Abstract

Cholangiocytes-the epithelial cells which line the bile ducts-are increasingly recognized as important transporting epithelia actively involved in the absorption and secretion of water, ions, and solutes. This recognition is due in part to the recent development of new experimental models. New biologic concepts have emerged including the identification and topography of receptors and flux proteins on the apical and/or basolateral membrane which are involved in the molecular mechanisms of ductal bile secretion. Individually isolated and/or perfused bile duct units from livers of rats and mice serve as new, physiologically relevant *in vitro* models to study cholangiocyte transport. Biliary tree dimensions and novel insights into anatomic remodeling of proliferating bile ducts have emerged from three-dimensional reconstruction using CT scanning and sophisticated software. Moreover, new pathologic concepts have arisen regarding the interaction of cholangiocytes with pathogens such as *Cryptosporidium parvum*. These concepts and associated methodologies may provide the framework to develop new therapies for the cholangiopathies, a group of important hepatobiliary diseases in which cholangiocytes are the target cell.

INTRODUCTIONS

The liver contains two types of epithelia: hepatocytes, accounting for ~65% of the liver cell population; and intrahepatic bile duct cells, or cholangiocytes, the epithelial cells that line the intrahepatic biliary tree and account for ~5% of the liver cell population.

In the past decade, interest in cholangiocyte pathobiology has exploded due to: (i) the development of new experimental techniques that allow hypotheses related to cholangiocyte biology to be directly addressed (Figure 1); (ii) the recognition that cholangiocytes are critically important to normal liver function, especially solute and water transport, cell-cycle phenomena, cell signaling, and interactions with other cells, matrix components, foreign organisms and xenobiotics; and (iii) the appreciation that cholangiocytes represent the major target of a group of serious genetic and acquired diseases termed the cholangiopathies. In a coordinated series of hypothesis-driven studies, we have explored selective aspects of cellular processing by cholangiocytes focusing on proteins (receptors, channels, exchangers, transporters, junctional proteins, molecular motors, pro/anti-apoptotic molecules) that we hypothesized were likely critically important in cholangiocyte secretion, absorption, intracellular transport, and structural modifications. Thus, we briefly review here a variety of novel *in vivo* and *in vitro* experimental models that have allowed us to expand our understanding of how cholangiocytes function and what happens when disease alters their normal physiology. Several more extensive reviews on cholangiocyte pathobiology are referenced for readers interested in more comprehensive reviews.

IN VIVO MODELS

The rat biliary tree has been shown to undergo selective proliferation in response to different experimental stimuli such as bile duct ligation (BDL)[1], 70% hepatectomy[2], carbon tetrachloride treatment[3], and feeding of α-naphthylisothiocyanate (ANIT)[4,5]. As best we know, the proliferated cholangiocytes retain a normal cholangiocyte phenotype. The bile duct ligated rat model has been useful in initiating studies on the effect of hormones on bile secretion. Infusion of secretin and somatostatin results in a choleretic and cholestatic response, respectively, in the bile duct ligated but not sham-operated rat, due not only to an increased number of cells but an increased expression of the receptors for secretin and somatostatin on individual cholangiocytes[6-8]. Much less is known about how the mouse biliary tree responds to hormones. To further explore the regulatory mechanisms of ductal bile secretion, it was necessary to develop additional novel *in vitro* experimental models.

IN VITRO MODELS

Freshly Isolated Cells

The development of *in vitro* models of biliary epithelia essentially began with the ability to isolate cholangiocytes of high purity from normal rat, mouse and human liver[9,10]. This experimental model allowed direct studies on the effects of hormones on cholangiocytes which demonstrated among other things, that secretin stimulated exocytosis via a cyclic AMP mechanism, and that this effect was blocked by somatostatin[11].

The technique of counter-flow elutriation has allowed refinement of cell isolation techniques from normal or BDL rats[12,13] by allowing separation of subpopulations of cholangiocytes which differ in size. Using this model, we have provided evidence that these small, medium and large cholangiocytes originate from different portions of the intrahepatic biliary ductal system. Using molecular and physiological approaches, we have also demonstrated that these subpopulations of cholangiocytes differ in their transport and proliferative capabilities[12,13].

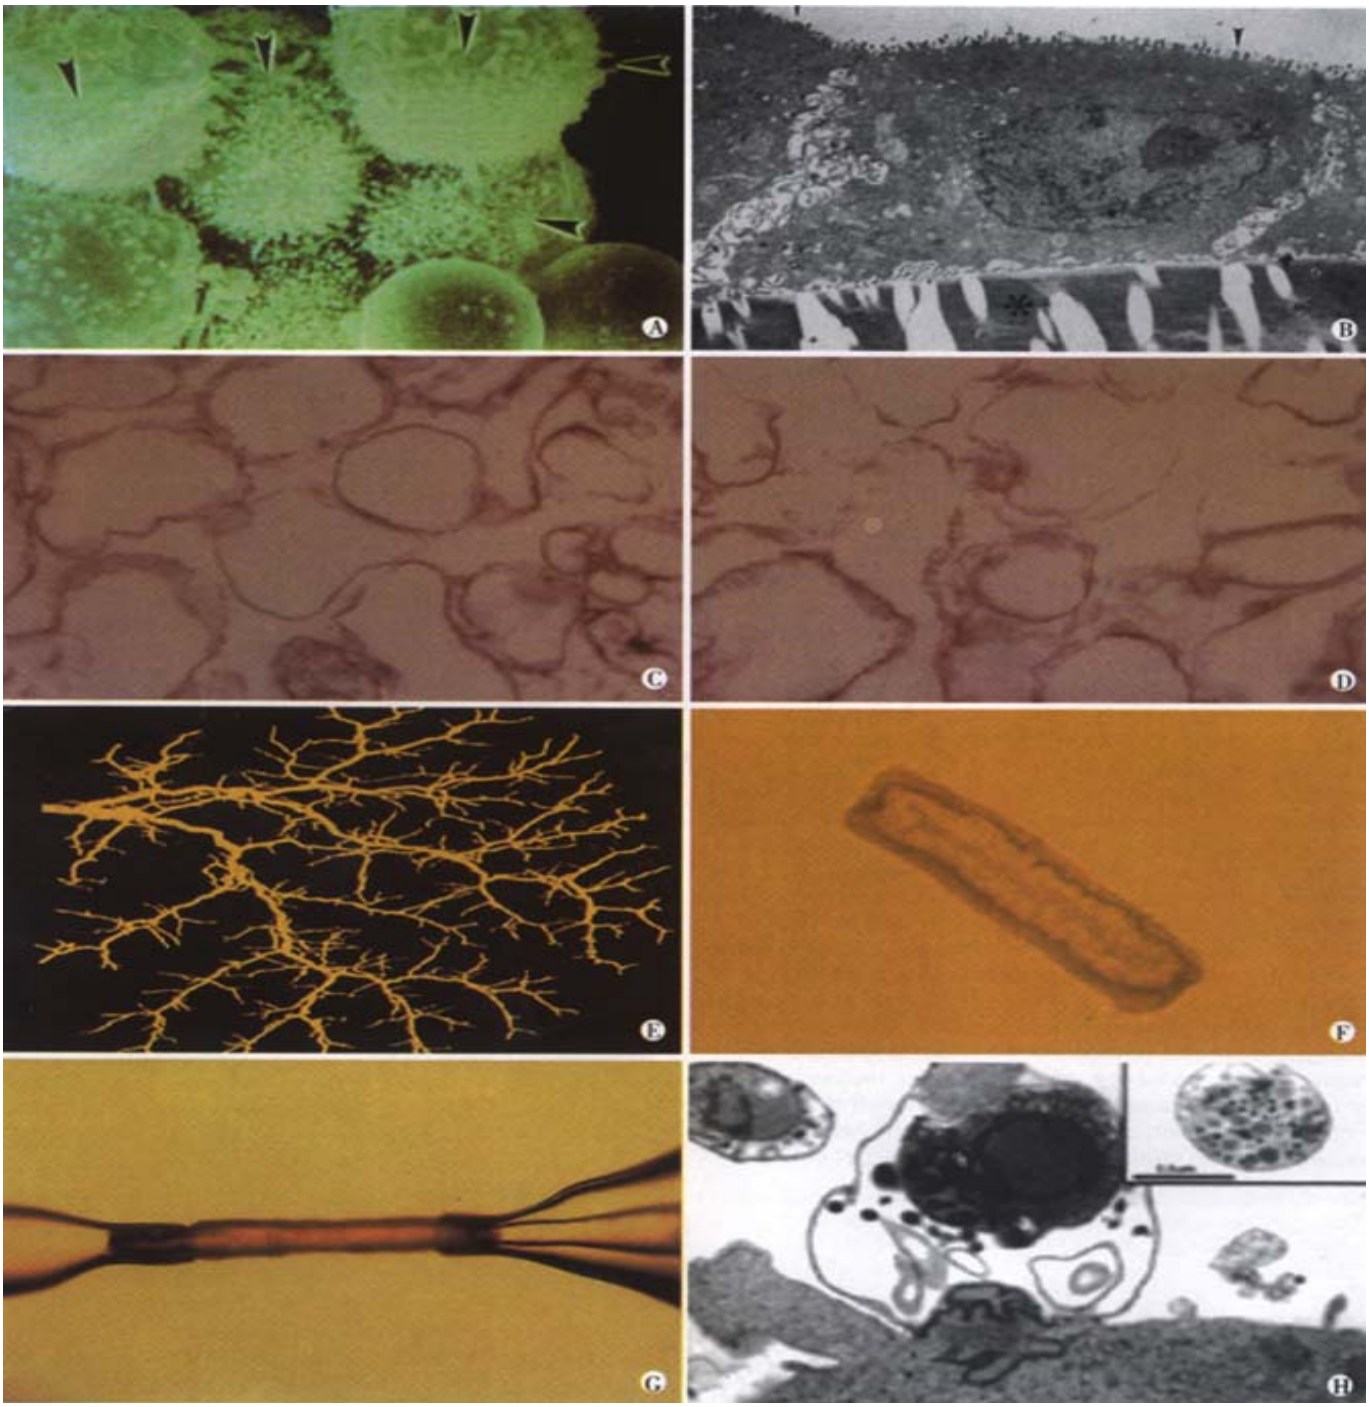

Figure 1 Experimental *in vitro* models of biliary epithelia.
(a) A scanning electron micrograph of a group of isolated cholangiocytes after separation using immunomagnetic beads. Note that the prominent microvilli (arrowheads) are limited to one side of the cells. Mag = 4,400.
(b) A transmission electron micrograph cross-section of normal rat cholangiocytes in culture demonstrates characteristics of polarized cells with apical microvilli (arrowheads) and numerous basolateral intercellular interdigitations near the collagen coated filter denoted by *, (Bar = 2 mm, Mag = 7,500).
(c) (d) A transmission electron micrograph of apical (c) and basolateral (d) plasma membrane domains revealed similar homogenous vesiculated membranes of varied shapes and sizes without apparent contamination of other organelles (Bar = 0.5 mm, Mag = 22,500).
(e) A three-dimensional reconstructed image of the intrahepatic biliary tree isolated from normal rat liver.
(f) A light micrograph of an unstained isolated bile duct unit from rat liver. After overnight culture, the two ends seal forming an enclosed unit. A single layer of epithelial cells with a thin outer layer of connective tissue surrounds the lumen.
(g) A microperfused intrahepatic bile duct unit isolated from rat liver, manually dissected and cannulated with micropipettes.
(h) Transmission electron micrograph of *C. parvum* infection of cultured human cholangiocytes. A parasitophorous vacuole contains a developing parasite stage which is intracellular but extracytoplasmic. A macrogamet is shown in the inset, demonstrating development of sexual stages of the parasite. Bar = 1 mm.

Cholangiocyte cDNA Library

A unique cDNA library has been constructed from highly purified cholangiocytes isolated from rats subjected to bile duct ligation for 2 weeks[14]. Total cellular RNA was extracted from cholangiocytes and poly(A)+ mRNA isolated. Subsequently, the poly(A)+ mRNA was reverse transcribed and directionally cloned. The cholangiocyte cDNA library allows screening and sequencing of positive clones for numerous molecules yet to be identified.

Cultured Cells

Freshly isolated cells maintained in short-term culture provided the opportunity to perform patch-clamp studies yielding novel insights into the electrophysiology of cholangiocytes[15]. Established long-term cultured cholangiocytes can be grown on semi-permeable cell culture filters by which they quickly reach confluence, maintain morphologic polarity and develop adequate transepithelial electrical resistance, making them a prototype for use in transport studies. This model has been utilized to characterize the uptake of glucose and bile acids and to study water transport[16-19].

Isolated Organelles

In order to perform more rigorous transport studies and to generate accurate kinetic transport parameters (i.e., Km and Vmax), we developed techniques for isolating vesicles enriched in either the apical or the basolateral domain of cholangiocytes starting either with whole rat liver or with cholangiocytes in culture[20,21]. An initial application of these vesicles was to generate kinetic values for sodium-dependent taurocholate uptake, a process that we demonstrated occurs in apical but not basolateral vesicles[17]. This tool allows continued studies to localize and functionally evaluate transport processes in cholangiocytes.

Intrahepatic Bile Duct Units

Experiments using intact intrahepatic bile duct units isolated by mechanical and enzymatic techniques from normal rats to study biliary epithelial transport physiology have been previously described[22]. An advantage of this model is that we can not only control the lumenal contents (by manipulating components of the perfusate) but we can independently and simultaneously modify the basolateral milieu (by manipulating components of the bathing buffer). With this approach, we were able to detect changes in intralumenal pH and electrolyte concentrations in response to agonists. We could also demonstrate water transport across this epithelial barrier in response to osmotic gradients, the characteristics of which (kinetics, temperature independence and mercury sensitivity) all suggested the presence of water selective channel proteins (i.e., aquaporins) (AQP) on the membranes of cholangiocytes. Using quantitative computer-assisted image analysis to measure expansion and reduction of lumenal area as a reflection of water movement, we have demonstrated that water movement across the bile duct units is transcellular and channel-mediated[13].

We have subsequently expanded this model using a microperfusion technique and an epifluorescence detection system[24]. With this modification, we have demonstrated the movement of water into (secretion) and out of (absorption) the lumen of the perfused ducts in response to inward and outward osmotic gradients. The calculation of both net water movement (Jv) and osmotic water permeability (Pf) provide evidence that the measured bi-directional fluxes reflect water movement through water channels.

In addition, we have demonstrated that isolated bile duct units actively absorb solutes such as bile acids and glucose, and transport ions such as bicarbonate. We have also shown that lumenal perfusion of ATP and other nucleotides activates P2Y ATP receptors on the apical cholangiocyte plasma membrane and induces increases in $[Ca^{2+}]_i$ and net ductular alkalization, suggesting that ductal bile secretion is regulated by these signaling molecules[25].

This technique has now been adapted to the mouse in which we can reproducibly isolate and microperfuse intact bile duct units from normal mouse liver with the anticipated application to transgenic or knockout mouse models[26]. Transgenic mice continue to be developed in which there is a selective knockout of one or more aquaporin water channels[27]. The isolated and perfused bile duct unit model would allow us to test the hypothesis that knockout mice lacking AQP1 and AQP4 water channels or perhaps other naturally expressed aquaporins may have substantially reduced choleretic and cholestatic responses to hormones since the flux of water molecules through these water channels should be absent.

The isolation of intact, polarized intrahepatic bile duct units from both rat and mouse allows the direct study of secretory and absorptive activities of the bile ducts in a way which most closely approximates the normal biliary ductal system.

Three-Dimensional Modeling

Although cholangiocyte functional and morphological heterogeneity likely contributes to the selective involvement of different portions of the biliary tree in the cholangiopathies, our understanding of the nature and mechanisms for normal and abnormal anatomical remodeling of the biliary tree is limited. To better define the heterogeneous nature of the biliary tree, we utilized a computer-aided three-dimensional imaging technique, first described in a study of the normal human biliary tree[28], to perform quantitative anatomical studies of the rat intrahepatic biliary system[29].

Computer generated three-dimensional reconstruction of the intrahepatic biliary tree using microscopic-computed tomography scanning and sophisticated software allowed us to generate key biliary tract dimensions (length, surface area, duct diameter, volume) and branching patterns (distance from the junction of intra- and extrahepatic ducts, number of bile duct branches and branching angles).

In various forms of liver disease, including the cholangiopathies, proliferation of cholangiocytes is a common pathological response[1, 30, 31]. The anatomical basis and remodeling process which occurs in response to various stimuli remain unclear. We have since applied the three-dimensional reconstruction of the biliary tree to rats in whom selective cholangiocyte proliferation was induced by ANIT feeding[4,5]. The anatomical remodeling and quantitative observations after selective cholangiocyte proliferation suggest that the proliferation process involves sprouting of new side branches. Recently three-dimensional modeling has been applied to generate data for the hepatic artery and portal vein within the same liver (Masyuk, LaRusso unpublished). This descriptive study allowed key findings on the length of vascular segments, diameter of blood vessel segments and volume of the hepatic artery and portal vein, associated with experimentally-induced cholangiocyte proliferation.

Three-dimensional reconstruction will provide complementary data that, at a minimum, will yield structural information on biliary tract architecture and biliary mapping (i.e.,which branches of the biliary tree are involved in absorption or secretion, the mechanisms by which ducts proliferate in response to injury, and the impact of these modifications on the peribiliary vasculature.) The significance of these studies relates not only to the intrinsic value of understanding cholangiocyte physiology but also to providing a biologic rationale for why only?certain segments of the biliary tree are involved in the individual cholangiopathies. Primary biliary cirrhosis, for example, leads to destruction of interlobular bile ducts, while intrahepatic cholestasis induced by drugs affects principally the cholangiocytes that line small bile ducts[30, 32, 33].

In Vitro Infection Model of Biliary Cryptosporidiosis

Using monolayers of human cholangiocytes derived from normal liver and immortalized by SV40 transformation, we developed an *in vitro* infection model of biliary cryptosporidiosis[34]. Cryptosporidiosis is an infectious disease caused by *Cryptosporidium parvum* (*C. parvum*), an emerging parasite which causes self-limited diarrhea in immunocompetent subjects and potentially life-threatening syndromes in immunocompromised individuals, primarily those with acquired immunodeficiency syndrome (AIDS). Despite the magnitude and severity of cryptosporidial infection, the pathogenesis is poorly understood, and there is currently no effective therapy. Using this novel infection model, we found that *C. parvum* sporozoites (derived from oocysts excysted *in vitro*) attach to the apical surface of biliary epithelia, invade the cells, reside in a parasitophorous vacuole, and undergo both sexual and asexual development.

C. parvum attachment to cholangiocytes involves interactions between specific glycoproteins on cholangiocytes and *C. parvum* sporozoite lectins while the invasion into cholangiocytes works through actin-dependent membrane spreading mediated by cortactin and RhoGTP-binding proteins[34-36]. While *C. parvum* is cytopathic to uninfected cells adjacent to infected cholangiocytes via Fas/FasL-dependent apoptosis, the organism prevents cell death of infected cells by inhibiting apoptosis via activation of NF-κB[37, 38]. This model provides a useful system for the development of novel therapeutic strategies for *C. parvum* induced enterology and AIDS-cholangiopathy.

CONCLUSION

Advances in medical knowledge most often are preceded by advancements in technology and experimental models. Results from experiments using these new models and methods have clarified which flux proteins are expressed in cholangiocytes, their intracellular topography and segmental distribution, what molecules control their cellular compartmentalization, and their physiologic relevance to ductal bile formation. In addition, the information has provided a theoretical framework for development of novel therapeutic strategies for the cholangiopathies, a group of cholestatic genetic/acquired hepatobiliary diseases in which the cholangiocyte is the principal target of diverse destructive processes.

Abstract

AIM: **To investigate the direct effect of croton oil (CO) on human intestinal epithelial cell (HIEC) and guinea pig colonic smooth muscle cells *in vitro*.**

METHODS: **Growth curves of HIEC were drawn by MTT colorimetry. The dynamics of cell proliferation was analyzed with flow cytometry, and morphological changes were observed under light and electron microscopy after long-term (6 weeks) treatment with CO.Expression of cyclooxygenase-2 (COX-2) mRNA was detected by dot blot in HIEC treated with CO. Genes related to CO were screened by DD-PCR, and the direct effect of CO on the contractility of isolated guinea pig colonic smooth muscle cells was observed.**

RESULTS: **High concentration (20 - 40 mg · L^{-1}) CO inhibited cell growth significantly (1, 3, 5, 7d OD sequence: (20 mg·L^{-1}) 0.040±0.003, 0.081±0.012, 0.147±0.022,0.024±0.016; (40 mg· L^{-1}) 0.033±0.044, 0.056±0.012, 0.104±0.010, 0.189±0.006; OD control 0.031±0.008, 0.096±0.012, 0.173±0.009, 0.300±0.016, *P*<0.01), which appeared to be related directly to the dosage. Compared with the control, the fraction number of cells in G1 phase decreased from 0.60 to 0.58, while that in S phase increased from 0.30 to 0.34 and DNA index also increased after 6 weeks of treatment with CO (the dosage was increased gradually from 4 to 40 mg · L^{-1}). Light microscopic observation revealed that cells had karyomegaly, less plasma and karyoplasm lopsidedness. Electron microscopy also showed an increase in cell proliferation and in the quantity of abnormal nuclei with pathologic mitosis. Expression of COX-2 mRNA decreased significantly in HIEC treated with CO. Thirteen differential cDNA fragments were cloned from HIEC treated with CO, one of which was 100 percent homologous with human mitochondrial cytochrome C oxidase subunit II. The length of isolated guinea pig colonic smooth muscle cells was significantly shortened after treatment with CO (*P*<0.05).**

CONCLUSION: **At a high CO concentration (>20 mg·L^{-1}), cell growth and proliferation are inhibited in a dosage-dependent manner. Increase in cell proliferation and in malignant conversion of the cellular phenotype is observed in cells cultured chronically with CO. COX-2 mRNA expression decreases significantly, while human mitochondrial cytochrome C oxidase subunit IImRNA expression increases markedly in HIEC treated with CO. CO also has a direct effect on the contractility of Guinea pig colonic smooth muscle cells.**

INTRODUCTION

Croton is the fruit of *Croton tiglium L*, which consists of 34%-57% croton oil and 18% proteins. Croton oil (CO) contains crotonoleic acid, crotonic acid, crotonyl alcohol, 16 kinds of crotonyl alcohol bisester and many kinds of crotonyl alcohol trisester. Also contained in the seed of croton are crotin, cocarcinogen C-3, crotonoside, isoguanine, β-sitosterol, amino acids and many kinds of enzymes. However, the principal component of croton extract is CO, which possesses multiple drug effects. CO is a stimulant in making inflammatory models, especially in models of skin and mucosal inflammation[1], such as animal models of hemorrhoids, pleuritis, ear edema and uveitis[2]. Investigations have shown that allergic contact dermatitis (ACD) induced by CO is not a kind of late pleoergy response, but is mediated by the immune system in skin[3,4]. Metalloprotease neutral endopeptidase (NEP) and neuropeptide play an important role in ACD[5]. After CO administration to mice for 3 h[6,7],there was no change in the mucosa of stomach and intestine under light microscope, but mucosal epithelial cell inflammation was observed under electron microscopy.

According to the recent, that dehydrocrotonin (DCTN), an extract of CO, had anti-ulcer effect[8], especially in ulcers induced by hypothermia, alcohol and pyloric ligation. This effect was supposed to the related to the increase in the release of prostaglandin E2, the non-specific competitive binding of H2 and M receptors of stomach, the reinforcement of mucosal protective action and the weakening of mucosa-impairing factors. So DCTN has the potential to be a new anti-ulcer drug[9,10].

It was reported that croton extract could not only suppress tumor growth but also promote tumor development. It has been confirmed that t-DCTN, which possesses neither genetic toxicity nor cytotoxicity, has anti-tumor activity and can significantly elongate the survival period of mice with S180 sarcoma and ascites neoplasia[11,12]. Recent research showed that 2,3-dihydroxy-labda-8 (17), 12(E), 14-triene, one of the croton extracts, had non-specific cytotoxicity for various tumor cells[13]. However, some investigations found that CO could cause skin carcinoma by lipid peroxidation and hydroperoxide production; it could directly bind protein kinase C, stimulating over-proliferation of epidermis, and repeatedly impair skin, which induces skin hyperplasia.

Croton is a strong cathartic; trace of croton can cause severe

diarrhea because of its potent in accelerating gastrointestinal motility. Now, Chinese medicine is the hot spot in the development of new drugs promoting gastrointestinal motility[14-28]. However, its mechanism in inducing diarrhea and accelerating gastrointestinal motion is not yet clarified[29-32].

The aim of this research is to observe the effect of CO on intestinal epithelial cells and isolated colonic smooth muscle cells; investigate the effect of CO on biological properties of intestinal epithelia, mRNA differential expression and intestinal smooth muscle cell contraction; and further clarifiy its molecular mechanism so as to lay the foundation of the development of new drugs promoting gastrointestinal motility.

MATERIALS AND METHODS

Cell lines and culture

Human intestinal epithelial cell line (HIEC), presented as a gift by Dr. Ren DQ from Department of Radiation Medicine, Fourth Military Medical University, was grown in RPMI 1640 medium with 100mL·L^{-1} fetal bovine serum. CO dissolved in dimethyl sulfoxide (DMSO) was added into the culture medium when the medium was exchanged[32]. The end-concentration of CO was 4mg·L^{-1}; then the concentration increased progressively to 40 mg·L^{-1} in 6 weeks.

Effects of CO on HIEC growth (MTT)

Add HIEC into 96 well plate(200μL/well); and add CO of different concentrations (4,20,40,80 mg·L^{-1}) and control DMSO(0.2,1,2, 4mL·L^{-1})to corresponding groups, with three wells in each group. Put the culture plates into culture cassette, then take out one 96-well plate each time (1,3,5,7d),add 20μL MTT solution(5g·L^{-1}) into each well, and resume culturing at 37℃ for 4 h. Afterwards, suck and throw away the culture medium from the 96-well plate and add 150μL DMSO to the plate. Detect OD in each well with photometer (wave length: 490nm) and draw the growth curve.

Flow cytometry analysis of HIEC proliferation treated with CO

Harvest HIEC in log phase growth that was treated with CO for 6 weeks. Cell proliferation cycle of HIEC was analyzed with flow cytometry after HIEC was routinely digested, washed twice with PBS and fixed with 700mL·L^{-1} ethanol. DNA index (DI) was calculated with the formula: DI= experimental group cells G0/1/ control cells G0/1.DNA.

Judgment standard of ploidy[33]. DI = 0.95-1.05 (DI=1±CV, CV is 0.05): diploid; DI≠1.00, between 0.90-1.10: proximal diploid; DI>1.10 or DI<0.9: increased or decreased heteroploid DNA content.

Morphological changes of HIEC treated with CO

Changes in cell morphology were observed dynamically under inverted microscope. HIEC in log phase growth that was treated with CO for 6 weeks was harvested, and its proliferation cycle was analyzed with flow cytometry after routinely digested, washed twice with PBS, centrifuged for 5 min at 1200-1400 r·min^{-1}, fixed with glutaraldehyde for 30 min at 4℃, and prepared into ultrathin section for transmission electron microscopic observation.

Expression of COX-2 mRNA in HIEC(Dot blot)

Total RNA was extracted from control and experimental cells treated with CO for 6 wk. RNA samples were pointed onto the nitric cellulose membrane, and specific COX-2 oligonucleotide probes were end-labeled. Expression of COX-2 mRNA was detected with dot blot.

mRNA differential display of HIEC treated with CO(DD-PCR)

Gene expressions of HIEC treated with CO for 6 weeks and of control were compared through DD-PCR. Primers were designed according to the literature: 3'end anchor primer H-T_{11}C: 5'-AAGCTTTTTTTTTTTC-3', 8 strips of 5'end random primers: H-AP_1-H-AP_8. The first chain of cDNA was synthesized by reverse transcription; then with RT products as templates, and PCR was performed with 8 strips of 5'-end random primers individually. Products of RT-PCR were run on 60g·L^{-1} urea degeneration polyacrylamide gels until the indicator arrived at the basal part of the gel at 200-300V for 6-8 h. The gels were stained with modified silver-stain. Differential cDNA fragments were cut, recovered and purified for secondary amplification with PCR, and amplification products were isolated by agarose gel electrophoresis and ligated with pUC-Tm vector after recovery and purification. Recombinant plasmids were transfected into DH5α Escherichia coli and the bacteria were plated and incubated at 37℃ overnight. Positive clones were picked out and the plasmids were extracted, followed by restriction enzyme cleavage identification. Further identification of the positive clones included reverse Northern blot and sequencing by automatic sequencer. Homology of the sequences of the differential expression cDNA fragments was searched in Gene Bank Database.

Direct effect of CO on Guinea pig colonic smooth muscle cells

Guinea pig colonic smooth muscle cells were isolated by modified methods reported by Bitar and Makhlouf[34,35]. Activity of the smooth muscle cells was detected with trypan blue, and the number of the cells were calculated under invert microscope. The number of smooth muscle cells with vitality must exceed 90% for experiment. CO was dissolved in dimethyl sulfoxide (DMSO)to make 4, 2, and 0.25 g·L^{-1} CO solutions. Ten μL CO solutions of different concentrations were added into 200μL colonic smooth muscle cell suspensions, the end-concentration of CO being 0.14, 0.07, and 0.009 g·L^{-1}, respectively. The cells were incubated with CO at 30℃ for 30 s and 80μL of 25g·L^{-1} glutaraldehyde was added to terminate the reaction.

The length change of the smooth muscle cells was detected with micrometer under invert microscope.The average length was calculated from every 50 cells randomly. The contractile response of the smooth muscle cells was measured by the decrease of average length of cells treated with CO compared with that of the control. The formula is:

Percentage of cell contractile change = (average length of experimental cells (average length of control cells)/ average length of control cells×100%.

RESULTS

Effect of CO on the growth and cell cycle-phase of HIEC

High dosage (80 mg·L^{-1}) CO resulted in the death of all HIEC; moderate dosage (20-40 mg·L^{-1}) significantly inhibited cell growth (1,3,5,7d OD sequence: (20 mg·L^{-1}) 0.040±0.003, 0.081±0.012, 0.147±0.022,0.024±0.016; (40 mg·L^{-1}) 0.033±0.044, 0.056±0.012, 0.104±0.010, 0.189±0.006; OD control 0.031±0.008, 0.096±0.012, 0.173±0.009, 0.300±0.016,P<0.01) in a dosage-dependent manner (IC_{50} is 52 mg·L^{-1}); and low dosage (4 mg·L^{-1}) had no effect on cell growth (P>0.05). The flow cytometry showed that S phase HIEC quantity significantly increased, G_2/M phase cell quantity decreased and DI rose to 1.15 after HIEC was treated with CO for 6 weeks.

Changes of HIEC morphology treated with CO

Morphologic changes of HIEC were dynamically observed under invert microscope in cells incubated with CO. Initially many cells exhibited

sheet shedding, intercellular space increased, toxic granules accumulated in the cytoplasm, and cell growth was significantly delayed. The growth behavior of the cells improved after treatment with CO for 11d. After the dosage of CO was progressively increased to 40 mg·L^{-1} at the 6th week, the following phenomena occurred: fusiform cells significantly increased, cell bodies shrank, the nuclei were enlarged, the cytoplasm was reduced, karyoplasm lopsidedness was developed, and cell growth was accelerated. Under transmission electron microscope, we observed many wide apophyses in cell membrane, abundant microvilli, enlarged nuclei, multiplied nucleoli, and abnormal nuclei with pathologic mitosis (Figure 1).

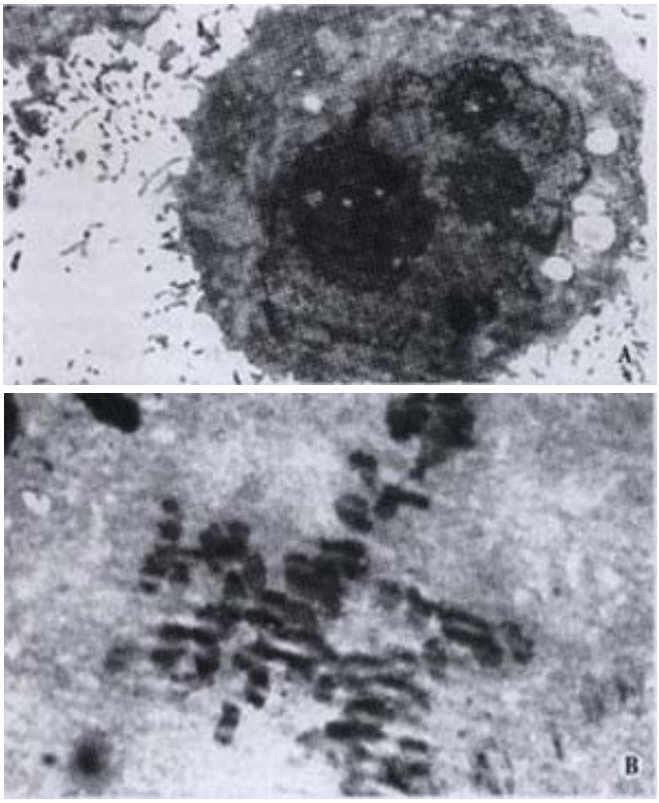

Figure 1 A: Rich microvilli, enlarged nuclei and increased nucleoli in HIEC treated with CO (left);
B: Abnormal nuclei with pathologic mitosis in HIEC treated with CO (right).

Expression of COX-2 mRNA in HIEC

Expression of COX-2 mRNA was significantly down regulated in HIEC after treated with CO for 6 week(Figure 2).

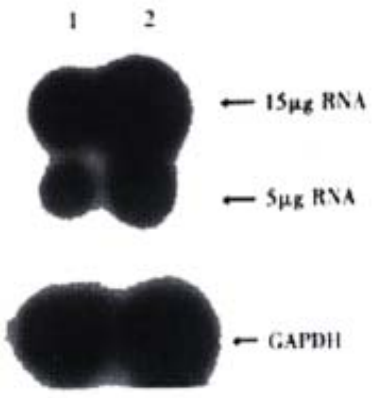

Figure 2 Expression of COX-2mRNA in HIEC 1:HIEC treated with CO for 6week; 2:Control HIEC

DD-PCR

Some cDNA fragments found in HIEC treated with CO were up-regulated, down-regulated, newly born or deleted in comparison of experimental cells with controls (Figure 3). Thirteen different cDNA fragments were successfully cloned; among the 13 positive clones, 2 fragments were significantly up-regulated and 11 down-regulated in HIEC treated with CO, which was confirmed through reverse Northern blot analysis. Sequencing and homology demonstrated that one over-expressed cDNA fragment is 100% homologous with the homeobox gene of mitochondrial cytochrome C oxidase subunit-2 gene.

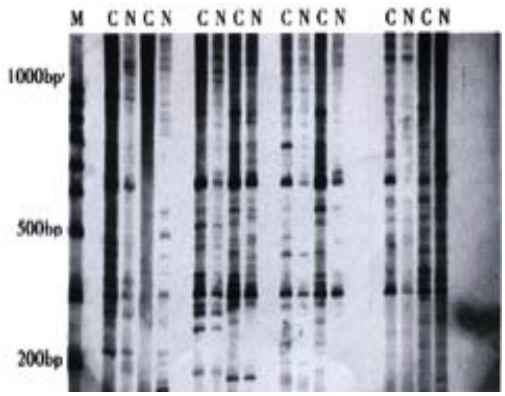

Figure 3 Differential display of mRNA in HIEC treated with COM: 100bp ladder; C: HIEC treated by CO; N: Normal HIEC

Direct effect of CO on guinea pig colonic smooth muscle cells

Free Guinea pig colonic smooth muscle cells appeared in fusiform shape with diverse length. Some of them were relaxed while others were at different phases of contraction (Figure 4). The length of normal guinea pig colonic smooth muscle cells ranged from 60μm to 160μm,with an average length being (102±23)μm. After incubated with different concentrations of CO(0.14, 0.07, 0.009g·L^{-1}),the average length of colonic smooth muscle cells became (72±27)μm, (74 ±26)μm and (72±17)μm, respectively, while that of the control cells was (104±22)μm (Figure 5). The percentages of decrease in cell length were 29. 5%, 28% and 29.6%, respectively, significantly smaller than that of the control(P<0.05).

DISCUSSION

Our study showed that[36] high dosage of CO could result in the death of HIEC; middle dosage could inhibit cell growth in a dose-dependent manner; low dosage had no effecton cell growth. Meanwhile, after long-term continuous incubation with CO, the cycle from G_1 to S of HIEC was shortened, the quantity of G_1 phase cells was reduced, the quantity of S phase cells was increased, and DI was raised. We found that the principal phenomena of HIEC treated with CO included cell degeneration, necrosis, diminished ability of cells adhesion, and delayed cell growth. As the drug action persisted, degenerated cell quantity decreased and cell proliferation was accelerated. We also observed that HIEC treated with CO proliferated faster than control cells, and abnormal nuclei with pathologic mitosis were observed under electron microscope. These phenomena indicated that the cytotoxicity of high concentration CO might be the major cause for cell growth suppression. CO had the potential effect on promoting cell over-proliferation and increasing the content of heteroploid DNA when HIEC was incubated with CO for a long time.

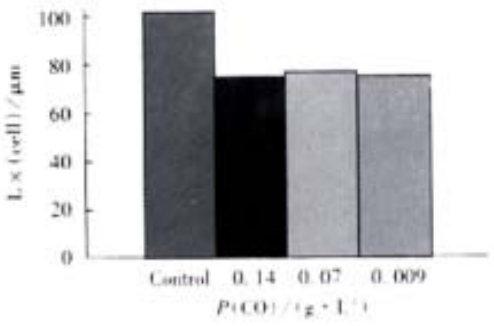

Figure 5 Direct contractile effect of CO on the colonic smooth muscle cells

COX-2 is an isoenzyme of cyclooxygenase discovered recently. Under normal conditions,COX-2 expression was low or non-existent in most tissues and cells in human body, but its expression could be promptly enhanced when cells were stimulated by a variety of factors. Recent studies showed that COX-2 is closely related to the development and progression of many kinds of human tumors, especially gastrointestinal tumors, such as colon cancer and gastric cancer. It has been confirmed that the expression of COX-2 increases more significantly in colon cancer tissues than in normal colonic tissues[37], and its expression is higher in many kinds of gastric cancer cell lines and tissues than in their normal counterparts[38,39]. The incidence and mortality of colon cancer were decreased with the long-term intake of non-steroidal anti-inflammatory drugs(NSAIDS), a COX-2 inhibitor, which is effective on familial adenomatous polyposis. These data indicated that COX-2 might play an important role in the pathology of these tumors. The specific mechanism of COX-2 induced tumorigenesis is yet unclear, but it is suspected to be related to the following factors: catalysis of carcinogen synthesis; catalysis of prostaglandin(PGs) synthesis,which can regulate the expression of genes and accelerate DNA synthesis and cell proliferation;inhibition of cell apoptosis; enhancement of adhesion between cells and extracellular matrix;promotion of tumor angiogenesis[40,41]; inhibition of immunological response[42]. The expression of COX-2 mRNA was detected in HIEC treated with CO for 6 weeks, and the results revealed its significant down-regulation. The relationship between CO-induced tumorigenesis and down-regulation of COX-2 in HIEC remains to be elucidated.

Thirteen differential expression gene fragments were detected in HIEC treated with CO for long time through mRNA differential display. Therefore, these genes may be related to the biological effects of CO on HIEC. One of the genes is human mitochondria cytochrome C oxidase subunit II gene, whose expression is high in CO treated HIEC. Human mitochondria cytochrome C oxidase consists of subunit I, II and III, which contributes substantially to the respiratory function of mitochondrion. In addition, two notably highly expressed genes were separated from Cisplatin-resistant human head and neck squamous epithelium cancer by Higuchi[43] through DDRT-PCR, and one of them is again the human mitochondria cytochrome C oxidase subunit II gene, which is putatively related to Cisplatin-resistance of tumor cells. We have also separated the highly expressed mitochondria cytochrome C oxidase subunit II gene from vincristine-resistant human gastric cancer cell SGC7901/VCR by DDRT-PCR (to be published separately). This suggests that mitochondria cytochrome C oxidase subunit II gene is closely correlated with drug-resistance. We found that CO-resistance of HIEC could be induced by gradually increasing the concentration of CO. However, the mechanism of CO-resistance in HIEC is unclear. As normal intestinal epithelial cells express certain multidrug resistance genes and proteins, such as P- glycoprotein (P-gp) in small intestinal epithelial cell line[44,45], it demands further investigation about whether the CO-resistance is mediated by P-gp or mitochondria cytochrome C oxidase subunit II gene product.

Croton possesses many kinds of drug actions; however, its clinical application is largely limited to treating constipation, while its effect in promoting gastrointestinal motility is neglected. The neglect is not only due to its complexity in components and severe side effects, but also to the ignorance of its molecular mechanism in promoting gastrointestinal motility. Pol[46] found that CO could accelerate gastrointestinal movement of mice at 3h after gastric administration. When CO was administrated to dogs[47],it could quickly evoke a rapid complex wave similar to the interdigestive myoelectric complex(IMC) III phase, although its contractile time was shorter its velocity of conduction faster than normal IMC. However, it was not affected by vague nerve ,which showed no relationship with α and (receptors. IMC cycle shortening induced by CO was the principal cause of diarrhea. Albuquerque made a series of gastrointestinal movement experiments on animals with CO[48]. The results showed that CO and its preparations could directly affect intestinal smooth muscles and rat diaphragm muscles and cause them to contract. Other researchers reported[49,50,51] that senna could induce diarrhea and accelerate gastrointestinal movement by enhancing the synthesis and release of endogenous prostaglandin E_2(PGE_2). Although we do not know whether the gastrointestinal motility enhancement of CO is related to PGE_2, the significant down-regulation of COX-2 expression in HIEC with long-term treatment of CO indicated that the mechanism of CO promoted motility is different from that induced by senna. Furthermore, our experiment confirmed that the average length of colonic smooth muscle cells was significantly shortened when they were incubated with CO of different concentrations, which showed that CO had a direct contractile effect on colonic smooth muscle cells.

To sum up, the effect of CO on the HIEC growth was in a dose-dependent manner. High dosage of CO could delay cell growth or cause cell death; and low dosage had no effect. A long-term administration with progressively increased CO dosage could promote cell proliferation,increase heteroploid DNA content, and induce malignant conversion of cells. COX-2 expression was significantlydown-regulated and mitochondria cytochrome C oxidase subunit-2 gene was significantly up-regulated in HIEC after induced by CO for a long time. At the same time, the expression of many genes

was changed. CO has a direct contractile effect on the colonic smooth muscle cells of guinea pig.

Abstract

AIM: **To confirm the existence of CD226 ligand and its distribution, which is a novel molecule that was cloned in 1996.**

METHODS: **The mRNA was extracted from TPA activated Jurkat cells and used as a template for reverse-transcription. After PCR amplification, the fragment including CD226 extracellular region and the splice donor sequence "ACTTACCTGT" was obtained and cloned into fusion expression vector pIG. The recombinant vector pCD226/Ig was transfected in COS-7 cells by DEAE-Dextran method, the secreting fusion protein was identified by Sandwich ELISA, and was purified by anti-CD226 affinity chromatography. This fusion protein was used as a probe in the investigation of CD226 ligand by immunohistochemistry. Existence of CD226 ligand was further identified by adhesion experiment.**

RESULTS: **Expression of a secreting fusion protein was identified by sandwich ELISA, indicating that both CD226 extracellular domain and IgGFc domain could be recognized respectively by anti-CD226 and anti-hIgFc mAb. About 130μg CD226/Ig fusion protein could be obtained from 100mL COS-7 culture supernatants by anti-CD226 affinity chromatography purification. SDS-PAGE showed that this fusion protein has a molecular mass of 83 ku. It was confirmed by immunohistochemistry that CD226 ligand expressed on the Colo205 cells, but not on Jurkat cell, U937 cell and mixed lymphocyte culture cells. In adhesive assay, resting Jurkat cells did not have significant adhesion to Colo205 cells. In contrast, activated Jurkat cells could bind to colon carcinoma Colo205 cells and this adhesive reaction could be blocked by CD226/Ig fusion protein or anti-CD226 mAb. Immunochemical experiment showed that Colo205 cells could be specifically stained by CD226/Ig, indicating that CD226 ligand exists on the surface of Colo205 cells.**

CONCLUSION: **Existence of CD226 ligand on the surface of Colo205 cells was identified by immunohistochemistry and adhesion blocking experiment. In addition, the secreting CD226/Ig fusion protein prepared in this study will be a potential tool for further investigation of CD226 ligand.**

INTRODUCTION

CD226 was initially reported by Burns in 1985 with a name TLiSA1 (T lineage specific activation antigen 1, TLiSA1)[1], and was renamed PTA1 (platelet and T cell antigen 1, PTA1) in 1989 because of its expression on platelet as well[2]. Since 1985, a lot of investigations have been done on CD226 expression, functions and its relationship with diseases[2-6]. CD226 was mainly expressed on the activated T cells, NK cells, monocytes, platelets and megakaryocytes lineage[4-8], taking part in signal transduction of T cell activation and differentiation as well as platelet activation and aggregation. CD226 mAb was found to stimulate the activation and aggregation of platelets[2,3], inhibit differentiation of CTL[2,9] and T and NK cell mediated cytotoxicity[7]. In 1997, PTA1 cDNA was cloned from cDNA library of TPA activated Jurkat cells[10]. It belongs to an immunolglobulin super family (IgSF) with a 232aa extracellular region, 25aa transmembrane region and 61aa intracellular region. Interestingly, PTA1 cDNA was almost the same as that of DNAM-1 (DNAX associated molecule-1), a novel molecule cloned by Shibuya in 1996[7]. In 2000, PTA1 (DNAM-1) was designated as CD226 on the 7th Workshop and Conference on the Human Leucocyte Differentiation Antigen in Harrogate. CD226 is the only IgSF member whose extracellular region consists of two IgV-like domains.

Almost all the important Ig-superfamily members are highly conserved during molecular evolution[11-13], such as CD2, CD4/CD8 and CD28. Homological analysis showed that CD226 molecules are highly conserved (93%-95%) among human, ape and monkey, suggesting that CD226 may have very important functions[14]. It seems that CD226 takes part in the mechanism of platelet function disorders, autoimmune diseases, transplantation, virus infection diseases and tumors[3,15-20], suggesting that CD226 plays an important role in immune system and may have a potential application to clinical diagnosis and treatment. Up to, little is known about CD226 ligand. So, the aim of this study is to make a preliminary research on CD226 ligand.

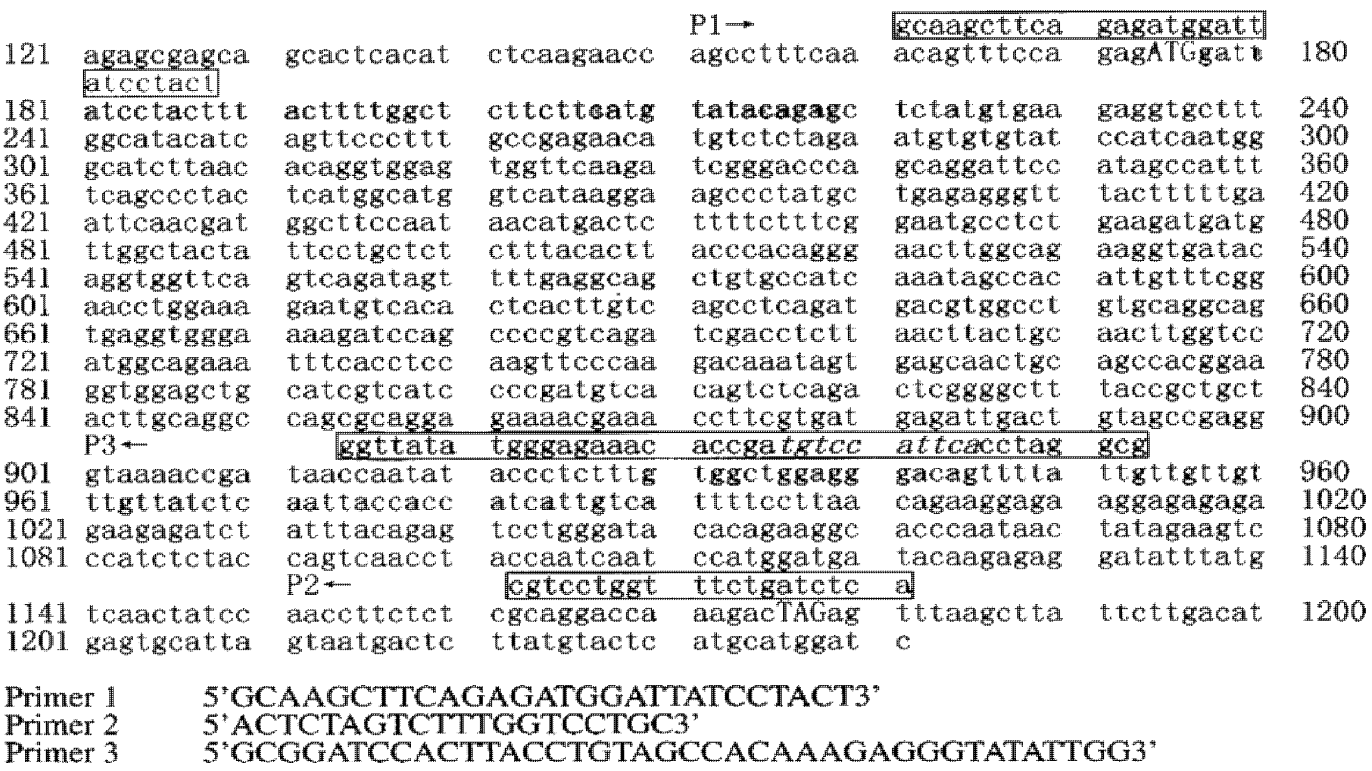
MATERIAL AND METHODS

Materials

pIG vector was a gift kindly presented by Dr. Xu. COS-7, U937, Jurkat, Colo205 cell line and CD226 hybridoma (secreting mAb Leo-A1 against the extracellular domain of CD226) were provided by Prof. Jin. Goat anti-human Ig-SABC immunohistochemistry kit was purchased from Boster Co. Vectors and restrict enzymes were purchased from Huamei Co; Trizol reagent kit was purchased from Gibco Co, and CNBr-Sepharose 4B is a product of Pharmacia Co.

Design of the primers for semi-nest RT-PCR

Primers were designed according to the sequence of CD226 cDNA: primer 1, 5'-GCAAGCTTCAGAGATGGATTATCCTACT-3' (forward, containing HindIII enzyme site at 5'); primer 2, 5'-GCGGATCCACTTACCTGTAGCCACAAAGAGGGTA TATTGG-3' (reverse, containing BamHIenzyme site and donor splice region "ACTTACCTGT" at 5'); primer 3, 5'-ACTCTAGTCTTTGGTCCTGC-3'. Primer1 and Primer 3 were used to amplify the whole length CD226 cDNA, and primer 1 and primer 2 were used to amplify cDNA encoding CD226 extracellular region (Figure 1).



Primer 1 5'GCAAGCTTCAGAGATGGATTATCCTACT3'
Primer 2 5'ACTCTAGTCTTTGGTCCTGC3'
Primer 3 5'GCGGATCCACTTACCTGTAGCCACAAAGAGGGTATATTGG3'

Figure 1 Sequence of CD226 cDNA and primers.
174-923bp: extracellular region of CD226; 174-227bp: signal peptide sequence; 924-998bp: transmembrane region; □labeled sequence: primers; underlined sequence was the splicing donor sequence.

Reverse transcription-polymerase chain reaction (RT-PCR)

Jurkat cells were cultured at a concentration of $1\times10^9\cdot L^{-1}$ with TPA ($50\mu g\cdot L^{-1}$) for 18-30 h at 37℃, and the total RNA was isolated by Trizol reagent kit. RNA was primed and reverse transcribed into cDNA in a 20μL reaction volume containing 10U reverse transcriptase, 10μg RNA, 10×Buffer 2μL, $10mmol\cdot L^{-1}$ dNTP complex 4μL, and primer 3. After incubation at 42℃ for 1 h, the reverse transcription product was PCR amplified by Primer 1 and Primer 3, and then by Primer 1 and Primer 2. The PCR parameters were 94℃ for 1 min, 60℃ for 1 min, and 72℃ for 80 s for 35 cycles.

Plasmid construction

Expression vector for CD226 extracellular region was prepared as previously described[21]. The corresponding PCR fragment was cloned into pUC-19 and M13mp18/19 vector for DNA sequencing. After DNA sequencing, the 793bp fragment encoding CD226 extracellular region and the splice donor sequence "ACTTACCTGT" was subcloned into pIG, a mammalian fusion protein expression vector containing the cytomegalovirus (CMV) promoter, splice acceptor, genomic human IgG1, and SV40 polyadenylation signal. The resulting expression vector pCD226/Ig was identified by PCR and restrict enzyme digestion.

COS-7 cell Transfection

COS-7 cell transfection was performed by a modified method [22]. Briefly, COS-7 cells at 50%-75% confluence were transfected in 7mL glucose Dulbecco's modified Eagle's medium (DMEM) containing $100mL\cdot L^{-1}$ fetal calf serum (FCS), 400μg DEAE-dextran/mL, 100 $\mu mol\cdot L^{-1}$ chloroquine diphosphate, and 40 μg purified DNA. After 3 h at 37℃, the transfection mixture was removed and the cells were treated with $100g\cdot L^{-1}$ dimethyl sulfoxide in PBS for 2 min. Cells were then returned to DMEM supplemented with $10mL\cdot L^{-1}$ fetal calf serum (FCS) for 4 d to allow CD226/Ig expression.

Purification and identification of CD226/Ig fusion protein

Leo-A1 affinity chromatography column was prepared as previously described[23]. The pCD226/Ig transfected COS-7 supernatant was spined out cell debris for 5 minutes at 10000 $r\cdot min^{-1}$, filtered through a 0.45μm filter and then purified by Leo-A1 affinity chromatography. The expression of a secreting fusion protein was identified by sandwich ELISA (anti-CD226 mAb and HRP-conjugated anti-hIg mAb, anti-IL-8 antibody was used as control). SDS-PAGE and Western-blot (polyclonal anti-hIgG antibody) were performed by routine methods.

Immunohistochemical staining by CD226/Ig

Immunohistochemical experiment was performed by SABC methods. For light microscopy, cytospin preparations of Colo205 cells were incubated with $3g\cdot L^{-1}$ methanol-hydrogen peroxide solution at 37℃ for 30 min to inactivate endogenous peroxidases. The slides were then blocked in goat serum blocking solution at 37℃ for 30 min. Without washing, the slides were incubated with CD226/Ig fusion protein ($10mg\cdot L^{-1}$) at 4℃. After overnight incubation, the slides were washed three times with PBS, and incubated with biotin labeled goat anti human IgG for 4 h at room temperature. Finally, the slides were washed, allowed to sit for 2 min, and then reacted with SABC complex and DAB peroxidase substrate solution. Human IgG1 was used instead of CD226/Ig in the control experiment.

