(Bio-Rad, USA) and the original intensity of every specific band was quantityed with the software Multi-Analyst (Bio-Rad, USA). The data were compared after being normalized by the intensity of GAPDH. After normalization, the adjusted intensities were calculated for the amplified gene products, and the ratios were calculated. The sequences of the PCR primer pairs of intergrin beta1 and GAPDH were designed using Primer3 Internet software program. (Whitehead Institute, Boston ,USA). Their specificity was confirmed by a BLAST Internet software assisted search for a nonredundant necleotide sequence database (National Library of Medicine, Bathesda, MD, USA).

Primer sequences were as follows: GAPDH, forward primer 5' -ACCACAGTCCATGCCATCAC-3' and reverse primer 5' -TCCACCACCCTGTTGCTGTA-3' ; Intergrin beta1, forward primer 5' -GGAGTCAGGCAAATGCTCTC-3' and revese primer 5' -GCTAAGGCCACTTCTGCATC-3' .

Northern blot

RNAs of HCC and normal liver tissues were seperated by electrophoresis in a 1.5 % agrose gel containing 2.2M formaldehyde in pairs then transferred onto a nylon membrane (Zeta-Probe, Bio-Rad, USA) by capillary action under 10×SSPE. RNA was permanently attached to the membrane by UV illumination for 150 s (GS Gene Linker, Bio-Rad, USA). RNA intactness was estimated by comparing the intensities of the 28S and 18S ribosomal RNA bands. Hybridization was performed overnight in a rolling bottles containing 8ml of hybridization buffer (5×SSPE, 5×Denhardt's solution, 0.5 % SDS, 0.2 mg/ml heat-denatured salmon sperm DNA, and 50 % formamide) and the hybridization probe that was obtained by PCR amplification. The primers were as follow: β-actin, forward primer 5' -CGTCTGGACCTGGCTGGCCGGGACC-3' and reverse primer 5' -CTAGAAGCATTTGCGGTGGACGATG-3' ; Intergrin beta1,forward primer 5' - GTGTGGCCCAAGACA GTTCT-3' and reverse primer 5' - GGTTACCCCACCCTCT GACT-3' .α-^{32}P-labeled cDNA probes were synthesized using Primer-a-Gene Random Labeling Kit (Promega,USA)and following the protocol.

The membranes were washed twice at room temperature in 2 × SSPE, 0.1 % SDS for 10 min, once at 42 ℃ in 1 × SSPE, 0.1 % SDS for 15 min and once at 50 ℃ in 0.5×SSPE, 0.1 % SDS for 20 min. Membrane were then exposed to X-ray films (Fuji Films, Tokyo, Japan) at -70 ℃ for 24-48 h.

RESULTS

Atlas human cancer cDNA microarray expression profile

Using a cDNA expression microarray technique we established the expression profile of intergrin genes selected from different areas of cancer research in human HCC and normal liver tissues (Figure 1A, 1B). No signals were visible in the blank spots (G1,G8,G15)and negative control spots (G2-4,G9-11,G16-18) indicating that the Atlas human cancer array hybridization was highly specific. The housekeeping genes' intensities were very similar at the same time, which indicatea that the results were credible (Figure 1A,1B).Two housekeeping genes, Ubiquitin and GAPDH, were used to normalize the intensities. The color image of the difference between HCC and normal liver tissue was produced by AtlasImage array software (Figure 1C) . The comparative analysis by AtlasImage software showed that there were 4 intergrin genes changed, all of them up-regulated in HCC versus normal liver tissues, based on the criteria that the ratio was ⩾1.5 or the difference was ⩾10 000 (Table 1). There were significant differences in the intergrin gene expression profile between the two tissues.

Table 1 Intergrin genes differentially expressed between HCC and adjacent noamal liver tissues generated by atlasImage software (Version 1.01a)

Gene	Ratio	Difference	Protein / gene
D4b	1.476895	12673	integrin alpha 8 (ITGA8)
D4e	1.507798	4363	integrin beta 1 (ITGB1)
D4j	1.997615	23003	integrin beta 7 precursor (ITGB7)
D4k	2.065331	23938	integrin beta 8 precursor (ITGB8)

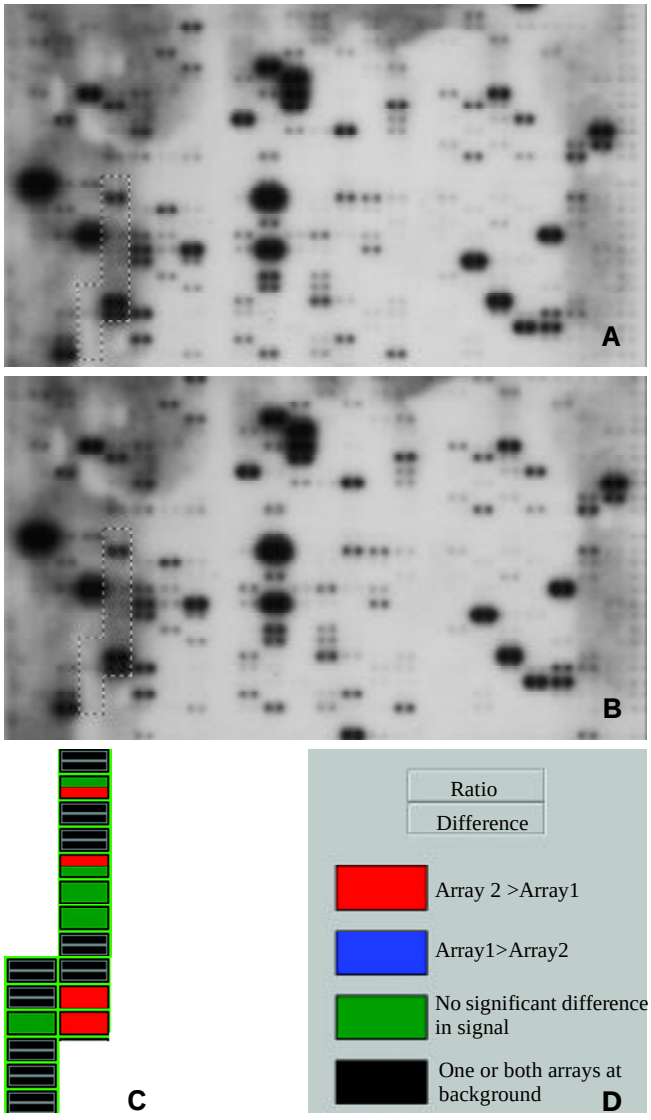

Figure 1 Parallel analysis of intergrin gene expression in human hepatocellular carcinoma and adjacent normal liver tissues. Atlas human cancer cDNA expression array (Clontech, USA) is hybridized with ^{32}P-labeled cDNA probes obtained by RT-PCR from total RNA of human hepatocellular carcinoma (A) and adjacent normal liver tissues(B). The intergrin gene region is marked in the photo. The colorful comparative diagram between human hepatocellular carcinoma and adjacent normal liver tissues is obtained when one aligns two arrays to AtlasImage Grid Temples and adjusts the alignments and backgroud calculations(C). Definitions of colors in the array comparison are showed (D).

Semi-quantitative RT-PCR

RT-PCR was performed is twenty four paired tissues in to verify accuracy and universality of the hybridization data. RT-PCR data of intergrin beta1 agreed well with hybridization data after normalization by comparing the band intensities. Among the 24 paired tissues, RT-PCR results of 18 pairs of specimen were identical to the microarray results (Figure 2).

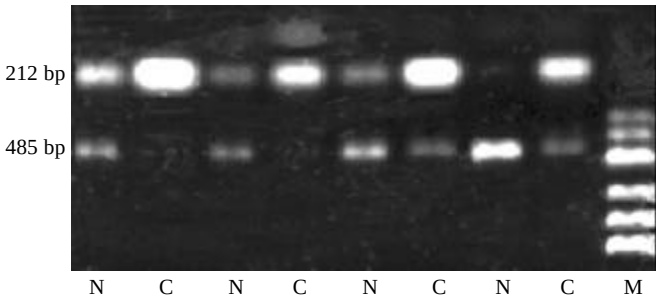

Figure 2 Partial semi-quantitative RT-PCR results for Intergrin beta1 in 24 paired tissues. A total of 10 μl RT-PCR products are electrophoresed on 2% agarose gel containing ethidium bromide. The level of GAPDH is used as an internal control. (RT-PCR , reverse transcription- polymerase chain reaction; N, adjacent noamal liver tissue; C, human hepatocellular carcinoma tissue; GAPDH, glyceraldehyde-s-phosphate dehydrogenase; M, pUC Mix Maker)

Northern Hybridization

Northern hybridization was performed in four paired tissues to verify accuracy of the microarray hybridization data. Northern hybridization data of 4 genes agreed well with microarray hybridization. Among the 4 paired tissues, the northern hybridization results of 4 genes further meant that the Atlas human cancer cDNA microarray data were reliable and comparable (Figure 3).

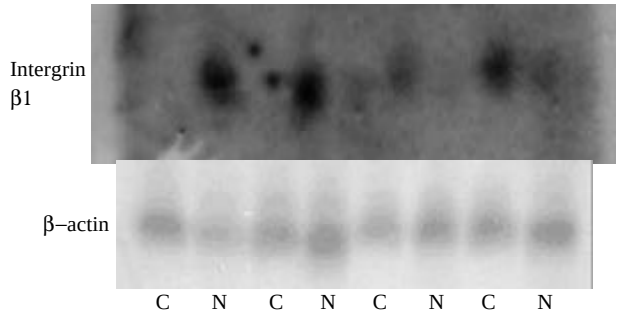

Figure 3 Nothern blot analysis of Intergrin beta1, which differentially express in human hepatocellular carcinoma and adjacent normal liver tissues, to confirm the Atlas human cancer cDNA expression array. Four paired cases are used to determine these genes expression patterns. Twenty μg RNA is analyzed on a 1.2% denaturing agrose gel and tansfer onto a nylon membrane. ^{32}P-labeled cDNA probes for these genes are hybridized to the RNA-bloted membranes. After stringent washes , membranes are exposed to X-ray film overnight at–70 ℃. The same membranes are rehybridized with human β-actin for an RNA loading control. (C, human hepatocellular carcinoma tissue; N, adjacent noamal liver tissue)

DISCUSSION

In this study, we have investigated the gene expression profiles in human HCC and adjacent noncancerous liver tissues using Atlas human cancer array which contains 17 genes that were classified according to intergrin. cDNA array technology is used to examine simultaneously the expression of specific genes on a single hybridization. Although human genome project has generated a large-scale sequence data for a great number of genes, the biological functions of such genes remain to be deciphered. It is very important to define differential gene expression profiles of tumors and normal tissues before understanding the functional significance of specific gene products. Although expression analysis techniques such as differential display polymerase chain reaction (DD-PCR), northern blot, and serial analysis of gene expression (SAGE) and RT-PCR have been widely used in the past, these studies are time-consuming and can only be used to deal with a limited number of genes. Thus a systematic approach to examine large number of genes simultaneously is required. Microarray techniques have been developed in this condition[21].

Microarray technique was firstly reported in 1995 by Schena and Brown [10] ,which allows simultaneous parallel expression analysis of thousands of genes . There is considerable interest in the potential application of cDNA microarray analysis for gene expression profiles in human cancers[22]. Such information might be useful for tumor classification , elucidation of key factors in tumor metastasis, and identification of genes which might be useful for diagnostic purposes or as therapeutic targets[23-25]. The analytical principle of human cDNA expression array is based on reverse northern blot hybridization. DNA fragments representing human genes are immobilized in duplicate onto a nylon membrane. Each cDNA fragment is 200-500 bp long and is selected as a unique sequence. This sequence is without a poly(A) tail, repetitive elements or homologous sequence to avoid cross-hybridization and nonspecific binding of a cDNA probe. α-^{32}P or α-^{33}P labeled cDNA probes generated by RT-PCR of total or messenger RNA samples are then hybridized to a microarray membrane. The hybridization image can be obtained by autoradiography after a high-stringency wash. The final result will be exported by a specific software designed to analyze the membrane[26,27].

All intergrin genes identified were up-regulated in human HCC. Integrins are cell surface receptors that mediate the physical and functional interactions between a cell and its surrounding extracellular matrix (ECM). Expressed as heterodimers, the specific alpha or beta chains that constitute the integrin receptor determine the repertoire of ECM proteins to which a specific integrin may bind. While classically, the role ascribed to integrins has been that of anchoring cells to the ECM, the more contemporary spectrum of integrin function greatly exceeds that of mere cell adhesion. Recent reports have demonstrated that the interaction between the ECM and cell surface integrins leads to intracellular signaling events that affect cell migration, proliferation, and survival, which in the context of neoplastic cells, can translate directly into the malignant phenotype. Indeed, the role of specific integrins in tumorigenesis has been demonstrated in numerous cancer types. Integrins are a major family of cell adhesion molecules involved in cell-cell and cell-extracellular matrix interactions[28] .

Each integrin is a heterodimeric glycoprotein composed of an alpha and a beta subunit. Intergrin beta7 was mainly reported in hematology. The beta 7 chain of integrin forms heterodimers with the alpha 4 or alpha E chains. Mature B cells express alpha4 beta7, which is a receptor for vascular cell adhesion molecule-1 and fibronectin [29]. The alpha4 beta7 integrin acts as a gut homing receptor. High levels of beta 7 mRNA was restricted to intra-epithelial mucosa T-lymphocytes[30,31]. Beta 7 integrins have been implicated in

the autoimmune process in rheumatoid arthritis[32]. It also involved in hematologic tumors that alpha4beta7 ligand in the adhesion of in vivo activated multiple myeloma blood B cell adhesion to bone marrow fibroblasts. The adhesion properties distinguish them from normal B cells. Although the malignant status of these cells is as yet undefined, their adhesion properties implicate multiple myeloma blood B cells in migratory spread of the disease[33].

Integrin beta8 subunit mRNA has been shown to be expressed at higher levels in the central nervous system than in other organs[34]. The present study demonstrates that αvβ8 is a growth-inhibitory molecule and provides the first evidence for an *in vivo* function of the divergent integrin subunit β8[35,36] and β8 integrin subunit is growth inhibitory in epithelial cells and that the divergent β8 cytoplasmic domain is sufficient to confer growth inhibition. It was not known why intergrin beta8 were up-regulated in HCC.

Intergrin alpha 8 subunit always associates with beta1 subunit. Integrin beta-1 is essential for epithelial-mesenchymal interactions and can interact with a number of alpha subunits. The integrin alpha 8 beta 1 has been reported to bind to fibronectin, vitronectin, tenascin-C and osteopontin in cell adhesion or neurite outgrowth assays[37-39]. Integrin alpha8 beta1 may help regulate kidney development and other morphogenetic processes[40]. Mice with a mutation in the alpha8 gene do not express the integrin alpha8 beta1 and exhibit profound deficits in kidney morphogenesis[39]. Alpha 8 beta 1 mediates neurite outgrowth of embryonic sensory and motor neurons on tenascin-C extracellular matrix protein[41]. The integrin family consists of a series of related alpha beta heterodimers involved in a variety of cell-matrix and cell-cell adhesion functions.

Integrin beta1 is essential for epithelial-mesenchymal interactions and can interact with a number of alpha subunits[42]. Cell adhesion to fibronectin can be mediated by the interaction of an integrin (alpha 5 beta 1) with the Arg-Gly-Asp-Ser (RGDS)-containing cell adhesion region of fibronectin. The beta 1 subunit plays an important role in binding and assembly of exogenous fibronectin, perhaps by participation in the organization, regeneration, or cycling of the assembly site rather than by a direct interaction with fibronectin[43]. Alpha 5 beta 1 and alpha 2 beta 1 integrins play an important role in transducing mechanical stimuli into intracellular signals. The integrin alpha 4 beta 1 (also known as very late antigen-4, VLA4) interacts with the immunoglobulin superfamily member vascular cell adhesion molecule-1 (VCAM-1), and with an alternatively spliced form of fibronectin[44]. The integrin alpha 3 beta 1 is a multiligand extracellular matrix receptor (VLA-3) found in many cell types. It may function as a receptor for fibronectin, laminin, collagen and also for ladsin, epiligrin and entactin[45,46].

To investigate the role of integrins in HCC invasion, we analyzed the relationship between the expression and activity of beta1 integrins. Some studies showed that different types of HCC cells showed various levels of constitutive activity of beta1 integrins as assessed by the TS2/16 requirement in cell adhesion. Remarkably, as a result of in vitro chemoinvasion assay, the levels of constitutive activity of beta1 integrins correlated with the invasive ability of HCC cells[47]. A new human HCC cell line with a highly metastatic potential was established from subcutaneous xenograft of a metastatic model of human HCC in nude mice (LCI-D20) by means of alternating cell culture in vitro and growth in nude mice, which has a high intergrin[48]. But there was still another result showed integrins beta 1 down-regulated in poorly differentiated HCC, whereas relatively high activity in metastatic tumors and the presence of all integrins in cirrhotic liver[49]. Most results showed neoplastic progression of HCCs may be correlated with an aberrant expression of adhesion molecules[50]. Our results showed magnificent up-regulation in HCC compared with adjacent normal liver tissues.

Members of the beta 1 subfamily of integrins contribute to cell adhesion, cytoskeletal organization and signal transduction processes. In some transformed cell lines and tumors, a correlation has been established between the level of expression of the beta 1 and neoplastic behavior. In other instances, normal and neoplastic tissues differ in beta 1 integrin expression or sub-cellular distribution. The level of expression of beta 1 integrins in tumor cells may affect tumor growth properties in several ways, including: (a) effects on anchorage dependence of growth; (b) direction of signaling processes; (c) organization of the extracellular matrix and presentation of matrix bound growth factors; (d) effects on the functions of host defense cells. Thus the interplay between integrin expression and tumor behavior is complex and might be viewed as a series of interactive feedback loops rather than in terms of a straightforward cause and effect relationship[51].

In conclusion, our study demonstrated that cDNA array is a powerful tool to explore gene expression profiles in cancer. The intergrin genes described in this study should therefore provide valuable resources not only for basic research, such as molecular mechanism of metastasis, progression and prognosis, but also for clinical application, such as development of new diagnostic markers and identification of therapeutic intervention in human HCC.

Abstract

AIM: **To investigate the expression of *p28/gankyrin* gene and its role in the carcinogenetic process of human hepatocellular carcinoma (HCC).**

METHODS: **64 specimens of HCC and para-carcinoma tissues, 22 specimens of non-tumor liver tissues (7 normal, 15 cirrhosis), 10 specimens of normal human tissues and 5 hepatoma cell lines were studied for the expression of *p28/gankyrin* by Northern blot. The expression of *p28/gankyrin* protein was detected immunohistochemically by using the specific polyclonal antibody.**

RESULTS: **Northern blot analysis indicated that the expression of *p28/gankyrin* mRNA was intensively distributed in brain and heart, weakly in lung, spleen and muscle, undetectable in digestive system including liver, pancreas, stomach, small and large intestines. *p28/gankyrin* mRNA was absent in normal liver, weakly detected in liver cirrhosis and in 18 of 64 para-carcinoma liver tissues. In contrast, the expression of *p28/gankyrin* mRNA was intensively detected in all 5 hepatoma cell lines tested, markedly increased in 57 of 64 and moderately increased in 5 of 64 HCC samples. In comparison with liver cirrhosis and para-carcinoma liver tissues, the average expression of *p28/gankyrin* mRNA in HCC was increased 3.6- (2.901 ± 0.507 *vs* 0.805 ± 0.252, $P<0.05$) and 5.2-fold (2.901 ± 0.507 *vs* 0.557 ± 0.203, $p<0.01$), respectively. In addition, *p28/gankyrin* mRNA expression level was higher in HCC with portal vein tumor thrombus and microscopic hepatic vein involvement ($P=0.021$ and $P=0.047$, respectively). The overexpression of *p28/gankyrin* protein in HCC was targeted in hepatic tumor cells, not in bile duct cells and other interstitial cells.**

CONCLUSION: **Overexpression of *p28/gankyrin* in HCC plays an important role and contributes to the metastasis potential in the process of carcinogenesis. *p28/gankyrin* may become a specific biological tissue marker for the pathological diagnosis of HCC.**

INTRODUCTION

Human primary hepatocellular carcinoma (HCC) is one of the most common types of malignant cancer in Asia and Africa where hepatitis virus infection and exposure to specific liver carcinogens are prevalent[1-4]. HCC has ranked second in cancer mortality in China since the 1990s and is increasing in frequency among males in many countries[5,6]. Although the major viral and environmental risk factors for HCC development have been unraveled[7,8], the oncogenic pathways leading to malignant transformation of liver cells have long remained obscure[9]. It has been widely reported that some tumor suppressor genes such as *p*53 and $p16^{INK4A}$ play a vital role in the development of HCC[10-13], while few oncogenes that control growth behavior or metastatic potential of HCC have been underscored.

*p*28 gene was initially cloned in human cDNA library by comparing the amino-acid sequence of a subunit isolated from the purified bovine erythrocyte PA700 complex with protein structures in databases of Homo-Protein cDNA Bank[14-16]. *p*28 protein is one of the non-ATPase subunits of PA700 (also called 19 S complex), a 700 kDa multisubunit regulatory complex of the human 26 S proteasome[17]. Intriguingly, *p*28 protein contained six conserved motifs known as ' ankyrin repeats' [18-20], implying that this subunit may contribute to interaction of the 26 S proteasome with other proteins. Recently, another gene named '*gankyrin*' was cloned by cDNA subtractive hybridization in HCC and its sequence is identical to *p*28 gene[21]. Because of the putative proteasome connection, the oncogenic effect of *p*28/*gankyrin* in HCC may be associated with the ubiquitin-proteasome pathway[22-24]. So far, the mechanism of up-regulation of *p*28/*gankyrin* in HCC is still unknown.

In order to elucidate the role of *p*28/*gankyrin* in carcinogenesis of HCC and its correlation with clinical parameters, the following study was carried out.

MATERIALS AND METHODS

Sample collection and processing

All 64 HCC specimens and their para-carcinoma tissues (more than 2 cm away from the focus), were sampled from 64 patients who had undergone curative hepatectomy (58 men and 6 women; mean age 46.4 ± 10.5 years). Patients who had received radiotherapy or chemotherapy before hepatectomy were excluded. Non-tumor liver tissues were obtained from

22 patients who had received hepatic hemangiomatomy. Ten different types of human normal tissues were from 2 men of accidental deaths. They were all cases from 1999 to 2000 in Eastern Hepatobiliary Surgery Hospital in Shanghai, China. Informed consent was obtained from all patients for subsequent use of their resected tissues. These specimens were immediately dissected into small pieces under aseptic condition within half an hour, quickly-frozen and preserved in liquid nitrogen before subsequent procedures. The specimens used for immunohistochemistry (IHC) were routinely processed, formalin-fixed and paraffin-embedded, at least 2 serial paraffin sections of 4 mm-6 mm thick were made, one for hematoxylin and eosin (HE) staining and the other for *p*28/*gankyrin* protein detection.

Cells lines

A series of cell lines (ATCC, Rockville, MD) were investigated in this study, including HepG2 (ATCC HB-8065), HuH-7, SK-Hep-1 (ATCC HTB-52), Chang liver (ATCC CCL-13), and a human fetal hepatocyte cell line WRL 68 (ATCC CL-48). They were maintained, as specified by the suppliers, in Dulbecco's modified Eagle medium or other recommended mediums supplemented with 10% fetal bovine serum at 37℃ in a humidified atmosphere of 5% CO_2 in air.

Northern blot analysis of p28/gankyrin transcript

Preparation and labeling of the probe Polymerase chain reaction (PCR) of a human fetal liver cDNA library (provided by Max-Planck Institute) was performed in a final volume of 50 ml containing all four dNTPs (each at 200 mmol/L), 1.25 mmol/L $MgCl_2$, 2.5 units of Taq (TaKaRa Biotech, Dalian, China) and each primer at 0.5 mmol/L. The following temperature program was used: 1 cycle at 94 ℃ for 5 min, 35 cycles at 94 ℃ for 40 s, 52 ℃ for 30 s and 72 ℃ for 55 s, followed by a final extension at 72 ℃ for 8 min. Primers used for amplification were human *p*28/*gankyrin* sense primer corresponding to nucleotides 2-19 (5'-GCGGATCCAGTAGTTGCTGGGACAGC-3'), and antisense primer complementary to nucleotides 830-847 (5'-GCGAATTCGGAACAAGAGTCAACATG- 3') with the BamHI and EcoRI restriction sites at their 5' strand ends respectively. The PCR product was cloned into pcDNA3.1 vector (Invitrogen, Groningen, Netherlands) to generate the clone full.hup28.pcDNA3.1, which was confirmed by sequencing with an automatic DNA sequencer (ABI model 3700). The purified PCR product was labeled with α-^{32}P-dATP by a random primer labeling method as described[25] with Prime-a-Gene Labeling System (Promega, Madison, WI).

RNA extraction and preparation of the hybridization membrane Samples subjected to RNA analysis were isolated from surgical specimens of HCC and the para-carcinoma liver tissues of 64 patients and from a series of non-tumor liver samples, normal human tissues and hepatoma cell lines by the acid guanidinium thiocyanate-phenol-chloroform extraction method as previously described[26]. Total RNA (40mg) was denatured and separated by electrophoresis in a 1.0 % agarose gel containing 2.2 mol/L formaldehyde and then transferred to nitrocellulose membranes (BA85, Schleicher Schuell, Germany). The membranes were dried in a vacuum drying over at 80℃ for 2 h and sealed in a plastic bag for use.

Northern blot analysis Hybridization of the membranes was performed by using the labeled *p*28/*gankyrin* cDNA as the probe at 42℃ for 20 h in a solution containing 50 % formamide, 5×SSC, 0.1 % SDS and 5× Denhardt's after the membranes had been pre-hybridized in the same solution with 0.1 mg/ml salmon sperm DNA at 42 ℃ for 4 h. After this hybridization, the membranes were rinsed in stringent conditions (65 ℃ for 30 min in a washing buffer of 0.1×SSC and 0.1 % SDS) and then exposed to Kodak X-ray film at -80 ℃ for 14 days. The expression level of mRNA was normalized with ethidium bromide-stained 18 s rRNA as internal standard and analyzed by Phosphor Imager (FLA 2000, Fujifilm, Japan).

Immunohistochemical analysis of P28/Gankyrin protein

Preparation of the polyclonal antibody A polyclonal antibody against *p28/gankyrin* protein (226 amino acid) was prepared. Briefly, a 683-bp fragment from nucleotide 2 to 684 (amino acid 1-221) was generated by PCR and subcloned into the fusion expression vector pPROEX-HTb (Gibco/BRL Life Technologies, NY) using *Bam*HI and *Xho*I. The expression vector was then transformed into competent *Escherichia coli* DH5a for induction of 6×histidine-fused protein with 0.6 mmol/L isopropyl-1-thio-b-D-galactopyranoside (IPTG) at 37℃ for 3 h. The cells were harvested and lysed with ice-cold TS buffer containing 50 mmol/L Tri-HCl (pH 8.0), 150 mmol/L NaCl, 1 mg/ml lysozyme, 5 mmol/L EDTA, 0.5 mmol/L phenylmethylsulfonyl fluoride, 0.2 mg/L aprotinin and 1 % Triton X-100. The lysates were purified by affinity chromatography with Ni-NTa agarose column (Qiagen, Germany) and identified by electrophoresis on a 10 % SDS-PAGE gel. The purified fusion protein emulsified with Freund's adjuvant (Gibco/BRL Life Technologies, NY) was used to immunize two New Zealand rabbits (male, 2.5-3.0 kg) for preparation of the polyclonal antibody. Antibody valence was determined by double immunodiffusion test on 1 % agar gel. For the specificity, affinity chromatography was applied to purify the antibody from the immune sera by an antigen column.

Immunohistochemical staining *p28/gankyrin* protein was detected in HCCs, para-carcinoma liver tissues and SK-Hep1 cell line by using peroxidase-labeled secondary antibody two-step IHC technique with the DAKO EnVision system (DAKO Corporation, carpinteria, USA). All paraffin embedded samples were deparaffined and rehydrated, and the SK-Hep1 cells cultured on coverslips were fixed in 4 % polyformalin for 30 min, then pretreated with citrate buffer (0.01 mol/L citric acid: pH 6.0) for 15 min at 100℃ in a microwave oven. After being treated with 0.3 % H_2O_2 for 10 min to block the endogenous peroxidase, the sections were incubated with 10 % fetal calf serum for 30 min to reduce nonspecific binding, and then the primary *p28/gankyrin* antibody was applied to the sections at 4℃ overnight. The sections were subsequently incubated with horseradish peroxidase (HR) -labeled goat anti-rabbit immunoglobulin for 30 min, followed by incubation with prepared liquid 3,3'-diaminobenzidine (DA) + substrate-chromogen solution for 10 min at room temperature. Finally, the sections were counterstained with hematoxylin. The negative controls were conducted by substituting rabbit normal serum for the primary antibody to verify the possibility of false-positive responses from the secondary antibody.

Clinical data and histopathological parameters

The following variables were evaluated: age, sex, HBsAg, accompanying cirrhosis, serum a-fetoprotein (AFP) level, tumor size, satellite nodules, formation of tumor capsule, fibrous capsular infiltration, portal vein tumor thrombus, microscopic invasion of the tumor into hepatic vein, and histological grade of HCC according to Edmonson and Steiner's classification[27].

Statistical analysis

Data of *p*28/*gankyrin* mRNA levels were presented as means

±SD. Significance of differences was assessed by analysis of variance (ANOVA) or Student' s *t*-test. *p* values of ≤0.05 were considered statistically significant.

RESULTS

Clinical profiles and histopathologic examination

64 patients with primary HCC were recruited in this study, including 58 males and 6 females with ages ranging from 24 to 74 years (mean, 46.4±10.5 years). Serum anti-hepatitis B virus was detected in 45 (70.3%) of 64 patients and positive anti-hepatitis C virus in serum was found in 6 (18.8%) of 32 patients examined. 50 (78.1%) patients showed increased serum AFP level and levels above 1000 mg/L were observed in 29 of them. Histopathologically, 47 of 64 HCCs and 15 of 22 non-tumor liver tissues displayed cirrhosis. Among the 46 patients with fibrocapsule formation around HCC, 21 had broken through and 19 of them had microscopic hepatic vein involvement. Portal vein tumor thrombus was found in 18 (28.1%) patients and 32 (50.0%) patients had satellite nodules in primary HCC. According to Edmonson and Steiner' s classification, 20 (31.3%) and 44 (68.7%) patients were classified to grade I-II group and grade III-IV group, respectively.

Tissue distribution of p28/gankyrin mRNA

Northern blot analysis showed that *p*28/*gankyrin* was expressed as one single transcript of 1.5 kb, corresponding well with the size of the cloned cDNA (Figure 1 A). *p*28/*gankyrin* was strongly expressed in brain and heart, whereas weaker expression was found in lung and spleen. Faint signals were discerned in muscle, but no signals were observed in digestive system including liver, pancreas, stomach, small and large intestine.

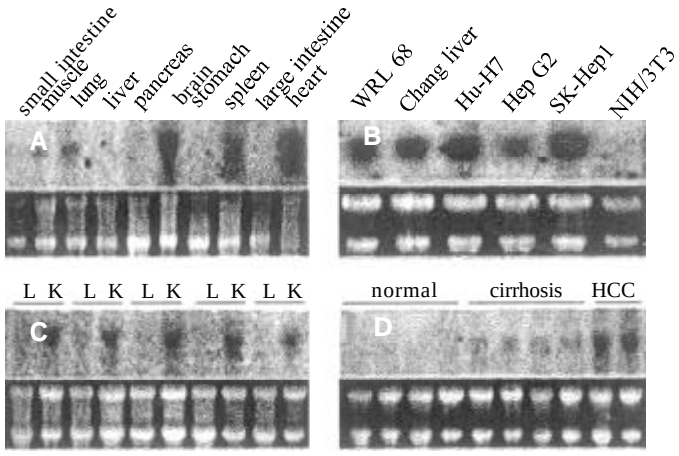

Figure 1 Northern blot of *p*28/*gankyrin* in a series of human normal tissues, hepatoma cell lines, HCC and non-tumor liver tissues. (A) *p*28/*gankyrin* expression in ten different normal adult human tissues. (B) *p*28/*gankyrin* expression in five hepatoma cell lines and NIH/3T3 cell. (C) *p*28/*gankyrin* expression in HCC and para-carcinoma liver tissues. L indicates the para-carcinoma liver tissues, and K indicates the HCC tissues. (D) Comparison of *p*28/*gankyrin* expression in normal human liver tissues, liver cirrhosis and HCC tissues. Each bottom panel showed equal amount of total RNA loading as indicated in 28s and 18s rRNA.

p28/gankyrin expression in hepatoma cell lines

In the 5 human hepatoma cell lines, *p*28/*gankyrin* mRNA was detected as the expected size with various expression levels (Figure 1 B). It was expressed strongly in SK-Hep1, weakly in HepG2 and no expression has been found in NIH/3T3 cell line.

p28/gankyrin expression in HCC, para-carcinoma and non-tumor liver tissues

*p*28/*gankyrin* mRNA expression levels were higher in the 64 HCC samples than in the para-carcinoma tissues (Figure 1 C). *p*28/*gankyrin* mRNA levels were markedly increased in 57 of 64 (89.1%), moderately increased in 5 of 64 (7.8%) HCC samples. In the remaining two HCC samples, *p*28/*gankyrin* mRNA was expressed at the same level as the para-carcinoma liver tissues. In contrast, *p*28/*gankyrin* mRNA expression was weakly detected in 18 of 64 (28%) and was below the level of detection in 46 of 64 (72%) para-carcinoma liver samples. In 22 non-tumor liver samples, *p*28/*gankyirn* was absent in 7 normal livers and weakly present in 15 liver cirrhosis tissues (Figure 1D). Densitometric analysis of all northern blots indicated that compared with liver cirrhosis and para-carcinoma liver tissues, the average expression of *p*28/*gankyrin* mRNA in HCC was increased by 3.6-(2.901±0.507 *vs* 0.805±0.252, $P<0.05$) and 5.2-fold (2.901±0.507 *vs* 0.557±0.203, $P<0.01$), respectively (Figure 2A).

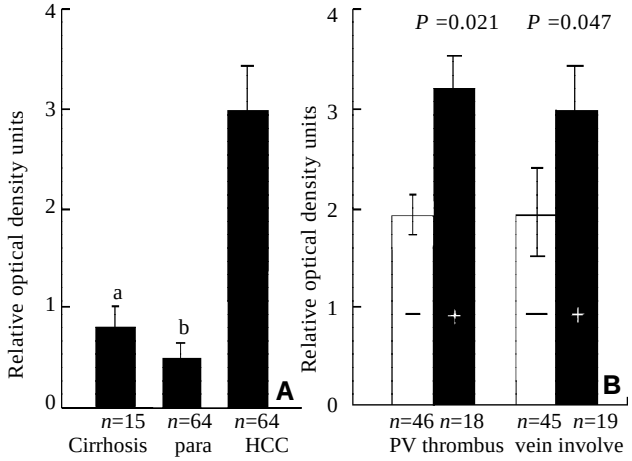

Figure 2 Densitometric analysis. The ratio of the optical density of *p*28/*gankyrin* mRNA to the corresponding 18 S rRNA signals was calculated and expressed as means ±SD. (A) Comparison of *p*28/*gankyrin* expression in human liver cirrhosis, para-carcinoma liver tissues and HCCs. [a]The expression in HCCs was significantly higher than that in liver cirrhosis ($P<0.05$). [b]The expression in HCCs was significantly higher than that in para-carcinoma liver tissues ($P<0.01$). (B) Clinicopathological significance of *p*28/*gankyrin* expression in HCCs. *p*28/*gankyrin* mRNA levels were significantly higher ($P=0.021$) in portal vein thrombus group than in non-thrombus group, higher ($P=0.047$) in microscopic hepatic vein involvement group than in non-hepatic vein involvement group.

Correlation of p28/gankyrin mRNA expression with clinicopathological parameters

Comparison of clinical profiles of HCC patients with *p*28/*gankyrin* mRNA expression was summarized in Table 1. From these results, age, sex, HBsAg, and accompanying cirrhosis were not significantly correlated with the expression levels of *p*28/*gankyrin* ($P>0.05$). Relationships of *p*28/*gankyrin* mRNA expression with histopathological parameters were listed in Table 2. These results showed that there were no significant correlation between *p*28/*gankyrin* mRNA expression and various parameters, including serum AFP level, tumor size, satellite nodules, formation of tumor capsule, fibrous capsular

infiltration, and histological grade of HCC. However, it was noted that *p*28/*gankyrin* mRNA levels (Figure 2B) were significantly higher (P=0.021) in portal vein thrombus group (n=18) than in non-thrombus group (n=46), higher (P=0.047) in microscopic hepatic vein involvement group (n=19) than in non-hepatic vein involvement group (n=45). This fact implies that tumors with high levels of *p*28/*gankyrin* mRNA expression tend to be more metastatic than those with low levels.

Immunohistochemical examination

Immunohistochemistry was performed in HCCs and corresponding para-carcinoma liver tissues to determine the exact cellular site of *p*28/*gankyrin* protein. *p*28/*gankyrin* was moderately to intensely present in the cytoplasm of most hepatocytes in HCC tissues, while nuclear immunostaining was also occasionally observed (Figure 3A). In para-carcinoma liver tissues, *p*28/*gankyrin* was weakly present in the cytoplasm of hepatocytes (Figure 3B). The histospecific expression of *p*28/*gankyrin* was absent in the bile duct cells, blood vein endometrial cells and other interstitial cells in liver tissues (Figure 3C). In SK-Hep1 cell line immunostaining, *p*28/*gankyrin* was mainly present in the cytoplasm, while occasionally in the nucleus (Figure 3D).

Table 2 Clinicopathological features of patients with HCC: comparison with *p*28 mRNA expression

Variables	*n*	mRNA level[a]	D*f*	*p*-value[b]
Serum AFP (ng / ml)			62	0.330

DISCUSSION

*p*28/*gankyrin* gene has been identified recently as an oncogene expressed in HCC and its up-regulation is not related to the grade or stage of the tumors[21]. However, the above mentioned study did not address the potential importance of normal or cirrhosis liver, in the context of high *p*28/*gankyrin* expression observed in HCC, nor did it investigate *p*28/*gankyrin* mRNA expression with respect to histopathological parameters of HCC. In the present study, *p*28/*gankyrin* mRNA expression was examined in the normal liver, liver cirrhosis, and HCC. *p*28/*gankyrin* mRNA was absent in normal liver samples, weakly expressed in liver cirrhosis samples and intensively expressed in 62 of 64 (96.8 %) HCC samples compared with the para-carcinoma liver tissues by northern blot analysis. These findings indicate that *p*28/*gankyrin* is a useful biological marker of HCC and plays an important role in the process of liver carcinogenesis.

Interestingly,*p*28/*gankyrin* mRNA levels were significantly higher in HCCs with portal vein tumor thrombosis than in those without. Microscopic hepatic vein involvement is also an important correlated parameter with regard to *p*28/*gankyirn* mRNA expression. It is well known that hepatocellular carcinoma has a strong propensity to invade vessel and duct systems[28-30]. Rapid invasion and metastasis of HCC seriously hold back the clinical therapy and also significantly affect the prognosis of patients with HCC, as well as HCC recurrence after surgery[31-33]. According to our study, *p*28/*gankyrin* may play a significant role in the promotion of metastatic potential in HCC. Though the detailed mechanism of the promotion role of *p*28/*gankyrin* in HCC metastasis is currently under investigation, more valuable clinical management of HCC can be applied by the evaluation of *p*28/*gankryin* expression combined with other effective markers.

In the present study, *p*28/*gankyrin* was highly expressed in human brain and heart, weakly expressed in lung, spleen and muscle, suggesting that *p*28/*gankyrin* has a physiological role in these tissues. However, *p*28/*gankyrin* mRNA was not detected in human digestive system including liver, pancreas, stomach, small and large intestines. This result indicates that *p*28/*gankyrin* expression may be developmentally heterogeneous. Up-regulation of *p*28/*gankyrin* mRNA in liver where it is normally absent correlates significantly with the occurrence of HCC, which is like the alteration of serum AFP levels in patients with HCC[34,35]. This incident implies that to understand the mechanism of liver carcinogenesis promoted by *p*28/*gankryin*, the involvement of *p*28/*gankryin* in liver development process should be considered.

*p*28/*gankyrin* was strongly expressed in SK-Hep1 cells, while weakly in HepG2 cells. It should be noted that SK-Hep1, not HepG2, has the tumorigenic potential when inoculated in nude mice[36]. Thus, the higher expression of *p*28/*gankyrin* in SK-Hep1, to some extent, contributes to the cell tumorigenesis. This conclusion coincides well with our experiment that *p*28/*gankyrin* caused cell transformation after being transfected into NIH/3T3 cells (data not shown).

By using our specific polyclonal antibody against *p*28/*gankyrin* protein, the cellular localization of *p*28/*gankyrin* expression in HCC was determined. *p*28/*gankyrin* protein was mainly localized in the cytoplasm of hepatocytes, from weakly in hepatocytes of para-carcinoma cirrhosis liver to intensely in hepatocytes of HCC. Occasionally, the nuclear localization of *p*28/*gankyrin* in malignant hepatocytes of HCC was also observed. It is interesting that *p*28/*gankyrin* protein can not be detected in bile duct cells, blood vein endometrial cells and other interstitial cells in liver tissues. The prospective application of *p*28/*gankyrin* in clinical pathological diagnosis as a specific tissue marker should be investigated further by collecting more examination data and statistical analysis.

In conclusion, *p*28/*gankyrin* mRNA is markedly overexpressed in HCC compared with para-carcinoma liver, normal liver or liver cirrhosis. In addition, in HCC, *p*28/*gankyrin* mRNA expression correlates significantly with metastasis potential of this cancer. The *p*28/*gankyrin* protein is particularly highly expressed in the hepatocytes of HCC. These findings suggest that *p*28/*gankyrin* plays an important role in the carcinogenesis of HCC by influencing tumor metastasis behavior and that it may serve as a new specific tissue marker for the pathological diagnosis of HCC.

Abstract

AIM: **To investigate the correlation between subcellular daunorubicin distribution and the multidrug resistance phenotype in drug-resistant cell line SMMC-7721/R.**

METHODS: **The multidrug resistant cell line SMMC-7721/R, a human hepatocellular carcinoma cell line, was established. Antisense oligonucleotides (AS-ODN) were used to obtain different multidrug resistance phenotypes by inhibiting the expression of mdr1 gene and/or multidrug resistance-related protein gene(mrp) using Lipofectamine as delivery agent. Expression of mdr1 and mrp genes was evaluated by RT-PCR and Western blotting. Intracellular daunorubicin (DNR) concentration was measured by flow cytometry. Subcellular DNR distribution was analyzed by confocal laser scanning microscopy. Adriamycin (ADM) and DNR sensitivity was examined by MTT method.**

RESULTS: **Low level expression of mdr1 and mrp mRNAs and no expression of P-Glycoprotein(P-gp) and multidrug resistance-related protein (P_{190}) were detected in parental sensitive cells SMMC-7721/S, but over-expression of these two genes was observed in drug-resistant cell SMMC-7721/R. The expression of mdr1 and mrp genes in SMMC-7721/R cells was down-regulated to the level in the SMMC-7721/S cells by AS-ODN. Intracellular DNR concentration in SMMC-7721/S cells was 10 times higher than that in SMMC-7721/R cells. In SMMC7721/S cells intracellular DNR distributed evenly in the nucleus and cytoplasm, while in SMMC-7721/R cells DNR distributed in a punctate pattern in the cytoplasm and was reduced in the nucleus. DNR concentration in SMMC-7721/R cells co-transfected with AS-ODNs targeting to mdr1 and mrp mRNAs recovered to 25 percent of that in SMMC7721/Scells. Intracellular DNR distribution pattern in drug-resistant cells treated by AS-ODN was similar to drug-sensitive cell, and the cells resistance index (RI) to DNR and ADM decreased at most from 88.0 and 116.0 to 4.0 and 2.3, respectively. Co-Transfection of two AS-ODNs showed a stronger synergistic effect than separate transfection.**

CONCLUSIONS: **P-gp and P_{190} are two members mediating MDR in cell line SMMC7721/R. Intracellular drug concentration increase and subcellular distribution change are two important factors in multidrug resistance (MDR) formation. The second factor, drugs transport by P-gp and P_{190} from cell nucleus to organell in cytoplasm, may play a more important role.**

Yang JY, Luo HY, Lin QY, Liu ZM, Yan LN, Lin P, Zhang J, Lei S. Subcellular daunorubicin distribution and its relation to multidrug resistance phenotype in drug-resistant cell line SMMC-7721/R. *World J Gastroenterol* 2002;8(4):644-649

INTRODUCTION

Multidrug resistance (MDR) remains a significant obstacle for cancer chemotherapy. The MDR observed in many cell lines is most commonly accompanied with overexpression of one or both of the members of the ATP-binding cassette superfamily of transport proteins, P-glycorprotein (P-gp) and multidrug resistance-related protein(Mrp, P_{190})[1-7]. P-gp or P_{190} acts as an energy-dependent outward transport pump, removing drugs from the cytoplasm and from the plasma membrane, thereby decreasing intracellular drug accumulation[8-12].

Human hepatocellular carcinoma drug-resistant cell line SMMC7721/R showed a strong multidrug resistance to DNR and other anthracycline, and overexpression of P-gp and P_{190} was observed in this cell line. Previous studies suggested that subcellular drug distribution contributing to cells drug resistance may be mostly mediated by P-gp and/or P_{190} in many other cell lines[13-20]. But there is no direct evidence suggesting the role of these two pump proteins in MDR of SMMC7721/R. In order to understand MDR phenotype and mechanism in SMMC7721/R, based on previous studies of antisense technology related to mdr1 gene and mrp gene, we used laser scanning confocal microscopy to evaluate the intracellular distribution of DNR and then explored the correlation of intracellular drug(DNR) transportation and distribution with multidrug resistance phenotype.

MATERIALS AND METHODS

Cell lines and culture conditions

Human hepatocellular carcinoma cell line SMMC-7721 was provided by Cancer Research Institution, West China Hospital of Sichuan University. Drug-resistance cell line was established by the stepwise selection with increasing concentration of ADM as previously described[21]. The ADM gradually increased from 0.005 μmg/ml to 0.1 μmg/ml.

Cells were grown in RPMI 1640 medium supplemented with 10 % fetal calf serum in a 5 % CO_2 atmosphere at 37 ℃.

Materials

Phosphorothioate antisense oligonucleotides(AS-ODN): targeting to mdr1 start codon region (AS-ODN/mdr1): 5' -CCA TCC CGA CCT CGC GCT CC-3' [22], targeting to mrp coding region (AS-ODN/mrp): 5' -TGC TGT TCG TGC CCC CGC CG-3' [23]. Control oligonucleotide (AS-ODN/nonsense) was a 20-mer nonsense phosphorothioate oligonucleotide. All oligonucleotides were synthesized by Life Technologies Inc, USA. Lipofectamine, TRIzol, RT-PCR kit, and primers were also purchased from Life Technologies Inc. Lumi-Light^{PLUS} Western Blotting Kit was purchased from Boehringer Mannheim, German. Antibodies against mdr1/P-gp and mrp/P_{190} were from Santa Cruz, USA. DNR was purchased from Minalo Inc, Italy.

Treatment of cells with AS-ODNs

The experimental protocols were similar to those previously described[22,24]. Briefly, cells(5×10^5) were seeded in a 25 ml flask at 1×10^5 cells/ml and grown to 75 % confluence. Cells were transfected with 1.5 nmol of AS-ODN with 50 ml of Lipofectamine. Cells were harvested at different times after transfection for analysis.

Detection of drug sensitivity of cells by MTT[25,26]

Cells were exposed to drug at 37 ℃ for 2 h, then were washed and seeded (50 000 cells/ml) in 96-well microplates for 72 h. MTT (20 μl, 2.5 mg/ml) was added to each well for 3 h. Medium was discarded and 150 μl of DMSO were added to each well. Optical densities were measured at 490nm (A490). The tumor cells living ratio (TCL) was determined according to the formula: $TCL=A490_{experient}/A490_{control}\times100$ %. The 50 % inhibitory concentration (IC_{50}) was calculated according to concentration-TCL curve. Resistance index (RI) was calculated using the formula: $RI=IC50_{drug\ resisant\ cells}/IC50_{parent\ cells}$.

Measurement of mdr1 and mrp mRNAs by RT-PCR

Primers mrp: 5' -TGA AGG ACT TCG TGT CAG CC-3' , 5' -GTC CATGAT GGT GTT GAG CC-3' ; mdr1: 5' -GGC TCC GAT ACA TGG TTT TCC-3' , 3' -TTC AGT GCG ATC TTC CCA GC-5' . β_2-microglobulin(β_2M): 5' -ACC CCC ACT GAA AAA GAT GA-3' ,5' -ATC TTC AAA CCT CCA TGA TG-3' .

β_2M expression was used as control for the amount of RNA used. Total RNA from cells was extracted using TRIzol. The effect of AS-ODN was studied after 24 h pre-incubation with AS-ODN and Lipofectamine. Mrp, mdr1, and β_2M RNA transcripts were detected using RT-PCR as described before[27,28]. An aliquot of each reaction mixture was then analyzed by electrophoresis on 2 % agarose gel. Densitometry was performed using UVP gel image analysis system (BIO-RAD, USA) and the ratio between the target and control PCR products was determined by dividing the densitometric volume of the target band by that of the control band.

Measurement of cell expression of P-gp and P_{190} with western blotting

The expression of the two proteins was detected according to the manufacturer' s instructions of Lumi-Light^{PLUS}Western Blotting Kit. The concentrations of the primary antibodies against P-gp and P_{190} were 1 μg/ml and 2 μg/ml, respectively. The concentrations of the secondary antibodies were both 0.4 μg/ml.

Observation of intracellular DNR distribution by confocal laser scanning microscopy (CLSM)

The experimental procedures were similar to those previously described[29-31]. Cells (1×10^5) were seeded to 960 mm^2 petri dish with a slide inside and incubated in a 5 % CO_2 atmosphere at 37 ℃. After cells had reached 75 % confluence, normal medium was replaced with serum-free RPMI 1640 medium and cells were incubated with DNR at 2 μg/ml for 1 h. The effect of AS-ODN was studied after 72 h pre-incubation with AS-ODN and Lipofectamine. After two washes with PBS and addition of drug free medium cells grown on slides were examined with CLSM (MRC-1024ES, BIO-RAD Inc., USA). Cover-slips were mounted on slides, supported and sealed on lacquer tiers to prevent compression and drying out. Intracellular drug fluorescence was observed using the 488 nm laser line for excitation and the filter that allows measurement of emitted light above 515 nm.

Detection of intracellular DNR concentration by flow cytometry (FCM)

Cells (1×10^5) were seeded into 25 ml flask and grown to 95 % confluence. They were then dissociated with pancreatin and suspended in serum-free medium. DNR was added to a final concentration of 2 μg/ml and incubated for 1 h at 37 ℃. After two washes with PBS each sample was divided into 3 tubes to be analyzed by FCM[32] (Elite ESP, Coulter Inc., USA). Results were expressed as the ratio of fluorescence intensity values between each experimental sample and control sample of SMMC7721/R cells without treatment.

RESULTS

Drug sensitivity

As shown in Table 1, the parental sensitive cells SMMC7721/S were highly sensitive to DNR and ADM. However, the drug resistant cells SMMC7721/R were 88-fold resistant to DNR and 116-fold to ADM, respectively, when compared with SMMC7721/S cells. Resistance index(RI) to DNR and ADM in SMMC7721/R cells co-transfected of AS-ODN/mdr1(0.5 μmol/L)and AS-ODN/mrp(0.5 μmol/L) decreased from 88 and 116 to 4 and 2.3, respectively. Treatment with separate AS-ODN/mdr1 or AS-ODN/mrp showed a lesser reversal effect on MDR than co-transfection of these two AS-ODNs. Nonsense oligonucleotides did not affect the drug resistance in SMMC7721/R cells.

Table 1 Effect of AS-ODN on drug sensitivity of cells ($\bar{x}\pm s$)

Cells	IC_{50}(mg/L)		RI	
	DNR	ADM	DNR	ADM
SMMC-7721/S	0.003±0.0006	0.004±0.0008	1.0	
SMMC-7721/R	0.264±0.0094	0.463±0.0254	88.0	116.0
AS-ODN/mdrr1	0.094±0.0065	0.079±0.0014	31.4	19.8
AS-ODN/mrp	0.072±0.0002	0.097±0.0009	24.0	24.3
SMMC-7721/R+ AS-ODN/mdr1+mrp	0.012±0.0011	0.009±0.0007	4.00	2.3
SMMC-7721/R+ AS-ODN/nonsense	0.245±0.0110	0.451±0.0187	81.7	112.8

Values(IC_{50}) represent the mean±standard deviation of at least three experiments and value(RI) represent the mean of three experiments. All values were calculated as described in MATERIALS AND METHODS. The concentration of each AS-ODN is 0.5 μmol/L and the treatment time is 72 hours.

Expression of mdr1 geng and mrp gene

As shown by RT-PCR, The amplification products of mrp, mdr1, and β_2M were 256bp, 168bp, and 120 bp, respectively. Over-expression of mrp and mdr1 mRNAs were detected in SMMC7721/R, but low level mRNA expression in SMMC7721/S was observed. The mRNA expression in SMMC7721/R cells treated with AS-ODN decreased to the level of SMMC7721/S (Figure 1).

No P-gp and P_{190} were detected in parental cells SMMC7721/S. Over-expression of P-gp and P_{190} was observed in drug resistant cells SMMC7721/R. Treatment of SMMC7721/R with AS-ODNs inhibited the expression of P-gp and P_{190} (Figure 2).

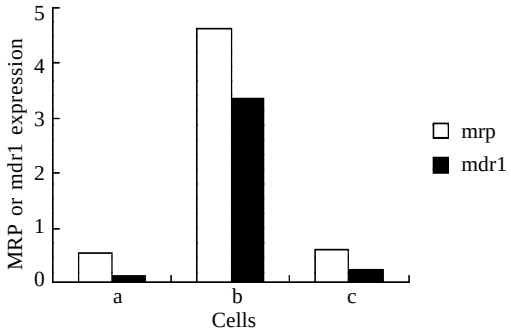

Figure 1 Quantification of PCR. The ratio between the mdr1 or mrp and β_2M gene is expressed as described in MATERIALS AND METHODS. (a. parental cell-SMMC7721/S; b. SMMC7721/R; c. SMMC7721/R incubated with 0.5 μmol/L AS-ODN for24 hours)

Figure 8 Intracellular DNR distribution in drug-resistant cells SMMC7721/R treated with AS-ODN/mrp(0.5 μmol/L) for 72 hours.
Figure 9 Intracellular DNR distribution in drug-resistant cells SMMC7721/R treated with nonsense oligonucleotides(0.5 μmol/L) for 72 hours.

Intracellular accumulation of DNR

Intracellular concentration of drugs in drug-resistant cells reduced to 10 percent of that in parental cells SMMC7721/S. Co-transfection of AS-ODN/mdr1+mrp up-regulated intracellular drug concentration to 4 times of that in SMMC7721/R cells. The up-regulation effect of separate transfection of AS-ODN/mdr1 or AS-ODN/mrp was much less than co-transfection (Figure 3).

Subcellular distribution of DNR

In parental cells SMMC7721/S DNR fluorescence mainly located in the nucleus and was diffusely present in the cytoplasm (Figure 4). In drug-resistant cells SMMC7721/R, DNR fluorescence retained in the perinuclear zone and in peripheral punctate vesicles, with little or no drug in the nuclear zone (Figure 5).

In SMMC7721/R cells incubated separately with AS-ODN/mrp or AS-ODN/mdr1 for 72 h, the subcellular distribution of DNR was similar to parental cells SMMC7721/S, with less intranuclear fluorescence intensity than in SMMC7721/S cells. Cells transfected separately with AS-ODN/mrp or AS-ODN/mdr1 did not show any difference in subcellular DNR distribution(Figure 7 and Figure 8). Co-transfection of AS-ODN/mdr1 and AS-ODN/mrp caused more drugs accumulation in nuclear than that in cells incubated separately with either AS-ODN (Figure 6). Nonsense oligonucleotides did not affect the drug subcellular distribution pattern in drug-resistant cells SMMC7721/R (Figure 9).

DISCUSSION

It has been reported that parental SMMC7721 cells have no or low level expression of mdri/P-gp and mrp/P_{190}. However, over-expression of P-gp and P_{190} was observed in drug-resistant cells SMMC7721/R, which was confirmed in our study.

In order to obtain cell line with different multidrug resistance phenotypes, we made use of the specificity of antisense oligonucleotides in down-regulating gene expression to specifically block mdr1/P-gp or mrp/P_{190} function. Antisense technology is increasingly becoming a reliable tool for manipulation of gene expression and rapidly moving into the therapeutic arena[33-47]. Down-regulation of expression of mdr1 mRNA/P-gp and mrp mRNA/P_{190} by AS-ODN was observed and accompanied with recovery of drug sensitivity in SMMC7721/R cells. Drug-resistant SMMC7721/R cells co-transfected with AS-ODN/mrp and AS-ODN/mdr1 showed 50-fold drug sensitivity to ADM, when compared with drug-resistant cells SMMC7721/R.

The fluorescence emitted by anthracycline DNR, a substrate of P-gp and P_{190}, can be detected by FCM and CSLM[14,17,31,48,51]. There is a good correlation between intracellular drug concentration and cells drug sensitivity[8,16,49,50,52,53]. In our studies, FCM data enforced the opinion that reduction of intracellular drug concentration results in increase of drug resistance in cells. Intracellular DNR concentration in cell line SMMC7721/R decreased to 10 percent of that in SMMC7721/S and meanwhile resistance to ADM and DNR increased by 116 times and 88 times respectively than that of SMMC7721/S. Co-transfection of AS-ODN/mrp and AS-ODN/mdr1 only restored intracellular DNR concentration to 40 percent of that of SMMC7721/S. Inconsistently, the drug resistance to DNR was reduced from 88-fold to 4-fold and to ADM from 116-fold to 2.3-fold when compared with SMMC7721/S. These data indicate that some other factors must play a more important role in MDR mechanism besides the reduction of intracellular drug accumulation. The mechanism focused in recently is modified drug localization[13,51,54]. We used CSLM technology to explore this interesting point.

In our studies, we observed that in cell line SMMC7721/S DNR fluorescence distributed evenly in the nucleus and cytoplasm, while in cell line SMMC7721/R DNR distributed in a punctate pattern in the cytoplasm and was reduced in the nucleus. Transfection of AS-ODN changed the the subcellular DNR distribution pattern in SMMC7721/S cells to that in SMMC7721/R cells. This observation indicates that P-gp or P_{190} not only pumps DNR out of cells, but also transports DNR from nuclear to cytoplasm and into some organelles such as Golgi apparatus. As P-gp or P_{190} probably locates in cell membrane, nuclear membrane,Golgi apparatus,or endoplasmic reticulum[13,54-59], the actions of these two proteins may cause reduction of intracellular and intranuclear drug concentration and drug accumulation in some organelles. The combined effect may prevent the targeting of the drugs to nucleus, which reduces cell death even if the total amount of drugs inside the cells was not dropped significantly. Golgi apparatus is widely believed to be the organelle which holds the drugs[54,59]. Previous studies found that there were some differences in subcellular drug distribution pattern between different cell lines in which MDR phenotype was mediated by P-gp and by P_{190}[49]. However, we did not observe such phenomenon in the present study.

Our studies suggest that after the potent inhibition of P-gp or P_{190} expression by AS-ODN intracellular drug concentration was increased and subcellular drug distribution changed, which leads to the reversal of multidrug resistance in cell line SMMC7721/R. Therefore, we believe that over-expression of P-gp and/or P_{190} is an important mechanism in mediating MDR in cell line SMMC7721/R.

Although co-transfection of AS-ODNs targeting the two genes didn' t enhance the inhibitory effect on expression of P-gp or P_{190} when compared with separate transfection of either AS-ODN, the synergistic effects of the two AS-ODNs on reduction of intracellular or intranuclear drugs and on recovery of cell drug sensitivity were much more prominent than separate transfection. This finding indicates that MDR in SMMC7721/R is mediated at least by both P-gp and P_{190}. The combination of MDR reversal methods against these proteins is effective in drug-resistant cells.

Abstract

AIM: **To investigate the expression of metallothioneins (MTs), which were recently thought to have close relationship with tumors, in human hepatocellular carcinoma.**

METHODS: **Histological specimens of 35 cases of primary human hepatocellular carcinoma with para-neoplastic liver tissue and 5 cases of normal liver were stained for MTs with monoclonal mouse anti-MTs serum (E9) by the immunohistochemical ABC technique.**

RESULTS: **MTs were stained in the 35 cases of HCC, including 6 cases negative (17.1 %), 23 weakly positive (65.7 %), and 6 strongly positive(17.1 %). But MTs were stained strongly positive in all the five cases of normal liver and 35 cases of para-neoplastic liver tissue. The differences of MTs expression between HCC and normal liver tissue or para-neoplastic liver tissue were highly significant ($P<0.01$). The rate of MTs expression in HCC grade I was 100 percent, higher than that in grade II(81 %) and grade III and IV (78 %). But the differences were not significant ($P>0.05$). No obvious correlations between MTs expression in HCC and tumor size, clinical stage or serum alpha fetoprotein concentration were found ($P>0.05$).**

CONCLUSION: **Decrease of MTs expression in HCC may play a role in carcinogenesis of HCC. MTs are stained heterogenously in HCC. We can choose the anticancer agents according to the MTs concentration in HCC, which may improve the results of chemotherapy for HCC.**

Huang GW, Yang LY. Metallothionein expression in hepatocellular carcinoma. *World J Gastroenterol* 2002; 8(4):650-653

INTRODUCTION

Metallothioneins (MTs) are a family of low-molecular weight, cysteine rich proteins which are widely distributed in various species. MTs are thought to be involved in heavy-metal detoxification, intracellular trace elements storage and scavenging free radicals. Recently, emerging data suggest that MTs have close relationship with tumors. They might play important roles in carcinogenic and apoptotic process and differentiation of tumor cells[1-12]. And besides, MTs are attributed to affording tumor cells resistance to some important chemotherapeutic agents[13]. This study is aimed to examine MTs expression in human hepatocellular carcinoma (HCC) and to explore its biological and clinical significance.

MATERIALS AND METHODS

Clinical material

The clinical information and pathological specimens from 35 patients, whose liver tumors were removed at XiangYa Hospital from 1998 to 2000, were analyzed. All the cases were reviewed to confirm the pathological diagnosis of HCC. All the 35 specimens of HCC contained their corresponding para-neoplastic liver tissue. The ages of patients ranged from 31 to 71 years, with a mean±SD of 49.92±9.32 years. 33 were men and 2 women. According to Edmonson pathologic grading, there were 5 cases of grade I, 16 grade II and 14 grade III-IV. According to the clinical staging of UICC, there were 22 cases of stage II, 5 stage III and 8 stage IV. All the cases had positive HBsAg. This study also included 5 cases of normal liver tissue, around the hepatic hemangioma excised also in XiangYa Hospital.

Immunohistochemical determination of MTs

All the specimens were fixed in 10 % buffered formalin and embedded in paraffin. Five-micrometre thick sections were cut from the tissue blocks, mounted onto glass slides and were used for staining. ABC technique was adopted. Briefly, 5 μm sections were deparaffinized and rehydrated first, and then were immersed in 3 % H_2O_2 with methanol for 30 minutes to remove the endogenous peroxidase activity. Sections were further incubated with 10 % normal goat serum for 1 hour, followed by incubation with monoclonal mouse anti-MTs serum (E9) (1:50) at 4 ℃ overnight. The sections were then washed in phosphate buffer solution (PBS) (0.01M, pH 7.2) and they were sequentially incubated with: (1) biotinylated goat anti-mouse IgG, and (2) avidin-biotin horseradish peroxidase complex following the manufacturers` instruction (ABC kit, BOSTER Ltd. Wuhan). Staining was developed by immersing slides in 0.05 % 3,3' -diaminobenzidine tetrahydrochloride (DAB) with 0.33 % hydrogen peroxide. All slides were counterstained with haematoxylin, dehydrated and mounted. PBS substituted for the primary antibody was used as the negative control. According to the proportion of positively stained cells, a grade was given from I to III, with Grade I indicating less than one third of cells stained and Grade III indicating more than two thirds of cells stained. The intensity of MTs expression was also graded and given a grade for 0 to II, with Grade 0 indicating no staining, and Grade II indicating the greatest intensity of staining. A weighted score was then generated to semiquantify the MTs expression level in the tissue by multiplying the MTs intensity score with the proportion of the positively stained tumors cells. A weighted score of zero indicated no MTs staining (-), more than 3 indicated strongly positive MTs staining (++) and that between zero and 3 indicated weakly positive MTs staining (+)[14].

Statistical analysis

The data were expressed semiquantitively. Ridit test was used to determine the difference. The results were considered statistically significant when $P<0.05$.

RESULTS

All negative control slides showed no staining for MTs, demonstrating the specificity of the monoclonal antibody E9. Strongly positive MTs immunoreactivity was observed in all the five control normal liver sections, mostly in cytoplasm with a few in nucleus. All the surrounding connective tissues, including blood vessels and bile ducts were negative for MTs staining. Twenty-nine of 35 HCC showed positive MTs staining, including 6 strongly positive (17.1 %) (Figure 1), 23 weakly positive (65.7 %) (Figure 2) and 6 negative (17.1 %) (Figure 3) . MTs expressed strongly in all the para-neoplastic liver tissue. The differences of MTs expression between HCC and para-neoplastic liver tissue or normal liver tissue were highly significant (Table 1, $P<0.01$).

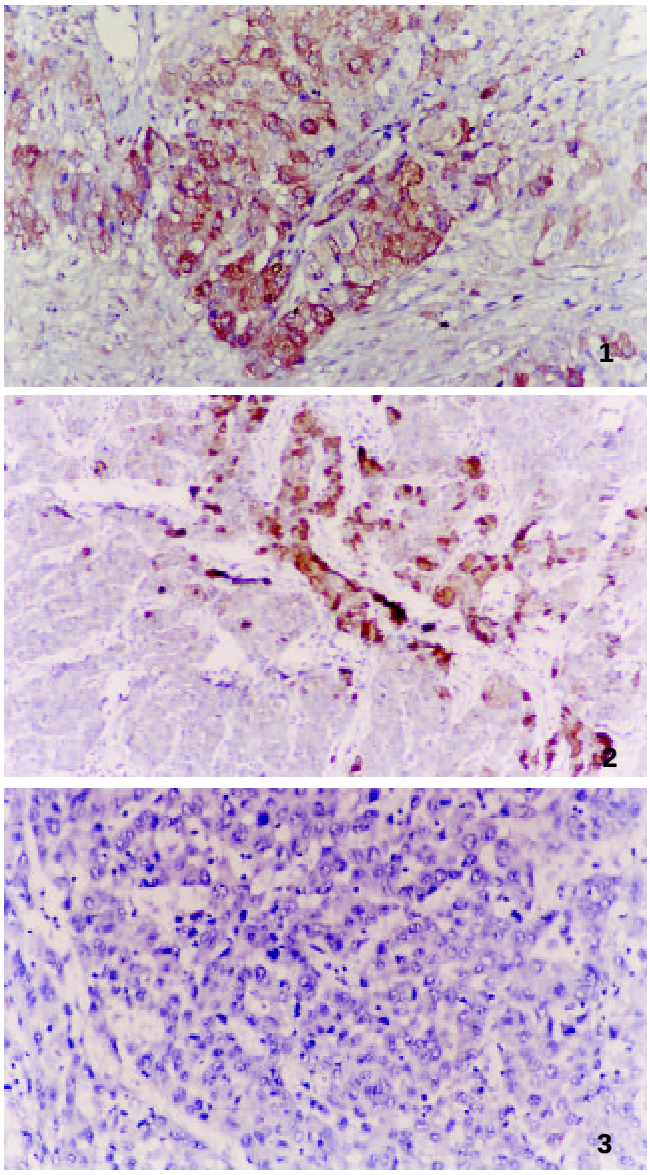

Figure 1 Strongly positive staining of MTs in hepatocellular carcinoma ABC ×200

Figure 2 Weakly positve staining of MTs in hepatocellular carcinoma ABC ×200

Figure 3 Negative staining of MTs in hepatocellular carcinoma ABC ×200

The positive ratio of MTs expression in grade I of HCC was 100 %, higher than that in grade II (81 %) and grade III and IV(78 %). But the differences did not reached the level of significance ($P>0.05$). In addition, the differences of MTs expression in HCC with different clinical stages, tumor sizes and serum alpha fetoprotein concentration were not significant either (Table 2).

Table 1 Levels of MTs expression in HCC, para-neoplastic and normal liver tissues

		MTs score		
	n	-	+	++
HCC	35	6	23	6
Para-neoplastic tissue[b]	35	0	0	35
Normal liver tissue[b]	5	0	0	5

[b]$P<0.01$, *vs* HCC

Table 2 Correlation between MTs expression and clinicopathologic data of HCC

		MTs score		
	n	-	+	++
Pathologic grade				
Grade I	5	0	3	2
Grade II	16	3	10	3
Grade III-IV	14	3	10	1
Clinical stage				
Stage I-II	22	5	14	3
Stage III-IV	13	1	9	3
Size (mm)				
≤50	9	3	6	0
>50	26	3	17	6
AFP concentration (ng/ml)				
≤50	13	3	6	4
>50	22	3	17	2

DISSCUSSION

Recently, much attention was paid to the association between MTs and tumors. Available information suggested that MTs might play important roles in carcinogenic and apoptotic process of some tumors[1-13,15-20]. Using immunohistochemical staining method, MTs have been localized intensively in various types of human tumors in organs and tissues such as skin, kidneys, prostate, testes, gallbladder, colon, breast and endometrium[15-32]. It was mainly attributed to loss of control of the transcription of MTs genes, which was caused by activation of some oncogenes, such as Ha-ras, in tumor cells[33]. However, the potential roles of MTs in carcinogenic process was not yet well understood[34]. Several pieces of evidence suggested that MTs could combine with and sequester those carcinogenic substances in cells. When the cells were invaded by the carcinogenic substances, many protective processes were activated to scavenge those substances. Elevation of MTs may be one of the processes[35-40]. But not all the tumors contained

elevated MTs[41], such as HCC. In this study, the authors have detected MTs expression in 35 cases of HCC and their corresponding para-neoplastic liver tissue and 5 cases of normal liver tissue. The results showed that MTs were strongly positive in all the normal liver tissue and para-neoplastic liver tissue, considerabely higher than those in HCC tissue, which conformed to the finding of Deng[14]. MTs are functional proteins in liver tissue, which is involved in heavy metal detoxification. The down-regulation of MTs expression in HCC suggested that these cells probably have different proliferative or differentiated characteristics as compared to the surrounding normal hepatocytes, and MTs may be a marker of hepatocellular differentiation. In addition, this down-regulation might play a role in carcinogenic process of HCC. MTs are one of the most important intracellular free radicals scavengers, and oxidateve injury may be one of the most important causes of gene mutation. As a result, this down-regulation of MTs expression might cause accretion of oxidative in cells, which might lead to activating some oncogenes or inactivating some tumor-suppressor genes[38-40].

Several other studies have also shown that the MTs levels may be related to the degree of differentiation of tumor cells. For example, using immunohistochemical staining method, a distinct difference between seminoma and nonseminoma of human testicular tumors was found[21]. Well-differentiated seminoma showed litter or no staining for MTs while less differentiated nonseminoma (embryonic carcinoma) strongly expressed MTs. MTs overexpression in human breast carcinoma, colorectal carcinoma, esophageal carcinoma, osteosarcoma, endometrial carcinoma and melanoma tended to correlate with poor prognosis[19,24-42]. In this study, the positive rate of MTs expression in grade I of HCC is 100 percent, higher than grade II (81 %) and grade III and IV (78%), but the differences have not reach the level of significance. So the genuine relationship between MTs and differentiation of HCC remains to be further investigated.

Resistance to antineoplastic agents is one of the major obstacles to curative therapy of HCC. The development of this resistance has been explained by several factors, including increased DNA repair processes and expression of MDR gene[43]. In 1998, Kelley *et al*[44] found that tumor cell lines with acquired resistance to the antineoplastic agent cisplatinum overexpressed MTs and demonstrated cross-resistance to other eletrophilic anticancer agents, such as melphalan, chlorambucil. Furthermore, cells transfected with bovine papilloma virus expression vectors containing DNA encoding human MTs were resistant to electrophilic anticancer drugs mentioned above, but not to 5-fluorouracil or vincristine. Thus, overexpression of MTs represented one mechanism of resistance to a subset of clinically important anticancer drugs. Those results were substantiated by a series of other experiments[45-49]. The mechanism that MTs were involved in drug resistance might be that MTs in tumor cells could combine with those electrophilic anticancer drugs and prevent them from acting on their targets, such as DNA. In this study, we have shown that MTs expressed heterogenously in HCC, including 6 cases with strong expression, 23 with weak expression and 6 negative. The authors therefore assumed that resistance to electrophilic antineoplastic agents in a portion of HCC might be related to MTs expression in tumor tissue.

Thus, anticancer agents could be chosen according to the levels of MTs expression in order to improve the efficiency of chemotherapy for HCC. For example, electrophilic antineoplastic agents were used in the treatment of HCC without MTs and non-electrophilic antineoplastic agents were used in HCC containing high levels of MTs. However, the effect of this design remains to be determined. Recently, a gene therapy by transactivating MTs to the chemoresistant tumour cells to reverse the chemoresistance have been reported[50]. In the near future, oncologists are really able to use the knowledge about MTs in overcoming cancer.

The down-regulation of MTs expression in HCC might play roles in carcinogenesis of HCC, but its biological and clinical significance is still uncertain. A further understanding of the association between MTs expression and resistance to anticancer agents should facilitate the chemotherapy for HCC.

Abstract

AIM: **To investigate whether CTL vaccine therapy is suitable for primary hepatocellular carcinoma (HCC) from the viewpoint of HLA class I antigens expression.**

METHODS: **The immunocytochemistry, image analysis, flow cytometry, and labeled streptavidin biotin (LSAB) method of immunohistochemistry were applied respectively to study 4 HCC cell lines (e.g. Alexander, HepG2, SMMC-7721, and QGY-7703) cultured *in vitro* and 6 frozen tissue specimens of HCC.**

RESULTS: **The positive control cell line Raji had very strong positive staining. Most mitotic and nonmitotic cells of the 4 HCC cell lines had various intensity of HLA class Ⅰ antigens expression. The negative control cell K562 and the control slides of all the cell lines had no positive staining. In the 6 HCC specimens immunohistochemically studied, histological normal hepatocytes had no or very weak positive staining and the liver sinus had very strong positive staining. Most HCC cells in the sections from the 6 HCC specimens had strong positive HLA class Ⅰ antigens staining. The positive staining was located in the cytoplasm, the perinuclear area, and at the cell membrane of the liver cancer cells. Flow cytometry also revealed that Raji and those 4 HCC cell lines had strong HLA class Ⅰ antigens expression, which was confirmed quantitatively by the image analysis. It showed that the objective grayscale values of Raji and those 4 HCC cell lines were significantly different from that of K562 (Raji 114.04±10.94, Alexander 165.97±5.35, HepG2 167.02±12.60, QGY-7703 161.46±7.13, SMMC-7721 165.93±5.21, K562 244.89±4.60, *P*<0.01). Significant differences were also found between Raji and the 4 HCC cell lines.**

CONCLUSION: **HCC cells express HLA class I antigens strongly. From this point of view, the active specific immunotherapy of CTL vaccine is suitable and practicable for HCC.**

INTRODUCTION

The immunity of cytotoxic T lymphocyte (CTL) is crucial for anti-tumor immune response. Tumor cells expressing MHC class I antigens is a necessary molecular basis and requirement for effective presentation, recognition, and cytotoxicity. Many tumors do decrease or lack MHC class I antigens to escape from immune surveillance. The monitoring of MHC class I antigens expression in tumors, therefore, is undoubtedly helpful to decide which immune strategy is suitable for a given tumor [1]. Therefore, it is necessary to start a preliminary investigation on the HLA class I antigens expression of HCC tissues *in vivo* and corresponding cell lines cultured *in vitro* before the design and construction of CTL vaccine against HCC.

MATERIALS AND METHODS

Main reagents

Mouse anti human HLA-ABC mAb, DAKO Corp; FITC labeled mouse anti human HLA-ABC mAb, Beckman Coulter Corp; biotin labeled goat anti mouse IgG and HRP-labeled streptavidin, from Beijing Zhongshan Corp; avidin biotin blocking system, Wuhan Boster Corp.

Cell lines and specimens

The erythromyeloid cell line K562 and the Burkitts' lymphoma cell line Raji were used as HLA class I antigens negative and positive control cells respectively [2,3].The human HCC cell lines Alexander [4], HepG2 [5], SMMC-7721, and QGY-7703 were all kept and passed by our group. The cells above were maintained in complete PRMI 1640 medium at 37 degrees in a incubator with 5 % CO_2. Fifteen pathological specimens were obtained from surgically resected tissues of patients with HCC in the First Affiliated Hospital of West China University of Medical Sciences. The specimens were frozen immediately in liquid nitrogen. Four ¦Ìm consecutive frozen sections were prepared and stored at -70 degrees. HE Staining was done by the routine method.

Immunocytochemistry and immunohistochemistry

HCC cell lines were grown on the glass slides until confluence and then fixed and washed. Some slides were coated with the fixed and washed Raji and K562 cells. The frozen sections were also fixed and washed. The endogenous peroxidase on the slides and sections were inactivated, and the slides and sections were blocked by normal goat serum. Additionally, the endogenous biotin in the frozen sections was blocked. The slides and sections were incubated with 50 μl of 1:100 diluted mouse anti-HLA-ABC mAb or 50 μl PBS as control at 37 degrees in humid box for 1h and then were washed twice with PBS for 5 min each time. Next, 50 μl of 1:200 diluted biotin labeled goat-anti mouse IgG was added. After being incubated for 30 min and washed as before, 50 μl of 1:200 diluted HRP labeled streptavidin was added. The following incubation and washing was exactly the same as above. Finally, 50 μl of DAB working solution was added for color reaction under the microscopical

scrutiny. The reaction was stopped with tap water rinse. The slides and sections were then counterstained with hematoxylin as routine assay.

Image analysis

The slides were focused under photographic microscope and the 24 bit true color images at a resolution 768×576 were captured in real time by the JVC TK-C1381 digital camera. The captured images were read into the Mias-2000 Medical Images Analyzer. The objective grayscale was obtained through color HSV splitting and half binary quantifying. The data were assessed by Newman-Keuls method of *q* test using statistical package PEMS2.1 for *Medical Statistics of Chinese Medical Encyclopedia*. Values of $P<0.05$ were considered statistically significant.

Flow cytometry

Cells were washed twice with PBS at 1200 r/min for 5 min per time. Then the cell concentration was adjusted to 1×10^6 Entries/ml and incubated with 10 μl of 1:10 diluted FITC labeled mouse anti HLA-ABC or mouse IgG as negative control at room temperature for 30 min. At last, cells were washed once and detected by Elite-ESP flow cytometer.

RESULTS

Routine HE stain

Raji and K562 cells were round in shape. QGY-7703, Alexander and HepG2 seem to be polygonal. SMMC-7721 cells were spindly. All the cell lines above had evident features of tumor cells, which were heterogeneous in nuclear size. Mononuclear tumor giant cells were commonly seen in these cell lines. In addition, binuclear or multinuclear, normal or abnormal mitotic tumor cells were frequent in QGY-7703, HepG2 and SMMC-7721. Ten of 15 specimens from patients clinically, were diagnosed as HCC pathologically in corresponding paraffin sections by the Pathological Department. The left 5 specimens were excluded from this study, which were confirmed to be combined hepatocholangiocellular carcinoma, cholangiocellular carcinoma, nodular cirrhosis, secondary liver cancer from nasopharyngeal carcinoma and colon cancer, respectively. In comparison between the HE stain of frozen sections with that of paraffin sections, HCC cells could be found in only 6 of the 10 paraffin sections corroborated specimens. The remained 4 frozen specimens without HCC cells, possibly due to the failure of sampling HCC tissue, were also excluded from this study.

Immunocytochemistry and immunohistochemsitry

Positive staining of HLA class Ⅰ antigens appeared brown in color. Raji cells had very strong positive staining. Most mitotic and nonmitotic cells of the 4 HCC cell lines have various intensity of HLA class Ⅰ antigens expression. The positive staining of HLA class Ⅰ antigens was located in the cytoplasm, the perinuclear area, and at the cell membrane, but none in K562 and the control slides of all the cell lines (Figures 1, 2). In the 6 HCC specimens studied immunohistochemically, histologically normal hepatocytes had no or very weak positive staining and the liver sinus had very strong positive staining. Most HCC cells in the sections from the 6 HCC specimens had strong positive staining of HLA class Ⅰ antigens, which were located in the cytoplasm, the perinuclear area, and at the cell membrane of the liver cancer cells (Figures 3, 4).

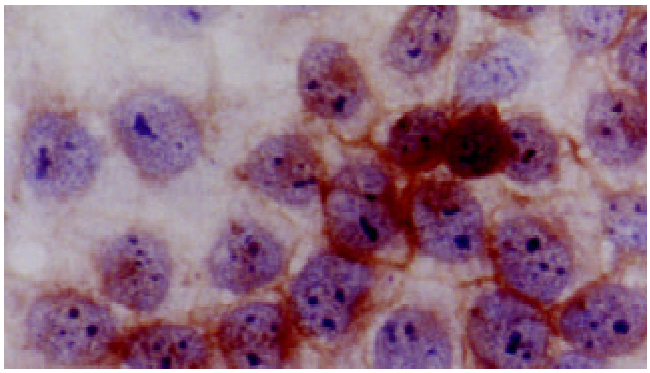

Figure 1 Positive staining of HLA-Ⅰ antigens at QGY-7703 cell membrane. LSAB×350

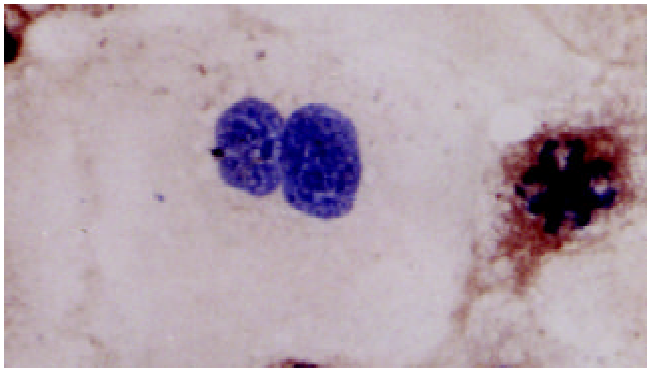

Figure 2 Positive staining of HLA-Ⅰ antigens in cytoplasm of dividing Alexander cells. LSAB×350

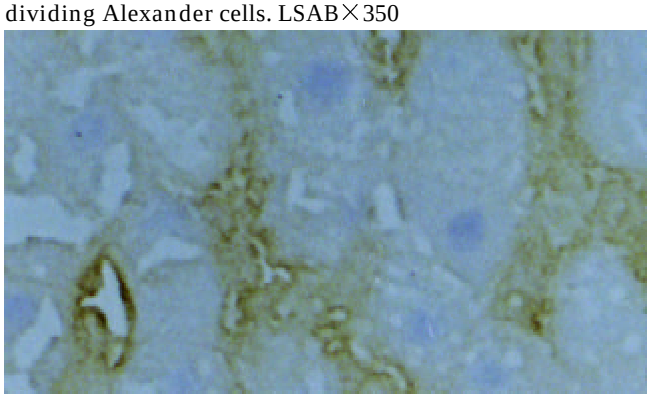

Figure 3 Negative staining of histologically normal liver cells and intensive positive staining within sinusoids. LSAB×100

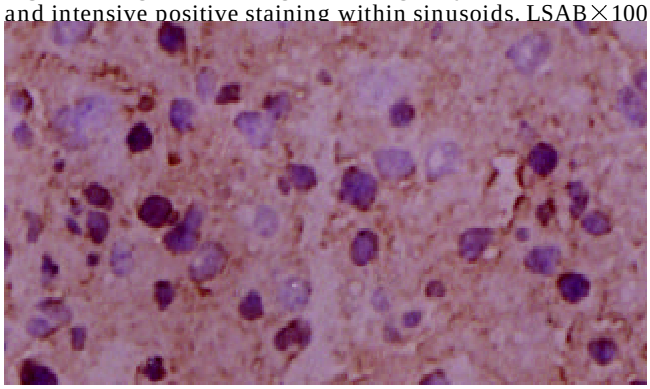

Figure 4 Positive staining of hepatocelluar carcinoma cells

LSAB×100

Image analysis

The image analysis of HLA class Ⅰ antigens expressions in the slides showed that the objective grayscale values of Raji and those 4 HCC cell lines were significantly different from that of K562 (P<0.01). Significant differences were also found between Raji and the 4 HCC cell lines (Table 1).

Table 1 Grayscale value comparison of HLA-Ⅰ antigens among different cell lines

Tumor cell lines	n	Grayscale value ($\bar{x}\pm s$)
Raji	7	114.04±10.94[a]
Alexander	7	165.97±5.35[ab]
HepG2	7	167.02±12.60[ab]
QGY-7703	7	161.46±7.13[ab]
SMMC-7721	7	165.93±5.21[ab]
K562	7	244.89±4.60

[a]P<0.01 *vs* K562; [b]P<0.01 *vs* Raji.

Flow cytometry

The positive control Raji cells had strong fluorescence intensity, but Raji cells incubated with FITC labeled mouse IgG had very weak fluorescence. Fluorescence intensities of QGY-7703, Alexander, HepG2, and SMMC-7721 were very high. Some cells of the 4 cell lines had equal or even higher fluorescence intensities than those of Raji. The negative control cells K562 had very weak fluorescence intensity of HLA class Ⅰ antigens, the irrelevant fluorescence stain of K562 was also weak (Figures 5, 6).

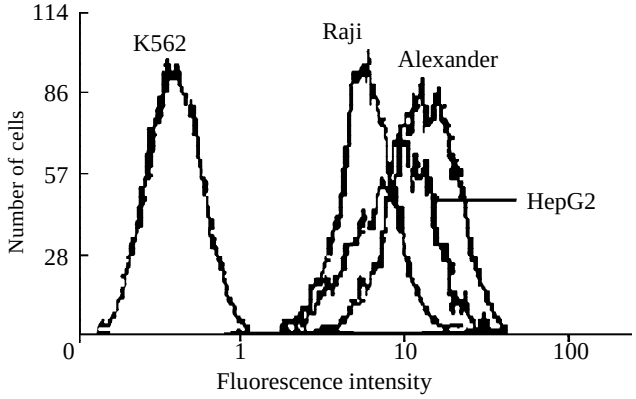

Figure 5 Flow cytometric histogram comparison of HLA-Ⅰ antigens among K562, Raji, Alexander, HepG2 cell lines

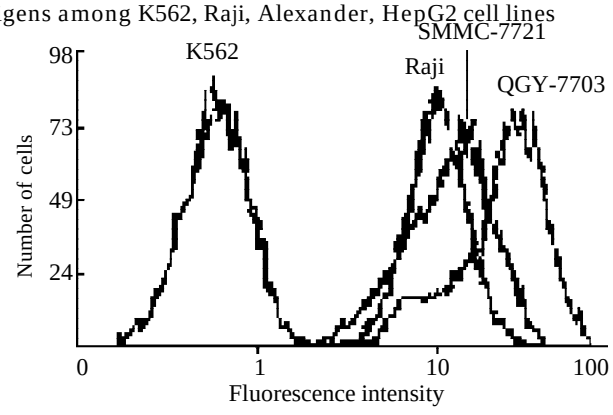

Figure 6 Flow cytometric histogram comparison of HLA-Ⅰ antigens among K562, Raji , SMMC-7721, QGY-7703 cell lines

DISCUSSION

HCC, one of the most common cancers, is the second cancer killer in China, and its mortality rate tends to increase year by year. About 11 000 of Chinese die of HCC annually. This number covers approximately half of the world population who die of HCC. At present, the overall curative effect of HCC is far from satisfaction. More than 2/3 of the HCC patients were found inoperatable. The surgically treated patients have to face the challenge that how to clear away the residual cells to prevent metastasis and relapse. Because of serious side effects of radiotherapy and chemotherapy, new therapy is urgent clinically to be searched and developed so as to improve the curative effect of HCC. In recent years, studies of CTL vaccines against HCC have become frontiers of HCC immunotherapy [6-8]. The expression of MHC class Ⅰ antigens is essential in CTL cytotoxicity. For example, the killing activity of mouse AFP specific CTL to mouse HCC cell lines Hepa1-6 and BWIC3, which express few MHC class Ⅰ antigens, is much lower than that of MHC class Ⅰ antigens positive EL4 cells[6]. Thus, whether HCC is suitable for CTL vaccine therapy depends to a great extent on the HLA class Ⅰ antigens expression status of HCC cells.

Although a few studies have reported that liver cancer cells in HCC tissue or cultured *in vitro* have strong HLA class Ⅰ antigens expression[2,3,9-12], few are aimed at Chinese. A Chinese research group, however, have initiated a study involving the expression of HLA-ABC on hepatocarcinoma. Our results of Alexander and HepG2 are consistent with results of other groups [2,3,10-13]. HCC cell lines QGY-7703 and SMMC-7721 have been established from HCC tissues of Chinese patients and frequently used in studies in China. Our results of these two cell lines indicate that both of them have strong HLA class Ⅰ antigens expression. In addition, we found that mitotic HCC cells also strongly express HLA class Ⅰ antigens. This phenomenon was not reported before, indicating that the corresponding specific CTL may kill the mitotic liver cancer cells. Our investigation on frozen specimens from 6 Chinese HCC patients shows that most liver cancer cells in the HCC tissue have strong HLA class Ⅰ antigens expression. This is also consistent with the results of other groups [2, 9, 13]. It is worth paying attention to the articles of Paterson *et al* [9]. They reported that liver cancer cells in a handful of HCC specimens (4/70, 5.7%) did not express HLA class Ⅰ antigens. However, this is not found in our study, possibly due to the limited amount of the specimens studied in our present study.

The results in our studies also indicate that in histologically normal liver HLA class Ⅰ antigens were mainly expressed on liver sinusoidal lining cells rather than on hepatocytes. This is consistent with the results of several other groups [2,9,14]. The reason why the phenomenon that histologically normal hepatocytes have no or only weak HLA class Ⅰ antigens expression though liver cancer cells strongly express HLA class Ⅰ antigens, may be related to the unique lymphocytes distribution in liver and NK-cell escape[1,15,16]. About 31 % of the liver resident lymphocytes are NK cells[15]. Therefore, re-expression or enhanced expression of HLA class Ⅰ antigens on HCC cells would be helpful for inhibiting the nonspecific cytotoxicity of NK cells. However, the cause of above phenomenon and its immunobiological implications remain to be explained by further studies.

In brief, the results of this study and other research groups indicate, from viewpoint of HLA class Ⅰ antigens expression, that CTL vaccine therapy is suitable and practicable for HCC. This would provide *in vivo* and *in vitro* experimental basis for

the follow-up study of CTL vaccine design and construction.

Abstract

AIM:**To evaluate the role and limitation of fast multiplanar spoiled gradient-recalled (FMPSPGR) MR dynamic contrast scanning in the follow-up of patients with HCC treated by transarterial chemoembolization (TACE).**

METHODS:**Twenty-two patients with 24 HCC lesions confirmed by biopsy or surgical resection underwent MR imaging in 4-9wks after TACE with a superconducting 1.5 T MR scanner, including SE T_1WI, T_2WI and FMPSPGR dynamic contrast scanning. The signal intensities of all lesions on SE T_1WI,T_2WI and the enhancement patterns on FMPSPGR dynamic contrast scanning were observed, and the comparison was made between MRI findings and pathological results in all the cases.**

RESULTS:**Of the 24 lesions, the signal intensities were various on SE T_1WI and T_2WI. On T_1WI, 13 lesions appeared as hyperintense, 4 lesions were isointense and the other 7 lesions were hypointensese. Histologically, hyperintense lesions showed on T_1WI were viable tumor or hemorrhage; isointensities were coagulative necrosis or inflammatory infiltration; hypointensities were tumor, liquified necrosis, coagulative necrosis or inflammatory infiltration. On T_2WI, 15 lesions appeared as hyperintense, 3 lesions were isointense and the other 6 lesions were hypointensese. Hyperintense lesions showed on T_2WI were residuals of viable tumor, hemorrhage, liquefied necrosis or inflammatory infiltration; isointense lesions were residuals of viable tumor or inflammatory infiltration; hypointense lesions were coagulative necrosis. On FMPSPGR dynamic contrast scanning, 18 of the 24 lesions enhanced on early-phase dynamic scanning corresponding to residuals of viable tumor and the other 6 lesions had no enhancement at this phase because complete necrosis were seen in the histologic examination. On delayed-phase dynamic scanning, 6 lesions had permanent enhancement appeared as inhomogeneous hyperintensity and both residuals of viable tumor and inflammatory infiltration were found by histologic examination. 18 lesions were hypointense at this phase and 8 of them coexisted with peripheral ring-like enhancement of the lesions resulting from viable tumors or inflammatory infiltration.**

CONCLUSION: **FMPSPGR MR dynamic contrast scanning can reflect the pathologic changes of HCC treated by TACE. Especially, early-phase dynamic scanning can evaluate accurately residuals of viable tumor and necrosis in HCC lesions. FMPSPGR dynamic contrast scanning is useful in the follow-up of patients with HCC treated by TACE combined with SE T_1WI and T_2WI, but it is difficult to differentiate peripheral viable tumors from inflammatory infiltration.**

Yan FH, Zhou KR, Cheng JM, Wang JH, Yan ZP, Da RR, Fan J, Ji Y. Role and limitation of FMPSPGR dynamic contrast scanning in the follow-up of patients with hepatocellular carcinoma treated by TACE.*World J Gastroenterol* 2002; 8(4):658-662

INTRODUCTION

Hepatocellular carcinoma (HCC) is a malignancy prevalent in the Asia countries. Surgical resection is the first choice for the treatment, but this option is not always possible because of coexisting severe cirrhosis, multiple lesions and other conditions not suitable for surgery. In case of unresectable HCC, transarterial chemoembolization (TACE) has been one of the widely used and effective treatment methods and demonstrated great potential in improving survival time, especially, it has been proved to be more effective in combination with percutaneous ethanol injection, Chinese traditional medicine or laser thermal ablation, etc[1-31]. Since TACE is difficult to kill the tumor cells for once completely, the treatment efficacy of TACE was influenced by many factors, such as the size of tumors, blood supply and the ultra- selectivity of the catheter etc. It is very important to assess objectively the viability and necrosis of the tumors after TACE in HCC, and to take further treatment to improve the general therapeutic effects and the survival rate. Magnetic resonance imaging (MRI) has been a useful modality in the diagnosis of HCC, especially fast multiplannar spoiled gradient recalled (FMPSPGR) sequence dynamic contrast scanning could reflect sufficiently the blood supply of HCC[32-39]. The therapeutic effects of TACE in HCC were evaluated with MRI in this study, and the role and limitation of FMPSPGR dynamic contrast scanning in the follow-up of patients with HCC treated by TACE were discussed.

MATERIALS AND METHODS

Twenty-two cases with massive or nodular types of HCC were collected from Sept. 1997 to May 1999. All cases were confirmed by biopsy (n =19) or surgical resection after TACE (n=3).

Transarterial chemoembolization was performed by selectively introducing a catheter into the hepatic artery and injecting antitumor agents (5-FU 1 000 mg, Cisplatin 80 mg

or Biaoroubixing 60-70 mg). Subsequently, the peripheral embolization of the tumors was done with 38 % ultrafluid iodized oil (Lipiodol) (10-25 ml) mixed with Mitomycin 16-20 mg, then the central embolization of the tumors was done with 3-5 strips of gelatine sponge (0.1-0.2 cm×1 cm).

MRI was performed in 4-9 wk after TACE with a superconducting 1.5 T MR scanner (GE Medical Systems Milwaukee, WI) , including T_1WI (TR/TE=500-700 ms/14-16 ms) and T_2WI (TR/TE=2 000-4 000 ms/30-90 ms) and FMPSPGR dynamic contrast MRI (Matrix 256×128, thickness 7 mm, gap 3 mm, TR/TE Flip Angle=100-150 ms/1.6~4.6 ms/60°-90°). Three to four repeated acquisitions were obtained at 25 s, 60 s, 90 s and 180 s respectively following power injection of 15-20 ml (0.15 mmol/kg) of Gd-DTPA (gadopentetic dimeglumine, Magnevist, Shering Pharmaceutical Ltd.) via antecubital vein.

Nineteen cases underwent biopsy with the CT guidance. The other 3 cases underwent surgical resection after TACE. The MRI images of all cases were read and analyzed by 2 experienced radiologists. The comparison of MRI images between before and after TACE was done in 6 cases. The comparison was also done between MRI findings and pathological results in all cases.

RESULTS

A total of 24 lesions were identified in the 22 cases of HCC. The size of the lesions ranged 3.9-8.2 cm in diameter, with average 5.3 cm(Figure 1).

Findings of HCC after TACE on SE sequence were showed in Table 1.

Table 1 Findings of HCC after TACE on SE sequence

SE sequence	signal intensity				
	hyperintensity		isointensity	hypointensity	
	homogeneity	inhomogeneity		homogeneity	inhomogeneity
T_1WI	9	4	4	2	5
T_2WI	3	12	3	3	3

Table 2 Comparison of MR findings on SE sequence with pathology

SE sequence	signal intensity	Pathological changes
	hyperintensity	viable tumors, hemorrhage
	isointensity	viable tumors, coagulative necrosis, inflammatory infiltration
T_1WI	hypointensity	viable tumors, coagulative necrosis, liquefied necrosis, inflammatory infiltration
	hyperintensity	viable tumors, hemorrhage, liquefied necrosis, inflammatory infiltration
T_2WI	isointensity	viable tumors, inflammatory infiltration
	hypointensity	coagulative necrosis

Table 3 Comparison of MR findings on FMPSPGR sequence with pathology

FMPSPGR sequence	enhancement	pathological changes
enhanced early phase	enhanced area	viable tumors
	no enhanced area	necrosis
	enhanced area	viable tumors,inflammatory infiltration
enhanced late phase	no enhanced area	viable tumors, necrosis
	peripheral ring-like enhancement	viable tumors,inflammatory infiltration

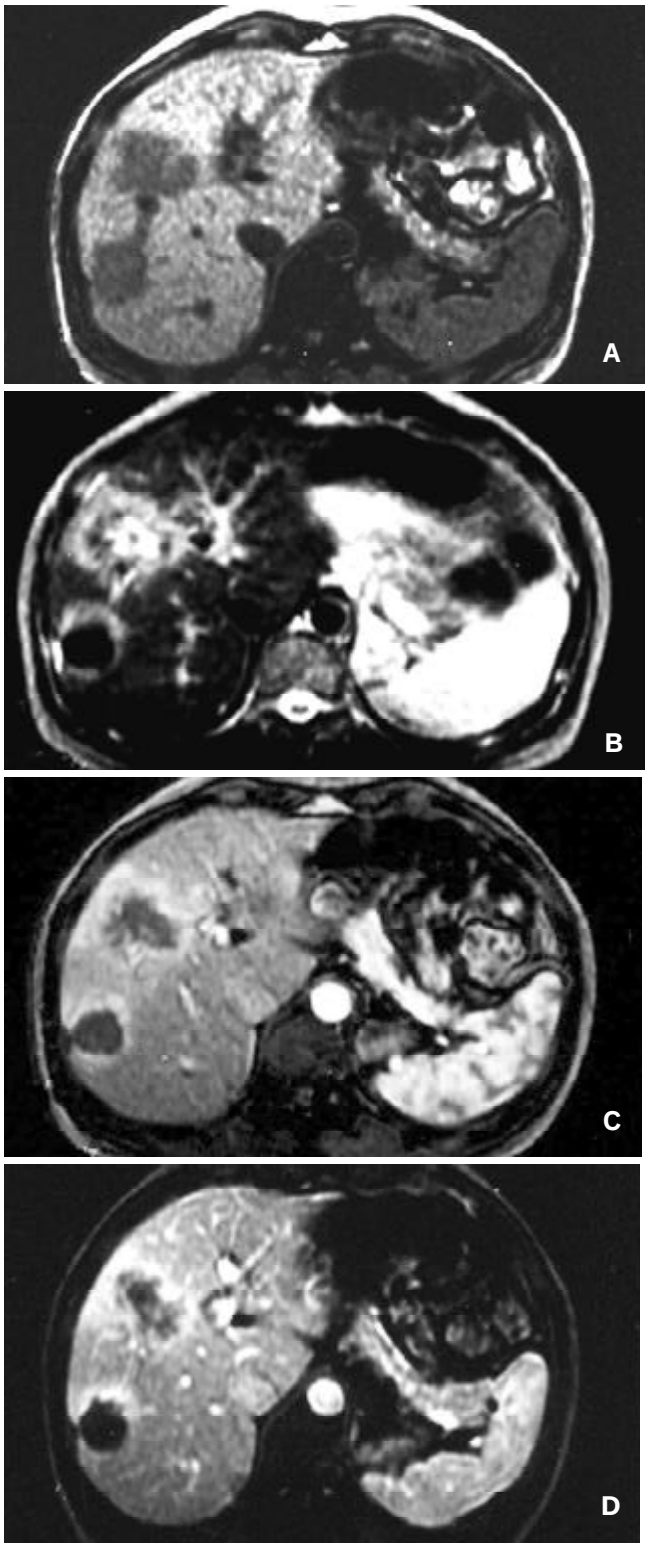

Figure 1 HCC after TACE. A T_1WI shows two hypointense lesions in the right anterior and posterior lobe. B T_2WI shows that the central coagulative necrosis of the right posterior lesion is hypointense and the peripheral residuals of viable tumors is hyperintense. The right anterior lesion is inhomogeneous intensity with liquefied necrosis (central higher hyperintensity), coagulative necrosis(punctual hypointensity)and peripheral residuals of viable tumors (peripheral hyperintensity). C FMPSPGR dynamic contrast early phase scanning shows that both of liquefied necrosis and coagulative necrosis have no enhancement and peripheral residuals of viable tumors enhanced. D The peripheral residuals of viable tumors have permanent enhancement at the dynamic contrast late phase.

Findings of HCC after TACE on FMPSPGR sequence

Eighteen lesions were enhanced at the dynamic early phase, in which one of the lesions revealed homogeneous hyperintensity, and the other 17 were inhomogeneous hyperintense. 6 lesions showed no enhancement on this phase. At the late phase of contrast scanning, 6 lesions were still inhomogeneous hyperintense, 18 hypointense and 10 homogeneous hypointensity, and peripheral ring-like enhancement of the tumors were seen in 8 lesions.

Comparison of MR findings with pathology was showed at Table 2-3

The MRI findings corresponding to the results of pathology showed that complete necrosis was seen in 6 lesions and various degrees of necrosis coexisted with viable tumors were seen in 17 lesions, except one. Peripheral ring-like enhancement of tumors seen on the FMPSPGR dynamic contrast late phase scanning, could be difficult to be differentiated viable tumors from inflammatory infiltration because of the limitation of bioptic spots.

DISCUSSION

TACE has been applied in unresectable HCC as an efficient therapy to improve the survival rate and also as a preoperative modality in some HCC patients to make the tumors diminution and then underwent surgical resection[5-31]. Since TACE is difficult to kill all the tumor cells for once completely, so it is generally used repeatedly. It is needed to evaluate the viability and necrosis of HCC accurately for optimally choosing the further proper managing methods. Angiography is an effective method for evaluating HCC lesions treated with TACE. It could reflect sufficiently the blood supply of viable tumors and demonstrate the blood supply of lateral circulation of HCC. But angiography is an invasive technique and therefore is not suitable for routine follow-up in such patients[40,41]. CT could be considered as a routine modality to judge the efficacy of TACE. It could demonstrate accurately the size, shape, location of the lesions, intrahepatic metastasic nodules and the distribution of lipiodol in the tumors and provide valuable imaging information to determinate the interval of TACE[42-49]. Generally, the homogeneous and complete deposition of lipiodol within the lesions would indicate the high degree necrosis of the tumors, but it is difficult to judge the viability and necrosis of the tumors correctly, due to the inhomogeneous deposition, because lipiodol negative area doesn' t actually represent the viability of the tumors. The necrosis within the lesions before TACE was also lipiodol negative area. On the other hand, the viable tumors could be enhanced on the CT contrast scanning, but the enhancement area within the lesions could also be affected by artifacts of the high concentrations of lipiodol, making it difficult to evaluate the therapeutic efficiency objectively.

Several authors considered that MR was valuable in the evaluation of therapeutic efficiency of TACE, especially on SE T_2WI, most of viable tumors were hyperintense and the coagulative necrosis within the tumors considered as a positive response to TACE were hypointense[50-58]. But this results showed that the signal intensity of the tumors after TACE were variable on the SE T_1WI and T_2WI, but all of viable tumors, hemorrhage, liquefied necrosis and inflammatory infiltration could also result in hyperintensity on the T_2WI. Therefore it was difficult to assess the viable tumors of HCC after TACE by conventional SE imaging. However, it was reliable to judge coagulative necrosis on T_2WI, especially the changes during the process of intratumor hemorrhage after TACE presenting as hyperintensity and then turned in to coagulative necrosis presenting hypointensity. This study also demonstrated that it was significant to compare the signal intensity of HCC on T_2WI before and after TACE to evaluate the degree of coagulative necrosis. The original hyperintensity of HCC turned to hypointensity indicated the presence of coagulative necrosis after TACE.

FMPSPGR dynamic contrast scanning plays a very important role in the detection and characterization of HCC. It is possible to obtain the high quality images of whole liver during a single breath-hold with rapid aquisition. It could demonstrate accurately the blood supply of tumors and reveal the contrast enhancement patterns of HCC. HCC is hypervascular and enhanced rapidly and obviously at the dynamic early phase scanning and declined at the late phase[33-39]. This results showed that FMPSPGR dynamic contrast scanning also had a great value in the evaluation of therapeutic efficacy of TACE. The residual viable tumors were showed as rapid enhanced portions within the lesions, homogeneous or inhomogeneous, when necrotic portions had no enhancement at the contrast early phase scanning. At the late phase scanning, the enhancement of the most lesions became hypointensity, and just a few lesions showed persistent enhancement. Pathologically, both viable tumors and inflammatory infiltration could present such changes, so the contrast early phase scanning was more reliable in the evaluation of viable tumors, combined by with conventional SE sequence, and more accurate to assess the viability and the necrosis of tumors and useful in the followed up of HCC patients after TACE.

This study has some limitation in which all MR images based on histological specimens, but false positivity or false negativity may be present because of the factors in sampling.

Abstract

AIM: **Regional chemotherapy using hepatic artery catheters is a good method of treating patients with colorectal cancer liver metastases. We investigated the survival of patients with liver metastases from colorectal cancer using 5-fluorouracil (5-FU) and mitomycin C Cthrough implantable hepatic arterial infusion port.**

METHODS: **Seventy-five patients with inoperable liver metastases from colorectal cancer were included between March, 1992 and November, 2001. We placed implantable hepatic arterial catheter (HAC) port by laparotomy. 5-FU, 1 000 mg/ m²/d continuous infusion for five days every four weeks, was delivered in the hepatic arterial catheter through the port. Mitomycin C, 30 mg/m²/d infusion in the first day every cycle through the port. Response to the treatment was evaluated by serial determinations of plasma CEA and imaging techniques consisting of computerized tomography and sonography of liver .**

RESULTS: **Sixty-eight were performed hepatic artery chemotherapy and fifty-six were followed up among seventy-five HAC patients. Twenty-six patients(46.4 %) have responded and 4 complete remission were achieved. Eight patients (14.3 %) had stable liver metastases. Twenty-two patients (39.3 %) were progressed with increased tumor size and number. Twenty-nine patients(51.8%) had a decreased serum CEA level, while 10 patients (17.9 %) were stable and 17 patients (30.4 %) had an increased serum CEA level. There were no operative death in this series. Complications, which occurred in 18 patients (32.1 %), were as followed: hepatic artery thrombosis in 11, Upper gastric and intestinal bleeding in 3, liver abscess in 1, pocket infection in 1, cholangitis in 1, and hepatic artery pseudo-aneurysm in one patient.**

CONCLUSION: **Combined infusion of 5-FU and mitomycin C by hepatic artery catheter port is an effective treatment for liver metastases from colorectal cancer. The high response and lower complication rates prove the adjuvant treatment of colorectal cancer with this treatment.**

Liu LX,Zhang WH, Jiang HC, Zhu AL,Wu LF,Qi SY,Piao DX. Arterial chemotherapy of 5-fluorouracil and mitomycin C in the treatment of liver metastases of colorectal cancer.*World J Gastroenterol* 2002; 8(4) :663-667

INTRODUCTION

Colorectal cancer is one of the leading causes of cancer-related mortality in China[1-29] . Approximately half of the patients undergoing apparently curative resection will die within 5 years because of recurrent disease, mostly with liver metastases[30]. Liver was the only site affected in 50 % of these patients. Synchronous hepatic metastases are detected in 20 % of patients under bowel resection, while metachronous disease occurs in another 30 %[31-33]. However about 5-20 % of patients with colorectal hepatic metastases undergo resection with curative intention, resulting in a five year survival of 20-40 %. The one-year and three-year survivals of untreated patients with liver metastases are 31 % and 2.6 %, respectively[34-36]. Most liver metastases were unresectable because of the number, size, position of tumors and general conditions unsuitable for liver resection.

Unfortunately, the results of conventional systemic chemotherapy have been disappointing. Single-agent 5-flourouracil(5-FU) , which has been used for many years to treat metastatic colorectal cancer , has a response rate of approximately less than 20 %. The addition of mitomycin C produces higher response rates with a trend towards increase survival and probably similar results can be achieved with high dose 5-FU alone[37,38].

As most drugs have a steep dose-dependent curve, it is a basic pharmacokinetic principle that if one can increase drug delivery to tumors then increased response rates can be achieved. An alternative approach to the therapy of liver metastases is therefore to deliver the drug intra-arterially[39,40]. Hepatic artery catheter chemotherapy is a therapeutic possibility for unresectable liver metastases for many years. The rational for Hepatic artery catheter chemotherapy is based on the fact that liver metastases over 1 cm derive most their blood supply from hepatic artery . The other rational is the high first pass hepatic extraction of the drug used for this approach. Both factors make high local drug concentrations with reduced systemic toxicity and allow treatment with relatively high dosages compared to intravenous treatment[41,42].

We report our experience of an intra-arterial combined use of 5-FU and mitomycin C in patients with unresectable colorectal liver metastases. The aim of this approach was firstly achieve high response with combination of drugs.

MATERIALS AND METHODS

Patients

Seventy-five patients (43 male, 32 female) with a median age of 58.3 years (range 31-76) with multifocal colorectal metastases confined to the liver and not suitable to surgical resection and other regional ablation which include radio frequence ablation, ethanol injection, cryotherapy and laser ablation, were included in the study between January 1992 and November 2001. Seventeen patients had synchronous and 58 patients had metachronous liver metastases. Preoperative assessment included computerized tomography(CT) scan of abdomen and pelvis , either radiographic or CT examination of the chest and colonscopy of bowel to exclude extrahepatic disease. Some patients were undergone Positron Emission Tomography (PET) recently. Selective superior mesenteric angiography was performed before surgery to define hepatic arterial anatomy in some patients. Histological confirmation of the presence of liver metastases was obtained by ultrasound guided fine needle biopsy or fine needle biopsy in laparotomy before implantation of hepatic artery catheter port. Blood test including hematology, liver function, renal function and CEA were performed before operation.

Hepatic artery catheter port

Patients underwent a laparotomy and the hepatic artery catheter (HAC) was positioned in the ligated gastroduodenal artery with the catheter tip located at the junction of the gastroduodenal and common hepatic artery, thereby gaining access to the hepatic arterial flow. The other end was connected to a subcutaneous infusion port placed over the left coastal margin. A cholecystectomy was routinely performed to prevent potential chemical cholecystitis during chemotherapy. Various surgical maneuvers were used in patients with aberrant hepatic arterial anatomy, which include position the catheter in other artery and bypass of hepatic artery with artificial vessels. Adequate perfusion of the liver was confirmed at the time of operation with a test of blue dye. The port was flushed with heparinized saline(1 000 μ/ml).

Chemotherapy

All patients received continuously hepatic arterial 5-FU and mitomycin C perfusion using an ambulatory pump. Patients received 1 000 mg/m^2/d 5-FU in 12 hours for five days every 4 weeks. thirty mg/m^2 mitomycin C was perfused in 2 hours after the use of 5-FU in first day every cycle. Ten microgram of dexamethasone was given before perfusion everyday. Cimetidine and Losec were prescribed as prophylaxis against gastroduodenal ulceration. Haemological and biochemical toxicity were assessed every 2 weeks and graded according to WHO toxicity criteria. In patients with significant side effects, the subsequent dose was delayed until recovery.

Study parameters

Evaluation of the HAC were performed every two cycles by CT scan or ultrasound of liver and serum CEA, while a chest film or CT and blood test were also made. Completed response was defined as the disappearance of all tumor. Partial response was defined as a >50 % decrease of the lesion size and number. Progressive response was defined as a >25 % increase in any measurable lesion or the appearance of a new lesion. Stable response was defined as <25 % increase and <50 % decrease of the lesion. The decisions of further treatment were made after 6 cycles intra-arterial chemotherapy. Patients who progressed were offered alternative treatment. Patient whose catheters were thrombosis or unusable because other complications but had complete, partial and stable response, were commenced on an intravenous chemotherapy using 5-FU and mitomycin C.

Statistical analysis

Time to progression and overall survival were estimated by Kaplan-Meier survival curves using SPSS. Seven patients, which were not regularly performed chemotherapy due to the toxicity or rejected chemotherapy, were excluded from the study. Twelve patients were not follow up in time and accurately were not included in this study.

RESULTS

Treatment and survival

Of the 75 patients, four patients rejected intra-arterial 5-FU and mitomycin C chemotherapy. Three patients would not continue the chemotherapy because of the severe toxicity of cytotoxic drugs, although many procedures were performed . During 68 patients who continued at least 6 cycles of chemotherapy, twelve patients were not completely and accurately followed up. So , only fifty-six patients were treated and studied. The median number of cycles received were 10 (range 6-25). Median follow up were 21 months (range 8-37months). Forty-one patients have died till the close day of follow up. Predicted median survival from the time of catheter insertion was 15 months (Figure 1).

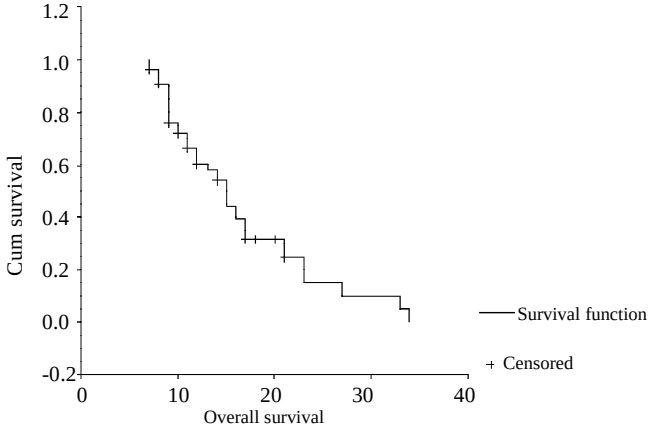

Figure 1 Kaplan-Meier survival curve. Median survival 15 months

Response

Response is expression as best response during the course of intra-arterial treatment. Twenty-six patients(46.4 %) were responded, of whom, 4 had complete response and 22 had partial response. Eight patients(14.3 %) were stable, whereas 22 patients(39.3 %) were progressed. Twenty-nine patients(51.8 %) had a decreased serum CEA level, while 10 patients(17.9 %) were stable and 17 patients(30.4 %) had an increased serum CEA level. There were no operative death in this series.

Complications

Hepatic artery thrombosis (in 11 patients, 19.8 %) is the complications most frequently observed in patients with HAC. The presenting symptoms of this complications were abdominal pain and obstruction of the catheter. It was confirmed by angiography in 6 patients and by Doppler ultrasound examination in 5 patients. Upper gastric and intestinal bleeding were present in 3 patients , which due to perforation of gastric and duodenal ulceration at surgery in 2 patients and duodenal ulceration bleeding at gastroscopy in 1 patient. There were all performed before 1995 when we did

not use blue dye. There were one patient presented with high fever after intra-arterial chemotherapy. She was diagnosed liver abscess by CT scan of liver and cured by ultrasound guide drainage. One patients which has a pocket infection has healed after intravenous antibiotics and drainage. One patients with cholangitis has to move the catheter and port. There are still one bleeding ulcer due to hepatic artery pseudo-aneurysm at surgery.

DISCUSSION

When colorectal cancer metastasises to liver, the prognosis becomes very awful. More than fifty percent colorectal cancer liver metastases patients will died in six months. For this reason, various treatment have been attempted, which include HAC, radio frequence ablation[44], cryotherapy[45], ethanol injection[46], systemic chemotherapy[47] and radiotherapy[48]. As most cytotoxic drugs have a steep dose-dependence response curve: the higher the concentration of the drug, the higher the antitumor effects[39]. Hepatic artery catheter chemotherapy emerged in this condition. Besides this, metastatic tumors in the liver derived their blood supply mainly from the hepatic artery (90-95 %). HAC can directly perfuse the chemotherapy to liver metastases from colorectal cancer. The drugs will result in a prolonged exposure of high concentration to the tumors , while reducing the systemic side effects following the metabolism of the drug in the liver. HAC were undertaken more than 30 years for these reasons[49-51].

There are some studies compared intra-arterial chemotherapy with conventional systemic chemotherapy showed consistently higher response rates in patients receiving intra-arterial chemotherapy[49]. In the United Kingdom, Patients were randomized to receive intra-arterial through a totally implantable infusion device; in the latter group 20 % patients were given systemic chemotherapy . Survival was significantly longer in the intra-arterial group (median survival 405days compared with 226days). The intra-arterial group also had a better quality of life than those received systemic chemotherapy[52]. Other study showed that the response rate was 43 % in the intra-arterial group compared with 9 % in the systemic chemotherapy group. Furthermore, the intra-arterial group showed a significant increase in survival of one year(64 % compared with 44 %) and two years (23 % compared with 13 %). Other studies also showed a higher response rates in intra-arterial chemotherapy than that in systemic chemotherapy[53].

In all studies , 5-FU and FUDR were chosen for the arterial route of administration. As 84-99 % of FUDR is extracted by the liver on first pass, it seemed logical to use FUDR to achieve the dual objective of high levels within the tumor and low plasma levels, thereby increasing the probability of the tumor' s response while minimizing the systemic toxicity[54]. But 55 % of patients using FUDR in the UK and French studies developed extra-hepatic progression, suggesting that these patients may have had occult extra-hepatic disease at the time of entry into the trial or during the intra-arterial chemotherapy. The lower plasma level of drugs have been misplaced. But, 5-FU which has a lower hepatic extraction rather than FUDR, allowed the drug to "spill over" into the systemic circulation[53]. Mitomycin C is also a valuable drug for the systemic chemotherapy in colorectal cancer. In this way, we hoped to maximize the response rates within the liver but also to suppress the development of extrahepatic metastases by combined use of 5-FU and mitomycin C. It seemed likely that both of these objectives could be achieved with a response rate of 46.4 %. At the same time, systemic toxicity was relatively mild and no chemical hepatitis or biliary sclerosis developed as that in FUDR.

Imaging and CEA are good markers in follow up of patients. Serum CEA determinations were the most sensitive indicator of tumor regression or recurrence and proceed changes in the imaging test by at least 1-2 months. Angiography CT(CTA) seems to be the most sensitive to change in tumor size and find new metastases. Sonography is the cheapest way to follow up.

Although there are some complications in HAC, it is still a feasible method for colorectal cancer liver metastases. Most complications was related to the technique of surgery and care of patients[55]. Meticulous attention to ligation of all vessels that would cause gastroduodenal misperfusion can eliminate gastritis, duodenitis, and gastroduodenal ulceration related to HAC chemotherapy[56]. The intraoperative blue injection are necessary to confirm total hepatic perfusion and to rule out any gastroduodenal misperfusion. Gastroscopy investigation of the gastroduodenal perfusion of blue injected through the port is very important before initiating HAC chemotherapy. Displacement of the catheter tip into the hepatic artery often leads to thrombosis of the artery. Dismal migration of the catheter into the gastroduodenal artery may cause vessel or catheter occlusion, hemorrhage, aneurysm, and rupture of the gastroduodenal artery[57]. These complications were all emerged in the early stage of this procedure when we did not have so much experience to avoid these. Liver abscess and infection of port were due to unstrictly sterilize procedure which can be avoided at all.

In conclusion, HAC 5-FU and mitomycin C chemotherapy is better than systemic chemotherapy and other combination of drugs in colorectal cancer liver metastases, which were not suitable for surgery , cryotherapy, radio frequence ablation and other adjunctive therapy, although there are still 39.3 % patients progression and some complications, some of them were dangerous.

Abstract

AIM: **The loss of heterozygosity (LOH) on tumor suppressor genes is believed to play a key role in carcinogenesis of colorectal cancer. In this study, we analyzed the LOH at 5 loci on the long arm of chromosome 22 in sporadic colorectal cancer to identify additional loci involved in colorectal tumorigenesis.**

METHODS: **Five polymorphic microsatellite markers were analyzed in 83 cases of colorectal and normal DNA by PCR. PCR products were eletrophoresed on an ABI 377 DNA sequencer; Genescan 3.1 and Genotype 2.1 software were used for LOH scanning and analysis. Comparison between LOH frequency and clinicopathological data were performed by c^2 test. *P* <0.05 was considered as statistically significant.**

RESULTS: **The average LOH frequency on chromosome 22q was 28.38 %. The region between markers D22S280 and D22S274 (22q12.2-q13.33) exhibited relatively high LOH frequency. The two highest LOH loci with frequencies of 35.09 % and 34.04 % was identified on D22S280 (22q12.2-12.3) and D22S274 (22q13.32-13.33). 8 cases showed LOH at all informative loci, suggesting that one chromosome 22q had been completely lost. On D22S274 locus, LOH frequency of rectal cancer was 50 % (9/18), which was higher than that of proximal colon cancer (12 %, 2/17) (*P*=0.018). The frequency of distal colon cancer was 42 % (5/12), also higher than that of proximal colon cancer. But there was no statistical significance. Putting both the tumors in distal colon and rectum together into consideration, the frequency, 47 % (14/30), was higher than that of proximal colon cancer (*P*=0.015), suggesting the mechanism of carcinogenisis was different in both groups.**

CONCLUSIONS: **This study provided evidence for the involvement of putative tumor suppressor genes related to the sporadic colorectal carcinoma on chromosome 22q. The tumor-suppressor-gene(s) might locate on the 22q12.2-12.3 and/or 22q13.32-13.33.**

INTRODUCTION

Colorectal cancer is one of the three leading causes of worldwide cancer mortality. The progression of the cancer is thought to result from an accumulation of genetic alteration at numerous loci controlling growth and proliferation. As a model for both multistep and multipathway carcinogenesis, colorectal neoplastic progression provides paradigms of both oncogenes and tumor suppressor genes[1,2]. The loss of heterozygosity (LOH) on tumor suppressor genes is believed to be one of the key steps to carcinogenesis of colorectal cancer[3]. The loss of one allele at a specific locus is caused by a deletion mutation or loss of a chromosome from a chromosome pair[4]. When this occurs at a tumor suppressor gene locus where one of the alleles is already abnormal, it can result in neoplastic transformation. In colorectal cancers, frequent allelic loss has been identified in chromosome 5q (30 %), 8p (40 %), 17p (75-80 %), 18q (80 %), and 22q (20-30 %)[5,6]. Indeed, much has been published on tumor suppressor genes APC, p53, and DCC, which have been localized to chromosome 5q, 17p, and 18q, respectively. The LOH analysis became an effective way to find informative loci and then to find candidate tumor suppressor genes[7,8]. In this study we analyzed the LOH at 5 loci on chromosome 22 in sporadic colorectal cancer to identify additional loci involved in colorectal tumorigenesis.

MARERIALS AND METHODS

Materials

This study was based on 83 consecutively collected tumors, including 40 males and 43 females, from unrelated patients with colorectal cancer, treated at the surgical department in Shanghai First people' s hospital, China, between 1998 and 1999. The patients' ages ranged from 31 to 84 years with a median of 66. All patients were confirmed by pathology, and were staged by Dukes criterion. Dukes stage A, B, C, D were 8, 21, 40, 14 cases respectively. Well-differentiated adenocarcinoma was 23 cases, moderate differentiated adenocarcinoma was 39, poorly differentiated adenocarcinoma was 6 and mucinous adenocarcinoma was 15. HNPCC patients were ruled out by Amsterdam criteria[9,10]. Each patient gave his or her informed consent for the use of his or her tissue in this study.

Methods

DNA Extraction The cancerous and adjacent normal tissues were fresh frozen within 30 min after removed. These tissues were then cut into cubes of approximately 2 mm^3 and immediately frozen in liquid nitrogen. DNA was extracted using standard methods with proteinase K digestion and phenol/chloroform purification.

Microsatellite Markers and PCR Five fluorescence-labeled primers for polymorphic microsatellite markers (PE Applied Biosystems Foster city CA, USA), at a density of approximately

one marker every 8 cM (Figure 1), was used to amplify matched pairs of normal and tumor DNAs for LOH analysis.

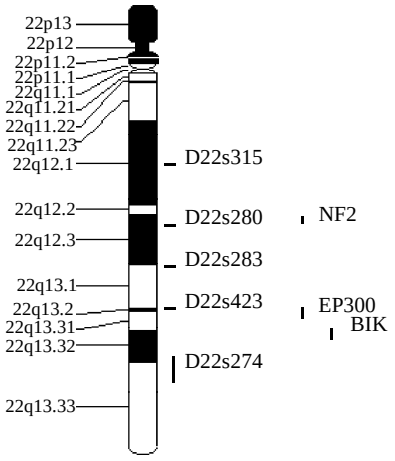

Figure 1 Microsatellite markers and the colorectal cancer related candidate tumor suppressor genes on the long arm of chromosome 22

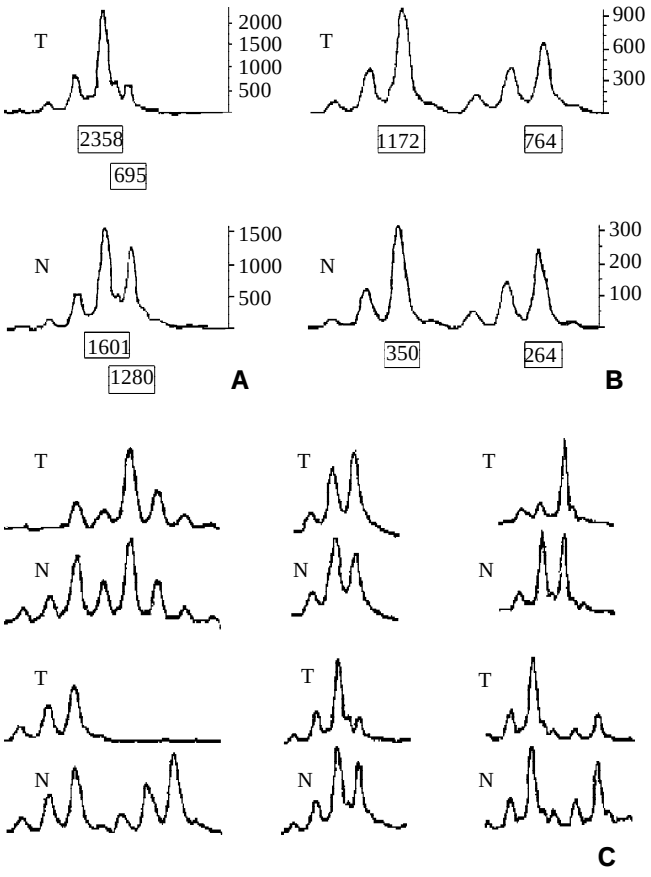

Figure 2 A: The typical peak of LOH: Allele ratio =(T1/T2)/(N1/N2)=(2358/695)/(1601/1280)=2.7>1.5; B: The peak of normal (no LOH): Allele ratio =(T1/T2)/(N1/N2)=(1172/764)/(350/264)=1.15; C: Various kinds of typical peaks of LOH
T: Tumor N: Normal

Polymorphic microsatellite markers were analyzed in each patient' s tumor and normal DNAs by PCR (GeneAmp PCR System 9 700, PE Applied Biosystems Foster city CA, USA). PCR conditions[11] were as follows: 5 μl total volume with approximately 1.4 ng of DNA as a template with 10×standard buffer, 0.3 μl Mg^{2+}, 0.8 μl deoxynueleotide triphosphetes, 0.3 unit of Hot-start taq polymerase and 0.06 ml of each oligonucleotide primer, with the forward primer fluorescence labeled with HEX, FAM or NED. Cycling conditions consisted of 3 stages: an initial denaturation at 96 degrees for 12 min in Stage I; 14 cycles each at 94 degrees for 20 sec, 63-56 degrees for 1min (0.5 degrees decreased per cycle), 72 degrees for 1 min in Stage II: 35 cycles each at 94 degrees for 20 sec, 56 degrees for 1 min, 72 degrees for 1 min in stage III.

LOH Analysis A portion of each PCR product (0.5 μl) was combined with 0.1 μl of Genescan 500 size standard (PE Applied Biosystems Foster city CA, USA) and 0.9 μl of formamide loading buffer. After denaturation at 96 degrees for 5 min, products were eletrophoresed on a 5 % polyacrylamide gels on an ABI 377 DNA sequencer (PE Applied Biosystems Foster city CA, USA) for 3 hours. Genotype 2.1 software displayed individual gel lanes as electopherograms with a given size, height, and area for each detected fluorescent peak. Stringent criteria were used to score the samples. Alleles were defined as the two highest peaks within the expected size range. A ratio of T1:T2/N1:N2 of less than 0.67 or greater than 1.50 was scored as a loss of heterozygosity (Figure 2). Most amplification of normal DNA produced two PCR products indicating heterozygosity. A single fragment amplified from normal DNA (homozygote) and those PCR reactions in which fragments were not clearly amplified were scored as not informative. The LOH frequency of a locus was equal to the ratio of the number between allelic loss and informative cases. The average LOH frequency of chromosome 22 long arm was the average value of each locus LOH frequency.

Statistics analysis

Comparison between LOH and clinicopathological data were performed by χ^2 test. $P<0.05$ was considered as statistically significant.

RESULTS

LOH of 5 microsatellite markers on chromosome 22q

The average LOH frequency at chromosome 22 q was 28.38 %. The region between markers D22S280 and D22S274 (22q12.2-q13.33) exhibited relatively high LOH frequency, the two highest LOH loci with frequencies of 35.09 % and 34.04 % was identified on D22S280 (22q12.2-12.3) and D22S274 (22q13.32-13.33). Of these 83 cases, 8 cases had behaved LOH in all informative loci, suggesting that one chromosome 22q had been completely lost (Table 1-2).

Table 1 LOH frequency of 5 microsatellite markers on the long arm of chromosome 22

Locus	Location	LOH case	Normal case	LOH rate (%)	Informative rate (%)
D22S315	22q12.1	12	56	17.65	81.93
D22S280	22q12.2-12.3	20	37	35.09	68.67
D22S283	22q12.3-13.1	17	43	28.33	72.29
D22S423	22q13.2	15	41	26.79	67.47
D22S274	22q13.32-13.33	16	31	34.04	56.63

The relationship of clinicopathological features and LOH on chromosome 22

On D22S274 locus, LOH frequency of rectal cancer was 50 % (9/18), which was higher than that of proximal colon cancer (12 %, 2/17) (P=0.018). The frequency of distal colon cancer

was 42 % (5/12), which was also higher than the frequency of proximal colon cancer. But there was no statistical significance. Putting both the tumors in distal colon and rectum together into consideration, the frequency, 47 % (14/30), was higher than that of proximal colon cancer (P=0.015). There was no association between LOH of each marker on chromosome 22q and other clinicopathological data (patient sex, age, tumor size, growth pattern or Dukes stage). It indicated that LOH of 22q was a

DISCUSSION

During tumorigenesis, loss of the wild-type allele (inherited from the non-mutation-carrying parents) is frequently observed at the appropriate locus. To date, loss of heterozygosity (LOH) on tumor suppressor genes plays a key role in colorectal cancer transformation[3]. And LOH analysis of sporadic colorectal cancer can promote the discovery of unknown tumor suppressor genes[7,8]. In this study, LOH scanning was carried out in 83 sporadic colorectal cancer samples with 5 highly polymorphic markers and analyzed by Genotyper software, that is, by the ratio of the fluorescence intensity of allele, with an effort to identifying additional loci involved in colorectal tumorigenesis.

In this study, the average LOH frequency of chromosome 22q is 28.38 %, which is consistent with previous observations[5,6]. D22S280 (22q12.2-12.3) and D22S274 (22q13.32-13.33) exhibited highest LOH frequency, indicating that colon cancer related tumor suppressor gene(s) located in this region and perhaps near D22S280 or/and D22S274. The previous study showed that 22q13.1-13.3 behaved high LOH frequency in

sporadic colorectal cancer[12,13]. This study is consistent with the finding, and also showed that 22q12.2-12.3 existed obvious LOH phenomenon, which was similar to the pancreatic adenocarcinomas[14].

By database referring, there are three candidate tumor-suppressor genes related to colon cancer, NF2 (22q12.2)[15], EP300 (22q13)[16], NBK/BIK (22q13.3)[17] on 22q12.2-13.33. NF2 gene was confirmed to be a tumor-suppressor-gene in neurofibromatosis type 2 syndrome[18-21]. And NF2 gene inactivation was also reported in NF2-assoicated tumor and some sporadic cancer[22-28]. NF2 gene encodes a 587-amino acid protein with striking similarity to several members of the ERM family of proteins proposed to link cytoskeletal components with proteins in the cell membrane, including moesin, ezrin, and radixin. Because of the resemblance to these 3 proteins, Trofatter et al called the NF2 gene product merlin [29]. Stokowski *et al* [30] found that 80 % of the merlin mutants significantly altered cell adhesion by causing cells to detach from the substratum. They stated that such changes in cell adhesion might be an initial step in the pathogenesis of NF2. And some scholars also studied the relationship between NF2 gene and sporadic colorectal cancer and found that NF2 gene was probably involved in some colorectal tumors, but was not the critical chromosome 22q tumor suppressor gene involved in colon tumorigenesis [31,32]. The results of this study suggested that there might be colon cancer related candidate tumor-suppressor-gene(s) on 22q12.2 and NF2 was the only known tumor-suppressor-gene in this region. So it was needed to evaluate the effect of NF2 gene on colorectal carcinogenisis, and the new tumor suppressor gene involved in colon tumorigenesis can not be excluded absolutely. There were 2 putative tumor-suppressor genes on 22q13.2-13.31, EP300 and NBK/BIK[33]. P300 is the number of the retinoblastoma protein family. Stein *et al*[34] supposed that p300 acted as a tumor suppressor firstly. Recently, Hasan *et al*[35] proposed the p300 might participate in chromatin remodeling at DNA lesion sites to facilitate proliferating cell nuclear antigen (PCNA) function in DNA repair synthesis. Muraoka *et al*[36] raised the possibility that inactivation of EP300 gene was involovled in the genesis or progression of colorectal cancer. And Gayther *et al*[37] described EP300 mutations that predicted a truncated protein in 6 (3 %) of 193 epithelial cancers analyzed and provided the first evidence that it behaved as a classic tumor suppressorgene. But EP300 mutation was rare in colorectal cancer tissue. So Castells *et al*[12] presumed that NBK/BIK gene, a proapoptotic BCL-2 family member[38-41], acted as a candidate gene in that region. However, SSCP sequencing analysis excluded mutations of this gene. The results of this study showed that the LOH frequency was also high on 22q13, especial on 22q13.32-13.33, suggesting that colorectal cancer associated candidate tumor-suppressor genes are likely to locate on chromosome 22q13.

Yana *et al*[13] indicated that loss of heterozygosity correlated with Dukes staging. Iino *et al*[42] suggested that allelic loss on 22q was significantly associated with the presence of lymph node metastasis. However, Castells *et al*[12] did not support their opinion. This result also agreed with Castells' study and suggested that there was no association between LOH of each marker on chromosome 22q and Dukes staging. However, we found on D22S274 locus, LOH frequency of rectal cancer was higher than that of proximal colon cancer. And the frequency of the tumors in distal colon and rectum was also higher than that of the tumors in proximal colon cancer. Now it was admitted that the mechanism of carcinogenisis in distal colon was different from that in proximal colon[43-45]. And the mechanism in rectal cancer was also different from that in the common phenomenon in sporadic colorectal cancer (Table 3). proximal colon[46]. Distal colonic cancer displayed a higher frequency of 17p and 18q allelic loss, p53 accumulation[47], *c-myc* expression and aneuploidy[48]. Right-sided tumors are more often diploid[48] and of the microsatellite instability (MSI) phenotype. Rectal cancers showed significantly more expression of p53 than that in proximal colon cancer[46], which was similar with distal colonic cancer. This study showed the D22S274 LOH was more frequent in distal colon and rectal cancer than in proximal colon ones, which proved the mechanism of carcinogenisis in distal colon and rectum was not completely same as that in the proximal colon.

Allelic loss on chromosome 22q is present not only in colorectal cancer but also in carcinomas of the ovary (55 %)[49-52], breast (40 %)[53-55], pancreatic endocrine (30 %)[27], oral cavity (40 %)[56], stomach[57], liver[58], lung[59], head and neck [60], and insulinoma[61]. After microsatellite DNA analysis, several attempts were made to identify a region of deletion and eventually the tumor suppressor genes responsible for these neoplasms. Allelic deletions were restricted to D22S274 (22q13) marker in oral squamous cell carcinoma[56]. Handel-Fernandez *et al* found that LOH region presented between marker D22S444 and D22S922 (22q13.2-q13.3), indicating the locations of tumor suppressor genes that may contribute to the devolopment of pancreatic cancer[14]. Considering these results, it is tempting to hypothesize that the same putative tumor suppressor genes might be involved in these different neoplastic processes. Further LOH scanning with high-density microsatellite markers in the region and the study of the relationship between these genes and the cacinogenesis of sporadic colorectal cancer may provide much more genetic information and find the potential tumor suppressor genes.

Abstract

AIM: **To investigate the role of TGF b1 in invasion and metastasis in colorectal cancer by analysing TGFb1 correlated with depth of tumor invasion, stage and metastasis.**

METHODS: **Serum TGFb1 levels were determined in 50 patients with colorectal cancer and 30 healthy volunteers using a TGFb1 enzyme-linked immunosorbent assay. TGFb1 expression in primary and lymph node metastatic lesions were detected in 98 cases of colorectal cancer by immunohistochemical staining and *in situ* hybridization.**

RESULTS: **Serum levels of TGFb1 in patients with colorectal cancer(40±18 mg • L^{-1}) were significantly higher than those in the healthy control group(19±8 mg • L^{-1}), *P*<0.05. Elevated levels of serum TGFb1 were found in 60 % of patients with colorectal cancer when the mean +2 s was used as the upper limit of the normal range (35.1 mg • L^{-1}). Increases in serum TGFb1 levels were significantly associated with Duke¡'s stage (*P*<0.05), but there was no significant difference between Duke¡'s stage B patients and Duke¡'s stage C patients. In the cytoplasm of cancer cells, TGFb1 was immunostained in 37.8 % (37/98) of colorectal cancer, and this expression was confirmed by *in situ* hybridization. Among 35 cases of colorectal cancer with lymph node metastatic lesions, TGFb1 positive staining was found in 18 (51.4 %) cases of primary tumor, and 25 (71.4 %) cases with lymph node metastatic lesions, respectively. Of 17 cases w ith no staining in the primary lesion, 7 (41.2%) casesshowed TGFb1 staining in the metastatic lesion. Serum TGFb1 levels and TGFb1 expression in colorectal cancer tissues were correlated significantly with depth of tumor invasion, stage and metastasis. Patients in stage C-D,T3-T4 and with metastasis had significantly higher TGFb1 levels than patients in stage A-B,T1-T2 and without metastasis (*P*<0.05).**

CONCLUSION: **These results suggest that transforming growth factor-b1 is closely related to the invasion and metastasis of colorectal cancer. It increased the invasive and metastatic potential of tumor by altering a tumor microenvironment. TGFb1 may be used as a possible biomarker.**

INTRODUCTION

The incience of colorectal cancer has become high in China and its biology is a hot topic of research[1-44].Tumor invasion and metastasis are complex processes in which cancer cells detach from the original tumor mass to establish metastatic foci at distant sites. Metastatic cells characteristically lose growth inhibitory responses, undergo alteration in adhesiveness and demonstrate enhanced production of enzymes that can degrade extracellular matrix components. Since it is the development of metastatic disease that is primarily responsible for cancer mortality, an understanding of the mechanisms that facilitate metastatic tumor progression is of great importance[1]. Transforming growth factor(TGF)-β1 is a 25-kd polypeptides. This growth factor regulates cell growth and differentiation in both normal and transformed cells. TGF-β1 was found to inhibit the growth of normal and neoplastic cells. Resistance to the negative growth-regulating properties of TGF-β1 has been observed in epithelial and mesenchymal tumors. Tumor cell lines that lack TGF-β receptors lose responsiveness to TGF-β1, and the escape of cells from TGF-β1 mediated negative regulation is linked to tumor progression[45]. Colorectal cancer is one of the most malignant neoplasms. TGF-β1 plays a crucial role in tumor extension. We examined the expression of TGF-β1 in primary and lymph node metastatic lesions in colorectal cancer, as well as serum TGF-β1 levels in the peripheral veins. Our objective is to determine the clinical significance of TGF-β1 in advance of colorectal cancer.

MATERIALS AND METHODS

Patients

Serum TGF-β1 assays were performed in 50 patients treated from July 1999 to June 2000. There were 32 men and 18 women, and their age ranged from 23 to 74 years (means, 53 ±11 years). According to Duke' s staging criteria, 9 cases were stage Ⅰ, 18 stage Ⅱ,18 stage Ⅲ and 5 stage Ⅳ. Thirty healthy volunteers were selected as control group among whom there were 17 men and 13 women. Their age ranged from 20 to 56 years (means, 45±8 years).

A total of 98 colorectal adenocarcinoma patients (including the 50 patients above)who had undergone surgical resection in the Affiliated Zhongnan Hospital of Wuhan University (Wuhan, China) from July 1998 to December 2000, TGFβ1 and TGFβRⅡ immunohistochemical staining and *in situ* hybridization were performed. There were 53 men and 45 women, and their age ranged from 23 to 74 years (means,

56±11 years). Among 98 patients, 17 were well differentiated adenocarcinoma, 47 moderately differentiated adenocarcinoma and 34 poorly differentiated adenocarcinoma. According to Duke' s staging criteria, 34 cases were stage Ⅰ, 29 stage Ⅱ, 30 stage Ⅲ and 5 stage Ⅳ.

Methods

Preparation of serum sample and TGF β 1 assay Two mL of blood sample, collected from the peripheral vein before surgery, were stored for approximately 3 h at 4 ℃ until the samples were centrifuged. Blood samples were centrifuged at 3 000 *g* for 20 min. The serum was separated and stored frozen at -70 ℃ until the time of analysis. TGFβ1 was assayed using human TGFβ1 enzyme-linked immunoabsorbent assay kits. The ELISA kits were obtained from Quantikine Co. of USA. The TGFβ1 assay was performed according to the methods outlined in the package insert. Standard samples of 200 μ*g* were added to each well, and incubated for 3 h at room temperature. After complete wash of each well, 200 μl TGFβ1 conjugate was added to each well and these were incubated for 1.5 h at room temperature. We repeated the aspiration/wash and added 200 μl of substrate solution to each well and incubated for 20 min. Finally, we added 50 μl of stop solution and absorbances in each well were measured using a spectrophotometric plate reader at a wavelength of 490 nm. To determine the TGF-β**1** concentration in each sample, we first calculated the average absorbance value in each set of duplicates. Serum levels of TGF-β**1** were calculated from linear regression equation.

Immunohistochemistry All the tissue specimens were fixed in 100 mL· L^{-1} neutral formalin and embedded in paraffin. Five-um thick sections were xylene dehydrated in ethanol. Tissue sections were washed three times in 0.05 moL· L^{-1} PBS,and incubated in endogenous peroxidase blocking solution. Non-specific antibody binding was blocked by pretreatment with PBS containing 5g· L^{-1} bovin serum albumin. Sections were then rinsed in PBS and incubated overnight at 4 ℃ with diluted anti-TGFβ1 and anti-TGFβRⅡ protein polyclonal antibody. The steps were performed using Immunostain kit according to the manufacturer' s instructions. PBS was used as substitutes of protein antibody for negative control groups. The sections were examined under light microscopy. Anti-TGFβ1 and anti-TGFβRⅡprotein polyclonal antibody were purchased from Bosden Comp. (Wuhan, China). S-P detection kit was purchased from Fuzhou Maixin Comp. (Fuzhou, China). Anti-TGFβ1 and anti-TGFβRⅡ protein polyclonal antibody were diluted to 1:100.

***In situ* hybridization** All the tissue specimens were fixed in 100 mL· L^{-1} neutral formalin and embedded in paraffin. Six-um thick sections were xylene dehydrated in ethanol, and digested with 10 mg· L^{-1} proteinase for 10 min. Sections were washed in 0.5 moL· L^{-1} PBS for 15 min. They were incubated overnight at 37 ℃ with the 500 μg· L^{-1} digoxigenin-labeled RNA probe in hybridization buffer. After hybridization, sections were washed in 2× SSC for 10 min at 37 ℃ and finally in 0.2×SSC for 15 min at 37 ℃. Sections were incubated with alkaline phosphatase-conjugated anti-digoxigenin antibody for 60 min at 37 ℃. The steps were performed using in situ hybridization kit according to the manufacturer' s instructions. The kits were purchased from Bosden Comp. (Wuhan, China).

TGFβ1 *in situ* hybridization probe sequences were:

(1)5-CGTTTCACCAGCTCCATGTCGATGGTCTTGCAAT-3'

(2)5-CTTGATTTTAATCTCTGCAAGCGCAGCTCTGCACG-3'

(3)5-TTGGTATCCAGGGCTCTCCGGTGCCGTGAGCTGTG-3'

Statistical analysis

The difference between each group was analyzed by Chi-square test and correlativity. The limit of significant difference was $P<0.05$.

RESULTS

*Serum TGF*b*1 levels in patients with colorectal cancer*

Serum TGFβ1 levels in patients with colorectal cancer (40.4 ±17.6 μg· L^{-1})were significantly higher than in normal controls (19.2±8.0 μg· L^{-1}),$P<0.01$. Elevated levels of serum TGFβ1 were found in 60 % of patients with colorectal cancer when the mean +2 s was used as the upper limit of the normal range (35.1 μg· L^{-1},Figure 1). Increased in serum TGFβ1 levels were significantly associated with Duke' s stage ($P<0.05$), but there was no significant difference between Duke' s stage B patients and Duke' s stage C patients. Serum levels of TGFβ1 were 29.2 ±7.3 μg· L^{-1} in Duke' s stage A patients, 39.5±11.9 μg· L^{-1} in Duke' s stage B patients, 43.1±15.8 μg· L^{-1} in Duke' s stage C patients, and 57.8±16.2 μg· L^{-1} in Duke' s tage D patients. Serum levels of TGFβ1 in each stage were significantly higher than those in the control group(Figure 2). Serum levels of TGFβ1 were not correlated with age, gender, tumor size and differentiation degree of tumor .

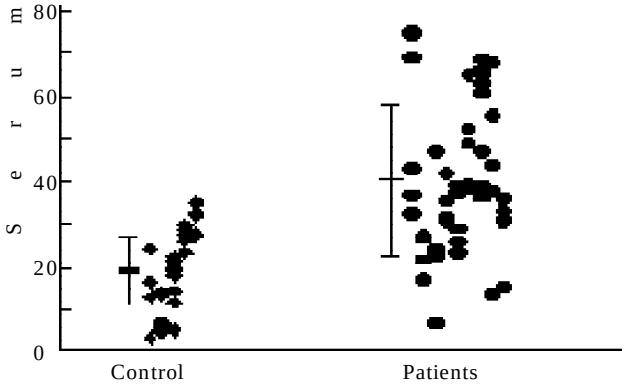

Figure 1 Serum TGFβ1 in patients with colorectal cancer. Bars represent mean ± standard deviation.

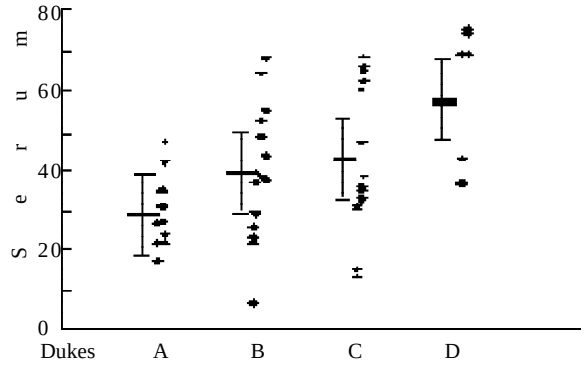

Figure 2 Serum TGFβ1 in patients with colorectal cancer according to Duke's stage. Bars represent mean ± standard deviation.

TGFβ1 and TGFβRⅡ Expression in colorectal cancer tissue The TGFβ1 and TGFβRⅡ protein were stained mainly in the cytoplasm and cell membrane of cancer cells, as shown in Figures 3 and 4. Staining was classified as negative if less than 10 % of the cells were positive and as positive if more than 10 % were positive[2].Thirty-seven(37.8 %) of 98 tissues from colorectal cancer patients were positive for TGFβ1

staining and forty-six(46.9 %) were positive for TGFβR Ⅱ staining. The expression of TGFβ1 and TGFβR Ⅱ was correlated significantly with the depth of invasion, stage of disease and metastasis (lymph node and distant metastasis). Patients in T_3-T_4, stage C-D and with metastasis had significantly higher expression of TGFβ1 than patients in T_1-T_2, stage A-B and without metastasis (P<0.05). Patients in T_3-T_4, stage C-D and with metastasis had significantly lower expression of TGFβR Ⅱ than patients in T_1-T_2, stage A-B and without metastasis (P<0.05). The expression of TGFβ1 and TGβR Ⅱ was not correlated with age, gender, tumor size and differentiation degree of tumor (Table1).

TGFb mRNA expression in colorectal cancer tissue

The expression of TGFβ1mRNA in 50 colorectal cancer tissues was examined. The degree of staining was prominent in cases of TGFβ1 positive immunohistochemical staining, but it was rare for negative cases of immunohistochemical staining. The pattern of distribution of TGFβ1mRNA is the same as immunohistochemical staining (Figure 5).

Relationship of TGFβ1 expression between primary and lymph node metastic lesions Among 35 cases of colorectal cancer with lymph node metastatic lesions, the TGFβ1 positive rate was 51.4 %（18/35) for primary lesions and 71.4 % (25/35) for metastatic lesions in the lymph nodes. Of 17 cases with no staining in the primary lesion, 7 cases (41.2 %) showed TGFβ1 staining in the metastatic lesion (Figure 6).

DISCUSSION

TGFβ1 has been found to be overexpressed locally in many tumors, and is believed to play a role in tumor transformation and progression, as well as in tumor regression[46-48]. Although

TGFβ1 acts as a potent inhibitor of cell growth and tumor progression, loss of this negative regulation can lead to tumor development. TGFβ1 switches to a growth stimulator with tumor progression. Growth inhibition is replaced in many tumors by the opposite response, growth stimulation. This paradoxical switch in the responsiveness of tumor cell to TGFβ1 during neoplastic progression may be due to the inactivation of the TGFβ1 signaling pathway such as mutations in the type 2 TGFβ receptor gene or through reduced expression and increase of blood supply to a tumor mass and inhibition of immunologic mechanisms involved in tumor identification and cytolysis. In cases of breast cancer, expression of TGFβ1 was positively associated with invasion and matastasis. Maehara *et al*[45] reported that the expression of TGFβ1 in gastric cancer cells was closely related to infiltrative growth of the cancer and to the higher rate of lymph node metastasis.

We found that TGFβ1 levels in the serum of patients with colorectal cancer were significantly elevated compared with normal controls. TGFβ1 was overexpressed in colorectal cancer tissue compared with normal colorectal mucosa. Elevated serum levels of TGFβ1 and over-expression of TGFβ1 in colorectal cancer tissue were correlated significantly with invasion and metastasis of colorectal cancer. Patients in T_3-T_4, stage C-D and with metastasis had significantly higher expression of TGFβ1 in tumor tissue and TGFβ1 levels in the serum than patients in T_1-T_2, stage A-B and without metastasis (P<0.05). The expression of TGFβ1 in tumor tissue and TGFβ1 levels in the serum were not correlated with age, gender and differentiation degree of tumor. Shim *et al*[49] reported that patients of colorectal cancer in stage C-D had significantly higher expression of TGFβ1 in tumor tissues and TGFβ1 levels in the serum than patients in stage A-B (P<0.05). TGFβ1 in colorectal cancer patients may be associated with disease progression. Among 35 cases of colorectal cancer with lymph node metastasis lesions, the TGFβ1 positive rate was 51.4 % (18/35) for primary lesions and 71.4 %(25/35) for metastatic lesions in the lymph nodes. Of 17 cases with no staining in the primary lesion, 7 cases(41.2 %)showed TGFβ1 staining in the metastatic lesion. The preferential expression of TGFβ1 in lymph node metastases suggests a clonal selection of tumor cells with TGFβ1 expression, specific for the higher potential of lymph node metastasis in tumor advance, and TGFβ1 plays a role related to the malignant progression of colorectal cancer. We also found that TGFβR Ⅱ expression was significantly lower in colorectal cancer tissues than in normal mucosa. The expression of TGFTGFβR Ⅱ in tumor tissues of Patients in T_3-T_4, stage C-D and with metastasis was significantly lower than that in patients in T_1-T_2, stage A-B and without metastasis (P<0.05). The expression of TGFβR Ⅱ in tumor tissues was not correlated with age, gender and differentiation degree of tumor. The lower expression of TGFβR Ⅱ in colorectal cancer may be associated with disease progression. In our previous study[50,51], we found that TGFβ1 expression was correlated significantly with angiogenesis in colorectal cancer tissues and inhibition of immunologic mechanisms involved in tumor identification and cytolysis.TGFβ1 is closely related to the invasion and matastasis of colorectal cancer, and it may be used as a possible biomarker.

Abstract

AIM: **To evaluate the clinical efficacy of s*alvianolic acid* B (SA-B) on liver fibrosis in chronic hepatitis B.**

METHODS: **Sixty patients with definite diagnosis of liver fibrosis with hepatitis B were included in the trial. Interferon-g (IFN-g) was used as control drug. The patients took orally SA-B tablets or received muscular injection of IFN-g in the double blind randomized test. The complete course lasted 6 months. The histological changes of liver biopsy specimen before and after the treatment were the main evidence in evaluation, in combination with the results of contents of serum HA, LN, IV-C, P-III-P, liver ultrasound imaging, and symptoms and signs.**

RESULTS: **Reverse rate of fibrotic stage was 36.67 % in SA-B group and 30.0 % in IFN-g group. Inflammatory alleviating rate was 40.0 % in SA-B group and 36.67 % in IFN-g group. The average content of HA and IV-C was significantly lower than that before treatment. The abnormal rate also decreased remarkably. Overall analysis of 4 serological fibrotic markers showed significant improvement in SA-B group as compared with the IFN-g group. Score of liver ultrasound imaging was lower in SA-B group than in IFN-g group (HA 36.7 % *vs* 80 %, IV-C 3.3 % *vs* 23.2 %). Before the treatment, ALT AST activity and total bilirubin content of patients who had regression of fibrosis after oral administration of SA-B, were significantly lower than those of patients who had aggravation of fibrosis after oral administration of SA-B. IFN-g showed certain side effects (fever and transient decrease of leukocytes, occurrence rates were 50 % and 3.23 %), but SA-B showed no side effects.**

CONCLUSION: **SA-B could effectively reverse liver fibrosis in chronic hepatitis B. SA-B was better than IFN-g in reduction of serum HA content, overall decrease of 4 serum fibrotic markers, and decrease of ultrasound imaging score. Liver fibrosis in chronic hepatitis B with slight liver injury was more suitable to SA-B in anti-fibrotic treatment. SA-B showed no obvious side effects.**

INTRODUCTION

Radix Salviae Miltiorrhizae (Sm) can activate blood circulation and resolve stasis and is a commonly used herb clinically[1]. Sm was applied to the late-stage schistosomial cirrhosis and splenomegaly at first time in 1958[2]. Later Dr. Yu used its injection to treat hepatitis B at the early-stage cirrhosis[3], the biopsy examination before and after treatment identified that Sm could effectively alleviate the pathological changes of liver fibrosis. *Salvianolic acid B* (SA-B), a major water soluble component in Sm[4], protected the tetrachloride carbon (CCl_4) induced fibrosis in rats, and reversed dimethylnitrosamine (DMN) induced liver fibrosis in rats. It could prevent liver cell injury, inhibit proliferation of hepatic stellate cells (HSC) and collagen production *in vitro*[5-9]. Based on the stable preparation procedures and long-term toxic test on rats, we used SA-B tablets and interferon-γ (IFN-γ) injection as control drug in the double blind randomized clinical trial[10-16]. The liver biopsy examination before and after treatment was used as a major evalulation standard, assisted by serum fibrotic markers, liver ultrasound imaging, liver function test, symptoms and dynamic observation of regular test of blood, urine, and renal function, in order to study the clinical efficacy, indications, and side effects of SA-B in liver fibrosis with chronic hepatitis B.

SUBJECTS AND METHODS

Subjects

Patients having liver fibrosis with chronic hepatitis B were included in the trial. Initially 77 patients were involved, but 17 of them were not included in the final analysis because of following reasons: 1) 4 patients showed no obvious liver fibrosis in their first liver biopsies; 2) 7 patients failed to undertake their second liver biopsies; and 3) 6 patients' liver specimen were too small to make pathological examination.

Before and after the treatment, the liver biopsy specimens of 60 patients were in accordance to pathological diagnosis 30 patients in SA-B group, 28 males and 2 females and 30 patients in IFN-g group, 28 males and 2 females. The age in SA-B group was 36.1±9 years, and in IFN-γ group 35.1±7.8 years. Duration of hepatitis B in SA-B group was 3.9±3.2 years, and 3.6±4.6 years in IFN-γ group. There was no significant difference in grade and stage of pathological examinations between two groups before treatment.

Diagnostic criteria

History: The patient had a history of hepatitis B or HBsAg carrier and still had the symptoms and signs of hepatitis and

abnormal liver function when included in the trial. Etiological marker: HBsAg was positive. Ultrasound imaging: In accordance to the ultrasound images of chronic hepatitis B. Liver biopsy examination: Definite pathological diagnosis of liver fibrosis. The fibrotic stage was S1-S4. Symptoms: Pain in the hepatic region, general fatigue, anorexia and abdominal distention. Signs: Hepatomegaly, splenomegaly, hepatica facies, palmar erythema, vascular spiders.

Criteria to enroll subjects

Age: 18-60 years, in accordance to the diagnostic criteria for liver fibrosis in hepatitis B. Histological fibrotic stage was S1-S4.

Criteria to exclude subjects

(1) Over 60, or less than 18 years of age. Patient in pregnancy or in breast feeding period. (2) Complicated with hepatitis C or other hepatic viral infection; suspicion of autoimmune hepatitis; and drug hepatitis or alcoholic hepatitis. (3) Decompensated post-hepatitic cirrhosis. (4) Severe complications of cardiovascular systems, renal, or hematopoietic system; mental diseases. (5) Failure to achieve twice liver biopsy or failure to make pathological diagnosis with liver biopsy specimens. Patients meeting any one of the above criteria were excluded from the trial.

Group and administration

Grouping The patients were divided into two groups based on their randomized number they received.

Drug The double blind randomized method was used. SA-B tablet (30 mg/tablet) and placebo tablet (made of excipient), having same package and labels, were named Gan Xian Ling I and Gan Xian Ling II respectively. All the tablets were prepared by the Shanghai Institute of Drug, Chinese Academy of Sciences. Interferon-g injection (IFN-γ, 1MU/injection) and placebo injection (made of substrate without IFN-γ activity) having the same package and labels were named IFN-γ I and IFN-γ II respectively. Injections were provided by the Shanghai Clone Biological High Technology Limited Company (Product NO.980508, revelation after treatment).

Drug administration Double blinded method was used in drug administration. The group I patients were orally administered with Gan Xian Ling I tablet, 2 tablets t.i.d for 6 months. And patient had muscular injection of IFN-γ-I once a day in the first month and then once every other day in the following five months. The group II patients were administrated with Gan Xian Ling II and IFN-γ-II. The usage was the same as in group I.

Regular items observed

Recording and observation of symptoms and signs Patient' s symptoms and signs were recorded in detail using "Clinical Observation Table" once a month before and during the treatment.

Etiological markers of hepatitis B HBV marker: ELISA, the kit was obtained from Shanghai Ke Hua Company. HBV-DNA: PCR, the kit was from Hua Mei Company (PCR-HT420III).

Liver function The patient had liver function examination (Tai Er Kang Automatic Biochemical Instrument) every month during the treatment, including contents of serum proteins, total bilirubin, direct bilirubin, and activities of ALT (Alanine Aminotransferase) and AST (Aspartate Aminotransferase). The kit was a product of Shanghai Ke Hua-Dong Ling Diagnostic Instrument Company.

Liver ultrasound imaging Specific professional technicians were assigned to do the ultrasound imaging of liver, gallbladder and spleen (HITACHIEUB-410 type) for the patients and made records. Based on the literature, rate and score each item (liver surface, liver parenchyma, liver edge, intra-hepatic vessels)[17], Table 1.

Table 1 Ultrasound image scoring for liver fibrosis

Items	1	2	3
Liver surface	Normal (smooth)	Irregular	Waved-shaped (or serrated)
Liver edge	Normal (sharp)	Blunt at tip	Blunt at the edge
Liver parenchyma	Normal (even)	Rough	Nodular(or patch-like)
Intra-hepatic vessels	Normal(clear)	Elusive	Unevenly narrow, wide,thick or thin

Serum fibrotic markers The serum from each patient was collected before, during,and after treatment and stored at-70 ℃. All the serum specimens, at one time, were examined by Shanghai Changzheng Hospital (PLA Clinical Immune Center) in a blinded manner.Hyaluronic acid (HA): radioimmunoassay, the kit was from Shanghai Navy Medical Institute. Laminin (LM): radioimmunoassay, the kit was from Shanghai Navy Medical Institute. Type IV Collagen (C-IV): ELISA, the kit was from Shanghai Seng Xiong Technology Enterprise Company. Type-III-procollagen-N-peptide (P-III-P): radioimmunoassay, the kit was from Shanghai Oren Diagnostic Instrument Limited Company.

Histopathological examincation of liver

Each patient had percutaneous liver biopsy guided by ultrasound imaging within one week before and after treatment. The liver biopsy specimens were fixed by 10 % formalin and embedded by paraffin according to the routine procedures. HE stain: sections (4 μm) were routinely HE stained. Collagen stain: double stain reticular fibers and collagen fibers by Gorden-Sweet method and Masson trichrome method.

Sections with HE stain and collagen stain and pathological diagnosis were made by three pathologists in a blinded manner, according to "1995 National Prevention and Treatment Plan of Viral Hepatitis" [18,19](inflammatory grades and fibrotic stages were determined when more than two pathologists reached the same diagnosis).

Side effects and security

Negative response of each patient was carefully observed and recorded during treatment. Each patient received EKG, renal function examination, regular blood test and regular urine test before, during and after treatment.

Images and analysis

Radit analysis was used for rank data of pathological grades and stages. *t*-test or analysis for variance was used for measurement data and χ^2 test for enumeration data.

RESULTS

Correlation between serum fibrotic markers and pathological changes of liver fibrosis

The serum fibrotic markers were generally consistent with the valuation of stages and grades (Tables 2 and 3, Figures 1 and 2). Although the standard deviation of markers (individual difference) was large, combined use of HA, P-III-P and IV-C was much better and serum LM content was in normal ranges.

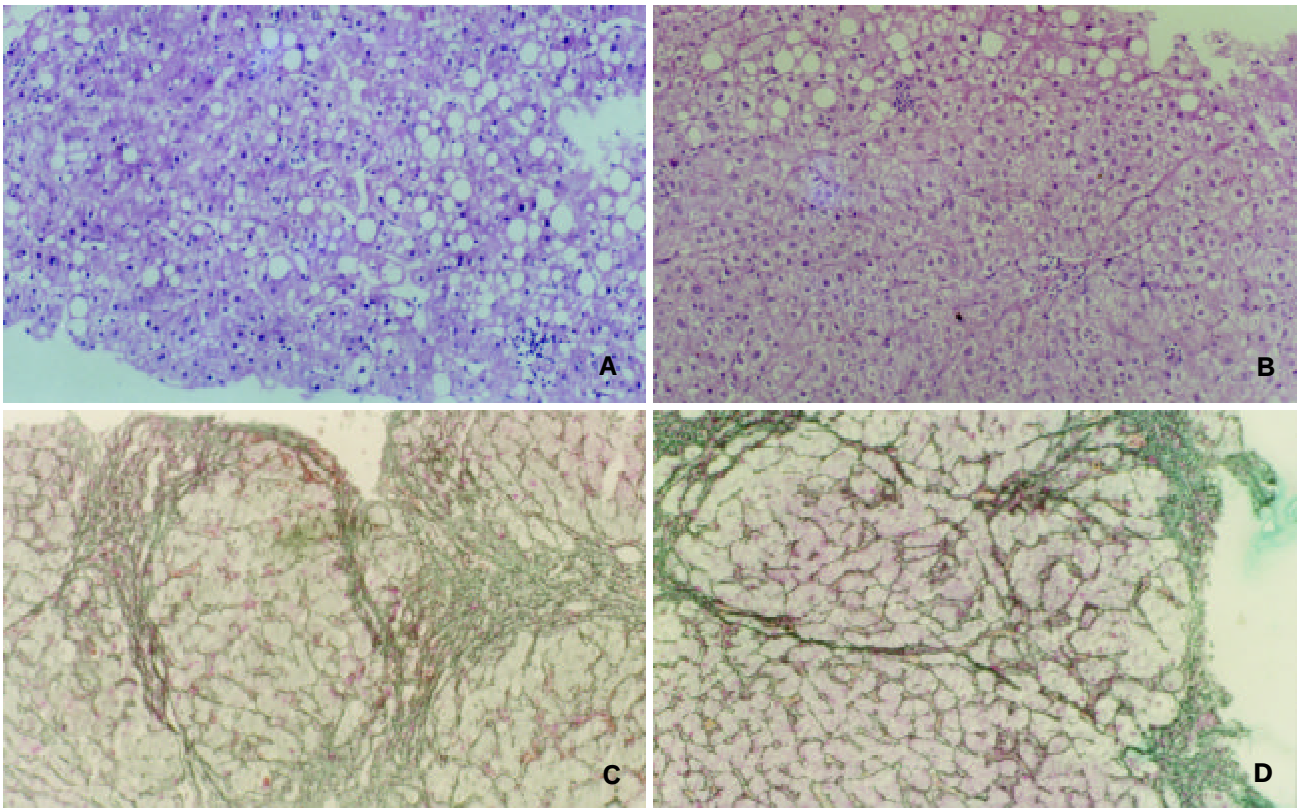

Figure 1 Histological changes of liver biopsy specimens before and after treatment in IFN-γ group:
A: First liver biopsy (G3, HE stain, ×100) before treatment; B: Second liver biopsy (G3, HE stain, ×100) after treatment;
C: First liver biopsy (S4, collagen stain,.×100) before treatment; D: Second liver biopsy (S3, GS stain, ×100) after treatment.

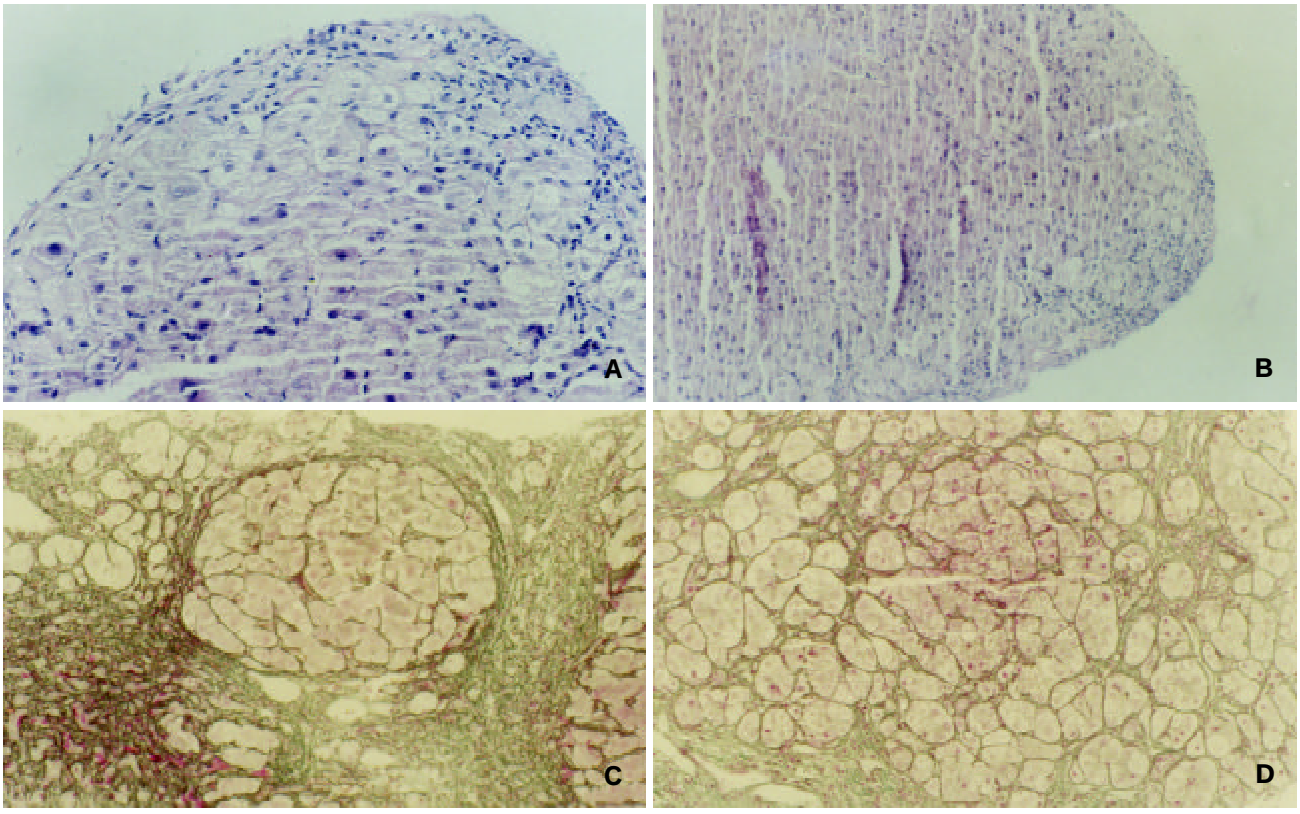

Figure 2 Histological changes of liver biopsy specimens before and after treatment in SA-B group:
A: First liver biopsy (G3, HE stain, ×100) before treatment;
B: Second liver biopsy (G3, HE stain, ×100) after treatment;
C: First liver biopsy (S4, collagen stain, ×100) before treatment;
D: Second liver biopsy (S3, collgen stain,. ×100) after treatment.

Changes of liver fibrotic stages and inflammatory grades

Based on the liver fibrotic stages and inflammatory grades before and after treatment, it was rated as improved (alleviated by ⩾1 stage), stable, or deteriorated (⩾1 stage). The improvement rates of inflammatory grades and fibrotic stages were 40.0 % and 36.67 % respectively in SA-B group, which were slighting higher than in IFN-γ group (36.67 % and 30.0 %). Deterioration rates were 16.7 % and 20.0 % in SA-B group, which were much lower than in IFN-γ group (20.0 % and 30.0 %). There was no significant difference between the two groups. Fibrotic stages of 4 patients in SA-B group decreased by 2 stages after treatment. But there was none in IFN-γ group.

Changes of serum fibrotic markers

There was no significant differences in serum HA, LM and P-III-P contents between the two groups before treatment. But the serum IV-C content in SA-B group was obviously higher than that in IFN-γ group before treatment. The average content of serum HA in SA-B group decreased remarkably after treatment ($P<0.05$), and decreased in IFN-γ group, but with no significant difference. The abnormal rate of serum HA content in SA-B decreased from 80 % to 36.67 % ($P<0.05$). But there was no significant difference in the changes of abnormal rate of serum HA content in IFN-γ group. Serum IV-C content decreased remarkably in SA-B group after treatment ($P<0.05$), but it increased in IFN-γ group. There was no significant difference in serum LM and P-III-P contents before and after treatment in both groups. Overall, the first three markers of 9 patients in SA-B group were lowered by ⩾30 % after treatment, but of only one patient in IFN-γ group (Tables 4-6).

Changes of serum liver function

There was no difference in liver function (Alb, globulin, Serum ALT, AST and GGT activities, serum total and direct bilirubin) between the two groups before treatment. Alb was within normal ranges but globulin was much higher than the normal before treatment in both groups. Alb increased significantly after treatment in IFN-γ group ($P<0.05$), but had no change in SA-B group. There was no significant change of globulin before and after treatment in both groups. The abnormally high ALT activities before the treatment in SA-B group decreased significantly in the first month ($P<0.05$) and maintained at low levels in the following months of the treatment. In terms of individual subject, ALT activities of 14 patients (46.67 %) in IFN-γ group and 7 patients (23.33 %) in SA-B group continued to increase after treatment, but with no significant difference between the two groups ($P<0.05$), (Table 7). AST activities decreased after treatment in both groups, but without significant difference (Table 8).

GGT activities decreased after treatment in both groups, without significant difference. Serum total and direct bilirubin content in both groups were close to the upper limit of normal ranges. Total bilirubin contents decreased after treatment in both groups without significant difference. Direct bilirubin contents decreased significantly after treatment in both groups. The remarkable decrease of direct bilirubin in SA-B group started in the 3rd treatment.

Changes of liver ultrasound imaging

There was no obvious change of portal veins and splenic veins before and after treatment in the two groups. SA-B showed an improving tendency based on the score of ultrasound imaging. The scores of only two patients in SA-B group rose (deterioration). But scores of 11 patients increased in the control group. There was significant difference between the two groups ($P<0.05$), (Table 9).

Table 4 Serum HA,LM,IV-C and PⅢP contents before, during and after treatment

		HA(μg/L)	LM(μg/L)	IV-C(μg/L)	PⅢP(μg/L)

Comparison of χ^2 test between two groups, [a]$P<0.05$

Changes of serum viral markers

HBsAg of each patient in both groups was positive before treatment. No changes happened for HBsAg/anti-HBs after treatment. HBV-DNA of 4 patients in each group became negative after treatment. HBeAg of 13 patients in IFN-γ group and of 15 patients in SA-B group were positive before treatment. But after treatment, 4 patients in IFN-γ group and 3 patients in SA-B group became negative. And at the same time, 2 patients in each group were positive in anti-HBe.

Changes of symptoms and signs

After 6 months treatment, major symptoms and signs such as anorexia, general fatigue, weakness and soreness in lumbar regions and knees, insomnia, yellow urine and hypochondriac pain were remarkably relieved in both groups.

Side effects and safety

The results of EKG, renal function, regular blood test and regular urine test showed no change during the treatment in SA-B group. There were no side effects or negative responses in SA-B group. Fifteen patients in IFN-γ group had fever at the beginning of the treatment. One patient was unable to tolerate the side effect, thus terminating the trial. The other patients succeeded in finishing the clinical trial after the disappearance of fever. One patient in IFN-γ group had transient decrease of leukocytes. Under careful observation, the patient recovered after treatment (without stopping drug administration or using special treatment). No other side effect was noticed.

Analysis of factors affecting anti-fibrotic treatment effect

Histopathological fibrotic stages before and after treatment were the evidence for evaluating the drug efficacy. It was divided into improved, stable and deteriorated groups. The analysis of liver function and serum fibrotic markers before treatment showed that the effect of SA-B in anti-fibrosis was related to the level of liver injury before treatment. The patient having regression of fibrosis after treatment had much lower ALT and AST activities and total bilirubin content before treatment than those having aggravation of fibrosis after treatment. There was no obvious correlation among the above factors in IFN-γ group (Tables 10 and 11).

DISCUSSION

The hepatic fibrosis is the important pathological feature of chronic liver diseases, which is characterized by HSC activation and the overproduction of extracellular matrix[20-36]. Therefore, inhibition or reversion of hepatic fibrosis is one of the main therapeutic strategies[37-50]. In this study, we found the SA-B effect on liver fibrosis in hepatitis B for the first time, through the double blind trial with IFN-γ as control drug and the observation of liver histopathology, serum fibrotic markers, liver function, liver ultrasound imaging, and symptoms and signs before and after treatment.

SA-B could effectively reverse fibrosis in hepatitis B

The 10th International Congress of Gastroenterology, Los Angeles, September 1994 suggested the etiological base in terms of the diagnosis of chronic hepatitis, making inflammatory grading criteria according to the severity of histological inflammatory necrosis and fibrotic stage standards according to the level of liver fibrosis. Currently liver biopsy is still the "Gold Standard" for scoring fibrosis. But the great

difference in the same liver specimens limited the value of biopsy, making it difficult to evaluate the fibrosis generally and correctly. Liver ultrasound imaging could reflect the specific images of fibrosis. Semi-quantitative evaluation of liver fibrosis and cirrhosis was simple and easily accessible. It was beneficial in the general evaluation of fibrosis, but it failed to precisely reflect the anti-fibrotic effect of the drug because of the insufficiency of quantitative determination. At the same time, multiple factors would affect serum fibrotic markers in the evaluation. It was favorable to combine multiple methods in evaluation. Total 120 biopsy specimens before and after treatment showed that serum fibrotic markers generally rose with the aggravation of fibrotic stages and inflammatory degrees. But the dispersion degree was large. The correlation was better in HA, IV-C and P-III-P. And LM was generally within the normal ranges.

Adapting to the current situation in diagnosis of liver fibrosis, histological fibrotic stages before and after treatment were fundamental in the evaluation of the efficacy in this trial. Improvement rates of fibrotic stages and inflammatory grades were 36.67 %(11/30) and 40 %(12/30) in SA-B group, and were 30 %(9/30) and 36.67 %(11/30) in IFN-γ group, with no significant differences between the two groups. Fibrotic stages of 4 patients decreased more than 2 stages in SA-B group, but none in IFN-γ group. HA and IV-C contents decreased significantly after treatment in SA-B group (P<0.05). The abnormal rate of HA was lowered from 80 % to 36.67 % in SA-B group (P<0.05). In the overall analysis of 4 serum fibrotic marker, 9 patients (30 %) in SA-B group had simultaneous decrease of 3 markers, better than one patient in IFN-γ group. Scores of liver ultrasound imaging with 2 patients in elevation in SA-B group was better than in IFN-γ group with 11 patients in elevation, with significant difference. General analysis of liver biopsy, serum fibrotic markers and ultrasound imaging showed superior effect of SA-B to IFN-γ.

There was no significant change in HBV antigen and antibody systems after treatment in both groups. Anti-fibrotic effect of SA-B or IFN-γ was not related to anti-viral effect. Both drugs were favorable in the relief of symptoms and signs.

Factors affecting anti-fibrotic effect of SA-B

After categorizing the changes of histological fibrotic stages, we analyzed the factors affecting anti-fibrotic effect of SA-B through the analysis of serum fibrotic markers and liver functions before treatment. Before treatment, ALT and AST activities and total bilirubin contents in fibrosis improvement group were significantly lower than those in fibrosis aggravation group. The effect was not related to the contents of serum fibrotic markers before treatment. Severity of liver inflammatory injury was the major factor affecting the anti-fibrotic effect of SA-B. SA-B had a satisfactory effect in regression of fibrosis with minor liver injury prior to treatment, but had no favorable results for severe liver injury prior to treatment. The fibrotic stage was not the major factor affecting the anti-fibrotic effect. There was no relationship in IFN-γ group. The result was instructive in the clinical application of SA-B. It was good anti-fibrotic effect in the treatment of fibrosis patients with minor inflammatory injury.

No side effects or toxicity of SA-B

There was no obvious negative response in SA-B group during the whole treatment. It showed high security in the 6-month administration. Fever and transient decrease of leukocytes were noticed in IFN-γ group.The rate of fever occurrence was 50 %, but it did not affect the completion of the whole treatment.

Abstract

AIM: **To investigate the dynamics of hepatitis C virus (HCV) variability through putative envelope genes during primary infection and the mechanism of viral genetic evolution in infected hosts.**

METHODS: **Serial serum samples prospectively collected for 12 to 34 months from a cohort of acutely HCV-infected individuals were obtained, and a 1-kb fragment spanning E1 and the 5' half of E2, including Thirty-three cloned cDNAs representing each specimen were assessed by a method that combined a single-stranded conformational polymorphism (SSCP) and heteroduplex analysis (HDA) method to determine the number of clonotypes hypervariable region, was amplified by reverse transcriptase PCR and cloned. Nonsynonymous mutations per nonsynonymous site (dn), synonymous mutations per synonymous site (ds), dn/ds ratio and genetic distances within each sample were evaluated for intrahost evolutionary analysis.**

RESULTS: **Quasispecies complexity and sequence diversity were lower in early samples and a further increase after seroconversion, although ds value in the envelope genes was higher than dn value during primary infection. The trend, pronounced in most of samples, toward lower ds values in the E1 than in the 5' portion of E2. Quasispecies complexity was higher and E2 dn/ds ratio was a trend toward higher value in later samples during persistent viremia. We also found individual features of HCV genetic evolution in different subjects who were infected with different HCV genotypes.**

CONCLUSION: **Mutations of actively replicating virus arise stochastically with certain functional constaints. A complexity quasispecies exerted by a combination of either neutral evolution or selective forces shows clear differences in individuals, and associated with HCV persistence.**

Chen S, Wang YM. Genetic evolution of structural region of hepatitis C virus in primary infection.*World J Gastroenterol* 2002; 8(4):686-693

INTRODUCTION

Hepatits C virus (HCV) is an important cause of morbidity and mortality worldwide [1,2]. Infection with HCV becomes chronic in >80 % of the cases and is a major cause of liver cirrhosis [3] and hepatocellular carcinoma [4]. In fact, HCV-related end-stage liver disease is now the leading reason for liver transplantation. HCV has also been linked to extrahepatic diseases, such as cryoglobulinemia and glomerulonephritis [5].

One of the important characteristics of HCV is that its genome exhibits significant genetic heterogeneity as a result of the accumulation of mutations during viral replication. This high mutation rate, which is characteristic of RNA viruses, can be attributed to an error-prone RNA-dependent RNA polymerase that lacks proofreading activity [6]. Several different genotypes have been described [7]. Analogous to other RNA viruses, HCV circulates in an infected individual as a population of closely related, yet heterogeneous, sequences: the quasispecies [7-11]. The distribution of mutations has been reported to be uneven but the basis of this variability is unexplained [12]. A hot-spot for mutation is described within the genome encoding a portion of E2 termed the hypervariable region (HVR), which encodes neutralizing epitopes [13,14]. It is postulated that genetic variation, translated into protein variability results in the production of HCV quasispecies. Interaction between host and virus selects those quasispecies better adapted to survival.

To date, the vast majority of studies describing HCV quasispecies evolution in humans have focused on the HVR1 of the HCV genome. In contrast, there have been very few longitudinal analyses of multiple HCV genes or entire structural genes in infected humans. Previous studies tracking multiple HCV genomic regions over time have been restricted to variations in few clones from infected individuals, and correlation with viral persistence [32]. We recently developed a method combining heteroduplex analysis (HAD) and single-stranded conformational polymorphism (SSCP) analysis (referred to herein as the HDA+SSCP method) that could assess genetic complexity with high sensitivity (ability to discriminate between distinct sequences) and specificity (chance that clones detected as distinct truly represent distinct sequences) and that could provide accurate estimates of genetic diversity in a previous investigation by sampling a sufficiently large number of cloned cDNAs [15]. In the prospective study we investigated the genomic complexity of HCV by HDA＋SSCP method of structural gene sequences in serial serum from HCV-infected individuals, In order to detect evidence of selection of HCV mutation by the host, we compared the frequency of mutations resulting in amino acid substitutions (nonsynonymous) with those that are "silent" at the protein level (synonymous).

MATERIALS AND METHODS

Patients

As a part of a prospective study of acute HCV infection, serial serum samples were obtained from individuals in the ALIVE

cohort of injection drug abusers (IDUs) in Chongqing. These samples were tested for antibodies to HCV by using the second-generation HCV enzyme immunoassay. Individuals were identified as seroconverters when a sample tested positive following at least one negative result. For all HCV seroconverters, The presence of HCV RNA was evaluated in sera collected 6 months before seroconversion, at seroconversion, and during subsequent semiannual visits (median of 7). HCV RNA were detected by a quantitative reverse transcriptase PCR (RT-PCR) assay (AMPLICOR HCV MONITER; Roche Diagnostic Systems, Branchburg. N. J.), the liner range of which was determined to be 500 to 500 000 copies per ml of serum by our and other laboratories [16,17]. Liver tests, including Alanine aminotransferase (ALT) levels in serum, performed at the first clinical examination and repeated during follow-up. Hepatitis B surface antigen, anti-HBc, anti-HBe and anti-HIV Ig M were negative in all subjects. The genome subtype was determined as described previously [18]. Clinical and virological backgrounds of the subjects studied are summarized in Table 1.

Table 1 Molecular, biochemical, and serological characterization of the nine HCV primary infections

Subject	Sample	Age(yr)/ Sex	Duration of infection (month)	Log_{10}[HCV RNA][a]	ALT level (IU/ml)[b]	Result of ELISA[c]
A		28/F

	C3		34	5.14	10	Pos

[a] Number of HCV RNA molecules per ml plasma. Time zero is the time where the first sample was available; other time are times after time zero. [b] Normal value, < 40 IU/ml. [c] ELISA: neg, negative; pos, posative.

METHODS

Envelope region amplification HCV RNA characterization was based on examination of 33 cloned cDNAs spanning the 1 025-nucleotide (nt) region thought to encode envelope protein E1 and a segment of E2, including HVR1. Total RNA was extracted from 100 μl serum by using 500μl Trizol LS Reagent (Life Technologics, Gaithersburg, Md.) at room temperature, followed by chloroform extraction and isopropanol precipitation in the presence of 20 μg glycogen (Boechringer Mannheim, Indianapolis, Ind.). The RNA pellet was washed with 75 % (vol/vol) ethanol and then air dried briefly and redissolved in 50μl diethyl pyrocarbonate-treated water with 10 mM dithiothreitol (Promega, Madison, wis.) and 5 U of RNasin ribonuclease inhibitor (Promega). After incubation at 65℃ for 5 min, 5μl purified RNA was used to generate cDNA in a 20-μl reaction mixture at 37℃ for 1 h with 20 U of Moloney murine leukemia virus RT (Promega) and first-round PCR reverse primer. The entire 20-μl cDNA synthesis reaction mixture was used for the first-round PCR in a 25-μl reaction mixture containing 0.75 U Expand HF polymerase mixture (Boechringer Mannheim, Indianapolis, Ind.), 1.5 mM $MgCl_2$, 0.2 mM concentration of deoxynucleoside triphosphates, and 500 μM concentrations of primers. The primers were outer forward (837 to 862; 5'-GCAACAGGGAAYYTDCCCGGTTGCTC-3'), outer reverse (2020 to 1998; 5'-TTCATCCASGTRCAVCCRAACCA-3'), inner forward (846 to 874; 5'-AAYYTRCCCGGTTGCTCYT TYTCTA-3'), and inner reverse (1882 to 1857; 5'-GTGAAR CARTACACYGGRCCRCANAC-3'). Degenerate bases are indicated with standard codes of the international union of Pure and applied chemistry. Nucleotide positions are numbered according to the HCV-J6 sequence. One microliter of the first-round reaction mixture was added to the second-round PCR, which had the same reagents as in the first round except for primers. Thermal-cycling conditions for the inner and outer reactions were denaturation for 120 s at 94 ℃, followed by 35 cycles of 45 s at 94 ℃, 45 s at 60 ℃, and 120 s at 72 ℃ (during the last 25 cycles, the elongation time was increased by 20 s per cycle).

Cloning of cDNA and complexity analysis of 33 cloned cDNAs by gel shift The 1-kb HCV cDNA product was ligated into vector pT-adv and used to transform *Escherichia coli* TOP 10F' competent cells (TA Cloning kit; CLONTECH Laboratories, Inc.). Transformants were detected per manufacturer's protocol, and cloning efficiency was >90 %.

Polyacrylamide gel electrophoresis (8 %) was carried out with the addition of 15 % (W/V) urea to increase the resolution. For each subject, the gel shift patterns of 33 cloned cDNAs were examined by amplifying a 573-bp region spanning HVR1 and by using a nonradioactive method that detects distinct variants within a sample by using a combination of heteroduplex analysis (HDA) and single-stranded conformational polymorphism (SSCP) on a single gel (HDA+SSCP) [15]. Sequences obtained from the serial passage were analyzed by using a divergent variant from the acute-phase sample from each subject. A clonotype is defined as two or more cloned cDNAs that have indistinguishable patterns of electrophoretic migration by HAD+SSCP. The complexity of the quasispecies was characterized by the clonotype ratio, calculated as the number of clonotypes divided by 33, the number of cloned cDNas examined. The clonotype ratio therefore varies from 0.03 (homogenous) to 1 (highly complex).

Nucleotide sequencing To examine each subject's quasispeces for signature sequences (motifs uniquely shared by a group of sequences) and for evolutions in the sensitivity of the HDA+SSCP method, a subset of cloned cDNAs was identified. For each subject, at least two cloned cDNAs were selected for sequencing based on gel shift patterns: one from the majority clonotype, another from each clonotype consisting of more than 10 % of the 33 cloned cDNAs examined, and the cloned cDNA with the largest heteroduplex gel shift. Sequences were positively determined from the M13 reverse primer and negatively from T7 promoter binding sites of plasimid clones by using a PRISM 377 DNA Sequencer (version 3.3; Applied Biosystems, Inc., Foster City, Calif.). Sequences were assembled by using the ESEE3s program, and primer sequences were removed.

Phylogenetic analysis DNA distance matrices were calculated by using the DNADIST program, maximum-likelihood, with a transition-to-transversion ratio of 4.25 [19], and phylogenetic trees were generated by the Neighbor-joining program with

random addition. Subtype reference sequences used for phylogenetic analysis had the following accession numbers: 1a, M62321; 1b, D10934; 2a, D00944; 2b, D10988; 3a, D17763; 4a, Y11604; 5a, Y13184; 6a, Y12083.

The proportion of nonsynonymous substitutions per potential nonsynonymous site (dn) and synonymous substitutions per potential synonymous site (ds) were calculated by the method of Nei and Gojobori [20].

Statistical analysis Quantitative values were compared by using the Student' s *t* test, the Kruskal Wallis test or the analysis of the variance when necessary. *P* values lower than 0.05 were considered significant. All statistical calculations were performed using the SPSS for Windows, version 8.0 software package.

RESULTS

Clonotypes detected by HDA+SSCP method

For each subject, use of a common cDNA clone to drive the HDA+SSCP gels permitted comparison of clonotypes among specimens. Among 99 cloned cDNAs from acute-Cphrase specimens, 16 distinct patterns (clonotypes) were identified, in which five clonotypes were observed in two subjects each, and six clonotypes detected in subject C. However, acute and chronic samples from three individuals each shared no clonotype.

The quqsispecies complexity was examined by assessing 33 cDNA clones from each specimen using the clonotype ratio. E2/HVR1 clonotype ratio values obtained for the samples from three individuals at each time point, ranging from 0.15 to 0.63, was plotted in Table 2. No trends were observed as clonotype ratio values changed with the changes in circulating viral load, serum ALT level (Figure 1).

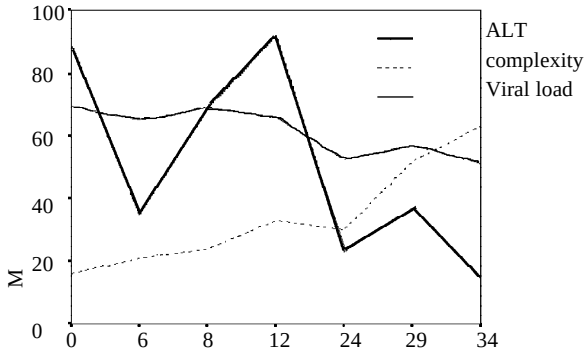

Figure 1 Changes in HCV viral load, ALT level, and HCV-E2 sequence clonotype ratio at serial samples from six individuals with HCV infection.

Initial sequence analysis

Using HDA+SSCP to select representative cloned cDNAs, 18 distinct cloned cDNAs were identified for sequencing. All such sequences were 1 022 bp, except for the sequences of single variants from subject F, which had a 1-bp delectation. To determine the genetic identity of cDNA clones of the same clonotype, two representative sequences representing the majority clonotype were compared for each specimen. There were eighteen differences among 14 pairs of 573-bp sequences (99.7 %). The ten sporadic substitutions were probably artifactual, occurring at a frequency of 4.1×10^{-5} sporadic substitutions per site per PCR cycle, similar the error rate of *Taq* during amplification of homogeneous sequences [21]. For each majority clonotype, one of the two sequences was free of sporadic substitutions and was used in all subsequent analyses to represent that clonotype. In addition, no two cloned cDNAs identified as being distinct by HDA+SSCP analysis had identical sequences. Therefore, the HDA+SSCP method is both highly sensitive and specific in detecting differences among cDNA clones, as previously reported.

Phyogenetic analysis revealed that two subjects' sequence (A and B) clustered with 3b, while those of another (C) clustered with subtype 1b (Figure 3).

Quasispecies complexity and the outcome of acute infection

In each pair of samples from the same individual, the complexity of the quasispecies assessed using the clonotype ratio increased with time from seroconversion, both during the acute phase and also during the chronic phase (Figure 1). Quasispecies complexity correlated with estimated duration of HCV infection ($r = 0.931$, $P < 0.01$).

Table 2 Characteristics of samples and results of SSCP / HDA*

Sample	Genotype	Clonotype distribution**	No.of clonotypes	Clonotype ratio

Figure 3 Alignment of inferred amino acid sequences for the majority clonotype and each clonotype from each subjects A, B, F at different time points. In the last column, an alphabetical label is given for each subject. Period indicate identity to the amino acid at that position in the first sequence. Position of the E1 and E2 region are in dicated above the alignment, whereas that of HVR1 is indicated below the alignment at the N terminus of E2. potential N-linked glycosylation site are boxed. For each subject, numbers indicate the different clones obtained.

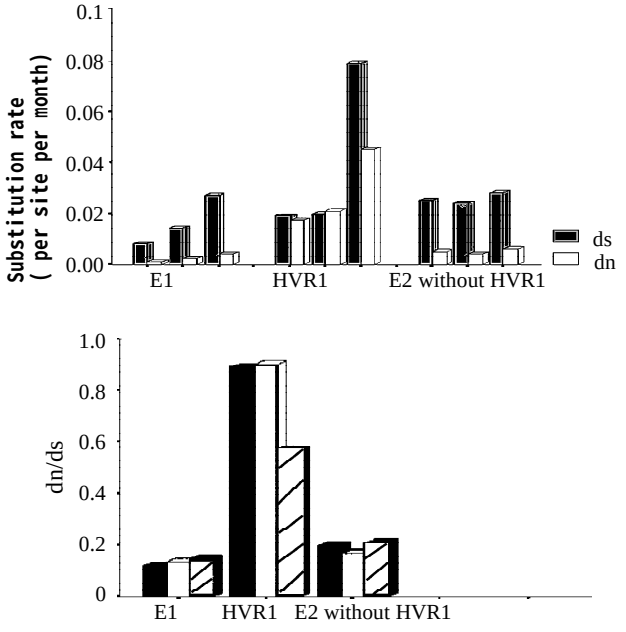

Figure 4 ds and dn , and dn / ds for acute-phase samples and persistent-phase samples from three individuals with HCV infection.. In each panel, The individuals are presented in the order A, B.

Detailed analysis of sequences from serial passages

Figure 3 shows the amindo acid alignment of the sequences derived from the cloned E2/HVR1 and the flanking E1subfragment obtained from the three individuals and highlights the nonsynonymous changes. A phylogenetic study of these sequences (Figure 2) revealed that sequences from two individuals (A and B) tended to cluster tightly, segregated away from clusters of sequences from the individual C. For individuals A and B, the sequences from samples A1 to A3 or B1 to B3 maintained a low mean intrasample genetic distance: 0.0009 (A1), 0.0131 (A2), 0.0089 (A3), and 0.0014 (B1), 0.0054 (B2), 0.0046 (B3), respectively. The sequences found in the samples from individual C displayed a greater intrasample distance with late sample (C3 [collected 34 months after C1]) documenting a sharp increase (0.0214). An additional intrasample parameter evaluated in this study was the proportaion of nonsynonymous substitutions per potential nonsynonymous site (dn) and synonymous substitutions per potential synonymous site (ds);It is showed in Figure 4 that ds values in the E1 region are lower than ones in E2/HVR1 at the samples from all individuals. There is the trend, observed during serial passages in three individuals, toward higher intersample dn/ds ratios in the E2/HVR1 than in E1, although

intersample dn/ds ratio were less than 1.0 with except for individual C (Figure 4). These data principally document that (i) early sequences have a low genetic divergence (oligoclonal profile), (ii) the dynamics and extent of the host selective pressure may differ among different individuals with different HCV genotypes, (iii) there are segmental effects of selective pressure on the envelope region of HCV genome.

DISCUSSION

Sequence analysis of cDNA clones derived from PCR products from individual patients has provided important information on the genetic variability of HCV HVR1 [22-29]. However, taking into account the quasispecies nature of HCV infection and the marked heterogeneity of patients with chronic HCV infection, sequence analysis of a large number of clones would be necessary for accurate assessment of viral evolution in individuals, but because of the effort and expense, published studies obtain sequence information from a small number of colonies per subject. To overcome this potentially serious limitation, HDA and SSCP assays have been developed and proposed as means of reducing sequence analyses [30-32]. Electrophoretic analysis of SSCP has been more expedient, but its sensitivity (ability to identify distinct clones) is limited and it does not provide an estimate of genetic distance [33,34]. Heteroduplex analysis (HDA) is also convenient and provides information on both genetic complexity and distance [35-43]. However, HDA alone may not be sufficiently sensitive. Because the HVR1 PCR product is less than 200 base, the distance between heteroduplexes and homoduplex does not accurately reflect the degree of heterogeneity [30]. Our approach is a method for measuring HCV quasispecies complexity that combines HDA and SSCP in a single gel visualized with UV light. Furthermore, we repeated studies using a larger region in the exposed portion of the envelope 2 gene. Similar sensitivity to the HVR1 has been shown. The method was sensitive and specific for detecting clonotypes, and the number of clonotypes detected correlated strongly with sequence diversity when 33 cloned cDNA are assessed [15].

Artifactual ‘ minor’ quasispecies can result from *Taq* polymerase-derived errors introduced during amplification[21] or from selection during amplification and cloning procedures[44]. In this study, PCR artifacts have been minimized by the use of thermostable polymerases with proofreading function; selection phenomena are not also considered, because the cloning efficiency is very high (>90 %) and defective sequences (deletion or stop codons) are not detected. It is important that the variability of the E1 and E2/HVR1 sequences in each sample was limited to segregating polymorphisms, suggesting that the nucleotide substitutions in these sequences are spontaneous mutations.

The current study principally document that low quasispecies complexity and intrasample genetic divergence was observed in the first samples collected from these three individuals, before a specific humoral immune response was elicited, or soon after antibody production, suggests that in its early phase HCV infection may be an oligoclonal event. Despite the vulnerability of IDUs to HCV multiple transmission through a variety of unknown routes, we found on evidence of mixed HCV genotype infection, neither did we find higher quasispecies complexity or genetic distance values in the first samples from the IDU compared to the blood donor (do not shown). Sequencing of inserted E1 and E2/HVR1 clones derived from all three subjects shows that variation in sequences of the minority variants involved single-nucleotide substitutions from majority variant, accounting for the tight clustering of sequences seen in a dendrogram. These data are consistent with quasispecies evolution from a single HCV founder strain and again point to the rarity of multiple HCV carriage in IDUs [45]. Meanwhile, We note that there were differences in quasispecies complexity and diversity in the circulation before and early after the appearance of antibody. In individual A with subtype-3b infection, there was only a single change in the E2/HVR1 region in the first sample (before seroconversion), and the variants that subsequently emerged possessed more changes suggesting that these and the dominant variant belong to one monophyletic group. By contrast, there was multple substitution in the E2/HVR1 region in the first sample (early after seroconversion) from individual C with subtype-1b infection. Such a disparity in genetic complexity of HCV in samples at the acute stage of infection has been noted in a previous study of three patients with acute hepatitis C [23]. Data from our study suggest that difference in viral quasispecies complexity and diversity in early samples could be due to a variety of factors, including whether effective humoral responses or cellular responses have been triggered, or possibly the subtype. However, it is possible that mixed infections are in fact common but that one subtype prevails and the other becomes undetectable. It would be feasible to apple the HAD+SSCP procedure to larger numbers of serum samples to confirm the absence or paucity of multiple infection in IDUs or patient subgroup. This confirmation would imply that vaccination programs employing live, attenuated HCV vaccines might be more effective in preventing primary HCV infections than inactived, subunit, or epitope vaccines would be.

From a mechanistic perspective, variation with the HCV genome is assumed to be caused by random mutation and selection of variants which are most fit to propagate in a given host [46,47]. Generally, synonymous changes are often thought to represent a molecular clock, independent of external pressure and expected to occur at a rate proportional to the organism’ s reproductive rate, Whereas nonsynonymous changes are selected by immune pressure [47]. The results shown in Figure 4 are the trend, pronounced in most of samples, toward lower ds values in the E1 than in the 5’ portion of E2. Lower ds values in the 5’ half of E1 than in a 3’ segment of E2 have been detailed in recent studies [24,51,52]. Lower ds values may indicate that E1 region has some constraints on synonymous variation, such as RNA secondary structure or binding sites for factors that regulate replication or translation. However, In protein-coding regions, multiple forces affect the balance between fixation of silent (synonymous) mutations versus those that alter amino acid sequence (nonsynonymous). In the present study, HVR1 variation during 6-8 months of infection did not reveal a common pattern of increasing diversity within each subject, though later sequences did diverge from earlier ones, indicating the action of selective forces. In addition, there is the trend, also pronounced in a longitudinal study of three subjects each, toward higher dn/ds ratios (as a surrogate indicator for immune pressure) in the E2/HVR1 than in E1. These results suggest that selective pressure acts differently on different genomic regions. Since the high mutation rate within the hypervariable regions of HCV E2 or the V loops Of HIV gp120 could be explained by the fact that these regions are free of structural constraints, a role for the HVR1 of HCV (and other viruses) as decoy antigen has recently been proposed, stimulating a strong immune response so that a early response to a highly immunogenic region might suppress or delay the response to other less-dominant epitopes, resulting in a diversion of the immune response away from more-conserved regions [48-50], but in some cases, is ineffective for viral clearance [51].

In conclusion, HDA+SSCP assay facilitates rapid and reliable assessment of HCV quasispecies diversity. Combined with nucleotide-sequencing procedure, it provides evidence that different dynamics of quasispecies evolution is associated with viral features and its fitness for individual environments. Mutations of actively replicating virus arise stochastically with certain functional constaints. In a longitudinal study of three subjects, HVR1 variation during the first 8 months of infection did not reveal a common pattern of increasing diversity within each subject, though later sequences did diverge from earlier one. We were unable to identify an envelope sequence motif that predicts the outcome of primary infection.

Abstact

AIM: **To explore whether HDV ribozymes have the ability to trans-cleave HCV RNA.**

METHODS: **Three HDV genomic ribozymes were designed and named RzC1, RzC2 and RzC3. The substrate RNA contained HCV RNA 5'-noncoding region and 5'-fragment of C region (5'-NCR-C). All the ribozymes and HCV RNA 5'-NCR-C were obtained by transcription in vitro from their DNA templates, and HCV RNA 5'-NCR-C was radiolabelled at its 5'-end. Under certain pH, temperature, appropriate concentration of Mg^{2+} and deionized formamide, these ribozymes were respectively or simultaneously mixed with HCV RNA 5'-NCR-C and reacted for a certain time. The trans-cleavage reaction was stopped at different time points, and the products were separated with polyacrylamide gel electrophoresis (PAGE), displayed by autoradiography. Percentage of trans-cleaved products was measured to indicate the activity of HDV ribozymes.**

RESULTS: **RzC1 and RzC2 could trans-cleave 26 % and 21.8 % of HCV RNA 5'-NCR-C under our reaction conditions with 2.5 mol·L^{-1} deionized formamide respectively. The percentage of HCV RNA 5'-NCR-C trans-cleaved by RzC1, RzC2 or combined usage of the three ribozymes increased with time, up to 24.9 %, 20.3 % and 37.3 % respectively at 90 min point. Almost no product from RzC3 was observed.**

CONCLUSION: **HDV ribozymes are able to trans-cleave specifically HCV RNA at certain sites under appropriate conditions, and combination of several ribozymes aiming at different target sites can trans-cleave the substrate more efficiently than using only one of them.**

INTRODUCTION

Ribozymes are sorts of small RNAs which have catalytic activity, and some of them can bind specifically through Watson-Crick base pairs with and trans-cleave substrate RNA in appropriate target sites[1-4]. Hammerhead ribozymes and hairpin ribozymes have been tried widely to cleave many target RNAs, such as pathogenic microbes RNA[5-10], oncogene mRNA[11-15] and other kinds of pathogenity-associated functional mRNA[16-18]. A great deal of experiments have demonstrated that these ribozymes, if well-designed, could be applied as antiviral or antitumor gene therapeutic drugs. Yet there are still few researches showing whether HDV ribozymes, owning a kind of pseudoknot-like secondary structure, have the ability to kill pathogenic virus or not. HDV ribozymes include genomic ribozymes (g.Rz) and antigenomic ribozymes (ag.Rz) , of them the latter is duplicate intermediates of HDV[19,20]. This study was to evaluate the ability of g.Rz to trans-cleave HCV RNA at molecular levels.

MATERIALS AND METHODS

Reagents

All the cDNA of ribozymes were synthesized in a DNA synthesizer and purified with 160 g·L^{-1} denatured (7 mol·L^{-1} urea) polyacrylamide gel electrophoresis in Shanghai Sangon Bioengineering Company. Plasmid pHCV-neo was kindly provided by Dr. Wang working in our institute. Polymerase chain reaction (PCR) reagents and T7 transcription kit (Ribomax™) were purchased from Sino-American Bioengineering Company. Agarose Gel DNA Purification Kit, calf intestinal alkaline phosphatase (CIP) and T4 polynucleotide kinase were bought from Boehringer Mannheim Co. γ-^{32}P-ATP was the product of Beijing Yahui Co,and KODAK X-ray film was chosen to do autoradiography.

Preparation of template for transcription of substrate in vitro

pHCV-neo contains full length of HCV RNA 5' -NCR (341nt), translation-initiating codon AUG and 5' -fragment of C region (90nt). Sequence of HCV RNA 5' -NCR-C has been proved to be identical with that of HCV strains isolated from Chinese people reported by Bi et al. pHCV-neo has T7 phage promoter sequence ahead of HCV cDNA. Transcription template of HCV RNA 5' -NCR-C was prepared by the PCR method. The upper primer was T7 phage promoter sequence: 5' -TAA TAC GAC TCA TAG-3' , and the reversed primer identified with the sequence from 413th to 383th nucleotide (nt) of HCV genome: 5' -GCG*GGATCC*CCGGAACTTGACGTCCTG-3' (the italic letter was cleavage site of BamH I designed for future cloning). Route PCR process was adopted. PCR products were purified by Agarose Gel DNA Purification Kit, and the unpaired A at 3' end was cut off with Klenow enzyme. All these procedures were made according to the kit guidebook. After that, PCR products were regained by phenol (pH8.0)/chloroform/ isoamyl alcohol (volume ratio 25:24:1) extraction, precipitated with ethanol, and redissolved with RNAase-free water.

Design of ribozymes and preparation of their transcription templates

Based on the structure of our formerly reportedg.Rz55, we designed here three kinds of HCV RNA-targetting g.Rzs named RzC1, RzC2 and RzC3 respectively. The target sequences and their location in HCV RNA 5' -NCR-C are shown in Table 1. Routine PCR process was adopted to prepare the transcription templates of the ribozymes. PCR templates were formerly synthesized cDNA of these ribozymes. The upper primer contained T7 phage promoter

sequence (Italic letters): 5' -TAATACGACTCACTATAG TCTAGAGTCCCAGCCTCCTCGCTGGC-3' , and the reversed primer was 5' -CTCGGATCCGTCCCATTCGCCATTCCG AAGAATGTTGCCC-3' . Purification of PCR products and treatment of their 3' -end were the same as that mentioned above.

Table 1 Target sequences and their location in HCV RNA 5'-NCR-C

Target sequence	Location in HCV RNA 5' NCR-C	Ribozyme
5'…CGU ↓ GCAGCCU…3'	107-113 nt	RzC1
5'…GUU ↓ GGGUCGC…3'	268-274 nt	RzC2
5'…CAU ↓ GAGCACG…3'	345-351 nt	RzC3

Transcription in vitro

Each transcription reaction was done under 37 ℃ for 4 h, with a total volume of 20 μl, containing template DNA 1.5 μg, rNTP (preservation concentration 25 mmol· L^{-1}) 6 μl, 5× transcription buffer 4 μl, T7 RNA polymerase 2 μl (preservation concentration 1 μ· μl^{-1}). Digestion of DNA templates, purification and quantification of transcription products were executed according to the kit guidebook.

Radiolabel of substrate RNA at 5' -end

Phosphate at the 5' -end of substrate RNA was deleted with CIP, then the substrate RNA was radiolabelled at the 5' -end with T4 polynucleotide kinase and γ-^{32}P-ATP. After that, substrate RNA was purified by routine phenol (pH4.5)/ chloroform/ isoamyl alcohol (volume ratio 25:24:1) extraction, precipitated with ethanol, and redissolved with RNAase-free water and then quantitified, and stored at -20 ℃. All operations were made according to the guidelines.

Trans-cleavage reaction and measurement of effects-time relationship

Trans-cleavage reaction was done under conditions with or without deionized formamide having a final concentration of 2.5 mol· L^{-1}. Each reaction system contained radiolabelled substrate RNA 50 nmol· L^{-1}, ribozymes 5 μmol· L^{-1}, Tris.cl (pH7.5) 50 mmol· L^{-1}, with a total volume of 10 μL. The standard reaction protocol was as follows: heat the tube containing the reaction mixtures to 95 ℃ for 3 min → place on ice for 10 min → dip into 37 ℃ water for another 10 min → add prewarmed $MgCl_2$ to the final concentration of 20 mmol.L^{-1} → keep the reaction temperature at 37 ℃ for 2 h → separate reaction products by electrophoresis on a 80 g· L^{-1} polyacrylamide gel containing 7 mol· L^{-1} urea → display the products by autoradiography at -70 ℃ (the X-ray film was exposed for 0.5 μs beforehand) for about 24 h → measure A value of the images with Gel Documentation-Analyzing Systems (Gel Doc™ 2000, Bio-Rad) and then calculate the percentage of substrate cleaved by the ribozymes.

Under the optimized cleavage conditions, following reactions were made in four tubes containing 15 μl mixtures each, of which three reactions were designed for each ribozyme to trans-cleave the target RNA,separately, and the fourth reaction for all the three ribozymes to trans-cleave the substrate RNA simultaneously and cooperatively. The reaction procedures were the same as that mentioned above, except that after $MgCl_2$ was added to the mixtures, the reactions were terminated at 10, 30 and 90 min time points. Five μL solution was removed from each tube at different time points for investigating the effects-time relationship.

Percentage of cleavage (%) =A value of cleaved substrate RNA / (A value of cleaved substrate RNA+A value of uncleaved substrate RNA)×100%

RESULTS

Effects of the ribozymes to trans-cleave substrate RNA under different conditions

Transcription templates of RzC1, RzC2, RzC3 and HCV RNA 5' -NCR-C were proven to be obtained successfully by 20 g· L^{-1} agarose gel electrophoresis. The ribozymes and substrate RNA were successfully synthesized by transcription *in vitro* known from 80 g· L^{-1} denatured (7 mol· L^{-1} urea) polyacrylamide gel electrophoresis.

According to the design, HCV RNA 5' -NCR-C should be trans-cleaved into 106nt (5' product) and 324nt (3' product) fragments by RzC1, 267nt and 163nt fragments by RzC2, and 344nt and 86nt fragments by RzC3. As HCV RNA 5' -NCR-C was radiolabelled at its 5' -end, only the 5' -products were displayed in X-ray films after autoradiography. The results showed that RzC1 and RzC2 are able to trans-cleave HCV RNA 5' -NCR-C under the selected reaction conditions, and the length of their cleavage products was set in accordance with the design. Percentage of substrate RNA cleaved by RzC1 and RzC2 under the conditions without deionized formamide at 2 h time point was 4.2 % and 3.5 %, respectively. With the addition of deionized formamide to the trans-cleavage reaction systems to a final concentration of 2.5 mol· L^{-1} , percentage of cleaved substrate RNA reached up to 26 % and 21.8 %, respectively at the same time point (Figure 1). It was surprising that under both conditions with or without deionized formamide, RzC3 almost had no trans-cleavage activity to HCV RNA 5' -NCR-C. Based on the whole experiment, we think that the reaction conditions with deionized formamide was better than that without it, thus being adopted in the future investigations.

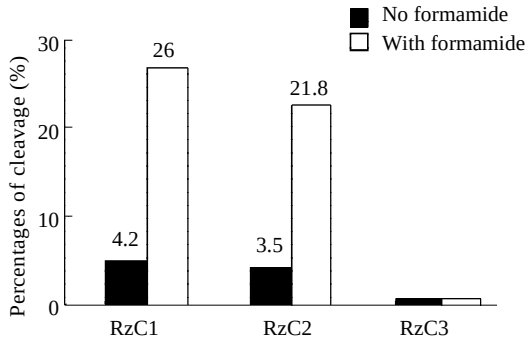

Figure 1 Effects of RzC1, RzC2 and RzC3 to trans-cleave HCV RNA 5'-NCR-C under different conditions (results came from image analysis).

Roles of the three ribozymes to trans-cleave substrate RNA at different time points

Under the optimized reaction conditions, fragments of HCV RNA 5' -NCR-C trans-cleaved by RzC1 and RzC2 were produced at the fixed time points (Figures 2 and 3). When the three ribozymes were added to one tube to trans-cleave HCV RNA 5' -NCR-C simultaneously, images of 106nt and 267nt fragments corresponding to the cleavage products of RzC1 and RzC2 respectively were observed in the same X-ray film (Figure 4), yet no marked image of 344nt fragment meaning the substrate RNA cleaved by RzC3 turned up at the same time.

Effects-time relationship of the ribozymes to trans-cleave substrate RNA

Percentage of cleaved substrate RNA by RzC1 and RzC2 was

6.1% and 4.6 % at 10 min time point, 14.0 % and 11.7 % at 30 min time point, and 24.9 % and 20.3 % at 90 min time point respectively. These results showed that the percentage of RzC1 and RzC2 to trans-cleave HCV RNA 5' -NCR-C increased with time. At the same time, nearly no effects of RzC3 to trans-cleave HCV RNA 5' -NCR-C was observed. The percentage of these ribozymes to trans-cleave HCV RNA 5' -NCR-C in one tube turned out to be 8.4 % at 10 min, 19.5 % at 30 min and 37.3 % at 90 min time point respectively (Figure 5). These results demonstrated that the combination of ribozymes aiming at different target sites could be applied to cleave substrate RNA more efficiently than using only one of them.

DISCUSSION

HDV ribozymes were first reported for their self-cleavage activity, also named cis-cleavage, which meant splicing reaction occurring within the catalytic RNA molecule itself, i. e. intramolecular cleavage[19,21]. Several years later, it was found that a self-cleavage HDV ribozyme could also be divided into two parts, one part ("ribozyme" component) still maintained the catalytic activity and the other part (homologous "substrate" component) could be cleaved by the former intermolecularly when they were taken together again. This kind of intermolecular cleavage was called trans-cleavage, and the "ribozyme" components having trans-cleavage activity were usually described as trans-HDV ribozymes[22]. Our previous studies have shown that trans-HDV genomic ribozyme g.Rz55 was able to trans-cleave its homologous substrate S87 with a percentage of about 69 % under conditions Tris-Cl 50 mmol· L^{-1} (pH7.5) and $MgCl_2$ 20 mmol.L^{-1}[23]. In recent years, some researches have found that the substrate-binding region of trans-HDV ribozymes might be changeable to some extent[24]. These findings are the theoretical and experimental bases for reconstruction and application of HDV ribozymes to trans-cleave HCV RNA 5' -NCR-C.

Many studies have shown that HDV ribozymes owned a kind of special pseudoknot-like secondary structure which was different from that of hammerhead ribozymes and hairpin ribozymes[25-29], so did their requirements to the target sequences of substrate RNA[30-36]. Roy *et al*. reported that trans-ag.Rz was able to cleave 814nt HDAg mRNA efficiently at several target sites, and concluded that all the sequences having the characteristic of 5'-$R_4R_3R_2$ Y_{-1} ↓ G_1 N_2 N_3 (A/C/U)$_4$ N_5 N_6 N_7-3' (R=A or G,Y=U or C) in HDAg mRNA might be the most possible sites to be cleaved by trans-ag.Rz[37]. The results are of significant value to design trans-g.Rz, because the secondary structure of g.Rz and ag.Rz is similar.

Five principles have been abided by during our selection of target sites of trans- g.Rz in HCV RNA 5' -NCR-C. Firstly, the target sequence was in accordance with the basic requirements of g.Rz, i.e., the first base G at 3' -end of the cleavage site was designed to form G· U wobble pair with the g.Rz. Secondly, the best first base at 5' -end of the cleavage site in substrate RNA was U. It should be noted that at any time G must not be selected when determine the first base at 5' -end of the cleavage site, and also it is necessary to avoid that more than two consecutive C located at 5' -end of the cleavage site. Thirdly, the more G-C or C-G base pair in the 7bp target sequences, the better for the ribozymes to bind the substrate. Fourthly, regions forming long intramolecular Watson-Crick base pairs in the reported HCV RNA 5' -NCR-C secondary structure were avoided as possible as it could. Finally, target sequences were located in the important functional regions of HCV RNA 5' -NCR-C such as internal ribosome entry site (IRES) and translation-initiating codon. These were the most important basic principles to design trans-HDV ribozymes and determine the target sites to be cleaved.

According to the theories and rules mentioned above, we tried to design trans-genomic ribozymes RzC1, RzC2 and RzC3 to cleave their heterologous substrate RNA, i.e. HCV RNA. The results showed that under the optimized cleaving reaction conditions, RzC1 and RzC2 exhibited the ability to trans-cleave HCV RNA 5' -NCR-C, and the percentage of cleaved substrate were increased with time, up to 24.9 % and 20.3 % respectively at 90 min time point. Combination of all these ribozymes resulted in 37.3 % substrate RNA to be cleaved at the same reaction conditions and time. From these results, we got to know that rationally designed trans-HDV ribozymes had the activity to cleave HCV RNA 5' -NCR-C which was the heterologous substrate to such ribozymes, and the cleavage effects could be improved by applying different trans-HDV ribozymes to cleave HCV RNA at multiple target sites simultaneously.

In comparison of the self-cleavage and trans-cleavage

activity of HDV ribozymes at natural target sites in homologous substrate RNA and other target sites in HDV mRNA, the activity of RzC1 and RzC2 to trans-cleave HCV RNA 5' -NCR-C was a little lower, and RzC3 had almost no cleavage activity. By comparing the sequences and structure of RzC1, RzC2 and RzC3 to cis-HDV ribozymes and trans-HDV ribozymes reported by others, and the differences among the target RNAs, we suppose that the possible reasons may lie in several respects. Firstly, the target sites in HCV RNA 5' -NCR-C and the structure of trans-HDV ribozymes should be further optimized by more methods. For example, the calculation and application of the free energies required for forming pseudoknot and binding of ribozyme to substrate[38], or other strategies to map the accessible sites in substrate for ribozyme to bind[39,40]. Secondly, it is likely that the activity of trans-HDV ribozymes might be weakened if the A-U or U-A base pair just adjoined the G· U wobble pair when A-U or U-A and C-G or G-C base pairs co-existed in the binding regions of ribozymes and substrate RNA. Thirdly, the special secondary structure of HCV RNA 5' -NCR-C might impede the cleavage activity of trans-HDV ribozymes[31,41]. Fourthly, other sequences at both ends of trans-HDV ribozymes might diminish their cleavage activity[42]. Finally, different reaction conditions such as the kind of buffer might significantly influence the cleavage effects sometimes[43]. Certain denaturing agents such as deionized formamide in an appropriate concentration may reduce the formation of complex secondary structure of substrate RNA, thus improve the trans-cleavage activity to some extent[41]. A suitable pH of solution was very important for the trans-cleavage to occur too, and pH7.0-7.5 was commonly used during researches *in vitro*. Divalent cations such as Mg^{2+}, Ca^{2+} and Mn^{2+} could bind and interact with the ribozymes' phosphate-pentose skeleton full of negative charges[44,45], thus facilitating the ribozymes to fold into and maintain active structure, and/or take part in trans-cleavage reaction directly[46-49].

HCV is an important pathogenic factor of chronic hepatitis, and related to the formation of cirrhosis and occurrence of hepatocarcinoma or cholangiocarcinoma[50]. Finding new ways to control HCV infection is difficult but necessary. IRES and translation-initiating codon of HCV RNA are usually chosen as the trans-cleave target sequences not only because they are the important functional regions, but also they are very conservative in each HCV variant[51]. As a result, ribozymes aiming at the two regions will have a universal cleavage effects on all of the HCV variants. Effects of HDV ribozymes to trans-cleave HCV RNA 5' -NCR-C at extracellular molecular levels are not completely in accordance with that exhibited intracellularly, because intracellular conditions and factors that influence the ribozyme activity are far more complicated than the extracellular ones. On the other hand, HDV ribozymes are the only kind of viral ribozymes which exist in mammalian cells naturally, especially in human hepatocytes. Based on these opinions and facts, it is expected that the intracellular location and cleavage activity of HDV ribozymes might be more efficient than that of hammerhead ribozymes and hairpin ribozymes, thus it is necessary and valuable to assess the roles of HDV ribozymes in trans-cleaving HCV RNA intracellularly.

Abstract

AIM: **To develop a rapid detection method of enteroviruses and Hepatitis A virus (HAV).**

METHODS: **A one-step, single-tube consensus primers multiplex RT-PCR was developed to simultaneously detect Poliovirus, Coxsackie virus, Echovirus and HAV. A general upstream primer and a HAV primer and four different sets of primers (5 primers) specific for Poliovirus, Coxsacki evirus, Echovirus and HAV cDNA were mixed in the PCR mixture to reverse transcript and amplify the target DNA. Four distinct amplified DNA segments representing Poliovirus, Coxsackie virus, Echovirus and HAV were identified by gel electrophoresis as 589-,671-, 1084-, and 1128bp sequences, respectively. Semi-nested PCR was used to confirm the amplified products for each enterovirus and HAV.**

RESULTS: **All four kinds of viral genome RNA were detected, and producing four bands which could be differentiated by the band size on the gel.To confirm the specificity of the multiplex PCR products, semi-nested PCR was performed. For all the four strains tested gave positive results .The detection sensitivity of multiplex PCR was similar to that of monoplex RT-PCR which was 24 PFU for Poliovrus,21 PFU for Coxsackie virus,60 PFU for Echovirus and 105 $TCID_{50}$ for HAV. The minimum amount of enteric viral RNA detected by semi-nested PCR was equivalent to 2.4 PFU for Poliovrus, 2.1 PFU for Coxsackie virus, 6.0 PFU for Echovirus and 10.5 $TCID_{50}$ for HAV.**

CONCLUSION: **The consensus primers multiplex RT-PCR has more advantages over monoplex RT-PCR for enteric viruses detection, namely, the rapid turnaround time and cost effectiveness.**

INTRODUCTION

Enteroviruses include Poliovirus, Coxsackie virus and Echo virus. Enterovuses and HAV can bring about many diseases[1]. The enteroviruses and HAV transmit through water or foods and constitute a risk to public health, even when their concentrations are very low. Therefore, to establish a set of fast and dependable technique for detecting enteroviruses and HAV in water is of great importance for preventing outbreak of virus diseases through water and, at the same time laying a foundation for working out virology sanitation standards for drinking water.

The traditional technique for detecting viruses at present is cell culture[2] and it is characterized by its large water volume treated and high sensitivity. Normally viruses can be cultured and reproduced even if there is only one infectious virus existing in water. But the technique also has some shortcomings: (1) it needs great efforts and is time-consuming. There are high technical demands on cell culture and its result is unstable. It takes more than 3 days from inoculating virus to the time when visible pathological cell change effect (PCE) appears. For HAV, there is no pathological cell change effect and it takes 6-8 weeks to carry out the test. (2) it is poor in specificity. It is impossible to draw a clear identification among enteroviruses on the basis of pathological cell changes.

In recent years, PCR has been adopted extensively in detecting enterovirus or HAV in environment owing to its high specificity and simpler operation[1,3-5]. But it also has its shortcomings. Firstly, the sensitivity is low. Although PCR itself possesses high sensitivity and it can pick out even there is only one virus, its sensitivity still does not come up to the standards for testing virus in water because the size of added samples is extremely small (about 10 ml). Even the viruses in the water are concentrated, the volume is still too large for PCR. Secondly, the testing capability is inconsistent with infectivity of the virus. It is unable to decide whether the virus is infectious even if the result is positive. Besides, conventional PCR can only detect one type of virus at one time. There are many types of viruses in water so it can't meet the needs of practical application. Tsai *et al*[6] used multiplex-PCR to detect poliovirus, hepatitis A virus and rotavirus at one time. Their technique requires more primers and these primers interfere with each other, making it more difficult to test the viruses over three types. Zoll *et al*[7] employed general primer PCR to detect enterovirus but their method can only show whether there is existence of enterovirus or not. It can not distinguish the types of viruses.

The combination of the cell culture with PCR technique is implemented organically in our study for the purpose of setting up a set of fast and dependable methods for testing viruses in water. This method can either preserve the advantages of the cell culture and PCR technique or overcome the shortcomings of each technique. Our technique is basically divided into three steps: first, to make collection and recovery of viruses in water; second, to make short-term cultivation of viruses; and third, to detect viral nucleic acid using multiplex-PCR and identified by semi-nested PCR.

MATERIALS AND METHODS

Viruses and viruses assays

Plaque-purified Poliovirus type 1, strain LSc, Cox B1,3 and 4 or Echo 7,9,11,12 virus were used as the model for the enteroviruses that may be present in the water. These viruses were grown and assayed by using African green monkey kidney (Vero) cells as previously described[1]. The viruses were titrated by the plaque method and expressed as plaque-forming units (PFU). The NJ-3 strain of HAV (Institute of Military Medical Research of Nanjing) was adopted to the human hepatoma cell line PLC/PRF/5 by serial passages. The HAV antigen was detected by ELISA method .

Virus seeding

A virus mixture containing 1.0×10^5 PFU of Poliovirus type 1, strain LSc, Cox B_3 or Echo 9 virus, and 1.0×10^5 $TCID_{50}$ of HAV was seeded into 10 liters of water samples. The seeded and unseeded samples were concentrated by electropositive filter media particle as described previously by Jun-Wen Li, and the recovery of seeded viruses was 88.7 % [8]. The final concentrates were 1.0 ml ,If needed, which was cultured for three days for HAV or one day for other enterovirues. The sensitivities of RT-PCR were evaluated with the ten-fold dilutions of HAV or other enteroviruses which were made with HPLC grade water.

RNA extraction and purification

Viral genome RNA was extracted and purified by the TRIzol Reagent kit (Life Technologies) according to the manufacturer' s recommendation,and the RNA was stored at -20 ℃ for future analysis.

Primers

The consensus primer of enteroviruses was from the 5' non-coding region because of their presence in many enteroviruses serotypes[7,9]; the specific primers for enteric viruses, including HAV, were selected from the 5' coding region; and the semi-nested PCR primers were designed within the fragment of the first PCR products. The information of primers was summarized in Table 1.

Table 1 Nucleotide sequences and positions of primers

Primers	Sequence(5'-3')	Position	band sizes (bp)
CE(+)	ATTGGATTGGCCATCCGGTG	620-639

H(+)2	GATTCATTCTGCAGATTGGC	989-1008	589

+; upstream primer, -; downsream primer, 1: semi-nested primer; 2: the first PCR primer, CE; general primer, P: primers of Polioviruses; C: primers of Coxsackie viruses; E: primers of Echoviruses; H: primers of HAV

One-step, single-tube multiplex PCR

2-10 μl of prified viral RNAs were added in a final 100 μl containing 1×PCR buffer with 1.5 mM $MgCl_2$, 0.2mM each of dNTP, 0.2 μM each of the primers, 10 U Rnase inhibitor, 5mM of DTT, 1 μl of mixture of reverse trancriptase and DNA polymerase. RT was carried out at 50 ℃ for 30 min. This was followed by an initial denaturation at 94 ℃ for 3 min, and 30 PCR cycles of denaturation at 94 ℃ for 0.5 min, annealing at 60 ℃ for 0.5 min and extension at 68 ℃ for 1 min with a fixed ramp time of 3 seconds for each cycle[10].

Semi-nested PCR

The semi-nested PCR was carried out on a final 50 μl containing 1×PCR buffer with 2.5 mM $MgCl_2$, 0.2 mM each of dNTP, 0.2 μM each of primers, 1 μl of the first PCR product and 2.5U of *Taq* polymerase. This was followed by an initial denaturation at 94 ℃ for 3 min, and 30 PCR cycles of denaturation at 94 ℃ for 0.5 min, annealing at 60 ℃ for 0.5 min and extension at 68℃ for 1 min[12,13].

Analysis of PCR products

10 μl of each amplified product was electrophoresed on a 1.5 % agarose gel in 1×TBE buffer containing 0.5 μg/ml ethidium bromide. The amplified bands were directly visualized under UV light[7,14].

RESULTS

Specificities of the primers

First, only one kind of viral RNA extracted from cell culture was tested in the multiplex PCR with all the primers. It is shown that only one amplicon was yielded, which was in agreement with the information on the designed primers (results not shown).

Secondly, two kinds of viral RNA were added to the multiplex PCR, it is expected that there were two PCR products on the gel which were conformed to the theoretical results (Figure1).

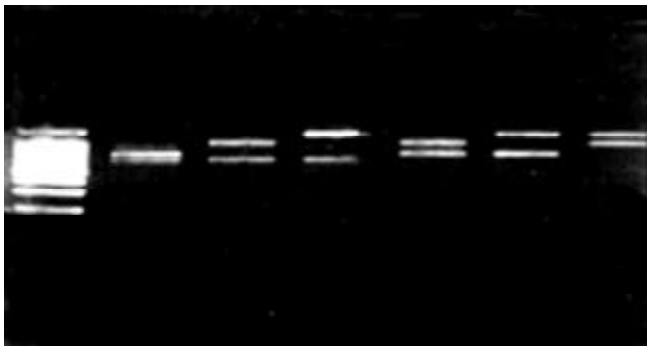

Figure1 PCR products of two types of viruses
M:DNA ladder,A: HAV and PV, B: HAV and CV,C: HAV and EV; D: PV and CV, E: PV and EV,F: CV and EV

Thirdly, three kinds of viral RNA were tested in the multiplex PCR, and given similar results (Figure2).

Fourthly, all four kinds of viral genome RNA were detected, and produced four bands which could be differentiated by the band size on the gel (Figure 3).

To confirm the specificity of the multiplex PCR products, semi-nested PCR was performed. For all the four strains tested gave positive results (Figure 4).

Figure2 PCR products of three types of viruses

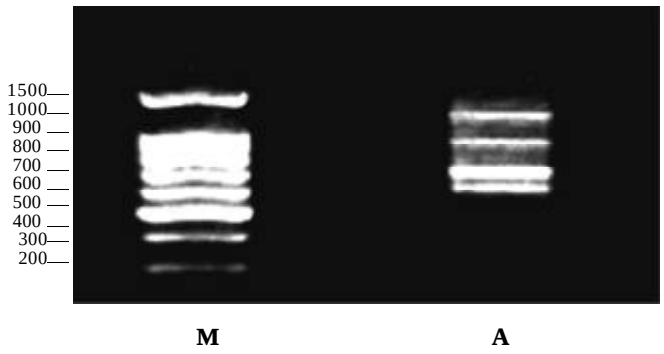

Figure3 PCR products of four types of viruses
M:DNA ladder,A: poliovirus 1(671bp), Coxsackie virus B3 (1084bp), Echo virus 9(1128bp),and HAV(589bp)

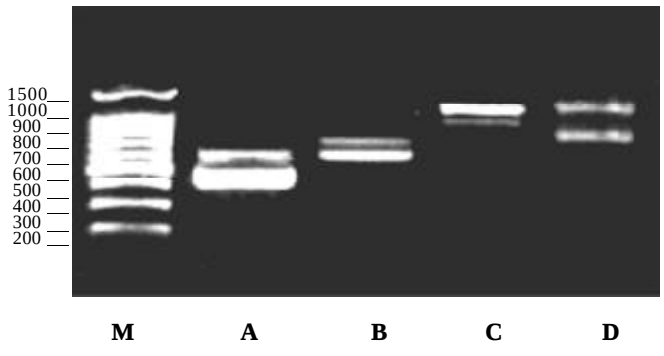

Figure4 Semi-nested PCR products of four types of viruses
M:DNA ladder,A: HAV(589,432bp) ,B: Poliovirus 1(671,571bp), C: Coxsackie virus B3(1084,870bp), D: Echo virus 9(1128,730bp)

Sensitivity of PCR

The detection sensitivity of multiplex PCR was similar to that of monoplex RT-PCR which was 24 PFU for Poliovrus,21 PFU for Coxsackie virus,60 PFU for Echovirus and 105 $TCID_{50}$ for HAV. The minimum amount of enteric viral RNA detected by semi-nested PCR was equivalent to 2.4 PFU for Poliovrus, 2.1 PFU for Coxsackie virus, 6.0 PFU for Echovirus and 10.5 $TCID_{50}$ for HAV (Table 2). The method achieved a 10 folds higher sensitivity than that of multiplex PCR.

