PCR, and radioimmunoassay.**

RESULTS: **From the 28 hygromycin-resistant cell strains, we selected one cell strain (tet293/Ins6) secreting insulin not only automatically, but in response to stimulation by Dox. The amount on insulin secretion was dependent on the Dox dose (0,10,100,200,400,800 and 1000μg·L^{-1}), the level of insulin secreted by the cells treated with Dox (1000μg.L^{-1}) was 241.0pU·d^{-1}·cell^{-1}, which was 25-fold that of 9.7pU·d^{-1}·cell^{-1} without Dox treatment. Northern blot analyses and RT-PCR further confirmed that the transcription of insulin gene had already been up-regulated after exposing tet293/Ins6 cells to Dox for 15 minutes, and was also induced in a dose-dependent manner. However, the concentration of insulin in the media did not increase significantly until 5 hours following the addition of Dox.**

CONCLUSION: **Human proinsulin gene was transfected successfully and expressed efficiently in 293 cells, and the expression was modulated by tetracycline and its derivatives, improving the accuracy, safety, and reliability of gene therapy, suggesting that conditional establishment of artificial β-cells may be a useful approach to develop cellular therapy for diabetes mellitus.**

INTRODUCTION

Owing to the steady improvement in methodology for islet and whole pancreas transplantation over the past three decades, this approach remains as the only means which is likely to substitute completely the function of the impaired β-cells in typeIdiabetics patients[1]. However, the limited availability of human donors, the immunological rejection, the low survival percentage of grafts, and the high expense limit the broad-scale applicability of islet transplantation[2-4]. As a result, in recent years much effort is being made to improve insulin secretion in the patient's non-beta cells to avoid the immune destruction[5-9]. To successfully mimic beta cell function, it is necessary to overcome three major obstacles: proinsulin synthesis, proinsulin processing, and mature insulin storage and regulated secretion. Our previous study (unpublished) and studies by other authors had demonstrated that correct proinsulin processing and insulin storage can be obtained in somatic cells transduced with the mutated proinsulin gene[10-13], so the major problem to ectopic insulin expression is the difficulty of reconstructing in non-beta cells the highly regulated insulin secretion of the normal beta cells[14-19].In 1992, Gossen and Bugard[20] developed the tetracycline (or doxycycline)-induced gene expression (Tet-on) system, which is useful for controlling the expression of targeted genes in quantitative manner and for determining the roles of the gene products in cellular functions[21-26]. In the present study, using this system, we generated the first non-beta cell line with deoxycycline-regulated insulin secretion. The strategy described here will contribute to the development of the use of insulin gene therapy for patients with typeIdiabetes.

MATERIALS AND METHODS

Tet-on system

pTet-on regulator plasmid (pTet-on),pTRE2 response plasmid (pTRE2) and pTK-Hyg plasmid, which contain hygromycin-resistance gene, were purchased from Clontech. Using the polymerase chain reaction, the proinsulin cDNA was amplified from expression vector pcDNA3.1/C-mINS, which had been reconstructed from plasmids pcDNA3.1/C and pN-PEPCK-INS (the genomic sequence of human proinsulin, kindly provided by Professor LI Changchen, Dalian Medical University) in our lab. The primers used in the amplification created restriction sites *Bam*HI and *Hind*III which allowed to clone the human proinsulin cDNA into the expression vector pTRE2. The sequences of the forward and reverse promers were: 5'-cat*ggatcc*tgccatggccctgtggatg-3 and 5'-cag*aagctt*gcaggctgcgtctagttgc-3' respectively. After verification by

restriction and sequencing, the vector, pTRE2.mINS, for expressing human insulin was generated.

Cell culture and gene transfection

To simplify the transfection procedure, the tet-293 cell line (human embryonal cell), which had been transfected with the plasmid pTet-on and stably expressed reverse tetracycline-controlled transactivator (rtTA), was purchased from Clontech. So the first step of transfection and clone selection was left out. The culture medium was DMEM supplemented with 100mL·L^{-1} fetal bovine serum and G418 (100mg·L^{-1}). The tet-293 cells were maintained at 37℃ under a 50mL·L^{-1} CO_2 atmosphere until the cells were 80% confluent, then pTRE2.mINS was cotransfected with pTK-Hyg in a ratio of 20∶1, using Lipofectin reagent (Gibco-Brl). After selection in the culture medium containing 30mg·L^{-1} hygromycin (Sigma) for more than eight weeks, one clone (tet-293/Ins6) expressing insulin under the control of Dox was selected by screening from 28 clones.

Radioimmunoassay

Tet293/Ins6 cells (1.0×10^6) were seeded in 35-mm-diameter dishes, and treated with Dox at 0, 10, 100, 200, 400, 800 and 1000μg·L^{-1} for 24h, or at 1000μg·L^{-1} for 0, 15 and 30min, 1, 2.5, 5, 12 and 24h. The amounts of insulin secreted in the medium were measured with specific radioimmunoassay kit (Haikerei Co. Peking).

RT-PCR

Total RNA was extracted from cells with TRIzol (Gibco), and the first chain of cDNA was prepared by RT with Superscript Ⅱ reverse transcriptase (Gibco) using a oligo(dT)11 primer. The proinsulin gene was amplified with Taq polymerase (Progema). The PCR primers for proinsulin gene were: sense 5'-tgccatggccctgtggatg-3',and anti-sense 5'-gcaggctgcgtctagttgc-3'.

Northern blot analysis

For each Northern blot, 10μg total RNA was loaded per lane and separated, transferred onto nylon membrane (Schleicher and Schuell, Germany) and crossed-linked by UV irradiation. The hybridization probe specific for proinsulin, was labeled with (^{32}P)dCTP using a DNA labeling kit (Takara). Following hybridization at 68℃ for 2h, blots were washed twice for 30min at room temperature with solution 1 (2×SSC,0.5g·L^{-1}SDS) and solution 2 (0.1×SSC,1g·L^{-1}SDS), respectively, and exposed to a phosphorimaging screen overnight. The blots were then washed with 5g·L^{-1}SDS at 95℃ until complete removal of the probe and rehybridized with human β-actin cDNA (Clontech).

RESULTS

Establishment of a stable cell line excreting insulin controlled by Dox

After screening in the culture medium containing hygromycin for more than eight weeks, a total of 28 independent Hyg-resistant cell lines were created from the tet-293 cells which had been cotransfected with pTR2.mINS and pTK-Hyg. Of the 28 clones, one (tet-293/Ins6) was obviously regulated to secrete insulin by Dox. The amount of insulin in the medium secreted by the cells treated with Dox (1mg·L^{-1}) was 241.0pU·d^{-1}·cell^{-1}, which was 25-fold that of 9.7pU·d^{-1}·cell^{-1} released by the cells without Dox treatment.

Verify the regulation of Dox on insulin secretion in tet-293/Ins6 cells at the protein level

Tet-293/Ins6 cells were amplified and passaged (1.0×10^6 cells) into 16 35-mm dishes, and the concentrations of insulin in the culture media were measured with RIA. As shown in Figure 1, the level of insulin secretion increased from 18.2 to 241.0pU·d^{-1}·cell^{-1} over a range of Dox concentrations from 10μg·L^{-1} to 1000μg·L^{-1}. Only a slightly increasing tendency of insulin concentration was observed at 2.5h following the addition of 1 mg·L^{-1} Dox to the culture medium. However, the amount of insulin increased significantly after exposing the cells to Dox for more than 5h (Figure 2).

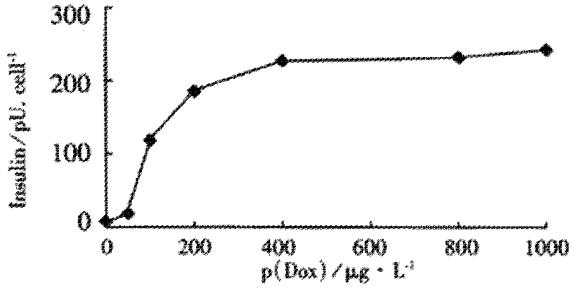

Figure 1 Insulin secretion from tet-293/Ins6 cells after treatment with Dox at different concentrations for 24h.

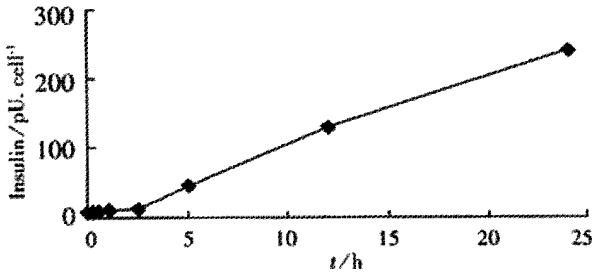

Figure 2 Time course of insulin secretion from tet-293/Ins6 cells after activation with Dox at 1000μg·L^{-1} in 24h.

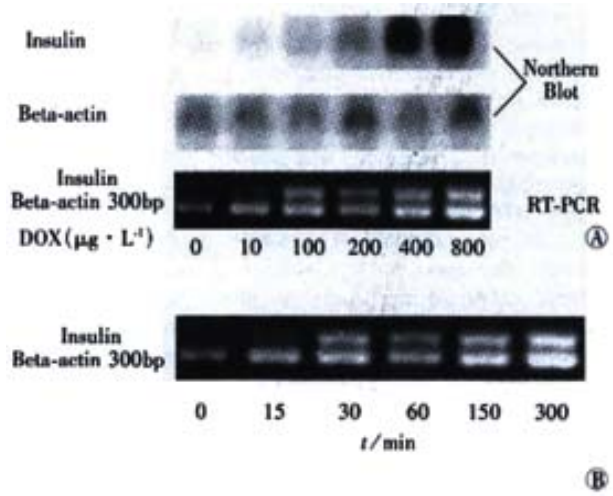

Figure 3 The conditional transcription of insulin gene by Dox in the tet-293/Ins6 cells using β-actin as loading control.

Verify the regulation of Dox on insulin expression in tet-293/Ins6 cells at the transcriptional level

Theoretically, the Tet-on system exerts its regulatory effect on target genes at the transcriptional level. So RT-PCR and Northern blot methods were used to further demonstrate the inducibility of insulin by Dox. After tet-293/Ins6 cells were cultured in the media containing different concentrations of Dox for 24h, it was found that 10μg·L^{-1} Dox could induce insulin expression obviously, and that the insulin mRNA level was up-regulated dramatically by Dox in a dose-dependent manner (Figure 3A). As shown in Figure 3B, the result of

RT-PCR indicated that the transcription of insulin gene ha d already been up-regulated significantly after exposing tet-293/Ins6 cells to 1mg·L^{-1} of Dox for 15 minutes.

DISCUSSION

Insulin-dependent diabetes mellitus (IDDM) results from the autoimmune destruction of the insulin-producing beta cells of the pancreas. As a consequence, diabetic patients experience profound metabolic derangements (hyperglycemia, ketosis and hyperlipemia) and develop vascular and neurologic chronic complications[27-29]. These alterations can be only partially controlled by the exogenous administration of insulin, which brings patients suffering and inconvenience[30]. In recent years, engineering insulin-secreting cell lines has received a great deal of interest and some exciting advances have been made. But the application of gene therapy to diabetes presents formidable challenges, one of which is how the level of insulin is restricted within a very narrow limit. Otherwise, if the engineered artificial β-cells were transplanted into the body, the excessive insulin for metabolism would cause hypoglycaemia[8], and even death. Several inducible promoters originating from eukaryotic genes have been used to deliver gene in a regulated manner. The substances inducing the promoters include steroid hormones, oxygen, heavy metals, or physical stimulus (such as radiation)[31, 32]. However, most of these promoters are not suitable for clinical application for various reasons: first, because these promoters are of mammalian origin, the exogenous regulation of transgene through such a promoter could at the same time affect the transcription of the host endogenous genes; and second, the inducers of these promoters are generally endogenous molecules (hormones, oxygen, etc.), the levels of which cannot be modulated significantly and safely. Other limitations include the potential toxicity or side effects of the inducer. Therefore, an inducer/promoter system, which regulates the transcription only of the transgene, without affecting endogenous genes, is acceptable for gene therapy in humans.

The Tet-on system, which utilizes an *E. coli* gene regulatory system[20], appears to fulfil the criteria for clinical application for several advantages[33-40]: (1)gene expression is easily regulated by administration of Dox; (2)Dox is minimally toxic; and (3)Dox acts specifically on the target gene, and does not activate other cellular genes. This expression system has two critical components, the regulatory plasmid and the response plasmid. The rtTA (reverse tetracycline-controlled transactivator) expressed by the regulated plasmid binds the TRE (tet-response element) in the response plasmid and activates the transcription of the target gene in the presence of Dox. Efrat *et al*[41] used the Tet-operon regulatory system to generate a β-cell line in transgenic mice, but there has been no report on the study of engineering non-β-cells for the treatment of diabetes in this regard. Efrat constructed a fusion protein, TETR-VP16 containing the tet repressor and the activating domain of the herpes simplex virus protein VP16,which converts the repressor into a transcriptional activator under the control of the insulin promoter. Then, the transgenic mice of the fusion protein were generated, whose β-cells could express the TETR-VP16 protein conditionally. In a separate lineage of transgenic mice, the simian virus 40 (SV40) large tumor (T) antigen (TAg) gene was introduced under the control of the tet operator sequences and a minimal promoter, which by itself is not sufficient for the expression of Tag gene. Mice from the two lineages were then crossed to generate double-transgenic mice. Expression of the TETR-VP16 protein in β-cells activated Tag transcription, resulting in the development of β-cells tumors. A stable β-cell line deriving from the tumor had the following characteristics: cell incubated in the absence of Tet proliferated normally; and cell incubation in the presence of Tet led to inhibition of proliferation. Thus, it is feasible that the expression of insulin gene can be regulated under the control of the proliferation of these β-cells. In the present study, utilizing the Tet-on system, we have established a cell line tet-293/Ins6 in which insulin gene can be expressed conditionally by Dox treatment. Ten μg·L^{-1} Dox can activate the tet-response element and significantly enhance the expression of insulin gene in the cells in a dose-dependent manner. Additionally, the RT-PCR results showed that it is at 15min that 1mg·L^{-1} Dox could activate the transcription of insulin gene in the tet-293/Ins6 cells following the addition of Dox, and that the amount of insulin in the media did not increase until 5 hours after the treatment of Dox, suggesting that there is a periodic interval of time from the process of gene transcription, translation, and protein synthesis, processing to the final step, secreting the protein from the cells. The strategy used here, by which a stable cell line with low background and high Dox-induced expression of insulin was generated, is more efficient and rapid for regulating insulin gene expression as compared with Efrats' method[41], and will contribute not only to the development of artificial β-cells for the treatment of diabetes but to the generation of other condition-secreting cell lines for gene therapy of human diseases.

However, responding to the variation of blood glucose concentration, the expression level of insulin gene should be regulated strictly for gene therapy of diabetes[42-44]. The tet-293/Ins6 cells still have their imperfections for replacing islet transplantation in humans for the treatment of diabetes. Under normal conditions, increasing glucose concentration in blood stimulates β-cells to secrete insulin immediately; but the tet-293/Ins6 cells release insulin by control of Dox at the transcriptional level, the kinetics of feedback loops on transcriptional changes is much slower than that of the secretory response in β-cells. Therefore, based on the experiments we have carried out, we are making efforts to establish an artificial β-cell line in response to glucose stimulation with gene engineering.

Abstract

AIM: **To provide scientific evidence for prevention and controlling of cryptosporidiosis, the infection of *Cryptosporidium parvum* and its epidemiological characteristics were studied in some areas of Anhui Province.**

METHODS: **The oocyst of Cryptosporidium parvum in 5421 fresh stool samples from eleven areas of Anhui Province was tested by auramine-phenol stain and improved anti-acid stain respectively. The specific antibody of IgG, IgM and T subsets of 41 patients with positive Cryptosporidium parvum in stools were detected by ELISA and biotin-streptavidin (BSA) respectively.**

RESULTS: **The total infective rate of Cryptosporidium parvum was 1.33% (74/5421). Among them, the positive rates of oocyst in the areas of Huaibei (1.82%) and Fuyang (1.80%) were higher. The positive rates of oocyst in stools of infants, pupils, middle school students, college students, adults, patients with diarrhea, and those with immunodeficiency were 3.15%(28/889), 0.82% (9/1098), 0.82%(9/1092), 0.83%(8/969), 0.85% (9/1095), 2.88%(8/278) and 8.33%(3/36)% respectively. The positive rates of oocyst in infants and the patients with diarrhea and immunodeficiency were significantly higher than those in controls ($P<0.01$). The positive rate of oocyst in males was similar to that in females ($P>0.05$). The positive rate of oocyst in urban areas (1.13%) was significantly lower than those in rural areas (1.72%, $P<0.01$). The positive rates of specific IgG, IgM and IgG+IgM in sera of the patients with positive oocyst in stool were 63.4% (26/41), 17.1% (7/41), 19.5% (8/41) respectively. The number fractions of T subsets of CD_3^+, CD_4^+, CD_8^+ and CD_4^+/CD_8^+ of the patients were 0.66±0.07, 0.44±0.06, 0.28±0.04 and 1.58±0.32 respectively. The difference between the patients and the controls was significant ($P<0.05$). The main manifestations of the patients were subclinical infection, in forms of slight abdominal pain, mild diarrhea, and loose stool.**

CONCLUSION: **There are two infection peaks in infection of Cryptosporidium parvum and its infection can be found more often in infants, patients with diarrhea or immunodeficiency, and in rural areas. Subclinical infection is the main manifestation and might be easily misdiagnosed. When the therapeutic effectiveness is low for diarrhea, the infection of Cryptosporidium parvum should be considered, concerning their age and immune function.**

INTRODUCTION

Cryptosporidiosis is a kind of zoonoses whose clinical manifestation is diarrhea caused by Cryptosporidium parvum[1-13]. Since the first report of the disease covered by Nime *et el*[14] in 1976, more and more studies have been reported. After the first report of the disease in 1978 covered by Hanfan *et al.* in Nanjing, many reports of the disease have been published from more than ten provinces[15-24]. In order to explore the infection, epidemiological characteristics and clinical manifestations, the investigation of the disease was taken cosmically in eleven areas of Anhui Province.

MATERIALS AND METHODS

Materials

A total of 5421 samples of stools were collected from eleven areas of Anhui Province. Among them, the number of infants, pupils, middle school students, college students, adults patients with diarrhea and immunodeficiency were 889, 1098, 1092, 969, 1373, 278 and 36 respectively. The patients with obstinate diarrhea, and immunodeficiency were the major target. The number of males and females was 3474 and 1947 respectively. The median age was 24.5 years (ranging from 4 to 63 years).

Methods

The different histories of present illness, anamnesis, health habit and healthy state of environment were taken.

Feces examination After fresh stools were collected by disposable boxes. The oocyst of Cryptosporidium parvum was tested by auramine-phenol stain and improved anti-acid stain respectively. The smears of stool were made on the surface of sheet glass (2cm^2). After these smears were left dry naturally and fixed with methanol, the auramine-phenol stain and improved anti-acid stain were made, and the examination under microscope was taken respectively. The oocyst of Cryptosporidium parvum with rose bengal was positive, and the other nonspecific granules were blue-black.

Biopsy examination The examination of colon biopsy was tested by sigmoidoscope for six patients with obstinate diarrhea, or immunodeficiency.

Serological examination The antigen of oocyst coming from guinea pigs was coated on the surface of polystyrene wells, and the specific antibodies of IgG, IgM were detected by ELISA.

Examination of T subsets The T subsets (CD_3, CD_4, CD_8) were detected by biotin-streptavidin (BSA) in 36 patients with immunodeficiency.

Statistical analysis was made by using Student's *t* test.

RESULTS

The results of oocyst of Cryptosporidium parvum in stools collected from eleven areas of Anhui Province are shown in Tables 1-4. The results of specific antibodies and T subsets are shown in Tables 5-6. The common clinical symptoms of the disease are shown in Table 7.

Examination of living tissue The examination of biopsy was tested by sigmoidoscope in six adults and old patients with obstinate diarrhea, or immunodeficiency. The results showed that there were many oocysts on the surface of intestinal mucosa, which had villus degeneration and mononuclear leukocyte infiltrations.

DISCUSSION

Cryptosporidium parvum is recognized as an important protozoon, whose life cycle is simple with nonspecific host. Large-scale surveys of selected animals suggest that Cryptosporidium parvum is more often found in farm cattle, sheep, dogs and cats. The disease can be transmitted in animals and people mutually. Water polluted with Cryptosporidium parvum is regarded as a source of infection by some experts[24-35]. Patients with immunodeficiency (AIDS) can easily be infected through respiratory tract. During the gastroenteritis of fulminant epidemic, the positive rate of Cryptosporidium parvum was 39% in 13000 patients with gastroenteritis[14].

The pathogenicity of Cryptosporidium parvum hasn't been, for a long time, taken into serious consideration. Since the report of severe diarrhea caused by Cryptosporidium parvum breaking out in Turkeys in 1955 (Stavin), and in 1976 (Nime)[14], the infection of the disease has been reported in many countries. The different positive rates of Cryptosporidium parvum are 1-2% in Europe, 0.6-4.3% in North America, and 3-4% or even 10.2% in Asia, Australia, Africa, and Central and South America.

The pathogenic mechanism of Cryptosporidiosis hasn't been clarified. The report of Hanfan (1990)[15,16] showed that after the infective oocyst invaded the intestine, its sporozoites intruded epithelium mucosae villus and its larva could reproduce in vacuole. With the development of the disease, the epithelium mucosae villus would collapse, light or medium inflammatory reaction with mononuclear leukocytes and watery stool could appear. Decreasing the

activity of lactase caused by infection of Cryptosporidium parvum was an important reason for losing lactose and diarrhea[36-46].

Since the first patient with the disease was diagnosed in 1987 in our country, many cases of the disease have been reported, especially in Jiangsu, Fujian, Hunan, Shandong Provinces and Inner Mongolia. The total detective rate of the disease was 1.36-13.3%. It was more often found in infants and children[47-55]. Our data of investigation suggest that the infection of Cryptosporidium parvum has existed in Anhui Province, and its detective rate was low (1.33%, 74/5421)[15,16]. The infective rate of Cryptosporidium parvum in males and females was 1.41% and 1.28% respectively. There was no significant difference between two sexes (P>0.05). Although stain of auramine-phenol is one of the good methods for the detection of oocyst, the specificity of stain can be interfered by impurity in stool. The stain of auramine-phenol and modified acid-fast can overcome false positive reaction and false negative reaction of oocyst so that the detective rate of oocyst can be increased (P<0.05). The infectious rates of Cryptosporidium parvum were higher in infants and patients with obstinate diarrhea or immunodeficiency than those in middle school students and college students (P<0.01). The possible reason was immunodeficiency, lower positive rate of CD_3^+, CD_4^+ and CD_4^+/CD_8^+, so that the patients had not enough immune reaction to Cryptosporidium parvum. The similar results of the isolation rate had been observed in our investigation, which was more often found in infants and children with diarrhea. The possible reason was the immune organs of infants and children hadn't matured. After Cryptosporidium parvum invaded the intestine, the structure of pithelium mucosae villus was demolished and few antibodies were produced. The extent of the disease for adults was not only associated with the level of infection of Cryptosporidium parvum but also associated with the immunity. It was more often found in parasite states and self-limited diarrhea for normal population. It was more often found in severe infection and continuous diarrhea for immunodeficiency. Scavenger worm was associated with the level of Th and ADCC of the patients. The production of restrain factor and the decrease of T cells and T subsets were caused by the common antigen of different enteric bactilli and infected epithelial cells of colon. For the patients with low or no treatment effect of antibiotic, taking into consideration their living environment and individual living habits, the possible infection of Cryptosporidium parvum should be considered. In the study of Pan *et al*[56-62], for thirteen patients with ulcerative *coli*tis and ten patients with clone disease, the function of T cells and restrain index number were all deficient in the patients with inflammation intestinal tract. The infective rate of Cryptosporidium parvum was higher in rural areas than that in urban areas (P<0.05). The possible reasons were poor living conditions, lack of necessary general health knowledge and health habits in the rural areas. Food and drinking water polluted by oocyst was the possible cause of the infection.

The main antigen of Cryptosporidium parvum was cyst wall antigen and sporozoite antigen. Most scholars considered that cellular immunity was important and the immune mechanism of cryptosporidiosis hadn't been clarified. Moon's study showed that IgG, IgM against Cryptosporidium parvum couldn't repress the infection, so that the immunity of cryptosporidiosis was dependent on cellular immunity. However, other scholars, for example Chrisp and Riggs, thought that the specific antibody could easily be made after adult and young mice were vaccinated by oocyst. The detective results of specific IgA, IgM, IgG in serum, stool and duodenal juice and cellular immune function prompted that the immunity of cryptosporidiosis was dependent on ADCC. The results of our study showed that type of antibody most frequently found was IgG, with IgM, and IgG+IgM following it. For IgM as target of early infection was not necessarily a verified index, if IgG or IgM in serum was positive, possible infection of Cryptosporidium parvum should be considered. The positive effects of circle antibody haven't been completely clarified according to the previous results that the circle antibody hadn't protective function[15-17]. It is possible that the effect of antibody in serum against Cryptosporidium parvum in intestinal pithelium mucosae villus is ineffective.

The expressive levels of CD_3^+, CD_4^+ and CD_4^+/CD_8^+ were lower in positive rates of oocyst in stool than those in negative rates of oocyst in stool (P<0.05). The result showed that the cellular immunity played a key role against the infection of Cryptosporidium parvum. When the levels of CD_3^+, CD_4^+ were low, the activity of T cells and its cellular factor were inadequate, and the infection of Cryptosporidium parvum would persist. However, the result of general level of CD_8^+ in the patients with positive rates of oocyst indicated that the activity and number of CTL hadn't significantly increased, and severe tissue injuries, generally speaking, wouldn't take place in the patients.

Most patients neglected diagnosis and treatment when they had no or light symptoms. Most people with normal immune functions suffering from self-limited diarrhea often had symptoms of acute watery stool (5-10times/d), nausea, vomiting, headache etc, and their course of disease was less than one month. The results of our study showed that about 83.78% infected persons had no obvious symptoms, the possible reason for it was associated with the infective level and the ability of immune response. The symptoms of the patients were easily confused with general gastroenteritis. If the treatment of antibiotic failed, the infection of this disease should be considered, eliminating some associated diseases.

As a conclusion, there were two infection peaks in the infection of cryptosporidium parvum, and the infection of Cryptosporidium parvum has existed in Anhui Province, and was more often found in infants, children and some patients with diarrhea or immunodeficiency. The effect of specific IgM, IgG in sera of the patients against Cryptosporidium parvum in intestine was much inferior. If the treatment of antibiotic failed, the infection of this disease should be considered, considering age and immune function of the patients, if some associated diseases are eliminated. In order to avoid the persistent and chronic state of the illness, antiscolic treatment must be taken earlier for the subclinical infective patients with confirmed diagnosis.

Abstract

AIM: **To investigate the relationship among gastrin, somatostatin, G and D cells in gastric ulcer and in its healing process in rats.**

METHODS: **Fourty-nine Wistar rats were divided into 7 groups. The gastric ulcer model was induced by acetic acid successfully. The gastrin and the somatostatin in rat plasma, gastric fluid and antral tissue were measured by radioimmunoassay(RIA). G and D cells in antral mucosa were analyzed with polyclonal antibody of gastrin and somatostatin by immunohistochemical method and Quantimet 500 image analysis system.**

RESULTS: **In gastric ulcer, the level of gastrin in plasma, gastric fluid, and antral tissue increased, that of somatostatin declined, and the disorder gradually recovered to the normal level in the healing process. Immunohistochemical technique of G and D cells in antral mucosa demonstrated that the number of G cells increased and that of D cells decreased, both areas of G and D cells declined, the ratio of number and area of G/D increased in gastric ulcer, and the disorder gradually recovered in the healing process.**

CONCLUSION: **In gastric ulcer, the increased gastrin secreted by G cells, the declined somatostatin secreted by D cells, and the disordered G/D cell ratio can lead to gastrointestinal dysfunction.**

INTRODUCTION

Gastrin is secreted in G cells, while somatostatin is secreted in D cells. Gastrin, somatostatin and other gastrointestinal hormones regulate the function of gastrointestinal tract such as secretion, movement, absorption, circulation and nutrition of cells[1-12]. The nerve system and the endocrine system participate in the healing process of gastric ulcer and regulate the absorption of inflammantory filtration, hyperplasia of granulation tissues, and regeneration of epithelial tissues. Obvious regular change takes place in many endocrine tissues[13-24]. In order to investigate the relationship between gastrin, somatostatin, G and D cells in the period of gastric ulcer and its healing process in rats, the gastrin and somatostatin in plasma, gastric juice and antral tissue were tested in rats. At the same time, the number of G and D cells was measured in the antral mucosa.

MATERIALS AND METHODS

Animal

Forty-nine healthy male Wistar rats weighing from 200g to 260g were obtained from the Experimental Animal Center of Sun Yat-Sen University of Medical Sciences. The rats were divided into seven experiment groups: 4, 7, 10, 14, 21, 28d groups, and a control group. The rats of six experimental groups were anesthetized with 30g·L^{-1} sodium pentobarbital intraperitoneally at a dose of 30mg·kg^{1}. The abdomen was opened and its stomach was found, 0.05mL acetic acid was injected into rat's antral tissues. Omentum majus and antral tissue of the injection site were stitched. The peritoneum, parietal abdomen and ventral muscle, and skin were stitched continually. After operation, the rats were raised separately, and fasted overnight with free access to water one day before sacrifice. No treatment was given to normal control group.

Plasma sampling

The rats' abdomen and chest chambers were opened and 4mL blood was directly withdrawn from the heart ventricle. Fourty μL(500u) aprotinin (Livzon Libao Biochemical & Pharmacertical Co. Ltd) and 60μL of 100g·L^{-1} EDTA was added to each blood sample. The samples were centrifuged at 3500r.min^{-1} for 15min to obtain plasma. The plasma samples were then stored at -70℃ until assay.

Gastric juice

After the rats' abdomen was opened, a plastic catheter was inserted into the stomach through pylorus and another catheter was inserted through oral cavitas and esophagus into stomach. Two mL saline(pH7.0, 35℃) was infused into the stomach at a flow velocity of 12mL/h. The gastric fluid was collected and 40μL(500u) aprotinin was added. The samples were centrifuged at 3500r.min^{-1} for 15 minutes to obtain gastric fluid. The gastric fluid samples were then stored at -70℃ until assay.

Antral mucosa

The rats' stomach was separated and was split from the greater curvature of stomach. The antral tissues in the ulcer area and non-ulcer area were separately taken with ophthalmic scissors. The tissue was quickly weighed by an electric analytical balance and was boiled in a microwave stove. The boiled tissue was homogenized into homogenate in a homogenizer with 1mL of 1mol.L^{-1} acetic acid. Then 1mL of 1mol.L^{-1} NaOH was added to neutralize it. The homogenate was centrifuged at 3500r.min^{-1} for 15 minutes and the supernatant was collected. The samples were then stored at -70℃ until assay. The stomach was separated and was split from the greater curvature of stomach. About 1.0×0.5cm antral tissues in the ulcer area and non-ulcer area was separately taken with ophthalmic scissors. The specimen was fixed in 100mL·L^{-1} neutrally buffered formalin. It was embedded with paraffin 24h later and was serially sectioned at 4μm. The sections were mounted onto histostick-coated slides. Adjacent ribbons were collected for immunohistochemical staining.

Measurement of gastrin and somatostatin

Gastrin and somatostatin were detected by using RIA method. The gastrin kits were purchased from Tianjin Qianye Biotech Co. Ltd, and the somatostatin kits were bought from the Department of Neurobiology of the Second Military Medical University. Measurement procedures were performed according to the instruction attached to the kits. The unit of result of plasma and gastric fluid was transformed to $ng \cdot L^{-1}$, while the unit of result of antral mucosa tissue to $ng \cdot g^{1}$.

Immunohistochemical staining for G and D cells

The anti-gastrin antibody(Sigma Co. USA) and anti-somatostatin antibody(GYMED Co. USA) were used and immunohistochemical staining for G and D cells was performed with the strept-avidin-biotin-peroxidase complex(SABC)(Wuhan Boster Biological Technology Co. Ltd), negative control sections were normal serum blocking and PBS instead of the primary antibody. Images of 5 views randomly selected under microscope(10×40) from each anti-gastrin immunohistochemical staining section were input into the Quantimet 500 image analysis system(Leica Co, Germany). The number and area of G cells were calculated by the computer. The mean number and area of G cells in 5 views of the section served as the number and area of G cells of a section. That of D cells was calculated in the same way as the G cells. The ratio of G/D number and G/D area was acquired by separately dividing the number of G cells and the area of G cells by the number of D cells and the area of D cells in adjacent sections.

Statistical analysis

The result of quantitative data was expressed as mean±SE. Data was analyzed using the variance analysis(ANOVA). Post hoc analysis between factors was performed using least significant difference test. Unpaired data was compared using the Wilcoxon ranksum test and correlated using Pearson's correlation.

RESULTS

The concentration of gastrin and somatostatin in the plasma, gastric juice, antral mucosa is shown in Tables 1 and 2. The number and area of G and D cells in the rat antral mucosa, and the ratio of G/D number and G/D area is shown in Table 3. The relationship between rat G and D cells, and the relationship between G or D cells with gastrin or somatostatin are shown in Table 4.

DISCUSSION

Both gastrin and somatostatin are gastrointestinal hormones closely related to the function of gastrointestinal system. Gastrin is mainly secreted in G cells in antral and upper small intestines. It has several kinds of molecules and distributes in plasma, tissues, gastric juice, and intestinal juice. Somatostatin is a 14 amino peptide. It also has several kinds of molecules and distributes vastly in the body. The somatostatin in gastrointestinal system is secreted in D cells. It is mainly in intestinal nerve plexus, stomach and pancreas, and it is also in gastric and intestinal fluid. In the antrum there are many G and D cells, most of which belong to the open type endocrine cells that can directly secrete gastrin or somatostatin into gastric fluid. Elevated gastrin level can increase the secretion of basal and peak gastric acid, pepsin and inner factor, increase the amount of circulating blood in the mucosa of upper gastrointestinal tract, improve the nutrition of gastric mucosa cells. Somatostatin can obstruct the secretion of basal gastric acid and pepsin and inhibit the invoking function of gastrin to the secretion of gastric acid[25-38]. Our experiment is to reveal the change of gastrin and somatostatin in gastric ulcer rats. The result shows that when the rat had gastric ulcer, the gastrin in plasma, gastric juice and antral mucosa tissue increased, and the somatostatin declined. With the healing of ulcer, gastrin and somatostatin gradually recovered to the normal level.

G and D cells have interactive relation in the function[39-49]. In order to study their morphology we used the immunohistochemical method to identify the G and D cells and to measure the number and area of G and D cells by the medical image analysis system. We found that with ulcer the number of G cells increased as compared with the normal control group, the D cells decreased, and both areas of G and D cells declined. And with the healing of the ulcer, the number and area of G and D cells gradually recovered to the normal level. This suggests that in the ulcer stage, the function of synthesis and secretion of G cells increased, while that of D cells declined. This inclined us that the increased secretion of gastrin in ulcer rat might be related to the increased number of G cells. The declined area of G cells may be related to the increased secretion of gastrin. The decline of somatostatin secretion in gastric ulcer is likely related to both the decreased number of D cells and the reduced area of D cells. It is known that somatostatin can inhibit G cells to secrete gastrin. Because in the gastric ulcer, the somatostatin secretion of D cells in rats lowered its inhibitory effect to G cells, gastrin secretion of G cells increased.

G and D cells are interrelated in morphology. In normal gastrointestinal mucosa, the ratio of G/D number and G/D area is stable. This is useful for keeping the normal gastrointestinal function. The ratio of G/D cells can be an important index for knowing the change of the two kinds of cells and its effect on focal endocrine function[50-58]. Our result showed that in gastric ulcer, the ratio of G/D number and the ratio of G/D area increased than that in normal control group. In the healing process, the disorder recovered gradually to the normal level. This proves that the number of G cells increased and the number of D cells declined in gastric ulcer. It also shows that in gastric ulcer rat, the decrease of the D cell area is more obvious than that of G cells. The statistical analysis indicates that there is a relationship between the number of G and D cells, and between the area of G and D cells. There is also a relationship between the number and area of G cells and gastrin in antral mucosa, and between the number and area of D cells and somatostatin in antral mucosa. In summary, our result further proves histologically that in gastric ulcer rat, the G cell secreted gastrin increased, and the D cell secreted somatostatin reduced, the ratio and function of G/D cells were imbalanced.

Abstract

AIM: **To investigate the expression of the transforming growth factor beta 1(TGF- beta 1) mRNA in different stages of alcoholic liver disease (ALD) and its clinical value.**

METHODS: **One hundred and seven male alcoholics were grouped by clinical findings into four groups: alcohol abusers without liver impairment (n=22), alcoholic steatosis (n=30); alcoholic hepatitis (n=31); and alcoholic cirrhosis(n=24). Using peripheral blood mononuclear cells (PBMC) as samples the gene expression of TGF-beta 1 was examined quantitatively by reverse transcription polymerase chain reaction (RT-PCR) and dot blot. There are 34 healthy subjects served as control.**

RESULTS: **The expression of TGF-beta 1 from all ALD patients was significantly greater than that in controls (1.320±1.162 *vs* 0.808±0.276, P<0.001). The differences of the expressions were significant between the patients from each groups (alcoholic steatosis, alcoholic hepatitis and alcoholic cirrhosis) and the controls (1.168±0.852, 1.462±1.657, 1.329±0.610 *vs* 0.808±0.276, P<0.050). No significant differences of TGF -beta 1 mRNA expression were observed between alcohol abusers without liver impairment and controls. The expressions in patients with alcoholic hepatitis and alcoholic cirrhosis were significantly greater than that in alcohol abusers respectively (1.462±1.657, 1.329±0.610 *vs* 0.841±0.706, P<0.050). No significant differences of TGF -beta 1 mRNA expression were observed between alcoholic fatty liver men and alcohol abusers.**

CONCLUSION: **TGF-beta 1 expression level can be a risk factor for alcoholic liver disease and might be related to the inflammatory activity and fibrosis of the liver in patients.**

INTRODUCTION

Alcoholic liver disease (ALD) is the most common cause of liver disease in late stage in the developed world[1],and ranked as the second cause of hepatic cirrhosis in China now. The increased deposition of extracellular matrix in the liver is a key factor in the developing of the disease.

In recent yeas, the role of TGF-beta 1 in ALD has been much emphasized[2,3],but the study of expression of TGF-beta 1 in peripheral blood mononuclear cells(PBMC) from ALD patients has scarcely been performed. This study was aimed at quantitative analysis of the expression of TGF-beta 1 mRNA in PBMC of ALD patients through reverse transcription-polymerase chain reaction (RT-PCR) technique and dot blot.

MATERIALS AND METHODS

Subjects

The subjects was from the epidemiologic survey of ALD in Zhejiang province including 107 male alcoholics, aged 25~70 yeas(χ=43.32±10.39), who had ingested more than 40g of alcohol a day for more than 5 years. According to the diagnostic criteria of Nanjing conference, there were 22 alcohol abuser without hepatic impairment, 30 alcoholic steatosis, 31 alcoholic hepatitis and 31 alcoholic cirrhosis. Percutaneous liver biopsy was performed in all cases, C and B hepatitis were ruled out by appropriate serological tests. 34 healthy subjects served as control, with age range from 26 to 68 years (χ=45.60±10.08). There were no significant differences in their ages among the alcoholics and healthy controls.

Design and synthesis of primers

TGF-β1primers and probe were synthesized by Gibco BRL Co. The forward primer, reverse primer and probe were 5'GGA CAC CAA CTA TTG CTT CAG3', 5'TCC AGG CTC CAA ATG TAGG3' and 5'CAG CTG TAC ATT GAC TTC CGC AAG GAC CT3' respectively. β-actin primers were synthesized by the Academy of Microrganism Science of Lubeck University, and kindly provided by Prof. Chen Zhi. The sequence of the primes were 5'TTC CAG CCT TCC TTC CTGG3' (forward primer) and 5'TTG CGC TCA GGA GGA GCA AT3'(reverse primer). The Primers were designed according to the previously reported sequence as shown in Roulot' s report[4].

Samples preparation and RNA extraction

Blood samples 3ml were mixed with Ficoll fluid to isolate the PBMC and then 150μl Trizol Reagent(Gibco BRL Co.) was added. Total cellular RNA was extracted by the guanidinium thiocyanate/phenol chloroform single-step method. RNA was washed in ethanol and dissolved in diethyl pyrocarbonate (DEPC)-treated water.

RT-PCR

The RT-PCR mixture consisted of RNA of each sample 5μl,2mM dNTP 5μl, 5×first stand buffer 5μl, 100mM TT 2.5μl, 100pmol/μl oligod(T) 15μl,MMLV-RT100 unit,Rnase 1μl(Pharmacia Biotech) to a total volume of 20μl. The reaction was allowed to proceed at 41℃ for 1 hour.

The PCR mixture consisted of RT-PCR products 5μl,10×PCR buffer 5μl, 20 pmol of each primer, 2mM dNTP 5μl and Taq polymerase 1.25 unit(Gibco BRL Co.) to a total volume of 40μl. This reactioo mixture was overlaid with 1 drop of mineral oil.

PCR was carried out in a DNA thermal cycler (Perkin-Elmer Cetus) for 30 cycles; after initial denaturation by heating to 95℃ for 2 minutes, each cycle consisted of denaturation at 94℃ for 60 seconds, annealing at 56℃ for 60 seconds and extension at 72℃ for 45 seconds. An extra extension at 72℃ for 10 minutes was performed after the final cycle.

Dot blot

The probe was labelled using a DIG oligonucleotide 3'-end labeling kit (Boehringer Mannheim). The efficiency of the labeling reaction was checked by comparing with the labelled control-oligonucleotide by direct detection.5μl PCR products was dropped to on a nylon membrane. The membranes were hybridized at 60℃ for 6h after being denatured, fixed, prehybridized and then washed and stained.

Quantitative analysis

Quantification of TGF -beta 1 mRNA was carried out using β-actin mRNA as an internal standard because the transcription levels of β-actin were very stable in all types of tissues. The dots on the membranes were quantitatively analyzed and pictures were taken using IS-1000 multifunction agarose imaging analysis system(Alpha Innotech Co.). The relative index (RI) of mRNA was calculated using a formula as RI=scan value of TGF -beta 1 mRNA dot/scan value of β-actin mRNA dot[5]. Here RI might represent the relative levels of TGF-β1 mRNA in PBMC.

Statistics

The data were presented as means±s,all the statstics were done with the software Statistical Package for the Social Sciences (SPSS) and the P value was considered significant when it was less than 0.05.

RESULTS

The expression of TGF -beta 1 from all ALD patients was significantly greater than that in the controls(1.320±1.162 *vs* 0.808±0.276, *t*=3.811, *P*=0.0001, Figure1).

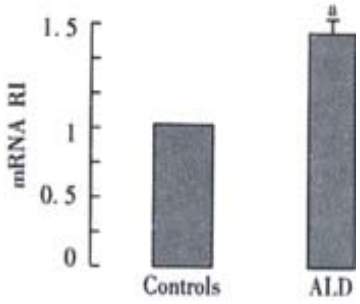

Figure 1 TGF-β1 mRNA RI values in ALD and Controls' $^aP<0.05$ *vs* controls

The expressions in patients with the alcoholic steatosis,alcoholic hepatitis and alcoholic cirrhosis were significantly greater than the expression in the controls respectively(1.168±0.852, 1.462±1.657, 1.329±0.610 *vs* 0.808±0.276, t=2.213, *P*=0.017, t=2.171, *P*=0.019, t=3.915, *P*=0.0002). No significant differences of TGF -beta 1 mRNA expression were observed between alcohol abusers and the controls (Figure 2).

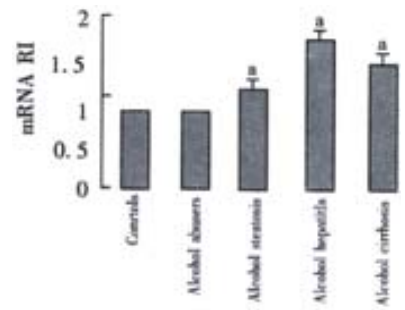

Figure 2 The TGF-beta 1 mRNA in alcohol abusers, alcohol steatosis, alcohol hepatitis, alcohol cirrhosis and controls.$^aP<0.05$ *vs* controls

The expression in patients with alcoholic hepatitis and alcoholic hepatic cirrhosis was significantly greater than that in alcohol abusers respectively(1.462±1.657, 1.329±0.610 *vs* 0.841±0.706, *t*=1.859, *P*=0.035, *t*=2.495, *P*=0.008), No significant differences of TGF-beta 1 mRNA expression were observed between alcoholic fatty liver males and alcohol abusers ((Figure3).

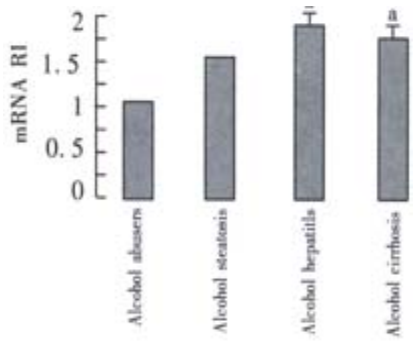

Figure 3 The TGF-beta 1 mRNA in alcohol abusers, alcohol steatosis, alcohol hepatitis, alcohol cirrhosis and alcohol abusers. $^aP<0.05$ *vs* alcohol abusers

DISCUSSION

In Western societies roughly 50% of all cases of liver cirrhosis are related with alcohol abuse. The increased deposition of extracellular matrix in the liver is a key factor in the morbidity and mortality of alcoholic liver disease[6]. This increased fibrosis may be due to a superabundance of profibrogenic factors such as transforming growth factor-beta 1 and/or relative decreacement of the factors that inhibit fibrogenesis such as collagenase or interferon[7-10].Transforming growth beta 1 (TGF-beta 1) is believed to play a key role in enhancing fibrogenesis and inhibiting extracellular matrix degradation[11]. Acetaldehyde, the oxidative metabolite of ethanol damages cell membranes, initiates lipid peroxidation and forms noxious protein adducts, which result in the activation of Kupffer cells and perisinusoidal lipocytes/portal fibroblasts[12-18]. The activation of lipocytes and fibroblasts to a proliferative and collagen-producing myofibroblast-like phenotype is triggered by the release of TGF-beta 1 from the activated Kupffer cells. In the liver,TGF-beta 1 is primarily responsible for activation of lipocytes, which are the main source of extracellular matrix proteins. Their deposition play a key role in the development of alcoholic liver cirrhosis[19-21].

A number of investigators have shown increase of TGF -beta 1 mRNA and protein levels in animal models of hepatic fibrosis[22-27]. A few studies also demonstrated increased levels of TGF -beta 1 mRNA and protein in animal models of ALD. Matsuoka *et al*[28]examined Kupffer cells and hepatic lipocytes isolated from a rat model of alcoholic liver fibrosis. The collagen formation was increased significantly in alcohol-fed group more than the control, which was completely inhibited by anti-transforming growth factor beta IgG. The major peak of the molecular weight was about 25000 which was revealed by high-performance liquid chromatography and demonstrated with Northern blotting and hybridization. Kamimura *et al*[29] examined Kupffer cell gene expression of TGF beta 1 in the rat model of ALD. Kupffer cells were isolated from the model after 10 and 17 weeks of intragastric ethanol infusion,the protein and mRNA levels of TGF beta 1 were significantly increased by 143% and 204% at 10 weeks and 238% and 295% at 17 weeks respectively in the ethanol-fed rats.

A number of studies have suggested a role for TGF -beta 1 in human liver disease[30].In our study, the expression of TGF -beta 1 was significantly greater in all the ALD patients than in the controls and the expression in the patients with the alcoholic steatosis, alcoholic hepatitis and alcoholic cirrhosis was significantly greater than

their expressions in the controls respectively. No significant differences of TGF -beta 1 mRNA expression were observed between alcohol abusers and the controls. The results demonstrated that the expression of TGF -beta 1 was related with ALD. Our study also showed that the expression of patients with alcoholic hepatitis and alcoholic cirrhosis was significantly greater than their expression in alcohol abusers respectively,and no significant differences of TGF -beta 1 mRNA expression were observed between alcoholic steatosis men and alcohol abusers. These results indicated that the expression of TGF -beta 1 was highes in more active and advanced ALD patients. Santos *et al*[31] also demonstrated similar results in liver specimens. The presence of TGF-beta1 expression could be recognized as a risk factor for active and advanced alcoholic liver disease.

Abstract

AIM: **To assess the diagnostic value of a combination of continuous intragastric pH and bilirubin monitoring in the detection of duodenogastric reflux (DGR), and the effects of diet on the bilirubin absorbance.**

METHODS: **30 healthy volunteers were divided into two groups: standard diet group (Group 1) 18 cases, free diet group (Group 2)12 cases. Each subjects were subjected to simultaneous 24hour intragastric pH and spectrophotometric bilirubin concentration monitoring (Bilitec 2000).**

RESULTS: **There was no difference of preprandial phase bilirubin absorbance between two groups. The absorbance of postprandial phase was significantly increased in group 2 than group 1. There was no difference between preprandial phase and postprandial phase absorbance in group 1. Postprandial phase absorbance was significantly higher in group 2. In a comparison of bile reflux with intragastric pH during night time, there were 4 types of reflux: Simultaneous increase in absorbance and pH in only 19.6%, increase in bilirubin with unchanged pH 33.3%, pH increase with unchanged absorbance 36.3%, and both unchanged in 10.8%. Linear regression analysis showed no correlation between percentage total time of pH<4 and percentage total time of absorbance>0.14, r=0.068, P<0.05.**

CONCLUSION: **Because of the dietary effect, high absorbance fluids or foods should be avoided in detection. Intragastric pH and bilirubin monitoring separately predict the presence of duodenal (and/or pancreatic) reflux and bile reflux. They can not substitute for each other. The detection of DGR is improved if the two parameters are combined simultaneously.**

INTRODUCTION

Duodenogastric reflux (DGR) is a natural physiologic phenomenon often occurring during the early hours of the morning and postprandial period[1]. When excessive, it may be pathological. Accurate detection of DGR has been a major problem for many years. Most methods used to detect DGR were of short periods, indirect and not in a physiological condition and with other shortcomings[2,3]. Ambulatory intragastric pH monitoring allows a physiological method of measuring rises in intragastric pH with an extended sampling period, but it cann't reliably distinguish between DGR and other causes of increased pH levels and it is an indirect technique. At present an ambulatory fiberoptic spectrophotometer that detects the presence of bilirubin (Bilitec 2000) is universally recognized as a reliable method[4-11]. This has made it feasible to qualitatively detect DGR for prolonged sampling periods in physiological setting. Up to date, there has been no report about the diagnostic value of a combined continuous intragastric pH and bilirubin monitoring in the assessment of DGR in China. We used Bilitec 2000 along with simultaneous ambulatory intragastric pH monitoring to evaluate its diagnostic value in DGR.

MATERIALS AND METHODS

Subjects

Thirty healthy control subjects, 16 male, 14 female, mean age 45±11, (range 20-70) years, were enrolled in this study. They were randomly divided into two groups: group 1 (standard diet group), 8 male, 10 female, mean age 45±11 years and group 2 (free diet group), 7 male, 5 female, mean age 46±10 years.

Methods

pH measurements were performed with an antimony electrode and bile measurement with a fiberoptic probe. Both catheter were connected to separate portable digital data recorders (Digitrapper Mark III and Bilitec 2000 recorder, Synectics). The pH electrodes were calibrated in buffer solution of pH 1 and pH 7 before and after the measurement. The calibration of the Bilitec 2000 was done in a small nontransparent tube before each test. The tip of pH catheter was tied with silk thread to the fiberoptic Bilitec probe, in a way the tip of the pH catheter slightly above the gap of the Bilitec probe, so that both measurements were registered almost at the same position.

Both probes were then passed transnasally after 12-h fasting and positioned in the gastric corpus 5cm below the lower border of the lower esophageal sphincter (LES)[3,12]. The localization of the LES was determined by esophageal perfusion manometry. After 24h the probes were removed, and the data were downloaded to a PC for analysis with Esophogram software. 24-hour gastric pH record was divided in four periods: the upright period, the supine period, the prandial pH plauteau period and the postprandial pH decline period[13]. The preprandial period pH and the postprandial period (include the prandial pH plauteau period and the postprandial pH decline period) pH were compared in this study. The absorbance $\geqslant$0.14 was used as Bilitec threshold values.

Group 1 were asked to take allowed food with bilirubin absorbance never exceeding 0.14 (rage 0.02-0.11) *in vitro*, such as milk, bread, rice, noodles, fish soup, chicken soup, boiled potatoes, lotus roots, pears and so on, the total calorie of three meals being about 8.4×10^6 J. The foods were detected in another unpublicized study. Group 2 were allowed to take free food except coffee and orange juice. The foods should be finely minced to avoid solid food pollution of the tip of the probe. All subjects were advised to eat three times a day and not to drink between meals. Smoking and alcohol were not allowed.

Statistcal analysis

All results were expressed as $\bar{x}\pm s$. Data were analyzed by Student's t test and linear regression. P<0.05 was considered statistically significant.

RESULTS

Intragastric pH of preprandial and postprandial period in two groups

Intragastric pH was significantly higher in postprandial period in two groups. In Group 1 and in group 2, intragastric pH of postprandial period compared with preprandial period were 3.6±1.1 *vs* 2.0±0.6, $P<0.05$, and 3.8±1.2 *vs* 2.1±0.8, $P<0.05$, respectively.

Intragastric bilirubin absorbance of preprandial and postprandial period in two groups

There was no difference of preprandial phase absorbance between two groups. The absorbance of postprandial phase was significantly increased in group 2 than group 1,0.20±0.04 *vs* 0.10±0.08, $P<0.05$. There was no difference between preprandial phase and postprandial phase absorbance in group 1. Postprandial phase absorbance was significantly higher in group 2, 0.20±0.04 *vs* 0.10±0.03,$P<0.05$.

Intragastric pH and bile reflux changes in overnight fasting

In a comparison of bile reflux with pH monitoring during night time in group 1, there were 4 types of reflux: Simultaneous increase in absorbance and pH in only 19.6%, increase in bilirubin with unchanged pH 33.3% or pH increase with unchanged absorbance 36.3%, increase in either one of the two parameters 69.6%, and both unchanged 10.8%. Moreover, Linear regression analysis showed no correlation between percentage total time of pH>4 and percentage total time of absorbance >0.14, r=0.068,$P<0.05$ (Figure 1-4).

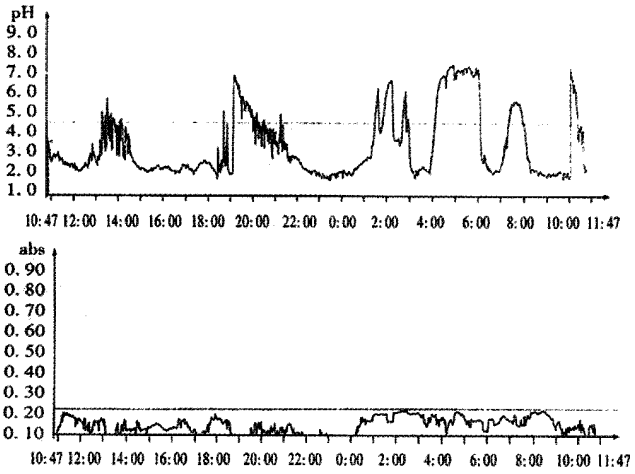

Figure 2 Intragastric pH increase with constant bilirubin absorbance

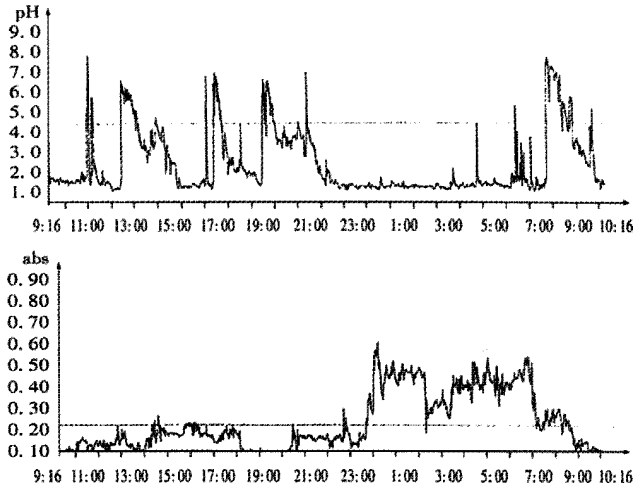

Figure 3 Bilirubin absorbance increase with constant intragastric pH

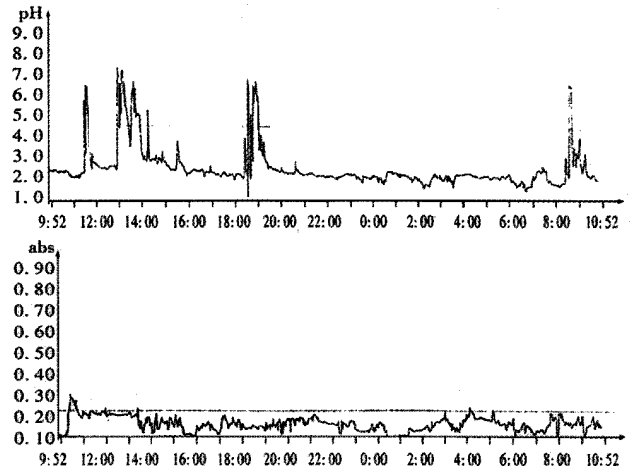

Figure 4 Intragastric pH and bilirubin absorbance both constant

DISCUSSION

Based on the experience in the esophagus in patients with gastroesophageal reflux disease, Litter *et al*[14] first applied intragastric 24 hour monitoring for evaluation of the alkaline reflux. Since then 24 hour intragastric pH monitoring has been used in many studies of DGR[15-20]. It is an indirect technique and is not capable of such detection in hypochlorhydric stomachs and in the prandial period. So there exist limitations in the diagnosis of DGR[21,22]. Bilitec 2000 is a new fiberoptic spectrophotometer that relies on the optical properties of bile to detect duodenogastric bile reflux (DGBR) in ambulatory setting independent of pH[23]. Bilirubin is the most common pigment in bile, with a characteristic absorption peak of 470 nm[24]. The basic working principle of the Bilitec 2000 is that an absorption at 470 nm automatically implies the presence of bilirubin, and therefore, bile in the sample under consideration. In the presence of bile alone, the degree of absorbance is proportional to the bilirubin concentration[25]. Bilitec may be an important advancement in the field of detecting DGR, permitting more accurate studies of patients with syndromes associated with DGR.

With Bilitec 2000 a threshold value is 0.14 absorbance[3,23,26], beyond which bile reflux is considered to be present. This threshold value takes into account scattering effects due to the gastric content such as suspended particles and mucus, which can give rise to a Bilitec readout ranging from 0 to 0.13 absorbance units, which, however, is not to be ascribed to bilirubin absorbance[23].

In this study the results showed that the intragastric pH in the postprandial period was higher than that in preprandial in both groups because of neutralization by food. In group 1 the bilirubin absorbance was lower than 0.14 in both period. In group 2 postprandial absorbance of (0.20±0.04) was significantly increased than preprandial (0.10±0.03). So measurement could be affected by the diet[27]. Some foods with an absorbance at between 400-450 nm are capable of resulting in false positive results. In order to accurately access DGBR, the foods with high absorbance should be avoided (e.g. coffee, coke, carrot, tomato, etc). Fein *et al*[28] reported if a threshold of absorbance of 0.25 was used, a free diet except coffee could be allowed for measurements.

In our study Bilitec 2000 along with simultaneous ambulatory intragastric pH monitoring showed a poor correlation between intragastric pH and DGBR. These results was consistent with other reports[29,30]. How to explain the discrepancy Duodenal juice consists of intestinal secretion, pancreatic secretion and bile. A previous study [1]using gastric aspiration and antroduodenal manometry showed a relationship among secretory activity, migrating motor complex (MMC) and DGR. DGR was highest during the late phase II of MMC and lowest after phase III. The duodenal bicarbonate output was highest after the onset of phase III while bile acid output was highest prior to the onset of phase III. Perhaps the reason for the poor correlation between intragastric pH and DGBR was related to variations of the amount of and different components in the regurgitated duodenal juice. If duodenogastric reflux fluid contains more bile and sufficient bicarbonate contents, both intragastric pH and absorbance are increased. If the reflux fluid consists mainly of duodenal bicarbonate and/or pancreatic secretion with less bile contents, rise of intragastric pH is observed owing to the buffering capacity of the fluid, and the absorbance remains unchanged. Conversely, if bile reflux occurs with less duodenal bicarbonate and pancreatic secretion, or in the absence of duodenoal bicarbonate and pancreatic secretion, absorbance is increased with unchaged pH, because the low bicarbonate buffering capacity can not change the pH. Fushs *et al*[31] studied the variability in the composition of physiologic duodenogastric reflux and found pancreatic enzyme aspirate was significantly more often associated with a rise in pH in comparison to bile reflux ($P<0.01$).

In conclusion, because of the dietary effect, high absorbance fluids or foods should be avoided in the detection. Intragastric pH and bilirubin monitoring separately predict the presence of duodenal (and /or pancreatic) reflux and bile reflux. They can not substitute for each other. The detection of DGR is improved if the two parameters are combined simultaneously.

Abstract

The prognosis of hepatocellular carcinoma (HCC) still remains dismal, although many advances in its clinical study have been made. It is important for tumor control to identify the factors that predispose patients to death. With new discoveries in cancer biology, the pathological and biological prognostic factors of HCC have been studied quite extensively. Analyzing molecular markers (biomarkers) with prognostic significance is a complementary method. A large number of molecular factors have been shown to associate with the invasiveness of HCC, and have potential prognostic significance. One important aspect is the analysis of molecular markers for the cellular malignancy phenotype. These include alterations in DNA ploidy, cellular proliferation markers (PCNA, Ki-67, Mcm2, MIB1, MIA, and CSE1L/CAS protein), nuclear morphology, the p53 gene and its related molecule MDM2, other cell cycle regulators (cyclin A, cyclin D, cyclin E, cdc2, p27, p73), oncogenes and their receptors (such as ras, c-myc, c-fms, HGF, c-met, and erb-B receptor family members), apoptosis related factors (Fas and FasL), as well as telomerase activity. Another important aspect is the analysis of molecular markers involved in the process of cancer invasion and metastasis. Adhesion molecules (E-cadherin, catenins, serum intercellular adhesion molecule-1, CD44 variants), proteinases involved in the degradation of extracellular matrix (MMP-2, MMP-9, uPA, uPAR, PAI), as well as other molecules have been regarded as biomarkers for the malignant phenotype of HCC, and are related to prognosis and therapeutic outcomes. Tumor angiogenesis is critical to both the growth and metastasis of cancers including HCC, and has drawn much attention in recent years. Many angiogenesis-related markers, such as vascular endothelial growth factor (VEGF), basic fibroblast growth factor (bFGF), platelet-derived endothelial cell growth factor (PD-ECGF), thrombospondin (TSP), angiogenin, pleiotrophin, and endostatin (ES) levels, as well as inratumor microvessel density (MVD) have been evaluated and found to be of prognostic significance. Body fluid (particularly blood and urinary) testing for biomarkers is easily accessible and useful in clinical patients. The prognostic significance of circulating DNA in plasma or serum, and its genetic alterations in HCC are other important trends. More attention should be paid to these two areas in future. As the progress of the human genome project advances, so does a clearer understanding of tumor biology, and mo re and more new prognostic markers with high sensitivity and specificity will be found and used in clinical assays. However, the combination of some items, i. e., the pathological features and some biomarkers mentioned above, seems to be mor e practical for now.

Qin LX, Tang ZY. The prognostic molecular markers in hepatocellular carcinoma. *World J Gastroenterol* 2002;8(3):385-392

INTRODUCTION

Liver cancer is one of the common malignancies worldwide, and has been ranked the 2nd cancer killer in China since the 1990s. Although many advances in the clin ical study of hepatocellular carcinoma (HCC) have been made, and long-term surv ival of patients has been obtained in some clinical centers, only a definitive s ubset of cases is cured by surgery, and the overall dismal outcome of patients w ith HCC has not been completely changed. Lack of control of metastatic foci and recurrence are the most prevalent causes of death in patients with HCC, and it is important for tumor control to identify the factors that predispose patients to death. Much effort has been made to predict HCC behavior, but specific prognos tic indicators are still lacking[1].

Prognostic factors in HCC conventionally consist of staging with the tumor node metastasis system (TNM) and grading by tumor cellular differentiation. There are also other factors useful in prognostic predication but most of them are clinic al. With new discoveries in cancer biology, pathological and biological factors of HCC in relation to prognosis have been studied quite extensively. Morphologic al features of the tumor, both gross and histological, have been found to signif icantly associate with tumor recurrence and patient survival[2-4]. A complementary way is to analyze molecular markers for their prognostic significance with reference to tumor recurrence and survival term in HCC. A large number of molecular biological factors have been shown to associate with the invasiveness of HCC, and have potential prognostic significance. However, routine biomarkers for the prediction of HCC prognosis are not yet available. In this review, we will focus on the recent advances in this aspect.

Cellular malignancy is a very important aspect for patient prognosis. In recent years, with the development of cellular and molecular biological techniques, many molecular markers related to invasion, metastasis, recurrence and survival hav e been explored. In HCC, DNA ploidy, the proliferating activity of tumor cells, tumor suppressor and promoter genes, cell cycle controllers, proteinases that d egrade extracellular matrix, adhesion molecules, angiogenic factors, and metabol ic genes, have been regarded as biomarkers for the malignant phenotype of HCC, and are related to prognosis and therapeutic outcomes[5].

CELLUAR MALIGNANCY-RELATED MARKERS

DNA-ploidy

Controversy still exists regarding the prognostic significance of DNA ploidy in HCC patients. Many reports indicate that DNA ploidy could be a predictive marker for HCC prognosis[6,7]. The overall survival rate of patients with aneuploid cells is much lower than that of patients with diploid ones, and those wit h multiple G0/G1 peaks have the

worst prognosis. Patients with higher cell proportions in proliferating stages have a higher early recurrence rate[7]. However, other studies could not find a relationship between DNA ploidy and prognosis.

Proliferating activity of HCC cells

Many antigens, such as proliferating cell nuclear antigen (PCNA), Ki-67, Mcm2, MIB1, MIA, and CSE1L/CAS protein (CAS), have been used as proliferation markers for cancer cells. The detection of PCNA with immunohistochemical methods is a co mmon way to study the proliferating activity of cancer cells[8]. Combine d with histopathological characteristics, the PCNA labeling index (PCNA-LI) is one useful marker for evaluating malignant grade, and for predicting recurrence time and the patients' prognosis of HCC[9].

The expression of the human Ki-67 protein is strictly associated with cell prol iferation. The fact that the Ki-67 protein is present during all active phases of the cell cycle, but is absent from resting cells, makes it an excellent marke r for determining the so-called growth fraction of a given cell population. Ki -67 protein expression is an absolute requirement for progression through the cell-division cycle. The fraction of Ki-67-positive tumor cells (the Ki-67 la beling index) is often correlated with the clinical course of the disease[10,11]. Higher Ki-67 labeling index (Ki-67-LI) has a very similar clinical significance to PCNA-LI, reflecting the existence of biologically aggressive ph enotypes and poor overall and disease-free survival rates in HCC. This could be a useful factor for predicting the long-term survival of patients with HCC fol lowing hepatic resection[12,13].

The CSE1L/CAS protein (CAS) is a Ran-binding protein with a function as a nuclear transport (export) factor. This protein plays a role in the mitotic spindle checkpoint, which assures genomic stability during cell division. This checkpoint is frequently disturbed in neoplasias of various origins, including hepatic tum ors. The degree of CAS expression correlates with the grade of tumor dedifferent iation, and could be a prognostic marker for HCC[14].

Nuclear morphology

Nuclear profiles have been reported as useful prognostic predictors in various c ancers, including HCC. The nuclear area of HCC correlates with cell differentiation and cell proliferating activity, and HCC with a large nuclear area has high potential for blood vessel invasion and intrahepatic metastasis. Computerized nu clear morphometry is more objective and quicker than conventional microscopic an alysis[15]. Recently, quantitative nuclear morphometry of cancer cells followed by computer-assisted image analysis (termed Quantitative nuclear grade, QNG) has proven to have potential use in cancer detection and predicting outcomes such as tumor stage, recurrence, and progression[16].

p53 gene and its related molecule MDM2

P53 protein plays a central role in cellular responses, including cell-cycle ar rest and cell death in response to DNA damage. p53 dysfunction can induce abnorm al cell growth, increased cell survival, genetic instability, and drug resistanc e. Mutations in the p53 gene are the most frequently reported somatic gene alter ation in human cancer. Associations of p53 mutation or positive immunohistochemi stry staining with higher grade and more advanced stage has been noted for cance rs of various origins. In addition, p53 mutation is considered as a strong marke r predicting an increased risk of local relapse, treatment failure, and overall and disease-free survival in many kinds of human carcinomas, such as breast[17-19], colorectal[20], esophageal[21], head and neck[22], lung[23,24], and ovarian[25], as well as sarcoma[26]. An increased intracellular concentration of the P53 protein, although no t identical to, is sometimes seen in tumors with p53 mutation, and has been corr elated with poor prognosis in some tumor types. Several studies have shown a rel ationship between the nuclear accumulation of p53 protein and poor disease-free and overall survival of cancer patients[27,28]. The presence of serum a nti-p53 antibody has also been shown to associate with survival of patients wit h breast, ovarian, and colorectal cancer[29,30]. p53 mutations in plasma DNA could also be detected in cancer patients, and may be used as a prognostic factor and an early marker to indicate recurrence or distant metastasis[31]. However, there is still a great controversy as to whether alteration of th e p53 gene adversely affects survival of cancer patients. Many reports failed to show the independent prognostic value of p53 in the carcinomas of tongue[32], breast[33,34], stomach[35], lung[36], ovarian[37], bladder[38], colorectal[39], and non-Hodgkin's lympho ma[40].

In a similar situation, there are many very controversial results with the progn ostic value of p53 overexpression or p53 gene mutation in HCC patients. Many stu dies showed that p53 mutation was involved in determining the dedifferentiation, the proliferating activity, and tumor progression[41], was strongly rel ated to the invasiveness of HCC, and may also influence the postoperative course (particularly the recurrence within 1 year)[42,43]. Mutations in the p53 gene or positive immunostaining for mutant P53 protein expression could be use d as a significant indicator of poor prognosis. HCCs with p53 mutations have a h igh malignant potential, and p53 mutation in the primary lesion is useful as an indicator for the biological behavior of recurrent HCCs. It is also a useful ind ependent prognostic factor affecting survival after recurrence[9,44,45].

In a recent prospective study, we found the 3-year and 5-year overall surviva l rates of HCC patients with positive P53 nuclear accumulation were much lower than those of the HCC patients with negative P53 expression. In univariate and mu ltivariate Cox analysis, p53 overexpression was the most significant factor that associated with the overall survival rates of HCC patients after resection. Its significance was even greater than that of factors such as tumor size, vascular invasion, and tumor capsule, though they were also related to the overall survi val. p53 mutation or nuclear accumulation of p53 expression could be a valuable marker for predicting the prognosis of HCC patients after resection[46].

Serum anti-p53 antibody also could be a useful prognostic factor for HCC patien ts[47]. However, many different results showed that neither the immunohi stochemical detection of p53 expression, nor the serum anti-p53 antibodies had a significant prognostic value for outcome of patients with HCC[48,49].

The transcription of the mdm2 gene is activated by p53 and this limits the growt h-suppressing activity of p53 by direct binding. It has been reported that MDM2 protein is overexpressed in several types of cancers. Endo found MDM2 overexpre ssion correlated positively with p53 mutation, and is a useful predictor of poor prognosis in patients with HCC following hepatic resection[50].

Cell cycle regulators

Disruption of the G1/S and G2/M check points leads to uncontrolled cell growth, resulting in the development and progression of cancers. Overexpression of cycli n A, cyclin D, and cyclin E have been found to correlate with the tumor relapse of human HCC, and are independent predictive markers for their recurrence and prognosis[51,52]. The enhanced expression of cyclin E correlates with hype rphosphorylation of pRb and a high frequency of Ki-67-positive cells. HCCs wit h enhanced cyclin E expression probably contain a relatively large number of pro liferating cancer cells[52]. cdc2 overexpression seems to play the most crucial role of the modulators in cell cycle progression and cell proliferation of HCC, and significantly predicts recurrence[53].

The p27 protein binds and inhibits cyclin/cyclin-dependent kinase complexes, is a negative regulator of cell-cycle progression. The central role of p27 makes it important in a variety of disease processes, particularly in neoplasia, that involve aberrations in cellular proliferation and other cell fates. Loss of p27 cooperates with mutations in several oncogenes and tumor suppressor genes to facilitate

tumor growth, indicating that p27 may be a "nodal point" for tumor suppression. In most tumor types, reduced p27 expression correlates with poor prog nosis, making p27 a novel and powerful prognostic marker[54]. High p27 e xpression, correlated with prolonged survival, is a favorable independent progno stic parameter for HCC[55,56].

The protein p73, the first identified homologue of p53 gene, has been shown to i nduce apoptosis. P73 expression status is significantly related to prognosis of HCC patients, and could serve as a useful indicator of prognosis in HCC patients [57]. There is still controversy with the prognostic value of the p16IN K4a and p15INK4B genes[58].

Tumor promoter genes and their receptors

Aberrations of many tumor promoter genes, such as ras, c-myc, c-fms have been indicated as indicators of malignant potential and poor prognosis i n HCC[9,59-61]. c-myc amplification and p53 alteration may be copa rticipating events in the progression of HCC. Disease-free survival in patients showing c-myc amplification is significantly shorter than in those without amplification.Hepatocyte growth factor/scatter factor (HGF/SF) is one of the most important hu moral mediators of liver regeneration. It is potentially related to molecular me chanisms of hepatocarcinogenesis via a paracrine system involving its cellular r eceptor, c-met. Up-regulation of c-met plays an important role in the development and progression of HCC, and may be a prognostic marker. Its express ion level is inversely correlated with survival coordinated with uPA expression [62,63]. However, there is no significant correlation between the HGF le vel in tumor and the survival rate of HCC patients[5].

Among of the erb-B receptor family members, c-erbB-2 (Her-2/neu) represents a well-established prognostic marker and therapeutic target in several human tu mor types, especially breast cancer. However, c-erbB-2 is neither a prognostic marker nor a relevant therapeutic target in human HCCs[9,64]. EGF-R and c-erbB-3 play important roles in the progression of HCC, affecting disease-free survival of HCC patients[5,65].

ets-1 has also been shown to link to cancer invasion and metastasis. ets-1 exp ression was observed with high incidence. However, the average labeling index (L I) in HCC is lower than in noncancerous lesions. Even lower expression levels we re found in HCCs of high TNM stage, poor differentiation, portal invasion, intra hepatic metastasis, large tumor size, and high Ki-67-LI. HCC patients with hig h ets-1 expression showed better outcomes for disease-free survival than those with low ets-1 expression[66].

Apoptosis related

The expression of Fas and Fas ligand (Fas L) play a role in apoptosis of cancer cells including HCCs, and associates with the prognosis of cancer patients. Fas expression level is significantly decreased in poorly differentiated HCC and of large size, while Fas L expression in carcinoma cells is observed exclusively in moderately or poorly differentiated cases. Each of them has prognostic signific ance for disease-free survival (DFS)[5,67,68].

Telomerase activity

The ribonucleoprotein telomerase extends telomeres in cancer cells and has been proposed as a prognostic marker for cancer. Telomerase activity can be identified as an independent predictor for recurrence after resection of HCC[69]. The peripheral blood telomerase activity can also be used as a molecular marker for the detection of circulating hepatoma cells in blood of HCC patients, which reflect haematogenous micrometastasis. This is potentially a practical diagnostic/predictive marker of HCC[70]. Quantitative analysis of telomerase act ivity shows that the patients with positive telomerase activity in noncancerous liver tissue have a higher recurrence rate after HCC resection. The relative tel omerase activity (RTA) of early recurrent patients is significantly higher than those without recurrence. So, RTA could be a predictive marker for early recurre nce after HCC resection[71].

CELL ADHESION AND EXTRACELLULAR MATRIX RELATED

Adhesion molecules

The expression level of E-cadherin inversely correlates with HCC histological g rade and prognosis. E-cadherin underexpression might have some contribution to the early recurrence of HCC[72,73]. In contrast, alpha-, beta-, and ga mma-catenin expression significantly correlated positively with HCC grade, bein g the highest in poorly differentiated HCC. Significant positive associations were found between gamma-catenin high expression and capsular invasion or presence of satellite nodules, and between beta-catenin high expression and vascular i nvasion. HCC patients with underexpression of E-cadherin, alpha-catenin, and gamma-catenin, and patients with overexpression of beta-catenin, had poorer sur vival rates[73]. HCCs with a nonnuclear type of beta-catenin overexpres sion were frequently larger than 5cm in diameter and had poorer cellular diff erentiation, more invasiveness, and the patients had significantly shorter disea se-free survival lengths[74,75]. beta-catenin mutation associat es with nuclear expression of the protein, and is a favorable prognostic factor related to low stage[76].

Serum concentration of intercellular adhesion molecule-1 (sICAM-1) in patients with HCC is a marker for disease progression and prognosis. Higher sICAM-1 lev els are more frequently observed in those patients with multiple lesions and int rahepatic metastasis, and their prognosis is also very poor. Detecting sICAM-1 is of important value in predicting tumor recurrence after surgery[77-79]. The CD44 proteins form a ubiquitously expressed family of cell surface adhesion molecules involved in cell-cell and cell-matrix interactions. The major physio logical role of CD44 is to maintain organ and tissue structure via cell-cell an d cell-matrix adhesion, but certain variant isoforms can also mediate lymphocyte activation and homing, and the presentation of chemical factors and hormones. The expression of multiple CD44 isoforms is greatly upregulated in neoplasia. CD 44, particularly its variants, may be useful as a diagnostic or prognostic marker of malignancy in at least some human cancers[80]. Up-regulation of CD 44 isoforms such as CD44s, CD44v5, CD44v6, CD44v7-8, and CD44v10, correlates with high histological grade, being the highest in poorly differentiated HCC. CD44 s positivity was an independent factor. Positivity for one or more CD44 isoforms was the most useful independent factor for overall survival[81].

Degradation of extracellular matrix

The matrix metalloproteinases (MMP) and the plasminogen activation system (PA) p lay crucial roles in the process of cancer invasion and metastasis. Their expres sion levels were found correlated to recurrence and survival after HCC resection[82,83].

MMP-2, MMP-9, and tissue inhibitors of metalloproteinases -1, -2 (TIMP-1, T IMP-2) have been found to be of prognostic significance in HCC. The content of MMP-2, MMP-9 in HCC being higher than that in surrounding liver parenchyma could be used as an important index to judge the invasion and metastasis of HCC [84,85]. Plasma MMP-9 levels can also be a candidate for a novel marker for HCC. The levels appear to reflect the potential and ongoing activity of vascula r invasion[5].

In several tumor types, elevated levels of urokinase plasminogen activator (uPA) , its receptor (uPAR) or its inhibitor plasminogen activator inhibitor-1 (PAI-1) is associated with a poorer prognosis[85]. uPA activity may be the mo st sensitive factor affecting HCC invasion in the plasminogen activation system and is a strong predictor for the recurrence and prognosis of HCC[86,87]. The PAI-1 proteinis a multifaceted proteolytic factor. It not only functions as an inhibitor of the protease uPA, but also plays an important role in signal

transduction, cell adherence, and cell migration. Thus,an apparent paradox cons idering its name-although it inhibits uPA during blood coagulation, it actually promotes invasion and metastasis. In many malignancies including HCC, elevated PAI-1 is associated with tumor aggressiveness and poor patient outcome[86].

ANGIOGENESIS RELATED

Tumor angiogenesis is critical to both the growth and metastasis of cancer, and is regulated by angiogenic factors. Circulating angiogenesis regulators have bee n evaluated not only as diagnostic and/or prognostic factors but also as predict ive factors in cancer patients. They could be used to determine the risk of deve loping cancer, to screen for early detection, to distinguish benign from malignant disease, and to distinguish between different types of malignancies. In estab lished malignances, they can be uses to determine prognosis, to predict the resp onse to therapy, and to monitor the clinical course[5,83,88]. HCC is typically a hypervascular tumor with a rich blood supply. In recent years, many angiogenesis-related markers, such as vascular endothelial growth factor (VEGF), b asic fibroblast growth factor (bFGF), platelet-deriwed endothelial cell growth factor (PD-ECGF), thrombospondin (TSP), angiogenin, pleiotrophin and endostatin (ES) levels, as well as inratumor microvessel density (MVD) have been evaluated and found to relate to HCC prognosis.

Intratumor microvessel density (MVD)

The intratumor MVD is a direct reflection of tumor angiogenesis. It can be visua lized by immunohistochemical staining with antibodies to anti-CD34, Factor VIII, and alpha smooth muscle actin[89]. MVD levels have a close relationshi p with the tumor capsule status, tumor size (HCC with 2-5cm in diameter has t he highest MVD level), intrahepatic recurrence and disease-free survival, and can be a predictive marker for disease-free survival[90]. In the authors ' institute, three types of intratumor microvessels, including capillary-like, sinusoid-like, and mixed-type, were found in HCC. The MVD level was not related to tumor size, capsule status, Edmondson's grade, or alpha-fetoprotein level; was an independent factor of disease-free survival in small HCC patients; and was a predictive marker for early recurrence[91].

Vascular endothelial growth factor (VEGF)

A substantial number of studies have demonstrated a strong association between elevated tumor expression of VEGF and advanced disease or poor prognosis in vario us cancers. Circulating VEGF seems to be a reliable surrogate marker of angiogen ic activity and tumor progression in cancer patients. It may be predictive of tumor status and prognosis in patients with different types of cancer, and may be useful in predicting and monitoring tumor response to anticancer therapies and i n follow-up!surveillance for tumor relapse. It may provide new prognostic infor mation that is not afforded by conventional clinicopathologic prognostic indicat ors[92]. In HCC, a high serum VEGF level significantly correlates with a bsence of tumor capsule, presence of intrahepatic metastasis, presence of micros copic venous invasion, and advanced stage, and it may be useful as a biologic ma rker of tumor invasiveness and a prognostic factor in HCC[93]. The data of the authors' institute also shows serum VEGF is a predictor of invasion and m etastasis of HCC and a potential biomarker of metastatic recurrence after curati ve resection[94,95].

Platelet-derived endothelial cell growth factor (PD-ECGF)

PD-ECGF may not be a major regulator of angiogenesis of HCC, but may play an im portant role in hepatocarcinogenesis, cooperating with hepatitis C virus. PD-EC GF expression associates with the venous invasion of HCC[96].

GENOMICS AND PROTEOMICS RELATED

Molecular genetic analyses have clarified that accumulation of genomic changes p rovides important steps in carcinogenesis and have identified a number of valuab le genetic markers for certain cancers. The association of these genomic aberrat ions with the progression and prognosis of cancer has drawn more and more attent ion. To date, allelic loss of 1p, 1q21-23, 2p21-16.3, 3p24-p25, 8p22, 8p23, 9 p21, 9q, 10, 13q12, 17p13.3, and 22q13 have been proposed to be related to the s urvival and prognosis of cancer patients[97-101].

Many chromosomal aberrations, including gain of 1q, 8q, and 20q, and loss of 16q , 4q, 17p, 1p, and 8p have been identified in HCC[102]. However, the rel ationship between these recurrent alterations and the clinical phenotypes and pr ognosis is still unknown. Towards the end of 1999, we compared the differences of chromosomal aberrations between the primary HCC tumors and their matched metas tatic lesions using a comparative genomic hybridization (CGH) technique, and fou nd chromosome 8p deletions might contribute to HCC metastasis[103]. This result was further confirmed by comparison between nude mice models of HCC with different metastatic potentials[104]. In addition, a more accurate loca tion was identified on 8p23.3, 8p11.2[105]. These findings provide new targets for exploring new predictive markers for the recurrence and prognosis of HCC. Recently, Itano *et al*. used restriction landmark genomic scanning (RLGS), a new high-speed screening method for multiple genomic changes, to detect un known genetic alterations in HCC. They found the disease-free survival r ate for patients with > or =16 changed RLGS spots was significantly lower than that for patients with fewer changed RLGS spots (<or =15 spots). In multivariate analysis, the number of changed spots was proven to retain an independent progno stic value. These results suggest that the number of changed RLGS spots may be a useful biological marker for recurrence of HCC[106].

One important trend in this area that should be paid attention to is the prognos tic value of circulating DNA in plasma or serum, and its genetic alterations in cancer patients. Small amounts of DNA circulate in both healthy and diseased hum an plasma/serum, and increased concentrations of DNA are present in the plasma of cancer patients. Characteristics of tumor DNA have been found in genetic mater ial extracted from the plasma of cancer patients. These features include decreas ed strand stability, the presence of specific oncogene or tumor suppressor gene mutations, microsatellite alterations, Ig rearrangements and hypermethylation of several genes. The results obtained in many different cancers have opened a new research area indicating that plasma DNA might eventually be a suitable target for the development of noninvasive diagnostic, prognostic and follow-up tests for cancer[107]. Blood testing for circulating tumor genetic markers may provide valuable prognostic information and guide future therapy[108].

However, there is still controversy over the prognostic significance [109]. We found loss of heterozygosity (LOH) on chromosome 14q (D14S62 and D14S51) could be detected in plasma DNA, and could be of prognostic significance in HCC patients[1].

Proteomics, regarded as a sister technology to genomics, is one of the technologies rapidly changing our approach to understanding tumor biology. By com paring the proteins present in diseased samples with those present in normal sam ples, it is possible to identify changes in expression of proteins that potentia lly may be related to tumor progression, invasion and metastasis, and prognosis. This technique has now made it possible to analyze proteins using high th roughput, automated techniques.Proteomic profiling can be applied to tissue sam ples as well as body fluids (e.g.serum,urine,etc.),and it can provide surrogate markers of disease processes,potential response to treatment, possibility of recu rrence and metastasis for cancers including HCC[110].

OTHERS

In addition, higher levels of urinary TGF-beta 1[111], heat shock prote in-27 (HSP-27)[112] and Glutamine synthetase (GS) expression

in the tu mor[113], increased levels of cyclooxygenase-2 (COX-2) in nontumor liv er tissue[114], preoperative serum IL-10[115], and HFE mutation s[116] or down-regulation of DRH1[117] are also powerful progno stic indicators for shorter disease-free survival and poor prognosis, related t o tumor progression of HCC.

The RECK (reversion-inducing-cysteine-rich protein with Kazal motifs) gene suppresses the invasive and metastatic activities of cancers, has negative effects on the invasiveness of HCC, and can be regarded as a promising prognostic molec ular marker for HCC[118].

EXPERIENCES OF THE AUTHORS' INSTITUTE

At the authors' institute, many molecular factors have been investigated and fou nd to be related to HCC invasiveness in recent years. They could be divided into two groups: one is positive invasiveness-related factors, including p16 and p53 mutations, H-ras, c-erbB2, mdm2, TGF-a, epidermal growth factor receptor (E GFR), MMP-2, uPA, uPA-R and PAI-1, ICAM-1, VEGF, PD-ECGF, bFGF, and osteopo ntin (OPN), etc. The other group is negative invasiveness-related factors, incl uding nm23-H1, Kai-1, TIMP-2, integrin a5, E-cadherin, etc. These factors co uld be potential predictive markers for the prognosis of HCC. Serum ICAM-1 and PAI-1 levels were higher in patients with metastasis than those without metast asis, while serum Thrombomodulin concentration negatively associated with the in trahepatic spreading and portal vein thrombi of HCC. Deletions of chromosome 8p and 17p, overexpression of MMP-2, TGF-a, and EGFR in HCC tissues, and LOH on c hromosome 14q (D14S62 and D14S51) in plasma DNA were also related to metastatic recurrence and prognosis of HCC patients. p53 mutation or nuclear accumulation of p53 expression could be a valuable marker for predicting the prognosis of HCC patients after resection. E-cadherin, nm23, TIMP-2 are promising prognostic ma rkers[1, 43,46,77,84,86,91,94-96,104-106].

To search for metastasis-associated genes on a global genomic scale, we recently used cDNA microarrays containing approximately 9984 human transcripts to inves tigate the gene expression profiles of primary tumors and their corresponding metastatic lesions (intrahepatic metastasis or tumor thrombosis of portal vein). A total of 79 significantly upregulated and 69 downregulated genes were identified. Some of them have proven to promote HCC metastasis[119]. These will p rovide new prognostic markers for predicting the possibillity of metastatic recu rrence and survival after operation.

QUESTIONS AND PROSPECTS

In summary, pathologic factors indicative of tumor invasiveness such as tumor size, number, capsule state, venous invasion, presence of satellite nodules, and advanced pTNM stage, are the best-established risk factors for recurrence and im portant aspects affecting the prognosis of patients with HCC. Recent molecular r esearch has identified many tumor biological factors as potential prognostic mar kers (biomarkers). However, to date, none of them has been proved to be specific enough, and most of the studies for specific molecular parameters were correlat ive and retrospective. Methodologies, sample sizes, and definitions differ. Cons ideration should be given to the design of prospective clinical trials in evalua ting the prognostic significance of these markers.

These biomarkers could be detected both in tissue and body fluids (serum, urine, bile, etc.). Body fluid (particularly blood and urinary) testing is easily acce ssible and useful in clinical patients, and is more important in "predicting" the possibility or "early diagnosis" of recurrence and metastasis. So, future work should be focused on serum or urinary markers.

The prognostic significance of circulating DNA in plasma or sesum, and its genet ic alterations in HCC, are important trends that deserve attention. Proteomics and cDNA array provide other ways to explore new prognostic markers. So, we can b elieve, with the continuing progress of human genome project, the development of new molecular and cytogenetic techniques, and a more complete understanding of tumor biology, more and more new prognostic markers with high sensitivity and specificity will soon be found and used in clinical assays. However, the combination of some items, i.e., pathological features and some biomarkers mention ed above, seems to be more practical now.

Abstract

Primary and secondary malignant liver cancers are some of most common malignant tumors in the world. Chemotherapy and radiotherapy are not very effective against them. Surgical resection has been considered the only potentially curtive option, but the majority of patients are not candidates for resection because of tumor size, location near major intrahepatic blood vessels and bile ducts, precluding a margin-negative resection, cirrhotic, hepatitis virus infection or multifocal. Radiofrequence ablation (RFA), which is a new evolving effective and minimally invasive technique, can produce coagulative necrosis of malignant tumors. RFA should be used percutaneously, laparscopically, or during the open laparotomy under the guidance of ultrasound, CT scan and MRI. RFA has lots of advantages superior to other local therapies including lower complications, reduced costs and hospital stays, and the possibility of repeated treatment. In general, RFA is a safe, effective treatment for unresectable malignant liver tumors less than 7. 0 cm in diameter. We review the principle, mechanism, procedures and experience with RFA for treating malignant liver tumors.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common solid cancers in the world, with an annual incidence estimated to be at least one million new patients[1].The mortality was secdonary to lung cancer in urban and gastric carcinoma in countryside in China[2,3]. Furthermore, the liver is second only t o lymph nodes as a common site of metastasis from other solid cancers, especially abdominal cancer[4]. It is not uncommon, particularly in patients with colorectal adenocarcinoma, for the liver to be the only site of metastatic dise ase[5]. Patients with liver metastases from colorectal carcinoma or other cancers seldom survive more than 1 year if untreated[6,7]. Surgical resection of HCC, hepatic metastases of colorectal cancer, and patients with liver- only metastases from other types of primary tumors can result in significant long-term survival benefit in at least 20-40% of patients[8-12]. Besid es these, surgical palliation through tumor cytoreduction in patients with sympt omatic neuroendocrine tumor (carcinoid, functioning islet cell) with liver metastases can ameliorate the symptoms related to excess hormone production and release.

Surgical resection has been considered the only potential curtive option, but on ly 5-20% of newly diagnosed HCC or colorectal cancer liver metastasis pati ents undergo a potentially curative resection[13, 14]. Patients with dis ease confined to the liver may not be candidates for resection because of multif ocal disease, proximity of tumor to key vascular or biliary structures that prec ludes a margin-negative resection, potentially unfavorable biology with the pre sence of multiple liver metastases, or inadequate functional hepatic reserve rel ated to coexistent cirrhosis. Thus, for so few patients with primary or metastat ic hepatic malignancies confined to the liver who are not candidates for surgica l resection, Surgeons and oncologists have turned to explore novel treatment app roaches to control and potentially cure the liver disease. Systemic chemotherapy for HCC and liver matestases results in less than 25% of patients; Complete r esponses are rare and significant improvements in survival are not sure. Althoug h hepatic artery infusion of chemotherapeutic agents for unresectable disease ha s led to 40% to 55% response rates in the liver, a survival advantage has b een difficult to demonstrate[15-18].

Localized treatment was used to HCC and colorectal cancer liver metastasis and b ased on the principle that decreasing the volume of viable tumor or preventing new growth can lead to longer survival and potential cure in selected patients, provided that diffuse micrometastatic disease is not present. These ablative tech niques include percutaneous ethanol injection[19-21], focused ultrasou nd[22-24], cryoablation[25-28], hyperthermia (ie, microwave tu mor coagulation[29-31]), laser photocoagulation[32-34], and ra diofrequency ablation[35-37] (RFA). Thermal energy produces destruction of tumor cells. When tumor cells are heated above 45-50℃, intracellular pro teins are denatured and cell membranes are destroyed through dissolution and mel ting of lipid bilayers[38-40]. RFA is a newly developed localized therm al treatment technique which was very useful in HCC and liver metastasis.

THE BACKGROUND AND MECHANISM OF RFA

The early usage of heat to treat tumors was back to early Egyptian and Greek whe n they used heat to cautize ulcer and superficial neoplasm. The first experiment in RF ablation of living tissues is credited to d'Arsonval, who demonstrated th at an alternating electric current greater than 10kHz could pass through livin g tissue without causing neuromuscular excitation. Beer and Clark used RF coagul ation in human cancers in early 20th century[41]. Coley suggested that that tumors were more sensitive to the effects of hyperthermia than normal cells and that tumors could not dissipate heat by augmenting blood flow as could adjacent normal tissues. RF techniques have gained acceptance as standard method for making well-controlled thermal lesions in the fields of neurology and cardiology since then[42-44]. It has been used in a variety of neurosurgical procedures aimed at ablating foci of spontaneous neuronal activity, in endoscopic techniques employed in gastroenterology, and in the ablation of aberrant conduct ion pathways in the heart for the treatment of dysrhythmias. Until the early 1990s, it is the technological modification of RF machine has made in to be used in focal thermal injuries deeper inside the body. More recently, Rossi and McGahan separately pioneered the application of RFA to primary and metastatic lesions i n the liver[45,46].

The so-called RF thermal ablation works by converting RF waves into heat. A hig h-frequency alternating current (100 to 500kHz), mostly 460kHz, passes from an uninsulated electrode tip into the

surrounding tissues and causes ionic vibr ation as the ions attempt to follow the change in the direction of the rapidly a lternating current. This ionic vibration causes frictional heating of the tissues surrounding the electrode, rather than the heat being generated from the probe itself. The goal of RFA is to achieve local temperatures such that tissue destr uction occurs. In general, thermal damage to cells begins at 42℃, with exposu re times required for cell death at this temperature ranging from 3 to 50 hours depending on the nature of the tissue. As the temperature is increased, there is an exponential decrease in the exposure time needed for cellular destruction. A t temperatures above 60℃, intracellular proteins including collagen denature, the lipid bilayer melts and cell death becomes inevitable. Thermal coagulation begins at 70℃ and tissue desiccation at 100℃, producing coagulation necros is of tumor tissue and surrounding hepatic parenchyma[46-50]. Tissue he ating also drives extracellular and intracellular water out of the tissue and re sults in further destruction of the tissue due to coagulative necrosis. Besides these, different studies have shown that hyperthermia can cause accelerated emig ration and migration of peripheral blood mononuclear cells, activation of effect or cells, induction and secretion of cytokines, expression of heat shock protein s, and increased induction of apoptosis[51,52].

RFA EQUIPMENT

Three primary RF devices, which worked on the same pricinples, are available in the world. The differences among the devices are the variations in probes and ge nerator designs.

The device made by RITA Medical Systems constites of a 50W alternating electric current generator and a 15-gauge needle electode. The needle electode has a mov able hub and 8 retracting curved electodes from the tip of the needle. Each tips of the needle contain a thermocuple that can register the temperature of the he ated tissues.

The device made by Radionics consists of a straight-tip internally cooled needl e electrode. The tip of the needle is cooled by perfusing its inner chamber with chilled saline which can prevent scorhing of the adjacent tissues and to increa se the size of the thermal injure. The device can be operated with not only a single electode but also with 3 electodes which placed in a triangular configuration. The device made by Radiotherapeutic is similar to the RITA device, consisted a n eedle with a movable hub that can deploy 10 curved needle tips. The multiple pro ngs are reported to produce a more uniform spherical injury than the devices wit h fewer prongs. But, this device does not have the temperature surveillance in the tips of the needles.

RFA PROBE

The first RFA probes were single, monopolar needles in the world. Because the RF energy delivered via the monopolar electrode decreases in proportion to the squ are of the distance from the electrode, coagulative necrosis was restricted to a maximum diameter of 1.6cm in which temperatures reached 80℃. Besides this, the surface temperature of the proximal and distal ends of the probe was higher than that in other parts. Thus, using a monopolar electrode results in an ellipsoid, ra ther than spherical, zone of necrosis, making evaluation difficult since most tu mors are spherical in shape. High temperatures at the surface of the electrode c ause a further limitation in size. Once the adjacent tissue reaches a high tempe rature and desiccates, the resulting tissue coagulum markedly reduces the propag ation of RF current and heat through the tissue, yielding a smaller zone of coag ulative necrosis[52].

One method to increase the zone of ablation is to use standard 0.9% saline or hypertonic 5% saline through the needle electrode during RFA. The infused saline solution acts as a liquid electrode to increase the area of RF current conduc tion around the needle tip[53]. Miao used 5% saline infusion into swin e liver before and during RFA. Both the electrode tip temperature and tissue imp edance decreased and coagulation diameter increased from less than 1.0cm to gr eater than 5.0cm[54].

Another technique to improve the volume of ablation involves the use of chilled perfusate into the lumen of electrodes. Lorentzen infused cool (room temperature) water into a specially designed electrode and noted a significant increase in delivered energy and ablation size in the *ex vivo* calf liver[55]. Goldb erg noted that both energy deposition and coagulation necrosis were significantl y greater with electrode cooling. This was also the case with *ex vivo* and *in vivo* muscle models. Studies in animals have also suggested that the combination of internally cooled electrodes and interstitial hypertonic saline infusion may result in a larger area of ablation than either technique alone[51, 56].

We can also use a second electrode within a few centimeters of the active electr ode to increase the diameter of necrosis. In ex vivo experiments, this bipolar arrangement demonstrated that heat was generated not only at the active electrode , but also adjacent to the ground electrode and between the two electrodes. The resulting focus (5cm) was therefore larger than that produced by traditionals ingle monopolar probes. The necrosis area produced by bipolar electrodes is stil l elliptical rather than spheroid, however, again making evaluation of its effec tiveness difficult[45,57].

Multiple active single probes can be clustered in an attempt to increase the coa gulation volume as well. Goldberg *et al*[60] investigated the effects of RFA via three electrodes placed 0.5cm apart from each other. This resulted in significant increases in the diameter of coagulation necrosis (2.9 to 7.0cm and 1.8 to 3.1cm, respectively) versus standard monopolar techniques. The use of c lustered electrodes requires multiple passes and positioning and it is often lab orious and difficult to ensure proper configuration. Although at times still used, this method has largely been supplanted by the development of multiprobe array electrodes[58].

The most promising and currently the most widely used technique for RFA is the m ultiprobe array system. This system can be placed into the target tissue with the array retracted. Using ultrasound guidance, the array is then deployed and che cked for proper positioning of all needles. These deployed multiple array needle s create a series of electrodes with an overall diameter ranging up to 3.5 to 7 cm across which RFA current can be passed. Using this multiprobe needle with a standard RFA protocol, a 4-6cm tumor can be completely ablated with the array fully deployed. In general, for lesions less than 2.5cm in diameter, the nee dle electrode is placed parallel to the plane of the ultrasound probe. For larger tumors, either a larger multiprobe array or multiple deployments of the needle electrode are required. The treatment is planned such that the zones of necrosi s overlap, keeping in mind that the entire volume of the tumor plus a margin of uninvolved tissue needs to be ablated.

RFA TECHNIQUES AND PROCEDURES

RFA of liver tumors can be performed percutaneously, using laparoscopic guidance, or as part of an open surgical procedure. The choice of treatment approach is individualized in any given patient. RFA is performed primarily by the liver sur geon and radiologist. The percutaneous approach differs from the laparoscopic and open surgical techniques only by the degree of hepatic exposure.

Patients with one to three small (<3.0cm diameter) cancers located in the peri phery of the liver are considered for ultrasound-guided or CT-guided percutane ous RFA. Lesions located high in the dome of the liver near the diaphragm are no t always accessible by a percutaneous approach. Furthermore, local anesthesia or monitored sedation is required for most patients treated percutaneously because of pain associated with the heating of tissue near the liver capsule. Patients treated percutaneously are usually discharged within 24h of

their RFA. Sonogra phy is used to localize the lesion to be treated. A percutaneous approach has been used in patients with small, early-stage hepatocellular cancers with coexist ent cirrhosis, and in patients with a limited number of small metastases from ot her organ sites[59,60].

A laparoscopic approach offers the advantages of laparoscopic ultrasonography, w hich provides better resolution of the number and location of liver tumors, and a survey of the peritoneal cavity to exclude the presence of extrahepatic disease. Using laparoscopic ultrasound guidance, the RFA needle electrode is advanced percutaneously into the target tumors for treatment. The laparoscopic ultrasound permits more precise positioning of the RF needle multiple array near major blo od vessels. Laparoscopic approach was used for patients with no prior history of extensive abdominal operations, and one or two liver tumors <4.0cm in diamete r located centrally in the liver near major intrahepatic blood vessels[61,62].

The majority of patients underwent RFA of hepatic tumors during an open surgical procedure. This approach is preferred in patients with large tumors (>4.0-5.0 cm diameter), multiple tumors, if tumor locates next to a major intrahepatic blood vessel, or if a laparoscopic approach is impractical because of dense post -surgical adhesions. In contrast to percutaneous RFA treatments, it is possible to perform temporary occlusion of hepatic inflow during the intraoperative RFA procedure. Hepatic inflow occlusion facilitates RFA of large or hypervascular tu mors and tumors near blood vessels. The amount of blood flow to a tumor is known to be a critical determinant of temperature response to a given increment of heat. Because heat loss or cooling effect is principally dependent on blood circul ation in a given area, temperature response and blood flow are inversely related. By temporarily occluding hepatic inflow during RFA, the cooling effect of bloo d flow on perivascular tumor cells is minimized[63]. The inflow occlusio n increases the size of the zone of coagulative necrosis and enhances the likeli hood of complete tumor cell kill, even if the tumor abuts a major intrahepatic blood vessel[64].

The RFA needle can be placed under computed tomorgraphy (CT) or ultrasound guida nce (percutaneous RFA) or ultrasound guidance (percutaneous, laparoscopic, or op en RFA). Ultrasound can be used with all techniques of RFA, and offers several o ther advantages as well, including real-time capabilities, vascular visualizati on, availability, speed, and low cost. The probes are usually placed at the deep margin of the tumor and subsequently repositioned anteriorly at intervals appro priate to the size of the needle array. Once the needle is localized in the gene ral vicinity of the tumor, the needle tip is placed into the desired portion of the tumor using a freehand technique. The abalation is started with the power se tting at 25W, and the setting is automatically advanced to 50W over about 30 sec onds. As the temperature at the tips of the deployed prongs exceeds 95℃, the times start to calculate. The temperature should be keep between 95-110℃ at least 10min to get full destory[51,65].

IMAGING TECHNIQUES IN RFA

Accurate imaging is essential for successful in situ tumor ablation. Tumors that are not seen can not be targeted, and residual foci of untreated tumor will continue to grow. With respect to tumor detection, and despite remarkable progr ess in US, CT and MR imaging over the past several years, no currently available imaging technique is perfectly sensitive for the detection of liver tumors, which means that some lesions will undoubtedly be overlooked with all imaging techniques. Generally, these overlooked lesions are small and will grow to a size that allows them to be detected, targeted and treated. Because currently available imaging techniques also may not precisely depict tumor margins, however, small foci of untreated tumor may not be identified. These will continue to grow in size and result in "local recurrence" after treatments that initially appeared to be successful. Improved imaging techniques should result in not only improved detection of additional lesions but also more accurate determination of tumor margins. Recent and ongoing developments in contrast agents for US and MR imaging coupled with technical innovations in US, CT, and MR imaging may provide the much needed improvements. Additional research will be needed to determine their effect on the efficacy of in situ tumor ablation with RF.

In situ tumor ablation is virtually always performed with imaging guidance. Currently, US is most commonly used for guidance in probe placement, owing to its flexibility, widespread availability, relatively low cost, and real-time imaging capabilities. RF ablation can also be performed with CT or MR imaging guidance; however, until recently, the static nature of CT and the complexity of the MR imaging environment have limited their use. The recent development of CT fluoroscopic systems may result in a larger role for CT in the future. Similarly, the developments of open-architecture MR imaging systems and MR-compatible interventional equipment have resulted in increased interest in the use of this modality to help guide interventional procedures. Preliminary experience now suggests that MR imaging may be useful for in situ ablation procedures with RF[66-68].

Imaging is used not only to help detect potentially treatable tumors and guide p robe placement but also to monitor the effects of therapy. When procedures are performed with US guidance, hyperechogenicity is generally seen surrounding the probe tip during the application of RF energy. This has proved to be only marginally useful for monitoring the effects of therapy because the hyperechoic zones correspond only roughly to the regions of eventual tissue necrosis. Furthermore, these changes evolve rapidly over time and can disappear within minutes of ablation[69-71]. Acoustic shadowing from more superficial treated areas can also preclude visualization of deeper portions of the tumor if one is not careful to treat deeper areas first. The use of US contrast agents may improve the accuracy of US with respect to monitoring the acute effects of therapy[72,73]. Contrast-enhanced CT, which is probably the most widely used technique for the follow-up of treated lesions, is less useful for the immediate assessment of treatment results. CT is not particularly helpful for confirming successful treatment or identifying a small focus of untreated tumor. MR imaging appears to be more accurate than US or CT for monitoring the acute affects of[66-68].

Follow-up imaging is very useful to assess the result of RF and the recurrence of new tumors, although sometimes it is very difficult. CT and MRI were showed more effective than ultrasound for monitoring the RFA ablation in animal studies. If the follow up imaging is performed soon after the procedure, a peripheral hype remic halo surrounding an area of hypoattenuation devoid of parenchymal enhancem ent is usually seen with spiral CT or MRI. Occasionally a hyperdense central are a corresponding to the needle tract is also seen. The interpretation of the foll ow-up CT scans required radiologists experience to prevent both diagnosis and u nderdiagnosis of the residual or recurrent tumor. The ablation process cause a h yperemic response in the liver parenchyma surrounding the ablation. The hyperemic prevents an accurate assessment of the completeness of the ablation in the early post-ablation period. The hyperemia usually resolved within 1 month after the procedure. After this time, persistent or new peritumoral hyperemia is considered an indication of recurrent tumor. Recurrent hypovascular tumors are detected as an enlargement of ablation area, or a subtle double-density halo developing around the margins of the treated area. All areas suspicious for tumor recurrence should be assessed by percutaneous biopsy.

RFA OF PRIMARY LIVER TUMORS

Primary liver cancer is a highly vascular cancer. A vascular sink phenomnon may contribute to the extended ablation times. Most of the

early reports on the use of RFA for HCC came from Rossi *et al*[74] in Italy in 1995. They repo rted their results with percutaneous RFA in twenty-four patients (16 men and 8 women; age range, 53 to 79 years) with 36 hepatocellular carcinoma nodules of not more than 3.0cm in diameter underwent radiofrequency interstitial thermal ablat ion treatment with the intent to achieve a cure. In each patient, the thermal ne crosis volume achieved was about double the tumor volume. During the mean follow -up interval of 24.8 months, 13 of 24 patients had recurrences, 9 of whom under went further radiofrequency thermal ablation treatment. Radiofrequency thermal a blation was again repeated in two patients who showed a second recurrence.

Marone *et al*[75]. reported percutaneous RF results using cooling sal ine in the tube of 13 cirrhotic patients with 19 hepatocellular carcinoma in 199 8. None of the patients had portal thrombosis or extrahepatic spread. They used a radiofrequency generator (100W power) connected to an 18G perfusion electr ode needle with an exposed tip of 2-3cm. The circuit is closed through a disp ersive electrode positioned under the patient's thighs. A peristaltic pump infus es a chilled (2-5℃) saline solution to guarantee the continuous cooling of t he needle tip. The needle was placed into target lesions under US guidance. Comp lete necrosis as assessed at dynamic CT (no enhancement during the arteriographi c phase) was achieved in 16 of 19 nodules (84%). No side-effects occurred. Du ring the follow-up (median: 11 months) no death occurred and five patients had recurrent hepatocellular carcinoma appearing either as single nodule or as multi nodular liver involvement? In a large series from Curley *et al*[76], 149 discrete HCC tumor nodu les in 110 patients had been followed for a minimum of 12 months(median follow- up 19 months) after RF. Percutaneous, laparscopic or intraoperative RFA was performed in 76 (69%) and 34 (31%) patients, respectively. Median diameter of tu mors treated percutaneously (2.8cm) was smaller than lesions treated during la parotomy (4.6cm, $P<0.01$). Local tumor recurrence at the RFA site developed in four patients (3.6%); all four subsequently developed recurrent HCC in oth er areas of the liver. New liver tumors or extrahepatic metastases developed in 50 patients (45.5%), but 56 patients (50.9%) have no evidence of recurrence. There were no treatment-related deaths, but complications developed in 14 pati ents (12.7%) after RFA.

RFA OF COLORECTAL CANCER LIVER METASTASES

The liver is the most common site of distant metastasis from colorectal cancer. Colorectal cancer is the fourth most commonly diagnosed cancer and second leading cause of cancer death in the world. Nearly half of patients will develop liver metastases during the course of their disease, with 15-25% having liver meta stases at the time of primary diagnosis and another 20% of patients developing metachronous liver metastases[10,11]. About one-fourth of patients with liver metastases from colorectal cancer have no other sites of matestases and can be treated with regional therapies directed toward their liver tumors. But o nly a minority of the patients are candidates for surgical resection. RFA, one o f the regional therapies, may be offered to patients with unresectable liver metas tases.

Most of the early reports on the use of RFA for colorectal cancer liver metastases also came from Rossi *et al*[74] in Italy. In 1996, they reported their results with percutaneous RFA in 50 patients, in which 11 patients had 13 me tastases ranging from 1 to 9cm in diameter. Monopolar and bipolar needles were utilized and multiple probe insertions and treatment sessions were performed. There were no associated complications or deaths. Of the 11 patients with metasta ses, two underwent subsequent surgical resection, of which one had complete tumor necrosis by histopathologic examination. At a median follow-up of 22.6month s, 10 of 11 patients (90%) were alive, but two (18%) had a local recurrence and seven (64%) had persistent or distant disease. Only one patient (9%), th erefore, was alive without disease. These studies suggested that although RFA was effective in preventing local recurrence of metastases, it may not affect the progressive course of the cancer.

Solbiati *et al*[77] reported on 117 patients with 179 metastatic lesi ons undergoing RFA with a mean follow-up of 3 years (range, 6 to 52 months). Co mputed tomographic follow-up was performed every 4-6 months. Recurrent tumors were retreated when feasible. Estimated median survival was 36 months. Estimated 1, 2, and 3-year survival rates were 93%, 69%, and 46%, respectively. Su rvival was not significantly related to number of metastases treated. In 77 (66 %) of 117 patients, new metastases were observed at follow-up. Estimated medi an time until new metastases was 12 months. Percentages of patients with no new metastases after initial treatment at 1 and 2 years were 49% and 35%, respec tively. Time to new metastases was not significantly related to number of metast ases. Seventy (39%) of 179 lesions developed local recurrence after treatment. Of these, 54 were observed by 6 months and 67 by 1 year. This study suggests th at long-term local control can be achieved in a majority of patients, but that the development of new metastases limits improvement in overall survival.

Wood *et al*[78] reported 231 tumors in 84 patients treated with 91 RFA procedures. The majority of patients had metastatic lesions (213 lesions in 7 3 patients) and 51 of the 91 treatments consisted of RFA alone. The other 40 inc luded RFA combined with surgical resection, cryoablation, and hepatic artery inf usion of chemotherapy. Of the 91 RF treatments, 39 were ablated at laparotomy, 27 by laparoscopy and 25 percutaneously; tumors ranged in size from 0.3 to 9.0c m. There were seven major complications including three deaths, one (1%) of wh ich was directly related to the RFA procedure. Ten patients underwent a second R FA procedure (sequential ablations) and, in one case, a third RFA procedure for large (one patient), progressive (seven patients), and recurrent (three patients) lesions. At a median follow-up of 9 months (range, 1-27 months), 15 patients (18%) had developed a local recurrence. Of the remaining 69 patients, 34 were alive without disease, 14 were alive with disease, and 21 died of their disease ; new hepatic tumors or extrahepatic disease therefore had developed in 35 patie nts. The average hospital stay was 3.6 days overall.

RFA OF OTHER LIVER METASTASES

Most of the papers discussed so far consisted of both primary liver tumors and c olorectal cancer liver metastases. RFA for liver tumors has also been evaluated for specific tumor types.

Livraghi *et al*[79] reported on 24 patients with 64 metastatic breast lesions ranging in size from 1 to 6.6cm. The liver was the only site of disea se in 16 patients, while the other eight patients had stable metastatic disease elsewhere. The patients were treated with the percutaneous approach utilizing mo nopolar or clustered electrodes. Minor complications were noted in two patients and no deaths were reported. Complete necrosis was achieved in 59 (92%) of 64 lesions. Among the 59 lesions, complete necrosis required a single treatment ses sion in 58 lesions (92%) and two treatment sessions in one lesion (2%). In 1 4 (58%) of 24 patients, new metastases developed during follow-up. Ten (71%) of these 14 patients developed new liver metastases. Currently, 10 (63%) of 16 patients whose lesions were initially confined to the liver are free of disea se. One patient died of progressive brain metastases. Although a preliminary stu dy, these results do suggest that RFA for selected patients with metastatic brea st carcinoma confined to the liver can be as effective as RFA for colorectal and other metastatic tumors to the liver.

Neuroendocrine tumors metastatic to the liver often produce symptoms secondary t o hormone production. Although only a minority are curable by surgical technique s, significant symptomatic relief can be obtained by surgical procedures. For th ose patients who are not surgical candidates, RFA may provide a viable therapeut ic alternative. Siperstein *et al*[80] reported 18 patients with 115 n euroendocrine tumors were ablated with RFA. The mean lesion size was 3.2cm (ra nge, 1.3 to 10cm) and the average number of lesions ablated per patient was six (range, one to 14). There were two complications consisting of arterial fibril lation in one patient and an upper gastrointestinal bleed in another. Fifteen pa tients (83%) with 100 lesions were followed for a mean of 12.1 months (range, 3 to 35months). Local recurrence was detected in three patients (20%) and si x (6%) lesions and three patients died during follow-up. However, data regard ing potential symptom improvement were not reported.

FOLLOW UP OF RFA

Initial imaging serves as an indicator of complete treatment, and provides a bas is for subsequent studies. However, the resolution and accuracy of current imagi ng techniques preclude identification of residual microscopic foci of malignancy at the periphery of a treated lesion. Hence, these viable tumor foci, if present, will grow and result in "local recurrence".

Multiphasic helical CT and contrast-enhanced MR imaging play a central role in the long-term assessment of therapeutic response, allowing confident discrimina tion between ablated and residual viable tumor. CT and MR studies are obtained a t 3-4 months intervals and are combined with tumor marker (serum CEA, AFP, CA19 -9) levels to detect local or distant recurrences. In general, sampling error a nd the histopathologic findings of thermally ablated tissue are too variable to render fine needle aspiration or core biopsy reliable indicators of the presence or absence of residual disease. US has proved valuable for immediate assessment of ablative results during the RF session, still in patients under general anes thesia, allowing for an immediate refinement of the ablation, if needed. US is a lso valuable for long-term follow-up and detection or confirmation of recurren ces; in many patients contrast-guided retreatment has been performed in order to precisely direct RF energy on recurrence areas[81-83].

ADVANTAGE AND DISADVANTAGE OF RFA

RF thermal ablation has several advantages over other therapies for primary liver cancer and metastasis liver cancer. It can be used as a percutaneous procedure , under the guiding of ultrasound, CT scan and MRI, done in local anesthesia, in out-patient department. The complications and morbidity are lower than hepatic resection and cryosurgery. RFA can be retreated in the patients whose tumors re cur at the margin of treatment or have new tumors develop elsewhere in the liver . It has similar results as hepatic resection because it destroyed the tumors co mpletely as taking it out in liver surgery, which is superior to ethanol injecti on. RF requires less sessions than other ablation procedures such as ethanol inj ection.

Although RF has a lot of advantages in the treatment of primary and metastasis liver tumors, it still has a few disadvantages and complications. These complicat ions included symptomatic pleural effusion, fever, pain, subcutaneous hematoma, subcapsular liver hematoma, and ventricular fibrillation. The severe complication is treatment-related death. As with all methods related to tumors, the outcome of RF thermal abalation will be related to the skill of physician performing the procedure. Exact placement of the ablation needles require considerable skill and some degree of guesswork by the radiologist and surgeon, which may be the most experienced in interventional procedures. Recurrence at the treatment margin may result from an inability to adequately kill the tumor the hepatic parenchym a adjacent to the treated tumors. The abundant portal venous blood flow present in normal hepatic parenchyma act as a heat pump, which makes the creation of the rmal injury in normal liver more difficult than that it is in liver tumors. RF a lso caused skin burn in percutaneous procedures, hemorrhage, diaphragmatic necro sis, hepatic abscess, hepatic artery injuries, bile ducts injuries, renal failure, coagulopathy and liver failure, which were severe and eventually fatal.

CONCLUSION

Despite the considerable progress that has been made to date, a number of challe nges remain for the future. These include the development of techniques that can increase the volume of tissue destroyed at a single treatment session, the deve lopment of more suitable and accurate imaging tests, and a better understanding of how to integrate in situ ablation techniques into the overall care of patient s with different specific neoplasms.

Although long-term observations are still not available, RFA will definitely give the surgeon a helpful hand and offer the patients a better prognosis. But, RF A is unlikely to be curative for most patients, it can relieve the symptom of pa tients and improve the quality of live of patients. RFA has been shown to be safer and better tolerated compared to other ablative techniques, such as cryotherapy, laser ablation and microwave ablation, has been associated with fewer local recurrence. However, surgical resection remains the gold standard for treating m etastatic and primary liver tumors. RFA of unresectable liver tumors provides a relatively safe, highly effective method to achieve local disease control in some liver cancer patients who are not candidates for liver resection. RFA also shown some better respect in combination with surgical resection, hepatic artery catheter and regional chemotherapy. With the development of RFA equipments and techniques, the treatment of a large primary and secondary liver cancer and malignant tumors at other body sites will be feasible and effective. The most interesting feature of RFA is the minimal-invasiveness with zero mortality rate, signif icantly lower complications, reduced costs and hospital days compared to surgery and other local therapies. Furthermore, with combination of other procedures, RFA will improve the survival of patients with cancer.

Abstract

Cell cycle progression is regulated by interactions between cyclins and c yclin- dependent kinases (CDKs). p21^{WAF1} is one of the CIP/KIP family which inhib its CDKs activity. Increased expression of p21^{WAF1} may play an important role in the growth arrest induced in transformed cells. Although the stability of the p21^{WAF1} mRNA could be altered by different signals, cell differentiation and numerous influencing factors. However, recent studies suggest that two known mechanisms of epigenesis, i.e.gene inactivation by methylation in promoter region and changes to an inactive chromatin by histone deacetylation, seem to be the best candidate mechanisms for inactivation of p21^{WAF1}. To date, almost no coding region p21^{WAF1} mutations have been found in tumor cells, despi te extensive screening of hundreds of various tumors. Hypermethylation of the p2 1^{WAF1} promoter region may represent an alternative mechanism by which the p21$^{WAF1/CIP1}$ gene can be inactivated. The reduction of cellular DNMT prote in levels also induces a corresponding rapid increase in the cell cycle regulator p21^{WAF1} protein demonstrating a regulatory link between DNMT and p21 ^{WAF1} which is independent of methylation of DNA. Both histone hyperacetylation and hypoacetylation appear to be important in the carcinoma process, and induct ion of the p21^{WAF1} gene by histone hyperacetylation may be a mechanism by which dietary fiber prevents carcinogenesis. Here, we review the influence of hi stone acetylation and DNA methylation on p21^{WAF1} transcription, and affect ion of pathways or factors associated such as p53, E2A, Sp1 as well as sever al histone deacetylation inhibitors.

Fang JY, Lu YY. Effects of histone acetylation and DNA methylation on p21^{WAF1} regulation. *World J Gastroenterol* 2002;8(3):400-405

INTRODUCTION

Cell cycle progression is regulated by interactions between cyclins and CDKs[1,2]. Especially, the transition of G_1 to S phase is known to be regulate d by a family of negative cell cycle regulators, CDKIs. The latter includes two families, the CIP/KIP family and the INK4 family[3-6]. p21^{WAF1} is one of the CIP/KIP family[7,8]. Increased expression of p21^{WAF1} may play a crucial role in the growth arrest induced in transformed cells[9].

p21^{WAF1} was first cloned and characterized as an important effector that a cted to inhibit cyclin-dependent kinase activity in p53 mediated cell cycle arrest induced by DNA damage[10,11]. It has been shown that this is a G C-rich region in the human p21^{WAF1} promoter[12]. Although the sta bility of the p21^{WAF1} mRNA could be altered by different signals cell diff erentiation[13] and oxidative stress[14] as well as numerous inf luencing factors including decorin[15], Ras/Raf protein[16], TGF-β[17] and Tax of human T cell leukemia virus type 1(HTLV-1)[18,19]. However, two known mechanisms of epigenetic modification, gene inactivat ion by methylation in promoter region and changes to an inactive chromatin by hi stone deacetylation, seem to be the best candidate mechanisms for the inactivati on of CIP/KIP family[20]. In this review, we focused on the methylation, histone acetylation and some transcription factor, co-transcription factor ass ociated with acetylation.

DNA METHYLATION AND HISTONE ACETYLATION

The post-translational modifications include acetylation, phosphorylation, meth ylation, ubiquitination and ADP-ribosylation[21]. In mammals, methylati on of the 5' position of cytosine in the CpG dinucleotide sequence is the only n aturally occurring covalent modification of the genome. The enzyme DNA 5-cytosi ne methyltransferase (DNMT) catalyzes the transfer of a methyl group from S -adenosylmethionine to the 5 position of cytosines residing in the dinucleotide sequence CpG[22]. DNA methylation patterns correlate inversely with gene expression[23] and, therefore, DNA methylation has been suggested to be an epigenetic determinant of gene expression.

DNA methylation is believed to be an on-off switch in gene expression, CpG isla nds present in the promoter regions have been shown to be susceptible to hyperme thylation in many cancer cells[24]. CpG islands near promoters and 5' re gulatory region are usually unmethylated in normal somatic cells. In contrast, widespread methylation of CpG islands occurs in autosomal genes and leads to the silencing of the genes during oncogenic transformation.

DNA in eukaryotes is packaged with histone and non-histone proteins into chroma tin. In general, regions of chromatin that are hyperacetylated are transcription ally active, whereas regions that are hypoacetylated are silenced. Indeed, a glo bal increase in core histone acetylation does not necessarily induce widespread transcription[25]. Histone acetylation results in charge neutralization and separation of DNA from the histones allowing nucleosomal DNA to become more accessible to transcription factors. Histone acetylation is believed to stabiliz e local nucleosomal structure, thereby allowing transcription factors and the ba sal trancriptional machinery access to DNA. Hyperacetylation of histones has bee n shown to mark open chromatin and to be required for trancriptional activation[26].