Adhesion assay

In 96 well plate, Colo205 cells with the density of 0.5×10^5/well were cultured for one day to let cells confluence, and 3.7 MBq ^{51}Cr labeled resting or activated Jurkat cells were added with 1×10^5/well and cultured for 4 h, and non-adhered cells were moved by gently washing, the adhered cells were lysed by $20g\cdot L^{-1}$ Triton X-100, and Bq was measured. Different concentrations of CD226/Ig fusion protein and anti-CD226 mAb Leo-A1 were used in the adhesion blocking experiment.

RESULTS

Construction of pCD226/Ig fusion expression vector

A very low level of CD226 molecules was expressed on resting Jurkat cells, and the expression level could be enhanced by TPA stimulation for 24 h. The CD226 mRNA from Jurkat cells was enriched by TPA stimulating. After retro-transcription, semi-nests PCR amplification, a single band about 800bp has been obtained. This fragment was then ligated into pUC19 and subcloned into M13mp18/19 vector for sequencing. The sequencing data showed that the fragment was 793bp long in total, a HindIII enzyme site could be found at the upstream and the "ACTTACCTGT"donor splicing sequence and a BamHI site could be found at the downstream. The 793 bp fragment was ligated between HindIII and BamHI sites of pIG vector. The recombinant vector pCD226/Ig was identified by restrict enzyme digestion assay and PCR identification (Figure 2).

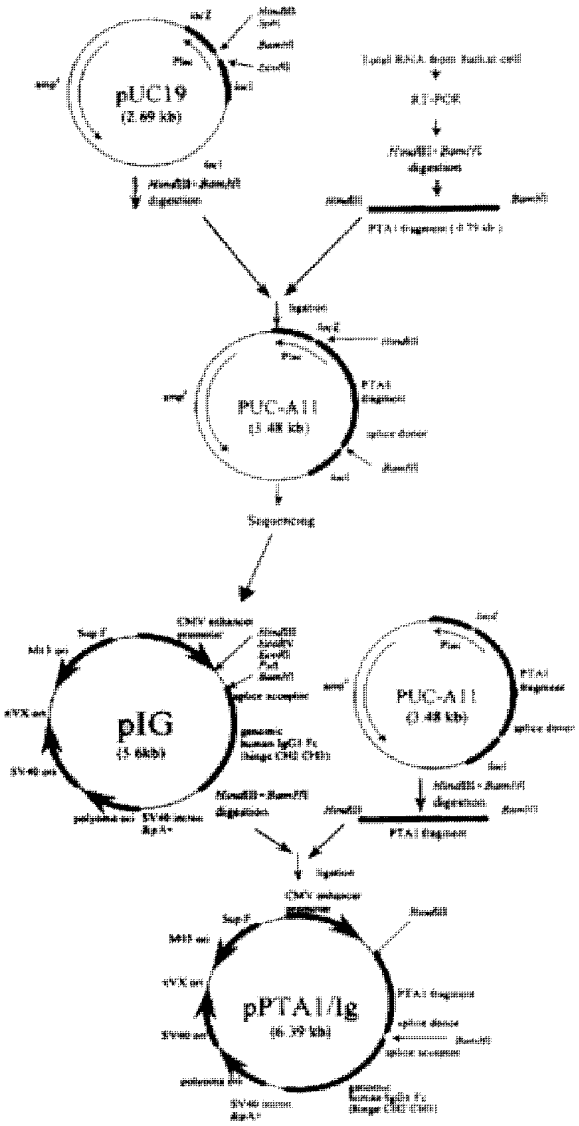


Figure 2 Construction of pCD226/Ig fusion vector.

Expression, identification and purification of CD226/Ig fusion protein

The pCD226/Ig vector was transiently transfected into COS-7 cells. The optimal conditions was checked before large-scale transfection, and it was found that transfected COS-7 cells cultured in medium with 10ml·L^{-1} serum for 96 h could produce CD226/Ig most effectively. The secreted CD226/Ig fusion protein was purified by Leo-A1 affinity chromatography, About 130μg CD226/Ig fusion protein could be obtained from 100mL COS-7 culture supernatants by anti-CD226 affinity chromatography purification. SDS-PAGE showed CD226/Ig fusion protein has a molecular mass of 83 ku (Figure 3) and could be recognized by anti-IgG polyclonal antibody in Western-blot assay (Figure 4). In ELISA assay, CD226/Ig expression could be identified in pCD226/Ig transfected COS-7 supernatant, but a negative result was obtained in pIG vector transfected COS-7 supernatant (Table 1). Both CD226 extracellular domain and Fc domain of the CD226/Ig protein could be recognized respectively by anti-CD226 and anti-hIg Fc mAb, suggesting that CD226/Ig could mimic the nature CD226 molecule and be a potential tool in the research of CD226 ligand and its functions.

Identification of CD226 ligand on Colo205 cells

Immunohistochemical experiment showed that Colo205 cells could be specifically stained by CD226/Ig but not by control protein (hIgG), indicating that CD226 ligand exists on the surface of Colo205 cells (Figure 5). Resting Jurkat cells had a low-level expression of CD226 on cell surface, whereas activated Jurkat cells expressed high level of CD226 after TPA treatment for 24h. In adhesive assay, resting Jurkat cells have a very low level adhesion to Colo205 cells. In contrast, activated Jurkat cells could bind to colon carcinoma Colo205 cells and this adhesive reaction could be blocked by CD226/Ig fusion protein or Leo-A1 mAb but not control Ig and anti-IL-1 mAb, indicating that CD226 takes part in this specific adhesion (Figure 6).

DISCUSSION

CD226 is a 65 ku glycoprotein expressed on the surface of activated T cells, NK cells, and platelets. It is a member of the Ig-superfamily containing 2 Ig-like domains of the V-set and is encoded by a gene on human chromosome 18q22.3[24]. Ig-superfamily members play essential roles in many aspects of immune responses by acting as immunoglobulin Fc receptors, cytokine receptors, adhesive molecules and accessory molecules[11,25-27]. The main function of Ig-super family concentrated in cell-to-cell recognition and interaction, such as LFA-1/CD2, CD4/MHC, CD28/B7, and many of these Ig-super family members are involved in the T cell activation[28-32]. Cross-linking CD226 with antibodies cause the activation of T cells and aggregation of platelets. Previous studies also showed the cross-linking of LFA-1 induced tyrosine phosphorylation of CD226, in which the Fyn protein tyrosine kinase may play a role[33,34]. The above results indicate that CD226 mediates cellular adhesion to other cells bearing an unidentified ligand and takes part in signal transduction. Interaction between ligand and receptor is the basis of immune response. So, identification of CD226L is very important for the further investigation of CD226.

Intercellular adhesive molecules play an important role in the immune response, they provide not only intercellular binding, but also participate in signal transduction, and are closely related with allograft rejection, tolerance, cell differentiation, lymphocyte homing and tumor immunity[35-39]. In addition to the specific antigen recognition signal provided by CD3-TCR complex, a lot of other signals are required in the T cells mediated immune response, such as signals provided by CD4/CD8, CD2, LFA-1, CD28[40-42]. Our previous results showed that resting T cells expressed low-level of CD226 molecule. When T cells were activated, they expressed high-level CD226 molecules. This finding suggested that CD226 might be closely related to the function of activated T cells. Differentiation of T cell to CTL could be inhibited when Leo-A1 mAb or Leo-A1 $F(ab')_2$ were added into mixed lymphocyte culture (MLC), and production of LAK cells was also reduced, this action of Loe-A1 was not dependent on Fc of Leo-A1. The inhibiting effect of Loe-A1 only works in the differentiation phase of CTL but not in the cytotoxicity phase, suggesting that the epitope recognized by CD226 is related with the differentiation of CTL[1,2,7]. Another mAb DX11 against CD226 (DNAM-1) was reported to significantly inhibit the cytotoxicity of CTL to several tumor cell lines, such as Colo205, PA-1, MCF7[7]. Therefore, epitope recognized by DX11 mAb was different from that recognized by Leo-A1 mAb, and these two different epitopes may take part in the differentiation and cytotoxicity of CTL.

Since the mid 1980s, there has been a rapid increase in our knowledge about the specific cell surface molecules mediating cell-cell interaction and adhesion events. This has been largely due to the success of molecular cloning techniques, allowing the isolation of functional cDNA clones that encoding these glycoproteins. Always methods have been successfully used in the cloning of novel cDNA. One of these methods reported by Aruffo and Seed is very effective[43,44]. This method is based on the transient expression of cDNA library in cells and specific mAb recognition (capture and panning). Several molecules, such as CD2, CD22, CD28, CD36 and CD58[43-47], have been cloned by this method. So, once a suitable antibody, ligand or cell line has been identified to recognize a cell surface molecule, the cDNA encoding this molecule could be cloned by this method. CD226 molecule or its homologue to be used in the investigation of CD226 ligand should have the following characteristics: easy to obtain, high in purity and natural in motif. So these molecules could be obtained by purification from platelet, preparations of anti-idiotype mAb or preparations of recombinant CD226 molecule. In this study, we prepared the CD226/Ig fusion protein containing CD226 extracellular region 232aa (including 10 glycosylation sites, 57ku) and IgG Fc region (CH2, CH3 and H region, 26ku), the putative molecule weight is consistent with that identified in SDS-PAGE and Western-blot. CD226/Ig fusion protein is expressed in secreting form that was detected by Sandwich-ELISA, its two different domains could be recognized by anti-CD226 mAb and anti-hIg Fc mAb, respectively, but could not be recognized by other mAb, suggesting CD226/Ig can mimic the nature of CD226 molecule and can be used in the research of CD226 ligand. Ig fusion proteins have many advantages such as easy to purify, easy to label and easy to detect, and thus were widely used in ligand identification[48-53], and disease protection[54-56]. These advantages make it more convenient to further clone CD226 ligand.

Immunohistochemical research suggested that CD226 ligand was expressed on Colo205 cells and this result was also supported by adhesion-blocking experiment. It was shown that resting Jurkat cells expressed very low level of CD226 molecules, but activated Jurkat cells expressed high-level CD226 molecules after TPA activation for 24

h, and the expression of CD226 was regulated by cytokines, such as TGF-β, TNF-α and IL-2[57]. In the experiment about adhesion, activated Jurkat cells could bind to colon carcinoma Colo205 cells and this adhesion reaction could be blocked by CD226/Ig fusion protein or Leo-A1 mAb but not by control Ig and anti-IL-1 mAb, indicating that CD226 ligand exist in Colo205 cells and takes part in this specific adhesion.

When T cells were activated, they expressed high-level CD226 molecules. Interestingly, CD226 ligand seemed to express on the surface of tumor cells. Activated T cells not only need the specific antigen recognition by TCR, but also the engagement of accessory molecules on T cells by their respective ligans expressed on the target cells[38,39,58,59]. More researches need to be done to reveal their relationship and what signal have CD226 transducted during immune response against tumors. The above results made a solid foundation for further cloning of CD226 ligand and is helpful for thorough investigations on CD226L structure and function.

ACKNOWLEDGMENT Dr. Xu and Dr. Lan for their valuable technical advice and assistance.

Abstract

AIM: **To study the effect of manganese (Mn) on heat stress protein 70 (HSP70) synthesis in the brain and liver of new-born rats whose mother-rats were exposed to Mn.**

METHODS: **32 female rats were randomly divided into four groups. One group was administrated with physiological saline only as control group, the other three groups were administrated with 7.5, 15 and 30 mg·kg^{-1} manganese chloride ($MnCl_2$) by intraperitioneal injection every two days for two weeks. After delivery, the mother-rats received $MnCl_2$ unceasingly for a week with the same method. Then the contents of Mn, Zn, Cu and Fe in the livers of the new-born rats were determined by atomic absorption spectroscopy; The level of HSP70 in the brains and the livers of the new-born rats as detected by Western-dot-blotting, and the SOD activities were measured simultaneously.**

RESULTS: **The contents of Mn in the livers of new-born rats of the experimental groups (respective 1.38±0.18, 2.73±0.65, 3.44±0.89μg·g^{-1}) were significantly increased compared with the control group (0.88±0.18μg·g^{-1}; P<0.01); The contents of Fe in the livers of new-born rats of 15 and 30 mg·kg^{-1} experimental groups (426±125, 572±175μg·g^{-1}, respectively) were significantly increased compared with the control group(286±42μg·g^{-1};P<0.05); the levels of Zn in the livers of the new-born rats of three experimental groups(254±49, 263±47, 213±28μg·g^{-1}, respectively) were lower than those of the control group (335±50μg·g^{-1}; respective$P$<0.05,P<0.01); and the levels of Cu showed no significant difference among the four groups (three experimental groups: 75±21, 68±241 and 78±18μg·g^{-1}; control group: 83±9μg·g^{-1}; P>0.05). There was a significant increase in the levels of HSP70 in the brains of new-born rats of the 30 mg·kg^{-1} group (19.5×10^3±1.3×10^3 A; control group: 14.3×10^3±1.4×10^{3}A; P<0.01),and the levels of HSP70 in the livers of new-born rats of three experimental groups(respective 19.6×10^3±3.9×10^{3}A, 18.5×10^3±3.8×10^{3}A, 22.4×10^3±1.9×10^{3}A) also increased than control group(13.3×10^3±1.0×10^{3}A;P<0.01), but the SOD activities showed no significant difference among brains of the four groups (experimental groups: 5.04±0.43, 4.83±0.48, 4.60±0.84 ku·g^{-1}; control group: 4.91±0.37ku·g^{-1};P>0.05). The SOD activities in the livers of 15mg·kg^{-1} group (5.41±0.44 ku·g^{-1}) was lower than the control group(5.95±0.36 ku·g^{-1}; P<0.05).**

CONCLUSION: **While mother-rats were exposed to manganese, the metabolisms of Mn, Zn and Fe of new-born rats in the livers were influenced and were situated in a stress status, thus HSP70 syntheses is induced in the brains and livers of new-born rats, but the mechanism of this effect in the developmental toxicity of Mn remains to be further studied.**

Zhang BY, Chen S, Ye FL, Zhu CC, Zhang HX, Wang RB, Xiao CF, Wu TC, Zhang GG. Effect of manganese on heat stress protein synthesis of new-born rats. *World J Gastroenterol* 2002;8(1):114-118

INTRODUCTION

Manganese(Mn) has bi-directional effect on the mammal[1-3], both deficient and excess intake of Mn result in altered enzymatic reactions and brain function because of its essential element nutrition[4] and neurotoxicant effect. With exposure to higher concentrations is harmful to health[5,6]. Excessive manganese has been associated with neurobehavioral deficits and neurological and/or neuropsychiatric illness[7]. As a nervous toxicant, Mn damages central nervous system, and has procreant toxicity. Mn also could transplacenta to embryo and affects growth of offspring[8,9]. Thus, excessive manganese also is an embryotoxicant and fetotoxicant in mammals[10]. but the mechanism of this effect has not been elucidated yet. It is well known that heat stress / shock proteins (Hsps) are induced by a series of occupational factors and their main biological action is to participate in thermotolerance and toxicant tolerance. Hsps participate in protein synthesis, folding, assemblage and intracellular protein transport as the molecular chaperones[11,12]. It has not been reported whether these functions are relative with toxicity of Mn. The HSP70 levels and the SOD activities of the brains and livers and the trace-element contents of the livers were measured in the new-born rats after their mother-rats were exposed to the manganese.

MATERIALS AND METHODS

Animal Treatment

Thirty-two healthy Wistar female rats that weigh 200~240g (obtained from center of experimental animal of Tongji Medical University) were randomly divided into four groups. Except one group as control, the other three groups were treated with Manganese chloride tetrahydrate ($MnCl_2 \cdot H_2O_2$). By mean of single intraperitioneal injection administration every two days for two weeks, the doses were 7.5, 15 and 30 mg·kg^1 respectively. The control group was similarly injected physiological saline. Then the rats (1 ♂ : 1 ♀) were housed together. The next morning gestation was defined as d 0 when sperms were founded in the vaginal smear. After

pregnancy, the mother-rats were treated with $MnCl_2$ at the same concentration of before, then harvested at time points up to a week with the same method as before. These female rats received $MnCl_2$ 11 times. The newborn rats were killed by cervical dislocation in 24 h. The brain and liver of the newborn rats was reserved in -20℃ immediately.

Determination of trace elements

The reserved livers were put into roaster for 2 h at 105℃ and reserved into desicator. Drying sample accurately Weighed up 0.0500~0.1000g was put into conical flask and added 2 mL nitric acid (G.R), 0.5 mL perchloric acid (G.R) and digested to dry approximately. After cooling, the digestive sample was dissolved with redistilled water that was distilled for 4 times, the sample was put into 10 mL test tube and fixed volume to 5 mL. Trace elements were measured with atomic absorption spectroscopy (Spectr AA-40 atomic absorption apparatus, VARIAN corp., USA). Mn was measured with graphite stove atomic absorption spectroscopy analysis, and adopted flame atomic absorption spectroscopy to mensurate Cu, Zn and Fe.

Brains and livers homogenate

Prepared homogenates of the brains and livers were done as described by routine technique. Mensurated contents of the protein of the brains and livers as Lowry.

Detection of SOD activities

Taking equal quality proteins of the brains and livers to determine SOD activities in the brains and livers with SOD kits supplied by Nanjing Jiancheng Bioengineering Graduate Institute.

Determination of HSP70

Equal amount proteins of the brains and livers was taken to determine the HSP70 levels in the brains and livers with Western-dot-blotting[13]. After Western blotting, HSP70 was detected using anti-HSP70 rabbit polyclonal antibodies (provided by Lab of Cell & Developmental Genetics, University Laval, Canada) and anti-rabbit horseradish peroxidase-conjugated secondary antibodies (Sigma), and visualized using 3-3'-diaminobenzidine (DAB). The results were quantified by a densitometry (CS-930, Japan).

Statistic analysis

The results were analyzed with SAS programs in IBM-PC.

RESULTS

Effect of Mn on female rat Reproduction

After female rats exposed to Mn, their gestation periods had no significant difference from the control group (P>0.05). The parturition indexes seem to reduce along with manganic dosage increment, but the difference is not significant compared with control group(P>0.05) yet. Average of fetiferous quality of puerperal female rats seem to reduce in 7.5 and 15mg·kg^{-1} groups, but the differences are not significant compared with control group (P>0.05) yet. However, 30 mg·kg^{-1} group significantly reduced compared with control group(P<0.01), Average of fetiferous quality of pregnant female rats in 15 and 30 mg·kg^{-1} groups significantly reduced compared with the control group(P<0.05,P<0.01). The viability index of 1-day-old filial rats in 30mg·kg^{-1} group significantly reduced compared with the control group (P<0.01). The newborn rats' weight and height showed not significant difference among four groups (P>0.05, Table 1).

Effect of Mn on traceelements in newborn rats

The manganese contents of the new-born rats' livers in three experimental groups significantly increased compared with control group (P<0.01), and there was a dose-dependent increase in these groups. The levels of zinc in the new-born rats' livers in three experimental groups were lower than those of control group too (P<0.05,P<0.01,respectively). The iron contents of the new-born rats' livers in 15 and 30mg·kg^{-1} experimental groups were higher than control group(P<0.05, P<0.01, respectively), but the copper levels of the newborn rats' livers showed no significant difference among four roups (P>0.05, Table 2).

Effect of Mn on SOD activities in newborn rats

Although the SOD activities of the newborn rat' brains seem to reduce in 15, 30mg·kg^{-1} groups and increase in 7.5mg·kg^{-1} group, but no significant difference showed among all the four groups (P>0.05). The SOD activities of the newborn rat' livers were lower in 15mg·kg^{-1} group than control group(P<0.05), but showed no significant difference among 7.5, 30mg·kg^{-1} and control groups (P>0.05, Table 3).

Effect of Mn on HSP70 synthesis in newborn rats

The level of HSP70 in the brain showed no significant difference among 7.5, 15$mg \cdot kg^{-1}$ and control groups ($P>0.05$), but showed significantly increased between 30$mg \cdot kg^{-1}$ and control groups ($P< 0.01$). The level of HSP70 in the livers significantly increased in three experimental groups to be compared with control group ($P<0.01$, Table 3).

DISSCUSION

The fetiferous quality reduces after female rats are imbued with Mn; parturition index also tended to reduce along with the manganese dosage increase, and livability of d 1 old filial rats significantly reduced along with the manganese dosage increase. The fact illustrates that manganese influences female rats' reproductive function. Manganese could transplacenta to enter filial central nervous system[15]. Yang BN reported that the new-born rats' manganese contents of the brain were significantly higher than those of control group with inductance coupling plasmic emanant spectroscopy after mother-rats exposed to by manganese[16]. This study determined that the new-born rats' manganese contents of the livers are significantly higher than control group with atomic absorption spectroscopy after mother-rats exposed to manganese, and have a dose-effect relationship. The results show that the manganese could be transferred to the embryo by placental barrier and accumulate in filial rat's brains and livers after mother-rats to be exposed by manganese in gestation. It has not been reported that the effect of Mn on other microelements in the newborn rats' liver of intoxicanted mother-rats. This study also detected that the levels of Zn in the new-born rats' livers of three experimental groups were lower than those of control group, and the iron contents in the new-born rats' livers of and 30$mg \cdot kg^{-1}$ treated groups were higher than the control group, but the copper levels showed no significant difference among four groups. It was obvious that the zinc and iron metabolism were disturbed in the livers of new-born rats after mother-rats exposed to manganese. Zn is an essential microelement and has much to do with many enzymatic bioactivities. Zn is very important to maintain normal body growth and reproductive function. While the body zinc dificiency, the hormone syntheses reduce and their activities decrease, which, therefore, result in serious obstruction of the growth, children' testicles agenesis, reducing spermic quantity, weakening spermic activity, agenesis of the immune apparatus in the thymus gland etc and immune estate. While serous zinc contents descend, it is degressive that the levels of neuropeptide somatostatin and arginine-vasopressin have much to do with capability of the learning and memory in rats' hippocampi, and make the rats' capability of learning and memory clearly decline[17]. When filial rats lack the zinc during the lactation and weaning stage, the brain weight, the hippocampal weight, the serum and hippocampal zinc concentrations are significantly lowered, and proportion of induced long-term potentiation (LTP) is zero and proportion of active avoidance response decreased profoundly[18], Cognition is a field of thought processes by which an individual processes information through skills of perception, thinking, memory, learning and attention. Zinc deficiency may affect cognitive development by alterations in attention, activity, neuropsychological behavior and motor development. The exact mechanisms are not clear but it appears that zinc is essential for neurogenesis, neuronal migration, synaptogenesis[19]. Excessive manganese arising zinc deficiency could interfere with neurotransmission and subsequent neuropsychological behavior.

This study determined zinc decrease in newborn rats' livers after mother-rats were administrated by manganese, it tallies with the phenomenon that as we observed, filial rats' neurobehavior functions deferred and the capability of learning and memory weakened[20]. The result enlightens that the effect of Mn on filial rats' developmental toxicity might be responsible for the manganese which leads to the zinc deficiency in the brain and liver. A new pathway is suggested in the manganese mechanism research on filial rats' neurotoxicity. Fe is also an essential microelement and has important physiologic function. The study also discovered that newborn rats' irons to heighten in the livers after mother-rats were imbued by manganese. The most actions are antagonistic between Fe and Zn. It is uncertain that whether the manganese cumulated in the liver to arise the zinc decreases and results in heightening Fe antagonistically. So, the reason needs further study.

Mn has an especial affinity with the mitochndrial and can largely cumulate in the cells that contain plentiful mitochndrial, so the manganese content is highest in the liver and the content is higher in the spleen, the kidney and brain[21]. The manganese mainly damages extrapyramidal system on central nervous system,, which is related to specifically organization and the neurons distribution in the substantia nigra and corpus striatum. Many melanin neurons and aminergic neurons are distributed in the dense area of substantia nigra. They have a speciality that collect and cumulate the amine and metal elements, such as manganese etc. Superfluous manganeses on one hand activate the cytochrome oxidase P-450 to engender the free radicals to deplete the sulthydyls and impair cellular resistivity, Mn on the other hand can also produce plentiful free radicals to damage mitochondrial, and to disturb energy metabolism, then mediate the toxicity of excitability amino acids and result in increasing intracellular calcium, activating the calcium-dependent protease, nuclease, phosphatase and promoting the cellular recessive denaturalization. The increase of calcium ions again, promotes the production of free radicals as result, forms a vicious circle. Therefore, cumulative manganese may destroy the protective barrier of the melanin neurons and constantly releases to beget continual toxicity in the extrapyramidal system). The free radicals play very important role in manganese neurotoxicity. SOD is a important enzyme among enzymes system that eliminates free radicals. The manganese is able to inhibit SOD by forming free radicals. In our study only the SOD activities of livers in 15$mg \cdot kg^{-1}$ group were lower than the control group. Although it inclined depression that the SOD activities of the livers in 7.5 and 30$mg \cdot kg^{-1}$ groups and of the brains in the three experimental groups, the differences were not significant to be compared with control group. This causation may be that SOD have a insensitivity on free radicals by the manganese toxicity, also may have other cause to be elucidated. The body was situated in a toxicant stress status and oxidative stress after the manganese was accumulated in the filial rat's brain and liver[22]. When body was situated in a toxicant stress / oxidative stress status, heat stress protein is markedly elevated *in vivo* on response of toxicant stress / oxidative stress.[23-26]. The stress response is a common physiological response from the prokaryotes to the human. It is the character of various stress responses that Hsps syntheses appear as increase or grow out of nothing in the cells. Hsps are a kind proteins that have protective function as quite conservation in the evolution. Hsps could respond stress responses by some injurious environmental factors, such as Pb[27], Cd[28], Hg[29], As[30,31], benzene[32,33], CO[34], ischemia[35], psychological tension[36]etc. Hsps have been proposed as

general markers of cellular aggression and their use for environmental monitoring is often suggested[37]. Hsps endow with resumptive capability of the cells or biology from various stress responses and protect them to keep from the damages of these factors[38-46]. The primary signification of Hsps is to keep protect the cells from suffering from ill conditions of high temperature, low oxygen, heavy metal and illness etc[47-54]. Therefore it is obvious that thermotolerance was formed, in other words, after the cells or organisms were exposed to subthermal death point, the livability significantly increases on the thermal death point. HSP70 exerts main action in the form of stress tolerance. HSP70 has important protective function in intracellular hereditary substance DNA, the process of biologic growth, development, differentiation and regulation[55-57]. HSP70 connects with many internal bioactive substances and take part in many biochemical processes. It is principal that HSP70 promote protein synthesis, folding, assemblage, transportation and take part in the elimination of metamorphic proteins as molecular chaperones under non-stress conditions[58-62]. These important functions may have to do with the function of the thermotolerance and poison tolerance. When cells experience thermal or toxicant stress, Hsps take on a new role, conserved from poison to humans, of protecting cells from the detrimental effects of stress. This role takes on added significance for the embryo in which the developmental program must be read linearly, with little opportunity to cycle backward to complete a missed segment of the program. Thereby Hsps will afford protection to the human embryo/fetus exposed to thermal/toxicant tress[63-65].

This study showed that some HSP70 were synthesized in normal newborn rats' brains and livers. The HSP70 contents of the newborn rats' brains in Low and medium dosage groups had a few increase, but the differences were not significant compared with control group. The HSP70 contents in the newborn rats' brains of high manganese dosage group significantly increased. The HSP70 contents all significantly increased in the newborn rats' livers of three experimental groups to be compared with control group. These results indicated that HSP70 had a certain degree role in normal growth and the manganese had effect on HSP70 syntheses in the newborn rats' brains and livers. However the HSP70 syntheses were low in very few newborn rats' brains and livers of experimental groups too. It remains to be elucidated that HSP70 synthesis is related to manganese toxicity in the pathology, clinic, susceptibility of manganese poisoning and other biochemical variety.

Through contrast affected degree of HSP70 syntheses in newborn rats' brain and livers,. induction of HSP70 is sensitive in the liver than in the brain. The reason may have to do with manganese accumulation that is higher in the liver than in the brain in the newborn rats. Recently some researcher explore HSP70 to relate to the fetation from the point of the development and had acquired many intersting results. They considered stress response to have diploid effects. On the one hand protect embryonic growth, on the other hand disturb as well as embryonic growth. Final procreant consequence mainly depend on the intensity and duration in the stress response whether to exceed self regulative level in intracellular HSP70 synthesis and also relate to injured period in fetation. Many results all had proved that HSP70 could influence embryonic growth *in vivo* and *in vitro*. HSP70 maybe is a biomaker as screening developmental toxicant[66], and excessive manganese may be considered a developmental toxicant.. Moreover, the stress status also leads to disorder of digestive system, for instance, gastrointestinal motility disorders[67,68], vasoactive intestinal peptide (VIP), neuropeptide Y(NPY) of colonic mucosa was increased[69], platelet derived growth factor (PDGF)[70], and tissue inhibitor of metalloproteinase 1 (TIMP-1) are increased[71], and heme oxygenase-1 (HO-1) mRNA and protein were highly induced and HO enzyme activity was higher after hemorrhagic shock and resuscitation (HR)[72]. Besides accelerates HSP70 synthesis *in vivo*,The manganese could induce the nitric oxide synthase(NOS) yet. The NOS begets increasing the synthesis of nitric oxide(NO). Superfluous NO could mediate neurotoxicity of excitative amino acid as a cytotoxicity molecule and could damage central nervous system in budding filial generation[73] [28], whereas, HSP70 could diminish the liver damage by NO. Re-induction of HSP70 expression by stress effect re-established resistance to NO toxicity[74].

Our study demonstrates that the excessive manganese cumulated largely filial rat's brain and liver by way of placenta after mother-rats exposed to manganese, and disturbed the microelement metabolisms of the l manganese, zinc and iron *in vivo* and injured the growth on the offspring. On the other hand the body was situated in a stress status and the embryo and filial generation growth were damaged by the inducement of HSP70 synthesis in the brain and liver. The mechanism of this effect in the developmental toxicity of Mn remains to be further reseached.

Abstract

AIM: **To study the mechanism and treatment of severe biliary complications arising from hepatic artery embolization (HAE).**

METHODS: **Of seven cases of intra- and extrahepatic biliary damage resulting from hepatic artery embolization reported since 1987 , 6 patients suffered from hepatic haemangioma, the other case was due to injection of TH compound into the hepatic artery during operation. The hepatic artery was injected with ethanol so as to evaluate the liver damage in experimental rats.**

RESULTS: **All the cases were found to have destructive damage of intra- and extrahepatic bile duct at the hilum with biliary hepatocirrhosis. Experimental results revealed necrosis of the liver parenchyma, especially around the portal tract and obliteration of intrahepatic bile duct.**

CONCLUSIONS: **To prevent the severe biliary complications of HAE, the use of HAE for hepatic haemangioma which was widely practiced in China, should be re-evaluated. Hepatic arterial embolization of hepatic haemangioma may resulte in severe destructive biliary damages and its indiscriminate use should be prohibited.**

INTRODUCTION

Hepatic artery embolization (HAE) has been used for the treatment of malignant tumors of the liver. At present, in Chinese literatures, HAE has been widely used for liver cancer therapy[1-6]. Recent reports showed that the method has been advocated for the treatment of liver benign tumors especially in hepatic hemangioma[7-15]. However, the value of HAE as well as the pitfalls of this form of treatment in hepatic hemangioma have not been fully evaluated. Some basic differences of hepatic hemodynamics between hepatic hemangioma and hepatic cell carcinoma[16], may in turn affect the result of treatment. Severe complications after HAE for hepatic hemangioma had rarely been mentioned in the literature, therefore, such kind of non-operative treatment may be taken as an "innocuous" procedure and it has been used indiscriminately. Little attention to the biliary complications of HAE has been paid and the treatment of the biliary complication is a very knotty problem[17]. We have treated 7 consecutive cases of severe destructive damages of the bile duct resulting from HAE from February 1987 to September 1999. In addition, damage of bile duct after HAE has been testified by a series of animal experiments. This report reviews our experience in the treatment of severe biliary complications of HAE and the results of animal experiment.

MATERIALS AND METHODS

Animal experiment

Male and female Wistar rats (220g-280g) purchased from the Laboratory Animal Unit of the General Hospital of PLA, Beijing. All animals were reared on a standard laboratory diet, and tap water. They were kept in a room where the temperature (20℃±2℃), humidity (65%-70%), and day : night cycle (12:12 light:dark) were controlled.

Hepatic artery embolization

Ethanol (100%) was selected as the embolizing agent for the study. Hepatic artery embolization was performed under inhalant anesthesia. Branches of the abdominal aorta, and the branches from coeliac artery to spleen, stomach and duodenum were temporarily ligated. Ethanol (100%) with small amount of methylene blue was injected into the abdominal aorta with syringe, 0.2 milliliter ethanol for each rat. After the injection, the ligated arteries were loosened.

The animals lost appetite and 3/20 had obstructive jaundice after the operation. The rats were randomly divided into two groups, ten rats for each group.

Ten rats were killed 3 days (group A) after the embolization, the others were killed after 7 days (group B). Blood samples of Group A, Group B and control (abdominal operation but without ethanol injection) were collected for liver function test including glutamic pyruvic transaminase (GPT), glutamic oxaloacetic transaminase (GOT), biliruin, alkalin phosphatase (ALP) and total bile acid (TBA). At the same time, the liver was removed and fixed in 10% formalin solution and embedded in paraffin. The specimens were sectioned and stained with hematoxylin-eosin (H&E).

Statistical analysis

The results were expressed as mean ±S.E. ($\bar{x}\pm S\bar{x}$).

RESULTS

Liver function changes

Changes of liver function differed among rats with or without jaundice after the embolization. GPT, GOT, ALP and TBA were significantly increased after HAE on the 3rd day and 7th day when compared with the control group, these changes seemed to be recovered on the 7th day (Table 1).

Table 1 Liver function changes ($\bar{x}\pm S\bar{x}$)

	GPT(U/L)	GOT(U/L)	TB(μmol/L)	DB(μmol/L)	ALP(U/L)	TBA(μmol/L)
Control	30±8	63±6	10±9	5±5	146±115	6±2
Group A	245±191	443±382	129±213	61±99	104±11	161±249
Group B	55±67	233±266	5±2	3±1	243±174	48±36

GPT=glutamic pyruvic transaminase, GOT= glutamic oxaloacetic transaminase, TB= total biliruin, DB= direct bilirubin, ALP= alkalin phosphatase, TBA= total bile acid.

Pathological changes

Small yellowish necrosis patches can be seen by naked eyes in some lobes of the liver of groups A and B.There were small local necrotic areas in the liver parenchyma of groups A and B, the control group showed no liver necrosis. Most of the necrosis was located near the portal triad, the necrotic areas showed eosinophilic staining. The damaged areas presented coagulation necrosis of hepatocytes, where the hepatocytes showed uniformly eosinphilic, the liver cell plate was still visible but the hepatic cell nuclei disappeared. There was a clear borderline around the necrotic areas after the 7th day with infiltration of inflammatory cells. Most of the portal veinules remained normal, but the wall of the surviving artery was thickened and bile duct disappeared from the portal tract. Proliferation of small bile ducts was easily seen outside the necrotic areas (Figure 1). Obliteration of the bile duct with impairment of biliary drainage was responsible for the above findings.

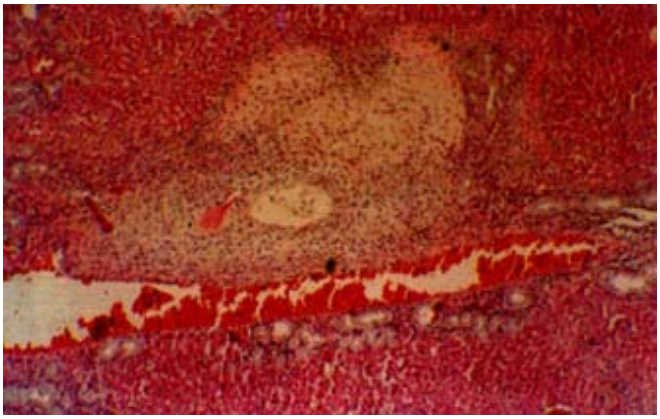

Figure 1 Liver necrosis after HAE in rats. The necrotic area is seen near the portal triad. HE×100

The above findings showed that the liver damage of HAE could be reproduced in animal experiment. Injecting ethanol through hepatic artery can certainly result in local necrosis of the liver, especially the biliary tract in the portal triads of the liver. Necrosis of portal triads or liver parenchyma will lead to biliary abscess formation and fibrosis of the liver.

CASE REPORTS

Case 1

A 55-year-old male was found to have a 4cm×4.5cm hemangioma in the right lobe of the liver during a routine physial examination in March 1989. He was advised to have his liver thrombosed. HAE with iodized oil 10ml and sodium morrhuate 4ml were injected with Seldinger technique. He felt severe abdominal pain at once after the injection. Pain was not relieved until 5 days after the embolization. Intense vomiting appeared 20 min after the embolization, and persisted for 4 days. Obstructive jaundice appeared after 20 days. Percutaneous transhepatic cholangiogram (PTC) showed changes of the right and left hepatic duct. Occlusion of extrahepatic bile duct was noted in July 1989. Ultrasound showed dilatation of the gallbladder and fluid accumulated around the gallbladder. Gallbladder necrosis with segmental bile duct necrosis were confirmed at operation on July 29, 1989. Cholecystectomy, partial hepatic bile duct excision and choledochocholedochostomy with T-tube stenting were performed. Serum icterus index descended from 90U to 20U with T-tube kept in place for two years. He was admitted to the General Hospital of PLA, Beijing, because of biliary cirrhosis, portal hypertension, enlarged spleen and ascites in 1994. Due to severe hepatocirrhosis, atrophy of the right lobe of the liver and portal hypertension, reconstructive biliary operation was deemed to be unsafe unless the portal pressure has been lowered down. So he was to under go staged operation, the first operation consisted of splenectomy and splenicocaval shunt on June 9, 1994. Hepatocholedocho-jejuostomy was performed 6 months afterwards. The patient remained well without jaundice since the last operation.

Case 2

A 55-year-old female was found to have a large mass (5cm×6cm) in the right lobe of liver in June 1996, but she experienced no remarkable symptoms. Nevertheless, HAE was performed with ethanol (100%) following doctor's advice. The patient suffered from irregular fever and epigastric pain after the HAE. Ultrasound showed liver abscess formation two months later. She was still febrile and appeared toxic in spite of drainage of bile containing pus by a percutaneous catheter. Laparotomy and liver abscess drainage were performed three months later. But jaundice reappeared 4 months after the operation. Computed tomography scan showed left hepatic duct dilatation, and infective necrotic lesion of unhomogenous density in the right lobe of the liver. Fistulography through the right liver drainage tube showed abnormal communication between the drainage tract and the extrahepatic bile duct, as well as a duodenal fistula. Hepatectomy, hepatocholedocho-jejunostomy and U-tube stenting were performed 4 months later in April 1997. Jaundice disappeared after the operation. The stenting tube was maintained for one and half years. She recovered after withdrawal of the tube.

Case 3

A 62-year-old woman was found to have an asymptomatic hemangioma (10cm×9cm) in the right liver by ultrasound in December 1994. HAE was advised and performed with iodized oil and sodium morrhuate. Persisted epigastric pain followed the procedure. Ultrasound and CT showed cystic lesions (5.6cm×6.1cm) in the left lobe of the liver 2 months later (Figure 2). The patient had had repeated attacks of high fever with chills, and antibiotics administration was not effective. She was admitted with the diagnosis of biliary multi-abscesses of the liver. A transcutancous catheter was placed with drainage of about 180-200 mL bile each day. The last operation was performed in June 1996. A large amount of bile stained necrotic tissue along the portal tract on both sides of the liver was removed. During the operation, the normal intrahepatic ducts were found destroyed. The right and left liver parenchyma was atrophied while the caudate lobe became hypertrophied. A fibrous stricture band was present around the common hepatic duct. The stricture band was removed and U-tube stents were placed during the operation. Jaundice disappeared 2 years after the operation.

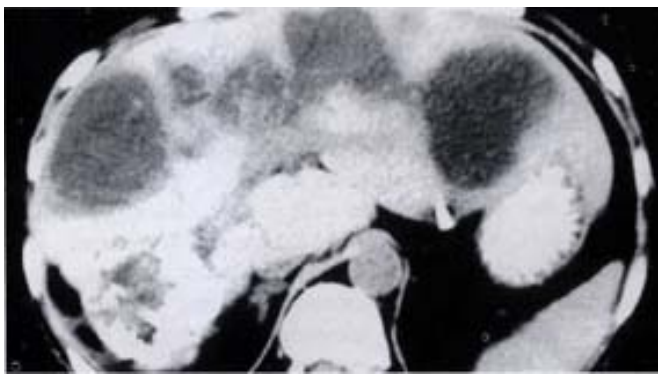

Figure 2 Biliary abscess of liver after HAE. CT shows multi-abscess along portal tract.

Case 4

A 24-year-old female was diagnosed having a space occupying lesion in the right liver. She was operated upon in 1987. Multiple nodular lesions were found in her right liver, which were supposed to be

metastatic nodules. A nodule was taken for pathological sections, and the hepatic artery was ligated and methacrylate (TH glue) was injected through distal end of the hepatic artery during operation. The postoperative course was very stormy. She developed continued abdominal pain with high fever and jaundice after the operation. The abdominal X-ray showed that the branches of the left, and right hepatic artery and gastroduodenal artery were embolized. However, the tissues from the right lobe of the liver was inflammotory in nature pathologically. Seven months later, she was admitted to the General Hospital of PLA, and PTC showed that stricture of hilar bile duct and the left hepatic duct with diffuse fibrosis in the perihilar region and necrosis of the right liver and the gallbadder. GI examination revealed an internal fistula between the first portion of duodenum and hepatic hilum. The operation undertaken was very difficult. However, the intestinal fistula was repaired, anastomosis of the dilated segment III bile duct and a long Roux-en-Y jejunal loop was created with a U-tube stent. The tube was removed 11/2 years later. The patient recovered from the operation. She delivered a child two years later, but eventually, the patient died of hepatocellular carcinoma 5 years after the operation.

Case 5

A 60-year-old male was found to have a hepatic hemangioma (5cm×5cm) in 1994. CT examination in 1998 showed an increase in the size of the tumor. HAE was advised and performed with iodized oil, steel wire ring and pingyangmycinum in July 1998. Persistent epigastric pain occurred for 3 days after the procedure, followed by jaundice and fever with gray colored stool 20 days later. This condition was aggravated 4 months later. The patient when seen was suffering from continual high fever and deep jaundice and was admitted to the hospital in January 1999. Diagnoses of hepatic abscesses and gallbadder necrosis after the embolization were made. ERCP showed extensive hepatic bile duct stricture (Figure 3), which was thought to be not amenable to surgery. The patient was treated conservatively.

Figure 3 Intrahepatic bile duct stricture after HAE. ERCP shows biliary stricture.

Case 6

A 43-year-old female was found to have a liver hemangioma in October 1998. HAE was performed which was complicated by severe abdominal pain and repeated vomiting for a week, and jaundice occurred 3 months later. Antibiotic therapy was effective. The patient was admitted with the diagnosis of obstructive jaundice in September 1999. MRI showed gallbladder necrosis perforation and with fluid collection around it (Figure 4). Intrahepatic bile ducts were dilated. A hemangioma(3cm×3.5cm) in the right lobe of the liver was still seen. The gallbladder was found to be necrotic, and the abscess cavity communicated with the common bile duct as seen at operation. Cholecystectomy, and T tube stenting were performed. Jaundice disappeared after the operation.

Figure 4 MRI showed fluid around the gallbladder.

Case 7

A 43-year-old man was found to have a hemangioma of the right liver during physical examination in June 1993. HAE was advised and was performed using iodized oil and sodium morrhuate. Serious epigastric pain occurred immediately after the embolization. Jaundice appeared in July 1995. He was then operated upon, three coagulated blood coagula were taken out during choledochostomy. The patient was reoperated in June 1996. Choledochoenterostomy and drainage of the III segmental duct were performed in January 1998. An external bile fistula was formed and biliary drainage of 300 mL was given each day but jaundice did not subside. The patient was admitted for operation in September 1999, marked biliary cirrhosis and atrophy of right lobe were found at operation. Cholangioenterostomy of the dilated III segmental duct and T tube stenting were performed. Jaundice subsided very slowly after the operation.

DISCUSSION

Blood supply of the hepatic duct and mechanism of bile duct injury in HAE

Branches of intrahepatic bile duct, artery and portal vein come together in the same Glisson sheath in the portal tract. Arterioles from the hepatic artery form a dense capillary network around the bile duct, which is the so-called peribiliary plexus. Therefore, only a small portion of hepatic arterial blood directly enters the sinusoids. The blood supply of the bile duct and structure of portal tract comes completely from hepatic artery. Hence, the intrahepatic bile duct receives unique nutrient blood supply from the hepatic artery in contrast to the double blood supply of hepatic cell[18-25]. Therefore, damages of the biliary system are more severe than the liver cell in hepatic arterial embolization. Clinically, continuous hepatic artery infusion of FUDR is expected to cause development of permanent stricture of the biliary system[26]. The complication was thought to be the result of regional drug toxicity and biliary vascular embolism. The end result is sclerosing cholangitis and diffuse fibrosis as well as scarring of biliary tree. Stapleton *et al*[27] in the study of the blood supply of the right and left hepatic ducts found that the peribiliary plexus of the caudate lobe has bilateral artery blood supply. This may be the reason for atrophy of right and left lobes but accompanied with hypertrophy of the caudate lobe after HAE injury which was consistently found in the cases in this report.

Hemangioma occurs more frequently in the right liver lobe and stricture of hilar hepatic duct was found in the HAE of right lobe lesions as shown in this report. This is explained by the finding that hilar bile duct blood supply chiefly derived from right hepatic and cystic arteries[28-30].

Sodium morrhuate is commonly used as a vascular sclerosing agent[31-33], but it is a strong irritant, it can cause local tissue necrosis and inflammation as well as compete occlusion of large blood

vessels in the injecting area. It was used for sclerosing therapy of varicosity vein and it is scarcely used for HAE. Four cases in this report used sodium morrhuate as the sclerosent, resulting in liver necrosis and abscess formation. We are of the opinion that the use of sclerosing drug as an embolizing agent in HAE is very dangerous.

Ethanol caused protein coagulation and damage of vascular endothelium which causes thrombosis and obstruction of blood vessel[34-36]. In this report, one case received ethanol as the embolizing agent. Animal experiment demonstrated that ethanol causes intrahepatic biliary obliteration and acute liver focal necrosis in the rat model.

Surgical treatment

Cases in this report have the following characteristics of: ① 6/7 cases were hepatic hemangiomas and strong destructive embolizing agents were employed; ②clinically, all patients presented persistent abdominal pain following the procedure; ③all resulted in extensive hepatic necrosis and damage of the biliary tree, hepatic biliary abscesses developed after the embolization; ④ damage of the intra- and extra-hepatic biliary system was destructive, it was difficult to rehabilitate the patients and a prolonged hospitalization is needed.

Treatment of the complications after HAE: Liver parenchyma necrosis was distributed along the portal tract after the HAE. Because of the disruptive effect of sclerosing agent on the biliary tract and the focal necrosis liver cells, some of the liver cells near the foci of necrosis are still secreting bile, the end result is biliary abscess forming in the necrosed area. The bile duct in its entire course may be completely destroyed. The damaged hepatic lobe will eventually be atrophied. Necrosis and fibrous stricture often consequently involve the hepatic duct bifurcation as well as the left hepatic duct, which results in obstructive jaundice in the end. In late cases, when complicated with biliary cirrhosis and portal hypertension, restorative biliary surgery is very difficult. Under such conditions, it is our experience that the treatment needs to be divided into several steps. The first step is the drainage of bile collection and removal of necrotic tissue to control the infection. First step of treatment is to improve patients¡ä general status as well as the local condition by maintaining biliary drainage. Treatment of the second step is hepatotomy and necrotic tissue elimination. If biliary stricture is of perihilar type, operation to relieve hilar bile duct stricture and Roux-en-Y hepatocholedocho-jejunostomy and place U tubes for stenting are neccesary[37-41]. If patients are complicated with biliary cirrhosis and portal hypertension, preliminary operation of portal pressure decompression, for example spleno-renal shunt is often needed before the difficult biliary restoration operation is attempted[42]. If bile ducts were badly damaged, bilateral biliary drainage with U tubes is a better alternative.

To prevent severe biliary complications of HAE, the use of HAE for hepatic hemangioma should be re-evaluated and the indiscriminate use of sclerosing agents in HAE should be prohibited.

Abstract

AIM: **To observe synthesis of CD14 protein and expression of CD14 mRNA in hepatic tissue and hepatocytes of rats during endotoxemia.**

METHODS: **The endotoxemia model of Wistar rat was established by injection of a dose of lipopolysaccharide (LPS) (5mg·kg^{-1}, *Escherichia coli* O111:B4) via the tail vein, and then the rats were sacrificed after 3, 6, 12 and 24 h in batches. Hepatocytes were isolated from normal and LPS-injected rats by in situ collagenase perfusion technique and were collected to measure the expression of CD14 mRNA and synthesis of CD14 protein by reverse transcript-polymerase chain reaction (RT-PCR) or Western blot analysis. The binding of fluorescein isothiocyanate (FITC)-CD14 polyclonal antibody to isolated hepatocytes was also assessed by flow cytometric analysis (FCM).**

RESULTS: **In the rats with endotoxemia, the expressions of CD14 mRNA in hepatic tissue and isolated hepatocytes were stronger at 3, 6, and 12 h than that in control rats (3.48±0.15, 5.89±0.62, 4.33±0.18, *vs* 1.35±0.14 in hepatic tissue, *P*<0.01; 4.12±0.17, 6.24±0.64, 4.35±0.18, *vs* 1.87±0.15 in hepatocytoes, *P*<0.01).The synthesis of CD14 protein in hepatic tissue and isolated hepatocytes increases also obviously in 6 and 12 h when compared to that in control rats (13.27±1.27, 17.32±1.35, 11.42±1.20, *vs* 7.34±0.72 in hepatic tissue, *P*<0.01; 14.68±1.30, 17.95±1.34, 11.65±1.19, *vs* 7.91±0.70 in hepatocytes, *P*<0.01). FCM showed that mean fluorescence intensity (MFI) and numbers of FITC-CD14 positive cells in the rats with endotoxemia increased obviously at 3,6,12 and 24h when compared with normal control group (43.4%, 70.2%, 91.4%, 32.6% *vs* 4.5%, *P*<0.01).**

CONCLUSION: **LPS can markedly promote the synthesis of CD14 protein and up-regulate the expression of CD14 mRNA in isolated hepatocytes and hepatic tissue. Liver might be a main source for soluble CD14 production during endotoxemia.**

INTRODUCTION

CD14 is a glycosylphosphatidylinositol-anchored lipopolysaccharide (LPS) receptor, and first reported to be a differentiation marker expressed on the surface of macrophages, neutrophils and other myeloid lineage cells[1,2]. Recent works have shown that the CD14 antigen is expressed in many types of cell and tissues[3-8]. But it is not yet clear whether hepatocytes can express CD14 protein and gene. Hepatocytes are the major source of most acute-phase proteins. If in fact soluble CD14 (sCD14) is an acute-phase protein, then hepatocytes might be expected to express CD14, which is upregulated during endotoxemia[9-11]. Furthermore, hepatocytes isolated from endotoxemic animals exhibit markedly enhanced responses to LPS, raising the possibility that these cells may express CD14[3,4,12-14]. To determine whether hepatocytes express CD14, our experiments were to observe the synthesis of CD14 protein and expression of CD14 mRNA in hepatocytes and hepatic tissue of rats during endotoxemia and to verify hepatocytes as a main source for soluble CD14 (sCD14) production.

MATERIALS AND METHODS

Reagents

LPS (Escherichia coli O111:B4) and type IV of collagenase were purchased from Sigma Chemical Company (St. Louis, Mo.). An anti-CD14 polyclonal antibody was purchased from Santa Cruz Biotechnology (Santa Cruz, Calif.). SP Reagent boxes and fluorescein isothiocyanate (FITC)-IgG were purchased from Zhongshan Biotechnology Company (Beijing, China).

Animals

Male Wistar rats, which were pathogen-free and weighed approximately 250 g each, were purchased from the Animal Center of Chongqing University of Medical Science. The rats were exposed each day 12 h of light and darkness. Rodent chow and water were provided ad libitum. Experimental protocols were approved by the Institutional Care and Use Committee of the Chongqing university of Medical Science.

The endotoxemia model of animals

The acute endotoxemia model of Wistar rat was established as described by Li SW, *et al*[4]. In brief, animals were injected with a dose of LPS (5mg·kg^{-1}, Escherichia coli O111:B4) via the tail vein, and then the rats were sacrificed at 3, 6, 12 and 24 h respectively. There were six rats at each time point, and other six animals were used as controls (0 h).

Hepatocyte Isolation

Hepatocytes were isolated from normal and LPS-injected rats by an in situ collagenase perfusion technique, modified as described previously[15, 16]. In brief, livers were removed after a portal vein

perfusion with Hanks' balanced salt solution (HBSS) and the homogenate was digested in a solution of 0.5g·L^{-1} collagenase. Hepatocytes were separated from the nonparenchymal cells by two cycles of differential centrifugation (50g for 2 min) and further purified over a 30% Percoll gradient. Hepatocyte purity exceeded 90% as assessed by light microscopy, and viability was typically greater than 95% as determined by trypan blue exclusion assay.

RNA Isolation and Complementary DNA Synthesis

Total RNA was isolated from rat liver tissue and hepatocytes by using the TRIZOL Reagent (Life Technologies, USA). The quality of RNA was controlled by the intactness of ribosomal RNA bands. A total of 0.5mg of each intact total RNA samples was reverse-transcribed to complementary DNA (cDNA) by using the reverse transcription-polymerase chain reaction(RT-PCR) kit(Roche, USA). cDNA was stored at -70℃ until polymerase chain reaction(PCR) analysis.

Determination of CD14 mRNA by RT-PCR

The PCR primers used were CD14: sense (5'-CTCAACCTAGAGCCGTTTCT-3'), anti-sense (5'-CAGGATTGTCAGACAGGTCT-3'); β-actin: sense (5'-ACCACAG-CTGAGAGGGAAATCG-3'),anti-sense(5'-AGAGGTCTTTACGGATGTCAACG-3'). The sizes of the amplified PCR products were 267 bp for CD14 and 281 bp for β-actin. The conditions for amplification were as follows: denaturation at 93℃ for 1 min, annealing at 57℃ for 1 min, and extension at 70℃ for 2 min for 30 cycles. The PCR products were electrophoresed in 20g·L^{-1} agarose gels, and the gels were ethidium bromide stained and video photographed on an ultraviolet transilluminator, and the results were showed with the relative absorbance (Ar: relative optical density, ROD).