Detection of viral genome after concentration

A tap water with and without seeding enteroviruses were collected for testing. Viruses added in the 10 liters of water which were not concentrated in primary could not be detected by the multiplex PCR or semi-nested PCR, even when 200-1 000 PFU or $TCID_{50}$ of viruses were seeded. However, viruses seeded in the waters which were concentrated with electropositive filter media could be detected by multiplex PCR and semi-nested PCR and obtained the similar sensitivity with that from cell cultures.

50 liters of tap water, or river water, or 5 liters of sewage, or 10 liters of ocean water were concentrated with electropositive filter media, and the virus RNAs were extracted from the concentrates. The multiplex PCR and semi-nested PCR were used to amplify the enteric viruses RNA. It is found that only Poliovirus RNA could be detected from the concentrate from 50 liters river water, other enteroviruses were not detected .

Table 2 Sensitivity of semi-nested-PCR for different viruses

	Virus concentration (PFU)				
Viruses	10^3	10^2	10^1	10^0	10^{-1}
Poliovirus	+	+	+	+(2.4)	-
Coxsackie virus B3	+	+	+	+(2.1)	-
Echovirus 9	+	+	+	+(6.0)	-
Three viruses	+	+	+(10.5)	-	-

DISCUSSION

In our studies, cell culture and PCR are combined together to improve the detection sensitivity and specificity . For the cell culture method, it has the advantages of large volume of testing water and high sensitivity. Viable viruses can be fostered and reproduced even if there is existence of only one type. But it is poor in specificity[15]. Types of virus can' t be distinguished according to pathological changes cell and immunology method is needed to make further identifications. So it is heavy, complicated and time consuming (at least 3 days; it will take 6-8 weeks to identify hepatitis A virus) to implement the test. As for PCR, it has the advantages of high specificity and simpler operation. But its sensitivity can' t come up to the testing standards owing to its small testing size, and the same positive results are obtained no matter the virus is infectious or not so long as nucleic acid is complete. The improved cell culturing-PCR technique combines the high sensitivity of cell culture with the high specificity of PCR together ,and avoids the shortcomings of low specificity and long testing period of cell culture, only two or four days are needed to detect Poliovirus, Coxsackie virus, Echovirus or HAV (cell culture for one or three days), thus two thirds testing time of cell culture is saved. Furthermore, cell culture dilutes the substances which play inhibiting effect on PCR in water, which further improves the sensitivity of PCR. In addition, this technique is only used to test the infectious viruses in water, hence inconsistency of PCR results with actual infectivity can be avoided [16].

The accuracy and reliability are ensured by using semi-nested PCR to identify PCR products. The techniques used at present to determine PCR products are Southern hybridization, PCR- depended DNA fingerprint pattern, nucleic acid sequencing and nested PCR, etc.[3,4,6]. Southern blot is poor in sensitivity and very complicated to handle [17-24]. It is generally taken as tool enzyme in molecule cloning and demands enzyme chip points existing in the expanded segment; DNA fingerprint pattern is poor in specificity with unstable results; nucleic acid sequencing is complicated, costly and low in efficiency; while

nested PCR has many strong points. It is not only good in specificity and sensitivity but also easy to handle and is low in price[4,25]; semi-nested PCR has similar principles and functions as that of nested PCR. It further cuts down the cost by saving a strip of primer.

The general primer multiplex-PCR is established for detection of four kinds of enteroviruses in our studies. There were many shortcomings in the researches prior to ours, such as, only one virus can be detected at one time using conventional PCR so it can't meet the needs of practical application; Tsai *et al*[6] used multiplex-PCR to detect Poliovirus, Hepatitis A virus and Rotavirus at one time. Their technique required more primers and these primers interfere with each other, making it more difficult to test viruses for three types or more; Zoll *et al*[7] employed general primer PCR technique to detect Poliovirus, Coxsackie virus, Echo virus and new enterovirus. But their method can only show whether there is existence of enterovirus or not. It can not distinguish the types of virus and is impossible to detect hepatitis A virus. Namely, general primer multiplex-PCR combines the general primer with multiplex PCR, giving consideration to the strong points of the two techniques and overcoming the weak points of each. Six primers are used in one reacting tube and four types of enteroviruses can be detected in one reaction while in conventional PCR, eight strips of primer are required.

The incidence of Poliovirus in developing countries is 4‰ while in developed countries, the infection of Poliovirus is of less clinical significance but it is generally used as an indicating virus in water[25,11]. Coxsackie virus and Echo virus can lead to diseases such as aseptic meningitis, viral myocarditis, diarrhea etc. Because group A Coxsackie virus is hard to culture and the virus source is very difficult to ensure, it is not tested hereon. To sum up, the technique can be used to detect Poliovirus, group B Coxsackie virus, Echo virus and Hepatitis A virus. Nearly all viruses can be detected among enteroviruses except group A Coxsackie virus.

Abstract

AIM: **The widespread use of antibacterial therapy has been suggested to be the cause for the decline in the prevalence of *Helicobacter pylori* infection. This study examine the serial changes of urea breath test results in a group of hospitalized patients who were given antibacterial therapy for non-gastric infections.**

METHODS: **Thirty-five hospitalized patients who were given antibacterial therapy for clinical infections, predominantly chest and urinary infections, were studied. Most (91 %) patients were given single antibiotic of either a penicillin or cephalosporin group. Serial ^{13}C-urea breath tests were performed within 24 hours of initiation of antibiotics, at one-week and at six-week post-therapy. *H. pylori* infection was diagnosed when one or more urea breath tests was positive.**

RESULTS: **All 35 patients completed three serial urea breath tests and 26 (74 %) were *H. pylori*-positive. Ten (38 %) *H. pylori*-infected patients had at least one negative breath test results during the study period. The medium delta ^{13}C values were significantly lower at baseline (8.8) than at one-week (20.3) and six-week (24.5) post-treatment in *H. pylori*-positive individuals (P=0.022). Clearance of *H. pylori* at six-week was only seen in one patient who had received anti-helicobacter therapy from another source.**

CONCLUSION: **Our results suggested that one-third of *H. pylori*-infected individuals had transient false-negative urea breath test results during treatment with antibacterial agent. However, clearance of *H. pylori* infection by regular antibiotic consumption is rare.**

Leung WK, Hung LC-T, Kwok CK-L, Leong RW-L, Ng DK-K, Sung JJ-Y. Follow up of serial urea breath test results in patients after consumption of antibiotics for non-gastric infections.*World J Gastroenterol* 2002; 8(4):703-706

INTRODUCTION

The rediscovery of *Helicobacter pylori* in 1984 had revolutionized our understanding of gastroduodenal diseases [1]. This bacterium is now generally considered to be the most important cause of peptic ulcer diseases, gastric adenocarcinoma and MALT lymphoma of the stomach[2, 3]. Unless given appropriate antibiotic treatment, most infected individuals will remain infected throughout their lifetime. Spontaneous clearance of infection, particularly in adult, is rare[4, 5].

Interestingly, recent epidemiological studies suggest a gradual reduction in the prevalence of *H. pylori* infection, particularly in developed countries[4]. This decline in *H. pylori* prevalence is accompanied by a parallel reduction in the incidence of gastric carcinoma[6]. The reason for this decrease remains unknown for the moment but widespread use of antibiotics in the community has been speculated to be an important cause for this decline. This study sought to determine the serial changes of urea breath test in patients after taking antibacterial agents given for conditions other than *H. pylori* infection. The aim is to elucidate the effects of antibacterial agents on urea breath test results and determine whether antibacterial therapy given for concomitant infections would result in clearance of *H. pylori* infection.

MATERIALS AND METHODS

Study design

Patients who were hospitalized for clinical infections, other than gastrointestinal tract infection, and requiring the use of antibiotics were recruited. The prescription of antibacterial agent was at the discretion of the attending clinicians. Patients were excluded if they were pregnant, had previous gastric surgery, had previously received anti-helicobacter treatment, or had been using acid-suppressive agents or antibiotics in the recent six weeks. For all eligible patients, informed consent was obtained from the patients or their parents. Since it is unethical to delay or withhold anti-bacterial therapy, urea breath test was performed as soon as possible but usually performed after the initiation of the antibacterial agents. All urea breath tests, however, should be performed within 24 hours of admission. Subsequent urea breath tests were repeated at one-week and at six-week after the completion of antibiotics. Drug history during the study period, including acid suppressive therapies and antibiotics, was recorded. All patients diagnosed with *H. pylori* infection were offered *H. pylori* eradication therapy at the conclusion of this study. The study protocol was approved by the Clinical Research Ethics Committees of the Chinese University of Hong Kong and the Kwong Wah Hospital of Hong Kong SAR.

^{13}C urea breath test

^{13}C-urea breath test (UBT) was performed in all patients, adult or children, following the same protocol. All patients were fasted for a minimum of four hours and were then given a citric acid test meal to delay gastric emptying. A 75-mg ^{13}C-urea tablet dissolved in water was then given. Breath samples

were collected before the test meal and 30 minutes after the ingestion of the urea solution. Two devices, a 10-ml glass tube and a sealed aluminum bag, were used for collection of exhaled air. The difference in $^{13}CO_2$ between the two breath samples was analyzed by both the isotope ratio mass spectrometry (Europa Scientific, Crewe, UK) and the infrared spectrometer (FANci2, Fischer Analysen Instrumente, Leipzig, Germany). A concordant delta $^{13}CO_2$ value greater than 5 was regarded as a positive result as described previously [7].

Determination of H. pylori infection status

Since none of these patients had indication for endoscopy, *H. pylori* infection status was determined by the non-invasive urea breath test. Patients were classified as *H. pylori*-positive when one or more of the three consecutive breath test results tested positive. This was based on the assumptions that urea breath test was accurate in diagnosing *H. pylori* infection, and that natural acquisition of *H. pylori* infections was extremely rare [4,5]. Serology test (ASSURE; Genelabs Diagnostics, Singapore) was used in patients with three consecutive negative urea breath tests for the detection of IgG anti-*Helicobacter* antibody to rule out the possibility of false negative breath test results. This serology test has been previously validated in our population[8].

Statistics

All statistical analysis was performed by GraphPad Prism version 2.01 (San Diego, CA, USA). Comparisons of the delta ^{13}C values among the three consecutive urea breath tests were made by Kruskal-Wallis test. Post-hoc analysis was performed by Dunn's multiple comparison test.

RESULTS

Patients' characteristics

A total of 35 patients were examined in this study (median age=66 years, range 5-81; 13 male and 22 female). Two study subjects were less than 18 years of age. The primary diagnoses of these patients were chest infection (n=20), urinary tract infection (n=12) and other infections (n=3). Thirty-two (91 %) patients received a single antibiotic whereas three (9 %) received two antibacterial agents during the hospitalization period. All patients received a one- to two-week course of standard dose penicillin (n=20) or cephalosporin (n=15) during the study period. Intravenous route was initially given in 25 (71 %) patients whereas the rest received oral antibiotics throughout the hospitalizations. One patient also received a course of anti-*Helicobacter* therapy from his primary care physicians during the follow up period.

Urea breath test

All 35 patients completed the three consecutive urea breath tests. By using the pre-defined criterion, 26 (74 %) patients were considered to be *H. pylori*-positive. None of the remaining 9 patients with negative breath tests had anti-*Helicobacter* antibody detected.

The serial breath test results of the study patients were given in Table 1. Ten (29 %) *H. pylori*-positive patients had at least one negative urea breath test results during the study period. Of these 10 patients, 7 had the first test result negative whereas the second and/or third test was (were) positive. Two patients had a single negative test result at one-week post-treatment. Among the 26 *H. pylori*-positive patients, only one was found to have a negative test result at six-week post-antibiotic treatment. However, this patient had been prescribed a one-week course of proton-pump inhibitor-based triple therapy for dyspepsia by his primary care practitioner two weeks after discharge from hospital. It thus appeared that the apparent clearance of *H. pylori* was attributed to the specific anti-*Helicobacter* therapy instead of the first course of antimicrobial agent.

Table 1 Results of serial urea breath tests in the study patients

UBT			
Baseline	1-wk post-antibacterial therapy	6-wk post-antibacterial therapy	No.of patients
Neg	Neg	Neg	9
Neg	Neg	Pos	1
Neg	Pos	Pos	6
Pos	Neg	Pos	2
Pos	Pos	Neg	1*
Pos	Pos	Pos	16
		Total	35

*This patient was given specific anti-Helicobacter therapy between second and third urea breath tests by his primary care physicians. Pos=positive; Neg=negative

For all *H. pylori* infected patients, the median delta $^{13}CO_2$ values taken at baseline, one-week and six-week post-treatment were 8.8, 20.3 and 24.5 respectively (P=0.022). Post-hoc analysis showed that the median value measured at baseline was significantly lower than at six-week post treatment (P<0.05). On the other hand, the difference between the first and second urea breath tests did not reach statistical significance (Figure 1).

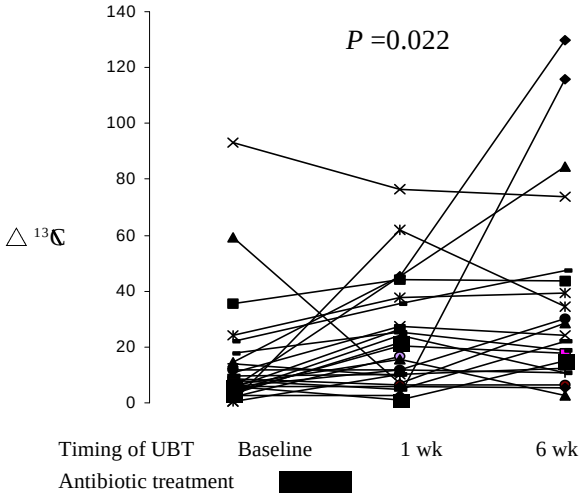

Figure 1 Changes in the delta ^{13}C values ($\Delta^{13}C$) of urea breath tests after consumption of antibiotics in *H. pylori*-infected patients. The broad line indicated the duration of antibiotics consumption. A delta ^{13}C value of greater than 5 was regarded as a positive result. There was a significant difference between the median delta ^{13}C values taken at baseline, one-week and six-week post treatment (P=0.022). Post-hoc analysis showed that only the difference between the first and the third urea breath tests reached statistical significance (P<0.05).

All patients who had a transient negative urea breath test result were given antibiotics by the intravenous route whereas

10 (56 %) of the *H. pylori*-infected patients with persistent positive breath test results received intravenous antibiotics ($P = 0.05$). On the other hand, the choice and duration of antibiotic therapy did not correlate with false negative breath test results.

DISCUSSION

Urea breath test is considered to be the best non-invasive test for diagnosis of *H. pylori* infection, which is useful in both diagnosis and post-treatment testing. However, it can be potentially influenced by drugs that cause suppression of *H. pylori* and hence, its urease activity. In this regard, the proton pump inhibitor is the drug that is most extensively examined. Laine et al showed that 33 % of *H. pylori*-infected patients had a negative breath test result when receiving standard dose of lansoprazole for the treatment of gastro-esophageal reflux disease[9]. The breath test results returned positive in all patients at 14-day after stopping the treatment. Although antibiotic combinations are used in the treatment of *H. pylori*, the effect of concomitant antibacterial agents given for other conditions, usually single drug, on urea breath test results has not been evaluated.

In this study, we prospectively studied the serial changes of urea breath tests in a small group of hospitalized patients who were given antibiotics for infections other than *H. pylori*. Despite the small number of patients examined, the results of this study could provide insights into the effects of antibacterial therapy on urea breath test results and hence *H. pylori* statuses post-treatment. Unlike proton pump inhibitor with limited choices and relatively well-defined standard doses, the choices of antibiotics and the duration of therapy are highly variable. Most of our study subjects suffered from chest or urinary tract infections and were given a 1-2 week course of penicillin or cephalosporin. As shown by our results, antibacterial agents frequently (38 %) caused false-negative breath test results in *H. pylori*-infected individuals. This was best illustrated by the significantly lower delta $^{13}CO_2$ value of first test results while receiving antibacterial treatment. This transient suppression occurred within 24 hours of antibiotics treatment and could last for more than one-week post-treatment. Nevertheless, none of the study subjects, except the one who had received specific anti-*Helicobacter* treatment, had a persistent negative breath test at 6-week.

This observation is important for three reasons. First, the widespread use of antibiotics in the community for various infections have been speculated to be a major reason for the decline in prevalence of *H. pylori* infection and possibly the decline in gastric cancer incidences worldwide. This is supported by a recent epidemiological study that demonstrated a reduced risk of gastric cancer among patients who were given antibiotic prophylaxis for hip replacement surgery[10]. Their protective effect is presumably due to the serendipitous eradication of *H. pylori* by the antibiotics, which leads to subsequent reduction in the risk of development of gastric cancer. However, if one looks into the rate of disappearance of anti-*Helicobacter* antibody in patients who were given antibiotics, it was not significantly higher than control suggesting that the reduction in cancer incidences may not be directly related to the clearance of *H. pylori*, at least from serological point of view. In the present study, clearance of *H. pylori* after a single course of antibiotic is rare. Despite the *in vitro* sensitivity of *H. pylori*, the eradication rate of a single standard dose of antibacterial agent is extremely low, particularly with the use of penicillin and cephalosporin groups. Previous data showed that the best single therapy for *H. pylori* is clarithromycin[11]. Nonetheless, the use of two-week high dose clarithromycin (2 gram per day) could only achieve eradication of *H. pylori* in about one-third of the patients[11]. In practice, the success of eradication is low without acid suppressive agent such as proton pump inhibitors or bismuth compounds[12]. The second importance of this study is the potential risk of inducing acquired resistance with repeated exposure to antimicrobial agent. Exposure of *H. pylori* to antimicrobial agents without eliminating the bacteria poses a major risk of inducing acquired resistance. This may offer a plausible explanation for the rising incidence of antibiotic resistance in countries where there is high consumption of antibiotics[13-15]. The third reason for the importance of this paper would be that treatment of antibiotics affect diagnostic accuracy of UBT.

The prevalence of *H. pylori* infection in this study (74 %) is much higher than previously reported in local dyspeptic patients. This is most likely due to random effect in study involving small number of patients. Ideally, baseline urea breath test should be performed prior to the administration of antibiotics and biopsy-based diagnosis should be used for the proper documentation of *H. pylori* status, but for ethnical reasons, these problems are difficult to overcome. However, we have performed serology tests in patients who had negative urea breath tests to detect presence of anti-helicobacter antibody. Thus, the chance of misclassifying *H. pylori*-positive patient as negative would be minimal.

In conclusion, this study showed that over one-third of patients had a transient suppression of urease activity and hence, false-negative urea breath test results during treatment with antibacterial agents. This usually reverts back to normal at six-week post treatment and thus, testing for *H. pylori* should be postponed accordingly. On the other hand, spontaneous clearance of *H. pylori* by antibacterial agent given for other conditions is extremely rare, and could not account for the fall in prevalence of *H. pylori* in most developed countries.

Abstract

AIM: **Stress-activated signaling pathways responsible for hepatic ischemia reperfusion injury and their modulation by protective interventions are widely unknown. Preconditioning of rat livers with Atrial Natriuretic Peptide (ANP) attenuates ischemia reperfusion injury (Gerbes et al. *Hepatology* 1998, 28: 1309-1317). Since ANP has recently been shown to be a regulator of the p38 MAPK pathway in endothelial cells (Kiemer et al. *Circ Res* 2002, 90:874-881), aim of this study was to investigate activities of MAPK during ischemia and reperfusion and effects of ANP on MAPK.**

METHODS: **Rat livers were perfused with KH-buffer in the presence or absence of ANP for 20 min, kept in cold UW solution for 24 h, and reperfused for up to 120 min. Activities of p38 MAPK and JNK was determined by *in vitro* phosphorylation assays using MBP and *c-jun* as substrates. After SDS/PAGE electrophoresis, gels were quantified by phosphorimaging.**

RESULTS: **Activity of p38 MAPK in control organs decreased in the course of ischemia and reperfusion by 85%, whereas ANP increased p38 activity by up to 30-fold. JNK activation of control livers increased in the course of ischemia and reperfusion by up to three-fold. This increase in JNK activity was slightly elevated in ANP preconditioned organs.**

CONCLUSION: **This work represents a systematic investigation of MAPK activation during liver ischemia and reperfusion. Employing ANP, for the first time a pharmacological approach to modulate these central signal transduction molecules is presented.**

INTRODUCTION

Ischemia reperfusion (I/R) injury is the main cause of severe complications following liver transplantation [1,2]. Therefore, measures to reduce I/R injury are of highest clinical interest. However, there is still incomplete understanding of the pathomechanisms leading to I/R injury and of signalling pathways responsible for protective interventions.

Mitogen activated protein kinases (MAPK) are dually phosphorylated serine/threonine protein kinases (for review see[3,4]. They regulate an extensive range of cellular processes including gene transcription, cytoskeletal organization, metabolic homeostasis, cell growth, and apoptosis [3,4]. They represent signalling molecules which can be activated by various cellular stresses and cytokines and which therefore play a crucial role in the stress response[5]. Their role in the stress response, however, either detrimental or protective, seems to strongly depend on the system looked at[6].

In mammalian cells, three closely related parallel cascades of MAPK are known, the p38 MAPK, the *c-jun* N-terminal kinase (JNK), as well as the extracellular signal-regulated protein kinases p42/p44 (ERK)[4]. ERKs are critical regulators of gene transcription in cell proliferation and differentiation, while JNK and p38 pathways seem to be involved in cellular responses to environmental stresses and inflammatory cytokines[3].

Several groups have observed activation of MAPK in the course of *warm* ischemia and reperfusion[7-11] whereas there is only limited information on activation of MAPK after *cold* ischemic storage[12-14]. However, these reports show controversial data on the activation pattern of MAPK.

Since recent data show that protective preconditioning strategies, such as whole animal heat shock[15,16] or short time hypoxic[17] or ischemic preconditioning[18,19] significantly activate stress-activated MAPKs, these kinases are suggested as central signal transduction pathways mediating protection from I/R injury. Therefore, we felt that a systematic investigation of MAPK activation after cold ischemic storage should lead to a more complete understanding of their role in I/R injury. Moreover, the potential pharmacological modulation of MAPK by the hepatoprotective Atrial Natriuretic Peptide (ANP) should be investigated. This cardiovascular hormone has previously been shown to attenuate I/R injury after both warm[20] and cold[21] ischemia of the rat liver. Protection conveyed by ANP involves the attenuated activation of pro-inflammatory transcription factors and the reduced expression of TNF-a[22] as well as induction of heat shock proteins[23]. The initial signalling events responsible for the protective potential of hormonal preconditioning by ANP, however, are still unknown. ANP has recently been reported by us and others as a regulator of the p38 MAPK cascade[24,25]. By investigating an effect of ANP on MAPK activation, an information on signalling events potentially involved in liver protection should be obtained.

MATERIALS AND METHODS

Materials

Rat ANP 99-126 was purchased from Calbiochem/ Novabiochem, Bad Soden, Germany. [γ^{32}P]-ATP (3000 Ci/ mmol) was from Amersham Pharmacia (Braunschweig, Germany);Complete® was from Roche (Heidelberg, Germany). Recombinant *c-jun* 1-79, polyclonal rabbit anti-p38, and anti-JNK antibodies were purchased from Calbiochem-Novabiochem (Bad Soden, Germany). Protein A-agarose, myelin basic protein, and all other materials were from Sigma, Deisenhofen, Germany.

Methods

Liver perfusion Male Sprague-Dawley rats weighing 250-300 g were purchased from SAVO (Kisslegg, Germany) and housed in a climatized room with a 12-hour light-dark cycle. The animals had free access to chow (Standard-Diet, Altromin 1314 Lage, Germany) and water up to the time of the experiments. After anaesthetizing the animals with pentobarbital (50 mg/kg body weight, intraperitoneally), the portal vein was cannulated and the livers were perfused *in situ* with hemoglobin-free and albumin-free, bicarbonate-buffered Krebs-Henseleit (KH) solution (pH 7.4,37 ℃) gassed with 95% O_2 and 5 % CO_2. The perfusion medium was pumped through the livers with a membrane pump at a constant flow rate of 3.0-3.5 ml×min^{-1}×g liver^{-1} in a non-recirculating fashion. After 10 min controlling the stability of the system, ANP (200 nM) was added to the perfusate for 20 min, livers were then perfused with 30 ml of cold (4 ℃) University of Wisconsin (UW) solution for 1 min. Then the organs were kept in 150 ml UW solution at 4 ℃ for 24 h. Following the period of ischemia, livers of each group were reperfused with KH buffer for 2 h. At the indicated times, i.e. before ischemia, at the end of ischemia and after 45 and 120 min of reperfusion livers were snap-frozen and stored at -85 ℃ until further analysis. Five independent experiments were performed.

The "Principles of laboratory animal car" (NIH publication No 86-23, revised 1985) as well as the German Law on the Protection of Animals were followed. The study was registered with the local animal welfare committee.

Immunoprecipitation and in vitro phosphorylation assay Tissue lysates were prepared from frozen liver sections. Briefly, tissue samples (100 μg) were homogenized in ice-cold lysis buffer (containing 2 mM EDTA, 137 mM NaCl, 10 % glycerol, 2 mM tetrasodium pyrophosphate, 20 mM Tris, 1 % Triton® ×-100, 20 mM sodium glycerophosphate, 10 mM sodium fluoride, 2 mM sodium vanadate, 1 mM PMSF, 1×Complete®) with a dounce homogenizer, and centrifuged at 11 180×*g* for 10 min at 4°C. Aliquots of the supernatant were taken for determination of protein concentrations and the tissue extract was frozen at -85°C. The protein concentrations were estimated after the method of Pierce. Equal amounts of protein were incubated with the respective antibody (1.5 μl of anti-p38, 3 μl of anti-JNK; polyclonal rabbit antibodies, Calbiochem-Novabiochem, Bad Soden, Germany) shaking for 2 h. Afterwards immunoprecipitation was performed with protein A agarose (5 μl) shaking overnight at 4 °C. After centrifugation (11 180×*g*, 4 min, 4°C) the precipitates were washed three times with lysis buffer and once with kinase buffer (containing 20 mM Hepes pH 7.5, 20 mM $MgCl_2$, 25 mM sodium glycerophosphate, 100 μM sodium vanadate, 2 mM DTT). Immunoprecipitates were resuspended in 20 μl of kinase buffer, 3 μl of substrate solution (1 mg/300 μl MBP for p38, Sigma, Deisenhofen, Germany and 1 mg/ml of recombinant c-jun 1-79, Calbiochem-Novabiochem, Bad Soden, Germany) and a 10 μl volume of ATP mix was added, containing kinase buffer with 10 mCi/ml [γ^{32}P]-ATP, (3 000 Ci/mmol, Amersham, Braunschweig, Germany), 5 mM ATP and 2 M $MgCl_2$. The reaction mixture was incubated at 30 ℃ for 20 min shaking. Phosphorylation was stopped by the addition of 6 μl 5× Laemmli buffer and heating for 3 min at 90 ℃. 30 μl of the reaction mixture were resolved in a 12 % (MBP) or 15 % (*c-jun*) SDS polyacrylamide gel in a Laemmli system at 200 V. Band intensities were quantified by phosphorimaging (Packard, Meriden, USA). Ratio of digital light units (DLU) of respective values *vs.* controls were determined.

Statistical analysis

Data are expressed as means ± SEM of three to five independent experiments. A P value of < 0.05 was considered significant (unpaired student' s t test, Graph Pad Prism, version 3.02).

RESULTS

MAPK activities in the course of ischemia and reperfusion

At the end of cold ischemic storage for 24 h rat livers displayed a significantly reduced activation of p38 MAPK activity (Figure 1). The p38 activity even further decreased in the course of reperfusion and at the end of the 120 min reperfusion period displayed only 15 % of pre-ischemic values (Figure 1).

The *c-jun* N-terminal kinase (JNK) was activated in the reperfusion period (up to 3-fold). No increase of *c-jun* phosphorylation could be measured at the end of ischemia (Figure 2).

Influence of ANP on MAPK activities

When rat livers were pre-conditioned by adding 200 nM of ANP to the pre-ischemic perfusion buffer the livers displayed a completely different pattern of MAPK activities. At the end of the preconditioning period ANP treated organs displayed a tremendous increase in p38 activity by 12-fold (Figure 3). In the course of the experiment the p38 activity even further increased compared to the respective control organs (Figure 3).

ANP did not affect JNK activity during preconditioning. However, ANP-pretreated organs showed elevated post-ischemic JNK activities (Figure 4).

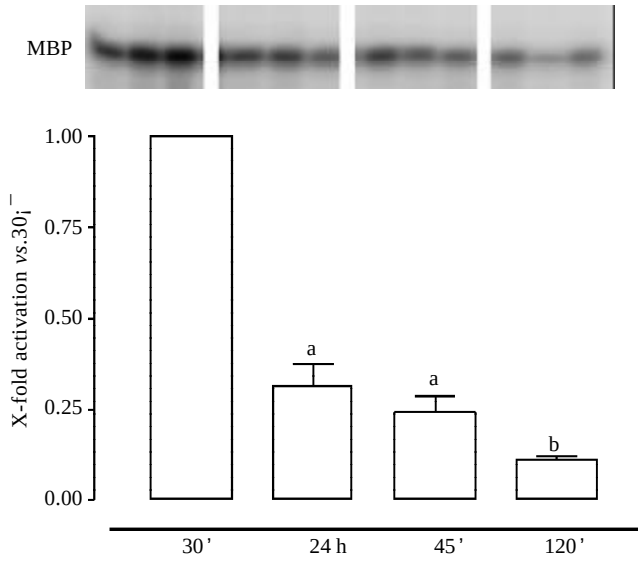

Figure 1 p38 MAPK activities in the course of ischemia and reperfusion. Livers were perfused through the portal vein with KH-buffer and snap frozen at 30 min, after 24 h of ischemic

storage in UW solution (4°C), and after 45 and 120 min of reperfusion. Deep-frozen organs were lysed and assayed for p38 MAPK activity as described under "Materials and Methods". Determination of density light units was performed by phosphorimaging and values for the respective time points are expressed as ration *vs.* values for pre-ischemic (30 min) organs. Bars show means ± SEM of three independent perfusion experiments. [a]$P<0.05$ and [b]$P<0.01$: statistically different from pre-ischemic 30 min controls.

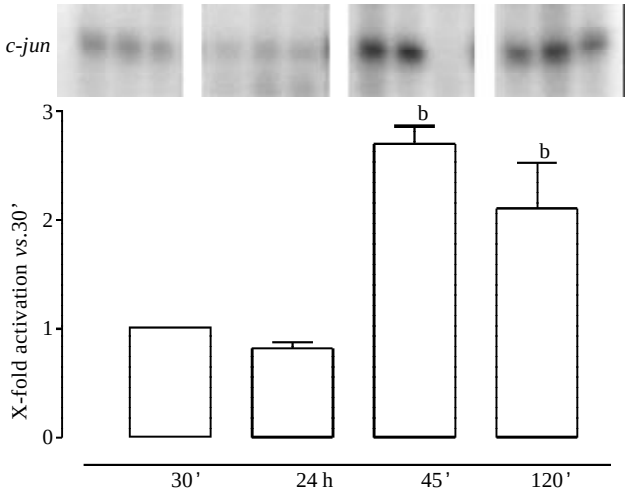

Figure 2 JNK activities in the course of ischemia and reperfusion. Isolated perfused rat livers were snap frozen at 30 min, after 24 h of ischemic storage in UW solution (4°C), and after 45 and 120 min of reperfusion. Deep-frozen organs were lysed and assayed for MAPK activity as described under "Materials and Methods". Determination of density light units was performed by phosphorimaging and values for the respective time points are expressed as ration *vs.* values for pre-ischemic (30 min) organs. Bars show means ± SEM of three independent perfusion experiments. [b] $P<0.01$: statistically different from pre-ischemic 30 min controls.

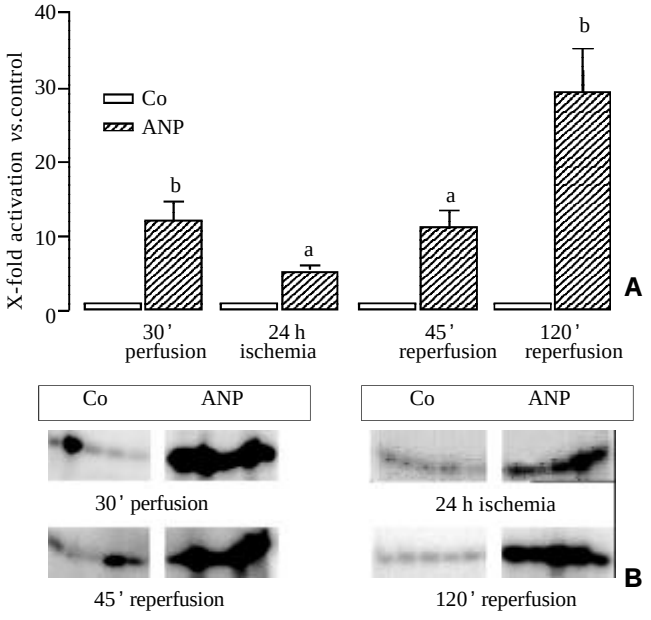

Figure 3 ANP increases the activity of p38 MAPK in the course of ischemia and reperfusion. Livers perfused with KH-buffer in the presence or absence of ANP (200 nM) underwent 24 h of cold ischemic storage and were snap frozen at the respective time points. p38 MAPK activity was determined as described under "Materials and Methods". Density light units were determined by phosphorimaging and values for ANP-treated organs were divided by mean values for control organs at the respective time points. Panel A: Bars show means ± SEM of five independent perfusion experiments with [a]$P<0.05$ and [b]$P<0.01$: statistically different from controls at the respective time point. Panel B: Data show representative autoradiograms.

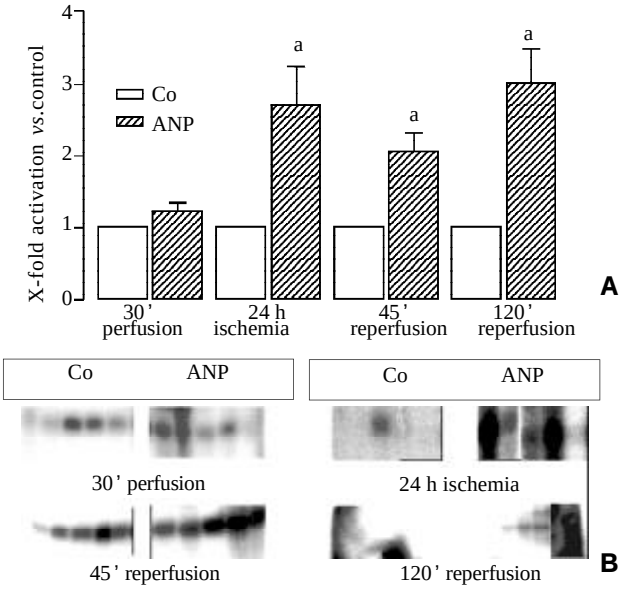

Figure 4 ANP and JNK activity. Isolated perfused livers were either left untreated or preconditioned with ANP (200 nM) for 20 min. After 24 h of ischemia and up to 120 min of reperfusion JNK activity was determined as described under "Materials and Methods". Determination of density light units was performed by phosphorimaging and values for ANP-treated organs were divided by mean values for control organs at the respective time points. Panel A: Bars show means ± SEM of five independent perfusion experiments with [a]$P<0.05$: statistically different from controls at the respective time point. Panel B: Data show representative autoradiograms.

DISCUSSION

This work represents a systematic characterization of the stress-activated p38 MAPK and JNK activities during ischemia and reperfusion of the isolated perfused rat liver. The following results were obtained: (I) p38 shows a decreasing activity in the whole course of ischemia and reperfusion whereas (II) JNK is only activated during reperfusion. (III) Even more importantly, our paper reports for the first time that preconditioning with Atrial Natriuretic Peptide exerts a tremendous increase of p38 MAPK activation but shows no effect on JNK.

Our data on the time course of MAPK activation during cold ischemia and reperfusion adds further information to the increasing discussion on the role of p38 MAPK during I/R. Decreased p38 activity at the end of cold ischemia was also seen by Iesalnieks *et al*[14] using a rat liver transplantation model, but not in the work of the Brenner group which reported no change of p38 activity[12]. After transplantation activation[14] as well as no effect on p38 MAPK[12] has been demonstrated. Since p38 is referred to as a stress-induced MAPK[5] the decline of p38 MAPK activities we observed in ischemia as well as reperfusion might surprise. However, p38 activity might not solely reflect a stress response, but also mediate the induction of protective mechanisms.

For JNK convincing evidence is available that this MAPK is stimulated in the course of reperfusion. The data presented

here are supported by several other observations of increased activity of JNK during reperfusion for models of both cold[12,14] and warm[7] ischemic livers.

Taken together, MAPK are affected by I/R. The differences between our data and other work most likely reflect the different experimental set-up and therefore different basal MAPK activities and time dependency of activation.

The most important question arising from this discussion is the role of MAPKs in I/R injury. To address this question known protective strategies have to be examined for their effect on MAPKs during I/R. Up to now, these kinds of studies in the liver are quite rare. The outcome of our work, namely that preconditioning with ANP leads to a striking increase of p38 MAPK activities but is without effect on JNK, is therefore of great importance. Both hyperthermic[26] as well as ischemic[18,19] preconditioning have also been shown to represent protective strategies against I/R injury. Both JNK and p38 MAPK were reported to be activated by hyperthermia[15,18] and a short time ischemic period of 10 min as used for ischemic preconditioning [18,19] was shown to activate JNK[8].

Our data point to p38 MAPK activation as a central signal transduction pathway of hepatoprotection during I/R. Hypoxic preconditioning of hepatocytes has recently been shown to also activate p38 MAPK[17], thus supporting our assumption. For the heart, in fact, activation of p38 is reported to be a key signal in protection by ischemic preconditioning[27]. Moreover, the hepatoprotective action of CO has very recently been reported to be exerted *via* p38 MAPK activation[28].

ANP must be administered at least 20 min before ischemia in order to protect against I/R injury of the rat liver[21]. Thus, the strong activation of p38 MAPK at the end of the preconditioning period i.e. *before* ischemia is suggested to be the crucial step in mediating hepatoprotection by ANP.

The meaning of increased MAPK activities by ANP at the end of reperfusion periods is less easy to explain. The augmented MAPK activities might simply reflect the increased number of vital hepatocytes in ANP preconditioned liver as compared to untreated tissue.

In summary, our data represent a systematic investigation of stress-activated MAPK in the course of ischemia and reperfusion. Second and even more importantly the pharmacological activation of MAPK as a mediator of preconditioning was achieved by the administration of the cardiovascular hormone ANP. The observation that protective strategies such as pre-treatment with ANP profoundly interact with the MAPK signalling cascade suggests them as crucial mediators of preconditioning.

Abstract

AIM: **To study the anti-inflammatory effects of cholecystokinin-octapeptide (CCK-8) on lipopolysaccharide (LPS)-induced endotoxic shock (ES) and further investigate its signal transduction pathways involving p38 mitogen-activated protein kinase (MAPK) and IkB-a.**

METHODS: **Eighty-four rats were divided randomly into four groups: LPS (8 mg • kg^{-1}, iv) induced ES; CCK-8 (40 mg • kg^{-1}, iv) pretreatment 10 min before LPS (8 mg • kg^{-1}); CCK-8 (40 μg • kg^{-1}, iv) or normal saline (control) groups. The inflammatory changes of lung and spleen, phagocytic function of alveolar macrophage, quantification of inflammatory cells in bronchoalveolar lavage (BAL) were investigated in rats by using hematoxylin and eosin (HE) staining, phagocytosis of Candida albicans and differential cell counting. Nitric oxide (NO) production in serum, lung and spleen was measured with the Griess reaction. The mechanism involving p38 MAPK and IkB-a signal pathways was investigated by Western blot.**

RESULTS: **Inflammatory changes of lung and spleen induced by LPS were alleviated by CCK-8, the increase of NO induced by LPS in serum, lung and spleen was significantly inhibited and the neutrophil infiltration in BAL was significantly reduced by CCK-8. The number of neutrophils was (52±10)×10^6 cells·L^{-1} in LPS group, while it decreased to (18±4)×10^6 cells·L^{-1} in CCK-8+LPS (P<0.01). The phagocytic rate of CCK-8 group increased to (62.49±9.49) %, compared with control group (48.16±14.20) %, P<0.05. The phagocytosis rate was (85.14±4.64) % in LPS group, which reduced to (59.33±3.14) % in CCK-8+LPS group (P<0.01). The results of phagocytosis indexes showed similar changes. CCK-8 may play an important role in increasing the expression of p38 MAPK and decreasing the degradation of IkB-a in lung and spleen of ES rats.**

CONCLUSION: **CCK-8 can result in anti-inflammatory effects, which may be related to activation of p38 MAPK and inhibition on the degradation of IkB-a.**

INTRODUCTION

Lipopolysaccharide (LPS), a main component of Gram-negative bacterial endotoxin[1], is the leading cause of sepsis or endotoxic shock (ES), and when administered experimentally to animals, it results in the same inflammatory response mimically. Physical stress such as infection can stimulate proinflammatory cytokine production and release. The overproduction of these cytokines has been postulated to contribute to the development of tissue injury[2]. The pathogenesis of inflammatory sepsis is also linked to the overproduction of nitric oxide (NO), a potentially toxic molecule, being possibly responsible in part for the cytotoxicity of the inflammatory process[3]. Nuclear factor (NF)-κB is a heterodimeric protein complex containing two members of the rel family of transcription factors, p50 and p65. At rest, the heterodimeric NF-κB complex is located in the cytoplasm bound to an inhibitory factor, I-κB. Upon stimulation, IκB-α is phosphorylated and proteolytically degraded or processed by proteasomes and other proteases. Free NF-κB then translocates into the nucleus where it binds to various gene promoter regions controlling the expression of various pro-inflammatory and proliferative agents[4]. NO augments the activation of NF-κB in macrophages and, therefore, may play a role in producing a positive cycle of inflammation[5]. One of the earliest responses to LPS is activation of the mitogen-activated protein kinase (MAPK) homolog p38. The p38 MAPK is involved in intracellular signals that regulate a variety of cellular responses during inflammation[6]. A slightly later cellular response to LPS is the activation of NF-κB, which does not require p38 kinase activity[7].

Cholecystokinin (CCK), a component from the gastrin-CCK family, first isolated from hog intestine, shows a widespread distribution in different organs and tissues. The sulfated carboxy-terminal octapeptide (CCK-8), isolated from the central nervous system and digestive tract, is the predominant active form. CCK-8 possessed both excitatory and inhibitory action on contractile activity of different regions of stomach in guinea pigs[8]. CCK-8 could antagonize the elimination of morphine on the potentiations of ACh to duodenal activities[9]. Besides the effects on the digestive tract, other biological actions of CCK-8 have been observed, for instance appetite inhibition and so on[10,11]. In the spleen, CCK-8 is formed in high abundance in the white pulp where it appears to surround cell clusters. It seems that CCK-8 increases the secretion of immunoglobulins *in vivo* [12], whereas it inhibits Molt-4 lymphoblast proliferation[13] and modulates mitogen-

induced lymphoproliferation and intracellular calcium mobilization *in vitro*[14,15]. CCK-8, a chemoattractant for human monocytes and rat macrophages[16], enhanceing human eosinophil chemotaxis induced by PAF and LTB4 in allergic patient[17] is a negative modulator of several murine macrophage and human neutrophil functions[18,19].

Our previous *in vivo* and *in vitro* study demonstrated that CCK-8 could protect animals from ES[20,21], which was related to its inhibitory effect on the overproduction of proinflammatory cytokines[22] and on the transcription of TNF-α[23]. In the present study, the effects of CCK-8 on NO production, inflammatory changes of lung and spleen induced by LPS and phagocytic function of rat alveolus macrophage and further on the p38 MAPK and IκB-α expression in lung and spleen were investigated.

MATERIALS AND METHODS

Materials

CCK-8 (sulfated), LPS (*E.coli* LPS, serotype 0111:B4), leupeptin, pepstatin A, Triton X-100 and p38 monoclonal antibody were all purchased from Sigma, RPMI-1640 from Gibcobrl, aprotinin from Boehringer, IκB-α polyclonal antibody from Santa Cruz. All other reagents used were of analytic grade.

Methods

Animal preparation[22] Sprague-Dawley rats (150-200 g BW, Experimental Animal Center of Hebei Province) were randomly assigned to four groups injected different agents via tail vein. For group receiving LPS, a bolus dose (8mg/ kg) of LPS was injected into the tail vein. For group of CCK-8+LPS, a bolus dose (40 μg/ kg) of CCK-8 was administered 10 min before the injection of LPS. Negative control animals received saline. CCK-8 (40 μg/ kg) was also administered alone in the other group.

Sample collection Animals were sacrificed at 2 h, 6 h or 12 h, spleen and lung were rapidly excised and rinsed of blood, and blood was taken and centrifuged to collect serum. The samples were stored at -80℃ for analysis of NO content. Additional groups of animals were sacrificed at 30 min and their lungs and spleens excised were analyzed for p38 MAPK and IκB-α expression.

Histological examination Rats were treated as described in animal preparation and sacrificed at 2 h, 6 h or 12 h after LPS administration. Lung and spleen were sliced into pieces and preserved in 10 % formalin. Tissue samples were embedded in paraffin, cut into 5-μm sections, and then assessed by routine staining with hematoxylin and eosin (HE) and examined by light microscopy.

Nitrate/nitrite analysis The samples (serum, spleen, lung) collected 2 h, 6 h or 12 h were analyzed. Tissues were homogenized with PBS (4℃, pH 7.2, 100 mg tissue/ml) and centrifuged at 12 000 rpm, 10 min. Supernatants and serum were assayed NO content based on the Griess reaction, which consists of measurement of stable end breakdown products of NO such as nitrite that are considered to be reliable markers for NO formation. The nitrite was converted to a deep purple compound and absorbance was read at 550 nm, and nitrite concentration was determined using $NaNO_2$ standards.

Phagocytic function Two hours after injection of LPS, bronchus alveolus lavage fluid (BALF) was obtained and macrophages were isolated from BALF by centrifugation (1 500 rpm, 10 min)[6]. Being washed with normal saline (NS), the cells were resuspended in RPMI-1640, adjusted to 10^6/ ml and incubated for 2 h. The adherent monolayer was washed with RPMI-1640 and then aliquots of Candida albicans (2×10^7 cells/ml medium), previously in water bath (100℃) for 30 min were added. After 60 min of incubation, the plates were washed with NS, fixed and stained and the number of yeasts ingested per 100 macrophages was counted. Phagocytosis rate and phagocytosis index were calculated according to the following equation:

Phagocytosis rate (%)= (macrophages with yeasts ingested/ total macrophages) %

Phagocytosis index = number of Candida albicans ingested / number of macrophages with Candida albicans ingested

Quantification of inflammatory cells Neutrophil influx was determined in the BALF samples obtained 2 h by differential cell counting. Total whole cell counts were obtained in BALF. The cells were smeared on slides and stained with Wrights-Giemsa stain. Three differential counts on 200 cells per slide were performed and the percentage of macrophages/ monocytes, lymphocytes and neutrophils were determined.

Western blot Lung and spleen were excised 30 min after injection of LPS. Tissues were homogenized in a buffer containing 50 mM Tris (pH7.5), 150 mM NaCl, 1 % TritonX-100, 0.5% deoxycholic acid, 0.1 % sodium dodecyl sulfate, 1 mM phenylmethylsulfonyl fluoride (PMSF), 10 mM NaF, 1mM sodium vanadate and a 40 μg/ml protease inhibitor cocktail and centrifuged at 18 000 rpm, 4 ℃, 10 min. Supernatants were fractionated on 12 % SDS-polyacrylamide gels, transferred to poly (vinylidene difluoride) membranes, and incubated with phospho-specific anti-p38 MAPK or IκB-α polyclonal antibody. Being washed three times in T-PBS, membranes were incubated in horseradish peroxidase-linked secondary antibody for 1 h at room temperature. Membranes were again washed three times with T-PBS and stained with diaminobenzidine (DAB).

Statistical analysis Data were reported as $\bar{x}\pm s$. Statistical differences between values from different groups were determined by one way ANOVA and Newman-Keuls *q* test. Significance was set at $P<0.05$.

RESULTS

CCK-8 alleviated inflammatory changes induced by LPS

Lung and spleen were harvested at 2 h, 6 h or 12 h. There were structural injury in LPS group and alleviated changes in CCK-8+LPS group at 2 h, while more significant changes at 6 h and 12 h. The lung of LPS-stimulated rats demonstrated widened septa of alveoli, diffuse infiltration and migration of acute inflammatory cells (PMN) accompanied by atrophied or disappeared alveoli, and slight alveolar atelectasis or emphysema. While in CCK-8+LPS group, the inflammatory changes were evident, but to a lesser extent. The spleen of LPS-stimulated rats showed hyperaemia in spleen sinusoids with concentrated red blood cells (RBC) and PMN, while it changes to a lesser extent in CCK-8+LPS group. There was not much difference between CCK-8 group and control group (Figure 1).

CCK-8 inhibited NO production

Studies of LPS-induced NO production in spleen, lung and serum showed increase in either nitrate or nitrite levels at 2 h, 6 h or 12 h after LPS administration. Significant increase was observed at 6 h, compared with that in control animals. CCK-8 produced inhibitory effect on increase of NO content induced by LPS (Table 1).

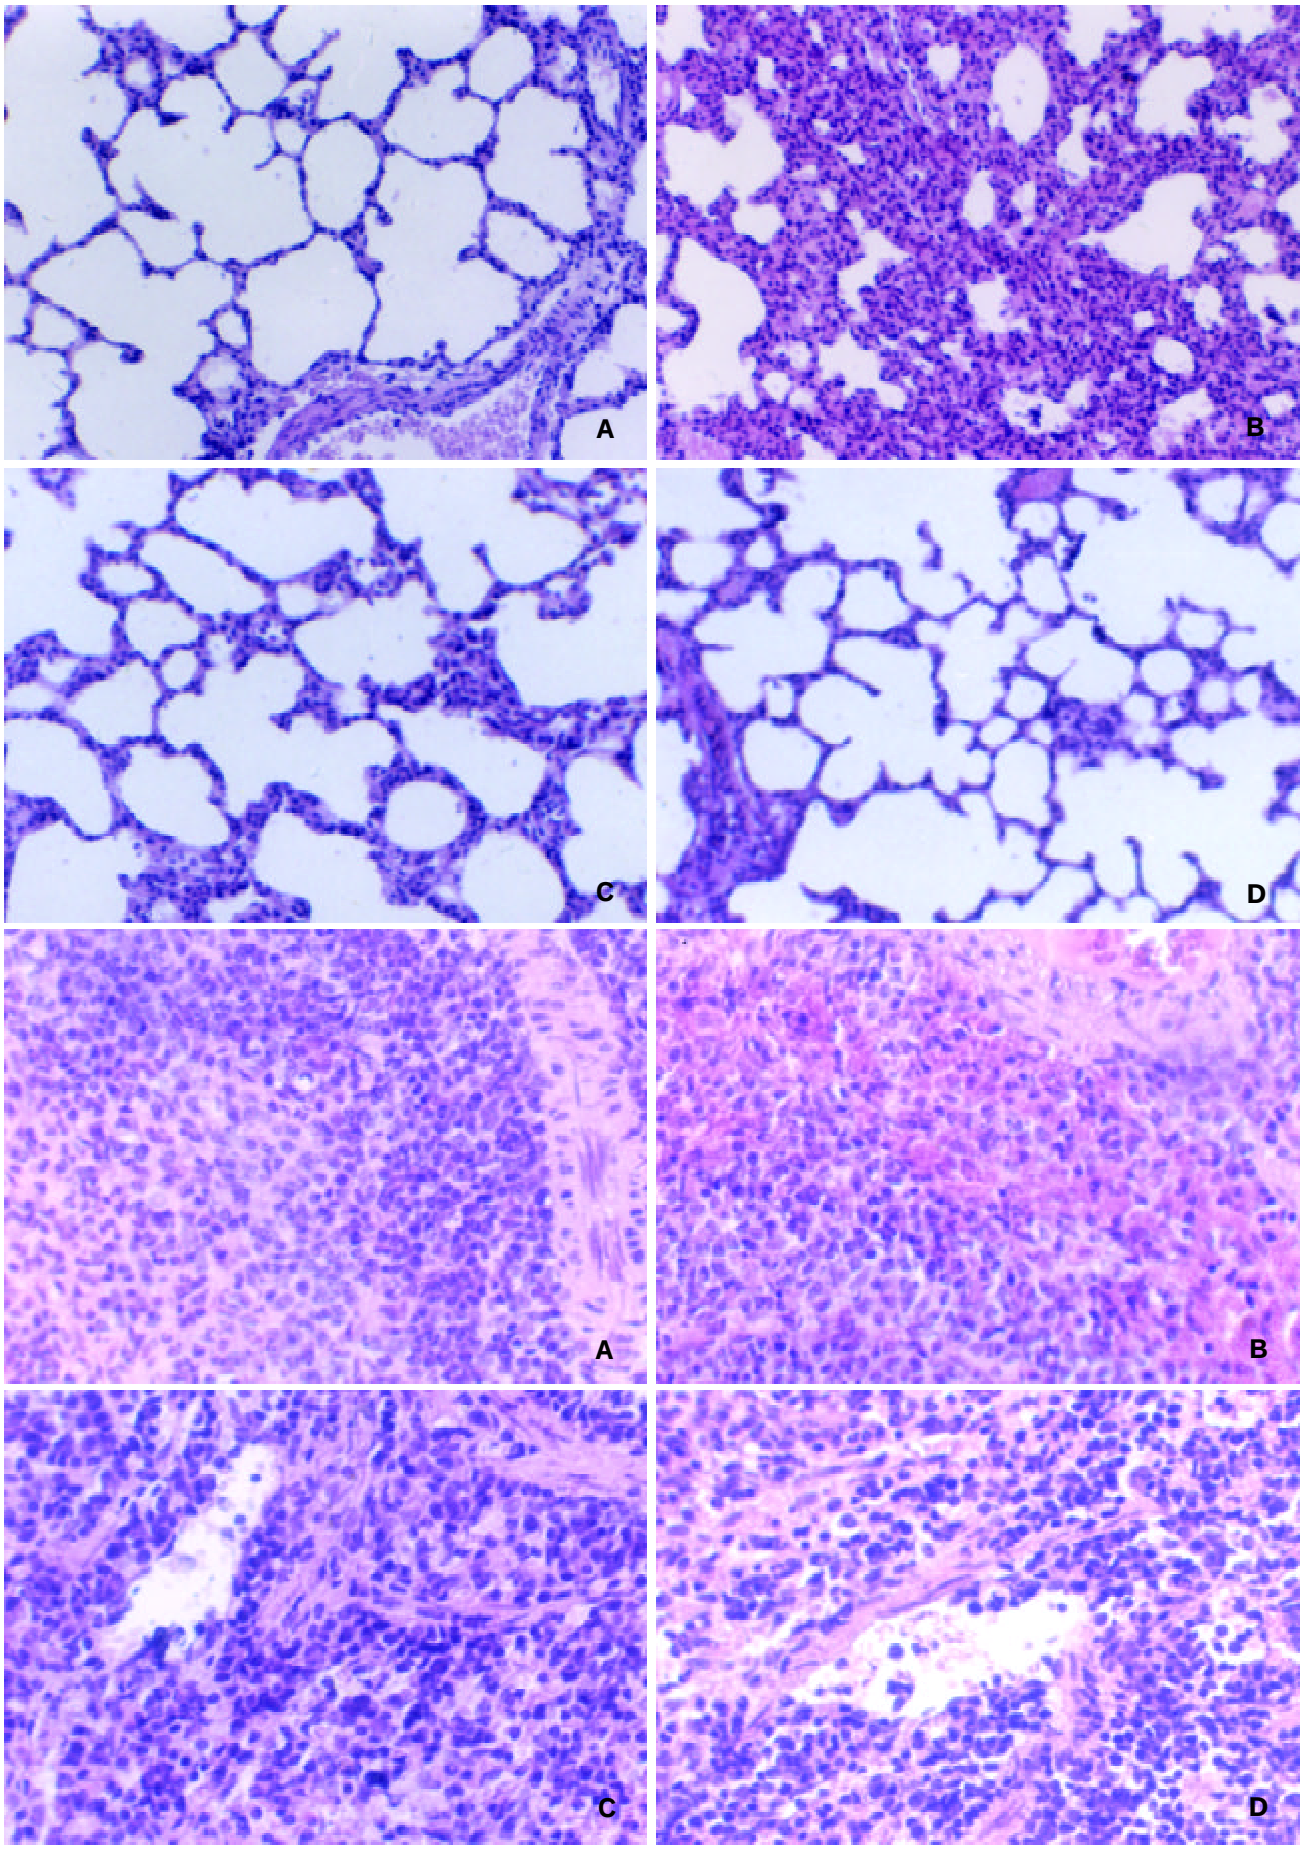

Figure 1 CCK-8 alleviated pulmonary (upper, ×100) and spleen (lower, ×200) structural injury 6 h after LPS administration. A. Control group. B. LPS group. C. CCK-8+LPS group. D. CCK-8 group. Plate depicts a representative field from one of three rats.

Table 1 Inhibitory effect of CCK-8 on LPS stimulated nitrite production in serum, lung and spleen (n=6)

Group	2 h	6 h	12 h
Serum (μmol·L^{-1})			
Control	36.8±2.2	39.2±3.2	33.8±4.1
LPS	78.2±7.4^{b}	250.9±19.6^{b}	302.9±41.2^{b}
CCK-8+LPS	48.5±5.3^{d}	124.8±4.9^{bd}

^{a}P<0.05, ^{b}P<0.01 vs Control, ^{c}P<0.05, ^{d}P<0.01 *vs* LPS

Phagocytic function changes

Phagocytosis of alveolar macrophages isolated from BALF 2 h after LPS administration was increased significantly, the phagocytosis index increased from 2.43±0.71 (Control) to 3.80±0.60 (P<0.05). CCK-8 showed an inhibitory effect on the LPS-induced increase of Candida albicans phagocytosis by macrophage. The phagocytosis index in CCK-8+LPS group reduced to 2.21±0.14, P<0.05. While the phagocytosis rate of CCK-8 group was (62.49±9.49)%, which was higher than control group (48.16±14.20)%, P<0.05 (Figure 2).

Changes of inflammatory cells

Compared with Control, significant increase of BAL neutrophils was observed in LPS group, The number increased from (1±0.2)×10^{6} cells • L^{-1} to (52±10)×10^{6} cells • L^{-1}, P< 0.01. It decreased to (18±4)×10^{6} cells • L^{-1},P<0.01, in CCK-8+LPS group compared with LPS group.

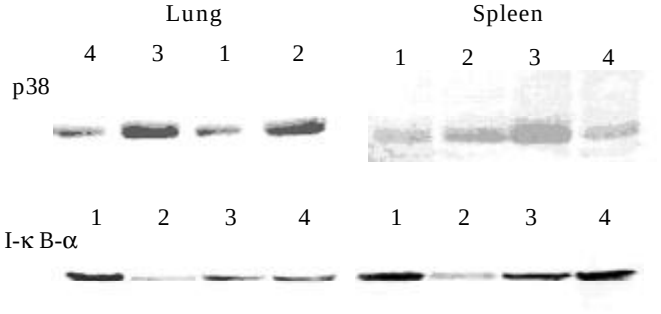

Figure 3 p38 MAPK (A) was activated by LPS and enhanced by CCK-8 in rat lung (left) or spleen (right) using Western blotting. Degradation of IκB-α in lung and spleen following LPS administration was observed and pre-administration of CCK-8 could reduce its degradation. These figures are representative of three different experiments. 1. Normal control, 2 LPS (8 mg·kg^{-1}), 3. CCK-8 (40 μ g·kg^{-1})+LPS, 4. CCK-8

Western blot

Significant phosphorylation of p38 MAPK was observed in lung and spleen of endotoxic rats 30 min post LPS administration. CCK-8 can enhance LPS-induced phosphorylation of p38 MAPK significantly. Phosphorylation of p38 MAPK was also observed in animals receiving normal saline or CCK-8. The degradation of IκB-α in lung and spleen following LPS administration was observed, while the procedure of pre-administration of CCK-8 could reduce its degradation (Figure 3).

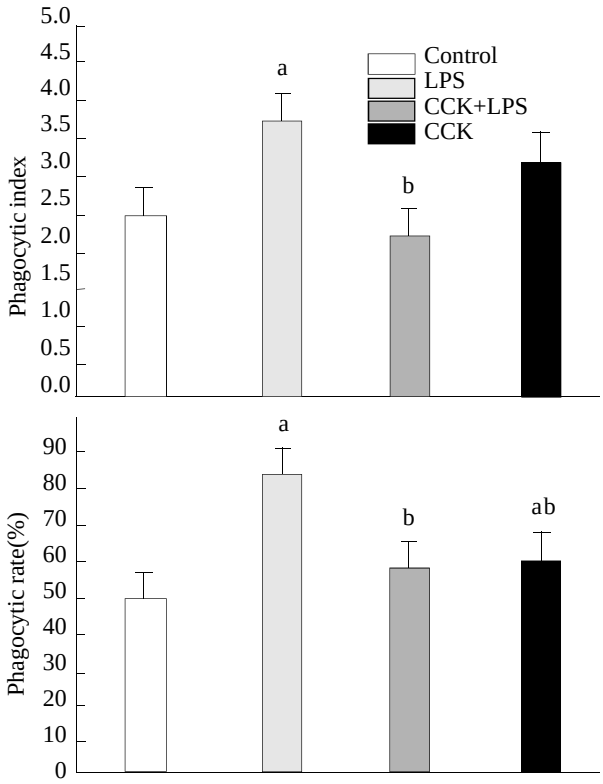

Figure 2 Effect of CCK-8 on LPS-induced increase of phagocytic capacity of Candida albicans by alveolar macrophages isolated 2 h after LPS administration.
^{a}P<0.05 *vs* Control,^{b}P<0.01 *vs* LPS.

DISCUSSION

Some studies examined *ex vivo* measures of immune function stimulated by LPS or CCK-8. While *ex vivo* determinations of immune function are useful, and yield important information concerning the status of the immune system, there is the concern that *ex vivo* stimulation of immune cells may not be naturalistic and consequently be of limited value when immunocompetence is assessed in a whole organism. Thus another approach which has been used to assess immunological status in laboratory animals, is to examine their ability to respond to an *in vivo* challenge with bacterial LPS[24]. Macrophages are the sources of proinflammatory cytokines[25]. Inflammatory mediators like cytokines, NO and reactive oxygen species are released by activated macrophages from various sources, including spleen and lung. NO is particularly important as a vasodilator but also participates in immunologic reactions, including the ability of macrophages to kill tumor cells and bacteria[26]. Some of the deleterious effects of LPS on organ function have been attributed to NO[27]. CCK-8 exerts an inhibitory effect on the overproduction of proinflammatory cytokines induced by LPS, which suggested its functions of anti-inflammatory effect[22]. In addition, CCK-8 inhibits LPS-

induced increase of NO, which may be related to its inhibition on inducible NO synthase[28]. In contrast, our data do not support the idea that CCK-8 may be mediating the anti-inflammatory effects by the production of NO, to which anti-inflammatory effects also have been described[29].

Members of the MAPK cascade are considered to play key roles in signal transduction pathways activated by a wide range of stimuli. The three best characterized members of this growing family of serine/threonine kinases are extracellular signal-regulated kinase (ERK), *c-jun* N-terminal kinase (JNK) and p38. Active MAPK are responsible for the phosphorylation of a variety of effector proteins including several transcription factors [30]. P38 may help reduce organ destruction while inhibition of p38 during induction of cerulein pancreatitis leads to the occurrence of acinar necrosis[31]. Recent evidence from other systems indicates that p38 activation can indeed be protective. Thus, p38 is reportedly important for protection observed after ischemic precondition in myocardial cells and it is evidenced that p38 may exert protective effects via its substrate MAPKAPK2 (MAPK activated protein kinase 2)[32,33]. Activated p38 inhibited iNOS induction, which may be due to the ability of p38 to inhibit LPS-induced JNK activation[34,35]. The anti-inflammatory effects of CCK-8 seem to involve the p38 MAPK pathway. The mechanism by which CCK-8 modulates the p38 MAPK remains unclear at this time. Sodium salicylate suppress TNF-α production, activates p38 MAPK and inhibits both ERK1/ERK2 and SAPK/JNK MAPKs in LPS-stimulated macrophages. Additionally, it has been shown that p38 activation is required for IκB-mediated inhibition of NF-κB[36]. It was reported that LPS-induced production of TNF-α was regulated mainly, but not exclusively, through the p38 MAPK pathway[37-40]. Other signal pathway may be involved. Induction of tolerance by sublethal hemorrhage(SLH) is dependent of p38 MAPK activation and this intracellular signal may be a necessary step in the initiation of the cellular reprogramming associated with tolerance. The normal activation of p38 MAPK is preserved in response to a "second insult" with LPS despite an attenuation in TNF production by tolerant cell[41].

NF-κ plays an important role in physiologic and pathologic conditions as an inducible nuclear factor. NF-κ B/Rel have been implicated in the inflammatory response. Degradation of IκB-α proteins frees NF-κB proteins, which then translocate into the nucleus, where they activate transcription[42]. Another study from our laboratory showed CCK-8 inhibited the increased activity of NF-κB induced by LPS in lung of rats, which may be related to its anti-inflammatory effect.

CCK-8 inhibits phagocytic function of alveolar macrophages isolated 2 h after LPS administration. *In vivo*, this would prevent the excess accumulation of phagocytic cells in the inflamed area, and thereby decrease the phagocytic process. This may be related to its anti-inflammatory effect. Interestingly, CCK-8 itself increases the phagocytic process compared with control. The result indicated that CCK-8 may play different immunoregulatory role in different conditions[43]. The development of tissue damage in shock is closely associated with the release of an ever-increasing number of mediators and acculmulation of neutrophils at the sites of infection or injury[44]. CCK-8 alleviated the accumulation of neutrophils in BALF, which may be related to its protecting effect on lung of ES rats.

The results of the present study show that administration of CCK-8 prevents inflammatory changes in lung and spleen of rats and attenuates increase of NO and inflammatory cells induced by LPS. Moreover, CCK-8 inhibits LPS-induced increase of macrophage phagocytic function while itself increases phagocytic function. CCK-8 enhances the expression of p38 MAPK while reduces the degradation of IκB-α induced by LPS, which may be involved in the signal transduction pathway.

Abstract

AIM: **To elucidate the anti-inflammatory mechanism of an intestinal neuropeptide, sulfated cholecystokinin octapeptide (sCCK-8), the effects of sCCK-8 on lipopolysaccharide (LPS)-induced tumor necrosis factor a (TNF-a) mRNA expression and NF-kB activity in pulmonary interstitial macrophages (PIMs) were studied.**

METHODS: **PIMs from rat were stimulated with LPS (1mg • L^{-1}) in the presence or absence of sCCK-8 (10^{-8}-10^{-6}mol • L^{-1}) or/and CCK receptor antagonist proglumide (2 mg • L^{-1}). The expression of TNF-a mRNA was assayed by reverse transcription polymerase chain reaction (RT-PCR) at 3h of the stimulation, and nuclear factor-kB (NF-kB) binding activity was analyzed by electrophoretic mobility shift assay (EMSA) at 1 h of stimulation. The IkB-a protein level in the cytoplasma at 30 min of the stimulation was detected by Western blot.**

RESULTS: **sCCK-8, at concentrations from 10^{-8} mol • L^{-1} to 10^{-6} mol • L^{-1} obviously inhibited LPS-induced TNF-a mRNA expression and NF-kB binding activity in a dose-dependent manner, $P<0.05$, $P<0.01$. Stimulation PIMs with LPS resulted in a reduction of IkB-a protein level, $P<0.01$, which was elevated by sCCK-8, $P<0.05$. The effects of sCCK-8 on NF-kB activity and IkB protein level were attenuated by CCK receptor antagonist proglumide, $P<0.01$.**

CONCLUSION: **sCCK-8 inhibits LPS-induced TNF-a mRNA expression by regulating NF-kB activity in rat PIMs, which is mediated through CCK receptors and inhibiting IkB-a degradation. This represents one of the anti-inflammatory mechanisms of sCCK-8.**

INTRODUCTION

Interactions between the central nervous system(CNS) and the immune system, particularly through neuropeptides, are of growing interest. Due to the abundant autonomic innervation and extensive lymphoid compartment localized in the gastrointestinal tract, a number of neuropeptides with observed and potential immunomodulatory effects have been isolated from gut tissues[1].These intestinal neuropeptides with immunomodulatory effects include growth hormone[2], somatostatin[3], vasoactive intestinal peptide(VIP)[4,5], calcitonin gene-related peptide(CGRP)[6], neuropeptide Y[7,8], neurotensin[9], and cholecystokinin(CCK)[10].

CCK is discovered initially in the gut with the function of contracting gallbladder, and subsequently localized in the central and peripheral nervous system[10]. CCK is identified as several different size of the peptide including 4, 8, 33, 39, and 58 amino acid forms. The sulfated carboxy-terminal octapeptide(sCCK-8) is the biologically predominant active form localized in the small intestine, blood and CNS[10]. In the last decade few studies have investigated the relation between CCK and immune cells. Okahata *et al*[11] demonstrated CCK immunoreactivity in peripheral blood leukocytes. Data from several labs suggest that CCK mediates an increase in intracellular calcium in human peripheral blood mononuclear cells and T lymphocyte cell line[12,13]. sCCK-8 can inhibit the mobility capacity and the mitogen-induced lymphocytic proliferation, but can increase the adherence and the spontaneous proliferation of lymphocytes[14,15]. In addition, sCCK-8 is a negative modulator of several functions of murine peritoneal macrophages and human neutrophils including the production of superoxide anion, phagocytosis and mobility[16-18]. Interestingly, sCCK-8 causes an *in vitro* inhibition of lipopolysaccharide(LPS)-induced TNF-α production, sCD14 release and mCD14 expression in rat pulmonary interstitial macrophages (PIMs) [19]. Consistently, the production of proinflammatory cytokines including TNF-α, IL-1α, and IL-6 in endotoxin shock(ES) rat was also inhibited by sCCK-8 *in vivo*[20,21]. These results suggested that sCCK-8 has anti-inflammatory effect to some extent, a new field about the biological action of CCK, which was also confirmed by a

morphological observation that sCCK-8 clearly lessened the inflammatory lesions in lung, spleen and liver tissues in ES rat[22].

It is well known that transcriptional factor NF-κB plays a pivotal role in LPS-induced TNF-α gene expression and involved in the inflammatory response[23]. To elucidate the anti-inflammatory mechanism of sCCK-8, we investigated the effects of sCCK-8 on TNF-α mRNA expression and NF-κB activity in the present study.

MATERIALS AND METHODS

Materials

Collagenase IA, LPS (*E. Coli* 0111: B4), sCCK-8 and proglumide were obtained from Sigma (St. Louis, MO). RPMI-1 640 culture medium and TRIzol reagents were obtained from Gibco BRL (Gercy-Pontoise, France). Avian myeloblastosis virus reverse transcriptase and Gel shift assay system were purchased from Promega (Madison, WI). Taq DNA polymerase was obtained from Sangon (Shanghai, China). Coomassie brilliant blue G250 assay kit was purchased from JianCheng Biotechnology (Nanjing, China). An anti-IκBα polyclonal antibody(C-21) was purchased from Santa Cruz (Santa Cruz, CA.) and horseradish peroxidase (HRP)-conjugated IgG was from Zhongshan Biotechnology(Beijing, China). Female, specific pathogen-free Sprague-Dawley rats (weighting 180- 220 g BW) were obtained from Experimental Animal Center of Hebei Province.

Preparation of rat PIMs

PIMs were isolated from perfused rat lungs with a collagenase digestion technique, modified as Wizemann *et al*[24] described. Alveoli were lavaged 12 to 14 times with 4 ℃ phosphate-buffered saline (PBS) containing 0.6 mmol • L^{-1} EDTA (PBS-EDTA) to remove alveolar macrophages. Lung vessles were perfused with 100 ml PBS-EDTA to remove the monocytes and other blood cells. Then the lung tissues were cut into 500 μm slices followed by digestion in 175 U • ml^{-1} collagenase IA containing 0.1 g • L^{-1} DNase and 100 ml • L^{-1} fetal bovine serum (FBS) in a shaking 37 ℃ water bath for 60 min. The suspension was then filtered through 30 μm mesh. After washing 2 times (400×g, 4℃, 10 min) with PBS, the cells were resuspended in RPMI-1640 medium containing 15 ml • L^{-1} FBS, 100 U • ml^{-1} penicillin, and 100 μg • ml^{-1} streptomycin and incubated for 2 h at the conditions of 37℃ and 50 ml • L^{-1} CO_2. Nonadherent cells were removed by gentle washing with warm medium. Remaining adherent cells contained more than 93 % PIMs and the contamination by polymorphonuclear leukocytes and alveolar macrophages was less than 7 %. PIMs viability was greater than 95 %, determined by trypan blue exclusion assay. PIMs (1×10^6) were plated on to culture dishes. After washing 3 times with serum-free medium, PIMs were stimulated with LPS (1 mg • L^{-1}), in the presence or absence of sCCK-8 (10^{-8}-10^{-6} mol • L^{-1}) or/and the CCK receptor antagonist proglumide (2 mg • L^{-11}) for indicated time.

Semi-quantitative RT-PCR for the detection of TNF-α

To determine whether sCCK-8 affect TNF-α transcription, PIMs were stimulated with LPS in the presence or absence of 10^{-8}-10^{-6} mol • L^{-1} sCCK-8 for 3 h. Total cellular RNA was prepared with TRIzol reagents. cDNA was synthesized from 4 μg of the total RNA by extension of random primers with avian myeloblastosis virus reverse transcriptase. PCR of the cDNA was performed in a final volume of 25 μl containing 2 mmol • L^{-1} $MgCl_2$, 4 units Taq DNA polymerase, and 25 pmol specific primers. Amplification of the house-keeping enzyme glyceraldehydes-3-phosphate dehydrogenase (GADPH) was always involved to serve as control of reaction efficacy. The PCR was performed at the conditions of denaturation for 45 s at 94 ℃, annealing for 45 s at 48 ℃ for TNF-α and 55 ℃ for GADPH, extension for 45 s at 72 ℃, and at the end of 35 cycles, further extension for 5 min at 72 ℃.The primers were TNF-α sense, 5'-CCAACAAGGAGGAGAAGT-3'; TNF-α antisense, 5'-GTATGAAGTGGCAAATCG-3' (323bp). The synthesized PCR products were separated by electrophoresis on a 20 g • L^{-1} agarose gel and analyzed by Gel-Pro analyzer version 3.1 software (Media Cybernetics). The ratio of arbitrary unit (AU, D_{area} • $D_{density}$) of target genes over GADPH was used for expressing the relative level of mRNA expression.

Electrophoretic Mobility Shift Assay (EMSA) for NF-κB activity

PIMs were stimulated with LPS in the presence or absence of sCCK-8 for 1 h. Nuclear extracts were prepared essentially as described by Liu *et al*[25]. Cells were washed with PBS, lysed with five-pellet volume of buffer A containing 10 mmol • L^{-1} HEPES (pH 7.9), 10 mmol • L^{-1} KCl, 1.5 mmol • L^{-1} $MgCl_2$, 0.5 mmol • L^{-1} DTT, 0.5 mmol • L^{-1} PMSF, and 5 ml • L^{-1} NP-40 and centrifuged for 10 min at 1 850× *g*. Then the pellets were resuspended with three-pellet volume of buffer B (same as buffer A, but without NP-40) and incubated on ice for 10 min. The cells were centrifuged for 15 min at 3 000×*g* to pellet the nuclei.Nuclear pellets were extracted by gently resuspending the nuclei in two thirth-nuclei pellet volume of buffer C (20 mmol • L^{-1} HEPES (pH 7.9), 10 mmol • L^{-1} KCl, 1.5 mmol • L^{-1} $MgCl_2$, 200 ml • L^{-1} glycerol, 0.2 mmol • L^{-1} EDTA, 0.5 mmol • L^{-1} DTT, and 0.5 mmol • L^{-1} PMSF) and one thirth-nuclei pellet volume of buffer D (same as buffer C but with 400 mmol • L^{-1} KCl). After the nuclei were shaken in buffer C plus buffer D for 60 min on ice, the supernatants were collected by centrifugation at 15 000×*g* for 30 min at 4 ℃. Protein concentration was determined using Coomassie brilliant blue G250 assay kit. Double-stranded deoxyoligonucleotides containing the NF-κB consensus recognition site (5'-AGTTGAGGGGACTTTCCCAGG-3') were end labeled with [γ-^{32}P]ATP using T4 polynucleotide kinase and purified with ethanol precipitation. The nuclear proteins (10 μg per lane) were incubated with the radiolabeled probe DNA (3.5pmol, 10 μCi) in the presence of 1mmol • L^{-1} $MgCl_2$, 0.5 mmol • L^{-1} EDTA, 0.5 mmol • L^{-1} DTT, 50 mmol • L^{-1} NaCl, 10 mmol • L^{-1} Tris-HCl (pH 7.5), 0.05 μg poly(dI-dC), and 40 ml • L^{-1} glycerol in a final volume of 10 μl. Binding reactions were then incubated at room temperature for 30 min. The DNA-protein complexes were separated on a 6 % nondenaturing polyacrylamide gel. The gel was then dried and visualized by autoradiography at -80 ℃.

Western blot analysis for IκBα protein level

PIMs were stimulated with LPS in the presence or absence of sCCK-8 for 30 min. Cytoplasmic protein was extracted using lytic buffer containing 100 mmol • L^{-1} HEPES, 10 ml • L^{-1} Triton X-100, 1 mmol • L^{-1} EDTA, 10 mmol • L^{-1} DTT, and 1 mmol • L^{-1} PMSF. The lysate was centrifuged 20 000×g for 15 min at 4 ℃ after ice bath for 15min. The supernatant was collected and the protein concentration was determined using Coomassie brilliant blue G250 assay kit. Each sample of 100 mg protein was separated on a SDS-10 % polyacrylamide gel and transferred to nitrocellulose membrane. The membrane was sequentially blocked in TBS containing 20 g • L^{-1} milk

and then incubated with 2 μg • ml^{-1} I κ Bα antibody C-21 (Santa Cruz) overnight, washed, and further incubated with a goat anti-rabbit IgG horseradish peroxidase-conjugated secondary antibody. Blocking and secondary antibody incubation each lasted 1 h at 37 ℃. After several washes, the membrane was developed with DAB. Semi-quantitative analysis of immunoreactivity were measured by Gel-Pro analyzer software, and the results were expressed as AU (D_{area} • $D_{density}$).

Statistical analysis

Data were presented as $\bar{x} \pm s$ and compared with ANOVA and least significant difference test using SPSS statistical program. A level of $P<0.05$ was considered statistically significant.

RESULTS

sCCK-8 inhibited LPS-induced TNF-α mRNA expression

Increase in TNF-α mRNA was observed 3 h after stimulating PIMs with 1 mg • L^{-1} LPS ($P<0.01$), and the increase was about 3.1 fold. However in the PIMs co-incubated by LPS and sCCK-8, TNF-α mRNA expression level was obviously lowered in comparison with LPS group ($P<0.05$, $P<0.01$). The inhibitory rate of 10^{-8}, 10^{-7} and 10^{-6} mol • L^{-1} sCCK-8 was 19 %, 41 % and 33 % respectively. TNF-α mRNA expression level was not affected by sCCK-8 alone ($P>0.05$) (Figure 1).

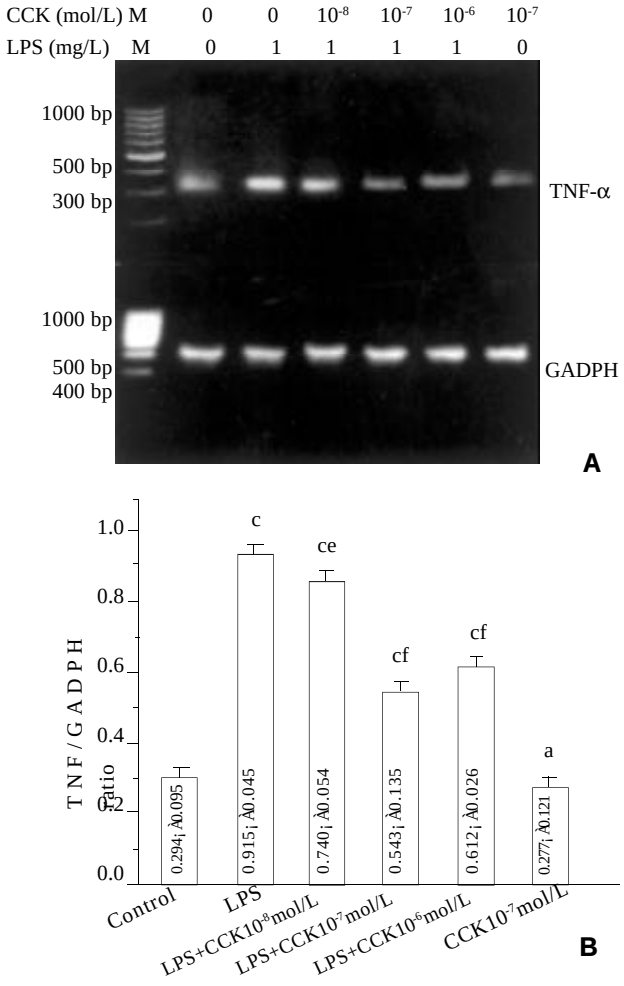

Figure 1 sCCK-8 inhibited LPS-induced TNF-α mRNA expression in PIMs in a dose-dependent manner. A: Representative pictures of three experiments of RT-PCR. B: Relative level of TNF-α mRNA expression. $n=3$, $\bar{x} \pm s$, $^{a}P>0.05$, $^{c}P<0.01$ *vs* control, $^{e}P<0.05$, $^{f}P<0.01$ *vs* LPS.

sCCK-8 inhibited LPS-induced NF-κB binding activity

The NF-κB binding activity was significantly higher in PIMs stimulated with 1 mg • L^{-1} LPS in comparison with unstimulated cells ($P<0.01$), and additional treatment with sCCK-8 markedly reduced the binding activity in a dose-dependent manner. sCCK-8 at the concentrations of 10^{-8}, 10^{-7}, and 10^{-6} mol • L^{-1} inhibited LPS-induced NF-κB binding activity by 34 %, 93 % and 100 % respectively ($P<0.05$, $P<0.01$). The effect of sCCK-8 was abrogated by proglumide ($P<0.01$). sCCK-8 alone had no effect on the NF-κB binding activity ($P>0.05$). The binding specificity was confirmed by using homologous (NF-κB) and nonhomologous (AP-2) oligonucleotides as competitors (Figure 2).

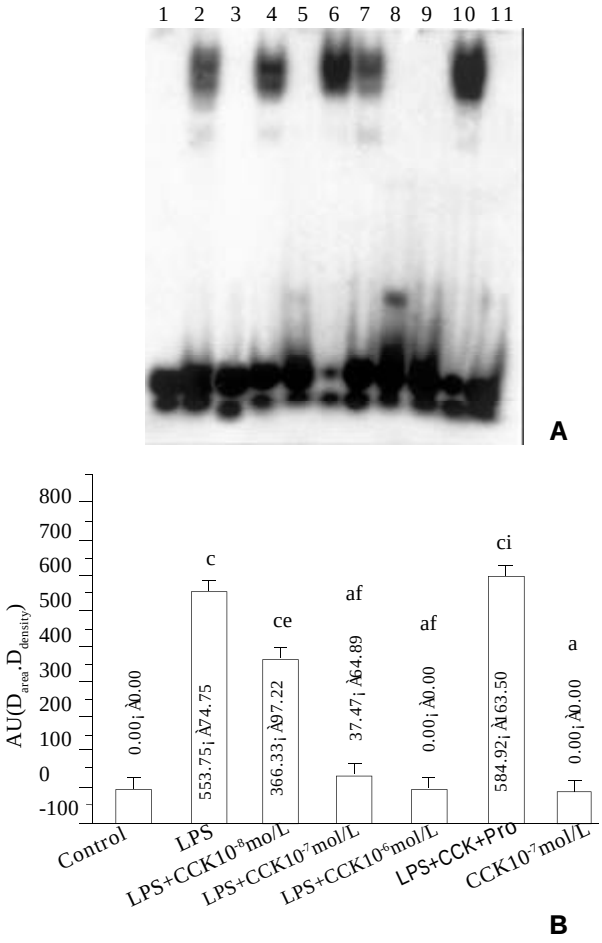

Figure 2 sCCK-8 inhibited LPS-induced NF-κB binding in PIMs in a dose-dependent manner through CCK receptor. A: Representative autoradiography picture of three experiments of EMSA. Lane 1, negative control; lane 2, positive control; lane 3, ^{32}P-labeled NF-κB Oligo plus unlabeled NF-κB Oligo (competitor); lane 4, ^{32}P-labeled NF-κB Oligo plus unlabeled AP-2 Oligo (noncompetitor); lane 5, control; lane 6, LPS; lane 7, LPS+CCK10^{-8} mol • L^{-1}; lane 8, LPS+CCK10^{-7} mol • L^{-1}; lane 9, LPS+CCK10^{-6} mol • L^{-1}; lane 10, LPS+CCK+proglumide; lane 11, CCK10^{-7} mol • L^{-1}. B: Densitometry of EMSA showing decreased NF-κB binding in PIMs treated with sCCK-8. $n=3$, $\bar{x} \pm s$, $^{a}P>0.05$, $^{c}P<0.01$ *vs* control; $^{e}P<0.05$, $^{f}P<0.01$ *vs* LPS; $^{i}P<0.01$ *vs* LPS+CCK10^{-7} mol • L^{-1}.

sCCK-8 increased I κ Bα protein level

The I κ Bα protein level in PIMs markedly decreased at 30 min of LPS incubation($P<0.01$), sCCK-8 at concentrations of 10^{-8}-10^{-6} mol • L^{-1} clearly increased I κ Bα protein level in

PIMs exposure to LPS(P<0.05). The effect was dose dependent and was attenuated by proglumide(P<0.01). sCCK-8 alone had no effect on the κ Bα protein level(P>0.05) (Figure 3).

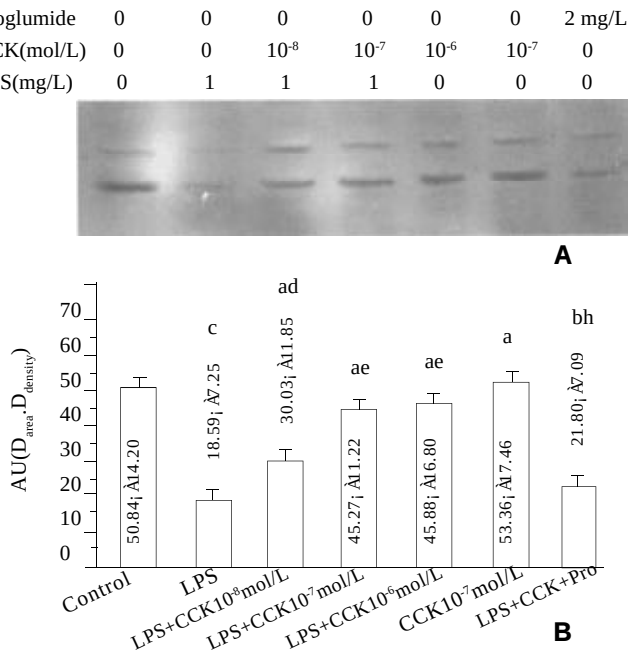

Figure 3 sCCK-8 increased I κ B α protein level at 30 min after LPS stimulation in a dose-dependent manner in PIMs. A: Representative Western blot of three experiments. B: Normalized total protein of I κ Bα immunoreactivity. n=3, $\bar{x}\pm s$, ^{a}P>0.05, ^{b}P<0.05, ^{c}P<0.01 *vs* control; ^{d}P>0.05, ^{e}P<0.05, ^{f}P<0.01 *vs* LPS; ^{h}P <0.05 *vs* LPS+CCK10^{-7} mol • L^{-1}.

DISCUSSION

As an intestinal neuropeptide, sCCK-8 not only protects gastric mucosa against alcohol-induced injury[26-28], but also is a potent protective agent against acute lung injury by LPS[22,29]. It obviously reduced the pulmonary artery hypertention and lessened the inflammatory lesion in lung tissues of ES rats[22,29]. We investigated the effect of sCCK-8 on PIMs since these cells play an important role in the inflammatory response to LPS in the lung. Recently, it was reported that treating rats with LPS resulted in a significant increase in production of reactive oxygen intermediates by PIMs, but not by alveolar macrophages(AM). This treatment also markedly enhanced phagocytosis only in PIMs and caused a significant increase in chemotaxis of PIMs towards C5a. These data demonstrated that PIMs play a role in the inflammatory response of the lung to acute endotoxemia[24]. In this study we showed that incubation of rat PIMs with sCCK-8 caused a decrease in LPS-induced TNF-α mRNA expression level in a dose-dependent manner, which suggested that the inhibitory effect of sCCK-8 on TNF-α production occured at a transcriptional level.

It is well known that transcriptional factor NF- κ B plays a pivotal role in LPS-induced TNF-α gene expression[23,30]. The present study indicated that sCCK-8 inhibited NF- κ B binding activity in PIMs response to LPS in a dose-dependent manner, which was consistent with our results in the previous *in vivo* study that sCCK-8 inhibited NF- κ B activity in ES rat lung tissues[31]. These results demonstrated that NF- κ B might be the upstream mechanism of the inhibitory effect of sCCK-8 on LPS-induced TNF-α mRNA expressions. Because NF- κ B activation can lead to enhanced expression of proinflammatory cytokines, chemokines, inflammaroty enzymes such as inducible NO synthase (iNOS) and cycloosygenase (COX-2), adhension molecules and inflammatory receptors[23,30,32,33], modulation of NF- κ B activation may provide a direct way of inhibiting inflammatory mediators[34]. Directing drug discovery efforts towards NF- κ B activation rather than towards any one of its many target genes could produce a much greater therapeutic benefit by inhibiting expression of the constellation of NF- κ B-induced pro-inflammatory genes[35]. Several anti-inflammatory drugs, including corticosteroids, the non-steroidal cyclooxygenase inhibitor sulindac, the benzophenanthridine alkaloid sanguinarine, aspirin and salicylate have all been shown to inhibit NF- κ B activation at different stages[35]. Corticosteroids inhibit NF- κ B by upregulating the expression of its inhibitor I κ B, which displaces DNA-bound NF- κ B and restores the latent cytoplasmic I κ B-NF- κ B complex[35,36]. Sulindac[37], aspirin and salicylate[38] specifically inhibit I κ Kα kinase activity, and it has also been demonstrated that sanguinarine inhibits NF- κ B activation at the level of I κ B phosphorylation [39]. In this study, we first demonstrated that the inhibitory effect of sCCK-8 on NF- κ B activity was an important signal transduction mechanism of its anti-inflammatory effect. This can also explain the anti-ES role of sCCK-8[22], because NF- κ B acts as an important transcriptional factor in the pathogenesis of ES.

Activation of NF- κ B is triggered by phosphorylation of an inhibitory subunit, I κ B. In unstimulated cells, NF- κ B is sequestered in the cytoplasm through interaction with I κ B α and I κ Bα inhibitory proteins. In response to proinflammatory stimuli(eg LPS, cytokines, viruses), I κ B is first phosphorylated in its N-terminal domain by a large multikinase complex, then polyubiquitinylayted, and finally degraded by the proteasome. The released NF- κ B complex translocates into the nucleus where it will initiate gene transcription upon binding its cognate DNA motifs in regulatory segments of TNF-α gene and other target genes involved in inflammatory and immune process[40]. To elucidate the upstream mechanism of sCCK-8 inhibiting NF- κ B activity, we further detected whether sCCK-8 affected I κ B α protein level with method of Western blot. And the results demonstrated that the decreased I κ B α protein level in LPS-stimulated PIMs was elevated by sCCK-8 in a dose-dependent manner. The increase in I κ B α protein level could be the result of decreased degradation, increased synthesis, or a combination of these two mechanisms. Because we detected the elevation of I κ B α protein level at 30 min of LPS and sCCK-8 incubation, it was not likely that there could be *de novo* protein synthesis in such short time. So the increase of I κ B α protein level was caused by its diminished degradation, suggesting that sCCK-8 inhibited the degradation of I κ B α, and subsequently abrogated the translocation to nucleus of NF- κ B. However, recently few studies showed that in pancreatic cells, supraphysiological concentrations of CCK(10^{-7} mol • L^{-1}) induced chemokine expression through the activation of NF- κ B[41,42]. CCK(10^{-7} mol • L^{-1}) also induced the degradation of I κ Bα in pancreatic cells[41]. So treatment rats with the supraphysiological concentrations of CCK analogue caerulein led to an acute inflammatory response resembling aspects of clinically important disease acute pancteatitis and it had been used to duplicate the experimental model of acute pancreatitis[41,42]. In our study, the same concentrations of CCK-8(10^{-7} mol • L^{-1}) showed significant inhibitory effect on NF- κ B activation and I κ B α degradation in LPS-stimulated PIMs, but had no effect on them in the unstimulated PIMs. This discrepancy may be

due to the specificity of the role of CCK in different cells. It is reported that stimulation murine peritoneal macrophages and human neutrophils with CCK led to an inhibition of protein kinase C(PKC) activity[16,18], yet it caused an activation of PKC in rat pancreatic cells[41,42].

Recent data demonstrated the presence of CCK receptors on human monocytes[43] and lymphocytes[44,45]. Our laboratory reported that the pulmonary macrophages expressed CCK receptor detected by *in situ* hybridization and *in situ* RT-PCR[46]. In this study, we found that a CCK receptor antagonist proglumide blocked the effects of sCCK-8 on NF-κB binding activity and IκB protein level, indicating that the roles of sCCK-8 were mediated through CCK receptor. Yet the signal transduction mechanisms between CCK receptor and IκB remain to be further determined.

In this study, the concentration of sCCK-8 that showed a distinct effect on LPS-induced TNF-α mRNA expression and NF-κB activity was from 10^{-8} to 10^{-6} mol • L^{-1}. However, sCCK-8 alone, at a concentration of 10^{-7} mol • L^{-1} had no effect on the above functions of the resting PIMs. Similarly, De la Fuente *et al*[16] reported that several functions of resting mouse peritoneal macrophages were inhibited by sCCK-8 at the lower concentrations of 10^{-10}-10^{-8} mol • L^{-1} but not the higher concentration of 10^{-6} mol • L^{-1}. They considered that the lower response to higher concentrations of sCCK-8 might be ascribed to a process of cell desensitization, which is characteristic of sequestration and/or down-regulation of CCK receptor. We reported that LPS up-regulated the expression of CCK receptor[47], so LPS activating PIMs rather than resting PIMs could response to higher concentration of sCCK-8.

In conclusion, our results show that sCCK-8 reduces LPS-induced TNF-α production at transcriptional level by inhibiting NF-κB activity, and the inhibitory effect of NF-κB activity is mediated through the decrease of IκBα degradation, which represents one of the anti-inflammatory mechanisms of sCCK-8.

Abstract

AIM: **To investigate the relationship between hyposmotic membrane stretch and muscarinic receptor agonist-induced depolarization of membrane potential in antral gastric circular myocytes of guinea-pig.**

METHODS: **Using whole cell patch-clamp technique recorded membrane potential and current in single gastric myocytes isolated by collagenase.**

RESULTS: **Hyposmotic membrane stretch hyperpolarized membrane potential from -60.0mV±1.0mV to -67.9mV± 1.0mV. TEA (10mmol/L), a nonselective potassium channel blocker significantly inhibited hyposmotic membrane stretch-induced hyperpolarization. After KCl in the pipette and NaCl in the external solution were replaced by CsCl to block the potassium current, hyposmotic membrane stretch depolarized the membrane potential from -60.0 mV±1.0mV to -44.8 mV±2.3mV ($P<0.05$), and atropine (1 μmol/L) inhibited the depolarization of the membrane potential. Muscarinic receptor agonist Carbachol depolarized membrane potential from –60.0mV±1.0mV to –50.3 mV±0.3mV ($P<0.05$) and hyposmotic membrane stretch potentiated the depolarization. Carbachol induced muscarinic current (I_{cch}) was greatly increased by hyposmotic membrane stretch.**

CONCLUSION: **Hyposmotic membrane stretch potentiated muscarinic receptor agonist-induced depolarization of membrane potential, which is related to hyposmotic membrane stretch-induced increase of muscarinic current.**

INTRODUCTION

In gastrointestinal smooth muscle, stretch is a very important physiological stimulation. However, the first quantitative electrophysiological evidence about such a myogenic response emerged until an experiment was done that the recordings of tension and intracellular membrane potential were simultaneously carried out in the rabbit taenia coli [1, 2, 4]. It has been demonstrated that when the muscle was stretched the tension relates closely to the depolarization of the membrane potential and the frequency of the action potential[1-4], but the mechanism is not very clear that how stretch excited cell membrane and caused smooth muscle contraction. It is well known that muscarinic current is nonselective cation current which can depolarize membrane potential[5, 6] and contribute to calcium influx[7]. In our previous study we found that mechanical stretch increased the voltage-dependent calcium current[8-10], and Kirber *et al*[11, 12]. reported that stretch activated ion channel (SACs)existed in gastric myocytes. In gut smooth muscle muscarinic current is very important for regulating motility of smooth muscle, but the relationship is not clear between muscarinic current and membrane stretch. In 1997, Waniishi *et al*[13] reported that hyposmotic membrane stretch increased muscarinic current in guinea-pig ileum. But the relationship of mechanical stretch and muscarinic receptor agonist-induced depolarization of membrane potential is not clear in gastric smooth muscle. Thus in this study, the relationship between hyposmotic membrane stretch and muscarinic receptor agonist-induced depolarization of membrane potential was investigated in antral gastric circular myocytes of guinea-pig.

MATERIALS AND METHODS

Preparation of cells

Guinea-pigs (obtained from the Experimental Animal Department of Norman Bethune University, Certificate No 10-6 004) of either sex weighing 300-350 g were anaesthetized by urethane(50 mg/kg). The antral part of the stomach was promptly excised and equilibrated in a Ca^{2+}-free solution which was oxygenated, then the circular muscle layer was separated from the muscle layer and dissected into small segments (1×4 mm). These segments were kept in a modified Kraft-Bruhe (K-B) medium at 4 ℃ for 15 minutes. Then they were incubated at 36 ℃ in 4ml digestion medium (Ca^{2+}-free PSS) containing 0.1 % collagenase (Ⅱ), 0.1 % dithioerythreitol, 0.15 % trypsin inhibitor and 0.2 % bovine serum albumin for 25-35 min. Then the softened muscle segments were transferred into the modified K-B medium, and single cells were dispersed by gentle agitation with a wide-bored fire-polished glass pipette. Isolated gastric myocytes were kept in modified K-B medium at 4 ℃ until use.

Electrophysiological recording

Isolated cells were transferred to a small chamber (0.1 ml) on the stage of an inverted microscope (Ⅸ-70 Olympus, Japan) for 10-15 min to settle down, and continuously superfused with isosmotic physiologic salt solution (PSS) by gravity (2-3 ml/min). Glass pipettes with a resistance of 2-5 MΩ were used to make a giga seal of 5-10 GΩ. Whole-cell currents and

Membrane potential were recorded with an Axopatch 1-D patch-clamp amplifier (Axon Instrument, USA) polygraph (RM 6200, Nihon Kohden, Tokyo, Japan).

Drugs and solutions

Ca^{2+}-free PSS containing (in mmol/L) NaCl 134.8, KCl 4.5, glucose 5, and N-[2-hydroxyethyl] piperazine- N-[2-ethanesulphonic acid] (HEPES) 10 was adjusted to pH 7.4 with Tris [hydroxymethyl] aminomethane (TRIZMA). Modified K-B solution containing (in mmol/L) L-glutamate 50, KCl 50, taurine 20, KH_2PO_4 20, $MgCl_2 \cdot 6H_2O$ 3, glucose 10, HEPES 10 and egtazic acid 0.5 was adjusted to pH 7.40 with KOH. Isosmotic solution containing (in mmol/L) NaCl 80, KCl 4.5, $MgCl_2 \cdot 6H_2O$ 1, $CaCl_2 \cdot 2H_2O$ 2, glucose 5, HEPES 10, sucrose 110, was adjusted to pH 7.4 with Tris; CsCl 99, HEPES 10, Sucrose 90, was adjusted to pH 7.40 with tris. Hyposmotic solution containing (in mmol/L) NaCl 80, KCl 4.5, $MgCl_2 \cdot 6H_2O$ 1, $CaCl_2 \cdot 2H_2O$ 2, glucose 5, HEPES 10 was adjusted to pH 7.40 with tris; CsCl 99, HEPES 10, was adjusted to pH 7.40 with Tris. Pipette solution containing (in mmol/L) K-aspartic acid 110, Mg-ATP 5, $MgCl_2 \cdot 6H_2O$ 1, KCl 20, EGTA 10, di-tris-creatine phosphate 2.5, disodium-creatine phosphate 2.5, HEPES 5,pH was adjusted to 7.30 with KOH; CsCl 135, Na_2ATP 3, $MgCl_2$ 3, di-tris-creatine phosphate 2.5, disodium-creatine phosphate 2.5, HEPES 5, EGTA 0.5 was adjusted to pH 7.30 with tris. Tetraethylammonium (TEA), Carbachol (CCh) and Atropine were made up as stock solutions (1mol/L, 10 mmol/L and 1μmol/L respectively). All drugs in this experiment were purchased from Sigma (USA).

Hyposmotic membrane stretch

Cells were superfused with normal and hypotonic solution.

Data analysis

Data were expressed as $\bar{x} \pm s$. Statistical significance was estimated by paired *t*-test. $P < 0.05$ were considered to be statistically significant.

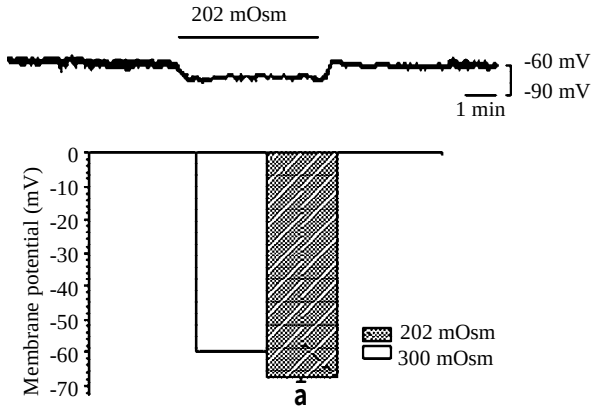

Figure 1 Effect of hyposmotic membrane stretch on membrane potential ($^aP<0.05$ *vs* control).

RESULTS

Effect of hyposmotic membrane stretch on membrane potential

Membrane current was clamped by the conventional whole-cell patch clamp configuration and membrane potential was modulated to about –60.0 mV, so that it is close to resting potential of the gastric myocyte. After being superfused with hyposmotic solution (202 mOsm), the membrane potential hyperpolarized from –60.0±1.0 mV to –67.9±1.0 mV in a few seconds，and the amplitude of polarization was increased by 13.4±1.6 % (Figure 1, $n = 10$, $P < 0.05$). TEA, a nonspecific potassium channel blocker (10 mmol/L) significantly inhibited the hyperpolarization induced by hyposmotic membrane stretch, the membrane potential depolarized from –70.9 ±2.2 mV to –65.7±1.6 mV, inhibited from 100 % of control to 47.8±6.6 % (n =7, P <0.05, Figure 2). In the condition of KCl in the pipette and NaCl in the external solution were replaced by CsCl to block the potassium current, hyposmotic membrane stretch depolarized membrane potential from -60.0±1.0 mV to -44.8±2.3 mV (n =5, P <0.05, Figure 3).

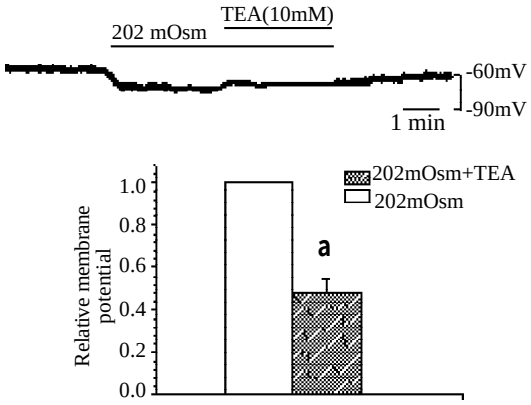

Figure 2 Effect of TEA on membrane potential caused by hyposmotic membrane stretch ($^aP < 0.05$ *vs* control).

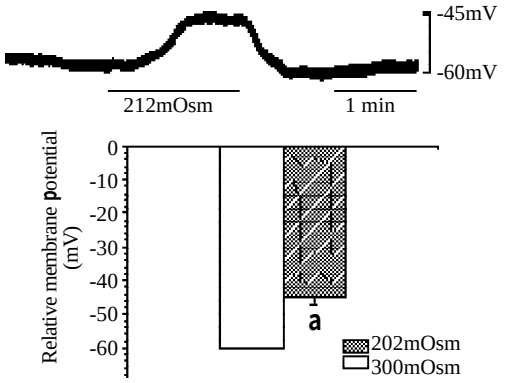

Figure 3 Hyposmotic membrane stretch induced depolarization of membrane potential in the solutionn including CsCl ($^aP<0.05$ *vs* control).

Effects of hyposmotic membrane stretch on muscarinic receptor agonist-induced depolarization of membrane potential

Potassium current was still blocked by CsCl, muscarinic receptor agonist carbachol depolarized membrane potential from –60.0±1.0 mV to –50.3±0.3 mV and hyposmotic membrane stretch potentiated the depolarization of the membrane potential from -50.3±0.3 mV to -37.3±1.8 mV, the potentiated percentage is 239.4±10.6 % (n =3, P <0.05, Figure 4). When the membrane potential depolarized by hyposmotic membrane stretch, atropine (1μmol/L) inhibited the depolarization, the membrane potential hyperpolarized from -47.3±2.4 mV to -53.0 ±1.9 mV, inhibited from 100 % of control to 47.6±4.7 % (n =4, P<0.05, Figure 5).

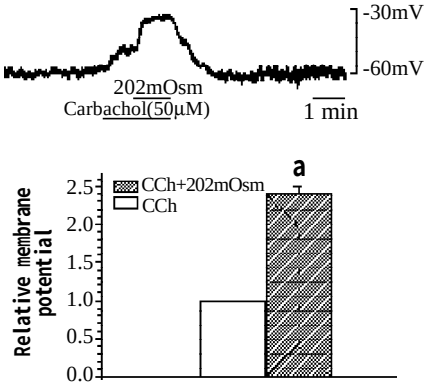

Figure 4 Hyposmotic membrane stretch increased the depolarization of membrane potential induced by CCh in the solutionn including CsCl ($^aP < 0.05$ *vs* control).

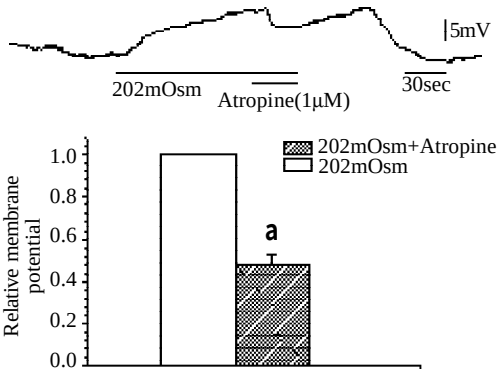

Figure 5 The effect of Atropine on membrane potential hyperpolarized by hyposmotic membrane stretch in the solution including CsCl ($^aP < 0.05$ *vs* control).

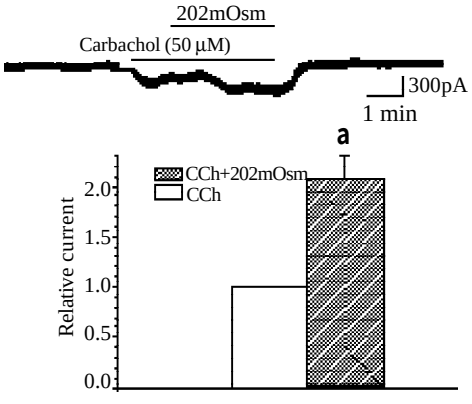

Figure 6 Hyposmotic membrane stretch increased the amplitude of the current induced by Carbachol ($^aP < 0.05$ *vs* control).

Effect of hyposmotic membrane stretch on muscarinic current

In conventional whole-cell patch clamp configuration, membrane potential was clamped at –20 mV, inward current was induced by carbachol and the mean value was 183.3±30.7 pA. Hyposmotic membrane stretch significantly increased muscarinic current induced by carbachol from 183.3±30.7 pA to 383.3±73.8 pA, and the increased percentage is 206.9±23.4 % (n=4, P<0.05, Figure 6).

DISCUSSION

The simple and main method of stretching cell membrane is hyposmotic cell swelling, in this study, we applied hyposmotic cell swelling to investigated the relationship between hyposmotic membrane stretch and muscarinic receptor agonist-induced depolarization of membrane potential. In present study, we observed that hyposmotic membrane stretch hyperpolarized membrane potential; TEA, a nonselective potassium channel blocker significantly inhibited hyposmotic membrane stretch-induced hyperpolarization. After KCl in the pipette and NaCl in the external solution were replaced by CsCl to block the potassium current, hyposmotic membrane stretch depolarized the membrane potential, and atropine inhibited the depolarization of the membrane potential. Muscarinic receptor agonist carbachol depolarized membrane potential and hyposmotic membrane stretch potentiated the depolarization; carbachol induced muscarinic current (I_{cch}) was greatly increased by hyposmotic membrane stretch.

It is must be mentioned here that we have applied hyposmotic membrane stretch which is not same as mechanical stretch under physiological condition, but it is the common method for stretching cell membrane now. It is well known that almost every kind of cells are able to regulate their volume so that they are still in the normal physiological condition[14,15]. In this experiment, hyposmotic cell swelling is inevitable to elicit the reaction resist to volume increase, so calcium sensitive potassium channels were activated and have potassium and chloride ion efflux to decrease cell volume, our previous studies have proved it[16, 17]. In this work, hyposmotic membrane stretch includes two kinds of stimulation, one is cell volume increase; the other is cell membrane stretch, so it is inevitable to activate potassium channel. However, the focus of our study is the relationship between membrane stretch and muscarinic receptor agonist-induced depolarization of membrane potential, so we blocked potassium current to observe depolarization induced by muscarinic receptor agonist clearly. When the cell superfused with hyposmotic solution, the membrane potential was hyperpolarized, but in the condition of KCl in the pipette and NaCl in the external solution were replaced by CsCl to block the potassium current, hyposmotic membrane stretch depolarized membrane potential. Therefore the hyperpolarization induced by hyposmotic stress related to activation of potassium channel which is very important mechanism in cell volume regulation. In gut smooth muscle, stretch is very important physiological stimulation, the stretch caused smooth muscle contraction. There are two theories about the mechanism of stretch-induced smooth muscle contraction, one is nervous mechanism; the other is muscular mechanism. But the ionic channel event in muscular mechanism is not very clear. It is reported that stretch activated channel(SACs) were activated by membrane stretch in gastric myocyte, and this channel is not voltage dependent and nonselective cation[18, 19]. Our previous study found that hyposmotic membrane stretch increased L-type calcium current and it is related to cytoskeleton in gastric myocytes of guinea-pig[8, 9]. Waniishi *et al*[13]. observed that hyposmotic membrane stretch increase carbachol-induced muscarinic nonselective cation current obviously in ileum smooth muscle of guinea-pig. In present study, hyposmotic membrane stretch potentiated carbachol-induced depolarization of membrane potential and M receptor blocker, atropine significantly inhibited hyposmotic membrane stretch-induced depolarization. Since in the condition of clamping membrane potential, hyposmotic membrane stretch significantly increased carbachol-induced muscarinic current, so hyposmotic membrane stretch via increasing muscarinic

current potentiated carbachol-induced depolarization of membrane potential.

Acetylcholine is very important for regulating gastrointestinal smooth muscle motility. When the muscarinic receptor is activated by acetylcholine, it not only releases the calcium from the calcium store through the G-protein path way[20], but also activates a nonselective cation channel which can depolarize the membrane potential. Activation of the muscarinic receptor operated channel is followed by the entry of the cations such as calcium, and it induces the contraction of the muscle eventually. Our results demonstrated that in the gut myocytes, the mechanical stretch is probably one of the important mechanisms of regulating the muscarinic receptor operated channel. Therefore when the stomach is distended by food in physiological condition, gastric tonic contraction is potentiated via long and short- vagus nerve reflex, in another way, stretch may be potentiated the effect of vagus nerve on gastric tonic contraction through increasing muscarinic current. Since hyposmotic membrane stretch potentiats carbachol-induced depolarization through increasing muscarinic current, it may be also one mechanism in smooth muscle contraction caused by stretch.

Abstract

AIM: **To examine the effect of *ganoderma lucidum* polysaccharide (GLP) on the immune liver injury induced by BCG infection, and investigate the relationship between degrees of hepatic damage and NO production in mice.**

METHODS: **Immune hepatic injury was markedly induced by BCG-pretreatment (125 mg·kg^{-1}, 2-week, iv) or by BCG-pretreatment plus lipopolysaccharide (LPS, 125 mg·kg^{-1}, 12-hour,iv) in mice *in vivo*.Hepatocellular damage induced by BCG-pretreated plus inflammatory cytokines mixture (CM), which was included TNF-a, IL-1b, IFN-g and LPS in culture medium *in vitro*. Administration of GLP was performed by oral or incubating with culture medium at immune stimuli simultaneity. Liver damage was determined by activity of alanine aminotransferase (ALT) in serum and in hepatocytes cultured supernatant, by liver weight changes and histopathological examination. NO production in the cultured supernatant was determined by the Griess reaction. Moreover, inducible nitric oxide synthase (iNOS) protein expression was also examinated by immunohistochemical method.**

RESULTS: **Immune hepatic injury was markedly induced by BCG or BCG plus inflammatory cytokines in BALB/c mice *in vivo* and *in vitro*. Under BCG-stimulated condition, augment of the liver weight and increase of the serum/supernatant ALT level were observed, as well as granuloma forming and inflammatory cells soakage were observed by microscopic analysis within liver tissues. Moreover, NO production was also increased by BCG or/and CM stimuli in the culture supernatant, and a lot of iNOS positive staining was observed in BCG-prestimulated hepatic sections. Application of GLP significantly mitigated hepatic tumefaction, decreased ALT enzyme release and NO production in serum/supernatant, improved the pathological changes of chronic and acute inflammation induced by BCG-stimuli in mice. Moreover, the immunohistochemical result showed that GLP inhibited iNOS protein expression in BCG-immune hepatic damage model.**

CONCLUSION: **The present study indicates that NO participates in immune liver injury induced by *Mycobacterium bovis* BCG infection . The mechanisms of protective roles by GLP for BCG-induced immune liver injury may be due to influence NO production in mice.**

INTRODUCTION

Ganoderma lucidum polysaccharide (GLP) is an important pharmacological ingredient extracted from fruit bodies and mycelium of mushroom *Ganoderma Lucidum* (Fr.) Karst. It has been extensively documented that GLP can improve the damage induced by specific and nonspecific immunity responses[1,2]. In our laboratory recently studies, it was confirmed that GLP enhanced phagocytosis of intraperitoneal macrophage, inhibited the growth of implanted Sarcoma 180 and HL-60 tumor cells *in vitro*[3-5]. However, the regulating mechanism of GLP in the immune response remain unknown. On the other hand, hepatitis is a prevalent disease in the Chinese population. It has been recognized that the immune factors, such as virus/parasite infection, autoimmune stimuli, etc., were the dominant reasons of hepatic damage in hepatitis[6-10]. But the commonly used model of liver injury induced by chemicals does not accurately represent the clinical situation[11, 12]. Therefore, It is required that development of new therapy drugs depends primarily on the availability of animal models relevant to human hepatitis or hepatocellular immune damage.

In the recently studies, *Mycobacterium bovis* bacillus Calmette-Guerin (BCG) infection has been proven to induce immune hepatic injury in rodent animal[13,14]. In this pathological model, the releases of hepatic endogenous cytokines, such as TNF-α, IFN-γ and IL-1β were observed *in vivo*[15-17]. Moreover, in our laboratory previously experiment, it has been observed that inflammatory cytokines including TNF-α and IL-1β stimulated NO production in the primary cultured rat hepatocytes *in vitro*[18], but the influence of GLP in this immune damage model and the exact function of NO production in the presence of inflammatory stimuli have not been elucidated yet. Therefore, the present study was performed to determine the effects of GLP on the BCG-stimulated immune liver injury *in vitro* and *in vivo*, and to investigate the possible mechanism of the influence induced by GLP in this immune response.

MATERIALS AND METHODS

Reagents

Following reagents were purchased from Sigma Chemical Co.: collagenase (Type IV, 340 kU· g^{-1}), bovine insulin, and lipopolysaccharide (LPS, E.*coli*.0111:B4). Other materials were obtained from the following sources: kit for determining

serum and culture supernatant alanine transaminase (ALT) was from Beijing Institute of Biological Products (Beijing); *Mycobacterium tuberculosis* Bacille Calmétte-Guérin (BCG) vaccine was from the National Vaccine and Serum Institute (Beijing); human recombinant (rh) tumor necrosis factor-alpha (TNF-α), interleukin-1 beta (IL-1β), interferon-gamma (IFN-γ) were from Academy of Military Medical Sciences (Beijing), and Dulbecco' s modified Eagle' s medium (DMEM) from Gibco BRL; *Ganoderma lucidum* polysaccharide (GLP) was isolated from mycelium of *Ganoderma lucidum* and provided by the Department of Phytochemistry, College of Pharmacy, Beijing University[5]. For using immunohistochemistry, iNOS polyclonal antibody (rabbit anti-mouse immunoglobulin) was purchased from Beijing Zhong-Shan Biotechnology co., LTD.

Animals treatment and liver damage induction

Male BALB/c mice weighing 18-22g (6-8 weeks old), were provided by Experimental Animal Center, Beijing University. Immune hepatic injury was induced by intravenous injection of BCG (125 mg· kg^{-1}) for two weeks, or induced by LPS (125 μg· kg^{-1}) for 12 hours at BCG-pretreated 14day later[13,19]. Control group mice were treated by same volume of phosphate buffered saline (PBS). After animals were BCG-pretreated 7 days, the different concentrations (25 mg· kg^{-1}, 50 mg· kg^{-1}, 100 mg· kg^{-1} and 200 mg· kg^{-1}, respectively) of GLP were intragastric administered once at everyday within succedent one week. At immune stimulating 2 weeks later, mice were killed by cervical dislocation,blood was collected and centrifuged at 3000 rpm for 5 min. Serum was obtained at the supernatant for mensuration enzyme level. Liver samples were removed rapidly for histopathological and immunohistochemical examination.

Hepatocyte isolation and culture

Hepatocytes were harvested from control mice or BCG-pretreated for 2 weeks mice using an *in situ* collagenase perfusion technique[20]. After inhalation anesthesia, the abdomen of the animals was opened and shaved,the portal vein was exposed and cannulated. Then the liver was perfused at 37 ℃ *in situ* first with a calcium-free phosphate-buffered saline solution (PBS) with 6~8 mL/min velocity of flow. This perfusion was continued for 5 min, then it was switched to 0.5 g· L^{-1} collagenase and 10 g· L^{-1} bovine albumin in PBS buffer for 15 min. The liver was removed and the cells were combed gently in tissue culture medium. Hepatocytes were pelleted, washed, and separated from nonparenchymal cells by differential centrifugation at 50×g. Viability of cells exceeded 85 % as determined by trypan blue exclusion. Hapatocytes were plated onto 6-well plastic tissue-culture plates (1×10^9 cells· L^{-1} in each well). Medium in the control consisted of DMEM with L-arginine (0.5 mmol· L^{-1}), insulin (1 mmol· L^{-1}), Hepes (15mmol· L^{-1}), L-glutamine, penicillin, streptomycin, and 100 mL· L^{-1} low-endotoxin newborn calf serum. After overnight incubation, the medium was changed with a cytokines mixture (CM) containing LPS (10 mg· L^{-1}), IL-1β (10 KU· L^{-1}), TNF-α (500 KU· L^{-1}) and IFN-γ (100 KU· L^{-1}). Other experimental conditions included addition of GLP, at the different concentrations (50 mg· L^{-1} or 200 mg· L^{-1}), to the CM. After primary cultures were maintained for 24 h at 37 ℃ in 50 ml· L^{-1} CO_2, hepatocytes or cultured supernatants were collected for nitrite and ALT activity assays[21].

Assay for hepatocellular enzyme release and NO production

As a marker of hepatocytes necrosis, activity of alanine aminotransferase (ALT) was spectrophotometrically measured using a determinating kit in serum and culture supernatants, at 520 nM in the presence of α-ketoglutarate, aspartate, NADH and malate dehydrogenase, as described[19]. The amount of NO production in the serum and the culture supernatants were determined as its stable oxidative product, nitrite, by an automated procedure based on the Griess reaction, as previously described[20].

Histopathological and immunohistochemical examination

Livers were removed, fixed overnight in 10 % buffered formalin, and paraffin-embedded. Six-micrometer sections were stained with hematoxylin-eosin for histological evaluation. Immunohistochemical staining for iNOS protein expression was carried out using rabbit polyclonal antibodies to iNOS on cryostat sections (five-micrometer). The sections were incubated with peroxidase-labeled rabbit anti-mouse immunoglobulin for 1 hour. After another wash in PBS, the sections were stained with AEC for several minutes to develop the color and washed in water. Each experiment was repeated two to three times with similar results. Three random sections of each liver were examined[19].

Statistics analysis

Data were presented with $\bar{x}\pm s$, Statistical analysis was performed using ANOVA. Differences were judged to be statistically significant when the *P* value was less than 0.05.

RESULTS

Effect of Ganoderma lucidum polysaccharide (GLP) on the liver weight and the activity of serum alanine transaminase (ALT) in BCG-induced immune hepatic injury in mice in vivo

Compared with the control of group, BCG-pretreatment markedly induced hepatic damage (Table 1). The augment of the liver weight and the serum ALT level were observed after BCG-administrated 2 weeks in mice ($P<0.01$). Furthermore, application of inflammatory lipopolysaccarides (LPS) for BCG-pretreated mice induced serum ALT activity further higher than that BCG-treated alone in mice ($P<0.05$), but the liver weights were not further increased than that BCG-stimulated only groups. On the other hand, under the presence of BCG stimuli conditions, administration of CLP decreased the liver weight within the range of 50 mg· kg^{-1} ($P<0.05$) to 200 mg· kg^{-1} ($P<0.01$), simultaneously, serum ALT release were significantly decreased by GLP treatment in a dose-dependent manner within the similar range of concentrations ($P<0.05$).

Table 1 Effect of Ganoderma lucidum polysaccharide (GLP) on the weight of liver and the activity of serum alanine transaminase (ALT) in BCG-induced immune hepatic injury in mice ($\bar{x}\pm s$)

Group	Liver weight (g)	ALT (U· L^{-1})
Control	0.99±0.16	22.03±10.99
BCG (125 mg· kg^{-1})	1.79±0.24 [b]	245.18±41.03[b]
BCG (125 mg· kg^{-1}) + LPS (125 μg· kg^{-1})	1.84±0.14[b]	285.88±23.81[b,c]
BCG (125 mg· kg^{-1}) + GLP (25mg· kg^{-1})	1.78±0.20[b]	236.86±27.94[b]
BCG (125 mg· kg^{-1}) + GLP (50mg· kg^{-1})	1.57±0.18[b, c]	189.81±43.99[b,c]
BCG (125 mg· kg^{-1}) + GLP (100mg· kg^{-1})	1.28±0.20[b, d]	178.78±13.16[b,d]
BCG (125 mg· kg^{-1}) + GLP (200mg· kg^{-1})	1.41±0.43[b, c]	208.18±27.93[b,c]

[a]$P<0.05$, [b]$P<0.01$ compared with control. [c]$P<0.05$, [d]$P<0.01$ compared with BCG-pretreated group. n=9 mice (liver weight groups) or 10 mice (ALT groups).

Hematoxylin and eosin.Mice were treated with (A) control, (B) Bacille Calmette-Guérin (BCG, 125 mg·kg $^{-1}$, 2 weeks) , (C) BCG plus lipopolysaccarides (LPS, 125 μg·kg $^{-1}$, 12hr), (D) BCG plus GLP (100 mg·kg $^{-1}$), as described in Materials and Methods. (Original magnification 200×)

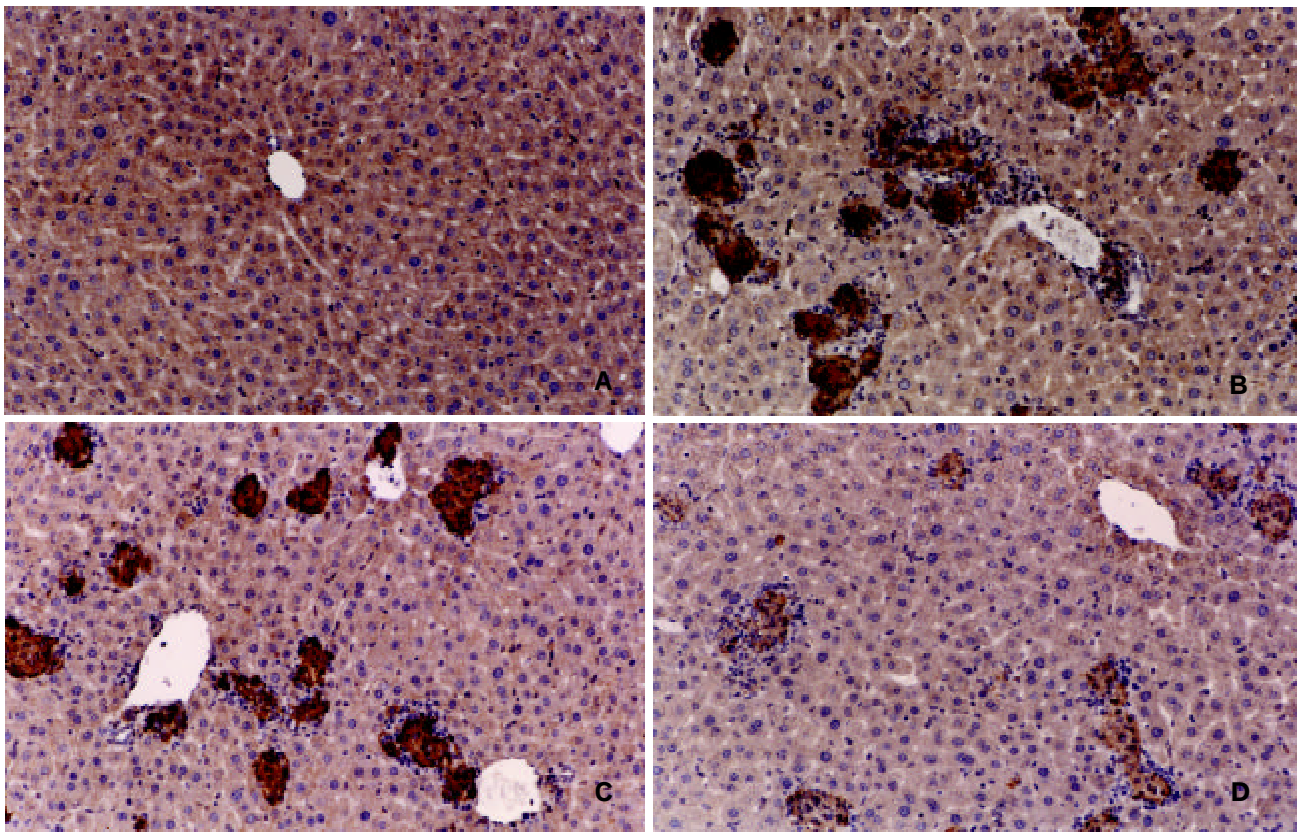

Figure 2 Immunohistochemical examination of inducible nitric oxide synthase (iNOS) protein expression stimulated by BCG in the presence or absence of *Ganoderma lucidum* polysaccharide (GLP) in mice. (Original magnification 200×). Mice were treated with (A) control, (B) Bacille Calmette-Guérin (BCG, 125 μg·kg $^{-1}$, 2 weeks) , (C) BCG plus lipopolysaccarides (LPS, 125 mg·kg $^{-1}$, 12hr), (D) BCG plus GLP (100 mg·kg $^{-1}$), as described in Materials and Methods.

Effect of Ganoderma lucidum polysaccharide (GLP) on the pathohistological changes in BCG-stimulated hepatic tissues in mice in vivo

As shown in Figure 1, oppositing with the results of control group, BCG-stimulated group were observed markedly changes of liver histologic structure (Figure 1-B), for example, infiltration within liver lobules by inflammatory cells, extensive hepatocytes hypertrophy, nuclear narrow, and granulation and vacuolization of the hepatocyte cytoplasm were observed in the liver section. Moreover, treatment with BCG plus LPS for mice resulted in more severe histological changes including thrombosis in the central hepatic vein and hemorrhage in the liver parenchyma(Figure1-C). Granulomas formation, a marker of chronic hepatitis fibrosis' were significantly increased by BCG-stimulated hepatic tissues (Tabel 2, $P<0.01$). But in the presence of BCG condition, the result showh that LPS was not triggered more the granuloma forming, on the contrary, triggered more fearful hepatic tissues hemorrhage (Figure 1 B-C).

On the other hand, the results of histological examination shown that GLP (100 mg· kg $^{-1}$) alleviated hepatic damage in BCG-induced acute inflammation, such as markedly decrease of infiltration within liver lobules by inflammatory cells, nuclear narrow,etc. in the observed liver section (Figure 1-D). Moreover, granulomas formation were also decreased by GLP treatment at concentration range from 100 mg· kg $^{-1}$ to 200 mg· kg $^{-1}$,($P<0.01$).

Table 2 Effect of Ganoderma lucidum polysaccharide (GLP) on the granuloma formation (numbers / microscopic view) in BCG -pretrested mice hepatic histological slides. ($\bar{x}\pm s$)

Croup	Granulomas
Control	0
BCG (125 mg·kg $^{-1}$)	64.67±4.97^{b}
BCG (125 mg·kg $^{-1}$) + LPS (125 μg·kg $^{-1}$)	54.40±4.93^{b}
BCG (125 mg·kg $^{-1}$) + GLP (50mg·kg $^{-1}$)	60.00±4.24^{b}
BCG (125 mg·kg $^{-1}$) + GLP (100mg·kg $^{-1}$)	4.00±1.22^{b,d}
BCG (125 mg·kg $^{-1}$) + GLP (200mg·kg $^{-1}$)	36.80±5.81^{b,d}

Effects of Ganoderma lucidum polysaccharide (GLP) on the ALT activity and NO production induced by BCG in the presence or absence of cytokines mixture (CM) in primary cultured mice hepatocytes in vitro

The result of this part of experiment shown that inflammatory cytokines increased NO production and ALT release into the supernatant in the primary cultured hepatocytes prestimulated by BCG ($P<0.01$, Table 3). In the absence of cytokines condition, addition of CLP only had not influence on the activity of ALT enzyme and NO production in BCG-pretreated cultured supernatant ($P>0.05$). Whereas, in the presence of inflammatory cytokines plus BCG prestimuli condition, ALT activity and NO production were markedly inhibited by application of GLP ($P<0.01$).

CM (Cytokines mixture):IL-1β 10 KU· L^{-1},TNFα 500 KU· L^{-1}, and IFNγ 100 KU· L^{-1} plus LPS 10 mg· L^{-1}; Cultured hepatocytes were harvested from control group, BCG-prestimulated group *in vivo*, and BCG plus CM-stimulated group *in vitro*, respectively, in the absence or presence of GLP for 24 h; Amount of nitrite and activity of ALT in the supernatant were assayed 24 h after start of stimulation *in vitro*.

Table 3 Effects of Ganoderma lucidum polysaccharide (GLP) on the alanine transaminase (ALT) activity and nitrite (NO_2^-) production induced by BCG-prestimulating in the presence or absence of cytokines mixture (CM) in primary cultured mice hepatocytes in vitro ($\bar{x}\pm s$)

Effect of Ganoderma lucidum polysaccharide (GLP) on the inducible nitirc oxide synthase (iNOS) protein expression in BCG-stimulated mice hepatic tissues in vivo

To confirm the possible mechanism about hepatoprotective role of GLP against BCG-stimulated in mice, the correlativity between iNOS expression and immune hepatic damage were investigated. As shown in the results of immunohistochemistry, compared with control group mice, there was a lot of iNOS positive brown stained agglomerate observed in BCG-stimulated hepatic section (Figure 2 A-B). But consisted with the results of granuloma forming , there were not more the iNOS expression induced by LPS in the presence of BCG stimuli condition (Figure 2-C). On the contrary, treatment of GLP significantly inhibited iNOS protein expression under similary BCG-stimulated condidtion (Figure 2-D).

DISCUSSION

In the present experiment, the results shown that the administration of GLP was effective against acute and chronic hepatic inflammation induced by BCG-immunostimuli in mice. Administration of GLP significantly decreased serum or supernatant ALT level in BCG-caused acute inflammatory response *in vivo* and *in vitro*. Histological changes, such as hemorrhage and necrosis in hepatic lobules, inflammatory infiltration of lymphocytes and kupffer cells around the central vein, were simultaneously improved by the treatment of GLP. These results were consistent with that GLP showed anti-inflammatory and antioxidative activities in the previous other laboratory observed results[22]. Moreover, pathohistological examination also showed that GLP decreased the granuloma formation, which is popularly considerd as the first step of fibrillar repair in the chronic inflammatory process[23-26]. This result suggested that GLP may be not only as an anti-inflammatory agent, but also may be used as an antifibrotic therapy for hepatocirrhosis.

To investigate the possible mechanisms of the hepatic protective effect of GLP in the immune-stimulated condition, we further detected NO production in primary cultured hepatocytes and iNOS protein expression in the BCG-stimulated hepatic tissues[27-30]. The results shown that GLP alone had no effect on the production of NO in the cultured hepatocytes. In the presence of BCG condition, cytokines

mixture (CM) including TNF-α, IFN-γ, and LPS, significantly increased the NO production. When combined with GLP, this effect had been remarkably reversed. At the same time point, GLP also attenuated the increase of ALT activity in inflammatory cytokines-stimulated hepatocytes *in vitro*. It has been recognized that NO is produced by cNOS and/or iNOS in mice liver[31-37]. The results of immunohistochemistry shown that GLP effect on NO production is mainly through iNOS under immunological stimuli condition. The results of this study suggested that although the exact mechanism of action of GLP on such macrophage/lymphocyte properties of granulomas remain unknown, nevertheless, it might be related to NO production induced by cytokines[38-42]. Therefore, inhibition of NO production is partly the mechanisms of GLP protective effect on the immunological injured liver.

In summary, the present study indicates that NO participates in immune liver injury induced by *Mycobacterium bovis* BCG infection. Furthermore, the mechanisms of protective roles by GLP for BCG-induced immune liver injury in mice may be due to influence NO production. However, further study is needed to understand the exact mechanisms of the antihepatotoxic activity and the free radical scavenging activity of GLP. The clinical applicability of GLP remains to be established.

Abstract

AIM: **To explore the role of focal adhesion kinase (FAK) in the apoptosis in culture-activated rat hepatic stellate cells (HSCs) using a specific anti-FAK antibody.**

METHODS: **Rat HSCs were prepared from Wistar rats by *in situ* perfusion of collagenase and pronase and single-step density Nycodenze gradient. Culture-activated HSCs were serum-starved and treated with the anti-FAK antibodies for 24, 48 or 72 h. The apoptosis of HSC was detected by DNA-fragment assay, flow cytometry and caspase-3 activity determination. The expression of tissue inhibitor of metalloproteinase-1 (TIMP-1) mRNA was assessed by reverse transcription polymerase chain reaction (RT-PCR).**

RESULTS: **The experiment showed that anti-FAK antibodies induced apoptosis of culture-activated rat HSCs. This phenomenon displayed the classical features of apoptotic cell death (DNA fragmentation, cell cycle analysis) after treated with 30 mg·L^{-1} FAK antibody for 72 h, and accompanied by a significant increase of caspase-3 activity(1208±76) *vs* (309±28) nmol·min^{-1}·g^{-1}, t=208.5, P<0.05. Meanwhile, treatment with the FAK antibody in HSCs could markedly decrease the TIMP-1 mRNA expression (0.07±0.01 *vs* 0.38±0.03, t=2.72, P<0.05).**

CONCLUSION: **FAK plays an important role in the survival of HSCs and the specific anti-FAK antibody could induce the apoptosis in rat HSCs.**

INTRODUCTION

Focal adhesion kinase (FAK) is a non-receptor tyrosine ubiquitously expressed in cells. It was initially shown to be the initiator of focal adhesion formation in adherent cells, after its binding to integrins which induce its autophosphorylation[1]. However, it can also be activated by a great variety of other stimuli being able to act on different intracellular signaling, and neuropeptides[2-4]. Its autophosphorylation is followed by a submembranous localization which is crucial for the biological roles of FAK, including cell spreading, migration, proliferation, survival and prevention of apoptosis[5-7]. Proteolytic cleavage of FAK by caspase-3 has been reported during growth factor deprivation-induced apoptosis in human umbilical vein endothelial cells[8], which implies an association between FAK and apoptosis[9,10]. The pathologic basis of hepatic cirrhosis is fibrosis and hepatic stellate cells (HSC) are presently regarded as one of the key cell types involved in the progression of liver fibrosis[11-13]. The perpetuation of HSC activation leads to an increased number of collagen-producing cells and finally to the accumulation of extracellular matrix (ECM)[14-16]. Therefore, the strategy for terminating the proliferation of activated HSC by apoptosis might be an exciting therapy for patients with chronic liver injury and fibrosis[17-19].

FAK has also been shown to play an important role in the HSC activation[20]. PLC γ recruitment by FAK during HSC adhesion is an important process implicating a link between integrin and PDGF-mediated signal pathways to regulate HSC adhesion and mobility[21]. An adherence dependent pp125FAK-paxillin signaling pathway in fibroblasts inhibited damage-induced apoptosis[22]. Thus, we hypothesized that the modulation of biological roles of FAK by a neutralizing anti-FAK antibody might stop the fibroproliferative response and induce apoptosis in HSC.

MATERIALS AND METHODS

Materials

Male Wistar rats were obtained from the Experimental Animal Center of West China Medical Center of Sichuan University (West China University of Medical Sciences, Chengdu, Sichuan). Dulbecco' s modified medium (DMEM), Trypsin-EDTA and new born calf serum (CS) were from GibcoBRL (Maryland, USA). Pronase, Collagenase B and DNAase I were from Roche Molecular Biochemicals, (Mannhein, Germany). Nycodenz was from Sigma (ST. Louis, USA). Antibodies to Desmin, α-smooth muscle actin (α-SMA) were obtained from Dako (Glostrup, Denmark). Affinity-purified polyclonal antibody to FAK (epitope mapping at the carboxy terminus of focal adhesion kinase) were purchased from Santa Cruz (Santa Cruz, USA). The caspase-3 cellular activity assay kit was purchased from CalBiochem-Novabiochem Corporation (San Diego, USA).

Methods

HSC isolation and apoptosis induction HSCs were isolated from male Wistar rats by *in situ* pronase-collagenase perfusion and single-step Nycodenz gradient[23]. The cells were seeded at a density of 1.5×10^5/cm^2 on glass coverslips in 6-well culture plate or 100-mm dishes (Falcon) and maintained in DMEM containing 200 ml· L^{-1} heat-inactivated new-born calf serum. The purity of HSC preparations was assessed by

intrinsic vitamin A autofluorescence and immuocytochemistry with antibody against desmin. The viability of the cells was evaluated by the Trypan blue dye exclusion test. The purity and viability of the primary cells exceeded 90 % and 95 %, respectively. Therefore, HSC cultured on uncoated plastic dishes spontaneously acquired an activated phenotype, characterized by expression of α-SMA and by loss of vitamin A droplets[24,25]. After reaching confluency (about 10-14 d after plating), activated HSC were detached by incubation with trypsin, and split in a 1:2 ratio. Experiments were performed on cells between the second and 5th passages using 3 independent cell lines, and the purity of activated HSC exceeded 98 %. HSC (5×10^6) were plated in uncoated plastic dishes for 4 h and the medium was changed to serum-free DMEM for 24 h to synchronize the HSC in the G_1 phase of the cell cycle [26]. The antibodies against FAK was filer-sterilized and added to the serum-free DMEM medium containing 1 g· L^{-1} bovine serum albumin (the final concentration of anti-FAK antibodies was 30 mg· L^{-1}). The analysis of apoptosis was carried out after 24-72 h of incubation with the antibodies. The serum-free DMEM medium containing the antibodies was changed every 24 h.

Analysis of DNA fragmentation HSC from the anti-FAK antibodies treated was pooled for DNA fragmentation analysis. A DNA fragmentation assay was performed as described previously[27]. In brief, HSC was gently lysed for 30 min at 48 ℃ in a buffer containing 5 mmol· L^{-1} Tris buffer (pH7.4), 20 mmol· L^{-1} EDTA, and 5 ml· L^{-1} Triton X-100. After centrifugation at 15 000r· min^{-1} for 15 min, supernatants containing soluble fragmented DNA were collected and treated with RNAase (20 mg· L^{-1}), followed by proteinase K (20 mg· L^{-1}) digestion.DNA fragments were precipitated in 990mL· L^{-1} ethanol. Samples were then electrophoresed on a 20g · L^{-1} agarose gel, visualized with 1 g· L^{-1} ethidium bromide and photographed under short-wave ultraviolet light.

Flow cytometry Cell viability was determined using trypan blue dye exclusion, and the existence of apoptotic cells was confirmed as well by the appearance of a sub-G_0/G_1peak fraction in the cell cycle analysis [28]. For the cell cycle analysis, ethanol-fixed cells were stained with propidium iodide (50 mg· L^{-1}) in the presence of RNase A (100 mg· L^{-1}), and then analyzed using the fluorescence-activated cell sorter (FACS, Coulter, EPICS ELITE ESP model), with a cell cycle analysis program.

Cellular caspase-3 activity determination The cellular caspase-3 activity assay from Calbiochem-Novabiochem Corporation measures the colorimetric reaction of the cleavage of the amino acid motif DEVD, thereby releasing the chromophorep-nitroanilide[29]. Following phosphate-buffered saline washing, cell lysate was prepared according to the manufactures' instructions. The level of caspase-3 enzymatic activity on the cell lysate is directly proportional to the color reaction that was quantitated spectrophotometrically at a wavelength of 405 nm, using a microplate reader for 96 wells (Bio Rad, model 550). And the total protein content of each cell lysate was determined by the Coomassie dye binding assay (Bradford method). Data were corrected for background (no substrate or no cell lysate) and caspase-3 activities were expressed as nmol· min^{-1}· g^{-1} of protein.

TIMP-1 mRNA detection by RT-PCR The total RNA was isolated from HSC using Trizol reagent (Life Technologies, Inc, USA), precipitated in ethanol and resuspended in sterile RNAase-free water for storage at -70 ℃, as described previously [30]. One-step reverse transcription-polymerase chain reaction (RT-PCR) was performed according to the method of the supplier (Titan™ one tube RT-PCR kit, Roche Molecular Biochemicals). Primers for rat tissue inhibitors metalloproteinase-1 (TIMP-1) and GAPDH were designed using the Primer3 program from Whitehead Institute for Biomedical Research (Cambridge, MA, USA)[31], synthesized and purified by HPLC in Gibco BRL Custom Primers (HongKong). Primer sequences were as follows: TIMP-1 sense, 5'-GAC CTG GTC ATA AGG GCT AAA-3'; antisense, 5'-GCC CGT GAT GAG AAA CTC TTC ACT-3'; GAPDH sense, 5'-ACC ACA GTC CAT GCC ATC AC-3'; antisense, 5'-TCC ACC ACC CTG TTG CTG TA-3', and the expected size was 216 bp and 452 bp respectively. One microgram RNA was added to each reaction and the RT-PCR was performed in the following steps: reverse-transcription was performed at 50 ℃ for 30 min; and amplification was performed in a thermal controller (model PTC-100, MJ Research, Watertown, USA) for 35cycles (denaturation at 94 ℃ for 1 min, annealing at 56 ℃ for 1 min and extension at 72 ℃ for 1 min), and 10 min at 72 ℃ for final extension after the last cycle. 5 μl of the PCR products was analyzed by 20 g· L^{-1} agarose gel electrophoresis with TAE buffer at 80V for 40 min, visualized with ethidium bromide and photographed under UV light. The semi-quantitative analysis was performed. TIMP-1/GAPDH quotient is the indication of TIMP-1. Experiments were performed at least three times with similar results.

Statistical analysis

Results of cell cycle analysis were expressed as percentage of total examined cells and statistical analysis was performed by χ^2 test. Other results were expressed as $\bar{x}\pm s$. Differences between means were analyzed with Student *t* test for paired samples. A value of $P<0.05$ was considered statistically significant.

RESULTS

DNA fragmentation assay

We investigated the role of FAK in the survival of HSC to rescue cells from apoptosis. An antibody to FAK that could inhibit it activation was used to test this hypothesis. This antibody binds to the COOH-terminal region of FAK, which contains the targeting sequence that is required for efficient recruitment of FAK to the focal adhesion[22, 32, 33]. HSC was treated with 30 mg· L^{-1} anti-FAK antibodies in DMEM without serum. Genomic DNA fragment analysis performed 48-72 h after treatment demonstrating an oligonucleosomal DNA ladder for the treated cells, and the cells after treatment for 24 h showed minimal DNA ladder whereas the control cells in DMEM without the antibodies displayed no DNA degradation (Figure 1).

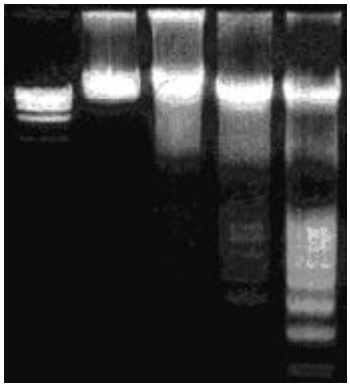

Figure 1 Oligonucleosomal genomic DNA fragmentation. Lane M: DNA marker of PBR322; Lane 1: Control HSCs; Lane 2, 3, 4: HSC treated with anti-FAK antibodies for 24, 48 or 72 h.

Flow cytometry

A predominant sub-G_1 population (39.8 %) characteristic of apoptosis was observed in anti-FAK antibodies treated HSCs for 72 hours by propidium iodide staining and flow cytometric analysis, while the control cells only had a (5.2 %) sub-G_1 population (Figure 2). There was significant difference between these two groups (39.8 % *vs* 5.2 %, χ^2=1716.4, P<0.001). And a significant sub-G_1 population (16.5 %) was also observed in anti-FAK antibodies treated HSCs for 48 hours, while the control cells only had a (3.1 %) sub-G_1 population (16.5 % *vs* 3.1 %,χ^2= 507.8, P<0.001). However, there was no significant difference between the 24-hour treatment and controls (3.1 % *vs* 2.7 %,χ^2=1.4, P>0.05).

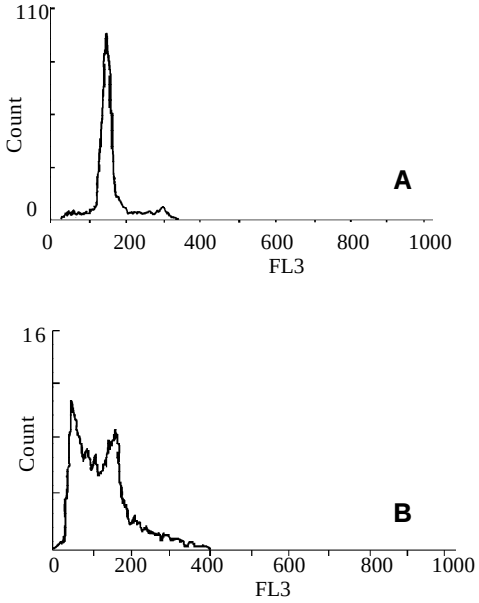

Figure 2 Flow cytometric analysis of HSCs.
A: Control HSC; B: HSC treated with anti-FAK antibodies for 72 h showed the presence of a hypodiploid (sub-G_1) fraction, indicating DNA degradation.

Cellular caspase-3 activity

Anti-FAK antibodies -induced apoptosis was accompanied by a significant time-dependent increase of caspase-3 activity (Table 1).

Table 1 Caspase-3 activation in HSCs by anti-FAK antibodies (n=6)

Groups	Caspase-3 activity (nmole · min^{-1} · g^{-1})
Control (24 h)	36.5±12.6
Treatment (24 h)	41.9±15.3
Control (48 h)	110.7±18.6

Control (72 h)	36.5±12.6
Treatment (72 h)	1208.5±76.4 [a]

[a]P<0.05, *vs* control (233.5±25.9 *vs* 110.7±18.6, t=33.9, P<0.05; 1208.5±76.4 *vs* 36.5±12.6,t= 208.5, P<0.05)

Effect of anti-FAK antibody on the expression of TIMP-1 in HSCs

To evaluate whether the anti-FAK antibody affects the expression of TIMP-1 in HSCs, RT-PCR analysis was performed to detect the gene expression lever of TIMP-1 after the treatment with anti-FAK antibodies in HSC. The mRNA expression levels of cells that treated with the antibodies for 72 h was remarkably decreased as against that of the controls (0.07±0.01 *vs* 0.38±0.03, P<0.05, Figure 3). But there was no significant difference between the cells treated with the antibodies for 48 h or 24 h and their controls (P >0.05).

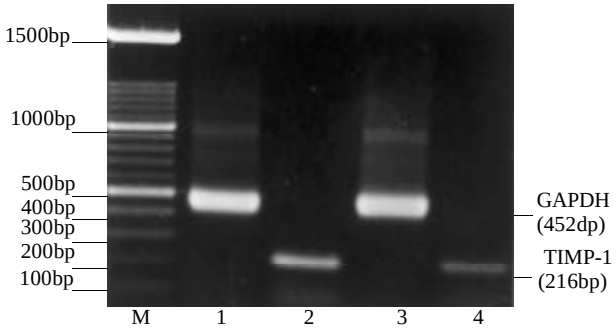

Figure 3 Electrophoresis analysis of RT-PCR product.
Lane M: 100bp DNA ladder; Lane 1, 2: amplified from cDNA from the control HSCs; Lane 3, 4: amplified from cDNA from HSCs treated with anti-FAK antibodies for 72 h. The positive bands of 452bp and 216bp represented GAPDH and TIMP-1 respectively. Lane 4 showed decreased expression of TIMP-1 in HSC compared with lane 2.

DISCUSSION

Liver fibrosis is characterized by an accumulation of extracellular matrix protein that impairs normal function with severity. It represents the common end point of the majority of chronic liver injuries. Ultimately, it results in distortion of the liver architecture (cirrhosis) which is associated with disturbance of liver function and significant morbidity and mortality[34 - 37]. At the cellular level there is now a wealth of evidence indicating that HSC represents the pivot of the fibrotic process. In the injured liver and during culture, quiescent HSCs transform from a retonoid rich pericyte-like cell to a myofibroblast-like cells (MFB). This so-called "activation" is associated with a loss of vitamin A droplets, increased proliferation, and sensitivity towards endothelins, increased production of ECM proteins, in addition to multiple alterations in gene expression[11-15]. Activation and transformation of HSCs into MFB may be viewed as a "wound-healing response", however, little is known about the termination of this process, while HSC is abundant in the diseased liver tissue during fibrogenesis, and resolution of liver fibrogenesis is associated with reduced number of HSC. In the recovery from liver injury, apoptositic HSC was detected in parallel to a reduction in the total number of HSC within the liver tissue and an essential element of this recovery process is apoptosis of activated HSC[17-19]. Apoptosis (or programmed cell death) is the controlled mechanism by which cells are eliminated from tissue without eliciting an inflammatory response. Apoptosis of HSC may therefore play a central role in the resolution of fibrosis by eliminating the source of both the neomatrix and the metalloproteinase (collagenase) inhibitors and thereby facilitating net matrix degradation. Therefore, promoting HSC apoptosis may be a viable method to facilitate matrix degradation in fibrotic liver, thereby manipulating the fibrotic process. An understanding of the control of HSC apoptosis is important precisely because regulating this process may provide a novel therapeutic approach to the treatment of advanced hepatic fibrosis[18 - 20].

Anchorage of cells to the ECM is mediated by integrins[38], which not only mediated cell adhesion but also initiate

intracellular signal transduction[39]. A family of nonreceptor tyrosine kinases, composed of FAK, proline-rich tyrosine kinase (PYK-2), and integrin-linked kinase complex with the intracellular domain of integrins, leading to activation of various signaling pathways subsequent to integrin stimulation. Since the initial discovery and characterization of FAK, a number of different functions have been proposed for this unusual tyrosine kinase. FAK plays a pivotal role in transducing survival signals mediated by engagement if integrins with the ECM, enabling the cell to enter the cell cycle, thereby preventing apoptosis[1,40]. In rat HSCs, a soluble RGD peptide that blocks attachment to fibronectin and vitronectin triggered apoptosis in the serum-free condition, suggesting that integrin-mediated events can regulate death decisions in HSC[27]. Furthermore, the authors[27] reported that RGD peptides reduce the phosphorylation of FAK in HSC. Therefore in the current study we have described the role of FAK in the apoptosis in HSC.

Recently, a potential role for FAK in the suppression of apoptosis has been suggested in different cell types[7, 41]. This study showed that anti-FAK antibodies induced apoptosis of culture-activated rat HSCs. This phenomenon displayed the classical features of apoptotic cell death (DNA fragmentation, cell cycle analysis), and accompanied by a significant increase of caspase-3 activity. Caspases, a family of the interleukin-1β converting enzyme (ICE) family of cysteine proteases, are key intracellular mediators of apoptosis[42, 43]. Caspase-3, also known as CPP32, Yama or apopain, is one of the principle caspases found in apoptotic cells[44]. Our observations suggest that induction of apoptosis in HSCs by anti-FAK antibodies may through the caspase-3 activation.

The data presented in this paper demonstrate that treatment of HSC with anti-FAK antibodies decreased the expression of TIMP-1 mRNA. Matrix metalloproteinases (MMP) and their specific inhibitors (TIMP) are thought to play an essential role in liver injury associated with tissue remodeling[45-47], and it was reported that antisense oligonucleotides directed to TIMP-1 had some anti-hepatic fibrosis effect in the experimental immune hepatic rat models[48]. MMP or their inhibitors (TIMP) have been suggested to regulate apoptosis, and TIMP-1 inhibits cell death induced by hydrogen peroxide, adriamycin, or X-ray radiation[49]. It has recently shown that recovery from established experimental fibrosis can occur through the apoptosis of HSCs and is associated with reductions in liver collagen and expression of the TIMP-1 and TIMP-2[47]. Furthermore, FAK signaling pathway plays a pivotal role in the secretion of MMPs[50]. Therefore, the anti-FAK antibody regulated apoptotic pathway in HSCs might be triggered by interference with the TIMP-1 function.

In conclusion, integrin-ECM interactions influence apoptosis in rat HSC, and FAK is required for transducing survival signals from ECM in HSC. Our experiment provided a link between FAK and caspase-3, the expression of TIMP-1 and HSC survival. Thus the regulation of apoptosis may be very important in HSC biology.

Abstract

AIM: **Hepatic stellate cell (HSC) plays a pivotal role in liver fibrosis and is considered as the therapeutic target for the treatment of hepatic fibrosis. Tyrosine protein kinase plays an important role in the proliferation, activation of HSC. The purpose of the study is to investigate the effects of the tyrosine protein kinase inhibitor genistein on the proliferation and activation of cultured rat HSC.**

METHODS: **Rat HSC were isolated from Wistar rats by *in situ* perfusion of collagenase and pronase and single-step density Nycodenz gradient. Culture-activated HSC were serum-starved and incubated with 10^{-9} to 10^{-5} mol/L concentration of genistein for 24, 48 or 72 h. In PDGF-induced HSC proliferation, HSC were stimulated with 10 mg·L^{-1}PDGF-BB for 15 min, and then treated with genistein for the same time. Cell proliferation was measured by MTT assay and based on flow cytometric analysis of cell cycle. The a-smooth muscle actin (a-SMA) expression in HSC was studied with confocal laser microscopy and flow cytometry. *c-fos*, *c-jun* and cyclin D_1 expression in HSC was also detected by flow cytometry.**

RESULTS: **Genistein inhibited basal and PDGF-induced proliferation of HSC at the concentration of 10^{-8} to 10^{-5} mol/L, and treatment with 10^{-7} mol/L concentration of genistein for 48 h inhibited the HSC proliferation significantly (the inhibition rate was 70.3 %, $P<0.05$). Immunofluorescence detected by confocal laser microscopy and flow cytometry showed that treatment with 10^{-7} mol/L genistein for 48 h suppressed the expression of a-SMA significantly in HSC (the specific fluorescence intensity were 60.2±21.5 *vs* 35.3±11.6 and 12.8±10.4 *vs* 9.54±6.39, respectively, both $P<0.05$). The intensity of *c-fos*, *c-jun* and cyclin D_1 expression of HSCs treated with 10^{-7} mol/L genistein for 48 h was also significantly decreased compared with the controls.**

CONCLUSION: **Genistein influences proliferation of HSC, suppresses the expression of a-SMA in HSC and t inhibits the intensity of *c-fos*, *c-jun* and cyclin D_1 expression of HSCs. Genistein has therapeutic potential against liver fibrosis.**

INTRODUCTION

Hepatic stellate cells (HSC) are liver mesenchymal cells located in the space of Disse, in close contact with hepatocytes and sinusoidal endothelial cells. In normal liver tissue, they are responsible for vitamin A storage and metabolism. During liver fibrogenesis, HSC undergo a process of activation by acquiring a myofibroblast-like phenotype characterized by increased proliferation and extracellular matrix component synthesis[1-3]. It is known that several cytokine can stimulate HSC proliferation (such as PDGF[4], EGF and bFGF) and collagen synthesis (TGF-β_1) in activated HSCs[5-7]. In addition, the activated cells express substantial amounts of α-smooth muscle actin (α-SMA) and show strong contracting activity. Taken together, HSC have been postulated to play critical roles in the development of fibrosis of the liver that was injured by viral infection, alcohol and various drugs[8-11]. Therefore, it is important to find out some agents that block HSC activation, a prerequisite to liver fibrosis.

During culture of HSC in a medium supplemented with serum, they spontaneously undergo activation. This culture-induced activation has been extensively studied as a model of the activation secondary to liver fibrogenesis. This *in vitro* model is useful to understand the molecular mechanism underlying the activation and/or inactivation of HSC in injured liver. In this context, interferons[12], nitrovasdilators[13], relaxin[14] and pentoxifylling[15] have been shown to inhibit the activation of cultured HSC. Molecular mechanism for the activation of HSC was found to involve intracellular signal cascades and transcriptional regulation of certain genes[16-19].

Recently, tyrosine protein kinase (TPK) signaling pathways were reported to play an important role in the activation of HSC[20]. TPK are involved in signal transduction pathways that control cell proliferation and differentiation and they may be classified into two general groups: (a) membrane receptor tyrosine protein kinases, including EGF-, PDGF-, CFS-, IGF- and insulin receptor[21], and (b) non-receptor linked and cytosolic tyrosine protein kinase[22]. Receptor tyrosine kinase that mediate HSC proliferation include the PDGF receptors[4, 23].

Among many polypeptide growth factors potentially involved in chronic liver inflammation, PDGF, a dimmer of two chain referred to as A-chain and B-chain, has been shown to the most potent mitogen for cultured HSC isolated from rat, mouse or human liver[24]. Of the three possible dimeric forms of PDGF (AA, AB and BB), PDGF-BB had been shown to be the most potent in stimulating HSC growth and relative

intracellular signaling, in agreement with a predominant expression of PDGF-Rβ(or type B) subunits as compared with the expression of PDGF-Rα (or type A) subunits in activated HSC. Importantly, co-distribution of PDGF with cells expressing the relative receptor subunits (α and β) has been clearly shown after chronic liver tissue damage[23], thus, confirming a functional role of this polypeptide mitogen in the development of hepatic fibrosis.

PDGF receptors are tyrosine protein kinases that are activated by dimerization and autophosphorylation after ligand stimulation. The phosphorylated tyrosine can then associate with intracellular signaling molecules including phospholipase Cγ (PLCγ), phosphatidylinositol 3' -kinase (PI-3K), Src, Grb2-Sos, and Ras-GTPase activating protein. In particular, the attention was focused on PDGF-induced activation of three major pathways recently shown to be highly relevant for transducing the mitogenic effect of this polypeptide mitogen, namely PI-3K, extracellular signal regulated kinase (ERK) and changed in intracellular calcium concentration ($[Ca^{2+}]_i$) [25, 26].

In the past decade many efforts were made to develop drugs that inhibit the tyrosine kinase receptors and their intracellular signal transduction pathway[26]. Inhibition of PDGF-R receptor tyrosine kinase activity has been reported for tyrphostin classes of compounds[27]. Tyrphostins are small molecules designed to inhibit tyrosine kinases either through competition for substrates or through adenosine triphosphate binding. Iwamoto *et al*[28] had shown that Tyrphostin AG1295 reduced the proliferation response of HSC, and their findings suggested a new strategy for the prevention of liver fibrosis with inhibitors of tyrosine kinase receptors. However, whether TPK inhibitors other than tyrphostin also have such effects on HSC is not known. Furthermore, the molecular mechanism by which TPK inhibitors suppress the activation of HSC also remains uncovered.

Genistein(4,5,7-trihydroxyisoflavone), a soybean-derived isoflavone,is a TPK inhibitor that attenuates growth factor- and cytokine- stimulated proliferation of both normal and cancer cells. Extensive epidemiological, *in vitro*, and animal studies have been performed, and most studies indicated that genistein has beneficial effects on a multitude of human disorders, including cancers, cardiovascular diseases, osteoporosis, and postmenopausal symptoms[29-31]. Although genistein has been shown to dose-dependently inhibit natural and PDGF-BB-induced proliferation and DNA synthesis of aortic smooth muscle cells from stroke-prone spontaneously hypertensive rats[32], it is unknown whether genistein could inhibit the proliferation of activated HSC. The aim of the present study was to investigate the effects of genistein on basal and PDGF-induced HSC proliferation and activation of HSC.

MATERIALS AND METHODS

Materials

Male Wister rats were obtained from Experimental Animal Center of West China Medical Center of Sichuan University (West China University of Medical Sciences, Chengdu, Sichuan). Genistein and Nycodenz were obtained from Sigma (ST. Louis, USA). Dulbecco' s modified medium (DMEM), trypsin-EDTA and new-born calf serum (CS) were from GibcoBRL (Maryland, USA). Pronase, Collagenase B and DNAase I were from Roche Molecular Biochemicals, (Mannhein, Germany).Monoclonal Antibodies to Desmin, μ-smooth muscle actin (α-SMA) were obtained from Dako (Glostrup, Denmark). Monoclonal antibody to phosphotyrosine containing protein (p-Tyr), polyclonal antibodies to cyclinD_1, *c-fos* and *c-jun* were purchased from Santa Cruz Biotechnology (Santa Cruz, USA).

Methods

HSC isolation and culture HSC were isolated from male Wister rats by *in situ* pronase, collagenase perfusion and single-step Nycodenz gradient according to our previous report [33]. The cells were seeded at a density of $1.5\times10^5/cm^2$ on glass coverslips in 6-well culture plate or 100-mm dishes (Falcon) and maintained in DMEM containing 20 mL· L^{-1} heat-inactivated new-born calf serum (CS). The purity of HSC preparations was assessed by intrinsic vitamin A autofluorescence and immuocytochemistry with antibody against desmin. The viability of the cells was evaluated by the Trypan blue dye exclusion test. The purity and viability of the primary cells exceeded 90 % and 95 %, respectively. Therefore, HSC were cultured on uncoated plastic dishes where they spontaneously acquired an activated phenotype, characterized by expression of α-SMA and by loss of vitamin A droplets[34, 35]. After reaching confluency (about 10-14 days after plating), activated HSC were detached by incubation with trypsin, and split in a 1:2 ratio. Experiments were performed on cells between the second and 5th passages using 3 independent cell lines, and the purity of activated HSC exceeded 98 %.

Cell viality and proliferation assay The HSC were plated at densities of 2×10^4/ml in 24-well plates and incubated for various time periods and various concentrations with genistein. The viability of cells was analyzed by light microscope, Trypan blue staining[35]. The proliferation of HSC was assessed with 3-(4,5-dimethylthiazol-2-yi)-2,5-diphenyltetrazolium (MTT), as described[36], using cell cultured in 96-well plates. The HSC were plated at a density of 2000cells/well in 96-well tissue culture dishes and allowed to grow for 24 hrs in DMEM containing 20 mL· L^{-1} CS under standard tissue culture conditions. After three cell washes with phosphate-buffered saline (PBS), the growth of HSCs was arrested by adding DMEM medium without serum for 24 h. First, HSC were incubated with a concentration of 0 (control) or 10^{-9} to 10^{-5} mol/L genistein in fresh DMEM medium without serum and allowed to grow for 24, 48 or 72 h. Second, in PDGF-BB (10 μg· L^{-1}), proliferation of HSC was induced for 15 min and cells were incubated with a concentration of 0 (control) or 10^{-9} to 10^{-5} mol/L genistein for 24, 48 or 72 h. Four replicates were used for each experimental point. Absorbance values for cell-free wells were subtracted from all values.

Cell cycle analyze by flow cytometry After 24 h of serum deprivation, HSC were stimulated with or without 10 μg· L^{-1} PDGF-BB for 15 min and treated with genistein. At the indicated time, HSC were harvested by trypsin-EDTA, washed twice with PBS, and fixed in 700 mL· L^{-1} ethanol overnight at 4 ℃. After washing once with PBS, fixed cells were stained with propidium iodide (50 mg· L^{-1}) in the presence of RNase A (100 mg· L^{-1}), and the cell cycle distribution was analyzed using the FACScan (Coulter, EPICS ELITE ESP model), with a cell cycle analysis program.

Immunoflurescence and confocal laser microscopy Rat HSC were cultured on glass cover slips in DMEM medium containing 20 mL· L^{-1}CS for 24 h, left in serum-free DMEM medium for an additional 24 h, and then incubated with genistein (10^{-9}-19^{-5} mol/L) for 24, 48 or 72 h. In PDGF treatment, genestein was added after incubated with PDGF-BB (10 μg· L^{-1}) for 15 min. The cells were fixed with 4 mg· L^{-1} buffered paraformaldehyde with a pH of 7.4 for 20 min and then permeabilized for 10 min with PBS containing 0.1 mg· L^{-1} Triton X-100. The cells were then stained for indirect

immunoflurescence using either a monoclonal antibody against α-SMA diluted 1:100 in PBS or a monoclonal antibody against phospho-tyrosine containing protein diluted 1:50 in PBS as primary antibodies. A goat anti-mouse fluorescein isothiocyanate (FITC)-conjugated affinity-purified antibody was used as secondary antibodies at 1:200 dilution in PBS. Cells were analyzed with a laser scanner confocal microscope Bio-Rad MRC 1024ES equipped with a Nikon (Tokyo, Japan) Diaphot inverted microscope.

Immunoflurescent detection of a**-SMA, cyclinD$_1$, *c-fos* and *c-jun* by flow cytometry** Rat HSC were cultured in plastic 100 mm dishes (Nunc) in DMEM medium containing 20 ml· L^{-1} CS for 24 h, left in serum-free DMEM medium for an additional 24 h, and then incubated with Genistein (10^{-9}-19^{-5} mol/L) for 24, 48 or 72 h. After treatment, the cells were detached by trypsin and fixed with 4 mg· L^{-1} buffered paraformaldehyde with a pH of 7.4 for 20 min and then permeabilized for 10 min with PBS containing 0.1 mg· L^{-1} Trixon X-100. The cells were then stained for indirect immunoflurescence using either a monoclonal antibody against α-SMA diluted 1:50 in PBS or a polyclonal antibody against cyclin D$_1$, *c-fos* and *c-jun* diluted 1:50 in PBS as primary antibodies. A goat anti-mouse fluorescein isothiocyanate (FITC)-conjugated affinity-purified antibody and a goat anti-rabbit FITC-conjugated antibody were used as secondary antibodies at 1:200 dilution in PBS. Cells were analyzed on a FACScan (Coulter, EPICS ELITE ESP model) to determine the expression of α-SMA, cyclin D$_1$, *c-fos* and *c-jun*.

Statistical analysis

Results of cell cycle analyze were expressed as percentage of total examined cells and statistical analysis was performed by χ^2 test. Other results were expressed as $\bar{x}\pm s$. Differences between means were analyzed with student *t* test for paired samples. A value of $P<0.05$ was considered statistically significant.

RESULTS

Effects of genistein on the viability of HSC

In order to determine toxic effects of genistein on rat HSC, they were treated for 3 days with concentration from 10^{-9} to 10^{-5} mol/L of genistein and analyzed by light microscope and trypan blue staining. Genistein concentration of 1×10^{-5} mol/L or lower concentrations had no detectable effects on the cellular morphology or Trypan blue staining.

Effects of Genistein on the proliferation of HSC

First, we observed effects of genistein on the proliferation of cultured HSC. As shown in Figure 1, genistein inhibited proliferation of HSC at the concentration of 10^{-8} to 10^{-5} mol/L, and treatment with 10^{-7} mol/L concentration of genistein for 48 h inhibited the HSC proliferation significantly (the inhibition rate was 70.3 %, and the absorbance value was 0.042 ± 0.014 *vs* 0.151 ± 0.055, $t=3.51$, $P<0.05$).

Second, in PDGF-BB-induced proliferation of HSC, the effective concentration for significant inhibition was 10^{-7} mol/L as shown in Figure 1.

Similar results were obtained with the cell cycle analyze in HSC. As shown in Figure 2, A and B, the percentages of S phase in HSCs of control or PDGF- stimulated groups were 24 % and 40.1 % respectively. In contrast, genistein treatment led to a significant inhibition of new DNA synthesis, and the percentages of S phase in HSCs of 10^{-7} mol/L concentration of genistein treated for 48 h were 16.3 % and 19.9 % respectively (Figure 2, C and D). (24 % *vs* 16.3 %,$\chi^2=53.01$, $P<0.01$; 40.1 % *vs* 19.9 %,$\chi^2=240.1$, $P<0.01$).

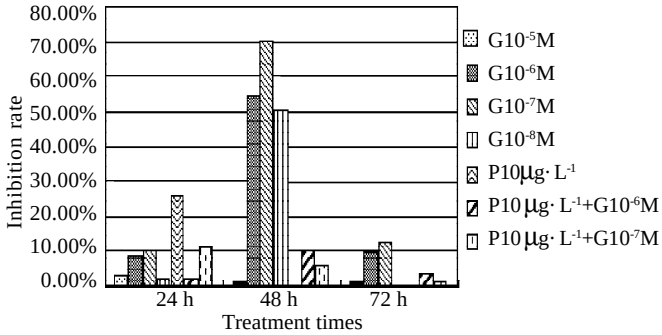

Figure 1 Genistein inhibited the basal and PDGF-BB induced proliferation of HSCs. Cell proliferation was measured by MTT incorporation

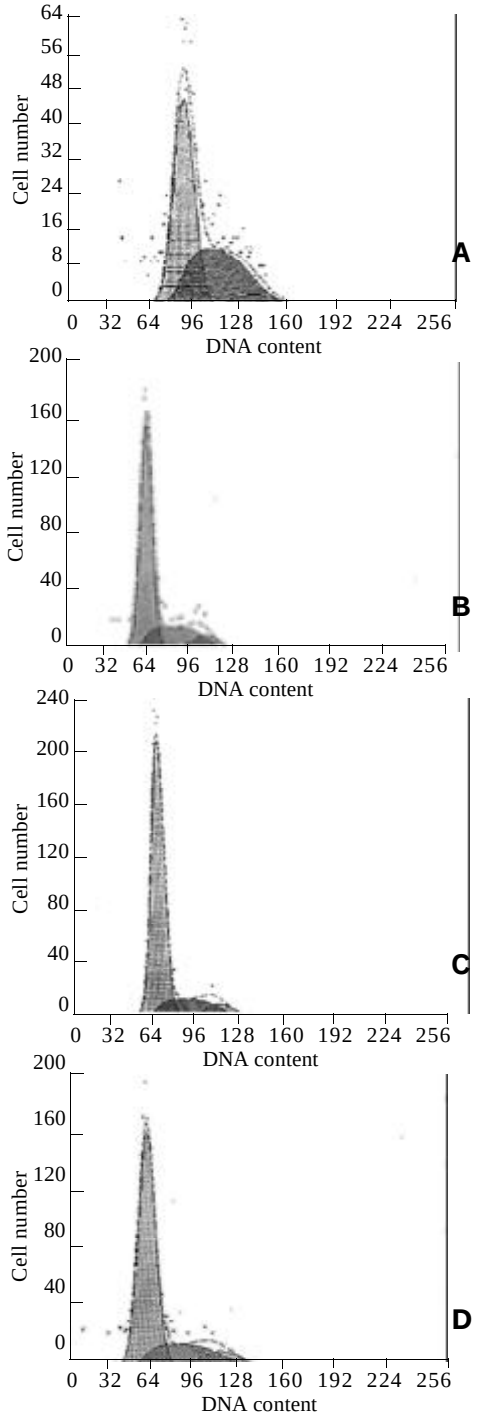

Figure 2 Flow cytometric analysis of cell cycle of HSC. (A)Control HSC;(B) HSCs stimulated with 10 μg·L^{-1} PDGF-BB for 15 min;(C) HSC treated with 10^{-7} mol/L genistein for 48 h;(D) HSC stimulated with 10 μg·L^{-1} PDGF-BB for 15 min and then incubated with 10^{-7} mol/L genistein for 48 h.

Effects of genistein of the expression of α-SMA in HSC

Smooth muscle α-actin has been accepted for use as one of the indicator of activated HSCs. Immunofluorescence detecting by confocal laser microscopy showed that treatment with 10^{-7} mol/L genistein for 48 h suppressed the expression of α-SMA significantly (the specific flurescence intensity was 60.2±21.5 *vs* 35.3±11.6, t=12.45, P<0.01, Figure3). And this observation was also confirmed by detecting the immunofluorescence expression of α-SMA in HSC by flow cytometey, as shown in Figure 4 and Table 1.

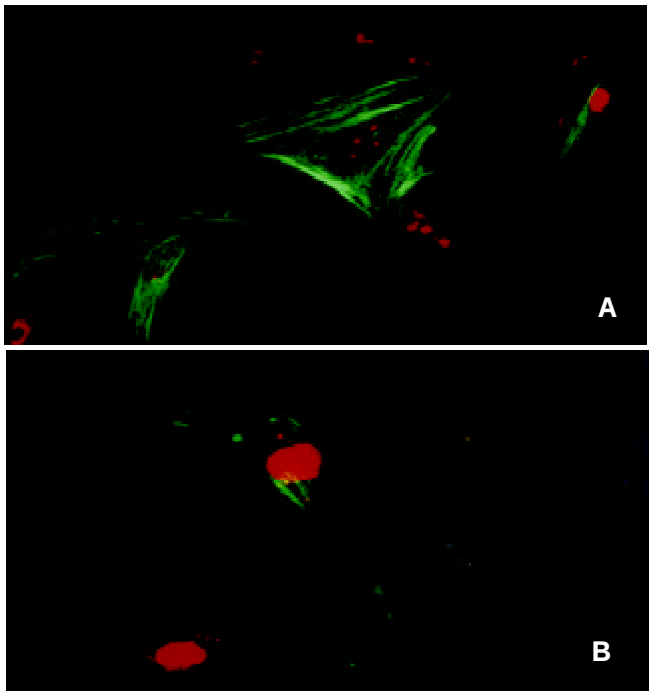

Figure 3 Immunoflurescence detection of α-SMA in HSC by confocal laser microscopy(×600). (A) Strong staining was observed in control HSC; (B) only a few cells were stained when HSC treated with 10^{-7} mol/L genistein for 48 h

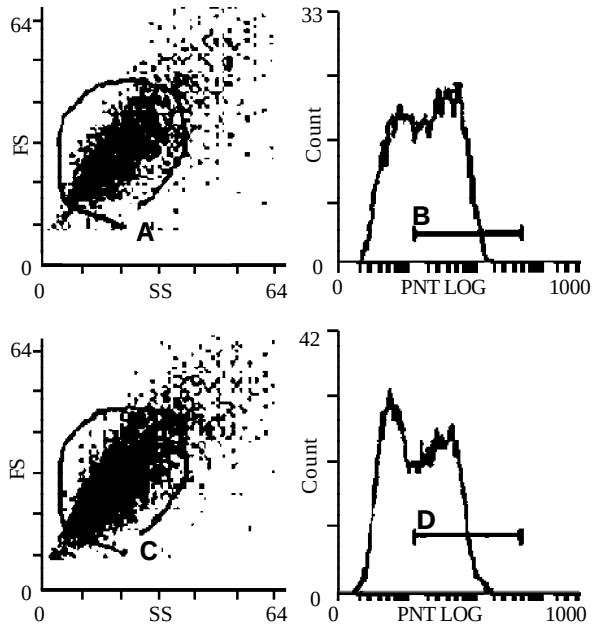

Figure 4 Flow cytometric analysis of α-SMA in HSC. (A,B) control HSC (C,D) HSC treated with 10^{-7} mol/L genistein for 48 h. showed significant decreased fluorescence intensity (P<0.05).

Effects of genistein on tyrosine phosphorylation in HSCs

Immunoflurescence detecting by confocal laser microscopy showed that PDGF-BB stimulated the tyrosine phosphorylation significantly after 10 μg·L^{-1} PDGF-BB incubated with HSC for 15 min (the specific fluorescence intensity was 27.1±18.8 *vs* 66.5±36.3, t=14.65, P<0.05); but treatment with 10^{-7} mol/L genistein for 48 h suppressed the expression of tyrosine phosphorylation significantly (the specific fluorescence intensity was 66.5±36.3 *vs* 46.6±16.4, t=7.39, P<0.05, Figure5).

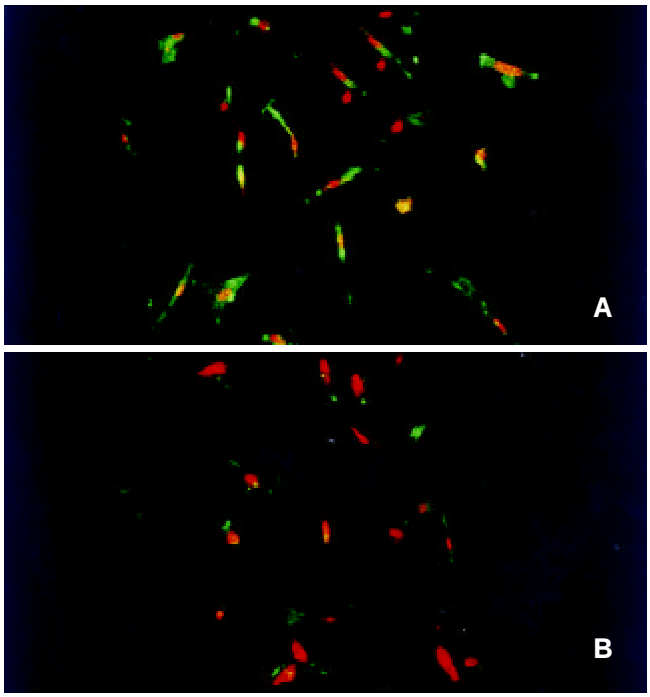

Figure 5 Immunoflurescence detection of the expression of tyrosine phosphorylation in HSC by confocal laser microscopy(×200). (A)HSC stimulated with 10 μg·L^{-1} PDGF-BB for 15 min showed a strong staining for phosphoyrosine containing protein; (B) HSCs stimulated with 10 μg·L^{-1} PDGF-BB for 15 min and then incubated with 10^{-7} mol/L genistein for 48 h showed significant decreased fluorescence intensity for phosphoyrosine containing protein.

Effects of genistein on expression of c-fos, c-jun and cyclin D_1

The expression of *c-fos*, *c-jun* and cyclin D_1 were remarkably lower in HSCs that incubated with 10^{-7} mol/L genistein for 48 hrs than in the controls, as shown in Table 1 and Figure 6.

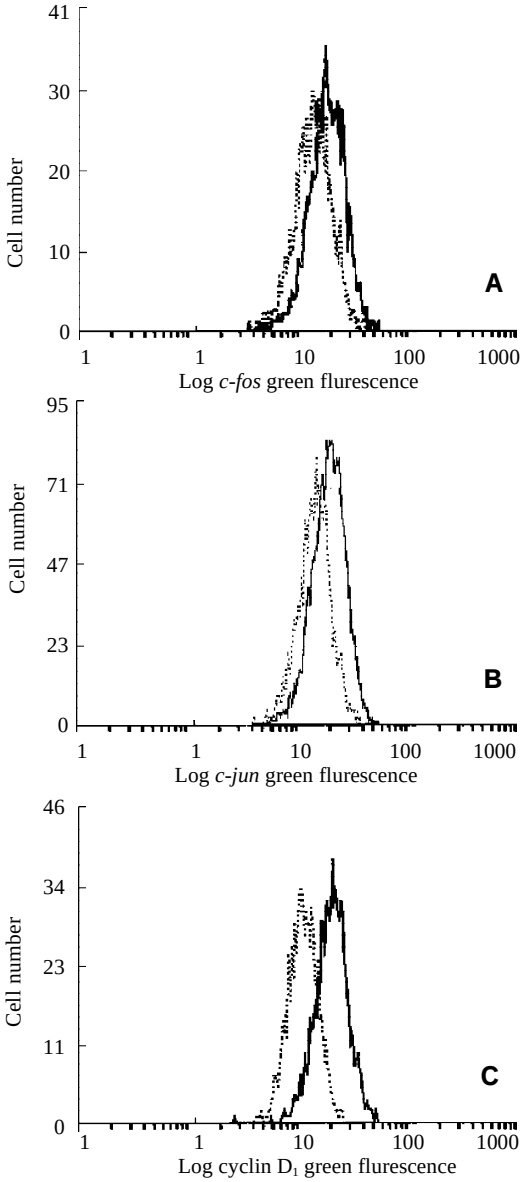

Figure 6 Flow cytometric analysis of *c-fos* (A), *c-jun*(B) and cyclin D_1(C) expression in HSC. -indicated the control HSC and -indicated HSC treated with 10^{-7} mol/L genistein for 48h.

DISCUSSION

Genistein-a soy derived isoflavone has recently attracted much attention of the medical scientific community. This compound was found to be a potent agent in both prophylaxis and treatment of cancer as well as other chronic diseases. In addition to its proposed actions on prevention cancer, genistein has recently been shown to have antitumor, anti-oxidant and anti-inflammatory effects[29, 30]. The great interest that has focused on genistein led to the identification of numerous intracellular targets of its action in the live cells. It was reported[37] that six flavonoids (fisetin, quercetin, apigenin, phloretin, hesperatin and chalcone) inhibited the proliferation of HSCs, but the underlying mechanisms responsible for theirs effects are not yet completely understood. And little is known about the effects of genistein on the HSCs, the cell type primarily involved in hepatic fibrogenesis. Therefore we used an *in vitro* model in which the activation and proliferation of HSCs were induced by growth on plastic dishes to study the effects of genistein on HSCs and its possible mechanisms.

This culture-induced activation process showed, as far as known, all features of the *in vivo* process. The present report describes that genistein influences several aspects of the HSC activation. It diminishes proliferation, decreases the expression of α-SMA, *c-fos*, *c-jun* and cyclin D_1 and these effects of genistein are not due to a toxic cell damage.

In this study, we observed the effect of genistein on the proliferation of activated HSCs. We found that 10^{-8} to 10^{-5} mol/L concentration of genistein not only inhibited the basal proliferation of activated HSC, but also inhibited the proliferation of HSCs induced by PDGF-BB. Inhibition of proliferation of HSCs by genistein is not surprising, because reduced cell growth by genistein has been extensively reported. The activated HSCs express receptors for various growth factors, such as PDGF[23,38], IGF[39], and bFGF[40], which are receptor tyrosine protein kinases (RTKs) that have been implicated in HSCs proliferation. One mechanism how genistein might influence the proliferation of HSCs might be the down-regulation of the RTKs in the membrane of HSCs.

In mammalian cells, the Ras/ERK pathway directs signals to the immediate-early genes, such as *c-fos*, *c-jun* and other co-regulated genes. *c-fos* has been reported to function by froming homodimer alone or heterodimer with *c-jun*, which forms the dimeric transcription factor complex activator protein-1 (AP-1)[41, 42]. Recently, it has been demonstrated that the motigen actvited protein kinase (MAPK) family, including *c-jun* NH_2-terminal kinase (JNK) and ERK, plays an important role in the HSC cellular response to stress[43]. Acetadehyde, the major active metabolite of alcohol, is known to stimulate alpha I (I) collagen production in HSC in a JNK-dependent pathway[44]. *C-fos* and *c-jun*, two important terminals of various signal transduction pathways and important nuclear factors involved in regulating cytokine gene expression, have been reported to express in activated human HSCs[45]. Recent evidence showed that genistein significantly attenuated the hydrogen peroxide-induced proliferation in aortic smooth muscle cells and *c-jun* gene expression[46], and the inhibition of *c-fos* expression, AP-1 transactivation and ERK phosphorylation may contribute to the growth-inhibitory effect of genistein in some breast cell types[47]. The results of our experiments showing an inhibition of *c-fos* and *c-jun* expression by genistein further support an effect of this drug on the activated Ras/ERK pathway, including downstream nuclear events leading to HSC cell proliferation.

Another interesting finding is that genistein reduced the protein level of cyclin D_1, a cell cycle related protein. Proliferation of eukaryotic cells is generally controlled at stages from G_1 to S transition phases. G_1 cyclins include three forms of cyclin D (D_1, D_2 and D_3) and cyclin E that associate with either cdk2, cdk4 or cdk6, and cyclin D_1, D_2, and D_3 are markers for G_1 phase[48]. It was reported that administration of genistein to rats with a acute renal injury decreased the activation of ERK, and the induction of cyclin D_1 was also prevented by this treatment[49]. The present study showed that genistein decreased the cellular level of cyclin D_1, and this notion was consistent with the results obtained by cell cycle analyze and MTT assay.

Genistein examined in the present study also inhibited the expression of α-SMA in HSCs. Expression of α-SMA is reported to be regulated by the discoidin domain receptor 2 (DDR2), a tyrosine kinase receptor expressed in mesenchymal tissue whose ligand is fibrillar collagen[50]. In general, HSC undergoing proliferation concomitantly express α-SMA[1-3]. Inhibitors for HSC activation, such as candesartan and perindopril [51], the semisynthetic analogue of fumagillin TNP-

470[52], interferon[12] and a selective ROCK inhibitor, Y27632 [53], block both cellular proliferation and expression of α-SMA. Therefore, proliferation and expression of α-SMA in HSC seem to be triggered by the same signal transduction pathway, although so far a detailed analysis has been lacking. Perhaps, growth-stimulatory signals involve the activation of positive transcription factors in the 5' -flanking region of α-SMA gene. However, the molecular mechanism by which genestein inhibits the expression of α-SMA in HSC should be further studied.

In summary, the present report showed that genistein regulated the proliferation and the expression of α-SMA,*c-fos*, *c-jun* and the cell cycle protein D_1, thereby modulating functions of HSC. This effect appears partially mediated by a reduction of PDGF-stimulated ERK activity as well as of other intracellular pathways. The mechanisms of action of genistein include its role as weak estrogens, inhibitor of TPK-dependent signal transduction processes and as cellular antioxidants[30, 54]. Findings[55, 56] suggest that estradiol is a potent inhibitor of HSC activation and transformation, and it suppressed the induction of hepatic fibrosis. So the effects of genistein to HSCs may also include its weak estrogens role. Because HSCs play pathological roles in inflammation and fibrosis of the liver, therapeutic potential of genistein to hepatic fibrosis should be studied further.

Abstract

AIM: **To evaluate the immunologic role and expression significances of nitric oxide(NO), nitric oxide synthase (NOS),and its isoenzyme in acute rejection to liver xenografts from golden hamster in rat.**

METHODS: **Liver transplantations were randomly divided into five groups(*n*=6-9):isografts (group Ⅰ); xenografts (group Ⅱ); xenografts plus cyclosporine treatment (group Ⅲ), xenografts plus cyclophosphamide treatment combined with splenectomy (group Ⅳ), and xenografts using cyclophosphamide in combination with splenectomy (group Ⅳ) and xenografts using splenectomy in addition to cyclophosphamide and cyclosporine treatments(group Ⅴ) .The levels of ALT,TNF-α, and nitric oxide production(NOx) in serum of reciprents were examined,and expressions of type Ⅱ (iNOS) and type Ⅲ (cNOS) nitric oxide synthase(NOS)-inducible NOS(iNOS) and constitutive NOS(cNOS) were observed by NADPH diaphorase histochemical and immunohistochemical staining.**

RESULTS: **The level of serum ALT,activity of serum TNF-a and systemic levels of NO metabolite in groups Ⅱ and Ⅳ were higher than those of groups Ⅰ and Ⅴ (serum ALT,2416±475, 2540±82.5) nkat.L^{-1} *vs* (556.8±43.5, 677.30±38.2) nkat.L^{-1}, *P*<0.01; (serum TNF-a, 353.5±16.1 , 444.6±28.1) ng.L^{-1}, *vs* 38.5±5.2, 52.0±5.7) ng.L^{-1}, *P*<0.01; (serum NOx 514.6±18.1, 336.0±43.0)nmol.g^{-1}, *vs* 26.1±5.7, 27.7±6.0) nmol.g^{-1}, *P*<0.01.Cyclosporine in group Ⅲ can repress the cellular immune response and the synthesis of nitric oxide and the expression of NO synthase,but not prolong the liver xenograft survival.The over-expression of NOS,iNOS and cNOS in liver xenograft rejection in groups Ⅱ and Ⅳ were detected by NADPH diaphorase histochemical and immunohistochemical staining.**

CONCLUSION: **The degrees of acute rejection can be effectively repressed in golden hamster to rat liver xenografts with splenectomy and cyclosporine. Nitric oxide metabolites,and nitric oxide synthase and its isoenzymes,above all inducible NOS (iNOS) can be used as potential diagnostic markers for acute rejection in liver transplantation. The cellular localization of nitric oxide varies according to the immunologic status of liver xenografts,thus thinking that hepatocyte derived nitric oxide may be protective in the hyporesponsive state,but hepatic injury is likely triggered by centrilobular iNOS expression in the superresponsive state.**

INTRODUCTION

Immune rejection remains an impediment to its overall clinical success in orthotopic liver transplantation,and acute rejection is seriously harmful to the grafts and recipients. Besides clinical symptoms and signs, histological analysis of biopsy remains the most useful tool for assessing the severity of rejection,but the liver graft may have been severely damaged at this time.It is an urgent issue of the moment to study the mechanisms of acute rejection and search for special early markers of diagnosis in liver transplantation.The cellular immunity has been testified to be a chief mechanism in rejecting liver transplantation[1-8].

In recent years,as an endothelium-derived relaxing factor (EDRF), nitric oxide(NO),which is a highly reactive free radical with a multitude of organ specific regulatory functions,has received a tremondous amount of attention within the realm of organ transplantation[9-11],for it can induce directly specific and nonspecific immunity of the body[12].While a great deal of research has centered upon its cellular and molecular biology and pharmacology,little is known about NO' s contribution to overall organ physiology or pathophysiology. In organ transplantation,NO has been postulated to possess immunomodulatory functions. However,it remains unknown whether NO is immunosuppressive or immunostimulatory. In addition,does NO have a role in immunologic function within the settings of acute rejection,chronic rejection,or hyporesponsiveness? Our previous studies suggested that the beneficial effects of hepatic nitric oxide on the reperfusion injury in the rat orthotopic liver transplantation (OLT) by supplementing NO pathway or inhibiting the endothelium NOS with NG Nitro-L-arginine methy ester(L-NAME)[13-15].It was reported that hepatocyte-derived NO may be protective in the hyporesponsive state. However, Jsobe *et al*[16]reported recently that a selective iNOS inhibitor attenuated ischemia-reperfusion injury in the pig liver,suggesting that NO produced by iNOS has a cytotoxic rather than a hepatoprotective effect on the hepatic warm I/R injury.As a result,further investigation regarding the immunologic role of NO in acute rejection in OLT is warranted. Our aim was to investigate the immunologic role of nitric oxide and expressing significance of NOS and its isoenzyme in acute rejection of golden hamster to rat liver xenografts.

MATERIALS AND METHODS

Materials

Male Wistar rats weighing 180-260 g purchased from Shanghai Experimental Animal Centre, Chinese Academy of Sciences,

and female golden hamsters weighing 150-200 g, purchased from the Shanghai Municipal Institute of Family Planning were used as donors and recipients respectively. All animals were maintained on a 12 h light/dark cycle and fed commercially available rat chow and had free access to water. Nitroblue tetrazolium and β-NADPH reduced nicotinamide adenine dinucleotide phosphate, rabbit antimouse iNOS(NOS Ⅱ) and cNOS (NOSⅢ) polyclonal antibody were obtained from Sigma.

Methods

Experimental Design All animals were randomly divided into five groups(n=6-9):Group Ⅰ (isografts) both donors and recipients were Wistar rats; Group Ⅱ,in which Wistar rats and golden hamsters served as donors and recipients respectively, is xenografts in acute rejection;GroupⅢ was subjected to orthotopic liver xenotransplatation treated with cyclosporine (30 mg/kg.d),served as cellular immunosuppresive group; Group IV was xenografts using cyclophosphosphamide (40 mg/kg·d) in combination with splenectomy,as humoral immunity defeat group; and group Ⅴ was xenografts using splenectomy,cyclosporine and cyclo-phosphamicle as double imminosuppresive group.

Orthotopic liver transplantation Orthotopic liver transplantation (OLT) was performed according to Harihara's three Cuff technique with minor modifications as previously reported[17,18], in which the suprahepatic vena cava (SVC) was reconstructed by the Cuff method, along with the infrahepatic inferior vena cava (IVC) and the portal vein.The bile duct was internally stented with a polyethylene stent. The splenectomy was simultaneously carried out in the grafted recipients.

Specimen measurement The blood samples were obtained *via* the tail vein at the days 3, 5, 7, 10, 14, and so on postoperatively, or *via* portal vein or infrahepatic IVC in the recipient being killed or its liver tissue being biopsyed, and then centrifuged by 3 000 r·min^{-1} at 4 ℃ for 10 min. The upper serum after snap-frozen was immediately stored at -80 ℃ refrigerator before determination of nitric oxide metabolite production by the improved Griess' s method, aspartate amino-tranaferase(AST),and α-tumor necrosis factor(TNF-α)according to MTT. The inferior lobe of right liver biopsy was carried out with methoxyfluorane anesthesia in groups Ⅱ,Ⅲ and Ⅳ5, 14 and 21days after postoperation .The samples were instantly stored in liquid nitrogen, and kept frozen at -80 ℃ refrigerator.

Histopathology Sections of the grafted liver were fixed in 100 ml·L^{-1} formalin and prepared with haematoxylin and eosin stain for routine light microscopy.

Histochemical staining for NO synthase (NADPH diaphorase staining) The grafed liver specimens were fixed in 40 g·L^{-1} paraformal-dehyde and 4 g·L^{-1} picric and in 0.1 mol·L^{-1} sodium phosphate buffer,pH7.4,for 4 h at 4 ℃. Subsequently,specimens were frozen at -80 ℃ until cutting the sections. Cryostat sections were immersed for 10 min in 0.1 mol·L^{-1} phosphate buffer,pH8.0, and were incubated for 40 min at 37 ℃ in prewarmed solution consisting of 0.1 mol·L^{-1} phosphate buffeer,pH8.0;3 g·L^{-1} Tritox X-100;0.5 mmol·L^{-1} nitroblue tetrazolium; and 1.0 mmol·L^{-1} NADPH. After washing in 0.1 mol·L^{-1} phosphate buffer,pH7.4,the sections were dehydrated with graded alcohol(70,80,95 and 100 mL·L^{-1}). Slides were rinsed in PBS and counter stained with fast red for 2 min, and cover slips were mounted on microscopic glass slides. Areas with a positive reaction for NADPH diaphorase were stained dark blue in cytoplasm, and in red nucleus[19-23].

Immunohistochemistry Immunohistochemical methods were used to detect the expressions of inducible NOS (iNOS)and constitutive NO synthase(cNOS) with specific polyclonal antibody against cNOS or iNOS by the avidin-biotin complex method using an ABC immunostaining kit (Vector Labs, Burlingame, Calif)Areas with a positive reaction were stained pale brown .

Statistical analysis Data are presented as means ± standard errors of the means ($\bar{x}\pm s$).Comparisons among different groups of samples were made by two-tailed test χ^2 test and F test. A value of $P<0.05$ was considered to be statistically significant.

RESULTS

Survival

The Survival of recipient in groups Ⅱ,Ⅲ and Ⅳ, in which no significant alteration was found(6.9±0.4 , 7.3±1.0d,7.0±0.6 d, respectively) significantly lowered as compared with that of groups Ⅰ and Ⅴ, the difference being not statistically significant(48.5±20.7d *vs* 37.1±9.9d, $P>0.05$,Table 1).

Biochemical parameters(Table 1)

Following OLT, serum samples were assayed for ALT,TNF-α and NO on 3,7 and 14 postoperative days (Table 1).The serum values for ALT and TNF-α in groups Ⅱ and Ⅳ were 4-11 times greater than those of groups Ⅰ and Ⅴ ($P<0.01$, *vs* groups Ⅰ and Ⅴ).The serum levels of NO metabolites (NOx) in groups Ⅱ and Ⅳ were 12-20 times greater than in groups Ⅰ, Ⅲ and Ⅴ.

Table 1 Effects of biochemical parameters and recipient survival on cellular and/or humoral immunosuppression in rat liver transplantation

Group	Serum ALT (nkat·L^{-1})	Serum TNF-α (ng·L^{-1})	Serum NO $\bar{x}$ (nmol·g^{-1})	Survival (d)
Ⅰ	556.8±43.5	38.5±5.2.	26.0±5.7	48.5±27.7
Ⅱ	2416±475[b]	353.5±16.1[b]	514.6±18.1[b]	6.9±0.4[b]
Ⅲ	2550±55.6[b]	66.0±2.9	41.5±3.6	7.3±1.0[b]
Ⅳ	2540±82.5[b]	44.6±28.1[b]	336.0±43.0[b]	7.0.±0.6[b]
Ⅴ	677.30±38.2	52.0±5.7	27.7±6.0	37.1±9.9

[b]$P<0.01$, *vs* I and V groups.

Histopathology

Histological examination of the grafted liver in groups Ⅰ and Ⅴ revealed almost normal liver sinusoidal architecture with the exception of complication of the secondary infections such as subhepatic abscess of cholangiojejunal fistula, pneumonia, etc. (Figures 1,2).Acute rejection appeared in heterogeneic OLT group Ⅱ,histological examination demonstrated only a small amount of cellular infiltrates in sinusoid areas by the 3rd postoperative day; inflammatory cell infiltration was increased significantly by the 5th postoperative day; diffuse polymorphonuclear and mononuclear cell infiltration, massive necrosis of hepatocytes and hepatic parenchymal interstitial hemorrhage were found by the 7th postoperative day (Figure 3). In group Ⅲ,cyclosporine decreased significantly cellular infiltration,but severe hepatocyte necrosis and cyclophosphamide greatly attenuated hepatic necrosis and interstitial hemorrhage,yet cellular infiltration still remained the principal feature. In group Ⅴ of xenografts using splenectomy,cyclophosphamide and cyclosporine, the architecture of the hepatic lobule was well preserved ,with no hepatocyte necrosis, and a small amount of cellular infiltrates only in the portal areas (Figure 4).

NADPH diaphorase and immunohistochemical staining findings

Expressions of nitric oxide synthase (NOS) in grafted liver tissue were detected by NADPH diaphorase staining methods. A small amount of NOS positive expressions in groupI was localized to vascular endothelium and hepatocytes.The expression levels of NOS in groups II,IIIand IV were obviously increased by the 2nd postoperative day,dominantly localized to hapatocyte and hepatic sinusoidal lining cells. The expression time of NOS was earlier at least two days than that of pathological damage (Figure 5).The intensity of NO synthase staining by the 5th-7th postoperative day swas strongest in both the portal inflammatory infiltrate and hepatocytes showing purple dark blue precipitation (Figure 6). In contrast, the intensity of NO synthase signal in group Ⅴ was significantly weaker than that of groups Ⅱ,Ⅲ and Ⅳ (Figure 7).

The immunohistochemical staining findings for grafted liver tissue demonstrated that a small amount of signal intensity of constitutive NO synthase was present in the grafted liver tissues in group Ⅰ,but no expression of inducible NO synthase. In contrast, the intensity of both cNOS and iNOS, in groups Ⅱ,Ⅲ and Ⅳ was significantly greater than in group Ⅰ (Figures 8,9). There was no significant difference in the staining intensity of both cNOS and iNOS between groups Ⅰ and Ⅴ(Figure 10).

DISCUSSION

Recently, the postoperative immunosurveillance after organ transplantation has received a tremendous amount of attention. It has been reported that the occurrence rate of rejection in clinical liver transplantation was still as high as 48-77 %,the liver allotransplants do not undergo hyperacute rejection even if the liver is transplanted in a crossmatch positive or ABO mismatched recipient. Acquiring easily immunologic tolerance, livers grafted between widely disparate species can be more easily accepted than other grafted organs such as heart, kidney etc, which were rapidly lost because of hyperacute rejection mediated by humoral immunity, the recipient of liver xenografts can even survive for days. Hamster-to-rat liver xenotransplantation (HORLT),as a concordant heterotopic liver transplantation, undergo acute rejection mediated by cellular and humoral immunity[14].Although the small amount of antibody titer was found in hamster-to-rat cardiac transplantation after recipient's splenectomy,the survival of recipient prolonged significantly. In contrast, the survival of liver xenograft failed to prolong significantly, though the antibody titer still was not high in hamster-to-rat liver xenotransplantation subjected to splenectomy. Our results demonstrated that the combined treatment with spenectomy and cyclophosphamide due to depressing humoral immune response could reduce significantly humoral antibody formation, and lighten the hapatocyte necrosis,and completely eliminate interstitial hemorrhage, but it failed to ameliorate infiltrating cells and the expression of NO synthase in liver xenografts, and prolong the xenograft survival. However, cyclosporine could obviously depress the cellular immunity to decreased cellular infiltration,but severe hepatocyte necrosis and hemorrhage remained unchanged,thus failed to prolong xenograft survival and to improve liver functions.Only the double immunosuppression of the combined treatment with splenectomy, cyclophosphamide, and cyclosporine completely repressed the rejection of liver xenografts,significantly reduced antibody formation and infiltrating cells,eliminated the grafted liver function and prolong xenograft survival.

Nitric oxide (NO) is a highly reactive and commonly synthesized free radical with a multitude of organ specific regulatory functions. Within the realm of solid organ transplantation, NO has been the focus of attention. Discordant reports have appeared regarding the functional role of NO in systemic physiology and pathophysiology[24-35]. In organ transplantation, elevated systemic levels of NO metabolites always accompany the acute rejection of heart[36-37], lung[38-39], liver[40-41], renal[42], pancreas[43-44], and small bowel [45] allografts in both humans and rats. The potential hepatoprotective or hepatotoxic effects of NO, however, have yet to be clarified, especially, the role of NO and sites of synthesis in the immunologic states following organ transplantation. Our preliminary studies confirmed that hepatocyte NO production may be hepatoprotective in state of free radical production in hemster-to-rat liver xenografts. Monitoring of NO levels has been suggested as a clinical diagnostic means for initiation of intervention in transplantation management. Nitric oxide synthesis is an important component of nonspecific defense synthesis for a number of pathogens.Until recently,the pathway for induction of iNOS was presumed to be initiated by macrophage cytokine elaboration or lipopoly-saccharide from gram-negative bacteria. The present knowledge suggests that specific and nonspecific immunity is mediated by iNOS. Therefore, nonreticulo-endothelial cells, such as hepatocytes, containing iNOS, may play an unrecognized role in immunity. The exact roles of NO in liver xenograft rejection are still not clear. Although NO,Possessing diverse functions, such as regulation of local blood as an endothelium-derived relaxing factor, Inhibition of platelet aggregation, and attenuation of neutrophil adherance, as a natural extracellular scavenger of superoxide anions,NO was considered to have cytoprotective effects against the rejection of liver xenograft, and cytotoxic and cytostatic effector functions through the nitrosylation and inhibition of cellular enzymes critical to mitochondrial respiration and DNA synthesis[48-51].However, the role of NO in oxidative stress mediated injury, has been controversial. It was reported that iNOS mRNA in rat heart transplantation was present in the inflammatory infiltrate but not within the cardiac myocytes.In our study,the expression of iNOS in liver xenotransplantation was identified in both hepatocytes and portal inflammatory cells. Therefore, the exact role of NO in liver xenograft acute rejection remains to be further studied using both a selective iNOS inhibitor (aminoguanidine hemisulfate) and a relatively selective iNOS inhibitor. Recent studies demonstrated that intraportal administration of aminoguanidine hemisulfate, a selective iNOS inhibitor, significantly suppressed nitric oxide production and serum aspartate aminotransferase after reperfusion,inhibited nitrotyrosine expression and attenuated hepatic damage[10]. Protective or injurying effects of NO may depend upon the relative local concentrations of NO and accompany of biologic modifiers such as IL-1,TNF-α or INF-γ**.** The process of acute rejection, which may be organ specific with respect to its biochemical modiators, is determined not only by the properties of inflammatory infiltrates, but also by the response of the parenchymal cells within the specific graft.

Our study also demonstrated that the serum levels of NO metabolites (NO_x) in unmodified xenografts (group Ⅱ)and xenografts using double-immunosuppressive action(group Ⅴ). The cellular immunosuppressant using cyclosporine alone can repress the expression and synthesis of nitric oxide without improvement of graft survival.The efficacy of cyclosporine having the suppression of specific activated T cells, as an immunosuppressant for organ transplantation and severe refractory autoimmune diseases, increased its clinical

application. Our study revealed that cyclosporine treatment resulted in inhibition of iNOS expression and consequently reduces iNOS enzyme activity during acute liver xenograft rejection. Unfortunately, cyclosporine administration is associated with renal vasoconstriction and vascular injury, which is thought to be a major pathophysiologic factor in chronic CSA-induced nephro-toxicity. Cyclosporine has been shown to generate superoxide through an as-yet-unclarrified alteration of cytochrome P-450-dependent mixed function oxidases, the primary pathway of CSA metabolism. *In vitro*, superoxide has been demonstrated to enhance inactivation of NO released from endothelial cells. It was reported that NO maintains a protective function with vasoconstricting effect to CSA.In addition,NADPH diaphorase and immunohistochemical staining findings in this study indicate that nitric oxide synthase (NOS) and its isoenzyme, especially iNOS could be used as potential diagnostic markers for acutely rejecting orthtopic liver transplantation.In conclusion,the degrees of acute rejection with double immunosuppresive action using spleenectomy, cyclophosphamide and cyclosporine can be effectively repressed in golden hamster to rat liver xenografts. The elevated systemic levels of NO metabolites and the overexpression of NO synthase and its isoenzymes, especially iNOS, accompanying the acute rejection of liver xenotransplantation can be used as potential diagnostic markers for acute rejection. The cellular localization of nitric oxide varies according to the immunologic status of liver xenografts,thus hepatocyte derived nitric oxide may be considered protective in the hyporesponsive state,but hepatic injury is likely triggered by centrilobular iNOS overexpression in the superresponsive state.

Abstract

AIM: **To evaluate the metabolic effects associated with administration of rhGH and/or Gln in parenterally fed, short-bowel rats.**

METHODS: **Forty SD rats subjected to 75 % intestinal resection and maintained with parenteral nutrition were randomly divided into 4 groups as follows: -rhGH, -Gln; -rhGH, +Gln; +rhGH, -Gln; +rhGH, +Gln. Body weight and nitrogen balance were evaluated daily. After 6 days of PN, rats were killed, various organs were dissected and weighted, the carcasses were used for analysis of body composition. Serum GH and IGF-1 were determined by RIA method.**

RESULTS: **Weight loss in rats with rhGH (17.4±12.8 g) and rhGH+Gln (23.8±3.5 g) was significantly less than rats with PN alone (29.6±6. 9 g) and rats with Gln-supplemented PN (31.85±12.8 g), *P*<0.05. The accumulated NB in rats with rhGH (1252.9±294.3 mg N/d) and rhGH+Gln (1261.7±85.5 mg N/d) was significantly greater than those with PN alone (704. 8±379.0 mg N/d) and with Gln-supplemented PN (856.7±284.4 mg N/d), *P*<0.05. The absolute weight of gastrocnemius muscle in rats with rhGH (2683.9 ±341.6 mg) and rhGH+Gln (2579.1±359.5 mg) was greater than those with PN alone (2176.3±167.1 mg) and with Gln-supplemented PN (2141.9±353.6 mg). Although the absolute weight of remnant small intestine itself was not significantly different in 4 experimental groups, the weight/length of the segments was greater in rats with rhGH and/or Gln (48.7±5.5, 52.7±4.1 and 67.4±5.3 respectively) than those with PN alone(47.8±5.0), there were synergistic effects between rhGH and Gln in improvement of the weight/length of remnant small intestine, *P*<0.05. Analyses of body carcass composition showed that a higher percentage of carcass weight as protein and a lower percentage of carcass weight as fat were occurred in rats with rhGH (20.8±4.0,6.0±2.6) and rhGH+Gln(21.3±2.4,4.4±1.5) than those with PN alone (16.4±2.4,9.2±3.7) and with Gln-supplemented PN (17.8±3.0,6.3±2.0), rhGH had significant effects on alteration of body composition, *P*<0.05. Serum GH and IGF-1 concentration in rats with rhGH(5.221±0.8 and 425.1±19.2 ng/ml respectively)and rhGH+Gln (5.507±1.0 and 461.1±49.9 ng/ml respectively) were greater than those with PN alone(3.327±1.7 and 325.8± 29.6 ng/ml respectively) and with Gln-supplemented PN(3.433±0.1 and 347.7±55.7 ng/ml respectively), *P*<0.01.**

CONCLUSION: **rhGH significantly improves the anabolism in parenterally fed. short bowel rats, anabolic effect with Gln is less dramatic, there is no synergistic effect between rhGH and Gln in improvement of whole body anabolism. IGF-1 plays an important part in growth-promoting effects of rhGH.**

Gu Y, Wu ZH. The anabolic effects of recombinant human growth hormone and glutamine on parenterally fed, short bowel rats. *World J Gastroenterol* 2002;8(4):752-757

INTRODUCTION

Short bowel syndrome follows therapeutic massive small bowel resection, following such surgery, affected patients often require long-term parenteral nutrition (PN) to provide adequate nutrition to meet the needs of the body[1-2]. However, long-term experience with conventional PN is unable to increase or even maintain body protein, the anabolic response to PN is often suboptical because of the concomitant presence of catabolism and /or alterations in the hormonal regulation of metabolism[3-4]. Thus the efficacy of treatment with anabolic opsonins, such as growth factors, glutamine (Gln) is currently under the investigation[5-7]. But few studies have made direct comparisons of the metabolic response to rhGH *vs*. Gln in the body. The objective of the present study was to evaluate the relative anabolic and metabolic effects associated with administration of rhGH, Gln and the combination of rhGH and Gln during PN in short-bowel rats and to gain insight regarding potential mechanism mediating the anabolic effects of these factors.

MATERIALS AND METHODS

Animals and experimental design

Forty male Sprague-Dawley rats weighing 180-220 g were housed and underwent an acclimatization period of 7 days. After overnight fasting, they were anesthetized with 0.5 % pentobarbital (40 mg/kg) shortly before surgery. Two operations were performed: 1, placement of PN catheter in the superior vena cava via the external jugular vein; 2, 75 % small intestinal resection. After operation, the rats were placed in individual metabolic cages[8].

The experimental design was a randomized complete block with four treatment groups arranged in a 2×2 factorial design as follows: -rhGH, -Gln; -rhGH, +Gln; +rhGH, -Gln; +rhGH, +Gln. The final sample size was 10 rats per group. In addition, an orally fed, nonoperated, age-matched group (n=8) was included to serve as reference for determination of net changes in total body content of protein, water and fat. After surgery, on day 0 only saline was provided through the catheter. From day 1 to day 6, PN solution was given and water was provided ad libitum. Rats received rhGH and/or Gln for 6 days, during which PN provided the sole source of nutrition.

At the end of the experiment, the rats were reanesthesized and laparotomy was performed under sterile conditions. Blood was collected by cardiac puncture, and thymus, heart, lung, spleen, liver ,kidney, adrenal, testis and gastrocnemius muscles were dissected, weighted, frozen and stored at -70 ℃.The entire gastrointestinal tract was removed, flushed with cold saline, the wet weight of stomach, remnant small intestine (from pylorus to cecum), and cecum was recorded. The length of remnant small intestine segment was also determined. After removal of the above tissues, carcass weights were recorded and carcasses were stored at -70 ℃ for body composition analysis.

Recombinant human growth hormone (rhGH)

rhGH (Saizen) was provided by Serono Singapore Pte. Ltd, Singapore. The dose of rhGH was 1 U/kg·d (0.33 mg/kg·d) administered once a day as a subcutaneous injection over a hind limb beginning on day 1 and continued for 6 days. Sham saline injection was given to rats not treated with rhGH[9].

Compositions of PN solution

The PN solution was prepared aseptically using 7 % Vamine (SSPC), 50 % dextrose, 20 % Intralipid (SSPC), vitamins, trace elements and electrolytes. Gly-Gln (Pharmacia &Upjohn Co. Germany) was added to the Gln-PN solution and Gly-Ala-Ser-Pro was added to the standard PN solution to equalize the total nitrogen to 8.62 g/L in both solutions. All rats received 166.4 Kcal/kg·d and 1.4 g N/kg·d parenterally with an infusion pump. Compositions of the Gln-PN and standard PN are shown in Table 1.

Table 1 Compositions of Gln-PN and standard-PN solution (100ml)

	Gln-PN	Standard-PN
50 % Dextrose (ml)	33	33
20 % Intralipid (ml)	17	17
7 % Vamine (ml)	30	30
17.54 % Gly-Gln (ml)	16	0
Gly-Ala-Ser-Pro (ml)	0	16
10 % KCL (ml)	1	1
10 %NaCL (ml)	1	1
Addamel(SSPC) (ml)	1	1
Soluvit(SSPC) (ml)	1	1
Non-protein Calories (Kcal)	104	104
Total nitrogen (g)	0.862	0.862

Body composition

Body composition analysis was performed on rat carcasses to determine the percent composition of water, protein and fat[10,11]. Total carcass water was determined by freeze-drying the carcasses to obtain a constant dry carcass weight and then subtracting it from total carcass weight. The freeze-dried carcasses were then homogenized, and aliquots of dried rat homogenate were assayed for nitrogen and lipid concentrations[10]. Carcass nitrogen concentration was determined by micro-Kjeldahl analysis of 0.50 g dried rat homogenate[12], and carcass protein concentration was calculated by multiplying carcass nitrogen concentration by 6.25. carcass lipid concentration was determined by extracting 1.0 g dried rat homogenate with 2:1 (v/v) Chloroform-methanol, and then determine lipid concentration gravimetrically[10].

Nitrogen balance

Nitrogen contents of urine samples were determined by micro-Kjeldahl procedure[12]. Daily nitrogen balance (NB) was determined by subtracting 24-hour urinary nitrogen from daily nitrogen intake, which was calculated from the volume of PN solution given. Accumulated NB was calculated by subtracting 6-day urinary nitrogen from 6-day nitrogen intake.

Serum GH and IGF-1 determination

Serum GH and IGF-1 concentrations were determined by radioimmunoassay in the isotope laboratory of Zhongshan Hospital[13]. Plasma IGF-1 was assayed with the DSL-2900 rat IGF-1 RIA kit (Diagnostic systems laboratories, Inc. USA), serum GH was assayed with the human GH RIA kit (Beifang biological technical institute, Beijing, China).

Statistical analysis

Data were analyzed by one-or two-way analysis of variance (ANOVA) using the Stata 5.0 program. The four PN groups in the factorial arrangement were compared in a two-way ANOVA, the reference group was excluded from the two-way ANOVA. Group means determined by the least-significant difference technique were considered significantly different at $P<0.05$. Values were expressed as means ±SE.

RESULTS

Body weight and body composition

Changes in body weight are summarized in Figure 1. There were no significant differences in body weight at the time of surgery and when PN was initiated, $P>0.05$. After 6 days of PN, rats given rhGH weighted significantly more than rats given without rhGH. Compared to the weight before the surgery, weight loss in rats with rhGH (17.4±12.18 g) and rhGH+Gln (23.8±3.46 g) was significantly less than those with PN alone (29.6±6.89 g) and with Gln-supplemented PN (31.8±12.75 g), $P<0.05$.

Results of body composition analysis are shown in Table 2. There were no significant differences in the absolute amount and percentage of water among the groups, $P>0.05$; the absolute amount of body fat in rats with rhGH+Gln was significantly decreased compared to those with PN alone and Gln-supplemented PN; however, rats with rhGH and rhGH + Gln showed a somewhat increase in the absolute amount and proportion of the body protein. rhGH had significant effects on alteration of body fat and body protein, $P<0.05$, Gln had no such effects, and there were no significant synergistic effects between rhGH and Gln in changes of body composition, $P>0.05$.

[a]$P<0.05$ *vs* rats with rhGH+Gln and reference rats; [b]$P<0.05$ *vs* rats with rhGH and PN alone; [c]$P<0.05$ *vs* rats with PN alone,Gln-supplemented PN and rhGH+Gln; [d]$P<0.05$ *vs* rats with Gln-supplemented PN and reference rats; [e]$P<0.05$ *vs* rats with PN alone and Gln-supplemented PN; [f]$P<0.05$ *vs* rats with PN alone and Gln-supplemented PN.

Daily and accumulated nitrogen balance

Changes in daily nitrogen balance were shown in Figure 2. the improvements in daily NB was significantly higher in rats with rhGH and rhGH+Gln than those with PN alone and Gln-supplemented PN from day 4-6, $P<0.05$. the accumulated NB in rats with rhGH (1252.9±294.3 mg N/d) or rhGH+Gln (1261.7±85.5 mg N/d) was significantly greater than those with PN alone (704.8±379.0 mg N/d) and with Gln-supplemented PN (856.7±284.4 mg N/d), $P<0.05$. rhGH had significant effects on changes of NB, $P<0.01$, action of Gln was not significant statictically and there were no synergistic effects between rhGH and Gln.

Organ and tissue weights

The absolute weights of thymus, heart, lung, liver, spleen, stomach, remnant small intestine, cecum, kidney, adrenal, testis and gastrocnemius muscles are shown in table 3. Treatment with rhGH significantly increased the absolute weight of the gastrocnemius muscles compared to those not given rhGH, $P<0.01$, whereas Gln showed no significantly effect on the weight of this muscle tissue, $P>0.05$, there was no evidence of an additive effect of rhGH and Gln on the weight of gastrocnemius muscles. Although rhGH or Gln didn't affected the absolute weight of the remnant small intestine, the ratio of weight/length was greater in rats treated with Gln, rhGH and rhGH+Gln than

those with PN alone (2-way ANOVA contrasting 4 experimental groups, P=0.019, 0.012 and 0.018 respectively), there were synergistic effects between rhGH and Gln in the increase of the weight/length of the remnant small intestine. Lung, liver and spleen weights were increased in rats treated with rhGH, others were not significantly affected by rhGH and/or Gln, P>0.05.

Serum GH and IGF-1 concentrations

Rats treated with rhGH or rhGH+Gln showed significantly higher serum concentrations of GH and IGF-1 than those treated without rhGH, P<0.05. Plasma GH and IGF-1 concentrations increased by 61 % and 42 % in rats with rhGH application respectively. There was no significant difference in concentrations of GH and IGF-1 between rats treated with PN alone and those treated with Gln-supplemented PN and between rats treated with rhGH and those treated with rhGH+Gln, P>0.05. Plasma GH and IGF-1 concentrations were unaffected by Gln administration. See Figure 3.

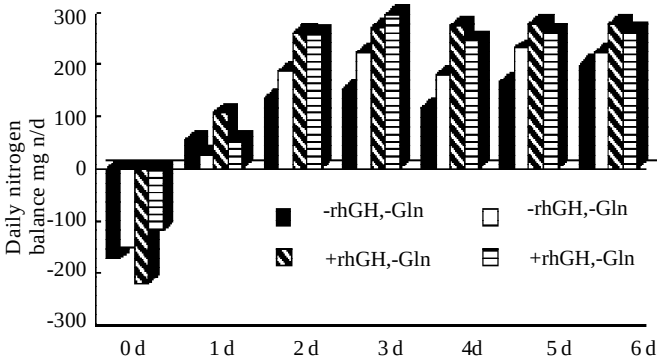

Figure 2 Daily changes of nitrogen balance in rats with PN

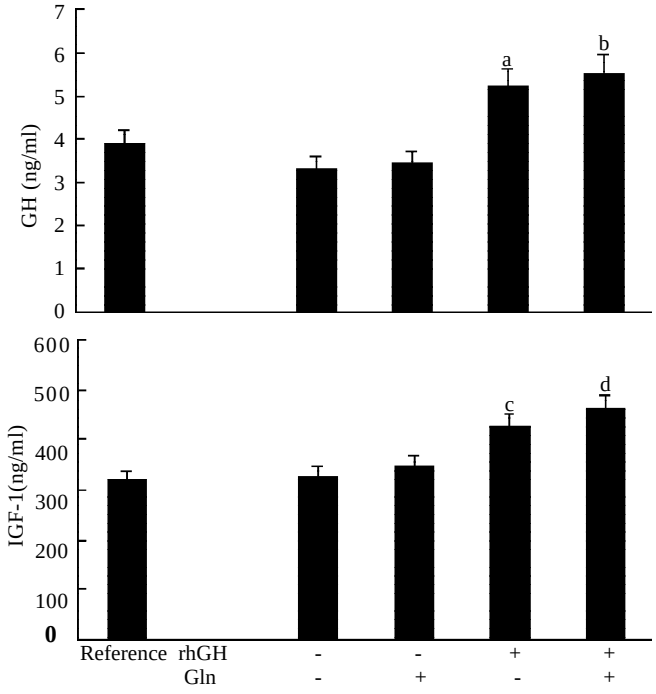

Figure 3 Concentrations in serum of GH and IGF-1 in rats maintained with PN and given rhGH and/or Gln for 6 days after massive intestinal resection. [a]P<0.05 *vs* rats with Gln-supplemented PN and reference rats; [b]P<0.05 *vs* rats with PN alone and rats with Gln-supplemented PN; [c]P<0.05 *vs* rats with PN alone and reference rats; [d]P<0.05 *vs* rats with PN alone, Gln-supplemented PN and reference rats.

DISCUSSION

Massive small bowel resection results in a marked decrease in the total surface area available for the absorption of luminal nutrients[14,15]. Affected patients often require long-term parenteral nutrition to provide adequate protein, energy and other essential nutrients to meet the needs of the body[16]. Although this approach attenuates protein losses, PN alone is often unable to increase or even maintain body protein[17], thus administration of rhGH and Gln have been of great interest in both of human and animal research in recent years[18-23]. Our experimental design provides new information about the relative anabolic and metabolic effects of rhGH *vs*. Gln and about interactive effects associated with simultaneous administration of these factors during PN.

Changes in body weight and nitrogen balance reflect the efficacy of PN[24]. We find in our study that PN alone doesn't reserve the weight loss and nitrogen catabolism induced by short-bowel. Coinfusion of rhGH in short-bowel rats significantly reduced the weight loss and nitrogen catabolism as demonstrated by a significantly decrease in nitrogen excretion and significantly greater weight gain compared with rats without receiving rhGH, there is no significant difference between rats with rhGH and with rhGH+Gln. The anabolic effects of Gln in rats given PN without rhGH were less dramatic compared with rats with PN alone in terms of increased weight gain and decreased nitrogen excretion. Body composition analysis further confirmed that increases in carcass weights and nitrogen retention with rhGH were due to retention of carcass protein rather than fat or water retention. Gln had no significant effects on body composition. Our results demonstrated that the administration of rhGH could result in significant anabolic effects on body growth and improve the efficiency of PN.

GH is anabolic in protein metabolism[25-27]. Treatment with rhGH significantly increased the absolute weights of gastrocnemius muscles compared with those not given rhGH, whereas weights of thymus, heart, kidney, stomach, remnant small intestine, cecum, adrenal, testis were not affected by rhGH. Gln showed no significant effect on the weight of tissues mentioned above. This specific anabolic effects of rhGH may reflect differences in the distribution of GH receptors within various organs and tissues[28,29]. As skeletal muscle is the main effectors of GH action[11], stimulation of rhGH on skeletal muscle is more prominent compared to other organs. In our experiment, although we didn't observe a rhGH and/or Gln effect on weights of small intestine, the ratio of weights/length of small intestine increased with rhGH and/or Gln administration, there is evidence of synergy, i.e., statistical interaction, between rhGH and Gln. Our studies of adaptation of the remnant small intestine in short-bowel rats also supported a synergistic response to rhGH and Gln[8]. Gln is the principal fuel utilized by the small intestine and is an essential precursor for purine and pyramiding synthesis required for DNA biosynthesis and cell division in the intestinal mucosa[30-32], Thus a constant supply of Gln to the intestinal mucosa in short-bowel is required and mandatory[33-35]. GH is another growth factor that may influence compensation of the small intestinal remnant[36-38]. Although opinions differ[39], GH is supposed to vigorously stimulate intestinal adaptation, it is suggested that GH takes part in the maintenance of the structure and function of the intestinal mucosa[40-42]. This study provides additional

evidence that simultaneous treatment with rhGH and Gln is more anabolic than administration of either rhGH or Gln alone in the remnant small intestine. In addition, in our study we find liver, spleen and lung weights increased with rhGH, but as the weight of these organs were easily affected by the deposited blood, further research is still needed to understand the effects of rhGH on these organs.

IGF-1 is an important peptide growth factor[43]. GH induces IGF-1 synthesis in the liver, which is thought to be the primary source of circulating IGF-1, and in many tissues with GH receptors including intestinal tissues[44-48]. IGF-1 has diverse regulatory functions, including stimulation of DNA and RNA synthesis, tissue amino acid uptake, and cellular protein accrual[49-51]. In our studies, circulating GH and IGF-1 concentrations were increased accordingly in rats treated with rhGH and with rhGH + Gln. However, supplemental Gln alone did not alter circulating GH or IGF-1 concentrations. Given the current experimental conditions, we may confirm in our study that the growth-promoting effects of rhGH are due to induction of IGF-1 production, enhanced IGF-1 synthesis contributes to the anabolic effects of rhGH.

In summary, our results indicate that treatment with rhGH during PN produced a whole body growth response that appeared to be mediated by greater concentrations of IGF-1, action of Gln is less dramatic, and there is no synergistic effect on the body anabolism between rhGH and Gln.

Abstract

AIM: **To establish a successful model of heterotopic total small intestinal transplantation (SIT) in rats in order to reduce the complications and increase the survival rate.**

METHODS: **A total of 196 Wistar rats underwent heterotopic SIT with microsurgical technique. Technical modifications included shortening fasting time and supplying energy before surgery, administering optimal volume of crystalloid fluid to the donor and recipient during surgical procedures, reducing mechanical and ischemic injuries to donor intestine, revascularizing small intestinal graft with a combination of conventional aorta to aorta anastomosis and a cuffed portal vein to left renal vein anastomosis which resulted in an acceptably short warm ischemic time, and also an adequate blood supply and drainage of the graft.**

RESULTS: **The average time for the donor surgery was 86min±20min, the mean operative time for the recipient was 115min±20min and warm ischemia time was shortened to 40min±5min. There was a shorter revascularizing time of the graft, the abdominal aorta (AA) to AA anastomosis being 21min±10min, and the cuffed portal vein (PV) to the renal vein anastomosis being 5min±5min.The one-week survival rate of 98 rats with SIT was 88.78% (87/98), without thrombosis and stenosis of anastomosis. The longest survival time of recipient rats was more than 389 days after SIT, the rats were maintaining normal weight, with perfect intestinal function and intact intestinal histology.**

CONCLUSION: **These modified techniques for SIT would remarkably reduce the complications and improve survival rate in rats, which provided a potentially more consistent and practical model for experimental and clinical studies.**

INTRODUCTION

Since Monchick and Russel[1] established the model of small intestinal transplantation (SIT) in 1971, much modification and development have been achieved[2-11]. However, the technical complexity and high mortality have hindered the wide use of this valuable model[12-24]. Parallel to our clinical SIT practice, we have successfully established a stable and practical model of heterotopic SIT with fewer complications and higher survival rate using the modified techniques.

MATERIALS AND METHODS

Animals

One hundred and ninety-six male adult Wistar inbred strain rats weighing between 180g and 310g (Shanghai Laboratory Animal Center of Academy of Sciences of China) were used as donors and recipients. Housed and fed at the Animal Center of Nanjing University, the rats were put accustomed to the environment for at least 7 days before surgery. The donor and recipient were paired according to the similar body weight.

Preoperational care and anesthesia

All the donor and recipient rats stayed fasting in metabolic cages with no access to waster but allowed to drink 5% glucose normal saline added with 160 000U/L gentamycin ad libitum for 10 h-12 h. The rats were anesthetized with an intraperitoneal injection of 1% ketamine (1mL/100g) supplemented with the 1/4 primitive dose of ketamine as required.

Donor operation

Lactated Ringer's solution with 2.5g/L Cefazomelin was infused via the penile vein by micropump (Perfusor Secura FT, B. Braun Melsunge AF, Germany) at 4 ml/h. The abdomen was opened using a "⊥" -shaped incision, and the jejunum was cut at 1cm away from the Treitz's ligament and ileum at 2 cm proximal to ileocecal valve. The entire colon was removed. The portal vein (PV) was separated from pancreas. The segment of abdominal aorta (AA) containing the superior mesenteric artery (SMA) was mobilized by ligating and dividing the lumbar artery. The lumbar arteries from the AA were meticulously ligated with 8-0 nylon sutures to minimize bleeding between the celiac and left renal artery. The left renal vessels were then ligated. The dissected AA was ligated below the left renal artery. The celiac artery was ligated, followed by the ligation of the pyloric vein and splenic vein. Five to eight ml 2.5g/L Cefazomelin in saline was injected into the small intestine through the upper end of the jejunum. The AA was cannulated with a fine polyethylene catheter and the PV was cut off near hepatic hilum. The graft was perfused in situ with 2-3 ml 4 ℃ lactate Ringer's solution containing 125 000U/L heparin by micropump at 40 ml/h until the graft intestine and mesentery turned pale, and the fluid in the PV became clear. At last, the intestine and its vascular supply including a part of AA were removed en bloc. Under operational microscope and

in lactated Ringer's solution ice-water bath, the PV end was placed into a polyethylene cuff tube and its end part of endothelium was turned over to cover the end of cuff tube. The PV end and cuff tube were fixed with 6-0 silk sutures. Hence, the round orifice of the PV was exactly in the center of the cuff tube (Figure 1). The small intestinal graft was stored in lactated Ringer's solution at 4 ℃[25-27].

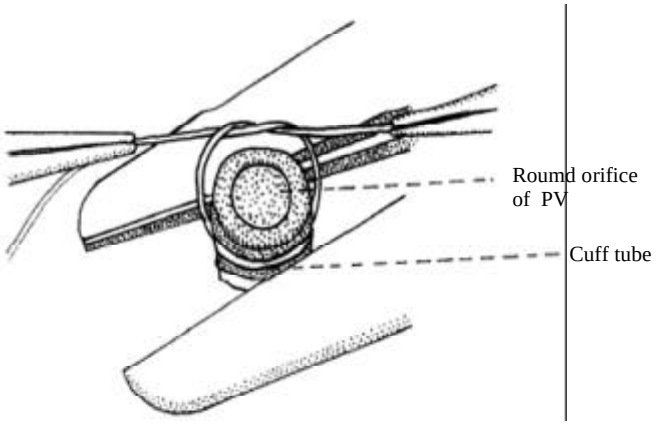

Figure 1 Fix cuff tub of PV

Recipient operation

Anesthesia and intravenous infusion for the recipient were the same as for the donors. The abdomen was opened via a midline incision from the ensisternum to the bladder level. The left ureter and renal atery were ligated. The left renal vein was dissected. The pedicle near renal helium was ligated and the ligating suture was left as a tractor after removal of the left kidney. Segment of the recipient's abdominal AA (0.6-1.0 cm) was mobilized below the vessels to the left kidney. Under operating microscope (×10 amplification), the AA of the adventitia membrance of the anterior wall was removed and opened via a longitudinal arteriotomy. The lumen was flushed with low molecular dextran solution. The donor's small intestine was picked up from the ice water, surrounded by a gauze sponge packed with ice crystals, and then placed onto the right flank of the rats. The arterial anastomosis was performed first. After ensuring that the artery was not twisted, an end-to-side anastomosis was performed using continuous 9-0 non-traumatic nylon suture. The posterior wall was anastomosed from the inside of the vessels. The anterior wall of the arterial anastomosis was sutured externally. Each lateral wall of the artery was sutured with 8 -10 sutures. The end of the left renal vein of the recipient was opened with a longitudinal incision. Two 9-0 nylon stay sutures were placed at the lateral sides of the anastomosis as a self-retaining retractor. The upper and lower sides of the incision were hauled by the pedicle ligating suture and microtweezer respectively. The cuffed PV of the small intestinal graft was inserted into the left renal vein of the recipient to revascularize the heterotopic small intestinal graft. The anastomosis was fixed with 5-0 silk suture (Figure 2). The left renal venous clamp was released first, followed by the clamps over and beneath the AA anastomosis, and the blood supply of the small intestinal graft was recovered. The arterial anastomosis was compressed lightly with a dry sponge for 1 to 2 min after reperfusion and then usually the oozing blood could be easily stopped. If blood was spouting from the arterial anastomosis, it should be quickly repaired with interruptive sutures. For the purpose of warm and flush, 20 mL warm saline was instilled in the peritoneal cavity. The small intestinal graft was put in order, and placed onto the left flank of the rats. Both ends of the graft were exteriorized as stomas. The stomas were sutured with four 7-0 silk sutures between the host perttoneum and the seromuscular layer of the graft and four 5-0 silk sutures between the skin and the everted mucosa of the graft (Figure 3). The abdomen was closed using two layers of 1-0 silk continuous sutures.