Histone acetylation is a reversible process: histone acetyltransferases (HATs) t ransfer the acetyl moiety from acetyl coenzyme A to the lysine neutralizes the positive charge, and histone deacetylases (HDACs) remove the acetyl groups re-es tablishing the positive charge in the histones. At least six human HDAC enzymes exist, and for higher eukaryotes, HDAC1 was first purified using an affinity mat rix based on the deacetylase inhibitor trapoxin[27]. HDAC inhibitor incl ude trichostatin A(TSA)[28,29], trapoxin (TPX)[30], Butyrate[31,32], MS-27-275 (a synthetic benzamide derivative)[33] and Apicidin[9,34]. Due to the inhibitory effects of the compounds of

endogeno us genes that plays significant roles in G1-S progression of the cell cycle, HD AC inhibitors have been considered to be a novel class of cancer treatment agent [34].

Methylation is not genomically uniform, as unmethylated CpG are found preferenti cally in transcriptionally active chromatin. The highest density of nonmethylated CpG islands, which usually contain promoter or other regulatory DNA that is required for active transcription of a gene. CpG island chromatin is enriched in hyperacetylated histones and deficient in linker histones[35]. Recent stu dies have suggested a strong link between histone acetylation, chromatin remodel ing, and gene regulation[26,36,37]. The results from many papers establi shed a link between DNA methylation, histone acetylation and sequence-specific DNA binding activity. In general, CpG island chromatin was found to contain highly acetylated histone H3 and H4. Deacetylation of histone H3 and H4 by the HDACs presumably leads to the formation of a chromatin environment that inhibits tran scription[38]. Hypoacetylated, transcriptionally silenced regions are of ten methylated[39], Furthermore, methylated DNA is transcriptionally rep ressed, but only under conditions in which the methylated template is assembled into uncleosomal structures[40], methylation density defines the level o f histone acetylation[41]. There are the roles of MeCP2, MBD1, MBD2, and MBD3[35], NuRD (nucleosome-remodeling histone deacetylase)[42,43] and DMAP1[44], as well as DNMT1[44,45] in the linkage of methylation with acetylation.

METHYLATION AND TRANSCRIPTION EXPRESSION OF p21^{WAF1} GENE

Usually, one could propose the negative regulation of p21^{WAF1} on the bindi ng of DNMT1 with PCNA in normal cells[46], however the loss of p21^{WAF1} from PCNA complexes could cause abnormal gains of methylation during repair of DNA damage[47]. Moreover, the p21^{WAF1} gene transcription level is regulated by methylation, due to that p21^{WAF1} promoter contains high d ensity of potentially methylatable CpG dinucleotides clustered around the initia tion site of transcription (Figure 1).

Figure 1 There are more CpG island at the domain near by the t ranscription start site in the promoter of p21^{WAF1} gene.

Dr. Nass *et al*[48] transfected three antisense DNMT1 (pCMV TMH) into human breast cancer MDA231 cell line, and found that the reduced DNMT1 protein and up-regulation of p21^{WAF1} suggesting that DNMT protein levels were inv ersely correlated with the level of p21^{WAF1} in breast cancer cells.

To date, almost no coding region p21^{WAF1} mutations have been found in tumor cells, despite extensive screening of hundreds of various tumors[49-51]. Hypermethylation of the p21^{WAF1} promoter region may represent an alter native mechanism by which the p21$^{WAF1/CIP1}$ gene can be inactivated. DNMT and p21^{WAF1} compete for the same binding site on PCNA, an increase in DNMT expression might promote dissociation of p21^{WAF1} from PCNA, perhaps making p21^{WAF1} more susceptible to ubiquitination and proteasome degradation [52]. A decrease in DNMT expression would then be expected to have an opposi te effect on p21^{WAF1} stability[48]. 5-Azacytidine (5-Aza-C, a demethylating agent) mediated Sp1 expression also up-regulated activities p21^{WAF1}[53].

Rat-1 is a cell line containing wild-type p53[54]. Allan and co-w orkers found which p21^{WAF1} 5'UTR contains a putative CpG island which is m ethylated in Rat -1 cells that used frequently to assess transformation and for apoptosis studies, the lack of p21^{WAF1} expression appears to be the resul t of hypermethylation of the p21^{WAF1} promoter region, as p21^{WAF1} protein expression could be induced by growth of Rat-1 cells in the presence of 5 -aza-2-deoxycytidine(5-Aza-dC). Furthermore, sequencing analysis of bisulfi te-treated DNA demonstrated extensive methylation of cytosine residues in CpG d inucleotides in a CpG-rich island in the promoter region of the p21^{WAF1} gene[55]. A report showed that altered DNA methylation was present in RMS tumors and that the DNA methyltransferase expression is increased in both embryonal and alveolar subtypes of this cancer[56,57]. They think that hypermethylation of the p21^{WAF1} gene at the proximal STAT-binding site, xorrelates with decreased p21^{WAF1} expression. The p21^{WAF1} gene is su bjected to methylation regulation at the transcription level and is a target of aberrant methylation in RMS cells.

However, several studies indicated that the hypermethylation of p21^{WAF1} was not the main machineries of p21^{WAF1} expression regulation. Although Young *et al*[58] reported that cells arrested and p21^{WAF1} expressed by DNMT inhibition in normal human fibroblasts. Milutinovic demonstrated that i nhibition of DNMT resulted in the rapid induction of the known tumor suppressor and cell cycle regulator p21^{WAF1} by a mechanism that did not involve DNA m ethylation of the p21^{WAF1} promoter, in human non-small cell lung cancer c ell line, A549 cells[59]. The reduction of cellular DNMT protein levels also induced a corresponding rapid increase in the cell cycle regulator p21^{WAF1} protein demonstrating a regulatory link between DNMT and p21^{WAF1} which was independent of methylation of DNA[60]. Shin's result showed that the promoter of the p21^{WAF1} gene was not been methylated in gastric cancer cells. This confirmed that methylation was not the mechanism for inactivation of p21^{WAF1} in gastric cancer cells[20]. In adenomatoid polyps, alth ough DNMT1 expression coincided with the expression of other cell proliferation markers, many DNMT1-expressing cells also expressed p21^{WAF1}. The fidelity of DNMT1 expression was further undetermined in colorectal carcinomas, in which a striking heterogeneity in DNMT1 expression, with some carcinoma cells contain ing very high DNMT1 levels and others containing very low DNMT1. These results indicate that human colorectal carcinogenesis is accompanied by a progressive dys regulation of DNMT1 expression and suggest that abnormalities in DNMT1 expression may contribute to the abnormal CpG dinucleotide methylation which changes the characteristic of human colorectal carcinoma cell DNA[61].

HYPERACETYLATION, HDAC INHIBITORS AND OVEREXPRESSION OF p21^{WAF1} GENE

Histone deacetylation is a general mechanism for inactivation of the p21^{WAF1} in gastric cancer cell lines[20]. Both histone hyperacetylation and hypoacetylation appear to be important in the carcinoma process, and induction of the p21^{WAF1} gene by histone hyperacetylation may be a mechanism by which dietary fiber prevents carcinogenesis[31].

Regarding the correlation of histone acetylation and p21^{WAF1} gene

expression, that HDAC inhibitor TSA, trapoxin, butyrate and apicidin induce $p21^{WAF1}$ transcriptional activity involved in most studies.

TSA is originally reported to be a fungistatic antibiotic, and it appears to be a promising tool for analyzing the many functions of histone hyperacetylation in cell proliferation and differentiation. TSA can stimulate $p21^{WAF1}$ express ion in HT29 cells[32].

TPX is the microbially derived cyclotetrapeptide[62], Sambucetti found t hat it increased the level of chromatin acetylation associated with histone H3 in the trapoxin-responsive region of the $p21^{WAF1}$ promoter, and it activated $p21^{WAF1}$ transcription that led to elevated $p21^{WAF1}$ protein levels in three kinds of human tumor cells. Since the domain of the promoter that is ne cessary for TPX- mediated activation does not contain p53 binding sites, hence $p21^{WAF1}$ expression upregulation by TPX is independent of p53[30].

Sodium butyrate is a short chain fatty acid produced in the human colon by bacte rial fermentation of carbohydrates[32], causes hyperacetylation of histo ne through the inhibition of HDAC. Three years ago, Archer and his coworkers sho wed firstly the critical importance of $p21^{WAF1}$ in butyrate-mediated growth arrest was able to cause growth arrest in the human colon cancer cell line HT -29[31]. Siavoshian[32] suggested that butyrate and TSA stimula ted, the $p21^{WAF1}$ expression both at the mRNA and protein levels, whereas t hey induced histone H4 hyperacetylation. Butyate sensitivity requires Sp1-3 site in conjunction with the Sp1-5 site and Sp1-6[29]. Shin *et al* [20] indicated that the overexpression of $p21^{WAF1}$ gene occurred in human gastric cancer cell lines after butyrate treatment. Butyrate increased histo ne H4-acetylation in human melanoma cell lines A375 and S91 and up-regulated $p21^{WAF1}$ gene transcription level[63].

Apicidin is a fungal metabolite shown to exhibit antiparasitic activity by inhib ition of HDAC. Han *et al*[64] indicated that inhibition of HDAC activ ity by apicidin was closely associated with monorphological change and induction of $p21^{WAF1}$, although The protein levels of cyclin D1, CDK2, HDAC1 and p 53 were not affected by the addition of apicidin for 24 hrs, whereas the induc tion of $p21^{WAF1}$ by apicidin was reversible.

Suberoylanilide hydroxamic acid (SAHA) is a hydroxamic acid-based hybrid polar compound, and it is an inhibitor of HDAC[65,66]. SAHA causes an accumula tion of acrtylated histones H3 and H4 in total cellular chromatin by 2h, which is maintained throughout 24h of culture with increased $p21^{WAF1}$ expressi on, but no change in chromatin associated with the actin and p27 genes, and SAHA also induces up to a 9-fold increase in $p21^{WAF1}$ mRNA and protein in T24 bladder carcinoma cells. $p21^{WAF1}$ by SAHA is regulated, at least in par t, by the degree of acetylation of the gene-associated histones and that this i nduced increase in acetylation is gene selective[66]. These studies also suggest that $p21^{WAF1}$ is HDAC inhibitor and that the $p21^{WAF1}$ promoter is a useful model for study in hsitone acetylation regulated transcription.

In addition, MS-27-275 inhibits HDAC and causes hyperacetylation of histones, as well as induces the expression of $p21^{WAF1}$ various tumor cell lines[33].

The data above indicated that the induction of histone hyperacetylation by HDAC inhibitor is responsible for the antiproliferative activity through the crucial role of $p21^{WAF1}$ in the regulation of cell cycle.

PATHWAY OR FATORS ASSOCIATED TO ACETYLATION OF $p21^{WAF1}$

Several genes or transcriptional regulatory proteins including p300/CBP associate to $p21^{WAF1}$ gene regulation.

p53

The $p21^{WAF1}$ expression may be dependent[11,67] or independent of p53 regulation[68-70]. Also, the mechanisms of $p21^{WAF1}$ transcription regulation fall into two general categories: dependent or independent of the p53 gene[31]. The $p21^{WAF1}$ promoter contains five natural p53 binding sites, at positions 4001, 3764, 2311, 2276, and 1391, respectively (GenBank accession number U24170)[19].

p53 gene regulates the expression of $p21^{WAF1}$, and HDAC1,2,and 3 are al l capable of downregulating p53 function, i.e., interactions of p53 and HDAC2 likely result in p53 deacetylation, thereby reducing its transcription al activity[71]. Clark and co-workers found that loss of the G_1/S che ckpoint in HIV-1-infected cells may in part be due to Tat's ability to bind p53 and sequester its transactivation activity, as seen in both in vivo an d in vitro transcription assays[72].

$p21^{WAF1}$ overexpression has been seen to inhibit two critical checkpoints i n the cell cycle, G1 and G2, through both p53-dependent and -independent[74].

p300/CBP

Up to now, four families of nuclear proteins including p300/CBP and p300/CBP-as sociated cofactors contain an intrinsic HAT activity have been confirmed that po ssess HAT activity[74-78]. Accumulating evidences suggest that p300 and CBP are adaptors for various DNA-binding transcription factors[79]. Alt hough the precise mechanism by which p300/CBP stimulates transcription remains unclear, the discovery that p300/CBP and an associated factor P/CAF have histone acetylase activities suggests that these cofactors may regulate transcriptionth rough acetylation[80]. These activities have been proposed to modify the amino-terminal tails of the core histone ptoteins in a manner that may allow for some as yet uncharacterized modification of nucleosome structure.

p300 has been found to be required for induction of $p21^{WAF1}$ expression in keratinocyte differentiation[70]. Xiao and coworkers indicated the evide nces that p300 is required for TSA-induced, Sp1-mediated $p21^{WAF1}$ transcr iption: cotransfection of p300 elevated $p21^{WAF1}$ promoter activity, and thi s elevation was dependent on TSA-responsive GC-box; TSA-induced promoter acti vation was blocked by the introduction of p300 dominant-negative mutant into ce lls; Sp1- or Sp3- mediated activation was also suppressed by this p300 dominan t-negative mutant [28]. Owen *et al*[81] demonstrated the prog esterone regulated transcription of the $p21^{WAF1}$ gene through Sp1 and CBP/p300. A report[82] showed that $p21^{WAF1}$ stimulated trans-activatio n by p300/CBP, $p21^{WAF1}$ induction of p300 results from the activity of a di screte domain in the amino-terminal half of the protein which functioned to rep ress transcription. they proposed a model in which p300/CBP activity might switc hed between promoters following $p21^{WAF1}$ induced cell cycle arrest.

P/CAF and GCN5

Two human homologs of GCN5 have been cloned and shown to have HAT activity[83,84]. One homolog is human p300/CBP associated factor (hP/CAF), which is a transcriptional co-activator with intrinsic histone acetylase activity, which c ontributes to transcriptional activation by modifying chromatin and transcriptio nal factors[84,95]. The second family member is hGCN5[85,86].The ability of hGCN5 to acetylate nucleosomal histones is significantly re duced relative to its activity on free histones, where it predominantly modifies histone H3 at lysine 14.

The co-activator/adaptor protein GCN5 is a conserved histone acetyltransferase, which functions as the catalytic subunit in multiple yeast transcriptional regu latory complexes.

E2A

E2A gene encodes two alternatively spliced products, E12 and E47[87,88]. The $p21^{WAF1}$ promoter contains eight putative E-box consensus sequences, two of which lie between the TATA box and the transcription starting site, E2 and E1(as Figure 2). E1 binds E47 hetero- and homodimers and E2 has mush less aff inity for E47[89], and

it contains a conserved basic region responsible for DNA binding and a helix-loop-helix domain for dimerization[90].

TATA box E Boxes

CGCTGAGCTGCGC***CAGCTG***AGGTGTGAG***CAGCTG***CCGAAGTCAGT
E2 E1 |→+1

Figure 2 The nucleotide sequence of the p21^{WAF1} promoter from -149 through +1. There are the E1 and E2 binding sites.

E2A plays important roles not only in promoting cellular differentiation but als o in suppressing cells grown[89]. E2A binds to p21^{WAF1}, so the ove rexpression of p21^{WAF1} may be due to the effects of E2A transcriptional fa ctor[19]. Moreover, the overexpression of E2A proteins, such as E47 has been shown to induce p21^{WAF1} promoter activity independent of p53 bind ing sites[89].

Histone H4 but not histone H3 is acetylated from the endogenous p21^{WAF1} pr omoter in vivo, implying that CBP/p300, and not the SAGA complex is critical in complexing with E2A and upregulation of p21^{WAF1} in HTLV-1 infected cells[19].

The E3 box located 130 bp upstream from the TATA box also contributes to the act ivation of p21^{WAF1} expression, but the E4 to E8 boxes have no effect on p2 1^{WAF1} expression[89]. E2A is shown to be upregulated in HTLV-1 in fected T cells.

Sp1 binding

Sp family of proteins comprise ubiquitous and tissue-restricted transcription f actors that bind GC-rich DNA sequences and other related GT and GA motifs throu gh their zinc-finger domains[91].The ubiquitously expressed and closely related Sp1 and Sp3 factors have been found to regulate the promoters of severa l genes, including cell-cycle regulated genes, with Sp1 defined as a potent coo perative transcriptional activator and Sp3 as weak trans-activator or a repress or[91,92]. Sp1-binding sites appear to play a critical role in the main tenance of the methylation-free CpG island[93].Both Sp1 and Sp3 bind th e promoter of p21^{WAF1} gene[94].

The proximal p21^{WAF1} promoter contains a TATA box[81] and six Sp1 binding sites, also Sp1-1,-2,-3,-4,-5 and -6 near the TATA box[29]. p21^{WAF1} is Sp1 dependent promoters[95]. The region between -15 4 and transcription starting site contains Sp1-1,-2,-3,-4,-5,-6 binding si tes[20,81]. Sp1 is a sequence-specific transcription factor that recogn izes GGGGCGGGG and closely related sequences, often referred to as GC boxes. To Sp1, at last there are at least three homologous, transcription factors in the S p1 family: Sp2, Sp3 and Sp4[96]. Xiao also reported[28] TSA-ind uced promoter activation was blocked by the introduction of p300 dominant-negat ive mutant into cells. Their result from gel-shift assay[29] showed tha t physical and functional evidence which strongly indicated that both Sp1 and Sp 3 were responsible for TSA-induced transactivation for he murine p21^{WAF1} promoter in NIH3T3 cells. p21^{WAF1} gene is one of the natural target s of HDAC inhibitors. Sp1 is a sequence-specific transcription factor that reco gnizes GGGGCGGGG and closely related sequences, often being referred to as GC bo xes. To Sp1 at last there are at least three homologous, transcription factors i n the Sp family: Sp2, Sp3 and Sp4[96].

The GC-rich region in the six consecutive Sp1 binding sites of the p21^{WAF1} promoter was digested either with methylation-sensitive HpaII or with me thylation-insensitive MspI. The resulting DNA was subjected to a PCR react ion. Sp1 binding sites are the common elements that exist in the promoters of bo th genes[20]. Using transient reporter gene assays, Pagliuca et al[94] determined that Sp1 was a stroung activator of p21^{WAF1} promoter, whereas Sp3 functioned as a weak transactivator.

Signal transducers and activators of transcription (STAT)

STAT proteins recognize and bind to the palindromic sequence TTCNNGAA[95]. Such sequences have been identified in the p21^{WAF1} promoter region at nt -692,-2557 and -4232, and designated as sis-inducible element (SIE)-1, -2 and -3, respectively[97]. All three SIEs have been shown to bind STA T1. Chen *et al* indicated that hypermethylation of p21 gene at the proximal Sis-inducible element (SIE)-1, a STAT-responsive element located upstream of the p21^{WAF1} CpG 5-Aza-dC, demethylation at SIE-1 reactivated p21 ^{WAF1} expression[98]. STAT could up-regulate activation of cyclin-dep endent kinase inhibitor p21^{WAF1}[98,99].

In addition to its role in cell cycle regulation, p21^{WAF1} is also believed to inhibit DNA replication through its ability to bind proliferating cell nucle ar antigen (PCNA), which is required for both replicative DNA synthesis and DNA repair. However, p21^{WAF1} has no inhibitory effect on the DNA repair functi on of PCNA[100,101]. Thus, p21^{WAF1}may play a central role in preve nting the replication of mutations incurred after exposure of cells to DNA damage.

CONCLUSIONS

Histone acetylation is the major mechanism for regulation of the p21^{WAF1} gene in most cell lines (shown as Figure 3). Both histone hyperacetylation and hy poacetylation appear to be important in the carcinoma process. The influence of methylation on p21^{WAF1} gene expression is dependent on differentiation of cells and tissue. It is our anticipation that induction of the p21^{WAF1} gen e by histone hyperacetylation may become a mechanism of dietary prevention of carcinogenesis.

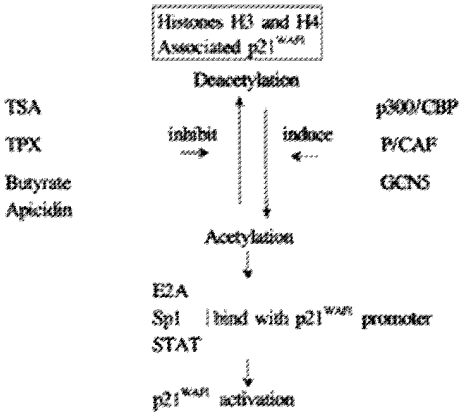

Figure 3 Butyrate,TSA,TPX and Apicidin inhibits HDAC enzyme ac tivity, and HAT from p300/CBP, P/CAF and GCN5 resulting in histone hyperacetylat ion of H3 or H4 associated p21^{WAF1} gene, and induces tran-scriptional activ ation of the p21^{WAF1} gene.

Abstract

Pancreatic microcirculatory disturbance plays an important role in the pathogenesis of acute pancreatitis, and it involves a series of changes includ ing vasoconstriction, ischaemia, increased vascular permeability, impairment of nutritive tissue perfusion, ischaemia/reperfusion, leukocyte adherence, hemorrhe ological changes and impaired lymphatic drainage. Ischaemia possibly acts as an initiating factor of pancreatic microcirculatory injury in acute pa ncreatitis, or as an aggravating/continuing mechanism. The end-artery feature o f the intralobular arterioles suggests that the pancreatic microcirculation is h ighly susceptible to ischaemia. Various vasoactive mediators, as bradykinin, pla telet activating factor, endothelin and nitric oxide participate in the developm ent of microcirculatory failure.

INTRODUCTION

Acute pancreatitis remains an important surgical problem with high morbidity and mortality[1-4]. It is not merely an injury caused by the activated pan creatic enzymes but also involves pancreatic ischaemia. Evidences in basic and clinical research suggest that disturbance of pancreatic microcirculation plays an important role in its pathophysiological processes[5-14]. The specific local microcirculatory changes cannot be prevented merely by adequate fluid therapy. In recent years, studies with modern molecular biological tools have elucidated that many factors are involved in the development of pancreatic microcirculatory disturbance. Whether the disturbance of pancreatic microcirculati on is an initiating factor or as a consequence of progressive pancreatitis is still debatable. The pathophysiological changes of pancreatic microcirculatory disturbance in acute pancreatitis are complex, they include local release of acina renzymes[15-25], vasoactive mediators[26-39], vasoconstriction, increase in vascular permeability, ischaemia[40-41], ischaemia/reper fusion, leukocyte adherence, intravascular coagulation, capillary stasis, etc., resulting in pancreatic oedema, hemoconcentration, and impaired capillary and ve nous drainage[42-44], consequently leading to hemorrhagic pancreatic ne crosis[45].

ROLES OF ISCHAEMIA IN PANCREATIC MICROCIRCULATORY DISTURBAN CE DURING ACUTE PANCREATITIS

Ischaemia as an initiating factor

There is a considerable evidence supporting ischaemia as an initiating factor of pancreatic microcirculatory injury in acute pancreatitis[46-48]. As long ago as 1862, Panum induced hemorrhagic pancreatitis by injection of wax droplets into pancreatic arteries. Later similar changes were noticed by intra-arter ial injection of 8-20μm microspheres, irreversibly obstructing terminal arte rioles and occluding the capillaries. While the use of larger particles only results in pancreatic oedema, because there are abundant arcade-like anastomoses between the pancreatic interlobular vessels. There is also evidence suggesting that microvascular injection of microspheres may progress to chronic active pancre atitis.

A clinical report revealed at autopsy that atheromatous thrombi embolized from the aorta into the pancreatic arteries were associated with acute pancreatitis in 10 of 12 cases. The incidence of pancreatitis in 182 patients died after cardiac surgery was 16%. There was also evidence for a high susceptibility of the pancreas to ischaemic injury in patients died of shock. A high incidence of acute pancreatitis shown after cardiopulmonary bypass operations seemed to be associated with intraoperative hypoperfusion in the splanchnic area.

By means of intravital microscopy in conjunction with technique of selected cells-labeling, direct impairments of pancreatic microcirculation in the early phase of acute pancreatitis have been observed in the experimental ischaemia induced by controlled haemorrhage or interruption of arterial blood supply to the pancreas [49], suggesting the pancreatic microcirculation being highly suscept ible to ischaemia. This is closely related to the microvasculature of pancreatic lobule; there is a single centrally-located intralobular artery as the exclusive vascular supply of each lobule, no anastomosis between the intralobular arter ies and their branches exists, indicating the cause of its high susceptibility to ischaemia[50,51].

Ischaemia as an aggravating and continuing mechanism

Temporary complete or partial ischaemia of pancreas would not cause hemorrhagic pancreatic necrosis, the slight histological and functional changes are completely reversible. However, temporary ischaemia has the potential of being transitio nal from edematous to necrotizing pancreatitis[52]. While temporary arte rial occlusion alone does not injure the pancreas following induction of edemato us pancreatitis by duct ligation[53] with hyperstimulation, arterial occ lusion for only 15 min can result in parenchymal necrosis, suggesting that isch aemia as an aggravating factor participates in the development of acute pancreat itis.

Impairment of microcirculatory perfusion of pancreas is the consequence of the effect of various local factors, such as vasoconstriction, free radicals, intravascular coagulation, release of vasoactive mediators taking part in the whole cou rse of acute pancreatitis (see below). Recently, ischaemia/reperfusion is consid ered one of the important causative factors for development of acute pancreatiti s after pancreatic transplantation. It has been repeatedly demonstrated that cha nge of pancreatic perfusion is an early event in experimental acute pancreatitis, and microcirculatory impairment in human pancreas also correlate well with the degree of ischaemic injury. These findings support the hypothesis that the micr ovasculature is the primary target of reperfusional injury after ischaemia.

CHANGES OF PANCREATIC MICROCIRCULATION IN ACUTE PANCREATITIS

Many indirect methods have been applied to assess the changes of panc reatic microcirculation during acute pancreatitis in previous studies[54]. Recently, intravital fluorescence microscopy combined with the technique of separate labeled-cells and computerized image analysis system has been successf ully used in the studies of pancreatic microcirculation in acute pancreatitis. Many important phenomena as vascular permeability change, vasoconstriction, capil lary blood flow, functional capillary density, leukocyte-endothelium int eraction, etc., have been continuously and directly observed during the course of acute pancreatitis. It is now believed that microcirculatory changes is import ant as well as early feature in the pathophysiology of acute pancreatitis[55].

Vasoconstriction

The first step in the sequence of microcirculatory events in pancreatitis is the constriction of interlobular vessels, especially in the proximal segments of the interlobular arterioles and venules[56,57]. The vasoconstriction occu rring in the early phase of acute pancreatitis may cause ischaemia and stasis of the microcirculation[58], which can be prevented by the radical scaveng ers, superoxide dismutase and N- (2-mercaptopropionyl)glycine in sodium tauroc holate-induced pancreatitis, suggesting that vasoconstriction might be induced by free radicals. There is also great support for the concept that solutions inj ected into the pancreatic duct to induce biliary pancreatitis exert their effect via the interstitial route. Even at a low injection pressure of 40 cmH_2O, ru pture of the ducto-acinar junction is detectable with subsequent fluid extravas ation in the interstitial space, where they gain access to the pancreatic microv asculature precipitating vascular spasm. It has been noticed that segmental cons triction of pancreatic arteries occured in bile-induced pancreatitis, and of me senteric arteries directly exposed to diluted bile. There is also pronounced dam age to the pancreatic vessels resulting in haemorrhage, endothelial detachment and thrombosis, as has been shown with the taurocholate, trypsin, and trypsin-di gested blood vessels. The vasotoxic effect of these substances was further subst antiated by the demonstration that interstitial injection into the omentum preci pitates similar changes at the injection site. The finding that stress and shock can convert oedematous to hemorrhagic experimental pancreatitis suggests that catecholamines mediators might participate in the process. Therefore, pancreatic vasoconstriction in acute pancreatitis might be relevant to a variety of factors.

Changes of permeability

The intravital microscopic findings of immediate leakage of the macromolecular plasma marker (FITC-Dextran 70) from the microvasculature into the interstitial tissue, and the scanning electron microscopic evidence of leakage of the cast ma terial through the capillary membrane in the early phase of acute experimental pancreatitis suggest that presence of increased permeability during the disease process. Further experiments demonstrate that permeability changes precede stasis and stasis precedes leukocyte adherence[59], suggesting that increased vascular permeability and ischaemia are the initial microcirculatory lesions in acute pancreatitis induced by sodium taurocholate leading to haemorrhagic necrosis. The non-specific detergent effect of sodium taurocholate and bile acids in general seems to be responsible for the initial changes due to the direct dissol ution of cellular membranes.

Changes of nutritive tissue perfusion

Acute pancreatitis is characterized by impairment of nutritive tissue perfusion as a consequence of gradually decreased capillary blood flow and functional capi llary density[60]. Reduction of capillary infusion volume and of functio nal capillary density has been observed with intravital microscopy and laser-Doppler flowmetry in the experiments of acute pancreatitis. In such experiments, capillaries are progressively excluded from perfusion starting 30min after the induction of pancreatitis, and with only few capillaries remaining perfused after 3h. At the same time, flow through the preferential pathways is maintained. Measurements of pancreatic blood flow during acute pancreatitis have ever yielded conflicting results. Some found no change or even increased blood flow, but most experiments have repeatedly demonstrated decreased total blood flow in acute pancreatitis. The perfusion values with an initial increase followed by a sharp decrease have been observed. Increased pancreatic blood flow is considered as a consequence of vasodilatation in acute inflammation. Because of the tremendousd istributional disturbances of the microcirculation in the pancreas, however, mea surements of total blood flow of the pancreatitis do not reflect proportionately the pathological status of different local regional perfusion within the pancre as. The pathological states, both the hyperemia and ischaemia, can be found at the same time in the different regions within the pancreas, thus emphasizing the importance of capillary blood flow measurement for accurate evaluation of microc irculatory blood flow changes. In most of the studies the degree of pancreatic h ypoperfusion was found to be disproportionately more severe than the decrease in cardiac output at comparable intervals. Moreover it has been shown that a decre ase in pancreatic perfusion cannot be prevented by adequate fluid therapy using Ringer's solution even though cardiovascular parameters are stabilized at the ba seline level, proposing a specific mechanism of local microcirculatory ischaemic impairment[61-63].

Impairment of ischaemia/reperfusion and leukocyte adherence

Ischaemia/reperfusion of the pancreas with impairment of the microcirculation has attracted attention both in experimental and clinical studies of acute pancrea titis[64-73]. Ischaemia/reperfusion leads to the adherence of leukocytes to the vascular endothelium. In parallel with reduction of functional capillary density, an increase of heterogeneity of capillary perfusion has been noted. Primary capillary perfusion failure after onset of reperfusion is a characteristi c microcirculatory feature of ischaemia and is called no-reflow phenomenon. Among various stimuli promoting leukocyte-endothelium interaction are ischaemi a/reperfusion and formation of oxygen free radicals leading to rolling and adher ence of leukocytes, the latter provoking the "reflow/paradox" phenomenon with loss of endothelial integrity and macromolecular leakage as an end result. Enhanced generation of oxygen radicals elicits ischaemia/reperfusion-induced leu kocyte infiltration in the tissue, which is instrumental in the progression of a cute pancreatitis. Degree of endothelial cell dysfunction and severity of leukocyte adherence is dependent upon the duration of ischaemia and reperfusion. Complete ischaemia/reperfusion of the pancreas induces extensive capillary stasis,i. e. pancreatic microcirculatory failure.

Effect of hemorrheological changes

Since blood viscosity is the inherent resistance of blood to flow, it is probable that the hemorrheological changes might be important to acute necrotizing panc ratitis[74-84]. 188 Wistar rats were studied by measuring hemorrheologi cal and stereological parameters of pancreatic microvasculature. The results sho wed that increased blood viscosity, causing red blood cell aggregation with roul eaux formation, and decreased erythrocyte deformability are responsible for panc reatic microcirculatory disturbances and play an important role in the transitio n of oedematous pancreatitis to necrosis.

It has been noticed that the time points in the course of

experimental acute pan creatitis are extremely variable. This can be explained as investigators with various pancreatitis models, different infused substance, concentration, volume as well as intraductal pressure, the latter may be more important than the others. The high intraductal injection pressure results in an increased leakage of bile and a more generalized distribution in the interstitial space, even immediateh emorrhagic pancreatic necrosis, thus emphasizing the pathophysiological signific ance of experimental models in acute pancreatitis. In the low-pressure ductal p erfusion model the etiological factor and the pathophysiological course are simi lar to those associated with the disease clinically.

VASOACTIVE MEDIATORS IN ACUTE PANCREATITIS

Bradykinin

Bradykinin probably exerts its influences upon microvessels via several pathways involving endothelial cells, including stimulating the formation and release of NO, arachidonic acid metabolites and tackykinins. Microcirculatory responses to bradykinin are biphasic: at low concentrations it causes vasodilatation, while at higher concentrations it causes vasoconstriction.

The role which bradykinin plays in microcirculatory impairment of acute pancreat itis is controversial. It was noticed that in sodium taurocholate-induced pancr eatitis, the number of perfused capillaries was increased and capillary flow pre served and the mean venular leukocyte adherence decreased and histopathological change improved in icatibant (a B2 receptor antagonist)-treated rats; kinase II inhibitor captopril or exogenous bradykinin in addition to an otherwise effective dosage of icatibant resulted in microcirculatory stasis, extensive venularleu kocyte adherence and severe histological damage, indicating that bradykinin may aggravate the microcirculatory disturbance[85,86]. But another study showed that B2 receptor antagonist increased the severity of acute pancreatitis, while lys-bradykinin substituting bradykinin didn't[87].

Platelet-activating factor(PAF)

PAF acts on microvasular diameter, permeability and leukocyte rolling, adhesion and migration through different mechanisms, including synthesis and release of NO and arachidonic acid metabolites, and upregulated expressions of ICAM-1 and CD11/CD18. Actions of PAF on microvasculature have the following features: constr iction response of venules to PAF is stronger than that of the arterioles; its a ction on arteriolar diameter is biphasic.

It was observed that treatment with PAF receptor antagonist improved pancreatic capillary blood flow, reduced the severity of pancreatitis-associated endothelial barrier compromise and pancreatic leukocyte recruitment, suggesting that PAF is proinflammatory in pancreatitis[88-92].

Endothelin(ET)

There are three kinds of endothelins, and endothelin-1 is predominantly expressed by vascular endothelial cells. There are three types of endothelin receptors, and ETA receptor is endothelin-1 selective, and found mainly on vascular smoot hmuscle cells, mediating vasoconstriction; ETB is nonselective and expressed by endothelial cells; it mediates vasodilatation through the release of NO and pro stacyclin. The action of endothelin-1 on microvessels is biphasic: at low conce ntration, it causes vasodilatation; at higher concentration, it causes sustained vasoconstriction.

Several experiments demonstrated that endothelin-1 was involved in the microcir culatory disturbance and in the development and progression of acute pancreatitis[93-99]. Administration of endothelin-1 after the caerulein injection decreased pancreatic blood flow significantly, aggravating microcirculatory dis turbance. Topically superfused endothelin-1 induced pancreatic microvascular de terioration and acinar cell injury similar to that induced by intraductal infusi on of sodium taurocholate in rats[100]. Studies also showed that ETA rec eptor antagonist is protective in microcirculatory disturbance of acute pancreat itis[101].

Nitric oxide (NO)

NO is formed from L-arginine by NO synthase(NOS). cNOS(constitutive form) catalyzes formation of NO of physiological level. Catalytic activity of iNOS(inducibl e form) is stronger and lasts longer than that of cNOS, and NO of higher than physiological level is produced by iNOS. NO dilates blood vessels, but at higher concentrations it is cytotoxic.

Pancreatic NO level in acute pancreatitis may be decreased[102] or signi ficantly elevated in different experiments. Intravenous administration of L-arginine to rats with hemorrhagic pancreatitis improved pancreatic blood flow and a meliorated the severity of pancreatitis in a dose-dependent manner, while nitro -L-arginine infusion to the rats with edematous pancreatitis caused a decrease in pancreatic blood flow and exacerbated pancreatitis, indicating that NO is pr otective[103-106]. However, some experiments showed that NO was not inv olved in the progression from edematous to hemorrhagic pancreatitis. Even microc irculatory changes were significantly alleviated in caerulein-induced pancreati tis pretreated with nitro-L-arginine, suggesting NO may be proinflammatory[107]; it was found that L-arginine improved the pancreatic microcirculation but worsened the microscopic alterations within the pancreas[108,109].

Adhesion molecules

Leukocyte-endothelial interaction is an important step in the development of ac ute pancreatitis. It was demonstrated by experiments that levels of ICAM-1, PEC AM-1 and ELAM-1 were upregulated, and expressions of P- and E-selectin enhanced, and leukocytes became CD18-positive in acute pancreatitis[110,111]. Immunoneutralization of adhesion molecules was proven effective in the treat ment of acute pancreatitis[112]. Administration of monoclonal antibody a gainst ICAM-1 to rats with acute severe pancreatitis significantly enhanced cap illary blood fow in the pancreas, reduced leukocyte rolling and stabilized capil lary permeability[113].

PATHOGENESIS OF MICROCIRCULATORY FAILURE IN ACUTE PANCREATITIS

The pancreatic microcirculation is impaired in acute pancreatitis[114-124]. Capillary stasis may be due to a variety of mechanisms including hemoconce ntation and intravascular coagulation, generation of oxygen free radicals in the microenviroment of the pancreatic ducto-acinar complex, increase in interstiti al pressure, increase in leukocyte-endothelium interaction[125], and local reduction of endothelial derived relaxation factor (nitrous oxide)[126]. An acinar abnormality may be the initiating factor arising from a combinat ion of ductal obstruction and exocrine hypersecretion followed by an increase in intraductal pressure and leakage of enzymes into the pancreatic interstitium with release of zymogen and lysozymes.

Hemoconcentration and intravascular coagulation play an additional role in the d evelopment of pancreatic ischaemia in acute pancreatitis. The increased capillary permeability is the initial feature of experimental biliary pancreatitis, resu lting in loss of fluid and cells into the pancreatic interstitium induced by osmolarity shifts either in the duct or extracellular fluid[127]. Local hem oconcentration takes place at the site of plasma sequestration, even if the syst emic hematocrit is maintained at the initial level. In conjunction with the impa irment of endothelium, intravascular coagulation occurs and causes a further dec rease of blood fluidity. These changes are

aggravated by a systemic hypercoagula rity in acute pancreatitis, probably due to thromboplastic material and activate d trypsin gaining access to the systemic circulation.

The mechanism of oxygen free radical is important in acute pancreatitis of any causes[128] and is a direct sequel of biliopancreatic reflux at the onset of acute biliary pancreatitis. Besides disintegration of cell membranes by lipid peroxidation, free radicals trigger the extravasation of granulocytes into the surrounding parenchyma representing an early lesion in acute experimental pancr eatitis. The initial margination of granulocytes in the capillaries may be a con tributing factor in endothelial injury and impairment of capillary perfusion. Ox ygen radicals mediate depletion of pancreatic sulphydryl compounds with changes in both lipid peroxide and oxygen radical scavengers. Serum concentrations of vi tamin C, a potent antioxidant, are depleted in acute pancreatitis so that synthe tic ascorbic acid derivatives have been used as a free radical scavenger.

Postischemic intensive adherence of leukocytes to the endothelium of the venules and adhesive leukocytes forming plaques partially occluding the lumen of the venules have been observed within the reperfusional period in the experimental acu te pancreatitis. This adhesive interaction is largely confined to postcapillary venules. And it is determined by a variety of factors such as expression of adhe sion molecules on leukocytes and/or endothelial cells, products of leukocyte (su peroxide) and endothelial cell (nitric oxide) activation and physical forces gen erated by the movement of blood along the vessel wall[129,130]. The fir m adhesion of leukocytes that take place within postcapillary venules may increases the postcapillary pressure more than 200 folds, cause the passive dilatation of the capillaries and microcirculatory stasis. Many studies show that some com pounds appear to be effective in reducing or abolishing leukocyte-endothelial cell adhesion, whereas some classical anti-inflammatory drugs such as indomethac in and aspirin actually promote leukocyte adhesion in the venules.

There may also be relation to lymphatic drainage[131]. Increase in local interstitial pressure as a consequence of obstructed lymph drainage further interferes with pancreatic microperfusion due to the venous outflow impairment. In the early period of acute experimental pancreatitis, dilated lymphatic vessels are visible macroscopically, and further progress of oedema with consequent focal hemorrhagic pancreatic necrosis is possible in case of insufficient lymphaticd rainage. Experiment demonstrates that an increase of thoracic duct lymph flow fo llowed by a pronounced and prolonged reduction. Erythrocytes originating from pa ncreatic interstitial hemorrhages were shown to enter and obstruct the microlymp hatics.

CONCLUSIONS

Recent advances in experimental research have helped witness the pathophysiology of acute pancreatitis. The phenomena of microcirculatory changes observed in ac ute experimental pancreatitis during the past few years gradually underlie the disturbance of the local microcirculation in acute pancreatitis, but several chal lenges remain. Still some questions remain unexplained concerning the mechanisms: (1)Which is the first event in the pathogenesis of acute pancreatitis? (2)Which factor determines the edematous or hemorrhagic necrotizing pancreatitis in a given experimental or clinical situation? (3)What is the role of impaired distribu tion of blood supply in early steps of acute pancreatitis? The potential vasoact ive mediators responsible for the progression of the disease severity have largely remained subjecting to speculation and debate.

Abstract

In this paper, we summarize the main progresses made in our group in the field of the mechanism of pigment gallstone formation. It was found that after treatment with free radicals, bilirubin (BR) was changed into free radical itself, and a semiquinone free radical and a superoxide free radical bound with metal were recognized, which was detected by ESR (electron spin resonance). By the means of NMR (nuclear magnetic resonance) and IR (Infra-red spectra), it was postulated that bilirubin polymerized through the reaction between the vinyl group and the hydroxyl group under the attack of free radicals. It was also found that bilirubin free radical were liable to calcify in a kinetic study. Because of its chemical properties, bilirubin free radical was shown to be cytotoxic to hepatocyte, which was demonstrated based on the following facts: induction of phospholipid peroxidation (LPO), leakage of lactate dehydrogenase (LDH) and decrease of glutathione. As to the mechanism of bilirubin-induced cytotoxicity, it was postulated that the main target of bilirubin free radical was the cell membrane, including phospholipid and membrane bound proteins, especially spectrin, a content of cytoskeleton. Based on the results mentioned above, it was deduced that bilirubin free radical is the key factor that initiates and promotes the formation of pigment gallstone, which is consistent with other researches in recent years.

Liu XT, Hu J. Relationship between bilirubin free radical and formation of pigment gallstone. *World J Gastroenterol* 2002;8(3):413-417

INTRODUCTION

For years, gallstone has been nearly the most common illness in digestive system all over the world, especially in China[1-9], and there are many methods to treat this illness[10-16], including many Chinese traditional medicines. Although some therapies were successful in the end, the best way to deal with the illness is to prevent it before it occurs. So it is important to clarify the key factors that promote the formation of gallstone. Although there were lots of researches in this field that intended to discover the secrets behind the gallstone[17-41], there are still lots of phenomena we cannot explain now.

For the mechanism of formation of pigment gallstone, the earliest suggestion came from Maki[42]. He indicated that bacterial infection induced the hydrolysis of conjugated bilirubin and increased the level of free bilirubin, which was the critical factor for gallstone formation. However, there are many cases of gallstone without bacterial infection. Moreover, the increase of bilirubin concentration is only an essential condition for the precipitation of bilirubin, but not enough to form stone.

In 1982, Elek *et al*[43] reported the ESR signal of pigment gallstone. Its intensity varied linearly with quantity of bilirubin. It gave a hint that the formation of pigment gallstone was likely to be linked with free radicals. Recently, a lot of facts indicate that free radicals are the triggers or important links of many diseases. They are relative to cell damages and mutation. In view of the relationship of pigment gallstone with inflammation and accompanying damages of liver, kidney, gastrointestinal system, probably there are certain carriers of free radicals in the circulation and the free radicals cause cell damages. Based on the Elek's experiment, the carrier might be bilirubin. However, we have to illustrate:

Firstly, the attackers during inflammation are superoxide free radicals and hydroxyl radicals, then, how we can link the formation of pigment gallstone to these free radicals.

Secondly, whether or not bilirubin free radicals formed in situ during inflammation can induce cell damages and initiate the following pathological processes.

In this report, we demonstrate that bilirubin free radicals can be formed under the attack of other free radicals and induce evident cell damages. Then, the relationship between the formation of pigment gallstone and bilirubin free radicals will be discussed.

FORMATION OF BILIRUBIN FREE RADICAL AND ITS CHEMICAL NATURE

As we find,solid bilirubin absorbs oxygen reversibly when exposed to air, and meanwhile bilirubin free radicals are detectable by ESR[44]. ESR spectra showed that the free radicals signals of solid bilirubin were composed of a semiquinone signal and a superoxide radical signal (Figure 1). The former may be formed from the carbonyl group, while the latter may be bound with a metal ion, especially the iron that might be released from the haem from which bilirubin was produced. High spin Fe (II) or Fe (III) was found to be coordinated with four tetrapyrrol nitrogens, which was the same as in haem. Various free radical sources, such as $FeSO_4$+EDTA, XO/XOD and ^{60}Co-irradiation were used to generate bilirubin free radicals. The ESR signals obtained were in accordance with those of natural pigment gallstone[45] (Figure 2). Moreover, the ESR signals of bilirubin became diminished after treatment with free radicals scavengers, such as SOD, mannitol and vitamin C, or ligand of Fe^{2+} or Fe^{3+}[46].

The above results support a mechanism suggested by Foote for photoxidation of bilirubin[47]: (where BR refers to bilirubin, and T1 represents the transition state of the reaction)

So(BR) h v T1(BR) O_2 $\cdot BR^+ + O_2^-$ - [$\cdot BR^+ + O_2 \cdot^-$] [BR $+O_2$]products

Bilirubin free radicals in solution were showed to be more complex than solid bilirubin free radicals. According to the ESR signals and computer simulation, it was deduced that the signals were composed of three groups of free radicals signals: $\cdot H, O_2 \cdot^-$, $RCH_2 \cdot$ (Figure 3)[48].$O_2 \cdot^-$ was from natural bilirubin, and the other two free radicals might be generated during attack of $O_2 \cdot^-$ to C-C bond. In

some experiments, only ·OH was trapped by DMPO, which was considered as the dismutation product of $O_2^{\cdot-}$. In experiment at 77K, semiquinone signal also could be identified just as in solid bilirubin.

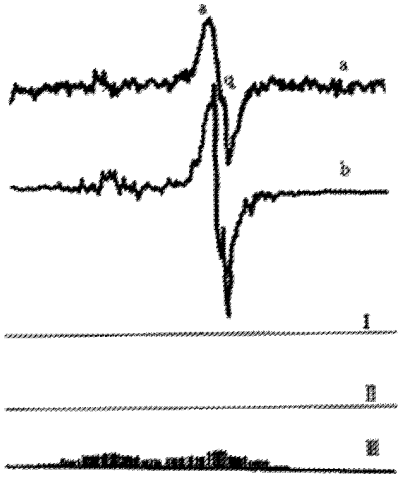

Figure 1 Simulation of ESR spectrum of bilirubin. (a)The experimental spectrum; (b): Simulating spectrum. (I) Superoxide radical; (II) Semiquinone radical; (III) Free electron of superoxideradical delocalized to tetrapyrrole (heterotropism is ignored).

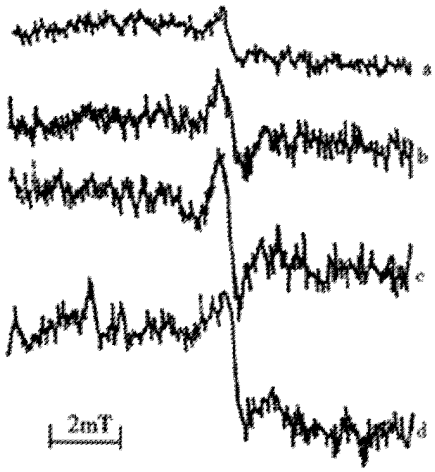

Figure 2 ESR spectra of bilirubin treated with: (a) Bilirubin(from Sigma) as control; (b) ^{60}Co(100Gy); (c)·OH(Fe(II)+EDTA); (d) $O_2^{\cdot-}$ (XO / XOD). The relative intensity of ESR peak is: a:b:c:d=1:2.1:2.8:3.9

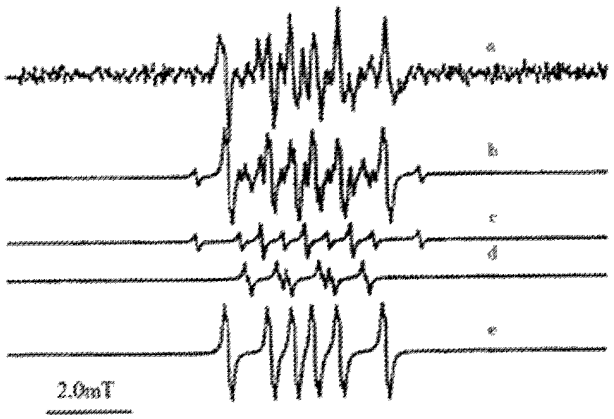

Figure 3 ESR spectra of spin-trapping of bilirubin free radical in solution. (a) DMPO-traping spectrum of bilirubin; (b) computer simulating spectrum; (c) Simulating spectru of DMPO-H; (d) Simulating spectrum of DMPO-OOH; (e) simulating spectrum of DMPO-CH_2R.

In conclusion, we proved that bilirubin free radicals consisted of at least semiquinone free radicals and metal bound superoxide free radicals. In solution, $O_2^{\cdot-}$ attacks bilirubin to generate ·H and $RCH_2^{\cdot}$, and also dismutates into ·OH. Because of the chemical properties of bilirubin free radical, its contributions to the formation of gallstone and its effects on cells discussed below become easier to understand.

PROPERTIES OF BILIRUBIN FREE RADICAL RELEVANT TO FORMATION OF PIGMENT GALLSTONE

To explore the polymerization of bilirubin induced by free radicals, IR and NMR were used to compare the polymerization of original bilirubin or bilirubin treated with free radicals sources. The only significant variation in IR spectra was the decrease of the absorbance at 990cm^{-1} (vinyl group). If the absorbance at 1610cm^{-1} (carboxyl group) was taken as the inner reference[49], the ratio A_{990}/A_{1610} was found to be 0.6470, 0.5646 and 0.5587 in untreated bilirubin and bilirubin treated with $FeSO_4$+EDTA and ^{60}Co irradiation respectively. In NMR spectra, increase of the integral area of the methyl group (1.237ppm) and decrease of that of the vinyl group (above 5ppm) were observed (Figure 4).

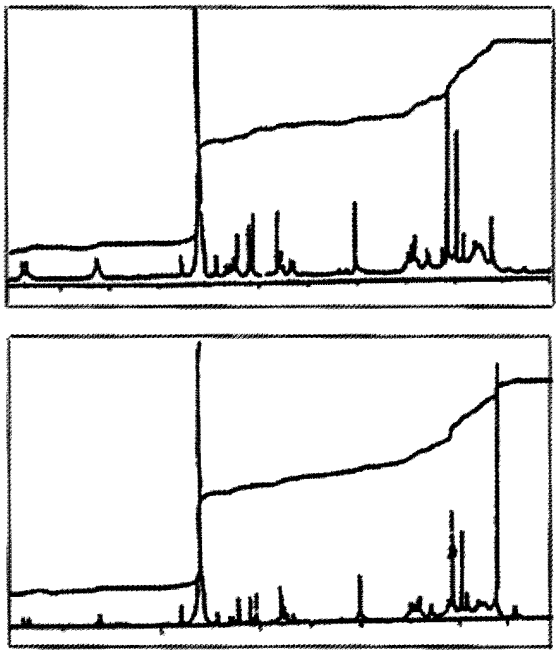

Figure 4 ^{1}H-NMR spectra of bilirubin. (A) commercial bilirubin (from Sigma); (B) bilirubin treated with ^{60}Co.

Thus, we postulated that bilirubin molecules polymerized through the reaction between the vinyl group and the hydroxyl group by free radicals attack. This hypothesis was consistent with William's suggestion[50].

By means of the light scattering method, the average molecular weight of the bilirubin free radicals in DMSO solution was determined in the range 60000-80000,which was higher than that of original samples (<20000). The particle size distribution was measured by means of Coulter counter and the result showed that bilirubin free radicals became larger[51]. A kinetic study showed that the treated bilirubin reacted with calcium ion more rapidly than the untreated sample, and the conditional solubility product was found to be lower. These results suggested that bilirubin free radicals tended to polymerize and deposit, leading to the formation of gallstone.

Based on the above results, we considered that during the gallstone formation bilirubin reacted with the active-oxygen species formed *in vivo* and was changed into free radicals, then polymerized, aggregated and calcified. This might be an important step of formation of pigment gallstone.

CYTOTOXICITY OF BILIRUBIN FREE RADICAL AND ITS CONTRIBUTION TO THE FORMATION OF PIGMENT GALLSTONE

It is well known that bilirubin is cytotoxic. In our experiments, we found that bilirubin free radicals could induce phospholipid peroxidation (LPO), lactate dehydrogenase (LDH) leakage from hepatocytes (Figure 5), and the decrease of intracellular total glutathione (GSH) and oxidized glutathione (GSSG) levels (Figure 6)[52].

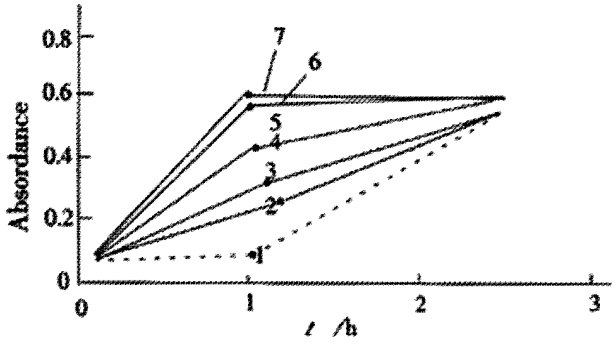

Figure 5 Leakage of lactate dehydrogenase(LDH) of hepa tocyte. 1. Control; 2-7. Treated with BR_{VC}, BR_{comm}+BSA, BR_{comm}, BR_{Co}, BR_{Fe},$BR_{XO/XOD}$

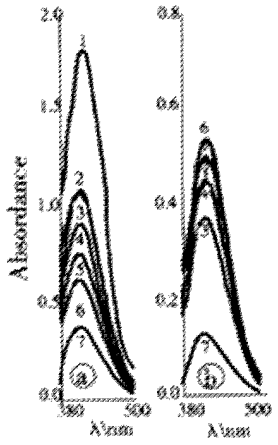

Figure 6 Absorption curve of total and oxidezed glutathione level of hepatocyte. (A) Total glutathione; (B) Oxidized glutathione 1. Control; 2-7. Treated with BR_{VC}, BR_{comm}+BSA, BR_{comm}, BR_{Co}, BR_{Fe},$BR_{XO/XOD}$

The above effects can be diminished when hepatocytes were incubated with bilirubin treated with free radicals scavenger. So cytotoxicity of bilirubin might come from its chemical nature-free radical, just as what had been discussed above. In order to clarify the mechanism of bilirubin-induced cytotoxicity, we investigated effects of bilirubin free radicals on erythrocyte membrane. The SDS-PAGE results showed that after treatment of membrane with bilirubin free radicals, the integral area of band 1 and 2 decreased and some small molecular bands appeared between band 2 and 3 (Figure 7), which indicated that a part of membrane bound proteins, especially the spectrin, were degraded, then the membrane structure might be damaged. The above result was also supported by means of labeling membrane protein with fluorescamine (Figure 8)[53]. In addition, due to the degradation of membrane bound proteins, the increase of lateral movements of phospholipids, decrease of polarizability as well as decrease of micro-viscosity of erythrocyte membrane were observed by means of fluorescence polarization measurement[54]. The studies on the reaction between membrane and bilirubin free radicals showed that the process comprised three steps: firstly, a rapid formation of an electrostatic complex between bilirubin free radicals and polar groups of phospholipid, then a slow inclusion of bilirubin into hydrophobic core of membrane, and finally an erythrocyte membrane-induced bilirubin aggregation[55].

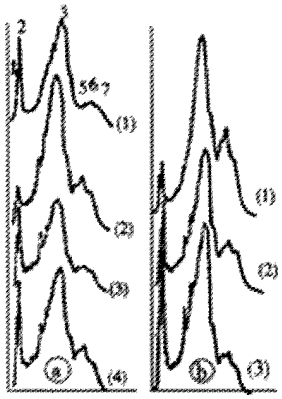

Figure 7 Scans of SDS-PAGE stained with Coomassie blue R-250. (A) 1. control, 2-4 human erythrocyte membrane treated with BR_{Co}, the irradation doses are 100, 50,5(Gy) respectively; (B)human erythrocyte membrane treated with BR_{Fe}, the concentrations of 1-3 are 16.67,13.3,6.7(mmol/L) respectively

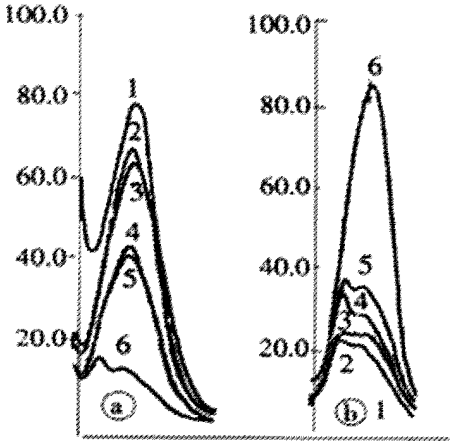

Figure 8 Fluorescence spectrum of erythocyte proteins labeled with fluorescamine. (A) In the precipitated proteins; (B) In the supernatants. 1. control,2.BR_{VC},3.BR_{comm}, 4-5. $BR_{Fe}{}^{aa}$(10 and 20 mmol/L) 6. BR_{Co} (100 Gy)

In summary, bilirubin free radicals can damage the liver cells, which can induce the change of ingredients of the bile, decrease the amount of bile acid. Meanwhile, the abnormal metabolism in hepatocyte can lead to hydrolysis of the conjugated bilirubin, increase the concentration of free bilirubin, thus make bilirubin supersaturated to the bile and promote the formation of pigment gallstone. Moreover, the cell damages caused by free radicals can also promote excretion of glucoprotein, which might act as adhesives and increase the particle size of calcium bilirubinate.

CONCLUTIONS

Based on our results, we considered that there were two ways by which bilirubin free radicals promoted the formation of pigment gallstone. On the one hand, due to the properties of free radicals, bilirubin free radicals formed *in vivo* were more liable to polymerize

and aggregate, then induced the formation of stone. On the other hand, the damages on hepatocytes induced by bilirubin free radicals also impaired the cell function, then led to the disorder of metabolism, which gave rise to the formation of stone indirectly, as well as symptoms in digestive systems. The whole process is illustrated as follows:

Abstract

AIM: **To confirm the value of blocking treatment by zenshengping (ZSP), a Chinese herb composite, and Riboflavin for esophageal epithelia dysplasia cases screened out in high risk area in northern china by exfoliative balloon cytology (EBC), so to reduce the incidence rate of esophageal cancer(EC).**

METHODS: **Esophageal epithelium dysplasia cases including mind esophageal epithelium dysplasia (MEED), stage one severe esophageal epithelium dysplasia (SEEDI), and stage two severe esophageal epithelium dysplasia (SEEDII) were screened out from people aged 40 years and older in the high risk area of Chixian. These cases were randomly divided into a treatment and control group. Subjects in the treatment and control groups took ZSP, riboflavin, and placebo daily for three years. EC cases registered by cancer registry and identified by EBC re-screening in the treatment and control groups were used to calculate incidence and blocking rates to demonstrate the effects of blocking medication.**

RESULTS: **It was found that 31.92% and 24.15% of people aged 40 years and older in Cixian could been diagnosed as MEED and SEED cases. The severity of dysplasia increased with age. ZSP had blocked EC occurrence by 47.79% after 3 year medication among the SEED cases.**

CONCLUSION: **ZSP can block the development from SEEDIand SEEDII to EC by 47.79%. Efforts should be made to screen and treat dysplasia cases in people aged 40 years and older in high risk areas to reduce the mortality figures.**

INTRODUCTION

The prognosis of esophageal and cardia cancer is the worst among digestive carcinomas because more than 90% of all its patients are clinically detected at advanced stages, and most of the patients can undergo only non-curative surgery due to either local tumor invasion into the surrounding tissue or distant metastasis at the time of operation[1-3]. The five year survival rate for clinically diagnosed EC is below 10%. On the other hand, treatment results for early digestive carcinomas are excellent. Several strategies exist for early treatment, including surgery, endoscopic resection, Chinese herbs, etc. The five year survival of early treated EC and gastric cancer patients can reach 90% or more[4-16]. Because most EC and gastric patients have no apparent symptoms until the disease develops into advanced stages, early diagnosis at hospitals seems unrealistic presently, and early detection is undergone mostly among high risk populations in area with high incidence by means of exfoliative ballon cytology (EBC) and/or endoscopy[17-24].

Besides treatment of early ECs such as carcinoma in situ or intramucosal carcinoma, another promising strategy of secondary prevention is receiving great interest presently. A number of researchers have demonstrated that esophageal epithelium dysplasia (EED) is a precancerous lesion which can either develop further into a more severe stage or cancer, stay unchanged, or reverse back to normal again for a period of several years or even a decade. It is therefore very promising to detect patients with EED and treat the precancerous lesions before they transform into the irreversible malignant stage in high risk populations[25-31]. There are several techniques and chemicals or nutrients that have been reported to be effective in blocking precancerous lesions from transforming into cancer[32-42]. Linpeizhong reported that an herb composite named Zenshengpin (ZSP) had shown an inhibitory rate of 50% after three years of medication for SEEDI and SEEDIIcases[25]. The present report came from "A Comprehensive Field Prevention and Treatment Study of Esophageal Cancer" carried out in the Chixian county of Hebei Province, which is adjacent to the Linxian county of Henan province, and also has the highest incidence rate of ECs in the world. This study was one of The National Eighth-Five-Year Scientific Championship Project. Its aim was to explore the feasibility of massive screening for EED patients among high risk people and to examine the long term effects of blocking treatment by ZSP and micronutrients in large samples of EED cases.

MATERIALS AND METHODS

Chixian is situated at 36°30" northern latitude, 114°40" eastern longitude, on the east side of the Taihang Mountain, along the Zhanghe River. Across the river to the south is the Anyang City of Henan province. Chixian county occupies an area about 951 square kilometers, and its population is 583611. There is a remarkable variation in the earth stratum of the county, with moutainous, hilly, and level land each constituting about one-third of its total area. The climate is influenced mainly by the warm mainland seasonal wind. The average temperature is 18-25℃ and the waterfall is 600-700 millimeters. The major soil there is brown and light colored weed earth. Farm products include wheat, corn, millet, rice, red potato, and beans. Iron ane coal are the main minerals, and coal is the main local fuel of the county.

The National Eighth-Five-Year Scientific Championship Project chose people aged 40 years and older in nine rural administrative units in the hilly part of Chixian County as the study population. The hilly

part of the county has a higher incidence rate of EC than the plain part. The nine rural administrative units were further randomly divided into two districts; a treatment and a control district. The number of the study population was 122497. They resided in 101 villages. There was no significant difference in the sex and age distribution of the study population between the treatment and control districts. In preparation for a massive EBC screen of the study population to detect EC, near esophageal cancer (NEC), MEED, SEEDI, and SEEDII cases, a county wide conference was convened by the Chixian County government for local leaders and cancer prevention professionals from the three administrative levels including the county, the rural administration unit, and the villages. At the conference, special committees were set up on each of the three administration level to be responsible for the execution of the EBC massive screen in the areas under their authority. After the conference, a forceful propaganda campaign was carried out countywide to advertise the benefits of massive EBC screenings such as early detection, early treatment and satisfactory survival results. One day prior to the screening, personal contacts with potential examinees were made by local physicians to arrange details for the screening. At the beginning of the screening, physical examination was performed by physicians to exclude persons with serious contraindication to EBC examination, then EBC examination was performed by specialists. Four slides were prepared from specimens obtained by the procedure. The slides were afterwards examined by cytologists with no knowledge about the design of the study. Diagnosis was made according to the five grade cytology classification system including gradeInormal, grade II MEED, grade IIIa SEEDI, grade IIIb SEEDII, grade IV NEC, and grade V EC[28]. A diagnosis of cancer was made only after verification by at least three cytologists. Patients initially diagnosed with grade IIIa, grade IIIb, grade IV, and grade V were reexamined by electronic endoscopy with biopsy.

Finally, 16748 people of the study population in the two districts accepted EBC screening. MEED, SEEDI, and SEEDII patients screened out from the treatment district were pre-chosen as the treatment group; while those of the MEED, SEEDI and SEEDII cases detected from the control district were chosen to be the control group. There were 1566 cases of MEED and 1396 cases of SEED (including SEEDI and SEEDII) in the treatment group; and 3780 MEED and 2649 SEED cases in the control group. The MEED patients in the treatment group took 8 calcium tablets (CT) which were equivalent to 3 grams of caco3and 5 milligrams of riboflavin. The SEED patients in the treatment group took 8 ZSP tablets daily. The MEED and SEED cases in the control group took 8 placebo tablets which were the same in color and size as ZSP and CT. The medication of ZSP, CT and placebo continued for three years. Half a year after initiation of the medication, EC cases diagnosed in the treatment and control groups were registered by a cancer registry constructed specifically for the study. At the end of the three year medication, EBC screening was re-initiated to identify EC cases in the treatment and control groups. EC cases registered by the registry and identified by the EBC re-screening were summarized to calculate the incidence rates for the treatment and control groups respectively.

RESULTS

Detection rates of MEED, SEEDI, SEEDII, NEC, and EC

As in Table 1, there were 179 cases of EC, 172 of NEC, 866 of SEEDII, 3179 of SEEDI, and 5346 of MEED as detected by the initial EBC screening from the 16,748 high risk participants aged 40 years and older in the treatment and control districts. The detection rates of MEED, SEEDI,SEEDII, NEC, and EC were 31.92%, 18. 98%, 5.17%, 1.03%, and 1.07% respectively. As the age increased by 5 year intervals, the detection rates of MEED, SEEDI,SEEDII, NEC, and EC all increased from the lowest for the 40-year-old group to the highest for the 60-year-old group, but the amount of increase in the detection rates with increase of age was not equal for MEED, SEEDI,SEEDII, NEC, and EC. The increase was the sharpest for EC and the lowest for MEED. An odds ratio (OR) defined as the ratio of the detection rates of the 60-year-old group against that of the 40-year-old group was 5.78 for EC, 2.56 for NEC, 1.80 for SEEDII, 1.61 for SEEDI, and only 1.18 for MEED.

EBC re-screening

EBC re-screening was carried out at the end of the three year medication period to detect EC patients among the MEED, SEEDI, and SEEDII cases in the treatment and control groups. Among the 4045 SEED cases, 77 EC cases had been diagnosed and registered before EBC re-screening (Table 2). With them excluded, there were 3968 SEED cases who should have been re-screened, and in the end 2976 (75.00%) were re-examined. The re-screening completion rate for the treatment and control groups of SEED was 78.4% and 74.2% respectively. As for the 5346 MEED cases, with the 76 EC cases already diagnosed and registered prior to re-screening excluded, 3775 (71.63%) were re-screened. The re-screening rates for the MEED treatment and control groups were 75.6% and 74% respectively.

Registered EC cases and incidence rates

From half a year after initiation of ZSP and CT medication to the time of re-screening, 77 cases of EC were diagnosed and registered among the 4045 SEED cases (Table 2). The three-year incidence rate by registered EC cases alone for all of the SEED cases was 1.90% (77/4045), and for SEED in the treatment and control groups were 0.78% (11/1396) and 2.49% (66/2649) respectively. A significant difference existed between the incidence rates of the two groups (χ^2=14.21,P<0.01). For the 5346 MEED cases, 76 EC patients were registered. The three year incidence rate for all of the MEED cases was 1.42% (76/5346), and was 1.14% (18/1566) and 1.54% (58/3780) for MEED in the treatment and control groups respectively.

There was no significant difference between the incidence rates of the two groups (χ^2=1.17,P>0.05).

Table 2 Effect of blocking treatment of MEED and SEED cases by ZSP,CT, and PLACEBO after three year medication

MEED

Group	No. subjects	EC Diagnosed			Incidence Rates (%)	Block Rates (%)
		EBC Re-screening	Registration	Total		
Treatment	1566	10	18	28	1.79	
Control	3780	26	58	84	2.22	
Total	5346	36	76	112	2.10	19.37

SEED

Group	No. subjects	EC Diagnosed			Incidence Rates (%)	Block Rates (%)
		EBC Re-screening	Registration	Total		
Treatment	1396	17	11	28	2.01	
Control	3649	36	66	102	3.85	
Total	4045	53	77	130	3.21	47.79

Re-screened EC cases and prevalence rates

By EBC re-screening, 53 EC cases were detected from the 2976 SEED cases. The prevalence rate was 1.78% (53/2976) for all of the SEED cases combined, and was 1.61% (17/1054) and 1.87% (36/1922) for SEED cases in the treatment and control groups respectively. There was no significant difference between the prevalence rates of the two groups (χ^2=0.26, P>0.05). Among the 3775 MEED cases, 36 EC cases were diagnosed by EBC re-screening, with a prevalence rate of 0.95% (36/3775) for the MEED combined, 0.89% (10/1114) for the treatment group, and 0.97% (26/2661) for the control group. There was no significant difference in the prevalence rates between the two groups (χ^2=0.15, P>0.05).

Combined incidence and blocking rates

During the first three year follow-up, 242 diagnoses of EC were made by registration and re-screening from the 9,391 SEED and MEED cases, yielding a total incidence rate of 2.58% (242/9391) for SEED and MEED combined, 1.89% (56/2962) for the treatment group, and 2.89% (186/6429) for the control group. A significant difference existed between the two groups (χ^2=8.12, P<0.01). A blocking rate of 34.60% calculated as (2.89-1.89%)/2.89%×100% was obtained to assess the effects of a three year period of medication by ZSP and CT.

As in Table 2, 112 EC cases were accumulated by three year registration and EBC-re-screening from the 5346 MEED cases (76 registered and 36 screened out). An incidence rate of 2.10% (112/5346) was calculated for the whole MEED group, 1.79% (28/1566) for MEED in the treatment group, and 2.22% (84/3780) for MEED in the control group. The difference between the incidence rates of the two groups did not reach a significant level (χ^2=1.02, P>0.05), and a blocking rate of 19.37% was calculated to demonstrate the effect of CT for MEED cases.

130 EC cases were diagnosed from the 4045 SEED cases by three year registration and EBC re-screening (77 registered and 53 re-screened out). The incidence rate was 3.21% for all of the SEED cases, 2.01% (28/1396) for SEED in the treatment, and 3.85% (102/2649) for SEED in the control group. The difference between the incidence rates of the two groups reached a significant level (χ^2=10.00, P<0.01), and the blocking rate by ZSP for SEED was 47.79%.

Incidence and blocking rates of EC for SEEDI and SEEDII

As in Table 3, 69 EC diagnoses were made during the three year study period among the 3179 SEEDI cases. The incidence rate was 2.17% (69/3179) for all of the SEEDI cases, 1.66% (20/1206) for SEEDI in the treatment group, and 2.48% (49/1973) for SEEDI in the control group. There was no significant difference between the incidence rates of the treatment and control group (χ^2=2.40, P>0.05), and the corresponding blocking rate was 33.06%.

There were 61 EC cases diagnosed from the 866 SEEDII cases during the same period, yielding an incidence rate of 7.04% (61/866) for all of the SEEDII, 2.87% (8/279) for SEEDII in the treatment group, and 9.03%(53/587) for SEEDII in the control group. A significant difference was observed between the two incidence rates of the two groups (χ^2=10.00, P<0.01), and the blocking rate of ZSP for SEEDII was 68.22%.

Table 3 Results of blocking treatment of SEEDIand SEEDII cases by ZSP and PLACEBO after three years of medication

DISCUSSION

Dysplasia is an atypical state of the epithelium with a basophilic matrix, a high matrix-core ratio, and hyperheterochromatin. It is historically classified into three grades according to the degree of atypical epithelium in comparision with the basal zone as defined by the World Health Organization's International Histological Classification of Tumors[43]. Atypical cells localized in the basal zone in MEED, while immature cells occupy more than three quadrants of the epithelium in SEEDIand SEEDII.

In this study, we found that 31.92% and 24.15% of people aged 40 years and older in Chixian could been diagnosed as MEED and SEED cases. Qiu and Yang[44] have reported a similar dysplasia rate of 32.28% in people aged 21 years and older in Linxian, which is a neighboring County to Chixian County situated in the same Taihang Mountain area in northern China where there is the highest incidence of EC. However, the rate of dysplasia in low risk regions was only 4.78%, most of the dysplasia belonged to MEED, and the frequency of dysplasia correlated well with the regional level of ECs.

The severity of dysplasia increased with age. As in Table 1, as patients got older, their chances of being detected as one of the dysplasia states grew higher. This was true with MEED, SEED I, and SEEDII. Moreover, the extent of increase in detection rates with age was small for MEED, large for SEEDI, and still larger for SEEDII. The Odds Ratios of the detection rates of the 60-year-old group versus that of the 40-year-old group for MEED, SEEDIand SEEDII were 1.18, 1.61, and 1.80 respectively. This increase with age is remarkably similar to the increase of incidence or mortality of EC with age[46-50], but the degree of the latter was much greater. As in Table 1, the Odds Ratio of detection rates of 60-year-olds against that of 40-year-olds grew up to 2.56 and 5.78 for NEC and EC. It may be suggested that the increase of dysplasia rates with age was small and unstable or reversible for the less severe states such as MEED, but

became fixed and remarkably large as the dysplasia progressed into more severe stages or transformed into NEC and EC.

While the chances of dysplasia increased with age, the total detection rates for MEED, SEEDIand SEEDIIdecreased from 31.92%, 18.98% to 5.17% in the direction of dysplasia development. It may suggest that although dysplasia may proceed further, only a limited portion proceeds into more severe or malignant.

Our finding and discussion so far support the notion that dysplasia belongs to a early form of carcinoma. The main difference between dysplasia and EC may be that dysplasia is an unstable or unfixed state of existence. It may develop further, but much of it will stay unchanged, or even return to normal or less severe again. Therefore, if we could detect and treat precancerous dysplasia lesions before they develop into carcinomas, then the long-term survival of ECs should dramatically improve.

The present study has focused primarily on the blocking treatment of dysplasia cases in high risk populations. The result was that ZSP blocked EC incidence rate by 47.79% after 3 years of medication for the SEED cases. In a previous National Seventh Five Research Project carried out in Linxian County, Lin found that ZSP reduced the EC transformation rate of SEED cases by 52.2% after 3 year medication[24]. These consistent findings by a series of population-based prospective cohort studies in the same high risk area enabled us to conclude that EC is preventable on the secondary blocking treatment level, and ZSP is an effective agent to treat precancerous EC lesions in high risk areas[51-53].

Experimental observations indicate that cancer preventive chemical agents take effect by acting on the promotion stage[25]. The anti-carcinogenicity of certain Chinese herbs is considered to share the same mechanism. In this study, the significant blocking rate of 47.79% by ZSP for the SEED cases resulted mainly from the difference in the registered incidence of EC between the treatment and control groups, as there was no significant difference in the re-screened EC incidence rates between the two groups. As we know, registered EC represents clinically diagnosed late-staged EC, while EC screened out by EBC belonged to the early asymptomatic patients. The finding that ZSP reduced only the registered three year incidence rate, but not the EBC re-screened incidence rate of EC suggests that ZSP may have blocked or delayed the appearance of clinically recognizable EC developed from SEED. In other words, ZSP acted mainly on the late stage of EC development. As in Table 3, the more remarkable blocking rate by ZSP for SEEDIIversus SEEDI(68.22% versus 33.06%) also supports the idea that ZSP was effective in blocking or delaying the appearance of EC during the late stages of EC development.

In a previous comprehensive field prevention and treatment study of esophageal cancer carried out in Linxian county, Lin found that Riboflavin had no significant effect on MEED cases at the end of three years of medication, but a blocking rate of 37.0% appeared at the end of 9 year follow up[24,25]. The result at the end of a three year medication period was the same as in the present study. Further findings will be reported by continuous observation.

In conclusion, we regard dysplasia as a precancerous lesion in people aged 40 years and older in high risk areas. Efforts should be made to screen and treat dysplasia cases before the disease transforms into the irreversible malignant state. Effective screening plus blocking treatment in high risk populations may reduce the mortality rate of EC over the long term. ZSP has been made from natural Chinese herbs which are cheap and share rich resources. Repeated demonstration of its ability will make it a promising agent for secondary prevention of EC.

Abstract

AIM: **To further understand the molecular basis for gastric cardia carcinogenesis and to provide etiological clues.**

METHODS: **Endoscopic mucosa biopsy and histopathological examinations were made on 37 subjects from a high incidence area for both esophageal and gastric cardia carcinomas in northern China. All the biopsy samples were fixed in 850ml.$^{-1}$ Lalcohol and embedded in paraffin. Each block contained one piece of tissue and was serially section at 5 μm. Immunohistochemistry (ABC) was carried out on these gastric cardia samples to determine the alterations of p16 and Rb.**

RESULTS: **Based on the histopathlogical examination there were 11 cases of chronic superficial gastritis, 12 cases of chronic atrophic gastritis and 14 cases of dysplasia. The immunostaining demonstrated different levels of unclear immunostaining of p16 and Rb in normal gastric cardia tissue and the tissues with different severity of lesions. With the lesions progressing, the positive immunostaining rates for p16 protein had a decreasing tendency. In contrast, the positive immunostaining rate for Rb protein had an increasing tendency. There was a significant negative relationship between the two parameters. Changes of p16 was CSG 11(100%), CAG 7 (58%), DYS 4(29%) and changes of Rb was CSG 2(18%), CAG 8(67%) and DYS 12(86%), (P<0.05).**

CONCLUSION: **The alterations of p16 and Rb protein may play a role in the early stages of gastric cardia carcinogenesis.**

INTRODUCTION

Gastric cardia cancer is subject being studied. An interesting observation is that gastric cardia cancer and esophageal cancer seem to occur together in many high-incidence areas in China, and both were referred to as esophageal cancer (EC) by the public because of the common syndrome of dysphagia[1,2]. Histologically, esophageal and gastric cardia cancers have been considered as single clinical entity for incidence and mortality calculation in China. The molecular changes in the early stage of gastric cardia carcinogenesis have not been characterized [3-5]. In the present study, we investigated the roles of p16 and Rb alteration in gastric cardia carcinogenesis by measuring the expression rates of p16 and Rb in normal gastric cardia tissues and the tissues with different severity of lesions from the symptom-free subjects at a high incidence area of gastric cardia cancers in Henan, northern China.

MATERIALS AND METHODS

Tissue collection and processing

Gastric cardia biopsies were taken from 37 symptom-free subjects at Huixian County and Linxian County, Henan Province, China, the high-risk areas for esophageal and gastric cardia cancers during the mass survey. All the biopsy specimens were fixed with 850ml·L^{-1} alcohol, embedded with paraffin, and serially sectioned at 5μm. The sections were mounted onto histostick-coated slides. Three or four adjacent ribbons were collected for histopathological analysis (HE stain), and immunohistochemical staining. Histopathological diagnosis for gastric cardia epithelia was made using the previously established criteria. Based on the cellular morphological changes and tissue architecture, the gastric cardia epithelia were graded as chronic superficial gastritis(CSG), chronic atrophic gastritis (CGT) and dysplasia(DYS)[6-9]. The polyclonal p16 antibody is rabbit antiserum against human p16 protein(Dakoco, USA). The polyclonal Rb antibody is rabbit antiserum against man Rb protein (Oncogene Science Inc., USA). After dewaxing, inactivating endogenous peroxidase activity, and blocking cross-reactivity with normal serum, we incubated the sections with a diluted solution of the primary antibodies overnight at 4℃(1:100 for p16, 1:100 for Rb). Location of the primary antibodies was achieved by subsequent application of a biotinylated anti-primary antibody, an avidin biotin complex conjugated to horseradish peroxidase, and diaminobenzidine (Vectastain Elite Kit, Dako, USA). Normal serum blocking and omission of the primary antibody were used as negative controls[10,15].

Statistical analysis

The data were expressed as the mean±SD unless otherwise stated. The χ^2 test was used for histopathological and immunostaining rate evaluation (P<0.05 considered significant).

RESULTS

Histopathology findings

Histopathlogical examination showed that there were 11 cases of chronic superficial gastritis, 12 cases of chronic atrophic gastritis and 14 cases of dysplasia (Table 1). Both p16 and Rb immunostaining-positive cells were observed in different severity of lesions of gastric

cardia epithelia. In CSG, the positive immunostaining rates of p16 was much higher than that of Rb. An interesting observation is that the positive immunostaining rate of p16 was much lower than that of Rb in DYS. As the lesions of gastric cardia epithelia progressed from CSG to DYS, the positive immunostaining rates of p16 decreased significantly ($P<0.05$), especially from CSG to CAG. However, the positive immunostaining rates of Rb increased significantly ($P<0.05$). Correlation analysis showed significantly negative correlation between the decreasing tendency of P16 and the increasing tendency of Rb with the lesions progressing from CSG, CAG to DYS.

Table 1 Changes of p16 and Rb in gastric cardia precancerous lesions

Histological types	Number examined	P16 IHC positive[a] *n* (%)	Rb IHC positive[b] *n* (%)
CSG	11	11(100)	2(18)
CAG	12	7(58)	8(67)
DYS	14	4(29)	12(86)

[a]$P<0.05$, CSC *vs* CAG, CAG *vs* DYS; [b]$P<0.05$, DYS *vs* CAG, CAG *vs*. CSG

DISCUSSION

Gastric cardia carcinoma (GCC) is one of the most frequent digestive malignant diseases in northern China. A remarkable epidemiological characteristic for GCC is the occurring together with esophageal cancer in the same high-incidence area (HIA). In contrast with the strikingly decreasing of incidence rate of distal gastric cancer around the world in the past two decades, especially in America and Europe, the incidence of GCC increased dramatically; the incidence of esophageal-gastric-junction cancer increased to 6 folds with a speed of 4% yearly, which was one of the fastest increasing malignant diseases, the mechanism in unclear. There are several distinct differences between GCC and distal gastric cancer with respect to epidemiology, etiological factors, histogenesis and clinical characteristics, and therefore GCC should be catergorized as a distinct clinical disease. Lacking of sensitive and diagnostic biomarker and technique in early stage of GCC as well as the deficiency of effective and specific reagents for its treatment and prevention leads to its poor prognosis and higher mortality. An interesting observation in this study was that the alterations of tumor suppressor gene p16 and Rb products occurred in the early stage of gastric cardia carcinogenesis, even in CSG. With the lesions progressing from CSG, CAG to DYS, the positive immunostaining rates of p16 decreased significantly, especially from CSG to CAG. However, the positive immunostaining rates of Rb increased significantly. The positive immunostaining rate of p16 was much higher than of Rb In CSG. But, in DYS, the positive immunostaining rates of p16 was much lower than that of Rb. These results suggested that the tumor suppressor gene p16 and Rb may play different roles in the different stages of gastric cardia epithelia carcinogenesis. CAG and GYS have been considered as precancerous lesions of stomach cancer. Although the role of CSG is not clear during the gastric cardia carcinogenesis, it may provide a favorable macroenvironment for gastric carcinogenesis. The significance of CSG in the development of stomach cancer remains to be further characterized.

P16 gene, located at chromosome 9p21, is a new tumor suppressor gene, which was identified by an American molecular geneticist in 1995 and is also called multiple tumor suppressor 1 (MTS1) for its suppressing function to multiple tumors. Recent studies showed that the changes of p16 gene and its products were found in many primary tumors and cell lines[9,11-15]. Rb gene is the first tumor suppressor gene identified by the location cloning method, located at chromosome 13p. The product of Rb is a nuclear phosphoprotein, which is distributed extensively in different kinds of tissues[16-22]. It was considered that the cell-cycle progression normally depends on regulation by cyclins and cyclin inhibiting proteins. The overexpression of cyclins and/or the deletion of inhibiting protein could result in overworking of cell-cycle dependent kinetics (cdk), which makes cells enter into proliferative stage. The p16 could functionally inhibit cdks activity specifically and make Rb unphosphorylated, thus preventing the cell cycle progression from G1 phase to S phase[22-26].

Tam *et al* found that inactive Rb and/or Rb protein exist in all of the p16 over-expression cell lines, and inactive Rb protein could act directly on p16, suggesting that Rb can inhibit p16 protein expression. P16, Rb and cdk may constitute a feedback regulation circle. In the present study, a significant negative relationship between p16 and Rb protein expression was observed, which is consistent with Tam's observation[26-33].

Abstract

AIM: **To optimize conditions of DHPLC and analyze the effectiveness of various DNA polymerases on DHPLC resolution, and evaluate the sensitivity of DHPLC in the mutation screening of mitochondrial DNA (mtDNA).**

METHODS: **Two fragments of 16s gene of mitochondrial DNA (one of them F2 is a mutant fragment) and an A3243G mutated fragment were used to analyze the UV detection limit and determine the minimum percentage of mutant PCR products for DHPLC and evaluate effects of DNA polymerases on resolution of DHPLC. Under the optimal conditions, we analyzed the mtDNA mutations from muscle tissues of mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS) and screened blindly for variances in D-loop region of mtDNA from human gastric tumor specimen.**

RESULTS: **Ten A3243G variants were detected in 12 cases of MELAS, no alterations were detected in controls and these results were consistent with the results obtained by analysis of RFLP with ApaI. We also identified 26 D-loop variances in 46 cases of human gastric cancer tissues and 38 alterations in 13 gastric cancer cell lines. The mutation of mtDNA at 80ng PCR products containing a minimum of 5% mutant sequences could be detected by using DHPLC with UV detector. Moreover, Ampli-Taq Gold polymerase was equally as good as the proofreading DNA polymerase (e.g., Pfu) in eliminating the false positive produced by Taq DNA polymerases.**

CONCLUSION: **DHPLC is a powerful, rapid and sensitive mutation screening method for mtDNA. Proofreading DNA polymerase is more suitable for DHPLC analysis than Taq polymerase.**

INTRODUCTION

A number of methods, such as PCR-SSCP, DGGE and CSGE, have been developed to screen the gene mutation. PCR-SSCP is a common method in mutation detection[1-16]. The low resolution and reproducibility or time-cost limit their application for mutation screening[17-23]. Recently, a more accurate and rapid DNA screening strategy[24-29]-Denaturing High-performance Liquid Chromatography (DHPLC) has been applied to mutation screening in human disease-related gene[30-42] and prenatal diagnosis[43,44].

However, there are few published data on detection of mitochondrial DNA (mtDNA) variation by DHPLC, especially in cancer. In order to detect effectively the mtDNA mutation, the optimizations of DHPLC for mtDNA mutation screening have been evaluated. The evaluation included the ultraviolet (UV) detection limit for PCR products with variant ingredients, minimal detected ratio of variant to wild type in PCR mixture. In addition, small peak was often observed preceding the chromatography profile in both amplimers of nucleus and mitochondrial genes when Taq DNA polymerases were used in PCR amplification. It may result in failure of DHPLC analysis. Therefore, we also evaluated the effect of DNA polymerasess on the resolution of DHPLC in detection of heteroduplex. Basing on those analyses, we identified the mutation of A3243G substitute for patients with mitochondrial encephalomyopathy with lactic acidosis and stroke-like episodes (MELAS). Finally, the variances of D-loop in mtDNA were blindly screened by DHPLC for patients with gastric carcinoma and gastric cancer cell lines.

MATERIALS AND METHODS

Samples and DNA preparation

The specimen in this study included: (1) 12 cases of MELAS, 72 cases of other mitochondrial encephalomyopathies and 30 cases of controls. (2) 46 paired samples of gastric tumor tissues and non-tumor tissues, and 13 gastric cancer cell lines. (3) A randomly selected fragment (fragment 6: from 2616 to 2884nt) within 16s gene was selected to evaluate effect of 11 brands of DNA polymerases on resolution of DHPLC. (4) Another variant fragment (fragment 2: from 1777 to 2069nt) in 16s gene of gastric cancer cell line MKN45 was used to analyze the UV detection limit of PCR products for DHPLC. A variant sample of MELAS,whose ratio of mutant type (G) to wild type (A) at 3243 allele site was about 60 percent, was employed to determine the minimum percentage of mutant PCR products for DHPLC. The genome DNA was isolated following standard phenol/chloroform and ethanol precipitation extraction procedures.

PCR conditions and quantification of PCR products

Fragment containing A3243G mutatioo in mtDNA of MELAS was amplified by using one pair of oligonucleotide primers. Fragments of D-loop were amplified by using four pairs of overlapping primers desribed by Levin *et al*[45]. Another pair of primers was used to amplify fragment 6 (F6) within 16s gene for assessing effect of DNA polymerases on DHPLC (Table 1). 20μL standard PCR reactive system contain genome DNA 15ng, forward and reverse primer 125nmol·L^{-1} each, 1×buffer (Mg^{2+} 1.6μmol·L^{-1}), dNTP 37.5μmol·L^{-1}, Pfu DNA polymerase 1.5units (or Taq DNA polymrases 1 unit). PCR was performed with 32 cycles consisting of a denaturing step of 94℃ for 35s, primer annealing for 50s and an elongation step of 72℃ for 90s. The final step at 72℃ was extended to 10min. Annealing temperature of each fragment was showed in table 1. In addition, one mutated fragment (F2), harboring in mitochondrial 16s

gene of gastric cancer cell line MKN45, was used to analyze the UV detection limit of PCR products for DHPLC and amplified by PCR protocol for 19, 21, 24, 27, 30 cycles at annealing temperature of 53℃ with Pfu polymerase.

Table 1 Primer sequence, PCR Conditions and DHPLC oven temperature used in this study

[a]Eluent buffer B was 0.1mmol·L^{-1} TAEE, 25% acetonitrile, pH7.0.

The PCR products of mutant fragment (F2) amplified with 19-30 cycles were electrophoresed by 2% agarose gel. The agarose gel was exposed to Koda Image Station 440CF, and the resulting signal qualified by using the Koda 1d Image Analysis software. Values were normalized against pUC18 message. A variant sample which ratio of mutant type (G) to wild type (A) at 3243 allele site was about 60 percent and a normal blood sample were amplified respectively. Both PCR products were mixed according to ratio of mutant: wild type to be 50%, 40%, 30%, 20%, 10%, 5% and 0%.

DHPLC analysis

PCR products from gastric cancer cell lines were mixed with about 30 percent of PCR ingredients of normal blood in order to detect homozygous mutation in cell lines. Prior to DHPLC analysis, all fragments were heated to 95℃ for 3min, followed by slow cooling to 45℃ over 50min to form a mixture of hetero- and homoduplex. The melting temperature and optimal gradient for each fragment (Table 1) can be obtained with WAVEMAKER4.0 software with some empirical optimization. Aliqots of 3μL PCR products were automatically loaded on the DNASep column and eluted on a linear acetonitrile gradient in a 0.1mol·L^{-1} triethylamine acetate buffer (pH 7.0) with a constant flow rate of 0.9mL·min^{-1}. Elution of DNA from the column was detected by absorbing at 260nm.

DNA sequencing

PCR products were purified by 4% PAGE gel. Direct sequencing of the PCR products was performed by use of the fluorescent terminators on an ABI Prism 377 sequencer (PE Biosystems, USA). The sequence data were checked with MITOMAP Human mtDNA "Cambridge" Sequences (http://www.gen.emory.edu/MITOMAP/mitoseq.html).

RESULTS

Optimization of DHPLC for mtDNA mutation detection

The UV detection limit was analyzed for PCR products with variants. The concentration of PCR products of 16s gene containing a variance from gastric cancer cell line MKN45 was about 8, 20, 40, 85 and 110ng·μL^{-1} after amplification with 19, 21, 24, 27, 30 cycles respectively. The UV detection limit was about 80ng for the PCR products whose mutated ingredients were efficiently detected by DHPLC.

The minimal ratio of heteroduplex detected by DHPLC was studied. To investigate the sensitivity of DHPLC in detection of mtDNA variants, we used PCR products from the mutated MELAS sample to mix with normal blood amplimers based on ratio of mutant to wild type to be 50%, 40%, 30%, 20%, 10%, 5%, 1% and 0%. Our results showed that heteroduplexes were sensitively detected by DHPLC, when the ratio (mutant:wild) range from 5% to 50% in the mixture of PCR products (Figure 1). Moreover, the chromatography profiles of DHPLC were similar when mutant products in mixture were about 10-40%. It suggested that homozygous mutation could be easily identified if 20-30% wild PCR products were added.

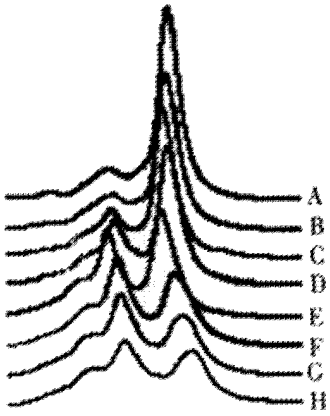

Figure 1 The minimal ratio of hetero-: homoduplex in mixture were identified by DHPLC. The composition of mutant type in PCR product mixture are 0% (A, wild type), 1% (B), 5% (C), 10% (D), 20% (E), 30% (F), 40% (G) and 50% (H) respectively. Chromatogram B has no difference to chromatogram A. Heteroduplex peak start to change in sample containing 5% variant (C). The heteroduplex can be obviously discerned in sample with 10% variant (D). Chromatogram E to H is almost similar. It indicates that about 5% mutant composition in PCR product mixture can be detected by DHPLC.

The effect of DNA polymerases on DHPLC was evaluated. A small peak was often observed preceding the main peak in most of fragments amplified by Taq DNA polymerases. In order to understand whether this was an universality gor DHPLC resolution induced by Taq polymerase, we chose 6 brands of Taq, 1 type of Taq Gold and 4 kinds proofreading DNA polymerases to amplify a randomly selected fragment (F6) for DHPLC analysis. Our findings displayed that all in this study gave a broadened peak proceeding the main peak, but Taq Gold and proofreading DNA polymerases (such as Pfu and Vent) had no or tiny peak before the main peak (Figure 2). To exclude the results that were induced by polymerase buffer, we further amplified the fragment using Taq polymerase to match with Taq Gold and proofreading polymerase buffer, or Taq Gold and proofreading polymerase with Taq polymerase buffer. The results indicated that the particular small peak was only related to Taq DNA polymerase itself.

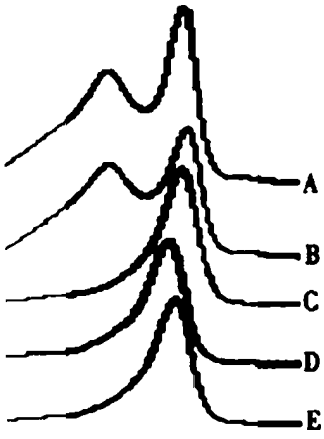

Figure 2 The universality of a broad small peak proceeding the main peak induced by Taq DNA polymerase. An extra small peak is observed preceding the eluted chromatography profile of A and B but not in chromatogram of C, D and E. Chromatogram A is a representative of products amplified by Taq DNA

polymerase. B is typical chromatography profile when Taq DNA polymerase matched with Pfu DNA polymerase buffer in PCR reaction. C and D respectively comes from amplimers amplified by Ampli-Taq Gold and Vent DNA polymerase. E is one of chromatograms coming from PCR amplification by using Pfu DNA polymerase.

Mutation screening of mtDNA

Patients with MELAS have been suggested to associate with mutation of A3243G in $tRNA^{Leu1}$[46,47]. 10 variant cases out of 12 MELAS patients were successfully identified by DHPLC. No alterations were detected in 72 cases with other mitochondrial encephalomyopathies and 30 controls at this allele site. These results were completely consistent with results obtained by restriction endonuclease Apa I.

Basing on above results, we further screened blindly the variants of non-coding D-loop region of mtDNA in gastric cancer using 4 pairs of overlapping primers. In the primary scanning, 28 heteroduplexes were identified in gastric tumor tissues and 38 variances were distinguished in cell lines. The typical chromatograms of heteroduplexes in each fragment were showed in Figure 3. To prove the results, all of positive samples were detected repeatedly. 26 heteroduplexes in tumor group were confirmed, 2 cases were checked to be negative. The two samples were distinguished to be positive due to change of retention time in contrast with other samples, but their chromatograms were similar with wild type. The detected variant frequency of mtDNA by DHPLC was listed in table 2. Ten variant fragments were randomly chosen for direct DNA sequencing, and all of mutated fragments were confirmed.

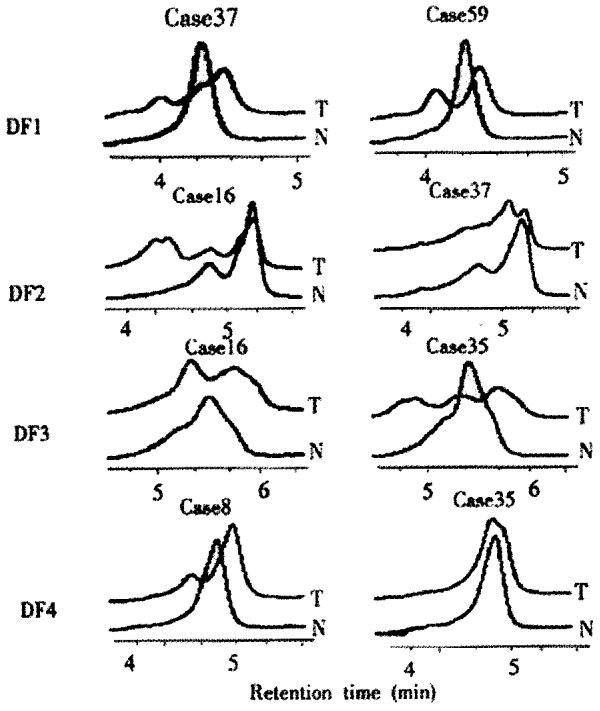

Figure 3 The representative DHPLC chromatograms of variant fragments detected blindly for patients with gastric cancinoma in D-loop of mtDNA. The chromatogram of tumor tissue is visibly different to that of its counterpart non-tumor tissue. The variant cases are listed on the top of each DHPLC chromatogram. DF1, DF2, DF3 and DF4 represent the tested fragments of D-loop respectively. T: tumor tissues; N: non-tumor tissues.

Table 2 The detected frequency of variance of mtDNA by using DHPLC

Fragments / Samples	A3243G			D-loop	
	MELAS	Other Encephal[a]	Normal blood	Tumor	Cell line
Positive / total fragments	10 / 12	0 / 72	0 / 30	26 / 184	38 / 52
Percent (%)	83.3	0	0	14.1	73.1

DISCUSSION

Mutation detection by DHPLC is performed at a temperature sufficient to partially denature the DNA heteroduplexes. The different retention times of hetero- and homoduplex on the DNASep matrix allow for high sensitivity and rapid detection[48,49]. In generally, the heteroduplex profile is easily distinguished from homoduplex peak.

Although the present data have showed that DHPLC is a convenient and sensitive method in mutation screening[17,22,24-26,28]. It may be a challenge to mutation detection of mtDNA because of complicated heteroplasmy in mitochondria[50,51] and various types of variances in mtDNA molecule. Due to hundreds to thousands mtDNA copies in a cell[52], the ratio of a special mutant to normal mtDNA is relatively low. However, a number of various variants may co-existence in a sample. For these reasons, sensitive and rapid detecting method is needed to distinguish different types of variances in large sets of mtDNA copies. We applied DHPLC to screen the mtDNA mutation in this study. Our data showed that DHPLC was a powerful screening strategy for mtDNA mutation. Firstly, about 80ng of PCR products with variant that could be identified by DHPLC were enough to UV detection limit. The heteroduplex peak was not visible when total PCR products were less than 50ng each injection. But the homoduplex peak could be satisfactorily detected. Next, about 5 percent of mutant products in PCR mixture were effectively discerned. These results indicated that DHPLC was sensitive to distinguish those minimal special variants from a large normal mtDNA. Finally, the results were reproducible.

In detection of A3243G mutation for MELAS patients, we proved our collaborators research. Ten variant samples identified by using restriction endonuclease ApaI were all distinguished by DHPLC. Heteroduplexes of tumor tissues obtained by DHPLC were also visibly different to that of non-tumor counterpart, when DHPLC was used to screen blindly the variances of D-loop of mtDNA in gastric cancer. These results also demonstrated that DHPLC, as same as research for nuclear DNA[25-27,29,34], was a sensitive method for mtDNA mutation screening.

As mutation detection of nucleus genes, several factors must be addressed when DHPLC is employed in mtDNA screening. These factors include primer design, PCR optimization, choice of optimal melting temperature or reverse-phase gradient[29,49,53] and DNA polymerase in this study. We find Taq polymerase may influence identification of mutation for DHPLC screening. Taq DNA polymerase tends to add a deoxyribonucleotide, preferentially dATP, to the 3'-hydroxyl terminus of a blunt-ended substrate, and the high-sensitivity of the WAVE system makes it capable of registering these A-tailed products to form an extra peak. In particular, the GC-rich small fragment with high Tm is easy to be influenced. Because the selected temperature of column oven is high, the retention time of heteroduplex will be reduced and the extra small peak is prone to form a false heteroduplex peak.

The concentration of dNTP in PCR reaction is factor of DHPLC resolution for heteroduplex detection. DNA molecules bind with the DNASep cartridge via the triethylammonium acetate (TEAA). The dNTP contends with DNA in interaction with TEAA and decrease DNASep cartridge's binding sites to TEAA-DNA complex. Therefore, ability of cartridge to bind with DNA and resolution of DHPLC will be reduced. In order to obtain improved resolution of DHPLC, it is necessary to elute the cartridge by 75% acetonitrile regularly.

In conclusion, DHPLC is a powerful screening method for mtDNA mutation because of its high-throughput, automation, sensitivity and high reproducibility.

ACKNOWLEDGMENT

We thank Dr. Z.X. Wan and J.J.Zhang for kindly providing of

mtDNA from MELAS and other known mutated samples. We also thank Dr. W.G. Liu, Assistant professor, Mayo Clinic, Rochester USA, for comments on the manuscript. This work was supported by the National Key Basic Science Research Program, No. G1998051203, and National Science Foundation of China (NSFC), No. 39602526.

Abstract

AIM: **To identify whether JTE-522 can induce apoptosis in AGS cells and ROS also involved in the process, and to investigate the changes in NF-kB, p53, bcl-2 and caspase in the apoptosis process.**

METHODS: **Cell culture, MTT, Electromicroscopy, agarose gel electrophoresis, lucigenin, Western blot and electrophoretic mobility shift assay (EMSA) analysis were employed to investigate the effect of JTE-522 on cell proliferation and apoptosis in AGS cells and related molecular mechanisms.**

RESULTS: **JTE-522 inhibited the growth of AGS cells and induced the apoptosis. Lucigenin assay showed the generation of ROS in cells under incubation with JTE-522. The increased ROS generation might contribute to the induction of AGS cells to apoptosis. EMSA and Western blot revealed that NF-kB activity was almost completely inhibited by preventing the degradation of IkBα. Additionally, by using Western blot we confirmed that the level of bcl-2 was decreased, whereas p53 showed a great increase following JTE-522 treatment. Their changes were in a dose-dependent manner.**

CONCLUSION: **These findings suggest that reactive oxygen species, NF-kB, p53, bcl-2 and caspase-3 may play an important role in the induction of apoptosis in AGS cells after treatment with JTE-522.**

INTRODUCTION

Apoptosis is an active cell death process, which requires specific gene regulation. A critical role for p53 in the execution of some forms of apoptosis has been suggested[1-6]. This protein is a sequence-specific DNA-binding protein, active as a transcription factor. It has been proposed that p53 may be involved in the cellular response to DNA damage, producing arrest in the G_1 phase of the cell cycle to allow efficient repair of DNA before entry to S phase, or cell death if the damage is too large to be repaired[7,8]. Another gene implicated in apoptosis is bcl-2. The bcl-2 gene product functions as an anti-apoptotic signal, suppressing apoptosis induced by a wide variety of stimuli, including chemotherapeutic drugs and γ radiation[9-13]. The exact mechanism of bcl-2 in preventing apoptosis is still not clear. However, bcl-2 has been implicated in cellular control of their redox state[14].

Previous studies have demonstrated that non-steroidal anti-inflammatory drugs (NSAIDs) given *in vivo* to rodents and human can inhibit tumor growth[15,16]. JTE-522 is a novel NSAIDs, which is a specific inhibitor of cyclooxygenase-2 (COX-2) with significant anti-inflammatory and analgestic properties[17]. Some reported that JTE-522 possesses strong chemopreventive activity against colon carcinogenesis[18], but the precise mechanism by which JTE-522 inhibits colon carcinogenesis is not clear. It is often attributed to specific inhibition of arachidonic acid metabolism via coxenzymes. However, recent studies showed that the antitumor effect had little connection with NSAIDs inhibitory activity against cyclooxygenase, and was not prevented by exogenous supplementation of 16,16-dimethyl prostaglandin E_2. Several groups have shown that certain NSAIDs induce apoptosis of tumor cell line, which is associated with the generation of reactive oxygen species (ROS)[19,20]. However, the signaling pathway leading to apoptotic cell death remains unclear.

ROS can play a central role in regulating cell proliferation and cell death. Evidence has been obtained that ROS such as superoxide and hydrogen peroxide can influence cell death triggered by internal cues (p53-mediated), external cues (TGF-beta-mediated) and immunogenic signals (TNF-alpha)[21,22]. In other instances, however, generation of ROS can inhibit apoptosis. Although the mechanism involved is still controversial, redox status and/or hydrogen peroxide have both been proposed as critical factors[19]. Therefore it is possible that ROS may play a role in regulating apoptosis in gastric epithehum.

The purpose of the present study is to identify whether JTE-522 can induce apoptosis in AGS cells and ROS are also involved in the process, and to investigate the changes in NF-kB, p53, bcl-2 and caspase in the apoptosis process.

MATERIALS AND METHODS

Cell line and reagents

Human gastric adenocarcinoma cell line AGS was provided by Cancer Institute, Zhongshan University. Cells were grown in RPMI-1640 medium and supplemented with 10% new bovine serum, penicillin G ($100kU.L^{-1}$) and kanamycin ($0.1g.L^{-1}$) at 37℃ in a 5% CO_2-95% air atmosphere. Antibodies used in this study included p53, bcl-2, IkBα and Beta actin were obtained from Santa Cruz. All other chemicals were purchased from Sigma Chemical Co (St. Louis,MO,USA).

MTT assay

AGS cells growing on 96-well plates were treated with JTE-522 (0.1 mmol/L - 1mmol/L) for 72h, untreated cells served as a control. 10μL of the $2.5g.L^{-1}$ stock solution of 3-[4, 5-dimethylthiaolyl]-2,

5-diphenyl-tetrazolium bromide (MTT) was added to each well. After 1h of incubation at 37℃, the medium was removed, 50μl of the extraction buffer (10% Trition-X100; 0.1mol/L HCl) was added, and plates were gently shaken for 30min at room temperature. The optical densities were measured at 570nm.

Morphological and biochemical analysis of apoptosis

Morphological changes in the nuclear chromatin of cells undergoing apoptosis were detected by electron microscopy (EM). Cells were peleted and fixed with 30mL/L glutaraldehyde in PBS. EM analysis was performed as described previously[23]. Oligonucleosomal cleavage of genomic DNA was detected by agarose gel electrophoresis. In brief, genomic DNA isolated as previously described[24] was subjected to 1.5% agarose gel electrophoresis, followed by ethidium bromide staining.

Assay for reactive oxygen species production

Generation of ROS was assessed using lucigenin. AGS cells grown in 75cm^2 culture flasks were incubated for 6h with JTE-522 (0.1-1mmol/L) in the presence or absence of 100μmol/L pyrrolidine dithiocarbamate (PDTC). The cells were then scraped off and washed in cold Hank's buffer. An aliquot containing 1×10^6 cells in 100μL of Hank's buffer was mixed in microtitrator wells with 100μl of lucigenin prepared at a concentration of 40μmol/L. Light emission was detected using a Berthold LB96V luminometer for 3min.

Assessment of caspase activity

Caspase-3 activity was measured using a caspase assay kit according to the supplier's instruction. In brief, caspase-3 fluorogenic substrates (Ac-DEVD-AMC or Ac-IETD-AMC) were incubated with JTE-522-treated with cell lysates for 1h at 37℃, then AMC liberated from Ac-DEVD-AMC or Ac-IETD-AMC was measured using a fluorometric plate reader with an excitation wavelength of 380nm and an emission wavelength of 420-460nm.

Western blot analysis

The cells were lysed in lysis buffer (25mmol/L hepes, 1.5% Triton X-100,1% sodium deoxycholate,0.1% SDS, 0.5mol/L NaCl, 5mmol/L EDTA, 50mmol/L NaF, 0.1mmol/L sodium vanadate,1mmol/L phenylmethylsulfonyl fluoride(PMSF),and 0.1g.L^{-1} leupeptin (pH7.8) at 4℃ with sonication. The lysates were centrifuged at 15000g for 15min and the concentration of the protein in each lysate was determined with Coomassie brilliant blue G-250.Loading buffer (42mmol/L Tris-HCl, 10% glycerol, 2.3% SDS, 5% 2-mercaptoethanol and 0.002% bromophenol blue) was then added to each lysate,which was subsequently boiled for 3min and then electrophoresed on a SDS-polyacrylamidel gel. Proteins were transferred to nitrocellulose and incubated sequentially with antibodies against IkBα, p53 and bcl-2 and then with peroxidase-conjugated secondary antibodies in the second reaction. Detection was performed with enhanced chemiluminescence reagent.

Electrophoretic mobility shift assay (EMSA)

Nuclear extracts were prepared from AGS cells treated with JTE-522. Synthetic double-strand oligonucleotides of consensus NF-kB binding sequence, GATCCCAACGGCAGGGGA, were end-labeled with [γ^{32}]ATP using T4 polynucleotide kinase. Nuclear extract was incubated with the labeled probe in the presence of poly (dI-dC) in a binding buffer containing 20mM N-2-hydrocyethylpiperazine-N'-2-ethanesulfonic acid at room temperature for 30min. For supershift assays, a total of 0.2μg of antibodies against p65 subunit of NF-kB were included in the reaction. DNA-protein complexes were resolved by electrophoresis in a 5% non-denaturing polyacrylamide gel, which was dried and visualized by autoradiography.

RESULTS

Effect of JTE-522 on cell proliferation and apoptosis

AGS cells were incubated with various does of JTE-522 for 72h. Analysis of cell viability using to MTT assay showed that JTE-522 significantly inhibited cell viability. The inhibition of cell viability was dependent on the dose of JTE-522 used (Figure 1).

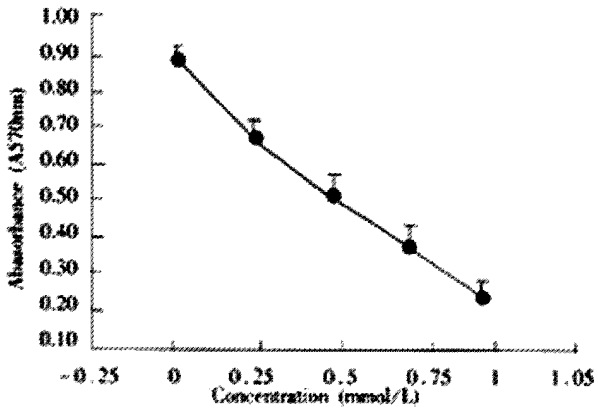

Figure 1 Effect of JTE-522 on cell growth in AGS cells. The cells were treated with various concentrations of JTE-522 for 72h. The antiproliferative effect was measured by MTT assay. Results are the means±SD from three independent determinations.

The effect was due to apoptosis as demonstrated by EM and electrophoresis of genomic DNA. JTE-522-treated cells showed compacted nuclear chromatin with finely granular masses marginated against the nuclear envelopeard condensed cytoplasm, the nuclear outline was convoluted and the organelles were preserved (Figure 2) and led to oligonucleosomal cleavage of genomic DNA (Figure 3), which were hallmarks of apoptosis.

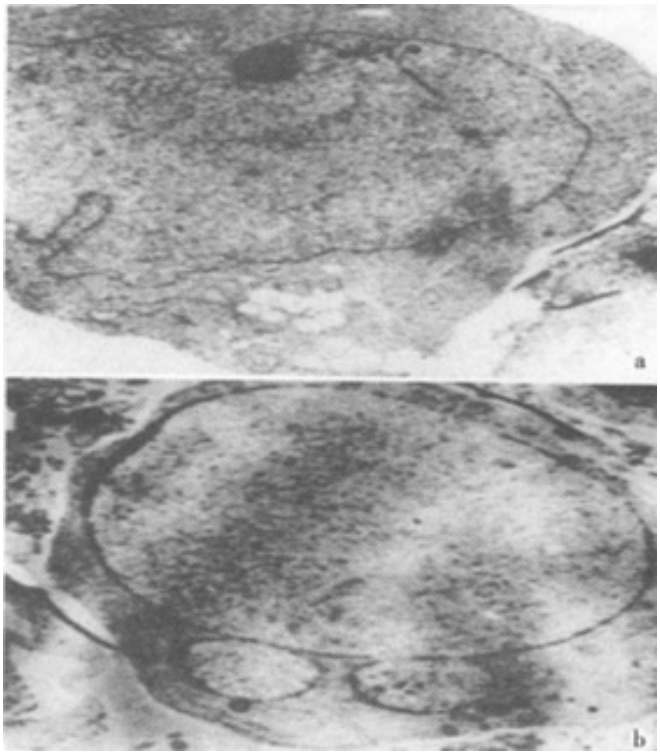

Figure 2 Electro micrographs of JTE-522-treated AGS cells. Control AGS cells (A), or treated with 1mmol/L (B) JTE-522 for 72h, were examined by EM as in "Materials and Methods". Magnification: ×4000

We next investigated whether the activaton of caspase was involved in JTE-522-induced apoptosis of AGS cells. JTE-522-induced apoptosis of AGS cells was accompanied by the induction of caspases activity as demonstrated by the cleavage of Ac-DEVD-AMC and Ac-IETD-AMC, respectively (Figure 4). These results indicated that JTE-522-induced cell death of AGS cells was a typical apoptosis associated with caspase activation.

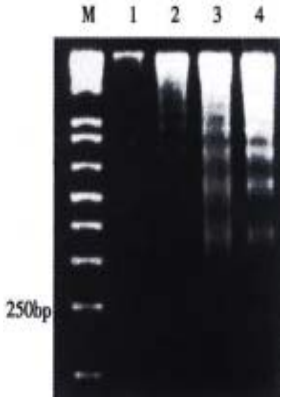

Figure 3 DNA ladder pattern formation of AGS cells. Cells treated with different concentrations of JTE-522 for 72h and uhe formation of oligonucleosomal fragments was determined by 1.5% agarose gel electrophoresis. M, DNA markers; lanes 1-4, AGS cells treated with 0, 0.25, 0.50, 1mmol/L of JTE-522

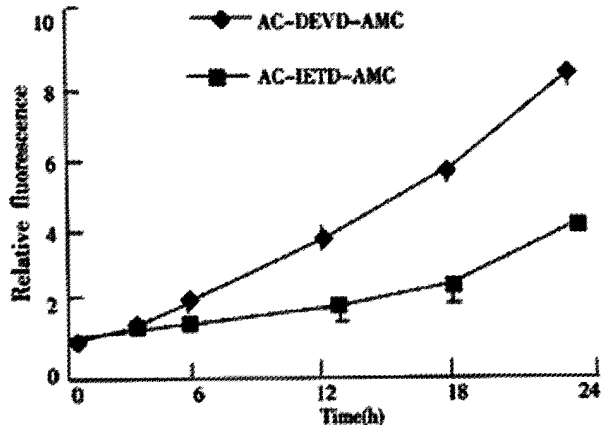

Figure 4 Activation of caspase-3 activities by JTE-522 in AGS cells for indicated time period. JTE-522 treatment (0.75mmol/L) induced cleavage of Ac-DEVD-AMC and Ac-IETD-AMC, indicating activation of caspase-3 activity, respectively

Effect of JTE-522 on the production of ROS in AGS cells

The effect of JTE-522 on the production of ROS in AGS cells, as assessed with lucigenin chemiluminesecence, was shown in Figure 5. Chemiluminesecence was significantly enhanced by incubation with various doses of JTE-522. This enhancement was prevented by co-incubation with PDTC at 100μmol/L. These results demonstrated the generation of reactive oxygen species in cells under incubation with JTE-522.

Effect of JTE-522 on the expression of p53, bcl-2, IkBα and the activation of NF-kB

NF-kB plays a complex role in regulating programmed cell death. In many instances the inhibition of NF-kB activaty can sensitize cells to death inducers[25]. In other instances, however, NF-kB activation has been found to play an important role in the induction of apoptosis. To determine whether the treatment with JTE-522 have any effect in the NF-kB transcriptional factors. We performed EMSA with nuclear extracts prepared from control or treated cells exposed to JTE-522 for various concentrations for 6h. The NF-kB specific complexes found in this cell line were almost complete inhibited in comparision with untreated cells (Figure 6A). In accordance with result, an analysis of IkBá proteins level by Western blot demonstrated that the degradation of this protein was greatly inhibited during the apoptotic process(Figure 6B).

Additionally, by using Western blot we confirmed that the level of bcl-2 was decreased, whereas p53 showed a great increase following JTE-522 treatment. Their changes were in a dose-dependent manner (Figure 7).

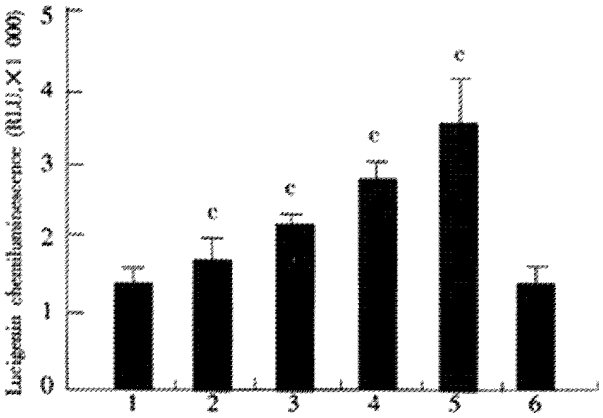

Figure 5 Effect of JTE-522 on the generation of ROS. AGS cells were incubated for 6h with JTE-522 (0.25-1mmol/L) in the presence or absence of PDTC at 100μmol/L. Lucigenic-associated chemiluminescence was measured for 3min with a lumirometer. (A). Lane 1: control; lane 2-5: AGS cells treated with 0.25, 0.5, 0.75, 1mmol/L of JTE-522; lane 6: JTE-522 (1mmol/L) +PDTC (100μmol/L) $^cP<0.01$ *vs* control. Results are the means±SD from three independent determinations.

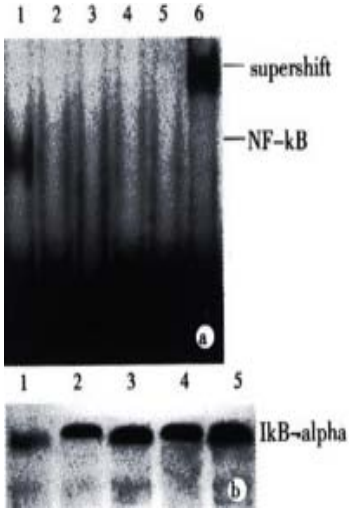

Figure 6 Effect of JTE-522 on NF-kB binding activity and IkBα degradation. Cells were treated with JTE-522 for 6h. Cells were harvested and EMSA was performed as described (A). Lane 1: control; lane 2-5: AGS cells treated with 0.25, 0.50, 0.75, 1mmol/L of JTE-522. The identity of DNA-complexed proteins was confirmed by supershift assays using antibodies against p65 subunit of NF-kB (lane 6). Immunobolt analysis of IkBα of corresponding cytosilic supernatant (B). Representative results from four independent experiments.

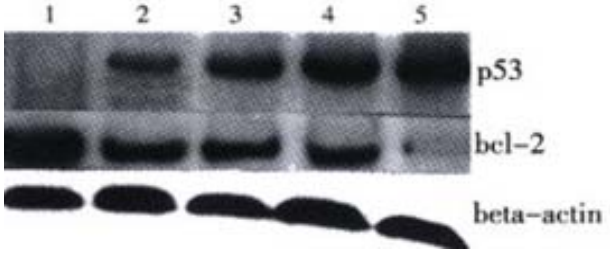

Figure 7 P53, bcl-2 protein levels in AGS cells treated with JTE-522. Cell lysates were collected and processed at 6h. The whole cellular protein was electrophoresed in SDS-PAGE gel, Western blot was performed using antibodies against p53, bcl-2. Beta actin was used as a lane-loading control. (1) control; (2) 0.25mmol/L; (3) 0.5mmol/L; (4) 0.75mmol/L; (5) 1 mmol/L. Representative results from three independent experiments.

DISCUSSION

Using cultured AGS human gastric adenocarcinoma cells, the observations described in this study demonstrate that JTE-522, a novel NSAIDs inhibits the growth of AGS cells and induces apoptosis in a concentration-dependent manner.

The onset of apoptosis is associated with the proteolytic activation of caspases. Caspases, a family of cysteine proteases, play a critical role in the execution of apoptosis[26-31]. They are synthesized as proenzymes that are processed by self-proteolysis and/or cleavage by another protease to their active forms in cells undergoing apoptosis Caspase-3 is a major executioner of apoptosis. It is promoted during the early stage of apoptosis and the activated form is a marker for cells undergoing apoptosis[32]. After activation by initiators, the proform (p32) is cleaved to the active forms p20, p17, or p11, respectively[33]. Therefore, activation of caspase-3 in AGS cells in this study not only indicated the occurrence of apoptosis, but also implied the involvement of caspase-3 in JTE-522-induced apoptosis.

ROS have been found to play a central role in regulating apoptosis in numerous instances. Given that reduced rates of apoptosis may contribute to carcinogenesis, the regulation of cellular ROS production may be an important variable in the development of neoplasias. Other studies have also suggested a potential role for ROS in cancer suppression. For example, the p53 tumor suppressor protein activates the expression of ROS-generating proteins that increase cellular ROS production and eventually trigger apoptosis[34,35]. Increased ROS generation by chemopreventive agents may serve to compensate the lower levels of ROS generation in p53 null cells (AGS cells are p53 null)[36,37]. Animal studies have also implicated ROS in regulating carcinogenesis. Mice with elevated levels of glutathione peroxidase are more sensitive to skin carcinogenesis than their wild type counterpart [32]. A similar correlation has been made in the colon, where strains with higher levels of glutathione peroxidase activity have a higher cancer risk. The role of ROS in carcinogenesis is however likely to be complex given the potential mutagenicity of ROS. For example, the NSAIDs inhibition of cyclooxygenase has been proposed to suppress carcinogenesis by suppressing the production of peroxyl radicals and the subsequent formation of mutagenic lipid peroxidation breakdown products[38]. The role of ROS in carcinogenesis may depend on the relative levels of different ROS generated, and where and when they are present. However, as demonstrated in this paper, we showed that JTE-522 increased ROS generation in AGS cells, and this increased ROS generation might contribute to the induction of AGS cells to apoptosis.

The bcl-2 protooncogene is unique among cellular genes for its ability in many contexts to block apoptotic cell death. A mechanism has been proposed in which bcl-2 regulates antioxidant pathways at sites of free radical generation[39]. The protein of bcl-2 also protects against apoptosis by blocking cytochrome C release hence this protein may have an antioxidant function[40]. In our experiment, the expression of bcl-2 decreased, and the p53 protein upregulated following JTE-522 treatment, these changes may implies that intracellular ROS may interfere with the expression of bcl-2 and p53, thereby contributing to inducing apoptosis in AGS cells.

In studying the mechanism by which the NSAIDs influenced cell death, common effects on the transcription factor NF-kB were noted. The NF-kB transcription factor is ubiquitous and can be detected under its inactive form in the cytoplasm of almost all cell types[41,42]. It supresses the expression of cytokines, chemokines, growth factors, cell adhesion molecules, and some acute phase proteins in health and various pathological states[43,44]. Experimental data clearly indicate that NF-kB is a major regulator of the inflammatory reaction by controlling the expression of pro-inflammatory molecules in response to cytokines oxidatives stress and infectious agents[45,46]. NF-kB is maintained under such an inactive cytoplasmic form by virtue of its association with an inhibitory molecule named IkB. IkBα is the best characterized member of this family. In our current work, EMSA revealed that JTE-522 inhibited NF-kB activation. Western blot experiments demonstrated that this effect was mediated by inhibition of IkBα degradation. Determining the role of NF-kB in gastric carcinogenesis could help to guide the development of improved chemoprevention and treatment strategies.

In summary, JTE-522 inhibited cell growth and induced apoptosis in AGS cells. Increased ROS may play an important role in this caspase-3 mediated apoptotic process. The inhibition of NF-kB by JTE-522 may be mediated by preventing IkBα degradation. The precise relationship and importance of each of these factors in the apoptotic process should be established by more direct and profound analysis.