Western blot analysis of CD14 protein

Cultured hepatocytes were washed twice with phosphate-buffered saline (PBS), pelleted by centrifugation. Cell pellets were resuspended in 50 ul of lysis buffer containing 20 mmol·L^{-1} HEPES (pH 7.9), 25% glycerol, 0.42 mmol·L^{-1} NaCl, 15 mmol·L^{-1} $MgCl_2$, 0.2 mmol·L^{-1} EDTA, 0.5 mmol·L^{-1} phenylmethylsulfonyl fluoride (PMSF) and 0.5 mmol·L^{-1} dithiothreitol (DTT). After three freeze-thaw cycles, cell lysates were centrifuged at 12000g for 30 min, and the supernatant was saved. The liver tissue was homogenized with homogenizer before the freeze-thaw lysis, as described above for cultured hepatocytes. For Western blot analysis, samples (20 μg per lane) were separated on an SDS-100g·L^{-1} polyacrylamide gel and transferred to nitrocellulose membrane. The membrane was sequentially blocked in PBS-Tween (1g·L^{-1}) containing 50ml·L^{-1} milk and then incubated with 5 ìg of anti-rat CD14 polyclonal antibody per mL, washed three times, and further incubated with a goat anti-rabbit immunoglobulin G horseradish peroxidase-conjugated secondary antibody. Blocking and antibody incubations each lasted 1 h at room temperature. After several washes, the membrane was developed with DAB reagent, and the results were showed with relative absorbance Ar (relative optical density, ROD).

Flow cytometric analysis (FCM)

Expression of CD14 protein in hepatocytes was examined by FCM. In brief, hepatocytes were incubated with the anti-CD14 polyclonal antibody (0.1mg·L^{-1}) after washing, cells were incubated with goat anti-rabbit immunoglobulin G labled with FITC, after being washed three times, and 10000 cells were analyzed by flow cytometry (Coulter, USA).

Statistical Analysis

All results were expressed as $\bar{x}\pm s$. Statistical difference between means were determined by using Student's t test. A P value of <0.01 was considered significant.

RESULTS

Expression of CD14 mRNA in liver tissue and hepatocytes

We postulated that hepatocytes and hepatic tissue could express CD14 gene which could be upregulated during endotoxemia. Rats were injected with LPS and total RNA was extracted from freshly isolated and purified hepatocytes and hepatic tissue at different time points indicated. RT-PCR analysis showed that hepatocytes and liver tissue from controls had low but detectable levels of CD14 mRNA. LPS treatment showed steady-state CD14 mRNA levels in hepatocytes, inducing a threefold elevation by as early as 3 h after LPS treatment. The levels increased with times, reaching a maximum of six-fold by 6 h after treatment, and subsequently declined to near baseline levels by 24 h. We also examined the CD14 mRNA levels in RNA isolated from hepatic tissue during endotoxemia and found that the pattern of CD14 mRNA induction by LPS was similar to that of the isolated hepatocytes, indicating that the upregulation of CD14 mRNA was not likely to be simply a consequence of the hepatocyte isolation procedure (Figure 1).

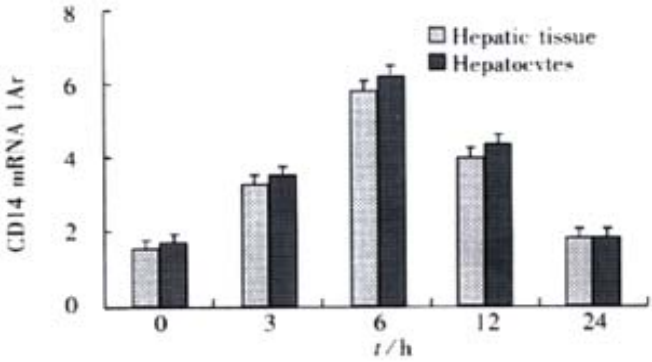

Figure 1 Expression of CD14 mRNA in hepatic tissue and hepatocytes P<0.01, *vs* 0 h.

CD14 protein expression in hepatocytes and hepatic tissue

To determine if the upregulation of CD14 expression could also be appreciated in protein levels, Western blot analysis was performed on both hepatocytes and hepatic tissue sample from LPS-treated animals or control animals. In hepatocytes extracts, increases of CD14 protein were seen 6 h after LPS treatment, peaked at 12 h, and declined thereafter. A similar increase of CD14 protein in hepatic tissue was observed. there were significantly different when compared with control animals (P<0.01, Figure 2).

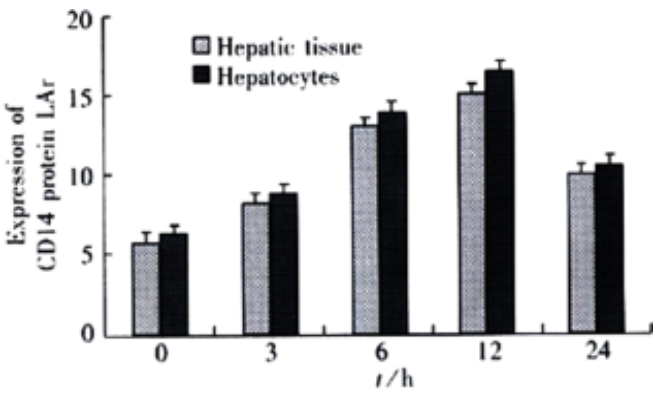

Figure 2 Expression of CD14 protein in hepatic tissue and hepatocytes P<0.01, *vs* 0 h

Binding of FITC to Hepatocytes

To confirm the expression of CD14 on hepatocytes, we also examined the binding of FITC to the cells. FITC-CD14 positive cells were 4.5% in rats of normal group. But in rats with endotoxemia, the mean fluorescence intensity (MFI) increased, the numbers of FITC-CD14 positive cells were 43.4%, 70.2%, 91.4%, and 32.6%, respectively in 3,6, 12 and 24 h after stimulation of LPS. There was significant difference when compared to normal group animals (P<0.01, Figure 3).

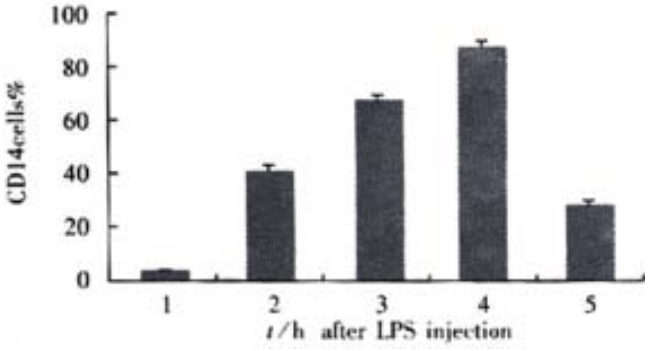

Figure 3 Percentage of CD14 positive cells$P$<0.01, *vs* 0 h.

DISCUSSION

CD14 was first described as a myeloid differentiation antigen in 1980'. It is a 55-kDa glycoprotein with multiple leucine-rich repeats and is encoded on chromosome (5q) together with growth factors, such as granulocyte macrophage colony stimulating factor. CD14 has been identified as a receptor for complexes of LPS and LPS-binding protein but it also binds other bacterial products[17-22]. The LPS-binding region within the CD14 molecule is remarkably conserved across species with a high degree of gene sequence homology, and it has therefore been suggested that CD14 is a pattern recognition receptor[17,23-25]. CD14 as a key LPS signaling molecule was reported to be expressed mainly in the monocyte-macrophages system[1,26-29]. Recent works have shown that the CD14 antigen is expressed in many types of cells and tissues[5-8,12]. But it is not yet clear whether hepatocytes express CD14. Although shedding from leukocytes has been proposed as the major source of sCD14 in blood, it is likely that other sources exist[3,5,30-32]. Some reports suggested that sCD14 behaves like other acute-phase proteins[9-11,33-36]. Hepatocytes are the major source of most acute-phase proteins. So we think if sCD14 is an acute-phase protein, then hepatocytes might be expected to express CD14 gene and synthesize CD14 protein, which is upregulated during endotoxemia[37-40].

To determine whether hepatocytes synthesize CD14 protein and express CD14 gene, we measured steady-state CD14 protein and its mRNA both in vivo and vitro. We found that: ① isolated hepatocytes and liver tissue could synthesize basal levels of CD14 protein and express basal levels of CD14 gene and that synthesis and expression of CD14 were markedly upregulated by LPS during endotoxicmia;these results are in agreement with previous report[41,42]; ② synthesis of CD14 protein and expression of CD14 mRNA in both Hepatocytes and liver tissue indicated that such synthesis and expression were not likely to be simple a consequence of hepatocyte isolation procedure; ③ in liver, besides hepatocytes, nonparenchymal cells such as Kupffer cells, endothelial cells, neutrophils and other cells can also express CD14 gene and synthesize CD14 protein[4,43-47], but the fact that both isolated hepatocytes and hepatic tissue expressed CD14 protein and its mRNA indicated that the nonparenchymal cells could hardly have any effect on such expression in liver tissue.

Although we do not provide direct evidence here that sCD14 in plasma originates from hepatocytes during endotoxemia, our results showed that there was the possibility that the liver is an important source for sCD14 during endotoxemia. Pan *et al*[5] found that the liver is one of the major organs for the production of soluble CD14. Liu *et al*[41,42] reported also that CD14 transcription rates were signficantly increased in hepatocytes from LPS-treated rat, indicating that the upregulation in CD14 mRNA levels observed in rats hepatocytes after LPS treatment was dependent, in part, on increased transcription, and their observations supportted the idea that sCD14 would be an acute-phase protein and hepatocytes might be a source for circulating sCD14 production[3,4,8,48-52]. Our data indicate that hepatocytes from LPS-stimulated rats express higher amounts of CD14 gene and CD14 protein, and may release more sCD14. Further investigation of the expression of CD14 in hepatocytes is actively ongoing in our laboratory.

In summary, our *in vitro* and *in vivo* data indicate that hepatocytes can synthesize CD14 protein and express CD14 mRNA and their synthesis and expression are upregulated effectively by LPS during endotoxemia. Liver is a main source for sCD14 production during sepsis or endotoxemia.

Abstract

AIM: **To identify the risk factors relating to early mortality after orthotopic liver transplantation.**

METHODS: **Clinical data of 37 adult patients undergoing liver transplantation were retrospectively collected and divided into two groups: the survived group (survival time ⩾30 d) and the death group (survival time<30 d). The relationship between multivariate risk factors and early mortality after orthotopic liver transplantation were analyzed by stepwise logistic regression.**

RESULTS: **The survival rate was 73%. Early mortality rate was 27%. APACAE Ⅲ, preoperative serum creatinine level and interoperative bleeding quantity had a significant independent association with early mortality. (*R*=0.1841, 0.2056 and 0.3738).**

CONCLUSION: **APACHE Ⅲ,preoperative serum creatinine level and interoperative bleeding quantity are significant risk factors relating to early mortality after orthotopic liver transplantation. To improve the recipient's preoperative critical condition and renal function and to reduce interoperative bleeding quantity could lower the early mortality after orthotopic liver transplantation.**

INTRODUCTION

In recent years, the success rates of orthotopic liver transplantation (OLT) have improved markedly as a result of rapid advances in immunosuppressions, surgical and preservation techniques. One-year survival rate after liver transplantation exceeds 80%. Orthotopic liver transplantation, as an accepted treatment for end-stage liver disease, has been widely performed in the world[1-5]. In our country, the early mortality after OLT remains relatively high and current studies have focused on the improvement of survival rate after liver transplantation[6,7]. Clinical data of 37 adult patients undergoing liver transplantation were retrospectively collected in our study. The significant risk factors relating to early mortality after OLT were analyzed and determined, which may contribute to the selection of candidate and improvement of survival in patients with liver transplantation.

MATERIALS AND METHODS

Materials

Thirty-seven adult patients undergoing OLT procedures at our transplantation center from September 1993 to January 2000 were studied. The study population consisted of 32 men and 5 women with a mean age of 39.8(range 17-64) years. The grafts were obtained from donors. Indications for liver transplantation were end-stage liver cirrhosis (*n*=9), fulminant hepatic failure (*n*=8), primary liver cancer (*n*=14), primary sclerosing cholangitis (*n*=2), Willson's disease (*n*=1), polycystic liver and kidney (*n*=1), hepatoangioma (*n*=1), and cholangiocarcinoma (*n*=1).

Multiple risk factors

Thirty-seven patients were divided into two groups: survival group (survival time ⩾30 d) and death group (Survival time <30 d).There were different possible risk factors relating to early mortality after liver transplantation including preoperative, interoperative and postoperative ones. Preoperative information consisted of age, APACHEⅢ hepatoencephalopathy, previous abdominal surgery, serum albumin, prothrombin time (PT),serum creatinine level (Cr),serum Aspartate transaminase (AST),white blood cells counts (WBC),platelet counts(PLC) and dismatch ABO group. Interoperative information included heat ischemic time, cold ischemic time, anhepatic time and bleeding quantity. Postoperative information included of rate of acute rejection and postoperative complications rate (including biliary leakage, cytomegalovirus(CMV)infection, hepatic artery thrombosis, hydrothorax and myocardiac infarction, etc).

Statistical methods

Experimental data were presented as $x \pm s$ and frequency. For continuous data, independent 2-tailed t tests were used to determine whether there were significant differences between the two groups. Pearson's Chi-square statistics were used to test differences in all frequencies. Data with significant difference were entered into a stepwise logistic regression analysis. And all of the statistical calculations were performed using the SPSS (version: 9.0, Chicago,USA).

RESULTS

Twenty-seven of the 37 adult patients survived more than one months after liver transplantation. Early survival rate was 73% while early mortality was 27%. The other 10 patients died postoperatively within 30 d and the major cause for their death were disseminated intravascular coagulation (DIC *n*=2), myocardial infarction (*n*= 2), acute renal failure (*n*=2), hepatic artery thrombosis (*n*=1), cerebral bleeding (*n*=1) and adult respiratory distress syndrome (ARDS)(*n*=1).

Comparison between the survival group and the death group showed significant differences only in terms of age, APACHE Ⅲ, serum creatinine level, PT, was PLC and interoperative bleeding quantity, (P<0.05, Table 1). The stepwise logistic regression were used to create the best statistical model relating to early mortality after transplantation. The factors that had significant independent

associations with early mortality after the stepwise procedure were APACHE Ⅲ, serum creatinine level and interoperative bleeding quantity, with regression coefficients of 0.1841, 0.2056 and 0.3738, respectively (Table 2).

Table 1 Risk factors relating to early mortality after liver transplantation

Risk factors	Survival group (n=27)	Death group (n=10)	P value
Age(yrs)	38.3±2.5	47.8±2.2	0.0000
Previous abdominal surgery	11% (3/27)	30% (3/10)	0.3130
APACHE Ⅲ (score)	40.5±6.7	63.4±12.9	0.0000
Hepatoencephalopathy	15% (4/27)	40% (4/10)	0.1712
Serum creatinine level (μmol·L^{-1})	82.2±10.8	132.8±33.2	0.0000
AST (nkat·L^{-1})	97.9±18.6	125.8±80.5	0.0951
Albumin (g·L^{-1})	36.9±1.7	32.7±2.9	0.0000
TB (imol·L^{-1})	298.3±67.9	314.9±87.1	0.5447
PT /s	22.5±3.2	25.5±3.7	0.0175
WBC/ (×10^{9}·l^{-1})	7.3±1.2	6.8±1.1	0.2351
PLC /(×10^{9}·l^{-1})	129.5±17.5	53.4±12.3	0.0000
Dismatich ABO group	7.3% (2/27)	30% (3/10)	0.1102
Heat ischemic time /min	3.8±0.1	3.9±0.3	0.1478
Cold ischemic time /s	464.9±26.9	471.2±46.3	0.6104
Anhepatic time/s	87.5±4.9	90.3±10.5	0.2704
Interoperative bleeding quantity /ml	5615.1±1003.7	12263.6±3606.1	0.0000
Rate of acute rejection	18% (5/27)	20% (2/10)	1.0000
Rate of postoperative complications	59% (16/27)	70% (7/10)	0.709

Table 2 Stepwise logistic regression analysis

Variable	B	SE	Wald	df	Sig	R
APACHE Ⅲ	0.340	0.0141	5.8481	1	0.0156	0.1841
Serum creatinine level (Cr)	3.6542	1.4013	6.8002	1	0.0091	0.2056
Interoperative bleeding quantity	2.0194	0.7516	7.2182	1	0.0020	0.3738

DISCUSSION

Orthotopic liver transplantation is a treatment for end-stage liver disease. Early mortality was below 10%[8,9], which remains high in our country. The serious preoperative condition of recipient and the late timing for operation may account for this result[10,11]. A number of investgators have examined the factors associated with outcome after liver transplantation including PT, APACHE Ⅲ and so on[12-16]. In our study, 10 of 37 patients died postoperatvely, with an early mortality of 27%. After analyzed with stepwise logistic regression, APACHE Ⅲ、preoperative serum creatinine level (Cr) and interoperative bleeding quantity showed significant associations with early mortality after liver transplantation.

While APACHE Ⅲ score is a best predictor of mortality [17,18,19], APACHE Ⅲ that results from the addition of 3 groups of variables (acute physiology, age and chronic health) consists of multiple organ function evolution, including heart, lung, liver, kidney, brain, etc. It is more accurate than APACHE Ⅲ. And now it has been widely used to evaluate the severely illed in patients' condition and to predict the mortality of patients[20,21]. In our study, the APACHE Ⅲ score was 40.5±6.7 and 63.4±12.9 in the survival group and the death group respectively. There was a statistical difference between the two groups in APACHE Ⅲ score,P<0.001. The stepwise logistic regression analysis showed a significant independent association with early mortality after transplantation, with a regression coefficient of 0.1841. As one of the main risk factors, it can act as a reference index of the selection of recipient and timing for operation.However because it is not specific to liver function, it needs combination with other indexs when used to predict outcome of OLT.

Renal dysfunction is a common dangerous complication in patients with end-stage liver disease. It results from acute tubular necrosis and caused by hepatorenal syndrome[22-25]. Gunning[26] reported a significant decrease of 43% in glomerular filtration rate (GFR) during transplantation in patients with normal renal function. Both high preoperative serum creatinine level and interoperative venovenous bypass can lead to renal hemodynamic unstablity during operation[27,28,29]. The postoperative nephrotoxic immunosuppressions can also contribute to the irreversible renal insufficiency, leading to renal failure after liver transplantation[30,31]. In our study, 2 of 10 patientsdied of renal failure, who were all along with high preoprative serum creatinine level and hepatorenal syndrome before transplantation. A significant differencewas found between the survival group and the death group was shown in serum creatinine level (P<0.001), with a mean of 82±11 and 133±33, respectively. The stepwise logistic regression analysis, it also showed a statistical independent association with early mortality after liver transplantation, with a regression coefficient of 0.2056. It is also a main risk factor which predicts early mortality after OLT. It is very important to correct renal malfunction before transplantation. How to prevent and treat renal failure Kuse[32] reported that Urodilatin can treat acute renal failure following OLT. Gonwa and the other investgators[33-36] reported that renal failure need dialysis. Our principles were to avoid using nephrotoxic treatments and drugs, to maintain stable hemodynamically and monitor central venous pressure,to use small dose of Dopamine (2-5μg·kg^{-1}min^{-1}) and Procaine to dilate renal artery and protect renal function,to use diuretics appropriately, to perform hemodialysis properly performed if needed, and not to use Alprostadil(PGE1).[37]

Interoperative bleeding quantity is the third important risk factor relating to early mortality after liver transplantation[38]. If it exceeded 10000ml, mortality was very high. The interoperative bleeding quantity of the death group was more than that of the survival group statistically (P<0.05), with a mean of 12264±3606mL and 5615±1004mL respectively. Logistic regression analysis showed a significant relationship between interoperative bleeding quantity and early mortality after transplantation, with a regression coefficient of 0.3738. Severe bleeding and a large amount of transfusion during operation may lead to hemodynamic unstablity and DIC. And long-term hypopiesia may accelerate preoperative renal insufficiency, leading to irreversible renal failure,and increasing the early mortality after operation[39,40]. Interoperative severe bleeding may due to previous upper abdominal surgery, abdominal extensive adhesions, portal hypertension, splenic hyperfunction, severe coagulation disorders,etc.[41-44] In our study, there was no significant difference between the two groups with previous surgical histories. But it should be emphasized that some of our findings might be accidental because of insufficient cases involved in the study. We should pay attention to these patients with previous surgical histories. In these patients, severe bleeding and coagulation disorders may occur during operation because of abdominal extensive adhesions and difficulties in sequestration and ligation, consequently DIC and acute renal failure may follow. In our centre, 2 patients developed DIC.

The other risk factors showed no significant associations with early mortality after liver transplantation. But some of the factors did influence the outcome of the recipients and should be considered carefully, including dismatch ABO group,heat ischemic time, cold ischemic time, rate of acute rejection, rate of postoperative complications., etc[45-51]. Except emergent cases, the recipients and the donors were matched in ABO group at our center. Heat ischemic time and cold ischemic time were also limited strictly within 5 min and 12 h respectively during operation. After transplantation, ultrasonography B, chest X-ray examination,CMV detection and liver biopsy were performed periodically. Acute rejection and other postoperative complications were diagnosed and treated earlier. In patients diagnosed as having acute rejection,a large dose of methylprednisolone and FK506 were administrated with a treatment rate of 100%. Therefore, these risk factors showed no significant value in statistical analysis in our study.

Abstract

The surgeon is invariably the primary specialist involved in managing patients with short bowel syndrome. Because of this they will play an important role in co-ordinating the management of these patients. The principal aims at the initial surgery are to preserve life, then to preserve gut length, and maintain its continuity. In the immediate postoperative period, there needs to be a balance between keeping the patient alive through the use of TPN and antisecretory agents and promoting gut adaptation with the use of oral nutrition. If the gut fails to adapt during this period, then the patient may require therapy with more specific agents to promote gut adaptation such as growth factors and glutamine. If following this, the patient still has a short gut syndrome, then the principal options remain either long term TPN, or intestinal transplantation which remains a difficult and challenging procedure with a high mortality and morbidity due to rejection.

INTRODUCTIONS

A remarkable feature of the gastrointestinal tract is how little of it we require in order to maintain a normal nutritional state. Nonetheless, there is a small group of patients who, following extensive loss of principally the small intestine, are unable to maintain their nutrition by oral intake alone. These patients are defined as having the short bowel syndrome.

The pathophysiological consequences of loss of the bowel is dependent upon two important points. Firstly, the extent and site of the intestinal resection, and secondly, the adaptability of the remaining intestine. In general, we need 50 to 70 cm (i.e. around 1 cm/kg weight) of healthy jejunum or ileum in continuity with a section of the colon in order to avoid developing the short bowel syndrome. This is remarkable considering that the normal human small intestine ranges from about 3 to 5 metres in length. Some have defined short bowel syndrome as the loss of 70% or more of the length of the small intestine[1]. But length is not everything, and if the remaining bowel is involved with the underlying disease process (e.g. Crohn's disease or ischaemia) then its capacity to adapt will be limited. The minimum amount of small intestinal absorptive area required to sustain life varies from individual to individual. Survival on an oral diet alone may occur in patients with as little as 15 cm of residual jejunum.

This review addresses the medical and surgical management of patients with short bowel syndrome. Particular emphasis is placed on the conduct of the initial surgical procedure and the therapies that may either constitute definitive methods of treatment or serve as useful adjuncts to other forms of surgery. The latter consisting of autologous gastrointestinal reconstruction and small bowel transplantation.

INITIAL SURGICAL PROCEDURE

The causes of short bowel syndrome differ between adults and children. In adults, it most often results after surgery for Crohn's disease or mesenteric infarction. Whilst in infants, the causes more commonly include necrotizing enterocolitis, gastroschisis, atresia, and volvulus[2-4].

It goes without saying that it is important to preserve as much of the small and large intestine as possible at the initial surgery. However, the subsequent patient progress will depend on not only the length of gut removed, but on whether the patient has a primary anastomosis or a stoma. Nightingale[5] has classified patients with short bowel syndrome into two groups: those with a primary jejunocolic anastomosis, and those with a jejunostomy. The latter have major problems with losses of water, sodium, and divalent cations such as magnesium; whereas, patients with a jejunocolic anastomosis rarely have problems with their fluid and electrolyte balance. Maintaining colonic continuity serves to decrease gastric emptying and decreases energy/carbohydrate losses. Nonetheless, if a surgeon is concerned regarding the risk of performing a primary anastomosis for fear of an anastomotic dehiscense, then it is safer to consider a primary stoma with reconstruction delayed for 2-3 mo. Although this can create its own problems of leaving *in situ* a segment of excluded gut. Careful consideration should be given to the siting of stomas. It may be advantageous to have an end stoma in close proximity to a mucus fistula.

Preservation of colonic length is not only important for the absorption of fluid and electrolytes, as has been discussed, but it also has nutritional advantages. Patients with the short bowel syndrome have malabsorption of carbohydrates, even after the ingestion of small amounts of otherwise easily absorbed carbohydrates, and this causes a spill-over of the ingested carbohydrates into the residual colon where it undergoes bacterial fermentation[6].

Jeppesen and Mortensen[7] have noted that colonic digestion can salvage up to 3-4 $MJ/d^{\cdot -1}$ in patients with the short bowel syndrome, which is about 50% of the daily requirements. They observed that preservation of more than one-half of colonic function is unusual in patients who require parenteral nutrition and have more than 100 cm of residual small bowel. This data reinforces the concept of the colon as an energy-salvaging organ.

Excluded gut may act as a reservoir for bacterial translocation and recurrent sepsis[8]. Defunctioned gut is

associated with mucosal atrophy and bacterial overgrowth that predispose to bacterial translocation. Reynolds *et al*[8]. reported a case where a patient with excluded bowel suffered episodes of clinical deterioration, fever and rigors without isolation of bacteria from blood cultures. It is possible that these episodes may have been the result of migration of viable bacteria from the excluded gut lumen into the mesenteric lymph system and peritoneum. In this situation pathogenic organisms cannot be cultured from the blood but may be isolated from the peripheral lymph nodes. Schafer *et al*[9]. reviewed the progress of newborns who had stomas created during surgery for a mechanical ileus or intrauterine perforation of the small bowel. To avoid non-use of the distal bowel, they used a roller pump to pass the effluent from the end enterostomy into the distal bowel through the mucus fistula. They reported that this enabled subsequent re-anastomosis to be performed under optimum bowel conditions. Al-Harbi *et al*[10]. described a similar experience in six neonates (gestational ages of 27-38 wk, birth mass of 533-3400g). Mass gain during refeeding ranged from 5 to 25g·kg^{-1}/d^{-1} with the refeeding lasting for 16-169 d. It was concluded that this technique lessens the need for parenteral nutrition and electrolyte supplementation prior to reanastomosis.

NATURAL HISTORY OF GUT ADAPTATION

Intestinal failure associated with the short bowel syndrome may be either transient or permanent. Most patients require nutritional support until their gut has undergone sufficient adaptation to allow survival on an oral diet. Results from animal studies have shown that structural adaptation of the remnant bowel involves both an increase in villous height and mucosal surface area, and an increase in bowel luminal circumference and wall thickness. Functional adaptation is characterised by an increase in rate of absorption of nutrients. This is postulated to be the result of structural change, a slowing of transit rate and/or alterations in intracellular molecular events such as increased transport and/or enzyme activity.

The intestinal mucosa produces several peptides that have a trophic effect upon the intestine (Table 1). Following small bowel resection the rate of secretion of these peptides increases in an attempt to compensate for the missing tissue. Recently, Nightingale [17] has discussed the role of one of these peptides, glucagon-like peptide-2 (GLP-2), in intestinal adaptation. L cells, located in the ileum and jejunum, secrete GLP-2. Nightingale noted that, in patients without an ileum, intake of a meal does not alter plasma GLP-2 concentration and that remnant jejunum of these patients does not adapt[18,19]. In contrast, intake of a meal induces an increase in plasma GLP-2 concentrations in ileal resected patients with a retained colon and remnant jejunum of these patients does adapt[20,21]. Collectively, these pieces of information suggest GLP-2 may be useful in adjunctive therapy for short bowel syndrome.

Table 1 The effect of small bowel resection on intestinal peptides that are known regulate intestinal growth

Factor	Source	Effect of Small Bowel Resection on Factor
Epidermal Growth Factor (EGF)	Salivery glands and Brunner's glands in the jejunum	EGF levels are increased in saliva and diminished in urine 3 d after resection in mice[11].
Enteroglucagon	L cells of ileum and colon	12 d after a 75% small bowel resection there was a significant increase in concentration of enteroglucagon in the plasma of rats[12].
Glucagon-like Peptide 2 (GLP-2)	L cells of ileum and colon	There is an increase in expression of GLP-2 mRNA in the ileum of rats after small bowel resection[13].
		There is a decrease in expression of dipeptidyl peptidase IV mRNA, the enzyme that inactivates GLP-2, in the ileum of rats after small bowel resection[14].
Insulin-like Growth factor-1 (IGF-1)	Cells of the small intestine	80% small bowel resection led to a 183% and 249% increase in IGF-1 mRNA in the jejunum and ileum respectively of rats[15].
Peptide tyrosine tyrosine (PYY)	L cells of ileum	After 70% resection in rats the concentration of PYY in plasma was elevated for at least 2 wk and there was a four and six-fold increase in PYY mRNA in ileum and colon at six hours after resection[14].
Neurotensin	Gut mucosal endocrine cells (N cells) in the jejunum and ileum	50% resection of the distal intestine in dogs was associated with a transient increase in neurotensin[16].

INITIAL SUPPORTIVE MANAGEMENT

The aim of supportive care of patients is to maintain nutritional state and promote gut adaptation.

Parenteral nutrition

An important historical use of parenteral nutrition was in keeping patients with short bowel syndrome alive both in the short and long term. The decision to commence parenteral therapy is based on a number of issues. These include, the extensive loss of gut where the clinician believes the patient will be unable to maintain their own nutrition, or where in the post operative period, the patient is unable to maintain their weight and plasma albumin concentration via oral intake alone. Once parenteral nutrition is commenced, for most patient, there follows a period of gradual transition to enteral nutrition and diet therapy.

The use of parenteral nutrition is associated with a number of side effects. Parenteral nutrition has been found to cause intestinal atrophy in humans and animals[22-24] and long-term parenteral nutrition is associated with complications that include recurring central venous line sepsis, high costs (Aus $ 150·d^{-1}), high mortality (20% in children, mainly due to liver dysfunction) and poor quality of life.

In children with short-bowel syndrome receiving long-term parenteral nutrition, hepatic dysfunction is a major problem. Its aetiology is multifactorial and includes alterations in gut motility which lead to intraluminal stasis which is thought to be a major etiologic factor for bacterial overgrowth and subsequent cholestasis, especially when the ileocecal valve is absent. Sondheimer *et al*[25]. reported that 67% of neonates with short bowel syndrome which were nourished by parenteral nutrition developed cholestasis. This progressed to liver failure in 17% of the neonates. As cholestasis developed shortly after the first infection in 90 % of infants[25] it seems sepsis may sensitize the liver to cholestatic injury. In spite of the problems associated with parenteral nutrition, Suita *et al*[26]. have commented that advances in parenteral nutrition have meant that infants with a small bowel measuring only 20 cm either with or without an ileocoecal valve can survive. However, patients do best in the presence of an ileocecal valve and an intact colon[27].

Medical Therapy

High-volume output from a jejunostomy requires restriction of oral fluids, a high-energy iso-osmolar diet with added salt, and the use of drugs that reduce motility (loperamide, codeine phosphate) and secretions (proton pump inhibitors, octreotide). Nightingale[5] has stressed that patients who have less than 100 cm of jejunum *in situ* and a stomal output in excess of their oral intake have the most to gain from the use of antisecretory drugs. This is because they usually lose more from the jejunostomy than they take in orally ('secretors') and are more likely to require long-term parenteral therapy. Yet Octreotide reduces nutrient transport in the small intestine, reduces the number of functional nutrient carriers, and is in general detrimental to gut adaptation. Hence its use in all patients with short bowel syndrome is not indicated.

Gastric hyperacidity is a frequently observed change which occurs transiently in the postoperative period following a massive bowel resection. Unless it is controlled with either proton pump inhibitors or H2 receptor blockers, it may result in extensive gastric or duodenal ulceration.

Enteral nutrition

Enteral nutrition is a key element in promoting the intestinal hyperplasia which is characteristic of gut adaptation. It does this by several mechanisms. Enteral nutrition provides epithelial work and stimulates the release of pacreatico-biliary secretions that are known to maintain the structure and function of the intestine. Food within the intestine also stimulates the release of various regulatory peptides from the intestine and can deliver specific nutrients to the cells of the intestinal mucosa.

There are a number of specific gut nutrients that are important in adaptation (Table 2). These nutrients promote intestinal structure and function by providing cells of the intestinal mucosa with substrates for the synthesis of essential molecules or by providing energy. For example, polyamines, small molecules that are essential for cell growth and regulation of the cell cycle, are synthesised from ornithine. Whereas, fermentable fibres and their products (i.e. short chain fatty acids) are important fuels for enterocytes. Glutamine is another important gut nutrient that promotes intestinal adaptation. This amino acid is the main fuel of enterocytes and also is a substrate for the synthesis of nucleic acids[34]. The information presented in Table 2 indicate that supplements of glutamine only promote adaptation in parenterally-fed animals. This suggests that supplements of glutamine can only enhance intestinal adaptation in the absence of epithelial work.

Table 2 Nutrients that regulate gut adaptation

Nutrient	Effect on Intestinal Adaptation
Soluble fibre and short chain fatty acids	SCFA-supplemented parenteral nutrition led to an increase in ileal uptake of D-glucose in rats with an 80% small bowel resection[28].
	A 2% pectin-enriched elemental diet led to a significant increase in intestinal weight, mucosal protein content, and mucosal DNA content in rats with an 80% small bowel resection[29].
Triglycerides	Rats fed with an elemental diet containing 60% long chain triglycerides after a 60% resection had a greater intestinal adaptation than rats fed a diet containing 17% long chain triglycerides[30].
Ornithine α-ketoglutarate	Enteral supplements of ornithine $2g \cdot kg^{-1} \cdot d^{-1}$ significantly increased jejunal crypt depth ratio and significantly increased glutamine concentration in anterior tibialis muscle[31].
	Enteral supplements of ornithine $1g \cdot kg^{-1} \cdot d^{-1}$ significantly increased ileal villus height and expression of ornithine decarboxylase mRNA in the ileum[32].
Glutamine	In rats with an 85% small bowel resection, feeding a 2% glutamine-enriched TPN solution, enhanced intestinal adaptation as assessed by mucosal villus height, and mucosal DNA content[33].
	A glutamine-enriched diet enhanced ileal hyperplasia in rats with an 80% small bowel resection[34].
	In rats with a 70% small bowel resection, feeding a 5% glutamine-enriched rats chow diet inhibited intestinal adaptation as assessed by duodenal protein content and ileal DNA content[35].
	A 2% glutamine-enriched elemental diet did not alter markers of intestinal adaptation in rats with a massive small bowel resection[36].
	A 4% glutamine-enriched oral diet did not significantly alter intestinal adaptation after intestinal resection in rats[37].

There are a number specific gut peptides which mediate the trophic effect of gut nutrients. Glucagon-like peptide-2, which is released by the intestinal L cells, plays a role in the trophic effect of short chain fatty acids (SCFA) on intes tinal adaptation. Treatment of rats with SCFA leads to an increase in expression of proglucagon mRNA, a precursor of GLP-2, in the L-cells[28,39]. Furthermore, Vanderhoof *et al*[30]. speculated that slower absorption of long chain triglycerides allows them to stimulate release of intestinal regulatory peptides, such as GLP-2 and PYY, from L-cells in the ileum. There also may be links between glutamine and PYY as a glutamine-enriched oral diet led to an increase in concentration of PYY in the portal blood after small bowel resection in a rat model[40].

Epithelial work is important for gut adaptation. Clarke[41] used a rat model to examine the effect of epithelial work on the structure of the intestine. Isotonic solutions of either glucose, galactose, sodium chloride, *d*-methyl *D*-glucoside, or *D*-mannose were infused into surgically prepared sacs of upper small intestine in rats which fed normally via the gut-in-continuity. Treatment with the glucose, a nutrient and galactose and α-methyl *D*-glucoside , molecules with no nutritional value, led to an increase in villus height. In addition, treatment with sodium chloride, a molecule that is absorbed by the intestinal mucosa, also led to an increase in villus height.

Age may influence intestinal adaptation as pediatric patients undergo better bowel adaptation than adults. Wasa *et al*[42]. reviewed 12 pediatric and 18 adult patients with short bowel syndrome from Osaka University Hospital. The length of the residual small intestine ranged from 0 to 75 cm (mean 47 cm) in pediatric patients and from 0 to 150 cm (mean 47 cm) in adult patients. Eight pediatric patients (67%) and 4 adult patients (22%) were weaned from TPN. None of the adult patients with residual small intestinal length less than 40 cm could achieve complete intestinal adaptation.

A number of specific oral nutritional regimens have been evaluated to assess their ability to promote gut adaptation. The provision of oral medium-chain triglycerides increases the absorption of energy in patients with short bowel syndrome who have a functioning colon[43]. Short-chain fatty acids are readily absorbed across the colonic mucosa, whereas long-chain fatty acids are not absorbed by the colon. Hence, patients with a short bowel syndrome and a functioning colon are able to absorb both short-chain and medium-chain C8-C10

triglycerides . Part of their efficacy in this role relates to the fact that both of these types of fat are water-soluble. Manipulation of the dietary fat intake has little appreciable advantage in patients without a functioning colon[44]. Sales *et al*[45]. reported on four patients, aged 40 - 65 years, with on aver age 54.5 cm of remaining bowel, who were managed with a progressive step diet. It involved the administration of pectin (Step 1), the use of medium-chain triacylglycerols and complex, nonfermentable sugars (Step 2); coconut oil (47% medium - chain triacylglycerols) and simple sugars (Step 3); and finally long-chain triacylglycerols and lactose (Step 4). Total parenteral nutrition was interrupted at steps 3 or 4 when the energy content of the diet reached 150% of the patient's resting energy expenditure, if serum albumin and weight were stable, or if there were no alterations in frequency, amount and consistency of the stool.

IRREVERSIBLE SMALL BOWEL FAILURE

From studies of patients on long-term parenteral nutrition, it seems that there are between two and three patients per million of population per year who develop irreversible small bowel failure[46]. Messing *et al*[47]. assessed prognostic factors in 124 consecutive adults with non-malignant short bowel syndrome. Survival and parenteral nutrition-dependence probabilities were 86% and 49% at 2 years, and 75% and 45% at 5 years. In multivariate analysis, survival was related negatively to end-enterostomy, to small bowel length of <50 cm , and to arterial infarction as a cause of short bowel syndrome, but not to parenteral nutrition dependence. The latter was related negatively to post-duodenal small bowel lengths of <50 and 50-99 cm and to absence of terminal ileum and/or colon in continuity. Cutoff values of small bowel lengths separating transient and permanent intestinal failure were 100, 65, and 30 cm in end-enterostomy, jejunocolic, and jejunoileocolic type of anastomosis. In adult short bowel syndrome patients, small bowel length of <100 cm is highly predictive of permanent intestinal failure. Presence of terminal ileum and/or colon in continuity enhances both weaning off parenteral nutrition and survival probabilities. After 2 years of parenteral nutrition, probability of permanent intestinal failure is 94%. These rates may lead to selection of other treatments, especially intestinal transplantation, instead of parenteral nutrition, for permanent intestinal failure caused by short bowel syndrome.

Gambarara *et al*[48]. have accumulated data that suggests that rather than depending on the length of intestine remaining or the presence of the ileocecal valve, the prognosis of patients with the extreme-short-bowel syndrome depends on recurrent sepsis and early onset liver impairment. In addition, their case review shows that the extreme-short-bowel syndrome is not necessarily an indication for bowel transplantation.

Patients with short bowel syndrome frequently develop other clincal problems which may require therapy. These include, hyperphagia, hyponatremia and hypochloremia, metabolic acidosis, including D-lactic acidosis, cholelithiasis and urolithiasis, gastro-esophageal reflux, dystrophy and symptoms caused by secondary dilatation of the lengthened bowel loops: a protruding abdomen, enteral stasis, leading to constipation or diarrhoea with bacterial overgrowth[49].

ADAPTATION

The main long term aim of therapy of short bowel syndrome is to promote intestinal adaptation to allow transition to an oral diet. Such management has focused on the use of preferred gut nutrients such as glutamine, and the use of either specific (e.g. intestinal growth factor IGF-1) or general growth factors (e.g. growth hormone). These treatments have followed from the knowledge that both nutrient and growth factor related events drive intestinal adaptation.

Table 3 Molecules that regulate intestinal adaptation

Molecule	Effect on Intestinal Adaptation
Glucagon-Like Peptide 2	Treatment of rats with a 75% mid small bowel resection with twice daily injections of 0.1ìg per gram of bodyweight for 21 d induced led to mucosal hyperplasia in the proximal jejunum but not in the terminal ileum and a significant increase in intestinal absorptive capacity[50].
Interleukin-11	Treatment of rats with a 90% small bowel resectionwith twice daily injections of 125mg·g-1[aa] Il-11 significantly increasedvillus height and crypt cell mitotic rates[51].
Keratinocyte Growth Factor (KGF)	Treatment of rats with a 75% small bowel resection with 3mg·kg^{-1}·d^{-1} of KGF enhanced intestinal adaptation as assessed by mucosal cellularity, and biochemical activity in duodenal, jejunal and ileal segments[52].
Transforming factor-α	Treatment of mice with a 50% small bowel resection with intraperitoneal TGF-α enhanced intestinal adaptation[53].
Growth Hormone	Treatment of rats with a 75% small intestinal resection with 0.1mg·kg-1·kg-1·2 d-1 d for 28 d enhanced ileal adaptation as assessed by ileal mucosal height. Treatment with growth hormone did not alter ileal mucosal DNA content or ileal mucosal IGF-1 content[54].
	Treatment of rats with an 80% jejunoileal resection with synthetic rat GH for up to 14 d did not enhance ileal adaptation[55].
	Treatment of an infant with only 25 cm of jejunum and 2 cm of ileum, with an ileocecal valve, with a 4-week course of 0.5U / kg of GH allowing wean ing from TPN[56].
	Ten patients with short bowel syndrome were treated with daily subcutaneous doses of recombinant human GH (rhGH) of 0.024mg·kg^{-1}·d^{-1} or a placebo for 8 wk in a crossover cli nical trial that included a wash-out period of at least 12 wk. Low-dose rhGH doubled serum levels of IGF-1 and increased body weight and lean body mass; but there were no significant changes in absorptive capacity of water, energy, or protein[57].
Insulin-like Growth Factor-1	Treatment of rats with 70% and 80% jejuno-ileal resection with IGF-1 or analogues significantly attenuated malabsorption of fat and increased weight of stomach and proximal small bowel[58].
	Gastrostomy-fed rats underwent 80% jejuno-ileal resection followed by infusion of 2.4mg·kg^{-1}·d^{-1} IGF-1 for 7 d. IGF-1 infusion led to a modest increase in ileal but not jejunal growth[15].
	Treatment of TPN-fed rats for 7 d with IGF-1 after a 60% jejunoileal resection led to an increase in jejunal mass, enterocyte proliferation and migration rates yet had minimal effect on colonic structure[59].
Epidermal Growth Factor (EGF)	Treatment of rabbits with 2/3 proximal resection with oral EGF (40μg·kg^{-1}·d^{-1}) for 5 d led to an increase in maltase specific activity and a 3 -4 fold increase in glucose transport and phlorizin binding[60].
	Treatment of rabbits with a 50%-60 % small bowel resection with 0.3μg·kg^{-1}·h^{-1} for 7 d led to a foufold increase in mucosal dryweight at 3 wk post-resection[61].
	Treatment of rats with a 75% small bowel resection with 6.25μg·kg^{-1}·h^{-1} of EGF increased mucosal thickness at 28 d post-resection[62].
Neurotensin	Treatment of rats with a 75% small bowel resection with 600μg·kg^{-1}·d^{-1} led to an increase in the rate of mucosal proliferation[63].

It makes sense to combine the administration of growth factors with an abundant supply of appropriate nutrients. Such approaches have worked well in animal models. Table 3 presents the results of studies that have evaluated the effect of cytokines and growth factors on intestinal adaptation. Clearly, there are a number of agents that can enhance adaptation. However, the effect of these agents is influenced by factors such as nutrition regimen and type of surgery. For example, Ziegler *et al*[15]. found that treatment of gastrostomy-fed rats with 2.4mg·kg^{-1}·d^{-1} IGF-1 for 7 d after 80% jejuno-ileal resection led to a modest increase in ileal but not jejunal growth. In contrast, treatment of TPN-fed rats for 7 d with IGF-1 after a 60% jejunoileal resection and cecectomy did not alter colonic structure[59]. The effect of treatment with other combinations on intestinal adaptation has yielded less equivocalresults. Ziegler *et al*[34]. used a rat model to examine the effect of glutamine and IGF-1 on intestinal adaptation in rats. Treatment with a glutamine-enriched diet or daily injections of IGF-1 enhanced ileal hyperplasia. More importantly, treatment with glutamine and IGF-1 synergistically increased ileal weight and protein content. Fiore *et al*[64]. examined the effect of treatment with IL-11 and EGF on intestinal adaptation in rats after 85% small bowel resection. The animals were treated with either 0.10µg·g^{-1} EGF,125µg·kg-1 IL-11, or 0.10µg·g-1 EGF and 125µg·kg^{-1} IL-11 for 8 d. Rats which received EGF and IL-11 had the most number of proliferating cells in the mucosal crypts.

The results in humans have been less convincing. In 1995, Byrne *et al*[65]. published the results of their investigation of the effect of GH, glutamine and a high complex carbohydrate/low fat diet on 47 patients with short bowel syndrome who had been dependent on TPN for many years. All patients were treated in hospital over a 4 week period. This treatment enabled 40% of patients to be weaned off TPN at one-year follow-up (Table 4). A number of these patients had small bowel length to weight ratios of a little as 0.5cm·kg^{-1}. Subsequent studies have been unable to reproduce these results[66-68]. The data presented in Table 4 indicates that there was little difference in the type of patients involved in each of the three clinical studies, nor were there large differences in treatment regimens. However, the patients involved in the study by Byrne *et al*[65]. were treated as inpatients whereas the other patients were all treated as outpatients. It is possible that this may have affected the results as outpatients may have been less compliant. Scolapio *et al*[67]. considered this issue and believed that the patients involved in their study did comply with the treatment regimen. These conflicting data emphasise the need for further studies to evaluate the effect of trophic agents on intestinal adaptation.

Table 4 The effect of glutamine, growth hormone, and a modified diet on patients with short-bowel syndrome

Authors	Design of Study	Treatment	Number and Type of Patients	Average Length of Remnant Bowel 43	Results
Byrne *et al*[65].	Uncontrolled study. Patients admitted to hospital and treated for 21d.	GH 0.11mg·kg^{-1}·d^{-1}, glutamine 0.16g·kg^{-1}·d^{-1}[aa] by the parenteral route with up to 30g·d^{-1} by the enteral route, and a diet containing 60% of total calories as carbohydrate, 20% as fat and 20% from protein.	47 patients that were chronically dependent on parenteral nutrition	patients with a colonic remnant had(50±7)cm[4]. patients with no colon had (102±24)cm.	At the end of the study 57% of the patients no longer needed TPN, 30% had reduced TPN requirements, and 6% required approximately the same amount of TPN as they did at the start of the study. One year later 40% of the patients no longer needed TPN, 40% had reduced TPN requirements, and 20% required approximately the same amount of TPN as they did at the start of the study
Scolapio[66] Scolapio *et al*[67].	Double-blind, placebo controlled, randomized crossover study. Patients were treated for 21d as out-patients.	GH 0.14mg·kg^{-1}·d^{-1}, glutamine 0.63g·kg^{-1}·d^{-1} by oral route, and a diet containing 60% total calories as carbohydrate, 20% as fat and 20% as protein.	8 patients that were dependent on parenteral nutrition for an average of 12.9 years.	71 cm^2 patients had colonic continuity.	Treatment led to a significant increase in bodyweight and lean body mass, a significant decrease in percent body fat and induced peripheral edema. All parameters returned to baseline levels within 14 d of stopping treatment. Treatment had no significant effect on intestinal villus height or crypt depth.
Szkudlarek *et al*[68].	Double-blind, placebo controlled , randomized crossover study. Patients were treated for 28 d as out-patients.	GH 0.14mg·kg^{-1}·d^{-1}, glutamine 30g·d^{-1} by oral route and glutamine-enriched parenteral nutrition (17% of nitrogen as glutamine).	8 patients that were dependent on parenteral nutrition for an average of 7 years .	104 cm.4 patients had colonic continuity.	No significant effect of treat ment on absorption of energy, carbohydrate, nitrogen, wet weight, sodium, potassium, calcium or magnesium. Treatment induced adverse effects.

SURGICAL MANAGEMENT

Non-Transplant Procedures - Autologous Gastrointestinal Reconstruction

Only a few patients with short bowel syndrome are candidates for non-transplantprocedures. Surgery in the form of autologous gastrointestinal reconstruction is designed to redistribute the patient's own residual absorptive bowel to enhance adaptation and, possibly, to increase the absorptive mucosal surface by neomucosal growth. The majority of such reconstructions have been performed on paediatric patients. Intestinal lengthening, as described by Bianchi, is the most commonly used method of gastrointestinal reconstruction for the therapy of short bowel syndrome. It divides the bowel in two longitudinal halves based on the bifurcated mesenteric blood supply, then reconnects the two halves in series with the rest of the small intestine.

Bianchi[69] has recently reviewed his 16-year experience of longitudinal intestinal lengthening procedures for 20 neonates and infants with short-bowel syndrome that included a dysfunctional dilated jejunum. There was no operative mortality and the long-term survival was 45%. Survivors had >40 cm residual jejunum and a greater number also retained their ileocaecal valve and a longer colonic length. Death was commonly due to end-stage liver failure. Weber[54] reviewed the outcome of 16 infants and children who had this procedure performed, with a resultant increase in the length of their bowel by 22%-85% (mean 42%). There were marked improvements in stool counts, intestinal transit time, intestinal clearance of barium, D-xylose absorption, and fat absorption. Fourteen of the 16 patients (88%) no longer required parenteral nutrition.

Small Bowel Transplantation

Intestinal transplantation, either alone or in combination with the liver, may eventually emerge as the preferred therapy for patients with permanent intestinal failure. However, in comparison with solid organ transplantations, such as the kidney and the liver, there has been slower progression from experimentation tow ards routine clinical practice. The first intestinal transplant was performed in Boston in 1964. It

involved the transfer of an ileal segment from the patients mother, but the recipient died 12 hours after surgery. In New York in 1970, a 170 cm jejunoileal segment was transplanted from an identical sister and the recipient lived for 79 d and was able to eat for 6 wk. At Kiel University in 1988, an intestinal transplant from an identical sister resulted in a survival for 4 years[70].

The high level of immune surveillance within the small intestine means that large number of 'passenger' immunocytes and dendritic cells are transplanted along with the intestinal tissue. This increases the risk of acute rejection, which leads to the use of high doses of immunosuppressive agents and a greater incidence of side effects. In addition, the immunocompromized recipient is vulnerable to infections such as cytomegalovirus enteritis. In fact, recipients can die of side effects in the presence of a functioning graft[71]. Improved results are only expected with newer immunosuppressive agents, better antiviral prophylaxis and treatment, and improved preservation and surgical techniques[72].

Grant[73] has recently reviewed the world experience in which 33 intestinal transplant programs provided data on 273 transplants in 260 patients. These patients received their transplants before March 1997. Only one-thirds of the recipients were adults and the commonest indication for transplantation was the short bowel syndrome. Many of the transplants involved other organs - intestine plus liver (48%); multi-viscera (11%). The one year graft survival for isolated in testinal transplants performed after early 1995 was 55% (the patient survival was 69%). Overall, 77% of the survivors were being sustained on oral nutrition and had no requirement for parenteral nutrition. The overall three-year survival has been about 40%, which is comparable with the results of lung transplantation.

Organ retrieval from a living donor can be performed safely for small bowel transplantation. However, further study of the management of rejection as well as viral infection is necessary for both living and non-living-related small bowel transplantation[74]. Endoscopic surveillance may be useful to detect early allograft rejection[75]. It has been suggested that a lower severity of graft rejection in combined liver-small bowel transplantation improves functional results of intestinal transplantation in children without additional mortality or morbidity[76].

Goulet *et al*[77]. have stressed that, because parenteral nutrition is generally well tolerated, even for long periods, each indication for transplan tation must be weighed carefully in terms of risk and quality of life. In this regard, it is of interest that a T cell lymphoma has been reported in the intestinal graft of a multivisceral organ recipient[78]. It may have special significance because the lymphoproliferative disorders that are usually observed after transplantation are invariably of B cell origin. Furthermore, Crohn's disease in the recipient can recur in the intestinal transplant[79].

Kato *et al*[80]. have used a rodent model to demonstrate that EGF augments both the structural and functional adaptation of intestinal grafts. Recipient Lewis rats underwent resection of the distal 80% of the small bowel followed by the insertion of a 20 cm isograft. EGF ($30\mu g \cdot kg^{-1} \cdot d^{-1}$), or a control, was infused intraperitoneally for 3 d immediately after surgery. After 7 d, the graft was isolated for morphologic studies and was used for analysis of glucose and water absorption and the expression of sodium glucose cotransporter 1. These were used as indicators of functional adaptation. After seven days, the EGF-treated group exhibited significantly increased mucosal villous height, crypt cell proliferation, glucose and water absorption, and expression of sodium glucose co-transporter 1 protein compared to the control group.

Other Surgical Techniques

A variety of surgical techniques have been devised to promoted oral absorption of nutrients and delay emptying. These include a reversed intestinal segments, artificial intestinal valves, and recirculating loops. None of these procedures has been associated with significant clinical success. Thompson *et al*[81]. studied 48 adults and 112 children with short-bowel syndrome. The eventual outcome was that 44% adapted and survived on enteral nutrition alone, 28% required long-term parenteral nutrition, and 28% underwent surgery. Thirteen of 15 patients with adequate intestinal length (>120 cm in adults), but dilated dysfunctional bowel, were improved by either stricturoplasty or tapering. However, the patients who received an artificial valve (n= 2) or a reversed segment (n= 1) did poorly and required further surgery for revision or reversal. In general, success is lowest for procedures designed to prolong intestinal transit time; thus, these procedures should be used only in carefully selected patients[82].