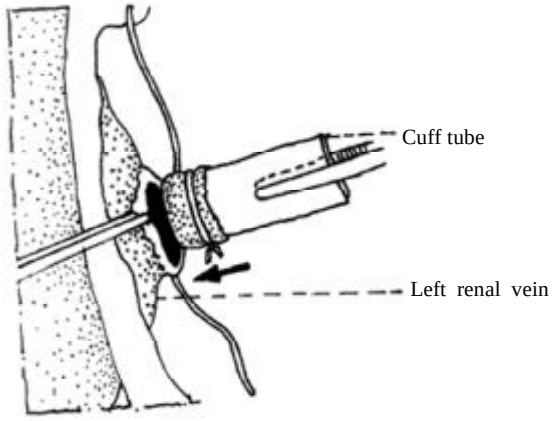

Figure 2 PV to left renal vein anastomosis

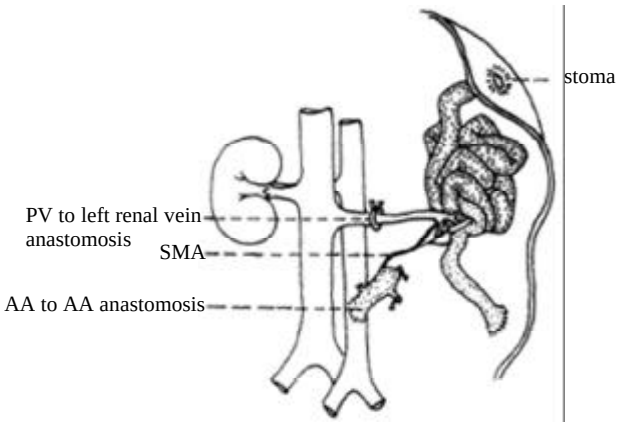

Figure 3 Heterotopic total small intestinal transplantation in rats

RESULTS

Operated by one person, the average time for the donor surgery was 86±20 min, and 115±20 min for the recipient and the average warm ischemic time being 40±5 min. There was a shorter revascularization time of the graft, the AA to AA anastomosis was 21±10 min, and the cuffed PV to the renal vein anastomosis was 5±5 min. Sixteen rats which died from anesthetic accidents and hemorrhage during operation were not included in the statistical data. Among the 98 heterotopic whole small intestinal transplantation, 11 rats died in 6 days, the autopsy verified 2 cases of arterial anastomotic hemorrhage, 3 cases of the native small intestinal dysfunction, 4 cases of infection of abdominal cavity, and 2 cases of the pulmonary complications (Figure 4). There was no gross or microscopic evidence of either vascular occlusion in any of the grafts or stoma-related complications. The one-week survival rate was 88.7% (87/98). The rats recovered vigor and vitality after the operative day. The shape and color of the transplanted small intestines were nearly the same as the native intestines from the tenth day. The longest survival time of recipient rats was more than 389 days after SIT when the data were collected. They maintained normal weight, perfect intestinal function and intact intestinal histology.

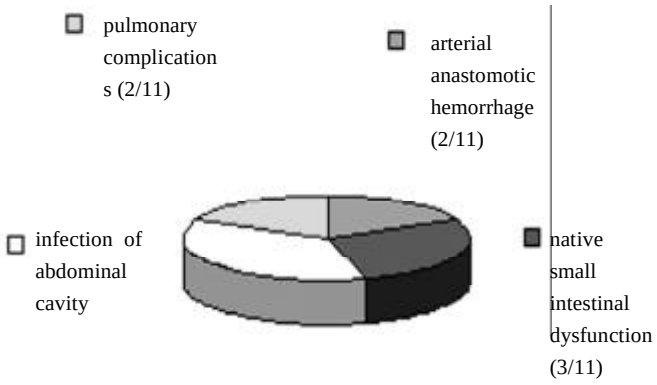

Figure 4 Cause of death in SIT rats

DISCUSSION

SIT of the rat remains a microsurgical technique which is difficult to manage. According to the need of clinical SIT practice, we used Wistar inbred strain rats as donors and recipients to practise heterotopic SIT, so that the model would not be affected by immune responses[28-40]. Following the modified methods of Zhong *et al*[2] and Kiyozaki *et al*[3], we have accumulated a great and original experience with reducing complications and increasing survival rate in rats.

Enhancement of operative tolerance

Shortening fasting time Both donor and recipient rats were placed in metabolic cages and kept fasting before surgery, without eatable cushion and dirt. The fasting time was shortened from 48 h (donors) and 24 h (recipients) respectively to less than 12 h, a satisfying result could be achieved through this management, only a little bile and bowel fluid were found in the small intestinal graft by surgery. The rats received 5% glucose normal saline ad libitum before surgery for a supplement of water, salt and energy.

Intravenous infusion Hypovolemic shock was the most common cause of postoperative death in SIT rats because of hemorrhage, evaporation and loss of bowel fluid[15].The total blood volume of rats was about 5.5-6.5 ml/100 g body weight, if the loss of blood exceeded 3 mL, ischemic damage of small intestinal graft would occur in donors, and death would happen in recipients. Besides improving dissecting and anastomotic techniques to reduce bleeding, continuous infusion with lactated Ringer' s solution via penile vein could keep blood pressure stable during surgery and increase survival rate. If there was a mass bleeding or blockage in intravenous infusion during surgical procedure, rats were given 4-5 ml (2 ml/100 g body weight) of 5 % glucose normal saline via back subcutaneous injections after SIT. Fatal pulmonary edema and heart failure could be caused by overdose solution or fast infusion, so the infusion should be controled to an optimum volume, never excessive.

Improvement in the vitality of small intestinal graft The quality of donor organ affected directly the result of transplantation. This is especially true for the small intestinal graft, which is much liable to mechanical and ischemic injuries during the procedure. The recipient rat "stupor" or "no vitality" or failure to death within 1 d-2d after SIT mostly occurred due to the quality of small intestinal graft. During the whole harvest procedure, the non-traumatic techniques should be adopted, a gauze sponge with saline was used to mobilize the graft gently instead of holding or clamping with hand and microtweezer, and not to toss and turn the graft repeatedly so as to avoid damage. Because of the "⊥" –shaped incision, the small intestinal graft dissected from the colon could be easily placed into abdominal cavity to reduce the exposure and vaporization damage. As vigorous intra-luminal irrigation and graft perfusion directly damaged the microcirculation of the graft[41-44], we changed the method of perfusion from parting body to in situ graft perfusion in living donors and significantly reduced the volume of intra-luminal irrigation from 50-70 ml[1] to 5-8 ml. The small intestine was put in order before graft perfusion, then the solution in the gut lumen could easily flowed out. The speed of irrigation was not quickened till the intra-luminal solution flowed out, avoiding over-distention of the donor small intestine. The volume of graft perfusion *in situ* was reduced from 12-20 ml[1] to 3-5 ml. The speed and volume of perfusion were accurately controlled by micropump instead of gravity, the graft perfusion was complete and the damage was reduced to minimum. Ischemic injury due to hypovolemic shock during the harvesting was often neglected by surgeons. For example, early ligation of the pyloric and splenic vein rapidly caused splanchnic venous congestion leading to shock[2].Therefore, we performed this procedure just prior to perfusion and after ligation of the celiac artery to avoid graft blood flow reduction. We also minimized ischemic injury to the donor small intestine by meticulous ligation of the lumbar vessels to avoid unnecessary blood loss, early ligation of the distal AA to improve perfusion of the graft and intravenous administration of 6-8 ml of lactated Ringer' s solution to supply blood volume and improve blood circulation of the small intestinal graft during the surgery. A shorter warm ischemic time was very important for the improvement of graft vitality, the warm ischemic time in our experiment was almost controlled in 40 min. If the time was too long, the normal blood circulation could not be recovered, the result of transplantation would be seriously affected, which appeared as the graft edema, segmental venous stasis, congestion and extremely thin enteric fluid.

Improvement of recipient surgical procedure

It was critical that there was an adequate blood flow from the SMA to the graft and out through the PV smoothly. Based on Zhong[2] and Kiyozak[3] surgery procedure, we refined some techniques. The blood flow of the inferior vena cava(IVC) was not blocked during surgery, so the blood circulation was not interrupted. The cuff technique was used with a cuffed anastomosis of the donor PV to the recipient left renal vein, the whole procedure of anastomosis spent about 5 min. Since the cuff tube was sculped from a polyethylene tube with 2.3 mm in outer diameter and 1.8mm in inner diameter, there was a larger and standard anastomosis. Furthermore, the endangium of the cuffed PV was well overturned, there was no any exposed anastomostic material in the venous lumen. So the unobstructed rate was much higher, none of rats died of the venous anastomostic complication. The AA column with SMA of the graft was anastomosed end to side to the AA of the recipient, the anastomotic bore was bigger and shapeable, so the anastomosis could be in progress smoothly without any tension. We used low molecular dextran solution without heparin to rinse the anastomosis, the damage to the endothelium was slighter[45-46], and the chance of anastomotic stenosis and thrombosis was greatly reduced[47-50]. These improved techniques resulted in an adequate blood flow to the graft without acute and chronic graft ischemia and the survival rate of the transplanted rat was obviously increased. It was true

that removal of one kidney did not increase the mortality in our experiment yet. After removal of one kidney, the remained kidney usually has a capacity to compensate. The adaptation may take place within 12-24 h and reach the largest degree during 1-2 wk. There was no an obvious disadvantage effect on physiological function and some experimental researches such as the absorptive function and permeability of transplanted small intestine could be studied on the model without any inconvenient.

In conclusion, our results suggested that applying these modified techniques would remarkably reduce the complications and improve survival rate in rats, the transplanted small intestine had a long-term fine function, this provided a potentially more consistent and practical model meeting the need of experimental and clinical studies.

Abstract

AIM: **To study the operative injury, post-operative complications, the hospitalization time, the post-operative survival rate of ultrasonic aspiration hepatectomy with a domestic new type of ultrasonic surgical device in comparison with that of conventional techniques of hepatectomy.**

METHODS: **A total 136 patients with hepatocellular carcinoma (HCC, including 12 patients in 1991 and 124 consecutive patients from July 1995 to December 2 000) underwent ultrasonic aspiration in liver resection (group T) and 179 HCC patients received conventional hepatectomy during the corresponding period (group C). The results of the two groups were compared statistically.**

RESULTS: **There was no significant difference in the mean operation time between group T (152±11 min) and C (144±11 min). No operation or hospital death occurred in both groups. In group T, the mean volumes of bleeding (463±15 ml) and blood transfusion (381±12 ml) were markedly less than those in group C (557±20 ml, and 507±18 ml, respectively, *P*<0.05). The mean hospitalization time of group T (8.9±0.6 d) was markedly shorter than that of group C (11.7d±0.6 d) (*P*<0.05). The incidence of complications in group T was markedly lower than in group C, post-operative jaundice occurred in 4/136 and 31/179, respectively (*P*<0.05), liver failure in 0/136 and 2/179, cholorrhea in 0/136 and 6/179, hydrothorax in 21/136 and 39/179 (*P*<0.05), ascices in 9/136 and 54/179, respectively (*P*<0.05). There was no significant difference in the 1-year survival rate between the two groups (*P*>0.05), while the 3-year survival rate of group T (64.2 %) increased markedly as compared with that of group C (55.7 %) (*P*<0.01).**

CONCLUSION: **The ultrasonic aspiration hepatectomy with a domestic new type of ultrasonic surgical device could evidently reduce the operative injury and post-operative complications, shorten the hospitalization time and prolong the survivals of HCC patients.**

INTRODUCTION

Hepatocellular carcinoma (HCC) is common in China [1-10], and its treatment is not satisfactory so far [11-17]. The first choice of treatment for HCC is hepatectomy, but the resectability is only about 4-20 %[18-25]. Therefore, it is important to improve the technique of liver resection and to increase the resectability. The invention of ultrasonic surgical device (also called ultrasound scalpel) is a breakthrough in medical field since the 1980 s, it was also one of the developing hotspots in the surgery. The reason for its attention is that when compared with electric surgery unit, laser and microwave as well as other methods[26-36], it has many advantages including less lesion for the tissue in or around the operating field, less bleeding (or no bleeding), clear operating field, less operating risk, high security and more convenient to operate [37-40]. Since the 1990s, ultrasonic aspiration hepatectomy has been popularized in many European and American countries, and is now a standard technique of hepatosurgery[41]. Our study on 136 ultrasonic aspiration hepatectomies indicated that ultrasonic aspiration hepatectomy could reduce operative injury and the incidence of the major operative complication markedly. In the meantime, it could shorten the duration of hospitalization, reduce the blood transfusion during the operation, and raise the survival rate.

MATERIALS AND METHODS

Materials

From April 1991 to December 2000, we observed randomly (completely random design) 136 primary liver carcinoma patients (group T) treated by ultrasonic aspiration hepatectomy and 179 primary liver carcinoma patients (group C) treated by conventional technique. The ages of patients in group T and C were 13-72 years(mean 57 ±15 years) and 19-74years (mean 55±16 years), respectively. There were 14 and 21 patients with intrahepatic metastasis in the group T and C, respectively (Table 1). NTY-300 multifunctional ultrasonic surgical device (made in China) was used. The equipment was composed of main unit that could work in multi frequency, several kinds of hand-pieces and control keyboard. It had multifunction of ultrasonic cutting, aspiration, and liposuction. The basic principle was that the computer device of the mainframe could produce electric signal ranging from 19 to 35kHz of frequency, and the signal was amplified by power amplifier, then sent to the hand-piece after impedance conversion by the output isolating transformer, thus producing ultrasonic vibration. At the same time, the sampling circuit could feed back the working status of the hand-piece to the computer device judging whether it was falling in the best working frequency. And the computer could modulate it automatically to assure that the portable therapeutic head fell in suitable resonance frequency to give

the maximal ultrasound energy output. There are several simple control keys for manual operation on the control panel. And the corresponding parameters were displayed on the display monitor.

Table 1 Clinical data of patients included in this study

Main parameter	Common hepatectomy (*n*=179)	Ultrasonic aspiration hepatectomy (*n*=136)
Mean age (yrs)	55±16	57±15
M/F	166/13	128/8
TB/ (μmol·L^{-1})	17.4±1.4	16.4±1.5
DB/ (μmol·L^{-1})	3.1±0.3	3.0±0.3
ALB/ (g·L^{-1})	40.0±7.0	42.4±7.4
ALT/ (nkat·L^{-1})	667.0±49.8	538.1±51.2
AST/ (nkat·L^{-1})	602.6±50.8	566.3±40.0
TT/ (g·L^{-1})	78.62±7.85	73.32±8.26
Size of tumor		
T≤2cm	84	67
2cm≤T≤5cm	59	44
5cm≥T	36	25
Location		
Right	40	32
Tri-liver lobe	3	2
Left tri-liver lobe	8	5
Ⅷ segment	19	16
Others	109	81
Number of tumor		
1	135	102
2	38	27
≥3	6	7

Methods

The bilateral subcostal approach, extended to the right as far as the midaxillary line, to the left as far as the lateral margin of the rectus muscle, and medially upwards the xiphoid process of the sternum (Mercedes incision) or a right subcostal incision extended along the median line (Invested-L incision) is the classic approach. JM-Ⅱ retractor (made in China) was routinely used for opening the abdominal wall. In the first stage the ligaments around the lobe to be resected were dissected until the lobe was mobilized. The liver to be resected was demarcated by cautery, and stitched to block the local blood supply.The ultrasonic aspirator was utilized in hepatoparenchyma dissection. Liver cells were broken and emulsified, and aspirated out of body. The intrahepatic canaliculi were exposed and can be dissected and ligated. The oozing sites were controlled by conventional methods.

Statistical treatment

t-test and c^2 test were used.

RESULTS

There was no significant difference in the mean operation time between groups T (152±11min) and C (144±11min). No operation or hospital death of patients occurred in both groups. In group T, the mean volumes of bleeding (463±15 ml) and blood transfusion (381±12 ml) were markedly less than those in group C (557±20 ml, and 507±18 ml, respectively, $P<0.05$). The mean hospitalization time of group T (8.9±0.6 d) was markedly shorter than that of group C (11.7±0.6 d), ($P<0.05$). The incidence of complications in the group T was significantly lower than in group C. There was no significant difference in the 1-year survival rate between the two groups ($P>0.05$), while the 3-year survival rate of group T (64.2 %) increased markedly as compared with that of group C (55.7 %), (Table 2).

Table 2 Comparison of operation and treatment conditions between the two groups

Main parameter	Common hepatectomy (*n*=179)	Ultrasonic aspiration hepatectomy (*n*=136)
Operation time/min	144±11	152±11
Bleeding volume/ml	557±20	463±15 [a]
Transfusion volume/ml	507±18	381±12 [a]
Hospitalization day	11.7±0.6	8.9±0.6 [a]
Liver failure	2	0
Postoperative jaundice	31	4 [a]
Cholorrhea	6	0
Hydrothorax	39	21 [a]
Ascites	54	9 [a]
1-year survival rate	92.5%	94.8%
3-year survival rate	55.7%	64.2% [b]

[a]$P<0.05$, [b]$P<0.01$, *vs* Common hepatectomy.

DISCUSSION

In the ultrasonic aspiration hepatectomy, semisolid liver tissue is broken and emulsified under the conjugated effects of ultrasonic shock acceleration and high-velocity liquid jet, and then is aspirated out by suction. Since most liver cancer patients (>90%) in China are complicated with liver cirrhosis [3-10], some researchers considered that it was difficult for the cirrhosis liver tissues containing plenty of connective tissue to be unbroken by ultrasonic knife. In fact, ultrasonic knife is just a common name, whose main function is not tissue-cut, but to expose intrahepatic canaliculi after breaking the cellular elements. For the intrahepatic fiberous tissue, the routine operative technique should be used [18-25].

Our data indicated that ultrasonic aspiration hepatectomy could significantly reduce the operative injury and the incidence of complication and shorten the mean hospitalization time by 3-4 days. Because of less blood transfusion required and tumor manipulation avoided in the operation, the 3-year survival rate of group T was higher than that of group C. The main technical advantages of this clinical application included **(1)** by the conventional operative procedure tissues are dissected with fingers, scissors or knife handle, and some fine canaliculi could not be exposed readily, so it is hard to avoid operative injury, which resulted in more bleeding during or after operation and higher incidence of cholorrhea. Ultrasonic knife can aspirate the liver tissues around the incision, the blood vessel and bile duct remained. The operators could ligate the vessel and bile duct perfectly, so cholorrhea and hematorrhea after operation may be avoided.(2)ultrasonic knife is actually a kind of ultrasonic aspirator. According to the principle that the highly hydrated tissues could be emulsified easily, ultrasonic knife could aspirate the cellular debris out of body, but it cannot replace the conventional operative technique. (3)since the main blood vessel and bile duct injuries can be avoided in the operation, the tumor near portahepatis can be cut off, thus it raises the resectability of liver cancer. Our first patient treated with this procedure was a 13 year old child with a tumor encroached on the first and second portahepatis. The pathologic diagnosis after operation was

hepatocellular carcinoma. The patient has been remained well and alive up to 10 years. In the 136 operations, there were 64 complicated operations, 32 right liver lobe resections, 16 Ⅷ liver segment resections, 5 tri-liver lobe resections, and 2 left tri-liver lobe resections. (4)local block of blood flow could reduce bleeding in operation and assure the safety of hepatectomy [2, 8], which is important in saving blood resources and accelerating the rehabilitation of patient. (5)ultrasonic aspiration hepatectomy with no demand to block the portahepatis, is especially suitable for the patients with impairment of liver function so as to avoid further injuries to liver parenchyma.

Abstract

AIM: **Endoscopic dilation of esophageal strictures is a commonly performed procedure in the management of dysphagia. The procedure is usually done with fluoroscopic guidance. The aim of this study was to assess the use of Tracer guide wire in conjunction with Savary-Gilliard dilators in the dilation of tight esophageal strictures without fluoroscopy.**

METHODS: **Fifty-five patients with significant dysphagia from strictures due to a variety of causes were dilated endoscopically. The procedure consisted of two parts. First, a guidewire was passed using endoscopic guidance, and then, dilation was performed without fluoroscopy. A modified Tracer wire was employed and was particularly effective in negotiating very tight esophageal strictures, in which the lumen is less than 6 mm. In general, the "Rule of Three" and "2-3 sessions in 10 days, maximum dilation up to 42 French" rules were followed. 401 dilations in a total of 55 patients(malignant strictures 30, benign 25) in 177 sessions were carried out.**

RESULTS: **The guide wire placement and Savary-Gilliard dilation were successfully performed without fluoroscopy, and improvement of dysphagia was achieved in all patients. Esophageal plastic stent (out diameter 40 French) was placed in five patients with malignant stricture-three of them with tracheo-esophageal fistula.**

CONCLUSION: **Dilation using Tracer guide wire without fluoroscopy is safe and effective in treatment of even very tight esophageal strictures.**

INTRODUCTION

Dilation of esophageal strictures is a commonly performed procedure used to relieve dysphagia due to malignant or benign stenotic lesions. In clinical practice, fluoroscopy is recommended for monitoring the position of the guide wire and dilator[1-6]. Some authors, however, believe that fluoroscopy is not necessary for Maloney dilation in chronic esophageal strictures[7,8]. Recently, Fleischer[9]and Kadakia[10] reported that esophageal dilation with polyvinyl bougies using a marked guide wire without fluoroscopy was safe. The aim of this study to describe our preliminary experience using a modified Tracer guide wire (MTGW) and marked Savary-Gilliard dilators without the use of fluoroscopy.

MATERIALS AND METHODS

Patients

Between September 1994 and February 1996, 55 consecutive patients (40 males, 15 females, from 10 to 80 years old, median age 58 years) with esophageal strictures were referred to our unit for dilation because of persistent or recurrent dysphagia. Whether a stenosis was benign or malignant, stenosis was ascertained using endoscopy and biopsy. There were 25 benign lesions and 30 malignant tumors. The diagnoses are summarized in Table 1. The strictures were classified by us into five grades according to clinical symptoms of dysphagia and endoscopic findings. The grading system is summarized in Table 2. Grade III and grade IV strictures (lumen less than 6 mm) are considered as very tight esophageal strictures (VTES). All of our patients had various degrees of dysphagia. Total of 177 sessions of dilation were performed for 55 patients who had various degrees of dysphgia prior to each session. 28 sessions (15.8 %) of dilation were carried out for grade I strictures, 99 (55.9 %) for grade II and 50 (28.3 %) for VETS. X-ray studies of the geography of the strictures were performed for each case before treatment.

Table 1 The Etiology of esophageal strictures

Malignant	*n*	Benign	*n*
Esophageal Cancer		Anastomotic stenosis	13
Upper	3	Postoperative stenosis	2
Middle	11	Caustic stricture	2
Lower	7	Achalasia	5
Esophageal stump ca	5	Esophagitis	2
Anastomotic ca	2	External compression	1
Lung ca	2		
Total	30		25

Table 2 The Classification of esophageal strictures

Grades	Passage (can eat)	Endoscopy* (can pass)	Lumen diameter
0	Normal diet(+)	Standard one(+)	>12mm
I	Solid diet (+)	GIF-XQ/240(+)	9-12mm
II	Half liquid (+)	GIF-XP (+)	6-9mm
III	Liquid diet(+)	GIF-XP (-)	<6mm
IV	Water (+)/(-)	Tracer wire(+)**	<1mm

*Endoscopy: used Olympus endoscope. **Tracer wire (Wilson-Cook Medical Inc.) is 300cm length with markers.

Instruments

Examinations were performed usually with Olympus GIF-XP 20 gastroscope (Olympus Corp, Tokyo, Japan). Dilation was performed with market Savary-Gilliard dilators and a modified Tracer guide wire (0.035', 300 cm length, with markers,) (Wilson-Cook Medical Inc. Winston-Salem, NC. USA).

Technique

If the stricture could be passed with a paediatric endoscope, the guidewire was placed under endoscopic guidance. Thereafter, dilation was performed without fluoroscopy. For very tight esophageal strictures, the Tracer guide wire was used by us as a path-finder and also for Savary-Gilliard dilation without fluoroscopy. The technique is as follows: 1) Under endoscopic guidance, the VTES is approached. The Tracer guide wire is gently inserted through the stricture until the wire has been advanced more than 70 cm (for normal anatomy) without strong resistance having been encountered. (2) Keeping the wire in place, the scope is withdrawn. The scope can be re-inserted alongside the wire. (3) The VTES is dilated over the Tracer wire starting with a 15 French or 21 French dilator using the markers on the wire and also on the dilators for guidance, or under endoscopic control. (4)Post the final dilation with a size 27 French or 33 French, the paediatric gastroscope is passed through the dilated lumen into the stomach.

In general, the "rule of three-dilator size increased step by step and dilation times is no more than three for each session " and "the rule of 2-3 sessions in 10 days, with maximum dilation up to 42 French" were followed. All procedures were performed without intravenous sedation, although local oropharyngeal anesthesia was given.

RESULTS

A total of 401 dilations in 55 patients in 177 sessions was done. The grade of benign and malignant stenosis before dilation was summarized in Table 3. The success rate for both placement of the guide wire and dilation was 100 % without use of fluoroscopy. There were no major complications (Table4).

Table 3 The grade before dilation (177 sessions / 55 patients)

Grade	Sessions	%
0	0	0
I	28	15.8
II	99	55.9
III & IV	50	28.3

Table 4 Adverse events and complications induced by the guide wire placement or dilation without fluoroscopic control

Complications	*n*	(%, 401 dilations)
Superficial mucosal tear	3	0.75
Tracheal intubation of Tracer	1	0.25
Severe hemorrhage	0	
Perforation	0	
Sepsis	0	
Death	0	

The Tracer wire was successfully used to pass the VTES. The diameters of Savary-Gilliard dilators employed in this study were 15 French dilators in 3.8 %, 21 Fr. in 14.2 %,27 Fr. and 33 Fr. dilators in 56.1%, 38 Fr. in 15.7 %, 42 Fr. in 5.9 % and 45 Fr. (only be used for patients with achalasia) in 4.3 %. The average number of dilators per session was 2.7. Esophageal plastic stent (outer diameter 40 Fr., Wilson-Cook Medical Inc. NC.) was placed over the Olympus GIF-XP endoscope for five malignant strictures after being dilated up to 42 Fr. without fluoroscopic guidance. Three of them had strictures associated with tracheo-esophageal fistulae. There were no procedure-induced serious complications such as perforation, bleeding, sepsis and death. One patient with tracheo-esophageal fistula developed a dry cough during insertion of the wire. The wire was withdrawn and then reinserted successful without further event. Superficial mucosal tear was found in one patient with a post-myotomy stricture performed for achalasia (grade II stricture, 4.0 cm on length) after 42 Fr. dilation, and in one patient with an alkali induced corrosive stricture involving the entire length of the esophagus (grade II to III) after 33 Fr. dilation. In both cases the superficial tears healed spontaneously 3-5 days later.

DISCUSSION

Successful esophageal dilation involves both successful placement of the guide wire and dilation. This study demonstrates that Savary-Gilliard dilation can be successful without fluoroscopic control. There were no serious procedure-induced complications. All 55 unselected consecutive patients had significant dysphagia due to different types of esophageal pathology. Symptom relief was achieved in all patients.

The results are similar to that reported by Fleischer in a series of 100 patients and Kadakia in a series of 68 patients. In these two studies, the endoscope could be passed through the stricture in most patients and the tip of the marked Savary-Gilliard wire was placed under endoscopic view. However, the endoscope was impassable in 5 % and 29.4 % respectively. For these cases, fluoroscopy was required. The passage of the marked Savary-Gilliard wire for VTES, especially for malignant ones with tracheo-esophageal fistula and abnormal anatomy of the esophagus, such as angulation and diverticulum, is both difficult and hazardous without the aid of the fluoroscopy. Instead of marked Savary-Gilliard wire, we used the modified Tracer wire. The Tracer wire has a very soft and flexible tip which is considered atraumatic. The wire is hydrophilically coated on its distal 60 cm making it very slippery when wet. It can be passed through the stricture easily without trauma and be coiled in the stomach. Esophageal or stomach perforation could not be induced with the coil-able and atraumatic wire tip. During insertion of the wire, if there is resistance or if the patient starts coughing (which indicates that the wire is inserted into trachea through the fistula), the wire should be withdrawn and reinsertion performed. The proximal part (240 cm) of the wire is Teflon coated making it stiff enough to have a dilator passed over it, and also is marked for control of the procedures. Our study shows that the Tracer wire is very safe as a "path-finder" for VTES. Furthermore, Savary-Gilliard dilation can be performed immediately without exchange to a standard Savary-Gilliard guidewire. This is different from the techniques reported by Ling *et al*[11] and Mohandas *et al*[12]. In order to prevent complications, the "rule of three" popularized by Boyce (4) was followed by us. Dilation should be terminated when resistance is encountered during three consecutive dilations. Our experience suggests that in

long (>3.0 cm), subglotic, caustic strictures and in lesions of stump esophagus, the rule should not be employed. We agree that experience can teach how much resistance is significant during dilation. The maximum size of dilator used is a very important factor in avoiding complications. It has been suggested that the maximum size be at most 48 French[3]. Based on our experiences, we believe that maximum dilation up to 42 French is sufficient for the Chinese population. This guarantees a normal diet and also reduces the risks associated with the procedure. In addition, in anastomotic strictures, the Tracer wire should be used when the endoscope can not be passed. In conclusion, the marked Savary-Gilliard dilatior via a marked Tracer guide wire without fluoroscopy is safe and effective. Adequate placement of a guide wire prior to dilation is crucial in achievement of successful dilation.

Abstract

The central role of sequential accumulation of genetic alterations during the development of cancer has been firmly established since the pioneering cytogenetic studies successfully defined recurrent chromosome changes in specific types of tumor. In the course of carcinogenesis, cells experience several genetic alterations that are associated with the transition from a preneoplastic lesion to an invasive tumor and finally to the metastatic state. Tumor progression is characterized by stepwise accumulation of genetic alterations. So does the dominant metastatic clone. Modern molecular genetic analyses have clarified that genomic changes accumulate during the development and progression of cancers. In comparison with the corresponding primary tumor, additional events of chromosomal aberrations (including gains or allelic losses) are frequently found in metastases, and the incidence of combined chromosomal alterations in the primary tumor, plus the occurrence of additional aberrations in the distant metastases, correlated significantly with decreased postmetastatic survival. The deletions at 3p, 4p, 6q, 8p, 10q, 11p, 11q, 12p, 13q, 16q, 17p, 18q, 21q, and 22q, as well as the over-representations at 1q, 8q, 9q, 14q and 15q, have been found to associate preferentially with the metastatic phenotype of human cancers. Among of them, the deletions on chromosomes 8p, 17p, 11p and 13p seem to be more significant, and more detail fine regions of them, including 8p11, 8p21-12, 8p22, 8p23, 17p13.3, 11p15.5, and 13q12-13 have been suggested harboring metastasis-suppressor genes. During the past decade, several human chromosomes have been functionally tested through the use of microcell-mediated chromosome transfer (MMCT), and metastasis-suppressor activities have been reported on chromosomes 1, 6, 7, 8, 10, 11, 12, 16, and 17. However, it is not actually known at what stage of the metastatic cascade these alterations have occurred. There is still controversial with the association between the chromosomal aberrations and the metastatic phenotype of cancer. As the progression of human genome project and the establishment of more and more new techniques, it is hopeful to make clear the genetic mechanisms involved in the tumor metastasis in a not very long future, and provide new clues to predicting and controlling the metastasis.

Qin LX. Chromosomal aberrations related to metastasis of human solid tumors.*World J Gastroenterol* 2002; 8(5):769-776

INTRODUCTION

The central role of sequential accumulation of genetic alterations during the development of cancer has been firmly established since the pioneering cytogenetic studies successfully defined recurrent chromosome changes in specific types of tumor. In the course of carcinogenesis, cells experience several genetic alterations (including gains and deletions) that are associated with the transition from a preneoplastic lesion to an invasive tumor and finally to the metastatic state. High frequency of chromosomal deletions elicited as losses of heterozygosity (LOH) is a hallmark of genomic instability in cancer. Functional losses of tumor suppressor genes caused by LOH at defined regions during clonal selection for growth advantage define the minimally lost regions as their likely locations on chromosomes. LOH is elicited at the molecular or cytogenetic level as a deletion, a gene conversion, single or double homologous and nonhomologous mitotic recombinations, a translocation, chromosome breakage and loss, chromosomal fusion or telomeric end-to-end fusions, or whole chromosome loss with or without accompanying duplication of the retained chromosome. Because of the high level of specificity, LOH has recently become invaluable as a marker for diagnosis and prognosis of cancer[1].

Many new molecular cytogenetic techniques, including various kinds of fluorescent in situ hybridization (FISH), comparative genomic hybridization (CGH), allelic imbalance (AI) and genotyping analyses, single nucleotide polymorphism (SNP) analysis, etc., have been established in recent years. These new techniques allow positional identification of gains and losses of DNA sequences in the entire tumor genome. These analytic approaches, particularly CGH and AI analysis, have already been applied over a wide range of tumor specimens, cell lines, and archival materials to define chromosomal imbalances. Molecular genetic analyses with these new strategies have clarified that genomic changes accumulate during the development and progression of cancers. A considerable amount of genetic alterations on solid tumors has been accumulated during the past few years.

Tumor progression is characterized by stepwise accumulation of genetic alterations. The dominant metastatic clone is also characterized by an accumulation of genetic alterations, but it is not actually known at what stage of the metastatic cascade these alterations have occurred. In comparison with the corresponding primary tumor, additional events of chromosomal aberrations (including gains or allelic losses) are frequently found in metastases and the incidence of combined chromosomal alterations in the primary tumor, plus the occurrence of additional aberrations in the distant metastases, correlated significantly with decreased postmetastatic survival. It is hypothesized that the occurrence of additional genetic aberrations is either involved in termination of dormancy of micrometastatic tumor cells at distant organ sites or acquired during further progression of metastases. However, only a few indications as to which genetic alterations among the multitude of changes might be

preferentially associated with the metastatic phenotype[2-8].

During the past decade, several human chromosomes have been functionally tested through the use of microcell-mediated chromosome transfer (MMCT), and metastasis-suppressor activities have been reported on chromosomes 1, 6, 7, 8, 10, 11, 12, 16, and 17. Such functional studies, combined with positional and expression-based gene cloning techniques, have enabled the identification of KAI1, KISS-1, MKK4/SEK1, and BRMS1 as metastasis-suppressor genes[9]. In this paper, we will review the chromosomal aberrations associated with the metastatic phenotype of solid tumor.

CHROMOSOME 8

Alterations of human chromosome 8p have been commonly detected in many tumor types[10-12]. Some studies have shown that loss of 8p is associated with the advance of tumors, and plays an important role in the tumor progression of many tumors including colorectal[13], bladder[14,15], breast[10] and liver cancers[16]. Recently, some studies have also shown that loss of 8p may be associated with the metastasis of laryngeal carcinoma[17], bladder cancer[18], renal cell carcinoma[19], colorectal carcinoma[20], lung cancer[21], mantle cell lymphoma (MCL)[22], and the poor prognosis of colorectal cancer patients [23]. Bockmuhl *et al* found that 8p23 allelic loss was an independent prognostic marker for disease-free interval, and was associated with poor prognosis in head and neck squamous cell carcinoma and could be useful in refining diagnosis of these tumors[24]. So, 8p might harbor one or more tumor suppressor genes that are important in the progression,especially in the metastasis of cancers, which was confirmed by irradiated MMCT technique[25, 26].

The presence of at least three tumor suppressor or metastasis suppressor genes loci on 8p (8p21, 8p22, and 8p23) that may be cooperative events has been suggested in HCC and ovarian cancer[12,27]. Several candidate tumor suppressor genes have been mapped to 8p including DLC-1(8p21.3-22)[28], FEZ1 gene (8p22)[29] and liver-related putative tumor suppressor (LTPS) gene (8p23)[30]. However, alterations of these genes may occur as an early event in the development of cancer, and their association with the metastasis is not confirmed[31]. Oba *et al*. found two putative tumor suppressor genes on chromosome 8p might play different roles, deletions on 8p22-p21.3 play an important role in tumor differentiation, while an 8p21.1-p21.2 deletion plays a role in the progression and metastasis of prostate cancer[32]. Allelic loss at 8p22 was associated with higher tumor grade, and no tumor that retained heterozygosity for markers at 8p22 had metastasized to distant organs, whereas a substantial portion of tumors that lost alleles in that region had done so. These imply that loss or inactivation of tumor-suppressing activity encoded on 8p contributes to malignancy and to the metastatic potential of bladder cancers[18]. Arai' s results suggest that putative tumor suppressor genes, which may be involved in the metastatic process of colorectal cancer, are located on chromosomes 8p21-22. Allelic losses in these regions are possible risk factors for early lymph node metastasis[33]. Nihei *et al*[26] used a functional positional cloning strategy to define the region harboring the metastasis suppressor gene in 8p21-12, and localized it to a 60-kb cloned region.

Chromosome 8p deletion is also one of the recurrent chromosomal aberrations in HCC that are common detected either by CGH or by microsatellite analysis[34-36]. In our previous study, we compared the differences of genomic alterations between matched primary and metastatic HCC by CGH, and found that the majority of chromosomal aberrations in both primary and metastatic lesions of HCC were consistent with those in previous reports. The most interesting finding in this study is the deletion of 8p which was detected in 8 metastatic lesions but only in 3 corresponding primary HCC, 5 cases of HCC acquired deletion on 8p as they progressed to metastatic stage, although some differences of genomic alterations between primary and its corresponding metastatic lesion were also found. These suggest that 8p may harbor one or more tumor suppressor genes that are important in the HCC progression especially in the tumor metastasis[37]. This result was confirmed in the metastatic model of HCC and its cell line[38]. Recently, in another genome-wide microsatellite analysis, deletion on chromosome 8p was further proved to be related to progression and metastasis of HCC, and 8p23.3, 8p11.2 were two likely regions harboring metastasis-related genes[39].

CHROMOSOME 17

The frequency of allele loss on 17p has been correlated significantly with prognostic features such as the number and size of liver secondaries, the depth of invasion, metastasis to the lymph nodes, and venous invasion of cancers[40-42]. Multiple regression analysis identified the numerical aberrations of chromosome 17 as independent significant determinants of lymph node metastasis. A similar result is also found in HCC. LOH on 17p13 of HCC correlates with the stage, portal invasion, intrahepatic metastasis, and nuclear morphometry of cancer cells. These suggest that the LOH on 17p13 is closely connected to the progression of HCC[43].

p53 is an important TSG on 17p13.1, and its aberration has been linked to the development and progress of human cancers including HCC[44]. However, in addition to 17p13.1, many studies showed that the frequently deleted region was 17p13.3[45-49]. The minimum region of LOH on chromosome 17p13.3 in HCC has been defined within the region between D17S643 and D17S1574. Moreover, D17S926 in the minimum region of LOH has the highest frequency of LOH, and its sequencing analysis has been accomplished. In this region, 6 novel genes have been characterized. One of them is designated HCC suppressor 1 (HCCS1)[45]. Our recent study showed that the AI ratio of chromosome 17p was as high as 74-87 % in primary lesions, and 73-87 % in metastasis lesions of HCC. Moreover, high level of AI was also identified in 17p11.2-12 (74-87 %). A 20cM segment within 17p11.2-13.1 was found related to metastasis phenotype, with the highest increased-grade AI (28-44 %) in metastatic lesions[39]. All these suggested that in addition to the p53 gene at 17p13.1, an as yet unidentified TSG(s) residing at 17p13.3 might play a role in development, progression and metastasis of HCC.

Discontinuous portions of human chromosome 17 (D17S952-D17S805, D17S930-D17S797, and D17S944-qter) that together suppress the metastatic ability of AT6.1 Dunning rat prostatic cancer cells when introduced via MMCT have been identified[50,51]. PCR and Southern blot analyses demonstrated that three of the four markers on 17p13, including HIC1 and TP53, and 12 of the 13 markers in 17q21-23, including BRCA1 and the metastasis-suppressor gene NME1 (nm23), were not retained in this region[50]. AT6.1 microcell hybrids containing this portion of chromosome 17 were tested in vivo in spontaneous metastasis assays. Spontaneous metastasis is measured by the ability of tumor cells to form a locally growing tumor at the site of injection and disseminate to and grow at secondary sites thereafter. At the experimental end point, the number of overt surface metastases observed in the lungs from mice with AT6.1-17 tumors was reduced 15- to 30-fold compared with lungs from mice bearing parental AT6.1 tumors[50]. This suppression could be due to the inhibition of any step within the metastatic cascade. A series

of in vivo experiments were conducted, and no evidence was found to suggest that there is a decrease in the number and/or viability of tumor cells colonizing the lung[51]. Development of overt metastases was associated with loss of the metastasis-suppressor region of chromosome 17[10,52,53].

CHROMOSOME 1

Frequent allelic losses on the short arm of chromosome 1 have been observed in a wide variety of human tumors. Allelic loss at 1p22-p31 was correlated with lymph node metastasis. Alterations of one or more tumor suppressor genes at 1p22-p31 may play a role at late stages of carcinogenesis, especially with regard to local progression and lymph node metastasis[54]. There may be at least two distinct tumor suppressor genes inactivated by allelic deletion on 1p36.1 and 1p36.3, respectively[55].

Amplification of 1q was also commonly detected in esophageal carcinoma, breast cancer, and colon cancer[56-58]. Gain of 1q might be one of the early genetic changes in HCC since it was one of the most commonly detected alterations in HCC[59, 60]. In most cases, the gain of 1q involved whole long arm. However, in our previous study, high copy number amplification on 1q was detected in 4 primary and 6 metastatic HCC with a minimum amplification region at 1q12-q22. Most interestingly, in two cases amplification of 1q12-q22 was only detected in metastatic HCC. This imply that overexpression of an oncogene(s) at 1q12-q22 confers a selective advantage in HCC. High copy number amplification of 1q12-22 may only occur in late stage of HCC and provide more advantage of growth selection. This suggests that 1q might harbor one or more oncogenes related to the development or progression of many cancers. Moreover, this provides us a candidate minimum amplification region on 1q12-q22 for further study to clone genes related to the development and progression of HCC[37]. A correlation of metastatic events with an increase in the copy number of genes located at 1q, in particular at 1q21-q23 is also found in renal clear cell carcinomas[61]. And more, an insertion of chromosome 13 material in the short arm of chromosome 1 has been only observed in micrometastatic cells[62].

CHROMOSOME 6

Highly frequent loss of 6q is found in many kinds of solid tumors, and is considered later events associated with tumor progression, and is thought to confer metastatic potential to the carcinomas (such as in biliary tract, etc.)[63]. Yoshida *et al*. introduced an intact chromosome 6 into the highly metastatic C8161 human melanoma cells by MMCT. Parental cells formed tumors in every mouse given an intradermal injection of 1×10^6 cells, and more than 90 % of the mice developed regional lymph node and lung metastases. In contrast, chromosome 6-C8161 hybrids (neo6/C8161) were still tumorigenic, but completely suppressed for metastasis. Intravenous injection of neo6/C8161 cells also did not produce metastases. Introduction of a version of chromosome 6 with deletions on the long arm allowed refinement of the metastasis-suppressor locus to a 40-megabase (Mb) region represented by chromosomal bands 6q16.3-q23. The neo6/C8161 cells were still locally invasive, and cells were even detected in efferent vessels. This finding implied that the step(s) in the metastatic cascade inhibited by introduction of chromosome 6 occurred subsequent to intravasation[9,64-71]. Shirasaki *et al*[72] found that inactivation of a tumor suppressor gene(s) mapping to 6q16.3-q23 by deletion or mutation coupled with LOH may lead to the down-regulation of a putative metastasis suppressor gene, KiSS1.

CHROMOSOME 10

LOH on chromosome 10q is found associated with tumour progression in SCC, SCLC, and prostate cancer. It may become a useful genetic marker in the assessment of the malignant potential and a potential genetic discriminator between progressors and nonprogressors after radical surgery of these tumour types[73,74]. Deletions on chromosome 10q25-q26 is responsible for the metastatic phenotype of squamous cell carcinomas in head and neck[75], and colorectal carcinomas[76], which may play a particular pathogenetic role in the metastatic process. One gene, LAPSER1 [an LZTS1(or FEZ1)-related gene] maps within a subregion of human chromosome 10q24.3 that has been reported to be deleted in various cancers, including prostate tumors, as frequently as the neighboring PTEN locus. This gene is involved in the regulation of cell growth, loss of its function may contribute to the development of cancer[77].

A telomerase repressor gene may be located on 10p15.1 by deletion mapping using MMCT, radiated microcell fusion (RMF), FISH and STS analysis. 10p15.1 harbors a gene involved in repression of telomerase RNA component in human somatic cells and each putative repressormay act independently [78].

CHROMOSOME 11

A strong relationship between LOH at chromosome 11q23.3 and the presence of extensive tumor plugs in lymphvascular spaces (LVS) has been demonstrated, which suggests that genes at this locus may regulate vasculoinvasion. Patients with LOH at 11q23.3 are significantly more likely to have disease recurrence than patients without LOH at 11q23.3. Although unlikely to have an impact early in carcinogenesis, tumor-suppressor genes located in the region of 11q23.3 appear to be important in tumor progression, facilitating lymphvascular space invasion and, by inference, spread to lymph nodes in squamous cell carcinoma of the cervix[79] and melanoma[80]. Deletion on 11q22-qter, together with the gains of 8q23-qter and 20q was observed in tumors metastatic to the lymph nodes. Gains of 8q23-qter and 20q and loss of 11q22-qter allow the prediction of lymph node metastasis[81]. LOH at 11q13.1-5, the region around the MEN1 locus, may be valuable in predicting the invasiveness of pituitary adenomas[82]. However, Pairwise found metastasizing tumors are characterized by overrepresentations on chromosomes 11q13 and 22q, and deletions on 18q[83].

The centromeric part of chromosome segment 11p15.5 contains a region of frequent allele loss in many adult solid malignancies. This region, called LOH11A, is lost in 75 % of lung cancers and is thought to contain a gene that may function as a metastasis suppressor. Genetic complementation studies have shown suppression of the malignant phenotype including reduction of metastasis formation. Bepler *et al*. constructed a high-resolution physical map and contig over 1.4 Mb that includes the beta-hemoglobin gene cluster and the gene for the large subunit of ribonucleotide reductase (RRM1). Through sequencing and computerized analysis, we determined that this region contains an unusually large number of transposable elements, which suggests that double-stranded DNA breaks occur frequently here. Twenty-two putative genes were identified. Because of its location at the site of maximal allele loss in the 650-kb LOH11A region and previous functional studies, RRM1 is the most likely candidate gene with metastasis suppressor function. The malignant phenotype results from a relative loss of function rather than a complete loss[84]. Two distinct tumor suppressor loci on chromosome 11p15, one is between D11S1318 and D11S4088 (approximately 500 kb)

within 11p15.5, a second, critical region of LOH spans the markers D11S1338-D11S1323 (approximately 336 kb) at 11p15.5-p15.4, may contribute to tumor progression and metastasis in breast cancer and lung cancer[85,86]. The human SRBC gene (hSRBC), a candidate tumor suppressor gene, is mapped to chromosome region 11p15.5-p15.4, close to marker D11S1323, at which frequent LOH has been observed in sporadic breast, lung, ovarian, and other types of adult cancers as well as childhood tumors[87]. Introduction of human chromosome 11 by MMCT could suppress MDA-MB-435 breast carcinoma cell metastasis[88]. One important metastasis-suppressor gene, KAI1, maps to 11p11.2-p13.

CHROMOSOME 13

LOH of 13q is a common event in oncogenesis and/or progression of oral SCC and larynx carcinoma, and significant correlation between LOH of 13q14.3 and lymph node metastasis is found. These suggest the existence of a new suppressor gene near D13S273-D13S176 loci which may play a role in these events[18,89]. Allelotype analysis of whole chromosomes showed that allelic loss at 13q12-13 of the primary ESC was closely associated with lymph node metastasis, and unidentified tumor suppressor gene(s) in this region might be involved[90]. The high LOH rate for different microsatellite markers in and around the putative TSG locus C13 on chromosome 13q13 has been found[91]. However, Hyytinen et al. found that gain of the 13q12-q13 chromosomal region as well as losses of 4, 6q24-qter, 20p and 21q were associated with androgen independence and tumorigenicity with additional changes correlating with metastasis[92].

CHROMOSOME 14

Significantly more LOH events at markers D14S62 and D14S51 in primary breast cancers from patients with lymph node-negative disease than these with lymph node-positive disease were found, suggesting the presence of a gene in this region that affects metastatic potential. Analysis of small interstitial or terminal deletions in the tumors of six especially informative patients with lymph node-negative disease places the putative metastasis-related gene in a 1490-kilobase region near D14S62. LOH in the D14S62 region may impede the process of metastasis. Therefore, the D14S62 region LOH profile may have prognostic implications, and the isolation of the metastasis-related gene(s) in this region may lead to better diagnosis and treatment of breast cancer[93]. This unusual observation suggests that, whereas the LOH of this region promotes primary breast cancer formation, some gene(s) mapping to this 1.6-Mb region is rate-limiting for breast cancer metastasis. Thus, if primary breast cancers delete this region, their ability to metastasize decreases. To identify this gene(s), Martin *et al*[94] physically mapped this area of chromosome 14q, confirmed the position of two known genes and 13 other expressed sequence tags into this 1.6-Mb region. One of these, the metastasis-associated 1 (MTA1) gene, previously identified as a metastasis-promoting gene, mapped to the center of our 1.6-Mb target region. Thus, MTA1 represents a strong candidate for this breast cancer metastasis-promoting gene.

CHROMOSOME 16

Genomic aberration at the chromosome 16q arm is one of the most consistent abnormalities observed by LOH and CGH analyses in human prostate cancer, suggesting that there are tumor suppressor or metastasis suppressor genes encoded by this chromosomal region. When the MMCT hybrid cells containing whole human chromosome 16 were injected, the number of metastatic lesions in the lung was significantly reduced as much as 99 % on average. Therefore, chromosome 16 has a strong activity to suppress the metastatic ability of AT6.1 cells while it did not affect the tumorigenesis and tumor growth rate. A PCR analysis of various microcell hybrid clones with sequence-tagged site markers indicates that the metastasis suppressor activity is located in the q24.2 region of chromosome 16. These suggest that there is a metastasis suppressor gene in this region that may play an important role in the progression of prostate cancer[95]. Deletion of chromosome 16q23-24 appears in a high frequency in metastases of prostate cancer. The strong correlations suggest that they may be important risk factors, contributing to the metastatic potential of the tumor[96-98]. The presence of putative tumor-suppressor genes on chromosome 16q23.2-24.1 has been suggested by LOH analysis in several cancer types. The candidate gene WWOX/FOR has been mapped within this region[99-101].

CHROMOSOME 18

Deletion on 18p is shown as one of the most frequent losses in metastasizing tumors in primary larynx tumor[102]. Two distinct minimum regions of AI on 18q have been identified. The first region is between the genetic markers D18S1119 and D18S64. The second region lies more distal on the long arm of the chromosome and is between the genetic markers D18S848 and D18S58. Significantly higher AI was found in the metastatic samples, which is consistent with 18q losses occurring late in tumor progression[103]. Detailed deletion mapping in these tumors identified a distinct commonly deleted region within a 5-cM interval in 18q21.1. The primary tumors had either no detectable abnormality of chromosome 18 or the region involving LOH was limited while the metastatic foci showed more frequent and extended allelic losses on this chromosome. These suggest that inactivation of one or more putative tumor suppressor genes on 18q21 other than DCC and DPC4 plays an important role in the progression of human prostate cancer[104]. Loss of 18q in metastatic and locally recurrent tumors, but not in primary tumors from the same patients, suggests that a tumor suppressor gene in this region may be important in the progression of breast cancer, squamous cell carcinoma, etc.[7,105,106].

OTHERS

In addition, losse of 9p and gains of 17q and Xq are other genomic changes which frequently occurred in metastases but not in the corresponding primary tumor[19].

The deletions at 3p12-p14, 3p21, 4p15-p16, 6q24-qter, 8p22-p23, 10q21-qter and 21q22, as well as the over-representations at 1q21-q25, 8q, 9q34, 14q12 and 15q12-q15, occurred significantly more often in the metastatic tumour group[107]. Areas of deletion predominantly or completely common to the colorectal and the metastatic tumour were detected on chromosomes 5q, 8p, 17p, 18q, and 22q. Preferential loss in metastatic tumours was observed on chromosomal arm 3p[108]. Chu *et al*[109] compared the genetic abnormalities specifically associated with varying metastatic potential of prostate cancer cell lines by CGH, and found that PC3M-LN4, the derivative line that produced significantly larger metastatic tumors in the lymph nodes and had higher incidences of distant metastases, had a specific gain of 1q21-q22 and losses of 10q23-qter and 18q12-q21. LNCaP-LN3, a derivative line that had a significantly higher incidence of

lymph node metastases and produced significantly larger metastatic tumors in the lymph nodes, had specific losses of 16q23-qter and 21q.

A strong association between 12p12-13 LOH and distant metastasis has been found, which raises the possibility that mutational inactivation of a gene at 12p12-13, possibly p27/kip1, plays a pivotal role in the development of metastatic disease[110, 111].

LOH of 19q13 was associated with overall survival in local-regional International Neuroblastoma Staging System stages 1, 2, and 3 patients and was specifically present in tumors at the site of recurrence[112].

The gain of chromosome 20 may be available as a genetic marker for the diagnosis or prediction of liver metastasis[113,114].

The Xq25 region harbors a putative tumor suppressor gene whose inactivation in breast cancer is associated with tumor progression and metastasis. LOH at this region, therefore, potentially could be used as a prognostic marker for disease development[115].

QUESTIONS AND PROSPECTS

There is still controversial with the association between the chromosomal aberrations and the metastatic phenotype of cancer. Some reports showed the frequencies of the most common aberrations were relatively similar in primary tumors and metastases, but no aberrations specific to metastases were detected[116]. And more, among of the chromosomes mentioned above, which one plays the most important role in the metastatic process. Based on the published data and the author' s experience, chromosomes 8 and 17 should be paid more attention to. To date, combined analyses of the different aberrations of various chromosomal regions would be much more valuable in predicting the metastatic potential and prognosis of human solid tumors[8]. As the progression of human genome project and the establishment of more and more new techniques, it is hopeful that the genetic mechanisms involved in the tumor metastasis could be made clear in a not very long future, and provide new clues to predicting and controlling the metastasis.

Abstract

AIM: To identify the differentially expressed proteins between the human immortalized esophageal epithelial cell line (SHEE) and the malignant transformed esophageal carcinoma cell line (SHEEC), and to explore new ways for studying esophageal carcinoma associated genes.

METHODS: SHEE and SHEEC cell lines were used to separate differentially expressed proteins by two-dimensional electrophoresis. The silver-stained 2-D gels was scanned with EDAS290 digital camera system and analyzed with the PDQuest 6.2 Software. Six spots in which the differentially expressed protein was more obvious were selected and analyzed with matrix-assisted laser desorption/ionization time of flying mass spectrometry (MALDI-TOF-MS).

RESULTS: There were 107±4.58 and 115±9.91 protein spots observed in SHEE and SHEEC respectively, and the majority of these spots between the two cell lines matched each other (r=0.772), only a few were expressed differentially. After analyzed by MALDI-TOF-MS and database search for the six differentially expressed proteins, One new protein as well as other five sequence-known proteins including RNPEP-like protein, human rRNA gene upstream sequence binding transcription factor, uracil DNA glycosylase, Annexin A2 and p300/CBP-associated factor were preliminarily identified.

CONCLUSION: These differentially expressed proteins might play an importance role during malignant transformation of SHEEC from SHEE. The identification of these proteins may serve as a new way for studying esophageal carcinoma associated genes.

INTRODUCTION

Since Wilkins and Williams first proposed the concept of "Proteome" in 1994, the studies on tumor proteome have been made mighty advances[1]. It is expected to find new special tumor markers and clone their associated genes via separating and identifying the tumor differentially expressed proteins by the proteomic approach to reveal the tumor pathogenesis and carry out the gene therapy[2-6].

Esophageal carcinoma is one of the most common malignant tumors in China[7-19], and its etiology and pathogenesis remain to be determined[20-23]. Recent studies are mainly focused on the relationship between the change of oncogenes/suppressor oncogenes and esophageal carcinoma. However, there is no strong evidence to indicate that these oncogenes and suppressor oncogenes, including myc, ras, EGFR, int-2, cyclin D1, p53, Rb, p16, MCC, APC which are cloned originally from other kinds of tumors, are closely related to the esophageal carcinoma[24-28]. Therefore, it is necessary to clone the new oncogenes or suppressor oncogenes, which might have an more intimate relationship with esophageal tumor pathogenesis, directly from esophageal carcinoma tissues or cells.

In recent years, it has been increasingly concerned about the roles of the human papilloma virus (HPV) played in the esophageal carcinogenesis[29-32]. In our previous work, we transfected human embryonic esophageal mucosa cells with HPV18 E6E7 genes, and established an immortalized epithelial cell line SHEE[33,34]. The SHEE cells were further exposed to the tumor promoter (12-O-tetradecanoyl-phorbol-13-acetate, TPA) to be induced malignant transformation, and from which a human embryonic esophageal epithelial carcinoma cell line SHEEC was then established[35,36]. These studies not only provided the evidence for the close relationship between HPV and the esophageal carcinogenesis, but also established a reliable model for studying the molecular mechanisms of esophageal carcinogenesis, and cloning new esophageal carcinoma associated genes. In the present study, the differential expression of proteins between SHEE and SHEEC was investigated by the proteomic approach including two-

dimensional electrophoresis and MALDI-TOF-MS, which might serve as a new way for studying esophageal carcinoma associated genes.

MATERIALS AND METHODS

Cell culture

SHEE and SHEEC were cultured in MEM medium (Gibco) supplemented with 100 ml/L fetal borine serum (100 u/ml penicillin, 100 u/ml streptomycin) and incubated at 37 ℃ in humidified atmosphere of 50 ml/L CO_2 incubator.

Whole soluble protein extraction and pre-treatment

To obtain whole soluble protein, the experimental procedures in *Molecular cloning* (2nd ed.) were employed[37]. Briefly, when the cultured cells grew into a full monolayer, they were washed with ice-cold phosphate-buffer saline (PBS) three times and then treated with cold buffer containing 50 mmol/L Tris-HCl, pH8.0, 150 mmol/L NaCl, 1 %Triton X-100, 100 μg/ml Phenylmethylsulfonyl fluoride (PMSF) for 20 min at 4 ℃. The broken cells were collected with a scraper and centrifuged at 12 000 g for 5 min. The supernatant, which contained the whole soluble proteins, was added to Micro Bio-Spin® chromatography columns, and the purified sample was obtained after centrifugation at 1 000g for 4 min. Protein concentrations were determined by Bradford method (BIOPhotometer, Eppendorf). The sample aliquots were stored at -20 ℃ until used.

Two-dimensional electrophoresis

Two-dimensional electrophoresis was carried out by using the Mini-PROTEAN II 2-D apparatus (Bio-Rad). 70 μg of the whole soluble proteins were mixed with the rehydration solution containing 8 mol/LUrea, 4 %CHAPS,10 mmol/L DTT, 0.2 %(w/v) IPG buffer (pH3-10,liner) to a total volume of 125 μl. The mixture was pipetted into IPG strip tray channels. Both the rehydration and focusing were performed in the same focusing tray. IPG dry strips (pH3-10, 7 cm) were lowered onto the mixture with the gel side down, and then covered with mineral oil. The rehydration and isoelectric focusing (IEF) were done as follows: 1) rehydration for 12-14h, 0V; 2) 250V, 30 min; 3) 250V to 4 000V, 2 h; 4) 4 000V, 5 h. All the procedures above were performed at 20 ℃. After IEF separation, the strips were immediately equilibrated for 2×10 min with 6 mol/L Urea, 0.375 mol/L Tris-HCl (pH8.8), 2 % SDS and 20 % glycerol. In the first equilibration solution, 2 % (w/v) DTT was included, and 2.5 %(w/v) iodoacetamide was added in the second equilibration. Then the IPG strips were placed on a 1.0 mm thick, 12 % SDS-PAGE gel and sealed with 1 % LowMelt agarose. Electrophoresis was carried out at a constant voltage (40 mV/gel) until the bromophenol blue frontier reached the bottom of the gels about 0.5 cm. After electrophoresis, the SDS-PAGE gels were stained with silver stain plus kit (Bio-Bad).

Image acquisition and analysis

Image scanning for the silver-stained 2-D gels was performed with EDAS290 digital camera system (Kodak) and image analysis with the PDQuest 6.2 Software (Bio-Rad). To get reliable results, three gels were employed for each cell line. After the background subtraction, spot detection and match, one standard gel for each cell line was obtained. These standard gels were then matched to yield information about the spots of differentially expressed proteins.

Protein identification by MALDI-TOF-MS

Six spots in which the differentially expressed protein was more obvious in each cell line were cut out from the gel. After washed with 300 μl milliQ water for 15 min, each protein spot was decolorized with the successive action of 50 μl of 15 mmol/L Potassium ferricyanide and 50 mmol/L sodium thiosulphate for 5-10 min. The faded gel pieces were dried in a vacuum centrifuge tube for 5 min. The cysteine reduction and alkylation were performed as incubated with 10 mmol/L DTT, 100 mmol/LNH_4HCO_3 at 56 ℃ for 1 h in the dark. The gel pieces were then dried again and incubated with 50 mmol/L fresh iodoacetamide in 100 mmol/L NH_4HCO_3 at room temperature for 30 min. Thereafter the gel pieces were rehydrated in digestion buffer containing 20 μl of 12.5 μg/ml modified trypsin and 20 mmol/L NH_4HCO_3 for 30 min in ice. The excess liquid was removed and the gel pieces were digested continuously at 30 ℃ overnight(>16 h). The resulting peptide mixture was extracted from the digested solution by centrifugation and then resuspended in 10 μl of 50 % CH_3CN and 0.1 % trifluoroacetic acid (TFA) for 10min at 30 ℃ on a shaking platform. Peptide mass maps were generated by Applied Biosystems Voyager System 6192 MALDI-TOF-mass spectrometry (ABI,USA). Peptide masses were analyzed using the MS-Fit search program (http://prospector.ucsf.edu/ucsfhtml4.0u/msfit.htm).

RESULTS

2-D map and image analysis

The whole soluble proteins of SHEE and SHEEC were extracted in one step and desalted with Micro Bio-Spin® chromatography columns, which made the 2-D electrophoretic patterns a much higher quality (to be published). Three pairs of gels from different batches of SHEE and SHEEC were analyzed for the purpose of quantitative and qualitative comparison with the software PDQuest6.2. There were 107± 4.58 and 115±9.91 protein spots observed in SHEE and SHEEC respectively, and the majority of these spots between the two cell lines matched each other (r=0.772), only a few were expressed differentially. Six spots in which the differentially expressed protein was more obvious were selected and analyzed with MALDI-TOF-MS. The spot 1 was only expressed in the samples of SHEEC and absent in that of SHEE. In contrast, the spots 2 to 6 were merely observed in the SHEE samples. These six spots were marked with arrows at the corresponding site in Figure 1.

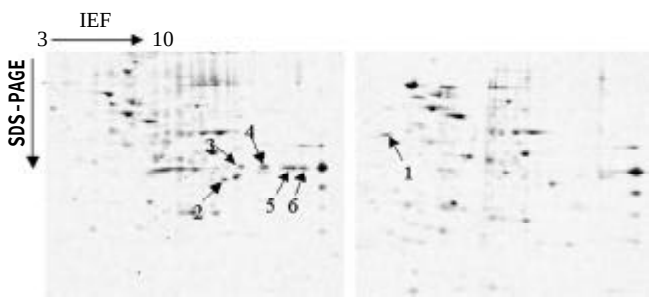

Figure 1 The differentially expressed protein spots observed in SHEE (left) and SHEEC (right) two-dimensional gels samples

Table 1 Protein identified by mass spectrometry

Spot No.	Accession No (NCBInr)	Theoretic M_r	Theoretic p*I*	Intensity Matched(%)	Length(AA)	expression	Protein name

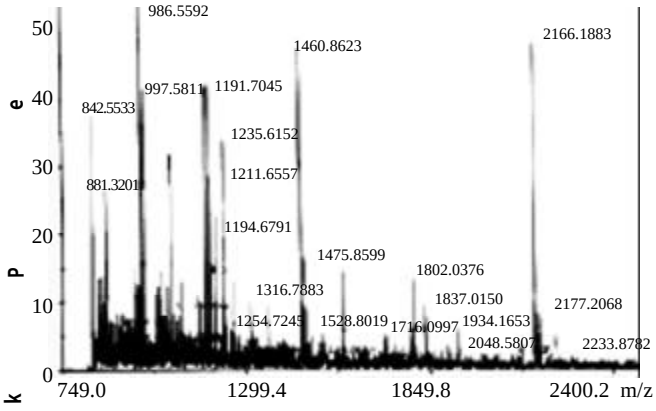
MALDI-TOF-MS analysis and protein identification

The proteins contained in the six spots were identified respectively by MALDI-TOF-MS on the basis of peptide mass matching; In this way, the peptide mass fingerprinting map for each protein spot was obtained as show in Figure 2. The experimental data revealed that the protein in spot 6 was with an unknown sequence (Figure 3), and its characteristics remains to be investigated. The identified protein names, accession numbers, as well as the number of the matching peptide, the theoretical *M*r and p*I* values, i.e. for each protein spot were listed in Table 1.



Mode of operation: Reflector Extraction mode: delayed Accelerating voltage: 20000 V
Acquisition mass range: 750-3500Da Number of laser shots: 150/spectrum Laser intensity: 2233

DISCUSSION

The investigation of differentially expressed proteins that occured during the generation and development of tumors is a new effective way to study tumor associated genes[38,39]. In the present study, we preliminarily studied several of the differentially expressed proteins between SHEE and SHEEC with two-dimensional electrophoresis and MALDI-TOF-mass spectrometry. By comparing the reference proteins or peptides, five sequence-known proteins and a novel sequence-unknown protein, which expressed more differentially in the course of malignant transformation of esophageal epithelial cells, were identified for the first time. It is therefore further indicated that the methods adopted in the present study could provide a new way to study esophageal carcinoma associated genes.

RNPEP-like protein being composed of 494 amino acid residues has 49 % identity with aminopeptidase B in amino acid sequence[40]. As judged by the parameters such as the numbers and intensity of peptide matching peak, the sequence coverage of matching peptide, as well as the theoretical and approximate values of *M*r and p*I*, RNPEP-like protein was considered as the much higher expression in SHEEC cells. However, the significance of its overexpression in SHEEC remains unknown.

Human rRNA gene upstream sequence binding transcription factor (hUBF) is a critical element in the regulation of rRNA transcription, which performs its function by binding to the rRNA gene upstream regulator sequence (-200 to -107 and -45 to 20)[41]. In our present work, it has been shown that the down-regulation of hUBF expression was obvious in the course of malignant transformation of SHEE, which might be the results of alterations in the regulation mechanism of rRNA gene transcription occurred in the malignant transformation of the human immortalized esophageal epithelial cells. In addition, whether or not the fact that diminished hUBF expression has been found in the well-differentiated teratocarcinoma cells[42] related hUBF to the neoplastic differentiation, remain to be investigated.

Uracil DNA glycosylase (UDG) is an enzyme for the DNA repairment. It can hydrolyse the N-glycosidic bond connecting the base to the deoxyribose and release free uracil base and DNA with an abasic site as its products[43]. Moon and his associates[44] found that the uracil DNA glycosylase gene (UNG) in sporadic glioblastomas had a point mutation in exon 3, and concluded that the genetic alterations of UNG might play an important role in the development of primary glioblastomas. In our study, the UDG expression shows absent or too low to be detected after SHEE malignantly transformed into SHEEC, which means that there might exist repairing deficiencies for the damaged DNA in the course of malignant transformation of the human immortalized esophageal epithelial cells.

Annexin A2 belongs to the family of annexins that bind to phospholipids in a calcium-dependent manner. So far at least 13 annexin family members have been found. There are four repeats of a 70 amino acid motif and a variable N-terminal end contained in all these annexin family members. According to lots of investigations, the annexins seem to be involved in various biological processes including endocytosis, exocytosis, the phospholipase A2 inhibition as well as ion channel and protein kinase C activity[45,46]. In recent years, it has been found that the annexin I was overexpressed in some kinds of malignant tumors such as human hepatocellular[47] and pulmonary carcinomas[48], which suggests that some of the annexin family members might relate to the carcinogenesis. Moreover, Chetcuti and his associates[49] found that the annexin II was expressed in the nomal and benign hyperplastic prostate tissue, and absent in all prostate cancer specimens. These results indicated that different members of the annexin family may have varied roles in the development and progression of tumors. The fact that the annexin A2 was expressed in SHEE but absent in SHEEC in our research indicates that annexin A2 might play a role of suppressor oncogene during malignant transformation of the human immortalized esophageal epithelial cells.

The p300/CBP-associated factor (P/CAF) that possessed intrinsic histone acetylase activity could regulate the gene expression of various sequence-specific factors that are involved in cell growth and/or differentiation including CREB, c-Jun, Fos and c-Myb through promoter-specific histone acetylation. Yang *et al*[50] found that the expression of P/CAF in HeLa cells could block the cell-cycle progression from G1 to S phase, and counteract the mitogenic activity of adenoviral oncoprotein E1A. The P/CAF expression was absent in the esophageal carcinoma cells found in our study suggests that the P/CAF might play a role in the suppressing of the esophageal carcinoma development.

Abstract

AIM: To investigate the effects of vitamin E succinate (VES) on the expression of *c-jun* gene and protein in human gastric cancer SGC-7901 cells.

METHODS: After SGC-7901 cells were treated with VES at different doses (5,10,20 mg·L^{-1}) at different time, reverse transcription-PCR technique was used to detect the level of *c-jun* mRNA; Western Blot was applied to measure the expression of *c-jun* protein.

RESULTS: After the cells were treated with VES at 20 mg·L^{-1} for 3 h, the expression rapidly reached its maximum that was 3.5 times of UT control (P<0.01). The level of *c-jun* mRNA was also increased following treatment of VES for 6 h. However,the expression after treatment of VES at 5 mg·L^{-1} for 24 h was 1.6 times compared with UT control (P<0.01). Western blot analysis showed that the level of *c-jun* protein was obviously elevated in VES-treated SGC-7901 cells at 20 mg·L^{-1} for 3 h. The expression of *c-jun* protein was gradually increased after treatment of VES at 20 mg·L^{-1} for 3, 6, 12 and 24 h, respectively, with an evident time-effect relationship.

CONCLUSION: The levels of *c-jun* mRNA and protein in VES-treated SGC-7901 cells were increased in a dose- and time-dependent manner; the expression of *c-jun* was prolonged by VES, indicating that *c-jun* is involved in VES-induced apoptosis in SGC-7901 cells.

INTRODUCTION

RRR-α-tocopheryl succinate (vitamin E succinate, VES), a derivative of natural vitamin E, has been shown to be a potent growth inhibitor of various cancer cell types *in vitro* and *in vivo*[1-7]. Growth inhibition by VES is attributed to cell cycle blockage[4,8-10], induced cellular differentiation[11,12], increased expression of biologically active transforming growth factor-βs (TGF-βs) and their type Ⅱ cell surface receptors[1,13,14] and the induction of apoptosis[15-18]. VES is noteworthy not only for its antiproliferative effects on tumor cells, but also for its non-toxic effect on normal cell types.

Gastric cancer is one of the most common tumors in China[19-28]. Up to date, the exact mechanisms of tumorigenesis is still unclear, but our previous studies showed that VES can block cell cycle, arrest DNA synthesis and induce apoptosis in human gastric cancer SGC-7901 cells, therefore inhibiting the cell growth[29-32]. In addition, our *in vivo* research in our laboratory demonstrated that VES inhibited benzo(a)pyrene (B(a)P)-induced forestomach carcinogenesis in female mice[33]. The exact mechanisms of apoptosis are not clearly known, but we found that VES can secrete and activate biologically active TGF-β and then TGF-β increases the kinase activity of *c-jun* N-terminal kinase (JNK) followed by phosphorylation of *c-jun*, and finally activated *c-jun* triggers apoptosis in human gastric cancer SGC-7901 cells[34]. In this study, the expression of *c-jun* mRNA was detected using reverse-transcription polymerase chain reaction (RT-PCR) technique and the level of *c-jun* protein was measured using western blot in order to further investigate the mechanisms of VES-triggered apoptosis.

MATERIALS AND METHODS

Materials

VES was purchased from Sigma Co. Ltd. RPMI 1640 media and TRIzol total RNA isolation kit were obtained from Gibco BRL, TITANIUM™ one-step RT-PCR kit from Clontech. Inc. *c-jun* (H79) rabbit polyclonal antibody was from Santa Cruz Biotechnologies.

Methods

Cell culture Human gastric cancer cell lines SGC-7901 were maintained in RPMI 1640 medium supplemented with 100mL·L^{-1} fetal calf serum (FCS), 100 kU·L^{-1} penicillin, 100 mg·L^{-1} streptomycin and 2 mmol·L^{-1} L-glutamine under 50 mL·L^{-1} CO_2 in a humidified incubator at 37 ℃. SGC-7901 cells were incubated for different time periods in the presence of VES at 5, 10 and 20 mg·L^{-1} (VES was dissolved in absolute ethanol and diluted in RPMI 1640 complete condition media correspondingly to a final concentration of VES and 1 mL·L^{-1} ethanol), succinic acid, vitamin E and ethanol equivalents as vehicle (VEH) control and condition media only as untreated (UT) control.

RT-PCR After SGC-7901 cells were treated with VES for 3, 6 and 24 h, respectively, total cellular RNA was isolated by using TRIzol Reagent according to the manufacturer's instructions. The concentration and purity of total RNA were determined by DU^{R} 640 nucleic acid and protein analyzer (Beckman, USA). One-step RT-PCR was carried out following the manufacturer's instructions. RT-PCR mixture was heated 1h at 50 ℃ for reverse transcription and 5 min at 95 ℃ for pre-denaturation, then into 34 PCR cycles of 30 s at 94 ℃ for

denaturation, 30 s at 60 ℃ for annealing, 30 s at 72 ℃ for extension in PTC-100 programmable thermal controller (MJ Research, USA). The corresponding fragment of *c-jun* gene was amplified with specific primers synthesized[35]. β-actin gene was designed as an internal standard with purpose to remove false negative outcome (Table 1).

Table 1 Nucleotide sequence and size of the expected PCR products for oligonucleotide primers used for RT-PCR

Genes		Sequence	Size (bp)
c-jun	Upstream:	5'-GGA AAC GAC CTT CTA TGA CGA GCC C-3'	315
	Downstream:	5'-GAA CCC CTC CTG CTC ATC TGT CAG G-3'	
β-actin	Upstream:	5'-GTG GGC CGC TCT AGG CAC CAA-3'	540
	Downstream:	5'-CTC TTT GAT GTC ACG CAC GAT TTC-3'	

The amplified products were seperated in 20 g·L^{-1} agorose gel stained with ethidium bromide. After electrophoresis, the gel was observed and photographed under ultraviolet reflector. The density and area of each band were analyzed using ChemiImager™ 4000 Digital System (Alpha Innotech Corporation, USA).

Western blot SGC-7901 cells treated with VES were harvested, washed in PBS and lyzed in lysis buffer containing 150 mmol·L^{-1} NaCl, 1 mL·L^{-1} NP-40, 5 mg·L^{-1} sodium deoxycholate, 1 g·L^{-1} SDS, 50 mmol·L^{-1} Tris (pH 7.4), 1 mmol·L^{-1} DTT, 0.5 mmol·L^{-1} Na_3VO_4, 10 mmol·L^{-1} phenylmethylsulfonyl fluoride (PMSF), 10 mg·L^{-1} trypsin, 10 mg·L^{-1} aprotinin and 5 mg·L^{-1} leupeptin. Following the centrifugation of 12 000×g for 30 min at 4 ℃, the amount of protein in the supernatant was determined using Biorad DC protein assay. Equal amount of protein was separated on 10 % SDS-PAGE and transferred to nitrocellulose filter (Gibco BRL, USA) overnight. Blocked with 50 g·L^{-1} defatty milk, the filter was incubated with *c-jun* (H79) rabbit polyclonal antibody and horseradish peroxidase-conjugated IgG, finally developed with DAB.

Statistical analysis

The data were expressed as $\bar{x}\pm s$. Statistical analysis was performed using student's *t*-test. $P<0.05$ was considered significant.

RESULTS

Effect of VES on the expression of c-jun mRNA in SGC-7901 cells

1 μg of total cellular RNA from groups of control, succinate, vitamin E, VES at 5, 10 and 20 mg·L^{-1} was added to amplify *c-jun* and β-actin genes by RT-PCR. Baseline expression of *c-jun* mRNA was observed in SGC-7901 cells (Figure 1). After the cells were treated with VES at 20 mg·L^{-1} for 3 h, the expression rapidly reached its maximum that was 3.5 times of UT control ($P<0.01$). The level of *c-jun* mRNA was also increased following treatment of VES for 6 h. However, the expression after treatment of VES at 5 mg·L^{-1} for 24 h was 1.6-fold increase compared with UT control ($P<0.01$), while there was no significant difference between 10 and 20 mg·L^{-1} VES groups and UT control group (Table 2).

Effect of VES on the expression of c-Jun protein in SGC-7901 cells

Western blot analysis showed that the level of c-Jun protein was obviously elevated in VES-treated SGC-7901 cells at 20 mg·L^{-1} for 3 h in a significant dose-dependent manner (Figure 2A, 2B). Meanwhile, compared with the cells in UT control group, the VES-treated cells at 20 mg·L^{-1} exhibited 1.8-, 2.0-, 2.3- and 2.8-fold increases in the expression of *c-jun* protein for 3, 6, 12 and 24h, respectively, with an evident time-effect relationship (Figure 3A,3B).

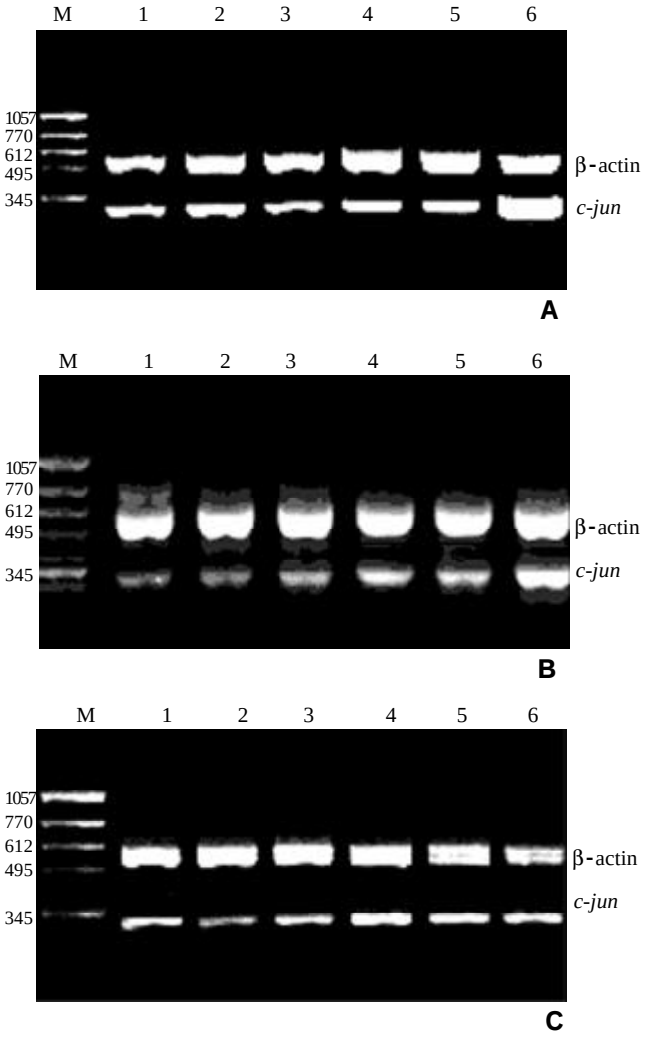

Figure 1 Effect of VES on the expression of *c-jun* mRNA in SGC-7901 cells for different time points by RT-PCR. A: treatment of VES for 3 h; B: treatment of VES for 6 h; C: treatment of VES for 24 h. 1: UT control; 2: succinate; 3: vitamin E; 4: VES at 5 mg·L^{-1}; 5: VES at 10 mg·L^{-1}; 6: VES at 20 mg·L^{-1}; M: molecular weight marker.

DISCUSSION

The oncogene, *c-jun*, belongs to an immediate early gene and can be rapidly and transiently induced in response to multiple extracellular stimuli[36-38]. The product of *c-jun* gene is a nuclear transcription factor, an important composition of activation protein 1 (AP-1) dimmers, involved in signal transduction and regulation of many kinds of genes[39-41].

Transcription of *c-jun* mRNA rises after exposure of cells to a number of treatment including ultraviolate, irradition, heat shock,H_2O_2,TNF-α and other apoptosis-associated factors[42-46]. In addition to this transcriptional mode of regulation, *c-jun* activity can also be modulated directly at the protein level. In certain cell types, induction of *c-jun* is observed during apoptosis. There is some evidence that prolonged expression of *c-jun* in selected vulnerable cells suggests neuronal cell death[47].

Apoptosis is an innate program of cell suicide that is required for removal of unnecessary or damaged cells from bodily structures. Apoptosis is complex and regulated by a variety of factors[48-58]. Previous studies showed that the induction of apoptosis in tumor cells is one of the important mechanisms of VES-induced cell growth inhibition[59-61]. In the present study, the expression of *c-jun* mRNA and protein was measured in human gastric cancer SGC-7901 cells treated with VES at different doses for different time points. We found that the expression of *c-jun* mRNA was evidently promoted after 3 h of VES treatment at 20 mg·L^{-1} and reduced to the normal level after 24 h of treatment; whereas in the case of VES treatment at 5 mg·L^{-1}, that was also increased after 3 h and remained a high level after 24 h. The data above showed that the *c-jun* activation was enhanced and prolonged by VES, therefore indicating that *c-jun* is involved in VES-triggered apoptosis in SGC-7901 cells. The results from western blot ananlysis showed that the level of *c-jun* protein was elevated following SGC-7901 cells were treated with VES at different doses for 3 h and with VES at 20 mg·L^{-1} for different time in a dose- and time-dependent manner.

The diversity of signals and signaling pathways that are directed toward *c-jun* is also reflected in the biological responses, in which the transcription factors have been implicated. It is reported that the mainly biological functions of *c-jun* are blockage of cell cycle and induction of apoptosis[62-64]. The study presented here demonstrated that VES can obviously increase the expression of *c-jun* mRNA and protein in human gastric cancer SGC-7901 cells, implicating that *c-jun* is involved in VES-induced apoptosis.

Abstract

AIM: To evaluate the role of APC mutation in gastric carcinogenesis and to correlate APC mutation with microsatellite instability (MSI) in gastric carcinomas.

METHODS: APC mutation was measured with multiplex PCR, denaturing gradient gel electrophoresis and DNA sequencing; and MSI was analyzed by PCR-based methods.

RESULTS: Sixty-eight cases of sporadic gastric carcinoma were studied for APC mutation at exon 15 and MSI. APC mutaions were detected in 15(22.1 %) gastric cancers. Frequence of APC mutation (33.3 %) in intestinal type of gastric cancer was significantly higher than that in diffuse type (13.1 %, $P<0.05$). On the contrary, no association was observed between APC mutation and tumor size, differentiation, depth of invasion, metastasis or clinical stages. Using five microsatellite markers, MSI in at least one locus was detected in 17 of 68 (25 %) of the tumors analyzed. APC mutations were all detected in MSI-L (only one locus, $n=9$) or MSS(tumor lacking MSI or stable, $n=51$), but no mutation was found in MSI-H ($\geqslant$2 loci, $n=8$).

CONCLUSION: APC mutation is involved in carcinogenesis of intestinal type of gastric cancer and is independent of MSI phenotype but related to the LOH pathway in gastric cancer.

INTRODUCTION

The mechanisms of carcinogenesis in the gastric mucosa remain unclear. Adenomatous polyposis *coli* or APC, has been characterized as a tumor suppressor gene and considered a "gatekeeper" because alterations in this gene occur as an early event in the neoplastic transformation[1-3]. The APC gene was first identified in the germline of individuals with the condition known as familial adenomatous polyposis or FAP[4] and has been shown to play a role in the developmemt of sporadic colorectal cancer[5,6]. Studies have attempted to characterize the mutation of APC in sporadic gastric cancer[7-10] and in a limited number of familial gastric cancer[11,12]. It has been found that inactivation of APC plays a role in the development of some gastric cancers, particularly very well differentiated adenocarcinomas and signet-ring cell carcinomas[13,14], and that the mutations of the APC gene, similar to those in colorectal tumorigenesis, occur during the early stages of gastric adenoma development[15,16].

Genetic instability is strongly involved in neoplastic transformation and progression[17]. In gastrointestinal carcinomas, such genetic instability may be classified into two different forms in which hypermutability occurs either by means of chromosomal instability or microsatellite instability (MSI)[18-23]. MSI represents an important new form of genetic alteration characterized by widespread instability in repetitive nucleotide sequences. MSI has been found in the majority of tumors associated with hereditary non-polyposis colorectal cancer (HNPCC)[24,25] in which germ-line mutation occurs within the mismatch repair genes hMSH2, hMLH1, hPMS2 or hMSH6[26-28]. Mutations of the transforming growth factor type β receptor gene (TGF-βRⅡ), and BAX gene are strongly correlated with MSI[29-31]. MSI is also a distinctive feature in about 10-15 % of sporadic colorectal tumors and to a varying degree in tumors of other organs, including the stomach[32-34]. Although mutations of APC have been reported in gastric cancer, less clear, however, is the relevance of APC mutation as a potential factor in MSI-positive gastric cancer. The aim of the present study is to correlate APC mutation with MSI in gastric carcinomas.

MATERIALS AND METHODS

Tissue samples

Sixty-eight cancer and corresponding normal tissues were obtained from surgically resected gastric carcinoma in Southwest Hospital. Each specimen was frozen immediately and stored at -80 ℃ until analyzed. A 5μm section was cut from each tissue and stained with hematoxylin/eosin in order to confirm whether the cancer cells in tissues were predominant or not. Genomic DNA was isolated by standard proteinase-K digestion and phenol-chloroform extraction protocols. Of the 68 patients with gastric cancer, 45 were men and 23 were women with an age range of 30-76 years (mean age of 56.2 years at diagnosis). None of the patients included in the present series had a family history suggestive of HNPCC and had received chemotherapy or radiation therapy.

Multiplex PCR

Multiplex PCR was utilized in order to visualize the product of several regions simultaneously. Singleplex PCR was also used to help confirm cases and for regions that were difficult to amplify. Multiplex PCR analysis of APC exon 15 was performed using primers with a GC clamp (Table 1). Genomic DNA(100-400 ng), 0.25 μM primer for multi-primer reaction,

1×buffer, 1.5 mM $MgCl_2$, 0.25 mM of each dNTPs, and 0.1 U/μl Amplitaq Gold were combined in 10 μl reaction. The PCR reaction consisted of a denaturation step at 95 ℃ for 12 minutes followed by 32 cycles of 40 seconds at 94 ℃, 60 seconds at 49 ℃, and 90 seconds at 72 ℃. Elongation occurred through 10 minutes at 72 ℃, 10minutes at 98 ℃, 30 minutes at 50 ℃ and 30 minutes at 37 ℃.

Denaturing gradient gel electrophoresis (DGGE)

DGGE analysis was performed for scanning mutations at 15 exon of APC gene. 8 μl of each sample was loaded on the gels consisting of 10 % polyacrylamide and 10-60 % urea-formamide. The gels were run at 90V for 17 hours in tanks of buffer at 50 ℃. Gels were stained with 0.5×Sybr Green I and Sybr Green Ⅱ for 20 minutes and visualized by UV transillumination. Heteroduplex samples were further analyzed by manual sequencing.

Manual sequencing

Samples were amplified for sequencing with PCR primers that did not include the GC clamp (Appendix A). The PCR reaction included 200-400 ng of genomic DNA, 0.25 μM primer, 1×buffer, 1.5mM $MgCl_2$, 0.25mM of each dNTPs, and 2.5U Amplitaq Gold were combined in a 10 μl reaction. The PCR reaction consisted of a denaturation step at 94 ℃ for 3 minutes followed by 35 cycles of 60 seconds at 94 ℃, 60 seconds at 55 ℃, and 60 seconds at 72 ℃. A final extension step included 10 minutes at 72 ℃. 1.5 % agarose gels were run at 150V to confirm the existence of PCR product. The product was purified following the instructions of the Wizard PCR Preps DNA Purification System (Promega, Madison, WI). Following the purification process, the product was run on a 1.5 % agarose gel at 150V to verify the product. Sequencing was performed following the instruction of the system. The film was read independently by two individuals according to the APC sequence.

MSI detection

MSI analyses included five microsatellite markers: BAT25, BAT26, BAT40, D2S123, and D5S346. PCR was performed as previously described[35]. MSI was defined as the presence of band shift in the tumor DNA that was not present in the corresponding normal DNA. Based on the number of mutated MSI markers in each tumor, carcinomas were characterized as MSI-H if they manifested instability at two or more markers, MSI-L if unstable at only one marker, and MSS if they showed no instability at any marker.

Statistical analysis

Chi-square test with Yates' correction was used. A P value <0.05 was considered significant.

RESULTS

Multiplex PCR and DGGE were used to scan the mutation at the exon 15 of APC in 68 gastric cancers (Figure 1). The samples that showed alterations by DGGE were further analyzed through munual sequencing (Figure 2). APC mutaions were detected in 15 samples (22.1%) held APC mutations that lead to premature protein truncation (Table 2). The truncation of the protein occurred as a result of a stop codon created through a base pair change, an insertion, or a deletion.

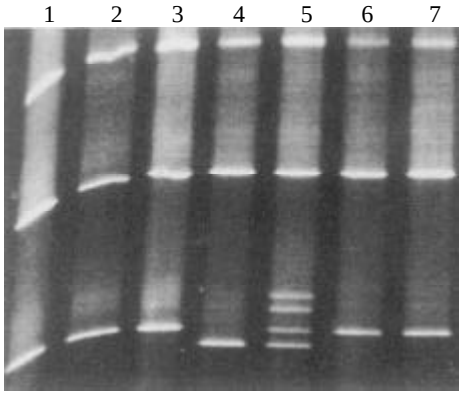

Figure 1 Abnormal four-band patterns in lane 5 after multiplex PCR and denaturing gradient gel

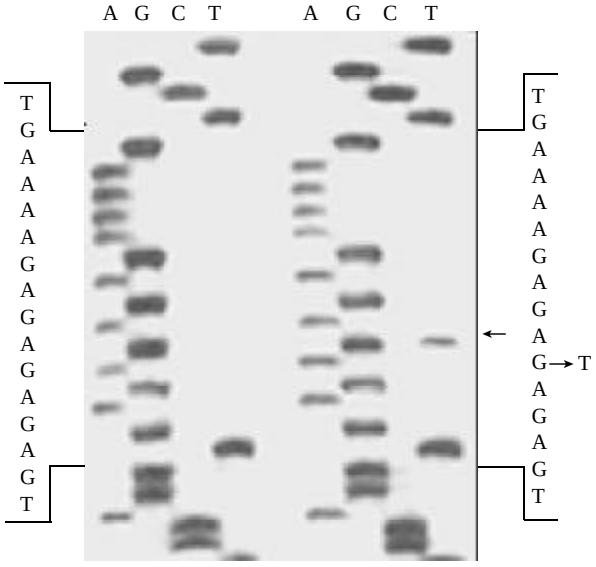

Figure 2 DNA sequencing shows a G→T change at 1464 coden

We compared mutation of exon 15 of APC gene in gastric cancer with various clinicopathological parameters including tumor size, differentiation, TNM status, clinical stage and Lauren's types. Table 3 shows the association of mutations of APC to the clinicopathological parameters of 68 gastric carcinomas. Mutations of APC gene were observed more common in intestinal type than in diffuse type tumors (P<0.05).

Alterations of electrophoretic patterns of PCR products of five microsatellite markers were compared between tumor and normal DNA in each patient. MSI affecting at least one locus was observed in 17 (25 %) of 68 tumors, among which eight (11.8 %) were MSI-H, nine (13.2 %) were MSI-L, and fifty-one (75 %) were MSS. Table 4 shows the association of mutations of APC to MSI of 68 gastric carcinomas. Three mutations were found in 9 tumors with MSI-L and 12 were found in 51 tumors with MSS, and no mutation was found in 8 tumors with MSI-H.

DISCUSSION

Mutations of APC gene has been shown to play an important role in colorectal tumorigenesis. A germline mutation in APC contributes significantly to the development of colitis-associated neoplasia[36]. In the current study, we investigated mutations of the APC gene in 68 gastric carcinomas obtained surgically. Mutations at exon 15 of APC gene were detected in 22.1 % of gastric cancers. This finding is similar to the previous studies[14,15]. This proportion may be an underestimate because the mutation of exons 1 through 14 were not detected in this study. Previous investigations have found that the 5' half of APC holds the majority of the germline mutations[3,37]. The mutations identified in the study were spread throughout the exon 15 of APC sequence. Sequencing analysis confirmed that the mutations resulted in truncation of the gene products or in an amino acid change. The APC gene encodes a large protein with multiple cellular functions and interactions. Mutations in this gene would lead to alterations in signal transduction of cell, differentiation, mediation of intercellular adhesion, stabilization of the cytoskeleton and possibly regulation of the cell cycle and apoptosis[38,39]. Our results imply that APC plays a crucial role in gastric carcinogenesis, as was observed in colorectal carcinogenesis.

In the current study, we did not find an obvious relationship between the APC mutation and tumor size, depth of invasion, node metastasis or clinical stages, indicating a limited role of the APC mutation in predicting prognosis of gastric carcinomas. This finding is in agreement with the recently published data on cholangiocarcinoma and breast cancer[40,41]. Gastric carcinomas can be divided into "intestinal" type and "duffuse" type. The intestinal type of gastric cancer is the predominant type in elderly population at high risk and preceded by well-defined precancerous lesions, such as intestinal metaplasia and atrophic gastritis. The diffuse type is relatively more frequent in low risk populations and is not as often preceded by intestinal metaplasia. A distinct genetic pathway exists in gastric carcinogenesis of different histological subtypes and their tumor progression[42-45]. Increased beta-catenin mRNA levels and mutational alterations of the APC and beta-catenin gene were present in intestinal type gastric cancer[46,47], whereas epigenetic inactivation of E-cadherin via promoter hypermethylation may be an early critical event in the development of undifferentiated tumors[48-51]. In this study, marked difference in APC mutation was noted in gastric cancer by histological type. APC mutations were significantly more frequent in intestinaltype gastric cancers as compared with diffusetype gastric cancers, suggesting that APC gene is not only a predisposing gene in colorectal cancer but also a predisposing gene in intestinal type of gastric cancer. The mutation of APC gene may be considered makers for intestinal or colonic differentiation. The mutation of APC in the majority of intestinal type cancers also supports the theory that these cancers result from transformation of intestinal metaplasia.

There is evidence that MSI cancer comprises distinctive MSI-H and MSI-L categories[14]. MSI-H cancers are distingushed clinicopathologically and in their spectrum of genetic alterations from cancers showing MSI-L and MSS cancers[14]. Our previous studies indicated that MSI-H gastric cancers often show lower frequency of LOH of APC, MCC and DCC genes than do MSI-L and MSS cancers[1]. In present study, 15 APC mutations were all detected in MSI-L and MSS, but no mutation was found in those showing MSI-H. This result indicates that APC is mutational target in MSI-L and MSS tumor cells and support the notion that APC mutation-positive tumors may identify an alternative pathway which is probably different from MSI-related phenomenon observed in HNPCC. Our analysis of APC mutation should further provide some clues to the molecular mechanisms underlying the profound genomic instability in the MSI and LOH pathway for gastric carcinoma.

Abstract

AIM: To explore the mechanism of the Sijunzi decoction and another Chinese herbal recipe (SRRS) based mainly on the Sijunzi decoction in treatment of gastric cancer.

METHODS: A human gastric adenocarcinoma cell line SGC-7901 grafted onto nude mouse was used as the animal model. The mice were divided into 3 groups, one control and the two representative experimental conditions. Animals in the two experimental groups received either Sijunzi decoction or SRRS over a 40-day period starting at 1st day after grafting. Control animals received saline on an identical schedule. Animals were killed 41 days after being grafted. The effect of therapy was assessed by two ways: **(1)** tumor size was periodically measured during the life of the animals; (2) tumor weight was determined by a electron balance immediately after the animals killed. For detection of apoptotic cells, apoptotic indices(AI) were examined by the terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate fluorescence nick end labeling (TUNEL) method. Morphological alterations were observed with electron microscopy. S-P immunohistochemical method was used to detect the expression of Ki-67 in xenografts. Expression of bcl-2 and p53 was semiquantitatively detected using a reverse transcriptase-polymerase chain reaction (RT-PCR) technique.

RESULTS: When compared with controls, tumor growth (size and weight) was significantly inhibited by treatment with the Sijunzi decoction ($P<0.05$) or SRRS ($P<0.01$). The tumor inhibitory rate in the Sijunzi decoction group was 34.33 % and SRRS group 46.53 %. AI of human gastric cancer xenografts in nude mice was significantly increased to 16.24 ±3.21 % using TUNEL method and 11.38±6.46 % by FACScan in the Sijunzi decoction group compared with the controls (TUNEL: 2.63±1.03 %, $P<0.01$; FACScan: 7.15± 1.32 %, $P<0.05$). SRRS group was also found a significantly increased AI by using TUNEL method and flow cytometry analysis compared with the controls (TUNEL: 13.18±3.05 %, $P<0.05$; FACScan: 11.58±5.71 % ($P<0.05$). Under electron microscope, cell shrinkage, nuclear chromatin condensation, formation of membrane blebs and apoptotic bodies were frequently observed in Sijunzi decoction group and SRRS group. The average labeling index (LI) for Ki-67 in SRRS group was significantly decreased to 8.43±2.22 % compared with the control group (10.37±4.91 %) ($P<0.05$). The average labeling index for Ki-67 in sijunzi decoction group was 7.95± 2.54 % which was lower than that of the control group, but showed no significance ($P=0.07$). The expression level of p53 mRNA was lower in both Sijunzi decoction group and SRRS group than that in control group ($P<0.05$; $P<0.01$). The expression of bcl-2 mRNA was also decreased in SRRS group compared with the control ($P<0.01$).

CONCLUSION: The inhibition of gastric cancer cell growth *in vivo* by Chinese Jianpi herbs and SRRS is related to induction of the cell apoptosis which may be involved in aberrant expression of p53 and bcl-2 genes

Zhao AG, Zhao HL, Jin XJ, Yang JK, Tang LD. Effects of Chinese Jianpi herbs on cell apoptosis and related gene expression in human gastric cancer grafted onto nude mice. *World J Gastroenterol* 2002; 8(5):792-796

INTRODUCTION

Apoptosis plays a crucial role in the proliferation and turnover of cells in various tumors. It has been clear that its extent is often enhanced in tumor by many anticancer drugs[1-5], such as cytotoxic drugs[6], hormone[1], or some Chinese herbal medicine[7-10]. In clinic studies, some Chinese Jianpi herbs had been proved to have effect on malignant tumors, especially on gastric and colorectal tumors[11-13]. Among these herbs we found that Codonopsis pilosula (Franch) Nannf., Atractylodes macrocephala koidz. and the Sijunzi Decoction might suppress gastric carcinoma cell proliferation and cause tumor cell loss and the nuclear condensation *in vitro*[14]. The Sijunzi Decoction and another Chinese herbal recipe SRRS of deheat-toxin, softening hard lumps and dissolving phlegm enhance apoptosis of human gastric cancer xenografts in nude mice[15]. Based on previous studies, we examined the apoptotic indices of human gastric cancer grafted onto nude mice after the treatment with Sijunzi Decoction and SRRS and investigate the underlying mechanism of the tumor suppressive effect of these Chinese Jianpi herbs.

MATERIALS AND METHODS

Materials

Animal models Thirty 6-7 weeks old female BALB/C-nu/nu mice (weight 18-22 g) and a human gastric carcinoma cell line SGC-7901 were obtained from Shanghai Tumor Institute (No.01842). The animals were subcutaneously grafted with the SGC-7901 cell. The tumor transplantation procedure was described previously[15].

Drugs The Sijunzi Decoction is composed of Codonopsis pilosula (Franch) Nannf., Atractylodes macrocephala koidz, Poria cocos (Schw.) Wolf, Glycyrrhiza uralensis Fisch. The concentration of the Sijunzi Decoction was 160 g/L; SRRS is composed of Atractylodes macrocephala koidz., Poria cocos(Schw.) Wolf, Sargentodoxa cuneata(Oliv.) Rehd. Et Wils., Prunella vulgaris L. And etc. The concentration of the SRRS decoction was 240 g/L.

Experimental schedule After grafting the mice were randomly divided into 3 groups, one control and the two experimental groups assigned to receive the Sijunzi Decoction or SRRS. Each animal in the two experimental groups was given 0.5 mL of the Sijunzi Decoction or SRRS by gastric perfusion every day over a 40-day period beginning at 1st day after grafting. The control animals received normal saline according to the same schedule. Animals were killed 41 days after being grafted.

Methods

Tumor growth The effect of therapy was assessed by two ways: (1)tumor size was measured twice a week by multiplying two perpendicular diameters. (2)tumor weight was determined immediately by electron balance after the animals were killed.

Apoptosis For detection of apoptotic cells, apoptotic indices were examined by the terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate fluorescence nick end labeling (TUNEL) method[16-18] and flow cytometry analysis. Morphological alterations were observed with electron microscope. (1)TUNEL: *In situ cell death detection Kit POD* (ISCDD, BOEHRINGER MANNHEIN) was used to detect the apoptotic cell. The procedures was according to protocol of the kit and the other references. The positive cells were identified, counted and analyzed under the light microscope. Non-necrotic zone was selected in the tissue section and images were sent to computer by AEC camera (Grundig Electronic Co. Ltd., Germany). 10 image at least 1000 cells were selected on the screen, positive ratio analyzed by KS400 Video Image Digital Analysis System (ZEISS, Germany). (2)Electron microscopy: Some of specimens in each group were fixed with 2.5 % glutaraldehyde. Semi-thin and ultra-thin sections were cut and viewed with scanning electron microscope. The characteristics of cell apoptosis showed nuclear chromatin condensation, peripheral masses of condensed chromatin with enclosed membrane or crescent. The nuclear membrane is complete. There is little or no swelling of mitochondria or other organelles. (3) Flow cytometry analysis: Propidium iodide (PI) staining[19-21] was used for flow cytometric detection of apoptosis. 10^6 cells from each of the sample were treated with RNase and stained with PI. The apoptotic cells having DNA strand breaks that had been labeled were measured on a flow cytometer (FACSCalibur, Becton Dickinson, USA). The data from 10^6 cells/sample were collected, stored, and analyzed using CELLQUEST (Becton Dickinson USA) and ModFIT LT for mac V1.01 software (Becton Dickinson, USA).

Cell proliferation The level of expression of Ki-67 was used as a marker of cell proliferation. In present study Ki-67 was measured by S-P immunohistochemical method.

Expression of bcl-2 and p53 mRNA The Expression of p53 (5-8 exons) and bcl-2 was semiquantitatively detected using RT-PCR technique[22-24]. A β-actin was used as an internal standard. Sequences of the primers used for RT-PCR analysis are described in Table 1. Total cellular RNA was isolated from tumor tissues using the acid-guanidium-phenol-chloroform technique. The RNA extracted from each sample was qualified by agarose gel electrophoresis and ethidium bromide staining and the amount of RNA was determined by electrophotometry *A*:260/280. The extracted RNA was converted to first strand cDNA with AMV reverse transcriptase (Promega). p53 and β-actin were amplified by polymerase chain reaction consisting of stage one: 2 minutes of denaturation at 94 ℃ before additon of Taq DNA polymerase; stage two: 1 minute of denaturation at 94 ℃, 1 minute of primer annealing at 56 ℃, and 1 minute of extension at 72 ℃ (Taq DNA polymerase, Shanghai Sangon Biology Engineering Technique Service Co. Ltd.). Gene expression of bcl-2 was also analyzed by RT-PCR, in the same manner except for annealing at 55 ℃. The cycler of PCR gene amplification is from Omn-E (Hybaid). Each reaction tube contained: 1.5 μl 25mM $MgCl_2$ +2.5 μl 10×PCR buffer +0.5 μl 10mM dNTP +1 μl×2 20 pmol/μl p53 or bcl-2 primers or β-actin primers (primer concentration: 0.8 μM) +2 μl cDNA +0.5 μl Taq (2.5-5U/μl) +16 μl ddH_2O. Quantitative analysis: After the amplification step was completed, equal amounts (5 μl) of PCR produces were loaded onto each lane of 1.7 % agarose gels and electrophoresed. FR-200UV/WHITE ANALYSIS (Shanghai Fu Ri Science & Technology Co. Ltd., China) took the image of electrophoresis with β-actin as internal standard, and FR-980 biological electrophoresis analysis system (Shanghai Fu Ri Science & Technology Co. Ltd., China) was used to analyze the quantity of nuclear acid.

Statistical analysis

The results were expressed as $\bar{x}\pm s$ and significant difference was assessed by Student' s *t* test.

RESULTS

Chinese Jianpi herbs-induced effects on tumor growth

Each one case that the xenograft emerged later was eliminated in Sijunzi decoction group and SRRS group. Compared with the control group, tumor growth (size and weight) was significantly inhibited by treatment with the Sijunzi decoction ($P<0.05$) or SRRS ($P<0.01$). The tumor inhibitory rate of the sijunzi decoction group was 34.33 % and that in the SRRS group was 46.53 % (Table 2).

Chinese Jianpi herbs-induced effects on tumor cell apoptosis

Apoptotic index (AI) of xenografts in nude mice was significantly increased to 16.24±3.21 % using TUNEL method and 11.38± 6.46 % FACScan in the Sijunzi decoction treatment group, compared with the controls (TUNEL: 2.63±1.03 %, $P<0.01$; FACScan: 7.15±1.32%, $P<0.05$). SRRS group was also found a significantly increased AI by using TUNEL method and flow cytometry analysis compared with the controls (TUNEL: 13.18±3.05 %, $P<0.05$; FACScan: 11.58±5.71%; $P<0.05$). But there was no significant difference between Sijunzi decoction group and SRRS group by using either TUNEL method or flow cytometry analysis. Under electron microscope cell shrinkage, nuclear chromatin condensation, formation of membrane blebs and apoptotic bodies were frequently observed in Sijunzi decoction group and SRRS group (Table 2).

Chinese Jianpi herbs-induced effects on tumor cell proliferation

The average labeling index for Ki-67 (LI) in SRRS treatment group (8.43±2.22 %) was significantly lower than that in the control group (10.37±4.91 %) ($P<0.01$). The average labeling index for Ki-67 in sijunzi decoction group was 7.95±2.54 % which was lower than that of the control group, but showed no significance as the P value was 0.07 (Table 2).

Chinese Jianpi herbs-induced genetic effects

Expression of p53 (exons 5-8) and bcl-2 was semiquantitatively detected with β-actin used as an internal standard. The expression level of p53 mRNAs was 0.36±0.27, significantly lower in Sijunzi decoction group than that in control group (0.69±0.20) ($P<0.05$), in SRRS group (0. 19±0.18) also significantly lower than that in control group ($P<0.01$). The expression of bcl-2 mRNA in SRRS group (0.33±0.23) was decreased, compared with the control (0. 81±0.40) ($P<0.01$). In Sijunzi decoction group the expression of bcl-2 (0.41±0.15) slightly decreased, compared with the control, but no statistics difference existed ($P=0.071$) (Table 3, Figure 1).

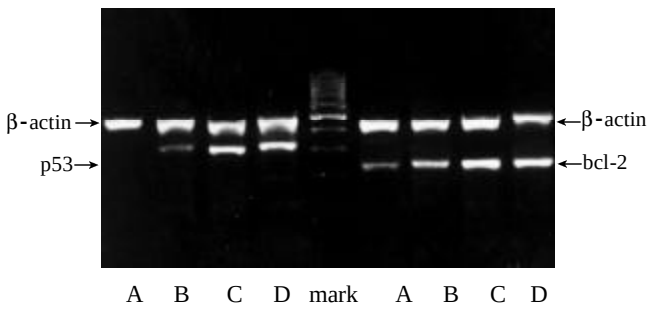

Figure 1 p53,bcl-2 mRNA expression in SGC-7901 grafted onto nude mice after treatment of Chinese Jianpi herbs by RT-PCR analysis. Lane A: SRRS group, Lane B: Sijunzi decoction group, Lane C: control group, Lane D: control group.

DISCUSSION

Despite its declining incidence, the gastric carcinoma remains one of the most common cause of cancer-related death in the world[25-27]. At present gastric carcinoma is still detected later in most patients throughout the world, and even with curative resection, they remain at a high risk of relapse. Thus, there is a great need for effective adjuvant therapy for patients with gastric carcinoma[28-30]. Our previous clinic paired comparative studies suggested that Chinese herbal recipe *SRRS* have therapeutic effects on advanced gastric cancer, with increasing the surviving period of the patients, improving the life quality, and decreasing the metastasis and recurrence rates after operation[12,14]. Because of its lower toxic side-effect compared with chemical therapy, it is worth to make a further research on its anti-cancer mechanism.

As the other malignant tumor, gastric carcinoma is not only a disease with abnormal cell proliferation and differentiation, but also a disease with abnormal apoptosis[5, 31-35]. The enhanced induction of apoptosis in human gastric carcinoma cells can be observed after treatment with 5-Fluorouracil[36],Cisplatin[37], arsenous oxide[38], etc. These data suggest that inducing cancer cell apoptosis may be a therapeutic method for gastric carcinoma. The present study indicated that tumor growth was significantly inhibited by treatment with the Sijunzi decoction or SRRS. TUNEL method and cytometry analysis clarified that Sijunzi decoction and SRRS enhanced apoptosis. The results suggest that the inhibition of gastric cancer cells *in vivo* by Jianpi herbs described here is related to inducing apoptosis. Immunohistochemical staining for Ki-67 showed that SRRS inhibited cell proliferation. So the inhibition of gastric cancer by SRRS is also related to suppressing the proliferation.

Apoptosis is a complex, tightly regulated, and active cellular process whereby individual cells are triggered to undergo self-destruction in a manner that will neither injure neighboring cells nor elicit any inflammatory reaction[1, 39-42]. Various triggering factor initiate corresponding proteo-lysis cascade reaction depending on mitochondrion or APO-1/FAS/ CD95 receptor mediate apoptotic pathways[40,43]. There are many oncogenes and tumor suppressor gene products in the regulation and execution of apoptosis. Among them are p53, Rb, myc, ras, raf, etc[23, 40, 41, 44, 45]. p53, because of its role in apoptosis , has earned the name "guardian of the genome". It monitors the state of DNA, and in case of DNA damage , stalls the cell cycle. This takes place through the induction of CIP/ WAF1/p21. In the absence of phosphorylated, active cyclin-dependent kinases, also another regulator of the cell cycle, Rb, remains inactive(unphosphorylated), and , hence, the cell cycle halts. This then leads to activation of DNA repair machinery. If the DNA repair fails, p53 takes over again and triggers apoptosis in a process that involves upregulation of the apoptosis-inducing bax and down-regulation of the apoptotic bcl-2[23]. p53 also upregulates KILLER/DR5, a 45-kd apoptosis-inducing member of the tumor necrosis factor receptor family. Analogous to the APO-1//FAS/CD95 receptor

system, its activation also lead to a caspase activation[37]. Thus p53 is known as one of the essential genes for cells to undergo apoptosis. In gastric cancer, mutant p53 expression decreased cancer cell apoptosis, p53 mutant provided selective growth superiority to the tumor cell. In our investigation we adopt the human gastric cancer cell line SGC-7901 which has point mutation in exon 6 codon 204 GAG→GCG coding Glu→Ala, which expresses mutant p53[46, 47]. RT-PCR detected p53 mRNA level was significantly lower in Sijunzi decoction group than that in control group. The expression level of p53 mRNA in SRRS group was also significantly lower than that in control group. The data suggest that these two recipes composed of Jianpi herbs induce SGC-7901 cancer cell apoptosis by down-regulation of mutant p53 mRNA expression.

We also detected apoptosis-inhibiting member of the bcl-2 family[41, 44]: bcl-2 mRNA. The expression of bcl-2 mRNA was decreased in SRRS group, compared with the control. In Sijunzi decoction group the expression of bcl-2 was slightly decreased compared with the control, but there was no statistics difference. It suggested that SRRS could suppress bcl-2 expression, but it was not stronger for than that of Sijunzi decoction. bcl-2 is the epitome of an antiapoptotic or survival gene. Attesting to its role in an apoptosis checkpoint, it counteracts apoptosis initiated by quite disparate signals, such as chemotherapeutic drugs, oxidative stress, viral infections, and p53. In gastric carcinoma, bcl-2 over-expressed at both protein and mRNA level in many cases[48].

In our study SRRS and Sijunzi decoction down-regulated the expression of p53 mRNA and SRRS also decrease the expression of bcl-2 mRNA in SGC-7901 cancer cell undergoing apoptosis. We inferred that p53 and bcl-2 may be involved in the regulation of these Chinese Jianpi herbs inducing gastric cancer cell SGC-7901 apoptosis. The interaction contact of p53 and bcl-2 in SRRS or Sijunzi decoction inducing apoptosis needs further investigation.

Abstract

AIM: To investigate the role of DNA-PKcs subunits in radiosensitization by hyperthermia on hepatocellular carcinoma HepG$_2$ cell lines.

METHODS: Hep G$_2$ cells were exposed to hyperthermia and irradiation. Hyperthermia was given at 45.5 ℃. Cell survival was determined by an *in vitro* clonogenic assay for the cells treated with or without hyperthermia at various time points. DNA DSB rejoining was measured using asymmetric field inversion gel electrophoresis (AFIGE). The DNA-PKcs activities were measured using DNA-PKcs enzyme assay system.

RESULTS: Hyperthermia can significantly enhance irradiation-killing cells. Thermal enhancement ratio as calculated at 10 % survival was 2.02. The difference in radiosensitivity between two treatment modes manifested as a difference in the α components and the almost same β components, which α value was considerably higher in the cells of combined radiation and hyperthermia as compared with irradiating cells (1.07 Gy^{-1} versus 0.44 Gy^{-1}). Survival fraction showed 1 logarithm increase after an 8-hour interval between heat and irradiation, whereas DNA-PKcs activity did not show any recovery. The cells were exposed to heat 5 minutes only, DNA-PKcs activity was inhibited at the nadir, even though the exposure time was lengthened. Whereas the ability of DNA DSB rejoining was inhibited with the increase of the length of hyperthermic time. The repair kinetics of DNA DSB rejoining after treatment with Wortmannin is different from the hyperthermic group due to the striking high slow rejoining component.

CONCLUSION: Determination with the cell extracts and the peptide phosphorylation assay, DNA-PKcs activity was inactivated by heat treatment at 45.5 ℃, and could not restore. Cell survival is not associated with the DNA-PKcs inactivity after heat. DNA-PKcs is not a unique factor affecting the DNA DSB repair. This suggests that DNA-PKcs do not play a crucial role in the enhancement of cellular radiosensitivity by hyperthermia.

INTRODUCTION

Hepatocellular carcinoma (HCC) remains one of the most difficult tumors to treat[1-15]. About 90 % of patients are unresectable at presentation because of tumor size, location, or underlying parechymal disease[16-20]. Those patients are sometimes recommended to receive non-surgical therapies, including radiotherapy[21-28], radiofrequency hyperthermia[29,30], or the hyperthermia as an adjuvant to radiation in the treatment of local and regional disease[31]. Thermoradiotherapy currently offers the most significant advantages in the treatment of certain types of cancer[32]. Numerous uncontrolled studies have been performed in which comparable lesions were treated with either radiation alone or combined with hyperthermia[33]. Although many of these studies are difficult to evaluate, they give strong evidence that adjuvant heat treatment increases the probability of complete response and, consequently, tumor control. The cause of this radiosensitization has not been firmly established, however, in part this sensitization is thought to be through inhibition of repair of radiation induced DNA damage[34-36]. The mode of this repair inhibition is still unclear. Protein denaturation and aggregation appear to be the most relevant process underlying the biological effects of hyperthermia.

Several studies have shown that hyperthermia could inhibit both recovery of radiation induced potentially lethal radiation damage (PLD) and sublethal damage (SLD)[37]. Such inhibition was dependent on the time, temperature, and sequence of hyperthermia treatment. It was shown that polymerase β may be one of the mechanisms involved in thermo-radiosensitization[38]. In addition, DNA-dependent protein kinase (DNA-PKcs) plays a central role in the repair of DSB[39]. DNA-PKcs is a complex consisting of three proteins: Ku70 and Ku80 and the catalytic subunit, DNA-PKcs[39]. The Ku70 and Ku80 proteins are involved in binding to the DNA ends at DSB and this binding activates the DNA-PKcs[39]. A possible mechanism for hyperthermic radiosensitization is mediated through the heat lability of Ku subunits of DNA-PKcs[40]. To support this mechanism, we have used Hep G$_2$ cells to study the relationship of DNA-PKcs activity in thermal radiosensitization and the kinetics of DNA DSB rejoining with the time after irradiation, addressing the main question that the role of DNA-PKcs subunits in thermal radiosensitization.

MATERIALS AND METHODS

Cell culture

$HepG_2$ cell line was obtained from the American Type Culture Collection (ATCC) and was grown in MEM medium supplemented with 100×10^3 U· L^{-1} penicillin, 100 mg· L^{-1} streptomycin, and 100 ml· L^{-1} fetal calf serum at 37 ℃ in a humidified incubator, at an atmosphere of 50 ml· L^{-1} CO_2 and 950 ml· L^{-1} air. Cells were maintained in a phase of nearly logarithmic growth by subculturing every 4 days at an initial concentration of 2×10^5 cells in T-25 tissue culture flasks for both clonogenic assay and DNA DSB rejoining studies, 2×10^6 cells in T-75 tissue culture flasks for determination of DNA-PKcs activity. The cells were passed several times through a 20-gauge needle in syringe to make the clamp cells single in each subculturing.

Hyperthermia treatment

Hyperthermia was carried out by sealing cell cultures grown in tissue culture flasks with parafilm and immersing the flasks into a temperature control waterbath (±0.05 ℃). The continuous heating experiments ranged from 5 to 30 minutes at an interval of 5 minutes. After heating at 45.5 ℃, flasks were put into ice for 10 minutes for the DNA DSB rejoining and DNA-PKcs activity studies, or a 37 ℃ waterbath for 5 minutes to equilibrate to 37 ℃ for clonogenic assay. At this point, if required, the flasks were irradiated on the ice.

Radiation treatment

Cells in flasks were irradiated using a Pantak X-ray machine operated at 320 kV, 10 mA with a 2 mm Al filter (effective photon energy about 90 kV), at a dose rate of 2.7 Gy· Min^{-1}. Dosimetry was performed with a Victoreen dosimeter which was used to calibrate an in-field ionization monitor.

Clonogenic survival

Cells were trypsinized at 37 ℃ for 10 minutes, and pipetted 7 times to keep the clamp cells to be single cell suspension using 20-gauge needle and 5 ml syringe in 5 ml medium. The single cell suspension was adjusted and seeded into 60-mm tissue culture dishes at various densities aiming at 20-200 colonies per dish. Cells were irradiated at room temperature in 5 mL medium and were immediately kept at 37 ℃, 50 ml· L^{-1} CO_2 incubator for 13 days. Cells were stained with crystal violet and colonies of more than 50 cells were counted. The radiation results presented for heat plus X-rays were corrected for the cell killing caused by heat alone.

Induction and repair of DNA DSB

Cells for DNA DSB repair experiments were labeled with 3.7MBq· L^{-1} ^{14}C-thymidine plus 2.5 μmol· L^{-1} cold thymidine for the entire period of growth. The cells were used 3 days later as the concentration reached 1×10^6 cells/T-25 flask. When indicated by the experimental protocol, cells were treated with 20 μmol· L^{-1} Wortmannin for 1 hour or hyperthermia at 45.5 ℃ for various times before irradiation. Cells were cooled to 4 ℃ prior to irradiation and were irradiated on ice. After irradiation, the medium was replaced with fresh growth medium pre-warm at 42 ℃ to rapidly restore to 37 ℃, and then cells were quickly returned to the incubator at 37 ℃ to allow for repair. Cells were prepared for DNA DSB analysis at various time intervals thereafter.

After completion of the repair time interval, cells were trypsinized for 90 minutes in ice for the first 4 hours, and 10 minutes at 37 ℃ at later points. The cells were collected with 5 ml cold medium, centrifuged at 4 ℃, and washed with 5 ml cold serum-free medium. The cells were resuspended in 165 μl cold serum-free medium. This cell suspension was mixed with an equal volume of 10 g· L^{-1} agarose(InCert agarose, FMC) to reach a concentration of 3×10^9 cells· L^{-1}. The cell-agarose suspension was then pipetted into a 3 mm diameter glass tubes and placed into ice to allow for solidification. The solidified cell-agarose suspension was extruded from the glass tubes and cut into 3×5 mm cylindrical blocks containing approximately 1.5×10^5 cells/block[41]. Blocks were then placed in lysis buffer containing 10 mmol· L^{-1} Tris, pH 8.0, 50 mmol· L^{-1} NaCl, 0.5 mol· L^{-1} EDTA, 2 g· L^{-1} N-Lauryl Sarcosyl (NLS), A0.1 g· L^{-1} proteinase E & O, and incubated first at 4 ℃ for 45 minutes and then at 50 ℃ for 16-18 hours. Following lysis, agarose blocks were washed for 1 hour at 37 ℃ in a buffer containing 10 mmol· L^{-1} Tris, pH 8.0 and 0.1 mol· L^{-1} EDTA, and were then treated for 1 hour at 37 ℃ in the same buffer, at pH 7.5, with 0.1 g· L^{-1} RNAase A. Cells from identically treated non-irradiated cultures were also processed at pre-defined times to determine the signal generated by non-irradiated cells as background. For dose response, a similar protocol was also employed to determine the induction of DNA DSB except that in this case cells were embedded in agarose prior to irradiation with various doses on the ice, and were lysed immediately thereafter.

Pulsed-field gel electrophoresis

Asymmetric field inversion gel electrophoresis (AFIGE) was carried out in 5 g· L^{-1} Seakem agarose (FMC), cast in the presence of 0.5 mg· L^{-1} ethidium bromide, in 0.5×TBE (45 mmol· L^{-1} Tris, pH 8.2, 45 mmol· L^{-1} Boric Acid, 1 mmol· L^{-1} EDTA) at 10 ℃ for 40 hours. During this time, cycles of 1.25 V· cm^{-1} for 900 seconds in the direction of DNA migration alternated with cycles of 5.0 V· cm^{-1} for 75 seconds in the reverse direction. The agarose gels were quantified to estimate DNA damage by means of a PhosphorImager (Molecular Dynamics). Gels were dried and exposed to radiation-sensitive screens for 48-96 hours. DNA DSB was quantitated by calculating the fraction of activity released (FAR) from the well into the lane in irradiated and non-irradiated samples. The FAR measured in non-irradiated cells (background) was subtracted from the results shown with irradiated cells. Gel images were obtained either by photographing ethidium bromide-stained gels under UV light, or from the PhosphorImager.

Repair kinetics were fitted assuming two exponential components of rejoining according to the equation $FAR=Ae^{-bt}+Ce^{-dt}$[42]. The first term in the equation was fitted to the slow and the second to the fast component of rejoining. Fitting was achieved using the non-linear regression analysis routines of a commercially available software package (SAS). Parameters A and C describe the amplitudes, and parameter b and d and the rate constants of the slow and the fast components of rejoining, respectively. From these parameters the half-time for the rejoining of the slow and the fast components were calculated as $t_{50,fast}=ln2/b$, and $t_{50,slow}=ln2/d$, respectively. The fraction of DSB rejoined by fast kinetics was calculated as $F_{fast}=A/A+C$ and $F_{slow}=C/A+C$.

Determination of DNA-PKcs activity

Cell extract preparation: Cells (2×10^6) were grown in the T-75 tissue culture flask for 5 days. After treatment, about 30×10^6 cells were collected in cold PBS after being trypsinized at 37 ℃ for 10 minutes, centrifuged at 4 ℃, and resuspended with 1 mL cold PBS and transferred to Eppendorf tube. After spun 1 500 r· min^{-1} for 5 minutes at 4 ℃, PBS was replaced with 0.5 ml (about 4 volumes of cells) hypotonic buffer containing 10 mmol· L^{-1} HEPES KOH pH 7.9 at 4 ℃, 5 mmol· L^{-1}

KCl, 1.5 mmol· L^{-1} $MgCl_2$, 20 mmol· L^{-1} b-Glu, 0.2 mmol· L^{-1} phenylmethylsulfonyl fluoride (PMSF), 0.5 mmol· L^{-1} dithiothreitol (DTT). The cells were put on ice for 10 minutes, frozen in liquid nitrogen and thawed for 3 cycles, adjusted salt being 50 mmol· L^{-1} KCl in hypotonic buffer (16 μl, 1.6 mol· L^{-1} KCl), and allowed to stay for 10 minutes on ice. After centrifugation (40 minutes at 14 000 r· min^{-1} at 4 ℃), cytoplasm extract was obtained from the collection of supernatants. Nuclei were resuspended with 50 mmol· L^{-1} KCl hypotonic buffer (100 ml), the salt was adjusted to 400 mmol· L^{-1} KCl with 3 mol· L^{-1} KCl in the buffer (13 μl), mixed in the cold room (4 ℃) for 30 minutes. After centrifuged at 14 000 r· min^{-1} for 15 minutes at 4 ℃, nucleic extract was obtained from the collection of supernatants. Protein concentration of both cytoplasm and nucleic extracts were determined using Bio-Rad protein II assay.

Activity assay of DNA-PKcs: In 1.5 ml microfuge tube, the reaction buffer was set up on ice in a mixture containing 4 μl 5X kinase buffer (250 mmol· L^{-1} HEPES, pH 7.5, 50 mmol· L^{-1} $MgCl_2$, 1 mmol· L^{-1} EGTA, 5 mmol· L^{-1} DTT), 2 μl 10X substrate peptide (2 mmol· L^{-1}), 2 μl 10X sonacated calf thymus DNA (100 mg· L^{-1}), 2 μl(7.4 MBq · L^{-1}) of (γ-^{32}P) ATP. In this reaction buffer mixture, an equal volume (5 μg in 10 μl) of nucleic extract was added and mixed quickly. The optimal incorporation time was found to be 15 minutes at 30 ℃. After incubation, the reaction was terminated with 20 μl stop solution (300 g· L^{-1} acetic acid, 1 mmol· L^{-1} ATP). Out of 40 μml reaction mixture, 20 μl was spotted on Watermann P81 phosphocellulose paper, and washed 4 times with 150 g· L^{-1} acetic acid for 15 minutes each time. The filters were placed in scintillation vials, and the adsorbed radioactivity was quantitated. To calculate the specific activity of (γ-^{32}P) ATP, we removed 5 μl from any two reaction tubes, and added to scintillation vial to count. Calculation of the specific activity of (γ-^{32}P) ATP in cpm/pmol is shown as follows (40/5)×X/10 000=X/1 250 [40 is the sum of the reaction volume (20 μL) + stop buffer (20 μl), 5 is the volume (μl) used for the specific activity of (γ-^{32}P) ATP, X is the average counts, and 10 000 is the number of pmoles of ATP in the reaction]. Calculation of incorporated ATP (pmol) is ($CPM_{\text{reaction with DNA}}$-$CPM_{\text{reaction without DNA}}$) / The specific activity of [γ-^{32}P] ATP in 10^{12}cpm· mol^{-1}.

RESULTS

The survival curves of $HepG_2$ cell exposure to X-ray combined with or without hyperthermia are shown in Figure1A and B. The mean dose of survival fraction at 2 Gy (SF_2) was 0.230±0.033 for the group of radiation alone, and 0.148±0.043 for the radiation combined with hyperthermia group. The linear-quadratic model $S=e^{-\alpha D-\beta D2}$ was applied to describe the survival data in Figure 1, where S is the fraction of cells surviving a dose D, and α and β are constants. The α and β values are 0.805±0.037 Gy^{-1} and 0.072 ± 0.012 Gy^{-2} for the group of radiation alone, and 0.950 ± 0.018 Gy^{-1} and 0.010 ± 0.001 Gy^{-2} for the group of radiation combined with hyperthermia. The α/β ratios are 11.2 Gy and 97 Gy for the groups of radiation alone and combination modes, respectively. Thermal enhancement ratio as calculated at 10 % survival (TER_{10}) was 2.02. The difference in radiosensitivity between these two groups can be interpreted as being due to some phenomena, which manifest as a difference in the a components.

Figure 1B shows the survival curves for cells exposed for various periods of time to 45.5 ℃. The combination of hyperthermia with 3 Gy X-ray significantly improved the killing effects in comparison of hyperthermia alone. Figure 1C shows a combination of hyperthermia at 45.5 ℃ for 15 minutes first and then 3 Gy of X-rays. When the time intervals between hyperthermia and radiation in existence, the cell survival increased with the time interval increase within 8 hours, but no significant change was observed 8 hours later.

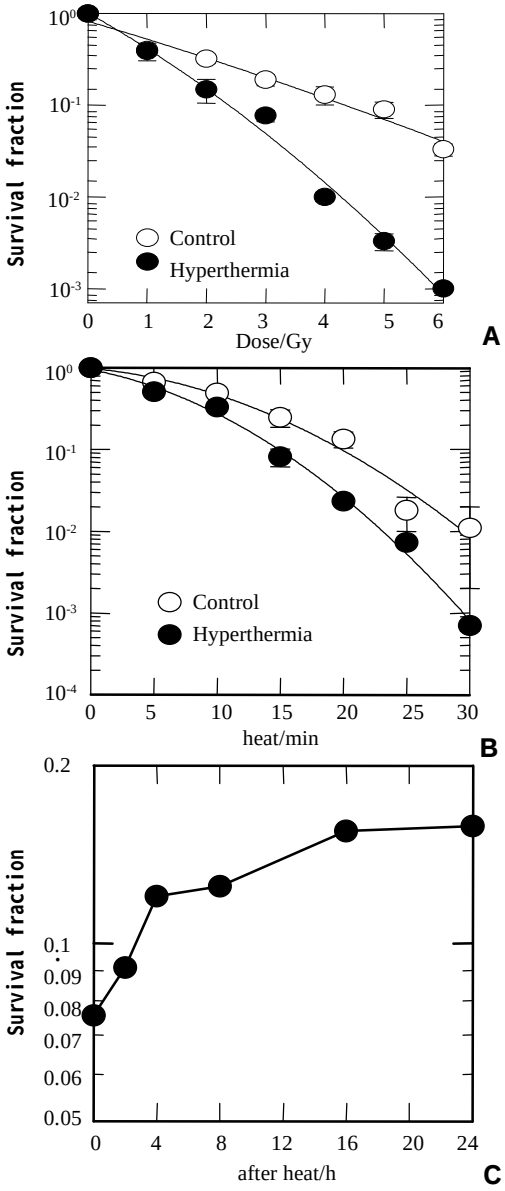

Figure 1 Survival fraction of $HepG_2$. A: Exposure to X-rays combined with (close circles) or without (open circles) 45.5 ℃ for 15 minutes; B: Heat-induced clonogenic cell death as a function of time combined with (close circles) or without (open circles) 3 Gy of X-rays; C: Irradiated with 3 Gy of X-rays at different hours after heat of 15 minutes at 45.5 ℃.

The DNA-PKcs activity was measured before and after irradiation with 40 Gy X-ray, or hyperthermia for 20 minutes at 45.5 ℃, or both. All of DNA-PKcs values were expressed with both relative percentage at left side and pmol at right of figures in this paper. Figure 2A shows that DNA-PKcs activity was inhibited by about 70 % at heating. Radiation stimulated DNA-PKcs activity increased about 30 % in the cells treated with or without hyperthermia at the 2nd hour. In order to determine whether the level of DNA-PKcs activity recovers its activity after hyperthermia, the time point was extended to 24 hours to correspond to clonogenic survival in Figure 1C.

As shown in Figure 2B, no restore was found in DNA-PKcs activity up to 24 hours. The DNA-PKcs activity was inhibited after the cells exposed to heat at 45.5 ℃ for 5 minutes (Figure 2C). The DNA-PKcs activity remained at almost the same level despite the hyperthermic time extending.

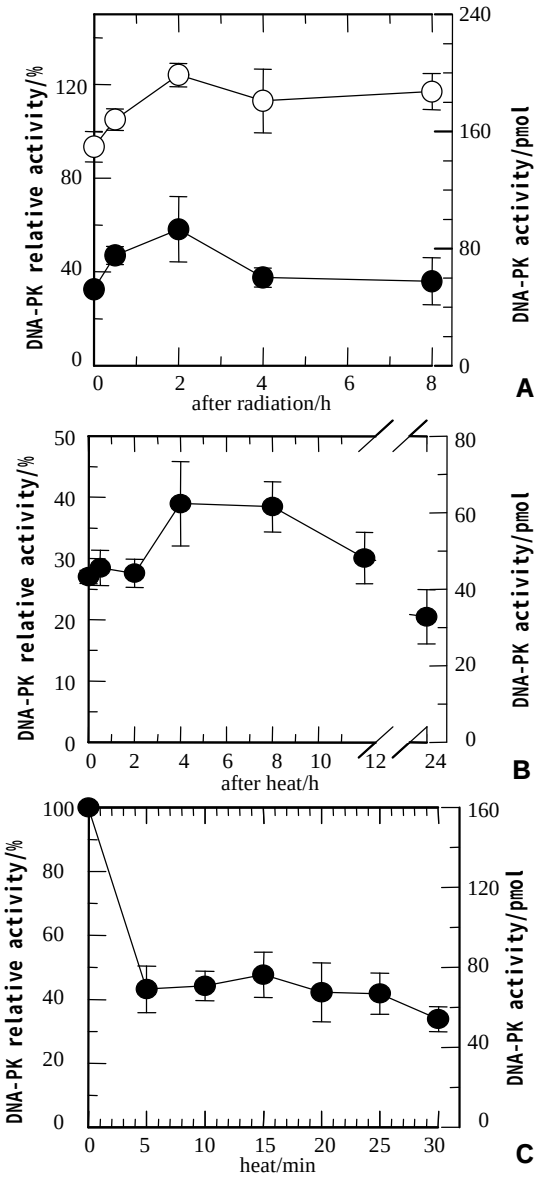

Figure 2 DNA-PKcs activity of HepG2 cells. A: Cells were heated at 45.5 ℃ for 20 minutes and then received 40 Gy of X-rays (closed circles) or irradiated with 40 Gy of X-rays only (open circles). At various periods, DNA-PKcs activity in heated cells was inhibited, and kept at low level about 30 %. The DNA-PKcs activity in both groups showed slight increase; B: After heated at 45.5 ℃ for 20 minutes, DNA-PKcs activity was still inhibited at various periods; C: DNA-PKcs activity was inhibited after exposure to heat at 45.5 ℃ for 5 minutes, even though the heat time was prolonged, DNA-PKcs activity levels still remained unchanged.

To understand the role of DNA-PKcs subunits in radiosensitization by hyperthermia, induction of X-ray induced DNA DSB was measured by AFIGE. Figure 3 shows the dose response curves for Hep G_2 cells receiving radiation combined with or without hyperthermia. The upper panel shows a typical gel scanned with ^{14}C-TdR, while the lower panel shows the quantitative data as described in the Methods. The FAR, a measure of DNA DSB presence, increased almost linearly with dose up to 30 Gy but bended downward at higher doses. Similar increases in FAR as a function of dose were observed in radiation alone or combined with hyperthermia, suggesting similar yields of DNA DSB.

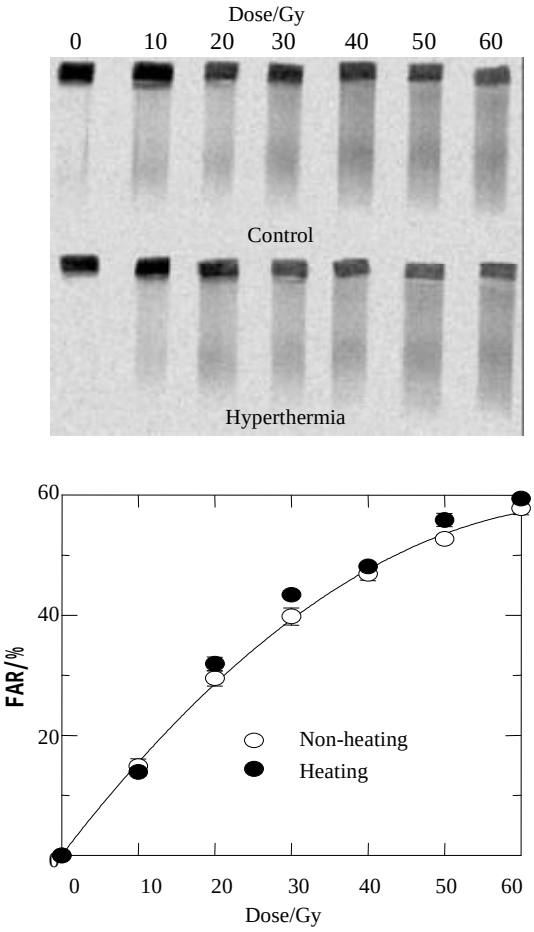

Figure 3 Dose response curves for Hep G2 cells received radiation combined with or without hyperthermia. The upper panel shows a typical gel scanned with ^{14}C-TdR, while the lower panel shows quantitative data as described in the Methods. The FAR increases almost linearly with dose up to 30 Gy but bends downward at higher doses. Similar increases in FAR as a function of dose are observed in radiation alone or combined with hyperthermia, suggesting similar yields of DNA DSBs.

The rate of rejoining of radiation-induced DNA DSB was subsequently examined to determine whether differences in repair between radiation alone and combined with hyperthermia for different periods of time account for the results shown in Figure 2A that the DNA-PKcs activity was inhibited after heat. Figure 4 shows that DNA DSB repairs kinetics in Hep G_2 cells. Cells were irradiated with 40 Gy and prepared for AFIGE after various periods of incubation at 37 ℃ to allow for repair. The upper panel in the Figure shows a typical AFIGE gel, while the lower panel shows its quantification as described in the Methods. The rejoining of DNA DSB decreased with increasing the lengths of hyperthermic time at 45.5 ℃. Table 1 shows that the half-time for rejoining of the fast components was shorter in the control group or exposure to heat for 5 minutes than the exposure to longer time (15 and 20 minutes). However, the half-time of slow components in both control and hyperthermic groups were almost the same which ranged between 7 and 9 hours.

Wortmannin inhibits the entire family of PI-3 kinases and probably also other cellular kinases. To evaluate the

contribution of DNA-PKcs to Wortmannin-induced inhibition of DNA DSB rejoining, we searched for Wortmannin treatment, which is able to compare heat-induced inhibition of DNA DSB rejoining. Figure 5 indicates the kinetics of DNA DSB rejoining after treatment with Wortmannin. We found that the slow rejoining component is strikingly high. The deficiency of DNA DSB rejoining was found in Wortmannin treatment cells after 2 hours. These results are different from those in hyperthermic groups.

Table 1 The half-time and fraction of DNA DSB rejoined by fast and slow kinetics

	$T_{50,fast}$	$T_{50,slow}$	F_{fast}	F_{slow}
Control	0.49	7.07	0.80	0.20
5 min	0.33	4.15	0.44	0.56
15 min	0.92	9.37	0.49	0.51
20 min	1.25	9.24	0.30	0.70
20 mmol·L^{-1} Wort.	0.87	7×10^{8}	0.44	0.56

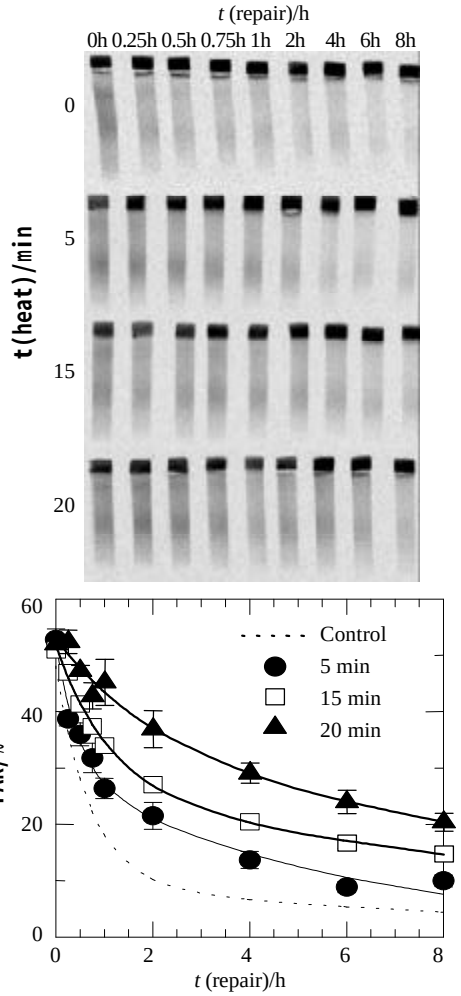

Figure 4 DNA DSBs repair kinetics in Hep G2 cells. Cells were irradiated with 40 Gy and prepared for AFIGE after various periods of incubation at 37 ℃ to allow for repair. The upper panel in the Figure shows a typical AFIGE gel, while the lower panel shows its quantification as described in the materials and Methods. The rejoining of DNA DSBs was decreasing with the increase of the lengths of hyperthermic time at 45.5 ℃.

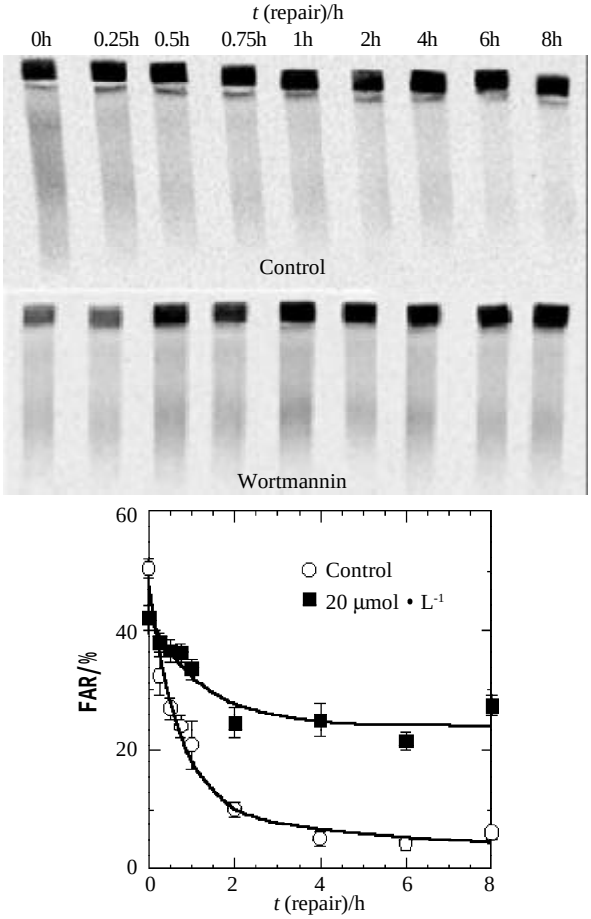

Figure 5 The kinetics of DNA DSBs rejoining after treatment with Wortmannin. The slow rejoining component is strikingly high. The deficiency of DNA DSBs rejoining was found in Wortmannin treatment cells after 2 hours.

DISCUSSION

Tumors of liver are among the most common malignancies in the world. Primary hepatocellular carcinoma was the second most common cancer and the leading cause of cancer deaths behind gastric cancer in China. Surgical resection has been accepted as the only curative therapy for primary liver cancer. Unfortunately, most patients were surgically unresectable[1-28]. Hyperthermia[29,30], radiation therapy[21-28], or combination of both[31,32] were introduced as an alternative therapeutic approach. The cause of this radiosensitization has not been firmly established.

The inhibition of DNA-PKcs by hyperthermia has been demonstrated in several studies[40, 43,44]. In our series, DNA-PKcs activity was inhibited by about 60 % after hyperthermia at 45.5 ℃ for 5 minutes, and no significant change was found after increasing hyperthermia time. This result is similar to other reports[40, 43]. Interestingly, the rejoining of DNA DSB was decreasing with the increase of the hyperthermic time at 45.5 ℃. The decrease of DNA DSB repair did not correspond proportionally to the heat inhibited DNA-PKcs activity which was kept at a same low activity level between 5 and 30 minutes. This means DNA-PKcs is not critical for DNA DSB repair in heat.

The activity of DNA-PKcs depends upon the presence of double-stranded DNA ends, and is based on the similarity of their DNA-binding properties, and Ku was identified as the DNA-targeting component of this protein complex[45-51]. This can be used to explain the fact that DNA-PKcs activity increased by about 30 % at the 2nd hour after 40 Gy X-ray irradiation, which produced plenty of DNA DSB. After

hyperthermia at 45.5 ℃ for 15 minutes, DNA-PKcs activity was stable at a low level (30 %) up to 24 hours. We are eager to know whether the low level DNA-PKcs affects the clonogenic survival. The results showed that the effects of thermal radiosensitization were lowered, even though DNA-PKcs activity did not restore. This indicated that there was no correlation between thermal inactivation of DNA-PKcs and radiosensitization by heat.

Wortmannin is a fungal metabolite originally characterized as an irreversible inhibitor of PI3K-like family including DNA-PKcs[52]. The inhibition of DNA-PKcs by Wortmannin could increase the slow rejoining component, resulting in deficiency of DNA DSB repair. The kinetics of DNA DSB rejoining in hyperthermia groups different from that treated with wortmannin, inhibited the DNA-PKcs activity. This confirms that DNA DSB repair is not completely affected by DNA-PKcs, other factors might also involve in the repair.

DNA-PKcs is not critical for radiosensitization by heat. What might explain the synergistic interaction between heat and radiation? One possibility is that homologous recombination may impair after heat shock, but the contribution of this repair pathway in mammalian cells seems limited[53]. Another possibility is that heat-induced loss of activity of DNA repair enzymes other than DNA-PKcs has been observed and proposed previously as the mechanism that underlies DNA repair inhibition and radiosensitization. These enzymes include DNA polymerases[37], ATM system[54], ATR system[38], etc. Motsumoto found recently that heating up to 90 minutes affected only marginally DNA-PKcs activity in four different human cell lines (results not published). The contradictory results are due to the methods of measurement, which can not distinguish between inhibition of ATM and DNA-PKcs as the substrate, and peptide is good for both kinases.

In clonogenic assay, the difference in radiosensitivity between radiation and thermal radiation groups manifested as α difference in the a components. The dose range over which the linear component dominates in a linear-quadratic (LQ) survival relationship depends on the relative values of α and β: the higher the relative value of α, the more linear response at low doses and the less sensitive it is to dose fraction[55]. In hyperthermia group, the α/β ratio is high, with no detectable influence of the quadratic function over the first two decades of reduction in cell survival, implying that accumulation of sublethal injury plays a negligible role in cell killing by thermal radiosensitization clinically[56]. From these results, we can deduce that heat inhibits the repair of radiation-induced single-strand breaks and radiation-induced chromosome aberrations. This inability to repair molecular damage translates into the inability to repair both sublethal damage and potentially lethal damage produced by radiation.

In conclusion, when the DNA-PKcs activity was determinated using the cell extracts and the peptide phosphorylation assay, DNA-PKcs activity was inactivated by heat treatment at 45.5 ℃, and could not restore. Cell survival is not associated with the DNA-PKcs inactivity after heat. DNA-PKcs is not a unique factor affecting DNA DSB repair. This suggests DNA-PKcs does not play a crucial role in the enhancement of cellular radiosensitivity by hyperthermia.

Abstract

AIM: Hepatocellular carcinoma(HCC) is a significant health problem in China. But the molecular mechanisms of HCC remains unclear. APC/β-Catenin/Tcf signaling pathway, also known as Wnt pathway, plays a critical role in the development and oncogenesis. As little is known about the alteration of human T-cell transcription factor-4 (hTcf-4) gene in HCC, it is of interest to study the expression and mutation of hTcf-4 gene in HCC and the relationship between hTcf-4 gene and progression of HCC.

METHODS: Reverse transcription-polymerase chain reaction (RT-PCR) method was used to detect the expression of hTcf-4 mRNA in 32 HCC and para-cancerous tissues and 5 normal liver tissues. PCR-single strand conformation polymorphism (PCR-SSCP) method was used to detect the mutation of hTcf-4 exons 1, 4, 9 and 15 in HCC. The correlation of expression and mutation of the hTcf-4 gene with clinicopathological characteristics of HCC was also analyzed.

RESULTS: RT-PCR showed that the expression rate of hTcf-4 mRNA in HCC, para-cancerous tissues and normal liver tissues was 90.6 %, 71.9 % and 80 %, respectively. The gene expression level in tumor was 0.71±0.13, much higher than that in para-cancerous liver 0.29±0.05 and normal liver 0.26±0.05 ($P<0.001$), although there was no significant difference in gene expression level between para-cancerous tissues and normal liver ($P>0.05$). Furthermore, hTcf-4 gene expression was closely associated with tumor capsule status and intrahepatic metastasis of HCC. On SSCP, 2 of 32 cases of HCC (6.25 %) displayed characteristic mutational mobility shifts in exon 15 of the hTcf-4 gene. No abnormal shifting bands were observed in para-cancerous tissues.

CONCLUSION: The high expression level of hTcf-4 in HCC, especially in tumors with metastasis, suggests that the over-expression of hTcf-4 gene may be closely associated with development and progression of HCC, but the mutation of this gene seemed to play less important role in this respect.

INTRODUCTION

Recent work has shown that APC/β-Catenin/Tcf pathway, also known as Wnt signaling pathway, plays a key role in regulation of development and growth of the cells[1-3]. The alteration of APC/β-Catenin/Tcf pathway leading to cancer has been described. In differentiated cells, the cytoplasmic level of β-catenin is maintained very low through degradation by the ubiquitin-proteasome pathway, whereby serine and threonine residues in exon 3 are phosphorylated by GSK3β[4-6] and ubiquitinylated by binding to proteins such as APC, axin and conductin[7-11]. In experiments with colorectal cancer and melanoma cell lines, dysfunction of APC resulted in stabilization of β-catenin and binding of excess β-catenin to Tcf/Lef to activate transcription in the nucleus[12-16]. Furthermore, in cell lines having no APC mutations, mutations of the β-catenin gene that altered amino acid residues representing potential GSK3β phosphorylation sites could confer resistance to degradation and lead to intracellular accumulation of β-catenin[12,17,18]. Activated cytoplasmic β-catenin, probably bound to Tcf/Lef, is thought to migrate into the nucleus and stimulate transcription of downstream genes in a constitutive manner[12,13]. However, recent studies focused mainly on the relationship between cancers and mutations of APC and β-catenin gene, and little is known about the change of human T-cell transcription factor-4 (hTcf-4) gene in tumors, especially about its expression and mutation in hepatocellular carcinoma (HCC). To further understanding the role of the APC/β-Catenin/Tcf pathway in HCC, the present study examined expression and mutation of the hTcf-4 gene in HCC by reverse transcription-polymerase chain reaction (RT-PCR) and PCR-single strand conformation polymorphism (PCR-SSCP).

MATERIALS AND METHODS

Patients

Thirty-two fresh HCC specimens and the para-cancerous tissues and 5 normal liver tissues were analyzed. All specimens were obtained from patients who underwent surgery for HCC or hemangioma between 1999 and 2000 at Liver Cancer Institute, Fudan University, and stored frozen at -70 ℃ until use. The diagnosis was confirmed by pathological examination. The patients with HCC consisted of 12 women and 20 men with the mean age of 56 years and range from 16 to 75 years. Of the 32 patients, 16 showed abnormal serum concentration of alpha-fetoprotein (AFP) (>20 μg/L), 18 had macronodular cirrhosis (cirrhotic nodules measuried at least 0.3 cm in greatest dimension) and 14 had micronodular cirrhosis (cirrhotic nodules measured <0.3 cm). HCC was large in 17 patients (>5 cm in greatest dimension) and small in 15 patients (≤5 cm). Macroscopically poorly encapsulated tumors were found in 18 patients (56 %) and cancerous thrombi in portal vein or intrahepatic metastasis were found in 15 patients (47 %).

RNA Extraction and RT-PCR

Total RNA was isolated from tissues using Trizol Reagent (Life

Technologies, Inc.) according to the manufacturer' s protocol. A 3-μg aliquot of total RNA from each specimens was reverse-transcribed into single-strand cDNA using oligo $(dT)_{15}$ primer and Superscript II (Life Technologies, Inc.). Each single-strand cDNA was diluted for subsequent PCR amplification of hTcf-4 and β-actin with the latter used as an internal quantitative control. The PCR was carried out in a reaction volume of 25 μl for 5 min at 95 °C for initial denaturing, followed by 25 (for β-actin) or 30 (for hTcf-4) cycles of 94 °C for 40 s, 60 °C for 40 s, and 72 °C for 40 s on the Gene Amp PCR system 9 600 (Perkin-Elmer Corp.). The primer sequences used for amplification were 5'-CTTCCTTCCTGGGCATGGAG-3' and 5'-TGGAGGGGCCGGA CTCGTCA-3' for β-actin and 5'-TGTACCCAATCACGACAGGA-3' and 5'-GCCAGCT CGTAGTATTTCGC -3' for hTcf-4. PCR products were resolved in 2 % agarose gels and visualized by staining with ethidium bromide. To quantify PCR products, the bands representing amplified products were analyzed by Pharmacia Biotect Image MASTER VDS.

PCR-SSCP-silver staining

DNA was isolated from tissues using a DNA extraction kit (BBST Corporation) according to the manufacturer' s protocol. The primers of PCR amplification of exons 1, 4, 9 and 15 of hTcf-4 were as follows: 5'-AATTGCTGCTGGTGGGTGA-3' and 5'-CCCGAGGGGCTTTT CCTA-3' for exon 1 (234bp); 5'-GAACGCTTTGATTTGGTTTC-3' and 5'-GCTTCAGAATCTCTTGCGT-3' for exon 4 (124bp); 5'-GATTCTGACGATTTACACAG-3' and 5'-GCTACGAAGAAGGTGAGAA-3' for exon 9 (196bp) and 5'-CGACCCACCATTGTGTTGTA-3' and 5'-AAAGGCCTCGCAGTGGTAAT-3' for exon 15 (144bp). The PCR reaction was performed by denaturation at 94 °C for 40s, annealing at 60 °C for 40s and extension at 72 °C for 40s for 30 cycles using 2.5 units of Taq DNA polymerase (BBST Corporation) per 25 μl reaction volume. The PCR products were detected on 2 % agarose gels. SSCP analysis was performed as follows: 15 μl of PCR sample plus 20 μl of formamide loading dye (95 % formamide, 0.05 % bromphenol blue, 10 mmol/L EDTA) were boiled for 10 min, snap-frozen on ice and electrophoresed on a 12 % non-denaturing polyacrylamide gel at 300 V for 5 min, then 120 V for 3-4 h, depending on the size of PCR fragment. Silver Staining for SSCP consisted of fixation in 10 % alcohol for 5 min, sensitizing in 1 % HNO_3 for 5 min, washing twice with distilled water for 2 min, silver reaction (silver nitrate 0.25 g, formaldehyde 50 μl, topped up with distilled water to 100 ml) for 10 min, washing with distilled water for 10s, developing (anhydrous sodium carbonate 6.0 g, formaldehyde 200 μl, 10 % sodium thiosulfate 20 μl, topped up with distilled water to 200 ml) for 10 min, stopping in 10 % glacial acetic acid for 10 min and anhydration in absolute alcohol for 2 min.

Statistical analysis

The statistical differences between different groups were analyzed by Student t-test or One-Way ANOVA. A value of P <0.05 was considered significant. All data were disposed by SPSS9.0 statistical software.

RESULTS

Expression of hTcf-4 mRNA in HCC specimens, para-cancerous tissues and normal liver tissues

2 % Agarose gel electrophoresis showed a 406bp hTcf-4 fragment by RT-PCR amplification from normal liver tissues, para-cancerous tissues and HCC tissues. The hTcf-4 mRNA amplification was successful in 29 of 32 HCC tissues (90.6 %), 23 of 32 para-cancerous liver tissues (71.9 %) and 4 of 5 normal liver tissues (80 %). The expression level was 0.71±0.13 in tumor, much higher than that in para-cancerous liver (0.29±0.05, P<0.001) and normal liver (0.26±0.05, P<0.001) (Figure1). However, there was no significant difference in hTcf-4 expression level between para-cancerous tissues and normal liver tissues (P>0.05).

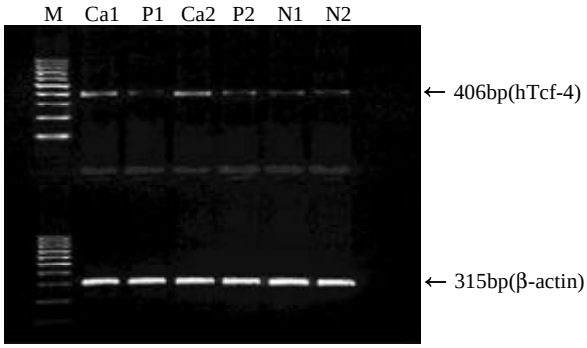

Figure1 Expression of hTcf-4 and ß-actin mRNA in HCC (Ca), para-cancerous tissue (P) and normal liver (N). Semiquantitative RT-PCR analysis revealed that the expression level of hTcf-4 gene in HCC was much higher than that in para-cancerous tissues and normal livers. M: 100bp DNA Ladder

The relationship between hTcf-4 mRNA expression and clinicopathological features of the patients

Statistical analysis showed that the expression level of hTcf-4 mRNA in poorly encapsulated tumors and in tumors with intrahepatic metastasis was much higher than that in well encapsulated tumors and in tumors without metastasis (P<0.05). However, no significant difference in hTcf-4 mRNA level was observed with variants of serum AFP levels, liver cirrhosis degree and tumor size (Table 1).

Table1 The relationship between hTcf-4 mRNA expression and clinicopathological features of the patients

	n	hTcf-4/β-actin	*P*
AFP			
≤20μg/L	16	0.71±0.14	>0.05
>20 μg/L	16	0.67±0.12	
Cirrhotic nodules			
<0.3cm	14	0.75±0.11	>0.05
≥0.3cm	18	0.67±0.14	
Tumor size			
≤5cm	15	0.66±0.13	>0.05
>5cm	17	0.76±0.12	
Capsule			
well capsule	14	0.61±0.10	<0.05

Metastasis			
Yes	15	0.78±0.12	<0.05
No	17	0.66±0.12	

N: number; Yes: tumors with cancerous thrombi in portal vein or intrahepatic metastasis; No: tumors without cancerous thrombi in portal vein and intrahepatic metastasis.

Detection of mutation by PCR-SSCP-silver staining

Abnormal SSCP migration bands were detected in exon 15 of the hTcf-4 gene from 2 of 32 tumor tissues (6.25 %), compared with the mobility pattern of the para-cancerous liver, demonstrating that there existed mutation in the exon 15. Among these two cases, one was complicated by portal vein thrombosis and the other had tumor without metastasis. The mobility pattern of PCR products from exons 1, 4, and 9 of the hTcf-4 gene was not altered (Figure 2).

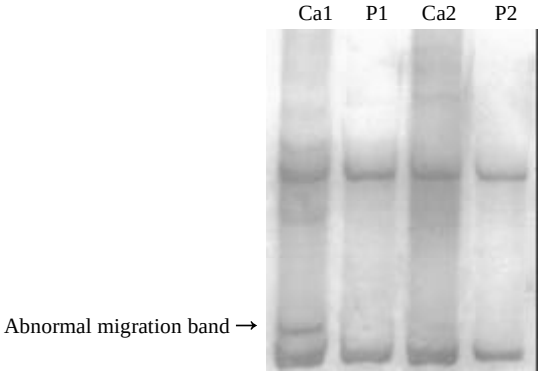

Figure 2 SSCP analysis of hTcf-4 exon 15 in HCC (Ca) and para-cancerous liver (P). Lane 1, abnormal SSCP pattern detected in exon 15 of patient 1, compared with the pattern of exon 15 from the corresponding para-cancerous liver in lane 2. Lane 3, normal SSCP pattern of exon 15 from patient 2, compared with the pattern of exon 15 from the corresponding para-cancerous liver in lane 4.

DISCUSSION

The Tcf-4 gene is a member of the APC/β-Catenin/Tcf pathway that is well known to play a crucial role in many developmental processes and human carcinogenesis[19-27]. Mapping to chromosome band 10q25.3[28], Tcf-4 encodes a transcription factor that interacts functionally with β-catenin to transactivate target genes[29-31]. Morin has recently shown that the nuclei of colon carcinoma cell lines contain constitutively active Tcf-4/β-catenin complexes as a direct consequence of either loss of function of the tumor suppressor protein APC or gain of function by mutations in β-catenin itself[12]. This is believed to result in the uncontrolled transcription of Tcf target genes, leading to transformation of colon epithelial cells and initiation of polyp formation. High level of hTcf-4 expression has been identified in colon cancer, mammary carcinoma and a variety of colorectal cancer cells[21,29]. Tcf factors have also been reported as tumor inducers which aberrantly activate their target genes, now known as the c-myc gene and cyclin D1 gene, in many types of cancer[30-32]. It has been reported that *c-myc* gene and cyclin D1 gene had a high expression level in HCC and were implicated in tumor progression and metastasis with the unclear mechanism[33-39]. Therefore, it is important to elucidate the internal link between APC/β-Catenin/Tcf pathway and liver cancer. Our present studies showed that the level of hTcf-4 expression in cancer tissues was much higher than that in para-cancerous tissues and normal liver tissues (P<0.001). Moreover, we found that hTcf-4 gene expression was closely correlated with the integrity of tumor capsule and intrahepatic metastasis of HCC but not with serum AFP levels, liver cirrhosis degree and tumor size, suggesting that hTcf-4 expression was associated with invasion and metastasis of HCC. This may be due to interaction between Tcf and E-cadherin. Huber *et al*. reported that the complex of Tcf andb-catenin in the nucleus binds to the E-cadherin gene promoter and down-regulates E-cadherin gene transcription[40]. On the other hand, loss of E-cadherin expression can contribute to the up-regulation of Tcf-β-Catenin pathway in human cancers[41]. As a result, the role of E-cadherin in cell-cell adhesion is reduced, which may contribute to the metastatic potential of tumor cells.

With regard to the relationship between Tcf-4 mutations and tumor, Duval *et al*[42]. reported that 50 % of human MSI-H (high frequency microsatellite instability) colorectal cell lines and 39 % of MSI-H colorectal primary tumors were found to have a 1-bp deletion in an (A)9 repeat within the coding region of this gene. The (A)9 repeat normally codes for several isoforms that could serve as modulators of Tcf-4 transcriptional activity. The deletion of one nucleotide in this repeat could change Tcf-4 transactivating properties by modifying the respective proportions of the different isoforms. In addition, one frameshift mutation in the β-Catenin binding domain (exon 1), one missense mutation in exon 4 and six nonsense or frameshift mutations localized in the 3' part of the gene were detected in a series of 24 colorectal cancer cell lines[43]. The latter alterations interfered with the Tcf-4 capacity to interact with COOH-terminal binding protein that was implicated in the repression of the Tcf family transcriptional activity. As a result, the Tcf-4 transcriptional activity was enhanced. This indicated that the mutation of Tcf could be an important event during colorectal carcinogenesis by modifying Wnt signaling. In our experiment, we used PCR-SSCP-silver staining analysis to detect mutation of hTcf-4 exons 1, 4, 9 and 15 from human liver cancer tissues. The sensitivity of this method is generally high and greater than 80 % of mutations in most DNA fragments of 300 bp or shorter can be detected since variation of DNA sequence often results in a shift in electrophoretic mobility, which is believed to be caused by sequence-dependent alteration in the tertiary structure of single-stranded DNA. We found SSCP variants in exon 15 of 2 HCC cases (6.25%) only, of which one was complicated by portal vein thrombosis and the other originated from the tumor tissue without metastasis. It seemed that, unlike in colorectal tumor, hTcf-4 mutation may play less important role in HCC and was irrelevant to invasion and metastasis of HCC. Therefore, the enhanced transcriptional activity of hTcf-4 due to aberrant mRNA expression may be the key to HCC occurrence and development. Further study on structure and function of hTcf-4 and its interaction with oncogenes should contribute to clarification of the mechanism of liver carcinogenesis and may provide the theoretical principle for the gene therapy.

Abstract

AIM: To elucidate the expression of the apoptosis-associated molecules in human primary hepatocellular carcinoma (HCC) cells, and prepare the monoclonal antibodies (mAb) against the apoptosis-associated antigens of HCC cells.

METHODS: Human HCC cell line HCC-9204 cells were induced apoptosis with 60 mL·L^{-1} ethanol for 6 h and their morphological changes were observed by transmission electron microscope. The cell DNA fragmentations were detected by Terminal Deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) assay, and the cell DNA contents by flow cytometry. Ten mice were immunized with ethanol-induced apoptotic HCC-9204 cells with the method of subtractive immunization, while the other 10 mice used as the control were immunized by the routine procedures. The tail blood of all the mice were prepared after the last immunization, and the produced antibodies were determined by the immunocytochemical ABC staining. The splenic cells of the mice whose tail blood sera-HCC-9204 cells serum reactions were most different between the apoptotic and the non-apoptotic were prepared and fused with the mouse myeloma cell line SP2/0 cells. The positive antibodies were selected by ELISA assay. The fusion rates of hybridoma cells and the producing rates of antibodies were calculated. The fused cells that secreted candidate objective antibody were cloned continually with the of limited dilution method, and then selected and analyzed further by the immunocytochemical ABC staining. The chromosomes of the cloned hybridoma cells that secreted objective mAb and the mAb immunoglobulin (Ig) subtype of the prepared mAb were also determined. The molecular mass of the mAb associated antigen was analyzed by Western blot assay.

RESULTS: HCC-9204 cells treated with 60 mL·L^{-1} ethanol for 6 h, manifested obvious apoptotic morphological changes, the majority of the cells were TUNEL-positive, and the sub-G1 apoptotic peak was evident. There were 2 mice in the experimental group whose tail blood serum reacted strongly with the apoptotic HCC-9204 cells, but weakly with their non-apoptotic counterparts.In the fusion rates of hybridoma cells as well as the producing rates of the antibody deseribed above, there did not show significant difference between the experimental and the control group, but weakly with non-apoptotic HCC-9204. However, the total producing rate of antibodies in the experimental group was significantly lower compared with the control ($P<0.01$), and so was the producing rate of the antibodies which reacted strongly with both apoptotic and non-apoptotic HCC-9204 cells($P<0.01$). After cloned continually for several times the cell that produce mAb which reacted strongly with the nuclei of ethanol-induced apoptotic HCC-9204 cells, but very weakly with that of non-apoptotic cells was selected out. Chromosome analysis revealed that the selected cell was with the universal characteristics of the monoclonal hybridoma cells which secreted mAb, and the Ig subtype of the prepared mAb was IgG1. The molecular mass of this mAb associated antigen of was about 75 ku.

CONCLUSION: Subtractive immunization is a useful method to prepare the mAb against the apoptosis-associated antigens of cells. The expression of some molecules increases to some extent in HCC-9204 cells in the process of apoptosis induced by low-concentration ethanol. The mAb that may be against ethanol-induced apoptosis-associated antigens of HCC cells was successfully prepared and primarily identified.

INTRODUCTION

Apoptosis is a process of active programmed cell death(PCD), which can be regulated by many kinds of biological factors encoded by a lot of mammalian genes[1-16]. There is not only the increase or decrease of the expression of some already-existed proteins in the process of apoptosis, but also the production and presentation of some new apoptosis-associated molecules that do not express in non-apoptotic cells[17-20]. Currently, the knowledge about apoptosis-associated molecules is still limited. The conventional process to discover new apoptosis-associated molecules is to clone and sequence the apoptosis-associated genes of cells by the methods such as differentiated PCR and phage display first, and then performe the experiments to study the function of the expressed product of the candidate apoptosis-associated genes[21-25]. Preparing the antibodies against the associated antigens of apoptotic cells is also a very hopeful way to investigate apoptosis-associated molecules. There are already some reports about the successful preparation of the polyclonal antibodies against apoptosis-associated molecules while their antigens are unclear and even monoclonal antibodies (mAb) at the condition that their associated antigens are specific[19, 26,27]. However, there has been no report until now about preparing the mAb against apoptosis-associated antigens at the condition that its associated antigens are still unspecific. In the present study, some mice were immunized by the method of subtractive immunization, and the splenic cells of the effectively immunized mice were fused

with mouse myeloma cells to prepare the mAb against the apoptosis-associated antigens of human primary hepatocellular carcinoma (HCC) cells, so as to elucidate the expression of the apoptosis-associated molecules of HCC cells and investigate the methodology and feasibility to prepare mAb against the apoptosis-associated molecules of cells at the condition that the associated antigens are not clear.

MATERIALS AND METHODS

Cells, animals and main reagents

Human HCC cell line HCC-9204 was established previously by our department. Balb/c mouse myeloma cell line SP2/0 was kindly provided by Mrs. Su-Zhen Zhang, Department of Genetic and Developmental biology of our university. Ten-wk old female Balb/c mice were provided by Expereimental Animals Center of our university. Cyclophosphamide (CP), PEG4000, HT (The compound of hypoxanthine and thymidine), HAT (The compound of hypoxanthine, aminopterin and thymidine), 3,3' -diaminobenzine tetrahydrochloride (DAB), 3-aminopropyltriethoxysilane (APES), propidium iodium (PI), colchicine and Giemsa were the products of Sigma Chemical Co., USA. RNase A was the product of Promega Co., USA. HRP-labeled sheep anti-mouse IgG mAb was the product of Dako Co., USA. Terminal Deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) kit was the product of Boehringer Mannheim Co., Germany. Immunohistochemical ABC kit was the product of Vector Laboratories Inc., USA. Mouse hybridoma immunoglobulin (Ig) subtyping kit was the product of Roche Molecular Biochemicals, USA.

Apoptosis induction and detection

Apoptosis induction HCC-9204 cells at log phage were cultured with RPMI1640 medium containing 60 mL· L^{-1} ethanol for 6 h to induce cellular apoptosis, and non-treated HCC-9204 cells was used as control.

Electron microscope observation The cells were fixed in glutaraldehyde, fixed further in osmium tetroxide, dehydrated and embedded in epikote. The sections were ultra thin, stained doubly with uranyl acetate and lead citrate, and bobserved with transmission electron microscope (JEC Co., Japan).

TUNEL assay[28] The cells cultured on cover slips were fixed in formitrol, and then put into penetrating solution (1 g· L^{-1} sodium citrate containing 1 g· L^{-1} Triton X-100) and reacted at 4 ℃ for 2 min. The cells were stained with TUNEL reaction solution contained FITC-labeled nucleotide and deoxynucleotide terminal transferase at 37 ℃ for 60 min, and then observed with fluorescence microscope.

DNA contents analysis The cells were fixed in 700 mL· L^{-1} cold ethanol. RNase A (1 g· L^{-1}) was added into the suspending solution of cells and reacted at 37 ℃ for 30 min. Then PI (0.1 g· L^{-1}) was added with the four times volume of that of the above solution and reacted at 4 ℃ for 30 min. The DNA contents of different cell cycles were analyzed with flow cytometer (Coulter Co., USA).

Methods of antibody detection

ELISA assay The cells adhered to 96-well culture plate with polylysine were fixed in 0.2 mL· L^{-1} glutaraldehyde. The supernatant of the culture medium of hybridoma cells were used as the primary antibody, and the PBS as its negative control. The HRP-labeled sheep anti-mouse IgG mAb was used as the second antibody. The indirect ELISA assay was performed with the standard procedures. Optical absorbance (*A*) was measured at 490 nm with ELISA detector (Bio-Rad Co., USA).

Immunocytochemical staining[29] The cells cultured on cover slips were fixed in 950 mL· L^{-1} ethanol. The supernatant of the culture medium of hybridoma cells was used as the primary antibody, and the PBS as its negative control. The immunocytochemical ABC staining was performed with routine procedures illuminated by the protocol of Vector Laboratories Inc.

Subtractive immunization for mice

Twenty Balb/c mice were divided randomly into 2 groups. The ten mice in the experimental group were immunized firstly with the non-apoptotic HCC-9204 cells at log phase through cavum abdominis. Then the mice were injected with CP (0.1 g· kg^{-1} body mass) into the cavum abdominis at 10 min, 24 h and 48 h respectively after the first immunization. At the 14th, 21st and 28th d after the first immunization, the mice were further immunized with the ethanol- induced apoptotic HCC-9204 cells through the same route. The ten mice in the control group were immunized with the ethanol-induced apoptotic HCC-9204 cells through cavum abdominis for 3 times at an interval of 2 wk. The tail blood sera of animals in both group were respectively prepared after the last immunization, and the immunocytochemical ABC staining was performed as described above to detect the production of antibodies.

Cell fusion and cloning

The mice whose tail blood sera-HCC-9204 cells reactions were most different between the apoptotic and the non-apoptotic were selected from the experimental group. The splenic cells of the selected mice were prepared at the 3rd day after the last immunization, and fused with SP2/0 cells at log phase promoted by PEG4000. Two 96-well culture plates were used for every mouse. The fused cells were cultured continually with RPMI1640 medium containing HAT and HT. Five d later, the culture wells where the monoclonal hybridoma cells were growing were marked and the producing rate of the clones, i. e. the fusion rate, of hybridoma cells was calculated. When the growing hybridoma cells had covered about 1/2 of the bottom area of a culture well, the antibodies that reacted strongly with ethanol-induced apoptotic HCC-9204 cells, but weakly with the non-apoptotic were selected by the ELISA assay as described earlier and the producing rate of antibodies was calculated. The data was statistically analyzed by χ^2 test. The interested cells were cloned continually by the method of limited dilution, selected and analyzed further by the immunocytochemical ABC staining.

Identification of the characteristic of mAb

Chromosomes of hybridoma cells The cells cultured on cover slips were treated with colchicine and stained with Giemsa by the routine procedures. One hundred hybridoma cells at metaphase were counted and observed.

Ig subtype of mAb The detection and analysis of the Ig subtype of mAb was performed with standard procedures illuminated by the protocol of Roche Molecular Biochemicals.

Molecular mass of mAb-associated antigen Some ethanol-induced apoptotic and non-apoptotic HCC-9204 cells were burst and shattered respectively by ultrasonic and the proteins of cells were prepared by the routine methods. Then SDS-PAGE was performed. The supernatant of the culture medium of hybridoma cells that secreted objective mAb was used as the primary antibody. HRP-labeled sheep anti-mouse IgG mAb was used as the second antibody. The proteins in the gel of SDS-PAGE were transferred to colloxylin filter film by Western blot system (Bio-Rad Co., USA) and stained following the protocol of Bio-Rad Co.. The color was developed with freshly dispensed DAB.

RESULTS

Detection of apoptotic cells

Electron microscope observation The majority of the cells treated with 60 mL· L^{-1} ethanol for 6 h showed cellular pyknosis and were densely stained. The processes and microvilli on the cell surface decreased significantly or even disappeared. Granular, crescent or cricoid nuclei (Figure 1), chromatin margination, as well as cytoplasm bubbling were observed. Endoplasmic reticulums expanded and its vacuolation occurred in some cells.

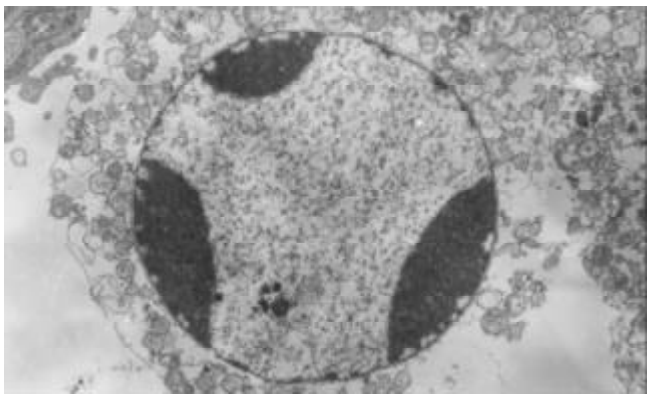

Figure 1 Morpholoical changes of HCC-9204 cells treated with 60 mL·L^{-1} etjanol for 6 h TEM ×6000

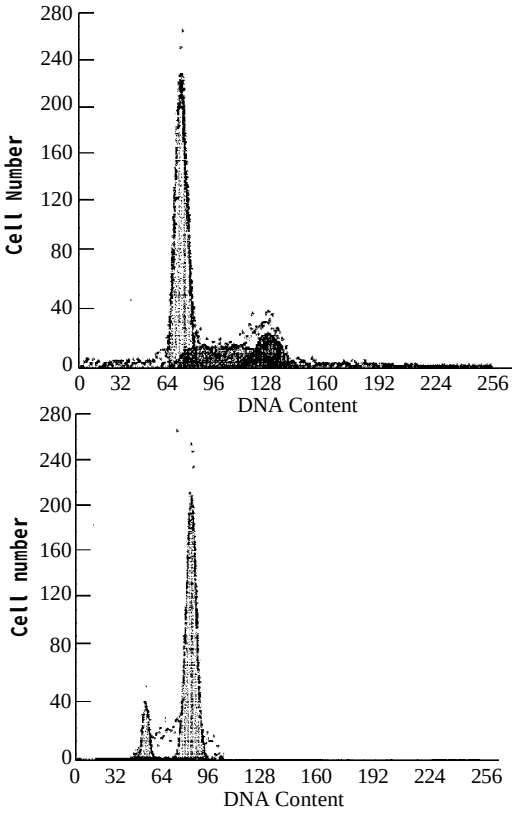

Figure 3 DNA contents of HCC-9204 cells treated with 60 mL·L^{-1} for 6 h. A: Non-treated HCC-9204 cells; B:HCC-9204 cells treated with 60 mL·L^{-1} etjanol for 6 h

TUNEL assay

The positive signal of TUNEL reaction was green or yellow in color within the round, oval, crescent or cricoid, nuclei of cells. The majority of the apoptotic cells in the experimental group were TUNEL-positive (Figure 2).

DNA contents analysis

Compared with that in the control of non-treated HCC-9204 cells, there was obvious sub-G1 apoptotic peak in the experimental group (Figure 3).

Table 1 The fusion rates of hybridoma cells and the producing rates of antibodies

Group	Fusion wells / Incubated wells (Fusion rate)	I(I / Fusion wells)	II(II / Fusion wells)	III(III / Fusion wells)	(I+II+III) ((I+II +III) / Fusion wells)
Experiment	241 / 384(62.8%)	46(19.1%)[a]	5(2.0%)	0(0%)	51(21.2%)[a]
Control	262 / 384(68.2%)	101(38.5%)	4(1.5%)	1(0.4%)	106(40.5%)

[a]$P<0.01$ *vs* Control. I: The wells whose antibodies reacted strongly with both apoptotic and non-apoptotic cells; II: The wells whose antibodies reacted strongly with apoptotic cells, but weakly with non-apoptotic cells(Difference is>8 times); III: The wells whose antibodies reacted weakly with apoptotic cells, but strongly with non-apoptotic cells (Difference is >8 times).

Subtractive immunization for mice

The tail blood sera of 8 mice in the experimental group and 10 mice in the control reacted strongly with both apoptotic and non-apoptotic HCC-9204 cells. However, the tail blood sera of the 2 other mice in the experimental group reacted strongly with apoptotic, but weakly with non-apoptotic HCC-9204 cells.

Cell fusion and cloning

Monoclonal hybridoma cells were growing in many wells of the culture plates at the 5th d after cell fusion (Figure 4).

In the fusion rate of hybridoma cells, as well as the producing rate of the antibodies that reacted strongly with apoptotic, but weakly with non-apoptotic HCC-9204 cells, there did not show significant difference between the experimental and the control group. The total producing rate of antibodies in the experimental group was significant. However, lower compared with that in the control group ($P<0.01$), and so was the producing rate of the antibodies that reacted strongly with both apoptotic and non-apoptotic HCC- 9204 cells ($P<0.01$, Table 1).

An mAb that reacted strongly with the nuclei of ethanol-induced apoptotic, but very weakly with that of non-apoptotic HCC-9204 cells was obtained after the hybridoma cells which secreted candidate objective mAb had been cloned continually for several times (Figure 5).

Characteristic identification of mAb

Chromosomes of hybridoma cells The number of the chromosomes in the hybridoma cells which secreted objective mAb was 83 - 105, their modal number was 94 - 98, and the majority of the chromosomes were the type of terminal centromere, which is consonant with the universal characteristics of the hybridoma cells which secrete mAb (Figure 6).

Ig subtype of mAb The subtype Ig of the prepared mAb was IgG1.

Molecular mass of mAb-associated antigen The molecular mass of the prepared mAb associated antigen was about 75 ku (Figure 7).

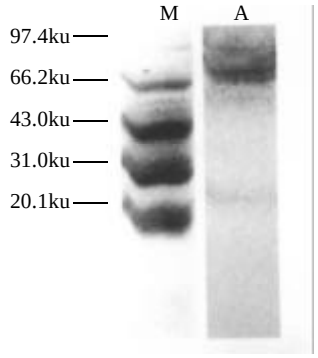

Figure 7 The molecular mass of the associated antigen of the prepared mAb. M: Standard molecular mass; A:HCC-9204 cells treated with 60 mL·L^{-1} ethanol for 6 h

DISCUSSION

To investigate the changes of the apoptosis-associated molecules on cell surface and the production of new antigens in the process of apoptosis is important in many fields of biomedical studies such as the mechanism of signal transduction and molecular regulation in cells and cellular immunology, *etc*., and many mammalian gene-encoded proteins can induce or suppress apoptosis in a variety of cell types[1-16]. It was discovered previously by the method of 2-dimentional gel electrophoresis that there are 17 new proteins, whose molecular mass are 12 - 80 ku, expressed in some cell types undergoing apoptosis induced by the transfection of wild-type *p53*[17]. A mitochondrial membrane protein 7A6 expresses only in some kinds of apoptotic but not in non-apoptotic cells, and its mAb has been used in the detection of apoptosis in some cell types[19, 26, 30-32]. The facts cifed above indicate that in the process of apoptosis, there exists not only the up or down-regulation of some proteins expressed already in non-apoptotic cells, but also the production of new proteins that did not exist in non-apoptotic cells.

Low-concentration ethanol can induce apoptosis in some cell types such as T lymphocytes, natural killer cells, macrophage, neutrophils, nerve cells, reproduction stem cells, mucosa epithelial cells, salivary gland cells, osteoblast, thyroid epithelial cells, leukemia cells, hepatocytes and HCC cells, *etc*.[33-40]. The results of present study showed that the majority of the HCC-9204 cells treated with 60 mL· L^{-1} ethanol for 6 h manifested marked morphological changes of apoptosis,the majority of the cells were TUNEL-positive, and the sub-G1 apoptotic peak detected by flow cytometry was obvious, suggested that low-concentration ethanol could induce apoptosis obviously in HCC-9204 cells and the model of ethanol-induced apoptosis in HCC cells was established successfully. The previous study with SDS-PAGE and folium scan in our laboratory have revealed that at least 7 kinds of new proteins whose molecular mass are more than 67 ku expressed in the HCC-9204 cells treated with 60 mL· L^{-1} ethanol for 6 h but not in non-apoptotic cells. It is well known that HCC is a common malignant tumor in China and some other places in the world, and its oncogenesis and development are related with apoptosis[41-60]. Therefore the ethanol-induced apoptotic HCC-9204 cells were used as antigen to prepare mAb against the apoptosis-associated antigens of HCC cells in this experiment.

Most of the proteins encoded by apoptosis-associated genes express only instantaneously in cells, and the quantity of the expressed products of apoptosis-associated genes is usually very little. The general procedures of the routine of immunization for the preparation of mAb are that the mice were further immunized twice respectively with the same antigen as the first immunization at an interval of 2 wk. In our previous studies, more than ten rabbits have been immunized with ethanol-induced apoptotic HCC-9204 cells by routine immunization procedures, there was no rabbit found whose

ear blood serum reacted strongly with apoptotic, but weakly with non-apoptotic cells. There is also no mouse whose tail blood serum reacted differently with apoptotic and non-apoptotic cells in all the 10 mice used as control in this experiment. The those results suggest that the antibodies against cell apoptosis-associated antigens are difficult to be prepared by the routine immunization procedures because of the interference of the large amounts of antigens not associated with apoptosis in the apoptotic cells.

Subtractive immunization is a special method of differentiated immunization used for the preparation of antibodies when the antigen components are complicated, unclear or cannot be extracted and purified[61-65]. The mechanism of subtractive immunization is that when certain antigens induce the immunoreaction of a animal body, the lymphocytes will proliferate, and the cells in split phase are prone to be selectively killed by the drug containing alkyls such as CP that is in common use in the procedures of subtractive immunization. When the same antigen is injected into the animal body again after the first immunization, the immunoreaction to the antigen is suppressed. CP can effectively inhibit the production of the antibodies against non-objective components of the antigen, but the production of objective antibodies cannot be influenced obviously, and neither are the fusion rates of hybridoma cells. Therefore the selection workload in the process of preparing mAb could reduce remarkably. The standard procedures of subtractive immunization are as the followings. Firstly, 2 groups of mixed antigens A and B whose components were similar were prepared. There is objective antigen in group A, but no objective antigen in group B. Secondly, group B is firstly used to immunize some animals. At the meantime, the immunized animals are treated with CP, or CP is injected 10 min, 24 h and 48 h later. Thirdly, the animals are further immunized with group A for 3 times respectively at an interval of 1 wk. At this time, the immunoreaction of the animal body to the common components of group A and group B is suppressed. Therefore the interference of non-objective antigens to the preparation of objective mAb is wakened or even may be eliminated, the immunoreaction to the objective antigens in group A is enhanced relatively, and the probability to obtain specific mAb increases significantly[48].

There were 2 mice whose tail blood sera reacted strongly with ethanol-induced apoptotic HCC-9204 cells, but weakly with non-apoptotic HCC-9204 cells in 10 mice immunized by subtractive immunization in this experiment, indicating that there are certain antigens which express strongly in apoptotic cells, but weakly or even do not express in non-apoptotic cells in the process of HCC cells apoptosis. The subtractive immunization is therefore a useful method to prepare the antibodies against the apoptosis-associated antigens of cells. The preferable results obtained only in 20 % (2 / 10) of the mice immunized by subtractive immunization, suggesting that there is obvious individual difference in the effect of subtractive immunization with CP. In order to get ideal effect, more mice are needed to be immunized in an experiment. The fusion rate of hybridoma cells in the experimental group did not differ distinctly from that in the control group, but the total producing rate of antibodies was lower significantly than that in the control group, suggesting that CP can suppress remarkably the production of antibodies while the fusion rate of hybridoma cells is not greatly influenced. The producing rate of the antibodies which reacted strongly with both apoptotic and non-apoptotic cells in the experimental group is significantly lower than that in the control, whereas there is no remarkable difference on the producing rate of the antibodies which reacted strongly with apoptotic, but weakly with non-apoptotic cells between the two groups, indicating that CP had partly suppressed the production of the antibodies against non-objective antigens to some extent, but not influenced that of the antibodies against objective antigens. The subtractive immunization can significantly decrease the selection workload in the process of preparing mAb when the antigen of mAb is unknown.

The mAb whose associated antigen located within the nucleus of ethanol-induced apoptotic HCC-9204 cells and reacted weakly with non-apoptotic HCC-9204 cells was prepared successfully and identified primarily in this experiment, which is consistent with some previous reports that injecting apoptotic cells into the cavum abdominis of mice can lead to the production of anti-nucleus antibodies[66]. The results of Western blot analysis revealed that the molecular mass of the associated antigen of this mAb was about 75 ku, which is consistent with the result of our previous study that new proteins whose molecular mass are more than 67 ku are discovered in 60 mL· L^{-1} ethanol-induced apoptotic HCC-9204 cells. The associated antigen of the mAb prepared in this experiment is the certain molecule that expresses in the nucleus of HCC-9204 cells and may be related with the ethanol-induced apoptosis. No antibody that reacted strongly with apoptotic cells, but completely absent with non-apoptotic cells is obtained in this experiment, suggesting that the antibodies against new apoptosis-associated antigens that do not exist in non-apoptotic cells is difficult to be prepared by the method of cell fusion used in this experiment. Low-concentration ethanol can not only induce apoptosis in HCC-9204 cells, but may also suppresses their proliferation and startup the expression of some molecules related with some other effect of ethanol on cells. The relationship between the mAb prepared in this experiment and its associated antigen and apoptosis in HCC cells is still to be determined and should be studied further. This experiment gives us a hopeful prospect to discover some new apoptosis-associated molecules in HCC cells.

Abstract

AIM: To clarify the significance of cyclooxygenase-2 (COX-2) expression in human primary hepatocellular carcinoma (HCC) and adjacent nontumorous tissues.

METHODS: The COX-2 protein and mRNA were investigated in 27 HCC tissues with adjacent nontumorous tissues, and 5 histologically normal liver tissues,using immunohistochemistry and in situ hybridization.

RESULTS: The well-differentiated HCC expressed COX-2 protein (5.68±1.19) more strongly than moderated HCC (3.43±1.98) and poor differentiated HCC (3.33±1.50) ($P<0.05$ respectively), adjacent nontumorous tissues (4.93 ±1.05) and normal liver tissues (3.20±1.92) ($P<0.01$ respectively); More intensive staining of COX-2 in adjacent nontumorous tissues was observed than that in normal liver tissues ($P<0.05$). There was no significant difference among adjacent nontumorous tissues, moderately differentiated HCC and poorly differentiated HCC ($P>0.05$). The expression of COX-2 mRNA was observed in the cytoplasm of the cells of HCC and of the hepatocytes in adjacent nontumorous tissues in which COX-2 protein was positive.

CONCLUSION: The overexpression of COX-2 in well-differentiated HCC suggests that COX-2 may play a role in the early stages of hepatocarcinogensis.

Qiu DK, Ma X, Peng YS, Chen XY. Significance of cyclooxygenase-2 expression in human primary hepatocellular carcinoma.*World J Gastroenterol* 2002; 8(5):815-817

INTRODUCTION

Cyclooxygenase (COX) is the rate-limiting enzyme involved in the conversion of arachidonic acid to prostaglandin H_2, the precursor of various compounds including prostaglandins, prostacyclin and thromboxanes. Two COX genes, COX-1 and COX-2, have been identified,which share greater than 60 % identity at the amino acid level. COX-1 is constitutively expressed in a number of cell types, whereas COX-2 is inducible by a variety of factors such as mitogen, cytokines, growth factor, and tumor promoters[1]. The expression of COX-2 is significantly increased in various types of carcinoma. There is also sufficient evidence indicating that selective COX-2 inhibitors produce effective prevention of carcinogenesis and that these compounds act by inducing of apoptosis of various cancer cells. These findings suggest that COX-2 may be involved in carcinogenesis and/or progression of certain types of human malignancies[2]. In this study, we examined the expression of COX-2 in human primary hepatocellular carcinoma (HCC) and adjacent nontumorous tissues.

MATERIALS AND METHODS

Tissue samples

HCC tissue and adjacent nontumorous liver tissues were obtained from 27 patients with hepatic tumor, who received hepatectomy at Renji hospital. Five specimens of grossly normal liver tissues from the area surrounding benign angiomas were used as controls. Specimens were fixed in 10 % neutral formalin and embedded in paraffin.

Histology

Serial 5-um sections were stained with hematoxylin and eosin. Each HCC was histologically graded into one of three categories: well-differentiated, moderately differentiated, or poorly differentiated, according to the criteria proposed by the Liver Cancer Study Group of Japan[3]. The tumor tissues consisted of 11 well-differentiated, 7 moderately differentiated, and 9 poorly differentiated HCCs, and the nontumorous sites consisted of 3 chronic hepatitis and 24 cirrhosis.

Immunohistochemistry

Immunohistochemical staining was performed on serial sections at room temperature, using the peroxidase method with the polyclonal antibody against human COX-2 (Santa Cruz Co.). The sections were deparaffinized in xylene and rehydrated through graded alcohol, immersed the sections in 3 % hydrogen peroxide for 10 minutes to inactivate endogenous peroxidases, then were incubated for 10 minutes with 10 % normal swine serum in Tris-buffered saline to block non-specific binding, subsequently incubated overnight at 4 ℃ with relevant antibody. The following day, the sections were incubated with biotinylated anti-mouse IgG (Maxim Biotech Inc. USA) for 45 minutes, followed by peroxidase-conjugated streptavidin (Maxim Biotech Inc.). The chromogenic reaction was developed with diaminobenzidine for 10 minutes, and all sections were counterstained with hematoxylin. In controls, the primary antibody was omitted.

The intensity of staining for COX-2 in HCC tissues and nontumorous adjacent tissues was scored in each specimen on a scale of 0 to 3, in which 0=negative staining, 1=weakly positive staining, 2=moderately positive staining, and 3=strongly positive staining. The percentage of positive cells in each specimen was estimated and scored on a scale of 0 to 4, in which 0=negative, 1=positive staining in 1 % to 25 % of cells counted, 2, in 26 % to 50 %; 3, in 51% to 75 %; and 76 % to 100 %. Each section was evaluated for the sum of these two parameters.

In Site Hybridization

Deparaffinized sections of liver tissue were treated with proteinase K (70 mg/ml) for 30 minutes at 37 ℃, followed by fixation with paraformaldehyde (0.4 %, 20 minutes). Sections were prehybridized for 1-hour, then hybridized at 55 ℃ overnight with digoxigenin-labeled (labeling-kit: Boehringer Mannheim) fragments of COX-2 (Cayman Chemical). After extensive washing of the tissue section, hybridization was visualized using anti-digoxiganin, alkaline phosphatase-conjugated antibody and NBT/BCIP.

Statistical analysis

Data are presented as the mean ±SD. Statistical significances were assessed using Mann-Whitney' s *U* test. Significance was accepted when $P<0.05$.

RESULTS

In immunohistochemical analysis, cytoplasmic staining for COX-2 was observed in HCC cells and nontumorous hepatocytes. The distribution of positive cells was mostly extensive, and occasionally focal or scattered. Different histological grades of HCC demonstrated different immunoreactivity for COX-2. A significantly high expression level of COX-2 (5.68±1.19) was found in well-differentiated HCC, compared with that of normal tissue (3.20±1.92), adjacent nontumorous tissues (4.93±1.05) ($P<0.01$, respectively), moderately differentiated HCC (3.43±1.98) and poorly differentiated HCC (3.33±1.50) ($P<0.05$, respectively). More intensive staining of COX-2 in adjacent nontumorous tissues was observed than that in normal liver tissues ($P<0.05$). These is no significant difference among adjacent nontumorous tissue, moderately differentiated HCC and poorly differentiated HCC ($P>0.05$, respectively) (Figure 1). The expression of COX-2 mRNA was observed in the cytoplasm of the cells of HCC and of the hepatocytes in adjacent nontumorous tissues in which COX-2 protein was positive.

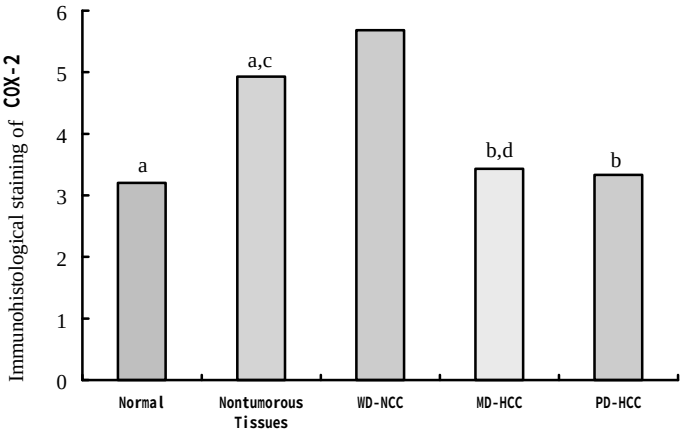

Figure1 Immunohistochemical staining scores of COX-2 in normal, adjacent nontumorous and HCC tissues. ([a]$P<0.01$ *vs* WD-HCC; [b]$P<0.05$ *vs* WD-HCC; [c]$P<0.05$ *vs* normal.)

DISCUSSION

Primary HCC is one of the most common tumors in China. The prognosis of HCC is generally poor, and the 5-year survival rate is limited to 25-39 % after surgery[4]. The present study showed that a significantly increased expression of COX-2 was observed in HCC, suggesting that COX-2 was being involved in hepatocarcinogenesis. Of interest, a profound expression of COX-2 was demonstrated in well-differentiated HCC. It is known that early HCC is usually a well-differentiated carcinoma and then gradually changes into a poorly differentiated phenotype during tumor progression[5]. In this context, it is suggested that COX-2 may be associated with the early process of the progression of HCCs. This result is consistent with those reported by Koga[6].

Recent studies have highlighted the relevance of COX-2 in human carcinogenesis. Epidemiological studies indicate that NSAIDs lead to a regression of colonic polyps in patients with familial adenomatous polyposis. NSAIDs are also known to reduce the risk of colorectal cancers, breast and lung cancers[7]. There is also a sufficient evidence from animal studies indicating that selective COX-2 inhibitors produce effective prevention of carcinogenesis. Introduction of COX-2 cDNA into colon carcinoma cells facilitated growth. COX-2 appears to prevent apoptosis because selective COX-2 inhibitors induced apoptosis in various cell culture systems[8]. Furthermore, it was shown that COX-2 promoted angiogenesis in malignant cells[9]. COX-2 mRNA and protein were recently found to be expressed in human colon carcinoma[10] and gastric carcinoma[11]. However, COX-2 protein was not expressed in human breast carcinoma or in human basal cell carcinoma. These observations have suggested that overexpression of COX-2 in carcinomas is not the universal event in carcinogenesis but may be specific. Recently, Kondo *et al*[12] showed that increased expression of COX-2 in nontumor liver tissue was associated with shorter disease-free survival in patients with hepatocellular carcinoma. Clinicopathological survey indicated a significant correlation between COX-2 expression and differentiated carcinoma. Moreover, high COX-2 expression in nontumorous tissue was significantly correlated with the presence of active inflammation. These findings suggest that COX-2 expression in nontumorous tissue may play a positive role in relapse of HCC after surgery.

Recent chemopreventive strategies for colon carcinogenesis have focused on using COX inhibitors, resulting in interesting data from animal models[13]. Denda et al[14] demonstrated that administration of NSAIDs suppressed cirrhosis and subsequent formation of HCC in the choline-deficient L-amino acid-defined rat model. The present finding of increased COX-2 expression in well-differentiated HCC tissues encourages chemopreventive studies for primary HCC. To clarity whether COX-2 is a principle enzyme involved in liver carcinogenesis, in vivo animal studies should be performed using a specific COX-2 inhibitor.

Dear editors:

We found some data errors in our paper entitled "Alternation of AFP-mRNA level detected in blood circulation during liver resection for HCC and its significance", which was published in World J Gastroenterol 2002 October; 8(5):818-821. All authors have made a decision to retract this paper from your journal and all databases as soon as possible.

We are so sorry about it.

Thank you very much.

Best regards,

Xiaoping Chen

Abstract

AIM: To investigate the possible roles of p53 and C-myc genes in the primary hepatocellular carcinogenesis and the relationship between the liver hyperplastic nodule(LHN) and hepatocellular carcinoma(HCC).

METHODS: The expression of p53 and C-myc genes was detected immunohist-ochemically in 73 and 60 cases of HCC and pericarcinomatous tissues, respectively.

RESULTS: The positive expression of p53 in HCC was significantly higher than that in pericarcinomatous tissues ($P<0.05$). In pericarcinomatous tissues, the p53 expression was observed only in LHN, but not in liver cirrhosis (LC) and normal liver tissues. The positive expression rate of C-myc in HCC or LHN was significantly higher than that in LC or normal liver tissues ($P<0.05$ and $P<0.01$), however, no significant difference was found between HCC and LHN ($P>0.05$). The positive expression rate of p53 and C-myc in HCC was correlated with the histological differentiation, that in the poorly differentiated was significantly higher than that in well differentiated samples ($P<0.05$).

CONCLUSION: The overexpression of p53 and C-myc genes might play a role in the carcinogenesis of HCC; And LHN seems a preneoplastic lesion related to hepatocarcinogenesis; No evidence supports that LC contribute directly to the hepatocarcinogenesis.

Niu ZS,Li BK,Wang M. Expression of p53 and C-myc genes and its clinical relevance in the hepatocellular carcinomatous and pericarcinomatous tissues.*World J Gastoenterol* 2002;8(5):822-826

INTRODUCTION

Primary hepatocellular carcinoma (HCC) is one of the most common malignant tumors in China[1-11], and the incidence of HCC reported has apparently increased in recent years. Despite a variety of therapeutic strategies, HCC remains a significant cause of cancer death. Therefore, to study the HCC pathogenesis is of the utmost importance to the prevention and treatment of this disease. With the advancement of HCC study, it becomes clear that the biologic behavior of HCC is closely related with the overactivation of the oncogenes and the inactivation of the tumor suppressor genes[12,13].

In the present study, the immunohistochemical LSAB (labelled streptavidin biotin) method was used to detect the expression of p53 and C-myc genes in HCC and pericarcinomatous tissues, in order to investigate the possible roles of these genes played in the HCC carcinogenesis, and to find out the relationship between the liver hyperplastic nodule and HCC. In addition, the relationship between the expression of p53 and C-myc genes and clinicopathological parameters of HCC was preliminarily investigated.

MATERIALS AND METHODS

Materials

HCC specimens of 100 cases obtained from surgical resections or biopsies performed at the Affiliated Hospital of Medical College of Qingdao University, China. Of these patients, 76 were male and 24 female with an average of 50.4 years. None of the patients had received chemo- or radio-therapy before resection. We randomly selected 73 and 60 cases of HCC to detect the expression of p53 and C-myc genes respectively owing to the limitation of antibodies. The specimens for detecting p53 were classified into 4 grades according to Edmondson's grading criteria, 4 specimens were in grade Ⅰ, 24 in grade Ⅱ, 39 in grade Ⅲ, and 6 in grade Ⅳ. All 73 specimens contained pericarcinomatous tissues, in which including 39 liver hyperplastic nodules (LHN), 35 liver cirrhosis(LC) and 10 normal liver tissues. Among the specimens for detecting C-myc gene, 4 were in grade Ⅰ, 17 in grade Ⅱ, 30 in grade Ⅲ, and 9 in grade Ⅳ. All 60 specimens contained pericarcinomatous tissues, in which including 37 LHN, 30 LC and 12 normal liver tissues.

Methods

All specimens were routinely processed, alcohol-fixed and paraffin-embedded. Serial paraffin sections of 4 um thickness were cut and used for hematoxylin and eosin(HE) and immunohistochemical stains. Immunohistochemical LSAB method was used to detect p53 and C-myc genes. Anti-p53 monoclonal antibody DO-7, anti-C-myc monoclonal antibody and LSAB kits were purchased from Dako Co. Before staining, the sections were heated with microwave in 0.05 mol • L^{-1} citric acid solution for antigen retrieval. In each staining , a known p53 or C-myc positive section was added as the positive control, and PBS was used as the substitute of the first antibody for the negative control.

Analysis of immunohistochemical staining

Cells with brown granules under microscope were regarded as positive. The criteria for the evaluation of the p53 expression in the present study were as follows: the positive nuclei number was semiquantitatively evaluated by counting that in 8-10 randomly-chosen medium power (×100 magnification), and the four degrees of the p53 expression were considered as: negative (-), no positive cells; weak positive (+), the positive cells <10 %; moderately positive (+ +), the positive cells between 10-50 %; strong positive (+ + +), the positive cells >50 %. For the evaluation of C-myc expression, the percentage of positively stained cells was employed as an index, which was obtained from counting 500 cells at more than 5 high power fields for each section, and classified into 4 grades: grade Ⅰ, the positive cells between 1-25 %; grade Ⅱ, the positive cells 26-50%; grade Ⅲ, the positive cells 51-75 %; grade Ⅳ, the positive cells 76-100 %.No positive cells were scored negative (-).

Statistical analysis

Results were analysed by χ^2 test. Differences at $P<0.05$ were considered to be statistically significant.

RESULTS

Expression of p53 gene in HCC and its pericarcinomatous tissue

The positive staining for p53 gene expressed as brown granules, which was mainly located in the cell nuclei of tumor cells (Figure 1). The staining intensity and extent varied among tumors, different tumor regions and individual tumor cells. Immunostaining of p53 protein was negative in all tumor stroma, bile duct epithelia, LC and normal liver tissues. A few p53 weakly positive cells were found in LHN (Figure 2). The significant difference existed between HCC and LHN (χ^2 value 10.57, $P<0.01$), and so did between LHN and LC (χ^2 value 6.94, $P<0.01$) (Table 1).

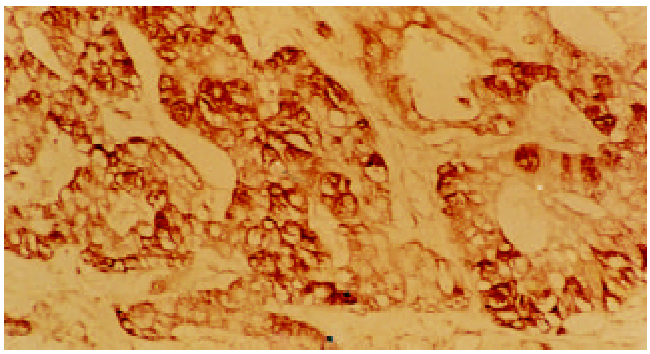

Figure 1 The positive expression of p53 gene in HCC. LSAB×200

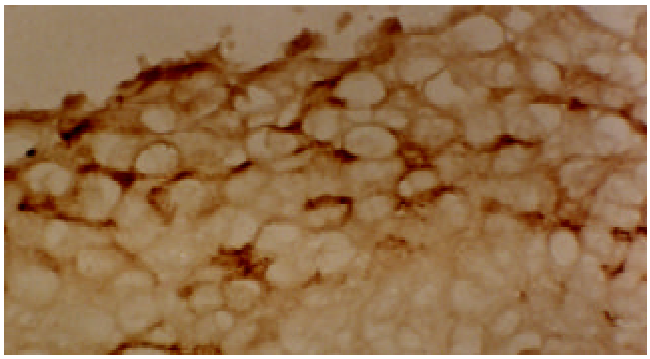

Figure 2 The positive expression of p53 gene in LHN. LSAB×200

Expression of C-myc gene in HCC and its pericarcinomatous tissue

The positive staining for C-myc gene was also expressed as brown granules, which was distributed mainly in cell nuclei, partly in cytoplasms. Although the expression rate of C-myc was higher in LHN than that in HCC, the statistical significance did not reached (χ^2 value 0.05, $P>0.05$). The expression of C-myc gene in HCC and LHN was significantly higher than that in LC (χ^2 values 4.38, 4.51, $P<0.05$). In HCC (Figure 3) and LHN (Figure 4) showing strong expression of C-myc, the positive-staining cells were distributed dominantly in a diffused pattern; whereas in LC (Figure 5) showing weak expression of C-myc, they preferred in a focalized pattern. The expression of C-myc was negative in normal liver tissues (Table 2).

Normal liver tissues	12	12	0	0	0	0	0

The relationship between the expression of p53 and C-myc genes and histological grade of HCC

There were varieties of positive rates of p53 and C-myc genes in different HCC histological grades of HCC, with a close relationship between the genes expression and the tumor differentiation. The positive rates of p53 expression in Edmondson' s grading Ⅲ and Ⅳ and Edmondson' s grading Ⅰ and Ⅱ were 60 %(27/45), 32.1 %(9/28), respectively, which manifested a significant difference (χ^2 value 5.36, P<0.05); The positive rates of C-myc expression in Edmondson' s grading Ⅲ and Ⅳ and Edmondson' s grading Ⅰ and Ⅱ were 48.7 %(19/39), 19 %(4/21), respectively, their differences were also significant(χ^2 value 5.08, P<0.05) (Table 3).

Table 3 The relationship between the expression of p53 and C-myc genes and histological grade of HCC

Edmondson's grading	Expression of p53 gene		Expression of C-myc gene	
	Negative	Positive	Negative	Positive
Ⅰ	4	0	3	1
Ⅱ	15	9	14	3
Ⅲ	18	21	18	12
Ⅳ	0	6	2	7

Correlation between p53 and C-myc protein expressions and HCC clinicopathological parameters

No significant relation was found between p53 or C-myc gene expression and patient age, sex and tumor size (P>0.05).

DISCUSSION

The p53 gene is one of the most important tumor suppressor genes determined so far[14-19]. In recent years, it has been found that the p53 protein seems not express in the benign and preneoplastic lesions, and that there was no obvious relation between the p53 protein and carcinogenesis[20]. However, in the present study, the positive rate of p53 protein staining in LHN was 17.9 %, which coincided basically with some results in literature[21-25]. The facts that the p53 protein expressed low in LHN and high in HCC, indicate that the high expression of p53 protein is probably associated with the cancerous transformation of hepatocytes, the early event in the carcinogenesis of HCC. It has been proved that wild type p53 protein can induce cell apoptosis whereas the mutant p53 protein can inhibit cell apoptosis and promote cell transformation and proliferation, resulting in carcinogenesis[26-30]; The p53 protein confirmed by immunohistochemical staining was considered as the mutation type[31]; Therefore, we speculate that p53 protein may exert its carcinogenic effect in the early stage of carcinogenesis on hepatocytes by two ways: **(1)** As described above, the mutant p53 protein might be associated with cell rapid proliferation and cell transformation, which ultimately results in hepatocellular carcinogenesis; **(2)** with the increase of the mutant p53 expression, and its inhibiting effect on apoptosis there will be an abnormal in cell numbers, which may eventually initiate the hepatocellular carcinogenesis. In addition, our results indicated that there existed a close relationship between the p53 gene expression and tumor cell differentiation in HCC, which suggests that the expression of p53 gene might serve as an index for the judgement of HCC malignant degree and its clinical prognosis.

It has been reported that the inept expression of C-myc gene correlated with carcinogenesis[23,32,33]. However, some authors held that the overexpression of C-myc gene could not be observed until the hepatocytes had thoroughly transformed into malignancy in the late stage of HCC, which reflected the continuous proliferation of tumor cells[34-36]. On the contrary, most experiments demonstrated the expression of C-myc in HCC and its pericarcinomatous tissue[24,37]. In the present study, the expression of C-myc gene was observed both in LHN and LC with varied degree and LHN was similar to HCC in the expression of C-myc, which were coincident with the results of others and suggests that the overexpression of C-myc gene occurs in the early phase of HCC formation, and correlates with preneoplastic transformation and proliferation. Our results also indicated that the expression of C-myc gene in HCC was related to the cell differentiation, which suggests that C-myc gene expression may exist in the sequential process of hepatocarcinogenesis, and be related to the phase of hepatocarcinogenesis.

In the present study, the expression of p53 gene in LHN was similar to that in HCC to some extent and the overexpression of C-myc gene was seen in both samples. The mutation of p53 gene that may lead to cell malignization, thus may reflect the alterations in different biologic state of LHN, and suggest that LHN is probably in the process of malignant transformation and in relation to hepatocarcinogenesis. In the present study the expression of C-myc gene in LHN had no significant difference from that in HCC, which reveals that parts of LHN were actually in the preneoplastic state or might be cancerous though they seemed normal in histology. Some study indicated that the increased oncogene expression brought cells into a state of active proliferation that resulted in an increased frequency of mutation[38]. This suggests that the overexpression of C-myc gene may make LHN be transformed

malignantly. Another study showed that not all altered hepatocyte foci manifested abnormal expression of C-myc in the early stage of experimental HCC and the high expression of C-myc was only seen in the poorly differentiated foci[39]. It shows that the overexpression of C-myc gene may relate to the tumor' s differentiation. Therefore, the overexpression of C-myc gene may be responsible for the low differentiation of LHN. It has been postulated that C-myc products might serve as a valid index for identifying preneoplastic lesion of HCC, the foci overexpressed C-myc were in danger of carcinogenesis[24,33]. However, few research reports till now have been found on the relationship between LHN and HCC. The present study thus provides a new possible way to diagnose HCC at earliest possible stage, which is of great importance in improving the prognosis because early diagnosis usually means high curability.

For many years, it has been generally considered that LC was closely associated with HCC and hepatocarcinogenesis. According to carcinogenic hypothesis on oncogene, at least two activated oncogenes are required-namely, the ras gene which was representative of transforming gene and the C-myc representative of immortalizing gene. Only when the two sorts of oncogenes function coordinately can stock-cultured cells be transformed malignantly. In the present study, we found that the expression rate of C-myc protein in LC was 26.7 %, but, the expression intensity of C-myc in LC was significantly less than that in LHN. Our previous studies have indicated that there was no mutation of the ras gene in LC, and that the expression of c-erbB-2 oncogene was negative in LC, indicating that there are no mutation and activation of c-erbB-2 in LC, that is, it is impossible in this situation for malignant transformation. In addition, according to the present study, there was no mutation of p53 in LC, suggesting that LC does not necessarily link with hepatocarcinogenesis. Alcohol is the major cause of cirrhosis in European countries and the United States, responsible for 60 to 70 percent of all cases of cirrhosis, but it only infrequently leads to HCC; carbon tetrachloride can lead to LC rather than HCC. However, the reason why the ratio of HCC accompanied by LC in China is obviously higher than that in European countries and the United States perhaps lies in HBV infections, there is not a cause and effect but a accompanying relationship between LC and HCC. The significance of C-myc expression in LC remains to be investigated.

What requires a special explanation is that the LHN used in the present study is totally different from the nodules in LC. We noticed that though the majority of the LHN developed from LC, it is a cell population that differs from LC in properties and proliferative patterns. Although the liver cell cords in LC are in disarray, the hepatocytes are primarily arranged in a single line, most of which are normal in morphology; However, the hepatocytes in LHN grow by expansion, one nodule primarily contains a sort of cells, and in mixed cell nodules there exists a clear margin between the cellgroups, suggesting the nodules are of clone origin.

As to the relationship between the expression of p53 and C-myc genes and clinicopathological parameters of HCC, we found that there was no link of p53 or C-myc gene expression with patient age, sex and tumor size, which was in accordance with the previous reports[40]. Some studies indicated that the overexpression of p53 or C-myc was closely related to the prognosis of HCC[18,33, 41-50], which was not our results have not yet confirmed that p53 or C-myc gene expression is directly associated with the prognosis of HCC. However, in the present study, the low expression of p53 gene and the overexpression of C-myc gene were found in LHN. It can be deduced that although normal in histology, LHN is surely abnormal in gene expression. Whether the phenomenon has a tie with the recurrence of HCC after resection needs to be further studied.

Abstract

AIM: To study the effects of doxorubicin on telomerase activity and telomere length in hepatocellular carcinoma.

METHODS: Telomerase activity was assayed with a non-radioisotopic quantitative telomerase repeat amplification protocal-based method. The effect of doxorubicin (DOX) on the growth of BEL-7404 human hepatoma cells was determined by microculture tetrazolium assay. Mean telomere length (terminal restriction fragment) was detected by Southern blot method. The expression of telomerase subunits genes was investigated by RT-PCR. Cell apoptosis and cell cycle distribution were evaluated by flow cytometry.

RESULTS: Telomerase activity was inhibited in a dose and time-dependent manner in BEL-7404 human hepatoma cells treated with DOX for 24, 48 or 72 h in concentrations from 0.156 to 2.5 μM which was crrelated with the inhibition of cell growth. No changes were found in the mRNA expression of three telomerase subunits (hTERT, hTR and TP1) after drug exposure for 72 h with indicated concentrations. The cells treated with DOX showed shortened mean telomere length and accumulated at the G_2/M phase. However, there was almost no effects on cell apoptosis by DOX.

CONCLUSION: The telomerase inhibition and the telomere shortening by DOX may contribute to its efficiency in the treatment in hepatocellular carcinoma.

INTRODUCTION

Telomeres form the ends of eukaryotic chromosomes consisting of an array of tandem repeats of hexanucleotide 5'-TTAGGG-3'. Telomeres protect the chromosomes from DNA degradation, end-to-end fushions, rearrangements and maintain nuclear structure[1]. Human telomerase is a ribonucleoprotein complex, composed of a catalytic reverse transcriptase subunit (hTERT), an RNA component (hTR) that serves as a template for the synthesis of telomeric repeats, and an associated protein subunit (TP1)[2-4]. It adds telomeric repeats to the 3' end of telomeric DNA. This telomere stabilization by telomerase can lead to unlimited cell proliferation.

Hepatocellular carcinoma (HCC), one of the most common malignancies in the world especially in Asia and Africa, is an aggressive cancer. It causes approximately 250 000 deaths annually[5]. It was reported that HCC exhibited a high incidence of telomerase activity and that the activity increased in accordance with the HCC degree of histological undifferentiaton which was absent in normal liver tissue[6,7]. Other reports revealed that hTERT expression was the rate-limiting determinant of HCC telomerase activity[8-10].

Doxorubicin (DOX), an antitumor antibiotic, can intercalate into base pairs of DNA and generate toxic oxygen free radicals, which not only causes single-or double-strand DNA breaks but also damages a variety of necessary macromolecules such as proteins, lipids and RNA[11]. DOX is one of the most efficient chemotherapy agents in the treatment of HCC, and its total efficiency rate can be up to 44 %[12]. However, the relationship between the efficiency of DOX and telomerase activity in HCC has not yet been elucidated. In the present study, we investigated the effects of DOX on the telomerase activity and telomere length in BEL-7404 human hepatoma cells.

MATERIALS AND METHODS

Cell and culture condition

BEL-7404 human hepatoma cell line from Cell Bank of Chinese Academy of Sciences[13], was cultured in RPMI-1640 medium (Gibco) supplemented with 10 % heat-inactivated newborn calf serum, at 37 ℃ in a humidified CO_2 incubator containing 5 % CO_2 and 95 % air.

Drug

DOX (Sigma) was dissolved in RPMI-1640 to the final concentration of 5mM and stored at 4 ℃.

Assessment of cell proliferation

An MTT assay was conducted to determine the cell proliferation. Cells were seeded at 1×10^4 cells /well in a 96-well plate and incubated overnight. The drug was added to the cultured cells with the final concentrations from 0.156 μM to 2.5 μM and culturing further for another 24, 48 or 72 h respectively. Following culture, the cells were incubated with 800 mg/L 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide(MTT, Sigma), which was used to assay the activity of mitochondrial dehydrogenases. Four hours later, 10 % sodium dodecyl sulphate - 5 % isobutanol-0.12 % hydrochloric acid solution was added to solubilize the formazan product. The plate was then incubated at 37 ℃ for another 12 h. The absorbance at 570 nm was measured with a model 550 microplate reader(Bio-Rad). The percent of cell growth inhibition was expressed as: (A-B)/A×100 %, where A was the absorbance value from the controls and B was that from the experimental cells.

Telomerase assay

Telomerase activity was assayed with PCR-based telomeric repeat amplification protocol (TRAP) as previously described[14, 15]. Cells were collected and washed with PBS, lysed in 1×3-[(3-cholamidopropyl) dimethylammonio]-1-propanesulfonic acid (CHAPS, Sigma) buffer, incubated on ice for 30 min, and centrifuged at 12 000 g for 30 min. The protein concentration was determined by Coomassie Protein Assay. Each of TRAP reactions contained 1 μg of total protein. The reaction mixture [20 mM Tris-HCl (pH 8.3), 1.5 mM $MgCl_2$, 63 mM KCl, 0.005 % Tween-20, 1mM EGTA,50 μM of each dNTPs and 0.1 μg TS (5'- AATCCGTCGAGC AGAGTT-3')] was incubated at 30 ℃ for 30 min , heated at 94 ℃ for 5 min. Then 0.1 μg of return primer ACX(5'-GCGCGG[CTTACC]$_3$CTAACC-3'), 0.1 μg of internal control primer NT(5'-ATCGCTTCTCGGCCTTTT-3'), 0.01 aM of internal control template TSNT(5'-AATCCGTCGAGC AGAGTTAAAAGGCCGAGAAGCGAT-3') and 2 units Taq DNA polymerase (Promega) were added. The reaction mixture was then subjected to 28 PCR cycles: 94 ℃ for 30s and 60 ℃for 30 s. PCR products were separated by electrophoresis on 12 % nondenaturing polyacrylamide gels and stained with SYBR Green I (FMC) for 15 min , visualized and analyzed by UVP system. In every experiment, a negative control (1 μl CHAPS lysis buffer) was included. All of experiments were repeated at least twice.

The relative telomerase activity was quantified by the formula: TP=[(A/B)/(A cell control/ B cell control)]×100

Where TP=total product, A=total intensity of telomerase product (50 bp,56 bp,62 bp..), and B=intensity of internal control (36 bp).

RT-PCR

Total cellular RNA was extracted from cells using Trizol (Life Technologies,Inc.) according to the instructions of the manufacturer. In each reaction, 1 μg of total RNA was reverse transcripted into cDNA using M-Mlv reverse transcriptase (Promega). Primer sets used to amplify specific sequences were 5'-CGGAAGAGTGTCTGGAGCAA-3' and 5'-GGATGAAGCGGAGTCGGA-3' for hTERT (146 bp); 5'-TCTAACCCTAACTGAGAAGGGCGTAG-3' and 5'-GTTTGCTCTAGAATGAACGGTGGAAG-3' for hTR (126 bp); 5'-TCAAGCCAAACCTGAATCTGAG-3' for TP1 (264 bp); 5'-GTGGGGCGCCCCAGGCACCA-3' and 5'-GTCCTTAATGTCACGCACGATTTC-3' for β-actin (539 bp). The PCR conditions of hTERT and TP1 were 94 ℃, 45s; 60 ℃, 45 s; 72 ℃, 90 s for 31 and 29 cycles, respectively. And the PCR conditions of hTR and β-actin were 94 ℃, 45 s;55℃, 45 s; 72 ℃, 90 s for 28 and 22 cycles, respectively[2].

Telomere length assay

Genomic DNA samples were prepared as described[16]. Cells were lysed and proteins were digested in 10 mM Tris-HCl (pH 8.0), 100 mM NaCl, 25 mM EDTA , 0.5 % SDS , 0.1 mg/ml proteinase K at 48 ℃ overnight. Following two extractions with phenol and one with chloroform, DNA was precipitated with ethanol and dissolved in 10 mM Tris-HCl (pH 8.0) and 1 mM EDTA (TE) Telomere length was detected using TeloTAGGG telomere length assay (Roche) according to the manufacturer's protocol. For each sample, 1 μg of genomic DNA was digested with Rsa I/Hinf I (Sigma), separated on a 0.8 % agarose gel, transferred to a nylon membrane (Amersham Hybond-N^+), and hybridized with a telomere specific digoxigenin(DIG)-labeled probe, incubated with anti-DIG-alkaline phosphatase and detected by chemiluminescence. The blotted signal was divided into 30 equidistant intervals from 1.9 to 21.2 kilobases to calculate mean telomere length (terminal restriction fragment, TRF) using the formula TRF= Σ(ODi)/ Σ(ODi/Li), where ODi was the chemiluminescent signal and Li was the length of the TRF fragment at position i[17].

Flow cytometry analysis of cell cycle and apoptosis

The cells were harvested and resuspended in the solution containing 40mM sodium citrate, 250mM sucrose and 5 % DMSO. The suspention was stored at -20℃ for 20 min, then thawed rapidly at room temperature and centrifuged to collect the cells. The cells were resuspended in a solution containing RNase A (5×10^4 unit/g, 50 mg/L) and 20 mg/L propidium iodide (PI). The cell cycle distribution and apoptosis were determined by the fluorescence of individual cells measured with flow cytometry[18].

RESULTS AND DISCUSSION

Inhibition of telomerase activity

Telomerase activity was inhibited in a dose and time-dependent manner in BEL-7404 human hepatoma cells treated with DOX (Figure 1A). To analyze the telomerase inhibition on the gene expression level, cells treated with DOX for 72 h were employed to study the telmerase mRNA expressions of its three major gene components , hTERT, hTR and TP1, using RT-PCR. Results showed that no changes were observed in the mRNA expression pattern of these subunits after the DOX exposure for 72 h with indicated concentrations (Figure 1B).

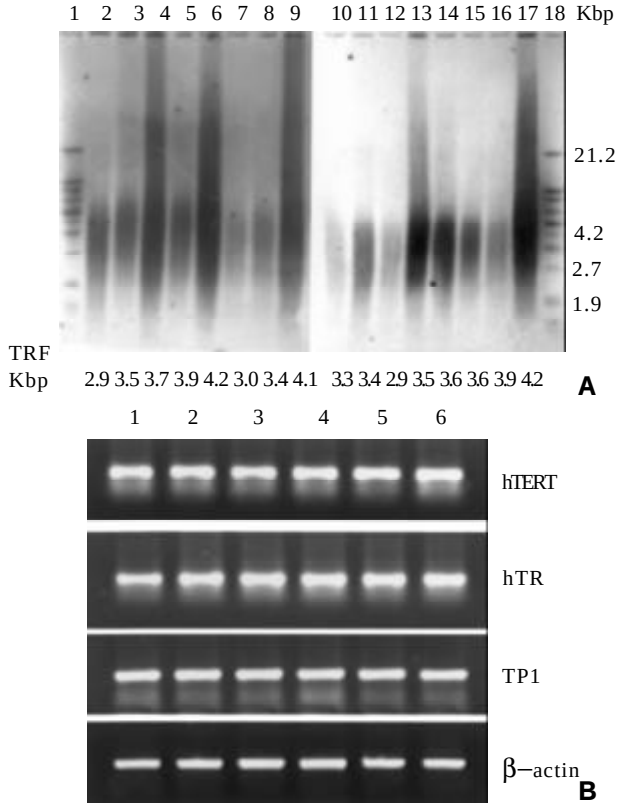

Figure 1 Telomerase inhibition by DOX in BEL-7404 human hepatoma cells. **(A)** Inhibition of telomerase activity by DOX in a dose and time-dependent manner in BEL-7404 human hepatoma cells. Lane 1, negative control; Lane 2, cell control; Lane 3–7, telomerase activity in presence of DOX for 24 h (2.5, 1.25, 0.625, 0.313 and 0.156 μM) ; Lane 8-12, telomerase activity in presence of DOX for 48 h (2.5, 1.25, 0.625, 0.313 and 0.156 μM); Lane 13-17, telomerase activity in presence of DOX for 72 h (2.5, 1.25, 0.625, 0.313 and 0.156 μM). All experiments were repeated at least twice and representative results were shown here. **(B)** RT-PCR analysis of hTERT, hTR and TP1 mRNA expression with DOX treatment for 72 h in a concentration range from 0.156

to 2.5 μM. Lane 1, cell control; Lane 2, 2.5 μM; Lane 3, 1.25 μM; Lane 4, 0.625 μM; Lane 5, 0.313 μM; Lane 6, 0.156 μM. β-actin was used as standard. Amplified sequences for hTERT, hTR, TP1 and β-actin are 146, 126,264 and 539 bp, respectively.

The first report on the telomerase inhibition by DOX was presented by Zhu et al, regarding the SW480 colon carcinoma cells[19]. However, the opposite observations were reported later, in which authors found no effect of DOX on telomerase regulation in nasopharyngeal cancer, testicular cancer and squamous cell carcinoma[20-22]. In this study, we found that the DOX treatment inhibited the telomerase activity in a dose and time-dependent manner in BEL-7404 human hepatoma cells. Considering the different results above, We think that this kind of inhibition might be cell-type specific and may be correlated with the clinical different efficiency of DOX in the treatment of different kinds and stages of tumors.

Abundant evidence indicated that the regulation of telomerase was multifactorial in mammalian cells and involves telomerase gene expression, post-translational protein-to-protein interactions, and protein phosphorylation[23]. However, there was no information regarding three telomerase subunits expression affected by DOX in Zhu's study[18]. In our investigation, there were no changes found in the expression of hTERT, hTR or TP1 mRNA. This indicated that the telomerase inhibition by DOX might be indirect with its antibiotic activity (eg.J damaging of necessary macromolecules).

Shortening of mean telomere length

Mean telomere length of BEL-7404 human hepatoma cells was decreased by the DOX treatment (Figure 2). Here, we believe that this is the first report regarding the shortening of telomere length by DOX treatment in BEL-7404 human hepatoma cells.

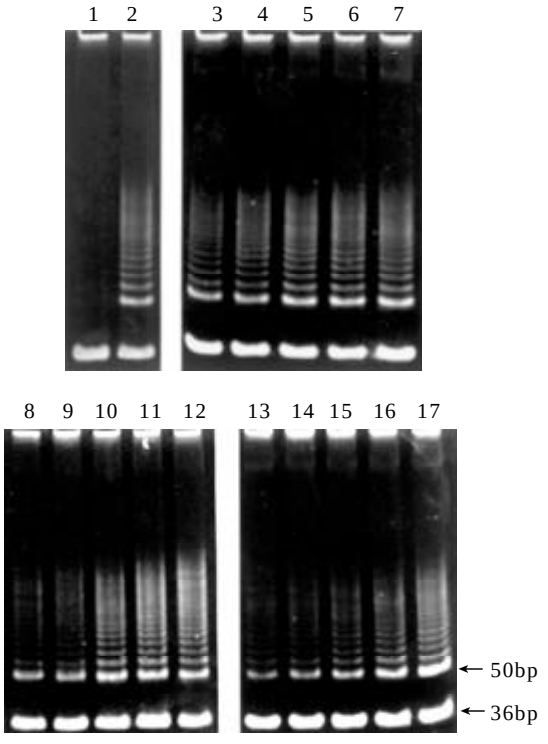

Figure 2 Shortening of mean telomere length (terminal restriction fragments,TRF) in DOX treated BEL-7404 human hepatoma cells. Lane 1 and 18, molecular marker;Lane 17,cell control; Lane 2 – 6, DOX treated for 72 h (2.5, 1.25, 0.625, 0.313 and 0.156 μM); Lane 7–11:DOX treated for 48 h (2.5,1.25,0.625, 0.313 and 0.156 μM); Lane 12-16:DOX treated for 24 h (2.5,1.25, 0.625, 0.313 and 0.156 μM).

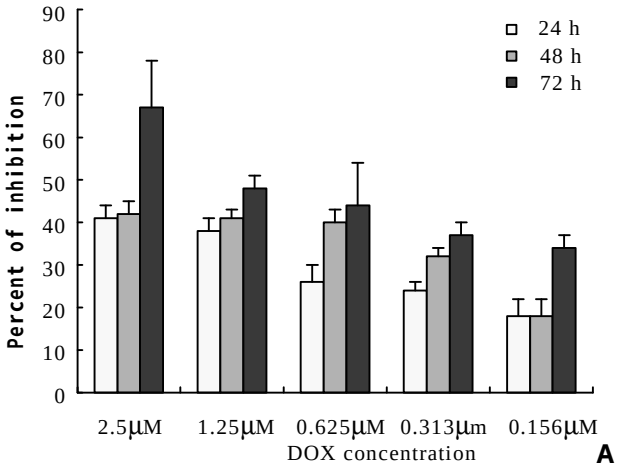
Compared with normal cells and some other carcinoma cells (such as Hela cells), the mean telomere length of BEL-7404 human hepatoma cells is relatively short. As a result, the hepatoma cells are sensitive to telomere shortening, which may account, at least in part, for their chemosensitivity. Results from telomere shortening by cisplatin indicate that the nucleotide-excision repair system and cell division dynamics might be involved in the telomere shortening process, which make the process showing in a non- dose or time dependent manner[24]. We assume that both of the factors may likewise participate in telomere shortening by DOX, because DOX can intercalate into DNA base pairs and result in non-dose or time dependent manner of telomere shortening.

Accumulation of cell cycle in G_2/M phase

The cell growth inhibition and cell cycle progression during DOX treatment were monitored in the present study to correlate these effects with telomerase activity inhibition and telomere loss. The growth of BEL-7404 cells was inhibited by DOX, which was indicated in (Figure 3 A). Following exposure to DOX, the hepatoma cells were accumulated in G_2/M phase, which revealed by flow cytometry (Figure 3 B). There were no marked changes observed in cell apoptosis in the experimental cells exposure to DOX for 24, 48 or 72 h with the concentrations from 0.156 to 2.5 μM, compared with the control cell.

Zhu *et al*[19] attributed the reduction in telomerase activity by DOX to the accumulation of cell cycle in G_2/M phase. But Holt *et al*[25] found that telomerase inhibition did not correlate with the cell cycle arrested at G_2/M phase but with the increasing in cell death. In present study, the cell apoptosis did not increase markedly compared with the control. Our previous research has also showed that antisense oligonucleotide to telomerase RNA component accumulated the cell cycle in G_2/M phase [26]. The present observation confirmed the reports above, which indicated that telomerase inhibition was correlated with the cell cycle arrested at G_2/M phase.

Previously, Ishibashi *et al*[24] have reported that telomere loss in HeLa cells associated with the apoptosis inducted by cisplatin. However, in our investigation the percent of cell apoptosis did not change markedly (Figure 3 B), although the mean telomere length was reduced by DOX. In BEL-7404 human hepatoma cells, we previously found that the cell apoptosis occurred when the mean telomere length reached to about 1.7Kb[27]. In this study, the mean telomere did not reach to this critical length, and the apoptosis had not been induced which was consistent with the previous observation. Therefore, we deduce that telomere shortening may not be correlated with the apoptosis.