Abstract

AIM: **To investigate the effects of antisense human telomerase RNA (hTR) on the biologic behavior of human gastric cancer cell line: MKN-45 by gene transfection and its potential role in the gene therapy of gastric cancer.**

METHODS: **The hTR cDNA fragment was cloned from MKN-45 through RT-PCR and subcloned into eukaryotic expression vector (pEF6/V5-His-TOPO) in cis-direction or trans-direction by DNA recombinant methods. The constructed sense, antisense and empty vectors were transfected into MKN-45 cell lines separately by lipofectin-mediated DNA transfection technology. After drug selection, the expression of antisense hTR gene in stable transfectants and normal MKN-45 cells was detected by RT-PCR, the telomerase activity by TRAP, the apoptotic features by PI and Hoechst 33258 staining, the cell cycle distribution by flow cytometry and the population doubling time by cell counting. Comparison among the stable transfectants and normal MKN-45 cells was made.**

RESULTS: **The sense, antisense hTR eukaryotic expression vectors and empty vector were successfully constructed and proved to be the same as original design by restriction endonuclease analysis and sequencing. Then, they were successfully transfected into MKN-45 cell lines separately with lipofectin. The expression of antisense hTR gene was only detected in MKN-45 cells stably transfected with antisense hTR vector (named as MKN-45-ahTR) but not in the control cells. In MKN-45-ahTR, the telomerase activity was inhibited by 75%, the apoptotic rate was increased to 25.3%, the percentage of cells in the G0/G1 phase was increased to 65%, the proliferation index was decreased to 35% and the population doubling time was prolonged to 35.3hours. However, the telomerase activity, the apoptotic rate, the distribution of cell cycle, the proliferation index and the population doubling time were not different among the control cells.**

CONCLUSION: **Antisense hTR can significantly inhibit telomerase activity and proliferation of MKN-45 cells and induce cell apoptosis. Antisense gene therapy based on telomerase inhibition can be a potential therapeutic approach to the treatment of gastric cancer.**

INTRODUCTION

Gastric cancer is a very common tumor in China. More and more patients with gastric cancer can now be found in early stage because of the improvement of the technology of diagnosis[1]. Although surgery and chemotherapy are effective for these patients with localized tumors, the prognosis of patients having advanced or metastatic tumors is not ideal[2-6]. As a result, it is absolutely necessary to explore a novel modality of treatment. Fortunately, with the development of molecular biology, medicine is on the brink of a new era-that of molecular genetic medicine. People are now equipped with a new and powerful weapon: gene therapy which was previously only the stuff of dreams and scientific fantasy to fight against disease. Just like other kinds of cancer, the gastric cancer is now recognized as a genetic disease. The gastric cancer cells contain many genetic alterations (caused by some pathogenic agents such as Helicobacter pylori) which accumulate as tumor develop[7-28]. This makes it possible to treat cancer with gene therapy[29,30]. Because the target aimed by the gene therapy is undoubtedly the abnormal gene, thus, the task to find an effective target gene directed against by the gene therapy is becoming increasingly important and urgent. Human telomerase is a ribonucleoprotein which can add the telomeric repeats (TTAGGG) to the ends of the chromosome to maintain the telomere length using its integral RNA component (hTR) as a template[31,32]. Initially identified in HeLa cell extracts, human telomerase has been detected in immortalised cell lines and more than 85% of tumors while normally quiescent in normal somatic cells (except for proliferative cells of renewable tissues such as activated lymphocytes)[33-35]. It is suggested that cancer cells maybe achieve cellular immortality, an important characteristic of cancer cell, through the reactivation of telomerase[36,37]. The seemingly essential roles of telomerase in maintaining telemere length, ensuring chromosome integrity and its nearly ubiquitious reactivation in human cancers have made telomerase a new therapeutic target for anticancer therapy[38,39]. It was reported that HeLa cells transfected with an antisense hTR lost telomeric DNA and began to die after 23 to 26 doublings. Accordiog to a recent review, telomerase activity was also detected in 85-88% of gastric carcinomatous tissues. To gastric cancer, hTR was expressed at a higher level in the tumor than that in the corresponding mucosa and tumors with telomerase activity were generally large in size with a high frequency of lymph node metastasis. Moreover, the patients with telomerase-positive tumors shared poorer prognosis than those with telomerase-negative tumors[40-45]. However, whether antisense gene therapy directed against telomerase will be useful in gastric cancer is so far unknown. We describe here the biologic behavior changes in MKN-45 cell line, a human gastric cell line, after transfected with antisense hTR expression vector and investigate the potential value of telomerase as a target fos antisense gene therapy in gastric cancer.

MATERIALS AND METHODS

Cell Culture

MKN-45 cell, a human gastric cancer cell line, was obtained from Shanghai institute of Cell Biology, Chinese Academy of Sciences. The cells were routinely cultured in RPMI-1640 media (Gibco BRL) supplemented with 10% heat-inactivated fetal bovine serum (Gibco BRL), 100u/ml penicillin and 100u/ml streptomycin in an atmosphere consisting of 5% CO_2 in air at 37℃ in a humidified incubator.

Construction of sense and antisense hTR eukaryotic expression vector

The hTR cDNA fragment was cloned from MKN-45 cell line through RT-PCR and subcloned into eukaryotic expression vector: pEF6/V5-His-TOPO vector (Invitrogen) in cis-direction or trans-direction by using DNA recombinant methods as described previously[46]. They were all proved to be the same as original design by restriction endonuclease analysis and sequencing. The sense, antisense and empty vectors were named as pEF-hTR, pEF-ahTR and pEF-empty correspondingly.

Transfection of eukaryotic expression vector

Stable transfection of pEF-hTR, pEF-ahTR and pEF-empty was carried out by standard lipofection mediated DNA transfection method. In brief, approximately 1.5×10^5 MKN-45 cells were transfected with 2μg vector DNA that had been complexed with 20μl lipofectin reagent (Gibco BRL). Two days after the transfection, the stable transfectants were selected by 2μg/ml blasticidin (Invitrogen) in the culture media. They were named as MKN-45-hTR, MKN-45-ahTR and MKN-45-empty correspondingly.

In addition, the pEF6/V5-His-TOPO/lacZ vector (pEF6/V5-His-TOPO vector carrying the reporter gene: lacZ gene in its multi cloning sites, provided by Invitrogen) was transfected into MKN-45 cells and selected by the same method as described above. It was named as MKN-45-lac correspondingly.

RT-PCR for detecting antisense hTR expression

Total RNA was extracted from the transfectants and normal MKN-45 cells using Trizol reagent (Gibco BRL). One microgram of total RNA was reversetranscribed with ahTR specific primer1 (5'-gaacgggccagcagctgacat-3') using THERMOSCRIPT RT-PCR system for first-strand cDNA synthesis (Gibco BRL). The RT condition was set for 65℃, 30min→85℃, 5min. Then, the cDNA was amplified with the PCR using PLATINUM Taq DNA polymerase (Gibco BRL) and employing ahTR specific primer1 and primer2 (5'-gggttgcggagggtgggcct-3'). The PCR conditions were set for 94℃, 2min→94℃, 20s;69℃, 20s;72℃,20s;30 cycles→72℃,2min. The product length is 196bp. The G6PDH was co-reversetranscribed empolying G6PDH specific primer1 (5'-cgccccttttcctcccccctcgtc-3') and co-amplified with PCR using G6PDH specific primer1 and primer2 (5'-cccgcccctcgctgctgctactac-3') as internal control. The product length is 247bp. Each RT-PCR product was electrophoretically separated in 2% agarose with EtBr.

β-Gal staining

The MKN-45 cells stably transfected with pEF6/V5-His-TOPO/lacZ vector were subjected to β-Gal staining by using β-Gal Staining Kit (Invitrogen) to detect whether the vector could effectively express lacZ gene.

Apoptotic features

To determine whether MKN-45-ahTR transfected with the pEF-ahTR vector displayed an apoptotic morphology, it was stained with the DNA binding fluorochrome bis (benzimide) trihydro-chloride, Hoechst 33258 (provided by Shanghai institute of Immunology) and observed under UV florescence microscope.

To determine the apoptotic rate and cell cycle distribution, the MKN-45-ahTR and control cells were stained with PI and analysed by flow cytometry.

Telomerase activity assay

Telomerase activity was measured using the commercially available $TRAP_{EZE}$ Telomerase Detection Kit (Intergen). In brief, the cell extract was made according to the protocol provided, then 2μl of the cell extract was added to 48μl of the reaction mixture containing 10× TRAP Reaction Buffer, 50× dNTP Mix, TS Primer, TRAP Primer Mix, Taq Polymerase and dH_2O in amounts and types specified by the $TRAP_{EZE}$ Telomerase Detection Kit. After centrifuged briefly, this mixture was incubated at 30℃ for 30min to allow telomerase elongation of the TS primer and then subjected to PCR amplification in a thermal cycler for 35 cycles: 94℃ for 30s;59℃ for 30s and 72℃ for 30s. The product was then electrophoresed on a 12.5% non-denaturing PAGE (without urea). After electrophoresis, the gel was stained with SYBR Green I (Molecular Probes) according to the manufacturer's instructions.

Quantification of telomerase product was calculated using BIO-RAD Fluor-S™ MultiImager and the formula (discussed in detail in the $TRAP_{EZE}$ Telomerase Detection Kit instruction booklet).

$$TPG(units)=\frac{(\chi-\chi_o)/c}{(\gamma-\gamma_0)/c_R}\times100$$

Abbreviation in the above formular is as follows: TPG, total product generated; χ, sample signal; χ_0, heat-inactivated control; γ, 0.1 amole quantitation TSR8 control; γ_0, 1× CHAPS Lysis Buffer only control; c, sample internal standard band; c_R, 0.1 amole quantitation TSR8 internal standard band.

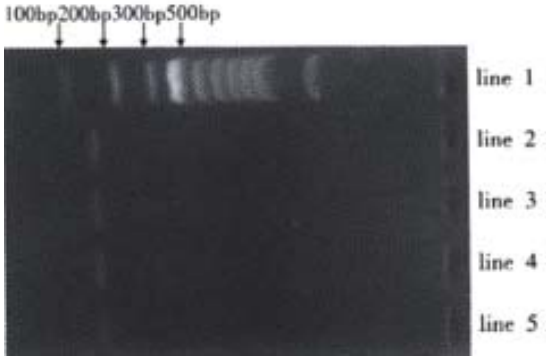
Cell growth curve and population doubling time

Cells were seeded at a density of 2×10^5 per 25ml flask in 1.5ml of cell culture media. The number of cells per flask was counted every day for 6 days. The population doubling time of cells transfected with pEF-hTR, pEF-ahTR and pEF-empty and normal MKN-45 cells were calculated and the cell growth curve was drawn.

RESULTS

Expression of antisense hTR gene in MKN-45 cells

We transfected MKN-45 cells with pEF-hTR, pEF-ahTR and pEF-empty vector respectively, following the blasticidin selection, the drug resistant cells were collected and RT-PCR was performed with antisense hTR specific primers. We detected the ahTR specific product only in the pEF-ahTR vector transfected cells but not in the pEF-hTR, pEF-empty vector transfected cells and parental cells. However, steady state expression of G6PDH (as internal control) was observed in all cells.



Line 1: 100bp DNA Ladder (Promega), Lane 2: normal MKN-45, Lane 3: MKN-45-hTR, Lane 4: MKN-45-empty, Lane 5: MKN-45-ahTR

Figure 1 The expression of antisense hTR gene.

Only the cells transfected with pEF-ahTR expressed the antisense hTR, however, the G6PDH was detected in all samples that indicated an appropriate RT-PCR reaction.

β-Gal staining

After drug selection, nearly all MKN-45 cells stably transfected with pEF6/V5-His-TOPO/lacZ vector were stained blue by β-Gal Staining Kit while parental cells were not.

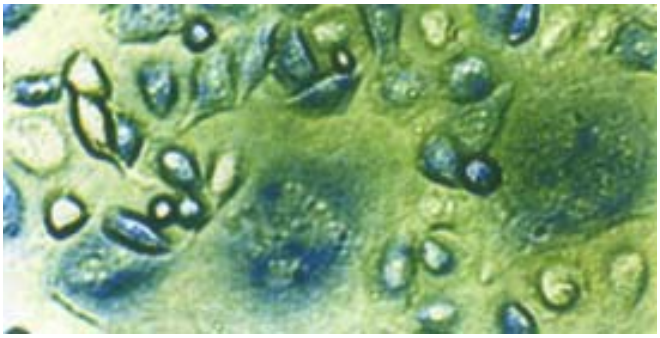


Figure 2 The result of β-Gal staining of MKN-45-lac. (×600)

Telomerase activity

We measured telomerase activity of the pEF-hTR, pEF-ahTR and pEF-empty transfected MKN-45 cells and parental cells through TRAP method described above. It was found that the level of telomerase activity in the pEF-ahTR transfected MKN-45 cells was greatly inhibited, compared with that in the parental MKN-45 cells. However, there was no difference between the level of telomerase activity in the pEF-hTR, pEF-empty transfected MKN-45 cells and parental MKN-45 cells.

Figure 3A Detection of telomerase activity with the telomeric repeat amplification protocol (TRAP) assay. A 36bp internal control band present in all samples indicated an appropriate polymerase chain reaction (PCR).

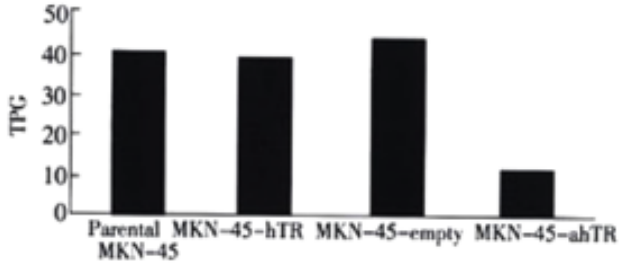

Figure 3B Comparison of telomerase activity in MKN-45-ahTR and control cells. Compared with control cells, the telomerase activity in MKN-45-ahTR was inhibited by about 75%.

Cellular effects of telomerase inhibition

As Figures 4, 5 and Table 1 showed, compared with controls cells, the MKN-45-ahTR cell displayed a longer population doubling time, an increased percentage of cells in the G0/G1 phase, a lower cell proliferation index and a higher apoptotic rate, which demonstrated that, through inhibiting telomerase activity, antisense hTR gene transfection could inhibit the proliferative capacity of NKN-45 and induce cell apoptosis.

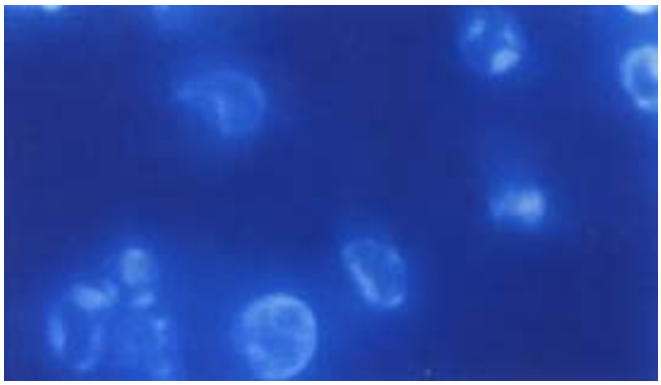

Figure 4 Hoechst 33258 staining of MKN-45-ahTR. (×600)
The cells undergoing apoptosis demonstrated apoptotic chromatin changes: blebbing, fragmentation and condensation under fluorescence microscope.

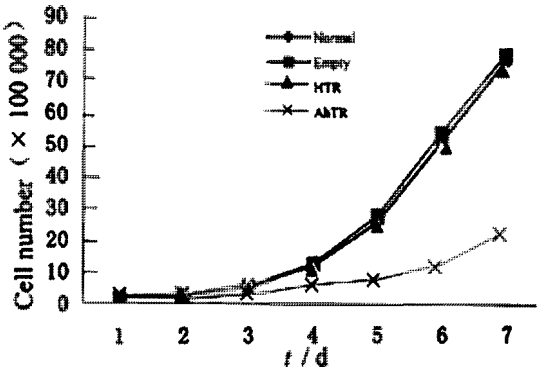

Figure 5 Cell growth curve.

Table 1 Comparison of distribution of cell cycle, cellular proliferation index, apoptotic rate,population doubling time of MKN-45-ahTR and those of control cells

	Distribution of cell cycle (%)			cell proliferation index (%)	Apoptotic rate (%)	population doubling time (hours)
	G0/G1	S	G2/M			
MKN-45-ahTR	65	34.2	0.8	35	25.3	35.3
MKN-45-hTR	55.7	37.5	6.8	44.3	0	23.2
MKN-45-empty	54.1	38.4	7.5	45.9	0	22.7
normal MKN-45	54.7	37.8	7.5	45.3	0	22.9

DISCUSSION

Compared with normal somatic cells, which reach the end of their replicative capacity after a limited number of population doubling and enter a senescence phase, the cancer cells have an unlimited replicative capacity. This important characteristic of cancer, named immortality, is gaining more and more attention, seeing that cancer cells may achieve cellular immortality through only a major pathway: activation of the telomerase[47].

Telomerase is a unique ribonucleoprotein that can synthesize telomeric DNA onto chromosomal ends using a segment of its RNA component (hTR) as a template to compensate for the lose of telomeric repeats (TTAGGG) caused by the so-called "end-replication" problem. Recent Study demonstrated that 758 of 895 (85 %) of malignant tumors but none of 70 normal somatic tissues

expressed telomerase activity. In addition, the level of telomerase activity influences the prognosis of patient to a certain degree. For example, high level of telomerase correlates with poor clinical outcome in neuroblastoma, while patients with metastatic IV-S neuroblastoma without telomerase activity experiences spontaneous regression of tumors. These findings indicate that telomerase plays an important role in carcinogenesis and therefore undoubtedly become the basis of the widely held view of telomerase as a highly selective target for antisense gene therapy of cancer[48].

The RNA component of telomerase (hTR) is crucial to the telomerase activity[49-51]. Human cell lines that expressed hTR mutated in the template region generated the predicted mutant telomerase activity. In addition, recent experiments have shown that antisense gene therapy directed against telomerase RNA component (hTR) could effectively inhibit telomerase activity and induce apoptotic cell death in ovarian cancer, prostate cancer, bladder cancer, malignant gliomas and human breast epithelial cells[52-56]. However, whether such anti-cancer effect can be obtained in human gastric cancer is still unknown. Therefore, we examined the effect of antisense hTR (ahTR) expression on the growth of human gastric cancer cell line:MKN-45 through transfection of an ahTR expression vector.

Given that whether the vector can effectively and stably express the exogenous gene it carries will directly influence the effect of antisense gene therapy. Firstly, we adopted two different methods to detect the expression of exogenous gene by the pEF6/V5-His-TOPO vector before conducting other experimental items. The first one was to detect the expression of reporter gene. pEF6/V5-His-TOPO/lacZ vector is the same as the pEF6/V5-His-TOPO vector except that the former carrying lacZ gene, a kind of widely used reporter gene, in its multi cloning sites. Usually by using â-Gal staining method, the researchers can easily detect the expression of lacZ gene through which they further evaluate the ability of the vector's promoter to express the exogenous gene. We found that nearly all cells stablely transfected with pEF6/V5-His-TOPO/lacZ vector were stained blue while control cells were not. Therefore, we believed that pEF6/V5-His-TOPO/lacZ vector could effectively express the exogenous gene (lacZ gene) it carried, so did the pEF6/V5-His-TOPO vector. The second one was to detect the expression of antisense hTR gene directly through RT-PCR method. Only the cells transfected with pEF-ahTR expressing the antisense hTR gene were found. Both the results proved that pEF6/V5-His-TOPO vector could effectively express the exogenous gene, thus laying the solid fundament for the study of following experimental items.

As the results showed, the most significant conclusions we could draw from this study were that telomerase in human gastric cancer cell line: MKN-45 could be inhibited by a vector expressing mRNA complementary to the template region of hTR and that the growth of cancer cells was retarded and cell apoptosis was induced after telomerase was inhibited by this method. Therefore, our experiment clearly demonstrated that blocking the RNA component of telomerase with antisense hTR expression vector appeared to be a rational approach to the treatment of gastric cancer. The telomerase may become an ideal target for antisense gene therapy in human gastric cancer.

However, it is noticeable that not all cells transfected with antisense hTR gene underwent apoptosis, and underlying mechanism is still unknown. The possible reason is that the carcinogenesis process is complicated and the reactivation of telomerase may play an important but by no means the sole role during this process. Many oncogenes and tumor suppressor genes are also involved in tumorigenesis[57,58]. While believed to be necessary for cancer cells to grow without limit, telomerase is not sufficient to transform a normal cell into a tumor cell. Thus, anti-cancer effect of antisense gene therapy will be more satisfactory if multitargets are aimed. For example, a recent report showed that the combination of 2-5A-anti-hTR and Ad5CMV-p53 had greater anti-tumor efficacy against all p53-mutant glioma cells than each treatment alone[59]. Seeing that telomerase activity and p53 dysfunction are also detected in gastric cancer[60,61], this approach may be effective in treating gastric cancer patients too and the similar investigation is being conducted in our laboratory now.

Abstract

AIM: **To investigate the expression and function of classical protein kinase C (PKC) isoenzymes in inducing MDR phenotype in gastric cancer cells.**

METHODS: **Two cell lines were used in the study: gastric cancer cell SGC7901 and its drug-resistant cell SGC7901/VCR stepwise-selected by vincristine 0.3, 0.7 and 1.0mg·L^{-1}, respectively. The expression of classical PKC (cPKC) isoenzymes in SGC7901 cells and SGC7901/VCR cells were detected using immunofluorescent cytochemistry, laser confocal scanning microscope and Western blot. The effects of anti-PKC isoenzymes antibody on adriamycin accumulation in SGC7901/VCR cells were determined using flow cytometric analysis.**

RESULTS: **(1) SGC7901 cells exhibited positive staining of PKC-α. SGC7901/VCR cells exhibited stronger staining of PKC-α than SGC7901 cells. The higher dosage vincristine selected, the much stronger staining of PKC-α was observed on SGC7901/VCR cells. (2) Both SGC7901 and SGC7901/VCR cells exhibited positive staining of PKC-βI and PKC-βII with no significant difference. (3) Compared with SGC7901, SGC7901/VCR cells had decreased adriamycin accumulation and retention. Accumulation of adriamycin in SGC7901 was 5.21±2.56mg·L^{-1},in SGC7901/VCR 0.3 was 0.85±0.29 mg·L^{-1}, in SGC7901/VCR 0.7 was 0.81±0.32mg·L^{-1}, and in SGC7901/VCR 1.0 was 0.80±0.33mg·L^{-1}; Retention of adriamycin in SGC 7901 was 2.51±1.23mg·L^{-1}, in SGC7901/VCR 0.3 was 0.47±0.14mg·L^{-1}, in SGC7901/VCR 0.7 was 0.44±0.15mg·L^{-1}, and in SGC 7901/VCR 1.0 was 0.41±0.11mg·L^{-1}. (4) Fluorescence intensity presented adriamycin accumulation in SGC7901/VCR cells was increased from 1.14±0.36 to 2.71±0.94 when cells were co-incubated with anti-PKC-α but not with anti-PKC-βI, PKC-αII and PKCγ antibodies.**

CONCLUSION: **PKC-α, but not PKC-βI, PKC-βII or PKCγ, may play a role in multidrug resistance of gastric cancer cells SGC7901/VCR.**

INTRODUCTION

Multi-drug resistance (MDR), the principal mechanism by which many cancers develop resistance to a variety of chemotherapeutic drugs, is a major factor in the failure of many forms of chemotherapy[1-4]. It affects patients with numerous blood cancers and solid tumors. Cellular drug resistance is mediated by different mechanisms operating at different steps of the cytotoxic action of the drug from a decrease of drug accumulation in the cell to the abrogation of apoptosis induced by the chemical substance. Several different mechanisms will switch on in the MDR cells, but usually one major mechanism is operating. The most investigated mechanisms with known clinical significance are: (1) activation of transmembrane proteins effluxing different chemical substances from the cells, in which P-glycoprotein (P-gp) is the most known efflux pump; (2) activation of the enzymes of the glutathione detoxification system; (3) alterations of the genes and the proteins involved into the control of apoptosis (especially p53 and Bcl-2)[5-12]. PKC comprises a family of at least 13 distinct serine/threonine kinase isoenzymes involved in signal transduction pathways that govern a wide range of physiological processes including differentiation, proliferation, gene expression, brain function, membrane transport and the organization of cytoskeletal and extracellular matrix proteins[13-26]. Recently accumulated evidence indicates that PKC activity, especially cPKC, plays a significant role in the formation of tumor MDR. The isoenzymes possess distinct differences in localization in different cells. Within a single cell, PKC isoforms also exhibit differences in expression and function, so research on distinct function in tumor MDR of isoenzymes has important significance in screening drugs with high specificity that could reverse MDR and in disclosing the mechanism of MDR formation and its regularity of the reversion.

MATESIALS AND METHODS

Materials

Human gastric cancer cell line SGC7901 was reserved by our institute and its drug-resistant sublines SGC7901/VCR were stepwise-selected by vincristine 0.3, 0.7 and 1.0mg·L^{-1}, respectively. RPMI 1640 medium was the product of Gibco (U.S.A.). Newborn bovine serum was purchased from Hyclone (U.S.A.). Chemical drugs vincristine and adriamycin were purchased from Farmitalia Carlo Erba

(U.S.A.) and Minsheng (Hangzhou, China). Rabbit-anti-human polyclonal antibody PKC-α, PKC-βI, PKC-βII and PKCγ were the products of Santa Cruz Biotechnology. SABC immunohischemistry kit and the HRP labeled goat-anti-rabbit IgG was purchased from Boste (Wuhan, China). FITC labeled goat-anti-rabbit IgG was purchased from Zhongshan (China).

Methods

Immunofluorescent cytochemistry The expression of PKC isoenzymes were detected by routine immunocytochemical fluorescence method[27,28].The procedures were as follows. Cells were maintained at 37℃ in a 50mL·L^{-1} CO_2-humidified incubator in RPMI 1640 medium supplemented with 25mmol·L^{-1} HEPES buffer and 100mL·L^{-1} new born bovine serum. SGC7901/VCR cells were cultured in the medium with extra adding vincristine at the concentration of 0.3, 0.7 and 1.0mg·L^{-1}, respectively. Cells at exponential phage were harvested, digested by 2.5g·L^{-1} trypsin and then cultured on the slides in the medium described above at 37℃ for further 24h; RPMI 1640 medium was then washed by PBS and cells were fixed in cold acetone for 5min; 50mL·L^{-1} H_2O_2 was added and incubated at room temperature for 10-15min and added 3g·L^{-1} TritonX-100 for another 15min; normal goat serum (1:10) was added and incubated at room temperature for 30min; rabbit-anti-human polyclonal antibody PKC-α, PKC-βI, PKC-βII and PKCγ (1:100) were added respectively and incubated at 4℃ over night; FITC labeled goat-anti-rabbit IgG was added and incubated at 37℃ for 1h; the slides were sealed by 500mL·L^{-1} glycerin buffer and observed with a fluorescence microscope. Unrelated monoclonal antibody and PBS were used as negative controls.

Laser confocal scanning microscope The laser confocal scanning microscope protocols used were as described[29,30].Methods of cell culture and stain with Ab were carried out as described in immunocytochemical fluorescence method. FITC labeled goat-anti-rabbit IgG was added in the darkness and incubated at room temperature for 3h; the slides were sealed by 500mL·L^{-1} glycerin buffer and observed with a laser confocal scanning fluorescence microscope. Unrelated monoclonal antibody and PBS were used as negative controls.

SDS-PAGE According to Chen et al and Xiao *et al*[31-33], cells at exponential phase were harvested and washed by cold PBS and suspended in extraction buffer (50mmol·L^{-1} Tris-Cl (pH7.5), 150mmol·L^{-1} NaCl, 0.2mmol·L^{-1} EDTA, 1mmol·L^{-1} PMSF and 10g·L^{-1} NP-40). The homogenate was heated for 5min in a boiling water bath and then centrifuged. The supernatants were harvested and the protein concentrations were assayed by Bradford method. 150μg total protein were electrophoresed on SDS-polyacrylamide gels with the stacking and the separating gels containing 50 and 100g·L^{-1} acrylamide, respectively, and the gels were stained with Coomassie brilliant blue dye.

Western blot analysis According to She *et al* [34],after SDS-PAGE, proteins were transferred onto nitrocellulose membrane under a constant current of mA for 1h. Non-specific binding sites were blocked by PBS with 50mL·L^{-1} milk plus 1g·L^{-1} Tween-20 at room temperature. Primary and secondary antibodies were rabbit-anti-human polyclonal antibody PKC and HRP labeled goat-anti-rabbit IgG, respectively. Films were exposed in DAB detection reagent to develop color of bands.

Flow cytometric analysis According to Jiang *et al*[35] and Feng *et al*[36], cells were cultured in 6-well culture plates at 37℃ for 48h, adriamycin was added to the final concentration of 5mg·L^{-1}. After further culture for 1h, rabbit-anti-human polyclonal antibody against different cPKC isoenzymes was added and incubated for 40min, PBS and normal rabbit serum were used as negative controls. And then, cells were harvested or cultured in drug-free medium for another 30 min and harvested. The harvested cells of the phases were suspended in cold PBS, intracellular adriamycin fluorescence intensity was determined by flow cytometric analysis with the stimulative and acceptant wave length at 488nm and 575nm, respectively.

Statistical analysis Data were presented as $\bar{x}\pm s$. Significant differences were determined by using ANOVA in statistical software SPSS10.0.

RESULTS

Immunofluorescent cytochemistry

To investigate the expression of PKC isoenzymes of SGC7901 cells and its drug-resistant cell subline SGC7901/VCR. immunofluorescent cytochemistry was performed. The positive signals were of fluorescent signals. Both SGC7901 cells and SGC7901/VCR cells expressed PKC-α, PKC-βI, PKC-βII and PKCγ. The expression of PKC-α was stronger in SGC7901/VCR cells than that in SGC7901 cells. There was no significant difference in the expression of PKC-βI and PKC-βII between SGC7901/VCR cells and SGC7901 cells. And the expression of PKCγ in SGC7901/VCR cells was positive as strongly as that in SGC7901 cells, and also no significant difference was found.

Laser confocal microscope analysis

PKC-α expressed in both SGC7901 cells and SGC7901/VCR cells. The positive signals were localized in cytoplasm and membrane. Compared with SGC7901 cells, the intensity of fluorescence in SGC7901/VCR cells was increased significantly when analysed by the intensity of pixel by using computer, which was 100 in SGC7901/VCR cells and 80 in SGC7901 cells.

Western blot

The expression of PKC-α was significantly higher in SGC7901/VCR cells than that in SGC7901 cells, in which expression increased with the increase of drug-dose-resistance of SGC7901/VCR cells. No significant difference was found in the expression of PKC-βI, PKC-βII and PKCγ between SGC7901/VCR cells and SGC7901 cells (Figure 1).

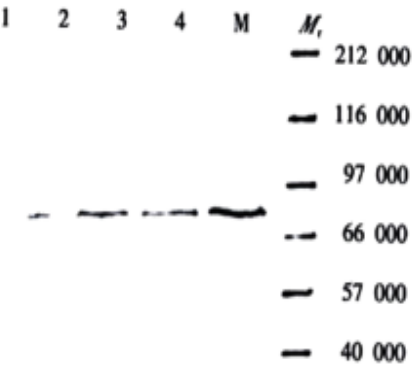

Figure 1 Western blot (detected with anti-PKC-α antibody)

Flow cytometric analysis

The effects of anti-PKC-α or βI antibody on adriamycin accumulation and retention in SGC7901/VCR cells were determined by flow cytometric analysis. When cells were cultured in drug-RPM1640, intracellular drug concentration would increase and finally stabilised at the highest plateau value, which was called adriamycin accumulation. When cells were cultured in drug-free medium, drug was effluxed from cells and subsequently, drug concentration stabilised at a lower plateau value, which was still higher than the

initial value and so called adriamycin retention. The results presented by the values of fluorescence intensity showed that adriamycin accumulation and retention decreased in SGC7901/VCR cells than that in SGC7901 cells. When co-incubated with anti-PKC-α antibody, the accumulation of adriamycin in MDR cells increased and showed partly dose-dependent effect, while PKC-βI, PKC-βII and PKCγ could not influence the ADR accumulation in SGC7901/VCR cells (Table 1,2).

Table 1 Adriamycin accumulation and retention in cells by flow cytometric analysis ($\bar{x}\pm s$ fluorescence intensity)

Adriamycin	SGC7901	SGC7901/VCR in different resistant drug dose (VCR.mg·L^{-1})		
		0.3	0.7	1.0
Accumulation	5.21±2.56	0.85±0.29[b]	0.81±0.32[b]	0.80±0.33[b]
Retention	2.51±1.23	0.47±0.14[b]	0.44±0.15[b]	0.41±0.11[b]

DISCUSSION

The development of resistance to chemotherapeutic agents remains one of the major obstacles for successful cure of cancer patients. Tumor cells may acquire MDR in the course of exposure to various compounds that are used in modern anticancer therapy, including cytotoxic drugs and differentiating agents. Therefore, the recurrence of the disease after the initial treatment may be associated with establishment of secondary MDR in the residual tumor. Research on resistance to cancer treatment was mainly focused for 20 years on MDR. No useful method of reversing MDR, suitable for clinical use, has yet emerged from this large quantity of work. The reason could be an complicated mechanism involved in it. There are several ways for cancer cells to develop resistance or defense mechanisms against cytotoxic drugs[37-43].

Resistance to therapy has been correlated to the presence of at least two molecular "pumps" that actively expel chemotherapeutic drugs from the tumor cells. This action thus spares tumor cells from the effects of the drug, which has to act inside the cells at the nucleus or the cytoplasm. The two pumps commonly found to confer MDR in cancer are P-gp and multidrug resistance-associated protein (MRP). But they can not explicate the phenomenon of MDR fully. It also reported that some cancer cells are resistant to signal of apoptosis and so making cell life longer might confer to the MDR phenotype.

Recent studies have indicated that the signal of phosphorylation might be an important part of MDR mechanisms. PKC isoforms are often overexpressed in disease states such as cancer and play a critical role in regulation of long term cellular events such as proliferation, differentiation and tumorigenesis. An increase in PKC activity might result in an oncogenic role and in MDR. Several studies indicate a role for PKC in the regulation of the MDR phenotype, since several PKC inhibitors are able to partially reverse MDR and inhibit P-gp phosphorylation.

The PKC family consists of several isoforms comprising three groups: classical, novel and atypical. PKC isoforms are widely distributed in mammalian tissues and have many important physiological functions[44-47]. cPKC subfamily shows significant specificity in tissue distribution. The isoenzymes possess distinct differences in localization in different cells. Within a single cell, PKC isoforms also exhibit differences in their distribution before and after their translocation following activation. For example, thymus cells express PKC-α and PKC-βI but not PKC-βII and PKCγ; Cortical and medullary cells of suprarenal gland express PKC-α, while the cortical cells also express PKC-βI and PKCγ.

To date in recent years, the MDR phenotype is also associated with variation in content of PKC isoenzymes. Different isoforms possess distinct differences in expression and function in different MDR cells. It has been confirmed that sensitive cells show the phenotype of MDR when transfected with cDNA encoding PKC-α, which indicats the effect of PKC on MDR. Resistance to ADR of mouse leukemia MDR cell-line could be reversed by anti- PKC-βmAb when it was incubated with anti-PKC-α or anti-PKC-βmAb[48-60].

This study confirmed that PKC-α, PKC-βI,PKC-βII and PKCγ were expressed in both SGC7901 cells and SGC7901/VCR cells. Our results showed that the expression of PKC-α was significantly higher in SGC7901/VCR cells than that in SGC7901 cells and the expression increased with the increase of drug-dose-resistance of SGC7901/VCR cells. There was no significant difference in the expression of PKC-βI, PKC-βII and PKCγ between SGC7901/VCR cells and SGC7901 cells. The result of flow cytometric analysis showed that ADR accumulation decreased in SGC7901/VCR cells much than that in SGC7901 cells, together with increase of the expression of PKC-α. Further study confirmed that anti-PKC-α antibody could reverse ADR accumulation in MDR cells to some degree and showed partly does-dependent effect, while PKC-βI, PKC-βII and PKCγ could not influence the ADR accumulation in SGC7901/VCR cells. The results suggested that the formation of MDR in SGC7901/VCR cells was associated with over expression of PKC-α but not with PKC-βI, PKC-αII and PKCγ. Since isoenzymes of PKC possess only 1-10 amino acid in there pseudo substrate action site in C1 domain, research on distinct function in tumor MDR of isoenzymes has important significance in screening effective drugs with high specificity that could reverse MDR and in disclosing the mechanism of MDR formation and its regularity of the reversion. Because gastric cancer is common in China and some areas in the world[61-80], this results may be important for further study.

Abstract

AIM: **To investigate the role of TR3 in induction of apoptosis in gastric cancer cells.**

METHODS: **Human gastric cancer cell line, MGC80-3, was used. Expression of TR3 mRNA and its protein was detected by Northern blot and Western blot. Localization of TR3 protein was showed by immunofluorescence analysis under laser-scanning confocal microscope. Apoptotic morphology was observed by DAPI fluorescence staining, and apoptotic index was counted among 1000 cells randomly. Stable transfection assay was carried out by Lipofectamine.**

RESULTS: **Treatment of MGC80-3 cells with TPA and VP-16 resulted in apoptosis, accompanied by the repression of Bcl-2 protein in a time-dependent manner. At the same time, TPA and VP-16 also up-regulated expression level of TR3 mRNA in MGC80-3 cells that expressed TR3 mRNA. When antisense-TR3 expression vector was transfected into the cells, expression of TR3 protein was repressed. In this case, TPA and VP-16 did not induce apoptosis. In addition, TPA and VP-16-induced apoptosis involved in translocation of TR3. In MGC80-3 cells, TR3 localized concentrative in nucleus, after treatment of cells with TPA and VP-16, TR3 translocated from nucleus to cytosol obviously. However, when this nuclear translocation was blocked by LMB, apoptosis was not occurred in MGC80-3 cells even in the presence of TPA and VP-16.**

CONCLUSION: **Induction of apoptosis by TPA and VP-16 is through induction of TR3 expression and translocation of TR3 from nucleus to cytosol, which may be a novel signal pathway for TR3, and represent the new biological function of TR3 to exert its effect on apoptosis in gastric cancer cells.**

INTRODUCTION

TR3 (also termed as NGFI-B and Nur77) is an orphan receptor that belongs to the member of the steroid/thyroid/retinoid receptor superfamily[1-3]. It is an immediate-early response gene, and its expression is rapidly induced by a variety of growth stimuli, including growth factors, phorbol ester and cAMP-dependent pathways[1,3-5]. Similar to other members of the superfamily, TR3 functions in nucleus as a transcriptional factor to positively or negatively regulate gene expression necessary to alter the cellular phenotype in response to the growth stimuli[6]. We found recently that TR3 heterodimerizes with retinoid X receptor (RXR) that binds to retinoic acid receptor â (RARâ) promoter, and regulates RARâ expression that is critical to inducing apoptosis[7]. In addition, TR3 also heterodimerizes with chicken ovalbumin upstream promoter transcription factor (COUP-TF) to inhibit COUP-TF binding to retinoic acid responsive element (RARE) through direct protein-protein interaction[8]. These evidences suggest that TR3 can mediate diverse signals through its ability either to bind to a variety of response elements or to interact with different protein factors. However, the mechanism by which TR3 exerts its biological functions remains largely unknown.

Apoptosis, as a distinct form of cell death, is an important process that can lead to tumor regression, and suppression of apoptosis is often associated with abnormal cell survival and malignant growth[9-15]. The involvement of TR3 in apoptosis was first demonstrated by showing that TR3 was rapidly induced by T-cell antigen receptor (TCR) signaling in immature thymocytes and T-cell hybridomas[16,17]. Overexpression of a dominant-negative TR3 protein or inhibition of TR3 expression by antisense-TR3 inhibited TCR-induced apoptosis, whereas constitutive expression of TR3 led to massive apoptosis[16,17]. These evidences clearly indicate that TR3 plays an important role in TCR-mediated apoptosis. The involvement of TR3 in apoptosis process is also observed in many cancer cell lines. Treatment of lung cancer cells with AHPN/CD437 strongly induced apoptosis, which was accompanied by a rapid induction of TR3. Inhibition of TR3 by antisense-TR3 effectively abolished apoptosis induction by AHPN/CD437[18]. Rapid induction of TR3 was also found in other cancer cells after stimulation of apoptosis by a variety of apoptosis-inducing agents[19-21]. Therefore, these observations suggest that expression of TR3 is required for induction of cell apoptosis.

How TR3 functions to regulate apoptosis in gastric cancer cells is less understood. In this study, we investigated the role of TR3 in inducing apoptosis in gastric cancer cells. The results showed that 12-O-tetradecanoylphorbol-13-acetate (TPA) and VP-16 (also called etoposide) induced apoptosis, accompanied by TR3 expression. More importantly, TR3 protein translocated from nucleus to cytosol, when apoptosis occurred by TPA or VP-16 induction. However, when the translocation was blocked by leptomycin B (LMB), apoptosis was not detected, even in the presence of apoptotic stimuli. Our findings, therefore, have drawn an inspiration that translocation of TR3 from nucleus to cytosol may be one of the essential links involved in the mechanism of apoptosis by apoptotic stimuli in gastric cancer cells.

MATERIALS AND METHODS

Cell line and culture condition

Human gastric cancer cell line, MGC80-3, was established by Cancer Research Center in Xiamen University[22]. The cells were maintained in RPMI-1640 medium, supplemented with 10% FCS, 1 mM glutamine, and 100u/ml penicillin.

Agents

TPA and VP-16 (Sigma) are used as apoptosis stimuli that can induce apoptosis in a variety of cells, including breast cancer cells, lung cancer cells, prostate cancer cells[23-30]. LMB is an antibiotic with anti-fungal and anti-tumor activity that was first discovered and purified from the fermentation broth and mycelia of streptomyces[31-33]. Recently, this antibiotic has become an important tool for studying nuclear localization[34-36].

Apoptosis analysis[37]

MGC80-3 cells were treated with TPA and VP-16 for different time indicated in figures, trypsinized, washed with PBS, fixed in 3.7% paraformaldehyde, and then stained with 50μg/mL of 4,6-diamidino-2-phenylindole (DAPI, Sigma) containing 100μg/mL of DNase-free RNase A to facilitate the examination of nuclei under fluorescence microscope. Apoptotic cells were counted among 1000 cells randomly. The apoptotic index was a mean of three independent experiments.

Immunofluorescence analysis[38]

MGC80-3 cells were cultured on cover glass overnight, and then treated with TPA and VP-16 as required. After washed with PBS, cells were fixed in 4% paraformaldehyde. After fixation, the cells were incubated firstly with anti-TR3 antibody (Santa Cruz), and then reacted with corresponding FITC-conjugated anti-IgG (Pharmingen) as secondary antibody. Fluorescent images were observed and analyzed under laser-scanning confocal microscope (Bio-Rad MRC-1024ES).

Western blot analysis[38,39]

Total 50μg of nuclear extract was electrophoresed on 8% denaturing gel and electroblotted onto a nitrocellulose membrane. The membrane was probed with anti-TR3 antibody followed by corresponding secondary antibody. The antibody reactivity was detected with an Amersham ECL kit according to the manufacturer's instruction. For the cytosolic and nuclear fractions, the cells were suspended in 500μl of 10mM Tris-Cl (pH 7.8), 1% Nonidet P-40, 10mM mercaptoethanol, 0.5mM phenylmethylsilfonyl fluoride, 1μg/ml leupeptin and aprotinin for 2 min at 0℃, then 500μl of DDW was added, and the cells were allowed to swell for 2min. The cells were sheared by 10 passages through 22 gauge needle. Nuclei were recovered by centrifugation at 400Xg for 6min, and the low-speed supernatant was centrifuged at 100000g for 30min. The high-speed supernatant constituted the cytosolic fraction.

Stable transfection

Antisense-TR3 expression vector (provided kindly by Dr. Uemura, and Dr. Chang[40]) was stably transfected into MGC80-3 cells by Lipofectamine™ (Gibco/BRL) as described previously[41], then screened with 600μg of G418. Expression of endogenous TR3 protein was determined by Western blot.

RESULTS

Expression of TR3 mRNA in response to apoptotic stimuli

TPA and VP-16 were both known as the apoptotic stimuli which induced apoptosis in many kinds of cancer cell lines, including the cancer cells of prostate, breast and lung[23-30]. To determine whether these apoptotic stimuli also functioned in gastric cancer cells, a specific, DAPT staining for display of apoptotic nuclear morphology was adopted under fluorescence microscope[38]. The observation indicated that treatment of MGC80-3 cells with TPA and VP-16 caused the classical morphological characteristics of apoptosis, including nuclear condensation and fragmentation (Figure 1A). The apoptotic index was further determined by counting 1000 cells randomly. In MGC80-3 cells, the apoptotic index was merely 3.89 %. However, the apoptotic index induced by TPA and VP-16 increased in a time-dependent manner (Figure 1B). The highest apoptotic index reached 44.33% (for TPA induction) and 32.16% (for VP-16 induction), respectively. Thus, the data demonstrated that TPA and VP-16 indeed induced apoptosis in gastric cancer cells.

Members of the Bcl-2 family were involved in the regulation of apoptotic process[42,43]. Since TPA and VP-16 induced apoptosis significantly in MGC80-3 cells shown above, it should be interrelated with some proteins that were associated with apoptosis initiation. To investigate this posibility, expression of Bcl-2 was detected. Western blot showed that when TPA treated with cells for different time, the expression of BCL-2 protein was repressed in a time-dependent manner (Figure 1C), which was consistent with the result shown in Figure 1A and B. Similar result was seen in the cells treated with VP-16 (data not shown). This result suggested that inhibition of Bcl-2 might render MGC80-3 cells more susceptible to the apoptosis-inducing effect of TPA and VP-16.

Several evidences showed that TR3 was involved in the regulation of apoptosis in different cell types[16, 44,45]. We investigated the role of TR3 in apoptosis of MGC80-3 cells induced by TPA and VP-16. Treatment of cells with TPA and VP-16 not only induced MGC80-3 cell apoptosis and repressed its relative protein, Bcl-2 (Figure 1A-C), but also enhanced expression of TR3 mRNA obviously that was expressed at relative low level in MGC80-3 cells (Figure 1D). Taken together, these results revealed a possible link between expression of TR3 and induction of apoptosis in gastric cancer cells.

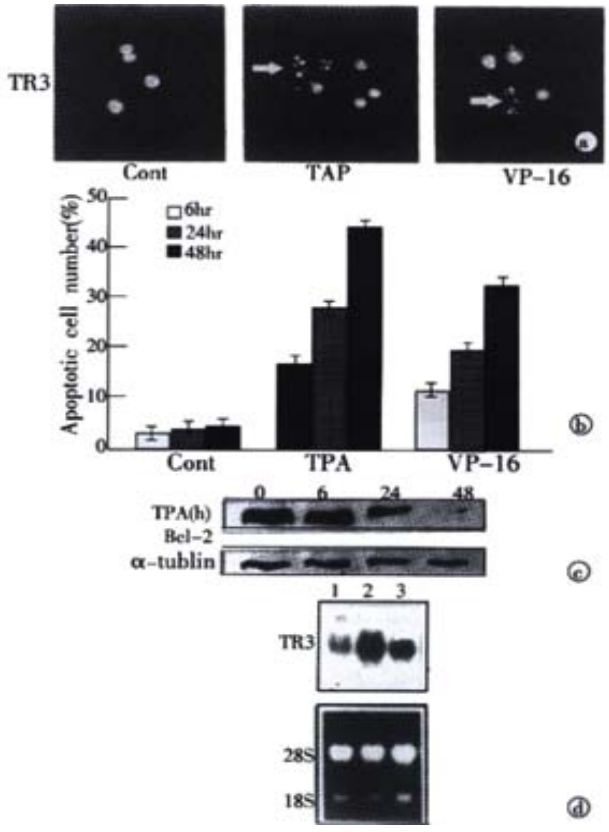

Figure 1 Induction of apoptosis and TR3 expression induced by TPA and VP-16 in MGC80-3 cells. (A) Morphological analysis of apoptotic cells. Cells treated with TPA and VP-16 for 24 hr, and then stained with DAPI. Nuclear morphology was visualized under fluorescence microscope. (B) Measure of apoptotic index by counting 1000 cells stained with DAPI under fluorescence microscope. The data shown represents mean of three independent experiments (±SE). (C) Analysis of Bcl-2 protein expression. Cells were treated with TPA for indicated time, and Western blot was preformed as described in

materials and methods. α-tubulin was used to quantify the amount of protein used in each lane. (D) Detection of TR3 mRNA expression. Cells were treated with TPA and VP-16 for 24 hr. Preparation of total RNA and Northern blot were carried out as described in materials and methods. 18S and 28S were shown to quantify the loading RNA. Lane 1: control; Lane 2: TPA treatment; Lane 3: VP-16 treatment.

Translocation of nuclear TR3 to cytosol induced by apoptotic stimuli

It was reported recently that trnaslocation of protein was closely associated with its biological function[24,38,47]. To determine whether the apoptotic stimuli could cause translocation of TR3 in MGC80-3 cells, the immunofluorescent localization of TR3 protein was conducted by using correspondent TR3-specific antibody and laser-scanning confocal microscope observation. The results illustrated that in MGC80-3 cells, TR3 protein was concentrative in nucleus (Figure 2A). When treatment of TPA for 6 hr, the majority of TR3 protein was still remained in nucleus, little in cytosol. However, after 24 hr of TPA treatment, the majority of TR3 protein translocated from nucleus to cytosol, little in nucleus (Figure 2A). Similar result was also seen in the cells treated with VP-16. After treatment of 24 hr, TR3 protein almost translocated to cytosol (data not shown).

To further verify this protein translocation, the cytosolic and nuclear fractions were isolated respectively, and TR3 protein level was detected by Western blot . As shown in Figure 2B, TR3 protein was expressed in MGC80-3 cells, which located in nucleus (Figure 2B). TPA and VP-16 treatment led to down-regulation of TR3 protein in nuclear and up-regulation in cytosol with a time-dependent manner. After treatment of the cells for 6 hr with TPA and VP-16, respectively, TR3 protein was distributed both in nucleus and cytosol. However, after 24 hr treatment of TPA and VP-16, TR3 protein appeared more in cytosol and little in nucleus clearly (Figure 2B). This result was in accordance with the result shown in Fig. 2A, suggesting that translocation of TR3 protein might be associated with induction of apoptosis, which was a novel signal pathway for TPA and VP-16 to exert their biological functions.

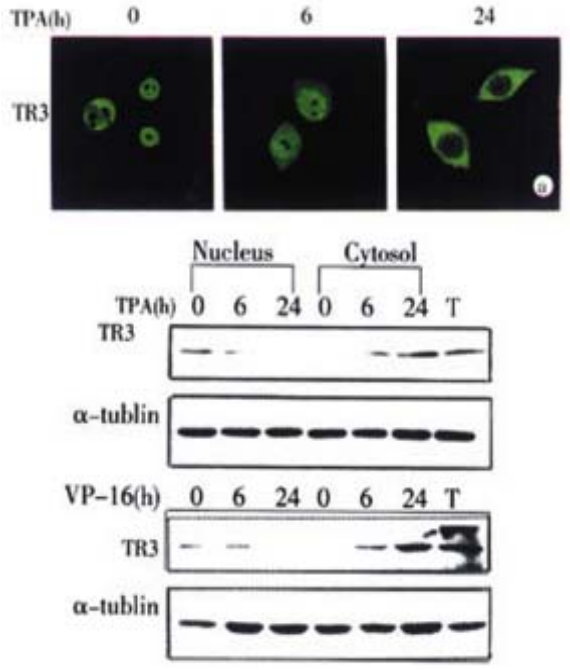

Figure 2 Translocation of TR3 protein from nucleus to cytosol in MGC80-3 cells. The cells treated with TPA for indicated time. (A) Translocation of TR3 protein observed by laser-scanning confocal microscope. TR3 protein was immunostained with anti-TR3 antibody and corresponding FITC-conjugated secondary antibody. (B) Western blot showed the translocation of TR3 protein. Nuclear and cytosolic fractions were prepared as described in materials and methods. α-tubulin was shown to quantify the loading protein. T: total protein.

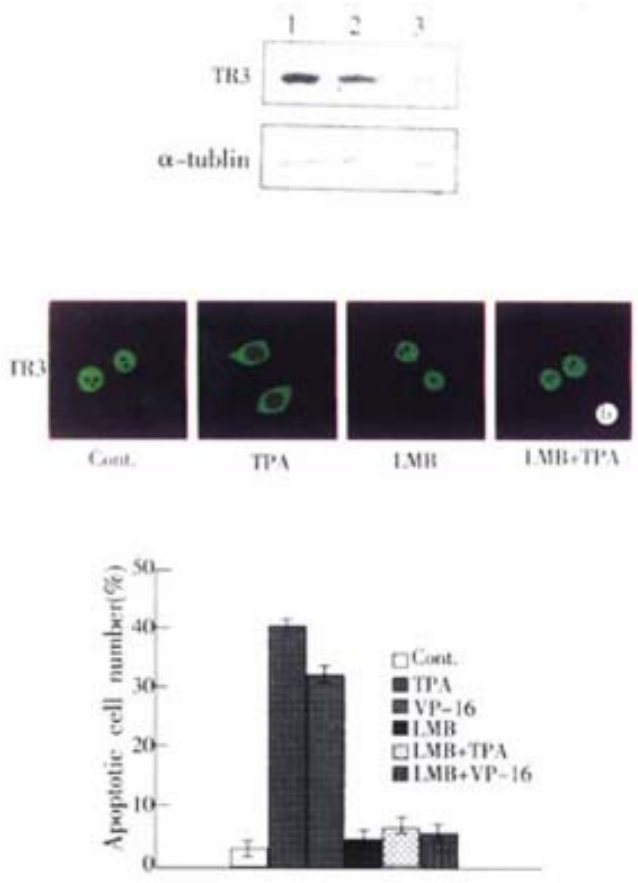

Figure 3 Inhibition of TR3 protein expression and its translocation in MGC80-3 cells. (A) Repression of TR3 protein expression by transfection of antisense-TR3 expression vector into MGC80-3 cells. Endogenous TR3 protein was determined by Western blot. Empty vector was also transfected into cells as a positive control. α-tubulin was shown to quantify the loading protein. Lane 1: protein from MGC80-3 cells; Lane 2: protein from the cells transfected with empty vector; Lane 3: protein from the cells transfected with antisense-TR3 expression vector. Inhibitory effect of LMB on TR3 protein translocation induced by TPA. The cells treated with different agents indicated as in the figure. The reaction with antibody was similar to the description in Fig. 2A. (C) Inhibitory effect of LMB on apoptosis induction by TPA and VP-16. Cells treated with different agents indicated as in the figure. Apoptotic index was measured as described in Fig. 1B.

Inhibition of both TR3 protein expression and its translocation

Since TR3 protein was expressed in MGC80-3 cells (Figure 2A, B), we transfected antisense-TR3 expression vector into the cells to determine whether inhibition of TR3 protein expression caused TPA and VP-16 fail to induce apoptosis. The stable transfection result was showed in Figure. 3A. Expression of TR3 protein was almost repressed in transfected cells, whereas TR3 protein still expressed in the cells transfected with empty vector, compared to MGC80-3 cells. In this transfected cells, TPA and VP-16 could not induce apoptosis. The apoptotic index only reached 5.14% (for TPA induction) and 4.62% (for VP-16 induction), which were less than that in MGC80-3 cells treated with TPA and VP-16 (Figure 1B) and those transfected with empty vector (apoptotic index amounted to 39.78% for TPA induction and 27.56% for VP-16 induction).

It was then necessary to probe into the intrinsic mechanism of whether there was some inevitable linkage between TR3 protein translocation and apoptosis induction. Since LMB has been used in many systems to demonstrate the nuclear localization and inhibited the export of a number of proteins, including actin, transcription factors, kinases and cell cycle regulators[48-54], we used LMB as inhibitor to block nuclear protein TR3 export from nucleus to cytosol. In MGC80-3 cells, TR3 protein was mainly located in nucleus, after treatment of

24 hr with TPA, the most of TR3 protein was translocated from nucleus to cytosol in the absence of LMB (Figure 3B). However, in the presence of LMB, TR3 protein was remained in nucleus, although MGC80-3 cells were treated by TPA for 24 hr (Figure 3B). The similar result was also observed in VP-16 treated-cells (data not shown). According to this inhibitory result, we detected the apoptotic index to determine the relationship between translocation of TR3 protein and apoptosis induction. As shown in Figure 3C, in the presence of LMB, TPA and VP-16 did not induced apoptosis, compared with that TPA and VP-16 induced apoptosis of MGC80-3 cells obviously in the absence of LMB. Thus, preventing the nuclear TR3 protein export from nucleus to cytosol repressed TPA and VP-16's ability to induce apoptosis. The result again confirmed that translocation of TR3 protein was associated with induction of apoptosis.

DISCUSSION

The TR3 orphan receptor is required for activation-induced apoptosis of T-cell hybridomas[16]. To gain insight into its function during apoptosis, we, in this study, analyzed the relationship between TR3 expression and its translocation and apoptosis induction in gastric cancer cells.

TR3 is an early response gene whose expression is induced by a variety of stimuli, including signals for cell survival, such as growth factors, and signals for cell death, such as TCR[1,3-5]. To study the role of TR3 in gastric cancer cells, we used TPA and VP-16 to induce apoptosis, and found that when apoptosis occurred and its related protein Bcl-2 was inhibited by TPA and VP-16 in MGC80-3 cells, TR3 mRNA was indeed up-regulated. After transfection of antisense-TR3 expression vector into MGC80-3 cells that expressed TR3 at protein level resulted in the inhibition of TR3 protein expression. In the transfected cells, we could not detect marked apoptosis, even in the presence of TPA and VP-16 induction. The apoptotic index was only 5.14% (for TPA induction) and 4.62% (for VP-16 induction), similar to the control MGC80-3 cells with 3.89% and less than the TPA and VP-16 treated-cells with 44.33% (for TPA induction) and 32.16% (for VP-16 induction). These results indicated that TPA and VP-16 regulated apoptosis through induction of TR3 expression at both mRNA and protein levels.

TR3 functions as a nuclear transcription factor in the regulation of target gene expression[6]. The movement of transcription factors between nucleus and cytoplasm is important in regulating its activity[24,47]. Our observation showed that TPA and VP-16-induced apoptosis involved in translocation of TR3 protein. In MGC80-3 cells, TR3 protein localized mainly in the nucleus in which it might be associated with other nuclear proteins related to stimulation of cell proliferation, such as PKB/AKT, cFos, and AP-1[18, 55-58]. However, when cells were treated with TPA and VP-16 for 24 hours, respectively, translocation of TR3 from nucleus to cytosol was observed, with an increase protein expression of TR3 in cytosol and a decrease in nucleus in a time-dependent manner. In this case, apoptosis induced by TPA and VP-16 did happened, also in a time-dependent manner, and during this process, Bcl-2 protein, known to induce cell survival in variety of cell types[59,60], was strongly inhibited by TPA and VP-16. In addition, when this nuclear export was blocked by LMB, apoptosis was not detected, regardless of the presence of TPA and VP-16. As a comparison, all-trans retinoic acid that could not induce TR3 translocation from nucleus to cytosol failed to induction of apoptosis in MGC80-3 cells although it could also induce TR3 expression (data not shown). Taken together, these data clearly demonstrated that induction of apoptosis by TPA and VP-16 was through the translocation of TR3 from nucleus to cytosol, which might be a novel signal pathway for apoptosis and the new function for TR3 to exert its effect on apoptosis induction. Bcl-2 may play an important role in the regulation of TPA and VP-16 -induced apoptosis. Of course, the link between the mechanism of TR3 function and the apoptosis induction in gastric cancer cells should be studied further from other aspects.

Abstract

AIM: **To study the effects of preoperative regional artery chemotherapy (PRACT) in inducing growth inhibition and apoptosis of gastric carcinoma (GC) cells.**

METHODS: **TUNEL (terminal-deoxynucleotidyl-transferase TdT-mediated dUTP-fluorescein and labeling) method and immunohistochemical techniques were used to detect the state of apoptosis and proliferation of GC cells in histopathologic sections. A total of 110 cases of GC and 68 cases of metastatic lymph node with or without PRACT were adopted. Correlations between apoptosis index (AI), proliferation index (PI) and PRACT and prognosis were analysed.**

RESULTS: **The apoptosis index (AI) was significantly higher in the PRACT group (12.5‰±4.33‰) than in the untreated group (7.1‰±3.43‰, *P*<0.001), whereas the proliferation index (PI) in the PRACT group (33.8%±8.8%) was significantly lower than that in untreated group (43.6%±12.8%, *P*<0.01). Both AI and PI were correlated to the differentiation degree of GC in PRACT group, the AI in the differentiated group was higher than that in undifferentiated group (*P*<0.001), but the PI was lower in the differentiated group than that of the undifferentiated group (*P*<0.01). The AI of GC cells in metastatic lymph node was also significantly higher in the PRACT group (7.9‰±3.41‰) than in the untreated group (3.6‰±2.93‰, *P*<0.01), though the PI of GC cells in metastatic lymph nodes in the PRACT group (17.2%±6.8%) was significantly lower than that in the untreated group (26.7%±9.3%, *P*<0.01). The severity of histopathologic changes was significantly higher in the PRACT group than in the untreated group (*P*<0.05). In addition, postoperative surveys demonstrated that the 5-year survival rate of GC patients in the PRACT group was significantly higher than that of patients in the untreated group (*P*<0.01).**

CONCLUSION: **Preoperative regional artery chemotherapy (PRACT) showed inhibitory action on the growth of GC cells mainly through inhibiting proliferation and inducing the apoptosis of tumor cells. PRACT can improve the prognosis of GC patients also.**

Tao HQ, Zou SC. Effect of preoperative regional artery chemotherapy on proliferation and apoptosis of gastric carcinoma cells. *World J Gastroenterol* 2002;8(3):451-454

INTRODUCTION

Human gastric carcinogenesis is a multistep and multifactorial process[1-8]. In this process, the state of apoptosis and proliferation of gastric epithelium will change[9,10]. The loss of balance between cell proliferation and apoptosis may result in tumor development and progression[11-16]. Cell necrosis and apoptosis are two fundamental processes of tumor cell death. Apoptosis is the biological process of tumor cell death regulated by genes[17-28]. Many (and perhaps all) agents of cancer chemotherapy effect tumor cell killing *in vitro* and *in vivo* through inducing the mechanisms of apoptosis. Many chemotherapy-induced side-effects and mass shrinkage may result from the increase of tumor cell apoptosis and the inhibition of tumor cell proliferation[17, 29-34].

To clarify the relationship between the effects of preoperative regional artery chemotherapy (PRACT) on inhibition and killing of GC cells with apoptosis, methods of terminal-deoxynucleotidyl-transferase (TdT)-mediated dUTP-fluorescein and labeling (TUNEL) and immunohistochemical techniques were used to detect the apoptosis and proliferation of GC cells in 110 cases of GC with or without PRACT. Histopathologic changes and prognosis were also observed and compared between the two groups.

MATERIALS AND METHODS

Clinical data

110 patients with GC who underwent curative resections at Zhejiang Provincial Peoples' Hospital from Dec. 1988 to July 1996 were studied, including 68 cases with PRACT and 42 cases without PRACT. No significant difference was found in the age, sex, and TNM staging between the two groups. The surgical specimens were fixed in 10% formaldehyde solution, and paraffin embedded tissue blocks were cut into 6μm sections and mounted on glass slides. All patients had been followed up at least 5 years after operation.

Scheme of preoperative chemotherapy

Celiac arteriography was performed by precutaneous transfemoral-artery catheters according to Seldinger's method and superselective catheterization proceeded to the supplying artery of focus of lesion. Antineoplastic agents of FAP(5-FU 1.0g/m^2, MMC 10mg/m^2, CDDP 80mg/m^2) or FMP(5-FU 1.0g/m^2, ADR 20mg/m^2, CDDP 80mg/m^2) scheme was infused into regional artery by a single administration and thereafter surgical operation was performed in 10-14 days.

Main reagents

Terminal-deoxynucletotidyl-transferase(TdT)-mediated dUTP-fluorescein and labeling(TUNEL) kits were purchased from Boehringers Inc. and stored in -20℃ for use. SP kits and PCNA monoclonal antibody were produced by Maixin Inc.(Fujian).

Histochemical detection of apoptosis

Tumor cell apoptosis was identified by the TUNEL method[35,36]. Briefly, deparaffinized and rehydrated sections were treated with proteinase K (20mg/L in 10mmol/L Tris, pH 8.0) for 20min at room temperature and washed with 1×TBS (20mmol/L Tris, pH 7.6,

140mmol/L NaCl). After, endogenous peroxidase was inactivated by using 30ml/L hydrogen for 5min and washing with 1×TBS. Equilibration buffer was added to each section and samples were incubated at room temperature for 20min. Terminal deoxynucleotidyl transferase (TdT) enzyme in TdT labeling reaction mixture at 1:20 dilution was piped onto the sections, followed by 2h incubation at 37℃. After terminating the reaction by immersing sections into stop solution and washing with blocking buffer for 10min at room temperature, the anti-digoxingenin-peroxidase was added to the sections. NBT/BCIP solution was used for color development. Sections were counterstained by fast red. A positive control was generated by covering a specimen with DNase I(1mg/L) as the first step of the procedure. Specific positive tissue sections were used for negative controls by substituting distilled water for the TdT in the reaction mixture. Positively stained tumor cells were identified as nuclei that were blue-brown in color, and were counted in ten randomly selected fields under high power of microscope to determine the rate of apoptosis cell among all tumor cells. Apoptotic index (AI)=(the number of apoptosis cells/total number of tumor cells)×1000‰.

Immunohistochemical staining for PCNA

SP immunohistochemical staining techniques were used. The primary antibody was PCNA monoclonal antibody (diluted 1:50). Before staining,the sections were microwave heated in 0.05mol·L^{-1} citric acid solution for antigen retrieval. PBS was substituted for primary antibodies as negative control. PCNA-positive cells (proliferative cells) were observed. The proliferative index (PI) was obtained by calculating the percentage of positively stained cells evaluated for each tissue section after counting 1000 cells at ten high power fields randomly.

Comparison of pathologichistology change

In H&E staining sections, tumor cell necrosis and degeneration, endothelium change, and the degree of fibrosis were observed and compared between the PRACT group and untreated group. The degree of histopathologic change was divided into four grades from 0 to III.

Statistical analysis

Data were expressed as $\bar{x}\pm s$, and the t test or Wilcoxin test were used for statistical analysis. Survival rate was calculated by using Kaplan-Meier method and analyzed by the log-rank test. The level of significance was $P<0.05$.

RESULTS

Comparison of tumor cell proliferation and apoptosis between PRACT and untreated groups

The main morphological characteristics of apoptosis cell consist of cell shrinkage, cytoplasmic condensation, nuclear pryknosis, cytomembrane blebbing or fragmentation, and formation of apoptotic bodies. More apoptosis and less proliferation were detected in the patients in the PRACT group. The apoptosis index (AI) of the PRACT group and untreated group was (12.5‰±4.33‰) and (7.1‰±3.43‰), respectively. The t test showed that the AI of the PRACT group was significantly higher than that of the untreated group ($P<0.001$), whereas the proliferation index (PI) in the PRACT group (33.8%±8.8%) was significantly lower than that in untreated group (43.6%±12.8%, $P<0.01$).

Relationship between tumor cell proliferation, apoptosis and the tumor differentiation degree in PRACT group

The pathologic diagnosis and grading of GC was determined according to the Histopathologic Standard of the Chinese National Gastric Cancer Association. GC was divided mainly into two histologic subtypes: a differentiated type which consists of papillary and tubular adenocarcinomas, and an undifferentiated type which consists of poorly differentiated adenocarcinomas, signet ring-cell carcinomas and mucinous adenocarcinomas. Among the 68 patients with PRACT, AI of 32 tumors of the differentiated type was (14.8‰±4.99‰), while that of undifferentiated type tumor was only (6.6‰±3.31‰), AI was significantly different between the two groups ($P<0.001$). However, the PI of 32 tumors of the differentiated type (29.6%±7.4%) was lower than that in the undifferentiated group (38.5%±11.2%, $P<0.01$).

Effect of PRACT on proliferation and apoptosis of metastatic lymph node GC cells

Among the 62 cases with lymph node metastasis, AI of metastatic lymph node GC cells in 34 cases with PRACT was (7.9‰±3.41‰), and that of 28 cases without PRACT was (7.9‰±2.93‰). The *t* test indicated that there was a significant difference between two groups ($P<0.01$). On the contrary, the PI in the metastatic lymph node GC cells in 34 cases with PRACT (17.2%±6.8%) was significantly lower than that of 28 untreated cases (26.7%±9.3%, $P<0.01$).

Comparison of histopathologic changes between PRACT and untreated groups (Table1)

The data are shown in Table 1. No change was marked as grade 0, I to III grade was defined change. The Wilcoxin test showed a significance difference between the two groups.

Table 1 Comparison of histopathologic changes between the PRACT group and the untreated group

Histopathologic grade	PRACT group (*n*=68)	Untreated group (*n*=42)

Effect of PRACT on the survival rate of GC patients

All patients underwent curative resection and had been followed up for at least 5 years, 49 died of tumor recurrence. A postoperative survey demonstrated that the 5-year survival rate of patients with PRACT (63.2%, 43/68) was significantly higher than that of patients without PRACT (42.8%, 18/42, $P<0.01$).

DISCUSSION

PRACT can effectively inhibit or kill cancer cells by a single administration of high concentration antineoplastic agent into the main supplying artery of the cancer focus. It can not only limit and reduced the tumor mass and improve the curative rate, but it can also act on the peri-operative area by means of drug infiltration to kill subclinical tumor foci which may exist before the operation as well as the invisible micrometastatic foci so as to increase the opportunity of curative resection[33,37]. Many *in vitro* and *in vivo* experiments indicated that the induction of apoptosis and inhibition of proliferation are the main mechanisms of eliminating tumor cells by most chemotherapeutic agents[17,29-34,38]. To explore the effect of PRACT on human GC cell apoptosis, TUNEL, a combined molecular biological and morphological technique, was used to investigate and compare the number of apoptotic cells in GC tissue sections as well as that in metastatic lymph node sections of the PRACT and untreated groups. This method, using an in situ staining technique, demonstrates not only the distribution pattern of apoptotic cells, but also the

sensitivity of the tequnique: it can detect very small amount of apoptotic cells, so it is wildly used in cell apoptosis studies[35,36]. Moreover, PCNA expression was detected by using an immunohistochemical technique in order to count the proliferation index.

Cell apoptosis is different from cell necrosis; the latter is a pathological form of extensive cell death under strong cell damage and it is not under gene regulation, while cell apoptosis is a normal physiological phenomenon for the active elimination of surplus cells or defective cells under strict genetic control[29]. It plays an important role in regulating total cell amount and also in malignant disease. After gene mutation and formation of malignancy, the rate of cell apoptosis lowers significantly. It is this depletion of cell apoptosis contributing to the expansion of tumor mass; hence it is possible to treat the cancer by means of increasing the proportion of tumor cell apoptosis. Recent studies have shown that 5-Fu, MMC, CDDP, ADR and many other chemotherapeutic drugs treat cancer by inhibiting proliferation and inducing apoptosis[29-34,39-41]. So induction of tumor cell apoptosis has already been used as an important indicator to detect the ability of chemotherapeutic drugs to inhibit tumor growth. FMC or FAP schemes composed of the aforementioned drugs are now frequently used for pre-operative chemotherapy of GC.

Our results demonstrate that: (1) The apoptosis index of GC cells in the PRACT group is significantly higher than that of the untreated group, and PI of GC cells in the PRACT group is significantly lower than that of the untreated group, indicating that PRACT has an obvious inhibition effect on GC cells. We also found that no significant necrosis was found in the rich blood supply area around the blood vessels, but instead much apoptosis was observed there, indicating that induction of apoptosis by PRACT is the main mechanism of inhibition of tumor growth. (2) Apoptosis rate is correlated with tumor differentiation degree in the PRACT group. AI of differentiated type of GC is significantly higher than that of undifferentiated type, but PI of differentiated type of GC is significantly lower than that of undifferentiated type. This may be due to the better blood supply of the differentiated type of GC[42], allowing more chemotherapeutic drugs to be delivered to the tumor tissue to increase the induction of tumor cell apoptosis so it is more sensitive to chemotherapy. (3) AI of GC cells in metastatic lymph nodes is significantly higher in the PRACT group than that of the untreated group, and PI of GC cells in metastatic lymph nodes is significantly lower in the PRACT group than that of the untreated group, suggesting that PRACT is able to inhibit proliferation and induce apoptosis of metastatic tumor cells. This is very interesting, because lymph node metastasis and recurrence of GC are main factors influencing the overall postoperative survival rate. If the apoptotic cell proportion in metastatic lymph nodes can be increased by effective measures, the prognosis of postoperative GC patients can be improved. Our results suggest that PRACT may approach this goal. (4) With respect to the histopathologic change of GC, including cancer cell reactions, endothelium changes, and the degree of fibrosis, the degree of severity is higher in PRACT group than that in untreated group, suggesting that PRACT can lead to more structural changes of GC tissue so as to enhance the killing effect of cancer cells by chemotherapy drugs. (5) With regard to prognosis, we have showed that PRACT can increase the relapse-free survival rate of GC patients[37]. In fact, altering the balance between apoptosis and proliferation may contribute to improving the prognosis of cancer[43-49]. The results of this paper indicate that PRACT can induce apoptosis and inhibit proliferation of GC cells. So we suggest that PRACT is a useful therapeutic scheme for GC.

In conclusion, this study of detecting the proliferation and apoptosis of GC with or without PRACT showed significant inhibition of GC cell growth by PRACT, with its mechanism mainly through inducing tumor cell apoptosis. PRACT can increase the survival rate of GC patients after operation.

Abstract

AIM: **Epidermal growth factor (EGF) plays an important role in the regulation of gastrointestinal tissue growth and development, and it can stimulate epithelial proliferation, cell differentiation and growth. It has been established that the EGF can promote gastric cytoprotection and ulcer healing. But the potential ability of EGF to regulate the gastric cancer growth is unknown. This study is to investigate the influence of EGF on human gastric cancer cell and the implanted tumor growth of nude mice.**

METHODS: **The cell growth rates of human gastric adenocarinoma cell lines MKN-28, MKN-45, SGC-7901 and normal human gastric epithelial cells 3T3 were assessed when incubated with recombinant human EGF (rhEGF, 0.05, 0.1, 0.5, 1.0, 10, 50, 100mg.L^{-1}) using MTT method. The cells of MKN-28, MKN-45, SGC-7901 (gastric cancer tissue 1.5mm^3) were implanted in the BALB/cA nude mice for 10 days. The EGF was given intraperitoneally (15, 30, 60μg.kg^{-1}) for 3 weeks. The body weights of the tumor-bearing animals and their tumor mass were measured afterwards to assess the mitogenic effect of rhEGF in the nude mice.**

RESULTS: **Within the concentration range of 0.05-100mg.L^{-1}, rhEGF could increase the cell growth of normal 3T3 cells (cell growth rate 100% *vs* 102.8%, *P*<0.05), but partially restrain the gastric cancer cell growth. The latter effect was related to cell differentiation. In 15-60μg/kg rhEGF groups, the mean implanted tumor mass of MKN-28 cell were 1.75g, 1.91g, 2.08g/NS group 1.97g (*P*>0.05), the mean tumor mass of SGC-7901 cell were 1.53g, 1.07g, 1.20g/NS group 1.07g (*P*>0.05), and for MKN-45 cell, the tumor mass were respectively 1.92g, 1.29g, 1.77g/NS group 1.82g (*P*>0.05). So rhEGF had no obvious effect on implanted MKN-28, SGC-7901 and MKN-45 tumor growth.**

CONCLUSION: **EGF has no stimulating effect on the human gastric cancer cell growth neither *in vitro* nor *in vivo*.**

INTRODUCTION

Growth factors are found in a variety of adult and embryonic tissues. They are important regulators of cell differentiation and proliferation, and play an important role in maintaining the integrity of the epithelium. They have also been implicated in malignancy. Epidermal growth factor (EGF), a single-chain polypeptide of 53 amino acid residues, is found mainly in the submandibular glands and Brunner's gland of the gastrointestinal tract. It can be combined with the specific receptor (EGF-R) of the target cell membrane[1]. Some studies suggested that the expression of EGF-R was increased in gastric cancer tissue. It was also reported that EGF can increase the mitosis *in vitro*[2]. Patients with EGF receptor-positive gastric cancer may have a poorer prognosis than those with EGF receptor-negative cancers. So, EGF has the function to influence the tumor cell growth. At present, the effect of EGF in this process has been unclear yet.

In this report, we seek to determine the effect of EGF on the growth of human gastric cancer cell (MKN-28, SGC-7901 and MKN-45) *in vitro*. In nude mice which underwent surgical implantation of the same gastric cancer cells, EGF was injected intraperitoneally to investigate the influence of EGF on tumor cell growth, so as to confirm the safety of EGF in the treatment of peptic ulcer[3-14].

MATERIALS AND METHODS

Materials

Gastric cancer cell lines, MKN-28, SGC-7901 and MKN-45, are well-differentiated, moderate-differentiated and low-differentiated human adenocarcinoma cell lines respectively. 3T3 cell is normal human gastric epithlium. They are all established and characterized in our laboratory. rhEGF was obtained from Institute of Biochemistry and Cell Biology, Shanghai Institute for Biological Science, Chinese Academy of Science (100μg/amp). 3-(4,5-dimethylathiazol-2-yl) and 5-diphenyltetrazolium bromide were the product of Fluda Chemie AG. Balb/cA nude mice: were obtained from Institute of Pharmatheutics, Shanghai Institute for Biological Science, Chinese Academy of Science. 35-40 day old, 18-20g, female. Mitomycin C (MMC) was the product of Kyowa Hakko, Japan, 2mg/Amp.

Methods

Cell cultures Human gastric cancer cells were propagated as adherent monolayers and removed from culture surfaces by treatment with trypsin, then seeded in microwells at 1×10^8.L^{-1} in complete medium composed of RPMI 1640 and 200mL.L^{-1} fetal bovine serum (FBS). The cells were grown in 96-well microplates of RPMI1640 tissue culture medium supplemented with 200mL.L^{-1} FBS at 37℃ in a humidified atmosphere of 50mL.L^{-1} CO_2 in air. After 24h incubation, the cells were then added by rhEGF at the concentration of 0.05, 0.1, 0.5,1.0,10,50,100mg.L^{-1} for further incubation of 72 hours. Uninoculated RPMI 1640 medium was used as a control under otherwise identical experimental procedures. At the end of cell incubation, cell numbers and their viability were determined by MTT method. Add MTT(1g.L^{-1}) in each microwell for 4h in 37℃ air. After centrifugation, 100μL dimethyl sulfoxode (DMSO) was added into each well for 30 minutes. Absorption rate of treated and control cells was measured at 570nm (A value) for quantitative measurement of cell growth. Each test kit contained a positive control and an additional

positive control. Experimental controls were treated with DMSO only.

Tumor implantation into nude mice Gastric cancer tissue (1.5mm^3) were implanted s.c. in the right dorsal area of 4-6wk old male nude mice. Animals were fed with an autoclaved diet and tap water (acidified to pH 2.5). After 10d, the animals were assigned into the rhEGF treatment groups (15,30,60ìg.kg^{-1}, intraperitoneally, 5 times per week for 3wk), negative control group (saline, 2mL intraperitonium) and positive control group(MMC, 2mg.kg^{-1}, twice every week, 6 times altogether). The body mass of Balb/cA tumor-bearing animals and their tumor weights were measured using anesthesia with ether.

Inhibitory rate (IR) of tumor growth = $m(tumor)_C$- $m(tumor)_T$/ $m(tumor)_C$

($m(tumor)_C$: mean tumor weight of negetive control group; $m(tumor)_T$: mean tumor weight of rhEGF treatment group).

Statistical analysis

Student's *t* test was performed to assess potentially significant differences between individual groups of observations. The test statistics were then compared with values obtained from standard two-tailed tables. A *P* value of <5% was accepted as indicating probable significance when comparing the various groups.

RESULTS

Mitogenic effects of EGF in vitro

We found that EGF had no significant growth-stimulatory effects on gastric cancer cells in a dose-dependent manner (Figure 1). The lowest cell growth rates in MKN-28, S-7901 and MKN-45 cell lines were 81.7%, 80.7% and 86.1% respectively, compared with the control at the 0.05,50,100mg.L^{-1} of rhEGF. EGF could inhibit the cancer cell growth within the level of 0.05 to 100mg.L^{-1}. But there was no probable significance within the same group. In contrast, for the normal 3T3 cells, EGF could increase the cell growth significantly after the coincubation (*P*=0.0008). We also found that the influence of EGF on the gastric cancer cell growth was dependent on the differentiation of the cell. Under the same concentration, the inhibition was greater in well-differentiated cells.

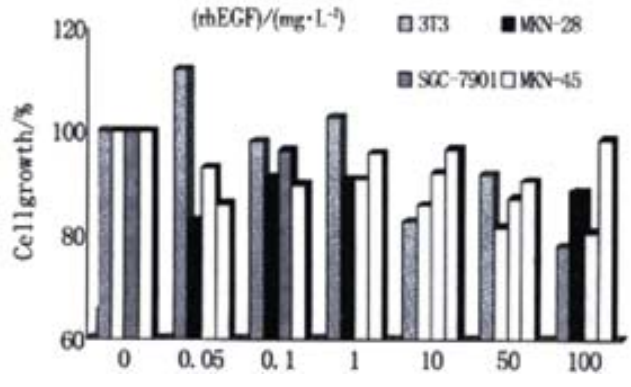

Figure 1 The effect of rhEGF on the growth of gastric cancer

Effect of EGF on the implanted tumor in nude mice

The mean tumor weight of negative control group after the study was 1.97g in MKN-28 nude mice. In MMC treatment group, the tumor weight was 0.47g (*P*<0.05). In rhEGF groups (15,30,60μg.kg^{-1}), the tumor weights were 1.75, 1.91 and 2.08g respectively. The inhibitory rate were -5.3% to 11.1%, compared with negative control group. In rhEGF60μg.kg^{-1} group, the positive data suggested that the weight was higher than control, but the difference was not significant. There were no significant difference compared with the negative control group (Table 1). In S-7901 and MKN-45 cell lines, the same results found indicated that intraperinoneal rhEGF treatment could not stimulate the tumor growth in nude mice within the concentration 15-30μg.kg^{-1} (Table 2,3).

DISCUSSION

We have examined the effect of EGF on the established cell line, MKN-28, SGC-7901 and MKN-45, derived from human gastric adenocarcinoma, both *in vitro* and *in vivo*. The results may be somewhat controversy to those formerly reported, that EGF had no obviously effect on the gastric cancer growth[15,16]. Growth factors are components of signal transduction pathways that have a considerable spectrum of biological activity, such as control of cell proliferation, differentiation, apoptosis and transformation[17,18]. Of these growth factors, EGF family are important agents for gastric mucosa. The EGF family include at least seven mammalian polypeptides: EGF, TGF-α, amphiregulin (AR), cripto heregulin, betacellulin and heparin-binding epidermal growth factor (HB-EGF). Except cripto and heregulin, all of these proteins have been shown to bind and activate the 170-kilodalton EGF receptor tyrosine kinase[19,20]. They share a similar spectrum of biological activities exerted through interaction with EGF-R. EGF-R is a transmembrane glycoprotein, which can stimulate cell proliferation mainly through induction of the proto-oncogenes c-fos and c-myc, and of molecules such as polyamines. The TGF can cause morphological transformation and promote anchorage independent growth in vitro. Although there is no evidence of TGF secretion from nonneoplastic adult tissue, it is synthesized during fetal development and produced by many tumor tissues[21,22]. TGF-α is frequently produced by malignant as well as normal cells and may stimulate their own proliferation. However, less is known about the role of EGF in oncogenesis[23-25]. The importance of growth factors in the healing and oncogenesis of gastrointestinal diseases has recently received much attention. In inflamed mucosa, EGF is found predominantly in the cytoplasm of the superficial epithelial and isthmus

cells, as in the normal mucosa[26]. In addition to providing a mitogenic stimulus, EGF may also help the proliferating cells to migrate into the superficial epithelium during the process of "cytoprotective" epithelial repair[27].

The development of monoclonal and polyclonal antibodies against EGF has allowed studies of the localization of EGF in normal and neoplastic tissues to be performed[28-31]. Immunocytochemical staining has shown distribution of epidermal growth factor and transforming growth factor α(TGF-α) in the gastrointestinal tract with high levels[32-35]. Normal epithelial cells secrete such growth factors to regulate cell replacement by autocrine or paracrine mechanisms. It is speculated that these growth factors may regulate the transition rate between G2-phase and mitosis of the cell cycle[36]. It has reported that HB-EGF is mitogenic for some types of cells, such as fibroblasts, vascular smooth muscle cells, keratinocytes and rat hepatocytes, but not endothelial cells[37].

The mitogenic action of EGF and TGF-α *in vitro* has been reported in many gastrointestinal tissues, including esophagus, stomach and intestine, and there i s little information about the association between the mucosal expression of these peptides and indices of cellular proliferation *in vivo*[38]. It was reported that EGF immunoreactivity was present in 26-37% of gastric cancers, and the presence of EGF in gastric cancer correlated with the degree of gastric wall invasion, lymph node metastasis and disease progression[39-42]. Although the epidermal growth factor/receptor system has been found abnormal in intestinal type gastric cancer, overexpression of EGF-R, erbB-2 and erbB-3 receptor genes was mainly found. There has been some controversy in the literature whether EGF-R overexpression related to tumor progression or to early stages of gastric carcinogenesis[43-46]. The study had shown that overexpression of the EGF-R gene was infrequent in the metaplastic gastric mucosa. A major problem in gastric carcinogenesis is to determine the changing point from benign pre-neoplastic lesions to malignancy. There is a general agreement that this process involves different steps in cellular changes, requiring both activation and inhibition of specific genes, but there is still no evidence to support EGF or EGF-R overexpression to be a reliable marker of increased cancer risk in patients[47-50]. The present study has sought to clarify their effect on the growth of gastric cancer cell *in vitro* and *in vivo*. In this study, we have found that there was no effect of EGF on the growth of established cell lines, MKN-28, SGC-7901, MKN-45, derived from human gastric adenocarcinoma, both *in vitro* and *in vivo*. Further study is headed to elucidate whether EGF could cause abnormal differentiation of the cells during the treatment of peptic ulcer for a long period.

Abstract

AIM: **To confirm if p53 mutation could be a routine predictive marker for the prognosis of hepatocellular carcinoma (HCC) patients.**

METHODS: **Two hundreds and forty-four formalin-fixed paraffin-embedded tumor samples of the patients with HCC receiving liver resection were detected for nuclear accumulation of p53. The percent of P53 immunoreactive tumor cells was scored as 0 to 3+ in P53 positive region (<10% -, 10-30% +, 31-50% ++, >50% +++). Proliferating cell nuclear antigen (PCNA) and some clinicopathological characteristics, including patients' sex, preoperative serum AFP level, tumor size, capsule, vascular invasion (both visual and microscopic), and Edmondson grade were also evaluated.**

RESULTS: **In univariate COX harzard regression model analysis, tumor size, capsule status, vascular invasion, and p53 expression were independent factors that were closely related to the overall survival (OS) rates of HCC patients. The survival rates of patients with 3+ for P53 expression were much lower than those with 2+ or + for P53 expression. Only vascular invasion (P<0.05) and capsule (P<0.01) were closely related to the disease-free survival (DFS) of HCC patients. In multivariate analysis, p53 overexpression (RI 0.5456, P<0.01) was the most significant factor associated with the OS rates of patients after HCC resection, while tumor size (RI 0.5209, P<0.01), vascular invasion (RI 0.5271, P<0.01) and capsule (RI-0.8691, P<0.01) were also related to the OS. However, only tumor capsular status was an independent predictive factor (P<0.05) for the DFS. No significant prognostic value was found in PCNA-LI, Edmondson's grade, patients' sex and preoperative serum AFP level.**

CONCLUSION: **Accumulation of p53 expression, as well as tumor size, capsule and vascular invasion, could be valuable markers for predicting the prognosis of HCC patients after resection. The quantitative immunohistochemical scoring for P53 nuclear accumulation might be more valuable for predicting prognosis of patients after HCC resection than the common qualitative analysis.**

INTRODUCTION

Liver cancer has been ranked the 2nd cancer killer in China since 1990s. The age-standardized mortality rate in China is as high as $34.7/10^5$, which accounts for 53% of all liver cancer deaths worldwide[1]. Although many advances in its clinical study have been made, a definitive subset is cured by surgery only, and encouraging long-term survival of patients have been obtained in some clinical centers, the overall dismal outcome of patients with hepatocellular carcinoma (HCC) have not been completely changed[2,3]. Lack of control of metastatic foci and recurrence is the most prevalent cause of death in patients with HCC, and it is important to identify the factors that predispose patients to death. Much effort has been made to predict HCC behavior, but there is still lack of specific prognostic indicators.

Prognostic factors in HCC conventionally consist of staging with the tumor node metastasis system (TNM) and grading by tumor cellular differentiation. With new discoveries in the cancer biology, pathological and biological factors of HCC in relation to prognosis have been studied quite extensively. Morphological features of the tumor, both gross and histological, are found to be significantly associated with tumor recurrence and patient survival. A complementary approach is to analyze the HCC for molecular markers with prognostic significance with reference to the recurring possibility and survival time. A large number of molecular biological factors have been shown to be associated with the invasiveness of HCC, and have potential prognostic significance, e.g. c-erbB-2, uPA, PAI-I, VEGF, CDKN2 and p53 mutations, p53 antibody, H-ras, mdm-2, TGF α, EGFR, VEGF, bFGF, PD-ECGF, MMP-2, ICAM-1 are positively related to HCC invasiveness, whereas nm23-H1, Kai-1, TIMP-2, Integrin α5 and E-cadherin are negatively relative factors[4]. Although a great amount of markers have been tried, a routine biomarker for prediction of prognosis of HCC is not yet available.

As early as in 1995, we found that p53 mutations were related to the invasiveness of HCC. Thereafter, we performed immunohistochemical staining for p53 overexpression in the surgical specimen of HCC patients treated in our institute, to see if p53 mutation could be a routine predictive marker for the prognosis of HCC patients. In the present study, we reviewed the results of the studies over the past 5 years, and evaluated whether nuclear accumulation of p53 would be a feasible prognostic marker in the routine diagnostic evaluation of HCC, in particular, to analyze the relationship between p53 overexpression and survival of patients with HCC.

MATERIALS AND METHODS

Tumor samples and HCC patients

Totally, 256 consecutive patients with HCC were enrolled in this study. All of them were surgically treated in the Liver Cancer Institute of Fudan University (former Liver Cancer Institute of Shanghai Medical University), Shanghai, China in the years 1996-1999. Except for 12 cases without informative follow-up data, 244 cases were reviewed, which included 197 male (80.7%) and 47 female (19.3%). The mean age was 50.4 (15-76) years. All specimens were formalin-fixed, paraffin-embedded, which were proved to be hepatocellular carcinoma (HCC). Some histological characteristics including the states of capsule, vascular invasion (both visual and microscopic), cell differentiation were reviewed by one pathologist. The mean tumor size was 5.9 (1-16)cm, <=5cm in 131 cases (53.7%), >5cm but <=8cm 56 cases (23.0%), and >8cm 57 cases (23.3%). The tumor of 128 cases (52.5%) had no capsule, and 116 cases (47.5%) were well-capsulated. The Edmondson grade distribution was grade I in 7 (2.9%) cases, Grade II-III in 235 (96.3%) cases, and grade IV in 2 (0. 8%) cases. Vascular invasion was found in 69 cases (28.3%), which included visual tumor thrombi in portal vein in 31 cases and microvascular invasion in 38 cases. Obvious evidence of liver cirrhosis was found in 217 (88.9%) cases, no cirrhosis in 27 (11.1%) cases. Two hundred and twenty-two cases (91%, 222/244) were followed up. The mean follow-up time was 21.6 (2.2-49) months.

Immunohistochemistry

A standard indirect immunoperoxidase protocol was used for immunohistochemistry (ABC-Elite; Vector Laboratories, Inc., Burlingame, CA). Monoclonal anti-p53, PCNA antibodies (Dako) were used for detection of p53 and PCNA, respectively (1 200 dilution in PBS containing 1% bovine serum albumin and 0.1% Triton X-100). A high-temperature (20 minutes in a pressure cooker) treatment procedure with antigen unmasking solution (Vector Laboratories, Inc.) was used to enhance the staining. The primary antibody was omitted for negative controls.

We used the percentage of p53-positive tumor nuclei in all major foci of cancer as p53 immunohistochemical scoring system. The percent of p53 immunoreactive tumor cells was scored as 0 to 3+ in p53 positive regions. Nuclear p53 expression in >=10% of tumor cells was scored as aberrant overexpression, <10% -, 10%-30% +, 31%-50% ++, and >50% +++.

The patients' sex, serum AFP level, and the pathological characteristics of tumor, including tumor size, capsule, vascular invasion (both visual and microscopic), Edmondson grade, etc. were also evaluated.

Statistical analyses

The log-rank test, Kaplan-Meier analysis and univariate and multivariate Cox regression modeling were used for evaluation of contribution of the variables to relapse and disease-specific survival. Overall and disease-free survival rates were calculated with the Life-Table method, and the survival time was calculated from the operative date. The survival curves were estimated by Kaplan-Meier analysis. The prognostic significance of these markers was analyzed using the log-rank test. A Cox regression analysis was performed to show the relationship of the markers studied with the overall and disease-free survival rates of the HCC patients, and to identify the prognostic factors of the HCC patient after operation. The results were correlated with clinicopathological parameters and the prognosis evaluated by uni- and multi-variate analysis using local control, freedom from distant metastasis, disease-free survival, and overall survival as endpoints.

RESULTS

The 1-, 3- and 5-year overall survival rates of the 244 cases of HCC patients studied were 81.9%, 57.6% and 48.7%, respectively. And, the 1-, 3- and 5-year disease-free survival rates were 55.2%, 38.3%, and 32.2%, respectively. p53 immunohistochemical staining was heterogeneous in the HCC tissues, and nuclear staining for p53 were found in 112 of the 222 (50.5%) cases. The 1-, 3- and 5-year overall survival rates of the HCC patients with positive p53 nuclear accumulation were 81.2% (91/112), 50.9% (57/112), and 33.0% (37/112), while those of the HCC patients with negative p53 expression were 88.8%, 66.3% and 60.6%, respectively. Furthermore, among the patients with positive P53 expression, those with 3+ (>50%) for P53 immunohistochemical scoring had a poorest prognosis, their 1-, and 3-year overall survival rates were only 38.5%, and 12.3%, which were much lower that those with 2+ (60.0% and 46.7%, respectively) and those with + (83.5% and 57.3%, respectively). Therefore, the score of P53 overexpression was adversely related to the survival rates of HCC patients (Table 1).

Table 1 Relationship between some clinicopathological parameters and overall survival rates of HCC patients (a univariate analysis)

Parameters	*n*	Overall survival rates %		
		1-year	3-year	5-year
P53 expression				
-	110	88.8	66.3	60.6
+	86	83.5	57.3	42.9
++	13	60.0	46.7	
+++[b]	13	38.5	12.3	
Tumors size (cm)				
<=5cm	122	92.6	69.0	55.8

No	112	74.0	42.0	26.4
Well[b]	110	90.5	75.9	75.9

[b]$P<0.01$

The overall survival rates of patients after radical resection of small HCC (<=5cm) were higher than those >5cm and <=8cm in diameter. The 3-year survival rate of those with tumor >8cm in diameter (23.9%) was much lower than those with tumor <=8cm in diameter (63. 0%) (Table 1). The 1- and 3-year overall survival rates of the HCC patients with vascular invasion (both visual and microscopic) were 64. 5% (42/62) and 30.6% (19/62), respectively. The patients with visual tumor thrombi in portal vein had a poorer prognosis, their 1- and 3-year overall survival rates were only 42.3% (11/26) and 7.5% (2/26), respectively. No 5-year survival was found. The 1-year, 3-year, and 5-year overall survival rates of patients without vascular invasion were 88.7%, 68.5%, and 60.7%, respectively, which were much higher than those with vascular invasion (P<0.01). A similar situation was also found with disease-free survival (Table 1). The 1-, 3-, and 5-year overall survival rates of patients with well-capsulated HCC were 90.5%, 75.9%, and 75.9%, respectively, while those of the patients without tumor capsule were 74.0%, 42.0%, and 26.4% Table. No significant relationship

between the PCNA-LI, Edmondson grade, patients' sex, or serum AFP level, and overall or disease-free survival rates was found ($P>0.05$).

In univariate Cox harzard regression model analysis, tumor size, capsule status, vascular invasion, p53 expression were independent factors that were closely related to the overall survival rates of HCC patients, while no obvious relationship was found between the PCNA ($P>0.05$) expression and the overall survival. Only vascular invasion ($P=0.0187$) and tumor capsule ($P=0.0059$) were closely related to the disease-free survival of HCC patients, no obvious relationship was found between p53, PCNA status and the disease-free survival (Tables 1, 2).

Similarly, in multivariate analysis, the p53 (RI 0.5456, $P<0.01$) was the most significant factor associated with the overall survival rates of HCC patients after resection. Tumor size (RI 0.5209, $P<0.01$), vessel invasion (RI 0.5271, $P<0.01$) and capsule (RI-0.8691, $P<0.01$) were also related to the overall survival. For the disease-free survival, tumor capsule status remained the only independent predictive factor ($P<0.05$, Table 3). No significant prognostic value was found in the PCNA-LI, Edmondson grade, or patients' sex, serum AFP level for the overall or disease-free survival both in univariate and multivariate Cox analyses.

Table 2 Parameters affecting the disease-free survival rates of HCC patients (a univariate analysis)

Tumor capsule	-0.87	10.30	-0.10	<0.01

DISCUSSION

It is difficult to predict the prognosis of patients with HCC, because so far, there is no any specific marker for that yet. Assessment of the clinicopathological and biological malignancy of HCC may help predict outcome. Some pathological features, such as size of the tumor, vascular invasion, fibrous capsule infiltration, and intrahepatic metastasis are thought as prognostic factors for HCC[5]. New invasiveness scoring system has been proposed based on the items such as venous invasion, tumor capsule, intrahepatic spreading, etc. In our previous report, tumor size was the most important factor for the prognosis of HCC patients and postoperative recurrence possibility[3]. In this study, in univariate Cox harzard regression model analysis, tumor size, capsule status, and vascular invasion were independent factors which were closely related to both of the overall and disease-free survival rates of HCC patients. Similarly, in multivariate analysis, they were also independent prognostic factors for the overall survival, and the tumor capsule status and vascular invasion were predictive factors for disease-free survival. All these further confirmed the significance of pathological characteristics of tumor itself in the survival of HCC patients, and the importance of early detection, early diagnosis and early treatment of HCC.

Some biomarkers such as the tumor DNA content, P53 protein expression, proliferating cell nuclear antigen (PCNA) labeling index, and argyrophilic proteins of nuclear organizer regions were used as markers of biological malignancy. P53 protein plays a central role in cellular responses, including cell-cycle arrest and cell death in response to DNA damage. p53 dysfunction can induce abnormal cell growth, increased cell survival, genetic instability, and drug resistance. p53 mutations occur in approximately half of human cancers. Associations of p53 mutation or positive immunohistochemical stain with higher grade and more advanced stage are common. p53 mutation has been found related to advanced tumor stage in cancers of endometrium, cervix, ovary, liver, prostate and bladder, indicating that for these tumors p53 mutation may be a late event contributing to tumor progression[6]. And p53 mutation has been reported to be a strong marker predicting an increased risk of local relapse, treatment failure, and overall and disease-free survival in many kinds of human carcinomas, such as breast[7-11], colon-recta[12,13], esophagus[14], head and neck[15], lung[16-18], ovarian[19], as well as sarcoma[20]. An increased intracellular concentration of the P53 protein, although not identical to, is sometimes seen in tumors with p53 mutation and correlated with poor prognosis in some tumors. Several studies have shown a relationship between the nuclear accumulation of p53 protein and poor disease-free and overall survival of prostate cancer[21,22], and oral cancer[23]. Detection of micrometastasis of the regional lymph nodes of ovarian cancer by immunohistochemical staining of P53 protein may be useful in predicting the prognosis of patients with stae I or II epithelial ovarian cancer[24]. The presence of serum anti-p53 antibody has also been found to be associated with survival of patients with breast cancer, ovarian cancer, and hepatocellular carcinoma, and colorectal cancer[25,26]. However, there is still a great controversy as to whether alteration of the p53 gene adversely affects the survival of cancer patients. Many reports failed to show the independent prognostic value of p53 in the carcinomas of tongue[27], breast[28-30], stomach[31], lung[32], ovarian[33], bladder[34,35], colorectal[36], and non-Hodgkin's lymphoma[37].

In a similar situation, there are controversial results about the relationship between the p53 overexpression or p53 gene mutation and the prognosis of HCC patients. It was shown that p53 mutation was involved in determining the dedifferentiation, the proliferative activity, tumor progression[38], and closely related to the invasiveness of HCC[4], which might also influence the postoperative course. Mutations of p53 gene or positive immunostaining for mutant P53 protein expression could be used as a significant indicator of poor prognosis[39-41]. Serum anti-p53 antibody could also be a useful prognostic factor for patients with HCC[42]. However, many studies showed that neither the immunohistochemical detection of p53 expression, nor the serum anti-p53 antibodies had a significant prognostic value for outcome of patients with HCC[43-45].

In this study, nuclear staining for P53 was found in 112 of the 222 (50.5%) cases, which was similar to the previous study. The 3-year and 5-year overall survival rates of the HCC patients with positive P53 nuclear accumulation were much lower than those of the HCC patients with negative P53 expression. Its significance was even better than that of the factors such as tumor size, vascular invasion and tumor capsule, though they were also related to the overall survival. Therefore, the score of P53 overexpression was adversely related to the survival rates of HCC patients. These indicated that p53 mutation or nuclear accumulation of p53 expression could be a valuable marker for predicting the prognosis of HCC patients after resection. Among the patients with positive P53 expression, those

with 3+ (>50%) for P53 immunohistochemical scoring had a poorest prognosis, their 1-, and 3-year overall survival rates were only 38.5% and 12.3%, respectively, which were much lower that those with 2+ (60.0% and 46.7%) and those with + (83.5% and 57.3%). Therefore, the quantitative immunohistochemical scoring for P53 expression might be more valuable than the common qualitative analysis for P53 expression for predicting the prognosis of HCC patients.

Proliferating cell nuclear antigen (PCNA) labeling index has been thought as another marker of biological malignancy. A correlation between PCNA-LI and recurrent time and rate was reported. PCNA-LI could be a valuable prognostic marker for HCC. However, in this study, no correlation between PCNA-LI and overall or disease-free survival was found.

In summary, HCC is one of the most common cancers in China. Although great advances in its clinical study have been made, metastatic recurrence is the most prevalent cause of death in patients with HCC. Over the past few years, much effort has been made on this target, including predicting HCC behavior[46-60]. In this study, through the retrospective review of the 244 HCC patients, we found that accumulation of p53 expression as well as tumor size, capsule or vascular invasion could be a valuable marker for predicting the prognosis of HCC patients after resection. The quantitative immunohistochemical scoring for P53 nuclear accumulation might be more valuable than the common qualitative analysis for P53 expression for predicting prognosis of patients after HCC resection.

Abstract

AIM: **To characterize the anticancer function of cytokine-induced killer cells (CIK) and develop an adoptive immunotherapy for the patients with primary hepatocellular carcinoma (HCC), we evaluated the proliferation rate, phenotype and the antitumor activity of human CIK cells from healthy donors and HCC patients *in vitro* and *in vivo*.**

METHODS: **Peripheral blood mononuclear cells (PBMC) from healthy donors and patients with primary HCC were incubated *in vitro* and induced into CIK cells in the presence of various cytokines such as interferon-gamma (IFN-γ), interleukin-1 (IL-1), IL-2, and monoclonal antibody (mAb) against CD3. The phenotype and characterization of CIK cells were identified by flow cytometric analysis. The cytotoxicity of CIK cells was determined by ^{51}Cr release assay.**

RESULTS: **The CIK cells were shown to be a heterogeneous population with different cellular phenotypes. The percentage of $CD3^+/CD56^+$ positive cells, the dominant effector cells, in total CIK cells from healthy donors and HCC patients, significantly increased from 0.1-0.13% at day 0 to 19.0-20.5% at day 21 incubation, which suggested that the $CD3^+$ $CD56^+$ positive cells proliferated faster than other cell populations of CIK cells in the protocol used in this study. After 28 day in vitro incubation, the CIK cells from patients with HCC and healthy donors increased by more than 300-fold and 500-fold in proliferation cell number, respectively. CIK cells originated from HCC patients possessed a higher *in vitro* antitumor cytotoxic activity on autologous HCC cells than the autologous lymphokine-activated killer (LAK) cells and PBMC cells. In in vivo animal experiment, CIK cells had stronger effects on the inhibition of tumor growth in Balb/c nude mice bearing BEL-7402-producing tumor than LAK cells (mean inhibitory rate, 84.7% *vs* 52.8%, $P<0.05$) or PBMC (mean inhibitory rate, 84.7% *vs* 37.1%, $P<0.01$).**

CONCLUSION: **Autologous CIK cells are of highly efficient cytotoxic effector cells against primary hepatocellular carcinoma cells and might serve as an alternative adoptive therapeutic strategy for HCC patients.**

Wang FS, Liu MX, Zhang B, Shi M, Lei ZY, Sun WB, Du QY, Chen JM. Antitumor activities of human autologous cytokine-induced killer (CIK) cells against hepatocellular carcinoma cells *in vitro* and *in vivo*. *World J Gastroenterol* 2002;8(3):464-468

INTRODUCTION

Cytokine-induced killer (CIK) cells are the major histocompatibility complex-unrestricted cytotoxic lymphocytes and generated by incubation of peripheral blood monocytes (PBMC) in the presence of various types of cytokines such as CD3 monoclonal antibody, interleukin-2 (IL-2), interleukin-1 (IL-l) and interferon-gamma[1]. CIK cells are the population of heterogenous effector cells possessing enhanced cytotoxicity and a higher proliferation rate as compared with lymphokine-activated killer (LAK) and tumor infiltrating lymphocytes (TIL) cells. The high anti-tumor activity of CIK cells is mainly due to the high proliferation of double $CD3^+$ and $CD56^+$ positive cells[2-5]. Some reports indicated that CIK cells, other than LAK and TIL cells, can be efficiently employed as an adjuvant in anticancer immunotherapeutic strategy for the eradication of residual cancer cells and prevention or delay of tumor relapse[6-9].

Hepatocellular carcinoma (HCC) is the malignant transformation of hepatocytes and is a common complication of chronic hepatitis mainly caused by hepatitis B virus (HBV) and hepatitis C virus (HCV) infection in China[10]. The mechanisms underlying the malignant transformation of hepatocytes are not well defined. Many driving factors including the persistent hepatitis B or C virus infections, host immunological and genetic factors might have been involved in the process. For example, a failure to mount an efficient immune response to HCC cells, either because of selective defects or immune tolerance in the host immune system or because of tumor interference with a function(s) of immune cells, could account for the inability of HCC patients to block the pathogenesis of HCC occurrence[11-18]. In attempt to characterize the anticancer function of CIK cells and develop an alternative adoptive immunotherapy for the patients with primary HCC, we evaluated the proliferation rate and phenotype of CIK cells from healthy donors and primary HCC patients. Furthermore, we compared the cytotoxic activity and antitumor effects of major effector CIK cells with double $CD3^+$ and $CD56^+$ positive markers against the primary and secondary HCC in *in vitro* cell culture system and *in vivo* tumor-bearing mice model.

MATESIALS AND METHODS

Reagents and cell lines

RPMI1640 and DMEM medium, recombinant human IL-1a, IL-2, interferon gamma (IFN-γ), TNF-α and monoclonal antibody against the CD3 surface antigen (mAb CD3) were all purchased from Gibco Co. The Flt-3 ligand, mouse anti-human FITC-conjugated CD3 and CD56 monoclonal antibodies were obtained from BD-Pharmingen and Fetal calf serum (FCS) from Hyclone. BEL7402 is human HCC cell line kept in liquid nitrogen in our laboratory.

Cell separation

The patients with primary HCC and healthy donors were submitted to cytopheresis after their writing contents were signed. An enriched peripheral blood mononuclear cells (PBMC) product was collected using the specific program of the Cobe Spectra blood separator. Cells were resuspended in phosphate buffered saline (PBS) without calcium and magnesium. The separation of PBMC was performed as previously described[2,19-21]. The concentrated PBMC cells were used immediately for CIK cell culture.

Generation of cytokine-induced killer (CIK) cells

CIK cells were generated as described previously[2,3,22,23]. Briefly, non-adherent Ficoll-separated human peripheral blood mononuclear cells were prepared and incubated in RPMI1640 medium containing 100ml·L^{-1} FCS and various types of cytokines added according to the reported protocol with minor modifications[23]. The final concentrations of the cytokines and antibody added were as follows: IL-2, 1000×10^{3}U·L^{-1}; IL-1, 100×10^{3}U·L^{-1}; IFN-γ, 100×10^{3}U·L^{-1}; mAb CD3, 50μg·L^{-1}. Cells were incubated at 37℃ in a humidified atmosphere of 50ml·L^{-1} CO_2 and fed every 3 days in fresh complete medium with 100ml·L^{-1} FCS and various types of cytokines at 0.5×10^{9}cells·L^{-1}.

Immunofluroescent staining of effector cells

Starting PBMC, LAK or CIK effector cells were stained with various types of FITC- or PE-conjugated mouse mAb's against human surface antigens. Antibodies used included anti-CD3, anti-CD4, anti-CD16, anti-CD56 and anti-TCR-α/β, anti-TCR-γ/δ (all from Becton Dickinson, Beijing, China). Five ×10^5 of cells were incubated with a optimal amount of antibody at 4℃ for 30min. To remove excessive antibody, the incubation mixture was centrifuged at 250×g for 10min. The pellet was resuspended in PBS containing 2ml·L^{-1} of human AB serum and treated as described before[21]. Stained cells were washed and analyzed with FACScaliber (Becton Dickinson) in our laboratory.

Isolation of primary HCC cells from patients

Fresh liver cancer tissues were obtained from the HCC patients at the department of Surgery in our hospital and immediately immersed in sterilized PBS (pH 7.0) solution containing penicillin, 100×10^{3}U·L^{-1}; streptomycin, 100×10^{3}U·L^{-1} and gentamycin, 500×10^{3}U·L^{-1} for 1h at room temperature, then washed with PBS for three times. The liver cancer tissues were cut into small pieces (1-2mm^3 in size), and digested with 37℃-prewarm serum-free medium with 1.25g·L^{-1} of collagenase-V for 2h. In order to separate them into single cell suspension, all the digested pieces of tissues were filtered through the 200 mesh of sterilized copper wire bag. The single cell suspension was further isolated by Percoll gradient centrifugation. Finally, the resuspended cells in DMEM medium with 200ml·L^{-1} FCS were the primary HCC cells.

Cytotoxic effects of CIK cells by ^{51}C release assay

^{51}Cr release cytotoxic assays were performed as reported previously[24]. Briefly, one ×10^6 of human primary HCC cells were incubated with culture medium containing 7.4MBq of ^{51}Cr solution at 37℃ for one hour. The labeling cells were washed with PBS solution for three times and added to 96-well culture plates at 2×10^{4}cells/well. CIK cells were incubated with tumor cells at various ratios of effector cells to target cells as 6.25∶1, 12.5∶1, 25∶1 and 50∶1. After 4h incubation, all cells were collected by centrifugation and an aliquot of supernant was counted in a gamma counter. The percentage of specific release was calculated as described[25].

Inhibitory Effects of CIK cells on HCC in tumor-bearing nude mice models

In pilot experiments, 1.5×10^6 of BEL-7402 cells injected subscapularly could produce solid tumor in Balb/c nude mice at the tenth day with 100% of incidence rate. The Balb/c nude mice used in the study were randomly divided into four groups treated with physical solution, PBMC, LAK and CIK cells, respectively. The nude mice received 3.0Gy of whole body irradiation and injected subscapularly with 5×10^6 BEL-7402 cells, which were at the stage of exponential growth (designated as day 0). On day 1, 0.25mL of 1×10^7 effector cells such as CIK, PBMC or LAK cells were injected locally where tumor cells were inoculated for 6 consecutive days. In controls, the nude mice received 0.25mL physical solution. The size of tumor was recorded every other day. The solid tumors were peeled off after the nude mice were dislocated by killing them on the 35th day.

Statistical analysis

The Wilcoxon matched-pairs test was used to analyze for statistical significance. The P value less than 0.05 was considered as significant difference.

RESULTS

Proliferation and phenotype of CIK cells

Figure 1A and B show the proliferation of CIK cells from healthy donors and patients with primary HCC at different incubation days. During cell generation, there was a steady increase in both the absolute number and the percentage of CD3$^+$/CD56$^+$ cells, e.g. the percentage of CD3$^+$/CD56$^+$ cells was 7.5% on 14d and 51.3% on 56d of in vitro incubation, respectively. After 14d in vitro incubation, the number of total incubated CIK cells increased significantly (500 fold from 8.07×10^5 to 1.02×10^8). The majority (as high as 82%±6.4%) of these cells were positive for TCR-α/β. Cells expressing TCR-γ/δ were relatively rare (4.5%±2.6%). The proliferation capability of PBMC obtained from normal donors was slightly higher than that of PBMC obtained from the HCC patients. The percentage of double CD3$^+$/CD56$^+$ positive cells varied during CIK cell generation. The percentage of CD3$^+$/CD56$^+$ positive cells in total CIK cells from healthy donors and HCC patients significantly increased from 0.1-0.13% at day 0 to 18.95-20.5% at day 21, which suggested that the CD3$^+$ CD56$^+$ positive cells proliferated faster than other populations of CIK cells in the protocol used in this study.

In peripheral blood, 24.2% of CD56$^+$ cells coexpressed CD3$^+$ as compared to 36.2% in LAK cell cultures and 76% in CIK cell cultures (Figure 2). Conversely, only 17.8% and 42.1% of CD3$^+$ cells in peripheral blood and LAK cells coexpressed CD56$^+$, whereas 76.6% of CIK CD3$^+$ cells coexpressed CD56$^+$. At d 28 of CIK cell generation, the percentage of CD3$^+$ cells coexpressing CD56$^+$ increased to 82.4%.

Table 1 Phenotype of CIK cells and cytotoxic activity of CIK subsets

Subset	Percentage positively of CIK	LU / 10^6 cell stained cells	Cell number ×10^6	Total LU per culture
CIK		43.6±4.8	712±24.3	29,074
TCR-α / β	82.0±6.4	20.6±3.8	583±41.6	12,088
CD56	30.4±5.6	78.4±6.9	214±70.3	13,948
CD16	15.8±5.4	60.4±6.0	89±40.9	4106

Note: Total LU per culture was calculated by multiplying the number of LU per million cells by the total number of cells.

Effect of different sera on CIK proliferation

When CIK cells were incubated in RPMI1640 medium containing 100 ml·L^{-1} of fetal calf serum or 100ml·L^{-1} human AB serum or free-

serum medium, respectively, they exhibited different growth curves (Figure 3). CIK cells had the highest proliferation rate in human AB serum-containing medium, the lowest in serum-free medium. The proliferated numbers of CIK cells increased by 500 fold in human AB serum-containing medium, 450 fold increase in fetal calf serum-containing medium, and 50-60 fold in free-serum medium, respectively.

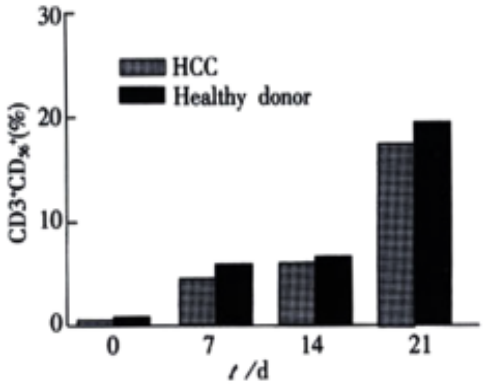

Figure 1B The percentages of double $CD3^+$ $CD56^+$ positive cells at various incubation time *in vitro* culture system

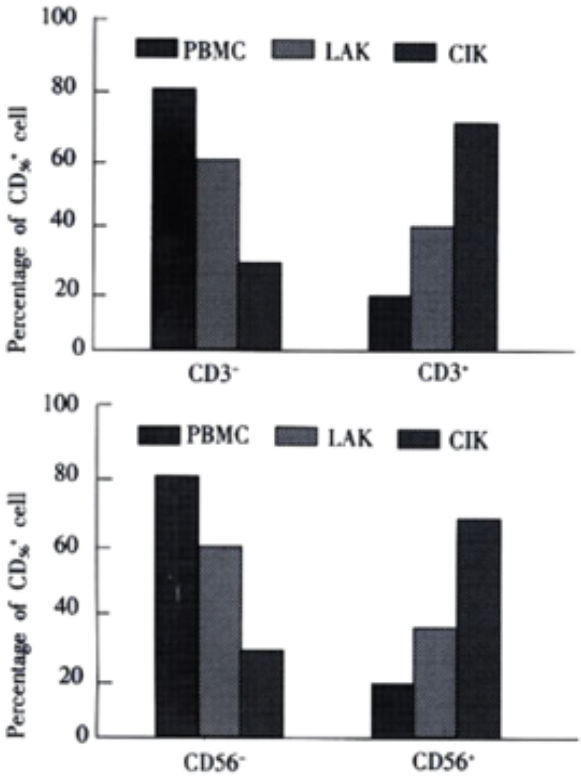

Figure 2 Subsets of CIK cells from patients with primary HCC. CIK cells were counterstained for CD3 and CD56 at day 12 of CIK generation and the percentage of positively stained cells was determined by flow cytometry. PBMC and LAK were stained like CIK cells. LAK cells were used at day 6 of generation. Upper. $CD56^+$ subsets of CIK cells, LAK, PBMC. Subsets of $CD56^+$ cells were compared to the total number of $CD56^+$ cells. The figure represents data from three different experiments. Results are presented as mean value ±SEM. Lower. $CD3^+$ subsets of CIK cells, LAK, PBMC. Subsets of $CD3^+$ cells were compared to the total number of $CD3^+$ cells. The figure represents data from three different experiments. Results are presented as mean value ± SEM.

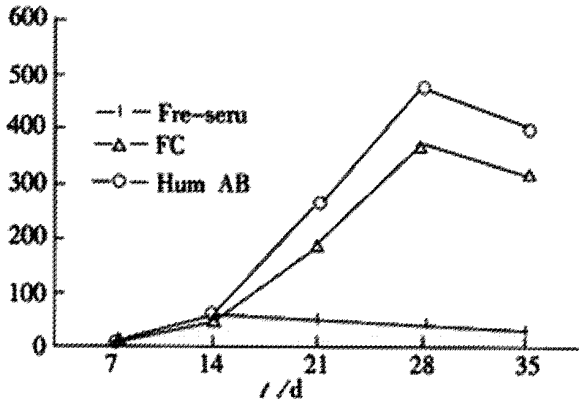

Figure 3 Effects of different culture system on growth of CIK cells

Cytotoxic activity of CIK cells on primary HCC cells

The CIK cell subpopulations were tested for cytotoxicity against the HCC cells as measured by ^{51}Cr release. The primary HCC cells were used as the target cells and the CIK cells from the same patients with HCC as the effector cells. Both of them at various ratios of effector cells to target cells were mixed together for evaluation of the cytotoxic activity of CIK cells. $CD3^+/CD56^+$ T cells were identified to be the major cytolytic effectors, as previously reported, the $CD3^+/CD56^+$ subpopulation of CIK cells exhibited maximum ^{51}Cr release cytotoxicity toward target cells (Figure 4) with the increased ratio of effector and target cells, the cytotoxic effects of CIK cells correspondingly became stronger. In controls, PBMC cells only showed a weaker cytotoxic effect on primary HCC cells compared with CIK cells, and maintained at a lower platform level even if the ratio of effector and target cells increased.

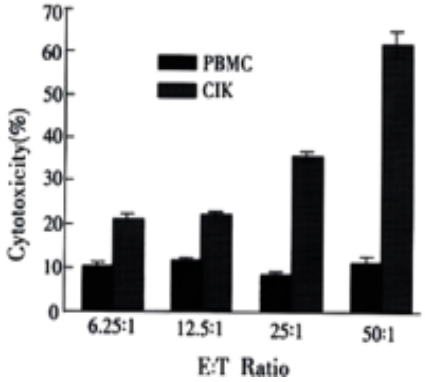

Figure 4 Cytotoxic activity of CIK, PBMC cells against primary HCC cells

Inhibitory effects of CIK cells on HCC in tumor-bearing nude mice

Inhibitory effects of CIK cells on HCC cells in tumor-bearing nude mice are summarized in Table 2. In CIK-treated group, 15 nude mice were inoculated with tumor cells and received treatment of CIK cells for six day consecutively. Tumorgenesis was found in ten of fifteen (66.7%) nude mice. However, tumorgenesis was formed in all the mice in PBMC and LAK treated groups. Furthermore, the tumor size was smaller and limited in the mice of CIK-treated group as compared with those in the mice of PBMC- and LAK-treated groups. There was an obvious difference between the CIK group and LAK group

(P<0.05), and between CIK group and PBMC group (P<0.01), which suggest that CIK cells have a great priority of inhibitory effects on tumorgenesis in tumor-bearing nude mice as compared with LAK cells.

Table 2 Inhibitory effects of CIK, PBMC and LAK cells on HCC cells in tumor-bearing nude mice

Group	*n*	Tumor / g	Tumorgenesis (%)	Inhibitory rate (%)
Control	9	2.10±0.41	100	0
PBMC	11	1.32±0.27	100	37.1
LAK	11	0.99±0.33	100	52.8
CIK	15	0.32±0.31	66.7	84.7[ab]

[a]P<0.05 *vs* LAK group, [b]P<0.01 *vs* PBMC group.

DISCUSSION

In this study, we found that aotulogous CIK cells had a higher proliferation rate and enhanced cytotoxic activity compared with lymphokine-activated killer cells[5,26,27]. The CIK cells from the primary HCC patients had a lower pro liferation ability than that from the healthy donors though no obvious difference was found in the phenotype and components of CIK cells between the two groups. Interestingly, the cytotoxic activity of CIK cells from healthy donors was proved to be stronger than that from the patients with primary HCC. This results might reflect the functions of CIK cells in HCC patients is probably inhibited to some content by itself, which is consistent with the fact that there is a decreased function of peripheral blood dendritic cells in patients with primary HCC[28,29]. Whether the dysfunctional dendritic cells led to the decreased proliferation and function of CIK cells? Martin et al reported that CIK cells significantly increased the cytotoxic activity after co-cultured with aotulogous dendritic cells, and they considered this phenomenon to be induced by IL-12 cytokine secretion from dendritic cells and cell-cell interactions between the two population[5].

Though LAK cells recognize and kill target cells by a non-MHC restricted mechanism in the same way like CIK cells, the CIK cells were found to have the greatest lytic activity[5]. Our results suggested that the CIK effector cells are the subpopulation coexpressing $CD3^+$/$CD56^+$ phenotypes, which supported the facts that CIK cells possessed a higher proliferation rate and higher antitumor cytotoxic activity in vitro than LAK cells[26,30,31].

Immunological effector cells involved in cell-mediated cytotoxicity, such as CIK cells, cytotoxic T lymphocytes (CTLs) and natural killer (NK) cells, possess cytoplasmic granules that are involved in target cell death. These granules contain a pore-forming protein called perforin or cytolysin, a family of serine esterases (granzymes), lysosomal enzymes, and proteoglycan molecules. The cytolysis of tumor cells produced by CIK effector cells might be mediated by the local direct exocytosis of cytoplasmatic granules that penetrate the cell membrane of the bound target cell. Stimulation of CIK cells with tumor cells or anti-CD3 mAb is sufficient for exocytosis of cytotoxic material. The detailed mechanism by which these effector cells recognize tumor cell targets has remained elusive. However, leukocyte function associated antigen-1 (LFA-1) and intercellular adhesion molecule-1 (ICAM-1) appears to be involved. CIK cells do not express the CD16 (Fc receptor) surface molecule, and therefore do not participate in antibody-dependent cellular cytotoxicity (ADCC). The $CD3^+$/$CD56^+$ cell subpopulation is derived from T cells. The cytotoxic effects of CIK cells against tumor cell targets are blocked by antibodies against the adhesion receptor LFA-1 and its counter receptor, ICAM-1, indicating that the adhesion molecule LFA-1 responsible for cellular interaction is necessary for CIK cell-mediated cytotoxicity. Cognate tumor cell targets could also induce BLT esterase release from CIK cells. These observations showed that the cellular interaction involving LFA-l is important for cytolysis of target cells by the CIK cells. The mechanism of exocytosis of cytoplasmic granules leading to cytolysis of the target cell is still unclear. Based on the previous reports, the pathway by which CIK cells can kill target cells, is probably dependent on LFA-l, which probably leads to a granule-dependent cytolysis and is usually the dominant one and accounts for CIK cell cytotoxicity against HCC target cells mediated by CIK recognition structures. Identification of the putative CIK receptors for tumor cell targets as well as other cell surface molecules involved in these cytotoxicity mechanisms will be extremely useful for further understanding of non-MHC-restricted lymphocyte cytotoxicity against tumor cells[5,21,32, 33].