This is in contrast with the experience of Panis *et al*[83]. who reported their experience with segmental reversal of the small bowel. Eight patients with short bowel syndrome underwent, at the time of intestinal continuity resto ration, a segmental reversal of the distal (n= 7) or proximal (n= 1) small bowel. The median length of the remnant small bowel was 40 cm (range, 25-70cm), including a median length of reversed segment of 12 cm (range, 8-15 cm). Parenteral nutrition cessation was obtained in 3 of 5 patients at 1 years and in 3 of 3 patients at 4 years. Segmental reversal of the small bowel could beproposed as an alternative to intestinal transplantation in patients with short bowel syndrome before the possible occurrence of parenteral nutrition-related complications.

COORDINATED INTERDISCIPLINARY MANAGEMENT

There have been proposals to develop multidisciplinary teams to care for patients with the short bowel syndrome. The key issues are the maintenance of optimum growth and development in infants and children, the promotion of intestinal adaptation, and the safe progression towards an oral diet. Koehler *et al*[84]. evaluated the effect of co-ordinated interdisciplinary team management of children with intestinal failure on nutritional outcome measures. Using an established registry, the authors conducted a comprehensive evaluation of patient data including anthropometric measures, organ system function, and mode of nutrition support. Linear growth velocity of neither pre- nor post-pubescent patientssignificantly improved during the 2-year study period of interdisciplinary team management.

When innovative, not yet fully proven therapies are introduced, physicians may have neither experience nor sufficient data in the medical literature to assist in their decision. When multiple physicians caring for a single patient have reached different conclusions regarding this new therapy, the potential for disagreement exists that could give rise to ethical issues as well as cause confusion to the patient. To explore these topics, Cooper *et al*[85]. investigated the attitudes of specialists to therapies for short bowel syndrome. A forced choice questionnaire was distributed to clinicians in neonatology and pediatric gastroenterology. Significant differences were noted among specialists as to whom would be involved in discussions of therapeutic options with patients about short bowel syndrome. Differences also were noted in the willingness of specialists to discuss and recommend therapies, in the perceived survival and quality of life by various specialists after transplant and palliative surgery, and in the local availability of various options. The neonatologists

and gastroenterologists at the same institution disagreed on responses in 34% of the questions with only 1 of the 25 pairs in full agreement. There is the potential for much patient confusion when counselling physicians recommend different options. Colleagues as individuals and specialists as groups should talk to each other before individual discussions with families to ensure that there is a clear understanding of differing beliefs.

Abstract

AIM: **To investigate the role of cytokine gene expression in organ damage at different tissue sites during sepsis.**

METHODS: **Male NIH mice were subjected to cecal ligation and puncture (CLP) or sham operation (Sham). Pro-inflammatory cytokine (TNFα, IL-1β and IL-6) and anti-inflammatory cytokine (IL-4) gene expression in the liver and lung tissue were assessed by RT-PCR. The permeability of microvascular and water content in the lungs and liver were also examined.**

RESULTS: **Significant increase in TNFα, IL-1β and IL-6 gene expression was observed at 3 and 12 h after CLP both in the liver and lungs ($P<0.01$).The level of IL-4 gene expression was not changed after CLP in the lungs, but increased at 12 h after CLP($P<0.01$) in the liver tissue. Both the liver and lungs showed a significant increase in microcirculatory permeability at 12 h after CLP($P<0.01$), and the increase in the lungs was higher than that in the liver. The water mass fractions in the liver ($P<0.05$) and lungs ($P<0.01$) were increased after CLP, and the increase in the lungs happened earlier and more severely than that in the liver.**

CONCLUSION: **The inflammatory response in the liver and lungs was different during sepsis. At the early stage of sepsis, pro-inflammatory reaction dominates both in the liver and lungs. But at the later stage of sepsis, induction of compensatory anti-inflammatory response was seen in the liver but not in the lungs. This difference *in situ* activity may contribute to the different vulnerability of organ damage during sepsis. The strategy of systemic administration of anti-inflammatory drugs to sepsis should be reconsidered.**

INTRODUCTION

Despite modern techniques of resuscitation and intensive care and an ever-increasing number of powerful and effective antibiotics, sepsis remainsa major cause of death in the critically ill[1], including severe trauma, burns, hemorrhage, major operations[2], etc. Sepsis-related mortality frequently results from multiple organ dysfunction syndrome, which is characterized by impaired pulmonary function, hepatic failure, cardiac dysfunction, acute renal failure, and disseminated intravascular coagulation[3,4]. The physiologic derangements of MODS are believed to result from the excessive activation of the systemic inflammatory response by infection, ischemia, injury, or immunologic activation[5,6].

Post-sepsis MODS is now believed to be caused by an overexpression of host defenses[7]. Mediators such as TNFα, IL-β and other cytokines are acknowledged to be pivotal early effectors. There is evidence that the development of tissue damage in sepsis is closely related to the release of an ever-increasing number of cytokines and accumulation of neutrophils at the sites of infection or injury[8,9]. Though there were many studies on the role of cytokines in sepsis. Most studies detect only circulating mediators, not mediators bound to cells or receptors[10,11]. Analyses of serum levels are troublesome to interpret. They may underestimate the effective amount of mediator acting at a cellular level. Bioassays, which measure the functional activity of cytokines, often lack specificity and may over-report amounts.

Polymicrobial sepsis induced by cecal ligation and puncture (CLP) is a model of sepsis which reproduces many of the inflammatory and pathological sequelae that are observed clinically[12]. Following CLP, animals develop bacteremia, hypothermia, hypotension, and damage to multiple organ systems[13]. The present study was designed to observe the gene expression of cytokines in hepatic and pulmonary tissues with CLP model, in order to investigate the role of cytokines in organ damage during sepsis.

MATERIALS AND METHODS

Animal model and experimental groups

NIH mice were obtained from the animal center of the general hospital of Chinese PLA. The mice were randomly divided into two groups: CLP group and sham group. Sepsis was induced by cecal ligation and puncture (CLP). The mice were anesthetized, and the cecum was ligated below the ileocecal junction; and intestinal continuity was maintained. The cecum was punctured twice with a 20-gauge needle and a small amount of cecal contents was expressed through the punctures. The incision was closed and 1ml of normal saline was administered subcutaneously. Sham-operated mice underwent the same surgical procedure, but without CLP. The mice were sacrificed at 3 or 12 h after the procedure.

Preparation of RNA

Total RNA was extracted from liver and lung tissues according to the guanidinium isothiocyanate single-step methods. The RNA concentration of each sample was estimated by measuring the absorbance at 260 nm.

Reverse transcription and PCR

Total RNA from experimental samples was used to synthesize cDNA using AMV reverse transcriptase. β-actin and β_2-MG were used as

internal control primers. The primers for the cytokines and control were as follows: β- actin (478bp): 5'AGG GAA ATC GTG CGT GAC ATC AAA 3', 5'ACT CAT CGT ACT CCT GCT TGC TGA 3';β_2-MG (300bp): 5'GGC TCG CTC GGT GAC CCT AGT CTT T 3',5'TCT GCA GGC GTA TGT ATC AGT CTC A 3';TNF-α (349bp): 5'TTC TGT CCC TTT CAC TCA CTG G3',5'TTG GTG GTT TGC TAC GAC GTG G 3';IL-1β (441bp): 5'ATT AGA CAG CTG CAC TAC AGG CTC 3',5'AGA TTC CAT GGT GAA GTC AAT TAT 3';IL-6 (156bp): 5'TGG AGT CAC AGA AGG AGT GGC TAA G 3', 5'TCT GAC CAC AGT GAG GAA TGT CCA C 3';IL-4 (181bp): 5'CGA AGA ACA CCA CAG AGA GTG AGC T 3',5'GAC TCA TTC ATG GTG CAG CTT ATC G 3'. PCR was performed in a 25μl reaction volume. A hot start was applied for 5min at 95℃. The amplification cycle (denaturation step at 94 ℃ for 30s, an annealing step at 55℃ for 30s and an extension step at 72℃ for 90s) was repeated 30 times and followed by a final extension for 10 min at 72℃. Amplified products were separated by electrophoresis in ethidium bromide-stained 15g·L^{-1} agarose gel and visualized with UV illumination. The bands representing reaction product on the film were scanned by densitometry. A normalization quotient (Q) was calculated between the integrated optical density values (IOD) for the adhesion molecules and the β-actin or β_2-MG bands (Q=IOD adhesion molecules band/internal control band). The level of adhesion molecules mRNA were expressed as the quotient of the integrated values for the adhesion molecules and the β-actin or β_2-MG bands.

Microvascular permeability in the liver and lungs

Evans blue (15g·L^{-1}) was injected intravenously in concentrations of 10μl·g^{-1} 0.1ml/10g. The liver and lung tissues were excised and weighed. To each sample of tissues, 4.0mL formamide was added and incubated at 56℃ for 72 h. If necessary, the incubation time was prolonged, until the blue color of the samples completely disappeared. After filtration with glass filter, the absorbance of the filtrate was measured at 620nm in a Beckman spectrophotometer. The total amount of dye can be calculated by means of a standard calibration curve. The permeability of microvascular in the liver and lungs was shown as the μg of Evans blue in every mg tissues.

Water mass fractions in the liver and lungs

Water mass fractions were used as a parameter of organ water accumulation after CLP. The liver and lung tissues were removed in a humidity chamber and the wet mass was measured immediately. The tissues were dried at 70℃ to a constant mass for the determination of dry mass. Organ edema was determined by calculating tissue water content according to the following formula: Water mass fractions (%) = (1-dry mass / wet mass)×100%.

Statistics

All data were reported as $x \pm s$. Data were analyzed by *t* test for comparisons between two groups.$P<0.05$ was accepted as the level of significance.

RESULTS

Cytokine mRNA expression in the liver and lungs

Significant increase in TNFα, IL-1β and IL-6 gene expression was observed at 3 and 12 h after CLP both in the liver and lungs. But the level of IL-4 gene expression was not changed after CLP in the lungs, while it was increased at 12 h after CLP (Figure 1, 2) in the liver tissue.

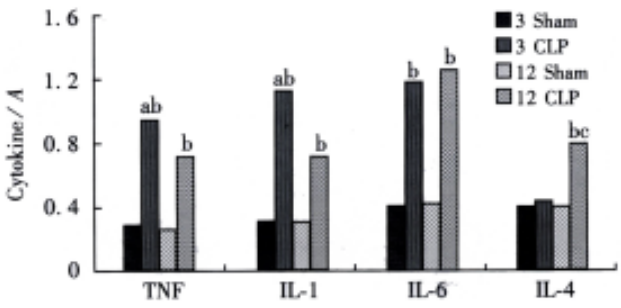

Figure 1 The cytokines gene expression in the river [a]$P<0.01$, *vs* CLP 12h group, [b]$P<0.01$, *vs* sham group, [c]$P<0.01$, *vs* CLP 3h group

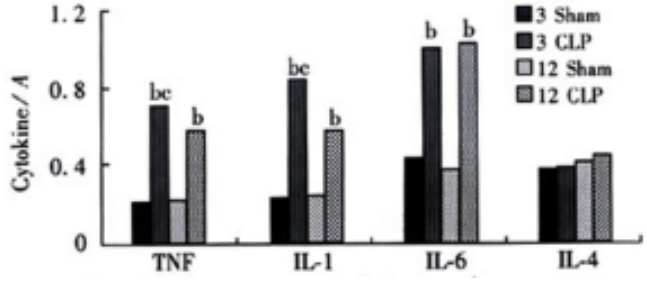

Figure 2 The cytokines gene expression in the lungs [b]$P<0.01$, *vs* sham group, [c]$P<0.05$, *vs* CLP 12h group

Microvascular permeability in the liver and lungs

Both the liver and lungs showed a significant increase in microcirculatory permeability at 12 h after CLP, and the increase in the lungs was higher than that in the liver (Figure 3).

DISCUSSION

SIRS affects all aspects of systemic homeostasis. It is arbitrary, but convenient, to consider its effects from the perspective of the dysfunction of certain key organ systems. It must be recognized, however, that there is no defining combination of systems or temporal sequence of physiologic deterioration that characterizes the syndrome[14]. A systematic review of 30 descriptions of MODS published between 1969 and 1993 revealed that respiratory system is the most commonly cited organ system[15,16]. The liver with its rich supply of blood and sinusoid is directly exposed to bacteria and endotoxins drained from the GI tract[17-19]. Previous works have proclaimed that liver is the most susceptible and vulnerable organ during sepsis and multiple organ failure[20]. So in this study, we chose the liver and lungs as the samples to study the role of local cytokine gene expression in organ damage.

Cytokines are polypeptides or glycoproteins of low molecular weight. Most cytokines are not stored as preformed molecules, hence their production requires new gene transcription and translation. Unlike mediators derived from the classical endocrine system, cytokines are produced. The production of cytokines at various tissue sites depends, in part, on the proximity of the site to the injurious stimulus. A lot of cells such as macrophage[21] and endothelial cells[22] can produce cytokines. Cytokines act predominantly as paracrine and autocrine messengers, not endocrine mediators. Thus, cytokines may exert their major effects locally, within organs and tissues. Assays of circulating cytokine concentrations may be misleading because they do not detect cytokines bound to soluble receptors[23]. These assays may also fail to detect cytokines when inhibitors or receptor antagonists are present[24]. Therefore investigations in this area require more precise determination of the temporal sequencing and tissue-specific expression of cytokines.

In this study we assessed the gene expression of pro-inflammatory and anti-inflammatory cytokines in the hepatic and pulmonary tissues. Pro-inflammatory cytokines such as TNFα, and IL-1β are known to play predominant roles in the normal inflammatory response. But exaggerated endogenous production is likely responsible for the complications associated with sepsis as tissue injury and ultimate organ failure[25]. These pro-inflammatory cytokines result in the production of secondary mediators (including nitric oxide, arachidonic acid metabolites, bradykinin, and histamine) which in turn activate neutrophils and endothelial cells to perpetuate tissue injury[26,27]. But attempts to modulate the biological activity of cytokines with monoclonal antibodies against endotoxin, TNFα, IL-1 have not been successful in improving outcome in several clinical series. Recently, evidence is accumulating that in response to the original inciting event (the inflammatory response), the body also mounts an anti-inflammatory response. Agents that have been identified so far as participating in this anti-inflammatory response include interleukins-4, -10, -11 and -13; transforming growth factor-α; colony-stimulating factors; soluble receptors to tumor necrosis factor and receptor antagonists to IL-1[28]. Because most of these mediators have been discovered recently, we know very little about their actions, and even less about their effects on the pro-inflammatory cascade. However, it had already been shown that some of these mediators, especially some of these interleukins, have a profound effect on monocyte function, including antigen presenting activity[29]. They also inhibit T- and B-lymphocyte activity, including antigen-specific T-lymphocyte proliferation. The result is immune suppression, which can sometimes be profound. Of great interest is the fact that these mediators can down-regulate their own synthesis, thereby providing a mechanism through which homeostasis can be restored. Results in this study showed that the conditions of inflammatory reaction in the liver and lungs were different during sepsis. At the early stage of sepsis, the power of pro-inflammatory reaction was stronger than that of anti-inflammatory reaction both in the liver and lungs. But at the later stage of sepsis, compensatory anti-inflammatory response was found in the liver but not in the lungs.

The consensus of the concept of systemic inflammatory responses has brought about a promising approach in the treatment of SIRS/MODS[30] - anti-inflammatory instead of anti-infection[31,32]. Various approaches aimed to interrupt the cascade of host inflammatory responses have been tested[33]. These include interventions targeted at the inflammation effector cells as monoclonal antibodies or receptor antagonist to pro-inflammatory cytokines[34,35]. However, many of these seemingly effective measures in experimental study failed when moved from the laboratory bench to clinical ward[36,37]. As results showed in this study that the conditions of inflammatory reaction in the liver and lungs were different during sepsis, it is postulated that in the strategy of anti-inflammatory interventions such as monoclonal antibodies against endotoxin and TNFα, in addition to timing, organ targeting may also be considered.

Abstract

AIM: **To establish an experimental model for exploring the role of hepatitis C virus (HCV) in the development of cholangiocarcinoma.**

METHODS: **Recombinant plasmid of HCV-core gene was constructed with molecular cloning technique and transfected into QBC939 cells with lipofection. After it was selected with G418, resistant colonies were obtained. The colonies were analysed by immunocytochemistry and Western blotting.The morphology was observed under transmission electron microscope(TEM) and microscope.**

RESULTS: **The recombinant plasmid was proved to carry the target gene by PCR and restriction enzymed mapping. Moreover, it could express HCV-C protein efficiently in QBC939 cells. The HCV-like particles were found in the cytoplasm by electron microscope, which were spherical with a diameter of 50nm-80nm possessing outer membrane.The transfected cells had lower differentiation and higher malignant degree under microscope.**

CONCLUSION: **Because HCV-core gene could express steadily in cholangiocarcinoma cells,the transfected tumor cells(QBC939-HCVC) could be used to study the effect of HCV in the development of cholangiocarcinoma.**

INTRODUCTION

Cholangiocar cinoma is the second cancer of hepatobiliary system. The incidence and mortality of cholangiocarcinoma are increasing yearly.There are 3000 new patients in America each year. Recent reports showing the expression of HCVRNA and HCV antigents in cholangiocarcinoma[1-8],have provided new insights into the pathogenesis of cholangiocarcinoma. Hepatitis C virus(HCV) is recognized as a kind of serious infectious source to harm the health of the humans.It could lead to cancer[9-17].Moreover,its core protein could act as a transcriptional regulator of various viral and cellular promoters to potentially disrupt normal cellular functions[18-21]. Thus,the function of core protein is important for carcinogenesis.We constructed the recombinant plasmid of HCV core gene with molecular cloning technique and transfected into cholangiocarcinoma cells with lipofection, and established an experimental model for exploring the role of HCV in the development of cholangiocarcinoma.

MATERIALS AND METHODS

Materials

Plasmids and bactrium strain PBK-HCV encompassing the core and envelope genomic regions of HCV,containing 330nt - 2020nt of HCV II strain, was provided as a gift by Dr.Chen (Institute of Infectious Disease,Zhejiang University),whose restriction sites were *Pst*Iand *EcoR*I.The prokaryotic expressing vector of PBK-CMV containing MCS(multiple cloning site),the neomycin- and kanamycin-resistance gene, SV40 poly(A), was purchased from Stratagene Co. *E.coli* JM109 was obtained from the collection kept in our research group.

Cells The QBC939 cells(a cholangiocarcinoma cell line)were a generous gift from Dr. Wang Shuguang(Third Military Medical University,China). QBC939 cells were cultured in RPMI 1640 supplemented with 100mL·L^{-1} FBS and incubated at 37℃ in a 50mL·L^{-1} CO_2 atomosphere.

Reagents Restriction enzymes(*Sal* I and *BamH* I),Taq DNA polymerase,T_4DNA ligase,were purchased from Hua Mei Co. Lipofection was provided by Boehringer Mannheim Co. Mouse anti-HCV C protein monoclonal antibody was purchased from Chemicon Co. House anti-mouse IgG(mouse)-AP,NBT/BICP were purchased from Zhong Shan Co. Biotinylated-conjugated sheep anti-mouse IgG was purchased from Boster Co.

PCR primers Two primers were designed according to the sequence of HCV core genomic regions and synthesized by the Shanghai GeneCore Bio Technologies Co. Primer 1:5'-CTCGTCGACCATGAGCACAAATCCTAA-3'; Primer 2:5'-CTCGGATCCTAAGCGGAAGC- TGGGATG-3'. Primer 1 was 5'primer containing *Sal*I site and Primer 2 was 5' primer containing *BamH*I site.

Methods

PCR amplification PCR amplification was done using the PBK-HCV as a template and primers 1 and 2 as primers.The reaction was performed according to the parameters of 94℃ 3min,94℃ 1min, 55℃ 30s and 72℃ 1min for 35 cycles.Then it was extended 10min at 72℃. The amplified fragment (approx 600bp)was analyzed by 9 g·L^{-1} agarose-gel electrophoresis.The product was purified and used for DNA recombinction.

DNA recombination DNA recombination was performed according to the methods described in reference[22]. A 0. 6kb fragment,containing HCV core gene,was obtained from the PCR product after digestion with *Sal*Iand *BamH*I.The fragment was recombinated into plasmid PBK-CMV and the resulted recombinant plasmid was designated as PBK-HCVC (Figure 1).

Transfection of cells Transfection was performed with lipofection.The constructed vector and control plasmid were used to transfect QBC939 cells in culture. Seven-two h after transfection, they were selected with G418. Then the cells were harvested and used for the detections.

Immunocytochemistry for HCV core protein Detection of HCV core protein expression was performed using a mouse anti-HCV core protein monoclonal antibody(1∶50) on cell sections of transfected QBC939 and control plasmid.

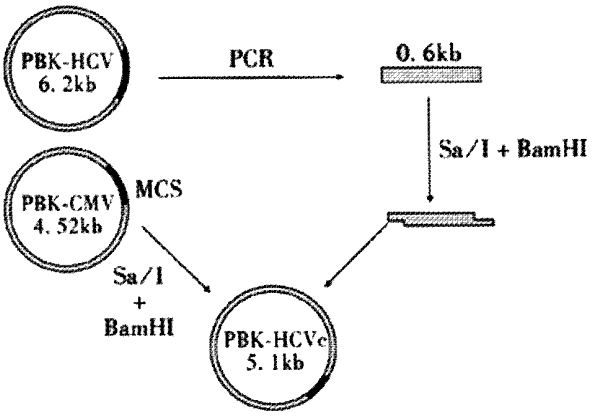

Figure 1 Construction of plasmid PBK-HCVC.

Western blotting Detection of HCV core protein by immunoblotting was performed. Briefly,cells (1×10^6) were scraped,centrifuged briefly,and lysed for 30min on ice in 50mmol·L^{-1} Tris-cl(pH 7.5), 150mmol·L^{-1} Nacl,0.2mmol·L^{-1} EDTA, 1mmol·L^{-1} PMSF and 10g·L^{-1} NP-40.The samples were cleared by centrifugation(140000r·min^{-1},30min,4℃),and assessed for protein concentration.SDS-PAGE was performed,and proteins were electroblotted onto nitrocellulose membranes.After 1h incubation in blocking solution,the membrane was exposed to the primary antiobody 2h at 4℃.After washing in PBS,the secondary AP-labeled antibody was added for 2h at room temperature.The proteins were visualized with NBT-BICP.

Transmission electron microscope A pellet of the transfected cells was fixed in 2.5g·L^{-1} glutraraldehyde,postfixed with 10g·L^{-1} osmium tetroxide,treated with 20g·L^{-1} uramyl acctate,dehydrated in ethanol, infiltrated with propylene oxide,and embedded in Epon mixture.Ultrathin sections were observed under Opton EM 10C(German).

Microscope After selected with G418, the cell sections were stained with HE.The cell sections were observed under microscope.

RESULTS

Identification of reconstructed plasmid by PCR and restriction enzymes

The reconstructed plasmid was amplified by PCR, using the PBK-HCVc as a template and primers 1 and 2 as primers, the reaction was performed according to the same parameters. PCR product was approx 600bp(Figure2). Then it was identified by the digestion with restriction enzymes(*Sal*Iand *BamH*I). Fragments of 4500bp and 600bp were produced from the digestion. It was proved to carry the target gene(Figure 3).

Expression of the HCV core protein

Cell sections of transfected with PBK-HCVC and control plasmid (PBK-CMV) were stained for HCV core protein. Staining for HCV core protein was seen in the PBK-HCVC transfected QBC939 cells. Positive staining was located to the cytoplasm(Figure 4).

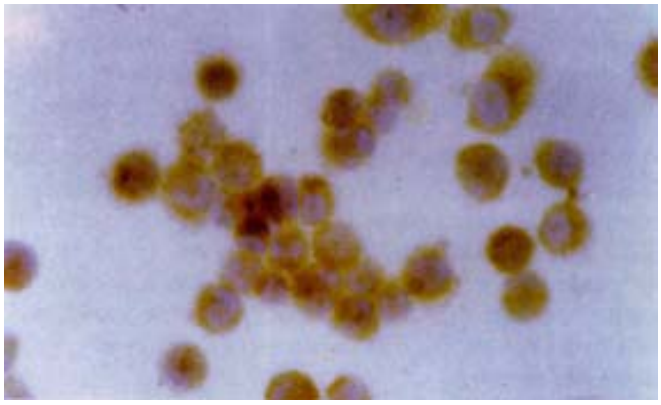

Figure 4 Detection of expressed HCV C antigen by immunocytochemistry. × 200

The expressed products in the supernatant which were transfected with PBK-HCVC and control plasmid(PBK-CMV) were identified by Western blotting. A appox 21ku band,similar to the size of HCV core protein,was observed in the supernatant of transfection with PBK-HCVC(Figure 5). These results showed that the QBC939 cells transfected with PBK-HCVC could express HCV core protein.

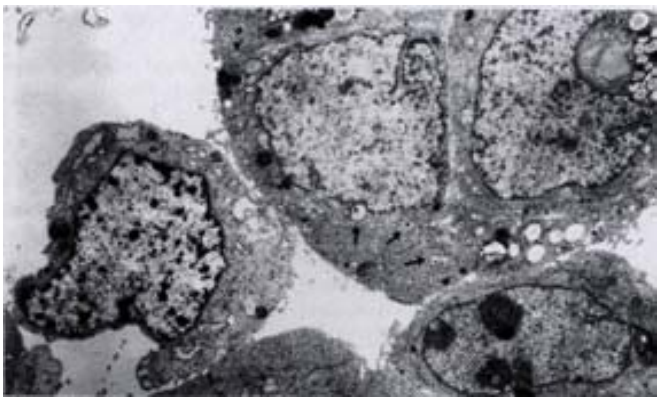

Figure 6 Morphology of QBC939-HCVC cells by TEM. ×6500

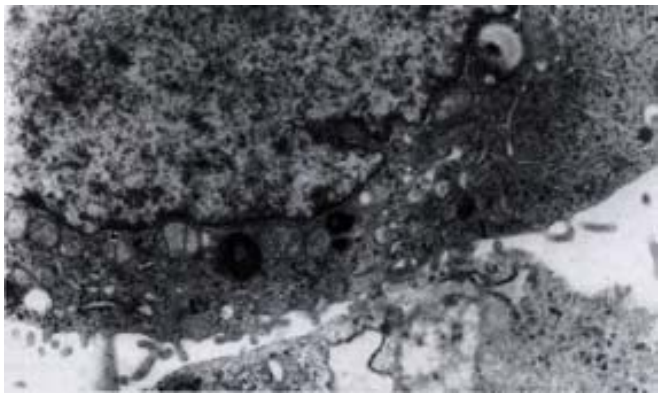

Figure 7 Morphology of QBC939-HCVC cells by TEM. ×60 000

The morphologic alteration of the transfected cells

On day 15 after QBC939 cells were transfected with PBK-HCVC, the HCV-like particles were found in the cytoplasm under TEM, which were spherical with a diameter of 50nm-80nm possessing outer membrane(Figures 6,7).The structures were absent in the negative control.The results suggested that the recombinent plasmid could express HCV core protein efficiently in cholangiocarcinoma cell lines.The splits of nuclei were increased significantly in transfected QBC939 cells with PBK-HCVC than PBK-CMV and QBC939 cells (Figure 8). It suggested that the exent of the differentiation was reduced and malignant degree was enhanced after QBC939 cells were transfected with PBK-HCVC.

DISCUSSION

The pathogenesis of cholangiocarcinoma is not clear. Cholelithiasis,cystic dilation of the biliary system,ulcerative colitis and primary sclerosing cholangitis are thought to be the risk factors for cholangiocarcinoma.Recently, laboratory and epidemiological studies found and epidemic found the infection of HCV was related to the development of cholangiocarcinoma [1-8,23-25].But the mechanism of how they are related has not been studied deeply. HCV infection is an important cause of morbidity and mortality worldwide,causing a spectrum of liver diseases ranging from an asymptomative carrier state to end-stage liver disease.The most important feature of persistent HCV infection is the development of chronic hepatitis in half of the infected individuals and the potential for disease progression to hepatocellular carcinoma.In our country there are 30-40 million of HCV-carriers patients[26-28].

HCV are hepatotropic viruses.Viral replication and cellar injury are largely confined to the liver.Recent studies,however,have suggested that HCV may replicate in tissues other than in hepatocyte only. Many scholars have reported the presence of HCVRNA and HCV-antigens in lymph nodes, pancreas, ovary, kidney, heart and bile duct epithelial cells[29-35]. The infection of HCV could lead to bile duct damage and loss. Moreover,bile duct injury is more commonly associated with HCV than either HBV or autoimmune hepatitis,which is the characteristic histologic feature of HCV. The bile duct damage and loss are defined as variable epithelial, steatosis,lymphocytic infiltration of bile ducts[36-38].The more injury of HCV infection in bile duct provides new evidence that bile duct epithelial cells could be an important reservoir of HCV and might lead to the pathogenesis of cholangiocarcinoma. An HCV genome contains a linear,positive-strand RNA molecule of 9500 nucleotides encoding a single ploy protein precursor of 3000 amino acids.The polyprotein is cleaved by viral proteases to generate three putative structural proteins(C, E1 and E2) and at least six nonstructural proteins(NS2,NS3,NS4A, NS4B, NS5A and NS5B)[39,40]. The genomic region encoding the putative C protein is also called core protein. The HCV core protein could act as a transcriptional regulator of various viral and cellular promoters to potentially disrupt normal cellular functions[18-21]. The core protein may cooperate with ras oncogene and transform primary rat embryo fibroblasts to a tumorigenic phenotype[41].It may also cause anti-apoptosis by ressive of tumor suppressor gene-p53 and activation of NF-κB and implicate a mechanism by which HCV may evade the host immune surveillance leading to viral persistence and possibly to carcinogenesis[42-51]. Thus,the HCV core protein plays a major role in the malignant transformation of cells. It is important to explore the role of HCV in the development of cholangiocarcinoma by establishing an experimential model which expresses efficiently HCV core protein in cholangiocarcinoma cell lines.

In our study, recombinant plasmid of HCV-core gene was constructed with molecular cloning technique,it was identified by restriction enzymes.Then it was transfected into QBC939 cells with lipofection.After it was selected with G418 made by the presence of the necomycin and kanamycin resistance gene, resistant colonies were obtained. The colonies were analysed by immunocytochemistry and Western blotting. The results suggest that the recombinant plasmid was proved to carry the target gene by PCR and restricted enzyme map, and it could express HCV core protein efficiently in QBC939 cells.The morphology was observed under transmission electron microscopy(TEM), and the HCV-like particles in the cytoplasm, were found spherical with a diameter of 50nm-80nm possessing outer membranes. Moreover, we also found that the splits of nuclei were increased in transfected QBC939 cells with PBK-HCVC, and the exent of differentiation was reduced. It suggested that the malignant degree was enhanced after QBC939 cells were transfected with PBK-HCVC. Because HCV-core gene could express steadily in cholangiocarcinoma cells, the transfected tumor cells(QBC939-HCVC) could be used to study the effect of HCV in the development of cholangiocarcinoma.

Abstract

AIM: **To study the effect of sulfated cholecystokinin-octapeptide (CCK-8) on systemic hypotension, gene and protein expression of TNF-α in spleen of lipopolysaccharide (LPS) nduced endotoxic shock (ES) rats, and further investigate the signal transduction mechanism of p38 mitogen-activated protein kinase (MAPK).**

METHODS: **The changes of blood pressure were observed using physiological record instrument in four groups of rats: LPS (8 mg·kg^{-1}, iv), CCK-8 (40 μg·kg^{-1}, iv) pretreatment 10 min before LPS (8 mg·kg^{-1}), CCK-8 (40μg·kg^{-1}, iv) or normal saline (control) group. The content of TNF-α in the spleen was assayed 2 h after LPS administration using ELISA kit and the expression of TNF-α mRNA was examined 30 min, 2 h and 6 h after LPS administration by reverse transcribed polymerase chain reaction (RT-PCR). Activation of p38 MAPK was detected with Western blot 30 min after LPS administration.**

RESULTS: **CCK-8 reversed LPS-induced decrease of mean arterial pressure (MAP) in rats. The content of TNF-α in the spleen was (282±30) ng·L^{-1} in control group, while it increased to (941±149) ng·L^{-1} in LPS group, P <0.01. CCK-8 significantly inhibited the LPS-induced increase of TNF-α content in spleen. It decreased to (462±87) ng·L^{-1} in CCK-8+LPS group, P<0.01. The expression of TNF-α mRNA 30 min and 2 h after treatment was stronger in LPS group, while it was lowered after CCK-8 pretreatment.The p38 MAPK expression increased significantly in LPS group (5.84 times of control) and CCK-8 increased the activation of p38 MAPK in ES rats (10.74 times of control).**

CONCLUSION: **CCK-8 reverses the decrease of MAP in ES rats and has inhibitory effect on the gene and protein expression of TNF-α in spleen, and p38 MAPK may be involved in its signal transduction mechanisms.**

INTRODUCTION

Lipopolysaccharide (LPS), main component of Gram-negative bacterial endotoxin[1], is the leading cause of sepsis or endotoxic shock (ES), and when administered experimentally to animals, mimics the same inflammatory response. LPS exerts its effects through cytokines[2]. The pathophysiological changes seen in sepsis are often not due to the infectious organism itself but instead to the uncontrolled production of pro-inflammatory cytokines, including tumor necrosis factor (TNF)-α[3]. TNF-α, which is produced by LPS-activated target cells, is thought to be LPS's primary mediator[4]. TNF is known to have cytotoxic and cytostatic effects on certain tumor cells, and with a pivotal role in inflammatory reactions and regulation of immunological response[5,6]. TNF-α was mainly produced in the early stage of endotoxemia, and decreased obviously from 6 h to 9 h after challenge[7]. Specific intracellular signaling pathways that modulate cytokine gene expression probably exist in target cells and may represent novel targets for tomorrow's antisepsis therapies[8]. Mitogen-activated protein kinases (MAPKs) are members of discrete signaling cascades that form focal points for diverse extracellular stimuli and function to regulate fundamental cellular processes[9]. The p38 MAPK, one class of MAPK family, is involved in intracellular signals that regulate a variety of cellular responses during inflammation[10].

CCK-8 possessed both excitatory and inhibitory action on contractile activity of different regions of stomach in guinea pigs[11]. In the spleen, CCK-8 is formed in high abundance in the white pulp where it appears to surround cell clusters. CCK-8 is a chemoattractant for human monocytes and rat macrophages, enhances human eosinophil chemotaxis induced by PAF and LTB4 in allergic patients. Our previous study demonstrated that CCK-8 could protect animals from LPS-induced ES and the protective effect of CCK-8 may be related to its modulation of cytokines[12-14]. Spleen, one of the targets stimulated by LPS, is an important immunological organ. In this study, we examined the expression of TNF-α with reverse transcribed polymerase chain reaction (RT-PCR) and enzyme linked immunoabsorbant assay (ELISA) in spleen and further investigated the mechanism involving p38 MAPK.

MATERIAL AND METHODS

Material

CCK-8 (sulfated), LPS (*E.coli* LPS, serotype 0111:B4), leupeptin, pepstatin A and Triton X-100 were all purchased from Sigma, and aprotinin from Boehringer. The ELISA kit was purchased from Medsystem (Austria) for assay of TNF-α. Total RNA isolation system and access RT-PCR system were purchased from Promega (USA). Monoclonal anti-p38 MAPK (diphosphorytlated p38) was purchased from Sigma (USA). All other reagents used were of analytic grade. Healthy male Sprague-Dawley rats (n=52, weighing 150 g-200 g BW) were obtained from Experimental Animal Center of Hebei Province.

Methods

The rats were randomly assigned to four groups and injected different agents via caudal vein. A bolus dose (8 mg·kg^{-1}, 5 g·L^{-1}) of LPS was injected to group receiving LPS and a bolus dose (40μg·kg^{-1}, 0.05 g·L^{-1}) of CCK-8 was given to the group of CCK-8+LPS 10 min before injection of LPS. Saline or CCK-8 (40μg·kg^{-1}) was administered separately to the control or CCK-8 group. Catheter was inserted into femoral artery and Mean arterial pressure (MAP) was detected using physiological record instrument (RM-6000, Japan). The agents were injected through caudal vein after the MAP became steady.Animals were sacrificed at 30 min, 2 h or 6 h after treatment, spleen was rapidly excised, rinsed of blood. The samples were stored at -80℃. The samples collected at different time points were for the assay of TNF-α mRNA using RT-PCR, samples collected at 2 h were for the assay of TNF-α protein by ELISA and at 30 min for the expression of p38 MAPK by Western blot.

TNF-α dection by ELISA

Frozen tissue samples were weighed and placed in homogenization buffer (4℃) at a ratio of 100 mg per milliliter of buffer. Buffer contained a protease-inhibitor cocktail including 1 mmol·L^{-1} phenylmethylsulfonglfluoride (PMSF), 1 mg·L^{-1} pepstatin A, 1 mg·L^{-1} aprotinin, and 1 mg·L^{-1} leupeptin in phosphate-buffered saline solution, pH7.2, containing 5 g·L^{-1} Triton X-100. Samples were homogenized and centrifuged at 18 000 r·min^{-1}, 4℃. Tissue supernatants were analyzed for TNF-α using ELISA kit.

Analysis of TNF-α mRNA by RT-PCR

Total RNA was extracted from spleen tissues. The concentration of RNA was determined from absorption at 260 nm. The primers for TNF-α and β-actin were as follows: β-actin (420bp), 5'-GAGACCTTC AACACCCAGCC-3', 5'-TCGGGGCATCGG AACCGCTCA-3'; TNF-α(468bp), 5'-GGATCATCTTCT CAAAACTCG-3', 5'-TCACAGAGCAATGACTCCAAA-3'. Polymerase chain reactions were performed in a 50 μL reaction volume. RT-PCR reaction was run in the following procedures: 48℃ for 45 min, 1 circle; 94℃ for 2 min, 1 circle; 94℃ for 30 s, 57℃ for 30 s, 68℃ for 1 min, 30 circles; 68℃ for 7 min, 1 circle. Six μL PCR product was placed on to 15g·L^{-1} agarose gel and observed by EB staining using Gel-Pro analyzer.

Detection of p38 MAPK expression by Western blot

Spleen was rapidly excised 30 min after agents administration. Tissues were homogenized with PBS (pH 7.2) and centrifuged at 4 ℃, 18,000 r·min^{-1} for 10min.Protein contents were detected in supernatants by coomassie brilliant blue (CBB). Sample loading buffer was added, and each sample was boiled for 8 min prior to loading equal content of protein onto a 12g·L^{-1} SDS-polyacrylamide gels, transferred to polyvinylidene fluoride (PVDF) membranes, and incubated with phospho-specific anti-p38 MAPK. Being washed three times in T-PBS, membranes were incubated in horseradish peroxidase-linked secondary antibody for 1 h at room temperature. Membranes were again washed three times with T-PBS and stained with diaminobenzidine (DAB).

Statistical analysis

Data were reported as $\bar{x}\pm s$. Statistical differences between values from different groups were determined by one way ANOVA and Newman-Keuls q test. Significance was set at $P<0.05$. Gel-Pro Analyzer was used to analyze the PCR and Western results.

RESULTS

Changes of MAP

There was no significant difference between groups before treatment. LPS administration resulted in a significant sustained decrease in MAP during the period of 2 h, decreased to (7.82±0.43) kPa 30 min after LPS administration and restored to (9.33±0.63) kPa by pretreatment with CCK-8 (Figure 1).

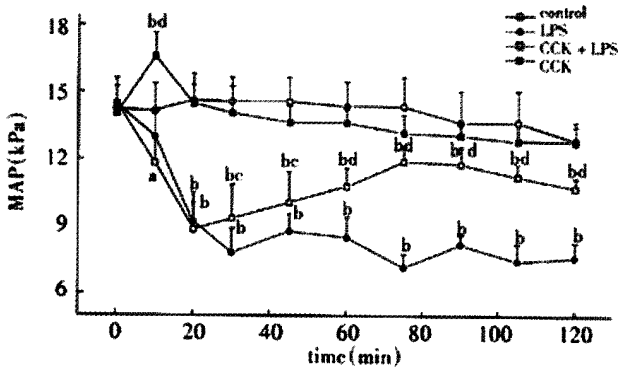

Figure 1 Mean arterial pressure (MAP) of animals injected normal saline, LPS, CCK+LPS and CCK, n=6. [a]$P<0.05$, [b]$P<0.01$, *vs* Control, [c]$P<0.05$, [d]$P<0.01$, *vs* LPS.

TNF-α content in spleen 2 h after LPS

Spleen TNF-α content became significantly higher 2h after administration of LPS as compared to the control animals (941 ±149) ng·L^{-1} *vs* (282±30) ng·L^{-1}, $P<0.01$, while CCK-8 significantly inhibited the LPS induced increase of TNF-α (462±87) ng·L^{-1},$P<0.01$. No significant changes were noted in TNF-α content following CCK-8 administration compared with normal saline administration (Figure 2).

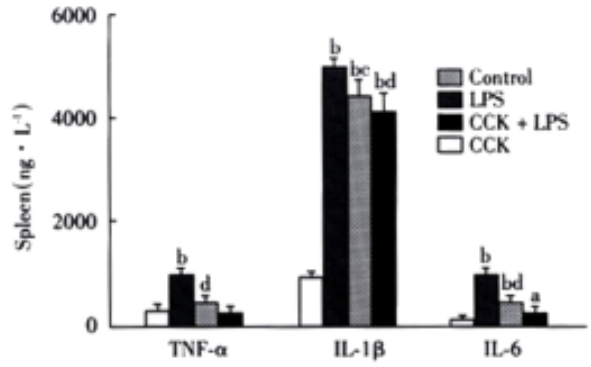

Figure 2 Effects of CCK on TNF-α, IL-1β and IL-6 2 h(TNF-α) or 6 h (IL-1β and IL-6) following LPS administration. n=6. [a]$P<0.05$, [b]$P<0.01$, *vs* Control; [c]$P<0.05$, [d]$P<0.01$, *vs* LPS.

RT-PCR detection of TNF-α

TNF-α mRNA in spleen was detected by RT-PCR analysis. The results showed that the spleen of rats 30 min and 2 h after LPS administration expressed the gene coding for TNF-α because RT-PCR generated a DNA fragment corresponding to the predicted length, 468bp, of the TNF-α amplification product. The expression of TNF-α decreased in CCK-8+LPS group compared with LPS group. The ratios of β-actin at 30 min and 2 h were (85±8)% and (57±7) % in LPS group, while it decreased to (30±6)% and (16±2)% respectively in CCK-8+LPS group. The TNF-α amplification product was not detected 6 h after agents administration. In each tissue sample, all β-actin amplification products were of 420bp length (Figure 3).

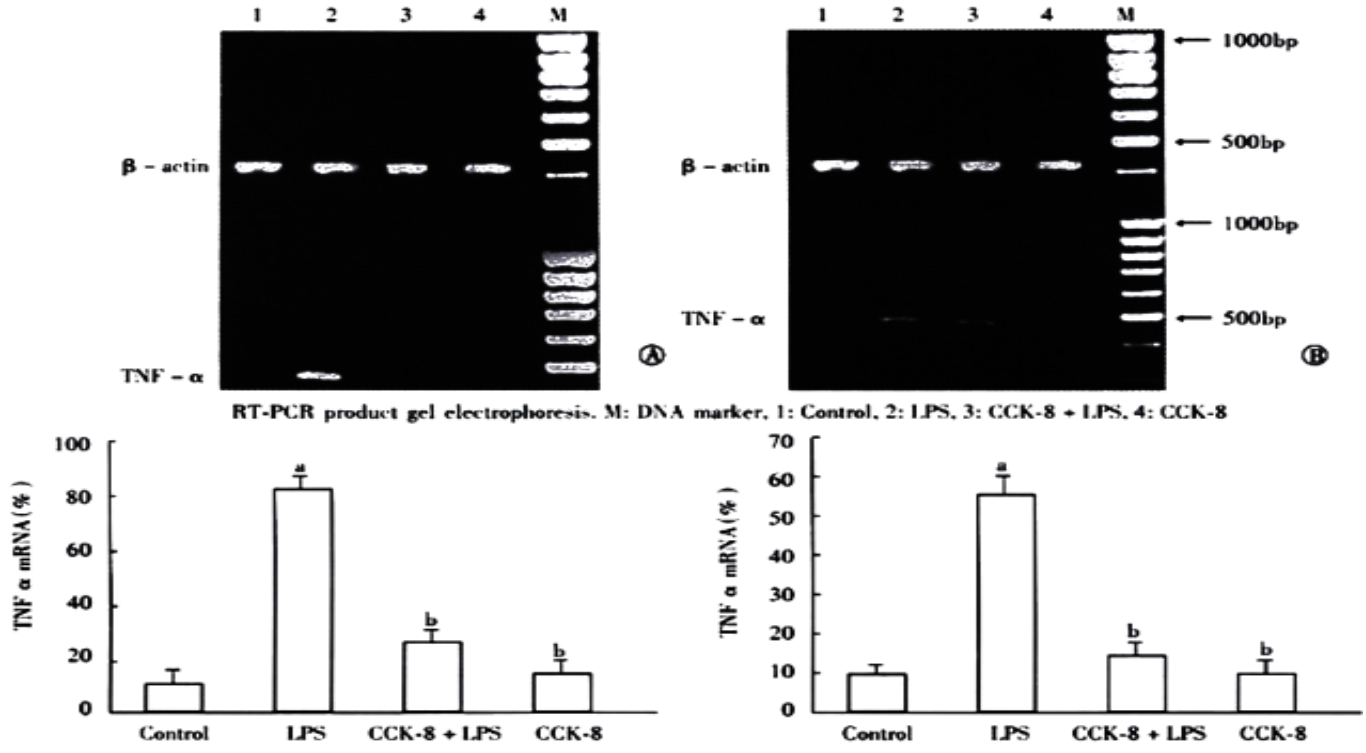

Figure 3 Effect of CCK-8 on LPS-induced TNF-α mRNA expression. Total RNA from the rat spleen was extrated at 30 min(A) or 2h(B) after LPS administration. n=3. ^aP<0.01 *vs* Control; ^bP<0.01 *vs* LPS.

Analysis of p38 MAPK expression by Western blot

Significant phosphorylation of p38 MAPK was observed in the spleen of rats 30 min after LPS administration, the densitometry units (DU) of LPS group is 5.84 times that of control. CCK-8 can enhance LPS-induced phosphorylation of p38 MAPK significantly, the DU of CCK-8+LPS group is 10.74 times that of control. Phosphorylation of p38 MAPK was also observed in control and CCK-8 groups (4.64 times of control)(Figure 4).

DISCUSSION

Although macrophages are the main secretors of TNF-α, other spleen cells, such as lymphocytes, may secret low amounts of TNF-α and may influence macrophage ability to generate and secrete the cytokine[15]. This has led to the suggestion that spleen is an important organ in the production of TNF-α following LPS administration, releasing the cytokines into the circulation, thereby contributing to the elevated serum level of the cytokine. Numerous TNF-α and IL-1β mRNA positive cells were observed using *in situ* hybridization in the marginal zone and in the red pulp of the spleen in rats after LPS injections, whereas sections from saline-treated animals showed minimal cytokine mRNA expression[16]. LPS resulted in a greater increase in circulating levels of TNF-α which peaked at 90 min and decreased at 150 min after LPS administration[17]. We found that CCK-8 significantly inhibits LPS-induced increase of TNF-α in spleen, which agreed with the results we obtained before[14]. While Cunningham *et al*[18] reported that CCK-8 stimulated production of TNF-α, IL-1β and IL-6 by monocytes, but was considerably less than LPS response. Later studies[19] suggest that the increase of cytokines induced by CCK-8 may be due to the detection of endotoxin/LPS in medium.

Despite convincing data indicating the protective function of

CCK-8 to organism in ES, the precise mechanism remains elusive. Our previous studies showed that CCK can protect pulmonary arterial endothelium against detrimental effects by LPS or TNF-α[20,21] The anti-inflammatory effect of CCK-8 shown in this study may mediate the cell protective function of CCK-8 in ES. The p38 MAPK pathway may be involved. Members of the MAPK cascade are considered to play key roles in signal transduction pathways activated by a wide range of stimuli[22]. CCK is known to activate MAPK signaling pathways[23]. Activated MAPK then tranduces into the nucleus and phosphorylates the ternary complex factor TCF which activates the expression of immediate-early genes, such as c-fos and egr-1[24]. The three best characterized members of this growing family of serine/threonine kinases are extracellular signal regulated kinase (ERK), c-jun N-terminal kinase (JNK) and p38. While ERK responds vigorously to growth factors and certain hormones, JNK and p38 are rather activated by stress stimuli and are widely believed to be part of the cellular stress response machinery[22,25]. The p38 MAPK is associated with immune cell activation, because this kinase is activated by a variety of inflammatory mediators. Challenge of neutrophils with LPS leads to activation of p38 but with slower kinetics than G-protein-coupled chemoattractant receptors[26]. CCK-A and CCK-B receptors are G-protein-coupled[27]. p38 is expressed in the pancreas and rapidly activated by CCK receptor agonist, cerulein[28,29]. p38 inhibition aggravated cerulein pancreatitis, indicating that p38 activation may support protection of the pancreas against damage through hyperstimulation stress. CCK activated p38 MAPK and increased the phosphorylation of HSP27[30]. The p38-MAPKAPK2-HSP27 pathway may be important for organ protection in the pancreas. Other studies indicate that p38 activation can indeed be protective[14]. Sodium salicylate (NaSal) significantly reduced TNF-alpha production in LPS-stimulated macrophages. LPS-stimulated activation of ERK and SAPK/JNK was inhibited by NaSal pretreatment. NaSal treatment of macrophages activated p38 MAPK independent of LPS stimulation[8]. Our data have raised the question of how the increase in p38 MAPK activity, a potent intermediate signal transducer involved in the production of TNF-α after LPS administration, could be associated with decreased production of TNF-α, detected by ELISA and RT-PCR analysis in the presence of CCK-8. LPS-induced production of TNF-α is regulated mainly, but not exclusively, through the p38 MAPK pathway[31]. TNF-α expression in T cells is regulated by several distinct MAPK pathways that functionally cooperate and are critical for transcriptional as well as for posttranscriptional processes[32]. Carbon oxide inhibited the LPS-induced production of TNF-α in mice, which was mediated by p38 MAPK activation[3]. Perhaps a delicate balance exists in the actions of p38, in that subtle cellular activation, as with LPS alone, is stimulatory for TNF-α synthesis, whereas hyperstimulation, as seen in spleen treated with CCK-8 and LPS, becomes inhibitory and thus results in downregulation of TNF-α.This modulation by CCK-8 of LPS-induced production of TNF-α exemplifies accumulating evidence emphasizing the complexity of the molecular regulation of TNF-α expression.

The results of the present study show that administration of CCK-8 prevents LPS-induced decrease of MAP and attenuates LPS-induced increase of TNF-α gene and protein expression in spleen. The different activation of p38 MAPK by LPS or CCK-8 may be involved in their effect on TNF-α production. CCK-8, therefore, might be used therapeutically to treat septic shock syndrome and other inflammatory disease states.

Abstract

AIM: **To analyze the influence of cholesterol liposome on the Ca^{2+} mobilization of cultured muscle cells in rabbit sphincter of Oddi's.**

METHODS: **New Zealand rabbit was sacrificed and the sphincter of Oddi (SO) segement was obtained aseptically. The SO segment was cut into pieces and cultured in DMEM solution. Then the smooth muscle cells were subcultured, and the 4th-7th passage cells were used for further investigation. The intracellular Ca^{2+} increase was measured under confocal microscope after the addition of 20mmol·L^{-1} KCl, 10^{-7}mol·L^{-1} acetylcholine and 10^{-7}mol·L^{-1} cholecystokinin, and different antagonists were added to analyze the Ca^{2+} mobilization pathway. After the cells were incubated with 1g·L^{-1} cholesterol liposome (CL)(molar ratio was~2:1), the intracellular Ca^{2+} increase was measured again to determine the effect of CL on cellular Ca^{2+} mobilization.**

RESULTS: **The resting cellular calcium concentration of cultured SO cell was 108nmol·L^{-1}±21 nmol·L^{-1}. The intracellular Ca^{2+} increases induced by 20mmol·L^{-1} KCl, 10^{-7} mol·L^{-1} ACh and 10^{-7} mol·L^{-1} CCK were 183%±56%, 161%±52% and 130%±43%, respectively. When the extracellular Ca^{2+} was eliminated by 2mmol·L^{-1} EGTA and 5μmol·L^{-1} verapamil, the intracellular Ca^{2+} increases induced by KCl, ACh and CCK were 20%±14%,82%±21% and 104%±23%, respectively. After the preincubation with heparin, the Ca^{2+} increases were 62%±23% and 23%±19% induced by ACh and CCK, as for preincubation with procaine they were 72%±28% and 85%±37% induced by ACh and CCK, respectively. Pretreatment with CL for 18h, the resting cellular Ca^{2+} concentration elevated to 152nmol·L^{-1}±26nmol·L^{-1}, however, the cellular Ca^{2+} increase percentages in response to these agonists were 67%±32%, 56%±33% and 34%±15%.**

CONCLUSION: **KCl elicite the SO cellular Ca^{2+} increase depends on influx of extracellular Ca^{2+}, ACh evoked the SO celllular Ca^{2+} increase is through the mobilization of intracellular Ca^{2+} pool and influx of extracellular Ca^{2+} as well, CCK excites the SO cells mainly through mobilization of intracellular IP3-sensitive Ca^{2+} store. After the incorporation with cholesterol liposome, KCl,ACh and CCK induced cellular Ca^{2+} increase percentages decreased.**

INTRODUCTION

Biliary tract diseases are becoming more common in recent years in China[1-10]. Sphincter of Oddi (SO) is an important part locatedat the distal part of biliary tract. And it is well accepted that SO plays an important role in the regulation of biliary system hydraulic pressure and bile flow[11-13]. SO dysfunction (SOD) is one of the causes responsible for biliary tract disorders[14-16], pancreatitis[17-18]and other disorders[19-21]. The mechanism underlying the occurrence of SOD is controversial, however, several investigators have noticed the relation between hypercholesterolemia and SOD[22-24]. Szilvassy *et al*[23] reported that patient has an impaired SO relaxation due to high serum lipids, but normalization of serum lipids improved the sphincter of Oddi relaxation. Wei *et al*[24] found the abnormalities in ultrastructure of SO in rabbits with hypercholesterolemia. Therefore, hypercholesterolemia might be one of causes of SOD. Meanwhile, the effect of cholesterol on gallbladder contractility has been interpreted by many authors[25-27], who found that the cholesterol incorporated into membrane can impair the cellular signal transdution and contractility as well.