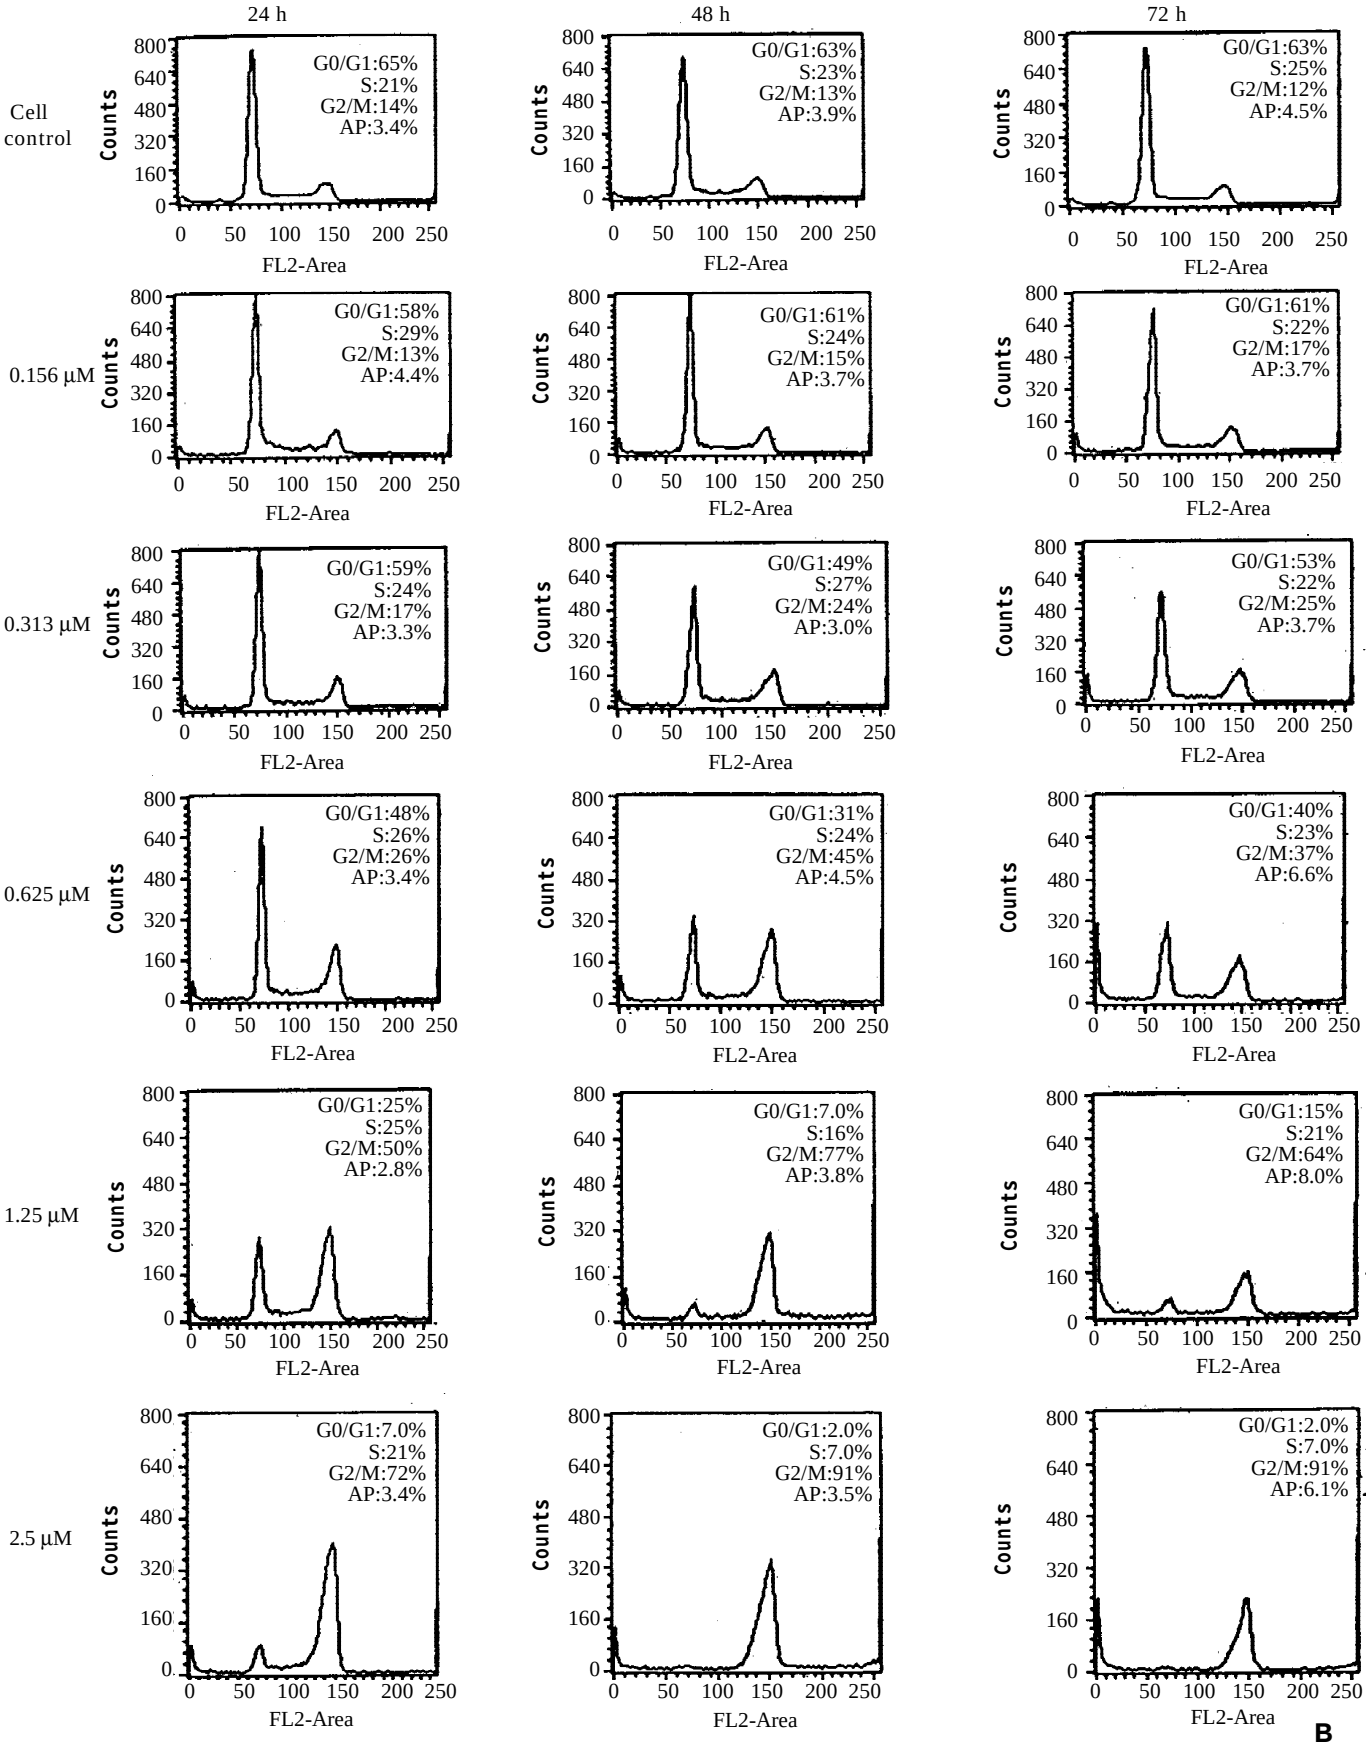


Figure 3 Effects of DOX on cell growth, cell cycle and cell apoptosis in BEL-7404 human hepatoma cells.
(A) Growth inhibition of BEL-7404 human hepatoma cells treated with DOX. Each value represents mean ± SD from triplicate wells. **(B)** Cell cycle distribution and apoptosis in DOX treated BEL-7404 human hepatoma cells, analyzed by flow cytometry. Cell cycle was arrested at G_2/M with the treatment of DOX. Histograms of DNA contents of untreated cell control and treated with 0.156, 0.313, 0.625, 1.25 and 2.5 μM were shown. Cells were maintained in the presence of DOX for 24, 48, and 72 h without a change in medium and collected at the times indicated. AP means the percent of apoptosis.

Many studies have shown that the telomerase activity was correlated with the cell growth[28]. Our finding also revealed a good correlation between the inhibition of telomerase activity and the reduction in cell growth. However, in this study, the cell growth inhibition was mainly the result of cell cycle arrest, but not the increasing of cell apoptosis.

In conclusion, we found that telomerase activity was inhibited in a dose and time - dependent manner and mean telomere length was decreased by the treatment of DOX in BEL-7404 human hepatoma cells. This process correlated with the cell growth inhibition and the cell cycle accumulation in G_2/M phase. The present study indicates that the telomerase inhibition and the telomere shortening by DOX may contribute to its efficiency in the treatment of HCC.

Abstract

AIM: To study the apoptosis of hepatoma cells SMMC-7721 induced by polysaccharide isolated from *Ginkgo biloba* seed.

METHODS: *Ginkgo biloba* seed polysaccharide (GBSP) was isolated by ethanol fractionation of *Ginkgo biloba* seed and purified by Sephadex G-200 chromatography. The purity of GBSP was verified by reaction with iodine-potassium iodide and ninhydrin and confirmed by UV spectrophotometer, cellulose acetate membrane electrophoresis and Sepharose 4B gel filtration chromatography. The Scanning Electron Microscope (SEM) and Flow Cytometry (FCM) were used to examine the SMMC-7721 cells with and without GBSP treatment at 500 mg/ml for 36 h.

RESULTS: GBSP product obtained was of high purity with the average molecular weight of 1.86×10^5. Quantitative analysis of SMMC-7721 cells *in vitro* with FCM showed that the percentages of G_2-M cells without and with GBSP treatment were 17.01 ± 1.28 % and 11.77 ± 1.50% ($P<0.05$), the debris ratio of the cells were 0.46 ± 0.12 % and 0.06 ± 0.06 % ($P<0.01$), and the apoptosis ratio of cells was 3.84 ± 0.55 % and 9.13 ± 1.48 %($P<0.01$) respectively. Following GBSP treatment, microvilli of SMMC-7721 cells appeared thinner and the number of spherical cells increased markedly. Most significantly, the apoptosis bodies were formed on and around the spherical cells treated with GBSP.

CONCLUSION: GBSP could potentially induce the apoptosis of SMMC-7721 cells.

INTRODUCTION

Ginkgo biloba L., also named after white-seed tree and gongsun tree, is one of the immemorial gymnosperm of the mesozoic era. It is regarded as a living fossil and is also best known for its pharmaceutical value. According to Pen-ts' so Kan-mu (i.e. Compendium of Materia Medica), *Ginkgo biloba* L. can help cure about 20 different diseases. More recently, it has been widely accepted that flavonoid and terpeneand are the effective components of leaves of *Ginkgo biloba*[1-5] for treating cardiovascular and nervous system diseases, scavenging free radicals and antioxidating, etc.[6-11]. Water-soluble polysaccharides of *Ginkgo biloba* leaves, endocarp, seeds and cultured cells were isolated and purified and their structures and some biological activities such as immunoregulation, antineoplastic action, scavenging free radicals and antioxidating were identified[12-16]. Furthermore, *in vivo* and *in vitro* induction of apoptosis of cancer cells by polysaccharides has been reported lately[17-22]. However, there was no report about the effects on apoptosis of tumor cells by polysaccharides isolated from *Ginkgo biloba* L. except from *Ginkgo biloba* endocarp[23]. In this study, high-purity polysaccharide was extracted from *Ginkgo biloba* seeds and the apoptotic effect of *Ginkgo biloba* seed polysaccharides (GBSP) on hepatoma cell line SMMC-7721 was investigated by scanning electron microscope (SEM) and flow cytometry (FCM).

MATERIALS AND METHODS

Materials

High-quality *Ginkgo biloba* seeds (*i.e.* milkwhite color, equal weight, and smooth surface without mildew) were purchased from Jianlian Chinese Traditional Medicine Store in Jinan, Shandong Province. Hepatoma cell line SMMC-7721 was obtained from Shanghai Cell Institute, China Academy of Sciences. Culture medium RPMI1640 was obtained from Gibco Co. (USA). Sephadex G-200, Sepharose 4B, monose as standard, calf serum and propidium iodide (PI) were obtained from Sigma Co. (USA).

Isolation and purification of GBSP

Ginkgo biloba seeds of 200 g were crushed into fine particles and extracted with 3000 ml of distilled water for 8 hours at 75 ℃ for 3 times. The extracts were pooled, concentrated to 30 % of the original volume in a rotary evaporator at 45 ℃ and then centrifuged at 3000 rpm for 15 min. The supernatant was collected and added with 3 volumes of 95 % ethanol to precipitate the polysaccharide. Following centrifugation at 4000 rpm for 15 min, the polysaccharide pellet was dissolved in appropriate volume of distilled water completely, dialyzed with distilled water and decontaminated by means of Sevag to remove protein. The polysaccharide was then freeze-dried, re-dissolved in salt solution and purified further by Sephadex G-200 chromatography. The purity of the resulting GBSP was analyzed by Sepharose 4B gel filtration chromatography and cellulose acetate membrane electrophoresis[24].

Culture of SMMC-7721 cells and treatment with GBSP[25-28]

The SMMC-7721 cells were grown to logarithmic phase of proliferation, washed 3 times with culture medium RPMI1640 and collected at a concentration of 10^6 cells /ml. This cell suspension was then aliquoted into 6 culture bottles and cultured at 37 ℃ and 5 % CO_2 (CO_2 incubator, MCO-17AC, SANYO, Japan) for 24h. For cultures that were prepared for

SCM test, cover slips were placed into bottles in advance. After the cells stuck on the walls of culture bottles, GBSP solution made up with culture medium was added into 3 of 6 culture bottles at the final concentration of 500 mg/ml. The other 3 culture bottles were added with equal volume of culture medium. The cells were cultured for further 36 h under the same conditions.

Flow Cytometry[29-31]

Supernatants of the cultures were discarded and SMMC-7721 cells with and without GBSP treatment were collected by digestion with pancreatin followed by centrifugation. PI was added to the cells for 15 min to label DNA. FCM (FACS/420, Becton Dickinson, USA) was used to analyze cell cycles and apoptosis ratios.

Scanning Electron Microscopy[32-33]

Supernatants of the cultures were discarded and SMMC-7721 cells stuck on the cover slips with and without GBSP treatment were examined by SEM (S-570, Hitachi, Japan).

RESULTS

Characterization of GBSP

One of the objectives of this work was to obtain high-purity GBSP product from the G*inkgo biloba* seeds. The purity of GBSP was first tested by reactions with iodine-potassium iodide and ninhydrin respectively. The results of these two reactions were negative, indicating absence of starch and protein in the GBSP product obtained. The reaction of GBSP with Molish reagent was positive, indicating that the GBSP product was composed of monose. The GBSP solution was then analyzed by UV absorption (UV-1200, The Second Beijing Optical Instrument Manufactory, China). As shown in Figure 1, there were no peaks at wavelengths of 260nm and 280nm on the UV spectrum, indicating that the GBSP product was not contaminated with nucleic acid and protein. The purity of GBSP was further analyzed by Sepharose 4B gel filtration chromatography and cellulose acetate membrane electrophoresis. The elution profile of Sepharose 4B was a single symmetrical peak (Figure 2). The cellulose acetate membrane electrophoresis displayed a single stripe of GBSP on the membrane. These indicated that the present GBSP was of high purity. The average molecular weight of the GBSP was 1.86×10^5 based on the linear calibration curve derived from Sephadex G-200 chromatography, as shown in Figure 3.

G_2-M cell ratio with and without GBSP treatment

The percentages of G_2-M cells without and with GBSP treatment were 17.01%±1.28% and 11.77%±1.50%($P<0.05$) respectively (Figures 4, 5 and Table). This indicated that GBSP inhibited the proliferation of SMMC-7721 cells.

Table 1 The cycles and apoptosis ratios of SMMC-7721 cell with and without GBSP treatment

GBSP treatment (mg/ml)	Number of culture bottles tested	G_2-M cell ratio (%)	Apoptosis cell ratio (%)	Debris ratio (%)
0	3	17.01±1.28	3.84±0.55	0.46±0.12
500	3	11.77±1.50[a]	9.13±1.48[b]	0.06±0.06[b]

[a]$P<0.05$, [b]$P<0.01$ *vs* control group (*t* test)

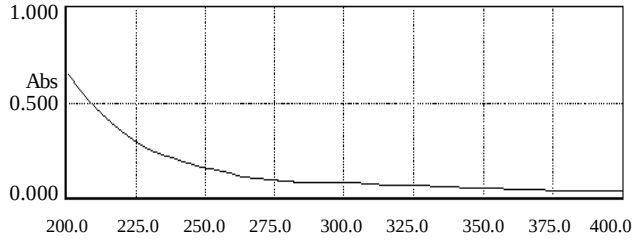

Figure 1 The UV spectrum adsorption curve of GBSP from 200nm to 400nm

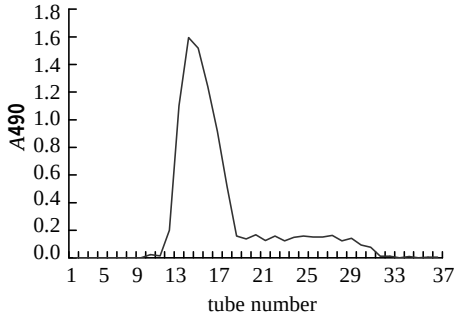

Figure 2 The profile of Sepharose 4B gel filtration chromatography

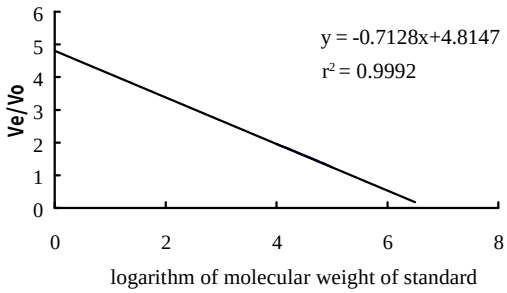

Figure 3 Standard linear calibration curve of Sephadex G-200 chromatography

Apoptosis ratio of the SMMC-7721 cell with and without GBSP treatment

The apoptosis ratio of SMMC-7721 cells without GBSP treatment was 3.84±0.55 % (Figure 4 and Table 1). After GBSP treatment, the apoptosis ratio increased to 9.13±1.48 % ($P<0.01$ *vs* control group) (Figure 5 and Table 1). The debris ratio of the cells without and with GBSP treatment was 0.46± 0.12 % and 0.06±0.06 %, respectively ($P<0.01$) (Figures 4, 5 and Table 1). These results showed that GBSP could induce and promote the apoptosis of SMMC-7721 cells, rather than kill SMMC-7721 cells directly.

Morphology of the SMMC-7721 cell with and without GBSP treatment

The morphology of SMMC-7721 cells with and without GBSP treatment was studied by SEM. The majority of SMMC-7721 cells without GBSP treatment was of shuttle shape (Figure 6) and small proportion of cells was of spherical shape. Close examination revealed dense microvilli on the surface of the cells, and occasionally, 2 to 3 protuberances were also observed on the cell surface. After the treatment of GBSP, these microvilli became thinner, protuberances disappeared (Figure 7) and number of spherical cells increased markedly. These spherical cells shrunk

so that their volume decreased and wrinkles were formed on their surface. Most significantly, apoptosis bodies were formed on and around the spherical cells (Figure 7). These observations suggest that GBSP could induce apoptosis in hepatoma cell line SMMC-7721, consistent with the results of FCM analysis.

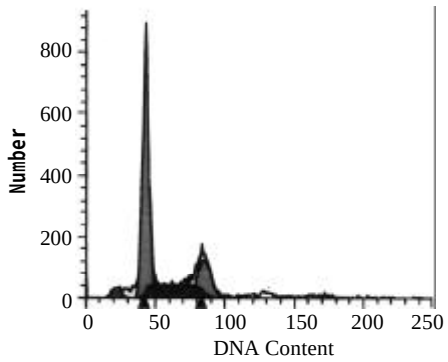

Figure 4 In the absence of GBSP treatment, the apoptosis ratio of SMMC-7721 cells was 3.84±0.55 %, the cells debris was 0.46 ±0.12 % and the percentage of G2-M cells was 17.01±1.28 %.

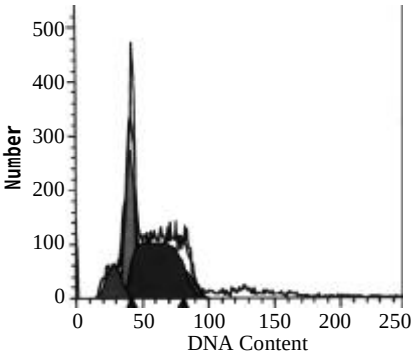

Figure 5 In the presence of GBSP treatment, the apoptosis ratio of SMMC-7721 cells was 9.13±1.48 %, the cells debris was 0.06±0.06 %,and the percentage of G2-M cells was 11.77±1.50%.

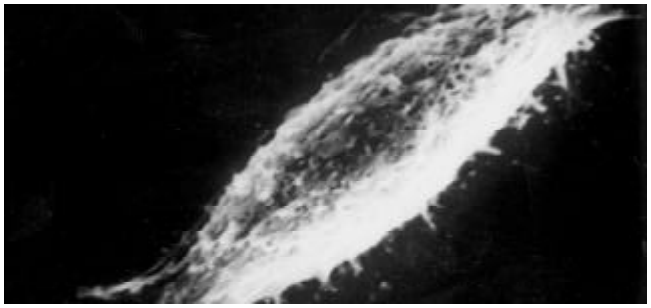

Figure 6 The majority of SMMC-7721 cells were of shuttle shape without GBSP treatment (×2500)

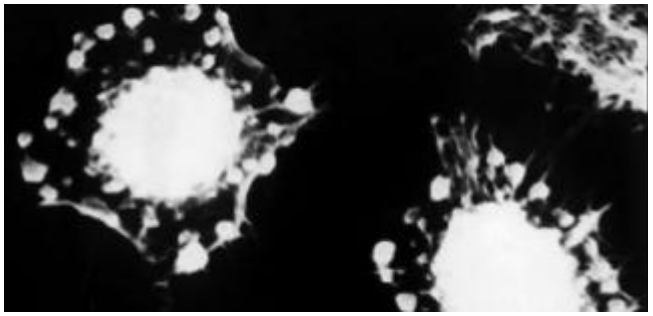

Figure 7 There were more spherical SMMC-7721 cells after GBSP treatment (×2200). These cells shrunk and apoptosis bodies were formed on and around them.

DISCUSSION

The expansion of neoplasma is associated with inhibition of apoptosis of tumor cells. There is evidence that high expression of the inhibition gene bcl-2 led to inactivation of the tumor suppression gene p53[34-45]. When apoptosis was inhibited, tumour cells would not be eliminated in time *in vivo* and, therefore, would proliferate and diffuse more rapidly. At present, drugs such as VP-16, ADR, MTX, and Hydroxyl urea etc. are commonly used in clinical chemotherapy. These agents interfere with growth, metabolism and proliferation processes of the cells so that the apoptosis of tumour cells can be induced [46-48]. However, like most of chemotherapical medicines, they have cytotoxic side-effects which cause damage to normal cells while killing neoplasma cells.

Experiments showed that ingredients of Chinese herbal medicine could induce apoptosis in tumour cells. For example, β-elemi-olefin, arabinose-cytidine and etoposide could induce apoptosis in leukemia cell line[49-55]. It was also reported that polysaccharides isolated from Chinese herbs could inhibit the growth of tumour by activating immune system *in vivo* rather than killing tumour cells directly[56,57]. In this *in vitro* study, we found that GBSP could effectively inhibit division of the SMMC-7721 cells and, meanwhile, induced apoptosis in hepatoma cell line SMMC-7721. Although *Ginkgo biloba* seed has been mainly used for treatment of asthm for over hundred years, it has not been known to have anti-tumour activity. The results of our present study provided valuable data for exploring the clinical application of GBSP for cancer therapy.

Abstract

AIM: The aims of this study were to identify the clinicopathological features of Chinese HNPCC families and to evaluate the value of criteria for suspected HNPCC (sHNPCC) in clinical diagnosis.

METHODS: According to the follow-up records, 54 HNPCC families (including 12 ICG-HNPCC families and 42 sHNPCC families) were screened out from patients with colorectal cancers (CRCs), operated upon in 2nd Affiliated Hospital of Zhejiang University from 1984 to 2001. Clinical data of probands and tumor spectrum in these families were listed and analyzed.

RESULTS: (1) Mean age, proportion of colonic cancer, poorly differentiated cancer, multiple CRCs and Dukes' A+B of the probands in ICG-HNPCC and sHNPCC kindred were 39ys and 47.5ys, 75 % and 62 %, 0 and 12.8 %, 16.7 % and 14.3 %, 58.3 % and 81 %,respectively. Compared with sporadic colorectal cancers, probands from ICG-HNPCC and sHNPCC families were obviously different at age of onset(P=0.025 and 0.031), tumor location (P=0.001 and 0.000), differentiation(P=0.002 and 0.011) and development of multiple tumors (P=0.014 and 0.002). (2) A total of 178 malignant neoplasms were found in 54 HNPCC families, including 139 colorectal cancers. Besides of colorectal cancer, extracolonic tumors occurred in stomach, endometrium, hepatobiliary system, and so on (8 gastric cancers, 6 endometrial cancers, 6 hepatobiliary system cancers and 19 others) can also be seen in Chinese ICG-HNPCC and sHNPCC families.

CONCLUSION: (1) Chinese HNPCC families have specific clinicopathological features, such as early onset, predilection for the involvement of colon, tendency of multiple CRCs, development of extracolonic tumors and well differentiation. (2) The criteria for suspected HNPCC is useful in clinical diagnosis and management of HNPCC.

INTRODUCTION

Colorectal cancer (CRC) is one of the most common malignant tumors. Various factors and mechanisms are involved in the development of CRC[1-5]. In recent years, much progress has been made in the studies of CRC[6-13], but its morbidity is still rising[14,15]. It has been thought that one-third of CRC have a genetic background. Hereditary nonpolyposis colorectal cancer (HNPCC) is a common autosomal dominant colorectal disorder with special clinicopathological features[16]. In clinic, it is diagnosed by Amsterdam criteria[17]: (1) three or more relatives with histologically verified colorectal cancer, one of whom is the first-degree to the other two; (2) colorectal cancer affecting at least two generations; and (3) one or more colorectal cancer cases diagnosed before the age of 50. Families fulfilling Amsterdam criteria were named as ICG-HNPCC in this study. As the criteria are too rigid for small families and it excludes extracolonic cancers associated with HNPCC, the Korean Hereditary Colorectal Cancer Registry designated the term"suspected HNPCC" [18] and designed its criteria for the families who do not fulfill Amsterdam criteria but in whom a genetic basis for colorectal cancer is strongly suspected. The criteria for suspected HNPCC are as following: (1) vertical transmission of colorectal cancer or at least two siblings affected with colorectal cancer in a family and (2) development of multiple colorectal tumors (including adenomas), or at least one colorectal cancer case diagnosed before the age 50, or development of extracolonic cancer in family member. Families fulfilling these criteria were named as sHNPCC in this paper. The criteria were accepted by the International Collaborative Group (ICG) on HNPCC for international collaborative studies. It[19] had been reported that ICG-HNPCC and suspected HNPCC have the similar molecular basis and genetic background. In China, there is still no systematic research on ICG-HNPCC or sHNPCC. Therefore, it is necessary and urgent to find out the characteristics of HNPCC in Chinese populations.

In this study we were to find out clinical phenotype of Chinese HNPCC families and to evaluate whether the criteria for suspected HNPCC is useful in clinical diagnosis and management of HNPCC.

MATERIALS AND METHODS

According to the follow-up records, 54 probands from HNPCC families (including 12 ICG-HNPCC families and 42 s HNPCC families) were screened out from patients with colorectal cancers operated upon in 2nd Affiliated Hospital of Zhejiang University from 1984 to 2001. Their clinicopathological features were compared with those of sporadic CRCs operated upon in the hospital[20]. There were 34 male and 20 female, age ranged from 19-76ys (average 45.7), 35 cases of colonic cancer and 19 cases of rectal cancer.The tumor spectrums in these families were also analyzed. All patients were diagnosed by Amsterdam criteria or criteria for suspected HNPCC.

All data were analyzed by software STATISTICA 5.0. A value of P<0.05 is considered to be statistically significant.

RESULTS

Clinicopathological features of Chinese HNPCC families

Data of 54 probands with HNPCC and sporadic CRCs were listed in Table 1. From Table 1, we found that mean age of the probands of 12 ICG-HNPCC families was 39ys, proportion of

colonic cancer, well differentiated cancer, poorly differentiated cancer, mucinous tumor, Dukes' A+B and multiple CRCs were 75 %, 54.5 %, 0 %, 8.3 %, 58.3 % and 16.7 % respectively. For the probands of 42 sHNPCC families were 47.5ys, 62 %, 30.8 %, 12.8 %, 21.4 %, 81 % and 14.3 % respectively. Compared with sporadic colorectal cancers, probands from ICG-HNPCC families were obviously different at mean age (P=0.025), tumor site (P=0.001), tumor differentiation (P=0.002) and multiple tumors (P=0.014). Similar result was obtained when compared probands of sHNPCC families to sporadic cases: there were obviously different at mean age (P=0.031), tumor site (P=0.000), tumor differentiation (P=0.011) and multiple tumors (P=0.002).

Table 1 Clinical data of 54 probands

Parameters		ICG-HNPCC	sHNPCC	Total	Sporadic CRC
Sex	male	6(50%)	14(33.3%)	20(37%)	319(43%)
	female	6(50%)	28(66.7%)	34(63.0%)	423(57%)
Mean age		39y	47.5y	45.7y	56y
tumor site	colon	9(75.0%)	26(62.0%)	35(64.8%)	226(30.5%)
	rectum	3(25.0%)	16(38.0%)	19(35.2%)	516(69.5%)
Dukes' stage	A+B	7(58.3%)	34(81.0%)	41(75.9%)	347(47.8%)
	C+D	5(41.7%)	8(19.0%)	13(24.1%)	380(52.2%)
Differentiation	high	6(54.5%)	12(30.8%)	18(36.0%)	89(15.3%)
	moderate	5(45.5%)	22(56.4%)	27(54.0%)	397(68.1%)
	poorly	0	5(12.8%)	5(10.0%)	97(16.6%)
Pathology	mucinous tumors	1(8.3%)	9(21.4%)	10(18.5%)	159(21.4%)
	Non-mucinous tumors	11(91.7%)	33(78.6%)	44(81.5%)	583(78.6%)
Multiple CRCs		2(16.7%)	6(14.3%)	8(14.8%)	25(3.4%)

Except mean age (P=0.035), there was no obvious statistical difference between probands of ICG-HNPCC and sHNPCC families, in clinicopathological features: tumor site (P=0.402), Dukes' stage (P=0.106), tumor differentiation (P=0.147), Pathology (P=0.303) and multiple tumors (P=0.838).

Tumor spectrum in HNPCC families

A total of 178 malignant neoplasms were found in 54 HNPCC families including 139 colorectal cancers, 8 gastric cancers, 6 endometrial cancers, 6 hepatobiliary cancers and 19 others. In 12 ICG-HNPCC families, there were 53 tumors, including 47 CRCs, and each family had 3.92 CRCs patients. In 42 sHNPCC families, there were 125 tumors, including 92 CRCs, and each family had 2.19 CRCs patients. Except CRCs, carcinomas of stomach, endometrium, hepatobiliary system and urologic system were the most common extracolonic malignancies in HNPCC families. Extracolonic malignancies were less in ICG-HNPCC than those in sHNPCC.

Table 2 Tumor spectrum in HNPCC families

Organs	ICG-HNPCC	sHNPCC	Total
CRCs	47	92	139
Stomach	1	7	8
Endometrium	0	6	6
Hepatobiliary system	2	4	6
Lymphatic/hemato-poieticsystem	1	1	2
Esophage	0	2	2
Breast	0	1	1
Urologic system	0	5	5
Pancreas	1	0	1
Others	1	7	8
Total	53	125	178

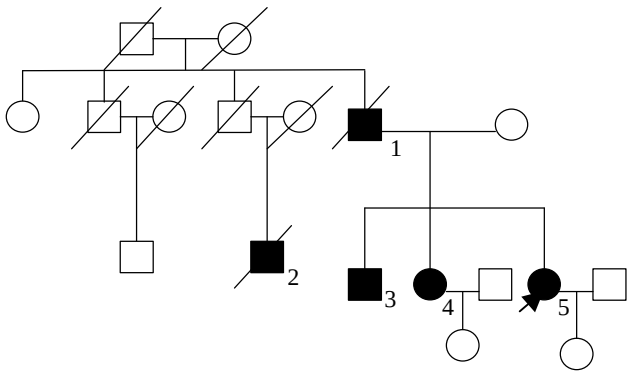

Figure 1 Pedigree of a ICG-HNPCC family.
1: father of proband, with CRC in 64ys, dead; 2: son of proband's uncle, with liver cancer, dead; 3: little brother of proband, with colonic polyps; 4: little sister of proband, with colonic cancer in 40ys, with gastric cancer 1 year later, alive; 5: arrow indicates the proband, 48ys, with colonic cancer, alive.

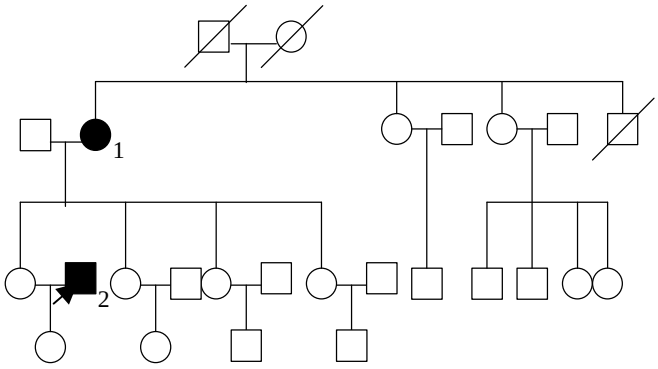

Figure 2 Pedigree of a sHNPCC family. 1: mother of proband, with CRC in 55ys, alive(80ys); 2: arrow indicates the proband, 38ys, with rectal cancer,alive.

DISCUSSION

In 1913, Warthin first described some families with an excess of colorectal, uterine and gastric cancers. It took more than half a century before Lynch undertook the task of collecting data that led to accurate description of these cancer-prone families[21]. According to the absence or presence of extracolonic malignancies, these families were divided into Lynch Ⅰ syndrome and Lynch Ⅱ syndrome[22]. Later, the syndrome was specifically called HNPCC. So HNPCC is also called Lynch syndrome.

HNPCC is an autosomal dominant disorder with special clinicopathological features[23-27], early onset (average <45ys), high frequency of cancers in proximal colon (60-70 %), excess of synchronous (18.1 %) and metachronous (24.2 %) tumors, development of extracolonic malignancies, excess of mucinous (30-40 %) and poorly differentiated tumors (23-39 %). It is often diagnosed by Amsterdam criteria, but the criteria is too strict for little families with strong genetic basis for CRCs, then sHNPCC criteria will be useful.

Mo[28] had described 10 Chinese HNPCC kindred. Among 10 kindred, patients had a mean age of 44.8ys and showed an excess of multiple CRCs (20.2%), a high frequency of cancers in colon (82.3 %). Zhao[29] got the similar results. In our study, compared with sporadic CRCs, 12 probands of ICG-HNPCC kindred showed special features, such as early onset (P<0.05),

predilection for involvement of colon (P<0.05) and tendency of multiple CRCs (P<0.05). They also had well but not poorly differentiated appearance (proportion of well differentiated cancer, poorly differentiated cancer, mucinous tumors and Dukes' A+B were 54.5 %, 0, 8.3 % and 58.3 % respectively). Perhaps it was due to the small sample of our study or the racial difference.

For the families who do not fulfill Amsterdam criteria but in whom a genetic basis for colorectal cancer is strongly suspected, sHNPCC criteria were used. It was proved that sHNPCC had the similar genetic background with ICG-HNPCC[19]. In our study, 42 probands of sHNPCC kindred had the similar clinicopathological features with ICG-HNPCC, early onset (mean age 47.5ys), predilection for involvement of colon (62 %), tendency of multiple CRCs (14.3 %) and well differentiation appearance.

No obvious difference was found between ICG-HNPCC and sHNPCC in their clinicopathological features (P>0.05), except the mean age (P<0.05). This difference might be due to the limited cases studied. According to phenotype of Chinese ICG-HNPCC and sHNPCC, it indicated that they might have similar genetic background. The criteria for sHNPCC will be helpful for clinical diagnosis and treatment of HNPCC.

Except CRCs, extracolonic tumors were often seen in HNPCC kindred[30-41], such as cancers of ovary, brain, small bowel, urologic system, breast, larynx, stomach, pancreas and biliary system as well as leukemia, lymphoma, soft tissue sarcoma, desoid tumor and cutaneous tumors. Gastric cancer, endometrial cancer, carcinomas of hepatobiliary system were the most common extracolonic malignancies. In our study, gastric cancer, endometrial cancer, carcinomas of hepatobiliary system and urologic system were the four common extracolonic malignancies. Cancers of esophagus, breast, pancreas, leukemia and lymphoma were also seen in Chinese HNPCC kindreds. We also found that extracolonic malignancies were less seen in ICG-HNPCC than those in sHNPCC, perhaps it was due to the limited cases studied.

Our results suggest that both ICG-HNPCC and sHNPCC families in China had the clinicopathological features, early onset, predilection for involvement of colon, tendency of multiple CRCs, extracolonic tumors and well differentiated appearance. They might have the similar genetic background. In recent years, Chinese families are becoming smaller and smaller due to the practising of family planning[42]. So criteria for sHNPCC will become more and more useful in clinical diagnosis of HNPCC. Now in China, establishment of HNPCC registry, genetic counseling and surveillance of high-risk asymptomatic family members are important and necessary. Endoscopic surveillance is recommended if any tumor found in some cases, and prophylactic operation is suggested[43-49].

Abstract

AIM: Our previous studies showed increased sensitivity to 5-FU in colon cancer cell lines with microsatellite instability, and considered that mutations of TGFβ-RⅡ, IGFⅡR, RIZ gene might enhance the potentials of cell growth and proliferation, which increased the sensitivity to 5-FU. Here we compared the distribution of cell cycle and P53 status between two human colon cancer cell lines with different sensitivity to 5-FU. Because mechanistic differences exist between 5-FU and CDDP, we also analyzed the efficacy of CDDP and combination therapy on two human colon cancer cell lines.

METHODS: We compared the sensitivity to CDDP of these two cell lines by MTT assay. Distribution of cell cycle under treatment of 5-FU, CDDP alone or both was analyzed by Flow Cytometry, and expression of P53 was detected by immunocytochemical staining.

RESULTS: SW480 cells were more sensitive to CDDP than LoVo cells at the concentrations above 16 μmol/l (Ratio of absorption is 0.64 and 0.79 at 16 μmol/l, respectively; $P<0.01$). Efficacy of combination therapy was conversely lower than that of single-therapy of 5-FU (Ratio of absorption in LoVo+5-FU, SW480+5-FU, LoVo+5-FU+CDDP and SW480+5-FU+CDDP is 0.53, 0.54, 0.72, 0.78, respectively; $P<0.01$). LoVo cells were negative whereas SW480 cells positive in P53 expression. 5-FU induced G1-phase arrest in both cell lines, but LoVo cells peaked 24 hours earlier than SW480 cells, and 48 hours earlier for an apparent hypodiploid DNA. However, CDDP showed the contrary, inducing S-phase arrest, and SW480 cells peaking 36 hours earlier. Both cell lines showed hypodipliod nuclei 48 hours after CDDP treatment. Percentage of cells in G1-phase and S-phase dominated alternatively under combination therapy in both cell lines.

CONCLUSION: These results suggest that colon cancer cells with microsatellite instability are more sensitive to 5-FU, whereas more resistant to CDDP. Combination therapy of 5-FU and CDDP shows fewer efficacies than 5-FU single-therapy, although it can render a cell cycle arrest. P53 may be involved in the shift of G1-phase to S-phase, but inessentially.

Chen XX, Lai MD, Zhang YL, Huang Q. Less cytotoxicity to combination therapy of 5-fluorouracil and cisplatin than 5-fluorouracil alone in human colon cancer cell lines. *World J Gastroenterol* 2002; 8(5): 841-846

INTRODUCTION

5-FU is currently the first-line agent for colorectal cancer after surgical cytoreduction with an overall response rate of less than 15 %[1,2], this has stimulated intensive effort in the development of novel compounds with improved pharmacological properties and new regimens for colorectal cancer patients. Efforts have been made in combination of 5-FU with several second-line agents, such as paclitaxel, mitomycin, calcium folinate, INF-α, irinotecan, leucovorin, suramin and tegafur, and so on, unfortunately, improvement is far from satisfaction. Our studies previously demonstrated that colorectal cancer cell lines with microsatellite instability showed increased sensitivity to 5-FU, and that mutations were found in 8 loci from different genes, among which 3 loci harbored in the exon of TGF-RⅡ, IGFⅡR, and RIZ, respectively. All these three genes are closely associated with cell growth and proliferation. On basis of these results, we proposed that these mutations may enhance the proliferative potentials of cancer cells and increase chemosensitivity to 5-FU.

In this study, We explored the differences of cell cycle arrest and apoptosis between two cell lines under 5-FU treatment, and found that in G1-phase arrest and presence of hypodiploid DNA in LoVo cells happened 48 hours earlier than that in SW480 cells. Because the options available to colorectal cancer patients for second-line therapy were limited, and mechanistic differences existed between 5-FU and CDDP, we analyzed the efficacies of CDDP and combination therapy on these two cell lines. Results indicated that SW480 cells were more sensitive to CDDP than LoVo cells, and that combination therapy of 5-FU and CDDP showed less efficacy than single-therapy of 5-FU in both cell lines, although it can render a cell cycle arrest. P53 may be involved in the entry of G1-phase to S-phase, but inessentially.

MATERIALS AND METHODS

Cell lines

LoVo, a human colon adenocarcinoma cell line, was purchased from the Shanghai Institute of Cell Biology, Chinese Academy of Sciences, Shanghai, China; SW480, a human colon adenocarcinoma cell lines, was donated by the Cancer Institute, Zhe Jiang University. They were maintained in RPMI1640 supplemented with 10 % fetal bovine serum in a humidified 5 % CO_2 atmosphere at 37 ℃.

Drugs and agents

5-fluorouracil (5-FU), [cis-diamminedichloroplatinum (Ⅱ)] (cisplatin/CDDP), 3-[4-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT), dimethylsulfoxide (DMSO) and propidium iodide (PI), were all purchased from the Sigma Chemical Co. The primary mouse antibody of P53 (DO-7), biotinylated anti-mouse immunoglobulin, horseradish peroxidase-conjugated streptavidin, and the chromogenic substrate solution 3,3-diaminobenzidine were bought from Santa Cruz Biotechnology (Santa Cruz, CA, USA).

MTT assay

MTT assay was performed as described by Lu *et al*[3]. Briefly, logarithmically growing cells were seeded in the 96-well plate at a concentration of 1×10^4 per well and incubated for 12 hours. Then medium with various concentrations of drugs was added in quadruplicate and exposed for 72 hours. The culture medium was then removed and about 300 μl fresh medium containing 0.5 mg/ml MTT was added to each well. 4 hours later, the medium was replaced with 100 μl DMSO and vortexed for 10 minutes. Absorbance (A) was then recorded at 570nm using an Enzyme-linked Immunosorbent Assay device DG3022A. Cell viability was assessed as follows: Viability [%]=$A_{treat}/A_{control}\times100$ %.

Immunocytochemical staining

Immunocytochemical staining was performed using DO-7 anti-P53 on logarithmically growing cell lines, LoVo and SW480, on coverslip. Firstly, cells were plated onto coverslips, adhered overnight. Then, rinsed three times with PBS, cells were fixed in cold acetone for 8-10 min. Endogenous peroxidase was blocked with 1 % hydrogen peroxide in absolute methanol for 30 min. The primary antibodies were applied for 2 hours at 37 ℃ at 1:300 dilution in a humidified chamber. Then the typical SP strategy followed.

Flow Cytometric analysis

Cells were incubated in medium containing 4 μmol/L 5-FU, 10 μmol/L CDDP alone or both (4 μmol/L 5-FU+10 μmol/L CDDP) continuously, and then were fixed in ice-cold 70 % ethanol at 0, 12, 24, 48, 72 and 96 h after initial treatment. Then approximately 10 000 cells each specimen stained by 10 μg/ml PI were analyzed by Flow Cytometry (FACS®), as described by Bunz *et al*[4].

Statistical analysis

Data of MTT assay were mean values of at least three different experiments and expressed as mean ±SD, analyzed by two-tailed Student's *t*-test and General Linear Model, *P* value of less than 0.05 was considered as statistically significant.

RESULTS

Response to CDDP in LoVo cells and SW480 cells

We compared the sensitivity and responsiveness of LoVo cells and SW480 cells to CDDP and the combination of CDDP+5-FU in cytotoxicity assays. As shown by the dose-effect curve, both cell lines are sensitive to CDDP, but more for SW480 cells (Figure 1A). Neither of the cell lines examined showed significantly synergetic response when the two drugs were combined simultaneously, when compared with single-therapy of 5-FU, indicating that CDDP, to some degree, may block the effects of 5-FU (Figure 1B).

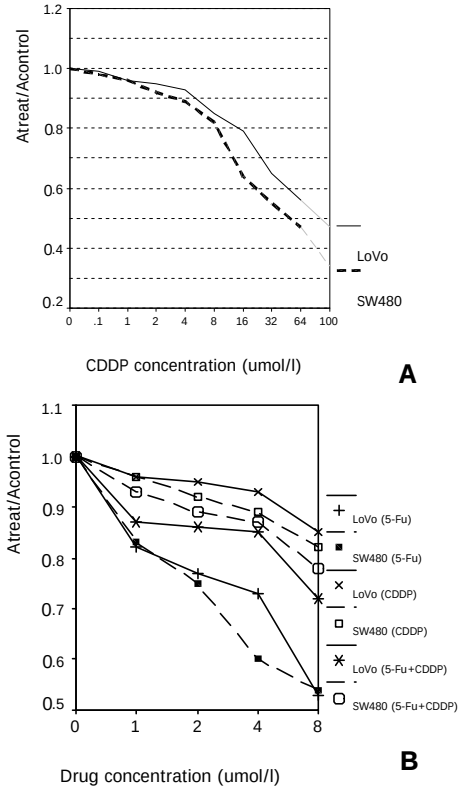

Figure 1 Comparison of sensitivity to 5-FU, CDDP or combination therapy in LoVo cells and SW480 cells. **(A)** SW480 cells show increased sensitivity to CDDP than LoVo cells at the concentrations above 16 μmol/l (Ratio of absorption is 0.64 and 0.79 at 16 μmol/l, respectively;$P<0.01$). **(B)** The dose-effect curve tells that the cytotoxicity diminishes in combination therapy of 5-FU and CDDP in both cell lines when compared with 5-FU single-therapy (Ratio of absorption in LoVo+5-FU, SW480+5-FU, LoVo+5-FU+CDDP and SW480+5-FU+CDDP is 0.53, 0.54, 0.72, 0.78, respectively; $P<0.01$).

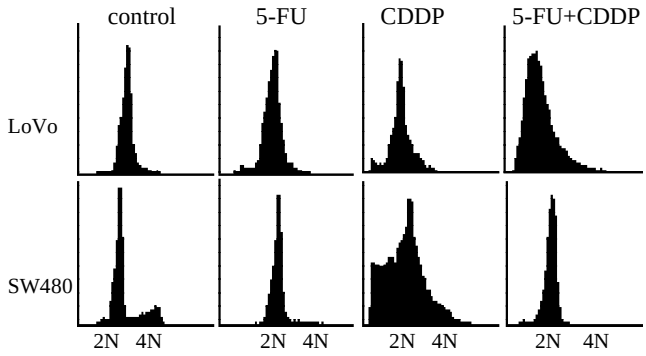

Figure 2 DNA content distribution of LoVo and SW480 cells after 48 hours exposure to 5-FU and/or CDDP. 5-FU causes a more apparent increase of the proportion of hypo diploid DNA cells in LoVo than in SW480. CDDP renders an apparent increase of the hypodiploid DNA cells in both cell lines, but SW480 has more than LoVo cells. Few hypodiploid DNA cells are observed in combination of 5-FU and CDDP treatment.

Distribution of cell cycle by FCM analysis

LoVo cells demonstrated an apparent peak of cells with hypodiploid DNA 48 hours after 5-FU exposure, 48 hours earlier than SW480 cells, which indicated that LoVo cells are more sensitive to 5-FU (Figure 2, 3A). When treated with CDDP for 48 hours, SW480 cells showed more cells with hypodiploid DNA than LoVo cells, about 2-fold increase at 96 hours (55.1 % and 28.5 %, respectively) (Figure 2, 3B).

However, when the two lines were exposed to 5-FU in combination with CDDP, this cytotoxicity significantly diminished. SW480 cells showed an 18 % cells with hypodiploid DNA, but not in LoVo cells in 96 hours (Figure 2, 3C). Both cell lines exposed to 5-FU showed an accumulation in G1-phase and a significantly decreased proportion of S-phase. On the contrary, CDDP arrests both lines mainly in S-phase instead of G1-phase. Percentage of cells in G1-phase and S-phase dominates alternatively in both lines treated with combination of 5-FU and CDDP (Figure 4).

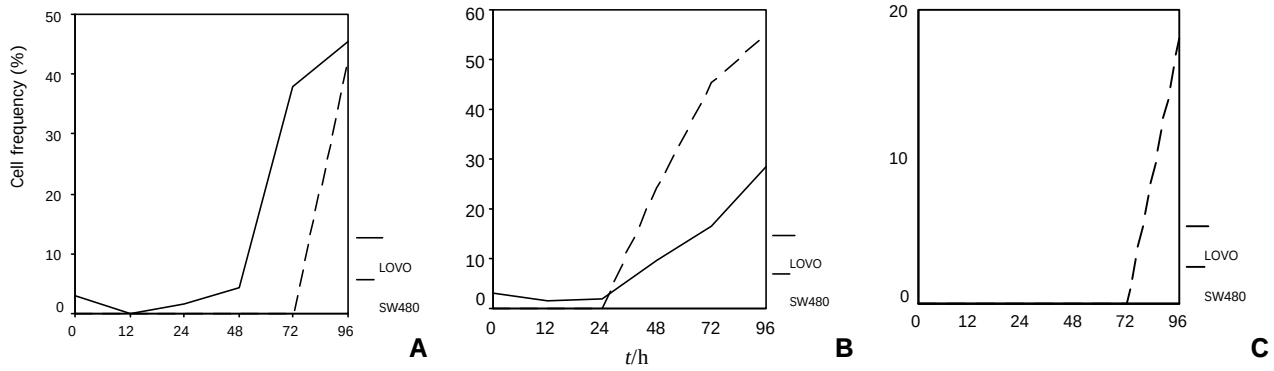

Figure 3 Hypodiploid DNA induced by 5-FU, CDDP or a combination therapy in LoVo cells and SW480 cells. LoVo cells treated with 5-FU show an earlier presence and higher percentage of cells with hypodiploid DNA. **B** When exposed to CDDP, SW480 cells showed a more dramatic increase in presence of hypodiploid DNA than LoVo cells after 48 hours. **C** When the two cell lines were exposed to 5-FU in combination with CDDP, SW480 cells have an 18% hypodiploid DNA, but not in LoVo cells in 96 hours after treatment.

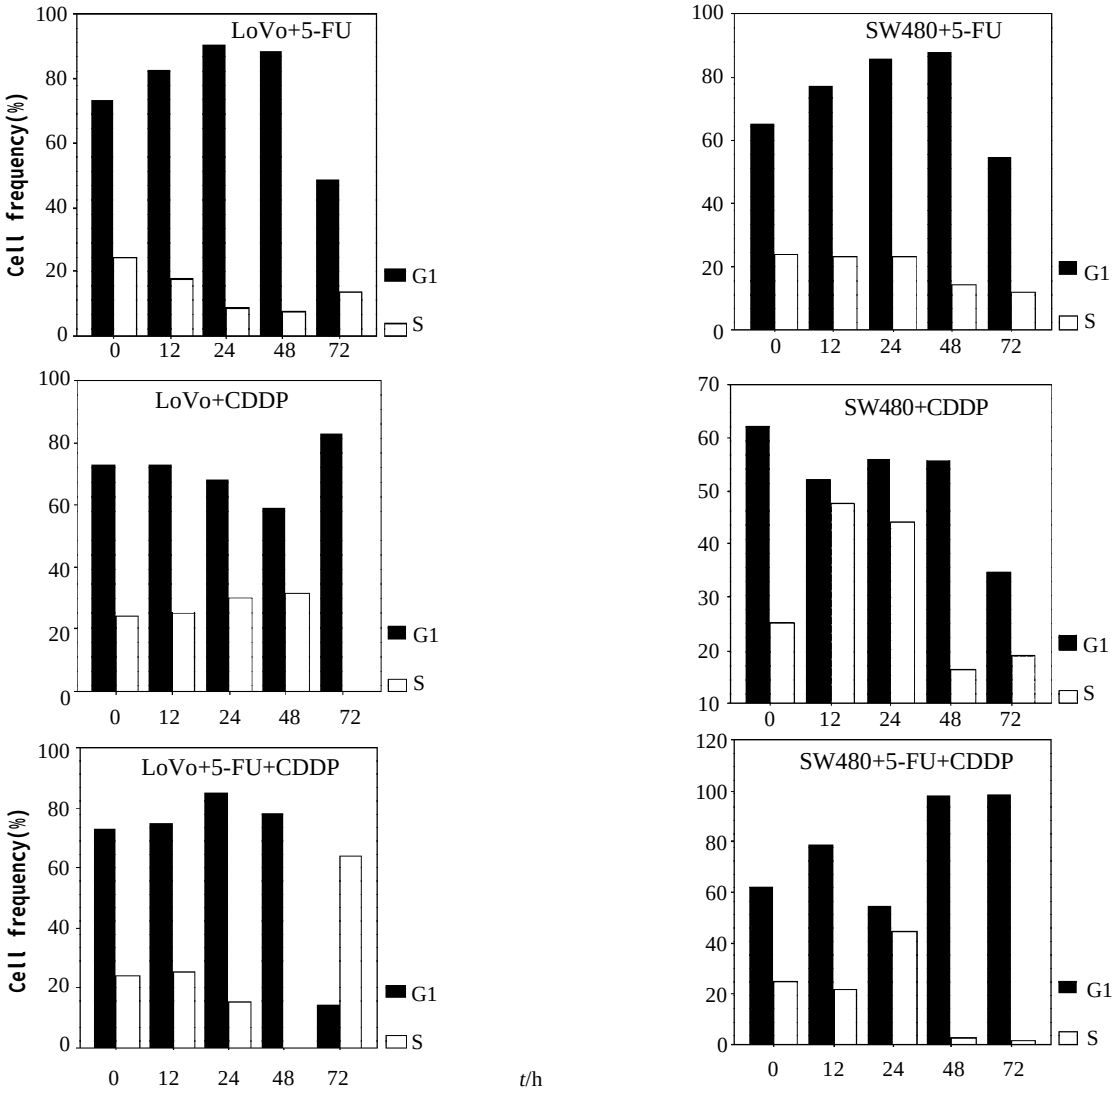

Figure 4 Effects on cell cycle distribution of LoVo cells & SW480 cells treated with5-FU, CDDP or combination therapy. Both cell lines show an accumulation of G1-phase exposed to5-FU. On the contrary, CDDP mainly renders an accumulation of S-phase. Percentage of G1-and S-phase dominates alternatively in both lines treated with combination of 5-FU and CDDP.

P53 expression by immunocytochemical staining

P53 staining scattered nestedly in LoVo cells, predominantly in nuclei, and the proportion of positive cells only accounts for less than 1 %, which was thus considered as wtP53. However, SW480 cells showed extensively and strongly P53 expression, and more than 98 % cells were labeled in nuclei, so it suggested a mutated P53 in this cell line (Figure 5).

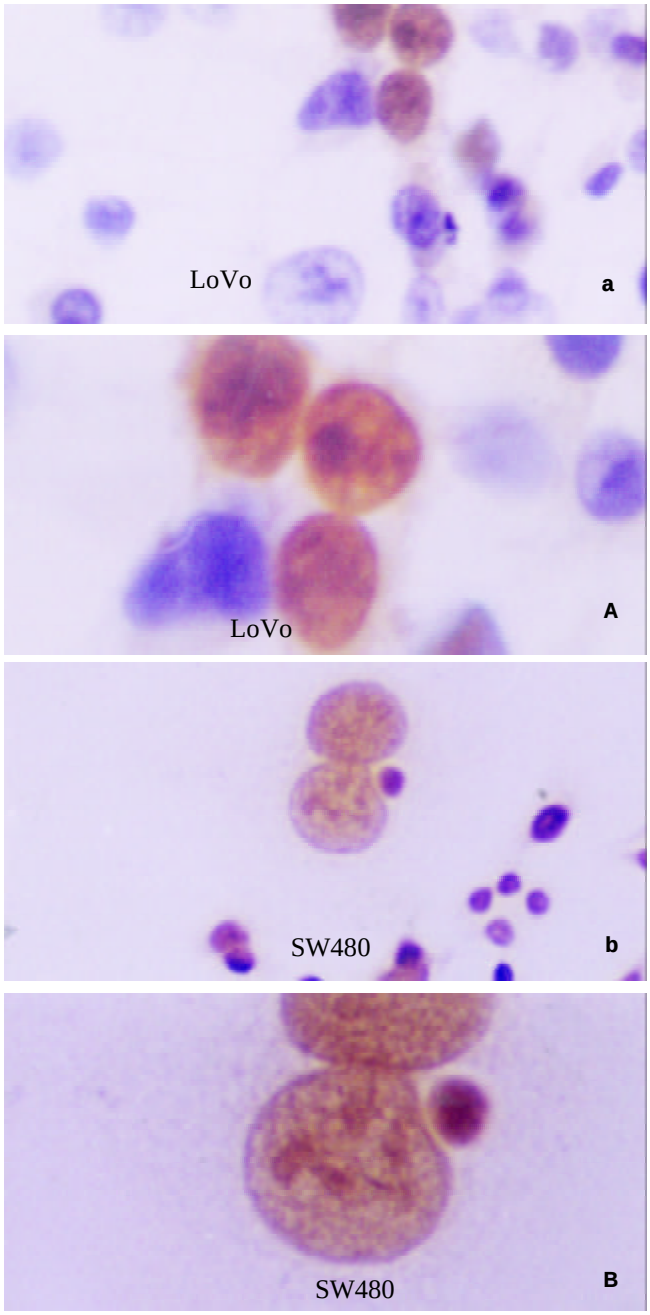

Figure 5 P53 staining with the anti-P53 mAb Do-7 in LoVo and SW480 cells.(**a,b**×100; **A,B**×200)

DISCUSSION

Our previous studies showed increased sensitivity to 5-FU in colon cancer cell lines with microsatellite instability, and considered that mutations of TGF-RⅡ, IGFⅡR and RIZ gene maybe enhance the potentials of cell growth and proliferation, which increases the sensitivity to 5-FU. This assumption is supported greatly by findings that the generation time of LoVo cells is significantly shorter than that of SW480 cells[4], and by our results here, we found that both cell lines demonstrated an accumulation of G1-phase after 12 hours 5-FU exposure, but apoptosis occurred earlier in LoVo cells.

Many researches have been done to reveal biochemical factors associated with 5-FU response, meanwhile, efforts are made to improve the efficacy of chemotherapy by combining 5-FU with other second-line drugs, such as paclitaxel, oxaliplatin, mitomycin, calcium folinate, INF-α, irinotecan, leucovorin, suramin, tegafur, and so on[5-10]. Considering mechanistic differences exist between 5-FU and CDDP, we supposed the possibility of their synergism and analyzed the efficacy of combination therapy of these two drugs.

However, our data didn' t agree with this supposition. We know that after administration 5-FU is rapidly taken up by cells and metabolized by enzymes by several pathways to produce two active metabolites, i.e. 5-FUTP, which may be incorporated directly into RNA, and 5-FdUMP. 5-FdUMP in the presence of reduced folates inhibits thymidylate synthase (TS) activity and depletes dTTP, a necessary precursor of DNA synthesis. Alternatively, it may be phosphorylated to the triphosphate and 5-FdUTP incorporated directly into DNA, inhibiting chain elongation and altering DNA stability, resulting in the production of single-strand breaks and DNA fragmentation[11-13]. Thus, 5-FU belongs to the phase-specific anticancer drug that means improved cytotoxicity to cells in S-phase. However, CDDP acts differently, it binds to DNA base pairs, creating adducts, crosslinks, and strand breaks that inhibit DNA replication.

As pointed above, the two cell lines both arrest in G1-phase, and LoVo cells precede SW480 cells in presence of hypodiploid nuclei with treatment of 5-FU. But CDDP rendered an apparent peak of cells with hypodiploid DNA after 48 hour, and LoVo cells showed less percentage of hypodiploid DNA cells, which suggested that, from view of population, SW480 cells are more sensitive to CDDP than LoVo cells. This result is consistent with most reports, i.e. colorectal cancer cells with microsatellite instability are more resistant to CDDP, and several assumptions have been made to explain this phenomenon: firstly, an assumption so-called *"Recognition, Excision, Futility of repairing"*[14,15]. The DNA-CDDP adducts are recognized and then excised by the mismatch repair system (MMR), the underlying molecular mechanism responsible for correction of mismatch base pairs or some sorts of DNA damages, but incapable to be repaired because of certain reasons. This failure may then lead to permanent single- or double-strand breaks which are now considered to be the initiation of cell death or apoptosis. Secondly, *"Protection mechanism"* [16]. DNA-CDDP adducts are recognized by MMR system or other nuclear factors, then the following binding functions a shelter which protects the damage from repairing by other mechanisms independent of MMR system, which renders cells to death or apoptosis. Thirdly, *"Cell cycle pathway"*. It is supposed that response of cancer cells to CDDP depends on the ability of G2/M arresting. Some workers considered that P53 is responsible for the shift of G1/S phases, whereas MMR system can inactivate CDK1-CylinB complex by phosphorylation of two amino acid residues, Thr14 and Thr15, of CDK1, and blocks cells in G2/M phase for repair, unrepairable DNA damage often results in activation of the apoptotic pathway (Hawn *et al*, 1995). This assumption is supported by many data[17-19]. Here, the first explanation disclaims itself because of the homogenous loss of hMSH2, one of most important members responsible for DNA-CDDP adducts recognition in MMR system. We also failed to detect

the G2/M phase arrest which is emphasized in the third assumption. As for the second supposition, further evidences are required to confirm it.

Combination therapy of 5-FU and CDDP showed less efficacy than single-therapy of 5-FU. Here we found that there was less cells with hypodiploid DNA in both cell lines treated with a combination of 5-FU and CDDP, which suggested that the 5-FU-induced cytotoxicity may, at least partially, diminish by the concomitant presence of CDDP. There are at least two mechanisms may explain the observed dominance of CDDP over 5-FU. One may simply involve a CDDP-induced cell cycle blockade, we called it *"cell cycle disturbance"*, analogous to that recently described by Judson et al in paclitaxel[20]. By arresting cells in S-phase of cell cycle, CDDP inhibited both cell lines undergoing apoptosis after exposure to 5-FU. Both cell lines firstly showed a G1-phase increase, a "5-FU-like response", and then followed by S-phase increase, a "CDDP-like response". In SW480 cells, particularly in SW480 cells, the percentage of G1-phase and S-phase dominates alternatively. These results demonstrate clearly that disturbance of cell cycle arrest and apoptosis occurred in the combination therapy. An alternative mechanism by which CDDP may exert dominance over 5-FU centers on the ability of each drug to modulate level of many biochemical molecules, we called it *"molecular antagonism"*. CDDP intercalates into DNA, forming adducts, and has been shown to both activate and block a variety of biochemical molecules, including transcription factors, such as *c-myc*, AP-1/AP-2, Oct-1, E2F1, P53 and P73; or molecules involved in cell signal transduction, such as Ras, PKA, EGF4, PKC-α/-ε/-θ; or factors associated with proliferation, DNA replication and cell cycle regulation, such as PCNA, TS,DNA pol-α/β,Topo Ⅰ, Cyclin E/D, P16, P21, P27; or Bax and Bcl-2, and so on. We have recently shown that there is a direct correlation between cytotoxicity and 5-FU induced transcriptional activation, i.e. some of these factors are also downstream elements induced by 5-FU and, in turn, affects sensitivity to 5-FU[21-24], leading us to postulate that at least part of the mechanism involves the antagonism of factors induced by each drug. In fact, these two possibilities are compatible with each other, the latter might just be the underlying biochemical explanation of the former.

Many evidences have shown that sensitivity of cancer cells to 5-FU is associated with a variety of mechanisms, including the key enzyme required for its activation and catabolism, folate substrate and the TS activity, and so on. The concept that P53 is involved in chemotherapy-induced cell cycle arrest and apoptosis is accepted by most scientists[5,12,25-32]. Yoshikawa *et al*[1] found there was no relationship between the sensitivity to 5-FU and P53 in colorectal cancer chemotherapy according to evidences from clinical trials, combining with these findings, they proposed that that 5-FU might act via two different pathways, depending on dose: (a) G1/S-phase cell cycle arrest and apoptosis at 1 000 ng/ml, and (b) G2/M-phase cell cycle arrest and mitotic catastrophe at 100 ng/ml in SW480. Our results accord with the higher concentration group they reported, i.e. cells undergo G1-phase or S-phase arrest and apoptosis. Controversies exist in the role of P53 in CDDP chemosensitivity, evidences from malignancies of lung, esophagus, cervix and bladder showed that wtP53 is a favorable prognostic predictor in chemotherapy, and that mutation of P53 will lead cells to chemoresistance[33-36]. However, in agreement with the findings of Pestell *et al*[37] in ovarian cancer, colon cancer cell line with mutant P53 exhibited more sensitivity to CDDP. We think this discrepancy may result from the different type of tissue. Up-regulation of P53 in response to 5-FU/CDDP-induced DNA damage may activates P21 and wee1/mik1, which inhibits the CDK activity, and consequentially, E2F1 failed to release itself from E2F1:RB complex due to down-regulation of RB phosphorylation, as a result, cells arrest in G1/S-phase. Alternatively, it is recently reported that P53-induced increase of P21 activity may also be mediated by the PI3K-AKT1/AKT2 signal transduction pathway[38]. Lin *et al*[39] found that activation of ATM induced by DNA damage can directly phosphorylate specific residues at the NH_2-terminal of E2F1 and can increase P53 expression. Nagashima *et al* described that P53 can also be acetylated and activated by DNA damage-induced $P33^{ING2}$ in CDDP and paclitaxel exposure[40]. All these evidences proved that P53 plays an important role in chemotherapy-induced cell cycle arrest and apoptosis. We' ve known that P21 and P53 are both mutant in SW480 cells, So blockage of cell cycle in G1/S-phase in this cell line may be P53-independent, compared with LoVo cells, apoptosis of SW480 cells treated with 5-FU or CDDP delayed, which may imply that apoptosis induced by P53 pathway is more effective than others. Huang once reported that a few or even one double-strand break of DNA would be enough to increase expression of P53, and led cells to cycle arrest for repairing, if failed, undergoing apoptosis[21,41,42]. So P53, cell cycle status, damage repair system and apoptotic pathway together determine cells to survive or not.

In conclusion, we have demonstrated that colon cancer cell lines with microsatellite instability are more sensitive to 5-FU, but CDDP goes conversely. Combination therapy of 5-FU and CDDP can lead cells to cycle arrest, but it shows less cytotoxicity than single-therapy of 5-FU. P53 may be involved in cell cycle shift of G1-phase to S-phase, but inessentially.

ACKNOLEDGEMENTS

We sincerely thank Mrs. Mi-Wei Li, from the Infective Disease Institute of No. 1 Affiliated Hospital of Medical School of Zhe Jiang University, for assistance with Flow Cytometry.

Abstract

AIM: To investigate the patterns of cell proliferation in proximal and distal colons in normal rats and rats with 1,2-dimethylhydrazine (DMH) induced carcinogenesis using the thymidine analogue bromodeoxyuridine.

METHODS: Colonic crypt cell proliferation was immunohistochemically detected using the anti-bromodeoxyuridine Bu20a monoclonal antibody.

RESULTS: Marked regional differences were found in both groups. Total labelling index (LI) and proliferative zone size in both normal (8.65±0.34 *vs* 7.2±0.45, 27.74±1.07 *vs* 16.75±1.45) and DMH groups (13.13±0.46 *vs* 11.55±0.45, 39.60±1.32 *vs* 35.52±1.58) were significantly higher in distal than in proximal colon ($P<0.05$), although the number of cells per proximal crypt was greater (31.45±0.20 *vs* 34.45 ±0.39, 42.68±0.53 *vs* 49.09±0.65, $P<0.0001$). Crypt length, total LI and proliferative zone size all increased in both proximal and distal regions of DMH rats compared to normal controls ($P<0.0001$). In DMH-treated rat colon a shift of labelled cells to higher crypt cell positions was demonstrated distally whilst a bi-directional shift was evident proximally ($P<0.05$).

CONCLUSION: Our results show that changes in cell proliferation patterns, as assessed by bromodeoxyuridine uptake, can act as a reliable intermediate marker of colonic cancer formation. Observed differences between proliferation patterns in distal and proximal colon may be associated with the higher incidence of tumors in the distal colon.

INTRODUCTION

Abnormality in epithelial proliferation is considered to be a characteristic of both human diseases associated with higher risk of colonic cancer and animal colonic cancer models[1-10]. Hyperproliferation of colonic epithelial cells was observed in tritiated thymidine-labelled colorectal specimens from patients with familial polyposis *Coli*, adenomas and hereditary non-polyposis colon cancer[11-16]. Assessment of colonic crypt cell proliferation, including detection of increased proliferative state and expansion of the proliferative zone is suggested as a putative intermediate marker of colon cancer risk[17-19]. Evidence from animal studies showed that experimental colonic tumors induced by procarcinogen 1,2-dimethylhydrazine (DMH) are of epithelial origin with a similar histology, morphology and anatomy to human colonic neoplasms[20,21]. Furthermore, prior to the development of colonic cancer, DMH injections result in increased colonic crypt cellularity, colonic crypt cell proliferation and colonic crypt proliferative zone[22,23]. This procarcinogen thus provides an adequate model for kinetic and therapeutic studies of the colorectal cancer[24-33]. In the normal rat colon, the location of the stem cells and the direction of colonocyte migration differ between the distal colon and the proximal colon[34]. Interestingly, differences in the incidence, morphology and clinical behaviour of colonic carcinoma have been identified in the proximal and distal colon[35,36]. However, there are no studies which use bromodeoxyuridine (BrdUrd) to compare cell proliferation patterns in the distal and proximal colonic locations of both normal and colonic cancer animals.

BrdUrd is a thymidine analogue which, after incorporation into normal and malignant cells during the S-phase of the cell cycle, can be detected using a monoclonal antibody. BrdUrd immunohistochemistry offers several advantages over thymidine autoradiography. Firstly, because a radioactive precursor is not required, there is less background interference in the tissue sections. Secondly, a clear distinction between the labelled cells and unlabelled cells is provided. Thirdly, the BrdUrd technique is less time-consuming, thus being more suitable for incorporation into routine diagnostic services. Finally, because BrdUrd is also a therapeutic agent, BrdUrd may be safely injected into the human body to study the cell proliferation in the patients without introducing additional procedures[37]. Several studies have demonstrated that the LI estimated by BrdUrd immunohistochemistry is equivalent to that obtained by thymidine autoradiography when an *in vitro* labelling technique is used[38]. This suggests that BrdUrd LI may be used to replace thymidine LI in both *in vitro* and *in vivo* studies.

In the present study, BrdUrd *in vivo* cell labelling was employed to determine the crypt cell proliferation patterns in the proximal and distal rat colons from normal and DMH-induced colon cancer animals.

MATERIALS AND METHODS

Twelve male Wistar rats with initial weight between 180 g and 220 g were housed, 3 in a cage, and maintained on standard laboratory diet (41 B (M)) with free access to water. Six of

these animals received weekly subcutaneous injections of colonic procarcinogen 1,2-dimethylhydrazine (DMH, Aldrich Chemical Company Inc) at a dosage of 20 mg/kg body weight for 20 weeks. The DMH was prepared as a 0.5 % solution in 1 mM ethylenediaminetetra-acetic acid (EDTA, BDH Limited Poole, England) adjusted to pH 7.0 with 10 % sodium bicarbonate immediately before injection. Animals were injected at the same time on the same day each week. Animals were sacrificed 2 weeks after the last DMH injection. Fifteen minutes before removal of the colon, the anaesthetized rats received a peritoneal injection of 5 mg 2 % BrdUrd (Sigma B-5002). This was always done between 9 a.m. and 11 a.m. to avoid diurnal variation. The colon was removed and rinsed with tap water. Following excision of the caecum and rectum, the remaining colon was divided into proximal and distal halves. A 1-2 cm segment of each end of the proximal and distal colon was discarded. After fixation in 70 % ethanol for 4 hours,the segments were rolled prior to processing and embedding in paraffin wax.

BrdUrd immunohistochemistry

Several 3 μm sections were cut and placed on poly-L-lysine coated slides. The slides were dewaxed before DNA was denatured in 1M HCl at 37 ℃ for 12 minutes. After rinsing in phosphate buffered saline (PBS, pH 7.1) the sections were incubated with 30 μl mouse anti-BrdUrd monoclonal antibody (M 744 Dako, Bucks, England) diluted 1:50 in PBS with 0.05 % Tween 20 (PBST) with added normal rat serum diluted 1:25 for 60 minutes at room temperature. After a further rinsing in PBS, the sections were incubated with biotinylated rabbit anti-mouse F(ab')$_2$ antibody (E 413 Dako, Bucks, England) at a dilution of 1:200 in PBST with added rat serum for 30 minutes at room temperature. Slides were again rinsed in PBS and then incubated with Streptavidin-Biotin Peroxidase complex (K 377 Dako, Bucks, England) for 30 minutes at room temperature. Finally, the reaction product was visualized using diaminobenzidine hydrochloride (DAB) (Sigma, Dorset, England) primed with 100 μl of 30 % H_2O_2 (diluted 1:20 with distilled water) for approximately 5 minutes. After DAB was washed off with distilled water, the sections were lightly counterstained in Harris haematoxylin before dehydration and mounting in DPX.

Counting and scoring

Only complete well-orientated longitudinally sectioned crypts which displayed lumen at the top and muscularis mucosae at the base was used for analysis. Comparisons between the following 4 groups were undertaken: distal colon from normal rats, proximal colon from normal rats, distal colon from DMH rats and proximal colon from DMH rats. To facilitate scoring, each crypt was divided at the base into 2 crypt columns (hemicrypts). Starting at the base of the hemicrypt, cells were numbered up to the luminal surface of the colon to determine the number of cells per hemicrypt (CPC) and then divided into 5 equal compartments each containing the same number of cells. The number and the position of BrdUrd-labelled cells in the hemicrypt were recorded. The proliferative zone, which was expressed as a percentage, was obtained by calculating the difference between the highest and lowest labelled cells in each hemicrypt and dividing this Figureure by the total number of cells in the hemicrypt. Labelling index (LI) was determined for the whole hemicrypt, for each compartment and for the proliferative zone, by dividing the number of labelled cells by the total cells and multiplying by 100. Each hemicrypt was then normalised to a notional 100 cell positions. The frequency of BrdUrd positive cells in each of the 100 positions was recorded.

Statistical analysis

All results are presented as the mean ±SEM. Two design variables were generated: (1) DMH, where 1 represents a case where DMH has been administered, 0 represents otherwise; and (2) POSITION, where 1 represents a sample from the proximal colonic crypt, while 0 represents one from distal colonic crypt. Multivariate linear regression analyses were performed using the two design variables as covariates against each of the measured parameters (Table 1). Whenever appropriate a two sided Student' s *t* test was used to identify the differences between individual variables. Kolmogorov-Smirnov 2 sample test (3) was used to compare the BrdUrd cumulative labelling frequency curves in the four subsets in the sample identified with reference to (1) the presence of DMH treatment, and (2) the site of origin of the sample from the colon. Results were considered to be significant when $P<0.05$ in all cases.

Table 1 Multivariate linear regression analyses with 2 design variables against 7 measured parameters

Response variable	Covariate	Coefficient	*P*-value
CPC	DMH	12.386	<0.05
	POSITION	5.004	<0.05
TOTLI	DMH	4.433	<0.05
	POSITION	-1.528	<0.05
INDLI 1	DMH	3.915	<0.05
	POSITION	-9.006	<0.05
INDLI 2	DMH	4.504	<0.05
	POSITION	-2.159	0.14
INDLI 3	DMH	10.425	<0.05
	POSITION	3.343	<0.05
PZONE	DMH	18.169	<0.05
	POSITION	-4.454	<0.05
PZONELI	DMH	-18.312	<0.05
	POSITION	1.725	0.43

CPC, cell per hemicrypt; TOTLI, total hemicrypt labelling index; INDLI 1, individual LI in compartment 1; INDLI 2 individual LI in compartment 2; INDL 3, individual LI in compartment 3; PZONE, proliferative zone; PZONELI, labelling index of proliferative zone.

RESULTS

Proximal compared to distal colon

CPC was significantly greater in the proximal compared to the distal colon in both normal ($t=7.42$, $P<0.0001$) and DMH-treated groups ($t=7.76$, $P<0.0001$, Table 1). The total hemicrypt LI was significantly higher in distal than proximal colon in both normal ($t=2.43$, $P=0.016$) and DMH treated animals ($t=2.47$, $P=0.014$). In the normal controls, BrdUrd labelled cells in the proximal colon were located predominantly in compartment 2 and 3 (88.4 %), whereas the labelled cells in the distal colon were found mostly in compartment 1 and 2 (85.3 %). In compartment 1, LI was significantly higher in distal than in proximal colon ($t=8.05$, $P<0.0001$), while in compartment 3 LI was significantly lower in distal than in proximal colon ($t=-4.46$, $P=0.0001$, Figure 1). Labelled cells

never appeared in compartment 5. The size of the proliferative zone was higher distally (t=2.57, P=0.011). When the cumulative labelling distribution curves of the proximal and distal colons of normal rats were compared the distal colon showed a significant shift to the left (K-S=2.192, P<0.0001, Figure 2).

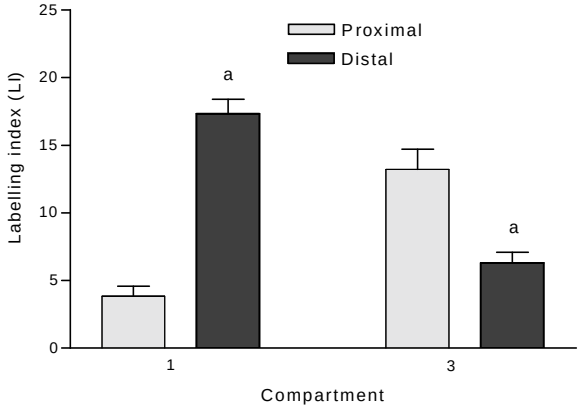

Figure 1 Labelling indices of compartment 1 and compartment 3 in proximal and distal colon of normal rats. [a]P<0.0001 when distal is compared to proximal colon in the same compartment. Values are mean±SEM.

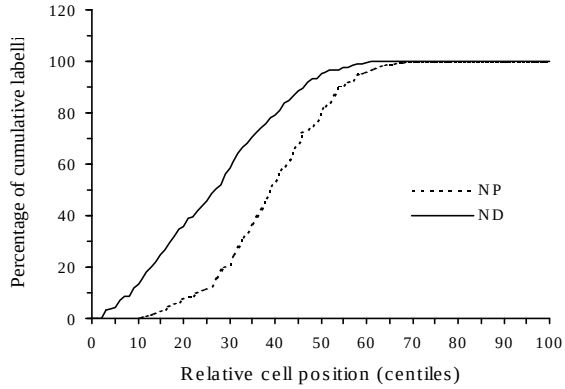

Figure 2 The different patterns of cumulative labelling distributions in proximal (NP) and distal (ND) rat colon of normal controls. The curve is significantly shifted towards the right when the proximal colon is compared to distal colon.

DMH compared with control rats

DMH treatment significantly increased CPC in both proximal (t=15.9, P<0.0001) and distal colon (t=20.6, P<0.0001) when compared with normal controls. Total LI was also increased significantly by DMH injections in both proximal (t=6.23, P <0.0001) and distal colon (t=7.94, P<0.0001, Table 2). The effects of DMH on the individual LIs for the 5 compartments in the proximal and distal colon are shown in Figures 3 and 4. In proximal colon, the increase in LI was in compartments 1 and 3, whereas in distal colon, the increase in LI in DMH rats was most marked in compartments 2 and 3. The extent of the increase in LI in compartment 3 of the distal colon was significantly greater than the corresponding increase in compartment 3 LI of the proximal colon (t=3.44, P=0.001). Additionally, DMH increased the size of the proliferative zone in both proximal (t=7.9, P<0.0001) and distal colonic crypts (t=10.6, P<0.0001). However the LI of proliferative zone was reduced because of the increased size. Further analysis of the cumulative labelling distributions showed a shift of the DMH distal curve to the 81st centile which was to the right of the plateau of the normal distal colon located at 61st centile (K-S=1.89, P=0.001, Figure 5). In contrast the cumulative labelling distribution curve in proximal colon demonstrated a shift to the left in the lower crypt cell positions and then shifted to the right high up the crypt (K-S=3.625, P<0.0001, Figure 6).

Table 2 Comparison of cell proliferation in proximal and distal hemicrypts of normal and DMH rat colon

	Normal control		DMH	
Parameters	Proximal	Distal	Proximal	Distal
Cells / hemi-crypt	34.45±0.39	31.45±0.2[a]	49.09±0.65[b]	42.68±0.53[a,c]
Labelled cells	2.49±0.16	2.74±0.11	5.7±0.24[b]	5.67±0.23[c]
Total LI	7.2±0.45	8.65±0.34[a]	11.55±0.45[b]	13.13±0.46[a,c]
Proliferative zone	16.75±1.45	21.74±1.07[a]	35.52±1.58[b]	39.6±1.32[a,c]
LI of proliferative zone	59.43±3.39	56.55±2.13	39.84±1.77[b]	38.89±1.5[c]

Values expressed as mean ±SEM. [a]P<0.05 when distal is compared to proximal in the same group, [b]P<0.05 when DMH proximal is compared to normal proximal, [c]P<0.05 when DMH distal compared to normal distal.

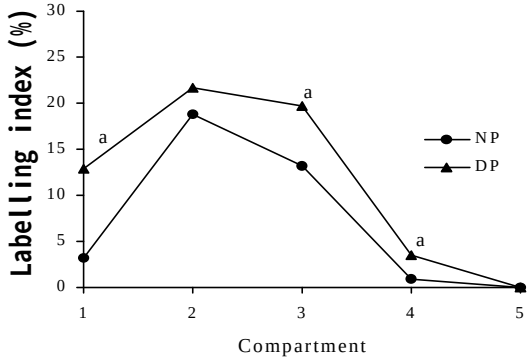

Figure 3 Labelling indices of normal proximal colon (NP) and DMH proximal colon (DP) for the 5 compartments. [a]P <0.0001 when labelling indices in the compartments of DMH proximal colons were compared to those found in normal proximal colons in the same compartments.

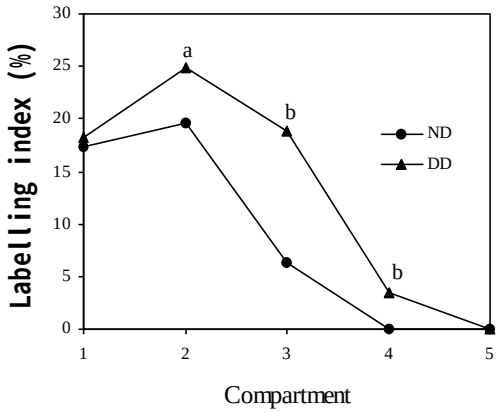

Figure 4 Labelling indices of normal distal colon (ND) and DMH distal colon (DD) for the 5 compartments. [a]P<0.05, [b]P<0.0001 when labelling indices in the compartments of DMH distal colons were compared to those found in normal distal colons in the same compartments.

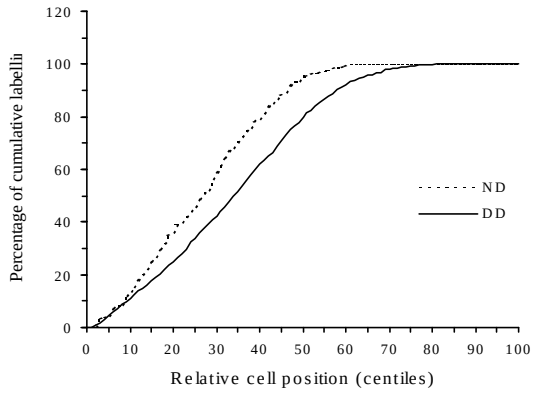

Figure 5 Cumulative labelling distribution in normal (ND) and DMH distal (DD) rat colon. The curve is significantly shifted towards the right in DMH distal colon compared to normal distal colon.

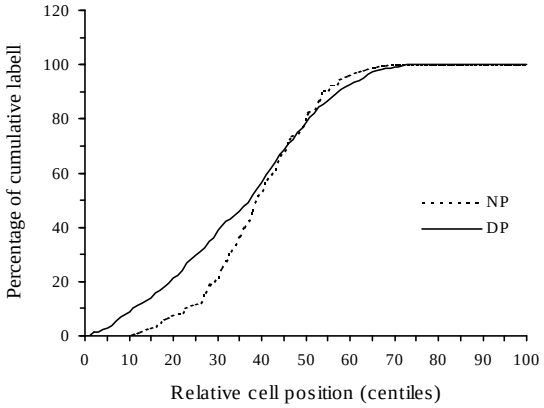

Figure 6 Cumulative labelling distribution in normal (NP) and DMH proximal (DP) rat colon. The curve of DMH treated proximal rat colon is initially significantly shifted towards the left and then in the higher centiles shifted to the right.

DISCUSSION

Significant regional differences in the distribution of BrdUrd-labelled cells located in proximal and distal rat colon have been demonstrated in this study. The total LI and the proliferative zone size are all significantly larger in the distal than in the proximal colonic crypt both in normal and DMH-induced carcinogenesis animals. These regional differences in proliferative cell distribution between proximal and distal colon were previously shown using other markers, e.g. ^{3}H-thymidine autoradiography and proliferating cell nuclear antigen (PCNA) immunohistochemistry. ^{3}H-thymidine LI and proliferative zone size have been reported to be significantly larger distally than proximally[39]. In the distal colon, PCNA expression was strictly confined in the lower third of the crypt, whereas in the proximal colon it was located in the mid-crypt[23].

Our results show that in the distal colon the proliferative cells are located predominantly in the compartments 1 and 2, whereas in the proximal colon, the proliferative cells are located in the 2nd and 3rd compartments. In earlier studies, using tritiated thymidine, Sunter *et al*[40] found the differences in the distribution of proliferative activity within the crypt from site to site along the length of the rat colon. In the proximal colon, Sunter noted that the peak LI was located in the middle third of the crypt while in distal colon the peak was located in the lower third near the base of the crypt.

These findings together with ours, tend to support the explanation of crypt cell origin and colonocyte migration described by Sato and Ahnen[34]. After double labelling with ^{3}H-thymidine and BrdUrd, they investigated the location of stem cells and the direction of colonocyte migration in normal rat colonic crypt. They reported that distal stem cells are located in the crypt base while proximal stem cells are located in the mid-crypt. They postulated that colonocytes migrate up toward the luminal surface in distal colon in contrast to the bidirectional migration, i.e. up toward the luminal surface and down toward the crypt base in proximal colon.

Our results show that after DMH injection colonic crypt cell proliferation is significantly increased regardless of the position (proximal or distal) and irrespective of the proliferative parameter assessed except the LI of proliferative zone (Table 1). The LI of the proliferative zone in the DMH animals may not increase because of the concomitant increase of the zone size. DMH treatment not only increases the colonic crypt cellularity, total BrdUrd LI but also increases the size of the proliferative zone in both proximal and distal colon. The LI of each compartment from 1 to 3 is also increased, especially in the distal colon. This can be confirmed by the cumulative labelling distribution curves (Figures 5 and 6). Although DMH treatment increases LI in both proximal and distal colon the cumulative labelling distribution is markedly shifted to the right in distal colon whereas the proximal curve shifts to the left (i. e. downwards in the crypt). These results are interesting because of the differences in colonic cancer distribution between proximal and distal colon. The distribution of DMH-induced colorectal cancer resembles human large bowel carcinoma, in which the majority of tumors are recorded distally[41,42]. In our previous work when total colon was exposed to the procarcinogen DMH, 73 % tumors occurred distally and only 12 % occurred proximally[33].

Further investigation is required to resolve the questions concerning the differences of tumor distribution and their relationship to the different crypt cell proliferation patterns observed in proximal and distal colon. It has been shown that in the proximal colon the lower one-third of the crypt contains predominantly mucous cells whereas the upper one-third mainly has columnar cells[43]. In contrast, crypts of the distal colon contain only a small number of mucous cells in basal positions. The undifferentiated cells or the cells with the lowest level of differentiation (presumptive stem cells) are the vacuolated cells located near or at the crypt base[44]. When the vacuolated cells migrate upward, they transformed into columnar cells and when they migrate downward, they give rise to mucous cells[45]. The major role which stem cells play in carcinogenesis is presumably to transform the malignancy [46]. If this hypothesis is true, there should be more mucinous tumors expected in proximal colon and the tumors in distal colon should originate from columnar cells. In DMH-induced rat colonic carcinogenesis the tumors tended to be more frequently sessile, often mucinous and invasive adenocarcinomas in proximal regions and polyps in distal areas[42].

In this study we observed a greater baseline value of crypt length in proximal than in distal colon, which is contrary to some other published literature[39,40]. This disparity may be due to the differences in defining the criteria for handling the overlapping nuclei, selecting crypts or ascertaining the top of the crypt. We have noticed that the nuclei in the proximal colon are not as typical as those in distal colon. In this study longitudinally well-oriented crypts was selected and all visible nuclei were counted.

Our study demonstrated regional differences in crypt cellularity and cell proliferation patterns. Additionally, we can

conclude that the procarcinogen DMH increased crypt cell proliferation and shifted the cumulative BrdUrd labelling distribution in both distal and proximal rat colon. The histochemical similarity of the distal rat colon to the human colon[43] permits the distal rat colon to be used as a model of colonic cancer[47-54]. Therefore, BrdUrd is an appropriate intermediate marker for the early detection of colorectal cancer in patients at high risk and the correct assessment of dietary interference.

Abstract

AIM: To study the effect of angiogenesis inhibitor TNP-470 on peritoneal dissemination of colon cancer in nude mice.

METHODS: The MTT assay was used to evaluate the inhibitory effect of TNP-470 on human colon cancer cell line Lovo. Lovo cells were injected into the peritoneal cavity of BABL/C nu/nu mice and the models of peritoneal dissemination were developed. Thirty nude mice were randomly divided into control and TNP-470-treated group. In TNP-470-treated group, TNP-470 was injected subcutaneously every other day from day 1 until sacrifice or death (30 $mg \cdot kg^{-1}$). The control group received a sham injection of the same volume saline solution.

RESULTS: *In vitro*, TNP-470 inhibited the growth of Lovo cells, with its IC50 at 2.14×10^2 $\mu g \cdot L^{-1}$. *In vivo*, TNP-470 demonstrated growth inhibition of tumors. Mice body weight and abdominal circumferences were significantly different between TNP-470-treated group (24.5±3.2 g, 7.0±1.1 cm) and control group (29.5±2.1 g, 10.3±1.5 cm), P=0.005 and P=0.001. The number of disseminated foci was significantly different between the control group (92.1±20.6) and the TNP-470-treated group (40.3±12.3), P<0.001. The maximal size of foci was significantly smaller in TNP-470-treated group (3.3±0.7 mm) than that of control (7.3±2.3 mm), P=0.004. Mean survival time was significantly longer in TNP-470-treated group(98.00±12.06 d) than that in control group (41.86±9.51 d), P<0.001.

CONCLUSION: Angiogenesis inhibitor TNP-470 might be effective in treating peritoneal dissemination of colon cancer and improve the survival rate of nude mice.

INTRODUCTION

Colorectal cancer still remains the most frequent malignancy in Japan, Unite States of American and China. Although combined therapies, including chemotherapy, radiation therapy and immunotherapy are performed in addition to surgical radical resection, nearly 50 % of patients still die of recurrence and a major form of recurrence was peritoneal dissemination[1]. Therefore, new therapeutic programs are needed to raise the survival rate of colorectal cancer patients. The importance of tumor angiogenesis is widely accepted in cases of blood-born metastases[2,3]. Although the form of blood supply is markedly different between metastases in solid organs and those at the peritoneum, it has been generally accepted that any foci larger than 0.2 mm require new tumor vessels for their growth[1-4]. Thus, inhibition of angiogenesis would prevent the tumor growth and their peritoneal dissemination.

TNP-470 is a semisynthetic analogue of fumagillin isolated from *Aspergillus fumigatus*. TNP-470 has been reported to inhibit neovascularization by preventing endothelial cells growth and proliferation[5-9]. Recently, the therapeutic effects of TNP-470 on various human and rodent tumors have been reported and this agent shows a marked inhibitory effect on tumor growth and metastasis *in vivo*[10-11]. However, the importance of angiogenesis in the establishment and growth of peritoneal dissemination remains unknown and there has been no report that evaluates the effect of TNP-470 on establishment and growth of peritoneal dissemination and ascites production of human colon cancer.

In this study, we investigated the inhibitory effects of TNP-470 on an establishment and growth of intraperitoneally inoculated human colon cancer cell line, Lovo, and survival of nude mice with this tumor *in vivo*. We also examined the inhibitory effect of TNP-470 on cell growth *in vitro*.

MATERIALS AND METHODS

Drug and reagents

TNP-470 was a generous gift from Takeda Chemical Industries (Osaka, Japan). 3-(4,5-Dimethylthiazole-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT), gum arabic and dimethyl sulfoxide (DMSO) were purchased from Sigma (St. Louis, MO); RPMI 1640 and heat-inactivated fetal calf serum (FCS) were purchased from Gibco (Grand Island, NY).

TNP-470 was stored dry at -20 ℃. *in vitro* experiments, TNP-470 was dissolved in DMSO and RPMI 1640 medium supplemented with 10 % FCS. The final concentration of DMSO was 0.1 %, while *in vivo* experiments, TNP-470 was suspended in a vehicle of 3 % ethanol and 5 % gum arabic in saline.

Cell line

Human colon adenocarcinoma cell line, Lovo was kindly provided by the Department of Pathology, Cancer Center, First Military Medical University(FIMMU). Cells were cultured in RPMI 1640 supplemented with 10 % FCS, and were maintained at 37 ℃ in 5 % CO.All experiments were performed using cells harvested at the 80-90 % subconfluent stage.

Animals

Female BALB/c nude mice were obtained from the Experimental Animal Center, FIMMU, and reared under specific pathogene-free condition. Four-week-old mice weighing 17-22 g were used in the experiments.

In vitro experiments

The MTT assays were made to evaluate the sensitivity of TNP-470 to Lovo cells[8]. Lovo cells were plated in 96-well mocrotiter plates at a concentration of 5×10^4 cells in 50 μL of RPMI 1640 medium. After 24 h incubation, the medium was changed to RPMI 1640 medium with various concentrations of TNP-470(5×10^{-4} μg· L^{-1}-5×10^5 μg· L^{-1}), and the medium was incubated for 48 h, 20 μL MTT (5 g· L^{-1}) solution was then added to each well. After the plates were incubated for 3 h, 150 μL DMSO was added. The absorbance at 570 nm was determined using a microplate reader (Bio-Rad Model 3550, Hercules, CA). Dose-response curves were plotted, and the 50 % inhibitory concentration (IC50) was extrapolated as the drug dose causing a 50 % reduction in absorbance as compared with control values. The experiments were repeated in three independent experiments.

In vivo experiments

Lovo cells were harvested after being cultured for 48 h and the model of peritoneal dissemination in nude mice was developed as follows. Approximately 5×10^7 cells in 0.2 mL saline solution were injected into the peritoneal cavity of an nude mouse (day 0). Thirty nude mice were randomly divided into a control group (n=16) and a TNP-470-treated group (n=14). In the TNP-470-treated group,TNP-470 of 30 mg· kg^{-1} was injected subcutaneously every other day from day 1 until sacrifice. The control group received a sham injection of the same volume of saline. On day 10, two mice in control group were sacrificed and disseminated nodules on the peritoneum were evaluated. Seven mice each were sacrificed on day 30. Body weight and abdominal circumferences (substitute abdominal circumferences for ascites) of each mouse in two groups were measured. The number and maximum size of disseminated nodules on the peritoneum and mesentery were evaluated. The remaining 14 mice, 7 in each group, were followed for the survival experiment.

Statistical analysis

Data were expressed as mean ±standard deviation. Comparison between two groups was made by the independent samples t test. The survival curve was calculated by the Kaplan-meier method and compared by the Log-rank test. $P<0.05$ was considered statistically significant. All statistics were carried out using SPSS10.0 statistics software.

RESULTS

Effects of TNP-470 on cell growth in vitro

In the colorimetric MTT assay, significant growth inhibition was observed in a dose-dependent manner. The IC50 value was 2.14×10^2 μg· L^{-1} extrapolated from the dose-response curve following 48 h exposure (Figure 1).

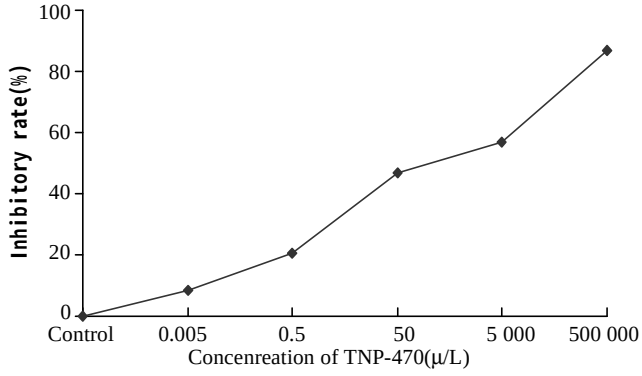

Figure 1 Inhibition curve of Lovo cells after TNP-470 treated 48 h

Effects of TNP-470 on establishment and growth of peritoneal dissemination in vivo

Two mice in control group sacrificed on day 10 developed disseminated nodules, suggesting that small nodules at the peritoneum developed within 10 days after inoculation in this model. Body weight and abdominal circumferences were gained in two groups when mice sacrificed on day 30. Body weight and abdominal circumferences in the control group and the TNP-470-treated group are summarized in Table 1. The difference of body weight and abdominal circumferences were statistically significant (P=0.005 and P=0.001). The number and maximum size of disseminated foci of the control group and the TNP-470-treated group are shown in Table 2. The difference of foci number and maximal size of disseminated foci were also statistically significant (P<0.001 and P=0.004).

Table 1 Body weight and abdominal circumference of two groups ($\bar{x}\pm s$)

Groups	Mice	Body weight (g)	Abdominal circumference (cm)
Control	7	29.5±2.1	10.3±1.5
TNP-470	7	24.5±3.2[a]	7.0±1.1[b]

[a]t=3.394, P=0.005, [b]t=4.624, P=0.001, *vs* control

Table 2 Numbers and Maximum size of disseminated foci of two groups ($\bar{x}\pm s$)

Groups	Mice	Number of foci	Maximum size of foci (mm)
Control	7	92.1±20.6	7.3±2.3
TNP-470	7	40.3±12.3[a]	3.3±0.7[b]

[a]t=5.715, P<0.001, [b]t=4.319, P=0.004, *vs* control

In the control group, mice died from day 31 to day 57. In a TNP-470-treated group, 5 mice were died from day 74 to day 110. Two mice survived more than 120 days and TNP-470 treatment was continued. These 2 mice did not have any disseminated foci and were sacrificed on day 120 and day 130, respectively. The median survival time in the control group and the TNP-470-treated group were 40 and 92 days, the mean survival time being 41.86±9.51 days and 98.00±12.06 days, respectively (P<0.001). The survival rate was significantly smaller in those in the control group than those of TNP-470-treated group (P<0.001) (Figure 2).

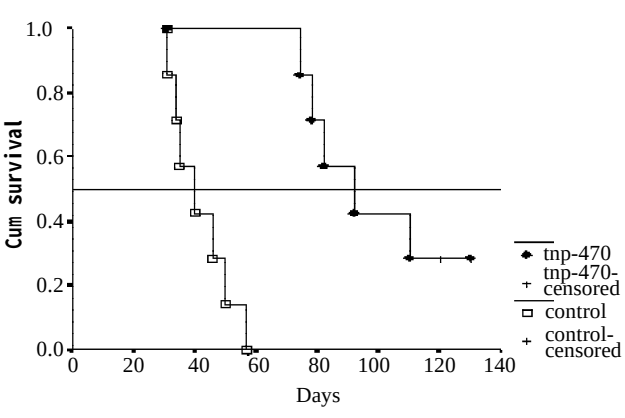

Figure 2 Survival curves in the control and TNP-470-treated groups

DISCUSSION

About 33 % patients with colorectal cancer have recurrence after operation and 50 % patients died of tumor metastasis[13,14], and the peritoneal dissemination or liver metastasis represents the most common form of recurrence. When the tumor has extended through the serosa or been resected , tumor cells are carried to distant points of the peritoneal cavity and "seeding" on peritoneum. Supported by peritoneal permeability and growth of neovascularization, these tumor cells would develop into micro-metastatic nodules, eventually producing generalized peritoneal dissemination[15,16]. With tumor recurrence as peritoneal dissemination, patient prognoses are extremely poor. Although combined therapies, including chemotherapy, radiation therapy and immunotherapy are performed in addition to surgical radical resection, no effective treatment can prevent the recurrence. New therapeutic strategies have to be invented to overcome the poor prognosis.

Angiogenesis, has been shown to be essential for tumor growth not only at the primary but also at the site of metastases, and the peritoneum would not be an exception[17-20]. Inhibition of angiogenesis is emerging as a promising strategy for cancer treatment[21-24]. Anti-angiogenic agents have demonstrated a remarkable inhibition effect on tumor growth and metastasis, and anti-angiogenic therapy may prevent the tumor recurrence[25].

Among the most potent inhibitors of angiogenesis is the fumagillin family of natural products. An analog of fumagillin, known as TNP-470 or AGM-1470, has the anti-angiogenic activity by inhibiting endothelial cell growth with high potency both *in vitro* and *in vivo*[26,27]. Studies have shown that the molecular mechanism of TNP-470 inhibiting endothelial cell proliferation is associated with the two type methionine aminopeptidase (MetAp-2). TNP-470 was found to bind MetAp-2 covalently, leading to specific inhibition of its activity, and strong correlation has been found between inhibition of MetAp-2 enzymatic activity and inhibition of endothelial cell proliferation[28-33]. Investigators for TNP-470 have demonstrated suppression of neovascularization, tumor growth, and distant metastases *in vivo*[34-44], and the proliferation of various cancer cell lines *in vitro*[45-49]. There are very few studies on peritoneal dissemination[50-52], and no data are available about preventing peritoneal dissemination or survival benefit of colon cancer treated by TNP-470.

Tsujimoto *et al*[53] reported that angiogenesis occurred in peritoneal foci 1 week after intraperitoneal inoculation of tumor cells in a mouse model. Our study indicated that TNP-470 inhibied the proliferation of Lovo cells *in vitro*, with its IC50 at 2.14×10^2 ug/L, and markedly suppressed the growth of peritoneal dissemination in vivo. The mice survival time was siginificantly longer in TNP-470 treated group than that of control. Our results suggest that these effects are exerted not only by inhibiting neovascularization necessary for tumor growth, but also by directly inhibiting the proliferantion of Lovo cells.

Body weight loss was known to be the major side effect of TNP-470. There was a slight body weight gain when mice were sacrificed on day 30, and the increase was associated with the production of malignant ascites. In the survival experiments, body weight loss was observed in the control group and 3 tumor-bearing mice became cachectic with the progression of tumor. No body weight loss was observed in the treatment group, suggesting that suppression of the growth of peritoneal dissemination foci by TNP-470 resulted in a preservation of body weight and prevention of cachexia in this model.

In conclusion, angiogenesis inhibitor TNP-470 might be effective in treating peritoneal dissemination of colon cancer by inhibiting the growth of the seeded tumor cells on the peritoneum.

Abstract

AIM: To determine the frequencies of HGV and TTV infections in serum and saliva samples of non-hepatitis patients with oral diseases in Hangzhou area, and to understand the correlation between detected results of HGV RNA and/or TTV DNA in sera and in saliva from the same patients.

METHODS: RT-nested PCR for HGV RNA detection and semi-nested PCR for TTV DNA detection were performed in the serum and saliva samples from 226 non-hepatitis patients with oral diseases, and nucleotide sequence analysis.

RESULTS: Twenty-seven (11.9 %) and 21 (9.3 %) of the 226 serum samples were only positive for HGV RNA and TTV DNA, respectively. 10 (4.4 %) and 9 (3.9 %) of the 226 saliva samples were only positive for HGV RNA and TTV DNA, respectively. And 7 (3.1 %) of the serum samples and 2 (0.9 %) of the saliva samples showed the positive amplification results for both HGV RNA and TTV DNA. 12 saliva samples from the 34 patients (35.3 %) with HGV or HGV/TTV viremia and 11 saliva samples from the 28 patients (39.3 %) with TTV or HGV/TTV viremia were HGV RNA detectable, respectively, including two patients positive for both HGV RNA and TTV DNA in serum and saliva samples. No saliva samples from the 226 patients were found to be HGV RNA or TTV DNA detectable while their serum samples were negative for HGV or TTV. Homologies of the nucleotide sequences of HGV and TTV amplification products from the serum and saliva samples of the two patients compared with the reported sequences were 88.65-91.49 % and 65.32-66.67 %, respectively. In comparison with the nucleotide sequences of amplification products between serum and from saliva sample from any one of the two patients, the homologies were 98.58 % and 99.29 % for HGV, and were 98.65 % and 98.20 % for TTV, respectively.

CONCLUSION: Relatively high carrying rates of HGV and/or TTV in the sera of non-hepatitis patients with oral diseases in Hangzhou area are demonstrated. Parts of the carriers are HGV and/or TTV positive in their saliva. The results of this study indicate that dentists may be one of the populations with high risk for HGV and/or TTV infection, and by way of saliva HGV and TTV may be transmitted among individuals.

Yan J, Chen LL, Lou YL, Zhong XZ. Investigation of HGV and TTV infection in sera and saliva from non-hepatitis patients with oral diseases.*World J Gastroenterol* 2002; 8(5):857-862

INTRODUCTION

Viral hepatitis is relatively common in China[1-13]. Except for human A-E hepatitis viruses, hepatitis G virus (HGV) and GB virus C (GBV-C) were recently identified as the causative agents of human non-A-E hepatitis[14,15]. Transfusion transmitted virus (TTV), another novel virus isolated from a patient suffering from non-A-G hepatitis, was considered to be responsible for human non-A-G hepatitis[16]. Since the nucleotide sequences and putative amino acid sequences of HGV and GBV-C genomes show high homologies of 85 % and 100 %, respectively, the two viral agents are considered to be the different isolates of the same virus belonging to *Flaviviridae* family[14,15]. TTV was proposed to be a member of a new virus family temporarily named *Circinoviridae*[17]. Although HGV is a positive-stranded RNA virus and TTV is a negative-stranded DNA virus, the two viruses are mainly transmitted through a hematogenous pathway[18-21], especially through blood transfusion[22-25]. Many investigation data demonstrated that HGV or TTV was able to cause a long-term asymptomatic viremia in non A-E hepatitis patients and only a few patients could suffer from hepatitis with mild liver injury[26-32]. On the contrary, a few references reported that HGV infection might accelerate the progression of chronic liver diseases and cause fulminant hepatic failure[33-37]. TTV was frequently found in non-A-G hepatitis patients with a single elevation of alanine aminotransferase (ALT)[38-40]. Recent published literatures revealed that HGV or TTV infection frequency in peripheral bloods of normal populations including healthy blood donors was found to be relatively high[41-50] and part of the infected individuals were HGV RNA or TTV DNA detectable not only in the serum samples but also in their saliva samples[51-55]. Therefore, dentists may be one of the populations at high risk of HGV and TTV infection, and may play an important role in HGV and TTV transmission among individuals. On the other hand, the possibility of HGV and TTV transmission through saliva is also an interesting subject for investigation.

To determine the frequency of HGV or TTV infection in non-hepatitis patients with oral diseases and to understand the correlation of HGV and TTV detection between in sera and in saliva from the same one patients, RT-nested PCR and semi-nested PCR were applied to detect HGV and TTV respectively in the serum and saliva samples from 226 non-hepatitis patients for oral treatment in Hangzhou area. The HGV RNA or TTV DNA positive amplification products from representatives of the serum and saliva samples were cloned and then sequenced. The results of this study may contribute to understand

transmission mechanism of the two viruses and populations with high risk of HGV and TTV infection, and may be helpful for the control of the prevalence of human hepatitis associated with HGV or TTV.

MATERIALS AND METHODS

Materials

Total 226 patients with tooth, pulp or periodontal diseases came from the oral departments of three hospitals in Hangzhou, Zhejiang Province of China, respectively. Each of the patients was told the aim and content of this study and all of them agreed to be the volunteers. A serum sample as well as a saliva sample from each of the patients was collected. These samples were immediately performed for HGV and TTV detection or temporarily stored at -20 ℃. The patients were confirmed to have no any clinical signals of hepatitis and no elevation of ALT by conventional hepatic examinations, and the serum samples were negative for hepatitis A-C viruses by PCR and EIA. The reagents used in reverse transcription (RT) and PCR were purchased from Boehringer and BMI, and the other reagents used in this study came from Sigma.

Methods

Isolation of total RNA and DNA in sera Total RNA in 200 μl of each serum samples was prepared by Trizol method according to the manufacturer' s instruction and then dissolved in 50 μl of DEPC treated super-purified water. 200 μl of each serum samples was mixed with 200 μl DNA extraction solution containing 20 mmol· L^{-1} EDTA, 0.5 % (W/W) SDS, 10 mmol· L^{-1} Tris-HCl and 40 mg proteinase K (pH8.0) and was treated at 55 ℃ for 30 min. Total DNA in the mixture was extracted by phenol-chloroform method[56] and then dissolved in 50 μl of TE buffer (pH 8.0).

Isolation of total RNA and DNA in saliva 200 μl of each saliva samples was mixed with 400 ml RNA extraction solution containing 4 mol· L^{-1} guanidine thiocyanate,0.1 mol· L^{-1} 2-mercaptoethanol, 0.5 % (W/W) sodium N-lauroylsarcosine and 25 mmol· L^{-1} sodium citrate (pH7.0). Vortex the tube gently for 15 min and lay the tube at room temperature for 5 min. 100 mL 2 mol· L^{-1} sodium acetate (pH4.0), 600 mL TE buffer (pH8.0) and 200 ml phenol (pH4.5)-chloroform (5:1, V:V) were added into the tube and then mixed. Supernatant of the mixture after centrifugation was added with 400 ml 2-propanol (-20 ℃) and then mixed. Lay the tube at -20 ℃ for 2 h to precipitate RNA. RNA pellet obtained by using centrifugation at 4 ℃ was washed with 75 % ethanol and then dissolved in 50 μl of DEPC treated super-purified water[51, 52]. 200 μl of each saliva samples was mixed with 200 ml DNA extraction solution containing 20 mmol· L^{-1} EDTA, 100 mmol· L^{-1} NaCl, 0.5 % (W/W) SDS, 10 mmol· L^{-1} Tris-HCl (pH8.0)and 80 μg proteinase K. Incubate the tube at 55 ℃ for 60 min. Total DNA was obtained by phenol-chloroform method[56] and then dissolved in 50 μl of TE buffer (pH 8.0)[53-55].

RT-nested PCR for HGV RNA detection Ten microliters of total RNA preparation was mixed with 10 μl RT master mixture containing 5 μmol· L^{-1} hexanucleotide as random primers, 12.5 mol· L^{-1} each of dNTP, 20U M-MuLV-reverse transcriptase, 20U RNase inhibitor and 4 μl of 5×RT buffer (pH8.3). The steps of RT were described as the following: at 70 ℃×5 min for denaturation, at 42℃×60 min for cDNA synthesis, and at 70 ℃×10 min to stop the reaction.

Primers derived from HGV 5' -NCR were used in the RT-nested PCR for HGV detection[13, 50]. The external primers: 5' -ATGACAGGGTTGGTAGGTCGTAAATC -3' (sense), 5' -CCCCACTGGTCCTTGTCAACTCGCCG-3' (antisense). The internal primers:5' -TGGTAGCCACTATAGGTGGGTCTTAA -3' (sense), 5' -ACATTGAAGGGCGACGTGGACCGTAC-3' (antisense). For the first round PCR, 10 μl of RT product was mixed with 90 μl PCR master mixture containing 250 nmol· L^{-1} each of the external primers, 2.5 mol· L^{-1} each of dNTP, 25 mol· L^{-1} $MgCl_2$, 2.5U of *Taq* DNA polymerase and 10 μl 10×PCR buffer (pH8.3). For the second round PCR, 5 μl product from the first round PCR was used as template, and the other reaction reagents were the same as that in the first round PCR except of the primers. DNA Thermal cycler 480 (Perkin Elmer) was used for amplification. The parameters for each of the PCR rounds were described as the following: 94 ℃5 min (×1); 94℃1 min, 56 ℃ 1 min, 72℃1.5 min (×35); 72 ℃7 min (×1). The expected size of target fragments amplified from HGV 5' -NCR RNA was 193bp.

Semi-nested PCR for TTV DNA detection The primers used in the semi-nested PCR for TTV DNA detection were the same described by Okamoto *et al*[57]. The external primers: 5' -ACAGACAGAGGAGAAGGCAACATG-3' (sense), 5' -CTGGC ATTTTACCATTTCCAAAGTT-3' (antisense). The internal primers: 5' -GGCAACAT GTTATGATAGACTGG-3' (sense), 5' -CTGGCATTTTACCATTTCCAAAGTT-3' (antisense). Except the primers, $MgCl_2$ concentration (15 mol· L^{-1}), total reaction volume (50 μl) and annealing temperature (60 ℃), the compositions and concentrations of other reaction agents and the parameters for the semi-nested PCR was the same as that of the RT-nested PCR for HGV detection. The expected size of target fragments amplified from TTV DNA was 271bp.

Examination of amplification products The results of amplification reactions were observed on UV light after electrophoresis of 20 g· L^{-1} agarose stained with ethidium bromide. 100bp DNA ladder was used as a size marker to estimate the length of products.

Cloning and sequencing of PCR amplification products The target DNA fragments of HGV or TTV amplification products by PCR were cloned into plasmid pGEM-T vector by using T-A cloning kit according to the manufacturer' s instruction. The recombinant plasmid was amplified in *E.coli* strain DH 5α and then recovered by Sambrook' s method. A professional company (Sangon) was responsible for the analysis of nucleotide sequences of the inserted fragments. Homology of the nucleotide sequences was compared with those reported respectively[14, 56].

RESULTS

Positive rates of HGV RNA and TTV DNA detection in the serum and saliva samples

Twenty-seven (11.9 %) and 21 (9.3 %) of the 226 serum samples were only positive for HGV RNA and TTV DNA, respectively. 10 (4.4 %) and 9 (3.9 %) of the 226 saliva samples were only detectable for HGV RNA and TTV DNA, respectively. And 7 (3.1 %) of the serum samples and 2 (0.9 %) of the saliva samples showed the positive results for both HGV RNA and TTV DNA. 171of the 226 serum samples (75.7 %) and 205 of the 226 saliva samples (90.7 %) were undetectable for both HGV RNA and TTV DNA. Representatives of the target fragments respectively amplified from HGV and TTV genomes in the serum and saliva samples were shown in Figure 1.

Distribution of HGV and TTV detection results in serum and saliva samples

Twelve saliva samples from the 34 patients (35.3 %) positive

for HGV RNA and 11 saliva samples from the 28 patients (39.3 %) positive for TTV DNA in their sera were HGV RNA and TTV DNA detectable respectively, including 2 patients with both HGV RNA and TTV in their serum and saliva samples. No saliva samples from the 226 patients were found to be positive for HGV RNA or TTV DNA but their serum samples were negative for HGV or TTV. Distribution of HGV and TTV detection results in serum and saliva samples of the 226 patients was shown in Table 1.

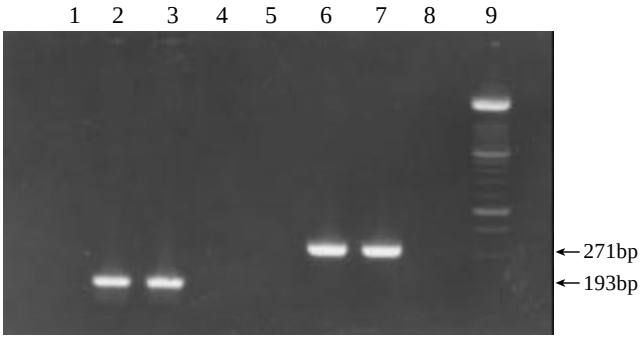

Figure 1 Target fragments respectively amplified from HGV RNA and TTV DNA in serum and saliva samples. (1: HGV negative serum sample; 2 and 3: HGV positive serum sample and saliva sample (No.: 010906); 4: blank control for HGV detection; 5: TTV negative serum sample; 6 and 7: TTV positive serum sample and saliva sample (No.: 011022); 8: blank control for TTV detection; 9: marker)

Nucleotide sequence analysis and homology comparison

In comparison with the reported HGV[14] and TTV genotype-1a[57] nucleotide sequences, the homologies of HGV and TTV amplification products from 2 serum and 2 saliva samples from the two same patients (No.: 010906 and 011022) were 88.65-91.49 % and 65.32-66.67 %, respectively. When to compare the nucleotide sequences of HGV and TTV amplification products between the 2 serum samples and between the 2 sliva samples, the homologies were as high as 98.65 % and 98.20 %, 93.24 % and 94.59 %, respectively. The homology comparison mentioned above did not contain the primer sequences (Figure 2 and 3).

DISCUSSION

Viral hepatitis is a common infectious disease of human beings, which is prevalent in all countries of the world and causes a serious healthy problem. Although hepatitis virus A-E have been demonstrated to be the causative agents of human hepatitis A-E respectively, approximately 20 % of acute and 15 % of chronic hepatitis were associated with unknown etiology[23, 24]. HGV and TTV were recently identified as transfusion-transmitted viruses and were considered to be responsible for human non-A-E hepatitis[14-17]. Many published literatures reported that among the patients infected with HGV or TTV, a few of them showed mild liver injury, which resulting in a conclusion of a low clinical importance of HGV or TTV infection[26-32]. However, a wide variety of questions about the potential pathogenicity of HGV and TTV infection still remain unanswered[13, 23]. So far the assays for HGV and TTV detection are not the routing laboratory examination items in many countries and areas. Not few of investigation data indicated that high frequencies of HGV or TTV infection were frequently found in different normal populations such as in healthy blood donors[41-50]. Some investigation results revealed that the genomic nuclear of HGV or TTV in saliva of partial infected individuals was also detectable[51-55], suggesting the possibility by way of saliva for transmission of the two viruses. Although HGV or TTV infection might be not clinically significant, the existence of extensive and potential infectious sources of the two viruses will still generate a great problem for human health.

In the present study, HGV and TTV infection rates in serum samples of the 226 non-hepatitis patients with oral diseases were 15.0 % (34/226) and 12.4 % (28/226) respectively, which indicated that HGV infection rate was obviously higher than that of the reported in other areas of China and abroad (1.3-10.6%)[7,8], and TTV infection rate was higher than that of the reported abroad (<5 %) [41, 43-47] but similar to the reported in China (9.3-16.8 %)[42, 48-50]. Such high HGV and TTV infection frequencies in the non-hepatitis population in Hangzhou are probably due to geographic difference. In the previous study, we found 2.5 % of healthy blood donors in Hangzhou coinfected with both HGV and TTV[50]. In this study, the serum samples from 7 of the 226 patients (3.1 %) were positive for both HGV RNA and TTV DNA, which offered further evidence for the existence of coinfection of the two viruses. Therefore, it is valuable to make further studies to determine the pathological and clinical significance of the coinfection.

Since the patients with oral diseases in this study did not show any clinical symptoms and laboratory markers for hepatitis, which suggested that most of the patients infected with HGV and/or TTV are usually asymptomatic. However, these asymptomatic patients carrying HGV and/or TTV may be more risky and important for the source of infection. It was worthy to notice that 5.3 % and 4.9 % of the non-hepatitis patients with oral diseases were HGV RNA and/or TTV DNA detectable in the saliva, indicating dentists may be one of the populations at high risk of HGV and/or TTV infection except of blood precipitants and hemodialysed patients[18, 25, 31, 32, 57, 58].

It was more important that HGV and TTV in saliva might be transmitted among the patients for oral treatment through dentists' hands and therapeutic instruments. So it is necessary to take effective measures to block the possible transmission of HGV and TTV by way of saliva.

In this study, 2 serum samples and 2 saliva samples from the two patients showed positive results for both HGV RNA and TTV DNA. The nucleotide sequences of HGV amplification products from these samples are highly homologous (88.65-91.49 %) to the sequence reported by Linnen *et al*[14]. This result of sequence analysis indicates that the RT-nested PCR used in this study is reliable for HGV RNA detection. To analyze the details of the nucleotide sequencing data, it seems to show a HGV genotype different from the reported[59-62]. Lower homology (65.32-66.67 %) of the nucleotide sequences of TTV Semi-nested PCR products from these samples of the 2 patients compared with the reported TTV genotype 1a sequence[56] reveals the genomic heterogeneity of TTV isolates from different areas, and this finding accords with the conclusions of previously published literatures[31, 56]. In this study, no saliva samples from the 226 patients were found to be positive for HGV RNA or TTV DNA while their serum samples were negative for HGV or TTV. Furthermore, the nucleotide sequence homology of HGV amplification products between the serum and saliva samples from any one of the 2 patients is 98.65 % and 98.20 %, respectively, and so is the nucleotide sequence homology of TTV amplification products (93.24 % and 94.59 %), which are much higher than that compared with the reported HGV and TTV sequences[14, 56]. These data indicate a closely and directly correlation between HGV and TTV genomes detected from serum and saliva from the same one patients.

Abstract

AIM: To screen human single chain Fv antibody (scFv) against hepatitis C virus E2 antigen and identify its application in immunohistochemistry.

METHODS: The phage antibody library was panned by HCV E2 antigen, which was coated in microtiter plate. After five rounds of biopanning,56 phage clones were identified specific to HCV E2 antigen. The selected scFv clones were digested by SfiI/NotI and DNA was sequenced. Then it was subcloned into the vector pCANTAB5E for expression as E-tagged soluble scFv. The liver tissue sections from normal person and patients with chronic hepatitis B and chronic hepatitis C were immunostained with HCV E2 scFv antibody.

RESULTS: The data of scFv-E2 DNA digestion and DNA sequencing showed that the scFv gene is composed of 750 bp. ELISA and immunohistochemistry demonstrated that the human single chain Fv antibody against hepatitis C E2 antigen has a specific binding character with hepatitis virus E2 antigen and paraffin-embedded tissue, but did not react with liver tissues from healthy persons or patients with chronic hepatitis B.

CONCLUSION: We have successfully screened and identified HCV E2 scFv and the scFv could be used in the immunostaining of liver tissue sections from patients with chronic hepatitis C.

INTRODUCTION

Hepatitis C virus (HCV) has been identified as the major etiological agent of post-transfusion non-A non-B hepatitis[1-10], responsible for most cases of non-A non-B hepatitis. Hepatitis C is a disease of clinical importance because of its high infection rate in blood donors and its persistence as chronic infections which may lead to cirrhosis and hepatocellular carcinoma in the long term[11-26]. The variability of the HCV genome has difficulties in serological detection and vaccine design. Recent advance in phage technology offers a means of cloning human anti-HCV antibodies of a defined specificity that may have potential therapeutic use[27]. We now report the generation of phage display antibody using phage antibody library. From this library we obtained specific single-chain Fv antibody that recognizes the viral envelope protein E2, using HCV E2 protein as the immobilized antigen and proceeding immunohistochemistry.

MATERIALS AND METHODS

Materials

Humanized scFv antibody phage library in which the variable region coding gene of VL and VH were amplified by polymerase chain reaction (PCR) with degenerate primers and connected with a glycine linker [(Gly4Ser)3] was widely used in the screen and identification of humanized scFv to various antigens[28-34]. The recombinant HCV E2 protein was purchased from Virostat Co, USA. Phage M13K07 was purchased from Pharmacia Co., Sweden. Other reagents used in this experiment are all domestic products of analytical grade.

Biopanning

The phage library was amplified in 37 ℃. The host *E. coli* TG1was infected with phage M13K07 and incubated at 37 ℃ for 12 hours, the phage in the supernatant was harvested and concentrated by PEG. Culture plate (Nunc) was coated with recombinant HCV E2 protein at the concentration of 80 mg/L. The coating buffer was 0.05 mol/L $NaHCO_3$, pH 9.6. The plate was blocked with BSA at the concentration of 20 g/L for 2 hours and the concentrated phages were added to the well of the plate, incubated at the room temperature for 90 min. The plates were washed 20 times with PBST and PBS buffer respectively. The bound phage was eluted by the 0.1M of triethylamine, and neutralized with 1M Tris buffer (pH 7.4). Recovered phages were used to infect the host *E. coli* TG1 at the log phase growth and HCV E2 protein-binding phages were amplified. The procedure of absorption-elution-amplification was repeated 5 times.

Identification of phage clones

After 5 rounds of biopanning, 56 phage clones were selected randomly. The clones grew in 400 μl 2×TY-AMP-Glu at 37 ℃ overnight. The culture was transformed to another Eppendorf tube when its A600 nm reached 0.5. The culture was continued at 30 ℃ overnight after adding helper phage. ELISA for determining the supernatants was repeated at least two times. The cross-reaction of the supernatants to the BSA antigen was conducted. According to the ELISA results to the HCV E2 and BSA, one clone with high reaction to HCV E2 and low reaction to BSA was selected.

Sequencing analysis

The plasmid DNA was prepared using Wizard plus minipreps DNA Purification System (Promega Co., USA) and sequenced using ABI automated DNA sequencing machine.

Expression of human HCV E2-scFv in E.coli

The selected HCV E2 scFv clone was subcloned as SfiI/NotI fragments into the vector pCANTAB5E for expression as E-tagged soluble scFv. DNA digestion and electrophoresis confirmed the recombinant vector pCANTAB5E-E2-scFv. Competent *E. coli* XL1-Blue was transformed with pCANTAB5E-E2-scFv and transformed XL1-Blue was induced by IPTG for 20 h. The *E. coli* was harvested by centrifugation at 10 000rpm. The culture supernatant was rendered for ELISA test according to the standard procedure. In ELISA detection, Nunc plate was coated with 1μg/well of recombinant HCV E2 antigen and blocked with 2 % bovine serum albumin (BSA) at 37 ℃ for 2 h. The supernatants from induced and non-induced transformed *E. coli* were added and incubated at 37 ℃ for 2 h. The plate was washed with PBS buffer, and 100 μl of HRP/anti-E Tag 1:4000 ratio diluted in PBS buffer containing 1 % BSA was added, and incubated at 37 ℃ for 1 h. The substrate solution was added and A450nm value was measured.

Immunohistochemical identification of scFv in liver tissue

Paraffin-embedded liver tissue slices were from patients with positive anti-HCV antibodies and HCV-RNA. After deactivating endogenous hyperoxidase, these slices were submersed in the methanol solution with 0.5 % H_2O_2 in the room temperature. Fifty min later, they were washed with PBS buffer for 3 times,5 % BSA was added and slices were stored overnight at 4 ℃. Self-made scFv primary anti- HCV E2 single-chain antibodies were diluted at 1:100 ratio and added on to the slice. They were kept in the 37 ℃ incubator for 1 h, then 4 ℃ refrigerator overnight. HRP-sheep anti-M13 antibodies (diluted to 1:200) solutions were dropped on to the tissue sections, incubated at 37℃ for 40 min. After washing 3 times with PBS buffer, DAB solutions (9 mg DAB, 13.5 ml Tris.cl, 1.5 ml $CoCl_2$, 15 μl 30 % H_2O_2) were dropped on to the tissue sections at room temperature. After ten minutes, the slices were washed with PBS buffer for 3 times again, and 1 % heamatin solution was used to stain the cell nucleus. Gradient ethanol was utilized to dehydrate and dimethylbenzene to clear the sections, then neutral resin to envelope them. The resultant slices were observed under microscope. The controls were set as follows: 1) PBS buffer instead of anti- HCV E2 scFv; 2) HBsAg, HBcAg double-positive liver tissue sections; and 3) Normal liver tissue sections.

RESULTS

Screening and identification phage clones

Using HCV E2 protein as immobilized antigen, the humanized scFv phage library was biopanned. After 5 rounds of biopanning, 56 phage clones were selected randomly. ELISA and cross-reaction of these clones to BSA confirmed their specificity to HCV E2. Among the 56 phage clones, 16 showed good reactivity to the recombinant HCV E2 protein with high A value in the ELISA. In the cross-reaction screen, 6 among the 16 showed low cross-reaction with BSA. The combined results indicated that 1 of the 6 showed the highest reaction to HCV E2 protein and lowest reaction to BSA. One clone has been selected for further DNA digestion and sequence analysis. The DNA sequence digestion was made by SfiI/NotI in Figure 1. Its nucleic acid sequence and deduced amino acid sequence about HCV-E2-scFv fragment are shown in Figure 2.

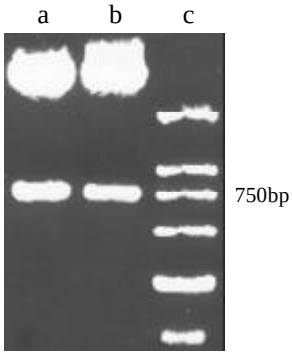

Figure 1 Restriction map of HCV E2-scFv by SfiI/NotI digestion. A,B: HCV E2-scFv; C: DNA Marker

Figure 2 Nucleic acid and deduced amino acid sequences of scFv for HCV E2 protein GenBank accession number for this sequence is AF317001

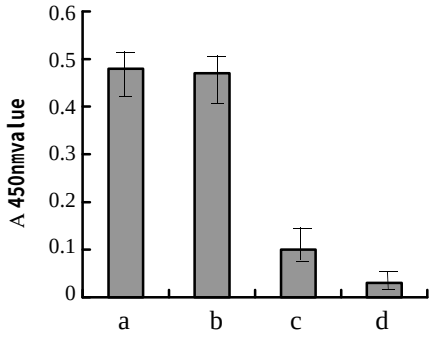

Figure 3 Absorbances of HCV-E2-scFv binding to E2 antigen by ELISA. (a). supernant from induced XL1-blue transformed with pCANTAB5E-E2-scFv; (b). posive control; (c). supernant from non-induced XL1-blue transformed with pCANTAB5E-E2-scFv, d. negtive control

Expression of human HCV-E2-scFv in E. coli.

The expressed HCV-E2-scFv antibody from *E. coli* XL1-blue transformed by pCANTAB5E and induced by IPTG was confirmed by ELISA as shown in Figure3. The recombinant HCV E2 antigen was taken as the positive control. The protein from induced and non-induced *E. coli* XL1-blue transformed by expression vector was positive. But the protein derived from the *E. coli* non-transformed by pCANTAB5E- HCV E2- scFv was negative. These results indicated that the soluble form of human HCV E2- scFv antibody has been successfully expressed in this procedure.

Immunostaining of HCV E2 antigen of liver tissue sections

The different sections from liver tissues of healthy persons and patients with chronic hepatitis B or C were immunostained. The positive immunostaining was seen only in the liver tissue section of patients with chronic hepatitis C, but not in the liver tissue of normal person and patients with chronic hepatitis B as seen in (Figure 4A). The HCV E2 antigen was mainly located in the cytoplasm of the hepatocytes infected by HCV virus (Figure 4B).

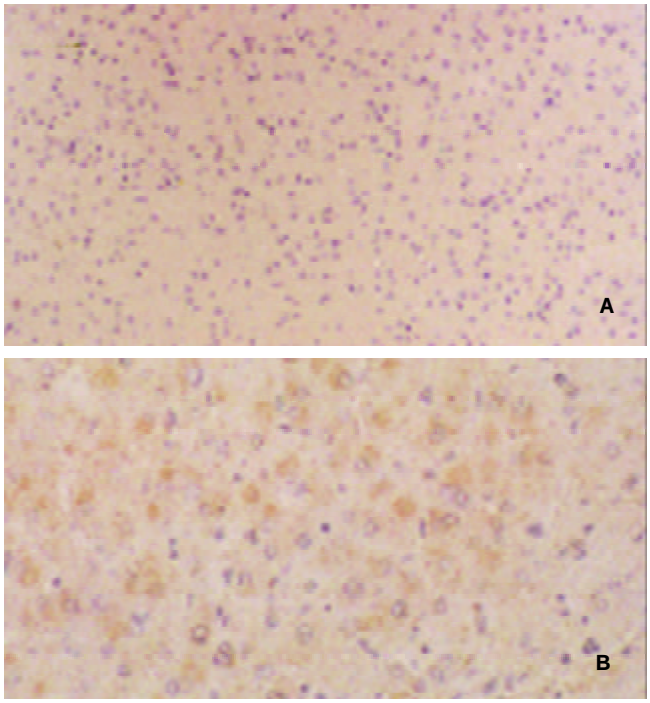

Figure 4 A. Immunohistochemistry of liver tissue from health person. B. Immunohistochemistry of liver tissue from patients with chronic hepatitis C E2 antigen was detected in the cytoplasm of some liver cells

DISCUSSION

HCV is the etiological agent responsible for most cases of non-A non-B hepatitis. It is a blood-related disease of clinical importance since a large number of cases developed chronic infections which may lead to cirrhosis and hepatocellular carcinoma. The variability of the HCV genome has posed serious problems in serological detection of HCV and vaccine design[27-38]. The possibility of using neutralizing antibodies in passive immunization is also hampered by the existence of genotypes and quasispecies[39-50]. To circumvent this, it is possible to envisage the use of cross reactive antibodies with a broad reactivity directed against functionally conserved surface domains common to various genotypes. There has been *in vitro* and *in vivo* evidence that HCV infection elicits a neutralizing antibody response in humans. The virus envelope protein is the primary target for the host immune system. Despite the high variability of the HCV envelope sequence, certain domains of biological importance, e.g. ligands required in viral attachment to host cell receptors, have to be preserved. Antibody specific for the envelope E2 protein has been shown to be cross-reactive HCV E2 and to be able to block viral attachment to cultured human fibroblast cells. However, attept to obtain human monoclonal anti -HCV antibodies is an urgency.

Phage library is a powerful tool for the selection of important and useful antibody specificities espeacially for getting humanized scFv[51-53]. It has many advantages. First, it is the only method to get specific antibody by passing the immunization step. It can mimic the maturation procedure of human antibody in vivo, so it is possible to get high affinity antibody from this selection. Second, the scFv with a low molecular weight, can make it potentially applicable in the clinical diagnosis and treatment of both infectious disease and cancer. Finally, it has no Fc fragment, so the backgroud is very low.

The phage technology offers a means of cloning human anti-HCV antibodies of a defined specificity that may be potential for therapeutic and diagnostic use. In this report, we have obtained anti-HCV E2 scFv by affinity selection and purified recombinant hepatitis C virus E2 as coating antigen from synthetic phage display antibody library. After 5 rounds of selection, 56 clones were evaluated by enzyme-linked immunosorbent assay (ELISA). One phage clone was selected from 56 clones according to the highest A450 nm value in the ELISA identification and lowest cross-reaction to the bovine serum albumin (BSA). The coding fragments of scFv were sequenced. The affinity and specificity of scFv were evaluated by ELISA and immunohistochemistry. HCV E2-scFv DNA digestion and sequence data showed that the scFv gene is composed of 750 bp. ELISA and immunohistochemistry demonstrated that the human single chain Fv antibody against HCV E2 antigen has a specific binding activity with hepatitis C virus E2 antigen. This study illustrated the feasibility of using antibody-engineering technology with the phage display library that may be useful for future therapeutic and detection purpose.

Abstract

AIM: To study the role of lamivudine in improving the efficiency of interferon for the treatment of mutant type chronic hepatitis B.

METHODS: Fifteen patients with mutant type chronic hepatitis B were prospectively studied. All patients had liver histology and serology to prove the diagnosis of chronic hepatitis B. Each patient received 4.5 millionunits of interferon alpha-2a thrice weekly and 100 mg of oral lamivudine daily for 24 weeks. Patients were observed and tested for blood chemistry every week for the initial 4 weeks and every 2 weeks thereafter during the treatment until 24 weeks. After the end of treatment, patients were followed up at 4-week intervals for an additional 6 months. Serum HBV DNA levels were tested using the liquid phase molecular hybridization assay. Those with non-detectable HBV DNA were also tested using the real-time polymerase chain reaction. One patient, who did not finish treatment due to depression, was excluded.

RESULTS: At the end of treatment, 7 (50 %) patients had serum ALT levels within normal limits; 12 (86 %) patients had serum HBV DNA levels <5 pg/mL using the liquid phase molecular hybridization assay, but only 8 (67%) were <20 copies/dL using the real-time polymerase chain reaction. Six months after treatment, only two (14 %) patients had a sustained complete response to the combination therapy with serum ALT level <35 iu/L and undetectable serum HBV DNA levels.

CONCLUSION: These pilot data showed that lamivudine did not increase the efficacy of interferon in the treatment of mutant type chronic hepatitis B. The liquid phase molecular hybridization assay was not sensitive enough to detect the low HBV DNA levels during combined interferon and lamivudine therapy.

Yang SS, Hsu CT, Hu JT, Lai YC, Wu CH.Lamivudine does not increase the efficacy of interferon in the treatment of mutant type chronic viral heaptitis B.*World J Gastroenterol* 2002;8 (4):868-871

INTRODUCTION

Hepatitis B virus (HBV) is one of the major causes of liver disease worldwide[1,2], and chronic hepatitis B can progress to cirrhosis and hepatocellular carcinoma[1,2]. It is thus important to conduct anti-viral therapy against chronic hepatitis B to minimize the amount of liver damage[4]. Recent studies suggest that around half of all patients with chronic HBV infection responded to a 6 to 12 month course of interferon therapy at the end of treatment with loss of serum hepatitis B viral deoxyribonucleic acid (HBV DNA) and hepatitis B e antigen (HBeAg), as well as normalization of serum alanine aminotransferase (ALT) activity[5,6]. However, a mutant type of HBV DNA has been identified in serum from patients with chronic hepatitis B, who presented with negative HBeAg and abnormal serum ALT levels[7]. The mutant type of HBV infection showed mutations at the precore region. Different from those patients with wild type HBV DNA, the respond rate of interferon mono-therapy against mutant type chronic hepatitis B was low[8,9]. Lamivudine has become a recent interest in the treatment of chronic viral hepatitis B[10,11]. However, the relapse rate after the end of lamivudine therapy is high[12-14]. Many different regimens, including a longer course of treatment or higher dosages of interferon, have been claimed to improve the interferon therapy, but the sustained response rate is still disappointing[15,16]. Recent studies from patients with chronic hepatitis C show that the combination of interferon alpha with ribavirin results in a higher sustained response rate than interferon alpha alone[17,18]. However, the role of combination of interferon and lamivudine against chronic hepatitis B remains uncertain[19]. We therefore conducted the present pilot study to investigate the possible role of combined interferon and lamivudine to improve the efficiency of interferon in patients with mutant type chronic hepatitis B.

MATERIALS AND METHODS

We prospectively studied 15 documented patients with mutant type chronic hepatitis B at Cathay General Hospital, Taipei, Taiwan between June 1999 and June 2001. All patients were males aged between 20 and 65 years old (mean ± SD: 44±8 years), and were naive without prior interferon or other anti-viral therapy. Chronic hepatitis B was defined as positive hepatitis B surface antigen (HBsAg, Auszyme, Abbott Laboratory, Abbott Park, IL 60064) and abnormal serum ALT levels (normal <35 IU/L) for more than 6 months. Mutant type chronic hepatitis B was defined as detectable HBV DNA, positive HBsAg, negative HBeAg [HBeAg; HBe (rDNA) EIA, Abbott Labratory], and abnormal serum ALT levels in patients having chronic hepatitis B. All patients had at least three documented occasions of abnormal serum ALT levels higher than twice the upper limit of normal with one month apart, within 6 months prior to enrollment. All patients underwent liver biopsy within one month before the start of treatment to confirm the chronic hepatitis without cirrhosis.

None of our patients were alcoholic, intravenous drug users

or homosexual. None had received hepatotoxic drugs, herbal medicine or immuno-suppressive therapy within the past 6 months. Further, none had decompensated liver function (prolonged prothrombin time >3 seconds *vs.* INR >1.50, serum total bilirubin >3.0 mg/dl, or serum albumin < 3.0 g/dL), cirrhosis, chronic renal failure, clotting abnormalities, hemophiliacs, serious neurological disorders, obesity, chronic viral hepatitis C (Murex anti-HCV, Version III, Murex Diagnostics Ltd., Dartford, England) or delta (Wellcozyme, Wellcome Diagnostics, Dartford, UK), autoimmune disease (anti-nuclear antibody titer >1:40, Fluoro HEPANA, Medical & Biological Lab., Nagoya, Japan), and/or inheritable disorders such as hemochromatosis, alpha-1-antitrypsin deficiency or Wilson' s disease. All patients with peripheral white cells <4 000 per mm^3 and platelet < 100 000 per mm^3 were excluded. Serum HBV DNA was measured using a commercially available liquid phase molecular hybridization assay (Digene Hybrid Capture™ System, Beltsville, MD) according to the manufacturer' s instruction. The lowest detectable HBV DNA level was 5 pg/ml. Serum samples with non-detectable HBV DNA were retrospectively tested using the real-time polymerase chain reaction (RT-PCR) methods after the end of clinical follow-up. The lowest detectable HBV DNA level was 20 copies/mL.

All patients received 4.5 millionunits (MU) of interferon alpha-2a (Roferon, F. Hoffmann-La Roche Ltd., Basel, Switzerland) thrice weekly and 100 mg of oral lamivudine daily for 24 weeks. Patients were observed and tested for blood chemistry every week for the initial 4 weeks and every 2 weeks thereafter during the treatment until 24 weeks. After the end of treatment, patients were followed up at 4-week intervals for an additional 6 months.

Normalization of serum ALT levels and absence of serum HBV DNA were assessed for the efficacy of treatment. A complete response was defined as the normalization of serum ALT levels together with the absence of serum HBV DNA by the end of treatment. A sustained complete response was defined as the continuation of the remission for at least 6 months after the end of treatment.

Informed consent was obtained from the patients before treatment. The study protocol was reviewed and approved by the Institutional Review Board of the hospital under the guidelines of the 1975 Declaration of Helsinki.

Statistical analysis

Was performed using two-tailed Student' s *t*-test and two-tailed Fisher' s exact test where appropriate.

RESULTS

The demographic data, biochemical data and serum HBV DNA levels are shown in Table 1. The total bilirubin were 0.9±0.2 mg/dL (data are presented as mean ±S.D. and so forth; range: 0.4-1.8 mg/dL), and prothrombin time (INR) was 1.01±0.08 seconds (range: 081-1.22) before treatment. The mean serum ALT levels were 132±71 iu/L (range: 42-290 IU/L), and mean serum HBV DNA were 224±255 pg/mL (range: 6-1924 pg/ml) before treatment.

The major side effects of treatment were: flu-like symptoms: 8 (53 %), fatigue: 12 (80 %), insomnia: 4 (29 %), hair loss: 5 (33 %), and depression: 1 (7 %). None developed anemia (hemoglobin <11 g/dL), leukopenia (leukocyte <3500/ μl), thrombocytopenia (thrombocytes $<100\times10^3/\mu l$), hyperbilirubinemia (>2.0 mg/dL), or pancreatitis during therapy.

Fourteen patients finished a 24-week-course of treatment. One patient (HSF) discontinued interferon after 2 months of therapy due to interferon-related depression. His serum ALT remained abnormal from 210 IU/L before treatment to 38 IU/L at the end of treatment, and serum HBV DNA levels dropped from 90 pg/mL before treatment to 29 pg/mL at the end of therapy. None of the remaining 14 patients experienced depression, aggression, hostility or hallucination.

The serum ALT levels dropped from 132±71 IU/L before treatment to 46±17 IU/L at the end of treatment (Table 2, P= 0.0002), and the serum HBV DNA levels decreased from 224±255 pg/ml before treatment to 8±12 pg/mL at the end of treatment (P=0.058). At the end of treatment, 7 (50 %) of the 14 patients had serum ALT levels within normal limits. Although 12 (86 %) patients had undetectable serum HBV DNA levels (<5 pg/mL) using the liquid phase molecular hybridization assay, only 8 of them had undetectable HBV DNA (<20 copies/mL) using the RT-PCR. Both of these patients had complete response with normal serum ALT levels and undetectable at the end of treatment. The remaining 12 patients had abnormal serum ALT levels and/or detectable HBV DNA.

Six months after the end of treatment, the mean serum ALT (90±58 IU/L, P=0.03) and HBV DNA (63±70 pg/ml, P=0.05) levels increased compared to those at the end of treatment. Three patients continued to have undetectable serum HBV DNA using the liquid phase molecular hybridization assay method. However, only two (14 %) of them had both complete response and sustained complete response to the combination therapy with serum ALT level <35 IU/L and undetectable serum HBV DNA levels using the RT-PCR method. One patient with undetectable HBV DNA using the liquid phase molecular hybridization assay had abnormal serum ALT levels after the end of treatment; his serum HBV DNA level was 93 copy/dL using the RT-PCR. All of the remaining 11 patients had abnormal serum ALT levels as well as detectable serum HBV DNA.

Table 1 Demographic data, biochemical data and serum HBV DNA levels of patients

Patient No	Age/Gender (y)	ALT (IU/L)	Total Bilirubin (mg/dL)	Prothrombin time (INR)	HBV DNA (pg/mL)
1*	52/M	210	0.9	1.02	90
2	65/M	42	0.9	0.93	24
3	61/M	162	1.4	1.18	1924
4	43/M	38	0.8	0.91	107
5	45/M	212	0.8	1.00	303
6	34/M	49	0.4	1.02	66
7	38/M	47	0.6	1.05	262
8	36/M	119	0.9	0.81	6
9	35/M	56	0.8	0.90	7
10	48/M	154	0.5	1.12	265
11	46/M	223	1.0	1.14	56
12	38/M	290	1.8	1.16	8
13	41/M	44	1.0	0.93	8
14	39/M	195	0.7	1.03	11
15	60/M	147	0.7	1.07	17

*Patient 1 received only 8 weeks of interferon therapy

Both of the two patients with sustained complete response were less than 40 years old (36 and 38 years old) with higher initial serum ALT levels >100 IU/dL (119 and 290 IU/dL), lower initial serum HBV DNA levels <10 pg/ml (6 and 8 pg/mL), and a histology with moderate intralobular degeneration and focal necrosis (range: 1/3-2/3 of lobules). Using the two-tailed Fisher' s exact test, age<40 year-old (P=0.11), serum ALT level >100 IU/dL (P=0.37), serum HBV DNA < 10 pg/ml (P=0.07), and moderate to severe intralobular degeneration and focal necrosis (P=0.07) were not significant factors in predicting sustained complete response.

ND: HBV DNA <5 pg / ml using the liquid phase molecular hybridization assay (LPMH); HBV DNA < 20 copies / dL using the real-time polymerase chain reaction (PCR). [a]Patient 1 received only 8 weeks of interferon therapy; [b]P=0.0002, [d]P=0.05 compared with those before treatment; [c]P=0.058, [e]P=0.05 compared with those at the end of treatment

DISCUSSION

At the end of treatment, the mean serum ALT level was decreased, and half of the patients had a serum ALT level within normal limits. Although most patients had undetectable HBV DNA levels using the liquid phase molecular hybridization assay, the change of serum HBV DNA levels was not statistically significant, a finding consistent with studies from patients of chronic viral hepatitis B with wild type HBV DNA[11,20].

Six months after the end of treatment, the mean serum ALT level was significantly increased compared with those at the end of treatment. Only 14 % of patients had sustained response with normal serum ALT levels as well as undetectable HBV DNA levels. The low sustained response rate to combined interferon alpha-2a and lamivudine was consistent with those of interferon mono-therapy for patients with mutant type chronic hepatitis B[8,9]. Our pilot data showed that lamivudine did not increase the efficacy of interferon in the treatment of mutant type chronic hepatitis B, a finding consistent with studies stating those having positive HBeAg that IFN and lamivudine did not offer additional benefit compared with lamivudine monotherapy[20].

Although 12 of the 14 patients (86 %) had an undetectable HBV DNA level at the end of treatment using the liquid phase molecular hybridization assay, half of them had abnormal serum ALT levels. Only 14 % and 21 % of the 12 patients with undetectable HBV DNA levels using the liquid phase molecular hybridization assay had normal serum ALT levels and undetectable serum HBV DNA using the RT-PCR method. RT-PCR is much more sensitive than liquid phase molecular hybridization assay in the detection of samples with low HBV DNA levels.

For the 15 serum samples with undetectable HBV DNA using the liquid phase molecular hybridization assay, only 10 of them had an undetectable HBV DNA level using the RT-PCR. These four samples were from eight and two patients at the end and 6 months after treatment. Both of these patients had sustained normal serum ALT levels and undetectable serum HBV DNA at 6 months after treatment. For the remaining 5 patients, low titer HBV DNA was identified using the RT-PCR, and all patients developed abnormal serum levels after the end of treatment. Our data showed that the liquid phase molecular hybridization assay was not sensitive enough to detect the low HBV DNA levels during combined interferon alpha-2a and lamivudine therapy. RT-PCR method is better than liquid phase molecular hybridization assay in the detection of low titer HBV DNA. The presentation of low levels of HBV DNA may result in subsequent abnormal serum ALT levels and increasing HBV DNA levels in 6 months.

Abstract

AIM: To investigate the molecular mechanism of cell adaptation and rapid replication of hepatitis A virus strain H2 in KBM17 cells.

METHODS: Virus of strain H2 at passage 7 was consecutively passaged in KBM17 cells for 22 passages, every passage was incubated for 14 days. Antigenic and infectious titers of every passage and one-step growth dynamics of passage 22 were determined with ELISA. Genomes of passage 6, passage 12, passage 18 and passage 22 were sequenced and compared with H2K7.

RESULTS: During continuous passage of vaccine strain H2 at passage K7 in KMB17 cells, infectious and antigenic titers increased with the increase of passages, infectious titers at day 14 reached 6.77LgCCID$_{50}$ml^{-1} for passage 6 (P6), 7.0 LgCCID$_{50}$ml^{-1} for passage 12 (P12), 7.33 LgCCID$_{50}$ml^{-1} for passage 18 (P18) and 7.83 LgCCID$_{50}$ml^{-1} for passage 22 (P22), respectively. The one-step growth dynamics showed that replicating peak of P22 appeared at day 14 with infectious titers of 7.83 LgCCID$_{50}$ml^{-1} and antigenic titer of 1:1024. After passage 22 a new cell-adapted variant (P22) of H2K7 with rapid and shortened replication cycle from 28 days to 14 days was obtained. Sequencing and comparisons of genomes of P6, P12, P18 and P22 showed that mutational numbers in genomes of different passages increased with adaptive passages, and mutations scattered over the genome. In comparison with that of K7, P6 had only 6 nucleotides (nt) mutations, P12 had 7 mutational changes, in addition to 6 same mutations with P6, there appeared a new mutation in 5'NTR at nucleotide position 591 resulting in a nucleotide exchange from A to G. P18 had 10 nt mutations, among the 10 mutations, 7 mutational changes were same as with P12, three new mutational changes appeared in the genome, one in 5'NTR, one in 3C coding region, one in 3D coding region, at P22 there appeared 18 nucleotide changes in the genome, on the basis of P18, there occured additional 8 nucleotide mutations, two in 5'NTR, three in 2C, one in 3A, one in 3C and one in 3D. The results suggested that although H2K7 was already an attenuated strain, the mutations of genome is not sufficient to completely adapt the KMB17, further mutations caused rapid replication adaptation.

CONCLUSION: 18-nt changes scattering over the genome are cooperatively responsible for further adaptation characterized by rapid and shortened replication cycle from 28 days to 14 days in KMB17 cells. The mutations in 2C coding region play more important role in increase of infectious titer than other mutations, the mutations in 2B coding region show less important role than it usually does in cell adaptation, nucleotide changes in 5' NTR seem to be not relevant to cell adaptation during initial stages (before P6), but do in late stages.

INTRODUCTION

Hepatitis A virus (HAV), one of the two members of genus *Hepatovirus*, is enterically transmitted primarily through the fecal/oral route causing sporadic and epidemic acute hepatitis in humans[1,2]. Human HAV is a nonenveloped icosahedral particle of 27-32 nm in diameter with a single-stranded, 7.5-kb positive-sense RNA genome with a long 5'-terminal nontranslated RNA segment (5' NTR) and a short 3' NTR with a poly(A) tail[1]. Similar to other picornaviruses, the HAV genome contains one large open reading frame encoding a polyprotein of about 250 kD, which is co-and posttranslationally cleaved into smaller structural proteins (2A, 2B and 2C) and nonstructural proteins (3A, 3B, 3C and 3D) by virus-encoding proteinases[3].

HAV has been adapted to grow in a variety of primate cell lines[4], but in contrast to that of other picornaviruses, the replication cycle of wild-type HAV isolated from infected human in cell culture is extremely low and inefficient. After prolonged incubation and several passages in cell culture, a persistent infection with low virus yields and little apparent impact on cellular growth and metabolism is normally established[5]. Only a few HAV strains have been reported to cause cytophethesis in vitro[6,7].

Unlike other picornaviruses, although HAV can be adapted to grow in a variety of primate cell lines, cell-adapted variants still grow poorly in cell culture. The molecular mechanisms of adaptation and slow replication cycle are still not completely understood.

That the genomes of a number of wild types and cell-adapted HAV strains have been completely or almost completely sequenced made it possible to determine the

nucleotide changes responsible for cell adaptation. By sequence comparison of different cell-adapted variants[8-19], and studies with chimeric HAV composed of sequence from wild-type and cell culture-adapted variants[20-22], mutations increasing virus replication in cell culture were identified. The adaptation of HAV to grow in cell culture is associated with a number of cooperative mutations over the whole genome, but the mutations within 5' NTR containing regulatory internal ribosome entry segment (IRES) for viral translation[23], and within 2B and 2C coding regions encoding enzymes for viral RNA replication[24], play more important role in cell adaptation. Moreover, the mutations in 2B and 2C coding regions were proven to be necessary for adaptation of growth in cell culture of HAV variants[10,11,21], the mutations in 5' NTR had no independent effect , but cooperatively acted with 2B and 2C coding regions to enhance replication in cell culture[21,24].To study further the molecular mechanisms of cell adaptation of HAV in cell culture, a cell-adapted variant of live HAV attenuated vaccine strain H2 was used for consecutive passage for 22 passages in human embryonic lung diploid fibroblast KMB17, during passages the replicating peak cycle was shortened from 28 days to 14 days, the genomes of different passages, 6th passage (HAVH2K7P6), 12th passage (HAVH2K7P12), 18th passage (HAVH2K7P 18) and 22nd passage (HAVH2K7P22), were sequenced and compared to identify the adaptive mutations.

MATERIALS AND METHODS

Cell

Human embryo lung diploid fibroblast strain (KMB17)[25] was used at passage 24-35 in this research.

Virus Strain

Hepatitis A virus strain H2, an attenuated strain at passage K7, was derived from the fecal specimen of a patient with hepatitis A in Hangzhou, China. After isolation and passage in a culture of newborn monkey (*Macaca Mulatta*) kidney cells, adaptation to grow in human embryo lung diploid fibroblast (KMB17), and serial passage at a low temperature (32 ℃) in KMB17 cells, the strain became attenuated[25] and licensed for production of live attenuated HAV vaccine.

H2 strain passage and rapidly replicating adaptation in KMB17 cells

KMB17 cells were grown in 25 cm^2 flask (Nunc, Weisbaden, germany) using Eagle' Minimal Essential Medium supplemented with penicillin (100 U/ml), streptomycin (100 μg/ml), and 10 % heat-inactivated newborn calf serum, and passaged every four days. HAV H2M20K7 with 28-day replication cycle were seeded onto KMB17 confluent monolayer cells,after 37 ℃ absorption for 2 hours, maintenance medium with 2 % newborn calf serum were added, and seeded cells were cultured at 35 ℃ for 14 days. The virus was harvested at the 14th day, and then seeded onto the monolayer cells again, the virus was serially passaged for 22 passages with 14-day cycle. The antigen titers and infectious titers were detected with ELISA[26, 27]. The virus at 6th, 12th, 18th, 22nd passage were designated as HAVH2K7P6(P6), HAVH2K7P12(P12), HAVH2K7P18(P18) and HAVH2K7P22(P22), respectively. The respective genomes were cloned and sequenced.

One-step growth dynamics

KMB17 cells were infected with a multiplicity of infection (MOI) of 5. The titer was assayed by inoculating the cells grown in25 cm^2 flask (Nunc, Weisbaden, germany), and infection was checked 4 weeks after inoculation by ELISA[26, 27].

Primers and sequencing strategy

Primers were designed according to the sequence of H2K7[29] with Goldkey software (Table 1), The sequencing strategy was showed as Figure 1.

Table 1 The primers used for amplification of HAV genomic RNA

Antigen-capture PCR amplification of the genomes

cDNA synthesis and cloning Antigen-capture PCR were used to prepare cDNA of genome of different passages[29] with some modifications. Sterile 0.5-ml conical tube (Ependorf) was coated 100 μl of human anti-HAV IgG diluted 1:1 000 in 50 mM sodium carbonate buffer (pH 9.6). After 4 h of incubation at 37 ℃, the unbound IgG was removed , and 150 μl of 1 % bovine serum albumin (Sigma) diluted in the buffer was added. After 1 h at 37 ℃, the tube was washed three times with 300 μl of PBS (pH 7.4) containing 0.05 % Tween 80. purified HAV (100 μl) was then added, and the preparation was incubated overnight at 4 ℃. The tube was washed six times with 500 μl of a 40 mM Tris (pH 8.4)-40 mM KCl-7 mM $MgCl_2$ solution. Then 100 μl of water was added and tube was heated to 95 ℃ for 5 min to disrupt captured viruses and melt any second structures within the viral RNA. The first strand cDNA was synthesized using SuperScriptTM Preamplification System kit (Gibco, Life Technologies), following the instruction by

manufacturer. The clones of different fragments were performed by PCR in a mixture (50 μl) including 5 μl 10×LA PCR buffer, 8 μl 2.5mM dNTPs, 2 μl template of RT-PCR products, 300nM positive-sense primer, 300nM negative-sense primer and 2.5U LA Taq DNA polymerase (TaKaRa), additing water to 50 μl. The reaction mixture was subjected to 95 ℃ for 5 min, then 30 automated cycles of denaturation at 95 ℃ for 30 sec, annealing at 50 ℃ for 30 sec, and extention at 72 ℃ for 1 min or 1 min 30 sec., The final reaction was incubated at 72 ℃ for 10 min. After the PCR products were recovered and purified, the fragments were ligated into pGEM-T Vector (Promega). The resulting products were transformed into competent *E.coli*. DH5α cells. Three ampicillin-resistant clones were picked out for each fragment. The size of inserts in positive clones was estimated with restriction enzyme site at either side of the inserted fragment. Rapid plasmid preparations were made with the Wizard plasmid purification kit (Promega).

DNA sequencing and analysis

Sequencing strategy was shown in Figure 1. Oligonucleotide primers specific for HAV and primers corresponding to the T7/SP6 promoter region of pGEM®-T Vector were used to sequence the Inserted and identified HAV fragment. a Taq DyeDeoxy Terminator Cycle sequencing kit and a 377 DNA sequencer (Perkin Elmer) were used to determine nucleotide sequences. To eliminate the possibility of errors in the sequence due to Taq polymerase for PCR, at least three clones of each amplified fragment derived from two individual PCR products were sequenced. Also to correctly determine the sequence of extreme 5 terminus of HAV genome, a 5' RACE reaction was used to obtain the a cDNA fragment from 5' NTR of genome with 5' -Full RACE Core Set (TaKaRa). Analysis, alignment and translation in the amino acids of the obtained nucleotide sequences were done using the sequence analysis program OMEGA (Oxford Molecular).

RESULTS

Dynamical characteristics of adaptive enhancement of H2K7 replication in KMB17 cells

Although HAV has been adapted to grow in cell culture, even cell culture adapted variants grow considerably slowly with low virus yields and characterized by an asynchronous onset of replication[30,31]. HAV usually established ersistent infection in cell culture with protracted replication cycle, but replication cycle of maximal accumulation of HAV in cell culture was dually shortened with the increase of passages, even cytopathic effect (CPE) appeared[32-35]. Attenuated HAV strain H2K7 didot cause CPE in KMB17 cells, its replicating peak of was days, the infectious titer reached. $0LgCCID_{50}ml^{-1}$. In this study, attenuated strain H2 at passage K7 were passaged in KMB17 cells every fourteen days. At last the change of incubation cycle, from 28 days to 14 days, resulted in the increase of both antigenic and infectious titers. At first passage of adaptation (P1) the antigenic and infectious titers were only 1:16 ELISA units (ELI.U) and $5.83LgCCID_{50}ml^{-1}$, respectively, at P6 the antigenic and infectious titers gradually increased o 1:64 ELI. U and $6.77LgCCID_{50}ml^{-1}$, respectively, at P12 obvious enhancement of antigenic and infectious titers (1:256 ELI.U and 7.0 $LgCCID_{50}ml^{-1}$, respectively) occured, More enhancement appeared at P18 with 1:512 ELI.U and 7.33 $LgCCID_{50}ml^{-1}$, respectively, at P22 antigenic and infectious titers reached the highest levels of 1:1024 ELI.U and 7.83 $LgCCID_{50}ml^{-1}$, respectively (Table 2). During the whole passages no CPE appeared. Furthermore, one-step growth dynamics showed that at P22 at days 2, 4, 6, 8, 10, 12 14 of culture antigenic and infectious titers gradually increased, at day 14 antigenic and infectious titers reached the highest levels of 1:1024 ELI.U and 7.8 $LgCCID_{50}ml^{-1}$, respectively, afterwards, the infectious titer gradually decreased, but antigenic titer remained unchanged until day 26 (Table 3). The increases of antigenic and infectious titers with consecutive passage showed that strain H2K7 had been further adapted successfully in KMB17 cells with shortened replication cycle of 28 days to 14days.

Mutational Characteristics in Consecutive Passage of Rapid Replication of Strain H2 during Cell Culture Adaptation

The process of adaptation of HAV in cell culture was also a process of serials of mutations in genome and results in attenuation[11]. The rapidly adaptive passages of H2K7 in KMB17 cells caused the change of replication cycle, from 28 days to 14 days. The maximal virus yields appeared at 14 days at P22 (Table 3). In order to investigate whether the shortened replication cycle of H2K7P1-22 in cell adaptation was reflected by mutational changes in the genome, which was thought to be responsible for adaptation of HAV, and whether related mutations were responsible for the adjustment of shortened replication cycle, we sequenced and compared the entire genome of four passages (P6, P12, P18, P22), the mutations correlating with adaptation at different passages were identified. The results revealed that mutational numbers in genomes of different passages increased with adaptive passages, and mutations scattered throughout the whole genome. There were only 6 nucleotides mutations appeared in the genome of P6, and nucleotide identity was up to 99.93 % in comparison with that of H2K7, as shown in (Table 4),

two mutations occurred in VP2 coding region (at nucleotide position 858 with exchange from G to U, resulting in amino acid exchange from A to S, at nucleotide position 1178 with silent exchange from C to U, resulting in no amino acid exchange), one mutation in 2B coding region (at nucleotide position 4022 with exchange from U to C, resulting in amino acid exchange from C to I), one mutation in 2C coding region (at nucleotide position 4968 with exchange from A to C, resulting in amino acid exchange from N to H), one in 3A coding region (at nucleotide position 5193 with exchange from C to T, resulting in amino acid exchange from R to C), one in 3D coding region (at nucleotide position 7256 with silent exchange from A to U). When H2K7 was passaged up to P12, 7 mutations appeared, in addition to 6 same mutations with P6, there was a new mutation appeared in 5' NTR at nucleotide position 591 resulting in a nucleotide exchange from A to G. P18 had 10 nucleotide mutations occurred in the entire genome, among 10 mutations 7 mutational changes were the same with P12, three new mutational changes appeared in genome, one in 5' NTR (one at nucleotide position 33 with nucleotide exchange from C to U), one in 3C coding region (at nucleotide position 5715 with exchange from A to G, resulting in amino acid exchange from U to A), one in 3D coding region (at nucleotide position 6427 with exchange from U to G, resulting in amino acid exchange from V to G). At P22 there were 18 nucleotide changes appeared in the genome, on the basis of P18 additional 8 nucleotide mutations appeared, two in 5' NTR (at nucleotide position263 with exchange from U to C, and 378 with exchange from U to C), three in 2C coding region (at nucleotide position 4 558 with exchange from A to C, resulting in amino acid exchange from Q to R, at nucleotide position 4802 with silent exchange from U to C, resulting in no amino acid exchange, at nucleotide position 4 949 with silent exchange from A to U), one in 3A coding region (at nucleotide position 5 217 with exchange from G to U, resulting in amino acid exchange from A to S), one in 3C coding region (at nucleotide position 5 336 with silent exchange from G to A), one in 3D coding region (at nucleotide position 7 256 with silent exchange from A to U).

Identity comparisons of genomes of different passages

Complete nucleotide sequence analysis of four-passage adaptive variants revealed an identity between H2K7 and P6 of 99.93 %, between H2K7 and P12 of 99.9 %, between H2K7 and P18 of 99.87 %, and between H2K7 and P22 of 99.76 %. The identity comparisons showed that mutations increased gradually with the increase of passages, but at high passage obvious mutations were concentrated in 5' NTR region, for example, P22 had 18 nucleotide mutations, 5 of 18 mutations appeared in 5' NTR region, the other mutations scattered throughout the coding region, during adaptive process no mutations appeared in VP4 coding region, VP3 coding region, VP1 coding region, 2A coding region, 3' NTR, the identities were 100 % (Table 5).

DISCUSSION

Although the wild-type HAV grew poorly in cell culture, it usually did not cause CPE, and tended to establish persistent infection, after consecutive passages cell-adaptive variants were characterized with higher replication yield, rapid replication cycle and attenuation[19], and nucleotide mutations increased with adaptive passages[17]. On this basis, the development of a live attenuated hepatitis A vaccine (H2 strain) showed good immumogenicity and protective efficacy[36]. a variant of vaccine strain H2 was isolated in the consecutive passages in KMB17 cells without CPE and characterized with rapid replication cycle of 14 days, higher infectious titer of 7.8 $LgCCID_{50}ml^{-1}$.

From the viewpoint of evolution, cell adaptation of HAV depends on the interaction of HAV and cell, the internal cell environments form a selective pressure on the virus, in order to survive the viral genome gradually mutates to form new phenotype to adapt cell environments, so the accumulations of mutation with increasing passages result in more adaptive phenotype, more rapid replication cycle and higher virus yield. In accordance with this, in a continued passage process of vaccine strain H2 at passage K7 in KMB17 cells, with the increase of infectious titers the mutational numbers of genomes of different passages increased, P6 had 6 mutations with infectious titer of 6.77 $LgCCID_{50}ml^{-1}$, P12 had 7 mutations with infectious titer of 7.0$LgCCID_{50}ml^{-1}$, P18 had 10 mutations with infectious titer of 7.33 $LgCCID_{50}ml^{-1}$, P22 had 18 mutations with infectious titer of 7.8 $LgCCID_{50}ml^{-1}$. One-step growth dynamics of P22 also showed that 18 mutations of P22 resulted in shortening the replication cycle from 28 days to 14 days. The results suggested that although H2K7 was already an attenuated strain, the mutations of genome was not sufficient to completely adapt the KMB17, only further mutations increased its adaptive ability in cell KMB17. The sequencing and analysis of genomes of different passages of several cell culture-adapted variants of the HM175 strain of HAV also showed that with the increase of infectious titers the mutational numbers of genomes of different passages increased[9, 19, 24].

In contrast to the other viruses of picornaviruses, mutations of cell adaptation of HAV scattered throughout the whole genome and cooperatively acted to enhance the growth of virus in cells. sequencing of cell culture-adapted variants of the HM175 strain of HAV showed that P16 had 19 mutations[24], P35 had 25 mutations[19] and P59 had 42 mutations[9], P6 of cell culture-adapted variants of the H2 strain in KMB17 had 6 mutations, P12 had 7 mutations, P18 had 10, P22 had 18, although different strains in different cells had different mutations, these variants shared common mutations in 5' NTR and in 2B, 2C, 3A, 3B, 3C, 3D coding region of the genomes. Experiments with chimeric infectious cDNA clones indicated that the mutations in both 5' NTR and in 2B, 2C, 3A, 3B, 3C, 3D coding region contributed to the ability of the virus to grow in cells of African green monkey kidney lineage[11,12]. These results revealed that mutations in 5' NTR and in 2B, 2C, 3A, 3B, 3C, 3D coding region of the genomes played more important role than others in cell adaptation.

The 5' NTR of HAV forms a highly ordered secondary and presumably tertiary structure, and contains elements necessary for both viral translation and RNA replication[37], HAV translation is initiated in a cap-independent fashion by a mechanism that involves the binding of the 40s ribosomal subunit at a site located hundreds of bases downstream of the 5' end of the RNA which has been termed a ribosomal landing pad or an internal ribosome entry segment (IRES)[23,37,38,]. Mutations analysis of 5' NTR showed that the IRES of 450 nucleotides was located downstream of nucleotide (nt)161 and extended to within 40 nt of the first initiator AUG[38-40]. The efficient translation activity by IRES necessitates the interaction of secondary and presumably tertiary RNA structure with a set of specific eukaryotic translation initiation factors and also noncanonical host factors[39-41]. Therefore, it is likely that these 5' NTR mutations enhance translation by altering the affinity of the RNA for cellular proteins that either positively or negatively influence the activity of the IRES.

In our study in the continuous cell adaptation of H2K7, the sequencing showed that increased infectious titers with the increased passages of H2K7 in KMB17 cells correlated well with the increased mutations in 5' NTR. P6 had no mutations in 5' NTR with infectious titer of 6.77 $LgCCID_{50}ml^{-1}$, P12 had 1 mutation in 5' NTR (nt 591) with infectious titer of 7.0 $LgCCID_{50}ml^{-1}$, P18 had 3 mutations in 5' NTR (nt 33, 591, 646) with infectious titer of 7.33 $LgCCID_{50}ml^{-1}$, P22 had 5 mutations in 5' NTR (nt 33, 263, 378, 591, 646) with infectious titer of 7.8 $LgCCID_{50}ml^{-1}$, in addition to 1 mutation (nt 33 of P18 and P22), all mutations appeared in IRES. According to the viewpoint mentioned above, one mutation (nt 591) in IRES of P12 may change the secondary and presumably tertiary structure of 5' NTR of K7, this changed IRES structure enhance the affinity of K7 RNA with cellular proteins, resulting in the enhancement of translation, among 3 mutations in 5' NTR of P18, 2 mutations in IRES further enhance the affinity of K7 RNA with cellular proteins, resulting in further enhancement of translation, among all mutations in 5' NTR of different passages, 4 mutations in IRES of P22 produce the most efficient affinity of RNA with cellular proteins, yielding the maximal progeny virus. A comparison with the modelof 5' NTR of RNA secondary structure of the HAV genome, proposed by Ali *et al*[39], suggest that the G to U mutation (nt 646) of 5' NTR of P22, located in the terminal part of the 5' NTR (loop V), could lead to an RNA duplex folding stabilized by an additional basepairing, resulting in further increase of infectious titer. Consistent with our result, Graff *et al* also showed that increased mutations in IRES of different-passage GBM/Hp8/24 played a role in enhancement of infectious titer and a common G to U mutation (nt 646) of 5' NTR of strain GBM appeared in GBM/Hp8/6, but mutations of different positions of 5' NTR of different HAV strains in different cells may reflect the different interactions of 5' NTR with different cellular proteins. It is worth noting that P6 had no mutation in 5' NTR, but the infectious titer only reached 6.77$LgCCID_{50}ml^{-1}$, 0.9 $LgCCID_{50}ml^{-1}$ more than that at P1, indicating less important role of 5' NTR in early cell adaptation. Consistent with our result, Frings *et al*[42] found that after 5-passage adaptation of primate cell-adapted hepatitis A virus strain HM175 to its growth in guinea pig cells, the infectious titer reached 6.3 $LgCCID_{50}ml^{-1}$, but no mutation in 5' NTR. Taken together with our result, it suggest that during early adaptation there were different ways to improve HAV fit with a specific complement of host cell factors and that growth restrictions in defined host cells had not been determined solely by regulatory interactions of cellular factors with 5' NTR sequence, which concerned mainly cap-independent translation initiation.

Previous studies showed that 2B and 2C coding region mutations are essential for cell adaptation of HAV, mutations in other regions have no independent effect, but act cooperatively with mutations in 2B and 2C coding region to enhance replication[43]. 2B and 2C coding region are found to have 251 and 335 amino acids, respectively. Protein 2B is involved in the rearrangement of cellular membrane[3]. Protein 2C is considered to have helicase and NTPase activities[3]. The

functions of 2B and 2C suggest that the mutations in these two regions play important roles in cell adaptation of HAV. During continuous passages from P6-P22 of H2K7, 4 mutations appeared in 2C coding region, two were silent mutations, two resulted in two- amino acid substitutions, one was common in P6, P12, P18 and P22, one mutation at nt 4558 from A to C only appeared in P22, causing amino acid substitution from Q to P, this substitution may enhance the function of 2C, and further increase the infectious titer at P22. In contrast to the previous results[15], in sequence of entire genome of 4 passages (P6,P12,P18,P22), only one mutation appeared in 2B coding region at nt 4022 from U to C, but not resulting in amino acid mutation, this might suggest that 2B protein play less important role than 2C in KMB17 cell adaptation of H2K7.

Mutations in 3A coding region of the isolate in Italy correlated with CPE[35], but our result showed that although mutations in 3A coding region appeared, even a unique amino acid mutation from A to S occurred at P22, no CPE appeared at all passages of H2K7 in KMB17 cell culture. The mechanism remains unknown. The other mutations in 3A, 3C, 3D coding region of P22 may cooperatively act to further enhance the virus replication.

Comparisons of entire genome of P22 with those of continuous passages of GBM and HM175 in different cells showed that although the mutations existed in the same 5' NTR, 2B, 2C, 3A, 3B, 3C, 3D coding regions, most of the mutational sites were different, these differences revealed different interaction of HAV with different cellular proteins under different selective pressures.

From our investigations of sequence analysis of consecutive H2K7 passages and a comparison of their growth characteristics, we can conclude that 18-nt changes scattering over the genome are cooperatively responsible for further adaptation characterized by rapid and shortened replication cycle from 28 days to 14 days in KMB17 cells, the mutations in 2C coding region play more important roles in increase of infectious titer than other mutations, the mutations in 2B coding region show less important role than it usually does in cell adaptation, nucleotide changes in 5' NTR seem not to be relevant during initial stages (before P6) of cell adaptation because of the significant enhancement in infectious titer not correlating with the mutations in this region, but in late passage (P22) mutations in 5' NTR which seem to affect obviously the replication cycle of H2K7 in cell adaptation.

Abstract

AIM: To assess and compare the efficacy and safety of two triple regimes: A) metronidazole, amoxicillin and omeprazole, which is still widely used in Russia, and B) azithromycin, amoxicillin and omeprazole in healing active duodenal ulcer and *H.pylori* eradication.

METHODS: 100 patients with active duodenal ulcer were included in the open, multicentre, randomized study with comparative groups. Patients were randomly assigned to one of the following one-week triple regimes: A) metronidazole 500 mg bid, amoxicillin 1 g bid and omeprazole 20 mg bid (OAM, *n*=50) and B) azithromycin 1 g od for the first 3 days (total dose 3 g), amoxicillin 1 g bid and omeprazole 20 mg bid (OAA, *n*=50). Omeprazole 20 mg od was given after the eradication course as a monotherapy for three weeks. The control endoscopy was performed 8 weeks after the entry. *H.pylori* infection was determined in the entry of the study and four weeks after the cessation of treatment by means of histology and CLO-test.

RESULTS: 97 patients completed the study according to the protocol (1 patient of the OAM group did not come to the control endoscopy, 2 patients of the OAA group stopped the treatment because of mild allergic urticaria). Duodenal ulcers were healed in 48 patients of the OAM group (96 %; CI 90.5-100 %) and in 46 patients of the OAA group (92 %; CI 89.5-94.5 %) (*p*=ns). *H.pylori* infection was eradicated in 15 out of 50 patients with OAM (30 %; CI 17-43 %) and in 36 out of 50 patients treated with OAA (72 %; CI 59-85 %) (*P*<0.001)- ITT analysis.

CONCLUSION: The triple therapy with omeprazole, amoxicillin and metronidazole failed to eradicate *H.pylori* in the majority of patients, which is an essential argument to withdraw this regimen out of the national recommendations. Macrolide with amoxicillin are preferable to achieve higher eradication rates. Azithromycin (1 g od for the first 3 days) can be considered as a successful component of the triple PPI-based regimen.

INTRODUCTION

A number of antimicrobial agents have been used in various regimens to eradicate *Helicobacter pylori*. The properties of different medications may have some impact on the therapy result. Clinical trails are undertaken to search for simpler but equally effective (or more effective) regimen. The modern macrolides are in the focus of attention from that point of view. Azithromycin, a new generation macrolide, has some special attributes, that makes it a promising compound in the regimens for *H.pylori* eradication. It is acid-stable, has a long half-life and achieves remarkably high concentration in the gastric tissue. Thus after a single oral dose of 500 mg the concentration of azithromycin persisted in the gastric mucosa above the MIC_{90} for *H.pylori* over a five-day period[1]. There were several clinical trails with azithromycin in the therapy of *H.pylori* infection. As pharmacological properties of azithromycin make possible to use shorter courses, the problem was to define an optimal dose and duration of azithromycin in the triple therapy. The triple regimens with the total course dose of azithromycin of 1.5 g gave high eradication rates[2, 3], but the result was not stable[4], the total course dose of 3 g appeared to be more reliable[5, 6].

There were just a few studies of azithromycin in the treatment of *H.pylori* infection in peptic ulcer and chronic gastritis in Russia[7, 8]. The results were satisfactory, and it was clear that further studies to reach the level of evidence-based medicine are needed.

The clinical trial of azithromycin (Sumamed®, PLIVA) in the triple regimen for the eradication of *H.pylori* in active peptic ulcer, that was planned according to the GCP criteria, was of priority significance for Russia. The aim of the study was to assess and compare the efficacy of two triple regimes: (A) omeprazole, amoxicillin and metronidazole, and (B) omeprazole, amoxicillin and azithromycin in healing active duodenal ulcer and *H.pylori* eradication. The safety and tolerability of the two drug combinations were also evaluated and compared.

MATERIALS AND METHODS

Study design

It was an open, randomized study with comparative groups conducted in three Moscow gastroenterological centers: V.

Vasilenko Clinic of internal deseases, gastroenterology and hepatology of the Moscow Sechenov Medical Academy, Gastroenterological Center of the Health Ministry of Russia and Central Institution of Gastroenterology. The study protocol was worked out by PLIVA pharmaceutical company (Zagreb, Croatia).

The study was conducted according to GCP guidelines and the Helsinki Declaration. All patients gave written informed consent and the protocol was approved by the local Ethic Committees of the above-mentioned centers.

Out-patients and in-patients of both sexes aged between 18 and 70 years with endoscopically proven one or more duodenal ulcers were eligible for entry into the study. *H.pylori* presence before the treatment was detected by a rapid urea test and histology. In the CLO-test (Delta-West Ltd, Australia) two biopsy specimens (one from the antrum and one from the corpus on the greater curvature) were examined. The positive result of the CLO-test was needed to involve the patient into the study. Four biopsy specimens (two from the antrum and two from the mid-corpus on the greater and lesser curvature) underwent histopathological assessment. Sections of paraffin-embedded specimens were routinely stained with haematoxylin-eosin for morphologic examination and with Giemsa for *H.pylori* detection.

The information about the study was accessible to all patients before the entry. The written consent was necessary for participation in the clinical trial. The criteria for exclusion were: intake of proton pump inhibitors, antibiotic or bismuth salts within 4 weeks prior to the study, ulcer complications, concomitant gastric ulcer or reflux oesophagitis of grade II or more according to the classification of Savari et Miller, stomach surgery (except for a simple closure of perforation), known hypersensitivity to one of the study medications, severe concomitant diseases with metabolic changes, suspected poor compliance. Patients were required to be a male or nonpregnant, nonlactating females; females were postmenopausal or using a contraceptive.

At the entry the patients had a full physical examination. Routine haemotological and biochemical (serum creatinine, urea, transaminases, alkaline phosphatase, total and direct bilirubine) screening was carried out.

The patients,that satisfied the inclusion criteria,were randomly assigned to one of the following one-week triple regimes: (A) metronidazole 500 mg bid, amoxicillin 1 g bid and omeprazole (Losec®, AstraZeneca) 20 mg bid (OAM) and (B) azithromycin (Sumamed®, PLIVA) 1 g od for the first 3 days (total dose 3 g), amoxicillin 1 g bid and omeprazole (Losec®, AstraZeneca) 20 mg bid (OAA).

Omeprazole (Losec®, AstraZeneca) 20 mg od was given after the eradication course as a monotherapy for three weeks.

Control examination was performed 4 weeks after the cessation of omeprazole monotherapy (8 weeks after entry). Physical status, adverse events, haemotological and biochemical analysis, endoscopy (ulcer healing) were assessed. *H.pylori* infection was determined by histology and CLO-test: cure of the infection was established if two tests of all biopsy specimens gave negative results (two from the antrum, two from the corpus on the greater and lesser curvature for histology and one from the antrum, one from the corpus on the greater curvature for CLO-test).

Statistical analysis

The duodenal ulcer healing rates and *H.pylori* eradication rates were compared between the two treatment groups using a χ^2-test. A two-sided 95 % confidence interval (95 % CI) was calculated using the normal approximation to the binominal distribution.

Patient population

100 patients entered the trial: 50 patients were randomized to group A, and 50-to group B. The two treatment groups had similar demographic characteristics.

The patients at the entry usually had the dyspeptic symptoms typical for active duodenal ulcer. The ulcers localized in the duodenum bulb were between 0.3 cm and 1.5 cm in size (the two thirds of patents had ulcers between 0.5 cm and 1.0 cm in size). Three patients with two duodenal ulcers were randomized to group B.

RESULTS

49 patients (out of 50) of group A (metronidazole, amoxicillin and omeprazole) completed the study without contravention to the protocol: one patient was lost for the follow-up. Two patients of group B (azithromycin, amoxicillin and omeprazole) had mild allergic symptoms (urticaria) in the beginning of the eradication course and stopped treatment. A short use of antihistamine medications led to relief of allergy. Thus, 48 patients of group B (out of 50) completed the study according to the protocol.

The efficacy of treatment regimens was assessed by duodenal ulcer healing. Endoscopy performed 4 weeks after the cessation of omeprazole monoterapy revealed that duodenal ulcers healed in 48 patients of the OAM group and in 46 patients of the OAA group. The causes of ulcer persistence were failed *H.pylori* eradication and drop-out from the protocol. A patient with missing data from group A and two patients of group B (drop-outs due to adverse events) were included in the analysis for ulcer healing as "not healed". Ulcer healing rate in group A was 96 % (CI 90.5-100 %) and in group B 92 % (CI 89.5-94.5 %). Statistical difference was not significant.

The main indicator of the triple regimen effectiveness was the rate of *H.pylori* eradication. Eradication rates were estimated for the population that completed the study according to the protocol (per protocol analysis) and for the population that was involved in the study (intention-to-treat analysis). One patient of group A, that did not come to the control examination, and two patients of group B, withdrawn from the study because of the adverse events, were estimated as a negative eradication result. *H.pylori* infection was eradicated in 15 out of 50 patients with OAM: eradication rate was 30.6 % (95 % CI: 17.6 %- 43.6 %) PP and 30 % (95 % CI: 17-43 %) ITT. *H.pylori* infection was eradicated in 36 out of 50 patients treated with OAA: eradication rate was 75 % (95 % CI: 63-87 %) PP and 72 % (95 % CI: 59-85 %) - ITT analysis (Figure 1).

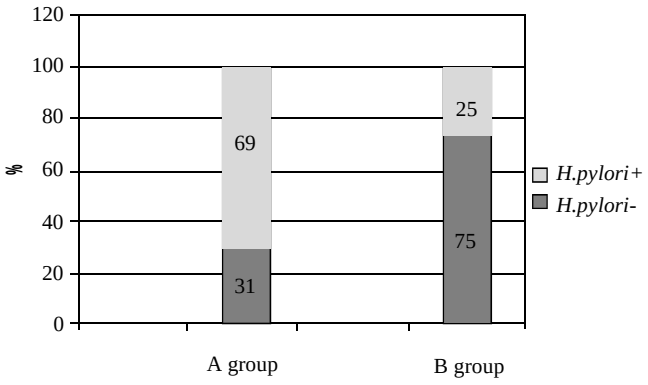

Figure 1 The results (per protocol) of *H.pylori* eradication in the treatment groups.

The difference between the treatment groups was statistically significant: $P<0.001$.

The treatment safety was assessed by adverse events recording, the laboratory tests deviation of clinical significance were also taken into consideration. The two cases of withdrawal because of an allergic urticaria were registered in group B. Quick relief of the allergic symptoms due to the antihistamine preparations allowed us to consider this adverse events as mild. The laboratory parameters of haemotological and biochemical tests (serum creatinine, urea, transaminases, alkaline phosphatase, total and direct bilirubine) were usually normal. There was no clinically significant changes from the baseline in the laboratory results.

DISCUSSION

The new triple regime for *H.pylori* eradication with new macrolide azithromycin was compared with the combination of metronidazole, amoxicillin and omeprazole, which is still widely used in Russia.

Both combinations were highly effective in ulcer healing. The analysis of cases with persistent duodenal ulceration revealed that most of them were connected with protocol nonfulfilment and failed eradication. High healing rates are expected results of triple therapies based on proton pump inhibitors. Both proton pump inhibitors action and the effect of *H.pylori* eradication are of importance in ulcer healing. Persistence of *H.pylori* infection in gastric mucosa is considered now as one of the factors preventing ulcer healing, or to be more precise, as a factor of distortion of the normal regeneration process[9]. This molecular events are not so evident in every-day clinical practice as potent effect of omeprazole. Proton pump inhibitors-based triple therapies even without "posteradicational" antisecretory monotherapy are advantageous in active duodenal ulcer. Rapid symptoms relief and ulcer healing in 96 % patients of group A and in 96 % patients of group B (per protocol) once more proved the effectiveness of eradication therapy based on omeprazole. Rapid ulcer healing did not depend on antibiotic composition.

There are no therapies that eradicate *H.pylori* infection in every case. That is why the search for better anti-*H.pylori* regimes is of present interest. Clinical experience of the Russian trials that are organized according to the principals of evidence-based medicine is of great importance. They give information about the possibility of application of foreign data to the Russian patient population. The therapy used in group A "metronidazole 500 mg bid, amoxicillin 1 g bid and omeprazole 20 mg bid" is widely used in the Russian practice. This regime is well-known to general practitioners and is included in "The guidelines for the management of *Helicobacter pylori* infection" of the Russian *Helicobacter pylori* Study Group and Russian Gastroenterological Association, adopted in 1997[10]. Since that time there were some reports that informed about very low eradication rates with proton pump inhibitor, metronidazole and amoxicillin[11, 12]. The present clinical trial demonstrated (by the example of the patients from three Moscow gastroenterological centers) discouraging eradication rate in the OAM triple therapy. This is a real argument in favour of withdrawing regime "proton pump inhibitor, metronidazole and amoxicillin" from the national guidelines as it was done in the Maastrcht 2-2000 European Consensus report[13].

Antimicrobial resistance of *H.pylori* strains is one of the main causes of treatment failure. *H.pylori* resistance to nitroimidazoles (metronidazole and tinidazole) is quite an often event in the Russian populations. Thus, in Moscow *H.pylori* strains with primary metronidazole resistance were found in more than 50 % of isolates[14]. Unsuccessful anti-*H.pylori* course of metronidazole-containing regimen usually leads to secondary resistance. One-third of the patients in the present study had a long duration of peptic ulcer disease (>5 years), almost all of them had used metronidazole. *H.pylori* susceptibility testing was not considered in the present trial, but we could suspect, with high probability, nitroimidazole resistance as a cause of eradication failure in two-thirds of the group A patients.

The proton pump inhibitor-based triple therapy with amoxicillin and clarithromycin gives steady high eradication rates. The European clinical trial MACH1 demonstrated the best result using omeprazole 40 mg with amoxicillin 1 g bid and clarithromycin 500 mg bid among five omeprazole-based combinations with different antimicribials for seven days[15]. The proton pump inhibitor (or ranitidine bismuth citrate) in combination with clarithromycin 500 mg bid and amoxicillin 1 g bid were named the preferable regimen for first-line eradication therapy in the Maastrcht-2 Consensus report[13]. The real chance to enhance the eradication rates in the countries with high levels of metronidazole resistance is to avoid metronidazole in the anti-*H.pylori* treatment. Provided the levels of clarithromycin resistance are low the macrolide and amoxicillin regimens would be the most beneficial.

The treatment regimen of group B "azithromycin 1 g od for the first 3 days, amoxicillin 1 g bid and omeprazole 20 mg bid for 7 days" eradicated *H.pylori* infection in 72 % of patients, the result is good for the Russian populations. This rate of *H. pylori* eradication seems to be lower that is acceptable. But according to some publications it is quite common with accepted PPI-based triple therapies. Thus J.P.Gisbert *et al*[16] . gave mean eradication rate (weighted mean) as 71 % for ITT analysis for 7-day to 14-day omeprazole-based therapies.

H.pylori has cross resistance to macrolides: the strain resitant e.g. to clarithromycin is resistant to every other macrolide. The level of clarithromycin resistance in Moscow is 8-14 %, unfortunately with the tendency for an increase[14]. The effect of drug synergism is of great value in combination treatment to heal *H.pylori* infection. P.M.Lepper *et al*[17].demonstrated in vitro synergistical effect of azithromycin and proton pump inhibitor lansoprazole. They speculate that this effect may enhance eradication rates even with macrolide-resistant *H.pylori* strains because of the unique pharmacological properties of the combination. Azithromycin could provide a potent anti-*H.pylori* effect and could simplify the bulky triple therapy. Of macrolides azithromycin develops the highest concentration in gastric tissue and mucus, its pharmacokinetic properties makes it possible to take azithromycin only once a day and only during three days in a week course. Clarithromycin for standard eradication is administered for 7 days twice a day (usually 4 tablets of 250 mg). Azithromycin is really an advantageous medication to reach simpler therapy, improving both tolerability and compliance. The correctness of the azithromycin dose chosen in our trial -1 g daily for three days - was confirmed by recent results[18].

In conclusion, we have shown that azithromycin has clinical (*in vivo*) activity against *H.pylori* infection. Azithromycin (1 g od for the first 3 days in a week course) can be considered as a successful component of the triple proton pump inhibitor-based regimen. It is necessary to eradicate *H.pylori* in peptic ulcer patients, using effective and simple regimens.

Abstract

AIM: Chronic liver diseases, such as fibrosis or cirrhosis, are more common in men than in women. This gender difference may be related to the effects of sex hormones on the liver. The aim of the present work was to investigate the effects of estrogen on CCL_4-induced fibrosis of the liver in rats.

METHODS: Liver fibrosis was induced in male, female and ovariectomized rats by CCL_4 administration . All the groups were treated with estradiol(1 mg/kg) twice weekly. And tamoxifen was given to male fibrosis model. At the end of 8 weeks, all the rats were killed to study serum indicators and the livers.

RESULTS: Estradiol treatment reduced aspartate aminotransferase(AST) , alanine aminotransferase (ALT), hyaluronic acid(HA) and type IV collagen(CIV) in sera, suppressed hepatic collagen content, decreased the areas of hepatic stellate cells (HSC) positive for α-smooth muscle actin (α-SMA), and lowered the synthesis of hepatic type I collagen significantly in both sexes and ovariectomy fibrotic rats induced by CCL_4 administration. Whereas, tamoxifen had the opposite effect. The fibrotic response of the female liver to CCL_4 treatment was significantly weaker than that of male liver.

CONCLUSION: Estradiol reduces CCL_4-induced hepatic fibrosis in rats. The antifibrogenic role of estrogen in the liver may be one reason for the sex associated differences in the progression from hepatic fibrosis to cirrhosis.

INTRODUCTION

Estrogen is frequently used for anticonception and treatments of menopausal disorders. Its clinical use has increased steadily during the last years due to reports of decreased morbidity and mortality during postmenopausal estrogen treatment[1]. There have been reports of decreased morbidity in cardiovascular disease, suggesting estrogenic effects on tissues other than on the classic reproductive organs.

Population data have long suggested that chronic liver disease progresses at unequal rates in both sexes for viral hepatitis and other forms of injury with a similar incidence in males and females. In chronic viral hepatitis the major sequelae, such as fibrosis or cirrhosis, are more common in men than in women[2,3]. Although establishing the actual rate of fibrosis in a patient would require serial liver biopsy, which is seldom done, a reasonable approximation can be inferred from the incidence of fibrosis-related complications[4-6]. The development of cirrhosis is more common in men than in women(2.3 to 2.6:1). Although the liver is not a classic sex hormone target, livers in both men and women have been shown to contain estrogen receptors and respond to estrogens by regulating liver function. Therefore, sex hormones may play a role in the progression from hepatic fibrosis to cirrhosis. It showed that estradiol treatment resulted in reducing hepatic fibrosis in rats induced by dimethylnitrosamine(DMN). However, much current evidence suggests that women develop alcoholic liver disease at lower levels of alcohol intake and over a shorter period of time as compared to men. In other words, females are more susceptible to alcohol-induced liver injury than males[7]. The specific mechanisms concerning a gender-related difference in susceptibility are largely unknown.

CCL_4-induced fibrosis shares several characteristics with human fibrosis of different etiologies; thus, it is an adequate model of human fibrosis[8-10] . The aim of the present work was to study the effects of estrogen on CCL_4-induced fibrosis of the liver in rats, and to investigate the possible mechanisms.

MATERIALS AND METHODS

Animals

Male and female Spratgue-Dawley rats (Experimental Animal Holding Unit of Shaanxi Province, China) were housed in a temperature-humidity-controlled environment with 12-h light-dark cycles (lights on from 07:00 to 19:00) and had unrestricted access to food and water. Forty male rats, weighing 220±21 g, corresponding to an age of approximately 10 weeks, were divided into four groups of ten each. For CCL_4 group, 400 mL/L CCL_4 in peanut oil were injected subcutaneously at a dose of 2 ml/kg twice weekly, and the first dosage was doubled. The estrogen group, apart from the used of CCL_4, was treated subcutaneously with estradiol 1 mg/kg twice weekly (The Ninth Pharmaceutical Plant of Shanghai,China). The anti-estrogen group, along with the CCL_4 treatment described above, was given Tamoxifen 6 mg/kg every day orally (The First Pharmaceutical Plant of Suzhou, China). The rats were fed a modified high fat diet containing 5 g/kg cholesteral and 200 g/kg pig oil. The control group was given normal food and water, and received injection of peanut oil vehicle twice weekly.

Fifty female rats 10 weeks old, weighing 208±17 g, were divided into five groups with ten each. The ovariectomy (Ovx) group was initiated with a bilateral ovariectomy and the sham operation group was initiated with just a sham operation. The

two estrogen groups, with bilateral ovariectomy and with sham operation, were treated subcutaneously with estradiol (1 mg/kg twice weekly). All of the above four groups received 400 ml/L of CCL_4 in peanut oil at a dose of 2 ml/kg twice weekly, and were fed with a high fat diet containing 5 g/kg cholesteral and 200 g/kg pig oil. The CCL_4 and estradiol were used after 2 weeks of operation. The control group was given normal food and water, and received injection of peanut oil vehicle twice weekly.

At the end of the 8-week experimental period, all the rats were fasted overnight and put to death by cervical dislocation after anaesthetised by intramuscular injection of sodium pentobarbital (40 mg/kg). Blood was collected from the animals and the serum obtained was analysed. The liver was removed rapidly.

Estimation of serum indicators

In serum, activities of aspartate aminotransferase(AST) and alanine aminotransferase (ALT) were assayed by a 917-Hitachi Automatic Analyzer. Serum hyaluronic acid(HA) and type IV collagen(CIV) concentrations were measured radioimmunologically using commercial kit(Shanghai Navy Medical Institute, China).

Parameters of hepatic antioxidation

Parameters of antioxidation in the liver was determined by measuring the levels of hepatic malondialdehyde (MDA) and superoxide dismutase (SOD) (kit: Jiancheng Medical Institute, Nanjing, China).

Histopathological study

Excised liver tissues from each rat were fixed in 100 ml/L neutral formalin, embedded in paraffin, and stained with hematoxylin-eosin(HE) and masson's trichrome. The evaluation of hepatic fibrosis was determined by a semi-quantitative method to assess the degree of histologic injury in chronic hepatic fibrosis[11,12].

Immunohistochemical examination

Liver tissue sections were mounted on slides, deparaffinized in xylene, and rehydrated in alcohol. The level of α-smooth muscle actin (α-SMA) (Neomarkers,USA), type Ⅰ collagens (Boster, Wuhan, China), transforming growth factor β_1 (TGF β_1) and platelet -derived growth factor(PDGF) (Dako,USA) were determined by immunohistochemical methods in female groups. Based on the extent of histological staging, the α-SMA, type Ⅰ collagens, TGFβ_1 and PDGF positive cells were expressed as a percentage of the total area of the specimen.

Statistical analysis

Data are presented as $\bar{x}\pm s$ unless otherwise indicated. The Mann-Whitney *u* test for nonparametric and unpaired values, student's *t*-test or Fisher's exact test was used as appropriate. Results were considered significant when $P<0.05$.

RESULTS

Changes of serum indicators and hepatic antioxidation date

At the end of 8-week experimental period, 8 rats were dead because of infection at the region of injection and hepatic crack by unsuitable handling. Table 1 gives the values for the activities of the serum indicator enzymes, the markers of hepatic fibrosis, and the hepatic antioxidation data.

It is evident that CCL_4 produced a marked increase in the activities of serum ALT and AST in both male and female rats. Although the extent of that was lower in female group than in male group, it was not statistically significant ($P>0.05$). The CCL_4 plus estradiol group showed a significant decrease in the enzyme levels, but the levels were still higher than those of control groups. In ovariectomy rats, when CCL_4 were given, the enzyme levels were higher than those of the sham operation rats in both estradiol used or none-used groups, but the differences were not statistically significant($P>0.05$). The levels of serum ALT and AST in Tamoxifen group were significantly higher than those of the CCL_4 group and estrogen used groups.

As for the changing trend of fibrotic markers in serums, HA and CIV were similar with those of the enzyme levels in all groups. The results showed that the levels of HA and CIV in CCL_4 used groups were significantly higher than those of control groups, especially in male group. Tamoxifen could increase the extent of that and estrogen could decrease it significantly. In ovariectomy groups, the HA and CIV were significantly higher than those of shame operation groups.

Tissue antioxidation date indicated that MDA was increased and SOD was decreased in CCL_4 treated rats significantly, whereas estradiol had the opposite effect. The MDA was higher and SOD was lower in males than those of females treated with CCL_4.

Histopathological and immunohistochemical changes

The control livers showed normal lobular architecture with central veins and radiating hepatic cords (Figure 1A). Prolonged administration of CCL_4 causes severe pathological damages: inflammation, necrosis, and collagen deposition (Figure 1B,male). The semiquantitative hepatic collagen staging value was 3.3±0.7 in males, and 2.4±1.1 in females. It was showed that the staging value was significantly decreased in female rats. After administration of estradiol, the extent of hepatic fibrosis was significantly weaker than that of CCL_4 groups (Figure 1C:male): the semiquantitative staging value was 2.0±1.1 in males and 1.6±0.9 in females respectively. Ovariectomy significantly increased the staging value (3.1± 0.7). Moreover, the staging value was highest when given Tamoxifen to the experimented rats (3.7±0.5 Figure 1D).

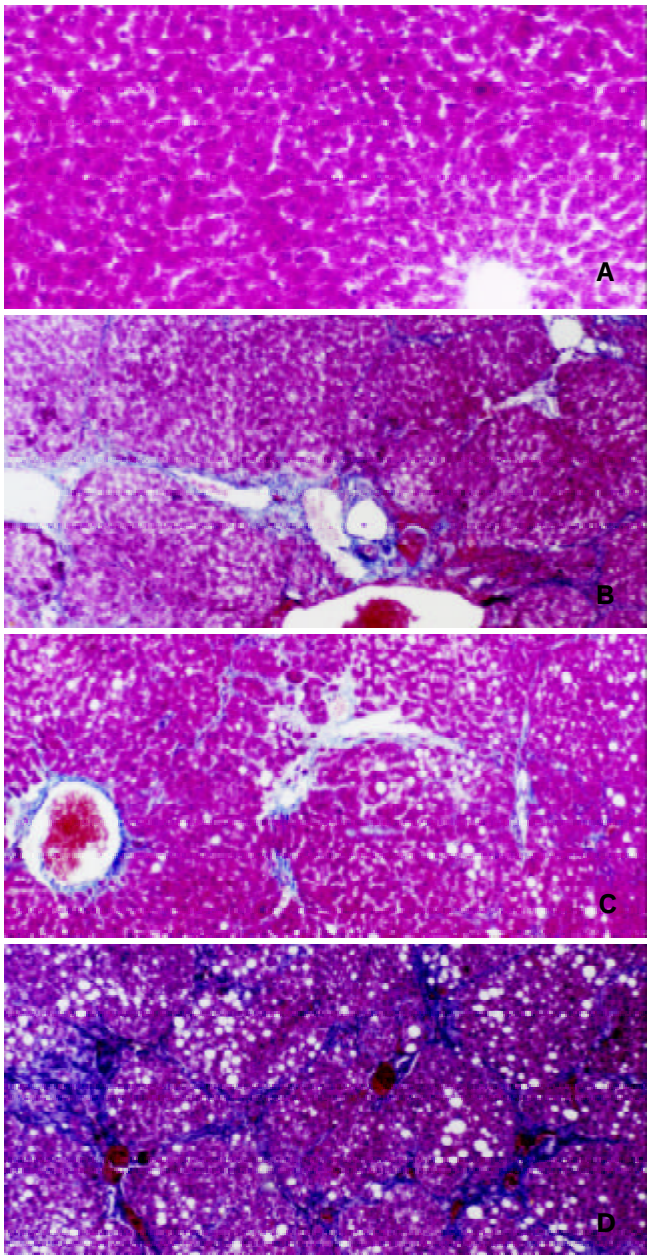

Figure 1 Effects of estradiol and tamoxifen on the histology of CCL_4 induced fibrotic rat liver. Masson trichome stain, scale bar=40 μ m, original magnification, × 100
1A: Normal rat liver; 1B: CCL_4 group shows fibrosis; 1C:Estrogen group with less fibrosis than in group B; 1D: Tamoxifen group shows marked fibrosis than in group B.

Analysis of α-SMA, an activation marker of rat hepatic stellate cells (HSC) by immunohistochemistry showed staining in vascular smooth muscle cell of control rat livers, but not in sinusoids. In the CCL_4 model, the positive cells of α-SMA, type I collagen, $TGF\beta_1$ and PDGF within centrilobular and periportal fibrotic bands. The percentage areas of these staining in the liver of female rats were showed in Figure 2. The results suggest that administration of CCL_4 significantly increased the percentage areas of all of the four marker staining. Ovariectomy group has a marked higher percentage area than that of CCL_4 group and it could be significantly suppresed by estradiol used.

DISCUSSION

Hepatic fibrosis is usually initiated by hepatocyte damage, leading to recruitment of inflammatory cells and platelets, activation of kupffer cells and subsequent release of cytokines and growth factors (e.g. TGFβ_1 and PDGF)[13,14]. These factors probably link the inflammatory and reparative phase of liver cirrhosis, by activating HSC[15-18]. Upon activation, HSC proliferate and transform into myofibroblast-like cells that deposit large amounts of connective tissue components[19-27].

The present study showed that estradiol reduces CCL_4-induced hepatic fibrosis in rats. Estradiol administration reduces HA and CIV in serums, suppresses hepatic collagen content, reduces the areas of HSC positive for α-SMA, and lowers the synthesis of hepatic type I collagen in both sexes. The fibrotic response of the female liver to CCL_4 treatment was significantly weaker than that of male liver. It suggested that physiological levels of estrogen have an antifibrogenic effect. These effects of estrogen were also confirmed by ovariectomy in female rats at the time of CCL_4 administration. These findings suggest that the antifibrogenic role of estrogen in the liver may be one reason for the sex associated differences in the progression from hepatic fibrosis to cirrhosis.

Hepatic fibrogenesis is often associated with hepatocellular necrosis and inflammation accompanied by the repair processes[28-29]. Chronic administration of CCL_4 caused fibrosis as indicated by an increase in serum marker enzymes. Raised serum enzyme levels in CCL_4-injected rats can be attributed to the damaged hepatocellulal structural integrity[30-32]. The administration of estradiol in this study seems to decrease the serum enzymes (ALT, AST), and then preserve the structural integrity of the hepatocellular membrane. Decreased hepatocyte damage suppressing the stimulant effect to the Kupffer cells and subsequent by lower the HSC activation[33].

Peroxidation of lipids can dramatically change the properties of biological membranes, resulting in severe cell damage and could play a significant role in the pathogenesis of disease. It has showed that lipid peroxidation, free-radical-mediated process, and certain lipid peroxidation products induce genetic overexpression of fibrogenic cytokines and increase the synthesis of collagen. Free radicals and MDA can stimulate the synthesis of collagen and initiate the activation of HSC[34,35]. Relevant to the latter findings, estradiol and its derivatives are strong endogenous anti-oxidants that reduce lipid peroxide levels in liver and serum. Free radicals, generated mainly by Kupffer cells, are thought to cause tissue injury by initiating lipid peroxidation and irreversibly modifying membrane structure. The present study shows that CCL_4 administration leads to parallel increase in MDA and collagen, and subsequent decrease in SOD, a radical scavenging agent, and that estradiol had the opposite effect. These findings suggest that the antifibrotic effect of estradiol may be caused, at least in part, by its radical scavenging action or antioxidant activity.

Cell proliferation, α-SMA expression, retinoid disappearance, and the formation of collagens and other ECM materials are characteristics of the activated phenotype of HSC[36]. So HSC are regarded as the primary target cells of hepatic fibrogenesis. Studies in vitro have shown that HSC and their activated counterparts may be induced to proliferate by polypeptide growth factors and cytokines, such as TGFβ_1 and PDGF[37,38]. As these growth factors are produced by infiltrating inflammatory cells, Kupffer cells and sinusoidal endothelial cells, they might act as paracrine mediators which trigger the transformation of HSC *in vivo*. The present data show that estradiol suppresses HSC proliferation and parallel with inhibit TGFβ_1 and PDGF expression in CCL_4-induced fibrosis in male and female rats. These findings suggest that estrogen may exert its suppressive effect on hepatic fibrosis by indirectly modulating the synthesis and releasing of cytokines and other growth factors which in turn altering HSC activation and proliferation.

Chronic fibrotic diseases can differ from each other in etiology. But, in terms of pathogenesis, they share some basic common features[1]. For instance, three serious chronic disease-atherosclerosis, glomerulosclerosis, and liver fibrosis-may appear very different in their development. In all three, though, a central, and indeed an essential, role is playd by macrophages and by ECM-producing cells: smooth muscle cells (SMC) in atherosclerosis, mesangial cell in glomerulosclerosis, and HSC in liver fibrosis. The three types of cells have many properties in common both structurally and functionally, including a changes in cell biology with deposition of matrix proteins. Therefore, factors which affect the development of atherosclerosis or glomerulosclerosis may affect liver fibrossis by similar mechanisms. Studies show that estradiol suppresses atherosclerosis and glomerulosclerosis in rats by directly affecting the estrogen receptor on SMC and mesangial cell. Livers in both male and Female rats have shown to contain high affinity, low capacity estrogen receptors and respond to estrogen by regulating liver function. In the present study, Tamoxifen, an antiestrogen act by occupying the estrogen-binding site of the receptor protein, increases fibrogenesis in CCL_4-induced fibrosis of the liver. It suggests that estradiol may suppress hepatic fibrosis also by a direct receptor mechanism. This remains to be confirmed.

In conclusion, estrogen may play an important role as an endogenous fibrosuppressant, accounting for sex-associated differences in the progression from hepatic fibrosis to cirrhosis. The following mechanisms have been hypothesized to explain the antifibrogenic effect of estrogens: (A) a hepatocellular membrane protection and radical scavenging action. (B) a modulation of HSC proliferation and collagen synthesis, (C) a modulation in the expression of pro-and anti-fibrogenic cytokines and may be (D) a estrogen receptor mechanism. However, the real importance of these mechanisms is still to be elucidated.

Abstract

AIM: The human cytochrome P-450 2C18(CYP2C18) has been characterized. However, the protein has not been purified from liver and very little is known regarding the specific substrate of CYP2C18. In order to study its enzymatic activity for drug metabolism, the *CYP2C18* cDNA was cloned and a stable CHL cell line expressing recombinant CYP 2C18 was established.

METHODS: The human *CYP2C18* cDNA was amplified with reverse transcription-polymerase chain reaction (RT-PCR) from total RNAs extracted from human liver and cloned into pGEM-T vector. The cDNA segment was identified by DNA sequencing and subcloned into a mammalian expression vector pREP9. A transgenic cell line was established by transfecting the recombinant plasmid of pREP9-*CYP2C18* to Chinese hamster lung (CHL) cell. The enzyme activity of *CYP2C18* catalyzing oxidation of tolbutamide to hydroxytolbutamide in postmitochondrial supernant(S9) fraction of the cell was determined by high performance liquid chromatography(HPLC).

RESULTS: The amino acid sequence predicted from the cloned cDNA segment was identical to that of reported by Romkes *et al* (GenBank accession number: M61856, J05326). The S9 fraction of the established cell line metabolizes tolbutamide to hydroxytolbutamide. Tolbutamide hydroxylase activity was found to be 0.509 ± 0.052 $\mu mol \cdot min^{-1} \cdot g^{-1}$ S9 protein or 8.82 ± 0.90 $mol \cdot min^{-1} \cdot mol^{-1}$ CYP, but was undetectable in parental CHL cell. In addition, we have identified a *CYP2C18* cDNA clone with exon 5 missing.

CONCLUSION: The cDNA of human *CYP2C18* was successfully cloned and a cell line, CHL-CYP2C18, efficiently expressing the protein of *CYP2C18*, was established. A spliced variant of CYP2C18 with exon 5 missing was identified in the cloning process.

INTRODUCTION

Cytochrome P450 (CYP) is a heme-containing enzyme widely distributed from bacteria to mammals, and catalyzes the oxidative and reductive metabolism of a wide variety of compounds including endogenous as well as exogenous compounds. Mammalian CYP present in liver microsomes is characteristic of its nature in metabolizing exogenous compounds including drugs, pesticides, environmental pollutants, and carcinogens[1]. Mammals contain at least 17 distinct *CYP* gene families that together code for an estimated 50-60 individual *CYP* genes in any given species[2]. The human CYP2C subfamily comprises four members, CYP2C8, CYP2C9, CYP2C18 and CYP2C19[3], accounting for 20 % of the total CYP in human liver. CYP2C18 mRNA was found in liver, albeit at mean levels 7-8-fold lower than those of mRNAs encoding CYP2C8 and CYP2C9[4,5]. The cDNA encoding human *CYP2C18* has been characterized, but the protein has not been purified from liver, and very little is known regarding the specific substrate of CYP2C18[4].

The combination of gene technology and cell culture technology has provided new opportunities for studying proteins because any gene from any species encoding a protein may be cloned and expressed in bacterial, yeast, or mammalian cell in a defined way[6-11]. This approach in drug metabolism is of particular importance because some of the enzymes are difficult to purify and to prepare in sufficient quantities, for its low expression levels, organ-specificity of its expression, or low abundance of native organ material. These restrictions apply especially for human enzymes. The heterologous expression of the cDNA bypasses these restrictions[12]. The human *CYP2C18* cDNA had been expressed in yeast[13,14], COS-1 cells[3], lymphoblast cells[15], and human liver epithelial cells THLE[16]. Several cell lines stably expressing human CYP1A1[17],CYP2B6[17],CYP2A6[18], CYP3A4[19],CYP2C9[20] and a phase II metabolism enzyme UDP-glucuronosyltransferase, UGT1A9[21] have been established in our laboratory. In this study human *CYP2C18* cDNA was amplified with reverse transcription-polymerase chain reaction (RT-PCR), and a transgenic cell line stably expressing CYP2C18 was established. In the cloning process, we have identified a spliced variant of CYP2C18 with exon 5 missing.

MATERIALS AND METHODS

Materials

Restriction endonucleases, moloney murine leukemia virus (M-MuLV) reverse transcriptase were supplied by MBI Fermentas AB, Lithuania. PCR primers, DNA sequence primers, random hexamer primer, Taq plus I, and dNTPs were synthesized or supplied by Shanghai Sangon Biotechnology Corp. DNA sequencing kit was purchased from Perkin-Elmer Corp. The TRIzol Reagent, G418, Minimum Essential Media(MEM) and newborn bovine calf sera were from Gibco. NADPH was from Roche molecular biochemicals. Diethyl pyrocarbonate (DEPC), tolbutamide and hydroxytolbutamide were purchased from Sigma Chemical Company. T4 DNA ligase and pGEM-T vector system were from Promega. Other chemical reagents used are all of analytical purity from the commercial sources.

Methods

Cloning of human CYP2C18 cDNA from a Chinese human liver The total RNA was extracted from a surgical specimen of human liver with TRIzol reagent according to the manufacture' s instructions. The RT-PCR amplifications were described before[20]. Two specific 28 mer oligonucleotide PCR primers were designed according to the mRNA sequence of CYP2C18 reported by Romkes *et al*[3] (GenBank accession no. M61856, J05326). The sense primer corresponding to base position 38 to 65 was 5' -TTATCTTCTTCAGCTAGCCAATGTTCAT-3' , with a restriction site of *Nhe* I, and the anti-sense primer, corresponding to the base position from 1681 to 1708, was 5' -TGACAGCACTCGAGCAGCCAAACTATCT-3' , with a restriction site of *Xho* I. The PCR was performed at 94 ℃ 2 min, then 35 cycles of 94 ℃ 60 s, 55 ℃ 60 s, 72 ℃ 2 min, and lastly 72 ℃ 10 min. An aliquot (10 ml) from the PCR was subjected to electrophoresis in a 1 % agarose gel stained with ethidum bromide.

Construction of recombinant pGEM-CYP2C18 and sequencing of CYP2C18 cDNA[22] The PCR products were ligated with pGEM-T vector, and transformed to the *E.coli* DH5a. Several cDNAs of *CYP2C18* cloned in pGEM-T were sequenced on both strands by dideoxy chain-termination method marked with BigDye with primers of T7 and SP6 promoters and two specific primers of 5' -GGACATGAGCAAATCCTTA-3' (343-361), and 5' -TGGGGATGAGGTAGTTTTTG-3' (1327-1346). The termination products were resolved and detected using an automated DNA sequencer (Perkin-Elmer-ABI Prism 310).

Construction of the pREP9 based expression plasmid for CYP2C18[22] The *Nhe* I/ *Xho* I fragment having the total span of human *CYP2C18* cDNA and the correctly deduced amino acids sequence in pGEM-*CYP2C18* was subcloned to a mammalian expression vector pREP9 (Invitrogen). The recombinant was transformed to *E.coli* Top 10, and screened by ampicillin resistant. The recombinant was identified by restriction mapping.

Transfection and selection[20,22] Chinese hamster lung (CHL) cells were transfected with the resultant recombinant plasmid, pREP9-*CYP2C18*, using a modified calcium phosphate method. A tansgenic cell line named CHL-*CYP2C18* was established.

Preparation of postmitochondrial supernant (S9) of CHL-CYP2C18 The procedure of preparation of the S9 fraction was described before[20]. The protein in S9 was determined by the Lowry' s method, with bovine serum albumin as standard. CYP was measured spectrally using the method of Johannesen *et al*[23].

Tolbutamide hydroxylase assays[20,24,25] The CYP2C18 tolbutamide hydroxylase activity of S9 was determined by high performance liquid chromatography (HPLC) as described before[20] .

RESULTS

Construction of recombinants and detection of an exon 5 skipping in transcripts of the human CYP2C18 gene

The recombinant of pGEM-*CYP2C18* (Figure 1) was constructed with the human *CYP2C18* cDNA inserted into the cloning site of pGEM-T vector. Selection and identification of the recombinant was carried out by *Nhe* I/ *Xho* I endonuclease digestion and agarose gel electorphoresis (Figure 2). Two cloned cDNA segments were sequenced completely. Comparing with the cDNA sequence reported by Romkes *et al*[3] (GenBank accession no. M61856, J05326), one has two base differences, 222T>C, 828C>T, while the encoding amino acid sequence was the same, I74 and H276. However, another cDNA clone was found to have only 8 exons (Figure 3). There is no base difference between this cDNA and the wild type one except the missing exon 5.

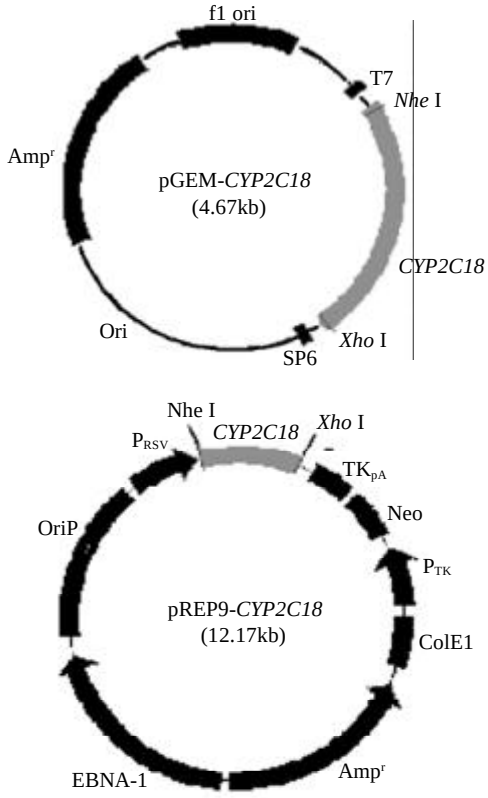

Figure 1 Scheme of recombinants of pGEM-*CYP2C18* and pREP9-*CYP2C18*

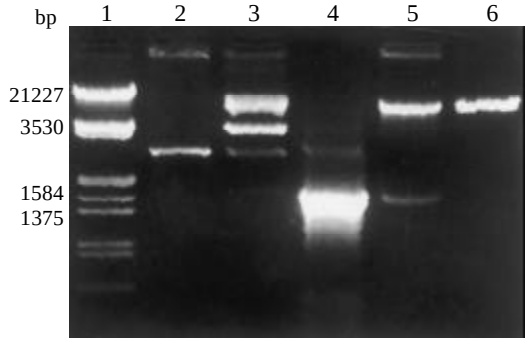

Figure 2 Electrophoresis identification of recombinants of pGEM-*CYP2C18* and pREP9-*CYP2C18*. Lane 1: Marker (λ / *Eco*R I and *Hin*d III); 2: pGEM-T vector; 3: Recombinant of pGEM-*CYP2C18* digested by *Nhe* I and *Xho* I(incompleted digestion); 4: PCR products of *CYP2C18*(1.67 kb); 5: Recombinant of pREP9-*CYP2C18* digested by *Nhe* I and *Xho* I; 6: pREP9 vector.

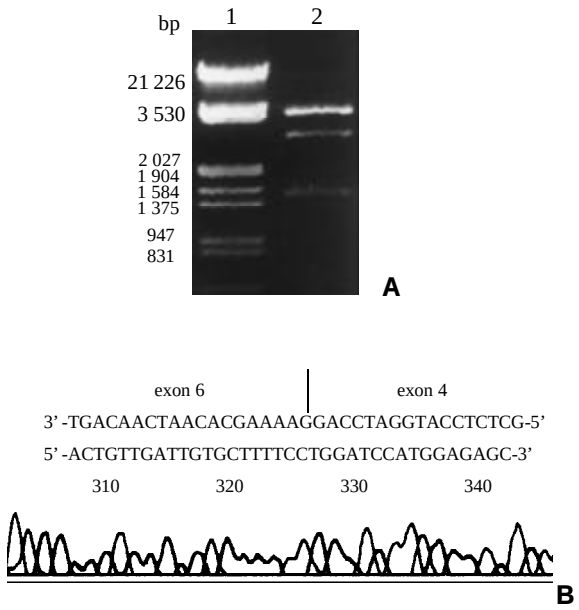

Figure 3 Electrophoresis and sequencing identification of a *CYP2C18* clone with exon 5 missing. A: Electrophoresis identification of a *CYP2C18* clone with an exon 5 being skipped; Lane 1: Marker (λ/*Eco*R I and *Hin*d III); 2: Recombinant of pGEM-*CYP2C18* digested by *Nhe* I and *Xho* I (incompleted digestion); B: Partial sequencing of an *CYP2C18* cDNA clone with an exon 5 being skipped. The upper sequence represent the sense strand and the underside sequence represent the antisense strand being sequenced.

The *Nhe* I/*Xho* I fragment (1.65 kb) containing the complete *CYP2C18* cDNA was subcloned into the *Nhe* I/ *Xho* I site of mammalian expression vector pREP9 (Figure 1). Selection and identification of the recombinant was carried out by *Nhe* I/ *Xho* I endonuclease digestion and agarose gel electrophoresis (Figure 2). The resulting plasmid was designated as pREP9-*CYP2C18* and contains the entire coding region, along with 162 bp of the 5' and 36 bp of the 3' untranslation region of the *CYP2C18* cDNA, respectively.

Establishment of transgenic cell lines with CYP2C18 enzyme activity

CHL cells were transfected with pREP9-*CYP2C18*, and selected with G418. The surviving clones were propagated and the cell line termed CHL-CYP2C18 was established. The tolbutamide hydroxylase activity of CYP2C18 in S9 of CHL-CYP2C18 cells was assayed by HPLC. A typical elution profile of hydroxytolbutamide in extracts was shown (Figure 4).

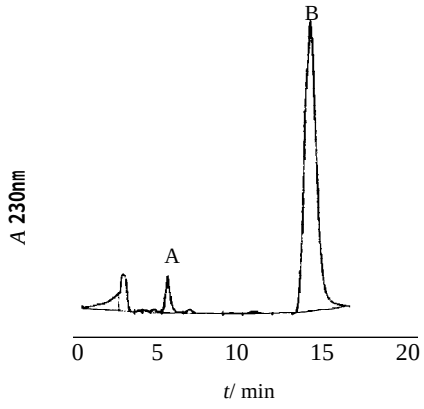

Figure 4 Representative chromatogram of extracts. A Shimpack CLC-ODS column (15×0.6 cm i.d.) was used. The mobile phase was constituted with 0.05 % phosphoric acid (pH 2.6), acetonitrile (6:4/V:V) with the flow rate of 1 mL·min^{-1}. Hydroxytolbutamide was monitored at 230 nm. A: hydroxytolbutamide; B:tolbutamide

The CYP2C18 enzyme activity towards tolbutamide was found to be 0.509±0.052 mmol·min^{-1}·g^{-1} S9 protein or 8.82 ±0.90 mol·min^{-1}·mol^{-1} CYP (n=3), but was not detectable in parental CHL cells. The CYP content was 53.9 pmol·mg^{-1} S9 protein from CHL-CYP2C18 and no detectable CYP was present in CHL cells.

DISCUSSION

The human *CYP2C18* gene is located on chromosome 10q24. Four *CYP2C18* alleles have been reported. T385 and M385 alleles exhibited the same regio-and stereoselectivities for warfarin[25]. There was no substantial difference in the ability of the T385 and M385 of *CYP2C18* to metabolize mephenytoin[26]. *CYP2C18*$_{m1}$, a substitution of 204T>A in exon 2, which creates a stop codon that yields a truncated protein lacking the heme-binding site[27]. *CYP2C18*$_{mFR}$, consisting of -460A>T substitution in the 5' -flanking region, the functional property of this mutant allele remains unclear[28]. One of the *CYP2C18* cDNA cloned by us belongs to the T385 allele in amino acids sequence. Although there are two base substitutions, 222T>C, 828C>T, the encoding amino acids have not been changed.

To express the functional activity of a CYP, a cell must have adequate heme biosynthetic capabilities and ample intracellular membrane[29]. CYPs also require other enzymatic components for full activity, including the flavoprotein NADPH-P450 oxidoreductase (OR) and, in some cases, cytochrome b_5. The OR must interact directly with the CYP to transfer the required two electrons from NADPH. Cytochrome b5 is necessary for increasing electron transfer for certain CYP forms and specific substrates. The CHL is a cell line originally derived from the lung of a newborn female Chinese hamster and has no or very limited activities of CYP enzymes, but has adequate OR and cytochrome b5 levels to support CYP activities.

To achieve high expression levels of CYP2C18, the *CYP2C18* cDNA was cloned into the eukaryotic expression vector pREP9, which had previously been used in this laboratory for the expression of human CYP1A1[17], CYP2B6[17], CYP3A4[18], CYP2A6[19], CYP2C9[20] and UGT1A9[21] in CHL cells. The salient feature of this vector has an EBV origin of replication and nuclear antigen (EBNA-1) to allow high-copy episomal replication in mammal cell lines. The Rous sarcoma virus long terminal repeat (RSV LTR) early promoter controls the expression of the *CYP2C18* cDNA.

CYP2C18 was expressed at a very low level in human liver[4]. Its protein had not been detected and its mRNA can not be induced by rifampicin or phenobarbital in human livers and cultured primary hepatocytes[5]. But it seems to be a major CYP2C in the skin and the lung judged by its mRNA levels[30]. Its mRNA was found in the brain, uterus, mammary gland, kidney, and duodenum[31]. It has been reported that CYP2C18 can metabolize (S)-mephenytoin[26], tolbutamide[26], warfarin[25], tienilic acid[20], diclofenac[13], aminopyrine[32], and bisphenol A[14] by yeast expression and metabolize all-trans-retinoic acid[15] by lymphoblast expression. Cyclophosphamide(CPA) and ifosfamide can be metabolized by M385 CYP2C18. CYP2C18-M385 plus CYP OR appear to be excellent gene combinations for use with CPA in P450/prodrug activation-based cancer gene therapy[33]. A 2-aroylthiophenes derived from tienilic acid by replacement of its OCH_2COOH substituent with $O(CH_2)_3OH$ function, appears to be a particularly good

substrate of CYP2C18[34].

Tolbutamide (1-butyl-3-p-tolylsulfonylurea) is an oral hypoglycemic agent which is being used in the treatment of diabetes. In humans it undergoes CYP-catalyzed hydroxylation of the tolyl methyl group which is the initial and rate-limiting reaction followed by further oxidation by cytosolic dehydrogenases yielding carboxytolbutamide. Overall this pathway accounts for up to 85 % of tolbutamide clearance in humans[35]. We used tolbutamide as a substrate for evaluating the expression of human CYP2C18 activity in CHL-CYP2C18 cells. The tolbutamide hydroxylase activity was 0.509 ± 0.052 mmol· min^{-1}· g^{-1} S9 protein or 8.82 ± 0.90 mol· min^{-1}· mol^{-1} CYP, which is slightly higher than that of our cloned human CYP2C9: 0.465 ± 0.109 μmol· min^{-1}· g^{-1} S9 protein or 8.62 ± 2.02 mol· min^{-1}· mol^{-1} CYP[20]. The tolbutamide hydroxylase activity was reported to be 0.273 ± 0.066[36] or 0.189 ± 0.008[37] mmol· min^{-1}· g^{-1} of human liver microsomes. Considering the low expression of CYP2C18 in liver, the tolbutamide hydroxylase activity in human liver might be contributed by CYP2C9. CHL-CYP2C18 cells efficiently expressing the CYP2C18 may be a useful tool for further studies of its enzymatic function and mechanism.

Interestingly, we find one of our cloned *CYP2C18* cDNAs has only 8 exons by DNA sequencing. This cDNA clone is identical to the wild-type one except the missing exon 5. This is consistent with Zaphiropoulos's report that an exon 5 skipping of human *CYP2C18* gene in epidermis[30]. The exon is spliced at the predicted sites indicating that it pre-exists in the mRNA samples and is not a PCR artifact. Transcripts that have skiped *CYP2C18* exon 4, exon 4,5 and 6, or exon 4,5,6, and 7 were also identified in epidermis[30]. The splicing process in higher eukaryotes is chracterized by the precise excision of introns that can be longer than 50 000 bases and the joining of exons that are rarely over 300 bases. Yet the mechanisms that regulate the splicing process and the generation of alternatively spliced mRNA products are still poorly understood[38]. In addition to alternative splicing in intragenic RNA molecule, chimeric RNA production had been detected in *CYP2Cs*[39-41] and *CYP3As*[42] genes. This finding suggests that intergenic mRNA formation may represent a generalized splicing pathway that deepens the complexity of splicing patterns in gene families[42] and the concept of gene transcription may not suffice to include all variations in expressed genomic sequences. Finta and Zaphiropoulos[43] proposed a more general term, "genome transcription".

The difference in enzyme activity between the full length clone and the spliced variant will be studied in the future.

Abstract

AIM: To investigate the effects of electroporation on primary rat hepatocyte and to optimize the electroporation conditions introducing foreign genes into primary hepatocytes.

METHODS: A single-pulse procedure was performed at low voltage (220-400 V) but with high capacitance (500-950 μF). Hepatocytes were divided into 4 groups according to the electroporation conditions: group Ⅰ, 220 V and 500 μF; group Ⅱ, 220 V and 950 μF; group Ⅲ, 400 V and 950 μF, and group IV. The control group was freshly isolated hepatocytes and directly cultured under the same conditions as those of electroporation groups. The effects of electroporation on primary rat hepatocytes were detected by trypan blue exclusion (TBE) and MTT analysis. Besides, albumin (Alb), alanine transaminase (ALT) and lactate dehydrogenase (LDH) in the supernatants of cultured hepatocytes were measured by biochemical assay.

RESULTS: Between day 1 and day 15 after incubation, primary rat hepatocytes of each electroporation group appeared normal, being the same with those of control group. TBE staining showed that slight hepatocyte damage and high survival rate were found in the electroporation groups and the control group. Cultured for 3, 7, 11 and 15 days, hepatocyte viability was approximatly 92.6±2.5 %, 89.5±3.3 %, 82.0±3.5 % and 74.3±1.2 %, respectively. MTT analysis indicated that the viabilities of hepatocytes had no significant difference between each electroporation group, and those were similar to that of control group. At the 36th hour after electroporation, Alb, ALT and LDH in the supernatants of control group were 5.3±0.1 g·L^{-1}, 183.7±8.4 nkat·L^{-1} and 896.8±58.5 nkat·L^{-1}; those of group Ⅱ were 5.7±0.1 g·L^{-1}, 215.4±16.7 nkat·L^{-1} and 1063.8±51.8 nkat·L^{-1}; and those of group Ⅲ were 5.8±0.2 g·L^{-1}, 217.1±8.4 nkat·L^{-1} and 1063.8±10.0 nkat·L^{-1}. Statistically, the proteins of group Ⅱ and group Ⅲ were significantly higher than those of control group (P<0.05), whereas the protein production of group Ⅰ, Alb, ALT and LDH were 5.3±0.2 g·L^{-1}, 205.4±3.3 nkat·L^{-1} and 1035.4±116.9 nkat·L^{-1}, were similar to those of control group. At the same time, TBE and MTT analysis indicated that there was no significant cell viability difference between electroporation groups and control group.

CONCLUSION: This single-pulse electroporation procedure performed at low voltage (220-400 V) but with high capacitance (950 μF) is one of the optimal choices to introduce foreign genes into primary rat hepatocyte.

INTRODUCTION

Electroporation technique has been widely used in the experiments of foreign gene transfection into cultural cells. Little is known about the effect of electroporation on the primary culture cells, especially on the primary hepatocytes, for most of the target cells are immortal carcinoma cells. At present, in the *in vitro* study of liver diseases, primary cultured hepatocytes have been used as one of the most important target cells, which are increasingly used in the research of basic and clinical medicine[1-17], and electroporation has also been used as preferred means introducing foreign genes into primary hepatocytes. It is known that primary hepatocyte does not proliferate in common culture, so the biological activities of electroporated hepatocytes must be the key points affecting the efficiency of transfection and expression of foreign genes in the target cells. In order to optimize the electroporation conditions introducing foreign genes into hepatocytes, we studied the effect of electroporation on the biological activities of primary cultured rat hepatocyte.

MATERIALS AND METHODS

Isolation and culture of hepatocytes

Wistar rats, male, about 200 g of body mass, were provided by the Center for Laboratory Animal at Chongqing University of Medical Sciences. Hepatocytes were harvested from adult Wistar rats using the *in situ* collagenase perfusion technique[18]. Injected into the peritoneal cavity with pentobarbital sodium (100 mg·kg^{-1} body weight) and heparin (200 IU·kg^{-1} body weight), the abdomen of the animals were opened and the portal vein was exposed and cannulated. Then the liver was perfused at 37 ℃ *in situ* first with a calcium-free Hanks' Balanced Salt Solution (HBSS) for 10 min, next with 0.2 g·L^{-1} collagenase (Type Ⅳ, 390 kU·g^{-1}) in calcium-presented HBSS for 15 min. The liver was removed and the cells were combed gently in tissue culture medium. Hepatocytes were pelleted, washed, and separated from nonparenchymal cells by differential centrifugations at 50×g. Viability of hepatocytes exceeded 98 % as determined by trypan blue exclusion (TBE).

Electroporation

Freshly isolated hepatocytes were diluted into 1×10^{10} cells·L^{-1} suspension with serum-free RPMI 1640 medium for

electroporation (electroporation apparatus is Bio Rad Gene Pulser Ⅱ), and were divided into three groups. In group Ⅰ, voltage was 220 V, and capacitance was 500 μF, in group Ⅱ, 220 V and 950 μF, and in group Ⅲ, 400 V and 950 μF. All of three groups were electroporated by single-pulse procedure, and electroporation time was about 19 ms. Before and after electroporation hepatocytes were put onto ice for 10 min. Electroporated hepatocytes diluted into 3×10^8.cells.L^{-1} suspension with hepatocyte culture medium was inoculated into 96-well plastic cell-culture plates (3×10^4 cells in each well). Medium contained RPMI 1640 with insulin (100 $U\cdot L^{-1}$), penicillin, streptomycin and 100 $ml\cdot L^{-1}$ fetal bovine serum. Control group, group Ⅳ, was freshly isolated hepatocytes and was directly cultured under the same conditions as those of electroporation groups. The medium was changed after 36 h incubation and later changed every two days.