Our study showed that the human CIK cells could eradicate 84. 7% of the established human hepatoma tumor in nude mice and had no toxic side effects, which is consistent with the reports described before [5,30,31]. In addition, CIK cells have an important property of efficiently killing the resistant tumor cells with overexpression of p-glycoprotein [33,34]. Recent studies proved that the activity of CIK cells killing tumor cells in a non-MHC restricted way could be enhanced by co-culture with dendritic cells or by using the bispecific antibody. In summary, CIK cells may have a major impact on the adoptive immunotherapeutic protocols for patients with primary HCC[35,36].

Abstract

AIM: **The goal of this study was to characterize the AFP receptor, its possible signal transduction pathway and its proliferative functions in human hepatoma cell line Bel 7402.**

METHODS: **Cell proliferation enhanced by AFP was detected by MTT assay, ^{3}H-thymidine incorporation and S-stage percentage of cell cycle analysis. With radioactive labeled ^{125}I-AFP for receptor binding assay; cAMP accumulation, protein kinase A activity were detected by radioactive immunosorbent assay and the change of intracellular free calcium ($[Ca^{2+}]_i$) was monitored by scanning fluorescence intensity under TCS-NT confocal microscope. The expression of oncogenes N-ras, p53, and p21^{ras} in the cultured cells in vitro were detected by Northern blotting and Western blotting respectively.**

RESULTS: **It was demonstrated that AFP enhanced the proliferation of human hepatoma Bel 7402 cell in a dose dependent fashion as shown in MTT assay, ^{3}H-thymidine incorporation and S-phase percentage up to 2-fold. Two subtypes of AFP receptors were identified in the cells with Kds of 1.3×10^{-9}mol.L^{-1} and 9.9×10^{-8}mol.L^{-1} respectively. Pretreatment of cells with AFP resulted in a significant increase (625%) in cAMP accumulation. The activity of protein kinase A activity were increased up to 37.5, 122.6, 73.7 and 61.2% at treatment time point 2, 6, 12 and 24 hours. The level of intracellular calcium were elevated after the treatment of alpha-fetoprotein and achieved to 204% at 4min. The results also showed that AFP(20mg.L^{-1}) could upregulate the expression of N-ras oncogenes and p53 and p21^{ras} in Bel 7402 cells. In the later case, the alteration were 81.1%(12h) and 97.3%(12h) respectively compared with control.**

CONCLUSION: **These results demonstrate that AFP is a potential growth factor to promote the proliferation of human hepatoma Bel 7402 cells. Its growth-regulatory effects are mediated by its specific plasma membrane receptors coupled with its transmembrane signaling transduction through the pathway of cAMP-PKA and intracellular calcium to regulate the expression of oncogenes.**

INTRODUCTION

Alpha-fetoprotein (AFP) is an oncofetal protein normally produced in the fetal liver and yolk sac, whose higher serum level is a useful marker for hepatocellular carcinoma and yolk sac tumors. Although the physicochemical and structural properties of this 70-kDa glycoprotein have been largely documented, its pathophysiological functions were limited in *in vitro* studies. In the last decade, the growth regulatory properties of AFP have aroused interest as a result of studies involving ontogenetic and oncogenic growth in both cell culture and animal models[1-3]. A myriad of studies has now described that AFP is capable of regulating growth in ovarian, placental, uterine, hepatic phagocyte, bone marrow, and lymphatic cells[4] in addition to various neoplastic cells[5]. This suggests that AFP is not merely a fetal form of albumin-like carrier protein and a marker for cancer and fetal disorders, but should rather now be considered as a potential factor associated with the regulation of growth, differentiation, regeneration, apoptosis and transformation in both ontogenetic and oncogenic growth processes. Although it is currently thought that a 62- to 67-kDa membrane protein on the surface of monocytes and phagocytes is specific for AFP binding[6,7], the properties of the binding sites were still unknown in most tumor cell lines. Furthermore, few studies have focused on its intracellular signaling events and gene expression. The goal of this study is to characterize the AFP receptor, its possible signal transduction pathway and its proliferative functions in human hepatoma Bel 7402 cells.

MATERIALS AND METHODS

Reagents

Purified AFP was from Sigma (USA). Monoclonal antibod against AFP (anti-AFP) was prepared in this laboratory and used to block AFP. The cAMP kit and Na[^{125}I] were purchased from Amersham, UK. Fluo-3 AM was from BIORAD (USA). Monoclonal antibodies for p53 and p21 were purchased from MBI (USA).

Purification of human AFP Human AFP was prepared as previously described[8]. Briefly, human cord blood AFP was precipitated by ammonium sulphate and passed through an anti-AFP affinity chromatography column. AFP-positive fractions were collected and concentrated. The purity of prepared AFP was 92.7% as determined by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The protein was stored at -80℃ until use.

Effect of AFP on the cell proliferation Total 1.5×10^4 cells per well of Bel 7402 cells were plated into 96-well plates and cultured in RPMI 1640 medium supplemented with 10% fetal calf serum (FCS) at 37℃ in a humidified atmosphere of 5% CO_2 for 48h. The cultures were replaced with medium without FCS for another 24h, and treated with different concentration of AFP (1-80mg.L^{-1}) for 48h. The effects of AFP on the proliferation of cells were measured by MTT assay and ^{3}H-Thymidine incorporation, which were performed following a regular procedure.

Effect of AFP on the cell cycle First, 3×10^4 cells per well of Bel 7402 cells were plated into 6-well plates. Culture and AFP treatment were then performed as described above. After being treated

for 24h, the cells were digested with 0.25% trypsin/0.02% EDTA and washed three times with PBS. A final density of 1×10^6 cells in 1ml was added 20μl (10mg.mL^{-1}) RNase (Promega USA) solution and incubated at 37℃ for 30min. The effects of AFP on the cell cycle were detected with flow cytometry.

AFP receptor binding assay Bel-7402 cells were maintained in a humidified atmosphere of 5% CO_2 at 37℃ in RPMI-1640 medium supplemented with 10% FCS. The cells were initially depleted of serum for 12h and then washed with cold medium. Resuspended cells were passed through a 300-mesh screen and adjusted to 1×10^6 cells per ml. ^{125}I-AFP was radioiodinated by the iodogen method and run through a column of Sephadex-G25 to remove free ^{125}I. The specific activity of ^{125}I-AFP was 2715 Ci per mmol and the purity of radioactivity ratio was 99.4%. Each reaction contained 7×10^5 cells, ^{125}I-AFP of 5×10^4 cpm and different concentrations of non-labeled AFP (0.25-64.5ng). The reaction was triplicated and performed at 4℃ for 2h. All samples were collected onto glassfiber membrane (presaturated with 0. 5% albumin) and washed three times with 15ml of PBS. The radioactivity of ^{125}I was detected by a γ-counter. Human serum albumin (HSA) as a non-labeled ligand was utimized for measuring IC_{50}. The parameters of binding were ed using a program of Radioligand Binding Assay of Receptors (RBA).

Extraction and measurement of cAMP The cells were adjusted to 4×10^4 cells per ml and cultured in 24 well plates. After 24h incubation, the cells were collected and resuspended in the medium supplemented with 0.1% egg albumin and 25mmol.L^{-1} of HEPES (pH 7.4) and 2mmol.L^{-1} IBMX (3-methyl-1-isobutyl-xanthine) at 37℃ for 15min. AFP (20mg.L^{-1}) and/or anti-AFP (40mg.L^{-1}) was added into each well respectively for 4h. Extraction of cAMP was performed according to the method described by Iwashia[9]. In short, the supernatant was removed and replaced with 1ml of cold PBS per well. After wash, the pellet was frozen in -80℃ for 30min and then 0.5ml of HCl (0.05N) was added into each well for another 30min. The samples were thawed and spun at 10000g for 5min. The supernatants were lyophilized, and the content of cAMP was measured by the radio immunoassay following the instruction of cAMP assay kit.

Determination of protein kinase A activity Total 4×10^5 cells per well were cultured in 24-well plates for 48h, changed to fresh medium without FCS for another 24h, and then treated with either AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}) or AFP (20mg.L^{-1}) plus anti-AFP (40mg.L^{-1}) respectively. After 2, 6, 12 and 24h treatment, the cells were washed and resuspended in 1ml PBS. The measurement of PKA activity has been described by Plet[10]. Briefly, 40μl of cell extract was mixed with 160μl of the reaction mixture at the final concentration of 20mmol.L^{-1} Tris-HCl (pH 7.5), 5mmol.L^{-1} $MgCl_2$, 0.25g.L^{-1} BSA, 0.5g.L^{-1} histone, 2×10^{-7}mol.L^{-1} ATP (γ-^{32}P ATP, 3.7×10^4 Bq) and 8.0μmol.L^{-1} cAMP at 37℃ for 10min. Followed by incubation on ice for 5min, the reaction mixture was filtered through Whatmen GF/C filter, washed with 10% TCA-2% phosphoric acid and 5% TCA for 30min. The radioactivities were measured by a liquid scintillation counter, and PKA activity was expressed as pmol value of ^{32}P in histone catalyzed by per mg protein per min.

Determination of intracellular calcium concentration The cell suspension was dispensed into specific culture plates at a density of 2×10^4 cells per ml and incubated at 37℃ in a humidified atmosphere of 5% CO_2 for 48h. The supernatant was removed and replaced with medium without FCS for 6h, followed by washing three times with Hank's solution. The measurement of intracellular calcium concentration has been described by Tsugorka and Petti *et al*[11,12]. Briefly, the cells were loaded with 10ml of Fluo-3AM in Hank's solution at a final concentration of 5μmol.L^{-1} and incubated at 37℃ for 30min. After washing 3 times with Hank's solution, either AFP (20mg.L^{-1}) or anti-AFP (40mg.L^{-1}) was loaded into each well. The change of intracellular free calcium ($[Ca^{2+}]_i$) was monitored by scanning fluorescence intensity under TCS-NT confocal microscopy every 10s.

RNA isolation and Northern blotting Cells were treated with either AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}) or AFP (20mg.L^{-1}) plus anti-AFP(40mg.L^{-1}) for 24h. Total cellular RNA was isolated from cell lines with TRIzol reagent(Promege, Madison,WI, U.S.A) according to the manufacturer's protocol. RNA (10-20μg/lane),quantitated by absorbance at 260nm, and fractionated by eletrophoresis through a 1% formaldehyde agarose gel, and the fractionated RNA was transferred(in 20×SSC) to nitrocellulose membranes(Millipore corporation Bedford, MA; U.S.A), by standard procedure[13] These membranes were hybridized with a ^{32}P labeled probe and washed using standard protocol. The membranes were then exposed to X-ray film at -70℃ for varying periods of time.

Western blot analysis Cells were treated with either AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}) or AFP (20mg.L^{-1}) plus anti-AFP(40mg.L^{-1}) for 24h. After three times wash, the cells in each reaction were lysed in 10μl of lysis buffer containing 0.2% Triton X-100, 500mmol.L^{-1} NaCl, 500mmol.L^{-1} sucrose, 1mmol.L^{-1} EDTA, 0.15mmol.L^{-1} spermine, 0.5mmol.L^{-1} spermidine, 10mmol.L^{-1} HEPES (pH 8.0), 200μmol.L^{-1} phenylmethylsulfonyl fluoride, 2mg leupeptin.L^{-1}, 2mg pepstatin.L^{-1}, 24 IU aprotinin.ml^{-1} and 7mmol.L^{-1} γ-mercaptoethanol. 40μg proteins were subjected to sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) and transferred to PVDF membrane for immunodetection. SDS- PAGE molecular weight markers (Bio-Rad) verified the correct location of the visualized bands. The membranes were blocked in 5% nonfat milk (w/v) in PBS-Tween, then probed with anti-p53 or anti-p21 and followed by secondary antibodies (goat anti-mouse Ig-alkaline phosphatase). Immunoreactive proteins were detected using color development system (NBT/BCIP).

Statistical analysis Data were analyzed by t test and expressed as mean±SD based on 3 or 4 independent experiments.

RESULTS

Effect of AFP on the cell proliferation

Pretreating Bel 7402 cells with AFP (1-80mg·L^{-1}) resulted in a dose-dependent increase in cell proliferation (Figure 1). The increase was about 2-fold at a dose of 80mg.L^{-1}as compared to the control (0mg.L^{-1}). The effects of AFP (20mg.L^{-1}) on cell proliferation could be blocked by anti-AFP (40mg.L^{-1}) which was observed both in MTT assay and ^{3}H-Thymidine incorporation (Figure 2). The increase was not observed in the HSA-treated group and non-treatment control. Flow cytometric analysis showed that AFP (20mg.L^{-1}) pretreatment increased the S phase cell population by 59.3% of Bel 7402 cells (Table 1).

Table 1 The effects of AFP on the cell cycle progression. Bel 7402 cells maintained in RPMI 1640 medium were respectively treated with either AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}), AFP (20mg.L^{-1}) + anti-AFP (40mg.L^{-1}) or HSA (20mg.L^{-1}) for 24 hours. The effects of AFP on the cell cycle progression were analyzed by flow cytometry. The data represented the mean values of four independent experiments performed each in triplicate

Bel 7402 cells were incubated with different concentrations of AFP for 48h and the cell proliferation was measured by MTT assay. The data represented the mean values of six independent experiments performed each in triplicate. $^{a}P<0.05$ and $^{b}P<0.01$ *vs* control (0mol.L^{-1}).

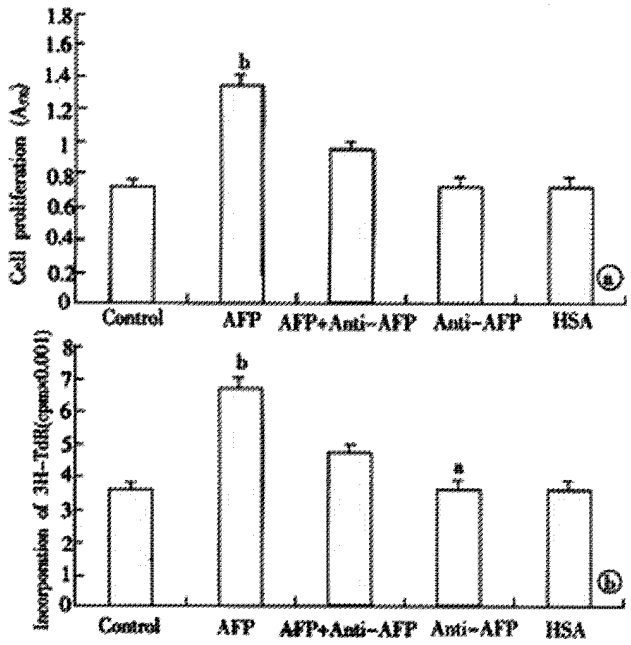

Figure 2 The blockage of anti-AFP to the effect of AFP on the proliferation of cells. A. The data of MTT assay. B. The data of ^{3}H-TdR incorporation. The cells were respectively treated with either AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}), AFP (20mg.L^{-1})+ anti-AFP (40mg.L^{-1}) or HSA (20mg.L^{-1}) for 48h. (MTT assay) or 18h (^{3}H-TdR incorporation). The data represented as the mean value of four independent experiments performed each in triplicate. $^{a}P<0.05$ and $^{b}P<0.01$ *vs* control (0mol.L^{-1}).

Distribution of AFP receptor on the membranes of Bel 7402 cells

The binding sites of AFP on the surface of the cells and Kd values were calculated based on Scatchard plot analysis of ^{125}I-AFP. Scatchard analysis showed that there were two classes of receptors with different affinities on Bel 7402 cells. As for Bel 7402 cells, K_D1 with 89400 sites per cell was 1.3×10^{-9}mol.L^{-1} and K_D2 with 582000 sites per cell was 9.9×10^{-8}mol.L^{-1}(Figure 3). To indicate a higher affinity of the binding sites for AFP, IC_{50} was calculated to achieve 50% inhibition. More than two fold of HSA were needed compared with AFP (data not shown), which indicated a higher affinity for the binding sites on the surface of cells to AFP.

Effect of AFP on intracellular camp

AFP markedly elevated the concentration of cAMP up to 625% in Bel 7402 cells (Figure 4). Anti-AFP could not alter the concentrations of cAMP when added alone, but it reversed the effect of AFP. As a control, HSA did not influence the content of cAMP.

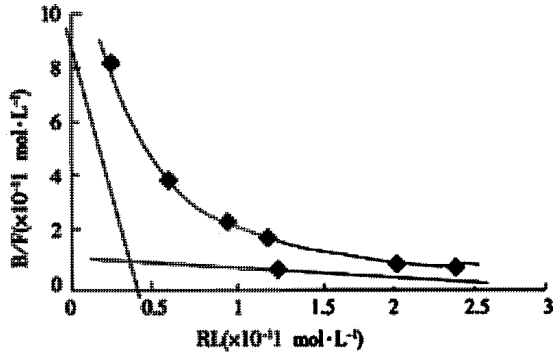

Figure 3 Scatchard analysis of ^{125}I-AFP binding to Bel 7402 cells. The properties of AFP receptor in Bel 7402 cells was detected with receptor binding assay and analyzed by a program of Radioligand Binding Assay of Receptor. The data were selected from three independent experiments.

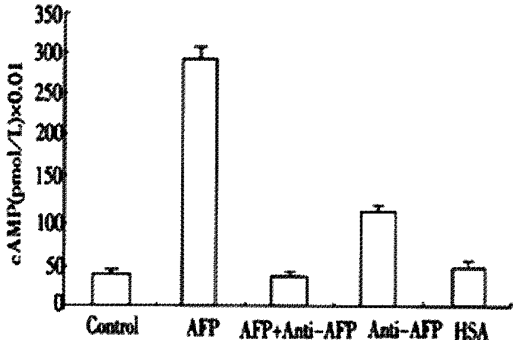

Figure 4 The effects of AFP on the cAMP concentration in cytosol of human hepatoma Bel 7402 cells. 4×10^{4} cells were respectively treated with AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}), AFP (20mg.L^{-1})+ anti-AFP (40mg.L^{-1}) or HSA (20mg.L^{-1}). The data represented the mean values of four independent experiments performed each in triplicate. $^{b}P<0.01$ *vs* control (0mol.L^{-1}).

Effect of AFP on PKA activity

The activities of PKA in the cytosol of Bel 7402 cells were obviously elevated after being treated with AFP (20mg.L^{-1}) for 2, 6, 12 or 24h (Figure 5). The activities of PKA were increased up to 37.5, 122.6, 73.7 and 61.2% in Bel 7402 cells at each time point. The peak value was achieved at 6h and then declined gradually, but still maintained a higher activity for several hours. Anti-AFP or HSA alone did not affect the activity of PKA in Bel 7402 cells, but anti-AFP could block the effects of AFP on the activity of PKA.

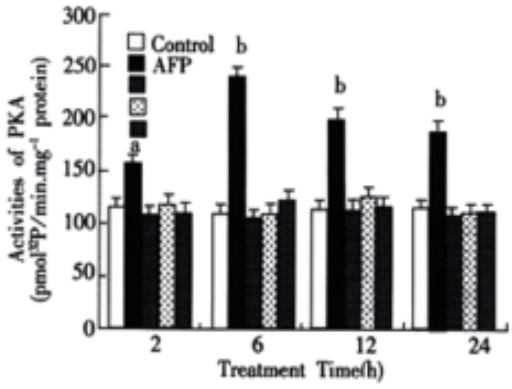

Figure 5 The effects of AFP on the activity of PKA in Bel 7402 cells. 4×10^{5} cells per ml were respectively treated with either AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}), AFP (20mg.L^{-1})+ anti-AFP (40mg.L^{-1}) or HAS (20mg.L^{-1}) for different time and the activities of intracellular PKA were then detected. The data represented the mean values of four independent experiments performed each in triplicate. $^{a}P<0.05$ and $^{b}P<0.01$ *vs* control (0mol.L^{-1}).

Determination of intracellular[Ca^{2+}]i release

Figures 6A1-5 and figure 6B showed that AFP increased the intracellular [Ca^{2+}]i after treatment of 2, 4, 6, 8 and 10 min in Bel 7402 cells. The peak was achieved at treatment time 4 min (increment 204.1% in Bel 7402 cells). Anti-AFP and HSA did not change the content of [Ca^{2+}]i in either cell type. However, anti-AFP could reverse the effect of AFP.

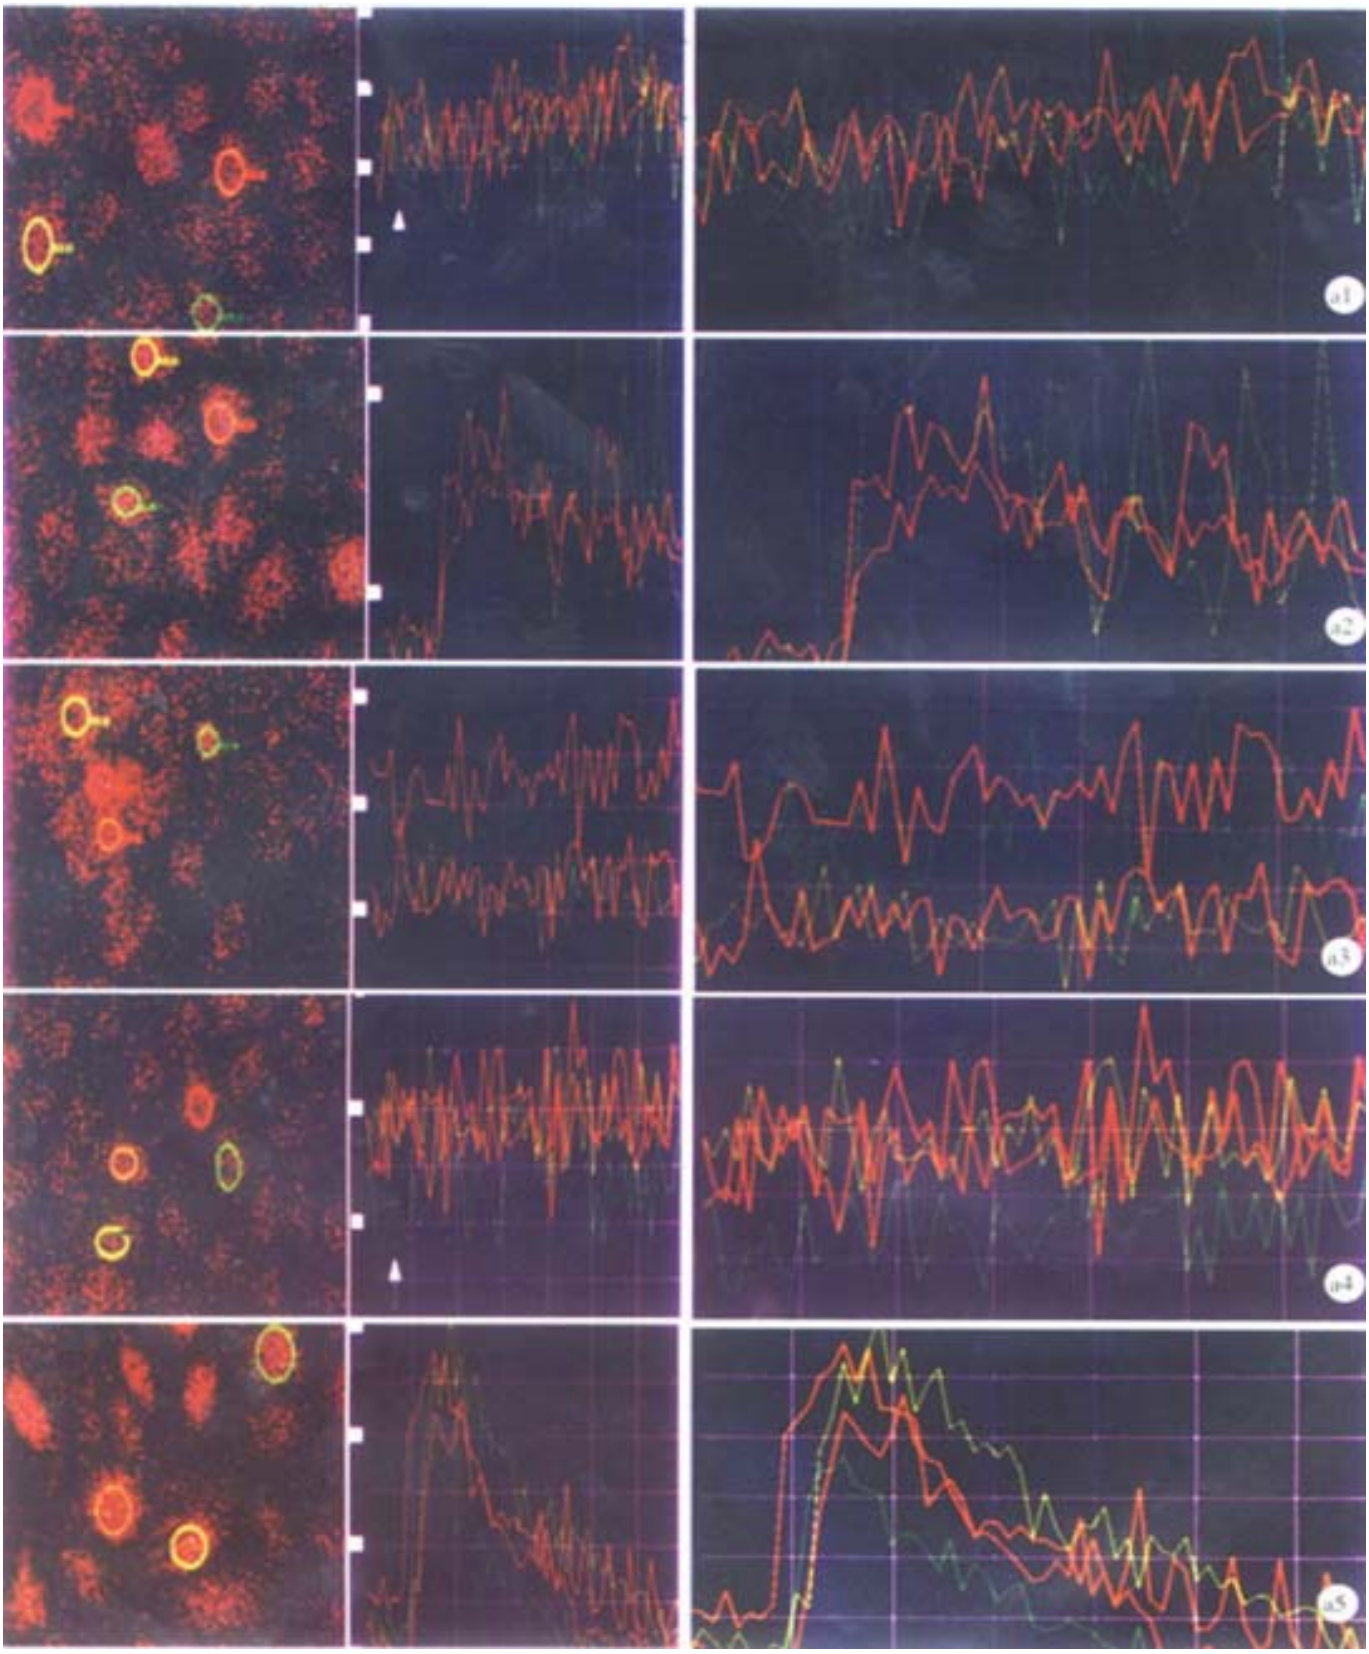

Figure 6A The change of Ca^{2+} concentration in human hepatoma Bel7402 cells was measured by confocal microscopic scanning. Cells were incubated with 5μmol.L^{-1} fluo-3/AM at 37℃ for 30min and then stimulated with Hank's. (1) AFP(20mg.L^{-1}); (2) HSA(20mg.L^{-1}); (3) Anti-AFP; (40mg.L^{-1}); (4) or AFP(20mg.L^{-1}) + Anti-AFP(40mg.L^{-1}); (5) The arrow indicate the stimulated time point.

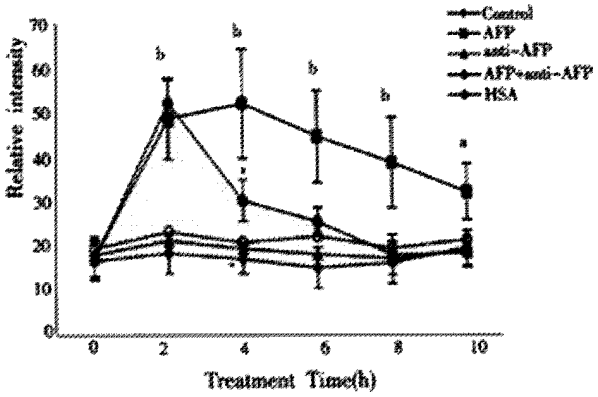

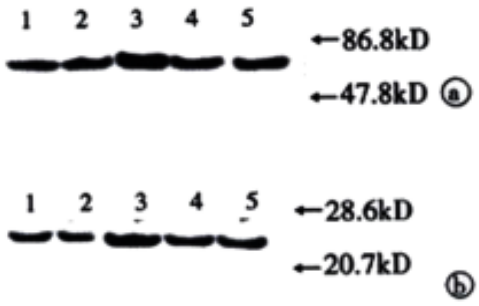

Figure 6B The graph shows the scanning results. The data represented as the mean value of 10 cells ±s. $^aP<0.05$ and $^bP<0.01$ *vs* control (0mol.L^{-1})

Expression of p53 and p21 proteins

The results in Figure 8 demonstrated the overexpression of mutant p53 and p21 protein in AFP-treated group in Bel 7402 cells. Anti-AFP could reverse the upregulated effects of AFP on the expression of p53 and p21 genes. HSA could not influence the amount of these proteins. Each graph was selected from 3 similar results.

Expression of N-ras mRNA

The results in Figure 7 demonstrated the overexpression of N-ras mRNA in AFP-treated group in the Bel 7402 cells. Anti-AFP could reverse the upregulated effects of AFP on the expression of N-ras mRNA. HSA could not influence the mRNA amount of the oncogene. Each graph was selected from 3 similar results.

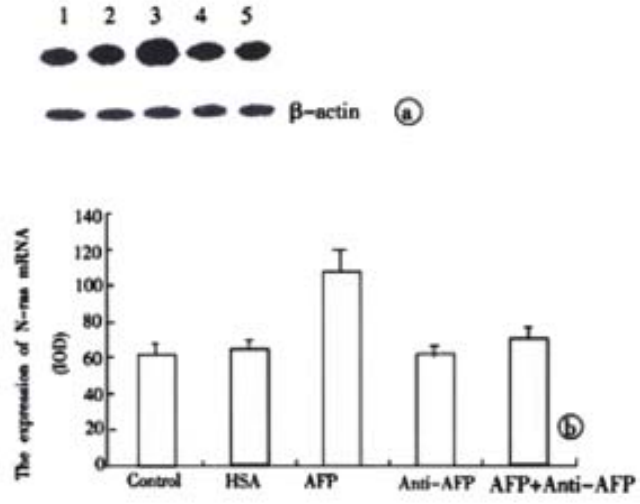

Figure 7 The effects of AFP on the expression of N-ras mRNA in Bel 7402 cells. 1×10^5 cells were respectively treated with AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}), AFP (20mg.L^{-1}) + anti-AFP (40mg.L^{-1}) or HSA (20mg.L^{-1}) for 12 hours and expression of N-ras mRNA was detected by Northern blot assay. Lane 1: control group; Lane 2: HSA treated group; Lane 3: AFP treated group; Lane 4: anti-AFP treated group; Lane 5: AFP plus anti-AFP treated group. The data was selected from 3 independent experiments. A: Autoradiograph of Northern blot. B: Quantitated by densitometric scanning of N-ras mRNA expression blot in Bel7402 cells (relative IOD units). The columns represent the means of triplicate determinations ±s.

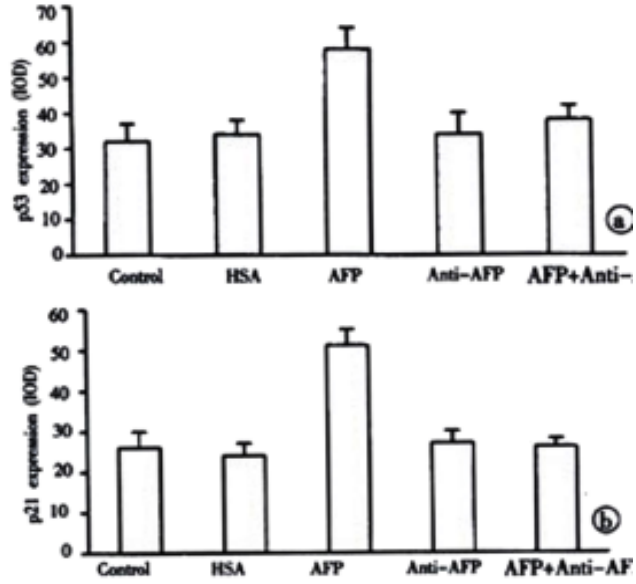

Figure 8 The effects of AFP on the expression of p53 (A) and p21 (B) proteins in Bel 7402 cells. 1×10^5 cells were respectively treated with AFP (20mg.L^{-1}), anti-AFP (40mg.L^{-1}), AFP (20mg.L^{-1}) + anti-AFP (40mg.L^{-1}) or HSA (20mg.L^{-1}) for 24 hours and the expression of p53 and p21protein were detected by Western blot assay. Lane 1: control group; lane 2: HSA treated group; lane 3: AFP treated group; lane 4: anti-AFP treated group; lane 5: AFP plus anti-AFP treated group. The data was selected from 3 independent experiments. A:p53; B:p21. The columns represent the means of triplicate determinations ±s.

DISCUSSION

AFP is an onco-developmental gene product. In the adult, AFP is highly expressed during liver regeneration and hepatocarcinogenesis and used as a maker for the diagnosis of hepatocellular carcinoma[14-16]. The regulation and activation on the expression of the AFP gene have been extensively investigated[17-21]. Although less data indicated AFP could causes apoptosis in tumor cells[22,23], the data from most current research demostrate that AFP is enhancer in tumor growth. The downregulation of expression of alpha-fetoprotein is able to induce the suppression of growth of malignant hepatocyte cell[24-26]. Although the biological role of AFP in cell growth has been reported[27-29], the properties of the AFP receptor as well as the subsequent events after AFP binding were still undefined. Our data indicate that a specific AFP receptor does exist in a human tumor cell line, Bel 7402 cells. There were two kinds of receptors with different affinities in Bel 7402 cells (K_D:10^{-9} and 10^{-8}mol.L^{-1}), which was consistent with similar experiments that characterized the K_D of binding protein in monocytes in the range of 10^{-11}-10^{-7}mol.L^{-1}[6,30]. The AFP-binding protein possibly containing the AFP-receptor has been isolated from human

embryos and human breast cancer tissue[31].

Based on the results of MTT assay, ^{3}H-thymidine incorporation and flow cytometry analysis, as well as the enhanced expression of mutant p53 and p21 and expression of protooncogenes N-ras mRNA, AFP appears to be a potential growth promoting factor.

Since the albumin and AFP genes are similar in structure, they are believed to be derived from a common ancestral gene, even in the same albuminoid gene family. In all our AFP studies, none of the results showed that human serum albumin (HSA) as a control was able to alter the parameters of cell proliferation although it can non-specifically bind to the cell surface.

Little information on the effect of AFP on signal transduction was available. The present experiments demonstrated that intracellular cAMP was significantly elevated 7 fold in Bel 7402 cells. PKA activities were also increased. This indicates that a cAMP-dependent protein kinase pathway is involved in the effects of AFP on the tumor cells, even though some data from other laboratory indicated that the alteration of activity of PKC affected only liver gene expression rather than cell growth in fetal hepatocytes[32]. Other experiments for the relationship between AFP and message has been tested[33].

In addition, the results of intracellular calcium showed that AFP markedly increased intracellular [Ca^{2+}]i. It has been reported that Bcl-2 suppresses apoptosis by inhibiting calcium activation of the permeability transition of mitochondria[34] and the inhibition of calcium influx was related to the suppression of lymphoma cell-line proliferation[35]. Furthermore, a reciprocal regulation between calcium signaling and hypertrophic growth has been identified[36]. According to these findings, a higher intracellular[Ca^{2+}]i elicited by AFP may play a role in tumorigenesis.

Although growing evidence has confirmed the effects of AFP on the growth of tumor cells, little work has focused on the subsequent events in the nucleus. The impacts of overexpression of protooncogenes N-ras, mutant p53, p21 and other genes on tumor growth have been largely documented[37-41]. In the present experiment, mutant p53 and p21 protein were over produced under the treatment of AFP, which was consistent with similar work[42,43]. It suggested that the mechanism by which elevated levels of mutant p53 and p21 proteins might be involved in AFP-induced oncogenesis.

The pattern inducing the hepatocarcinogenesis is multimode[44,45], but the effect of AFP on the growth of tumor has been confirmed. Based on our experiments, the functional mechanism of AFP on the growth of tumors may be attributed, at least in part, to receptor-mediated cAMP pathway and/or calcium signaling resulting in overexpression of certain genes. The clarification of the mechanism will provide a possibility for the gene therapy of liver tumor[46-48]. Further investigations on the function of AFP may shed further light on the mechanism of AFP action.

Abstract

AIM: **To investigate the influence of hepatic arterial blockage on blood perfusion of transplanted cancer in rat liver and the expression of vascular endothelial growth factor (VEGF) and matrix metalloproteinase-1 (MMP-1), and to explore the mechanisms involved in transarterial embolization (TAE)-induced metastasis of liver cancer preliminarily.**

METHODS: **Walker 256 carcinosarcoma was transplanted into rat liver to establish the liver cancer model. Hepatic arterial ligation (HAL) was used to block the hepatic arterial blood supply and simulate TAE. Blood perfusion of tumor in control, laparotomy control, and HAL group was analyzed by Hoechst 33342 labeling assay, the serum VEGF level was assayed by ELISA, the expression of VEGF and MMP-1 mRNA was detected by in situ hybridization.**

RESULTS: **Two days after HAL, the number of Hoechst 33342 labeled cells which represent the blood perfusion of tumor directly and hypoxia of tumor indirectly in HAL group decreased significantly compared with that in control group (329±29 *vs* 384±19, $P<0.01$). The serum VEGF level in the HAL group increased significantly as against that of the control group (93ng·L^{-1}±44ng·L^{-1} *vs* 55ng·L^{-1}±19ng·L^{-1}, $P<0.05$). The expression of VEGF and MMP-1 mRNA in the tumor tissue of the HAL group increased significantly compared with that of the control and the laparotomy control groups ($P<0.05$). The blood perfusion data of the tumor, represented by the number of Hoechst 33342 labeled cells, showed a good linear inverse correlation with the serum VEGF level ($r=-0.606$, $P<0.05$) and the expression of VEGF mRNA in the tumor tissue ($r=-0.338$, $P<0.01$).**

CONCLUSION: **Blockage of hepatic arterial blood supply results in decreased blood perfusion and increased expression of metastasis-associated genes VEGF and MMP-1 of transplanted liver cancer in rats. Decreased blood perfusion and hypoxia may be the major cause of up-regulated expression of VEGF.**

INTRODUCTION

Primary liver cancer (PLC) is one of the most common cancers in Asia. Patients with PLC usually have very poor prognoses, and the overall 5-year survival rate was not more than 5% worldwide[1-3]. Surgery is considered as the only potential cure. However, the resection rate for PLC is only 10%-30%. Transarterial embolization (TAE) is one of the main non-surgical treatments for liver cancer in Asia via selectively blocking of the hepatic arterial blood supply of the tumor. However, a prospective controlled study showed that TAE enhanced the rate of lung metastases and accelerated metastases in patients with PLC[4]. Other reports also showed that preoperative TAE for resectable PLC or TAE after curative resection of PLC could result in introhepatic recurrence or extrahepatic metastasis, and a shorter survival[5,6]. Metastases induced by TAE will undoubtedly reduce the long-term efficacy of TAE for PLC, but the mechanisms responsible for that have not been previously reported and there is no good method to inhibit metastasis.

In the present study, we have observed the influence of hepatic arterial ligation (HAL) which simulate TAE on metastasis related genes expression in Walker 256 tumor transplanted in rat liver to explore the mechanisms involved in TAE-induced metastasis of liver cancer preliminarily.

MATERIALS AND METHODS

Tumor model and treatment schedule

An implanted liver cancer model was obtained from Shanghai Medical Industry Research Institute, China. Male pathogen-free Wistar rats, weighing 100-120g, were anesthetized with pentobarbital sodium (40mg/kg). Following midline laparotomy, Walker 256 carcinosarcoma (about 1mm^3) was implanted into one hepatic lobe of the rat. Seven days later, the rats that developed tumors were divided randomly into 3 groups:a control group without any treatment (n=8), a laparotomy control group (n=4) which underwent laparotomy only, and a HAL group (n=8). In the HAL group, after anesthesia and laparotomy, the proper hepatic artery was ligated by a sewing line.

Staining of perfused vessels with Hoechst 33342

The perfusion marker Hoechst 33342 (Sigma, USA) was dissolved in sterile saline immediately before use. Two days after HAL, all rats from all three groups were anesthetized and then their abdominal cavity was opened. The inferior vena cava was punctured to collect 0.5mL blood and to inject 0.2mL Hoechst 33342 (at a concerntration of 6.25g·L^{-1}). The hepatic lobes bearing tumor were excised 1min after injection of Hoechst 33342 to prevent diffusion of Hoechst 33342 into adjacent non-perfused vascular structures. Hoechst 33342 is removed very rapidly from the circulation (half-time of 2min) and is very stable, once bound to DNA. Thus, Hoechst 33342 specifically labels the nuclei of endothelial cells and nuclei of the cells adjacent to the vessel walls, thereby delineating the perfused vessels[7-9]. The tumors were excised and frozen in liquid nitrogen and then stored at -80℃ until tumors were sectioned. Frozen sections (5μm) were cut and Hoechst 33342 labeled cells were visualized and photographed

under a fluorescence microscope equipped with a camera with 365nm excitation and 420nm emission filters showing blue fluorescence. Four high power fields under the fluorescence microscope were photographed and Hoechst 33342 labeled cells were counted. The mean number of labeled cells reflected the blood perfusion of tumor and has been shown to be inversely related to the level of hypoxia in tumor[7].

In situ hybridization (ISH) detection

ISH kits (Boster, China) were used to detect vascular endothelial growth factor (VEGF) and matrix metalloprotenase-1 (MMP-1) mRNA expression. Experiments were performed following the manufacturer's instructions. Briefly, frozen sections (5μm) were taken from the tumor and fixed with 40g·L^{-1} polyformaldehyte in PBS (0.1mol·L^{-1}) for 30min, then digested in pepsin for 3min at 37℃. The material was prehybridized for 2h and then hybridized with Digoxin labeled probe overnight at 40℃. After hybridization, sections were washed with 2×SSC, 0.2×SSC, and then incubated with rabbit anti-Digoxin antibody, biotinylated secondary antibody IgG, SABC. Slides were stained with DAB and studied under a light microscope equipped with a camera. A positive stain should be present as intracytoplasmic. The level of mRNA expression was evaluated by two of the authors on blinded sections and was expressed as a positive staining rate.

Serum VEGF assay with ELISA

Blood samples collected from the inferior vena cava of rats were pooled, coagulated, and centrifuged at 1000×g for 10min. After the serum was aspirated, the VEGF level was assayed with an ELISA kit (MEGA, USA). Experiments were performed following the manufacturer's instructions.

Statistical analysis

The number of Hoechst 33342 labeled cells,the percentage of positive staining cells of ISH detection, and the serum VEGF level were expressed as mean±SD.The difference between mean values were compared by Student's *t* test.A *P* value less than 0.05 was considered to be statistically significant.Linear regression was used for the correlation assessment. Statistical analyses were performed using SPSS software.

RESULTS

Blood perfusion of tumor

The mean number of Hoechst 33342 labeled cells represents the blood perfusion of tumor, and indirectly represents the level of hypoxia in tumor. The lower number of labeled cells suggests an impaired blood perfusion and a higher level of hypoxia in tumor. The mean number of Hoechst 33342 labeled cells in the control, the laparotomy control, and the HAL groups were 384±19, 369±27, and 329±29, respectively. The number of labeled cells in the HAL group decreased significantly compared with that in the control and the laparotomy control groups (P<0.05, Table 1 and Figure 1). This suggests a decreased blood perfusion and a more serious hypoxia of tumor after HAL.

VEGF and MMP-1 mRNA expression

ISH showed both VEGF and MMP-1 mRNA expressed in the implanted tumor of control and laparotomy control groups. There was no significant difference between these two groups (P>0.05). The expression of VEGF and MMP-1 in the HAL group was elevated significantly compared with values in the control and the laparotomy control groups (P<0.05). Results of their expression in the different groups are shown in Table 1, and Figures 2 and 3.

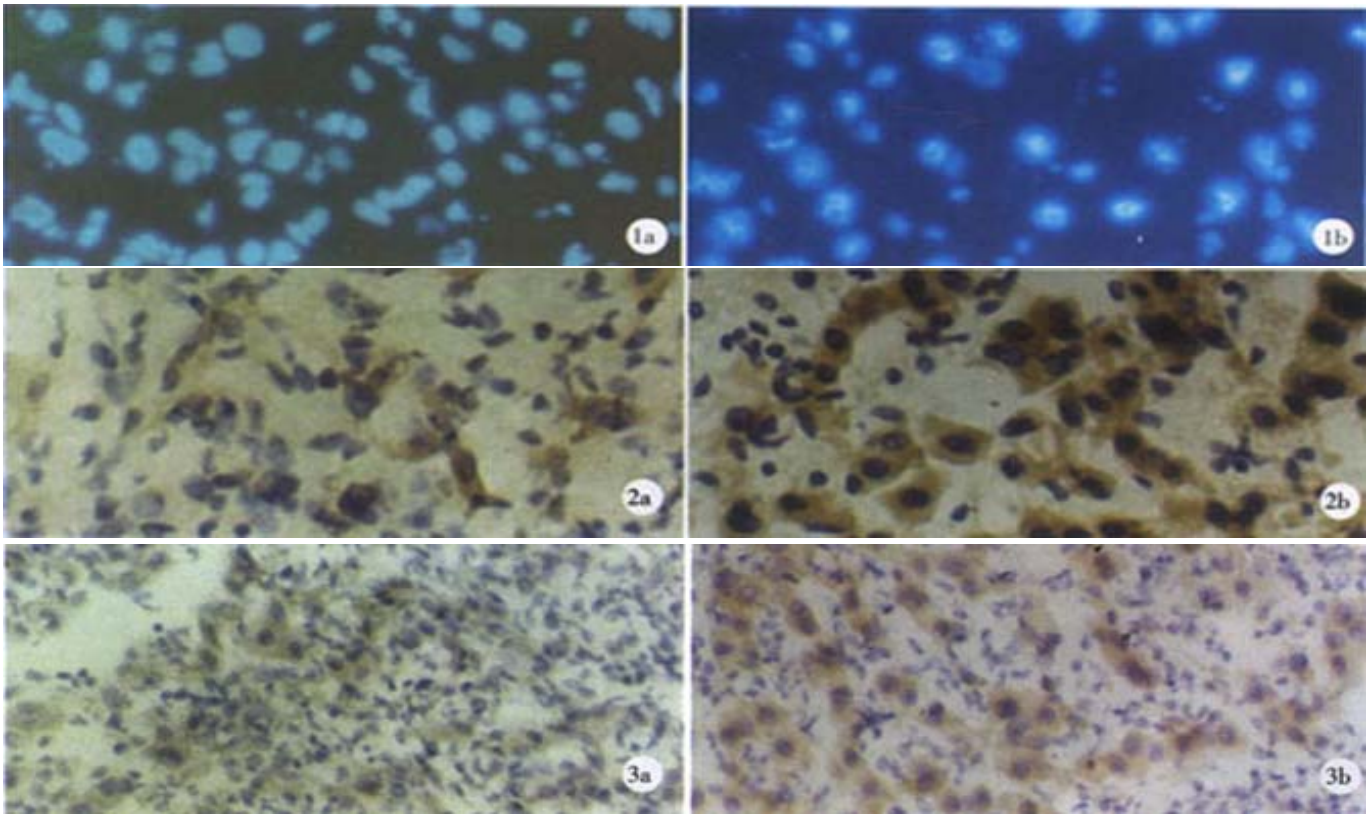

Figure 1 Hoechst 33342 labeled cells. A: Control animals; B: HAL group, decreased number of labeled cells means decreased vascular supply.
Figure 2 VEGF mRNA in hybridization. A: Low expression in tumor of control animals; B: HAL group, a higher VEGF expression.
Figure 3 MMP-1 mRNA in hybridization. A: Low expression in tumor of control animals; B: HAL group, a higher MMP-1 expression.

Serum VEGF level

The serum VEGF level was 55ng·L^{-1}±19ng·L^{-1} in the control group, and 70ng·L^{-1}±40ng·L^{-1} in the laparotomy control group, which was elevated slightly, but not significantly, as compared to the control group. While in the HAL group, the level of serum VEGF was 93ng·L^{-1} ±44ng·L^{-1}, which was elevated significantly when compared with the control group (P<0.05, Table 1).

Table 1 Number of Hoechst labeled cells, serum VEGF, and VEGF, MMP-1 mRNA expression in tumor ($\bar{x}$±s)

Groups	n	Hoechst 33342 labeled cells	Serum VEGF (ng·L^{-1})	VEGF mRNA	MMP-1 mRNA
Control	8	384±19	55±19	0.34±0.14	0.24±0.17
Laparotomy control	4	369±27	70±40	0.19±0.17	0.30±0.02
HAL	8	329±29^{bc}	93±44^{a}	0.51±0.15^{ad}	0.47±0.11^{bc}

^{a}P<0.05, ^{b}P<0.01 *vs* control group; ^{c}P<0.05, ^{d}P<0.01 *vs* laparotomy control group.

Correlation between blood perfusion and VEGF, MMP-1 expression

There was a positive correlation between the serum VEGF level and the expression level of VEGF mRNA in tumor tissue (r=0.206, P<0.05). The blood perfusion data of tumor, represented by number of Hoechst 33342 labeled cells, showed a good linear inverse correlation with the serum VEGF level (r=-0.606, P<0.05) and VEGF mRNA expression in tumor tissue (r=-0.338, P<0.01). These data suggest that deteriorating blood perfusion and increased hypoxia of tumor correlated with a higher level of VEGF expression. There was no linear correlation between the number of Hoechst 33342 labeled cells and MMP-1 mRNA expression in tumor tissue.

DISCUSSION

TAE is an excellent debulking procedure and destroys malignant cells by selectively blocking the blood perfusion of the liver cancer. However, TAE can not block the blood supply of liver cancer and eliminate tumor cells completely, because the liver cancer receives the blood supply not only from the hepatic artery, but also from the port vein. Besides, it has been found that TAE could promote metastases of liver cancer[4-6]. Thus, the long-term efficacy of TAE was disappointing: the 5-year survival rate was not above 20%[10-14]. Even in several prospective randomized trials, TAE failed to improve significantly the survival of patients with PLC[15,16]. Currently, the mechanisms involved in TAE-induced metastases of PLC are unknown. Understanding the mechanisms will facilitate the development of methods for blocking metastases and promoting long-term efficacy of TAE for treatment of liver cancer.

In recent years, many *in vitro* studies showed that hypoxia could enhance the metastatic ability of cancer cells by different mechanisms. It was reported that hypoxia stimulated carcinoma cell invasiveness by way of up-regulation of urokinase receptor expression[17,18]. Hypoxia is the most important stimulus for the up-regulation of VEGF, one of the key cytokines for angiogenesis[19-21]. Hypoxia could also induce the expression of other genes that promote angiogenesis and metastasis, such as basic fibroblast growth factor (bFGF) and angiogenin in tumor cells[22-24]. Rofstad *et al*[25] found that hypoxia could induce metastasis of human melanoma cells via VEGF-mediated angiogenesis. *In vivo* research also suggested that hypoxia may be one of the important stimuli of metastases. Hypoxia of tumor correlated with the expression of VEGF[26-29], which was found to be correlated with metastases of the tumor and poor prognosis[30-34]. Hypoxia in the squamous cell carcinoma of the uterine cervix with lymph node metastases was more serious than that in the carcinoma without lymph node metastases[35]. Thus, we hypothesized that the inefficient vascular supply after TAE would result in hypoxia of some of the liver cancer cells, as it blocks the blood supply incompletely. We also suggest that hypoxia caused by TAE may induce metastasis-associated factors, such as VEGF mediated metastases of liver cancer. It was found that the serum VEGF level in patients with liver cancer elevated 7 days after TAE therapy[36]. In the present study, we blocked the hepatic arterial blood supply of implanted cancer in rat liver by HAL to simulate TAE therapy, and found that the blood perfusion decreased. This appears to suggest a more serious hypoxia. The expression of VEGF, both in serum and in tumor tissue, increased 2 days after the blockage of the arterial blood supply. Furthermore, we found that there was an inverse correlation between the blood perfusion of tumor and the serum VEGF level or VEGF mRNA expression in tumor tissues. These data indicate that hypoxia after HAL may be the major cause of the elevated expression of VEGF. The results of our study provide evidence for our hypothesis preliminarily. The hypoxia after TAE should be detected directly by hypoxyprobe-1[37,38], and if the hypoxia and expression of VEGF play a direct role in the mechanisms involved in TAE-induced metastases of liver cancer requires further studies. MMP is a secreted or transmembrane protein that is capable of digesting extracellular matrix and basement membrane and was associated with invasion and metastases of human tumor, such as hepatocellular carcinoma and colon cancer[39-46]. It has been found that hypoxia could increase cellular invasiveness by inducing the expression of MMP[47-50]; but there was no report about the change of MMP expression in liver cancer after TAE or HAL therapy. In the present study, we found that the expression of MMP-1 in tumor tissue increased 2 days after the blockage of the arterial blood supply, but there was no linear correlation between the blood perfusion of the tumor and MMP-1 mRNA expression in tumor tissue. Which is the cause of elevated MMP-1 expression and whether it played a direct role in the mechanisms involved in TAE-induced metastasis need further study.

In conclusion, the blood perfusion of implanted liver cancer in rats decreases and the expression of metastases-associated genes VEGF and MMP-1 increases after blockage therapy of the hepatic arterial blood supply. Decreased blood supply and hypoxia may be the main cause of VEGF expression. A more complete understanding of the mechanisms involved in TAE-induced metastasis may lead to an enhancement of the long-term effects of TAE on liver cancer.

ACKNOWLEDGMENT

We would like to thank Mrs. Margaret-Hiatt Rosen, Director of Admission, the Mead School, Stamford, USA, for her correction of the English translation of the paper.

Abstract

AIM: **In hepatocellular carcinoma (HCC) prevalent areas of China, the point mutation of p53 exon7 is highly correlated with Hepatitis B virus(HBV) infection and aflatoxin B intake. While in non-HCC-prevalent areas of China, these factors are not so important in the etiology of HCC. Therefore, the point mutation of p53 exon7 may also be different than that in HCC-prevalent areas of China. The aim of this study is to investigate the status and carcinogenic role of the point mutation of p53 gene exon7 in hepatocellular carcinoma from Anhui Province, a non-HCC-prevalent area in China.**

METHODS: **PCR,PCR-SSCP and PCR-RFLP were applied to analyze the homozygous deletion and point mutation of p53 exon7 in HCC samples from Anhui, which were confirmed by DNA sequencing and Genbank comparison.**

RESULTS: **In the 38 samples of hepatocellular carcinoma, no homozygous deletion of p53 exon7 was detected and point mutations of p53 exon7 were found in 4 cases, which were found to be heterozygous mutation of codon 249 with a mutation rate of 10.53%(4/38). The third base mutation(GiúT) of p53 codon 249 was found by DNA sequencing and Genbank comparison.**

CONCLUSION: **The incidence of point mutation of p53 codon 249 is lower in hepatocellular carcinoma and the heterozygous mutation of p53 exon7 found in these patients only indicate that they have genetic susceptibility to HCC. p53 codon 249 is a hotspot of p53 exon7 point mutation, suggesting that the point mutation of p53 exon 7 may not play a major role in the carcinogenesis of HCC in Anhui Province, a non-HCC-prevalent area in China.**

INTRODUCTION

Hepatocellular carcinoma is one of the most common cancers in the world. Abnormalities of p53 are the most frequent genetic alterations in human cancers, and the role and mechanism of p53 gene mutations have been well studied in many types of cancer[1-3]. Genetic analysis of 26 HCC samples from North America and Europe revealed a high incidence of an AGG→AGT transversional changes in codon 249 of the p53 gene; and recently exon7 has been proven a hotspot of p53 gene mutation[4-6]. Zhang *et al*[4] reported the high relationship between HBVx gene and codon 249 mutation of the p53 gene in HCC-prevalence areas in China. Our previous studies have also indicated that hepatitis B virus infection is an important risk factor for HCC[7]. These data indicate that p53 mutations generally occur in the process of HCC carcinogenesis in HCC-prevalent area in China. However, further mutation analyses will be necessary to clarify the status of p53 mutations for HCC in non-HCC-prevalent areas in China.

In this study, we analyzed p53 exon 7 point mutation in HCCs from non-HCC-prevalent areas in China using the polymerase chain reaction(PCR), PCR-single-strand conformational polymorphism (PCR-SSCP), PCR-restriction fragment length polymorphism (PCR-RFLP) and DNA sequencing analysis.

MATERIALS AND METHODS

Specimens

The surgical specimens of HCC were collected from the First Affiliated Hospital of Anhui Medical University, which were confirmed by pathological diagnosis and stored at -80℃. The patients were born in and permanent residents of different places of the Anhui Province, China.

PCR of p53 exon7

DNA was extracted from tissues with standard proteinase K-phenol/choloroform methods[9].The primers for p53 gene exon7 amplification were designed according to the sequence of p53 exon7 published[4,5]. 3'primer(GW-Ⅺ-1C): 5'CTT GCC ACA GGT CTC CCC AA,5'primer (GW—Ⅺ-1D): 5' TGT GCA GGG TGG CAA GTG GC; CDK4 as a control, 3'primer(GW-Ⅳ-1K): 5'GGA GGT CGG TAC CAG AGT G,5'primer(GW—Ⅳ-1J): 5'CAT GTA GAC CAG GAC AGG. Into 100ng of DNA template of each sample was added PCR reaction solution (10mmol/L Tris, 50mmol/L KCl, 2mmol/L $MgCl_2$, 0.001%"Gelatin, 200mmol/L dNTPs, 6%"DMSO and 0.5mmol/L primers). Hotstart was performed: 97℃ 5min; chilled on ice at once. 0.9U of Taq polymerase was added, which was diluted with 1×PCR buffer for each sample. Ran PCR: 94℃ 30s, 60℃ 30s, 72℃ 30s, 35 cycles in all and checked with 2% agarose gel electrophoresis stained with ethidium bromide. The result of homozygous deletion should be the one with no specific band of p53 exon7 while its counterpart of CDK4 appeared.

PCR-SSCP of p53 exon7 [1]

8μl of PCR products were aspirated, into which was added equal volumes of deionized formamide and 4μl of DNA loading buffer (0.25% bromophenol blue, 0.25% xylene cyanol FF, 30% glycerol).

They were mixed well, boiled for 5min, and then chilled on ice for 3min. The samqles (20μl in volume) were loaded into separate wells. Samples were run in an 8% non-denaturing polyacrylamide gel at 80V for 5 hrs. The gel was taken off from the electrophoresis apparatus and readied for silver staining. The gel was submerged in 5% ethanol for 5min; 3min in 1% HNO_3; 20min in 0.012mol·L^{-1} $AgNO_3$; washed with dd-H_2O for about 10 sec; developed with 0.28mol·L^{-1} Na_2CO_3; fixed with 10% acetic acid; and finally washed with dd-H_2O. When the bands appeared, photos were taken and the gel was dried with Slab Gel Dryer or wrapped with a membrane and air dried for several days. Na_2CO_3 was changed 2-4 times when the developing solution turned black.

Restrictive endonuclease digestion of p53 exon7 and Restrictive enzyme mapping

Into each restrictive endonuclease system was added 2μl of 10×Buffer C, 2μl of DTT(1%),2μl of BSA(1%) and 0.25μl of HaeⅢ(20U·$μl^{-1}$). The total volume was brought up to 20μl with PCR products. They were incubated at 37℃ for 3hrs and checked with an 8% non-denaturation polyacrylamide gel, electrophoresed at 40V for 4hrs and developed with silver staining[8] as described above.

DNA sequencing of PCR products

The sample of p53 exon7 mutation was confirmed by PCR-SSCP and RFLP and PCR products of p53 exon7 were sent the to Bioasia Biotechnoloy Company, Shanghai, China for DNA sequencing with ABI 377 automatic DNA sequencer.

RESULTS

PCR of p53 exon7

With 100ng of genomic DNA extracted from surgical HCC tissue as template, p53 exon7 and CDK4 genes were amplified with different specific primers in separate tubes. The products were checked with 2% agarose gel electrophoresis. The results showed that the products amplified with each pair of specific pairs were of the same length with that reported in the literature(Figure 1). No homozygous deletion of p53 exon7 was found in any HCC surgical sample.

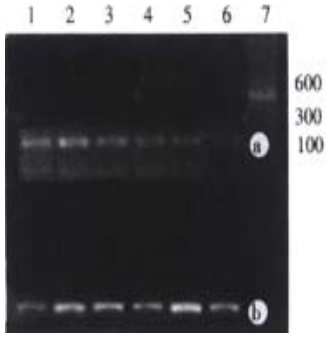

Figure 1 Agarose gel electrophoresis of PCR products of p53 exon7. A: 1-6. PCR products of p53 exon7 amplified from HCC genomic DNA 7.100bp DNA ladder; B: 1-6. PCR products of CDK4 gene amplified from HCC genomic DNA as control

PCR-SSCP of p53 exon7

Point mutations of p53 exon7 were found in 4 cases out of the 38 samples of HCC examined. No.1, 6 and 9 sample had point mutations of p53 exon7 (Figure 2).

PCR-RFLP of the codon 249 of p53 exon7

With PCR-RFLP, we found that 4 samples have heterozygous point muation of p53 codon 249, which has a band of 150bp in addition to wild type bands(40, 60, and 90bp) as shown by agarose/EB gel electrophoresis(Figure 3). However, no homozygous point mutation was found among these samples, which would have had bands of 40bp and 150bp. We found that those samples which have point mutation of p53 codon 249 was the same samples that were found to have point mutation of p53 exon 7 by PCR-SSCP.

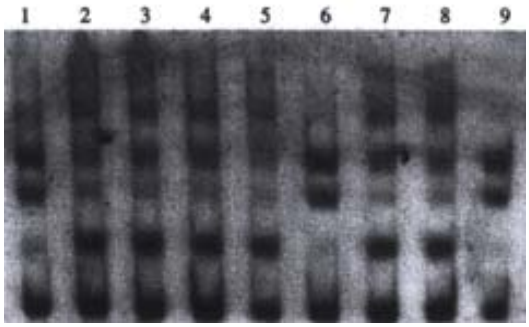

Figure 2 PCR-SSCP of p53 exon7 Samples of 1,6,9 have point mutations of p53 exon7 Samples of 2,3,4,5,7,8 don't have point mutations of p53 exon7

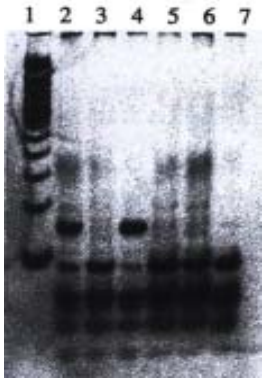

Figure 3 PCR-RFLP of p53 codon249. 1. 100bp DNA ladder; 2 and 4: heterozygous point mutation of p53 codon249;3, 5, 6 and 7: p53 Exon7 wild type.

DNA sequencing

One sample that has been found by PCR-SSCP to have point mutation of p53 exon7 was randomly chosen for DNA sequencing. The DNA sequencing result is shown in the following graph. The sequence was compared with that published by the Genbank (gbAF136270.1 HOMOTSP1), which shows that a point mutation exists in p53 codon 249 with ggAc taken place of ggCc (Figure 4,5).

DISCUSSION

The tumor suppressor gene p53 is found to be involved in the carcinogeneses of diverse types of cancer[1-3, 10-16]. Some domains of the p53 protein are highly conservated, which also reflect their significance for the function of the p53 protein. The exons that encode the domains are hotspots for point mutations. If point mutations occur in these sites, the peptides that are translated from these templates will affect the correct folding of the p53 protein. Hence, the cell cycle suppressing function of p53 will be affected, which will result loss of cell proliferation control. Recent research has found that p53 exon 7(codon 249) is a hotspot for point mutation in hepatocellular carcinoma(HCC), and most of the point mutations are G→T changes at the third base of codon 249(Arginine→Serine), and others are G→C(Arginine→Serine). Point mutations of codon 249 will lead to the loss of the Hae III restricion site in the tumor's genomic DNA(GGCC →GTCC)[4-6, 17,18]. Therefore, PCR-RFLP should be a expedient and convenient method to detect the point mutation of p53 codon 249. In our experiments, the 4 specimens that were found to have point mutation in p53 exon7 by PCR-SSCP were all found to have the point mutation in codon 249 by PCR-RFLP, which confirmed the previous reports discussed above.

It was reported that in Qidong, Jiangsu Province, a HCC prevalent area in China, about half of the HCC patients had point mutations of p53 gene exon 7, and codon 249 was the hotspot of point mutation, while no point mutation was found in other exons[4]. In order to investigate whether it is the same case in non-HCC prevalent areas of China, we collected surgical specimens from Anhui province, a non-HCC prevalent area in China[7], and tried to examine the status of point mutation in p53 exon7, which turned out to be only 4 specimens of point mutation that were all heterozygous p53 codon 249 mutations. No homozygous mutation was found among these specimens. These results showed that p53 codon 249 was the hotspot for the mutation of p53 exon 7 and its mutation was not a frequent event in non-HCC prevalent area. The fact that they are heterozygous mutations only suggests these patients are susceptible to cancer. Therefore, in non-HCC prevalent areas of P.R. China, the point mutation in p53 codon 249 may play some role but not a major role in the carcinogenesis of hepatocellular carcinoma. In HCC prevalent areas in P.R. China such as Qidong, Jiangsu Province, HBV, aflatoxin B and polluted water are the major causes of cancer, therefore the genetic alteration in the HCC patients may have correlations with the point mutations or deletions in some set loci in the genome. In Anhui province, a non HCC prevalent area in China, factors like HBV infection and aflatoxin B intake are not so prominent in the etiology of HCC. Our results suggest that the causes of HCC in non-HCC prevalent areas are multiple and complex and therefore the genetic alterations caused by them are also diverse.

Abstract

AIM: **Cyclooxygenase-2 (COX-2) has been suggested to be associated with carcinogenesis. We sought to investigate the effect of the selective COX-2 inhibitor, Nimesulide on proliferation and apoptosis of SMMC-7721 human hepatoma cells.**

METHODS: **This study was carried out on the culture of hepatic carcinoma SMMC-7721 cell line. Various concentrations of Nimesulide (0,200μmol/L,300μmol/L, 400μmol/L) were added and incubated. Cell proliferation was detected with MTT colorimetric assay, cell apoptosis by electron microscopy, flow cytometry and TUNEL.**

RESULTS: **Nimesulide could significantly inhibit SMMC-7721 cells proliferation dose-dependent and in a dependent manner compared with that of the control group. The duration lowest inhibition rate produced by Nimesulide in SMMC-7721 cells was 19.06%, the highest inhibition rate was 58.49%. After incubation with Nimesulide for 72h, the most highest apoptosis rate and apoptosis index of SMMC-7721 cells comparing with those of the control were 21.20%±1.62% *vs* 2.24%±0.26% and 21.23±1.78 *vs* 2.01±0.23 ($P<0.05$).**

CONCLUSION: **The selective COX-2 inhibitor, Nimesulide can inhibit the proliferation of SMMC-7721 cells and increase apoptosis rate and apoptosis index of SMMC-7721 cells. The apoptosis rate and the apoptosis index are dose-dependent. Under electron microscope SMMC-7721 cells incubated with 300μmol and 400μmol Nimesulide show apoptotic characteristics. With the clarification of the mechanism of selective COX-2 inhibitors, These COX-2 selective inhibitors can become the choice of prevention and treatment of cancers.**

Tian G, Yu JP, Luo HS, Yu BP, Yue H, Li JY, Mei Q. Effect of Nimesulide on proliferation and apoptosis of human hepatoma SMMC-7721 cells. *World J Gastroenterol* 2002;8(3):483-487

INTRODUCTION

Hepatic carcinoma was one of most common malignant tumors in China. Its death rate was the third among all cancers, second to gastric carcinoma and lung carcinoma. Although there is a progress in diagnosis and treatment of hepatic carcinoma, its prognosis is still poor. Investigating its pathogenesis and finding new diagnostic and treatment methods is important. Recent epidemiological studies indicate an inverse relationship between the risk of colorectal cancer and intake of NSAIDs. NSAIDs could reduce the incidence of gastric carcinoma and pancreatic carcinoma. It could inhibit tumor cells proliferation and induce apoptosis[1-41]. Cyclooxygenases (COXS) are key enzymes in the conversion of arachidonic acid to prostaglandins and other eicosanoids. Recently two isoforms of the enzyme have been identified. COX-1 is constitutively expressed in a number of cell types, whereas the isoform designated COX-2 is inducible by a variety of factors, as cytokines, growth factors, and tumor promoters. Some studies have suggested that COX-2, but not COX-1, was involved in colon carcinogensis and might thus be the target of chemopreventive effect by the COX inhibor, nonsteroidal anti-inflammatory drugs. The effects of COX-2 on inflammation, procancarous conditions and cancers have been delineated[42-47]. To date the effects of Nimesulide on the growth and apoptosis of human hepatoma cell line SMMC-7721 in vitro have not been analyzed, and that is the aim of this study.

MATERIALS AND METHODS

RPMI 1640 medium is a product of CIBCO; Nimesulide and MTT were from Sigma; In situ cell death detection kit was from Boehringer Mannheim, Germany; 96-well plates were from Costar.

Cell lines and culture

Human hepatoma SMMC-7721 cells were obtained from the Wuhan University Center for type culture collection. The cells were grown as monolayers in RPMI1640 medium supplemented with 10% fetal calf serum (FCS, Gibco) and incubated at 37℃ in the humidified incubator with 5% CO_2 in air.

Assay of cell proliferation

The SMMC-7721 cells were seeded at 5×10^4/ml density in 96-well plates 200μl cell suspension per well. Each group had four wells with a non-treated group as control. When the cells anchored to the plates, various concentrations (0,200μmol/L,300μmol/L,400μmol/L) of Nimesulide were added and the slides were incubated at 37℃, 5% CO_2 for 5 days. In order to maintain Nimesulide concentrations, we changed the culture medium (included various concentrations of Nimesulide) every day. When the cells described above were cultured for 48h, 72h, 96h, 120h, 0.5% MTT 20μl was added to each well and cultured for another 4h. The supernatant was discarded and dimethyl sulfoxide (DMSO) 200μl added. When the crystals were dissolved, the optical density(OD) value of the slides was read on an enzyme-labeled Minireader II at 492nm. Cellular proliferation inhibition rate (CPIR) was calculated using the following equation: CPIR=(1-average OD value of experimental group/average OD value of control group)×100%

Electron microscopic observation

The SMMC-7721 cells were seeded in culture flasks. Four culture bottles were divided into normal group and control group. When the cells were anchored to the plates, various concentrations (0,200μmol/L, 300μmol/L,400μmol/L) of Nimesulide were added and the cells incubated at 37℃, 5% CO_2 for 3 days. Then hepatoma cells were

digested by 0.25% trypsinase and collected. After rinsing with PBS, the cells were fixed with 2.5% glutaraldehyde for 30min and washed with PBS. After routine embedding and sectioning, the cells were observed by Hitachi H-600 electronic microscope.

Flow cytometric analysis

The SMMC-7721 cells were seeded in culture flasks. The culture bottles were divided into normal and three control groups. Each group had three culture bottles. When the cells were anchored to the plates, various concentrations (0,200μmol/L,300μmol/L,400μmol/L) of Nimesulide were added and the cells incubated at 37℃, 5% CO_2 for 3 days. Then each group of cells were washed with PBS, trypsinized and fixed with 70% ethanol at -20℃ for 30 minutes. Fixed cells were incubated with IP/Rnase solution for 15 minutes and 10^6 cells of each culture bottle were harvested and analyzed with FACScan Becton Dickeuson Flow Cytometer.

In situ apoptotic cell death detection by TUNEL

A TUNEL kit (Boehringer Mannhein, IN) was used to detect DNA fragmentation, the characteristic of apoptotic cell death. The SMMC-7721 cells were seeded in culture flasks. Culture bottles were divided into normal and three control groups. Each group had three culture bottles. When the cells were anchored to the plates, various concentrations (0,200μmol/L,300μmol/L,400μmol/L) of Nimesulide were added and the cells incubated at 37℃, 5% CO_2 for 3 days. In order to maintain Nimesulide concentrations, we changed the culture medium (including various concentrations of Nimesulide) every day. After having been cultured for 3 days, each culture bottle cells were scraped and centrifuged 800r/min for 5 minutes. Then the deposited cells were smeared and air-dried. Following the manufacturer's directions, smears were incubated with the TUNEL reaction mixture for 60min at 37℃ and then with converter-POD for 30min. The DAB-substrate solution was added to the smears and kept at room temperature until positive signal appeared. Then they were dried and analyzed under light microscope.

Under light microscope, the TUNEL positive nuclei were stained brown. Selecting 5 fields randomly (the number of cells in each field >1000).

Apoptosis index (AI)=(number of apoptotic cells/ the number of cells in each field) ×100%.

Statistical analysis

Statistical analysis was performed using the student's t test and analysis of variance. $P<0.05$ was considered significant.

RESULTS

Effect of Nimesulide in various concentrations on the growth of SMMC-7721

We analyzed the effects of Nimesulide on cell proliferation in cultured human hepatoma cell line SMMC-7721 after 5 days of treatment. Nimesulide, a selective COX inhibitor, produced a dose-dependent inhibition of cells growth (Table 1 and Figure 1). The lowest inhibition rate produced by Nimesulide in SMMC-7721 cells was 19.06%, the highest being 58.49%.

Morphology observation

Under the electron microscope, SMMC-7721 cells exhibited characteristics of apoptosis including plasma membrane blebbing, cytoplasmic condensation, pyknotic nuclei, condensed chromatin and apoptotic bodies. Compared with control groups, 300μmol/L and 400μmol/L groups cells had many more cells with apoptotic characteristics (Figure 2).

Table 1 Inhibition effect of Nimesulide on proliferation and growth in hepatic carcinoma cell line SMMC-7721

Nimesulide Concentrations (μmol/L)	OD Value			
	the 2nd day	the 3ird day	the 4th day	the 5th day
0	1.039±0.066	1.516±0.117	2.142±0.072	2.467±0.080
200	0.841±0.027[a]	1.109±0.231[a]	1.416±0.080[a]	1.341±0.021[a]
300	0.796±0.019[a]	1.002±0.274[a]	1.101±0.028[a]	1.243±0.168[a]
400	0.581±0.164[a]	0.825±0.016[a]	0.943±0.032[a]	1.024±0.026[a]

[a]$P<0.05$ *vs* control group

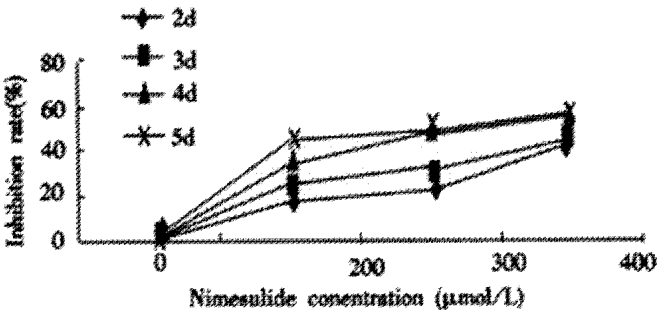

Figure 1 Inhibition rate of Nimesulide on proliferation of SMMC-7721 cells. Cells were incubated with 200μmol/L,300μmol/L,400μmol/L Nimesulide for 2d,3d,4d,5d respectively.

Figure 2 Transmission electron micrograph of SMMC-7721 cells treated with Nimesulide at the concentration of 300μmol/L for 72h.The picture showed early change of apoptosis, the nuclear chromatin condensation.

Flow-cytometry analysis of cell apoptosis

The peak value appearing before the G_1 peak is called apoptotic peak. As shown in Figure 3 and Table 2, the apoptotic peak and rate increased with increasing concentrations of Nimesulide. Furthermore, Nimesulide induced cells apoptosis in a dose and time-dependent manner ($P<0.01$).

Table 2 Apoptosis rate of SMMC-7721 cells induced by Nimesulide

Nimesulide concentration (μmol/L)	Apoptosis rate (%)
0	2.24±0.26
200	7.42±0.43[b]
300	9.84±1.54[b]
400	21.20±1.62[b]

[b]$P<0.01$ *vs* control group

Analysis of apoptosis by TUNEL

As shown in Figure 4 and Table 3, the apoptotic index increased with increase of Nimesulide concentrations which what appeared to be dose-dependent relationship in the alone groups ($P<0.05$).

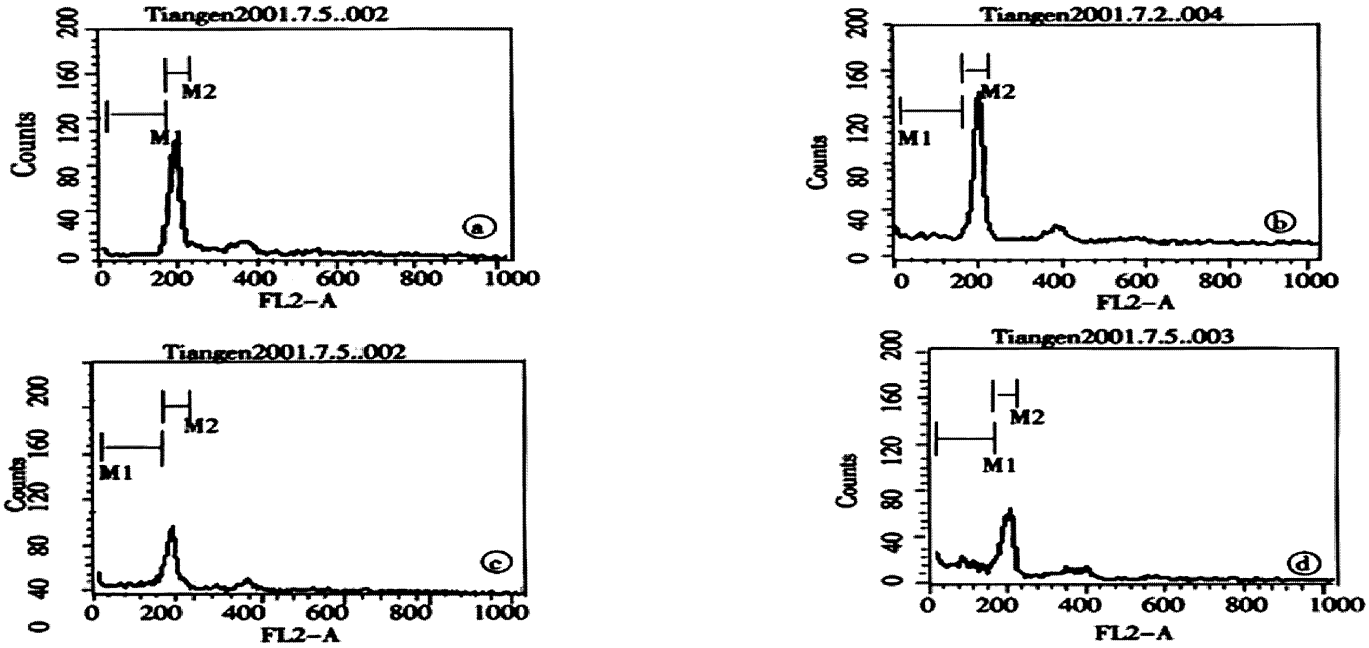

Figure 3 Cell apoptosis was determined by flow-cytometry,SMMC-7721 cells were treated with Nimesulide at various concentrations (0,200,300,400μmol/L respectively A to D).

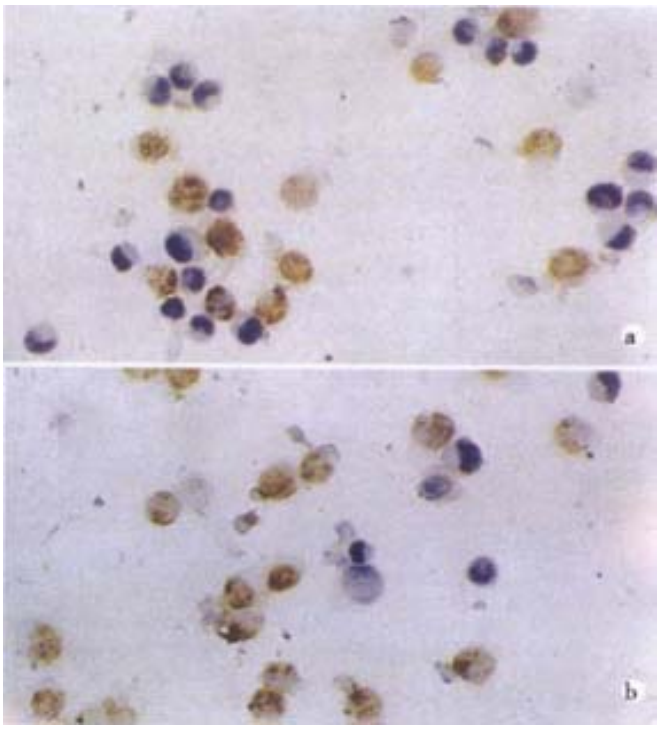

Figure 4 TUNEL stain showed SMMC-7721 cells apoptosis. SMMC-7721 cells were treated with Nimesulide at various concentrations (300,400μmol/L A and B).

Table 3 Aapoptosis index of SMMC-7721 cells induced by Nimesulide

Nimesulide concentration (μmol/L)	Apoptosis index (%)
0	2.016±0.23
200	7.64±0.34[a]
300	10.14±1.42[a]
400	21.23±1.78[a]

DISCUSSION

It had been shown that selective COX-2 inhibitors inhibited tumor cells proliferation and induced tumor cells apoptosis, in colon and prostate carcinoma cell lines[48,49]. To date, their effects on human hepatoma SMMC-7721 cell lines have not yet been studied. The aim of this study was to investigate the effect of Nimesulide, a selective COX inhibitor, on the proliferation and apoptosis of SMMC-7721 cell lines. The results indicated that various concentrations of Nimesulide could change the morphology of SMMC-7721 cells and inhibit SMMC-7721 cells proliferation obviously in a dose and time-dependent manner. Nimesulide could induce SMMC-7721 cells apoptosis and cause death in a dose-dependent manner. The precise mechanism by which selective COX-2 inhibitors inhibit tumor cells growth and induce tumor cells apoptosis was not been clearfield. The available data supported the two hypotheses.

Some studies indicate that COX-2 is a key enzyme in the conversion of arachidonic acid to prostaglandins. Selective COX-2 inhibitors can decrease prostaglandins biosynthsis, and prostaglandins can inhibit cell-mediated immunity, which enables the tumor cells escaping the host-immunity[50,51]; PG_S also can conjugate with PPARá and activate cell proliferation passage of signal conduction, promote cells proliferation[52]; PG_S can also inhibit cells apoptosis and cause cells division uncontrollable, thus accelerating tumor genesis[53,54]; the effects of COX-2 inhibitors might involve prostaglandin biosynthesis. Some studies indicated that the effects of COX-2 were not related to COX-2 expression and PG_S. Hanif *et al*[55] verified that $NASID_S$ (nonselective COX inhibitors) could induce apoptosis of colon carcinoma cell line HCT-15. HCT-15 cells have no COX gene transcription, and does not produce PG_S. When adding exogenous PG_S to the HCT-15 cells, it could not reverse the induction of HCT-15 cells apoptosis by $NASID_S$.

On the whole, Nimesulide, a selective COX-2 inhibitor, can inhibit the growth of hepatoma cells and induce tumor cells apoptosis. With the clarification of the mechanism of selective COX-2 inhibitors, These COX-2 selective inhibitors can become the choice of prevention and treatment of cancers.

ACKNOWLEDGMENT

I would like to thank my wife and all those who provided assistance for this study.

Abstract

AIM: **To reduce the incidence and mortality of rectal cancer and address the hypothesis that colorectal cancer often arise from precursor lesion(s), either adenomas or non-adenomatous polyps, by conducting a population-based mass screening for colorectal cancer in Haining County, Zhejiang, PRC.**

METHODS: **From 1977 to 1980, physicians screened the population of Haining County using 15cm rigid endoscopy. Of over 240000 participants, 4076 of them were diagnosed with precursor lesions, either adenomas or non-adenomatous polyps, which were then removed surgically. All individuals with precursor lesions were followed up and reexamined by endoscopy every two to five years up to 1998.**

RESULTS: **After the initial screening, 953 metachronous adenomas and 417 non-adenomatous polyps were detected and removed from the members of this cohort. Further, 27 cases of colorectal cancer were detected and treated. Log-rank tests showed that the survival time among those cancer patients who underwent mass screening increased significantly compared to that of other colorectal cancer patients ($P<0.0001$). According to the population-based cancer registry in Haining County, age-adjusted incidence and mortality of rectal cancer decreased by 41% and 29% from 1977-1981 to 1992-1996, respectively. Observed cumulative 20-year rectal cancer incidence was 31% lower than the expected in the screened group; the mortality due to rectal cancer was 18% lower than the expected in the screened group.**

CONCLUSION: **Mass screening for rectal cancer and precursor lesions with protocoscopy in the general population and periodical following-up with routine endoscopy for high-risk patients may decrease both the incidence and mortality of rectal cancer.**

INTRODUCTION

Colorectal cancer is the second most common cause of death from cancer in the United States[1,2] and the fifth in mainland of China[3]. Dietary modification and non-steroidal anti-inflammatory drugs (NSAID) may reduce the risk of colorectal cancer[4-6]. Nevertheless, few of the Chinese people have benefited from these chemoprevention strategies so far. Recently, the results of several randomized controlled trial showed that fecal occult blood testing (FOBT) based on mass screening might reduce the mortality caused by colorectal cancer in general population[7-9]. Unfortunately, the incidence of colorectal cancer could not be reduced by this protocol.

As reviewed by Potter[10-13], colorectal cancer is a result of accumulation of multiple genetic alterations within the epithelial cells. The concept of the adenoma-to-carcinoma is well accepted, and describes a stepwise progression from normal colorectal epithelium to adenoma, and to carcinoma[14-16]. The adenomatous polyps, the precursor lesion resulted from epithelial cell hyperproliferation and crypt dysplasia, have malignant potential. Progression from precursor lesions to colorectal cancer is a multi-step process that requires ten to fifteen years[15]. Approximately 30-60% of patients with a history of adenomas will develop a metachronous adenoma within three to five years after their initial polypectomy[17,18]. Therefore, it has been hypothesized that removing colorectal polyps might change the natural history of colorectal cancer; mass screening and following up with endoscopy might reduce the incidence and mortality of colorectal cancer. Nevertheless, evidence for the effectiveness of colonoscopy is indirect, since no large trials with mortality endpoints have been conducted to evaluate the efficacy of screening for colorectal cancer with colonoscopy[19-21].

According to census survey of death causes in 1970 in China, more than 66% of colorectal cancers were found in the rectum[22-24]. It is suggested that about 60% of colorectal cancer could be effective by screening with proctoscopy in China. To prove above hypothesis, we conducted a population-based mass screening with 15cm rigid endoscopy in Haining County, PRC from 1977 to 1980. Results presented herein are based on findings at the initial screening as well as 20 years of follow-up examinations in those individuals with precursor lesions.

MATERIALS AND METHODS

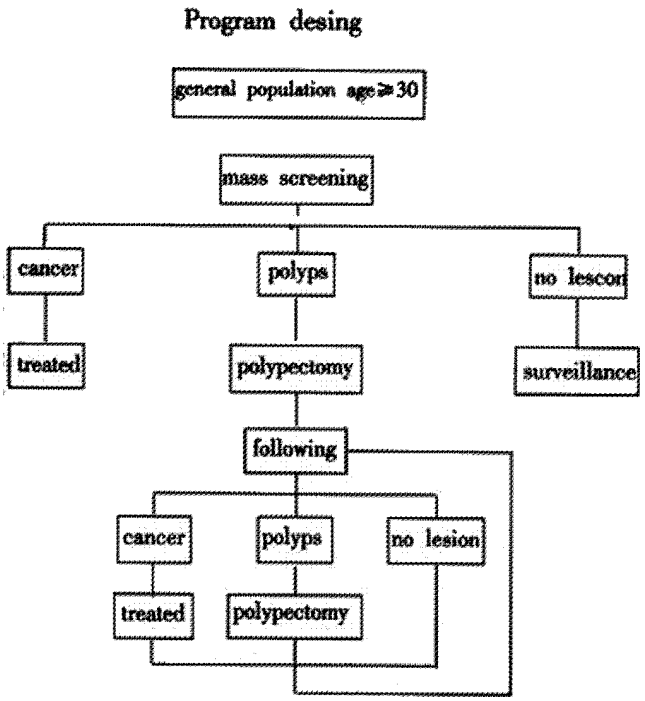
Study design was described in Figure 1. The high-risk population with rectal polyps was identified by proctoscopy through a general population-based mass-screening program, and followed with endoscopy periodically. All detectable polyps including adenomatous or non-adenomatous polyps were removed.

As previously described in detail[25,26], population-based screenings with 15cm rigid endoscopy was conducted from 1977 to 1978 in Haining County, a rural community located in the eastern part of China. Only residents in Haining County who were at least 30 years old were eligible for the screenings. The screening team includes

epidemiologist, physician, pathologist, surgeon and investigators, who had been trained before starting the program. We screened 186234 of the 223866 eligible individuals (83% response rate), of which 2815 were found carrying polyps and/or adenomas. The detectable adenoma and/or polyp were surgically removed thereafter. All individuals with precursor lesions were eligible for follow-up endoscopic screenings, which were performed in the years of 1979-1980, 1981, 1983, 1987, 1993 and 1998. In addition, of the 53987 volunteers who aged 30 or over screened during 1979-1980's following-up, polyps and/or adenomas were detected and removed in 1,261 individuals. These patients were eligible for follow-up endoscopic screenings in 1982, 1984, 1988, 1994 and 1998. Due to technological advances in screening methods during this time period, all screenings after 1985 were performed with 60cm flexible sigmoidoscopy rather than 15cm rigid endoscopy.

Pathologic material was reviewed independently by three senior pathologists using standard criteria developed by the World Health Organization (WHO). A final diagnosis was made when at least two of the pathologists agreed on the patient's diagnosis. The age distribution of patients from both screenings is presented in Table 1. Table 2 lists the pathologic features of the initial polyp or adenoma for each patient; for patients with more than one adenoma or polyp, the most advanced lesion is listed.

Cancer mortality data was collected since 1974, and Cancer incidence data was available since 1977 by the population-based cancer registry in Haining County. The International Classification of Disease (ICD-9) was employed by the registry for site-specific histologic classification. Population estimates were based on the periodic censuses, with age-and sex-specific annual estimates derived by linear inter- and extrapolation for the remaining years. Rates for each period are age-adjusted to the world standard population using the direct method for each 5-year age group. From 1974 to 1976, before mass screening program carried out, the adjusted mortality of colon and rectum cancer was 2.66 and 4.20 per 100000 respectively. From 1977 to 1996, histologic confirmation was available for 94.4% of the 1005 incident colorectal cancer cases and 92.3% of the 735 deaths due to colorectal cancer.



Note: Polyps include adenomatous polyps and non-adenomatous polyps All polyps would be removed when detected by endoscopy examiner

RESULTS

From 1979 to 1998, patients diagnosed with adenomas and/or polyps during the first screening have been followed up six times. Of 2815 cases with polyps, 20.5% of them participated whole six times endoscopy examination, and 89.6% finished at least three times. While those patients diagnosed at the group of volunteers have been re-screened five times, and 82.5% of them were re-examined at least two times. Table 3 summarizes the expected and observed incidence rates of adenomas, polyps and colorectal cancer for both groups. After the initial screening, 953 metachronous adenomas and 417 non-adenomatous polyps were detected and removed from members of this cohort. Further, 27 cases of colorectal cancer were detected and treated, we analyzed data collected by the cancer registry of Haining County, Zhejiang Providence, PR China. Both rectum cancer incidence and mortality were decreased steadily from 1977 to 1996(Table 3). The age and sex adjusted incidence rates of rectal cancer decreased from 7.27 per 100000(1977-1981) to 3.71 per 100000(1992-1996), and mortality was decreased from 4.20 per 100000 (1974-1976) to 2.98 per 100 000(1992-1996). Thus, age-adjusted incidence and mortality of rectal cancer decreased by 41% and 29% respectively. Nevertheless, both adjusted incidence rates and mortality of colon cancer increased slightly at the same period.

*Following with 60cm flexible sigmoidoscopy since 1987

Cumulative 20-year incidence and mortality caused by colon and rectal cancers are presented in Figures 2,3 and table 4. Figure 2 shows the incidence of colon and rectal cancers in those individuals aged 30 years and older in the mass screening in 1977. Figure 3 shows mortality caused by colon and rectal cancer in the screened population (those aged 30 years and older in 1977). According to incidence and mortality of age and sex sub-group during 1977 to 1981, we calculated the annual expected rate of sub-group for this cohort population from 1977 to 1996, and then 20-year cumulative incidence and mortality. Observed cumulative 20-year rectal cancer incidence was 31% lower than expected in the screened group; mortality caused by rectal cancer was 18% lower than expected in the screened group. There is no significant difference of incidence and mortality of colon cancer almost between observed and expected. Results showed incidence and mortality were only reduced in the rectal cancer, but not colon cancer.

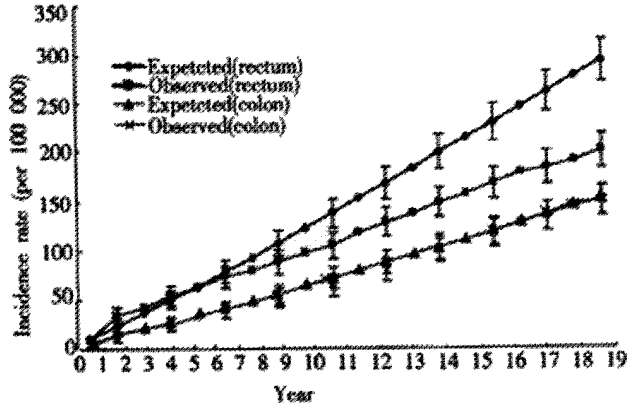

Figure 2 The Expected and Observed Twenty-year Cumulative Incidence of Colon and Rectum Cancer

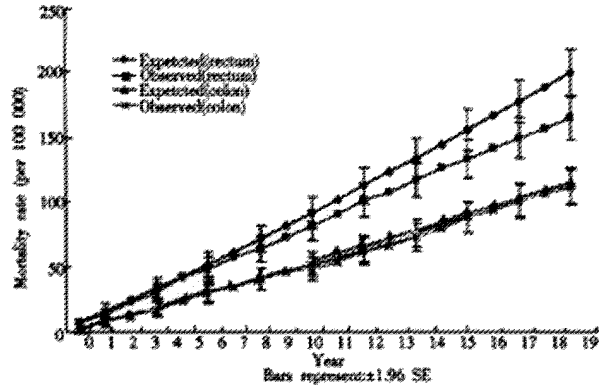

Figure 3 The Expected and Observed Twenty-year Cumulative mortality of Colon and Rectum Cancer

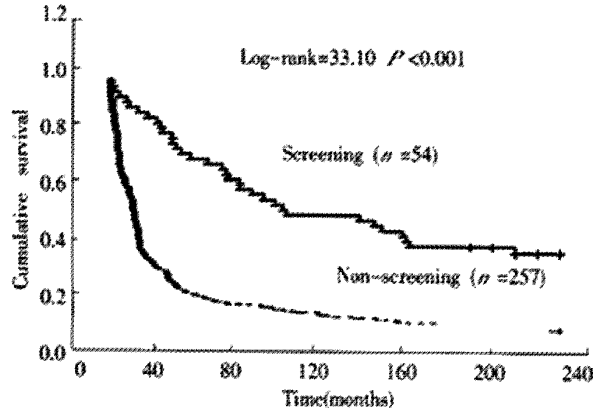

Figure 4 Survival curve (Kaplan-Meier) of rectal cancer diagnosed during 1977-1982

During the initial screenings, 54 cases of colorectal adenocarcinomas were detected and treated. Survival analyses showed that patients with rectal cancers detected during the screenings had significantly longer survival time than rectal cancers identified in patients who were not included in the mass screenings at the same period (log-rank=27.12; $P<0.001$) (See Figure 4). The mean age of screened rectal cancer patients was 57 years (SD=12.8) while the mean age of non-screened rectal cancer patients was 59 years (SD=12.1). The median survival time of screened patients was 133 months (95% CI=56-210mos.) compared with only 14 months (95% CI=11-15 mos.) in non-screened patients. Excluded the leading time bias, the median survival time for screened patients was prolonged by 7.9 years.

DISCUSSION

In the 1980's, it was suggested that population-wide screening with fecal occult blood test (FOBT) was not cost-effective[27,28]. However, more recent analyses suggest that FOBT-based screening can reduce colorectal cancer mortality[29-32]. Mandel and colleagues at the Mayo Clinic in Minnesota conducted a randomized screening of over 46,000 individuals[33,34]. Participants were randomized to annual or biannual FOB test group and a control group. The cumulative 18-year colorectal cancer mortality was reduced by 33% in the annually screened group and 21% in the biennially screened group compared to the control group. It is important to note that although FOBT may be important in early detection of colorectal cancer, this test does not affect the underlying process of neoplastic transformation in the large bowel. In addition, the use of a rehydrated hemoccult test instead of an unrehydrated hemoccult test increased test sensitivity but decreased test specificity resulting in over 10% of participants undergoing colonoscopy exam at each screening. Moreover, a total of 38% of the screened group had at least one colonoscopy during the entire study period. It was proposed by Lang and colleagues that approximately one third to one half of the observed reduction in mortality found in Mandel's study was the result of chance selection for colonoscopy rather than the FOBT itself[35-37]. Another two randomized screening trials using unrehydrated hemoccult test every two years resulted in only 4% of the test group requiring colonoscopy, yet reduced colorectal cancer mortality by 15-18%[39-43]. However, no evidence showed incidence rate has been reduced from colorectal cancer by FOBT-based mass screening.

The population-wide mass screenings were conducted from 1977-1980 among 246252 residents of Haining County aged 30 years or older. The overall participation rates were 83%. A total of 54 cases of rectal cancer were detected and treated. Overall survival in these patients was significantly increased compared to non-screened rectal cancer patients (log-rank=33.4; $P<0.0001$). Excluding leading time bias, the survival time was prolonged by almost 8 years in screened patients. In addition, 4076 patients with newly discovered adenomas and/or nonadenomatous polyps were treated by polypectomy and followed with periodic examinations through 1998. During follow-up, 953 metachronous adenomas and 417 nonadenomatous polyps were detected and removed; an additional 27 colorectal cancers, 12 of which were carcinoma in situ, were diagnosed and treated. According to the Haining County Cancer Registry, from 1977 to 1996 both age- and sex-adjusted colorectal cancer incidence and mortality decreased by 41% and 29% respectively. Further, cumulative 20-year observed incidence and mortality from rectal cancer in the screened population decreased by 31% and 18%, respectively. If interest, incidence rates of rectal cancer in Shanghai, PRC (located 120km from Haining) increased by 11.3% in males and 6.0% in females from 1972 to 1994[44,45]. Chinese official data showed from 1973-1975 to 1990-1992, age and sex adjusted mortality caused by colorectal cancer increase by 3.61% in urban and decrease by 5.22% in rural population of China[3]. Above evidence supported that

both incidence and mortality of rectal cancer decreased in Haining due to the population-wide mass screening and following-up with endoscopy to high-risk population.

Winawer and colleagues reported a 76-90% reduction in colorectal cancer incidence in 1418 adenoma patients who underwent periodic coloscopy after initial polypectomy compared to age-, sex-, and polyp-size-adjusted control groups. Further, follow-up colonscopy performed three years after initial colonoscopy detection and removal was found to be as effective as follow-up colonoscopy performed after only one or two years. Thus, it is suggested that a screening interval of three years is sufficient following colonscopic removal of newly diagnosed adenomas[15,16]. Anyway, our results showed only 31% reduction of incidence of rectal cancer through population-wide mass screening with proctoscopy. It is suggested that there are other pathways besides except of adenoma pathway.

These results suggest that colorectal cancer may be prevented by mass screening with FOBT or endoscopy. Further, removal of precursor lesions may slow or halt the natural history of rectal neoplasms. Our data suggest that mass screening by endoscopy can reduce the incidence and mortality of colorectal cancer. Screening guidelines for asymptomatic individuals suggest that all individuals aged 50 years or older may be benefited by periodic digital rectal examinations, stool guaiac and/or colonoscopy. For patients without adenomas or polyps, these exams should be repeated every three to five years, while patients with precursor lesions should be re-examined for new lesions after one year[46-48]. Data from cancer statistics of United States indicated that approximately 60% of colorectal cancers are found in the distal colon or rectum[49,50]. However, according to 1980's report by the Research Team in China, 80% of colorectal cancers are found in the distal colon or rectum, with up to 66% in the rectum alone[24]. Therefore, it was suggested that mass screening and following up with sigmoidoscopy periodically might be more cost-effective than colonoscopy in China.

Abstract

AIM: **Ursolic acid (UA) and oleanolic acid (OA) are triperpene acids having a similar chemical structure and are distributed wildly in plants all over the world. In recent years, it was found that they had marked anti-tumor effects. There is little literature currently available regarding their effects on colon carcinoma cells. The present study was designed to investigate their inhibitory effects on human colon carcinoma cell line HCT15.**

METHODS: **HCT15 cells were cultured with different drugs. The treated cells were stained with hematoxylin-eosin and their morphologic changes observed under a light microscope. The cytotoxicity of these drugs was evaluated by tetrazolium dye assay. Cell cycle analysis was performed by flow cytometry (FCM). Data were expressed as means±SEM and Analysis of variance and Student' *t*-test for individual comparisons.**

RESULTS: **Twenty-four to 72h after UA or OA 60μmol/L treatment, the numbers of dead cells and cell fragments were increased and most cells were dead at the 72nd hour. The cytotoxicity of UA was stronger than that of OA. Seventy-eight hours after 30μmol/L of UA or OA treatment, a number of cells were degenerated, but cell fragments were rarely seen. The IC_{50} values for UA and OA were 30 and 60μmol/L, respectively. Proliferation assay showed that proliferation of UA and OA-treated cells was slightly increased at 24h and significantly decreased at 48h and 60h, whereas untreated control cells maintained an exponential growth curve. Cell cycle analysis by FCM showed HCT15 cells treated with UA 30 and OA 60 for 36h and 72h gradually accumulated in G_0/G_1 phase (both drugs $P<0.05$ for 72h), with a concomitant decrease of cell populations in S phase (both drugs $P<0.01$ for 72h) and no detectable apoptotic fraction.**

CONCLUSION: **UA and OA have significant anti-tumor activity. The effect of UA is stronger than that of OA. The possible mechanism of action is that both drugs have an inhibitory effect on tumor cell proliferation through cell-cycle arrest.**

INTRODUCTION

Ursolic acid (UA) and oleanolic acid (OA) are triperpene acids having a similar chemical structure and are distributed widely in plants all over the world[1-20]. They are of interest to scientists because of their biological activities. OA has antifungal[21,22], insecticidal[23], anti-HIV[24,25], diuretic[26], complement inhibitory[27], blood sugar depression[28] and gastrointestinal transit modulating[29] activities. UA and OA also possess liver-protection[30-33] and anti-inflammatory effects[34-37]. In recent years, it was found that they had marked anti-tumor effects and exhibited cytotoxic activity toward many cancer cell line in culture[38-44]. Concerning their effects on colon carcinoma cells, there is little available so far in the current literature. The present study was designed to investigate their inhibitory effects on the human colon carcinoma cell line HCT15.

MATERIALS AND METHODS

Drugs and reagents

UA and OA were gifts from Professor Qing-Yao Yang, Department of Biology, Shanghai Teachers University. UA was extracted from Catharantus roseus L. with purity 99%, and OA from Ziziphus jujuba Mill. with purity 98%. The drugs were dissolved in 100% ethanol and then diluted 10 times with RPMI-1640 as the working solution, the final concentration of ethanol being less than 2%. Me^a-2SO was purchased from the Sigma Company (USA).

Cell line and culture medium

HCT15 had been introduced from the NCI (USA) and was cultured and kept in this laboratory. The culture medium used was RPMI-1640 with 10% BSA (Huamei BG, Co Ltd, China).

Cell morphology observation

The morphology of the live cells was observed with an inverted microscope and the live and dead cells were identified after 1% Trypan blue staining[45]. Cell smear was stained with hematoxylin-eosin (HE).Cytotoxicity identification with tetrazolium dye assay (MTT)1.8×10^4 cells were inoculated to each of the 3 parallel wells on a 96-well plate and cultured over night. Different concentrations of UA and OA were added with a final volume of 0.2mL and cultured for 72 more hours. MTT 20μL (5g/L) was added to each well. 4h later samples were centrifuged and the supernatant was discarded. 180μL Me_2SO was added and the 570nm absorbance was read. The mean value of each concentration (3 well) was obtained. Experiments were repeated three times[46].

The inhibition rate (%) =(1-average rate of the treated/average of the control)×100

Flowcytometric detection of cell cycle

Cell cycle was determined by flowcytometric assays[47]. To 1ml of cell suspension with a concentration of 1×10^8/L, 30μmol/L UA and OA 60μmol/L were added. The cells were collected after being cultured for 36h and 72h, respectively. Collected cells were treated with absolute alcohol, then with 1% Triton X-100 (Sigma, USA) for 10min at room temperature. The samples were centrifuged, and the supernatant discarded. 0.01% Rnase was added and samples were shaken for 10min in a 37℃ water bath. Samples were stained with 0.05% propidium iodide for 10min in 4℃ in darkness. The cell cycle distribution was detected with flowcytometer (Model FACSCALIBAR, B.D., USA) and 10000 cells were analyzed with MODFIT software.

Data analysis

Data are displayed as percentage of control condition. Data were expressed as means±SEM and Analysis of variance and Student' *t*-test for individual comparisons. $P<0.05$ was considered statistically significant.

RESULTS

Changes in cell morphology

When HCT15 cells were treated with UA 60μmol/L for 24hours, a number of cells were found dead with a lot of cellular fragments. Among the intact cells, the dead ones accounted for more than 30%. Seventy-two hours later, the number of cells decreased significantly and the remaining cells became shrunken with disappearance of cellular refraction. On the smear stained with HE, a large amount of cellular fragments could be found. When treated with OA 60μmol/L for 24hours, a few cells were dead. There were relatively large amounts of cellular fragments and the dead cells accounted for about 15% at 72h. Within 72 hours of either UA or OA treatment at a concentration of 30μmol/L, a percentage of the cells became rugate at the periphery with blurred cellular borders. There was no obvious cell fragmentation. Relatively large amount of degenerated cells could be seen on HE stained smear, but degenerated cells with OA were markedly less than that with UA.

The cytotoxicity

Cell viability was significantly decreased by treatment of UA and OA for 72h in a dose-dependent manner. Their IC_{50} were 30μmol/L for UA and 60μmol/L for OA (Figure 1). Proliferation assay showed that proliferation of UA and OA-treated cells slightly increased at 24h and significantly decreased at 48h and 60h, whereas untreated control cells maintained exponential growth curves (Figure 2).

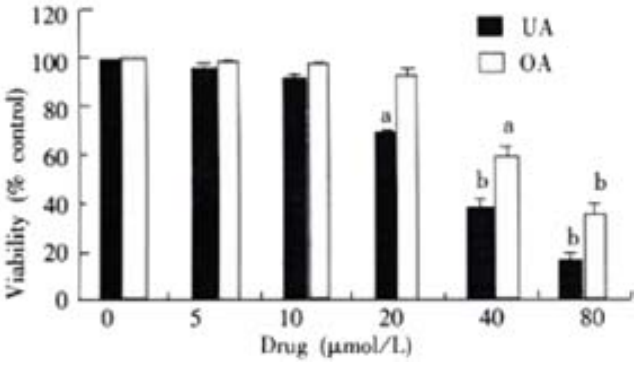

Figure 1 Effects of UA and OA on viability of colon carcinoma cell line. Relative cell viability was assessed by MTT assays. HCT15 cells were treated with various concentrations of UA and OA, respectively for 48h. Data points represent mean values of 3 replicates, with bar indicating SEM. $^aP<0.05$, $^bP<0.01$ *vs* control.

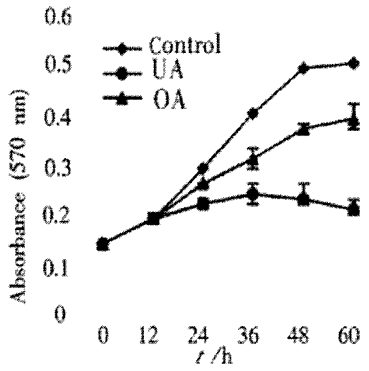

Figure 2 Effects of UA and OA on proliferation of HCT15 cells. HCT15 cells were treated with 30μmol/L UA and OA, respectively. The absorbance of 570 nm means the amount of living cells. Data points represent mean values of 3 replicates, with bar indicating SEM. $P<0.05$, $^bP<0.01$ *vs* control.

Change in cell cycle

When treated the HCT15 cells with different doses of UA and OA for different times, the cell cycle obtained by FCM were as shown in Table 1. HCT15 cells treated with UA 30μmol/L and OA 60μmol/L for 12h and 48h gradually accumulated in G_0/G_1 phase, with a concomitant decrease of cell population in S phase and no detectable apoptotic fraction.

Table 1 The cell cycle distribution of colon carcinoma cell line HCT15 treated with UA and OA ($n=3$ $\bar{x}\pm s$)

Cell cycle	Control		UA (30μmol/L)		OA (60μmol/L)	
	36h	72h	36h	72h	36h	72h
G_0+G_1	62±7	50±7	70±6	81±10[a]	68±9	76±6[a]
S	31±5	42±8	22±4[a]	9±3[b]	26±4	12±3[b]
G_2+M	7±2	8±2	8±3	10±2	6±1	12±2

$^aP<0.05$, $^bP<0.01$ *vs* control.

DISCUSSION

UA and OA both belong to pentacyclic triterpenoid acids. They have a similar molecular structure, but have different sites of the methyl group on the E loop: if the methyl group at C_{19} of UA is moved to C_{20}, it becomes OA. They are distributed widely in plants. In Korean traditional medicine, UA was used in anti-tumor therapy for a long time. Recently, it has been indicated in and outside China that UA and OA have a definitive antitumor activity by various routes[48-50].

This paper observed the anti-tumor activity of UA and OA on the HCT15 cells with some preliminary studies on their mechanism of action. With concentrations higher than their IC^{50}, there was obvious cell death and fragmentation. With the IC_{50} concentration, a few cell fragments were found, but cell death was also obvious. To investigate the effects of UA and OA on the viability of HCT15 cells, HCT15 viability was assessed by MTT assay. In addition, we performed a proliferation assay to identify the anti-proliferation effect of UA and OA. The results showed that cell viability was significantly decreased in a concentration-dependent manner and proliferation was markedly inhibited by both drugs. It was shown that both drugs possessed an inhibitory effect on HCT15 cells. The activity was significantly stronger with UA than with OA. According to changes in HCT15 cell morphology, UA and OA have a direct cytotoxic effect on HCT15 cells. Also it has been reported that UA exhibited both cytotoxic and cytostatic activity in A431 human epidermoid carcinoma cells[48] and OA has a cytotoxic activity against many cancer cell lines[43]. After incubation of the HCT15 cells with UA or OA for different times, the cell cycle was notably changed. When treated with IC_{50} concentration for 36 and 72 hours, the G_0/G_1 phase cells were gradually increased, with a concomitant decrease of cell population in S phase and no detectable apoptotic fraction. This result was in accordance with an inhibitory effect of UA and OA on HCT15 cells proliferation. These observations suggest that UA and OA may be involved in the action of the G_0/G_1 checkpoint and inhibition of DNA replication. Some studies have supported this inference. They have found that oleanane-type triterpenoids had inhibitory effects on DNA polymerase beta and DNA topoisomerases[51,52]. Many papers have demonstrated that UA can induce apoptosis[53,54]. But in the present study FCM assays showed that no apoptotic fraction in treated HCT15 cells. It is worth studying this further by using other methods of detecting apoptosis.

In conclusion, UA and OA have a definite anti-tumor activity on HCT15 cells. The effect of UA is stronger than that of OA. The possible mechanism of action is that both drugs have an inhibitory effect on tumor cell proliferation through cell-cycle arrest.

The toxicity of UA and OA is low and their distribution in plants is extensive. Besides their anti-tumor activity, they also possess immuno-regulatory and liver-protective effects. Therefore, they have

a bright future in clinical application. Further investigation to explore their potential in tumor treatment may prove to be worthwhile.

Abstract

AIM: **Transforming growth factor(TGF)β_1 is involved in a variety of important cellular functions, including cell growth and differentiation, angiogenesis, immune function and extracellular matrix formation. However, the role of TGF β_1 as an angiogenic factor in colorectal cancer is still unclear. We investigate the relationship between transforming growth factor β_1 and angiogenesis by analyzing the expression of transforming growth factor(TGF) β_1 in colorectal cancer, as well as its association with VEGF and MVD.**

METHODS: **The expression of TGF β_1, VEGF, as well as MVD were detected in 98 colorectal cancer by immunohistochemical staining. The relationship between the TGF β_1 expression and VEGF expression, MVD was evaluated. To evaluate the effect of TGF β_1 on the angiogenesis of colorectal cancers.**

RESULTS: **Among 98 cases of colorectal cancer,37 were positive for TGF β_1(37.8%), 36 for VEGF(36.7%), respectively. The microvessel counts ranged from 19 to 139.8, with a mean of 48.7(standard deviation,21. 8). The expression of TGF β_1 was correlated significantly with the depth of invasion, stage of disease, lymph node metastasis, VEGF expression and MVD. Patients in T3-T4, stage III-IV and with lymph node metastasis had much higher expression of TGF β_1 than patients in T1-T2, stageI-II and without lymph node metastasis (P<0.05). The positive expression rate of VEGF(58.3%) in the TGF-β_1 positive group is higher than that in the TGF-β_1 negative group(41.7%, P<0.05). Also, the microvessel count (54±18) in TGF-β_1 positive group is significantly higher than that in TGF-β_1 negative group (46±15, P<0.05). The microvessel count in tumors with both TGF-β_1 and VEGF positive were the highest (58±20,36-140, P<0.05). Whereas that in tumors with both TGF-β_1 and VEGF negative were the lowest (38±16, 19-60, P<0.05).**

CONCLUSION: **TGF β_1 might be associated with tumor progression by madulating the angiogenesis in colorectal cancer and TGF β_1 may be used as a possible biomarker.**

INTRODUCTION

Angiogenesis is essential for tumor growth and metastasis[1-6]. An association between poor prognosis and increase in microvascular density (MVD) of tumor has been reported in certain tumors[5-10]. This neoangiogenesis depends on the production of angiogenic factors by tumor cells and normal cells[7-15]. Vascular endothelial growth factor (VEGF) also plays a key role in angiogenesis of tumor[3-20], but the role of transforming growth factor-β1 is not clear yet. Now the expression of TGF-β_1 and VEGF, MVD were detected in 98 colorectal cancer by immunohistochemical staining, in order to investigate the correlation of TGF-β_1 and angiogenesis in colorectal cancer.

MATERIALS AND METHODS

Patients

All total of 98 colorectal adenocarcinoma patients who had undergone surgical resection in the Affiliated Zhongnan Hospital of Wuhan University (Wuhan) from July 1998 to December 2000 were included. There were 53 male and 45 female, with an age range from 23 to 74 years (mean, 56±11.2 years). Among the 98 adenocarcinoma patients, 17 were well differentiated, 47 moderately differentiated and 34 poorly differentiated. According to Dukes stage criteria, 34 cases were stageI, 29 stageII,30 stage III and 5 stage IV.

Methods

Immunohistochemistry All the tissue specimens were fixed in 100mL·L^{-1} neutral formalin and embedded in paraffin. Five-micrometer-thick sections were treated with xylene, dehydrated in ethanol. Tissue sections were washed three times in 0.05mol·L^{-1} PBS, incubated in endogenous peroxidase blocking solution. Non-specific antibody binding was blocked by pretreatment with PBS containing 5g·L^{-1} bovin serum albumin. Sections were then rinsed in PBS and incubated overnight at 4℃ with diluted anti-TGF β_1 protein polyclonal antibody, anti-VEGF protein polyclonal antibody and anti-CD34 protein monoclonal antibody. These steps were performed using immunostain kit according to the manufacturers instructions. PBS was used as substitutes of protein antibody for negative control groups. The sections were examined under light microscopy. Anti-TGF β_1 protein polyclonal antibody were purchased from Bosden Co (Wuhan). Anti-VEGF protein polyclonal antibody, anti-CD34 protein monoclonal antibody, and S-P detection kit were purchased from Fuzhou Maixin Co. Anti-TGF β_1 protein polyclonal antibody was diluted to 1:100. Anti-VEGF protein polyclonal antibody and anti-CD34 protein monoclonal antibody were impromptu type.

Results Positive signal was located in the cytoplasm or/and cell membrane. Immunoreactivity was graded as follows: +, ⩾10% stained tumor cells; -, <10% o stained tumor cells[21-23]. The microvessel counting procedures have been described in the published studies[21-24]. Briefly, the stained sections were screened at a magnification of ×100(×10 objective and ×10 ocular lens) under a light microscope to identify the 3 regions of the section with the highest microvessel density. Microvessels were counted in these areas at a magnification of ×200, and the average numbers of microvessels were recorded. The average number is known as MVD of the tumor.

Statistical analysis The difference between each group was analyzed by Chi-square test and correlativity. Significant difference was taken of P <0.05.

RESULTS

TGF β$_1$ expression in colorectal cancer and clinicopathologic findings

TGF β$_1$ was localized mainly in the cytoplasm and cell membrane of the tumor cells(Figure1). TGF β$_1$ expression was detected in 37 tumors (37.8%). The correlation between TGF β$_1$ expression and the clinicopathologic findings was shown in Table 1. The expression of TGF β$_1$ was correlated significantly with the depth of invasion, stage of disease and lymph node metastasis. Patients in T3-T4, stage III-IV and with lymph node metastasis had much higher TGF β$_1$ than patients in T1-T2, stageI-II and without lymph node metastasis (P<0.05). The expression of TGF β$_1$ was not correlated with age, gender and differentiation degree of the tumor.

Relationship between TGF β$_1$ expression, VEGF expression and MVD

VEGF was localized mainly in the cytoplasm and cell membrane of the tumor cells (Figure2). VEGF expression was detected in 36 tumors (36.7%), and TGF-β$_1$ expression was correlated closely with VEGF expression (Table 1). The positive expression rate of VEGF(58.3%) in the positive TGF-β$_1$ group was higher than that in the negative TGF-β$_1$ group(41.7%, P<0.05).

The number of the microvessel counts in all cases were 19-140 (±s, 49±22). Moreover, the microvessel counts were 54±18 in TGF-β$_1$ positive tumors and 46±15 in TGF-β$_1$ negative tumors (P<0.05, Table 1). TGF-β$_1$ expression, VEGF expression and MVD were significantly correlated one another (r=0.5816, 0.2619 and 0.5182, respectively. P<0.05). The microvessel counts in tumors with both positive TGF-β$_1$ and VEGF were the highest (58±20, 36-140; P<0.05). The microvessel counts in tumors with both negative TGF-β$_1$ and VEGF were the lowest (38±16, 19-60; P<0.05). The microvessel counts in tumors with positive TGF β$_1$ and negative VEGF were 25-128(49±18), and that in tumors with negative TGF β$_1$ and positive VEGF were 31-133 (50±20), lower than that in tumors with both positive TGF-β$_1$ and VEGF (P<0.05).

DISCUSSION

The process of angiogenesis is the outcome of an imbalance between positive and negative angiogenic factors produced by both tumor cells and normal cells. Numerous angiogenic factors have been described. Of these, VEGF play a key role in the angiogenesis in the colorectal cancer[3-25]. VEGF is a multi-functional cytokine, and has direct relationship with angiogenesis. The factors that regulate VEGF expression in tumor and non-tumor cells have now been elucidated[20-31]. The TGF βs represent a family of multifunctional cytokines that modulate the growth and function of many cells, including those with malignant transformation. The over-expression of TGF β$_1$ has been reported in tissue from patients with different carcinoma, and is believed to play a role in tumor transformation and progression, as well as in tumor regression[23-33]. Studied the correlation of TGF β$_1$ and angiogenesis of gastric cancer, and found TGF β$_1$ might regulate angiogenesis through an up-regulation of the expression of VEGF. A direct correlation between TGF β$_1$ expression and microvessel counts had not been identified in the current study[20-30]. TGF β$_1$ has no relationship with VEGF expression in breast cancer tissue, but is correlated with the expression of platelet-derived growth factor, and co-regulate angiogenesis[20-24]. The modulating mechanisms of TGF β$_1$ in angiogenesis are not entirely the same in different type of tumor.

The role of TGF β$_1$ in angiogenesis of colorectal cancer is not identified yet. This study found that the expression of VEGF and MVD in positive TGF β$_1$ group are significantly higher than that in TGF β$_1$ negative group. The expression of TGF β$_1$ is significantly positively correlated with the expression of VEGF. It demonstrated that TGF β$_1$ may be correlated indirectly with angiogenesis through an up-regulation of the expression of VEGF. The expression of TGF β$_1$ is also significantly positively correlated with MVD in colorectal cancer.

It demonstrates that TGF β_1 may modulate angiogenesis directly or indirectly through up-regulating the expression of other angiogenic factors. The microvessel counts in tumors that were both positive TGF-β_1 and VEGF were the highest of all. It demonstrates that TGF-β_1 and VEGF may co-modulate the angiogenesis.

TGFβ_1 expression was detected in 37 tumors (37.8%). The expression of TGF β_1 was correlated significantly with the depth of invasion, stage of disease and lymph node metastasis. Patients in T3-T4, stage III-IV and with lymph node metastasis had much higher expression of TGF β_1 than patients in T1-T2, stageI-II and without lymph node metastasis (P<0.05).