The thin optical sectioning capability of laser scanning confocal microscopy rejects light from out-of-focus planes and permits imaging of $[Ca^{2+}]_i$ in single alive cells in optical sections less than 1ìm thick, which makes it possible to measure intracellular Ca^{2+} alteration instantaneously. So, this experiment was designed to analyze the effect of different agonists on Ca^{2+} mobilization of SO cells and cholesterol liposome on this process, in order to explore the mechanism that hypercholesterolemia affected the SO motility.

MATERIAL AND METHODS

Materials

The fluo 3/AM was obtained from Molecular Probes (USA), trypsin, HEPES, cholecystokinin-octopeptide (CCK) and bovine serum albumin (BSA) were from Sigma Chemicals (USA), and Dulbecco's modified Eagle's medium (DMEM) was from Gibco Laboratories(USA). The ethylene glycol-bis(β-amino ethyl ether)-N,N,N'-tetraacetic acid (EGTA), verapamil, procaine, egg phosphatidylcholine and cholesterol were obtained from Shanghai Chemical Co. (China), and the acetylcholine from Suzhou Chemical Co. The dimethyl sulfoxide (DMSO) was purchased from Beijing

Chemical Co. All other chemicals were commercial products of the highest available grade of purity.

Cells preparation

The New Zealand rabbits(<30d) were euthanized by intravenous injection of ketamine (20mg·kg^{-1}), and the segment of Oddi was removed quickly and washed by PBS solution containing penicillin(500×10^{3}u·L^{-1}). The experiments were conducted in accordance with the institutional ethical guidelines. Mucosa and serosa were dissected carefully, then washed twice with culture medium. The sphincter strip was cut into 1-2 mm^3 squares and placed into culture chamber, the chamber was everted and added into 3mL DMEM medium, and pH was adjusted to 7.4 by addition of 24mmol·L^{-1} $NaHCO_3$ before the use. After 3 h incubation at 37℃, when the tissue squares sticked to the chamber then turn over the chamber, replaced the medium every 4-5 d.

Subculture: Cells migrated from the explants 10-15d, as the chamber was confluenced with cells, then subcultured by addition with 2.5g·L^{-1} trypsin at 37℃ for 10 min. The trypsin was inactived by bovine serum, and the cell suspension was centrifuged at 1000r·min^{-1} for 7 min. The supernant was removed and cell pellet resuspended in fresh medium to a concentration of 5-7×10^5·mL^{-1} and repassaged into several chambers.

Differentiation: Three glass cover slips (18mm×18mm) placed into a 6cm diameter chamber, then cell suspension was added and incubated for 48 h. The slips covered with cells and fixed with 950mL·L^{-1} ethanol for 30min, washed with PBS for 5min and desiccated naturally. The β-actin staining was performed with immunohistological kits. The positive stain was localized in long, straight, noninterrupted fibrils scattered densely along the longitudinal axis. Under phase-contrast microscope, the cultured cells showed a characteristic "hill- and - valley" growth pattern, and the 4th-7th passage cells were used in this experiments.

Preparation of cholesterol liposome

Liposomes were prepared as described previously[28,29]. Cholesterol (200mg) and phosphatidylcholine (100mg) were added into 5mL chloroform and soluted completely. After the organic solution was evaporated, the container was placed in the desiccator overnight at 4℃. Then PBS (pH 7.2) was added into the container, the finalconcentration of CL was 10g·L^{-1}. After the sonication, the mixture was centrifuged at 21 000×g for 30min to sediment the undispersed lipid, then the supernatant was collected. The cholesterol-to-phospholipid molar ratio (FC/ PL) of the liposome was ~2:1. Control liposome (Cholesterol 100mg and phosphatidylcholine 200mg) was prepared in the same way, FC/PL molar ratio was ~0.5:1. Both liposomes were sterilized by filtration through a 0.45μm filter and mixed with sterile DMEM (Dulbecco's modified Eagle's medium) at a concentration of 1g·L^{-1}, which is in accordance with the serum concentration of rabbit model with hypercholesterolemia[57], pH was adjusted to 7.4, control and cholesterol-rich media were determined to be isomolar before experimentation.

Calcium measurement

A 10mm hole was made in a plastic chamber (Made in Denmark), then a 22mm glass coverslip was used to seal the hole tightly from the bottom. Then it was cleaned thoroughly and sterilized by ultra-violet lamp for 2h. The cell suspension was added into the chambers and incubated for 48h, they were incubated with or without CL overnight.

Preparation of fluo-3/AM: The concentration of free cytosolic Ca^{2+} in SMCs was determined using the fluorescent Ca^{2+} indicator fluo-3/ AM. Fifty μg fluo-3 was dissolved in 50μL dimethyl sulfoxide (DMSO) (about 885μmol·L^{-1}), and mixed thoroughly. Then it was subdivided into ten vials and stored at -20℃. Five μL of vial of stock solution was diluted by D-Hanks with a proporation of 1:200(V/V). The final concentration of fluo-3 was about 4.5μmol·L^{-1}. This loading solution should be used in 3 h, to maximize loading efficiency. Ca^{2+} measurement: The SO cells culture media was removed and washed for 10 min with D-Hanks solution. Remove the final wash solution, add the loading solution, incubate about 50 min at 37℃. Then remove the loading solution, wash the cells with D-Hanks, measure the fluorescence soon after loading. The measurement was performed under Bio-Rad MRC 1024 laser scanning confocal microscope, select cellular Ca^{2+} indicator from the method menu, then select the button for fluo-3, numerical aperture being 1.3, and pixel 512. The data was treated at Compaq Pentium 90. The peak excitation was about 506nm and the peak emission was about 526nm.

Solution

HEPES buffered solution (in mmol·L^{-1}): 134 NaCl, 6 KCl, 2 $CaCl_2$, 1 $MgCl_2$, 10 HEPES, 10 Glucose, 0.49 EDTA; D-Hanks: 138 NaCl, 5.4 KCl, 0.37 $Na_2HPO_4·H_2O$, 0.44 KH_2PO_4, 4.17 $NaHCO_3$. PBS: 138 NaCl, 2.7 KCl, 10 $Na_2HPO_4·H_2O$, 1.6 KH_2PO_4; High K+ solution contained the following (in mmol·L^{-1}): 120 NaCl, 20 KCl, 2 $CaCl_2$, 1 $MgCl_2$, 10 HEPES, 10 Glucose. Heparin was diluted by D-Hanks with 7×10^{5}U·L^{-1}, procaine concentration was 10mmol·L^{-1}.

Statistical analyses

Results were expressed as $\bar{x}\pm S\bar{x}$. Student's test or an analysis of variance (ANOVA) was performed to test the statistical significance as necessary,P<0.05 was regarded as significant.

RESULTS

Cultured SO cells showed a typical smooth muscle cell characteristics which presented as "hill-and -valley" and α-SM actin positive staining, filament was demonstrated along the longitudinal axis of the cells(Figure 1).Loading with fluo-3/ AM for 50min, the fluorescence distributed inhomogenously under LSCM, which may represent the Ca^{2+} pool, is inhomogenous. All experiments were conducted at room temperature(21℃-23℃). The value of Ca^{2+} concentration was calculated and based on the following equation:$[Ca^{2+}]_i = K_d \times (F-F_{min})/(F_{max}-F)$, where K_d is the dissociation constant for Ca^{2+} (316nmol·L^{-1}), Fmax is fluorescence maxima which was obtained by saturating intracellular signal values; Fmin is fluorescence minima which represented zero-Ca^{2+} signal. The resting cellular Ca^{2+} concentration was 108±21nmol·L^{-1}.

Figure 1 Cultured SO cells characterized with á-SM actin positive staining, filament were demonstrated along the longitudinal axis of the cells.

Distinctive agonists induced alteration of intracellular fluorescence

At the presence of extracellular Ca^{2+}, intracellular Ca^{2+} concentration changed under the LSCM after the addition of agonists, and it showed spatially heterogeneous alteration of fluorescent intensity in SO cells (Figure 2).

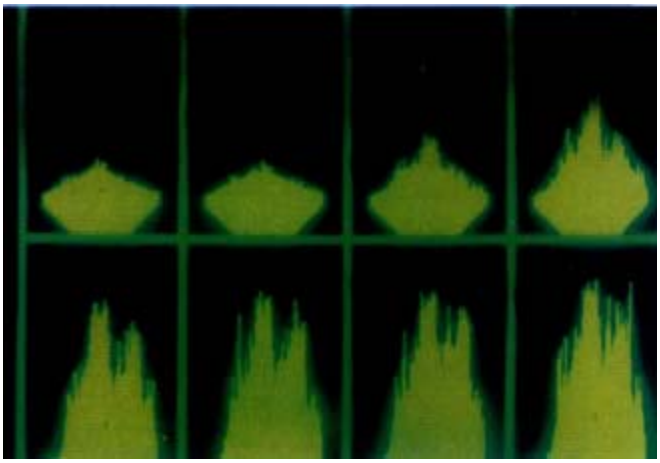

Figure 2 At the presence of extracellular Ca^{2+}, intracellular Ca^{2+} concentration changed under the LSCM(1 image·s^{-1}) after the addition of agonists, and it shows spatially heterogeneous alteration of fluorescent intensity in SO cells.

After the addition of 20mmol·L^{-1} KCl, the increase of intracellular fluorescence was 183±56% (n=4), 10^{-7} mol·L^{-1} ACh caused fluorescence increase was 161±52 % (n=4), 10^{-7} mol·L^{-1} CCK agonized an increase of 130±43 % (n=4), the maximum Ca^{2+} concentration were 297±66nmol·L^{-1}, 275±58nmol·L^{-1} and 251±45nmol·L^{-1}, respectively.(n=4, Figure 3).

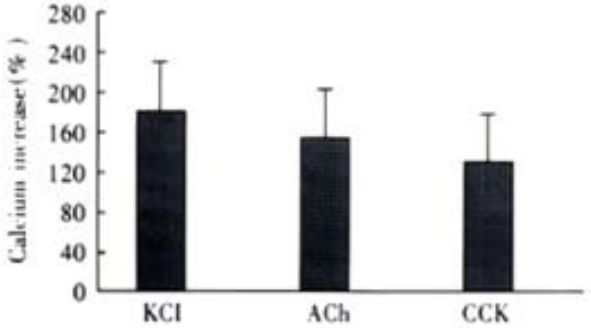

Figure 3 Intracellular fluorescence increases induced by different agonists. Ca2+ Concentration increased from resting level of 108±21nmol·L^{-1} to 297±66nmol·L^{-1}, 275±58nmol·L^{-1} and 251±45nmol·L^{-1}, respectively. ANOVA was performed for the analysis, F=0.9184, no significant difference between three groups (n=4).

The elimination of extracellular Ca^{2+} was performed by incubation of 2mmol·L^{-1} EGTA and 10μmol·L^{-1} verapamil for 10min. The extracellular Ca^{2+} was chelated by EGTA (a highly specific chelator for free Ca^{2+} ions) and inward Ca^{2+} current was inhibited by verapamil (inhibitor of L-type Ca^{2+} channels). Compared with the presence of extracellular Ca^{2+}, under this circumstance, the cellular fluorescence decreased from the peak rapidly.

At absence of extracellular Ca^{2+} treated by EGTA and verapamil, 20mmol·L^{-1} KCl induced an Ca^{2+} increase of 20%±14% (P< 0.01, *vs* control, t= 4.882), with maximal Ca^{2+} concentration of 131±17nmol·L^{-1}, which indicated the induction of KCl depends on the presence of extracellular Ca^{2+}. Under the same condition, ACh increased the cellular Ca^{2+} by 82%±21%, with a maximal Ca^{2+} concentration of 192nmol·L^{-1}±22nmol·L^{-1}. After pretreatment of heparin (inhibitor of IP3-sensitive Ca^{2+} release channel) and procaine(inhibitor of IP3-insensitive Ca^{2+} release channel), the cellular influoscence increase by 62%±23 % and 72%±28%, respectively, the maximal cellular calcium was 175nmol·L^{-1}±26nmol·L^{-1} and 186nmol·L^{-1}±30nmol·L^{-1}, and there was no significant difference from that of untreated cells (Figure 4).

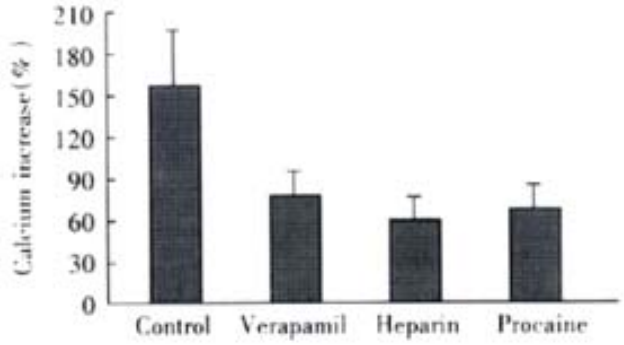

Figure 4 Effect of different antagonists on ACh induced cellular Ca^{2+} increase (x±Sx, n=4). Maximal Ca^{2+} concentration increased to 192±22nmol·L^{-1},175nmol·L^{-1}±26nmol·L^{-1} and 186±30nmol·L^{-1}, respectively. ANOVA was performed for the analysis, F= 1.324, with no significant difference between the three experimental groups (n=4).

CCK induced an cellular Ca^{2+} increase of 104%±23% after the elimination of extracellular Ca^{2+}. After incubation of heparin and procaine, CCK induced calcium increase were 23%±19% and 85%±37%, which was different from that of acetylcholine(Figure 5).

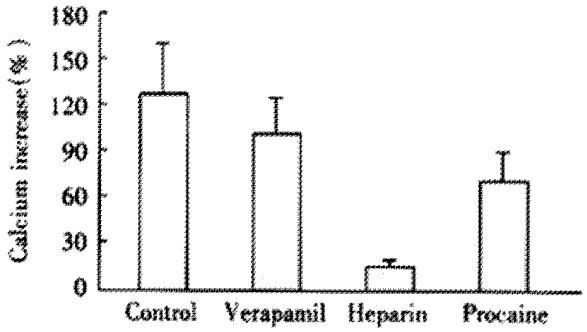

Figure 5 Effect of different antagonists on CCK induced cellular Ca^{2+} increase (x±Sx, n=4). Maximal Ca^{2+}concentration increased to 220±26nmol·L^{-1}, 133±21nmol·L^{-1} and 201±40nmol·L^{-1}, respectively. SNK-q test was performed, there was a statistical difference between heparin treated group and other two groups, P<0.01.

Intracellular calcium increase after the incubation of cholesterol liposome

After the incubation of 1g·L^{-1} CL for 18h, many CL incorporated into the membrane, the cells changed slightly as mentioned by others[45]. The intracellular calcium concentration of control liposome(FC/PL molar ratio with~0.5∶1) treated cells were 117±19nmol·L^{-1}, there was no significant difference as compared with untreated cells. However, the resting cellular Ca^{2+} concentration was elevated obviously by incubation of CL(FC/PL molar ratio with ~2:1), which was 152±26nmol·L^{-1}. But, after addition of agonists, the Ca^{2+} concentrations increased to 257±54nmol·L^{-1}, 238±57nmol·L^{-1} and 204nmol·L^{-1}±26nmol·L^{-1}, respectively, the calcium increase percentages were significantly decreased, the celllular influorescence increases induced by KCl, ACh and CCK were 67±32%(t=3.597), 56±33% (t=3.410) and 34±15%(t= 4.216), respectively,(P<0.05,*vs* control) (Figure 6).

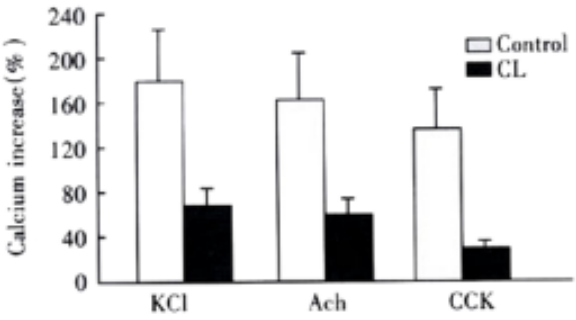

Figure 6 Effect of cholesterol liposome on cellular Ca^{2+} mobilization ($x\pm Sx$, n=4). Agonists induced cellular influorescence increase percentages were markedly less than that of control group.

DISCUSSION

The present study shows that Ca^{2+} mobilization of SO cells evoked by potassium, acetylcholine and cholecystokinin were impaired after the cells incubated with cholesterol liposome (CL). And it also indicated that CL affects the different pathways of Ca^{2+} mobilization, for our results demonstrated that KCl induced intracellular Ca^{2+} increase depe nds on the extracellular Ca^{2+} influx, acetylcholine may agonize the Ca^{2+} increase through both intra- and extracellular pathway, while CCK elicited SO cells via mobilizing intracellular Ca^{2+} store. These observations agree with other authors' in gallbladder muscle cells[30-34].

Based on literatures and our results, potassium excited the smooth muscle cells depend on Ca^{2+} influx through L-type voltage-dependent Ca^{2+} channel which could be inhibited by verapamil. As for acetylcholine and cholecystokinin, 2mmol·L^{-1} EGTA and 10ìm verapamil could not inhibit the cellular Ca^{2+} increase completely, demonstrating that both Ach and CCK elicit SO cells do not depend on influx of extracellular calcium. However, heparin could inhibit the cellular Ca^{2+} increase induced by CCK, which indicate a CCK evoked Ca^{2+} increase of SO cells through IP3-sensetive pathway.

The normal function of SO is the precondition of biliary tract homeostasis, and the motility was under the coordination of hormone and innervation[35-38]. SOD is responsible for many disorders including gallbladder stasis,stone formation and unexplainable upper abdominal ache post-cholecystectomy[13]. Additionnally, it was proved that the occurrence of SOD was correlated with intestinal dysmotility[20,39,40] and it was also correlated with recurrent and chronic pancreatitis[41,42]. On the other hand, most researches on SO were concentrated on the SO manometry, in such a situation, the results and conclusions were always full of discrepancy due to the complex effect of hormone and nerve or differences in species[12,13]. Therefore, isolated and cultured SO cells were used to study its characteristics in order to rule out complex influences *in vivo*[43-46].

It was well known that motility regulation of smooth muscle cells depends on several mechanisms, including: influx of extracellular Ca^{2+}, intracellular Ca^{2+} mobilization and sensitivity modulation of intracellular Ca^{2+}. If this process was inhibited, the contractility will be impaired. In our previous experiments, high molar ratio CL (molar ratio~2:1) impaired the SO muscle cell contractility[43], whereas, low molar ratio CL(0.5:1) had no effect on cells contractility. According to previous literatures,cholesterol enrichment of the SMC membrane occurs rapidly, and the aortic smooth muscle cells in hypercholesterolemic rabbit has impaired relaxation[47-49], and reduced contraction as well[50]. Cholesterol incorporation into membrane could also result in an alteration of membrane conduction of ions[51,63]. Because the cholesterol liposome was readily incorporated into cells membrane, that the duration, CL and cells incubation needed, was not a routine one. In another previous experiment, we used 2h for incubation[43]. Broderick *et al* used 3h in the study of CL effect on arterial smooth muscle[50].

Our aim was mainly to observe the Ca^{2+} mobilization alteration affected by CL. There are many evidence *in vivo* and *in vitro* showing an impaired contractility in human and animal gallbladders with cholesterol stones[28,52]. Li *et al*[53] measured the actin and myosin isoform in gallbladders smooth muscle following feeding in prairie dogs and found that cholesterol feeding induced a shift in actin isoforms, but whether it is really responsible for the decreased contractility is uncertain. It was proved that cholesterol could alter smooth muscle membrane and cell function by changing the physical state of the membrane phospholipid bilayer[54], and therefore affect the function of integral membrane proteins, such as Ca^{2+} and potassium channels, as well as transmembrane receptors[26]. Membrane fluidity decreased with excessive cholesterol incorporation and subsequently restricted optimal function of membrane proteins, such as receptor binding of ligands, receptor coupling with G proteins and activation of enzymes[55, 56]. Thus, it could explain the impaired activation of signal transduction pathways responsible for contractile responses to receptor-dependent agonists, such as CCK and ACh. It has been shown that muscle cell contraction, membrane fluidity, membrane cholesterol and phospholipid content are reversible after the membrane cholestrol was leached out by incubation of cholesterol-free liposomes for several hours[27,28]. Whether the effects of cholesterol liposome observed in this study were due to cytotoxicity Other authors reported that high concentration of CL might have influence to cultured muscle cells[46]. The similar procedures had been done by many reseachers[27,29,64], and the cholesterol was within the serum concentration range of hypercholesterolemia rabbit model[57]. So, the cytotoxicity of liposomes to cells in this study, if any, might be unconsiderable.

The effect of cholesterol on SO has not been elucidated yet. SO manometry of hypercholesterolemic rabbit shows that abnormal SO motility had been observed before the formation of gallstone[57], basal pressure rose and amplitude of phasic contraction decreased that represented an impaired relaxation and decreased contraction, too. Szilvassy *et al*[58] observed that the SO of hypercholesterolemic rabbits restored the nitrergic transmitter mediated relaxation by farnesol treatment. The SO segments of rabbits, prairie dogs and guinea pigs belong to extraduodenal type[59-61] and were able to pump fluid from the bile duct to duodenum. Therefore, it could be concluded that cholesterol affected the SO contractility which was responsible for a reduced peristaltic function to pump bile into duodenum. CCK receptors located in SO neurons and muscle cells were G-protein coupled receptors[62] which could be affected by excessive cholesterol incorporation resulting in decreased release of neural mediators or an impaired contraction. Therefore, we can conclude that hypercholesterolemia could not only impair relaxation but also contraction of rabbits sphincter of Oddi, which could lead to the occurance of SO dysfunction.

In summary, the present study shows that potassium induced rabbits SO cells Ca^{2+} increase depends on Ca^{2+} influx through L-type channel; acetylcholine induces SO cells Ca^{2+} increase from both intra- and extra-cellular Ca^{2+} release; cholecystokinin evokes the SO cells by mobilizing IP3-sensitive Ca^{2+} stores; and cholesterol liposome could affect the intracellular Ca^{2+} increase induced by

different agonists.

Abstract

AIM: **To investigate the diagnostic standard for early identification of severe acute cholangitis in order to lower the incidence of morbidity and mortality rate.**

METHODS: **A diagnostic standard was proposed in this study as follows: documented biliary duct obstruction by ultrasound or computerized tomography or other imaging tools with the manifestation of systemic inflammatory response syndrome (SIRS). The surgical procedures included emergency common bile duct exploration with T tube insertion or cholecystostomy with secondary common bile duct exploration. And incidence of postoperative multiple organ dysfunction syndrome (MODS), duration of systemic inflammatory response and hospital mortality were analyzed.**

RESULTS: **Fourty-three patients conforming to the diagnostic standard described above were employed in this study. 1 patient was admitted in acutely ill condition and complicated with acute relapse of chronic bronchitis, cholecystostomy procedure was performed but the patient was complicated with postoperative acute lung injury which was treated by assisted mechanical ventilation for 5 d; 2 wk later, two-stage common bile duct Exploration and T tube insertion were performed. The remaining 42 patients underwent primary common bile duct exploration and T tube insertion, 1 developed acute lung injury and recovered 3 d later, 2 patients developed acute renal dysfunction, 1 of which recovered 2 d later and the other died on d 4. For all patients, the postoperative systemic inflammatory response persisted for 2 to 8 d with median of 3 d.**

CONCLUSION: **Early diagnosis of severe acute cholangitis can be made using this diagnostic standard, further development of systemic inflammatory response could be prevented and incidence of MODS as well as hospital mortality decreased.**

INTRODUCTION

Severe acute cholangitis takes a severe clinical course, systemic inflammatory response syndrome (SIRS) appears at early stage and followed by multiple organ dysfunction syndrome (MODS), which signifies poor prognosis[1-8]. Recently, the perioperative management and technique of anesthesia have been much improved, however, the mortality and morbidity of the patients with severe acute cholangitis remain high, especially in local hospitals. This study was performed to investigate the standard for early diagnosis of severe acute cholangitis and its surgical timing in order to decrease the complications.

MATERIALS AND METHODS

Diagnostic criteria

In this study, we proposed the diagnostic criterion for severe acute cholangitis as follows: documented obstruction of biliary duct by ultrasound, CT or other radiological imaging[9-19] if the patient presents two or more of the following conditions: ①temperature more than 38℃ or less than 36℃, ②elevated heart rate more than 90·min^{-1}, ③ respiratory rate more than 20·min^{-1} or $PaCO_2$ less than 4.27KPa, and ④white blood cell count more than $12\times10^9\cdot L^{-1}$, less than $4\times10^9\cdot L^{-1}$, or immature granulocyte more than 0.10[20].

Clinical materials

Between January 1997 and November 2000, 43 consecutive patients conforming to proposed diagnostic criterion for severe acute cholangitis were admitted in surgical department of our hospital, of which 26 were male and 17 were female, the average age was 53±8 years and the average APACHE II score was 9. 2±2.6. 27 patients had stones only in common bile duct; the remaining 16 had both intrahepatic and extrahepatic stones.

After admission, proper preoperative preparation was carried out and all patients underwent emergency biliary duct decompression, including common bile duct exploration with T tube drainage or cholecystostomy with secondary choledochostomy.

After operation, patients were intensively monitored on multiple organ systems. Hospital mortality was taken as death during hospitalization for the severe cholangitic attack, and death attributed to the underlying biliary sepsis in the absence of other obvious contributory cause within 48 h after emergency biliary duct drainage.When postoperative serum creatinine doubled or exceeded $180\mu mol\cdot L^{-1}$ among patients who had a normal preoperative value or when it increased $100\mu mol\cdot L^{-1}$ over its deranged preoperative level, the diagnosis was renal dysfunction. Respiratory dysfunction was taken as the necessity for mechanical ventilation at any time after admission because of acute cholangitis. And duration of systemic inflammatory response was measured.

RESULTS

One patient aged 65 years was admitted in critically ill condition with APACHE II score of 15 and was complicated with acute relapse of chronic bronchitis, therefore, cholecystostomy procedure was performed but he was complicated with postoperative acute lung injury which was treated by assisted mechanical ventilation for 5 d; 2 wk later, common bile duct was explored and T tube inserted. After 20 d, he was discharged. The remaining 42 patients underwent first-stage common bile duct exploration and T tube placement, however, 1 developed acute lung injury and was managed by mechanical ventilation for 3 d; 2 patients developed acute renal dysfunction, one of which recovered 2 d later and the other died on d4. For all

patients, the postoperative systemic inflammatory response persisted for 2 to 8 d with median of 3 d.

DISCUSSION

Acute cholangitis caused by obstruction of common bile duct can easily induce systemic inflammatory response and later MODS or MOF, the clinical mortality is high. In China, a symposium on hepatic and biliary duct stones was held by Chinese Association of Surgery at Chongqing city in 1983, and the diagnostic standards for severe acute cholangitis was recommended. The diagnosis was met when patient presents shock or two of following six parameters: nervous symptoms; pulse more than $120 \cdot min^{-1}$; white blood cell counts more than $20 \times 10^9 \cdot L^{-1}$; temperature more than 39℃ or less than 35℃; biliary duct filled with pus and highly pressured; positive blood culture. In western country, diagnosis of severe acute cholangitis was established when septic shock or mental obtundation was confirmed in patients with acute cholangitis[21]. However, many patients with severe acute cholangitis were not manifested with nervous dysfunction and hypotension; the incidence of Reynolds' pentad was low; recent study showed that culture is far less sensitive than PCR method in detecting microbes present in blood[22-23]; and with progress in technique of modern imaging, obstruction of biliary duct can be identified early and accurately and proper management can be achieved timely; last but not least, patients with the diagnosis of severe acute cholangitis by this standard usually presented severe systemic inflammatory response, suggestive of the presence of multiple organ dysfunction, so if the patients were operated on at this time, second hit would ensue and course leading to MOF was accelerated[24], mortality increased accordingly. At that time, when diagnosis was established, biliary drainage was of immediate concern, the surgical procedures included common bile duct exploration and T tube insertion, or cholecystostomy when patient's condition was unstable, but mortality rate carried between 10 per cent and 40 per cent.[1-3, 25]

In the era of minimally-invasive surgery, when the diagnosis of severe acute cholangitis is confirmed, the principle of management has much changed[26-32]. Non-operative biliary decompression is attempted before any definitive surgical procedure is undertaken. A nasobiliary catheter by endoscopy can be left in place to provide short-term biliary decompression until the patient's cholangitis resolves. The goal of such treatment is to convert an urgent or emergent problem into one that can be managed in an elective setting.Emergent surgical decompression of the common bile duct is reserved for patients in whom endoscopic procedure is either unsuccessful or unavailable. Should a surgical procedure be necessary, the goal is to establish biliary decompression only by means of a choledochotomy, and placement of a large diameter T-tube. Overall, non-operative drainage can be accomplished with morbidity rates of less than 40 per cent and overall mortality of less than 10 per cent.

Lai *et al* in early 1990s conducted a randomized prospective study on the role of endoscopic biliary drainage for severe acute cholangitis, the diagnosis of severe acute cholangitis was based on the presence of either septicemic shock or evidence of progressive biliary sepsis including mental confusion and persistent or relapsing fever despite appropriate antibiotic treatment, however, the mortality rate remained up to 10 percent. Recently, they conducted a retrospective study to evaluate the combined endoscopic and laparoscopic approach in managing gallstone cholangitis, in their series, 60 patients had severe acute cholangitis defined by the presence of septic shock, mental confusion, or persistent high fever despite antibiotic treatment and the mortality rate among patients with severe acute cholangitis decreased to 5.0 per cent (3/60)[21]. They concluded that combined approach is safe and effective for managing gallstone cholangitis. Other authors had reported similar advantages of nonoperative decompression[27-30].

The advent of endoscopic retrograde cholangiopancreatography, endoscopic sphincterotomy and newer laparoscopic procedures including common bile duct exploration has remarkably decreased the mortality of severe acute cholangitis[33-37]. However, the performance of these procedures is dependent on training, technical skills and experience of the surgeon. In the hands of an experienced surgeon, a laparoscopic approach is reasonable for the treatment of acute cholangitis in the tertiary hospitals[33]. But in the primary or local hospitals which don't have the experienced endoscopic surgeon or equipment, the management of patients with severe acute cholangitis has to be turned to traditional procedures. Furthermore, a recent multicenter randomized trial comparing surgical treatment with endoscopic management in patients with common bile duct stones showed that surgical treatment was associated with lower major complications like MODS (4% *vs* 13%) and less retained stones (6% *vs* 16%) than endoscopic management[38]. And other complications of nonoperative management were also noted.[39-40]

As we know, in the situation of severe acute cholangitis, the intraductal pressure rises secondary to obstruction, bacteria and endotoxins can leak into the systemic circulation and induce systemic inflammatory response[4-7] and a frequent complication of this inflammatory response is the development of organ system dysfunction or failure[20, 41-42]. Therefore, the management of severe acute cholangitis should be based on the early awareness of the disease by clinicians, the objective of this study was to establish the early diagnosis of severe acute cholangitis.

An American College of Chest Physicians/Society of Critical Care Medicine Consensus Conference (ACCP/SCCM) was held in August 1991 to produce a series of universal definitions for SIRS (systemic inflammatory response syndrome), sepsis and other clinical conditions related to sepsis, the aim of the consensus conference was to improve our ability to make early detection of the disease possible, and thus allow early therapeutic intervention to decrease morbidity and mortality[20, 42]. Based on this background, we recommended a new diagnostic standard since January 1997, that was, SIRS manifestation with documented obstruction of biliary duct by imaging, and surgical procedure for decompression mainly was common bile duct exploration and T tube drainage. 43 consecutive patients conforming to proposed diagnostic criterion for severe acute cholangitis were employed in this study. 1 patient aged 65 years was admitted in acutely ill condition and complicated with acute relapse of chronic bronchitis, cholecystostomy procedure was performed but he was complicated with postoperative acute lung injury which was treated by assisted mechanical ventilation for 5 d; 2 wk later, two-stage common bile duct Exploration and T tube insertion were performed. The remaining 42 patients underwent primary common bile duct exploration and T tube insertion, however, 1 developed acute lung injury and recovered later; 2 patients developed acute renal dysfunction, one of which recovered 2 d later and the other died on d4. Therefore, all patients in this cohort were diagnosed and managed timely, preventing SIRS from further progressing, thus the incidence of MOD was low (9.3%, 4/43) and mortality rate decreased (2.3%, 1/43).

In conclusion, the preliminary results of this prospective study showed that if the systemic inflammatory response is identified early in the disease process of severe acute cholangitis, MODS can be effectively prevented and mortality decreased, the proposed definition for severe acute cholangitis is practical and should be clinically accepted. Furthermore, a randomized controlled prospective study should be done to confirm this conclusion.

Abstract

AIM: **To evaluate the effect of reactive oxygen species such as hydrogen peroxide on the progression of human colon cancer.**

METHODS: **Human colon carcinoma cell lines, LS174T and HCT8, were treated respectively with 10^{-5},10^{-7}or 10^{-9} mol·L^{-1} hydrogen peroxide for 24h, and co-cultured with human endothelial cell line ECV-304. The migration of ECV-304 induced by cancer cells was calculated and the expression level of vascular endothelial growth factor in cancer cells was determined by RT-PCR analysis and ELISA. Dactinomycin of 1.5mg·L^{-1} which could block transcription of cancer cells was applied to observing the effects of H_2O_2 on transcriptional activity and the relative half-life of VEGF mRNA. Finally, to evaluate the effect of H_2O_2 on NF-κB activity in colon cancer cells, NF-κB in cytoplasm and nucleus of the cells were detected with FITC-tagged antibody and its presence in the nucleus(Fn) *vs* cytoplasm(Fc) was monitored by measuring the green fluorescence integrated over the nucleus by laser scanning cytometry(LSC).**

RESULTS: **Exogenouse hydrogen peroxide of low concentration increased the migration of endothelial cell induced by colon cancer cells. When cancer cells were treated with 10^{-5} mol·L^{-1} H_2O_2, the migration number of endothelial cells induced by LS174T cells was 203±70, and the number induced by HCT8 cells was 145±65. The two values were significantly higher than those treated with other concentrations of H_2O_2 (P<0.01).The expression of vascular endothelial growth factor in cancer cells, which could be blocked by dactinomycin, were increased to a certain degree, while the relative half-life of VEGF mRNA was not prolonged after treatment with hydrogen peroxide. The activity of NF-κB in colon cells rose after the cells were exposed to hydrogen peroxide for 24h.The Fn values in HCT8 cells were 91±13 (0 mol·L^{-1} H_2O_2) and 149±40(10^{-5} mol·L^{-1} H_2O_2) (P<0.05),in LS174T cells were 127±35(0 mol·L^{-1} H_2O_2) and 192±11(10^{-5} mol·L^{-1} H_2O_2) (P<0.05). It is similar to the case of VEGF expression in cancer cells.**

CONCLUSION: **Hydrogen peroxide increases vascular endothelial growth factor expression in colon cancer cells, and it is likely that reactive oxygen species such as hydrogen peroxide facilitates the development of colon cancer.**

INTRODUCTION

Reactive oxygen species (ROS) can be easily produced in intracolonic cavity,due to large amounts of bacteria and dietary metabolites in it. Several reports on the relationship between ROS and cancer suggested that ROS such as oxygen radicals, hydroxyl radicals and hydrogen peroxide (H_2O_2), were involved in the pathogenesis of colon tumors[1-14]. H_2O_2, a special intermediate in redox reaction, is able to cross cell membranes in a free manner and modify protein and nucleic acid after being changed into radicals, and now it is thought to be a kind of signal molecular which plays an important role in the growth of tumor cells. Evidences have been given in some reports that H_2O_2 could promote cell growth and related gene expression in human tumors such as prostate cancer and breast cancer. Considering the special environment in colon and rectum we think it is necessary to evaluate the effects of ROS, especially H_2O_2, on the progression of colorectal cancer[15-27]. As angiogenesis, which induced by several factors such as vascular endothelial growth factor(VEGF), is often demonstrated in solid tumors, and thought to be an essential requirement for the development of malignant tumors[28-33], we investigated the effects of H_2O_2 on VEGF expression in colon cancers in this study to find evidences that ROS such as H_2O_2 plays a role in the progression of the tumor.

MATERIALS AND METHODS

Cell culture and culture conditions

Human colon cancer cell lines, LS174T and HCT8, and human umbilical vein endothelial cell line ECV-304 were purchased from American Type Culture Collection. These cell lines were cultured and maintained in RPMI1640 supplemented with 100 ml·L^{-1} fetal bovine serum at 37℃ in 50 ml·L^{-1} carbon dioxide and 950 ml·L^{-1}air.

H_2O_2 treatment of cancer cells and MTT assay

To determinate the effects of H_2O_2 on the growth of cancer cells, LS174T and HCT8 cells were grown (10^3 per well)on 96-well plates and treated with the culture media containing H_2O_2 (ten concentrations from 10^{-10}mol·L^{-1}to 10^{-1} mol·L^{-1})(300 ml·L^{-1}H_2O_2 solution was purchased from Sigma). After 48h, MTT assay showed that H_2O_2 inhibited the growth of cancer cells when its concentration was >10^{-5} mol·L^{-1}, while had no effect on cell growth when its concentration was ≤10^{-5} mol·L^{-1}. Therefore, those concentrations of H_2O_2, 10^{-5},10^{-7} and 10^{-9} mol·L^{-1}, were used in subsequent studies.

Endothelial cell migration induced by cancer cells

To clarify the effects of H_2O_2 on the migration of vascular endothelial cells, which could be promoted by VEGF, colon cancer cells were co-cultured with endothelial cells. LS174T and HCT8 cells were plated on 12-well plates (Falcon) at a density of 4×10^5 per well. Four hours later, the cells were washed with serum-free medium, and

exposed to 10^{-5},10^{-7} or 10^{-9} mol·L^{-1}H_2O_2 with the H_2O_2-containing complete media for 24h. Cell culture inserts with polyethylene terephthalate membranes(PET) and 8 ìm pore size (Becton Dickinson, USA) were then placed into the 12-well plates, and endothelial cells ECV-304 were seeded into the inserts with a density of 1×10^4. Six hours later, the cells on the upper surface of the PET membranes were wiped off completely, and the inserts were fixed and stained. The migration capacity of endothelial cells was estimated by counting the number of the cells beneath the PET membranes. The controls were the groups without cancer cells in the wells or without treating cancer cells with H_2O_2.

Expression of VEGF in colon cancer cell

To determine the effects of H_2O_2 on expression of VEGF, LS174T and HCT8 were grown to 90% confluence to avoid the effects of cell density and incubated in complete media in the presence of H_2O_2 (10^{-5},10^{-7} and 10^{-9} mol·L^{-1}) for 24h. Total RNA was extracted and resuspended in sterile RNase-free water for storage at -70℃. Access RT-PCR system (Promega) with the sensitive feature was used to determine the relative VEGF mRNA expression. All primers were synthesized by Life Technology, Hongkong.

VEGF sense: 5'-AAGCCATCCTGTGTGCCCCTG ATG-3'

β-actin sense: 5'-AACACCCAGCCATGTACGTTG-3'
antisense: 5'-CGGATGTCCACGTCACACTTCAT-3'

The 50μL mixture for reverse transcription and PCR amplification were added in one-tube including *AMV* reverse transcriptase 5U, Tf1 DNA polymerase 5U, $MgSO_4$, 20μL dNTP mixture, reaction buffer and 20pmol of each primer and 0.1μg total RNA sample. The condition for RT-PCR included a 48℃ reverse transcription, a 94℃ *AMV* inactivation and denaturation, a 60℃ annealing and a 72℃ extension. PCR amplification was subjected to 40 cycles. A volume of 10μL RT-PCR products was added in 20g·L^{-1} agarose gel containing 0.5mg·L^{-1} EB. After electrophoresis, the density and area of each band were measured using Fluro-sTM image software (Bio-Rad, USA). The relative RNA level of VEGF in tumor cells was calculated using the house-keeping gene β-actin as an internal control. The experiments were repeated at least four times.

Analysis VEGF transcriptional activity and VEGF mRNA half-life

To confirm that the effect of H_2O_2 on expression of VEGF in colon cancer cells was due to an increase in transcription, transcription activity of cancer cells was blocked by Dactinomycin (ActD, purchased from Sigma). LS174T cells were incubated in the presence of ActD(1.5mg·L^{-1}) for 4h before their exposure to 10^{-5}mol/L H_2O_2 in serum-free medium. Total RNA was extracted from cells after 24h, and RT-PCR analysis was made. Control cells were treated with ActD without H_2O_2.

To determine the effect of H_2O_2 on VEGF mRNA stability, LS174T cells were incubated in the presense or absence of 10^{-5}mol·L^{-1} H_2O_2 for 24h. Further transcription in cells was then blocked by addition of 1.5mg·L^{-1} ActD. Total RNA was extracted from cells at 0, 0.25, 0.5, 1, 2 and 4h. RT-PCR analysis was made and the relative level of VEGF mRNA expression at each point was compared with the control value (total RNA extracted from cells before ActD treatment was defined as 100%). The relative half-life of VEGF mRNA was determined by plotting relative VEGF mRNA expression levels on a semilogarithmic axis versus time.

Determination of VEGF protein levels

The VEGF protein levels in the supernantant were determined with an enzyme-linked immunosorbent assay (ELISA) kit. Examinations were repeated three times.

Activity of transcriptional factor NF-κB in colon cancer cells

To evaluate the effects H_2O_2 on NF-κB activity in colon cancer cells, NF-κB in cytoplasm and nucleus of the cells was detected with FITC-tagged antibody and its presence in the nucleus vs cytoplasm was monitored by measuring the green fluorescence integrated over the nucleus by laser scaning cytometry(LSC) according to the Deptala's report. Briefly, the cells were first attached to the mocroscope slides, and exposed to 10^{-5} mol·L^{-1} H_2O_2 for 0.5, 1,3,6,12 and 24h. The cells on slides were fixed and incubated with NF-κB P65 antibody (Santa Cruz) and FITC-tagged goated-antirabbit Ig (Santa Cruz)at room temperature. Cellular DNA was then counterstained by addition of a solution containing propidium iodide and RNase (Sigma). The cells were placed on microscope slides mounted under coverslips and analyzed by LSC. At least 10^3 cells were analyzed by LSC per slide. Fluorescence intensity in nucleus (Fn) and in cytoplasm (Fc) were detected and the activity of NF-κB was detected by estimating the value of Fn or Fn/Fc.

Statistics

When appropriate, data were expressed as $\bar{x}\pm s$. Analysis of variance and *t* test were applied to assess the significance of differences. Statistical significance was accepted at $P<0.05$.

RESULTS

H_2O_2 promotes the migration of endothelial cells induced by colon cancer cells

The migration of endothelial cells induced by cancer cells was promoted to a certain degree when LS174T and HCT8 cells were exposed to 10^{-5}, 10^{-7} or 10^{-9}mol·L^{-1} H_2O_2 for 24h. When cancer cells were treated with 10^{-5} mol·L^{-1}H_2O_2, the migration number of endothelial cells induced by LS174T cells was 203±70, and the number induced by HCT8 cells was 145±65. The two values were significantly higher than those treated with other concentrations of H_2O_2(Table 1,Figue 1). When there was no cancer cell in the co-culture system, the number of random motility of endothelial cells was about ten cells.

Upregulation of VEGF expression by H_2O_2

Electrophoresis of RT-PCR products showed the three positive bands, 243,375 and 509bp, representing VEGF121,VEGF165 andâ-actin respectively. The internal control demonstrated a stable expression in colon cells treated with each dose of H_2O_2 The analysis of electrophoresis showed that expression levels of VEGF were elevated in LS174T and HCT8 cells with H_2O_2 exposure, especially with 10^{-5} mol·L^{-1} H_2O_2 (Figure 2). After inhibition of transcriptional activity by ActD before addition of H_2O_2, induction of VEGF mRNA expression was completely inhibited in LS174T cells(Figure 3), indicating that H_2O_2 -induced VEGF expression possibly occurred at the transcriptional level. The relative half-life of VEGF mRNA in LS174T cells treated with H_2O_2 was similar to that of the cells without H_2O_2 exposure, demonstrating that the stability of VEGF mRNA was not affected by the treatment with H_2O_2 (Figure 4). To determine whether secretion of VEGF is increased by H_2O_2 in colon cancer cells, the supernatant was assayed and the results showed that H_2O_2 also promoted the VEGF protein expression. The levels of VEGF protein peaked when LS174T and HCT8 cells were incubated in the media containing 10^{-5} mol·L^{-1} H_2O_2. This situation is similar to the increase of VEGF expression.

Table 1 The migration of endothelial cells induced by colon cancer cells ($\bar{x}$±s)

Cell line	H_2O_2 in media(mol·L^{-1})			
	0	10^{-9}	10^{-7}	10^{-5}
LS174T	155±38	162±38	174±40	202±70[a]
HCT8	113±73	114±71	122±68	145±65[b]

[a]P<0.01, t=3.4751, *vs* LS174T, without H_2O_2 treatment [b]P<0.01, t=3.4183, *vs* HCT8, without H_2O_2 treatment

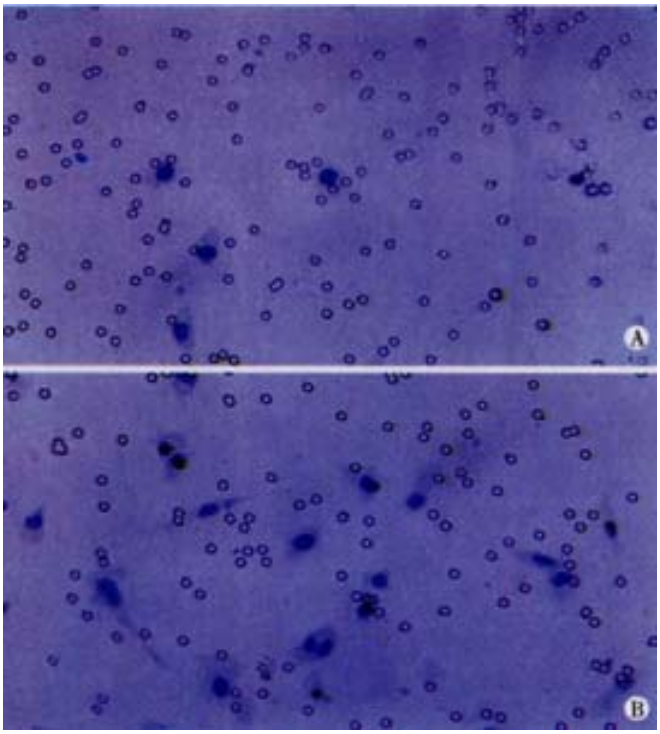

Figure 1 The migration of endothelial cells induced by LS174T cells was increased after the cancer cells were exposed to 10^{-5}mol·L^{-1} H_2O_2. The regular circles is the 8ìm pores located in PET membrane. A: induced by cancer cells without H_2O_2 treatment. B: induced by cancer cells with H_2O_2 treatment. ×200

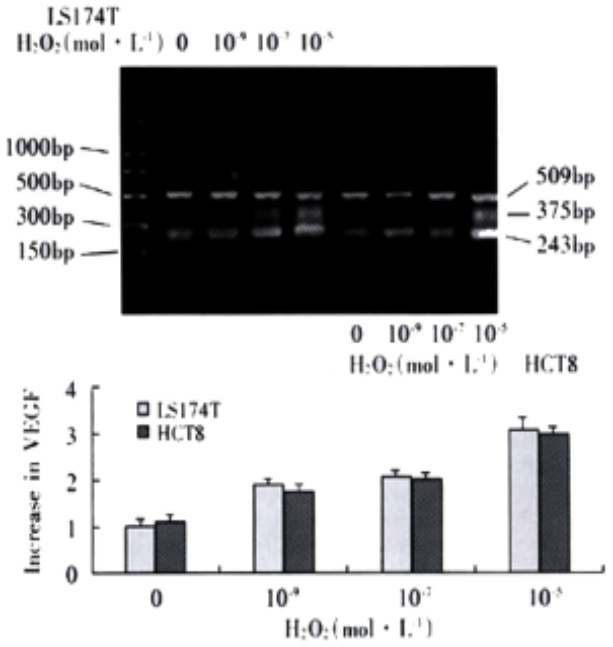

Figure 2 Expression levels of VEGF were increased in LS174T and HCT8 after exposure to 10^{-9},$10^{-7}$and 10^{-5}mol·L^{-1} H_2O_2, demonstrating a dose-dependent feature.

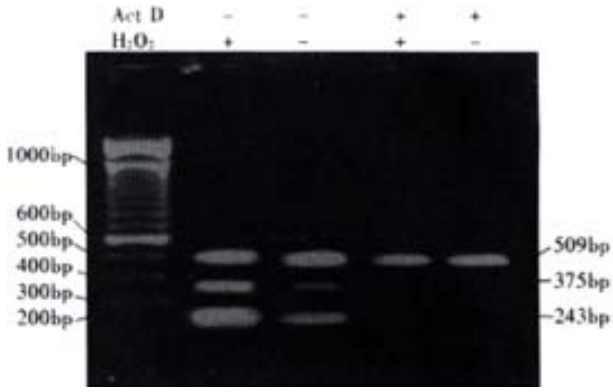

Figure 3 LS174T cells were treated with 1.5mg·L^{-1} Act D for 4h, followed by exposure to 10^{-5} mol·L^{-1} H_2O_2 for 24h. RT-PCR was done. The control was those without Act D treatment.

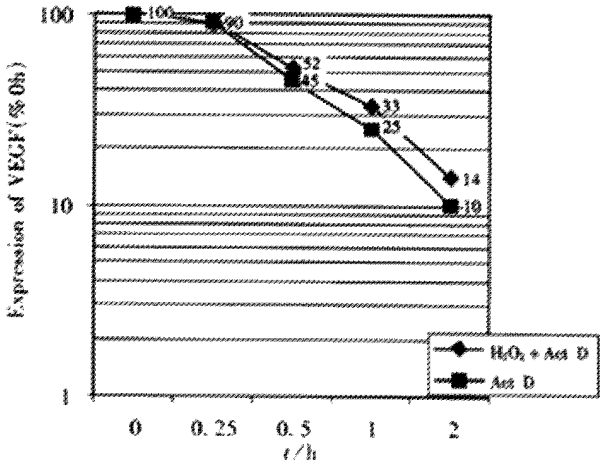

Figure 4 Effect of H_2O_2 on the half-life of VEGF mRNA in LS174T cells with or without H_2O_2 exposure following Act D treatment. No difference in half-life was showed between the two groups.

H_2O_2 increases the activity of NF-κB

LS174T and HCT8 cells were incubated in the presence of H_2O_2 (10^{-5}mol·L^{-1}) for 0.5,1,3,6,12 and 24h in complete medium. NF-κB activity peaked after exposure to H_2O_2 for 24h. We investigated the changes of NF-κB activity in LS174T and HCT8 cells treated with 10^{-5} , $10^{-7}$and 10^{-9} mol·L^{-1}H_2O_2 in media. Compared with the cells without H_2O_2 treatment, administration of 10^{-5} mol·L^{-1} H_2O_2 for 24h led to a more remarkable increase in green fluorescence intensity measured over nuclear area (Fn) (Table 2,Figure 5), indicating the increase of NF-κB activity in LS174T and HCT8 cells.

Table 2 Change of NF-κB activity in colon cancel cells ($\bar{x}$±s)

Cell line	H_2O_2(mol·L^{-1})	
	0	10^{-5}
HCT8 Fn	91±13	149±40[a]
Fn / Fc	0.75±0.14	2.18±0.54
LS174T Fn	127±35	192±11[b]
Fn / Fc	2.18±1.17	3.99±1.38

[a]P<0.05, t=3.4179, *vs* HCT8, no H_2O_2 treatment
[b]P<0.05, t=3.0981, *vs* LS174T, no H_2O_2 treatment

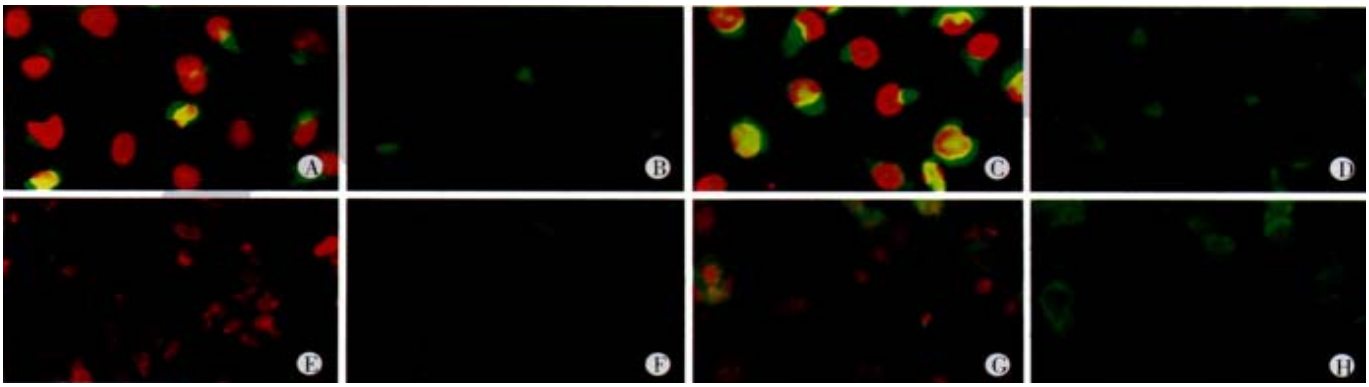

Figure 5 Measurement of nuclear and cytoplasmic NF-κB associated fluorescence by LSC. The red fluorescence represents the nuclear area, and the intensity of green fluorescence over nucleus(Fn) reflects NF-κB activity. A, B: LS174T cells without H_2O_2 treatment. C, D: Increase in NF-κB activity of LS174T cells with H_2O_2 exposure. E, F: HCT8 cells without H_2O_2 treatment. G, H: Increase in NF-κB activity of LS174T cells with H_2O_2 exposure.

DISCUSSION

The reactive oxygen species(ROS), which are ubiquitous and occur naturally in all aerobic species, may be divided into two categories :free oxygen radicals (·OH,·NO and $O_2^{\cdot-}$) and nonradical ROS such as H_2O_2. For decades, H_2O_2 has been one of the ROS that has been well investigated in flammatory response and oxidant-induced stress. Recently, numerous evidence has been presented to show that H_2O_2 can act as a signaling molecule involved in many cellular function such as apoptosis and proliferation[1-10].And the regulation of series of genes involved in carcinogenesis and progression is associated with the function of H_2O_2[3,5,6,9,11-14].Several reports have suggested that ROS such as H_2O_2 plays a role in the pathogenesis of tumor in colon, where there are a great deal of bacteria and dietary metabolites[15-27]. Diet rich in fat increased the formation of ROS in feces, which then possibly damaged the stem cells in the colon[20,22,26]. However, up to date, little information has been available about the role of H_2O_2 the special reactive oxygen intermediate, in the biological behaviors of colon cancer cells.