Hepatocyte viability and function

To detect the viabilities of hepatocytes of electroporatin groups and control group, TBE staining was used from day 1 to day 15 after incubation. Besides, MTT analysis was also used to measure the cell viability. At 36 h after incubation, the medium was changed with phenol red-free RPMI 1640 medium (0.1 mL each well), 10 μL MTT (5 $g\cdot L^{-1}$) was added into each well, and incubated for another 4 h. Then discard the supernatants, add 0.1 ml dimethyl sulfoxide into each well and oscillate the culture plate for 5 min. Next, the 96-well culture plate was put into Elx800 type automatic reader and absorbance values in each well was detected at 405 nm wave length. Each group had more than 6 wells each time. Three more of these tests were repeated. To measure albumin (Alb), alanine aminotransferase (ALT) and lactic dehydrogenase (LDH) in the supernatants of cultured hepatocytes of electroporation groups and control group, biochemical assays were used.

RESULTS

Effect of electroporation on the viability of hepatocytes

From day 1 to day 15 after incubation, primary rat hepatocytes of each electroporation group appeared normal, the same as those of control group. TBE staining showed that the viabilities of hepatocytes had no significant difference between each electroporation group, which were similar to that of control group (Table 1). Culture for 7 d showed that hepatocyte viability was still around 90 %, and about 74 % hepatocytes survived 15 d after electroporation. MTT analysis also showed the same results, after 36 h of culture, primary rat hepatocytes of electroporation groups had the same viabilities as that of control group ($P>0.05$, Student's *t* test), the absorbance values (405 nm wave length) of group Ⅰ to Ⅳ were 0.317±0.069, 0.369±0.059, 0.279±0.085 and 0.332±0.072, respectively.

Table 1 Viabilities of electroporated hepatocytes measured by TBE

Culture time (day)	Survival rate (%)
1	95.4±1.8
3	92.6±2.5
5	91.3±2.4
7	89.5±3.3
9	87.2±4.6
11	82.0±3.5
13	77.0±0.9
15	74.3±1.2

Effect of electroporation on hepatocyte function

To detect the effect of electroporation on Alb, ALT and LDH production of primary rat hepatocytes, biochemical assays were used to measure these proteins in the supernatants of cultured hepatocytes. Amounts of Alb, ALT and LDH in the supernatants were assayed 36 h after incubation. The results (Table 2) showed that Alb, ALT and LDH production of electroporation groups Ⅱ and Ⅲ were significantly higher than those of control group, whereas the protein production of group Ⅰ was similar to those of control group.

Table 2 Alb, ALT and LDH production in the supernatants of primary cultured rat hepatocytes

Groups	Alb/($g\cdot L^{-1}$)	ALT/($nkat\cdot L^{-1}$)	LDH/($nkat\cdot L^{-1}$)
Ⅰ	5.3±0.2	205.4±3.3	1035.4±116.9
Ⅱ	5.7±0.1[a]	215.4±16.7	1063.8±51.8[a]
Ⅲ	5.8±0.2[a]	217.1±8.4[a]	1063.8±10.0[a]
Ⅳ	5.3±0.1	183.7±8.4	896.8±58.5

DISCUSSION

Primary hepatocytes have been increasingly used in basic and clinical medicine researches, such as the study of hepatocyte function, the mechanism of hepatocyte injuries and the protective approaches of hepatocyte biological activities[19-25], and the use of hepatocytes in bioartificial liver support system (BALSS)[26,27] and gene therapy[28]. Besides, more and more researchers utilize primarily cultured hepatocyte model to study foreign genes' activities and effects on host cells, for example, hepatitis B and C viruses replication and expression in hepatocytes[29-31]. In order to keep the normal biological activities and functions *in vitro* of hepatocytes, more methods have been used to optimize primary hepatocyte model, especially the introduction techniques of foreign genes into hepatocytes.

The introduction and stable expression of foreign genes in mammalian hepatocytes have been demonstrated by several techniques[32-37], including the use of physical approaches such as direct injection of a DNA calcium phosphate precipitate, electroporation of plasmid DNA and the exposure to liposome-erythrocyte ghost complexes as well as the biological approach of infection of primary hepatocyte cultured with retrovirus vectors. Among these techniques, electroporation has been considered as one of the most useful methods introducing foreign into target cells[38-41]. However, it is not defined that which electroporation condition is the best one under which foreign genes can be efficiently transduced into primarily cultured hepatocytes, and this condition could cause little damage to target cells.

It is known that primarily cultured hepatocytes are well-differentiated cells, most of which are resting cells, arrested in G0, and do not proliferate in common culture conditions. To be an ideal model, in which foreign gene can get highly efficient transfection and expression, primarily cultured hepatocytes after electroporation could not only keep a high survival rate, but also maintain excellent cellular functions. Therefore, optimizing electroporation conditions has become the key point affecting the biological activities of primary hepatocytes.

Our results showed that a single-pulse procedure performed at low voltage (220-400 V) but with a high capacitance (950

μF) caused minimal cell damage and kept hepatocyte with a high survival rate, cultured for 7 d and 15 d, greater than 90 % and 74 % respectively, and hepatocyte viabilities of electroporation groups were similar to that of control group and much higher than those reported by other savants. Our current data further indicated that this electroporation procedure could not only maintain hepatocyte function, but also facilitate Alb, ALT and LDH expression in hepatocytes and production in the culture medium. Its mechanism is not clear, possibly related to two reasons: first, Alb, ALT and LDH might leak into culture medium through electroporated hepatocyte membrane, while minimal cell damage had been found by TBE and MTT assay. Second, this electroporation condition may have a potentiation to stimulate wave of DNA synthesis in electroporated rat hepatocytes. In conclusion, this single-pulse procedure performed at low voltage (220-400 V) but with a high capacitance (950 μF) could not only cause minimal cell damage, but also potentiate DNA synthesis in rat hepatocytes. For instance, up to date, we have used this electroporation procedure in transduceing hepatitis B virus gene into primary rat hepatocytes and primary duck hepatocytes and successfully observed that hepatocytes are competent for transfection with HBV gene, which can stably replicate and express in primary hepatocytes[42,43]. Therefore, this single-pulse procedure can be used as one of the optimized electroporation procedures introducing foreign genes into primarily cultured hepatocytes.

Abstract

AIM: To investigate the effect of N-desulfated heparin on hepatic/renal ischemia and reperfusion injury in rats.

METHODS: Using rat models of 60 minutes hepatic or renal ischemia followed by 1 h,3 h,6 h and 24 h reperfusion,animals were randomly divided into following groups,the sham operated controls,ischemic group receiving only normal saline,and treated group receiving N-desulfated heparin at a dose of 12 mg/kg at 5 minutes before reperfusion. P-selectin expression was detected in hepatic/renal tissues with immunohistochemistry method.

RESULTS: P-selectin expression, serum ALT, AST, BUN and Cr levels were significantly increased during 60 minute ischemia and 1 h, 3 h, 6 h and 24 h reperfusion,while the increment was significantly inhibited,and hepatic/renal pathology observed by light microscopy was remarkably improved by treatment with the N-desulfated heparin. Furthermore,the heparin was found no effects on PT and KPTT.

CONCLUSION: P-selectin might mediate neutrophil infiltration and contribute to hepatic/renal ischemia and reperfusion. The N-desulfated heparin might prevent hepatic/renal damage induced by ischemia and reperfusion injury without significant anticoagulant activity.

INTRODUCTION

Hepatic/renal ischemia-reperfusion injury is very common clinically. So far, no effective treatment for this pathological injury is available. It has been found that cell adhesion molecule P-selectin plays an important role in hepatic/renal ischemia-reperfusion injury by mediating the interactions of polymophonuclear neutrophils with endothelium. P-seletin monoclonal antibody has been demonstrated to prevent effectively reperfusion-induced hepatic/renal tissue damage[1-22]. Heparin, a highly sulfated proteoglycan, has anti-inflammatory activity besides its anticoagulant function. Recently reports suggested that heparin could prevent leukocyte adhesion through inhibiting the role of P-selectin and might be used to treat inflammatory diseases[23]. However, the clinical use of heparin for treatment of inflammation is impeded by its strong anticoagulant activity[24]. Chemically modified heparins which have been developed have relatively low anticoagulant activity remain their anti-inflammatory activities[25,26]. In this study, we investigated the effect of N-desulfated heparin (NNH) on hepatic/renal ischemia-reperfusion injury in rats.

MATERIALS AND METHODS

Animal model

Ninety male Wistar rats (Shanghai Experimental Animal Centers of Chinese Academy of Sciences), weighing 200±10 g, were given free access to food and water for three days before the experiments. The rats were anesthetized with 2.5 % sodium pentobarbital intraperitoneally, and randomly divided into 2 groups. In one group of rats, the ligament linking liver, diaphragm and abdominal wall were separated, portal vein and liver artery that drain blood to left hepatic lobe were freed by blunt dissection and then blocked with a microvascular clamp for 60 minutes, after that clamp was removed, and reperfusion was started; while in another group, the left renal artery was freed, blocked with a microvascular clamp for 60 minutes, then the clamp was removed and reperfusion was started, simutaneously, the right kidney was cut off. The two groups of rats were randomly divided into NNH-treated group (n=20) and non-treated group (n=20). They were divided into subgroups according to the indicated time: 1, 3, 6, 24 hours after reperfusion. NNH (12 mg/kg, Institute of Biochemistry and Cell Biology, Chinese Academy of Sciences), or saline were injeted by veins five minutes before reperfusion. A sham-operated group (n=5, anesthesia and opening celiac cavity, no blocking of hepatic or renal blood flow) served as control.

Collection and measurement methods of specimens

Blood, hepatic and renal tissues were harvested at the indicated time. Serum levels of aspartate aminotransferase (AST) and alanine aminotransferase (ALT), and blood urea nitrogen (BUN) and creatinine (Cr) were measured with a 747 automatic analyzer (Hitachi boehringer Mannhein, Mannhein, Germany). Hepatic and renal tissue samples were fixed in 10 % formalin and embedded in paraffin. Sections were cut 5 μm thick and stained with hematoxylin and eosin for light microscope examination. Expression of P-selectin in hepatic/renal tissue

was detected by an immunohistochemistry method with a labelled streptavidin biotin (LSAB) kit (Fujian Maixin Biotechnology Co., products of Biotechnology co. CA, USA). Activated partial thromboplastin time (APTT) and protothrombinogen time (PT) were also measured.

Statistical analysis

Data was presented with $\bar{x}\pm s$, and Student' s *t* test was used to determine changed between different groups. $P<0.05$ was considered significant.

RESULTS

Histopathologic evaluation

One hour after reperfusion, visual observation revealed that the left hepatic lobe was more swollen than the right lobe, and was dark in color. Under the light microscope, interstitial congestion and infiltration of inflammatory cells were observed. 1 hour after reperfusion, with the observation of naked eyes, the renal cortex was pale, the renal medulla displayed blood stagnation and was dark in color. Under the light microscope, edema, denaturation with different extent and necrosis of renal tubular epithelial cells were observed. Simultaneously, interstitial congestion, edema and infiltration of inflammatory cells were also observed. However, in the N-desulfated heparin-treated group. The outward apperance of the liver and kidney was similar to that of normal control. Hepatic cells and tubular cells showed less swelling and no denaturation or necrosis, and interstitial changes were not obvious.

Hepatic and renal function evaluation

Twenty four hours after hepatic reperfusion, the serum levels of ALT (628±91 μ/L) and AST (1608±199 μ/L) in the saline-treated group were much higher than the sham-operated group (52±11 μ/L and 80±17 μ/L respectively, $P<0.01$). The NNH-treated group revealed significantly lower levels of ALT (161±24 μ/L) and AST (360±49 μ/L) compared with saline-treated group ($P<0.01$).

Twenty four hours after renal reperfusion, the serum levels of BUN (14.54±0.67 mmol/L) and Cr (102.2±4.67 μmol/L) were much higher than the sham-operated group (7.88±0.57 mmol/L and 39.00±4.47 μmol/L, respectively, $P<0.01$). The NNH-treated group presented with significantly lower levels of BUN (10.60±0.80 mmol/L) and Cr (67.78±5.01 μmol/L) compared with saline-treated group ($P<0.01$).

P-selectin expression in hepatic and renal tissues

P-selectin was expressed widely within hepatic and renal tissues 1 hour after reperfusion, which was mainly distributed on small vessels of left hepatic lobe and tubular epithelium. In addition, it was also expressed on part of hepatic cellular membrane, glomerulomesangium, capillary loops, and interstitium. After treatment with the NNH, there were no obvious yellow-brown positive granules in the hepatic and renal tissue, suggesting that the P-selectin expression was not displayed.

PT and KPTT assays

Twenty four hours after hepatic reperfusion, PT (15.0±1.6 s) and KPTT (21.9±4.1 s) in the saline-treated group were similar to that of sham-operated group (13.4±1.7 s and 17.9±2.9 s respectively, $P>0.05$). PT(14.6±1.9 s) and KPTT (18.7±3.7 s) in NNH-treated group did not differ from those in saline-treated group ($P>0.05$). 24 hours after renal reperfusion, PT and KPTT were 13.7±1.4 s and 17.6±3.1 s respectively, while in NNH-treated group they were 13.3±1.6 s and 17.1±3.5 s respectively ($P>0.05$).

DISCUSSION

Recently, the role of cell adhesion molecules and neutrophil in orgen ischemia and reperfusion injury has attracted attention[27-48]. As a potential member of the selectin family, P-selectin is found in both weibel-plade body of epithelial cell of middle and small blood vessels and a-granule of platelet. It is expressed rapidly on the surface of these cells after their activation. P-selectin plays an important role in inflammation by initiating neutrophil rolling, adhesion and recruitment to injured tissue[27]. Blockade of P-selectin expression or interaction with its ligands can attenuate leukocyte adherence and infiltration during ischemia and reperfusion injury. And P-selectin monoclonal antibody was found to have protective effects on the injury[21,22].

Heparin and its analogue have been shown to bind to cell adhesion molecule P-selectin. The binding can inhibit adhesion of leukocytes mediated specifically by the adhesion molecules and are of anti-inflammatory activity[25,26]. Although heparin can be used to treat inflammatory diseases, their clinical potentials are limited due to their potent anticoagulant activity. Several chemical modifications of heparin that have reduced anticoagulant activities while preserving their anti-inflammatory activities have been reported. For example, the O-desulfated heparin derivatives have been shown to be of treatment for inflammation, while they still retained 5-30 % anticoagulant activities as compared with heparin[49]. Further, N-acetylheparin is known to have lower anticoagulant activity while preserving the anti-inflammatory activity[50]. N-desulfated heparin has been reported to have significantly reduced anticoagulant activity[51,52]. However, the anti-inflammatory roles of the heparin have not been extensively studied before.

The effect of N-desulfated heparin on ischemia and reperfusion injury was observed in this study based on the established rat model of hepatic/renal ischemia-reperfusion.

Hepatic and renal tissue displayed significant histopathologic damage after hepatic/renal ischemia-reperfusion while the serum levels of ALT and AST as well as BUN and Cr were increased. We showed that ischemia-reperfusion induced hepatic/renal injury was remarkably attenuated when NNH was given 5 min before reperfusion as shown by improved hepatic/renal function and less pathologic damage. The results suggest that the NNH has a protective effect on hepatic/renal reperfusion injury by inhibiting the interaction of neutrophils and endothelium.

After ischemia and reperfusion, P-selectin expression was up-regulated in hepatic and renal tissue, suggesting that P-selectin is related to hepatic/renal reperfusion injury. It has been found that leukocyte rolling and recuitment was delayed when deficient mice were infected,suggesting that P-selectin is involved in the early events of inflammation mediated by leukocytes[53]. Results from this study showed that P-selectin expression in hepatic and renal tissue was inhibited in NNH-treated group. This is consistent with down-regulated expression of sialyl lewis X, a ligand for P-selectin located mainly in neutrophils, as with anti-P-selectin therapy (unpublished data). These suggest that P-selectin might mediate neutrophil infiltration within the liver and kidney in the early stage of hepatic/renal reperfusion injury. Furthermore, blockade of P-selectin can attenuate inflammatory cell infiltration and pathological damage. N-desulfated heparin can be of protective role in the hepatic and renal injury caused by ischemia-reperfusion by inhibiting the adhesion and activation of neutrophils mediated by P-selectin. In addition, we found the heparin had no significant effects on PT and KPTT. It is

consistent with Bjornsson' s study[51]. Therefore, the N-desulfated heparin might be an efficient approach for the treatment of reperfusion injury with no obvious anticoagulant activity.

Abstract

AIM: The present study was conducted to test the hypothesis that the introduction of the collagenase gene into tissue culture cells and into a rat model of liver fibrosis would result in the expression of enzymatically active product.

METHODS: FLAG-tagged full-length rat collagenase cDNA was PCR amplified and cloned into a mammalian expression vector. NIH3T3 cells were then transiently transfected with this construct. Expression of exogenous collagenase mRNA was assessed by RT-PCR, and the exogenous collagenase detected by Western blotting using anti-FLAG monoclonal antibody. Enzymatic activity was detected by gelatin zymography. To determine the effects of exogenous collagenase production *in vivo*, the construct was bound to glycosyl-poly-L-lysine and then transduced into rats that had developed liver fibrosis as a result of CCl_4 plus ethanol treatment. The hepatic expression of the construct and its effect on the formation of liver fibrosis were demonstrated using RT-PCR and immunohistochemistry.

RESULTS: It was found that exogenously expressed rat collagenase mRNA could be detected in NIH3T3 cells following transfection. Enzymatically active collagenase could also be detected in the culture medium. The recombinant plasmid was also expressed in rat liver after *in vivo* gene transfer. Expression of exogenous rat collagenase correlated with decreased deposition of collagen types I and III in the livers of rats with experimentally induced liver fibrosis.

CONCLUSION: The expression of active exogenous rat collagenase could be achieved *in vitro* and *in vivo*. It was suggested that *in vivo* expression of active exogenous collagenase may have therapeutic effects on the formation of liver fibrosis.

INTRODUCTION

Matrix metalloproteinases (MMPs) are a group of proteolytic enzymes that require zinc ions for their activities, they take part in a variety of normal and disease-associated matrix lysis and remodeling events[1-3]. For example, interstitial collagenase, one member of MMPs, also called collagenase, mainly initiates the degradation of collagen types I, II, III, V, VII, and X, which are fibrillar collagens[4-6]. Interstitial collagenase probably contributes importantly to tissue repair, embryogenesis, bone renewal, and to some pathogenic processes such as rheumatoid arthritis, tumor metastasis, and also organ fibrosis[7-10]. Changing the expression or the activities of interstitial collagenase by regulatory factors or by gene transfer may have therapeutic effects on those disease processes.

Liver cirrhosis often shortens life expectancy and decreases the quality of life. In liver cirrhosis, a major pathological feature is the accumulation of extracellular matrix (ECM). Within the major components of ECM, collagen types I and III constitute more than 95 % of the total content of increased collagen in fibrotic liver. The abnormal accumulation of ECM may reflect alterations in the synthesis of matrix proteins, their degradation, or both[11,12]. The reversibility of liver fibrosis/ cirrhosis has been found in patients with various chronic hepatopathy[13, 14] and in experimental cirrhotic animals[15], indicating a therapeutic approach of this disease condition through improving ECM degradation. It has been reported that the mRNA transcription of interstitial collagenase is not up-regulated in experimental hepatic fibrosis[16,17] and the interstitial collagenase proteins in cirrhotic human livers and in serum of chronic hepatitis patients decrease[18,19]. Previous study also shows that the activity of collagenase decreases in advanced liver fibrosis[20-22] and in serum from patients with chronic liver disease[23,24]. Therefore, we proposed that exogenous gene expression of active collagenase might have therapeutic effects on the chronic liver diseases processes. The present experiments were performed to test the hypothesis that the introduction of a collagenase expression vector into tissue culture cells resulted in the enzyme expression, and that similar introduction of exogenous collagenase into a rat model of chemically induced liver fibrosis, altered the development of fibrosis. The *in vitro* results suggest that rat collagenase could be transiently expressed in NIH3T3 cells, and that rat liver fibrosis could be delayed by transducing the collagenase gene *in vivo*.

MATERIALS AND METHODS

Vector construction

A 6 amino acids deleted rat collagenase cDNA containing plasmid (UMR5.4) was kindly provided by Dr John J. Jeffrey[25] and used as starting material. Full-length rat collagenase cDNA was PCR amplified using the primers RIC-UP1 and RIC-DP1 with UMR5.4 as the DNA template (Table 1). The sense primer RIC-UP1 contained the sequences of the deleted 6 amino acids. The PCR fragments were then inserted into the PCR2.1 vector (Invitrogen, Carlsbad, CA, USA) to form PCR2.1-RIC. Using PCR2.1-RIC as template, the cDNA was further PCR amplified with RIC-UP2 and RIC-DP2 as primers (Table 1). The FLAG epitope was added to the C-terminus of the rat collagenase

gene in this construct by using RIC-DP2 that contained the FLAG sequence at the 3' end adjacent to the translation stop codon TAA (Table 1). The PCR reaction was performed as follows: the total reaction volume was 100 μl which contained 1ng DNA template (PCR2.1-RIC), 10 pmol· L^{-1} of each primer of RIC-UP2 and RIC-DP2, 2.5 μmol· L^{-1} dNTP, 10×PCR buffer and 5U Taq polymerase; 35 PCR cycles at 95 ℃ for 1.5 min, 55 ℃ for 1.5 min, and 72 ℃ for 2 min. The 1400 kb PCR product was purified and inserted into mammalian expression vector pTarge™ by the method of TA cloning following the protocol suggested by manufacture (Promega, Madison, Wis, USA) and named as pCMV-RC-F (Figure 1, Map of the plasmid pCMV-RC-F). The pCMV-RC-F was DNA sequenced using T7 primer. The large-scale of plasmid DNA was prepared using Qiagen tip100 (Qiagen, Hilden, Germany). The vector pTarge™ that was self-ligated without any inserted DNA was also isolated and used as control in the transfection study.

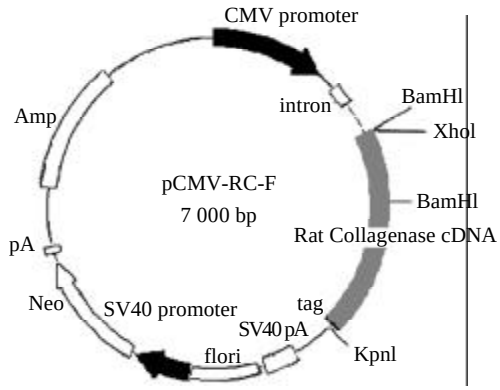

Figure 1 Map of plasmid pCMV-RC-F**.** The FLAG tagged full length rat collagenase cDNA was inserted into a mammalian expression pasmid vector Ptarge™ which carries the human cytomegalovirus (CMV) immediate-early enhancer / promoter region.

In vitro transfection

Exponentially growing NIH 3T3 cells were seeded into 6-well tissue culture dishes at 5×10^5 cells/well and grown overnight to 60 % confluency in culture medium supplemented with 10 % FCS. Each well was then transfected with 5 μg DNA constructs using lipofectamine according to the instruction provided by the manufacturer (Gibico BRL, Eggenstein, Germany). Encapsulated DNA was incubated for 5 h on cells in serum free medium, then in medium containing 10 % bovine serum. After further incubation of the cells for 24 h, the culture medium was discarded and replaced by normal culture medium. Fifty-six h after transfection, the NIH 3T3 cells and their media were harvested for further analysis.

RT-PCR analysis for mRNA expression

The collected cells were washed twice with ice-cold phosphate-buffered saline (PBS), and the mRNA extracted with mRNA Capture Kit (Boehringer Mannheim). The samples were further incubated with biotin-labeled oligo $(dT)_{20}$ working solution for 5 min to hybridize the mRNA with oligo $(dA)_n$. The mixture was added to a streptavidin-coated PCR tube, and incubated for 3 min at 37 ℃ to immobilize the poly $(A)_n$ RNA. Tubes were then washed three times and amplified by RT-PCR. The RT-PCR reaction system contained 0.3 μmol· L^{-1} each of the primer pairs RIC-UP3 and RIC-DP3 (corresponded to nucleotides 785-808 of the collagenase encoding region and the FLAG domain coding region, amplificated a PCR product of 652 bp), 5 mmol· L^{-1} DTT, 6 U RNAsin, 1.5 mmol· L^{-1} $MgCl_2$, 5×RT-PCR buffer and 1 μl Titan™ Enzyme mix provided with the Titan™ RT-PCR System (Boehringer Mannheim). Samples were placed in a thermocycler equilibrated at 50 ℃ for 30 min, at 94 ℃ for 5 min, then for 34 cycles at 94 ℃ for 1 min, 55 ℃ for 2 min, and 72 ℃ for 3 min, with a final extension at 72 ℃ for 10 min. The amplification products were then analyzed on 10 g· L^{-1} agarose gels containing 0.5 mg· L^{-1} ethidium bromide.

Western blot analysis of FLAG-tagged rat collagenase expression

The amount of protein in the collected culture medium of transfected cells was determined with Dye-binding method (Bio-Rad, Hercules, CA, USA). For each samples 30 μg total protein was electrophoresed on sodium dodecyl sulfate-polyacrylamide gel and then transferred to polyvinylidene difluoride (PVDF) membrane (Gelman Inc, Ann Arbor, MI, USA) by electroblotting. Pre-stained rainbrow recombinant protein molecular weight markers (Amersham International plc, Little Chalfont, Buckinghamshire, England) were used for molecular weight determinations. Membranes were blocked with a blocking buffer containing 50 g· L^{-1} non-fat milk powder, 10 mmol· L^{-1} Tris/HCl (pH 7.5), 100 mmol· L^{-1} NaCl and 1 g· L^{-1} Tween 20 and incubated with 1:100 diluted solution of anti-FLAG M_2 McAb[26] (Kodak, New Haven, CT, USA) at 37 ℃ for 1 h. After washing for 30 min the membranes were treated with HRP-conjugated secondary antibody (1:5000) (Bio-Rad) for 1 h at room temperature followed by another 30 min of washings. The ECL Western blotting system (Amersham Life Sciences) was used in accordance to the manufacturer' s instructions for chemiluminescence of proteins, and the blots were then exposed to photographic films (Fuji Photo Film Co., Tokyo, Japan).

Gelatin zymography assay for the enzyme activity

The activity of collagenase was detected by gelatin zymography as previously described[27, 28] with minor modifications. Culture supernatants that contained 60 μg /lane total protein were prepared and mixed with 5× zymogram sample buffer consisting of 0.4 mol· L^{-1} Tris (pH 6.8), 50 g· L^{-1} SDS, 200 g· L^{-1} glycerol, and 0.3 g· L^{-1} bromphenol blue, then electrophoresed with protein molecular weight markers as described before on 100 g· L^{-1} sodium dodecyl sulfate-polyacrylamide gels containing 10 g· L^{-1} gelatin under an ice water cycle. After electrophoresis, the position of molecular weight markers were marked and the gels were rinsed in washing buffer consisting of 50 mmol· L^{-1} Tris, pH 7.6, 1 μmol· L^{-1} $ZnCl_2$, 5 mmol· L^{-1} $CaCl_2$, 250 g· L^{-1} TritonX-100 at 4 ℃ on a rotary shaker. The Triton X-100 solution was decanted and replaced with rinsing

buffer consisting of 50 mmol· L^{-1} Tris (pH 7.6), 1 μmol· L^{-1} $ZnCl_2$, 5 mmol· L^{-1} $CaCl_2$ for further washing. The gel was then incubated with enzyme buffer containing 50 mmol· L^{-1} Tris (pH 7.6), 1 μmol· L^{-1} $ZnCl_2$, 5 mmol· L^{-1} $CaCl_2$, 0.2 g· L^{-1} Brij-35 at 37 ℃ for 42 h. Each gel was stained with 0.5 g· L^{-1} Coomassie blue G-250 in an aqueous solution of 300 g· L^{-1} methanol and 100 g· L^{-1} acetic acid and destained with three changes of 300 g· L^{-1} methanol, 100 g· L^{-1} acetic acid. Areas of digestion were visualized as non-staining regions of the gel and photographed.

Animal model of liver fibrosis

Thirty-six male Wistar rats (Shanghai Experimental Animal Center, Chinese Academy of Sciences) weighing 130±10 g were randomly distributed into four groups, 6 in a normal control group (A), 10 in an experimental liver fibrosis model without plasmid treatment as disease control group (B), and 10 in each of two pCMV-RC-F plasmid transfection as treatment groups (C1 and C2). Animals in the normal control group were treated with olive oil and received food and water *ad libitum*. Rats in the other three groups received a subcutaneous injection of CCl_4 solution (500 g· L^{-1} in olive oil) twice a week for eight weeks at a dose of 0.3 ml per 100 g of body weight after an initial dose of 0.6 ml per 100 g. The only source of fluid for the rats was 100 g· L^{-1} ethanol in water during the entire period of experiment. In addition, animals in the C1 group were intravenous injected with of 100 μg of galactosyl poly-L-lysine (G-PLL, obtained from Dr. Wen Shouming, The Air Force General Hospital of Chinese Peoples Liberation Army, Beijing, China) encapsulated recombinant plasmid through tails vein every two weeks, beginning two weeks after the start of treatment with CCl_4. G-PLL was included to accelerate the targeting effect of the transduced plasmid to the livers[29-31]. Animals in the C2 group received the same treatment as those in group C1 but the plasmid was administrated four weeks after starting the treatment with CCl_4. Animals in the B group received G-PLL encapsulated pTarge™ empty plasmid vector at the same dosage and the same time as those in the C1 group. The molecular ratio of galactose and poly-L-lysine is 15:28 and the average molecular weight of the G-PLL is M_r 8 500.

After weeks 8 treatment, the surviving 6 or 7 rats in each of the C1, C2, B groups and all the 6 rats in the A group were narcotized with 20 g· L^{-1} pentobarbital sodium. The middle lobes of the livers were removed and specimens were fixed in Carnoy' s fixative (glacial acetic acid, chloroform, and ethanol in volume ratio of 1:3:6) and then embedded in paraffin for histological analysis. The remaining tissue was quickly partitioned and immediately frozen and stored under liquid nitrogen for RNA extraction and RT-PCR analysis. Then the animals were humanly killed.

Collagenase mRNA expression in rat liver

Total RNA was isolated from the liver tissues using Trizol (Gibco BRL) according to the manufacturer' s directions. Integrity of RNA was confirmed by visual examination on an ethidium bromide-stained 10 g· L^{-1} Tris-acetate and EDTA agarose gel. Total RNA of 1 mg from each sample was used for reverse transcription and amplification using a RT-PCR kit (Sino-American Biotechnology Co. Shanghai. China). The RT-PCR reaction contained 10 pmol each of the primer pairs RIC-UP3 and RIC-DP3 for detecting the recombinant collagenase mRNA (a product of 652 bp), or each primer pairs of IC-UP4 and IC-DP4 (designed within nucleotides 711-734 of the coding region and nucleotides 1440-1463 of 3' untranslated region of collagenase, Table 1) for amplifying the endogenous collagenase mRNA (a product of 753 bp)[25]. The later primer pairs could not amplify the expression of recombinant collagenase that was lack of the nature 3' untranslated region of collagenase gene. Additionally primer pairs β-UP5 and β-DP5 were included for amplifying the expression of b-actin 335 bp DNA fragment) as internal control[32]. Samples were placed in a thermocycler with the incubation programme of 37 ℃ for 40 min, 94 ℃ for 7 min, then 36 cycles of 94 ℃ for 1 min, 56 ℃ for 1 min, and 72 ℃ for 1 min, with a final extension of 72 ℃ for 10 min. Products of RT-PCR were electrophoresed on a 20 g· L^{-1} agarose gel to show the amplified bands.

Histology and Immunohistochemistry

For immunohistochemical staining, 5 mm sections of each group were treated with anti-FLAG M_2 McAb to assay the expression of recombinant collagenase. After dewaxed with xylene and rehydrated through a graded alcohol series, sections were digested with 4 g· L^{-1} trypsin. Nonspecific binding was blocked with calf serum 1:5 in PBS. The sections were incubated with mouse anti-FLAG M_2 McAb (1:100) overnight at 4 ℃ and then with biotinylated horse anti-mouse IgG (Vector) for 30 min, avidin-peroxidase complex for 30 min, and the substrate solution (3,3-diaminobenzidine tetrahydrochloride in H_2O_2 in Tris buffer, pH 7.4) for 10 min, followed by counterstaining with hematoxylin. The sections were washed with 0.01 mol· L^{-1} PBS (pH 7.4) three times after each step. Finally, ten high power fields of each section were observed under microscope and the positive signals were counted.

Some sections of each group were treated with the monoclonal antibodies against collagen types I and III (1:100), then with secondary antibody and the procedure of the immunostaining were same to the above-mentioned except without counterstaining with hematoxylin. The slides were then analyzed with an Image Analyzing system (TJTY 300 System) to obtain the integral light density (ILD) of stained collagen types I and III.

Morphological examination was performed with Hematoxylin and Eosin staining (H&E) for histological changes of liver fibrosis.

Statistical analysis

The ILD values of collagen types I and III were analyzed by one-way ANOVA. The statistics were calculated by software SPSS 7.0 for Windows. The data are expressed as mean ±S. E. M. Values of $P<0.05$ were considered statistically significant.

RESULTS

In vitro expression and secretion of active FLAG-tagged rat collagenase

After *in vitro* transfection of plasmid in NIH 3T3 cells, the transcription of recombinant collagenase gene was confirmed by RT-PCR amplification of 652 bp cDNA fragment from cells transfected with pCMV-RC-F, but not from cells transfected with control plasmid pTarge™ (Figure 2). This product was of the size expected from mRNA of the tagged collagenase. Further demonstration of transfected gene expression was performed by Western blot analysis using anti-FLAG McAb. The immunoreactive band at about M_r 55 000 was observed in the culture supernatant of cells transfected with pCMV-RC-F but not in that with pTarge™ transfection or in culture medium alone (Figure 3). Collagenase activities were also found around the M_r 55 000 in gelatin zymogram analysis of the culture supernatant of pCMV-RC-F transfected cells and still could be observed after 1:64 dilution. A weak activity of collagenase was also observed in the culture supernatant of pTarge™

transfected cells but was almost undetectable after 1:2 dilution. No enzyme activity of M_r 55 000 collagenase could be detected in culture medium alone (Figure 4).

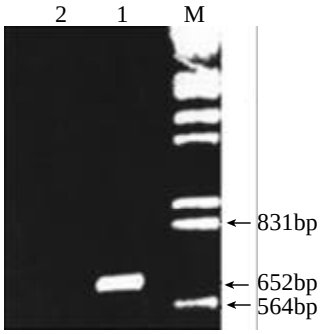

Figure 2 RT-PCR assay of the mRNA expression of recombinant collagenase in NIH 3T3 cells. The PCR-amplified 652 bp fragment of recombinant collagenase cDNA derived from their respective mRNA was found in NIH 3T3 cells which were transfected with pCMV-RC-F (lane 1), while no signal was detected in cells which transfected with control plasmid pTarge™ (lane 2). Lane M is the molecular weight marker (DNA / *Hind* III, *BamH* 1).

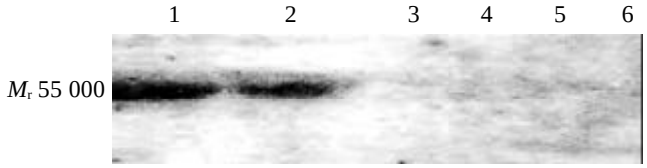

Figure 3 Westernblot analysis of the FLAG-tagged rat collagenase expression using mouse anti-FLAG M_2 McAb. The immunoreactive band with anti-FLAG M_2 McAb at about M_r 55 000 was observed in the culture supernatant of cells transfected with PCMV-RC-F (lane 1) and the supernatant of 1:2 dilution (lane 2). No immunoreactive was found in the supernatant of cells transfected with pTarge™ (lane 3, 4) or in culture medium alone (lane 5, 6).

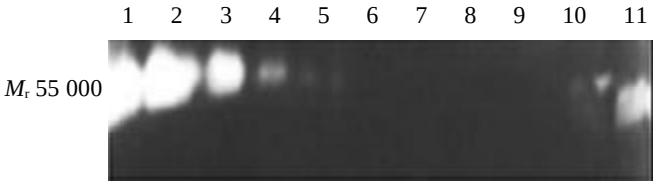

Figure 4 Gelatin zymography analysis for the activity of collagenase. The enhanced gelatin degradation activity was found in the culture supernatant of pCMV-RC-F transfected cells (lane 1-7 represent the zymograph of 1:1, 1:2, 1:4, 1:8, 1:16, 1:32, 1:64 diluted solutions of the supernatant) when compared with pTarge™ transfected cells (lane 10,11 represent the zymograph of 1:2 and 1:1 diluted solutions of the surpernatant). No activity was found at about M_r 55 000 in the culture medium (lane 8, 9).

In vivo expresson of FLAG-tagged rat collagenase in rat livers and its effects on liver fibrosis

The 650bp amplified product was detected in the RT-PCR samples from pCMV-RIC-F plasmid transduced rat groups (C1 and C2 group) but not in the control animal groups (A and B groups) (Figure 5). The 753 bp amplified product by primer IC-UP4 and IC-DP4 which represent the endogenous collagenase gene expression was detected in all samples (Figure 6). In addition to RT-PCR, the expression of exogenous collagenase was observed in C1 and C2 groups by immunostaining with anti-FLAG antibody (Figure 7). Nearly about 30 percent of total cells presented positive signals in C1 and C2 groups, and the distributions of positive signals were found in both the hepatocytes and the perisinusoidal cells.

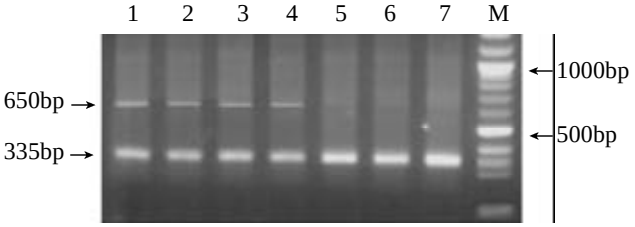

Figure 5 RT-PCR assay for the expression of recombinant interstitial collagenase in rat livers. The 652bp PCR amplified fragment of recombinant collagenase cDNA which was derived from their respective mRNA could be detected in liver samples from pCMV-RIC-F plasmid transduced rat groups C1 (lane 1, 2) and C2 (lane 3, 4) but not in the normal control group A (lane 5, 6) and disease control group B (lane 7). 335 bp fragment was PCR amplified b-actin cDNA. Lane M was 100 bp-1200 bp DNA marker ladders.

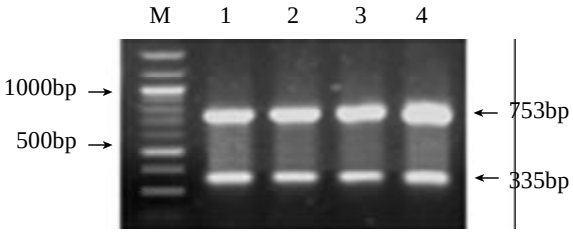

Figure 6 RT-PCR assay for the endogenous expression of collagenase in rat livers. The 753bp PCR-amplified fragment of endogenous collagenase cDNA which was derived from their respective mRNA could be detected in all liver samples from the normal control groups A (lane 1) and disease control group B (lane 4), as well as pCMV-RIC-F plasmid transduced rat groups C1 (lane 3) and C2 (lane 4). 335 bp fragment was PCR amplified b-actin cDNA. Lane M was 100bp-1200bp DNA marker ladders.

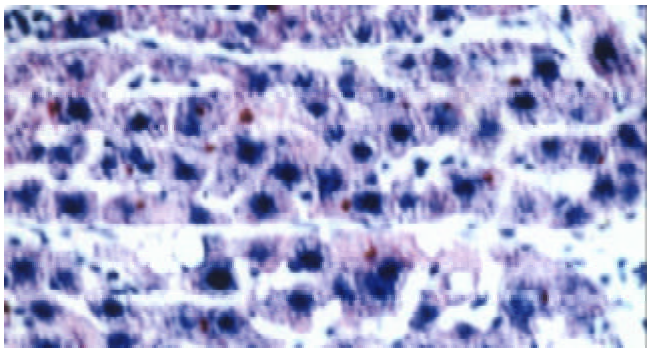

Figure 7 Immunohistochemical analysis of the expression of recombinant plasmid with anti-FLAG antibody in pCMV-RIC-F plasmid transduced group C1 (×400). Nearly about 30 percent of total cells presented positive signals. The distributions of positive signals were found in both the hepatocytes and the perisinusoidal cells.

The accumulation of collagen types I and III in the livers of animals in group B was more severe then that in group C1 and C2 according to the quantitative analysis of the immunohistochemical findings (P<0.05) (Table 2,Figure 8A-D).

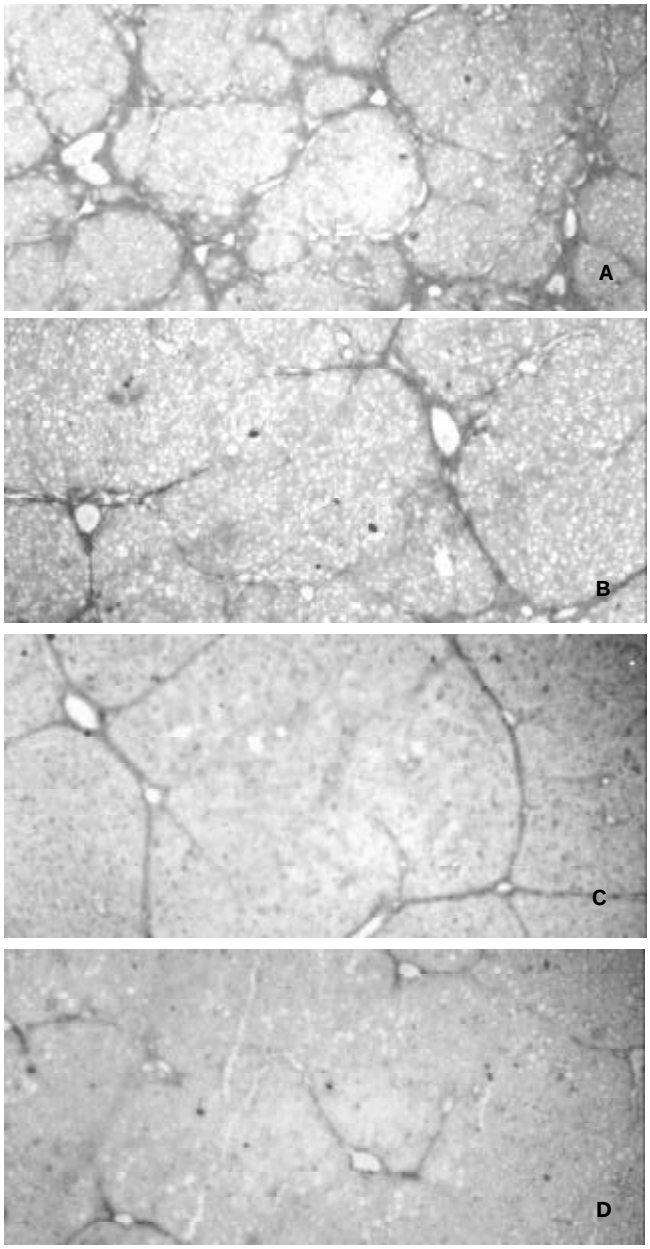

Figure 8 Immunohistochemical analysis of collagen types I (A, B) and III (C, D) in livers (×100). The accumulations of collagen in the disease control group (A, C) were more severe than that in the pCMV-RIC-F plasmid transduced C1 group (B, D).

Table 2 Effects of in vivo transfection of FLAG-tagged rat collagenase on the accumulation of collagen type I and III in experimental liver fibrosis

Group	*n*	ILD of collagen I	ILD of collagen III
A	6	17.35±2.62	18.94±3.78

C1	7	69.25±12.31[ab]	62.10±9.72[ab]
C2	7	72.18±14.18[ab]	64.80±11.69[ab]

[a]P<0.05 when compared with normal control group (group A); [b]P<0.05 when compared with disease control group (group B). ILD: Integral Light Density; N: number of rats in each group

DISCUSSION

In the present study the expression of FLAG-fusion rat collagenase was detected in pCMV-RC-F transfected NIH 3T3 cells and the secreted FLAG-fusion collagenase was found in the culture supernatant. This recombinant collagenase also exhibited enhanced gelatin degradation activity. These results suggest that the construction of recombinant collagenase plasmid is successfully function *in vitro* and could be used in further study *in vivo*. NIH 3T3 cell is a cell line of mouse embryonic fibroblasts. The mouse and the rat interstitial collagenase share highly homology when comparison was made between the amino acid sequences of their active forms[33]. Constitutive expression of collagenase gene had been found in NIH 3T3 cells before[34]. In our study, the weak activity of collagenase found in the culture supernatant of pTarge™ transfected cells in our gelatin zymography study might reflect this constitutive expression of mouse collagenase. Similar situation may also exist in liver tissues *in vivo*. Using anti-FLAG McAb we can easily distinct the recombinant rat collagenase that is tagged with FLAG domain from the natural mouse collagenase or the natural rat collagenase.

Collagen types I and III constituted the main components found in the increase of ECM[35, 36]. It has been proposed that the degradation of collagen types I and III is very important in the reversion of liver fibrosis. Theoretically the degradation of collagen could be enhanced if the expression of active collagenase increases. In this study, it was found that the recombinant plasmid could be delivered to liver by G-PLL and could be expressed in the tissue of liver. It was observed immunohistochemically that there were significant decrease of collagen types I and III deposition after transducing the recombinant collagenase plasmid into fibrostic livers. This suggests that the exogenous collagenase gene was able to degrade collagen.

Experimental gene therapies of liver cirrhosis have been tried by other research groups with different gene transfer methods and targeted genes[37-42]. In our study glycosyl-poly-L-lysine was used in the recombinant collagenase gene transfer into the livers since hepatocytes possess receptors that recognize galactose-terminal (asialo-) glycoproteins and thus they are particularly well suited for receptor-mediated methods of gene transfer. In our previous study it was proved that the recombinant plasmid could be delivered to liver and hepatocytes more specifically by G-PLL than lipofectamine[33]. In the present study it was also found that the positive signals of anti-FLAG McAb binding protein were in the hepatocytes of the rats of C1 and C2 groups. The less amounts of perisinusoidal cells which had positive signals as well might be the activated kupffer cells that had the function of phagocytosis. In addition, the previous study also observed the obvious expression of recombinant FLAG-tagged rat collagenase in liver at 24 h after plasmid transfection and persisting for longer than three weeks[31]. No detrimental effects of the transfection and expression of plasmid on important organs of normal rats such as liver, lung, heart and kidney were found by monitoring the serum levels of alanine transaminase, aspartic transaminase and creatinine and by observing the histological manifestation of these organs before and after transfection. These results indicated that the *in vivo* transfection of recombinant collagenase in liver that was mediated by glycosyl-poly-L-lysine was functionally expressed in liver and safe for other tissues.

The regulation of collagenase activity was affected by multiple factors[43, 44]. These include regulation of gene-transcription and protein-biosynthesis by cytokines or other factorsm, transformation of proenzymes into active forms, the

influence of specific or non-specific inhibitors on the activity of activated enzyme. Some studies have shown that the level of tissue inhibitor of metalloproteinase-1 (TIMP-1), which is a specific inhibitor of metalloproteinase, became very high during progressive liver fibrosis[45-49]. However the changes of regulation mechanisms such as the expression of TIMP-1 after collagenase gene transduction are still unknown. Whether the treatment effect on liver fibrosis by transferring an antisense gene of TIMP-1 is better than directly transferring collagenase gene as it was performed in this study worth further investigation.

In summary, the exogenous FLAG-tagged rat collagenase can be transferred by a recombinant plasmid and is expressed functionally in NIH3T3 cells and in a rat liver fibrosis model. As the result demonstrated that *in vivo* transduction of exogenous FLAG-tagged rat collagenase reduced liver fibrosis, this may stimulate the effort for which, the new therapeutic strategies in the management of liver fibrosis through regulation of collagenase activity and/or its inhibitors.

ACKNOWLEDGEMENTS

We gratefully acknowledge professor John J. Jeffrey (Departments of Biochemistry and Medicine, Albany Medical Center, USA) for his kind provision of rat collagenase UMR5.4 plasmid. Dr Shouming Wen (Air Force General Hospital of PLA, Beijing, China) for his supply of galactosyl-poly-L-lysine. Dr. Wei-tian Liu and Dr. Lin-Xun Duan(GenWay Biotech Inc Suite E2, Welsh Commons, PA 19454, USA) for the helping construction of plasmid. We also gratefully thank Dr. Arkady Mak, Dr. M. W. L. Koo and Professor M. A. Zern for their critical review of the manuscript.

Abstract

AIM: To estimate the effect of a therapeutic vaccine against pancreatic carcinoma based on dendritic cell (DC) vaccine modified with tumor lysate and Interleukin-18 gene.

METHODS: The BALB/C mice model of pancreatic carcinoma was induced with DMBA. DC vaccine was constructed through pulsed with tumor lysate and transfected by the recombinant adenoviral vector encoding IL-18 gene.The immnotherapeutic effects of DC vaccine on mice with pancreatic carcinoma were assessed (divided into DC-IL18-Lysate group, DC-Lysate group, DC-IL18 group, DC group, PBS group).

RESULTS: After vaccination of the DC vaccine, the concentration of IL-18 and IFN-γ were 2161±439 ng • L^{-1} and 435±72 ng • L^{-1} in DC-IL18-Lysate group and there was significant difference compared with other groups ($P<0.01$). After vaccination of the DC vaccine, the transplanted tumors were observed on 30 days in DC-Lysate groups, on 16 days in DC-IL18 groups, on 3 days in control group, but mice remained tumor-free for at least 50 days in DC-IL18-Lysate group and there was significant difference between DC-IL18-Lysate group and other groups ($P<0.01$). The median survival exceeds 62 days in DC-IL18-Lysate group. But the median survival was 48.6 days in DC-Lysate group, 33 days in DC-IL18 group, 17 days in PBS group. The survival period was obviously prolonged in DC-IL18-Lysate group than in other groups ($P<0.05$, $P<0.01$). The weight of pancreatic tumor was 0.22±0.083 g in DC-IL18-Lysate group, 1.45±0.74 g in DC-Lysate group, 1.89±1.34 g in DC-IL18 group, 3.0±1.6 g in DC group, 2.9±2.0 g in PBS group and the weight of tumor obviously reduced in DC-IL18-Lysate group than in other groups ($P<0.05$, $P<0.01$).

CONCLUSION: DC vaccine modified with tumor lysate and Interleukin-18 gene can induce a specific and effective immune response against pancreatic carcinoma cell.

Tang ZH, Qiu WH, Wu GS, Yang XP, Zou SQ, Qiu FZ. The immunotherapeutic effect of dendritic cells vaccine modified with interleukin-18 gene and tumor cell lysate on mice with pancreatic carcinoma. *World J Gastroenterol* 2002; 8(5):908-912

INTRODUCTION

Because of the lack of methods for early diagnosis and the limited effects of surgical treatment, chemotherapy and radiation therapy, about 98 % of the patients with pancreatic carcinoma don' t live more than 5 years[1-4]. So we clearly need the new therapies to improve the prognosis of the patients with pancreatic carcinoma. Immunotherapy is moving close to become a promising approach of anticancer therapy as it has fewer side effects and, more importantly, the opportunity to generate long-term immunity[5-7]. Dendritic cell (DC) is highly effective antigen presenting cell (APC) with the unique capability of inducing primary immune response against tumor-associated antigens. Animal studies have shown that the DC vaccine pulsed with tumor antigen could elicit specific T-cell response against tumor[8-12]. Recently, *Geiger et al*[13] reported that they have completed the first phase trial of tumor lysate-pulsed DC vaccine in the therapy of pediatric solid tumor, including osteosarcoma and fibrosarcoma, which were partial or complete regression.

Interleukin-18 (IL-18), originally termed IFN-inducing factor, induces IFN-γ production in both T cells and NK cells[14-15]. In addition, IL-18 induces T cells to produce GM-CSF, and enhances the cytolytic activity of T cells and NK cells[16]. In some animal model systems, IL-18 gene transfected into tumor cells should enhance both specific and nonspecific antitumor immune responses, which indicate if IL-18 gene were transfered into DC, it should induce highly effective antitumor immune responses[17-20].

In this study, an *in vivo* model to estimate the effect of a therapeutic vaccine against pancreatic carcinoma based on DC vaccine modified with tumor lysate and Interleukin-18 gene was designed. We hope those results should provided a scientific basis for our next step, clinical trials, in the future.

MATERIALS AND METHODS

Materials

BALB/c mice (6-8 week old, male) were purchased from the experimental animal center of the TongJi Medical Collegy. ^{3}H-TdR, ^{51}Gr was from Beijing Institute of Atomic Energy, 7,12-Dimethylbenzanthracene(DMBA) from Aldrich Co. Germany. IL-18, IFN-γ ELISA Kits from Zhongke Biotech Co. Wuhan. A recombinant adenoviral vector encoding IL-18 gene termed pCR3.1-IL-18 was kind gift from Dr. Chenwen Ye (Department of Immunology, Institut Pasteur de Lille, Paris, France). The mouse dendritic cell line MTSC4 derived from

the thymic of BALB/c mice (4 week old) were obtained from the department of immunology of Beijing medical university, which were maintained in CM.

Methods

The mice model of pancreatic carcinoma The membrance and partial parenchyma of BALB/c mice' s pancreas were opened about 1 mm depth and the DMBA (7 mg) was put into there, as previously described [21]. After 3-4 months, the mice developed pancreatic ductal adenocarcinomas with glandular duct-like distribution of cancer cells. The tumors from mice' s pancrease were removed, carefully detached with a cell scraper, washed twice in PBS, and resuspended at a density of 2×10^7/ ml in serum-free medium. 0.5 ml (2×10^7 /ml) viable tumor cells were injected into the left flank of BALB/c to develop the mice model of pancreatic carcinoma.

DC pulsed with tumor lysate Pancreatic carcinoma cells from the fresh solid tumor of mice were incubated with 0.01 % EDTA-solution for 10 min, washed twice in PBS, and resuspended at a density of 5×10^6/ml in serum-free medium. The cell suspensions were frozen at -80 ℃ (2 min) and thawed in 37 ℃ water (4 min), which were disrupted by four freeze-thaw cycles. For the removal of crude debris, the lysate was centrifuged for 10 min at 300×g. The supernatant was collected and passed through a 0.2-um filter for later use. Dendritic cells (DCs) were incubated with tumor lysates at a ratio of three tumor cells equivalents to one DC (i.e., 3:1) in CM. After 18 hr of incubation, DCs were harvested, washed twice in HBSS, and resuspended in HBSS for further study.

Cell transfection A recombinant adenoviral vector encoding IL-18 gene termed pCR3.1-IL-18 was kind gift from Dr. Chemen Ye (Immunology, Paris, France). For the transfection, DC and DC pulsed with tumor lysates were washed twice in HBSS, and incubated at 37 ℃ with the adenoviral vectors, respectively. Virus was used at a dose of 100 multiplicity of infection (MOI). Under these conditions, more than 80 % of DCs were infected.

Induction of tumor-specific CTL *in vivo* 30 BALB/c mice were at random divided into five groups. Every group included 6 mice, which were immunized s.c. in the right flank,(1)0.2 ml DC-IL18-Lysate (2×10^4 DCs modified with tumor lysate and IL-18, DC-IL18-Lysate group);(2)0.2 ml DC-Lysate (2×10^4 DCs modified with tumor lysate, DC-lysate group);(3)0.2 ml DC-IL18 (2×10^4 DCs modified with IL-18, DC-IL18 group);(4) 0.2 ml DC (2×10^4 DCs, DC group);(5)0.2 ml PBS (control group), respectively, twice at 7 days. After 7 days, spleen-derived T cells were isolated from mice by Nylon wool-separated and were cocultured *in vitro* with tumor cells for 5 days. After 5 days, T cells were tested for cytolytic activity in a standard 4-hr ^{51}Cr-release assay. Effector-to target (E/T) ratio were from 20:1 to 100:1. Each assay was performed in triplicate and triplicate wells were averaged and percentage of special CTL was calculated by the formula [(sample-spontaneous release)/ (maximum release-spontaneous release)×100 %][22].

Immunological protection of DCs vaccine 30 BALB/c mice were at random divided into five groups and were immunized s.c. in the right flank with DC-IL18-Lysate, DC-Lysate,DC-IL18,DC,PBS, respectively, twice at 7 days (described above). These mice were challenged 7 days after the last immunization with 0.5 ml(1×10^7/ml) viable tumor cells from mice pancreas by s.c. in the left flank. The development of pancreatic carcinoma was observed in every mice.

Immunotherapeutic effect of DCs vaccine 30 mice from the mice model of pancreatic carcinoma with average tumor size 0.3×0.5 cm^2 were at random divided into five groups (described above), which were respectively injected in the right flank with 2×10^4 DC-IL18-Lysate,DC-Lysate,DC-IL18, DC, PBS, respectively, twice at 7 days. The size of the tumors was recorded twice weekly by measuring the largest perpendicular diameters (PD) and transverse diameter (TD) with calipers. The weight of the tumor was calculated by the formula[(PD×TD^2)/2].

Cytokine analysis After 7 days of the mice with pancreatic carcinoma immunized (described above), serum was obtained from the carotid artery of mice. The concentration of IL-18 and IFN-γ in the serum were measured by ELISA.

Statistical analysis

Data were expressed as the mean ±SEM and were analyzed by *t* test or ANOVA. Differation were considered significant when *P* was <0.05.Tests were performed using SAS (Statistical Analysis Software).

RESULTS

Tumor-specific CTL in vivo

Spleen cells obtained from mice at 7 days after the final immunization were cocultured with pancreatic carcinoma cells for 5 days. T cells of DC-IL18-Lysate group, DC-Lysate group and DC-IL18 groups were able to efficiently lyse the pancreatic carcinoma cells. The lytic efficiency increases following the rise of E/T ratio. The lytic efficiency of DC-IL18-Lysate group was the best, DC-Lysate group was the subsequence, and DC-IL18 group was the final. But T cells from additional groups obviously lack this ability (*P*<0.01, Figure 1).

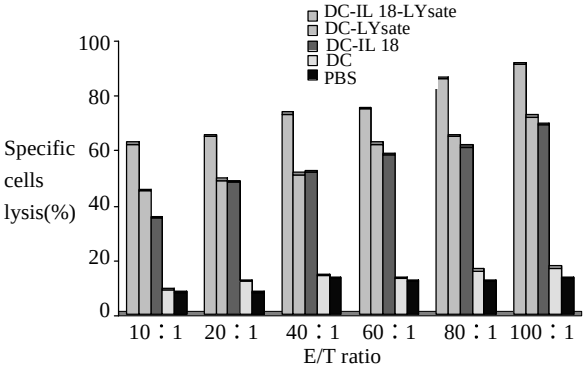

Figure 1 T cells were tested for cytolytic activity in a standard 4-hr ^{51}Cr-release assay. Effector-to target (E / T) ratio were from 20:1 to 100:1.

Cytokine analysis

After 7 days of the mice immunized, the concentration of IL-18 and IFN-γ in the serum were measured by ELISA. The concentration of IL-18 and IFN-γ were 2161±439 ng • L^{-1} and 435 ± 72 ng • L^{-1} in DC-IL18-Lysate group.There were significant differences in DC-IL18-Lysate group versus other groups (*P*<0.05, *P*<0.01,Figure 2a-2b).

Immunological protection of DCs vaccine

The transplanted tumors were not observed in DC-IL18-Lysate group after the viable tumor cells from mice pancreas injected into the left flank 50 days. After 30 days, the transplanted tumors were observed in DC-Lysate groups. The first time was 16 days the transplanted tumor observed in DC-IL18 groups after the tumor cells injected into mice. Additional

groups all were observed the development of transplanted tumors from 3 to 9 days (P<0.01, Figure 3).

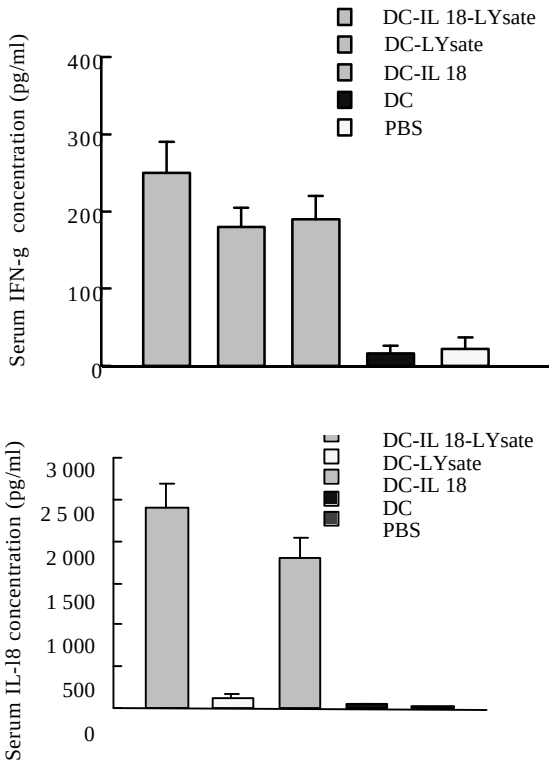

Figure 2a,2b The concentration of IL-18 and IFN-γ in the serum were measured by ELISA

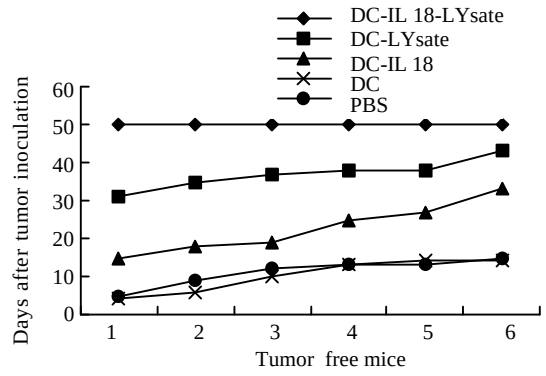

Figure 3 The development of the transplanted tumors was observed in every day

Immunotherapeutic effect of DCs vaccine

The growth velocity of tumor was observed obviously slowing in the mice immunized with DC-IL18-Lysate, DC-Lysate and DC-IL18. There were 3 cases in DC-IL18-Lysate group and 1 case in DC-Lysate group observed almost complete regression of the tumors. In contrast, the tumor cells displayed infiltrating style and adherent with nearby tissue in the mice immunized with PBS and DC. There was significant difference in the weight of tumor between the DC-IL18-Lysate group and the other groups (P<0.01,versus PBS group, DC group and DC-IL18 group; P<0.05, versus DC-Lysate group).The median survival exceeds 62 days in DC-IL18-Lysate group. But the median survival was only 48.6 days in DC-Lysate group, 33 days in DC-IL18 group, 17 days in PBS group (Table 1).

Table 1 Immunotherapeutic Effect of DCs Vaccine in Mice with Pancreatic Carcinoma

	DC-IL18-Lysate Ⅰ group	DC-Lysate Ⅱ group	DC-IL18 Ⅲ group	DC Ⅳ group	PBS Ⅴ group

DISCUSSION

Dendritic cells (DCs) play an important role as primary antigen-presenting cell to initiate and maintain T-cell responses[23-25]. In our study, we designed an *in vivo* model to estimate the effect of a therapeutic vaccine against pancreatic carcinoma based on DCs modified with tumor lysate and Interleukin-18 gene. It was observed that DCs were pulsed with tumor lysate could obviously increase the efficiency against the pancreatic carcinoma cells.

At present, potential targets for the immunotherapy of pancreatic carcinoma are antigens such as carcinoembryonic antigen[26], HER-2/neu[27], mutant ras[28], p53[29]. However, vaccinating a single antigen has disadvantages, because it is unknown which of the identified antigens was the potential to induce an effective antitumor immune response. Furthermore, immunity against a single antigen maybe ineffective in tumors with pancreatic carcinoma and carries the risk of inducing tumor antigen escape variant[30,31]. In addition, this strategy is restricted to those patients with a specific HLA type.

In our research, we selected the tumor lysate as the target antigent because these unfractionated tumor-derived antigens could circumvent these disadvantages. Tumor lysates contain multiple known as well as unknown antigens that could be presented to T cells by MHC class I- and class II-pathways[32-35]. Therefore, lysate-load DCs are more likely to induce a polyclonal expansion of T cells, including MHC class II restricted T-helper cells. These have been recognized to play an important role in the activation of CTLs, which were probably the most important cells in antitumor immune response. The generation of CTL clones with multiple specificities may be an advantage in heterogeneous tumors and could also reduce the risk of tumor escape variants. Furthermore, lysate from the autologous tumor can be used independently of the HLA type the patient. A major drawback of unfractionated tumor antigens is the possibility of inducing an autoimmune reactivity to epitopes that are shared by normal tissues[36]. However, in clinical trials using lysate as the source of antigen, no clinically relevant autoimmune responses were detected[37-44].

IL-18 is a recently discovered cytokine cloned from mice with fluminant hepatitis induced by challenge with propionibacterium acnes and subsequent administration of LPS[14]. IL-18 lacks a signal sequence and is processed into the mature form by an IL-1β-converting enzyme (ICE)[15]. IL-18 is produced by cells of monocyte lineage, augments NK cytolytic activity, and enhances proliferation of T cells. IL-18 also promotes NK and T cells to secrete IFN-γ and GM-CSF. Based on those findings, IL-18 was demonstrated to confer a superior antitumor activity in some murine tumor systems. However, the systemic administration of recombinant IL-18 proteins, though effectively inhibited the tumor growth, resulted in death of all animals because of toxicity[45-47].

Systemic administration of IL-18 also was associated with severe dose-dependent toxicity in patient during the first human trial. The transfer of cytokine genes may circumvent the toxicity of systemic IL-18,at same time, may delivery and provide adequate local cytokine levels for immune cell activation.

In our study, the IL-18 gene was transfected into DCs by recombinant adenoviral vector and we observed cytokine releases in serum of the mice were immunized with DCs modified with IL-18 and tumor lysate by ELISA. After 7 days of the mice immunized, the concentration of IL-18 and IFN-γ was obviously increased in DC-IL18-Lysate group. This indicated DCs transfected with the cytokines gene exhibited significant levels of IL-18 production, At same time, augmented the production of IFN-γ.

In our research, the effect of immunological protection and immunotherapy of DCs vaccines was obviously increased when DCs were modified with IL-18 gene and tumor lysate than IL-18 gene alone, tumor lysate alone. Especially, from the results of our study we found DCs modified with IL-18 gene alone induced a limited antitumor immunologic reaction. These findings strongly suggest that IL-18, tumor lysate and DC interacted and there were congenerous effect against pancreatic carcinoma. At first, IL-18 enhanced NK cytolytic activity to induce more frequent and effective tumor cell death and promoted NK and T cells to secrete IFN-γ. Zitvoget *et al*[48] reported the antitumor effect of DC-based vaccination was dependent on production of Th1-associated cytokines such as IFN-γ. Therefore, IL-18 may play an important role in antitumor activity of DCs through enhancing the production of IFN-γ[49]. In turn, DCs sever as effective antigen-presenting cells to induce potent and specific immunologic reaction. At same time, DCs expressed more ICE that was required when the preprotein of IL-18 was processed into the biological activity form. As shown in a recent study, the functions of DCs were affected by contact with tumor cells. Dynamic changes in chemokine receptor expression (up-regulation of CCR7) were identified on DCs following contact apoptotic tumor cells[50]. Fumiaki *et al*[51] also demonstrated that direct contact with DCs and tumor cell could be important for generating CTLs. Thus, the implications are that IL-18/Tumor cell/DC plays a critical inductive and interactive role in promoting the efficiency of immunotherpy against pancreatic carinoma.

In summary, DC vaccines modified with tumor lysate and Interleukin-18 gene can induce a specific and effective immune response against pancreatic carcinoma cells. However, the feasibility and security of this DCs vaccine still need to be observed in additional experiments.

Abstract

AIM: To synthesize dexamethasone-succinate-dextran (DSD) conjugate and to evaluate the potentiality of DSD for the treatment of inflammatory bowel diseases.

METHODS: Dexamethasone was attached to dextran (average molecular weight=70 400 Dalton) using succinate anhydride in an anhydrous environment catalyzed by 4-dimethylaminopyridine and 1, 1'-carbonyldiimidazole. The chemical structure of DSD was identified by UV, IR and NMR, and the *in vivo* drug release behavior of this prodrug was investigated after oral administration of DSD suspension.

RESULTS: The DSD conjugate was obtained in two steps and the content of dexamethasone in DSD was 11.28 %. The dextran prodrug was stable in rat stomach and small intestine and negligibly absorbed from these tracts. Four to nine hours after the oral administration, most of the prodrug (>95 %) had moved to the cecum and colon, and was easily hydrolyzed by an endodextranase. Recover of dexamethasone from colon and cecum after administration of DSD conjugate was 6-12 folds higher than the recovery after administration of unmodified dexamethasone(t=2.74, P<0.05). The preferential release of free dexamethasone in cecum and colon over that in the small intestine was statistically significant (t=2.27, P<0.05).

CONCLUSION: The results of this study indicate that dextran conjugates may be useful in selectively delivering glucocorticoids to the colon.

INTRODUCTION

Inflammatory bowel diseases, which include ulcerative colitis and Crohn's disease are currently treated with glucocoticoids and other anti-inflammatory agents[1,2]. For a steroidal anti-inflammatory drug, e.g. dexamethasone or prednisolone, a long-term administration would produce systemic side effects, including adrenosuppression, Cushinoid symptoms, immunosuppression, and diabetes. In this case, it is desirable to localize the release of dexamethasone insofar as possible to the afflicted sites in the colon. Release of drug in the proximal GI tract should be avoided to circumvent absorption from the small intestine, and consequent drug wastage and systemic side effects[2]. Because of the unique physiological characteristics of the large intestine, drug delivery to the colon can be achieved in different ways, including pH dependent approaches utilizing the changes in pH along the GI tract[3-12], coated dosage forms[13-17], time-controlled or pulsatile release systems[18-24], pressure-controlled colon delivery systems[25-30], coating drugs with bacterially degradable polymers[31-40], and delivery of drugs as prodrugs[41-47].

The bacterial count in the colon is higher than that in the preceding sections of the GI tract by many orders of magnitude in humans and other animals. Enzymes of the colonic bacteria can specifically degrade some kind of polysaccharides and azo-polymers or break the chemical bonds between the parent drug and the carrier, and then the pharmacological active component can be released from natural and synthetic prodrugs. The most important issue for this approach is a selection of the functional groups that can survive the passage through stomach and small intestine, but are degraded by enzymes of the colonic microflora thus specifically releasing the drug into the colon[2].

This project used dexamethasone as the model drug to synthesize a prodrug via a succinate tetracarbon-bridge that links the parent drug to the dextran carrier. Compared with unmodified dexamethasone, dexamethasone-succinate-dextran conjugate is more hydrophilic and has a larger molecular weight, which may decrease its possibility of being absorbed into the systemic circulation through the small intestinal epithelial cells. When it arrives to the colon, the dextran structure is hydrolyzed quickly by endogenous dextranase and then the esterase breaks the ester bond to release the dexamethasone. Distributions of dexamethasone in plasma and luminal contents were investigated after gastric intubation of DSD suspension or equivalent dose of dexamethasone to male SD rats.

MATERIALS AND METHODS

Material and apparatus

Dexamethasone was purchased from Tianjin Pharmacy Ltd., China. 4-dimethylaminopyridine (DMPA), 1,1'-carbonyldiimidazole and dextran (weight-average molecular weight=70 400 Dalton) were obtained from Sigma Chemical Company, St. Louis, MO. Succinate anhydride was purchased from Beijing Medicine Corporation, China. Molecular sieve (5Å) was obtained from Shitian Chemical Ind. China.

Methods

Synthesis of dexamethasone-dextran conjugate

Dexamethasone 3.98 g, succinate anhydride 1.27 g and 4-dimethylaminopyridine 1.55 g were dissolved in 400 ml anhydrous acetone over 5Åmolecular sieves. The reaction solution was stirred at 25 ℃ for 30 minutes, and the resulting solution was evaporated in a rotary evaporator to produce light

yellow solid. After the solid was dissolved in anhydrous ethanol, distilled water was added to achieve a solution of ethanol and water (29:71v/v). The solution was kept at -4 ℃ for 48 h to crystallize and filtered under reduced pressure. The resulting crystals were dried in a P_2O_5 drying pistol with refluxing of 95 % ethanol under vacuum (10 mmHg) for 24 h to produce dexamethasone succinate hemiester (DS). The yield is 85.28±4.57 %.

3.08 g of DS and 1.78 g of 1,1' -carbonyldiimidazole were dissolved in 15 ml of anhydrous dimethyl sulfoxide (DMSO). The reaction was run at 25 ℃ with stirring for 30 min. Then a solution of dextran in anhydrous DMSO(200 ml) and triethylamine(17.5 ml) was added, and the mixture was stirred at 25 ℃ for 21 h. The dextran conjugate was precipitated by adding 300 ml of ethanol/ether (50:50v/v) to the DMSO solution with stirring. The resulting polymer was dispersed in ethanol again and filtered under a stream of dry nitrogen. The precipitate was collected by filtration under reduced pressure, then washed with anhydrous ether three times to produce DSD white powder (yield: 81.27±5.09 %): UV λmax: 242 nm (ε14 500); IR(KBr): 3420(OH), 2930(CH_2),1740(C=O), 1660 (C=C), 1020(C-O-C) 898 cm^{-1}; ^{1}HNMR (DEXO-d_6): δ7.310, 7.285(d,1H,C-1), 6.233, 6.207(d,1H,C-2), 6.002 (s,1H, C-4), 3.488, 3.508, 3.623, 3.742,4.668 (s,1H,C-5' ,C-4' ,C-3' ,C-2' , C-1'), 3.202(s,2H,C-6'), 2.054(s,2H, C-21), 1.464 (s,3H,C-19), 0.860(s,3H, C-18), 0.758, 0.774 (d,3H,C-16).

The content of dexamethasone in DSD was measured by HPLC after alkaline hydrolysis.

Preparation of DSD granules and DSC test To evaluate the potential colon specificity of DSD *in vivo* test, granules of DSD or dexamethasone were prepared with the following ingredients: DSD or dexamethasone, cornstarch and lactose (5:50:45). A wet granulation method was applied. The granules were partially dissolved and suspended in water before dosing. Before granulation, all the ingredients were subjected to Differential Scanning Calorimetry (DSC). Measurements were performed on a calorimeter DSC7 connected to a Thermal Analysis Data Station 3 700 (Perkin-Elmer, Germany). Five mg of bulk materials were accurately weighed into standard aluminum pans. Thermograms were recorded from 303 to 573 K at a heating rate of 10 K • min^{-1}.

***In vivo* test** Male SD rats (weighing about 150 g) were fed a standard diet (R-2, Chengdu) and were fasted for 18 h prior to drug administration with free access to drinking water. The rats were divided into the test group and control group randomly. Each group was subdivided further into seven subgroups. The test groups were administered with suspension of DSD (equivalent to 3 mg of dexamethasone per Kg of rat body weight) by gastric intubation, and the control groups were administered with suspension of dexamethasone. After the drug administration, blood samples of the test subgroups and the control subgroups were collected at each predetermined time (1,3,4,5,6,7,9 h). Then the rats were sacrificed by decapitation and the stomach, proximal small intestine (PSI), distal small intestine (DSI), cecum and colon were removed. The contents of the GI tract were removed by gently squeezing the GI segments. The separated contents and tissues were quickly frozen to -20 ℃ and stored until analysis. Rat blood samples were collected and centrifuged at 700 g for 10 min. The plasma was frozen to -20 ℃ and stored until analysis was performed.

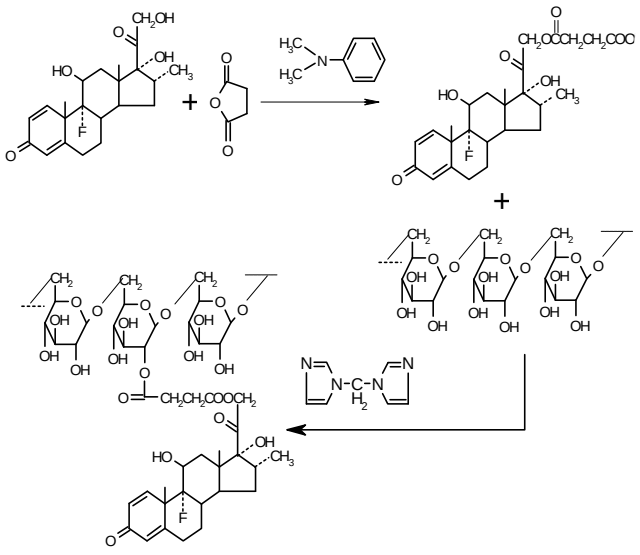
Analysis The frozen intestinal contents were thawed, weighed, and diluted to 50 %(w/v) with phosphate buffer (pH6.8). The suspended samples were homogenized by vortexing, and then 0.5 g of the diluted contents was placed in a 5-ml centrifuge tube. 200 μl of isotonic phosphate buffer (pH2), 100 μl of internal standard solution (0.1336 mg • ml^{-1}) and dexamethasone solution in different concentrations were added to the 5-ml centrifuge tube. The samples were extracted with acetic ester (3 ml) by vortexing for 2 min. After centrifuging for 10 min at 1000 g, 2 ml of the organic phase was removed and evaporate at 45 ℃ under vacuum. The residue was redissolved in mobile phase solution and centrifuged for 10 min at 1000 g. 20 μl of the supernatant fluid was subjected to HPLC analysis under the following conditions: Shimadzu CTO-10A system controller, LC-10AT pumps, SPD-10A variable wavelength detector, a Shimpack CLC C18 column(5 μm,4.6×150 mm). The mobile phase consisted of 35 % acetonitrile and 65 % buffer (50 mM trisodium citrate adjusted to pH4.6 with phosphoric acid). A flow rate of 1 ml.min^{-1} and a detection wavelength of 241nm were used. Prednisolone acetate was used as the internal standard. The plasma samples were treated by the same method described above.

RESULTS

Chemistry

DSD was prepared in two steps with a modified Mcleod reaction[2]. It is essential to keep the reaction continuing under the anhydrous condition to ensure high yield. Succinate anhydride was coupled to the dexamethasone hydroxyl group in anhydrous acetone in the presence of 4-dimethylaminopyridine to produce hemiester. Then the hemiester was coupled to dextran in DMSO using 1,1' -carbonyldiimidazole as catalyzer (Scheme 1).

The chemical structure was identified by ^{1}HNMR and IR, confirming the procedure of scheme 1. The content of dexamethasone in DSD was 11.28 equals to about 20 dexamethasone (molecular weight=392 Dalton) molecules were coupled to one dextran molecule (average molecular weight=70 400 Dalton).



Scheme 1 Preparation of DSD

Differential scanning calorimetry (DSC)

Study on interaction between the supplementary ingredients of suspension and DSD was performed by DSC. The thermogram displayed two transition peaks at 343K and 561K corresponding to DSD, and another two peaks at 420K and 486K corresponding to mixed ingredients. No new transition peak was observed when the physical mixture of DSD and ingredients were subjected to DSC, indicating that there was no interaction between DSD and the supplementary ingredients.

In vivo testing

The recovery of free dexamethasone from rat blood and GI tract at various times following oral administration of DSD suspensions is shown in Table 1. During the whole observation period (0-9 h), no dexamethasone was detected in blood. This observation indicated that DSD conjugate was so stable that it could not be degraded in upper GI tract and could not be absorbed into blood. Three hours after dosing, only very small amount (<3 % of total recovery) of dexamethasone was detected in small intestine in spite of the high level of esterase in small intestine. After 6h, the recovery of dexamethasone in small intestine further decreased. At the same time, a large portion (>95 % of total recovery) of the prodrug reached the cecum and colon intact.

Control experiments in which unmodified dexamethasone was administered showed that dexamethasone was absorbed primarily from the small intestine and the blood concentration of dexamethasone was much higher than test groups. Meanwhile, very small amount of dexamethasone was observed either in the cecum or in the colon (Table 2).

Table 1 Recovery of free dexamethasone from the rat blood and GI tract at various times after administration of DSD suspensions [a, b] (equivalent to 15mg of dexmethasone per Kg body weight)

t	T	Recovery of dexamethasone(%)

[a]Values represent the average of three animals. [b]t, Time; T, Total recovery; B, Blood; S, Stomach; PSI, Proximal small intestine; DSI, Distal small intestine; Ce, Cecum; Co, Colon. nd: Not detected

The dexamethasone recoveries from cecum and colon after the oral administration of DSD suspensions or dexamethasone suspensions were also shown graphically (Figure 1 and Figure 2). It was obvious that the recovery of test groups from cecum and colon after administration were higher than that of control groups by 6-12 folds (t=2.74, P<0.05).

The specificity of dexamethasone release was further evaluated by comparing the amount of free dexamethasone recovered in the small intestine with that in the colon in the test group. A paired t-test indicated that the preferential release of free dexamethasone in cecum and colon over that in the small intestine was statistically significant (t=2.27, P<0.05). Meanwhile, a similar analysis in the control group showed that the difference between the dexamethasone concentration in the colon and that in the small intestine was not statistically significant.

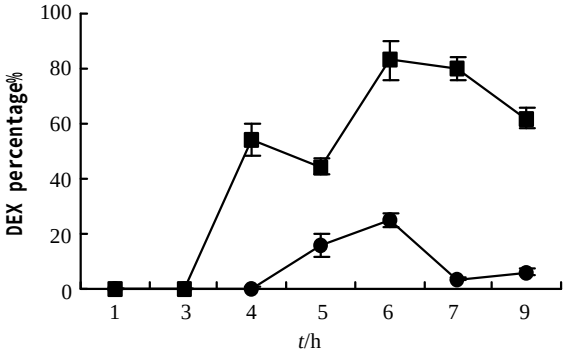

Figure 1 The dexamethasone contents-time curves in cecum after the oral administration dexamethasone suspensions (●-●) and DSD suspensions (■-■)

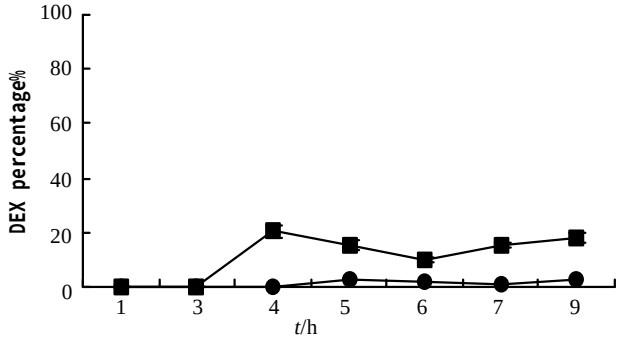

Figure 2 The dexamethasone contents-time curves in colon after the oral administration dexamethasone suspensions (●-●) and DSD suspensions (■-■)

DISCUSSION

The bacterial count in the colon is much higher than that in upper GI tract[2]. The colonic micro flora produce a variety of enzymes, including azoreductase, various glycosidases and amidases, which are not present in the stomach or the small intestine. Therefore, enzyme dependent drug release, which relies on the existence of enzyme-producing microorganisms in the colon, could be used to deliver drug to the colon after enzymatic cleavage of degradable carrier bonds and premature drug release does not occur in this case.

Besides treating inflammatory bowel diseases, colon-specific drug delivery system might be useful in other situations. The delivery of certain antineoplastic agents to the

colon might be beneficial in controlling colon cancer[48]. Enzyme prodrug gene therapy for colon cancer is also investigated by several researchers[49,50]. Antibiotics might be delivered specifically to the colon via cyclodextrin carriers[51-53]. In each of these cases, colon-specific delivery would allow the use of higher doses of potent agents with fewer systemic side effects.

The present results showed that the ester type prodrugs of dexamethasone/dextran release dexamethasone preferentially on cecal and colonic contents after the hydrolysis of dextran to small oligosaccharides, suggesting that dextran could serve as a new class of colon-specific drug carrier. The dextran conjugate survives the passage through upper GI tract although the high level of esterase in small intestine, indicating that dextran protects ester bond from hydrolysis by esterase. This result, together with the observation mentioned above, suggests that bacterial enzymes in the colon are responsible for hydrolysis of dextran conjugates. When DSD reached the colon, dextran was completely hydrolyzed into smaller oligosaccharides and exposed the ester bonds to esterase, which led to the rapid release of dexamethasone.

In summary, a colon-specific drug-delivery system has been developed based on drug-dextran conjugation and the unique glycosidase activity of the colonic microflora. Colonic drug delivery can be achieved with carriers by making prodrugs that survive the passage through stomach and small intestine, but the active moiety is released by enzymes specifically produced in colon.

Abstract

AIM: Toosendanin is a pre-synaptic blocker at the neuromuscular junction and its inhibitory effect is divided into an initial facilitative/stimulatory phase followed by a prolonged inhibitory phase. The present study investigated whether the subsequent inhibitory phase was due to exhaustion of the secretory machinery as a result of extensive stimulation during the initial facilitative phase. More specifically, this paper examined whether toosendanin could directly inhibit the secretory machinery in exocrine cells.

METHODS: Rat pancreatic acinar cells were isolated by collagenase digestion. Secretion was assessed by measuring the amount of amylase released into the extracellular medium as a percentage of the total present in the cells before stimulation. Cholecystokinin (CCK)-induced increases in intracellular calcium in single cells were measured with fura-2 microfluorometry.

RESULTS: Effects of toosendanin on CCK-induced amylase secretion and calcium oscillations were investigated. Toosendanin of 87-870 μM had no effect on 10 pM-100 nM CCK-stimulated amylase secretion, nor did 8.7-870 μM toosendanin inhibit 5 pM CCK-induced calcium oscillations. In contrast, 10 nM CCK_1 receptor antagonist FK 480 completely blocked 5 pM CCK-induced calcium oscillations.

CONCLUSION: The pre-synaptic "blocker" toosendanin is a selective activator of the voltage-dependent calcium channels, but does not interfere with the secretory machinery itself.

Cui ZJ, He XH. The pre-synaptic blocker toosendanin does not inhibit secretion in exocrine cells. *World J Gastroenterol* 2002; 8(5):918-922

INTRODUCTION

Toosendanin is a tetracyclic triterpenoid isolated from the seeds and barks of *Melia toosendan Seib. et Zucc* and *Melia azedarach L.* It has been used as an anthelmintic for many centuries, and has also been found to have pesticidal effects[1-5], and have anti-botulismic and other effects in whole animals[6, 7]. Work on nerve-muscle and other preparations (neuromuscular junction)[8-14] has established that toosendanin is a potent, long-lasting pre-synaptic inhibitor. The neuromuscular blocking effect of toosendanin is divided into two phases: an early stimulatory phase that is due to direct activation of voltage-dependent calcium channels[8, 12-18], and a delayed inhibition[9, 14]. However, it is not known whether or not the delayed blockade of the neuromuscular transmission is due to direct interference with the secretory machinery involved in neurotransmitter release.

Whether toosendanin has any direct effect on the secretory machinery can only be examined in secretory cells with no voltage-dependent calcium channels. If indeed the delayed blocking effect of toosendanin is due to direct inhibition of the secretory machinery, only will an inhibitory phase be observed in secretory cells which lack voltage-dependent calcium channels. The pancreatic acinar cell is an ideal model in which to address this question. The molecular mechanisms of secretion in pancreatic acinar cells are well elucidated[19-24], and these non-excitable cells have no voltage-dependent calcium channels[25, 26]. Therefore, this study examined if toosendanin has any inhibitory effect on secretion induced by a physiological secretagogue, cholecystokinin (CCK), in freshly isolated rat pancreatic acinar cells.

MATERIALS AND METHODS

Materials

CCK octapeptide, α-amylase and amylose azure were purchased from Sigma (St. Louis, MO, USA), Cell-Tak was purchased from Collaborative Biomedicals (Bedford, MA, USA). Toosendanin was a gift from Professor He LI (Department of Chemistry, Beijing Normal University). Collagenase P was bought from Boehringer Mannheim (Mannheim, Germany). Fura-2 AM was purchased from Molecular Probes (Eugene, OR, USA). (s)-N-[1-(2-fluorophenyl)-3,4,6,7-tetrahydro-4-oxo-pyrrolo[3,2,1-jk][1,4] benzodiazepin-3yl]-1H-indole-2-carboximide (FK480) was donated by Fujisawa Pharmaceutical Co. Ltd. (Osaka, Japan). Toosendanin and FK480 were both dissolved in DMSO as stock solutions before dilution to final concentration.

Isolation of rat pancreatic acini

Pancreatic acini were isolated from male Sprague-Dawley rats with body weight ranged from 170 g to 250 g according to the method reported previously[23, 27, 28].

Measurement of amylase secretion

Isolated acini were aliquoted into 2 ml portions and stimulated at 37 ℃ in a shaking water bath (50 cycle · min^{-1}) for 30 min. The amylase secreted into the buffer was assayed according to the procedures reported previously[29- 32] and expressed as percentage of the total present in the acini before stimulation.

Measurement of intracellular calcium $[Ca^{2+}]_i$

Ten microlitre of 1mM Fura-2 AM was added to1 ml of isolated acini (final concentration 10 μM) and the mixture was incubated in a shaking water bath at 37 ℃ and 50 cycle · min^{-1} for 40 min.

Fura-2-loaded acini were attached to the cover-slip of a Sykus-Moore chamber and perfused on the stage of an Olympus fluorescence miscroscope (IX70) attached to a microfluorometric calcium measurement system (M40, Photon Technology International, NJ, USA). Calcium increases were expressed as fluorescence ratios measured at 510 nm (F340/F380)[23, 27, 33-35].

Standard buffer used in this work was composed of (all in mM) NaCl 118, KCl 4.7, $MgCl_2$ 1.16, $CaCl_2$ 2.5, NaH_2PO_4 1.16, glucose 5.6, bovine serum albumin 2 mg • ml^{-1}, soybean trypsin inhibitor 0.1 mg • ml^{-1}, N-(2-hydroxyethyl) piperazine-N' -(2-ethanesulfonic acid) (HEPES) 10, MEM amino acid mixture (GIBCOBRL, Grand Island, NY, USA) 2 % and glutamine 2. The buffer was adjusted for pH to 7.4 with 4 mM NaOH and oxygenated with O_2 for 30 min before use.

RESULTS

Effects of toosendanin on CCK-induced amylase secretion

CCK stimulated amylase secretion from the freshly isolated rat pancreatic acini in a concentration-dependent manner (Figure 1). The maximum stimulation was achieved at CCK concentration of 100 pM, with a percentage secretion of 33± 1.6 (*n*=6). This bell-shaped dose response curve is consistent with previous report[36].

In separate experiments, acini were first incubated with toosendanin at 870 μM or 87 μM for 10 min before stimulation with CCK for a further 30 min in the continued presence of toosendanin (Figure 2). When toosendanin was added at 87 μM, the maximum stimulating CCK concentration shifted from 100 pM (18.2±1.6, *n*= 6) to 1 nM (19.7±1.2, *n*=6). With the addition of toosendanin at 870 μM, the maximum CCK concentration also shifted from 100 pM (18.2±1.6, *n*=6) to 1 nM (19.2±1.9, *n*=4). The slight rightward shift indicates a mild but statistically insignificance inhibition (Student' s *t* test, *P*>0.05). In control experiments, neither 0.01 % solvent DMSO nor toosendanin at each concentration used had any effect on amylase secretion (data not shown).

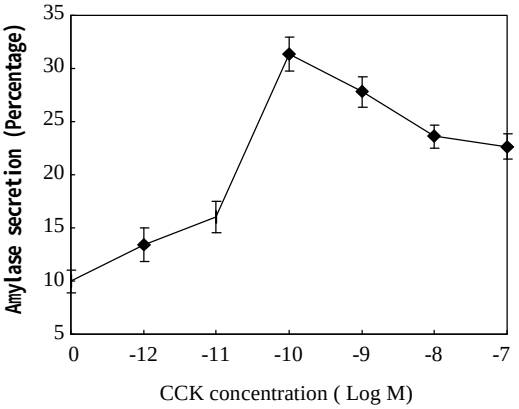

Figure 1 Concentration dependence of cholecystokinin (CCK)-stimulated amylase secretion. Note that maximum secretion was achieved at 100 pM of CCK. *n*=6

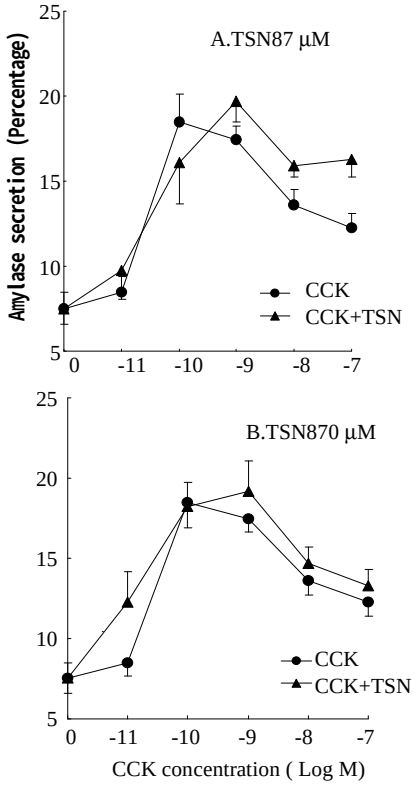
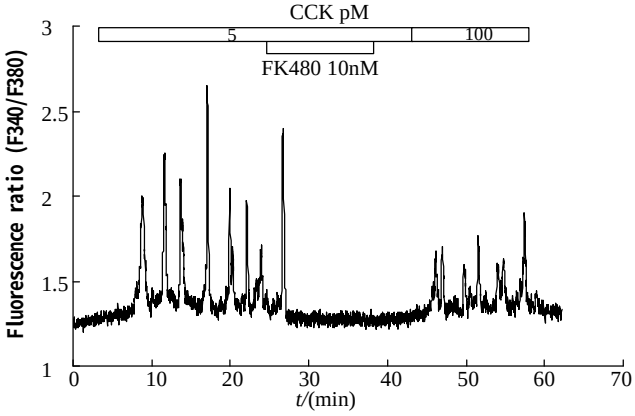
Effects of toosendanin on CCK-induced $[Ca^{2+}]_i$ oscillations

CCK of 5 pM induced regular calcium oscillations in perfused rat pancreatic acinar cells (Figure 3), which is consistent with previous reports[27, 28]. Addition of toosendanin at 8.7 μM to the CCK-stimulated acinar cells for 10-20 min had no apparent effect on CCK-induced calcium oscillations (Figure 3A, *n*=4). Even when toosendanin was increased to 87 μM, there was still no obvious inhibition observed (Figure 3B, *n*=7). At 870 μM, toosendanin induced a very mild inhibition: a single spike appeared missing in the trace shown (Figure 3C, *n*=8).

For comparison, FK480, an antagonist for CCK_1 receptors[37-39], produced immediate and complete inhibition of 5 pM CCK-induced calcium oscillations (Figure 4, *n*=5). FK480 at 10 nM abolished 5 pM CCK-induced calcium oscillations immediately upon addition, reducing the calcium to pre-stimulation level (Figure 4). After washout of FK480, calcium oscillations did not re-appear immediately, indicating that FK480 might bind to the acinar cells very tightly. It was possible, however, to re-introduce calcium oscillations when CCK was increased to 100 pM. At a lower FK480 concentration of 1 nM, a much longer time was needed before complete abolition of 5 pM CCK-induced Ca^{2+} oscillations was observed (data not shown).



igure 2 Effect of toosendanin (TSN) on CCK-stimulated amy-ıse secretion. TSN was added to the pancreatic acini 10 min efore stimulation with CCK which was maintained for an-ther 30 min. A. TSN 87 μM, *n*=6. B. TSN 870 μM, *n*=4. Note ıat, for clarity, the same CCK dose-response curve (*n*=6) was



the horizontal bars. *n*=5.

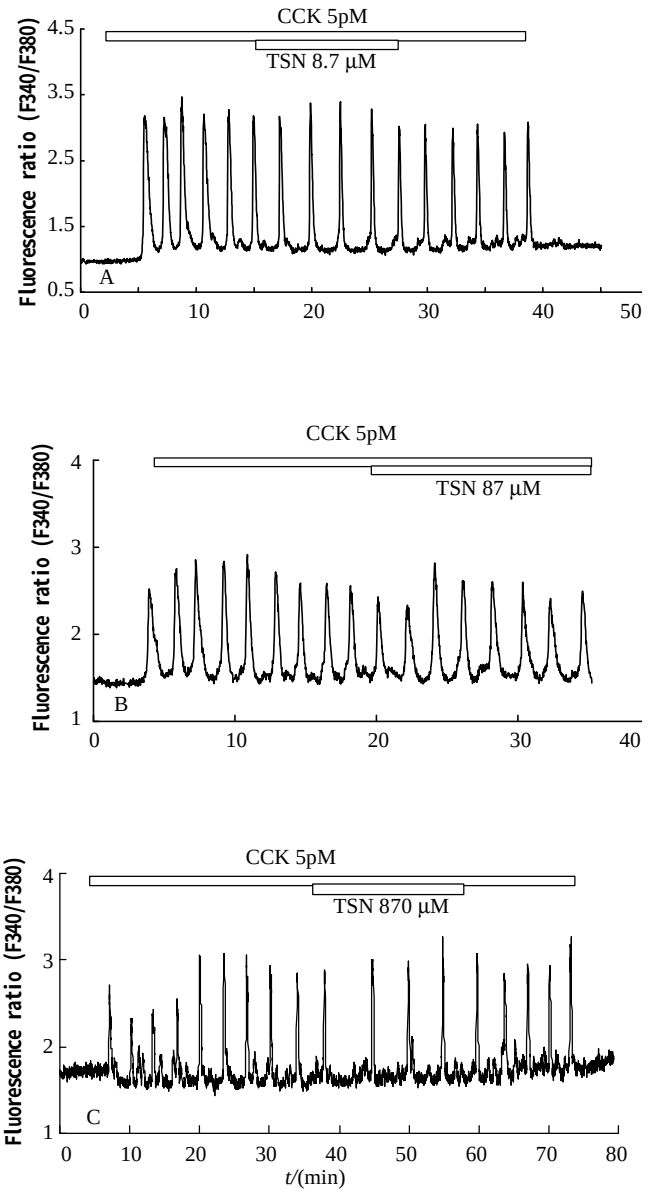


Figure 3 Effect of toosendanin on 5 pM CCK-induced calcium oscillations. CCK and TSN were added as indicated by the horizontal bars. A. TSN 8.7 μM, *n*=4. B. TSN 87 μM, *n*=7. C. TSN 870 μM, *n*=8.

DISCUSSION

The present work demonstrated that toosendanin, a pre-synaptic inhibitor of the neuromuscular transmission[7, 9, 13, 14], had little effect on CCK-stimulated amylase secretion. Although treatment with toosendanin at both concentrations tested (87 μM, 870 μM) resulted in a rightward shift in concentration of CCK that was needed to induce a maximum stimulation, i.e. from 100 pM in untreated cells to 1 nM in treated cells (Figure 2)[36], the toosendanin inhibition was not statistically significant for each CCK concentration (P>0.05).

Toosendanin of 8.7- 87 μM had no effect on 5 pM CCK-induced calcium oscillations. At a much higher concentration of 870 μM, a mild inhibition was observed because one spike seemed missing (Figure 4). This lack of marked inhibition of toosendanin on CCK-induced calcium oscillations is in sharp contrast with the complete blockade of CCK-induced calcium oscillations by FK480, a CCK_1 receptor antagonist [38, 40, 41]. Toosendanin at the neuromuscular junction had dual effects, a fast-onset stimulation which lasts about 40 min followed by a long-lasting inhibition[7-9, 12-14]. The fast phase has been postulated to be due to activation of voltage-dependent calcium channels[8, 12-18]. However, toosendanin had no effect on CCK-induced calcium oscillations in rat pancreatic acinar cells. This indicates that toosendanin had no effect on stores-operated calcium channels as they are the only calcium channels existing in the freshly isolated pancreatic acinar cells[20, 26] and are important for the continued presence of calcium oscillations[23, 27].

In view of the above findings, the pre-synaptic blocking effect of toosendanin should be looked at under a new light. The delayed inhibition of neuromuscular transmission could just be due to massive stimulation of synaptic vesicle fusion after activation of the voltage-dependent calcium channels at the nerve terminal, resulting in the depletion of synaptic vesicles and delayed depression. The fact that toosendanin administration in rat leads to a decrease in synaptic vesicles[42, 43] strongly supports this hypothesis. The initial strong stimulation of voltage-dependent calcium channels would afford the early stimulatory effects of toosendanin, providing an antidote to botulism[6, 18].

An activator for voltage-dependent calcium channels as toosendanin may be, a long-lasting inhibition of the neuromuscular junction[7- 9,12-14] or an extended period of synaptic vesicle depletion would require the stimulatory effect of toosendanin to be long-lasting. This stimulatory effect has indeed been found to last 40 min in nerve-muscle preparations[7-9, 12-14]. It is well known that voltage-dependent calcium channels inactivate rather quickly after opening, although with different kinetics[44-49]. Therefore, the long-lasting effect must be due to something other than constant opening of the calcium channels. It is known that intracellular calcium signals are subsequently encoded into activation of calcium/calmodulin-dependent protein kinases[50-52], and short-duration calcium signals could be transformed into long-lasting activation of calcium/calmodulin-dependent protein kinase II[53], therefore it would be interesting in the future to further investigate the possible effect of toosendanin on calcium oscillations in excitable cells, and on oscillation-associated activation of calcium/calmodulin-dependent protein kinase II. It would also be interesting to identify which types of voltage-dependent calcium channels are activated by toosendanin since a number of them are involved in neurotransmitter release[54-56]. In this conjunction, it is important to note that decreased calcium influx into motor nerve terminals has been found to recruit additional neuromuscular junctions during the synapse elimination period [57].

Abstract

AIM: To determine the *in vivo* effects of phagocytic blockade of Kupffer cell (KC) on the release of proinflammatory cytokines in small intestinal lesion and on the integrity of intestinal tract by using gadolinium chloride ($GdCl_3$) during early endotoxemia.

METHODS: Wistar rats were divided into three groups: Group A, rats were injected with endotoxin (*E. coli* O111:B_4, a dose of 12 mg.kg^{-1}) only; Group B, rats were pretreated intravenously with 25 mg of $GdCl_3$ per kg 24 h are given endotoxin; and Group C, sham operation only. All animals were sacrificed 4 h after endotoxin injection. In portion of the rats of three groups, bile duct was cannulated, which the bile was collected externally. Morphological changes of ileum were observed under light microscopy and electronic microscopy. The KC were isolated from rats by collagenase perfusion and in KC, expression of TNF-α and IL-6 mRNA were determined by RT-PCR analysis. Plasma and bile TNF-α and IL-6 Levels were determined by enzyme-linked immunosorbent assay (ELISA).

RESULTS: In group A, there were neutrophil infiltration and superficial epithelial necrosis of the ileal villi, sloughing of mucosal epithelium, and disappearance of some villi. In group B, the ileal mucosal damage was much reduced. which in group C, no significant morphological changes were seen. $GdCl_3$ pretreatment decreased significantly the expression of TNF-α and IL-6 mRNA in group B (4.32±0.47 and 4.05 ±0.43) when compared to group A (9.46±1.21 and 9.04± 1.09) (P<0.05). There was no significant expression of TNF-α and IL-6 mRNA in group C (1.03±0.14 and 10.4±0.13). In rats of group A, the levels of TNF-α and IL-6 in bile and plasma were 207±29 ng·L^{-1}, 1032±107 ng·L^{-1}, 213±33 ng·L^{-1}, and 1185±127 ng·L^{-1}, respectively. In group B, they were 113±18 ng·L^{-1}, 521±76 ng·L^{-1}, 147±22 ng·L^{-1}, and 572±54 ng·L^{-1}, respectively. In group C, they were 67±10 ng·L^{-1}, 72±13 ng·L^{-1}, 109±18 ng·L^{-1}, and 118±22 ng·L^{-1} respectively. There were significant difference between the three group (P<0.05).

CONCLUSION: KC release cytokines TNF-α and IL-6 causing damage to the integrity of intestinal epithelium and play a crucial role in the initiation and progression of intestinal mucosal damage during early endotoxemia.

INTRODUCTION

LPS (lipopolysaccharide) is now considered to be a potent inducer of a series of inflammatory mediators[1-6]. In the early as infection, the main symptoms can be ascribed in part to the inflammatory cytokines as tumor necrosis factor alpha (TNF-α), interleukin-1 (IL-1), IL-6 and platelet-activating factor[7-9]. Recently, Jackson *et al*[10] reported that intestinal damage is mediated by factors derived from the bile. KC (Kupffer cell) constitute 80-90 % of the fixed tissue macrophages of the reticuloendothelial system (RES) and their activation and subsequent release of cytokines have great influence on the systemic response during sepsis[11-14]. KC has been shown to be a major source of released IL-6 following traumatic or hemorrhagic shock and after resuscitation[15]. Since LPS has been removed from the blood by the liver, we speculated the cytokines from KC in the bile may likely cause the damage to the intestinal during endotoxemia. Therefore, the aim of this study was to determine whether the *in vivo* phagocytic blockade of KC by using gadolinium chloride ($GdCl_3$) had any effects on intestinal integrity during early endotoxemia and whether the proinflammatory cytokines played crucial role in small intestinal lesions.

MATERIALS AND METHODS

Animals model

Wistar rats 10 wk old, weighing 220 g to 250 g were used in this experiment. The rats were obtained from Laboratory Animal Center of Chongqing University of Medical Science. These animals were divided into three groups: Group A, rats injected endotoxin only; Group B, rats pretreated with $GdCl_3$ and given endtoxin; and group C, sham operation only.

In vivo blockade of Kupffer cells by gadolinium chloride

In group B, animals were treated intravenously with 25 mg of $GdCl_3$ per kg 24 h prior to the operation as described by Koo *et al*[15]. In the preliminary experiment, the optimum dose and time of administration of $GdCl_3$ were determined by assessment of loss of KC labeled with India ink. In some of animals, in order to collect the bile, the animals were fasted overnight with free access to water. Bile duct was cannulated in rats of the three groups under ether anesthesia as described by Jackson *et al*[10]. Briefly, the abdomen was opened through a midline incision of 1.5-2.0 cm immediately below the sternum. The

bile duct was located, and approximately 1 to 1.5 cm of a 25 cm polyethylene cannulation tube (external diameter, 0.8 mm; internal diameter, 0.4 mm) was inserted into bile duct and tied in place, the other end of the tube was exteriorized through an opening in the right flank by an 18-gauge needle, allowing bile to be collected externally. The abdominal incision was then sutured, and the rats were held in restraining cages. Rats from group A and B were then injected iv with LPS from *E. coli* serotype O111: B4 (Sigma, St. Louis, Mo. USA), using a dose of 12 mg • kg^{-1}. Animals from group C were infused with some dose of pyrogen-free sterile saline. Plasma were separated from tail vein blood, and bile was collected 4 h after LPS administration when these rats were killed and the macroscopic appearance of the whole small instestine was assessed.

Morphological observation of ileum

One-to two-centimeter segments of the ileum from each rats were fixed in 100 ml • L^{-1} buffered formalin or 25 g • L^{-1} glutaraldehyde immediately. For light microscopy, the tissue blocks were embedded in paraffin, and the 5-um sections were stained with HE. For electronic microscopy, the tissue blocks were embedded in Epon 618 resin and ultrathin sections stained with uranyl acetate and lead citrate. A H-2000 transmission electronmicroscope was used.

Kupffer cell isolation

KC were isolated as described previously[16,17]. In brief, the livers were removed after a portal vein perfusion with Hanks' balanced salt solution (HBSS) and the homogenate was digested in a solution of 5 g • L^{-1} collagenase (Type IV, Sigma). The digest was washed thoroughly and plated on plastic dishes in RPMI medium containing 50 ml • L^{-1} fetal calf serum (FCS). After 3 h incubation at 37 ℃ in O_2 and CO_2 (0.95/0.05), nonadherent cells were removed with pipet. The adherent cells were collected with a rubber policeman. 70 % to 90 % viable KC was obtained in this manner. $GdCl_3$-treated and control cells exhibited similar viability, morphology, and *in vitro* phagocytosis, although the livers from $GdCl_3$-treated rats yielded 10-20 % fewer KC than saline-injected rats.

Expression of TNF-a and IL-1 mRNA in kupffer cell

RNA isolation and C-complementary DNA synthesis Total RNA was isolated from KC by using the Trizol Reagent (Life Technologies, USA). The quality of RNA was controlled by the intactness of ribosomal RNA bands. A total of 0.5 mg of each intact total RNA samples was reverse-transcribed to complementary DNA (cDNA) by using the reverse transcription polymerase chain reaction(RT-PCR) kit(Roche, USA). cDNA was stored at -70 ℃ till polymerase chain reaction (PCR) analysis.

Determination of TNF-a **and IL-6 mRNA by RT-PCR** The PCR primers used were TNF-α: sense (5'-CACCATGAGCACGGA AAGCA-3'), antisense (5'-GCAATGACTCCAAAGTAGAC-3'); IL-6: sense (5'-CTTCCAGCCAGTTGCCTTCT-3'), anti-sense (5'-AGCCAGAGTCATTCAGAGCA-3'); β-actin: sense (5'-ACCACAGCTGAGAGGGAAATCG-3'), antisense (5'-AGAGGTCTTTACGGATGTCAACG-3'). The sizes of the amplified PCR products were 692 bp for TNF-α, 309 bp for IL-6, and 281 bp for β-actin. The conditions for amplification were as follows: denaturation at 94 ℃ for 1 min, annealing at 57 ℃ for 2 min, and extension at 72 ℃ for 2 min for 31 cycles. The PCR products were electrophoresed in 15 g.L^{-1} % agarose gels, and the gels were ethidium bromide stained and video photographed on an ultraviolet transilluminator.

Bioassay for cytokines in plasma and bile

Plasma and bile levels of TNF-α and IL-6 were determined by enzyme-linked immunosorbent assay (ELISA) kits according to the manufacture's instructions and guidelines (Biosource International, Camarillo, CA).

Statistical analysis

All data were expressed as $\bar{x} \pm s$ and compared by one-way analysis of variance (ANOVA). Differences in values were considered significant if $P \leqslant 0.05$.

RESULTS

Effect of phagocytotic blockade of Kupffer cells on the intestinal integrity

We investigated the effect of phagocytotic blockade of Kupffer cells by $GdCl_3$ on the histological appearance of the ileum. 4 h after inoculation with LPS, macroscopic examination showed marked hyperemia, edema, and fluid accumulation within the lumen of small bowel in rats of group A. In contrast, in animals of group B, there was substantial reduction in hyperemia and no fluid accumulation. There was neither hyperemia nor fluid accumulation in group C.

In group A, there was marked tissue damage. Under light microscope, there were neutrophil infiltration in the villi, severely damaged epithelial layer with superficial necrosis and sloughing, some villi completely disappeared (Figure 1A). In contrast, the rats of group B, intestinal mucosal damage were much reduced, there was no evidence of hyperemia, vasodilatation or edema in the lamina propria, and the epithelial layer was intact, only modest hyperemia in the submucosa, only occasional edematous apex at the villi (Figure 1B). In group C, The histological appearance was normal (Figure 1C).

Figure 1A Superficial epithelial necrosis of villi and complete absence of some villi (HE×198).

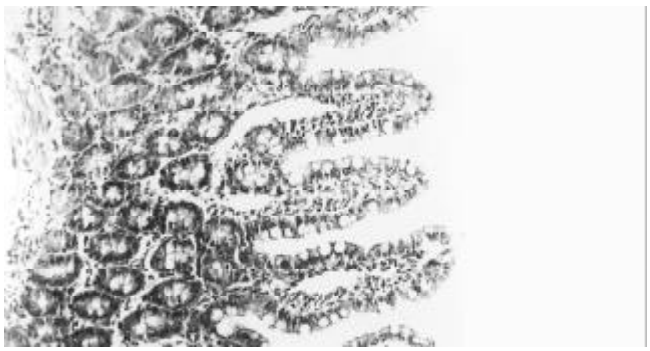

Figure 1B In intestinal mucosal damage much reduced (HE×198)

Figure 1C Normal appearance of intestinal mucosa (HE×198).

Effect of $GdCl_3$ on expression of TNF-α and IL-6 mRNA in Kupffer cells

$GdCl_3$ clearly resulted in sustained loss of phagocytic activity of KCs diminishing concentrations of TNF-α and IL-6 in bile and plasma. We found that $GdCl_3$ pretreatment decreased KCs cytokines transcripts after injection of LPS so that expression of TNF-α and IL-6 mRNA in group B were significantly less than those in group A (P<0.05). There were no expression of TNF-α and IL-6 genes in rats of group C (Figure 2).

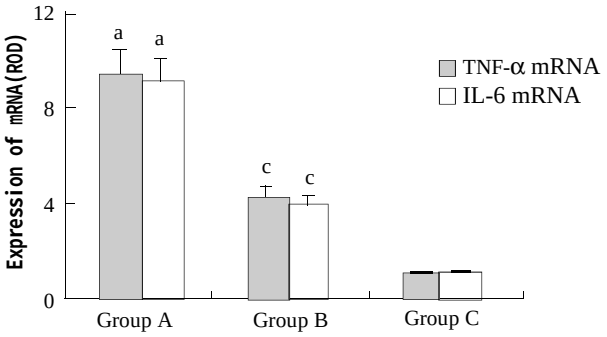

Figure 2 Expression of TNF-α and IL-6 mRNA. [a]P<0.05, *vs* other two groups, [c]P<0.05, *vs* group C.

Cytokines production in bile and plasma

TNF-α and IL-6 in the bile and plasma of above three groups were measured by bioassay (Table 1). In rats of group A, there were significant increase of TNF-α and IL-6 in bile and plasma, the concentration of the two cytokines in the bile were over 5-fold and 4-fold higher than those at in the plasma, respectively. In animals of group B, $GdCl_3$ given 24 h prior to LPS markedly reduced the levels of TNF-α and IL-6 in bile and plasma when compared to those in group A (P<0.05). Low levels of TNF-α and IL-6 were detectable in bile and plasma in rats of group C.

Table 1 Plasma and bile TNF-α and IL-6 levels of in rats ($\bar{x}\pm s$, n=7)

Group	TNF-α (ng.L^{-1})		IL-6 (ng.L^{-1})	
	Plasma	Bile	Plasma	Bile

DISCUSSION

The role of cytokines in the bile causing gastrointestinal damage during sepsis has received little attention to date, and the bile continues to be viewed upon as having a purely digestive function. Other investigators reported after the relief of obstructive jaundice by internal drainage, endotoxemia could be reversed. But, the ratio of villous height to crypt depth in the mucosa of the terminal ileum was deceased in the rats with external drainage. The absence of bile from the gut may promote bacterial translocation to visceral organs[10,18]. These findings implicate the use of bile to prevent intestinal mucosal damage and reduce postoperative complications of jaundiced patient with endotoxemia. In fact, a growing body of evidence points to the presence of inflammatory mediators and other factors in bile. These factors include cytokines IL-1, IL-6, TNF-α, and epidermal growth factor, complement components, and acute-phase proteins, which are released by KC and other macrophages[13,19-27]. Recently, Jackson *et al*[10] reported the involvement of bile in gastrointestinal tract damage in endotoxemia. External drainage of bile or bile duct occlusion markedly reduced the effects of LPS to the intestine and prolonged survival of the animals[£Û18£Ý]. These studies indicate that after treatment with LPS, the bile contains substances that are capable of mediating intestinal damage. Our results showed there were higher concentrations of TNF-α and IL-6 in rats with endotoxemia than those in the control rats, and there were 5-fold and 6-fold higher levels of TNF-α and IL-6 in bile than in plasma. The intestinal mucosal epithelia of these animals were severely damaged. These findings suggest the luminal cytokines derived from the bile, contribute to the intestinal damage during early endotoxemia.

Where do these cytokines in bile come from The precise molecular mechanism of the cytokines in bile is uncertain. There are several reasons to believe that cytokines in the bile originate from synthesis by KC in the bile rather than extracted from the circulating blood. First, The KC are the main site for the clearance of endotoxin, they constitute about 80-90 % of sessile macrophages of the RES. LPS is taken up by KC and leads to production of cytokines by these cells[12,15-16,19,21,28,29]. Second, the concentration of TNF-α and IL-6 in the bile was more markedly increased than those in the plasma. Finally, the levels of these cytokines were significantly reduced by treatment with $GdCl_3$ which preferentially inhibited the KC function, again supporting the concept of production of cytokines by the hepatic KC. A number of studies had been conducted to examine the role of KC function during endotoxemia and other circulatory conditions. Studies dealing with the blockade of KCs phagocytosis in lethal endotoxic shock models had shown increased animal survival that underwent $GdCl_3$ pretreatment[30-32]. Moreover, utilizing KC blockade by $GdCl_3$ revealed the mediators released by KC during sepsis played a significant role[33]. Although studies had shown that intestinal damage occured during sepsis, it remained unknown whether blockade of KC prior to the onset of endotoxemia could prevent the occurrence of intestinal damage. The present study was designed to determine whether the *in vivo* phagocytic blockade of KC by $GdCl_3$ prior to the onset of sepsis had any salutary effects on intestinal integrity and expression of proinflammatory cytokines such as TNF-α and IL-6, their genes and proteins. Our results indicated that expression of TNF-α and IL-6 mRNA significantly increased 4 h after the induction of LPS. However, rats that underwent $GdCl_3$ treatment prior to LPS demonstrated significantly reduced expression of the genes and proteins of these cytokines in bile and plasma. Thus, KC can play a crucial role in the

initiation and progression of intestinal damage following endotoxemia[34-38].

The role of cytokines in intestinal pathology has not been welle lucidated. But, cytokines in intestinal tract could promote bacterial association with the epithelium, or might act upon luminal microorganism to enhance their invasive characteristics[39-43]. There are evidences that TNF-α is able to affect directly the virulent properties of some organisms. For example, TNF-α enhances the invasion of cultured cells, promoted by cytokines. IL-1 has been shown to act as a growth factor for pathogenic *E.coli*. Fluid accumulation in the intestine of LPS-treated rats indicates presence of altered permeability. Furthermore, TNF-α can affect directly the permeability of epithelial barriers, and loosening of the tight junction so as to facilitate the early entry of bacteria into the mesenteric lymph nodes and other target organs. TNF-α can induce expression of adhesion molecules ICAM-1 and LFA-3 in human intestinal epithelial cell lines. It can also influence cytokines production and proliferation in intestinal cell lines[44-48]. These findings reveals the presence of specific receptors on such cells, the TNF-α receptors are predominantly located on the basolateral aspect of intestinal epithelial cells, as are receptors for IL-1. After LPS stimulation, macrophages release cytokines damaging the intestinal epithelial integrity, allowing luminal TNF-α nd IL-6 to gain assiss to their receptors on the basolateral aspect of the epithelial cells and increase epithelial permeability, finally cause the intestinal damage.

Abstract

AIM: To provide scientific evidence for prevention and controlling of blastocystosis, the infection of *Blastocystis homonis* and to study its clinical significance in Huainan City, Anhui Province, China.

METHODS: Blastocystis homonis in fresh stools taken from 100 infants, 100 pupils, 100 middle school students and 403 patients with diarrhea was smeared and detected with method of iodine staining and hematoxylin staining. After preliminary direct microscopy, the shape and size of Blastocystis homonis were observed with high power lens. The cellular immune function of the patients with blastocystosis was detected with biotin-streptavidin (BSA).

RESULTS: The positive rates of Blastocystis homonis in fresh stools taken from the infants, pupils, middle school students and the patients with diarrhea, were 1.0 % (1/100), 1.0 % (1/100), 0 % (0/100) and 5.96 % (24/403) respectively. Furthermore, the positive rates of Blastocystis homonis in the stool samples taken from the patients with mild diarrhea, intermediate diarrhea, severe diarrhea and obstinate diarrhea were 6.03 % (14/232), 2.25 % (2/89), 0 % (0/17) and 12.31 % (8/65) respectively. The positive rates of *Blastocystis homonis* in fresh stools of male and female patients with diarrhea were 7.52 % (17/226) and 3.95 % (7/177) respectively, and those of patients in urban and rural areas were 4.56 % (11/241) and 8.02 % (13/162) respectively. There was no significant difference between them ($P>0.05$). The positive rates of CD_3^+, CD_4^+, CD_8^+ in serum of Blastocystis homonis-positive and-negative individuals were 0.64 ± 0.06, 0.44 ± 0.06, 0.28 ± 0.04 and 0.60 ± 0.05, 0.40 ± 0.05 and 0.30 ± 0.05 respectively, and the ratio of CD_4^+/CD_8^+ of the two groups were 1.53 ± 0.34 and 1.27 ± 0.22. There was significant difference between the two groups ($P<0.05$, $P<0.01$).

CONCLUSION: The prevalence of *Blastocystis hominis* as an enteric pathogen in human seems not to be associated with gender and living environment, and that *Blastocystis hominis* is more common in stool samples of the patients with diarrhea, especially with chronic diarrhea or obstinate diarrhea. When patients with diarrhea infected by *Blastocystis hominis* , their cellular immune function decreases, which make it more difficult to be cured.

Wang KX, Li CP, Wang J, Cui YB. Epidemiological survey of Blastocystis hominis in Huainan City, Anhui Province, China. *World J Gastroenterl* 2002;8(5):928-932

INTRODUCTION

Blastocystis homonis (B.h) is increasingly recognized to be a cause of human enteric disease. Its presence has been reported in a wide variety of intestinal disorders resembling irritable bowel syndrome (IBS) such as bloating, flatulence, mild to moderate diarrhea, abdominal pain, and nausea[1-35].The geographic distribution of *Blastocystis homonis* appears to be global, with infections common in tropical, subtropical and developing countries[36-40]. In general, studies from developed countries report approximately a 1.5 % to 10 % overall prevalence of *Blastocystis homonis*[41-45]. However, few reports of the prevalence and the importance of the protozoan *Blastocystis homonis* as an intestinal pathogen in China have been found. In order to explore the epidemiological characteristics and clinical significance of blastocystosis in population of the city of Huainan, a prospective study was carried out from July to August in 2001.

MATERIALS AND METHODS

Population

The study was performed in the following groups of the population in Huainan: in a healthy population (n=300, normal group), including infants in day-care centers (n=100), pupils (n=100) and middle school students (n=100), and in outpatients with diarrhea (n=403, male 226 and female 177, aged from 6 to 52 years). In addition, we paid more attention to the patients with intractable diarrhea.

Methods

A questionnaire, administered by a nurse, was used to collect detailed information of each subject investigated. Information was collected by means of in-person, telephone and interview, including age, gender, history of present illness, anamnesis, symptomatology (i.e. fever, upper respiratory tract infection, nausea, diarrhea, abdominal cramps, bloating, steatorrhea), date of symptom onset, duration of symptoms, personal health habits, and living environmental condition and the date of stool sample collected.

Stool examination All individuals were asked to provide one stool sample in disposable stool boxes for analysis. Samples were sent to the Department of Etiology and Immunology, School of Medicine, Anhui University of Science & Technology in Huainan for *Blastocystis homonis*. Then the sample was smeared to semitransparent feces membrane on the surface of sheet slides. After these smears were left to dry naturally and fixed with methanol, iodine solution and hematoxylin staining were made, and examination under microscope was carried out. The shape and size of *Blastocystis homonis* were observed.

Detection of T lymphocyte subsets To investigate possible changes of cellular immune function in Blastocystis homonis-infected individuals, the level of CD_3^+, CD_4^+,CD_8^+ and CD_4^+/CD_8^+ in peripheral blood of Blastocystis homonis-positive individuals were tested with biotin-streptavidin (BSA) method. Firstly, peripheral venous blood of subjects was withdrawn, anticoagulated with heparin, and diluted with fluid free of Ca^{2+}, Mg^{2+}. Secondly, peripheral blood mononuclear cells were separated with lymphocytes separating medium, cleaned, and the number of cells was adjusted to (1-3)×10^9/L of which 10 μl was taken and smeared in an acid-proof varnish circle on the surface of the slides. When it dried naturally, McAb of anti-CD_3^+, anti-CD_4^+ and anti-CD_8^+ and sheep anti-guineapig IgG, SA- HRP were added into the circle. After development with DAB, the slides were observed under microscope. Only brown cytomembrane staining was regarded as positive, otherwise, as negative specimen. A total of 200 cells were counted, and the positive percentage of cells were analyzed respectively.

Statistical analysis

The positive rates were expressed as percentage, and the statistical analysis was carried out by using χ^2 and *t*-test. A probability value of less than 0.05 was considered statistically significant.

RESULTS

Stool examination

Of the 703 stool samples examined, 3.70 % (26/703) were found to be positive for *Blastocystis hominis*. Furthermore, the positive rate of *Blastocystis hominis* in 300 stools of healthy people was 0.67 % (2/300); and those of infants, pupils and middle school students were 1.00 % (1/100), 0 (0/100) and 1.00 % (1/100) respectively. In addition, The positive rates of *Blastocystis hominis* in the stools taken from the outpatients with mild diarrhea, intermediate diarrhea, severe diarrhea and obstinate diarrhea were 6.03 % (14/232), 2.25 % (2/89), 0 % (0/17) and 12.31 % (8/65) respectively. There was significant difference in the positive rates between each type of patients (P<0.05). The detailed results are showed in Table 1.

Table 1 The detective results of *B.h* in fresh feces (*n*, %)

Group	*n*	*B.h* positive	
		n	rate
[b]Normal	300	2	0.67
Infants	100	1	1.00
Pupils	100	1	1.00
Middle school students	100	0	0.00
[b]Diarrheic outpatients	403	24	5.96
[a]Mild	232	14	6.03
[a]Intermediate	89	2	2.25
[a]Severe	17	0	0.00
[a]Obstinate	65	8	12.31

Relationship between gender and infection of Blastocystis hominis

Of the 403 outpatients, the positive rates of Blastocystis hominis in male and female patients were 7.52 % (17/ 226) and 3.95 % (7/177) respectively. Statistics found no significant difference in positive rate between male and female.

Relationship between living place and infection of Blastocystis hominis

The positive rates of *Blastocystis hominis* in stools taken from patients with diarrhea living in urban and in rural areas were 7.52 % (17/226) and 3.95 % (7/177) respectively. There was no significant difference between the two groups (P>0.05).

Relationship between types of diarrhea and infection of Blastocystis hominis

The positive rate of *Blastocystis hominis* in stools of healthy people was 0.67 % (2/300), while that of diarrheic patients was 5.96 % (24/403). Among the patients with diarrhea, the positive rates of *Blastocystis hominis* in loose stools ,watery stools and mucopurulent bloody stools were 3.70 % (21/305), 4.23 % (3/81) and 0 % (0/17) respectively. There was no significant difference between each type of patients (P>0.05). Results are showed in Table 2.

Table 2 Relationship between types of diarrhea and infection of B.h (*n*, %)

Group	*n*	*B.h* positive

DISCUSSION

Results from this study showed that *Blastocystis hominis* as an intestinal pathogen in humans was found in Huainan area by stool examination, and the prevalence was not related to gender

and living circumstances, and that statistically significant association was observed between the presence of diarrhea and infection with *Blastocystis hominis*.

In this study, *Blastocystis hominis* was found in 26 (3.70 %) of the 703 stool specimens examined. The positive rates of male was similar to that of female, and there is no significant difference in the positive rates between the diarrhea patients living in urban areas and those in rural areas (P>0.05), which showed the prevalence of the organism was not related to gender and living environment of the individuals examined.

The results of this study supported the idea that *Blastocystis hominis* was associated with diarrhea. The positive rates of *Blastocystis hominis* in stools of the healthy people was 0.67 % (2/300), while that of the diarrheic patients was 5.96 % (24/403), and the difference between them was significant (P<0.05). To be exact, the positive rates of *Blastocystis hominis* was high in stools of the patients with mild diarrhea, intermediate diarrhea and obstinate diarrhea, but there was no *Blastocystis hominis* found in stools of patients with severe diarrhea. In accordance with other reports[46-49], vacuolar *Blastocystis hominis* were found in stools of patients with diarrhea with iodine solution and hematoxylin staining. This finding suggested that vacuolar *Blastocystis hominis* might be the main type of *Blastocystis hominis* causing diarrhea. Although the reasons why the organism had been found in both symptomatic and asymptomatic individuals have been largely unknown[50-56], one possibility was that it was due to infection time, infection dose, poly-infection with bacteria and the ability of host immunity that might decide whether the symptom turned up or not, because only over 24 h could the cysts of *Blastocystis hominis* develop into a large number of vacuolar forms[57-58].

In addition, this experiment demonstrated that the hematoxylin staining offered a very convenient and easy method to differentiate the various stages of *Blastocystis hominis*. As a matter of fact, there is high affinity between hematoxylin and *Blastocystis hominis*. By hematoxylin staining, the walls, nucleus, chromatoid bodies and other structures of *Blastocystis hominis* can be observed clearly, and vacuolar, granular, metamorphotic *Blastocystis hominis* can be easily differentiated from small amebae which do not cause any disease[59-61].

Our study provided evidence for the changes of cellular immune function in *Blastocystis hominis*-infected individuals. In this paper, the level of CD_3^+,CD_4^+,and CD_4^+/CD_8^+ decreased in *Blastocystis hominis*-infected individuals , but that of CD_8^+ was normal. Compared with the *Blastocystis hominis* negative group, the difference was significant (P<0.05).Recent advances in *Blastocystis hominis* found that in subjects suffering from immunodepression *Blastocystis hominis* showed a significant association with gastrointestinal symptoms[62-71]. All of these showed that the infection of *Blastocystis hominis* was related to the hosts' cellular immune function.

The level of CD_4^+/CD_8^+ is key to immunoregulation. When decreased, it suggested that T helper lymphocytes took part in the course of diarrhea caused by *Blastocystis hominis*. Indeed, both the ability of humoral immunity and that of cellular immunity decreased in the patients with low level of CD_4^+/CD_8^+, which made it difficult to cure diarrhea[72-75]. Because of low ability of immunological kill mediated by CD_8^+ cell, the cellular immunity of human bodies played an important role in the course of diarrhea.

In conclusion, Blastocystis hominis should be kept in mind of parasitologists and physicians when dealing with patients with diarrhea. Blastocystis hominis has long been described as a non-pathogenic protozoan parasite until recently, when claims have been made that it can result in pathogenic conditions[76-78]. Many labs do not know that it is now considered harmful to human bodies, or do not know how to test for it. Moreover, because of absence of specific symptoms, the disease was easily confused with other intestinal diseases and was easily misdiagnosed. The authors suggested that stool examination should be carried out on patients with diarrhea in order to decide whether or not the patients were infected by *Blastocystis hominis*, and the stool samples should be collected more than once from patients showing clinical signs and symptoms.

ACKNOWLEDGEMENTS

We thank Associate Professors Zhu Yu-Xia, Xu Li-Fa, Tang Xiao-Long, Cai Ru, Qian Zhong-Qing, Yang Qing-Gui, He Ji, Zhang Xiu-Yun, Zhou Hui-Sheng, Lu Jun (Department of Etiology and Immunology, School of Medicine, Anhui University of Science & Technology) and some students of our college for their help in sample collection and experimental studies.

Abstract

AIM: To study the feature of pancreatic microcirculatory impairment, especially the initial changes, in caerulein-induced experimental acute pancreatitis (AP).

METHODS: The pancreatic microcirculation of caerulein-induced AP model was studied by intravital fluorescence microscopy with FITC-labeled erythrocytes (FITC-RBC), scanning electron microscopy of vascular corrosion casts, and light microscopy of Chinese ink-injected/cleared tissues.

RESULTS: Animals in caerulein-treated group showed hyperamylemia (×2), pancreatic oedema, infiltration of inflammatory cells in pancreas. Constrictions of intralobular arteriolar sphincters, presence of vacuoles in all layers of sphincter, and gross irregularity in capillary network of acini were found in the AP specimens. The decrease of pancreatic capillary blood flow (0.34 ± 0.10 nl·min^{-1} *vs* 0.91 ± 0.06 nl·min^{-1} of control, $P<0.001$), reduction of functional capillary density(277 ± 13 cm^{-1} *vs* 349 ± 8 cm^{-1} of control, $P<0.001$), and irregular intermittent perfusion were observed in caerulein-induced groups.

CONCLUSION: Impairment and constriction of pancreatic intralobular arteriolar sphincter are the initial microcirculatory lesions in the early phase of acute pancreatitis, and play a key role in the pancreatic ischaemia and pancreatic microvascular failure in acute pancreatitis.

Zhou ZG, Chen YD, Sun W, Chen Z. Pancreatic microcirculatory impairment in experimental acute pancreatitis in rats. *World J Gastroenterol* 2002; 8(5):933-936

INTRODUCTION

Etiopathology of acute pancreatitis (AP) is not fully understood[1-19]. Microcirculatory impairment has long been recognized as one of the etiological factors of acute pancreatitis[20]. Pancreatic microcirculatory disturbance may act as initiating factor or aggravating/continuing factor. However, the mechanism of microcirculatory impairment in acute pancreatitis is complex; there are questions concerning local pancreatic microcirculatory change in acute pancreatitis and the features of pancreatic microcirculatory disturbance in various stages of AP remain subject to further study[21-28]. To investigate the feature of the pancreatic microcirculatory impairment in the early-stage of caerulein-induced experimental acute pancreatitis, dynamic method of microcirculatory research combined with static method had been carried out in this study.

MATERIALS AND METHODS

Animals

48 adult male Wistar rats, weighing 250-350 g, were randomly assigned to 4 groups: (1) control group (group 1, *n*=12). (2) intravital study group, panceatic microcirculation observed with FITC-labeled RBC and intravital fluorescence microscope (group 2, *n*=12). (3) light microscopy and scanning electron microscopy study group, pancreatic microvasculature perfused with ink and methylmethacrylate (group 3, *n*=12). (4) histocellular study group (group 4, *n*=12).

Experimental pancreatitis

Caerulein used to induce acute pancreatitis was obtained from Sigma Co.. All experimental groups were injected caerulein subcutaneously 5.5 and 7.5 μg·kg^{-1} 1 and 2 h after the beginning of experiment respectively, while control group was injected physiological saline solution subcutaneously. All groups were observed 4 after the beginning of the experiment.

Erythocytes labeling

Erythocytes were labeled by fluorescein isothiocyanate (FITC, purchased from Sigma Co.) using a combined approach of the procedures of Klar (1995). The labeled cells were stored a maximum of 24h before use.

In vivo microscopy

The pancreas of the studied animal was exteriorized on a stage, then FITC-labeled RBC was intravenously injected and intravital fluorescence microscope (Olympus X-70) were used to dynamically observe the pancreatic microcirculatory indices, and the images were simultaneously picked up by high-resolution video cassette recorder.

Morphology of microvasculature

Thoracic aortas of the studied animal were cannulated for perfusion. After flushing the vessels with warmed heparinized physiological saline solution, a diluted resin mixture or China ink was injected through the cannula with an injection pressure of 12-16kPa, until the portal vein and inferior vena cava was filled with the injected resin or ink.

The pancreas of resin-injected animal was corroded overnight or longer in a hot 300-400 g·L^{-1} KOH solution, washed in running water and rinsed again several times in distilled

water, air-dried, coated with gold in a vacuum evaporator, and observed in a scanning electron miscroscope.

The pancreas of ink-injected animal was fixed overnight or longer in Bouins solution, cleared in trichloromethane, embedded in paraffin, serially sectioned (thin sections of 5-7 μm for observation of the relationship between capillaries and cells, thick sections of 50-100 μm for observation of the vessel continuation), and observed with an Olympus X-60/50 light microscope. Serial reconstruction was carried out, camera lucida tracings of photographs were made at x330 final magnification on transparent sheets and superimposed for analysis.

Assays

Serum amylase level was determined and adopted as an indicator of AP. The increase in water content of pancreatic tissue served to indicate the formation and severity of pancreatic edema. The wet weight/dry weight ratio was expressed in per cent. Pancreatic tissue blocks of all groups were routinely paraffin wax-embedded, sliced, stained with hematoxylin/eosin and toluidine blue/basic fuchsin, then the sections were microscopically studied.

Statistical analysis

The results were expressed in mean ± standard deviation, and *t*-test was used to evaluate differences between control and AP groups. Difference was considered significant at the $P<0.05$ level.

RESULTS

Pancreatic edema

Gross appearance of pancreatic tissue of control group remained normal, and presented 72 % of water content. In comparison, pancreatic edema gradually appeared in Group2, 3 and 4 four hours after subcutaneous injection of caerulein, in parallel with an increase in pancreatic tissue volume. Edema of pancreatic head and body was much prominent, and the water content increased to 75 %. Inflammatory exudate accumulated in the anterior pararenal space and lesser omental sac in 50 % cases.

Morphology

Injury of intralobular arteriolar sphincter became visible 4 h after animal model established, and numerous cytoplasmic vacuoles formed; massive interstitial edema and inflammatory cell infiltration gradually emerged at 6 h. While in control group, pancreatic acini, tubules and blood vessels were normal microscopically.

Serum amylase

Serum amylase measurement in control group presented normal level (20.8 $\mu kat \cdot L^{-1}$). Serum amylase in all AP groups showed hyperamylasemia (45.0 $\mu kat \cdot L^{-1}$), significant higher than that of control group ($P<0.01$).

Light microscopy and scanning electron microscopy

Animals in the caerulein-treated group showed constriction of intralobular arteriolar sphincter 4 h after beginning of the experiment, presence of vacuoles in all the layers of sphincter, gross irregularity in capillary network of acini, reduction of capillary density, and blebs protruded from the surface of casts reflecting a substantial increase in capillary permeability.

In vivo fluorescence microscopy

Comparing with the control group, 4 hours after the start of experiment in AP groups the pancreatic microcirculatory in the caerulein-treated group showed the reduction of the velocity of FITC-labeled RBC, decrease of pancreatic capillary blood flow ($P<0.01$, Table 1), reduction of functional capillary density and arterioles diameter ($P<0.05$), and irregular intermittent perfusion of capillary network ($P<0.05$). Arterioles of pancreatic lobules and capillary density experienced significant changes at 6 h. The calibers of venules and capillaries showed no marked change in 6 h, while there was significant change by 8 h ($P<0.05$, Table 2).

DISCUSSION

In 1862 Panum demonstrated that acute hemorrhagic pancreatitis could be induced with wax droplets injected into pancreatic arteries. From then on, the etiological role which pancreatic ischaemia and tissue hypoperfusion plays in AP has been extensively discussed[29]. Many researches suggested that local microcirculatory disturbance, not insufficient blood flow in peripheral circulation, was responsible for perfusion failure of pancreatic tissue. In recent years, various animal models such as hemorrhagic shock, embolization of pancreatic microvasculature by minute particles and ligation of pancreatic arteries, have been used to verify that microcirculatory impairment of pancreas is the initial stage of AP. But the following questions haven't been answered conclusively: whether all types of AP are initiated by pancreatic microcirculatory impairment? What are the characteristics of early-stage pancreatic microcirculatory change? And what are the features of pancreatic microcirculatory disturbance in the natural process of AP? Insights into all these areas are crucial to the development of prevention and treatment measures.

Animal model

Sodium taurocholate-induced experimental pancreatitis was used by many authors to investigate microcirculatory change of AP; this model can reflect soundly the pathological features of acute necrotizing pancreatitis. Since direct injury to pancreatic ductules, acini and blood vessels may happen in several minutes, the gradual evolution of early-stage pathological change of pancreas in AP cannot be explored. In addition, modulation of intraductal pressure in the process of retrograde pancreatobiliary injection of sodium taurocholate also poses a real challenge. In this study, caerulein-induced experimental pancreatitis was chosen to investigate the features of early-stage pancreatic microcirculatory change. Subcutaneous administration of caerulein is easy to operate, and can result in acute edematous pancreatitis similar to that induced by intravenous injection of caerulein. In this model, the pathological changes develop slowly and gradually, the microcirculatory and histological changes of pancreas become prominent 4 h after the beginning of experiment, and pancreatic edema reaches its zenith by 8 h. This gradual development course allows us to study the triggering factor and the features of early-stage pancreatic microcirculatory impairment without haste.

Study techniques

For decades, pancreatic microcirculatory study heavily depended on the following techniques: injection of minute particles, Indian ink and methylthionine chloride into pancreatic arteries; measurement of pancreatic blood flow through pancreatoduodenal arteries and veins; measurements of relative blood flow and tissue perfusion of pancreas with intravenous injection of nuclide Rb-86, etc. Since acute necrotizing pancreatitis is characterized with progressive regional or focal necrosis of pancreatic tissue, observation with a single method has the following disadvantages: (1) dynamic and direct observation of local microcirculatory change of pancreas is impossible, since the animal must be sacrificed at a specific time; (2) observation of local blood flow of pancreas and tissue perfusion cannot be made simultaneously on the same specimen; (3) as to traditional intravital observation of pancreatic microcirculation, quantitative study cannot be effective due to dim image. This experiment has solved the above problems by developing a new approach; this approach combined intravital microcirculation observation technique, using selective blood element fluorescent marker, with another technique-maintaining dynamic and tissue message on static specimen.

Pancreatic microcirculatory impairment in AP

In recent years, applied basic researches on the morphology of pancreatic microcirculation revealed that the blood supply of pancreatic lobule, in most cases, is provided by a single intralobular arteriole. This arteriole sends forth tree-like branches when entering pancreatic lobule; it has no anastomosis with adjacent intralobular arterioles and their branches, and can be considered end-artery[30]. This characteristic suggested that pancreatic lobules are susceptible to ischaemic injury due to spasm of intralobular arterioles, embolization of arterioles by emboli, formation of microthrombi or compression by interstitial edema. However, causative factors of early-stage ischaemia and the precise triggering factor of local microcirculatory disturbance are not evident.

This study showed that, manifested as lasting spasm of arteriolar sphincter and multiple cytoplasmic vacuoles within smooth muscle cells of sphincter, the main feature of early-stage pancreatic microcirculatory impairment of AP is injury of sphincter of pancreatic intralobular arteriole. This experiment also demonstrated that among many factors causing early-stage ischaemia, the key one is injury and spasm of sphincter of pancreatic intralobular arteriole. In this study, injury of arteriolar sphincter occurred earlier than microcirculatory impairment, which reflected that injury of intralobular arteriolar sphincter was the initial stage of pancreatic perfusion failure and local microcirculatory disturbance. Microcirculatory hypoperfusion happened almost simultaneously with injury and spasm of arteriolar sphincter, indicating that pancreatic tissue is highly sensitive to ischaemic stress and has no compensatory reserve. Since sphincter of pancreatic intralobular arteriole serves as main lockgate to control blood flow to pancreatic lobule, and intralobular arteriole has characteristics of end-artery, even sphincter spasm of very short time will quickly evoke obvious pancreatic microcirculatory impairment. Other factors causing ischaemia[31-37], such as compression from interstitial edema, microemboli or obstruction due to thombosis, tend to be secondary ones, which may happen gradually in the course of pathological change of AP. These traumatic factors help to sustain and aggravate pancreatic microcirculatory impairment. To clarify relationship between traumatic factors of pancreatic microcirculatory impairment and pathological evolution of AP has guiding value in making treatment plans for clinical AP cases of various development stages. Features of early-stage microcirculatory change of experimental pancreatitis suggested that early adoption of spasm relieving and counter-injury measures are of vital importance in prevention and treatment of local microcirculatory disturbance of AP.

Abstract

AIM: To summarize systematically our ten-year experience in non-surgical treatment of postoperative bile leakage, and explore its methods and indications.

METHODS: The clinical data of 57 patients with postoperative bile leakage treated non-surgically from January 1991 to December 2000 were reviewed retrospectively.

RESULTS: The site of the leakage was mainly the disrupted or damaged fistulous tracts of T tube in 25 patients (43.9 %), the fossae of gallbladder in 14 cases (24.6 %) , the cut surface of liver in 7 cases(12.3 %), and it was undetectable in the other 2 cases. Besides bile leakage, the wrong ligation of bile ducts was found in 3 patients, residual stones of the distal bile duct in 5 patients, benign papillary strictures in 3, and biloma resulting from bile collections in 2. The diagnoses were made according to the history of surgery, clinical situation, abdominal paracentesis, ultrasonography, ERCP, PTC, MRI/MRCP, gastroscopy and percutaneous fistulography. All 57 patients were treated non-surgically at the beginning of bile leakage. The non-surgical methods included keeping original drainage unobstructed, percutaneous abdominal paracentesis or drainage, percutaneous transhepatic cholangial/biliary drainage (PTCD/PTBD),endoscopic management, traditional Chinese medicine and so on. Of the 57 patients,2 patients died,5 were converted to reoperation later, the other 50 were directly cured by non-surgical methods without any complication. The cure rate of the non-surgery was 82.5 %(50/57).

CONCLUSION: Many nonoperative methods are available to treat postoperative bile leakage. Non-surgical treatment may serve as the first choice for the treatment of bile leakage for its advantages in higher cure rate, convenience and safety in practice. It is important to choose the specific non-surgical method according to the volume, site of bile leakage and patient's condition.

INTRODUCTION

Bile leakage is one of the most common and serious complications after hepatobiliary surgery. In recent years, the treatment strategy of bile leakage has generated fundamental changes due to the excellent effect of non-surgical therapy and its minimally invasive intervention[1-6]. Non-surgical treatment has been regarded as the first choice in the management of postoperative bile leakage in many cases. Only when there is no essential condition or no effect by non-surgery, will operation be considered[1,2]. Although there are many nonoperative approaches that could be used to cure bile leakage, most literatures only reported one of these methods[7-53], being deficient in systematization and comprehensiveness. Thus, surgeons could not often apply them synthetically and reasonably. Over the past decade from 1991 to 2000, we treated 57 patients with postoperative bile leakage non-surgically in our two hospitals. In this article, we summarized the methods and indications of the non-surgical treatment for postoperative bile leakage.

MATERIALS AND METHODS

Patients

From January 1991 to December 2000, a total of 57 patients with postoperative bile leakage, including 23 males and 34 females, were treated non-surgically in the Department of Surgery of the Second Affiliated Hospital, Medical School of Zhejiang University and the Affiliated Yijishan Hospital of Wannan Medical College. The mean age of the patients was 46 years, with a range from 25 to 73 years. All of them belonged to postoperative bile leakage. The original operations were performed with simple open cholecystectomy (OC) in 21 cases, OC plus choledochotomy with T tube drainage in 25, simple hepatectomy in 7, hepatectomy plus Roux-en-Y cholangiojejunostomy in 3, and repair of bile duct injury plus choledochoduodenostomy in 1, respectively. The clinical presentations were diverse. Most patients were presented with sudden or gradual abdominal pain after operation, and T tube removal/ slippage or U tube exchange. Almost half of the cases had much bile-like liquid outflowing from the original drainage tubes or the fistulous tracts of T tube. Twelve patients had light to moderate fever, four hyperpyrexia, six jaundice, and two had nausea and vomiting.

Diagnosis

The diagnoses were made according to the operational history, clinical situation, abdominal paracentesis (21 person times), ultrasonography (17), ERCP (8), PTC (5), MRI/MRCP (3), gastroscopy (3), and percutaneous fistulography (2). The site of the leakage was the cystic duct in 3 cases, the fossae of gallbladder in 14 (Figure 1), the disrupted or damaged fistulous tracts of T tube in 25 (Figures 2 and 3), the damaged bile duct in 3 (Figures 4 and 5), the cut surface of liver in 7 (Figure 6) , the stomas of bilioenteric anastomosis in 3 and it was

undetectable in the other 2 cases. Besides bile leakage, the wrong ligation of bile ducts beyond the leakages was also found in 3 patients with common bile duct injury. Of the 25 patients with bile leakage following T tube removal, residual stones of the distal bile duct were also found in 5 cases (Figures 3 and 7) and benign papillary strictures were detected in 3 (Figure 5). Bile collections in 2 patients developed biloma, which oppressed pylorus, resulting in pyloric obstruction. Bile collections at two different sites, including hepatorenal recess and hepatogastric interspace with only a slender and bent tract (diameter <0.5 cm) between them, were confirmed in one patient undergoing hepatectomy, whose original subphrenic drainage was removed owing to occlusion before the bile leakage was found. Although the drainage on the anterior abdominal wall was still retained, it only drained bile from hepatogastric interspace.

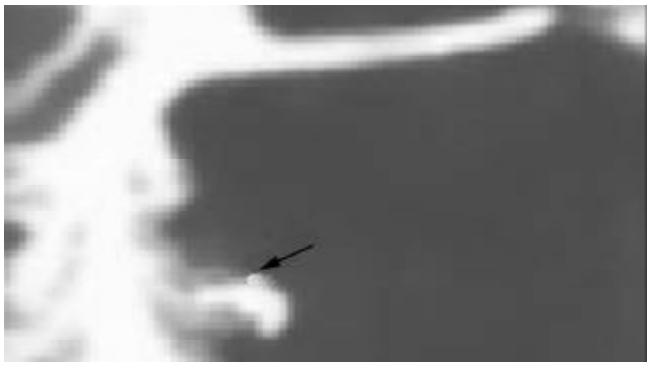

Figure 1 ERCP showed a bile leak from the fossae of gallbladder (↑).

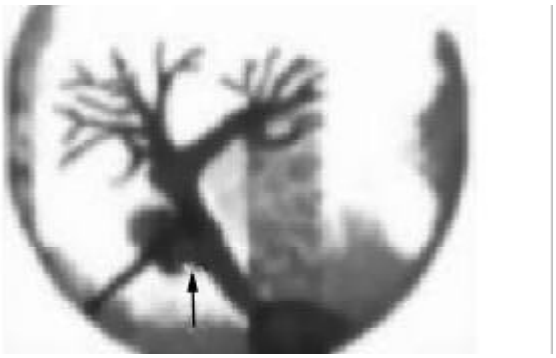

Figure 2 Cholangiography through T tube showed a leak from common bile duct (↑).

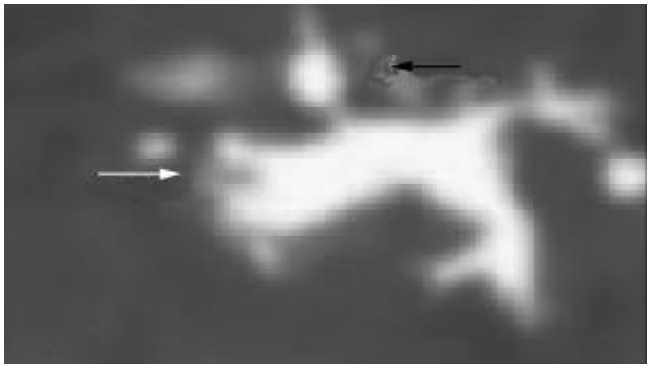

Figure 3 ERCP showed a leak from the fistulous tract of T tube (↑) and stones at distal duct (⇪).

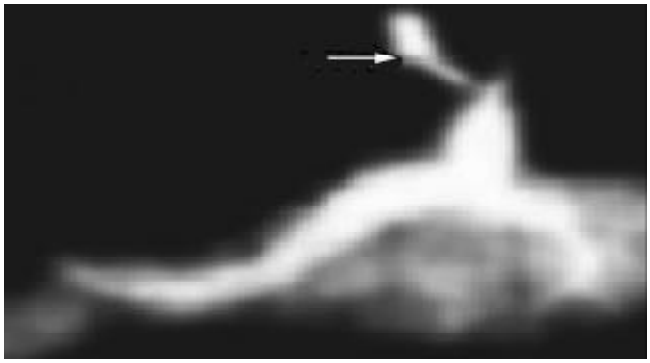

Figure 4 ERCP showed a leak from right hepatic duct (⇪).

Figure 5 MRCP showed stricture at distal duct (↑) and liquid collection in the right subhepatic region (⇪).

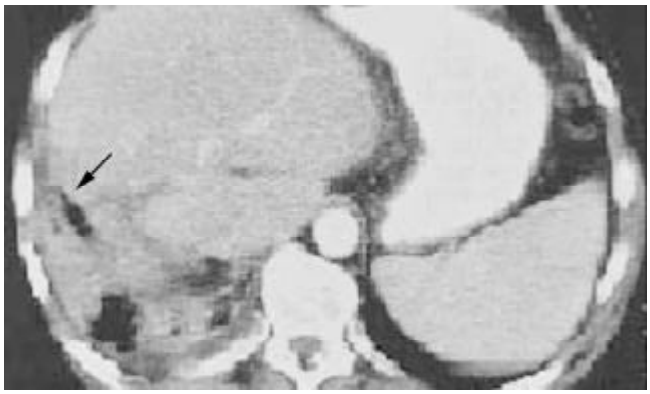

Figure 6 CT showed bile accumulating in the cut surface of right liver (↑).

Figure 7 The distal duct stones was removed with choledochoscope (⇪).

Management

When patients revealed the symptoms of bile leakage or biliary peritonitis,some essential disposal measures were immediately used such as right lateral decubitus position, semi-reclining position, gastrointestinal decompression, complementing water-electrolyte, antibiotic and appropriate nutritional support[1,2]. After that, specific non-surgical methods were chosen according to the volume, site of bile leakage and patient's condition. The original drainage in 19 patients undergoing OC or hepatectomy were kept unobstructed because they still produced some effect of drainage. The cannulae were changed in 5 cases of OC or hepatectomy due to their occlusion. In addition, washing with antibiotic was performed through the cannulae. In all the 25 patients with bile leakage following T tube removal or slippage, a new drainage was once again placed into the fistulous tract of T tube. Repeated abdominal cavity suction and drainage with a percutaneous catheter were performed by percutaneous abdominal paracentesis in 3 of 25 patients while percutaneous transhepatic cholangial drainage (PTCD) or percutaneous transhepatic biliary drainage (PTBD) were performed in 2 patients whose intrahepatic bile ducts were dilated. The residual ductal stones in 5 patients were eliminated by choledochoscope (Figure 7), endoscopic sphincterotomy (EST) and the traditional Chinese medicine, respectively. The traditional Chinese medicines included bitter orange, costusroot, mongolian milkvetch, rhubarb, christina loosestrife herb, etc. In order to maintain the pressure of bile duct and facilitate stones passage, it was necessary to obstruct the T tube at intervals when the Chinese medicines were administered. The bile duct stricture in 3 cases was relieved by choledochoscope and EST, respectively. Percutaneous catheter drainages guided by ultrasound were used in one patient with biloma and 3 patients with common bile leakage. As to the patient with subhepatic fluid accumulations at two different sites detected by ultrasonography, MRI and percutaneous fistulography, it was inappropriate to reoperate on him or her due to the postoperative weak health, and it was very dangerous to apply abdominal paracentesis because the hepatorenal recess was just near the right thoracic cavity. A new drain tube was first placed into hepatogastric interspace and afterwards into the bent tract and hepatorenal recess through the fistulous tract on the anterior abdominal wall. The whole process was guided by gastroscope and X-ray. Flushing with antibiotic was performed everyday.

RESULTS

In the early stage of our study, one patient with stoma leakage died of infectious shock, and one with post-hepatectomy bile leakage died of multiple organ failure (MOF). After 1996, no patient died of bile leakage. Five patients were converted to operation due to ineffective non-surgical management, presentation of jaundice or concomitant wrong ligation of bile duct. All the 5 patients were cured by late reoperation. Of the 5 cases, one with biloma belonged to the early stage of our study. Owing to the absence of experience in the non-surgical treatment at that time (1993), he only received some essential disposals except percutaneous catheter drainage at the beginning of bile leakage. He underwent exploratory laparotomy plus drainage a week later because nausea and vomiting were not relieved. Two patients with bile leakage from cystic duct stump underwent exploratory laparotomy plus re-ligation of cystic duct after 2-3 days drainage. The other two patients all underwent hepatojejunostomy 2-3 months later due to concomitant wrong ligation of bile duct. The other 50 patients were directly cured by non-surgical treatment without correlated complications. The mean closure time of bile leakage was 9 days, with a range from 5 days to 3 months. The cure rate of non-surgical treatment was 82.5 % (50/57).

DISCUSSION

When bile leakage occurs, it is necessary to adopt some essential disposals such as gastrointestinal decompression, fluid replacement, antibiotic therapy, etc. However, it is important to choose operation or nonoperation according to the volume of bile leakage and patient' s condition. In recent years, the treatment strategy of bile leakage has generated fundamental changes due to the invention or finding of some new non-surgical methods, which have further improved the therapeutic effect of bile leakage with minimal invasive intervention or no trauma. Non-surgical treatment has been regarded as the first choice in the management of postoperative bile leakage in many cases, and it is acceptable by such patients. Only when there is no essential condition for non-surgery, or no effect, will operation be considered[1-6].

Non-surgical methods

In our study, the 57 patients with postoperative bile leakage were all managed by non-surgical treatment at the beginning of bile leakage. Fifty patients were cured except that two died and five were converted to reoperation later. The cure rate of non-surgical treatment was 82.5 % (50/57). The total therapeutic efficacy is satisfactory. Based on our data, the following non-surgical methods could be used in the treatment of bile leakage.(1)Keep the original drain tube unobstructed or chang it[1,2,5]. The original drainage should be maintained when it still drains some bile, and should be changed for a new drain tube when obstructed. In addition, we think it is equally of importance to wash with antibiotic through the cannulae[9], because it could increase the local concentration of antibiotic and improve anti-infection effect. It was difficult for the bile leakage to heal in patients of older age, malnutrition, complicated diabetes and using hormone. Besides drainage, some related therapy should be continued in these cases, the hormone should be cancelled, and the time of drainage be properly prolonged. (2) Insert a new catheter through the fistulous tract of T tube[1,5,16,17]. It is necessary to place a new catheter immediately through the fistulous tract of T tube if the bile leakage occurs after a T tube removal or slippage.The procedure should be performed as early as possible to prevent the occlusion of fistulous tract. Suction with negative pressure could be additionally used when necessary[1,16,18]. (3) Percutaneous abdominal paracentesis[1,5,6,8,10-13]**.** As an important nonoperative method, abdominal paracentesis can be applied because it does not need special device except an injection syringe. If the site of leakage was deep or near important organs, abdominal paracentesis should be guided by ultrasound. It is helpful to not only the diagnosis of bile leakage but also the abdominal cavity suctions or percutaneous catheter drainage. In this group, abdominal paracentesis was performed in five patients (4 with bile leakage after T tube removal and 1 with post-cholecystectomy biloma). Among them, the biloma was punctured under the guidance of ultrasound[1]. All 5 were cured. (4) PTCD/PTBD or placement of a percutaneous transhepatic stent[1,14,15]. Owing to some dangers(including hemorrhage, new bile leakage and so on),it should be generally performed under the guidance of ultrasound in patients with intrahepatic cholangiectasis[54]. PTCD is helpful to the healing of bile leakage because it may reduce the volume of leakage. In our

study, PTCDs were used in 2 cases because both abdominal drainages were insufficient. Two weeks later, both patients were cured. (5) Endoscopic management[1,6,8,24-53].As a new progression in the nonoperative treatment of bile leakage, endoscopic management generally means EST, endoscopic nasobiliary tube drainage (ENBD) and endoscopic biliary stent (EBS)[32,33,55], which are all finished by duodenoscope. It is mainly applied to the patients with bile duct stone, stricture or biloma[32,33,55]. These endoscopic methods could effectively remove the residual ductal stones, relieve the stricture of bile duct and facilitate the healing of leakage. However, endoscopes include choledochoscope and gastroscope besides duodenoscope. Because choledochoscope may not only gets rid of the residual stones but also dilate the narrow bile duct, it should also play an important role in the nonoperative treatment of bile leakage, and should not be neglected. In our study, choledochoscopic treatments were given to 4 patients (2 with residual stones, 2 with bile duct stenosis). All were cured. Gastroscope may occasionally be used in the nonoperative treatment of bile leakage. In this group, the new drain tube in the patient with bile accumulations at two different sites was placed under the guidance of gastroscope and X-ray. The leakage closed 3 months later. Thus, we should not confine our sights to the duodenoscope when using endoscopic treatment. Besides duodenoscope, gastroscope and choledochoscope may also be applied.(6)Traditional Chinese medicines[1]**.** It is mainly applied to the patients with bile duct stone. Some Chinese medicines may faciliate the passage of residual stones, resulting in accelerated healing of leakage. In this group, after Chinese medicines were administered to 2 patients for 5-7 days, the residual stones were all precluded that was confirmed by ultrasound and contrast examination. Both leakages closed within 2 weeks. In addition, there are some other non-surgical methods including laparoscopy[19-22], ethanol ablation[23] and so on.

Indications

Non-surgical treatment therapy plays an important role in the management of bile leakage due to its many advantages. First, the cure rate is high[33,39]. Binmoeller *et al*[33] reported that the total cure rate of endoscopic management was 86 % .In Fuji's study, all 8 postoperative bile leakages were cured by endoscopic treatment[39]**.** In our study, 57 patients were treated with various non-surgical methods, 50 were directly cured, the rate being 82.5 %. Next, non-surgical treatment is convenient, safe[1,10,40,41], atraumatic or micro-traumatic[43]. If only it is properly used, reoperation could be avoided in most patients with postoperative bile leakage, and the pain and costs of patients could be reduced. Thus, it is acceptable by patients, and fits the general trend and direction of modern surgery. The non-surgical therapy is especially suitable for the elderly patients who are physically weak, poor in common state, complicated by other serious diseases, unbearable or unwilling to accept reoperation in a short time. In this group, more than half of the patients belonged to such cases. Owing to correct choice of treatment, they not only avoided reoperation, but also safely passed the dangerous period. As for the patients who need surgery but could not be operated on at the early stage of bile leakage due to their conditions, non-surgical treatment can not only serves as interim measure before operation but also wins precious time for preoperative preparation. It was quite obvious that such condition was present in the 5 patients who were converted to late reoperation. When the patients with bile leakage were treated non-surgically, its indications should be strictly controlled. Based on our data, we think that nonoperative therapy could be first attempted in the following cases[1]. (1) Patients with early bile leakage[2](within 4-6 hours),relatively minor leakage, rather light or local peritonitis and no infectious shock or following shock by estimation; (2) Postoperative early patients who are poor in general state, complicated with other serious diseases, unbearable or unwilling to accept reoperation in a short time; (3) Patients whose original subhepatic drainages were still reserved and unobstructed; (4) Patients who suffer from bile leakages after T tubes removal or slippage and can be implanted with new drain tubes through the fistulous tracts of T tubes; (5) Patients who can be treated with percutaneous abdominal paracentesis or drainage; (6) Patients with intrahepatic bile duct dilataltion who can be managed by PTCD/PTBD; (7) Patients whose residual bile duct stones or strictures can be cured by endoscopic management or traditional Chinese Medicine. Of course, it is essential to pay close attention to the change of patient' s condition and complications during nonoperative treatment, and it also necessary to be simultaneously ready to reoperate at any time. Surgery should be considered as soon as possible if the patient' s condition has not improved even aggravated such as abdominal pain degree worsening, scope expanding, temperature apparently rising and so on[1,10]. Reoperation should also be considered if only the patient' s condition goes beyond the limit of nonoperative therapy such as relatively major bile leakage, serious peritonitis[1,2], persistent leakage or concomitant wrong ligation of bile duct. In our study, 5 patients were converted to reoperation later due to inefficiency of non-surgical management, occurrence of jaundice or wrong ligation of bile duct.

Abstract

AIM: To evaluate the influence of various clinicopathologic factors on survival of patients with bile duct carcinoma after curative resection.

METHODS: A retrospective analysis was made for 86 cases of bile duct carcinoma treated from January 1981 to September 1995. Fifteen clinicopathologic factors possibly influencing survival were selected. Independent variables were first analyzed by univariate methods. Survival for variable was estimated by the method of Kaplan and Meier. The variables that were statistically significant by univariate analysis were included in a multivariate analysis, which were confirmed using the Cox stepwise proportion hazard model with the help of SPSS 10.0 for Windows software.

RESULTS: The overall cumulative survival rate was 72.6 % at 1 year, 32.4 % at 3 years, and 18.7 % at 5 years. The results of univariate analysis showed that the major significant prognostic factors influencing survival of these patients were histological type of lesion, lymph node metastasis, pancreatic invasion, duodenal invasion, perineural invasion, macroscopic vessel involvement, resected surgical margin and depth of cancer invasion (P=0.02, 0.02, 0.004, 0.005, 0.01, 0.43, 0.03 and 0.04). Age, sex, location of tumor, size of tumor, macroscopic type of lesions, hepatic metastasis, and hepatic invasion were not significantly associated with prognosis (P>0.05). Pancreatic invasion, perineural invasion and lymph node metastases were the three most important prognostic factors by multivariate analysis using the Cox proportional hazards model.

CONCLUSION: Pancreatic invasion, perineural invasion and lymph node metastases are the most important prognostic factors for bile duct carcinoma after curative resection.

INTRODUCTION

With the recent improvement of surgical techniques in hepatobiliary surgery, a curative surgical resection of bile duct carcinoma can be accomplished with acceptable morbidity and mortality[1-8]. However, the prognosis for such patients is frustrating, although this tumor is small, grows slowly and metastasizes late[7-13]. In the present article, an effort is made to evaluate the influence of various clinicopathologic factors on survival of patients with bile duct carcinoma using the Cox proportional hazards model. The results of these analyses were used when surgical treatment was performed for patients with bile duct carcinoma.

MATERIALS AND METHODS

General data

Eighty-six cases of bile duct carcinomas were resected in the Department of Hepatobiliary Surgery, First Hospital of Xi' an Jiaotong University from January 1981 through September 1995. The resected specimens were examined pathologically, and the relation between clinicopathologic findings and patient survival was studied.

Variables

The following clinicopathologic variables were considered for prognosis: age, sex, location of primary tumor, size of the tumor, macroscopic type of lesion (papillary, nodular, infiltrating), histological type of lesion (papillary adenocarcinoma, well-differentiated, moderately differentiated, and poorly differentiated adenocarcinoma, and adenosquamous cell carcinoma), hepatic metastasis, lymph node metastasis, hepatic invasion, pancreatic invasion, duodenal invasion, perineural invasion, vascular invasion, resected margin of the bile duct, depth of cancer invasion (invasion limited to fibromuscular layer, to adventitia and subserosal layer, to and beyond the serosal exposure).

Analysis

Independent variables were first analyzed by univariate methods. Statistical significance of the variables was determined by *t*-test and Chi-square test. Survival for variable was estimated by the method of Kaplan and Meier. The variables with statistical significance in univariate analysis were included in a multivariate analysis, which were further confirmed using the Cox stepwise proportion hazard model with the help of SPSS 10.0 for Windows software.

RESULTS

Clinical findings

Of the 86 surgically treated patients, 51 were male and 35 female aged from 33 to 78 years, averaging 58.6 years. The patients aged from 50 to 78 years made up 66.5 %. Of the lesions, 40 (47 %) were upper bile duct cancer, 13 (15.2 %) were middle bile duct cancer, and 33 (38.8 %) lower bile duct cancer. All the lesions were resected at operation. The type of operation depends on the site and extent of tumor. Bile duct resection was done with cholangiojejunostomy in 17 patients,

bile duct resection in 26 with irregular hepatectomy and cholangiojejunostomy, pancreatduodenectomy in 42 patients, and hepatopancreatoduodenctomy in one.

Overall survival

The overall cumulative survival rates were 72.6 % at 1 year, 32.4 % at 3 years, and 18.7 % at 5 years. Fifteen clinicopathologic factors were analyzed, and the prognoses were significantly related to 8 of the 15 variables analyzed by univariate method (Table 1).

Table 1 Univariate analysis of the clinicopathologic factors for the survival of 86 patients with bile duct carcinoma

Factors	No. of patients	*P* value
Sex		0.90
Male	51	
Female	35	
Age (yrs)		0.33
<50	29	
⩾50	57	
Location of tumor		0.15
Upper	40	
Middle	13	
Lower	33	
Size of tumor		0.21
<2cm	11	
2 - 4cm	62	
>4cm	13	
Macroscopic type of lesions		0.43
Papillary	17	
Nodular	32	
Infiltrating	37	
Histological type of lesion		0.02
Papillary adenocarcinoma	7	
Well differentiated adenocarcinoma	27	
Moderately differentiated adenocarcinoma	36	
Poorly differentiated adenocarcinoma	14	
Adenosquamous cell carcinoma	2	
Hepatic metastasis		0.88
Present	2	
Absent	84	
Lymph node metastasis		0.02
Present	37

Hepatic invasion		0.36
Present	29	
Absent	57	
Pancreatic invasion		0.004
Present	21	
Absent	65	
Duodenal invasion		0.005
Present	14	
Absent	72	
Resected margin of the bile duct		0.03
Present	19	
Absent	67	
Perineural invasion		0.01
Present	65	
Absent	21	
Vascular invasion		0.04
Present	17	
Absent	69	
Depth of cancer invasion		0.04
Invasion limited to fibromuscular layer	9	
Invasion limited to adventitia and subserosal layer	59	
Invasion to and beyond the serosal exposure	18	

The significant variables were lymph node metastasis, duodenal invasion, pancreatic invasion, perineural invasion, vascular invasion, resected margin of the bile duct, histological type of lesion, and depth of cancer invasion. The following factors were not significantly associated with prognosis: age, sex, location of tumor, size of tumor, macroscopic type of lesions, hepatic metastasis, and hepatic invasion.

Multivariate analysis using the Cox proportional hazards model involving the 8 significant factors determined by univariate analysis identified the three prognostic variables (Table 2). They were the pancreatic invasion, the perineural invasion and the lymph node metastasis. Pancreatic invasion was observed in 21(24.4 %) of the 86 patients with bile duct carcinoma. The 5-year survival rates for patients with negative and positive pancreatic invasion were 36 % and 2 %, respectively. A statistically significant difference in survival could be observed between the patient with positive and negative pancreatic invasion (P=0.005). Perineural invasion was seen in 75.6 % of the patients with bile duct cancer. Univariate analysis showed a statistically significant difference of survival between the perineural invasion and perineural noninvasion groups (P= 0.01) (Table 1). The 5-year survival rate was 47 % for patients without perineural invasion, whereas 13 % for the perineural invasion-positive patients. Lymph node metastasis was observed in 37(43 %) of the 86 patients with bile duct carcinoma. The 5-year survival rate was 44 % for patients without lymph node metastasis, and 11 % for patients with lymph node metastasis.

Table 2 Relative values of three prognostic variables derived from Cox stepwise proportional hazards model

Variables	β	SE	Sig(*P*)	Exp(B)	95%CI for Exp(B)

DISCUSSION

With the continuing progress of diagnostic and surgical techniques in biliary surgery, a great deal of biliary cancers can be resected with acceptable morbidity and mortality. However, the 5-year survival was only 10-20 %, and only one-third of the patients could be treated surgically at the time of diagnosis[14-18]. The local recurrence of bile duct cancer is relatively high even after curative resection of this lesion. Therefore, a proper surgical procedure should be considered for preventing this undesirable outcome. It is important to know what prognostic factors relate to the survival of the patients with bile duct cancer.

In our study, the overall cumulative survival rates for 86 patients with bile duct carcinoma were 72.6 % at 1 year, 32.4 % at 3 years, and 18.7 % at 5 years. This study showed that the prognoses for patients with bile duct cancer were significantly associated with pancreatic invasion, perineural invasion, duodenal invasion, histological type of lesion, lymph node metastasis, vascular invasion, resected margin of the bile duct, and depth of cancer invasion (P<0.05). Age, sex, location and size of tumor, macroscopic type of lesions, hepatic metastasis, and hepatic invasion were not significantly associated with survival (P>0.05).

Our study also showed that pancreatic invasion, perineural invasion and lymph node metastases were the three most important prognostic factors by multivariate analysis using the Cox proportional hazards model (Table 2). Todoroki *et al* revealed that the primary tumor and tumor node metastasis (TNM) stage were independent predictors of survival using multivariate analysis of 67 patients with bile duct cancer[19]. Havlik *et al* found that lymph nodes, vascular invasion, advanced tumor stage, positive tumor margins, and p53 mutation were associated with poor survival by multivariate analyses[20]. Inoue *et al* identified that surgical margin, lymph node metastasis, lymph node dissection, vascular invasion, and left-side location of the main tumor were significant risk factors for overall survival using univariate analysis and confirmed that surgical margin, lymph node metastasis, and vascular invasion were independently significant variables for overall survival using multivariate analysis[21]. All of them did not mention pancreatic and perineural invasion were prognostic factors for the survival of patients with bile duct carcinoma. Other scholars[22,23] and we, however, have all observed a significant correlation between perineural invasion and postoperative survival.

Pancreatic invasion is the first prognostic variable (Table 2). Patients with negative pancreatic invasion survived significantly longer than those with positive pancreatic invasion after resection of the lesion. Our findings show that the 5-year survival rate for patients with negative pancreatic invasion was 36 %, whereas it was 2 % for patients with positive pancreatic invasion. This poor prognosis might be due to the fact that when the bile duct cancer invades pancreatic tissue it behaves like a primary pancreatic cancer, and the 5-year survival rate was only around 6 %[24-28], leading to a worse prognosis. Since bile duct cancer possess biological characteristic of the invasive growth and anatomical location, lower bile duct carcinoma mostly invade pancreas, making that the 5-year survival rate for postoperative patients with lower bile duct carcinoma less than 10 %[29].

Perineural invasion and lymph node metastasis were also determined to be the independent prognostic factors for survival by the multivariate analysis (Table 2). Some scholars had studied extensively the clinicopathologic significance of perineural invasion, and the results of this study substantiated these findings[22,23]. In our study, the 5-year survival rate for patients with negative perineural invasion was 47 %, whereas it was 13 % for patients with positive perineural invasion. It is well accepted that lymph node metastasis is an independent prognostic factor for bile duct cancer patients[19-21,30]. According to our study, the 5-year survival rate was 44 % for patients without lymph node metastasis, and 11 % for patients with lymph node metastasis. As a result of abundant lymphatic, blood vessel, nerve fibers and loose connective tissue around the bile duct, the cancer cells provided with the way of ' jump model' growth. The excessive metastasis fashion results in the inevitable local recrudescence postoperatively. Consequently, we emphasize the need for dissection of autonomic nerve fibers and plexuses around the hepatic and celiac arteries and the portal vein during operation. In addition the lymph nodes, lymphatic vessels, and connective tissues must be dissected for radical operation on bile duct carcinoma.

Abstract

AIM: To re-evaluate the algorithm that has been used for over 40 years for diagnosis of acute abdominal pain among children.

METHODS: Among the 937 cases admitted to the surgical emergency ward in 2000, 656 cases of acute appendicitis were studied to evaluate the usefulness of the present algorithm for its calculated accuracy, false positive and false negative rates, the sensitivity and specificity in the instant diagnosis of various types of acute appendicitis in different age groups. The algorithm used was established in 1958 and revised for this study in 1999. It includes a 3-step analysis of clinical presentations, i.e.: firstly, a diagnosis of surgical pain by definite organic abdominal signs; then a diagnosis of the subgroup of surgical condition by special signs; and finally the diagnosis of the present disease by specific signs. A footnote describes a "comparative technique" of abdominal examination in non-cooperative children.

RESULTS: The general accuracy of diagnosis was 92.8 %, overall mortality 0.1 % among 973 cases of abdominal pain in 2000. 373 attending surgeons and 241 residents including trainees joined the diagnosis and treatment with no remarkable difference in the results. The incidence of acute appendicitis, 656 in 973 cases, was 67.4 % representing the majority of abdominal pain. In the series of 656 cases, the accuracy of diagnosis of acute appendicitis was 93.6 %, false positive 6.4 %, false negative 0.9 %, sensitivity at first visit 82.7 %, specificity for appendicitis 98.0 %, no death or documentary complication.

CONCLUSION: The present algorithm used for diagnosis of acute abdominal pain is effective and preferable in reducing misdiagnosis and maltreatment at emergency. The use of some modern technology should be further explored.

Zhou H, Chen YC, Zhang JZ. Abdominal pain among children re-evaluation of a diagnostic algorithm**.** *World J Gastroenterol* 2002; 8(5): 947-951

INTRODUCTION

In recent literature, the incidence of perforated appendicitis seems to be rising, and most of the late cases are due to misdiagnosis[1-3] In China, we have not yet had the similar poor impression[4]. For many years, we' ve achieved good results in the management of acute abdomen in pediatric surgery[5]. The best results as reported by Beijing Children' s Hospital (BCH) are: no death in 20 years in 10 000 consecutive cases of acute appendicitis[6], no death in 3 years in 100 consecutive cases of strangulated intestinal obstruction including all those cases that came in shock state[7], and over 90 % of cases of early intussusception that were reduced without emergency surgery even in county hospitals[8,9]. In 1958, a systematical analysis method, the algorithm, for diagnosis of acute abdominal pain among children was published[10]. and popularized in many places of China. It has been generally followed, with timely revisions, for over 40 years. However, with the rapid progress of the modern diagnostic tools in recent years, it is necessary to have a re-evaluation of the above mentioned diagnostic algorithm for abdominal pain among children and try to find out some reasonable modern technology to make it further improved and popularized.

MATERIALS AND METHODS

This is a prospective study of the diagnostic algorithm, which was established in 1958. With the improvement of medical sciences, and changes in the incidence of common diseases in pediatric surgical emergency clinic, the algorithm has been revised many times. Generally, for over 40 years, it has been proved helpful in the diagnosis of acute abdomen of children. For this study, the algorithm was revised again in 1999 as shown in Table 1.

Table 1 Algorithm for diagnosis of abdominal pain

Abdominal Pain		
Acute abdomen (long time pain definite signs)		Non-acute abdomen (short pain no definite sign)
1 Focal inflammation	2 Intestinal obstruction	1 Primary enterospasm (allergic,idiopathic)
(1)local tenderness (appendicitis, etc.)	(1)intestinal pattern (adhesive obstruction)	(1)weaning colic
(2)tender mass (torsion ovarian cyst)	(2)movable mass (intussusception)	(2)school-boy colic
3 generalized peritonitis (full and silent abdomen)		2 secondary enterospasm (organic, non-acute)
(1)spreading peritonitis (inflamed organ)	(2)gangrenous peritonitis (strangulation)	(1) chronic G-I ulcers (2) pancreticobiliary colic
(3)perforating peritonitis (peptic ulcer, typhoid)	(4)primary peritonitis (bacteremia,vaginitis)	(3) chronic gastritis (4) cerebrospinal colic (5) hemo-vascular disease (6) metabolic disease (7) auto-immue disorder (8) intoxication

*Footnote: (1) "comparative technique" of abdominal palpation, watching different reaction of the child on different part of abdomen. (2) "dynamic comparison" of clinical presentation, is today better or worse than yesterday?

It consists of a 3-step analysis of clinical presentations. The first step is to make the diagnosis of a surgical abdomen by finding definite abdominal signs indicating organic lesion, i.e. tenderness, spasm, intestinal pattern and mass. The second step is to make the diagnosis of the subgroup of surgical abdomen, namely organ inflammation, intestinal obstruction and generalized peritonitis by their special signs respectively. The third step is to make the diagnosis of the present disease, like acute appendicitis or intussusception by their specific cardinal signs. In the footnote, the "comparative technique" of abdominal examination for non-cooperative children and its "comparative dynamic evaluation" are described.

Strictly following the above algorithm, 973 cases of acute abdominal pain admitted to the surgical emergency ward of BCH in 2000 (Table 2) were reviewed. The overall rate of misdiagnosis and a general status of the diagnosis and result of treatment were studied (Table 3). In order to make a differential evaluation, 614 cases of acute appendicitis which is the representative disease occupying 68.0 % in 2000 (Table 4) were investigated in detail. The accuracy of diagnosis, the false positives, false negatives, the sensitivity and the specificity of the use of the diagnostic algorithm were calculated accordingly. Different-level doctors concerned in making diagnosis were also recorded.

Table 2 Came with abdominal pain to emergency ward, BCH, 2000

Category	*n*	%

Adhesive obstruction	25	2.8
Fecalith obstruction	19	2.1
Miscellaneous	115	12.7
Total	903	100.0

[a]The other 90 % of early cases cured in OPD by rectal insufflation

RESULTS

Among 973 cases in 2000, the overall mortality was 0.1 %. It was a boy aged 6 yr, who died of strangulation perforation of stomach in uncontrolled Crohn' s disease. There was still no death of acute appendicitis. The general accuracy of diagnosis of acute abdomen was 94.5 %. Concerning the 656 cases of acute appendicitis in 2000, the following figures were calculated: Diagnosis at discharge (614)/Diagnosis on admission (656)=93.6 % overall accuracy; Non-surgical abdomen (42)/Appendicitis admitted (656)=6.4 % false positive at admission; Admission after 2nd visit (196)/ Appendicitis admitted (656)=29.9 % false negative at the 1st visit, mostly delayed in other hospital due to transfer; Second visits in BCH surgery (6)/Appendicitis admitted (656)=0.9 % false negative BCH; Admitted by 1st visit (258)/Appendicitis in 24 h (312)=82.7 % sensitivity (It means, 82.7 % of early appendicitis within 24 h can be diagnosed at first visit); Proved appendicitis (542)/Cases operated (553)=98.0 % specificity (It means, 98.0 % of appendicitis can be differentiated from other surgical conditions); Ratio between cases diagnosed at first visit by surgeons of high level and low level=373:241 cases (in BCH, surgeons under 3 years of training are not allowed to manage on-call emergency); Acute appendicitis (656)/ Abdominal pain (973)=67.4 % incidence at admission. There was no mortality, no documentary complication, but 5 perforated cases in moderate postoperative morbidity. Pathology of 614 case of acute appendicitis in 2000 is shown in Table 5.

DISCUSSION

Theoretic basis of the diagnostic algorithm

Because the basic pathology of surgical conditions must be an organic lesion inside the abdomen, the chief symptoms and signs must be persistent and definite[11]. Acute pain shorter than

6 hours is hard to rule out from the more common abdominal pain due to functional intestinal spasm unless some specific abdominal signs are found[12,13]. By the term "definite", it means definite pain, definite location and definite area involved. Therefore, the child has to be examined many times in an appropriate period of time. In BCH, people usually do the 1st time examination at the first visit, the 2nd examination after laboratory tests, and the 3rd repeat of examination before sending the patient to the ward or back home. Full agreement of the positive findings in the 3 examinations will make the final diagnosis. If negative sign appears in any one examination, further observation and re-examination should be made. The common positive abdominal signs indicating surgical condition are local tenderness, muscular spasm, palpable intestinal pattern and mass. By a soft flat abdomen without the above mentioned signs, people can rule out acute surgical abdomen.

According to common presentations of surgical abdomen, it can be classified into 3 sub-groups: (1) Definite local tenderness and spasm usually indicate a focal inflammation. (2) A palpable distended intestinal loop or a movable solid sausage mass indicates intestinal obstruction. (3) A resistant and silent abdomen indicates generalized peritonitis. These practically cover up all common diseases seen in children. (1) In the sub-group of focal inflammation, the diagnosis depends on the location of tenderness, e.g. in RLQ of abdomen which is usually acute appendicitis; pelvic rectal tenderness with mass is usually torsion of ovarian tumor; flank tenderness is usually renal colic or perinephretic abscess; (2) In the sub-group of intestinal obstruction, a distended intestinal pattern indicates extraluminal obstruction of intestine, e.g. adhesional strangulation, or a solid mass usually indicates intraluminal obstruction, e.g. intussusception or ascaris bezoar; (3) In the sub-group of generalized peritonitis: a marked tender point indicates the focus of spreading peritonitis, e.g. perforated appendicitis; a palpable loop or mass indicates gangrenous peritonitis, e.g. strangulated intestinal obstruction. Pneumoperitoneum by percussion or X-ray indicates perforating peritonitis, e.g. peptic ulcer perforation; thin pus by abdominal puncture aspiration indicates most probably primary peritonitis.

After 3-step analysis, the final diagnosis of a surgical disease is usually made. And then, a comparison between the cardinal signs of the disease and the signs found in this particular patient should be made as a feed-back checking. Any disagreement must be carefully investigated or the diagnosis be reconsidered otherwise.

Method of abdominal assessment in non-cooperative children

Examination of abdomen needs cooperation of the patient. Answering tenderness must be accurate. A crying kid always makes the palpation confused. Even the school-boy may not be able to give an accurate answer to abdominal examination. So the surgeon has to try all means to search for cooperation of a bigger child and to evaluate the findings carefully by repeated examinations. At the same time, he has to observe every action of the kid carefully. Quick squatting or jumping up and down from the examination table without hesitation may rule out abdominal tenderness[14]. For examination of crying kids, a 3-step "comparative technique" of abdominal palpation has been practiced satisfactory in BCH. (1) The 1st step: the mother stands by the head to beguile the baby and hold both its hands. The surgeon stands by the right side of the examination table and palpates the abdomen from LLQ, LUQ, RUQ to RLQ subsequently. Carefully watching the reaction of baby, a high pitch crying might be the answer of tenderness. (2) The 2nd step: let baby' s left hand free, surgeon presses the abdomen with two hands on RLQ and LLQ. Baby naturally uses his free hand to push away the hand in the tender point, e. g. RLQ. (3) The 3rd step: surgeon makes a finger press at the tender area, e.g. McBurney' s point. Baby will try all means to get rid of the finger. By this time, the surgeon may press all other parts of abdomen, to make sure no tenderness beside McBurney' s point or elsewhere.

By the same way, surgeon' s two hands press on both sides of the baby' s abdomen. After several cryings, people may find the hand on left side having pressed much deeper than that on the right side if there is spasm in RLQ of abdomen.

In difficult cases, a dose of short action sedative can be used, e.g. 10 % choral hydrate by dose 1 ml/mos of age. This is limited only to the last examination. Under sedation, deep palpation in six parts (4 quadrants, periumbilical and pelvis) can be made. In order to feel the deep structures in abdomen, the abdominal aorta or other landmarks of posterior abdominal wall should be reached. In rectal pelvic bimanual examination, infiltration or abscess of peri-appendiceal structure can be felt in right iliac fossa and incarcerated inguinal hernia can be felt at the middle along the inguinal ligament from interior by the endo-rectal examination finger[15,16]. It must be kept in mind that the pathology of an acute abdomen is continuously changing. Therefore dynamic comparative observation and evaluation are essential. For making an instant diagnosis in emergency clinic, the information from mother' s impression about baby' s appetite and general activity, whether today is better or worse than yesterday, will be very helpful in making decision of emergency surgery[17].

Supplementary diagnostic techniques (Table 5)

By quick plane X-ray film of erect position, especially in suspected intestinal obstruction, preferably with low pressure barium enema, perforating peritonitis, intestinal obstruction and intussusception can be well demonstrated (Figure 1, 2)[18]. By ultrasound, acute appendicitis and abscess, intussusception, peritoncal fluid, and ovarian cyst or tumor, and perinephretic lesions may be demonstrated (Figure 3, 4)[19-32]. By paracentesis, the abdominal puncture fluid may tell the peritonitis, strangulation of intestine, perforation of intestine or gall bladder[33,34]. Bloody aspirate always calls for an immediate surgical exploration. In case of fine needle puncture getting into intestine under pressure, don' t hurry, keeping on aspiration until negative pressure will prevent intestinal leakage after withdrawal of needle. CT, MRI, Scintiscanning and other fantastic modern tools are used only occasionally[35-38]. But dramatic improvement of the diagnosis of acute abdomen in children must depend on further exploration for the use of high technology. e.g. laparoscopy and portable ultrasound computerized[39-44].

We conclude that the algorithm has been used and accepted for more than 40 years in thousands of patients by hundreds of surgeons of different levels. It proves helpful in handling acute abdominal pain among children. The prospective study of appendicitis in 2000, has proved its accuracy, false positive, false negative, specificity and sensitivity, all being of acceptable value. However, there are still doubtful cases needing observation, especially in cases with 6 hrs duration without definite signs, partial intestinal obstruction without toxic reactions, and late appendicitis may not need operation. Besides, in the other half of the algorithm (Table1), non-surgical abdominal pain, it includes a large number of diseases needing systemic examination and investigation. However none of them need immediate surgical operation. The most common "school-boy colic" (or primary intestinal spasm) characterized by short pain in attacks, normal appetite and activities in intervals, repeated attacks for months without impairment of nutrition or growth occupies about 60 % of school-boy abdominal pain. Keep this in mind, and it may reduce the false positive diagnosis of acute abdomen.

PROSPECTIVE TECHNOLOGY

(1)Since this algorithm is simple and regular, it can be put into a software of computer to up-grade it into high technology; (2)Portable ultrasonography machine to be used on emergencies examination table could take place of manual palpation of abdomen for uncooperative kids, making the examination more objective; (3)Further improvement of laparoscopy, exploratory laparotomy in acute abdominal pain may be unnecessary.

Abstract

AIM: Globus pharyngeus is not an uncommon symptom. Presently, its unclear dated pathophysiology remains unclear and the disease can not be evaluated correctly with routine diagnostic methods. The objective of this study is to establish the normal values of pharyngeal and UES pressure, pharyngeal transit time in healthy volunteers and to compare the differences between healthy volunteers and patients with globus pharyngeus.

METHODS: Twenty-four healthy volunteers and thirty-two patients clinically diagnosed as globus pharyngeus entered the study. Pressures of pharynx and UES were measured. Pharyngeal transit time was measured by videofluoroscopic procedure.

RESULTS: Normal pressure of pharynx, and normal resting pressure of UES were 157.81±63.86 mmHg and 68.33± 37.56 mmHg, respectively. The corresponding values in the patients were 175.50±93.47 mmHg and 71.38±41.42 mmHg. The pharyngeal transit time was 1.44±0.30 s in normal control group, among them there were 4 cases with stasis of barium in the valleculae and one in the piriform sinus. No laryngeal penetration or aspiration was found. In the patient group, the pharyngeal transit time was 1.37 ±0.41 s, among them there were 6 cases with stasis of barium in the valleculae and 5 in the piriform sinus. 9 cases had laryngeal penetration and 2 had aspiration. There were no statistical differences of pressures of pharynx, UES and the pharyngeal transit time between the two groups. But there was an association between laryngeal penetration and globus pharyngeus.

CONCLUSION: Radiographic examination of the pharynx show specific findings of pharyngeal dysfunction in patients with globus pharyngeus. UES pressure is normal in most patients. Hence, we find no role for UES hypertonicity as an etiologic factor in globus pharyngeus.

INTRODUCTION

Globus sensation (globus pharyngitis, globus pharyngeus) is best described as a constant sensation of something stuck or a lump or tightness in the throat. Typically, a lump, or crumb-like (foreign body) sensation, a constriction or choking[1-3] is complained. Nearly half of the general population has had intermittent symptoms resembling globus[4-6]. More severe and distressing symptoms comprise up to 4 % of referrals to otolaryngological specialists[4]. In addition to emotional stress, mood, and personality disorders, it has been attributed to a high upper esophageal sphincter (UES) resting pressure, gastroesophageal reflux (GER)[7,8], esophageal dysmotility, hiatal hernia, kinematic pharyngeal transit time and local anatomic abnormalities[9-16]. Although the associations are diverse and broadly investigated, the etiology of globus still remains unclear[4].

The aim of our study was to investigate the association of globus pharyngeus with UES resting pressure and kinematic pharyngeal transit time.

MATERIALS AND METHODS

Study subject

Two groups of persons were studied: globus pharyngeus patients and the control group. The globus pharyngeus group comprised thirty-two consecutive patients presenting themselves to the otolaryngology and gastroenterology departments with predominant symptom of globus pharyngeus with no abnormality on examination of neck, larynx, or pharynx between December 2000 and March 2001. The diagnostic criteria of the globus sensation is in accordance with Rome Ⅱ criteria: At least 12 weeks, which need not be consecutive, in the preceding 12months of: (1) The persistent or intermittent sensation of a lump or foreign body in the throat;(2) Occurrence of the sensation between meals; (3) Absence of pathologic gastroesophageal reflux, achalasia, or other motility disorder with a recognized pathologic basis as scleroderma of the esophagas. The control group consisted of twenty-four healthy volunteers. The male: female ratio in the globus pharyngeus group was 1:1.29, as conpared with 1:1.4 in the control group. The mean age in the globus pharyngeus group was 47±11 years (range: 28-73 years), as compared with 49±17 years (range: 21-77 years). These differences were not significant. A single investigator examined all patients by videofluoroscopy and esophageal manometry.

Esophageal manometry

After an overnight fast, manometry was performed using a solid-state intraluminal transducer assembly (Konigsberg Instruments, Inc., Pasadena, USA). The catheter consists of a flexible tube containing four pressure microtransducers. The distal two are circumferential transducers that record the average pressure over 360°. The circumferential transducer consists of a 4.6-mm-diameter silastic annulus enclosing a small transducer within a castor oil-filled chamber. The two

proximal transducers with a single sensor oriented in one direction. The transducers, starting at the distal end, are separated by 3, 2 and 5 cm. Pressure data are collected on-line by means of a computerized motility system and analyzed using Polygram equipment and software [Synectics (Medtronics), Shoreview, Minnesoda].

Before the examination, the transducers were calibrated at 0 mmHg and 50 mmHg after balneum in 37 ℃ water 10 minutes. Manometry of the UES and pharynx was performed in the upright position. The catheter was passed through a nostril into the stomach. Then it was withdrawn in 1-cm increments every 20 seconds back into the esophagus. UES resting pressure was assessed using a station pull-through of the distal transducer with at least 15-sec intervals for stabilization between each 1-cm movement of the catheter, since the UES is somewhat reactive to the catheter movement. After identifying the high-pressure zone during this slow pull-through, at least 15-sec is allowed to elapse before measuring the resting UES pressure. Maximal stable pressure is recorded in millimeters of mercury using esophageal pressure just distal to the UES as zone baseline. Five 5-ml water (room temperature) swallows were used to assess UES relaxation, pharyngeal contraction, and UES/pharyngeal coordination. Swallows were 30 seconds apart. The swallows were performed with the circumferential transducer placed just proximal to the high-pressure zone of the UES to allow accurate recording of the pressure throughout the cycle of elevation of the sphincter during deglutition. Placement of the circumferential transducer proximal to the high-pressure zone of the sphincter compensates for orad movement during swallowing.

Mamometry helped clarify the specific timing of pressure events during pharyngeal contraction and UES relaxation[17].

Videofluoroscopy

Detailed sequential analysis of videofluoroscopic images recorded at 25 frames/s clarifies timing of the events that occur during pharyngeal contraction and UES opening. It clearly defines the key role of muscle contraction occuring early in the swallowing sequences that produce the elevation of the hyoid and larynx, which is an essential element in the opening of the UES[18-20].

Kinematic pharyngeal transit time is defined as the time from the first movement of the bolus, which results in a complete swallow, to the time the epiglottis returns to its initial position. The definition excludes oral preparation time and tongue movements that do not result in a complete swallow[21].

Videofluoroscopy was completed in both anteroposterior and lateral projections with 5-ml thin barium at room temperature[22-23]. To standardize the evaluations in our study, timing measurements were completed in the lateral projection.

The following data were collected by one physician evaluator: (1) quantitative kinematic pharyngeal transit times including the time of arrival of the head of the bolus reaching the level of the posterior inferior border of C_2 verterbral body (C_2L), the inferior level of the valleculae (BV), the posterior inferior border of C_4 verterbral body (C_4L), and the time at which the epiglottis returned to its original position (Em); These data points were selected to provide more easily identifiable radiologic landmarks for measurement[21,24-26]. (2) The presence or absence of vallecular or piriform pooling, and (3) the presence or absence of penetration of part of the bolus to or through the true vocal cord[27-29].

Statistical analysis

Fisher *P* test was used to compare patients and controls, with statistical significance set at the level of 0.05.

RESULTS

Kinematic pharyngeal transit time

The data of kinematic pharyngeal transit time from the control group and globus pharyngeus group were presented in Table 1.

Table 1 Kinematic pharyngeal transit time

	Control group(n=24)	Globus sensation group(n=32)	*P*
C_2L	0.50±0.27	0.45±0.33	>0.05
BV	0.57±0.26	0.51±0.34	>0.05
C_4L	0.67±0.27	0.63±0.36	>0.05
EM	1.44±0.30	1.37±0.41	>0.05

Note: Times are given in seconds.

There was no statistically significant difference between the control group and globus pharyngeus group, which showed ^aP>0.05. There were four cases of volunteers presenting stasis of barium in the valleculae and one in the piriform sinus. No laryngeal penetration and aspiration were found. Meanwhile, there were six and five of patients representing stasis of barium in the valleculae and piriform sinus respectively. Nine and two of patients had laryngeal penetration and aspiration. The results of valleculae and piriform sinus stasis and airway aspiration had no statistically significant differences between the two groups. But there was an association between laryngeal penetration and globus pharyngeus.

Esophageal manometry

The data of esophageal manometry from the control group and globus pharyngeus group were presented in Table 2.

Table 2 Data of esophageal mamometry

	Control group (n=24)	Globus pharyngeus group(n=32)
UES		
Resting pressure	68.33±37.56mmHg	71.38±41.42mmHg
Residual pressure	-7.30±6.48mmHg	-11.04±6.90mmHg
Relaxation time (from the beginning of relaxation to the nadir)	0.27±0.06s	0.28±0.15s
Duration (time from beginning of relaxation to the end)	0.54±0.08s	0.59±0.15s
Recovery (time from nadir of relaxation to the end)	0.27±0.08s	0.33±0.15s
Pharynx		
Peak pressure	157.81±63.86mmHg	175.50±93.47mmHg
contraction time (from the beginning of contraction to the nadir)	0.20±0.06s	0.22±0.08s
duration (time from beginning of contraction to the end)	0.42±0.08s	0.44±0.12s
Recovery (time from peak of contraction to the end)	0.22±0.05s	0.22±0.06s

There was no significant difference between the two groups (P>0.05). And also no difference in gender in the two groups (Table 3)

Table 3 Data of male and female in two groups

	Control group		Globus pharyngeus group	
	Male	Female	Male	Female
UES resting pressure(mmHg)	65.55±34.02	70.32±38.49	67.61±34.39	73.65±44.00
UES residual pressure (mmHg)	-9.33±6.80	-5.84±5.82	-8.80±6.98	-12.39±6.49
Pharyngeal peak pressure(mmHg)	165.72±69.19	151.45±57.36	163.19±105.47	182.89±81.99

DISCUSSION

Globus pharyngeus is a common disorder, accounting for 3-10 % of otolaryngologic outpatient referrals[1,4]. The cause is unknown, and is likely to be of multifactorial origin. Abnormal function of the upper esophageal sphincter (UES) may produce the globus sensation symptom[14,30]. Disorders of the UES include the hypertonsic and hypotonsic sphincter and various abnormalities of relaxation. Globus sensation has been associated with hypertonsic upper esophageal sphincter and a persistent cricopharyngeal impression (i.e., bar), and Zenker diverticulum may be seen in patients with abnormal sphincter relaxation[9-13,30-31].

Hypertonicity of the UES was suggested as an etiologic factor in the genesis of globus sensation by Watson and Sullivan[32] in a study involving only nine patients suggested hypertonicity of the UES as an etiologic factor in the genesis of globus pharyngeus. This observation was in contradiction with a previous controlled study by Calderelli *et al*[33], who found normal UES pressures in their patients with globus sensation. The techniques used for UES manometry in both studies might have questionable accuracy, as they did not count for the radial asymmetry of the UES pressure profile. In a more recent study, Cook *et al*[34] failed to demonstrate any difference in resting UES pressure between normal controls and those with a history of globus sensation. Our study, using computerized solid-state manometry with a circumferentially recording transducer has not shown increased prevalence of UES hypertonicity in patients with globus sensation.

Through studies using multi-lumen catheters, radial asymmetry of the UES has been demonstrated over a number of years[35,36]. Pressures recorded in the anterior and posterior directions were usually two or three times greater than pressures recorded laterally. This was believed to result from the anatomical disposition of the cricopharyngeus, but might be due in some extent to the compressive effect of the posterior lamina of the cricoid cartilage against the vertebral bodies of the cervical spine. So we believe that values for UES pressure are best obtained using a circumferential sensing solid-state transducer[37]. In addition to radial asymmetry, oral movement of the sphincter during deglutition complicates the manometric assessment of the UES. With the transducer located in the sphincter high-pressure zone, a recording artifact will usually occur. As the swallow is initiated, the sphincter moves oral, leaving the transducer recording esophageal pressure. This fall in pressure may be erroneously interpreted as sphincter relaxation. If, however, the transducer is located proximal to the high pressure zone, when the subject swallows and the larynx elevates, the UES (which has not yet relaxed) moves onto the transducer, which then records a rise in pressure followed by a fall in pressure as the sphincter relaxes. The pressure rises again as the sphincter regains tone and falls as the larynx returns to its original position, moving the sphincter distal to the transducer. The manometric recording in the UES that results from this sequence of events resembles the letter 'M' and this configuration can be used to ascertain correct transducer placement[38-41].

The manometric findings in our study did not demonstrate any possible origin for the globus sensation.Detailed sequential analyses of videofluoroscopic images recorded at 25 frames/s have clarified timing of the events that occur during pharyngeal contraction and UES opening[42,43]. These studies have clearly defined the key role of muscle contractions occurring early in the swallowing sequence that produce the elevation of the hyoid and larynx which is an essential element in the opening of the UES[44,45]. Videofluoroscopy was completed in both anteroposterior and lateral projections with 5 ml 250 % barium sulfate liquid[27].

The initiating event in our kinemic times is approximately at the beginning of the oropharynx. Consequently, BV in our study represents transit time through the oropharynx and mesopharynx. Pharyngeal dysfunction was defined as the presence of one or more of the following findings: (1) poor laryngeal elevation and epiglottic motion, (2) laryngeal penetration or aspiration, and (3) stasis of barium in the vallecula and piriform sinuses[46,47].

Radiographic evidence of pharyngeal dysfunction such as stasis and aspiration was seen in patients, but these findings were not specific for upper esophageal sphincter dysfunction. Batch and Wilson et al also found that pharyngeal abnormalities were rarely seen at radiography in patients with globus pharyngeus[48-50]. Thus, radiographic findings suggestive of upper esophageal sphincter dysfunction were rarely present in patients with globus sensation[30].

In conclusion, findings by radiographic examination of the pharynx may show specific findings of pharyngeal dysfunction in patients with globus pharyngeus. Results of the pressures of the UES are normal in most patients with this symptom. So we find no role for UES hypertonicity as an etiologic factor for globus, but a strong association between laryngeal penetration and globus pharyngeus.

Abstract

AIM: To present a case of combined small bowel and reduced auxiliary liver transplantation.

METHODS: A 55-year-old patient with short bowel syndrome and TPN-related liver dysfunction received small bowel transplantation combined with a reduced auxiliary liver graft. A liver was added to restore the patient's liver function and to protect the intestinal allograft from rejection. His own liver was not removed.

RESULTS: Without donor pretreatment and by conventional immunosuppresive therapy following transplantation, the patient experienced had only one episode of mild intestinal rejection, which was easily reversed by treatment with Methylprednisolone. No liver rejection occurred. Unfortunately, the patient died of heart and lung failure 30d after transplantation, despite successful graft replacement. Histopathologic examination of specimens after death demonstrated normal structure in both intestinal and liver grafts.

CONCLUSION: The auxiliary liver graft might play a role in preventing intestinal allograft rejection. However, the observation period in this case is short. Further study is needed to determine the risks, effect on the protecting the small-bowel from rejection, and feasibility of general application of this procedure.

INTRODUCTION

Small bowel transplantation is a possible choice of treatment for patients with irreversible failure of the intestine[1-8]. Compared with the success in other solid organ allografts, attempts at small bowel transplantation in human have got poor results in terms of patient and graft survival[9-17]. Rejection, immunosuppression-related infections and graft-versus-host reaction (GVHR) are the main obstacles to clinical application[18-30].

In 1990, Grant *et al*[31] first reported a case of successful small-bowel transplantation combined with a liver graft. This patient had only one episode of mild intestinal rejection, which was easily reversed by treatment with OKT_3. She had maintained normal nutrition for more than 2 years after surgery. The authors considered that the lack of serious intestinal rejection in this case may be due to immunological protection provided by the liver graft. Subsequently, some investigators demonstrated the same observations[32-38], others reported that combined liver-bowel transplantation has no immunologic advantage over bowel transplantation alone[39-41]. Furthermore, it has been shown that auxiliary liver transplantation had a slight protective effect on simultaneously transplanted small bowel, and it was not as strong as has been observed with orthotopic liver transplantation[42].

We report a case of short-bowel syndrome and secondary TPN-related hepatic dysfunction who received small-bowel transplantation combined with a reduced auxiliary liver graft in our institute. After operation, only one episode of mild intestinal rejection occurred without liver rejection.

CASE REPORT

Case history

A 55 year old patient has had the short-bowel syndrome since February 1999 after the resection of whole small bowel and right colon because of thrombosis of the superior mesenteric artery. He was then alive on total parenteral nutrition (TPN), but was not discharged from hospital due to uncontrollable diarrhea. Besides, the TPN-related liver impairment developed. After extensive discussion with the patient and his family, small-bowel transplantation was performed on April 15, 1999. An auxilliary liver was simultaneously transplanted for the purpose of both restoring his liver function and protecting the intestinal graft from rejection. We did not remove his own liver.

Transplantation procedures

The donor is a brain death adult. Both donor and recipient were blood group O. The donor's HLA phenotype was A11,-; B75, -; DR12, 15 and DQ6 (1),-. The recipient's HLA phenotype was A2,23;B44,62;DR7,- and DQ2,5. The lymphocytotoxic crossmatch was negative. No pretreatment was given to alter the graft immunogenicity with antilymphocyte or other modalities.

To reduce the volume of donor liver, left lateral lobectomy and right frontal lobectomy were performed. The reduced liver and small bowel including the duodenum, jejunum and partial ileum were grafted into the abdominal cavity of the recipient. The donor's abdominal aorta duct containing the origins of the superior mesenteric artery and coeliac artery was anastomosed end-to-side to the recipient's infrarenal aorta. The donor's infrahepatic vena cava was anastomosed end-to-side to the recipient's infrarenal vena cava. The end of the donor

jejunum was anastomosed to recipient' s duodemum; intestinal continuity was restored with an end-to-side ileocolic anastmosis. The end of the donor' s ileum was exteriorized as an ileostomy (Figure 1).

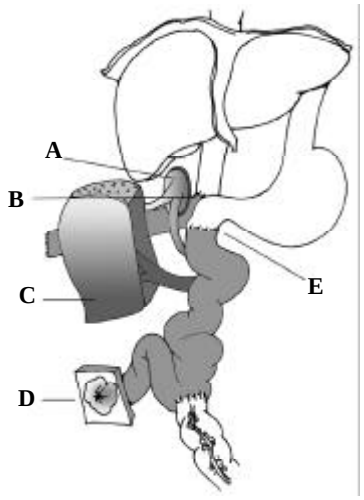

Figure 1 Small-bowel and auxiliary liver allograft. A. Carrel patch containing the origin of the superior mesenteric artery and the coeliac artery is anastomosed to the recipient's aorta; B. Anastomosis of end of the donor infrahepatic vena cava to the side of recipient's vena cava; C. The reduced liver; D. Ilesotomy; E. Anastomosis of donor jejunum to the recipient's duodenum

Immunosuppression management

Methylprednisolone was given intravenously 30 min before graft revascularization (first dose of 500mg bolus) and rapidly tapered to 20 mg· d^{-1} over the next 10 days. Cyclosporin A by continuous intravenous infusion was begun intraoperatively (3mg· kg· d^{-1}) to maintain the whole blood concentration of 350-450 μg· L^{-1} by monoclonal radioimmunoassay. Cyclophosphamide 100 mg was also given intravenously daily for the first 3 days. Prostaglandin E_1 (600 μg· d^{-1}) was began intraoperatively and continued for 20 days.

Postoperative course

Detection of graft rejection was based primarily on clinical observations and mucosal biopsies. During his postoperative course, the bowel graft developed only one histologic evidence of rejection. Mucosal biopsy on the seventh postoperative day showed lymphocyte infiltration in epithelium, slight fattening of the villi, decreased numbers of goblet cellls, but the mucosal destruction and necrosis were not observed (Figure 2). The rejection was successfully reversed by a 3 day course of methylprednisolone bolus (15mg· kg· d^{-1} per day in tapering doses).

There was no clinical or histological evidence of liver rejection. The liver function including ALT, AST, Tbil, cholesterol, triglyceride returned to the normal range 5 days after surgery. On the 9th and 23rd postoperative day, laparotomy was performed because of surgical complications. During the operation, the liver was biopsied, and a normal histological appearance was found (Figure 3).

The patient did not receive any specific treatment for preventing graft-versus-host disease (GVHD) other than the immunosuppression therapy previously described. No sign of GVHD developed. Unfortunately, some severe complications occurred including intestinal fistula, stress ulcer and bleeding, ARDS, pulmonary and abdominal infection. The patient died of heart and lungs failure 30 days after transplantation despite successful graft replacement. The histopathologic examination of specimens after death demonstrated normal structure in both intestinal and liver grafts.

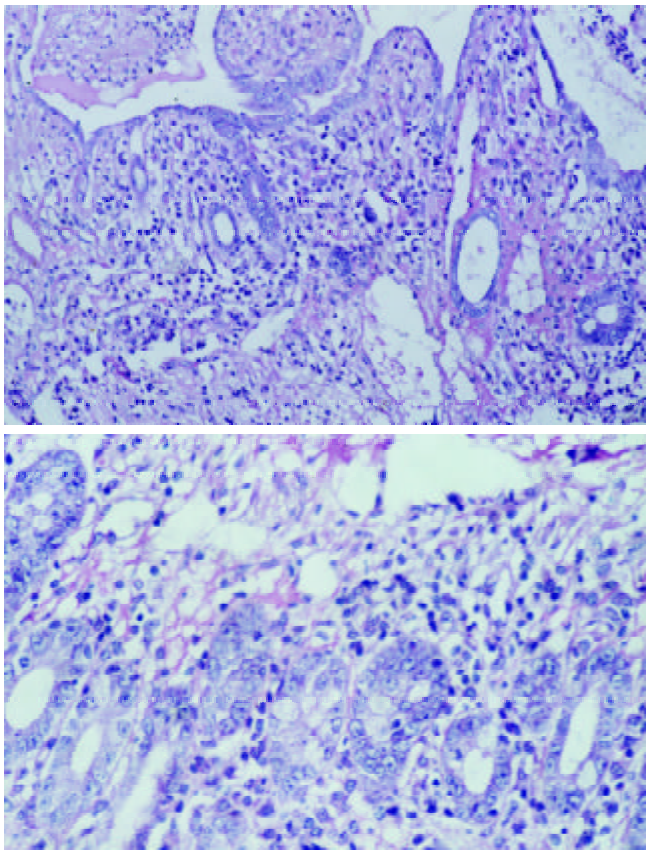

Figure 2 Photomicrographs showing acute rejection with lymphocytic crytitis on the 7 th postoperative day, the mucosal destruction and necrosis were not observed (H&E, A, ×200; B. ×400).

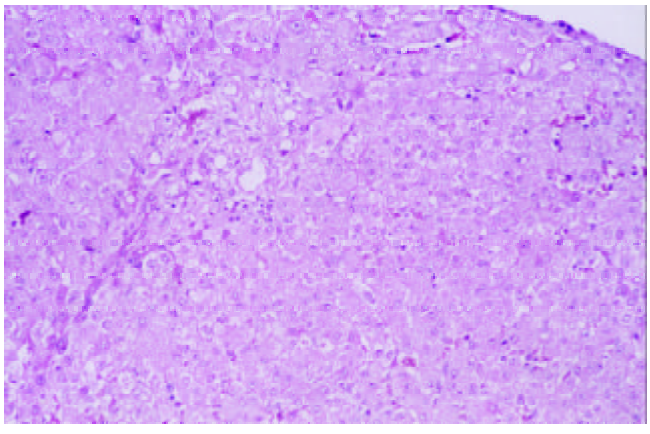

Figure 3 Liver biopsy specimens on the 9th postoperative day showed normal appearance of the allograft (×200), no inflammatory infiltrate in the portal tract.

DISCUSSION

Liver dysfunction is a well-recognized complication of intestinal failure. Advances in TPN have allowed the patient

suffering from short bowel syndrome to survive. However, in many instances total parenteral nutrition causes severe liver damage leading to cirrhosis. Thus, combined liver and small bowel transplantation becomes an established life-saving therapy for the treatment of liver disease and intestinal failure[43-46]. In the general, an orthotopic liver and small bowel are transplanted. To our knowledge, this case is the first report of transplantation of combined auxiliary reduced liver and small bowel in human. We tried to restore the patient' s liver function and to protect the intestinal allograft from rejection. For these reasons, an auxiliary liver was simultaneously transplanted. The auxiliary reduced liver-small bowel transplantation model represents a new, less aggressive possibility for multiorgan transplantation[31,47,48]. It offers some advantages over multivisceral transplants, including simplicity and less mortality than the combined orthotopic liver-intestinal transplantation. This procedure is useful for the patients with reversible hepatopathy associated with intestinal insufficiency because it can offer temporal or definitive hepatic support.

Without donor pretreatment and under conventional immunosuppresive therapy, this patient had only one episode of mild intestinal rejection, which was easily reversed by treatment with Methylprednisolone. These data indicate a possible role of the auxiliary liver graft in preventing intestinal allograft rejection. In fact, the immunoprotecting effect of the liver was first described by Calne in 1969 in a porcine model[49]. The animal can reject skin, kidney and hearts rapidly. However, orthotopic and accessory heterotopic liver allografts can protect preferentially from rejection grafts of donor specific skin, kidney and heart. Injected soluble liver antigen may also protect donor specific tissue from rejection. It suggested that allogeneic liver can induce immunological tolerance in immunologically mature pigs[49]. Subsequent studies demonstrate that specific tolerance can be achieved in combined liver/small bowel transplantation after a transient rejection crisis[32-38].

The mechanism of immunological protection of the liver is not very clearly until now[50-52]. Apoptosis of T lymphocytes may be involved in graft rejection and tolerance induction[50]. Apoptosis is a mechanism for eliminating autoreactive cells during T cell maturation in the thymus. T cells themselves use apoptosis to eliminate alloantigen-expressing donor cells during rejection responses. Apoptosis of parenchymal cells in the grafted livers correlated directly with interleukin-2 receptor expression of the infiltrating T cells. In the late phase of rejection, a peak of apoptosis in the lymphocyte infiltrate was demonstrated, characterized as predominantly apoptotic $CD8^+$ T lymphocytes. T cell inactivation seems to result in apoptosis of cytotoxic T cell and tolerance[50]. In addition, microchimerism is associated with long-term graft acceptance in combined liver/small bowel transplantation[51,52]. Donor specific leucocytes could be detected immunhistochemically in the combined liver/small bowel group and isolated liver group in spleen, host Peyer patches, and mesenteric lymph nodes. Particularly in the liver sinusoids investigators[52] found a great number of persisting donor leukocytes in all long-term survivors in combined liver/small bowel rats. The persisting leucocytes obviously originate from the initially transplanted white cell population of the liver. The liver as constant source of antigen plus a persisting and obviously active leukocyte popuolation may provide the basis for a long-term survival of the liver graft and any cotransplanted organ.

However, the observation period in this case was short and it is difficult to extrapolate that the complex immune responses between the donor and recipient are affirmatively associated with adding a liver graft. Moreover, other studies found that liver grafting failed to prevent intestinal rejection in human and large animal model[39-41]. Further studies are needed to determine the risks, effect on the protecting the small bowel from rejection, and feasibility of general application of this procedure.

Abstract

Liver injury induced by various pathogenic factors (such as hepatitis virus, ethanol, drugs and hepatotoxicants, etc.) through their respective special pathogenesis is referred to as "primary liver injury" (PLI). Liver injury resulted from endotoxin (lipopolysaccharide, LPS) and the activation of Kupffer cells by LPS while intestinal endotoxemia (IETM) occurred during the occurrence and development of hepatitis is named the "secondary liver injury" (SLI).The latter which has lost their own specificities of primary pathogenic factors is ascribed to IETM. The "secondary liver injury" is of important action and impact on development and prognosis of hepatitis. More severe IETM commonly results in excessive inflammatory responses, with serious hepatic necrosis, further severe hepatitis and even induces acute liver failure. The milder IETM successively precipitates a cascade, including repeated and persistent hepatocytic impairment accompanied by infiltration of inflammatory cells, hepatic fibrosis, cirrhosis and hepatocarcinoma. Generally, the milder IETM ends with chronic hepatic failure. If PLI caused by various pathogenic factors through their independent specific mechanismis regarded as "the first hit" on liver, then SLI mediated by different chemical mediators from KC_s activated by IETM in the course of hepatitis is "the second hit" on liver. Thus, fusing and overlapping of the primary and scondary liver injuries determine and influeuce the complexity of the illness and outcome of the patient with hepatitis. For this reason, the viewpoint of "SLI" induced by the "second hit" on liver inflicted by IETM suggests that medical professionals should attach great importance to both "PLI" and "SLI" caused by IETM. That is, try to adjust the function of KS_s and eliminate endotoxemia of the patient.

Han DW. Intestinal endotoxemia as a pathogenetic mechanism in liver failure. *World J Gastroenterol* 2002; 8(6): 961-965

INTRODUCTION

Gut is a vast pool of bacteria and endotoxins (lipopolysaccharide, LPS) in the body. There are endotoxemia in severe trauma, burn or scald, Intestinal ischemia and liver diseases. They are mainly resulted from large quantities of endotoxin produced by overgrowth of gram-negative bacteria in gut that are increasingly taken into portal vein because of the incereased permeability of intestinal wall. Endotoxemia will be generated if the level of endotoxin surpasses the hepatic capacity for endotoxin scavenging due to decreased phagocytic ability of liver kupffer cells (KCs) and then endotoxin spills over into systemic circulation. For these reasons, it is named IETM because endotoxin comes from gut.

In recent years, the relationship between IETM and liver diseases has been increasingly paid much attention to. Animal studies have demonstrated that various experimental liver diseases were commonly accompanied by IETM. Clinical observations have also showed evidences that the highest incidence(80-100 %) and severe degree of IETM in patients with severe hepatitis was generally recognized, though the incidences of IETM in patients with acute or chronic hepatitis, severe hepatitis, cirrhosis and hepatocarcinoma were not reported equally. Incidences of IETM investigated in our institute in acute or chronic hepatitis, severe hepatitis and cirrhosis were 75 %,79 %,93.3 % and 84.3 % respectively[1].

LPS activates KCs via two pathways: one is membrane attachment from mCD_{14} which is the classical CD_{14} dependent pathway, that requires LPS binding protein (LBP) as a cofactor carring LPS to the membrane of KCs bound to the receptor CD_{14}; the soluble compound formed by combining LBP with LPS increases affinity of LPS with CD_{14}. Whereas the other pathway-sCD_{14} may not require LBP, combines with corresponding receptor on KCs by aid of other proteins (such as HDL, LDL etc). These two pathways finally activate signal transduction system and trigger the synthesis and release of cytokines and inflammatory mediators[2].

KCs stimulated by LPS release chemostatic substances such as TNF-α, interleukins, leukotriene B_4 and complement C_5, which attract circulating neutrophilic leucocytes. Activated neutrophilic leucocytes up-regulate adhesion molecules receptor (CD_{11b}/CD_{18}) on its membrane surface, then adhere to endothelial cells of hepatic sinusoids. In the meanwhile, adhesion molecules ICAM-1 and ELAM-1 on surface of endothelial cells are also up-regulated and precipitate neutrophilic leucocytes moving to hepatic sinusoids. Oxygen-derived free radicals produced by these activated neutrophilic leucocytes cause lipid peroxidation of cells. Moreover, toxic mediators (PAF, NO, ET-1 etc) released from KCs enhance further liver injury and make platelets aggregated into microthrombi. Hepatic sinusoids being blocked by adhering neutrophilic leucocytes, Platelets and swelling KCs induce slowing of blood flow with following hypoxia. The onset of liver necrosis in this situation is ascribed mainly to abnormal microcirculation. Therefore, liver damage is an overall outcome that is induced by the interactions between inherent KCs, immigranting neutrophilic leucocytes and hepatocytes[3].

Additionally, it shoud be mentioned that LPS not only induces liver necrosis directly or indirectly by chemical mediators released from activated KDs, but also is a promoting factor for other hepatotoxicants (such as D-galactosamine, tetrachloride [CCl_4],ethanol, etc) to induce liver necrosis. The

use of anti-LPS antibody can significantly attenuate liver necrosis induced by hepatotoxicants and prevent from the occurrence of acute liver failure[4].

There are still some arguments on whether or not LPS directly injures hepatocytes at present. It is reported that there is high content of lipoid (phospholipid mainly) in the membrane of hepatocellular mitochondria. The affinity of diphosphatidyl glycerol, which is the special component of the lipoid, with is the special component of the lipoid, with LPS is very strong. Its acyl group that binds to LPS induces the structural damage of mitochondria, interferes with biological oxidation, inhibits production of ATP and causes hepatocellular injury. LPS can directly insert into double layers of lipid molecule of membrane or conjugate to membrane receptors and initiate the metabolism of membrane phosphatidyl inositol. Large quantities of phosphatidic acid (PA) and inositol triphosphate (IP_3) are produced. Degeneration and necrosis of hepatocytes are induced by elevated Ca^{2+} in cytoplasm, which is resulted from PA with Ca^{2+} carrier-like action and IP_3 which causes the opening of Ca^{2+} channel in membrane, with great deal of Ca^{2+} flowing the cell. Structural and functional injuries of hepatocytes and mitochondria can also be caused by degradation of membrane phospholipid and lipid peroxidation mediated by PLA_2 activation induced by LPS. LPS phagocytosed by KCs can damage the membrane of lysosome and lead to release of various lysosomal enzymes resulting in cell autolysis.

To explore LPS directly acting on hepatocytes *in vitro*, we found that hepatocytes showed typical ladder pattern of apoptotic cells morphologically and this process could be inhibited by apoptotic inhibitor ATA. The number of apoptotic hepatocytes was proportional with the dosage of LPS; the number of apoptotic hepatocytes treated with LPS within 24 hours was also in positive ratio with time. It implicated that LPS could directly induce apoptosis of hepatocytes and this action was more prominent at the early phase of treatment[5].

The interaction of LPS with KCs plays a determinant role during the occurance of liver injury and acute liver failure. It was confirmed in a large number of animal experiments that liver injury induced by CCl_4, D-galactosamine, thioacetamide (TAA), ethanol, etc. could be reduced or prevented by performing colectomy or administering antibiotics (such as polymyxin B, mycifradin) to decrease the level of intestinal LPS, or by administering gadolinium chloride ($GdCl_3$), silica (SiO_2)to block KCs.

The research performed by Ahmad et al. indicated that there was high expression of ICAM-1 on hepatocytes, KCs, endothelial cells during acute endotoxemia; there was no expression of ICAM-1 on hepatocytes and KCs when KCs were blocked by $GdCl_3$; there is no occurrence of TNF-α and LTB_4, which is released from KCs activated by LPS, attracting neutrophilic leucocytes to infiltrtate into liver. These results implicated that KCs played a vital role in hepatitis and liver injury induced by LPS[6].

Many researches suggested that ethanol can increase permeability of intestinal mucosa, macromolecules such as LPS were intaken into blood and the plasma level of LPS thus rose up. While phagocytosing LPS, KCs released chemical mediators such as TNF-α, PGE_2 to promote oxidation of alcohol in the liver. Owing to increased oxygen consumpsion, hepatocytes was injured by free radicals formed in the state of hypoxia. Experiments verified that the level of plasma LPS in alcoholism animals was significantly correlated with hepatic pathological change (cellular steatosis and necrosis, inflammatory infiltration); the steatosis and necrosis of liver induced by alcohol could be prevented by administering $GdCl_3$ to block KCs[7].

D-galactosamine can induce focal necrosis of whole hepatic lobule with severe infiltration of neutrophlic leucocytes, but liver injury can be thoroughly prevented by $GdCl_3$ injection in caudal vein before D-galactosamine injection intraperitoneally in rats. Liver injury and apoptosis induced by D-galactosamine and small dose of LPS can be markedly alleviated via treatment with TNF-α antiserum, so did alcoholic liver injury. Because TNF-α was mainly stemmed from activated KCs, the key role of KCs played in the liver injury was thus certified[8,9].

In summary, previous researches on mechanism of liver injury were mostly confined to parenchymal liver cells, whereas large amount of current experiments have demonstrated that activation of KC by LPS plays a more important role in the occurance and development of liver injury.

Based upon the above-mentioned understanding we have conceived the following hypothesis on liver injury induced by various pathogenic factors and the development and prognosis of hepatitis (Figure 1)

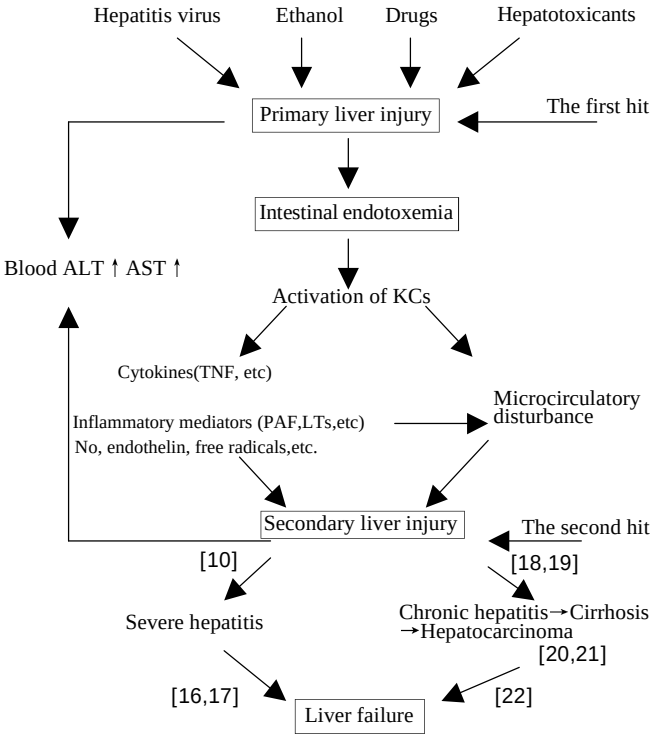

Figure 1 Diagram of the hypothesis of IETM in liver failure

The "primary liver injury (PLI)" is the hepatic damage that various pathogenic factors (such as hepatitis virus, alcohol, drugs, hepatotoxicants, etc.)induced by specific mechanism separately. In contrast, IETM is formed in the course of the development of hepatitis. Liver injury, which is resulted from LPS, activation of KCs by LPS and others, is refered to as "secondary liver injury (SLI)" The SLI which has lost their own specificities of primary pathogenic factors is ascribed to IETM.

The SLI has an important effect on the development and prognosis of various hepatitis. The severe IETM, which commonly causes over-inflammatory reaction and serious hepatic necrosis, will lead to severe hepatitis and even acute hepatic failure[10]. The mild IETM will successively precipitate a cascade, including the repeated and persistent hepatocellular injury accompanied by infiltration of in- flammatory cells,

hepatic fibrosis, cirrhosis and even hepatocarcinoma. Generally, it ends with chronic hepatic failure[11].

Certainly, the mechanism of occurrence and development of various viral hepatitis is not so simple but a considerably complicated issue related to virus itself, host immune state, etc. It is difficult to cover it by only one hypothesis.

PRIMARY LIVER INJURY

Hepatic damage induced by various pathogenic factors (such as hepatitis virus, alcohol, drugs, hepatotoxicants,etc) via specific mechanism separately is named the "primary liver injury (PLI)".

Hepatic damage resulted from various hepatitis virus is mainly ascribed to host immune reaction. Cytotoxic T lymphocytes (CTLs)attack hepatocytes with HbcAg, HLA-1 and ICAM-1. It results in lysis and apoptosis of a large amount on of hepatocytes. Drugs cause hepatic damage either by direct action, metabolic product or immune mechanism. Ethanol may give rise to be oxidative stress and direct necrosis of hepatocytes in alcoholic liver injury. The new antigen formed by the combination of lipid peroxide products, acetaldehyde (ethanol-derived metabolite) and protein triggers immunity reaction and makes CTLs to attack hepatocytes. TAA, a hepatotoxicant, is taken by liver then is metabolized into TAA-sulfoxide by cytochrome P_{450} mixed-function oxidase and further transformed into the intermediates and other polar molecules, which irreversibly combine with intrahepatic biomacromolecules to cause hepatic necrosis. Moreover, TAA also activates PLA_2 which can increase lysolecithin and destray hepatocellular membrane. CCl_4 is biotransformed into active trichloromethyl free radical by intrahepatocellular cytochrome P_{450}, which may lead to lipid peroxide and injury of cell membrane. In brief, various pathogenic factors may all induce the liver damage by their own mechanism respectively.

IETM INDUCED BY KCs WITH PHAGOCYTIC DYSFUNCTION

When PLI is present, the structural and functional injuries of KCs occur at the same time with injuries of hepatic parenchymal cells. Our research indicated that mitochondria swelled, decreased and phagocytosis of KCs was markedly weakened during acute hepatic failure resulted from galactosamine or TAA. Other researchers observed KCs injury under electronmicroscopy at the first hour and almost all cells were necrotic at about the second hour after exposure to a lethal dose of ranine virus. The damage of hepatic parenchymal cells emerged at the fourteenth hour under the same circumstance. The function of mononuclear phagocyte system was inhibited in mice vaccinated with sub-lethal dose of ranine virus within 24 hours in other reports[10].

Because of the serious destruction of tissues in severe hepatitis, KCs are overburdened in that they not only must phagocytize virus and immune complexes, but also remove cellular debris and other foreign bodies. Thus, the function of phagocytosis and elimination of endotoxin by KCs were impaired badly.

In physiological condition, the powerful phagocytosis of KCs require the help of nonspecific opsonin (such as fibronectin, Fn). In acute hepatic failure, the level of plasma Fn showed a significantly reduction due to the decline or loss of function that Fn is synthesized and secreted by hepatocytes. Experimental results revealed that there was a positive correlation between the decrease of Fn and phagocytosis of KCs[1]. In conclusion, IETM is further aggravated by the impaired phagocytosis of KCs after "Primary liver injury".

SECONDARY LIVER INJURY

The SLI refers to the liver damage mediated by a battery of chemical mediators that were synthesized and released from KCs activated through IETM induced by PLI.

The SLI has been confirmed in a large number of animal experiments and clinical studies. First, In rats colectomized before administration of TAA, the level of plasmic endotoxin had no statistical difference from that in control group, the content of TNF-α was markedly lower and plasmic ALT activity was only one fifth of that in TAA group. Our findings indicated that severity of PLI induced by TAA was only one fifth of that by SLI[12].Second, it has been demonstrated in our extensive experiments that either inhibiting the function of KCs($GdCl_3$ and SiO_2) or lightening IETM can attenuate the release of chemical mediators from KC and subsequent hepatic injury[10]. Third, it has been reported from plenty of domestic and foreign clinical data that there are a battery of chemical mediators, which were released by activated KC in plasma of patients with various hepatitis(derived from virus, alcohol etc.) and hepatic diseases (such as posthepatitic cirrhosis) in variable degrees, correspondingly brought about sorts of clinical signs and symptoms[13]. The "second liver injury" makes a great impact on the development and prognosis of hepatitis.

Severe hepatitis

The plasma endotoxin level in patients with severe hepatitis was approximately five to eighttimes that of the normal person. The higher the level of endotoxin was, the severer the hepatitis would be. These data suggested that IETM had a great impact on the progress of hepatitis. KCs activated by LPS released a great deal of proinflammatory cytokines(TNF-α, IL-1, IL-6, etc.), lipid inflammatory mediators (LTs,PAF,TXA_2,etc.), NO, endothelin and oxygen-derived free radicals, which further amplified the inflammatory reaction. TNF-α, the most crucial proinflammatory cytokine of all, could mobilize neutrophilic leukocytes chemofactically into liver and initiated a series of reactions, i.e. respiratory burst, release of oxygen-derived free radical, lipid peroxide and hepatocellular necrosis . It also could induce considerable intercellular adhesion molecule-1(ICAM-1) expression on sinusoidal endothelia and hepatocytes and promote CTLs to attack hepatocytes and led to massive hepatocellular necrosis. It was reported that there was a significantly positive correlation between TNF-α level and ICAM-1 mRNA content. Whereas ICAM-1 level also showed a significantly accordant positive correlation with serum ALT activity, the degree of hepatic necrosis, the degree of neutrophilic leucocytes infiltration in liver tissues. 67 percent of the necrotic area will be decreased if pretreated with anti-ICAM-1 antibody. These findings demonstrated that ICAM-1 played a vital role during the transformation of severe hepatitis into acute liver failure[6].

Liu *et al*[14]. have observed that endotoxin-induced liver injury predominantly accounted for severe microcirculatory disturbance of liver. The response of hepatic microvasculum to LPS was directly related to the quantity and activated degree of KCs. The stronger the activated degree of KC was, the severer the hepatic microcirculatory disorder was. The histological observation showed that there was a large number of filiform ball microthrombi within hepatic sinusoids and micrangiums. The hemagglutination and the adhesion of activated leukocytes to vascular endothelium in sinusoids were observed too. The area of hepatic necrosis reached beyond 50 percent. The activity of plasmic ALT was significantly elevated. Obviously, the microcirculatory disturbance induced by LPS is predominantly responsible for hepatic persistent

necrosis and the further development of acute liver failure.

Ren *et al*[15]. used intoxication by TAA to duplicate rat model of severe hepatitis. The results indicated that in the TAA group, the level of plasmic endotoxin and the serum ALT activity were all significantly higher than those in the control group, the arterial ketone body ratio of acetoacetate to β-hydroxybutyrate(AKBR) decreased below 0.4, the ATP content of hepatocellular mitochondria was notably lower. While in the TAA plus colectomy group, there was no endotoxemia, the ATP content of hepatocellular mitochondria was sharply higher than that in the TAA group, but the serum ALT activity significantly lower than that in the TAA group. Thus, we might conclude that IETM played a key role in the occurrence of acute liver failure, the metabolic imbalance and dysfunction of liver might be caused by IETM through damaging hepatic energy metabolism.