Abstract

AIM: **To study HCV polyprotein processing is important for the understanding of the natural history of HCV and the design of vaccines against HCV. The purpose of this study is to investigate the affection of context sequences on hepatitis C virus (HCV) E2 processing.**

METHODS: **HCV genes of different lengths were expressed and compared in vaccinia virus/T7 system with homologous patient serum S94 and mouse anti-serum M_{E2116} raised against *E.coli*-derived E2 peptide, respectively. Deglycosylation analysis and GNA (Galanthus nivalus) lectin binding assay were performed to study the post-translational processing of the expressed products.**

RESULTS: **E2 glycoproteins with different molecular weights (~75kDa and ~60kDa) were detected using S94 and M_{E2116}, respectively. Deglycosylation analysis showed that this difference was mainly due to different glycosylation. Endo H resistance and its failure to bind to GNA lectin demonstrated that the higher molecular weight form (75kDa) of E2 was complex-type glycosylated, which was readily recognized by homologous patient serum S94. Expression of complex-type glycosylated E2 could not be detected in all of the core-truncated constructs tested, but readily detected in constructs encoding full-length core sequences.**

CONCLUSION: **The upstream conserved full-length core coding sequence was required for the production of E2 glycoproteins carrying complex-type N-glycans which reacted strongly with homologous patient serum and therefore possibly represented more mature forms of E2. As complex-type N-glycans indicated modification by Golgi enzymes, the results suggest that the presence of full-length core might be critical for E1/E2 complex to leave ER. Our data may contribute to a better understanding of the processing of HCV structural proteins as well as HCV morphogenesis.**

INTRODUCTION

Hepatitis C virus (HCV), the major cause of post-transfusion and community-acquired non-A, non-B hepatitis[1, 2], is a member of the Flaviviridae family[3]. This virus has a positive-sense, single stranded RNA genome of about 9.6 kb, which encodes a polyprotein precursor of about 3000 amino acids. The polyprotein is further processed into various precursors and mature viral proteins[4, 5]. The structural proteins are encoded in the order NH_2-core-E1-E2-P7, which are processed into core (C), E1, E2, and P7 by host membrane- associated signal peptidase(s)[6-11]. The downstream nonstructural region is processed by a viral metalloprotease and a viral serine protease located at the N-terminus of NS3[12-17]. The core protein is thought to constitute the viral capsid with E1 and E2 being the virus envelope proteins. Numerous studies have shown that E1 and E2 are heavily glycosylated and associate to form a noncovalent heterodimeric complex[9,10,18,19]. E1 and E2 are believed to be type I transmembrane proteins with an N-terminal glycosylated ectodomain and a C-terminal hydrophobic anchor.

The lack of an efficient *in vitro* cell culture system for productive HCV propagation[20-27] and low levels of HCV particles in the liver tissues or blood of infected patients[28,29] have hampered the study of native viral proteins. Fortunately, a variety of prokaryotic and eukaryotic expression systems have proved useful for the production and characterization of HCV encoded proteins[8, 9, 11, 30-32]. However, diverse findings have been reported, regarding the molecular weights of E2, which most likely is a reflection of the differences in efficiency of HCV polyprotein processing and post-translational modification achieved in the particular systems[7-9, 11, 17-19, 30]. In this study, the E2 expression of recombinant plasmids carrying various length of HCV C-E1-E2 coding sequences was analyzed in the vaccinia virus/bacteriophage T7 RNA polymerase expression system[33]. The results suggest that the upstream conserved core coding sequence is required for the production of E2 glycoproteins carrying complex-type N-glycans which react strongly with homologous patient serum and therefore possibly represent more mature forms of E2.

MATERIALS AND METHODS

Cells and viruses

Human HeLa (ATCC #CCL-2) and monkey BS-C-1 (ATCC #CCL-26) cells were maintained in Dulbecco's modified essential medium (DMEM/HG) supplemented with 5% heat inactivated fetal calf serum (FCS) at 37℃ in a 5% CO_2 atmosphere. Recombinant vaccinia virus vTT7 that expresses the bacteriophage T7 RNA polymerase gene under the control of vaccinia virus early/late promoter P7.5 was generated and propagated as previously described[34]. PFU (plaque forming unit) titration was performed on BS-C-1 cell monolayers.

Plasmid constructions

The vaccinia virus/T7 promoter expression vector pTM1 was kindly provided by Bernard Moss (NIH, Bethesda, USA) and all of the expression plasmids carrying HCV cDNA encoding structural proteins described below were derived from pTM1. Figure1 depicts the HCV gene fragment in the expression plasmids. Plasmids pCEH-2 (1-730)

and pEH containing HCV C, E1 and E2 gene of subtype 1b[35] (GENBANK accession #D10934) were described previously[34]. Briefly, cDNA sequences encoding HCV polyprotein amino acids 192 to 730 were inserted into pTM1 to obtain pEH. HCV sequences encoding complete C were fused with the E1/E2 sequences of pEH to result in plasmid pCEH-2(1-730). The latter plasmid served as basis for PCR cloning to generate plasmids pCE1(1-341), ptCEH-2(108-730), ptCEH-2(120-730), ptCEH-2(137-730), ptCEH-2(156-730), ptCEH-2(167-730), pCEH-2(1-661) and pTM1/EH(192-661) for the expression of 5' or/and 3' truncated HCV sequences encoding HCV polyprotein amino acids as indicated by numbers in parenthesis. Plasmid pC-E2tH(1-195/394-661) was generated by deleting E1 coding sequences from pCEH-2(1-661) and linking polyprotein amino acids aa194 and aa394 together. Authenticity of HCV cDNA sequences in all constructed plasmids was confirmed by automatic sequencing.

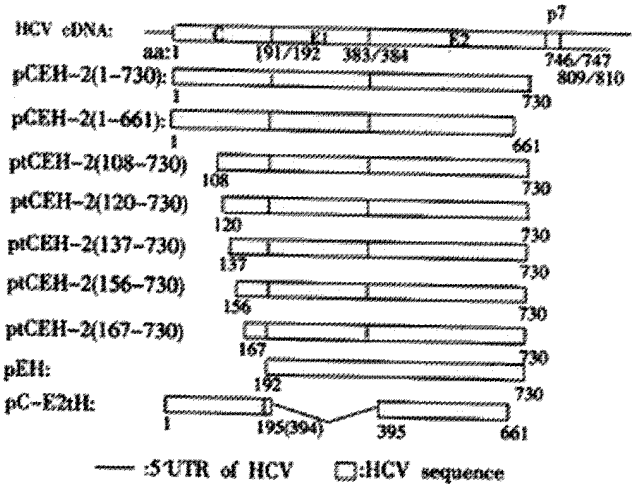

Figure 1 Schematic maps of HCV coding sequences inserted into the plasmid pTM1 and expressed under transcriptional control of the bacteriophage T7 pol promoter. Numbers refer to amino acids of the HCV polyprotein.

Transient expression of recombinant genes using vaccinia virus/T7 RNA polymerase (VV-T7pol)

HeLa cells grown to 80% confluency were infected with recombinant vaccinia virus vTT7 at a multiplicity of infection (MOI) of 10 PFU per cell to allow for production of recombinant T7 RNA polymerase. At 2h post-infection, the inoculum was removed and DNA of pTM1 based expression plasmids was transfected using DOTAP liposomal transfection reagent as described by the manufacturer (Roche Molecular Biochemicals, Mannheim). After 24 hours of incubation, infected/transfected cells were washed twice with PBS, harvested by scraping, pelleted upon brief centrifugation, and resuspended in a small volume of PBS. Cell lysates were prepared by adding SDS-PAGE sample loading buffer and stored at -80℃ until further analysis.

Western blot analysis

Cell lysates were separated by reductive SDS-PAGE and then transferred onto nitrocellulose membranes (Schleicher & Schuell). Blocking was done using 5% fat-free milk powder. For immunodetection of HCV proteins, blots were incubated with primary antibodies, washed, and incubated with 1000 fold diluted HRP-protein A (Sigma). The membranes were then washed again and reactive proteins were detected using the ECL system (Amersham Phamacia Biotech) according to the manufacturers' instructions. The primary antibodies used in this study include: anti-HCV human serum S94 at a dilution of 1:500 (kindly provided by Wang, Y., Beijing University, China), anti-HCV human serum S268 at a dilution of 1:500 (kindly provided by Lu Z., Shanghai Ruijin Hospital, China), anti-E2 mouse polyclonal antibody M_{E2116}[36] at a dilution of 1:300 (raised against E. Coli-derived HCV E2 polypeptide aa450 to 565), and anti-E1 rabbit polyclonal antibody $R_{E1135\text{-}C}$ at a dilution of 1:250 (raised against an *E. coli*-derived C-terminally truncated HCV E1 fragment).

Characterization of N-glycans on expressed E2 glycoproteins

For deglycosylation analysis, cell pellets were directly lysed in denaturing buffer provided by the manufacturer and digested with PNGase F (NEB) or Endo H (NEB) for 2 hours at 37℃.

The type of N-glycans on expressed E2 glycoproteins was also analyzed by testing its ability to bind to GNA (Galanthus nivalus) lectin. HeLa cells infected with vTT7 and transfected with pCEH-2 (1-730) were collected by scraping, washed in cold PBS, and then lysed with lysis buffer (50mM Tris-HCl [pH8.0], 150mM NaCl, 0.5% Nonidet P-40, 1mM PMSF). After centrifugation at 10000g, the supernatant was allowed to bind to GNA-agarose (Sigma). The flow-through fraction was collected and the gel matrices were washed with lysis buffer. Bound proteins were eluted with 1M α-D-mannopyranoside (Sigma) in lysis buffer. Samples were then analyzed by Western-blotting.

RESULTS

Detection of E2 glycoproteins of different Molecular Weights using antibodies of distinct origins

The hybrid vaccinia virus/T7 bacteriophage RNA polymerase expression system was used to study the expression of the HCV structural proteins. The transient expression products of plasmids pCEH-2(1-730) and pCEH-2(1-661), which contain HCV cDNA encoding the structural region terminating at amino acid 730 and 661 of the polyprotein respectively, were analyzed by Western blot using polyclonal mouse serum M_{E2116} raised against E.coli-derived E2 protein[36]. E2 products with apparent molecular weights (MWs) of ~60kDa and ~50kDa were detected for pCEH-2(1-730) and pCEH-2(1-661) respectively (Figure 2, lane 1, 3). The apparent molecular weights were higher than calculated values, which, along with the heterogeneous appearance of the detected bands, suggested that these were glycosylated expression products. The lower molecular weight of the E2 species obtained from expression of pCEH-2(1-661) in comparison to pCEH-2(1-730) was consistent with the introduced truncation at the 3' end of the E2 coding sequences leading to the loss of 70 amino acids in the recombinant polypeptide backbone.

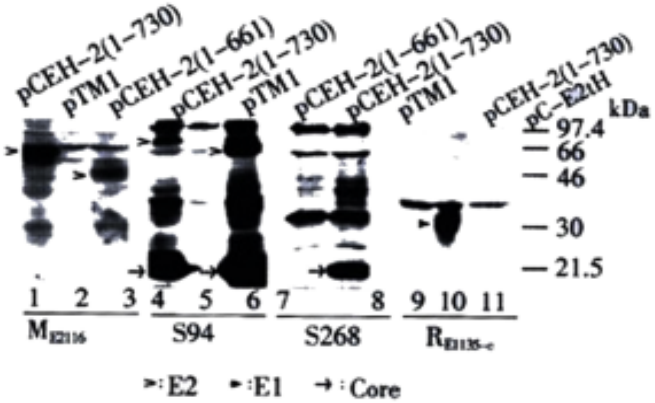

Figure 2 Detection of E2 glycoprotein species of different molecular masses. Transient expression products were analyzed by Western blot with antibodies of distinct origin: mouse polyclonal antibody M_{E2116} (lane 1, 2, 3); HCV patient serum S94 (lane 4, 5, 6); HCV patient serum S268 (lane 7, 8); rabbit polyclonal antibody $R_{E1135\text{-}C}$ (lane 9, 10, 11). Empty vector pTM1 was used as the negative control. HCV-specific protein bands are indicated by arrowheads. The plasmids used for transfection are indicated at the top of the lanes.

The expression products were also analyzed with HCV patient serum S94. Multiple prominent bands were detected for pCEH-2(1-730) and pCEH-2(1-661), but not for vector plasmid pTM1, representing expressed HCV structure proteins and possibly some precursors. The bands of ~75 kDa and ~66 kDa (Figure 2, lane 4, 6), which again consistent with the different length of E2 coding sequence in both plasmids, should represented the E2 proteins, although their MWs were higher than that detected by M_{E2116}. It is worth noting that the analyzed HCV cDNA originated from the same patient from whom S94 was collected. The core antigen and some precursors of expression products could also be detected by another HCV patient serum S268, but we could not detect the E2-specific 75kDa band (Figure 2, lane 8), which could be attributed to the high variability of the E2 glycoprotein[37, 38].

The antibody dependent detection of different E2 glycoprotein species was surprising. To rule out that the E2 bands of higher MW is the uncleaved E1-E2 precursors, the expression products from pCEH-2(1-730) were analyzed with anti-E1 rabbit sera. A heavy band of about 30kDa was detected, possibly representing multiple forms of E1 proteins (Figure 2, lane 10), while no E1-specific band with higher MW was detected. Another possible explanation could be that E2 polypeptides of varying sizes were synthesized due to incomplete or irregular processing of the polyprotein. This hypothesis was abandoned when we subjected recombinant proteins to deglycosylation with PNGase F prior to Western blot analysis with mouse polyclonal antibody M_{E2116}. After PNGase F treatment, only one E2-specific band with apparent molecular weight of 30 kDa was detected for pCEH-2(1-661) expression products, while an E2-specific doublet band of 33/34 kDa was detected for pCEH-2(1-730) expression products (Figure 3), which is consistent with the MWs of calculated E2 polypeptide backbones. It suggests that difference of the MWs of E2 species detected by M_{E2116} and S94 from the same transient expression products (pCEH-2(1-730): ~60kDa and ~75kDa, pCEH-2(1-661): ~50kDa and ~66kDa) is mainly due to different N-glycosylation. The detection of a E2 peptide doublet with pCEH-2(1-730) but not with pCEH-2(1-661) is in agreement with the fact that E2 contains a PKR-eIF2a phosphorylation site (PKR: RNA-activated protein kinase) at aa659-670[39], which is largely deleted in the pCEH-2(1-661) construct.

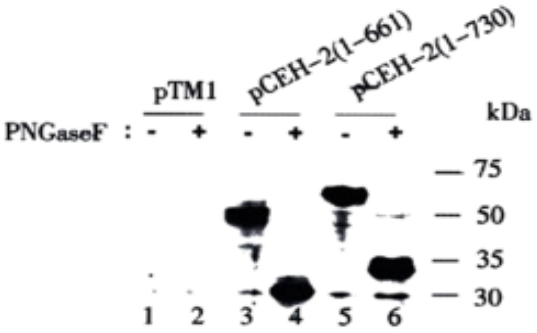

Figure 3 Deglycosylation analysis of the expressed HCV E2 proteins with PNGase F. Transient expression products were subjected to Western blot analysis with M_{E2116} as the primary antibody. pTM1 transfected cells were used as control. The plasmids used for transfection are indicated at the top of the lanes. Samples incubated with deglycosylation buffer were run in parallel. +: samples digested with PNGase F, -: samples incubated with PNGase F reaction buffer.

Altogether, the above results suggest that the 75kDa and 66kDa bands detected by S94 are HCV E2 glycoproteins of heavier glycosylation and thus higher molecular weight.

M_{E2116}- and S94- reactive E2 glycoproteins carried different types of N-glycans

Since M_{E2116}- and S94-reactive E2 species had polypeptide backbones of the same size, the difference in apparent molecular weight and antibody reactivity could only be attributed to differences in the degree and/or type of glycosylation. The glycan type on different E2 species expressed from pCEH-2(1-730) was then analyzed by testing their sensitivity to PNGase F and Endo H. PNGase F hydrolyzes all types of N-glycan chains from glycopeptides and glycoproteins unless they carry α-1-3 linked core fucose residues present in insect and plant glycoproteins[40], while Endo H cleaves only high mannose structures and hybrid structures on N-linked oligosaccharides of glycoproteins[41]. Figure 4A shows that the M_{E2116}-reactive E2 species was sensitive to both PNGase F and Endo H digestion. The S94-reactive E2 species disappeared after PNGase F digestion (Figure 4B). It was difficult to detect the deglycosylated E2 with S94 after PNGase F treatment, because there were multiple HCV polyprotein precursor proteins of about 30000 reacted strongly with S94 and unglycosylated E2 seemed to react weakly with S94 (unpublished data). However, the highly glycosylated, S94-reactive E2 band remained after Endo H digestion (Figure 4B). The glycan type of different E2 species expressed from pCEH-2(1-730) were also analyzed by testing their ability to bind to GNA lectin. GNA is specific for the non-reducing end of α-D-mannosyl residue of glycoconjugate and therefore can be used to probe the presence of high mannose type or hybrid type glycans on glycoproteins[42, 43]. The M_{E2116}-reactive E2 species could quantitatively bind to and be eluted from GNA-agarose, whereas no obvious binding could be demonstrated for S94-reactive E2 species (Figure 5).

The resistance of S94-reactive E2 glycoprotein species to Endo H digestion together with the fact that it could not bind to GNA indicates that the S94-reactive E2 protein carries complex-type glycans.

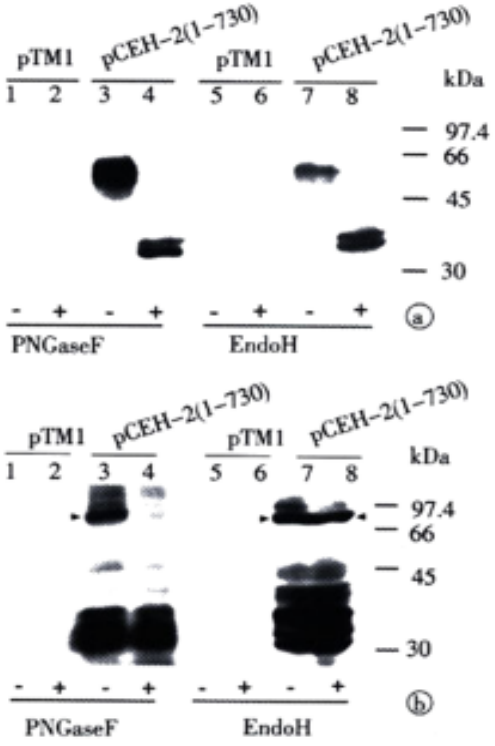

Figure 4 Different sensitivities of two glycosylated E2 species to PNGase F and Endo H. Transient expression products of pCEH-2(1-730) were digested with PNGase F or Endo H, respectively. The digested samples were analyzed by Western blot with M_{E2116} (A) and S94 (B). Empty vector pTM1 was used as negative control.
Samples incubated with deglycosylation buffer were run in parallel. +: samples digested with Endoglycosidase, -: samples incubated with Endoglycosidase reaction buffer.The plasmids used for transfection are indicated at the top of the lanes. Endoglycosidases used in this study are indicated at the bottom of the lanes. S94-reactive E2 proteins are indicated by arrowheads.

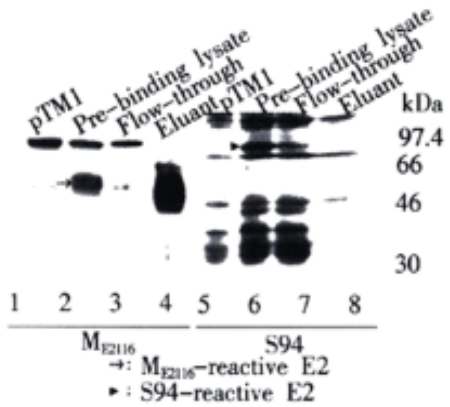

Figure 5 Different ability of differently glycosylated E2 speicies to bind to GNA-agarose. HeLa cells infected with vTT7 and transfected with pCEH-2(1-730) were collected, washed and lysed with lysis buffer. The cleared supernatant was then allowed to bind to GNA-agarose. The gel beads were washed and eluted with 1M α-D-mannopyranoside in lysis buffer. Pre-binding lysate, flow-through and eluant fractions were analyzed by Western blot analysis. HeLa cells infected with vTT7 and transfected with pTM1 were served as negative control. The sera used as primary antibodies are indicated at the bottom of the lanes. E2 proteins are indicated by arrowheads.

HCV core sequence dependent formation of complex-glycosylated E2

We also assessed if co-expression of core or E1 coding sequences had any effect on the production of the E2 proteins, which was readily recognized by homologous patient serum S94. A set of expression plasmids containing HCV cDNAs with various deletions in the core sequence (ORF starting at aa108, aa120, aa137, aa151, or aa167, respectively) were constructed. The lysates from vTT7-infected and plasmid DNA transfected HeLa cells were analyzed by Western blot with either the mouse anti-serum M_{E2116} or the patient serum S94 (Figure 6).

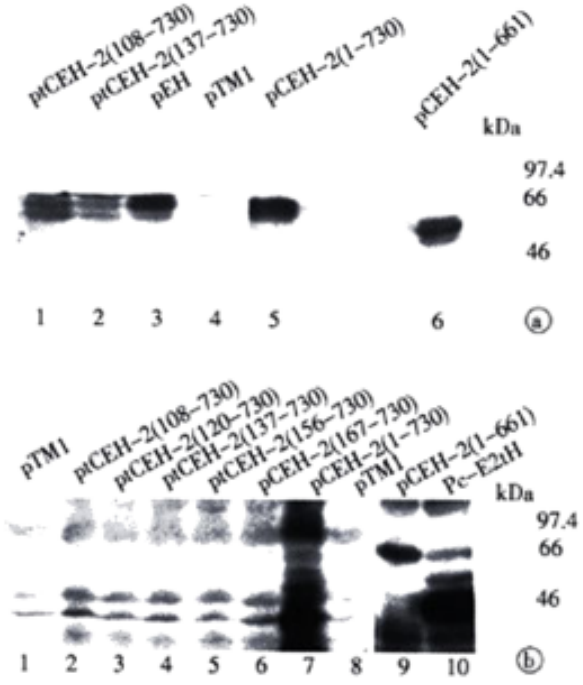

Figure 6 Requirement of the core sequence for the expression of complex-type glycosylated E2. Expression products of differently truncated HCV structural genes were analyzed by Western blot analysis. Blots were probed with M_{E2116} (A) or with S94 (B). Empty vector pTM1 was used as negative control. The plasmids used for transfection are indicated at the top of the lanes.

When using mouse antibody M_{E2116}, recombinant E2 of ~60kDa and ~50kDa could be detected upon expression of all constructs tested (Figure 6A). Patient serum S94 allowed detection of E2 for pCEH-2(1-730) and pCEH-2(1-661) with full-length core coding sequences (Figure 6B, lanes 7, 9), similar to that described in Figure 2. In contrast, no E2 products could be visualized after expression of constructs containing no or only partial core sequences (Figure 6B, lanes 1-6). Interestingly, deletion of E1 coding sequences had no significant effect on the synthesis of S94 detectable E2 protein (Figure 6B, lane 10). These results suggests that the presence of complete HCV core sequence is crucial for the expression and/or post-translational processing of the complex-type glycosylated form of E2.

DISCUSSION

In this study, various constructs of HCV cDNAs placed under transcriptional control of the bacteriophage T7 promoter were transiently expressed using vaccinia virus/T7 system. Upon characterization of the HCV gene products with different antibodies, two species of E2 with different MWs were identified in the expression products of the same plasmid. The high molecular weight forms of E2 were readily recognized by a patient serum, but displayed weak reactivity with antibodies raised against E. coli derived E2. These high molecular weight forms of E2 were not likely produced from inefficient proteolytical processing at the E1/E2 boundary as these proteins were not stained with E1-specific antibodies. Efficient processing at E1/E2 was confirmed by deglycosylation analysis. The difference of the MWs of E2 species detected by S94 and by M_{E2116} was therefore mainly due to different N-glycosylation. The S94-reactive E2 glycoproteins, which were resistant to Endo H digestion and could not bind to GNA, carry complex-type glycans.

The specific recognition of the complex-type glycosylated E2 but not the high-mannose-type glycosylated E2 by homologous patient serum S94 suggested that the former could be a better representation of native E2 proteins on HCV virions. Similar results were also reported by Inudoh *et al*[44]. By comparing the reactivity of complex-type glycosylated E2 and the high-mannose-type glycosylated E2 with different patient sera, they demonstrated that the former is superior in diagnosing HCV infection. Their results and our results reported here are in concordance with the finding that E2 protein on patient derived virions contained complex-type sugars indicating Golgi-specific modification[45].

Expression of full-length or C-terminally truncated envelop proteins in eukaryotic cells has demonstrated that E1 and E2 are retained within the ER membrane system due to the presence of ER-retention signals in the C-termini of both envelope proteins[46-50]. However, recent study indicates that HCV E2 proteins could also present in the Golgi apparatus of the stably transfected cell line expressing HCV C-E1-E2-NS2 fragment. A possible explanation could be that Martire *et al*[51] used an HCV gene fragment including full-length core sequences in their study while structural protein sequences without full-length core sequences were used to study the localization of envelop proteins. The results reported here demonstrated that the complex-type glycosylated, possibly more mature form of E2 is only detectable upon co-expression of the complete HCV core coding sequence. Deletion of the first 107 N-terminal core amino acid residues was obviously sufficient to abrogate production of complex-glycosylated E2. This result suggest that the core protein might allow for targeting the envelope glycoproteins to Golgi-specific modification, which could be a key step in the morphogenesis of HCV virions. HCV-like particles were observed when HCV cDNA encoding whole core, E1 and E2 was expressed in baculovirus-insect expression system[52]. After binding of core to the E1-E2 complex statically located on the ER membrane, virus-like particles might be formed and the conformation of E1-E2 complex changed, which could result in the abrogation of the ER-retention

signal for the E1-E2 complex. Then the virus-like particles might migrate along the secretion pathway, where E2 (and E1) proteins undergo more complex glycosylation by the Golgi enzymes.

In summary, upon expression of recombinant HCV core, E1, and E2 sequences, the E2 proteins of different glycosylations could be identified. The complex-glycosylated E2 protein might represent a more mature form of E2 and its formation required the conserved core coding sequences. Our data may contribute to a better understanding of the processing of HCV structural proteins as well as HCV morphogenesis.

ACKNOWLEDGMENT

We thank Wang, Y. and Lu, Z. for providing the HCV clones and the HCV specific patient sera.

Abstract

AIM: **Both Hepatitis B virus (HBV) and Hepatitis C virus (HCV) are major causative agents of transfusion-associated and community-acquired hepatitis worldwide. Development of a HCV vaccine as well as more effective HBV vaccines is an urgent task. DNA immunization provides a promising approach to elicit protective humoral and cellular immune responses against viral infection. The aim of this study is to achieve immune responses against both HCV and HBV by DNA immunization with fusion constructs comprising various HCV E2 gene fragments fused to HBsAg gene of HBV.**

METHODS: **C57BL/6 mice were immunized with plasmid DNA expressing five fragments of HCV E2 fused to the gene for HBsAg respectively. After one primary and one boosting immunizations, antibodies against HCV E2 and HBsAg were tested and subtyped in ELISA. Splenic cytokine expression of IFN-γ and IL-10 was analyzed using an RT-PCR assay. Post-immune mouse antisera also were tested for their ability to capture HCV viruses in the serum of a hepatitis C patient *in vitro*.**

RESULTS: **After immunization, antibodies against both HBsAg and HCV E2 were detected in mouse sera, with IgG2a being the dominant immunoglobulin sub-class. High-level expression of INF-γ was detected in cultured splenic cells. Mouse antisera against three of the five fusion constructs were able to capture HCV viruses in an *in vitro* assay.**

CONCLUSION: **The results indicate that these fusion constructs could efficiently elicit humoral and Th1 dominant cellular immune responses against both HBV S and HCV E2 antigens in DNA-immunized mice. They thus could serve as candidates for a bivalent vaccine against HBV and HCV infection. In addition, the capacity of mouse antisera against three of the five fusion constructs to capture HCV viruses in vitro suggested that neutralizing epitopes may be present in other regions of E2 besides the hypervariable region 1.**

INTRODUCTION

Both Hepatitis B virus (HBV) and Hepatitis C virus (HCV) are major causative agents of transfusion-associated and community-acquired hepatitis worldwide[1,2]. It is estimated that there are 250 million HBV carriers in the world and more than 10% of chronically infected HBV patients eventually develop cirrhosis and hepatocellular carcinoma[3]. About 2-3% of the world population are HCV carriers. More than 70% of HCV infections become chronic, among which 5-20% progress to liver cirrhosis and hepatocellular carcinoma[4,5]. Available HBV vaccines have proven to be safe and effective in preventing HBV infection. However, high costs, exclusion of some escape mutants and neonatal intolerance are elimilating their wide use[6]. So far, no vaccine is available against HCV infection. IFN-γ treatment is the only useful therapy available. However, only 20-30% of treated patients develop long-term responses[7]. Therefore, HBV and HCV infections pose a worldwide health threat and the development of uniformly effective vaccines of affordable prices is an urgent task.

DNA immunization, which allows the de novo synthesis of antigens in host's cells, is able to elicit protective humoral and cellular immune responses in several animal models of viral infection[8-10]. The cellular context for de novo synthesized proteins to achieve proper maturation is a particularly important advantage for proteins such as those constituting viral envelopes whose maturation requires the help of additional cellular factors. Increasing data showed that DNA immunization against HBsAg elicited strong humoral and cellular immune responses that protect chimpanzees against the challenge with HBV. Moreover, DNA immunization in transgenic mice expressing HBsAg in the liver resulted in the clearance of HBsAg and long-term control of transgene expression, suggesting that DNA immunization is a potential tool in the treatment of HBV chronic carriers[11-15]. DNA immunization with HCV E2 protein that was believed to carry the major neutralization epitopes of HCV[16] also was studied in several animal models including primates[17-21]. These studies demonstrated that DNA immunization with HCV E2 elicited strong humoral and cellular immune responses in various animals, though it did not elicit sterilizing immunity in chimpanzees against the challenge with a monoclonal homologous virus. The DNA immunization did appear to modify the infection and might have prevented the progression to chronicity, suggesting that DNA vaccine could be a promising approach for HCV treatment.

The objective of this research was to simultaneously stimulate immune responses against both HBV and HCV by DNA immunization with fusion constructs comprising of various HCV E2 gene fragments fused to the HBsAg gene of HBV. HBsAg carries all the information required for membrane translocation, particle assembly and secretion from mammalian cells. We have previously shown that HBsAg carrying HBV preS1 (21-47) at its truncated carboxyl terminal end could present the preS1 epitope on the surface of the chimeric particle and induce preS1 specific antibodies in mice[22-24]. Moreover, humoral and cellular immune responses were successfully induced via

direct injection of the plasmid containing the HBsAg-preS1 fusion gene[15]. These data indicated that gene fragments of proper size could be fused to the C-terminal of HBsAg without affecting particle assembly and secretion, and were capable of inducing immune responses against both HBsAg and the fused epitope. Although the epitopes on envelope protein E2 are not very clear yet, there have been some successful experiments to determine the immune determinants[25-27]. Based on these previous findings, five fragments of HCV-E2 were selected in the hydrophilic region of E2 protein and fused to the truncated 3' end of HBsAg gene. The humoral and cellular immune responses of the plasmids expressing fusion proteins were evaluated. Furthermore, virus-capture ability of antibodies against those HCV-E2 fragments was also examined. The results are opening a new approach to the development of a bivalent vaccine against HBV and HCV, and lead to a better understanding of the immunological property of HCV-E2.

MATERIALS AND METHODS

Expression plasmids

Five HCV E2 gene fragments (A to E) were amplified from pUC18/E (E1-E2 gene of HCV genome type 1b inserted in pUC18)[28] with following primers:

Fragment	Sense Primer	Antisense Primer
A(384-413)	P1 CGGCGTTGTATACAACACCTACG	P2 TGGGAATTCAAAGCTGGATTTTCT
B(414-443)	P3 GAAAATCGTATACGTGAACACCA	P4 CCGAATTCAGTAGAACAGCGCG
C(460-489)	P5 CATGGCCGTATACCGCTCCATTG	P6 GTCGAATTCAGTAGTGCCAGCA
D(490-519)	P7 TTGCTGGGTATACCCACCTCGA	P8 GAGAATTCAGGTCGTCCCCACCAC
E(529-549)	P9 GGTGGGGGTATACGATCGCCTC	P10 TACGAATTCACCAGTTGCCTTGCGG

*Acc*I and *Eco*RI sites were introduced in sense and antisense primers, respectively. After digestion with *Acc*I and *Eco*RI, PCR products were inserted downstream from the HBV S gene in pcDNA3S[29] to obtain pcDNA3SE2-A, pcDNA3SE2-B, pcDNA3SE2-C, pcDNA3SE2-D and pcDNA3SE2-E (Figure 1). A fragment coding for amino acids 384 to 649 of HCV-E2 was also amplified from pUC18/E with primers P11 (5'-CCGGCGGATCCATGAACACC-3') and P12 (5'-GCGAATTCATCCTCGAGTCCAG-3'). PcDNA3E2 was constructed by inserting this PCR product digested with *Bam*HI and *Eco*RI into the MCS of pcDNA3 (Figure 1).

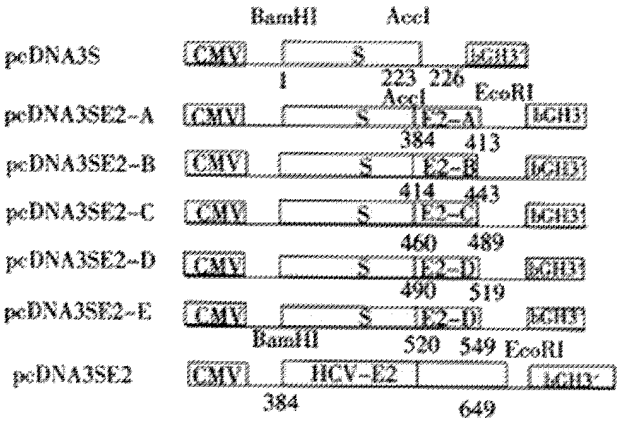

Figure 1 Schematic diagram of the expression plasmids.
The coordinates below the bars refer to the corresponding amino acid residues of HBV surface antigen (HBsAg) and HCV E2 protein. The fusion genes were under the control of CMV immediate early promoter in pcDNA3. Bovine growth hormone (bGH) 3'-untranslated sequences were used as polyadenylation signals.

ELISA for transiently expressed HBV surface antigen

COS-M6 cells were maintained in Dulbecco's Modified Eagle's medium (DMEM) supplemented with 5% fetal calf serum (Gibco, BRL, USA). 10μg of plasmid DNA and 5μg of an internal control pSK110, which expresses β-galactosidase, were transfected into 5×10^5 COS-M6 cells by calcium phosphate co-precipitation method. Forty-eight hours after transfection, cells and media were collected. The activity of β-galactosidase in cell lysate obtained by cycles of freezing and thawing was analyzed to normalize the variation of transfection efficiency among different samples. HBsAg in cell lysates and media was determined with a commercial ELISA kit (Sino-American Co., Shanghai, China). The kit was adapted for quantitative measurements of HBsAg using purified yeast derived HBsAg (National Vaccine and Serum Institute, Beijing, China) as potency standard. Results were presented as means of three independent experiments[23,30].

Western Blotting of transiently expressed products

HeLa cells were maintained in DMEM supplemented with 5% fetal calf serum. To enhance the expression level of fusion genes, cells were first infected with vaccinia virus vTT7 that expresses T7 RNA polymerase at a M.O.I. of 10 pfu per cell[31]. Two hours post-infection, $1\text{-}2\times10^5$ cells were transfected with 10μg of plasmid DNA by calcium phosphate method. Eighteen hours after transfection, cells were collected and cell lysate was electrophoresed on a 12.5% SDS-PAGE and subsequently electro-blotted onto nitrocellulose membrane. After blocking for 1h with 5% powdered lipid-free milk in PBST (PBS containing 0.1% Tween 20), the membrane was incubated with anti-HBs McAb H116 (kindly provided by Dr. E. Hildt, Munich, Germany) or anti-HCV E2 (450-565) polyclonal antiserum RE2-116[32], followed by incubation with HRP conjugated secondary antibody (Dako Co., Denmark). Signals were detected by enhanced chemi-luminescence (ECL) blotting analysis system (Amersham-Pharmacia Co., UK).

DNA immunization of mice

C57BL/6 (H-2^b) mice were purchased from Shanghai Laboratory Animal Center. Groups of five female mice, 6-8 weeks old, were injected with 100μg of expression plasmids into regenerated tibialis anterior (TA) muscles 5 days after treatment of 100μl 10^{-5}mol/l cardiotoxin (Sigma, USA)[15,29]. Four weeks later, the mice were boosted in the same way.

Serologic tests

Sera were collected by tail bleeding at different time points pre-and post-injection and assayed for anti-HBs and anti-HCV-E2 by ELISA. Microwell plates were coated with serum derived HBsAg particles[29] (Kehua Co., Shanghai, China), or 0.1μg/well HCV-E2 (385-565) expressed in *E. Coli*[32]. After blocking with 5% powdered lipid-free milk in PBST (PBS containing 0.1% Tween 20), serial two-fold dilutions of sera were added. The bound antibodies were detected with HRP-conjugated rabbit anti-mouse IgG (1:1000) (Dako Co., Denmark) after extensive washing with PBST. Sera from mice immunized with pcDNA3 vector at 1 in 20 dilution were used as negative controls. A positive result was defined as an absorbance value of great than twice the absorbance of negative control with a cutoff of 0.050. Seroconversion was defined as giving a positive reading at 1:20 dilution. Antibody titres of pooled seroconverted animal sera were set as the highest dilution giving a positive reading (end-point dilution method)[22,32].

To type the subclasses of IgG, mouse sera of each group were collected 6 weeks after the first immunization, and the titers of IgG1 and IgG2a antibodies assayed individually by a similar end-point dilution method, using the HRP-conjugated rabbit anti-mouse IgG1 and IgG2a (Serotec Co., Oxford, UK) for detection.

Splenic cytokine expression test

Expression of IFN-γ and IL-10 were assayed semi-quantitatively as described[33,34]. Mice were killed 10 weeks after the first injection and spleens were removed aseptically. The single cell suspensions of the splenocytes were prepared and maintained in DMEM supplemented with 5% fetal calf serum and 5×10^{-5} M β-ME at a density of 10^7 cells per well. Cells were stimulated with 0.5μg/ml rDNA yeast derived HBsAg (National Vaccine and Serum Institute, Beijing, China), followed by culture at 37℃. At 0, 24, 48 hr post-stimulation, splenic cells were sampled. Total RNA was extracted with Trizol (Gibcol, BRL, USA) and reverse transcribed with random hexamer primers (New England Biolabs Inc, Beverly, USA.). Messenger RNAs for IFN-γ and IL-10 were semi-quantitated by competitive RT-PCR[33,34]. Splenic cells from mice immunized with pcDNA3 and mitogen ConA (5μg/ml) served as a negative and a positive control respectively.

Analysis of the virus capture capability of immune sera

The virus capture capability of antibodies in immune sera was assessed according to the method of affinity capture RT-PCR (AC-RT-PCR) detection of HEV in patient stool specimens[35] with a few modifications. Briefly, 0.5ml microcentrifuge tubes were coated with 50μl goat anti-mouse IgG F(ab')^a-2 (0.02μg/μl, Jackson ImmunoResearch Laboratories, Inc., West Grove, USA), capped and incubated at room temperature for 1hr. After blocking with 5% powdered lipid-free milk in PBST for 15 min at 37℃ and overnight at 4℃, tubes were aspirated and washed with 150μl PBST. The mouse sera were adjusted to same titre of 1:80 by dilution with PBS, to avoid the variations of the results caused by different antibody titers in different samples. Tubes were subsequently loaded with 25μl properly diluted mouse immune sera and 25μl HCV-RNA-PCR-positive patient's serum (1.6×10^7 HCV genome Equivalent [Geq] per ml, provided by Dr. X. Zhang, Ruijin Hospital, Shanghai, China) diluted 1:50 in PBS. The mixtures were mixed gently and incubated for 1 hr at room temperature and overnight at 4℃. Tubes were then washed three times with 150μl wash buffer (25 mM Tris-HCl pH8.0, 75mM KCl, 2.5mM $MgCl_2$). Captured virus was detected with a commercial HCV PCR testing kit (Sino-American Co., Shanghai, China) which specifically amplifies a 225 bp fragment in the 5' UTR of HCV RNA. HCV which was captured directly by a conformation specific monoclonal antibody (McAb) against HCV-E2, 219A2, (kindly provided by Dr. S. Abrignani, IRIS, Siena, Italy) was used as positive control.

RESULTS

Transient expression of HBsAg-HCV E2 fusion proteinsFive expression plasmids containing the HCV-E2 coding sequences (corresponding to amino acids 384-413, 414-443, 460-489, 490-519, 529-549) fused to the 3' end of HBV-S gene were constructed as described in "Materials and Methods". COS-M6 cells were then transfected with these plasmids respectively.

Forty-eight hours post-transfection, the presence of HBsAg fusion protein in the cell lysates and culture media was measured with HBsAg ELISA. HBsAg was detected in both the cell lysates and culture media, indicating that the fusion constructs were able to express and secrete HBsAg efficiently (Figure 2).

Expressed HBsAg and HCV-E2 fusion proteins were also evaluated by Western Blot. They were separated by SDS-PAGE gel, followed by incubation with HBsAg specific McAb H116 (Figure 3A). Compared with HBsAg expressed by pcDNA3S (Figure 1), which contained the major surface gene of HBV only and displayed 24000 and 27000 protein bands for the unglycosylated and glycosylated forms respectively (Figure 3A, lane1)[29], all the fusion antigens showed slower migratory bands (27000 and 29000), indicating successful expression of the fusion proteins. Two fusion constructs SE2-B (414-443) and SE2-D (490-519) displayed additional bands at 31000, which might result from multi-glycosylation. Expressed fusion proteins SE2-C (460-489), SE2-D (490-519) and SE2-E (529-549) were also incubated with polyclonal antibody RE2-116. The band pattern in the Western Blots (Figure 3B) was consistent with that in Figure 3A, suggesting that these fusion proteins possess both HBV-S and HCV-E2 antigenicity. SE2-A(384-413) and SE2-B(414-443) were not assayed for HCV-E2, since they did not locate in the reactive region (450-565) of RE2-116. By contrast, the non-fused truncated E2(384-649) (Figure 1) displayed only a single band as large as the expected unglycosylated product (Figure 3B, lane 1).

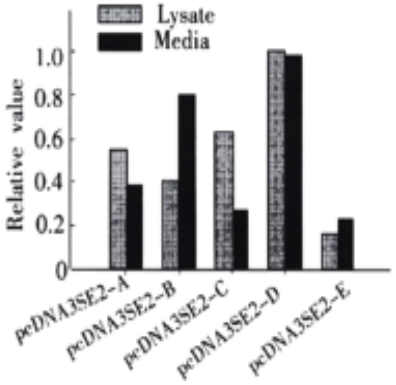

Figure 2 Comparison of the expression and secretion level of fusion proteins in COS cells.
pcDNA3SE2-A, pcDNA3SE2-B, pcDNA3SE2-C, pcDNA3SE2-D, pcDNA3SE2-E are the plasmids expressing HBsAg fused with different HCV E2 fragments. The HBsAg in the culture medium (gray) and cell lysates (black) was measured by a commercial ELISA kit (Sino-American Co., Shanghai, China). Results were presented as means of three independent experiments (see Materials and Methods). The amount of HBsAg expressed by pcDNA3SE2-D in cell lysates was arbitrarily taken as 1.0.

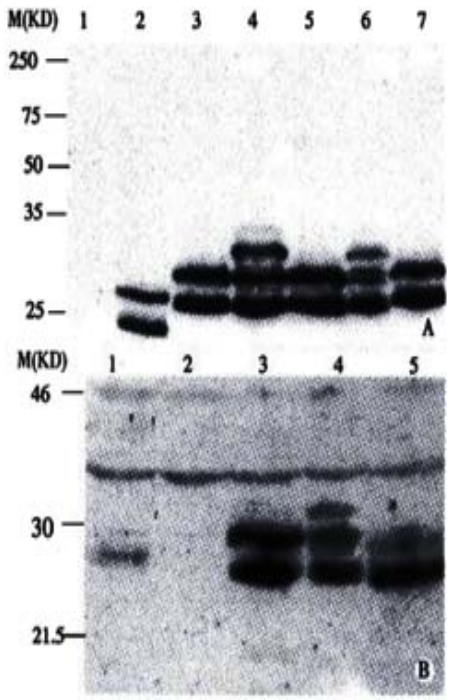

Figure 3 Characterization of the fusion antigens transiently expressed in HeLa cells by Western blotting.
After separation by a 12.5% SDS-PAGE, the proteins were blotted onto a nitrocellulose membrane and incubated with (A) anti-S McAb (H166, 1:300 diluted), (B) anti-HCV E2 (450-565) polyclonal antiserum RE2-116 (1:500 diluted) respectively. (A) lane 1-7, fusion proteins expressed by pcDNA3, pcDNA3S, pcDNA3SE2-A, pcDNA3SE2-B, pcDNA3SE2-C, pcDNA3SE2-D and pcDNA3SE2-E respectively. (B) lane 1-5, fusion proteins expressed by pcDNA3E2- pcDNA3, pcDNA3SE2-C, pcDNA3SE2-D, pcDNA3SE2-E respectively.

Humoral responses to fusion antigens in DNA-immunized mice

C57BL/6 mice were injected with HCV-E2 and HBV-S fusion constructs. As shown in Table 1, the immunized mice produced antibodies against both HBsAg and HCV-E2 after the first injection, and the seroconversion rate increased quickly after the boost, reaching 100% at week 6 or 8. Antibodies were still detectable after 24 weeks. Impressively, the anti-HCV E2 antibody titers elicited in mice immunized with fusion constructs were much higher than that induced in mice injected with pcDNA3E2 (up to 40 fold difference), which contained non-fused HCV E2(384-649). Compared with the humoral response induced by pcDNA3S, all the fusion constructs were able to induce equivalent or slightly smaller anti-HBs antibody responses.

Subsets of IgG against both HBsAg and HCV-E2 were also determined. The IgG profiles specific to HBsAg indicated the obvious predominance of IgG2a (Figure 4A), while IgG profiles specific to HCV-E2 varied among different constructs (Figure 4B). Only pcDNA3SE2-A and pcDNA3SE2-D induced predominant IgG2a against HCV-E2, suggesting that the T helper responses elicited against these two fragments were Th1 dominant.

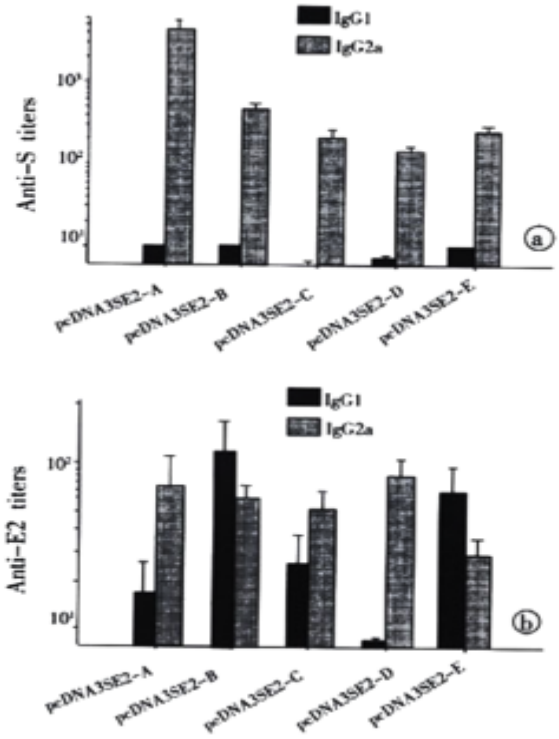

Figure 4 IgG subtypes profile of antibodies against HBsAg and HCV E2. Sera collected from mice 6 weeks after boosting were assayed for the IgG1 and IgG2a antibodies against HBsAg and HCV E2. For each group of 5 mice, titers of IgG1 and IgG2a antibodies were determined individually by serial two-fold dilution titration methods using HRP-conjugated rabbit anti-mouse IgG1 and IgG2a (Serotec Co., Oxford, UK) for detection. (as described in Materials and Methods). The arithmetic mean ± standard deviation (SD) (n=5) is shown. (A) Anti-HBs, (B) Anti-HCV E2.

Expression of cytokines in the cultured splenic cells from DNA-immunized mice

After the *in vitro* stimulation of splenic cells derived from immunized mice, expressions of cytokines were analyzed by competitive RT-PCR. 24 hrs post-stimulation with rDNA yeast derived HBsAg (National Vaccine and Serum Institute, Beijing, China), high levels of IFN-γ were detected in the splenic cells from the mice immunized with pcDNA3SE2-A, pcDNA3SE2-B, pcDNA3SE2-C and pcDNA3SE2-E (Figure 5). The IL-10 expression was also detectable, but weaker than IFN-γ expression.

Table 1A Sero-conversion Ratios and Titres of Anti-HBsAg in DNA Immunized Mice

Weeks	DNAImmunogen					
	pcDNA3S	pcDNA3SE2-A	pcDNA3SE2-B	pcDNA3SE2-C	pcDNA3SE2-D	pcDNA3SE2-E
0[a]	(0/5)	(0/5)	(0/5)	(0/5)	(0/5)	(0/5)
2	(5/5)	(1/5)	(1/5)	(1/5)	(1/5)	(2/5)
4[b]	1280[d](5/5[c])	1280(4/5)	640(2/5)	320(2/5)	320(2/5)	320(4/5)
6	10240(5/5)	10240(5/5)	5120(4/5)	5120(4/5)	5120(5/5)	2560(5/5)
8	5120(5/5)	5120(5/5)	5120(5/5)	5120(5/5)	5120(5/5)	5120(5/5)
10	5120(5/5)	5120(5/5)	2560(4/5)	2560(5/5)	2560(5/5)	5120(5/5)
16	1280(5/5)	1280(5/5)	640(4/5)	320(5/5)	640(5/5)	80(5/5)
24	1280(5/5)	1280(5/5)	640(4/5)	320(5/5)	640(5/5)	80(5/5)

Note: Groups of mice (n=5) were injected i.m. with the respective plasmids, and anti-HBsAg antibody titers were measured at different time points by ELISA. Sera from mice immunized with pcDNA3 vector were used as negative controls and showed no reactivity with any coated antigens (data not shown). For sero-conversion, 1:20 starting dilution were assayed and the sera giving positive reading were taken as converted one. To determine antibody titers, serial two-fold dilutions of pooled seroconverted immune sera were incubated in antigen-coated wells. A positive result was defined as an absorbance value of greater than twice the absorbance of the negative control with a cutoff of 0.050(also see Materials and Methods). At week 2 only sero-conversion testing was performed at 1:20 dilution. [a]the first immunization; [b]the second immunization (boost); [c](n/n); sero-conversion ratio, numbers of sero-converted mice relative to the total number tested; [d]titer; reciprocal of the two-fold dilution factor at end point; pools of seroconverted sera from test groups were tested.

24	40(5/5)	40(5/5)	80(5/5)	80(5/5)	160(5/5)	40(4/5)

Note: Groups of mice (n=5) were injected i.m. with the respective plasmids, and seroconversion ratio and anti-HCV E2 antibody titers were measured at different time points by ELISA. With the exception of coating antigen (E2 (385-565)), all experimental procedures were the same as described in Table 1A. [a]the first immunization; [b]the second immunization (boost); [c](n/n); sero-conversion ratio, numbers of sero-converted mice relative to the total number tested; [d]titer; reciprocal of the two-fold dilution factor at end point, pools of positive sera from test groups were tested.

Virus-capture ability of antisera from DNA-immunized mice

To test the virus-capture capability of antibodies elicited in response to DNA immunization, affinity-capture-RT-PCR (AC-RT-PCR) was performed as described in "Materials and Methods". The HCV virions bound to anti-HCV-E2 were detected by nested RT-PCR to amplify a specific fragment in the 5'-UTR of HCV genome. The results indicated that immune sera of mice immunized with pcDNA3SE2-A, pcDNA3SE2-B and pcDNA3SE2-D were able to capture HCV virions in the serum of a hepatitis C patient in vitro (Figure 6).

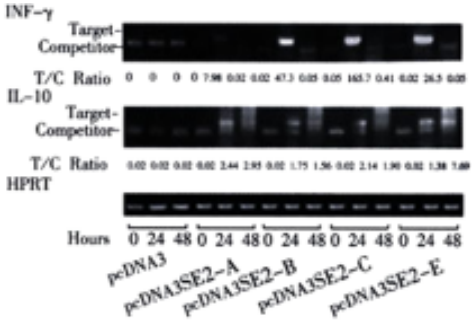

Figure 5 IFN-γ and IL-10 mRNA expression.
mRNA was isolated from splenic cells of immunized mice after stimulation with HBsAg for 0, 24, 48 hours. IFN-γ and IL-10 mRNA expression was

determined by semi-quantitative RT-PCR after standardization of the cDNA concentration by amplification of HPRT. Level of expression is indicated as ratio of target to competitor, calculated from densitometric analysis of their PCR products. (High ratio indicates high expression of target mRNA).

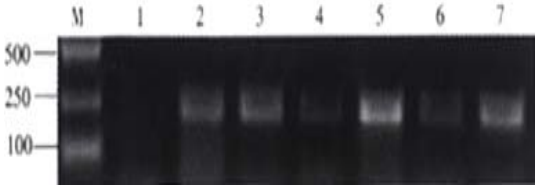

Figure 6 Detection of HCV captured by mouse antisera by nested RT-PCR. After immuno-capture of HCV from hepatitis C patient serum (1.6×10^7 HCV GEq per ml) by antisera from groups of mice immunized with pcDNA3, pcDNA3SE2-A, pcDNA3SE2-B, pcDNA3SE2-C, pcDNA3SE2-D and pcDNA3SE2-E (lane 1 to lane 6), viruses were detect1ed by nested RT-PCR using the HCV RT-PCR testing kit (Sino-America Co., Shanghai, China). Lane 7, the positive control using McAb against HCV E2 to capture HCV. Lane M, molecular markers.

DISCUSSION

In this report, five fusion constructs comprising various fragments within the hydrophilic region of HCV-E2 fused to the 3' end of the S gene of HBV were constructed. The immune responses of mice to immunization with these fusion construct s indicated that all five constructs were able to elicit strong antibody responses against both HBsAg and HCV-E2. Importantly, antibody typing showed the HBsAg specific Th1 like responses, which were consistent with the high levels of IFN-γ expression in cultured spleen cells from the immunized mice after stimulation with HBsAg. The IgG subtype responses to HCV-E2 also showed E2 specific Th1 like responses to E2-A and E2-D. Since Th1 like response is essential for triggering a wide range of cellular responses against infectious agents, including NK cell responses, CTL responses and inflammatory reactions, the results of the DNA immunization with our fusion plasmids suggest a promising strategy to clear both HBV and HCV in the host.

The excellent vaccine potential of our constructs may be ascribed to the use of HBsAg as a carrier. HBsAg has the advantage of assembling into large secretable particles, which form a virus-like polymeric structure that enhances antigenic stability and provides a high-density presentation to antigen-presenting cells (APC). HBsAg has been used successfully as vaccine carrier to present various antigens[15,23,29,36,37]. The successful immune responses to both HBV S and HCV E2 in these reports support our prelimilary observation that antigens of a proper size fused to C-terminal of HBsAg could be successfully presented without affecting the immunogenicity of HBsAg. Moreover, our fusion constructs were able to elicit higher levels of antibody responses to HCV E2, compared to pcDNA3E2 that encodes only a truncated HCV-E2 (384-649). This of course suggests that fusion to HBsAg may help these fragments to be presented more effectively to APCs, and hence induce stronger humoral responses against HCV-E2. These fusion constructs may turn out to be promising candidates for the vaccines against HCV and HBV.

It is well established that the intact E2 glycoproteins expressed alone or together with E1 (E1-E2 heterodimer) are retained in the endoplasmic reticulum[38] and that E2 proteins expressed in mammalian cells without the signal sequence at the C-terminus of E1 are not glycosylated[39]. Consistently, we also observed that the truncated E2 (384-649) was expressed in unglycosylated form in mammalian cells. However, the use of HBsAg as carrier seems to give rise to expression of fusion proteins carrying HCV-E2 epitopes in glycosylated and secretable form, which emphasizes the advantage of HBsAg as a carrier. Notably, two products, SE2-B and SE2-D expressed by pcDNA2SE2-B and pcDNA3SE2-D, produced an additional 31000 glycosylated form, suggesting that in addition to the glycosylation site in HBsAg, some sites in fragment B and D also may be glycosylated. Since glycosylation is a decisive factor for biological molecules to carry out correct biological functions, the additional glycosylation of the fusion constructs may elicit immune responses similar to that of natural infections by the HCV. This may be an additional reason that our constructs are able to elicit strong immune responses.

The results presented here also suggest that the DNA immunization with different HCV E2 fragments fused to HBsAg may be a useful approach to screen for epitopes or immune determinants on HCV-E2. Nakano *et al*[18] inserted different regions of HCV E2 into the preS2 region of HBV surface protein, and evaluated the humoral immune responses of these fusion constructs via DNA immunization. Their study also suggest that fusion constructs of E2 with HBsAg might be an efficient way to identify restricted immunogenic domains within E2. In our study, each of the chosen E2 fragments contained only 30 amino acids, it provides a possibility to study the antigenic domains of HCV E2 more precisely. Antibody responses and IgG subtype typing against these E2 fragments suggest that B- and T- epitopes were present in fragment D(490-519). Furthermore, the results of virus-capture assay showed that HCV virions in the serum of a hepatitis C patient could be captured by immune sera against SE2-A, SE2-B and SE2-D *in vitro*. In particular, antibodies against fragment D exhibited the strongest ability to capture HCV virions. Because the ability of antibodies to bind viruses is a prerequisite for neutralizing viruses *in vivo* and preventing bodies from being infected, our data suggest that besides HVR1-containing fragment A, fragments B and D probably also harbour neutralizing epitopes. So far, only HVR1 has been confirmed to be an important epitope[40-48] whose corresponding antibody can neutralize the binding of HCV-E2 to susceptible cells in vitro, and prevent HCV infection after *in vitro* neutralization[42,43]. Recently, correlation between circulating antibodies against HVR1 and resolution of chronic hepatitis C has been confirmed[49]. However, the high variability of HVR1 interferes with the development of HVR1-based vaccines. Some researchers suggested that there may be B-cell epitopes located downstream from HVR1[17,18,50]. Rosa *et al*[43] speculated that there may be at least one additional neutralizing epitope located somewhere other than HVR1 of HCV E2, this was based on the finding that HVR-1 peptide failed to completely block the binding of HCV to susceptible cells. Our results suggest that potential neutralizing epitopes may be present within fragments B (414-443) and D (490-519) that are downstream from HVR1. Since fragments B and D are relatively more conservative than HVR1, it would seem that vaccines containing fragments B and/or D may be more promising than that containing only HVR1. Further studies on these neutralizing epitopes are under way, which hopefully will lead to a better understanding of the immunological property of HCV E2, and facilitate the design of efficient HCV vaccines.

ACKNOWLEDGMENT

The authors are grateful to Dr. E. Hildt for providing monoclonal antibody (McAb) H166, Dr. S. Abrignani for McAb 219A2, Dr. Yuan ZH for HRP-Rabbit antibody against mouse IgG1 and IgG2a, Dr. Zhang XX for HCV patient serum and Qu D for her help in cytokine test.

Abstract

AIM: **To investigate the effects of Chinese herb Yigan Decoction on proliferation and apoptosis of the hepatic stellate cells (HSC) *in vitro*.**

METHODS: **The study *in vitro* was carried out in the culture of HSC lines. Various concentrations of Yigan Decoction were added and incubated. Cell proliferation was detected with MTT colorimetric assay. Cell apoptosis was detected by electron microscopy, flow cytometry and TUNEL.**

RESULTS: **The proliferation of HSC was inhibited by Yigan Decoction, which depending on dose and time significantly. The HSC proliferation rates of groups at the end concentrations 144 and 72($g\cdot L^{-1}$) were 21.62% and 40.54% respectively, significantly lower than that of normal control group($P<0.01$). The HSC proliferation rates of groups at the end concentrations 36, 18 and 9($g\cdot L^{-1}$) were 54.05%, 45.95% and 51.35% respectively, lower than that of control group ($P<0.05$). When the end concentration was 4.5$g\cdot L^{-1}$, the proliferation rate was 83.78%, which appeared no significant differences compared with control group. At the same concentrations of 18$g\cdot L^{-1}$, the inhibitory effects of Yigan Decoction at 24h, 48h and 72h time point were observed, the effects were time-dependent, and reached a peak at 72h. Meanwhile, it was showed that the inducing effects of Yigan Decoction on HSC apoptosis were dose-dependent and time-dependent. The apoptosis index(AI) was detected by TUNEL. After Yigan Decoction had been incubated for 48h at the end concentration of 18$g\cdot L^{-1}$, the AI (14.5±3.1)% was significantly higher than that of control group (4.3±1.3)% ($P<0.01$). When visualized under transmission electron microscopy, some apoptotic stellate cells were found, i.e. dilated endoplasmic reticulum, irregular nuclei, chromatin condensation and heterochromatin ranked along inside of nuclear membrane. By flow cytometry detection, after HSC was treated with Yigan Decoction at different concentrations of 36, 18 and 9($g\cdot L^{-1}$) for 48 h, AI (%) were 13.3±3.2, 10.7±2.7 and 10.1±2.5 respectively, which were significantly higher than that of control group(4.1±1.9) ($P<0.01$). At the same concentration of 18$g\cdot L^{-1}$ for 24h, 48h and 72h, AI (%) were 9.3±1.8, 10.7±2.7 and 14.6±4.3 respectively, which were significantly higher than that of control group ($P<0.01$).**

CONCLUSION: **Yigan Decoction could significantly inhibit HSC proliferation and increase the apoptosis index of HSC dose-dependently and time-dependently, which may be related to its mechanism of antifibrosis.**

INTRODUCTION

As the mechanisms of hepatic fibrosis have been gradually clarified and thus, many attempts to treat hepatic fibrosis have been made recently. But up to date there is still no effective way to treat hepatic fibrosis[1]. Recent insights[2-11] into the molecular pathogenesis of hepatic fibrosis and the efficacy of TCM have provided hope for the foreground of successful therapy, such as compound 861[12], Kangxianfang[13], Fuzhenghuayu decoction[14-16],Ganyanping[17] etc. Yigan Decoction, which was designed in our lab, was used in clinical setting for nearly twenty years. Our clinical practice has revealed that it has a marked curative effect on treating chronic liver diseases[18]. Hepatic sinusoidal cells such as the hepatic stellate cells (HSC),endothelial cells or Kupffer cells are deeply involved in hepatic fibrogenesis or fibrolysis. Recent studies have made their morphology and functions clear. A wealth of evidence now indicates that HSC is the key to produce fibrosis which served as the major source of fibrillar and nonfibrillar matrix proteins. Quiescent HSC synthesize low levels of matrix proteins, but as a result of injury, HSC could be proliferated and transformed to myofibroblast, a process termed activation[4]. So to inhibit HSC activation and proliferation and induce apoptosis of the activated HSC is one of the most important strategies for preventing and curing liver fibrosis. HSC cultured in uncoated plastic plates in vitro spontaneously undergo activation and share the similar features of cell activation *in vivo*[19]. This culture-induced activation has been extensively studied as a model of the activation secondary to liver fibrogenesis. In order to testify the action of Yigan Decoction on liver fibrosis and investigate its mechanism, the effects of Chinese herb Yigan Decoction on the proliferation and apoptosis of HSC in vitro were observed.

MATERIALS AND METHODS

Cell culture

HSC lines (CFSC) (established by Professor Greenwel) were provided by Southwest Hospital, Third Military Medical University. The phenotype was activated HSC[20, 21]. Cells were cultured in RPMI1640 (Gibco) medium plus 100mL·L^{-1} fetal calf serum, penicillin 1×10^5U·L^{-1} and streptomycin 100mg·L^{-1}, and kept in a controlled atmosphere (5% CO_2) incubator at 37℃.

Drug treatment

Yigan Decoction consists of Radix Salviae Miltiorrhizae, Radix Angelicae Sinensis, Radix Paeoniae Rubra and Hirudo, etc. The decoction was made by Hebei Institute of Gastroenterology, containing 0.72g of crude herbs in each milliliter. Exponentially growing cells were seeded in plates for 24h and treated with Yigan Decoction at

various concentrations (144, 72, 36, 18, 9 and 4.5g·L^{-1}) for 24h, 48h and 72h, respectively. The cells not treated with this drug served as control cells.

Dose-dependent effects of Yigan Decoction on cell proliferation

Colorimetric MTT assays[23] were used to observe cell proliferation. HSC were incubated in 96 well plates. The concentration of cells was modulated to 1×10^{8}·L^{-1}. After cultured for 24h, Yigan Decoction was added in different concentrations such as 144, 72, 36, 18, 9 and 4.5 (g·L^{-1}) for 48h. Each group was arranged three duplicate wells. After the supernatant was extracted and 0.05% MTT solution 10ìL was added to all wells for 4h, DMSO 100μL was added for coloration. After a few minutes at room temperature to ensure that all crystals were dissolved, the optic-metric density (OD) was read on ELISA reader at test wavelength of 570nm and referent wavelength of 630nm.

Time-dependent effects of Yigan Decoction on cell proliferation

The cultured cells were grown up to logarithmic growth phase, digested with 2.5g·L^{-1} trypsin. The concentration of cells was modulated to 1×10^{8}·L^{-1}. HSC were incubated in 24 well plates. Each well was added with 1mL. After being cultured for 24h, Yigan Decoction (50μL) was added into wells at the same end concentration of 18g·L^{-1}. Cell proliferation was observed at different times, i.e., 24h, 48h and 72h after the herb was treated, each was arranged three duplicate wells. The number of HSC was counted at the end of each time.

Apoptosis examined by TUNEL

In situ cell death detection kits were purchased from Boehringer Mannheim Company, Germany. The cells were adjusted to a density of 2×10^{3} cells/cm^{2}, added to 24-well plates with cover glass-slides in 0.5mL each well. After being incubated with Yigan Decoction at the end concentration of 18g·L^{-1} for 48h, the glass slides were taken out, rinsed, fixed and stained. The negative control with omission of TUNEL enzyme was designed according to the manufacturer's manual. The cells stained with dark brown nucleus were considered as positive cells. Ten optical fields, about 500-1000 cells were selected randomly and counted in each glass-slide under the high magnification (×400) microscope. Apoptosis Index (AI) = (apoptotic cells/ total cells)×100%.

Apoptosis examined by transmission electron microscopy

HSC were treated with Yigan Decoction at the end concentration of 18g·L^{-1} for 48h. Then the cells were centrifugated and fixed in glutaraldehyde for observation of transmission electron microscopy.

Apoptosis examined by flow cytometry

HSC were treated with Yigan Decoction at the end concentration of 36, 18 and 9(g·L^{-1}) for 24h, 48h and 72h. Cells were digested by 2.5g·L^{-1} trypsin, washed by PBS, fixed by cold ethanol at 4℃ and dyed with PI (propidium iodide), and then were analyzed by flow cytometry.

Statistics

Results were expressed as mean ± SD ($\bar{x}\pm s$). Differences between groups and differences over times were analyzed using analysis of variance and Newman-Keuls methods where appropriate. *P* values less than 0.05 were considered to be statistically significant.

RESULTS

Dose-dependent inhibitory effects of Yigan Decoction on cell proliferation

Yigan Decoction could significantly inhibit HSC proliferation dose-dependently compared with the control group (Table 1). The inhibitory effects of groups at concentrations of 144 and 72(g·L^{-1}) were stronger than those of groups at concentrations of 36, 18 and 9(g·L^{-1}), and no obvious inhibitory effect was found at the herb concentration of 4.5g·L^{-1}.

Time-dependent inhibitory effects of Yigan Decoction on cell proliferation

At the end concentration of 18g·L^{-1}, HSC were significantly inhibited compared with control group. The number of cells was manually counted. The effect was time-dependent, and reached a peak at 72h (P<0.01) (Table 2).

Apoptosis of HSC induced by Yigan Decoction examined by TUNEL

Based on the above results that Yigan Decoction could inhibit HSC proliferation at concentrations of 9-144g·L^{-1} from 24h to 72h, we selected the 18g·L^{-1} of Yigan Decoction and 48h affecting period as experimental conditions so as to better compare with the results of the herb on HSC lines. After Yigan Decoction had been incubated for 48h, the AI 22.5±7.1% was significantly higher than that of control group 4.3±1.3% (P<0.01). Apoptotic cell is characterized by compaction of nuclear chromatin and condensation of cytoplasm. By TUNEL stain the most condensed cells demonstrated evidence of DNA fragmentation and were strongly stained (Figure 1, arrowed).

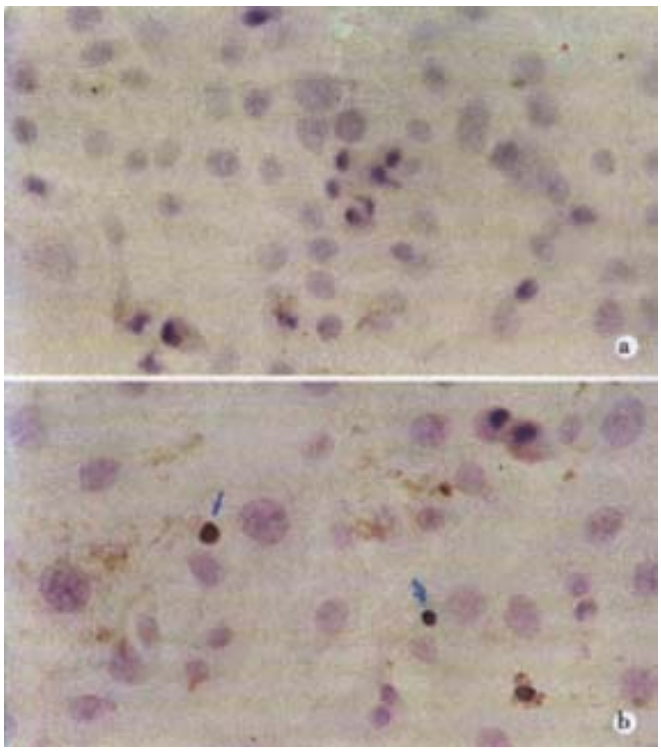

Figure 1 (A) Control HSC (TUNEL×400). (B) Apoptotic cell characterized by compaction of nuclear chromatin and condensation of cytoplasm (TUNEL×400). By TUNEL stain the most condensed cells demonstrated evidence of DNA fragmentation and were strongly staining (iü).

Apoptosis of HSC induced by Yigan Decoction examined by transmission electron microscopy

After 24~48h treatment of Yigan Decoction, we visualized under inverted microscopy. Small rounded cells were observed on the surface of the monolayer. These cells could be displaced by agitation of the tissue culture plate, demonstrating that they were very loosely adherent to the monolayer and that some were detached and floating in the culture supernatant (Figure 2). These features are compatible with HSC that have undergone programmed cell death or apoptosis[24].

When visualized under transmission electron microscopy, the apoptotic HSC were found, i.e. dilated endoplasmic reticulum, irregular nuclei, chromatin condensation and heterochromatin ranked along inside of nuclear membrane. All of these features are characteristic of apoptosis and distinguish programmed cell death from necrosis (Figure 3).

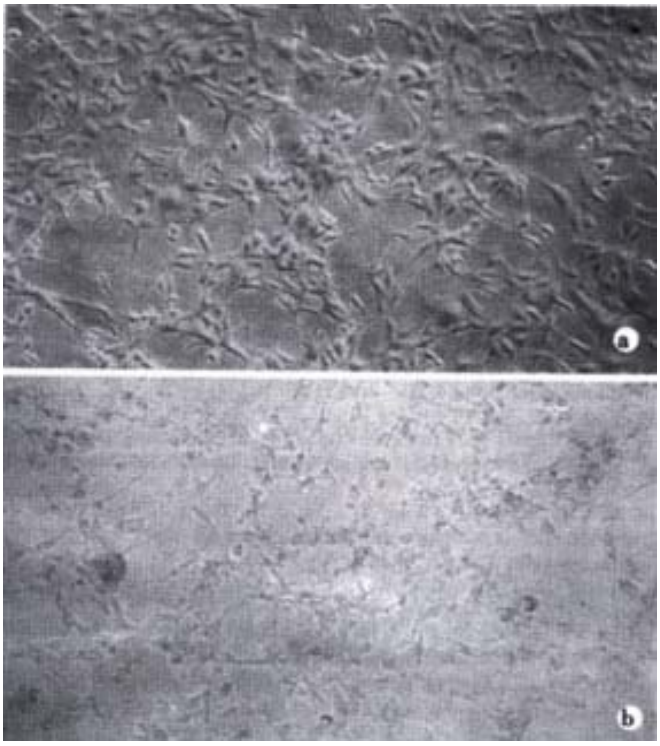

Figure 2 Morphological changes of HSC observed by light microscopy treated by Yigan Decoction. (A) Untreated cells (×200); (B) some HSC got round, detached and floating in the culture supernatant after exposure to 18g·L^{-1} Yigan Decoction for 48h (×100).

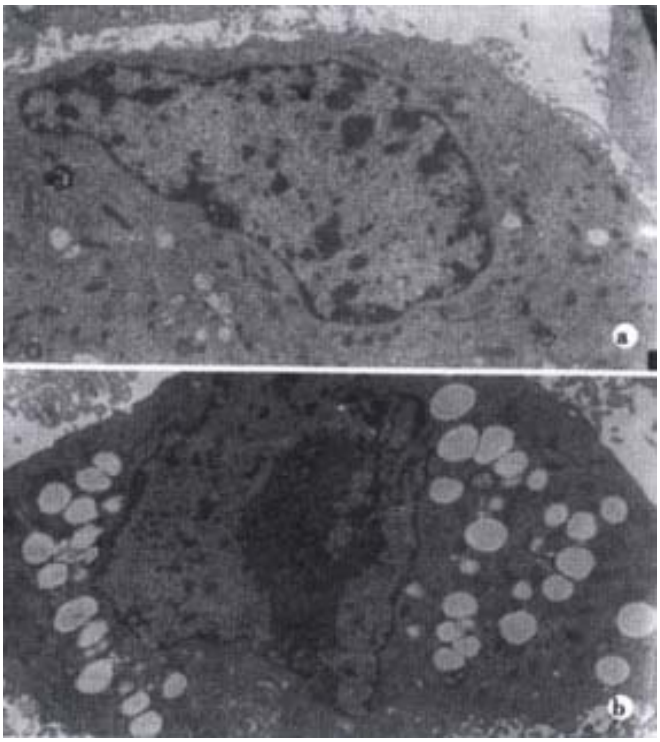

Figure 3 Ultrastructures of HSC with or without treatment with Yigan Decoction. Following 48h treatment of Yigan Decoction, dilated endoplasmic reticulum, irregular nuclei, chromatin condensation and heterochromatin ranked along inside of nuclear membrane could be found (A 5000×). Untreated cells (B 5000×).

Apoptosis examined by flow cytometry

After HSC were treated with Yigan Decoction at different concentrations of 36, 18 and 9(g·L^{-1}) for 48h, the apoptosis rate was significantly higher than that of control group (P<0.01) (Table 3). Our experiments showed that Yigan Decoction could increase the apoptosis rate dose-dependently and time-dependently compared with the control group. (Table 3 and 4, Figure 4).

$^b P$<0.01 *vs* control group.

DISCUSSION

Recent studies have found clearly the key role of HSC in developing liver fibrosis. HSC could activate, proliferate and largely synthesize various components of extracellular matrix in chronic liver disease, that would lead to liver fibrosis[22]. Studies suggest that HSC numbers are controlled by apoptosis in addition to proliferation during progressive fibrosis and particularly during recovery from fibrosis. The key event in the process of injury-fibrosis-recovery sequence is the loss of activated HSC mediated by apoptosis[23]. Therefore to induce apoptosis of activated HSC is one of the most important therapeutic strategies for liver fibrosis. Recent evidence has demonstrated that a mechanism to eliminate activated HSC in culture and in animal models is inducing apoptosis. Interestingly, activated HSC are more sensitive to some mechanisms of apoptosis than quiescent HSC. Such a mechanism may serve in the future to eliminate the undesirable activated HSC without affecting their normal quiescent counterpart.

The CFSC used in present study is activated HSC. So it shared some features with activated HSC *in vivo* and could be used as a desirable cell model for the test of antifibrotic drugs. Although the desirable antifibrotic drugs have not been found up to now, some herbal decoctions have been reported to prevent fibrogenesis effectively, showing a good prospect of using Chinese herbs in treating chronic liver diseases[24]. It was reported that Radix Salviae Miltiorrhizae (RSM) can inhibit fibroblast cells[25]. RSM can prevent liver fibrosis if it is used for a long time[26]. Large doses of RSM can activate collagenase and help reduce extracellular matrix. The level of P Ⅲ P and laminin were decreased in patients with liver disease after treatment of RSM. Studies demonstrated that long-term treatment of RSM for 10-12wk can reduce portal vein, spleen diameters and blood flow, but the velocity of blood flow did not change[27]. These results demonstrated the advantage of Chinese herbs in treating chronic hepatic diseases. Yigan Decoction, one of formally produced herbs, could prevent extracellular matrix production and deposit in CCl_4 induced rat liver fibrosis[28], and improve fibrotic liver structure and liver function in patients with chronic hepatitis or cirrhosis[18]. It is mainly composed of RSM, Radix Angelicae Sinensis (RAS), Radix Paeoniae Rubra and Hirudo, which have the actions of promoting blood circulation, removing blood stasis, shrinking the liver and spleen.

The present results suggest that Yigan Decoction could significantly inhibit HSC proliferation and increase the apoptosis rate of HSC dose-dependently and time-dependently compared with the control group ($P<0.01$). After Yigan Decoction had been incubation for 48h, the apoptosis rate of HSC was 27.5% compared with 7.1% in the control group ($P<0.01$). Our findings strongly suggest that inhibition of HSC proliferation and induction of HSC apoptosis may play an important role in the antifibrotic actions of Yigan Decoction. Our data may provide a new idea for the future development of therapeutic antifibrotic strategies by means of traditional Chinese medicine.

The antifibrotic effect of Yigan Decoction has been well proved by the results of experimental and clinical studies. However, Chinese herbs have very complicated components and their metabolisms are not well clarified yet. There's still a long way to go. With the ever-increasing in-depth studies about the pharmacodynamics, pharmacokinetics, reasonable combinations of drugs, the best preparation form and dosages of each herb and courses, Yigan Decoction is expected to be an effective antihepatofibrotic drug.

Abstract

AIM: **To investigate the effects of IH764-3 on HSC apoptosis,and the expression of caspase-3 protein in HSC apoptotic process.**

METHODS: **HSCs were cultured in medium with different IH764-3 doses(10μg·mL^{-1},20μg·mL^{-1}, 30μg·mL^{-1},40μg·mL^{-1}) and without IH764-3,and HSC proliferation was quantitatively measured by ^{3}H-thymidine incorporation. The morphological changes of HSCs were observed with transmission electron microscope after exposure to the dose of 40μg·mL^{-1} of IH764-3 for 48 hr. The apoptosis rates were detected by annexin V/PI and TdT-mediated dUTP nick end labeling (TUNEL). The expression of caspase-3 protein was determined by flow cytometry.**

RESULTS: **(1) HSC proliferation rates induced with different IH764-3 doses (10μg·mL^{-1},20μg·mL^{-1},30μg·mL^{-1}, 40μg·mL^{-1}) were significantly reduced compared with that of the control group (P<0.01). (2)With the doses above,IH764-3 dose-dependently produced HSC apoptosis rates of 6.7%(9.4%),9.3%(21.6%),15.1% (27.2%) and 19.0%(28.4%) respectively,by annexin V and PI-labeled flow cytometry assay(or TUNEL), while it was only 2.3%(6.7%) in the control. (3) The expression of caspase-3 protein in IH764-3 groups was significantly higher than that of the control (P<0.05).**

CONCLUSION: **Within the dose range used in present study,IH764-3 can inhibit HSC proliferation,as well as enhance HSC apoptosis. Furthermore,IH764-3 can significantly increase the caspase-3 protein expression.**

INTRODUCTION

Hepatic fibrosis occurs as a result of the accumulation of excess extracellular matrix (ECM) around the hepatic sinus and portal vein[1-19]. Activated hepatic stellate cells (HSCs) are the main source of ECM in the process of hepatic fibrosis. Therefore,HSCs play a central role in the hepatic fibrogenesis[20-34]. Either proliferation or apoptosis of HSCs or both may affect the population of HSCs[35-39]. Recent studies have shown that apoptosis is the main process to eliminate the activated HSCs during the resolution of hepatic fibrosis[40-42]. To induce the apoptosis of HSCs,therefore,might be an important strategy for the hepatic fibrosis therapy[43-45].

Chinese herbal medicine Salviae Miltiorrhiza,which can improve circulatory status and eliminate stasis,exhibits a series of important pharmacological effects on anti-inflammation,antioxidation,and inhibiting the platelet aggregation[46-49]. IH764-3,extracted from Salviae Miltiorrhiza,preserves all of these beneficial effects. Furthermore,in recent studies,It has been documented that IH764-3 could play an important role in anti-fibrosis,inhibiting the proliferation of HSCs and the synthesis of collagens[47,50]. However,there are few reports so far concerns about the effects of IH764-3 on HSC apoptosis and its mechanisms. In present study,we therefore used annexin-V/PI double labeling flow cytometry,TUNEL and transmission electron microscope to examine the effects of IH764-3 on HSC apoptosis. Meanwhile,the effects of IH764-3 on the expression of caspase-3 protein during HSC apoptosis were also observed.

MATERIALS AND METHODS

Materials

HSC line CFSC was established and kindly provided by Prof. Greenwel in America. which phenotype was activated HSCs,and derived from the CCl_4- induced cirrhotic rat[51]. RMPI-1640 medium was purchased from GIBCOL Co. Fetal calf serum was from Four Season Green Biological Co,Hangzhou,China. IH764-3 was kindly provided by Prof.Chun-Zheng Yang from Hematopathy Institute, Chinese Academy of Medical Science. ^{3}H-TdR was from Isotope Institute,Chinese Academy of Atomic Energy. Annexin-V cell apoptosis assay kit was purchased from Baosai Biological Technology Co,Beijing. TUNEL assay kit was from Boster Biological Engineering Co,Wuhan,China. Caspase-3 assay kit was from CLONTECH Co, USA. Goat anti-mouse FITC-IgG was the product of Microorganism Institute,Academy of Military Medical Sciences,China. Other reagents were analytically pure.

Methods

Cell culture The HSCs were thawed and plated in RMPI-1640 medium containing 100mL·L^{-1} fetal calf serum,100KU·L^{-1} penicillin, 100mg·L^{-1} streptomycin,4mmol·L^{-1} L-glutamine and 0.1mmol·L^{-1} HEPES. Cells were kept in culture at 37℃ in a 50mL·L^{-1} CO_2 atmosphere and 100% humidity. The HSCs were digested with 0.25% trypsin and subcultured from one to three when the cells proliferated into a full monolayer. The first change of the culture medium was made about 24 hr after subculturing,and then the cells were subcultured again about 72 hr. Experiments were carried out while the cells were in exponential growth phase. Cells were plated in 25cm^{2} plastic flasks at a density of 2×10^{8}·L^{-1} or onto 96-well plates at a density of 5×10^{6}·L^{-1}. When the cells were nearly 100% confluent,they were continued uo incubate for another 12 hr in serum-free RPMI-1640 culture medium. At that time most of the cells were in G_0 phase,they were divided into different groups. The dose-response studies were performed using different doses of IH764-3 (10μg·mL^{-1},20μg·mL^{-1},30μg·mL^{-1} and 40μg·mL^{-1}) and lasted for 12-48 hr,while the time-response studies were carried out at the timepoints of 12,24,48 and 72 hr with the dose of 30μg·mL^{-1} of IH764-3.

Inhibition of cell proliferation assays HSCs were plated to triplicate wells in a 96-well plate with the concentration of $5\times10^3\cdot mL^{-1}$. When the cells were nearly 100% confluent,they were cultured in serum-free medium for 12 hr. Then the medium was replaced with fresh medium containing 2% fetal calf serum and different IH764-3 doses, 1.11×10^4 Bq ^{3}H-Thymidine was added to each well. After 24 hr of incubation,HSCs were collected onto filter membrane and baked 1 hr at 100℃. The radioactivity (cpm) was determined with the beta-scintillation counter (Beckman). The inhibition of HSC proliferation was expressed by inhibitory rate,which was calculated as:inhibition rate = [(cpm of control group-cpm of IH764-3 group)/cpm of control group]×100%.

Apoptosis detection The following methods were used to detect apoptosis:(1)Transmission electron microscope:After exposure to the dose of $40\mu g\cdot mL^{-1}$ of IH764-3 for 48 hr, cells were trypsinized, collected,washed with PBS and centrifuged at 1200g for 10min. The cell pellet was fixed in 4% glutaral for 2 hr,1% osmium acid for 1 hr and dehydrated gradiently,then stained by uranium acetic acid and lead citromalic acid. The cells were observed with transmission electron microscope and the ultrastructural changes were recorded. (2)Annexin-V/PI labeling to detect apoptotic rate[52]:Briefly,the trypsinized HSCs were washed twice with PBS,stained with annexin-V(10(L) and PI (5μL) for 10min,and the apoptotic rate was quantified by FACSCalibur flow cytometry(Becton Dickinso Inc.) at 488nm wavelength. More than 1×10^4 cells were detected, and the results were analyzed with Modfit LT software. The stained cells were divided into three subgroups: The cells in V^-/PI^- subgroup were survived cells which membrane was intact, The cells in V^+/PI^- subgroup were apoptotic cells which membrane intact but with phosphatidylserine translocation; The cells in V^+/PI^+ subgroup were necrotic cells which membrane was impairment and with phosphatidylserine translocation. (3)Determination of apoptosis by TUNEL method:After trypsinization and collection, cells were fixed with 4% paraformaldehyde for 30min. Apoptosis was assayed by TUNEL method. Briefly,the cells were incubated with proteinase K($5\mu L\cdot mL^{-1}$) at 37℃ for 5min,labeled by TdT and digoxin-d-UTP at 4℃ in a humidified chamber to stay overnight,anti-digoxin antibody was added. After being incubated at 37℃ for 30min, the cells were stained with diaminobenzidine(DAB). Apoptotic cells presented as brownish stain in the nucleus,but we should pay special attention to distinguish the stained DNA fragments in cytoplasm due to some nuclear leakage. At least 500 cells were examined and the rate of apoptotic cells was calculated as the percentage of stained-cell per 100 cells.

Determination of Caspase-3 expression Trypsinized cells were washed in PBS,and fixed at 4℃ in 70% ethanol overnight. Fixed cells were precipitated and washed in PBS. Cells (6×10^5) were suspended in 0.5mL permeable buffer diluted by PBS,and subsequently incubated with anti-Caspase-3 antibody,FITC-labled goat anti-rat IgG antibody (1:20)[53]. then cells were washed with PBS,assayed by flow cytometer. The relative quantity of the protein was expressed by Fluorescence index (FI).

Statistical analysis

Data were expressed as $\bar{x}\pm s$. One-way analysis of variance was used for multiple comparisons,and Newman-Keuls test and χ^2 test were used for intra-groups comparisons. *P* values less than 0.05 were considered to be statistically significant.

RESULTS

Effect of IH764-3 on proliferation of HSCs

Compared with the control group,IH764-3 had a significant inhibitory effect on ^{3}H-TdR incorporation;the inhibition was dose-dependent (Table 1).

Table 1 The effect of IH764-3 on ^{3}H-TdR incorporation ($\bar{x}\pm s$)

Dosage ($\mu g\cdot mL^{-1}$)	Cpm	Inhibitory rate (%)
0	19749±7222	
1	018339±5344	7.1
2	014147±1850[b]	28.4
3	09125±916[b]	53.8
4	05313±426[b]	73.1

[b]$P<0.01$ *vs* control

Morphological changes

The shape of cells incubated with $30\mu g\cdot mL^{-1}$ or $40\mu g\cdot mL^{-1}$ of IH764-3 for 6hr changed from stellate or shuttle to spherical, and the intercellular space was increased. 12hr later,the cells began to detach from the plate and it is more remarkable at 24hr. With the transmission electron microscope,the decreased volume,condensed chromatin and decreased nucleo-cytoplasmic ratio of apoptotic cell were noted. Some cells showed typical apoptotic changes: the pyknosis and margination of the nuclear chromatin. Moreover, the nuclei fragment,annular or crescent body, cytoplasm vacuoles and swellen Mitochondria were also observed. Some cells were karyolysis and turn into the specific apoptotic bodies (Figure 1).

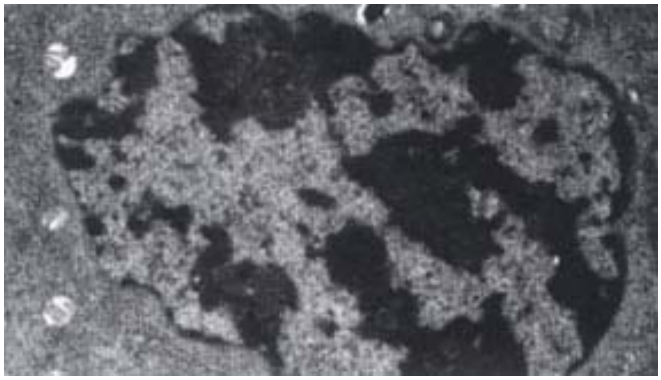

Figure 1 The apoptotic cells in $40\mu g\cdot mL^{-1}$ IH764-3 for 48hr (TEM 10000×) Apoptotic cells became small, the chromatins condensed

Annexin-V/PI combined labeling flow cytometry

The rate of apoptosis was both dose-dependent and time-dependent (Table 2A, 2B). For the $40\mu g\cdot mL^{-1}$ group at 24 hr and $30\mu g\cdot mL^{-1}$ group at 48-72hr,the apoptotic cells presented worse progressive changes,most of the cells were V^+/PI^+ subclass,namely necrosis. The necrotic rate was 21.0-31.3%. Figure 2A,2B.

Table 2A Apoptotic rates of HSCs exposed IH764-3 with different doses by Annexin-V/PI(%)

Time / doses	$0\mu g\cdot mL^{-1}$	$10\mu g\cdot mL^{-1}$	$20\mu g\cdot mL^{-1}$	$30\mu g\cdot mL^{-1}$	$40\mu g\cdot mL^{-1}$
12hr	0.3	2.2	3.7	6.7	15.1
48hr	2.3	6.7	9.3	15.1	19.7

Table 2B Percentage of apoptotic HSCs exposed to IH764-3 ($30\mu g\cdot mL^{-1}$) at different timepoints by Annexin-V/PI(%)

Time	0hr	12hr	24hr	48hr	72hr
Apoptosis rate	0.3	6.7	10.3	15.1	19.6

Detection of HSC apoptosis by TUNEL

After exposure of HSCs to different dose of IH764-3,the apoptotic indexes in experimental group by TUNEL assay at 48hr were 9.4%

±2.6%(10μg·mL^{-1}),21.6%±5.5%(20μg·mL^{-1}),27.2%±6.2%(30μg·mL^{-1}) and 28.4%±6.5%(40μg·mL^{-1}),respectively, which were significantly higher than that in control group (6.7%±0.6%, P<0.01) (Figure 3).

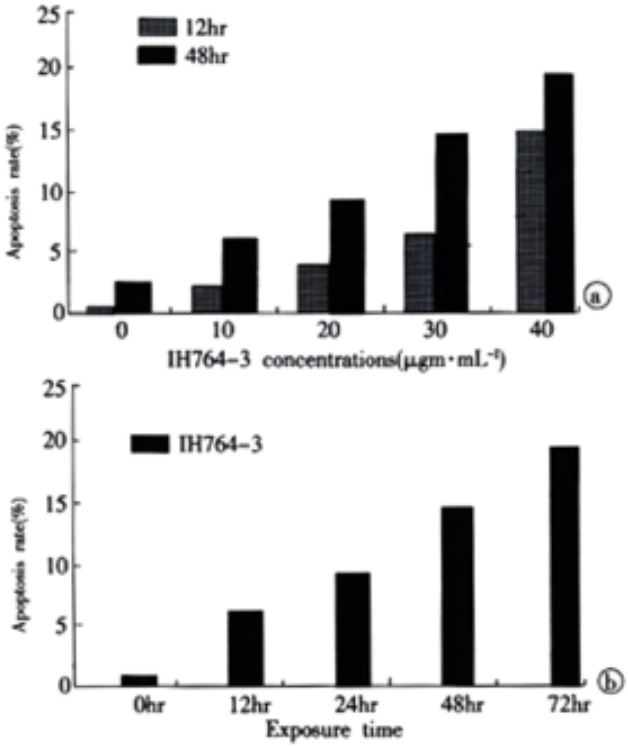

Figure 2 apoptosis rates of HSCs exposed to IH764-3. (A) dose-dependent; (B) time-dependent with the concentration of 30μg·mL^{-1} of IH764-3.

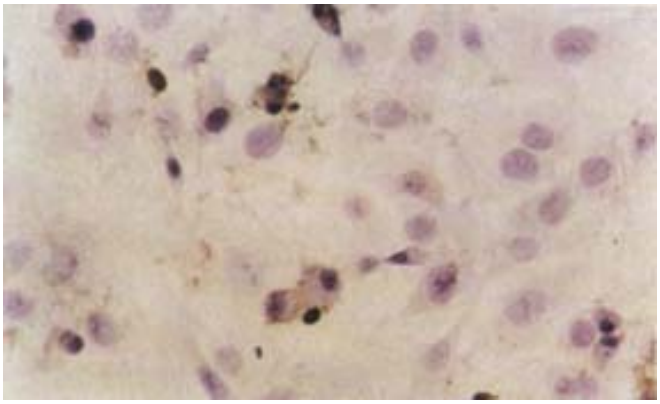

Figure 3 The apoptotic cells in 30μg·mL^{-1} IH764-3 for 48hr(TUNEL10×40)

IH764-3 induced caspase-3 protein Expression in HSCs

With the given doses,IH764-3 could increase Caspase-3 protein expression dose-dependently. There was also a positive relationship between Caspase-3 protein expression and apoptosis rate (Table 3).

Table 3 Fluorescence index of caspase-3 protein in HSCs ($\bar{x}$±s)

Dosage (μg·mL^{-1})	Caspase-3	P value
0	175.6±22.5	
10	215.1±26.9	<0.01
20	231.6±28.6	<0.01
30	304.7±30.7	<0.01
40	338.9±32.1	<0.01

DISCUSSION

The dynamic balance between the cell proliferation and apoptosis plays a key role in growth,development and maintenance of physiological functions of individuals. Once the balance is broken, varieties of pathological and pathophysical changes will take place. HSCs are the major cells that produce ECM components and proliferated significantly in hepatic fibrosis[36]. It has been considered that apoptosis may play at least a partial role in reducing HSC population and decreasing the production of ECM components in hepatic fibrosis,thus triggering the process of HSC apoptosis is perhaps an important strategy to resolve the hepatic fibrosis[45,54]. IH764-3,an extract of Salviae Miltiorrhiza,has been proved to be an effective agent for anti-hepatic fibrosis in animal model. However,up to the present,whether its anti-fibrotic mechanism was related to the induction of HSC apoptosis or not has not been elucidated yet.

Cell apoptosis,which is different from necrosis,is an initiative cell death process that activates endogenous DNA endonuclease,with the morphological characteristics of pyknosis and the chromatin margination to become lump or crescent bodies. Then cytoplasm condenses and cell shrinks,which finally forms apoptotic bodies. However,the cell membrane is integrated and the organelles keep intact. In present study,a great deal of typical apoptotic cells was found on plates treated with IH764-3,which demonstrated that IH764-3 did trigger the HSC apoptosis.

Apoptosis is a dynamic developing process that can be divided into early phase,metaphase and late phase. It has been reported that flow cytometry is the most sensitive method to examine apoptosis[52,53]. In early apoptotic phase,the translocation of phosphatidylserine,which has high affinity to Annexin-V,from the inner leaflet to the outer layer of the plasma membrane,could be easily recognized by Annexin-V labeling method. Moreover,when combining with PI stain,It could also distinguish from necrotic cells. In this study,we found that IH764-3 could dose-dependently induce apoptosis at 12 and 48 hr timepoints,the apoptotic rate was 2.2% in 10μg·mL^{-1} group and 15.1% in 40μg·mL^{-1} group. In 30μg·mL^{-1} group,the apoptotic rate was time-dependent. In 40μg·mL^{-1} group at 24hr and 30μg·mL^{-1} group at 48-72hr,the apoptotic cells presented progressive worse advanced changes,most of the cells became necrotic,the necrotic rate reached 21.0-31.3%. Similar changes were also observed with transmission electron microscope. Thus it could be concluded that low doses of IH764-3 mainly induced apoptosis,while in high doses,It could not only induce apoptosis,but also necrosis.

The remarkable biochemical characteristic of apoptosis is the genome DNA fragmentation. This is because the activated endogenous endonuclease can degrade the connected DNA between nucleosomes into 180-200bp oligonucleotide fragments. With terminal deoxynucleotide transferase,utilizing exogenous biotin-labled-free-nucleotides,the free nucleotides in 3 terminal can be catalyzed to get together in a non template-dependent manner,making the break nickings of DNA is labled. Therefore,we used TUNEL method as another way to prove the apoptosis further. The results showed that apoptosis indexes in IH764-3 groups were higher than that of the control, Furthermore,the indexes were dose-dependent in IH764-3 groups. All of the above demonstrated that IH764-3 could induce HSC apoptosis in time and dose-dependent manner,but the signal transduction process remains unclear.

Caspase-3,a key proteinase in apoptosis pathway,is one of the proteases in cysteine aspartic acid specific proteases family,and is also called as cysteine proteases P32. It splits the peptide bond at asparagic residue of specific motif sequence in substrate protein. The activated caspase-3 may cause apoptosis[55] and results in what we saw the apoptotic signs under microscope. Caspase-3 can split inhibitory caspase activated deoxyribonuclease (ICAD) into CAD[56,57],which

degrades DNA in nucleus.

To examine the possible mechanism of HSC apoptosis induced by IH764-3,we observed the expression of caspase-3 protein. The results showed that IH764-3 from 10μg·mL^{-1} to 40μg·mL^{-1} could increase the expression of caspase-3 protein. The more the apoptosis developed,the more the caspase-3 protein expressed. So we deduced that HSC apoptosis induced by IH764-3 was mediated by caspase-3 activation. Increased expression of caspase-3 protein was possibly one of the mechanisms in HSC apoptosis induced by IH764-3. Any reagents that increase caspase-3 protein expression might have a potential possibility to become new drugs to treat patients with hepatic fibrosis[58].

ACKNOWLEDGEMENTS

The authors wish to thank Professor Greenwel for his kindly providing the cell line and Professor Chun-zheng Yang for presenting IH764-3. We also thank Dr Hong-Qun Liu and Dr Shuang Chen for their critical reading of the manuscript.

Abstract

AIM: **To explore the possible mechanism why drinking Maotai liquor dose not cause hepatic fibrosis.**

METHODS: **After being fed with Maotai for 56 days consecutively, the male SD rats were decollated for detecting the biological indexes, and the livers were harvested to examine the liver indexes and the level of hepatic metallothioneins (MT). Hepatic stellate cells (HSC) proliferation and collagen generation were also observed.**

RESULTS: **Hepatic MT contents were 216.0ng·g^{-1}±10.8 ng·g^{-1} in the rats of Maotai group and 10.0ng·g^{-1}±2.8 ng·g^{-1} in the normal control group, which was increased obviously in Maotain group (P<0.05). In the rats with grade CCL_2 poisoning induced by Maotai, hepatic MT content was 304.8ng·g^{-1}±12.1ng·g^{-1} whereas in the controls with grade CCL_4 poisoning, it was 126.4ng·g^{-1} ±4.8ng·g^{-1} (P<0.05). MDA was 102.0nmol·g^{-1}±3.4 nmol·g^{-1} in Maotai group and 150.8nmol·g^{-1}±6.7 nmol·g^{-1} in the control group (P<0.05). When both of the groups were suffering from grade CCL_4 poisoning, hepatic MT contents was negatively correlated with MDA (r=-0.8023, n=20, P<0.01). The 570nmA values of each tube with HSC regeneration at concentrations of 0, 10, 50, 100, and 200g·L^{-1} of Maotai were 0.818, 0.742, 0.736, 0.72, 0.682, and 0.604, respectively. From the concentration of 10g·L^{-1}, Maotai began to show obvious inhibitory effects against HSC, and the inhibition was concentration-dependent (P<0.05, P<0.01). Type I collagen contents in HSC were 61.4, 59.9, 50.1, 49. 2, 48.7, 34.4μg·g^{-1} at concentrations of 0, 10, 50, 100, and 200g·L^{-1} of Maotai. At the concentration of 100-200g·L^{-1}, Maotai had obvious inhibitory effect against the secretion of type I collagen (P<0.05). Gene expression analysis was conducted on cells with Maotai concentrations of 0, 50, 100g·L^{-1} respectively and the ash values of β-actin gene expression were 0.88, 0.74, and 0.59, respectively,suggesting that at the concentration of 100g·L^{-1}, Maotai could obviously inhibit gene expression of type I procollagen (P<0.05), but the effect was not obvious at the concentration of 50g·L^{-1} (P>0.05). At the concentration of 10g·L^{-1}, HSC growth *in vitro* inhibition rates were 16.4±2.3 in Maotai group and -8.4±2.3 in the control group (P<0.05).**

CONCLUSION: **Maotai liquor can increase metallothioneins in the liver and inhibit the activation of HSC and the synthesis of collagen in many aspects, which might be the mechanism that Maotai liquor interferes in the hepatic fibrosis.**

INTRODUCTION

Long term alcohol abusing may result in alcoholic liver diseases, and the volume and duration of drinking has a close relationship with alcoholic liver diseases[1-5]. According to recent studies, the main cause of alcoholic hepatic injury[6-12] is due to acetaldehyde and hydroxy free radicals oxidized from alcohol which can injure the hepatocytes and activate the lipid peroxidation. The necrosis, inflammation, alcohol, its metabolites and lipid peroxidation are all able to activate Kupffer cells to secrete many cytokines which in turn activate hepatic stellate cells to produce various components of extracelluar matrix (ECM). When a large amount of ECM is deposited in the liver, it will lead to hepatic fibrosis[13-18]. Now many studies have demonstrated that metallothionein (MT) has the cytoprotective effect of clearing away the oxygen-derived free radicals[19-24]. It is found[25,26] that alcohol can induce the increase of metallothionein in rats liver, but the mechanism has not been elucidated. MT is endogenous anti-injury substance and plays a role in the defence of stress reaction[27]. Maotai liquor has its unique brewing technique, at the same time, there are multiple microorganisms in the special geographical situations which are able to absorb abundant amino acids, vitamins and many essential microelements [28]. It was reported by Li Xinyan *et al* that drinking Maotai liquor 150g for ten years daily did not result in significant damage to the liver, moreover, it could help protect one's health. Epidemiological study showed that no one died of liver disease in those workers who had drunk Maotai liquor for about 30 years. No obvious hepatic fibrosis or cirrhosis of liver was found in the epidemiological study of 99 workers who had a long history of drinking, or in the pathological examination of their liver needle biopsies nor were they seen in rats fed with Maotai liquor for a successive 56 days[28]. In order to explore the effect of Maotai liquor on the liver, we observed its effect on hepatic stellate cell proliferation *in vitro*, collagen generation,gene expression and growth of human hepatic stellate cells, and the effect of Maotai liquor in inducing metallothioneins in the rats liver and the relationship between it and CCL_4 hepatic injury were also studied in order to demonstrate the possible mechanism in the inhibition on the hepatic fibrosis.

MATERIALS AND METHODS

Materials

Male SD rats, weighing (300±20)g, were purchased from the

Experimental Animal Center of the Third Military Medical University, Chongqing, China. Maotai liquor (530±2)g·L^{-1}, was produced by Guizhou Maotai Distillery with bar code 6902952880026 provided by Section 4 of Guizhou Oil & Foodstuff Export and Import Company. MT standard was provided by Dr. Jie Liu in National Institute of Environmental Health Sciences, U. S. A. 3-[4,5-dimethylthiazol]-2,5-diphenyltetrazolium bromide. MTT were bought from Sigma Co., U. S.A; trypsin was purchased from Difco. U. S. A and; 199 culture medium and MEM culture medium without calcium are the products of Gibco Co., U. S. A; newborn bovine serum (NBS) was produced by Shanghai Huamei Co.; type I rat tail collagen standard (diluted slowly with Na^a-2CO_3/$NaHCO_3$ to 10 -200ng.L^{-1}) and rabbit anti-rat type I collagen antibody (diluted 1∶500 with 0.01mol.L^{-1} PBS) were products of Cambiolem Co.; horseradish peroxidase marker labeled goat anti-rabbit antibody (IgG-HRP, diluted 1∶1000 with PBS containing 100ml.L^{-1} NBS) was purchased from Hua Mei Company; Total protein determination agent (dcproteinassag) was the product of Biorad Co., U. S. A.; RT-PCR reaction agent and PCR marker were purchased from Promega Co.; diethylpyrocarbonate, guanidine sulfocyanate, saturated mixture of phenol and chloroform, and agarose were bought from Shanghai Sangon Co. Freezing High-speed Centrifuge (1.0R, 22R), CO_2 incubator and ultra low temperature freezer were purchased from German Heraeus Co.; inverted microscope was produced by Japanese Olympus Co.; thermostat water bath, thermostat water bath vibrator were produced by Shanghai Medical Equipment Factory; Labsystems Multiskan MS Enzyme Marker Device, was produced in Finland; Danbury CT ultrasonic membrane breaker was the product of Sonicsmaterials Co.; 90mm culture plate, 60mm culture plate, 6-well, 24-well, and 96-well culture plate were the products of Danish Nunc Co.; Beck Wallac 1410 Liquid Scintillation Counter was the product of Beckman Co. U. S. A; Watson-Marlow 101U Constant current pump was produced in U. S. A.

Effect of maotai liquor on liver MT of rats

Forty SD male rats were divided into two groups averagely. 20 rats were fed with Maotai liquor at 2mL·kg^1 diluted 1∶1 by distilled water once everyday for 56 days. The other 20 rats in the control group were fed with saline at the same volume. After all rats had been fed for the last time, 10 rats of each group were given mixture of CCl_4 and olive oil in a volume ratio of 1∶1 at 2.5mL·kg^1. All rats were sacrificed after the last feed to get blood for testing biological indexes, to calculate liver indexes by liver quantity, and to determine the content of MT in the liver by saturation method of Cd- hemoglobin, and the lipid peroxidation product of aldehyde measured by the method of thiobarbiturate.

Isolation and culture of hepatic stellate cells (HSC)

HSC were isolated by in situ perfusion. The test of cell proliferation was done by MTT. When monolayer HSC appeared in the 96-well culture plate, they were cultured in the medium containing Maotai liquor with different concentration of 1-400mg·L^{-1} and 50g·L^{-1} NBS for 18 hours, then 20μL MTT (5g·L^{-1}) was added in each well and continued the culture for 4 hours. After that, suspension was removed and the plate was aired, then 100μL acid isopropanol with 0.05mol·L^{-1} HCl was added to each well, little black crystals were dissovled by agitating which formed the steady purple solution. The absorbance (A) in each well was determined by ELSIA at the wave-length of 570nm. There were 4 well in each sample. When the subculturing HSC grew into full monolayer in the 24-well culture plate, then they were cultured in the medium containing Maotai liquor with different concentration from 1mg·L^{-1} to 400mg·L^{-1} and 50g·L^{-1} NBS for 24 hours.

Determination of type I collagen and total protein

After the culture was ended, it was centrifugated at 450×g at 4℃ for 20 minutes. Both the suspension and cell layer were collected separately. The collected cells were dissolved by 0.2mol.L^{-1} NaOH 0.5ml in each well and washed with 0.5ml double distilled water. Ultrasonic membrane-breaking was done for 10s at 40℃. Type I collagen in the suspension was determined by ELISA (the enzyme labelling plate was coated with type I collagen standard and samples at different concentration were kept overnight at 4℃; then IgG-HRP was used for incubation after they bound to type I collagen antibody; pyrocatechol oxidation was used for staining, and value A was obtained at 492nm wavelength by Labsystem ELISA equipment, which automatically calculated the standard curve and contents of each specimen.). Total protein in the cell layer was determined by DC protein assay kit.

Semiquantitative RT-PCR

Total RNA was isolated from HSC by phenol-chloroform extraction and isopropanol precipitation. The primer of procollagenβ1(I) was synthesized, purificated and evaluated by Shanghai Sangon Company (See Table 1). One μg of total RNA was reversely transcribed according to the instructions of the RT-PCR Kit at 48℃ for 45min. The PCR mixture contained 50pmo1·L^{-1} primer of procollagen β1[I] or GAPDH, 1μL 10mmol·L^{-1} dNTPs, 2μL 25mmol·L^{-1} $MgSO_4$, 5 units AMV reverse transcriptase, 5 units Tfl DNA polymerase and 10mL AMV/Tfl buffer. The PCR conditions included an initial denaturation-2min at 94℃, 30 cycles consisting of (a) 30s denaturation at 94℃;(b)1 min primer annealing at 60℃; (c) 2min elongation at 38℃; and one final step of 7min at 68℃. The PCR product or DNA marker mixed with 5μL loading buffer were elcectrophoresed on a 1.5% agarose gel, visualized by UV and quantified densitometrically. Procollagenβ1[I], pre-albumin, or hydroxyproline expression was calculated by determining the ratio of Procollagen α1[I], relative to β-actin mRNA.

Table 1 Primer sequence and expected PCR product length

Primer designation	Sequence	Product length
α1(I)upstream	CACCCTCAAGAGCCTGAGTC	253bp
α1(I)downstream	GTT CGGGCTGATGTACCAGT	
β-actin upstream	ACATCTGCTGGAAGGTGGAC	163bp
β-actin downstream	GGTACCACCATGTACCCAGG	

The effect of Maotai liquor on human HSC

80000 human HSC cells were inoculated in each well in the 96-well plate, and they were cultured in the DMEM medium with 100mL·L^{-1} FBS at 37℃ in a humidified atmosphere containing 5% CO_2 for 24 hours. Then they were continuously cultured in the DMEM medium with 20mL·L^{-1} FBS for 24hours. At last they were cultured in the medium containing different concentration of Maotai liquor (Maotai liquor was diluted to 0.5g·L^{-1}, 1g·L^{-1}, 5g·L^{-1}, 10g·L^{-1}, 50g·L^{-1} by DMEM medium with 20mL·L^{-1} FBS or alcohol). Cells cultured in the DMEM medium with 20mL·L^{-1} FBS was used as the control. After they were cultured for 20 hours, 20μL MTT (5g·L^{-1}) was added in each well and the culture continued for 4 hours more. Then the medium was removed, 100μL acid isopropanol with 0.05mol·L^{-1} HCl was added in each well, after little black crystals were dissovled, value A was obtained at 570nm wavelength by Labsystem ELISA equipment and the inhibiting rate of cell proliferation was calculated.

Statistics analysis

Data were analyzed by *t* test and *q* test.

RESULTS

Effect of Maotai liquor on rats liver MT content

Maotai liquor could induce the MT in rats liver to increase to 22 times of its original level (See Table 2). It is thought that lipid peroxidation of cell memb rane and the intracellular accumulation of Ca^{2+} are the important links of hepatocellular damage. In the control group, MDA in the liver was obviously increased after they were intoxicated by CCl_4, merely Maotai liquor did not influence MDA in rats' liver. MT in rats fed with Maotai liquor when intoxicated by CCl_4 was increased obviously more than those rats they were not fed with Maotai liquor, but MDA was decreased. There was a negative relationship between MT and MDA in rats liver intoxicated by CCl_4 in the control and trial group (r=-0.8023, n=20, P<0.01).

Table 2 The effect of Maotai liquor on MT and MDA in rats liver (n=10,$\bar{x}\pm s$)

Group	MT(ng·g^{-1})	MDA(ng·g^{-1})
Control group	10.0±2.8	60.2±3.1
Maotai liquor group	216.0±10.8^{b}	60.1±2.4
CCL_4 Group	126.4±4.8^{b}	150.8±6.7^{b}
CCL_4 + Maotai liquor group	304.8±12.1^{bd}	102.0±3.44^{bd}

^{b}P<0.01,*vs* control group;^{d}P<0.01,*vs* CCL_4 group(analysis of variance and q test)

Effect of Maotai liquor on rats' HSC

We normally obtained (3-5)×10^7 HSC from one rat. Lipid droplets in the primary HSC were obvious, but during the course of culture, lipid droplets decreased. And as they were passaged, HSC became extended, and looked like myofibroblasts. Each concentration of Maotai liquor had no effect on the shape of HSC. The absorbance (A) at 570nm of HSC in the medium with 0mg·L^{-1}, 10mg·L^{-1}, 50mg·L^{-1}, 100mg·L^{-1} and 200mg·L^{-1} Maotia liquor were 0.818, 0.742, 0.736, 0.72, 0.682 and 0.604, respectively. From the concentration of 10g·L^{-1}, Maotai liquor had obvious inhibiting effect on the proliferation of HSC, and the effect was enhanced with the increase of the concentration of Maotai liquor (P<0.05, P<0.01). The content of type I collagen of HSC in the medium with 0mg·L^{-1}, 10mg·L^{-1},50mg·L^{-1},100mg·L^{-1} and 200mg·L^{-1} Maotia liquor were 61.4μg·g^{-1},59.9μg·g^{-1},49.2μg·g^{-1},50.1μg·g^{-1},48.7μg·g^{-1} and 34.4μg·g^{-1}, respectively. The 100-200g·L^{-1} Maotai liquor had obvious inhibiting effect on the secretion of type I collagen (P<0.05). The analysis of gene expression of HSC in the 0mg·L^{-1}, 50mg·L^{-1} and 100mg·L^{-1} Maotia liquor group showed that the relative density of β-actin (n=3) analyzed by computer were 0.88,0.74 and 0.59, respectively. The result showed that 100g·L^{-1} Maotia liquor could significantly inhibit the gene expression of type I procollagen (P<0.05), but 50g·L^{-1} Maotia liquor did not have such effect (P>0.05).

Table 3 The effect of Maotai liquor on HSC of human (n=3, $\bar{x}\pm s$)

Group	Inhibiting Rate of HSC
Alcohol group (10g·L^{-1})	-8.4±2.3
Maotai liquor group (0.5g·L^{-1})	-4.52±0.3
Maotai liquor group (1g·L^{-1})	12.4±10.4^{b}
Maotai liquor group (5g·L^{-1})	17.4±1.6^{b}
Maotai liquor group (10g·L^{-1})	16.4±2.3^{b}

^{b}P<0.01,*vs* alcohol group

Effect of Maotai liquor on the growth of HSC (See Table 3)

There were three experiment groups in our study: blank control group, control group and trial group. First alcohol was diluted to 530 g·L^{-1} (the same concentration as Maotai liquor) and then it was dispensed to different concentrations which was the same as Maotai liquor. We used 0.5g·L^{-1},1g·L^{-1}, 5g·L^{-1} and 10g·L^{-1} Maotai liquor to study the different inhibiting effect on HSC. Our result showed that there was a significant difference between the 10g·L^{-1} alcohol group and 10g·L^{-1} Maotai group (P<0.01). That was Maotai liquor had a significant inhibiting effect on the proliferation of HSC, but alcohol did not have such effect.

DISCUSSION

MT is a low molecular weight metal-binding protein with rich cysteine existing widely in the biosphere and can be induced *in vivo* by many factors[29-32]. MT is also a non-enzyme protein which has bioactive functions of binding heavy metals, clearing free radicals, anti-oxidation and cytoprotection. It is now the most powerful bioactive substance which can remove free radicals. In recent years, a lot of research studies show that MT can protect hepatic cells from injury and be helpful in repairing hepatocytes without inducing hepatic fibrosis[33-38]. Induced by Maotai liquor, the increased MT in rats' liver was able to decrease the lipid peroxidation product of MDA in the liver intoxicated by CCl_4. Our result showed that there was a negative correlationship between MT and MDA in the liver and it proved that Maotai liquor was able to induce MT to antagonize the effect poisoning by CCl_4. It may be one of the possible mechanisms in explaining why long term drinking proper volume of Maotai would not cause hepatic fibrosis or cirrhosis.

Hepatic fibrosis is an important pathologic process resulted from many chronic liver diseases and may process to liver cirrhosis. It is also the key point that many chronic liver diseases are hard to cure completely. Many investigations showed that the activation of HSC is the key point in the pathological process of hepatic fibrosis. HSC was activated by many pathological factors so that alterations in the phenotype and function of HSC happened. HSC was highly proliferated and secreted a large amount of extracellular matrix deposited in the liver which would result in hepatic fibrosis. Collagen was the most important component in the extracellular matrix[46-48]. The degree of increase of collagen was type I>type III>type IV. The cell proliferation and the enhanced generation of collagen were the main characteristics of activation of HSC. [^{3}H]thymidine incorperation was able to reflect the cell division and proliferation. In the inhibiting experiments of different concentration of Maotai liquor in both HSC from rats and HSC from human beings showed that Maotai liquor had a concentration-dependent inhibiting effect on the proliferation of HSC. The generation of collagen was that first the collagen gene was transcribed and then translated into procollagen and the product secreted in the extracellular matrix. Our experiment showed that Maotai liquor had inhibiting effect on the expression of collagen gene and the secretion of collagen protein, but 10g·L^{-1} alcohol had no such inhibiting effect. All those showed that Maotai liquor could inhibit the activation of HSC in many links. The inhibiting effect of Maotai liquor in the activation of HSC and the generation of collagen may be the possible reasons why Maotai liquor can interfere with the process of hepatic fibrosis.

Abstract

AIM: **This investigation was to reveal the characteristics and mechanism of enzyme secretion and increase in $[Ca^{2+}]_i$ stimulated by saikosaponin(I) [SA(I)] in rat pancreatic acini.**

METHODS: **Pancreatic acini were prepared from male Wistar rats. Isolated acinar cells were suspended in Eagle's MEM solution. After adding drugs, the incubation was performed at 37℃ for a set period of time. Amylase of supernatant was assayed using starch-iodide reaction. Isolated acinar single cell was incubated with Fura-2/AM at 37℃, then cells were washed and resuspended in fresh solution and attached to the chamber. Cytoplasm $[Ca^{2+}]_i$ of a single cell was expressed by fluorescence ratio F340/F380 recorded in a Nikon PI Ca^{2+} measurement system.**

RESULTS: **Rate course of amylase secretion stimulated by SA(I) in rat pancreatic acini appeared in bell-like shape. The peak amplitude increased depended on SA(I) concentration. The maximum rate responded to 1×10^{-5}mol/L SA(I) was 13.1-fold of basal and the rate decreased to basal level at 30min. CCK-8 receptor antagonist Bt_2-cGMP markedly inhibited amylase secretion stimulated by SA(I) and the dose-effect relationship was similar to that by CCK-8. $[Ca^{2+}]_i$ in a single acinar cell rose to the peak at 5min after adding 5×10^{-6}mol/L SA(I) and was 5.1-fold of basal level. In addition, there was a secondary increase after the initial peak. GDP could inhibit both the rate of amylase secretion and rising of $[Ca^{2+}]_i$ stimulated by SA(I) in a single pancreatic acinar cell.**

CONCLUSION: **SA(I) is highly efficient in promoting the secretion of enzymes synthesized in rat pancreatic acini and raising intracellular $[Ca^{2+}]_i$. Signaling transduction pathway of SA(I) involves activating special membrane receptor and increase in cytoplasm $[Ca^{2+}]_i$ sequentially.**

INTRODUCTION

Bupleurum, one kind of traditional Chinese Drug, have a variety of roles in clinical practice. Our pharmacological investigations have indicated Bupleurum has significant promoting effect on enzyme secretion in rat pancreatic acini[1], Saikosides is the compound of the active Saikosaponin component in Bupleurum. The kinetics of enzyme secretion stimulated by Saikosides in a dose-dependent manner can be divided into first phase of high-potency secretion and later phase of low-potency secretion. The accumulation of enzyme secretion stimulated by 200mg/L Saikosides with 30min incubation is 6.5 folds of the basal level[2]. Based on the results of separation, purification and identification for Saikosides[3], we have compared the activities of nine kinds of Saikosaponins. Saikosaponin(I) [SA(I)] has the best effect of promoting secretion. The promoting effect of SA(I) increase in a dose-dependent manner, and the enzyme release stimulated by 5×10^{-5}mol/L SA(I) is 9.5 folds of basal[4,5].

Cholecystokinin (CCK) and Carbachol (CCh) are two important secretagogues for enzyme secretion from pancreatic acini. The promoting response associated with CCK-8 is in a dose-dependent manner, and high concentrations of CCK have submaximal amylase release. Furthermore, the relative potency of CCK to mobilize intracellular Ca^{2+} is dependent on the concentration of CCK-8. At low concentration of CCK-8 (10^{-12}mol/L-10^{-11}mol/L), it induces a series of transient increase in $[Ca^{2+}]_i$ termed "Ca^{2+} oscillations", and high concentration of CCK-8 evokes the single peak of $[Ca^{2+}]_i$[6-8]. Cellular signaling transduction pathway of increase in $[Ca^{2+}]_i$ evoked by CCK-8, involves activating G protein coupled receptors by CCK-8 binding its receptor, producing inositol 1,4,5-triphosphate(IP_3) and diacylglycerol(DAG) by activating the phospholipase C (PLC), and releasing Ca^{2+} from endoplasmic reticulum (ER) by activating the IP_3 receptor[9-14]. Increase in $[Ca^{2+}]_i$ evoked by CCk-8 and CCh not only result from ER, but from influx of extracellular Ca^{2+}[15-17]. Recently, it was shown that both activated PKC and elevated intracellular Ca^{2+} mediate activation of NF-κB and mob-1 expression by supraphysiological CCK[18,19]. Our investigations have indicated Saikosides is also a significant Ca^{2+}-mobilizing secretagogue. The kinetics of $[Ca^{2+}]_i$ induced by Saikosides varied with two peaks, and promotion of Saikosides on pancreatic exocrine could be correlative with the kinetics of $[Ca^{2+}]_i$. The effect of 200mg/L Saikosides was reduced by 35% and the second peak of $[Ca^{2+}]_i$ dramatically declined in Ca^{2+}-free medium[2]. These results showed that increase in $[Ca^{2+}]_i$ evoked by SA(I) include both Ca^{2+} release from the intracellular Ca^{2+} pool and subsequent influx of Ca^{2+} through plasmic membrane.

In order to elucidate the characteristics and mechanism of enzyme secretion and increase in $[Ca^{2+}]_i$ in SA(I) stimulated rat pancreatic acinar cells, here we report an analysis in rate kinetics of SA(I) stimulated amylase secretion, Characteristics of ligand-receptor binding and kinetics of $[Ca^{2+}]_i$ evoked by SA(I) in a single cell as well as the effects of guanosine-5'-diphosphate trisodium salt (GDP) on amylase secretion and $[Ca^{2+}]_i$.

MATERIALS AND METHODS

Materials

Cholecystokinin-8(CCK-8), Carbachol(CCh), Dibutyrlguanosine-3',

5'-cyclic monophosphate (Bt_2-cGMP), Guanosine-5'-diphosphate trisodium salt(GDP), Fura2-AM, Collagenase IA, soybean trypsin inhibitor were from Sigma Chemical Co(St. Louis, MO); Other chemicals were from Tianxiangren Bio. Co.Ltd.(Beijing, China). Saikosaponin I was separated and identified by the School of Pharmaceutical Science, Beijing University.

Methods

Preparation of isolated acini Isolated pancreatic acini were prepared by the method of Duan from male Wistar rat (200-250g) that had been fasted overnight[20]. Individual Acini were prepared by 0.3g/L collagenase digestion at 37℃ and purified by centrifugation through the Eagle's MEM containing 4% bovine serum albumin. The isolated acini were then allowed to resuspend at 37℃ for 30min in HEPES-buffered Ringer solution supplemented with 11.1mmol/L glucose, minimal Eagle's amino acids medium and 0.1g/L soybean trypsin inhibitor and were through gas with 1000mL/L O_2.

Measurement of amylase release Acini were suspended in Eagle's MEM solution. After adding the drug, the incubation was performed at 37℃ for a set period of time. Then the supernatant was removed and assayed for amylase. Amylase release was expressed at the ratio of the content of amylase released into the medium during the incubation to the total content. The total amylase content was estimated by measuring the amylase activity present in the acini broken at the beginning of the incubation.

Detection of cytosolic free Ca^{2+} concentration According to the method of Cui et al[21] briefly, isolated acini were incubated with 5×10^{-6}mol/L Fura-2/AM at 37℃ for 40min and then washed and resuspended in fresh physiological salt solution. Isolated acini were attached to Sykus-Moor perfusion chamber and continuously superfused by a buffer medium containing agonist at 1ml/min. Stimulus was introduced by changing perfusion buffer containing relevant chemicals. Inlet perfusion buffer was pre-warmed to 37℃ in a water bath. Fluorescence ratios of f340/f380 were recorded in a Nikon PI Ca^{2+} measurement system, with a pin-hole size of 0.5 focused onto the apical portion of a single acinar cell within acinar formation or formations, and a Nikon neutral density filter (#8) was placed in the excitation light path.

Statistical analysis Values of each group were expressed as $\bar{x}\pm s$. Group comparison was performed using student's *t* test. $P<0.05$ was considered significant.