VEGF is a potent and unique angiogenic protein that stimulates capillary formation and has specific mitogenic and chemotactic activity for vascular endothelial cells[28].In colon cancer, VEGF levels are elevated and correlated with a poor clinical outcome[29-33]. VEGF expression is regulated by some pathological processes such as hypoxia[34-36]and by numerous cytokines and growth factors including interleukin1β, interleukin 6, platelet-derived growth factor, transforming growth factorβ, epidermal growth factor, hepatocyte growth factor, insulin-like growth factor, angiotensin Ⅱ, hypoxia -inducible factor Ⅰ and EIF4E etc.[37-52] Recently,oncogene p53 is also found to be a regulator of VEGF gene in colon cancer cells[53,54].In the present study, we found, to our knowledge, for the first time, that exogenous H_2O_2 could up-regulate the expression of VEGF in human colon cancer cells and the migration of endothelial cells induced by the cancer cells after we reviewed those results from RT-PCR assay, ELISA and migration experiment of endothelial cells. Considering the important role of VEGF in neovascurization in solid tumors, we believe that hydrogen peroxide may have the promoting effects on the progression of colon cancer. Related studies also found that hydrogen peroxide could not only increase the expression of VEGF in cultured human vascular smooth muscle cell, human retinal pigment epithelial, melanoma cells and glioblastoma cells, but also promote the growth of prostate and breast cancer cells[55-58].

NF-κB activation, as expressed by its translocation from the cytoplasm to nucleus, can be conveniently assayed by LSC by measuring the intensity of NF-κB-associated immunofluorescence over the area of cell nucleus and comparing it with the intensity over cytoplasm[59]. NF-κB, as a transcriptional factor controlling a variety of target genes such as adhesion molecular and apoptosis, is closely related to the pathogenesis and progression of tumors. NF-κB activity in cells like leukocyte, could be increased by hydrogen peroxide and NF-κB activation was an essential step before VEGF expression level was increased by hydrogen peroxide in murine osteoblastic cells[60,61].It is noteworthy in the present experiment that the increase of NF-κB activity was accompanied by the promotion of expression of VEGF in colon cancer cells exposed to hydrogen peroxide. Thereby, we estimate that the NF-κB activation may be the prerequisite of the effect of hydrogen peroxide on VEGF expression in colon cancer cells.

In view that such reactive oxygen species as hydrogen peroxide are likely to promote the development of colon cancer, it would be helpful in releasing oxidative stress by antioxidants in the colon cancer therapy.

Abstract

AIM: **To analyze the characteristics of ulcerative colitis (UC) in China.**

METHODS: **From 1981 to 2000, a total of 10218 patients of UC reported in Chinese medical literature and including our cases diagnosed were analyzed according to the diagnostic criteria of Lennard-Jones.**

RESULTS: **The number of cases increased by 3.08 times over the past 10 years (2506 patients were diagnosed from 1981 to 1990 while 7512 patients were diagnosed from 1991 to 2000).Lesion range were described in 7966 patients, 5592 (70.20%) were proctosigmoiditis or proctitis, 1792(22.50%) left-sided colitis, 582(7.30%) pancolitis. Among the 8122 patients, 2826 (34.8%) had first episode, 4272 (52.6%) had chronic relapse, 869 (10.7%) were of chronic persist type, 154 (1.9%) were of acute fulminant type. The course of the illness were described in 5867 patients, 4427(75.5%) were less than 5 years, 910 (15.5%) between 5 and 10 years, 530 (9.1%) more than 10 years. Six hundred and sixteen patients patients(6.1%) had extraintestinal manifestations.The mean age at the diagnosis was 40.7 years(range 6-80 years, and the peak ages 30-49 years). The male to female ratio was1.09. Among 270 patients diagnosed in our hospital, 36 had histories of smoking, there was no negative association between the severity of UC and smoking (P>0.05), 21 smokers were followed up for one year, 15 of them had given up smoking when the disease were diagnosed, and one year later, 7 patients relapsed, another 6 patients continued smoking, and one year later, 2 patients relapsed. Among 270 UC patients diagnosed in our hospital, 4 patients(1.48%) from 2 families had familial history of UC. Treatment was mentioned in 6859 patients, only 5-ASA and/or corticosteroid only in 1276 patients(18.6%), only Chinese herbs in 1377 patients(20.1%), combined Chinese and western medicine in 4056 patients(59.1%), surgery was performed in 87 patients(1.3%), other treatments in 63 patients(0.9%).**

CONCLUSIONS: **In China, number of UC patients increased significantly in the past 10 years. Lesions are commonly located to left side colon. The course is short with rare extraintestinal manifestations. The age of onset is relatively high. Males and females are nearly equally affected. No negative relation was found between smoking and severity of the disease. Familial relatives are rarely involved**

Traditional Chinese medicine(TCM) is widely used in the treatment of UC.

Jiang XL, Cui HF. An analysis of 10218 ulcerative colitis cases in China. *World J Gastroenterol* 2002;8(1):158-161

INTRODUCTION

Ulcerative colitis(UC) was first described by Wilks in 1859. In China, the first case of UC was reported in 1956[1]. The diagnostic criteria of UC was published firstly in1978 and was revised in 1993 on the National Conference of Chronic non-infective Diarrhea Disease in Taiyuan city, China[2-4]. The criteria are similar to Lennard-Jones, on the three major aspects: mainly by exclusion. A multi-center study was set up in Chinese PLA General Hospital of Jinan Command (Shandong province, China) in 1999, with eight comprehensive hospitals from different areas using unique diagnostic criteria and method treatment[1].

UC was thought to be infrequent in China in the past, however, it was increasing over the last 20 years[1,2,5]. Figure 1.

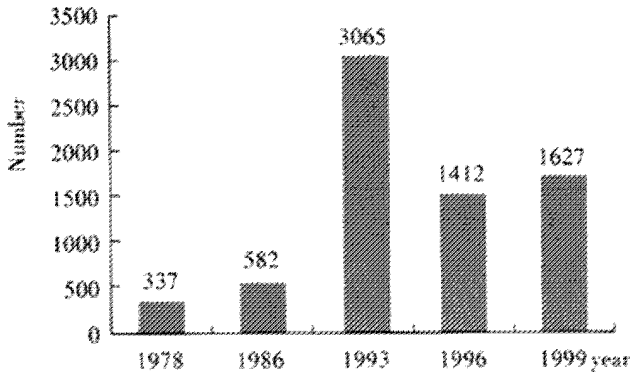

Figure 1 Cases reported on the conferences in China.

No precise statistics are available in China, in our hospital, 57 cases were admitted from 1981 to 1990, whereas 213 cases were hospitalized from 1991 to 2000[1]. According to the statistics of World Digestology Network(http://www.wd.org.cn) data base, more than 1560 Chinese papers on this subject were published in the past 20 years, of which, 102 articles were published on World Chinese Journal of Digestology (founded in 1993) and World Journal of Gastroenterol,ogy(founded in 1995), regarding the animal model[6-16], etiology and pathogenesis[17-36], diagnostic criteria[1-4] and results of treatment, etc[37-102]. Of these 1560 papers, a total of 10218 patients of UC were reported in Chinese medical literature including those diagnosed in our hospital.

MATERIALS AND METHODS

The diagnosis of UC was based on endoscopic or radiological findings and mucosal biopsies or surgical pathology using Lennard-Jones criteria. Only those verified were included in the study. A total of 10218 patients of UC reported in Chinese medical literature including ours according to the diagnostic criteria of Lennard-Jones were

analyzed. Ridit test was used, a value of $P<0.05$ was regarded as statistically significant.

RESULTS

Case number

From 1981 to 2000, a total of 10218 cases of UC were reported, of these, 2506 were diagnosed from 1981 to 1990 whereas 7512 were diagnosed from 1991 to 2000, an increasing to 3.08 times in the past 10 years.

Extent of lesions range

As described in 7966 patients, 5592 (70.20%) were proctosigmoiditis/proctitis, 1792(22.50%)left-sided colitis, 582 (7.30%) pancolitis.

Clinical types

Of those described in 8122 cases, 34.8%(2826 patients) were first presentation, 52.6%(4272 patients) were chronic relapsing, 10.7%(869 patients) were chronic persistent, 1.9%(154 patients) were acute fulminant.

Course

Of those described in 5867 cases, 4427(75.5%) patients were less than 5 years, 910 patients(15.5%) between 5 and 10 years, 530 patients(9.1%) more than 10 years.

Extraintestinal manifestations

618 patients(6.1%) had extraintestinal manifestations.

Age

The mean age at the diagnosis was 40.7 years(range 6-80 years, peak age range 30-49 years).

Sex

The male to female ratio was1.09.

Smoking

In our 270 patients, 36 patients (30 male, 6 female) had histories of smoking(more than 20 cigarette one day), there was no negative association between the severity of UC and smoking($P>0.05$, Table 1), 21 smokers were followed up for one year, 15 of them had given up smoking when the disease were diagnosed, and one year later, 7 patients relapsed, another 6 patients continued smoking, and one year later, 2 patients relapsed.

Table 1 The association between the severity of UC and smoking

Group/severity	mild	moderate	severe
Smokers	20	11	5
Non-smokers	130	72	32

Ridit test, $P>0.05$

Family study

In our 270 UC patients, 4 patients(1.48%) from 2 families had familical history of UC. In one family, the patients were mother and son, in the other family, the patient were two sisters, and their mother had a history of bloody stool more than 9 years without seeking medical advise.

Treatment

Of the 10218 patients, treatment was mentioned in 6859 cases, only 5-ASA and/or corticosteroid only in 1276 patients(18.6%), only Chinese herbs in 1377 patients(20.1%), combined Chinese and western medicine in 4056 patients(59.1%),surgery was performed in 87 patients(1.3%),other treatments in 63 patients(0.9%).Figure 2.

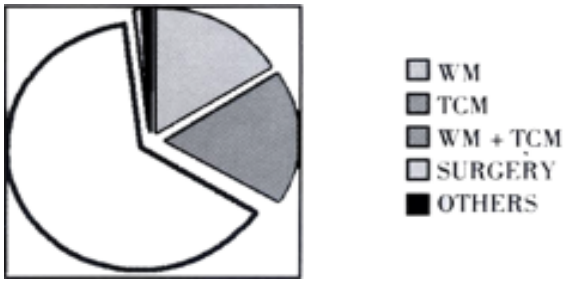

Figure 2 Treatment of UC in China. WM:western medicine TCM:traditional Chinese medicine.

DISSCUSION

The characteristic features of UC in China are as follows:

UC increased significantly in the past 10 years

The incidence of UC varies greatly in different geographical areas of the world[90-92,95,101-102]. A high incidence is seen in Northern Europe and North America. In the western world, a sharp rise in the incidence of UC has been observed since early 1950s[95], and now the incidence is stable. UC has been thought uncommon in China, however, an analysis of 1560 papers and 10218 cases indicate that the incidence is rising in recent years. From 1981 to 1990, 2506 patients were diagnosed while 7512 patients were diagnosed from 1991 to 2000. The number of cases increase by 3.08 times in the past 10 years. This is due to increasing awareness, better health care and improved study diagnostics. However, it may also be a real increase, reflecting changes in life style and dietary composition. These may shed some light on the role of environmental factors in the etiology of UC[1].

Lesions mostly affect left sided colon

In China, UC is usually restricted to the rectum, sigmoid and descending colon, proctocolitis are common. Our data showed 92.7% were restrict to left colon(70.20% proctosigmoiditis/proctitis, 22.50% left-sided colitis), 7.30% pancolitis, the later was commonly seen in the Western countries[101].

The course of illness is shorter with less extraintestinal manifestations

Occasionally, the disease may present as a single mild episode of diarrhea, but may at anytime relapse. In China, 34.8% were first presentation, 52.6% chronic relapsing, 10.7% chronic persistent, only 1.9% acute fulminant. Usually, the history revealed months or years of general ill health with continuous or intermittent diarrhea. In China, among that, the course of UC is commonly less than 5 years(75.5%), only 9.1% more than 10 years. Symptoms may be mild, systemic complications are rare, only 6.1% has extraintestinal manifestations, much less than that in the Western countries[99].

The onset of illness is relatively higher

In china, the onset of UC is relatively higher in the middle and old-age group(30-49 years old), mean age at the diagnosis was 40.7 years, but may occur at any age (range 6-80 years), while in the western countries the peak age is 30 years old[91].

Male and female are nearly equally affected

The reports on sex difference are variable, but there seem to be a

tendency to a male preponderance especially in high incidence areas. Our data suggest that the male to female ratio was 1.09, with nearly equal frequencies.

No relation between smoking and severity of illness

Smoking is the only consistent risk factor in case-control studies of UC, and there is no apparent relation seen between ulcerative colitis and cigarette smoking in our cases.

Familial relatives are rarely involved

Genetic study of UC are rarely performed in China. In our 270 UC patients, 4 patients(1.48%) from 2 families had family history of UC, which is much rarer than expected. The familial tendency may be much lower than that seen in western countries[91,102].

Traditional Chinese medicine are widely used for the treatment of UC

SASP, is still the major drug used for the treatment of UC in China, which is effective in inducing remission and maintenance in mild-to-moderate cases. 5-ASA is too costly, corticosteroids are more commonly used, whereas 6-MP is only used by some authors. Heparin or oral low molecular weight heparin has been found to paradoxically induce remission in occasional patients with corticosteroid-resistant UC in China[48,57,60]. In China, herb medicine as heartleaf houttuynia[12,13], has been widely used in patients with mild-to-moderate disease, as well as an adjunct to patient with moderate-to-severe disease. Combined Chinese and western medicine is the predominance treatment in China.

Abstract

AIM: **To isolate the proteins involved in pharmacologic action of senna extract (SE) from mouse gastrointestinal tract and to explore the molecular mechanism of gastrointestinal motility change induced by SE.**

METHODS: **SE was administrated to mice by different routes. Gastrointestinal motility of mice was observed using cathartic, gastrointestinal propellant movement experiments and X-ray analysis. Mouse model for gastrointestinal motility enhancement was established through continuous gastric administration of SE at progressively increased dose. At 3 h and week 3, 4, 6 and 10, morphological changes of gastrointestinal tissues were found under light microscope. Ultrastructural changes of intestinal and colonic tissues at week 6 were observed under transmission electron microscope. The colonic proteomic changes in model mice were examined by two-dimension polyacrylamide gel electrophoresis with immobilized pH gradient isoelectric focusing to screen the differentially expressed proteins, and their molecular masses and isoelectric points were determined. Two N-terminal sequences of the samples were also determined by mass spectrometry.**

RESULTS: **SE (0.3g) caused diarrhea after gastric administration in 1-6h and enhanced gastrointestinal propellant (65.1±7.5%; 45.8±14.6%, $P<0.01$) in mice, but intramuscular and hypodermic injection had no cathartic effect. X-ray analysis of gastrointestinal motility demonstrated that gastric administration of SE enhanced gastric evacuation and gastrointestinal transferring function. At 3 h and week 3 and 4 after gastric administration of SE, light microscopic examination revealed no apparent change in gastrointestinal mucosal tissues, but transmission electron microscopic examination revealed inflammatory changes in whole layer of intestinal and colonic wall. Twenty differential proteins were detected in the colonic tissues of the model mice by two-dimensional electrophoresis, and the N-terminal amino acid sequences of two proteins were determined.**

CONCLUSION: **SE causes diarrhea and enhances gastrointestinal motility through digestive tract administration. Long-term gastric administration of SE induces inflammatory changes and cell damage in the whole gastrointestinal tract. The differential proteins screened from the colonic tissues of the model mice might mediate the enhancing effect of SE on gastrointestinal motility.**

INTRODUCTION

Senna, a traditional Chinese medicine, has potent cathartic effect[1-4]. Its extract(SE), composed of a few dozens of chemical substances, possesses multiple pharmacological activities. Especially, it can promote the motility and secretion of gastrointestinal tract. However, its application is greatly restricted due to its toxicity[5-17]. Much attention is being paid to the effect of traditional Chinese medicine on the regulation of gastrointestinal motility[18-37]. We analyzed the role of senna in gastrointestinal motility and in diarrhea of mice and observed its action pattern, the ultrastructural changes in the active sites, and the changes in protein expression. In doing so we intended to screen from the gastrointestinal tissues the biological molecules mediating diarrhea and the enhancement of gastrointestinal movement, to elucidate the mechanism of catharsis induced by senna at the molecular level, and to lay a foundation for the development of pharmaceutical agents enhancing gastrointestinal motility.

MATERIALS AND METHODS

Materials

Imported senna (Shaanxi Medicine Corporation) was used, and its quality was confirmed by the Institute of Pharmaceutics, Fourth Military Medical University. The extract was obtained through solvent recovery and stored at -20℃. Acrylamide, bisacrylamide, SDS, Tris base,PMSF (all from Sino-America Biotechnology Co); ultrapure urea (Shanghai Biotechnology Co); ampholyte pH 3-10L, IPG dry strips pH 3-10L, IPGphorTM Isoelectric Focusing System (Pharmacia Co); ultradispersor GF-1 (Jiangsu Qilin Medical Equipment Factory); two-dimensional electrophoresis bath DYY-III 26, gradient mixer (Beijing 61 Factory); electrophoresis apparatus (Bio-Rad Co) were used.

Induction of diarrhea by SE in different Administration routes

Thirty Balb/c mice (both sexes, 8 week, 18g-23g) were used. Before experimental manipulation, the mice was fasted without water deprivation for 24h, and each was kept in a single cage re-based with filter paper. After being divided into different groups, the mice were administered 0.3g SE in different routes, and the diarrhea status was examined.

Effect of SE on gastrointestinal motility in mice

Effect of SE on gastrointestinal motility for carbon Thirty Balb/c mice (both sexes, 6-8weeks, 18-23 g) were divided randomly into 3 groups: Group I, II, and Control Group. SE of 0.3g was delivered to each mouse in Group I through gastric administration; 0.3g SE was im injected into each mouse in Group II; and the same volume of 9g·L^{-1} NaCl was delivered through gastric administration to the mice in control group. After 20 min, 0.1 mL of 100 g·L^{-1} mixture of Arabic gum and charcoal powder was administrated to all mice. Then, all mice were killed after 20 min. Whole gastrointestinal tract was taken out and pulled straight. The length of gastrointestinal tract from pylorus to anus and that from pylorus to the anterior extremity of carbon powder were measured. Percentage of migration distance of carbon powder out of whole length was calculated.

Effect of SE on gastrointestinal motility for barium Eight Balb/c mice (both sexes, 8weeks, 18~20 g), fasting without water deprivation within 24 h prior to the experimental manipulation, were divided randomly into 2 groups. SE of 0.3g was given through gastric administration to each mouse in Group I, and the same volume of 9 g·L^{-1} NaCl to each mouse in the control group. After 20 min, 0.8 mL of 1.6kg·L^{-1} barium sulfate suspension was given to each mouse. The mice were put into cloth bags that could restrict their movement, and the bags were placed on the flat of the X-ray digital machine. The migration of barium in the gastrointestinal tract was visualized and X-ray photos were taken at 5 and 40 min, 1, 1.5, 2, and 3h after barium administration[38].

Effect of SE on morphology of gastrointestinal tissue

Thirty Balb/c mice (both sexes, 8weeks, 18-23 g) were fed separately according to their sexes. Ten were classified into the control group, and 20 into the experimental group. SE was given through gastric administration to the mice in the experimental group once a day. The frequency of drug delivery increased progressively from 1·d^{-1} to 4·d^{-1} and the dosage increased progressively from 0.1g·d^{-1} to 0.8g·d^{-1} in 6 weeks. The same volume of 9 g·L^{-1} NaCl was given to the control group. Four mice in the experimental group and 2 in the control group were killed at 3 h, 3, 4 and 6week after reagent administration. Gastric, intestinal and colonic tissues were obtained and fixed in 40 g·L^{-1} paraformaldehyde and embedded routinely with paraffin. Sections were made. Morphological changes were examined under light microscope after HE staining. Intestinal and colonic tissues at week 6 were collected and fixed with 30 g·L^{-1} glutaraldehyde for 6h at 4℃. Ultrathin sections were routinely made. Cellular ultrastructural changes in the whole layer of the intestinal wall were examined under transmission electron microscope.

Two-dimensional polyacrylamide gel electrophoresis of proteins[39]

Establishment of animal model for chronic gastrointestinal motility enhancement Fourty Balb/c mice (both sexes, 8 weeks, 18-20 g) were selected. Twenty five mice in the experimental group received SE through gastric administration once a day, with the frequency and dosage increasing progressively from 0.1g, 1·d^{-1} to 0.8g, 4·d^{-1}. Fifteen mice in the control group received the same volume of 9 g·L^{-1} NaCl.

Preparation of protein sample from intestinal tissue of mice Tweenty mice were killed at 6 weeks after receiving gastric administration of SE (10 mice) and 9g·L^{-1} NaCl (10 mice). The colons were collected and put immediately into ice-cold 9g·L^{-1} NaCl containing 0.1mmol·L^{-1}PMSF. The colonic tracts were dissected and colonic contents were washed out. The moisture on the tissues was absorbed with filter paper, and the tissues were put into liquid nitrogen immediately. The whole procedure must be finished in 5 min. Then, the tissues were either stored at -70℃ until used again, or taken for immediate use. In the latter case, the tissues were weighed on electric scale, and lysed by adding tissue lytic solution (9.5mol·L^{-1} urea, 20g·L^{-1} NP, 402g·L^{-1} ampholyte pH 3-10, 20g·L^{-1} 2-ME, 1.5 mmol·L^{-1} EDTA, 40 mmol·L^{-1}Tris and ion-free water) by a mass volume ratio of 1 ∶ 5. Tissue homogenate was prepared with high-speed disperser in ice-bath (3500 r ·min^{-1} ×5s×5), and DNase and RNase (both 0.4 g·L^{-1}) were added into the homogenate. After the incubation for 20 min in ice-bath and addition of PMSF (0.1 mmol·L^{-1}), the homogenate was centrifuged at 10,000×g for 10 min. The supernatant was harvested and stored in designated volume at -70℃ until used again. The total protein concentration in the supernatant was measured by Bradford method[40-42].

Solid-phase pH gradient isoelectric focusing For each group, 100 μg protein sample was solved in 250μL mixture of deuteroxide solution and IPG buffer, placed at room temperature for 1h, and then applied to sample tank which was placed with IPG dry gel strip (13 cm in length), and covered with mineral oil. The isoelectric focusing program was: deuteroxidization for 12 h; isoelectric focusing 0-300 V, 1 h; 300-500 V, 1 h; 500-1000 V, 1 h; 1000-2000 V, 1 h; 2000-4000 V, 1 h; 4000-8000 V, 4 h. All operations above were performed at 20℃.

Equilibration and transfer of IPG slab gels The slab gels were collected and equilibrated with SDS-balanced buffer (50mmol·L^{-1} Tris, 6 mol·L^{-1} urea, 300 g·L^{-1} glycerin, 10 g·L^{-1} DTT, ion-free water) for 15 min followed by a second equilibration with balanced buffer (50 mmol·L^{-1} Tris, 6 mol·L^{-1} urea, 300 g·L^{-1}glycerin, 25 g·L^{-1} idocetamide, ion-free water) for another 15 min. Two pieces of 125 g·L^{-1} separation gel (17cm×17cm×0.15cm) was prepared in absence of sticking gels. IPG slab gels were fixed on the top of the seperation gel using 5 g·L^{-1} agarose. Protein marker was applied at the other terminus.

Second dimension SDS-PAGE Two pieces of 125 g·L^{-1} SDS-PAGE (17cm×17cm×0.15cm) were prepared and underwent polymerization for 2 h in absence of sticking gels; IPG slab gels were fixed onto the top of SDS-PAGE gels; electrophoresis was performedfor 11 h at room temperature (15℃-20℃) with constant electric current (20 mA/gel, 40mA in total) and terminated when the marker arrived at the bottom.

Silver staining of gels The gels were collected and stained with silvery salt based on a modified protocol. The gels were fixed with the fixing solution (300 g·L^{-1} ethanol, 0.5 mol·L^{-1} sodium acetate, 5 g·L^{-1} glutaraldehyde, 2 g·L^{-1} sodium thiosulfate), rinsed with ion-free water for 15 min×3, stained with 1 g·L^{-1} $AgNO_3$ and 0.1 g·L^{-1}formaldehyde for 20 min, washed with ion-free water for 30sec, and colored with 25 g·L^{-1} sodium carbonate, 0.5 g·L^{-1} sodium thiosulfate and 0.1 g·L^{-1} formaldehyde. The color development was terminated with 10 g·L^{-1} acetic acid.

Analysis of protein map on two-dimensional gels After silvery salt staining, the gels were scanned with transmission laser scanner at 500 bpi resolution and analyzed with image pattern analyzer under identical conditions. The position, shape and density information for each

detected spot was compared to screen obviously differentially expressed proteins and to determine their molecular masses and isoelectric points.

Identification of the screened proteins by sequencing[43] One mg colonic proteins from the animal model was sampled and underwent solid-phase pH gradient isoelectric focusing and second dimension SDS-PAGE and transferred from gel slabs to polyvinylidene difluoride (PVDF) membranes (transferring buffer: CAPS, DTT, methanol and ion-free water, pH 11.0; transferring condition: 350 mA,4.5 h, 10℃). The proteins on the PVDF membranes were stained with 1 g·L^{-1} Coomassie brilliant blue. PDVF membrane was air-dried at room temperature. The protein spots stained with Coomassie brilliant blue were excised from the membrane, and their amino acid sequences at the N-termini were determined by mass spectrometry.

Statistical analysis

Student's *t* test and χ^2 test were used for data measurement and enumeration, respectively.

RESULTS

Cathartic Effect of SE in different Administration routes

One to 1.5 h after gastric administration of SE, mice started to suffer from diarrhea, defecating water-thin feces, which lasted 4-5h. When the mice received im and sc injection of extract of doubled dosage, they did not develop diarrhea within 6 h (Table 1).

Table 1 Carthartic effect of SE in different administration routes

	Groups	Dose / g	*n*	Administration routes	Diarrhea (in 6h)
I	Normal saline	0.3	6	ig	-
II	SE	0.3	6	ig	+(6)[b]
III	Normal saline	0.3	6	im	-
IV	SE	0.3	6	im	-
VC	SE	0.3	6	sc	-

[b]$P<0.01$, *vs* all other groups.

Effect of SE on gastrointestinal motility in mice

Effect of SE on gastrointestinal propellant movement While ig administration of SE could enhance gastric motility, im delivery did not show such effect (Table 2).

Table 2 Effect of SE on gastrointestinal propellant rate in mice ($\bar{x}\pm s$)

	Group	Dose / g	Administration routes	*n*	Propellant rate / %
I	Normal saline	0.3	ig	10	45.8±14.6
II	SE	0.3	ig	10	65.1± 7.5[b]
III	SE	0.3	im	10	48.3±12.4

[b]$P<0.01$, *vs* I, III groups.

X-ray analysis of SE effect on gastrointestinal motility In mice with gastric administration of SE (0.3 g), barium sulfate was excreted at 40 min, and more at 2 h. The migration speed was significantly higher than that shown in the control group (Figure 1).

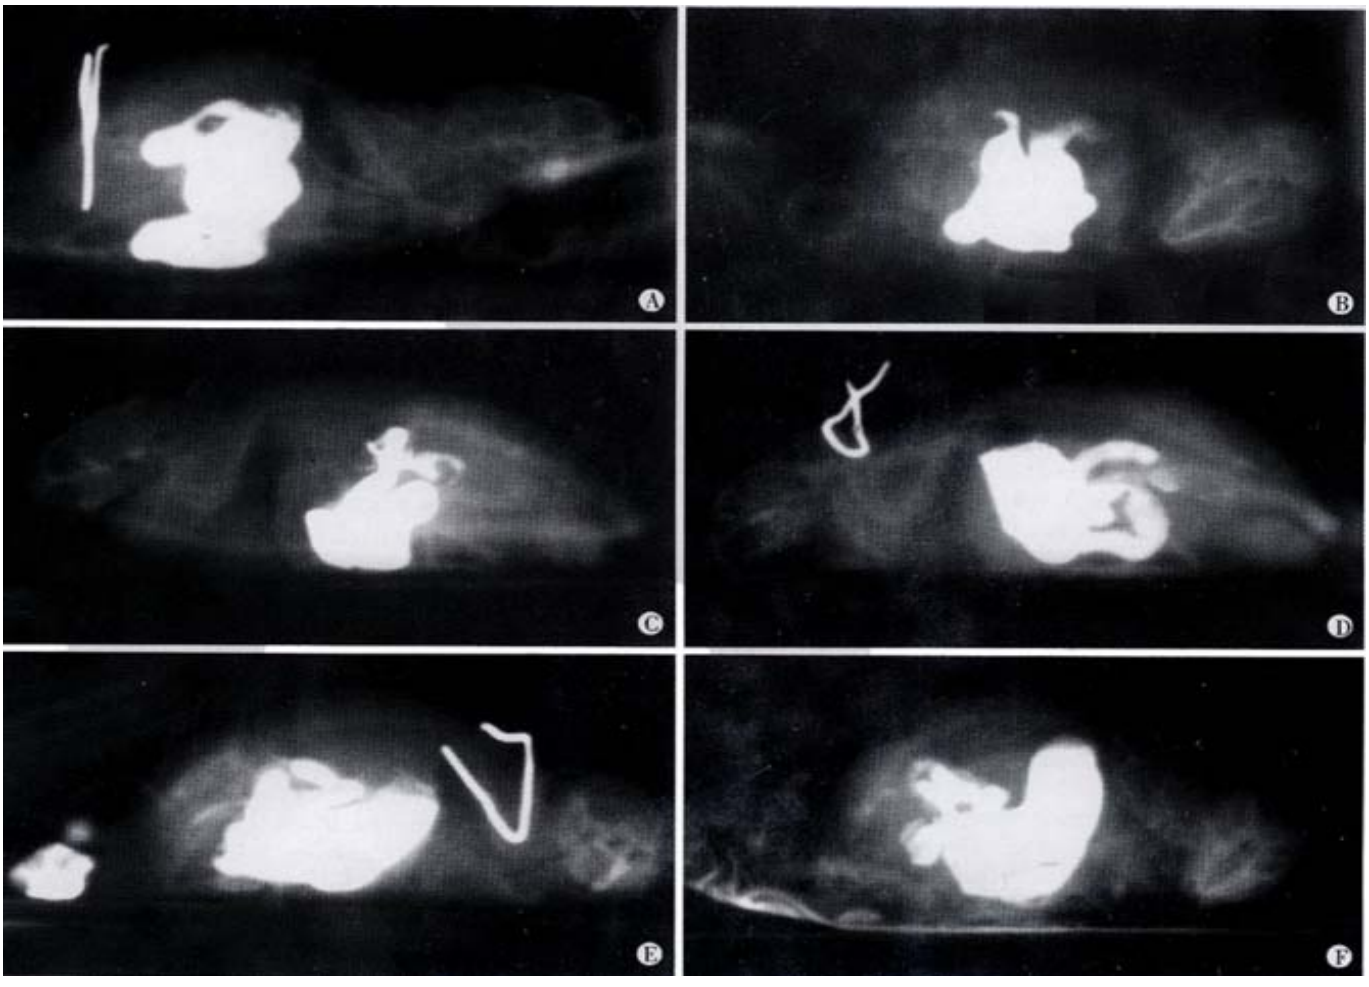

Figure 1 X- rays of gastrointestinal peristalsis in mice administered with SE
A, B, C: 5min, 2h, 3h after 9 g·L-1 NaCl gastric administration, respectively D, E, F: 5 min, 2h, 3h after 0.3 g SE gastric administration, respectively

Morphological effects of SE on gastrointestinal tissue No pathological changes were observed in gastrointerestinal tissues under light microscopy examination at 3 h, 3, 4 and 6weeks after gastric administration of SE. However, at week 6, it was observed under transmission electron microscope that some small intestine epithelial cells underwent degeneration and necrosis. Although the microvilli were normal, the mitochondria in the cells were slightly swollen, with part of the cristae broken. In the mucosa, macrophages containing phagocytic particles were found to increase, and so were plasmacytes. Cell degeneration and necrosis occurred more frequently in the mucosal epithelial cells in colon than those in the small intestine (Figure 2). The mitochondrial abnormalities mentioned above were observed in both small intestine and colon smooth muscle cells, along with the occurrence of vacuolation.

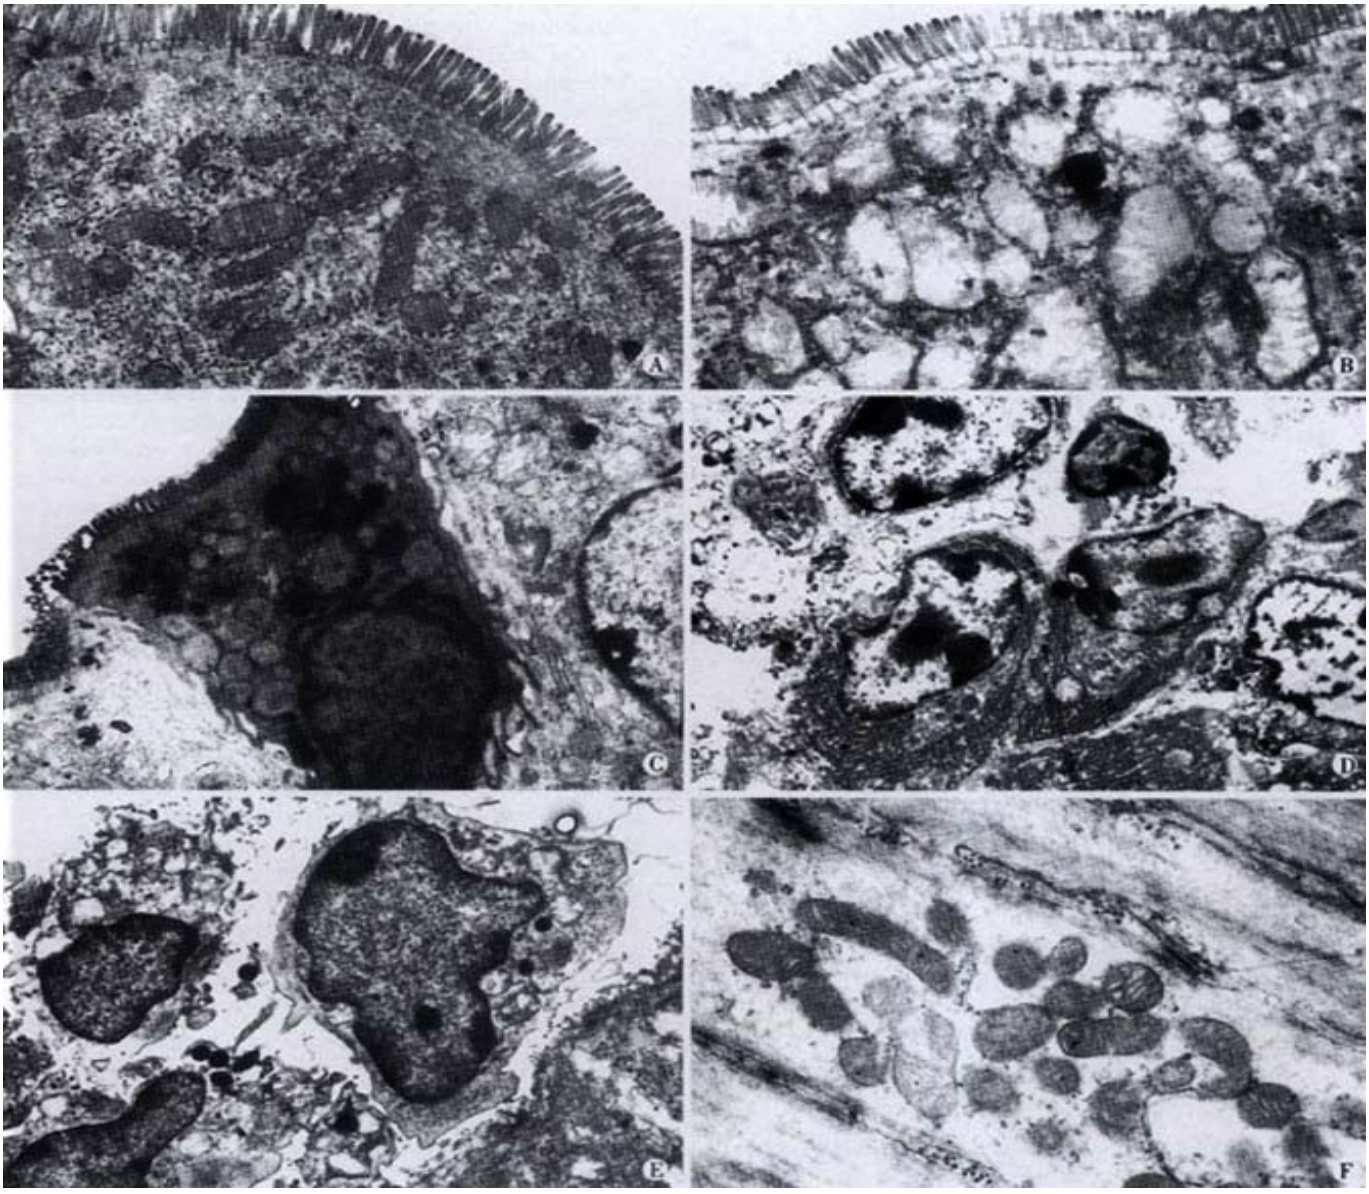

Figure 2 Ultrastructure of intestine and colon cells in mice receiving SE at week 10.
A: Normal epithelial cell; B: Intestinal cell after treatment with SE; C: Colon cell after treatment with SE; D: Increase in submucosal plasmacytes; E: Increase in submucosal macrophages; F: Minor degeneration of smooth muscle cells in intestine

Gastrointestinal proteins in mice

Establishment of mice model for chronic gastrointestinal movement enhancement Gastrointestinal propellant movement experiment and X-ray analysis of gastrointestinal motility demonstrated that gastric administration of SE could significantly enhance the gastrointestinal motility in Balb/c mice. Therefore, continuous gastric administration of SE might keep the gastrointestinal tract in constant enhanced motility. At week 6, the weight of the mice in the model group was significantly lower than that in the control group.

Differential expression of gastrointestinal tissue proteins in mice In the first dimension IPG isoelectric focusing, pH gradient was pH 3-10 L, 100 μg protein sample was added. In the second dimension IPG -PAGE 125 $g \cdot L^{-1}$ uniform gel was used, the gels were stained with silver salt (Figure 3).

Identification of differentially expressed proteins The colonic proteins of one control mouse and one model mouse were screened and compared, and the process repeated for 5 such pairs. Twenty proteins were found different in abundance (Table 3).

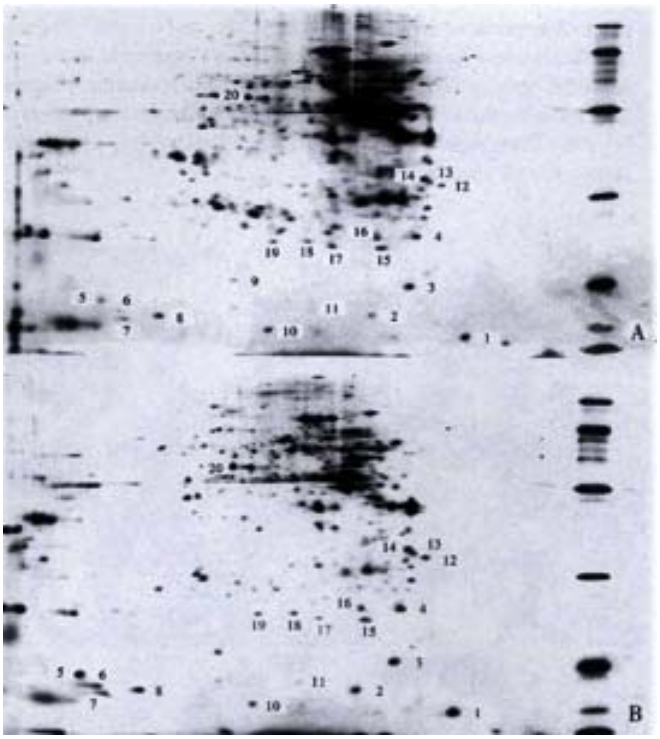

Figure 3 Proteins on two-dimension electropherosis maps
A: Normal mice; B: Model mice

Table 3 Identification of the differential proteins

No.	Molecular mass/ku	Isoelectric point/pI	No.	Molecular mass/ ku	Isoelectric Point/pI
1	15.0	3.9	11	18.0	5.9
2	17.5	5.2	12	33.0	4.3

7	16.5	8.5	17	24.5	5.7
8	17.0	8.0	18	25.0	6.1
9	20.0	7.0	19	25.0	6.5
10	16.0	6.6	20	52.0	7.0

Identification of differential proteins by sequencing The N-terminal amino acid sequences of protein No. 4 and No 12 were determined by sequencing (No. 4: N-MIX/IYR-C; No 12: N-GFXDX/L-C). Protein database search showed that these two proteins were unknown proteins.

DISCUSSION

Senna is a traditional Chinese medicine containing various chemicals, the effective components of which are sennoside A, B, C and D. It has been shown that sennosides are decomposed into Rhein anthrone by bacteria in colon, and then take effects on the colonic smooth muscle, significantly promoting colonic motility in animals and humans. The mechanism is that sennoside and its active forms affect on the intestinal mucosal epithelium and submucosal nerve bundles, stimulating prostaglandin (PG) synthesis and endogenous acetylcholine release, and subsequently enhancing colonic smooth muscle contraction.[44-46] Meanwhile, sennosides may affect directly the colonic smooth muscle, evoking its spontaneous spike potential and promoting its contraction[47]. In addition, sennosides can stimulate the colonic mucosa to release PG, NO and 5-HT, efficiently inducing the excretion of water and electrolytes by epithelial cells[48-50]. Our study showed that 1-1.5 h after gastric administration of SE, mice started to suffer from diarrhea, defecating water-thin feces, which lasted 4-5h. When the mice received im injection of extract of doubled dosage, they did not develop diarrhea within 6 h, but after 6 h, 3 mice had light diarrhea. It suggested that the possible pathway might be that the drug delivered through im injection entered blood circulation and was excreted into the intestinal tract with bile. With hypodermic injection of larger dosage of extract, no mice developed diarrhea. However, no enhanced gastrointestinal motility was observed after im injection of SE. These results indicate that the cathartic effect of SE can only be exerted through the digestive tract rather than other pathways.

Our study also indicated that SE could promote the propellant movement in mice, a result in agreement with the reports of other researchers. Although most researchers believe that the active components of senna mainly work on colon and promote colonic motility. We think that it may also affect small intestine, as our gastrointestinal propellant movement experiment has revealed that it promoted the motility of mice small intestine in mice. In order to locate the effective site of the drug, we continuously observed the movement of marked liquid ($BaSO_4$) in the gastrointestinal tract after administration of SE, and discovered that it in hibited rather than promoted gastric empty; however, it promoted small intestinal motility, and especially colonic motility.

We made histological examinations of mouse gastrointestinal tracts at different stages after gastric administration of SE. No apparent change was found under light microscope, but transmission electron microscopy showed lesions and degenerative changes of small intestinal mucosal epithelial cells, increase in submucosal macrophages and plasmacytes, minor degeneration of smooth muscle cells, and severe extensive degeneration and necrosis of colonic epithelial cells. Mengs *et al*[10] observed the changes in guinea pig colonic epithelial cells after continuous gastric administration of sennoside for 2 weeks, and discovered epithelial cell degeneration. These results show that SE can injure the intestinal cells.

Using improved two-dimensional electrophoresis of proteomic analysis[42,51,52], we compared the protein expression in the colon tissues of promoted gastrointestinal motility model mice and that of normal controls. The conditions in the whole process were identical for the two groups, and the location, shape, size and density of many protein spots were similar on the two-dimensional electrophoresis maps. Hence, the two groups were comparable. Image analysis showed differential proteins in the colon tissues of the model animals; the differences were primarily the increase or decrease in the amount of protein expression. Most of the differential proteins had moderate or low molecular mass, as shown in Table 3, which are probably regulatory proteins induced or affected by SE. Two of the proteins were sequenced with mass spectrometry and were confirmed to be novel ones through protein database search. However, the pharmacological functions they mediate remain to be discovered.

SE administered through the gastrointestinal tract promotes diarrhea and gastrointestinal motility, especially that of the small intestine and the colon; it also injures the digestive tract mucosa and smooth muscles, and promotes differential protein expression in the colon tissues of model animals. We have isolated and identified some of the molecules that may be involved in mediating the motility promotion and secretion effect of senna, and will continue to investigate the molecular mechanism of the aforementioned effects so as to lay the foundation for further research.

Abstract

AIM: **To investigate the mechanism underlying intestinal barrier function damage after severe trauma and the therapeutic effect of glutamine.**

METHODS: **Burned patients, and animal models of severe trauma replicated by hemorrhagic shock combined with endotoxin infusion and burn injury, were included in a serial experiment. Effects of oral glutamine on intestinal barrier function were observed in scalded rats. Parameters measured in these experiments were as follows: plasma levels of diamine oxidase (DAO), tumor necrosis factor (TNFα), endotoxin (LPS), and lactate as well as D-lactate by biochemical methods, lactose/mannitol (L/M) ratio in urine by SP-3400, and pathological examination of intestinal mucosa under light microscopy.**

RESULTS: **Plasma DAO activity was significantly increased after injury. There was a negative correlation between plasma DAO and intestinal mucosal DAO or pHi (r=-0.93, plasma 0.80±0.93,2.83±1.71,1.14±0.64,2.36±2.06 and 2.49±1.67 *vs* intestinal 0.52±0.12,0.34±0.03, 0.45±0.18,0.37±0.26 and 0.41±0.07; r=-0.533, plasma 0.87±0.75,1.89±1.13,1.21±0.23,3.03±2.61 and 4.70±1.22 *vs* pHi 7.03±0.05,7.05±0.06,7.14±0.096, 7.20±0.08 and 7.05±0.07; P<0.01-0.05). Positive correlations were found between DAO activity and plasma TNFα, LPS,, lactate, L/M and D-lactate (r=0.817, 0.842, 0.872, and 0.951; plasma DAO 0.87±0.75, 1.89±1.13,1.21±0.23,3.03±2.61 and 4.70±1.22 *vs* TNFα 0.08±0.02,0.03±0.25,0.17±0.09,0.34±0.15 and 0.33±0.18; *vs* LPS 0.14±0.03,0.16±0.04,0.21±0.02, 0.18±0.16 and 0.37±0.10; *vs* lactate 9.03±2.19, 18.30±2.56,9.81±2.83,12.01±6.83,12.01±6.84 and 43.61±11.27; *vs* L/M 0.03±0.01,0.41±0.27,0.62±0.20, 1.70±0.60; r=0.774, plasma DAO 1.25±0.41,2.17±0.71, 2.29±0.87,1.23±0.55 and 1.11±0.47 *vs* D-lactate 8.37±2.48,18.25±6.18,13.96±4.94,8.93±3.00 and 12.39±4.94;all P<0.01), repestively. Damage of intestinal mucosa was found by pathological examination. Intestinal barrier function was improved to a certain extent by oral glutamine in scalded rats.**

CONCLUSION: **Intestinal barrier function was damaged in the early stage after trauma. Plasma DAO activity, D-lactate content, intestinal pHi and urine L/M may be sensitive markers of intestinal mechanical injury, and glutamine may protect against intestinal barrier dysfunction after severe trauma.**

INTRODCTION

It is generally accepted that the intestine may serve as an important organ in the development of severe complications under critically ill conditions, including trauma, burns, shock, etc.[1-3] Hemorrhagic shock and/or gut ischemia-reperfusion injury commonly occur in the early stage after acute insults, leading to gut-derived sepsis as a result of gut barrier dysfunction[4-10]. In order to investigate the mechanism underlying intestinal barrier function damage and its potential interventional measures, burned patients and animal models of severe trauma were employed in our current experiments[6,11-15].

MATERIALS AND METHODS

Animal models

Animal models of severe trauma were replicated by hemorrhagic shock combined with endotoxin infusion. Male Wistar rats, weighing 190g-230g, were anaesthetized with intraperitoneal injection of 30g·L^{-1} barbitone sodium (35mg·kg^{-1}), and the femoral artery and jugular vein were cannulated under aseptic conditions. The rats were then bled via the jugular vein catheter until a mean arterial pressure of 30-35 mmHg (4.6 kPa) was reached. At the end of shock, endotoxin (*E.coli*O55 B5, Sigma) was infused through tail vein at a dose of 2mg·kg^{1}. A goat model of hemorrhagic shock combined with endotoxin challenge was established according to the previous report(n=20)[5]. Animals received *E.coli*O26 B6 endotoxin via portal vein 24h after the recovery from shock, and the dosage was 30 ng·kg^{1}·min^{1}, which was given in a continuous infusion lashing for 5d. Wistar rats were divided randomly into three groups: normal controls, early feeding with standard feed plase Gln 0.5g after scalding, and animals (except control group) sustained a 30% TBSA full-thickness scald covering the back and flanks[6]. Determination of plasma diamine oxidase in 21 burned patients (17 male and 4 female) at the age of 33±10 years, with burn area (64±21)%, and (35±20)% ⅢⅢ0. Plasma DAO activity was determined on day 1, 3, 7, 14 and 21 postburn.Blood and intestinal DAO levels were tested according to our previous report[17]. Plasma lactate and D-lactate concentrations were determined by biochemical methods as described by Brandt *et al*[18]. Microassay for quantitation of endotoxin in blood was made with new PCA treatment using chromogenic limulus amebocyte lysate[19].

Tumor necrosis factor (TNFα) assay. Plasma TNF content was measured by radioimmunoassay.Lactulose/mannitol (L/M) ratio tests in urine were made by SP-3400[20].

Pathological examination. Tissue samples were examined under light microscopy.

Statistical Analyses

Data were expressed as the mean±standard error, and were statistically evaluated by Students t test and correlation analysis. Differences were considered to be significant with P<0.05.

RESULTS

Plasma DAO levels were elevated in double-peak patterns, one at early stage after trauma and another during invading infection in animal models. Similar results were also obtained in burned patients. Meanwhile, intestinal DAO levels were decreased to certain extent after trauma in animal model. There was a significantly negative correlation between plasma and intestinal DAO activity (Table 1; Figures 1 and 2).

Figure 2 Pathological changes of intestinal mucosa after 8d oral GLN in scalded rats. HE×100

Plasma DAO concentrations and the level of the related index, and plasma TNFα significantly increased at various intervals after trauma in goats. Plasma endotoxin levels notably increased at 24h and 72h after injury. Blood lactic acid significantly increased from 2h to 72h after trauma. The plasma DAO activity was obviously correlated with plasma TNFα, LPS and lactate (P<0.01; Table 2 and 3). Changes in DAO activity were significantly related with plasma TNFα and LPS levels in scalded rats. Plasma DAO activity and plasmaD-lactate were significantly correlated in rats secondary to hemorrhage followed by endotoxin challenge (r=0.774; P<0.01).

Glutamine could protect against intestinal barrier function damage. The results indicated that plasma DAO activity was decreased in animals with early glutamine supplementation compared with those without glutamine treatment (10h after trauma P<0.05). Results of intestinal pathological examination. The pathologic examination of the intestine showed that the damage of epithelial cells of intestinal mucosa, hemorrhage and necrosis, accompanied by the inflammatory cell infiltration in intestinal wall in goats suffering from hemorrhagic shock combined with endotoxin infusion. It was revealed that there was disruption of intestinal mucosa after scald and gut ischemia-reperfusion combined with endotoxin challenge in rats, whereas oral glutamine supplementation could markedly improve intestinal mucosa following acute insults (Figure 2).

Table 2 Changes in parameters in goats after hemorrhagic shock combined with endotoxin infusion

	Before injury	T (after injury) / h			
		2	24	48	72
TNF / μg·L^{-1}	0.08±0.02	0.03±0.25[a]	0.17±0.09[a]	0.34±0.15[a]	0.33±0.18[a]

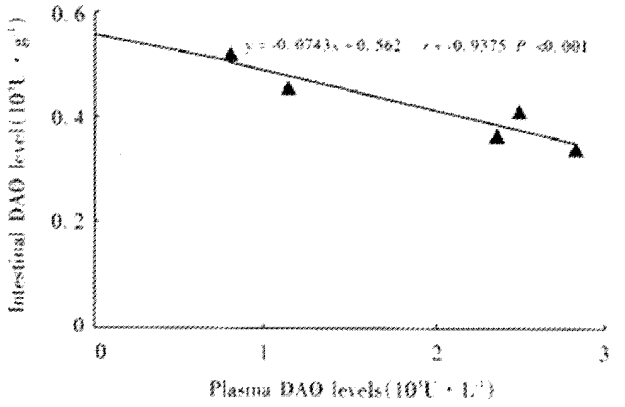

Figure 3 Relationship between intestinal and plasma DAO level.

DISCUSSION

DAO is located in the upper part of intestinal mucosa in human as well as in mammals, and is a highly active intracelluar enzyme. Under certain circumstances, intestinal mucosa cells became necrosed and dropped into the intestinal cavity, leading to decrease in intestinal mucosal DAO, and increase in DAO activity inside the intestinal cavity. DAO can also outer into the mucosal space between cells, lymphatic vessel[21-27] and blood flow, making plasma DAO markedly elevated. Gut as an important organ, may play an important role in the pathogenesis of serious complications. Intestinal mucosal surface layer with tight epithelial cells is an important component for intestinal barrier function, thus it can be seen that intestinal epithelial tissue integrated property is a key part to preserve intestinal barrier function. The changes in DAO activity is an ideal index to investigate intestinal barrier function damage after trauma, specially the changes in plasma DAO activity[2,6,10,11]. Therefore, intestinal barrier function injury after severe trauma could result in bacterial/toxin translocation, in turn evoke systemic inflammatory response syndrome

and multiple organ dysfunction syndrome[3,28-29].