We further investigated the role that functional state of KCs played in the occurrence of acute liver failure. The findings suggested that though a large single dose of CCL_4 could induce severe injury of hepatic parenchymal cells, no liver failure occurred in rats, because the structure and function of KCs were not affected. At the twenty fourth hour after intragastric infusion of rats, the granular turbid fluid of silica (18 μg/100 g B.W.)was injected into caudal vein the level of plasma endotoxin was remarkably increasd due to inbibition of KCs. 0At the twenty seventh hour urine volume, excretion of urea nitrogen and creatinine dcereused markedly, with marked inerease of blood urea nitrogen and creatinine indicating renal failure. Obvious lethargic phenomenon in rats with electroencephalograph (EEG) showing specific triphasic wave of the early stage of hepatic coma was observed at the 36th hour. EEG presented large and slow alternative wave after 40th hour. These findings suggested hepatic coma had occurred in rats. All these results demonstrated that although there was not significant change in parenchymal liver cells, rats experienced hepatic failure quickly, presenting as renal failure and coma in comparision with rats intragastrically infused with CCl_4 but without treatment with SiO_2[16]. Similar results could be observesd in the model of fulminant hepatic failure induced by TAA. In rats intragastrically infused with TAA but preceded by injection of SiO_2 in caudal vein, hepatic failure occurred rapidly. There was no significant difference in the injury extent of hepatic parenchymal cells as compared with rats without pretreatment with SiO_2. These findings demonstrated that IETM induced by KCs dysfunction played a determinative role in promoting hepatic insufficiency to develop into hepatic failure[17].

Chronicity of hepatitis (acute hepatitis →chronic hepatitis → hepatic fibrosis → cirrhosis of liver →hepatocarcinoma or hepatic failure)

In the presence of persistent and mild IETM, repeated and sustained hepatocellular injury and concomitant inflammatory cell infiltration frequently develops and transforming growth factor β (TGF-β) controls the repairment of liver tissues via restricting the regeneration of hepatocytes and increasing extracellular matrix (ECM). Long-term injection of CCl_4 in small dose or oral intake of TAA in low concentration can cause chronic mild IETM with continous expression of TGF-β in the experiment rats which successively result in hepatic fibrosis, micronodular cirrhosis then hepatocarcinogenesis in part and hepatic failure often resulted from some inducing factors within 2-6 months.

Jia *et al*. had established rat model of hepatic fibrosis induced by compound factor(CCL_4 mainly). Liver tissues were characterized by steatosis and necrosis attended by inflammatory infiltration within 1-2 weeks. Then hepatic fibrotic proliferation developed within 3-4 weeks. Hepatic fibrosis continuosly became aggravated, pseudulobuli were formed and hepatocirrhosis eventually developed within 5-8weeks. In the meanwhile, IETM became increasingly serious and the level of plasma endotoxin rose gradually, which was positively correlated with the amount of hepatic collagen. It was indicated through immunohisto chemical location that TNF-α was involved in the liver fibrosis mediated by endotoxin. By ultrastructural observation, the phenotype transformation of fat-storing cells suggested that functional state of fat-storing cells was closely related to endotoxin in the development of hepatic fibrosis[18].Cirrhosis which developed in rats drinking 0.03 % TAA for four months was accompanied by IETM with higher plasma levels of TNF-α, endothelin, NO, MDA, and hepatic collagen contents simultaneously in experiment performed by Zhao *et al*[19]. Under electronmicroscopy, fat-storing cell nucleus showed the shape of star, cytoplasm projected outwardly, fat drop in cytoplasma diminished, its morphology was gradually transformed into that of myofibroblast. Collagen fibres apparently were increased around cell body. It was demonstrated by animal experiments that endotoxin could aggravate proliferation of hepatic fibers that developed into cirrhosis.

In the experiment by Yang *et al*[20,21]. 41.7 percent of rats drinking 0.03 % TAA for 6 months developed hepatocarcinoma on the basis of cirrhosis with elevation of endotoxin. Endotoxin could increase both overexpressions of bcl-2, P53 protein and point mutation of N-ras, P53 genes; increase the generation of free radicals and reduce antioxidase activity with aggravation of injury of DNA. These results provided evidences that endotoxin could precipitate cancerous change induced by TAA.

In above experiments, drugs against intestinal endotoximia (such as herbal mixture "shuang Li Gan")could alleviate cirrohsis, and bring about decreased incidence of hepatocarcinoma. It was demonstrated again that prevention and treatment of IETM could stop the prooress of hepatitis into chronicity.

Li *et al* have found that rats with cirrhosis became wilted somnolent and comatous and showed typical EEG changes at the fourth hour after a small dose of endotoxin injected once intraperitoneally. These manifestations suggested that hepatic encephalopathy (HE) had occurred in rats with cirrhosis. At this time blood ammonia level was elevated more than twice and plasma glucagons elevated more than ten times of that in normal rats. Glutamine contents of plasma and cerebrum were obviously higher than that in the cirrhotic control group. There were significant positive correlations between the levels of plasma endotoxin and plasma glucagon or ammonia, between the level of plasma ammonia and that of glutamine in cerebral homogenate. Apart from these, the contents of 5-hydroxytryptamin(5-HT),free tryptophan and 5-hydroxyindole acetic acid were all increased, whereas the contents of noradrenaline and dopamine were reduced in cerebral cortex.

It was exhibited from ultrastructural analysis that cellular swell and the diminished number of organellesin astrocytes of cerebral cortex markedly appeared in rats with HE induced by endotoxin. Immunohistochemical staining of TNF-α indicated that there was positive staining on endothelial cells of intracephalic micrangium and some astrocytes of cerebral cortex.

Based on the above results, HE in rats with cirrohsis induced by endotoxin might be associated with sharp rise of plasma glucagons and subsequent rise of blood ammonia. Owing to the high level of blood ammonia, a great deal of

ammonia accumulated in cerebra and were transformed into glutamine under the action of glutamine synthetase of astrocytes. A great amount of glutamine was excreted from cerebra via blood-brain barriers (BBB) and resulted in a great amount of neutral amino acids transported into cerebra through the mechanism of carriers exchange. Great quantities of aromatic amino acids might inhibit tyrosine hydroxylase, and keep aromatic aminoacids (phenylalanine, tyrosine) from synthesizing true neurotransmitter-noradrenaline and dopamine, but transformed into false neurotransmitter. Besides, trytophan entering into the cerebra might form 5-HT under the action of corresponding enzyme. Thus, decreased true neurotransmitter with a coexisting increased inhibitory and(or) false neurotransmitter led to the functional inhibition of central nervous system followed by HE[22].

In summary, if PLI caused by various pathogenic factors through their independent specific mechanism is regarded as "the first hit" on liver, then SLI mediated by different chemical mediators from KCs activated by IETM in the course of hepatitis is "the second hit" on liver. Thus fusing and overlapping of the primary and secondary liver injuries determine and influence the complexity of the illness and outcome of the patient with hepatitis.

For this reason, the viewpoint of "secondary liver injury" induced by "the second hit" on liver inflicted by IETM suggests that medical professionals should attach great importance to both "primary liver injury", and "secondary liver injury" caused by IETM. That is, try to adjust the function of KCs and eliminate endotoxemia of the patient. Thus, it is beneficial in the short term to the cure of hepatitis and prevention from developing to severe hepatitis. it facilitates blocking the risk of development from hepatitis to cirrhosis and hepatocarcinoma in the long term. So the defence line against liver failure should be constructed through clearing IETM.

Abstract

AIM: Esophageal carcinoma is one of the most common malignant tumors in China. But the molecular mechanisms of esophageal carcinoma remains unclear. Gut-enriched Krüppel-like factor (GKLF) is a newly identified transcription factor which is expressed abandantly in the epithelial cells of the gastrointestinal tract and deregulation of GKLF was linked to several types of cancer. It is of interest to study the expression and role of GKLF in esophageal carcinoma.

METHODS: Semi-quantitative RT-PCR was used to compare GKLF expression in esophageal squamous cell carcinoma to normal mucosa of the same patients. The serum deprivation inducibility of GKLF was observed in an esophageal squamous cancer cell line by comparison to the primary culture of human fibroblast. The effect of antisense GKLF transfection on the proliferation and adhesion of esophageal squamous cancer cell line was also observed.

RESULTS: The level of GKLF transcript is lower in esophageal squamous cell carcinoma compared to paired normal-appearing mucosa in 14 of 17 of the tumors analyzed. The serum deprivation inducibility of GKLF was greatly decreased in an esophageal squamous cancer cell line compared to the primary culture of human fibroblast. Decreased expression of GKLF in the esophageal cancer cell by antisense GKLF transfection increased its proliferation rate compared with that of vector transfected cell control ($P<0.05$). Transfection of antisense GKLF decreased its adhesion ability ($P<0.05$).

CONCLUSION: The findings of this study demonstrate the down-regulation of GKLF in esophageal squamous cancer, and suggest that deregulation of GKLF may play a role in initiation and/or progression as well as the metastasis of esophageal squamous cancer.

Wang N, Liu ZH, Ding F, Wang XQ, Zhou CN, Wu M. Down-regulation of gut-enriched Krüppel-like factor expression in esophageal cancer. *World J Gastroenterol* 2002; 8(6):966-970

INTRODUCTION

The gut-enriched Krüppel-like factor (GKLF), also named as epithelial zinc finger (EZF) or KLF4, is a recently identified transcription factor with three C_2H_2 zinc fingers in the carboxyl terminus[1-3]. The expression of GKLF is enriched in the epithelial cells of the gastrointestinal tract and skin[1,2]. Although the physiological role of GKLF is not clear, experimental evidences[1] suggest that GKLF is potentially a negative regulator of cell proliferation and involves in the differentiation process of epithelial cells. In the gene targeting experiment[4], GKLF knockout mice showed the impairment of skin barrier function, indicating that GKLF is both vital to and selective for the barrier acquisition.

GKLF expression is decreased in the intestinal adenomas of mice and colon adenomas of patients[5,6]. Experimental data[7] also suggest that down-regulation of GKLF may play a role in the initiation stage of tumorigenesis of colon. In oral dysplastic epithelium and squamous cell carcinoma, GKLF expression was increased and diffusely distributed[8,9]. In breast cancer, GKLF expression was increased and associated with the stages of tumor progression in the breast[9]. These observations indicated that GKLF expression is regulated during neoplastic progression in a tissue and tumor type-specific fashion.

GKLF expression was enriched in esophageal epithelia[2]. In esophageal cancer cell lines, abundant GKLF expression was also observed[10,11]. The regulating effect of GKLF on the squamous epithelium-specific keratin 4 and Epstein-Barr virus ED-L2 promoters[10] suggests GKLF plays an important role in the differentiation of esophageal squamous epithelium. The human GKLF gene was mapped onto chromosome 9q31[3], which is a hot site of chromosome abnormality in esophageal cancer[12,13]. GKLF gene aberration was observed in colon cancer in which the function of GKLF was demolished[14]. These evidences led us to the research on the expression of GKLF in esophageal cancer, and consequent effect on the cancer cells. To our knowledge, this is the first report on the down-regulation of GKLF in esophageal cancer, and the first evidence of association of GKLF function with cell adhesion ability.

MATERIALS AND METHODS

Tissue samples and cell culture

Fresh surgical specimens of 17 pairs of esophageal squamous cell carcinoma and corresponding normal tissues were immediately frozen and stored in liquid nitrogen after resection. Squamous esophageal cancer cell line EC9706 was kindly provided by Dr. Mingrong Wang in the lab. The cell was grown in M199 (Gibco BRL, Gaithersburg, MD) supplemented with 15 % FCS. Primary culture of fibroblast was derived from resected normal esophageal tissue of an esophageal cancer patient, and maintained in McCoy 5A (Gibco BRL, Gaithersburg, MD) supplemented with 10 % FBS. Cells were incubated at 37 ℃ with 5 % CO_2. For the serum deprivation experiments, cells were seeded into 25 ml flasks with 4 ml full medium and cultured until 50 % confluency. The content of

FCS in the cell media was reduced to 0.5 %. Cells were then incubated continuously at 37 ℃,in 5 % CO_2 for various periods.

RNA preparation and RT-PCR

Total RNA was extracted by TRIzol method (Gibco BRL, Gaithersburg, MD). Up to 5 μg of total RNA was reverse transcripted in 20 μl volume of reaction with both oligo (dT) and random primers, using SuperScript Preamplification System (Gibco BRL, Gaithersburg, MD) according to the instruction.

PCR was carried out in 30 μl total reaction mixture which contains 10 mmol/L Tris-HCL, pH 8.3, 50 mmol/L KCL, 1.75 mmol/L $MgCl_2$,0.1 % Triton X-100, 200 μmol/L each of dGTP, dATP, dTTP, and dCTP, and 200 nmol/L each of the forward and reverse primers; 0.5-2 μl of cDNA template after RNase-free DNase I digestion was added. The primers used in the PCR reaction were synthesized according to the published cDNA sequences encoding human GKLF and GAPDH (GeneBank Accession numbers AF105036 and NM_002046, respectively). For the measurement of GKLF mRNA expression in tissue and cell samples, forward primer 5'-GTC GGA CCA CCT CGC CTT ACA CAT-3' and reverse primer 5'-GGT CTT CCC TCC CCC AAC TCA CG-3' of GKLF were used which amplify the region containing 3' noncoding sequence of GKLF cDNA (+1 374 to +1 749) and the expected PCR product was 376 bp; For the measurement of GKLF mRNA expression in cells after transfection of GKLF cDNA, forward primer 5'-CCA CCG GCC GGC TGC ACA CGA CT-3' and reverse primer 5'-TCA TCT GAG CGG GCG AAT TTC CAT CCA CA-3' of GKLF were used which amplify the coding sequence of GKLF cDNA (+864 to +1 298) and the expected PCR product was 435 bp. GAPDH primers (forward primer 5'-GGC AAA TTC CAT GGC ACC GTC AAG-3' and reverse primer 5'-GCA ATG CCA GCC CCA GCG TCA AA-3') were added in the same PCR reaction, and the expected PCR product of 746 bp was used as internal control. PCR was set up for 27 cycles: 30 s at 94 ℃, 30 s at 56 ℃ 45 s at 72 ℃.

GKLF cDNA cloning and sequencing

The full length GKLF cDNA coding sequence was amplified from reverse transcripted cDNA of EC9706. The forward primer 5'-CTG CTT CGG GCT GCC GAG GAC CTT CTG GG-3' and reverse primer 5'-GGC AGT GTG GGT CAT ATC CAC TGT CTG GGA-3' of GKLF were used and the expected PCR product was 1511 bp (-67 to +1444 nucleotides). The cycling condition was 30 s at 94 ℃, 30 s at 63 ℃ 1 min at 72 ℃ for 30 cycles. The PCR product was electrophoresed onto 0.9 % agarose and 1.5 kb fragment was purified with the purification system (Qiagen, Hilden, Germany). The fragment was then cloned into PCR cloning vector pMD18T (TaKaRa, Dalian, China) and sequenced commercially (TaKaRa, Dalian, China).

Transfection

DNA fragment containing GKLF cDNA (-67 to +1444 nucleotides) was cut out from pMD18T vector by *BamH*I and *Hind*III digestion and subcloned into pCDNA3.1 expression vector (Invitrogen, San Diego, CA) in antisense orientation. EC9706 cells were transfected with antisense GKLF cDNA as well as pCDNA3.1 vector using the Lipofectamine method according to the manufacture's protocol (Gibco BRL, Gaithersburg, MD). Briefly, cells were incubated with 1 ml of the transfection mixture containing 4.0 μg plasmid DNA and 25 μl Lipofectamine reagents in serum-free medium for 6 h, followed by adding 1 ml fresh media supplemented with 30 % FCS. The medium was exchanged with fresh complete media after overnight incubation.

RNA content determination

For semi-quantification of GKLF mRNA expression, the PCR products were electrophoresed onto 1.2 % agarose gel containing ethidium bromide. The images were analyzed with Multi-Analyst software (Bio-Rad, Hercules, CA) after scanned and the densities of GKLF and GAPDH bands were determined. The ratios of GKLF to GAPDH were compared in each paired sample.

Cell proliferation assay

Cells were inoculated into 96 well plates (2000/well) 36 h after transfection and incubated for further 24 h at 37 ℃ in CO_2 incubator. CellTiter 96 AQuous One Reagent (Promega, Madison, WI) was added into each well and OD490 was measured according to manufacture' s method. The cells were washed three times with PBS and incubated in complete media for another 24 h. The assay was repeated and the ratio of OD490 to that of the first assay was calculated as the relative cell proliferate rate.

Cell adhesion assay

Cells were detached from culture flasks by trypsinisation 48 h after transfection and inoculated into 96 well plates (5000/well). After 2 h incubation, unattached cells were then removed by washing 3 times with PBS. CellTiter 96 AQuous One Reagent was added into each well and OD490 was measured. The percentage adhesion was determined by comparing the OD490 of attached cells to that of corresponding cells without washing.

Statistics

Results are expressed as mean ±S.E.M. The statistical significance was determined with paired or grouped *t*-test.

RESULTS

GKLF expression in esophageal cancer

The GKLF mRNA expression was determined semi-quantitively using RT-PCR method. In 17 pairs of tissue specimens, GKLF expression was detected in all samples as an expected PCR product of 376 bp in length, and 14 of them showed decreased expression in cancer sample compared to corresponding normal tissue. Paired *t*-test has a significant difference ($P<0.05$) between cancer sample and normal tissue. Representative cases of GKLF expression detected by RT-PCR are shown in Figure 1.

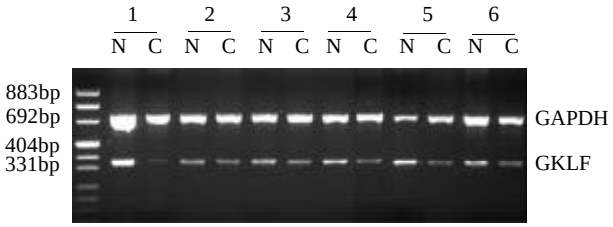

Figure 1 Semi-quantitative RT-PCR of GKLF in esophageal squamous cancer patients. RNA from specimens of normal appearing mucosa (N) and cancer (C) were extracted and GKLF as well as GAPDH were amplified. This figure showed the representative results from several individual patients.

GKLF cDNA coding sequence

GKLF gene resides at 9q31 of human genome[3], which is a frequent site of LOH in esophageal cancer[15,16]. Gene mutation

of GKLF coding sequence was also reported in a colon cancer cell line[14]. In this Laboratory, the genomic alterations were observed in squamous esophageal cancer cell line EC9706 which includes 9q region by comparative genomic hybridization (unpublished data). To find out if GKLF cDNA was mutated in esophageal cancer cell line EC9706, the full length cDNA of coding region of GKLF was amplified by RT-PCR from cDNA of EC9706. An 1.5 kb length of PCR product was detected as expected. The single band was cloned into pMD18T vector and sequenced. The sequence conformed to cDNA of GKLF (GeneBank Accession number AF105036) completely without any mutation.

Serum deprivation induction of GKLF

GKLF expression was induced in murine fibroblast by serum deprivation[1]. As GKLF expression was down-regulated in esophageal squamous cell carcinoma, we were interested in observing the inducibility of GKLF expression in esophageal cancer by serum deprivation. The cell line EC9706 was serum deprived and GKLF mRNA expression was detected by RT-PCR at 0 h, 6 h, 1 d, 2 d and 3 d. A primary culture of human fibroblast was also serum deprived as a positive control. Figure 2 showed the inducibility of GKLF by serum deprivation in both EC9706 and fibroblast. Although GKLF was induced in EC9706, the level was greatly decreased compared to that in human fibroblast.

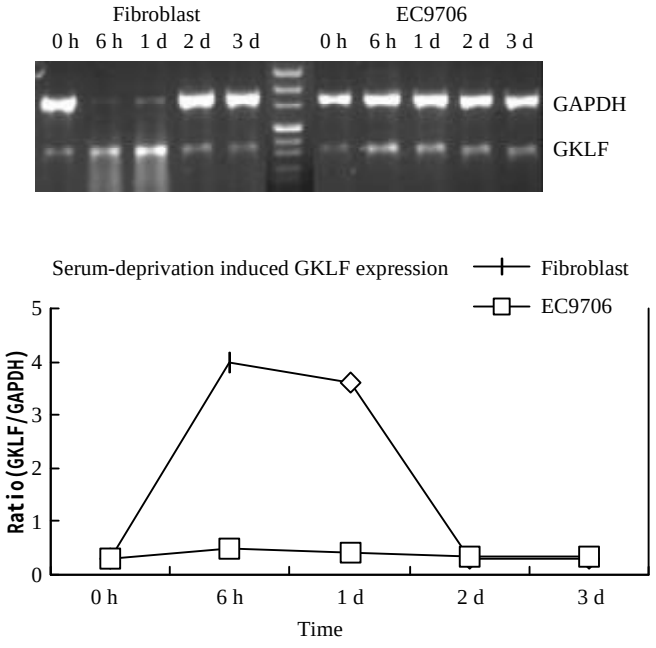

Figure 2 Serum deprivation induced GKLF expression. Both human primary cultured fibroblast and an esophageal squamous cancer cell line EC9706 was underwent serum deprivation. GKLF expression was measured semi-quantitively by RT-PCR. The magnitude of GKLF expression was calculated as ratio of GKLF to GAPDH.

Cell growth and adhesion properties in esophageal cancer cells with low GKLF expression

It was reported that forced overexpression of GKLF inhibited DNA synthesis[1] and decreased cell proliferation[17]. We transiently transfected the esophageal cancer cell line EC9706 with antisense GKLF expression vector, which caused low expression of GKLF in the transfected cells (shown in Figure 3). The cell proliferative rate was assayed as described above. Compared to the controlled cells, the low GKLF expression cells grew at a greater rate with a significant difference (P<0.05). As we noticed that cell adhesion ability changed in individual stable transfectants of EC9706 with GKLF expression vectors (data not shown), cell adhesion assay was also carried out in these transiently transfected cells with low GKLF expression. In these cells, the adhesion ability was decreased significantly compared to the controlled cells (P<0.05) (Figure 3).

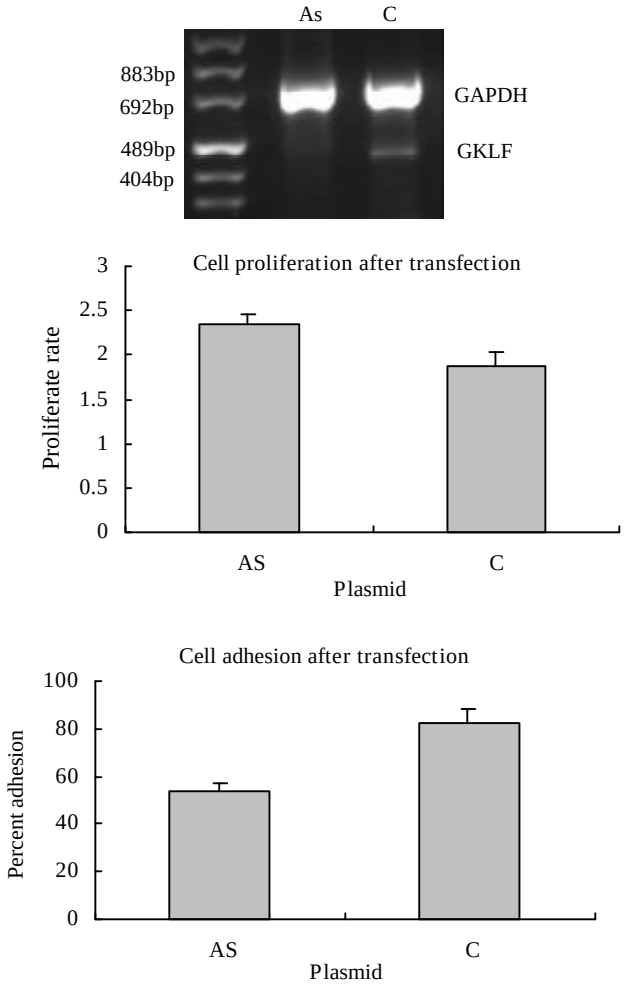

Figure 3 Cell growth and adhesion in GKLF transfected EC9706 cells. The cells were transiently transfected with antisense GKLF expression plasmid (AS) and pCDNA3.1 as control (C). The GKLF expression levels detected by RT-PCR were shown in the upper panel. The cell growth rates were shown in the middle panel; each data point represents mean ±S.E.M. of 7 repeats; there was a significant difference between AS and C (P<0.05). The cell adhesions were shown in the lower panel; each data point represents mean ±S.E.M. of 4 repeats; AS had significant difference compared to C (P<0.05).

DISCUSSION

Alterations of GKLF expression in cancer cells are tissue and tumor type-specific. Our current findings showed that GKLF was down-regulated in esophageal squamous cell carcinoma. It is known that down-regulation of GKLF occurred in intestinal adenoma and colonic adenoma[6] while up-regulation of GKLF occurred in breast carcinomas and oral squamous cell carcinoma[9]. The mechanism of altered GKLF expression and its difference among different tumor type is not clear yet. The results from colon cancer cells[6] showed that no involvement of DNA methylation in the down-regulation of GKLF, while

mutated CDX2 expression in some colon cancer cell lines may help to explain the low levels of GKLF expression[18].

Serum deprivation induces growth arrest and apoptosis in normal cells while the inducibility of serum deprivation is usually decreased in cancer cells. Experimental evidence showed that p21[19] and cyclin D1[20] involved in the serum deprivation induces growth arrest and apoptosis. In some kind of cancer cells, serum deprivation did not induce the expression of p21[21]. As a transcription factor, GKLF involves in the p53-p21 regulating pathway[22]. It also regulates the cell cycle factors such as cyclin D1[23]. Decreased inducibility of GKLF by serum deprivation in EC9706 cells may suggest a role of GKLF in decreased response of cancer cells to serum deprivation.

GKLF overexpression inhibits proliferation of NIH3T3 and of HT-29 colon cancer cells[1,7]. Similar to the report[7], we found that antisense expression of GKLF promotes cellular proliferation of EC9706 cells. Combined with the finding that GKLF was down-regulated in esophageal cancer tissues, the result suggested that GKLF might play a role in the initiation and/or progression of esophageal cancer. It was shown that GKLF exerted its effect on cell proliferation at G_1 phase of cell cycle[7,24]. That GKLF mediates the p53-p21 regulating pathway[22] could be a mechanism of its cell cycle effect as this pathway is important for the regulation of G1/S transition[25]. Cyclin D1-RB pathway is another possible effecting pathway of GKLF for its cell cycle regulation, since GKLF directly down-regulates cyclin D1 expression[23] while cyclin D1 facilitates progression through the G1 phase which plays a role in the initiation of esophageal cancer[26]. Overexpression of cyclin D1 was observed in the early phase of esophageal tumors in zinc-deficient rat model[27], suggesting an important role of zinc proteins in regulating cyclin D1 expression, and conforming to our proposition that down-regulation of GKLF plays a role in the initiation and/or progression of esophageal cancer.

The basic mechanism of tumour cell metastasis is reduced expression of adhesion molecules which results in an increased migratory ability of the cancer cells[28]. We showed here that alteration of GKLF expression in EC9706 cell decreased its adhesion, implicating that GKLF involves in the metastasis of esophageal cancer. Abnormal expression of such cell adhesion molecules as cadherin, integrin and mucin has definite relationship with cancer metastasis[29-31]. It is known that GKLF could regulate MUC5B gene transcription directly[32]. GKLF also regulates laminin expression[33,34] while laminin is a component of extracellular matrix which plays a key role in cell adhesion and migration. More frequent allelic loss at 9q region where the GKLF gene located was reported in esophageal squamous cell carcinoma patients with metastasis[15], suggesting a clinically significant role of GKLF gene in esophageal cancer.

GKLF belongs to a family of Krüppel-like factors that is the most abundant transcription factors in human cells[35]. It targets to the specific DNA sequence[36] which represents one of the most abundant classes of conserved motifs of intergenic regions over the human genome[37], besides to the common DNA sequences through which this family of factors binds and acts[36,38]. More and more target genes are being discovered[39,40], that will expedite our understandings of GKLF mediated action in both normal and malignant cells.

In summary, the results of this study showed that GKLF is down-regulated in esophageal squamous cell cacinoma, and GKLF deregulation in esophageal cancer cell line EC9706 sho wes a manner of decrease inducibility to serum deprivation. Furthermore, down-regulation of GKLF in EC9706 cells results in the proliferation and decreased adhesion of cancer cells, suggesting that down-regulation of GKLF may contribute to malignant phenotype of esophageal cancer.

Abstract

AIM: To study the expression of early growth response gene-1 (Egr-1 gene) and Bcl-X/$_L$ protein and its relationship with the cell apoptosis in human esophageal carcinoma(EC) and precancerous lesions.

METHODS: *In situ* hybridization(ISH), immunohistochemistry (IHC) and TUNEL method were used respectively to detect Egr-1mRNA,Egr-1 protein, apoptosis related-protein Bcl-X/$_L$ and cell apoptosis *in situ* from 66 cases of esophageal squamous cell carcinoma and their upper cut edge and paracancerous mucosa.

RESULTS: Egr-1 gene *in situ* hybridization, Bcl-X/$_L$ immunohistochemistry positive products were located in the cytoplasm, while Egr-1 immunohistochemistry and TUNEL positive signal were located in the nuclei. The apoptosis index(AI) and the frequency of apoptosis occurrence were increased gradually from precancerous lesion to cancer (P<0.01) and the expression of Egr-1mRNA and Egr-1 protein in dysplasia was the highest among all specimens (P<0.01). The AI of Egr-1 positive cancer tissues was much higher than that of Egr-1 negative cancer tissues (P<0.01), while the AI of Bcl-X/$_L$ positive cancer tissues was much lower than that of Bcl-X/$_L$ negative cancer tissues (P<0.01). The AI and Egr-1 expression were not correlated with invasiveness and lymphatic metastasis in EC.

CONCLUSION: Cell apoptosis was present through esophageal carcinogenesis. The expression of Egr-1 mRNA and Egr-1 protein were high in precancerous lesion of esophagus. The AI was increased significantly in Egr-1 positive squamous cell carcinoma. Egr-1 might promote apoptotic effect. Egr-1 expression and cell apoptosis may have an important biological significance in esophageal carcinogenesis.

INTRODUCTION

Esophageal carcinoma is one of the most common malignant tumors in China[1-5]. Its pathogenesis and development are closely related to the expression of some proto-oncogenes and their products and apoptosis of the cancer cells[6-19]. The expression of oncogenes and tumor suppressor genes in esophageal carcinoma has been studied; the relationship between Egr-1 and carcinoma has been reported as well[20]. Our previous studies have indicated that Egr-1 gene inhibited the growth of Eca109 after the exogenous introduction of Egr-1 gene[21]. But the relationship between expression of Egr-1 and cell apoptosis in esophageal carcinoma is not well understood so far. In this paper, we have performed the examination of Egr-1mRNA and Egr-1protein expression, apoptosis related-protein Bcl-X/$_L$ expression and cell apoptosis of the carcinoma tissue, upper cut edge mucosa and paracancerous lesions from 66 cases esophageal carcinoma using *In situ* hybridization, immunohistochemistry and terminal deoxynucleotidyl transferase (TdT)-mediated dUTP-digoxigenin nick end labeling method (TUNEL) respectively. The purpose is to understand the correlation of Egr-1 expression and cell apoptosis in esophageal carcinogenesis.

MATERIALS AND METHODS

Sample collecting and processing

Fresh esophagus specimens after operation including esophageal mucosa at the upper cut edge, cancer tissue and mucosa just adjacent to the tumor mass were taken from 66 patients of esophageal carcinomas who had not received accepted chemotherapy or radiotherapy before operation. All specimens were from Department of Pathology Shantou University Medical College, from January to December, 2000. The specimens were fixed in 40 mL/L neutral formalin; the slides were applied by 1/1 000 diethyl pyrocarbonate (DEPC, Sigma Chemical Co, USA), paraffin embedded, cut in 4 μm, HE stained.

Histopathology analysis

Histopathological diagnosis of esophageal para-cancer epithelia was made according to Liu *et al*'s criteria including 39 cases of normal epithelium, 52 cases of simple hyperplasia and 41 cases of dysplasia. 66 cases of esophageal carcinoma were diagnosed using WHO histological tumor classification including 2 cases of carcinoma *in situ*, 18 cases of grade I squamous cell carcinoma, 33 cases of grade II and 13 cases of grade III. 22 cases had invaded the superficial muscular layer, and others had invaded the serosa. 36 of 66 cases had lymphatic metastasis.

In situ hybridization

Eukaryotic expression vector of PCMV-Egr-1 plasmid was donated by Dr RP Huang (Molecular Medicine, Northwest Hospital, WA, USA). The plasmid was confirmed by amplification, purification and endonuclease cutting, then

retrieved the DNA. The expression of Egr-1 was detected by digoxigenin-labeled gene probe from a commercial kit (Boster company, China) according to the manufacturer's instructions. Sections were dewaxed in xylene, then into graduated ethanol, and then into 30 mL/L hydrogen peroxide methanol for 30 min. Proteinase K at 37 ℃ for 20 min in 20 μg/ml and then fixed in 40 g/L PFA for 10 min in sequence. 90 % ethanol 5 min at -20 ℃ precold, digoxigenin-labeled cDNA probe (1:40) were denatured in hybridization buffer at 95-100 ℃ for 10 min, then -20 ℃ for 3 min, added on tissues and cover slipped at 42 ℃ overnight. Sections were washed with SSC and then mouse anti-digoxigenin antibody, biotinylated goat anti-mouse and then streptavidin-biotin complex(SABC) for 30 min, finally, with 3.3′-diaminobenzidine (DAB) visualization. Human breast tissue and the mouse brain tissue were used as the positive control. Incubation solution instead of the probe and sections digested by RNase (10 μg/ml) before Egr-1 detection were designed for the negative control.

Immunohistochemistry

Egr-1 and Bcl-X_L were analyzed by using Egr-1(588): cat#SC-110 rabbit polyclonal antiserum (1:200,Santa Cruz Biot Co, USA) and Bcl-X_L(H-62): sc-7195 polyclonal antibody (ready to use) with the SABC method according to the manufacturer's instructions (Boster company, China), and finally DAB visualization. The human breast tissue and the esophageal carcinoma tissue were used as the positive control. Negative control was designed by using PBS instead of Egr-1 antiserum or instead of Bcl-X_L polyclonal antibody.

Detection of cell apoptosis

Apoptosis was detected by the TdT-mediated dUTP nick end labeling (TUNEL) method using a detection kit from Boster company (China) according to the manufacturer's instructions. Section were dewaxed in xylene, then into graduated ethanol, and then into Fresh 30 mL/L hydrogen peroxide in room temperature for 10 min, washed with PBS, digested by proteinase K(20 μg/ml) at 37 ℃ for 10 min, and incubated with TdT and DIG-dUTP reaction mixture at 37 ℃ for 2 h. Samples were washed with PBS, and then biotinylated mouse anti-digoxigenin antibody , and then streptavidin-biotin complex(SABC) at 37 ℃ for 30 min,and finally,with DAB visualization. The small intestine mucosa of mouse was used as the positive control. Negative control was designed by PBS instead of TdTase.

Judgement of the results

The Egr-1mRNA positive expression showed brown stained signal in the cytoplasm; the Egr-1 protein positive signal showed brown stained signal in the nucleus. Either Egr-1mRNA positive or Egr-1 protein positive was considered to be positive result. Bcl-X_L positive expression showed brown stained signal in the cytoplasm; the result was considered positive if the positive cells accounted for more than 20 % in each slide. The nuclei of apoptotic cells were stained brown as detected under light microscopy(Olympus CHK). Apoptotic cells were counted according to the Schepop's method. Ten optical fields which were the strongest positive areas were counted (×400, field diameter 0.545 mm, area 2.33 mm^2) and the vicinity of the necrotic areas were not evaluated in each slide. The apoptosis index (AI) was the average of positive cells per mm^2 in the slide.

Statistical analysis

Statistical significance was determined by χ^2 test or Student's *t* test.

RESULTS

Changes of cell apoptosis in esophageal precancerous lesions and cancer tissues

Apoptotic cells were observed in tissues with different lesions of esophageal epithelia and cancer tissues(Figure 1, 2). The AI and the frequency of apoptosis occurrence were low in the normal epithelia, but they were increased gradually from normal epithelia to dysplasia and to cancer tissues. The AI and the frequency of apoptosis occurrence of dysplasia lesions group was significantly higher than that of normal epithelia group (P<0.01, P<0.01, Table 1).

The relationship between the expressions of Egr-1mRNA and Egr-1 protein and cell apoptosis in esophageal precancerous lesion and cancer tissues

The expressions of Egr-1mRNA and Egr-1 protein were observed in the cytoplasm and nuclei in different lesions of esophageal epithelia and cancer lesions respectively (Figure 3). The positivity results of Egr-1 ISH and Egr-1 IHC were nearly identical, but ISH showed slightly higher. The AI and the rate of Egr-1 positivity were increased gradually from normal epithelia to simple hyperplasia and to dysplastia; the AI and the rate of Egr-1 positive expression of dysplasia lesions group was significant higher than that of normal epithelia group (P<0.01, P<0.01); the Egr-1 positivity rate of invasive carcinoma group was significant lower than that of dysplasia lesions group (P<0.01, Table 2).

The relationship between the protein expression of Bcl-X and cell apoptosis in esophageal precancerous lesions and cancer tissues

The expression of Bcl-X/$_L$ protein was observed in tissues with different lesion of esophageal epithelia and cancer tissues. The AI and Bcl-X/$_L$ immunostaining positivity rate were increased gradually as the lesion progressed. The AI and the rate of Bcl-X/$_L$ positive expression of dysplasia lesions group was significanly higher than that of normal epithelia group (P<0.01, P<0.01). In the Bcl-X/$_L$(+) cases (Figure 4) the AI was low, while in the Bcl-X/$_L$(-) cases had higher AI in the cancer tissues (P<0.01, Table 3).

The relationship between the expression of Egr-1 and cell apoptosis and biological behavior in esophageal squamous cell carcinoma

All Egr-1 positive cases were of keratinized squamous cell carcinoma (grade I,II). The AI and Egr-1 positivity rate of keratinized squamous cell carcinoma group were significantly higher than that of the non-keratinized squamous cell carcinoma group ($P<0.05$, $P<0.01$). In Bcl-$X/_L$ protein positive group, the AI and the Egr-1 positivity rate were lower significantly than those in Bcl-$X/_L$(-)group ($P<0.01$, $P<0.01$, Table 4).

DISCUSSION

Modern molecular biology investigations have indicated that proliferative inhibition of some neoplasm cells is related to apoptosis induction by the oncogene expression of these cells[22-28]. Apoptosis, or programmed cell death, is a process in which a genetic program is activated, may be positively or negatively modulated by several oncogenes and tumor suppressor genes. The cancerigenic course of esophageal carcinoma has been identified as a successive course from simple hyperplasia of basal cell, dysplasia, carcinoma *in situ* to invasive carcinoma. Our studies suggest that The AI and the frequency of apoptosis occurrence increased gradually in esophageal carcinogenesis.

Egr-1 is one of the immediate early gene family, the Egr-1 gene was localized in human chromosome 5q31.1. Egr-1 is a nuclear protein that contains three zinc-finger domains, which regulate the cellular growth and differentiation by activating Cyclin D1 to promote the cell from the G0/G1 phase into the G2/M phase[29]. It was reported[30,31] that Egr-1 was originally in dormancy, and would be activated by the induction of stress, ischemia, hypoxia, bacterial toxin, cell factors, ionizing radiation and some oncogenic factors through membrane depolarization. We have detected tissue series of esophageal carcinogenesis using *In situ* hybridization and immunohistochemistry, and found that the rate of Egr-1 positive expression in dysplasia was the highest among all specimens (65.9 %). This might be explained that the paracancerous mucosa is much more stimulated, and this is in accordance with that Egr-1 expression is activated by many factors. High expression of Egr-1 might preserve the stabilization of chromosome and suppress proliferation, and also improve differentiation and apoptosis of the cell. Egr-1 expression is decreased significantly from dysplasia to cancer tissues[32,33].

Recent studies have shown[34] that there are several genes which participate in apoptosis regulation. Apoptosis regulation genes are divided into two groups: existence gene and death gene. Living gene includes cell promoting gene, while death gene includes proliferation suppressing gene. Studies using diverse tumor cells suggest that endogenous levels of Egr-1 act to impede proliferation[21,29]. Consistent with its anti-tumor role, Egr-1 has been identified an important gene for impeding proliferation, and apoptosis of certain tumor cells needs Egr-1. Some studies indicated that the mechanism of Egr-1 inducing apoptosis might be involved by the activation of some oncogenes, e.g. wild type P53 gene, TNF-α and the concentration of calcium ions[35,36]. Another gene that implicates apoptotic pathway is bcl-2. Bcl-2 has been identified to be an apoptosis inhibitor. Recently, a new bcl-2 relayed gene Bcl-X was identified. Alternative splicing results in two bcl-X-derived mRNA species, called bcl-X_L and bcl-X_S. Bcl-X_L appears to have functions similar to Bcl-2 in that it is capable of suppressing cell apoptosis in cancer cells[37].

Abnormal hyperplasia and cell apoptosis of cancer cell are the dynamic process in the pathogenesis and development of esophageal carcinoma. Many studies indicated that cell hyperplastic cycle and cell apoptosis were two importance essential portions to maintain homostasis by many genes constituted complex modulation system. Our studies detected that cell apoptosis existed in normal epithelia and different lesion of esophagus, but AI and the frequency of apoptosis occurrence were increased gradually as the lesions progressed. In the similar lesions, the AI in Egr-1 positive group was higher than that in Egr-1 negative group. In contrast, the AI of Bcl-$X/_L$ positive group was lower than that of Bcl-$X/_L$ negative group. The AI and the expression of Egr-1 were not correlated with invasiveness and lymphatic metastasis of the cancer tissues. Our study suggests that cell apoptosis might be an important process in esophageal carcinogenesis. Egr-1 might promote apoptosis effect while Bcl-$X/_L$ inhibit it. But further study is necessary to explore the mechanism and significance of Egr-1 and Bcl-$X/_L$ improving or suppressing apoptosis in esophageal carcinogenesis.

Abstract

AIM: To investigate the progressive transformation of immortal cells of human fetal esophageal epithelium induced by human papillomavirus, and to examine biological criteria of sequential passage of cells, including cellular phenotype, proliferative rate, telomerase, chromosome and tumorigenicity.

METHODS: The SHEE cell series consisted of immortalized embryonic esophageal epithelium which was in malignant transformation when cultivated over sixty passages without co-carcinogens. Cells of the 10th, 31st, 60th and 85th passages were present in progressive development after being transfected with HPV. Cells were cultivated in a culture flask and 24-hole cultural plates. Progressive changes of morphology, cell growth, contact-inhibition, and anchorage-dependent growth characteristics were examined by phase contrast microscopy. The cell proliferation rate was assayed by flow cytometry. The modal number of chromosomes was analyzed. HPV18E_6E_7 was detected by Western blot methods and activities of telomerase were analyzed by TRAP. Tumorigenicity of cells was detected with soft agar plates cultivated and with tumor formation in SCID mice.

RESULTS: In morphological examination the 10th passage cells were in good differentiation, the 60th and 85th passages cells were in relatively poor differentiation, and the 31st passage cells had two distinct differentiations. The characteristics of the 85th and 60th passage cells were weakened at contact-inhibition and anchorage-dependent growth. Karyotypes of four stages of cells belonged to hyperdiploid or hypotriploid, and bimodal distribution of chromosomes appeared in the 31st and 60th passage cells. All of these characteristics combined with a increasing trend. The activities of telomerase were expressed in the latter three passages. Four fourths of SCID mice in the 85th passage cells and one fourth of SCID mice in the 60th passage cells developed tumors, but the cells in the 10th and 31st passage displayed no tumor formation.

CONCLUSION: In continual cultivation of fetal esophageal epithelial cells with transduction of HPV18E_6E_7, cells from the 10th to the 85th passage were changed gradually from preimmortal, immortal, precancerous to malignantly transformed stages. All of these changes were in a dynamic progressive process. The establishment of a continuous line of esophageal epithelium may provide a *in vitro* model of carcinogenesis induced by HPV.

INTRODUCTION

The cell line SHEE was derived from immortalized embryonic esophageal epithelium induced by gene E6E7 of HPV 18 in our laboratory[1,2] being cultivated and propagated over 100 passages. The 31st generation (SHEE31) had begun to express partial cell differentiation into two directions with some nests of cells with good differentiation and some with poor differentiation[3]. The 61st generation cells (SHEE61) were premalignant cells[4], and displayed a fully malignant transformation with a strong invasive potency at the 85th passage (SHEE85)[5]. We believe that this established cell line (SHEE), continually affected by expression of HPV, would change its biological characters such as cell proliferation, differentiation, chromosome and telomerase, and that this might be controlled by cytogenesis (chromosomes) and molecular genetics (genes).

In general, the immortalized or transformed cells caused by carcinogens are always accompanied by chromosome abnormality and mutation of gene[6]. The chromosome's changes are manifested in structure and the number of chromosomes[7,8]. All of these changes appear in the procedure from quantitative to qualitative changes. The length of telomere in living cells was continually shortened after cellular mitosis[9]. Because the somatic cells have no or lower levels of telomerase activity, telomere would be shortened, so it limits the division and lifespan of cells[10,11]. Immortal or malignant cells manifest telomerase activities, which can maintain the telomere length[12,13], so they will be immortal. With exposure of the early passage of immortal cell line to viral oncogenes, HPV or SV40T, conversion of these telomerase from negative expression to high levels of telomerase activity resulted[14]. Telomerase would be present in benign lesions and activated during the late stage of carcinogenesis[15].

Changes occurred in SHEE cells from the 10th to the 85th passage, with emphasis on their phenotypes, cytogenetic changes, telomerase activity and tumorigenicity, were studied in this paper. Phenotype of cells included the morphological changes of proliferation and contact-inhibition growth, and the modal number of chromosomes and the tumorigenicity, especially soft-agar culture and tumor formation in severely combined immuno-deficient (SCID) mice.

MATERIALS AND METHODS

Cell culture

The SHEE cells were routinely cultivated in culture medium 199 (GIBCO) with 10 % bovine serum, 100 units of penicillin and streptomycin in a humidified atmosphere of 5 % CO_2. Selected generations at the 10th passage (SHEE10), 31st passage (SHEE31 60th passage (SHEE60) and 85th passage (SHEE85) were inoculated in culture flask and 24-hole culture plate with glass slide inside.

Living cell examination

The cell shape, anchorage dependent and contact-inhibited growth were examined by phase-contrast microscopy.

Cell cycle analysis

Cultured cells of each passage were collected from suspended and digested cells, fixed by 70 % alcohol, then filtered through nylon mesh, to generate single-cell suspension (1×10^6/ml). The cells were stained with propidium iodide (Sigma) and were analyzed using flow cytometery (FCM) (FACSort Becton-Dickinson). Data of DNA of cells were collected and analyzed with Lysis II software, then a histogram was drawn and the cell percentages of each proliferation stage in the cell cycle and the number of cells more than 4n of DNA were calculated. The proliferation index formula: $S+G_2M/G_0G_1+S+G_2M$ and the cell amount at $preG_0G_1$ stage, the apoptotic cells, were calculated.

Cytogenetic analysis

Metaphase spreads were obtained using standard cytogenetic methods. Briefly, the culturing cells of each passage were preserved at 3-4 ℃ for 3-4 h to make cells on synchronous stage, then cultivated at 37 ℃ for 3-4 h, and added in 0.05 ug/ml colchicine for 1 h. Harvesting was by standard method and stained with Giemsa, 50-100 metaphases were scored for each line.

Telomerase activity assay[16]

Telomerase activity was measured using the telomeric repeat amplification protocol (TRAP). Frozen samples were homogenized in 10-50 μL of ice-cold lyses buffer (10 mmol· L^{-1} Tris-HCl, pH7.5, 1 mmol· L^{-1} EGTA, 0.1 mmol· L^{-1} Benzamidine, 5 mmol· L^{-1} βmercaptothanol, 5 g· L^{-1} CHAPS, 100 mL· L^{-1} glycerol). After 30 min of incubation on ice, the lysate was centrifuged at 12 000 g for 20 min at 4 ℃. TRAP-eze Telomerase Detection Kit (Oncor Inc.) reaction was performed using 1 μL lysate or 1/10 diluted lysate, 2.5 μL 10×TRAP buffer (200 mmol· L^{-1} Tris-HCl, pH8.3, 15 mmol· L^{-1} $MgCl_2$, 630 mmol· L^{-1} KCl, 0.5 % Tween 20, 10 mmol· L^{-1} EGTA, 1 g· L^{-1} BSA), 0.5 μl 2.5 mmol· L^{-1} dNTP, 0.5 μL Ts primer, 0.5 μL TRAP primer mix, 19.5 μL water, 0.5 μL taq (2 μ· L^{-1}). After incubation at 30 ℃ for 30 min, the reaction mixture was immediately transferred to 94 ℃ and performed PCR (GenAmp PCR System 2400, PE, USA) at 94 ℃ for 30s, 55 ℃ for 30s, for 35 cycles. PCR products were separated in a non-denaturing 125 g· L^{-1} PAGE in 1×TBE at 5V· cm^{-1}. The gel was stained using $AgNO_3$ and was photographed.

Soft agar assays

Four passages of cells (1×10^4) were cultivated in each hole of the 6-hole plastic plate (Corning Co.) which was covered with two layers agarose (Agarose, V312A, Promega), the bottom, 1 % and the upper. 0.5 %. The cells were incubated in 5 % CO_2 at 37 ℃ incubator for 40 d and the cell colony formations were scored every ten days. Each soft-agar cloning experiment was carried out at least in duplicate.

Tumorigenicity assays

In vivo tumor graft experiments were performed on the severely combined immunodeficient (SCID) mice (C.B-17/IcrJ-scid, Animal Lab of Chinese Academy of Medical Sciences). Cells of each passage were injected into the subaxillary skin of four mice with 1×10^6 cells for every one. Mice were observed weekly for two months and the tumor tissues were examined histopathologically.

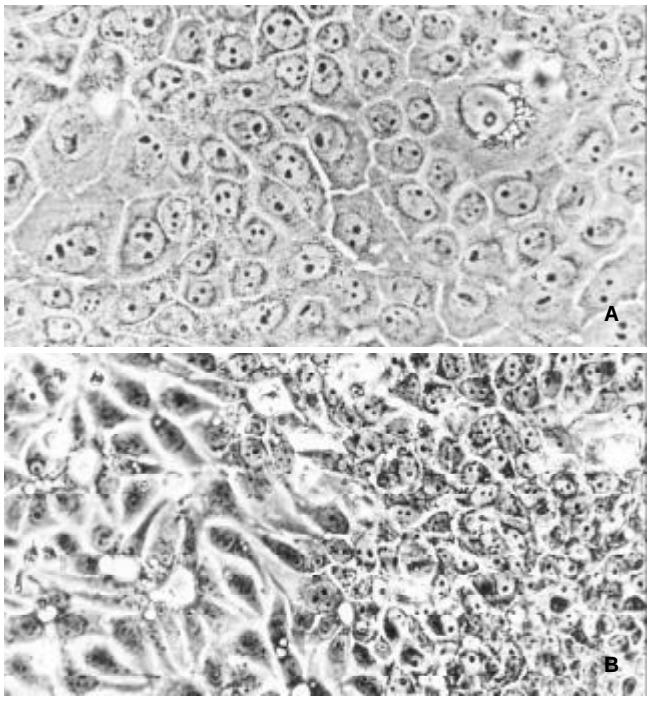
HPV18E_6E_7 assays

The protein expression of HPV18E_6E_7 was detected by Western blot method. The cells were washed three times with ice-cold PBS, then were lysed in buffer [50mM Tris-HC1, pH8.0, 150mM NaCl, 100 μg/ml phenyl-methyl-sulfonyl fluoride (PMSF), 1 % TritonX-100] for 30 min at ice. After removal of cell debris by centrifugation (12 000 g, 5 min), the protein concentration of lysates was measured by Bradford method. 50 μg proteins of different passage boiled for 5 min in sample buffer were separated by 10 % SDS-PAGE, transferred onto nitrocellulose membrane (Bio-Rad). Nonspecific reactivity was blocked by incubation overnight at 4 ℃ in buffer (10mM Tris-HCl, pH7.5, 150mM NaCl, 2 % Tween-20, 4 % bovine serum albumin). The membrane was then incubated with antibody of mouse anti HPV18E_6, (SC-264, Zhong Shan Biotech Co.), followed by reaction with anti-mouse IgG antibody. Reactive protein was detected by ECL chemiluminescence system (Amersham).

RESULTS

Proliferation and differentiation of SHEES

The cells of SHEE10 grew evenly on the flask. Cells appeared to have the characteristics of squamous epithelium (Figure 1, A) with multiangular outline and oval nucleus. SHEE31 were attached to the dish with partial differentiating into squamous epithelium and partial undifferentiated basal cells (Figure 1, B). The cells of SHEE60 and SHEE85 were differently shaped and sized and cells were crowded and overlapped (Figure 1C, D).



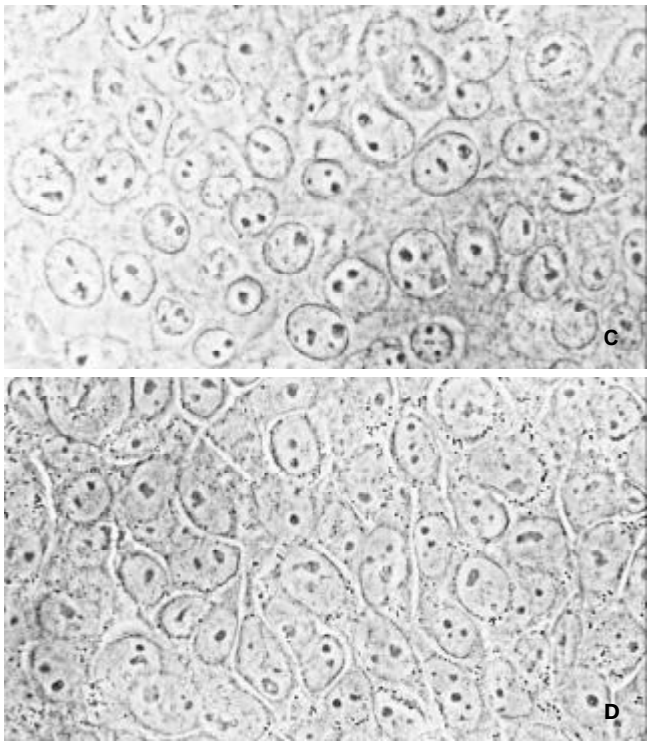


Figure 1 Morphology of SHEE cell (photographs of phase contrast microscope) A, SHEE10, good differentiation (×400); B, SHEE31, differentiated to two directions, well differentiated (left), and poorly differentiated (right) (×200); C, SHEE60, poor differentiation (×400); D, SHEE85 shows different shape and size with larger nucleolus (×400)

FCM analyzed cell cycle

In the DNA histogram (Figure 2), the distribution of DNA content of SHEE31 was similar to that of SHEE10, the proliferative indexes of SHEE10 and SHEE 31 were at the same level (32.0 %, 35.2 %), but different from SHEE60 (47.5 %) and SHEE85 (54.3 %). Of all DNA>4n cells there were SHEE10, 2.5 %; SHEE31, 4.7 %; SHEE60, 6.1 % and SHEE85, 7.2 %. This showed that heteroploid and hyperploid tumor cells increased with progressive culture of SHEE.

The modal number of chromosome

The number of chromosomes in SHEE10, SHEE31, SHEE60 and SHEE85 (Table 1) ranged between 32 and 196, and these chromosomes were mainly hyperdiploids and hypotriploids. Most cells of hypertriploids were found at SHEE60. Modal number of chromosomes at SHEE10 was 58-62, at SHEE31 and SHEE60 were bimodal distribution, 55-57, 61-63, and 58-60, 63-65 respectively, at SHEE85 was 59-65. The modal number from the 10th passage to the 85th passage increased slowly.

Table 1 Number of Chromosome in SHEE Series

Number of passage	Number of cell	≤46	47-57	58-68	≥69	modal number
SHEE10	91	17(18.7%)	45(49.5%)	22(27.7%)	4 (4.3%)	58-62
SHEE31	100	12(12.0%)	38(38.0%)	46(46.0)	4 (4.0%)	55-57,61-63
SHEE60	52	5 (9.6%)	13(25.0%)	22(42.3%)	12(23.1%)	58-60,63-65
SHEE85	85	4 (4.7%)	16(18.8%)	54(63.5%)	11 (12.9)	59~65

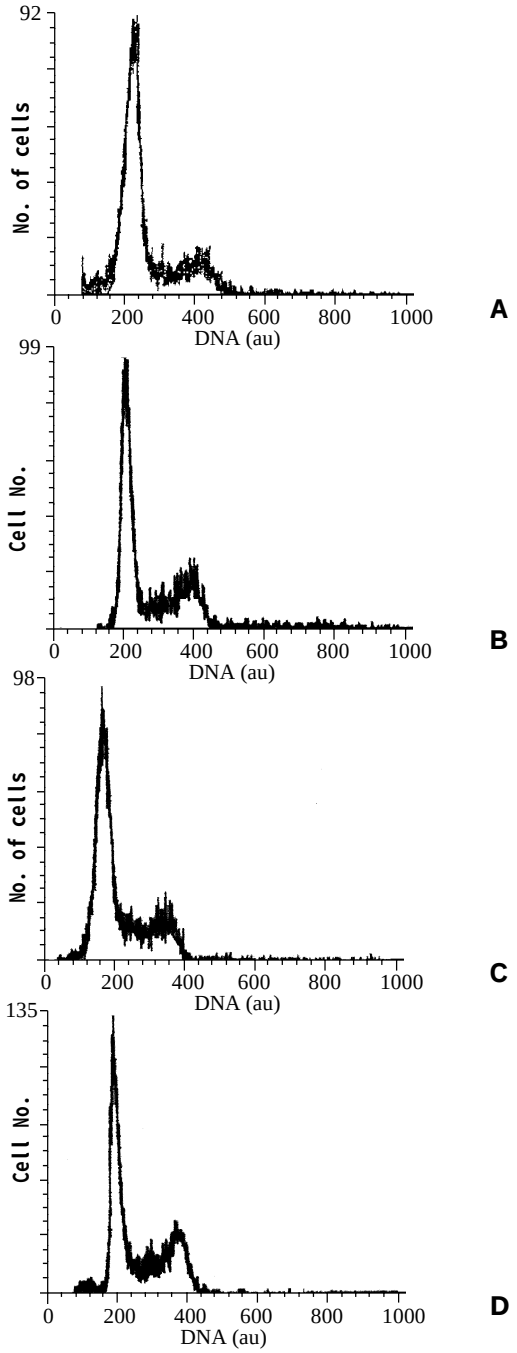

Figure 2 DNA histograms of SHEE. A, SHEE10; B, SHEE31; C, SHEE60; D, SHEE85; au, arbitrary unit.

Telomerase activity

Telomerase activation was absent in normal esophageal epithelium and SHEE10. The activity of telomerase appeared in the 31st passage, and it was strongly positive in SHEE60 and SHEE85.

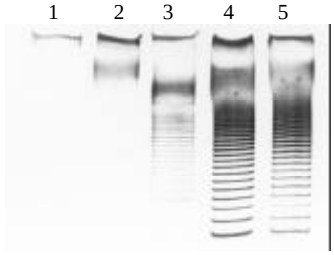

Figure 3 Activity of telomerase SHEE series 1, normal esophageal epithelium; 2, SHEE10; 3, SHEE31; 4, SHEE60; 5, SHEE85.

Expression of HPV18E$_6$E$_7$

The expression of HPV18E$_6$E$_7$ was examined by Western blot method. The figure (Figure 4) showed the expression of protein of HPV18E$_6$E$_7$ at cells of four stages of SHEE cell lines.

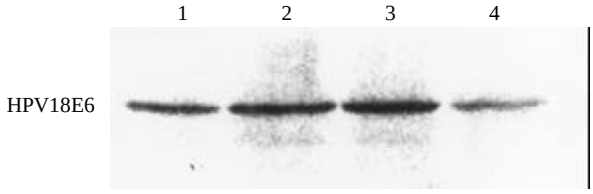

Figure 4 Western blot analysis of protein of HPV18E6 in SHEE 1, SHEE10; 2, SHEE31; 3, SHEE60; 4, SHEE85.

Tumorigenicity

SHEE10 could not grow on soft agar, but SHEE31, SHEE60 and SHEE85 could. SHEE31 formed small colonies, (less than 20 cells in a colony) compared to SHEE60 and SHEE85 in which large colonies (more than 50 cells in a colony) were formed. SCID mice inoculated with cells of SHEE10 and SHEE31 did not form tumors, but one quarter of SCID mice with inoculation of SHEE60 cells formed tumors with a latency period of over 2 months (data not shown). It was determined that a percentage of cells of SHEE60 manifested malignancy. All SCID mice inoculated with SHEE85 cells manifested tumor formation, which infiltrated into muscular layer histopathologically (Figure 5).

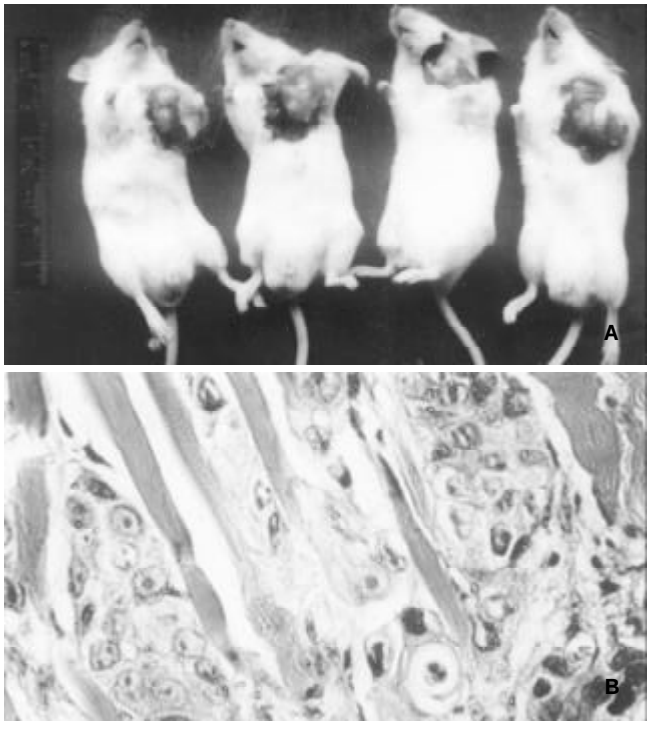

Figure 5 Heterotransplanting SHEE85 cells into SCID mice Tumors in right axiua (arrow) of SCID mice are found (A). Invasion of tumor cells is found in muscular layer (B). HE, ×400

DISCUSSION

Cellular proliferation, differentiation and apoptosis are fundamental life activities, and are also the growth markers of immortal cells. According to the DNA content and proliferation index, the cells of SHEE10, SHEE31, SHEE60 and SHEE85 all show proliferative characteristics. The proliferation index and cell numbers of polyploid (DNA>4n) of each passage were compared as a result of SHEE10<SHEE31<SHEE60 <SHEE85. SHEE31 cells showed differentiation in two directions: one displayed relatively large and multiangular cells with abundant cytoplasm and oval nucleus; the others displayed small cells with less cytoplasm and small round nucleus. SHEE60 cells overlapped to grow, which were differently shaped and poorly differentiated. SHEE85 cells were crowed in cultivation with cells of poor differentiation and received less contact-inhibition. Detecting anchorage growth and contact inhibition specificity by cultivation on the soft agar is of help to judge its malignant character[17,18]. The small colony formation of SHEE10 and SHEE31 cultivated in soft agar, and large colonies in SHEE85 and SHEE60 showed that the characteristics of anchorage-dependent growth decreased but tumorigenicity increased. A few tumors are formed in SCID mice incubated with SHEE60. So we judged that they were not at a fully malignant stage but at a premalignant stage. SHEE85 cells, which were transplanted into 4 SCID mice and developed tumors in all mice, expressed malignant transformation.

There were more hyperdiploid and hypotriploid in the chromosomes of four stages of SHEE cell lines. The separate modal number of chromosomes first appeared in SHEE31 and continued to SHEE60. The number of chromosomal sets and the percentage of hyperploid in SHEE31 varied between SHEE10 and SHEE60, and SHEE85 has more hypotriploid cells than the others. All above showed that chromosomes of SHEE series cell lines were unstable and more susceptible to malignant transformation by promoters[19, 20]. The changes of cytogenetics will control the proliferation and differentiation of cells[21].

In 1965, Hayflick reported that the culture life of human diploid fibroblast was limited to 50-100 generations, the same to epithelial cells. In 1985, Greider discovered the activity of telomerase. In 1994, Kim also identified a specific association between the telomerase activity and immortal cells or cancer cells. Telomerase activity was demonstrated in cancers of the digestive tract[22-24], such as gastric[25-29], hepatic[30-32] colorectal[33-35] and esophageal cancer[36-38]. The telomerase activity is possibly both a prerequisite and a diagnostic criterion for immortal cells[39]. Weitzman and Hahn believed T-antigen of SV40 and *ras* gene induce transformation of normal epithelium cells which require expression of telomerase activity[40,41], so over-expression of telomerase related to proliferation is the early event of cancer[42]. In our data the telomere was 30kb in length in the normal fetal esophageal cell, shortened to 17kb in SHEE 10, then further shortened to 3.5kb in SHEE 31, and then maintained at this level continually[43]. The telomerase, first appeared in the 20th passage, could not prevent shortening of telomere, because it was in a low-or noncatalytic function, therefore cells had difficulty to survive in cultivation before the 20th passage. The cells grew stably after the 31st passage. Our results indicated that immortalization of SHEE might require activation of telomerase.

Infection of HPV can cause karyotype confusion, such as breaking of chromosome, abnormal structure and number of chromosomes[44]. It also suggests that immortal esophageal cells induced by HPV18 E6E7 may affect the changes of chromosomes, and cause instability of genetic characters[45]. Viruses can cause loss of contact inhibition, decrease of adhesion between cells, confusion of cellular skeletal structure, and loss requiring to growth factor[46]. The virus genome inserts and integrates with the chromosome of host, causing the activation and expression of oncogenes[47]. HPV E6E7 protein is conjugated with anti-oncoprotein p53 and pRb[48], thus

causing loss of control of cellular growth, and encouraging the phenotyping production of cellular transformation. Previous reports have shown that activation of telomerase can be achieved by the E_6 and E_7 proteins of HPV[49]. It has been reported that E_6 could promote malignant change, while E_7 may cause benign neoplasm[50]. It has been indicated elsewhere that virogene HPV16 E6 alone can cause cellular malignant change[51]. In this experiment, we found that immortal cells contained HPV18 E6E7 and that, therefore, the SHEE series can gradually lead to the malignant transformation. It is also postulated that HPV is likelly be a major risk factor for esophageal cancer[52].

In summary, of all these cells, some underwent aging, apoptosis and died, whereas others proceeded to malignant transformation. To search the direction of development of cells, we evaluated these changes by referring to the cytogenetic index. In these four series of immortal cells, the chromosomes presented characteristics of hyperdiploid and hypotriploid along with separation of modal number. The positive activity of telomerase can help determine the cells that are progressing from preimmortal toward immortal stages. The SHEE60 passage showed initial partial malignant change which could be regarded as premalignancy. The cells of SHEE85 were in fully malignant transformation with tumor formation and invasive potential. In conclusion, it is possible to demonstrate multiple stages in the transformation process that are associated with different genetic and phenotypic characteristics.

Abstract

AIM: To investigate the roles of Fas signaling pathway in vitamin E succinate-induced apoptosis in human gastric cancer SGC-7901 cells.

METHODS: Human gastric cancer SGC-7901 cells were treated with VES at 5, 10, 20 mg·L^{-1}, succinic acid and vitamin E as vehicle control and condition media only as untreated (UT) control. Apoptotic morphology was observed by DAPI staining. Western blot analysis was applied to measure the expression of Fas, FADD and caspase-8 proteins. After the cells were transiently transfected with Fas and FADD antisense oligonucleotides, respectively, caspase-8 activity was determined by flurometric method.

RESULTS: The morphologically apoptotic changes were observed after VES treatment by DAPI staining. 23.7 % and 89.6 % apoptosis occurred after 24 h and 48 h of 20 mg·L^{-1} VES treatment, respectively. The protein levels of Fas, FADD and caspase-8 were evidently increased in a dose-dependent manner after 24 h of VES treatment. The blockage of Fas by transfection with Fas antisense oligonucleotides obviously inhibited the expression of FADD protein. After SGC-7901 cells were transfected with Fas and FADD antisense oligonucleotides, caspase-8 activity was obviously decreased (P<0.01), whereas Fas blocked more than FADD.

CONCLUSION: VES-induced apoptosis in human gastric cancer SGC-7901 cells involves Fas signaling pathway including the interaction of Fas, FADD and caspase-8.

INTRODUCTION

RRR-α-tocopheryl succinate (vitamin E succinate, VES), a derivative of natural vitamin E, has been shown to be a potent growth inhibitor of many kinds of cancer cell types[1-5]. Antiproliferative effects of VES on tumor cells are diverse, including G1 cell cycle blockage[6-8], DNA synthesis arrest[9-11], induction of differentiation[12-14] and apoptosis[15-17]. Meanwhile, tumor cell growth inhibition by VES has also been demonstrated *in vivo*[18,19]. VES is noteworthy for its non-toxic and non-inhibitory effects on normal cell types, indicating that VES can be used as a chemopreventive/chemotherapeutic agent against tumors.

Up to date, the precise mechanisms of VES-induced inhibition of tumor cell growth are not well understood, but some studies show that VES can increase the secretion and activation of transforming growth factor-βs (TGF-βs) and enhance the expression of TGF-β receptor Ⅱ[10,20]. Yu *et al*[21] reported that VES-triggered apoptosis in human breast cancer cell lines is inhibited by 50 % with antibody neutralization of TGF-β ligand and transient transfection of TGF-β antisense oligonucleotides, implicating that TGF-β plays a crucial role in VES-induced apoptosis and VES may induce cancer cells to undergo apoptosis through other pathways as well. Turley *et al*[22] observed that the expression of Fas, a cell surface receptor, is increased after treatment of breast cancer cells with VES and VES-induced apoptosis in breast cancer cells is inhibited when Fas neutralized antibody or transfection of Fas antisense oligonucleotides are applied to cancer cells, showing that Fas-mediated apoptosis may be another important pathway by which VES inhibits tumor cell growth.

Gastric cancer is one of the most common malignant tumors in China[23-32]. Our previous studies found that VES can block cell cycle, arrest DNA synthesis and induce apoptosis in human gastric cancer SGC-7901 cells, therefore inhibiting cell growth[33-36]. In addition, our *in vivo* research demonstrated that VES inhibits benzo(a)pyrene (B(a)P)-induced forestomach carcinogenesis in female mice[37]. The exact mechanisms of apoptosis are not clearly known, but we found that VES can secrete and activate biologically active TGF-β and then TGF-β increases the kinase activity of c-Jun N-terminal kinase(JNK) followed by phosphorylation of c-Jun, and finally activated c-Jun triggers apoptosis in human gastric cancer SGC-7901 cells[38]. In this study, signaling pathway of Fas-induced apoptosis in VES-treated SGC-7901 cells is determined to further investigate the mechanisms of VES-induced growth inhibition.

MATERIALS AND METHODS

Materials

VES was purchased from Sigama Co. Ltd. RPMI 1640 media and LIPOFECTAMINE PLUS™ Reagent were obtained from Gibco BRL, ApoAlert™ Caspase-8 Fluorescent Assay kit from Clontech, Inc. DAPI (4',6-diamidine-2'-phenylindole dihydrochloride), FADD and caspase-8 rabbit polyclonal antibodies, Fas antisense (GAG GGT CCA GAT GCC CAG CAT) and FADD antisense (CAG CAC CAG GAA CGG GTC CAT) oligonucleotides were gifts from Dr. Sanders BG (University of Texas, Austin, USA). Fas rabbit polyclonal antibody was from Santa Cruz Biotechnology, Inc.

Methods

Cell culture Human gastric cancer cell lines SGC-7901 were maintained in RPMI 1640 medium supplemented with 100 mL· L^{-1} fetal calf serum (FCS), 100 kU· L^{-1} penicillin, 100 mg· L^{-1} streptomycin and 2 mmol· L^{-1} L-glutamine under 50 mL· L^{-1} CO_2 in a humidified incubator at 37 ℃. SGC-7901 cells were incubated for different time periods in the presence of VES at 5, 10 and 20 mg· L^{-1} (VES was dissolved in absolute ethanol and diluted in RPMI 1640 complete condition media correspondingly to a final concentration of VES and 1 mL· L^{-1} ethanol), succinic acid, vitamin E and ethanol equivalents as vehicle (VEH) control and condition media only as untreated (UT) control.

Determination of apoptosis Cells were treated with VES at 20 mg/L^{-1} for 48 h, then harvested, washed with PBS and stained with 2 mg· L^{-1} DAPI in 100 % methanol for 30 min at 37 ℃. Cells were viewed using a fluorescence microscope with ultraviolet (UV) excitation at 300-500 nm. Cells with nuclei that contained clearly condensed chromatin or cells with fragmented nuclei were scored as apoptotic.

Western blot analysis SGC-7901 cells treated with VES were harvested, washed in PBS and lyzed in lysis buffer containing 150 mmol· L^{-1} NaCl, 1 mL· L^{-1} NP-40, 5 mg· L^{-1} sodium deoxycholate, 1 g· L^{-1} SDS, 50 mmol· L^{-1} Tris (pH 7.4), 1mmol· L^{-1} DTT, 0.5 mmol· L^{-1} Na_3VO_4, 10 mmol· L^{-1} phenylmethylsulfonyl fluoride (PMSF), 10 mg· L^{-1} trypsin, 10 mg· L^{-1} aprotinin and 5 mg· L^{-1} leupeptin. Following the centrifugation of 12 000×g for 30 min at 4 ℃, the amount of protein in the supernatant was determined using Biorad DC protein assay. Equal amount of protein was separated on 10 % SDS-PAGE and transferred to nitrocellulose filter (Gibco BRL, USA) overnight. Blocked with 50 g· L^{-1} defatty milk, the filter was incubated with Fas, FADD and caspase-8 rabbit polyclonal antibodies, respectively, and horseradish peroxidase-conjugated IgG, finally developed with DAB.

Transient transfection The cells were washed twice with serum-free medium without antibiotics and incubated for 3 h in 2 ml of serum-free medium containing 30 ul of LIPOFECTAMINE Reagent and 2 ug of Fas or FADD antisense oligonucleotides. After 3 h, the cells were treated with VES.

Caspase-8 activity assay Caspase-8 activity was determined according to the manufacurer' s instructions. Briefly, 50 ul of supertanant from VES-treated cell extracts were mixed with 50 ul of a mixture of 2× reacion buffer and DTT, then 1 ul of 1 mmol· L^{-1} IETD-fmk and incubated for 30 min at 37 ℃ in water bath. Next, 5 ul of 1 mmol· L^{-1} IETD-AFC was added, followed by incubation for 1 h at 37 ℃ in water bath. The fluorescent absorbance (A) was measured at 400nm for emission and at 505nm for excitaion.

Statistical analysis

The data were expressed as $\bar{x}\pm s$. Statistical analysis was performed using student' s *t*-test. $P<0.05$ was considered significant.

RESULTS

VES induced apoptosis in SGC-7901 cells

SGC-7901 cells in untreated control group and 20 mg· L^{-1} VES group were cultured for 48 h, collected and stained with DAPI. The morphological changes were observed with fluorescent apoptosis occurred after 24 h and 48 h of 20 mg· L^{-1} VES treatment, respectively.microscope at 300-500nm (Figure 1). The nuclei in UT control group exhibited circular-like shape, clear edge, and homogeneous staining; while those treated with VES showed uneven edge, chromatin condensation, pyknosis and formation of apoptotic body. 23.7 % and 89.6 %.

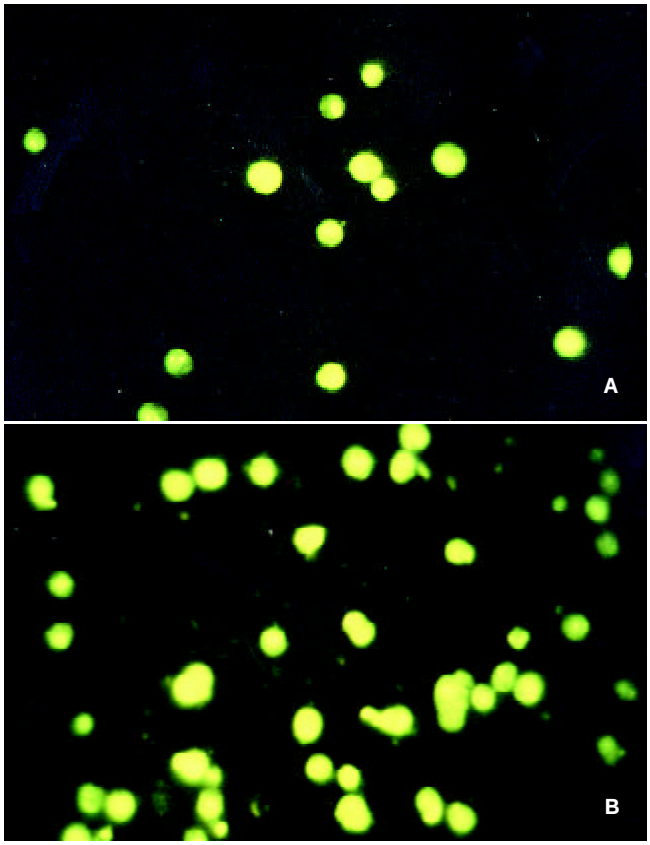

Figure 1 SGC-7901 cells stained with DAPI. A: UT control; B: VES at 20 mg·L^{-1}

Effects of VES on protein expression

The protein levels of Fas, FADD and caspase-8, as determined by western blot analysis of cells extracts obtained from VES-treated SGC-7901 cells, were evidently increased in a dose-dependent manner after 24 h of VES treatment (Figure 2,3,4).

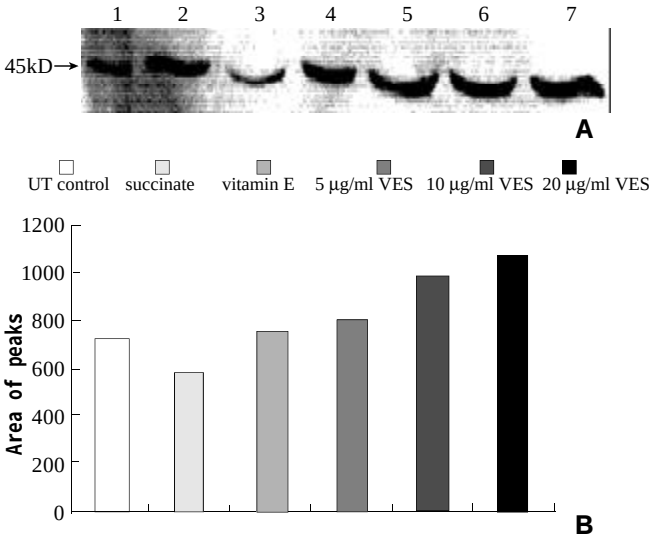

Figure 2 The expression of Fas protein in SGC-7901 cells following treatment of VES for 24 h. Lane1: Molecular weight marker; Lane2: UT control; Lane3: succinate; Lane4: vitamin E; Lane5: VES at 5 mg·L^{-1}; Lane6: VES at 10 mg·L^{-1}; Lane7: VES at 20 mg·L^{-1}.

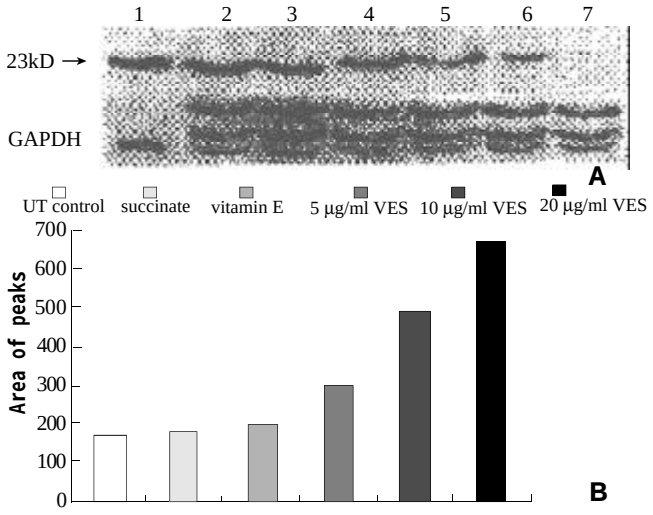

Figure 3 The expression of FADD protein in SGC-7901 cells following treatment of VES for 24 h. Lane1: Molecular weight marker; Lane2: VES at 20 mg·L^{-1}; Lane3: VES at 10 mg·L^{-1}; Lane4: VES at 5 mg·L^{-1}; Lane5: vitamin E; Lane6: succinate; Lane7: UT control.

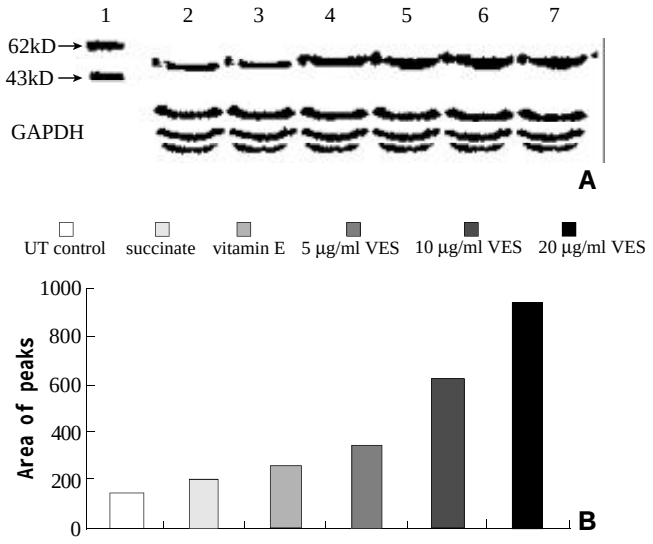

Figure 4 The expression of caspase-8 protein in SGC-7901 cells following treatment of VES for 24 h. Lane1: Molecular weight marker; Lane2: UT control; Lane3: succinate; Lane4: vitamin E; Lane5: VES at 5 mg·L^{-1}; Lane6: VES at 10 mg·L^{-1}; Lane7: VES at 20 mg·L^{-1}.

The expression of FADD protein when Fas was blocked in VES-treated SGC-7901 cells

SGC-7901 cells were transiently transfected with antisense oligonucleotides to Fas, followed by 20 mg·L^{-1} VES treatment for 24 h. The expression of FADD protein was decreased by 77 % compared with that in control group (Figure 5), indicating that the blockage of Fas signal obviously inhibited the expression of FADD protein.

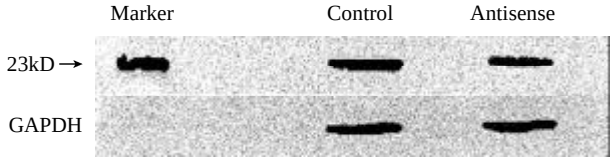

Figure 5 The expression of FADD protein when Fas antisense was transfected into SGC-7901 cells following treatment of VES for 24h.

Effects of blockage of Fas and FADD on caspase-8 activity in VES-treated SGC-7901 cells

SGC-7901 cells were transfected with Fas and FADD antisense oligonucleotides, respectively, followed by VES treatment for 24 h at different doses. Caspase-8 activity in both cases was decreased with significant differences compared with the activity in the same dose of VES-treated cells untransfected in an obviously dose-dependent manner (Table 1). Meanwhile, caspase-8 activity in Fas antisense-transfected cells was reduced more than that in FADD antisense-transfected cells and the differences were significant.

Table 1 Effects of blockage of Fas and FADD on caspase-8 activity in VES-treated SGC-7901 cells

Groups	Doses (mg·L^{-1})	Caspase-8 activity
VES	5	12.1±0.70
	10	21.6±0.88
	20	32.4±1.71
Fas antisense +VES	5	5.1±0.35[b]
	10	10.9±0.39[b]
	20	16.9±0.87[b]
FADD antisense +VES	5	9.6±0.34[bd]
	10	15.7±0.29[bd]
	20	21.9±0.83[bd]

[b]P<0.01, *vs* VES at the same dose; [d]P<0.01, *vs* Fas antisense at the same dose.

DISCUSSION

Fas (also called CD95/APO-1), a 45kDa type I transmembrane protein, belongs to the nerve growrth factor(NGF)/tumor necrosis factor (TNF) receptor superfamily. As a member of five death domain-containing receptors, Fas intiates a signal-transduction cascade leading to programmed cell death[39-42]. In this study, we determined the expression of Fas protein in VES-treated SGC-7901 cells. The data showed that after 24 h of VES treatment, the expression of Fas protein was evidently increased with a marked dose-dependent relationship in comparison with control, indicating that Fas signal pathway is initiated in the course of VES-triggered apoptosis. After VES treatment following transfection of Fas antisense oligonuceotides into SGC-7901 cells, the expression of Fas protein and caspase-8 activity were obviously reduced and VES-induced apoptosis was inhibited by 50 %, implicating that Fas may play an essential role in VES-mediated apoptosis in human gastric cancer SGC-7901 cells.

All the death receptors' cytoplasmic regions contain a death domain (DD) reqired for cytotoxic signal transduction. Engagement of death receptors by their ligands can lead death receptors to oligomerization; then an adaptor protein is required to recruit death receptors to their effectors. Engagement of Fas by Fas ligand or agonistic anti-Fas antibodies can induce apoptosis in Fas-bearing cells[43-46]. The main death pathway initiated from Fas activation involves a series of death associated molecules including FAP-1 (Fas-associated protein 1), RIP (receptor interaction protein) and FADD (Fas-associated death domain-containing protein)[47]. Therefore, the roles of FADD in VES-treated SGC-7901 cells were also investigated in the present study.

FADD (also known as MORT1), a cytoplasmic protein,

contains 208 amimo acids and N-terminal amino acids of FADD constitute a death effector domain (DED) essential to death signal transduction[47-50]. We treated SGC-7901 cells with VES and found that the level of FADD protein was obviously elevated compared with control in an evident dose-dependent manner, showing that FADD was also involved in the signaling pathway of VES-mediated apoptosis in SGC-7901 cells. In addition, we transfected SGC-7901 cells with FADD antisense oligonucleotides followed by treating them with VES. The results showed that the expression of FADD protein and caspase-8 activity was obviously inhibited, further suggesting that FADD was associated with VES-triggered apoptosis in human gastric cancer SGC-7901 cells.

Caspase-8 (MACH1/FLICE), a member of interleukin 1β-converting enzyme family of proapoptotic proteases, contains two N-terminal stretches that are apparently homologous to death effector domain (DED) of FADD through which FADD recruits to caspase-8 leading to the activation of the proteolytic cascade of caspases[51-54]. Kim *et al*[55] found that Fas-mediated apoptosis was completely blocked in caspase-8-deficient Jurkat T lymphocytes and restored in the case of recruitment of wild-type caspase-8, indicating that caspase-8 is an important mediator of Fas-induced apoptosis. We show here that the expression and activity of caspase-8 in SGC-7901 cells were apparently elevated, demonstrating that caspase-8 is associated with VES-induced apoptosis. In order to explore the relationship among Fas, FADD and caspase-8 in VES-induced apoptosis in SGC-7901 cells, we determined the activity of caspase-8 following transfection of SGC-7901 cells with Fas and FADD antisense oligonucleotides. The data showed that the blockage of Fas and FADD obviously reduced the activity of caspase-8 in VES-treated SGC-7901 cells, while the blockage of Fas did more than that of FADD.

In summary, the adaptor protein FADD is recruited to Fas receptor via mutual interaction of their DDs. FADD in turn recruits procaspase-8 through interaction between DEDs of FADD and procaspase-8. Upon formation of this death-inducing signaling complex, procaspase-8 is activated leading to the activation of the proteolytic cascade of caspases, so Fas may play a crucial role in VES-mediated apoptosis in human gastric cancer SGC-7901 cells. VES-mediated apoptosis is very complex. It is reported that mitochondria permeability transition (MPT) participates in apoptosis[56-61]. Therefore, additional studies should provide insight into the role of the biological significance of mitochondria in the mechanisms of tumor cell growth inhibition by VES in future.

Abstract

AIM: The E-cadherin-catenin complex is important for cell-cell adhesion of epithelial cells. Impairment of one or more components of this complex is associated with poor differentiation and increased invasiveness of carcinomas. We evaluated the expression pattern of E-cadherin and β-catenin in gastric carcinoma and dysplasia and analyzed their relationship with tumor clinicopathological features and patient survival.

METHODS: Immunohistochemical staining of E-cadherin and β-catenin was performed from paraffin specimens of 163 gastric carcinomas, 44 gastric mucosal dysplasia, and 25 intestinal metaplasia, 28 atrophic gastritis and 12 healthy controls.

RESULTS: Normal membrane staining was observed in intestinal metaplasia, atrophic gastritis and control biopsy specimens for E-cadherin and β- catenin. 36 % and 16 % of gastric dysplasia were stained abnormally for E-cadherin and β- catenin respectively. Abnormal expression of E-cadherin and β- catenin was demonstrated in 46 % and 44 % of gastric carcinoma respectively. Abnormal expression of E-cadherin and β- catenin occurred more significantly in Borrmann Ⅲ/Ⅳ than in Borrmann Ⅰ/Ⅱ type ($P<0.005$, respectively). A significantly higher proportion of signet-ring, mucinous and tubular adenocarcinomas were abnormally expressed for E-cadherin and β- catenin as compared with papillary adenocarcinomas ($\chi^2=8.47$, $P<0.005$, and $\chi^2=7.05$, $P<0.01$, respectively). Morever, abnormal E-cadherin and β- catenin staining occurred more frequently in diffuse than in intestinal type of tumor ($\chi^2=18.18$ and 17.79, $P<0.005$, respectively). There was a significant correlation between abnormal β- catenin expression and positive lymph node metastasis. A survival advantage was noted in tumors retaining normal membranous expression of β-catenin, independent of type, grade, or stage of the disease ($P<0.0005$).

CONCLUSION: Abnormal expression of the E-cadherin-catenin complex occurs frequently in gatric carcinoma, closely related to its histogenesis. Abnormal expression of the E-cadherin- catenin complex in gastric dysplasia may be an early event in the tumorigenesis. The close correlation with poor survival suggests that abnormal β-catenin may be a useful prognostic marker.

INTRODUCTION

It is well-known that anchorage of cells to substrate is critical for the integrity of many cell types including epithelial cells. The cadherins are a major class of adhesion molecules which play an important role in the homotypic cell-cell adhesion and hence cancer cell metastasis and invasion. E-cadherin is a member of the cadherin family which is expressed in all epithelial cells[1,2]. It is a calcium-dependent cell adhesion molecule that binds to other E-cadherin molecules on adjacent cells and is located at the adhesion junction of epithelial cells[1]. Functional cadherin-dependent cell adhesion requires the formation of complexes between E-cadherin and the cytoplasmic proteins known as the catenins. The catenin, which interacts with the cytoplasmic domain of E-cadherin, consists of at least three proteins: α-,β-, and γ- catenin. β- catenin forms a complex with E-cadherin, while α- catenin links this complex to the actin cytoskeleton[3,4]. It is postulated that changes in cell-cell and cell-matrix interactions account for the ability of cancer cells to cross normal tissue boundaries and metastasize[5]. In addition, loss of cell adhesion may contribute to loss of contact inhibition and thus play a role at the earlier stage of the neoplastic process.

Previous studies have provided evidence that perturbation of E-cadherin-mediated cell adhesion is involved in tumor progression and metastasis[6,7]. Loss of E-cadherin expression or function *in vitro* has been associated with loss of differentiation and increased invasive capacity of cancer cell lines[8,9]. A variety of human cancers exhibit altered expression of E-cadherin that correlates with high grade and advanced tumor stage[10-12]. These changes may result from deletions, point mutations of the E-cadherin genes or CpG methylation of the promoter region.

β- catenin appears to bind directly and most tightly to E-cadherin and so affects the strength of cell-cell adhesion[13]. It is also involved in the Wingless/Wnt signaling pathway and interacts with epidermal growth factor receptor[14,15], with the APC tumor suppressor gene, and with two novel nuclear transcription factors,T-cell factor (TCF)-4 and lymphoid enhancing factor (LEF)-1[16,17].

Gastric cancer is the second most common malignancy worldwide, and is among the leading causes of mortality in countries such as Japan, China, and Chile. Even in the developed Western countries, the 5-year survival rate for gastric cancer is only 10-19 %[18]. In China, gastric cancer is the most common malignancy diagnosed annually, with a high cancer-related mortality (25 %)[19]. Among the highly prevalent geographic areas of gastric cancer is Lanzhou, a city of northwest China. It is currently unknown what factors contribute to the development, progression, and metastasis of gastric cancers in this geographic area[20,21].

Reduced or completely lost E-cadherin-catenin complex expression has been found in gastric, although results regarding the degree of aberrant E-cadherin-catenin complex expression and its relationship with clinicopathological features and patient survival are contradictory. In this study, by using the immunohistochemical staining, we investigated the expression pattern of E-cadherin or β- catenin in gastric cancers, dysplasia, intestinal metaplasia, atrophic gastritis and normal gastric mucosa and the possible role of E-cadherin- catenin complex in the pathogenesis of gastric cancers in Lanzhou area. The possible relationship between the expression of the E-cadherin and β-catenin and the tumor clinicopathology, as well as its potential value in the evaluation of patient survival were also discussed.

MATERIALS AND METHODS

Patients and tissue samples

The specimens of gastric cancers were obtained from 185 consecutive patients who underwent gastrectomy at the Department of Surgery (First Teaching Hospital, Lanzhou Medical College, Lanzhou, P. R. China) between January 1995 and December 1996. None of the patients received chemotherapy or radiotherapy before surgery. Clinico-pathological information and survival data were obtained from hospital records and patients' doctor in charge. Six patients who died within 4 weeks following surgery were excluded from the survival analysis for the purpose of eliminating bias caused by surgical operation-related death. In sixteen cases, suitable well-preserved blocks could not be obtained, thus a total of 163 patients were included in the final study. There were 123 males and 40 females (3.08:1), with median age of 54.5 years (range, 28-77 years). Samples were taken from the representative cancerous lesions as well as adjacent non-cancerous mucosa. In addition, mucosal biopsy specimens from 32 patients with dysplasia (plus 12 cases from gastrectomy, total 44 cases), 25 with intestinal metaplasia, 28 with atrophic gastritis and 12 healthy controls were examined.

For microscopic examination, tissues were routinely fixed with formalin before being embedded in paraffin. A 4-μm section from each specimen block was stained with H & E for histological evaluation, and representative blocks were chosen for immunohistochemical study. In addition, normal colonic epithelium was used as positive control and adjacent normal gastric mucosa as internal control. Negative controls included adjacent section of the same block in which the primary antibody was replaced by phosphate-buffered saline (PBS).

Tumor staging and classification

Tumors were staged at the time of surgery by the standard criteria for TNM staging using the unified international gastric cancer staging classification[22] and the following morphological details were recorded: depth of invasion (pT category), lymph node involvement (pN category). By Lauren system[23], tumors were classified into intestinal and diffuse types. According to the criteria of WHO classification, tumors were classified into adenocarcinoma, which was defined as papillary adenocarcinoma, tubular adenocarcinoma, mucinous adenocarcinoma and signet-ring cell carcinoma, and undifferenciated carcinoma. The gross appearance of tumors was diagnosed using the Borrmann' s classification. Dysplasia was diagnosised according to the Padova International Classification[24] for gastric dysplasia.

Antibodies and other chemicals

The following items were purchased from Maxim Biotech (Maxim Biotech Inc., South San Francisco, CA, USA): mouse monoclonal antibodies against human E-cadherin and β-catenin; UltraSensitive S-P Kit; and peroxidase-conjugated streptavidin. Diaminobenzidine tetrahydrochloride (DAB) and other routine chemicals were obtained from Sigma-Aldrich Corp. (St. Louis, MO, USA).

Immunohistochemical staining

To detect the presence and patterns of E-cadherin and β-catenin, we utilized the peroxidase-conjugated streptavidin immunostaining technique, as previously described by others[25]. Briefly, 4 μm tissue sections were dewaxed and rehydrated through changes of xylene and graded alcohol, then to water. Endogenous peroxidase activity was blocked by incubating the sections with 0.6 % hydrogen peroxide for 10 min. Heat-mediated antigen retrieval was performed by heating the sections (immersed in 0.01M citrate buffer, pH 6.0) in a microwave oven (750 W) for 20 min. The slides were then washed with PBS before being exposed to 10 % normal goat serum for 10 min to block the non-specific background reaction. The slides were then incubated with respective primary antibody overnight at 4 ℃. Following washes with PBS, the slides were incubated for 15 min with the secondary antibody, biotinylated goat anti-mouse IgG.The slides were further washed for 3×10 min in PBS, followed by incubation with peroxidase-conjugated streptavidin for 10 min. The peroxidase reaction was developed in PBS using hydrogen peroxide as substrate and DAB as a chromogen. Sections were counterstained with haematoxylin, dehydrated, and evaluated under a light microscope.

Evaluation of immunostaining

Slides were independently examined by two experienced pathologists who were blinded to the stage of the tumor and to the initial score of the other observer, and a high level of concordance (90 %) was achieved. In case of disagreement, the slides were reviewed and a consensus view achieved. Staining intensity was graded semiquantitatively from 0 to 3, as previously described[25,26]. 0:negative staining; 1: cytoplasmic staining; 2: heterogeneous staining (tumors composing of both normal and abnormal staining areas); and 3: a normal membranous staining. Because the staining pattern sometimes varied within the same tumor particularly when the differentiation status varied, the final score was based on the dominant pattern. For the ease of data analysis, all tumors with loss of membranous expression were classified as abnormal which included those with absent,heterogeneous or cytoplasmic staining patterns.

Statistical analysis

The correlation between the expression of the E-cadherin or β- catenin and clinicopathological features was analysed for statistical significance by the χ^2 (chi-square) test. Survival curves were constructed according to the method of Kaplan

and Meier. For differences between curves, the *P* value was calculated using the log rank test. A multivariate Cox regression analysis was performed to assess the prognostic significance of different staining patterns and their relationship with other pathological variables. A *P* value of less than 0.05 was considered as statistically significant. All statistical analyses were performed using the SPSS 8.0 statistical package (USA).

RESULTS

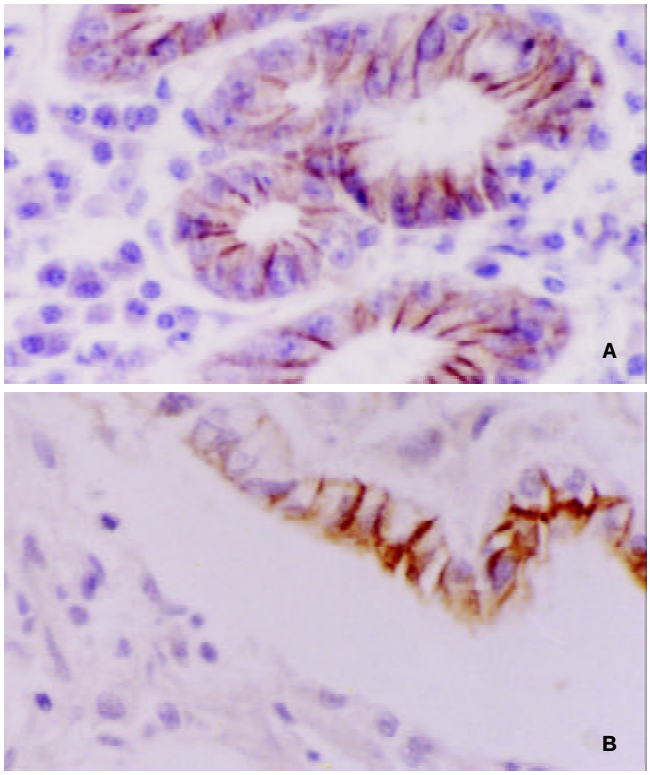
Immunohistochemical staining of E-cadherin and b-catenin

Normal gastric mucosa Gastric mucosa specimen from 12 normal health controls were examined. E-cadherin and β-catenin stained intensely in a membranous distribution throughout the epithelium in all the normal control cases (Figure 1).

Atrophic gastritis, intestinal metaplasia, dysplasia and gastric cancer Areas of atrophic gastritis, intestinal metaplasia showed normal membranous distribution of staining for E-cadherin and β- catenin in all cases. Abnormal expression was shown in 36.4 % (16/44) of dysplasia for E-cadherin, and in 15.9 % (7/44) for β- catenin. Of the total of 163 primary tumors examined, the abnormal expression rate of E-cadherin and β-catenin were 46.0 % and 44.8 %, respectively (Table 1). Representative examples were shown in Figure 1.

Table 1 Abnormal expression of E-cadherinin and β-catenin in gastric carcinoma and precancerous condition

	Total *n*	E-cadherin n (%)	β-catenin n (%)
Gastric carcinoma	163	75 (46.0)	73 (44.8)
Dysplasia	44	16 (36.4)	7 (15.9)
Intestinal metaplasia	25	0	0
Atrophic gastritis	28	0	0
Health controls	12	0	0



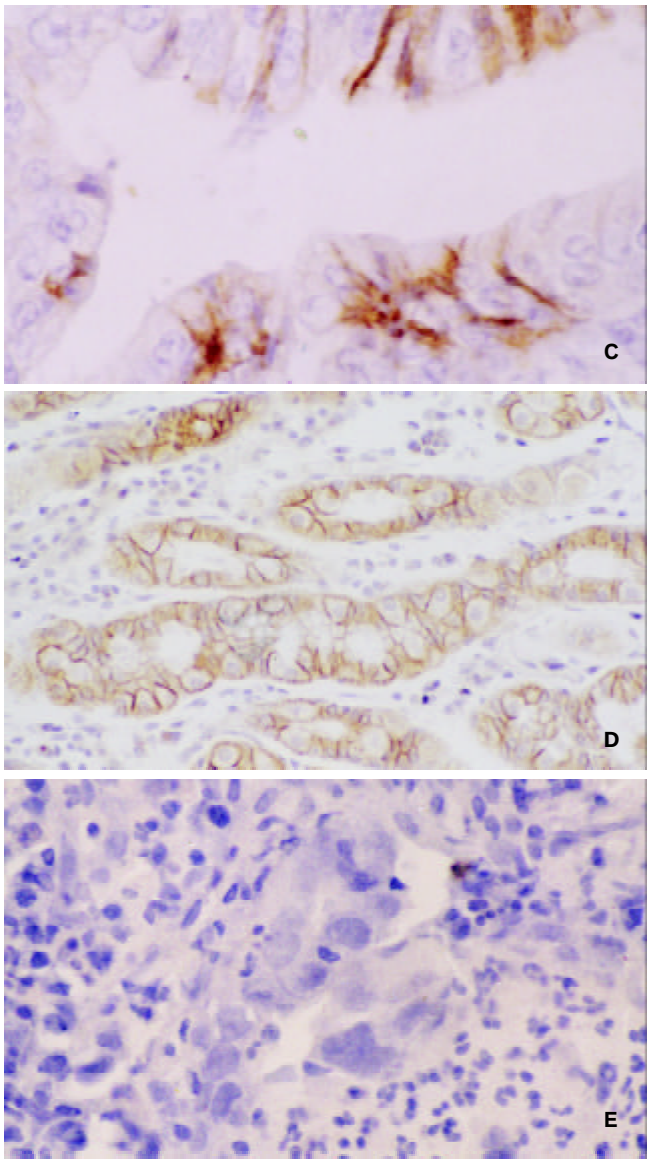


Figure 1 Immunoreactivity of E-cadherin and β-catenin in Gastric Carcinoma. A. Normal membranous staining pattern of E-cadherin (SP×200); B. Poorly differentiated tumor with complete loss of membraous staining with E-cadherin in the majority of cells. Membranous staining can be seen in a few cells retaining gastric gland (SP×400); C. Morderately differentiated tumor showing cytoplasmic staining with β-catenin, partly nuclear β-catenin expression (SP×400); D. Staining of E-cadherin showing preserved strong membranous expression in gastric mucosa with intestinal metaplasia (SP×200); E. Mucosal biopsy specimen with dysplasia (high grade) showing loss of membranous expression of E-cadherin.(SP×400)

Expression of E-cadherin or b-catenin and gross appearance in gastric cancer

The frequencies of abnormal expression in tumors less than 5 cm, 5.1-10 cm and more than 10 cm in length were 33.3 %, 35.5 %, and 74.4 % for E-cadherin, respectively,and 28.2 %, 36.2 %, and 78.9 % for β-catenin, respectively (Table 2). The rate of abnormal expression in tumors more than 10 cm was significantly higher than that in tumors less than 10 cm in length ($P<0.005$, respectively). As shown in Table 2, analysis of 139 cases of gastric cancer (24 cases were excluded from 163 cases because of incomplete surgical record) revealed that the expression of E-cadherin and β-catenin were significantly

correlated with the Borrmann classification: Abnormal expression occurred more significantly often in Borrmann Ⅲ and Borrmann Ⅳ than in Borrmann Ⅰ and Borrmann Ⅱ type (P<0.005, respectively).

Table 2 Expression of E-cadherin or β-catenin and Gross Appearance

	No	E-cadherin expression (%)		β-catenin expression (%)	
		Abnormal	*P* value	Abnormal	*P* value
Tumor size (cm)	163				
0-4.9	48	16 (33.3)		14 (28.2)	
5.0-9.9	76	30 (35.5)	16.58	29 (36.2)	21.41

Expression of E-cadherin or β-catenin and histopathological findings

Table 3 shows no correlation could be verified between expression of E-cadherin or β-catenin and the invasion depth of the tumor (T_1/T_2 *vs* T_3/T_4). Among the 163 cases of gastric cancers in our series, lymphatic metastasis was observed in 92 cases (56.4 %). We found that there was no correlation between the abnormal expression of E-cadherin and the positivity of lymphatic metastasis. However, the expression of β-catenin was closely correlated with lymphatic metastasis (P<0.005).

According to the WHO classification, papillary adenocarcinoma showed abnormal expression of E-cadherin and β-catenin more frequently compared with signet-ring carcinoma and mucinous and tubular adenocarcinoma (P<0.005 and P<0.01, respectively). Furthermore, according to the histological classification of Lauren, abnormal expression of E-cadherin and β-catenin was significantly higher in diffuse than in intestinal types (P<0.005, respectively).

Survival analysis

Survival data were obtained for 113 of the patients. Kaplan-Meier curves were computed to compare survival of patients with normal versus abnormal expression of E-cadherin and β-catenin. The overall median survival of patients in this study was 1067 days (range 78-2365). Average survival time for patients showing abnormal expression of E-cadherin was 1065±118 days, normal expression of E-cadherin was 1508±121 days. Patients with normal expression of E-cadherin appeared to have a longer survival time compared with those who have abnormal E-cadherin expression, although the difference was not statistically significant (P=0.058). The average survival time for patients with abnormal expression of β-catenin was 764±110 days, as opposed to the survival time of 1798±105 days for patients with normal expression (P<0.0005) (Figure 2). A multivariate Cox regression analysis confirmed statistically significant association of abnormal β-catenin expression with poor survival (P<0.0005), independent of tumor type, grade, or stage.

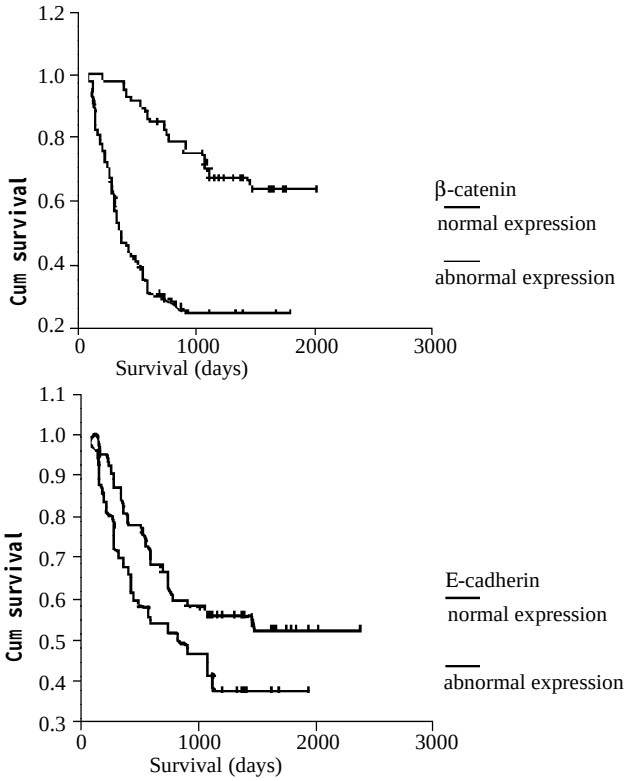

Figure 2 Kaplan-Meier survival curves showing a statistically significant survival advantage found in all tumors with normal membranous expression of β-catenin (B) compared with those with loss of membranous expression (P<0.0005). Abnormol E-cadherin (A) staining pattern showed a trend toward worse survival, but not statistically significant (P=0.058).

DISCUSSION

Aberrant expression of E-cadherin and β-catenin with loss of membranous localization has been detected in a number of human cancers. Previous studies[27-30] have shown variable abnormal expression of E-cadherin-catenin complex ranging from 20 % up to 90 % of tumors. In gastric carcinoma or other human carcinomas, the overall expression of E-cadherin-catenin complex as reported in different studies is difficult to compare due to different score systems and different antibodies used. In this study, 46 % of gastric carcinomas showed abnormal E-cadherin expression and 44 % showed abnormal β-catenin expression, so our data are in line with previous reports which revealed alteration of E-cadherin and β-catenin expression in gastric carcinomas. In addition, by using the Kaplan-Meier curve and A multivariate Cox regression analysis, we found that β-catenin but not E-cadherin expression abnormalities were associated with poor survival, confirming the findings of Jawhari *et al*[25] and Ramesh *et al*[48]. However, the use of E-cadherin as a patient survival indicator needs to be further verified, as previous findings by Gabbertz *et al*[30], Shun *et al*[29], and Grabsch *et al*[31] indicated that there was correlation between abnormal E-cadherin expression and patient survival in gastric carcinoma.

We demonstrated a significant correlation between expression of E-cadherin-catenin complex and tumor differentiation. Aberrant E-cadherin or β-catenin expression was associated with diffuse-type (poorly differentiated) carcinomas. Similarly, abnormal expression rate of E-cadherin and β-catenin was significantly higher in low- and un-differentiated adenocarcinomas than in well-differentiated adenocarcinomas. Previous *in vitro* studies[8] have shown that loss of E-cadherin in human carcinoma cell lines is associated with poor differentiation and fibroblastoid morphology. Furthermore, down-regulation of E-cadherin protein product after E-cadherin-specific antisense RNA transfection results in an invasive and de-differentiated phenotype[9]. Transfection of E-cadherin cDNA into undifferentiated carcinoma cells produces an epithelioid morphology and increases intercellular adhesion. These effects are reversible using anti-E-cadherin antibodies and provide direct *in vitro* evidence of the crucial role of E-cadherin in the regulation of cell polarity, cellular differentiation, and epithelial morphology[9,32]. Our results support the above findings, suggesting that E-cadherin-catenin complex may play an important role in the genesis of histological differentiation and may be used as a differentiation marker in gastric carcinoma[33,34].

The E-cadherin-mediated cell adhesion system is known to act as an "invasive suppressor system"[24,35,36] and tumors with reduced E-cadherin expression were also reported to have a higher frequency of lymph node involvement, distant metastasis and morphologic degree of invasiveness than those with preserved E-cadherin expression[37,38]. In this study, decreased E-cadherin expression occurred more frequently in tumors of more infiltrative growth on gross appearance or in those of larger size than in their counterparts, but showed no association with the invasion depth of the tumor, and lymph node metastasis. This findings strongly suggests that the presence of E-cadherin as revealed by immunohistochemistry might not indicate that E-cadherin is necessarily functional. For instance, certain mutations in the E-cadherin gene or changes in E-cadherin associated cytoplasmic proteins, the catenin, may alter their adhesive functions. Mutations affecting intercellular adhesion mechanisms have emerged as important steps in the development and progression of many human epithelial tumors. In gastric carcinomas, mutations of the E-cadherin gene have been reported[39-42]. A germline mutation in E-cadherin associated with familial gastric carcinoma was recently reported in a New Zealand kindred[43]. Moreover, *in vitro* studies with E-cadherin-negative carcinoma cell lines suggested that methylation around the promoter region CpG island may be one mechanism of E-cadherin inactivation in human carcinomas[44,45]. Catenins have been classified into α, β,and γ. The cytoplasmic tail of E-cadherin interacts with either β- or γ-catenins which bridge E-cadherin to the cytoskeleton through α-catenin[46,47]. Many studies indicate that the association of E-cadherin with catenins is essential for their cell-cell adhesion[25,48]. Mutations in α-and β-catenins have not been convincingly demonstrated[49], but protein expression abnormalities are relatively frequent, and occur in both diffuse and intestinal carcinomas[50,51]. As the function of E-cadherin is modulated by α-catenin, loss of α-catenin expression or deletion of α-catenin could suppress E-cadherin-mediated cell-cell adhesion activity, despite normal E-cadherin and β-catenin expression[52]. β-catenin is a multifunctional protein, and plays an important role in Wingless/Wnt signal transduction in addition to its function as a cell-adhesion components[53]. Posttranslation modification of β-catenin molecule by phosphorylation has been shown to disrupt the interaction between E-cadherin and α-catenin, causing loss of E-cadherin-dependent intercellular adhesiveness and in turn potentiating the neoplastic process[53,54]. Furthermore, the association of abnormal β-catenin expression with a worse survival, independent of tumor type, grade, or stage, seems to suggest that it acts as an independent prognostic variable.

The pathogenesis of gastric carcinoma remains largely unknown. Although a number of genetic and molecular alterations have been described in gastric carcinoma[55-57], the exact sequence and number of genetic or molecular alterations are not yet known. There were several patterns postulated on how histomorphological changes of the gastric mucosa will progress to the development of gastric carcinoma. The best known was proposed by Correa *et al*[58] who described the development of gastric tumors from gastritis through intestinal metaplasia, dysplasia, and eventually to gastric carcinoma. Recent *in vitro* and *in vivo* studies have shown that alteration or loss of E-cadherin expression seems to be critical for the development of gastric carcinomas. Furthermore, Ohene *et al*[59], Xiangming *et al*[60], Blok *et al*[61] and Shun *et al*[62] reported that abnormal E-cadherin-catenin complex expression occured in early gastric carcinomas and changes in E-cadherin expression might be early events in gastric carcinoma. Our analysis aimed at investigating E-cadherin-catenin complex expression in the possible precancerous conditions, such as atrophic gastritis, intestinal metaplasia and dysplasia and evaluating the role of E-cadherin-catenin complex expression in the development of gastric carcinoma. In this study, we found that abnormal expression was shown in 36.4 % of dysplasia for E-cadherin and 16 % for β-catenin, respectively, while atrophic gastritis, intestinal metaplasia showed normal expression. Our observations of decreased E-cadherin and β-catenin expression in dysplasia raises the possibility that changes in the E-cadherin-catenin complex occur at an early stage in the neoplastic process.

In conclusion, abnormal expression of E-cadherin and β-catenin occurs in a considerable proportion of gastric carcinomas and correlates with loss of differentiation. Loss of normal β-catenin expression showed a close correlation with poor survival, independent of tumor type, grade, and stage, suggesting that it may be an independent prognostic marker. Our results also indicate that changes in abnormal expression of E-cadherin-catenin complex may be early events in gastric carcinomas.

ACKNOWLEDGEMENT

We are grateful to Drs. M. Jiang, MT. Gao and JS. Wang, Department of Pathology, Lanzhou Medical College, Lanzhou, China, for providing the tissue specimens.

Abstract

AIM: The expression of vascular endothelial growth factor (VEGF) and its receptors KDR and Flt-1 by gastric carcinoma tissues and different gastric carcinoma cell lines was detected to elucidate the molecular mechanism of this growth factor in promoting tumor growth.

METHODS: The expression of VEGF, Flt-1 and KDR was determined by reverse transcription-polymerase chain reaction (RT-PCR) in gastric cancer cell lines RF-1, RF-48, AGS-1, NCI-N87, NCI-SNU-1, NCI-SNU-5, NCI-SNU-16 and KATO-**III**. The expression of Flt-1 and KDR in paraffin-embedded specimens of gastric cancer was determined by immunohistochemistry. The 3-(4,5-dimethylthiazol-2-yl)-2, 5-diphenyltetrazolium bromide (MTT) assay was used to assess the role of VEGF in tumor cell proliferation.

RESULTS: All 8 gastric cancer cell lines analyzed expressed $VEGF_{121}$ and $VEGF_{165}$ and six of them expressed both Flt-1 and KDR, while cell line NCI-SNU-5 expressed Flt-1 only and cell line KATO**III** expressed neither Flt-1 nor KDR. The gastric carcinoma tissues expressed Flt-1 and KDR widely, with the positive rate of expression of Flt-1 and KDR being 84.6 % and 70 % respectively. The exogenous VEGF stimulated the growth of KDR-positive cell lines NCI-N87 and AGS-1 in a dose-dependent manner but exhibited no effect on the growth of KDR-negative cell line NCI-N87.

CONCLUSION: VEGF and its receptors KDR and Flt-1 were expressed widely in gastric carcinoma cells and the VEGF stimulated KDR-positive tumor cell growth directly. These results suggest that VEGF may play a role in promoting tumor growth and metastasis by participating in both paracrine and autocrine pathways.

INTRODUCTION

Angiogenesis is essential for the continued growth of solid tumors. Among the factors contributing to angiogenesis, vascular endothelial growth factor (VEGF, also called vascular permeability factor) is recognized as one of the most important molecules in the formation of new blood vessels[1-8]. A variety of malignant human tumors, including breast, lung and prostate carcinomas, are known to secrete VEGF. The level of VEGF expression correlates with tumor progression and metastasis. Moreover, over-expression of VEGF was suggested to participate in carcinogenic processes. Different investigators reported that VEGF might play an important role during the pre-malignant stages of tumorigenesis in colon, pancreas, and cervix.

VEGF binds with high affinity to its cognate VEGF receptors (VEGFRs) Flt-1/VEGFR-1, flk-1/KDR/VEGFR-2, and neuropilin-1[9,10]. KDR is responsible for mitogenic signaling, and plays an important role in vasculogenesis and blood island formations. However, Flt-1 does not mediate cell growth when introduced into NIH3T3 cells or into porcine aortic endothelial cells that do not express VEGFRs, but regulates the assembly of endothelial cells and tissue factor production in endothelial cells. Recently the third receptor of VEGF, neuropilin-1, was purified from tumor cells. It binds $VEGF_{165}$ but not $VEGF_{121}$, and modulates VEGF binding to VEGFR-2/Flk-1 and the subsequent bioactivity [9].

Recently a few studies have proved that Flt-1 and/or KDR were also expressed in tumor cells, such as hematopoietic malignancies[11-14], pancreatic cancer[15], breast cancer[16], neuroblastoma[17], Kaposi sarcoma[18], and lung carcinomas induced by N-nitrisobis (2-hydroxypropyl) amine in rats[19]. We previously demonstrated that the VEGF and KDR were co-expressed in gastric adenocarcinoma MGC803 cells, and exogenous recombinant human $VEGF_{165}$ stimulated growth of MGC803 cells directly[20]. The present study extended our previous work and detected the expression of VEGF, Flt-1 and KDR in eight gastric cancer cell lines by RT-PCR, and the expression of Flt-1 and KDR in gastric tumor specimens by immunohistochemistry. The results showed that VEGF and VEGFR were co-expressed in gastric tumor cells widely, and exogenous $VEGF_{165}$ stimulated the growth of KDR-positive gastric carcinoma cells, indicating that there is a possible autocrine pathway for VEGF in gastric cancer.

MATERIALS AND METHODS

Cell culture and reagents

Human gastric cancer cell lines from American Type Culture Collection (ATCC) were generously supplied by Dr. Ji JF. The cell lines RF-1 and RF-48 were cultured in Leibovitz' s L-15 medium containing 10 % fetal calf serum (FCS), AGS-1, NCI-N87, NCI-SNU-1 and NCI-SNU-16 were cultured in RPMI1640 medium containing 10 %FCS and NCI-SNU-5 and KATOIII were cultured in RPMI1640 medium containing 20 % FCS. Anti-Flt-1 rabbit polyclonal antibody was purchased from Santa Cruz Biotechnology, Inc. Anti-KDR mouse monoclonal antibody 6E2 was prepared in our laboratory. Recombinant human $VEGF_{165}$ was purchased from Sigma Inc.

RT-PCR

Total RNA was extracted from eight carcinoma cell lines of 2×10^6 cells each using TRIZOL following the manufacturer' s instructions. First-strand cDNA was synthesized from 10 μg of total RNA in a 50 μl reaction volume by reverse transcription (RT) using random hexamer and MMLV reverse transcriptase (GIBCO BRL) as described by the manufacturer. The cDNA of 2 μl was amplified by PCR in a 25 μl reaction volume with primers designed to span intron-exon boundaries to distinguish amplified cDNA from genomic DNA (Table 1). VEGF was amplified for 40 cycles at 94 ℃ for 45 sec, 55 ℃ for 40 sec and 72 ℃ for 1 min and its primers were chosen to recognize all the known VEGF splice variants according to the published sequences (GenBank: AF022375). GAPDH was amplified for 30 cycles using the same cycling conditions as for VEGF. Flt-1 and KDR were amplified by semi-nest PCR. The Flt-1 was first amplified with forward-1 (corresponding to nucleotides 1-15,GenBank:AF063657) and reverse primers (corresponding to nucleotides 1287-1270) for 30 cycles at 94 ℃ for 45sec, 64 ℃ for 1 min and 72 ℃ for 2 min, then amplified with forward-2 (corresponding to nucleotides 94-109) and reverse primers for 30 cycles. The KDR was first amplified with forward (corresponding to nucleotides 1316-1330, GenBank: AF063658) and reverse-2 (corresponding to nucleotides 2275-2260) primers for 30 cycles at 94 ℃ for 45 sec, 52 ℃ for 1min and 72 ℃ for 2 min, and then amplified with the forward and reverse-1 (corresponding to nucleotides 2225-2207) primers for 30 cycles at 94 ℃ for 45 sec, 64 ℃ for 1 min and 72 ℃ for 2 min.

The PCR products of Flt-1 were analyzed by restriction endonuclease digestion with *Sac*I and *Pst*I (New England Biolabs Inc.) and KDR were analyzed with *Hind*III(New England Biolabs Inc.). The amplified cDNA of Flt-1 and KDR from AGS-1 cells were cloned into pGEM-T Easy vector (Promega) and sequenced.

Immunohistochemical analysis

Paraffin-embedded gastric carcinoma specimens were collected from the Department of Pathology, Beijing Institute for Cancer Research. The tissue sections were deparaffinized, treated with 3 % H_2O_2 to inhibit endogenous peroxidase and incubated in 0.1M sodium citrate buffer, pH6.0, at 92-98 ℃ for 10 min for antigen retrieval. The tissues were blocked with 10 % normal goat serum at 37 ℃ for 30 min and stained for Flt-1 with rabbit polyclonal antibody at 1:200 dilution, or for KDR with mouse monoclonal antibody 6E2 at 4 μg/ml, at 4 ℃ overnight. This was followed by sequential incubations in biotin-conjugated secondary antibody, streptavidin-peroxidase and 3, 3' -diaminobezidine (DAB) for visualization. Normal rabbit serum (1:10 000 dilution) or normal mouse IgG (4 μg/ml) was used as negative controls.

Cell proliferation assay

Cells AGS-1 and NCI-N87 were seeded into 96-well plates with 2×10^4 and 5×10^4 cells per well respectively and incubated in 10 % RPMI1640 medium for 24 hours. The culture medium was then replaced with serum-free medium and cells cultured for another 24 hours. KATO Ⅲ cells were seeded at 2×10^4/well and incubated in serum-free medium for 24 hours. All these cells were then treated with varying concentrations of $VEGF_{165}$ (0-10 ng/ml) for 72 hours followed by treatment with 3-(4,5-dimethylthiazol-2-yl)-2, 5-diphenyl tetrazolium bromide (MTT) for 4 hours. The medium was gently aspirated, cells were lysed in 150 μl of dimethylsulfoxide and the cell lysates were measured for absorbance at 492 nm with a Model 550 microplate reader. (Bio-Rad Co.). The viability was expressed as mean percentage of untreated controls ±SE (n=4). Statistical analysis was performed by means of Student's t-test.

RESULTS

Expression of VEGF and its receptors in human gastric carcinoma cell lines

RT-PCR with primers designed to amplify all 5 known splicing variants of VEGF generated two products of 531bp and 663bp in size corresponding to VEGF isoforms $VEGF_{121}$ and $VEGF_{165}$ in all eight gastric carcinoma cell lines (Figure 1A). Flt-1 of the expected size (1212 bp) was amplified in all cell lines except KATOⅢ cells (Figure 1B) and the amplified products were successfully digested with *Sac*I and *Pst*I respectively (data not shown). KDR of the expected sized (927bp) was amplified in all cell lines except SNU-5 and KATOⅢ cells (Figure 1C) and the amplified products were successfully digested with *Hind*III (data not shown).

The fragments of Flt-1 and KDR amplified from AGS-1 were cloned into pGEM-T Easy vector and sequenced.

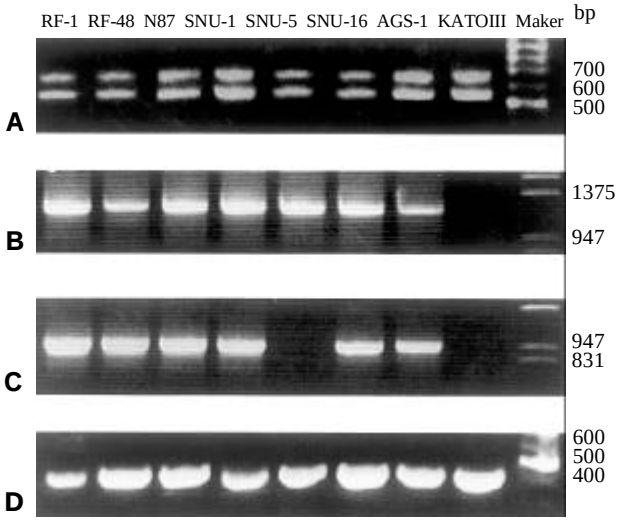

Figure 1 Detection of expression of VEGF and VEGFR in eight gastric carcinoma cell lines by RT-PCR. A. VEGF was amplified using primers designed to detect all known splicing variants and two isoforms 531bp and 663bp corresponding to $VEGF_{121}$ and $VEGF_{165}$ were obtained in all cell lines. B. Flt-1 of the expected size (1212bp) was amplified in all cell lines except KATOⅢ. C. KDR of the expected size (927bp) was amplified in all cell lines except SNU-5 and KATOⅢ. D. GAPDH was amplified in each cell line as a positive control for RT-PCR.

Flt-1 and KDR were widely expressed in gastric carcinoma

Specimens from 52 cases of gastric carcinoma were examined by immunohisto-chemistry to detect the expression of Flt-1. The results showed that Flt-1 was not only expressed in endothelial cells, but also in the tumor cells with a positivity of 84.6 % (44cases/52cases) (Figure 2A). The intensity of immunostaining was stronger in well-differentiated adenocarcinomas than in poorly differentiated adenocarcinomas. The vascular smooth muscles were also positive for Flt-1, consistent with published report[21], so were some normal cells in the bottom of gastric gland. Immunostaining was not observed on tumor tissues when normal rabbit serum was used as primary antibody.

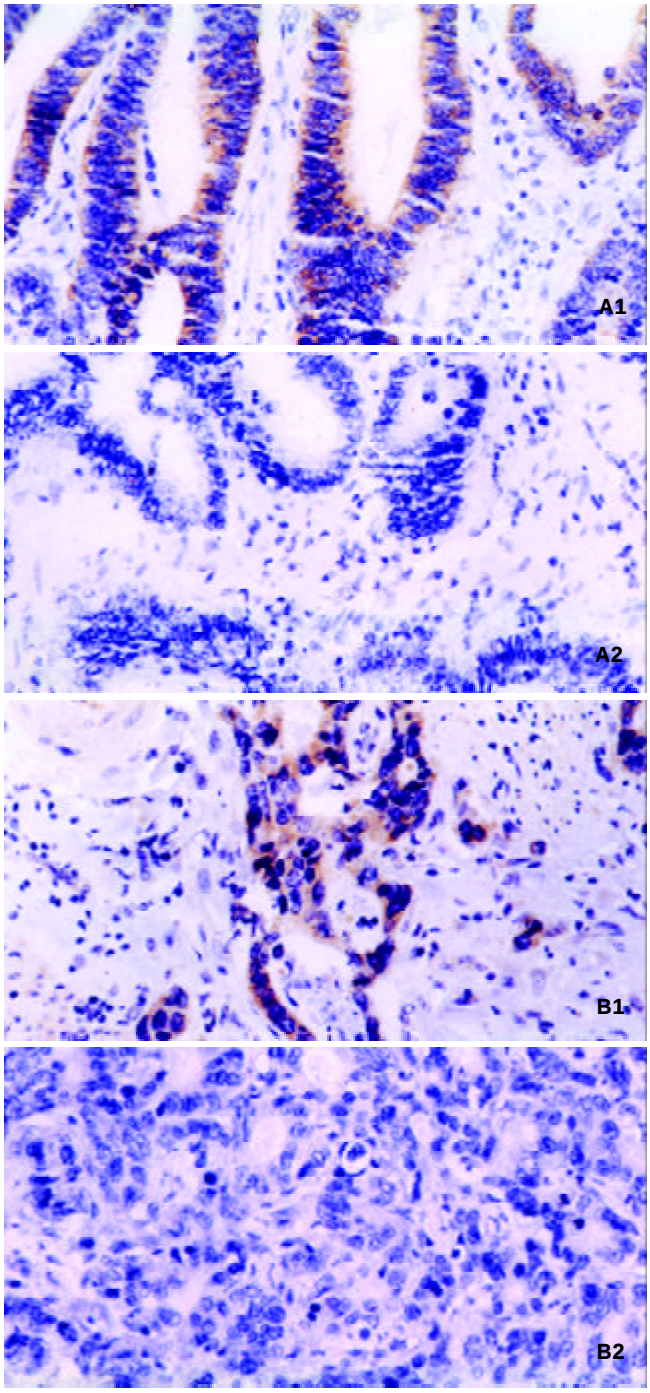

Figure 2 Immunohistochemical analysis of Flt-1 and KDR on gastric carcinoma specimens (x400). A. Expression of Flt-1. B. Expression of KDR. below sections are respectively negative controls of the left-hand side sections of the same specimens.

Specimens from 30 cases of gastric carcinoma were detected for expression of KDR and the results were similar to those of Flt-1 except that the positive rate was slightly lower (70 %) (Figure 2B). Among 24 cases detected for both receptors, Flt-1 was always positive when KDR was positive (Table 2).

Table 2 Expression of Flt-1 and KDR on gastric carcinoma specimens

Expression of Flt-1 and KDR	*n*	Percentage of 24 cases
Flt-1(+) KDR(+)	15	62.5
Flt-1(-) KDR(-)	5	20.8
Flt-1(+) KDR(-)	4	16.7
Flt-1(-) KDR(+)	0	0

VEGF stimulated growth of KDR-positive gastric carcinoma cell lines

To determine whether the exogenous recombinant human $VEGF_{165}$ was able to stimulate proliferation of gastric carcinoma cells through KDR receptor, AGS-1, NCI-N87 and KATOIII cells were incubated with varying concentrations of $VEGF_{165}$ and its effects were measured using MTT assay (Figure 3). The results showed dose-dependent effect of $VEGF_{165}$ on the growth of KDR-positive cells NCI-N87 and AGS-1 and the maximum dose of 10 ng/ml VEGF stimulated the growth of KDR-positive cells NCI-N87 and AGS-1 to 131.5 % (± 5.4 %) and 130.8 % (±11.3 %), of controls respectively (P<0.01). However, $VEGF_{165}$ had no effect on KDR-negative KATOIII cells (P>0.05).

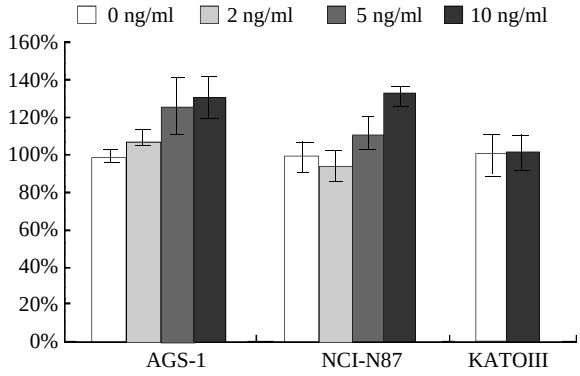

Figure 3 Effects of recombinant human $VEGF_{165}$ on proliferation of AGS-1, NCI-N87 and KATOIII cells. The cells were treated with concentrations of $VEGF_{165}$ indicated, and their viability was assessed using MTT and expressed as mean percentage of the untreated controls ±SE (n=4).

DISCUSSION

It is well known that tumor cells can secret VEGF, and its receptors KDR and Flt-1 are primarily expressed in endothelial cells. Therefore, it seems that the receptors of VEGF are endothelial cell-specific. However, recent emerging evidences have shown that VEGFRs are expressed in cell types other than endothelial cells, especially in tumor cells, indicating there is an autocrine pathway of VEGF on tumor cells. The presence of VEGF autocrine growth factor activity has been demonstrated in 5 different human tumor types, including melanoma, ovarian and pancreatic carcinoma, Kaposi sarcoma, and leukemia[11-19]. Gastric cancer is common in China and aboard[22-36]. Our previous study by Tian *et al*[20] demonstrated that VEGF acted as an

autocrine growth factor for human gastric adenocarcinoma cell MGC803. To investigate whether this is a common mechanism in gastric carcinoma, we determined the expression of VEGF and VEGFRs in eight gastric carcinoma cell lines at mRNA level. It was found that all the cell lines examined expressed $VEGF_{121}$ and $VEGF_{165}$. Meanwhile, both Flt-1 and KDR were expressed in these tumor cells, except that NCI-SNU-5 cells expressed Flt-1 only, and KATOIII expressed neither of the receptors. It seems that the co-expression of VEGF and VEGFR is common in gastric carcinoma cell lines. To investigate this phenomenon further, we detected the expression of VEGFRs in gastric carcinoma specimens. The immunohistochemical analysis showed similar results to that from cell lines, e.g. VEGFRs were expressed in endothelial cells of tumor tissue as well as in tumor cells. The positive rate of Flt-1 expression was slightly higher than that of KDR expression and the KDR-positive specimens were always Flt-1 positive. These results suggest that VEGF acted not only as a paracrine factor on endothelial cells, but also as an autocrine factor on tumor cells.

It has been reported that the expression of KDR in non-endothelial cells is associated with increase in DNA synthesis in response to VEGF stimulation. We therefore investigated whether the exogenous VEGF could stimulate the growth of KDR- positive tumor cells. $VEGF_{165}$ of 10 ng/ml increased the growth of AGS-1 and NCI-N87 cells, which were KDR positive, to 130.8 % and 131.5 % of the control unstimulated cells respectively, but showed no effect on KDR-negative KATOIII cells, indicating that the KDR receptor on gastric carcinoma is functional. Although the concentrations of VEGF in different cell cultures reported were lower (from 0.1 ng/ml to 2.8 ng/ml[11,12,14,17]) than what we used in this experiments, it is believed that the VEGF is actively secreted by tumor cells and its local concentration might be much higher, so that an autocrine pathway through KDR receptor for the growth factor is possible in gastric carcinoma. The expression of VEGF is regulated by several factors, including hypoxia, cytokines such as interleukin (IL)-1, activation of certain oncogenes (Ras, Raf, Src), and loss-of-function mutations of p53 and the von Hippel-Lindau genes. Mutation of ras and p53 is usually seen in early stage of gastric carcinogenesis[37], which can result in significant up-regulation of VEGF. Therefore, autocrine pathway of VEGF may play an important role in the progression of early stage gastric carcinoma and the antagonist of VEGF/VEGFR may inhibit tumor progression by direcly inhibiting angiogenesis. In fact, this has been confirmed in animal model of human leukemia[13]. Dias *et al* used neutralizing antibodies specific for murine endothelial cell or human endothelial cell VEGFR-2 to inhibit the paracrine or autocrine VEGF/VEGFR pathway. They showed that blocking either the paracrine pathway or the autocrine VEGF/VEGFR-2 pathway delayed leukemic growth and engraftment *in vivo* but failed to cure inoculated mice, and long-term remission with no evidence of disease was achieved only if mice were treated with antibodies against both murine and human VEGFR-2.

In conclusion,we first demonstrated that VEGF and VEGFR were co-expressed in gastric cancer, and the exogenous VEGF could stimulate the growth of KDR-positive tumor cells. These results suggest that there might exist an autocrine mechanism of VEGF in gastric carcinoma, and VEGF could promote tumor growth and metastasis by both direct and indirect pathways.

Abstract

AIM: To determine the effect of apoptosis on gastric cancer cells (SGC-7901) induced by cis-9, trans-11-conjugated linoleic acid (c9, t11-CLA) and its possible mechanism in the inhibition of cancer cells growth.

METHODS: Using cell culture, flow cytometery and immunocytochemical techniques, we examined the cell growth, frequency of apoptosis and distribution of cell cycle, expression of ki67, bcl-2, Fas, and *c-myc* of SGC-7901 cells which were treated with various c9, t11-CLA concentrations (25,50,100 and 200 μmol· L^{-1}) of c9, t11-CLA for 24h and 48 h, with a negative control (0.1 % ethanol).

RESULTS: The growth of SGC-7901 cells was inhibited by c9,t11-CLA. Eight days after treatment with various concentrations of c9,t11-CLA, as mentioned above, the inhibition rates were 5.9 %, 20.2 %,75.6 % and 82.4 %, respectively. The frequency of apoptosis on SGC-7901 cells induced by different concentrations of c9, t11-CLA (except for 25 μmol· L^{-1}, 24 h) was significantly greater than that in the negative control ($P<0.01$). To further investigate the influence of the cell cycle progression, we found that apoptosis induced by c9, t11-CLA may be involved in blocking the cell cycle of SGC-7901 cells. Immunocytochemical staining demonstrated that SGC-7901 cells preincubated in media supplemented with different c9, t11-CLA concentrations for various time periods significantly decreased the expressions of ki67 (the expression rates were 18.70-3.20 %, at 24 h and 8.10-0.20 % at 48 h, respectively), bcl-2 (4.30-0.15 % at 24 h and 8.05 %-0 at 48 h),and *c-myc* (4.85-2.20 % at 24 h and 4.75-0.30 % at 48 h) as compared with those in the controls (the expressions of ki67, bcl-2, and *c-myc* were 15.1 % at 24 h and 13.5 % at 48 h, 6.80 % at 24 h and 8.00 % at 48 h, 5.50 % at 24 h and 5.30 % at 48 h, respectively) ($P<0.01$), whereas the expressions of Fas were increased (0.60-2.75 %, 24 h and 0.45-5.95 %, 48 h).

CONCLUSION: The growth and proliferation of SGC-7901 cells are inhibited by c9, t11-CLA via blocking the cell cycle, pathways of bcl-2-associated mitochondria with reduced expression of bcl-2 and Fas-associated death domain protein (FADD) with enhanced expression of Fas. But expression of *c-myc* on SGC-7901 cells is lower than that in negative control, which needs to be studied further.

Liu JR, Chen BQ, Yang YM, Wang XL, Xue YB, Zheng YM, Liu RH. Effect of apoptosis on gastric adenocarcinoma cell line SGC-7901 induced by *cis*-9, *trans*-11-conjugated linoleic acid. *World J Gastroenterol* 2002; 8(6):999-1004

INTRODUCTION

Conjugated linoleic acid(CLA), a derivative of a fatty acid linoleic acid (LA), is a minor fatty acid found especially in red meat and in dairy products. The biosynthesis of CLA in ruminants is the result of a rumen bacterium, which is known to convert linoleic acid to stearic acid via CLA. In recent years, CLA has received considerable attention as a chemopreventive agent. This is because CLA was shown to inhibit in vitro the proliferation of human gastric cancer cells(SGC-7901)[1,2], mammary cancer cells(MCF-7)[3-7], of human malignant melanoma cells, colorectal cancer cells[8], and rat hepatoma cells[9] and in animal studies to prevent the development of mouse epidermal carcinogenesis, mouse forestomach cancer[10,11] and of rat mammary tumorigenesis[12-15].

Although the exact mechanisms are not clear, the inhibitory effect of CLA on the proliferation of rapidly dividing cells has been attributed to the induction of cell cycle arrest[1] and the induction of apoptosis[2,16]. In many instances, growth inhibition following terminal differentiation or anticancer drug treatment results in apoptosis. Apoptosis, namely, programmed cell death, is an active and physiological process characterized by a series of morphological and biological alterations in which the cells become smaller, shrinking, the nuclei round up, the chromatin becomes agglutinated and marginated, the nuclear membrane breaks down, and followed by the degenerative changes of the cells. The exact mechanisms of apoptosis are still unclear, but our earlier studies indicated that CLA can induce apoptosis in human gastric cancer SGC-7901 cells[2].

Gastric cancer is both common in China and the other parts of the world[17-30], and chemoprevention is always used as the main treatment for advanced cancer so far, which has become a focus topic in this area[31-54]. In this study, we investigate the pathways of apoptosis induced by *cis*-9, *trans*-11-CLA (c9, t11-CLA) which are thought to be high in proportion and activation as potential antioxidant and anticarcinogenic agents in CLA' s isomers and probe into the possible mechanism of apoptosis on human gastric adenocarcinoma cells SGC-7901.

MATERIALS AND METHODS

Materials

c9, t11-CLA, a monoisomer of c-9, t11-octadecadienoic acid with 98 % purity, was obtained from Dr. Ruihai Liu (Food Science and Toxicology, Department of Food Science, Cornell

University, Ithaca, NY, USA). The c9, t11-CLA was dissolved in 96 ml· L^{-1} ethanol, and diluted to the following concentrations: 25, 50, 100 and 200 μmol· L^{-1}.

Methods

Cell culture Human gastric adenocarcinoma cells(SGC-7901), purchased from Cancer Research Institute of Beijing (China), were cultured in RPMI 1640 (Gibco) medium, supplemented with calf serum 100 ml· L^{-1}, penicillin (100×10^3U· L^{-1}) and streptomycin (100 mg· L^{-1}). The pH was maintained at 7.2-7.4, by equilibration with 5 % CO_2. The temperature was kept at 37℃.The cells were sub-cultured with a mixture of Ethylenedinitrile tetraacetic acid (EDTA) and trypsin.

Cell growth curve The SGC-7901cells were seeded in six 24-well plates (Nuc, Co.), each well containing 2×10^4 cells. After 24 h, the medium of different plates was replaced with media supplemented with c9,t11-CLA at different concentrations. On the next day, the numbers of cells of 3 wells from each plate was determined by using the trypan blue staining. The means were obtained on each of eight days and were used to draw a cellular growth curve. The inhibitory rates (IR) on the 8th day was calculated as follows:

$$IR(\%)=\frac{\text{Total number of cells in negative control (8d)- Number of cells in test groups(8d)}}{\text{Total number of cells in negative control(8d)}}\times100\%$$

Apoptosis detection and cell cycle analysis

SGC-7901 cells (5×10^5 cells in 25 ml bottles) were seeded in appropriate medium for 24 h prior to the beginning of the experiment. The medium was then replaced with different concentrations of c9, t11-CLA. After 24 h and 48 h, the cells were harvested using a mixture of trypsin/EDTA, washed twice with cold PBS, fixed in 70 % ethanol on ice for 30 minutes, and washed once again. Cells were then stained by adding 1 ml of PI mixture (containing 50 μg propidium iodide, 0.2 mg RNAse, 5 μL Triton X-100, and 1 mg citromalic acid) in the dark (4 ℃, 30 minutes). Cell apoptosis and cell cycle analysis were subsequently performed by flow cytometry using a FACSCalibur Analyzer (BD Biosciences) with a 15-milliwatt air-cooled argon laser (excitation=488 nm). Sub G_1 peak was observed and DNA content in phases of cell cycle was analyzed using software of ModiFix LT.

Cell samples

SGC-7901 cells were treated for 24 h and 48 h with various concentrations of c9, t11-CLA and collected by centrifugation. Specimens were fixed immediately in 40 g· L^{-1} formaldehydum polymerisatum and embedded in paraffin. Gastric cancer tissue from a patient served as a reference.

Primary antibody

To examine the expression of Ki67 cell proliferation and the expression of bcl-2, *c-myc* and Fas in SGC-7901 cells, we used four primary antibodies: corresponding rabbit polyclonal antibodies for bcl-2 and Fas and corresponding mouse monoclonal antibodies for ki67 and *c-myc*. Antibodies of bcl-2 and Fas were purchased from the Calbiochem Co. USA; and others from Zhongshan Co. China.

Immunocytochemistry

Immunocytochemical staining was performed on serial sections at room temperature using the horseradish peroxidase method. The sections were deparaffinized in xylene and rehydrated through graded alcohol. The sections were incubated for 10 min at 95 ℃ in 10 mmol· L^{-1} sodium citrate(pH 6.0) buffer for ki67 staining. Endogenous peroxidases were inactivated by immersing the sections in hydrogen peroxide for 10 min, and then were incubated for 10 min with 100 ml· L^{-1} normal goat serum in PBS to block the non-specific binding. The sections were subsequently incubated overnight at 4 ℃ with relevant antibodies(1:50 dilution) respectively. The next day, the sections were incubated with biotinylated anti-mouse or anti-rabbit IgG (Zhongshan Co., China) for 30 min, followed by peroxidase-conjugated streptavidin (Zhongshan Co., China) for 30 min. The chromogenic reaction was developed with DAB (diaminobenzidine) for 10 min, and all sections were counterstained with hematoxylin. Controls consisted of omission of the primary antibody. The positive rate (PR) was calculated as follows:

$$PR(\%)=\frac{\text{Number of positive cells}}{\text{Total number }(2\times10^4)}\times100$$

Statistical analysis

Analysis of data was performed using the Student' s *t* test or χ^2 test. A value of $P<0.05$ is considered to be statistically significant.

RESULTS

Effect of c9,t11-CLA on SGC-7901 cell growth

As shown in Figure 1, growth of the cells in various concentrations (except for 25 μmol· L^{-1} and 50 μmol· L^{-1}) of c9, t11-CLA did differ from the negative control within 8d. SGC-7901 cells incubated in 25 μmol· L^{-1} of c9,t11-CLA grew at a higher rate than that of the negative control, while in 100 and 200 μmol· L^{-1} concentrations of c9, t11-CLA, proliferation of SGC-7901 cell was significantly inhibited. The inhibitory rate of various c9, t11-CLA concentrations were 5.9 %, 20.2 %, 75.6 % and 82.4 %, respectively.

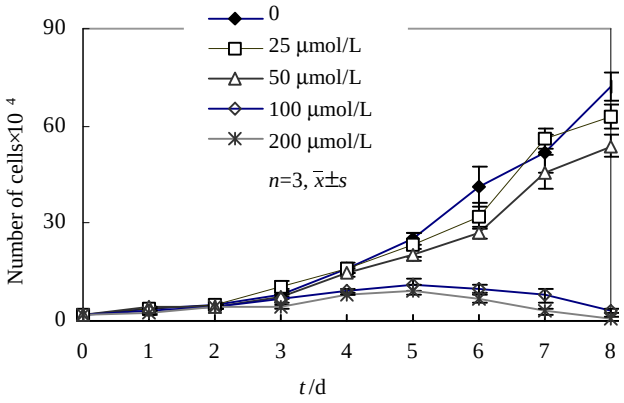

Figure 1 Growth curve of SGC-7901cells cultured in various concentrations of c9,t11-CLA

Analysis of flow cytometry

To investigate the influence of c9, t11-CLA on apoptosis and cell cycle progression of SGC-7901 cells, we determined apoptosis and cell cycle distribution by flow cytometry. The results are shown in Table 1. We observed that apoptotic peaks and intention of the cells accumulating in the G_0/G_1 phases and of cells decreased in the S phase of the cell cycle in SGC-7901 cells with different c9, t11-CLA concentrations at various time periods, whereas G_2/M did not. The results suggested that c9, t11-CLA may induce apoptosis and arrest the progression of cell cycle of SGC-7901 cells.

Cell proliferation

Ki67 is a marker for the proliferation of cells. To determine the

effect of c9, t11-CLA on the proliferation of SGC-7901 cells, we investigated the expression of ki67 using immunocytochemistry. The results are shown in Figure 2. Expression rates of ki67(Figure 3A) on SGC-7901 cells gradually decreased after SGC-7901 cells were incubated with different concentrations of c9,t11-CLA at various time periods. Moreover, SGC-7901 cells expressed significantly less ki67 than did the negative control (P<0.01). The expression rate of ki67 on SGC-7901 cells displayed a dose-response relationship as the concentrations of CLA increased.

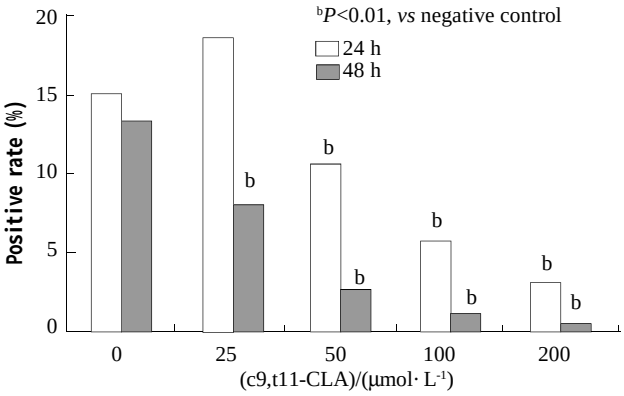

Figure 2 Expression of ki67 on SGC-7901 cells treated with c9, t11-CLA

Expressions of bcl-2, Fas and c-myc

We detected the expression of bcl-2, Fas, and *c-myc* on SGC-7901 cells treated by various concentrations of c9, t11-CLA with immunocytochemical technique. The expression rates of bcl-2 and *c-myc* (Figure 3B, 3D) on SGC-7901 cells was decreased (Table 2) after SGC-7901 cells were incubated with different concentrations of c9, t11-CLA for 24 h and 48 h while expression of Fas increased (Table 2; Figure 3C). In the meantime, there was no expression of Fas at doses of c9,t11-CLA (25 and 50 μmol· L^{-1} at 24 h).

DISCUSSION

CLA is a natural fatty acid in animal' s food. CLA has a mixture of positional (9/11 or 10/12 double bonds) and geometric (various *cis*/*trans* combinations) isomers of linoleic acid (LA) formed by rumen and colonic bacteria. There are eight potential isomers of CLA, but the *cis* 9, *trans* 11 and *trans* 9, *cis* 11 isomers are thought to be active as potential antioxidant and anticarcinogenic agents. Therefore, it is of interest to investigate extensively the mechanism of anticancer activities of CLA.

Over the past ten years, a number of animal experiments have supported the observation that CLA is an effective chemopreventive agent for cancer, and that it can inhibit carcinogenesis of different tissues at various stages of induction by chemical agents[14,15]. Several investigators in our group have reported that c9, t11-CLA is an effective agent to prevent carcinogenesis[10,11] and cancer[1-3,7]. Zhu' s study[10] demonstrated that c9, t11-CLA could significantly inhibit the mice forestomach neoplasia induced by B(a)P (50 mg·kg^{-1}) in post-initiation in short term (23 weeks). The incidences of tumors in mice of B(a)P group, B(a)P with high dose CLA (5 μL·g^{-1}) group and B(a)P with low dose CLA(2.5 μL·g^{-1}) group were 100 %, 60 % and 69 %, respectively (P<0.05). Xue' s study[10] also indicated that the incidence of neoplasm in mouse forestomach in the B(a)P group, 75 % pure c9, t11-CLA group, 98 % pure c9, t11-CLA group and 98 % pure t10, c12-CLA group were 100.0 %, 75.0 %, 69.2 % and 53.8 %, respectively. This may be due to an inhibiting mitogen of activated protein kinase (MAPK)- an approach to reduce carcinogenesis.

The data in this series suggested that c9,t11-CLA could inhibit the proliferation of cancer cells, i.e. SGC-7901 cells[1,2] and MCF-7 cells[3,7], and induced cancer cell (SGC-7901) apoptosis[2]. Liu' s study[1] indicated that cell growth and proliferation and DNA synthesis of SGC-7901 cells were inhibited and SGC-7901 cells preincubated in media supplemented with different c9,t11-CLA concentrations at various time periods significantly decreased the expressions of PCNA (the expression rates were 7.2-3.0 %, at 24 h and 9.1-0.9 % at 48 h, respectively), Cyclin A (11.0-2.3 %, at 24 h and 8.5-0.5 %, at 48 h), B_1 (4.8-1.8 % at 24 h and 5.5-0.6 % at 48 h) and D_1 (3.6-1.4 % at 24 h and 3.7 %-0 at 48 h) as compared with those in the negative controls (the expressions of PCNA, cyclin A, B_1 and D_1 were 6.5 % at 24 h and 9.0 % at 48 h, 4.2 % at 24 h and 5.1 % at 48 h, 9.5 % at 24 h and 6.0 % at 48 h, respectively) (P<0.01), whereas the expressions of $p16^{ink4a}$ and $p21^{cip/waf1}$, cyclin-dependent kinases inhibitors (CDKI) were increased. Our results showed that the proliferation marker Ki67 was inhibited and the cells were accumulating in the G_0/G_1 phase and cells decreasing in the S phases of the cell cycle on SGC-7901 cells with different c9, t11-CLA concentrations at various time periods, whereas G_2/M did not have. All these results suggested that c9, t11-CLA may arrest the progression of cell cycle of SGC-7901 cells. Our previous works[2] indicated that at the early stage morphological changes of cell apoptosis were observed using fluorescent dye (Hoechst 33342) under electronic microscope and SGC-7901 cells preincubated in media supplemented with different c9, t11-CLA concentrations at various times significantly decreased the expressions of mutant p53 as compared with those in the negative control. The inhibitory rates of mutant p53 on SGC-7901 cells induced by various c9,t11-CLA concentrations (25-200 μmol·L^{-1}) were -19.2 %, 13.7 %, 53.4 %, and 89.0 % at 24 h and 1.8 %, 29.1 %, 87.3 %, and 86.8 % at 48 h, respectively. p53 is one of the major factors controlling cell proliferation, suppressing both growth and transformation of cells. A common idea[55] is that p53 acts as "guardian of the genome" by preventing damaging of DNA in cell proliferation or DNA damage leads to an increase in the level of p53, resulting in $p21^{CIP1/WAF1}$-mediated cell cycle arrest in the G_1 phase, which persists until DNA repair is completed or by arresting the cell division cycle induces damaged-cell apoptosis. In the absence of functional wild-type p53, the "guardian" function is lost; cells accumulate genetic damage and show marked genetic instability, often to the extent of gross aneuploidy. However, wild-type p53 protein has a very short half-time, many point mutants have a greatly enhanced stability, allowing for the immunohistochemical detection of mutant p53 in clinical material. Mutant p53 protein loses its biochemical functions which may facilitate DNA repair as well as apoptosis, and displayed over-proliferation of cancer cells. In addition, Natalie *et al*[56] found that a fraction of p53 protein localizes to mitochondria at the onset of p53-dependent apoptosis. The accumulation of p53 to mitochondria is rapid (within 1 h after p53 activation) and precedes changes in mitochondrial membrane potential, cytochrome c release, and procaspase-3 activation. Overexpression of anti-apoptotic bcl-2 inhibits signal-mediated mitochondrial p53 accumulation and apoptosis but not cell cycle arrest. Our results showed that c9, t11-CLA may reduce the expression of mutant p53 protein and may recover the bio-function of wild p53 protein that blocks the cell cycle of SGC-7901 cells by $p21^{CIP1/WAF1}$ and processes to another apoptotic pathway of mitochondria by bcl-2.

At the same time, we investigated further the expressions of bcl-2 and Fas from pathways of cell apoptosis such as mitochondria and Fas-associated death domain (FADD) as well as expression of *c-myc* on SGC-7901 cells treated with various concentrations of c9,t11-CLA. Bcl-2 is an inhibitor of apoptosis and shown to exert anti-apoptotic activity by one of the following mechanisms[57]: 1) sequestration of the proforms of two major initiator caspases, pro-caspase-9 (through binding to Apaf-1) and pro-caspase-8 (through unidentified molecules); 2) inhibition of apoptogenic mitochondrial changes, including cytochrome c release and the mitochondrial membrane potential ($\Delta\Psi$) loss resulting in AIF (apoptosis-inducing factor) release, as demonstrated using isolated mitochondria bearing endogenous bcl-2 and recombinant forms of these proteins, and 3) Inhibition of accumulation of p53 in mitochondrial membrane[56]. Fas is a potent inducer of apoptosis in tumor cells but not in normal cells. Fas/CD95 requires ligand receptor (FasL/CD95L) which binds to FasL and via downstream signaling molecules FADD activates caspase-8. Fas binding to FasL can activate two routes downstream of caspase-8 activation[58]: type I apoptosis signaling: direct activation of effector' s caspases by caspase-8; type II apoptosis (inhibition of bcl-2 overexpression): cleavage of proapoptotic members of bcl-2 family, $\Delta\Psi$, release of cytochrome c and activation of caspase-9. The present study indicated that expression of bcl-2 protein decreased and expression of Fas increased on SGC-7901 cells induced by c9, t11-CLA as compared with that in negative control. c9, t11-CLA may induce apoptosis via pathways of bcl-2-assiciated mitochondria, p53-associated cell cycle and FADD on SGC-7901 cells. The relationship among p53, bcl-2 and Fas is still

unclear in the effect of apoptosis on SGC-7901 cells induced by c9,t11-CLA. The *c-myc* oncogene product (*c-myc*) is a transcription factor that dimerizes with Max and recognized E-box sequence, and it plays key functions in cell proliferation, differentiation and apoptosis[59]. *C-myc* expression can not only promotes proliferation but also induce or sensitize cells to apoptosis. Overpression of *c-myc* under the circumstances that this gene is usually down regulated such as serum deprivation, results in apoptotic cells in nonhepatic cells and in a hepatoma cell line[60]. But our result showed that expression of *c-myc* with 10 % calf serum was lowered with c9, t11-CLA in SGC-7901 cells. We have not known the reason why expression of *c-myc* on SGC-7901 cells is lower than that in negative control, and this needs further studies.

In conclusion, c9, t11-CLA may inhibit proliferation and induce apoptosis by decreasing in the expression of ki67, bcl-2 and increasing that of Fas in SGC-7901 cells. This result suggested that the inhibition effect of c9, t11-CLA on SGC-7901 cell proliferation is related to the pathways of bcl-2-associated mitochondria, p53-associated cell cycle and FADD on SGC-7901 cells. In the meantime, we found that expression of *c-myc* was lowered, but we do not know its action how to regulate apoptotic progression in SGC-7901 cells. The apoptotic mechanism of c9, t11-CLA in SGC-7901 cells awaits further studies.

Abstract

AIM: To investigate the relationship between the mast cell density (MCD) and the context of clinicopathological parameters and expression of p185, estrogen receptor (ER), and proliferating cell nuclear antigen (PCNA) in gastric carcinoma.

METHODS: Mast cell, p185, ER, and PCNA were detected using immunohistochemical S-P labeling method. Mast cell was counted in tissue of gastric carcinoma and regional lymph nodes respectively, and involved lymph nodes (ILN) were examined as usual.

RESULTS: MCD was significantly related to both age and depth of penetration (χ^2=4.688,P<0.05 for age and χ^2=9.350, P<0.01 for depth of penetration) between MCD>21/0.03 mm^2 and MCD≤21/0.03 mm^2 in 100 patients; MCD in 1-6 ILN group patients was significantly higher than that in 7-15 ILN or >15 ILN group patients (u=6.881, 8.055, P<0.01); There were significant differences intergroup in positive expression rate of p185, ER and PCNA between MCD >21/ 0.03 mm^2 and MCD≤21/0.03 mm^2 in 100 patients.

CONCLUSION: Mast cell may have effect on inhibiting invasive growth of tumor, especially in the aged patients; The number of mast cells, in certain degree, may predicate the number of involved lymph nodes, which is valuable for assessment of prognosis; MCD was related to the expression of p185, ER, and PCNA in gastric carcinoma. It suggests that mast cell accumulation may inhibit the proliferation and the dissemination of the gastric carcinoma.

INTRODUCTION

Recently, many studies have reported on the association of mast cell with various tumors[1-9]. In several malignancies, mast cell has been found to correlate with growth, penetration and prognosis of tumor[10-13]. Therefore, our study was undertaken to investigate the relationship between the mast cell density (MCD) and the context of clinicopathological parameters and expression of p185, estrogen receptor (ER), and proliferating cell nuclear antigen (PCNA) in gastric carcinoma.

MATERIALS AND METHODS

Materials

The specimens of gastric carcinoma, histologically confirmed, were surgically obtained from 421 patients. The patients had undergone curative tumor resection at our hospital between 1984 and 1998. And only 100 patients were chosen at random in our study. Among 100 patients, 41 patients had lymph node metastases. All resected tissue specimens were fixed in formalin, embedded in paraffin, and cut into 3-4 μm serial sections. 459 lymph nodes were collected from 41 patients (range, 8-26 per patient).

Methods

Mast cell, p185, ER, and PCNA were detected using immunohistochemical method (agents from Maixin-Bio Corp. Fuzhou, China).The count of mast cells in the tissue of gastric carcinoma was as described by Takanami *et al*[10]. A grid (0.15 mm by 0.2 mm) which was defined an area of 0.03 mm^2 per field was used for to count mast cells. Similarly, that of mast cells in regional lymph nodes was described by Bowers *et al*[14].A grid which defined an area of mm^2 per field was used. ILN was examined using routine pathological method. The results were expressed as the means ±SD. Statistical analyses were performed using the Chi-square and u test. A P value less than or equal to 0.05 was considered significant.

RESULTS

Table 1 showed the clincopathologic parameters for two groups (high MCD group, MCD was more than 21/0.03 mm^2, and low MCD group, MCD was equal to 21/0.03 mm^2 or less). There were no significant differences between two groups regarding both degree of differentiation and largest dimension of tumor. However, MCD was significantly related to both age and depth of penetration (P<0.05 for age and P<0.01 for depth of penetration) (Figure 1).

Table 2 showed correlation between MCD and cancerous metastases in regional lymph nodes. MCD in 1-6 ILN group patients (n=21) was 12±3.11, 7-15 ILN (n=14), 6±2.06, >15 ILN (n=6), 5±1.33, respectively. MCD in 1-6 ILN group patients was significantly higher than that in 7-15 ILN or >15 ILN group patients (P<0.01), but, MCD in 7-15 ILN group patients was not significantly higher than that in >15 ILN group patients (P>0.05) (Figure 2).

Table 1 Correlation between MCD and Clinicopathologic finding of gastric carcinoma (n=100)

Variable	MCD>21/0.03 mm²	MCD≤21/0.03 mm²	*P* Value
Age (yrs)			
<60	16	25	<0.05
≥60	36	23	
Degree of differentiation			
Well	18	14	>0.05
Moderately	23	21	
Poorly	11	13	
Largest dimension of tumor (in mm)			
≤30	30	36	>0.05
>30	22	12	
Depth of penetration			
Involved serosa	21	34	<0.01
Not involved serosa	31	14	

Table 2 Correlation between MCD and cancerous metastases in regional lymph nodes (n=41)

Variable	*n*	MCD ($\bar{x}\pm s$, /mm²)
1-6 ILN	21	12±3.11
7-15 ILN	14	6±2.06
> 15 ILN	6	5±1.33

ILN: involved lymph nodes

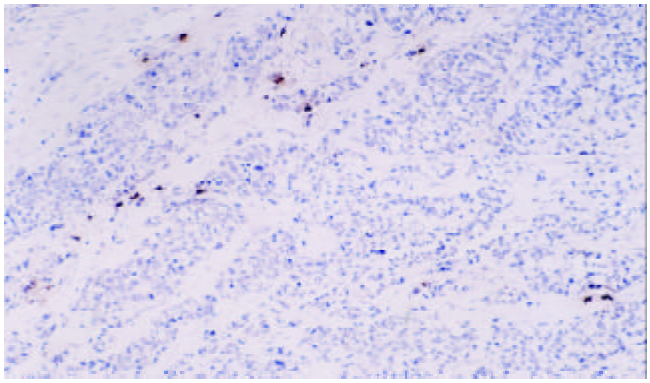

Figure 1 Mast cells of gastric carcinoma (Tryptase labeling, DAB staining, original magnification, ×100)

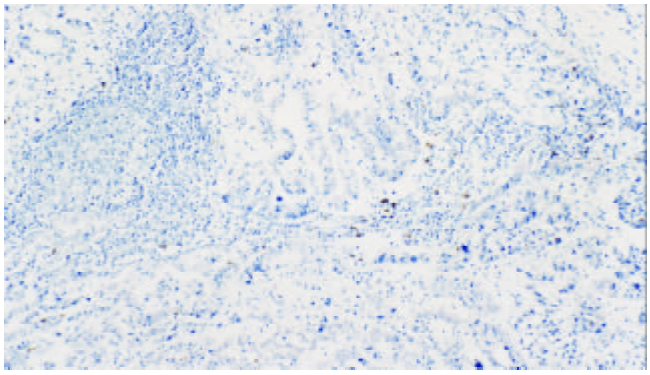

Figure 2 Mast cells of regional lymph nodes of gastric carcinoma (Tryptase labeling, original magnification, ×100)

There were significant differences intergroup in positive expression rate of p185, ER and PCNA between high MCD group (the MCD was more than 21/0.03 mm²) and low MCD group (the MCD was equal to 21/0.03 mm² or less) (P<0.01). As was shown in Table 3 (Figure 3,4,5).

Table 3 Correlation between MCD and the positive expression rate of p185, ER, and PCNA in the gastric carcinoma tissues

MCD	*n*	Positive expression rate (%)		
		p185	ER	PCNA
>21/0.03 mm²	52	22(42.31)	11(21.15)	12(23.08)
≤21/0.03 mm²	48	31(59.62)	28(53.84)	27(51.92)
P Value		<0.01	<0.001	<0.01

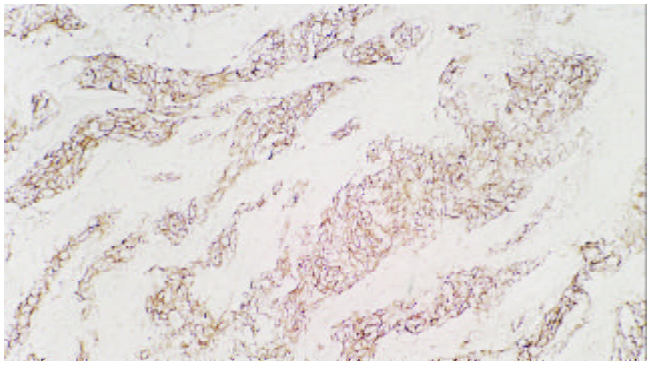

Figure 3 p185 of gastric carcinoma (Original magnification,×100)

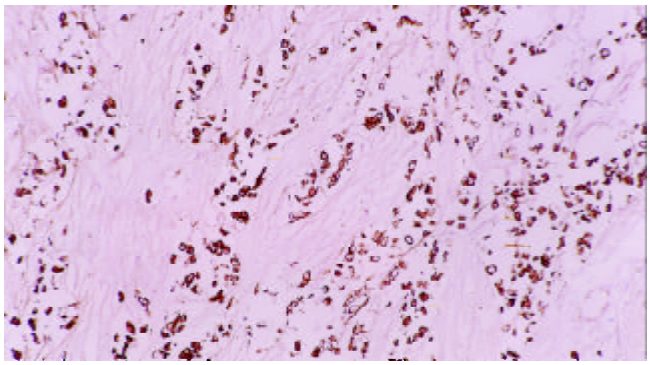

Figure 4 Estrogen receptor of gastric carcinoma (Original magnification, ×100)

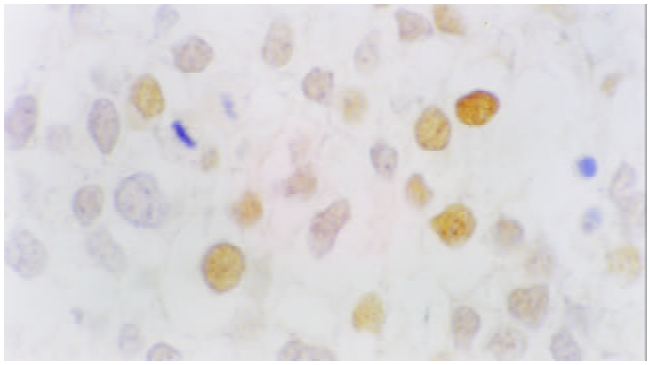

Figure 5 PCNA of gastric carcinoma (Original magnification,×400)

DISCUSSION

Numerous studies have shown that mast cell plays an important role in tumor growth. Dabbou *et al*[15,16] found that mast cells were accumulated around the periphery of the invasive and metastatic rat mammary adenocarcinoma, and they believed that interactions between mast cell and tumor cell were important for the growth and invasive properties of the tumor. Nakamura *et al*[17] found the mechanism of mast cell accumulation at sites of tumors was that tumor cells could produce a factor which might not be the already known mast cell growth factors. Wang *et al*[18] found that the anti-tumor effect of mast cell might be related to releasing of tumor necrosis factor (TNF) and non-TNF cytotoxicity. Our results revealed there were no significant differences intergroup regarding both degree of differentiation and largest dimension of tumor between MCD >21/0.03 mm^2 and MCD$\leqslant$21/0.03 mm^2. MCD was significantly related to both age and depth of penetration (P<0.05 for age and P<0.01 for depth of penetration).

The data indicate the lymph node status is associated with the patients' prognoses in many malignancies, and may be useful in assessing the outcome of this disease[19-28]. The treatment regimen was depended on not only whether involved lymph node was present or not, but also the number of involved lymph node[20,29]. Maurel *et al*[30] had examined 7.7±0.2 lymph nodes per specimen in 851 patients with resected colorectal carcinoma, the results strongly pointed out that at least eight lymph nodes must be examined and they called the number of eight as a "golden number". At least eight lymph nodes per specimen were examined in our study as done by Maurel *et al*[30]. Roder *et al*[20] followed up 477 patients with gastric carcinoma of lymph node metastasis, and they found that 5-year survival rates were as follows (1) 1-6 involved lymph nodes: 45.5 %; (2) 7-15 involved lymph nodes:29.7 %; (3) >15 involved lymph nodes: 10.4 %. There was a highly significant difference in survival (P<0.0001). Our results indicated that MCD in 1-6 ILN group patients was 12±3.11, 7-15 ILN, 6±2.06, >15 ILN, 5±1.33, respectively. MCD in 1-6 ILN group patients was significantly higher than that in 7-15 ILN or >15 ILN group patients (P<0.01), but, MCD in 7-15 ILN group patients was not significantly higher than that in >15 ILN group patients (P>0.05). In other words, the higher MCD was in regional lymph nodes, the lower number of ILN of gastric cancerous metastases was. It demonstrates that the number of mast cells, in certain degree, may predicate the number of involved lymph nodes of gastric cancerous metastases. Therefore, MCD is a valuable parameter for assessing the prognosis of patients with gastric carcinoma.

The C-erbB-2 was first identified in ethylnitosourea-induced rat neuroblastoma. It encodes a 185 kilodalton (kDa) glycoprotein. It was reported recently that overexpression and gene amplification of C-erb B-2 were frequently observed in the intestinal type gastric adenocarcinoma, and it was a prognostic indicator in tumor[31-33]. ER is commonly known to be present in the cell of the breast and endometrium, but have also been identified in diverse normal and neoplastic nonreproductive tissues. The expression of ER has been considered to be a favorable prognostic factor in breast carcinoma and endometrial carcinoma but a poor prognostic factor in gastric carcinoma[34]. PCNA is an auxiliary protein of DNA polymerase delta which plays a major role in synthesizing DNA and is expressed in the nuclei, particularly in the late phase of G_1 and S. Therefore PCNA is a useful marker for proliferative activity[35-37]. Our results showed there were significant differences intergroup in the positive expression rate of p185, ER and PCNA between MCD>21/0.03 mm^2 and MCD $\leqslant$21/0.03 mm^2. It suggests that mast cell accumulation may inhibit the proliferation and the dissemination of gastric carcinoma. This finding may provide a molecular foundation of the further study on relation between mast cell and gastric carcinoma.

Abstract

AIM: To investigate the relationship between the antigen MG7 antigen expression and gastric cancer as well as precancerous condition; to study the relationship between the MG7 antigen expression and *H. pylori* infection in benign gastric lesions in order to find out the effect of *H. pylori* infection on the process of gastric cancer development.

METHODS: The level of MG7 antigen expression was determined by immunohistochemical method in 383 gastric biopsied materials. The intestinal metaplasia was determined by histochemistry method. The *H. pylori* infection was determined by HE stain, PCR and ELISA in 291 specimens, among which only 34 cases of *H. pylori*-associated gastric lesions were followed up.

RESULTS: The positive rate of MG7 expression in normal gastric mucosa, intestinal metaplasia, dysplasia and gastric cancer increased gradually in ascending order ($P<0.01$). The positive rate of MG7 antigen expression in type III intestinal metaplasia of gastric mucosa was higher than that of type I and II intestinal metaplasia, being highly significant ($P<0.05$). The positive rate of MG7 antigen expression in superficial gastritis, atrophic gastritis and gastric cancer increased gradually (11.9 %, 64.8 %, 91.2 %, $P<0.01$). There was no significant difference between *H .pylori*-negative and *H. pylori*-positive intestinal metaplasia, atrophic gastritis and dysplasia of gastric epithelium in the positive rate of MG7 antigen expression. There was no expression of MG7 antigen in *H. pylori*-negative superficial gastritis. The positive rate of MG7 expression in *H. pylori*-positive superficial gastritis was 20.5 %, and the difference between them was significant ($P<0.05$). During following up, one of the three *H. pylori* negative cases turned positive again, and its MG7 antigen expression turned to be stronger correspondingly. 3 of 31 *H. pylori* positive cases were detected as early gastric cancer, among which one with "+++" MG7 antigen expression was diminished after *H. pylori* eradication.

CONCLUSION: MG7 antigen expression is highly specific in gastric cancer and can be used as a good marker for screening of gastric cancer; type III intestinal metaplasia, atrophic gastritis and dysplasia should be followed up and MG7 antigen expression has high clinical value in the dynamic follow-up study; although the positive -MG7 in positive -*H. pylori* superficial gastritis show benign morphology in features, there is still the potential risk of developing into gastric cancer, hence special attention should be paid to those showing increasing MG7 antigen expression.

Guo DL, Dong M, Wang L, Sun LP, Yuan Y. Expression of gastric cancer-associated MG7 antigen in gastric cancer, precancerous lesions and *H. pylori*-associated gastric diseases. *World J Gastroenterol* 2002; 8(6):1009-1013

INTRODUCTION

Gastric monoclonal antibody MG7 was first gotten by immunizing the BALB/C mice directly with poor-differentiated adenocarcinoma gastric cancer cell line MKN-46-9[1]. By immunohistochemistry method the MG7 antigen is distinguished limited in the gastric cancer tissue[2-5], which is specific and serves as a marker of gastric cancer. *Helicobacter pylori (H. pylori)* infection is established as a major cause of gastritis, peptic ulcer disease and gastric cancer[6-8]. The current study is to investigate the dynamic expression of MG7 antigen in different gastric mucosa, including the normal gastric tissue, *H. pylori*-associated gastric lesions as well as other precancerous conditions and gastric cancer, also to investigate the influence of *H. pylori* on MG7 antigen expression.

MATERIALS AND METHODS

Clinical data

The gastric cancer-associated antigen MG7 expression was studied in 383 gastric mucosal biopsied materials, including 26 normal gastric mucosa, 67 superficial gastritis, 21 gastric ulcer, 71 atrophic gastritis, 82 intestinal metaplasia, 59 dysplasia, and 57 gastric cancerous tissue, among which 29 were differentiated and 28 undifferentiated.

Reagents

The MoAb MG7 was gifted by Professor Fan Daiming in No. 4 China Military Medical University; The ABC kit was the product of American Vecter Company.

HID-ABpH2.5-PAS mucin histochemistry stain

82 IM were categorized into three types according to the morphology, degree of differentiation and mucin-protein secreted. These were stained with Alican blue pH 2.5/ periodic acid Schiff (AB/PAS) to visualize neutral mucin and some acidic mucins, and with high iron diamine/Alcian blue pH 2.5 (HID/AB) to identify sulphomucin and sialomucin[9]. Type I

(complete) was characterized by mature absorptive and goblet cells, the latter secreted sialomucin. Paneth's cells were often present. Type Ⅱ (incomplete) showed few or no absorptive cells, but with 'intermediate' columnar cells in various differentiated stages, secreting neutral and sialomucins, while Paneth's cells might not be present. In type III (incomplete), cell dedifferentiation was more obvious than that in type Ⅱ, with 'intermediate' cells secreting predominantly sulphomucin and goblet cells containing sialo- and/or sulphomucin. Paneth's cells were usually absent. A variable degree of disorganized architecture was often present in type III IM.

H. pylori examination

The *H. pylori* infection was detected by HE stain, PCR and ELISA. *H. pylori* was considered positive if two of the above three methods were positive. *H. pylori* could be found in the gastric epithelium or in the mucus by histological examination. Detection of *H. pylori* with *H. pylori*-DNA-PCR method followed the protocol of kit. The band in the same position as the positive control was defined as positive. When ELISA method was performed, the sample with OD value/ OD average value of negative controls ≥2.1 was defined as positive.

Immunohistochemistry stain (ABC method) of gastric cancer-associated antigen MG7

4 μm thick sections were cut from paraffin wax blocks, mounted on acid cleaned glass slides, and heated at 55 ℃ for 60 minutes. The slides were dewaxed and dehydrated, then the endogenous peroxidase activity was inhibited by incubation with 3 % H_2O_2 (20 minutes at room temperature). To reduce the non-specific background staining, the slides were incubated with 2 % horse serum (20 minutes at room temperature), then were incubated with MG7 antibody in a moist chamber at 4 ℃ overnight. The avidin-biotin-peroxidase complex procedure was then performed as described by ABC immunohistochemistry kit. Peroxidase activity was detected with diaminobenzidine as substrate. Finally, the sections were weakly counterstained with Harris's haematoxylin. Negative controls with PBS replacing specific primary antibodies were included in each run. Positive controls were cases of undifferentiated gastric cancer with MG7 expression. The sections were considered positively stained only when unequivocal cellular membrane and cytoplasm staining for MG7 were present. Diagnosis was made by brown coloration with varied intensities and the number of cells with brown coloration[10] . score 1: light brown; score 2: brown; score 3: deep brown. score 1: stained cells <30 %; score 2: stained cells 30-70 %; score 3: stained cells > 70 %. According to the sum of the two index, as that comprehensive scores were made. Comprehensive score 0 was defined as negatively expressed, comprehensive scores 2-4 were defined positively expressed, the cases and that above 4 was defined as over-expressed.

Statistical analysis

The results were analyzed by χ^2 test.

RESULTS

The expression of gastric cancer-associated MG7 antigen in different gastric mucosal tissues

The coloration in gastric cancerous tissue was often brown or deep brown, which was mainly located in the cellular membrane, cytoplasm and the glandular lumen, but not in the nucleus. The brown coloration was usually diffusely and non-polar distributed in the cytoplasm of cancer cells and might also be present in the luminal surface of the glands, sometimes it was located in some cancer cell nests or glands. The coloration in benign gastric lesions was often light brown, which was mainly located at the apex of the cytoplasm, the luminal surface membrane, none was seen in the cell nucleus. There were less positive cells in benign gastric lesions.

There was no expression of MG7 antigen in normal gastric mucosa. The positive rate of MG7 antigen expression in gastric cancer was 91.2 %. The level of MG7 antigen expression in undifferentiated gastric cancer was higher than that of differentiated gastric cancer (89.7 %, 92.3 %, $P>0.05$). From the viewpoint of histology, the positive rates of MG7 expression in normal gastric mucosa, metaplasia/dysplasia and gastric cancer increased gradually ($P<0.01$), see Table 1. From clinical viewpoint the positive rates of MG7 expression in superficial gastritis, atrophic gastritis and gastric cancer also increased gradually ($P<0.01$), see Table 2. The expression rates of MG7 antigen in the increasing order were normal gastric mucosa, superficial gastritis, intestinal metaplasia, atrophic gastritis, dysplasia and gastric cancer, there was significant difference between gastric cancer and other benign gastric lesion groups ($P<0.05$), see Table 1 and 2.

Table 1 The expression of MG7 antigen in various gastric lessions

Gastric lessions	*n*	No. of cases with MG7expression				Positive rate(%)	Over-expression rate(%)
		–	+	++	+++		
Normal gastric mucosa	26	26	0	0	0	0.0[b]	0.0[b]
Intestinal metaplasia	82	34	43	4	1	58.5[bd]	6.1[b]
Dysplasia	59	30	23	4	2	49.2[bd]	10.2[b]

[b]$P<0.01$ *vs*: compared with gastric cancer; [d]$P<0.01$ *vs*: compared with superficial gastritis

The expression of gastric cancer-associated MG7 antigen in different types of intestinal metaplasia

According to different mucin secreted, the intestinal metaplasia of gastric mucosa could be categorized into three types. The positive rate of MG7 antigen expression in type III intestinal metaplasia of gastric mucosa was significantly different as compared with type I and type Ⅱ intestinal metaplasia ($P<0.05$), but was close to gastric cancer ($P>0.05$). The over-expression rate of MG7 antigen in type I, type Ⅱ, type III intestinal metaplasia and gastric cancer increased gradually, and there was significant difference between gastric cancer group and other groups respectively ($P<0.05$), see Table 3.

Table 3 The expression of MG7 in different types of intestinal metaplasia and gastric cancer

Types of intestinal metaplasia	*n*	No. of cases with MG7expression				Positive rate(%)	Over-expression rate(%)
		–	+	++	+++		
type Ⅰ and Ⅱ intestinal metaplasia	53	28	24	1	0	47.2[bb]	1.9[b]
type Ⅲ intestinal metaplasia	29	6	19	3	1	79.3[dd]	13.8[b]
gastric cancer	57	5	23	18	11	91.2[dd]	50.9[d]

The expression of MG7 antigen in H. pylori-associated gastric diseases

On examination, *H. pylori* infection was detected in 291 specimens of different gastric mucosa tissues including 66 superficial gastritis, 20 gastric ulcer, 70 atrophic gastritis, 80 intestinal metaplasia and 55 dysplasia. The MG7 antigen expression was also examined in *H. pylori*-positive and *H. pylori*-negative groups of different gastric diseases. It was found that the positive rates of MG7 antigen expression in *H. pylori*-positive and *H. pylori*-negative cases of superficial gastritis, gastric ulcer, atrophic gastritis, intestinal metaplasia and dysplasia were 20.5 %/0, 25 %/12.5 %, 62.5 %/65.8 %, 52 %/66.7 %, 30.3 %/54.5 %, respectively. The positive rate of MG7 expression in *H. pylori*-positive superficial gastritis (20.5 %) was significantly higher than that in *H. pylori*-negative superficial gastritis ones (0), ($P<0.05$). There was no significant differences between *H. pylori*-negative and *H. pylori*-positive atrophic gastritis, intestinal metaplasia and dysplasia of gastric epithelium in positive rates of MG7 antigen expression, see table4. In the MG7 antigen expression positive ones, positive-*H. pylori* in superficial gastritis, intestinal metaplasia, atrophic gastritis and dysplasia of gastric epithelium was counted as 8/8, 26/46, 20/45, 10/22 respectively. Among the 8 superficial gastritis with MG7 expression, the rate of *H. pylori* infection was 100 %.

Table 4 The expression of MG7 antigen in *H. pylori*-associated gastric lesions

Gastric lesions	*H. pylori*-positive			*H. pylori*-negative		
	n	MG7 expression		No.of cases	MG7 expression	
		No. of cases	rate (%)		No.of cases	rate (%)
superficial gastritis	39	8	20.5	27	0	a
gastric ulcer	12	3	25	8	1	12.5
atrophic gastritis	32	20	62.5	38	25	65.8
intestinal metaplasia	50	26	52.0	30	20	66.7
dysplasia	33	10	30.3	22	12	54.5

[a]$P<0.05$ *vs* compared with *H. pylori*-positive cases of the same gastric lesion

The follow-up of cases with H. pylori-associated gastric diseases

34 cases were followed up for 2 years, among which 3 cases without *H. pylori* infection and 31 cases with *H.pylori* infection. There were 19 with negative MG7 antigen expression (-); 13 with weakly positive MG7 antigen expression (+); (++) and (+++) each. One year later, among the 3 without *H. pylori* infection, 1 case was found newly *H. pylori* infected accompanied by increased MG7 expression. Among 31 cases of *H. pylori*-positive diseases, early gastric cancer was detected in 3 with MG7 antigen expression, of which one with weakly positive MG7 antigen expression (+) was atrophic gastritis, one with MG7 antigen expression (++) was also atrophic gastritis but one case with MG7 antigen expression (+++) was superficial gastritis, see Table 5. After surgical operation and drug treatment, the reduced MG7 expression with *H. pylori* eradication was found in a case of superficial gastritis.

Table 5 The follow-up results of 34 cases with *H. pylori*-associated gastric diseases

Change of *H. pylori* status	No.of cases	MG7 antigen expression			
		mitigated	unchanged	aggravated	malignant change
H. pylori infection unchanged	19	4	13	1	1
H. pylori eradicated	14	4	7	1	2
H. pylori newly infected	1	0	0	1	0

DISCUSSION

Gastric cancer is still a major health problem and the leading cause of cancer mortality despite a worldwide decline in incidence. Early detection and early diagnosis are important in prevention and treatment of gastric cancer. The antigen recognized by gastric monoclonal antibody MG7[1] is different from other gastrointestinal tumor markers as reported[11,12]. It has been taken as a promising index in gastric cancer screening because of its specificity[1-4,13,14]. In this study, we found that the expression of MG7 antigen in different gastric tissue was different. The positive rate of MG7 antigen expression in gastric cancer is 91.2 %.The positive rate of MG7 expression in normal gastric mucosa, metaplasia/dysplasia and gastric cancer increased in ascending order ($P<0.01$). The positive rate of MG7 expression in superficial gastritis, atrophic gastritis and gastric cancer increased in succession ($P<0.01$). The expression rate of MG7 antigen in undifferentiated gastric cancer was higher than that of differentiated gastric cancer ($P>0.05$), cases with positive expression cells are more above 70 % in undifferentiated gastric cancer than that in differentiated gastric cancer ($P<0.05$), showing the presence of somewhat tendency of certain histopathologic type. The dynamic changes in expression of MG7 antigen in normal gastric mucosa, precancerous lesions and gastric cancer implicated that in the gastric precancerous conditions, MG7 antigen increased gradually with the development and progression of gastric cancer and its sensitivity was higher in gastric cancer, and could be used as a marker for screening.

This study showed that among the benign gastric lesions the positive rate of MG7 expression in atrophic gastritis and dysplasia were significantly higher than that in superficial gastritis but significantly lower than that in gastric cancer, implicating there were more gastric cancer-associated antigens in the cell membrane and cytoplasm of atrophic gastritis and dysplasia which was in access to gastric cancer. Intestinal metaplasia is taken as gastric precancerous lesion[16,17]. It was found that type Ⅲ (incomplete) intestinal metaplasia had cancerous potential, our study demonstrated the positive rate of MG7 antigen expression in type Ⅲ intestinal metaplasia of gastric mucosa was significantly different compared with type Ⅰ and type Ⅱ intestinal metaplasia ($P<0.05$), and was

analogous, even more closed to gastric cancer (P<0.05). Since the dynamic changes in of MG7 antigen expression was closely related with the development and progression of gastric cancer, cases with atrophic gastritis, dysplasia and type III intestinal metaplasia should be closely followed up for the early detection of gastric cancer.

The development of gastric cancer is a multistep process that is multifactorial. Several factors may act in stages of development of cancer[9]. Epidemiology data show the close relationship between *H. pylori* and gastric cancer[18,19]. *H. pylori* has been assigned as a class I carcinogen by WHO, and acts as the initiating agent. It virulence factors can damage gastric epithelial cells[20-22], break the balance between proliferation and apoptosis[23-33]. but it is still unclear weather *H. pylori* plays a role after development of atrophic gastritis and intestinal metaplasia[34,35].

Our study found that the positive rate of MG7 expression in *H. pylori*-positive superficial gastritis was higher than that in *H. pylori*-negative cases (P<0.05). There were 8 cases of positive *H. pylori* superficial gastritis with MG7 antigen expression, which suggested that *H. pylori* infection was directly stated to MG7 antigen expression. But there was no significant difference between *H. pylori*-negative and *H. pylori*-positive atrophic gastritis, intestinal metaplasia and dysplasia in the positive rate of MG7 antigen expression. This might be due to the change of the environment in atrophic gastritis, intestinal metaplasia and dysplasia, which was unsuitable for the growth of *H. pylori.*

By following up of the 34 cases of *H. pylori*-associated disease, we detected early gastric cancer in 3 *H. pylori*-positive cases with MG7 antigen expression, (2 cases of atrophic gastritis, one case of superficial gastritis). After surgical operation and drug treatment with *H. pylori* eradication reduced MG7 expression was found in the case of superficial gastritis. Among the 3 cases without *H. pylori* infections, 1 case had newly emerged *H. pylori* infection accompanied by increased MG7 expression. These implicated the close relationship between the *H. pylori* infection and the expression of MG7 antigen in gastric mucosa, although some *H. pylori*-positive gastric lesions with MG7 antigen expression showed benign morphology, there is still the potential risk of developing into gastric cancer, hence follow up study is essential; more attention should be paidto those with increased MG7 antigen expression.

Abstract

AIM: JNK cascade plays an important role in cell proliferation, differentiation and apoptosis. However, the exact function of JNK cascade for apoptosis induction remains largely unknown. In this study, the role of JNK activation stimulated by TPA in the process of apoptosis induction and its signaling transduction pathway in gastric cancer cells were investigated and determined.

METHODS: Expressions of mRNA and protein were detected by Northern blot and Western blot. Transcription activity was measured by transient transfection and CAT assay. Apoptotic cells were displayed through staining the nucleus with DAPI and were observed under fluorescence microscope. The apoptotic index was determined by counting 1000 cells randomly.

RESULTS: JNK protein was stimulated rapidly by TPA, and reached its highest peak within 3 hr, then decreased in a time-dependent manner, but the expression level of JNK protein induced by TPA was always keeping higher than that in untreated cells. Similar pattern was seen in *c-jun* mRNA level induced by TPA. TPA significantly activated the transcriptional activity of activator protein-1 with a TPA-dose-dependent manner. Furthermore, activation of JNK was mediated through PKC pathway. Treatment of cells with PKC specific inhibitor, Wortmannin, led to repression of JNK even in the presence of TPA. More importantly, all these effects were associated with induction of apoptosis in gastric cancer cells. TPA inducted apoptosis obviously in gastric cancer cells. The apoptotic cells became smaller and rounded, and their nuclei became condensation and fragmentation with brightly stained chromatin. However, suppression of JNK by PKC specific inhibitor, Wortmannin, resulted in the decrease of apoptosis induced by TPA in a time-dependent manner, apoptotic index dramatically decreased from 32.56 % to 8.71 %.

CONCLUSION: TPA stimulates JNK cascade, including up-regulation of JNK protein expression level and *c-jun* mRNA expression level, and activation of activator protein-1 transcriptional activity. Activation of JNK is mediated through PKC pathway, which has an association with induction of apoptosis by TPA. Thus, activation of JNK via PKC pathway may represent one of important mechanisms for TPA to induce apoptosis in gastric cancer cells.

INTRODUCTION

Mitogen-activated protein kinase (MAPK) pathway is an important signal transduction pathway that transduces extracellular signals in intracellular responses and has been implicated in a wide array of physiological processes including cell growth, differentiation, and apoptosis[1-6]. The extracellular signal-regulated kinase (ERK), the *c-jun* N-terminal kinase (JNK) and the p38 MAPK are the members of MAPK family[7-9]. Among them, JNK is one of the key mediators of stress signal and inflammatory response evoked by a variety of agents such as UV-irradiation, γ-irradiation, heat shock, and inflammatory cytokinase[10,11]. Once activated by specific kinases, JNK mediates the phosphorylation and activation of the transcription factors, such as *c-Jun*, ATF2, and ElK1[12,13].

JNK can be strongly activated through stress signal that ultimately leads to apoptosis. Accumulating reports have recently been focused on the potential role of JNK in apoptotic signaling. In PC12 cells, JNK plays a critical role in mediating apoptosis caused by nerve growth factor withdrawal[14]. The JNK pathway is also required for the induction of apoptosis by ceramide, γ- and UV-irradiation, some chemotherapeutic drugs[15-17]. Inversely, other reports have shown evidences that activation of JNK is not mechanistically implicated in the apoptotic process. activation of JNK does not correlate with apoptosis induced by the detachment of epithelial cells[18]. Inhibition of JNK activity by the expression of *c-jun* mutant does not prevent TNF-mediated cell death[19,20].

The present study investigates the effects of 12-O-tetradecanoyl-Phorbol-13-acetate (TPA) on activation of JNK and its role in apoptosis induction in gastric cancer cells. Our results indicated that TPA activated the expressions of JNK protein, which led to induction of *c-jun* mRNA expression, and was associated with activation of activator protein-1 transcriptional activity. Furthermore, activation of JNK cascade was mediated through protein kinase C (PKC) pathway. All these effects had an association with induction of apoptosis by TPA. Thus, activation of JNK via PKC pathway might represent one of mechanisms for TPA to induce apoptosis in gastric cancer cells.

MATERIALS AND METHODS

Cell line and culture condition

Human gastric cancer cell line, MGC80-3 was established by

Cancer Research Center, Xiamen University[21]. Cells were maintained in RPMI-1640 medium, supplemented with 10 % FCS, 1 m mol/L glutamine, and 100 u/ml penicillin. The concentration of TPA was 100 ng/ml.

Western blot analysis[22]

Cells treated by TPA were harvested, and suspended in RIPA buffer (10 m mol/L Tris (pH7.4), 150 m mol/L NaCl, 1 % Triton X-100, 1 % Deoxycholic Acid, 0.1 % SDS, 5 m mol/L EDTA (pH8.0), 1 m mol/L PMSF). Protein concentration was determined by using the Bio-Rad protein assay system according to the manufacturer' s direction (Bio-Rad Hereules, CA). Total protein (50 μg) was subjected to SDS-PAGE and transferred to nitrocellulose membrane for western blot analysis. The membrane was subsequently blocked with 5 % dry milk in TBS-T and then immunnoblotted with the corresponding antibody. Protein was detected by using the ECL kit (Amersham Inc.) according to the manufacturer' s direction. Before incubation with antibody, the same membrane was stained by ponceau S. (Sigma) to show the amount of protein used in each well. The intensities of bands indicated by Western blot were quantified by densitometer.

RNA preparation and northern blotting

Extraction of total RNA was performed by the guanidine hydrochloride/ultracentrifugation method. Total RNA (20 μg) was separated on 1 % agarose gel containing formaldehyde, and then transferred to nylon membrane, hybridized with α-^{32}p-dATP and α-^{32}p-dCTP labeled *c-jun* probe (Zhong Shang Biotec. CO., China), washed, and autoradiographed as described previously[23]. The same membrane was probed again with β-actin cDNA to show the amount of RNA used in each well. The intensities of bands indicated by Northern blot were quantified by densitometer.

Transient transfection and CAT assay[24]

Cells were seeded in a six-well plate and were approximately 70 % confluent at the time of transfection.Cells were transfected by CeLLFECTINtm (Gibco/BRI Life Technologies) by the following procedure: 6 μl CeLLFECTINtm in 1.0 ml standard medium was added to each well containing 1.0 ml of standard medium supplemented with the -73Col-CAT reporter plasmid (100 ng), β-galactosidase expression vector (400 ng, pCH110, pharmacia). CAT activity was determined using ^{3}H-acetyl-CoA as substrate. β-galactosidase activity was measured to normalize transfection efficiency.

Apoptosis analysis[25]

Cells were treated with TPA, trypsinized, washed with PBS. The harvested cells were fixed in 3.7 % paraformaldehyde on ice, washed with PBS, then stained with 50 μg/mL of 4,6-diamidino-2-phenylindole (DAPI, Sigma) containing 100 μg/mL of DNase-free RNase A to facilitate the examination of nuclei under fluorescence microscope. Apoptotic cells were investigated and counted among 1000 cells randomly. The apoptotic index was a mean of three independent experiments.

RESULTS

Stimulation of JNK expression by TPA

To determine whether TPA activates the JNK expression in gastric cancer cells, MGC80-3 cells were treated with TPA in a time course, and the expression level of JNK protein was detected by western blot analysis. As shown in Figure 1, JNK expressed in MGC80-3 cells, after cells were treated with TPA, the JNK expression was stimulated markedly. It was noted simultaneously that JNK expression was stimulated rapidly by TPA and reached a highest peak within 3 hr. After 3 hr treatment of TPA, although TPA-stimulated JNK expression decreased in a time course manner, the level of JNK protein was always keeping higher than that in MGC80-3 cells (Figure 1). Thus, the result clearly indicates the activation of JNK by TPA.

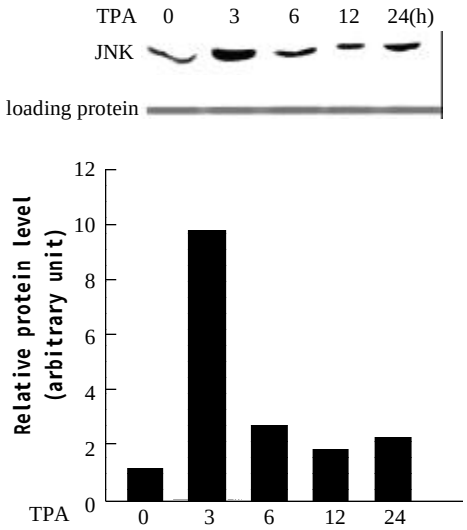

Figure 1 Expression of JNK protein in response to TPA induction. Cells treated with TPA for different time indicated. Expression of JNK protein was detected by Western blot. Amount of protein used in each lane was indicated by staining with ponceau S. The intensity of each band was quantified by densitometer.

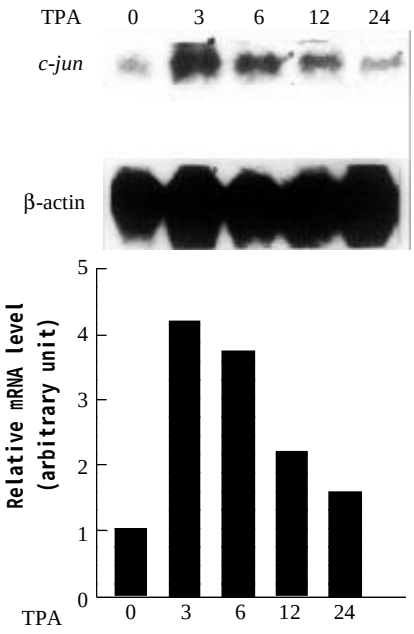

Figure 2 Expression of *c-jun* mRNA in response to TPA induction. Cells treated with TPA for different time indicated. Expression of *c-jun* mRNA was revealed by Northern blot. The same membrane was probed again with β-actin cDNA to show the amount of RNA used in each well. The intensity of each band was quantified by densitometer.

Effect of TPA on c-jun mRNA expression

Since activation of the JNK cascade is know to induce *c-jun* expression in several cell systems[26,27], we examine whether *c-jun* expression in mRNA level is also induced by TPA in gastric cancer cells. Northern blot analysis, using *c-jun* as a probe, revealed that MGC80-3 cells expressed *c-jun* mRNA at lower level, after treatment of TPA, expression level of *c-jun* mRNA was upregulated in a time-dependent manner (Figure 2). More interestingly, the induction patterns between JNK and *c-jun* by TPA were very similar. *c-jun* mRNA also reached its maximal peak induced by TPA within 3 hr, followed by a decrease with extension of TPA treatment in a time-course. Taken together, the data with Figure1 demonstrate that JNK cascade indeed plays a role in TPA signaling in gastric cancer cells.

Transcriptional activity of activator protein-1 in response to TPA

Activator protein-1 is composed of products of the proto-oncogenes *c-jun* and *c-fos*[28]. The result mentioned above implies that TPA may affect transcriptional activity of activator protein-1 due to the activation of *c-jun*. To further determine whether TPA activates the transcriptional activity of activator protein-1, we measured transcriptional activity of activator protein-1 in MGC80-3 cells treated with various concentrations of TPA by the methods of transient transfection and CAT assay. When the reporter -73Col-CAT expression vector that contains an AP-1 binding site[29] was transfected into MGC80-3 cells, a strong induction of reporter transcriptional activity was observed when cells were treated by TPA. This induction of reporter transcriptional activity was TPA-dose-dependent obviously (Figure 3). Thereby, TPA had a capability of activating the transcriptional activity of activator protein-1.

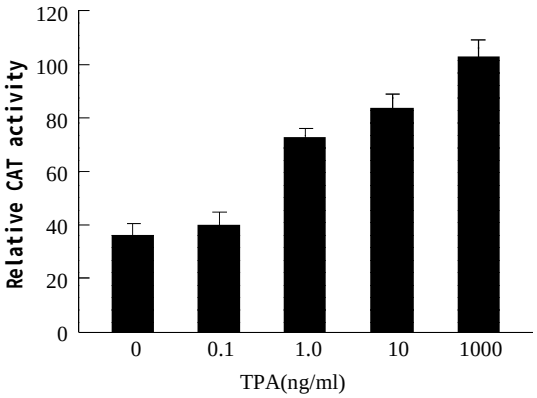

Figure 3 Effect of TPA on transcriptional activity of activator protein-1. Cells were treated with various concentrations of TPA indicated. Various expression vectors were transfected into cells as described in materials and methods. Transcriptional activity was measured by the method of transient transfection and CAT assay. Data shown represent mean of duplicate experiments (±SE).

TPA activates JNK cascade through PKC pathway

Since the target of TPA is protein kinase C (PKC)[30,31], we examine whether stimulation of JNK cascade by TPA is through PKC pathway in gastric cancer cells. When MGC80-3 cells were pretreated with PKC specific inhibitor, Wortmannin[32,33] for 2 hr, and then treated with TPA for another 3 hr, there was a significant inhibition observed in TPA-stimulated JNK protein expression (Figure 4, lane 4). As controls, JNK expression was clearly detected in MGC80-3 cells (Figure 4, lane 1) and TPA-stimulated JNK expression was seen obviously in the TPA-treated cells (Figure 4, lane 3), and Wortmannin alone slightly repressed JNK expression (Figure 4, lane 2), respectively. The similar result was observed in MGC80-3 cells treated with another PKC inhibitor, PKC inhibitor peptide[34] (data not shown). These results suggest that activation of JNK by TPA is mediated through PKC pathway.

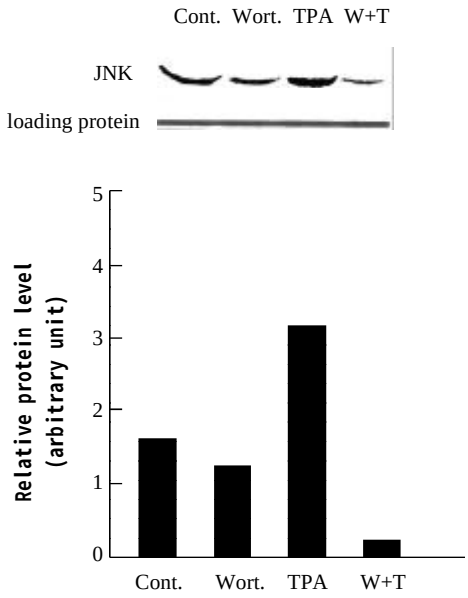

Figure 4 Effect of various agents, including Wortmannin (shown by Wort. or W), a PKC specific inhibitor, on expression of JNK protein. Cells were treated with Wortmannin for 2 hr, following by TPA induction for another 3 hr. Protein was detected by Western blot. Amount of protein used in each lane was indicated by staining with ponceau S. The intensity of each band was quantified by densitometer.

TPA-induced apoptosis is correlated with JNK expression through PKC pathway

To determine the effects of TPA on JNK and PKC functions, and their relationship with induction of apoptosis in gastric cancer cells, we analyzed apoptotic rate in MGC80-3 cells treated with relevant agents. Compared to the untreated MGC80-3 cells, treatment of cells with TPA caused the classical morphological characteristics of apoptosis, cells became smaller and rounded, and their nuclei became condensation and fragmentation with brightly stained chromatin (Figure 5A). However, when treatment of cells with PKC specific inhibitor, Wortmannin, subsequently with TPA, the apoptotic cells were decreased obviously, cells displayed a normal nuclear morphology similar to that of untreated cells (Figure 5A). In addition, the number of apoptotic cells was increased by the induction of TPA in a time-dependent manner. The highest apoptotic rate reached 32.56 % after treating cells with TPA for 48 hr, but only 5.46 % in untreated MGC80-3 cells (Figure 5B).

Since TPA-activated JNK cascade was mediated through PKC pathway in MGC80-3 cells (Figure 4), we analyzed whether this pathway was an association with apoptosis induced by TPA. Compared to TPA that induced apoptosis obviously, pretreated cells with PKC specific inhibitor, Wortmannin, significantly inhibited apoptosis induced by TPA, apoptotic rate was rather low, the highest apoptotic rate was only 8.71 %, although those cells were treated subsequently by TPA for another 48 h (Figure 5B). Accordingly, all these data further suggest that induction

of apoptosis by TPA is through PKC pathway, which may associate with the activation of JNK cascade.

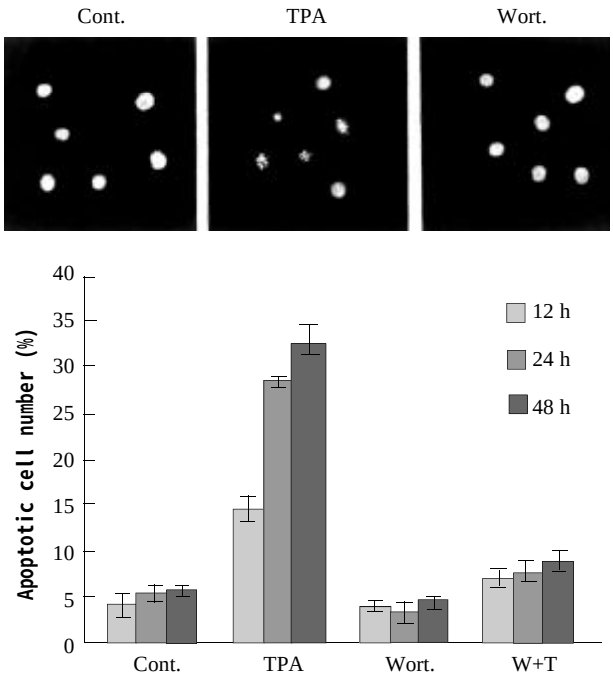

Figure 5 Effect of various agents, including TPA and Wortmannin, on apoptosis induction. Cells were treated with TPA and / or Wortmannin for different time indicated, and then the apoptotic rate was analyzed as described in material and methods. (A) The morphological changes in nucleus in response to different agents. (B) Apoptosis index.

DISCUSSION

The dynamic balance among the extracellular signal-regulated kinase (ERK), the *c-jun* N-terminal kinase (JNK) and the p38 Mitogen-activated protein kinase (p38 MAPK) activities critically determines the cellular fate in response to stimuli of proliferation, differentiation and apoptosis[35,36]. The role of ERK signaling in the processes of cell differentiation and proliferation has been clearly recognized[37,38], while requirement of JNK and p38 MAPK activations for apoptosis remains controversy. In some cases, JNK and p38 MAPK activity is strictly required for apoptosis[39-41]. However, in other circumstances, they are not associated with the induction of apoptosis[42]. In this study, we demonstrate that TPA stimulates JNK cascade through PKC pathway, which is associated with induction of apoptosis in gastric cancer cells.

JNK cascade plays an important role in cell proliferation, differentiation and apoptosis[43,44]. In HeLa cells, the activation of JNK was very rapid and sustained for at least 24 hr post-irradiation[45]. We also found that JNK activity was activated by TPA in gastric cancer cells, MGC80-3. This activation occurred very rapidly within 3 hr of the TPA addition (Figure 1), suggesting that JNK protein may be one of the TPA primary response targets. More importantly, JNK expression level activated by TPA was always keeping higher than that in untreated MGC80-3 cells. This evidence also suggests that the JNK pathway is a major one for mediating TPA effect, which should be functional in gastric cancer cells.

JNK cascade involves many factors. Activated transcription factor 2 (ATF-2) and *c-jun* are activated mainly by JNK[43]. Transcriptional regulation of *c-jun* expression is mainly mediated by a TPA-response element in its promoter, which binds to *c-jun*/ATF-2 heterodimers[46]. Increase of *c-jun* mRNA by various stimuli is highly regulated by phosphorylation of *c-jun* or ATF-2 that bind to the activator protein-1 binding sites present in the *c-jun* promoter[47]. Our observation showed a possible interrelation between JNK and *c-jun*, which were activated rapidly by TPA and reach its maximal peak within 3 hr, and then decreased with time-dependent manner (Figure 1, 2). Activator protein-1 is a transcriptional factor mainly composed of the *c-jun/c-jun* homodimer or *c-jun/c-fos* heterodimer. The fact that TPA also activated the transcriptional activity of activator protein-1 significantly in MGC80-3 cells (Figure 3) suggests that signaling that causes the transcriptional activity of activator protein-1 is functional in gastric cancer cells. Thus, induction of *c-jun* by TPA in MGC80-3 cells is likely due to the activation of JNK, which led to the activation of activator protein-1 transcriptional activity. This is a JNK cascade stimulated by TPA indeed.

How to function for JNK activation by TPA in gastric cancer cells is still largely unknown. MGC80-3 cells underwent apoptosis in response to TPA, as evidenced by typical morphological changes (Figure 5A, B), which is consistent with our previous observation[48,49]. Our results demonstrated that apoptosis induction by TPA was associated with JNK activition via PKC pathway. When PKC specific inhibitor, Wortmannin was used to treat MGC80-3 cells prior to TPA treatment, it would prevent TPA further to activate JNK expression (Figure 4). In this case, apoptotic cells were much fewer than that in TPA-treated cells, apoptotic index dramatically decreased from 32.56 % to 8.71 % (Figure 5A, B). Thus, these data not only confirm that TPA-induced apoptosis is associated with JNK activation through PKC pathway, but also indicate that JNK cascade is required for apoptosis induction by TPA, which may be one mechanism for TPA to inhibit the growth of gastric cancer cells.

In summary, the present study demonstrates that the activation of JNK cascade is mediated through a signaling transduction pathway that involves PKC-dependent pathway, which leads to activation of JNK, induction of the *c-jun* expression and activation of activator protein-1 transcriptional activity in response to TPA. The activation of JNK cascade is closely associated with induction of apoptosis by TPA in gastric cancer cells.

Abstract

AIM: To investigate the prophylactic and therapeutic efficacy of intraperitoneal IL-2 immunotherapy following intraperitoneal thermochemotherapy in the metastasis and recurrence of gastric and colorectal cancer after operation.

METHODS: Forty-two gastric cancer patients at T_3II-T_4 III_B stages and 96 patients with colorectal cancer at B to D stages admitted from January 1996 to October 1998 were randomly divided into control group (group Ⅰ, 65 cases) receiving intraperitoneal thermochemotherapy, and group Ⅱ (73 cases) receiving both intraperitoneal thermochemotherapy and intraperitoneal IL-2 immunotherapy. Distilled water at 43-45 ℃ containing 5-Fu 0.5 g/L and MMC 8 mg/L was perfused into peritoneal cavity before closure at the end of operation for 1 h, and from the third day, IL-2 10 million IU in 500 ml 0.9 % sodium chloride was intraperitoneally administrated daily for 10 times. One month after operation, all the patients underwent regular intravenous chemotherapy. Before and after the IL-2 immunotherapy, some Th1 type cytokines in the peripheral blood of the patients in the two groups were detected by ELISA, and the intraperitoneal recurrence and liver metastasis rates and the 3-year survival rate were statistically evaluated after intensive follow-up.

RESULTS: IL-2 intraperitoneal immunotherapy significantly elevated the level of some Th1 type cytokines (P<0.01 compared with that of control group), and the 3-year survival rate of group Ⅱ was 18.1 % higher and the rates of intraperitoneal recurrence and liver metastasis were 16.9 % and 6.0 % lower than those of group I significantly (P<0.05-0.01).

CONCLUSION: The combination of intraperitoneal IL-2 immunotherapy and thermochemotherapy could promote Th1 immune paradigm and enforce anti-tumor activity of bodies, which plays a positive role in preventing gastric and colorectal cancer from intraperitoneal recurrence and development.

INTRODUCTION

Occurring frequently, that the gastrointestinal cancers spread in abdominal cavity and metastasize to the liver after resection, and in a number of cases, the lesion penetrated to serosa and implanted to peritoneum before operation. More and more clinical studies have revealed that postoperative intraperitoneal thermochemotherapy was obviously efficient in reducing the intraperitoneal recurrence and liver metastasis incidence[1-7]. Intraperitoneal thermochemotherapy can increase the sensitivity of tumor cells to chemotherapy drugs[8], and simultaneously enhance the antigenicity of tumor cells[9] which would be conducive to immunotherapy, therefore, based on this hypothesis, we conducted a clinical study on the efficacy of intraperitoneal thermochemotherapy and intraperitoneal immunotherapy involved in 42 cases of gastric cancer and 96 cases of colorectal cancer, and reported below.

MATERIALS AND METHODS

From January 1996 to October 1998, 42 cases of gastric cancer at T_3II-$T_4$$III_B$ stages and 96 cases of colorectal cancer at B-D stages were randomly divided into 2 groups (control group, group I and treatment group, group II, Table 1), among whom 87 cases were males, and 51 cases females, with an age from 21 to 73 years, averaging 64.4±7.1 years.

Method

Therapeutic method Radical operation was performed on 35 gastric cancer patients and the B-C_2 stage colorectal cancer patients, and palliative operation on 4 gastric cancer and colorectal patients of D-stage. The localized mesenteric and peritoneal infiltration lesions were removed as clear as possible or electrically burned if the lesions were at feasible locus. Before closure under general anesthesia, 4000 ml distilled water at 43-45 ℃ containing 5-Fu 0.5 g/l and MMC 8 mg/l was perfused in 4 equal volumes into peritoneal cavity, 1000 ml per quarter for an hour. Ice bags were put at groins, axilla and lateral chest and with ice cap on the head. Patients with heart, kidney, lung diseases or diabetes were not accepted in the study. Blood pressure, pulse, ECG and saturation of oxygen in blood were closely monitored during the treatment. On the 3rd day after operation, Group II was treated with IL-2, 1 million u dissolved in 0.9 % sodium chloride 500 ml, through trocars fastened in the abdominal wall. Patients were directed to change body positions to help defuse the drug. The puncture spots were adjusted to the tumor sites, and the therapy was carried out once a day and 10 times in all.

Both groups were administered intravenous chemical therapy from the 1st month after operation, which lasted one year. Routine of blood and urine, function of liver and kidney, CT, and B-ultrasound were performed regularly.

Evaluation of patients' immune function Both before and after intraperitoneal thermochemotherapy and immunotherapy,

Table 1 The clinicopathological stages and surgical procedures in each group

Groups	*n*	Male	Female	Age(yrs)	Stages(n)	Radical	Non-radical
Group I	65	39	26	62.5±6.6	-	57	8
Gastric cancer	19	12	7	61.7±5.5	T_3 II (9)T_4III$_A$(7)T_4III$_B$(3)	16	3
Colorectal cancer	46	27	19	64.4±3.9	B(20)C1(12)C2(9)D(5)	41	5
Group II	73	48	25	65.4±8.7	-	62	11
Gastric cancer	23	16	7	67.1±7.6	T_3 II (11)T_4III$_A$(8)T_4III$_B$(4)	19	4
Colorectal cancer	50	32	18	63.3±5.2	B(22)C1(13)C2(8)D(7)	43	7

Control group: (1) Gastric cancer: papilloadenocarcinoma, 7 cases; tuboadenocarcinoma, 6 cases; lowly-differentiated adenocarcinoma, 2 cases; mucoadenocarcinoma, 1 case; signet ring cell carcinoma, 2 cases; and undifferentiated carcinoma 1 case; (2)Colorectal cancer: highly and intermediately differentiated adenocarcinoma, 29 cases; mucoadenocarcinoma, 12 cases; and undifferentiated carcinoma 5 cases. Therapy group: (1) Gastric cancer: papilloadenocarcinoma, 9 cases; tuboadenocarcinoma, 6 cases; lowly-differentiated adenocarcinoma, 2 cases; mucoadenocarcinoma, 2 cases; signet ring cell carcinoma, 2 cases; and undifferentiated carcinoma 2 cases; Colorectal cancer: highly and intermediately differentiated adenocarcinoma, 33 cases; mucoadenocarcinoma, 12 cases; and undifferentiated carcinoma 5 cases.

Table 2 The levels of some Th1 cytokines in peripheral blood of patients before and after immunotherapy (pg / ml)

Groups *n*	The level of the cytokines						*P*
	IL-2		TNF-β		IFN-γ		
	Pre-therapy	Post-therapy	Pre-therapy	Post-therapy	Pre-therapy	Post- therapy	
group I (65)	10.2±3.7	9.5±3.8	25.3±7.4	24.9±4.5	29.5±6.9	27.7±7.3	>0.25
group II (73)	13.5±6.7	38.4±6.2	18.0±4.6	55.4±10.1	27.4±7.1	77.1±18.2	<0.01

serum levels of several Th1 type cytokines (IL-2, TNF-β, IFN-γ) were detected with ELISA techniques in both groups to contrast results and evaluate the anti-tumor immune activity of the patients in two groups. The ELISA Kit was bought from Bangding Biotechnic Company in Beijing, and the results were recognized with a mean value of A450nm.

Method of follow-up The follow-up was made by a group of experienced doctors. Patients were checked regularly at a 3-6 month interval after operation in the outpatient department. Checking items included general physical examination such as supraclavicular lymph nodes and anus digital palpation, blood and urine routine, liver and kidney function, serum CEA, B-ultrasound of liver and spleen, also CT when necessary. We managed to keep in corresponding and phonic touch with these patients. Patient' s situation and tumor status were determined according to the clinical manifestation and associated examinations. The death time and cause were defined and recorded carefully. Those who lost to follow-up were also recognized as dead.

Statistical methods

The result of cytokine detection was analyzed with Student *t* test, the recurrent rate in abdominal cavity and metastasis rate in liver with χ^2 test,and 3-year-survival rate with survival curve.

RESULTS

The changes of some Th1 cytokine levels in the peripheral blood of the patients after intraperitoneal immunotherapy with IL-2

The levels of IL-2, TNF-β, INF-γ in the peripheral blood of the patients who received IL-2 intraperitoneal therapy were obviously increased as compared with the control group. The difference was significant (P<0.01). And there were no significant changes in the levels of the same cytokines in control group (P>0.25, Table 2).

The effect of IL-2 intra-peritoneal immunotherapy

The 3-year follow-up ratio of the cases was 91.3 %, the result is shown in Table 3.

Table 3 The therapeutic efficiency of intraperitoneal thermochemotherapy combined with IL-2 immunotherapy

Groups	*n*	Intraperitoneal recurrent rate (%)	Hepatic metastasis rate(%)	3-year survival rate(%)
Group I	65	29.2(19 / 65)	16.9(11 / 65)	47.7(31 / 65)
Group II	73	12.3(9 / 73)[b]	10.9(8 / 73)[a]	65.8(48 / 73)[a]

[a]P<0.05 *vs* control group, [b]P<0.01 *vs* control group

Based on the comparison of intra-peritoneal recurrence rate, hepatic metastasis rate and 3-year survival rate, we could draw a conclusion that intraperitoneal thermochemotherapy combined with immunotherapy was effective in decreasing intraperitoneal recurrence and hepatic metastasis rate and raising 3-year survival rate (P<0.01-0.05 contrasted with control group). In our study, 4 cases were lost in group I and 8 in group II, and they were calculated as dead cases. Intraperitoneal spread, metastasis in liver and lung, uncontrollable hydrothorax and hydroperitoneum and dyscrasia at the end of advanced-stage cancer were accounted

for the death. In group I, only one patient with gastric carcinoma who received palliative operation survived for 2 years, while there were 2 cases in group II. And 4 (4/5) colorectal cancer cases of D-stage and 3 (3/7) in group II died from intraperitoneal spread. Although the number of cases was not big enough for statistical study, the therapeutic effect was indicated in some degree.

DISCUSSION

Nowadays in most of formal hospitals, there are no technological difficulties with the radical operation of gastrointestinal cancer. Thus, how to raise the survival rate and the life quality of these patients depends much on the compound therapy following operation. Although routine chemotherapy (intravenously or orally) could help inhibit the liver metastasis, intraperitoneal spread and recurrence, its effect is still not satisfactory. In recent ten years, a large number of clinical studies have proved that postoperative intra-abdominal thermochemotherapy has exerted obvious therapeutic effect in inhibiting the recurrence of gastrointestinal cancer in abdominal cavity and liver metastasis[10-15], which is routinely applied in many hospitals. Intra-abdominal chemotherapy can be given at any time, but it can cause peritonitis, abdominal pain, and sometimes overlapped at short interval with intravenous or oral chemotherapy. Meanwhile, being a single therapy, it would bring about severe adverse effect following a long-term administration. On the other hand, intraperitoneal thermochemotherapy should be administered under general anesthesia and could not be applied repeatedly. Although its therapeutic effect is among the best, the low frequency of administration is its unavoidable defect. Based on this idea, more research should be made to seek a compound strategy with complementary therapeutic effect[16-24].

The intraperitoneal thermochemotherapy can increase the sensitivity of tumor cells to chemotherapy drugs and kill even more tumor cells than routine administration,and can efficiently lower the incidence of intraperitoneal recurrence and liver metastasis[24-27]. More importantly, thermal effect can increase the antigenicity of tumor cells and facilitate the expression of tumor antigens (such as heat shock proteins), which is conducive to immune effector cells to recognize and kill the tumor cells[28-30].

IL-2 is an effective anti-tumor cytokine, and it can induce and promote the activation and proliferation of T lymphocytes, increase the tumor-killing effect of effector cells, such as TIL, CTL, LAK and NK, and improve the general anti-tumor immune function of the body[31-37]. There are many lymph nodes and abundant lymphatic network in the abdominal cavity, and lots of lymph organs in the intestinal wall. When a high concentration of IL-2 is administered into the abdominal cavity and act on those lymphatic tissues and organs, the proliferation and killing capacity of lymphocytes is efficaciously promoted, under the background that the antigenicity of residual cancer cells has already increased due to the thermal effect, the anti-tumor effect of IL-2 would be maximized. The lymphocytes activated by IL-2 spreading with blood circulation will kill the metastatic foci in liver or other sites. In this study, the level of major Th1 cytokines in peripheral blood was significantly increased after immunotherapy, demonstrating that IL-2 could activate anti-tumor immune effect cells, induce the production of Th1 cytokines, enhance the anti-tumor immune function of the body, and kill tumor cells. In the immunotherapy group, the intra-abdominal recurrence and the incidence of liver metastasis were decreased by 16.9 % and 6.0 %, respectively as compared with the control group, which support the point that IL-2 immunotherapy combined with intraperitoneal thermochemotherapy is effective and applicable, and that it is appropriate to perform immunotherapy after thermochemotherapy, which may be a more scientific and reasonable strategy than other combinations and may contribute to the immunotherapeutic function and the complementation of the two therapies. Because IL-2 could promote the proliferation of lymphocytes and the latter might be inhibited by chemotherapy drugs, we did not combine IL-2 with chemotherapy drugs. This is worth of further research. During immunotherapy, most patients could tolerate and no obvious side-effect was observed. The common side-effect was the increase of body temperature (4 cases reached 38.8 ℃ and others in the range of 38.2-38.6 ℃) and physical cooling could take effect. Fever is another common side-effect of IL-2, which may disappear after the withdrawal of IL-2.

In this study, we found that, in the patients with peritoneal infiltration, the removal of the tumor as complete as possible during operation combining with thermochemotherapy and immunotherapy could produce satisfactory therapeutic effect. Four patients of this type survived for more than 3 years. So the intra-abdominal therapy for the gastrointestinal cancers should be paid enough attention, even to the intraperitoneal metastasis and infiltration in certain degree, resection or partial resection should be performed as completely as possible other than giving up. Immediate postoperative thermochemotherapy and immunotherapy could also improve the prognosis of some patients.

In conclusion,intra-abdominal metastasis of gastrointestinal cancer is an important factor in affecting the prognosis of the patients. In our study, the intraperitoneal thermochemotherapy and intraperitoneal immunotherapy have displayed a promising therapeutic and prophylactic effect, and research is need on this compound therapy upon our observation.

Abstract

AIM: To assess the safety and efficacy of different intravenous chemotherapeutic regimens in patients with gastric carcinomas who had undergone gastrectomy.

METHODS: A meta-analysis of all the relevant randomized controlled trials (RCTs) was performed. Language was restricted to Chinese and English. RCTs were identified from Medline and Embase (1980-2001/4), and Chinese Biomedicine Database (1990-2001/1). Literature references were checked at the same time. We included randomized and quasi-randomized trials comparing the efficacy of intravenous chemotherapy after gastrectomy with that of surgery alone in patients with confirmed gastric carcinomas who had undergone gastrectomy. Selection criteria were: randomized or quasi-randomized trials with following-up results; Trials could be double-blind, single-blind or not blind; Chemotherapy groups were given intravenous chemotherapy after gastrectomy without neo-adjuvant chemotherapy, intraperitoneal hyperthermic perfusion, radiotherapy or chemoimmunotherapy; Controlled group included those receiving gastrectomy alone. The following data were extracted: the number of survival and death by the end of the follow-up; the different agents and doses of the intravenous chemotherapy; the baseline of the chemotherapy group and the controlled arm; the serious adverse events; the statistical consideration; cost-effectiveness analysis. The statistical analysis was performed by RevMan4.1 software which was provided by the Cochrane Collaboration. A *P* value of <0.05 was considered statistically significant. Meta-analysis was done with random effects model. Heterogeneity was checked by chi-square test. Sensitivity analysis was performed by excluding the trials in which Jadad-scale was only 1 score. The result was expressed with odds ratio (OR) for the categorical variable.

RESULTS: Fourteen trials involving 4543 patients were included. Meta-analysis was done with random effects model. Heterogeneity and sensitivity analysis were performed also. The effect of intravenous chemotherapy after gastrectomy was better than surgery alone (odds ratio 0.56, 95 %CI 0.40-0.79). There was a significant difference between the two groups by u-test (*P*=0.0008). Sensitivity analysis revealed the same difference (odds ratio 0.81, 95 % CI 0.70-0.94). Of fourteen trials, only three studies were of high quality according to the Jadad-scale (with three score). There was one meta-analysis trial and the others, about ten trials, were of low quality. There was no trial which mentioned sample-size calculation, allocation concealment, intention-to-treat analysis. Most of the trials didn't describe the blind-procedure. There were five trials which detailed the side-effects according to the toxicity grade by WHO standard. The side-effects halting treatment were haematologic and biochemical toxicity, debilitating nausea and vomiting. There were two patients died of chemotherapy toxicity.

CONCLUSION: Based on the review, intravenous chemotherapy after gastrectomy may have positive treatment effect on gastric cancer. However, the evidence is not strong because of the general low methodologic quality of the RCTs. Therefore, we can't make the conclusion that intravenous chemotherapy after gastrectomy may have better treatment effect on gastric cancer than that of surgery alone. Rigorously designed, randomised, double-blind, placebo-controlled trials are required.

Hu JK, Chen ZX, Zhou ZG, Zhang B, Tian J, Chen JP, Wang L, Wang CH, Chen HY, Li YP. Intravenous chemotherapy for resected gastric cancer: meta-analysis of randomized controlled trials. *World J Gastroenterol* 2002; 8(6):1023-1028

INTRODUCTION

Gastric cancer is one of the most common cancers worldwide. The outcome of patients with gastric carcinoma has recently been significantly improved with advances in experimental researches, early diagnosis and surgical techniques[1-44].Although chemotherapy and radiation therapy have been tried as either an adjuvant or palliative treatment, their values are limited by toxicity or the lack of efficacy[45].While surgery remains the mainstay of potentially curative treatment, survival rates for patients able to undergo complete resection are poor[46].The five year survival rate for resected gastric cancer is about 30-60 % which has been disappointing. A number of studies have investigated whether intravenous chemotherapy after a resection improves the survival rate or not, but the results are different and disputed. Hermans *et al*[47] reviewed the randomized controlled trials by meta-analysis, the results indicated that postoperative chemotherapy in general offered no additional survival benefit for patients with curatively resected gastric cancer. Janunger *et al* [48]performed a systematic overview of chemotherapy effects in gastric cancer by the Swedish Council

of Technology Assessment in Health Care(SBU). A meta-analysis of 21 randomised adjuvant studies revealed a statistically significant survival benefit (OR=0.84, 95 % CI 0.74-0.96).

The aim of meta-analysis is to summarize the results of randomized trials performed to evaluate the effect of intravenous chemotherapy for gastric cancer[47]. The analysis is restricted to trials published since 1980. Surgical resection without any adjuvant therapy is considered standard treatment. Only intravenous chemotherapy trials with gastrectomy control arm were taken into consideration in this meta-analysis.

MATERIALS AND METHODS

Materials

Randomized or quasi-randomized trials comparing the efficacy of intravenous chemotherapy after gastrectomy with that of surgery alone in patients with confirmed gastric carcinomas who had received gastrectomy were included in this meta-analysis. Language was restricted to Chinese and English.

Selection criteria were: randomized or quasi-randomized trials with following-up results; Trials could be double-blind, single-blind or not blind; Chemotherapy groups were given intravenous chemotherapy after gastrectomy without neo-adjuvant chemotherapy, intraperitoneal hyperthermic perfusion, radiotherapy or chemoimmunotherapy; Controlled group included those receiving gastrectomy alone.

Exclusion criteria were prior malignancy; neo-adjuvant chemotherapy, intraperitoneal hyperthermic perfusion, radiotherapy or chemoimmunotherapy; patients who didn' t receive gastrectomy; the controlled studies also included those without gastrectomy.

Methods

Search strategy Search was applied to the following electronic databases: the Cochrane Library, MEDLINE (1980-2001.4), EMBASE (1980-2001.4) and Chinese Bio-medicine Database (1990-2001/1). Literature reference proceedings were handsearched at the same time. The searching words were chemotherapy, stomach neoplasms and surgery.

Data collection and analysis Data were extracted independently by two reviewers. The methodological quality of trials was evaluated using the Jadad-scale plus allocation concealment. Intention-to-treat analyses were performed.

The following data were extracted: the number of survival and death by the end of the follow-up; the different agents and doses of the intravenous chemotherapy; the baseline of the chemotherapy group and the controlled arm; the serious adverse events; the statistical consideration; cost-effectiveness analysis.

The statistical analysis was performed by RevMan4.1 software which was provided by the Cochrane Collaboration. A P value of <0.05 was considered statistically significant. Meta-analysis was done with random effects model. Heterogeneity was checked by chi-square test. If the results of the trials had heterogeneity, random effects model was used for meta-analysis. Sensitivity analyses was performed by excluding the trials which Jadad-scale was only 1 score. The result was expressed with odds ratio(OR) for the categorical variable.

RESULTS

There were 1076 papers relevant to the searching words. Through the steps of screening the title, reading the abstract and the entire article, twenty-seven randomized trials were identified. Only fourteen randomized trials comparing the efficacy of intravenous chemotherapy after gastrectomy with that of surgery alone in patients with confirmed gastric carcinomas, including 4543 patients, met the inclusion criteria[47,49-56,1A-5A]. There were six trials which were excluded for repetitive studies[57-60,6A,7A], five for having been included in the result of the Hermans' meta-analysis[61-65], two for no available data[66,67]. Of fourteen included trials, four trials were conducted in China (see appendix)[2A-5A], three in England[50,55,1A], two in Italy[49,54], two in Spain[51,56], one in Korea[52], Germany[53] and Netherlands[47] respectively. The average sample size was 324 patients (from 25 to 1967 patients). The follow-up time was from forty-eight months to one hundred and twenty months. The chemotherapy regimens used were FAM,MMC,MFV,MFC,FEM and 5-FU+BCNU(Table 1). All the baselines of the trials were parallel. None of them performed the cost- effectiveness analysis.

Table 1 Data from 14 trials on intravenous chemotherapy versus surgery alone after resection for gastric cancer

Author	Published time	Chemotherapy regimens	Chemotherapy group (number of death / total)	Surgery group (number of death / total)	Follow -uptime (months)

Lawton	1981	5Fu+BCNU	11 / 13	10 / 12	60
Cirera	1999	MMC+Tegafur	33 / 76	44 / 72	37
Hermans	1993	Meta-analysis	720 / 1098	588 / 869	NA

Abbreviations: F / 5-Fu, fluorouracil; A,doxorubicin; M / MMC, mitomycin; C / Ara-C,cytarabine; E,etoposide; V,vinblastine; BCNU,1,3-bis-(2-chloroethyl)-1-(nitrosourea); NA,no available.

The effectiveness of intravenous chemotherapy after gastrectomy was better than surgery alone (odds ratio 0.56, 95 % CI 0.40-0.79). The results of the trials showed inconsistency, as checked by the chi-square test (χ^2=52.54, P<0.00001). There was a significant difference between the two groups by u-test (P=0.0008) (Figure 1). By excluding the low quality trials[2A-5A], the sensitivity analysis was performed and revealed the same difference between chemotherapy and surgery alone (odds ratio 0.81, 95 %CI 0.70-0.94, P=0.005) (Figure 2).

Of fourteen trials, only three studies[49,50,56] were of high quality according to the Jadad-scale (with three score). There was one meta-analysis trial[47] and the others, about ten trials were of low quality. There was no trial which mentioned sample-size calculation, allocation concealment, intention-to-treat analysis. Most of the trials didn' t describe the blind-procedure. Therefore, the methodologic quality of the RCTs is not strong enough to testify the conclusion.