RESULTS

Rate dynamics of amylase secretion in SA(I) stimulated pancreatic acini

Under the different stimulation of 1×10^{-6}mol/L, 5×10^{-6}mol/L and 1×10^{-5}mol/L SA(I) in pancreatic acini, the amylase release accumulation from acini within 37℃ incubation at different time were detected. Rate course of amylase release was obtained by differential analytics of enzyme accumulation with a computer program (Figure 1). The kinetics of rate-time effect could be divided into two phases,named by increasing phase and declining phase. With the concentration of SA(I) increasing, secreting rate rose more quickly and reached the higher peak, then it fell into basal level soon. The maximum rates of amylase secretion stimulated by 1×10^{-6}mol/L, 5×10^{-6}mol/L and 1×10^{-5} mol/L SA(I) were 3.2-fold,7.4-fold,and 13.1-fold of basal,corresponding time at 16.5min, 14.5min, 12.5min. Those data indicated that though the SA(I) stimulated enzyme release obviously, the main promoting effect of SA(I) took place in the 20min after adding the drug, and promoting action disappeared at 30min.

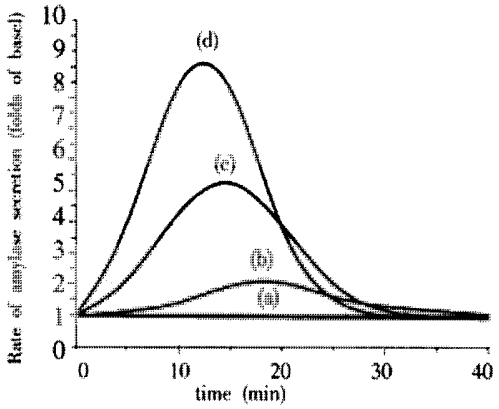

Figure 1 Rate kinetics of amylase secretion stimulated by SA(I) in the rat pancreatic acini. The results were expressed at the ratio of amylase secretion during the incubation to the basal secretion. a: basal value was standardized as 1, b: 1×10^{-6}mol/L SA(I), c: 5×10^{-6}mol/L SA(I), d: 1×10^{-5}mol/L SA (I). The values represented the $\bar{x}\pm s$ from four independent experiments.

Dose-response of inhibition of receptor antagonist on amylase secretion stimulated by SA(I)

In order to explore whether SA(I) stimulated signal was transduced through the effect of membranous receptor, the effects of CCK-8 receptor antagonist Bt_2-cGMP and CCh receptor antagonist atropine on SA(I) stimulated amylase secretion had been studied. In Table 1, enzyme secretion induced by SA(I) was markedly depressed by Bt_2-cGMP. The inhibitory effects of Bt_2-cGMP on action of SA(I) and CCk-8 had similar characteristics of dose-effect relationship. Amylase secretion stimulated by secretagogues decreased within the medium containing 1×10^{-7}mol/L Bt_2-cGMP ($^aP<0.05$). With increasing concentration of Bt_2-cGMP, the inhibition was enhanced ($^bP<0.01$). 1×10^{-4}mol/L Bt_2-cGMP decreased action of SA(I) and CCK-8 by 31.3% and 34.4% respectively.

In Table 2, atropine was observed to depress amylase secretion stimulated by CCh ($^bP<0.01$). 1×10^{-5}mol/L atropine eliminated the promoting effect of CCh,but had no apparent inhibition on the that of SA(I) at 1×10^{-8}mol/L$^{-1}\times10^{-5}$mol/L atropine range ($P>0.05$).

Table 1 Effect of different concentrations of Bt2-cGMP on amylase secretion stimulated by SA(I) and CCK-8

Bt^a-2-cGMP concentration (mol/L)	Amylase release (% of total)	
	1×10^{-9}mol/L CCk-8	5×10^{-6}mol/L SA(I)
Control	19.5±1.6	31.0±2.1
1×10^{-7}	17.8±1.9^a	27.4±2.5^a
1×10^{-6}	15.6±2.0^b	25.6±1.4^b
1×10^{-5}	14.0±1.2^b	23.1±1.8^b
1×10^{-4}	12.8±1.7^b	21.2±0.9^b

Rat pancreatic acini were incubated with either 1×10^{-9}mol/L CCk-8 or 5×10^{-6}mol/L SA(I) in adding different concentrations of Bt_2-cGMP medium. After 30min, the incubation was stopped and the content of amylase in the supernatant was assayed. The values represented the $\bar{x}\pm s$ from 4 separate experiments. $^aP<0.05$, $^bP<0.01$ *vs* control.

Table 2 Effect of different concentrations of atropine on amylase secretion stimulated by SA(I) and CCh

Atropine concentration (mol/L)	Amylase release (% of total)	
	1×10^{-5}mol/L CCh	5×10^{-6}mol/L SA(I)
Control	15.2±1.3	30.8±3.3
1×10^{-8}	11.6±1.6^b	27.9±11.4
1×10^{-7}	10.5±1.2^b	25.1±7.4
1×10^{-6}	8.8±1.3^b	27.5±6.9
1×10^{-5}	8.3±1.6^b	25.5±6.2

Rat pancreatic acini were incubated with either 1×10^{-5}mol/L CCh or 5×10^{-6} mol/L SA(I) in adding different concentration of atropine medium. After 30min, the incubation stopped and the content of amylase in the supernatant was assayed. The values represent the $\bar{x}\pm s$ from 4 separate experiments. $^aP<0.05$, $^bP<0.01$ *vs* control.

Dynamics of SA(I)and CCK-8 evoked $[Ca^{2+}]_i$ in single pancreatic acinar cell

The time courses of SA(I)and CCK-8 evoked $[Ca^{2+}]_i$ in a single pancreatic acinar cell were shown in Figure 2. 1×10^{-9}mol/L CCK-8 induced a monophasic $[Ca^{2+}]_i$ spike resulting in an increase of 4.2 folds from basal and declined to basal speedily. 5×10^{-6}mol/L SA(I) evoked $[Ca^{2+}]_i$ gradually increased within 5min after addition of SA (I), and peak of $[Ca^{2+}]_i$ was 5.0 folds of basal. Unlike CCK, $[Ca^{2+}]_i$ rose again after falling, caused a diphasic Ca^{2+} spike.

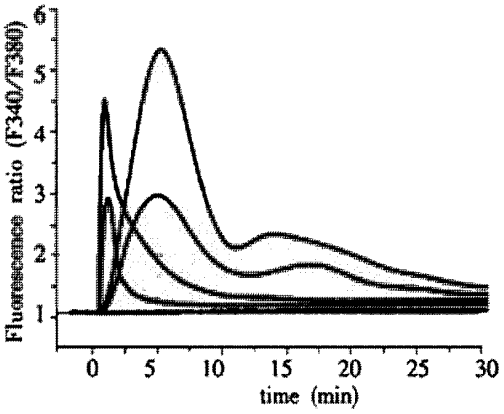

Figure 2 Kinetics of SA(I) and CCK-8 evoked $[Ca^{2+}]_i$ and effects of GDP in a single rat pancreatic acinar cell. $[Ca^{2+}]_i$ were expressed by Fluorescence ratio F340/F380. a. 1×10^{-9}mol/L CCk-8; b. 1×10^{-9}mol/L CCk-8 + 5×10^{-3}mol/L GDP; c. 5×10^{-6}mol/L SA(I); d. 5×10^{-6}mol/L SA(I)+5×10^{-3}mol/L GDP; e. Base. Time 0 is determined by the time of adding drug.

Effects of GDP on dynamics of amylase secretion rate and $[Ca^{2+}]_i$ induced by SA(I)in pancreatic acini

Figure 3 illustrated the effects of GDP on rate change of amylase release stimulated by SA(I). GDP could inhibit the rate of amylase secretion stimulated by 5×10^{-6}mol/L SA(I), whose rate-time curve of amylase secretion was similar to that of SA(I) in configuration, but addition of 5×10^{-3}mol/L GDP decreased the maximal rate by 54%. These data suggested GDP mainly inhibited high-potency phase of amylase secretion stimulated by SA(I).

In the kinetic experiments of $[Ca^{2+}]_i$ induced by SA(I) and CCK-8 in a single pancreatic acinar cell(Figure 2), addition of 5×10^{-3}mol/L GDP inhibited 1×10^{-9}mol/L CCK-8-induced $[Ca^{2+}]_i$ peak amplitude by 39%, with similar dynamic characteristics of $[Ca^{2+}]_i$. Addition of 5×10^{-3}mol/L GDP caused diphasic spike of $[Ca^{2+}]_i$ induced by 5×10^{-6} mol/L SA(I) decrease either, this resulted in a 44% decrease of initial Ca^{2+} peak, but a secondary increase in $[Ca^{2+}]_i$ still appeared.

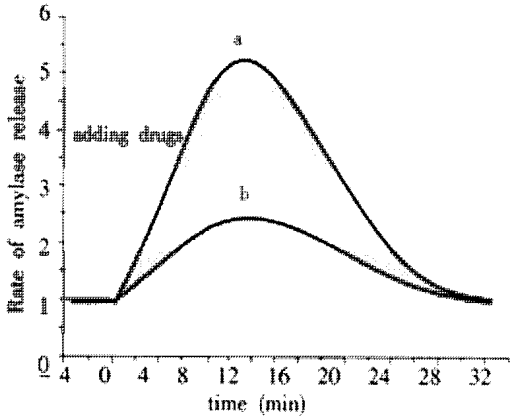

Figure 3 Inhibitory of GDP on rate course of SA(I) stimulated amylase secretion in rat pancreatic acini (base secretion rate is normalized as 1.0). a.5×10^{-6}mol·L^{-1} SA(I); b. 5×10^{-6}mol·L^{-1} SA(I)+5×10^{-3}mol·L^{-1} GDP. The data points represent from four separate experiments

DISCUSSION

A series of investigation for amylase secretion stimulated by Bupleurum and its effective components show that they have the rapid and high-potency ability of promoting pancreatic acini enzyme secretion and the validity of reversing functional disorder of pancreas exocrine. From the analysis of rate kinetics of amylase secretion stimulated by SA(I) (Figure 1), within 15min following adding SA (I), the rate of amylase secretion increased rapidly, then gradually decreased and returned to basal level at 30min. It indicates that different from CCK to enhance the synthesis of protein[22,23], the main effect of SA(I) is to hasten secretion of the exocrine protein synthesized and accumulated in granules.

To determine whether the stimulating signal of SA(I) on acinar cells is transduced by binding to the receptor on the cellular membrane, is the first task in the investigation of its mechanism of action. It is known that physiological functions of CCK-8 and CCh are mediated by specific types of receptors now termed the CCK_A and M_3 receptors. CCK_A and M_3 receptors belong to the receptors of G protein-coupled superfamily which transduce the stimulating signal by generation of intracellular second messengers, primarily IP_3 and DAG[9-11,14,24]. We compared the effects of CCK-8 and CCh receptor antagonist, Bt_2-cGMP and atropine, on amylase secretion caused by SA(I) (Table1, 2), the results showed that atropine had no detectable influence on the action of SA(I). Moreover, the dose-effect relationships of inhibition of Bt_2-cGMP on SA(I) and CCK-8 were similar. The results suggested that interaction between SA(I) and its membrane receptor initiated intracellular signaling transduction. The receptor of SA(I) has similar characteristics as that of CCK-8. To clarify the detail machinery of receptor of SA(I) will require further study.

As mentioned in our previous papers[25], the rising dynamics of mean intracellular $[Ca^{2+}]_i$ induced by SA(I) in rat pancreatic acinar cells could produce two peaks. When pancreatic acini were incubated in Ca^{2+}-free medium, in the second step, $[Ca^{2+}]_i$ did not rise and fell to the basal level gradually, and the second peak disappeared. The finding demonstrated the Ca^{2+} release from intracellular Ca^{2+} pool resulted in the first $[Ca^{2+}]_i$ peak, and second $[Ca^{2+}]_i$ peak depending on the extracellular Ca^{2+} influx in sequence. In the present experiments of single acinar cell $[Ca^{2+}]_i$ was concordant with our previous report, 1×10^{-9}mol/L CCK-8 could cause a large transient increase in $[Ca^{2+}]_i$. But it is different from CCK-8 that the change of $[Ca^{2+}]_i$ caused by SA (I) had relatively slow rate and higher peak value. In addition, there was a secondary increase after the initial peak of $[Ca^{2+}]_i$. The data suggested SA(I) had a different mechanism from that of CCK inducing Ca^{2+} release from ER and might be through more signaling tranduction pathways to initiate the intracellular calcium mobilization and subsequent extracellular calcium influx. So the intracellular increase in $[Ca^{2+}]_i$ caused by SA(I) could maintain a longer time course. These mechanisms correlated with high-potency effect of SA(I) on pancreatic exocrine. It is now known that the changes of intracellular calcium play a key role in many functions of cells. Recently, several reports showed that the spatio-temporal patterns of the intracellular calcium carried the Ca^{2+} signals to regulate gene expression and cell differentiation[26-29]. The specificity of Ca^{2+} signal is somewhat more acute in polarized secretory cells such as pancreatic acinar cells[30-32]. These researches suggest that such pattern of Ca^{2+} signal induced by SA(I) in our present studies may offer specific signal to modulate enzymes secretion in pancreatic acinar cells.

In addition, GDP could cause obvious decrease of amylase secretion and increase in $[Ca^{2+}]_i$ induced by SA(I). GDP mainly inhibited the early peak of $[Ca^{2+}]_i$ and high-potency phase of secretion stimulated by SA(I). The decrease of $[Ca^{2+}]_i$ anticipated the inhibition of amylase secretion in sequence (Figure 2,3). Several

investigators had reported that the increase in intracellular level of GDP could cause the inhibition of G-protein activity in pancreatic acini[33-35]. These G-proteins, including both ras-like small GTP-binding proteins and heterotrimeric G-proteins, had important role on the release of intracellular calcium and amylase secretion stimulated by secretagogues[14, 36-40]. More experimental data are required whether intracellular signal of stimulatory effect of SA(I) transducing to down stream through activation of G protein coupling receptor.

In summary, the results presented in this study prove that SA(I) has high-potency in stimulating the amylase secretion in rat pancreatic acini and its main effect is to promote exocytosis of enzymes synthesized by the cells. The transmembrane signal of SA(I) is transduced through interaction with its membrane receptor. Subsequently, $[Ca^{2+}]_i$ is increased by intracellular Ca^{2+} release and extracellular Ca^{2+} influx, so as to enhance the function of cellular enzyme secretion.

Abstract

AIM: **To study the effects of endotoxin on portal hemodynamic of normal and noncirrhotic portal hypertensive rats.**

METHODS: **Normal rats were intraperitonealy injected with 0.1, 0.25, 0.5, 1.0, 2.0, 4.0mg·kg^{-1} of lipopolysaccharide(LPS) respectively, portal vein ligation(PVL) and intrahepatic portal occlusion (IPO) rats as well as sham-operated rats were treated with an intraperitoneal injection of 1.0mg·kg^{-1} of LPS, the portal vein pressure(PVP), portal venous flow(PVF), inferior vena cava pressure(IVCP) and portal vein resistance(PVR) were detected 4 hours after injection.**

RESULTS: **PVF of the 5 groups of rats accepting intraperitoneal injection of LPS were increased from 14.0 to 18.0, 22.2, 26.2, 34.8, 39.6, 38.8mL·min^{-1} 4 hours after injection of LPS(P<0.01). PVP of the 4 groups of rats accepting more than 0.1mg/kg·b.w of LPS was increased from 1.04 to1.25, 1.50, 1.80, 1.95, 2.05 kPa(P<0.01). The increments of PVF and PVP were in a dose-dependent manner of LPS. PVR of the 5 groups of rats was decreased from 51 to 42,44, 48,45,44,47kPa·min·L^{-1} (P<0.05) and no dose-dependent manner was observed. PVF of PVL, IPO and sham-operated rats increased from 22.6 to 32.8, 22.0 to 28.0, 14.0 to 34.8mL·min^{-1} (P<0.01), and PVP increased from 1.86 to 2.24, 1.74 to 1.95, 1.04 to 1.80kPa(P<0.01), PVR decreased from 71 to 61, 67 to 61, 52 to 44kPa·min·L^{-1} after intraperitoneal injection of 1mg·kg^{-1} of LPS. The increments of PVF and PVP of PVL and IPO rats were significantly less than the sham-operated rats(P<0.01), There was no significant difference between the amounts of PVR decreased in the two groups of PHT model rats and sham-operated rats(P>0.05) after intraperitoneal injection 1mg·kg^{-1} of LPS.**

CONCLUSION: **Endotoxin could prompt portal hypertension of the normal and noncirrhotic portal hypertensive rats by increasing portal blood flow mainly.**

INTRODUCTION

Endotoxin is lipopolysaccharide(LPS), a component of the outer membrane of the Gram-negative bacteria, which is released from the Gram-negative bacterial cell wall. Its functional component is lipoid A. Many researchers have discovered that endotoxemia can lead to an alteration of systemic hemodynamics and some organs' blood circulation such as the lungs, liver and kidney[1-4]. However, some researchers have displayed evidence against a role for endotoxin in the hyperdynamic circulation of rats with prehepatic portal hypertension[5]. The activation of endotoxin occurs through a series of vaso modulators such as nitric oxide (NO), endothelin and others[4-11]. These vaso modulators could modulate portal venous flow(PVF), portal vein resistance(PVR) and/or portal vein pressure(PVP). In patients suffering from liver cirrhosis with PHT, endotoxemia is often present and might contribute to the development of liver cirrhosis and PHT[12-14]. Whether or not PHT models without liver cirrhosis are more sensitive to endotoxin is still unclear[15,16]. Little has been done to study the effects of various dosages of LPS on portal hemodynamics. So, to detect what role endotoxin plays in PHT, we designed the following experiments to discover the effects of various dosages of LPS on the portal hemodynamics of both normal rats as well as non-cirrhosis PHT rats.

MATERIALS AND METHODS

Animals

Female Sprague Dawley rats weighing 200-250g were obtained from the Laboratory Animal Center of Sun Yat-sen University, and fed with standard rat chow. (1)Surgery was performed as in Yachida's method[17]. Under penbarbital (50mg·kg^{-1}, intraperitoneal injection) anesthesia, the portal vein was isolated and a single ligature placed around both the portal vein and a 16-gauge needle. The needle was ligated together with the portal vein and immediately removed to allow the portal vein to expand to the limit imposed by the ligature. A catheter was inserted through the mesentery vein into the portal vein and another into the inferior vena cava. Pressure transducers(Philips CM 130) recorded PVP and IVCP. PVF was recorded with an electromagnetic flow meter (Nihonkohden). The abdomen was closed and the rats were allowed to recover for 2 wks. In sham-operated rats, surgery consisted of dissection and visual inspection of the portal vein without ligature. (2)Surgery was performed as in Li's *et al*[18] method. Under penbarbital anesthesia as above, microspheres (about 2×10^4 each time) of Sephadex LH-20(Pharmacia) were injected into the mesentery vein; injection was repeated 5 times. The portal venous and vena cava pressure were recorded as above. The abdomen was closed and the rats were allowed to recover for 2wks. Sham-operated rats above were used as a control.

Effects of LPS on portal hemodynamics

Normal rats were divided into seven groups, each group containing five rats. Rats were intraperitoneally injected with LPS(from Escherichia coli serotype, Sigma) at dosages of 0.1, 0.25, 0.5, 1.0, 2.0, 4.0mg·kg^{-1} respectively. Equivalent volumes of saline were intraperitoneally injected as a control. 4h later, anesthesia and operation were manipulated as above. A catheter was inserted through mesentery vein into portal vein and another catheter into the inferior vena cava. Pressure transducers(Philips CM 130) recorded PVP and IVCP. PVF was recorded with an electromagnetic flow meter (Nihonkohden). PVF, PVP and IVCP were checked four hours after injection and PVR was determined according to the formula: PVR= (PVP-IVCP)/PVF.

PHT rats were divided into PVL, IPO model, and sham-operated groups, each group containing ten rats, and then divided at random into two groups of five rats. PVL, IPO and sham-operated rats were each intraperitoneally injected with LPS at the dose of 1.0mg·kg^{-1}. The other PVL, IPO and sham-operated rats were intraperitoneally injected equivalent volumes of saline as control. PVF, PVP and IVCP were checked as above 4h after injection and PVR was determined according to the formula: PVR=(PVP-IVCP)/PVF.

The alteration of portal hemodynamics of the noncirrhotic and sham-operated rats after injection of LPS was analyzed. The means and increment percentages of PVF, PVP, and PVR of the PVL and IPO groups were compared with that of the sham-operated group.

Statistical analysis

Data were expressed as $\bar{x}\pm s$. Statistical analysis between groups was made by means of the student's unpaired *t* test by means of SPSS10.0 software, with $P<0.05$ being regarded as statistically significant.

RESULTS

Portal hemodynamic of model rats after operation

Just after portal vein ligation, PVF averaged 10.8mL·min^{-1}, PVP increased to 1.85kPa and PVR increased to 142kPa·min·L^{-1}. Two weeks after operation, PVF, PVP and PVR averaged 22.6mL·min^{-1}, 1.86kPa and 71kPa·min·L^{-1}. After finishing portal vein occlusion, PVF averaged 9.6mL·min^{-1}, PVP increased to 2.05kPa and PVR 180kPa·min·L^{-1}. Two weeks after operation, PVF, PVP and PVR averaged 22mL·min^{-1}, 1.74kPa and 67kPa·min·L^{-1}. PVP of the models was significantly increased the moment after operation and 2 wks after operation ($P<0.01$).

Effects of LPS on portal hemodynamic

PVF of all the groups of rats accepting intraperitoneal injection of LPS was significantly increased 4h after injection ($P<0.01$). Except for the group of rats accepting intraperitoneal injection of 0.1mg·kg^{-1} of LPS ($P>0.05$), the other groups of rats were all significantly increased in PVP 4h after injection ($P<0.01$). PVF and PVP increased in a dose-dependent manner with increasing LPS concentration. Except for the group of rats accepting intraperitoneal injection of 0.5mg·kg^{-1} of LPS($P>0.05$), the other groups of rats were all decreased in PVR 4h after injection ($P<0.05$) and no dose-dependent manner of LPS was observed(Table 1).

Table 1 Effects of LPS on portal hemodynamics

Dose of LPS (mg·kg^{-1})	PVF (mL·min^{-1})	*P*	PVP (kPa)	*P*	PVR (kPa·min·L^{-1})	*P*
0.00	14.0±0.44		1.04±0.020		51	
0.10	18.0±0.44	0.000	1.05±0.022	0.743	42	0.001
0.25	22.2±0.66	0.000	1.25±0.026	0.000	44	0.003
0.50	26.2±0.80	0.000	1.50±0.015	0.000	48	0.086
1.00	34.8±0.80	0.000	1.80±0.023	0.000	45	0.003
2.00	39.6±0.74	0.000	1.95±0.035	0.000	44	0.001
4.00	38.8±0.33	0.000	2.05±0.022	0.000	47	0.008

Compare rats accepting intraperitoneal injection of various doses of LPS with rats not accepting LPS.

Effects of endotoxin on portal hemodynamic of PHT models

PVF and PVP of sham-operated rats increased from 14.0mL·min^{-1} and 1.04kPa to 34.8mL·min^{-1} and 1.80kPa. PVR decreased from 52kPa·min·L^{-1} to 44kPa·min·L^{-1} 4h after intraperitoneal injection of 1mg·kg^{-1} of LPS. PVF of PVL and IPO model rats increased to 32.8mL·min^{-1} and 28.0mL·min^{-1} respectively; PVP increased to 2.24 kPa and 1.95 kPa respectively; and PVR decreased to 61kPa·min·L^{-1} and 61kPa·min·L^{-1} respectively. In the three groups of rats, intraperitoneal injection 1mg·kg^{-1} of LPS significantly changed PVF, PVP and PVR($P<0.01$, Table 2).

The percentages of PVF increase in the PVL, IPO and sham-operated groups of rats were 45.1%, 27.3%, and 148.6% respecitvely. PVP increased 20.4%, 12.1%, and 73.1% respectively. PVR increased -14.1%, -9.0%, and -15.4% respectively (Table 3). The increase of PVF and PVP in the two groups of PHT model rats were significantly different from sham-operated rats ($P<0.01$). There was no significant difference between the decrease of PVR in the two groups of PHT model rats and sham-operated rats($P>0.05$ Table 3).

Table 2 Effects of LPS on portal hemodynamics of sham-operated and PHT rats

Group	PVF (mL·min^{-1})	PVP (kPa)	PVR (kPa·min·L^{-1})
Portal vein ligation	32.8±1.6	2.24±0.073	61
Control	22.6±1.7	1.86±0.044	71
Intrahepatic portal occlusion	28.0±2.1	1.95±0.054	61
Control	22.0±2.1	1.74±0.037	67
Sham-operated	34.8±0.7	1.80±0.046	44
Control	14.0±0.4	1.04±0.039	52

Table 3 Alteration of portal hemodynamics of the noncirrhotic and sham-operated rats after injection of LPS

Group	PVF (mL·min^{-1})	Increment (%)	PVP (kPa)	Increment (%)	PVR (kPa·min·ml^{-1})	Increment (%)
PVL	10.2±0.8	45.13	0.38±0.047	20.43	-10	-14.08
IPO	6.4±1.14	27.27	0.21±0.026	12.07	-10	-8.96
Sham-operated	20.8± 0.84	148.57	0.76±0.038	73.08	-8	-15.38

DISCUSSION

Portal hypertension (PHT) is mainly due to two factors, PVF and PVR. Increase of PVF could lead to portal congestion, and PVR could prevent portal output and lead to portal gore. PHT is apt to be associated with a series of cytokines and vasodilators[19]. Endotoxin could enhance synthesis of a series of vasoconstrictors such as endothelins, as well as a series of vasodilators such as nitric oxide (NO). These modulators are able to adjust portal and systemic hemodynamics functionally. Across the cell's membrane, NO could spread to smooth muscle cells, enhance synthesis of cyclic guanosine monophosphate (cGMP), and consequently decrease intracellular Ca^{2+} concentrations, thus inducing vasorelaxation[11]. NO could also increase cardiac output and lower the vessel's reaction to vasoconstrictors, causing systemic and splanchnic hyperdynamic circulation[20,21]. Our research proved LPS could increase PVF of normal and noncirrhotic portal hypertensive rats and that this increase was associated with the dosage of LPS, which demonstrated increasing PVF was an important factor to form PHT. Endotoxemia could modulate the intrahepatic portal vessel and consequently alter the resistance of the intrahepatic portal vessel[23, 24]. Endotoxin signals hepatic cells to secret a series of cytokines such as tumor necrosis factor (TNF α) and endothelin and consequently enhances synthesis and deposition of collagens[25-27]. Endothelin has been reported to be able to induce constriction of the smooth muscle cells of the hepatic vasculature[28]. Endothelin can also prompt hepatic stellate cells(HSC) to proliferate and constrict[29]. Endotoxin was thought to increase PVP by the ways above. However, endotoxin-induced increase of NO synthesized by inducible nitric oxide synthase could lead to vasorelaxation and lower the vessel's response to vasoconstrictors, which might account for the increase of PVR. Yokoyama reported the liver maintains its microcirculatory flow by vascular remodeling from the hepatic arterial vasculature following PVL[30], which might induce the decrease of PVR in noncirrhotic

PHT rats. This research shows the PVR of normal and noncirrhotic PHT rats decreased after intraperitoneal injection of LPS, which demonstrated effectively that increasing PVF was the main factor to forming PHT.

PHT models moderate PVP through a new balance of vasoconstrictors and vasodilators[1]. PHT model rats were reported to be sensitive to LPS[15] by means of portal vein ligature. But Chu suggested some evidence against a role for endotoxin in the hyperdynamic circulation of rats with prehepatic portal hypertension[5]. Our experiments show that after intraperitoneal injection of LPS, PVF and PVP of PVL and IPO model rats increased significantly less than that of sham-operated rats($P<0.01$). Another report found artery vessel of PVL rats more blunt to LPS and the increment of NOS was significantly less than sham-operated rats[16], which might act as an explanation of our results. We would perform research with vasoconstrictors and vasodilators to further demonstrate our results.

Abstract

AIM: **Critical illnesses such as sepsis, trauma, and burns cause a growth hormone insensitivity, which leads to an increased negative nitrogen balance. Endotoxin is generously released into blood under these conditions and stimulates the production of proinflammatory cytokines such as TNF-α, IL-6, and IL-1, which may play a very important role in inducing the growth hormone insensitivity. The objective of this current study was to investigate the role of endotoxin, TNF-α and IL-6 in inducing the growth hormone insensitivity at the receptor and post-receptor levels.**

METHODS: **Spague-Dawley rats were injected with endotoxin, TNF-α, and IL-6, respectively and part of rats injected with endotoxin was treated with exogenous somatotropin simultaneously. All rats were killed at different time points. The expression of IGF-I, GHR, SOCS-3 and β-actin mRNA in the liver was detected by RT-PCR and the GH levels were measured by radioimmunoassay, the levels of TNF-α and IL-6 were detected by ELISA.**

RESULTS: **There was no significant difference in serous GH levels between experimental group and control rats after endotoxin injection, however, liver IGF-I mRNA expression had been obviously down-regulated in endotoxemic rats. Liver GHR mRNA expression also had a predominant down-regulation after endotoxin injection. The lowest regulation of liver IGF-I mRNA expression occurred at 12h after LPS injection, being decreased by 53% compared with control rats. For GHR mRNA expression, the lowest expression occurred at 8h and had a 81% decrease. Although SOCS-3 mRNA was weakly expressed in control rats, it was strongly up-regulated after LPS injection and had a 7.84 times increase compared with control rats. Exogenous GH could enhance IGF-I mRNA expression in control rats, but it did fail to prevent the decline in IGF-I mRNA expression in endotoxemic rats. Endotoxin stimulated the production of TNF-α and IL-6, and the elevated IL-6 levels was shown a positive correlation with increased SOCS-3 mRNA expression. The liver GHR mRNA expression was obviously down-regulated after TNF-α iv injection and had a 40% decrease at 8h, but the liver SOCS-3 mRNA expression was the 4.94 times up-regulation occurred at 40min after IL-6 injection.**

CONCLUSION: **The growth hormone insensitivity could be induced by LPS injection, which was associated with down-regulated GHR mRNA expression at receptor level and with up-regulated SOCS-3 mRNA expression at post-receptor level. The in vivo biological activities of LPS were mediated by TNF-α and IL-6 indirectly, and TNF-α and IL-6 may exert their effects on the receptor and post-receptor levels respectively.**

INTRODUCTION

Infection especially severe intra-abdominal infection is characterized by catabolic status associated with severe protein loss and negative nitrogen balance[1-7]. Meantime, the levels of many important hormones such as glucocorticoid, insulin and growth hormone (GH) do not decline, but their biological activities have reduced obviously. Critical illnesses such as sepsis, trauma and burns can usually cause a elevated level of growth hormone at early stage, however the insulin-like growth factor I (IGF-I), which is a growth hormone-dependent growth factor that inhibits protein breakdown, has been showing decreased predominantly, this phenomenon indicating a status of growth hormone insensitivity[8-12]. In this condition, the administration of high doses of recombinant human growth hormone could not improve negative nitrogen balance, in contrary, it may lead to other metabolic disorders and result in increased morbidity and mortality[13].

Endotoxin is generously released into blood under the infected condition and stimulates the production of proinflammatory cyotkines such as TNF-α, IL-6, and IL-1[14-18], which play very important roles in inducing the GH insensitivity. The GH insensitivity can occur at receptor and post-receptor levels, the receptor level associates with down-regulated GHR mRNA expression[19, 20]; the post-receptor insensitivity mainly occurs on the intracellular signal transduction pathway of growth hormone. Recent studies have suggested that the SOCS protein family, especially SOCS-3 play a very important role on this level[21,22]. In this study, we investigated whether the GH insensitivity could be induced by LPS, TNF-α and IL-6 iv injection, and what kind of roles they played.

MATERIALS AND METHODS

Animals

All experimental procedures were carried out in compliance with the appropriate institutional and national ethical guidelines for work with laboratory animals. 156 adolescent male Spague-Dawley rats (240-260g) were obtained from animal center of Jinling Hospital (Nanjing, China). They were given free access to food and water for three days before experiments.

Endotoxin and cytokines preparation

Escherichia coli lipopolysaccharide (LPS; serotype O111:B4 phenol extract), obtained from Sigma Chemical (St. Louis, MO), was resuspended in sterile endotoxin-free saline to obtain 4mg/ml

solutions. The recombinant rat TNF-α and IL-6 provided by Pepro Tech EC Ltd (London, England), were resuspended in sterile endotoxin-free saline to obtain 100000U/ml solutions. Human growth hormone, kindly provided by Serono, was resuspended in sterile endotoxin-free saline to obtain a 1mg/ml solution.

Experimental protocols

Male Spague-Dawley rats (provided by Animal Center of Jingling Hospital), weighing 250±10g, were given free access to food and water for three days before experiments. Rats were anesthetized with ether and received LPS, GH, TNF-α, IL-6, and saline injection, LPS, TNF-α, and IL-6 were administered through superficial dorsal veins of penis and GH was injected subcutaneously. All rats were killed at different time points; blood of rats with LPS injected was collected and centrifuged at 500g for 10min at 4℃ to collect serum. Livers were removed, flash-frozen in liquid nitrogen, and stored at -80℃ until homogenate preparation and RNA extraction.

Effect of endotoxin on liver expression of IGF-I, GHR, and SOCS-3 mRNA

After the 3-day adaptation period, 42 rats were randomly divided into laboratory group (n=36) and control group (n=6), LPS (7.5mg.kg^{-1} iv) was administered to the laboratory group, every six rats were killed at 1h, 2h, 4h, 8h, 12h, and 24h after injection. The control rats were given intravenous saline.

Effect of GH on liver expression of IGF-I, GHR, and SOCS-3 mRNA along with endotoxin injection

After 3-day adaptation period, 24 rats were divided into 4 groups (6 rats/group). The first group received one injection of LPS (7.5mg.kg^{-1} iv) and one injection of saline (sc), the second group received one injection of GH (1.5mg.kg^{-1} sc) and one injection of saline (iv), the third group received one injection of LPS (7.5mg.kg^{-1} iv) and one injection of GH (1.5mg.kg^{-1} sc), the fourth group received two injections of saline. All rats were killed at 10h after injection.

Effects of TNF-α and IL-6 on liver expression of GHR and SOCS-3 mRNA

After the 3-day adaptation period, 102 rats were randomly divided into laboratory group (n=96) and control group (n=6). Rat recombinant TNF-α and IL-6 (100000U/kg.wt) were injected through the same pathway and every six rats were killed after 20min, 40min, 1h, 2h, 4h, 8h, 12h and 24h. The control rats were given intravenous saline.

Analysis of mRNA by RT-PCR

Freshed-frozen liver samples were homogenized and total RNA was performed using TRIZOL Reagent (Biobasic Inc, Scarborough, Ontario, Canada). With Access RT-PCR system kit (Promega Coporation, Madison, WI), the cDNA synthesis and amplification was done in one tube following the manufacture's instructions. In brief, 1μg RNA, 1μM primers for SOCS-3, GHR, IGF-I and β-actin were added to each reaction mixture respectively, which included 0.2mM dNTP, 1mM MgSO4, AMV reverse transcriptase 5U, Tfl DNA polymerase 5U, and AMV/Tfl 5×buffer 10μL. The reaction final volume was 50μL and was covered with 30μL mineral oil. RT-PCR reaction was run in the following procedures: (1)Reverse transcription: 48℃ for 45min, 1 cycle. (2)AMV RT inactivation and RNA/cDNA/primers denaturation: 94℃ for 2min, 1 cycle. (3) Second strand cDNA synthesis and PCR amplification: denaturation 94℃ for 30s, annealing 60℃ for 1min, extension 68℃ for 2min, 28 cycles for SOCS-3 and 21 cycles for GHR and IGF-I, β-actin as intra-control to be amplified along with SOCS-3, GHR and IGF-I. (4) Final extension: 68℃ for 7min, 1 cycle. 5μL each RT-PCR reaction was electrophoresed in a 1.7% Metaphor agarose (FMC Bioproducts, Rockland, ME) gel and stained with ethidium bromide. Products of RT-PCR reactions were photographed and analyzed by densitometry. The expression of IGF-I, GHR, and SOCS-3 mRNA in laboratory group is represented as a percentage or times compared with their expression in control group.

Polymerase chain reaction primers were as follows: IGF-I sense, (5') CAC ATC TCT TCT ACC TGG CAC TC (3'); IGF-I antisense, (5') GGA TGG AAC GAG CTG ACT TTG TA (3'), to give a 270 base pair product; GHR sense, (5') CTG GGT TGA GTT CAT TGA GCT GGA T (3'); GHR antisense, (5') TGT AGA GGG GAG TTG GTG GGT TGA C (3'), to give a 394 base pair product; SOCS-3 sense, (5') ACC AGC GCC ACT TCT TCA CG (3'); and SOCS-3 antisense, (5') GTG GAG CAT CAT ACT GAT CC (3'), to give a 450 base pair product; β-actin sense, (5') CAT TTC CGG TGC ACG ATG GAG (3'); β-actin antisense, (5') GCC ATC CTG CGT CTG GAC CTG (3'), to give a 599 base pair production. All primers spanned at least one intron of genomic DNA.

Serum levels of GH, TNF-α and IL-6

Blood was obtained from the inferior vena cava at the time of sacrifice. Serum growth hormone levels was measured by radioimmunoassay according to manufacture's instructions (Northern Isotope Co, Beijing, China). Serum samples were analyzed for TNF-α and IL-6 content by enzyme-linked immunosorbent assay according to manufacture's instructions (BioSource International, Camarillo, CA).

Statistics ananlysis

All data are expressed as means ± SEM. Correlation between data was analyzed with linear regression. Comparisons between two groups were performed using an unpaired Student's t test. Differences were considered statistically significant when P<0.05.

RESULTS

Levels of serum growth hormone after endotoxin injection

The levels of serum growth hormome at each time points after LPS injection had no significant difference compared with control rats, it maintained a relatively stable status (Table1).

Table 1 Serum GH levels in LPS injected rats at different time points and control rats

	n	GH levels(ng/ml)
Control	6	2.19±0.48
1h	6	1.85±0.37[a]
2h	6	1.95±0.45[a]
4h	6	1.76±0.27[a]
8h	6	1.79±0.27[a]
12h	6	1.77±0.20[a]
24h	6	1.79±0.55[a]

[a]Statistically no difference compared with control rats.

Liver IGF-I mRNA expression

Liver IGF-I mRNA expression had already declined by 25% *vs*. control rats at 8 hours. On the time of 12 hours, we observed the lowest level of expression, which was a 53% decrease compared with control rats. It did not recover to the normal level and had a 15% reduction at 24 hours (Figure 1A, 1B). Although exogenous GH administration in control rats significantly enhanced the liver IGF-I mRNA expression, it did fail to prevent its decline in endotoxemic rats (Figure 1C).

Liver GHR mRNA expression

Liver GHR mRNA expression had already down-regulated by 45% at 2 hours after LPS injection, the lowest regulation occurred at 8 hours, which was a 89% decrease compared with control rats. After 24 hours, it did not recover to the normal level and had a 44% decrease (Figure 2A, 2B). the exogenous GH administration had no effect on the liver GHR mRNA expression in control and endotoxemic rats (Figure 2C).

Liver SOCS-3 mRNA expression

The liver SOCS-3 mRNA was weakly expressed in control rats, however, it was strongly up-regulated by 7.84 times *vs*. control rats at 1 hour after LPS injection. This level was maintained at 2 hours and it still had a 1.8 times increase at 24 hours (Figure 3A, 3B). the exogenous GH infusion had no effect on the liver SOCS-3 mRNA expression in control and endotoxemic rats (Figure 3C).

Levels of serum TNF-α and IL-6 after LPS injection and the correlation between liver SOCS-3 mRMA expression and IL-6 concentration

The TNF-α level was increased rapidly after LPS injection, but it decreased obviously from the second hour and returned to the normal level at 4h. The IL-6 level was also elevated rapidly after LPS injection; it got to the highest level at 2h and then decreased gradually (Table 2). Linear regression analysis was shown a positive correlation of IL-6 with liver SOCS-3 mRNA expression (r=0.935, P<0.01).

Table 2 Serum TNF-α and IL-6 levels in LPS injected rats at different time points and control rats

	n	TNF-α levels(pg/ml)	IL-6 levels(pg/ml)
Control	6	<20	<8
1h	6	342.80±50.01	1438.74±323.07
2h	6	75.81±11.50	1678.03±126.57

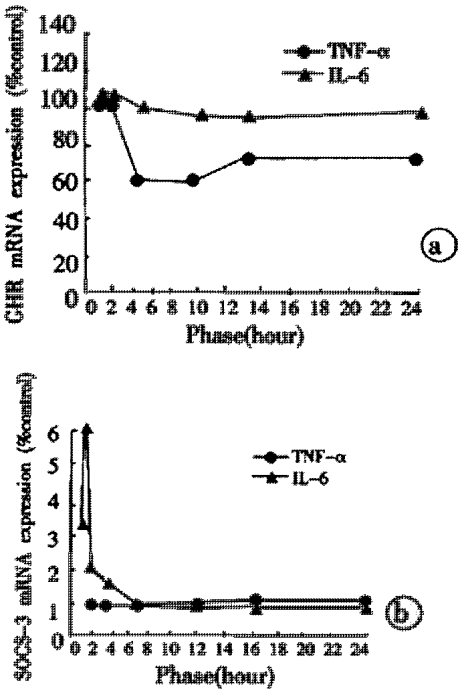

Figure 4 LiverGHR(A) and SOCS-3(B) mRNA expression response to TNF-α and IL-6 iv injection at different time points.

Effects of TNF-α and IL-6 on liver expression of GHR and SOCS-3 mRNA

The liver GHR mRNA expression after TNF-α injection had already down-regulated at 4 hours and it reached the lowest level at 8 hours, which was a 40% decrease compared with control rats. At 24 hours, a 27% reduction still existed. The IL-6 injection had no effect on the liver GHR mRNA expression at different time points (Figure 4A). The liver SOCS-3 mRNA had weak expressions at all time points after TNF-α injection, no difference could be found compared with control rats. The IL-6 injection was able to up-ragulate rapidly the liver SOCS-3 mRNA expression, the latter showing a 2.73 times increase at 20 minutes and the highest level occurred at 40 minutes with a 4.94 times increase compared with control rats (Figure 4B).

DISCUSSION

In this report, using an experimental method of *E. coli* endotoxin infusion in laboratory rats, we have found endotoxin-induced growth hormone insensitivity. At 12 hours after LPS injection, there was no difference in serous growth hormone concentration between the experimental and control rats, however, the liver IGF-I mRNA expression had already declined obviously. In control rats, the liver IGF-I mRNA expression was up-regulated by 25% after exegeous GH administration, but in endotoxemic rats, GH did fail to prevent the decline in liver IGF-I mRNA expression. Several groups have observed that decreased IGF-I may result from a state of GH insensitivity. Ross *et al*[8]. reported low circulating IGF-I levels in critically ill patients despite elevated GH secretion. More recently, the sdudy[19] showed that after a single injection of LPS in rats, plasma IGF-I level remained low despite the fact that GH level had returned to normal value. In agreement with these authors, our study support the possibility that the GH insensitivity maybe one of the important factors for the reduced liver IGF-I mRNA expression after LPS injection.

Growth hormone insensitivity can occur at receptor and post receptor levels, on the receptor level GH insensitivity is associated with the reduced GHR numbers on target cell sueface[19,20]. Because of the shorter half-life of liver GHR (30-40min)[23] and the decreased liver GHR mRNA expression by endotoxin, these led to the reduced GHR synthesis. Our results shown that liver GHR mRNA expression was obviously down-regulated after LPS injection, manifested that LPS had effect on the receptor level GH insensitivity indeed.

The factor of post-receptor level GH insensitivity has caused more and more attention recently, and it is associated with a novel family of suppressor of cytokine signalling (SOCS) which includes eight members (SOCS-1 to SOCS-7 and CIS) that act in a classical negative feedback loop to regulate cytokine signal transduction[24-29]. SOCS-3 is a strong inhibitor on growth hormone intracellular signal transduction[30-32].

Once growth hormone binds to its receptor, the intracellular signal transduction is activated through JAK-STAT pathway[33, 34]. The first activated tyrosine kinase is JAK2, which promotes the tyrosyl phosphorylation of both JAK2 itself and signal transducer and activator of transcription 5b (STAT 5b). Phosphorylated STAT 5b causes its dimerization and then the dimerized STAT 5b translocates into the nucleus, where it binds with high affinity to the promoters of various target genes and then activates the gene transcription such as IGF-I. SOCS-3 can block the GH intracellular JAK/STAT-dependent signaling pathway at different levels[35-44], including Competitively inhibits the phosphorylation of STAT 5b. Binds to GHR and leads to the degration of GHR-JAK2 compound directly or indirectly through Elongin B and Elongin C, in the end the JAK2 kinase loses its activity. Through binding to GHR, SOCS-3 can inhibit the JAK2 kinase activity directly. Our experiment observed that after LPS injection, liver SOCS-3 mRNA expression was rapidly up-regulated with a 7.84 times increase at 1 hour compared with the weak expression in control rats, this

indicating that LPS induced the production of post-receptor GH insensitivity.

The *in vivo* biological activities of LPS are largely mediated by the production of proinflammatory cytokines such as tumor necrosis factor-α(TNF-α), interleukin-1β(IL-1β), and IL-6[45-50], which is illustrated in our experiment by the marked stimulation of the secretion of TNF-α and IL-6 in blood. TNF-α and IL-6 had different roles in inducing the GH insensitivity, TNF-α injection leading to a reduced expression of liver GHR mRNA, and IL-6 being associated with the up-regulated SOCS-3 mRNA expression after injection. The elevated IL-6 levels stimulated by LPS had significant positive correlation with the increased liver SOCS-3 mRNA expression induced by LPS.

The mechanisms of TNF-α-induced GHR mRNA suppression was mostly mediated by inhibition of Sp transactivator binding to the L2 promoter of GHR gene[51], the other way might be associated with some other cytokines stimulated by TNF-α, such as IL-1[52].Both IL-6 and GH, belonging to the cytokine receptor superfamily, can transduce their signal from cell surface to nucleus through the same JAK-STAT pathway[53-55]. Hence, the elevated IL-6 levels stimulated by LPS promoted the increased expression of SOCS-3 mRNA, which not only had a negative feedback to IL-6 biological activities, but also inhibited the GH intracellular signal transduction[56-60].

In summary, our study observed that the growth hormone insensitivity could be induced by endotoxin, which suggested that the endotoxin played a very important role in inducing the GH insensitivity. The endotoxin not only had predominant effect on the GHR gene expression, but also induced the phenomenon of negative feedback loop at post-receptor level. The toxic effect of endotoxin was mostly mediated by TNF-α and IL-6 indirectly, and TNF-α maily had effect on the receptor gene expression, but for IL-6, it mainly caused the negative feedback loop at post-receptor level.

Abstract

AIM: **To study the distribution of the constitutive nitric oxide synthase (NOS) in the jejunum of adult rat.**

METHODS: **The distribution of endothelial NOS (eNOS) was detected by immunohistochemistry. Immunofluorescence histochemical dual staining technique were used for studying the distribution of neuronal NOS (nNOS) and eNOS. The dual stained slides were observed under a confocal laser scanning microscope.**

RESULTS: **Positive neuronal NOS (nNOS) and endothelial NOS (eNOS) cells were found to be distributed in lamina propria of villi, and the epithelial cell was not stained. eNOS was mainly located in submucosal vascular endothelia, while nNOS was mainly situated in myenteric plexus. Some cells in the villi had both nNOS and eNOS. More than 80% of the cells were positive for both nNOS and eNOS, the rest cells were positive either for nNOS or for eNOS.**

CONCLUSION: **The two constitutive nitric oxide synthases are distributed differently in the jejunum of rat. nNOS distributed in myenteric plexus is a neurotransmitter in the non-adrenergic non-cholinergic (NANC) inhibitory nerves. eNOS distributed in endothelial and smooth muscle cells of blood vessels plays vasodilator role. eNOS and nNOS are coexpressed in some cells of lamina propria of villi. NO generated by those NOS is very important in the physiological and pathological process of small intestine.**

INTRODUCTION

Nitric oxide (NO) is an intercellular and endocellular signal molecule, and has an important role in the physiological process of intestine. For example, NO can regulate muscular contraction and blood circulation of the intestine[1,2]. Nitric oxide synthase (NOS) is widely distributed in the intestine, and has several isoforms, such as constitutive nitric oxide synthase (nNOS and eNOS) and inducible NOS (iNOS)[3]. In previous studies, NOS was mostly located in small intestine and could be shown by enzyme cytochemistry, but different isoforms of NOS[4-8] coud not be distinguished. In order to study the characteristics and distribution of NOS, immunohistochemistry and immunofluorescence histochemical duel staining technique were used to investigate the distribution of the constitutive nitric oxide synthase (NOS) in the jejunum of adult rat, to provide morphological basis of digestive physiology.

MATERIALS AND METHODS

Specimens

Segments (1-2cm) of the jejunum were removed from decapitated male Sprague-Dawley rats (250-300g) and placed immediately in a fixative consisting of 4% paraformaldehyde and 0.1 M phosphate buffer (PB, pH7.4). The fixed jejunum segments were rinsed for at least 12h at 4℃ in 0.1 M PB (pH7.2) containing 30% sucrose, and then cryostat sections were made at 6μm thickness and mounted onto glass slides.

Reagents

Rabbit anti-rat eNOS antibody and SP kit were purchased from Beijing Zhongshan Biotechinical Company. Mouse anti-rat nNOS antibody, FITC-conjugated anti-mouse IgG and PE-conjugated anti-rabbit IgG were purchased from Wuhan Boster Biological Technology Company.

Immunohistochemistry

Immunohistochemical staining for eNOS was performed using SP technique with the following procedure.

(1)The slides were washed in 0.01 M phosphate-buffered saline (PBS). Endogenous peroxidase was blocked by 0.3% H_2O in methanol for 25 minutes, followed by incubation in normal goat serum for 30 minutes at room temperature. (2)The slides were the incubated with a 1∶75 dilution of the primary rabbit anti-rat eNOS antibody for 12 hour at 4℃. A biotin-streptavidin detection system was employed with diaminobenzidine as the chromogen. (3)Then the slides were washed with PBS and incubated with a reagent (biotinylated anti-immunoglobulin) for 60 minutes at 37℃. After rinsing in PBS, the slides were incubated with the peroxidase-conjugated streptavidin label for 60 minutes at 37℃, and incubated with diaminobenzidine and H_2O_2 for 5 minutes. Finally the sections were counterstained with hematoxylin.

Immunofluorescence histochemical dual-staining technique

The slides were incubated with normal goat serum for 30 minutes, followed by incubation with rabbiu anti-rat eNOS antibody and mouse anti-rat nNOS antidody for 48 hour at 4℃. Then, These were washed with PBS and incubated with FITC-conjugated anti-mouse IgG and PE-conjugated anti-rabbit IgG for 24 hour at 4℃. After rinsing in PBS, the slides were observed under a confocal laser scanning microscope (MR/A_2, Nikon). Excitation of FITC and PE were 488 and 495 nm respectively, emission of FITC and PE were 525 and 578 nm. 0.01 M PBS was used as a substitute for primary antibody for negative control groups.

RESULTS

Immunohistochemistry showed that eNOS was lealid in the cytoplasm solely. eNOS was distributed mainly in the endothelia of submucosa vessels. Part of the smooth muscle of submucosa vessels was also positive

for eNOS (Figure 1). There were strongly positive substances in the cells of lamina propria of the villi, and in the cells near the striated border of villous epithelia. The epithelial cells were unstained (Figure 2).

Under the confocal laser scanning microscope, the positive substances of nNOS labeled by FITC were green, and those of eNOS labeled by PE were red. The positive substances of nNOS were distributed mainly in myenteric plexus, rarely in the submucosal plexus (Figure 3). In the lamina propria of the villi, more than 80% of the cells were positive for both nNOS and eNOS, the rest of them were positive either for nNOS or for eNOS (Figure 4 and 5).

DISCUSSION

The two constitutively expressed, Ca^{2+}-dependent NOS isoforms previously identified in neurons (nNOS) and endothelial cells (eNOS) are now known to be distributed more widely[9-11]. eNOS is found in cardiac myocytes[12,13], epithelial cells[14-16], human platelets[17] and various neurons, particularly the pyramidal neurons of the hippocampus, where it is coexpressed with nNOS[18]. nNOS is found in the cytoskeleton of fast-contracting skeletal muscle fibers[19]. In our study, we found nNOS and eNOS were coexpressed in some cells of lamina propria of the villi. NO generated by those cells plays an important role in absorption and protection of microvasculature. Inhibition of endogenous NOS by N_G-nitro-L-auginine methyl ester (L-NAME) caused secretion of water and ions, and this secretion was reversed by administration of the NOS substrate L-arginine[20]. Previous studies indicated that norepinephrine[21, 22], somatostatin[23], and neuropeptide Y[24] increased ileal water and ion absorption at a similar magnitude to that observed with L-arginine. It is consistent with the hypothesis that endogenous NO has a proabsorptive influence in the intestine in the basal state. Furthermore, endogenous NO can reduce the vascular albumin leakage provoked by lipopolysaccharide (LPS)[25] and maintain microvascular integrity[26-29].

Our study showed that nNOS was distributed mainly in the myenteric plexus, rarely in submucosal plexus. Recent pharmacological and physiological studies demonstrated that NO is a neurotransmitter in the non-adrenergic non-cholinergic (NANC) inhibitory nerves of the gut[30-34]. During nerve stimulation, NO generated by nNOS in nerve terminals regulates the release of vasoactive intestinal polypeptide (VIP) when diffuses to muscle cells to participate in muscle relaxation[35-38]. Teng *et al*[39] found eNOS was selectively expressed in rabbit gastric and human intestinal smooth muscle cells. In turn, VIP acts on smooth muscle cells to generate NO. The NO formed in the muscle cells constitutes the predominant component (60-80%) of NO formed during nerve stimulation.

Using NOS histochemistry and endothelial cell immunohistochemisty, Nichols *et al*[40] provided the first anatomic evidence of NOS in both endothelial and smooth muscle cells of submucosal blood vessels in the intestines of rat and human, but he could not distinguish the isoform. We found eNOS was distributed in the endothelial and smooth muscle cells of submucosal blood vessels. This particular localization of eNOS was unexpected since only the inducible isoform of NOS had been reported in the vascular smooth muscle cells[41-44]. These anatomical data strongly supported the proposed vasodilator role of NO in the mammalian gastrointestinal tract. There is both basal and stimulated release of NO from the endothelium. Stimulated NO release is affected by certain antagonists (acetylcholine, ATP, or bradykinin) or by physical stimuli such as fluid shear stress[45-49] or low arterial PO_2[50]. Vascular smooth muscle-derived NO behaves as an autocrine factor that plays a role in modulation of vasodilator tone and represents a reserve pool of NOS, which may be required when the tissue is under a local stress. The

source of NO within the vascular wall, either intimal or medial, should be a consideration in future studies in terms of the relative contribution of these sources to vasodilator tone in the gut wall.

Abstract

AIM: **To determine whether Salmonella Typhimurium (STM) in gastrointestinal tract can induce the functional activation of brain, whether the vagus nerve involves in signaling immune information from gastrointestinal tract to brain and how it influences the immune function under natural infection condition.**

METHODS: **Animal model of gastrointestinal tract infection in the rat was established by an intubation of Salmonella Typhimurium (STM) into stomach to mimic the condition of natural bacteria infection. Subdiagphragmatic vagotomy was performed in some of the animals 28 days before infection. The changes of Fos expression visualized with immunohistochemistry technique in hypothalamic paraventricular nucleus (PVN) and superaoptic nucleus (SON) were counted. Meanwhile, the percentage and the Mean Intensities of Fluorescent (MIFs) of CD4+ and CD8+ T cells in peripheral blood were measured by using flow cytometry (FCM), and the pathological changes in ileum and mesenteric lymph node were observed in HE stained sections.**

RESULTS: **In bacteria-stimulated groups, inflammatory pathological changes were seen in ileum and mesenteric lymph node. The percentages of CD4+ T cells in peripheral blood were decreased from 42%±4.5% to 34%±4.9% (P<0.05) and MIFs of CD8+ T cells were also decreased from 2.9±0.39 to 2.1±0.36 (P<0.05) with STM stimulation. All of them proved that our STM-infection model was reliable. Fos immunoreactive (Fos-ir) cells in PVN and SON increased significantly with STM stimulation, from 189±41 to 467±62 (P<0.05) and from 64±21 to 282±47 (P<0.05) individually, which suggested that STM in gastrointestinal tract induced the functional activation of brain. Subdiagphragmatic vagotomy attenuated Fos expression in PVN and SON induced by STM, from 467±62 to 226±45 (P<0.05) and from 282±47 to 71±19 (P<0.05) individually, and restored the decreased percentages of CD4+ T cells induced by STM from 34%±4.9% to original level 44%±6.0% (P<0.05). In addition, subdiagphragmatic vagotomy itself also decreased the percentages of CD8+ T cells (from 28%±3.0% to 21%±5.9%, P<0.05) and MIFs of CD4+ (from 6.6±0.6 to 4.9±1.0, P<0.05) and CD8+ T cells (from 2.9±0.39 to1.4±0.34, P<0.05). Both of them manifested the important role of vagus nerve in transmitting immune information from gut to brain and maintaining the immune balance of the organism.**

CONCLUSION: **Vagus nerve does involve in transmitting abdominal immune information into the brain in STM infection condition and play an important role in maintenance of the immune balance of the organism.**

INTRODUCTION

It has been suggested in recent studies that the vagus nerve, the tenth cranial nerve, might play an important role in transmitting immune information into the brain[1-5]. However, this conclusion is based on the experiments in which cytokines, endotoxins or exotoxins were usually used as immune stimulators through intraperitoneal or intravenous injection. All these immune stimulations, however, are non-natural and the role of vagus in natural infection condition has not been established yet. Salmonella Typhimurium (STM) belongs to the group B of Salmonella. It can infect both human beings and animals through gastrointestinal tract and leads to a local or general infection by inhibiting the host immune system[6]. Thus, in the current experiments we introduced Salmonella Typhimurium (STM) into stomach to mimic the natural bacteria infection in gastrointestinal tract and to reassess the role of vagus in transmission of immune signal by subdiagphragmatic vagotomy. The production of c-fos, an immediately early gene, has been used as a morphological marker of functionally activated brain neurons[7-15]. In the present study we observed the STM-induced Fos expression in hypothalamic paraventricular nucleus (PVN) and superaoptic nucleus (SON) and the effect of vagotomy. We also studied the importance of integrity of vagus nerve in the balance of T cell subpopulations.

MATERIALS AND METHODS

Animals

Adult male Sprague Dawley albino rats (180-210g, offered by Animal Center, Fourth Medical University) were used. Rats were housed individually in a temperature-controlled room in a natural light/dark cycle, with food and water available freely. The animals were trained for adaptation to handling and gastric intubation before the following procedures started.

Procedures

Subdiagphragmatic vagotomy Rats were anesthetized with pentobarbital sodium (40mg/kg, i.p.) and subjected to a complete subdiagphragmatic vagotomy (n=10) or sham operation (n=10). Briefly, after laparotomy, the two trunks of vagus were identified under an operating microscope. Both trunks were cut off close to the

diaphragm. For sham vagotomy, the vagus was similarly exposed but was not cut. After surgery, a recovery period of 28 days was allowed.

Preparation of STM Wild strain of STM (offered by Laboratory of Bacteria, Xijing Hospital, Fourth Medical University) was preserved in freeze-dried powder before use. In order to enhance the pathogenicity of the bacteria, STM were sub-cultured in mice abdomen (Kunming mice offered by Animal Center, Fourth Medical University) for 3 times and then the number of the bacteria was adjusted to 10^{10}/ml for use.

Intubation of STM Rats (n=20) were divided into 4 groups randomly, 5 for each. Group 1, saline(NS) + sham operation; 2, NS + vagotomy; 3, STM + sham operation; 4, STM + vagotomy. Food was taken away from the rats 24h prior to intubating STM or saline. After anesthetized with ether, all rats were intubated with 30g/L NaHCO3 300μl to neutralize gastric acid. Then the aminals of groups 3 and 4 were gastrically intubated with STM (10^{10} in saline, 1ml) and in the others (Groups 1 and 2) 1 ml of saline were given.

Perfusion and Sectioning After intubation for 22h, all rats were deeply anesthetized with pentobarbital (80mg/kg) and 1ml of blood was taken via heart as quickly as possible. The rats were then perfused transcardially with saline 100ml followed by 4% paraformaldehyde in 0.1M phosphate buffer (PB) 500ml, pH 7.4, at 4℃. Blood was anti-coagulated with heparin. Brains, part of ileum and mesenteric lymph node were taken out and cryoprotected in 20% sucrose in 0.1 M PB overnight at 4℃. Frontal sections in 50μm-thickness were cut through whole brains with a microtome and collected in cold cryoprotectant and stored at -20℃ until immunohistochemistry processing. Serial ileum and mesenteric lymph node sections in 5μm-thickness were cut with a cyostat and mounted onto slides coated with gelatin and stored at -20℃ until histochemistry processing.

HE staining of ileum and mesenteric lymph node sections Slides of ileum and mesenteric lymph node were immersed successively in dimethylbenzene (10min×2), graded ethanol (100% 5min×2, 95% 2min, 80% 2min, 70% 2min and distilled water 2min), Harris hematoxylin (5-10min) and 10% acid ethanol for several seconds. After rinsed with tap water for 30min, slides were immersed again successively in distilled water (10-30min), graded ethanol (70%, 80%, and 95% 2min for each), 0.5% eosin (5-10min), 95% ethanol from several seconds to minutes, 100% ethanol (5min×2) and dimethylbenzene (10min×2). At last, the slides were sealed with gum and observed under a light microscope (Olympus B×60).

Flow cytometry (FCM) of blood T Cell Blood CD4+ and CD8+ Tlymphocytes were labeled by using indirect immunofluorecent labeling method. First, 80μl of anti-coagulated blood was incubated with mice anti rat CD4 mAb (1:100, Serotec company) or 15μl of mice anti rat CD8 mAb (1:100, Serotec company) for 30min at 4℃, then with 40μl of goat anti mice IgG-FITC (1:100, Serotec company) after washing twice with 0.01Mol/L Phosphate-buffered saline (PBS). FCM was used to detect the percentages and the Mean Intensities of Fluorescence (MIFs) of CD4+ and CD8+ T cells.

Immunohistochemistry of Brain Sections ABC immunohisto chemical technique was used to detecte Fos-immunoreactive (Fos-ir) cells in brain. One-in-five of brain sections were incubated with primary antibody raised from rabbit against Fos protein (Sigma Inc.) at a dilution of 1:3000. After incubation at room temperature for 36h, sections were rinsed with 0.01Mol/L Phosphate-buffered saline (PBS) (10min×3) and then incubated with biotinylated secondary antibody against rabbit IgG (Sigma Inc, diluted at 1:500) at room temperature for 4h. After rinsing with 0.01Mol/L PBS (10min×3), sections were incubated with avidin-biotin-horseradish peroxidase (1:500, Sigma Inc.) at room temperature for 2h. The reaction product was visualized with amine nickel sulfate-enhanced 3,3'-diaminobenzidine (DAB) method. The sections were dehytrated in graded ethanol, cleared with dimethylbenzene, and coverslipped with gum.

Counting of Fos-ir cells Sections of hypothalamus were observed with a light microscope (Olympus BX60). The number of Fos-ir cells was quantified by counting immunostained nuclei in PVN or SON at two consecutive typical sections with an image analysis system (Leica Quantimet 570 C). The number of Fos-positive nuclei in PVN or SON was the group mean ± SE.

Statistical analyses All data were expressed as mean ± SE and were analyzed by one-way ANOVA. Post hoc analysis was done by using the Student-Newman-Keuls (SNK) multiple comparison test. *A* value of $P<0.05$ was considered significant.

RESULTS

HE staining

Inflammation change was seen in ileum and mesenteric lymph node in the rats stimulated with STM. There are numerous bacilli in ileum cavity in the infected rats. The structure of the villus of the infected ileum was destroyed (Figure E2), part of epithelial cells were scaled, and many neutrophil, red blood cell and fibroblast infiltrated into the villus. At the same time, secondary lymphoid folliculi appeared in mesenteric lymph node (Figure E4). Figures.E1 and E3 show the normal tissue image of the villus and mesenteric lymph node in saline-treated rat.

FCM

Table 1 shows the percentages and MIFs of CD4+and CD8+ T cells in every group.

Figure1 A shows that subdiagphragmatic vagotomy itself in normal animals had no evident effect on the percentages of CD4+ T cells, but the stimulation of STM itself in sham-operated animals decreased the percentages of CD4+ T cells from 42%±4.5% to 34%±4.9% ($P<0.05$) and after subdiagphragmatic vagotomy the decreased percentages of CD4+ T cells in STM stimulated rats restored from 34%±4.9% to 44%±6.0%, the level of non- STM stimulated rats ($P<0.05$).

Figure1 B shows that subdiagphragmatic vagotomy itself in NS+operation animals decreased MIFs of CD4+ T cells from 6.6±0.6 to 4.9±1.0 ($P<0.05$), indicating the inhibition of subdiagphragmatic vagotomy to CD4+ T cells.

Figure1 C and Figure1 D show that subdiagphragmatic vagotomy itself in normal rats decreased the percentages of CD8+ T cells (from 28%±3.0% to 21%±5.9%, $P<0.05$) as well as MIFs of CD8+ T cells (from 2.9±0.39 to 1.4±0.34, $P<0.05$). STM stimulation itself in sham-operated rats also depressed the percentages of CD8+ T cells (from 28%±3.0% to 21%±5.9%, $P>0.05$) and MIFs of CD8+ T cells (from 2.9±0.39 to 2.1±0.36, $P<0.05$). Subdiagphragmatic vagotomy in STM-challenged rats aggravated the inhibition of STM to the percentages of CD8+ T cells (from 23%±2.0% to 17%±5.8%, $P<0.05$) and MIFs of CD8+ T cells (from 2.1±0.36 to 1.1±0.06, $P<0.05$).

Table 1 Percentages (%) and MIF of CD8+ and CD4+ T cells ($\bar{x}\pm s$)

	NS+sham	NS+vagotomy	STM+sham	STM+vagotomy
CD4	42±4.5	46±4.6	34±4.9[b]	44±6.0[a]
CD4 MIF	6.6±0.6	4.9±1.0[b]	6.8±1.1	6.1±1.0

Immunohistochemistry

Table 2 shows the number of Fos-ir cells in PVN and SON in each group. The numbers of Fos-ir cells in PVN and SON of STM+sham-operated rats increased significantly compared with that of NS+sham from 189±41 to 467±62 (*P*<0.05) and from 64±21 to 282±47 (*P*<0.05) individually (Figures.E5, E6, E9, E10). The positive neuron distributed in both magnocellular and parvocellular portions of PVN as well as dorsal and ventral parts of SON. Fos expressions were attenuated in PVN and SON in the rats of STM+vagotomy group compared with that of STM+sham group from 467±62 to 226±45 (*P*<0.05) and from 282±47 to 71±19 (*P*<0.05) individually (Figures. E6, E7, E10, E11), but it was still higher than that of saline-treated animal (189±41 and 64±21 individually). There was no significant changes of Fos expression in NS + vagotomy rats compared with NS + sham rats (Figures.E5, E8, E9, E12).

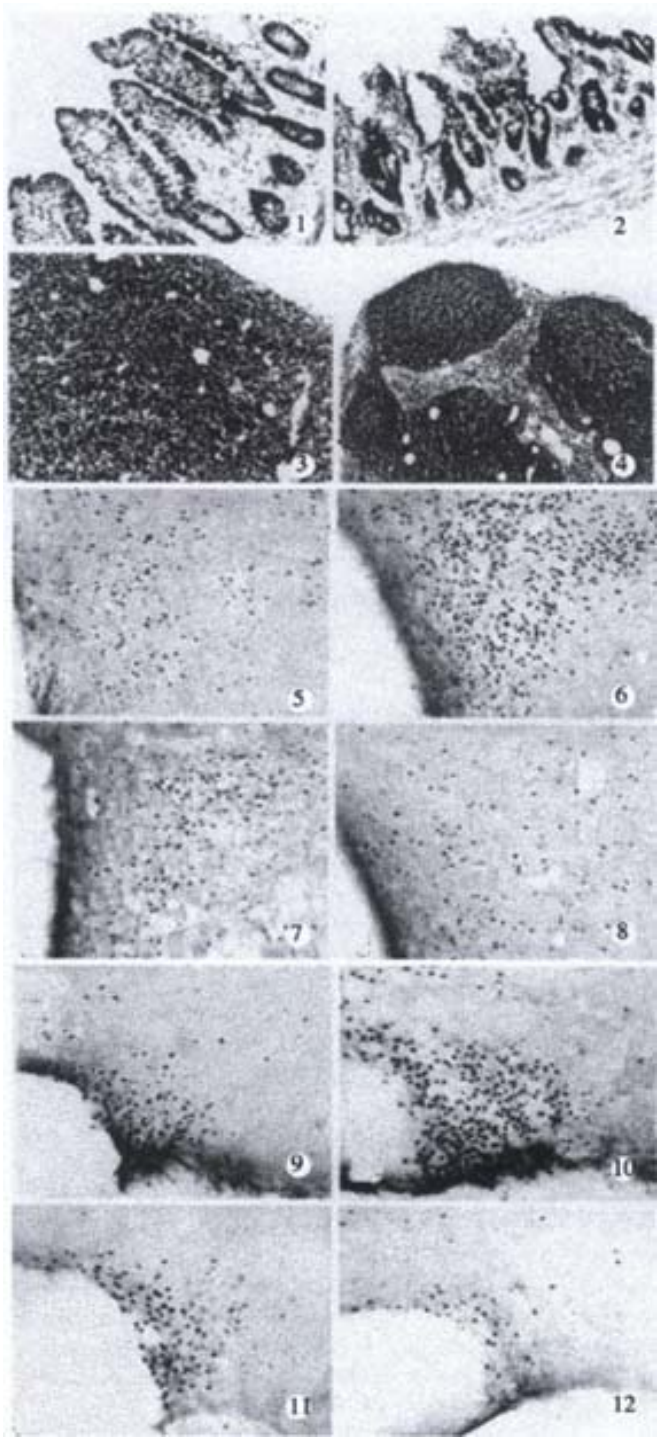

Figure 2 In Figures E 1 and 3 show the normal structures of the villus and mesenteric lymph node in saline-injected rats; 2 and 4 show the villus and mesenteric lymph node in STM-challenged rats. 5 and 9 show Fos expression in PVN and SON respectively in NS +sham rats; 6 and 10 show Fos expressions in PVN and SON respectively in STM +sham rat; 7 and 11 show Fos expressions in PVN and SON respectively in STM +vagotomy rat; 8 and 12 show Fos expressions in PVN and SON respectively in NS +vagotomy rat. ×50

DISCUSSION

More and more evidences have shown that there is a complicated bidirectional inter-relationship between nervous system and immune system[4,16-23]. Immune signals produced during antigen challenge can be transmitted into central nervous system (CNS) and influence the function of the latter. In turn, CNS can modulate the activity of immune system. However, it is still an unsolved problem up to now how the immune signals are transmitted into CNS. Two of hypothesises have been proposed[1-4]: one is through humoral route and the other, via neural pathway. Among the neural pathways the vagus nerve in transferring peripheral immune signals into CNS has been paid more attention to[1-5,24,25]. A large amount of evidences indicate that vagus plays an important role in surveying the peripheral immune information into CNS. For example, subdiagphragmatic vagotomy inhibits a series of brain-mediated responses to peripheral administration of lipopolysaccharide (LPS), IL-1β or TNF-β, such as induction of IL-1β mRNA within mice brain[26,27], activation of hypothalamic corticotropin-releasing hormone neurons and ACTH secretion[28,29], LPS-induced fever in guinea pigs[30], Fos immunoreactivity in primary afferent neurons of the vagus[31], the inhibition of social exploration[32], a monophasic fever[33], the hyperalgesia[34,35] etc. Administration of IL-1β in hepatic portal vein induced afferent discharges of hepatic branch of vagus, but the discharges disappeared in vagotomy rats[36]. Nucleus tractus solitarius lesions attenuated the first fever peak induced by intraperitoneal injection of IL-1β[37].All of the above mentioned experiments indicate that intact vagus is necessary for transmitting the immune information from periphery, especially from peritoneal cavity, to the brain. According to the anatomical structure of vagus, the abdominal organs such as liver, stomach, intestines, lymph node, etc. are innervated mostly by subdiagphragmatic vagus and the vagus contains important visceral sensory afferent fibers from abdominal organs[38,39]. Thus, we conjecture that subdiagphragmatic vagus may play an important role in transmitting the abdominal immune information into the brain and is important in maintaining immune balance.

All the immune challenges used in previous studies were bacterial toxins such as LPS or immune cytokines injected intraperitoneally or intravenously. In this experiment we established a rat model of gastrointestinal tract infection by STM intubation to mimic the natural infection and a subdiagphragmatic vagotomy was performed to further observe the role of vagus in immune signal transmission. According to aetiology, STM can invade intestinal mucosa and largely reproduce, and then further spread into the drained mesenteric lymph nodes and disseminate via the bloodstream[40]. STM is an intracellular Gram-negtive bacterial pathogen that infects both phagocytic and non-phagocytic cells[6,40-43]. It can inhibit the host immune system and cause a range of diseases including enteric fever and gastroenteritis[6]. It has been reported that the depletion of either CD4+ or CD8+ T cells by STM impairs their ability to transfer protective immunity to virulent S. typhimurium[6]. These studies indicate that CD4+ and CD8+ T cells act synergistically to control infection with virulent S. typhimurium[6,44,45]. In our experiment the villus of the infected ileum was destroyed, part of epithelial cells scaled, and the number of neutrophils, red blood cells as well as fibroblasts increased in the villus. At the same time, secondary lymphoid folliculus stimulated with STM emerged in mesenteric lymph nodes. The percentages of CD4+ and CD8+ T cells and MIFs of CD8+ T cells of peripheral blood were all inhibited, which was consistent with the previous reports. These changes induced by STM suggest that our STM infection model was reliable.

The result showed that in NS+sham rats Fos proteins expressed in a few of PVN and SON neurons, which suggests that in normal condition some PVN and SON neurons are active, and may is related to the modulation of routine metabolic activities. After being stimulated with STM the number of Fos-ir cells significantly increased in PVN and SON. It indicated that these cells were activated by STM-challenge. It is well known that CNS, especially hypothalamus, involves in modulation of acute immune reaction[46]. PVN and SON, which are two most important nuclei in hypothalamus related to autonomic function, are mainly composed of three kinds of neurons neurochemically: oxytocinergic, vasopressinergic and CRH neurons[46]. All of these three kinds of neurons can involve in neuroimmunomodulation[46]. Yang *et al*[46] reported that, as the neuroimmunomodulation integrating center, hypothalamic PVN modulates the immune function through three pathways: The first is CRH -ACTH-adrenal cortex axis, the second is oxytocin neuroendocrine pathway, and the third is PVN-spinal cord sympathetic preganglionic projection. Although we can't determine which kind of neurons were activated in this experiment since we did not apply double-labeling technique to identify them, we proposed from the observation of distribution of Fos positive neurons in the subnuclei of PVN and SON that, maybe, all these three kind neurons were activated.

But, how the immune signals are transmitted into the brain is an important and unsolved question. Is it through vagus or humoral pathway, or both of them? What we focused on in the present study was the role of vagus in the sensation and transmission of immune signals to brain. So, we severed subdiagphragmatic vagus to observe whether the Fos expressions in PVN and SON induced by STM infection and the T cell subpopulation were influenced. After subdiagphragmatic vagotomy, Fos expressions in PVN and SON were attenuated. At the same time we found that the decreased percentage of CD4+ T cells in STM-infected rats restored after subdiagphragmatic vagotomy. These results indicate the importance of intact subdiagphragmatic vagus in signaling immune information from abdominal organs to CNS. We tend to conclude from our results that subdiagphragmatic vagus does play a role in transferring immune information into brain during the abdominal inflammatory phase.

However, the detailed mechanism about how vagus nerve senses the immune stimulation and transfers it into electric signal is still not fully understood. It is known that macrophages, dendritic cells, and other immune cells detect and present antigens and respond by releasing proinflammatory mediators, such as IL-1β, IL-6 and TNF-α[23,47,48]. Goehler *et al*[47] found that between the fibers of abdominal vagus there exist immune cells which can produce IL-1β. IL-1β acts to both coordinating the peripheral immune response and signaling the CNS[49]. The globe cells of vagus paraganglia near liver hilus could be stained by biotinylated IL-1 receptor antagonist[50] and by anti rat IL-1 receptor type I antibody[51], which suggested the possibility for vagus to sense the local IL-1. We[51] and others[52] also have reported that the primary sensory neurons in nodose ganglia of vagus contain IL-1 receptor protein and mRNA, which indicates that vagus nerve probably can sense IL-1 directly.

It is necessary to point out that vagus is definitely not the only route for immune signal getting into the brain, since it is found in the present study that although the number of STM stimulation-induced Fos expressed neurons in hypothalamus is attenuated after vagotomy, the number is still higher than that in control. So the humoral pathways or other nerves may also involve in the immune signals transmission in some degree, which still needs further study.

Our results also showed that subdiagphragmatic vagotomy itself decreased the percentages of CD8+ T cells and MIFs of CD4+ and CD8+ T cells, which indicated the importance of intact vagus in maintaining the host immune balance. This is also accordant with our previous study[53]. As we know that CD4+ and CD8+ T cells are necessary in clearing STM[6,54,55]. Vagotomy inhibits the subpopulation of T cells, which is a disadvantage to STM clearance and only aggravate the inhibition to CD4+ and CD8+ T cells induced by STM. How does the vagus influence the phenotype of lymphatic cells? Vagus contains both afferent and efferent fibers innervating abdomen. The former can transmit abdominal information into CNS and the latter innervates some immune organs or immune cells, such as abdominal lymph node. When we cut off subdiagphragmatic vagotomy, on the one hand, the abdominal immune information can't be transmitted into the brain; on the other hand, the brain can't influence the abdominal immune organizations via vagus. We suppose that this is probably the answer.

In summary, subdiagphragmatic vagus is able to signal immune information from abdomen into the brain and intact vagus is necessary in maintaining the host immune balance.

Abstract

AIM: **To investigate the relationship between lymphocyte apoptosis in peripheral blood, spleen and mesenteric lymph nodes(MLN) and endotoxin translocation after thermal injury in rats.**

METHODS: **In a Wistar rat model inflicted with 30% TBSA Ⅲ degree scalding, serum LPS levels in portal vein and vena cava were quantified by tachypleus amebocyte lysate (TAL) technique. The analysis of peripheral blood lymphocyte was employed in in situ Cell Death Detection Kit and evaluated by flow cytometry. Apoptotic lymphocytes in paraffin-embedded spleen and MLN sections were examined by histologic analysis, in situ deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL) and peroxidase (POD) staining. The imagines were taken by Cooldccd camera system, and the count and optical density value (transmission light) of apoptotic lymphocytes were analyzed with software Spot and Imagine proplus 4.10a(IPP4.10a).**

RESULTS: **In the period of 3 to 48 postburn hours (PBHs) serum LPS level ($\times 10^3$ EU·L^{-1}) in portal vein (2.11±0.02, 5.66±0.20, 3.70±0.22, 2.56±0.28, 0.90±0.11) was higher than that in vena cava (0.63±0.01, 1.53±0.18, 0.83±0.32, 0.52±0.12, 0.23±0.02, *P*<0.01), but both increased sharply in postburn rats (*P*<0.01) and reached a peak at 6 PBH. Analysis of apoptotic lymphocytes showed that the proportion (%) of postburn apoptotic cells was much higher than that in healthy rats (8.34±1.53, 8.13±1.81, 20.77±3.94, 23.90±3.92, 11.23±1.35 and 13.26±2.09 at 3, 6, 12, 24, 48 and 72 PBH, respectively, *vs* 3.99±1.72, *P*<0.01), especially after 6 PBH. The concentrations of lymphocytic apoptosis at 12 and 24 PBH were markedly higher than that at other time points. Meantime, few apoptotic lymphocytes were found in normal MLN, but increased postburn obviously (3±1 *vs* 546±83, 285±39, 149±30, 58±10, 36±11 and 33±9 in turn, *P*<0.01), especially at 3 PBH, whereas apoptotic lymphocytes were concentrated in splenic cortex before the burn and decreased obviously during 72 PBHs (499±186 *vs* 12±8, 19±15, 12±7, 100±15, 123±25 and 226±26 in turn, *P*<0.01) though a slight rise was found in the medulla after 24 PBH. Optical density of apoptotic lymphocytes was significantly reduced in spleen in the 24 PBHs and raised in MLN during 48 PBHs than that prior to the burn, respectively.**

CONCLUSION: **Gut-origin LPS is a major cause of endotoxemia taken place early in rats following severe thermal injury and could induce extensive lymphocyte apoptosis in blood and MLN, which suggests an immunosuppression state could follow the initial injury and favores a septic state based on apoptotic mechanism.**

Xia PY, Zheng J, Zhou H, Pan WD, Qin XJ, Xiao GX. Relationship between lymphocyte apoptosis and endotoxin translocation after thermal injury in rats. *World J Gastroenterol* 2002;8(3):546-550

INTRODUCTION

Endotoxin or lipopolysaccharide (LPS) is a major cause of the local inflammation and septic shock and has been shown to impair host immune defense[1-10]. With the experimental endotoxemia or sepsis in C3H/HeN (endotoxin-sensitive) mice, it was demonstrated in recent studies that LPS could cause thymic atrophy and bring about the increased apoptotic lymphocytes in thymus, spleen and gut-associated lymphatic tissue[11-13]. Since the lymphocytes appear essential to both competent immune function and to the control of inflammatory response[14,15], the lymphocyte apoptosis induced by LPS may play important roles in the development and regulation of the immune system, especially in the gut-dysfunction situations induced by sepsis or severe injuries. Endotoxemia in the patients with severe injury has been suggested to be an important factor in the systemic inflammatory response syndrome (SIRS)[16,17]. It was found in the previous *in-vivo* study that gut-origin endotoxemia following the intestinal mucosal barrier dysfunction could occur in early postburn period and lead to the injury of systemic organs such as lungs, liver etc[18,19]. Although the exact routes by which translocating LPS reach the blood and systemic organs are not known with certainty, most researchers believed that LPS was capable of translocating from the gut via both the mesenteric lymphatics and the portal blood[20]. Because the mesenteric lymph nodes (MLN) receives its lymphatic drainage from the small intestine, cecum and proximal colon, we believed that MLN should be a major site and pathway of translocated gut-origin LPS. However, little has been known about lymphocyte apoptosis in circulating blood and MLN induced by endotoxin translocation after thermal injury and the relationship between them.

The present experiments were performed in severe scalded rats to determine the effects of gut-origin LPS translocation on the apoptosis of lymphocytes in circulating blood, spleen and MLN, and to investigate the relationship between them.

MATERIALS AND METHODS

Animals and reagents

Forty-two adult Wistar rats weighing 235-345g were randomly distributed in the normal control and 6 thermal injury groups, i.e. 3, 6, 12, 24, 48 and 72h after scalding. Each group contained 6 animals (half males and half females). Rats in the thermal injury groups were inflicted with 30% total burn surface area (TBSA) Ⅲ degree scalding on their back after anesthetized with 30mg/kg of

intraperitoneal pentobarbital. Then under general anesthesia at the different time points after the thermal injury, the blood of rats' portal vein and vena cava were collected for LPS test and the isolation of peripheral blood lymphocyte, respectively. MLN and spleen were harvested by aseptic manipulation and fixed in 10mL·L^{-1} paraformaldehyde solution (pH 7.4) for 24h. All chemicals used in this study were purchased from Sigma Chemical Co. (USA) unless specified otherwise. Endotoxin-free glassware and plasticware were prepared by baking at 250℃ for 1.5h and radiating with ^{60}Co, respectively.

Determination of serum LPS levels in portal vein and vena cava

Sera were obtained from the blood samples of portal vein and vena cava by clotting for 60min on ice and then centrifuged at 2500g at 4℃ for 5min respectively, filtered, aliquoted, and frozen at -70℃. After all serum samples were collected, the serum LPS levels were determined with a commercially available kit for tachypleus amebocyte lysate (TAL) technique (Zhanjiang A & C Biological Ltd, Zhanjiang, China) according to the manufacture's guidelines.

Isolation and preparation of lymphocyte

Lymphocyte in the heparinized blood from vena cava were isolated by density gradient centrifugation using ficoll-hypaque (d=1.077) followed by two washing steps in phosphate buffered saline (PBS) and lysis of residual erythrocytes using nine volumes of an ice-cold isotonic ammonium chloride solution (NH_4Cl 155mmol·L^{-1}, $KHCO_3$ 10mmol·L^{-1}, EDTA 0.1mmol·L^{-1}) to one volume of cell pellet at 4℃ for 7min[21]. Lymphocytes were greater than 98% as analyzed by microscopy using Hemacolor staining (Merk, Germany). Cell viability was greater than 97% as assessed by the trypan blue exclusion test. Isolated lymphocytes were maintained in a glass bottle in RPMI 1640-medium without fetal calf serum (endotoxin-free; Gibco BRL, Life Technologies, USA) at a concentration of 1×10^9 cells·L^{-1} in 5mL·L^{-1} CO_2 at 37℃ for 2h to exclude macrophage before the analysis of apoptosis. Then the cells were collected by centrifugation and washed twice in PBS.

Flow cytometric analysis of apoptotic lymphocyte

The analysis of apoptotic lymphocytes was performed by an in situ Cell Death Detection Kit, Fluorescein (Roche, Germany). The procedures in brief was according to the manufacture's guidelines as follows: lymphocyte were suspended and fixed with 40mL·L^{-1} paraformaldehyde solution (pH 7.4), rinsed in PBS twice, and incubated in permeabilization solution (1 g·L^{-1} Triton X-100 in 1 g·L^{-1} sodium citrate) for 2min on ice. The cells were again rinsed in PBS, centrifugated and incubated in terminal deoxynucleotidyl transferase (TdT)-mediated dUTP nick end labeling (TUNEL) reaction mixture for 1h at 37℃ in a humidified atmosphere at dark. Then cells were rinsed in PBS again. TUNEL fluorescence of individual nuclei in a final volume of 500μL cells solution was analyzed by an FACS Calibur (Becton Dickinson, USA), while gating on physical parameters was enacted to exclude cell debris. A minimum of 10000 events were counted per sample. The results were reported as the percentage of hypodiploid (fragmented) nuclei reflecting the relative proportion of apoptotic cells.

Analysis of apoptotic lymphocytes in spleen and MLN

Paraffin-embedded spleen and MLN tissue were cut into sections of 5μm and mounted on Vectabond Reagent slides, deparaffinized and rehydrated through xylene, graded ethanol to distilled water. Then the tissue sections were pre-treated with 20mg·L^{-1} proteinase K for 30min, and analyzed with an in situ Cell Death Detection Kit, POD (Roche, USA) according to the manufacture's guidelines. Each experiment set up by TUNEL reaction mixture without terminal transferase served as negative control. The images were taken by Cooldccd camera system, and the count and optical density (OD) value of apoptotic lymphocytes were analyzed with software Spot and Imagine proplus 4.10a (IPP 4.10). The counts and optical density values (transmission light) of TUNEL-POD positive lymphocytes in spleen and MLN were determined in three high-resolution fields selected randomly in the area concentrated positive apoptotic lymphocytes and two thousand cells per field were counted per slides.

Statistical analysis

All the data was analyzed by Student's *t* test and expressed as $\bar{x}\pm s$. The statistical difference $P<0.05$ was considered as significantly and $P<0.01$ as very significant.

RESULTS

Serum LPS in portal vein and vena cava increased after thermal injury

Serum LPS levels in portal vein and vena cava increased sharply postburn ($P<0.01$) and reached to a peak level at 6 PBH and decreased thereafter. LPS level in portal vein was higher than that in the vena cava ($P<0.01$) in the period of 3 to 48 PBHs, but both decreased to near control level at 72 PBH (Figure 1).

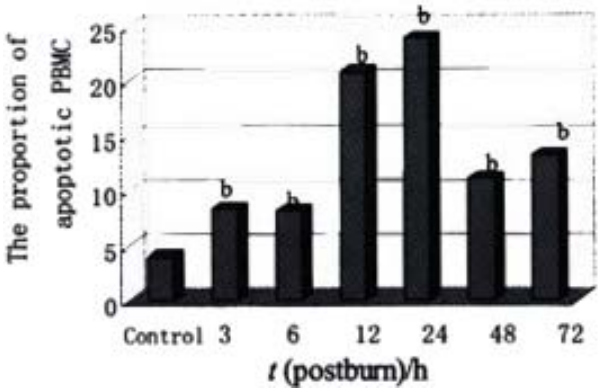

Figure 1 Comparison of the LPS levels postburn in portal vein and in vena cava. $^bP<0.01$, *vs* control; $^cP<0.01$, portal vein *vs* vena cava

Apoptosis of lymphocytes

Lymphocytes isolated from the circulation of healthy rats exhibited a low proportion of apoptotic cells at (3.99±1.72)%, but increased obviously during the whole postburn period of the experiment ($P<0.01$), especially after 6 PBH. The concentrations of lymphocytic apoptosis at 12 and 24 PBH were markedly higher than that at other time points (Figure 2,3).

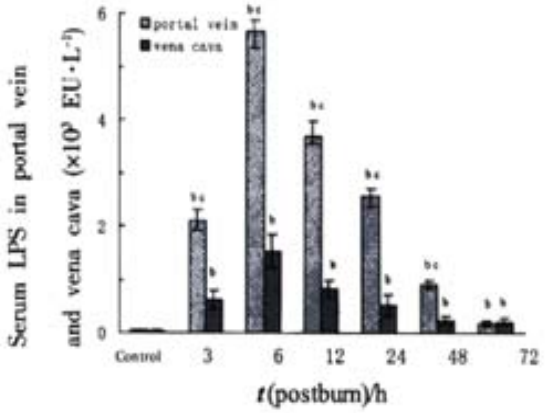

Figure 2 The relative proportions of apoptotic lymphocytes postburn. $^bP<0.01$, *vs* control

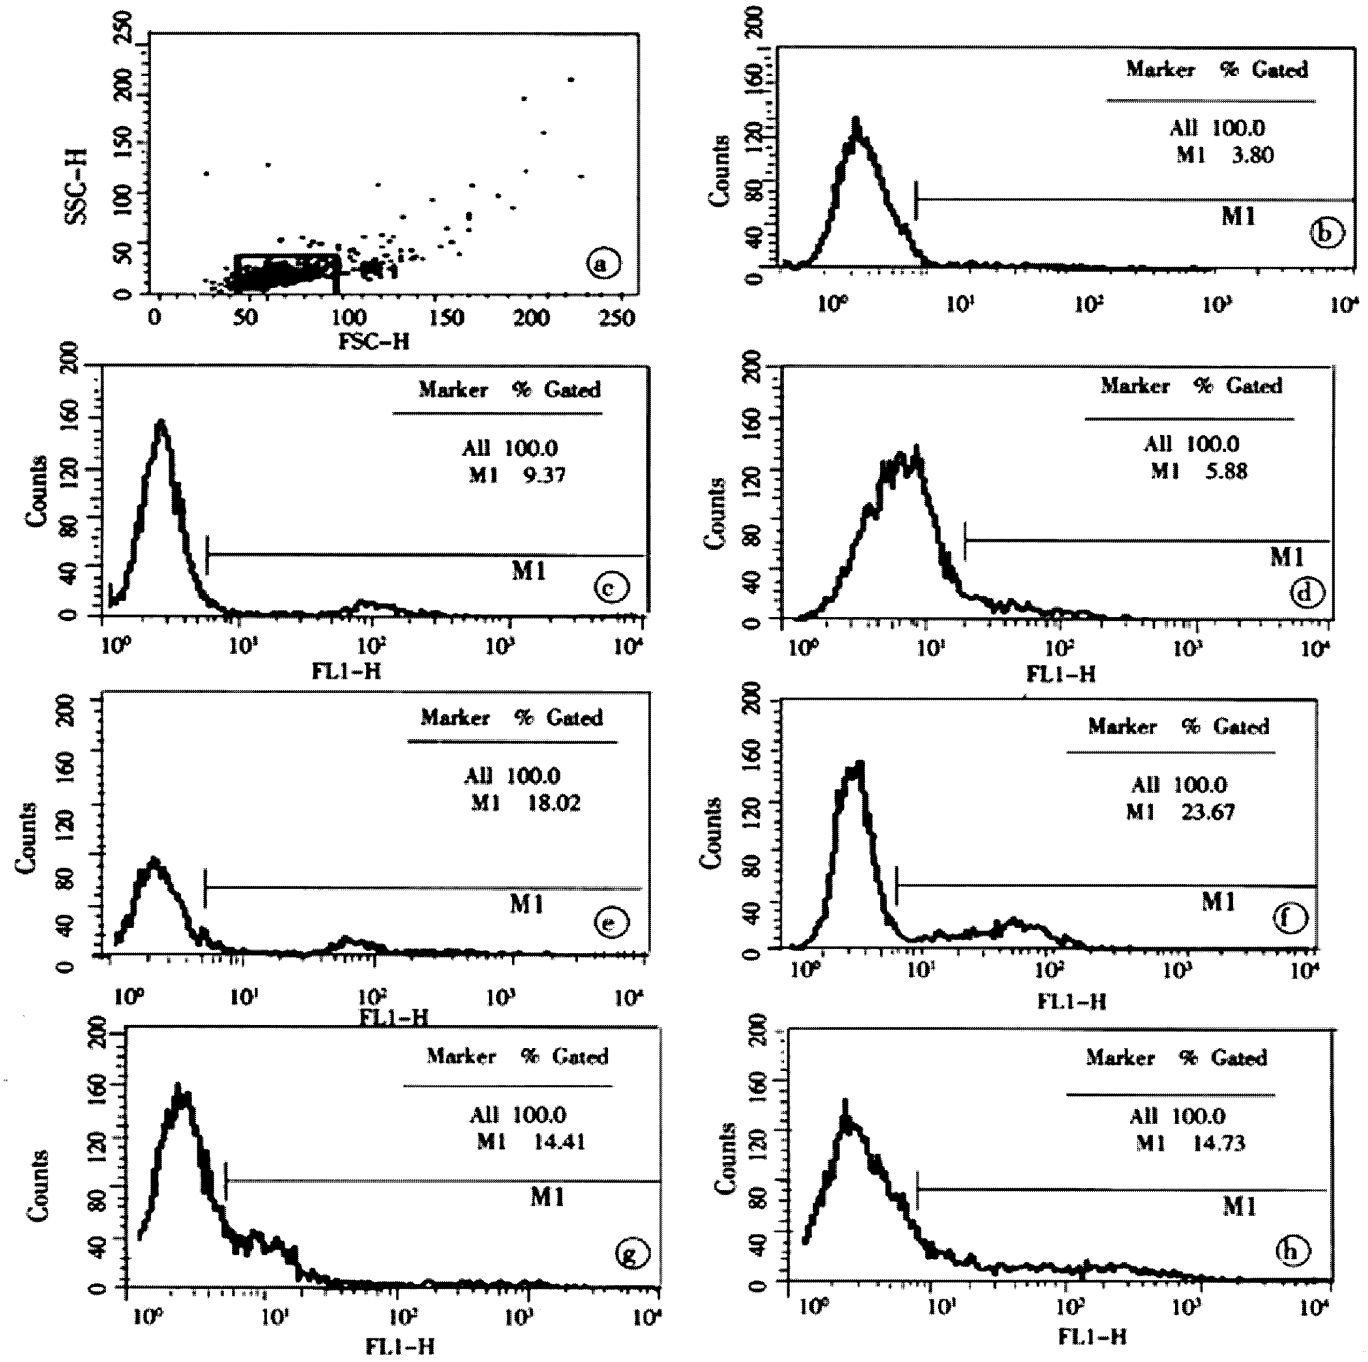

Figure 3 The results of typical flow cytometric analysis of postburn apoptotic lymphocytes. a, b, c, d, e, f, g and h were the relative proportion of apoptotic lymphocytes isolated from one rat in the control and group 3, 6, 12, 24, 48 and 72 PBH, respectively.

Apoptotic lymphocytes in spleen and MLN

It was shown by the results of TUNEL-POD staining and the counts of apoptotic lymphocytes that the apoptotic cells were few in normal MLN (Figure 4a), but increased postburn obviously (P<0.01), especially at 3 PBH (Figure 4b, Table 1). Opposite to MLN, apoptotic lymphocytes were concentrated in spleen cortex before burn (Figure 4c), but decreased obviously during 3 to 72 PBHs (P<0.01) though a slight rise was found in the medulla after 24 PBH (Figure 4d, Table 1). Since the principle of TUNEL-POD is to label the fragmented genomic DNA, the biochemical hallmark of apoptotic cell, the color density of nuclei staining could indirectly reflect the extent of DNA fragmentation. Optical density of TUNEL-POD staining in apoptotic lymphocytes was significantly reduced in spleen in the 24 PBHs, but raised in MLN during 48 PBHs than that before burn, respectively (Table 2).

Table 1 Apoptotic lymphocyte counts in 2000 total cells of spleen and MLN

DISCUSSION

Translocation of gut bacteria and endotoxin is a common situation after severe trauma, probably as a consequence of loss of physical integrity of the mucosal barrier, increments in permeability, or impaired local immune function resulted from ischemia-reperfusion injury of intestine. The gut-origin LPS translocated to the portal circulation or gut lymphatics has been thought to subsequently initiate a septic process leading to the development of SIRS[22]. In this study, the LPS levels in portal vein and vena cava increased sharply after the severe thermal injury (Figure 1) indicating that endotoxin could enter the blood circulation in the early period of trauma and might be a main cause of endotoxemia.

The gastrointestinal tract contains numerous immune effector and regulatory cells of lymphoid and myeloid origin that are thought to play a critical role in host defense against enteric infections[23]. And at a systemic level, the lymphocytes, through the production of regulatory cytokines, are important in mediating and controlling the host immune response. This was well illustrated by the spontaneous appearance of gastrointestinal inflammatory disease in a number of animals deficient in different cytokines, including IL-2 and IL-10, etc[24-26]. Thus, the increased lymphocyte apoptosis in circulatory blood and gut-associated lymphoid tissues must impair the balance between the functions of host defense and immune tolerance in the gut immune system[27,28]. The observation presented here provided some evidence that local and systemic pathologic lymphocyte apoptosis following an initial event of injury could impair the immune system. In the scalded rats, the counts of apoptotic lymphocytes in peripheral blood and MLN increased dramatically during the whole 72 PBHs, and reached a peak level at 12-24 PBHs and 3 PBH, respectively (Figure 2,3, 4, Table 1, 2). The results of lymphocyte apoptosis in MLN were consistent with that reported by Mongini *et al*[22]. Moreover, It was surprised to observe the apoptotic lymphocytes in the spleen decreased obviously after thermal injury in this study (Figure 4, Table 1, 2) though splenic lymphocyte seemed to be less sensitive to apoptosis triggered by LPS and oxidative stress[11,12,29]. Specifically, we also found that splenic apoptotic lymphocytes were located mainly in the cortex in healthy rats, but being present in the medulla after thermal injury. The implications of these results are unclear. During normal lymphocyte development, immature lymphocytes are located in the cortex and migrate to the medulla in the course of maturation. The depletion of cortical lymphocytes by apoptosis may be one mechanism of eliminating potentially autoreactive immune cells[22]. As for the decreased splenic apoptotic lymphocytes in the scalded rats, whether it is a reaction induced by the lymphocyte apoptosis in peripheral blood remains to be clarified.

Taking that both change tendency of lymphocyte apoptosis and serum LPS level after thermal injury into consideration, it was found that the peak level of lymphocyte apoptosis appeared earlier in MLN and much later in circulatory blood than that of LPS in the blood. The results indicated that MLN was an advanced station in the routing of the LPS translocation and suggested that the translocation of gut-origin LPS was a major factor of lymphocyte apoptosis in rats with severe burn injury. Furthermore, LPS translocated into the blood could lead to a further breakdown of gut immune barrier and thus accelerate the entrance of enteric bacteria and their toxins into the circulation[30] and result in an immunosuppressive state due to the induction of lymphocyte apoptosis[14,22,31]. This might explain why the peak level of apoptotic lymphocytes came forth much later in circulatory blood than that in MLN.

In addition to our observations in the present study, thymocyte and mucosal lymphocyte apoptosis after thermal injury had been recently reported[32,33]. Although in these two studies the increased lymphocyte apoptosis in thymus and gut-associated lymphoid tissue seemed mainly due to the increased corticosterone concentration in plasma and in the lymphoid tissue, the presence of lymphocyte apoptosis in the peripheral blood, thymus and gut-associated lymphoid tissue following injury could explain the immunosuppressive state following such injury. In fact, decreased lymphocyte apoptosis in

sepsis can improve survival by overexpression of Bcl-2 in transgenic mice[34]. In summary, we can reach the conclusion that an immunosuppression state could follow the initial injury and favor a septic state based on apoptotic mechanism, and that the immunosuppressive state after the thermal injury can be the event induced by translocation of gut-origin LPS and bacteria spreading to other tissues,and which in turn causes a recurrence of sepsis.

Abstract

AIM: **To observe expression of CD14 protein and CD14 gene in rat liver sinusoidal endothelial cells (LSECs) during endotoxemia, and the role of CD14 protein in the activation of lipopolysaccharide (LPS)-induced LSECs.**

METHODS: **Wistar rat endotoxemia model was established first by injection of a dose of LPS (5mg/kg, Escherichia coli O111:B4) via the tail vein, then sacrificed after 0h,3h,6h, 12h, and 24h, respectively. LSECs were isolated from normal and LPS-injected rats by an in situ collagenase perfusion technique. The isolated LSECs were incubated with rabbit anti-rat CD14 polyclonal antibody, then stained with goat anti rabbit IgG conjugated fluorescein isothiocyanate (FITC) and flow cytometric analysis (FCM) was performed. The percentage and mean fluorescence intensity (MFI) of CD14-positive cells were taken as the indexes. LSECs were collected to measure the expression of CD14 mRNA by in situ hybridization analysis. The isolated LSECs from normal rats were incubated firstly with anti-CD14 antibody, then stimulated with different concentrations of LPS, and the supernatants of these cells were then collected for measuring the levels of tumor necrosis factor (TNF)-a and Interleukin (IL)-6 with ELISA.**

RESULTS: **In rats with endotoxemia, LSECs displayed a strong MFI distinct from that of control rats. CD14 positive cells in rats with endotoxemia were 54.32%, 65.83%, 85.64%, and 45.65% at 3h, 6h, 12h, and 24h respectively, there was significant difference when compared to normal group of animals (4.45%) ($P<0.01$). The expression of CD14 mRNA in isolated LSECs was stronger than that in control rats. In LPS group, the levels of TNF-α and IL-6 were 54±6ng.L^{-1}, 85±9ng.L^{-1}, 206±22ng.L^{-1}, 350±41ng.L^{-1}, 366±42ng.L^{-1} and 103±11ng.L^{-1}, 187±20ng.L^{-1}, 244±26ng.L^{-1}, 290±31ng.L^{-1}, and 299±34ng.L^{-1}, respectively at different concentration points. In anti-CD14 group, the levels of TNF-α and IL-6 were 56±5ng.L^{-1}, 67±8ng.L^{-1}, 85±10ng.L^{-1}, 113±12ng.L^{-1}, 199±22ng.L^{-1} and 104±12ng.L^{-1}, 125±12ng.L^{-1}, 165±19ng.L^{-1}, 185±21ng.L^{-1}, and 222±23ng.L^{-1}, respectively at different concentration points. There was significant difference between the two groups ($P<0.01$).**

CONCLUSION: **LSECs can synthesize CD14 protein and express CD14 gene during endotoxemia. CD14 protein plays an important role in the activation of LPS-induced LSECs. This finding has important implications for the understanding of the mechanisms by which LPS may injure liver sinusoidal endothelial cells during sepsis.**

INTRODUCTION

Lipopolysaccharide (LPS) has been shown to play a key role in the pathogenesis of severe sepsis and septic shock caused by gram-negative bacteria. LPS stimulates monocytes and macrophages to release proinflammatory mediators, such as tumor necrosis factor (TNF)-α and interleukins[1-10]. Recent studies have reported that LPS-binding protein (LBP) and LPS receptor CD14 mediate responses of activated monocytes, macrophages and other cells to LPS[11-13]. CD14 is a 55-kDa glycoprotein with multiple leucine-rich repeats and was first described as a myeloid differentiation antigen[14]. CD14 has been identified as receptor for complexes of LPS and LBP. It is known that CD14 is linked to the cell membrane by a glycosylphosphatidylinositol anchor in myeloid lineage cells, and it plays a pivotal role in the activation of LPS-induced monocytes and macrophages[15, 16]. But it is not yet clear whether CD14 is expressed by vascular endothelial cells. Indeed, it has been generally accepted that endothelial cells do not express CD14[17]. Soluble CD14 (sCD14) is thought to facilitate LPS-induced activation of endothelial cells[18]. However, recent studies have shown that endothelial cells are sensitive to low concentration of LPS and anti-CD14 antibodies can block endothelial cell activation even in the absence of serum, which is an observation inconsistent with the concept that endothelial cells do not express CD14[19]. Our aim was to demonstrate that liver sinusoidal endothelial cells (LSECs) synthesize CD14 protein and express CD14 gene in rats with endotoxemia, and the role of CD14 protein in the activation of LPS-induced LSECs.

MATERIALS AND METHODS

Reagents

LPS (Escherichia coli O111: B4) and collagenase (type IV) were purchased from Sigma Chemical Company (St. Louis, Mo.). A rabbit anti-rat CD14 polyclonal antibody was purchased from Santa Cruz Biotechnology (Santa Cruz, Calif). Fluorescein isothiocyanate (FITC)-IgG were purchased from Zhongshan Biotechnology Company (Beijing, China). In situ hybridization analysis kit of CD14 mRNA was purchased from Boshide Biotechnology Company (Wuhan, China).

Animals

Male Wistar rats, which were pathogen-free and weighed

approximately 225g each, were purchased from the Animal Center of Chongqing University of Medical Science. The rats were exposed each day to 12h of light and darkness respectively. Rodent chow and water were provided ad libitum. Experimental protocols were approved by the Institutional Care and Use Committee of Chongqing University of Medical Science.

The endotoxemia model of animals

The Wistar rat endotoxemia model was established as described previously[20].In brief, animals were injected with a dose of LPS (5mg/kg, Escherichia coli O111: B4) via the tail vein, then the sacrificed after 3h, 6h, 12h, and 24h, respectively. There were six rats at each time point. Other six rats were used as control group (0h).

LSECs isolation

LSECs were isolated from normal and LPS-injected rats by an in situ collagenase perfusion technique, modified as described previously[21]. In brief, livers were removed after a portal vein perfusion with Hanks' balanced salt solution (HBSS) and the homogenate was digested in a solution of 0.5% collagenase. LSECs were separated from other nonparenchymal cells by two cycles of differential centrifugation (50×g for 2min) and further purified over a 30% Percoll gradient. LSECs purity exceeded 90% as assessed by light microscopy, and viability was typically greater than 95% as determined by trypan blue exclusion assay.

Determination of CD14 mRNA by in situ hybridization

In situ hybridization was performed as described previously[22]. Positive result: positive location was blue.

Flow cytometric analysis

Expression of CD14 protein in LSECs was examined by flow cytometric analysis as described previously[23]. In brief, LSECs were incubated with rabbit anti-rat CD14 polyclonal antibody (1ug/ml) after washing, and then cells were incubated with goat anti-rabbit immunoglobulin G labeled with FITC. After being washed three times, 10000 cells were analyzed by flow cytometry (Coulter, USA), and the percentage and mean fluorescence intensity (MFI) of CD14-positive cells were taken as the indexes.

Blocking test of anti-CD14 antibody

To determinate the role of CD14 in the activation of LPS-induced LSECs, LSECs were isolated from normal rats. These cells were harvested and adjusted to a concentration of 1×10^6/ml/well and were divided into two groups. Group of LPS: LSECs were incubated at different concentrations of LPS (0, 0.01ug/ml, 1ug/ml, 10ug/ml, and 100ug/ml). Group of anti-CD14 antibody blockade: LSECs were pre-incubated for 30min with 0.2ml CD14 antibody (1:100 dilution) before different concentrations of LPS were added. Supernatants were then collected for measuring the levels of TNF-α and IL-6 with ELISA.

Statistical analysis

All results were expressed as mean ± SEM. Statistical differences between means were determined by using Student's *t* test. The value of $P<0.01$ was considered significant.

RESULTS

Binding of FITC to LSECs

To confirm expression of CD14 on LSECs, we examined the binding of FITC to the cells. CD14 positive cells were 4.45% in rats of normal group. But in rats with endotoxemia, CD14 positive cells were 54.32%, 65.83%, 85.64%, and 45.65% at 3 h, 6 h, 12 h, and 24 h respectively after stimulation of LPS, which were significant different when compared with normal group of animals ($P<0.01$) (Figure 1).

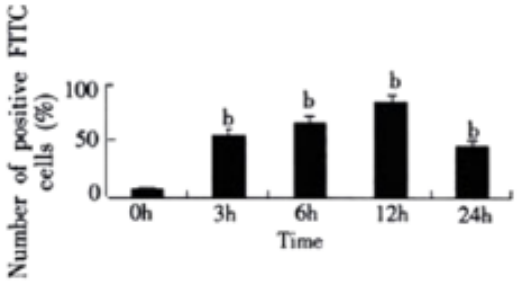

Figure 1 The percentage of positive FITC cells. $^bP<0.01$ *vs* 0h

Expression of CD14 gene in LSECs

We postulated that LSECs could express CD14 mRNA during endotoxemia. In order to examine the cell-specific expression of CD14 mRNA, freshly isolated and purified LSECs were analyzed by in situ hybridization with a riboprobe specific for rat CD14. Our analysis showed that LSECs from controls had no detectable level of CD14 mRNA. LPS treatment increased the level of CD14 mRNA in LSECs, inducing expression as early as 3h after LPS treatment. The expression of CD14 gene increased with time, reaching a maximum induction by 12h after treatment of LPS, and subsequently declined to low level by 24h.

Results of blocking test

In LPS group, with increasing of LPS concentrations, the levels of TNF-a and IL-6 in supernatant of LSECs also increased. In group of anti-CD14 antibody blockade, productions of TNF-α and IL-6 in supernatants of LSECs were obviously inhibited by Ab against CD14 when compared with LPS group ($P<0.01$). (Figure 2 and 3)

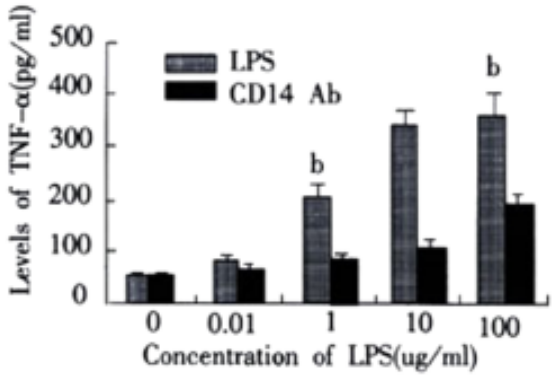

Figure 2 Effect of CD14 Ab on production of TNF-α in supernatants of LSECs. $^bP<0.01$ *vs* CD14 Ab

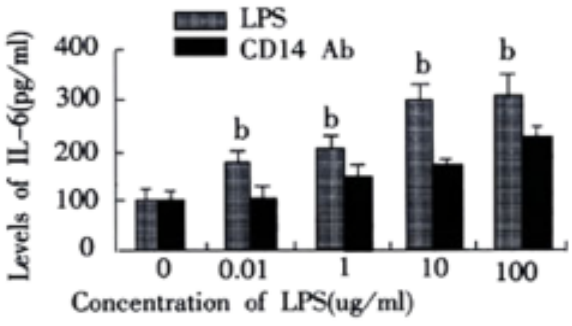

Figure 3 Effect of CD14 Ab on production IL-6 in supernatants of LSECs. $^bP<0.01$ *vs* CD14 Ab

DISCUSSION

CD14 as a key LPS signaling molecule was first reported to be expressed in monocyte-macrophage system[4,12,23]. Recent works have showed that the CD14 antigen is expressed in many types of cells and tissues[20, 24-32]. But it is not yet clear whether vascular endothelial cells could synthesize CD14 protein and express CD14 gene. Beekhuizen *et al* reported endothelial cells did not express CD14. With method of in situ hybridization, Fearns *et al*[24]found that endothelial cells did not express CD14 protein. Wang *et al*[18]considered that sCD14 was thought to facilitate LPS-induced activation of endothelial cells. But, Lee *et al*[33] found CD14-negative murine pre-B cells (70Z/3), which were unresponsive to low concentrations of LPS (0.1ng/ml) even in the presence of serum, showed responses to LPS when transfected with CD14. Surprisingly, anti-CD14 antibody blocked endothelial cell activation by LPS even in the absence of serum, which is an observation inconsistent with the concept that endothelial cells do not express CD14 protein.

In this experiment, we selected LSECs to represent vascular endothelial cells as targets of our experiment, and determined whether LSECs could synthesize CD14 protein and express CD14 gene. We found: (1)LSECs from normal rats did not synthesize CD14 protein and express CD14 gene, but the synthesis and expression of CD14 were markedly upregulated by LPS during endotoxemia, accompanied with the expression of CD14 mRNA, which showed that CD14 protein in LSECs was not passively acquired from serum. (2)Anti-CD14 antibody could block LSECs activation by LPS in the absence of serum, which further indicated that LSECs could synthesize and express CD14 molecules.

Why were our findings different from previously published data that endothelial cells were CD14 negative? We think there were a few possibilities: (1)many authors used routine passaging of multiple culture of human vascular endothelial cells (HUVEC) or HUVEC purchased from tissue culture laboratories to observe whether these cells expressed CD14, but these cells might lose CD14 gene when they were cultured at multiple passages. Jersmann *et al*[34] reported when HUVES were cultured at passages 3 to 5, these cells were indistinguishable from passage 1 HUVEC in a number of properties and displayed normal morphology and viability and response to TNF to the same extent as passage 1 cells. However, unlike passage 1 cells, HUVEC that had undergone multiple passing expressed extremely low amounts of CD14 protein. We used freshly isolated primary rat LSECs to study the expression of CD14 and found they could obviously synthesize and express CD14 during endotoxemia. (2) LSECs were different from other endothelial cells in location, construction, and function. LSECs are located in hepatic sinus and stimulated by LPS from gut via portal vein blood, so these cells have their property which are different from other endothelial cells[35]. (3) The choice of Ab against CD14 for the flow cytometric analysis may have been an additional explanation for the previously reported lack of CD14 on the endothelial cells' surface. Jersmann *et al*[34] stained HUVEC with five different primary mAbs (MY4, 2D-15C, TUK4, LeuM3, and Rmo52) against CD14, and found only MY4 and TUK4 produced a positive stain and MY4 was the most effective mAb for detection of CD14 expression in endothelial cells. We stained LSECs with rabbit anti-rats primary antibody against CD14 from Santa Cruz Biotechnology and found this Ab against CD14 was effective for detecting the expression of CD14 protein. As expression of CD14 in animals is probably different from that in humans, further investigation of the expression of CD14 among animals is going on actively in our laboratory.

Abstract

AIM: **To determine if anisodamine is able to augment mucosal perfusion during gut I/R ischemia-reperfusion.**

METHODS: **A jejunal sac was formed in Sprague Dawley rat. A Laser Doppler probe and a tonometer were inserted into the sac which was filled with saline. The superior mesenteric artery was occluded (SMAO)for 60 minutes followed by 90 minutes of reperfusion. At the end of 60 minutes of SMAO, either 0.2mg/kg of anisodmine or dobutamine was injected into the jejunal sac. Laser Doppler mucosal blood flow and regional PCO_2 ($PrCO_2$)measurements were made.**

RESULTS: **Mucosal blood flow was significantly increased at 30,60 and 90 minutes of reperfusion (R_{30},R_{60},R_{90}) when intraluminal anisodamine or dobutamine was present compared to intraluminal saline only(44±3.3% or 48±4.1% *vs* 37±2.6% at R_{30}, 57±5.0% or 56±4.7% *vs* 45±2.7% at R_{60}, 64±3.3% or 56±4.2% *vs* 48±3.4% at R_{90},respectively *P*<0.05). Blood flow changes were also reflected by lowering of jejunal $PrCO_2$ measurements after intraluminal anisodamine or dobutamine compared with that of the saline controls (41±3.1mmHg or 44±3.0mmHg *vs* 49±3.7mmHg at R_{30},38±3.7mmHg or 40±2.1mmHg *vs* 47±3.8mmHg at R_{60},34±2.1mmHg or 39±3.0mmHg *vs* 46±3.4mmHg at R_{90}, respectively, *P*<0.05). Most interesting finding was that there were significantly higher mucosal blood flow and lower jejunal $PrCO_2$ in anisodamine group than those in dobutamine group at 90 minutes of reperfusion(64±3.3% vs 56±4.2% for blood flow or 34±2.1mmHg *vs* 39±3.0mmHg for $PrCO_2$,respectively,*P*<0.05),suggesting that anisodamine had a more lasting effect on mucosal perfusion than dobutamine.**

CONCLUSION: **Intraluminal anisodamine and dobutamine can augment mucosal blood flow during gut I/R and alleviate mucosal acidosis. The results provided benificial effects on the treatment of splanchnic hypoperfusion following traumatic or burn shock.**

INTRODUCTION

With remarkable advancement in our understanding of shock and greater ability to resuscitate patients from shock, few people today died of hypovolemic shock. However there still exists an inadequate splanchnic perfusion, especially gut ischemia, despite apparent normalization of global hemodynamic parameters. Clinical and experimental studies have implicated gut hypoperfusion as an important inciting event which contributes to gut origin sepsis and multiple organ dysfunction[1-10]. To improve gut perfusion, thus averting compensated shock, is still an important goal of resusucitation of shook[11,12].Anisodamine and dobutamine are commonly used as antishock drugs,as they can improve the microcirculation flow and splanchnic perfusion[13-16].Anisodamine,an anticholinergic drug extract from a Chinese herb Anisodus tanguticus, also processes many other beneficial effects such as inhibition of thromboxane synthesis and protection of cell from reperfusion injury[17-20].Some researches indicated that anisodamine and dobutamine augmented gut perfusion during the shock[21,22],but there was no report concerning their intraluminal effects on mucosal blood flow and metabolism in the gut. The purpose of this study is to investigate the effects of local administration of anisodamine and dobutamine on mucosal blood flow and $PrCO_2$ in a gut ischemia-reperfusion (I/R) rat model.

MATERIALS AND METHODS

Animal model

Male Sprague-Dawley rats weighing 350-450 grams were employed after acclimatization to the experimental environment. Rats were fasted overnight but allowed free access to water.Anesthesia was induced and maintained with 2% isoflurane and body temperature maintained at 37℃ by the use of a warming blanket. Through an upper midline laparotomy, a segment of jejunum measuring 16cm in length was isolated 5cm distal to the ligament of Treitz with preservation of its mesentery. The isolated loop was closed at both ends with 3-0 silk ligatures[23,24]. The superior mesenteric artery (SMA) was isolated at its origin and clamped for 60 minutes, followed by release of the clamp and restoration of blood to the intestine for 90 minutes to produce gut ischemia and reperfusion injury (I/R injury). At the time of release of the clamp, either 0.2mg/kg of anisodamine or dobutamine was injected into the jejunal sac. At the conclusion of the experiment, cardiac puncture and exsanguination were used to achieve euthanasia.

Animals were divided into three groups: Group one (*n*=15): I/R + anisodamine + saline; group two (*n*=15): I/R + dobatamine + saline and group three (*n*=10): I/R + saline as control.

Measurement of mucosal blood flow

A Teflon-coated laser optic flow probe (Peri flux PF409, flexible probe with 0.25mm fiber separation) was inserted through a small enterotomy at the proximal end of the jejunal sac and it was positioned along the antimesenteric border of the jejunum to the center of the sac. Mucosal blood flow was continuously recorded with a laser Doppler flow monitor (Peri Flux 4001 Master; Perimed, Jaarnfalla, Sweden). Blood flow measurements using Laser Doppler flow meters are not absolute but rather indicate flow in arbitrary perfusion units. Measurements were taken as the average flow over a five-minute period following an initial 30 minute period of stabilization. The quality of the signal was monitored by visualization on the computer screen so that motion artifact and noise were excluded from measurement[25,26].

Measurement of PCO_2 ($PrCO_2$)

In the same animal, a 5F saline tonometer was inserted through a small enterotomy at the distal end of the sac and positioned to the center of the sac. The system was allowed to equilibrate for 30 minutes at which time a baseline $PrCO_2$ measurement was obtained by discarding the first 0.3ml saline from the tonometer balloon and using the remaining 0.7ml for analysis (model 1610 pH/blood gas analyzer, Milano,Italy), Regional PCO_2($PrCO_2$) was calculated using the following formula: $PrCO_2$=measure PCO_2×EF. EF=equlibration factor, and based on the equilibration period for saline which gained from the handbook[27-29].

Doppler measurements and $PrCO_2$ determinations were made every 30 minutes throughout the experimental period.

Statistics

Data were reported as mean ±SEM and were analyzed by one-way analysis of variance (ANOVA)or student *t* test, significance was set at $P<0.05$.

RESULTS

Laser doppler flow

Table 1 showed the effects of anisodamine and dobutamine on gut mucosal blood flow. Laser Doppler baseline flow(arbitrary units)was not different among groups. Flow dropped significantly during ischemia, with a reduction to 12% of baseline level,but notably not down to zero.With reperfusion,flow increased over time in all groups ($P<0.05$)but did not reach baseline by 90 minutes. When compared to saline group, mucosal blood flow were higher in the anisodamine and dobutamine groups ($P<0.05$) throughout the reperfusion period. Blood flow was also significantly higher at 90 minutes after reperfusion in anisodamine group compared with dobutamine animals($P<0.05$).

Table 1 Effects of anisodamine and dobutamine on gut mucosal blood flow (%)

Goups	B	I_{60}	R_{30}	R_{60}	R_{90}
Anisodamine	98±3.8	14±3.9	$44±3.3^{ab}$	$57±5.0^{ab}$	$64±3.3^{abc}$
Dobutamine	100±5.2	18±2.1	$48±4.1^{ab}$	$56±4.7^{ab}$	$56±4.2^{ab}$
Saline	103±6.9	16±3.4	$37±2.6^{a}$	$45±2.7^{a}$	$48±3.4^{a}$

Mean ± SEM; $^{a}P<0.05$, *vs* I_{60}; $^{b}P<0.05$, *vs* saline; $^{c}P<0.05$, *vs* Dobutamine;B, baseline;I_{60},ischemia 60 minutes;R_{30},reperfusion 30minutes;R_{60},reperfusion 60 minutes;R_{90}, reperfusion 90 minutes.

Tonometry $PrCO_2$

Table 2 depicts jejunal $PrCO_2$ during I/R. Jejunal $PrCO_2$ did not differ in baseline among the groups, but it was significantly increased at 60 minutes of ischemia in all groups, amounting to 204% of baseline level. With reperfusion, $PrCO_2$ dropped over time in all groups($P<0.05$), but did not reach the baseline. When compared with saline group, $PrCO_2$ values were lower in the anisodamine and dobutamine groups ($P<0.05$) throughout reperfusion period. There were no significant differences between anisodamine group and dobutamine animals at 30 and 60 minutes of reperfusion,but by 90 minutes of reperfusion anisodamine administration resulted in a significantly lower $PrCO_2$ than dobutamine($P<0.05$).