The intestinal blood flow might keep relatively low despite of systemic circulation recovery during trauma, which was evident by significant decrease in intestinal mucosal pHi[30-33]. This may be the pathological basis for intestinal origin sepsis and multiple organ dysfunction syndrome. The changes in intestinal permeability were reflected by blood D-lactate and L/M rate in urine. Secretory IgA is an important component part for regulation intestinal immune function, it can prevent the bacteria from adhering to intestinal epithelial cells, and prevent gut-derived bacteria from invading through the intestinal barrier, which might reduce the toxicity of bacterial products to epithelial cells. Therefore, IgA may possess the beneficial effect on the preservation of intestinal mechanical barrier[34-37]. From our data that changes in several indexes of intestinal barrier function in various animal models after trauma, it was shown that DAO was released to increase in blood, and decreased in intestinal tissues. Thus, determination of DAO activity might reflect the condition of intestinal injury and repaired process.

The change in plasma D-lactate, lactulose, mannitol and ratio of L/M could reflect the increased intestinal permeability. The intestinal IgA levels appear to be associated with the local immunological dysfunction[38-41]. The change in intestinal pHi showed that intestinal hemorrhagic injury may result in the release of intestinal mucosal enzyme, subsequently leading to significant elevation of plasma DAO activity. This study showed that there is a close relationship between plasma DAO and TNFα, LPS, D-lactate, lactate, L/M, and the change of intestinal pathology and intestinal barrier function index was similar, indicating that intestinal barrier function was damaged after trauma.

We also observed that the plasma DAO activity was increased 2h and 72h after trauma, especially at 72h, and change of plasma TNFα and LPS was similar to the former. These results suggest that stress injury can cause changes of intestine barrier function index following intestinal ischemia-reperfusion injury, repair or endo/inextra protection, but the trends and degrees of changes were varied. Therefore, it is important to reduce development of SIRS to MODS by protection of intestinal barrier function in early trauma, and prevention of translation of intestinal origin bacteria and toxins[6,10,14,42-45].

Recent studies have shown that GLN may provide protection against intestinal barrier function injury after trauma[46-52]. Blood DAO activity was reduced to different extents at 10h,5d and 8d after early stage of oral GLN in scalded rats. Intestinal pathogical examination showed that the damage of epithetial cells of intestinal mucosa could be markedly improved, and the close correlation between plasma DAO and LPS and TNFα could also be changed after scalding[6]. The results indicate that GLN can protect against the intestinal barrier function damage after trauma.

Abstract

AIM: **To observe the location of neurokinin receptor (NK3r) in the mouse gastrointestinal tract.**

METHODS: **The abdomens of 8 male Kunming mice were opened under anaesthesia with sodium pentobarbital. The exposed gut organs were kept moisture and temperature at the same time. Then the esophagus, jejulum, ileum, colon, etc were respectively cut and the segments from the stomach to the distal colon were opened along the mesenteric border. A circular 4mm~6mm enteric part(pieces of 1 cm^2 were to be prepared) and mucosa and submucosa were removed, then the longitudinal muscle layer was pulled off from the circular muscle layer under microphotograph. They were rinsed in 50n $mol \cdot L^{-1}$ potassium phosphate-buffered saline(PBS). Immunohistochemistry and immunoreactive fluorescence were used in the staining procedures.**

RESULTS: **There was not NK3r-Like(-Li) positive material on the smooth muscle cells of the esophagus, stomach, and intestines and other regions. The nerve cell bodies with immunoreactivity for NK3r were mainly distributed in the submucousal nerve plexus or myenteric nerve plexus of the gastrointestinal tract except for the esophagus, stomach and rectum. The reaction product was located on the surface of the nerve cell plasma. It was occasionally observed in the cell plasma endosomes, but was very weakly stained. Among the NK3-like positive neurons in the plexus,the morphological type in many neurons appeared like Dogiel II type cells. Some neuron cell bodies were big, having many profiles, some were long ones or having grading structure. Cell body diameter was about 10μm-46μm and 8μm-42μm in myenteric plexus and submucous plexus.**

CONCLUSION: **This study not only described the distribution of neurokinin B receptor in the mouse gut in detail, but also provided a morphological basis for deducing the functional identity of the NK3r-LI immunoreactivity neurons, suggesting the possibility that these neurons were closely related to gastrointestinal tract contraction and relaxing activity.**

INTRODUCTION

The tachykinin family of neuropeptides mainly includes neurokinin A(NKA) neurokinin B(NKB),and the neurotransmitters in the peripheral and central nerve systems[1]. Tachykinin and their receptors (NK1\NK2\NK3) play an important role in the nerve system. Various studies have been undertaken in NK3 receptor's distribution in rat CNS[2,3].Our previous experiments suggest that NK3 receptor in the paraventricular and supraoptic nuclei of the rat hypothalamus may be involved in the modulation of the release of vasopressin from the hypothalamus when the internal environment was disturbed[3]. Some research results[4] implicated that tachykinin located in the intestine intrawall neurons is attributable to the activation of gut and its modification. Pharmacological research work has proved that NK3r was located in neurons rather than in muscle cells[5,6]. Having characterized the antisera, researchers localized the neurokinin receptor in the rat/guinea gut[6,7]. NK2r was also detected in the muscularis mucosa of the small intestine and the colon. NK2r was localized in the plasma membrane of smooth muscle cells and was present on numberous nerve terminals in both the submucosal and the myenteric plexus of the small intestine[4,7,8], but NK1r-Li reactive product existed only in the neurons that resemble the interstitial cells of Cajal[9-11]. Mann *et al*[12] and Grady *et al*[7] reported that in rat myenteric plexus there were neurons that could express NK1r. These neurons had colocalization with NK3r-Li positive neurons. Although all these results implicated that tachykinin receptors existed in the mouse gastrointestinal tract, and that they might be related to intestinal muscle contractile activity[13] in addition to its influence in blood pressure and increase of vascular penetration. Up to now, we have not seen reports about this receptor's distribution in mouse gastrointestinal tract.Our aim was to further investigate this receptor distribution in mouse gut.

MATERIALS AND METHODS

Animals and material preparation

Ten male Kunming mice weighing 20g-30g were chosen and the abdomens of 8 mice were opened under anaesthesia with sodium pentobarbital. To keep moisture and temperature we cleaned the exposed gut organs with 0.01 $mol \cdot L^{-1}$PBS (phosphate-buffered saline, pH 7.0) continously. Then the esophagus, jejulum, ileum, colon, etc were respectively cut and the segments from the stomach to the distal colon were opened and cleaned by 0.01$mol \cdot L^{-1}$ PBS containing smooth muscle relaxing medicine. And they were filled with 40$g \cdot L^{-1}$ polyformaldehyde and the two ends were closed tightly and fixed for 6-8 h. The stomachs were fixed for 8 h following Peng Xi's suggestion(1999)[14] and incubated in 300$g \cdot L^{-1}$ sucrose for 24 h (overnight) together with other organs after cut and cleaned with 0.01 $mol \cdot L^{-1}$ PBS. Gastrointestinal tract was processed from stomach to the distal colon and was opened along the mesenteric border. A circular 4-6mm enteric part(pieces of 1 cm^2 were to be prepared)

was obtained, the longitudinal muscle layer was pulled off from the circular muscle layer with fine forceps and processed for immunohistochemical examination along the mesenteric border rinsed in phosphate-buffered saline and prepared for layer separation. Gastrointestinal tracts were cut into small pieces of 1 cm^2 and mucosa and submucosa were removed with forceps. Then they were rinsed in 50 $nmol \cdot L^{-1}$ potassium phosphate-buffered saline(PBS) and prepared for layer separation. These procedures can be done under anatomy microphotography.

Staining procedures

Staining procedures: whole-mount free-floating tissues and slide-mounted sections were washed in 50 $mmol \cdot L^{-1}$ KPBS, incubated with 0.3%H_2O_2 (30min), rinsed again in 50m $mol \cdot L^{-1}$ KPBS, and incubated in diluent containing of 50mM KPBS, 4$g \cdot L^{-1}$ Triton X-100, 10 $g \cdot L^{-1}$ bovine serum albumin, and 10 $ml \cdot L^{-1}$ normal goat serum for 30min at 22℃, then transferred to NK3r affinity-purified antibodies diluted to 1:50 in the same diluent for 48-96 h at 4℃. Tissues were washed in 50m $mol \cdot L^{-1}$ KPBS with 0.2$g \cdot L^{-1}$ TritonX-100 and incubated with biotinylated goat anti-rabbit IgG(Vector) diluted to 1:200 for 3 h at 22℃(Vector),followed by avidin-biotin complex coupled with horseradish peroxidase 1:200 for 2 h at 22. C(Vector). The horseradish peroxidase reaction product was virsualized with 0.4 $g \cdot L^{-1}$ diaminobenzidine tetrahydrochloride and 0.1 $mL \cdot L^{-1}$ H_2O_2 dissolved in 0.1 $mol \cdot L^{-1}$ sodium acetate. The reaction was terminated by two consecutive 9 $g \cdot L^{-1}$ NaCl washes.

The gastrointestinal tracts of the remaining mice were pulled off and cut on a cryostate at -20℃, rinsed by 0.01 $mol \cdot L^{-1}$ PBS and incubated in 40 $g \cdot L^{-1}$ formaldehyde fixative overnight at 4℃. They were incubated again in 300 $g \cdot L^{-1}$ sucrose and embedded by OCT on the next day. Their cryostat sections were 10μm in thickness, and immunohistochemically stainied after the slides were cooled according to the earlier procedure.

RESULTS

Immunohistochemical results showed that NK3-Li neurons and fibers existed in enteric plexus(submucous plexus and myenteric plexus) in the duodenum, jejunum, ileum and colon (Figures 1-8). Staining intensity in myenteric plexus was a little stronger. And the esophagus and the stomach were immunoreactively negative. No positive immunoreactive product was found in esophagus smooth muscle cells.

NK3-Li positive substance existed mostly in the membrane, some or a little in the plasma, but none in the nuclei. The surface of the positive neurons was well stained and was more apparent than those in the cell body(Figures 1,2,4,8). The neurons stained in myenteric plexus had high intensity, the NK3-Li neurons and fibers were web-like(Figure 3). And the fibers between the positive neurons were often of a beaded or granular appearance(Figure 7). Between fibers just like necklace among longitudinal muscle-myenteric plexus neuronal fibers there were striated fibers, that connect with them. From the cryostat sections, NK3r-Li immunoreactive product was found in intestinal myenteric plexus.

Among the NK3-like positive neurons in the plexus, the morphological type of many neurons were like Dogiel Ⅱ type cells: round or ellipse shape or presenting several dividing beaded profiles. Some neuron cell bodies were bigger, having many profiles, some of which were long or having grading structures. Results by microscopic counting are shown in Figures 1 and 2.

Table 1 The number of NK3r immunoreactivity neuron cell bodies in mouse gastrointestinal Tract*

Region	Neuronal density /(cells·cm^{-2}) ($\bar{x}$±s)	
	Myenteric plexus	Submucous plexus
Esophagus	Almost no	Almost no.
Stomach	Almost no.	Almost no.
Duodenum	82±14	95±12
Jejunum	249±37	237±31
Ileum	143±24	140±19
Colon	118±17	107±15

*neurons in areas of 0.05 cm^2 were counted.

DISCUSSION

There were some reports about tachykinin B receptor(NK3r) distribution in mammal gastrointestinal tract[7,12]. It was proved that NK3r-Li neurons were localized in enteric nervous system of rats and guinea pig[15]. We observed the NK3r distribution in mouse gastrointestinal tract. Our results were consistent with the previous results, and support the research work of Mann *et al*[12], and Grady *et al*[7], but we must claim several valuable differences: ① In our experiments we found that immunoreactivity was mainly located in the enteric nervous system neurons, rather than in mouse esophagus or other parts of the gut smooth muscles, which was different from the results of Maggi *et al*[5] and Guard *et al*[16]. ② We also found that there were different morphological type of NK3r-Li neurons in mouse jejulum and ileum nervous plexus: the first part gut plexus had more neurons than the second part gut plexus In ileum plexus NK3r-Li neurons were mostly of Dogiel Ⅱ type neurons[17], which was different from the results by other authors that NK3r-Li neurons were only located in the ileum. ③Although the immunoreactive products existed mainly in the enteric system neurons membrane, they were also detected in some positive neurons plasma. On the whole, cell morphology(size and shape) was similar to the cells that were observed and described by Mann *et al*. and Furness[18]. We also found that there were some small cell body neurons, which did not have clear characteristic positive shapes, so we might deduce that they had possibly different functions or belonged to dividing disparity. The location of the NK3r-Li immunoreactivity observed through the subnuclei of the NTS (solitary tract nucleus) suggested that NK3r-Li immunoreactive neurons might be involved in the medullar integration of the information conveyed by the afferent vagus nerve from the lower digestive tract[19]. The distribution of the NK3r-containing neurons coincided with the afferent fibers arising from the lower digestive tract. Vagal afferent fibers from the stomach and intestine terminated preferentially in the subnuclei medialis and commissuralis and in the substantia gelatinosa of the NTS (solitary tract nucleus)[20] as well. In the NTS, the subnucleus centralis represented the preferential termination sites for afferent fibers arising from the esophagus(vagus nerve). No or very few NK3r-Li neurons have been found in this subnucleus. We also found the supporting example for these referrences of NK3 receptor in the central nervous system and added proof to NK3 receptor in the peripheral nervous system. In the rat

brain, by situ hybridization method for NK3r mRNA, the results agreed well with the immunohistochemical results, however low levels of NK3r mRNA were found in rat stomach and intestines[21] which suggests that our detection of a large population of enteric neurons with NK3r immunoreactivity contradicts with Tsuchida *et al*'s results[22]. Binding studies also failed to detect NK3r in the gastrointestinal tract[22]. Our experiments showed that morphology of NK3r-Like neurons was in agreement with Dogiel II type neurons in size, shape and localization.The number of neurons was not very large and was less than the proportion of NK1r-Li neurons in the enteric nervous system.Considering NK3r-Li neurons' size in diameter, and the morphologic and pharmacological results, we speculate that NK3r-Li neurons are possibly a part of afferent internal neurons related to the enteric construction, relaxing the activity of mouse enteric nervous system, which was closely relatied to with some vice sympathetic nerve fiber functions. This is determined according to Furness *et al*'s[23] dividing method in guinea enteric nervous system neurons that is regarded as right, but at the same time it needs further verifications by functional test. Functional experiments supported the neuronal localization of the NK3r: the NK3 agonists NKB senktide stimulated contraction of rat duodenum and guinea pig ileum[24,25]. The response of the guinea pig ileum were abolished by tetrodotoxin and reduced by atropine which indicated the presence of NK3r in the cholinergic neurons of the myenteric plexus[26]. Indeed, senktide stimulated acetyl choline to release from the myenteric neurons[16]. Barthó *et al* (1999)[24,25] proved that NK3r existed in rodent gastrointestinal (interwall) neurons and regulated tachykinin inducing the excitement of the enteric nervous system thus influencing construction[27].Our findings that neurons in the myenteric plexus could express NK3r is of particular interest and NK3r reacting production existed mainly on the plasma membrane of gastrointestinal tract intrawall neurons, implicating that tachykinin B transmitter possibly influence membrane receptor thus influencing the contraction and relaxing smooth muscle and even regulating the exocrine of gastrointestinal tract as well as the contents that some articles have described[28-33].

In summary, our research not only observed the distribution of NK3r-like neurons and fibers in mouse gastrointestinal tract, but also provided new insight into the cellular colocalization of receptor proteins in the mouse gut tract and a base for investigating NK3r-like neuron functions in the gut tract. These results might also give implications about muscle activity of contracting or relaxing action related to the neurokinin receptor.

Abstract

AIM: **To study the bioadhesive property of carbomer934 in dog alimentary tract.**

METHODS: **Carbomer934 and ethylcellulose were radiolabelled with technetium-99m; and Gastrointestinal emptying rate of materials was measured using the technique of gamma scintigraphy.**

RESULTS: **After oral administration, the maximum intestinal radioactivity of non-bioadhesive granules and bioadhesive granules were observed in the second hour and the sixth hour respectively. Constants of stomach emptying rate of nonadhesive granules, bioadhesive granulesI and bioadhesive granulesII were $0.774h^{-1}$,$0.265h^{-1}$ and $0.321h^{-1}$ respectively on the base of gastric residual amount. Compared to nonadhesive material (ethylcellulose), the migration rate of adhesive material(carbomer934) was remarkably slower in dog alimentary canal.**

CONCLUSION: **It is concluded that, in the dog, interactions between gastrointestinal mucus layer and adhesive material or nonadhesive material were significantly different. Carbomer934 had stronger *in vivo* bioadhesive property than ethylcellulose.**

INTRODUCTION

A problem frequently encountered with controlled release dosage forms is the inability to increase residence time of the dosage form in the stomach and proximal portion of the small intestine. Under fast condition, gastric residence of a dosage form is typically short, which is not more them an hour and it is also common for dosage forms to transit rapidly through the small intestine for not more than 3h[1]. Rapid GI transit phenomena may consequently diminish the extent of absorption of many drugs. Since many drug compounds are absorbed exclusively in the small intestine or in a limited segment of the intestine, it would therefore be beneficial to develop sustained release dosage forms, which remain in the stomach for an extended period of time. Several approaches have been tried to prolong gastric residence, one of which is the use of oral bioadhesive formulation[2,3]. A number of charged and neutral polymers have been classified as bio/mucoadhesives, since they are known to bind very strongly to mucus via non-covalent bonds.[4,5] Carbomer is a polyacrylic acid polymer, crosslinked with allyl sucrose. As a mucoadhesive polymer, carbomer has been investigated extensively by the pharmaceutical researchers because of its high viscosity at low concentration and low toxicity.[6-15] *In vitro* experiment has proved that carbomer934 have good bioadhesion with the gastrointestinal mucus[16-19]. Our research strategy is to investigate the *in vivo* bioadhesion of carbomer934 through measuring the migration rate of radioactive carbomer934 granules in dog alimentary tract by a gamma camera. Gamma scintigraphy is an elegant imaging technique which allows the intestinal performance of pharmaceutical formulations to be visualized.[20] Over the past 20 years the approach has become the technique of choice for probing the complex interaction of drug preparation/formulations with the heterogeneous environment of the gut.[21-29]

MATERIALS AND METHODS

Materials and apparatus

Ethylcelluose200cps (EC, imported from Roth Co. Ltd., obtained from Shanghai Chemical Agents Distributing Factory); Stearic acid(AP, supplied by Shanghai Stock and Accommodate Station of Chemical Agents); Carbomer934 (Cb934, purchased from Shanghai Shenxing Pharmacy Co. Ltd); ^{99}m TcO_4(China Institute for A-energy and Isotope); γ-ray camera(Orbiter, Semens Co. Ltd, Germany); and Dog (provided by Laboratory Animal Center, Sicuan University).

Methods

Radiolabeling of Cb934 and ethylcellulose Procedures of Cb934 and ethylcellulose radiolabelled were described in brief as follows: In vacuum bottle, 1ml of 0.1mol·L^{-1} hydrochloric acid containing 1mg $SnCl_2$ and 1mg vitamin C was added to 2mL of 15g·L^{-1}Cb934(or 30g·L^{-1}EC) of ethanol solution, then with incorporation of Tc $^{99}mO_4$. The mixture was warmed at 90℃ for 10 minutes. Radioactivity chemical purity of radiolabelled materials measured by TLC was beyond 95%.

Preparation of radioactive granules According to the materials proportion of granules listed in Table 1, the mixed materials were solved in ethanol and dried in a rotated vaporizing apparatus. The product was crushed, then manually sieved. The collecting fraction have a size range of 20-40 mesh. An amount of the final blend was filled into hard gelatin capsules (size No.0). Each capsule has an activity of about 111MBq technetium99m at the time of administration.

Table 1 Component proportion of radioactive granules

granules	Percentage/%		
	EC	Cb934	Stearic acid
Non-bioadhesive	100	0	0
Bioadheive I	0	100	0
Bioadheive II	0	50	50

Measurement of migration rate of granules in dog alimentary tract

The study was an open-labeled, three-period, three treatment crossover study in three dogs (15-20kg). Each subject received the

following treatment in a randomized order: Treatment A: control nonbioadhesive granules, 2×111MBq radioactivity following 24 h fast. Treatment B: bioadhesive granulesI, 2×111MBq radioactivity following 24 h fast. Treatment C: bioadhesive granulesII2×111MBq radioactivity following 24 h fast. Percentage of granules in different segments of dog alimentary canal could be determined according to radioactivity by a γ-ray camera.

RESULTS

Migration rate of three kinds of granules

The dog alimentary tract was divided into three segments of stomach, intestine and colon(including colon,rectum and anus). Radioactivity was measured respectively in different segments (Tables). The gastric emptying rate of granules containing Cb934 (bioadhesive granules Iand bioadhesive granulesII) was significantly slower than the control non-bioadhesive granules. After 4h, percentage of non-bioadhesive granules in stomach was only 7.63%, while bioadhesive granulesI 45.92% and bioadhesive granulesII 37.52%. In the sixth hour, percentage of non-bioadhesive granules,bioadhesive granulesI and bioadhesive granulesIIin dog stomach was 0, 23.2%and 15% respectively.

Table 2 Non-bioadhesive granules in alimentary tract of dog (*n*=3)

Sites	Granules in different segment of alimentary tract(%)					
	1h	2h	4h	6h	8h	12h
Stomach	83.7	26.9	7.6	0	0	0
Intestine	16.3	73.2	59.7	0	0	0
Colon	0	0	32.6	43.2	10.6	0

Table 3 Bioadhesive granulesI in alimentary tract of dog (*n*=3)

Sites	Granules in different segment of alimentary tract(%)					
	1h	2h	4h	6h	8h	12h
Stomach	100	79.6	45.4	23.3	7.5	0
Intestine	20.4	54.7	59.7	55.1	30.9	0
Colon	0	0	0	21.8	61.6	54.3

Table 4 Bioadhesive granules IIin alimentary tract of dog (*n*=3)

Sites	Granules in different segment of alimentary tract(%)					
	1h	2h	4h	6h	8h	12h
Stomach	100	67.1	37.5	15	0	0
Intestine	0	32.8	51.6	57.9	29.6	0
Colon	0	0	10.9	29.7	70.4	64.8

Non-bioadhesive granules were emptied to intestine in the first hour and the maximum intestinal radioactivity was observed in the second hour, then intestinal radioactivity was completely eliminated in the sixth hour, bioadhesive granulesI and bioadhesive granulesII began to intestine migrated to in the second hour, and the maximum intestinal radioactivity was observed in the sixth hour. Furthermore considerable intestinal radioactivity could been inspected in the eighth hour. Compared with the non-bioadhesive granules, the bioadhesive granules had delayed onset of emptying to intestine and the maximum radioactivity in intestine. This result indicated that bioadhesion of Cb934 granules on the intestinal mucus was stronger than nonbioadhesive granules. In the fourth hour, a considerable non-bioadhesive pellets have entered the colon and were completely discharged out of anus in the eighth hour. Meanwhile, only very small parts of bioadhesive granules migrated into colon, and as long as the twelfth hour a great deal of granules were still in the dog alimentary tract.

Emptying half life of three kinds of granules in dog stomach

Emptying rate of stomach is fit to the first order kinetics[30]. $LogV_t=LogV_0-Kemt/2.303$ V_t:Gastric residual amount at the time of t V_0:Gastric residual amount at the time of 0 in stomach Kem: Constant of stomach emptying rate.

Constants of stomach emptying rate of nonadhesive granules, bioadhesive granulesI and bioadhesive granulesII can been calculated as $0.774h^{-1}$, $0.265h^{-1}$, $0.321h^{-1}$ respectively on the base of gastric residual amount. According to gastric residual amount of the first three points of time, constant of gastric emptying rate of bioadhesiveIgranules can be calculated as $0.265h^{-1}$, while according to the latter three points of time, constant can be calculated as $0.449h^{-1}$.

Pictures of γ-ray camera

A majority of nonadhesive granules have been emptied into intestine in the second hour (Figure 1B), then reached colon in the fourth hour (Figure 1C) and a great deal collected at anus in the seventh hour (Figure 1D). In the fourth hour, most bioadhesiveIgranules still mustered in the stomach(Figure 2C) and reached colon in the twelfth hour(Figure 2D). In the fifth hour, most bioadhesiveIIgranules were still in the intestine (Figure 3C) and reached colon in the seventh hour.

DISCUSSION

According to radioactivity measured by a gamma camera, migration rate of granules containing Cb934 was significantly slower than nonbioadhesive granules. It can be concluded that Cb934 has good bioadhesive properties *in vivo* and is a possible candidate material for oral bioadhesive preparation.

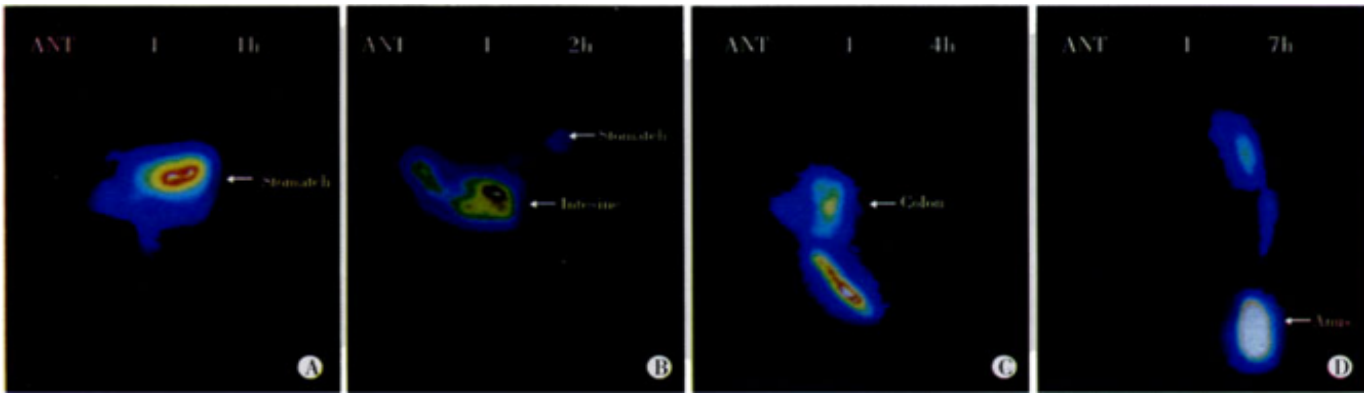

Figure 1 Radioactivity in alimentary tract of dog swallowing nonadhesive granules.
A, B, C, D: radioactivity at 1, 2, 4 and 7h.

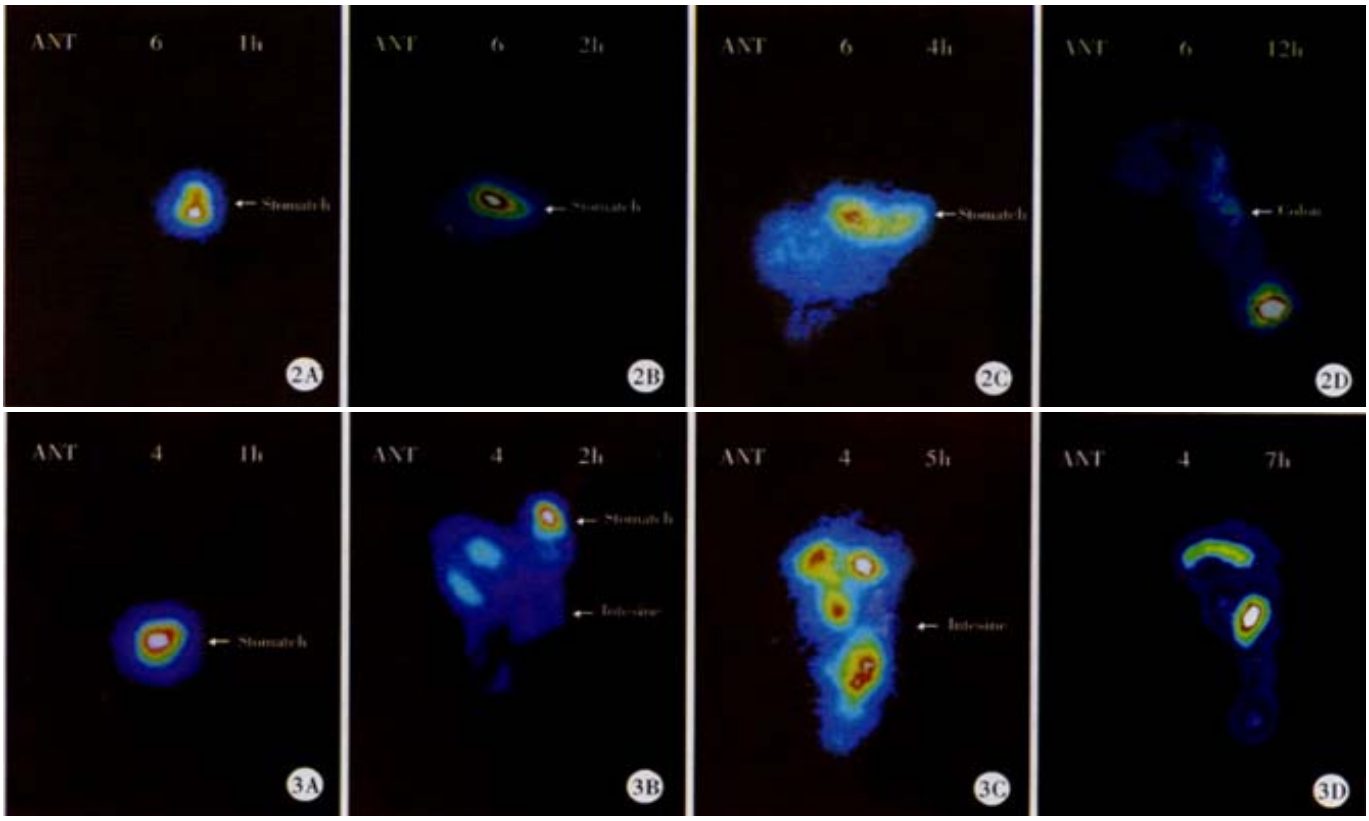

Figure 2 Radioactivity in alimentary tract of dog swallowing bioadhesiveIgranules.
A, B, C, D: radioactivity at 1, 2, 4 and 12h.

Figure 3 Radioactivity in alimentary tract of dog swallowing bioadhesiveIIgranules.
A, B, C, D: radioactivity at 1, 2, 4 and 7h.

Compared with the rate constant ($0.265h^{-1}$) at gastric prophase emptying, gastric anaphase emptying rate constant ($0.449h^{-1}$) of bioadhesive granulesIbecame larger. This result showed that gastric emptying rate of Cb934 granules became faster as time went along. It can be inferred that Cb934 was excessively hydrated and caused a lubricative effect, which quickened the gastric emptying of granules. This implied that materials, which not only have good bioadhesive properties and but also can maintain gel status to avoid excessive hydrating, should be preferably considered in oral bioadhesive preparation design.

INTRODUCTION

Recently,electrogastrography(EGG) has received more and more attention.Although gastroenterologists are interested in its clinical application,concerns remain to the reliability and analysis of the EGG and the correlation between the EGG and gastric motility[1-13]. This study was to investigate gastric myoelectrical activity and gastric emptying(GE) and their relationship in diabetic patients with dyspeptic symptoms using electrogastrography and isotopic method.

MATERIALS AND METHODS

Subjects

The study was performed on 22 healthy asymptomatic subjects (11 women,11 men,mean age 50 yr) and 32 non-insulin dependent diabetes mellitus(NIDDM) patients with dyspeptic symptoms (15 women,17 men,mean age 51 yr) based on clinical and laboratory diagnoses. NIDDM was diagnosed by the WHO criteria(1980).All patients had a minimum 3-month history of chronic,persistent,or recurrent epigastric pain and fullness,early satiety, nausea and/or vomiting.The result of esophagogastroduodenoscopic examination were negative for any focal lesions, including esophagitis,gastric,or duodenal ulcers or erosions,or esophageal or gastric malignancy.Exclusion criteria were:①history of abdominal surgery;②history of gastroesophageal reflux disease or irritable bowel syndrome;③evidence of cardiovascular, pulmonary, hepatic,or renal disease.All subjects fasted an overnight before the study and took no medications known to affect gastrointestinal motility during 3 d before the study.

Gastric emptying test

Gastric emptying test was taken by using SPECT technique.The standard meal for gastric emptying test consisted of 100g scrambled eggs labeled with ^{99m}Tc-DTPA(11.1MBq) and 200mL of water. After eating, the anterior/posterior images of the stomach were taken by the same operator using a technetium scanner for 2 h.Retention and half-emptying time($T_{1/2}$) were calculated by a specialist at the Department of Nuclear Medicine.Delayed gastric emptying was defined as the half-emptying time $\geqslant x+2s$ as controls.

Recording of gastric myoelectrical activity

Gastric myoelectrical activity was measured with surface EGG. The EGG recording including a 30-min fasting study using an EGG recording unit (Digitrapper, Synectics Medical, Sweden), after which the patient ate a standard test meal (1883J).This was immediately followed by another 30-min recording.The EGG data was analyzed by the "multigram" Synectics software package running on a personal computer. The EGG parameters including dominant frequency(DF), dominant power(DP), postprandial / preprandial DF, postprandial /preprandial DP.

Statistical analysis

Data were expressed as $\bar{x}\pm s$. Statistical analyses used are *t* test and χ^2 test.Statistical significance is taken as $P<0.05$.

RESULTS

Gastric emptying test

The mean percentage of gastric retenton and half-emptying time in diabetic patients with dyspeptic symptoms were substantially higher than in the healthy subjects (Table 1). Of 32 patients, 15 (47%) had delayed gastric emptying. Of 22 controls,1 (5%) had delayed gastric emptying. The incidence of gastric emptying delay was higher in patients than in controls($P<0.01$).

Table 1 Gastric Emptying In NIDDM ($\bar{x}\pm s$)

Groups	*n*	Percentage of gastric retenton %				$T_{1/2}$min
		30min	60min	90min	120min	
NIDDM	32	75±7[a]	61±8[b]	54±10[b]	43±10[b]	92±10[b]
Controls	22	61±7	45±6	33±4	24±10	49±9

[a]$P<0.05$ *vs* controls; [b]$P<0.01$*vs* controls

Electrogastrographic findings

EGG dominant frequency corresponds to gastric slow wave. DF ranging from 2.4 to 3.7 cycle per min(cpm) was considered as normogastria,DF<2.4 cpm was defined as bradygastria, DF> 3.7 cpm was defined as tachygastria. DF<2.4 cpm and/or DF>3.7 cpm was defined as dysrhythmia or abnormal EGG. The patients had a lower incidence of normogastria than did controls both in the fed state (34% *vs* 86%,$P<0.01$) and in the fasting state (38% *vs* 96%,$P<0.01$).However,the patients had a higher incidence of dysrhythmia (tachygastria and bradygastria) than did controls both in the fed state (66% *vs* 14%, $P<0.01$) and in the fasting state (63% *vs* 5%,$P<0.01$). The mean postprandial dominant frequency and postprandial/preprandial dominant frequency ratio were lower in patients than in controls (2.61±0. 29 cpm *vs* 3.76 ±0.14 cpm,$P<0.05$;1.01±0.10 *vs* 1.28±0.11,$P<0.05$). The mean postprandial dominant power increase and the mean postprandial/preprandial dominant power ratio was significantly less in the patients than in the controls(121.50±67. 02 V^2.cpm *vs* 688.61±72.73 V^2.cpm,$P<0.01$; 0.71±0.60 *vs* 2.40±0. 61,$P<0.01$).No differences were found in the mean preprandial dominant frequency and the mean preprandial dominant power (2.57±0.24 cpm *vs* 2.91 ±0.22 cpm,$P>0.05$; 144.10±27C40 V^2.cpm *vs* 288.40±56.72 V^2.cpm,$P>0.05$).

Comparison of EGG and gastric emptying

Of 32 diabetic patients with dyspeptic symptoms,15 (47%) had

delayed gastric emptying and 21 (66%) patients with dysrhythmia. 12 patients with dysrhythmia had slow gastric emptying. There was no significant correlation between gastric electrical rhythm and gastric emptying (P>0.05).

DISCCUSION

Gastric emptying and EGG were measured in diabetic patients with dyspeptic symptoms in this study. The results showed that fifteen of 32 (47%) diabetic patients with dyspeptic symptoms had delayed gastric emptying, and 21 of 32 (66%) patients had abnormal gastric myoelectrical activity. 12 patients with dysrhythmia had slow gastric emptying. The major abnormalities in gastric myoelectrical activity observed in diabetic patients with dyspeptic symptoms were the abnormal rhythmicity of the gastric slow wave and the reduced postprandial increase in the dominant power.

Our findings in this study are similar to those in previous studies in patients with various gastric motor disorders[14-19]. In studies using cutaneous electrodes,abnormal EGG were found in 50% of patients with functional dyspepsia[14]. In an electrogastrographic study using cutaneous electrodes,a high proportion of adult patients (60%) with functional dyspepsia had abnormally slow gastric emptying and abnormalities in gastric myoelectrical activity[15]. We found that 66% of the patients had abnormal rhythmicity of the gastric slow wave(bradygastria and tachygastria)and some patients had a reduced postprandial increase in the dominant power. EGG findings similar to those in this study have been also reported in studies in patients with gastroparesis[20,21]. However,Pfaffenbach *et al*. reported that the EGG values obtained in diabetics did not differ significantly from those in healthy subjects and did not correlate with radioscintigraphy, the EGG values in diabetics with delayed gastric emptying(about 40%) did not differ from data in diabetics without gastroparesis[22]. Jebbink *et al*. also reported that no differences between patients with functional dyspepsia and healthy volunteers were found in the incidence of dysrhythmias[23]. These discrepencies probably results from differences in patient selection ,differences in definition of dyspepsia and EGG analysis method [24]. Prior studies have demonstrated that gastric emptying in dyspeptic patients was found to be delayed in 30~80% of the patients[15,20, 25-28]. In agreement with prior studies,this study demonstrated 47% delayed gastric emptying in diabetic patients with dyspeptic symptoms. The present study shows that 12 patients with dysrhythmia had delayed gastric emptying,but there was no correlation between gastric rhythmicity and gastric emptying. An other interesting finding was the reduced increment of amplitude(power),expressed as absolute or relative changes (fed/fasting power ratio). A possible cause for a decrease in the power ratio was the reduced gastric distention or/and contractility of the stomach. A increase in amplitude were reported in numerous studies in normal adults and in normal children[29-32]. Some authors believed that it was related to the increased contractility of the stomach after the meal[30,33-35],whereas others reported a major effect of gastric distention. Faure *et al*. suggested that both gastric distention and motor activity contributed to the increase in EGG amplitude, the greater contribution being attributable to gastric distention[36]. Gastric emptying and EGG findings were agreement with our finding in previous study[37] and other authors'findings[38]. A study by Barbar *et al*. showed that EGG did not correlate with nuclear scintigraphic gastric emptying studies in children with suggestive symptoms of gastric motility disorders[38]. Zhang *et al*. reported that they can't predict a delayed GET by an abnormal EGG[39]. However,controversial findings were reported. Pfaffenbach *et al*. reported that in 25 adult patients with functional dyspepsia,patients with delayed gastric emptying showed significantly more pre- and post pradial tachygastrias than patients with normal gastric emptying[40]. Gastric emptying is a complex procedure. EGG reflects gastric myoelectrical activity and gastric emptying reflects gastric motility,so EGG and gastric emptying should complement each other in studying gastric motor disorders[14,41].

In conclusion, diabetic patients with dyspeptic symptoms have delayed gastric emptying and abnormalities in gastric myoelectrical activity including dysrhythmia and the reduced postprandial increase in the dominant power. However, the abnormal EGG isn't able to predict delayed gastric emptying.

Abstract

AIM: **To determine whether the gastrin stimulated intestinal crypt cell (IEC-6) proliferation by induction of ornithine decarboxylase (ODC).**

METHODS: **IEC-6 cells were grown in DMEM containing 50mL·L^{-1} dialyzed fetal bovine serum for 24h and then were treated with gastrin. The proliferative capability of the cells was monitored subsequently on d 1, 2, 3, and 4 after treatment with MTT assay at aborbance 570nm. The cellular ODC mRNA expression, ODC activity, and putrescine content were examined by RT-PCR method, radiometric technique and high-performance liquid chromatography(HPLC) analysis respectively after 12h of treatment.**

RESULTS: **On d1 after exposure of IEC-6 cells to pentagastrin, the proliferation increased initially and reached a peak on d3 at 250μg·L^{-1} concentration. Pentagastrin 500μg·L^{-1} increased cell proliferation on day 1 and day 2, and then decreased. Compared with control group, pentagastrin 250μg·L^{-1} increased ODC mRNA level by 1.09-fold (P<0.05), ODC activity by 1.71-fold(P<0.01), and putrescine content 5.30-fold (P<0.01), respectively. Similarly, pentagastrin of 500μg·L^{-1} also increased ODC mRNA level by 1.16-fold (P<0.05), ODC activity 1.63-fold(P<0.05), and putrescine content 4.41-fold (P<0.01), respectively. But there was not significant difference between them.**

CONCLUSION: **Gastrin is an agent which promotes IEC-6 cell proliferation involved in regulating ODC activity mechanism.**

INTRODUCTION

Increasing evidence has demonstrated that cell proliferation, differentiation and migration in the intestinal mucosa is dependent on the supply of polyamines to the dividing cells[1-8]. Intracellular polyamine levels are highly regulated[9-15] and completely depend on the activation or inhibition of ornithine decarboxylase (ODC), which is the first rate-limiting step in polyamine biosynthesis[16-22]. In addition to the general effect of metabolic hormones, the amount of ODC in the gastrointestinal mucosa is also regulated by growth-related gut peptides present in the diet or secreted from digestive glands[23-29].Gastrin is an important gut peptide which stimulates cell proliferation in the mucosa under physiological condition[30]. Administration of gastrin significantly increases ODC activity and intracellular polyamine levels in intestinal epithelial cells[30]. Intestinal epithelial restitution is a complex process.Because of the limitation to study such issues in natural mucosae,cultured rat small intestinal epithelial cell lines(IEC-6) were commonly employed to characterize the physiological events such as growth, differentiation, metabolism and so on during restitution in detail. In the present study, we investigated the influence of gut peptide gastrin on the proliferation, expression of the ODC gene, ODC activity and polyamine biosysthesis in cultured normal rat intestinal crypt cells (IEC-6 cell line).

MATERIALS AND METHODS

Chemicals and supplies

IEC-6 cell line (CRL-1592) was purchased from American Type Culture Collection (ATCC, Rockville, MD) at passage 13. Disposable culture was purchased from Corning Glass Works (Corning, NY). Dulbecco's modified Eagle's medium containing 4500mg·L^{-1} D-glucose, L-glutamine, 25mmol·L^{-1} HEPES buffer and pyridoxine hydrochloride (DMEM), dialyzed fetal bovine serum (dFBS), trypsin-EDTA solution, gentamicin sulfate and insulin, Dulbecco's PBS(D-PBS), and biochemicals such as pentagastrin, putrescine, sodium dodecyl sulfate(SDS) and 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl-tetrazolium bromide (MTT) were from Sigma (St. Louis, MO). L-[1-14C]ornithine (sp act 1.93TBq·mol^{-1}) was purchased from NEN (Boston, MA).

General experimental protocol

To insure the highest level of viability, the culture was started as soon as possible upon receipt of the vial.Thaw the vial by gentle agitation in 37℃ water bath and decontaminate by dipping in 700mL·L^{-1} ethanol, transfer the vial contents to 25cm^2 tissue culture flasks containing 10mL DMEM supplemented with 50g·L^{-1} dFBS, 10mg·L^{-1} insulin, and 50mg·L^{-1} gentamicin sulfate(cDMEM) then place into the incubator for 15min prior to addition of the vial contents to allow the medium to reach its normal pH(7.2). Incubate the cells at 37℃ in a humidified atmosphere of 900mL·L^{-1} air-100mL·L^{-1} CO_2. Stock cells were subcultured once a week; and the medium was changed three times weekly. The cells were restarted from frozen stock every five to six passages. Tests for mycoplasma were routinely negative. For cell counting and subculturing, the cells were dispersed with 0.5g·L^{-1} trypsin and 0.2g·L^{-1} EDTA. Remove the solution and add 1 - 2 mL of trypsin-EDTA solution. Allow the flask to sit at room temperature until the cells detach. Add fresh culture medium, aspirate and dispense into new culture flasks.

Treatment of pentagastrin on IEC-6 cells

IEC-6 cell numbers were directly measured with the help of a cell counter, and plated in 96-wells with 200μL cDMEM, or 6-wells with 2000μL cDMEM. The cells were incubated in a humidified atmosphere at 37℃ in 900mL·L^{-1} air-100mL·L^{-1} CO_2, which was followed by a period of different experimental treatments. Pentagastrin was dissolved in two or three drops of 300g·L^{-1} ammonium hydroxide (sterile), adjusted to pH 7.5, and then diluted with medium to the desired concentrations before use. Media pentagastrin were prepared immediately before the experiments.

In the first series of studies, we examined the effect of pentagastrin on cell proliferation in IEC-6 cells. Cells were plated in

96-well microplates at a density of 1×10^4 cells per well with 200μL cDMEM and grown in incubator under the condition described above. After 24h, 10μL media pentagastrin were added at final concentrations of 500 and 250μg·L^{-1}. Control cells were fed with fresh medium without gastrin as well. To determine the time course of cell proliferation, cell numbers were measured at different time points after exposure of the cells to pentagastrin with MTT assay.

In the second series of studies, we examined the effect of pentagastrin on cellular ODC mRNA levels, ODC enzyme activity and putrescine content in IEC-6 cells. Cells were plated in 6-well microplates at a density of 2×10^6 cells per well with 2000μL cDMEM and grown under incubator at the condition described above. After 24h,100μL media pentagastrin were added at final concentrations of 250 and 500μg·L^{-1}, respectively. Control cells were fed with fresh medium without gastrin as well. Cultures were harvested at 12h after exposure of the cells to pentagastrin. The dishes were placed on ice, the monolayers were washed three times with ice-cold D-PBS, and different solutions were then added according to the assays to be conducted.

Measurement of ODC mRNA level

Total RNA was isolated from IEC-6 cells using RNA TRIzol reagent from Gibco(Gaithersburg, MD). Isolation and extraction were performed according to the manufacturer's protocol. Briefly, the cells were washed with Dulbecco's PBS and were lysed with 1.0mL Trizol/well.

RNA was extracted with 0.2mL chloroform and precipitated with 0.5 mL isopropanol. The precipitated RNA was washed with 1mL 700mL·L^{-1} ethanol and redissolved in RNase-free water. The concentration of the extracted RNA was calculated by measuring the absorbance at 260nm.The ratio of the absorbance at 260nm to that at 280nm was always >1.9.

Aliquots of RNA (5μg) were reverse-transcribed using an RT-PCR kit from Gibco(Gaithersburg, MD).Briefly, 5μg RNA in 10μL of diethyl pyrocarbonate-treated water(DEPC-water) was mixed with 1μL of 50μmol·L^{-1} oligo$(dT)_{20}$, heated at 65℃ for 5min, and then plased on ice. The following reagents were added to the tubes: 4μL of 5× concentrated cDNA synthesis buffer,1μL of 0.1mol·L^{-1} DTT, 1μL of RNaseOUT(40MU·L^{-1}), 1μLof DEPC-water,2μl of 10mmol·L^{-1} dNTP Mix,and 1μL of Thermoscript RT(15MU·L^{-1}).The reaction mixture was incubated for 50min at 50℃ before the reaction was terminated by incubating the tube at 85℃ for 5min.The mixture was added with 1μl RNase H and incubated at 37℃ for 20min. The tube was stored at -80℃ until PCR was performed using the Platinum Taq DNA polymerase with rat-specific primers prepared on a DNA synthesizer (Seagon, Shanghai, China). The primers were designed according to sequences of rat ornithine decarboxylase gene (EC 4.1.1.17). as follows: upstream primer: 5'>TGG CTG GCG CTG GTC TGT AGT< 3';downstream primer:5'>AGC TCC TGC CTG GGT.CTT.ATG A< 3'.

The cDNA amplification products were predicted to be 300bp in length for ODC. To initiate the PCR, 2μL RT products were added to the PCR master mix, including 5μL 10× PCR reaction buffer, 2μL 50mmol·L^{-1} $MgCl_2$, 0.2μL Platinum Taq DNA polymerase(5MU·L^{-1}), 1μL 10μmol·L^{-1} each of the primers, 10mmol·L^{-1} dNTP Mix and 37.8μL DEPC-water. Tubes were placed in a programmed tempcontrol system (PE) as follows: 1) incubation at 94℃ for 2min (initial denaturation); 2) 40 cycles of the following sequential steps: 94℃ for 30s (denaturation), 60℃ for 30s(annealing), and 72℃ for 1min (extension); and 3) incubation at 72℃ for 7min (final extension). The PCR products were size-fractionated by agarose gel electrophoresis. After electrophoresis and ethidium bromide staining, DNA bands were visualized and the relative levels of mRNA for ODC were corrected for cDNA loading as measured with an ultraviolet transilluminator.

Assay for ODC activity

ODC activity was determined with radiometric technique in which the amount of $^{14}CO_2$ liberated from DL-[L-^{14}C]ornithine was estimated. Samples were collected as described above and placed in 0.5mL of 20mmol·L^{-1} Tris buffer (*pH*7.4) containing 0.05mmol·L^{-1} EDTA, 0.05mmol·L^{-1} pyrodoxal phosphate, and 5m mmol·L^{-1} dithiothreitol. The cells were frozen and thawed three times, scraped, and transferred to Eppendorf tubes. Cells were centrifuged at 12000g at 4℃ for 15min. The ODC activity of an aliquot of the supernatant was determined during incubation in stoppered vials in the presence of 7.6nmol of [^{14}C] ornithine (sp act 1.93TBq·mol^{-1}) for 15min at 37℃. The $^{14}CO_2$ liberated by the decarboxylation of ornithine was trapped on a piece of filter paper impregnated with 20μl of 2mol·L^{-1} NaOH, which was suspended in a center well above the reaction mixture. The reaction was stopped by the addition of trichloroacetic acid to a final concentration of 100g·L^{-1}. The $^{14}CO_2$ trapped in the filter paper was measured by liquid scintillation spectroscopy at a counting efficiency of 95%. Aliquots of the 12000g supernatant were assayed for total protein, by Lowry method. Enzymatic activity was expressed as picomoles of CO_2 per milligram of protein per hour.

Analysis of cellular putrescine

The cellular putrescine content was analyzed by HPLC as described previously[5]. In brief, after monolayers were washed three times with ice-cold D-PBS, 0.5mol·L^{-1} perchloric acid were added and the monolayers were frozen at -80℃ until ready for extraction, dansylation, and HPLC cells were harveated, and centrifuged at 1600g for 10min.This supernatant was collected, neutralized to pH 7.0 with 3mol·L^{-1} KOH, and centrifuged to remove the precipitate.A 0.5mL aliquot of solution was delivered to clean Eppendorf tubes. After addition of 0.25mL saturated Na_2CO_3 and 0.5mL dansyl chloride solution(10g·L^{-1} acetone), reaction was allowed to proceed by heating at 70℃ for 30min and then added to 1.5mL toluene. After mixing and centrifugation, the organic protein portion was collected and dryed by vacuum centrifugation. To the residue, 300μL methanol was added and filtered, and an aliquot of 200μL was used for HPLC analysis. Solvent A and B were composed of acetonitrile, water, glacial acetic acid,and triethylamine in the volume proportions of 80:20:0.02:0.001 and 95:5:0.02:0.005, respectively.The mobile phases used in this separation consisted of 60% solvent A and 40% solvent B. Each sample was run for 20min, and the equilibration delay between injections was 2min. Sufficient mobile phases (A and B) were prepared fresh before starting the automatic injector. The polyamine putrescine was measured by comparing ratios of polyamines to 1,10-diaminodecane peak areas with a standard curve. Protein was dissolved in 1mol·L^{-1} NaOH and determined by the Lowry method. The results were expressed as nanomoles of polyamines per milligram of protein.

Statistics

All data are expressed as $\bar{x}\pm s$ from three-four dishes. The significance of the difference between means was determined by independent *t* test using SPSS statistical software.

RESULTS

Effect of gastrin on the proliferation Of IEC-6 cells

IEC-6 cells were grown in cDMEM in the presence or absence of pentagastrin. Exposure of IEC-6 cells to pentagastrin, the proliferation increased initially on d1 and reached a peak on d3 in 250μg·L^{-1} concentration. Pentagastrin 500μg·L^{-1} increased cell proliferation on d1 and d2 and then decreased as shown in Figure 1.

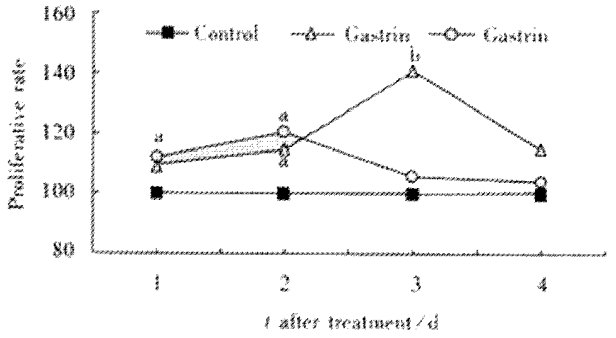

Figure 1 Gastrin effect on IEC-6 proliferation by the MTT assay. [a]$P<0.05$, [b]$P<0.01$ *vs* control.

ODC mRNA amount in IEC-6 cells treated with gastrin

Administration of pentagastrin 250 and 500μg·L^{-1} significantly raised the ODC mRN levels by 1.16-fold and 1.09-fold, respectively as compared with control group (Figure 2). But there was no significant difference between the two doses of gastrin.

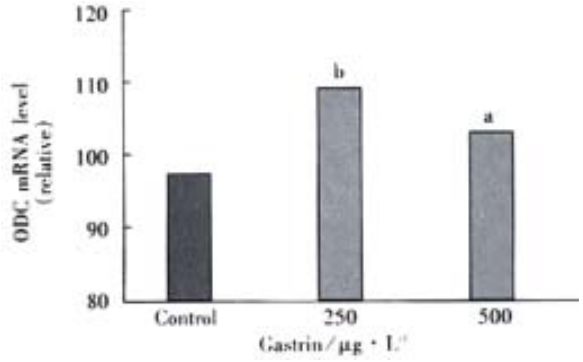

Figure 2 ODC mRNA levels in IEC-6 cells. [a]$P<0.05$, [b]$P<0.01$ *vs* control.

Gastrin induction of ODC activity

In these studies, IEC-6 cells were grown in cDMEM in the presence or absence of pentagastrin. This exposure of IEC-6 cells to pentagastrin 250 and 500μg·L^{-1} caused ODC activity to increase significantly by 1.71-fold and 1.63-fold, respectively at 12h after treatment as compared with control group. But there was no significant difference between them (Figure 3).