There were five trials[49,53-56] which detailed the side-effects of medicine according to World Health Organization grade. The side-effects halting treatment were haematologic and biochemical toxicity, debilitating nausea and vomiting. There were two patients died of chemotherapeutic toxicity (one died of cardiac toxicity and the other of massive alimentary tract

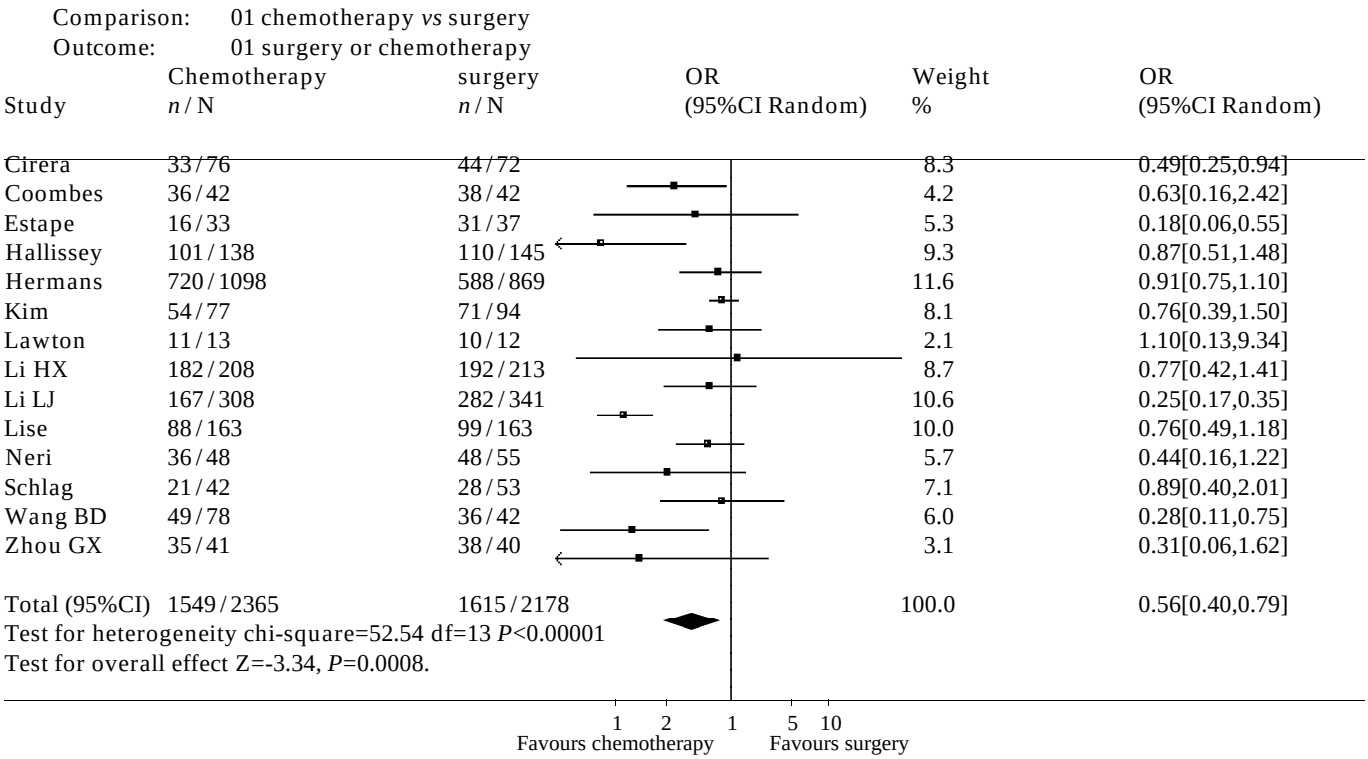

Figure 1 The effectiveness of intravenous chemotherapy versus surgery alone

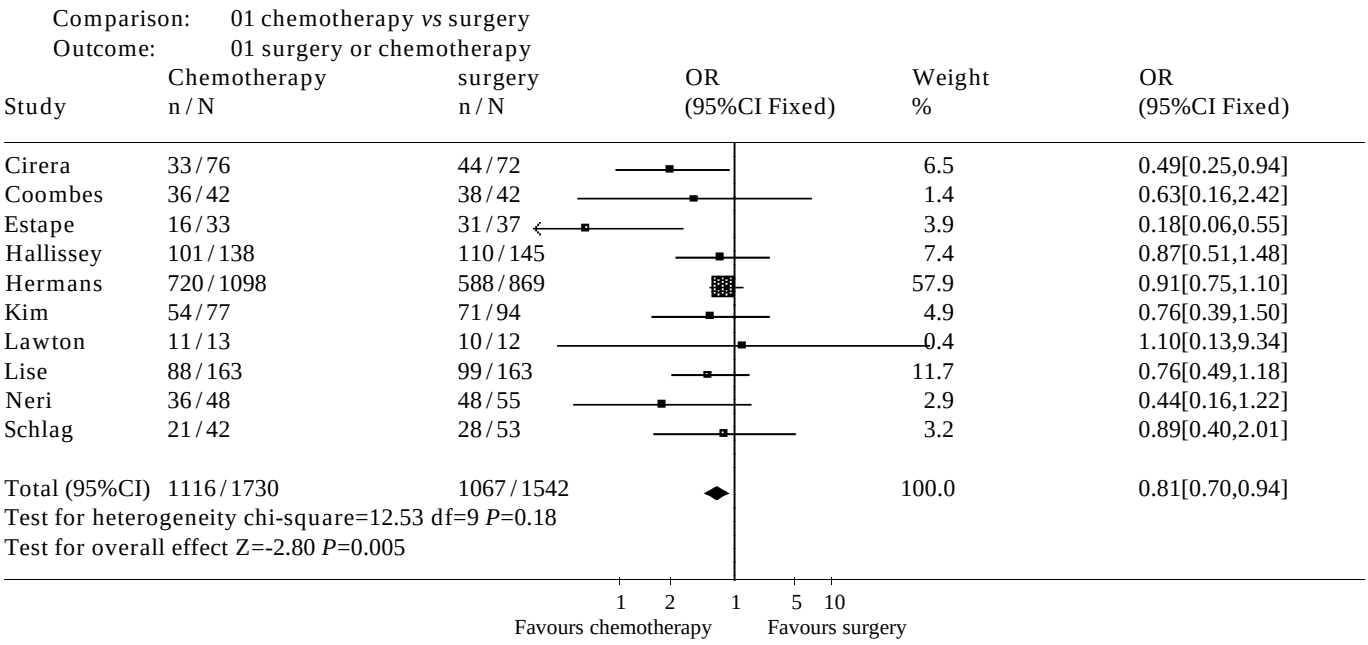

Figure 2 Sensitivity analysis

hemorrhage because of thrombopenia). Severe toxicity (grade 3 or 4 according to the WHO scale) occurred in 5.33 %, with alopecia in 39 patients, leucopenia (WBC values less than 2 000/μL) in 18, nausea in 21, thrombopenia (platelet count less than 50 000/μL) in 13, anemia in 9, vomiting in 5, diarrhea in 5, gastritis in 5, stomatitis in 4, cardiac toxicity in 4, septicemia in 2 and neural toxicity in 1.

DISCUSSION

It is well recognized that most patients who undergo curative resection of gastric carcinoma remain at high risk of local and systematic relapse. Thus, a worldwide effort has been done to develop effective adjuvant therapy to reduce this risk[68].

The aim of meta-analysis is to summarize the results of randomized trials performed to evaluate the effect of intravenous chemotherapy for gastric cancer. Surgical resection without any adjuvant therapy is considered standard treatment. Only intravenous chemotherapy trials with gastrectomy control arm were taken into consideration in this meta-analysis. There are two meta-analyses to assess the effect of intravenous chemotherapy for gastric cancer with gastrectomy. Hermans *et al*[47] researched the randomized controlled trials by meta-analysis; the results indicated that postoperative chemotherapy in general offered no additional survival benefit for patients with curatively resected gastric cancer. Janunger *et al*[48] performed a systematic overview of chemotherapy effects in gastric cancer by the Swedish Council of Technology

Assessment in Health Care (SBU). A meta-analysis of 21 randomised adjuvant studies revealed a statistically significant survival benefit (OR=0.84, 95%CI 0.74-0.96). But We couldn' t get the original article of Janunger, therefore we didn' t include the trials in this meta-analysis.

Measuring an effect on survival by calculating the odds ratios was proved to be effective in an analysis[47]. Only four trials which were performed by Cirera[56], Estape[51], Li *et al*[2A] and Wang *et al*[4A] respectively, demonstrated a positive effect of intravenous chemotherapy versus the controlled group by calculating the odds ratios.

Of included fourteen trials, only three studies were of high quality according to the Jadad-scale. There was one meta-analysis trial and the others, about ten trials were of low quality. There was no trial which mentioned sample-size calculation, allocation concealment, intention-to- treat analysis. Therefore, the methodologic quality of the RCTs is not strong enough to testify the conclusion. Based on the review, intravenous chemotherapy after gastrectomy may have positive treatment effect on gastric cancer. However, the evidence is not strong because of the general low methodologic quality of the RCTs. Rigorously designed, randomised, double-blind, placebo-controlled trials are required.

The toxicity of medicine is an important factor to influence the outcome of the chemotherapy. But unfortunately, there were only five trials which detailed the side effects of medicine according to World Health Organization grade in this meta-analysis. Hence, in the future research, we should put in mind to observe the side effects carefully and describe them by the WHO grade standard.

Recently, such therapies as intraperitoneal hyperthermic perfusion[69-74], neo-adjuvant chemotherapy[75-84], radiotherapy[85-89] and chemoimmunotherapy[52] are demonstrated with a positive effect to reduce the relapse risk. Tao *et al*[90] revealed that preoperative regional artery chemotherapy had the effect to induce growth inhibition and apoptosis of gastric carcinoma cells. Cao *et al*[91] found that human primary gastric cancer cell *in vitro* were methionine-dependent; methionine-free environment might strengthen the killing effect of chemotherapy on human primary gastric cancer cells. But, the scientific conclusion should be supported by the high quality randomized, double-blind, controlled trials.

Abstract

AIM: To investigate the resistance mechanism of 5-fluorouracil (5-FU) in Bel_{7402}/5-FU cells which was established in our lab by *in vitro* continuous stepwise exposure of human hepatocellular carcinoma (HCC) cell line Bel_{7402} to 5-FU.

METHODS: The expression of multidrug resistance-associated protein (MRP) and thymidylate synthase (TS) in Bel_{7402} cells was detected by immonocytochemistry. The fluorescein (FLU) accumulation, an index of MRP functional activity, was determined by flow cytometry. The distribution of FLU was observed by confocal laser scanning microscope. The spectrofluorometry was used to show the intracelluar content of glutathione (GSH). Cell growth inhibition was determined by MTT assay. The activity of glutathione S-transferases (GSTs) was determined by spectrophotometry.

RESULTS: A higher expression of MRP in the Bel_{7402}/5-FU cells was observed by using monoclonal mouse anti-MRP antibody, MRPr-1, in comparison with Bel_{7402} cells. Bel_{7402}/5-FU cells also showed a significant decrease of FLU accumulation. FLU mainly accumulated in the nucleus with a high nuclear/cytoplasmic ratio in Bel_{7402} cells, whereas there was no difference of FLU accumulation between the nucleus and cytoplasm in Bel_{7402}/5-FU cells. The intracellular GSH content in Bel_{7402}/5-FU cells was almost 3 folds higher than that in Bel_{7402} cells. Addition of D, L-buthione-S, R-sulfoximine (BSO) dose-dependently reduced the GSH content in Bel_{7402}/5-FU cells, however, only a weak enhancement on the cytotoxicity of 5-FU and doxorubicin (Dox) to Bel_{7402}/5-FU cells was observed. Bel_{7402}/5-FU cells also exhibited 29.1 % higher total GSTs activity than Bel_{7402} cells. Immunocytochemical staining by using anti-TS monoclonal antibody TS 106 showed that the level of TS in Bel_{7402}/5-FU cells elevated markedly as compared with Bel_{7402} cells.

CONCLUSION: The continuous exposure of Bel_{7402} cells to 5-FU led to overexpression of TS and MRP, as well as increased intracellular GSH content and total GST activity.

INTRODUCTION

It is well known that HCC is one of the malignant tumors with poor chemosensitivity to anticancer agents. To date, the fluoropyrimidine fluorouracil, such as 5-FU, is still the first choice drug in the treatment of HCC[1-3]. However, its usage is limited because of the rapid development of acquired resistance. So far, there is no paper dealing with the establishment of acquired resistance of 5-FU in HCC and its active mechanism of resistance in the literature. Then we established a 160-fold 5-FU resistant cell line named Bel_{7402}/5-FU from the parental HCC Bel_{7402} cell line through about 6 months of continuous 5-FU selection. In addition to resistance to 5-FU, the Bel_{7402}/5-FU cells also showed 3-4-fold cross-resistance to Dox and cytarabine, but no cross-resistance to vincristine, taxol, cisplatin and hydroxycamptothecine. Our prior study revealed that Bel_{7402} and Bel_{7402}/5-FU cells showed no difference in P-glycoprotein (P-gp) levels.

Nishiyama[4] showed that the increased expression of MRP was closely related to 5-FU resistance in gastrointestinal cancer cell lines. MRP is also a member of the ABC superfamily of membrane transport proteins, which has certain sequence homology with P-gp. The drug-resistance pattern conferred by MRP is similar but not identical to that of P-gp[5,6]. It is believed that MRP prefers to transport anionic drugs and neutral drugs conjugated to acidic ligands, such as GSH, glucuronate, or sulfate[7,8]. GSH has been suggested as an important component of MRP-mediated MDR and drug transport[9]. GSH can combine with anticancer drugs to form less toxic and more water soluble GSH conjugates, which can be exported from cells by MRP[10,11]. The conjugation reaction is catalyzed by GSTs. The elevation of cellular GSH and the elevated expression and activity of GSTs are associated with the development of drug-resistance phenotype of tumor cells to alkylating compounds, including melphalan, cyclophosphamide, chlorambucil, nitrogen mustard, doxorubicin[12-14].

TS catalyses the reductive methylation of deoxyuridine monophosphate to deoxythymidine monophosphate using 5, 10-methylene-tetrahydrofolate as a methyl donor co-substrate. This reaction provides the only de novo source of dTMP and is an essential step in DNA biosynthesis. TS is a critical target for fluoropyrimidine, including 5-FU. *In vitro* and *in vivo* studies have reported that increased TS protein levels and gene amplification and/or decreased inhibition of TS activity may be associated with the resistance to 5-FU[15,16].

The purpose of the present study was to determine whether the change of MRP, GSH/GST and TS contributed to the 5-FU resistance observed in Bel_{7402}/5-FU cells.

MATERIALS AND METHODS

Materials

Drugs and reagents 5-FU was purchased from Xudong Haipu Pharmaceutical Inc. (Shanghai, China). 1-chloro-2,4-dinitrobenzene (CDNB) and O-phthalaldyhyde (OPT), GSH and 3-4,5-dimethyl-thiazol-2,5-diphenyl tetrazolium bromide

(MTT) was obtained from Sigma Chemical Co. (St. Louis, MO). Monoclonal mouse anti-MRP, MRP-r1 and FITC-labeled goat anti-mouse IgG were obtained from Zhong Shan Biotechnology Co., LTD (Beijing, China). Thymidylate synthase Ab-1 TS 106 was obtained from Neomarker (Fremont, CA). Fluorescein (FLU) was obtained from Amresco (Solon, Ohio).

Cell lines The parental human hepatocelluar carcinoma Bel_{7402} cells and the 5-FU selected drug-resistant Bel_{7402}/5-FU cells were grown in RPIM1640 (GIBCO) media containing 10 % newborn calf serum, 100 unit/mL penicillin and 100 μg/mL streptomycin. Cells were kept at 37 ℃ in a 5 % CO_2-95 % air atmosphere, and passaged by 0.25 % trypsin plus 0.02 % EDTA treatment. Bel_{7402}/5-FU cells were routinely maintained in the presence of 10 μg/mL 5-FU. Cells were however cultured in the absence of 5-FU for at least 3 days before their use for experiments.

Methods

Immunofluorescence assay of MRP expression Bel_{7402} and Bel_{7402}/5-FU cells were seeded on to sterilized slides. After 24hr of incubation, cells were washed twice with cold PBS and fixed with 70 % methanol at -20 ℃ for 10 min. All subsequent procedures were done at room temperature. All slides were washed once with blocking solution (1 % bovine serum albumin/5 % normal goat serum/PBS), incubated in blocking solution with 0.1 % Tween 20 for 30 min, followed by incubation with MRPr1 which was diluted 1:30 in blocking solution with 0.1 % Tween 20 for 1 hour. Then slides were washed once with blocking solution and incubated with FITC-conjugated goat anti-mouse IgG which was diluted 1:50 in blocking solution at room temperature for 1 hour. Finally, Slides were examined under confocal laser scanning microscope (BIO–RAD MRC1024) for fluorescence intensities[17].

FLU accumulation Assessment of MRP functional activity was carried out by measuring the intracellular accumulation of FLU[18]. The confluent Bel_{7402} and Bel_{7402}/5-FU monolayers were preincubated for 30 min at 37 ℃ in the culture medium, then exposed to 100 μmol· L^{-1} FLU for 3hr at 37 ℃. After washing for three times with ice-cold PBS, cells were rapidly collected and intracellular fluorescence of FLU was immediately measured with flow cytometer (Coulter, EPICS XL).

Cellular FLU distribution Bel_{7402} or Bel_{7402}/5-FU cells were plated onto 6-multiwell plate (Coster) for examining FLU distribution by using confocal laser scanning microscopy. The cells were exposed to 100 μmol· L^{-1} FLU for 3hr at 37 ℃. After this incubation period, the loading solutions were removed and cells were washed for three times with ice-cold PBS containing 1 % bovine serum albumin and examined under confocal laser scanning microscope (MERIDIAN™ Ultima 212)[19].

Measurement of cellular GSH content Bel_{7402}/5-FU cells incubated with or without different concentrations of BSO for 24 hrs and Bel_{7402} cells were lysed by addition of 0.2 % Triton X-100 in PBS. Afterwards, 20 % HPO_3 was added to precipitate proteins. The cells were centrifuged at 4 ℃ at 10 000 r.p.m. for 10 min and the supernatant fraction was used for the measurement of GSH[20]. Briefly, to 0.4 mL of the supernatant, 0.1 mL OPT (containing 0.1 mg OPT) and 2.5 mL PBS (0.1 mol· L^{-1})-EDTA (5 mmol· L^{-1}) buffer (pH 8.0) were added. After thorough mixing and incubation at room temperature for 15 min, the solution was transferred to a quartz cuvette. Its fluorescence intensity at 420nm was determined with the excitation at 350nm by a fluorescence spectrophotometer (HITACHI, MPF-4).

Chemosensitivity testing The effect of BSO on the cytotoxicity of Dox and 5-FU to Bel_{7402}/5-FU cells was assayed by a MTT method[21]. Briefly, Bel_{7402}/5-FU cells were plated in 96-well plates at 3000 cells per well. After 24hr, various concentrations of the test drugs were added in quadruplicate samples for each concentration. The cells were exposed to drugs for continuous 3 days. Then MTT (0.5 mg· mL^{-1}) was added and the plates were incubated at 37 ℃ in 5 % CO_2 for 4hr before 150 μL 100 % dimethyl sulfoxide was added to each well. The optical density of each well was determined by a microplate reader (Bio-Rad Model 450) at a wavelength of 570nm.

Total GST activity Bel_{7402} and Bel_{7402}/5-FU cells were washed with PBS and resuspended in 200 μL TMS solution (50 mmol· L^{-1} Tris, pH 7.5, 3 mmol· L^{-1} $MgCl_2$, 200 mmol· L^{-1} sucrose). After sonication at 4 ℃ (60sec), they were centrifuged at 10 000rpm for 25 min. To 10 μL cell supernatant, 2.9mL sodium phosphate buffer (0.1 mol· L^{-1}, pH 6.5) and 0.1mL reduced GSH were added. The reaction was carried out at room temperature by the addition of 30mM CDNB (in DMSO). Formation of S-2,4 dinitophenyl glutathione was monitored spectrophotometrically by the increase in absorbance at 340nm (ε 340=9.6 mM^{-1}· CM^{-1}). GST activity was expressed as nmol· min^{-1}· mg^{-1} protein in the cells[22].

TS expression Bel_{7402} and Bel_{7402}/5FU cells in the exponential phase of growth were seeded onto sterile slides and incubated at 37 ℃ in 5 % CO_2 for 24hr. After washing with cold PBS, cells were fixed in cold acetone for 10 min. The cells were subsequently rinsed in PBS and incubate with normal goat serum (10 % in PBS) at room temperature for 30 min to reduce nonspecific binding. Cells were then incubated with TS 106 (1:50 dilution) at 37 ℃ for 2hr. After being washed with PBS, all slides were incubated with FITC-labeled goat anti-mouse IgG at 37 ℃ for 1hr. All slides were washed with PBS again and examined under confocal laser scanning microscope (BIO-RAD MRC1024)[23].

RESULTS

Expression of MRP

Fluorescence immunostaining signal was weakly detectable in Bel_{7402} cells and a denser staining was found in plasma membrane of Bel_{7402}/5-FU cells. The resistant Bel_{7402}/5-FU cells (Figure 1B) showed an enhanced immunoreactivity to MRP compared to that of sensitive Bel_{7402} cells (Figure 1A), which indicated that the resistant cells contained elevated level of MRP.

FLU accumulation as an index of MRP functional activity

The previous result showed that Bel_{7402} and Bel_{7402}/5-FU cells differed in MRP expression, then we performed the functional MRP assay to demonstrate if the established difference in the levels of MRP in the two cells were indicative for differences in the MRP activity. FLU is a well-recognized substrate of MRP but not of P-gp. The use of FLU and FLU analogs as probes for MRP functional activity has been reported by Huai-Yun *et al*[24]. The results of flow cytometry showed that the accumulation of FLU in Bel_{7402} cells was almost two timed higher than that in Bel_{7402}/5-FU cells (Figure 2). In other word, MRP functional activity in the resistant Bel_{7402}/5-FU cells was higher than that in the parental cells.

FLU redistribution

In drug-selected MRP-overexpressing cells, alterations in drug localization have been observed in addition to decreased accumulation[25]. The intracellular distribution of FLU was directly examined by confocal laser scanning microscopy (Figure 3). When exposed to FLU for 3 hours, besides the difference in FLU accumulation between the two cell lines, different localization of FLU in both cell lines was also

observed. FLU mainly accumulated in the nucleus with a high nuclear/cytoplasmic ratio in Bel_{7402} cells (Figure 3A), whereas there was no difference of location between nucleus and cytoplasm in Bel_{7402}/5-FU cells (Figure 3B).

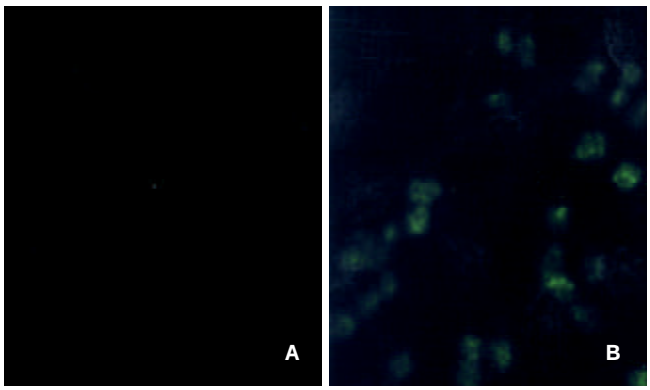

Figure 1 Immunocytochemical detection of MRP in Bel_{7402} and its 5-FU resistant cells in cytoprep slides. (A) Bel_{7402} cells; (B) Bel_{7402}/5-FU cells. The cells were fixed in 70 % methanol, and incubated with anti-MRP monoclonal antibody MRPr-1 for 1hr at room temperature. FITC-conjugated goat anti-mouse IgG was added to examine the fluorescence staining of MRP under confocal laser scanning microscope

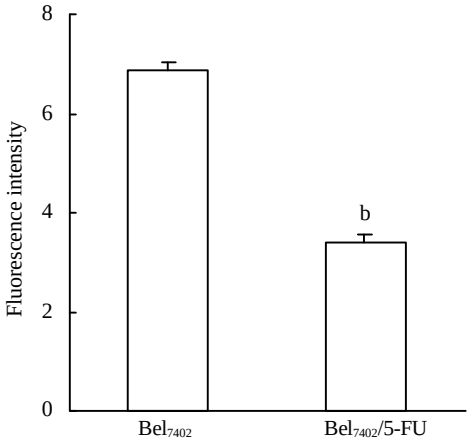

Figure 2 FLU accumulation in Bel_{7402} and Bel_{7402}/5-FU cells. The cells were incubated with 100 μmol·L^{-1} FLU for 3hr. After washing, the cells were trypsinized and intracellular fluorescence of FLU was determined with a flow cytometer. Data were pooled from three independent experiments. $^bP<0.001$ *vs* Bel_{7402} cells

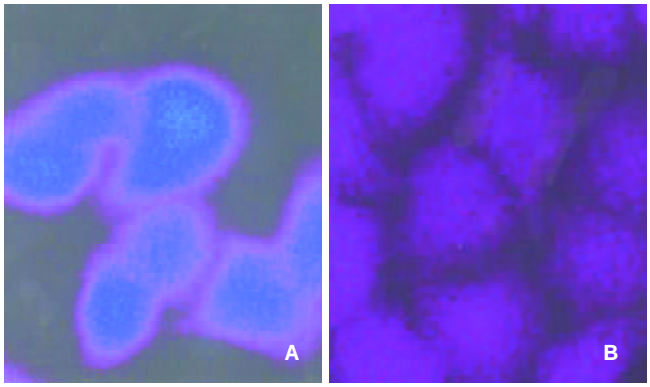

Figure 3 FLU distribution in Bel_{7402} and Bel_{7402}/5-FU cells. The cells were incubated with 100 μmol·L^{-1} FLU for 3 hr. Then the intracellular distribution of FLU was revealed by confocal laser scanning microscopy. (A) Bel_{7402} cells; (B) Bel_{7402}/5-FU cells.

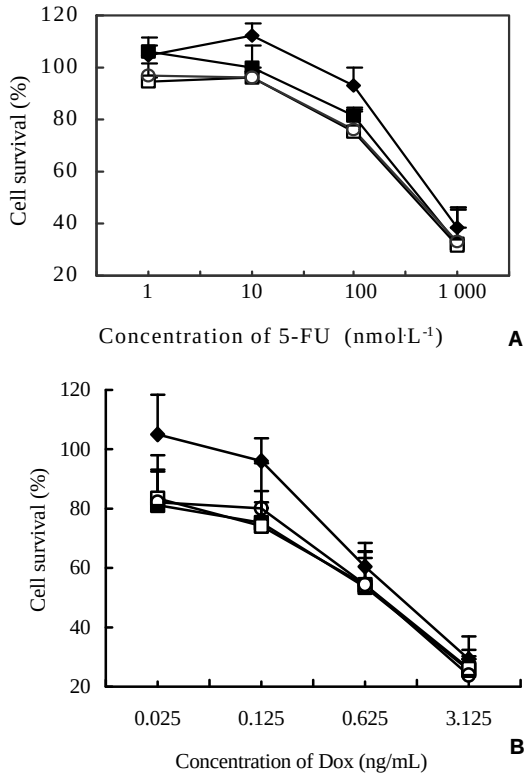

Figure 4 Effect of BSO on the cytotoxicity of 5-FU and Dox to Bel_{7402}/5-FU cells. The cells were incubated with different concentrations of 5-FU (Figure 4A) or Dox (Figure 4B) in the absence (◆) or presence of BSO at the concentration of 5 μmol·L^{-1} (□), 50 μmol·L^{-1} (○) and 100 μmol·L^{-1} (■) respectively for 72 hr. Cell survival was determined by MTT assay. The values represent the means ± SD of three experiments.

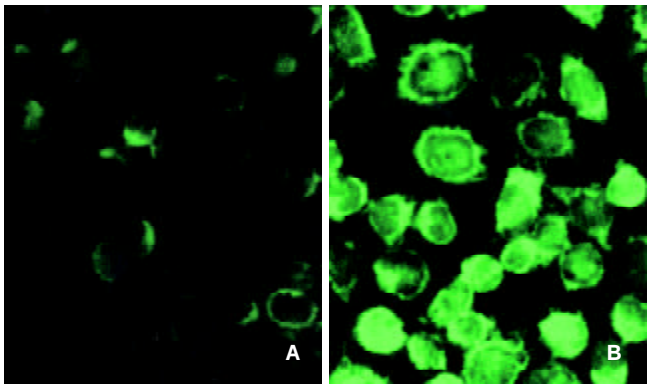

Figure 5 Immunocytochemical analysis of TS from parental and 5-FU resistant Bel_{7402} cells. The cytoprep slides were made as described in "Methods". The slides were fixed in acetone, incubated with TS 106 and stained by using FITC-conjugated goat anti-mouse IgG. TS expression was determined by confocal laser scanning microscopy. (A) Bel_{7402} cells; (B) Bel_{7402}/5-FU cells.

GSH levels and depletion of GSH by BSO

Since GSH implicates in the mechanism of MRP-mediated drug resistance, the intracellular GSH content was determined in Bel_{7402} and Bel_{7402}/5-FU cells. As shown in Table 1, the GSH content in Bel_{7402}/5-FU cells increased almost two folds in comparison with that in Bel_{7402} cells. When Bel_{7402}/5-FU cells were incubated with BSO, an inhibitor of GSH biosynthesis, at 5, 50 and 100 μmol·L^{-1} for 24 hours, the GSH content in the cells decreased in a dose-dependent manner.

Table 1 GSH content and GSTs activity in Bel_{7402} and Bel_{7402}/5-FU cells and the effect of BSO on the intracellular GSH content in Bel_{7402}/5-FU cells

		Subline	
	BSO (μmol·L^{-1})	Bel_{7402}/5-FU	Bel_{7402}
GSH content (mg/mg protein)	-	0.952±0.257	0.322±0.196[b]
	5	0.520±0.107	
	50	0.427±0.200[a]	
	100	0.403±0.135[a]	
GSTs activity (nmol/min/mg protein)	-	19.1±1.9	14.8±1.2[c]

GSH content was determined in Bel_{7402}/5-FU cells treated with or without BSO for 24 hr and Bel_{7402} cells. GSTs activity was assayed by the method of Ghalia *et al*[22] using 30 mmol·L^{-1} GSH and 30 mmol·L^{-1} CDNB as substrates. Results are presented as mean ±SD from three independent experiments, each performed in triplicates. Differences for significance were tested by using a Student's *t*-test: [a]$P<0.05$, [b]$P<0.01$ *vs* Bel_{7402}/5-FU cells without the addition of BSO; [c]$P<0.05$ *vs* the GSTs activity in Bel_{7402}/5-FU cells

Effect of BSO on the resistance of Bel_{7402}/5-FU cells

Sublethal concentrations of BSO (5, 50, 100 μmol·L^{-1}) were added to test the role of GSH in the sensitivity of Bel_{7402}/5-FU cells to 5-FU and Dox. As a result, the addition of BSO caused a slight left shift in the dose-effect pattern of 5-FU (Figure 4A) and Dox (Figure 4B) in Bel_{7402}/5-FU cells, indicating that the inhibition of GSH biosynthesis by BSO only had a weak reversal activity on the resistance of Bel_{7402}/5-FU cells.

GST enzymatic activity

GSTs catalyze the coupling reaction of intracellular electrophiles with GSH. Elevation of GSTs particularly GSTp is associated with an acquired resistance of cells to certain anticancer drugs. Table 1 showed the total GST activity in Bel_{7402}/5-FU cells were 29.1 % higher than that in Bel_{7402} cells. The difference between both cell lines was significant ($P<0.05$).

TS levels

In order to determine whether there is difference of TS expression in Bel_{7402} and Bel_{7402}/5-FU cell lines, an immunocytochemical analysis was performed by using MAb TS 106. As shown in Figure 5, the pattern of TS 106 reactivity was a dark granular appearance and diffusely spread throughout the cytoplasm in Bel_{7402}/5-FU cells. The cytochemical staining intensity of TS 106 in Bel_{7402}/5-FU cells (Figure 5B) markedly increased as compared with the parental Bel_{7402} cells (Figure 5A).

DISCUSSION

In vitro continuous stepwise exposure of HCC cell line Bel_{7402} to 5-FU for 6 months resulted in a 160 fold resistant subline Bel_{7402}/5-FU in our laboratory. The established resistance to 5-FU only slightly decreased or remained unchanged without continuous exposure to 5-FU for one month. Verapamil, a classical MDR reversal agent, significantly reversed the resistance to VCR, taxol and Dox with similar fold reversal in Bel_{7402} and Bel_{7402}/5-FU cell lines, but it only had little effect on the chemosensitivity to 5-FU and hydroxycamptothecine in both cells. In our previous study on the required resistant mechanism of Bel_{7402}/5-FU cells to 5-FU, we found that there was no difference in the expression level of the mdr-1 product P-gp between the two cells by immunocytochemical staining and Western-blotting analysis.

Up-regulation of MRP protein was observed by using the monoclonal antibody against MRP, MRPr-1 in this study. It was reported that[26] the gene expression of MRP correlated well with 5-FU resistance in 7 human gastrointestinal cancer cell lines. In some multidrug resistance cancer cells without alterations in levels of MRP, no resistance to 5-FU was found[27,28]. MRP has been postulated to cause multidrug resistance by exporting the anticancer drugs out of the cells, then the accumulation of drugs in cells decreased. Unlike P-gp, MRP can be localized in both the plasma membrane and membranes of intracellular organelles, including the endoplasmic reticulum and Golgi apparatus, thus cause intracellular or cytoplasmic sequestration of drug and prevent pharmaceuticals from reaching their cellular targets[25,29]. Anticancer drugs such as anthracyclines localize to the nucleus and cytoplasm with a high nuclear/cytoplasmic ratio in sensitive cancer cells. In contrast, anthracyclines accumulate mainly in the perinuclear region or in cytoplasmic vesicles in drug-selected MRP-overexpressing cells, and much less in the nucleus. In our experiments, the functional activity of MRP was investigated by flow cytometry using FLU accumulation as a probe. The accumulation of FLU in Bel_{7402}/5-FU cells was only about half of the amount of FLU in the parental Bel_{7402} cells, suggesting an increased activity of MRP in the resistant Bel_{7402}/5-FU cells. Furthermore, decreased nuclear/cytoplasmic ratio of FLU fluorescence was observed in Bel_{7402}/5-FU cells as compared to that in the parental Bel_{7402} cells. All of these observations indicated that the decreased accumulation of FLU and the alteration in FLU distribution in Bel_{7402}/5-FU cells may stem from up-regulated MRP.

MRP has been suggested to be the GS-X pump for multivalent organic anions such as cysteinyl leukotrienes, GSH disulfide and various GSH S-conjugates[8,30]. Intracellular GSH content is closely related to MRP-mediated multidrug resistance, since GSH interacts directly with MRP and this interaction causes a change in MRP structure that facilitates the binding and/or transport of anticancer drugs. Alternatively, GSH and anticancer drugs may spontaneously form a complex that behaves as a MRP substrate[31,32]. Using selective GSH modulators to decrease cellular GSH levels can sensitize tumor cells to the killing effects of chemotherapeutics[33]. BSO is a specific inhibitor of the rate-limiting enzyme of the GSH biosynthetic pathway, γ-glutamylcysteine synthetase. Treatment of either drug-selected or transfected resistant cells with BSO markedly depletes GSH and restores sensitivity to anticancer drugs that are transported by MRP[34-36]. In the present report, the resistant Bel_{7402}/5-FU cells exhibited a significantly higher intracelluar GSH content and higher overall GST activity than 5-FU sensitive Bel_{7402} cells. Addition of BSO dose-dependently reduced the GSH content in Bel_{7402}/5-FU cells. However, only a weak enhancement in the cytotoxicity of 5-FU and Dox to Bel_{7402}/5-FU cells by BSO was observed in growth inhibition assay. Moreover, BSO restores sensitivity to Dox more effectively than to 5-FU. Till now there is no direct evidence that 5-FU is a substrate of GSTs or MRP. It appeared that the elevated levels of the GSH/GST system and higher expression of MRP did not to play an important role in the 5-FU resistance development. These alterations maybe associated with the cross-resistance of Dox and cytarabine in the Bel_{7402}/5-FU cells.

5-FU is widely used in the treatment of breast, gastrointestinal, and head and neck cancers. The induction of TS following short-term 5-FU exposure is a generally observed phenomenon in malignant breast and colon cells[37]. A number of clinical

evaluations referred to the relationship of TS expression in tumors to clinical response and survival of cancer patients receiving 5-FU-based chemotherapy[38,39]. Fukushima *et al*[40] established a human tumor sub-line resistant to 5-FU by using colorectal xenografts in nude mice and an increase in TS activity was observed in this resistant cell. According to our study, the 5-FU resistant HCC cells exhibited the elevated levels of TS protein by immunocytochemical detection, which is a sensitive and quantitative method of detecting human TS by monoantibody TS 106 by a direct comparison of Western blotting and biochemical TS assay[22]. Although it has been demonstrated a close correlation between TS protein levels and sensitivity to 5-FU in clinic, several other mechanisms of acquired resistance to 5-FU have been attributed to TS, such as gene amplification, increased dUMP levels, decreased FdUMP accumulation, decreased stability of ternary complex, depletion of intracellular folates and so on[41]. Only TS protein expression was investigated in this research. Further investigations should be performed to determine whether other altered effects on TS occur in this Bel_{7402}/5-FU cells.

In summary, our results clearly showed that TS expression increased remarkably in 5-FU resistant Bel_{7402}/5-FU cells. In addition, the expression of MRP as well as GSTs activity and GSH content also increased. The overexpression of TS may be the main cause for the resistance development of 5-FU. The changes in MRP and GSH/GST system seemed to result in the cross-resistance of Dox in Bel_{7402}/5-FU cells.

Abstract

AIM: To establish an ideal implantable rat liver tumor model for interventional therapy study and examine its angiographic signs and MRI, CT features before and after embolization.

METHODS: Forty male Wistar rats were implanted with Walker-256 tumor in the left lateral lobe of liver. Digital subtraction angiography (DSA) and transarterial chemoembolization were performed on day 14 after implantation. Native computer tomography (CT, n=8) and native magnetic resonance (MR, n=40) were performed between the day 8 and day 21 after implantation. The radiological morphological characteristics were correlated with histological findings.

RESULTS: Successful implantation was achieved in all forty rats, which was confirmed by CT and MRI. MR allowed tumor visualization from day 8 while CT from day 11 after implantation. The tumors were hypodensity on CT, hypointense on MR T1-weighted and hyperintense on T2-weighted. The model closely resembled human hepatocarcinoma in growth pattern and the lesions were rich in vasculature on angiography and got its filling mainly from the hepatic artery. Before therapy, tumor size was 211.9±48.7 mm^3. No ascites, satellite liver nodules or lung metastasis were found. One week after therapy, tumor size was 963.6±214.8 mm^3 in the control group and 356.5±78.4mm^3 in TACE group. Ascites (4/40), satellite liver nodules (7 /40) or lung metastasis (3 /40) could be seen on day 21.

CONCLUSION: Walker-256 tumor rat model is suitable for the interventional experiment. CT and MRI are helpful in animal optioning and evaluating experimental results.

INTRODUCTION

Hepatocellular carcinoma (HCC) is a relatively common malignant tumor and its prognosis is poor[1,2]. The first choice of treatment is hepatectomy, but most cases are considered inoperable due to extreme tumor extension at the time of diagnosis and/or accompanying advanced cirrhosis[2,3]. Moreover, it will respond neither to radiotherapy nor to systemic chemotherapy, the most frequently applied palliative treatment option for locally advanced tumors is transarterial chemoembolization (TACE)[3-7]. Various protocols have been proposed with different chemotherapeutic agent, different embolization materials and different approaches. Lack of carefully designed, prospective and randomized trials has caused the most suitable scheme of TACE not yet established[8]. In order to accelerate the study of TACE strategies for HCC, it is necessary to have a suitable and reproducible animal model.

The aim of the present study was to establish an implantable rat liver tumor model for experimental TACE therapy, and deliberate its angiographic signs and MRI, CT features before and after TACE.

MATERIALS AND METHODS

Tumor and animals

The Walker-256 carcinosarcoma cell line was obtained from the Cell Preservation Center of Wuhan University (Wuhan, Hubei, P. R. China). Forty male Wistar rats weighing 200±20 g (experiment animal center, Tongji Medical College, Huazhong University of Science and Technology) were used.

Tumor implantation

Tumor implantation was performed using a modification of the technique described by Yang *et al*[9]. A 2-week-old subcutaneously growing solid tumor was explanted from a donor animal and minced into small cubes of about 2 mm^3. The recipient animals were laparotomized through a midline abdominal incision under intraperitoneal anesthesia with 1 % pentobarbitale sodium (30 mg/ kg body weight). The left lateral lobe of the liver was protruded out of the abdominal cavity and a subcapsular tunnel about 3-5 mm depth was made by a fine-point tweezer. Then a solid tumor fragment was inserted into the subcapsular tunnel and fixed with a small piece of gelfoam on the liver surface. No hemostasis was necessary.

Catheterization of the hepatic artery

14 days after the implantation, a second laparotomy was performed for angiographic studies and TACE therapy[10]. Another midline abdominal incision was performed under the general anesthesia. The common hepatic artery, the gastroduodenal artery and the right hepatic artery were isolated using a binocular operative microscope (Suzhou Medical Instruments Factory, Jiansu, China). Through an arteriotomy of the gastroduodenal artery, a polyethylene catheter (0.3 mm in inside diameter and 0.5 mm in outside diameter) was inserted retrogradely into the gastroduodenal artery and temporarily fixed by a suture.

Animal group and drugs doses

Forty rats were randomly divided into two groups (Control

group and TACE group) of twenty rats each. Control group received 0.3 ml normal saline and TACE group received 0.5 ml / kg of iodized oil (Lipiodol UltraFluid, Andre Guerbet, Aulnay-sous-Bois, France) which were given by slow retrograded manual injected into the gastroduodenal artery while the common hepatic artery and right hepatic artery were temporarily ligated.

Imaging

Hepatic artery angiography was performed by using a digital angiographic unit (Bicor Top, Siemens, Germany). A 0.3 ml bolus of contrast medium (300 mg iodine/ml, Ultravist 300, Schering, Germany) was manually injected retrogradely via the surgically implanted catheter into the gastroduodenal artery. CT (n=8) and MR imaging (n=40) were performed at 8, 11, 14 days after the implantation and 7 or 8 days after the angiography and TACE therapy. Animals were anesthetized as described earlier prior to imaging. CT scans were performed on Somatom Plus 4 spiral Scanner (Siemens, Germany) with 3.0 mm scan thickness and 3.0 increments (pitch=1.0), a field of view of 150 mm, 140 mA and 80kVp. Documentation was performed with a window width of 250 and a center of 50 Hounsfield units. MR images were performed on 1.5-Tesla system (Siemens Vision, Siemens, Germany) supplemented by a cervical coil. T1-weighted (TR/TE, 450/12 msec) and T2-weighted (TR/TE, 2800/96 msec) transverse SE images (slice thickness 2mm) were acquired using acquisition times of 7:25 and 6:16 min, respectively.

Tumor volume was determined from MR measurements of the largest and smallest diameter and calculated according to the following formula: Tumor volume (mm^3)=largest diameter (mm)×[smallest diameter (mm)]^2/2.

Histologic evaluation

Forty rats were sacrificed at 2 (ten rats) and 7 (thirty rats) days after TACE, respectively. Samples of liver tumors were fixed in 10 % formalin, dehydrated and embedded in paraffin; 5-μm sections were stained with hematoxylin-eosin for light microscopy and measurement of the degree of tumor necrosis.

RESULTS

Tumor uptake, Tumor growth, and Histopathological findings

Tumor implantation led to the outgrowth of liver tumor nodules in all forty rats. The lesions were located in the left lobe of the liver as a solitary mass. Mean volume of the tumor measured by MR examination was 211.9±48.7 mm^3 14 days after implantation, there was no statistic difference between the control and the TACE groups. No ascites, satellite liver nodules or lung metastasis was found. One week after therapy, mean volume of the tumor were 963.6±214.8 mm^3 in the control group and 356.5±78.4 mm^3 in TACE group and there were significant statistic differences between them (t=8.396, P<0.001). Ascites (4/40), satellite liver nodules (7/40) or lung metastasis (3/40) could be seen in some models at day 21.

Hematoxylin-eosin (H & E) stained sections of the liver specimens showed a poorly differentiated carcinoma, which were usually roughly spherical or ovoid in shape. Tumor cells arranged in irregular groups and the signs of malignancy, including hyperchromatosis, polymorphism and numerous mitoses were detected. The mass had a sharp demarcation from the surrounding normal hepatic parenchyma; its capsules were thin and composed of collagen fibers, which were caused by the compression of the tumor. The tumor showed inhomogeneous signs of hypervascularization consisting mainly of small arteries and capillaries. Satellite nodules or portal vein tumor embolization could be seen in some models (Figure 1).

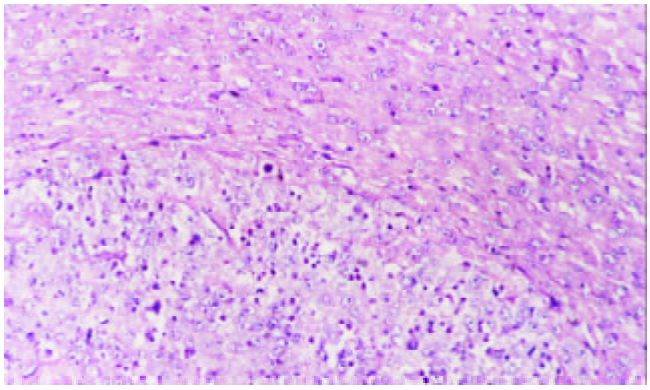

Figure 1 Control group, 7 days after hepatic artery infusion, show tumor and thin capsule. Hematoxylin-eosin ×200

Spontaneous spotty, scattered necrosis were seen in all cases of the control group 7 days after the therapy. 2 days after iodized oil embolization, the range of tumor central necrosis obviously enlarged to moderate (16/20) or even severe degree (4/20). Intra-tumor hemorrhage and bile stasis were seen in some cases. Tumor cells tended to remain viable in the periphery of nodules in the samples 7 days after embolization. We also found thick fibrous capsules around the tumor with chronic inflammation and granulomatosis. Different degree of degeneration or necrosis were seen in normal hepatic parenchyma adjacent the tumor (Figure 2).

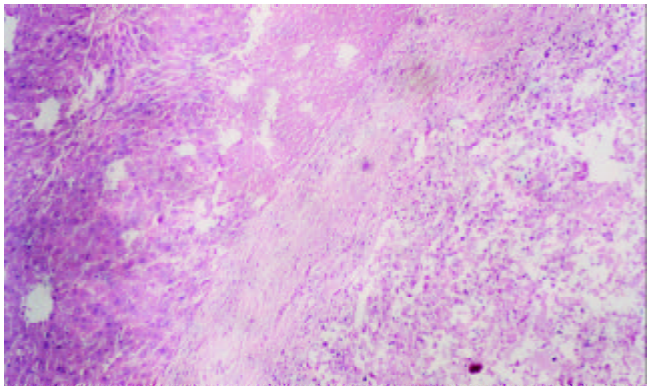

Figure 2 TACE group, 7 days after hepatic artery embolization, show tumor center necrosis, thick fibrous capsules, and degeneration or necrosis in normal hepatic parenchyma adjacent the tumor. Hematoxylin-eosin ×100.

Tumor imaging

8 days after the implantation, MR could show node with clear shape in some cases, which showed hypointensity on T1-weighted and hyperintensity on T2-weighted (Figure 3). 14 days after the implantation, MR could detect lesions in all cases. Some degree of necrosis was seen in the center of the mass in 17 cases, presented as a lower intensity on T1 and T2-weighted as compared with the pathologic tissue without necrosis (Figure 4).

One week after hepatic artery infusions, necrosis was found in all cases of control group and little change was found before and after therapy. While in TACE group, MR features were as follows: the signal in the center of lesion was asymmetrical

and mixed (high, intermediate, and low) on T2-weighted. Rim sign with varying thickness of slight high signal intensity was seen on T1 and T2-weighted (Figure 5). In addition, the presence of ascites, satellite liver nodules or lung metastasis could be shown well on MR imaging.

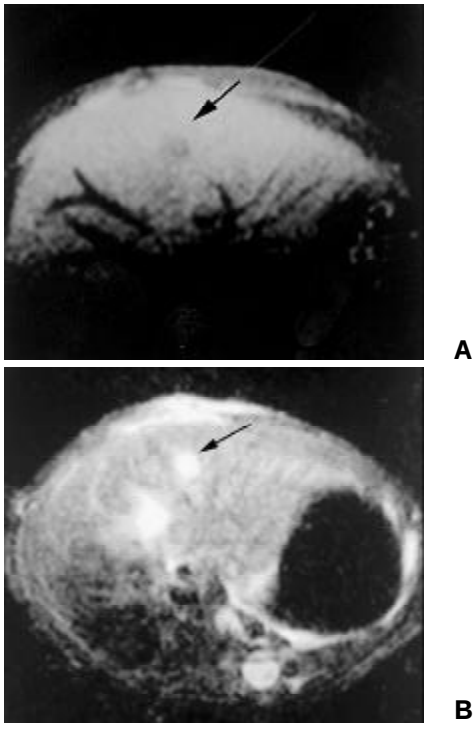

Figure 3 8 days after the implantation, MR demonstrate a node with clear shape, hypointensity on T1- weighted (A) and hyperintensity on T2 – weighted (B)

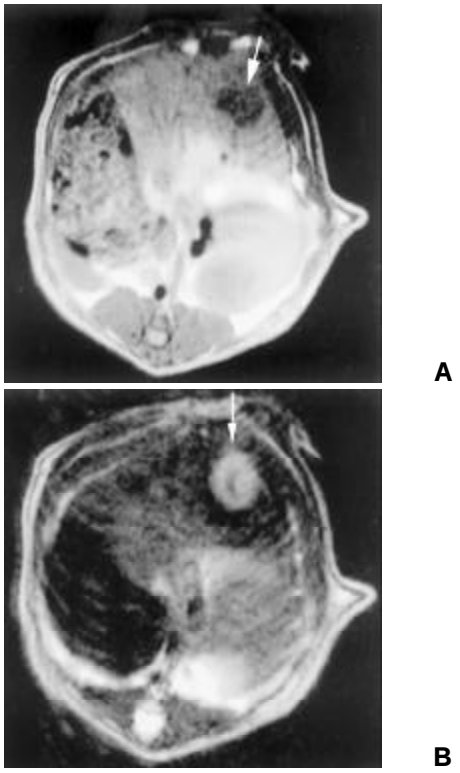

Figure 4 14 days after the implantation, tumor center showed lower intensity on T1 (A) and T2-weighted (B) than that of periphery, which indicate coagulation necrosis

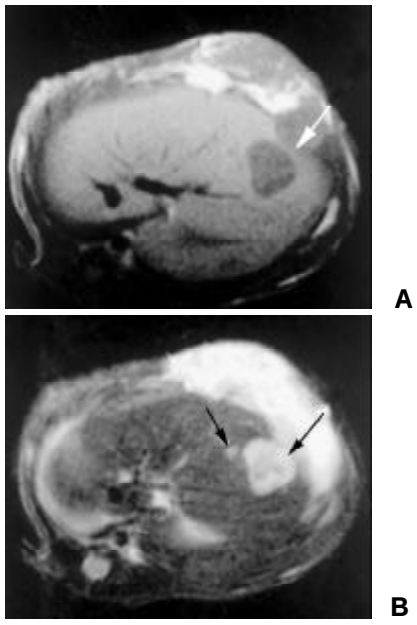

Figure 5 One week after TACE, MR showed center necrosis, periphery rim sign of slight higher T1 (A) and T2 (B) intensity, and the satellite nodular (B)

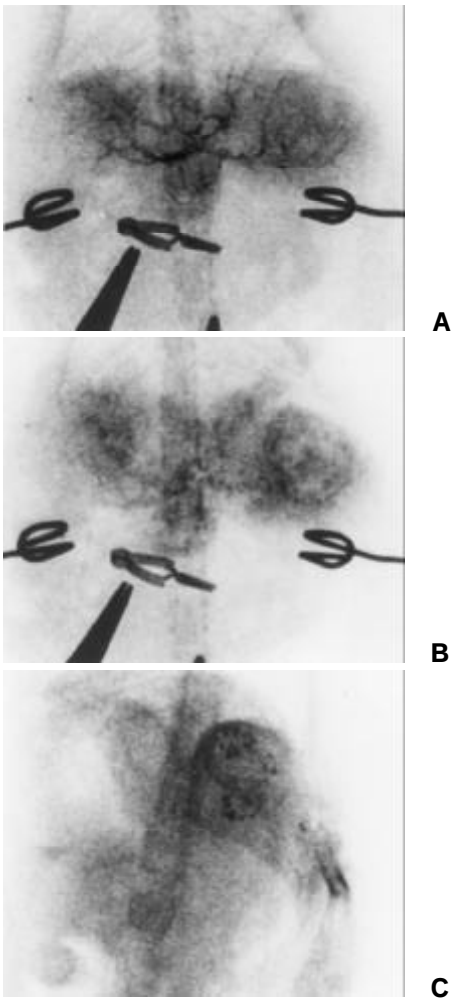

Figure 6 The tumor were mainly fed by the hepatic artery. Angiography features including hypervascularity, irregular tortuous and convoluted vessels (A), tumor stain (B) and the deposition of iodized oil in tumor after embolization (C)

Tumor could first be identified at day 11 after implantation on native CT. CT depicted the tumor as hypodensity masses and well discernible from the surrounding liver tissues. Some lesions were less dense in the central areas. After TACE, CT scans showed the dense deposition of iodized oil in tumor.

The hepatic artery mainly fed the tumors. Angiographic features included neovascularity, hypervascularity, irregular tortuous and convoluted vessels, tumor stain and sometime with contrast puddling. But no arterivenous shunts or early venous drainage were seen. Those with central necrosis showed a contrast-enhancing periphery and a nonenhancing center. After embolization, main branches of the left hepatic artery were occluded and the deposition of iodized oil in tumor could be seen (Figure 6).

Comparative study of image and pathologic findings

The clear border shown by MR represented the fiber septum caused by the compression of the tumor on neighboring normal liver tissue. Central areas of lower density in CT, lower signal intensity on T1-weighted images and T2-weighted images were compatible with central necrosis. After therapy, central areas of high signal intensity on T2-weighted images correlated with areas of liquefaction necrosis, which were more common in larger lesion. Areas of low or intermediate signal intensity of the lesion on T2-weighted images corresponded to coagulation necrosis. The peripheral rim with varying thickness of slight high signal intensity on T1 and T2-weighted images correlated with the thick fibrous capsules and the granulation tissues.

DISCUSSION

TACE has been widely carried out and is considered an effective treatment for HCC patients who are not candidates for surgery[3-8]. But as to selection of patient, TACE approaches and therapeutic efficacy, there were great variation by the different studies reported to date[5,11-13]. Standardization of proper patient selection and choice of optimal TACE methods selection remain to be determined, which severely embarrass the further progress of TACE in HCC therapy. Many scholars advocate prospective randomized controlled trials to assess the efficacy of different TACE strategies[8,14,15]. But the reaction to TACE is influenced by many factors, such as tumor differentiation, size, blood supply, liver function and adverse effect to the treatment make it difficult to judge the real efficacy of a certain TACE regime[16-21]. Replication a suitable animol model for TACE therapy can overcome these shortages. We can study the efficacy of TACE on tumor of same differentiation and similar size, location and number. Experiments on tumor model will help in exploring new technique of TACE, studying the effectiveness of different therapeutic strategies and evaluating TACE related adverse effect.

Various methods have been introduced to develop intrahepatic tumor models. Nude rats transplantation models are relatively hard to feed, need more complicate manipulation in tumor implantation and hepatic artery therapy and were more expensive[22-24]. Induction with hepatocarcinogens (such as diethylnitrosamine or aflatoxin) will produce multifocal liver tumors[25,26]. Many implantation tumors (such us Novikoff hepatoma or DHD K12 colon carcinoma cells) show early central necrosis, early systemic metastasis, or appear hypovascular[27-29]. All of these models were not suitable for TACE study. In the present study we establish Walker-256 transplanted liver tumor model and examine its tumor growth characteristic, blood supply and imaging features to judge the potential of this model in the experimental study of TACE[30].

The models show reproducibility on tumor growth rate and growth characteristic. The lesions get it' s blood supply mainly from hepatic artery, rich in vasculature and had similar angiographic features similar to that of HCC[31,32]. We concluded the tumor around 14 days after implantation was suitable for TACE experimental study-by the time the tumor had proper size, hypervascularization and no evident central necrosis.

Imaging procedures allowed monitoring of tumor size at the time of intervention and during the follow-up period without sacrificing animal and thus reduced the number of animals needed. In this series, we investigated the visualization and sizing of tumors using native CT and MR, which had been proven very useful for the clinical assessment of the effects of TACE in HCC[33-35]. The CT and MR appearance of Walker-256 carcinoma before and after TACE is similar to that of HCC in humans. It can reflect the histopathologic changes in some degree and determine the treatment efficacy preliminarily. We found MR is superior to CT in tumor detection. In further studies, MR and CT features before and after contrast media administration will be carried out to obtain further information[36-38].

The left lateral lobe is the largest one in many rat liver lobes and the left hepatic artery has a larger caliber than the right one. So we chose the left lateral lobe as the target during the tumor implantation. After the liver was returned to the abdominal cavity, the implantation site was spontaneous covered by parts of the median lobe. Simultaneously, we fixed the tumor fragment with a small piece of gelfoam on the liver surface. Our implantation techniques guaranteed the intra-parenchyma tumor growth and avoided the artificial technique -induced tumor dissemination.

According to our trial experiment and literature, the iodized oil dosage chosen for embolization was 0.5 ml / kg, which can obstruct the secondary branches of the left hepatic artery[39]. When the embolic agent was injected retrograded slowly into the gastroduodenal artery, the common hepatic artery was temporarily ligated to avoid reflux of embolic agent into the celiac trunk. Simultaneously, for the purpose of segmental embolization, we temporarily ligated right hepatic artery and this could help the rat to survive after embolization.

By the study of the imaging and pathological features, we considered the advantages of the model are: (1) We can choose the position of implantation as designed. (2) It has a high tumor uptake rate and high reproducibility of tumor growth characteristics, the procedure of implantation is simple and can be performed quickly. (3) Blood supply of the tumors mainly comes from hepatic artery and the lesions were rich in vasculature, indicating that the model is suitable for TACE experimental study. (4) The experimental methods (including tumor implantation and hepatic artery catheterization) guarantee a high post-therapy survival rate and allow the dynamic evaluation of image characteristics and treatment efficacy possible. (5) MR and CT scan can display the lesion clearly and show ascites, satellite liver nodules or lung metastasis in some models. These are helpful in animal optioning and allows noninvasive evaluation of treatment efficacy.

We conclude that the model can resemble the natural course of human HCC and have similar angiographic, CT and MR features. This tumor model has the potential to be effectively used in the experimental study of TACE.

Abstract

AIM: To study the relationship between prognosis and pathological characteristics, proliferating cell nuclear antigen labeling index (PCNA-LI) and DNA index (DI) in patients with moderately differentiated hepatocellular carcinoma(HCC).

METHODS: 51 cases of moderately differentiated HCC were analyzed with respect to the relation between their clinical follow-up data and pathological characteristics. Meanwhile, PCNA-LI of HCC cells was detected by immunohistochemistry assay and DI was measured by Feulgen staining and automatic image analysis technique.

RESULTS: Patients with a single tumor nodule, less than 5 cm in diameter, no tumor emboli, no daughter nodules and necrosis had relatively better prognosis; patients with euploidy HCC had better prognosis than those with aneuploidy; among the aneuploidy patients those with DI <1.5 had better prognosis than the cases with DI>1.5; The higher the PCNA-LI, the worse would be the prognosis. The increase in DI was correlated with the increase in PCNA-LI, and both of them were correlated with the pathological changes of the tumor.

CONCLUSION: A composite analysis of the pathological characteristics of tumor tissue, DI and PCNA-LI might be useful in predicting the prognosis of HCC patients.

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors in the world. Since 1990s HCC has become the second killer in various cancers in China[1]. Metastasis and recurrence of the neoplasm after surgical removal is still high. The frequency of 5-year recurrence after radical resection is 61.5 % overall[2]. So the knowledge of the indexes related to recurrence and survival is very helpful in predicting the prognosis of patients with HCC and to make decision on adjuvant therapies for those patients. It has been generally accepted that the degree of differentiation of tumor cells is one of the most important aspects affecting the prognosis, but even among patients of a similar differentiation of HCC, the survival period is quite different. To explore this difference, we analyzed 51 cases of moderately differentiated HCC with respect to their clinical follow-up data, the histopathological characteristics, proliferating cell nuclear antigen labeling index (PCNA-LI) and DNA index (DI). We expected to find some simple and applicable indexes for estimating the prognosis of HCC by examining the surgical specimens of HCC.

MATERIALS AND METHODS

Materials

Formalin-fixed and paraffin-embedded HCC tissues blocks from 51 cases of patients with moderately differentiated HCC, the clinical data, data of the specimens (tumor size, portal vein tumor emboli, daughter nodules and so on) and follow-up data (including ultrasound examinations of liver every half a year after surgery) were collected in Zhongshan Hospital affiliated to Fudan University during 1989-1990. We used tumor-free survival (TFS) to estimate prognosis in order to eliminate the affection of various therapies after tumor recurrence. TSF was recorded dating from the time of operation, up to the time of death or detection of HCC recurrence by ultrasound examination. The follow-up ended in December, 1999 (2 cases were lost to follow up at 67, 88 months respectively). The TFS time ranged from 8 days to more than 129 months. The probability of 1-year TFS was 62.7 %, that of 3-year TFS was 35.3 % and that of 5-year TFS was 27.5 %. 8 cases had no recurrence and were still alive at the end of the follow-up.

Histopathological inspection

4 μm tissue thick sections were cut from each block and stained with hematoxylin-eosin. We examined morphological characteristic and arrangements of tumor cells, infiltration of mononuclear cells in the stroma, tumor capsules formation and its thickness, state of tumor cells invasion, and tumor emboli and microscopic daughter nodule in vein around the cancer. The infiltration of mononuclear cells was graded as follow: 0, none or occasionally found; 1, diffuse; 2, crowded together or even lymphoid follicles formed. Tumor without capsule was defined as tumor tissue directly bordering on normal liver tissue. If ten or more layers of stratified fibrous collagen together with fibroblasts separate them, it was defined as thick

capsule; less than this was defined as thin capsule. The diameter of cancer was indicated with geometric mean of three-dimensional parameters of single cancer nodule and cube root of total volume of multiple ones.

Immunohistochemical staining

Formalin-fixed and paraffin-embedded liver tissue sections of 4 μm thickness were dewaxed in xylene and graded alcohols, hydrated, and washed in phosphate-buffered saline. The endogenous peroxidase was inhibited by 0.6 % H_2O_2 for 30 minutes, and the sections were incubated with normal goat serum (1:20 for 20 minutes). A 1:40 diluted rabbit polyclonal antibody to PCNA was applied 1 hour at 37 ℃ and then at 4 ℃ overnight in a moist chamber. Phosphate-buffered saline replaced the first antibody as blank control. A standard avidin-biotin peroxidase technique (ABC assay) was applied. Briefly, biotinylated goat anti-rabbit Ig and avidin-biotin peroxidase complex were applied for 1 hour each, with 15 minute washing in phosphate-buffered saline. The reaction was finally developed with 3-3' diaminobenzidine solution in 0.003 % H_2O_2 buffer phosphate (PH 7.8) for 10 minutes. Sections were counterstained with hematoxylin, dehydrated in alcohol, cleared in xylene, and mounted in DPX. The antibody and ABC kit were purchased from Dako Co. Copenhagen, Denmark.

To get average positive level of each case, six microscopic fields of 400× magnification were selected which included two representative fields each of considerable, medium and a few positive cells. PCNA-LI is the percentage of immunohistochemical staining positive cells in 1 000 HCC cells counted. The criterion to evaluate the expression of PCNA-LI was as following:1,>15 % (high); 2,5-15% (medium); 3, <5 % (low).

Determine of DNA-index

Feulgen staining was applied on 4 μm thick sections, and IMS Cell Analysis System (Shenteng Co. Shanghai, P.R. China) was used to detect DNA index. In each case six representative microscopic fields were chosen and the integral optical density (IOD) of 100 discrete HCC cells was measured with lymphocyte nuclei in stroma as diploidy control. Then the DNA index was automatically calculated.

Statistical analysis

SPSS for windows 10.0 software was used in statistical analysis. Data were expressed as means ±SD in the presence of continuous variables and as counts (percentages) for the categorical variables. Continuous variables were compared with the student *t* test, and categorical variables were compared with c^2 test. The probability of TFS time was calculated using the Kaplan-Meier approach and differences between survival curves were tested by the Log-rank test.

RESULTS

General conditions

51 patients were from 27 to 71 years old, median 53 years old. 48 cases were male (94.1 %). The probability of 3-year TFS in single nodule group was 44.4 %, significantly higher than multiply nodules group 13.3 % ($P<0.05$). The probability of 5-year TFS in tumor size ≤5 cm was 43.3 %, higher than group with tumor size >5 cm 4.8 % ($P<0.01$) (Table 1).

Inspection of tissue section

Tumor emboli were found in 19 cases and tumor necrosis in 16 cases during surgical operation and/or in pathological sections. The probability of 5-year TFS in those without tumor emboli was obviously higher than those with them ($P<0.01$). The probability of 1-year TFS in those without tumor necrosis was significantly higher than those with it ($P<0.01$). 45 of 51 cases had well-preserved wax blocks and had one or two sections available to show capsules and tissues around tumor. We found that the probability of 1-year TFS in those with daughter nodules was lower than those without them ($P<0.01$) and the probability of TFS in those with thick capsule was slightly higher than those with thin capsule or no capsule. The mononuclear cells infiltrating in the tumor and surroundings were mainly lymphocytes, mixing with fibrous collagen and fibroblasts, which were mostly distributed at the interface between HCC and the surroundings (Figure 1). They formed thin or thick capsule, some of which extended to tumor tissue and connected with stroma in HCC. Various degrees of lymphocytic infiltration occurred in tumor stroma (Figure 2), coordinated with that of the interface area. Only very few of the lymphocytes infiltrating tumor parenchyma showed direct contact with tumor cells. The probability of TFS in those with more heavy lymphocytic infiltration was slightly higher. (Table 1).

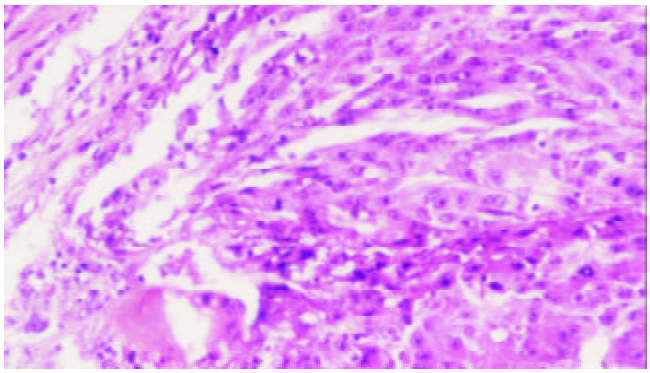

Figure 5 PCNA positive cells (the continuous section of Figure 4, PCNA immunohistochemical staining, ×100)

PCNA-Labeling Index

PCNA positive granules were found in the nuclei, and all cells with recognizable nuclear stain were considered as positive. PCNA positive cells were mainly distributed in the peripheral area of tumor nest and also in tumor emboli and at the site of HCC invasion (Figure 3,4,5). The prognosis in the case with higher PCNA-LI was worse, $P<0.01$ (Figure 6). With a higher PCNA-LI, the tumor size was usually larger and the probability of tumor emboli, daughter nodules and tumor necrosis was also higher ($P<0.05$, Table 2).

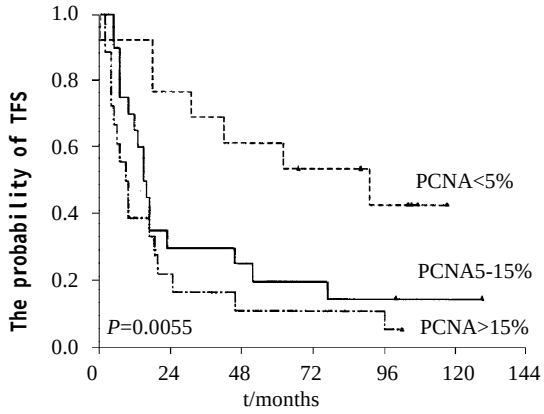

Figure 6 The Kaplan-Meier curves of different PCNA-LI groups

Table 2 The relationship of pathological characteristics to DI and PCNA-LI

Variables	*n*	Diameter (cm)	Multiple nodules	Tumor necrosis	Tumor emboli[a]	Daughter nodules[a]
DI						
Euploid	8	4.30±1.97	2	1	0/6	0/6
Aneuploid DI<1.5	22	3.64±1.29	5	4	8/19	4/19
Aneuploid DI>1.5	21	6.34±2.65[be]	8	11	11/20	11/20[d]
PCNA-LI						
<5 %	13	4.09±1.44	0	1	0/10	2/10
5-15 %	20	4.53±2.50	10[c]	4	8/18	3/18
>15 %	18	5.78±2.60[b]	5	11[ce]	11/17[c]	10/17[e]

[a]The denominator was the number of observed cases, the numerator was the number of those presenting tumor emboli or satellite nodules. [b]$P<0.05$, [c]$P<0.01$ compared with the first group; [d]$P<0.05$, [e]$P<0.01$ compared with the second group.

DNA-index

In diploidy DI=1±0.1, and in tetraploidy DI=2±0.1. DI out of the above range was aneuploidy. The prognosis of HCC cases with euploidy was better than those with aneuploidy, and in the latter DI<1.5 was better than DI>1.5, $P<0.001$ (Fig ure 7). In the group of DI>1.5 aneuploidy, tumor size was larger and the probability of tumor emboli, daughter nodules and tumor necrosis was higher (Table 2).

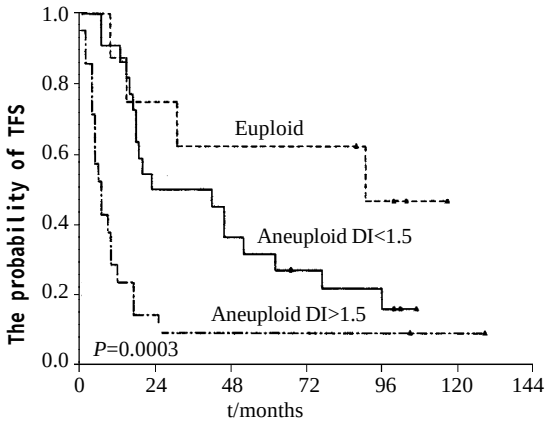

Figure 7 The Kaplan-Meier curves of different DI groups

The relationship between PCNA-LI and DI

The PCNA-LI in DI<1.5 aneuploidy group was obviously higher than in euploidy group ($P<0.05$), and that in DI>1.5 aneuploidy group was also higher than DI<1.5 aneuploidy group ($P<0.05$, Table 3). Aneuploidy DI>1.5 was seen more in higher PCNA-LI cases ($P<0.01$), and no euploidy was found in 18 cases with high PCNA-LI (Table 4). The TFS time in 13 aneuploidy cases with high PCNA-LI and DI>1.5 was from 2 to 25 months; their average TFS time was 8.1 months and the probability of 1-year TFS was only 15 %, much lower than that of the total cases (62.7 %, $P<0.01$).

Table 3 PCNA-LI in different DI groups

DI	*n*	PCNA-LI (%)
Euploid	8	5.076±3.904
Aneuploid DI<1.5	22	9.300±6.896[a]
Aneuploid DI>1.5	21	15.113±9.527[bc]

[a]$P<0.05$, [b]$P<0.01$ compared with the first group, respectively; [c]$P<0.05$ compared with the second group.

Table 4 The DNA-index distribution in different PCNA groups

PCNA-LI	*n*	Euploidy	Aneuploidy DI<1.5	Aneuploidy DI>1.5
<5%	13	5	6	2
5-15%	20	3	11	6
>15%	18	0	5	13

χ^2 test $P<0.01$, compared aneuploidy DI>1.5 and the others among the groups.

DISCUSSION

According to pathomorphological inspection of HCC, the TFS of patients with single tumor nodule (diameter ≤5 cm, no tumor emboli, no daughter nodules and tumor necrosis) was obviously high and these factors are indicators of better prognosis, which are consistent with results of other retrospective researches[3-6]. The mononuclear cells reaction may represent the response to local irritation by the tumor, but it also may be a host immunological defense mechanism aganinst the neoplastic process.Tumor-infiltrating lymphocytes are important in immunotherapy for tumors[7-9]. The presence of collagen I and III in tumor tissues may inhibit tumor cell infiltration and metastasis and such patients may have a better prognosis[10]. The expression of MMPs (a matrix-degrading enzyme family) in tumor and its relation to prognosis is one of hot points in tumor research[11-16]. Our studies also implied that patients with more mononuclear cells infiltrating in the tumor and surrounding tissue had better prognosis, and those with a thick capsule also had a longer TFS, though the differences were not statistically significant because of small number of cases.

Detection of DNA content and ploidy of tumor cells is still a common method to evaluate tumor malignancy and patient' s prognosis[17-22]. Our studies demonstrated that the prognosis of patients with euploidy HCC was better than that of patients with aneuploidy HCC, and in the latter the prognosis of DI <1.5 cases was better than that of DI>1.5 ones. In aneuploidy, DI=1.5 seemed to be a borderline, and the probability of 3-year TFS in DI>1.5 cases (13.6 %) was obviously lower than in DI<1.5 cases (52.4 %, $P<0.01$).

PCNA, auxiliary protein of DNA polymerase delta, accumulates in the nuclei during the S-phase of the cell-cycle, i.e, proliferating cells[23]. PCNA-LI can explicitly reflect proliferating degree of tumor. It was reported that PCNA-LI> 2.0 % was the strongest independent predictor of HCC in patients with compensated cirrhosis[24]. Previous research found that PCNA-LI was closely related with HCC differentiation, but others reached a conclusion that PCNA was not related with patients survival[25]. We found that PCNA-LIs were very different even in the similar moderately differentiated HCC cases, and the prognosis was worse in patients with higher PCNA-LI, and the probability of 5-year TFS in PCNA-LI> 15 % group was only 11.1 % which was far lower than that in PCNA-LI<5 % group (61.5 %, $P<0.01$). Closset el at reported that PCNA-LI<30 % appeared to be a good prognostic factor in patients without cirrhosis[26]. Besides differentiation of HCC, the difference of PCNA-LI borderline is most closely due to fields selection. We noticed that PCNA positive cells often mainly distributed in the peripheral area of tumor nest and also in tumor emboli and at the site of HCC invasion, while seldom in the middle of tumor nest. Such uneven distribution caused difficulty in selecting fields for immunohistochemistry. We applied an objective way to solve the problem: firstly, we went over the whole section, then selected six microscopic fields of 400× magnification, including two representative fields for each one of a considerable number, medium and a few positive cell areas, and finally calculated positive ones in 1 000 tumor cells.

Both PCNA-LI and DI can reflect the degree of tumor proliferation[19]. Studies in 51 cases HCC showed a certain relationship between them: the PCNA-LI in aneuploidy group was higher than in euploidy group, and a higher PCNA-LI had a higher proportion of aneuploidy. In 18 cases with a high PCNA-LI not a single case of euploidy was detected and the proportion of DI>1.5 aneuploidy was also high ($P<0.05$). However, it should be pointed out that merely judged by PCNA-LI or DI a few exceptions were found, for example, the TFS of 2 cases in the high PCNA-LI group was more than 5 years and one of them was still alive at the end of follow-up, and similarly 2 cases in DI>1.5 aneuploidy group were alive

at the end of follow-up. But all 13 cases with high PCNA-LI and DI>1.5 aneuploidy had bad prognosis. So we consider that PCNA-LI and DI should be applied together in evaluating HCC patient' s prognosis.

Surely other indexes, for instance, microvessel density, etc, are also helpful for evaluating prognosis through pathological examinations of HCC surgical specimens[2, 27-30]. We believe that a composite prospective analysis of the pathological characteristics of tumor tissue, DI and PCNA-LI is a simple and objective means to evaluate the risk of recurrence and prognosis for those patients with HCC after surgery.

Abstract

AIM: To study the effect of human endostatin mediated by retroviral gene transfer on the growth of human hepatocarcinoma cell line SMMC7721 in nude mice.

METHODS: Human endostatin gene together with rat serum albumin signal peptide was transferred into human liver carcinoma SMMC7721 cells by retroviral vector pLncx to build a stable transfectant (SMMC-endo). PCR and Western blot analysis were used to verify the transfection and secretion of human endostatin gene in SMMC7721 cells. The endothelial cell proliferation assay *in vitro* was conducted to test the biological activity of the expressed human endostatin. The inhibitory effect of endostatin expressed by transfected SMMC7721 on the growth rates of tumor cells *in vivo* was observed. The mean microvessel density in the specimen was also counted.

RESULTS: PCR amplification proved that the genome of SMMC-endo cells contained a 550bp specific fragment of endostatin gene. Western blot analysis confirmed the secretion of human endostatin gene in the conditioned medium of transfected SMMC-endo cells. The endothelial proliferation assay showed that the conditioned medium of SMMC-endo cells significantly inhibited the proliferation of human umbilical vein endothelial cells by 48 %, significantly higher than that of SMMC-pLncx (10.2 %, $P<0.01$). *In vivo* experiments revealed that only in 3 out of 5 mice tumors were formed and the mean size of flank tumors from SMMC-endo cells was 94.5 % smaller than that from the control SMMC-pLncx cells 22 days after tumor inoculation ($P<0.001$). The mean microvessel density in tumor samples from SMMC-endo cells was only 8.6±1.1, much fewer than that of 22.6 ±4.5 from SMMC-pLncx cells ($P<0.01$).

CONCLUSION: Human endostatin mediated by retroviral gene transfer can inhibit human liver carcinoma cell SMMC7721 growth in nude mice.

INTRODUCTION

It has become clear that angiogenesis not only is essential for a number of physiological processes such as embryonic development, organ and tissue regeneration, but also plays a pivotal role in tumor growth and metastases[1-4]. Folkman[2] demonstrated that suppression of tumor angiogenesis leads to tumor starvation and tumor regression. Thus, the tumor vascular system has become an important target for cancer therapy, and methods to inhibit angiogenic process provide an unique opportunity to inhibit tumor growth[4]. An increasing number of antiangiogenic agents have been discovered recently. These included angiostatin,endostatin and interleukin-12[5-7]. Among them, endostatin is one of the most hopeful antiangiogenic proteins. Its antiangiogenic effect, most potent discovered so far, can specifically inhibit the proliferation and migration of endothelial cell, and subsequently promote the development of apoptosis and regression of tumor[8-14]. However, antiangiogenic therapy with endostatin requires multiple and prolonged administrations, and the problems of such as bioactive protein production in large quantities, high costs and the cumbersome daily administration can often be met during cancer therapy[15]. Gene transfer therapy could provide an alternative approach to continuous local delivery of this antiangiogenic factor *in vivo*[16]. So, in order to explore the effect of human endostatin expressed by human liver carcinoma cell on tumor growth, stable transfectant from human liver carcinoma cell line SMMC7721 transferred with human endostatin gene was built and the inhibitory effect of endostatin on tumor growth *in vitro* and *in vivo* were observed.

MATERIALS AND METHODS

Cell culture

Human liver carcinoma cell line SMMC7721 was kept by our laboratory. Human umbilical vein endothelial cell line (HUVEC) was purchased from Institute of Cell Biology, Chinese Academy of Sciences. HUVEC and human liver carcinoma cell line SMMC7721 were maintained in RPMI 1640 medium (Gibco) supplemented with 100 mL· L^{-1} FBS, 100 units/mL penicillin and 100 ug/mL streptomycin. Retrovirus packaging cell line PA317 was kindly provided by Dr.Qian Qijun (Second Military Medical University, Shanghai, China), and maintained in DMEM (Gibco) supplemented with 100 mL· L^{-1} FBS,100 units/ml penicillin and 100 μg/mL streptomycin.

Plasmid

The recombinant retroviral plasmid pLncx-endo containing the cDNA for human endostain gene with a HA tag attached to the C-terminus as a fusion protein was engineered by our laboratory[17]. In this plasmid, human endostain cDNA was put downstream of rat serum albumin signal peptide.

Generation of stable transfectants

Recombinant plasmid pLncx-endo was transferred into PA317

cells by Lipofectamine (Gibco) following the manufacturer' s instructions. G418 selection at 500 μg/mL was added at the same time. Two weeks after transfection, G418-resistant colonies emerged and were expanded respectively. The supernatants of G418-resistant PA317 colony were collected and stored at -80 ℃ for usage. 5×10^5 SMMC7721 cells were plated on 6-well plate and incubated for 24 h. The cells were rinsed with serum-free RPMI 1640 medium twice, and 100 μL supernatant of endostatin- transfected PA317 colony was added and incubated for 3 h. Another 3 mL 1640 medium was added with the final concentration of polybrene at 2 mg· L^{-1} and G418 at 500 mg· L^{-1}. Four weeks after transfection, G418-resistent cells were expanded for preservation and tested for endostatin-HA fusion protein by immunohistochemistry and Western blot analysis. The endostatin-transfected colony was designated as SMMC-endo. Control transfectant (SMMC-pLncx) was generated in a similar way except the parent plasmid pLncx-endo was replaced by empty plasmid pLncx.

PCR amplification of endostatin from transfected SMMC7721 cells

According to human endostain sequence, two primers were devised. The primers used were E1: 5' CCG GAA TTC ATG CAC AGC CAC CGC GAC TTC CAG CCG and E2: 5' GCC GGA TCC CTA CTT GGA GGC AGT CAT GAA GCT. SMMC-endo and SMMC-pLncx cells were harvested and DNA extracted. PCR was performed in 50 μL reactive volume containing 2 μL cDNA, 2 μL 10×PCR buffer, 2 μL 4×dNTP (2 mmol· L^{-1}), 50 pmol· L^{-1} primer, and 1 μL *Tag* DNA polymerase. The samples were subjected to 30 thermal cycles of 5 min at 94 ℃ for predenaturation, 1 min at 94 ℃ for denaturing, 1 min at 60 ℃ for annealing, 1 min at 72 ℃ for extension, and 10 min at 72 ℃ for final extension after the last cycle. PCR products were checked on 10 g· L^{-1} agarose gels (containing 0.5 mg· L ethidium bromide).

Western blot analysis

SMMC-endo and SMMC-pLncx cells were plated in six-well plates at 2.5×10^5 cells/well respectively and incubated for 24 h. The medium was replaced with 1 mL serum-free RPMI 1640 and collected after 48 h. One mL of conditioned medium was concentrated in a microcon 10 microconcentrator (Amicon, Berverly, MA) to 20 μL and subjected to a 120 g· L^{-1} reducing SDS/PAGE gel. Protein was transferred to a nitrocellulose membrane and incubated overnight in 50 mL· L^{-1} nonfat milk in PBS at 4 ℃. After briefly washing in 10 mL· L^{-1} fat-free milk, the membrane was incubated with anti-HA mouse monoantibody diluted 1:500. After three 10-min washes in 1 mL· L^{-1} fat-free milk, membrane was incubated in horseradish peroxidate-conjudated antimouse immunoglobulin diluted 1:1000. After three 10-min washes in TBS, proteins were detected using 3,3-diaminobenzidine as the chromagen.

Endothelial cell proliferation assay

SMMC-endo, SMMC-pLncx and SMMC7721 cells were plated onto six-well culture plates at a density of 2.5×10^5 cells/well and incubated for 24 h. The cells were washed with PBS, and 1.5 mL of serum-free RPMI1640 were added and incubated for another 48 h. The total of 9 mL serum-free RPMI 1640 were collected and concentrated to 1.8 ml using Centriplus 10 concentrator (Amicon), and stored at -80 ℃ for usage. HUVEC cells were seeded at a density of 4000 cells/well into gelatinized 40-well culture plates and incubated (37 ℃, 50 mL· $L^{-1}CO_2$) for 24 h in 100 μL RPMI 1640 medium. The medium was replaced with 20 μL of above concentrated conditioned medium and incubated for 30 min. 80 μL of RPMI 1640 supplemented with 100 mL· L^{-1} fetal bovine serum and 1 μg· L^{-1} bFGF (Sigma) was then added for 72 h. The numbers of cells were determined using a colorimetric MTT assay. Tests were conducted in quadruplicate.

In vivo evaluation of tumor growth

To test whether endostatin expressed by host cells could inhibit tumor growth *in vivo*, we used the human liver carcinoma cell line SMMC7721. This model has been widely used in experiment. 4-week-old female BALB/c (nu/nu) mice (purchased from Shanghai Institute of Cancer Research) were chosen. SMMC7721 cells were inoculated s.c. into the right flank of nude mice and changes in tumor growth were monitored. In this experiment, flank tumors were generated by s.c. injection of 5×10^5 cells in 100 μL of HBSS into the right flank of athymic BALB/c (nu/nu) mice for SMMC-endo and control SMMC-pLncx cells (n=5). Tumors were measured by calipers in two dimensions every 2 days, and the volume was calculated as length×width^2×0.52.

Histological analysis

To determine the effect of endostatin on vascular growth *in vivo*, microvessel density counting was conducted on frozen sections of tumors from SMMC-endo and SMMC-pLncx cells as described previously[18] by immunostaining with anti CD_{34} (Gibco). Anti-CD_{34} antibody was used at a dilution of 1:500. Immunohistochemistry was accomplished utilizing an avidin-biotin technique. SMMC-endo and control SMMC-pLncx were grown on six-well glass slides and fixed in acetone at room temperature. After washing in PBS, the cells were incubated with a 10 mL· L^{-1} H_2O_2 solution at room temperature for ten minutes to quench endogenous peroxidases. Nonspecific binding was blocked with 50 mL· L^{-1}normal horse serum at room temperature for five minutes. The cells were then incubated with anti-HA at a 1:300 dilution at 4 ℃ overnight. Following washing in PBS, the secondary antibody, biotinylated antimouse, was added and the cells were incubated at room temperature for one hour. After washes in PBS, Vectastain reagent (a solution containing strepavidin-horseradish peroxidase) was added and then incubated at room temperature for ten minutes. 3,3-diaminobenzidine was used as the chromagen. After ten minutes, the brown color signifying the presence of antigen bound to antibodies was detected by light microscopy and photographed at ×200. The blood vessels were counted from five areas in each tumor section.

RESULTS

Generation of stable transfectants

A 550-bp fragment was seen in the PCR product from DNA of SMMC-endo cells,but not from the control (Figure 1). On a reducing 120 g· L SDS/PAGE gel, a distinct band at around M_r22 000, corresponding to the size of endostatin, was only visualized in the supernatant of SMMC-endo cells. Monoclonal mouse anti-HA antibody reacted positively in a Western blot with the M_r22 000 protein only. It confirmed that endostatin protein expressed by transfected SMM-endo cells could be secreted into the supernatant of cells (Figure 2).

Antiangiogenic effect of human endostatin expressed by endostatin-transfected cells

The effect of expressed endostatin on HUVEC proliferation was tested. The result showed that there were no significant differences among the concentrated conditioned media from SMMC7721, SMMC-pLncx cells and RPMI1640 medium in inhibiting the growth of HUVEC. Compared to RPMI 1640 medium, the inhibitory rate on HUVEC proliferation for conditioned medium from SMMC-endo cells was 48 %,

significantly higher than that of 10.2 % for control SMMC-pLncx. There was a significant difference on the antiangiogenic effect between conditioned medium from SMMC-endo and SMMC-pLncx (P<0.01, Figure3).

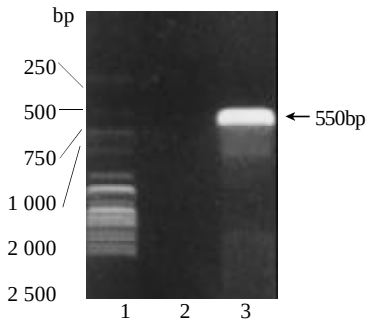

Figure 1 Analysis of PCR product of endostatin-transfected SMMC7721 cells by 1 % agarose gel electrophoresis. 1: DNA Marker. 2: PCR product of SMMC-pLncx. 3: PCR product of SMMC-endo.

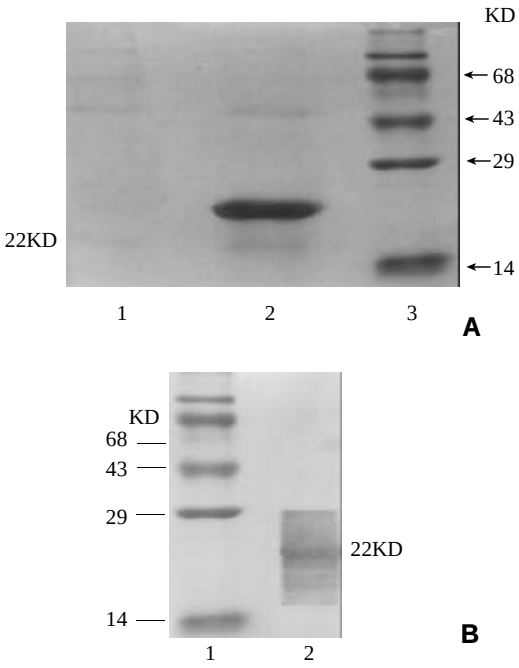

Figure 2 SDS-PAGE analysis and Western blot of endostatin expressed in supernatant of virally transduced SMMC7721cells (A) SDS-PAGE analysis; 1, supernatant of control SMMC-pLncx cells; 2, supernatant of endostatin-transfected SMMC-endo cells; 3, protein marker; (B) Western blot analysis; 1 protein marker; 2, supernatant of endostatin-transfected SMMC-endo cells.

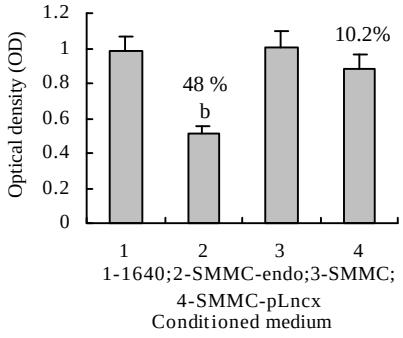

Figure 3 Inhibition of endothelial cell proliferation by conditioned medium from SMMC-endo cells. Conditioned medium from SMMC-endo (2), SMMC7721 (3) and SMMC-pLncx (4) were concentrated and applied to HUVEC cells grown in 40-well plate. Three days later, cell number, as measured by absorbance(OD), was then quantified by using a colorimetric MTT assay. Bars, SD. ^{b}P<0.01, compared with conditioned medium from control SMMC-pLncx.

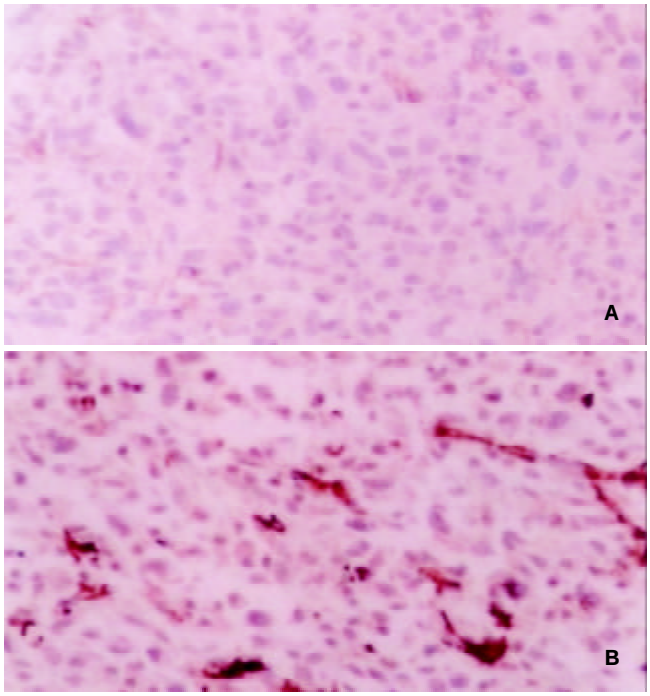
Human endostatin inhibits tumor growth in nude mice

To determine the anti-tumor effect of endostatin expressed by transfected SMMC7721 cell, 5×10^5 cells were injected s.c. into right flanks of nude BALB/c mice. SMMC7721 cells and SMMC-pLncx cells formed tumor rapidly within 14 days. While flank tumors from SMMC-endo cells grew very slowly in nude mice. The first palpable tumor from SMMC-endo cells appeared 16 days after injection and only in 3 out of 5 nude mice formed tumors. The mean size of flank tumors from SMMC-endo cells was 94.5 % smaller than that from SMMC-pLncx cells 22 days after tumor inoculation, a significant difference between SMMC-endo and SMMC-pLncx groups (P<0.001, Figure 4). The mean microvessel density(MVD) in tumors was determined by utilizing anti- CD_{34}. The number of vessels was counted and the results showed that the MVD in tumor samples from SMMC-endo cells was only 8.6±1.1, much fewer than that of 22.6±4.5 from SMMC-pLncx cells (P<0.01, Figure 5). It meant that endostatin expressed by SMMC-endo cells could decrease tumor vascularization.



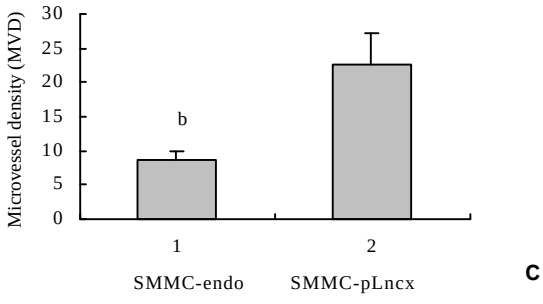


Figure 5 Tumor sections were stained with an antibody reactive to CD_{34}. A: Tumor section from endostatin-transfected

g1roup showed only a few positively stained vascular endothelial cells. B: Similar section of the control group showed highly vasuclarized tumor tissue. C: Microvessel density (MVD) was quantified by counting of positively stained endothelial cells from 5 fields in each tumor section. Bars, SD. $^bP<0.01$, compared with control SMMC-pLncx . ×200.

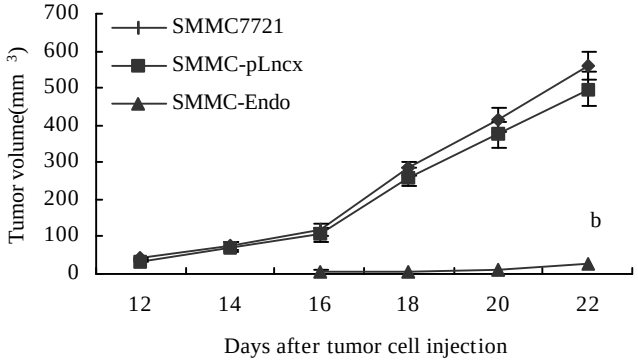

Figure 4 Inhibition on the growth of human liver carcinoma implanted in nude mice by human endostatin. $^bP<0.001$, SMMC-endo compared with control SMMC-pLncx.

DISCUSSION

It is known to all that blood supply is necessary for tumor progression and metastasis[1-4]. Folkman[2] noted that tumor will stop growing or die when it exceeds 2 mm to 3 mm in diameter if new blood vessel for tumor is not formed. Numerous studies have also shown that inhibition of tumor growth and metastases could be reached by administration of recombinant antiangiogenic proteins[15,19-21]. Moreover, the genome of endothelial cells, targeted by antiangiogenic proteins has a stable inheritance property and rare mutation rate. So, unlike tumor cells in chemotherapy, acquired resistance to recombinant antiangiogenic protein is rarely developed during antiangiogenic therapy. Therefore, antiangiogenic therapy is probably one of the most effective and promising approaches to cancer treatment[14].

Antiangiogenic therapy will require sustained maintenance of therapeutic levels *in vivo*[22,23]. Continuous delivery and high doses of recombinant antiangiogenic protein in circulation by repeated administrations seem expensive and impossible. Gene therapy transfer of foreign antiangiogenic gene into host cells represents an alternative method to tumor therapy. The aim of generating high efficient protein in areas around tumor with no toxin and keeping long time relatively high expression of antiangiogenic protein can be achieved by a single administration of gene transfer. There have been successful reports of antiangiogenic gene therapy with viral vectors being used to treat tumor[24-27]. Endostatin is a new kind of potent antiangiogenic factor consisting of 184 amino acids in C-terminal fragment of endogenous collagen18 a. It was first isolated as a M_r20 000 protein from conditioned medium of the EOMA murine hemangioendothelioma cell line by Professor O' Reilly in 1997[28-33]. *In vivo* and *in vitro* experiments had demonstrated that endostatin has specific inhibitory effect on the formation of new blood vessel. It could inhibit tumor growth with reduction of virtually all tumor neovascularization and without detectable systemic sign of toxicity[34-37]. In the same way, antiangiogenic therapy with endostatin in cancer requires prolonged administration and high doses of recombinant protein. Furthermore, the production of soluble functional polypeptide endostatin has proven difficult and nearly 95 % of the recombinant protein used will be excreted out of the body because of its insoluble and instable property[38]. However, all of the above problems can be overcome by gene transfer of endostatin gene. As gene transfer mediated by retroviral is most commonly used among the various ways of transducing methods and retroviral can be integrated into chromosome of host cells. So, gene transfer mediated by retrovirus can be inherited to next generation and stably expressed in host cells for a long duration[27]. In this experiment, recombinant retroviral plasmid pLncx-endo was transferred into human liver carcinoma cell SMMC7721 by using lipofectamine. The following PCR examination and Western blot analysis confirmed the transfection and stable expression of human endostatin by SMMC-endo cells. The expressed protein was secreted outside of cells under the influence of rat albumin signal peptide[10,39]. It revealed that a stable transfectant that could secrete human endostatin was built. *In vitro* endothelial cell proliferation assay verified the biological activity of endostatin, which showed that conditioned medium from SMMC-endo could significantly inhibit the proliferation of endothelial cells by 48 %, while the inhibitory rate for conditioned medium from control SMMC-pLncx was only 10.2 %. It suggested that the secreted protein expressed by the stable transfectant had a potent antiangiogenic effect[40,41]. In vivo experiments showed that tumor formations from SMMC-endo cells were dramatically inhibited. Compared to control group, only in 3 out of 5 mice inoculated with SMMC-endo cells tumors were formed and a remarkable reduction in tumor size was also exhibited 22 days after tumor injection. The mean size of tumors from SMMC-endo cells was about 94.5 % smaller than that from control SMMC-pLncx. Meanwhile, histological analysis showed that the MVD in tumors from SMMC-endo cells was also remarkably decreased compared to control SMMC-pLncx. It meant that human endostatin expressed by SMMC7721 could indeed inhibit the formation of tumor *in vivo*. In another word, endostatin arrests tumor growth by inhibiting the formation of microvessels *in vivo*, and gene transfer therapy mediated by retrovirus could meet the requirements for tumor treatment. But we also noted that the expressed endostatin did not completely inhibit the formation of tumor in nude mice. Some proangiogenic factors such as VEGF and bFGF, produced by SMMC7721 cell itself may be responsible for this phenomenon[42,43]. Another probable reason is the low amount of endostatin expressed by retroviral plasmid pLncx. So, in a word, gene transfer of endostatin mediated by retroviral pLncx could significantly inhibit the growth of SMMC7721 cells in nude mice by affecting angiogenesis and is probable one of the effective ways to deal with tumor. But the application of new efficient expression plasmid and combined therapy with multiple genes may further improve the therapeutic effect of endostatin in the future.

Abstract

AIM: To evaluate the function of the longer transcripts LPTS-L in hepatocellular carcinoma cell line SMMC-7721.

METHODS: SMMC-7721 cells were transfected with LPTS-L expression construct and stably transfected cells were selected by G418. Multiple single clones formed and were checked for their phenotype. In the study of the effect on telomerase activity of LPTS-L *in vitro*, GST-LPTS-L fusion protein was expressed in *E.coli* and purified by glutathione-agarose column. Telomeric repeat amplification protocol (TRAP) assays were performed to study the influence of telomerase activity in SMMC-7721 cells.

RESULTS: Over-expression of LPTS-L induced SMMC-7721 cells into crisis. LPTS-L could inhibit the telomerase activity in SMMC-7721 cells *in vitro*.

CONCLUSION: LPTS-L is a potent telomerase inhibitor. Over-expression of LPTS-L can induce hepatoma cells into crisis due to the reduction of telomerase activity.

INTRODUCTION

Telomeres are a specialized structure composed of deoxyribonucleic acid (DNA) with associated proteins in the ends of chromosomes in the nuclei of all eukaryotic organisms[1]. Telomeric DNA consists of long head-to-tail arrays of repeated DNA sequences and the repetitive hexanucleotide in human is TTAGGG[2]. Telomeres provide a mechanism to compensate for under-replication of the linear DNA ends, distinguish true chromosome ends from breaks in DNA, and protect chromosome ends from fusing with others or broken chromosomes. In some cells, telomeres also control the positions of chromosomes within the nucleus[3, 4].

Telomerase, a special reverse transcriptase enzyme,extends the telomeric DNA using intrinsic RNA template and helps stabilization of telomere length in human stem cells, reproductive cells and cancer cells[5-7]. Telomerase activity has been found in almost all human tumors, while in most somatic tissues, including the liver, it cannot be detected, and telomere length is shortened by 50-200 nucleotides with each cell division[8-10].

The telomere and telomerase serve as a kind of clock controlling life span, which forms the telomere and telomerase hypothesis of cell aging and tumorigenesis. The prominent hypothesis states that a signal is initiated to cease cell dividing and induce cell senescence when the telomere is shortened with cell doubling and reach to a certain threshold level. The maintenance of telomere stability is required for the long-term proliferation of tumor cells.Thus, escaping from cell senescence and becoming immortal by activating telomerase, or an alternative mechanism to maintain telomeres, constitutes an additional step in tumorigenesis[8, 9].

LPTS gene is a human novel liver-related putative tumor suppressor gene (LPTS), identified by our laboratory[10]. It is located in chromosome 8p23, a hot spot of tumor suppressor in hepatocellular carcinoma (HCC) with a high frequency of loss of heterozygosity (LOH). LPTS gene is transcribed to two isoforms of mRNA. The longer transcript, referred to as LPTS-L, encodes a 328-a.a. protein and is down-regulated in HCC cell lines and tissues at both RNA and protein levels (unpublished data). LPTS-L is highly homologous with PinX1, identified as a telomerase inhibitor recently[12], with quite different sequences in 3' untranslational region.

In this study, we determined the function of LPTS-L through transfecting the LPTS-L into hepatoma cell line SMMC-7721, and analyzing its effect of cell proliferation and morphology. We also detected the effect of LPTS-L to the telomerase activity. The results clearly showed that LPTS-L is a potent telomerase inhibitor and could induce hepatoma cells into crisis.

MATERIALS AND METHODS

Cell line

The previously characterized hepatoma cell line SMMC-7721 was obtained from the Cell Bank of the Chinese Academy of Sciences (Shanghai, China) and cultured in RPMI medium 1640 (Life Technologies Inc.) plus 10 % new-born calf serum at 37 ℃ at a 5 % carbon dioxide atmosphere in a humidified incubator.

Transfection of LPTS-L into SMMC-7721

The coding region of LPTL was subcloned into eukaryotic expression vector pcDNA$_3$ (Invitrogen, Inc., Carlsbad CA) and constructed pcDNA$_3$-LPTS-L. The plasmids were purified with QIAGEN Plasmid Kit (QIAGEN Inc.) and transfected with 2 mg of plasmid with LipofectAMIN (Life Technologies, Inc.) according to the manufacturer' s protocols. Twenty-four hours after transfection, G418 (Life Technologies, Inc.) was added to the medium at a final concentration of 700 mg/L to kill untransfected cells.

Expression and purification of GST fusion protein

The coding sequence of LPTS-L was cloned in frame into the *E.coli* GST fusion expression vector pGEX-4T2 (Amersham Pharmacia Biotech Inc.), then the construct was transfected into *E.coli* BL21(DE3). The protein was expressed with IPTG induction for 3 hours and purified by glutathione-agarose (Sigma) column.

TRAP telomerase activity assay[13]

HCC cells SMMC-7721were lysed in lysis buffer (10 mM TrisHCl pH7.5, 1 mM $MgCl_2$, 1 mM EGTA, 0.1 mM PMSF, 5 mM 2-mercaptoethanol, 0.5 % CHAPS, 10 % glycerol) on ice for 30 min and centrifuged at 13 000 rpm for 30 min, the telomerase was contained in the suspension of cell extract. The protein of LPTS-L was incubated with cell extract for 10 min at 4 ℃ before subjecting to telomerase extension according the reference[11]. Telomerase products were separated on 10 % polyacrylamide gels, which were stained with silver.

RESULTS

Over-expression of LPTS-L in SMMC-7721 induces crisis

To investigate the function of LPTS-L in hepatoma cells, 987-bp coding region of LPTS-L was subcloned into $pcDNA_3$ eukaryotic expression vector to construct $pcDNA_3$-LPTS-L, then the construct was transfected into SMMC-7721 cell lines, with $pcDNA_3$ vector as control. The growth of hepatoma cells transfected with LPTS-L became slow, possibly due to an increase rate of cell death, as compared with control. In most cases, the cells transfected with LPTS-L exhibited increased size and flattened-morphology, with the characteristics associated with crisis (Figure 1).

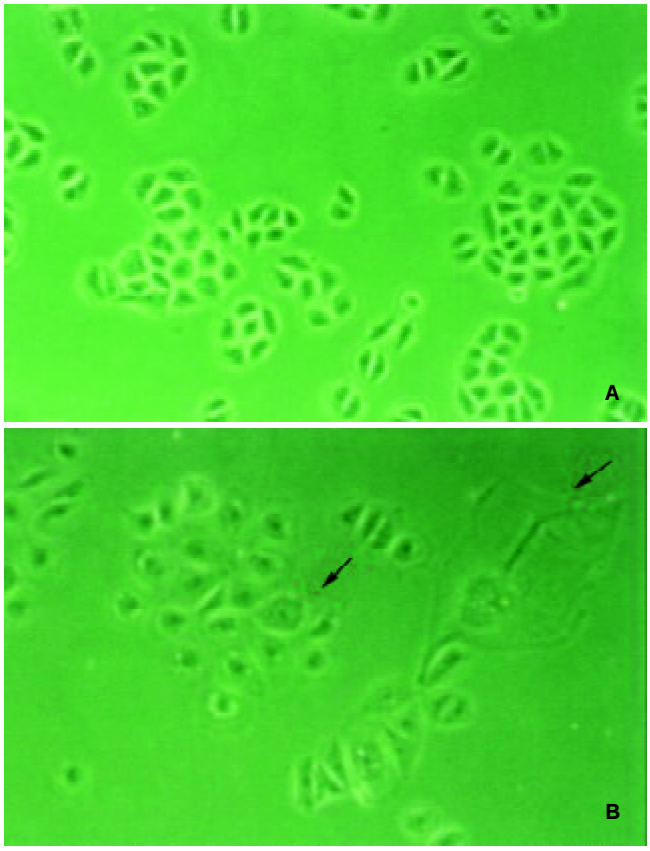

Figure 1 Morphologic changes induced by LPTS-L in hepatoma cell line SMMC-7721. A. cells expressing control vector; B. large flat cells in crisis expressing LPTL.

LPTS-L could inhibit telomerase activity of SMMC-7721 cell extract in vitro

To study the mechanism of the induction of the hepatoma cells into crisis by LPTS-L, we used telomerase activity assay *in vitro* to determine the correlation between LPTS-L protein and telomerase. Firstly, we subcloned the coding sequence of LPTS-L into GST fusion protein expression vector in frame and purified the GST-LPTS-L fusion protein by affinity chromatography (Figure 2). The purity of the fusion protein was enough for the next telomerase activity assay. We next added the GST-LPTS-L protein into the cell extract of SMMC-7721 and then performed the TRAP assay. The results showed clearly that LPTS-L inhibited telomerase activity greatly, 1 mg fusion protein could almost inhibit the telomerase activity, while 10 μg GST protein had no effect at all (Figure 3).

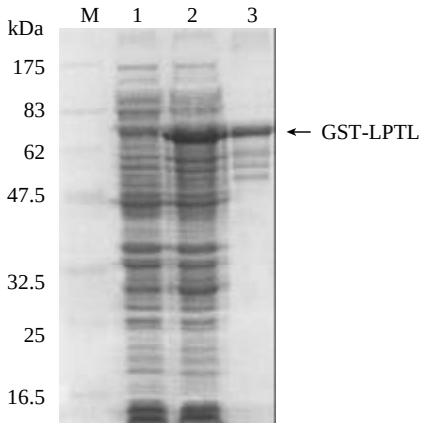

Figure 2 The expression of GST fusion protein with LPTS-L. M: protein marker; 1. total protein before IPTG induction; 2. total protein after IPTG induction for 3 hours; 3. purified GST fusion protein by affinity chromatography on glutathione-agarose column.

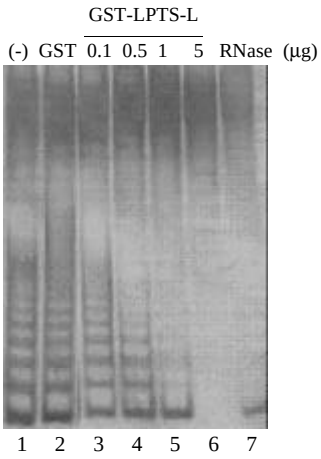

Figure 3 LPTS-L fusion protein inhibits telomerase activity in hepatocellular carcinoma cell line SMMC-7721 by TRAP assay *in vitro*. 1. SMMC-7721 cell extract alone; 2. plus 10 μg GST protein; 3-6. plus 0.1, 0.5, 1, 5 μg GST-LPTS-L fusion protein and the lane 7 is cell extract plus RNase.

DISCUSSION

Normal hepatocytes seldom divide, which is reflected by a fact that their telomeres length does not decrease with age. Telomerase activity is absent in the resting liver but transiently reappears during hepatic regeneration. The telomere length of

HCC cells is relatively shorter than that of the normal hepatocytes, but is stable due to the activation of telomerase activity[14,15]. The telomerase activity could be detected in all HCC tissue samples smaller than 3 cm, regardless of the patient's age, sex, viral marker and degree of tumor differentiation[16]. Telomerase activity was also detectable in hepatoma cell line SMMC-7721 as assayed by TRAP assay. Over-expression of LPTS-L in SMMC-7721 cells could inhibit telomerase activity, and induce cells into crisis. From the results above, we can conclude that LPTS-L encoded by LPTS gene is expressed in normal liver cells and serves as a telomerase inhibitor. In the HCC cells, LPTS-L was down-regulated or absent, while transformed LPTS-L into HCC cells could stop the cell proliferation and the cells became large, flat and dead. LPTS gene must be inactivated to depress the telomerase inhibitory activity during hepatocarcinogenesis.

Recently, the correlation between telomerase and immortalization of tumor cells, makes the telomere and telomerase a hotspot in tumor molecule pathological study. Reactivation of telomerase appears to be a universal and obligatory step towards cell immortalization. Telomerase activity has been found in about 85-90 % of all human tumors, including liver cancer, but not in adjacent normal cells. As a result, telomerase has become a novel target not only for cancer diagnosis but also for the development of novel therapeutic agents[17,18]. LPTS-L encoded by LPTS gene, which could inhibit the activity of the telomerase directly, is an important protein inhibiting telomerase activity. LPTS gene might be a new target in the "battle" against hepatocellular carcinoma, and could be used in tumor gene therapy through reactivation of its expression in tumor cells.

Abstract

AIM: To investigate the antitumor activities of tachyplesin on human hepatocellular carcinoma (HCC) cells.

METHODS: Tachyplesin, isolated from acid extracts of Chinese horseshoe crab (*Tachypleus tridentatus*) hemocytes, was used to treat the human HCC cell line SMMC-7721. Effects of tachyplesin on the proliferation of SMMC-7721 cells were measured with trypan blue dye exclusion test and HE staining. The morphology and ultrastructure of the cells were examined by light microscopy and transmission electron microscopy, respectively. The activities of γ-glutamyltransferase (γ-GT) and tyrosine aminotransferase (TAT) were assayed with biochemical methods. The levels of alpha fetoprotein (α-FP), proliferating cell nuclear antigen (PCNA), $p21^{WAF1/CIP1}$ and *c-myc* were examined by immunocytochemistry.

RESULTS: After treatment with tachyplesin 3.0 mg/L, the proliferation of SMMC-7721 cells was inhibited significantly, with the cell growth inhibitory rate amounted to 55.57 % and the maximum cell mitotic index declined by 43.68 %. The morphology and ultrastructure underwent restorational alteration. The activity of γ-GT declined while TAT activity increased obviously, and the levels of α-FP and PCNA decreased. Moreover, the expression of $p21^{WAF1/CIP1}$ protein was up-regulated and that of *c-myc* protein was down-regulated.

CONCLUSION: Tachyplesin could effectively inhibit the proliferation of hepatocarcinoma cells, reverse the malignant morphological and ultrastructural characteristics, alter the levels of enzymes and antigens, regulate the expression of differentiation-associated oncogene and tumor suppressor gene, and induce hepatocarcinama cell differentiation.

INTRODUCTION

The induction of tumor cell differentiation is a new strategy of drug therapy of tumors. In recent years, many studies showed that malignant tumor cells could be induced to terminal differentiation by some inducers. Differentiation-inducing therapy has already been applied to leukemias, lymphomas, and other solid tumors[1]. On the other hand, the study on antitumor activities of marine bioactive substances has became an important field in exploiting marine bioactive substances and antitumor drugs[2-4]. In order to explore the method and means of regulating the proliferation of tumor cell and reversing its malignant phenotypes artificially, we focus on screening and identifying marine bioactive substances, especially those with low molecular weight which can adjust cell signal transduction and regulate cell proliferation and differentiation.

Horseshoe crab, a kind of marine animal, which has survived relatively unchanged for the past 350 million years, now is at the center of a resource tug of war. During the past two decades, many bioactive substances with special functions, including clotting factors, lectins, proteinase inhibitors, defensins, tachyplesin and tachystatins, have been found in the hemocytes and hemolymph plasma of horseshoe crab[5-9]. In our previous works, we reported that tachyplesin could alter the malignant morphological and ultrastructural characteristics and regulate the proliferation and differentiation of human gastric carcinoma cells[10,11]. In this paper, the antitumor activities of tachyplesin on hepatocellular carcinoma cell line SMMC-7721 were investigated to further clarify the antitumor mechanism of tachyplesin.

MATERIALS AND METHODS

Drugs and reagents

Tachyplesin was isolated from acid extracts of Chinese horseshoe crab (*Tachypleus tridentatus*) hemocytes as described by Nakamura *et al*[12]. RPMI-1640 medium were obtained from Gibco. Fetal calf serum was supplied by Si-Ji-Qing Biotechnology Co. (Hangzhou, China). Trypan blue were purchased from Sigma Co. γ-GT kit was purchased from Shanghai Lianyang Biotechenical Co. Mouse anti-human α-FP, PCNA, $p21^{WAF1/CIP1}$, *c-myc* monoclonal antibodies were purchased from Santa Cruz. SP detection kit and DAB kit were purchased from Beijing Zhongshan Biotechnology Co.

Cell culture and treatment

SMMC-7721 cells, provided by the Institute of Biochemistry and Cell Biology, Shanghai Institute of Biological Sciences, Chinese Academy of Sciences, were maintained in RPMI-1640 medium supplemented with 20 % heat-inactivated fetal calf serum, 100 units/mL penicillin, 100 mg/L streptomycin and 50 mg/L kanamycin at 37 ℃, 5 % CO_2 in air atmosphere. SMMC-7721 cells were treated with culture medium containing tachyplesin after being seeded for 24 hours.

Determination of cell growth curve and cell mitotic index

SMMC-7721 cells (5×10^4/mL) were seeded in small culture flasks or in little penicillin bottles with cover slips respectively. Tachyplesin treatment was performed after cells being subcultured for 24 hours. From the first to seventh day, three flasks of untreated or tachyplesin-treated cells were harvested every day, and the viable cells were counted by the trypan blue dye exclusion test. Meanwhile, the cover slips with untreated or tachyplesin-treated cells were also taken out every day, fixed in Bouin-Hollande fixative, and stained with Hematoxylin-Eosin (HE) staining. The mitotic cells in 1000 cells on each cover slip were counted.

Sample preparation for the light microscopy

SMMC-7721 cells and the cells treated with 3.0 mg/L tachyplesin for 5 days were seeded in little penicillin bottles with cover slips, and grown in the normal culture medium or in the medium containing 3.0 mg/L tachyplesin for 48 hours, respectively. The cells on cover slips were rinsed with D-Hank's solution twice at 37 ℃, fixed overnight in Bouin-Hollande fixative, stained with Hematoxylin-Eosin staining, and observed under light microscope.

Sample preparation for transmission electron microscopy

SMMC-7721 cells and the cells treated with 3.0 mg/L tachyplesin for 7 days were rinsed with D-Hank's solution twice at 37 ℃, shaved into centrifuge tubes with plastic scraper. Cells were centrifuged at 2000 rpm for 15 min, and the supernatants were removed. The precipitates were prefixed in 2.5 % glutaraldehyde for 2 hours and postfixed in 1 % osmian tetroxide for 2 hours, dehydrated in ethanol series, embedded in epoxy resin 618, stained with lead citrate and uranyl acetate, and observed under the JEM-100CX Ⅱ transmission electron microscope.

Assays for the activities of γ-glutamyltransferase (γ-GT) and tyrosine aminotransferase (TAT)

SMMC-7721 cells and the cells treated with 3.0 mg/L tachyplesin for 7 days were harvested, counted, and sonicated in ice-cooled 0.1 mol/L PBS. The homogenates were centrifuged and the supernatants were subjected to assay of enzymatic activities. The γ-GT activity was determined with γ-GT reagent kit and the TAT activity was detected according to the method described by Marston *et al*[13]. The activities of γ-GT and TAT were valued as OD unit per 1×10^6 cells.

Immunocytochemistry analysis

SMMC-7721 cells and the cells treated with 3.0 mg/L tachyplesin for 5 days were seeded in little penicillin bottles with cover slips for 48 hours respectively. The cells grown on cover slips were fixed with cold acetone for 10 min, rinsed twice in PBS for 15 min. They were then immersed in 3 % hydrogen peroxide for 10 min, washed with distilled water and PBS for 15 min, blocked with 10 % normal goat serum for 10 min at room temperature, and incubated with the monoclonal mouse anti-human α-FP, PCNA, $p21^{WAF1/CIP1}$, *c-myc* antibodies at 4 ℃ overnight. After incubation with primary antibodies, cover slips were rinsed twice in PBS for 15 min, incubated with biotin-labeled secondary antibody at 37 ℃ for 10 min, rinsed twice in PBS for 15 min, and then incubated in streptavidin-peroxidase at 37 ℃ for 10 min. The antigen-antibody complex was visualized with diaminobenzidine (DAB) substrate. Negative controls were incubated in the absence of primary antibodies.

Statistical analysis

Student's *t* test was used to compare the difference between control group and tachyplesin treatment group. The data of cell growth, mitotic index and enzymatic activities were presented as the mean with the corresponding standard deviation. *P* value of less than 0.05 is considered statistically significant.

RESULTS

Effects of tachyplesin on the proliferation of SMMC-7721 cells

Under concentration of 2.5, 3.0, 3.5 mg/L, tachyplesin significantly inhibited the proliferation of SMMC-7721 cells. The growth inhibitory rates on SMMC-7721 cells on the seventh day were 47.09 %, 55.57 % and 62.77 %, respectively ($P<0.05$) (Figure 1). According to the principle of induced differentiation treatment, we chose 3.0 mg/L tachyplesin for induced treatment. Cell mitotic index determination showed that SMMC-7721 cells had vigorous proliferation capability, reached to the divided peak on the fourth day, and the maximum mitotic index amounted to 35.19±2.17 ‰However the mitotic index of the cells treated with 3.0 mg/L tachyplesin was only 19.82±1.89 ‰at the divided peak, declined by 43.68 % ($P<0.05$), and the divided peak was on the third day after tachyplesin treatment (Figure 2).

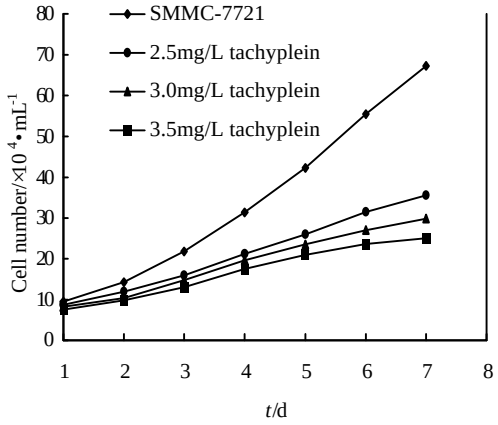

Figure 1 Effect of tachyplesin on the growth of SMMC-7721 cells

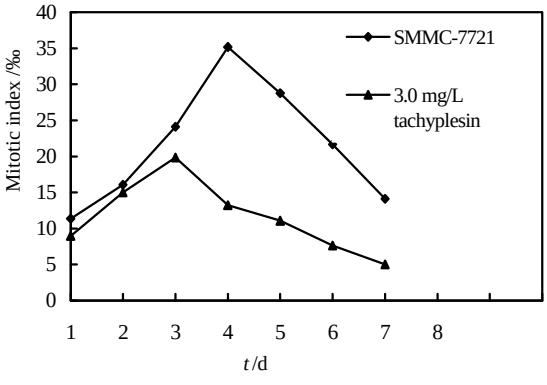

Figure 2 Effect of tachyplesin on the mitotic index of SMMC-7721 cells

Effects of tachyplesin on the morphology and ultrastructure of SMMC-7721 cells

SMMC-7721 cells showed typical malignant morphological and ultrastructural characteristics in SMMC-7721 cells like other epithelial cancer cells. Under light microscope, the volume of SMMC-7721 cells was relatively small, nuclei were

large and irregular with several nucleoli in it, and cytoplasm volume was small (Figure 3A). And it was revealed by transmission electron microscope that the necleo-cytoplasmic ratio of SMMC-7721 cells was relatively large, nuclei were irregular with many heterochromatins and few euchromatins and large nucleolus in it, while cell organelles were not well-developed in the cytoplasm (Figure 3C). However, after being treated with 3.0 mg/L tachyplesin, SMMC-7721 cells had undergone a significant morphological and ultrastructural changes and appeared as normal differentiated epithelial cells. The cells turned to be more spread and flat, the necleo-cytoplasmic ratio was reduced, the shape of nuclei became regular, heterchromatin in nucleus decreased while euchromatin increased, the volume of nucleolus was reduced, and cytoplasm was abundant with well-developed cell organelles (Figure 3B,D).

Effects of tachyplesin on the activities of γ-GT and TAT in SMMC-7721 cells

The human hepatocarcinoma SMMC-7721 cells had high γ-GT activity and low TAT activity. After treatment with 3.0 mg/L tachyplesin, the activity of γ-GT in SMMC-7721 cells were declined from 0.48±0.04 Unit to 0.30±0.02 Unit ($P<0.05$) while TAT activity increased from 0.44±0.04 Unit to 0.90±0.04 Unit ($P<0.05$) as shown in Figure 4.

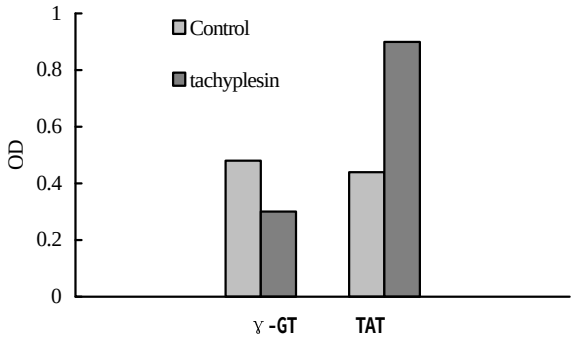

Figure 4 Effects of tachyplesin on the activies of γ-GT and TAT in SMMC-7721 cells

Effects of tachyplesin on α-FP, PCNA levels in SMMC-7721 cells

High level of α-FP was detected in the cytoplasm and nucleus of SMMC-7721 cells (Figure 5A). However, after being treated with 3.0 mg/L tachyplesin, the cells had a very low level of α-FP (Figure 5B). The PCNA level was also high and mainly distributed in the nucleus of SMMC-7721 cells, especially in the spherical cells, while the immunocytochemical signal was weak in the tachyplesin-treated cells (Figure 5C,D).

Effects of tachyplesin on protein p21$^{WAF1/CIP1}$, c-myc levels in SMMC-7721 cells

To investigate the effects of tachyplesin on the expression of differentiation-associated tumor suppressor gene and oncogene, the levels of p21$^{WAF1/CIP1}$ and *c-myc* proteins were also examined. Immunocytochemistry showed that the level of p21$^{WAF1/CIP1}$ protein was low in the nucleus and cytoplasm of the untreated cells while it was very high in the cells treated with tachyplesin (Figure 5E,F). High level of *c-myc* was observed in SMMC-7721 cells and exposure of the cells to tachyplesin resulted in an obvious decrease of c-myc protein (Figure 5G,H).

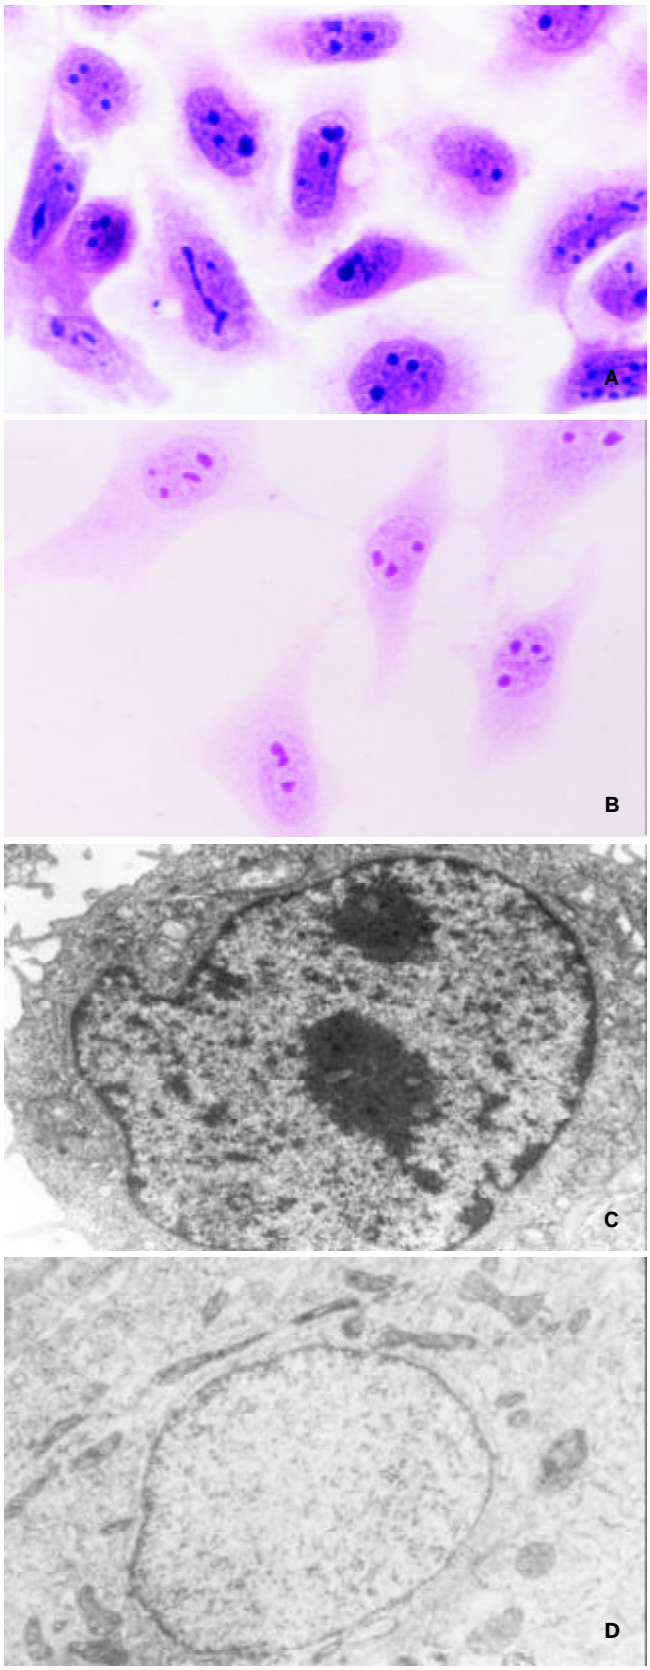

Figure 3 Effects of tachyplesin on the morphology and ultrastructure of SMMC-7721 cells. A: SMMC-7721 cells (×536); B: SMMC-7721 cells treated with tachyplesin (×536); C: The nucleo-cytoplasm ratio is large, the shape of nucleus is irregular and cell organelles are not well-developed in the cytoplasm of SMMC-7721 cell (×8800); D: The nucleo-cytoplasm ratio decreased, the shape of nucleus is regular and cell organelles are well-developed in the cytoplasm of tachyplesin-treated SMMC-7721 cell (×11000)

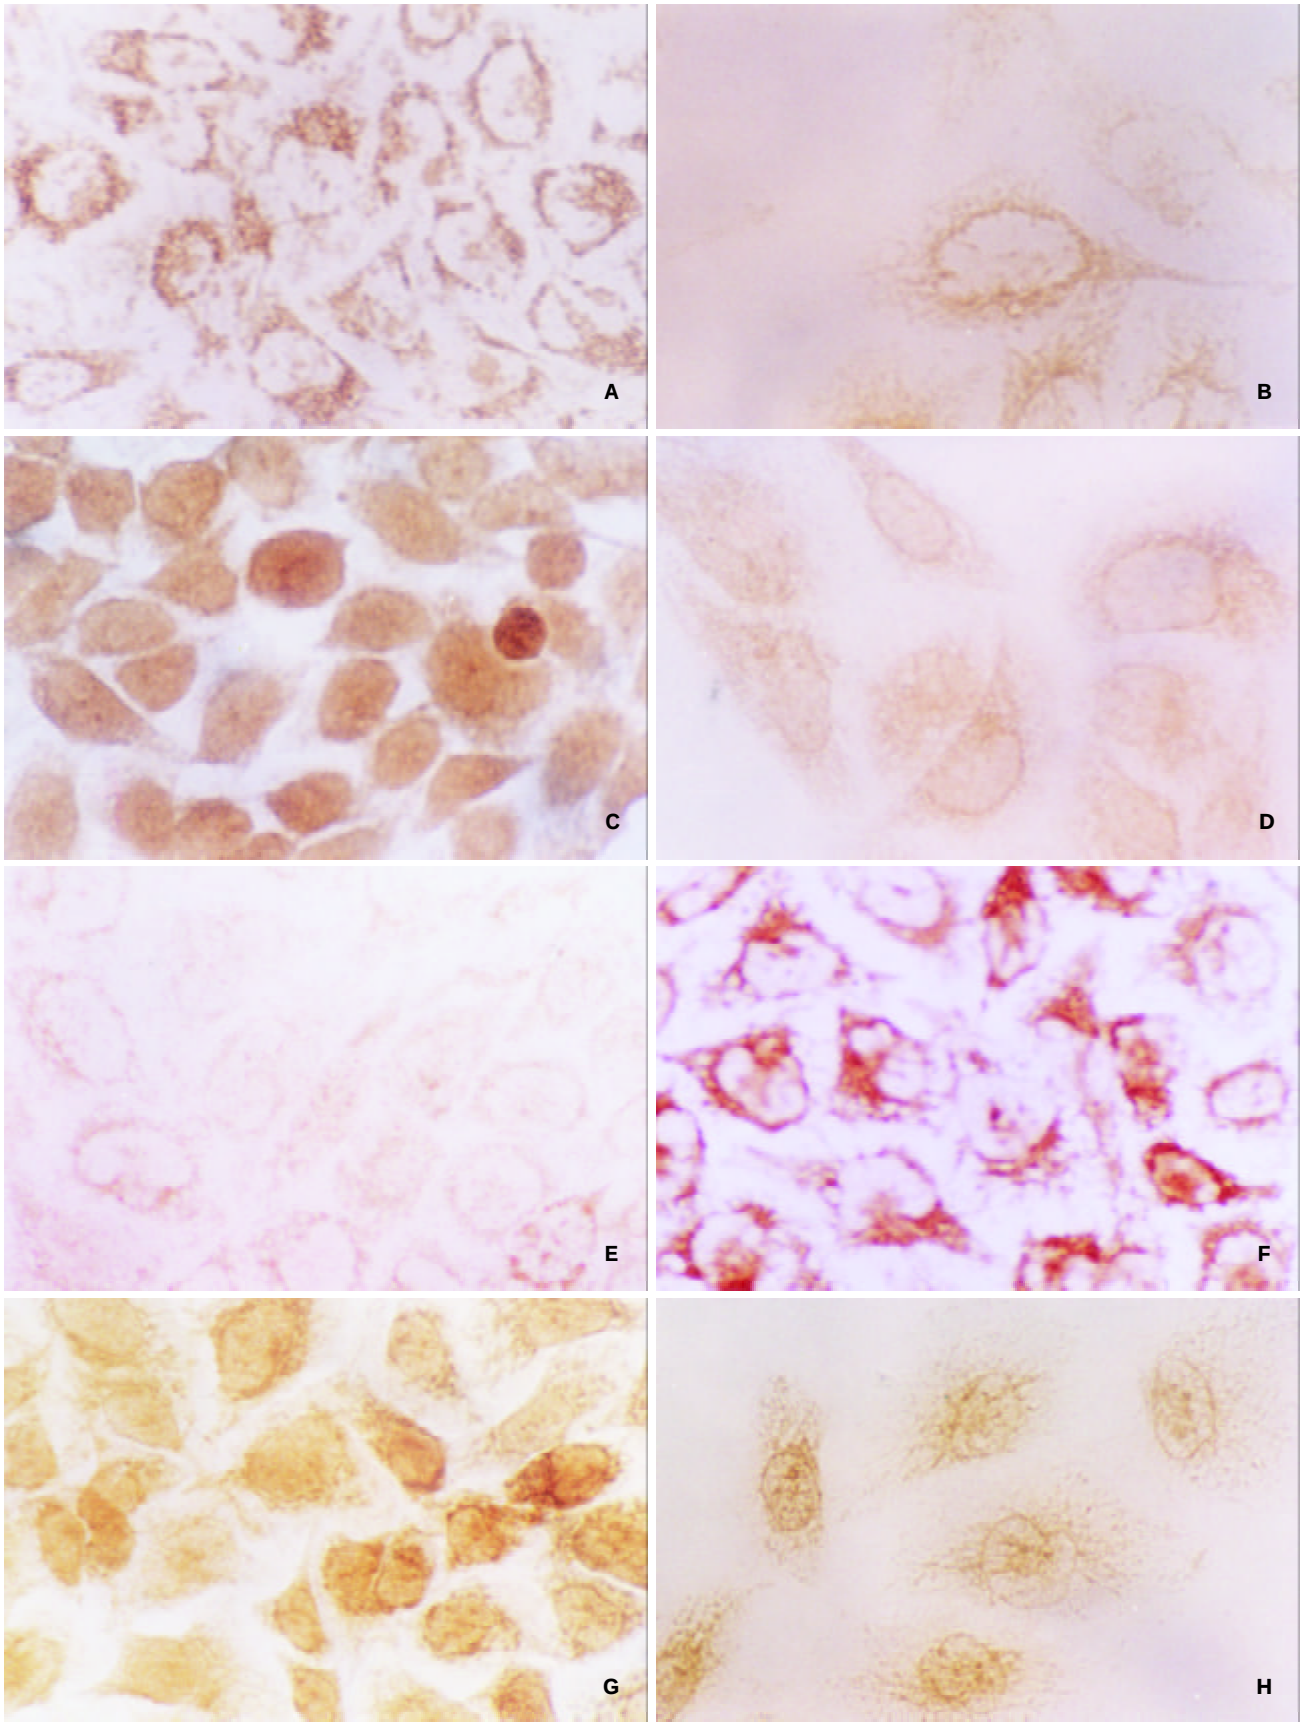

Figure 5 Effects of tachyplesin on the levels of α-FP, PCNA, $p21^{WAF1/CIP1}$, c-myc proteins in SMMC-7721 cells (×536).
A: The high level of α-FP in SMMC-7721 cells detected by immunocytochemistry; B: The level of α-FP in the tachyplesin-treated SMMC-7721 cells is decreased; C: The high level of PCNA in SMMC-7721 cells; D: The level of PCNA in the tachyplesin-treated SMMC-7721 cells is decreased; E: The low level of $p21^{WAF1/CIP1}$ in SMMC-7721 cells; F: The level of $p21^{WAF1/CIP1}$ in the tachyplesin-treated SMMC-7721 cells is increased; G: The high level of *c-myc* in SMMC-7721 cells; H: The level of *c-myc* in the tachyplesin-treated SMMC-7721 cells is decreased.

DISCUSSION

It is important to examine the changes of the main malignant characteristics of cancer cells in order to evaluate the malignant phenotype reversion. Continual division and constant proliferation are important characteristics of tumor cells. The proliferating activity of cells is inversely correlated with the degree of differentiation. Therefore, inhibiting the proliferation of tumor cells is a significant index in induction of differentiation[1,14]. In the present study, the results of the cell growth curve and mitotic index assay indicated that tachyplesin could inhibit the multiplicative activity of hepatocarcinoma cells effectively, with similar effects of growth inhibition as retinoic acid, HMBA and dimethyl sulphoxide on human hepatocarcinoma cells HepG2 and SMMC-7721[15-20]. It suggests that tachyplesin could suppress tumor cell growth as other differentiation inducers.

Malignant morphology and ultrastructure are other important characteristics of tumor cells. Previous studies had revealed that lots of differentiation inducers could reverse the morphology and ultrastructure of tumor cells. Therefore, evaluating the changes of these two characteristics in tumor cells is important in determining the effects of exotic substances, especially differentiation inducers on tumor cells. Our results showed that tachyplesin could reverse the malignant morphological and ultrastructural characteristics of SMMC-7721 cells as it did on gastric carcinoma cells or other inducers on hepatocarcinoma cells and other tumor cells[10,18,19].

α-FP, an oncofetal antigen, is as an important tumor-specific marker for the diagnosis of hepatocellular carcinoma and has been widely used in clinical setting[21-25]. PCNA, the auxiliary protein of DNA polymerase δ, ε, plays an important role in DNA replication, repair and cell cycle control, and can be used as differentiation marker of hepatocarcinoma[26-30]. The increased levels of α-FP and PCNA are correlated with hepatocyte malignancy, and many differentiation inducers such as HMBA, retinoic acid and sodium butyrate could decrease their levels in hepatocarcinoma cells[18-20]. γ-GT and TAT also can be used as tumor markers of hepatocellular carcinomaIn[31-33]. The decreased activity of TAT and the increased levels of α-FP, PCNA and γ-GT activities are correlated with hepatocyte malignancy. Many differentiation inducers, such as retinoic acid and HMBA, could reduce the levels of α-FP and PCNA and γ-GT while increase the level of TAT in hepatocarcinoma cells[18,19,34]. Our results revealed that the levels of α-FP and PCNA and γ-GT were down-regulated and the activity of TAT was increased in the tachyplesin-treated cells, indicating that tachyplesin could alter the activities of differentiation-associated enzymes and decrease the levels of tumor-associated antigens as many differentiation inducers.

In addition, many tumor suppressor genes and oncogenes, which were correlative with the tumorigenesis and progression and prognosis of hepatocarcinoma, also could serve as index of induced differentiation. $p21^{WAF1/CIP1}$, the pioneer member of p21 family of cyclin-cdk inhibitor class of proteins, has been implicated as a growth arrest mediator in cell terminal differentiation and apoptosis[1,30,35]. Many inducers such as sodium butyrate could increase the expression of $p21^{WAF1/CIP1}$ of hepatocarcinoma cells[20]. In the meantime, *c-myc* gene also plays an essential role in cell proliferation, differentiation, and apoptosis[36,37]. Down-regulation of *c-myc* expression induced by differentiation signals is regarded as a hallmark of cell differentiation[38-40]. The expression of *c-myc* level was reduced in sodium butyrate-induced differentiation of human hepatoma cells[41], and in *all-trans* retinoic acid-induced differentiation of human leukemic U937 cells with an increase in $p21^{WAF1/CIP1}$ expression[42]. Our results showed that tachyplesin could increase the expression of $p21^{WAF1/CIP1}$ and down-regulate the levels of *c-myc* protein in SMMC-7721 cells, and induce the cells to terminal differentiation as other differentiation inducers[42,43].

Taken together, the results of the current study indicated that tachyplesin could effectively inhibit the proliferation of human hepatoma SMMC-7721 cells, reverse the malignant morphological and ultrastructural characteristics, alter the activities of differentiation-associated enzymes and the levels of tumor-associated antigens, adjust the expression of oncogenes and tumor suppressor gene correlative with hepatocellular carcinoma, and so induce hepatocarcinoma cell differentiation.

Abstract

AIM: To investigate the expression of bax, bcl-2 and bcl-xL mRNA in the tissues of normal liver and hepatocellular carcinoma (HCC), and analyze the relationship between the expression of bax, bcl-2 and bcl-xL mRNA and clinical parameters of HCC patients.

METHODS: The expression of bax, bcl-2 and bcl-xL mRNA of normal liver and HCC was measured by Northern blot. Statistical analyses were made by *t* test and correlation analysis.

RESULTS: A very low mRNA level was indicated at bax, bcl-2 and bcl-xL in the HCC tissues in contrast to the tissues of normal liver by Northern blot analysis. The analyses of mRNA level revealed that HCC tissues exhibited a mean 7.6-fold decrease in bax, 4.2-fold in bcl-2 and 3.5-fold in bcl-xL in comparison with normal control tissues, respectively. Positive correlation was found between bax and bcl-xL (r=0.7061,P<0.01). There was no significance between the mRNA expression of these three genes and age, gender, tumor differentiation and tumor stage of HCC patients .

CONCLUSION: The results are consistent with the fact that apoptosis rarely occurs in normal livers but increases in HCC, indicating that bcl-2 and bcl-xL may play a very important role in regulating the apoptosis of normal liver and HCC.

INTRODUCTION

Apoptosis is a highly regulated form of programmed cell death defined by distinct morphological and biochemical features. Programmed cell death is involved in a type of cell death, in which the cell actively uses a genetically controlled program to cause its own demise during the tissue remodeling of embryogenesis[1]. Apoptosis is a key mechanism causing cell death and organ diseases, failure of apoptosis is now understood to contribute to the development of human malignancies[2-5].

The bcl-2 family is the best characterized group of apoptosis-mediating factors, which include bcl-2, mcl-1, bcl-x, bax, bak, and several others. Although its members share close structural homologies, their biologic functions differentiate into apoptosis-promoting (bax, bak, bcl-xS) or apoptosis-inhibiting (bcl-2, mcl-1, bcl-xL) properties[1, 6]. The bcl-2 related genes regulate cell death and are considered to correlate with the pathogenesis and progression of cancers[7-14].Since the relationship between bcl-2 family and HCC is still unclear, we investigated the expression of the three genes in HCC and normal controls and evaluated the mediating action in HCC and the relationship between the genes and clinical parameters as well.

MATERIALS AND METHODS

Patients

Ten cases of (4 women, 6 men) normal liver tissues were obtained. The median age in the control group was 57 years, with a range of 39-75 years. HCC tissues were obtained from 21 patients (9 women, 12 men) undergoing surgery for HCC. The median age of the HCC patients was 64 years (a range of 33-76 years). According to the TNM classification of the International Union against Cancer, there were 6 patients with stage Ⅱ,13 with stage Ⅲ,and 2 with stage Ⅳ disease. Tissues destined for RNA extraction were frozen in the operating room in liquid nitrogen immediately on surgical removal and maintained at -80 ℃ until use.

Northern blot analysis

Total RNA was extracted by the guanidinium isothiocyanate method, fractionated on 1.2 % agarose. 1.8 mol· L formaldehyde gels, and stained with ethidium bromide for verification of RNA integrity and loading equivalence[15]. The RNA was electrotransferred to Nylon membranes (GeneScreen; DuPont, Boston, Massachusetts, USA) and cross linked by UV irradiation. The filters were then prehybridized, hybridized, and washed under conditions appropriate for digoxigenin labelled antisense riboprobes (bcl-2 and bax) or the ^{32}P labelled antisense riboprobe (bcl-xL) and cDNA probe (7S) as previously described[15,16].

In the case of the digoxigenin-labelled bcl-2 and bax cRNA probes, the filters were prehybridized and hybridized overnight at 68 ℃ (bcl-2) or 65 ℃(bax) in a buffer containing 50 % formamide, 2×SSC (1×SSC is 0.15M NaCl/0.015 M sodium citrate buffer) (bcl-2) or 5×SSC (bax), 2 % blocking reagent (Boehringer Mannheim, Mannheim, Germany), 0.1 % N-lauroylsarcosine, and 0.02 % sodium dodecyl sulphate (SDS). The filters were then washed in 2×SSC/0.1 % SDS at room temperature, followed by three 15 minute washing at 68 ℃ (bcl-2) or 65 ℃ (bax) in 0.065× SSC/0.065% SDS/35% formamide (bcl-2) or 0.1×SSC /0.1 % SDS (bax). The filters were then incubated in a blocking buffer (1 % blocking reagent in 100 mmol· L maleic acid/150 mmol· L NaCl, pH 7.5) for 30 minutes, and in blocking buffer containing anti-digoxigenin alkaline phosphatase antibody (1:20 000; Boehringer

Mannheim) for 30 minutes, washed three times with maleic acid buffer for 15 minutes, and incubated with 25 mmol/L CDP-Star (Boehringer Mannheim). The membranes were then exposed to X ray films.

For the ^{32}P labelled antisense riboprobe (bcl-xL), the blots were prehybridized for 6 hours in 50 % formamide,0.5 % sdiumm dodecyl sulfate (SDS), 5×SSC (sodium chloride/ sodium citrate buffer), 5×Denhardt' s solution (1×Dennhard' s solution=0.02 % ficoll, 0.02 % polyvinylpyrrolidone, and 0.02 % bovine serum albumin), 250 mg/L salmon sperm DNA, and 50 mmol/L sodium phosphate buffer (pH 6.5). The blots were then hybridized for 18 hours at 65 ℃ in the presence of 1×10^6 cpm/ml labeled antisense riboprobe, washed twice at 65 ℃ in a solution containing 1×SSPE (150 mmol/1 NaCl, 10 mmol/1 NaH_2PO_4, and 1 mmol/1 EDTA) and 0.5 % SDS, and twice at 65 ℃ in a solution containing 0.1×SSPE and 0.5% SDS.

In the case of the 7S cDNA probe, blots were prehybridized for eight hours at 42 ℃ in a buffer which contained 50 % formamide, 1 % SDS, 0.75 mol/L NaCl, 5 mmol/L EDTA, 5 ×Denhardt' s solution, 100 mg/L salmon sperm DNA, 10 % dextran sulfate, and 50 mmol/1 phosphate buffer (pH 7.4). The hybridization was carried out at 42 ℃ for 18 hours by adding the ^{32}P labelled cDNA probe (1×10^5 cmp/mL). The blots were rinsed twice in 2×SSC at room temperature and washed three times at 55 ℃ in 0.2× SSC/2 % SDS under conditions appropriate for cDNA probes. Blots were then exposed at -80 ℃ to Fuji X ray films with intensifying screens (DuPont).

For statistical analysis of the Northern blot results, the intensity of the radiographic bands was quantified by laser densitometry (Bio-Rad 620; Richmond, Califirnia, USA). The ratio between the bax, bcl-2 or bcl-xL and the corresponding 7s signal was calculated in each sample.

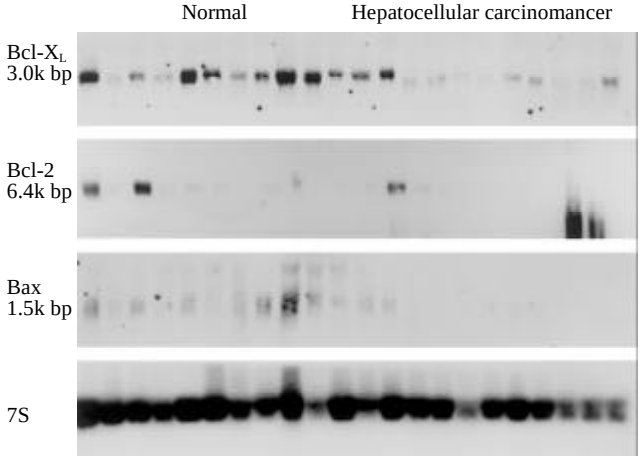
Statistical analysis

The data were expressed as median and range. Statistical analyses were carried out using the SPLM software (Statistical Department of Fourth Military Medical University). For statistical analysis, the *t* test and correlation analysis were used. Significance was defined as $P<0.05$.

RESULTS

Northern blot analysis

Northern blot analysis was carried out to determine bax, bcl-2 and bcl-xL mRNA expression in the normal and the cancerous liver. In contrast, hybridization signals of mRNA of three genes were higher in normal liver tissues as compared with the signals in cancerous samples (Figure 1). A low mRNA level of bax, bcl-2 and bcl-xL mRNA was almost present in all HCC tissue samples. In some HCC tissues the expression levels for all three genes were very faint and were only visible on the original autoradiographs. None of the normal or cancer samples showed any aberrant bax, bcl-2 or bcl-xL mRNA transcripts, and bax and bcl-2 mRNA were reduced in 100 % of cancer samples, and bcl-xL mRNA was reduced in 95 % of cancer samples in contrast with the normal controls. Densitometric analysis of the Northern blots indicated that the bax and bcl-2 mRNA levels in all cancer samples were 7.6- and 5.4-fold (P=0.0002; P=0.00887) higher than those in the matched control samples; bcl-xL mRNA levels in all cancer samples were 3.5-fold lower (P=0.0002) than those in the normal samples (Table 1). The expression of bax and bcl-xL mRNA was positively correlated in HCC (r=0.7061, $P<0.01$), but there was no correlation between bax and bcl-2 or bcl-2 and bcl-xL (r=0.1637, r=0.4830).



Normal Hepatocellular carcinoma
Figure 1 result of Northern blot analysis

Table 1 The expression of bax, bcl-2 and bcl-xL mRNA in hepatocellular carcinoma and normal liver

	Hepatocellular carcinoma (21 cases)	normal liver (10 cases)	*t* value	*P* value
Bax	0.929±1.233	7.060±6.574	4.197	0.0002
Bcl-2	1.414±1.331	5.930±7.227	2.815	0.0087
Bcl-xL	2.433±2.218	8.500±5.743	4.277	0.0002

Correlation of Northern blot analysis with clinicalpathological parameters

To determine whether the presence of bax, bcl-2 or bcl-xL mRNA in the HCC tissues is of clinical significance, the Northern blot data were statistically analysed in patient data (sex, age) and clinical data (tumor stage, tumor differentiation). No significance was found between the expression of bax,bcl-2 or bcl-xL and these parameters (Table 2).

Table 2 The relationship between the expression of bax,bcl-2 and bcl-xL and clinical parameters of patients with hepatocellular carcinoma

		n	bax	bcl-2	bcl-xL
Age	≤65	10	0.980±1.530	1.960±1.678	3.020±2.549
	>65	11	0.882±0.962	0.918±0.663	1.900±1.825
gender	male	13	1.100±1.471	1.654±1.532	2.600±2.645
	female	8	0.650±0.699	1.025±0.871	2.163±1.386
grading	well and moderate	12	0.975±1.384	1.592±1.540	2.775±2.453
	poor and undifferentiated	9	0.867±1.076	1.178±1.028	1.978±1.901
tumor stage	Ⅰ Ⅱ	6	0.583±0.454	0.700±0.616	2.000±1.616
	Ⅲ Ⅳ	15	1.067±1.423	1.700±1.445	2.607±2.445

Statistical analysis revealed no relationship between bax,bcl-2 or bcl-xL expression and these parameters.

DISCUSSION

Apoptosis is a central regulator of tissue homeostasis. It contributes to the elimination of damaged cells in normal tissues and balances the appropriate cell number under the circumstances of physiologic cell proliferation and tissue repair.

In the past few years, scientific interest has focused on the process of apoptosis. Like cell replication, apoptosis is controlled by the network of positive and negative growth signals. Based on the currently prevailing views, it is assumed that malignant cells should be incapable of apoptosis and /or not responsive to death signals, thereby allowing unrestrained growth of cancer. Recently, more and more studies indicated that apoptosis is of importance in the growth and development of many tumors, but the pattern of apoptosis varies in different tumors[11-19]. In contrast with normal tissues, there is often reduction of apoptosis in most cancerous tissues[20-23], but hepatic cancer is different. HCC is one of the most common and aggressive tumors in the world today, and little is known about the cellular pathogenesis[24-34]. The apoptosis is rare in normal liver tissues (there is only 2-4 apoptotic cells per 10 000 hepatic or biliary cells[35]), while the HCC tissues have higher rates of apoptosis[37].These findings indicate that the apoptosis-related genes are expressed in various frequencies in different cancers, and a general pattern of activation or inactivation of these genes in malignant tumors cannot be defined. Therefore, the function of apoptotic genes in different human cancers must be evaluated individually.

In this study, we analysed the concomitant expression of bax, bcl-2 and bcl-xL in the HCC tissues and normal liver. These genes belong to the same family of apoptotic genes. Although the structures are similar, they exert opposite effects on apoptosis. bcl-2 and bcl-xL inhibit apoptosis and contribute to cell survival and the resistance of cells against damaging influences. In contrast, bax, which is considered to be a central regulator of apoptosis, is a promoter of programmed cell death[37]. The relationship between bcl-2 related genes and HCC is still unclear.

By the analysis of 21 HCC patients , reduced bax and bcl-2 signals were present in all samples and reduced bcl-xL signals were present in 95 % of the cancer samples. The low expression of bcl-2 and bcl-xL is consistent with enhanced apoptosis in the HCC, but the low expression of bax does not account for this phenomenon. The findings revealed that anti-apoptotic genes, but not apoptosis-promoting genes, might play a more important role in regulating the apoptosis of normal liver and HCC. There was no correlation between bax, bcl-2 and bcl-xL and age, gender, differentiation or stage of tumor in HCC patients. We can not give a reasonable explanation for the finding that the expression of bax and bcl-xL was positively correlated in HCC. We concluded that anti-apoptotic genes do not influence the differentiation and development of HCC, but these genes can increase the rate of apoptosis in HCC by reducing their expression or changing the ratio with other genes. The influencing factors of apoptosis increased in HCC are not known, which may include 1) inherent metabolic process of tumor tissues;2) hypoxia of tumor tissues;3) some cytokines such as tumor necrosis factor;4) attack of CTL, etc.

The low expression of anti-apoptotic genes, which increase apoptosis in HCC, may have negative impact on growth of tumors as a homeostasis mechanism that inhibits cell group with extensive growth, and this effect can delay the development of tumors. But it may also be a selective pressure, which removes the aging tumor cells or some tumor cells with phenotype similar to normal cells and selects more aggressive and prosperous clone of tumor cells, accelerating the development of tumors. Further studies on the regulating action of apoptotic genes will deepen the understanding about the growth and development of HCC and offer valuable information to genetic therapy of HCC, thus enhancing the sensibility to radiotherapy and chemotherapy.

Abstract

AIM: To analyze the causes and management of hemorrhage in spontaneous liver rupture.

METHODS: Seventy cases of spontaneous liver rupture were retrospectively analyzed for causes of hemorrhage and therapeutic effects of surgical approaches.

RESULTS: It was demonstrated that the causes of spontaneous liver rupture were primary liver cancer in 60 cases (85.7 %), cirrhosis in 3 cases (4.3 %), liver angioma in 2 cases (2.9 %), liver adenoma in 4 cases (5.7 %),and secondary liver cancer in 1 case (1.4 %). Hemostasis was achieved with surgical approaches in 68 cases (97.1 %) and non-surgical approaches in 2 cases (2.9 %). Surgical interventions included suture, ligation of hepatic artery, hepatic artery chemoembolization and partial hepatic resection.

CONCLUSION: The results suggest that surgical intervention is still the main therapeutic method and the best procedure that should be selected according to causes of disease and patient's condition and history.

INTRODUCTION

Bleeding of spontaneous liver rupture is a severe complication in liver diseases, owing to its clinical signs being usually not specific. Therefore, correct diagnosis and management are very important. At present, it is a difficult problem in surgery for the diagnosis and therapy of spontaneous liver rupture. In this paper, the etiology and management in seventy cases of spontaneous liver rupture treated in Tian Jin medical university general hospital in ten years were analysed.

MATERIALS AND METHODS

Seventy patients with spontaneous liver rupture (41 male and 29 female) with a median age of 49±4.3year (range,17-75years) were admitted from January 1992 to December 2001.There were 68 cases with surgical intervention and 2 cases with non-surgical therapy.

Majority of patients initially experienced some abdominal complaints, such as abdominal pain, anorexia, vomiting and abdominal distention. The serious cases had signs of anemia, shock and acute peritonitis (Table1).

Table 1 Clinical symptoms of spontaneous liver rupture in 70 cases

	Abdominal pain	anemia	shock	acute peritonitis
number	63	48	37	19
percentage	90.0%	68.6%	52.9%	27.1%

Twenty one patients had hepatitis history and 1 patient had undergone Mile's operation two years ago because of rectum carcinoma before the liver rupture. Abdominal paracentesis showed that blood was incoagulable in 61 patients. B type ultrasonography and/or computed tomography (CT) displayed hydroperitonia and liver tumor or liver cirrhosis in 68 patients. Thirty seven patients had hematoglobin(Hb) below 100 g/L. Liver functions of all patients were classified according to Child's criteria: Child A in 17 patients, Child B 39 patients, Child C 14 patients. Alpha-fetoprotein(AFP) was positive in 41 cases. Sixty eight cases had diagnosed pathological diagnosis: primary liver carcinoma 60 cases, liver cirrhosis 3 cases, liver angioma 2 cases, liver adenoma 4 cases, secondary liver cancer 1 case (Table2). Twenty six patients had history of slight injury.

Table 2 Cause of spontaneous liver rupture in 70 cases

	Primary liver cancer	cirrhosis	liver angioma	liver adenoma	secondary liver cancer
number	60	3	2	4	1
percentage	85.7%	4.3%	2.9%	5.7%	1.4%

Two patients were treated by non-surgical method, selective hepatic artery chemoembolization via femoral artery. Sixty-eight patients had undergone operation and surgical methods included partial resection of liver and ligation of hepatic artery (Table3).

Table 3 Therapeutic methods of spontaneous liver rupture in 68 patients

	suture	packing	ligation of hepatic artery	hepatic artery chemoembolization	hepatic partial resection
number	17	7	23	2	40
percentage	24.3%	10.0%	32.9%	2.9%	57.1%

Operative methods were as follow: (1) suture: Long and thin needles with thick silk were selected to enter the normal liver tissue near the lesion in one side of the split and came out

of the other side through the health tissue after hepatic artery and portal vessels were blocked. Silk was finally ligated after suture of the split had been finished. (2) packing: If bleeding of the gap had not been controlled completely after ligation of hepatic artery, suture should be applied to the lesion and if the patient was too weak to undergo the complicated operation, packing with gause cushion should be used to procare hemostasis. The edge of gause cushion was let out from the incision and left there for three days after surgery. Finally, if hemostasis was successful, the gause cushion should be pulled out. (3) ligation of hepatic artery: When the hepato-duodenal ligament was pulled up near the Winslow pole, the pulse of hepatic artery could be palpated, the artery was then isolated and ligated. It should be prudent to ligate the stem of the hepatic artery in cirrhosis, lest hepatic coma would occur after the procedure. (4) hepatic artery chemoembolization: The catheter was inserted to proper hepatic artery or right and left hepatic artery, gelfoam and iodized oil were used as suppository, and injected via gastroduodenal artery or right gastro-epiploic artery. Methylene blue was injected to locate the site of embolization before procedure.(5) liver partial resection: Eleven, seven, two and twenty one patients had recived hepatic left lateral lobectomy, left hemihepatectomy, right hemihepatectomy and non-regular hepatic partial resection respectively.

RESULTS

Two patients (AFP positive) who were given non-surgical intervention with bleeding entirely controlled could not survive over one year. All the rest adopted surgical therapeutic methods. Suture with addition of ligation of hepatic artery were performed in seventeen patients, with their primary diseases proved by pathology. There were 16 cases of primary liver cancer, and one liver cirrhosis. Hemostasis was achieved in 13 patients, bleeding of three patients could not be controlled and one patient developed liver failure and died during seven days after operation. Only one patient survived about one year. Ligation of hepatic artery supplemented with packing was used in seven patients with four died of hemorrhagic recurrence. The mean survival time in the seven patients was about nine months. Single ligation of hepatic artery was applied in two patients with primary carcinoma and their survival time was less than one year. Two patients of primary liver carcinoma were given hepatic artery chemoemoblization and died within one year. Bleeding in forty patients was controlled by partial hepatectomy, but liver failure took place in two patients who died ten days after the surgery. Fourteen patients with four patients of hepatic adenoma among them lived more than one year.

DISCUSSION

Spontaneous liver rupture can happen not only in the primary liver cancer but also in liver benign tumor and liver cirrhosis. Careful history, physical and examination with necessary laboratory tests and imaging examination can provide enough clew for the diagnosis of liver rupture without difficulty. A typical patient usually presented with severe upper abdominal pain, abdominal distension, anorexia and vomiting. Rupture usually occurred during working or after slight injury. Facial pallor, cold sweat, pulse >100 times/minute, systolic pressure <90 mmHg, tenderness, rebound tenderness and muscular tension over upper abdomen, positive abdominal paracentesis, Hb<100 g/L and hematocrit 25-30 % suggest that the disease would be quite serious. B-ultrasonography(B-us) can detect 72.5 % tumor of liver and is a helpful and simple method to diagnose liver cancer, detect cancerous embolus of portal vein and evaluate the degree of intraperitoneal hemorrhage[1]. However, computed tomography (CT) especially helical CT is more sensitive to diagnosis liver tumor than B-us owing to its higher resolving power[2,3]. CT can detect tumors as small as 1 cm in diameter, and it may also differentiate the quality, the position and the invasion range of the tumor accurately[4]. Patient's therapy should be individualized because each case is not exactly similar.

Spontaneous rupture of primary liver carcinoma

As we know that hepatocellular carcinoma (HCC) is the most common primary liver tumor. Worldwide annual incidence of HCC was estimated to be at least one million new patients[5]. Its incidence of spontaneous rupture was about 10 %[6,7]. Liver rupture is short of special symptoms, especially it can usually be misdiagnosed if liver cancer is not diagnosed before rupture. But it is not very difficult if the diagnosis of intraperitoneal hemorrhage is made and examinations of B-us and CT are done. Primary liver cancer accompanied with cirrhosis accounted 53.9-85.0 % of liver malignancies. Because liver function in these cases is generally poor, the principle of treatment is to resuscitate rapidly, control bleeding, resect canceraous tissue and to retain as much healthy liver tissue as possible[8-10]. Firstly the vital physical signs and blood loss should be evaluated; Secondly the number of tumors, it's size, location, invasive range, and the possible presence of cancerous in portal vein should all be considered.Thirdly, liver function must be assessed, and presence or not jaundice and ascitic fluid as well as the degree of cirrhosis should be evaluated. The liver functional status should be classified according to Child's criterion. Hepatic partial resection should be performed immediately if patients's vital physical signs are stable, Child's classification was A or B, tumor's range is localized in one hepatic segment or lobe, and the first or the second hepatic hilus and the inferior vena cava are not invaded. Operation program include hepatic lobe or segment resection and non-regular hepatic partial resection[11-14]. If a great deal of blood is lost, despite the rest conditions are better or Child's classification of liver is C, tumor is too massive to be resected and tumor invades the hepatic portal vessels and the inferior vena cava, hemostasis should be considered first. In this situation the most simple surgical methods such as ligation of hepatic artery and hepatic artery chemoembolization should be selected[15-19]. Because blood supply of primary liver carcinoma is mainly by hepatic artery, ligation of hepatic artery can thus block the blood supply and nutrition of the carcinoma. If bleeding can not be controlled by blocking or embolization of hepatic artery, suture should be used in addition, and packing would be the final choice[20-23].

Spontaneous rupture of cirrhosis without malignant change

Liver cirrhosis usually supervenes hemorrhage of upper digestive tract[24], but rarely supervenes spontaneous rupture. Macronodular cirrhosis or varicose veins and lymphatic vessels can occasionally produce spontaneous rupture and leads to bloody abdomen. Once rupture in macronodular cirrhosis happens, the patient would die of liver failure in a short time. Rupture of varicose veins and lymphatic vessels is manifestation of terminal hepatic disease owing to high pressure of portal vein, therefore its prognosis is very poor[25]. Hepatic partial resection is not indicated in this kind of rupture, and control of hemorrhage by ligation of hepatic artery with packing and suture is the best choice. Liver tissue of cirrhosis is very crisp, inappropriate manipulation can lead to

uncontrollable bleeding. Thin bending needle and thick silk should be selected in suture, and silk should be ligated after suture.

Rupture of liver angioma

Hemangiomas which arise from mesenchymal cells are the most common benign tumor of the liver[26,27]. It can occur in all age groups, with incidence of 7 % in general population. The circumscribed lesions are composed mostly of closely packed hyperplastic vascular channels lined by a single layer of normal appearing endotheial cells. The majority of hemangiomas are small without symptom. However, it may be enlarged and associated with diffuse hemangiomatosis and even nearly replace the liver. Spontaneous rupture in hemangiomas is not usual but can be dramatic and very dangerous. Patients can die of massive hemorrhage in a short time. In this condition patients are too weak to endure massive operation owing to hematorrhea. Therefore, hemostasis is the first choice of treatment[28,29]. Ligation of hepatic artery or packing should be performed to control bleeding instantly as soon as shock is being treated. If the hemorrhage is stopped and the patient's condition is good, secondary operation to cure angioma should be selected. Suturing the split should be between healthy livertissue, otherwise the massiver bleeding may recur.

Rupture of liver adenoma

Liver adenomas which arise form epithelial tissue are relatively common benign tumors of liver[30]. Majority of adenoma have capsules and minority of adenoma without capsule are prone to malignant change. Live adenoma usually is solitary and varies in size. Occasionally they may be multiple and cluster within families. Tumor rupture or dramatic bleeding occurs in approximately one third of patients. Microscopically, the adenoma are closely approximated cords of hepatocytes that have vacuolated sinusoidal borders. Centers of adenomas may undergo degenerative changes. Some adenoma have abundant blood supply which are separate from adjacent normal hepatic tissue[31]. At present, adenomas are associated with the use of oral contraceptives and usually occur in young women[32]. The incidence goes up gradually. For rupture of adenoma the treatment principle is similar to that of primary liver cancer. If patients's conditions are stable and tumors are localized in one lobe or segment of liver, partial hepatectomy should be performed instantly. If blood loss is big , and the tumors are unresectable, then therapy should be ligation or embolization of hepatic artery to control bleeding[33,34]. Delayed resection can be prepared after successful hemostasis[35]. Liver transplantation can be considered for diffusi adenomatosis or the tumor exceeds half of the liver in diameter[36].

Rupture of secondary liver carcinoma

Liver is a frequent site for metastases arising from gastrointestinal cancers, which is a significant oncologic problem. Secondary liver carcinomas are generally diffusive but may present as a single cirrhotic nodule which is distinguished from healthy liver tissue with degenerative changes in its center. The histological structures of metastatic carcinoma resemble the primary cancer outside the liver. Secondary liver cancers grow slowlier than primary liver carcinoma and are usually unresectable. Ligation or chemoembolization of the hepatic artery should be selected to control bleeding first, then the next step in treatment will be decided. Cancer should be resected, if the patients's condition gets better and the metastatic cancer may be limited to one lobe or a segment of the liver ,the partial hepatectomy can be selected as emergency operation.

Abstract

AIM: To evaluate the possibility of the induction of anti-tumor immune response by transfecting the colorectal cancer cells with chemokine MCP-3 gene.

METHODS: Mouse MCP-3 gene was transduced into mouse colorectal cancer cells CMT93 by using of Liposome. G418-resistant clones were selected and the MCP-3 mRNA expression was detected by RT-PCR. The chemotactic activity of MCP-3 in the cell culture supernatant was detected by Chemotaxis assay. The tumorigenicity of wild type CMT93 and CMT93 gene transfectants were detected by *in vivo* experiments. The immune cell infiltrations in tumor tissue and tumor metastasis were detected histopathologically.

RESULTS: MCP-3 mRNA expression was detected by RT-PCR in gene-transfected cells (CMT93/MCP-3), but not in control groups. And MCP-3 secreted in the cell culture supernatant possessed chemotatic activity. The results from *in vivo* experiments showed that the tumorigenicity of CMT93/MCP-3 had not decreased, but the tumors derived from CMT93/MCP-3 cells grew more slowly than those from CMT93 cells (1.021±0.253) cm^2 *vs* (1.769±0.371) cm^2, $P<0.05$) or CMT93/mock cells (1.021±0.253) cm^2 *vs* (1.680 ±0.643)cm^2, $P<0.05$). Histophathological results showed few immune cells infiltrating in the tumor tissue derived from the controls. In the tumor tissue derived from CMT93/MCP-3, infiltrating immune cells increased. In addition, no tumor metastasis was found in all mice inoculated with CMT93/MCP-3 tumor cells. But all mice had tumor metastasis in CMT93 controls and 4 in 5 mice had tumor metastasis in CMT93/mock controls.

CONCLUSION: The results suggested that the transfection of chemokine MCP-3 gene could promote the induction of anti-colorectal cancer immunity, but the tumor growth could not be inhibited completely by merely MCP-3 gene transfection.

INTRODUCTION

Chemokines, a kind of polypeptide with low molecular weight, can activate and chemoattract immune cells and play a pivotal role in host defense and in immunological conditions such as autoimmune reaction and malignant tumors[1]. Chemokines such as monocyte chemotactic protein-1 (MCP-1) is produced by a variety of tumors such as ovarian carcinoma[2] Kaposi's sarcoma[3], cervical carcinoma[4], and melanoma[5]. There are evidences suggesting that chemokines play an important role in immune cells infiltrating in tumor tissue. Chemokine gene transferred into tumor cells elicits anti-tumor effect such as reducing tumorigenicity and inhibiting tumor growth[1].

MCP-3 is a CC chemokine identified from osteosarcoma supernatant[6]. By binding to CCR1, CCR2, and CCR3[7-11], MCP-3 acts on a lot of immune cells. Tumor gene therapy with MCP-3 had been reported in p815 mastocytoma mouse model[12] and human cervical carcinoma xenografts[13]. But the anti-tumor effect by MCP-3 gene transfer in colorectal cancer model has not been determined. In our study, we found that after the transfecting of CMT93 colorectal cancer cell with MCP-3 gene, tumor growth was retarded and tumor metastasis was inhibited completely by promoting immune cells infiltration in tumor tissue.

MATERIALS AND METHODS

Materials

Male or female C57BL/6 mice, 6-8 weeks old, were purchased from Shanghai Experimental Animal Center of Chinese Academy of Sciences. CMT93 is a mouse colon cancer cell line from an induced carcinoma of mouse rectum[14], which was purchased from ATCC in America. Plasmid pCMV/MCP3 containing mouse MCP3 gene and plasmid pCDNA/YT4 containing mouse CCR1 (C-C chemokine receptor 1) gene were presented kindly by Dr. Ji Ming Wang in NCI in America. MCP-3 RT-PCR primers were presented kindly by Dr. Ji Ming Wang as well.

Transfection of tumor cells with MCP-3 gene

According to the LipofectAMINE (Gibco) kit protocol. Briefly, (1)2 μg plasmid DNA and 15 μl LipofectAMINE are added to 200 μl DMEM without FCS, mix gently, and incubate at 37 ℃ for 30min. (2) Wash the CMT93 cells in 6 well plate with FCS-free DMEM. (3) Add 0.8ml of serum-free DMEM to the tube containing the DNA and lipofectAMINE complexes, mix gently and overlay the rinsed cells. (4) Incubate the cells with complexes for 5 h at 37 ℃ in CO_2 incubator. (5) Add 1ml of DMEM containing 200 $mL \cdot L^{-1}$ serum, incubate overnight. (6)

Replace the medium with fresh DMEM. (7) Digest the cells and plate them to the 100 ml bottles, incubate 24 h. (8) Replace the medium with fresh DMEM containing 800 μg/ml G418 and select the positive clones.

RNA preparation and reverse transcription polymerase chain reaction (RT-PCR)

The Total RNA from cells was extracted with RNeasy Mini kit (QIAGEN) according to the manufacture's instructions. Total of 0.5 μg RNA was used for RT-PCR. For mouse MCP-3, sense primer 5'-TCTGTGCCTGCTGCTCATAG-3' (nucleotide 73-92) and antisense primer 5'-CTTTGGAGTTGGGGTTTTCA-3' (nucleotide 321-340) were used to yield a 268-base pair product. For mouse β-actin, sense primer 5'-TGTGATGGTGGGAATGGGTCGG-3' and antisense primer 5'-TTTGATGTCACGCACGATTTCC3' were purchased from STRAATAGENE to amplify a 514-base pair fragment. RT-PCR was performed with high fidelity ProSTRAR™ HF single-tube RT-PCR system (STRATAGEBE), consisting of a 15-min reverse transcription at 37 ℃, 1 min of inactivation of Moloney murine leukemia virus reverse transcriptase at 95 ℃, 40 cycles of denaturing at 95 ℃ (30 s), annealing at 60 ℃ (30 s), and extension at 68 ℃ (2 min), as well as a final extension for 10 min at 68 ℃.

Chemotaxsis assay

Chemotaxis assays were performed using 48-well chemotaxis charmbers (Neuro probe, Cabin John, MD, USA). As described previously[15]. First 27-29 μl cell culture supernatants from CMT93 and its gene transfectants were placed in the wells of the lower compartment of the chamber. 50 μl cells (1×10^6/ml in binding medium, BM: RPMI1640 containing 10 mL· L^{-1} BSA, 25 mmol· L^{-1} HEPES) were plated in the wells of the upper compartment. The upper and lower compartments were separated by a polycarbonate filter (Osmonics, Livermore, CA, USA; 10 μm pore-size) which was pre-coated with 50 μg· mL^{-1} collagen type I (Collaborative Biomedical Products, Bedford, MA, USA). After incubation at 37 ℃ for 5 h, the filter was removed, stained, and the cells migrated across the filter were counted under light microscope after coding the samples. The results were expressed as chemotaxis index (CI), which represents the fold increase in the number of migrated cells in response to chemoattractants over the spontaneous cell migration in response to control medium.

Tumorigenicity

As previously reported[16], Balb/c mice were inoculated subcutaneously on the back with 5×10^6 CMT93/MCP-3 cells (8 mice), or CMT93/mock cells (7 mice) or CMT93 cells (5 mice). Tumor sizes were assessed for every 5 days by measuring perpendicular diameters with caliper (0.002 cm). The tumor sizes from each groups were expressed as mean square (long diameter ×short diameter). On day 14, one mice in each groups was selected randomly and sacrificed for histologic evaluation. The other mice were observed and the tumor metastasis was measured.

Histologic evaluation

Tissues were removed from the site of tumor cell inoculation 14 days after injection, or from the drainage lymph node of the site of tumor cell inoculation. Then fixed in 100 mL· L^{-1} formalin, blocked in paraffin, sectioned at 4-6 um, and stained with hematoxylin and eosin. The infiltrating leukocytes in tumor tissue were observed and evaluated, and the tumor metastasis in the drainage lymph node was determined.

RESULTS

RT-PCR

After gene transfection and the following G418-resistant clone selection, we detected MCP-3 mRNA expression in MCP-3 gene transfected CMT93 cells by RT-PCR using one-step kit. In contrast, the wild type CMT93 cells and the mock transfected CMT93 cells did not express MCP-3 (Figure 1).

Chemotaxsis

After the detection of MCP-3 mRNA expression, we tested the biological function of MCP-3 secreted in the culture supernatant. Chemotaxis analyses revealed that the RBL/2H3 cells transfected with CCR1, which is one of the receptors of MCP-3, migrated when supernatants from MCP-3 transfected CMT93 (CMT93/MCP-3) cells were present in the lower wells of the chemotaxis chamber (Figure 2, 3D). No increased cell migration occurred when supernatants from mock transfected CMT93 (CMT93/mock) or wild type CMT93 cells were present in the lower wells of the chemotaxis chamber (Figure 2, 3C,3B). These results showed that not only the transfected MCP-3 gene expressed but also the expressed protein possessed biological function.

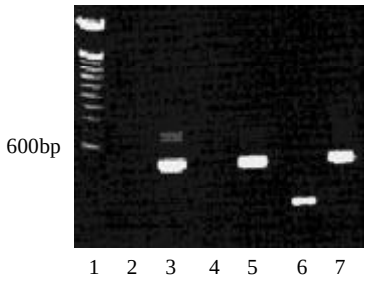

Figure 1 MCP-3 mRNA expression of CMT93 or its gene transfectants (RT-PCR). from CMT93 cells or its gene transfectants. $^aP<0.05$ *vs* CMT93 or CMT93/mock group.

MCP-3 retards tumor growth

To examine whether MCP-3 secretion retard tumor growth, we injected MCP-3 transfectants subcutaneously into Balb/c mice to test their tumorigenicity. As showed in Figure 4, all mice had tumor growth on day 5 after tumor cell inoculation. But tumors from CMT93/MCP-3 grew more slowly than that from mock transfectants or wild type CMT93 ($P<0.05$, Table 1). These results suggested though MCP-3 secretion could not inhibit tumor formation completely; it retarded tumor growth.

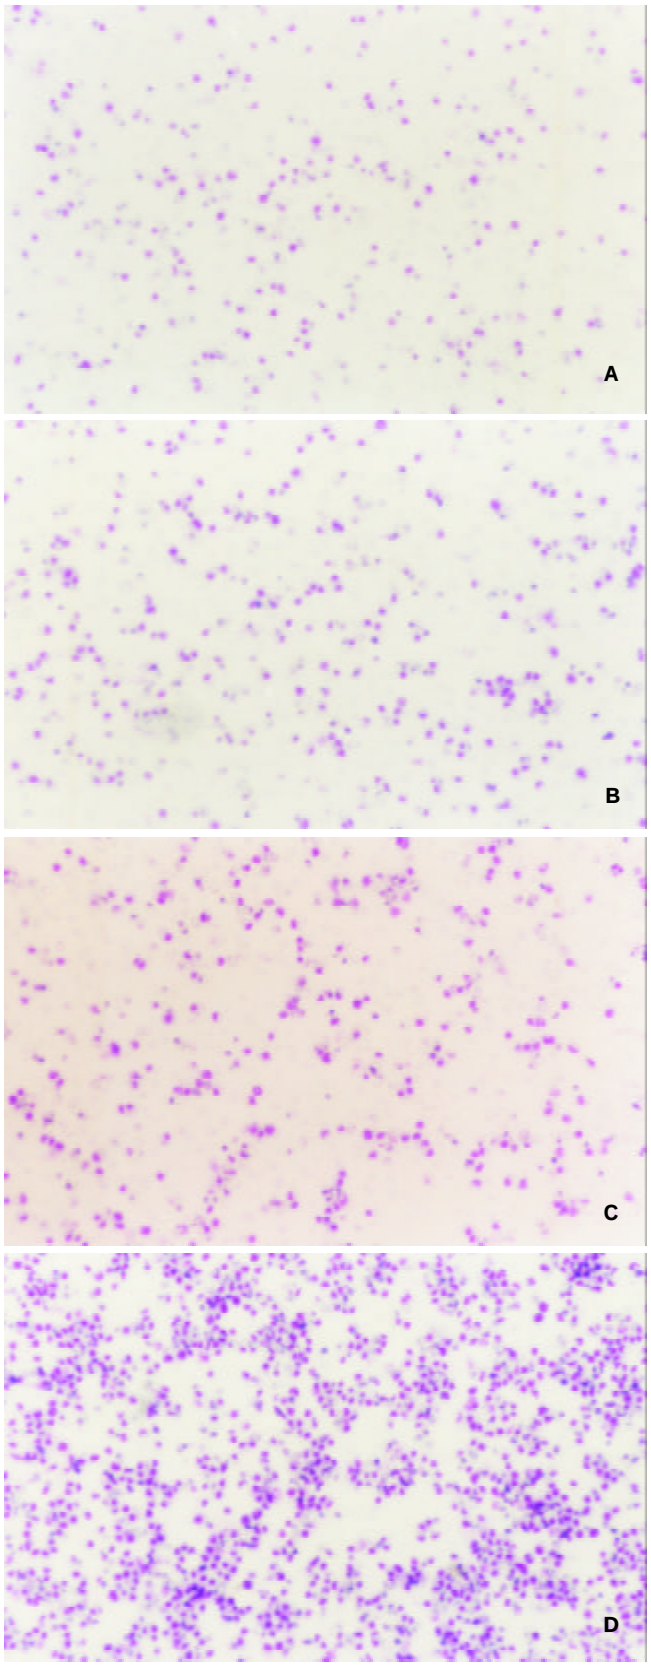

Figure 3 Chemotactic activity of MCP-3 in supernatant from CMT93 or its transfectants (Wright staining showed the chemoattracted target cells ×25). A: medium; B: CMT93 supernatant. The chemoattracted cells were not increased significantly; C: CMT93/Mock supernatant. The chemoattracted cells were not increased significantly; D: CMT93/MCP-3 supernatant. The chemoattracted cells were increased significantly.

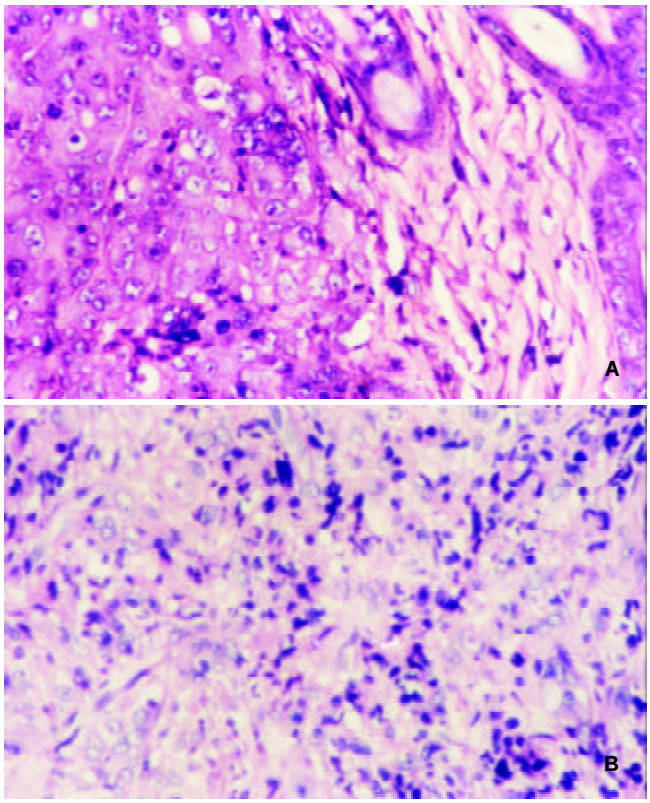

Figure 5 Histopathology of the tumors derived from CMT93 or CMT93/MCP3 (HE staining ×200). A: tumor derived from CMT93 cells; few infiltrated immune cells were found; B:tumor derived from CMT93/MCP-3 cells, the infiltrated immune cells were increased.

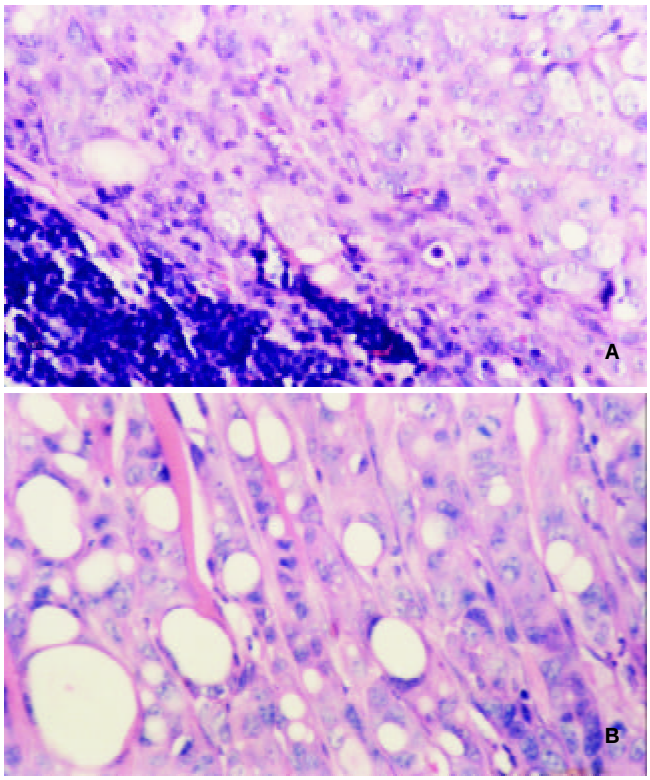

Figure 6 Histopathology of tumor derived from CMT93 metastasized to the local drainage lymph node(HE staining × 200). A: up-left is the lymph tissue, down-right is the tumor tissue; B: tumor infiltrated to the muscle tissue.

Table 1 Tumor size in the mice inoculated with CMT93 or its gene transfectants (cm^2, $\bar{x}\pm s$)

Days after tumor injection	Tumor size in the mice inoculated with		
	CMT93	CMT93/mock	CMT93/MCP-3
5	0.181±0.020	0.170±0.012	0.097±0.012[a]
10	0.398±0.030	0.397±0.025	0.186±0.019[a]
15	0.720±0.185	0.751±0.157	0.372±0.104[a]
20	0.950±0.303	0.954±0.309	0.416±0.167[a]
25	1.385±0.222	1.335±0.292	0.699±0.170[a]
30	1.769±0.371	1.680±0.643	1.021±0.253[a]

Immune cells infiltration

MCP-3 gene transfer profoundly altered leukocyte recruitment in tumors grown in syngeneic Balb/c mice. On day 14 after tumor inoculation, all the mice showed tumor growths of about (0.6-0.8)×(0.6-0.8) cm^2 in size, which allowed a histologic study. Histologic results showed that tumor derived from MCP-3 gene transfected CMT93 cells contained much more infiltrating leukocytes, but tumor derived from the wild type CMT93 cells contained less leukocytes (Figure 5). Infiltrating leukocytes were located in the cancer nests mainly. The tumors derived from mock transfectants contained less leukocytes as well (data not shown). These results suggested that the effect of MCP-3 gene transfer in retarding tumor growth maybe related to the infiltration of leukocytes which were chemoattracted by MCP-3.

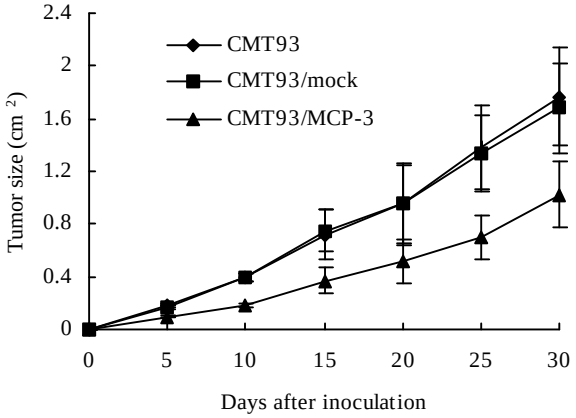

Figure 4 The tumor growth curves of CMT93 or its gene transfectants

Tumor metastasis

On day 30, tumors in all 4 mice inoculated with CMT93 cells into the backs metastasized, two to inguinal drainage lymph node, other two to cervical drainage lymph node. Of tumors in 5 mice inoculated with CMT93/mock cells in the backs, 4 metastasized to inguinal drainage lymph node, and the other one did not metastasize. Tumors in all 7 mice inoculated with CMT93/MCP-3 did not metastasize. Histological study showed a metastatic lymph node (Figure 6a). In another metastasis lesion, tumor cells went out of the lymph node to invade the muscle tissue (Figure 6b). The percentage of tumor metastasis of MCP-3 gene transfectants was significantly lower than that of wild type or mock transfected CMT93 tumor cells (Table 2, $P<0.05$).

Table 2 Tumor metastasis in mice inoculated with CMT93 or its gene transfectants

Mice inoculated with	No. metastasized	No. not metastasized	Percentage (%)
CMT93	4	0	100
CMT93/Mock	4	1	80
CMT93/MCP-3	0	7	0[a,b]

DISCUSSION

Chemokines characterized by their ability to induce directional migration and activation of leukocytes comprise the superfamily of polypeptides which is the largest family of cytokines. Produced by a variety of cell types including hematopoietic and non-hematopoietic origin, chemokines regulate leukocyte adhesion, trafficking, homing and angiogenesis, and contribute to lymphopoiesis and hematopoiesis. *In vivo* studies using neutralizing antibodies, antagonists, or by deletion of chemokines and their receptors have revealed that chemokines and their receptors play a pivotal role in host defense and in immunological conditions[1].

The fact that chemokines attract different leukocyte populations and promote their functions has prompted a number of studies on the effect of chemokine gene transduction into tumor cells. Not only CC chemokines such as MCP-1 (monocyte chemotactic protein-1)[17,18], MCP-3 (monocyte chemotactic protein-3)[12,13], MIP-1alpha (macrophage inflammatory protein-1alpha)[19], MIP-1beta (macrophage inflammatory protein-1beta)[20], SLC (secondary lymphoid tissue chemokine)[21], MIP-3alpha (macrophage inflammatory protein 3alpha)[22], TCA3(T-cell activation gene 3)[23], RANTES(regulated on activation normally T cell expressed and secreted)[24], but also CXC chemokines including ELR- (angiostatic) chemokines such as IP10 (interferon-inducible protein 10)[25-28], MIG (monokine induced by interferon gamma)[29,30], PF4 (platelet factor 4)[31], and ELR+ (angiogenic) chemokines such as IL-8 (interleukin-8)[32-33] had been selected for tumor gene immunotherapy. In addition, C chemokine lymphotactin[34-36] had been reported in tumor gene therapy as well. Divergent results were obtained depending on the tumor models and whether human or murine chemokine genes were used.

MCP-3 had a wide spectrum of action on different immune cells, including monocytes[10], T cells[37,38], NK cells[39], basophils[40], eosinophils[40], and neutrophils[10]. In addition, MCP-3 was active on DC as well[41-43]. In P815 mastocytoma mouse model, MCP-3 gene transfer reduced tumorigenicity by augmenting immune cell infiltration in tumor tissue and dendritic cells accumulation in peritumorous tissue[12]. MCP-3 gene transfer also induced leukocyte infiltration and reduces growth of human cervical carcinoma cell xenografts[13].

In our study, MCP-3 gene was transduced into mouse colorectal cancer CMT93 tumor cells to determine the anti-tumor activity of MCP-3 in colorectal cancer model. Though tumorigenicity of CMT93 was not reduced, and the tumors can't be rejected completely after MCP-3 gene transfer, but the tumors grew more slowly than those of controls. And MCP-3 gene transfer inhibited tumor metastasis thoroughly. In the tumor tissue from MCP-3 gene transfectants, infiltrated immune cells increased. We speculate that the anti-tumor immunity elicited by MCP-3 gene transfer is type I T cell-dependent just as reported[12]. We found the humoral response against CMT93 tumor cells in the serum from CMT93/MCP-

3 primed mouse did not increase (data not shown), and few neutrophils was found in tumor tissue. These results reversely suggested a type I T cell-dependent response was contributed to the anti-tumor immunity in MCP-3 gene transfer. Further study is needed to prove whether dendritic cells contribute to the anti-tumor immunity elicited by MCP-3 gene transfer or not.

Abstract

AIM: Use Receiver operating characteristic (ROC) curves to find out the relationship between serum level of hyaluronic acid (HA), type III procollagen (PCIII), N-terminal procollagen III peptide (PIIINP), laminin (LN), type IV collagen (C-IV) and hepatic fibrosis, as well as to determine their value in clinical practice.

METHODS: 114 serum samples from chronic hepatitis patients were assayed for fibrosis indices including HA, PCIII, PIIINP, LN and IV-C with radioimmunoassay (RIA). Liver biopsy was also performed in all these patients and the biopsy material was examined histopathologically.

RESULTS: ROC curves analysis showed that area under the curve (AUC) of PIIINP, HA, PCIII, C-IV and LN was 0.800, 0.728, 0.727, 0.583 and 0.463, respectively. The analysis also showed that PIIINP (r=0.452), HA (r=0.497) and PCIII (r=0.404) have greater diagnosis performances than C-IV (r=0.238) and LN (r=0.128) according to fibrosis staging. The sensitivity of HA plus PIIINP was 55.1 %, it was the most sensitive combination. Combined three or more than three indices that based on HA, the specificity was 100 %. Using combination assays can improve the specificity, but its sensitivity was not high. Serum fibrosis indices increased as the grade of inflammation aggravated. But only PIIINP and PCIII had significant difference between G1 and G2 (PIIINP: 13.16±8.07 *vs* 8.32±5.09; PCIII: 164.22±65.69 *vs* 138.23±77.63). The coefficient correlation of the results of inflammation grade and fibrosis staging to HA was 0.525 and 0.553 respectively, that to PCIII, 0.446 and 0.412, that to LN, 0.234 and 0.194, and that to IV-C, 0.363 and 0.351, respectively.

CONCLUSION: Serum fibrosis indices can indicate tendency of hepatic fibrosis, but it cannot replace liver biopsy. However, as diagnostic markers, more efficient serum fibrosis indices for the diagnosis of hepatic fibrosis need to be explored.

Zheng M, Cai WM, Weng HL, Liu RH. ROC curves in evaluation of serum fibrosis indices for hepatic fibrosis. *World J Gastroenterol* 2002; 8(6):1073-1076

INTRODUCTION

Chronic injury leading to fibrosis in the liver[1-11]. Liver biopsy has traditionally been the standard method for assessing hepatic fibrosis, but the procedure is associated with complications in patient under biopsy and so it is difficult to put into practice. Reports showed that serum fibrosis indices, including PCIII, PIIINP, LN, HA and C-Ⅳ and others, can reflect the activity of hepatic fibrosis to some extent[12-19]. Mean ±SD has always been used to express the standard for hepatic fibrosis[20]. In resent years, some scientists have recommended to use Receiver operating characteristic (ROC) curves in determination of indices of hepatic fibrosis in clinical practice[21]. Reports using ROC curves to evaluate fibrosis indices were seen, but histopathological results of the liver have not been used as control. In this study, levels of all the five fibrosis indices were measured in patients with chronic hepatitis B and comparison with biopsy results of the liver was carried out to determine if the measurements of these indices have any clinical value as markers of chronic hepatic fibrosis. ROC analysis was used to determine the sensitivity and specificity of the assays in detecting the liver disease.

MATERIALS AND METHODS

Subjects

During the Sixth National Conference for Infectious and Parasitic Diseases, the protocol of prevention and treatment for virus hepatitis was modified in 2000 (abbreviated as "2000 criteria")[22]. According to the "2000 criteria", 114 patients had typical presentations of chronic hepatitis. 99 were males and 15, females. Among them, 75, 30 and 9 showed mild, moderate and severe degree of the disease, respectively. The patients' histories were mainly collected from the First Affiliated Hospital of School of Medicine, Zhejiang University and several hospitals in Zhejiang Province between July, 1998 and September, 1999. Their age ranged between 16 and 57 years and the disease course was from one to 30 years. All patients showed positive in HBV markers (HBVM) and the diagnosis was made by liver biopsy according to the "2000 criteria"[22].

Histology

Biopsy fragments of the livers were fixed in 10 % neutralized formadehyde, embedded in paraffin, and then stained with hematoxylin and eosin. Reticulation fibrosis stain and the Sirius red method were used specially for staining fibrous tissue components. Histological assessment of the liver was done according to Wang's report[23], and the stage of fibrosis was divided into four, expressed as S1 to S4 according to the "2000 criteria"[22]. S1 shows expansion in portal tract areas with fibrosis; S2, fibrosis around portal tract areas with fibrosis segregation formation, while maintaining lobule structure; S3, formation of fibrosis segregation and disorder of lobule structure without hepatic cirrhosis, and S4, early stage or confirmed cirrhosis. S0 shows no fibrosis.

Determination of serum fibrosis indices

The serum specimens were divided into five proportions and stored at -20 ℃. The assay of the levels of serum HA, PCIII, PIIINP, Ⅳ-C and LN was done by RIA. The kits of HA, IV-C and LN were provided by the Shanghai Navy Medical Institute. The kit of PCIII was provided by the Chongqing Tumor Institute. The kit of PⅢNP was provided by the Shanghai Orion Diagnostic Reagent Corporation (produced by Finland Orion Corporation). The operations were performed according to the user' s manual.

Statistical analysis

Results were expressed as mean ± standard deviation ($\bar{x}\pm s$) and compared when necessary. The relationship between noninvasive markers and stage of histological liver fibrosis was analyzed by the Spearman rank-correlation test and nonparametric one-way ANOVA for nonparametric data. Tests were considered statistically significant at $P<0.05$. Sensitivity of the assays was plotted against the false positivity (1-specificity) using ROC curves using SPSS 10.5 statistical program. Comparison of AUC was performed, which compares the AUC to the diagonal line of no information (AUC 0.5). The pathologist was blind to the results of serum indices in the study subjects. In order to determine the specificity and sensitivity of the assays, S≥1 for one with hepatic fibrosis was arbitrarily defined. Take (1-specificity) as x-axis, and take sensitivity as y-axis. If AUC=1.0, the index is an ideal test, and if AUC<0.5, the index has no diagnostic value.

RESULTS

ROC curves of five serum fibrosis indices

From Figure 1 the AUC of serum fibrosis indices in ROC curves is in the order of PIIINP>HA>PCIII>C-IV>LN. It means that PIIINP, HA and PCIII are more useful than C-IV and LN in terms of the fibrosis index for diagnosis. PIIINP is the most sensitive index among the five indices, but its specificity is not as high as HA and PCIII. Take both sensitivity and specificity into account, the cut-off point was selected according to max number of sensitivity add specificity. Table 1 shows the cut-off point, sensitivity, specificity and correct diagnosis index of the five indices.

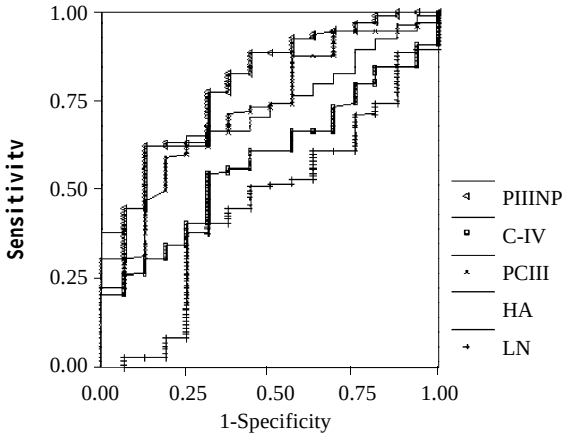

Figure 1 ROC curves of five serum fibrosis indices

The value of combination of the five indices for diagnosis

HA is the generally used index for diagnosis. From Figure 1, HA is the best one among the five indices. So HA was taken as a basic index and was used in combination with other indices for the diagnosis of hepatic fibrosis. Each index result of ROC analysis is shown in Table 1. Table 2 shows the sensitivity and specificity of combination diagnosis. Among two index combination groups HA+PIIINP is better than HA+PCIII and HA+C-Ⅳ and HA+LN. In combinations of the above three indices, specificity is all 100 %. The best sensitivity was seen in HA+C-Ⅳ+PIIINP and HA+C-IV+ PCIII combinations.

Table 1 ROC curves of five serum fibrosis indexes

Indices	AUC	*P* Vaule	cut-off point	Sensitivity	Specificity	*r* Vaule
PⅢNP	0.800	0.000	≧5.61μg/L	82.7%	62.5%	0.452
HA	0.728	0.003	≧145.2 ng/ml	62.2%	87.5%	0.497
PCⅢ	0.727	0.004	≧137.4μg/L	59.2%	81.2%	0.404
C-Ⅳ	0.583	0.287	≧74.2μg/L	55.1%	68.7%	0.238
LN	0.463	0.636	≧156.65 ng/ml	37.8%	75.0%	0.128

HA + LN+ PCIII	24.5	100
HA +C-IV+PIIINP	38.8	100
HA +C-IV+PCIII	38.8	100
HA + LN+C-IV+ PIIINP	19.4	100
HA + LN+C-IV+PCIII	19.4	100

The relationship between hepatic fibrosis indices and inflammation grades

Table 3 shows that numerical value of serum fibrosis indices, excluding LN, increased along with the development of inflammation grades. Only PIIINP and PCIII, but not others, have significant difference between G2 and G1. Values of PIIINP, PCIII, HA and C-Ⅳ in the stage G3 and G4 have significant differences as compared to those in the stage G1.

DISCUSSION

Hepatic fibrosis is a result in loss of normal liver cell function due to the disorganized over-accumulation of extracellular matrix (ECM) components in the liver[24-29]. It is clear that the increase production and decrease degradation of ECM components are responsible for the altered ECM metabolism in fibrotic liver. So the metabolism production of ECM in serum can be regarded as the indices of hepatic fibrosis. Different serum fibrosis indices represent different ECM metabolism. Such as PIIINP and PCIII reflect collagen metabolism[30], and HA reflects hepatic fibrosis activity and liver injury[31,32]. LN reflects basement membrane transformation and has some relation to portal hypertension[32,33].We have reported an integral project for the diagnosis of hepatic fibrosis and serum fibrosis index spectrum for the serodiagnosis of hepatic fibrosis[34]. But along with the development of the technology of testing and statistic, new evaluation for serum hepatic fibrosis indices is necessary. ROC curves and AUC of ROC curves can assess the value of one test[35,36]. ROC curves can do comparison of several diagnostic techniques for one disease. In this way, clinicians can get help for screening out the most suitable scheme. So ROC analysis has become an important method for the assessment of diagnostic markers for hepatic fibrosis.

From Figure 1 and Table 1 it is clear that PIIINP is the most sensitive index among the five indices. However, its specificity is comparatively low. Also a conclusion can be got from Figure 1 and Table 1 that HA is the most specific index. This is consistent with the results of our previous study on the relationship between serum fibrosis indices and liver histological changes[37], and is also consistent with other reports[38,39]. The cut-off point is used in our study to confirm the critical value of serum fibrosis indices when they are used in the diagnosis of hepatic fibrosis. Not only the cut-off point meets the requirement of study on clinical epidemiology, but also it can get more reliable result. One may get conclusion from the figure that using only one index to diagnose fibrosis may be prejudicial. From the ROC curves we can see, no single serum index has both ideal sensitivity and specificity. Our results also showed that excluding LN, other serum indices have close relation with inflammation. This is also the reason why the specificity is low if only one serum fibrosis index is used in the diagnosis. Ye *et al*. reported that serum PCⅢ index can exclude the influence of hepatocyte inflammation and necrosis. But their results just took serum alanine aminotransferase (ALT), bilirubin, albumin, HBVDNA and HBVM as standards for estimation. As we know that serum liver function tests and HBVDNA are not very objective indices. Our results based on histological examination of the liver hinted that PCⅢ also has close relation with inflammation grades of chronic hepatitis. The correlation coefficient of PCIII is just lower than HA and PIIINP. So PCIII examination cannot get rid of interference of inflammation. And PIIINP is more sensitive than PCIII in early hepatic fibrosis[40].

As influenced by the metabolism of connective tissue in the body, one index can only reflect one aspect of synthesis or degradation of ECM. So combined test of several indices for the diagnosis of hepatic fibrosis is the way of choice. Use several noninvasive markers combination to diagnose hepatic fibrosis have been reported[37,41]. However, no identical standard has been made in terms of index selecting. Positive rate of HA in the diagnosis was 91-94 % in liver cirrhosis, so it is the most sensitive index to screen hepatic fibrosis and cirrhosis. According to the cut-off point and take HA as the basis index to combined with other indices to diagnose hepatic fibrosis, our study was carried out. From Table 2 tests of HA plus PIIINP or PCIII are the most sensitive combination with rather high specificity. Although other combinations seem to be more specific, their sensitivity is quite low. The sensitivity of our combinations is lower than other report, but the specificity is higher[42]. Reports already published usually took $\bar{x}\pm s$ of serum indices for the diagnosis of chronic active hepatitis. However, using serum markers to diagnose fibrosis caused by chronic hepatitis without liver histological results for control may be over-estimated the sensitivity of the diagnosis. This study divided different groups by stage according to histological results and utilized ROC curves concatenation variable to ascertain cut-off point and in doing so attention was paid to both sensitivity and specificity. One of the reasons of low sensitivity may be due to patient selection for the study among them most were cases of chronic hepatitis. As we only use fibrosis stage $S\geqslant 1$ as grouping standard, the inflammation in the groups between S=0 and $S\geqslant 1$ may influence the result of sensitivity.

In conclusion, serum HA, PIIINP,PCIII,C-Ⅳ and LN levels reflect some aspects of ECM synthesis and degradation. Although serum fibrosis indices can reflect degree of fibrosis impersonally, the stage classification of fibrosis is too simple. And, as a result, fibrosis in the same stage may have considerable difference. So if quantified measurement of liver fiber with computer analysis is done first[43-45], and then followed by using ROC curves to assess the serum fibrosis indices, as a noninvasive diagnosis technique, serum fibrosis indices will have more significant meaning in clinical evaluation of the liver disease.

Abstract

AIM: To detect the expression of soluble TRAIL (TNF-related apoptosis inducing ligand, TRAIL) in the peripheral blood of HBV infected patients and try to elucidate whether the expression level of sTRAIL have any correlativity with the clinical staging, the expression level of HBV markers and the degree of liver damage.

METHODS: 52 cases of HBV infected patients were investigated, including 8 HBV carriers, 30 chronic hepatitis B, 11 cirrhotics and 3 HBV infection related hepatocellular carcinoma. Expression of soluble TRAIL and markers of the hepatitis B were mearsured by enzyme-linked immunosorbent assay.

RESULTS: The expression level of sTRAIL in the peripheral blood of the HBV infected patients was significantly higher than that of healthy controls (1378.35±540.23 pg/ml *vs* 613.75±175.80 pg/ml, $P<0.001$). In the group of chronic hepatitis, the expression level of sTRAIL was coincident with the status of the disease and was significantly correlated with the level of ALT. In the group of cirrhosis and liver cancer, its expression level was significantly higher than that of the healthy persons and HBV carriers, but lower than that of the hepatitis B patients; meanwhile, the expression of sTRAIL did not have any correlativity with the functional indexes of the liver.

CONCLUSION: The soluble TRAIL in the HBV infected people may participate in the liver damage. Our results indicated that the expression level of soluble TRAIL may reflect the ravage of liver caused by host immune reaction to a certain degree.

Han LH, Sun WS, Ma CH, Zhang LN, Liu SX, Zhang Q, Gao LF, Chen YH. Detection of soluble TRAIL in HBV infected patients and its clinical implications. *World J Gastroenterol* 2002; 8(6): 1077-1080

INTRODUCTION

TRAIL (TNF-Related Apoptosis Inducing Ligand), a new member of the TNF superfamily that could induce apoptosis, was first cloned and identified by Wiley in 1995[1]. TRAIL can potentially interact with five different receptors. These receptors include death receptor 4, death receptor 5, decoy receptor 1, decoy receptor 2[2-8], and a soluble receptor called osteoprotegerin[9].TRAIL can induce rapid and effective apoptosis of tumor cells while spare normal tissue cells successfully, which makes it a novel molecule that has the potential for treatment of malignant tumors. *In vivo* investigation of rTRAIL revealed that TRAIL could selectively kill tumor cells, but not normal cells, leaving the host organ systems unharmed[10,11]. However, since TRAIL is also an effective molecule participating in the immune surveillance, it is not known whether it takes part in the pathogenesis caused by hepatitis B virus and what role it may play in the HBV infection related inflammation. The expression level of soluble TRAIL in the peripheral blood of the HBV infected patients was detected and analyzed in our experiments. We tried to find out whether there is any relationship between the expression of soluble TRAIL and liver damage caused by hepatitis B virus.

MATERIALS AND METHODS

Cases and specimens

52 HBV infected patients with an average age of 41.9 years from Jinan Infectious Hospital and Shandong University Qilu Hospital were investigated, including 8 HBV carrier, 30 chronic hepatitis B patients, 11 cirrhotics and 3 HBV-related liver cancer. The diagnosis of hepatitis and cirrhosis were in accordance with the criteria emended in the Third National Conference of Infectious and parasitic held in Beijing 1995. 24 healthy blood donors with an average age of 31.4 years were taken as controls.

Major reagents

Soluble TRAIL ELISA detection kit was the product of Diaclone company in France with the detection range from 64 pg/ml to 3000 pg/ml. The HBsAg and HBeAg detection kits were the products of Lizhu Group.

Detection of soluble TRAIL in the peripheral blood

The standard specimen was diluted to 3000, 1500, 750, 375, 187.5, 93.5 pg/ml in turn. Specimens ,diluted standards and the negative control were put into the 96 wells plate coated with the antibody of TRAIL. The specimens were detected according to the procedures described in the protocol. A_{450} value was utilized to draw the standard curve and the expression level of sTRAIL was obtained from the curve.

Detection of Hepatitis B viral particles

Specimens, negative control and positive control were put into the ELISA kit coated with antibodies to HBsAg and HBeAg, respectively. The type B hepatitis markers were obtained from the ratio of A_{450} value of specimens to A_{450} value of negative control(S/N value).

Evaluation of liver function

The indexes that could reflect the function of the liver including alanine transaminase (ALT), albumin (ALB) and total bilirubin (Tbil) were assayed by the automatic biochemical analyzer equipment according to its protocol.

Statistical analysis

The results were expressed as means ± SD, and statistical analysis was performed with the analysis of variance (ANOVA). A value of $P<0.05$ was considered statistically significant.

RESULTS

Comparison of the expression level of sTRAIL in the chronic hepatitis patients and that of the healthy control

The expression level of sTRAIL was much higher in the HBV infected group than that of the healthy controls (1378.35±540.23 pg/ml *vs* 613.75±175.80 pg/ml, $P<0.001$).

Study on the correlation between the expression of sTRAIL and the clinical staging of hepatitis B patients

There was significant difference in sTRAIL expression among the groups of hepatitis patients divided by the stage and severity of the illness. The expression level of sTRAIL became higher gradually with the change of severity of the ailment in the group of chronic hepatitis patients. In the group of liver cirrhosis and liver cancer, the expression level of sTRAIL was significantly higher than that of the healthy controls and the HBV carriers, but lower than that of chronic hepatitis patients group. The statistical analysis of the expression level of sTRAIL and the status of the HBV infected patients was referred to Table 1.

Table 1 Statistical analysis of the relevance of expression of sTRAIL and clinical staging of hepatitis B

	n	sTRAIL($\times 10^{-9}$ μg/ml)
HBV carriers	8	876.88±369.59
Chronic hepatitis	30	1494.97±533.24
Mild chronic hepatitis	9	1138.90±424.90
Moderate chronic hepatitis	12	1558.65±489.87[a]
Severe chronic hepatitis	9	1812.78±499.99[b]
HBV infectious related cirrhosis	11	1375.00±526.08[c]
HBV related infectious liver cancer	3	1561.00±449.56[d]

[a]$P<0.01$ *vs* mild chronic hepatitis group; [b]$P<0.001$ *vs* mild chronic hepatitis group; [c]$P<0.05$ *vs* severe chronic hepatitis group; [d]$P<0.05$ *vs* severe chronic hepatitis group

Study on the relationship between the expression of sTRAIL and clinical indices of the hepatitis B patients

In all the HBV infected patients, the expression level of sTRAIL was positively correlated with the ALT ($r=0.425$, $P<0.01$). But not with the level of Albumin and Tbil. Further study indicated that in hepatitis patients, the expression level of sTRAIL was positively correlated with the value of ALT and AlB, but not between sTRAIL and any of the clinical indices in the group of HBV carrier and cirrhosis.In the HBV infection related liver cancer group, it could not be analyzed because the number was too small. The related results referred to Table 2.

Table 2 Analysis of corelation between the expression of sTRAIL and clinical indices of hepatitis B

	sTRAIL	clinical indices		Correlativity coeffficient
HBV carrier	876.88±369.59	ALT	28.38±5.09	
		Tbil	17.73±3.34	
		ALB	39.5±1.20	
Chronic hepatitis	1494.97±533.24	ALT	173.61±135.32	$r=0.496$($P<0.01$)
		Tbil	66.79±61.73	
		ALB	32.95±5.86	$r=-0.392$($P<0.05$)
HBV infectious related cirrhosis	1375.00±526.08	ALT	150.36±132.72	
		Tbil	82.83±118.00	
		ALB	34.01±5.79	
HBV infectious related liver cancer	1561±449.56	ALT	85.67±48.76	
		Tbil	58.81±24.43	
		ALB	36.63±10.07	

Relationship between sTRAIL and the expression level of HBVmarkers

Our results indicated that the expression level of sTRAIL was positively correlated with the level of HBeAg ($r=0.3$,$P<0.05$), but it not with the level of HBsAg. The statistical analysis please referred to Table 3 and Table 4.

Table 3 Analysis of correlation between the expression of HBsAg and that of sTRAIL

Group divided by S/N	*n*	Expression of HBsAg(S/N)	Expression of sTRAIL in peripheral blood ($\times 10^{-9}$ μg/ml)

DISCUSSION

It was believed in the past that the HBV related liver damage was caused by hepatocytic necrosis. With the development of investigation methods, more and more researchers realized that

the hepatic dysfunction was caused by apoptosis rather than necrosis[1,12,13]. Many apoptosis inducing molecules have been found to participate in the progress. FasL was the first apoptosis inducing ligand found to play a role in apoptosis elicited by HBV. With the cloning and definition of TRAIL, it was found that many apoptosis reactions caused by combination of FasL were indeed induced by FasL and TRAIL, furthermore, TRAIL played a key role in many reactions[12-14].

FasL was proven to participate in the pathogenesis of HBV infection related disease[15-17], but it had not been elucidated whether TRAIL also played a role in the HBV infection related illness. Our results indicated that the expression level of soluble TRAIL in the circulating blood of the HBV infected patients was significantly higher than that of the healthy controls. In the patients whose livers were severely damaged,the expression level of sTRAIL was even higher, which suggested that sTRAIL might be activated by the HBV infection and played a role in the immune reaction elicited by HBV leading to liver damage.

It was reported that soluble TRAIL could induce massive and rapid apoptosis of the tumor cells at pmol concentration but spared the normal tissue cells. Soluble TRAIL may exert its function by binding with the death receptors in the liver cells after secreting into the circulating blood. TRAIL may act as an effective immune molecule after HBV infection, its mechanism may be explained in two ways. On the one hand, the HBV infected cells may be eliminated by the apoptosis inducing effect of sTRAIL; on the other hand, when the apoptosis reaction induced by sTRAIL is excessive, it may cause massive destruction of the liver tissue and lead to persistence of HBV infection related inflammation.

Our results indicated that sTRAIL was greatly upregulated in chronic hepatitis and was positively correlated with the liver damage. However, in cirrhotic and carcinoma patients, the level of sTRAIL fell somewhat. This indicated that the body immune surveillance would be activated after HBV infection, thereafter TRAIL and many other immune molecules could eliminate the virus from the body. On the other hand, HBV itself still replicates and become persistent in the body. The liver damage is caused mainly by the associated immunologic reaction rather than by the virus itself. It indicated that the immune reactions elicited by HBV would determine the outcome of the infection to a certain degree. Since TRAIL was an immune surveillant molecule widely expressed throughout the body, which probably participated in the HBV infection related immune reaction. Our results indicated that in case of chronic infection, liver damage was positively correlated with the expression of sTRAIL which suggested that sTRAIL may participate in the immune destruction elicited by HBV. This is the first report in the world concerning the role of the sTRAIL plays in HBV infection and only FasL was reported to have some effect on the HBV infection in the past[15-19].

To further analyze the mechanism of the upregulation of sTRAIL,secretion of HBsAg and HBeAg were detected. It showed that the expression of sTRAIL had no correlation with the secretion of HBsAg, but was positively correlated with the secretion of HBeAg. This suggested that HBeAg may play an even more important role in the activiation of TRAIL than HBsAg. HBeAg is a secreted nonparticulate version of hepatitis B core Ag (HBcAg), and its function is not completely known. It was reported that HBeAg may have an immunoregulatory function in promoting viral persistence[20-22]. Since HBeAg was reported to induce T-cell tolerance to HBV infected cells[21], we propose that the upregulation of sTRAIL correlated to the secretion of HBeAg maybe some immune regulation elicited to rectify the virus evasion caused by HBeAg.

HBV carrier also had an upregulated expression of sTRAIL compared with the healthy control, which indicated that the immune system of these HBV carrier was also activated though they had not yet shown any symptoms of the disease. If this activation did not break the balance between HBV replication and the immune destruction, the hepatitis virus would persist in the body for a long time. However, it also indicated that the HBV carrier already had slight or undetectable immune destruction before the appearance of clinical symptoms, they were at risk of developing into the chronic hepatitis. Once the balance between the viral replication and immune destruction being broken, hepatitis symptoms would appear.

It is the first report that HBV infection may activate the expression of sTRAIL and the HBV infected hepatocytes can be killed by the upregulated expression of sTRAIL. The inappropriate upregulation of sTRAIL can lead to the liver damage and the spreading of the virus.Our results indicated that the exprssion of sTRAIL could reflect the liver damage to a certain degree which may help estimate the status and prognosis of the disease.

Abstract

AIM: To investigate the prevalence of hepatitis G virus (HGV) infection and to analyse the homology of different HGV strains in Southern China.

METHODS: A total of 1993 sera from different groups in Guangdong, Hong Kong, and Yunnan were detected by reverse transcription polymerase chain reaction (RT-PCR). The nucleotide sequences of 5'untranslated region (5'UTR) derived from 20 strains and NS5 region from 3 strains were determined.

RESULTS: The positive rate of HGV RNA was 0.89 % in community population, 2.57 % in blood donors, 17.86 % in intravenous drug abusers, 14.13 % in patients with hemodialysis, 13.66 % in those with hepatocellular carcinoma, 25.30 % in non A-E hepatitis, 7.22 % in hepatitis B, 12.73 % in hepatitis C, 41.67 % in patients received bone marrow transplantation, respectively. The homology was 90.40-100 % in 5'UTR among different strains, while that of NS5 region was 93.3-94 % in nucleotide sequence, and 97-99.2 % in amino acid sequence.

CONCLUSION: These results showed that there was a high incidence of HGV infection in patients from Southern China, being treated for bone marrow transplantation, hepatocellular carcinoma and those on haemodialysis. Furthermore, there was also a high frequency of co-infection of HGV with HBV, HCV, non A-E viral hepatitis and that among intravenous drug abusers. The study also showed that sequence variation in different strains was associated with geographical factors but there was no significant difference in 5'UTR in circulating viruses between different patient groups. Finally, by sequential analysis of viral species present in individual patients over a three months period there was no evidence of sequence variation in the 5' UTR.

INTRODUCTION

Recently, a novel RNA virus of the Flaviviridae family has been identified by two groups of researchers working independently and designated as GBV-C or HGV[1,2]. These viruses are now considered to be different isolates of the same virus. The predominant route of transmission of HGV appears to be parenteral by contaminated blood and blood products although other routes, such as vertical transmission or through saliva may also exist[3-14]. HGV contains a positive-sense, single stranded RNA genome approximately 9.4kb in length that encodes a single long open reading frame (ORF) coding for two putative envelope proteins (E1 and E2), and several nonstructural proteins (NS1-NS5) (Figure 1). The coding region is flanked by a long 5' -untranslated region (5' UTR) and 3' -untranslated region (3' UTR). The putative core protein which has been described in related viruses such as HCV appears to be truncated or even absent in different isolates of HGV[15]. 1-3 % of healthy blood donors are infected with HGV in the USA and in Europe and HGV infection was found to be common in subjects with various forms of chronic liver disease[16,17]. It has been reported that HGV can be associated with either acute or persistent infection[18,19]. Some studies suggested the possibility of a link between fulminant hepatitis and HGV infection[20-22]. However, the clinical implications of HGV infection have not been clearly determined since the vast majority of infected individuals do not show liver injury[23-28]. In this report, HGV prevalence in Southern China was investigated using an RT-PCR-based survey of different patient populations. Furthermore, sequence analysis of some PCR products from the 5' UTR and NS5A regions allowed homology comparisons to be carried out for epidemiological analysis.

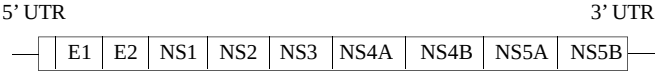

Figure 1 Structure of HGV genome

MATERIALS AND METHODS

Subjects

From 1994 to 1997, 1993 serum samples from 1991 subjects were obtained from Guangdong province, Yunnan province, and Hong Kong Special Administrative Region in Southern

China. These serum samples were stored at -70 ℃. Hepatitis C virus infection was confirmed by RT-PCR and enzyme-linked immunosorbent assay (ELISA, second-generation). Commercially available ELISAs were used for immunoglobulin M (IgM) antibodies to hepatitis A virus, for hepatitis B surface antigen (HBsAg) and antibodies to hepatitis B core antigen (HBcAb), hepatitis D virus and hepatitis E virus. Patients with hepatocellular carcinoma were histologically confirmed.

In 2 patients serial serum samples were collected 3 months after the first sample. In addition, 22 different samples derived from 20 subjects were analysed by nucleotide sequencing of either PCR fragments from the 5' UTR (19 patients), the NS5A region (2 patients) or both (1patient) (Table 1).

Table 1 Samples for sequencing

Sample	Sex	Age (yrs)	Origin	Diagnosis	Regions for sequencing
GD1	F	58	Guangdong	non A-E hepatitis	5'UTR

HK9 and HK12 were derived from the same patient after a 3-month interval; HK11 and HK116 were also from a patient after a 3-month interval

Detection of HGV RNA by reverse transcriptase-polymerase chain reaction

RNA was extracted from 100 μl of serum using a modification of the enzyme digestion and heat-denaturation method. The serum was added to 10 μl enzyme digestive mixture (Tris 10mM pH 7.8, EDTA 5mM, proteinase K 300 μg/ml) at 55 ℃ for 30 min and then 98 ℃ for 15 min. After centrifugation, 5 μl of supernatant were used for the synthesis of cDNA. The synthesis was performed at 42 ℃ for 45 min with 2.5U AMV reverse transcriptase (Promega) in a 10 μl reaction mixture containing 1×buffer,0.25mM dNTPs,8U RNAsin (Promega) and 100 ng specific antisense external primer (G2 or 36) (Table 2).

PCR amplification was performed using primers specific for 5' UTR and NS5A region (Table 2). The first-round PCR amplification of the cDNA was carried out in 20 μl of reaction mixture containing 5 μl of cDNA product, 1×PCR buffer (Promega), 1.5mM $MgCl_2$, 100pmoles of each sense and antisense external primers (G1 and G2, or 35 and 36), 20 μM each dNTP and 2U Taq DNA polymerase (Promega). PCR was performed for 30 cycles with the following reaction cycle: 94 ℃ for 40 secs, 55 ℃ for 40secs, 72 ℃ for 60secs (2 min for NS5A amplification). 5 μl of the first PCR product were subjected to a second amplification for 35 cycles under the same condition as for the first PCR, using sense and antisense inner primers (G3 and G4, or 33 and 34). The amplified products were visualized by 2 % agarose gel electrophoresis and ethidium bromide staining.

Table 2 Primers used in RT-PCR

Primer	Polarity	Position	Nucleotide sequence
G1	+	117-136	5' ATGCGTGATGACAGGGTTGG 3'
G2	-	451-471	5' TAGGTGGCCCCATGCATTTCC 3'
G3	+	161-180	5' GGTAGCCACTATAGGTGGGT 3'
G4	-	379-398	5' CACTGGTCCTTGTCAACTCG 3'
33	+	6672-6697	5' GTTGAATTCGCGATGGAGCGCTACAC 3'
34	-	7267-7292	5' CTGGGATCCGTATCATGTATGGTTCT 3'
35	+	6573-6592	5' TCGATTGCTGTAGCTGAGCC 3'
36	-	7327-7346	5' GGTAAGTTCATTGCCCACCA 3'

The numbering is identical to that of the PNF2161 strain of HGV[1].

Cloning of HGV NS5A PCR fragments

The PCR products of HGV NS5A were purified by phenol-chloroform extraction, precipitated by ethanol, dissolved in water and digested with EcoRI and BamHI (Boehringer Mannheim). The fragments were recovered from low melting point agarose gels and cloned into vector pUC19. Resulting recombinants were identified by enzyme-digestion and the same NS5A-specific second PCR procedure as that described above.

Sequence determination and homology analysis

The 238-base pair amplification products of HGV 5' UTR were directly sequenced by HGV 5' UTR-specific inner primers (G3 and G4), while the NS5A clones were sequenced using pUC19-specific primers hybridizing to sequences flanking the cloned fragment. The sequencing was performed using a double-strand DNA cycle sequencing system by the dye termination method in a ABI 310 automated DNA sequencer (Applied Biosystems Inc.). Nucleotides obtained and putative amino acid sequences were then compared with each other and with the published HGV prototype sequences by program DNASIS, program PROSIS and program Lasergene.

RESULTS

Prevalence of HGV in Southern China

Statistical analyses were performed using Fisher' s exact tests and a significance level was set at P=0.05. The prevalence of

HGV infection from different groups in Southern China was shown in Table 3.

The infectious rate of HGV in general population from Southern China is 0.89 %. The following groups were highly significantly different from both the blood donors and general population group: recipient of bone marrow transplantation, haemodialysis patients, intravenous drug abusers, patients with hepatocellular carcinoma, non A-E hepatitis, hepatitis B (P<0.0001), and hepatitis C (P<0.002). Patients with bone marrow transplantation had the highest carrier rate of 41 %, which was significantly higher than the other groups (P<0.05). The following groups were not significantly different from the blood donors or general population group: hepatitis B+A, hepatitis B+C, hepatitis B+E, hepatitis E (P>0.05). There was no significant difference between the blood donor and general population groups (P=0.054).

Table 3 Prevalence of HGV infection from different groups in Southern China

Group	cases	HGV RNA Positive cases(%)
Bone marrow transplantation	108	45(41.67)
Haemodialysis	92	13(14.13)
Intravenous drug users	84	15(17.86)

Nucleotide sequence of the 5'UTR from 20 HGV isolates

An alignment of the nucleotide sequence of the 5' UTR from the 20 HGV isolates we studied being presented in Figure 2. Sequence analysis demonstrated that the 5' UTR was highly conserved and the homology varied between 90.4 % and 100 % among different isolates from Southern China. We found that the 5' UTR of HGV consisted of highly conserved domains interspersed between variable domains. The most variable domain spans 38 nucleotides (positions 187 to 222). Molecular evolutionary phylogenetic tree was constructed to clarify the relationship among different HGV strains, using Clustal method with Weighted residue weight table.

Some highly conserved regions were observed, including No.223 to No.298, No.327 to No.345, No.349 to No.372, but relative diversity regions were also observed, such as the regions from No.187 to No.222, No.299 to No.306. Some isolates had 100 % identical sequence in 5' UTR, such as GD3040, GD3064 from Guangdong and HKC16, HK9, HK12, HK108 from Hong Kong.

Geographical variability was also demonstrated: greater homology was seen in strains obtained from Southern China, the homology was from 95 % to 100 % among Guangdong strains, 93 % to 100 % within Hong Kong strains, 94 % to 100 % between Guangdong and Hong Kong strains. While a lower level of homology compared to the strain from Northern China, which was 90 % to 94 % between Southern China and Northern China strains, with even lower homology when compared with those from other countries, which was 85 % to 92 % between Southern China and the reported prototype strains from USA and West Africa.

We also studied the HGV 5' UTR sequence in the same patients over a period of 3 months and observed no mutation, as shown in Figure 2. HK9 and HK12 were from one patient, HK11 and HK116 from another one.

Nucleotide sequence of partial NS5A region from 3 HGV isolates

Similar to 5' UTR, 621 base pair of NS5A region from 3 HGV isolates in Southern China are well conserved with the homology of 93.3-94.0 % (Figure 3). While a lower homology was seen when compared to those in USA and West Africa, which was from 87.3 % to 93.5 %. Different nucleotides were randomly distributed throughout the sequences and most mutations were silent, with the result of deduced amino acid homology of 97.9-98.9 % (Figure 4). The study also suggests that the variation may be associated with geographical factor.

DISCUSSION

We studied 1993 sera from 1991 patients with various forms of viral hepatitis, hepatocellular carcinoma, intravenous drug abusers, recipients of bone-marrow transplantation, blood donors and general population from 3 different regions in Southern China, including Guangdong, Hong Kong and Yunnan. HGV RNA was detected in as high as 41.67 % (45/108), 14.13 % (13/92), 17.86 % (15/84), 13.66 % (22/161), 12.73 % (7/55), 25.30 % (21/83) of patients with bone-marrow transplantation, hemodialysis, intravenous drug abusers, hepatocellular carcinoma, hepatitis C and non A-E hepatitis, respectively. It is noteworthy that nearly 42 % of recipients of bone-marrow transplantation were HGV RNA positive. This is understandable, because these patients have usually received many transfusions or blood products from a large number of donors. This also demonstrated the fact, that HGV was transmissible via blood transfusion[29].

13 (2.57 %) out of 506 blood donors were positive for HGV RNA, the difference of the positive rate from the general population (0.89 %) was statistically not significant. In addition, HGV RNA was found to be 7.22 % (19/263) among patients with hepatitis B, 6.90 % (2/29) among patients with hepatitis E, 6.25 % (1/16) among patients with coinfection of hepatitis B and hepatitis A, 16.67 % (1/6) among coinfection of hepatitis B and hepatitis C, and 11.54 % (3/26) among coinfection of hepatitis B and hepatitis E. Using Fisher' s exact tests to work out the exact P-values in situations where the number of positive cases was less than 5, the P-values obtained were dependent on the magnitude of the difference in prevalence of HGV infection between those groups, but also on the total number of cases in each group. Hence, although the prevalence of HGV infection was 16.7 % in hepatitis B+C group, we were not able to show it was different from either blood donors or the general population because the number was small (only 6 cases) in hepatitis B+C group. Same situations occurred in groups of hepatitis B+A, hepatitis B+E, and hepatitis E. However, the difference between hepatitis B and the general population was significant even though the prevalence of HGV infection was only 7.22 % because of large number of cases (263 cases) in hepatitis B group.

Figure 4 Comparison of deduced amino acid sequence of HGV A132 NS5 with the corresponding sequences from A711, GD3027 strains and C964, PNF2161, R10291, GBV-C isolates.

In this study we determined the nucleotide sequence of the 5' UTR spanned 238 nucleotides with positions 161 to 398 from 20 HGV isolates in Southern China. The data confirmed that the 5' UTR of the HGV genome was well conserved among HGV isolates from Southern China, with homology more than 90.4 %, even 100 % identical sequence in some strains, such as GD3040, GD3064, HKC16, HK9 and HK108. Phylogenetic analysis here supported the conclusion that sequence variation in different HGV strains was associated with geographical factors because greater homology was seen between the Southern China strains, while a lower homology when compared to the strains from Northern China, even lower homology was observed in comparison with those from other countries[30,31].

Partial sequences of NS5A gene region flanking positions 6672 to 7292 from 3 HGV strains were also determined. Nucleotide variations from each other were seen at 6.3 % to 7.1% scattered along the genome and most of them had not caused change in amino acid, which implied that this region might have a biological role.

Sequencing samples for 5' UTR were derived from different patient groups, including non A-E hepatitis, hepatitis B, hepatitis C, hepatocellular carcinoma, intravenous drug abusers, recipient of bone marrow transplantation and blood donor. However, no apparent variation in 5' UTR was found between different groups in Southern China, which suggested that the heterogeneity among different HGV isolates was not related to patient groups in the same geographical area.

HK9 and HK12 were from one patient over a period of three months, HK11 and HK116 from another patient in the same interval. The follow-up study of HGV 5' UTR sequence changes in the two patients with bone-marrow transplantation from Hong Kong suggested that the 5' UTR was not susceptible to mutations as frequently observed in other RNA viruses during a 3-month interval. However, this is only within a relatively short period and whether it has the potential to mutate over a longer period remains to be seen.

Abstract

AIM: To establish a simple and convenient assay *in vitro* for the Hepatitis C virus NS3 serine protease based on the recombinant protease and substrate, and to evaluate its feasibility in screening the enzyme inhibitors.

METHODS: Based on the crystallographic structure of hepatitis C virus (HCV) serine protease, a novel single-chain serine protease was designed, in which the central sequence of cofactor NS4A was linked to the N-terminus of NS3 serine protease domain via a flexible linker GSGS. The fusion gene was obtained by two-step PCR that was carried out with three primers and then cloned into the prokaryotic expression vector pQE30, and the recombinant clone was verified by DNA sequencing. The single-chain recombinant protease was expressed when the *E.coli* was induced with IPTG and the expression conditions were optimized to produce large amount of soluble protease. The recombinant substrate NS5ab that covers the cleavage point NS5A/B was also expressed in *E.coli.* Both of the protease and substrate were purified by using Ni-NTA agarose metal affinity resin, then they were mixed together in a specific buffer, and the mixture was analyzed by SDS-PAGE. The cleavage system was used to evaluate some compounds for their inhibitory activity on serine protease.

RESULTS: The single-chain recombinant protease was over-expressed as soluble protein when the *E.coli* was induced at a low dosage of IPTG (0.2 mM) and cultured at a low temperature (15 ℃). The protease was purified by using Ni-NTA agarose metal affinity resin (the purity is over 95 %). The recombinant substrate NS5ab was expressed in an insoluble form and could refold successfully after purification and dialysis. A simple and convenient assay *in vitro* was established, in which the purified single-chain serine protease could cleave the recombinant substrate NS5ab into two fragments that were visualized by SDS-PAGE. PMSF had an effect on inhibiting activity of serine protease, while EDTA had not.

CONCLUSION: A simple and convenient assay *in vitro* for hepatitis C virus NS3 serine protease is based on recombinant substrate NS5ab and single-chain serine protease. This assay can be used in screening of enzyme inhibitors.