Table 2 Effects of anisodamine and dobutamine on $PrCO_2$ (mm Hg)

Goups	B	I_{60}	R_{30}	R_{60}	R_{90}
Anisodamine	28±2.2	55±3.9	$41±3.1^{ab}$	$38±3.7^{ab}$	$34±2.1^{abc}$
Dobutamine	31±3.8	61±7.8	$44±3.0^{a}$	$40±2.1^{ab}$	$39±3.0^{ab}$
Saline	26±2.5	57±5.4	49±3.7	$47±3.8^{a}$	$46±3.4^{a}$

DISCUSSION

Both laboratory and clinical studies have demonstrated that splanchnic perfusion remains significantly impaired following resuscitation in traumatic, hemorrhagic and septic shock[30-33]. Intravital video microscopic studies by F1ynn *et al*[34,35] have shown that although inflow and premucosal arterioles return to normal after resuscitation from hemorrhagic shock, there is a progressive arteriolar constriction resulting in a decrease in blood flow. There have been few reports about effects of intraluminal vasoactive agents on gut mucosal blood flow during both ischemia and reperfusion. It has been demonstrated that dobutamine could augment gut microcirculatory blood flow in septic shock[36,37].Observation in extensively burned patients by Sheng, *et al*[22] have shown that intravenous administration of anisodamine 12 hours postburn resulted in a significant elevation in gastric pHi and decrease in plasma level of TNF. In a porcine model of 30% TBSA full-thickness burn, anisodamine (0.4mg/kg)infused intravenously for one hour could increase portal blood flow, and it showed a positive correlation with intestinal pHi[38]. The use of Laser Doppler-measured tissue perfusion is a reliable technique that has been validated in the assessment of gastrointestinal mucosal blood flow, and the results were shown to correlate with other techniques of measurement of local blood flow[33,38]. Recently, its use as a clinical tool for assessing jejunal mucosal perfusion had also been demonstrated[39]. In this study with advanced Laser Doppler technique, we further demonstrated the beneficial effect of anisodamine on gut mucosal perfusion during I/R injury in comparision with dobutamine. The results showed that intraluminal anisodamine or dobutamine did increase mucosal blood flow throughout reperfusion as compared to intraluminal saline only. Blood flow augmentation was reflected by lower jejunal $PrCO_2$ measurements with intraluminal anisodamine or dobutamine. The most interesting finding was that there were significantly lower jejunal $PrCO_2$ and higher mucosal blood flow in anisodamine group than those in dobutamine at 90 minutes of reperfusion, suggesting that anisodamine had a more lasting effect on mucosal perfusion than dobutamine.

Tissue CO_2 gas tonomery provides an indirect measurement of perfusion and /or mucosal metabolic stress. Gastric tonometry, in particular, has been suggested as a tool to monitor splanchnic perfusion in experimental animals and critically ill patients[40-43]. Though studies have demonstrated low gastric intramucosal pH (pHi) is a good predictor of poor outcome in critically ill patients, no improvement in outcome has been ascertained when patients are resuscitated based on the results of gastric tonometry[44-46]. In this study we used 5F gut tonometry, in which the air pocket can be matched with rat small bowel sac, and the results are more accurate than gastric tonometry in detecting gut perfusion and metabolism[47-50]. In our study significant increases in gut $PrCO_2$ following gut I/R were found, which could be markly reduced by intraluminal anisodamine or dobutamine. These results might suggest that anisodamine or dobutamine is capable of augmenting mucosal blood flow, thus improving gut mucosal metabolism.

In conclusion, we have demonstrated in this laboratory model of gut ischemia and reperfusion that intraluminal anisodamine or dobutamine could augment mucosal blood flow, alleviate mucosal acidosis, improve metabolism in mucosal cell. These results provided reliable evidence to clinicians to adopt anisodamine or dobutamine in the treatment of splachnic hypoperfusion, espcially gut mucosal blood flow reduction following traumatic or burn shock.

Abstract

AIM: **Common bile duct microlithiasis (CBDM) is found in majority of patients with acute biliary pancreatitis (ABP) and no CBD stones in fluoroscopy during urgent ERCP. It is unclear, however, weather CBDM is a cause or the result of the disease. This prospective study was done to investigate the presence and density of CBDM in patients with ABP, when endoscopic retrograde cholangiopancreatography (ERCP) was done in different periods from the onset of the disease.**

METHODS: **One hundred fifty one consecutive patients with ABP and no CBDS on ERCP, performed as an urgent (<24h of admission) procedure, (101 - with gallbladder stones, 50 post-cholecystectomy patients), treated during last 4 years were prospectively included to the study. The presence and density of CBDM (cholesterol monohydrate crystals-CMCs and calcium bilirubinate granules-CBGs) in bile collected directly from common bile duct during ERCP was prospectively calculated according to Juniper and Burson criteria. High density of crystals was considered,when we found >10CMCs and/or >25 clusters of CBGs on 1 slide.**

RESULTS: **CBD microlithiasis was present in given number of patients: on d1-30/34 (88.2%), on d2 41/49 (83.7%), on d3-23/33 (69.6%), on d4-7-24/35 (68.6%) [*P* for trend=0.018]. In patients with CBD microlithiasis the high density of crystals was observed in given number of patients:on d1-27/30 (90%), on d2-34/41 (82.9%), on d3-18/23 (78.3%), on d4-7-16/24 (66.7%)[*P* for trend=0.039].**

CONCLUSION: **In patients with ABP and no CBDS on ERCP, CBD microlithiasis is observed in the majority of patients, especially during the first day of the disease. Density of CBD microlithiasis is the highest in the first day of the disease. This suggests that CBD microlithiasis can be the cause and not the result of ABP.**

INTRODUCTION

Some cases of acute biliary pancreatitis (ABP) are due to the biliary microcrystals (microlithiasis). The pathogenesis of acute pancreatitis (AP) produced by biliary crystals is unknown. It is probably related to the temporary impaction or migration of very small stones or clusters of crystals at the level of the ampoule of Vater. The mechanism of such pancreatitis is presumably the same as that when "normal size" biliary stones are impacted in the ampoule of Vater in the onset of the disease[1, 2]. Literature on this problem started with simple case reports[3-5]. In the end of 1980's and the beginning of 1990's some larger series of patients with acute pancreatitis possibly associated with biliary sludge or microlithiasis were presented[1, 6-10]. However, most of patients presented in these papers suffered from acute pancreatitis classified as so called "idiopathic" pancreatitis, as they do not bear gallbladder sludge, gallbladder stones and they did not have the history of cholecystectomy.

The methodology of these reports was based on the microscopic bile examination (MBE), which was a widely used technique in the diagnosis of gallstone disease before the advent of modern imaging procedures such as ultrasonography[11, 12]. Almost all authors studied gallbladder bile obtained after stimulated gallbladder contractions via either blindly or endoscopicaly placed tube at the level of the papilla of Vater. Even in one of the best papers by Lee *et al*[6] the common bile duct bile has been investigated only in less than half of the patients. In the rest of cases the stimulated gallbladder bile was the matter of study. The minority of authors studied the bile obtained directly form the biliary tree on ERCP or via the T-tube placed in common bile duct during cholecystectomy with choledochotomy[13, 14].

To our knowledge the study of common bile duct microlithiasis (CBDM) in patients with gallbladder stones or prior cholecystectomy and no CBD stones on ERCP is scanty[13, 14]. In our previous paper we have found CBDM in vast majority of ABP cases (76%)[15]. One can argue, however, that the MBD microlithiasis can be the result and not the cause of the disease-CBD microlithiasis can be produced in the biliary tree due to the obstructed outflow of bile. This cholestasis can be related to the compression of distal common bile duct stone made by swollen pancreatic head during acute pancreatitis. Thus, we conducted the study of the presence and density of CBD microlithiasis in patients with ABP and no CBD stones on ERCP performed in the different periods from the onset of the disease. The aims of our work were to study the presence of CBD microlithiasis in different periods form the onset of the acute biliary pancreatitis, and the density of CBD mirolithiasis in patients with microlithiasis in different periods from the onset of acute biliary pancreatitis.

MATERIALS AND METHODS

Materials

The study had been performed between September 1993 and January 1997 in the Department of Gastroenterology of the Silesian Academy of Medicine in Katowice, which is the reference centre for gastrointestinal diseases for approximately 4 million inhabitants area. Informed consent was obtained from all the subjects. Protocol of the study was approved by the local Ethics Committee in February 1993.

Methods

ERCP was done urgently - up to 24 hours of admission. Only patients with no more than 7 days from the onset of ABP were included to the study. We included patients with gallbladder stones or patients previously cholecystectomized. Patients without suspected biliary pathology [e.g. with pancreas divisum or with metabolic

(hyperlipidaemia) acute pancreatitis] were excluded. Patients with alcoholic pancreatitis were also excluded. The diagnostic criteria for ABP were (both criteria must be present): (1) Typical clinical picture (epigastric pain), elevated levels of pancreatic enzymes (exceeding at least 3 times upper normal range), typical patterns of pancreatitis in abdominal imaging methods (ultrasonography, CT-scan), and (2) History of gallstones (e,g, cholecystectomy), positive laboratory criteria of biliary etiology of acute pancreatitis according to Goodman *et al*[16], gallstones on ultrasonography.

After the cannulation of the orifice of the ampoule of Vater was verified and the diagnostic catheter was placed in the common bile duct by injection of contrast medium (Meglumine diazotriacetas, Uropolinum, Polfa, Poland), the examiner confirmed that there were no "macroscopic" bile duct stones on fluoroscopy and X-ray films. Then the CBD bile was collected by manual suction through the standard ERCP catheters (Olympus and Boston Scientific companies) to the sterile syringe attached to the proximal end of the catheter. Approximately 5mL of bile was achieved from every patient. All the following procedures were done in the sterile conditions. Immediately after the collection the bile sample was divided into two parts of the same volume. One part was examined immediately, while the second one was incubated in the temperature of 37℃ for 24h. The presence of biliary microlithiasis was recorded as the combined result from both microscopic bile examinations. We established the diagnosis of CBD microlithiasis when at least we found crystals (immediately after incubation or on both microscopic bile examinations). The patients did not receive any antibiotic treatment prior to ERCP that can influence microscopic bile examination due to the drug precipitation in the bile.

The sample of bile was centrifuged 12 000 $r \cdot min^{-1}$ for 10 min. Centrifugation enables to separate bile from the contrast medium we used during ERCP. The contrast medium floated over the bile after centrifugation. The sediment found on the bottom of the bile was than examined under direct and polarising light microscope, equipped with a heating stage. The same was done on the next day with the second portion of incubated bile. Three slides with bile sediment were examined for each sample. We prospectively used criteria of Juniper and Burson for counting crystals, as shown in Table 1[17]. Cholesterol monohydrate crystals (CMC) were identified on the basis of their rhomboid shape and their birefringence under cross - polarisation. Calcium bilirubinate granules (CBG) were identified on the basis of their reddish - brown colour and tendency to aggregate[17]. The number of crystals were graded as 1 - 4 when present and 0 when absent. Grades 1 - 4 corresponded to the grades specified by Juniper and Burson[17]. A positive result (at once, after incubation or both) for CMCs was taken if graded 1 - 4, and for CBGs if graded 3 -4 (> 25 crystals per slide). The diagnosis of high density of crystals was done only if we have found > 10 CMCs and/or > 25 CBGs per one slide - as proposed by Juniper and Burson[17]. These criteria were derived directly from the original paper of Juniper and Burson, who discovered, that some cases with small number of calcium bilirubinate granules (graded 1 and 2, < 25 crystals per slide) were healthy and did not present cholelithiasis. All the bile samples were examined by one of the investigators, who were unaware of any clinical information.

The data were prospectively collected in the purpose-made database and analysed with the statistical package STATISTICA 5.0PL. The results are expressed as $\bar{x} \pm s$. Unpaired t Student tests (Fisher's exact test - two-sided or Mann-Whitney's test when needed) and chi - 2 test when appropriate were used for statistical analyses. The level < 0,05 was considered as statistically significant.

RESULTS

Demographic clinical and biochemical data of all the patients are shown in Table 2. The comparison of the characteristics of the patients with and without microlithiasis is given in the Table 3. There were no differences in the sex, mean age, the presence of gallbladder stones, mean BMI, mean levels of biochemical cholestasis (bilirubin, alkaline phosphatase and alanine transaminase) of patients in both subgroups. Presence and density of common bile duct microlithiasis (CBDM) in patients with acute biliary pancreatitis and no CBD stones on ERCP done in different periods from the onset of the disease are presented in Figures 1 and 2, respectively. The results showed statistically significant decrease in the presence of microlithiasis, when the patient moved away from the onset of acute biliary pancreatitis. We observed also the fall in the presence of high density of microlithiasis. The highest density was in the first day of acute biliary pancreatitis, falling down in next days of the disease. These results also achieved the statistical significance.

Men	27	22	0.066
Age[years] (mean)	52.4	54.2	0.623
Gallbladder stones present	81	20	0.770
BMI (mean)	27.8	28.7	0.490
Number of cases with Goodman's criteria of ABP present (at least 1 criterion)	106	23	0.670
Bilirubin [($mol \cdot L^{-1}$)] (mean)	54.4	49.3	0.607
Alkaline phosphatase [$IU \cdot L^{-1}$]] (mean)	213.7	178.9	0.148
Alanine transaminase [$IU \cdot L^{-1}$]] (mean)	350.4	383.4	0.577

Results of microscopic bile examination (types of detected crystals) are shown in Figure 3. Calcium bilirubinate granules present alone (50% of cases with microlithiasis) were found the most frequently on MBE (Figure 3). CBGs together with CMCs were present in 43. 2% cases with microlithiasis. Cholestrol monohydrate crystals were present alone only in 6.8% of patients with microlithiasis. We did not record any case of microspherolites.

DISCUSSION

Duodenal bile fractions was microscopically checked since decades in search for gallstone disease[11, 12, 17]. This method has shown the sensitivity and specificity around 70-90%. The microscopic examination of stimulated gallbladder bile collected via the tube, placed either under radiological guidance or endoscope in the duodenum at the level of the papilla has been shown to be reliable in the diagnosis of gallstone disease as well[18, 19]. Both methods of MBE had lost its attractivity after the advent of ultrasonographic examination of the gallbladder and bile ducts. However, the bile is still examined in some patients, especially with acute pancreatitis of uncertain origin[1,3,4-10]. Common bile duct bile has been microscopically examined in patients with endoscopically placed naso - biliary tube or surgically placed T - tube in CBD[13]. Sensitivity of 100% of such microscopic examination for CBD stones recognition was reported[13].

In another study common bile duct bile was obtained directly from the duct during ERCP[14]. We has shown the sensitivity of 85% in the diagnosis of choledocholithiasis[14] and the same methodology was used in this study.

Our study was designed to find out the presence and density of CBD microlithiasis in patients with acute biliary pancreatitis and no CBD stones on ERCP, when ERCP was done in different periods from the onset of the ABP. ABP was diagnosed according to the typical abdominal symptoms of acute pancreatitis, ultrasound and CT changes of pancreatic gland and the presence of gallbladder stones or prior cholecystectomy. All the patients presented also a significant (more than 2× N) elevation of at least one of biochemical markers of cholestasis (alkaline phosphatase, alanine transaminase, and bilirubin).

ERCP is one of the diagnostic standards in choledocholithiasis. This method can give false (positive and negative) results, but the sensitivity and specificity of the method is believed to be above 90-95%[20]. In this respect, we can exclude almost all cases with CBD stones during fluoroscopy with high confidence that our group of patients contains really no cases with CBD stones.

No one of the tested biochemical parameters achieved statistical significance as a marker of microcrystals (Table 2). Similar values of biochemical data in patients with or without microlithiasis can be explained by the finding of signs of recent stone passage through the papilla of Vater in some patients. Swollen papilla with enlarged (usually quite easy to cannulate) reddish orifice, sometimes with a drop of blood, were found on ERCP in some ABP patients, mostly without microlithiasis. In these patients elevated biochemical markers were seen, as in patients with microlithiasis and without recent passage signs. The absence of microlithiasis in patients with signs of recent passage of stone may be explained so called "flushing out" mechanism after decompression of bilio - pancreatic duct system. This deserves further studies.

Microcrystals within the biliary tree are present intermittently[19]. We observed very high percentage of microlithiasis in studied group of patients with ABP. This can be explained by the fact that majority of cases were admitted and ERCP performed on first three days of the disease. In previous studies, done few weeks or even months after the acute episode of acute pancreatitis, the percentage of cases with microlithiasis was lower[3-5,7-9,11,12,18].

The main idea behind our study was to exclude the biliary microlithiasis as the result of acute pancreatitis. The presented results confirmed our presumption, that the percentage of cases with microlithiasis falled down, when the beginning of the acute pancreatitis was becoming distant. The percentage of patients with high density of microlithiasis also falls down with time. We can speculate that the high density microlithiasis was potentially more harmful in the sense, that it can easily aggregate at the level of the orifice of the ampoule of Vater, leading to the obstruction of the outflow of pancreatic juice. It suggests, that microlithiasis is the cause and not the result of the acute pancreatitis.

Results of microscopic bile examinations, found in this study (Figure 3), confirm previous observation, that calcium bilirubinate granules (CBG) are more frequently found in patients with AP[1, 6, 7]. CBG were present alone (50%) or in association with CMC (43.2%) of all cases with microlithiasis. CMC were found alone in only 6.8% of cases. Previously CMCs were also less frequently found in endoscopically obtained duodenal bile, than in gallbladder bile in the same patient[21].

In our opinion one important etiopathogenetic conclusion comes from the study: microlithiasis can provoke acute biliary pancreatitis. Crystals can irritate the papilla, leading to inflammation of the papilla and obstructed outflow of pancreatic juice. If very high percentage of patients with microcrystals is present in the first day of ABP and if the high percentage of high density microlithiasis is also present in the first day of the disease, it seems logical to perform next step - the investigation of the influence of endoscopic sphincterotomy in such patients.

List of abbreviations

ABP	- acute biliary pancreatitis
CBD	- common bile duct
CBDS	- common bile duct stones
CBDM	- common bile duct microlithiasis
CMCs	- cholesterol monohydrate crystals
CBGs	- calcium bilirubinate granules
ERCP	- endoscopic retrograde cholangiopancreatography

Abstract

AIM: **Cytokine release by macrophages critically determines the type of immune response to an antigen. Therefore, we studied hepatitis C virus (HCV)-specific induction of interleukins-1β, -10, -12 (IL-1β, IL-10, IL-12), and tumor necrosis factor-α (TNF-α) in monocytes.**

METHODS: **Intracellular cytokine expression was studied by flow cytometry in 23 patients with chronic hepatitis C, 14 anti-HCV seropositives without viremia and 11 controls after stimulation of peripheral blood mononuclear cells with recombinant core, NS3, NS4, NS5a and NS5b proteins.**

RESULTS: **Patients with HCV viremia revealed greater spontaneous expression of IL-1β, TNF-α, and IL-10. Furthermore, greater than twofold higher IL-10 expression was induced by the HCV antigens in chronic hepatitis C than in the other two groups ($P<0.05$). In contrast, neither IL-12 nor TNF-α was induced preferentially.**

CONCLUSION: **In chronic hepatitis C antigen-specific cytokine induction in monocytes is apparently shifted towards predominant IL-10 induction - not counterbalanced by antiviral type 1 cytokines. This may contribute to persistent viral replication.**

INTRODUCTION

Resistance or susceptibility to viral infections is critically linked to cytokine release, which can be polarized towards a type 1 (IFN-γ, TNF-α, IL-2) or type 2 (IL-4, IL-10, IL-13) pattern in helper as well as cytotoxic T lymphocytes[1]. Type 1 and type 2 T lymphocytes are not derived from different lineages but develop from the same precursors, and their differentiation is influenced by the environment during priming. The most important signals are cytokines themselves: IL-12 produced by activated macrophages is the principal cytokine inducing type 1 responses, whereas the development of type 2 T lymphocytes is induced by IL-4 and IL-10.

Hepatitis C virus (HCV) infection frequently leads to persistent viral replication, which may be facilitated by selective alterations in the host's immune response[2]. In this context, studies of T cell functions in patients with chronic hepatitis C have indicated an inappropriately low production of antiviral type 1 cytokines in response to HCV antigens[3-7] possibly facilitating persistent infection. However, it is not clear, whether the imbalance in the cytokine pattern is due to direct alterations of T cell function or a consequence of altered T cell priming. Because of their critical role for the type of immune reaction triggered in response to an antigen, we used flow cytometric detection of intracytoplasmic cytokines to study at the single cell level the HCV-specific induction of IL-1β, IL-10, IL-12 and TNF-α in peripheral blood monocytes.

MATERIALS AND METHODS

Patients

Three groups of patients were included into this study: Group 1 consisted of 23patients with chronic hepatitis C (male, *n*=20; female, *n*=3; median age 33, range 21-61), elevated liver enzymes and detectable HCV-RNA in the serum. The mean virus load was 6. 3×10^6 copies/mL (SD 1.0×10^6 copies/mL) (Quantiplex™ HCV RNA 2.0 assay, Chiron, Emeryville, CA). Group 2 consisted of 14 carefully selected patients with previous HCV infection (male, *n*=12; female, *n*=2; median age 28.5, range 18-63), who had consistently normal aminotransferases without detectable viral RNA on repeated examination over at least 2 years. Finally, 11 anti-HCV negative volunteers (male, *n*=5; female, *n*=6; median age 30, range 24-66) served as a control group (group 3).

There were no significant differences between the two anti-HCV groups with respect to total immunoglobulin levels, and all were free from cryoglobulins or autoantibodies. None of the individuals in this study had hepatitis B virus or human immunodeficiency virus co-infection. The study was approved by the local ethical committee and conformed to the ethical guidelines of the 1975 Declaration of Helsinki.

Diagnosis of HCV Infection

HCV antibodies were detected with a microparticle enzyme immunoassay (MEIA) (Axsym, Abbott, Wiesbaden, Germany) according to the instructions of the manufacturer. Positive results were confirmed by dot immunoassay (Matrix, Abbott, Wiesbaden, Germany). HCV RNA was detected with a nucleic acid purification kit (Viral Kit, Qiagen, Hilden, Germany) followed by reverse transcription and nested polymerase chain reaction as described elsewhere[8]. Quantitative determination of HCV RNA copies was done via branched DNA technology (Chiron, Emeryville, CA). In group 1, genotypes of the infecuing HCV strains were determined by the INNO-LiPA HCV II test (Innogenetics, Zwijndrecht, Belgium) except one patient, who could not be genotyped. This group revealed

the following isolates: 1a (n=8), 1b (n=9), 2b (n=1), 3a (n=1), and mixed (n=3; genotypes 1b/2b; 2a/2c; 4c/4d).

Patients of group 2 were characterized by genotype-specific antibodies to NS4 (Murex, Abbott Wiesbaden, Germany). Serotypes 1 and 4 were found in 10 and 1 patients, respectively. Three patients had indeterminate serotypes.

HCV antigens

The purified recombinant proteins [r-core (truncated): aa 1-115, r-NS3: aa 1007-1534, r-NS4: aa 1616-1862, r-NS5: aa 2007-2268] derived from the HCV-1 prototype sequence[9] were purchased from Mikrogen, Munich, Germany. The bacterial lipopolysaccharide content of the proteins was between 4.0-20 pg/μg recombinant protein as determined by the Limulus assay. Lipopolysaccharide from *E. coli* OH101 (Sigma, Munich, Germany) was used in the control experiments.

Antibodies

Fluoresceinisothiocyanate (FITC)- and phycoerythrin (PE)-labelled antibodies were purchased from the following companies: FITC- and PE-labelled -anti-CD14 (mouse IgG2b, clone MÖP9) from Becton Dickinson (Heidelberg, Germany); FITC- and PE-labelled anti-IL-1β (mouse IgG1, clone H9.5) was purchased by Holtzel Diagnostica (Cologne, Germany). Anti-IL-10/PE (rat IgG2a, clone JES3-19F1), anti-IL-12/PE (mouse IgG1, clone C11.5.14), anti-TNF-α/PE (mouse IgG1, clone MAb11) as well as appropriate isotype controls from Pharmingen (Hamburg, Germany). Unlabelled mAbs for blocking experiments were purchased from Pharmingen (Hamburg, Germany) except for IL-1β that was a gift of Holtzel Diagnostica (Cologne, Germany).

Cells and cell culture

PBMC (1.1×10^6/ml) isolated from fresh EDTA blood by Ficoll density-gradient centrifugation (Biochrom, Berlin, Germany) were resuspended in low endotoxin level culture medium (RPMI 1640, Biochrom, Berlin, Germany) containing 10% autologous human serum, 100 units/ml penicillin, 100 units/ml streptomycin and incubated at 37℃ with 5% CO_2 in 96 well microtiter plates (Sarstedt, Berlin, Germany) in the presence of recombinant HCV proteins (1μg/ml) or LPS (10-200ng/ml). Kinetic experiments showed that the antigen-specific cytokine induction indicated a maximum after 12 hours of stimulation. Further experiments revealed 1.0μM monensin (Sigma, Munich Germany) for 12hours to be optimal to enhance the signal/noise ratio as well as to exclude relevant toxicity[10-12].

Dual-colour flow cytometry for immunophenotyping and intracytoplasmic staining of cytokines

CD14 and iotracytoplasmic cytokines were detected by direct immunofluorescence using a paraformaldehyde (PFA)-saponin procedure with 4% PFA as fixative and 0.2% saponin for permeabilisation. In brief, cultured cells were washed twice in Hank's balanced salt solution (HBSS) (Gibco, Eggenstein, Germany) and stained for the surface markers (20 minutes incubation at 4℃ in the dark). After one further wash, the cells were fixed in ice cold HBSS containing 4% PFA for 5 minutes and washed again. Cells were resuspended in HBSS containing 0.2% saponin (saponin buffer). Then cytokine specific antibodies diluted in saponin buffer were added at a concentration of 0.5-3.0μg/ml and incubated for 30 minutes at room temperature in the dark. Cells were washed in saponin buffer and analyzed by dual-colour flow cytometry on a FACSort flowcytometer (Becton Dickinson, Heidelberg, Germany). Forward and side scatter as well as gating for $CD14^+$, cells were used to identify monocytes. The data were analyzed with the CellQuest(software (Becton Dickinson) after counting 5000 $CD14^+$ cells. All experiments were performed in triplicate.

To ensure specificity of the cytokine staining procedures, the binding of each mAb was blocked with an excess of unlabelled mAb.

Statistics

Results are given as median and range. Differences between the groups were analyzed by the Kruskal-Wallis test, Mann-Whitney U test and Wilcoxon signed rank test, as appropriate. All calculations were performed on a personal computer with Statview 4.5 software (Abacus Concepts inc., Berkeley CA, USA). P values <0.05 were regarded as significant.

RESULTS

Using flowcytometric detection of intracytoplasmic cytokines in combination with CD14 staining, we were able to specifically measure spontaneous as well as HCV antigen-induced production of IL-1β, IL-10, IL-12 and TNF-α in peripheral blood monocytes (Figure 1). Following stimulation with LPS, intracytoplasmic expression of the cytokines did not show statistically significant differences between the study groups for the cytokines with the exception of IL-1β, which was higher in patients with chronic hepatitis C when compared to the controls (Table 1). Cytokine production after 12 hours of HCV-specific stimulation together with the corresponding spontaneous and LPS-induced production is summarized in Table 1.

With respect to spontaneous production of IL-1β, TNF-α, IL-10, and IL-12, there was considerable individual variability which was most pronounced in the group with chronic hepatitis C. The numbers of monocytes with detectable spontaneous production of IL-12 were low in general (0.1-5.1%) and on average not significantly different between the three study groups. In contrast, average numbers with detectable spontaneous production of IL-1β, TNF-α, and IL-10 were higher in patients with chronic hepatitis C than in aviremic anti-HCV seropositives. However, due to considerable inter-individual variations, these differences between the groups reached statistical significance only for IL-1β and IL-10 (P<0.05).

Antigen-specific stimulation of peripheral blood mononuclear cells resulted in increased numbers of monocytes with production of IL-1β, TNF-α, IL-10, and IL-12 in each study group for most of the tested HCV proteins (Table 1). However, after stimulation with the HCV proteins core, NS3, NS4, NS5a, and NS5b, the numbers of IL-1β and IL-10 producing monocytes were at least twofold higher in patients with chronic hepatitis C than in aviremic anti-HCV seropositives and the controls (P<0.05 for each HCV protein). In contrast, statistically significant differences (P<0.05) in the numbers of TOF-α and IL-12 producing monocytes between patients with chronic hepatitis C and the other groups were only seen after stimulation with HCV core and NS5b (Table 1). The marked difference in the balance between IL-1β and IL-10 producing monocytes,and TNF-α and IL-12 producing ones among the patients with chronic hepatitis C is illustrated in Figure 2, which shows the stimulation experiments with recombinant NS4 as a representative example. Since stimulation of monocytes was performed in the presence of T cells, we undertook control experiments with untouched isolated monocytes. When these purified monocytes were stimulated with HCV antigens or LPS, the cells showed a similar behaviour although the number of cytokine producing macrophages was strongly reduced compared to the PBMC assays (data not shown).

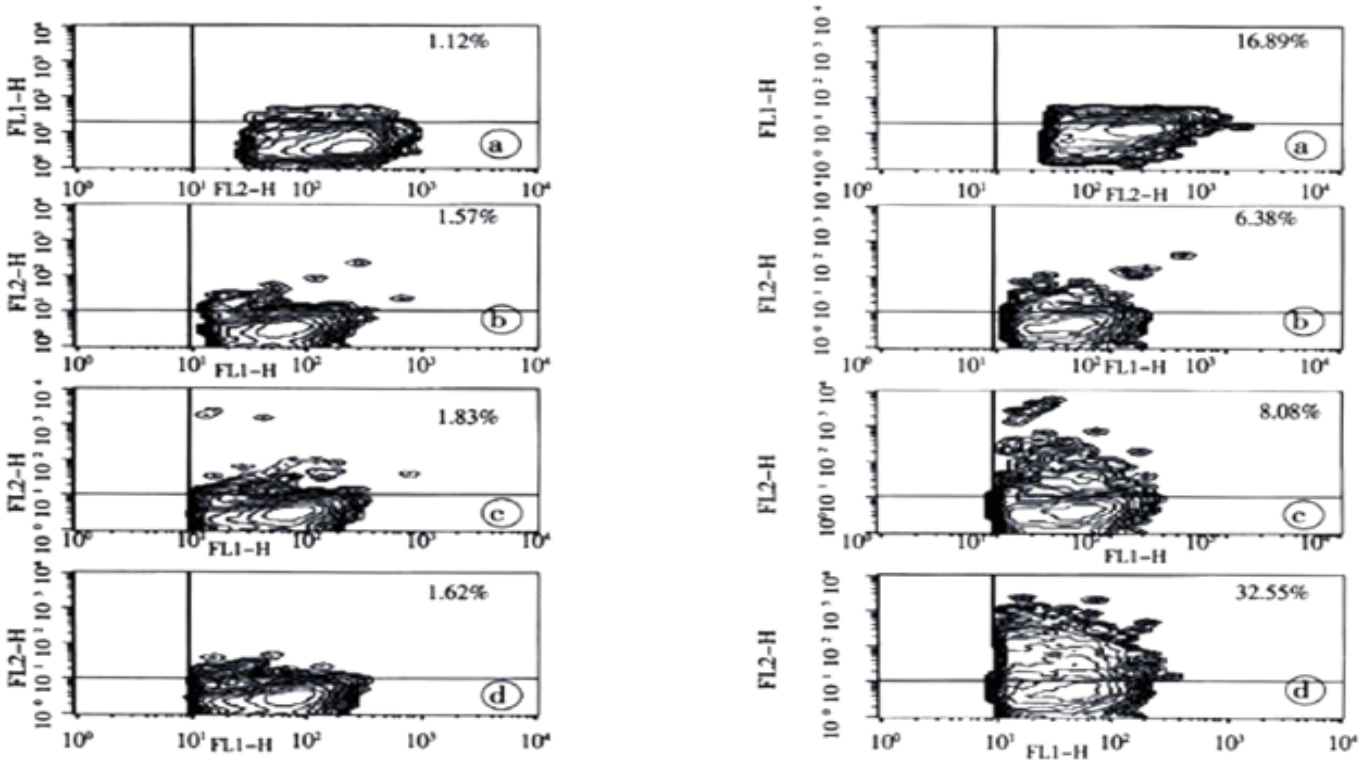

Figure 1 Contour plots of cytokine expression in CD14+ cells. These contour plots show representative experiments for the detection of spontaneous expression (buffer control, left column) and HCV NS5b-induced expression (1μg/mL, right column) of IL-1β (a), IL-10 (b), IL-12 (c) and TNF-((d) in peripheral blood CD14+ monocytes of patient # 23 with chronic hepatitis C at 12 hours of incubation.

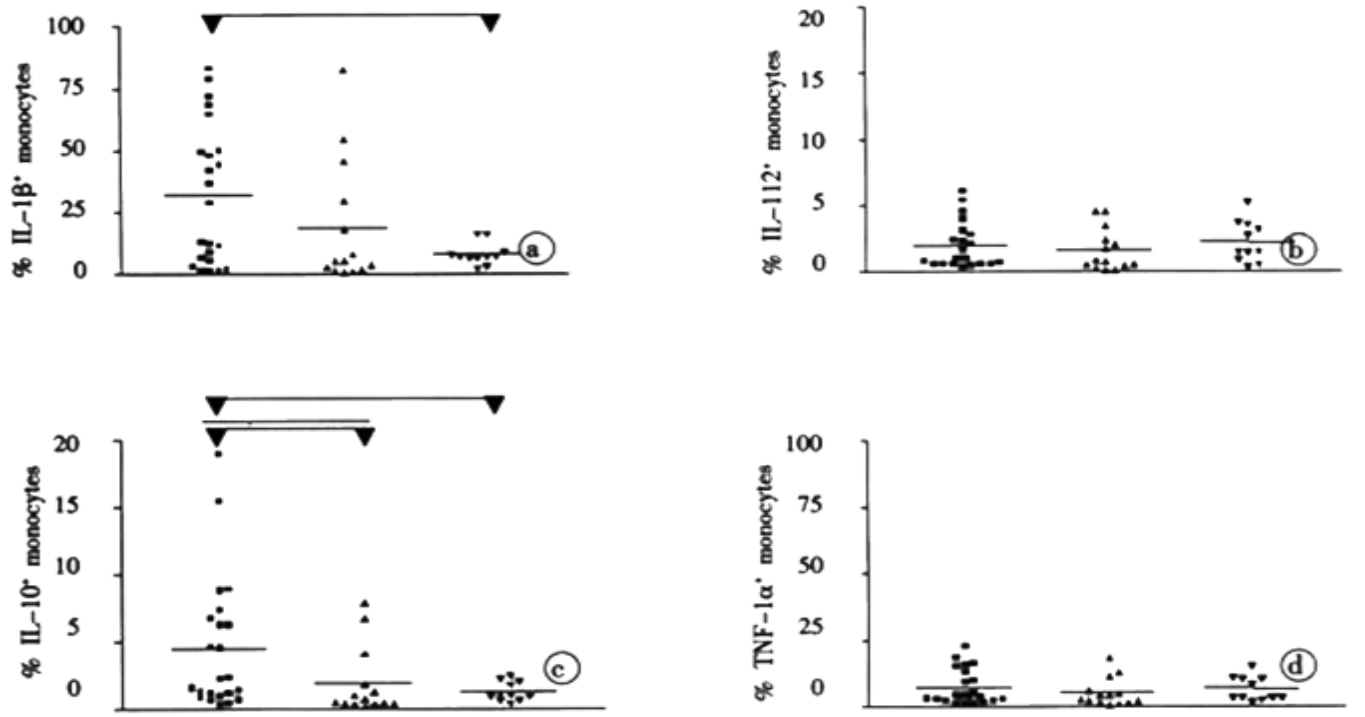

Figure 2 Induction of cytokines by the HCV NS4 protein. The graph displays the fractions of IL-1β (a), IL-10 (b), IL-12 (c) and TNF-((d) producing monocytes 12 hours after stimulation with recombinant NS4 protein (1μg/mL) for patients with chronic hepatitis C (filled squares), aviremic anti-HCV seropositives (upward triangles), and non-HCV related controls (downward triangles). Each dot represents the mean percentage of a single patient obtained from triplicate experiments. The horizontal bar gives the mean of each group.

DISCUSSION

Impaired function of macrophages has been described repeatedly in infection with HCV and also the closely related Dengue virus[13-17]. Our study adds to these observation that in chronic hepatitis C altered macrophage function may also comprise the pattern of cytokines produced in response to HCV antigens. Of note, the various cytokines appeared to be involved differentially. Despite considerable individual variability, we found significantly greater average numbers of monocytes with spontaneous IL-1β and IL-10 production in patients with chronic hepatitis than that in aviremic anti HCV seropositives or the HCV-naive controls. This finding appears to be compatible with in vivo pre-activation of the monocytes from patients with chronic hepatitis C. However, the numbers of monocytes with spontaneous IL-12 production did not reveal any conspicuous differences between our study groups. Thus far, studies on the cytokine production in hepatitis C have produced conflicting results for macrophages, mainly because monocytes were assessed only indirectly by measuring cytokines in the supernatants of peripheral blood mononuclear cells after stimulation with mitogen or LPS. This flowcytometric study is the first investigation, which provides HCV-specific data for monocytes at the single cell level in a more or less physiological environment that enables natural interactions to take place between the monocytes and other peripheral blood mononuclear cells, e.g. $CD4^+$ T lymphocytes. Control experiments with untouched isolated monocytes showed that these interactions were crucial for an effective cytokine induction. Despite similar behaviour after stimulation the amount of cytokine producing macrophages was strongly reduced (data not shown). With the flowcytometric approach, we could demonstrate that the numbers of IL-$1\beta^+$ and IL-10^+ monocytes increased significantly upon stimulation with the HCV antigens, whereas a similar induction of TNF-α and IL-12 was not observed.

After exposure to the HCV proteins a slight increase in the number of monocytes with expression of IL-1β, TNF-α, IL-10, and IL-12 was also seen in the HCV-naive control group. This finding most likely indicates a non-specific stimulatory effect of the HCV antigens on the monocytes, probably due to small amounts of contaminating endotoxin. Compared to this non-specific effect this results indicate marked (2-7 fold) antigen-specific induction of IL-1β and IL-10 in response to all HCV antigens, but a less prominent induction of IL-12 and TNF-β in response to HCV core and NS5b in the group with chronic hepatitis C.

Similar responses were occasionally seen in few patients of our aviremic anti-HCV seropositive group. However, we cannot exclude completely that HCV replication below the detection limit of PCR technique was present in some of these patients, despite the fact that the group of aviremic anti-HCV seropositives was selected carefully to ensure that these patients had gained immune-mediated control of their HCV infection. Thus persistent low level viremia might be an explanation for the occasional altered cytokine responses in this group.

In general, our findings are in line with a previous report by Kakumu *et al*, who reported increased IL-10 levels but unaltered IL-12 production in mononuclear cells of patients with chronic hepatitis

C[18]. Furthermore, increased spontaneous TNF-α expression in patients with chronic hepatitis C is in line with previous work published by Kishihara and co-workers[19]. As our flowcytometric approach enabled interactions between the monocytes and other immunoregulatory cells, which are important for the generation of antigen- specific responses, it was not unexpected that our results differed from those studies, which used purified monocytes[20]. Thus, we could not confirm reduced numbers of IL-1β and TNF-α monocytes in chronic hepatitis C, as has been reported for purified monocytes from patients with chronic hepatitis C by Mendoza and co-workers[21].

The reasons for altered macrophage functions in chronic hepatitis C are unclear at present. Although HCV RNA has been detected in macrophages of a variable proportion of patients with chronic hepatitis C[22], the reported percentages of HCV-RNA positive monocytes seem to be too low as to explain the altered cytokine induction by a direct infection of the monocytes[23]. Persistent antigenic stimulation due to chronic hepatitis C viremia provides a better alternative explanation. For instance, continued production of HCV antigens may lead to the formation of antigen-antibody complexes, which can bind to Fcγ receptors on immunocompetent cells. Fcγ receptor ligation on monocytes will then result in reversal of macrophage pro-inflammatory responses as IL-10 up-regulation together with a reciprocal inhibition of IL-12 production can result from such Fcγ receptor triggering[24]. Likewise, the blunted TNF-α responses observed in our *in vitro* stimulation experiments are likely to reflect altered immunoregulation, because loss of inducible TNF-α secretion has been well documented in pre-activated monocytes[25].

Irrespective of the underlying cause, altered cytokine production by macrophages in chronic hepatitis C is likely to have important functional consequences. The high proportion of macrophages, which produce IL-1β either spontaneously or after antigen-specific challenge may indicate that these macrophages are pre-conditioned towards pro-inflammatory reactions. However, proinflammatory cytokines required for efficient antiviral responses such as IL-12 and TNF-α show blunted responses to the HCV antigens. On the contrary, cytokine production appeared to be markedly biased towards IL-10 already at the level of the macrophages. Due to the pivotal role of monocytes and macrophages for the initiation of immune responses, the uniform up-regulation of IL-10 in response to HCV antigens, not counterbalanced by IL-12, may explain poor HCV-specific type I cytokine responses, which have been observed repeatedly in chronic hepatitis C[3-7]. Thus, altered cytokine production by monocytes and macrophages might contribute to HCV persistence, because these cells may not support sufficiently effective antiviral immune responses.

Abstract

AIM: **To investigate the serum positive percentage of TT virus (TTV) in patients with chronic hepatitis B or C and the response of the coinfected TTV to interferon (IFN) during IFN therapy for chronic hepatitis B and C.**

METHODS: **We retrospectively studied the serum samples of 70 patients with chronic hepatitis who had received IFN-alfa therapy from January 1997 to June 2000, which included 40 cases of hepatitis B and 30 hepatitis C. All the patients had been followed up for at least 6 months after the end of IFN therapy. The serum TTV DNA was detected using the polymerase chain reaction (PCR) before and every month during the course of IFN treatment.**

RESULTS: **TTV infection was detected in 15% (6/40) of the chronic hepatitis B group and 30% (9/30) of the chronic hepatitis C group. Loss of serum TTV DNA during IFN therapy occurred in 3 of 6 patients (50%) and 6 of 9 (67%) of hepatitis B and C groups, respectively. Seronegativity of TTV was found all during the first month of IFN therapy in the 9 patients. There was no correlation between the seroconversion of TTV and the biochemical changes of the patients.**

CONCLUSION: **TTV is not infrequently coinfected in patients with chronic hepatitis B and C in Taiwan, and more than half of the TTV infections are IFN-sensitive. However, the loss of serum TTV DNA does not affect the clinical course of the patients with chronic hepatitis B or C.**

Lai YC, Hu RT, Yang SS, Wu CH. Coinfection of TT virus and response to interferon therapy in patients with chronic hepatitis B or C. *World J Gastroenterol* 2002;8(3):567-570

INTRODUCTION

In 1997, a novel DNA virus was isolated from a patient with post-transfusion hepatitis of unknown etiology in Japan, and was designated as TT virus (TTV) after the initials of the index patient[1]. From then on TTV has been studied worldwide. Now we know that TTV genome is non-enveloped, circular, single-stranded DNA and comprises 3,852 bases with a particle size of 30-50nm. These findings suggest that TTV is closely related to the Circoviridae[2,3].

In the original studies from Japan, the agent was found in 34/290 (12%) of healthy donors, compared to 9/19 (47%) of patients with fulminant non-A to G hepatitis and 41/90 (46%) with non-A-G chronic liver disease[2]. In 72 patients with chronic liver disease in the United Kingdom, TTV DNA was demonstrated in 18 cases (25%), compared to 10% of 30 cases of healthy controls[4]. Chronic liver disease caused by hepatitis B virus (HBV) and hepatitis C virus (HCV) infection is common in Taiwan[5,6] and interferon (IFN) has been used for the treatment of chronic infections. Therefore, we aimed to study the serum positive percentage of TTV infection in such patients who had received IFN therapy and also to see the response of TTV to IFN during the course of the treatment.

MATERIALS AND METHODS

Patients

We retrospectively studied the frozen-stored serum samples from the patients who had received IFN therapy for chronic hepatitis B and C at Cathay General Hospital from January 1997 to June 2000.

For chronic hepatitis B, we only included the cases with both positive HBsAg (Auszyme, Abbott Lab., North Chicago, Il.) and positive HBeAg [HBe (rDNA) EIA, Abbott Lab.]. Hepatitis C was confirmed with positive results for the anti-HCV antibody (Murex anti-HCV, version Ⅲ, Murex Diagnostics Ltd., Dartford, England). All the cases had elevated serum alanine transaminase (ALT) levels for more than 6 months and had had at least three documented occasions of levels higher than twice the upper limit of normal (<35 IU/L), at least 1 month apart, and within 6 months prior to enrollment. All the patients underwent liver biopsy within 1 month before the start of IFN treatment. The diagnosis of chronic liver disease was based on clinical and pathological results. Serum samples taken from the patients were stored at -70℃ until use.

None of our patients was alcoholic, an intravenous drug abuser or homosexual. None had received hepatotoxic drugs, herbal medicine or immuno-suppressive therapy within the 6 months prior to IFN therapy. Patients with metabolic liver diseases including hemochromatosis, Wilson's disease or α-1 anti-trypsin deficiency and autoimmune hepatitis were excluded by clinical and laboratory examinations. None had decompensated liver function (prolonged prothrombin time > 3 seconds, serum total bilirubin > 3.0 mg/dl, or serum albumin <3.0 gm/dl), chronic renal failure, clotting abnormalities, or serious neurological disorders. Those who coinfected with both HBV and HCV were also excluded. Informed consent for the IFN therapy and examinations, including virological assays, was obtained from all the patients.

Laboratory assays

The patients underwent blood biochemical tests every week for the initial 4 weeks and every 2 weeks thereafter during the treatment until 24 weeks. After the end of the treatment, the patients were followed up at 4-week intervals for 12 months.

Serum samples from hepatitis C patients were examined for HCV RNA using reverse transcription-nested polymerase chain reaction (PCR) with primers for the 5'-noncoding region of HCV RNA. Genotyping of HCV RNA was assayed by PCR with type-specific primers[7]. Serum HBV DNA was quantified with the use of a signal amplified solution hybridization antibody capture assay (Hybrid capture system, Digene, Gaithersburg, MD, USA). The presence of serum HCV RNA or HBV DNA was determined before the initiation of IFN therapy, at the end of therapy, and at 24 weeks after the completion of therapy.

Detection of TTV DNA

Serum TTV DNA was determined in specimens before the initiation of IFN therapy and regularly checked every 1 month during the course of the treatment. TTV DNA was examined using the PCR method with nested primers as previously described[8]. Briefly, DNA was extracted from 100 μL of serum using a QIAMP blood kit (QIAGEN Ltd., Crawley, UK) and resuspended in 50 μL of elution buffer. For the first round of PCR, 25 μL of reaction mixture containing 2 μL of the cDNA sample, 1×PCR buffer (10mM tris-HC1 pH 9.0, 50mM KC1, 1.5mM $MgC1_2$, 0.01% gelatin, and 0.1% Triton X-100), 10mM of each dNTP, 100ng of each outer primer T-1 (sense: 5'-ACA GAC AGA GGA GAA GGC AAC ATG-3') and T-2 (anti-sense: 5'-CTA CCT CCT GGC ATT TTA CC-3'), and 1 unit of Taq DNA polymerase was amplified in a thermal cycler (Perkin-Elmer Cetus, Norwalk, CT) for 30 cycles. One microliter of the PCR products was re-amplified for another 30 cycles with 100ng of inner primers, T-3 (sense: 5'-GGC AAC ATG TTA TGG ATA GAC TGG-3') and T-4 (anti-sense: CTG GCA TTT TAC CAT TTC CAA AGT T-3'). The amplified products were separated by 3% agarose gel electrophoresis and stained with ethidium bromide.

Interferon therapy

For the patients with chronic hepatitis B, 10 million units (mu) of recombinant interferon alfa-2b (Intron A, Schering-Plough, Co. Kenilworth, NJ, USA) was subcutaneously administered three times weekly for 24 weeks. For those with hepatitis C, 4.5 million units of recombinant alfa-2a (Roferon-A, F. Hoffmann-La Roche Ltd., Basle, Switzerland) was used subcutaneously three times a week for 24 weeks. The response to IFN was classified into two patterns according to the serum ALT level. Patient who had normalized serum ALT level (<35 IU/L) during therapy and remained constant for up to 6 months after the end of therapy was considered to have a biochemical sustained response. Non-sustained response was defined as serum ALT level that could not be normalized either at the end of therapy or during the follow-up period. The virological sustained response was defined as the absence of HBV DNA and HBeAg for hepatitis B, HCV RNA for hepatitis C and TTV DNA for TTV infection at 6 months after the end of therapy.

Statistical analysis

Data were analyzed by Student's *t* test, Chi-squared test with Yates' correction or Fisher's exact test where appropriate. All statistical tests were two-sided. A *P* value of less than 0.05 was considered significant.

RESULTS

The sera of 70 patients were studied, which included 40 patients with chronic hepatitis B and 30 patients with chronic hepatitis C (Table 1). The difference of ages between the two groups was statistically significant ($P<0.001$). In those with chronic hepatitis B, the mean age was 33 years; whereas in the chronic hepatitis C group, it was 41 years. As for the gender distribution and serum ALT levels, there was no statistically significant difference between the two groups.

Serum TTV DNA could be detected in 6 cases (15%) of chronic hepatitis B and 9 cases (30%) of chronic hepatitis C. However, the difference was not statistically significant ($P=0.130$) (Table 1).

During IFN therapy loss of serum TTV DNA was found in 3 of 6 (50%) TTV-positive patients with chronic hepatitis B and 6 of 9 (67%) TTV-positive patients with chronic hepatitis C (Table 2). Because this was a retrospective study and the doses of IFN used for chronic hepatitis B and C were different, we could not compare the rate of TTV disappearance between the two groups. Of interest, disappearance of serum TTV DNA occurred during the first 4 weeks of IFN therapy in all the 9 cases despite the regimen of treatment or the type of chronic viral hepatitis (Table 2). In addition, serum ALT levels did not change when TTV disappeared from the serum. Serum TTV DNA was still examined every 4 weeks after the cessation of IFN therapy in the 9 cases of TTV seroconversion and had continued for 24 weeks. There was no case having the re-emergence of TTV DNA during this follow-up period.

Disappearance of TTV occurred in different genotypes of chronic hepatitis C (1a: 1/1 case, 1b: 3/5 cases, 2a: 1/2 cases, 2b: 1/1 case.). However, the number of cases was small.

In the group of chronic hepatitis B, 10 patients had virological peristent response to IFN therapy, and all the 10 patients also had biochemical peristent response. Whereas, only one patient (1/3 cases) with virological persistent response of TTV DNA had biochemical persistent response (Table 3). If we further exclude the patient with concomitant loss of HBV DNA, HBeAg and TTV DNA, none of the patients (0/2 cases) with TTV virological persistent response had biochemical persistent response.

In the group of chronic hepatitis C, all the 7 patients with virological persistent response of HCV RNA to IFN therapy had biochemical persistent response, and 2 patients (2/6 cases) with virological sustained response of TTV DNA had biochemical persistent response (Table 4). Nevertheless, none of the patients (0/4 cases) of TTV virological sustained response had biochemical persistent response after exclusion of 2 patients of concomitant loss of TTV DNA and HCV RNA.

Table 1 Demographic data and serum positive percentage of TTV in the two groups

Type	Sex (M/F)	Age (yr)	ALT (IU/L)	TTV DNA

DISCUSSION

Epidemiologic studies have confirmed that TTV is a parenterally transmitted agent as demonstrated by donor-recipient linkage in transfused patients and by a high prevalence among hemophiliacs and intravenous drug abusers[9-11]. In general, TTV is common in populations at risk of infection with blood-borne viruses[2,12-14]. Many hepatitis viruses share the same modes of transmission, thus multiple viral infections may occur in a given patient[15].

Coinfection of TTV has been observed frequently in patients with chronic hepatitis B or C[4]. Chronic infection of hepatitis B or C virus is common in Taiwan. Thus, we made use of such patients who underwent interferon treatment to study the TT virus. In our series TTV DNA was detected in 15% of chronic hepatitis B and 30% of chronic hepatitis C, which were comparable to the results of Kao *et al* [16], (22% and 37%, respectively) and apparently higher than that (10%) of healthy adults in Taiwan[8]. In a prior study by Naoumov et al, TTV infection was detected in 21% of 33 patients with chronic hepatitis C and 20% of 10 patients with chronic hepatitis B[4]. In Thailand, Tanaka et al, also found that 36% of 59 patients with HBsAg (+) and 36% of 10 patients with HCV RNA (+) had TTV infection[17]. Several other studies also reported that the serum positive rates of TTV DNA in the patients with chronic hepatitis C, and the range was 20-46%[18-20]. The variation might be due to the different primers used for the detection of TTV DNA. These results imply that HBV, HCV, and TTV may share common modes of transmission[16].

The interferons possess antiproliferative, antiviral and immunomodulant properties[21]. Extensive clinical trials have confirmed the efficacy of recombinant interferon-alfa for patients with chronic hepatitis B, C and D[22-26]. However, because the causal role of TTV in liver disease has not been established, there is only a few papers which studied the response of TTV to IFN therapy. Taking advantage of previous research of IFN therapy for chronic hepatitis B and C, we were able to retrospectively study the prevalence of TTV in these patients and to see the response of TTV to IFN treatment. In our study, loss of serum TTV DNA during IFN therapy was noted in 50% (3/6) of chronic hepatitis B and 67% (6/9) of chronic hepatitis C. Regretfully, the comparison of these results was not feasible because this was a retrospective study and the doses of IFN used in two groups were different. Kao et al[16]. had similar results and they found that 41% (17/41) of patients with HCV and TTV coinfection lost serum TTV DNA at 24 weeks after the end of IFN therapy for chronic hepatitis C. Virological sustained response of TTV DNA after IFN therapy was detected to be 40-55% in patients coinfected with chronic hepatitis C according to the recently published reports[18-20, 27]. These findings suggest that TTV was actually vulnerable and responsive to IFN therapy. In addition, all the 9 IFN-responsive cases in our series lost their TTV DNA within the first 4 weeks of IFN therapy. This kind of seroconversion occurred in the same way in both hepatitis B and C groups, but we need more cases to further observe and confirm this phenomenon. With the results above, we know that TTV could be divided into 2 types according to the response to IFN therapy: IFN-sensitive and IFN-resistant. For the IFN-sensitive virus, the 4-week course of IFN therapy was enough to cause the seronegativity of TTV DNA. Moreover, virological sustained response could be achieved in all the 9 IFN-sensitive cases.

TTV was detected in patients with different genotypes of chronic hepatitis C. Loss of serum TTV DNA during IFN therapy occurred in all the genotypes in our study. The conversion rate between each genotype could not be compared because the number of patients was not enough. Nevertheless, the loss of serum TTV DNA during IFN therapy did not seem to be associated with the genotype of HCV.

Investigations of TTV showed considerable diversity among different isolates. The genetic diversity has continued to expand as more and more isolates have been studied[2,4,12]. The different response patterns to IFN therapy must be related to the genetic diversity. Comparison of partial viral DNA nucleotide sequences and phylogenetic analysis done by Chayama *et al*[27] showed that viral strains that had a high identity to the prototype virus were more resistant to IFN than those showing low nucleotide sequence identity. The variants with multiple substitutions in the genomic sequence were more apt to be eliminated by IFN. Further analysis with new genotyping assays will reveal more information in this field.

During the course of IFN treatment, we did not find any correlation between the seroconversion of TTV DNA and the change of serum ALT levels. Although TTV was sensitive to IFN therapy in many subjects, the improvement in ALT levels after IFN therapy was not attributable to the eradication of TTV but rather to that of HCV or HBV. The disappearance of TTV DNA had no effect on the biochemical response to IFN therapy[18,20]. According to such results, TTV may lack pathogenicity or clinical association with liver disease in these patients, which is consistent with the conclusions of many other reports[4,8,28,29].

In summary, the serum positive percentage of TTV in chronic hepatitis B or C in our series was not low. During the IFN therapy for chronic hepatitis B or C, disappearance of coinfected TTV occurred in more than half of the patients. IFN-sensitive TTV usually lost its DNA during the first month of treatment. Genotyping of TTV might further clarify the cause of diverse responses to IFN therapy. The finding that the disappearance of TTV DNA did not affect the clinical course of chronic hepatitis favors the null hypothesis of no significant association of TTV with liver disease.

Abstract

AIM: **To explore the relevance of Maotai liquor and liver diseases.**

METHODS: **Epidemiological study was conducted on groups of subjects, each consisting of 3 subjects from the Maotai liquor group consisting of 99 individuals and one from the non-alcoholic control group consisting of 33 individuals. Liver biopsy was performed on 23 volunteers from Guizhou Maotai Distillery who had a constant and long history of drinking Maotai liquor. Experimental histopathological study was conducted as follows: sixty male Wistar rats were divided into 3 groups randomly and fed with Maotai liquor, ordinary white wine, and physiological saline respectively for a period of 8 and 12 weeks. The rats were sacrificed in batches, then serum ALT, AST, TBil, and AKP were measured. Rat livers were harvested to measure the liver indexes, GSH, and MDA. Histopathological examinations were also performed. Another eighty mice were randomly divided into 4 groups and fed with Maotai (at different dosages of 10 ml·kg^{-1} and 20 ml·kg^{-1}), ethanol, and physiological saline. The animals were sacrificed after 4 weeks and serum ALT was determined. Then the livers were harvested and liver indexes and MDA were measured.**

RESULTS: **The incidence rate of hepatic symptoms, splenomegaly, liver function impairment, reversal of Albumin/Globulin and increased diameter of portal veins in the Maotai liquor group were 1.0%(1/99), 1.0%(1/99), 1.0%(1/99), 1.0%(1/99), 0(0/99)and 0(0/99), 0(0/99),0(0/99), 0(0/99), 0(0/99), respectively. There was no significant difference between the Maotai group and the non-alcoholic control group(P>0.05). Various degree of fatty infiltration of hepatocytes was found in the 23 volunteers receiving liver biopsy, but there was no obvious hepatic fibrosis or cirrhosis. A comparison was made between the Maotai liquor group and the ordinary white wine group. It was found that hepatic MDA in rats and mice were 0.33±0.10 and 0.49±0.23 respectively in Maotai group and 0.61±0.22 and 0.66±0.32 in the ordinary white wine group; MDA had an obvious decrease in the Maotai liquor group (P<0.05); hepatic GSH were 0.12mg·g^{-1}±0.06mg·g^{-1} in rats of the Maotai liquor group and (0.08±0.02)mg.g^{-1} in white wine group, it was obviously increased in the Maotai liquor group (P<0.05). After the 20 rats had been fed with ordinary white wine for 8 weeks consecutively, disarranged hepatocyte cords, fatty infiltration of hepatocytes, and fibrous septa of varying widths due to hepatic connective tissues proliferation were observed; after 12 weeks, the fibrous tissue proliferation continued and early cirrhosis appeared. Compared with the ordinary white wine group, fatty infiltration was observed in the 8-week and 12-week groups, but no necrosis or fibrosis or cirrhosis was found in the Maotai liquor group (P<0.05).**

CONCLUSION: **Maotai liquor may cause fatty liver but not hepatic fibrosis or cirrhosis, and it can strengthen lipid peroxidation in the liver.**

INTRODUCTION

Alcohol can cause fatty liver, hepatitis and liver cirrhosis[1-5]. A lot of research showed that there was a close relationship between liver diseases and alcohol content of liquor. If one drinks ardent spirits 80 to 150g daily for more than ten years, he will get alcoholic hepatitis, hepatic fibrosis, liver cirrhosis and even hepatocellular carcinoma[6-13]. Maotai liquor has a very unique brewing technique which is different from that for ordinary white wine, and there are multiple microorganisms in the special geographical situations which are able to absorb abundant amino acids, vitamins and many essential microelements[14], so the taste of Maotai is very sweet and pure. A study on 40 individuals reported by Li et al showed that drinking Maotai liquor more than 150g daily for ten years would not cause liver injury. Our previous study showed that Maotai liquor was able to induce increase of metallothioneins(MT), inhibit the proliferation of hepatic stellate cell (HSC) and generation of collagen and enhance the effect of antioxidation[13]. Our study has initially interpreted the anti-fibrosis mechanism of Maotai liquor. A study was conducted on groups of subjects from Guizhou Maotai Distillery, each consisting of 3 subjects from the Maotai liquor group of 99 individuals who had a constant and long history of drinking Maotai liquor and one from the non-alcoholic control group of 33 individuals. Liver biopsy was performed on some of them and liver biopsy and serological tests in rats and mice fed with Maotai liquor were performed in order to explore the effect of Maotai liquor has on the liver.

MATERIALS AND METHODS

Materials

One hundred and thirty two individuals from Guizhou Maotai Distillery, aged from 30 to 60 years old, were divided into Maotai

liquor group consisting of 99 individuals and non-alcoholic control group consisting of 33 individuals. All members of the Maotai liquor group have the capacity for liquor of more than 250g.d^{-1} and drinking history of longer than ten years. There was no significant difference between the two groups in sex and age. The male Wistar rats weighing (300±20)g were employed in this study (Provided by Experimental Animal center, the Third Military Medical University); the mice of Kunming species weighing (22±2)g (Provided by Experimental Animal center,Guiyang Medical College) were also used. Maotai liquor of (530±2)g·L^{-1} was produced by Guizhou Maotai Distillery, China, whose code bar was 6902952880026; the ordinary white wine of (530±2)g·L^{-1} was provided by the Fourth Department of Guizhou Food Export and Import Company.

Methods

Questionnaires were prepared in advance including sex, age, drinking history (capacity and duration), history of liver diseases, and history of gastropathy, etc. Physical examination, abdominal B ultrasound (the size of liver and spleen, diameter of portal vein), serum ALT,A/G,LN and HA were also done at the same time. Liver biopsy was performed in twenty three volunteers from the Maotai group, the liver tissue was fixed by formalin of 40g·L^{-1}, embedded by paraffin, sectioned and stained by HE. Sixty male Wistar rats were randomly divided into Maotai liquor group, ordinary white wine group and normal control group. Rats in the wine group were fed with 2mL·kg^{-1} Maotai liquor and 2mL·kg^{-1} ordinary white wine both of which were diluted one fold by distilled water, and in the control group were fed with the same volume of saline. All rats were fed once everyday continuously for 8 weeks, and after the last feed, 15 rats were fasted for 20 hours and then sacrificed to get blood for testing serum ALT, AST, TBil and AKP were tested, and Rat livers were harvested to measure the liver indexes, GSH, MDA, the liver tissue was embedded, sectioned and stained with HE. The remaining 5 rats in each group were sacrificed for histopathological examination after fed for 12 weeks. Eighty mice (40male,40female) were randomly divided into 4 groups [two Maotai groups (at different dosage of 1 ml·kg^{-1} and 2 ml·kg^{-1}), ethanol group, and physiological saline group].Mice were fed with dosage of 1 ml·kg^{-1} and 2 ml·kg^{-1} Maotai in the two Maotai groups respectively. In the ethanol group, mice were fed (with) 53 g·L^{-1} ethanol at dosage of 1 ml·kg^{-1}, they were fed once everyday for 4 weeks. After the last feed, the mice were killed to measure serum ALT, the liver indexes and MDA. Questionnaires were done by special messenger, and were examined and verified by persons in charge of the study.

Statistic analysis

The data were analyzed by t test and χ^2 test.

RESULTS

Epidemiologic analysis

The 98 individuals who had a long history of wine drinking had no symptoms abnormal, signs or liver function; only one who had a history of hepatitis showing cirrhosis of liver. He had symptoms of liver disease, splenomegaly, lightly increase of ALT and reversed A/G. There was no increase in the diameter of portal vein trunk in those individuals, compared with that of the control group, (P>0.05). None of those who had a history of drinking Maotai for more than 30 years died of liver diseases. (See Table 1). There was a slight increase of serum LN, but a significant increase of HA, (P<0.05) (See Table 2). All twenty three individuals in the Maotai group who had biopsy had varying degrees of fatty infiltration of hepatocytes. One of them had slight necrosis, but none had obvious hepatic fibrosis or cirrhosis of liver, in compared with that of the white wine group (P<0.05).

Experimental study in rats

Neither Ordinary white wine nor Maotai liquor had obvious effect on ALT, AST, TBil, ALP and liver indexes in rats fed for 8 weeks, compared to the normal control group. There was no significant difference between them (P>0.05) (See Table 3); but Maotai liquor was able to increase the level of GSH and decrease the level of liver MDA (See Table 4). There were no obvious pathologic changes in rat liver of the normal control group (See figure 1). In the ordinary white wine group, all twenty rats had disarrangement of hepatocyte cords, fatty infiltration and hyperplasia of fibrous tissue which formed the fibrous septa (See Figure 2) after they had been fed for 8 weeks. The fibrous tissue had further hyperplasia in the rats of the 12-week group and there were also signs of early cirrhosis of liver (See figure 3).But after the Maotai group had been fed for 8 weeks and 12 weeks, all rats had fatty infiltration, 17 were mild degree and 3 were moderate degree; all were devoided of necrosis of hepatocytes, hepatic fibrosis and cirrhosis (P<0.05) (See figure 4,5) when compared with that of the white wine group.

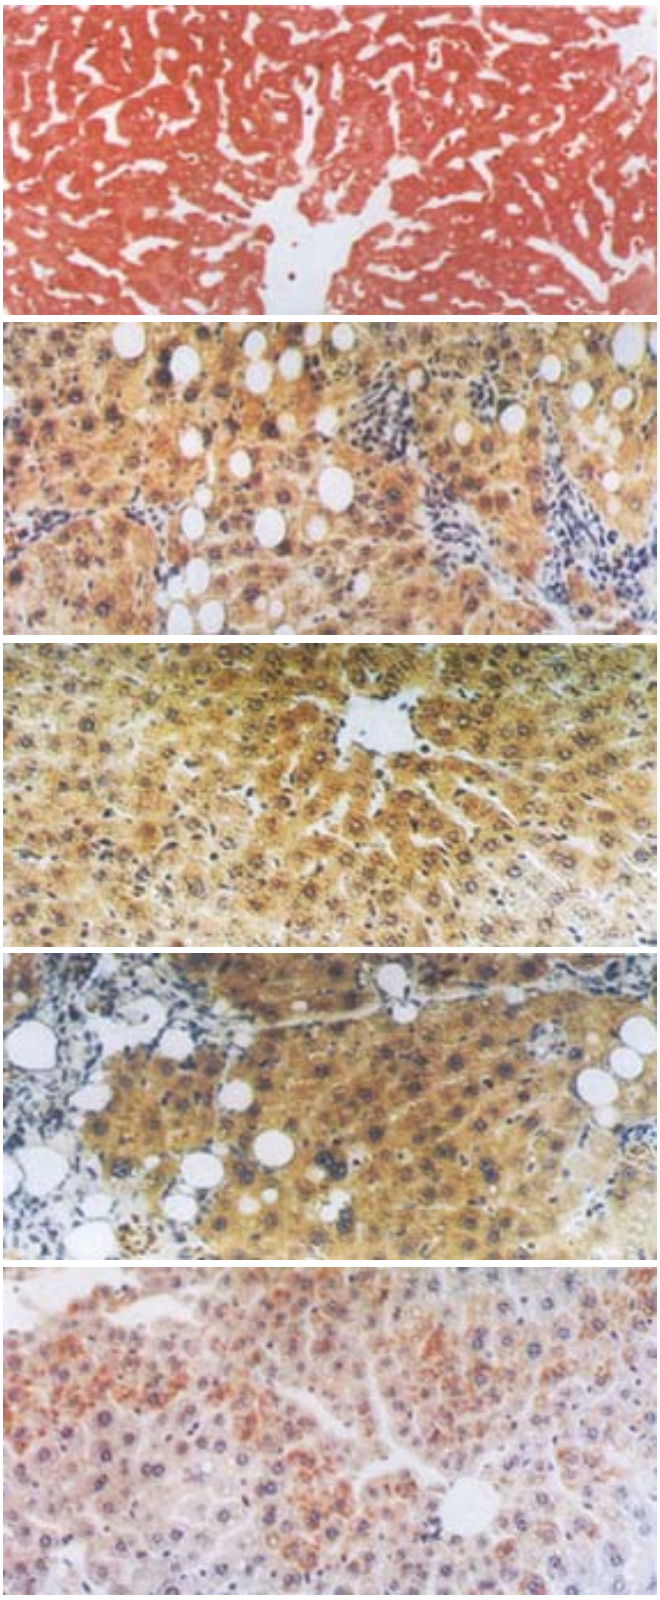

Figure 1 Normal liver tissue, hepatic cords were well arranged, the structure of hepatic lobule were intact. (HE.×200)

Figure 2 After fed with alcohol for 8 weeks, disoraganized hepatic cords, fatty infiltration, mesenchymal hyperplasia, and fibrosis could be seen. (HE.×200)

Figure 3 After fed with alcohol for 12 weeks, there were fatty infiltration of hepatocytes, hyperplasia of connective tissue, and early manifestation of cirrhosis. (HE.×200)

Figure 4 After fed with Maotai liquor for 8 weeks, there were a few infiltrating inflammatory cells, normally arranged hepatic cords, liver sinusoids were dilatated and lipid droplet could be seen in hepatocytes . (HE.×200)

Figure 5 After fed with alcohol for 12 weeks, brown changes and lipid droplet could be obviously seen in hepatocytes. (HE.×200)p

DISCUSSION

About 40% of those who drank 150g ardent spirits every day would have fatty liver and alcoholic hepatitis[15]. Alcoholic fatty liver diseases can be manifested as fatty liver, alcoholic hepatitis, hepatic fibrosis and cirrhosis of liver, frequently they are overlapping. And fatty liver can proceed to hepatic fibrosis via inflammatory progress. The varying pathology of alcoholic fatty liver diseases have similar pathogenesis in hepatic fibrosis and cirrhosis[16-22]. They are mainly caused by activation of HSC, resulting in excessive deposition and relatively insufficient degradation of ECM. Alcohol, acetaldehyde, lipid, fatty acids, etc can activate and stimulate Kupffer cells to secrete many cytokines which activate HSC to produce various components of ECM, as collagen, laminin, and hyaluronic acid, etc.

In recent years, studies have shown alcohol has direct damage effect to the hepatcytes[23-32]. Alcohol can be oxidized to acetaldehyde with elimination hydroxy free radicals, which causes lipid peroxidation, hepatocytic damage and apoptosis. Lipid peroxidation and its metabolic products malondialdehyde (MDA) and free radicals have strong cellular toxicity[33-37]. GSH[38-44] being an antioxidant is able to inhibit lipid peroxidation, and is also involved in hepatic detoxication, thus it can process cytoprotective effect. MT is a low molecular weight metal-binding protein rich in thioaminopropionic acid. Studies in recent years showed that MT has the effects of eliminating hydroxy free radicals and other oxidation products, being also protective[45-49].

Hepatic hatholigcal changes of human being and animals show that Maotai liquor can lead to fatty infiltration in the liver, but no obvious hepatic fibrosis or cirrhosis of liver. Similar findings were shown in epidemiological study, B mode ultrasound and liver biopsy in the Maotai liquor group One died of liver diseases in this group.

By contrast, various widths of fibrous septa and cirrhosis can be seen in the liver of rats fed ordinary white wine. Why is fatty infiltration in which Maotai liquor group dose not lead to liver fibrosis and cirrhosis of liver? The answer is that Maotai liquor was able to lower the MDA level in the rats and mice liver and increase the level of liver GSH as comparing with those in the. ordinary white wine group, $P<0.05$. It also showed that Maotai liquor had the inhibitory effect on lipid peroxidation and was cytoprotective. Moreover, study in vitro showed that Maotai liquor could increase MT which was the most powerful bioactive substance of scavenging free radicals and antagonizing liver damage. Maotai liquor may also inhibit the activation of hepatic stellate cells and generation of collagen.

Our study revealed that Maotai liquor was able to elevate the level of workers' serum LN and HA in Maotai liquor group vs. ordinary white wine group, ($P<0.05$). It may be related with the activation of hepatic stellate cells (HSC) by ethanol, acetaldehyde, lipid and fatty acid. The elevation of LN was mild, but HA was very obvious whose reason may be that the serum level of HA was related with the ability of hepatic secretion and the renal excretion. In the acute hepatic injury caused by alcohol, inflammation and drugs, the level of serum HA may be very high, but it only points at a possible hepatic fibrosis or the early stage of hepatic fibrosis because researches show that the level of HA is not very high, even normal, in the late stage of hepatic fibrosis[50].

As one of the three most famous distilled sprits of the world, Maotai liquor was brewed with open solid state fermentation in a special geographical environment, so it has formed its own style which is hard for others to imitate. According to the analysis of the nutritive component in Maotai liquor in recent years, in every 100 ml Maotai Liquor, there were 18mg protein, 6667 u superoxide dismutase (SOD), 0.06 mg vitamin B_1, 0.1 mg vitamin B_2 and 1.19 mg vitamin C, 0.022 mg manganese (Mn), 0.026 mg copper (Cu), 0.42 mg iron (Fe), 1.0 mg potassium (Ka), and <0.005 mg zinc (Zn); 4.7 mg methanol, 4.7 mg aldehyde compounds. And there were also 18 kinds of amino acids and 6 kinds of essential amino acids

except acimetion and tryptophan which were never found in the Jiang flavor white wine before Maotai. There were SOD and multiple human essential microelements in Maotai liquor, especially rich in Fe, Mn and Cu. The components of methanol, benzene and aldehyde were much lower than it was ruled in the international standard.

Abstract

AIM: **To investigate the levels of D-dimer(DD) and von Willebrand factor(vWF) and the relationship between DD and vWF in ulcerative colitis(UC) patients.**

METHODS: **A total of 29 plasma specimens were obtained from patients with ulcerative colitis (male 13, female 16), aged 21-47 years (33±11). Disease activity was assessed by Truelove-Writeria. Patients with a score of above 5 were regarded as having active colitis. Twenty healthy people(male 12, female 8), aged 19-53 years(31±14), served as normal controls. Blood samples were taken from an antecubital vein puncture. Blood(1.8 mL) was injected into the tubes containing sodium citrate (0.13 mmol/L). The plasma was obtained by centrifugation at 3000 r·min^{-1} for 10 min, and stored at -80 ℃ until assayed by ELISA.**

RESULTS: **The mean plasma levels of DD and vWF in active UC patients were significantly higher than those of the controls (0.69±0.41 *vs* 0.27±0.11, *P*<0.01; 143±46 *vs* 103±35, *P*<0.01). The mean plasma levels of DD in the patients with active disease were higher than those with inactive disease(0.69±0.41 *vs* 0.48±0.29, *P*<0.05). The levels of vWF were not different between active and inactive patients. DD levels were positively related to vWF levels(*r*=0.574, *P*<0.01). There was no significant difference between levels of DD and vWF and the scope of disease and sex of the patients.**

CONCLUSION: **vWF is an important feature and a good marker of UC; intravascular thrombus and endothelial cell dysfunction were found in UC patients; and the combined test of DD and vWF is helpful to distinguish the activity of the UC patients.**

INTRODUCTION

The pathogenesis of ulcerative colitis(UC) is still unknown[1,2]. Some studies suggested that intestinal vascular injury caused by intramural vascular thrombosis or vasculitis was considered as a potential pathogenetic mechanism of inflammatory bowel disease. The D-Dimer (DD) is known to be a special fibrin degradation product, which is used as an index of fibrin turnover and intravascular thrombogenesis[3]. von willebrand factor(vWF) is released from endothelial cells, which is used as a marker for endothelial damage[4]. In this study, we investigated the change of DD and vWF levels in UC patients and the relationship between these two markers.

MATERIALS AND METHODS

Patients

A group of 29 patients (male 13, female 16), aged 21-47 years(33±11), were diagnosed by routine clinical, radiologic, endoscopic and histologic means(excluding heart and brain vessel diseases, diabetes and other diseases that affect blood coagulation). Disease activity was assessed by Truelove-Writeria. Patients with a score of above 5 were regarded as having active colitis. Meanwhile 20 healthy people(male 12, female 8), aged 19-53 years (31±14), served as normal controls.

Measurement of plasma DD and vWF levels

Blood samples were taken from an antecubital vein puncture. Blood (1.8 mL) was injected into the tubes containing sodium citrate(0.13 mmol/L). The plasma was obtained by centrifugation at 3000 r·min^{-1} for 10 min, and stored at -80 ℃ until assayed by ELISA(The Sun Biotechnology Company, Fujian, China).

Statistical analysis

Statistical analysis of mean value of DD and vWF levels were made by Student's *t* test and Student -Newman-keuls's test. $P<0.05$ was considered to be significant.

RESULTS

DD and vWF levels in patients with UC

The mean plasma levels of DD and vWF in active UC patients were significantly higher than those of the controls ($P<0.01$, Table 1). The mean plasma levels of DD in the patients with active disease were higher than that of inactive disease ($P<0.05$). The levels of vWF had no difference between active and inactive patients. DD levels was positively related to vWF levels($r=0.574$, $P<0.01$).

Table 1 Changes of DD and vWF levels in patients with UC ($\bar{x}\pm s$)

	n	DD(mg/l)	vWF(%)
controls	20	0.27±0.11	102.75±34.91
UC active	17	0.69±0.41[ab]	142.71±45.96[a]
Inactive	12	0.48±0.29[a]	135.00±26.25[a]

[a]$P<0.01$, *vs* control; [b]$P<0.05$, *vs* inactive

Table 2 The levels of DD and vWF in different sex and scope of disease ($\bar{x}\pm s$)

		n	DD(mg/l)	vWF (%)
Sex	Male	13	0.58±0.11	142.84±42.85
	Female	16	0.55±0.15	138.75±36.75
Scope of disease

DD and vWF levels in gender of disease and scope of disease

DD and vWF levels seemed to be increased with the scope of disease gradually, but differences were not significant with different scope of disease. There was no statistical difference between males and females (Table 2).

DISCUSSION

Von willebrand factor(vWF) is a high molecular weight multimeric glycoprotein, synthesized and released by vascular endothelial cells and megakaryocytes. It has two functions: firstly, this glycoprotein carries factor VIII in the circulation and is required for factor VIII stability in the plasma. Serving as the carrier for factor VIII, vWF may also coordinate formation of the fibrin rich thrombus at the site of endothelial cell injury; secondly, this glycoprotein may mediate initial platelet adhesion to the subendothelium by linking to specific platelet membrane receptors and to constituents of subendothelial connective tissues. This is pertinent to the damage of the vascular endothelium[5]. Most of plasma vWF is derived from endothelial cells rather than from platelets under normal circumstances, suggesting that vWF is a good marker of endothelial dysfunction[6,7]. Clinically, in vitro and animal studies support the concept that increased levels of circulating vWF reflect endothelial cell damage or injury[8]. Elevated vWF levels have been demonstrated in the patients with inflammatory vascular disease and associated disorders, including rheumatoid arthritis, systemic sclerosis, systematic lupus erythematosus, Felty's syndrome, giant cell arteritis and polyarteritis nodosa. Intestinal vascular injury caused by intramural vascular thrombosis or vasculitis is considered as a potential pathogenetic mechanism of inflammatory bowel disease. We investigated the role of vascular injury in the pathogenesis of UC by examining the levels of plasma vWF. The results showed that vWF levels were more significantly raised in the active or inactive patients with UC, as compared with the controls. The levels of vWF were unrelated to the scope of the disease, and there was no statistical difference between males and females. Our results confirmed and extended those of other investigators[9], showing that concentration of circulation vWF is elevated in UC patients. Our results supported the hypothesis that intestinal endothelial cell damage was an important feature of UC and proved that vWF was a good marker of UC.

It is well known that DD is a marker of ongoing intravascular thrombogenesis. In the previous researches, DD test was established as a useful aid in the diagnosis of the deep-vein thrombosis of the lower limbs and pulmonary embolism[10]. Some reports showed higher DD levels in patients with coronary artery disease, Sickle cell disease, systemic lupus erythematosus, several sorts of neoplasms[11,12] and acute pancreatitis[13]. Weber's results showed that DD levels were higher in patients with UC[14]. Our results showed significantly higher DD levels in patients with UC, both in active and inactive patients, as compared with the controls. It confirmed the presence of intravascular thrombus in UC patients. Thus anticoagulant treatment, with either warfarin or heparin, may have a positive influence on UC.

Several reports indicated that DD is used as a marker of inflammation. Elevated level is a well-established marker of acute-phase reaction and may reflect the presence of inflammation[12,15]. Our results showed that DD levels were significantly higher in patients with active UC than those with inactive UC, but there was no statistical difference in vWF levels between active and inactive UC patients. There was positive correlation between vWF and DD, we therefore, proposed that the combined test of DD and vWF is helpful to distinguish the activity of the UC patients.

Abstract

Co-infection with hepatitis C virus and human immunodeficiency virus is common in certain populations. Among HCV (+) persons, 10 % are also HIV (+), and among HIV (+) persons, 25 % are also HCV (+). Many studies have shown that in intravenous drug users, co-infection prevalence can be as high as 90-95 %. There is increasing evidence supporting the concept that people infected with HIV have a much more rapid course of their hepatitis C infection. Treatment of co-infection is often challenging because highly active anti-retroviral therapy (HAART) therapy is frequently hepatotoxic, especially in the presence of HCV. The purpose of this review is to describe the effects that HIV has on hepatitis C, the effects that hepatitis C has on HIV, and the treatment options in this challenging population.

Maier I, Wu GY. Hepatitis C and HIV co-infection: a review. *World J Gastroenterol* 2002; 8(4):577-579

INTRODUCTION

Hepatitis C is an RNA flavivirus that infects 4 million people in the United States making up approximately 1.8 % of the population, and 150-200 million worldwide. In persons with HIV, its prevalence is estimated to be approximately 50 %[1]. Main sources for transmission include IV drug use, transfusion of blood products prior to screening, and to a lesser extent sexual intercourse and needle sticks. It is almost universal among hemophiliacs who received transfusions prior to July 1992[2]. HCV is the leading indication for liver transplantation in the U.S. today, and is responsible for approximately 10 000 deaths per year. It is estimated that by 2 015, HCV will be responsible for 40 000 deaths per year.

Seventy to eighty percent of acute HCV infections become chronic. Approximately 25 % of these patients develop end stage cirrhosis after 20 to 25 years, and 1 to 4 % of patients with cirrhosis develop hepatoma each year. The median time to cirrhosis is about 19 years. Once cirrhosis is present, the risk of hepatoma increases dramatically. The median time to develop hepatoma is about 29 years. Factors that promote progression of HCV include: alcohol intake, age over 45 at the time of infection, HIV co-infection, male gender, and co-infection with hepatitis B or other viruses. HIV infection and alcohol consumption are independently associated with accelerated progression of fibrosis[3].

Potential mechanisms of HCV-induced liver disease include direct cellular toxicity, immune-mediated toxicity, viral replication, immune selection, and role of cryoglobulins. In patients that are immunosuppressed, there is an increased rate of viral replication and an increased progression rate of HCV.

The diagnosis of HCV is made by an ELISA test, which is sensitive and specific. In immunosuppressed persons, however, there may be a false negative test in the presence of hepatitis C viremia. Therefore, in a high risk HIV patient who has a negative antibody test, a quantitative PCR is also recommended[2].

The standard treatment for persons who do not have HIV is combination therapy consisting of interferon alfa and ribavirin. Should this be the standard of care in HIV positive patients as well? The approach to the co-infected patient is somewhat more complicated.

HCV/HIV CO-INFECTION

Epidemiology

Not all HIV (+) persons are at risk for HIV. Of HCV (+) persons, approximately 10% are also HIV (+), and of HIV (+) persons, approximately 25% are also HCV (+)[4-6]. Table 1[7] shows the incidence of HCV and HIV infection by special population.

Table 1[7] The incidence of HCV and HIV infection by special population

	% HCV Infection	% HIV
IV Drug Users	60%	31%
Homosexual Men	Unclear	47%
Heterosexual Men	20%	10%
Transfusion <1992	7-20%	2%
Occupational	<1%	<1%
Unknown	10%	9%

Table 2[11] Similarities and differences of HCV and HIV

Statistics	HCV	HIV
U.S. Infected	4 million	1 million
Globally Infected	60-180 million	45 million
Primary transmission	Blood	Sex
Treatment Cure	Yes (40%)	No
T 1/2	2.3	6.4
Daily Replication	10^{12}-10^{13}	10^{9}-10^{10}
Mutation Rates	10^{-3}-10^{-4}	10^{-3}-10^{-4}

In developed countries, the majority of HIV positive persons who acquired infection by IV drug use (IDU) are co-

infected with HCV[8]. In many studies, more than 90-95 % of IV drug users are co-infected. Only 4-8 % of gay men who are HIV (+) are also HCV (+)[9], since HCV is not as easily transmitted by sexual contact. If a patient has both HIV and HCV infection, that patient will be more likely to transmit HIV compared with HCV through heterosexual contact. The presence of HIV may increase the risk of acquiring HCV, as seen in some studies[10]. Two to 10% of women co-infected with HIV/HCV transmitted HCV to their newborns. The risk of transmission was directly related to the degree of HCV viremia. Also, HIV transmission is more likely in mothers with high HCV-RNA levels. Table 2[11] lists some statistics for HCV and HIV.

Natural history

In infections with HCV alone, the host cell-mediated immune response often determines the long term outcome. It has been evident that HIV makes the course of HCV infection more rapid and that end stage liver disease is the leading cause of death in HIV patients. It is thought that the more rapid progression of HCV in co-infected patients is due to a weakened cellular immune response. The estimated mean interval from HCV infection to development of cirrhosis is significantly shorter for patients co-infected with HIV (7 *vs* 30 years)[12-15]. Co-infected patients have higher levels of HCV RNA than HCV-only infected patients. Titers usually correlate with the CD4 count[16]. Viral load is considered to be a predictor of response to therapy, but HCV viral loads in HCV-only infected patients cannot be compared to HIV/HCV patients with any prediction to outcome of treatment. Patients with HIV/HCV infection may also have more severe liver damage (higher score of piecemeal necrosis and a higher stage of fibrosis) than those without HIV infection[17-19].

However, the impact that HCV has upon HIV disease progression is less clear. Some studies have reported a significantly faster HIV progression (predominantly in hemophiliac patients infected with HCV genotype 1)[20], while others showed no impact. IL-10 has been proposed to decrease inflammation in HCV patients. It also should be noted that patients that have HIV naturally have lower levels of IL-10, which may explain the observed accelerated liver disease in co-infected patients[21].

Treatment options

HIV patients have been living longer making the HCV infection a pressing problem[22]. Regarding treatment of HCV in co-infected patients, the main factor in deciding who should be treated is the CD4 count. Patients with CD4 counts greater than 500 have been found to have response rates not significantly different from patients without HIV. Patients with CD4 counts less than 200 have been shown to have no significant response. Hence, therapy in those cases is not recommended. Patients with CD4 counts less than 500, but greater than 200 have intermediate response rates[17]. Accordingly, patients are generally treated with HAART first to optimize the immune system before initiating anti-HCV therapy.

Interferon

Interferon monotherapy for hepatitis C in patients with HIV, without AIDS, is similar to that observed in patients with HCV alone. Periodic monitoring of CD4 count is warranted since up to 80 % of the patients treated had significant reductions in the absolute CD4 count[23].

Interferon plus ribavirin

Standard treatment in co-infected patients with satisfactory CD4 counts is to treat the HCV with interferon alfa plus ribavirin for 24 weeks[24-27]. If the quantitative HCV RNA PCR is negative at the 24 week point, then treatment should be continued for an additional 24 weeks (for a total of 48 weeks). However, if the PCR is positive at 24 weeks, the risks of continuing treatment are likely to outweigh benefits of the regimen[23].

Further treatment options

Pegylated interferon is an alternative to interferon plus ribavirin that seems to provide similar treatment efficacy without the ribavirin side effects[28,29].

There are no definitive data on pegylated interferon and ribavirin in co-infected patients, but preliminary reports suggest a further increase in the sustained viral response rate compared to standard thrice weekly interferon plus ribavirin[30]. It is likely that the dependence of response rates on CD4 counts will likely be similar to standard interferon-ribavirin.

Liver toxicity is a potential problem with all of the HAART medications[1]. There is a higher rate of hepatotoxicity in co-infected patients who are being treated with HAART therapy. Of the protease inhibitors, several sources cite Ritonavir as the most liver toxic. Ritonavir trough levels are often twice as high in patients with HCV infection. Indinavir can cause severe hyperbilirubinemia in patients with HCV co-infection. Nelfinavir and Saquinavir are the safest among protease inhibitors in patients with compromised liver function. Among the NNRTIs, Nevirapine frequently causes elevation in transaminases, while Efavirenz is least likely to cause liver toxicity[31].

Ribavirin may interact with selected nucleoside reverse transcriptase inhibitors (AZT, ddi, d4T) and reduce their anti-HIV activity due to interference with intracellular phosphorylation. If AZT is given concomitant with ribavirin, there is an increased incidence of anemia and complete blood counts should be carefully monitored[32].

Future challenges

In order to maximize therapeutic efficacy, we will need to determine the immunological defect that is responsible for the diminished cellular immune response to HCV in HIV/HCV co-infected patients. It will be of value to determine the mechanism causing the defect that leads to an increase in hepatotoxicity in anti-retroviral drugs so that drug therapy can be better managed. Hepatotoxicity can possibly be decreased by manipulating the chemical structures of some of these medications. More studies need to done on the interactions between HIV and HCV in man.

Abstract

AIM: **To investigate the expression of cancer related genes in gastric carcinoma (GC) through the use of Atlas Human Cancer Array membranes with 588 well-characterized human genes related to cancer and tumor biology.**

METHODS: **Hybridization of cDNA blotting membrane was performed with ^{32}P-labeled cDNA probes synthesized from RNA isolated from gastric carcinoma and adjacent noncancerous gastric epithelial tissue. AtlasImage, which is a software specific to array, was used to analyze the result.**

RESULTS: **The differentially expression cell cycle/ growth regulator in GC showed a stronger tendency toward cell proliferation with 2.7-fold up-regulation of CK1. The promoter genes of apoptosis were down-regulated, including caspase-8 precursor, caspase-9 and caspase-10. Among the oncogene/tumor suppressor genes, ABL2 was down-regulated. In addition, some genes were up-regulated , including matrix metalloproteinse 2(MMP-2), MMP-16(MT3-MMP), SKY, CD9 and semaphorin V. A number of genes were down-regulated, including neuroendocrine-dlg (NE-dlg), retinoic acid receptor gamma and tumor suppressor DCC colorectal. In general, The expression of the cancer progression genes were up-regulated, while the expression of anti-cancer progression genes were down-regulated.**

CONCLUSION: **Investigation of these genes should help to disclose the molecular mechanism of the onset, progression and prognosis of GC. Several genes are reported herein to be altered in GC for the first time. The quick and high-throughout method of profiling gene expression by cDNA array provides us with an overview of key factors that may involved in GC, and may aid the study of GC carcinogenesis and provide molecular targets for diagnosis and therapy. The precise relationship between the altered genes and gastric carcinogenesis is a matter for further investigation.**

Liu LX, Liu ZH, Jiang HC, Qu X, Zhang WH, Wu LF, Zhu AL, Wang XQ, Wu M. Profiling of differentially expressed genes in human Gastric carcinoma by cDNA expression array. *World J gastroenterol* 2002; 8(4):580-585

INTRODUCTION

Gastric carcinoma (GC) is one of the most common malignant tumors worldwide, which ranks the first in frequency among human cancer in China[1]. However, the molecular mechanism underlying GC are currently unknown. Some genes may play a significant role in carcinogenesis, such as p53, bcl-2, bax, and *c-myc*[2-4]. However, these genetic changes do not precisely reflect the biological nature of tumor cells or the clinical characteristics of GC patients.

Tumor development and progression involves a cascade of genetic alterations. Techniques frequently used to study gene expression alterations, such as Reverse Transcription Polymerase Chain Reaction (RT-PCR), Differential Display Polymerase Chain Reaction (DD-PCR) and Northern blot analysis, have their limitations: some need large amounts of RNA, others are time-consuming and can only study a small number of genes simultaneously. Hence, analysis of expression profiles of a large number of genes in clinical GC material is an essential step toward clarifying the detailed mechanisms of carcinogenesis and discovering target molecules for the development of novel therapeutic drugs.

The cDNA microarray technology, which has recently undergone rapid development, enables investigators to study the gene expression profile and gene activation of thousands of genes and sequences[5,6]. This technique allows the large-scale comparison of multiple genes in a single hybridization and has been used successfully to explore the gene expression profile of various carcinomas and diseases[7-11].

In this study, we used cDNA expression microarray technology containing 588 genes related to carcinoma to analyze genes that are differentially expressed in human GC and normal gastric epithelial tissues. This large body of information not only furthers our understanding of the mechanism of carcinogenesis but also reveals novel features of known genes and identifies potential candidates for GC diagnosis and therapy.

MATERIALS AND METHODS

Tissues and specimens

Sixteen pairs of GC and corresponding noncancerous gastric epithelial tissue were obtained with informed consent from patients who underwent gastrectomy at the First Clinical College of Harbin Medical University and Cancer Hospital of Chinese Academy of Medical Science. Tumor tissue was

dissected from the resected specimen. The normal tissue block was taken from the distal resection margin. The specimens were immediately frozen in liquid nitrogen. Histopathological classification was performed by a single pathologist.

RNA isolation and purification

Total RNA were obtained by extracting frozen tissues in Trizol (Life Technologies Inc., Gaitherbur, MD, USA) according to the manufacturer' s instructions. Normal gastric epithelial tissue and GC tissue were morsellated and homogenized in Trizol solution (1ml/100mg). Homogenates were incubated for 15 min on ice, and then a 1/5 volume of choloform was added to the homogenates. After vigorous agitation for 5 min, the inorganic phase was separated by centrifugation at 12000×*g* for 20 min at 4 ºC. RNA were then precipitated in the presence of 1 volume of isopropanol and centrifuged at 10 000×*g* for 15 min at 4 ºC. RNA pellets were washed with 70 % ice-cold ethanol and then dissolved in diethyl pyrocarbonate (DEPC) – treated H_2O. Total RNA concentration and quantity was assessed by absorbency at 260nm using an Nucleic Acid and Protein Analyzer (BECKMAN 470, USA).

cDNA microarray membrane

Atlas Human Cancer cDNA Expression Array (7742-1) was purchased from Clontech Laboratories Inc(Palo Alto, USA). The membrane contained 10ng of each gene-specific cDNA from 588 known genes and 9 housekeeping genes(Figure 1A). Several plasmid and bacteriophage DNAs and blank spots are also included as negative and blank controls to confirm hybridization specificity. The cancer-related genes analyzed in this study are divided into six groups: (A)cell cycle regulators, growth regulators intermediate filament markers; (B) apoptosis, oncogenes, and tumor suppressors; (C) DNA damage response/repair and recombination; cell fate and development; and receptors; (D) cell adhesion and motility; and angiogenesis; (E) invasion regulators and cell-cell interactions; (F) growth factors and cytokines. A complete list of the 588 genes with the array positions and GeneBank accession number spotted on the array is available at Clontech' s web site (http://www.clontech.com).

cDNA synthesis , labeling and purification

Total RNA was reverse-transcribed into cDNA and labeled with α-^{32}P dCTP using Superscript™ Preamplification system for First Strand cDNA Synthesis (Life Technologies, Gaithersburg, MD, USA). Before labeling, 5 μg total RNA of each type was treated with 2 μl DNase I (10 μnits/μl, Boehringer Mannheim, Mannheim, Germany), 1 μl RNasin (40 μnits/μl, Promega, Madison, WI, USA) at 37 ℃ for 15 min to remove contaminated DNA. For each labeling, the treated 5 μg total RNA was raised in volume to 6 μl with diethyl pyrocarbonate (DEPC)-treated H_2O and first incubated with 4 ul oligo dT (0.5 μg/μl, Life Technologies, Gaithersburg, MD, USA) at 70 ℃ for 10 min. Then, 6 μl 5× first strand reaction buffer, 1 μl 0.1 M DTT (Life Technologies, Gaithersburg, MD, USA), 1.5 μl dNTP mixture containing dATP, dGTP, dTTP at 20 μM (Promega, Madison, WI, USA), 10 μl α-^{32}P dCTP (10 μCi/μl, NEN Life Science, Boston, MA, USA) and 1.5 μl SuperScript II reverse transcriptase (200 μnits/μl, Life Technologies, Gaithersburg, MD, USA) were added and incubated at 37 ℃ for 90 min. The labeled first strand cDNA probes were purified by Spin 200 column (Clontech, Palo Alto, CA, USA) to remove the unincorporated nucleotides. After purification, labeled cDNAs were denatured in a boiling water bath for 3 min before use.

Membrane hybridization and exposure

Five milliliters ExpressHyb hybridization solution (Clontech, Palo Alto, CA, USA) and 5 μg Cot-1 DNA (Life Technologies, Gaithersburg, MD, USA) were added to the tube containing Atlas human cancer cDNA expression array, which were pre-hybridized at 68 ℃ for 2 h. Then different incubated probes were added to different tubes and hybridization was performed at 68 ℃ for 18 h in rolling bottles. The membranes were washed twice at 68 ℃ in 2 × SSC, 0.1 % SDS for 20 min, once at 50 ℃ in 1 × SSC, 0.5 % SDS for 20 min , once at room temperature in 0.5 × SSC, 1% SDS for 20 min and 0.5 × SSC10 min. Membrane were then exposed to X-ray films (Fuji Films, Tokyo, Japan) at -70 ℃ for 24-48 h.

Images and analysis

The images were scanned with Fluor-S MultiImager (Bio-Rad, Hercules, CA, USA) and saved as TIFF format files. The TIFF images were imported into the AtlasImage analysis software Version 1.01 a (Clontech, Palo Alto, CA, USA) and analyzed step by step with the guide. Housekeeping gene Ubiquitin was selected for normalization, because its expression was constant in cancer array hybridization system. Then the normalized intensity of each spot representing a unique gene expression level was acquired. Genes were considered to be up-regulated when the intensity ratio was $\geqslant$1.5 and the difference was $\geqslant$10 000 between the expressions of GC tissues and normal gastric tissues.

RESULTS

Using a cDNA expression microarray technique we established the expression profile of 588 genes, selected from different areas of cancer research, in human GC and normal gastric tissue (Figure 1B, 1C). No signals were visible in the blank spots and negative control spots indicating that the Atlas human cancer array hybridization was highly specific. The housekeeping genes' density were very similar at the same time which indicate that the results were credible (Figure 1B,1C). We used the housekeeping gene, Ubiquitin, to normalize the intensities. The color image of the difference between GC and normal gastric tissue was produced by AtlasImage array software (Figure 1D) . The comparison results analyzed by AtlasImage software showed that there were 63 genes altered, 8 were up-regulated and 55 down-regulated in GC versus normal gastric tissue, using the criteria that the ratio was=1.5 or the difference was=10 000 (Table 1). There were pronounced differences in the gene expression profile between the two tissues.

DISCUSSION

In this study, we have explored the gene expression profiles in human GC and adjacent noncancerous normal gastric tissues using Atlas human cancer array which contains 588 genes that were classified according to their function to be relevant for cancer. cDNA array technology is used to examine simultaneously the expression of specific genes on a single hybridization. Although human genome projects have generated large-scale sequence data for millions of genes, the biological functions of such genes remain to be clarified. It is very important to define differential gene expression profiles of tumors and normal tissues before understanding the functional significance of specific gene products. Although expression analysis techniques such as Differential Display Polymerase Chain Reaction (DD-PCR), northern blot, and serial analysis of gene expression (SAGE) and RT-PCR have been widely used in the past, these studies are time-consuming and can only be used to deal with a limited number of genes.

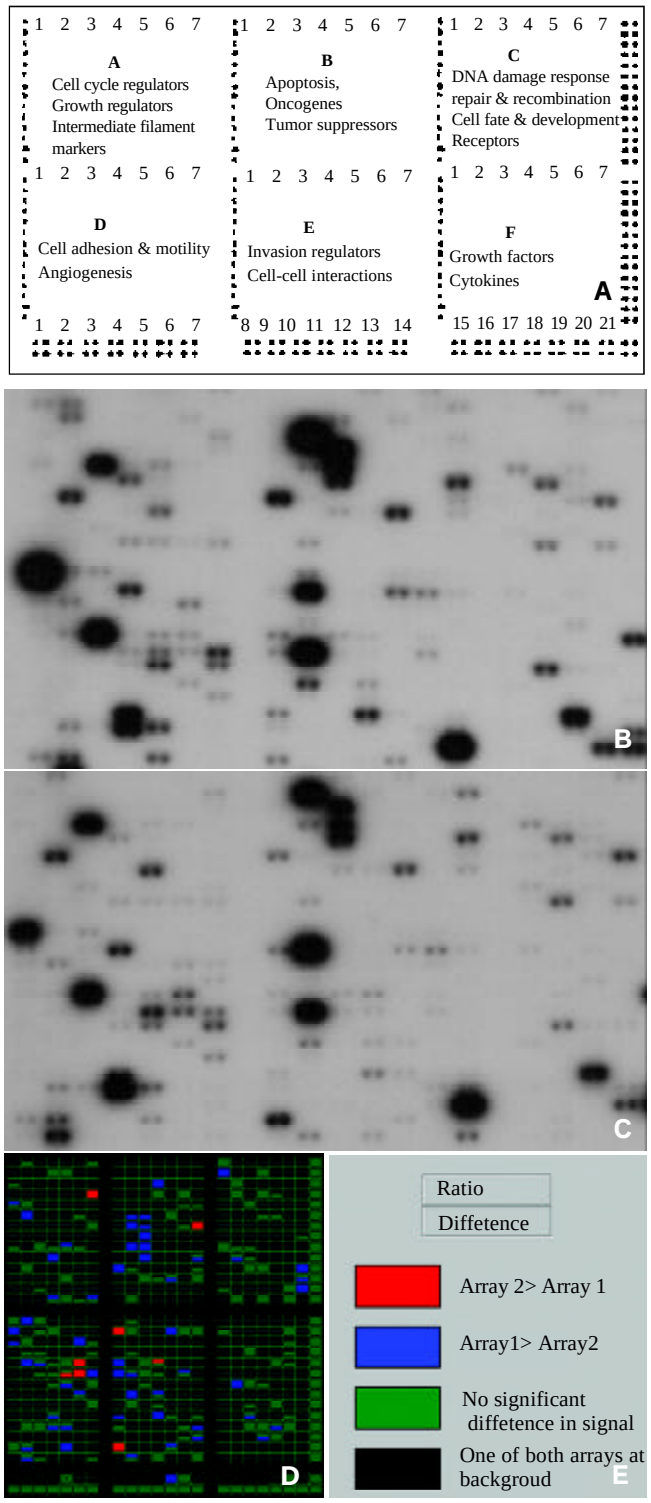

Figure 1 Parallel analysis of gene expression profiles in human gastric carcinoma and adjacent normal gastric mucosa. The schematic diagram of Atlas human cancer expression array contains 588 cancer-related human cDNA spotted as duplicates. Nine housekeeping genes are spotted at the bottom line to serve as positive controls. Dark grey spots at the outer end of the array represent genomic DNA spots, which serve as orientation marks (A). Atlas human cancer cDNA expression array (Clontech, USA) was hybridized with ^{32}P-labeled cDNA probes obtained from total RNA of human gastric carcinoma (B) and adjacent normal gastric tissues (C). The colorful compare diagram between human gastric carcinoma and adjacent normal gastric tissues was got when you aligned two arrays to AtlasImage Grid Temples and adjusted the alignments and background calculations (D). Definitions of colors in the array comparison were showed (E).

Table 1 Genes differentially expressed between HCC and adjacent noamal liver tissues generated by atlasImage software (Version 1.01a)

Gene	Ratio	Differ-ence	Protein / gene
B2f		-42675	TRAF6

E1m	2	17032	MMP-16 (MT3-MMP)

The microarray technique was first reported in 1995 by Schena *et al*[5] and allows the simultaneous parallel expression analysis of thousands of genes . There is considerable interest in the potential application of cDNA microarray analysis for gene expression profiles in human cancers[12]. Such information might be useful for tumor classification, for elucidation of key factor in tumors and for the identification of genes which might be useful for diagnostic purposes or as therapeutic targets[13-15]. The Atlas Human cDNA Expression system provides a convenient and quick method for simultaneously profiling the expression of 588 genes related to cancer at the same time.

Among the genes showing differential expression in human GC, compared with the adjacent normal gastric tissue, several different classes of genes were up-regulated. Cytokeratin 1 (CK1), which is an intermediate filament protein, has a 2.7-fold up-regulation. The cytokeratins assembly *in vivo*, with obligatory heterologous dimeric combinations of different cytokeratins from each of the two major groups, comprising together more than 20 different individual cytokeratins. The keratin polypeptide expression common to all melanoma cells include K1 protein expression. A measure of keratin expression universality in malignant melanoma cells may have implications regarding their invasive and metastatic behaviors [16]. However it has never been reported in GC. Sky is a member of a subfamily of related receptor tyrosine kinases. Sky may function as a cell adhesion molecule and mediate cell-to-cell or cell-matrix interactions between hematopoietic cells and their respective microenvironments [17]. CD9 belongs to the tetraspanin superfamily of cell-surface proteins that span the membrane four times, forming two extracellular loops [18]. A low CD9 expression by tumors of the lung may be associated with poor prognosis [19]. Although the expression of CD9 was markedly down-regulated in basal cell carcinoma [20], it was up-regulated in GC. CD9 was found to be useful for prognosis of patients with colorectal cancer [21] or pancreatic cancer [22]. CD9 gene is a useful indicator of a poor prognosis in breast cancer patients [23].

Matrix metalloproteinases (MMPs) are members of a multigene family of zinc- and calcium-dependent enzymes involved in the degradation of numerous extracellular matrix (ECM) components[24,25]. MMP-2 and MT3-MMP were up-regulated in GC. MMP-2 may initiate and promote angiogenesis[26] and is considered to play a critical role in cell migration and invasion[27]. It is also thought to play an important role in tumour progression [28]. It has been reported that some kinds of malignant tumor tissues, including lung and stomach carcinomas, contain activated MMP-2[29]. MT3-MMP plays a role in extracellular matrix (ECM) turnover by activating proMMP-2 and also by acting directly on ECM macromolecules [30].

As described above, numerous genes were up-regulated, however more genes were down-regulated. Caspases are essential components of the mammalian cell death machinery. Caspase-8,9 and 10 were all down-regulated in GC. Caspase-9 is the member of the apoptotic protease cascade that is triggered by cytochrome c and dATP[31]. Caspase-9 in the presence of cytochrome c and dATP can form an initiating complex for an apoptotic protease cascade[32]. Activated caspase-9 in turn cleaves and activates caspase-3, -6 and -7 zymogens[33]. Activation of the above caspases is blocked by a dominant negative form of caspase-9[32]. The Fas/APO-1-receptor associated cysteine protease Mch5 (caspase-8), a member of the interleukin-1beta-converting enzyme family, is believed to be the enzyme responsible for activating a protease cascade after Fas-receptor ligation, leading to cell death[34,35]. A total of eight different isoforms of caspase-8 have been described. Only two of the caspase-8 isoforms (caspase-8/a and caspase-8/b) were predominantly expressed in cells of different origin. Both isoforms were recruited to the CD95 death-inducing signaling complex and were activated upon CD95 stimulation with similar kinetics[36]. Caspase-10 is involved in CD95 and p55 signal transduction. Caspase-10 is recruited to both the CD95 and p55 tumor necrosis factor receptor signaling complexes in a FADD-dependent manner[37] and may be responsible for activation of the ICE-like proteases[38].

Retinoic acid receptors (RARs) are members of the steroid/thyroid hormone receptor superfamily. RARs serve as ligand-activated transcription factors[39]. RARs are found in all tissues but predominantly in the developing fetus, dividing tumor cells and adult skin[40]. Retinoic acid (RA) exerts its effects by differentially regulating its own receptor gene expression, including RAR alpha, beta,and gamma[41]. RAR-gamma selectively binding retinoids are potent inhibitors of breast cancer cell proliferation alone and in combination with interferon-gamma (IFN-gamma)[42]. RAR-gamma plays a critical role in mediating growth suppression by RA in ovarian cancer cells[43]. Reduced endogenous RAR gamma expression may contribute to the malignant phenotype of human NB[44]. RAR-gamma plays a critical role in a genetic switch between melanocytes and melanoma and induction of ligand-dependent apoptosis[45]. It is still not know if RAR plays a similar role in GC.

The DCC (deleted in colorectal cancer) gene was originally identified as a candidate tumour suppressor gene in colonic carcinogenesis on the basis of allelic losses in chromosome 18q.21 in 70 % of colon cancers. DCC appears likely to play a significant role in differentiation, cell fate determination, and migration in the nervous system and perhaps other tissues as well[46]. Absence of DCC expression however is not associated with colonic tumour progression[47,48].

Neuroendocrine-Dlg (NE-Dlg, neuronal and endocrine dig) is a member of the discs-large-related (DLG) subfamily of the membrane-associated guanylate kinase-related proteins[49]. NE-dlg is a human homolog of the Drosophila discs large (dig) tumor suppressor protein[50]. The NE-dlg appears to be critical for synaptogenesis, acting as a site-specific organizational center for integral membrane proteins and their downstream signaling molecules associated with the cytoskeleton[50]. NE-Dlg directly interacts with the colorectal tumor suppressor gene adenomatous polyposis coli (APC), suggesting that it may play a role in regulating cell proliferation in epithelial cells[50].

In conclusion, our study demonstrates that cDNA array is a powerful tool to explore gene expression profiles in cancer. The genes described in this study should therefore be a valuable resource for basic research, into molecular mechanism of carcinogenesis and the progression and prognosis of tumors. In addition, the clinical application of this work, may include the development of new diagnostic markers and the identification of novel therapeutic strategies for GC.

ACKNOWLEDGMENTS

We thank Dr. Michael Kelly (Department of Surgery , St. George Hospital , University of New South Wales, Sydney, Australia) for his review of the manuscript and helpful suggestions.

Abstract

AIM:**To observe the expression of Human telomerase reverse transcriptase (hTERT) in gastric carcinomas and precancerosis lesions, to evaluate the immune state of such patients, and to then study the clinical significance of hTERT and immune state for the diagnosis, treatment and prognosis of gastric cancer.**

METHODS: **In situ hybridization was used to detect the expression of hTERT mRNA in 116 endoscopic of gastric mucosa. Analyzed tissue samples were as follows: 30 cases of chronic superficial gastritis (CSG), 44 of precancerosis lesions (including 27 of chronic atrophic gastritis, 8 of adenomatous polyp and 9 of gastric ulcer) and 42 of gastric cancer (GC). In addition, the T lymphocyte subsets ($CD3^+$, $CD4^+$, $CD8^+$, $CD4^+/CD8^+$) and natural killer cells (NK) in peripheral blood were determined by flow cytometric analysis (FCM) in 30 cases of CSG, 27 of precancerosis (chronic atrophic gastritis, CAG), and 42 of GC. The data were compared with those of normal control (NC).**

RESULTS:**The detected positive rate of hTERT varied as follows: 86 % (36/42) in GC, 36 % (16/44) in precancerosis lesions and 0 % (0/30) in CSG. The expression of hTERT mRNA was not associated with patient gender, tumor location, macroscopic type, lymph node metastasis, or degree of differentiation. It was found that the $CD3^+$, $CD4^+$ of the CSG group were lower than that of NC ($P<0.05$). Meanwhile, the T lymphocyte subsets ($CD3^+$,$CD4^+$, $CD4^+/CD8^+$ ratio) and NK cells of CAG were remarkably lower than that of NC and CSG groups ($P<0.05$-0.01). Values of T cells and NK cells of the GC group were significantly abnormal when compared with the CAG group ($P<0.05$-0.01). Furthermore, with tumor progression, the function of T cells was weakened gradually.**

CONCLUSION: **The expression of telomerase may be a crucial step in gastric carcinogenesis and increased hTERT mRNA may serve as a novel marker for diagnosis of GC. The immune state of patients with GC and precancerosis was somewhat depressed, which indicates the importance of cellular immunological assays in cancer patients.**

IINTRODUCTION

There are many factors that contribute to gastric carcinogenesis[1-10]. Currently, telomerase has been a major focus[11-23]. Telomerase activation is associated with an early stage of stomach carcinogenesis[24-33]. Human telomerase reverse transcriptase (hTERT) has been identified as a catalytic subunit of human telomerase. Recent studies have demonstrated a close correlation between telomerase activity and hTERT expression[32-41]. In this study, *in situ* hybridization (ISH) was used to detect hTERT expression in patients with GC and precancerosis, which could help us better understand the role of telomerase in the carcinogenesis and development of GC.

In the meantime, many studies have suggested that immune responses to tumor cells play an important role in GC[42-54]. We detected tumor specific lymphocytes (T lymphocytes) and nonspecific natural killer (NK) cells in order to clarify the correlation between cell mediated immunity and the clinicopathologic factors of GC.

MATERIALS AND METHODS

Tissue samples

Gastroscopic removal tissues were obtained from the second affiliated Hospital of Heibei Medical University from January 2 000 to July 2 000. Totally, 116 gastroscopic samples were analyzed. The patients (mean age, 48.3 years; range, 40-56 years) are as follows: 42 cases of GC, 44 chronic gastritis with atypical hyperplasia (including 27 of CAG, 8 of adenomatous polyp and 9 of gastric ulcer), and 30 CSG. In case selection, the disease of liver, circulatory, endocrinopathy and rheumatic systems were excluded. The gastroscopic samples were fixed into formalin with 1 % DEPC to prevent mRNA degradation. For FCM of T lymphocytes and NK cells, 1ml samples of venous blood from each patient was put into a heparinized tube . The value of T lymphocytes and NK cells of 20 blood donors in the same age range were run as NC.

hTERT assay

ISH was carried out by using an hTERT ISH Detection Kit (produced by Wuhan Boster Biological Technology Ltd.). The antisense poly-oligonucleotide probe was digoxin-labeled.

Formalin-fixed, paraffin-embedded samples were cut at 5 μm and adhered to poly-l-lysine treated slides. Samples were deparaffinized and rehydrated through a graded series of ethanol, and endogenous peroxidase was blocked using 3 % hydrogen peroxide for 10 min. The slides were digested with pepsin at 37 degrees for 15-20 min. 20 μl of probe was hybridized

to each slide for 16-20 h at 40 degrees. After hybridization, excess probe was removed by washing in 2×SSC at 37 degrees. Tissue sections were preblocked for 20 min with blocking reagent, then the primary antibody (rabbit anti-digoxin antibody) was added for 60 min at 37 degrees.After washing with 0.5 M PBS three times at 5 min each, the slides were incubated with the secondary goat anti-rabbit immunoglobulin (IgG) antibody conjugated with biotin for 20 min at 37 degrees, then washed with 0.5 M PBS again as previously described. Samples were next incubated with SABC for 20 min at room temperature and rinsed with 0.5M PBS for four times at 5 min each. The reaction products of peroxidase were visualized by incubation with chromogen diaminobenzidine for 15-20 min. Finally, the slides were counterstained for nuclei by haematoxylin stain. A negative control was prepared for each sample using a hybridization solution without probe. The positive signals of hTERT mRNA expression were stains with the color of brown-yellow located in cell plasma. The average percentage of positive cells was determined in at least 5 areas at ×400 and assigned to one of four categories: (-)-negative or equivocal staining; (+)-weak positive, cells were stained in 1-25%; (++)-middle positive, cells were stained in 25-50 %; and (+++)-strong positive expression, cells were stained over 50 %.

Flow cytometric analysis of cellular immunity

The heparinized venous blood samples were made into suspensions of single cells, then plated in reaction tubes. Monoclonal antibodies of mature T cells ($CD3^+$), $T_H(CD4^+)$, $Ts(CD8^+)$, and NK cells(CD^+) were added, then shaken into a well-distributed solution. The solution was incubated for 30 min at room temperature, then rinsed with distilled water for 10 min. The cells were collected after centrifugation at 1000 rpm for 10 min and kept at 4 degrees. Measurement of T cells and NK cells was performed by using a FACSCalibur flow cytometer (Becton Dickinson).

Statistical analyses

The χ^2 test was used for statistical analysis of the frequency of positive hTERT among each group. The data of T cells and NK cells were expressed as mean±standard deviation ($\bar{x}\pm s$), and the differences between the value of different groups were analysed by the *t* test. The criterion of significance was set at $P<0.05$.

RESULTS

Expression levels of hTERT

The positive signals of hTERT mRNA expression were brown-yellow stains located in the cell plasma. (Figure 1 and 2). The expression levels of hTERT in different gastric mucosae are summarized in Table 1. There was no hTERT mRNA expression in CSG (0/30). Positive hTERT was detected in 16 of 44 (36 %) of precancerosis lesions and 36 of 42 (86 %) GC.

Carcinomas exhibited positive hTERT significantly more frequently than did precancerosis lesions ($P<0.05$,by χ^2 test). The positive rate of three groups with dysplasia of CAG, adenomatous polyps (AP) and gastric ulcers (GU) are 37 % (10 of 27), 38 % (3 of 8) and 3 3 % (3 of 9) respectively. There was no significant difference among the three groups ($P>0.05$). Positive rate of early-stage GC and advanced-stage GC are 88 % (7 of 8) and 85 % (29/34) respectively. There was no significant difference between the two groups ($P>0.05$). We also grouped the cancer patients by gender, tumour location, macroscopic type, histological grade, and lymph node metastasis, and found the positive rates of hTERT were not correlated with these clinicopathological factors.

[a]$P<0.05$, [b]$P<0.01$ *vs* early-stage cancer; [c]$P<0.05$ *vs* the cancer patients without lymph node metastasis

The results of T cells examination were as follows:(1) The values of $CD3^+$ and $CD4^+$ in CSG were significantly lower than that in NC ($P<0.05$ *t* test).$CD8^+$ and $CD4^+/CD8^+$ ratio were slightly lower in CSG than in NC, but the change was not significant ($P>0.05$). (2)The values of $CD3^+$,$CD4^+$,$CD4^+/CD8^+$ in CAG were significantly lower compared with CSG and NC ($P<0.05$-0.01). There was no significant change in $CD8^+$ ($P>0.05$). (3)Compared with CAG, all the values of T cells had remarkable changes ($P<0.05$-0.01). (4)The values of $CD3^+$, $CD4^+$, and $CD4^+/CD8^+$ in advanced cancer were remarkably lower than in early-stage cancers ($P<0.05$-0.01). (5) The values of $CD3^+$, $CD4^+$, and $CD4^+/CD8^+$ in the cancer patients with lymph node metastasis were significantly lower than that of cancer patients without lymph node metastasis ($P<0.05$).

The results of NK cell examination were as follows: (1)There was no significant difference between CSG and NC ($P>0.05$). (2)The value of NK was significantly lower in CAG than in CSG ($P<0.01$). (3)The value of NK is also significantly lower in GC than in CAG ($P<0.01$). (4)There was no significant difference between early-stage cancer and advanced cancer ($P>0.05$). The value of NK was not associated with lymph node metastasis ($P>0.05$).

DISCUSSION

Most current studies have proposed that reactivation of telomerse is a critical step in tumorigenesis[24-41]. There is a close correlation between hTERT and telomerase activity[32,33]. Several researchers have reported high levels of hTERT expression in malignant tissues but not in non-malignant tissues by using ISH techniques[14,15,34]. In this study, we used the ISH method to analyze the localization of hTERT mRNA expression in formalin-fixed, paraffin-embedded tissues and got similar results as those previously reported . High levels of hTERT expression were found in the plasma of most carcinoma cells (Figure 1), and the positive rate was 86 %. hTERT expression also increased in precancerosis lesions with the positive rate of 36 %, most of them were weakly positive (Figure 2). No expression was observed in CSG. There is great significance among the three groups above ($P<0.01$). Very high levels of hTERT were detected in 7 of 8 early-stage GC (88 %), which is remarkably greater than that of the precancerosis group (36 %). These data indicate that hTERT overexpression may be not only an early event but also a critical step in carcinogenesis of the stomach. Our result is good evidence that telomerase can be an important marker for diagnosis of early-stage cancers.

It is now almost axiomatic that host immunological reaction is an important factor in resistance to tumors. Immunological cells, either sensitized or nonspecifically activated, are considered necessary to inhibit or kill tumor cells[42-54]. The cell-mediated immunity (CMI) in contact with tumor cells plays an important role in host immune defense of GC patients. Immune response to cancer cells may be mediated mainly by T lymphocyte subsets and nonspecific natural killer (NK) cells. Many studies indicate that T lymphocyte activity is correlated closely with carcinogenesis and development of GC. Critically, the T_H/T_S ratio is a more important index to evaluate the state of cellular immunity and anti-tumor activity[46-50]. NK cells are the main components of nonspecific immune surveillance, which is capable of killing tumor cells without being sensitized previously, and makes up the first defense line to eliminate cancer cells[51-53]. In order to realize the importance of immune state in the process of gastric carciogenesis, we used FCM to detect the mature T lymphocyte, T_H,T_s, T_H/Ts, and NK cells in peripheral blood, whose superficial markers are $CD3^+$, $CD4^+$, $CD8^+$, $CD4^+/CD8^+$, and $CD(16+56)^+$, respectively.

Our results suggested that T lymphocyte subsets and NK cells have significant changes in every stage of the progression from normal gastric mucosa to GC: (1)In NC the values are as follows: $CD3^+$, 68.02±2.01; $CD4^+$, 39.89±4.50; $CD8^+$, 27.14±4.51; $CD4^+/CD8^+$, 1.42±0.21; and NK, 21.44±3.74. (2)$CD3^+$ (61.61±4.39) and $CD4^+$(35.92±3.30) in CSG were significantly lower than that of NC, which indicated that CSG patients not only had the infiltrating lymphocytes in local pathological change but also had a remarkable imbalance in the T cell immunity of the host body. In the CAG group, $CD3^+$ (57.55±3.13), $CD4^+$(33.54±2.82), $CD4^+/CD8^+$ (1.22±0.13), and NK (13.48±3.44) were all remarkably decreased, which indicated the cellular immunity of CAG patients had a distinct abnormality. In the GC group, $CD3^+$ (53.37±10.55), $CD4^+$ (29.37±7.61), $CD4^+/CD8^+$ (0.90±0.39) and NK (9.40±4.38) became much lower than ever. Furthermore, the impairment of cellular immunity became more and more critical with tumor progression and metastasis (Table 3). All these results indicated: (1)The state of cellular immunity of patients with GC was correlated with prognosis. The deficiency of cellular immunity may play an important role in the continuing growth and metastasis of GC; and (2) Using a combination of immunotherapy with other modalities, e.g. chemotherapy or radiation, may lead to effective antitumor therapy.

Reports regarding the relationship between hTERT and local pathological lesions, and the cellular immunity of the host in the process of gastric carcinogenesis are still rare. We found that hTERT had a certain expression in precancerosis lesions while the immunity state of most of those patients decreased. In early-stages of GC, the expression of hTERT had remarkably increased and the cellular immunity had decreased at the same time. These situations are worthy of more attention. According to previous studies, the main mechanism of cellular immunological insufficiency of GC patients is that tumor cells can produce a large amount of immunosuppressive factors. Before the metamorphoses of precancerosis cells, the components of their antigens have had the characteristics of cancer cells in the process of transition from precancerosis to cancer. Such cells can also produce immunosuppressive factors to impair host's cellular immunity. Thus, the insufficiency of the immune system may lead the cancer to worsen, which may cause a vicious cycle. It has been demonstrated that telomerase activation is a crucial step in gastric carcinogenesis. When the expression of telomerase changes the antigenic components of cells in the process of gastric carcinogenesis, then can cancer cells avoid immune surveillance? When telomerase activation affects the role of apoptosis, can this cause T cell or NK cell damage? Such questions need further research. Discussing such questions will

be helpful to realize the mechanism of further reduction of cellular immunity in the process of carcinogenesis and cancer proliferation, and also will provide good prospects of gene therapy which combine anti-tumor telomerase and immunotherapy.

Abstract

AIM: **To investigate the relationship between the expression of inducible nitric oxide synthase(iNOS), vascular endothelial growth factor(VEGF),the microvascular density(MVD) and the pathological features and clinical staging of gastric cancer.**

METHODS: **Immunohistochemical staining was used for detecting the expression of iNOS and VEGF in 46 resected specimens of gastric carcinoma; the monoclonal antibody against CD34 was used for displaying vascular endothelial cells, and MVD was detected by counting of CD34-positive vascular endothelial cells.**

RESULTS: **Of 46 resected specimens of gastric carcinoma, the rates of expressions of iNOS and VEGF were 58. 70% and 76.09%, respectively,and MVD averaged 55.59±19.39.Judged by the standard TNM criteria, the rate of expression of iNOS in stage IV (84.46%) was higher than those in stage I,II, III(Fish exact probabilities test,*P*=0.019,0.023 and 0.033, respectively);the rates of expression of VEGF in stage III,IV (76.0%,92.31%,respectively) were higher than those in stageI,II (Fish exact probabilities test, *P*=0.031,0.017,0.022 and 0.019). MVDs in stage III, IV(64.72±14.96,67.09±18.29,respectively) were higher than those in stage I,II(*t*=2.378,4.015,2.503 and 2.450,*P*<0.05,*P*<0.001,*P*<0.001,*P*<0.05, respectively). In 37 gastric carcinoma specimens with lymph node metastasis, MVD(68.69¡À18.07) and the rates of expression of iNOS and VEGF(70.27%,83.78%, respectively) were higher than those in the specimens with absence of metastasis (*t*=2.205, c^2=6.3587, c^2=6.2584,*P*<0.01, *P*<0.05,*P*<0.05, respectively). MVD and the expressions of iNOS and VEGF were not correlated to the location ,size or grade of tumor,nor with the depth of invasion of tumor; MVDs in the positive iNOS and VEGF specimens(59.88±18.02,58.39±17.73, respectively) were higher than those in the negative iNOS and VEGF specimens (c^2=6.3587 and 6.1574, *P*<0.05, *P*<0.05,respectively);thus the expressions of iNOS and VEGF was correlated to MVD,but the expression of iNOS was not correlated to that of VEGF. In addition,of the 46 surviving patients, the 5-year survival rate of patients with positive iNOS or VEGF tumors was significantly less than that of patients with negative iNOS-or VEGF tumors(c^2=4.3842 and 5.4073,*P*<0.05, *P*<0.05,respectively).**

CONCLUSION: **The expressions of iNOS and VEGF are closely related to tumor angiogenesis,and are involved in the advancement and the lymph node metastasis; thus MVD and the expressions of iNOS and VEGF may serve indexes for evaluating staging of gastric carcinoma and forecasting its risk of metastasis, which will help establish a comprehensive therapeutical measure of post-operative patients and provide a new approach to tumor therapy.**

Song ZJ,Gong P,Wu YE. Relationship between the expression of iNOS,VEGF,tumor angiogenesis and gastric cancer. *World J Gastroenterol* 2002;8(4):591-595

INTRODUCTION

Gastric carcinoma, as one of the most common human malignant tumor,ranks worldwide as the first leading cause of gastrointestinal cancer-related mortality.In China, it now ranks the second. It had been shown that tumor angiogenesis played an important role in its growth, invasion, metastasis and recurrence[1-9]. We studied the relationship between the expression of iNOS,VEGF,MVD and the pathological features, lymph node metastasis and clinical staging of gastric carcinoma, and evaluated the relationship between tumor angiogenesis and the expression of iNOS,VEGF as well as the relationship between tumor angiogenesis and the advancement and the metastasis of gastric cancer using immun ohistochemical staining method in order to reveal the biological features of iNOS and VEGF,which will contribute to further understanding of oncogenesis and provide a new approach to tumor therapy.