INTRODUCTION

Hepatitis C virus (HCV) is a member of the *Flaviviridae* and now recognized as the major aetiological agent of post-transfusion non-A non-B hepatitis[1-3]. The viral genome is a 9.6-kb, positive-sense single-stranded RNA molecule that contains a single open reading frame encoding a polyprotein of 3010 to 3030 amino acids[4-6]. The polyprotein undergoes proteolytic processing by both host signal peptidases and viral proteases, giving rise to at least 10 mature proteins, and the cleavage of the 5 nonstructural proteins (NS3, NS4A, NS4B, NS5A and NS5B) were carried out by viral protease NS3/4A[7,8]. Since NS3/4A serine protease is very important for releasing functional proteins from the polyprotein, which are essential for replication and maturation of virus, it is currently being targeted in the development of drugs and diagnostics[9-11].

Previous studies indicate that the NS3/4A serine protease is a heterodimer formed by NS3 protein and its cofactor NS4A[12]. Analysis of the X-ray structures of the truncated NS3 protein complexed with the NS4A-derived peptide revealed that the serine protease domain adopts a chymotrypsin-like fold that means the NS3/4A is a member of chymotrypsin-like serine protease[13,14]. Although the protease domain of NS3 expressed without its cofactor is enzymatic active, its activity is partial and it can only recognize and cleave the NS5A/B site while the other two sites (NS4A/B and NS4B/5A) can not be cleaved[15,16]. That is, the NS4A enhances the cleavage at NS5A/B site and is absolutely required for cleavage at the NS4B/5A site[17,18]. In order to carry out detailed characterization of this enzyme and develop the antiviral agent, a reproducible and convenient large-scale production of the purified enzyme and its substrate is essential[19]. In this report, we constructed and over-expressed a novel single-chain serine protease in a soluble form in *E.coli*, and established a simple assay *in vitro* for HCV serine protease based on the recombinant substrate NS5ab and single-chain protease. In addition, we examined the effect of several well-known protease inhibitors by the established assay system.

MATERIALS AND METHODS

Materials

Prokaryotic expression vector pQE30, *E.coli* M15 cells and metal affinity chromatography resins (Ni-NTA agrose) were obtained from Qiagen Inc. (Chatsworth, California). Restriction

enzymes (BamHI and HindIII), T4 DNA ligase and Ex.Taq DNA polymerase were purchased from Takara Inc. (Dalian, Liaoning). PCR Pure® PCR purification kit were obtained from Clontech Inc. The prokaryotic expression plasmid pGEX-3X-NS3N that carries the gene of amino terminal 181 amino acids of HCV NS3 protein is a gift from Dr. Chen *et al*[20].

Methods

Construction of expression plasmids pQENS3N4A To generate fusion gene of $NS4A_{21-32}$-GSGS-$NS3_{3-181}$, three primers were designed. Primers P2 (5'-ATT ATT TTA TCT GGT AGT GGT AGT ATC ACG GCC TAC TCC CAA-3') and P3 (5'-CCC AAGCTT TTA GGA CCG CAT GGT AGT TTC-3') were used to amplify the $NS4A_{29-32}$-GSGS-$NS3_{3-181}$ using the plasmid pGEX-3X-NS3N as template. After that the PCR products were used as template to generate $NS4A_{21-32}$-GSGS-$NS3_{3-181}$ with primers P1 (5'-C GGATCC GGT TCT GTT GTT ATT GTT GGT AGA ATT ATT TTA TCT GGT-3') and P3. Underlined sequences represents HindIII and BamHI restriction sites, respectively. The highlighted sequences represents overlapping region of primers P1 and P2. The fusion gene $NS4A_{21-32}$-GSGS-$NS3_{3-181}$ contained the sequence encoding the NS4A peptide, GSVVIVGRIILS (NS4A a.a 21-32), the linker, glycine-serine-glycine-serine (GSGS)[21], and the NS3 a.a 3-181. The expression vector pQE30 and fusion gene were both digested with BamHI and HindIII, then they were ligated after purification. The resulting plasmid was used to transform competent *E.coli* M15 and the recombinant clones were selected on LB agar plates with ampicillin (100 mg/mL) and kanamycin (25 mg/mL), and identified by restriction enzyme mapping and sequencing. The resulting recombinant plasmid is termed as pQENS3N4A.

Construction of expression plasmids pQENS5ab To construct the expression plasmid pQENS5ab, a cDNA fragment encoding amino acid residues 2263-2498 in the HCV polyprotein was isolated from the serum of a healthy HCV carrier in China by nested PCR using appropriate oligonulceotides, (1: 5'-AGT (G/A)AT (C/T)CT GGA CTC TTT CG-3', 2: 5'-TGC TGG ATA GGT TCC TGA CGT-3', 3: 5'-TAT GGTACC GAG GA(C/T) GAG AGG GAA GTA TC-3', 4: 5'-TGC AAGCTT AAC TGT GGA CGC CT 3'), which was inserted a *KpnI* site at the 5'-end and *HindIII* site at the 3'-end of the sequence. The PCR product amplified using Ex. Taq (Takara) was cloned into expression plasmid pQE30 that was digested with *KpnI* and *HindIII*. The resulting plasmid pQENS5ab encodes the cleavage site of NS5A/B with a N-terminal 20 non-virus encoded amino acids possessing a consecutive stretch of 6 His residues, which allows fusion protein to be purified in a single step by metal chelating affinity chromatography. The cloned DNA fragment was sequenced in order to exclude the introduction of mutations by PCR and also to confirm the in-frameness of the insert.

Expression and purification of recombinant single-chain serine protease in *E.coli* A single clone from *E.coli* M15 transformed with the recombinant plasmid pQENS3N4A was used to initiate growth in Luria broth supplemented with 100 μg/mL ampicillin and 25 μg/mL kanamycin. When the absorbance reached a value of 0.8 OD_{600}, IPTG was added to give a final concentration of 0.2 mM and the incubation continued for additional 6 h at 20 ℃. Under this condition a high level expression of NS3N4A in a soluble form was observed. The cells were harvested by centrifugation and washed extensively with PBS (20 mM sodium phosphate; pH7.4,140 mM NaCl). The cell pellet was resuspended in lysis buffer (50 mM Tris· HCl; pH7.4, 10 % glycerol, 0.3M NaCl, 2 mM β-mercaptoethnol, 0.5 % NP-40) and disrupted by sonication on ice using sonifier (60s×10 strokes at 150W output with 30s intervals). The homogenate was centrifuged at 15000×g for 30 min to remove cell debris and was chromatographed on a nickel-agrose column (Qiagen). The column was washed extensively with 10 column volumes of lysis buffer and subsequently washed using 20 column volumes of buffer W (50 mM Tris· HCl; pH7.4, 10 % glycerol, 1M NaCl, 20 mM imidazole, 2mM β-mercaptoehanol, 0.5 % NP-40) and finally eluted with buffer E (50 mM Tris· HCl; pH7.4, 10 % glycerol, 1M NaCl, 250 mM imidazole,2mM β-mercaptoehanol, 0.5 % NP-40). Eluted fractions were subjected to SDS-PAGE and the pooled enzyme was dialyzed against buffer D (50 mM Tris· HCl; pH7.4, 10 % glycerol, 1M NaCl, 2mM β-mercaptoehanol, 0.5 % NP-40) to remove imidazole before stored in aliquots at -20℃.

Protein concentrations were estimated from UV absorbance at 280 nm and 260 nm and calculated according to the formula: concentration of protein (g/L)= $1.45 \times A_{280} - 0.74 \times A_{260}$.

Expression, purification and refolding of recombinant substrate NS5ab The transformed cells were grown at 37 ℃ in Luria broth supplemented with 100 μg/mL ampicillin and 25 μg/mL kanamycin. When cell density reached an OD_{600} of 0.8-1.0, induction was initiated by the addition of 1mM IPTG. Cells of 500 mL culture were harvested 5 hours after induction and resuspended in 10 mL lysis buffer (50 mM sodium phosphate; pH7.8, 300 mM NaCl). After disruption by sonication on ice, the inclusion bodies were collected by centrifugation at 12 000×g for 15 min and washed three times in the lysis buffer. The inclusion body was solubilized in 8M urea (50 mM sodium phosphate; pH8.0, 300 mM NaCl, 8M urea) and was chromatographed on a nickel-agrose column (Qiagen). The purification was performed according to the manual of Qiaexpressionist®. To refold the purified NS5ab protein, the protein was dialyzed against refolding buffer with a stepwise gradient of urea from 6M to 4M, 2M, 1M, 0.5M, 0.25M and finally to TBS (50 mM Tris· HCl; pH7.4, 140 mM NaCl). The concentration of substrate NS5ab was calculated according to the foregoing formula on the basis of UV absorbance at 280 nm and 260 nm.The purified recombinant substrate NS5ab was stored in aliquots at -20℃.

***In vitro* proteolytic assay for HCV NS3 serine protease** 20 μg of purified single-chain serine protease was incubated with 20 μg of recombinant substrate NS5ab in 100 μl of 25 mM Tris· HCl (pH7.4), 10 % glycerol, 0.5M NaCl, 10mM DTT and 0.5 % NP-40 at room temperature. After the reaction was terminated at various time points, there were mixed with same volume of 2×loading buffer and heated at 90 ℃ for 10 min, then analyzed by SDS-PAGE and stained with Coomassie brilliant blue R-250 (CBB R-250).

Effects of some known serine protease inhibitors In this assay, the single-chain serine protease was mixed with appropriate amount of PMSF or EDTA at room temperature for 30 min before they were incubated with recombinant substrate NS5ab to pursue the reaction. 45 min later, the reaction was terminated and analyzed with SDS-PAGE and CBB R-250.

RESULTS

Cloning and expression of recombinant single-chain serine protease

To produce a recombinant HCV NS3N4A protein complex with structural confirmation similar to its biological counterpart, an expression plasmid encoding HCV NS4A central peptide GSGVVIVGRILLS (NS4A a.a. 21-32)

covalently jointed to a NS3 N-terminal protease domain via an flexible amino acid linker GSGS was engineered[22]. The cDNA fragment encoding this single-chain protease was inserted into a pQE30 expression vector that provided additional six amino acids and six histidine residues at the amino terminus of the NS4A peptide (Figure 1). Induction of the bacteria harboring this expression plasmid with a low concentration of IPTG (0.2 mM) at low temperature (20 ℃) resulted in the production of a 23 kDa recombinant protein (Figure 2, lane 2). Much of the expressed recombinant protein existed in the soluble fraction of the bacterial lysate (Figure 2, lane 3). Further purification of the expressed protein using nickel-affinity chromatography yielded a product with greater than 95 % homogeneity as measured by SDS-PAGE and thin layer scanning assay (Figure 2, lane 5). Approximately 7.5 mg of protein was obtained from 500 ml culture following purification.

Cloning and expression of recombinant substrate NS5ab

To produce a recombinant substrate of HCV NS3 serine protease, the gene that encoding HCV NS5A C-terminal 157 amino acids residues, cleavage site of NS5A/B, and NS5B N-terminal 78 amino acids residues was isolated by nested RT-PCR from the serum of a healthy HCV carrier in China. The cDNA fragment was inserted into pQE30 expression vector that provided additional 20 amino acids residues (including six histidine residues) at the amino terminal of the viral peptide (Figure 1). Induction of the bacteria harboring expression plasmid pQENS5ab resulted in the production of recombinant protein of 35kDa (Figure 3, lane 2). The majority of the expressed recombinant protein existed in the insoluble fraction of the bacteria lysate. After purification of the recombinant protein NS5ab using nickel-affinity resin, the purified protein was refolded by dialysis method to produce soluble substrate with greater than 90 % homogeneity (Figure 3, lane 3). Approximately 7.6 mg of protein per liter of culture was obtained by following purification and refolding.

In vitro proteolytic assay for HCV NS3 serine protease

The soluble single-chain serine protease and soluble substrate NS5ab was incubated in a reaction buffer and then investigate whether the enzyme can process the substrate correctly and efficiently[23]. Figure 4 showed that the single-chain serine protease could cleave the substrate NS5ab into two fragments with molecular weight about 24kDa and 11kDa respectively. In addition, the amount of products increased and the substrate decreased along with reaction time (Figure 4, lane 1-5). That means the single-chain serine protease has highly active proteolytic activity and the substrate is active, too.

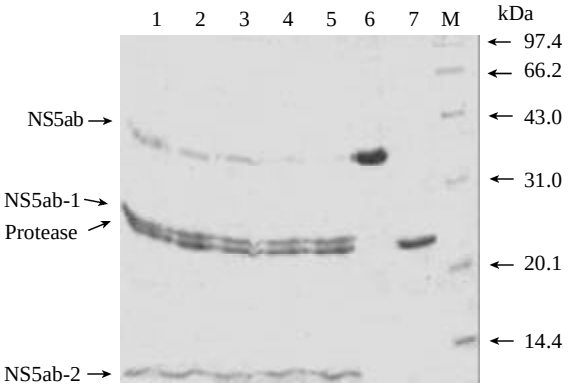

Figure 4 *In vitro* trans-cleavage at the NS5A / 5B site of single-chain serine protease. Lane 1-5, cleavage reaction after 10, 20, 30, 45 and 60 mins; lane 6, protein substrate NS5ab;lane 7, single-chain serine protease; M, low molecular weight markers.

Effects of some known serine protease inhibitors

The *in vitro* trans-cleavage assay system described made it possible to examine the effect of known serine protease inhibitors[24]. Two kinds of known proteinase inhibitors (PMSF and EDTA) were added to the reaction system and the effect visualized by SDS-PAGE and CBB R-250 staining. It was shown that the well-characterized inhibitor PMSF could inhibit

proteolytic activity at 5 mM *in vitro* (Figure 5, lane 4), while the metal chelator EDTA had no observable effect on the protease activity even at a concentration of 5mM (Figure 5, lane 6).

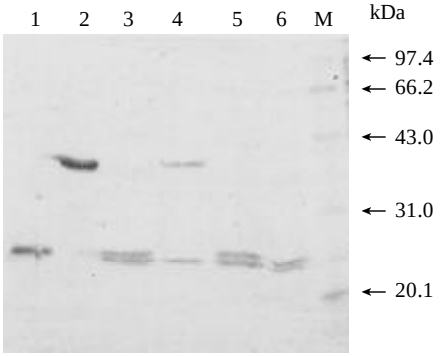

Figure 5 The inhibitory effects of PMSF and EDTA on single-chain protease activity. M, low molecular weight markers; lane1, single-chain serine protease; lane 2, protein substrate NS5ab; lane 3, without PMSF; lane 4, with 5 mmol/L PMSF; lane 5, without EDTA; lane 6, with 5 mmol/L EDTA.

DISCUSSION

This study aimed at establishing a simple *in vitro* assay for hepatitis C virus NS3 serine protease, since such an assay is the most important for screening specific antiviral inhibitors from combinatorial chemical library and random biological library[25-27]. To accomplish this object we have to obtain substantial amounts of purified NS3 serine protease with complete functional activity. Previous studies had shown that there are two methods to produce fully active HCV serine protease. The first method is to express full length $NS3_{1-631}$ which was fused to the N-terminal of $NS4A_{1-54}$ in eukaryotic cells[28], and the second one is to express protease domain in *E.coli* and mix them with excessive synthetic NS4A core peptide to form heterodimer[29]. Although the two methods work, there still are many shortages. The former can only provide little amount of protein and the enzymatic activity of protein produced by later method is very low[28,29]. According to Yan's report[30], the reason that poor activity of the heterodimer formed *in vitro* by synthetic peptide and protease domain lies in that the affinity of synthetic peptide is much lower than that of the full-length NS4A, which makes the complex is unstable. So it is reasonable to express the fusion protein of NS3 protease domain and NS4A in *E.coli*.

Inoue and his colleague[31] expressed NS3 protease fused at the amino terminal of NS4A in *E.coli*, which showed ideal stability and activity, but the products existed in inclusion bodies that lead to the poor productivity. In addition, the crystallographic structure of NS3 serine protease domain complexed with synthetic peptide indicated that it might be better for NS4A fused to amino terminal of NS3 protease domain[21,22]. Since the central part of NS4A is embedded in the cleft formed by NS3 protease domain and its C-terminus lies close to the amino terminus of NS3 (Figure 6A), it is reasonable to fuse the NS4A central peptide to amino terminal of NS3 via a flexible linker. This fusion format will change the natural intermolecular interaction to intramolecular interaction (Figure 6B), which will increase the stability of NS4A-NS3N complex. In this study, we constructed a single-chain serine protease that contained central peptide of NS4A fused to amino terminal of NS3 protease domain via GSGS linker, and it could process the recombinant substrate NS5ab efficiently.

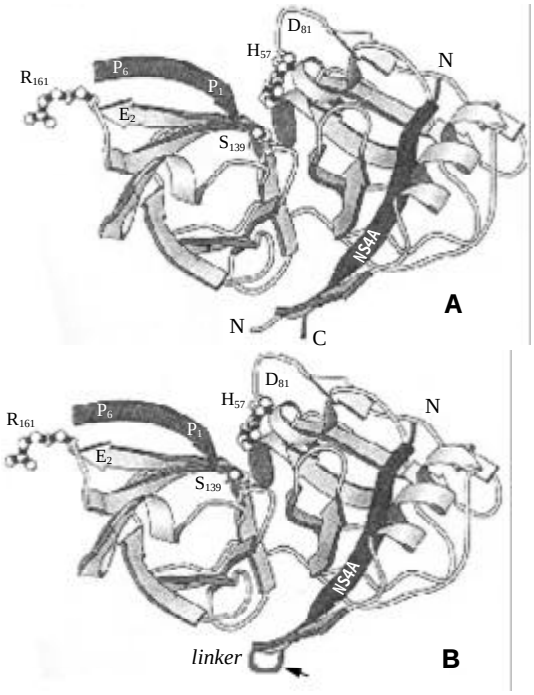

Figure 6 The crystal structure of serine protease domain and NS4A central sequence. A. cocrystal structure of the $NS3_{1-181}$ / $NS4A_{21-32}$ complex (adapted from reference 11). B. cocrystal structure of the $NS3_{1-181}$ / $NS4A_{21-32}$ complex with a flexible linker

The reason that single-chain serine protease can express in a soluble form at high level in *E.coli* lies in two points: 1) the low concentration of inducer and low temperature culture reduced the synthesis speed of peptide, which enhance the folding of protein[32-34]; 2) the central sequences of NS4A may increase the solubility of the single-chain serine protease. The NS3 domain was in various prokaryotic expression vectors with failures to produce soluble recombinant protein in this study, though various measures had been taken, such as lowering temperature and lowering concentration of IPTG (unpublished materials). In the same condition, the protease domain that fused to the C-terminal of NS4A central segment could express in a soluble form, which means that the central sequences of NS4A may increase the solubility of NS3 protease domain. Previous studies had confirmed that NS3 protease' s N-terminus would be changed from disorded structure to regular structure when it formed a complex with the NS4A peptide, that is why the NS4A central peptide is capable of promoting the folding of protein[35,36]. In addition, the NS4A central peptide is highly hydrophobic, which will reduce the synthesis of peptide in host and be beneficial to protein' s refolding[37].

Based on the recombinant single-chain protease and substrate protein NS5ab, we established a simple and cheap *in vitro* assay for HCV NS3 protease. In this assay system, the results were analyzed by SDS-PAGE and visualized by Coomassie brilliant blue R-250 staining (CBB R-250), which make it an attractive system because of its convenience, low cost and intuitiveness. To assess the applicability of this assay system in identification of serine protease inhibitors, we examined the effects of two known serine protease inhibitors on the activity of HCV protease. The results confirmed that the PMSF could inhibit the proteolytic activity of HCV serine protease completely at 5 mM, while the metal chelator EDTA had no observable effect on it, which had been observed by other researchers[38,39]. In conclusion, the *in vitro* assay

established here is applicable in evaluating the effect of chemical compounds and biological molecules on the activity of HCV serine protease. Furthermore, this assay can be used in high throughput screening of the potential inhibitors of HCV protease[40,41].

Abstract

AIM: p73, as a novel member of a family of p53-related transcription factors, shares redundant functions with p53, such as the abilities of inducing apoptosis and suppressing growth. It is well known that p53 can repress HBV expression and transcription efficiently. The aim of this paper is to investigate the transcriptional effect of p73α and p73β on hepatitis B virus (HBV) and to understand the correlation between HBV and p73.

METHODS: To construct an x-gene inactivated HBV plasmid which was cotransfected with p73α or p73β expression vectors into HepG2 cells. After transiently transfection, HBV surface antigen (HBsAg) and HBV e antigen (HBeAg) were detected by ELISA. Viral transcripts synthesized by HBV were evaluated by Northern blotting analysis. The activities of HBV regulatory elements, including enhancer I/X promoter (ENI/Xp) and enhancer II/core promoter (ENII/Cp) were monitored by luciferase assays.

RESULTS: Both p73α and p73β could repress HBsAg and HBeAg expression by downregulating the ENI/Xp and ENII/Cp activities. But p73β exerted stronger inhibition on the activity of ENI/Xp than p73α, resulting in much lower level of viral transcripts and the antigens expression.

CONCLUSION: p73β as a novel member of p53 family can efficiently inhibit HBV transcription mainly through downregulating the activities of the HBV ENI/Xp regulatory elements.

INTRODUCTION

p73 gene maps to chromosome 1p36.1, a region which was frequently deleted in several tumors, including neuroblastoma, colorectal cancer and breast cancer[1]. Moreover, it has been found to share significant homology with the tumor suppressor gene p53 within the transactivation domain, DNA binding domain and oligomerization domain. Both p53 and p73 have redundant functions in the regulation of gene expression, because they have amino acid sequence identity reaching to 63 % in the DNA binding domain[2]. p73 can activate p53-regulated genes and suppress growth or induce apoptosis, and expression of p73 can be induced by DNA damage as p53 does[3,4]. Although deletion of p73 gene is observed in neuroblastoma and a subtype of T-cell lymphoma, it is rarely mutated in human cancer[5-9], unlike p53 which is mutated in about 50 % of human cancers[5,7,10-12]. Other evidence suggests that p73 is important for regulation of normal development[13]. p73 gene is expressed as p73α, a 636 amino acid polypeptide, and p73β, a 499 amino acid polypeptide that is encoded by an alternatively spliced transcript lacking 96 nucleotides corresponding to exon 13[1]. Until now, at least six different p73 proteins (α-ζ) have been found[14].

Hepatitis B virus[15-17] is a causative agent of chronic hepatitis and hepatocellular carcinoma. Upon infection or DNA transfection, four major viral transcripts are detected. The largest 3.5 kb mRNA is composed of precore and pregenomic mRNA, that direct the synthesis of HBV e antigen (HBeAg) and HBV core antigen (HBcAg) respectively. Pregenomic RNA also serves as a template for reverse-transcription to synthesize the viral DNA genome. The largest surface antigen is synthesized from 2.4 kb mRNA, and the middle and major surface antigen are synthesized from 2.1 kb mRNA. The smallest transcript is a 0.7 kb mRNA, which is responsible for HBx protein production[18]. The transcription of these RNAs are governed by the core, S1, S2 and X promoters, respectively. The activities of these promoters are under the control of enhancer I and II[19].

In addition to a function as a tumor suppressor, p53 can defend host cell from the invading virus. p53 actively inhibits viral replication as in the case of SV40 and HBV[20,21]. p53 binds to a sequence adjacent to the replication origin of SV40 and abrogates the helicase activity of T antigen by directly binding to it. It has been reported that p53 can bind specifically to the HBV enhancer I and repress the activity of enhancer I and X promoter, resulting in HBV gene expression downregulated[22]. In addition, p53 can interfere with the life cycle of HBV through down-regulation of the enhancer II and pregenomic/core promoter. Although p53 can not directly bind the enhancer II, it represses the transcriptional activity of HBV through protein-protein interaction[23].

p73, as a novel member of a family of p53-related transcription factors, has attracted more attention during these years. However the relationship between p73 and the hepatitis B virus is not elucidated. Based on the similarity between p53 and p73, we examined whether p73, mainly p73α and p73β, can affect HBV antigens expression and the viral transcription.

MATERIALS AND METHODS

Construction of plasmid

p3.8II, kindly provided by Prof. Wang Yuan, is an HBV plasmid which contains terminally redundant HBV genome

and can replicate in liver cell. The x-gene inactivated p3.8IIXm was constructed by changing the start condon of the X open reading frame on p3.8II. The pENI/XpLuc and pENII/CpLuc reporter plasmids were constructed by inserting nt1067-1403 and nt1430-1879 which contain enhancer I/X promoter and enhancer II/core promoter respectively in front of the pGL3 basic vector (Promega). The mammalian expression vectors pcDNA3-HA-73α and pcDNA3-HA-73β encode epitope tagged p73 proteins which were kind gifts from Dr. Lu Hua. p53 expression plasmid pRC/CMV hp53 was provided by Dr. Judith Roth. All the constructs were confirmed by restriction enzyme analysis and DNA sequencing.

Cell culture and transfection

HepG2 cells were cultured in DMEM supplemented with kanamycin (250 IU/ml), gentamycin (40 IU/ml) and 10 % fetal calf serum in 5 % CO_2 at 37 ℃. Transfection was carried out by the calcium phosphate method[24]. Each transfection reaction contained a constant amount of 10 μg DNA per 6 cm dish.

Preparation of cell lysate and measurement of HBV antigens

Five days after transfection, cells were washed twice with PBS and were detached from dishes with 10 mM EDTA in PBS. After centrifugation (5 000 rpm, 1 min), cells were resuspended in 100 μl 250 mM Tris-HCl (pH7.5) and lysed by three thawing and freezing cycles. After centrifugation, the supernatant was transferred and stored at 4 ℃. The protein concentration was estimated by Bradford method (Biocolor). Culture medium was collected every day after transfection. HBsAg and HBeAg were measured with ELISA kits (Sino-America). All procedures were performed according to the descriptions of the manufacturers.

RNA analysis

Total RNA was extracted from transfected cells using TRIzol reagent (Gibco BRL). The RNA samples were treated with RNase-free DNaseI (Pharmacia). For Northern blotting analysis, 20 μg of total cellular RNA per sample was separated on 1 % formaldehyde-agarose gel and blotted to a Hybond-N nylon membrane (Amersham). The membrane was prehybridized in Quick-Hyb buffer (Amersham) for at least 1 hour, followed by 2 hr hybridization at 65 ℃ with the probes of α-^{32}p-dCTP labeled 3.2 kb HBV DNA and G3PDH fragments. After hybridization, the membrane was washed in 2 %SSC, 0.1 %SDS buffer (RT, 20 min), 0.2 % SSC, 0.1 %SDS (65 ℃,30 min), then exposed to an X-ray film at -70 ℃.

Luciferase assay

Cells were lysed and analyzed with a luciferase assay system (Promega). Corrections of the luciferase activity were made based on the protein concentrations of the lysates. The luciferase activity was measured with a Lumat LB9507 luminometer (Berthold) in 10 μl of the lysate after addition of 100 μl assay reagent.

RESULTS

p73β represses HBsAg and HBeAg expression more efficiently than p73α

Before investigating whether p73 could affect HBV transcription like p53, we established the X protein-minus HBV mutant p3.8IIXm to avoid the interaction between p73 and the HBV X protein. This HBV mutant had no ATG start codon of the X-ORF (Figure1). ELISA results revealed that the HBV antigens expression in mutant type of p3.8IIXm was just a half of that in wild type p3.8II.

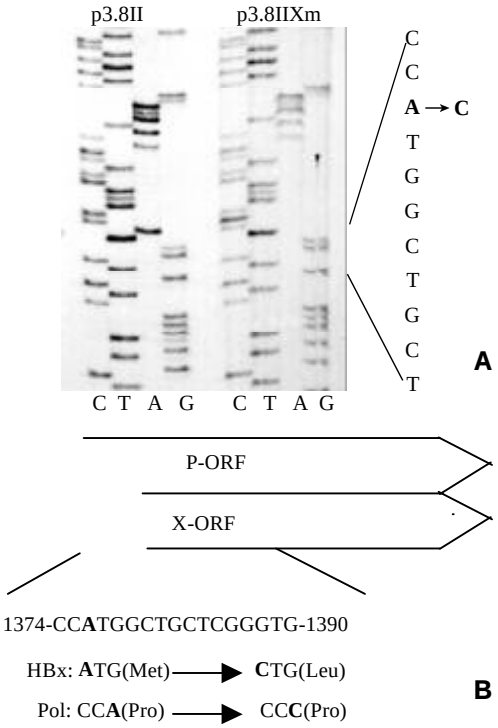

Figure 1 Partial DNA sequences of p3.8II and p3.8IIXm is indicated in the left panel (A). The point mutation A→C results in the amino acid changes in the ORF of HBV polymerase (P) and X protein(X) (B).

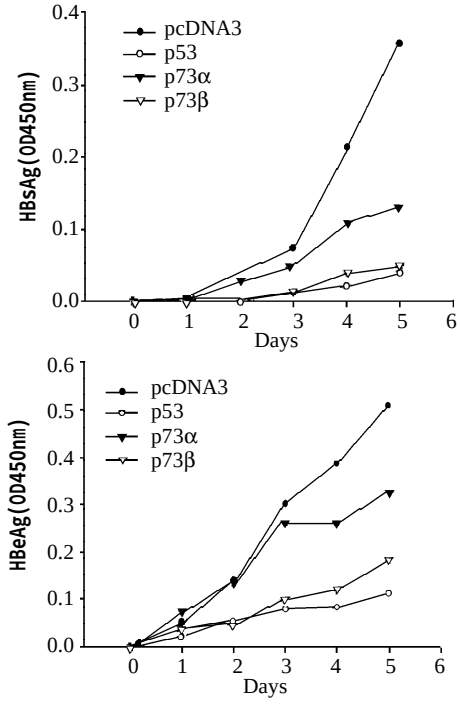

Figure 2 Time course of HBV antigen expression. HepG2 cells were transiently transfected with X-minus p3.8IIXm, and cotransfected with pcDNA3, p53, p73α, or p73β individually. Culture medium were harvested at certain days, and detected by ELISA kit.

As shown in Figure2A, P3.8IIXm could secret HBsAg into the medium continuously starting from day 2. Cotransfection of p3.8IIXm with p73β expression plasmid resulted in a reduced level of HBsAg (87 % reduction on day 5 post transfection), which was similar to p53 (89 % reduction on

day 5 post transfection). Cotransfection of p3.8IIXm with p73α expression plasmid exhibited weak repression on HBsAg synthesis (only 63 % reduction on day 5 post transfection). The time-dependent alteration in the level of HBeAg (Figure2B) displayed a similar pattern to that of HBsAg. On day 5 post transfection, the expression of HBeAg was changed at the level of 36 % reduction for p73α and 64 % reduction for p73β. Also as shown in Figure2B, p53 could inhibit HBeAg more efficiently (78 % reduction on day 5 post transfection) than p73α and p73β. It is concluded that both p73α and p73β can downregulate HBV expression including HBsAg and HBeAg, but p73β can repress the HBV antigens expression more efficiently than p73α.

p73b can repress the synthesis of viral transcripts including pregenomic/precore RNA and preS/S RNA

The roles of p73α and p73β in viral transcription were assessed at the HBV RNA levels after cotransfection of p3.8IIXm and p73 expression plasmids. Using Northern blot hybridization with ^{32}P-labeled 3.2 kb HBV fragment as a probe, we detected the pregenomic RNA and precore RNA as well as preS/S mRNA. As Figure 3 shown, cotransfection of p73β resulted in the reduction of the viral transcript level like p53, but p73α seems to exhibit very weak repression on HBV transcription. These results are in accordance with the above ELISA data.

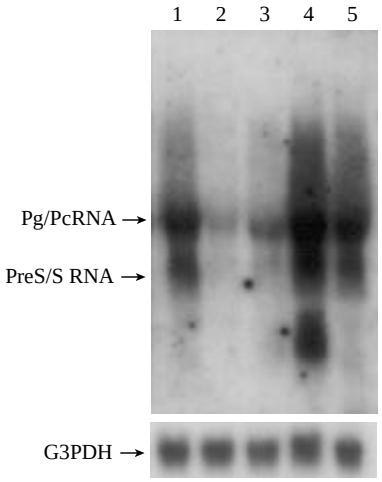

Figure 3 Northern blotting analysis of HBV viral transcripts, including pregenomic/precore RNA and preS/S RNA. HepG2 cells were transiently transfected with p3.8IIXm, and also with the expression plasmids. Lane 1 represents pcDNA3, lane 2, p53, lane 3, p73β, lane 4, pHBX and lane 5, p73α respecitively. Total cellular RNA were extacted and α-^{32}p-dCTP labeled 3.2 kb HBV DNA or G3PDH used as probe.

p73b inhibits HBV transcription mainly through downregulating the activity of HBV ENI/Xp regulatory elements

To explain the molecular mechanism of the p73β mediated repression of HBV transcription, we investigated the possibility of p73 regulating the enhancer and promoter activity. pENI/Xp reporter plasmid containing HBV enhancer I and X promoter was cotransfected into HepG2 cells with p73α and p73β expression plasmids, and the levels of luciferase activity were determined. As shown in Figure 4A, the luciferase activity of the pENI/Xp was decreased with transfection of p73β and p73α, down to 65 % and 35 % of the control value respectively. Therefore, p73β can repress the activity of enhancer I and X promoter more efficiently than p73α. The activity of HBV enhancer II and core promoter were repressed by p73α and p73β at a similar level, but the effects of inhibition were weaker than that by p53 (Figure 4B). Therefore, it is concluded that p73β represses HBV gene expression mainly through the enhancer I and X promoter.

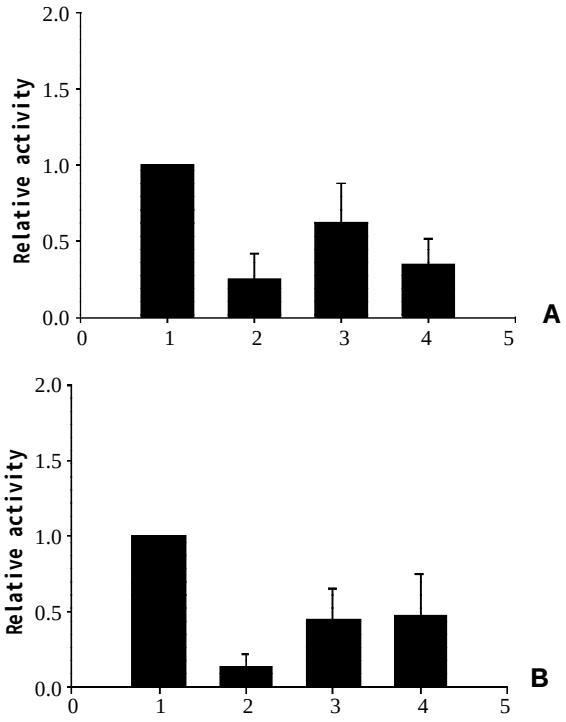

Figure 4 Effects of p73α and p73β on the regulatory sequences of hepatitis B virus. HepG2 cells were transfected with expression plasmids, pcDNA3(1), p53(2), p73α (3), and p73β (4). In each case, 1 μg of reporter plasmids, pENI/XpLuc, containing the enhancer I/X promoter (**A**) and pENII/CpLuc, containing enhancer II/core promoter (**B**), were individually cotransfected. 42 hours after transfection, the cells were harvested and luciferase activity was determined. The value obtained with reporters alone was arbitrarily set to 100 %, and the other values were normalized accordingly. The column heights reflect the average of at least three independent experiments.

DISCUSSION

HBV, an important risk factor of hepatitis and hepatocellular carcinoma, employs a reverse transcription step which is controlled by cellular transcription factors and some cellular signal transduction pathways, including the tumor suppressor gene p53[25,26]. Physiologically activated p53 can repress HBV transcription, and this repression can be abrogated by physiological levels of HBx protein. It is generally believed that p53 can interact with HBx, and the latter destroys p53 function, including the repression of virus transcription. To exclude the interaction between p73 and the X protein, we constructed the X-minus HBV strain p3.8IIXm which could replicate in hepatoma cells without producing X protein.

HBsAg and HBeAg are translated from preS/S mRNA and precore mRNA individually. HBV core promoter is in charge of the transcription of pregenomic RNA as well as precore mRNA. ENI and ENII are the two enhancers in the viral genome. ENI is usually able to upregulate all the HBV promoters, and ENII has a particularly significant stimulatory effect upon the core promoter. In this report, we found that p73β repressed HBsAg and HBeAg expression more efficiently, and it inhibited the viral transcripts level mainly through downregulating the enhancer I and X promoter. In the ENI/Xp construct, there were two sites with homology to

the 10 bp half-consence (RRRCWWGYYY) for p53 binding, which had been reported to bind specifically to the HBV enhancer I and repress its activity[22]. Liver-specific enhancer II had also been found to be the target for the p53-mediated inhibition of hepatitis B viral gene expression. p53 could not directly bind to the enhancer II, and it repressed the ENII activity through protein-protein interaction[23]. p73 protein has significant homology with p53, and p73 can interact with the consensus p53-responsive sequences. But that whether the mechanism of repression on enhancer of HBV by p73 and p53 is the same awaits further investigation. In our results, p73α exerted a very weak repression on HBV transcription and antigen expression, while Doitsh *et al* reported that p73β did not repress but activated HBV transcription[27], probably due to the high dose of the protein we used in this study.

It was noted that p73 was less active than p53, whereas p73β displayed stronger transcriptional activity than p73α. The difference between p73α and p73β in the potential to regulate transcription may be due to the ability of these proteins to form oligomers. p73β is the truncated form of full-length p73α. While p73β is known to oligomerize with itself efficiently, p73α forms oligomers with a poor efficiency, at least when assayed in the yeast two-hybrid system[2]. Therefore it can be used to explain why p73β exerts more efficient inhibition on HBV transcription than p73α.

Although p73β has been found to interfere with the HBV transcription in this report, whether HBV can inactivate the function of p73 to affect the viral-infected cell fate, and the relationship between the X protein and p73β remain to be investigated.

ACKNOWLEDGEMENTS

The authors would like to thank Prof. Wang Yuan for providing p3.8II plasmid, Dr. Lu Hua for pcDNA3-HA-p73α, pcDNA3-HA-p73β, and Dr. Vogelstein for the pRC/CMV-p53.

Abstract

AIM: To prepare poly (D,L-lactide)-polyethylene glycol copolymer (PELA) microspheres loaded *H.pylori* lysates or *Cystografin* and observe their targeting in gastrointestinal mucous membrane or analyze the mucosal immune responses by oral administration.

METHODS: PELA microspheres loaded *H.pylori* lysates or *Cystografin* were prepared by double emulsion evaporation method. Their distribution in gastrointestinal mucous membrane was observed by CT.Balb/c mice orally immunized in mucosal immune responses, whose antibody production in salivary and gut washing and antibody secreting cells in Peyer's patches (PP) were estimated by ELISA and ELISPOT, respectively. The microspheres' physical properties, such as particle size, protein level and morphology were investigated.

RESULTS: All prepared microspheres were found to have a smooth surface morphology from 3.20-4.05 μm in diameter and high encapsulation efficiency from 74.9-82.2 %. No significant correlation in their physical properties was shown, depending on their molecular weight at the similar composition ratio. Immunization with all types of PELA-*Hp* microspheres elevated the saliva sIgA level at week 3 by approximately 3-4 times that with soluble antigen, which was greatly enhanced after boosting. At one week after last immunization with all types of PELA-*Hp* microspheres (week 8), the specific sIgA-ASCs, IgG-ASCs and sIgA in salivary rose obviously. In intestinal Peyer's patches, the specific sIgA-ASCs were 5.92-6.98$\times 10^4$/ml cell and IgG-ASCs were 3.47-4.02$\times 10^4$/ml cell, about 5-9 times higher than those with soluble antigen ($P<0.01$). ASCs in intestine were more than those in stomach and the majority of the ASCs were sIgA-ASCs. The sIgA in gut washing fluid was 1.62-1.85 OD, about 3-6 times tthat of those with soluble antigen. There were significant differences of the ASCs and sIgA in gut washing fluid as compared with those of PBS and MS-0 ($P<0.05$). There appeared to be good correlation between sIgA level in gut washing fluid and sIgA-ASCs in intestinal Peyer's patches.

CONCLUSION: PELA microspheres may be used as vehicle to delivery antigen and adjuvant in designing oral vaccination.

INTRODUCTION

Helicobacter pylori (*Hp*) is a major pathogen causing type B gastritis, peptic ulcer and mucosa-associated lymphoid tissue gastric lymphoma[1-12]. A triple antimicrobial therapy is often adopted for patients with infection[13-16], for *Hp* reinfection easily occurs and the drug resistance strains are increasing, therefore, antimicrobial treatment may be ineffective in prevention of reinfection[17-21]. Oral immunization is considered a convenient and safe method to induce mucosal immunity against infection. This has become a focus topic among the researchers[22-26].

The biodegradable and biocompatible microsphere as a vaccine delivery vehicle has many advantages[26]. The biodegradable polyesters (including polylactic acid (PLA), polyglycolic acid (PGA) and their copolymers (PLGA)) had been widely studied and used in biomedical engineering[27-30]. For hydrophobicity of the PLA and the PLGA, this type of material is usually not desirable for protein and peptide. Their degraded products, lactic acids or glycolic acids will create a local acidic environment that may be harmful to the surrounding tissues[31]. These microspheres loaded vaccines can be rapidly captured by phagocyte in the reticulo-endothelial system, while the microspheres (nanospheres) prepared with PLA-PEG-PLA (type A-B-A) triblock copolymers, which was produced by copolymerization of hydrophilic polyethylene glycol with lactide, showed longer circulating half life of the proteins *in vivo*[32]. They can overcome the disadvantages of the PLA or PLGA microspheres as drug vehicle.

MATERIALS AND METHODS

Bacterial culture

*Hp*971023, *Hp*980706, *HpM* bacterial strains were isolated by our laboratory. The strains were inoculated onto blood plat in the microaerobic cultivation at 37 ℃ for 48 h. The organisms were washed 3 times with 0.15 mol/L phosphate buffered saline (PBS, pH7.4) and were harvested by centrifugation at 5 000rpm for 10 minutes at 4 ℃. The resulting suspensions was added to 0.15 mol/L PBS(pH7.4), EDTA 0.65 g/L and phenylmethylsufonyl fluoride (PMSF) 1 mmol/L and sonicated (200W$\times$30s$\times$10 times). The *Hp* lysate was collected by centrifugation at 12 000 rpm for 20 minutes. The protein concentration was determined by UV spectrophotometer (Beckman DU-640, USA).

Preparation of the PELA microspheres loaded Hp

PELA (weight ratio of D, L-lactide to PEG-2000, 95:5; the inherent viscosity of the PELA ranged from 0.1271 to 0.3329 dL/g measured in tetrahydrofuran at 25 ℃) was synthesized

according to procedures described in literature[32]. The PELA microspheres loaded *Hp* were manufactured using double emulsion evaporation method as described[32,33]. One ml aqueous solution mixed 4 % *Hp* lysate (inter-water phase) was emulsified with 10 ml of 6 % (w/v) PELA in methylene chloride using T25B homogenizer (USA) at 8 000 rpm for 5 min (w/o), After homogenization, 30 ml aqueous solution of 2 % PVA (degree of polymerization n = 1 500-1 800) was added to the primary water-in oil (w/o) emulsion and the stirring was continued further for 5 min. The resulting w/o/w suspensions were stirred magnetically at 1 200 rpm for 10-12 h at room temperature (over 25℃) to evaporate the solvent. The microspheres were obtained by centrifugation and washed three to eight times with distilled water. The cleaned microspheres were lyophilized and stored at 4 ℃ under desiccation. If the aqueous solution mixed *Hp* lysate (inter-water phase) was replaced by pure water or some concentration of *cystografin*, the blank PELA microspheres and PELA-*cystografin* microspheres can be obtained respectively. The amount of protein loaded in the PELA microspheres was determined by dissolving a fixed amount of microspheres in methylene chloride, the protein content was measured with UV spectrophotometer (Beckman DU-640, USA). The protein loading efficiency was calculated directly by recovering the protein from the microspheres[34].

Measurement of microsphere size and morphology

The mean size of microspheres and distribution were calculated using a LeitzDiaplan light microscope (Wild MPS52, Japan) to measure the diameter of microspheres, whose amount was no less than 200. The surface structure of micropheres was examined by scanning electron microscopy (AMRAY, USA-China).

PELA-cystografin microspheres targeting

Miniture pigs (*sus scorfa domestica*) weighing 15-20 kg were used in the study. PELA-*cystografin* microspheres (mean diameter of 3.72 μm, the amount of *cystografin* loaded was about 16 %) were suspended in 7.5 % sodium bicarbonate solution and 100 ml suspension (10 g PELA-*cystografin* microspheres) was orally administered by intubation feeding to miniture pigs. After 0, 3, 8 and 15 days, the distribution of PELA-*cystografin* microspheres in the all gastrointestinal tract was observed by CT. The pigs were killed and the images of all gastrointestinal tract were taken after being washed up.

Immunization procedures

BALB/c mice (female, 6-8 weeks old, and 18-25 g in weight) were offered by our experimental animal center. Mice were randomly assigned to one of the seven immunization groups (twenty mice per group). Before administration, mice stopped feeding for 2 h and then took orally 0.5 ml mixture of the Hanks' equilibration salt and 7.5 % sodium bicarbonate solution (4:1 ratio) in order to neutralize gastric acid fluids. Each experimental group was orally immunized on week 0, 1 and 2. The immunized mice were given a booster immunization on week 7 with the same agents as the primary immunization. The first four groups were immunized by oral administration with different PELA-*Hp* microspheres (that is MS-1, MS-2, MS-3 and MS-4 group, 1mg *Hp* per mouse). The fifth group, sixth and seventh group of mice received free 1 mg of souble *Hp* lysate antigen, PBS solution or blank PELA microspheres under similar conditions, respectively. One week after the last immunizations (week 8), mice were killed and assayed by indirect ELISA and ELISPOT.

Detection of ASCs in lymphocytes from intestine and gastric mucosa

Peyer' s patches (PP) in intestine and gastric mucosa were selected[35] and placed into 0.5 ml 5 % FCS RPMI-1640 medium. The tissues were ground and recovered on 70 μm cell strainer. The recovered tissues were harvested by centrifugation at 1 500rpm for 15 minutes and washed two times to collect suspensions, which were added 15 ml 70 % Percoll medium and centrifuged at 1500rpm for 15 minutes. Cell pellets are resuspended in 0.5 ml RPMI-1640 medium to form 5×10^5/ml. The cell suspensions were stained with 2 % trypan blue. The cell viability and purity were assessed. The ELISPOT assay[36] was used to detect ASCs in the intestine and gastric tissues of the mice. Briefly, 96-well (Millipore) were coated with 0.2 ml *H. pylori* sonicate preparations dissolved in 0.05 mol/L sodium bicarbonate solution (50 μg protein per well) and left overnight at 4 ℃. After washed three times in PBS, well plates were saturated with 2 % BSA (100 μl per well) and incubated at 37 ℃ for 1 hour. The plates were washed once in RPMI-1640 and each well was added 0.2 ml 5×10^5/ml of the cell suspensions.

The cells were incubated at 37 ℃ in 10 % CO_2 for 4 hours. The plates were washed three times in PBS-Tween and then added 100 μl biotinylated monoclonal IgA or IgG antibodies to specific mouse , which had been diluted 1:1500 and 1:2000 in 10 % FCS-PBS, respectively. The plates were incubated at 37 ℃ for 2 hours. After three washes, the avidinperoxidase solution, diluted 1:2 000 in PBS, was incubated at 37℃ for 30 minutes. After three washes in PBS-Tween, 100 μl substrate solution (containing 7.5 % gelatin, 1 g/L 3,3', 5,5'-tetramethylbenzidine (TMB), 0.03 % H_2O_2) was added to each well. The reaction was coagulated quickly in ice-water bath. After 10-30 minutes, the immunospots were counted under inverted microscope (Olymps, Tokyo, Japan). The number of ASC was the mean number of immunospots deducting the mean number of each contrast.

Assay of saliva sIgA and gut sIgA by ELISA

Saliva was collected from immunized mice[37]. Gut washing fluids was collected after the last immunization one week (week 8). Each well was coated with 100 μl of *H. pylori* lasate solution at concentration of 50 μg/ml in 0.05 mol/L sodium carbonate-bicarbonate buffer (pH 9.6) overnight at 4 ℃. After suction and three washes in PBS-Tween, 100 μl of 2 % BSA solution in PBS was added to each well and further incubated for 1hour at 37 ℃. The initial dilution of sample (saliva and gut washing fluids) was 1:20. 100 μl diluted samples was added to wells and incubated for 1hour at 37 ℃. After three washes in PBS-Tween, 100 μl of biotinylated goat anti-mouse IgA incubated for 1hour at 37 ℃. After washing three times with PBS-Tween, 100 μl of the avidinperoxidase solution was added and incubated for 1 hour at 37 ℃. Then washed and added 100 μl substrate solution. The plates were incubated for 20 minutes at 37 ℃. The reaction was stopped by addition of 100 μl of 0.5 mol/L hydrochloric acid, and the color development was measured by plate reader set at 405 nm.

Statistical analysis

Data were analyzed using Student' s t test. Results were expressed as mean±standard error. Differences were considered significant for values $P<0.05$.

RESULTS

Properties and morphology of PELA-Hp microspheres

The properties of PELA-*Hp* microspheres prepared with

different inherent viscosity of PELA (ranged from 0.1271-0.3329 dL/g) are shown in Table 1. The properties of microspheres were examined under light microscope in particle size and by UV spectrophotometer in protein loading and encapsulation efficiency. The morphology of microspheres was examined under scanning electron microscopy. The morphology of MS-2 is shown Figure 1.

Table 1 The properties of the PELA-*Hp* microspheres

Lot	PELA[η] (dL / g)*	Mean dimeter(μm)	Protein loading (%,w / w)	Encapsulation efficiency (%,w / w)
MS-1	0.1271	3.87	5.06	77.6
MS-2	0.2083	3.20	5.53	82.2
MS-3	0.3054	3.53	5.40	74.9
MS-4	0.3329	4.05	5.27	79.5

*The inherent viscosity of PELA is measured in tetrahydrofuran at 25 ℃.

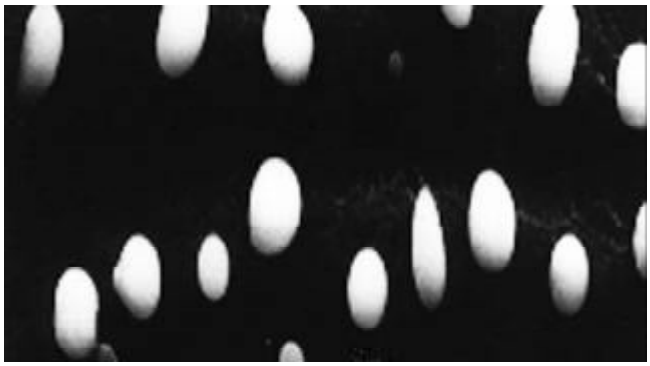

Figure 1 Scanning electron micrographs of MS-2 loaded *Hp*.

PELA-cystografin microsphere targeting

The images of the miniature pig by oral administration with PELA-cy*stografin* microsphere were observed by CT. The experiment could indirectly obtain the distribution of PELA microsphere in all gastrointestinal tract as time (day). The results suggested that PELA-*cystografin* microsphere mainly was distributed in the gastric cavity and at the surface of gastric mucosa after oral administration for three days. Then part of the microspheres gradually moved to enter the intestine by the stomach peristalsis and adhered to their surface (images not shown). After 15 days, the microspheres were found mainly distributed at the surface of intestine. The images are shown Figure 2.

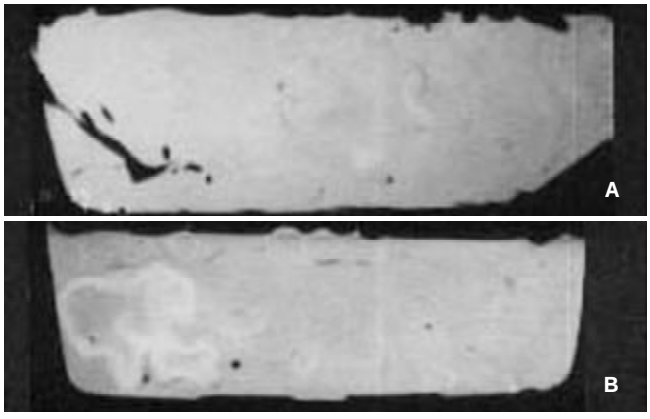

Figure 2 Images of pig stomach and gut after oral administration. (a) blank PELA microsphere; (b) PELA-*cystografin* microsphere.

Mucosal immune responses of orally immunized PELA-Hp microspheres

Saliva sIgA responses after oral immunization with soluble antigen, PELA-*Hp* microspheres with different inherent viscosities of PELA (ranged from 0.1271 to 0.3329 dL/g) were measured at week 3, week 5 and week 8 (Table 2). Immunization with soluble antigen induced weak saliva IgA antibodies. Immunization with all types of PELA-*Hp* microspheres elevated saliva sIgA level at week 3 (approximately 3-4 times higher than those with soluble antigen) and greatly enhanced after boosting (week 8). The changes of saliva sIgA at different stages after oral immunization related to the properties of PELA.

Table 2 Comparison of sIgA titres in saliva at different stages after oral immunization ($\bar{x}\pm s$)

Groups	Week 3	Week 5	Week 8

DISCUSSION

The relationship between the properties of PELA-*Hp* microspheres and molecular weight of PELA copolymer are shown Table 1. All types of PELA-*Hp* microspheres prepared with the same component PELA, whose protein loading, encapsulation efficiency and size were 5.06-5.40 %, 74.9-82.2 % and 3.20-4.05 μm, respectively, were not significantly different This confirmed the previous investigations[38]. Morphology of PELA microspheres using double emulsion evaporation method were investigated under sanning electron microscopy. The obtained microspheres were all spherical, homogeneous particles and had smooth surface (as shown in Figure 1). The results coincided with the report of SY Kim *et al*[39], while Kofler *et al*[40] reported that the microspheres were

porous particles with a rough surface. This is likely that different processing and manufacturing conditions of microspheres (such as o/$w_{out\text{-}water\ phase}$, $w_{inter\text{-}water\ phase}$ /o, stirring velocity, temperature etc), which result in morphologies of microspheres.

The images of the miniature pigs by oral administration of PELA-*cystografin* microspheres are shown in Figure 2. This indirectly clarified the conclusion arrived by Eldridge *et al*[41], which was that microspheres (mean diameter <10 μm) after oral administration firstly adhered to the surface of the gastrointestinal mucous membrane, then arrived at their Peyer' s patches (PP) to induce mucosal and systemic immune responses. Therefore, our obtained microspheres (mean diameter <5 μm) could induce mucosal and systemic immune responses by particle uptake into the PP. After oral administration, all types of PELA-*Hp* microspheres (week 8), the specific sIgA-ASCs, IgG-ASCs and sIgA in gut washing fluids obviously rose by ELISA and ELISPOT. The specific sIgA-ASCs and IgG-ASCs were approximately 5-9 times that with soluble antigen. ASCs in the intestine were more than those in stomach, and the majority of the ASCs were sIgA-ASCs. This result indicated that there appeared to be a good correlation between sIgA level in gut washing fluid and sIgA-ASCs in intestinal PP. The sIgA in gut washing fluid was about 3-6 times higher than those with soluble antigen (as shown in Table 3), that is very important for oral immunization to effectively induce mucosal immune response and protect against *Hp* infection[21,35]. The protein release of PELA-*Hp* microspheres was influenced by several parameters including PELA copolymer molecular weight, diameter, the ratio of lactide/PEG and the manufacturing technology. Immunization with all types of PELA-*Hp* microspheres elevated the saliva sIgA level at week 3 (approximately 3-4 times higher than those with soluble antigen) and greatly enhanced after boosting (week 8) (Table 2). At the same components of PELA (feed ratio of lactide/PEG=95:5 in this study), after oral immunization for 3 weeks, mice with PELA-*Hp* microspheres prepared with lower molecular weight of PELA , the saliva sIgA level became higher than the mice with PELA-*Hp* microspheres prepared with higher molecular weight of PELA. However, after oral immunization for 8 weeks, there was no differences in antibody production level between those formulations. This result can be explained as follows: the initial burst release of *Hp* was bigger from PELA-*Hp* microspheres prepared with lower molecular weight PELA, meanwhile because low molecular weight of PELA was degraded easily and can not effectively protect *Hp* release from microspheres ($t_{1/2}$ was short)[36], this means that mice orally immunized with PELA-*Hp* microspheres prepared with lower molecular weight PELA induced stronger mucosal and systemic immune responses after oral immunization in earlier stages. All types of PELA-*Hp* microspheres (η=0.1271-0.3329 dL/g PELA, 1-2 month degradation *in vitro*) were degraded fully and released encapsulated antigens at week 8 irrespective of differences of copolymer molecular weights. We also found in this study that antigen release from microspheres can be controlled and accommodated by dictating the component and molecular weight of polymer. This will play an important role in designing oral vaccines for the protection against diseases in the future.

Abstract

AIM: To explore the association between *Helicobacter pylori* (*Hp*) infection and risk of gastric cancer in China.

METHODS: Utilizing gastroendoscopic biospsy tissue banks accumulated from1980 to1988 in Shandong, Zhejiang, and Jiangsu, where stomach cancer incidence was high, during stomach cancer screening conducted by Health Science Center of Peking University, School of Medicine of Zhejiang University, and Zhongshan Hospital of Fudan University. Warthin Starry silver staining method was applied to determine *H. pylori* infection status of biopsies collected during gastroendoscopic examination. In the retrospective study, the subjects were divided into two cohorts, the exposure cohort was positive *H. pylori* infection, and the non-exposure cohort was negative. Death from stomach cancer was determined as the outcome of the study. Logistic regression and Cox regression were applied to analyze the association between *Helicobacter pylori* infection and gastric cancer risk. In the nested case-control study, there were 28 deaths from gastric cancer in the fields of Muping, Shandong province, and Zhoushan, Zhejiang provinces. 4 controls were matched to each case on the basis of age (±5 years old), sex, residential place at the same time entered into the study. Conditional logistic regression analysis was used to analyze the data.

RESULTS: There were a total of 2 719 subjects (male 1 399, female 1 320) with gastroendoscopic biopsies stored available treated as a cohort. *H. pylori* positive cohort included 1 671 subjects (61.5 %) and *H. pylori* negative cohort 1 048 subjects(38.5 %). These subjects were followed up for 1-19 years, averaged 10.88 years. The outcome of death from stomach cancer in the exposure cohort was 33, and in the non-exposure cohort 11. After adjustment for age and sex, RR=1.9850 (P=0.0491), 95 % CI was 1.0026, and 3.9301. The results of conditional logistic regression showed an OR of 4.467 and 95 % CI of 1.161, and 17.190 for the nested case control study.

CONCLUSION: The results from the retrospective cohort study and the nested-case control study on the association of *H. pylori* infection and gastric cancer in China suggested that *Helicobacter pylori* infection might increase the risk of stomach cancer.

Wang RT, Wang T, Chen K, Wang JY, Zhang JP, Lin SR, Zhu YM, Zhang WM, Cao YX, Zhu CW, Yu H, Cong YJ, Zheng S, Wu BQ. *Helicobacter pylori* infection and gastric cancer: evidence from a retrospective cohort study and nested case-control study in China. *World J Gastroenterol* 2002; 8(6):1103-1107

INTRODUCTION

Large volume of literature on the association of *H. pylori* infection and gastric cancer has been published since Warren and Marshall first isolated *Helicobacter pylori* from human gastric mucosa in 1983[1]. The first compelling evidence linking *H. pylori* infection to gastric cancer was obtained from seroepidemiologic studies using nested case-control study design in the United States and Britain[2-4]. Although there were discrepancy among epidemiological studies[5-22], some meta-analyses indicated the magnitude of the association *H. pylori* infection and risk of gastric cancer was ORs=2-6[23-27]. Most of the studies based on serological data; the status of whether the *H. pylori* harbored in gastric mucosa at the time of sample collection was uncertain and it only indicated past infection of *H. pylori*. Using the *H. pylori* detected by microscopy from biopsy had some limitations because only several specimens were taken during endoscopy underwent, which might lead to underestimation. However, the bacilli found under microscope might reveal actual status of *H. pylori* harbored in the gastric mucosa. Under the support of foundation of Chinese Medical Board of New York Inc., Health Science Center of Peking University, Medical School of Zhejiang University and Zhongshan Hospital of Fudan University cooperated in the study of the association of *H. pylori* infection and gastric cancer. The subjects of *H. pylori* infection was positive when there were bacilli found under the microscope, the outcome of the study was gastric cancer death. A nested case-control design was carried out using gastric cancer death from Muping, Shandong province and Zhoushan, Zhejiang province where most of the subjects resided in the rural areas.

MATERIALS AND METHODS

Field of investigation

The field of Health Science Center of Peking University is Gaoling town in Muping County of Yantai City of Shandong province (short for Muping below), the mortality rate of gastric cancer was averaging 40/100 000 population during the last two decades. Screening and early diagnosis program were undertaken for those over 35 years old in 1987 and 1988. 2200 subjects' biopsies were taken and underwent histopathological diagnosis The field of School of Medicine of Zhejiang University is Daishan county in Zhoushan archipelago of Zhejiang Province (short for Zhoushan below), the mortality rate of gastric cancer was about 50/100 000 population, gastric cancer screening had been conducted and gastroendoscopy and histological diagnosis had been done on about 1800 subjects from 1980 to 1983. The field of Zhongshan Hospital of Fudan University is Changzhou city in Jiangsu province (short for Changzhou below), the mortality rate of gastric cancer was about 40/100 000 population, gastroendoscopy had been carried out in 1500 subjects.

Pathological and laboratory examination criteria

The histologic sections stained by H&E was according to the National Gastric Cancer Prevention Study Pathological Diagnostic Criteria, and gastric cancer was confirmed by pathological diagnosis. The *H. pylori* infection was determined by histologic assessment. Warthin Starry silver staining was applied to the histologic section of endoscopic biopsies and to determine the status of *H. pylori* infection of the subjects. The diagnostic criteria followed the Criteria for diagnosis on histologic sections on the first meeting of experts when an agreement was reached in April 1999[28].

Subjects of retrospective cohort study

Biopsies were available for histologic sections and Warrthin Starry silver staining from Muping, Zhoushan and Changzhou comprised the cohort. There were 1055, 875 and 793 subjects' biopsies available, respectively. The pathologic diagnosis was retrieved according to the record of diagnosis, and gastric cancer patients were excluded either for those diagnosed at the time of screening or diagnosed within one year after screening program. The histologic assessment of *H. pylori* infection was conducted by pathologists well trained on diagnosing *H. pylori* infection with Warrthin Starry silver staining slides. The exposure cohort was *H. pylori* infection positive after the histologic section assessment, and the non-exposure cohort was negative.

Subjects of nested case-control study

The cases were those who died from gastric cancer during the following period after the screening program and met the criteria set forth above in Muping and Zhoushan. For each case of gastric cancer death, we matched 4 controls on the basis of age (not ±5years), sex, date of biopsy specimen sampling and residential place, who were gastric cancer-free at the end of 1999.

Questionnaire survey

All subjects whose biopsies for histologic assessment were given a questionnaire interview, which included demographic data, family history of gastric cancer, life style such as smoking habit etc., and diagnosis and treatment of *H. pylori* infection in the past. The interviewers were village doctors trained on the interviewing skills. The interviews started from 1998 to the end of 1999. The subjects died and those who could not answer the questions while interviewing, was helped by their relatives familiar with them.

Statistical analysis

A database was established by the EPI info package, was put in according to standard procedure after the questionnaires evaluation and met the requirements. The SPSS package was used to conduct logistic regression analysis of the cohort and the Egret package (A Commercial System for Advanced Epidemiologic Statistics 1999) was applied to conduct Cox regression analysis of the survival data of the cohort, conditional logistic regression was used to compute the asymptotic ORs for the nested case control data.

RESULTS

General information of the cohort

The total subjects of the cohort were 2 719. There were 1 055 subjects from Muping, 875 subjects from Zhoushan and 793 subjects form Changzhou.

1 399 (51.5 %) subjects were male, and 1 320 (48.5 %) female. 1 671 (61.5 %) subjects were *H. pylori* positive; 1 048 (38.5 %) were *H. pylori* negative. Table 1 listed the general information of the three cohorts.

Table 1 The general information of the *H. pylori* positive and *H. pylori* negative cohorts

	H. pylori positive cohort	*H. pylori* negative cohort	Total	*P*
Gender (male/female)	1671(881/790)*	1048(520/528)	2719 (1399/1320)	>0.05
Muping	675(424/251)	380(239/141)		=1.000
Zhoushan	501(285/216)	370(183/187)		=0.033*
Changzhou	495(172/323)	298(98/200)		=0.643
Age (<50, 50-60, ≥60)	1671 (604,505,562)	1048 (366,310,372)	2719 (970,815,934)	>0.05
Muping	675(216,189,270)	380(102,110,168)		0.082,0.096
Zhoushan	501(221,138,142)	370(142,109,119)		0.097,0.224
Changzhou	495(167,178,150)	298(112,91,85)		0.108,0.131
Economic Status (well,poor)	1612 (1513,99)	1007 (949,58)	2619 (2462,157)	>0.05 (0.719-0.734)
Smoking (yes, no)	1610 (877,733)	1006 (566,450)	2616 (1433,1183)	>0.05 (0.123-1.0)
Alcohol drinking (yes, no)	1610 (624,986)	1006 (384,622)	2616 (1008,1608)	>0.05 (0.07-0.814)
Family history of gastric cancer (yes, no)	1670 (167,1503)	1046 (98,948)	2716 (265,2451)	>0.05 (0.277-0.948)

*The number in the parenthesis indicated the relevant number of each category defined in the first column.

Average follow-up duration of the subjects (Table 2)

Table 2 Follow-up duration of the cohort

Fields	*n*	Average follow-up duration(yrs)	Standard devisiom
Muping	1055	11.1496	2.8798
Zhoushan	871	14.1883	2.5603
Changzhou	793	6.5596	2.1343
Total	2719	10.8805	4.0358

There were 2 719 subjects' biopsies available for histologic assessment of *H. pylori* infection in the three fields where the prevalence rate of gastric cancer was high in China and were followed up to observe the outcome. The average follow-up duration was 10.88 years.

Number of gastric cancer deaths observed in cohort

The number of gastric cancer deaths observed in each field in *H. pylori* positive and *H. pylori* negative cohorts was listed in Table 3.

Table 3 The distribution of gastric cancer deaths observed in the follow-up period of the cohorts

Field	*H. pylori* positive cohort		*H. pylori* positive cohort		Total	
	n	No. of gastric cancer death	*n*	No. of gastric cancer death	*n*	No. of gastric cancer death
Muping	675	9	380	3	1055	12
Zhoushan	501	10	370	6	871	16
Changzhou	495	14	298	2	793	16
Total	1671	33	1048	11	2719	44

There were 1 671 subjects in the exposure cohort and 1 048 subjects in the non-exposure cohort, 33 and 11 cases respectively died from gastric cancer during the follow-up period.

The results of cohort study

The average age of gastric cancer death cases of the *H. pylori* positive and *H. pylori* negative cohorts was 60.41 and 69.18, respectively. The *t* test showed that there was significant difference between the two cohorts (t=2.494, P=0.017). The results of logistic regression analysis of association of *H. pylori* infection and gastric cancer death of different age groups were shown in Table 4. The results of Cox regression analysis was shown in Table 5.

Table 4 Result of logistic regression analysis of different age groups

Variables	OR	95 %
<50 years old	4.601	1.885,11.229
50-60 years old	1.916	0.961,3.822
⩾60 years old	Do not convergence	

Table 5 The results of Cox regression analysis with adjustment of age and sex

Variable	β	S.E	Wald	df	*P*	RR	95%CI	
							lower	upper
H. pylori	0.6856	0.3485	3.8705	1	0.0491	1.9850	1.0026	3.9301
Age	0.9062	0.5005	3.2773	1	0.0702	2.4748	0.9278	6.6010
Sex	-0.3237	0.3203	1.0215	1	0.3122	0.7234	0.3861	1.3554

The RR=1.9850, P=0.0491, 95 % CI is 1.0026 to 3.9301 for exposure of *H. pylori* infection cohort to non-exposure cohort with adjustment of age and sex.

The cumulative hazard function for positive and negative *H. pylori* infection and gastric cancer death adjusted age and sex was shown in Figure 1: a higher hazard for subjects with positive *H. pylori* infection, the difference was statistically different.

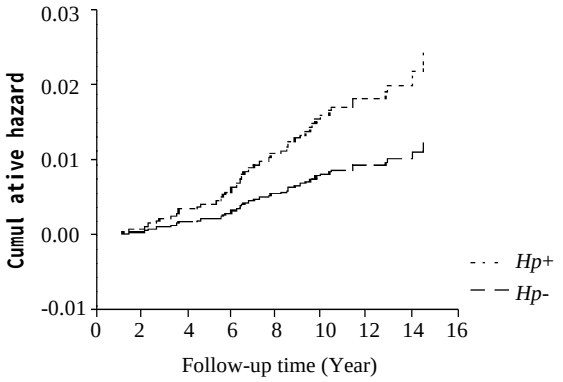

Figure 1 Cumulative hazard funtion for subjects with positive and negative *H. pylori* infection

The results of nested case-control study

The total number of gastric cancer death within the cohort of Muping and Zhoushan was 28, and 21 were male, 7 female. The average age of the subjects of cases and controls was 65.89 and 65.21, and the statistical analysis showed no difference between the two cohorts.

After univariate analysis, the result of multivariate analysis with adjustment of potential confounding factors was shown in Table 6.

Table 6 The result of conditional logistic analysis of *H. pylori* and gastric cancer risk

	β	P	OR	95% CI (lower)	95% CI(upper)
H. pylori infection	1.497	0.0295	4.467	1.1610	17.1900

Wash hands before meals	-1.896	0.0241	0.150	0.0289	0.7798
Like to eat smoked food	0.913	0.2102	2.492	0.5974	10.3900
Lower vegetables intake	0.5153	0.4542	1.674	0.4342	6.4550
Smoking	5.808	0.0037	332.800	6.5840	1.683e+004
Older age started to smoke	-0.145	0.0137	0.865	0.7707	0.9707
Lower fruits intake	-0.524	0.4836	0.592	0.1367	2.5660
History of upper addominal pain	0.678	0.3027	1.970	0.5425	7.1530

After adjusted some potential confounding factors, it showed that *H. pylori* infection was significantly associated with gastric cancer death, the OR was 4.467, 95 % CI was 161-17.19, P<0.05.

DISCUSSION

The aim of this study was to explore the association between *H. pylori* infection and gastric cancer risk. The average follow up duration was 10.8 years. The results of retrospective analysis showed that the risk of death from gastric cancer in the *H. pylori*

positive cohort was 1.985 times to *H. pylori* negative cohort (95 % CI (1.0026, 3.9301)); the results of the nested case-control showed the association between *H. pylori* infection and gastric cancer risk increased after adjustment of some potential confounding factor, the OR was 4.467, 95 % CI was 1.161 to 17.190. The result suggested that the *H. pylori* infection was associated with gastric cancer death. The results were in accordance with those retrospective and nested case control studies[2-4,10,12,14,18,19, 21,22] and meta-analyses of *H. pylori* infection and gastric cancer risk published recently[23-27]. It was also similar to the magnitude of association between *H. pylori* infection and non-cardia gastric cancer 2.29[29] in Linxian of China reported by Limburg *et al* in a nested case control study and the results of Hansen *et al*[14]. The average age of gastric death in the *H. pylori* infection cohort was younger than that of negative cohort, the difference was statistically significant, the ORs of different age groups were in favor of that *H. pylori* infection was risk factor for the young[10,30,31]. Because the carcinogenesis of gastric cancer was of multiple stages and multiple factors involvement, *H. pylori* infection is not an independent risk factors on the carcinogenesis of gastric cancer. The prevalence of *H. pylori* infection is high in developing counties, only a small proportion of people infected with the bacteria develop gastric cancer. The biological mechanism of gastric carcinogenesis remains unclear. Our results suggested that *H. pylori* infection played different role at different ages of life.

The gastric cancer death in this study was those histologically confirmed cases and excluding those followed after gastroendoscopic screening within one year in each field and cardia gastric cancer, all these limitations might strengthen the virtual epidemiological evidence generated by this study.

There are several methods to determine the *H. pylori* infection of the stomach; the sensitivity and specificity are approximate[32-34]. The application of these methods would render different results' false negative results in different population[7,13,33,34], and the use of multiple tests may help to provide a more accurate diagnosis of *H. pylori* infection[35]. Although the seroconversion rate was a bit lower[36,37]. The loss of *H. pylori* infection may occur earlier in those using serological assessment of *H. pylori* infection than using histological assessment of *H. pylori* infection, because sera *H. pylori* IgG can be detected after the eradication of *H. pylori*. Histologic assessment of biopsies was more reliable and with less information bias. The data of this study was a combined analysis in high gastric cancer prevalence areas in China. The recent mortality rate of gastric cancer was about 40-50/100 000 persons by screening and early diagnostic program carried out in the three regions and the biopsies reserved made such a study feasible. Although the subjects screened could not represent the natural population and some biopsies used by other studies, there might be selection bias, which could result some bias in the estimation the association between *H. pylori* infection and gastric cancer risk. Since strict quality control and the confounding factors controlled during the analysis were conducted, the chance of misclassification of diagnosis and exposure was minimized, and the overall result was reliable.

Although we had provided evidence for positive association between *H. pylori* infection and gastric cancer risk based on histologic assessment of *H. pylori* infection by limited cohort subjects, it needs to expand the study in a natural population to minimize the selection bias. The association between *H. pylori Cag A* positive strain, which is considered more virulent than others, and gastric cancer should be further investigated. More convincing evidence of *H. pylori* infection and gastric cancer risk would be gained by *H. pylori* eradication interventional study.

Abstract

AIM: To investigate the pathogenic mechanism of Hirschsprung's disease (HD) at the molecular level and to elucidate the relationship between RET oncogene and Chinese patients with HD.

METHODS: Exon 13 of RET oncogene from 20 unrelated HD patients was analyzed with polymerase chain reaction-single strand conformation polymorphism (PCR-SSCP). The positive amplifying products were then sequenced. According to the results of SSCP and DNA sequence, SSCP was done as well for the samples from the family other members of some cases with mutated RET gene.

RESULTS: SSCP analysis indicated that mobility abnormality existed in 4 unrelated HD patients. Direct DNA sequence analysis identified a missense mutation, T to G at the nucleotide 18 888 and a frameshift mutation at the nucleotide 18 926 insG. In a HD family, the sicked child and his father were the same heterozygous missense mutation (T to G at nucleotide 18 888).

CONCLUSION: Among Chinese HD patients, RET gene mutations may exist in considerable proportion with different patterns. These new discoveries indicate that RET mutations may play an important role in the pathogenesis of unrelated HD in the Chinese population. PCR-SSCP combined with DNA sequence can be used as a tool in the genetic diagnosis of HD.

INTRODUCTION

Hirschsprung's disease (HD), with the incidence of 1/5 000, occupies the second in the congenital malformation, manifests as complete or incomplete ileus clinically[1-5]. As a complex disease, HD has been ascribed to the absence in the terminal hindgut of ganglion cells from the neural crest, which causes the abnormal contraction of involved intestines, and then the proximal end of the sick colon appears compensatory dilated thickness and forms megacolon. However, the reason for the deficit of ganglion cells remains in dispute[5]. With the development of the molecular biology, the molecular pathogenesis of HD have attracted the attention of many scholars. In 1993, Genetic mapping in multiplex families and the mutational analysis of candidate genes have led to the definitive identification of the defects that contribute to the HD risk. It has been found that the gene defects present in a major proportion of Hirschsprung's disease families are mutations in chromosome 10q11.2, which have now been found to be associated with RET gene[6-9]. Subsequently, various kinds of mutation of RET gene have been reported abroad[10-19]. However, there existed less reports about HD in Chinese population. In order to further investigate the pathogenic mechanism of HD, we examined exon 13 mutations of RET gene in 20 unrelated patients with the single strand conformation ploymorphism analysis of polymerase chain reaction products (PCR-SSCP).

MATERIALS AND METHODS

Case selection and extraction of DNA

Twenty unrelated cases with HD by pathological verification were collected after operation at Zhejiang Children's Hospital during 1998 to 2000. Four milliliters of peripheral blood samples used for the experiment were obtained from each patient and the control blood samples were taken from anonymous donors provided by Zhejiang Children's Hospital. The blood samples were anti-coagulated by sodium citrate and DNA was extracted according to the standard protocols.

PCR amplification

The designed primers were synthesized by Shanghai Shenggong Biology Company. The primer sequence of exon 13: (Forward) 5'-GACCTGGTATGGTCATGGA-3', (Reverse) 5'-AAGAGGGAGAACAGGGCTGTA-3'. The PCR mixture contained 200 ng of template-DNA and PCR reaction buffer containing 50 mmol/L KCl, 10 mmol/L Tris-HCl (pH 8.4), 1.5 mmol/L $MgCl_2$, 0.5 μmol/L each of two fragment-specific primers, 100 μmol/L each of dATP, dGTP, dTTP and dCTP, and 2 units of Taq DNA polymerase (provided by Shanghai Shenggong Biology Company) for a reaction volume of 50 μl. The conditions for temperature cycling for all PCR amplifications were 94 ℃ for 5 min for pre-denaturation, 94 ℃ for 45 second, 58 ℃ for 45 second and 72 ℃ for 45 second. Amplifications were carried out for 30 cycles with a final extension for 10 min at 72 ℃. The amplified fragments were run in 1 % agarose gel, and were confirmed to be 253bp in size using 100-bp ladder markers.

SSCP analysis

SSCP analysis of fragments was performed on a Mini

Electrophoresis Unit (Bio-Rad Company, U.S.A). 10 ul of the PCR product was diluted with 10 ul of sample buffer containing 90 % formamide, 0.05 % Bromphenol Blue dye and 0.05 % xylene cyanol. The samples were heated at 100 ℃ for 8 min, transferred into an ice-cold water bath for 3 min, and analysed by 8 % PAGE in 45 mM-Tris-borate (pH8.0)/1mM-EDTA (TBE) buffer under 13 v· cm^{-1} at 10 ℃.

DNA silver staining

Gels were stained with silver as follows: fixed in 100 ml· L^{-1} alcohol for 10 min→oxidized in 100 ml· L^{-1} nitric acid for 3 min→drip washed for 1 min with double distilled water→ stained in 2 g· L^{-1} silver nitric acid for 5 min→drip washed for 1 min with double distilled water →showed appropriated color in 15 g· L^{-1} anhydrous sodium carbonate and 4 ml· L^{-1} formalin →ended reducing response by 7.5 ml· L glacial acetic acid→ drip washed with double distilled water →analysis results and photographed.

Purification of PCR product , T clone and DNA sequence

Abnormal PCR products screened by SSCP was cut from gel and purified by VIOGENE kit. Agarose gel-purified PCR products was subcloned to pUCm-T vector through TA clone. Sequence analysis was carried out with a PE377 automated sequencer.

RESULTS

The analysis of PCR products

The increment of all DNA samples from HD patients was a single strand with the length of 253 bp, and so was that from normal control, which indicated that a large fragment insertion and deletion did not exist in the region of exon 13 of RET gene among 20 HD patients.

Results of SSCP-Ag dying and DNA sequencing

Of all the patients and normal control analyzed, four showed abnormal SSCP patterns in exon 13. In Figure 1,2, the mobility of one single-strand was abnormal in case 2,3,4. In case 6, the mobility of two single-strand was abnormal. DNA sequence analysis showed nucleotide changes in all variable SSCP bands. Of the two patterns of nucleotide change, one was missense mutation, and the other was frameshift mutation (Figure 3, Table 1).

Table 1 The mutation analysis of exon 13 of RET gene from four cases

case	he heterozygous of allele gene	Nucleotide change	Amino acid change	Mutation types
case2	Heterozygote	18 888 T→G	Cys→Phe	missense mutation
case3	Heterozygote	18 888 T→G	Cys→Phe	missense mutation
case4	Heterozygote	18 888 T→G	Cys→Phe	missense mutation
case6	Homozygote	18 926 ins G	--	frameshift mutation

The parents genotypes of the case 2,3 and 4 were also examined by SSCP. We found that the mobility pattern of the father was in coincidence with his son in case 4, while the mobility pattern of the mother was normal (Figure 4). DNA sequence analysis showed the same mutation between the father and the son, implied that the exon 13 of RET gene in case 4 was originated from his paternal heredity. No abnormal patterns of DNA migration was observed in the parents of the case2,3.

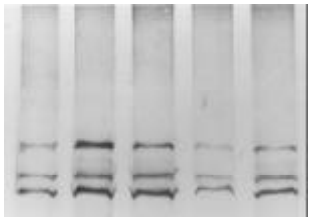

Figure 1 The abnormal shifted SSCP bands in exon 13. Lanes 1,2:normal control; Lanes3-5:case 1,2,3.

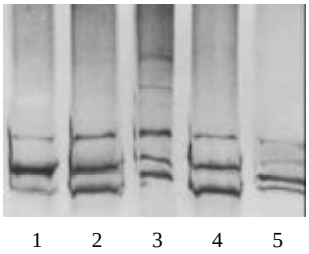

Figure 2 The abnormal shifted SSCP bands in exon 13. Lanes 1,2:normal control; Lanes 3-5:case 4-6.

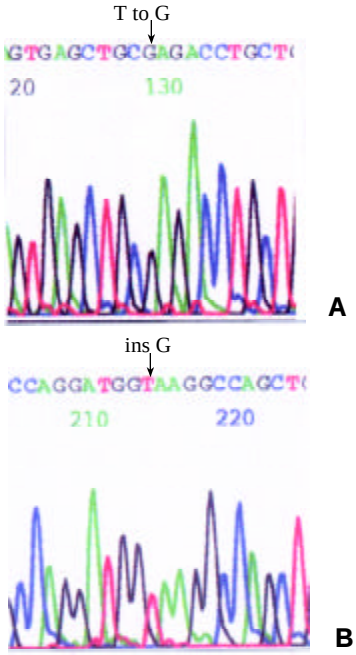

Figure 3 A fragment of sequence in exon 13 of case2(a),3(a),4 (a),6(b). The arrows indicate the position of mutation.

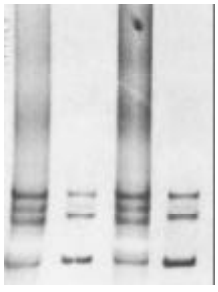

Figure 4 The abnormal shifted SSCP bands in exon 13 of case 4 and his parents. Lanes1: normal control; Lane2: case 4; Lane3: mother of case 4; Lane4: father of case 4.

DISCUSSION

The human RET gene lies on chromosome band 10q11.2 and comprises 20 exons, with the length about 80 kb[20-26]. The RET gene encodes a receptor tyrosine kinase consisting of an intracellular tyrosine kinase domain, a transmembrane domain and an extracellular domain which includes a "cadherin-like" region. Receptor tyrosine kinases generally function as ligand dependent dimers, which phosphorylate "second messenger" proteins in the cytoplasm and they are commonly associated with regulation of cell growth and differentiation, the development of normal nerves, and expressed in gangliogenic source cells (such as neurogenic ganglia and ganglia of peripheral nerve system, neuroendocrine cells, epidermic pigment cells, etc.). Mutations of the RET gene may lead to the premature termination of the transcription and translation procedures or the alteration of amino acid sequence, and thus, during the embryogenesis, the signal conduction was obstructed, causing the nerve cells migration stagnated and the colonic nerves defected.

Exon 13 of RET gene played a key role in encoding the tyrosine kinase domain and therefore the exon 13 on 20 unrelated Chinese HD patients was examined with PCR-SSCP in the present study. The PCR result revealed that the increment of all DNA samples from HD patients was a single strand with the same length of 253 bp as that of the samples from the control, which indicated that a large fragment insertion and deletion did not exist in the exon 13 region among 20 HD cases. The SSCP analysis indicated that the mobility abnormality existed in 4 cases and further DNA sequencing analysis exhibited two novel mutations: a transition, T to G at the nucleotide 18888, which lead to a Cysteine transformed phenylalanine and the disulfide bond was disrupted of the receptor tyrosine kinase. And thus the RET protein was destroyed and the signal conduction was obstructed which finally caused HD. Another frameshift insert G at the nucleotide 18 926, which could altered the amino acid sequence and thus Hirschsprung's disease arose from the abnormal RET protein as mentioned above. In 4 HD cases, among which 3 cases were heterozygous mutation and 1 case who was two-day-old child was homozygous mutation, accompanied by serious icterus. It has been reported that only a half quantity of RET gene mutation are likely to cause HD and homozygous mutation of RET gene may be fetal in human[24-26], which has been confirmed by our finding.

So far, a variety of frameshift, nonsense, or missense mutations scattered along the entire RET proto-oncogene have been identified in HD patients. However, the 'hot spot' region has not been found, which causes the difficulties in the design of specific primer and the detection of the RET gene mutation by routine diagnostic method. Single-strand conformation polymorphism (SSCP) analysis enables the discrimination of DNA fragments of the same size containing sequence variations and has been employed in the investigation of the monogenic and polygenic diseases as well as the oncogene and anti-oncogene studies[27-38]. The technique is based on the facts that partially denatured double stranded DNA (dsDNA) migrates as two single stranded DNA (ssDNA) in non-denaturing polyacrylamide gel edectrophoresis (PAGE), and that small changes in the nucleotide sequence may alter the ssDNA conformation and therefore its electrophoretic profiles. Thus, the single-strand conformational polymorphism analysis is useful to screen out the mutations in a small region with 150-500bp in size on a gene of interest with the rapid, economic and sensitive characteristics. Because of the fragment of RET gene exon 13 being 253bp, it is therefore suitable to take the PCR-SSCP analysis in our experiment. Furthermore, we found that increasing the concentrations of acrylamide and methylene bisacrylamide, using the thin gel (0.75 mm-thick) and applying the 100 ml· L^{-1} glycerin made the straps obtained more be clear and distinguishable.

Hirschsprung's disease is considered a heterogeneous genetic disorder with dominant, recessive, sex-linked and polygenic forms, and associated with a number of other genetic disorders including Down's syndrome[39], familial leukoplakia, congenital central dysfunction of ventilation, etc. Up to now, it has not been reported yet on the inheritance patterns in the Chinese patients with HD. In the present study, SSCP analysis was performed as well for the samples from the family members of some cases with mutated RET gene. The results showed that in a HD family, the sicked child and his father were the same heterozygous missense mutation (Cys→Phe). However, the inheritance patterns for the family remain to be investigated. Besides, the sequencing analysis proved that even the same exon 13 on the RET gene manifested the allele heterogeneity in the sites and ways of mutation (missense mutation and frameshift mutation). Therefore, congenital megacolon is a highly heterogenous disease.

At present, the clinical therapy for Hirschsprung's disease includes early diagnosis and excision of involved intestine segments[40-42]. But as for the patients with the long segment or the whole colon involved, the effect of the surgical intervention is extremely poor. In the present case, there were 4 cases of mutation screened out by the exon 13 on RET gene from 20 HD cases. The mutation rate of RET gene was 20 %. Considering the false-negative result by SSCP analysis, the rate of the RET mutation should be higher. The higher mutation rate of RET gene implied that the checkout of gene mutation can be taken as a routine technique of molecular genetics for diagnosing congenital megacolon; together with the chromosome aberration analysis, the method can be applied in the clinical prenatal diagnosis.

Abstract

AIM: To study the effect of matrine on activation of Kupffer cell during cold ischemia and reperfusion injury in rat orthotopic liver transplantation (OLT).

METHODS: 168 syngeneic SD rats were randomly divided into four groups: untreated group, small-dose treated group, large-dose treated group and sham operation group. After 5 hours of preservation in Ringer's (LR) solution, orthotopic implantation of the donor liver was performed. At 1 h, 2 h, 4 h and 24 h after reperfusion of the portal vein, 6 rats were killed in each group to collect the serum and the liver for assay and pathology.

RESULTS: Matrine markedly inhibited the activation of Kupffer cells and their release of tumor necrosis factor (TNF). TNF cytotoxicity level at 2 h decreased significantly by matrine treatment (7.94±0.42, 2.39±0.19 and 2.01±0.13 U/ml, respectively; $P<0.01$), so did the other three time points. The level of hylluronic acid (HA) and alanine transaminase (ALT) decreased significantly in both treated groups, and matrine treatment markedly ameliorated focal necrosis of hepatocytes, inflammatory cells aggregating, rounding and detachment of sinusoidal endothelial cells (SEC). And no significant difference was observed between the treated groups.

CONCLUSION: Matrine can inhibit the activation of Kupffer cell and prevent the donor liver from cold preservation and reperfusion injury in rat orthotopic liver transplantation.

INTRODUCTION

Preservation injury continues to be a major clinical problem in orthotopic liver transplantation (OLT) with a 10 % incidence of primary nonfunction[1,2]. Additionally, there is clinical evidence that severe preservation injury is associated with an increase in liver graft rejection[3]. Therefore, it is clinically and pathophysiologically important to elucidate the mechanism and prevention of cellular injury during hepatic ischemia and the subsequent reperfusion. Kupffer cells become activated during cold preservation and subsequent reperfusion, as has been demonstrated by enhanced endocytosis of carbon particles[4], an increased release of TNF-α[5-8] and ultrastructural changes[9]. When activated, they generate a plethoric inflammatory cytokines and oxygen-derived free radicals, which play a particularly important part in the pathogenesis of hepatic ischemia and reperfusion injury[10].

Matrine (matridin-15-one) is a typical lupine alkaloid along with lupinine, sparteine and cytisine, and has an absolute structure of 5S, 6S, 7R, 11R[11] (Figure 1). This alkaloid, isolated from kinds of *Sophora* plants in *Leguminosae*, shows pharmacological effects as anti-inflammation[12], immunity-inhibition[13], B and C hepatitis virus inhibition[14], anti-tumor[15] and anti-arrhythmia activity[16], and has been used in treatment of chronic viral hepatitis. Pharmacological studies revealed no obvious side-effect of matrine[17]. The present study was designed to evaluate the effects of matrine on Kupffer cell activation caused by preservation and reperfusion with an orthotopic liver transplantation model.

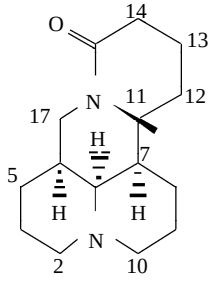

Figure 1 Chemical structure of (+)-Matrine

MATERIALS AND METHODS

Reagents

Marine, a parenteral solution (50 mg/5 ml), was purchased from Ming Xing Pharmaceutical Factory, Guangzhou, China. HA RIA kit was from Shanghai Ocean Research Biomedical Technology Center, China. Recombinant human TNF (1000 units/ml) was from Genzyme Co. in Boston, America. Rat TNF-α ELISA kit was purchased from Bender MedSystems Co. in Vienna, Austria. Endotoxin quantitation kit was from Shanghai Medical Test Center, China.

Animals

168 male inbred SD rats weighing 200 to 220 g were purchased from the Animal Center of Jin Ling Hospital (Nanjing, China). All rats were provided with standard laboratory chow and water and housed in accordance with institutional animal care

policies. Prior to being used in the study, the rats were fasted for 12 hours and were allowed free access to water.

Experimental design

Rat orthotopic liver transplantation was performed using the technique of Kamada and Calne[18] under ether anesthesia, and the hepatic artery was not reconstructed. Ringer' s (LR) solution was used for perfusion. The liver graft was preserved for 5 h in Ringer' s solution at 4 ℃, then transplanted orthotopically. The explantation of the recipient liver required <10 minutes and the rewarming time of the graft (i.e, clamping of the portal vein and the subhepatic vena cava during implantation) did not exceed 18 minutes.

The animals were randomly assigned into four experimental groups as follows: (1) a control group in which the recipients were injected ip Normal Saline (N.S, 1ml) before laparotomy. (2) a small-dose treated group (ST) in which the recipients were injected ip matrine (40 mg· Kg^{-1}) before surgery. (3) a large-dose treated group (LT), in which the transplantation was performed following the injection of matrine (80 mg· Kg^{-1}) as above. (4) a sham operation group (Normal), in which the liver was mobilized as the others without hepatectomy to exclude the influence of surgery.

At 1 h, 2 h, 4 h and 24 h after reperfusion of the portal vein, 6 rats were killed in each group to collect the blood sample via the infrahepatic vena cava and the median lobe of liver for assay. The serum was separated and stored at -70 ℃ until analysis. Washed with cold Saline solution, the liver samples were stored immediately in liquid nitrogen until analysis.

Hepatic enzyme assays

Alanine aminotransferase (ALT) activity of the serum samples collected at 4 h and 24 h after reperfusion was determined by automatic biochemistry analyzer (HITACHI 7 600).

Assessment of HA plasma level

HA plasma levels of those samples collected at 1 h, 2 h, and 4 h after reperfusion were determined in duplicate using a HA RIA kit according to the manufacturer' s protocols.

Plasma endotoxin level

Endotoxin plasma levels of the samples collected at 1h and 2h were determined in duplicate using a limulus amebocyte lysate assay kit according to the manufacturer' s instruction.

Plasma TNF cytotoxicity determination

Plasma TNF cytotoxicity of all samples were determinated with TNF cytotoxicity L929 assays as described[19,20]. Each sample was assayed in duplicate wells.

Hepatic TNF-α assay

Coomassie Light Blue assay was used for protein quantitation of all hepatic samples. Hepatic levels of TNF-α were assayed with a rat TNF-α ELISA kit from the Bender MedSystems corporation. This was an enzyme-linked immunoabsorbent assay for the quantitation of natural or recombinant rat TNF-α levels. The assay was carried out according to the manufacturer' s instructions.

Light microscopy

Six hepatic specimens were collected at 4 hr after reperfusion of portal vein in each group. The liver specimens for light microscopy were fixed with 10 % formalin and then embedded in paraffin. The sections were stained with hematoxylin and eosin for histologic examination.

Transmission electron microscopy

For transmission electron microscopy, liver fragments of approximately 1 mm^3 were fixed in 2 % glutaraldehyde containing 0.1 M phosphate buffer for 3 hours. After washing in phosphate buffer, specimens were postfixed with osmium tetroxide, dehydrated in graded alcohols, and embedded in Epon 812. Ultrathin sections were stained with uranyl acetate and lead citrate and examined under an electron microscope (JEM-1200EX).

Statistical analysis

The results are expressed as mean ±SD. Data were analyzed using Statistical Analysis System (SAS). One-way analysis of variance (ANOVA) was used for multiple comparisons with Student-Newman-Keuls (snk) test. A P value of < 0.05 was considered statistically significant.

RESULTS

Effect of matrine on ALT serum levels

ALT serum levels in both treated groups decreased significantly compared with control values at different time points after reperfusion, and two folds-dose matrine provided the large-dose treated group with a significant decrease in ALT. (Figure 2).

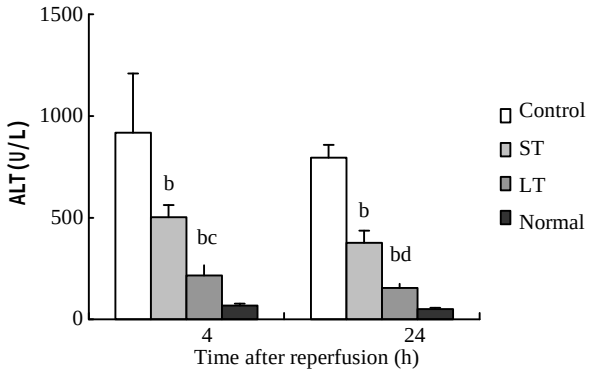

Figure 2 Effect of matrine on ALT plasma level after 5-hour cold preservation and reperfusion in rat orthotopic liver transplantation. (n=6 at each time); b: very significantly different from control (P<0.01); c: significantly different from the small-dose treated group (P<0.05); d: very significantly different from the small-dose treated group (P<0.01).

Effect of matrine on HA plasma levels

Compared with the sham operation group, a significant elevation of serum HA was observed in the other three groups at different time points, with the peak level at 2 h after surgery. HA levels at different time points were ameliorated markedly by matrine treatment, and two folds-dose matrine provided the large-dose treated group with a significant elevation in HA. (Figure 3).

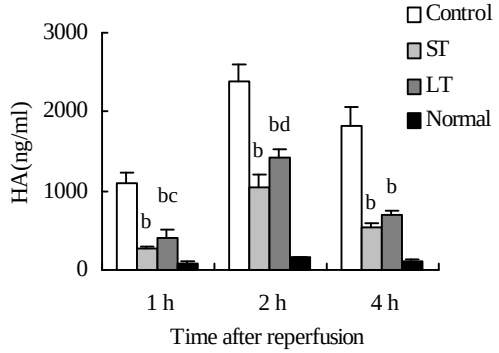

Figure 3 Effect of matrine on plasma HA level after 5-hour cold preservation and reperfusion in rat orthotopic liver

transplantation. (n=6 at each time); b: very significantly different from control (P<0.01); d: very significantly different from the small-dose treated group (P<0.01).

Effect of matrine on plasma endotoxin levels

In both treated groups, plasma endotoxin levels increased significantly compared with control values at 1 h and 2 h after reperfusion. No significant difference was noted between the two treated groups (Figure 4).

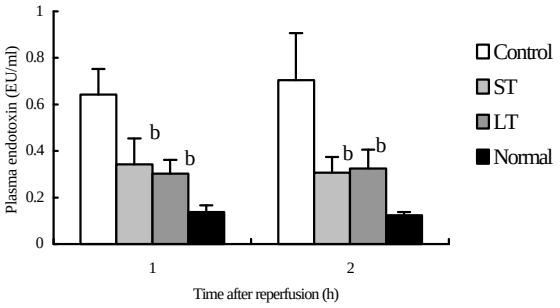

Figure 4 Effect of matrine on endotoxin plasma level after 5-hour cold preservation and reperfusion in rat orthotopic liver transplantation. (n=6 at each time) b: very significantly different from control (P<0.01)

Effect of matrine on plasma TNF cytotoxicity

Almost no plasma TNF cytotoxicity was detected in the sham operation group. In the other three groups, the maximum TNF values were obtained 2 h after surgery as shown in Figure 5. TNF cytotoxicity level at 2 h decreased significantly by matrine treatment (7.94±0.42, 2.39±0.19 and 2.01±0.13 U/ml, respectively; P<0.01), so did the other three time points. No significant difference was noted between the two treated groups.

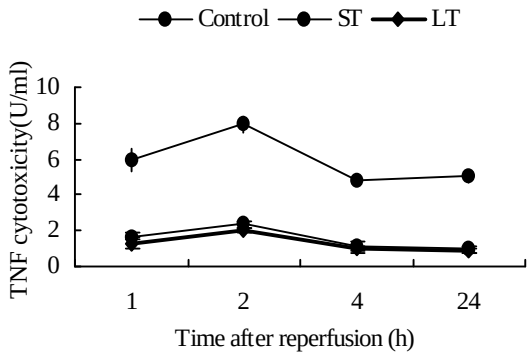

Figure 5 Effect of matrine on TNF cytotoxicity after 5-hour cold preservation and reperfusion in rat orthotopic liver transplantation. (n=6 at each time).

Effect of matrine on hepatic TNF-α levels

The hepatic TNF-α level of sham operation group was low (56.8±13.2 pg/mgprot). In the other three groups, the maximum TNF-α levels were obtained at 2 h after surgery as shown in Figure 6, and TNF-α levels at different time points post reperfusion were significantly decreased by matrine treatment, but no significant difference was noted between the two treated groups.

Light microscopy

In sham operation group, the histological findings indicated that the degree of liver cell injury, Kupffer cell hyperplasia, and inflammatory cell infiltration in portal areas and sinusoids were mild. As shown in Figure 7, histological examination revealed some focal necrosis of hepatocytes, extensive congestion, and inflammatory cells aggregating in hepatic sinusoid lumen in the control group, and the obvious Kupffer cell hyperplasia and rounding and detachment of SEC were observed, too. These were ameliorated markedly in both treated groups, and no significant difference was observed between the two treated groups.

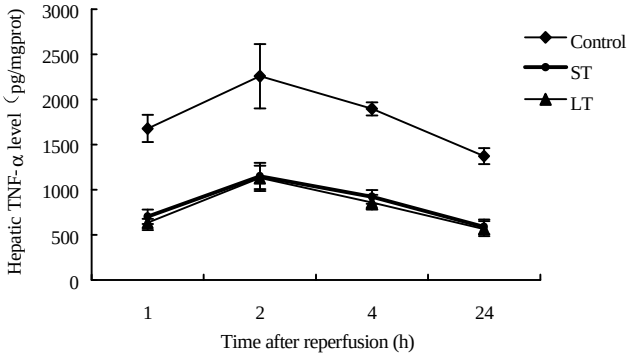

Figure 6 Effect of matrine on hepatic TNF-α level after 5-hour cold preservation and reperfusion in rat orthotopic liver transplantation. (n=6 at each time)

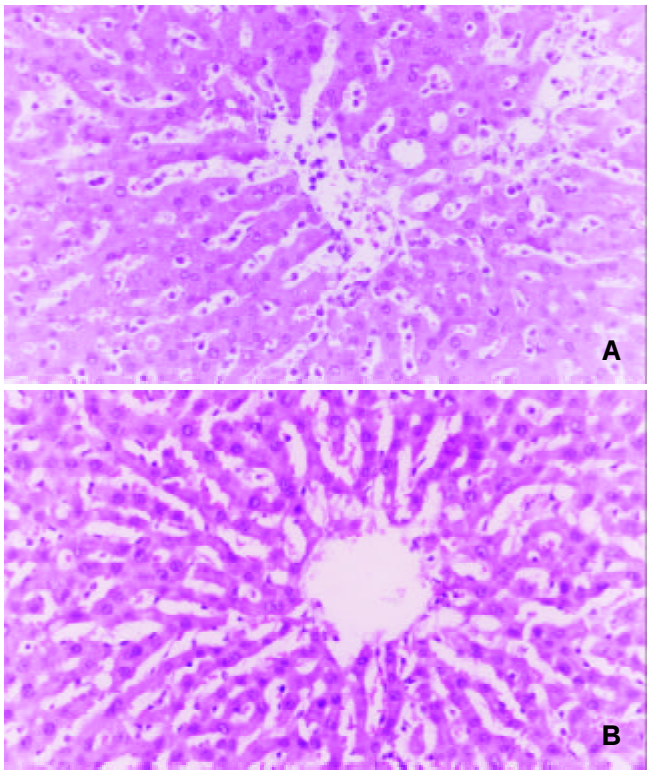

Figure 7 Histological appearance of the rat liver at 4 hours after reperfusion A: control group; B: a small-dose treated group. (HE staining paraffin-embedded 5 μm thick-sections. ×200)

Transmission electron microscopy

Samples taken from the control group showed obvious activation of Kupffer cells, including increase of cytoplasmic processes, irregular nucleus and many phagolysosomes, hyaline vacuoles, and granules in cytoplasm. (Figure 8) The treated groups showed a nearly normal ultrastructure of Kupffer cells in the samples examined compared with the control. This was reflected in

rounding of Kupffer cell, regular nucleus, and a reduction in the amount of cytoplasmic processes. No significant differences were noted between the two treated groups.

DISCUSSION

With donor shortage becoming worse, preservation injury continues to be a major clinical problem with a 10 % incidence of primary nonfunction[1,2]. Kupffer cells play an important part in mediating ischemia and reperfusion injury after hepatic transplantation. It is likely that they are primed during cold preservation and then activated at the time of reperfusion. The addition of an inhibitor of Kupffer cell activation to liver preservation solutions may further increase the duration of cold storage times and also improve the outcome of grafts[21-23].

In the present investigation, rat livers were kept for 5 hours in cold Ringer' s solution (4 ℃), exceeding the safe limit of 4 hours[24].Under these preservation and transplantation conditions (i.e., a portal vein clamping time of less than 20 minutes), a postoperative survival rate of about 40 % was obtained. Thus, 5 hours in cold Ringer' s solution, although a severely compromising condition, should allow an adequate assessment of the mechanisms of cold ischemia and reperfusion injury that lead to primary nonfunction. Usually, the rats without matrine treatment recovered well from anesthesia; however, their clinical status began to deteriorate within 4 to 6 hours, and nonsurvivors died within 24 hours, mostly between 10 to 20 hours.

After reperfusion, serum endotoxins immediately bind to lipopolysaccharides binding protein (LPSBP) and are ususlly trapped by Kupffer cells[25]. Kupffer cells exhibited progressive rounding, ruffling of the cell surface, polarization, appearance of wormlike densities, vacuolization, and degranulation. After activation, Kupffer cells produce TNF-α and induce neutrophil chemotaxis and activation[5,26]. TNF-α has potent proinflammatory actions, which can induce IL-8 synthesis and up-regulate the expression of adhesion molecules giving rise to increased leukocyte-sinusoidal endothelial cell interactions [23,27], which result in further cytokine production. In our study, serum endotoxin levels at different time points post transplantation were ameliorated markedly by matrine treatment, and the results have confirmed matrine markedly inhibited the activation of Kupffer cells and their release of TNF, inflammatory cell infiltration and injury of sinusoidal endothelial cell.

The serum ALT and HA levels were determined as functional indices of hepatocyte and sinusoidal endothelial cell damage, respectively. ALT and HA levels at different time points post-transplantation improved markedly by matrine treatment, and their pathological changes of liver graft ameliorated, too. Two folds-dose matrine treatment can' t give rats the better therapeutic effect, and no obvious side effect was noted in our study.

In conclusion, the results of this study demonstrated the inhibition effect of matrine on Kupffer cell activation and its protective effect against the cold ischemia reperfusion injury of the graft in liver transplantation.

Abstract

AIM: To study the effects of hydrogen peroxide on mitochondrial gene expression of intestinal epithelial cells in *in vitro* model of hydrogen peroxide-stimulated SW-480 cells.

METHODS: RNA of hydrogen peroxide-induced SW-480 cells was isolated, and reverse-transcriptional polymerase chain reaction was performed to study gene expression of ATPase subunit 6, ATPase subunit 8, cytochrome c oxidase subunit I (COI), cytochrome coxidase subuit II (COII) and cytochrome c oxidase subunit III (COIII). Mitochondria were isolated and activities of mitochondrial cytochrome c oxidase and ATPase were also measured simultaneously.

RESULTS: Hydrogen peroxide led to differential expression of mitochondrial genes with some genes up-regulated or down-regulated in a dose dependent manner. Differences were very obvious in expressions of mitochondrial genes of cells treated with hydrogen peroxide in a concentration of 400 μmol/L or 4 mmol/L. In general, differential expression of mitochondrial genes was characterized by up-regulation of mitochondrial genes in the concentration of 400 μmol/L and down-regulation in the concentration of 4 mmol/L. In consistence with changes in mitochondrial gene expressions, hydrogen peroxide resulted in decreased activities of cytochrome c oxidase and ATPase.

CONCLUSIONS: The differential expression of mitochondrial genes encoding cytochrome c oxidase and ATPase is involved in apoptosis of intestinal epithelial cells by affecting activities of cytochorme c oxidase and ATPase.

INTRODUCTION

Hidden injuries of gut during early stage of severe burn may occur, and lead to endogenous translocation of intestinal endotoxin or bacteria. But factors contributing to gut barrier dysfunction are multiple and its mechanism is unclear[1-10]. Apoptosis of intestinal epithelial cells induced by excessive reactive oxygen species released by activated polymorphonuclear cells and vascular endothelial cells plays a role in the pathogenesis of intestinal mucosal dysfunction. The role of mitochondria in the development of apoptosis has been well clarified recently[11-15]. As we know, there are some proteins related to mitochondrial electron transport chain such as cytochrome coxidase subunits and ATP synthase subunits encoded by mitochondrial genome, which may be involved in mitochondrial injuries of intestinal epithelial cells. Our study focused on the effects of hydrogen peroxide on mitochondrial gene expression of intestinal epithelial cells.

MATERIALS AND METHODS

Cell line and culture

Human intestinal epithelial cell line SW-480 stored routinely in our laboratory was cultured in RPMI1640 supplemented with 10 % (v/v) heat inactivated newborn calf serum (Hyclone), 100 units/ml of penicillin, 0.1 mg/ml streptomycin and 2 mM L-glutamine at 37 ℃ in a humidified 5 % CO_2, 95 % air incubator. Confluent cells were prepared for further studies.

Treatment and groups

Cells were treated with 4 mmol/L or 400 μmol/L hydrogen peroxide. Cells without any hydrogen peroxide were prepared as control.

Primers design

WWW primer picking software (primer3) from Whitehead Institute for Biomedical Research was used to design the primers of ATPase6, ATPase8, COI, COII and COIII genes encoded by mitochondrial genome in accordance with the latest Human Mitochondrial DNA "Cambridge" Sequence (Table 1). Housekeeping gene β-actin was regarded as internal control.

Table 1 Primers of ATPase6, ATPase8, COI, COII and COIII genes encoded by mitochondrial genome

Target genes	Sequence of base pairs	Size of PCR products(bp)
COI	5'-GTTGTAGCCCACTTCCAC-3'	222
	5'-CATCGGGGTAGTCCGAGTAA-3'	
COII	5'-TTCATGATCACGCCCTCATA-3'	187
	5'-TAAAGGATGCGTAGGGATGG-3'	
CO III	5'-AAAGCACATACCAAGGCCAC-3'	195
	5'-CTTCTAGGGGATTTAGCGGG-3'	
ATPase 6	5'-GCCCTAGCCCACTTCTTACC-3'	256
	5'-TTAAGGCGACAGCGATTTCT-3'	
ATPase 8	5'-CCCACCATAATTACCCCCAT-3'	102
	5'-TTTTATGGGCTTTGGTGAGG-3'	
β-actin	5'-TGACGGGGTCACCCACACTGTGCCCATCTA-3'	661
	5'-CTAGAAGCATTGCGGTGGACGATGGAGGG-3'	

Isolation of total RNA

Total RNA was isolated by Tripure isolation reagent (Roche) according to manual provided by the kit. Any subject used in RNA isolation was treated with DEPC (Sigma) followed by vapor sterilization. A260/A280 of RNA samples were between 1.6 and 2.0.

Expression of ATPase6, ATPase8, COI, COII and COIII genes

Titan One Tube RT-PCR Kit (Roche) was applied according to manual for studying expression of mRNA of ATPase6, ATPase8, COI, COII and COIII genes. The PCR profile was as follows: a reverse-transcription reaction at 50 ℃ for 30 min and initial denaturation at 94 ℃ for 2 min, followed by 35 cycles of denaturation at 94 ℃ for 30 s, annealing at 56 ℃ for 30 s, primer extension at 68 ℃ for 45 s and a final extension at 68 ℃ for 10 min. PCR products were separated by electrophoresis on a 1 % vertical agarose electrophoresis and observed under ultraviolet and stored in computer by gel imaging system. Relative density of genes was calculated by dividing density of respective gene with density of β-actin.

Isolation of mitochondria

Mitochondria were isolated as described previously[16]. Cells about 1×10^7 were typsined followed by washing for one time, and then cells suspended in ice-cold isolation buffer (0.25 M sucrose, 10 mM Tris-HCl, pH 7.4) were homogenized with a glass homogenizer for 10 strokes in ice. The supernatants was further centrifuged at 1 500×g for 10 min at 4 ℃, the pellet was suspended again in ice-cold isolation buffer and homogenized in ice. Two supernatants were mixed and centrifuged at 17 000 ×g for 10 min at 4 ℃. Fresh isolated mitochondria was suspended in isolation buffer, protein concentration were determined by Folin-Phen assay and adjusted to 4 mg/ml. Activities of cytochrome c oxidase and ATPase were measured within 6 h after isolation of mitochondria.

Cytochrome c oxidase activity

In 1 ml reaction volume, 70 μl reduced ferrocytochrome c, 10 μl isolation mitochondria (4 mg/ml) and 920 μl 10 mM K_2HPO_4 (pH 7.4) were mixed at room temperature, and the absorbance was measured every 30 seconds. The decreased absorbance represents activity of cytochrome c oxidase[17].

ATPase activity

Ten micro-liter of isolated mitochondria (4 mg/ml) and 1 ml of 10 % TCA were mixed in Eppendorf tubes at 37 ℃ for 60 min, and the reaction was terminated by incubation in ice. Then 250 μl of 0.02 mol/L ATP-Na_2 and 100 μl of 0.05 mol/L $MgCl_2$ were added respectively, and the reaction was ended by adding 1 ml of 10 % TCA after 5 min at 37 ℃, followed by centrifugation at 3 000 rpm for 15 min at 4 ℃. The contents of inorganic phosphorus in supernatants representing ATPase activity were determined[18].

Statistical analysis

Data were expressed as *mean* ±*SD*. To analyze the data statistically, student's *t* test was used to determine statistical differences, and $P<0.05$ was considered significant.

RESULTS

Expression of house-keeping gene b-actin mRNA

After treating with hydrogen peroxide, no significant changes of house-keeping gene β-actin mRNA could be observed, indicating its value as an internal control (Figure 1).

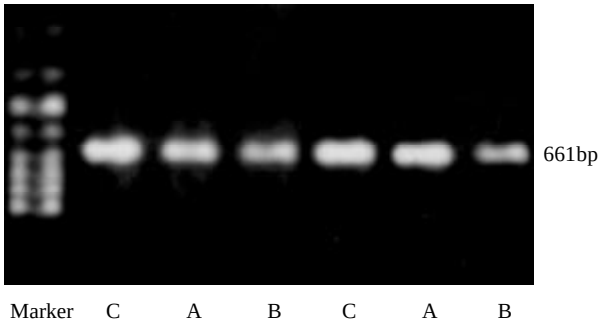

Figure 1 Effects of hydrogen peroxide on expression of homing gene β-actin mRNA.
C: control cells; A: 4 mM H_2O_2-treated cells (3 h); B: 400 mM H_2O_2-treated cells (3 h).

Expression of COI mRNA

Cells from normal control expressed certain amount of COI mRNA. Increasing expression of COI mRNA was found after treating with hydrogen peroxide in the concentration of 400 μmol/L, but no significant changes could be observed in the concentration of 4 mmol/L (Figure 2).

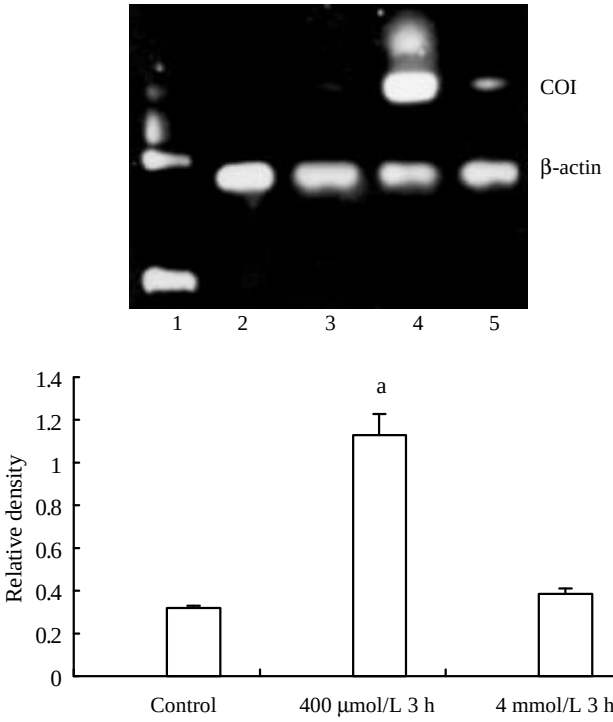

Figure 2 Effects of hydrogen peroxide on expression of COI mRNA ($^aP<0.05$, *vs.* normal control).
1 DNA marker: lDNA / Hind III, 2 positive control, 3 normal control, 4 400 μmol / L 3 h, 5 4 mmol / L 3 h.

Expression of COII mRNA

Weak expression of COII mRNA was found in control cells. Significant increase could be found in both 400 μmol/L and 4 mmol/L hydrogen peroxide-stimulated cells (Figure 3).

Expression of COIII mRNA

Stable expression of COIII mRNA was found in control cells. Significant decrease could be found in 400 μmol/L hydrogen peroxide-stimulated cells (Figure 4).

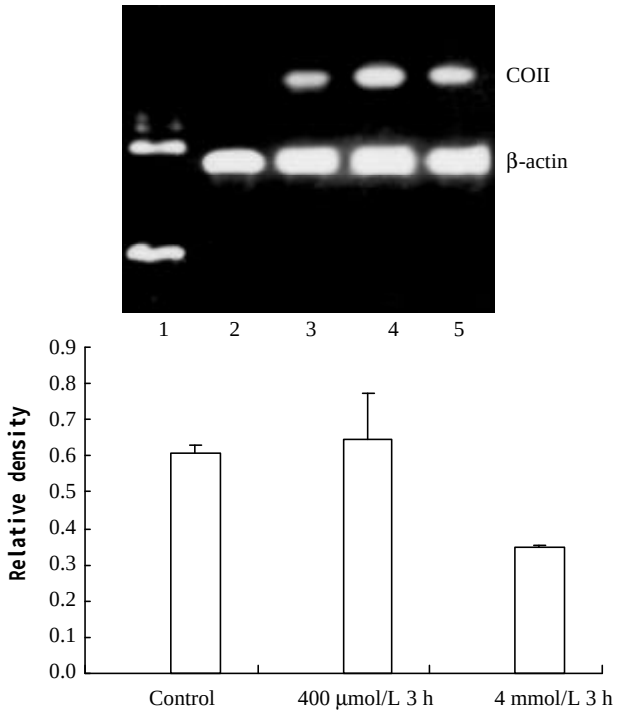

Figure 3 Effects of hydrogen peroxide on expression of COII mRNA ($^aP<0.05$, *vs* normal control).
1 DNA marker; lDNA / Hind III, 2 positive control, 3 normal control, 4 400 μmol / L 3 h, 5 4 mmol / L 3 h.

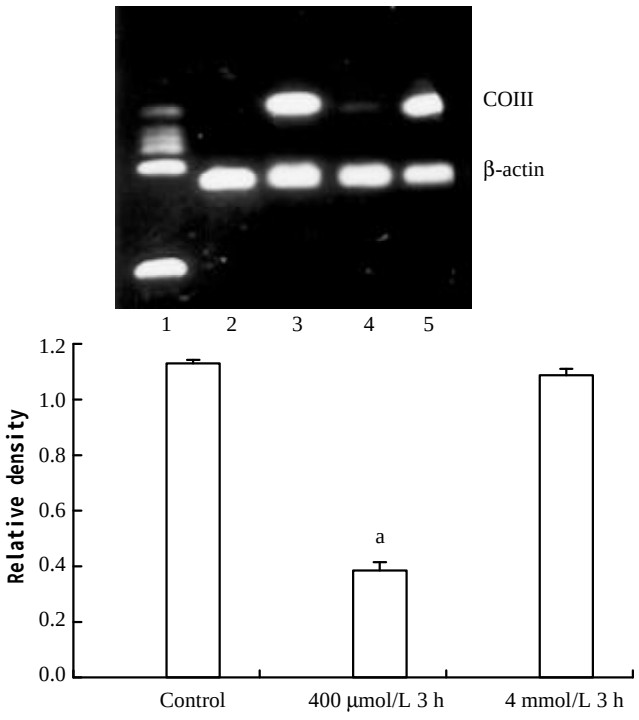

Figure 4 Effects of hydrogen peroxide on expression of COIII mRNA ($^aP<0.05$, *vs* normal control).
1 DNA marker: lDNA / Hind III, 2 positive control, 3 normal control, 4 400 μmol / L 3 h, 5 4 mmol / L 3 h.

Expression of ATPase6 mRNA

Expression of ATPase6 mRNA increased significantly in 400 μmol/L hydrogen peroxide stimulated-cells, meanwhile decreased expression could also be found in 4 mmol/L hydrogen peroxide-stimulated cells (Figure 5).

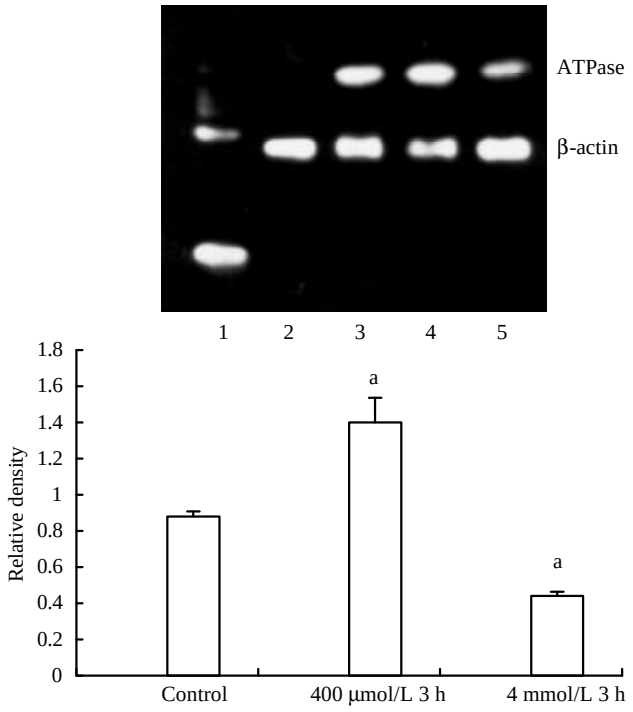

Figure 5 Effects of hydrogen peroxide on expression of ATPase6 mRNA ($^aP<0.05$, *vs* normal control).
1 DNA marker: lDNA / Hind III, 2 positive control, 3 normal control, 4 400 μmol / L 3 h, 5 4 mmol / L 3 h.

Expression of ATPase8 mRNA

Stable expression of ATPase8 mRNA was found in control cells. No significant increase could be found in 400 μmol/L hydrogen peroxide-stimulated cells. Decreased expression of ATPase8 mRNA in 4 mmol/L hydrogen peroxide-stimulated cells was found (Figure 6).

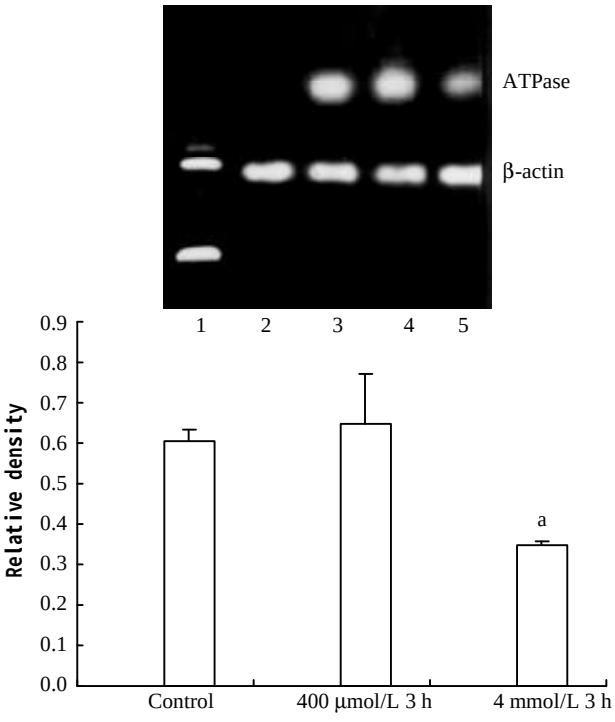

Figure 6 Effects of hydrogen peroxide on expression of ATPase8 mRNA ($^aP<0.05$, *vs*. normal control).
1 DNA marker: lDNA / Hind III, 2 positive control, 3 normal control, 4 400 μmol / L 3 h, 5 4 mmol / L 3 h.

Activity of cytochrome c oxidase

Activities of cytochrome c oxidase decreased significantly in both 400 μmol/L and 4 mmol/L hydrogen peroxide-stimulated cells (Figure 7).

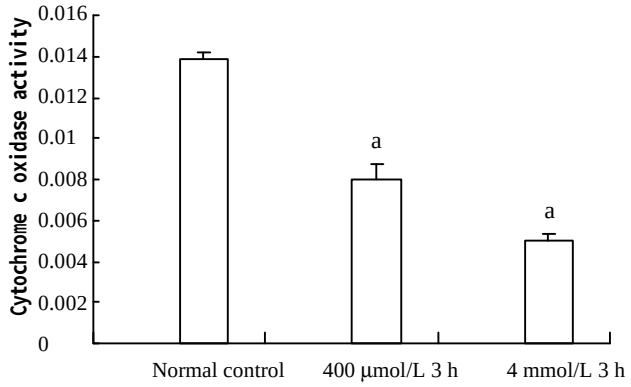

Figure 7 Activity of cytochrome c oxidase in hydrogen peroxide-stimulated SW-480 cells ($^aP<0.05$, *vs.* normal control).

ATPase activity

Although only ATPase activity in 4 mM hydrogen peroxide-stimulated cells decreased significantly on the view of statistics, the trend is very obvious (Figure 8).

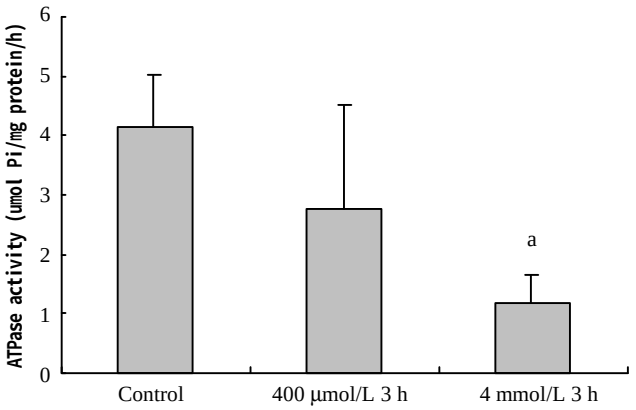

Figure 8 Activity of ATPase in hydrogen peroxide-stimulated SW-480 cells ($^aP<0.05$, *vs.* normal control).

DISCUSSION

The role of mitochondrion in the pathogenesis of apoptosis has been well defined. Mitochondrion, a kind of organelle controlling growing, breeding and dying of eukaryocyte, embodies its functions through: (1) production of ATP; (2)production of ROS, which regulates nuclear gene expression; (3) link between cytoplasm and nucleus; (4)sensitive response to stimulator or signals outside cytoplasm; (5) triggering of cell death[19, 20]. Evidences show the central role of mitochondria in the development of apoptosis. Many stimulators like ROS, Ca^{2+} and cytokines lead to activation of caspases by inducing release of cytochrome C and thereby trigger a cascade in apoptosis[11].

Release of mitochondrial apoptosis-inducing substance caused by collapse of mitochondrial membrane potential and open of mitochondrial permeability transition pore controlled by Bcl 2 family is the key step to initiate apoptosis. Mitochondrial respiration depends on maintenance of mitochondrial membrane potential.

Now the relationship between DNA injuries and apoptosis has been recognized[21]. Although mitochondrial genome was sequenced in 1981[22], there is little study on function of mitochondrial genes. Thirteen proteins encoded by mitochondrial genome make up parts of enzymes involving mitochondrial oxidative phosphorylation. Without protection of histone, mitochondrial genome is much easier to be injured compared with nuclear genome. Our research also confirmed this (results to be published). Many researches indicated that oxidative stress led to mutation of mitochondrial genes[23-32]. The relationship between mutation of DNA and expression of genes needs to be well investigated.

Hydrogen peroxide led to differential expression of mitochondrial genes with some genes up-regulated or down-regulated in a dose-dependent manner. Differences were very obvious in expression of mitochondrial genes of cells treated with hydrogen peroxide in the concentration of 400 μmol/L or 4 mmol/L. In general, differential expression of mitochondrial genes was characterized by up-regulation of mitochondrial genes in the concentration of 400 μmol/L and down-regulation in the concentration of 4 mmol/L. In consistence with changes of mitochondrial gene expression, hydrogen peroxide led to similar decreased activities of cytochrome C oxidase and ATPase. Differential expression reflected the difference in the sensitivity of gene responding to oxidative stress, which may relate greatly to cellular physiological process next. In rat lung epithelial cells treated with hydrogen peroxide for for 8 or 24 h, the differential display of genes showed that mutation of genes from mitochondrial genome encoding NADH dehydrognase subunit 5, subunit 6 and 16 S ribosome could be detected; the results also suggested that mitochondrial genes played a role in the control of apoptosis[33]. Researches showed that there were some links between mitochondrial dysfunction and injuries of mitochondrial DNA or expression of mitochondrial genes in hydrogen peroxide-stimulated vascular endothelial cells and smooth muscle cells[34].

Meanwhile we also found a large scale of point mutation of mitocondrial gene such as ATPase8 subunit in 4 mmol/L hydrogen peroxide treated SW-480 cells, suggesting its correlation with down-regulation of ATPase expression.

It is considered now that the mitochondrial permeability transition (MPT) plays a key role in the pathogenesis of apoptosis and necrosis[35-38]. If MPT initiates rapidly with depletion of ATP, cells undergo necrosis, and if MPT occurs without depletion of ATP, cells evolved into apoptosis. So we may conclude that complete inhibition of ATPase would lead to necrosis and partially inhibition of ATPase would lead to apoptosis. Consistent with this conclusion, our study proved a partially inhibition of ATPase in both 4 mmol/L and 400 μmol/L hydrogen peroxide-treated SW-480 cells, suggesting its potential role in apoptosis. But there are still many problems to be clarified, including the relationship between different expressions of mitochondrial genes, activities of cytochrome C oxdiase and ATPase, oxidative phosphorylation and regulation of apoptosis.

Studies including ours showed that mitochondrial genes played the role in apoptosis. To establish mtDNA deletion cells (ρ^0 cells) provided in our studies more direct evidences[39-42].

It is unclear about the pathway leading to increasing expression of mitochondrial genes. Defects of mitochondrial energy supply may be one of the compensatory mechanisms leading to increasing expression of mitochondrial genes[43].

Our results showed that differential expression seemed to be incompatible with decreasing activities of cytochorome C oxidase or ATP synthase. To answer this question, we should

pay attention to mitochondrial proteins encoded by the nuclear genome, which form main parts of mitochondrial proteins. For example, only subunits 6 and 8 of ATP synthase were encoded by mitochondrial genome, which may also be controlled by some nuclear transcriptional factors[44-46]. Meanwhile most parts of ATPase were encoded by the nuclear genome. Cross-talk between mitochondrial genes and nuclear genes will be the next key or difficult question to be answered[47-50]. It will become available to study cross-talk between mitochondrial genes and nuclear genes from the view of genome and proteome by the developing techniques of genome and proteome.

Abstract

AIM: To purify and identify heme oxygenase (HO) isomers which exist in rat liver, spleen and brain treated with hematin and phenylhydrazine and in untreated rat liver and to investigate the characteristics of HO isomers, to isolate and confirm the rat HO-1 cDNA that actually encodes HO-1 by expressing cDNA in monkey kidney cells (COS-1 cells), to prepare the rat heme oxygenase-1 (HO-1) mutant and to detect inhibition of HO-1 mutated enzyme.

METHODS: First, rat liver, spleen and brain microsomal fractions were purified by DEAE-Sephacel and hydroxylapatite. The characteristics including activity, immunity and inducibility of two isomers (HO-1 and HO-2), and their apparent molecular weight were measured by detecting enzymatic activities, SDS-polyacrylamide gel electrophoresis (SDS-PAGE) and Western blotting analysis, respectively. Second, plasmid pcDNA3HO1 containing native rat HO-1 cDNA and pcDNA3HO1D25 carrying mutated rat HO-1 cDNA (His25Ala) were constructed by site-directed mutagenesis. COS-1 cells transfected with pcDNA3HO1 and pcDNA3HO1D25 were collected and disrupted by sonication, the microsomes were prepared by ultracentrifugation. Third, the inhibition of rat HO-1 mutant was analyzed.

RESULTS: Two isomers were purified and identified in treated rat liver, spleen, brain and untreated rat liver. HO-1 was the predominant form with a ratio of 2.0:1 and 3.2:1 of HO-1 and HO-2 in liver and spleen, respectively, but only the activity of HO-2 in the brain and untreated liver could be detected. The apparent molecular weights of HO-1 and HO-2 were about M_r 30 000 and M_r 36 000 under reducing conditions, respectively. The antiserum against liver HO-2 was employed in Western blotting analysis, the reactivity of HO-1 in the liver was not observed. The plasmid pcDNA3HO1 was highly expressed in endoplasmic reticulum of transfected COS-1 cells. The specific activity was ≈5-fold higher than that of the control. However, the enzyme activity of mutated HO-1 declined. While an equal amount of mutant was added to the enzyme reaction system, the levels of bilirubin decreased 42 %.

CONCLUSION: The studies suggest that HO-1 and HO-2 exist in the hematin and phenylhydrazine treated rat liver and spleen, but only HO-2 in the brain and untreated liver. Two constitutive forms are different in molecular weight, inducibility and immunochemical properties. The activity of expressed HO-1 in COS-1 cells is higher than that of purified enzyme from rat spleen tissue. It suggests that this clone has an insert of 1030 base-pairs encodes HO-1. His25Ala mutant reduced the formation of bilirubin and it suggests that the mutant could competely bind the heme with native enzyme.

Xia ZW, Cui WJ, Zhang XH, Shen QX, Wang J, Li YZ, Chen SN, Yu SC. Analysis of Heme oxygenase isomers in rat. *World J Gastroenterol* 2002; 8(6):1123-1128

INTRODUCTION

Cellular levels of heme are regulated by the rates of its synthesis and degradation. Heme catabolism occurs by oxidative cleavage of the -methene bridge of the tetrapyrrole, eventually leading to the formation of equimolar amounts of biliverdin and the release of contained iron atom. Biliverdin is then rapidly reduced to form bilirubin. The heme oxygenase (HO) system controls the rate-limiting step in heme catabolism. Three isomers (HO-1, HO-2 and HO-3) have been identified that catalyze this reaction. HO-1 is a M_r 30 000 that is inducible by heme and other numerous stimuli being the predominant form in liver and spleen. HO-2 is a constitutively synthesized M_r 36 000 protein that is abundant in brain and testis. HO-3 is a M_r 33 000 protein that, so far, has only been expressed constitutively in rat neurones. They are the products of different genes[1-32].

Overexpression of HO-1 gene can lead to hyperbilirubinemia in human with certain hepatic disorder, especially patients in whom bilirubin disposition is impaired for developmental or genetic reasons, i.e., in newborns and in patients with Crigler-Najjar type I syndrome. So, the characterization of the two constitutive forms and the expression of HO-1 gene would have considerable experimental value in elucidating the role of the enzyme in physiological and pathological processes and finally in effective prevention and treatment of hyperbilirubinemia.

The objective of this study was to purify and identify HO isomers (HO-1 and HO-2) in treated rat liver, spleen, brain and untreated rat liver, to construct the expression plasmid pcDNA3HO1 carrying HO-1 cDNA and to confirm that the cDNA actually encodes HO-1 by expressing cDNA in COS-1 cells. On the basis of these findings, we have expected the substitution of histindine residues essential for heme binding would eliminate HO activity, so site-directed mutagenesis was applied to construct mutated rat HO-1 cDNA (Histindine25→Alanine, His25Ala), then the activity of mutant was detected and compared with that of native enzyme. The inhibition of this mutant was also examined by determining the levels of bilirubin in the enzymatic reaction mixture.

MATERIALS AND METHODS

Preparation of tissue

The rats (purchased from Shanghai Institute of Cell Biology,

Academia Sinica) were allowed to food and water *ad libitum* and were injected with 40 μmol/kg hematin (pH 7.4), intraperitoneally; 100 mg/kg phenylhydrazine, intravenously. The animals were killed 20 hours after treatment.

Purification and identification of HO-1 and HO-2

All operations were carried out below 4 ℃. The rat liver, spleen and brain tissues were added 2 volumes of 0.25 mol/L sucrose solution containing 0.1 mmol/L EDTA. The mixture was homogenized and centrifuged at 9 000 g for 5 minutes. The supernatant fractions were collected and subsequently centrifuged at 150 000 g for 1 hour. The microsomal pellet was treated according to the method described by Maines *et al*. The solubilized microsomes were diluted with 1 volume of 0.05 mmol/L DTT solution, with pH adjusted to 8 and loaded onto DEAE-Sephacel column (2.5×13.6 cm) that was previously equilibrated with 20 mmol/L Tris-HCl buffer (pH 7.5) containing 0.05 mmol/L EDTA, 0.5 % TritonX-100, 0.1 % sodium cholate and 0.05 mmol/L DTT. The column was eluted with concurrent linear gradients of KCl (0-0.4 mol/L) and TritonX-100 (0.5-0.9 %) prepared with the equilibration buffer. 3-4 ml fractions were collected and analyzed for HO activity.

The pooled DEAE-Sephacel fractions containing the first peak of HO activity and the second peak of HO activity were dialyzed against distilled water for 24 hours below 4 ℃, and then concentrated and loaded onto a hydroxylapatite column equilibrated with 10 mmol/L potassium phosphated buffer, pH 7.5, respectively. The column was washed with 10 mmol/L potassium phosphate buffer, pH 7.2, containing 0.05 mmol/L EDTA, 0.4 % TritonX-100 and 0.1 % sodium cholate, followed by the same solution containing 20 % glycerol. The column was eluted with a linear gradient of 10-260 mmol/L potassium phosphate in the above buffer. The fractions containing HO activity were collected.

Construction of expression plasmid carrying native rat HO-1 cDNA

The expression vector pcDNA3 was linearized by digestion with BamHI and the single-stranded ends were filled in by treatment with DNA polymerase I (Klenow fragment). The resulting blunt ends were used for ligation with XhoI (-59) / HindIII (971) cDNA fragment isolated from pRHO1, which was provided by Shibahara. Both ends of the fragment were converted to blunt ends before ligation. The plasmid pcDNA3HO1 that encodes native HO-1 was constructed.

Mutagenesis of cDNA for rat HO-1 and construction of pcDNA3HO1D25

The expression vector pcDNA3HO1 was cleaved with XbaI. The region of the template was amplified in polymerase chain reaction. 5' -terminal primers was T7 and 3' -terminal primer was a synthetic oligonucleotide (5' -CTCAGAATTCTCTGCA CGGGTGGCCACCTCC-3'). The amplified products were digested by HindIII/EcoRI and the resulting DNA fragments (HindIII→EcoRI, 171bp) were ligated to pBS KS which had been pretreated with HindIII/EcoRI. The recombinant plasmid (pBS KSHO1-171) was digested with EcoRI and the single stranded ends were filled in by treatment with Klenow frangment followed by dephosphorylation with calf intestinal alkaline phosphatase.

To construct the plasmid pBS KSHO1D25 (4034bp), the pcDNA3HO1 was digested with EcoRI. The DNA fragments (EcoRI→EcoRI, 932bp) from pcDNA3HO1 was purified and inserted into EcoRI site of pBS KSHO1-171.

Finally, the vector pBS KSHO1D25 was cut with HindIII and BamHI, and ligated to pcDNA3, which had been also pretreated with HindIII and BamHI, to construct pcDNA3HO1D25 (6525bp).

Transfection of COS-1 cells

COS-1 cells, which were provided by Shanghai Institute of Cell Biology, Academia Sinica, were maintained in Dulbecco' s modified Eagle' s medium containing 2.5 % newborn calf serum. Confluent cells, seeded in 75 ml culture flask, were fed with medium 4 hours before addition of plasmid DNA. Plasmid DNA (10 μg per flask) was used to transfect COS-1 cells by the calcium phosphate method. DNA (at 10 μg/ml) was adjusted to 250 mmol/L $CaCl_2$ and added slowly to an equal volume of sterile 2×HBS with constant agitation. The calcium phosphate-DNA precipitate was allowed to form for 30 minutes, and 1 ml of precipitate was added to an adequate volume of medium that covered recipient cells. After 4 hours of exposure to DNA, the medium was replaced with fresh medium, and the cells were allowed to incubate for an additional 48 hours, then cells were collected and stored at-70 ℃ until assay for HO-1. The cells were disrupted by sonication and pellets (microsomes) were prepared by centrifugation at 105 000 g, 0-4 ℃, 1 hour. The microsomes were suspended in 50 mmol/ L potassium phosphate buffer, pH 7.4/0.1 % Triton X-100, subjected to SDS-PAGE to confirm whether the specific band was located in the position of M_r 30 000.

Measurement of heme oxygenase isomers and expressed products activity

The activity of HO isomers and expressed products was determined by measuring the bilirubin formation monitored as an absorbance increase at 464 nm. One unit of the enzyme was defined as the amount catalyzing the formation of 1 nmol of bilirubin per 1 hour.

SDS-polyacrylamide gel electrophoresis of HO isomers and expressed products

Electrophoretic procedures were performed according to Laemmli' s method in order to identify HO isomers and their molecular weight.

Production of antiserum

The purified rat liver HO-2 fraction mixed with 100 μl of 0.9 % NaCl solution and injected intraperitoneally into Kunming mice (10-15 g) purchased from Shanghai Institute of Cell Biology, Academia Sinica. Then these mice were boosted with antigen every second week, for three times. The mice were bled 10 days after the final boost and sera were collected and stored under -20 ℃.

Western blotting

Western blotting was performed as follows. Protein samples, rat liver HO-1 and rat brain HO-2 fractions, were subjected to SDS-polyacrylamide gel electrophoresis (SDS-PAGE) in 1.5 mm slab gels according to the procedure of Laemmli and the separated polypeptides were then transferred electrophoretically from the gel to a nitrocellulose sheet using a transfer buffer consisting of 48 mmol/L Tris base, 39 mmol/L glycine, 20 % (v/v) methanol and 0.07 % (w/v) SDS, pH 8.3. Following electroblotting, the nitrocellulose paper was stained with Ponceau S for protein detection.Destaining was performed with distilled water. For immunostaining the nitrocellulose blot was incubated at 37 ℃ for 1 hour with bovine serum albumin in 20.0 mmol/L Tris-HCl buffer, pH 7.5, containing 0.5 mol/L sodium chloride in order to saturate all protein binding sites.

The nitrocellulose blot was then incubated with antiserum against rat liver HO-2 at 37 ℃ for 1 hour, and washed several times with peroxidase-anti-mouse IgG diluted with PBS solution. The blot was stained with diaminobenzidine (DAB) solution, washed with distilled water.

RESULTS

Purification and identification of the two forms of HO from different tissues

Two peaks exhibiting HO activity from rat liver and spleen treated with hematin and phenylhydrazine were eluted using DEAE-Sephacel chromatography. The peaks were designated as HO-1 and HO-2 according to the sequence of their elution from column. The pooled DEAE-Sephacel fractions containing HO-1 and HO-2 activities were loaded onto hydroxylapatite column, and the final purified HO-1 and HO-2 products exhibited only a single band when visualized by staining of SDS-PAGE with Coomassie Blue. The values obtained for HO-1 and HO-2 activities were shown in the Figure 1, with the ratio of HO-1 to HO-2 being approximately 2.0:1 and 3.2:1, respectively.

The treated rat brain and untreated rat liver microsomal fractions were also solubilized and subjected to ion-exchange chromatography of DEAE-sephacel, respectively. The chromatography elution patterns of HO activity were compared with those of treated rat liver and spleen. Only one peak of HO activity was detected from the treated rat brain and untreated rat liver (Figure 1). An activity peak was not present in the elution at the inducible isomer of HO (HO-1) region.

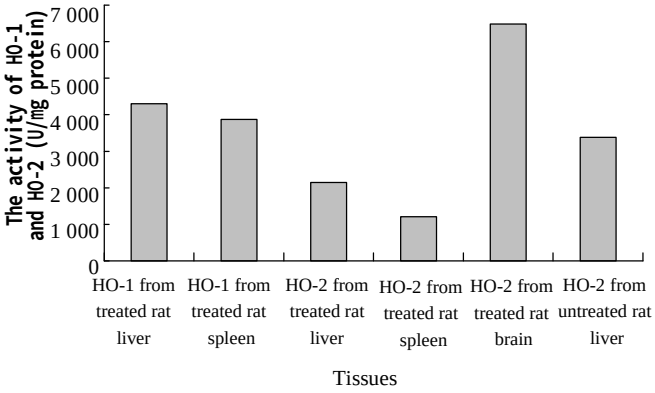

Figure 1 The measurement of HO isomers from different tissues

Characterization of HO-1 and HO-2

Two forms of HO were subjected to electrophoresis, in which two distinct bands exhibiting HO activity were detected, the migration patterns of HO-1 and HO-2 being different. The purified HO-2 on SDS-PAGE displayed a higher monomeric molecular weight. The apparent molecular weight of HO-1 and HO-2 were M_r 30 000 and M_r 36 000, respectively. The apparent molecular weight in treated brain microsomal preparation was identical to the purified liver and spleen HO-2. The HO-1 activity was increased in response to hematin and phenylhydrazine, while that of HO-2 was fully refractory to these agents. The blot was treated with anti-rat liver HO-2 serum followed by anti-mouse IgG-peroxidase conjugate and then stained for peroxidase activity. As expected, rat brain HO-2 preparation gave a reddish brown band in the region of molecular weight M_r 36 000. However, the rat HO-1 preparation failed to show a stained band.

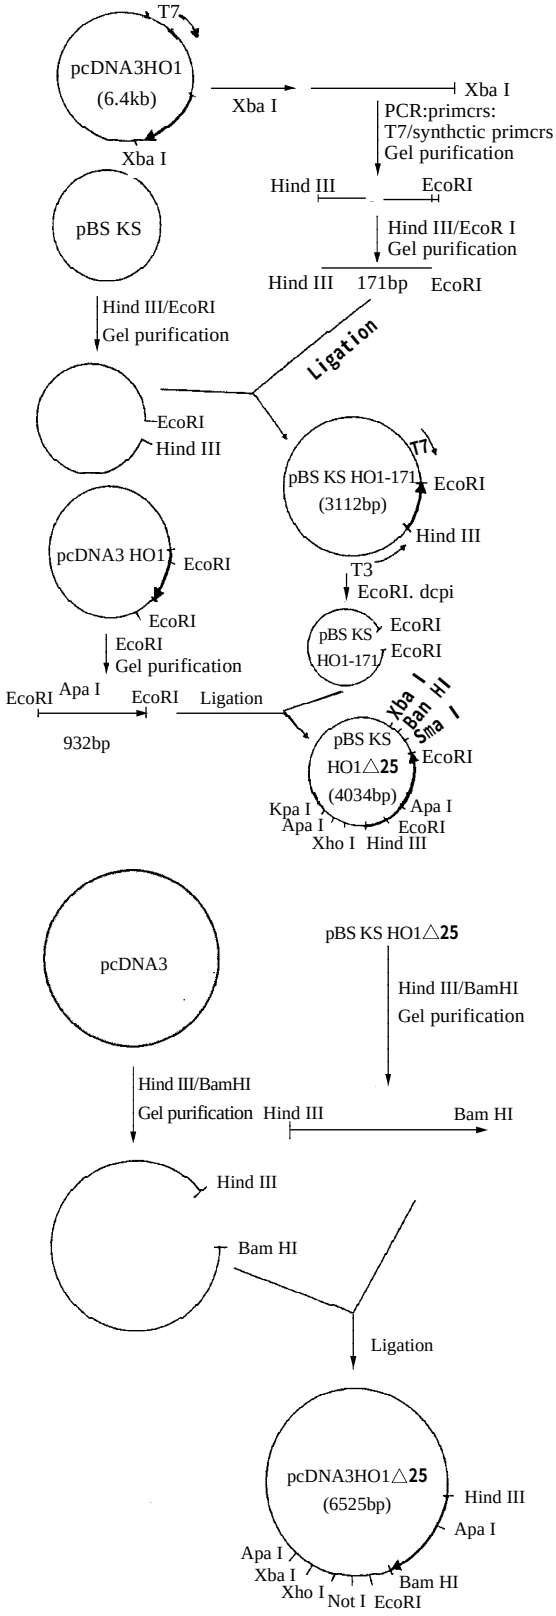

Figure 2 The strategy for construction of the expression vector of pcDNA3HO1△25

Construction of plasmid pcDNA3HO1 containing rat HO-1 cDNA

The pcDNA3HO1 containing HO-1 cDNA was screened out. The fragments of 916 bp and 5 567 bp were observed after digestion of the resulting plasmid with EcoRI indicating that the plasmid had HO-1 cDNA in a correct direction.

Expression of native rat HO-1 cDNA in COS-1 cells

The activity of HO-1 product transiently expressed in COS-1 cells was detected. The results suggested that the specific band was located in the position of M_r 30 000, the specific activities of HO-1 in COS-1 cells transfected with plasmid pcDNA3HO1 and plasmid pcDNA3 were 13 688 and 2 920 units/mg of protein/hour, respectively. The activity of expressed enzyme was 4.5-fold, 3.1-fold and 3.5-fold higher in comparison with that of the control transfected with plasmid pcDNA3, purified HO-1 from rat liver and spleen tissue, respectively.

Construction of mutated rat HO-1 cDNA (His25Ala) and assay of its activity

Figure 2. showed the strategy for construction of the expression vector of pcDNA3HO1D25. The histidine-25 residue was replaced with an alanine residue by site-directed mutagenesis. The whole nucleotide sequence of insert of mutant rat HO-1 was confirmed by the dideoxynucleotide chain-termination method. COS-1 cells transfected with pcDNA3HO1D25 were harvested by centrifugation. The activity of mutant rat HO-1 was detected and the value was 1 948-2 160 units/mg protein per hour.

The molecular weight and mobility of native and mutant rat HO-1

The protein concentrations from native and mutant rat HO-1 were 7.38 mg/ml and 7.22 mg/ml, respectively. 10 μl samples were subjected to SDS-PAGE for detecting their molecular weight and mobility. The results revealed that native and mutant rat HO-1 had the same mobility and molecular weight as that of rat liver HO-1 with a molecular mass of about M_r 30 000.

The inhibition of mutant to native HO-1

The inhibition of His25Ala mutant was confirmed by detecting the levels of bilirubin. Formation in the reaction system decreased to 42 % after addition of the mutant.

DISCUSSION

The oxidation of heme is carried out by three isozymes of microsomal HO. HO-1 is inducible by inflammatory cytokines and oxidants, including nitric oxide (NO), whereas HO-2 and HO-3 are expressed constitutively[31,32]. They are the key enzymes in the catabolic pathway of heme, and the conversion of biliverdin to bilirubin is catalysed by biliverdin reductase[33,34]. So it is highly important to inhibit the activities of HO isomers for reducing the products of bilirubin[35,36], finally to prevent and treat hyperbilirubinemia.

The microsomal HO isomers had been purified in other laboratory. The results showed HO-1, which is inducible and highly expressed in liver and spleen tissues, and HO-2, which is constitutive and distributed throughout the body. HO-3 has only been expressed constitutively in rat neurones[31,32]. The isomers have different molecular masses and are products of distinctly different genes[37]. HO-1 gene from a rat genomic DNA library was isolated using cloned cDNA as hybridization probes and determined its complete nucleotide sequence. The gene is composed of 6 830 nucleotides and consists of four introns and five exons[37]. Preliminary mutagenesis studies on rat HO-1 by Ito-Maki *et al*[38] have shown that the His25→Ala25 mutation completely abolished the enzyme activity, and histindine has been considered to be an essential residue for the enzyme activity.

In our studies, we have purified and identified two constitutive forms of HO in rat liver, spleen and brain tissues and provided evidences for a decidedly different characterization for the two forms, HO-1 and HO-2. The results indicate that in the treated rat liver and spleen, there exist two different molecular species of HO. It appears that HO-1 and HO-2 substantially differ in their molecular composition and structure as judged by their chromatographic behavior and electrophoretic migration patterns. Difference in amino acid composition or sequence usually results in such observation. In the induced liver and spleen, the microsomes contain mostly the HO-1, with the ratio of HO-1 being approximately 2.0:1 and 3.2:1, it suggests that the liver and spleen are among the main sites of haemoglobin heme degradation. Hematin and phenylhydrazine are the inducers known for their ability to increase the activity of the microsomal HO-1 in the liver, the activity of which can be induced by up to 100-fold, but the spleen HO-1 activity could not be increased after treatment of hematin and phenylhydrazine, in comparison with the results reported by Maines and Braggins. It suggests that HO activity is constantly maintained in the induced state as a result of sustained exposure to haemoglobin released in the course of disruption of senescent erythrocytes.

With the same procedure, only the form of HO, HO-2, could be clearly detected and the HO-1 was absent in the brain after inducement with hematin and phenylhydrazine. The result, however, does not suggest that this isomer is absent in the tissue, rather, it may reflect the inability of the presently used procedures to detect the exceedingly low level of HO-1, and the expression of the HO-1 isomer in the brain may be suppressed under most conditions. Surprisingly, the brain displayed a higher HO-2 activity than the liver, possibly reflecting a major biological adaptation. HO-1 and HO-2 preparation were analysed by the Western immunoblotting technique. The rat brain HO-2 preparation exhibited immunological reactivity with antibody to rat liver HO-2, but not to the rat liver HO-1, indicating that these two HO preparations are antigenically different.

pRHO1 contains 1 557 nucleotides excluding the dG tail and the poly (dA) tract (≈150 residues). The vector pcDNA3 is designed for eukaryotic expression and has an expanded multiple cloning sites to faciliate cloning of inserts besides having the same characterization of other vectors. pcDNA3HO1 harbouring the rat HO-1 cDNA. was constructed and transfected into COS-1 cells for confirming that the isolated cDNA, XhoI(-59)/HindIII(971) fragment, actually encodes HO-1. COS-1 cells have endogenous HO-1 activity and this basal activity did not change after transfection with plasmid pcDNA3HO1. Accordingly, the activity of HO-1 in cells transfected with pcDNA3 was used as control. The results indicated clearly that isolated cDNA encoded HO-1. Furthermore, these results also show that the expressed HO-1 was actually incorporated into the endoplasmic reticulum of COS -1 cells, as we isolated microsomes for assay of HO-1. Shibahara *et al*. constructed the pKCRHO21 carrying the entire protein-coding region in correct orientation as pcDNA3HO1, XhoI(-59)/HindIII(971) fragment. The cells transfected with pKCRHO21 have 2-fold higher activity than that of rat spleen. Ishikawa et al. reported that during cultivation, a few degraded forms of HO-1 that had lost their membrane-associating, C-terminal region appeared. Among these soluble enzymes, a degraded form of HO-1 with molecular mass of M_r 30 000 was found to retain ability to decomposed heme to biliverdin[37,38]. These results are in accordance with ours[39]. So it clearly indicates that isolated cDNA encodes HO-1.

There are 10 histindine residues in HO-1 and 5 of them are located between amino acid residues 100-132. Up-to-date, the report showed that the axial heme ligand in the ferrous

heme-HO-1 complex is a neutral form of the imidazole of a histindine using optical absorption, EPR, and resonance Raman scattering[38,40,41]. Histindine residues at positions 25, 84, 119 and 132 in the HO-1 sequence are conserved in rat, human, mouse and chicken HO-1. These histindines may be important for heme-binding. Preliminary mutagenesis studies on rat HO-1 by Ito-Maki *et al* have shown that the His25Ala mutation completely abolished the enzyme activity but that the replacement of either His84 or His119 by Ala did not alter the enzyme activity. On the basis of this work, His25 has been considered to be an essential residue for the enzyme activity. In this study, pcDNA3HO1D25, containing the mutated rat HO-1 cDNA (His25Ala), was constructed using site-directed mutagenesis and transfected to COS-1 cells. The activity of mutant declined but did not completely abolish. At present, no reasoning can be offered for this discrepancy. Maybe it is because the enzyme reaction system is different.

After successfully expressing mutant protein, an equal amount of mutant HO-1 was added in reaction system. The result showed that His25Ala mutant reduced the formation of bilirubin. This suggests that the mutant may competely bind the substrate-heme with native enzyme. Some researches found that the precursor of bilirubin, heme, could be discharged from bile while the metabolic procedure of heme to bilirubin was inhibited by Sn-protoporphyrin.

Further studies are required to identify His25Ala mutant characteristics before using this mutant to prevent and treat hyperbilirubinemia.

Abstract

AIM: Liver regeneration is associated with apoptosis of hepatocytes, which is mediated via tumor necrosis factor receptor 1(TNFR1). The shedding of TNFR1 in liver regeneration and its mechanism to regulate this shedding were investigated.

METHODS: The shedding of TNFR1 in liver regeneration and changes of TNF-α, PMA and plasma membrane purified from hepatocytes on this shedding process were measured with Western blot. Then, the relationship between TNFR1 shedding and apoptosis of hepatocytes induced by TNFα was studied by detecting apoptotic index.

RESULTS: The shedding of TNFR1 began at 4 hours and terminated before 2 months after partial hepatectomy. In culture system, serum from rats at 36 h after partial hepatectomy could also promote this shedding process. With the stimulation of TNF α, PMA or purified plasma membrane from hepatocytes at 36 h after partial hepatectomy or from hepatocytes treated with TNF α for 2 h, membranous TNFR1 was also shed. With the stimulation of both TNF α and plasma membrane from hepatocytes affected with TNF α for 2 h or from hepatocytes at 36 h after partial hepatectomy, apoptotic index of hepatocytes decreased from 21 % to 7.52 % and 8.45 %, respectively. PMA could also reduce apoptotic index to 13.67 %. This descent occurred in hepatocytes cultured in serum from rats at 36 h after partial hepatectomy too, but not in serum from rats at 2 months after partial hepatectomy and sham-operated rats.

CONCLUSION: Shedding of TNFR1 may help reduce apoptosis of hepatocytes induced by TNF α. Membrane-anchored metalloprotases could play a role in shedding membranous TNFR1. At the same time, PKC may take part in regulation of this shedding process.

INTRODUCTION

Tumor necrosis factor alpha (TNF-α), secreted predominantly by monocytes and macrophages, is an important mediator of various inflammatory and immune responses[1]. During liver regeneration after a partial hepatectomy, TNFα levels are elevated leading to the activation of a number of transcription factors such as STAT-3, *c-jun*, *c-fos*, activating protein-1(AP-1) and nuclear factor-κB (NFκB)[2-4]. And soluble TNF-α exerts its biological functions by binding to special target cell surface receptors[5] which have been identified as TNFR1(p55) and TNFR2 (p75)[6,7]. After ligand binding, TNFR1 or TNFR2 can be bound by TNFR-associated protein-2 and the serine/threonine kinase receptor-interacting protein, and then mediate survival and proliferating signals via the transcription factor NFκB and via activation of jun N-terminus kinase (JNK), which in turn mediates new gene transcription via AP-1[8]. On the other hand, TNFR1, not TNFR2, could be bound by the death domain of the Fas-associated death domain protein (FADD) via the adapter protein TNF-R1-associated death domain protein (TRADD), which mediates its interaction with caspase 8 and activates the caspase cascade during apoptosis.

Membranous proteins undergo shedding of ectodomain extensively, among these are cytokines such as TNFα[9,10] and kit ligand[11], cytokine receptors like the TNFα receptors[12] and the p75 nerve growth factor receptor[13], adhesion proteins such as L-selectin[14,15], and other proteins, including the β-amyloid precursor protein[16,17],the angiotensin-converting enzyme[18,19], and the protein tyrosine phosphatases LAR and PTP σ [20]. It has been postulated that shedding of membranous protein ectodomain might play a role in controlling a cell' s survival[21]. And this shedding of membranous protein happens extensively in miscellaneous cells, such as monocytes and hepatocytes. For TNFR, both the p55 and p75 form could be shed on the surface of a cell[22-25]. Recently, there had been several reports demonstrating that TNF α could induce the shedding of its own receptor in lymphocyte[26,27]. However, whether membranous TNFR1 of hepatocyte is shed during liver regeneration remains unclear. In present study, we examined this issue in rat regenerative liver.

To clarify which elements affected the shedding of membranous TNFR1, we also determined the shedding of membranous TNFR1 of hepatocyte under stimulations of TNFα, phorbol 12-myristate 13-acetate (PMA) or metalloprotease inhibitors. And then the effect of TNFR1 shedding on the apoptosis of hepatocytes was investigated.

MATERIALS AND METHODS

Partial hepatectomy

Partial hepatectomy (PH) was performed on *Sprague-Dawley Rattus norvegicus* according to Higgins' method[28].

Separation and purification of parenchymal hepatocytes

After isolated with collagenase according to the method as

described previously[29], 4 ml suspension of hepatocytes was laid on 15 ml 60 % (v/v) Percoll (Sigma) in 30 ml centrifuge tube, and then centrifugated at 400 g for 5 min at 4 ℃. Finally, obtained precipitate was washed three times with PBS at 50 g for 2 min at 4 ℃.

Primary culture of hepatocytes and treatment

After isolation, hepatocytes were cultured in 50 mL· L^{-1} CO_2 at 37 ℃ in RPMI1640 containing 10 % fetal bovine serum (BSA) and penicillin/streptomycin for 2 h according to standard protocols. Then the medium was replaced by fresh RPMI 1640 deprived of BSA to remove the non-attached cells.

To determine the effect of serum on shedding of TNFR1, serum from rats after partial hepatectomy for 36 h was added into culture medium. Thirty minutes later, cultured hepatocytes were harvested with policeman from culture dish.

For other incubations, plasma membrane purified from hepatocytes after partial hepatectomy for 48 h or from cultured hepatocytes induced by TNF-α at a concentration of 5 nmol· L^{-1} for 2 h were added at a concentration of 2 μg membranous protein per milliliter culture medium. Addition of plasma membrane boiled for 5 min and plasma membrane from hepatocytes of rats without partial hepatectomy were used as control. Then 2 mmol· L^{-1} BB-1101 (Sigma), and staurosporine at 5 ng· L^{-1} were respectively added into culture medium. Two hours later after various stimulations as above, hepatocytes were collected.

Phorbol 12-myristate 13-acetate (PMA, Sigma) alone concentrated at 10 μmol· L^{-1} (in DMSO) or PMA accompanied with staurosporine (3 nmol· L^{-1}, Sigma) were added into culture medium of attached hepatocytes for 30 min.

Purification of plasma membrane and membranous protein

Isolated or cultured hepatocytes (1×10^7) were homogenized in buffer A (1 mmol· L^{-1} $NaHCO_3$, pH7.5; 0.5 mmol· L^{-1} $CaCL_2$; 2 μmol· L^{-1} aprotinin, 10 μmol· L^{-1} E-64, 100 μmol· L^{-1} PMSF, 100 μmol· L^{-1} TPCK) on ice. After centrifuged at 1 500 g for 3 ×10 min at 4 ℃, the precipitate was suspended with 5 ml buffer A, and then mixed with 5 ml 69 % (w/v) sucrose solution. And 5 ml 42.3 % (w/v) sucrose solution was added on top of the mixture. They were then centrifuged at 100 000 g for 2 h at 4 ℃. The snip on the top of centrifugal solution was washed with buffer A at 100 000 g for 3×10 min at 4 ℃. Finally, the membranes were purified about 25-fold from homogenate, judging by their 5' -nucleatidase activity. Obtained membranes were resolved in 1 ml TrittonX114 buffer (2 % TrittonX114, 50 mmol· L^{-1} Tris- HCL, pH7.5) on ice for 15 min, then centrifuged at 10 000 g for 5 min at 4 ℃, and then incubated at 37 ℃ for 10 min and centrifuged at 2 000 g at 37 ℃ for 5 min. Detergent fraction was collected to perform procedures as described above once again. Finally, pure membranous proteins were in TrittonX114 detergent phase.

TNFR1 and membrane-anchored metalloprotease assays

Total membranous proteins were prepared as described above. Concentration of protein was determined according to described method[30]. Ninety micrograms membranous protein was separated by SDS-PAGE and electroblotted to nitrocellulose. After incubation with fresh blocking solution, blots were exposed to TNFR1 primary antibody (1:1 000, Santa cruz, USA). Blots were then incubated with a 1:1 000 dilution of rat alkaline phosphatase-colligated secondary antibody (Zhong Shan Biotech Co. China) for 1 h at 37 ℃. Blots were again washed for 3×5 min in PBS and then developed by NBT/Bcip III (Dingguo Biotech Co. China).

Assessment of apoptosis

The percentage of apoptotic cells was determined by evaluating propidium iodide and *Hoechst* 33 342 stained preparations by fluorescent microscopy and scoring 8-10 randomly selected fields containing more than 1 000 cells. In the meantime, the results were confirmed by DNA fragmentation by agarose electrophoresis[31].

Statistical analysis

All data values are expressed as means ± SE for statistical analysis, the significance of differences between experimental conditions was determined using the Student' s test for unpaired observations. A *P* value (two tailed) of less than 0.05, compared with hepatocytes cultured in RPMI1640 with 10 % BSA, was considered significant.

RESULTS

Shedding of TNFR1

Shedding of membranous TNFR1 ectodomain after partial hepatectomy was examined by Western blotting. Shedding of TNFR1 began at 4 h after hepatectomy, but not at 2 h, in which process a 55 kD form of TNFR1 was shed into a 39 kD form. And this process lasted at least for 144 h and ended before 2 months after hepatectomy (Figure1). In culture system *in vitro*, serum from rats at 36 h after partial hepatectomy could also promote this shedding process. However, serum from sham-operated rats and from rats at 2 months after partial hepatectomy could not (Figure 2). And with the stimulation of TNFα, PMA and purified plasma membrane from hepatocytes at 36 h after partial hepatectomy and from hepatocytes treated with TNFα for 2 h, TNFR1 also could be shed. But this shedding of membranous TNFR1 was inhibited by staurosporine and BB1101 (Figure 2-5).

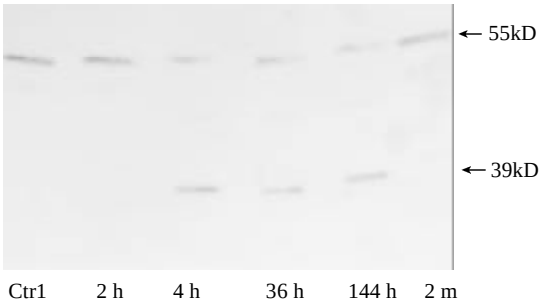

Figure 1 TNFR1 shedding on the surface of parenchymal hepatocytes occurs in regenerative liver. Data shown represent time course of TNFR1 shedding after partial hepatectomy. Plasma membrane from normal liver was used as control.

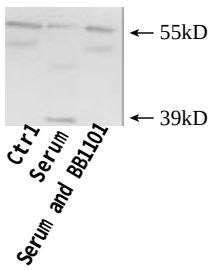

Figure 2 TNFR1 shedding under the stimulation of serum from rats after partial hepatectomy. Cultured hepatocytes were treated with serum from regener-ative liver at 36 h for 30min, or the serum accompanied with metalloprotase inhibitor BB1101 at 2mmol·L^{-1}. Cultured hepatocytes under no any treatments were used as control.

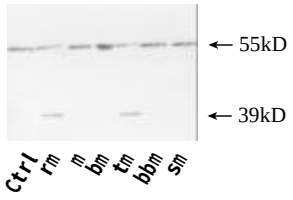

Figure 3 TNFR1 shedding induced with plasma membrane of hepatocytes from regenerative liver. Cultured hepatocytes were treated for 30 min with plasma membrane from hepatocytes at 36 h after hepatectomy (rm) or sham-operated (m) or from hepatocytes treated with TNFα at 10 μg·mL^{-1} for 2 h (tm). Plasma membrane boiled for 5 min (bm) as control. Then metalloprotase inhibitor BB1101 at 2 mmol·L^{-1}(bbm), or staurosporine at 5 ng·mL^{-1}e (sm) was added into culture medium. Cultured hepatocytes under no any treatments were as control.

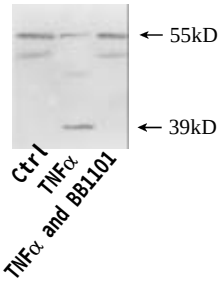

Figure 4 TNFR1 shedding under the stimulation of TNF α. Cultured hepatocytes were treated respectively with TNFα at 10 μg· mL^{-1} for 2 h, or TNFα accompanied with metalloprotase inhibitor BB1101 at 2 mmol·L^{-1}. Cultured hepatocytes under no any treatments were as control.

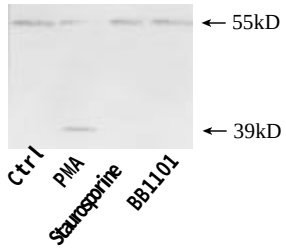

Figure 5 Effect of PMA on TNFR1 shedding. Cultured hepatocytes were treated with PMA at 10 μg·mL^{-1} for 30 min, staurosporine accompanied with PMA at 5 ng·mL^{-1}, or PMA accompanied with BB1101 at 2 mmol·L^{-1}. Confluent cultured hepatocytes without any treatment were used as control.

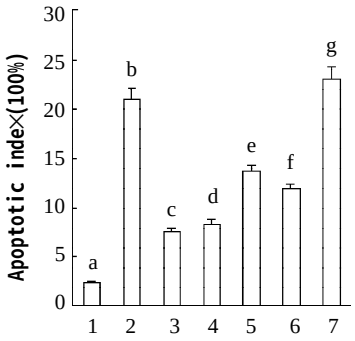

Figure 6 Induction of apoptosis after treatment with TNFα. Means of data shown in figure were: 1. Control; 2. Treated with TNFα at 10 μg·mL^{-1}; 3. Treatment with TNFα at 10 μg·mL^{-1} after treated with plasma membrane purified from liver at 36 h after partial hepatectomy at 2 μg·mL^{-1}; 4. Treated with plasma membrane at 2 μg·mL^{-1} purified from hepatocytes induced with TNFa accompanied with TNFa at 10 μg·mL^{-1}; 5. Treated with PMA at a concentration of 10 μmol·L^{-1} (in DMSO) accompanied with TNF at 10 μg·mL^{-1}; 6. Treated with serum from rat after partial hepatectomy for 36 h at 5 % accompanied with TNFα at 10 μg·mL^{-1}; 7. Treated with TNFα at 10 μg·mL^{-1} after treated with plasma membrane purified from rat liver regenerated for 2 months at 2 μg·mL^{-1}. Apoptotic index=(numbers of apoptotic cells / total cells numbers per well)×100. Data were means from 6 separate experiments ×SE (n=6 wells). Different letters over bars indicate significant differences, P<0.05. The results are confirmed by DNA fragmentation by agarose electrophoresis (data not provided).

Effects of TNFR1 shedding on apoptosis of hepatocyte

Purified plasma membrane from hepatocytes at 36 h after partial hepatectomy or from hepatocytes induced with TNFα or PMA reduced the apoptotic index induced by TNFα from 21 % to 7.52 % , 8.45 % and 13.67 %, respectively. This descent also occurred in hepatocytes cultured in serum from rats after partial hepatectomy for 36 h. But cultured in serum from rats at 2 months after partial hepatectomy, apoptotic index of hepatocytes was even higher than that in serum from sham-operated rats (Figure 6).

DISCUSSION

In adult liver, hepatocytes are highly differentiated and predominantly in G_0 state of cell cycle. Partial hepatectomy can induce these hepatocytes to undergo rapid proliferation, leading to organ regeneration[3,32,33]. However, the exact mechanisms that initiate and terminate this highly regulated proliferative event remain unclear. In present studies, we assessed the shedding of TNFR1 during liver regeneration and the association between this shedding and apoptosis of hepatocytes.

Several recent works had provided obvious evidences that tumor necrosis factor-α (TNF-α) functioned as a two-edged sword in the liver. It is an important cytokine of the early signaling pathways leading to regeneration and an antiapoptotic effector. On the other hand, it is also an intensive mediator of apoptosis[2,3]. TNFR should be involved in all these process above because TNFα must bind to TNFR before it can exert its roles. And down-regulation of membranous TNFR1 expression levels of hepatocyte had been previously confirmed as an important pathway to regulate the role of TNF-α[34]. Our results demonstrated that the shedding of TNFR1 occurred during liver regeneration. This shedding of TNFR1 could reduce apoptotic rate of hepatocytes induced by TNF-α.These results suggested that TNFR1 shedding might also be a pathway to down-regulate membranous TNFR1 levels of hepatocyte. Our finding that shedding of TNFR1 induced by serum from rats after partial hepatectomy progressively suggested that some factors were secreted into serum during liver regeneration. These factors might regulate liver regeneration by inducing the shedding of TNFR1.

Several peptide hormones had been shown to down-modulate their own receptors[35-38]. This down-modulation was believed to require the binding of the ligand with its receptor, followed by internalization of the ligand-receptor complex into the cell. After the dissociation of the receptor from its ligand inside the lysosome, the receptor was either degraded or recycled back to the cell surface[39]. Our results showed that the TNFR1 shedding was induced by TNF-α, though only parts

of membranous receptor were shed. Higuchi reckoned that TNFR2, not TNFR1, was shed in lysosome[40]. However, our results showed that membranous TNFR1 could be shed on the cell surface.

Our results also showed that metalloprotase inhibitor inhibited the shedding of TNFR1. This suggested that some metalloprotases played a role in this shedding process. Two possible sources of these metalloprotase could be proposed for the shedding of TNFR1. One possibility was that these metalloprotases presented in serum because the shedding of TNFR1 could be induced by serum from rats after partial hepatectomy and inhibited by BB1101. It was also possible that these metalloprotases were membrane-anchored proteins. TNFR1 was shed when cells were treated with plasma membrane purified from hepatocytes of regenerative liver. At the same time, this shedding of TNFR1 could be inhibited by metalloprotase inhibitor either.

We also found that PMA could induce the shedding of TNFR1. This shedding of TNFR1 was inhibited by staurosporine. These results suggested that PKC was involved in regulating the shedding of TNFR1. Perhaps phosphorylating of TNFR1 by PKC made it sensitive to metalloprotase. However, further investigations are needed to identify which protease should be responsible for the shedding of TNFR1.

Abstract

AIM: To investigate the therapeutic effects of recombinant human growth hormone (rhGH) on rat septic shock with intraabdominal infection by *E. coli* and its possible mechanism.

METHODS: 76 SD rats were divided into 3 groups randomly: control group (group C, n=16) without any special treatment, septic shock group (group S, n=30) received bolus injection of *E.coli* (1×10^{10} cfu·L^{-1},15 ml·kg^{-1}, ip), treated group (group T, n=30) received bolus injection of *E.coli*, and then followed by rhGH injection (2.25 U·kg^{-1}·d^{-1}, im). Group S and group T were further divided into 1d and 3d subgroups, respectively (n=15 each). Mean arterial pressure (MAP), levels of plasma TNFα and endotoxin and leukocyte count were determined on 1st day and 3rd day after *E.coli* injection. Another 39 SD rats were divided into groups C, S and T (n=13 each) just for observing survival rate within 1 week.

RESULTS: (1) On 1st and 3rd day, MAP in group S decreased markedly, and MAP on 1st day lowered more than that of 3rd day (P<0.01), while MAP in group T just decreased slightly. The survival rate within 1 week was much higher in group T (84.6 %) than in group S (46.2 %) (P<0.01). (2)On 1st day, plasma TNFα and endotoxin elevated significantly in group S and group T (P<0.05), and endotoxin in group S had more increase (P<0.01). On 3rd day, TNFα in group S returned to the level of group C (P>0.05),while TNFα in group T went down below the level of group C(P<0.01). On 3rd day, endotoxin in group S declined, but was still higher than that of group C (P<0.01), endotoxin in group T returned to the level of group C (P>0.05). (3) On 1st day, neutrophil ratio in total leukocyte count in both group S and group T increased significantly (P<0.05 *vs* group C).

CONCLUSION: rhGH showed beneficial effects on rat septic shock. The possible mechanisms may involve the attenuation of bacteria/endotoxin translocation and decreased systemic endotoxin level; inhibition of the production and release of TNFα; improved circulatory function; improved systemic host defenses and maintenance of intestinal mucosa barrier.

Huang Y, Wang SR, Yi C, Ying MY, Lin Y, Zhi MH. Effects of recombinant human growth hormone on rat septic shock with intraabdominal infection by *E. coli*. *World J Gastroenterol* 2002; 8(6):1134-1137

INTRODUCTION

Septic shock is a common and severe disease, the incidence and mortality of septic shock are still very high now-a-days. Growth hormone is an important anabolic hormone. Experimental study showed that recombinant human growth hormone (rhGH) enhanced protein synthesis[1], promoted tissue recovery, improved host defenses[2-4], decreased stress and maintained intestinal mucosa barrier[5,6]. The present study was to investigate the therapeutic effects of rhGH on rat septic shock with intraabdominal infection by *E.coli* and its possible mechanism.

MATERIALS AND METHODS

Animal models and groups

76 female Sprague-Dawley rats weighing between 200 and 240 g were obtained from the Animal Center of Sichuan University. The rats were divided randomly into 3 groups: control group (group C, n=16) without any special treatment; septic shock group (group S, n=30) ,injected intraperitoneally with a bolus of *E.coli* (1×10^{10} cfu· L^{-1}, 15 ml· kg^{-1}); treated group (group T, n=30) received a bolus injection of *E.coli*, and then followed by rhGH intramuscular injection (2.25 U· kg^{-1}· d^{-1}). Group S and group T were further divided into 1d and 3d subgroups, respectively (n=15 each).

Another 39 female Sprague-Dawley rats weighing between 200 and 240 g were divided into groups C, S and T (n=13 each) just for observing the survival rate within 1 week.

Reagents

rhGH (Saizen) was obtained from Serono Co. in Switzerland. Bacterial suspension of *E. coli* was supplied by Dept. of Microbiology in Huaxi School of Basic Medical Sciences and Forensic Medicine. Limulus amebocyte lysate (LAL) kit and radioimmunoassay (RIA) kit of rat TNFα were purchased from Shanghai Laboratory of Medical Science and Institute of Radioimmunology, Chinese PLA General Hospital, respectively.

Methods

Measurement of blood pressure Rats were anesthetized with sodium pentobarital (15 ml· kg^{-1}, ip) on 1st day or 3rd day after receiving *E.coli*. An arterial cannula connected with Four-Channel Physiological Measuring Instrument (RM-6200, Japan) was inserted into a carotic artery for recording mean arterial pressure (MAP).

Leukocyte count 0.5 ml blood anticoagulated by heparin was collected through a venous cannula which was inserted into an external jugular vein. Leukocyte count was measured by using CELL-DYN 1600.

Plasma endotoxin determination Levels of plasma endotoxin was determined by LAL test, according to the manual of the kit.

Measurement of plasma TNFa Concentrations of plasma TNFα was measured using RIA, according to the manual of the kit.

Statistical analysis

All data except survival rate were expressed as mean ± standard deviation ($\bar{x}\pm s$). Data were analyzed by *t*-test or variance analysis using SPSS 10.0 software, and $P<0.05$ was considered as the significant level of difference.

RESULTS

Mean arterial pressure (MAP) and survival rate

On 1st day and 3rd day, MAP in group S decreased obviously, and MAP on 1st day showed a 46 % decrease($P<0.01$,*vs* group C). MAP in group T was just about 10 % reduction($P<0.05$, *vs* group C). These results suggested that rhGH could attenuate the hypotension induced by septic infection. 7 Rats in group S were dead within 1 week, the survival rate was 46.2 % (6/13). 2 Rats in group T were dead within 1 week, the survival rate was 84.6 %(11/13). All rats in group C survived. The survival rate was much higher in group T than in group S ($P<0.01$, See Table 1). These findings indicated that rhGH could improve the outcome of septic shock significantly.

Table 1 Effects of rhGH on mean arterial pressure (MAP) ($\bar{x}\pm s$) and survival rate within 1 week in rat septic shock

Group	MAP (mmHg)		Survival rate within
	1 d	3 d	1 week (%)
C	124.6±13.9		100.0
S	67.4±22.6[b]	98.9±23.2[ad]	46.2
T	114.4±15.9[ad]	109.9±10.2[a]	84.6[f]

[a]$P<0.05$,[b]$P<0.01$, *vs* group C,[d]$P<0.01$, *vs* group S in 1 d; [f]$P<0.01$, *vs* group S.

Leukocyte count

On 1st day, the numbers of leukocyte in both group S and group T showed no significant difference from that of group C($P>0.05$), while neutrophil ratio in total leukocytes was higher in both group S and group T than in group C, and more in group T($P<0.05$). On 3rd day, both the numbers of leukocyte and neutrophil ratio in total leukocytes had no significant changes among the three groups($P>0.05$, See Table 2).

Table 2 Effect of rhGH on leukocyte count in rat septic shock ($\bar{x}\pm s$)

Time	Leukocyte ($\times 10^9$/L)			Neutrophil (%)		
	Group C	Group S	Group T	Group C	Group S	Group T
1 d		8.42±2.44	9.61±3.58		28.75±8.83[a]	36.77±11.84[bc]
	7.73±4.57			16.14±6.0		
3 d		6.75±2.18	6.07±2.45		13.74±7.06	14.96±5.35

[a]$P<0.05$, [b]$P<0.01$, *vs* group C; [c]$P<0.05$, *vs* 1 d in group S.

*Plasma endotoxin and TNF*a

On 1st day, plasma TNFα and endotoxin increased significantly in group S and group T ($P<0.05$), and endotoxin in group S had more increase ($P<0.01$). On 3rd day, TNFα in group S returned to the level of group C ($P>0.05$), while TNFα in group T went down below the level of group C ($P<0.01$). Endotoxin in group S decreased, but was still higher than that of group C($P<0.01$). Endotoxin in group T returned to the value of group C ($P>0.05$, See Table 3). These results suggested that rhGH could extinguish plasma endotoxin and inhibit the production and release of TNFα.

Table 3 Effects of rhGH on the concentrations of plasma endotoxin and TNFα in rat septic shock

Time	Endotoxin (U·L^{-1})			TNFα (μg·L^{-1})		
	Group C	Group S	Group T	Group C	Group S	Group T
1 d		256±52[a]	150±39[bc]		3.59±0.69[b]	3.66±1.33[b]
	111±53			2.88±0.74		
3 d		189±52[a]	108±42[d]		2.23±1.09	1.54±0. 36[ad]

[a]$P<0.01$,[b]$P<0.05$, *vs* group C; [c]$P<0.01$,*vs* group S in 1 d; [d]$P<0.01$, *vs* group S in 3 d.

DISCUSSION

When acute peritoneal bacterial infection happens, there are two lines of host defense against peritoneal bacterial invasion. The first line of host defense is peritoneal resident cells, which consist mainly of macrophages. Peritoneal macrophages begin the process of phagocytosis and killing of bacteria immediately after bacterial inoculation[7]. Inoue T *et al* demonstrated that administration of rhGH augmented the numbers of peritoneal macrophages significantly in gram-negative sepsis model. The second line of host defense is an acute inflammatory response involving the influx of neutrophils. Neutrophils are attracted to the site of infection by chemotactic factors, then phagocytize, kill and eliminate bacteria[7]. In our study, neutrophil ratio in total leukocyte count in both group S and group T increased significantly than that in group C on 1st day, and more in group T. Our results indicated that rhGH could significantly increase neutrophil ratio in total leukocytes. Taken together, it could be inferred that rhGH could enhance the two lines of host defense, accelerate the clearance of bacteria from the peritoneal cavity, minimize the spread of bacteria to blood, and then diminish plasma endotoxin and proinflammatory cytokines levels.

Endotoxin, the main toxic component of gram-negative bacteria, is the leading cause of sepsis or septic shock[8-10]. Our experiment showed that plasma endotoxin levels both in group S and group T elevated obviously after *E.coli* challenge. The main reason of higher endotoxin level in plasma was related to the proliferation of *E.coli* in blood and peritoneal cavity. In addition, it was also associated with the impairment of intestinal mucosa barrier, which may cause and accelerate bacteria/endotoxin translocation[11].

An important function of intestinal mucosa barrier is to prevent translocation of bacteria/toxins from gut lumen into circulation[12-23]. Glutamine (Gln), the preferred fuel for gut[24], is a required nutrient for maintaining the normal structure and function of intestinal mucosa barrier[25,26]. The ability of intestinal mucosa uptaking and utilizing Gln directly influences the function of intestinal mucosa barrier. In septic shock, ischemia, hypoxia and proinflammatory cytokines may result in impairment of intestinal mucosa barrier, meanwhile, Gln

intake by intestinal mucosa and the activity of glutaminase, which catalyzes the hydrolysis of Gln to glutamate and ammonia, could also be injured, so result in marked reduction of the utilization of Gln by gut. An injured Gln metabolism may be another contributor in the breakdown of the intestinal mucosa barrier. The impairment of intestinal mucosa barrier facilitating the entering of bacteria/endotoxin into portal venous and lymphatic systems was defined as bacteria/endotoxin translocation[27-29]. Moreover, higher systemic endotoxin level could significantly compromise the integrity of intestinal mucosa barrier, and further enhanced the translocation of bacteria/endotoxin[30].

On 1st day, plasma endotoxin increased significantly in group S than in group T. On 3rd day, endotoxin in group S remained at higher level, while endotoxin in group T returned to control level. These results suggested that rhGH could decrease plasma endotoxin level, which might be due to: (1) rhGH binding growth hormone receptors localized extensively in intestinal mucosa could increase the activity of glutaminase, promote intestinal mucosa to uptake and utilize Gln, ameliorate the impairment of intestinal mucosa barrier. (2) rhGH could also protect intestinal mucosa barrier by enhancing the paracrine and autocrine mechanism of IGF-1 and upregulate the expression of IGF-1 mRNA in intestine[31]. Thereby, rhGH administration showed beneficial effects in maintaining the integrity of intestinal mucosal barrier[32,33], attenuating bacteria/endotoxin translocation[27,34,35] and decreasing plasma endotoxin level[31]. In addition, Prieto *et al*[7] also demonstrated that rhGH could promote the release and chemotaxis of neutrophils, minimize the spread of bacteria and attenuate bacteria/endotoxin translocation, and then reduce plasma endotoxin level.

Endotoxin could trigger a series of inflammatory processes, leading to release of many other proinflammatory cytokines[34]. TNF, a central mediator of the complex network of proinflammatory cytokines[35], plays a critical role in the pathogenesis of gram-negative-induced sepsis. Our results showed plasma TNFα increased significantly on 1st day after *E. coli* injection. The mechanism of higher plasma TNF may be due to[35]: (1) TNF released from macrophages in gut wall and peritoneal cavity in response to endotoxin stimulation, which may be one of the reasons of early higher TNF level in portal vein and systemic circulation. (2) Endotoxin entering liver via portal venous, stimulated Kupffer cells to produce more TNFα and then further elevated plasma TNFα level[36-38]. On 3rd day, TNFα in group S returned to the level of group C, while TNFα in group T reduced even lower than that in group C,suggesting that rhGH could inhibit the production and release of TNFα. The mechanism may involve: rhGH maintained intestinal mucosa barrier, diminished bacteria/endotoxin translocation and downregulated the production of TNF.

After *E.coli* injection, MAP in rats of group S decreased obviously, MAP declined even more obviously on 1st day than on 3rd day; while MAP in group T just decreased slightly on 1st day and 3rd day. The data revealed that rhGH could attenuate the decline of blood pressure in septic shock. The mechanism of rhGH improving circulatory function may be related to inhibition of production and release of proinflammatory cytokines and decrease of systemic endotoxin level.

The survival rate within 1 week was much higher in group T (84.6 %) than in group S (46.2 %), which indicated that rhGH could increase survival rate and improve outcome in septic shock.

In summary, the above results showed that rhGH treatment had desirable beneficial effects on rat septic shock, which may involve the following mechanism that rhGH administration could improve host defenses[2-4]; maintain intestinal mucosa barrier[5,6], diminish bacteria/endotoxin translocation[17-19]; decrease systemic endotoxin level[18]; inhibit the production and release of TNFα and improve circulatory function.

Abstract

AIM: To study the correlation between expression of MMP-2, TIMP-2 protein and the ratio of MMP-2/TIMP-2 and clinical-pathological parameters of patients with gallbladder carcinoma.

METHODS: Carcinomas (n=45) and polypoid lesions (n=15) of the gallbladder were studied for the expression of MMP-2 and TIMP-2 protein by immunohistochemical avidin-biotin-complex method and image analysis. Clinical-pathological data of patients with gallbladder carcinoma such as histological type, grade of differentiation, level of infiltration, liver invasion and lymph node involvement, etc, were recorded.

RESULTS: There was significant difference between the average level (1.123±0.108 *vs* 1.030±0.054, P=0.002) of MMP-2, the ratio (1.050±0.013 *vs* 0.937±0.078, P=0.003) of MMP-2/TIMP-2 in gallbladder carcinomas and in polypoid lesions of the gallbladder. Significant difference was found between the expression of MMP-2 in early stage and advanced tumors, but there was no correlation between MMP-2 protein expression and histological type, differentiation degree, infiltration level, lymph node involvement or liver invasion. Although no difference was observed between TIMP-2 expression and histological type or differentiation degree, significant difference was found between TIMP-2 expression and different Nevin stage, infiltration level, local lymph node involvement or liver invasion (1.168±0.067 *vs* 1.048±0.075, 1.170±0.062 *vs* 1.039±0.069, 1.039±0.076 *vs* 1.147±0.083, 1.048±0.074 *vs* 1.103±0.095, P<0.05). MMP-2/TIMP-2 ratio did not correlate with histological type, grade of differentiation and liver invasion, but significant differences were found between MMP-2/TIMP-2 ratio and different Nevin stage, infiltration level and lymph node involvement in patients with carcinoma of gallbladder.

CONCLUSION: TIMP-2 and MMP-2/TIMP-2 ratio could reflect more accurately biological characteristic of gallbladder carcinoma and MMP-2/TIMP-2 ratio might be a new significant marker in early diagnosis, in the judgment of invasion or metastasis and the estimate of prognosis in patients with gallbladder carcinomas.

INTRODUCTION

Primary carcinoma of gallbladder represents a very lethal malignant tumor because of its early metastasis, strong invasion and poor prognosis[1-3]. It is very important to estimate the malignant degree and invasion tendency in order to guide clinical diagnosis and treatment of gallbladder carcinoma. Breakage or degradation of ECM (extracellular matrix) and BM (basement membrane) is necessary in the process of tumor invasion[4,5]. Matrix metalloproteinases (MMPs) and their tissue inhibitors of metalloproteinases (TIMPs), specially, MMP-2 and its tissue inhibitor (TIMP-2), take important roles in degradation of ECM and BM[6,7] and relating to tumor invasion[8-11]. So far, there are no reports on the expression of MMP-2, TIMP-2 and the ratio of MMP-2/TIMP-2 in gallbladder carcinoma. An effort is presently made to examine expression of MMP-2 and TIMP-2 protein and ratio of MMP-2/TIMP-2 in carcinomas and polypoid lesions of the gallbladder, to study correlation between expression of MMP-2, TIMP-2 and ratio of MMP-2/TIMP-2 and clinical-pathological parameters of patients with gallbladder carcinoma and to evaluate their clinical significance.

MATERIALS AND METHODS

Materials

45 carcinomas and 15 polypoid lesion of the gallbladder underwent operational resection and confirmed histopathologically at Tongji hospital of Tongji University from 1995 to 2000 were studied. All samples were fixed in 10 % formalin and embedded in paraffin. In 45 patients with carcinoma of gallbladder, there were 6 males and 39 females with a mean age of 61.9 years (range 36-80 years). Of these, there were histologically 30 adenocarcinomas, 6 papillary carcinomas and 9 others (squamous, mucinous, undifferentiated and clear cell carcinoma); there were 24 G1 (well differentiation), 11 G2 (moderate differentiation) and 10 G3 (poor differentiation), according to the criteria established by World Health Organization for histological type of tumors of the gallbladder and extrahepatic bile ducts. Clinical-pathological dates of each patient with carcinoma of gallbladder, such as histological type, grade of differentiation, level of infiltration, liver invasion and lymph node involvement, etc, were recorded. 15 polypoid lesions of the gallbladder were used as controls. Of them, there were 7 males, 8 females with a mean age of 45.5 years (range 27-74 years).

Methods

Immunohistochemistry Immunohistochemical staining was performed on sections from formalin-fixed paraffin-embedded blocks by the avidin-biotin-complex method (*SABC kit, BOSTER*). Monoclonal MMP-2 antibody (*Neomarker's*) was used at a concentration of 1:100 and TIMP-2 antibody (*Antibody Diagnostic*) at 1:20. Goat serum, biotinylated secondary antibody (goat anti-mouse *IgG*) and DAB are all purchased from BOSTER. For negative control, the slides were treated with PBS in place of primary antibody.

Quantified analysis of stained intensity[12] Stained intensity was quantified with the software Analysis System of Clinicopathological Image (*version 2, for windows 95/ OSR*). The methods were as follows: (1) estimating the percentage of positive tumor cells, no positive cells, regarded as 0 %. (2) examining average gray value of positive cells of individual slide with image analysis system to be used as antigen concentration. (3) calculating antigen content: Content=gray value×percentage of positive cells. Control samples were examined with the same methods.

Data alternating and statistical analysis Because some samples were negative the examined data needed to be alternated. Regarding examined data as X, alternated data as Y. Alternating method was as following:

$$Y=e^{x} \qquad e=2.71828$$

In this way MMP-2/TIMP-2 ratio was calculated.

All the statistical analyses were performed using *SPSS 10.0* for windows. $P<0.05$ or $F<0.05$ was considered to be of statistical significance.

RESULTS

Expression of MMP-2 and TIMP-2 protein and the ratio of MMP-2/TIMP-2 in carcinomas and polypoid lesions of the gallbladder

Expression of MMP-2 and TIMP-2 protein was observed in tumor cells and epithelial cells of benign lesions, tumor stromal tissues, muscularis of gallbladder and vas wall. Some endangium of vas wall were stained. The protein of MMP-2 and TIMP-2 was mainly expressed in cytoplasm of positive cells (Figure1-4). Although the expressing pattern of MMP-2 and TIMP-2 protein in carcinomas of gallbladder was identical to that in polypoid lesions of gallbladder, expressed value of MMP-2 in carcinoma was significantly higher than that in polypoid lesions while there was no difference in TIMP-2 protein expression between the two groups (Table 1). In addition, the ratio of MMP-2/TIMP-2 in carcinoma of gallbladder was significantly higher than that in polypoid lesions of gallbladder (P=0.003, Table 1).

PLG: polypoid lesions of the gallbladder; GBC: gallbladder carcinoma. [a]P=0.002, [b]P=0.003.

Correlation between expression of MMP-2, TIMP-2 protein and ratio of MMP-2/TIMP-2 and clinical-pathological parameters in patients with carcinoma of gallbladder

Correlation between expression of MMP-2, TIMP-2 protein and ratio of MMP-2/TIMP-2 and clinical-pathological parameters in patients with carcinoma of gallbladder were shown in Table 2 and Figure 3-8. There were no correlation between expression of MMP-2 or TIMP-2 protein and ratio of MMP-2/TIMP-2 and the patients' histological type or degree of differentiation (F test, $P>0.05$). Based on Nevin stage criteria, our files included early stage (S1, S2. n=11) and advanced stage tumors (S3-S5, n=34). Expression of MMP-2 protein was only correlated with Nevin stage ($P<0.05$); while expression level of TIMP-2 protein was positively correlated with Nevin stage and infiltration level ($P<0.05$), but was reversely correlated with lymph node metastasis and liver invasion ($P<0.05$). There were significant differences between ratio of MMP-2/TIMP-2 and different Nevin stages, infiltration levels, lymph node metastasis and liver invasion in patients with gallbladder carcinoma.

DISCUSSION

One of the typical characteristics of malignant tumor is invasion and metastasis. Its ability of invasion and metastasis is mainly responsible for their lethality. So it is necessary to understand the molecular and cellular mechanism of tumor dissemination so as to develop novel therapies basing on this knowledge. Tumor invasion is considered to be a dynamic, complex and multi-step process[13], but the essential step is the degradation of extracellular matrix (ECM) and basement membrane (BM)[13,14]. It was reported that MMPs (matrix metalloproteinases) are important for the degradation of ECM. MMPs hydrolyze specifically type Ⅳ, Ⅴ, Ⅶ, Ⅹ collagens and fibronectin, elastin *et al*, which are all important components of ECM and BM, and are closely associated with the invasiveness and metastasis of tumor[15-20]. TIMPs (tissue inhibitors of metalloproteinases), as the specific inhibitors of MMPs, have such ability to form tight binding, non-covalent inhibitory complexes with multiple members of the MMP family that they inhibit MMP activity of ECM degradation and have anti-metastasis function[21,22].

There have been many reports about correlation between expression of MMP-2 and TIMP-2 and tumor development[22-28]. However, no reports concerning correlation between expression of MMP-2 and TIMP-2 and clinicopathological parameters in gallbladder carcinoma have been found. In an immunohistochemical study of 27-pancreatic cancers conducted by Branhall[29], a strong correlation was found between over-immunoreactivity of MMP-2 and the aggressive phenotype of pancreatic carcinoma. Another study of 177 breast cancer consisting mainly of invasive ductal carcinoma showed that the activation rate of pro-MMP-2 is significantly higher in node-positive carcinomas than in nod-negative cancers or benign neoplasms. Patients with positive staining for MMP-2 were significantly associated with shortened survival and a 3.6 fold increase in the risk of death. MMP-2 was an independent prognostic indicator in multivariate analysis[30]. Transfection of TIMP-2 gene into HT-1080 cell line and C-H-ras transformed rat embryo fibroblast inhibited their invasion potential in a murine tumor model. Ara *et al*[4] have observed the expression of high level of TIMP-2 in early stage and the inverse correlation with the corresponding MMP-2 in cases of neuroblastoma, which may represent a mechanism by which tumor cells and stromal tissues control the proteolysis and remodeling of ECM that occurs during invasion and advancement of stages. Also, the correlation of TIMP-2 over-expression with better chance of survival seemed to be associated with the ability of TIMP-2 to inhibit MMP-2 activities and tumor invasion. But recently some studies have suggested that the expression level of TIMP-2 relates to poor prognosis. Ree *et al*[31] showed that TIMP-2 mRNA level correlated with the development of distant metastases. It was reported in another study that TIMP-1 and TIMP-2 mRNA levels were positively correlated with lymph node metastasis, reduced 5-year survival and Duke' s classification in primary colorectal carcinomas. A study on stomach cancer showed that TIMP-1 and TIMP-2 were identified in 41 % and 57 % of tumors, respectively, whereas normal gastric mucosa was negative. No correlation was observed between the presence of TIMP-2 and tumor stage, histological type, lymph node status or survival[32].

Primary carcinoma of the gallbladder represents a lethal malignant tumor because of its early metastasis, poor prognosis and great difficulties in management[1-3]. Focusing on the key step of ECM degradation in metastasis, studying on the expression of MMP-2 and TIMP-2 and evaluating the correlation between these expression levels and clinicopathological parameters would be important for early diagnosis, judgment of invasion or metastasis and prognosis in patients with carcinoma of gallbladder. The present study examined the expression of MMP-2 and TIMP-2 in primary carcinoma of gallbladder by immunohistochemical and image analysis methods in order to evaluate accurately the invasive potential of tumor cells. Results showed that several types of tissues expressed MMP-2 and TIMP-2 protein, such as tumor cells, muscularis of gallbladder and vas wall, stromal cells and epithelial cells of benign lesions, indicating that MMP-2 and TIMP-2 are from epithelial cells (normal or transformed) and other stromal cells. The staining pattern of tumor cells and epithelial cells of benign lesions was cytoplasmic type, identical to previous immunohistochemical studies[33]. Although the expression of MMP-2 and TIMP-2 could be observed in carcinomas and polypoid lesions of the gallbladder, the expression level of MMP-2 and the ratio of MMP-2/TIMP-2 in tumor was significantly lower than those in benign lesions. But there was no difference in TIMP-2 levels between the two groups, indicating that the relatively high expression of MMP-2 was the basis of tumor invasion and metastasis.

With regard to correlations between the expression of MMP-2 or TIMP-2 and clinicopathological parameters of patients with carcinoma of gallbladder, the present study showed that the expression of MMP-2 related to Nevin stage. Expression value in advanced stage was obviously higher than in early stage (1.143±0.110 *vs* 1.063±0.077, $P<0.05$), but had no correlation with lymph node status and infiltration level. These seemed in contradiction with above reports. The reasons were, on one hand, difference of study method and antibody[14], on the other hand, double effects of TIMP-2. TIMP-2 not only inhibits MMP-2 activities but also takes part in activation of MMP-2 on the cell surface. If the relationship between MMP-2 and TIMP-2 was not considered, invasive characteristic of cancer cells would not be reflected completely by only examining the expression of MMP-2. In addition, there was no significant difference in the expression value of TIMP-2 between groups of different histological type and grade of differentiation. Expression of TIMP-2 in early stage was obviously higher than in advanced stage, and correlated with infiltration level, local lymph node metastasis and liver invasion. All these suggested that there was a correlation between TIMP-2 expression and the clinicopathological parameters standing for the patients' prognosis. TIMP-2 may be one of indicators in the judgment of Nevin stage, invasion and lymph node metastasis in patients with carcinoma of gallbladder.

MMPs play a major role in ECM degradation while TIMPs are the specific regulators of MMPs. The balance of MMPs/TIMPs is the decisive factor for the maintenance of ECM steadiness and integrity, and the roles of MMPs in tumor metastasis do not depend on the absolute concentration of MMPs in local area, but the MMPs/TIMPs ratio. The expression levels of MMPs and TIMPs would alter in varying degrees in many biological or pathological processes, such as blastocyst implantation, embryonic development, never growth, tissue remodeling, wound healing and the breakdown of blood brain barrier, ulceration, liver fibrosis *et al*[34-41], but the MMPs/TIMPs balance is controlled accurately. During tumor metastasis the balance of MMPs/TIMPs is broken, favoring ECM degradation without regulation. A study demonstrated recently that the increased adhesion of A2058 cells was associated with increased secretion of MMP-2, which was then inhibited by the increase of TIMP-2. The author

believed the imbalance of MMP-2 and TIMP-2 was critical for tumor cells to have strong invasive potential. Thus examining the absolute concentration of MMPs in local area had no significance and could not reflect the invasive potential of tumor cells. MMPs/TIMPs might act as a prognostic factor indicating malignant invasion and metastasis.

Based on this point, the author evaluated for the first time the correlation between the ratio of MMP-2/TIMP-2 and the clinicopathological parameters of gallbladder carcinoma when examining the expression of MMP-2 and TIMP-2 protein. The results showed that the ratio of MMP-2/TIMP-2 was obviously lower in ploypoid lesions of the gallbladder than that in carcinoma of gallbladder (P=0.003). The ratio of MMP-2/TIMP-2 related to Nevin stage and was significantly higher in advanced cases than in early cases. Significant difference of the ratio between lymph involvement (+) and (-) was also observed (1.092±0.122 *vs* 0.973±0.114, P<0.05). Moreover, the ratio of MMP-2/TIMP-2 also correlated with infiltration level. Gohji and coworkers[42] have examined MMP-2/TIMP-2 of 53 advanced urothelial cancers, and reported that MMP-2/TIMP-2 ratio was obviously higher in 31 patients with recurrence than that in patients without recurrence. COX multiple regression analysis showed MMP-2/TIMP-2 as a new marker predicting recurrence in urothelial tumors. They[43] also found the higher the serum MMP-2/TIMP-2 ratio of advanced bladder cancer, the earlier recurrence and the poorer prognosis. Serum MMP-2/TIMP-2 ratio could exert a predictive role, identical to our conclusion. We propose that, compared with the expression of MMP-2 or TIMP-2, the ratio of MMP-2/TIMP-2 could reflect more accurately the biological characteristics of invasion and metastasis in patients with carcinoma of the gallbladder. As a new prognostic marker, the ratio of MMP-2/TIMP-2 might be useful in early diagnosis and in estimating the invasion and metastasis or survival crisis in patients with carcinoma of the gallbladder.

Abstract

AIM: To investigate the infection of *Cyclospore cayetanensis* in Anhui Province.

METHODS: Identification of *Cyclospore cayetanensis* was made microscopically by finding the oocysts of *Cyclospore cayetanensis* in fecal smears taken from the infants, pupils and adults with obstinate diarrhea, and immunocompromised individuals by using a auramine-phenol stain and modified acid-fast stain. Cellular immune function was detected with biotin-streptavidin (BSA), and the specific antibody against *Cyclospore cayetanensis* was detected with method of ELISA.

RESULTS: (1) The positive rates of *Cyclospore cayetanensis* infection in infants, pupils, infants and adults with obstinate diarrhea and with immunocompromised individuals were significantly different ($P<0.01$), with the rates of 0 %, 0.50 % (1/200), 5.62 % (10/178), and 9.38 % (3/32) respectively. (2) The infection rates of males and females were 2.61 % (10/383) and 1.44 % (4/227) respectively, with no significant difference ($P<0.05$). (3) The positive rates of population with oocysts in urban and rural areas were 0.92 % (3/325) and 3.86 % (11/285) respectively. (4) The positive rates of CD_3^+, CD_4^+, CD_8^+ and the ratio of CD_4^+/CD_8^+ of individuals with and without oocysts were significantly different ($P<0.05$, $P<0.01$), and their values were (64.28±6.55) %, (43.55± 5.80) %, (28.23±4.32) %, 1.52±0.32 and (58.97±5.23) %, (39.26±4.93) %, (30.54±5.17) %,1.26±0.21, respectively. (5) Specific IgG, IgM and IgG+IgM in serum of the patients with oocyst were significantly different ($P<0.01$) with the positive rates of 63.41 % (9/14), 17.07 % (1/14) and 19.51 % (4/14) respectively.

CONCLUSION: *Cyclospore cayetanensis* infection is present in Anhui, China and it was confirmed to be a new pathogen associated with children diarrhea, adults obstinate diarrhea and diarrhea in immunocompromised individuals. Among all the infected individuals, adult obstinate diarrhea patients and immunocompromised individuals are common. Feces examination of oocysts and serological examination of the specific antibody will be of much help in the diagnosis of *Cyclospore cayetanensis* infection.

INTRODUCTION

Cyclospore cayetanensis is an emerging protozoan pathogen associated with diarrhea and human immune function[1-16]. It is a kind of enteric parasite that infests in the gastrointestinal tract of human causing severe diarrhea. Jejunal biopsies showed an altered mucosal architecture with shortening and widening of the intestinal villi due to diffuse edema and infiltration by a mixed inflammatory cell infiltrate[17,18]. There was reactive hyperemia with vascular dilatation and congestion of villous capillaries. Cyclosporiasis occurs in persons of all ages and in either immunocompetent or immunocompromised hosts[19-30]. Human being is the only natural host for this parasite[31]. Clinical symptoms of Cyclosporiasis are characterized by watery diarrhea (approximately 6 stools/day), nausea, anorexia, abdominal cramping, fatigue, and weight loss, and they are not so specific and can often be misdiagnosed[32-37]. So cyclospora oocysts detection is needed by phase contrast microscopy, modified acid-fast staining, autofluorescence, and amplification by the polymerase chain reaction[38-48].

In order to investigate the infection of *Cyclospore cayetanensis* in Anhui Province, we took an investigation of *Cyclospore cayetanensis* in rural and urban areas of Anhui Province. The results of our investigation showed that *Cyclospore cayetanensis* infection was present in Anhui Province and it was confirmed to be a new pathogen associated with children diarrhea and adult obstinate diarrhea.

MATERIALS AND METHODS

Materials

A total of 610 individuals from 11 cities, including Huainan, Hefei, Bengbu, were involved in this investigation. All of them aged from 1 to 55 years, 383 male and 227 female. And they were divided into 2 groups (control group and experimental group).

Screening population (Control group) 400 individuals (infants and pupils) were included in the control group, 217 male and 183 female.

Diarrhea patients (Experimental group) 178 individuals with undefined diarrhea from outpatients (infants and adult with obstinate diarrhea) as well as 32 immunocompromised individuals with obstinate diarrhea were involved in the experimental group, 166 male and 44 female. And 210 feces specimens from the experimental group were collected. Those who had any 2 of the following 5 criteria were considered as immnocompromised individuals: (1) weakened proliferation reaction in lymphocyte transformation test, reduction or lopsided development in T-cell subsets; (2) lower expression of one or more immune globulin (IgG, IgM, IgA, IgD and IgE); (3) deficiency in cytokine, such as IL-2, IFN-g as well as loss of expression in IL-1R and in IL-2R; (4) weakened function of phagocyte and (5) frequent occurrence of infection such as opportunistic pathogen, virus, fungi and parasites.

Methods

Inquiry of diarrhea history Histories of present illness, anamnesis, symptoms, personal hygiene habits, living

environmental hygiene of the objects and so on were inquired.

Feces examination 2-3 g fresh feces per person was collected with disposable boxes and smeared into translucent layers. Then the smears were microscopically examined after auramine-phenol stain and modified acid-fast stain. It was described as positive when oocysts were found with apparent internal structure in red, but other non-specific granules revealed black-blue, which was significantly different from the oocysts.

Serological examination Oocysts of *Cyclospore cayetanensis* were taken as antigen from artificially infected guinea pigs and embraced on polystyter board. Serological examination was performed with ELISA to detect the specific antibody of IgG and IgM in individuals with oocysts. Each time, values of OD of 3 holes (empty, positive, and negative respectively) were read from enzyme labeling meter, and it was judged to be positive when it was 2.1 times as much as the negative.

Detection of T lymphocyte cell subsets Cellular immune function of the individuals with oocysts was detected. The percentage of CD_3^+, CD_4^+ and CD_8^+, and the ratio of CD_4^+/CD_8^+ were detected with biotin-streptavidin (BSA) method. Mixed with heparin, peripheral blood was taken and diluted with an equivalence of liquid free of $Ca^{2+}$and Mg^{2+}, then mononuclear cells were separated with lymphocytes separating medium and were made into cell suspension with concentration of (1-3)×10^6 cells per ml after washing and adjustment. 10 μl of the cell suspension was smeared in acid-proof varnish rings on the surface of slides each time, and when it dried naturally, McAb of anti-CD_3^+, anti-CD_4^+ and anti-CD_8^+, IgG of sheep against guinea pig, and SA-HRP were added. After development with DAB, the smears were observed under microscope. Cytomembrane in brown was regarded as positive, and non-pigmenting as negative. Each time a total of 200 cells were counted for statistics of the positive percentage of cells.

Statistical analysis

Data were expressed as mean ± standard deviation. And multiple comparison tests were performed with χ^2 test and *t* test.

RESULTS

Feces examination

The positive rates of *Cyclospore cayetanensis* from feces taken from the control group and the experimental group were 0.25 % (1/400) and 6.19 % (13/210) respectively. To be exact, the positive rates of the diarrheal and immunocompromised individuals were 5.62 % (10/178) and 9.38 % (3/32) respectively. And the positive rates of the two groups were significantly different (P<0.01). The results are shown in Table 1.

Common clinical symptoms

Among individuals with *C.cayetanensis*, some had no or slight symptoms in early stage. In our survey, healthy pupils and immunocompromised individuals had no self-conscious symptoms. However, others had clinical symptoms mainly in lower digestive tract (60 %), such as abdominal distention, abdominal pain, loose stool and watery stool. After retrospective studies on 14 cases of *Cyclospore cayetanensis* infection, it was found that 10 of them (71.43 %) were misdiagnosed as bacterial enteritis (*n*=5), viral enteritis (*n*=3), non-specific enteritis (*n*=2), parasitic infection (*n*=2) and abdominal discomfort (*n*=2). The results are shown in Table 2.

Table 2 Clinical symptoms caused by *Cyclospore cayetanensis* (*n*,%)

Group	Case number	Case Percentage
Non-self-conscious symptom	4	28.57
Self-conscious symptom	10	71.43
General symptom	2	14.29

Total	14	100

General symptom: acratia and fever;
Upper digestive tract symptom: anorexia, nausea and vomiting;
Lower digestive tract symptom: abdominal distention, abdominal pain, loose stool and watery stool.

Relationship between infection of Cyclospore cayetanensis *and gender*

Total 610 individuals from different population groups were involved in this investigation on oocysts of *C.cayetanensis* in stools. It was shown that the total positive rate of oocysts was 2.30 % (14/610). In detail, the positive rates were 2.61 % (10/383) in male and 1.44 % (4/227) in female, and there was no significant difference between them (P>0.05). The results are shown in Table 3.

Table 3 Feces examination of *Cyclospore cayetanensis* of different gender

Group	*n*	Auramine-phenol stain+Modified anti-acid stain	
		Positive number	Positive rate (%)
Male	383	10	2.61
Female	227	4	1.44
Total	610	14	2.30

P>0.05, χ^2=0.4581

Relationship between infection of Cyclospore cayetanensis and living environmental condition as well as personal hygiene habits

It was shown that the positive rate of oocysts in rural areas was significantly higher than that in urban areas (P<0.05). The

survey showed that there were much difference in living environmental condition and personal hygiene habits between the individuals in rural areas and in urban. In rural areas, plenty of simple toilets, deficiency of sanitary facilities and diffusing feces contamination were commonly seen, and most people were unaware of health knowledge and good hygiene habits. Thus, higher infection rate occurred in rural areas. The results are shown in Table 4.

Table 4 Feces examination of *Cyclospore cayetanensi* in different areas

Group	*n*	Auramine-phenol stain+Modified acid-fast stain	
		Positive number	Positive rate (%)
Urban area	325	3	0.92
Rural area	285	11	3.86
Total	610	14	2.30

$P<0.05$, $\chi^2=5.8419$

Detection of specific antibody

It was shown that specific antibody of IgG was frequently positive in oocysts-positive individuals, and those of both IgG and IgM were positive in some cases. The results are shown in Table 5.

Table 5 Detection of specific antibody of individuals with *Cyclospore cayetanensis* (*n*, %)

Group	*n*	IgG[b]		IgM[b]		IgG+IgM[b]	
		Number	Rate	Number	Rate	Number	Rate
Oocysts positive	14	9	63.41	1	17.07	4	19.51
Oocysts negative	20	0	0.00	0	0.00	0	0.00

[b]$P<0.01$, $\chi^2=10.4962$ *vs:* oocyst negative

Detection of cellular immune function

It was found that the levels of CD_3^+, CD_4^+ and CD_4^+/CD_8^+ decreased compared with those of the oocysts-negative individuals ($P<0.05$, $P<0.01$). And the expression of CD_8^+ seemed to be stable. The results are shown in Table 6.

Table 6 Detection of T lymphocyte cell subsets of individuals with *Cyclospore cayetanensis* (*n*, $\bar{x}\pm s$,%)

DISCUSSION

Cyclospore cayetanensis is a new human coccidian parasite associated with human prolonged diarrhea. Twenty years ago, the first known human cases of cyclosporiasis were reported in medical literature[11,18,32]. And prevalence or case reports about it were presented only in about 20 countries[49-58]. Its characteristics of pathogenic immune had not been clarified until now. In 1986, Soave separated a kind of "coccidian-like body" for the first time, later more and more people found similar organisms in stools of diarrheic patients. Accordingly, a kind of round granular coccidian-like body was found in stools of patients with diarrhea in Peru in 1992, then it was termed *Cyclospore cayetanensis* and confirmed to be a new kind of pathogen that caused human coccidiosis enteritis[59,60]. Later, Chinese scholars Chen and Han *et al* verified the presence of infection caused by *C.cayetanensis* in China after comparing the feces specimens between those collected from different areas of China and those from America by Cterling. In survey of cryptosporidium in 2001, we isolated red and round granular coccidian-like bodies from feces of patients with diarrhea, and considered 14 cases of them to be *Cyclospore cayetanensis* infection.

Cyclospore cayetanensis has a worldwide distribution. Patients with this prolonged diarrheal illness are described in North, Central and South America, the Caribbean, Africa, Bangladesh, Southeast Asia, Australia, England, and Eastern Europe[49,58]. Routes of transmission are still unknown, although the fecal-oral route, either directly or via water, is probably the major one. And it was considered that there were two sources of infection: contaminated drinking water and fruits[61-68].

This investigation showed that the infection rate of *Cyclospore cayetanensi* was 0.25 % in normal population including infants and pupils, but 5.62 % in patients with diarrhea and 9.32 % in immunocompromised individuals, which was significantly different from normal population. The results showed that the positive rates of oocysts had no significantly different between males and females, but was significantly different between individuals in rural and urban areas, which was 0.92 % and 3.86 % respectively. So infection of *Cyclospore cayetanensis* is present in both urban and rural areas in Anhui Province, and it seemed to be related to personal hygiene habits and immune functions. When ingesting *Cyclospore cayetanensis*or oocysts contaminated food and becoming immunocompromised, one could be infected. Individuals only infected by *Cyclospore cayetanensis* were fewer, and they were chiefly non-apparently infected with slight or no symptoms. On the other hand, multi-infection was very common. *Cyclospore cayetanensis* usually co-infected with bacteria and caused non-specific symptoms, including inertia, anorexia, abdominal distention, abdominal pain, loose and watery stool, which could easily be confused with other common intestinal diseases[69]. So it should be considered as *Cyclospore cayetanensis* infection if individuals experienced prolonged diarrhea.

Detection of cellular immune function in this study showed that the level of CD_3^+, CD_4^+ and CD_4^+/CD_8^+ in the individuals with oocysts decreased, and the expression of CD_8^+ seemed to be stable. It indicated that *Cyclospore cayetanensis* infection was related to cellular immune function of individuals, and it appeared with the decrease of CD_3^+ and CD_4^+ cells, which was associated with the decrease of immune defense, immune clearance and immune reaction to invading *Cyclospore cayetanensis*. CD_4^+/CD_8^+ is the hub of immunoloregulation network. The decrease of CD_4^+ cells indicated that auxiliary T lymphocyte cell took part in the pathogenesis process of diarrhea, and that both humoral immunity of *Cyclospore cayetanensis* antibody and cellular immunity response to *Cyclospore cayetanensis* infection were limited. So it made prolonged diarrhea and led to weak immulogical killer effect. Thus we concluded that cellular immune took part in pathogenic process of diarrhea caused by *Cyclospore cayetanensis.*

The specific antibody detection showed that after *Cyclospore cayetanensis* infection, the specific antibody was mainly of IgG, sometimes both IgG and IgM, in rare cases of IgM only. It indicated that *Cyclospore cayetanensis* infection was a kind of chronic infection, and present infection should be considered even if there was IgG (+) only. ELISA usually served in the specific antibody detection, and it was more simple, practical, specific and sensitive. Furthermore, it was convenient to perform and capable of being widely used. Serological examination of specific antibody performedamong patients with prolonged diarrhea would be more effective at early diagnosis and treatment.

Cyclospore cayetanensis discussed in the present study was encountered in our survey of *Cryptosporidium* in 2001. We found that auramine-phenol stain could be used in the detection of *Cyclospore cayetanensis* as well. More attention should be paid to the distinction between *Cyclospore cayetanensis* and *Cryptosporidium*: (1) The average diameter of the former (7.953×8.253 mm) was larger than that of the latter (about 5mm); (2) The internal structure of the former was not too clear to be seen any feature of the oocysts of the latter; (3) The density and quantity of the former was less than the latter and (4) The brightness of fluorescence under cryptoscope of the oocysts after auramine-phenol stain of the former was weaker than that of the latter. It remained to be further confirmed that the wall of the oocysts and its structure of *Cyclospore cayetanensis* might vary in different stages of the development of the protozoa. *Cyclospore cayetanensis* is differentiated from other coccidians by its sporulation characteristics and autofluorescence. Because of the autofluorescent properties of the oocysts, particular attention should be drawn to the role of fluorescent microscopy in providing a rapid, inexpensive, and sensitive technique for diagnosis of Cyclospora infections in stool samples[50].

We' ve tried to deal with the disease caused by *Cyclospore cayetanensis* with spiramycin, and it seemed to be effective. It was reported that oral trimethoprim-sulfamethoxazole was a better choice in the treatment for Cyclospora infection[70-76]. Sometimes, it can also be healed with non-antibacterial therapy. In immunocompetent individuals, diarrhea is usually self-limited but might last for several weeks. In immunocompromised hosts it is prolonged, severe and can be associated with biliary tract involvement.

In conclusion, *Cyclospore cayetanensis* infection may not be so rare in China, and further studies should be carried out on its prevalence areas, prevalence principle, life history, mode of transmission and prevention.

Abstract

AIM: To investigate the sequential changes of body composition in the metabolic response that occurred in a group of patients with enterocutaneous fistula after admission to the hospital.

METHODS: Sixty-one patients with enterocutaneous fistula admitted to our hospital had measurements of body composition by multiple-frequency bioelectrical impedance analysis after admission and 5, 10 days later. Sequential measurements of plasma constitutive proteins were also made.

RESULTS: The body weight, fat-free mass, body mass index, and body cell mass were initially well below the normal range, especially the body mass index and body cell mass. And all the data gradually moved up over the 10-day study period, only a highly significant difference was found in body cell mass. Once the patients received nutrition supplement, ECW began to return to normal range slowly as well as ICW and TBW began to rise up, and ECW/TBW significantly declined to near normal level by day 10 in either male or female patients. There was a reprioritization of plasma constitutive protein synthesis that was obligatory and independent of changes in FFM.

CONCLUSION: Serial measurements can quantify the disturbance of body composition in enterocutaneous fistula patients. The early nutritional intervention rapidly ameliorates the abnormal distribution of body water while the state-of-the-art surgical management prevents the further deterioration in cellular composition.

Wang XB, Ren JA, Li JS. Sequential changes of body composition in patients with enterocutaneous fistula during the 10 days after admission. *World J Gastroenterol* 2002; 8(6):1149-1152

INTRODUCTION

Malnutrition is common in patients with enterocutaneous fistula, over a period of time, giving rise to alterations in body composition, as well as systemic and multiorgan manifestations. Malnutrition is also associated with adverse outcomes, whereas clinical stability is associated with nutritional stability[1]. Unfortunately, accurate nutritional assessment is difficult in patients with enterocutaneous fistula because standard laboratory methods are inaccurate and the techniques used to precisely assess metabolic compartments are complex, expensive, and of limited availability, especially in China. Assessment of body composition may provide important information about the nutritional status[2] .The applicability of one safe and convenient methods for body composition analysis, multiple-frequency bioelectrical impedance analysis (MFBIA) in malnourished patients with enterocutaneous fistula has been sparsely elucidated[3] .

Thus, the aim of the present study is to investigate the sequential changes of body composition in the metabolic response that occurred in a group of patients with enterocutaneous fistula after admission to the hospital.

MATERIALS AND METHODS

Patients

Between December 1, 2000, and November 30, 2001, 86 patients suffering from enterocutaneous fistula (EF) were admitted to the EF Treatment Group of Institute of General Surgery at Jinling Hospital, Nanjing, China. All of these patients wholly recruited from other inpatient clinic were included in the study. EF care at our hospital took place more than thirty years ago in a well coordinated system of pre-hospital and in-hospital care that includes good co-operation with other hospitals, radio-telephone communication, and a high-level, in-hospital EF team response and experience, which includes rapid assessment, resuscitation, stabilization, and sequential therapeusis according to well-established principles[4].

At the time of admission, all patients studied were able to accomplish the analysis of body composition in standing position for 3 minutes. None of the patients were treated with diuretics and prednisolone and they had exclusion of any metabolic disease. For each patient, diagnosis was made on clinical presentation: definite history of operation, temperature spikes, elevated white cell counts, increasing abdominal tenderness, wound infection, and drainage of succus entericus from intraperitonal drains. Initial management of the patients invariably involved fluid resuscitation, repletion of depleted electrolytes, maintenance of systemic and multi-organic function, active suction drainage of succus entericus, appropriate broad-spectrum antibiotic therapy to control sepsis, pharmacological approaches including H_2 antagonists, somatostatin and growth hormone if needed[5] ,and nutritional supplementation. Some patients who needed prompt exploration of the abdominal cavity to control generalized peritonitis or definitive pus were excluded from the study.

Nutrition was given enterally (Peptide, Nutricia, Dutch) when possible[4]. The caloric distribution of the formula was 16.5 % protein, 22.7 % fat, and 60.8 % carbohydrate administered by the nasogastric, nasojejunal, gastrostomic, jejunostomic, or any available intestinal route[4, 6] . Nutritional intake was increased up to 2000Kcal/d according a standard

protocol. Patients with contraindications to enteral feeding were given parenteral nutrition by dedicated single-lumen central venous catheters. The initial daily prescription of 17 g nitrogen, 1000Kcal from glucose, and 500Kcal from fat was modified on the basis of size, renal function, and indirect calorimetry.

Study protocol

Patients underwent serial measurements of plasma protein concentrations and body composition during a period of 10 days. The first studies were performed as soon as hemodynamic stability was achieved without either colloid infusion or increasing inotropic support (day 0). The body composition measurements were repeated 5, 10 after admission in the Department of General Surgery by one medician. Measurements of the plasma protein were also made 10 days later.

Techniques of body composition analysis

Body composition measurements were made in all subjects using an multiple-frequency bioelectrical impedance (MFBIA) model InBody 3.0 (Biospace, Seoul, Korea). As one of the latest impedance analyzers, InBody 3.0 uses state-of-the-art technology, an 8-point tactile electrode system that measures the total and segmental impedance and phase angle of alternating electric current at four different frequencies (5 kHz, 50 kHz, 250 kHz, and 500 kHz).

Impedance measurements were made with the subject standing in an upright position, on foot electrodes in the platform of the instrument, with the legs not touching the thighs and the arms not touching the torso. The subject stood on the four foot electrodes: two oval shape electrodes and two heel shape electrodes, and gripped the two Palm-and-Thumb electrodes in order to yield two thumb electrodes and two palm electrodes, without shoes or excess clothing (coats, sweaters, vests). The skin and the electrodes were precleaned using the specific electrolyte tissue according to the manufacturer' s instructions. Prior to this, height (stadiometry) was recorded to the nearest 0.1 cm. All the subjects were instructed to fast and to avoid exercise 8 h before measurement and had been resting for at least 30 min before measurement.

All the body composition data were performed in the instrument by inner software and typed in the result sheet immediately after measuring. The software performs provides a plot of reactive and resistive components of the measured impedance at each frequency, as well as body weight, fat-free mass (FFM), total body water (TBW), intra-/extra-cellular water (ICW/ECW), segmental fluid distribution, fat mass (FM), body cell mass (BCM) and body mass index (BMI).

Plasma proteins

Fibronectin, transferrin, and prealbumin were measured as markers of the constitutive plasma proteins. These were determined by ELISA assay using kits of Pointe, UK.

Statistical methods

Analyses were performed using SPSS10.0. Paired student' s *t* test was used to detect significant changes over time. Values are expressed as means $\pm$SD. *P* values less than 0.05 were considered significant.

RESULTS

Patients

Sixty-one of the 86 patients who were recruited into the study completed the protocol, and their clinical diagnostic details are listed in Table 1. During the 10 days after admission, Of the 25 patients who did not complete the protocol, 11 underwent prompt laparotomy exploration to control sepsis, the remaining 14 were too weakness to stand up to complete the body composition measurement. The 61 enterocutaneous fistula patients were all secondary to alimentary tract operation, 18 secondary to cancer, 10 secondary to inflammatory bowel diseases, 2 secondary to pancreatitis, 5 secondary to digestive ulcer, 26 secondary to trauma, intestinal obstruction, and cholelithiasis.

Of the 51 male patients, 24 received total parenteral nutrition, the remaining 27 received enteral nutrition with or without parenteral feeding. Of the 10 female patients, 3 received TPN, and the remaining 7 received total or partial enteral feeding. Nutrition was administered continuously. There was no apparent clinical manifestation of peripheral extremity edema, ascites, or other intra-abdominal fluid collections just before body composition measurement. The median time from admission to receiving the nutritional support was 2 days (range 1 to 3 days).

Table 1 Clinical data of patients recruited for the study

	Male	Female
Esophageal and gastric fistula	4	0
Duodenal fistula	11	3
High-output intestinal fistula	9	2
Low-output intestinal fistula	18	4
Colonic fistula	10	2
Pancreatic and biliaric fistula	5	0
Total	51[a]	10[a]

[a]Some patients had multiple-origin enterocutaneous fistulas.

Body composition measurements

The body weight, BMI, FFM, and BCM in the male patients were initially well below the normal range (in our own data), especially BMI and BCM, which can be accounted for the severely malnutritional state of these enterocutaneous fistula patients. All the data gradually moved up over the 10-day study period (in Table 2), only a highly significant difference was found in BCM. As is also shown in Table 3, except for the female patients received a significant increase in FFM as well as in BCM. As to the differences of FFM in gender-specific, the causes may be attributed to the small case number, the gentle state of illness, and the high proportion of enteral feeding of the female patients. The latter intensifies the benefits of enteral nutrition in the treatment of enterocutaneous fistula in early course and needs further refinement in future research.

Once the patients received nutrition supplement, ECW began to return to normal slowly as well as ICW and TBW began to raise to normal, and ECW/TBW (which should be the index of edema) significantly declined to near normal by day 10 in either male or female patients. Finally, TW and TW/TBW in male patients significantly increased on Day 5 and then slowly decreased on Day 10, which may be attributable to excess fluid locating in the trunk for abdominal infection or intolerance to early enteral feeding.

Plasma proteins

Twenty of 61 patients at random underwent serial measurement of plasma protein concentration (Shown in Table 4). We found that fibronectin, transferrin, and prealbumin concentrations, which were initially well below the normal range increasingly raised up without significance by Day 10 ($P>0.05$).

DISCUSSION

Estimation of body composition is important in the assessment and monitoring of enterocutaneous fistula patients. Enterocutaneous fistula is a condition in which overnutrition, edema, and undernutrition can coexist simultaneously, or successively, over a period of time, giving rise to alterations in body composition, as well as systemic and multiple-organic manifestations. The development of a noninvasive, inexpensive, and accurate technique to assess body water and nutritional compartment would be of great clinical value to identify those patients with impaired morbidity and mortality in enterocutaneous fistula, and enhanced nutritional support is indicated in those patients with persisting nutritional deficits[4, 7].

Bioelectrical impedance analysis is a technique of assessing body composition such as total body water and thus fat-free mass in the healthy population[8]. And in a number of conditions such as hemodialysis[9], pregnancy[10], hepatic cirrhosis[11], after surgery[12], and in critical illness[13], changes in TBW have been shown to be accompanied by changes in impedance. However, in situations where there are clinically important changes in intraceullar and extracellular water distribution, such as ascites[11] and critical illness[14], the value of single-frequency BIA is limited. It is proposed that multiple-frequency BIA (MFBIA) may be of particular use in patients with altered distribution of body water[2]. At low frequency, the current passes through the extracellular fluids because of the capacitance effect of cell membranes and tissue interfaces, whereas at high frequencies, the current is conduced through both intra-and extracellular fluids. The Biospace InBody 3.0 body-composition analyzer is a novel device to estimate body water compartments and body fat. It differs from other impedance systems, which uses an 8-point tactile electrode system that measures the total and segmental impedance and phase angle of alternating electric current at four different frequencies between 5 and 500 kHz.

BMI was found to be an important predictor of mortality in clinic study, with the association between body mass index and mortality suggesting the U-shaped relation corroborated by many studies[15]. Although BMI in our study was initially well below the normal range, there were no significant differences in BMI over the study period for male and female patients as well as in body weight and FFM. However, there were highly significant differences in BCM changes over the study period (Table 2 and Table 3). Weight and BMI do not definitely evaluate changes in body compartments and therefore do not reveal if loss of FFM or gain in FM occurs[16]. The keenness and speediness in the response of BCM to medical intervention made a strong impression on us. BCM provides an ideal reference for metabolic studies in enterocutaneous fistula, while less specific parameters such as body weight, BMI or FFM (which include non-metabolic compartments such as ECW) should be interpreted with caution[17]. Therefore, we emphasize the importance of measurement of the growth of the metabolically active body compartment, the BCM, in accurately assessing nutritional status in enterocutaneous fistula. And it would be useful in future research to investigate whether the relation between BCM and mortality is also U-shaped in critical illness especially in enterocutaneous fistula. This question may be more amenable to investigate in relatively small, short studies, provided that an appropriate tool for assessment of body composition in enterocutaneous fistula patients is used.

Our results show once again that there is a reprioritization of hepatic protein synthesis in enterocutaneous fistula[18] that is obligatory and independent of changes in FFM. Concentrations of the constitutive plasma proteins fallen initially raised up over the study period without significance ($P>0.05$) because of their well known turnover rates. There were no significant correlations between the changes of FFM and those of the constitutive plasma proteins. These obligatory

changes may occur in face of continuing proteolysis and high energy expenditure in critical illness. And our results confirm that the measurements of the constitutive plasma proteins have no significant values in demonstrating changes in cellular composition early in the course of enterocutaneous fistula.

Once the patients received nutrition supplement, ECW began to return to normal slowly as well as ICW and TBW began to rise to normal, while ECW/TBW (which should be the index of edema) significantly declined to near normal range by day 10 in either male or female patients (P<0.0001 in male, and P=0.017 in female). These results are partially similar to those obtained in the critical illness study[19,20]. In our experience, these findings may be relevant to the clinical manifestations of enterocutaneous fistula patients, especially when persistent severe malnutrition was detected. There may be a reduction in ICW by a compensation for increased ECW in the patients especially those received inappropriate nutritional supplement. And in the early course of nutritional intervention, the rapid amelioration was found not in body protein but in body water compartments. These findings in our study have two implications. First, the present understanding of the degree of abnormal body water distribution that occurs in such patients is largely correct. In the second, it is clear from this study that most effects of the early administered nutritional intervention lie in the rapid improvement of body water distribution. It seems unlikely that much more can be done to preserve cellular composition in early stage of treatment, but state-of-the-art surgical management appears to have prevent further deterioration.

Finally, BIA is a technique that can be readily applied in clinical situations, easy, portable, noninvasive, and inexpensive. Because of these advantages, it can be repeated frequently as necessary and therefore gives a picture of the patient's body composition status and responses to therapy. However, there are still many debates on the validity of MFBIA in clinical assessment of nutritional status especially body water compartment[21, 22]. MFBIA may not accurately predict water compartments in critically illness especially in those with greatly altered distribution of water, which may alter the capacitant effect of all membranes on conductance through the fluid compartment, although this is highly speculative. It is also recognized that the whole-body BIA is insensitive to fluid changes in the trunk. In our data, we found that the BCM correlated with resting energy expenditure (r^2=0.61, P<0.001 on Day0, and r^2=0.59, P<0.001 on Day10) in 12 enterocutaneous fistula patients who were admitted to our hospital consecutively. The slope of the line relating BCM to REE was the same on Day0 and on Day10 (P=0.34) in these 12 patients. These findings encouraged us to elucidate the applicability of MFBIA in the enterocutaneous fistula patients. We also suggest that patients with enterocutaneous fistula during treatment phases be followed periodically with BIA measurements. Longitudinal follow-up would permit evaluation of treatment side effects (eg, overfeeding, undernutrition) or sepsis, which are known to have catabolic effects on FFM and FM. And in the future, we will introduce more sophisticated and more invasive techniques such as dual-energy x-ray absorptiometry (DXA).

In conclusion, we have for the first time quantified the changes of body composition during 10 days after admission in enterocutaneous fistula patients by use of MFBIA and have shown that the early nutritional intervention rapidly ameliorates the disturbance of body water while the state-of-the-art surgical management prevents the further deterioration in cellular composition.