MATERIALS AND METHODS

Materials

The resected specimens from 46 cases of gastric cancer confirmed pathologically were obtained from our hospital from January 1999 to October 2000. Of these, 35 patients were male, and 11 female, with a mean age of 56.96±11.26(32 to 78).All of them had not received any radiotherapy or chemotherapy. Among these specimens, 8 were situated in the upper third of the stomach, 13 in the middle third, and 25 in the lower third. Histologically, they were classified by the WHO criteria, 5 were highly differentiated adenocarcinoma, 10 moderately-differentiated, 28 poorly-differentiated, 2 undifferentiated, and 1 was gastric mucous adenocarcinoma. As regards to the size of cancer,2 were <3 cm, 18.3-5 cm, 26 >5 cm. 34 tumors invaded to the serosa and 12 tumors did not.By TNM staging of UICC, 2 cases were in stageI,6 in stageII,25 in stage III,and 13 in stage IV.Only 37 cases had local lymph node metastasis.

Reagents and metdods

Antibody against iNOS was purchased from Wu Han Boster Co. Ltd; antibodies against VEGF and CD34 and ready-to-use

SP immunohistochemical reagent box were purchased from FuJian Maxin Co. Ltd. Formalin-fixed, paraffin-embedded surgical specimens from 46 cases of gastric carcinoma were available and sliced sequentially with a thickness of 4 μm. The slices carrying the detected antigen were dyed with SP immunohistochemical staining method, and those in the control group were dyed according to the above method, with the first antibody substituted by PBS.

Statistical methods

The data were presented as $x \pm s$; numerical variable by the chi-square test; enumeration data by t test; the differences of these groups were compared by analysis of variance.

RESULTS

The cytoplasm of the gastric cancer cells staining brown granules were identified to be positive iNOS or VEGF, and the slices were graded respectively according to the density and the percentage of positively stained gastric carcinoma cells into score 0,1,2 or 3. If the sum of two scores was 0-2, the slice would be considered as the negative iNOS or VEGF; whereas 3-6,it would be considered as positive iNOS or VEGF. When the cytoplasm of theirs stained brown or brownish yellow, vascular endothelial cells were CD34- positive;the microvessels were counted according to the number of single endothelial cell or endothelial cell cluster showing brownish yellow granules in the cytoplasm.The slices were observed first microscopically under the low power (×40),then selected the most dense arear of microvessel under the high power(×200, the surface area of every vision field being 0.785 mm^2), and the number of microvessel in 3 vision fields were counted and took the average as MVD of this specimen[10]

.

The relationship between the expressions of iNOS and VEGF, MVD and pathological features of gastric carcinoma

The positive iNOS and VEGF stained were located at brownish yellow stained granules in the cytoplasm. The positive expression rate of iNOS was 58.7%(27/46)and that of VEGF was 76.09%(35/46). In addition,the positive expression of CD34 was mainly presented at brownish yellow or brownish granules in the cytoplasm of vascular endothelial cell. In all cases, MVD was 20.7 to 81.7 per vision field of high power with an average of 55.59±19.39.

As shown in Table 1,MVD and the rate of expression of iNOS in gastric carcinoma tissue had no significant differences among the site,the size,the degree of differentiation and the depth of invasion of gastric cancer.MVD and the rate of expression of iNOS in cases having lymph node metastasis was significantly higher than those having no lymph node metastasis (t=2.205, χ^2=6.3587, P<0.05, P<0.05,respectively). The rate of expression of VEGF in the gastric carcinoma tissue also had no significant differences among the site, the size, the degree of differentiation of gastric cancer.The rate of expression of VEGF in the gastric carcinomas invading serosa was higher than that failed to invade serosa(χ^2=6.2584, P<0.05). Likewise, the rate of expression of VEGF in cases having lymph node metastasis was significantly higher than cases having no lymph node metastasis (χ^2=6.1574,P<0.05).

The relationship between the expression of iNOS,VEGF, MVD and TNM staging of gastric carcinoma

As shown in Table 2,the rates of expression of iNOS ,VEGF, MVD,the tumor angiogenesis were all related to the clinical staging of gastric carcinoma, and increased with the progression of disease.

Table 1 The relationship between the expressions of iNOS and VEGF,MVD and pathological features of gastric carcinoma

Pathological characteristics	MVD ($\bar{x}\pm s$)	positive iNOS (%)	positive VEGF (%)	total
Site of gastric cancer lesion				
Upper one third	61.50±14.50	5(62.50)	4(50.0)	8
Middle one third	59.82±16.54	8(61.54)	10(76.92)	13
Lower one third	54.52±20.01	14(56.00)	21(84.0)	25
Size of tumor				
< 3 cm	61.50± 20.51	1(50.0)	2(100.0)	2
3~5cm	59.78±16.58	11(61.11)	14(77.78)	18
> 5cm	54.86±17.99	15(57.69)	19(73.08)	26
Depth of invasion				
Invading serosa	62.35±32.97	22(64.71)	29(85.29)[c]	34
Not invading serosa	55.15±18.28	5(41.67)	6(50.0)	12
Metastasis of lymph nodes				
Positive	68.69±18.07[a]	26(70.27)[b]	31(83.78)[d]	37
Negative	54.40±14.23	3(33.33)	4(44.44)	9
Degree of differentiation*				
Well differentiated	49.49±20.10	10(66.67)	11(73.33)	15
Poorly differentiated	59.24±16.80	17(54.84)	24(77.42)	31

Note:*Well differentiated cancer cells include highly and moderately differentiated ones;poorly differentiated cancer cells include poorly differentiated and undifferentiated ones and mucous adenocarcinoma. [a]P<0.01(t=2.205),*vs* MVD in cases having no lymph node metastasis; [b]P<0.05(χ^2=6.3587),*vs* the rate of expression of iNOS in cases having no lymph node metastasis; [c]P<0.05(χ^2=6.2584),*vs* the rate of expression of VEGF in gastric carcinomas not invading to serosa; [d]P<0.05(χ^2=6.1574),*vs* the rate of expression of VEGF in cases having no lymph node metastasis.

Table2 The relationship between the expression of iNOS, VEGF , MVD and TNM staging of gastric carcinoma

Clinical staging	n	Expression of iNOS(%)	Expression of VEGF(%)	MVD ($\bar{x}\pm s$)
StageI	2	1(50.0)	1(50.0)	51.00±7.0[d]
StageII	6	2(33.33)	3(50.0)	47.66±8.71[e]
StageIII	25	13(52.0)	19(76.0)[b]	64.72±14.96[f]

[a]P<0.05, (Fish exact probabilities test, P=0.019, 0.023 and 0.033),*vs* the rate of expression of iNOS in stageI,IIandIII, recpectively; [b]P<0.05(Fish exact probabilities test,P=0.031 and 0.017),*vs* the rates of expression of VEGF in stageIandII, recpectively; [c]P<0.05(Fish exact probabilities test,P=0.022 and 0.019),*vs* the rates of expression of VEGF in stage ⅠandII, recpectively; [d]P<0.05(t=2.378,*vs* MVD in stageIII; [e]P<0.001(t=4.015),*vs* MVD in stageIV; [f]P<0.001(t=2.503),*vs* MVD in stage Ⅱ; [g]P<0.05(t=2.450),*vs* MVD in stage Ⅰ.

The relationship between MVD and the rates of expression of iNOS and VEGF

The above results show that MVD(59.88±18.02) in the iNOS-

positive gastric tissue was higher than that (49.64±12.06) in the iNOS-negative one (t=3.980, P<0.05); and MVD (58.39±17.73) in the VEGF-positive gastric tissue was higher than that (45.43±18.21) in the VEGF-negative one(t=4.098,P<0.05),suggesting that the expressions of iNOS and VEGF were related to MVD and tumor angiogenesis.

The relationship between the expressions of iNOS and VEGF and the prognosis of gastric carcinoma

As shown in Table 3, among 46 patients,the 5-year survival rate of the patients with iNOS-or VEGF-positive tumors was significantly less than that of the patients with iNOS- or VEGF-negative tumors(χ^2=4.3842 and 5.4073,P<0.05, P<0.05, respectively).

Table 3 The relationship between the expressions of iNOS and VEGF and the prognosis of gastric carcinoma

	n	survival period		rate of five-year survival (%)
		< 5 years	>5 years	
iNOS expession				
Positive	27	22	5	18.52[a]
Negative	19	10	9	47.37
VEGF expession				
Positive	35	30	5	14.29[b]
Negative	11	5	6	54.55

[a]P<0.05,(χ^2=4.3842),*vs* the iNOS-negative gastric cancer patients;

[b]P<0.05,(χ^2=5.4073,*vs* the VEGF-negative gastric cancer patients.

DISCUSSION

MVD is related to the increase of the risk of metastasis and/or the decrease of survival period of gastric carcinoma patients[11], and being a reliable index of tumor angiogenesis[12].In the present study, we labeled the vascular endothelial cells with monoclonal antibody against CD34 and detected MVD in all specimens by immunohistochemical staining method, and finally found MVD averaging 55.59±19.39 per visionl field of high power, indicating active tumor angiogenesis. In addition, MVD in the specimens having lymph node metastasis was significantly higher than that having no metastasis,suggesting that increase of MVD and tumor angiogenesis in gastric carcinomas might result in cancer cells entering into the blood circulation, and the lymph node metastasis could be promoted when the gastric cancer cells invade lymphatic vessels. In 46 resected gastric cancer specimens, MVDs in stageIIIandIV were significantly higher than those in stageIand II(t=2.378,4.015,2.503 and 2.450,P<0.05,P<0.001,P<0.001, P<0.05,respectively), indicating MVD was closely related to clinical staging of gastric carcinoma, and MVD and tumor angiogenesis increased with the invasion of gastric cancer. This result reveals MVD may reflect the advancement of gastric carcinoma and the extent of tumor angiogenesis and metastasis[13]; thus it can serve an important index forecasting the prognosis of gastric cancer[5,14].

It is shown that the expression of iNOS in most tumor tissue is higher than that in the normal one[15]; Nitric oxide produced through iNOS induction may increase the vascular permeability and accelerate the nutrient supply of tumor tissue and finally promote the tumor growth[16,17]. In this study, we found that the rate of expression of iNOS of gastric carcinoma in stage Ⅳ was higher than those in stageI, IIand III(Fish exact probabilities test, P=0.019,0.023 and 0.033,respectively), revealing the expression of iNOS of gastric cancer increased with staging of the cancer ,and was higher in late stage[18],the higher the expression of iNOS of gastric cancer ,the more the advancement and the worse the prognosis[19,20]. We also found that the rate of expression of iNOS of gastric carcinoma in those having lymph node metastasis was higher than that having no metastasis(χ^2=6.3587, P<0.05),suggesting the significant increase of its expression in the gastric cancer tissue can promote its lymph node metastasis.

VEGF plays an important role in each stage of tumor angiogenesis[21,22],and its over expression is closely related to clinical staging,lymph node metastasis and recurrence of gastric carcinoma[23,24]. In the present study, we found that the rate of expression of VEGF was related to the depth of invasion,it was higher in gastric cancers with the invasion of serosa than in gastric cancers without that(χ^2=6.2584, P<0.05), indicating VEGF may contribute to the invasive growth of gastric carcinoma, and is relevant to the lymph node metastasis[28]. These are corroborated in stage IIIor Ⅳ lesions. These results show the over expression of VEGF in the gastric cancer tissue has prognostic significance[25-47].

VEGF produced by tumor cell can bind with the surface acceptor of vascular endothelial cell, and promote the production of nitric oxide that can transmit messages between the cells and induce tumor angiogenesis[48,49]This study showed that the rates of expressions of iNOS and VEGF of gastric cancer were related to MVD (t=3.980 and 4.098, P<0.05, P<0.05, respectively), indicating iNOS and VEGF were closely related to tumor angiogenesis[50,51],and might be important factors involved in gastric carcinoma angiogenesis.Moreover,iNOS and VEGF and their effects on angiogenesis can promote the lymph node metastasis and the prognosis ,thus iNOS,VEGF and MVD may all serve important indexes reflecting the biological behaviors, advancement and prognosis of gastric carcinoma.

In conclusion,active angiogenesis exists in the gastric cancer tissue,and MVD is closely relevant to lymph node metastasis,clinical staging and advancement of gastric carcinoma and may act as a valuable index of gastric cancer prognosis; the rates of expressions of iNOS and VEGF in gastric carcinoma are higher than those in the normal gastric tissue, and are related to lymph node metastasis and clinical staging, suggesting they are involved in the advancement and metastasis of gastric cancer which are relevant to its prognosis[52]; the rates of expressions of iNOS and VEGF in the gastric cancer tissue are closely related to MVD,and they may be important factors involved in gastric carcinoma angiogenesis,thus iNOS,VEGF and MVD can act as important indexes reflecting the biological behaviors,advancement and prognosis of gastric cancer. In addition, further study on the mechanism of their regulation will probably offer a new approach to anticancer treatment.

Abstract

AIM:**To study the interactions between human gastric carcinoma cell (HGCC) and human vascular endothelial cell (HVEC), and the role of KDR in these interactions.**

METHODS:**Antisense oligodexynucleotide(ASODN) specific to KDR gene was devised and added to the culture medium of HGCC and HVEC. After the action of ASODN, the proliferation of two cells was measured by MTT method. The role of KDR in regulating the proliferation of two kinds of cells was known through observing the effect of ASODN on them. The conditioned mediums (CMs) of HGCC and HVEC were prepared. The CM of one kind of cell was added acting on the other kind of cell, then the cell proliferation was measured by MTT. After the action of ASODN or CM, the cellular expression of KDR gene was detected with *in situ* hybridization(*ISH*) for mRNA level and with immunohistochemical staining for protein level. *ABC*-ELISA was used to detect *h*VEGF in the CMs of two cells.**

RESULTS: **KDR ASODN could specifically inhibit the proliferation of HGCC and HVEC significantly. The growth inhibitory rate amounted to 55.35 % and 54.83 %, respectively ($P < 0.01$). HGCC and HVEC could secret a certain level of hVEGF(92.06±1.69 ng/L, 77.70±8.04 ng/L). The CM of HGCC could significantly stimulate the growth(2.70±0.01 times) and KDR gene expression of HVEC($P < 0.01$) while the CM of HVEC could significantly inhibit the growth(52.97±0.01 %) and KDR gene expression of HGCC ($P < 0.01$).**

CONCLUSION: **KDR plays a key role in regulating the proliferation of HGCC and HVEC. There exist complicated interactions between HGCC and HVEC. HGCC can significantly stimulate the growth of HVEC while HVEC can significantly inhibit the growth of HGCC. KDR is involved in the interactions between them.**

INTRODUCTION

There exist many kinds of cells besides tumor cell in the solid neoplasm. The relations among all kinds of cells are very complicated. These cells depend on each other and contribute together to the genesis, development, invasion and metastasis of tumor. During the tumor angiogenesis and hematogenous metastasis, there exist complicated interactions between tumor cell (TC) and vascular endothelial cell(VEC). In the pre-angiogenesis, how does TC induce VEC to establish the tumor vascular system? How does TC influence the proliferation, degeneration, morphogenesis and functions of its neighbouring VEC? On the other hand, the interactions between the two cells play a role in the tumor hematogenous metastasis. There exist some complicated mechanisms in these processes. The study of tumor angiogenesis mainly focuses on the interactions among the vascular component cells while the study of tumor metastasis mainly focuses on the interactions between TC and its surrounding stroma. Seldom does anyone notice the interactions between TC and VEC. To better understand some mechanisms in gastric carcinoma angiogenesis and hematogenous metastases, we select human gastric carcinoma cell (HGCC) and human vascular endothelial cell(HVEC) to study their interrelations and some factors in these interactions[1]. Conditioned mediums (CMs) of HGCC and HVEC were prepared. The CM of one kind of cell was added to the other kind of cell, then the cell proliferation was measured by MTT. Many studies have found that KDR, VEGF receptor 2, played an important role in regulating the biological functions of TC and VEC. In order to make clear the role of KDR in regulating the growth of HGCC and HVEC, antisense oligodexynucleotide(ASODN) specific to KDR mRNA was devised and was added acting on the two cells[2,3]. There has been no one to devise KDR ASODN up to now. After the action of CM, the expression of KDR gene was detected. The purpose is to probe into the interactions between HGCC and HVEC and if KDR is involved in the interactions.

MATERIALS AND METHODS

Materials

Cell line HGCC line SGC7901 and HVEC line Eahy926 were employed. The expression of KDR on two cells was (++).

KDR antisense oligodexynucleotide(ASODN) and the action of KDR ASODN ASODN, sense oligodexynucleotide (SODN) and mismatch oligodexynucleotide(MODN) specific to KDR mRNA were designed by the software "Primer 3". The sequence of ASODN was: 5' CAC CTT GCT CTG CAT CCT G 3' , The sequence of SODN was 5' CAG GAT GCA GAG CAA GGT G 3' , The sequence of MODN was 5' CAC TTT GAT CTA CAC CCT G 3' ; The way of KDR ASODN action: cells were placed in serum free medium for growth arrestting. At different periods, ASODN in different doses and culture medium with serum were added at the same time. After different periods:the proliferation of cell was measured by MTT. The cell without the action of ODN was taken as control.

Methods

Preparing CM, measuring activity of conditioned medium (CM) and measuring level of hVEGF Cells in different confluent states were washed twice with PBS, then 3 mL culture medium was added to the cells. The medium what was taken as CM was collected after different periods. After the growth of HGCC and HVEC was arrested for 24 h and 6 h respectively, CM was added. The proliferation of cell was measured by MTT after different culturing periods. The cell without the action of CM was taken as control. The level of *h*VEGF in CMs of two cells was measured by ABC-ELISA kit(*Jingmei, Beijing*).

MTT (methyl tetrazolium colorimetry) 20 μl MTT solution (5 g/L) was added to 200 μl medium in each well of 96 well plate. 4 h later, the supernant was discarded, 150 μl DMSO (Dimethylsulphoxide)was added. After the crystal was dissolved completely, absorption spectrum was measured at 490 nm in the enzyme linked immunosorbent assay meter. The inhibitory rate of cell proliferation=[1-(the mean *A* of experimental group /The mean *A* of control group)] ×100 %

Detecting the expression of KDR gene After the action of KDR ASODN or the action of CM of one kind of cell on the other kind of cell, the expression of KDR gene was measured by *in situ* hybridization for KDR mRNA level and immunohistochemical staining for KDR protein level. Probe for KDR mRNA was designed by the software "Primer 3". The sequence is 5' GGT AGG AGA GGA TAT CCA GCC TG 3' ; Probe labeling and *in situ* hybridization(*ISH*) were carried on according to the manuals of the Dig Oligodexynucleotide Tailing Kit and Dig Detection Kit (*Boehringer Mannheim, Germany*) respectively. PBS was substituted for anti-Dig-Ap as negative control. Immunohistochemical staining for KDR protein on the cells was carried on according to the manual of the S*ABC* Kit (*Huamei, Henang*). KDR polyclonal antibody(*Santa cruz, USA*) was diluted 1:100. Secondary mouse-anti-rat antibody (*Huamei, Henang*) was diluted 1:25. PBS was substituted for primary antibody as negative control. The sections were analyzed for *A* value in the image analysis apparatus.

Statistical analysis

t test was used to compare the means.

RESULTS

Effects of KDR ASODN on the proliferation of HGCC and HVEC

KDR ASODN inhibited the proliferation of HGCC and HVEC significantly. It produced effects in 0.5-1 μmol/ L and 3-6 h later. The cell proliferation inhibitory rate could amount to more than 50 %. The inhibitory rate was related to the dose and action periods(Table 1, 2).

Difference between the effects of KDR ASODN and SODN, MODN on HGCC, HVEC

There existed significant difference between the effects of KDR ASODN and SODN, MODN on the proliferation of HGCC and HVEC (Table 3).

Effects of KDR ASODN on the expression of KDR gene in HGCC and HVEC

Through *ISH* for detecting KDR mRNA level and immunohistochemical staining for KDR protein level, it was found that KDR ASODN inhibited the expression of KDR gene in HGCC and HVEC significantly(Table 4) (Figure 1).

Effect of conditioned medium of gastric carcinoma cell on vascular endothelial cell The conditioned medium of HGCC could stimulate the proliferation of HVEC(^aP <0.05 *vs* no-CM action group) significantly. The stimulation effect was related to the CMs of different cell confluent state, different preparing periods, different volume fraction and different action periods (Table 5, 6).

80%CM	54.26±0.01^a	30.46±0.01^{ab}
50%CM	23.46±0.01^a	19.00±0.01^{ab}
30%CM	21.70±0.00^a	2.13±0.01^b
10%CM	14.36±0.00^a	1.61±0.00^b

^aP<0.05 *vs* No-CM action group;^bP<0.05 *vs* subconfluent group

Expression of KDR gene in HVEC before and after the action of HGCC CM

The mRNA level(*A* value of *in situ* hybridization) before and after the action of HGCC CM was (0.37±0.03), (0.48±0.01^b) respectively (^bP<0.01 *vs* before the action). The protein level (*A* value of immunohistochemical staining) before and after the action of HGCC CM was (0.34±0.03), (0.48±0.02^b) respectively,(^{b}P<0.01 *vs* before the action).So, after the CM of HGCC acted on HVEC, the expression level of KDR gene in HVEC was increased significantly (Figure 1).

Expression of KDR gene in HGCC before and after the action of HVEC CM

The mRNA level(*A* value of *in situ* hybridization) before and after the action of HVEC CM was (0.35±0.03), (0.22±0.02^b) respectively.The protein level(*A* value of immunohistochemical staining) before and after the action of HVEC CM was(0.33± 0.03), (0.23±0.02^b) respectively,(^bP<0.01 *vs* before the action). So, after the CM of HVEC acted on HGCC, the expression level of KDR gene in HGCC was inhibited significantly (Figure 1).

The hVEGF levels in the CMs of HGCC and HVEC

The *h*VEGF level in the CMs of HGCC and HVEC was (92.06 ±1.69 ng/L), (77.70±8.04 ng/L) respectively.

DISCUSSION

An important advance in oncology is that the importance of the tumor angiogenesis in the tumor genesis, growth and metastases, and the importance of the vascular targeting therapy in the tumor treatment have been proved. One of the most important factors in the tumor angiogenesis is vascular endothelium growth factor(VEGF). VEGF can promote and maintain the establishment of tumor vascular system. And it can promote the tumor growth directly. VEGF can induce the mitogenesis and chemotaxis of vascular endothelial cell(VEC)

and tumor cell(TC) intensely. Almost all types of TC and tumor VEC can secret VEGF. But the expression of VEGF in the normal tissue is very low. In the four VEGF receptors, R_2: KDR is the main receptor which gives play to VEGF functions, while other receptors play little role in cell growth. KDR is highly expressed on the TC and tumor VEC while lowly expressed on the normal tissues. In order to make clear the role of KDR in regulating the growth of HGCC and HVEC, We devised the antisense oligodexynucleotide(ASODN) specific to KDR mRNA. There has been no one to devise KDR ASODN up to now. The results showed that KDR ASODN could inhibit the growth and expression of KDR gene of HGCC and HVEC significantly. There was a great difference between the effects of ASODN and SODN, MODN. The CMs of two cells had a certain level of *h*VEGF. This illustrated that KDR ASODN could really enter into the cells and specifically block the expression of KDR gene to interrupt the selfscrine and parascrine growth-stimulation pathway of VEGF. The results showed that VEGF and its receptor KDR played a key role in regulating the proliferation of HGCC and HVEC.

In the human solid neoplasm, there exist many kinds of cells besides the tumor cell, such as: interstitial cell,immunocyte and vascular cell. They depend on each other to contribute to the tumor genesis, development, invasion and metastasis. The interactions among them are complicated. During the tumor angiogenesis and tumor hematogenous metastasis, both VEC and TC contribute to finishing the pathology processes. The interactions between them act in close coordination in establishing tumor vascular system and finishing hematogenous metastasis. There exist very complicated interrelations between TC and VEC. In the pre-angiogenesis, how does TC induce VEC to establish the tumor vascular system? That is, how does TC influence the proliferation, degeneration, morphogenesis and functions of its neighboring VEC? Or, how does VEC influence these characters of its neighboring TC? These are all unclear. On the other hand, the interactions between two cells are involved in the tumor infiltration and hematogenous metastasis. Tumor vascular provides the passage for tumor infiltration and metastasis. The integrated vascular endothelium is the barrier to the tumor infiltration and metastasis. How do these two kinds of cells interact reciprocally to render the tumor cell to adhere to and destroy the vascular endothelium to enter vascular lumen and damage it again to enter stroma? There exist some complicated mechanisms in this process. The study of tumor angiogenesis mainly focuses on the interactions among the vascular component cells while the study of tumor invasion and metastasis mainly focuses on the interactions between TC and surrounding stroma. Seldom has anyone noticed the interactions between TC and VEC. The relations between TC and VEC are not clear. Studies on this aspect are very few. Studies abroad always choose melanoma, glioblastoma, cephalo-cervical squamous carcinoma and hepatocellular carcinoma [4-19], but not gastric carcinoma as the target research yet. And the results are also controversial. We have not found anyone who studies gastric carcinoma yet. There are lots of studies on gastric carcinoma [20-45], but seldom in this aspect. To better understand some mechanisms in gastric carcinoma angiogenesis and hematogenous metastases, we select HGCC and HVEC to study their interrelations and the mechanisms. Considering the results showed that KDR was an important regulator to the growth of HGCC and HVEC, we study the role of KDR in the interactions between the two cells.

Results showed that CMs of HGCC with different confluent state, different preparing periods, different volume fraction and different action periods stimulated the growth of HVEC significantly. The activity of CM of subconfluent cell was stronger than that of CM of confluent cell. The activity of CM preparing for 24 h was stronger than that of CM preparing for 48 h. After the nutrition exhaustion was replenished, the more of the volume fraction, the stronger of the activity. This is consistent with the results of some studies. Someone found CM of bladder carcinoma stimulated the growth of HVEC. Others found that cephalo-cervical squamous carcinoma cell stimulated the growth of HVEC through secreting FGF and VEGF. But there were other contrary viewpoints. Zhao found bladder carcinoma cell inhibited the growth of HVEC through a 10-16bp tRNA fragment. Albini found some kinds of tumor cells inhibited HVEC to form vascular through secreting IFN-γ. There was also a neutral objection: TC has little effect on the proliferation of HVEC. Some researchers found that although TC had no effect on the growth of HVEC, TC could change morphology of HVEC or its sensitivity to TNF-α. we think these different results are due to different cell types. Results showed that HGCC could secret a certain level of *h*VEGF. CM of HGCC could up-regulate the expression of KDR gene in HVEC. It illustrated that KDR played an important role in the growth-stimulation of HGCC to HVEC. It needs further study to show if there exist other factors and mechanisms involved in this effect of HGCC on HVEC.

Our results also showed that CM of HVEC could significantly inhibit the growth of HGCC. The activity of CM of subconfluent cell was stronger than that of CM of confluent cell. After the nutrition exhaustion was replenished, the more of the volume fraction, the stronger of the activity. We do not know what this inhibition means exactly. Maybe in the tumor angiogenesis, the inhibition could prevent HGCC to occupy the place of vascular or participate into the vascularition. Then the stimulation of vascular system to growth of gastric carcinoma is not through the direct interaction between HGCC and HVEC, but the establishment of the vascular system passes nutrition to HGCC and excretes its metabolism waste. HVEC also secreted a certain level of *h*VEGF and VEGF could stimulate the proliferation of HGCC. But CM of HVEC inhibited the growth of HGCC and the KDR gene expression in HGCC. Although HVEC produced growth-stimulator, VEGF, HVEC could interrupt the role of VEGF on HGCC through reducing the level of its main functional receptor,KDR. It illustrated that KDR play an important role in the growth-inhibition of HVEC to HGCC. Whether HVEC secretes some other growth-inhibiting factors to inhibit the proliferation of HGCC or not needs further study.

Abstract

AIM: **To study the interactions between human gastric carcinoma cell (HGCC) and human vascular endothelial cell (HVEC), and if the expression of sphingosine kinase (SPK) gene was involved in these interactions.**

METHODS: **The specific inhibitor to SPK, dimethyl sphingosine (DMS), was added acting on HGCC and HVEC, then the cell proliferation was measured by MTT. The conditioned mediums (CMs) of HGCC and HVEC were prepared. The CM of one kind of cell was added to the other kind of cell, and the cell proliferation was measured by MTT. After the action of CM, the cellular expression of SPK gene in mRNA level was detected with *in situ* hybridization(*ISH*).**

RESULTS: **DMS could almost completely inhibit the proliferation of HGCC and HVEC. The growth inhibitory rates could amount to 97.21 %, 83.42 %, respectively ($P<0.01$). The CM of HGCC could stimulate the growth of HVEC (2.70±0.01, $P<0.01$) while the CM of HVEC could inhibit the growth of HGCC (52.97±0.01 %, $P<0.01$). There was no significant change in the mRNA level of SPK gene in one kind of cell after the action of the CM of the other kind of cell.**

CONCLUSION: **SPK plays a key role in regulating the proliferation of HGCC and HVEC. There exist complicated interactions between HGCC and HVEC. HGCC can significantly stimulate the growth of HVEC while HVEC can significantly inhibit the growth of HGCC. The expression of SPK gene is not involved in the interactions.**

INTRODUCTION

There exist many kinds of cells besides tumor cells in the solid neoplasm. These cells depend on each other and contribute together to the genesis, development, invasion and metastasis of tumor. The relations among all kinds of cells are very complicated. During the tumor angiogenesis and hematogenous metastasis, there exist complicated interactions between tumor cell(TC) and vascular endothelial cell(VEC)[1]. In the pre-angiogenesis, how does TC induce VEC to establish the tumor vascular system? On the other hand, the interactions between the two cells play a role in the tumor hematogenous metastasis. There exist some complicated mechanisms in these processes. The study of tumor angiogenesis mainly focuses on the interactions among the vascular component cells while the study of tumor metastasis mainly focuses on the interactions between TC and its surrounding stroma. Seldom does anyone notice the interactions between TC and VEC. To better understand some mechanisms in human gastric carcinoma angiogenesis and hematogenous metastasis, we selected human gastric carcinoma cell (HGCC) and human vascular endothelial cell(HVEC) to study the interactions between HGCC and HVEC and some mechanisms involved in these actions. Sphingosine kinase(SPK) is a newly found important kinase in regulating many biological functions of most kinds of cells. SPK can induce the synthesis of extracellular transmitter and intracellular second messanger, sphingosine-1-phosphate (SPP). To determine whether SPK took part in regulating the proliferation of HGCC and HVEC, the specific inhibitor to SPK, dimethyl sphingosine(DMS), was acted on the two cells [2]. The present study aims to probe into the interrelationships between HGCC and HVEC and if the expression of SPK gene was involved in these effects. The cell proliferation and the expression of SPK mRNA were measured after the action of the conditioned medium(CM) of the other kind of cell.

MATERIALS AND METHODS

Materials

Cell line HGCC line SGC7901 and HVEC line Eahy926 were employed.

Methods

Conditioned medium(CM) preparation, the ways of the actions of CM and DMS Cells in different confluent states were washed twice with PBS, then 3 mL culture medium was added to the cells. The medium what was taken as CM was collected after different periods. Cells were placed in serum free medium for growth arresting. After the growth of HGCC and HVEC was arrested for 24 h and 6 h respectively, the CM of the other kind of cell was added to the cell. The cell proliferation was measured by MTT after different culturing periods. The cell without the action of CM was taken as control. The action way of DMS was as same as the way of CM. The cell without the action of DMS was taken as control.

MTT (methyl tetrazolium colorimetry) 20 μl MTT solution (5 g/L) was added to 200 μl medium in each well of 96 well plate. 4h later, the supernant was discarded, 150 μl DMSO was added in. After the crystal was dissolved completely, absorption spectrum(A) was measured at 490 nm in the enzyme linked immunosorbent assay meter. The inhibitory rate of cell

proliferation =[1-(the mean *A* of experimental group /The mean of control group)] ×100%

Detecting the expression of SPK gene After the action of CM of the other kind of cell, the cellular expression of SPK gene was detected by *in situ* hybridizition(*ISH*) for mRNA level. There has been no antibody to SPK available up to now, so that it is impossible to detect the level of SPK protein. Probe specific to SPK mRNA was designed with the software "Primer 3". The sequence of SPK probe is 5' ATA TAC CAA GTA GGG GCA TTC ATA CTC 3' ; Probe labeling and *ISH* were carried on according to the manual of the Dig Olignucleotide Tailing Kit and Dig Detection Kit (*Boehringer Mannheim, Germany*) respectively. PBS was substituted for anti-Dig-Ap as negative control. The sections were analyzed for *A* value in the image analysis apparatus.

Statistical analysis

t test was used to compare the means.

RESULTS

Effects of DMS on the proliferation of HGCC and HVEC

DMS could almost completely inhibit the proliferation of HGCC and HVEC. The growth inhibitory rates could amount to 97.21 % and 83.42 % respectively ($^bP<0.01$ *vs* control). DMS could produce effects in 1 μmol/L and 3 h later. The inhibitory rate was related to the dose and action periods. 10 μmol/L DMS inhibited the proliferation of HGCC significantly, and the effect was increasing by leaps and bounds when the dose was from 3.5 μmol/L to 5 μmol/L or the action period was from 24 h to 48 h. 25 μmol/L DMS inhibited the growth of HVEC significantly, and the effect was increasing by leaps and bounds when the dose was from 10 μmol/L to 15 μmol/L or the action period was from 48 h to 72 h(Table 1, 2).

Effect of conditioned medium of gastric carcinoma cell on vascular endothelial cell

The conditioned medium of HGCC could stimulate the proliferation of HVEC([a]P<0.05 *vs* no-CM action group) significantly. The stimulation effect was related to the different cell confluent states, different preparing periods, different volume fractions and different action periods (Table 3,4).

Effect of conditioned medium of vascular endothelial cell on gastric carcinoma cell

The conditioned medium of HVEC could inhibit the proliferation of HGCC significantly([b]P<0.01 *vs* no-CM action group). The inhibitory effect was related to the different cell confluent states and different volume fractions(Table 5).

Table5 Effects of CMs of subconflunt and confluent HVEC on HGCC for 48 h (n=8, $\bar{x}\pm s$)

Expression of SPK gene in HVEC before and after the action of HGCC CM

The mRNA level (*A* value of *ISH*) in HVEC before and after the action of HGCC CM were(0.265±0.016),(0.264±0.021) respectively. There was no significant difference between them. So, after the CM of HGCC acted on HVEC, the expression level of SPK gene in HVEC had no significant change (Figure 1).

Expression of SPK gene in HGCC before and after the action of HVEC CM

The mRNA level (*A* value of *ISH*) in HGCC before and after the action of HVEC CM were(0.244±0.016), (0.243±0.018) respectively. There was no significant difference between them. So, after the CM of HVEC acted on HGCC, the expression level of SPK gene in HGCC had not been significantly changed (Figure 2).

DISCUSSION

In the human solid neoplasm, there exist many kinds of cells besides the tumor cell, such as: interstitial cell,immunocyte and vascular cell. They depend on each other to contribute to the tumor genesis, development, invasion and metastasis. There exist complicated interactions among these cells. During tumor angiogenesis and tumor hematogenous metastasis, both vascular endothelial cell (VEC) and tumor cell (TC) contribute to finishing the pathology processes. The interactions between VEC and TC act in close coordination in establishing tumor vascular system and finishing hematogenous metastasis. There are very complicated interrelations between TC and VEC. In the pre-angiogenesis, how does TC induce VEC to establish the tumor vascular system? That is, how does TC influence the proliferation, degeneration, morphogenesis and functions of its neighboring VEC? Or, how does VEC influence these characters of its neighboring TC? These are all unclear. On the other hand, the interactions between two cells are involved in the tumor infiltration and hematogenous metastasis. Tumor vascular provides the passage for tumor infiltration and metastasis. The integrated vascular endothelium is the barrier

to the tumor infiltration and metastasis. How do these two kinds of cells interact reciprocally to render tumor cell to adhere to and destroy the vascular endothelium to enter vascular lumen and damage it again to enter stroma? There exist some complicated mechanisms in this process. The study of tumor angiogenesis mainly focuses on the interactions among the vascular component cells while the study of tumor invasion and metastasis mainly focuses on the interactions between TC and surrounding stroma. Seldom has anyone noticed the interactions between TC and VEC. The relations between TC and VEC are not clear. Studies on this aspect are very few. Studies abroad always choose melanoma, glioblastoma, cephalo-cervical squamous carcinoma and hepatocellular carcinoma[3-18], but not gastric carcinoma as the target research yet. And the results are also controversial. We have not found anyone who studies gastric carcinoma yet. There are lots of studies on gastric carcinoma[19-29], but seldom in this aspect. To better understand some mechanisms in gastric carcinoma angiogenesis and hematogenous metastases, we select human gastric carcinoma cell(HGCC) and human vascular endothelial cell(HVEC) to study their interrelations and the mechanisms.

Results in this study showed that CMs of HGCC with different confluent states, different preparing periods, different volume fractions and different action periods could all stimulate the growth of HVEC significantly. The activity of CM of subconfluent cell was stronger than that of CM of confluent cell. The activity of CM preparing for 24 h was stronger than that of CM preparing for 48 h. After the nutrition exhaustion was replenished, the more of the volume fraction, the stronger of the activity. This is consistent with the results of some studies. Someone found CM of bladder carcinoma stimulated the growth of HVEC. Others found that cephalo-cervical squamous carcinoma cell stimulated the growth of HVEC through secreting FGF and VEGF. But there were other contrary viewpoints. Zhao found bladder carcinoma cell inhibited the growth of HVEC through a 10-16bp fragment of tRNA. Albini found some kinds of TCs inhibited HVEC to form vascular through secreting IFN-γ. There was also a neutral objection: TC has little effect on the proliferation of HVEC. Some researchers found that although TC had no effect on the growth of HVEC, TC could change morphology of HVEC or its sensitivity to TNF-α. We think these different results are due to different cell types. Our results also showed that CM of HVEC could inhibit the growth of HGCC significantly. The activity of CM of subconfluent cell was stronger than that of CM of confluent cell. After the nutrition exhaustion was replenished, the more of the volume fraction, the stronger of the activity. We do not know what this means exactly. Maybe in the tumor angiogenesis, this inhibition could prevent HGCC to occupy the place of vascular or participate into the vascularition. Then the stimulation of vascular system to the growth of gastric carcinoma is not through the direct interactions between HGCC and HVEC, but through the establishment of the vascular system that passes nutrition to TC and excretes its metabolism waste. Whether HVEC secretes some growth-inhibiting factors to inhibit the proliferation of HGCC or not needs further study.

Sphingosine 1-phosphate(SPP) is a newly found important extracellular transmitter and intracellular second messanger. SPP regulates many biological functions of most kinds of cells through taking part in several signal transduction pathways which include MAPK/ERK(mitogen activated protein kinase/ extracellular regulating kinase, MAPK/ERK)pathway, CAMP signal transduction pathway, Ca^{2+}/CaM(Caldesmon, CaM) pathway and phospholipase D pathway. The functions of SPP include: regulating the proliferation, morphology, migration, adhesion and apoptosis of cells, maintaining the structure of the endothelium and epithelium, regulating vasculagenesis, regulating the cardiovascular function, regulating the intracellular level of Ca^{2+} and K^+, regulating tumor metastasis and so on[29-39]. The synthesis of SPP depends on the activation of sphingosine kinase(SPK). The activation of SPK is closely related to the survival and function of cells[40-49]. Lots of factors can activate SPK such as PDGF(platelet derived growth factor, PDGF) and Fc receptors. The concentrations of SPK in the plasma and serum are 200 nM, 500 nM respectively. There are several phosphorylated sites and combination sites for Ca^{2+} and CaM in the SPK sequence. The sequence of SPK is highly conservative from yeast, protozoon to mammal. The activity of SPK can be detected in the cytoplasm and cell membrane. The functions of SPK are somewhat similar to the functions of PLC(phospholipase C, PLC). To define the role of SPK in regulating the proliferation of HGCC and HVEC, the specific inhibitor to SPK, DMS, was added to the two cells. Results showed that DMS could almost completely inhibit the proliferation of HGCC, HVEC and DMS could produce effects in 1 μmol / L and 3 h later. This illustrated that the regulation of DMS on the proliferation of two cells was prompt, sensitive and striking. Considering SPK was an important regulator to the growth of HGCC and HVEC, we studied the role of SPK in the interactions between these two cells. We found that the expression of SPK mRNA in one kind of cell with no significant change after the action of the CM of the other kind of cell. This showed that the expression of SPK gene didn't involve in the interactions between two cells. Maybe the regulation of one cell on the other cell is through some other factors or pathways. It needs further study to define the other mechanisms involved in the interrelationships between HGCC and HVEC.

Abstract

AIM: **To evaluate the therapeutic effect of compound Chinese drugs, Jianpiyiwei capsule (JPYW) on gastric precancerous lesions in rats and to explore its mechanism of action.**

METHODS: **Model of gastric precancerous lesions was constructed in male Wistar rats: a metal spring was inserted and fixed through pyloric sphincter. One week after recovery, each rat was given 50-60 ℃ hot paste containing 150 g/L NaCl 2 mL orally, twice a week for 15 weeks. Then 10 normal and 11 model rats were anaesthetized, after the measurement of gastric mucosa blood flow (GMBF), the rats were killed and the mucosal hexosamines and malonic dialdehyde (MDA) were measured. The morphological changes of gastric mucosa were observed macroscopically and microscopically, and by an automatic imaging analysis system. Other rats were treated with JPYW 1.5 g/kg·d^{-1} or 4.5 g/kg·d^{-1}, or distilled water as negative control respectively (n=10 in each group). After 12 weeks, all the rats were examined as above.**

RESULTS: **The gastric mucosa of model rats showed chronic atrophic gastritis with dysplasia and intestinal metaplasia (IM), GMBF and hexosamine content were reduced significantly and MDA was increased as compared to the normal group (P<0.01). After 12 weeks treatment, the pathological changes of the negative control group became worsened, while in JPYW treated groups the changes were modified with significant increase of GMBF and reduction of MDA, although the hexosamine concentration increased only mildly.**

CONCLUSION: **JPYW increases GMBF and reduces MDA content in gastric mucosa and has therapeutic effects on gastric precancerous lesions.**

INTRODUCTION

Jianpiyiwei capsule (JPYW), a compound Chinese drug, has the effect of replenishing *qi* (vital energy) and invigorate the spleen, promoting blood flow and regulating the stomach function. This study investigates the therapeutic effect of JPYW on gastric precancerous lesions in rats, and tries to elucidate its mechanism of action in part.

MATERIALS AND METHODS

Male Wistar rats, weighed 250 g to 300 g, were purchased from the Laboratory Animal Center, Chinese Academy of Medical Science. The rats were housed in an air-conditioned animal room at 25±2 ℃ and 60 % humidity with food and water available *ad libitum*, and drinking water was changed every day.

The establishment of gastric precancerous lesions in rats was modified according to Zhao' s method[1] with modification: a metal spring was inserted and fixed through pyloric sphincter. One week after recovery, each rat was given 50-60℃ hot paste containing 150g/L NaCl 2 mL orally, twice a week for 15 weeks. Then, all the survived rats were divided randomly into 4 groups: (1) model group (n=11), (2) negative control (n=10), (3) small dose JPYW group (n=10), (4) large dose JPYW group (n=10). Group 1 rats were killed 16 weeks after the operation, group 2-4 were given diluted water 2 mL/d, JPYW 1.5g/kg· d^{-1} or JPYW 4.5g/kg· d^{-1}, separately, 6 times per week for 12 weeks. Moreover, a group of normal rats (n=10) were raised for 16 weeks and killed together with group 1.

Gastric mucosa blood flow (GMBF) assays

Before the rats were killed, they were forbidden from food except drinking freely for 24 hours, then they were anaesthetized. After incision of the abdominal wall, an ultrasonic detective probe was put to the junction between antrum pylori and corpus ventriculi in gastric curvature of stomach through an incision at the provetriculus, and the voltage number were read to represent the relative level of GMBF.

Morphological study

After the detection of GMBF, the rat was killed and stomach was removed and cut off through the greater curvature, washed by physiological saline and residual liquid was absorbed. The whole stomach was first observed in gross, and then the gastric mucosa of posterior wall was scraped off and frozen to-20℃ immediately for the detection of hexosamines and malonic dialdehyde(MDA). The anterior wall was fixed in 10 % neutral buffered formalin over 24 hours, then were cut into 2 mm-wide pieces, all the pieces were embedded in paraffin. 5 μ m sections, stained with hematoxylin and eosin and with alcian blue, periodic acid-schiff and high iron diamine (AB-PAS/HID), were examined under light microscopy.

Quantitative histologic evaluations were performed using

an automatic imaging analysis system (produced by Beijing University of Aeoronautics and Astronautics). Ten cases of each group were selected for the morphometric measurements, including: (1) thickness of glandular layer *vs* thickness from surface to the end of muscular layer of mucosa (T_1/T_2, five low visual fields in corpus ventriculi and 5 in antrum pylori for each section), (2) neuclear area *vs* cytoplasma area of epithelioglandular cells(N/C), (3) intra-cavity periphery of a gland *vs* the diameter of the circle whose area was equal to the glandular cavity(P_1/D_1), (4) periphery of basal coil in a gland *vs* the diameter of the circle whose area was equal to the gland (P_2/D_2). (2)-(4), each measured 10 middle visual fields in one section.

Hexosamines and MDA assays

The achievement of gastric mucosa has been described as above. The hexosamine content in gastric mucosa was detected according to Neuhaus' s method[2], and the measurement of MDA by thiobarbituric acid method.

Statistical analysis

Numerical values were expressed as $\bar{x}\pm s$. Comparisons of data between groups were performed with *student' s t* test or χ^2 test. $P<0.05$ was considered significant.

RESULTS

Effects of JPYW on the morphrological changes of gastric precancerous lesions in rats

Gross examination of stomach in model and negative control groups showed thinning and paleness of gastric mucosa, with disarrayed plicae and small white nodules, while in the normal groups it was pink, moistened and smooth. In JPYW treated groups, the gross change of gastric mucosa was only modest as compared with negative control group, especially in 4.5 g/Kg· d^{-1} group ($P<0.05$ or 0.01) (Table 1).

Histopathology of gastric mucosa in the model and the negative control groups revealed increased incidence of chronic superficial gastritis (CSG), chronic atrophic gastritis (CAG), intestinal metaplasia (IM) and gastric mucosa dysplasia, as compared with normal and JPYW treated groups ($P<0.05$ or 0.01)(Table 2,). AB-PAS/HID staining showed both complete and incomplete IM (Figure 1).

Data by automatic image pattern analysis were shown in table 3. The ratios of T_1/T_2, representing the degree of mucosal atrophy, were greatly reduced in model and negative control groups both at the gastric body and the antrum, and ratios of N/C, P_1/D_1, P_2/D_2 representing the degree of dysplasia, were increased more prominently in those two groups as compared with normal group ($P<0.01$). In JPYW treated groups, all the ratios approached normal, although there were still some difference between 1.5g/Kg· d^{-1} group and normal ($P<0.05$ or 0.01). (Table 3)

Effects of JPYW on GMBF

The GMBF in model group was reduced more obviously than that in the normal group ($P<0.01$). After 12wk treatment, there was no increase of GMBF in negative control group, but great improvements were seen in JPYW treated groups as compared with model or negative control group ($P<0.01$). (Table 4)

Figure 1(E-F) Effects of JPYW on histological changes of gastric precancerous lesions in rats E-F Show the histologic changes of gastric mucosa in model group, E: Moderate dysplasia with IM HE 100×, F: Incomplete IM AB-PAS/HID 200× G: Moderate to severe dysplasia in gastric mucosa in negative control group HE 100× H: The histological figure of gastric mucosa in JPYW 4.5g/Kg·d^{-1} group is close to normal HE 100×

Effects of JPYW on gastric mucosal contents of hexosamines and MDA

In the model group, the gastric mucosa hexosamine content was lower and MDA was higher than that in the normal group. After 12 wk treatments, no differences were seen between them in the negative control group and model group, yet in 4.5 g/Kg· d^{-1} group there was some increase in hexosamine content, significant difference was still present when compared with normal group (P<0.05). Moreover, the MDA content in JPYW treated groups was greatly reduced (P<0.05 or 0.01). (Table 4)

DISCUSSION

Although the over all incidence of gastric cancer has steadily declined in the western world[3], it is still the most common fatal malignancy in China[4], therefore the treatment of gastric precancerous lesions should be one of the important measures for preventing gastric cancer.

Since 1988 correa and his colleagues proposed a human model of gastric carcinogenesis, which is gastric cancer develops through a complex sequence of evens from normal mucosa to superficial gastritis, chronic atrophic gastritis, IM, dysplasia and finally to intestinal type gastric cancer, numerous studies have found genetic alterations in gastric percancerous lesions and supported the hypothesis[5-10]. But the etiology of gastric precancerous lesions has not been fully elucidated. Many factors are thought to have close relations to gastric carcinogenesis, such as a diet high in salt[11,12] and starch[13] , consumption of high temperature food[14], Helicobacter pylori (HP) infection[15-19], drinking alcohol[19,20] , smoking[20,21] and bile reflux[21-23].

Some experimental studies have shown that the high-salt diet may potentiate HP-associated carcinogenesis in mice by inducing proliferation, pit cell hyperplasia, and glandular atrophy[24], and 50-week bile reflux may cause gastric cancer in rats[25].In this article, we establish a model of gastric precancerous lesions in rats by inserted a metal spring through gastric pylorus sphincter and given hot paste containing high concentration of NaCl, which lead to the development of precancerous gastric lesions. The typical feature of this model are glandular atrophy, lamina propria infiltration of chronic inflammatory cells, thickening of muscularis mucosa, glandular dysplasia and IM, simulating human gastric percancerous lesions. JPYW was found to have obvious effects on gastric precancerous lesions in rats with thickening of gastric mucosa and decreased incidence of dysplasia and IM that firmly supported our hypothesis that JPYW has therapeutic effects on gastric precancerous lesions.

GMBF is an important part of mucosal defense system, bringing oxygen and nutrients to the mucosal cells, against penetration of carcinogenesis into gastric mucosa[26], maintaining the structure and function of the stomach and is closely associated with the pathogenesis and the healing of gasrtrointestinal lesions[27]. In the JPYW treated groups, the GMBF recovered to normal, which indicates that the increase of GMBF may be one of the mechanisms of JPYW on gastric precancerous lesions.

Etiologic studies find that blood levels of natural antioxidants in patients with gastric precancerous lesions or cancer are much lower than healthy people[28] and low level of dietary vitamin C may contribute to the progression of precancerous lesions to gastric cancer[29], whereas a dietary high intake of antioxidants may lower the risk for gastric cancer[30]. Farinati *et al*[31] reported that there was an oxidative DNA damage accumulation with mutagenic and carcinogenic potential in chronic gastritis. MDA content, an metabolite of lipid peroxidant, were found higher in gastric mucosa of patients with HP gastritis[32] and in N-methyl-N' -nitro-N-nitrosoguanidine induced gastric cancer in rats[33]. In our experiment, the MDA content of gastric mucosa in the model rats increased significantly, which implied that the free radicals participated in the occurrence of gastric precancerous lesions. And the reduction of mucosal MDA content in JPYW treated groups indicates that JPYW has a protective action on gastric mucosa.

We also noticed that the hexosamines content, which partially represented the function of gastric mucosal barrier[34] decreased obviously in gastric mucosa of model rats, and only increased slightly in JPYW treated groups with absence of statistical differences. This suggests that the therapeutic effects of JPYW in gastric precancerous lesions dose not involve hexosamine content.

In conclusion, JPYW has therapeutic effects on gastric precancerous lesions, it increases GMBF and reduces mucosal MDA content which may also play a role in its mechanism of action.

Abstract

AIM: **To detect the expression pattern of FAK (focal adhesion kinase) and integrin α5and β1subunits in different kinds of cancerous tissues and to study their correlation with clinicopathological data including tumor type, grade and lymph node status. METHODS: Using an immunohistochemical technique, we examined the expression of FAK and integrin and1 subunits in cancerous and noncancerous tissues obtained from 75 patients with gastric carcinomas, 21 colorectal carcinomas, 16 hepatocellular carcinomas, 20 uterocervical carcinomas, and 20 breast carcinomas.**

RESULTS: **The staining of FAK was stronger in cancerous than in noncancerous areas. Enhanced expression of FAKwas detected in poor-differentiated carcinoma of the stomach and colorectum. Tumors with lymph node metastases had more FAK protein than those without metastases. In addition, the deeper the extent of tumor infiltration, the higher the FAK expression. The expression of integrin α5 and β1subunits was lower in cancerous areas than in noncancerous areas, but it was higher in well-differentiated cancerous tissues than in poor differentiated tissues. The relationship between the expression of integrin α5 and β1subunits and infiltration or metastasis was not significant. Cancerous tissues with stronger FAK expression (++ or +++) also had a higher expression of integrin α5 and β1subunits in the tumor and its unaffected margins.**

CONCLUSION: **FAK is a better marker for carcinogenesis and the progression of cancer than integrin α5 or β1 subunit, and it may be not only a transformation-linked enzyme but also a progression-linked enzyme.**

INTRODUCTION

In recent years, much attention has focused on cell adhesion molecules. These studies have shown that adhesion molecules affect cell behaviors and mediate signal transduction, especially in cancer cells. Integrins are a large family of cell surface receptors that are found in many animal species [1]. They can affect signal transduction, cell proliferation, differentiation, survival and apoptosis, cell cycle and invasion and metastasis of carcinoma cells [2-7]. Previous studies have provided a better understanding of the signaling pathways activated by integrins in adherent cells [1]. As integrins bind to the extra cellular matrix (ECM), they become clustered in the plane of the cell membrane and activate a variety of non-receptor protein tyrosine kinases (PTKs), such as FAK, Abl, Syk and Src-family PTKs.[7-13] Upon activation of FAK, a number of focal adhesion components, such as paxillion, tensin, Shc and P130cas, are phosphorylated and activate the ERK2/MAPK signaling pathway network[13-20] . Therefore, FAK may play a central role in integrin-stimulated signaling events[20], but it is a precondition that integrins bind to the ECM and cluster in the plane of the cell membrane. Integrin expression has been studied[21-34], but studies on the expression integrin α5 and β1 subunits and FAK in gastric cancer and uterocervical cancer are rare. Furthermore, the correlation between integrin and FAK expression has not been studied, and the difference of integrin or FAK expression among these five kinds of cancer has not been reported either.

In the present study, the authors used an immunohistochemical technique to examine the expression of integrin α5 and β1 subunits and FAK in gastric cancer, colorectal cancer, hepatocellular carcinomas, uterocervical cancer, and breast cancer. In addition, the authors correlated the expression of FAK and integrin α5, and β1 subunits with clinicopathologic data, including tumor differentiation, infiltration and metastasis.

MATERIALS AND METHODS

Specimens

Tissue samples were obtained from 75 cases of gastric carcinoma (40 males and 35 females), 21 colorectal cancer (11 males and 10 females), 16 hepatocellular carcinomas (10 males and 6 females), 20 uterocervical cancer, and 20 breast cancer that had undergone total or partial resection in Tumor Hospital, Shanghai Medical University from Jan. 1995 to Jan. 1996. Patient age ranged from 20 to 85 years old. Of the specimens, 51 cases of gastric cancer, 16 colorectal cancer, 16 hepatocellular carcinomas, 18 uterocervical cancer and 17 breast cancer were with unaffected margins. The specimens were fixed in 4 % methanal solution, embedded in wax, and cut in 5 μm serial sections.

Reagents

Antibodies used in this study were as follows: rabbit anti-mouse FAK polyclonal antibody, biotinylated sheep anti-rabbit IgG, and biotinylated sheep anti-mouse IgG from Santa Cruz Biotechnology, Inc. (California, U.S.A.). Monoclonal mouse antibodies directed against human integrin α5 subunit and human integrin β1 subunit were provided by Dr. Mingzhe Zheng at University of Washington, Seattle, U.S.A

Immunohistochemistry

Immunohistochemical staining was performed using the avidin-biotin-peroxidase technique[35]. Anti-FAK antibody was diluted into1:100, anti-α 5 1:15, and anti-β1 1:80. The avidin-biotin-peroxidase reagent kit was purchased from Vector Labratories Inc.

A semiquantitative evaluation system was used to determine antigen expression in tissue samples[36]. Expression was graded on the following scale: negative reaction, (-); mild positive, (+); moderate positive, (++); strong positive, (+++). Evaluation of cell-surface and cytoplasmic staining was performed independently by two of the authors. In the occasional instance of disagreement, the slide was reviewed by the third observer, and a consensus opinion was obtained. The protein expression was correlated with tumor grades, which was in accordance with WHO classification.

Statistical analysis

was performed by using the χ^2 test. A *P* value of <0.05 was considered significant.

RESULTS

Expression of FAK and integrin subunits a5 and b1 in human gastric carcinomas

The expression patterns of the integrin subunits α5 and β1 and FAK in the 75 cases ofgastric carcinomas and 51 unaffected margins are summarized in Table 1. Of the 51 unaffected margin specimens, only 2 (4 %) showed moderate (++) FAK, others showed either negative or minimal FAK, but 39 (76 %) cases showed moderate (++) or strong (+++) integrin α5 immunoreactivity(Figure1 A), and 43 (85 %) showed moderate (++) or strong (+++) integrin b1 immunoreactivity. Of the 75 cancer specimens, 43 (57 %) samples showed moderate (++) or strong (+++) FAK immunoreactivity (Figure3 A), 22 (30 %) samples had moderate integrin α5 immunoreactivity, and 19 (25 %) showed moderate integrin immunoreactivity. None of 75 cancer specimens showed strong immunoreactivity (+++) and neither integrin α5 nor β1 subunit. In contrast with 51 unaffected margin specimens, 35 (69 %) carcinoma specimens had reduced α5 immunoreactivity, 43 (85 %) had reduced β1 immunoreactivity, and 46 (90 %) had increased FAK immunoreactivity. So a significant difference was found between gastric carcinomas and their unaffected margins in the expression of FAK, integrin α5, and β1 subunit.

When FAK expression was compared with histopathological and clinical parameters, the authors found that 30 (68 %) of 44 cases of poorly-differentiated cancer showed moderate or strong immunoreactivity, however, only 13 (42 %) of 31 well-differentiated cancer showed moderate or strong; Of the 59 deep or full stratum invasive cancer, 40 (68 %) showed moderate or strong, and only 3 (23 %) of 16 superficial or mucous invasive cancer showed moderate or strong; 30 (77 %) of 39 cases with lymph node metastasis showed moderate or strong, but 13 (36 %) of 36 cases without lymph node metastasis showed moderate or strong activity. So, a significant association was found between enhanced expression of FAK and poor differentiation, deep invasion, and lymph node metastasis of gastric carcinomas.

In addition, of the 44 cases of poorly-differentiated cancer, 36 (81.8 %) showed negative or minimal α5 and 37 (84 %) showed negative or minimal β1, of the 31 moderate or well differentiated cancers, 17 (55 %) showed negative or minimal α5 and 19 (61 %) showed negative or minimal β1. Reduced expression of subunit α5 and β1 was significantly associated with poorly-differentiated carcinomas, but not with invasion and lymph node metastasis.

Finally, the authors found that 30 of the 43 gastric carcinomas with high FAK expression (++ or +++) had over expression of integrin subunit α5 and β1 in the tumor tissues and unaffected margin of the same specimens.

Expression of FAK and integrin subunits a5 and b1 in human colorectal carcinomas

The expression patterns of the integrin subunits α5 and β1 and FAK in the 21 colorectal carcinomas and 16 unaffected margins are summarized in Table 2.

In contrast with 16 unaffected margin specimens, 10 (62 %) carcinoma specimens had reduced α5 immunoreactivity (Figure1 B), 6 (37 %) had reduced β1 immunoreactivity (Figure2A,2B), and 13 (81 %) had increased FAK immunoreactivity(Figure3 B). So a significant difference was found between colorectal carcinomas and their unaffected margins in the expression of FAK, integrin α5 , and β1 subunit.

When FAK expression was compared with histopathological and clinical parameters, A significant association was also found between over expression of FAK and poor differentiation, deep invasion, and present lymph node metastasis of colorectal carcinomas.

In addition, low expression of subunit α5 and β1 was significantly associated with poorly-differentiated colorectal carcinomas, but not with invasion and metastasis.

Expression of FAK and integrin subunits a5 and b1 in human hepatocellular carcinomas

The expression patterns of the integrin subunits α5 and β1 and FAK in the 16 hepatocellular carcinomas and their unaffected margins are summarized in Table 3.

Table 3 Expression of FAK and integrin subunits α5 and β1 in human hepatocellular carcinomas and their relation to clinical and histological variables

	FAK		Integrin α5		Integrin β1	
	-/+	++/+++	-/+	++/+++	-/+	++/+++

Moderate or well	2	5	3	5	4	5
	$P < 0.05$		$P < 0.01$		$P < 0.05$	

In contrast with 16 unaffected margin specimens, 11 (69 %) carcinoma specimens had reduced a5 immunoreactivity, 7 (44 %) had reduced b1 immunoreactivity, and 11 (69 %) had increased FAK immunoreactivity. So a significant difference was found between hepatocellular carcinomas and their unaffected margins in the expression of FAK, integrin α5 and β1 subunit.

When these protein expression was compared with the degree of differentiation the authors found a significant association between these protein expression of FAK and poor differentiation in hepatocellular carcinomas.

Expression of FAK and integrin subunits a5 and b1 in human uterocervical carcinomas

The expression patterns of the integrin subunits α5 and β1 and FAK in the 20 uterocervical carcinomas and 18 unaffected margins are summarized in Table 4. Comparing with 18 unaffected margin specimens, 13 (72 %) carcinoma specimens had reduced α5 immunoreactivity, 14 (78 %) had reduced β1 immunoreactivity, and 3 (17 %) had increased FAK immunoreactivity. So the positive percentage of integrin α5 or β1 had a significant difference between carcinomas and their unaffected margins. That of FAK was not apparent.

A significant association was not found between increased expression of FAK and poor differentiation or deep invasion of uterocervical carcinomas. Reduced expression of subunit α5 and β1 was significantly associated with poor differentiated carcinomas, but not with invasion.

Expression of FAK and integrin subunits a5 and b1 in human breast carcinomas

The expression patterns of the integrin subunits α5 and β1 and FAK in the 20 breast carcinomas and 17 unaffected margins are summarized in Table 4. Similarly, the increased FAK expression was significantly associated with breast carcinogenesis and lymph node metastasis of breast carcinomas. Reduced expression of subunit α5 and β1 was significantly associated with breast carcinogenesis and poorly-differentiated carcinomas, but not with lymph node metastasis. In contrast with 17 unaffected margin specimens, 14 (82 %) carcinoma specimens had reduced α5 immunoreactivity, 16 (94 %) had reduced β1 immunoreactivity, and 14 (82 %) had increased FAK immunoreactivity.

DISCUSSION

This study indicated that the expression of the FAK antigen was lower in unaffected noncancerous margin tissues than in carcinoma tissues, whereas expression of integrin α5 and β1 subunits was higher in unaffected margin than in carcinoma tissues. The quantity of all three proteins related to the degree of differentiation of the cancer. The reasons for these findings are complex. First, the contents of fibronectin and laminin in the ECM is lower in normal tissues than in cancerous counterparts. However, the fibroblast is stimulated by cancer cells to produce more matrix proteins thereby increasing the concentration of matrix proteins [37]. Second, the increased expression of integrin α5 and β1 subunits in preliminary cancer tissue make the matrix proteins relatively much more deficient. Under these conditions, FAK can exist in a state with high tyrosine-phosphorylated on the Tyr-397/Src SH2 binding site[30-42]. However, the Src-family PTKs are not significantly associated with FAK that has only low levels of kinase activity and its expression is reduced [13, 20, 43-45]. In unaffected margin tissues, the negative regulators of integrin-stimulated signaling events include the FAK-associated PTP, PTEN and the p130cas that all reduced the kinase activity of FAK [46-48]. The quantity of matrix proteins is increased in the ECM of cancerous tissue. Integrins bind to the ECM, and become clustered in the plane of the cell membrane where they increase FAK tyrosine phosphorylation and kinase activity. Src-PTKs can significantly associate with FAK. Since FAK kinase activity is important for the FAK-enhanced increase in Src-PTK activity[49] and Src-PTKs can also phosphorylate FAK within the kinase activation loop (Tyr-576 and Tyr-577) to promote maximal FAK kinase activity, the transient complex formed between FAK and Src after integrin stimulation of cells may lead to the maximal activation of both PTKs[38, 50]. The survival signals are continually magnified, and cells with overexpression of FAK can inhibit the effects of PTEN on PI3-K activity and partially inhibit its effects on PIP_3 levels, Akt phosphorylation and cell apoptosis [51]. Cells proliferate extensively, Therefore the authors believe overexpression of FAK is required for carcinogenesis. The reduced expression of integrin α5,β1 subunit in carcinomas does not decrease the FAK kinase activity. Ca^{2+}, PKC and Phorbol 12-myristate 13-acetate (PMA). can also increase FAK kinase activity[20].

This study indicates that the relationship between integrin α5,β1 subunits and metastasis is not significant in cancer cells, whereas FAK expression is significantly associated with metastasis or invasiveness. The process of cancer invasion or metastasis is complex, and involves attachment of the cancer cell to the ECM, decomposition of the ECM by proteases, and migration of cancer cells. The integrin subunits that aid cell adhesion are reduced in cancerous tissue, but integrin subunits that relate to cell migration are increased or constant [52]. On the basis of these findings, the expression of a single integrin subunit may not correlate with metastasis, but FAK is different because it can associate with integrin β2, β3 and some a subunits[20, 53]. Several other cellular stimuli that generate signals through either G-protein linked receptors, transmembrane growth factor receptors or other unknown mechanisms can increase the level of FAK tyrosine phosphorylation in cells [20]. Thus, FAK may play a central role in signaling events stimulated by integrin or other molecules.

This study also indicates that the quantity change of integrin α5,β1 and their related signal molecule FAK is relate to the type of cancer. For integrin α5, breast carcinoma (82 %) had the most reduced expression, then uterocervical carcinoma (72%), gastric carcinoma (69 %), hepatocellular carcinoma (69 %), colorectal carcinoma (62 %) successively. For integrin α1, breast carcinoma (94 %) also had the most reduced expression, then gastric carcinoma (85 %), uterocervical carcinoma (78 %), hepatocellular carcinoma (44 %), colorectal carcinoma (37 %) successively. For FAK, gastric carcinoma (90 %) had the most increased expression, then colorectal carcinoma (80 %), breast carcinoma (80 %), hepatocellular carcinoma (69 %), uterocervical carcinoma (37 %) successively. From the above data, the authors find that the changes of integrin â1 and FAK is much more related with the type of cancer.

In summary, the authors have shown in the present study that expression of FAK is more significantly associated with carcinogenesis, differentiation and metastasis than that of integrin α5 and β1 subunits. FAK may be not only a transformation-linked enzyme but also a progression-linked enzyme. The level of FAK expression might be a valuable marker for the carcinogenesis and progression of some types of carcinoma. The expression of integrin α5, β1 and FAK is relate to the type of cancer.

ACKNOWLEDGMENTS

We are grateful to Dr. Ming-Zhe Zheng, University of Washington, Washington, USA, for providing the integrin antibody and to the Pathology Department of the Cancer Hospital of Shanghai Medical University for providing surgical specimens. We also thank Mrs. Xiu-Fong Zhang and Mrs. Yue-Zheng Dai for their instruction in preparing this manuscript.

Abstract

AIM:**To study the feasibility of panning and screening phage-displaying recombinant single-chain variable fragment (ScFv) of anti-tumor monoclonal antibodies for fixed whole cells as the carriers of mAb-binding antigens.**

METHODS: **The recombinant phage displaying libraries for anti-colorectal tumor mAb MC3Ab, MC5Ab and anti-gastric tumor mAb MGD1 was constructed. Panning and screening were carried out by means of modified fixation of colorectal and gastric tumor cells expressed the mAb-binding antigens. Concordance of binding specificity to tumor cells between phage clones and parent antibodies was analyzed. The phage of positive clones was identified with competitive ELISA, and infected by *E.coli* HB2151 to express soluble ScFv.**

RESULTS:**The ratio of positive clones to MC3-ScF-MC5-ScFv and MGD1-ScFv were 60 %, 24 % and 30 %. MC3-ScFv had M_r 32 000 confirmed by Western blot. The specificity to antigen had no difference between 4 positive recombinant phage antibodies and MC3Ab.**

CONCLUSION:**The modified process of fixing whole tumor cells is efficient, convenient and feasible to pan and screen the phage–displaying ScFv of anti-tumor monoclonal antibodies.**

Nie YZ, He FT, Li ZK, Wu KC, Cao YX, Chen BJ, Fan DM. Identification of tumor associated single-chain Fv by panning and screening antibody phage library using tumor cells.*World J Gastroenterol* 2002; 8(4) :619-623

INTRODUCTION

Tumor specific or associated antibodies *in vivo* diagnosis and treatment in tumor patients have been sought recently[1-4]. Most tumor-specific or tumor-associated antibodies have been obtained by the approach to immunizing animals with tumor cells, which inevitably cause allergic reaction against animal antibodies[5,6]. To miniaturize animal antibodies is an efficient way to decrease the rejection and allergy reaction. Gene engineering methods, especially phage display(PD), have great advantages[7-9]. It is the best way that purified tumor antigens (TA) were coated to capture recombinant antibodies in phage antibody library[10-12]. Unfortunately, many TA corresponding to tumor specific antibodies have not yet been isolated and purified, even not yet identified[13,14]. It hinders the production of miniaturizing tumor-specific antibodies specific to un-isolated TA. It was speculated that the whole tumor cells which expressed TA might have been considered for replacement of TA. However, It was reported that the panning and screening of PD was non-specific by means of replacing TA with whole tumor cells[8]. This could be attributed to the much lower antigen density and much complicated antigens. Nevertheless, significant progress on the methods has been made, allowing the utilization of PD using whole tumor cells[15,16]. But this utilization is just limited to screen new unknown recombinant antibodies. In this study, we modified the fixing conditions of whole cells for panning and screening phage libraries constructed for the unique monoclonal antibodies such as anti-colon cancer MC3, MC5mAb and anti-gastric cancer MGD1 mAb [13,17-21], and cell ELISA for screening ScFv clone. The results were satisfactory.

MATERIALS AND METHODS

Cell lines

Gastric tumor cell lines[2, 10] KATO-III, AGS, MKN-45, GC803, SGC7901, colorectal tumor cell lines W480, HT-29, CoCa-2, and human fibroblast cells were grown in RPMI 1640 or DMEM supplemented with 100 mL· L^{-1} new born bovine serum (NBS). All cell lines were grown adherently except KATO-III.

Construction of phage ScFv libraries

mRNA was isolated from the corresponding antibodies hybridoma cells. VH and VL cDNA were amplified with RT-PCR and linked with ScFv by linker DNA to form ScFc DNA, which then were inserted into plasmid PCANBSE. Plasmid DNA was transformed into *E.coli* strain TG1. ScFv-phage was induced by superinfection with helper phage M13KO7.

Cells fixation

The fixed cells were used for libraries panning and as antigens of cell ELISA. Methods reported by Ridgway *et al*[8] were used with the following modifications. Fixation of suspending cells: the cells were washed with PBS, resuspended, and transferred to 96-well enzyme-labeled plates at (4-5)×10^5 cells/well. The volume of cell suspension was no less than 300 μl each well. Otherwise, the cells would be distributed unevenly during centrifugation. The plates were centrifuged for 12 min at 1 200 r· min^{-1}, and the supernatants were discarded immediately without disturbing the pellets. The plates were allowed to dry at 37 ℃ for 15-20 min. Into each well, 2.5 g· L^{-1} glutaraldehyde prepared with 60 μl of 0.1 mol· L^{-1} PBS was added. Twelve min later, the fixative solution was discarded. The cells were washed 5 times by PBS. The plates were blocked with 100

g· L^{-1} skimmed milk powder overnight at 4 ℃. Coating of suspending cells for library panning: the cells were plated into 6-well plates at(1-1.5)×10^7 cells/well. The cell suspension volume was no less than 7mL in each well. The rest procedures were as described above. Fixation of adherent cells: the cells were plated into 96-well plates at 0.2×10^4 cells/well. The cells were allowed to incubate 48-72 h. When the cells were 80 % confluent, the medium was removed. The plates were washed twice with prewarmed PBS and dried at 37 ℃ for 20 min. The cells were fixed for 8 min as described above.

Detection of intracellular peroxidase

The fixed cells were divided into 2 groups. Cells in one group were treated with 3 mL· L^{-1} H_2O_2 prepared with methanol and washed 3 times with PBS. The plates were blocked with 50 g· L^{-1} skimmed milk powder overnight at 4 ℃ (or 37 ℃ for 2h). Cells in another group were treated with blocking solution directly. After the blocking solution was removed, the plates were washed 3 times with PBS containing 0.5 g· L^{-1}Tween20, and OPD substrate(50 μl/ well) was added to develop color. thirty min later, the color development was terminated with 2 mol· L^{-1} sulfuric acid. *A*490 were read. The well without substrate was designed as background control. Negative control and blank control were also designed.

Panning of phage libraries

The TG1 recombinant phage antibodies and soluble ScFv secreted by *E.coli* HB2151 were obtained according to the kit instructions (Pharmacia Biotech) [7]. Wash the 6 well plate coated with tumor cells three times with PBS, empty it completely after each wash. Fill the plate completely with blocking buffer to block any remaining sites on the plate surface. Incubate at room temperature for 1 h. Wash the flask three times with PBS, and empty it completely after each wash. Prepare 14 mL of blocking buffer containing 1 mL· L^{-1} thimerosal or 100 mL· L^{-1} sodium azide as a preservative. Dilute the 16 mL of PEG-precipitated recombinant phage with 14 mL of blocking buffer and incubate at room temperature for 10-15 min. Add 20 mL of the diluted recombinant phage to the plate and incubate for 2 h at 37℃. Wash the plate 20 times with PBS and 20 times with PBS containing 10 mL· L^{-1} Tween 20. Empty the plate completely each time. To isolate colonies for small-scale rescue, reinfect *E. coli* TG1 cells with bound phage directly in the panning vessel and plate the reinfected cells. Subsequent rounds of panning are to be performed. Add the entire 10 mL of log-phase TG1 cells to the flask or panning vessel. Incubate with shaking at 37 ℃ for 1 h. Transfer the entire 10 mL from the panning vessel into a sterile 50 mL disposable polypropylene centrifuge tube. To the cell suspension, add ampicillin to 0.1 g· L^{-1}, and glucose to a final concentration of 200 g· L^{-1}. Also add 4×10^{10} pfu of M13KO7 volume of stock to add = 4×10^{13} pfu ÷ M13KO7 pfu/L. Incubate the culture for 1 h at 37℃ with shaking. Sediment the cells by centrifugation and complete the rescue. The selection produre was repeated 4 times before isolated clones were tested by ELISA.

Cell ELISA

Detection of parent antibodies activity[22,23]: cellular endogenous peroxidase activity was rather low, so treatment of cells with H_2O_2 was unnecessary. The procedures were as follows. mAb were added to the blocked wells (50 μl/well). The plates stood for 1h at 37℃. The cells were washed 5 times by PBST. fifty μ L horseradish peroxidase (HRP) conjugated sheep anti-mice IgG was added to each blocked well. The plates stood for 1h at 37 ℃. Cells were washed 5 times with PBST. OPD substrate (50 μl/well) was added to develop color. Ten to twenty min later, *A*490 was read. Normal mice IgG and PBS served as negative and blank controls respectively.

Screening of recombinant phage antibodies or recombinant soluble ScFv clones: recombinant phage antibodies (M13KO7 as negative control) or soluble antibodies bearing anti-E-tag label protein displayed on phage served as the first antibody. Incubation condition was set as 2h at room temperature, gently shaking at 120 r· min^{-1} with cradle. Correspondently, rabbit anti-M13-HRP polyclonal antibody (1:5 000, Pharmacia) or mouse anti-E-tag IgG (1:1000, Pharmacia) were chosen as the second antibody, for the latter sheep anti-mouse IgG HRP, should be used. The rest procedures were as described above.

Concordance of the specificity to tumor cells between the positive recombinant phage clones and parent mAb: the blocked cells were coated as described above (including tumor cells or normal cells expressing antigen highly, lowly and blankly). Pairs of ScFv and parent antibodies were added to all cell plates respectively. A values for each well were read by the same method. Correlation coefficient was obtained through correlation analysis[24-26].

Competitive ELISA

The aim was to screen positive clones with high affinity[27-29]. The cells were coated as described previously. ScFv-phage supernatants or recombinant soluble ScFv (50 μl/well) were added to plates after co-incubation with 1/4 volume of 200 g· L^{-1} skimmed milk powder for 15min. The plates stood for 1hr at 37 ℃. Twenty-five μl corresponding mAb was added to each well. After standing for 1h at 37 ℃, the plates were washed. Fifty μl HRP conjugated sheep anti-mouse IgG were added to each well. After standing for 1 h at 37 ℃, the plates were washed 5 times with PBST. 50 μl OPD substrate were added to each well to develop color. *A*490 were read 10-20 min later. M13KO7 served as negative control. Inhibition rate (%)=1-(*A*490 for experimental well/*A*490 for control well)× 100%.

Western blot

Routine methods were applied[30-33].

Statistical methods

The data were analyzed with SPSS software package.

RESULTS

Detection of parent antibody activity with cell ELISA

The least dilution for MC3mAb was 25 mg· L^{-1}, for MC5mAb was 50 mg· L^{-1}, and for MGD1mAb was 12.5mg· L^{-1}. *A*490 were all more than 0.600, indicating that the mAb used in the experiment were active.

Construction of the ScFv antibody libraries

The VH, VL and ScFv DNAs were about 340, 320 and 750 bp respectively(Figures 1,2).

Panning of phage libraries with coated cells

When suspending cells were plated, if the cell suspensions adding to each well were not enough (<5 mL) or the cell number in each well was too many (>2×10^7 cells/well), the cells would be distributed unevenly during centrifugation. In 4 outer wells, the cells were found to be distributed in a half-moon shape, which was inconvenient for next fixation and panning steps. To avoid the above problems, we added no less than 7 mL cell

suspensions to each well with (1-1.5)×10^7 cells/well, and speeded centrifugation to 1 200 r· min^{-1} gradually. The TG1 containing recombinant phage recovered after 4 rounds of panning were plated on SOB-AG (A: ampicillin ,G: glucose). After 14 h, dense clones were observed.

Screening of recombinant phage antibodies or recombinant soluble clones with cell ELISA

Sixty clones were selected randomly from each panned library. The positive clones, whose *A*490 were over 0.300 (positive control), were counted. The ratio of positive clones were obtained. Soluble expression of *E.coli.* HB2151 was carried out using the positive clones. Its positive rate was determined by cell ELISA and Western blot. The result is shown in Table 1.

Concordance of binding specificity of phage library and parent antibody to tumor cells

Taking MC3-ScFv clone19 as example, the binding specificity of ScFv and parent antibody MC3 to AGS, SW480, SGC7901 fibroblasts were analyzed as shown in Table 2. *A*490 of parent antibodies were set as Y axis, and that of ScFv as X axis. Correlation analysis revealed r =0.991,P<0.01, primarily indicating the concordance of binding specificity of MC3-ScFv clone 19 and parent antibody to tumor cells. Other clones of MC3-ScFv displayed similar characteristics to MC3-ScFv clone 19.

Table 1 Ratio of positive recombinant phage antibody clone and soluble ScFv

	Recombinant phage antibodies		Soluble ScFv	
	Ratio of positive clone (%)	Ratio of competitive clone (%)	Ratio of positive clone (%)	Ratio of competitive clone (%)
MC3 ScFv	60	8	30	8
MC5 ScFv	24	6	18	4
MGD1 ScFv	30	4	10	4

Table 2 Concordance for MC3-ScFv-19 and it's parental mAb specificity to cells

Cell lines	MC3-ScFv 19	MC3 Ab
AGS	1.403±0.132	0.929±0.187
SW480	0.921±0.201	0.647±0.132
SGC7901	0.257±0.045	0.259±0.078
Fibroblast	0.325±0.106	0.297±0.056

Screening of positive ScFv clones with competitive ELISA

Inhibition rate over 30 % was put as criteria[8]. Positive clones from all libraries were obtained as shown in Table 1. As an example ,inhibition rates of 4 positive recombinant phage MC3 antibodies were 56.2 %, 53.6 %, 49.7% and 46.7 %. And inhibition rates of their soluble ScFvs were 41.5 %, 36.9 %, 33.7 % and 21.6 % respectively.

Western blot

Soluble products expressed by *E.coli*. HB2151 were all about M_r 32 000, consistent with the expected molecule weight of soluble ScFv. The result is shown in Figure 3.

DISCUSSION

Phage display (PD) has many advantages in preparing minimized mouse and man antibodies. But the operation has met great difficulties due to severe conditions. The most difficult to satisfy is purified antigen, which is necessary for library panning and clone screening[32-35]. Recently, whole cells have been used in PD to obtain tumor-associated or tumor-specific antibodies. The results are encouraging. Kupsch *et al*[32] obtained human melanoma specific antibody by panning of a phage library using melanoma cells as negative screening, peripheral mononuclear cells as negative screening. Ridgway *et al*[8] cloned a human anti-CD55 ScFv by subtractive panning of a phage library using tumor and nontumor cells. In their studies,

they panned the known libraries to obtain new tumor specific ScFv, so most possible integrity of tumor antigen should have been retained, so they used live cells in panning and cell ELISA. However, the procedures were complicated, and the specialized equipments were required. Particularly, only tumor-associated membrane antigens could be obtained, as for intracellular antigens, the method was powerless[36-38]. The defects could be avoided by using fixed cells. But fixation procedures could destroy antigens partially, resulting in loss of some information. In the present report, we have studied the amenability of fixed cells to phage panning in PD technique.

Since development of mAb technique in the 1980s, many tumor specific or associated mAb have been cloned. However, most tumor antigens have not been identified and purified, and most mouse mAb had great molecular weight, and heterogeneity, which limited the application[39-42]. So, it is necessary to minimize some specific mAb. We constructed recombinant phage displaying libraries for anti-colorectal tumor mAb MC3Ab, MC5Ab and anti-gastric tumor mAb MGD1. Panning was carried out using fixed coated colorectal and gastric tumor cell lines. The positive recombinant phage clones were screened by means of cell ELISA. The concordance of the specificity to tumor cells with parent mAb was analyzed. The affinity of positive clones with tumor antigens was detected with competitive ELISA. The molecules and product amounts were determined by Western blot. All results suggested that fixed cells could be used to panning tumor-associated mouse ScFv using PD.

However, only the following conditions were satisfactory, it successful manipulation was confirmed. Activity of antigen should not be influenced during cell fixation procedures[43-45]. If the structure of antigen determinant cluster were changed during the fixation procedures, the fixation procedures should be modified or the fixative should be changed. We got satisfactory results using coating cells and cell ELISA with the following modifications. Cell lines highly expressing target antigens were used. Adherently or half-adherently grown cells were used because they easily plated and distributed evenly after plating. Fixation with glutaraldehyde could be half shortened. Cell lines highly expressing endogenous peroxidase were excluded to avoid destruction of lipoprotein antigens caused by methanol and H_2O_2 blocking[46-48]. So previous detection of endogeneous peroxidase activity of cell lines is very important; Fixation condition with glutaraldehyde should be modified. Kupsch *et al*[32] recommended that the cells should be fixed with glutaraldehyde at concentration of 5 $g \cdot L^{-1}$ for 30 min in cell ELISA. But we found that the results were more satisfactory with glutaraldehyde at concentration of 2.5 $g \cdot L^{-1}$ for 12 min for suspending cells and for 9min for adherent cells. Other precise conditions, such as centrifugation condition of suspending cells, drying prior to fixation, should also be paid great attention to[49,50]. Application limits: Firstly, fixed cells could be applied to minimization and gene engineering of known mouse mAb. The phage libraries were constructed by using hybridoma. Panning of phage libraries and screening of positive clones were feasible theoretically and practically by using cell lines which strongly expressed these mAb-binding antigens. Secondly, fixed cells might be also applied to panning of large human, mouse phage libraries to obtain unknown tumor specific antibodies. Although fixation procedures might destroy antigens partially so as to lose some information, application of live cells also had disadvantages, such as unfeasibility of screening of intracellular antigens. In present study, gastric tumor specific antigen corresponding to MDG1-ScFv did belong to intracellular antigens, which further indicating the amenability of the fixed cells.

ACKNOWLEDGMENT

We would like to thank Prof. Bo-Rong Pan from Oncology Center, Xijing Hospital for his great contributions to this article.

Abstract

AIM: **To study local therapeutic efficacy, side effects, and complications of radiofrequency ablation (RFA), which is emerging as a new method for the treatment of patients with hepatocellular carcinoma (HCC) with cirrhosis or chronic hepatitis and metastatic liver cancer.**

METHODS: **Thirty-six patients with primary and secondary liver cancers (21 with primary hepatocellular carcinoma, 12 with colorectal cancer liver metastases and 3 with other malignant liver metastases), which were considered not suitable for curative resection, were include in this study. They were treated either with RFA (RITA2000, Mountain View, California, USA) percutaneously (*n*=20) or intraoperatively (*n*=16).The procedures were performed using the ultrasound guidance. The quality of RFA were based on monitoring of equipments and subject feeling of the practitioners. Patients treated with RFA was followed according to clinical findings, radiographic images, and tumor markers.**

RESULTS: **Thirty-six patients underwent RFA for 48 nodules. RFA was used to treat an average 1.3 lesions per patient, and the median size of treated lesions was 2.5 cm (range, 0.5-9 cm). The average hospital stay was 5.6 days overall (2.8 days for percutaneous cases and 7.9 days for open operations). Seven patients underwent a second RFA procedure (sequential ablations). Sixteen HCC patients with a high level of alpha fetoprotein (AFP) and 9 colorectal cancer liver metastases patients with a high level of serum carcinoembryonic antigen (CEA) have a great reduction benefited from RFA. Four (11.1 %) patients had complications: one skin burn; one postoperative hemorrhage; one cholecystitis and one hepatic abscess associated with percutaneous ablations of a large lesion. There were 4 deaths: 3 patients died from local and system diseases (1 at 7 month, 1 at 9 month, and 1 at 12 month), 1 patients died from cardiovascular shock, but no RFA-related death. At a median follow-up of 10 months (range, 1-24 months), 6 patients (16.7 %) had recurrences at an RFA site, and 20 patients (56.7 %) remained clinically free of disease.**

CONCLUSION: **RF ablation appears to be an effective, safe, and relatively simple procedure for the treatment of unresectable liver cancers. The rate and severity of complications appear acceptable. However, further study is necessary to assess combination with other therapies, long-term recurrence rates and effect on overall survival.**

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common solid cancers in the world, with an annual incidence estimated to be at least one million new patients, especially in Eastern Asian and South African[1]. Furthermore, the liver is second only to lymph nodes as a common site of metastasis from other solid cancers, particularly in patients with colorectal adenocarcinoma[2]. Surgical resection of HCC, colorectal cancer hepatic metastases, and patients with other types of primary tumors with liver-only metastases can result in significant long-term survival benefit in 20 % to 35 % of patients[3-5]. However, the majority of hepatic cancers are not suitable for curative resection at the time of diagnosis. Only 5 % to 15 % of newly diagnosed HCC or colorectal cancer liver metastasis patients undergo a potentially curative resection. Difficulties related to surgical resection are those of the size, site, number of tumors, adjacent to vascular and biliary structures, extrahepatic involvement, poor general condition, and poor liver function especially in HCC with inadequate functional hepatic reserve related to coexistent cirrhosis[6,7]. Thus, for the majority of patients with primary or metastatic hepatic malignancies who are not candidates for surgical resection, novel treatment approaches to control and potentially cure the unresectable tumors in the liver must be explored. In the last few years, minimal invasive techniques have become available for destruction of hepatic carcinomas. These include percutaneous ethanol injection (PEI), hepatic arterial embolization and thermoablation with cryoprobes, microwave, laser or radiofrequency [8-18].

Radiofrequency ablation (RFA) is a relatively new procedure for treatment of hepatic tumors not amenable to resection. RFA employs a high-frequency alternating current to cause thermal coagulation and protein denaturation. The procedure is carried out using a needle electrode connected to a radiofrequency generator. As ions attempt to follow the

change in direction of the alternating current, there is frictional heating within the tissue. The result is a coagulative necrosis of the targeted tissue. Previous studies have employed both imaging studies and pathologic evaluation of ablated lesions to show complete tumor eradication[19-28].

The purpose of this analysis was to evaluate our initial experience with RFA of hepatic tumors, and examine the associated complications and local recurrence rate. Although the number of patients is limited and the follow-up is short, we provide some insight for the future wider application of this method.

MATERIALS AND METHODS

Patients

The study was performed with approval from the institutional ethics committees at the First Clinical College of Harbin Medical University. Informed consent was obtained from all patients at the time of enrollment.

Between January 2000 and December 2001, 36 consecutive patients (22 men, 14 women; mean age, 48.1 years; age range, 35-74 years) with HCC and liver metastases underwent the RF procedure. Twenty-one patients suffered HCC and 3 was recurrent HCC. Twelve patients got liver metastases from colorectal carcinoma, 2 patients from breast cancers, 1 from gastric carcinoma. The cirrhosis, which existed not only in HCC but also in liver metastases, were in 26 patients. It was related to hepatitis B in 15 patients, related to hepatitis C in 3, related to hepatitis B or C in 6 and related to alcohol use in 2. The Child-Pugh class of cirrhosis was determined in each patient, and at the time of the ablation procedure, Twenty-five patients were judged to have Child-Pugh class A; and 11 class B. Pathologic result of HCC was obtained by means of ultrasonographically (US) guided biopsy with a 21-gauge cutting needle or viral hepatitis or cirrhosis history with a high level of AFP. Biopsy was not performed in patients in whom US and CT findings consistently indicated HCC and AFP levels were more than 200 ng/mL (>200 μg/L). The pathologic result of liver metastases was got by the same way and a history of primary colorectal carcinoma or other cancer with an increasing of CEA and other serum makers. Biopsy was only performed in patients in whom US and CT findings not consistently indicated metastasis and CEA levels were normal. The characteristics of 36 patients treated with RFA are summarized in Table 1.

All the patients had been examined by three experienced surgeon and were considered to be unsuitable for surgical intervention. Patients with coexistent morbidity-related poor life expectancy, multinodular or diffuse intrahepatic tumor, extrahepatic spread, portal thrombosis, Child-Pugh class C cirrhosis, refractory ascites, prothrombin activity less than 50 %, or a platelet count lower than 50×10^9/L were excluded from this study.

Before enrollment, the stage of intrahepatic disease was determined by using US and contrast material-enhanced spiral computed tomography (CT) in all the patients. Selective hepatic angiography and magnetic resonance (MR) images were acquired in 11 patients. Dual-phase spiral CT was performed with injection of 150 mL of contrast. Selective hepatic angiography and MR were only conducted in patients whose images of ultrasound and CT were not clear. The size and location of the HCC nodules were assessed with Couinaud nomenclature by means of consensus between at least two observers who compared the images obtained with each of the radiological techniques.

All patients who underwent RF ablation, the following serologic values were measured before treatment and 24 hours, 48 hours, 7 days, and 1 month after treatment,induding AFP, CEA, CA19-9, transaminases, alkaline phosphatase, bilirubin, electrolytes, hemoglobin, fibrinogen, haptoglobin, creatinine, prothrombin activity, and complete blood cell count.

Table 1 Characteristics of 36 patients treated with radiofrequence ablation

Characteristics [a]	HCC	CLM	OLM
No. of patients	21	12	3
No. of nodules	28	17	3
Mean age	45.9(35-70)	52.3(41-74)	50.6(48-54)
Male/Famale	15/6	9/3	0/3
Child-Pugh cirrhosis			
Class A	11	11	3
Class B	10	1	0
Class C	0	0	0
Positive HBsAg	10	4	1
Positive Antibody against Hepatitis C	2	1	0
Positive HBsAg and Hepatitis C	6	0	0
Lesion size			
< 3.0 cm	15	10	2
>3.0 cm and <5.0 cm	8	4	1
>5.0 cm	5	3	0

Equipments

Multielectrode, 15-gauge and radiofrequency probes, which was expandable by 8 hooks, were supplied by RITA Medical Systems (Mountain View, California). The hook-shaped retractable electrodes are deployed to a maximum diameter of 5.0 cm. The probe is insulated to within 1 cm of the tip to prevent cauterization along the shaft. Each electrode tip contains a thermistor that allows temperature monitoring in the tissue around the needle. The radiofrequency generator (RITA Medical Systems) delivers a 460 kHz continuous unmodulated sinusoidal waveform in the monopolar output mode (50-150 W). A computer (IBM ThinkPad, USA) with dedicated software (Micro Interactive, USA) connected to the generator recorded the power delivered, impedance values, thermistor temperatures, and timing of each procedure.

RFA procedures

The percutaneous procedure was performed in a hospital procedure room by one radiologist , one surgeon and one nurse. One hour before treatment, the patient received an orally administered sedative and an intravenously administered analgesic. The patient was monitored continuously before, during, and after the procedure. A 20-cm-long, 15-gauge and multielectrode RF probe with an expansion at 2, 3, 4, 5 cm (Starburst XL, RITA, California, USA) was used to deliver

RF energy. Grounding was achieved by attaching a dispersive pad with a surface area greater than 400 cm^2 to each of the patient's thighs. The patients were under local anesthesia induces by using 10 ml of 1 % Lidocaine injected from the skin into the peritoneum along the predetermined puncture line. The electrode was then attached to a 460-kHz RF generator .

Celiotomy was performed if the percutaneous method was not feasible or the leisions located near diaphragm and major hepatic vessel or bile ducts. The lesions were identified by a combination of manual palpation and handheld intraoperative ultrasonography. During the period of RFA using open laprotomy, Pringle' s occlusion was applied to increase the effectiveness by preventing heat conduction from surrounding vessels.

All procedures were under the guidance of ultrasound. During lesion ablation, a thermocouple embedded in the electrode tip continuously measured the local temperature. Tissue impedance was monitored continuously by means of circuitry incorporated in the generator. For each treatment session, a single RF probe was positioned at the center of the tumor less than 3 cm in diameter. Otherwise, RF probe was introduced into a 1.0 cm deep position from the center of the lesion more than 3.0 cm diameter. Following satisfactory deployment of the multiple array, the initial power was applied at 50W and then increased in 10W increments at 1, 2, 3, and 4 minutes to a maximum power of 90W. Power and tissue impedance was monitored continuously from the RF generator. Treatment started automatically when the temperatures of each tips were above 95 ℃. Treatment continued until power "roll-off" occured, indicating a precipitous drop in power output as tissue impedance increased markedly from coagulative necrosis. Before took out the probe, the ablation of the puncture line was necessary to prevent tumor cell metastasis.

During energy deposition, a hyperechoic patch due to vaporization and cavitation effects was observed around the electrode tip; the patch progressively increased to cover all of the neoplastic area or a larger area. Several minutes after the end of treatment, the hyperechoic patch cleared and was replaced by a hyperechoic ring, which was usually smaller. RF energy was applied for 10-12 minutes. After RF therapy, patients were hospitalized for 2-3 days for percutaneous, whereas were 7-10 days in open celiotomy, unless complications necessitated longer hospitalization.

Effectiveness of RFA

All treatment sessions were completed within 1 month after the beginning of the therapies. Dynamic CT was performed 1 week and 1 month after the initial treatments. The CT scans were interpreted by the same radiologist. When a nonenhancing area with a diameter equal to or greater than that of the treated nodule was detected, tumor necrosis was considered to be complete. When nodule enhancement was seen at dynamic CT, tumor necrosis was considered to be incomplete. Additional RFA was performed in nodules that showed incomplete necrosis at dynamic CT performed 1 week after the initial treatment. The therapeutic effect was evaluated with dynamic CT 1 month after the initial treatment, and when no enhancing lesion was seen, the therapeutic effect was considered to be complete. When nodule enhancement was still seen, the therapeutic effect was considered to be incomplete and one more procedure was offered to these patients.

Follow-up dynamic CT was performed every 3 months. A newly appeared and enhanced lesion in or near the treated nodule or an enlargement of the treated nodule was considered to be residual foci of the disease. The follow-up periods ranged from 1 to 24 months (mean, 10 months).

RESULT

Therapeutic efficacy

The results of RF treatment, according to tumor size and pathology, are summarized in Table 2. Seven lesions required repeat treatment within 1 month after the initial ablation, and one lesion was re-treated after 6 months of follow-up owing to the identification of small foci of persistent viable tumor that were undetectable at the previous examination. Overall, when compared with tumor pathology, tumor size was highly significant in predicting treatment success. Tumors less than 3.0 cm in diameter were fully ablated once with recurrence. Tumors 3.1-5.0 cm in diameter were more successfully treated significantly than those greater than 5.0 cm in diameter. At 6-month follow-up, abnormal α-fetoprotein levels normalized (<20 ng/mL [20 μg/L]) in 6 of 21 patients, decreased in 10 patients, and increased in 5 patients. CEA levels normalized in 4 of 12 patients, decreased in 5 patients, and increased in 2 patients. There were 4 deaths: 3 patients died from local and system diseases (1 at 7 month, and 1 at 9 month and 1 at 12 month), and 1 patients died from cardiovascular shock.

Table 2 Summary of results of RFA in liver cancers

Results[a]	HCC			CLM			OLM		
	<3.0cm	>3.0cm <5.0cm	>5.0cm	<3.0cm	>3.0cm <5.0cm	>5.0cm	<3.0cm	>3.0cm <5.0cm	>5.0cm

[a]HCC=Hepatocellular carcinoma, CLM=Colorectal cancer liver metastases, OLM=Other malignancies liver metastases, AFP=α-fetoprotein, CEA=carcinoembryonic antigen

Imaging findings

A rim of hyperattenuation surrounding the region of coagulated tumor was apparent in the majority of cases during the portal phase of contrast enhancement on CT scans obtained 24 hours after RF treatment. This was attributed to reactive hyperemia rather than residual viable tumor and disappeared progressively on subsequent follow-up studies. Thickening of the hepatic capsule was sometimes observed on CT scans obtained 1 month after ablation and beyond, particularly when the tumor was located close to the surface of the liver. This finding also progressively disappeared on subsequent follow-up studies.

Immediately following RF therapy, treated areas of tumor appeared as areas of hypoattenuation ,compared with both surrounding liver and residual tumor. However, tumor size was unchanged, compared with pretreatment tumor size, regardless of treatment response. On subsequent follow-up CT scans, areas of successfully treated tumor remained either unchanged in size or diminished at unpredictable rates.

Although the diameter of the hyperechoic focus seen during treatment was used to guide the duration of RF application, and grossly corresponded to the diameter of necrosis demonstrated at CT, conventional US was not used for the evaluation of therapeutic response. This was principally

because of the heterogeneous and variable extent of hyperechogenicity observed after treatment (Figure 1,2).

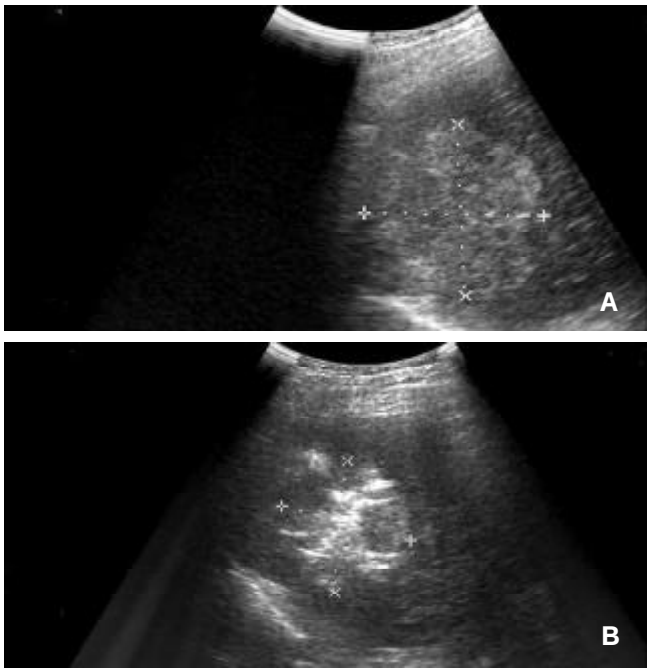

Figure 1 (A) Intercostal oblique sonogram shows a 5.7cm diameter nodular HCC in segment 8. (B)The RF electrode has been placed in the lesion, and the electrode tip is recognizable as an echogenic area in the tumor. Sonogram obtained after several minutes of energy deposition shows a hyperechoic patch around the electrode tip.

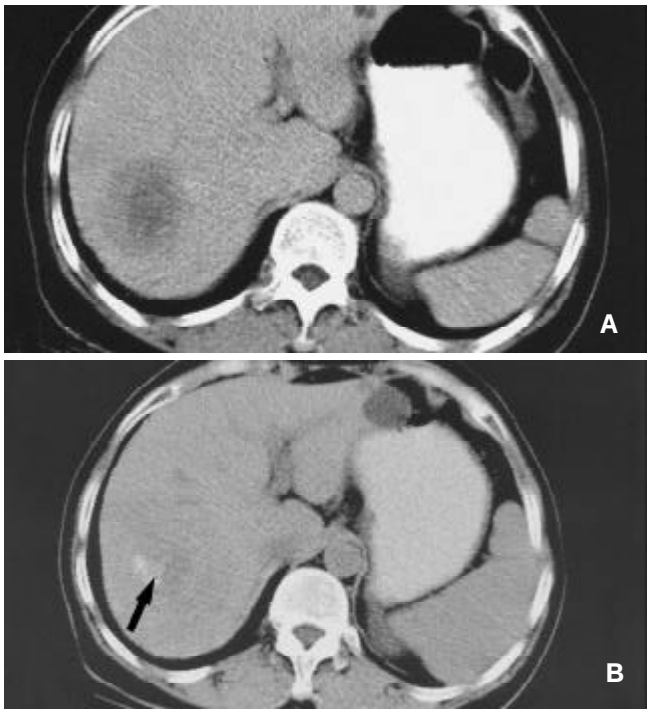

Figure 2 Nearly complete necrosis in a large HCC located in segment 7 and treated with RF therapy in a 57-year-old colorectal cancer liver metastases. (A) CT scan obtained prior to therapy demonstrates a large, 5.3 cm nodules. (B) CT scan obtained 6 months after RF therapy shows nearly complete tumor necrosis. A small hypervascularized area of viable neoplastic tissue(arrow) remains at the posteromedial aspect of the tumor.

Side effects

The majority of patients treated with the use of sedation or analgesia had mild or moderate pain during the percutaneous procedure. This disappeared 1-2 days following the cessation of RF application. However, in 2 cases, propofol and additional analgesia with assisted ventilation were administered to complete the procedure. In 1 of 25 patients, RF application had to be interrupted temporarily because of severe pain and transfer to open operation. In the majority of patients, a small asymptomatic right pleural effusion that lasted for less than 1 month was observed.

In the majority of patients, transaminase levels increased two to nine times over baseline during the first 3 days following therapy. Moreover, a slight increase in leukocytes and bilirubin and a decrease in platelets were observed. All of these test results returned to baseline levels by 7 days following RF ablation. No significant changes in other test results were observed.

Complications

Four (11.1%) patients had complications: one liver abscess; one skin burn; one postoperative hemorrhage and one cholecystitis.

Major complications

One 51 year old patient with cirrhosis and diabetes and two hepatocellular carcinoma nodules of 5.0 and 2.5 cm diameter had a liver abscess (2.7 %). On day 15 after the procedure, this patient had fever with leukocytosis. US showed a big liver abscess in the remnant of big tumor . The patient was treated successfully with percutaneous drainage of the abscess. This complication was attributed to a break in sterile technique and not to the application of RF. As a result of this complication, however, antibiotic prophylaxis with 1 000 mg of ceftriaxone sodium (Rocephin, Roche, Shanghai, China) is currently administered to all patients.

Minor complications

One (2.7 %) of 36 patients developed self-limited intraperitoneal hemorrhage (the appearance of peritoneal effusion with an associated 1-2 g/dL decrease in serum hemoglobin). This patient did not require blood transfusion or other interventions. Another had a mild cholecystitis with a severe leukocytosis. The patient had been given antibiotic for 5 days and recovered quickly. One patient got a skin burn due to incorrectly grounding for not attaching the dispersive pad to skin in the early stage of performing RFA. None of these complications required further treatment, although hospital discharge was delayed.

DISCUSSION

The management of HCC and liver metastases is challenging. HCC and liver metastases from other solid tumors are major causes of morbidity and cancer-related death worldwide. The poor prognosis of HCC is underscored by a mortality index of 0.94. That is mean that 94 % of the patients diagnosed with HCC will die as a result of this disease[1]. Similarly, the development of solid tumor liver metastases is frequently a sign of rapidly death if not be treated. Although resection of primary or metastatic hepatic lesions can be curative in some cases, most patients have unresectable tumors. Unfortunately, systemic chemotherapy is rarely effective and often associated with significant toxicity , with few complete responses and rare long-term progression-free survival, and usually do not

significantly improve overall patient survival[29-31]. As previously noted, the majority of patients with primary or metastatic liver tumors are not candidates for resection; however, because potentially curative or palliative benefit may be derived from destruction of the liver tumors, in situ ablative techniques like PEI, cryoablation and RFA were developed.

The mechanism of RF is that a high-frequency alternating current (100 to 500 kHz), mostly 460 kHz, passes from an uninsulated electrode tip into the surrounding tissues and causes ionic vibration as the ions attempt to follow the change in the direction of the rapidly alternating current. This ionic vibration causes frictional heating of the tissues surrounding the electrode, rather than the heat being generated from the probe itself. The goal of RFA is to achieve local temperatures so that tissue destruction occurs. In general, thermal damage to cells begins at 42 ℃, with exposure times required for cell death at this temperature ranging from 3 to 50 hours depending on the nature of the tissue. As the temperature is increased, there is an exponential decrease in the exposure time needed for cellular destruction. At temperatures above 60 ℃, intracellular proteins including collagen denature, the lipid bilayer melts and cell death becomes inevitable. Thermal coagulation begins at 70 ℃ and tissue desiccation at 100 ℃, producing coagulation necrosis of tumor tissue and surrounding hepatic parenchyma. Tissue heating also drives extracellular and intracellular water out of the tissue and results in further destruction of the tissue due to coagulative necrosis[19,20,32-34].

The first probe used in RF was a monopolar which only destroyed 1.5 cm tissues in diameter. Advances in RF technology led to the development of monopolar and bipolar tissue ablation devices designed to destroy larger areas of tissue, particularly malignant tumors. For tumor ablation, a needle electrode is placed in the tumor via a percutaneous or intraoperative approach, and an indifferent dispersive electrode pad is applied to the patient's outer skin surface, much like the grounding pads used for hemostatic electrocautery during surgical procedures. The final size of the sphere of heat-ablated tissue is proportional to the square of the radiofrequency current, also known as the radiofrequency power density. The radiofrequency power delivered via a monopolar electrode decreases in proportion to the square of the distance from the electrode. Therefore, the tissue temperature falls rapidly with increasing distance away from the electrode. The zone of tissue necrosis can be increased to 2.0 to 3.0 cm by the use of bipolar needle electrodes. New needles have been developed with multiple array hook electrodes used in our patients. The needle electrode shaft is placed into the tumor with the array retracted. Using real-time ultrasound guidance, the array is then deployed from the needle tip into the tumor. These deployed multiple array hooks create a series of electrodes with a diameter up to 5 cm, across which the radiofrequency current can be passed. Using a radiofrequency current generator with a 50 to 150 watt power output for 5 to 15 minutes, a 4.0 to 5.0 cm diameter tumor, can be ablated with 3.5 cm diameter hook electrodes fully deployed. In larger tumors, the needle electrode can be repositioned and the hook electrodes redeployed to create overlapping zones of coagulative necrosis to produce complete ablation of the tumor and a surrounding rim of hepatic parenchyma [35-38].

RF thermal ablation has proved to be safe and effective for the treatment of hepatic tumors in patients who are considered to be unsuitable for surgical intervention and recently has attracted much attention. It has some merits compared with the other percutaneous techniques: The treatment time is shorter than that with the more popular percutaneous ethanol injection[39], the thermal lesions are larger than those obtained with a microwave electrode[40], and it is less expensive and easier to perform than interstitial laser photocoagulation, in which multiple fiber insertions are always required[41], and It is more safer and lower complications than cryotherapy[42].

HCC with cirrhosis responded best to treatment with RFA than liver metastases. Large lesions over 3 cm were treated showing lesion stability on CT scan and a dramatic fall in AFP levels. The reason for a good response in this group of tumors is probably due to the characteristic features of hepatocellular carcinomas, which offer better heat conduction. It is clear that RFA is a useful primary therapy in patients with unresectable HCC, especially in cases with a poor liver reserve from cirrhosis and with multiple and deep-sited lesions. Prior experience treating small HCC described the "oven effect" [39], whereby cirrhotic liver surrounding individual HCC nodules acts as a thermal insulator that increases tissue heating during RF therapy. The results of this study further support the importance of this effect.

Colorectal liver metastases are usually hard. Patients with colorectal liver metastases usually have no cirrhosis, and as they have good liver reserve, most patients without extrahepatic spread are suitable for liver resection. Unresectability is commonly due to extensive multiple, bilateral disease or central lesions. For patients with colorectal metastases, we found that those with large liver deposits over 5 cm in diameter often required two applications of RFA because of the large diameter in relation to the radius of the thermal coagulation.

The local recurrence rate in the present study was 19.5 %. Previous studies have reported highly variable local recurrence rates associated with RFA, ranging from 0 % to 100 % . Curley *et al*[43] reported a local recurrence rate of 1.8 % in one of the largest series published to date. In our experience, local recurrences were evident at a median follow-up time of 6 months and were associated with ablation of larger tumors. It is possible that the rate of local recurrence may be reduced by specific interventions. For example, newer probes have been developed to produce larger spheres of coagulation necrosis. We are now more likely to deploy the electrode in several overlapping ablation sites to encompass tumors greater than 5 cm in diameter. For larger tumors requiring more than one deployment, we have used open operation to perform the procedure and prolonged the acting time. Selective use of the Pringle maneuver in patients with larger tumors or tumors in the vicinity of large vessels may provide larger zones of ablation. Additionally, based on our limited experience, repeat RFA seems to be well tolerated.

However, recurrence in the liver is frequently accompanied by extrahepatic disease, and careful preoperative staging is essential to select patients who could potentially benefit from repeat RFA. More recently, it has been understood that HCC is a multifocal disease in due time . In other words, the first lesion to be detected is only the prelude to other neoplasms. For this reason , we believe that it is appropriate to offer repeat RFA for selected patients with isolated hepatic recurrence[44-46].

There is growing interest in applying RFA technology via minimally invasive approaches. Some have reported on the use of percutaneous and laparoscopic RFA procedures. In suitable patients, the percutaneous approach can be performed without general anesthesia. The laparoscopic approach can be used to evaluate for extrahepatic disease and spares the patient a laparotomy. However there are limitations with the more minimally invasive approaches, so patients must be carefully selected. We do not have experience with laparoscopic

procedures for RFA, and long-term follow-up is necessary to determine whether this approach is equivalent to an open procedure. We have limited experience with percutaneous RFA. Difficult localization of the lesion under transcutaneous ultrasound guidance was thought to be the cause of failure. Few data are available regarding long-term follow-up of patients undergoing percutaneous RFA. Major complications, such as bilioperitoneum, intrahepatic abscesses, acute thrombosis of the portal vein, and a death related to necrosis of the diaphragm have been reported following percutaneous RFA. We have been hesitant to perform percutaneous RFA except in cases of relatively small tumors that are well within the hepatic parenchyma, away from adjacent organs. The potential for inadvertent ablation of the diaphragm, colon, stomach or other organs is an important consideration. In our experience, there is one patient who have liver abscess after percutaneous RFA due to instrict sterilization. But, minimal invasive do have less harm to patients with cancers, especially in HCC with cirrhosis and late-stage liver metastases. We have chosen to perform RFA as a percutaneous procedure in the vast majority of cases. We therefore believe that the decision to perform percutaneous ablation should be a multidisciplinary effort[47,48] .

Resection or ablation of liver tumors will not cure most patients with primary or metastatic malignant disease, although long-term disease-free survival rates of 20 % to 40 % .We are very encouraged by our initial experience with RFA as a treatment for malignant liver tumors because it is safe, well-tolerated, associated with few complications, and usually effective in controlling grossly or ultrasonographically evident in liver tumors. If there are a combination of cryotherapy, percutaneous ethanol injection, RFA with regional and systemic chemotherapy, such a multimodality treatment approach will reduce hepatic and extrahepatic recurrence rates, and thus enhance long-term survival rates.

Abstract

AIM: **To investigate gene expression profiles of intergrin genes in hepatocellular carcinoma (HCC) through the usage of Atlas Human Cancer Array membranes, semi-quantitative reverse transcription polymerase chain reaction (RT-PCR) and Northern blot.**

METHODS: **Hybridization of cDNA array membrane was performed with α ^{32}P-labeled cDNA probes synthesized from RNA isolated from hepatocellular carcinoma and adjacent non-cirrhotic liver. AtlasImage, which is a software specific to array, was used to analyze the result. RT-PCR of 24 pairs specimen and Northern blot of 4 pairs specimen were used to confirm the expression pattern of some intergrin genes identified by Atlas arrays hybridization.**

RESULTS: **Among 588 genes spotted in membrane, 17 genes were related to intergrin. Four genes were up-regulated, such as intergrin alpha8, beta1, beta7 and beta8 in HCC. Whereas there were no genes down-regulated in HCC. RT-PCR and Northern blot analysis of intergrin beta1 gene gave results consistent with cDNA array findings.**

CONCLUSION: **Investigation of these intergrin genes should help to disclose the molecular mechanism of the cell adhesion, invasive and metastasis of HCC. A few genes are reported to have changed in HCC for the first time. The quick and high-throughout method of profiling gene expression by cDNA array provides us overview of key factors that may involved in HCC, and may find the clue of the study of HCC metastasis and molecular targets of anti-metastasis therapy. The precise relationship between the altered genes and HCC is a matter of further investigation.**

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors worldwide, which ranks eighth in frequency among human cancer especially in Asia, Africa and South Europe, accounting for an estimated one million deaths annually. Men are afflicted at least twice as often as women. Although HCC ranks eighth in frequency among cancers worldwide, it is the sixth among men and eleventh among women[1]. It is one of the few human cancers for which an underlying etiology can be identified in most cases, and has a background of chronic inflammatory liver diseases caused by viral infection that induces cirrhosis[2]. HCC is unusual in patients with primary biliary cirrhosis but common when cirrhosis is secondary to chronic viral hepatitis[3,4]. However, it is not clear how this disorders result in HCC. Some tumor suppressor genes, such as RB and p53, may play a significant role in hepatocarcinogenesis[5,6] . Besides this, growth factor including transforming growth factor-α (TGF-α) have been implicated in the development of HCC[7]. It is early-stage metastasis that causes lower 5-year survival rate. However, these genetic changes do not precisely reflect the biological nature of cancer cells or the clinical characteristics of HCC patients. So, the molecular mechanism of metastasis of HCC is currently unknown. Cell adhesion and migration are fundamental properties of the metastasis. Changes in cell adhesion and migration are very important in the formation of tumors, and invasion and metastasis by neoplasms[8].

The integrin family of cell adhesion receptors plays a fundamental role in the processes involved in cell division, differentiation and movement. The extracellular domains of integrin alpha/beta heterodimers mediate cell-matrix and cell-cell contacts while their cytoplasmic tails associate with the cytoskeleton. Integrins are capable of transducing information in a bidirectional manner and the beta subunit is now recognized to play an important role in this process. Recent studies have led to the identification of a ligand-binding region on the beta subunit similar to that already characterized on some alpha subunits, and sequences in the cytoplasmic tails of the beta subunits that interact with cytoskeletal and signaling components. Adhesive events can also play a role in the progression of all four major classes of human disease--neoplastic, inflammatory, traumatic and infectious--and the specific nature of integrin adhesion mechanisms make them an attractive target for therapy[9].

Tumor development and progression involves a cascade of genetic alterations. Techniques frequently used to study gene expression alterations, such as RT-PCR, differential display PCR and Northern blot analysis, have their limitations: some need large amounts of RNA, others are time-consuming and can only study a small number of genes simultaneously. Hence, analysis of the expression profiles of a large number of genes in clinical HCC materials is an essential step toward clarifying the detailed mechanisms of metastasis and discovering target molecules for the development of novel therapeutic drugs.

The cDNA microarray technology, recently developed,

enables investigators to study the gene expression profile and gene activation in thousands of genes and sequences[10-15]. This technique allows the large-scale comparison of multiple genes in a single hybridization and has been used successfully to explore the gene expression profiles in some kinds of carcinomas and other diseases[16-20].

In this study, we used cDNA expression microarray technology containing 17 intergrin genes related to cell adhesion and invasion that are differentially expressed in human HCC. This large body of information not only furthers an understanding of the mechanism of metastasis but also reveals novel features of intergrin genes and identifies potential candidates for cancer metastasis detection and HCC therapy.

MATERIAL AND METHODS

Tissues and specimen

Twenty-four pairs of primary HCC and corresponding noncancerous liver tissues without cirrhosis were obtained with informed consent from patients who underwent hepatectomy at the First Clinical College of Harbin Medical University and Cancer Hospital of Chinese Academy of Medical Science. Cancerous and noncancerous tissues were enucleated separately from the tumourous and nontumourous part of resected liver. The normal tissue block was from the distal incision tissue. Histopathological diagnosis and classification were performed by the same pathologist. The specimen were immediately frozen in liquid nitrogen.

RNA isolation and purification

Total RNA were extracted from frozen tissues in Trizol (Life Technologies Inc, Gaitherbur, MD) according to the manufacturer's instructions. Normal liver tissues and HCC tissues were made in spices and homogenized in Trizol solution (1 ml/100 mg). Homogenates were incubated for 15 min on ice, and then a 1/5 volume of choloform was added to the homogenates. After vigorous agitation for 5 min, the inorganic phase was separated by centrifugation at 12 000×*g* for 20 min at 4 ° C. RNA were then precipitated in the presence of 1 volume of isopropanol and centrifugated at 10 000×*g* for 15 min at 4 ° C. RNA pellets were washed with 70 % ice-cold ethanol and then dissolved in diethyl pyrocarbonate (DEPC) - treated H_2O. Total RNA concentration and quantity was assessed by absorbency at 260 nm using an Nucleic Acid and Protein Analyzer (Beckman 470, USA).

cDNA microarray

Atlas human cancer cDNA expression array (7742-1) were purchased from Clonech Laboratories Inc (Palo Alto, USA). The membrane contained 10 ng of each gene-specific cDNA from 588 known genes and 9 housekeeping genes. Several plasmid and bacteriophage DNAs and blank spots are also included as negative and blank controls to confirm hybridization specificity. These genes analyzed in this study related to cell adhesion and motility, includeing laminin, collagen, fibronectin and intergrin . A complete list of the intergrin genes with the array positions and GeneBank accession number spotted on the array is available at Clontech' s web site (http://www.clontech.com).

cDNA synthesis , labeling and purification

Total RNA was reverse-transcribed into cDNA and labeled with α-^{32}P dCTP using Superscript™ Preamplification System for First Strand cDNA Synthesis (Life Technologies, Gaithersburg,MD). Before labeling, 5μg total RNA of each sample was treated with 2 μl DNase I (10 units/μl, Boehringer Mannheim, Germany), 1 μl RNasin (40 units/μl, Promega, Madison, USA) at 37 ℃ for 15 min to remove contaminated DNA. For each labeling, the treated 5 μg total RNA was raised in volume to 6 μl with diethyl pyrocarbonate (DEPC)-treated H_2O and first incubated with 4 μl oligo dT (0.5 μg/μl, Life Technologies, USA) at 70 ℃ for 10 min. Then, 6 μl 5×first strand reaction buffer, 1 μl 0.1 M DTT (Life Technologies, Gaithersburg, MD), 1.5 μl dNTP mixture containing dATP, dGTP,and dTTP at 20 μM (Promega, Madison, USA), 10 μl α-^{32}P dCTP (10 μCi/μl, NEN Life Science, Boston, MA) and 1.5 μl SuperScript II reverse transcriptase (200 units/μl, Life Technologies, USA) were added and incubated at 37 ℃ for 90 min. The labeled first strand cDNA probes were purified by Spin 200 column (Clontech, Palo Alto, CA) to remove the unincorporated nucleotides. After purification, labeled cDNAs were denatured in a boiling water bath for 3 min before use.

Membrane hybridization and exposure

Five milliliters ExpressHyb hybridization solution (Clontech, Palo Alto, CA) and 5 μg Cot-1 DNA (Life Technologies, USA) were added to the tube containing Atlas human cancer cDNA expression array, which was pre-hybridized at 68 ℃ for 2 hr. Then different incubated probes were added to different tubes and hybridization was performed at 68 ℃ for 18 hr in a rolling bottle. The membranes were washed twice at 50 ℃ in 2×SSC, 0.1 % SDS for 20 min, once at 68 ℃ in 1×SSC, 0.5 % SDS for 20 min, once at room temperature in 0.5×SSC, 1 % SDS for 20 min and 0.5×SSC 10 min. Membrane were then exposed to X-ray films (Fuji Films, Tokyo, Japan) at -70 ℃ for 1-3 days.

Image and Analysis

The images were scanned with Fluor-S MultiImager (Bio-Rad, Hercules, CA) and saved as TIFF format files. The TIFF images were imported into the AtlasImage analysis software Version 1.01 a (Clontech, Palo Alto, CA) and analyzed step by step with the guide. Housekeeping genes Ubiquitin and GAPDH were selected for normalization, because their expression was constant in cancer array hybridization system .Then the normalized intensity of each spot representing a unique gene expression level was acquired. Genes were considered to be up-regulated when the intensity ratio was ⩾1.5 and the difference was ⩾10 000 between the expression of HCC tisssues and normal liver tissues.

Semi-quantitative RT-PCR

To confirm the cDNA array results, semi-quantitative RT-PCR of 24 pairs of HCC tissues and normal liver tissues was performed for intergrin beta1 displaying expression alterations. Five micrograms of total RNA in each hybridization sample was used to synthesize the first strand cDNA with SuperScript Preamplification System For First Strand cDNA Synthesis kit (Life Technologies, USA). Then 1 μl product was used as the template to amplify specific fragments in a 25 μl reaction mixture under the following conditions: denaturation at 95 ℃ (3 min); 22 cycles of 94 ℃ (25 sec), 60 ℃ (25 sec) and 72 ℃ (45 sec); then 72 ℃ extension (3 min). In each PCR reaction, primers for the human glyceraldehyde-3-phosphate dehydrogenase (*GAPDH*) gene were used as an internal control. *GAPDH*, which is considered a housekeeping gene, showed similar expression levels by cDNA array analysis for the control and tumor samples. The 5 μl RT-PCR reaction product was analyzed by electrophoresis on a 1.5 % agarose gel. The electrophoresis images were scanned by Fluor-S MultiImager