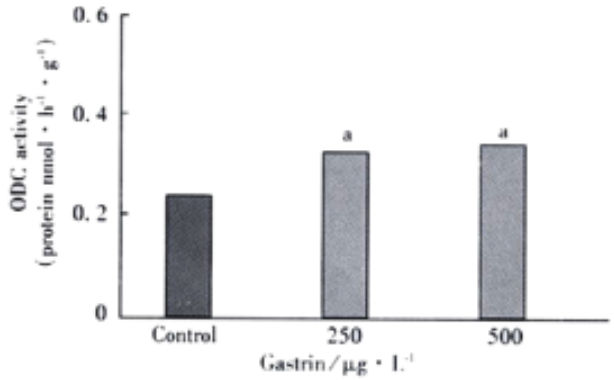

Figure 3 ODC activity in IEC-6 cells exposed to pentagastrin. [a]$P<0.05$ *vs* control.

Effect of pentagastrin on putrescine content in IEC-6 cells

Increases in ODC activity in cells exposed to pentagastrin were paralleled with increases in cellular putrescine levels. Compared with a value of 0.46±0.02μmol·g^{-1} from 4 cultures in the control group, the cellular putrescine levels treated with pentagastrin 250 and 500μg·L^{-1} significantly increased($P<0.01$), the values were 2.44±0.05μmol·g^{-1} and 2.03 ± 0.03mol·g^{-1} from 4 cultures, which were 5.30-fold and 4.41-fold of control group, respecticely.

DISCUSSION

Numerous studies have demonstrated that polyamine biosynthesis plays a critical role in the control of normal mucosal growth and repair[1-12] and that ODC in small intestinal mucosa has a high basal activity compared with most tissues and significantly increases in response to a variety of chronic and acute mitogenic stimuli[16-29]. The rapid and striking increases in ODC and polyamine levels are absolutely required for the stimulation of intestinal mucosal growth[16-21].

IEC-6 cells which were established by Quaroni *et al* are derived from neonatal normal rat small intestine and have characteristics of crypt-type epithelial cells as judged by morphological and immunologic criteria which do not exhibit differentiated morphology or specific gene expression. They are nontumorigenic and retain the undifferentiated character of epithelial stem cells. These cells exhibit a number of features of normal cells in culture: i.e. a normal rat diploid karyotype, strong density inhibition of growth, lack of growth in soft agar, and a low plating efficiency when seeded at low density. The establishment of IEC-6 cell lines play an important role in functional researches of small intestine epithelial cells such as growth, differentiation, metabolism, the pharmacological effects, and the pathophysiological changes and the mechanism of intestinal mucosa resulted from various pathogic factors. This cell line also provided an appropriate *in vitro* model for the study on cell proliferation and mucosal healing.This cell line was broadly used in the studies on cellular, molecular and genetic mechanism of small intestinal mucosal repair since the establishment[31-40].

The gastrointestinal mucosa must maintain a barrier against the harsh luminal contents of acid, enzymes, bacteria, and toxins. Disruption of this barrier is the salient feature of a variety of common and important gastrointestinal disorders, including inflammatory bowel disease and peptic ulcers. The mucosal epithelium of the small intestine has the capacity for rapid renewal and adaptation after injury or resection. Crypt cell proliferation leading to intestinal growth and promoting re-establishment of mucosal integrity after injury are essential processes for the differentiation, maintenance, and repair of the intestinal epithelium and are regulated via a complex interplay of nutrients, pancreatic and biliary secretions, and both locally derived and circulating growth factors[41-51].

It is of interest and important to investigate the effect of growth-related gut peptides on the regulation of ODC activity in intestinal epithelial cells. The current study clearly shows that, in small intestinal crypt cells maintained in cDMEM, gastrin stimulates cell proliferation, increases ODC mRNA levels, ODC activity and polyamine content, in which the effects of pentagastrin 250μg·L^{-1} seems to be better than those of 500μg·L^{-1}. Consistent with the results reported by other authors[30] higher dosage of pentagastrin (>1000μg·L^{-1}) inhibited IEC-6 cell proliferation(data not shown).

In summary, our results indicate that the increased ODC activity in IEC-6 cells treated with gastrin is associated with a rise in ODC mRNA levels and an increase of intracellular putrescine resulting in cell proliferation. It suggests that the induction of ODC activity by gastrin plays an important role in the regulation of cell proliferation in the intestinal mucosa under physiological condition.

ACKNOWLEDGEMENTS We would like to thank Prof. Wang

Zhou, Drs Han and Yu, and Mr Pan for their technical advice and excellent assistance.

Abstract

AIM: **To study the mechanism of Chinese herbal medicine (CHM, the prescription consists of Radix Salviae Miltiorrhizae, Radix Codonopsitis Pilosulae, Rhizoma Atractylodis Alba and Rhizoma Alismatis, Leonurus Heterophyllus Sweet, etc) on the regulation of the peritoneal lymphatic stomata and the ascites drainage.**

METHODS: **The mouse model of live fibrosis was established with the application of intragastric installations of carbon tetrachloride once every three days; scanning electron microscope and computer image processing were used to detect the area and the distributive density of the peritoneal lymphatic stomata; and the concentrations of urinary ion and NO in the serum were analyzed in the experiment.**

RESULTS: **Two different doses of CHM could significantly increase the area of the peritoneal lymphatic stomata, promote its distributive density and enhance the drainage of urinary ion such as sodium, potassium and chlorine. Meanwhile, the NO concentration of two different doses of CHM groups was 133.52±23.57μmol/L, and 137.2±26.79μmol/L respectively. In comparison with the control group and model groups (48.36±6. 83μmol/L,and 35.22±8.94μmol/L,$P<0.01$), there existed significantly marked difference, this made it clear that Chinese herbal medicine could induce high endogenous NO concentration. The effect of Chinese herbal medicine on the peritoneal lymphatic stomata and the drainage of urinary ion was altered by adding NO donor(sodium nitropurruside, SNP) or NO synthase (NOS) inhibitor (N(G)-monomethyl-L-arginine, L-NMMA) to the peritoneal cavity.**

CONCLUSION: **There existed correlations between high NO concentration and enlargement of the peritoneal lymphatic stomata, which result in enhanced drainage of ascites. These data supported the hypothesis that Chinese herbal medicine could regulate the peritoneal lymphatic stomata by accelerating the synthesis and release of endogenous NO.**

INTRODUCTION

Numerous investigatious have demonstrated that the peritoneal lymphatic stomata are small openings of the subperitoneal lymphatic vessels both in animals and in humans[1-18]. It has also been observed that particles, cells and solutions containing vital dyes are absorbed rapidly by the peritoneal lymphatic stomata[19-22]. Subsequent researches suggested that the peritoneal cavity is an integral part of the lymphatic system with enormous absorption powers, functioning primarily by means of the subperitoneal lymphatics via the peritoneal lymphatic stomata[23-29]. Thus, it has important clinical implications, especially in ascites drainage[30-32]. In recent years, therapeutic effect of Chinese herbal medicine (CHM) on the ascites has also drawn world wide attention among he scholars. It is further confirmed that Chinese herbal medicine can regulate the lymphatic stomata and promote the excretion of substance from the peritoneal cavity, which showed a good future in the treatment of the hepatocirrhosis with ascites[33-44]. However, it is still unclear how the lymphatic stomata is regulated by the Chinese herbal medicineThis article aimed at the regulation of CHM on the lymphatic stomata in the mouse liver fibrosis model induced by CCl_4, which provided theoretical evidence on ascites. Furthermore, by the application of NO donor (SNP) and NOS inhibitor (L-NMMA), the effect of NO was studied on the peritoneal lymphatic stomata in order to clarify the mechanism of CHM on the regulation of the peritoneal lymphatic stomata.

MATERIAL AND METHODS

Experimental CHM

By examining a computerized media index, the conventional remedies of CHM was selected for the treatment of hepatocirrhosis with ascites. The Chinese composite prescription was supplied by Zhejiang Academy of Traditional Chinese Medicine. The prescription consisted of Radix Salviae Miltiorrhizae, Radix Codonopsitis Pilosulae, Rhizoma Atractylodis Alba and Rhizoma Alismatis, Leonurus Heterophyllus Sweet. The medicament was immersed in the 750ml·L^{-1} alcohol for 24 hrs, then purified with rotatory evaporator (ZFQ85A type, produced by Shanghai 11th Factory of Electron Tube). The crude drug content was 15.2 g·ml^{-1}.

Animal and grouping

Ninety healthy mature NIH male mice, weighing 25g-30g, provided by the Experimental Animal Center of Zhejiang Academy of Medical Sciences, were selected and divided at random into six groups (each of 15 mice): the control group (NS group), model group, low dose of CHM group (CHM Ⅰ), high dose of CHM group (CHMII), the donor group (DR group) and the inhibitor group (IR group).

Mouse liver fibrosis model

Except the NS group, the other experimental mice were fed freely with 50ml·L^{-1} alcohol solution instead of water for 1 week, then the

mice were given 100ml·L^{-1} CCl_4 rape-seed oil solution 0.1ml/10g by gastrogavage every 3 days for 6 weeks to induce liver fibrosis. After liver fibrosis was confirmed by pathological examination, low dose of the Chinese herbal medicine (0.1ml/10g/day) was given to CHM Ⅰ group, high dose of the Chinese herbal medicine (0.2ml/10g/day) was give to CHMII group, normal saline (0.2ml/10g/day) was given to DR group, for 3 weeks respectively. After the 10th week, DR and IR group was additionally injected intraperitoneally with 50μg/10g/day NO donor (SNP) or 80μg/10g/day NOS inhibitor (L-NMMA) for two days respectively. Model group was untreated and NS group was given 0.2ml/10g of normal saline per day.

Preparation of samples for scanning electron microscopic examination and computer image processing

The diaphragmatic peritoneum on the right side was cut into 5.0×5.0 mm^2 pieces and put into 25ml·L^{-1} glutaraldehyde solution for 1 h, then postfixed for 1h in 10ml·L^{-1} OsO_4, dehydrated in a graded series of alcohol, CO_2 critical-point dried, mounted on aluminum tubs and sputter-coated with gold. Specimens were examined with a Stereoscan 260 SEM operated at 25kV. The result was treated with the computer image processing system attached to SEM. The system consists of video, A/D, IBM386. Software was designed for processing and quantitatively analyzing the area and the distributive density of the lymphatic stomata.

Urinary volume and ionic concentration analysis

Mouse urine was collected in 2 hrs and ionic concentration of Na^+, K^+ and Cl^- was measured using auto-biochemical analyzer (Beckman CX △7 type).

Measurement of serum NO

Five hundred microliters of the serum was de-proteinized with 200mL of 75mM zinc sulfate and 250mL of 55mM sodium hydroxid and subsequently were centrifuged at 3000rpm for 10min. One hundred microliters of the deproteinized solution was mixed with 0.3ml ddH_2O and 0.25g newly-activated Cadmium sufficiently for 1h. The nitrite concentration was determined by mixing 0.1ml of the supernatants from the mixed solution with an equal volume of Griess reagent (1 part of 0.2% N-(1-naphthyl) ethylenediamine dihydrochloride to 1 part of 1% sulfanilamide in 2% phosphoric acid) for 15min. The absorbance at 545 nm was measured, and the nitrite concentration was determined from a standard curve calibrated with NaNO2 solution[45].

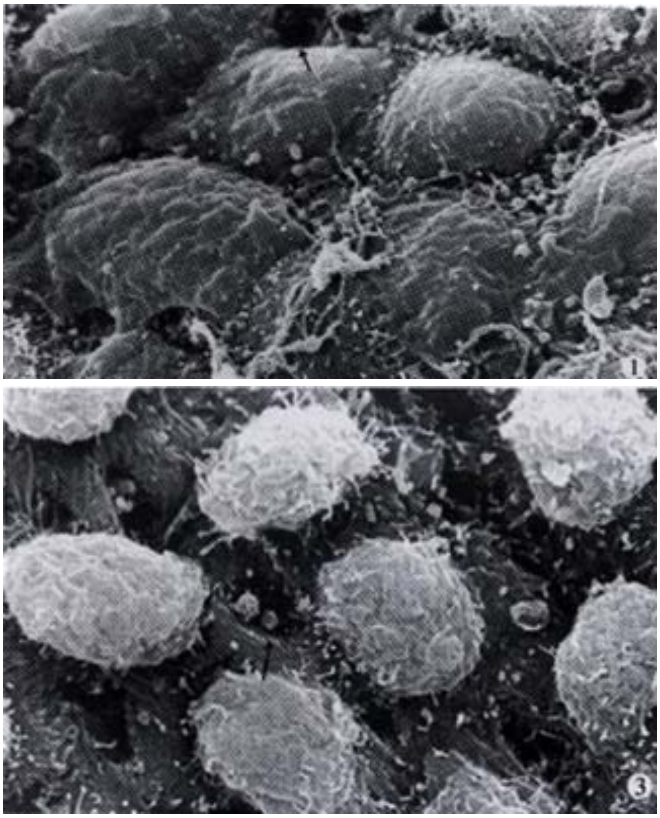
Statistic analysis

The experimental results were described by $\bar{x}\pm s$ and the difference among the groups was analyzed by *t* test.

RESULTS

Changes of peritoneal lymphatic stomata

In SEM, there were cuboidal and flattened cells in the mesothelium. The lymphatic stomata which was round or ellipse were located only among the cuboidal cells and most of them were distributed in cluster. In NS group and model groups, there were few and small lymphatic stomata (Figures 1,2). In contrast, there were was many and large lymphatic stomata in CHMI and CHMIIgroups (Figure3, 4). In DR group, there were fewer and larger lymphatic stomata than in the model group (Figure 5), while in the IR group fewer and smaller than that of the CHMII group (Figure 6).



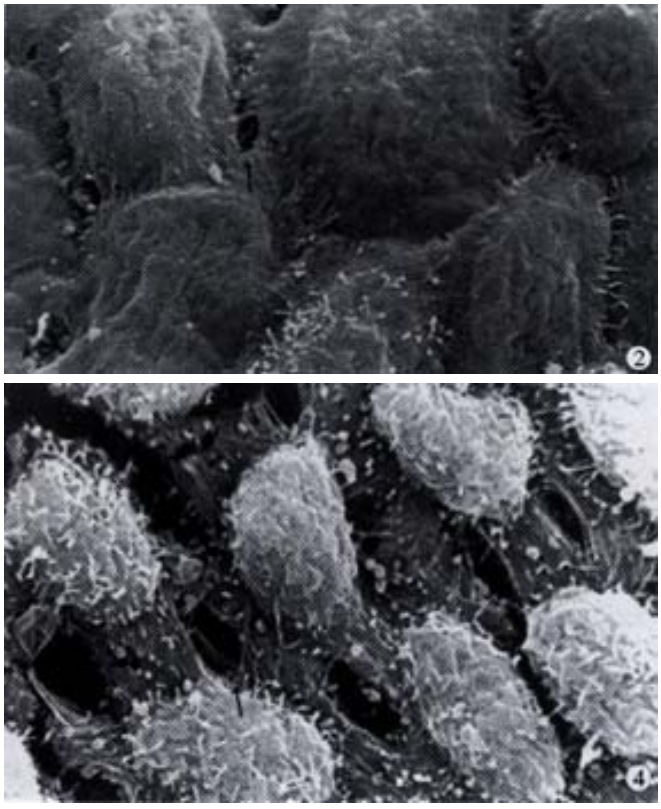


Figure 1 SEM observation of mouse diaphragmatic peritoneum in the control group. Both the area and distribution density of the peritoneal lymphatic stomata (arrow) are small. ×3500

Figure 2 SEM observation of mouse diaphragmatic peritoneum in model group showing the peritoneal stomata (arrow).×3500

Figure 3 SEM observation of mouse diaphragmatic peritoneum in CHMI group. The area and distribution density of the peritoneal lymphatic stomata (arrow) are significantly increased. ×3500

Figure 4 SEM observation of mouse diaphragmatic peritoneum in CHMII group. The area and distribution density of the peritoneal lymphatic stomata (arrow) are significantly increased. ×3500

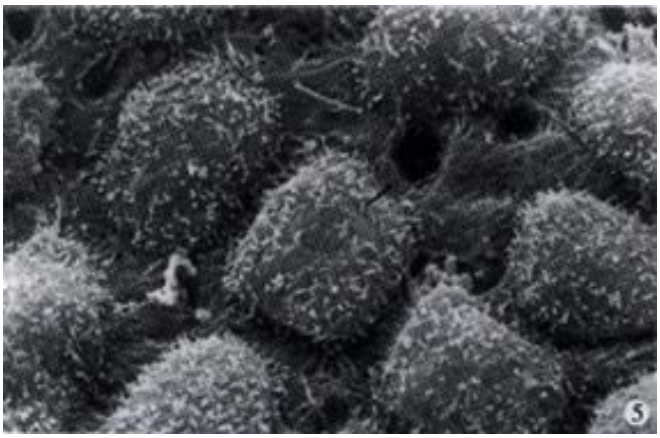

Figure 5 SEM observation of mouse diaphragmatic peritoneum in DR group. Compared with model group, the area and distribution density of the peritoneal lymphatic stomata (arrow) are relatively increased. ×3500

Figure 6 SEM observation of mouse diaphragmatic peritoneum in IR group. Compared with CHMII group, the area and distribution density of the peritoneal lymphatic stomata (arrow) are relatively decreased. ×3500

With image processing, the average area of the stomata was 3.59±1.29 μm^2 in NS group and 3.02±1.11 μm^2 in model group, whereas in CHMI group and CHMII group, the average area of the stomata was 5.89±0.33 μm^2, and 5.93±1.87 μm^2 respectively. There were significant differences in the enlargement of the stomata between CHMI and CHMII groups, based on the analysis of variance (P<0.01). By comparing the area at the 99% confidence interval of population means, we found that the stomata area of CHMI and CHMII groups were much larger than those of NS and model groups (Table 1).

When the mouse was injected intraperitoneally by SNP, the average area of the stomata was 4.37±0.10 ìm^2, which was larger than that of the corresponding model group. When the mouse was injected intraperitoneally by L-NMMA, the average area of the stomata was 2.70±1.30 μm^2, which was smaller than that of the corresponding CHMII group. These showed that the area of the stomata could be altered by SNP or L-NMMA significantly (P<0.05 or P<0.01).

Table 1 The influence of CHM, NO donor and NOS inhibitor (n=15) on the area of the lymphatic stomata

Groups	Mean (μm^2)	SD	Min.(μm^2)	Max.(μm^2)
NS	3.59	1.29	0.91	8.93
model group	3.02	1.11	1.83	7.53
CHMI^{bd}	5.89	0.33	2.00	9.82
CHMII^{bd}	5.93	1.87	2.08	10.15
DR^{c}	4.37	0.10	1.92	8.70
IR^{f}	2.70	1.30	1.75	9.19

^{a}P<0.05, ^{b}P<0.01, *vs* NS group; ^{c}P<0.05, ^{d}P<0.01, *vs* model group; ^{e}P<0.05, ^{f}P<0.01, *vs* CHMII group

The average distribution density of the stomata of NS group, and model group were 66.99±5.43/0.01mm^2, 42.80±13.35/0.01mm^2, whereas those of CHMI and CHMII group were 92.08±0.44/0.01mm^2, and 96.24±4.62/0.01mm^2 respectively. The results showed that CHM can promote the distribution density of the stomata significantly (Figure 7) (P<0.01).

When the mouse was injected intraperitoneally by SNP, the average distribution density of the stomata was 79.06±5.37mm^2/0.01mm^2, which was much migher than that of the corresponding model group. When the mouse was injected intraperitoneally by L-NMMA, the average distribution density of the stomata was 60.82±30.79mm^2/0.01mm^2, which was much lower than that of the corresponding CHM group. The above statistics show that the distribution density of the stomata could be altered by SNP or L-NMMA significantly (P<0.01).

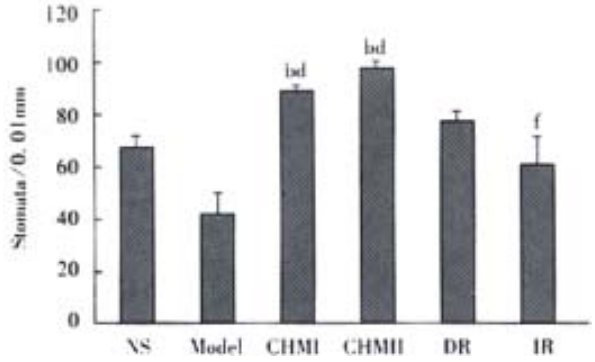

Figure 7 The influence of CHM, NO donor and NOS inhibitor on the distribution density of the lymphatic stomata.

Comparison of urinary ionic concentration

Subsequent experiment showed that the excretion of Na^+, K^+ and Cl^- in CHMI and CHMII group was significantly higher than those in NS group and model groups respectively (P<0.01) (Table 2).

When NO donor was injected intraperitoneally, the excretion of Na^+, K^+ and Cl^- in DR group was significantly higher than those in the model group (P<0.05 or P<0.01). When NO inhibitor was injected intraperitoneally, the excretion of Na^+, K^+ and Cl^- in IR group decreased significantly in comparison with the corresponding CHMII group (P<0.05 or P<0.01).

Table 2 The effect of CHM, NO donor, NOS inhibitor on the urinary ion of the mice (mmol/L, n=15)

Groups	Na^+	K^+	Cl^-
NS	91.55±23.42	106.15±34.16	111.18±30.05
model group	97.48±42.12	129.65±46.91	121.90±41.65
CHMI	202.09±35.30^{bd}	217.30±57.78^{bd}	176.00±0.00^{bc}
CHMII	170.78±17.05^{bd}	210.11±51.49^{bd}	184.72±13.81^{bd}
DR	126.74±51.27^{d}	142.16±6.33^{c}	134.18±30.36^{c}
IR	139.28±26.02^{f}	88.29±22.59^{f}	154.98±14.88^{e}

^{a}P<0.05, ^{b}P<0.01, *vs* NS group;^{c}P<0.05, ^{d}P<0.01, *vs* model group;^{e}P<0.05, ^{f}P<0.01, *vs* CHMII group

Comparison of NO concentration

There were significant difference in the concentration of NO between groups. The NO concentration of NS, model groups was 48.36±

6.83 μmol/L and 35.22±8.94 μmol/L respectively, however that of CHMI and CHMII group was 133.52±23.57 μmol/L and 137.2 ±26.79 μmol/L. The results showed that the concentration of NO in CHMI and CHMII groups was higher than that in NS and model groups (P<0.01) (Figure 8). The results indicated that Chinese herbal medicine could induce higher endogenous NO. When NO donor was injected intraperitoneally, NO concentration in DR group was 62.56±18.91 μmol/L, which was significantly higher than that in the model group (P<0.05). When NO inhibitor was injected intraperitoneally, NO concentration in IR group was 99.88±21.03 μmol/L, which decreased significantly as compared with that of CHMII group (P<0.01).

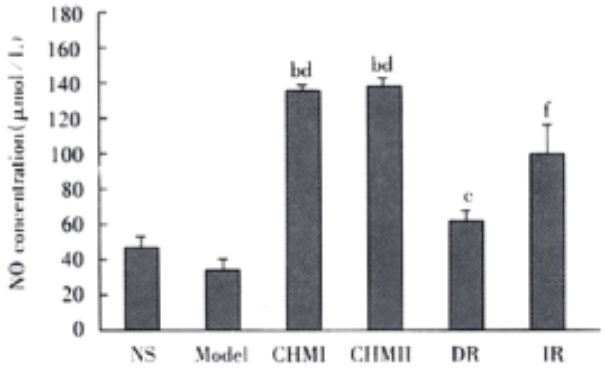

Figure 8 The change of NO concentration by using CHM,NO donor and NOS inhibitor in the mice.

DISCUSSION

In the mesothelial cells constituting the lymphatic stomata, there exists bundles of actin microfilaments, the contraction and relaxation of the microfilaments could result in the change of the diameter of the lymphatic stomata. Because the lymphatic stomata is the main pathway of the drainage of the material from the peritoneal cavity[23-29], further investigation on regulating mechanism of the lymphatic stomata could promote the treatment of ascites and other associated illness.

With regard to the regulation of patency of the stomata, some authors have proposed that the peritoneal lymphatic stomata open passively when the diaphragm stretches during expiration, and close passively when it contracts during inspiration. Tsilibary and Wissig observed the regulation of the stomata by means of intravenously injecting carbacholine and succinylcholine, which cause the contraction and relaxation of the mouse diaphragm[3]. Their experimental results showed that stomata opened and closed with drug-induced relaxation and contraction of the diaphragm. Changes of the intra-abdominal pressure also play an important role on the regulation of the peritoneal lymphatic stomata. When the intra-abdominal pressure is increased experimentally by injecting normal saline intraperitoneally, the amount of the peritoneal lymphatic stomata is much larger than that of the normal group.On the contrary, when the intra-abdominal pressure is decreased experimentally, the patent number of the peritoneal lymphatic stomata is much less than that of the normal group[3].

Li *et al* and Lv *et al* further confirmed the effect of some Chinese herbal medicine such as Radix Salviae Miltiorrhizae, Radix Codonopsitis Pilosulae, Rhizoma Atractylodis Alba and Rhizoma Alismatis in the regulation of the peritoneal lymphatic stomata significantly by increasing the average diameter and the average distribution densities respectively, which can enhance fluid drainage into the vascular system[37-44].This is of important clinical significance in treating ascites caused by liver cirrhosis. In the present study, the prescription is made up according to the traditional Chinese medicinal therapeutic principle in treating "hypocondriac pain", "lump" and "tympanites". The drug has the effects of activating blood circulation to remove stasis, strengthening Spleen, supplementing Qi, and smoothening Qi to eliminate fullness. Our study showed that the CHM in the experiment could regulate the peritoneal lymphatic stomata significantly by increasing the average area and the average distribution densities respectively. Meanwhile, the medicines could enhance the drainage of urinary ion such as sodium, potassium and chlorine. The finding has further confirmed Li *et al*'s results[37-39] and Lv *et al*'s results[40-44].

It can also be seen that both dosage of CHM could induce higher concentration of NO, that is, the high endogenous NO production is associated with the enlargement of the peritoneal lymphatic stomata and the increase of the drainage of urinary ion. Further results indicated that great changes could occur in the area and the distribution density of the lymphatic stomata when the NO donor or NOS inhibitor was injected intraperitoneally. When NO donor was injected intraperitoneally,i.e., the concentration of the endogenous NO increased, the area and the distribution density of the lymphatic stomata in the NO donor group were much larger than those of the model group (P<0.05 or$P$<0.01). Moreover, when NO inhibitor was given, the concentration of the endogenous NO decreased, these indexes of the lymphatic stomata in NO inhibitor group were much less than those of the corresponding large dose of CHM (P<0.01). Thus, it could be seen that the effect of CHM on the peritoneal lymphatic stomata was altered by adding NO donor or NOS inhibitor to the peritoneal cavity.

It has confirmed that the endothelium-derived relaxing factor (EDRF) is nitric oxide[46-49], which has an effect in relaxing the blood vessel. Li *et al* reported that, with the proceeding of the peritoneal dialysis.Clinically, numerous macrophages were found to enter the peritoneal cavity to form milky spots. Damages of mesothelial cells, increased density of their distribution and enlargement of the peritoneal lymphatic stomata were found to be associated with the increase of macrophage NO quantity. Furthermore, increased NO production was related to the enlargement of the peritoneal lymphatic stomata in the long-term peritoneal dialysis. Therefore, Li *et al* proposed that NO could relax the lymphatic stomata which lead to the enhanced lymph absorption or ultrafiltration failure[50]. On these grounds, we suggested that the regulation of CHM on the lymphatic stomata may be related to endogenous NO.Chinese herbal medicine may regulate the lymphatic stomata by accelerating the synthesis and release of endogenous NO. Nitric oxide as an endothelium-derived relaxing factor,mediates its biological effects by activating soluble guanylyl cyclase and increasing cyclic GMP synthesis from GTP and decreasing the concentration of Ca^{2+}. These reactions result in the strong relaxation of the lymphatic stomata, with the area and the distribution densities of the lymphatic stomata enlarged, which would lead to the drainage of ascites from the peritoneal cavity.

Abstract

AIM: **To review the present studies on early diagnosis of colorectal cancer.**

METHODS: **The detective rate for early cancer is 1.7%-26.1% based on various statistical data, with much higher detective rate in endoscopy. Since early cancer means invasion involved in the mucosa or submucosa, the diagnosis can only be made when the invasive depth is identified. Pathological tissue materials from both surgical operation or endoscopic resection are suitable for early cancer evaluation.**

RESULTS: **Incidence of polyp malignancy is 1.4%~20.4%. The various constitutive proportion of polyps may explain the different rates. Malignant incidence is higher in adenomatous polyps, that for villous polyps can reach 21.3%-58.3%. Type II early stage of colorectal carcinoma is rarely reported in China. It is shownd that majority of them were not malignant, most of type IIa being adenoma or hyperplasia, and IIb being inflammatory and IIc might be the isolated ulcers. The occurrence of malignancy of type II is far lower than that of polypoid lesion. In China, the qualitative diagnosis and classification of neoplasm generally adopted the WHO standard, including surgical excision or biopsies. There is impersonal evaluation between colorectal pre-malignancy and cancer. The former emphasizes the dysplasia of nuclei and gland, while the latter is marked with cancer invasion. Diagnosis of early stage colorectal cancer in endoscopy is made with too much caution which made the detective rate much lower. Mass screening for asymptomatic subjects and follow-up for high risk population are mainly used to find the early stage colorectal cancer in China. Fecal occult blood test is also widely made as primary screening test, galactose oxygenase test of rectal mucus (T antigen), fecal occult albumin test are also used. The detective rate of colorectal cancer is 24-36.5 per 105 mass population.**

CONCLUSION: **Although carcinoma associated antigen in blood or stool, microsatellite DNA instability for high risk familial history, molecular biology technology for stool oncogene or antioncogene, telomerase activity and exfoliative cytological examination for tumor marker, are utilized, none of them is used in mass screening by now.**

INTRODUCTION

The colorectal cancer is one of the most common malignant tumors which threatens the people's health[1-3]. The occurrence of colorectal cancer has been rising over the past 3 decades. At present, the colorectal cancer is the second cause of death in western countries, and the forth in China[4,5]. It is clear that the prognosis of colorectal cancer is related to early diagnosis[6-8], For instance, the five-year survival after operation of colorectal cancer, diagnosed in early stage, is over 80%, but in the advanced stage it is lower than 40%. So, it is very important to improve the colorectal cancer's prognosis by means of early diagnosis[9-13]. Recently, much attention has been paid to early detection for colorectal cancer in China. The popularity of the colonoscopy and the mass screening for colorectal cancer in the population who have no symptoms has raised the rate of the early diagnosis of colorectal cancer greatly. However, the study and progress vary among regions in the country, and there are also misdiagnoses. This paper reviews the present study of early diagnosis of colorectal cancer in China.

THE DETECTIVE RATE OF EARLY STAGE COLORECTAL CANCER IN CHINA

At present, the data of detective rate for early stage colorectal cancer are not perfect, and the detective rate is 1.7%-26.1%, based on various reports (Tabel 1)[14-20]. The major reason for the different rate is the various statistical data. In virtue of the endoscopy popularity, the early stage of cancers are detected increasingly. Most of them can be treated by non-surgically. So, there are great differences between the endoscopic and the surgical data. For example, 997 cases of colorectal cancer were treated surgically during 1990-1999 in Nan Fang Hospital, 21 cases are in early stage (2.1%), while 1087 cases of colorectal cancer were found from 20 353 colonoscopied cases during the corresponding period, in which, 146 early stage of cancers were identified (13. 4%). Because most of early cancers are polyps-like and easy to be resected under endoscopy, the percentage of early stage cancer in surgical samples is low.

Table 1 The detective rate for early stage of colorectal cancer in China

Authors	Colorectal cancer		
	Total *n*	Early stage *n* (%)	Year
Lu *et al*[14]	569	85(15.1)	1997
Ni *et al*[15]	132	15(11.4)	1997

Cai *et al*[18]	1058	59(5.6)	1999
Zeng *et al*[19]	300	5(1.7)	1996
Sun *et al*[20]	180	47(26.1)	1998

MORPHOLOGY OF EARLY STAGE COLORECTAL CANCER UNDER ENDOSCOPY

There are two types of early colorectal cancer based on the morphological classification under endoscopy. Type I also called protruded or polyps type, can be further grouped as pedunculated (Ip), subpedunculated (Isp) and sessile (Is) superficial type. Type II can be classified as elevated(IIa), flat(IIb) and depressed (with or without protruded)[6,19]. Since early cancer means invasion involving the mucosa or submucosa, which is not related to the tumor size or special morphology, the diagnosis only can be

made when the invasive depth is identified. Pathological tissues from both surgical operation and endoscopic resection are suitable for early cancer evaluation. It is important that early cancer diagnosis can not be made based on the endoscopic biopsy since invasion is not observed.

Histopathological examination of polyps under endoscopy is a crucial method to detect early cancer in China, and most of them are polyp malignancy[9,14,21,22]. Generally, polyp formation is mostly involved in the proliferation of mucosa and submucosal tissues. As long as cancerous tissues do not touch upon pedicle, they can attribute to early-stage carcinoma. If pedicle of polyp invasion in colorectal cancer can not be observed for incomplete resection or embedded in the wrong direction, diagnosis of early-stage carcinoma can not be made rashly. Incidence of polyp malignant transformation is 1.4%-20.4% (Table 2). Different result may be from various constitutive proportion of polyps. Malignant incidence is high in adenomatous polyps. In villous polyps, it can reach 21.3%-58.3% according to the documents in China [23-31]. Moreover, as some adenomatous ingredient are observed by biopsy,some advanced colorectal cancers are diagnosed as polyp malignancy by pathologists. This kind of lesions can not be included in the early-stage carcinoma. In our previous study, 87/127 (68.6%) advanced colorectal carcinoma had residual of adenoma.

Table 2 The malignant transformation rate of polyps in China

Authors	Area	*n*	Incidence (%)
Zhou *et al*[22]	Guangzhou	539	3.4
Cai *et al*[23]	Guangzhou	216	9.7
Zhang *et al*[24]	Changchun	2000	5.1
Shen *et al*[25]	Kunming	533	6.4
Zhu et *et al*[26]	Beijing	219	1.4
Zhu *et al*[27]	Nanjing	644	5.8
Wang *et al*[28]	Xi'an	548	9.7
Zhang *et al*[29]	Zhejiang	321	14.6
Zhang *et al*[30]	Ha-erbing	494	20.4
Gao *et al*[31]	Shanghai	334	6.6

Type II early stage of colorectal carcinoma is rarely reported in China. Huang *et al* first summarized 6304 patients detected by colonoscopy from 1974 to 1996 in a hospital of Beijing[32], only 36 Type II lesions were discovered, including 31 (86.1%) type IIa,4 (11.1%)type IIb and 1 (7%) type IIc. Thirty-two tubular adenomas, 3 villous adenoma and 1 carcinoid were confirmed by histopathological examination,. Only one case was identified as malignancy by follow-up.

In 137 cases of early stage colorectal cancer detected in Nanfang Hospital from 1990 to 1999, 95.6% were polypoid type, only 6 cases were considered as type II(4.4%)(Table 3). We also analyzed the histopathological features of 186 cases of type II lesions, only 3.2% were diagnosed as early stage carcinoma(Table 4). It indicated that the majority of so-called type II cancer under endoscopy were not real malignancy. Most of type IIa were adenoma or hyperplasia polyps, and most of type IIb were inflammatory changes of mucosa. A large number of type IIc cases might be the isolated ulcers. The occurrence of malignancy of type II is far lower than that of polypoid lesion.

Table 3 Morphology of 137 cases of early stage colorectal cancer under endoscopy

Morphology	Type	*n*	Ratio
Polypoid	I	131	95.6
Elevated	IIa	2	1.4
Flat	IIb	1	0.7
Depressed	IIc or IIc+IIa	3	2.3

Table 4 Histopathology of 186 cases of type II lesion

Morphology	Type	*n* (%)	Histopathologic diagnosis		
			Early cancer	Adenoma	Other
Elevated	IIa	155(83.3)	2(1.3)	86(55.4)	67(43.3)
Flat	IIb	22(11.8)	1(4.5)	2(9.00)	19(86.4)
Depressed	IIc or IIc+IIa	9(4.8)	3(33.3)	4(44.4)	2(22.2)

THE DIAGNOSTIC STANDARD FOR EARLY STAGE OF COLORECTAL CANCER

In China, the qualitative diagnosis and classification of neoplasm generally adopted the WHO standard for both surgical excision and biopsies[17,33]. The evaluation is objective between colorectal pre-malignancy and cancer. The former emphasizes the dysplasia of nuclei and gland, while the latter is marked with cancer invasion[34-37]. Although pathologists hold different opinions about the classification of dysplasia, it could be classified generally into 3 grades. The simpliest classification depends on the ratio of dysplasia karyon in epithelium. Mild dysplasia indicates the crowding nuclei limited within 1/2 depth of epithelium in basement, moderate dysplasia means that atypical nuclei occupied more than 1/2 epithelium, and severe dysplasia refers to the atypical nuclei occupying the whole epithelium with integrated basement. The essential difference between dysplasia and malignancy is invasion. The malignancy is manifested by the destroyed basement, and sporadical dysplasia glands. It is called intra-mucosal cancer if the cancer cell invasion limited within the mucosa. If the cancer destroyed mucosal muscle into submucosa, it is called sub-mucosal cancer. These two types are generally designated as early stage cancer. From the literature reviews, we found that the diagnosis of early stage colorectal cancer in China is made with much cautions under endoscopy. On the one hand, pathologic diagnosis generally adopted the WHO standard, which depends on the invasion, and sometimes it is difficult to observe the invasion on biopsy sections. On the other hand, patients always feel panic to cancer, once the colorectal cancer is diagnosed, they would rather choose surgical operation than endoscopic resection. Besides, they often require consultation of the pathological sections, if diagnostic standard is different, this may cause the psychological pressure to the pathologic doctors in different regions.

In European countries, colorectal cancer is the most common malignant tumor of digestive tract. But the diagnositic rate of early cancer is usually reported less than 9%. In Japan, the diagnostic rate of early stage of cancer detected by endoscopy is 17%-53%. The cases of early stage cancer reported in China is the same as in European countries but far lower than in Japan[14-20]. Schlemper RJ *et al* compared the differences in pathological diagnosis of early carcinoma from strippling or surgically resected specimens of colonic mucosa between Japan and Europe-America[34]. It was found that 4 cancer cases were diagnosed by Japanese pathologists in 11 adenoma with mild dysplasia based on European-American standard. This is because Japanese pathologists emphasize the nuclei dysplasia and gland structural change evaluating malignancy[37], but pathologists in China usually take above changes as markers of pre-malignancy.

DETECTION FOR EARLY STAGE OF COLORECTAL CANCER

Mass screening for asymptomatic subjects and follow-up for high risk population are the major ways to find the early stage of colorectal cancer in China[38-42]. High risk factors are old age, histories of colorectal polyps, familial history of cancer and some colorectal related positive tests[43-51]. Since mass screening for asymptomatic population need a large amount of work, and exact diagnosis must depend on endoscopical and histopathological examination, screening test has been paid much attention. So far, fecal occult blood test is widely used as primary screening test in China[52-55]. Other screening tests include galactose oxygenase

test of rectal mucus(T antigen)[56-60], and fecal occult albumin test[61,62]. If the screening tests appear positive, colonoscopy is then taken. Although carcinoma associated antigen in blood or stool[63-81], microsatellite DNA instability for high risk familial history[82-86], molecular biology technology for stool oncogene or antioncogene[87-99], telomerase activity[100-104] and exfoliative cytological examination[105,107] have been used for tumor marker, none of them is used in mass screening.

There are some excellent work reported in China on mass screening for colorectal cancer. Most of them are based on immune fecal occult blood test(Table 5)[54,55,62]. In mass screening (age above 35 years), the occurrence of colorectal cancer is 24-36 per 10^5 population.

Table 5 Mass screening for colorectal cancer in asymptomatic population

Authors	Region	Age(yrs)	Population	Cancer	Dukers(%) A/B	Detection rate
Li *et al*	North	>35	102 800	25	52.0	$24/10^5$
Zhen *et al*	East	>35	62 667	16	57.2	$25.5/10^5$
Zhou *et al*	Mid-south	>45	24 677	9	55.6	$36.5/10^5$

Tantigen detection in rectal mucus is also used in some mass screenings[57-60,108,109]. In 3820 asymptomatic population, the positive rate of T antigen is 9.1%, among them, 2 cases of early cancer and 28 cases of adenoma were identified. The detective rate of pathologic change is 12.7%. It is shown that T antigen test is not specific for colorectal examination. In 103 cases of T antigen positive subjects, 85 cases were found without any lesion under colonoscopy. The sensitivity is not better than that of feces occult blood examination[110-114].

Since screening tests used so far are not specific for colorectal detection, there are some misdiagnoses either by feces occu1t blood examination or rectal mucous T antigen test. To improve the detective rate of the early stage cancer, it is suggested that combined complementary screening should be taken. Zhejiang University School of Medicine optimized the screening protocol for colorectal cancer among a high-incidence population[113]. Through increasing the cases for colonoscopy follow-up, the detective rate of early cancer was increased. Beijing General Hospital reported that by combined test of sequencial fecal occult blood and albumin in the screening of colorectal neoplasma, 3 cases of carcinoma were found from 883 positive asymptomatic subjects[114]. The Nanfang Hospital recommended the complementary schemes by combining occult blood and T antigen detection. In 5 cases of colorectal cancer, which were found by colonoscopy in 2832 asymtomatic subjects, 3 were positive in feces occult blood examination and 2 in T antigen test. The missed cases will be reduced if complementary screening was taken[13]. Our study showed that the mass screening can reduce the colorectal occurrence(Table 6)[113].

FUTURE STUDY IN EARLY DIAGNOSIS FOR COLORECTAL CANCER

It is definite that asymtomatic mass screening is the important way to identify the early cancer. Because of the poor specificity of screening test, and the high cost, it is difficult to popularize. Target screening will be highlighted. In 1992, Sidransky *et al* first extracted DNA successfully from feces and reported ras gene variation with Southern-Blot[116]. It is considered an effective screening for colorectal cancer in the 21st century. PCR-SSCP technology has a high sensitivity, good specificity and easy manipulation. Gene mutation such as P53, ras, c-erbB-2, APC and MCC was identified in feces (Table 7)[94-96,117,118]. Since no specific gene mutation is found in colorectal cases, the detective rate by molecular technique is low. Though combined genes detection can enhance the screening rate, it is too complex and expensive.

Table 6 The follow-up results in 3,641 cases of asymtomatic population

	Cancer (*n*)	Adenoma		
		n	>1.0 cm	Dysplasia(>II grade)
First screen	4	48	17(35.4%)	12(25.0%)
Two years later	0	18	4(22.2%)	2(11.1%)

Table 7 Gene mutation analysis in colorectal cancer stool (Nanfang Hospital)

Gene	*n*	Tissue DNA		Fecal DNA	
		Positive	%	Positive	%
APC	41	20	48.8	14	34.1
MCC	45	13	28.9	11	24.4
P53	32	32	37.5	10	31.3

Analysis of gene offers possibility and practical significance for detecting high risk population. For example, HNPCC generally represents the microsatellite DNA instability and characteristic DNA mismatch repair gene. Therefore, detecting MIN and DNA mismatch repair gene may identify some high risk population with cancer familial predisposition[119-122]. We analyzed 46 cases of colorectal carcinoma for MIN, and found 14 cases of MIN positive patients, 12 of them with familial predisposition (85.7%). It is suggested that MIN might reflect colorectal carcinoma with familial predisposition in some extent.

Abstract

AIM: **To investigate the effects of growth inhibition of human gastric cancer SGC-7901 cell with RRR-α-tocopheryl succinate (VES), a derivative of natural Vitamin E, via inducing apoptosis and DNA synthesis arrest.**

METHODS: **Human gastric cancer SGC-7901 cells were regularly incubated in the presence of VES at 5, 10 and 20mg·L^{-1} (VES was dissolved in absolute ethanol and diluted in RPMI 1640 complete condition media correspondingly to a final concentration of VES and 1mL·L^{-1} ethanol), succinic acid and ethanol equivalents as vehicle (VEH) control and condition media only as untreated (UT) control. Trypan blue dye exclusion analysis and MTT assay were applied to detect the cell proliferation. 37kBq of tritiated thymidine was added to cells and [^{3}H] TdR uptake was measured to observe DNA synthesis. Apoptotic morphology was observed by electron microscopy and DAPI staining. Flow cytometry and terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) assay were performed to detect VES-triggered apoptosis.**

RESULTS: **VES inhibited SGC-7901 cell growth in a dose-dependent manner. The growth curve showed suppression by 24.7%, 49.2% and 68.7% following 24h of VES treatment at 5, 10 and 20 mg·L^{-1}, respectively, similar to the findings from MTT assay. DNA synthesis was evidently reduced by 35%, 45% and 98% after 24h VES treatment at 20 mg·L^{-1} and 48h at 10 and 20 mg·L^{-1}, respectively. VES induced SGC-7901 cells to undergo apoptosis with typically apoptotic characteristics, including morphological changes of chromatin condensation, chromatin crescent formation/margination, nucleus fragmentation and apoptotic body formation, typical apoptotic sub-G1 peak by flow cytometry and increase of apoptotic cells by TUNEL assay in which 90% of cells underwent apoptosis after 48h of VES treatment at 20 mg·L^{-1}.**

CONCLUSION: **VES can inhibit human gastric cancer SGC-7901 cell growth by inducing apoptosis and DNA synthesis arrest. Inhibition of SGC-7901 cell growth by VES is dose- and time-dependent. Therefore VES can function as a potent chemotherapeutic agent against human gastric carcinogenesis.**

INTRODUCTION

Vitamin E is charactered as a fat-soluble membrane antioxidant[1,2]. Vitamin E succinate (RRR-α-tocopheryl succinate; VES), a derivative of natural vitamin E, however, does not possess antioxidant properties unless the succinate group is removed by a nonspecific esterase. VES has been demonstrated to be a potent growth inhibitor of various cancer cell types *in vitro* and *in vivo*[3,4]. For example, VES has been shown to inhibit the growth of human monoblastic leukemia cells *in vitro*[5], murine B-16 melanoma cells *in vitro*[6], hamster buccal pouch tumor cells *in vivo*[7], avian lymphoid cells *in vitro*[8,9], murine EL4 T lymphoma cells *in vitro*[4,10], human gastric cancer cells *in vitro* and *in vivo*[11-13], and human breast cancer cells *in vitro* and *in vivo*[14,15].

The exact mechanisms are not clearly known, but the inhibitory effect of VES on the proliferation of rapidly dividing cells can be attributed to the induction of cell cycle blockage[16], increased secretion and activation of transforming growth factor-β_s (TGF-β_s) and TGF-β receptor II[9,14,17], and the induction of apoptosis[18-20]. In many instances, growth inhibition following terminal differentiation[21-23] or anticancer drug treatment[24-26] results in apoptosis. Apoptosis, namely, programmed cell death, is an active and physiological process characterized by a series of morphological and biological alterations including condensation of cytoplasm, loss of plasma membrane microvilli, segmentation of nucleus and extensive degradation of chromosomal DNA into oligomers of 180bp[27-30]. The exact mechanisms of apoptosis are still unclear, but our earlier studies indicated that VES can secrete and activate biologically active TGF-β and then TGF-β increases the kinase activity of c-Jun N-terminal kinase(JNK) followed by phosphorylation of c-Jun, and finally activated c-Jun triggers apoptosis in human gastric cancer SGC-7901 cells[31].

Gastric cancer is common in China[32-41]. Since VES is a potential tumor chemopreventive and chemotherapeutic agent, it is worthwhile to investigate the manner in which VES inhibits the cell growth and thereafter gain a better understanding of the molecular events involved. In this study, we demonstrate the ability of VES to inhibit cell proliferation, arrest DNA synthesis and induce human gastric cancer SGC-7901 cells to undergo apoptosis, address the involvement of certain apoptosis-related events in this process and prove that VES-triggered apoptosis is different from VES-induced DNA synthesis arrest.

MATERIALS AND METHODS

Materials

VES, DAPI (4',6-diamidine-2'-phenylindole dihydrochloride,

succinic acid, MTT [3-(4,5-dimethylthiazole-2-yl)-2,5-dipenyltetrazolium bromide] and propidium iodide were purchased from Sigma Co. Ltd. RPMI 1640 media was obtained from Gibco, BRL. *In situ* cell death detection kit was purchased from Boehringer Mannheim, Indianapolis, Inc. ^{3}H-TdR was supplied by Chinese Academy of Sciences.

Methods

Cell culture Human gastric cancer cell lines SGC-7901 were maintained in RPMI 1640 medium supplemented with 100mL·L^{-1} fetal calf serum (FCS), 100kU·L^{-1} penicillin, 100mg·L^{-1} streptomycin and 2mmol·L^{-1} L-glutamine under 50mL·L^{-1} CO_2 in a humidified incubator at 37℃. SGC-7901 cells were incubated for different time periods in the presence of VES at 5, 10 and 20mg·L^{-1} (VES was dissolved in absolute ethanol and diluted in RPMI 1640 complete condition media correspondingly to a final concentration of VES and 1mL·L^{-1} ethanol), succinic acid and ethanol equivalents as vehicle (VEH) control and condition media only as untreated (UT) control.

Growth curve Exponentially growing SGC-7901 cells were trypsinized and aliquoted into 24-well flat-bottomed tissue culture plates at 5×10^4·well^{-1}. The cells were allowed to attach overnight and then incubated for seven days in the presence or absence of VES. Cell number and viability were determined by trypan blue dye exclusion analysis.

MTT assay The cells were inoculated in a 96-well plate (5×10^3·well^{-1}) as described previously[42]. In brief, cells after 24h of incubation were treated with VES and controls and then cultured for six days. The cells in eight wells at every dose were supplemented with 0.2mL of 5g·L^{-1} MTT every day. After 4h, culture media were discarded followed by addition of 0.2ml of DMSO and vibration for 10min. The absorbance (A) was measured at 570nm using a microplate reader. The percentage of viable cells was calculated as follow:(A of experimental group /A of control group)×100%. [^{3}H] Thymidine incorporation. The cells were treated with VES for 24 or 48h as described previously[43]. 37kBq of tritiated thymidine were added to cells during the last 6h of culture and harvested onto glass fiber filters. [^{3}H] TdR uptake was measured in a Beckman LS5000 TD liquid scintillation counter.

Electron microscopy The cells treated with VES or VEH were trypsinized and harvested after 24h and 48h, respectively. Subsequently the cells were immersed with Epon 821, imbedded in capsules and converged for 72h at 60℃, the cells were prepared into ultrathin section (60nm) and stained with uranyl acetate and lead citrate. Cell morphology was examined by transmission electron microscopy.

DAPI staining Treated cells were pelleted and washed three times with distilled water, and then stained with 2mg·L^{-1} DAPI in 100% methanol for 15min at 37℃. Cells were viewed using a fluorescence microscope with ultraviolet (UV) excitation at 300~500nm. Cells with nuclei that contained clear condensed chromatin or cells with fragmented nuclei were scored as apoptosis.

TUNEL assay Apoptosis of SGC-7901 cells was analyzed by using *in situ* cell death detection kit. The method is essentially based on the terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) technique, and it can detect apoptosis at very early stages. In brief, cells were treated in the presence or absence of VES and fixed overnight in 100g·L^{-1} formaldehyde, treated with proteinase K and then H_2O_2, labeled with fluorescein dUTP in a humid box for 1h at 37℃. The cells were then combined with POD-Horseradish peroxidase, colorized with DAB (3,3-diaminobenzidine) and counterstained with methyl green. Cells were visualized with light microscope.

Flow cytometry Cells were incubated with various doses of VES, harvested, washed with phosphate-buffered saline (PBS) twice and fixed with 700mL·L^{-1} ethanol at 4℃ overnight. Fixed cells were washed twice with PBS and stained with 800μL propidium iodide and 200μL deoxyribonulcease-free ribonuclease A in PBS. The fluorescence indensity of propidium iodide-stained nuclei was determined by a FACscan.

Statistical analysis Student's *t* test was used to assess statistical significance of differences. If $P<0.05$, the difference was considered significant.

RESULTS

Inhibition of Human Gastric Cancer SGC-7901 Cell Proliferation by VES

Growth curve VES has been previously shown to function as a growth inhibitory agent. In this study, VES inhibited SGC-7901 cell growth in a dose-dependent manner. The growth curve showed that cell growth was suppressed by 24.7%, 49.2% and 68.7% following 24h of VES treatment at 5, 10 and 20mg·L^{-1}, respectively. The percentage of inhibition was 100% on day 4 with the treatment of VES at 20mg·L^{-1} (Figure 1).

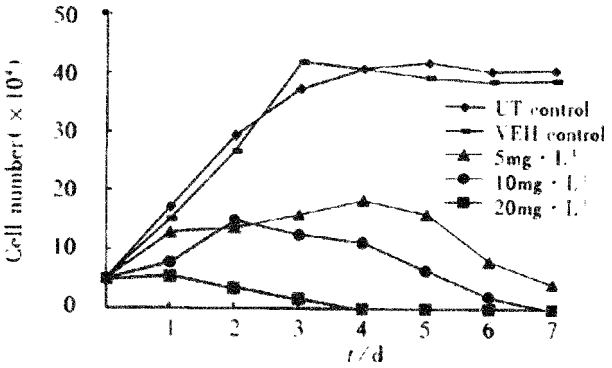

Figure 1 Growth curve of SGC-7901 cell treated with VES.

MTT assay SGC-7901 cells were treated in the presence or absence of VES for six days and cell viability was daily measured by MTT proliferation analysis. VES significantly inhibited cell growth and VES at 10 and 20 mg·L^{-1} had an obviously inhibitory effect by 100% on the 5th and 4th days, respectively (Table1), similar to the findings from growth curve.

Table 1 Effect of VES on the viability of SGC-7901 cells

Group	Rate of viable cells /%					
	1	2	3	4	5	6
UT control	100	100	100	100	100	100
VEH control	105.5	102.4	92.1	95.3	105.7	97.5
5 mg·L^{-1} VES	94.8	101.2	91.4	144.3	91.4	74.6
10 mg·L^{-1} VES	91.4	64.6	20.8	4.2	0	0
20 mg·L^{-1} VES	53.4	32.9	4.3	0	0	0

DNA synthesis arrest by VES

VES treatment of SGC-7901 cells inhibited [^{3}H] thymidine

uptake with a dose-response relationship. DNA synthesis was evidently reduced by 35%, 45% and 98% after 24h VES treatment at 20 mg·L^{-1} and 48h at 10 and 20 mg·L^{-1}, respectively, compared with UT control (P<0.01). On the other hand, VEH control did not affect SGC-7901 cell proliferation (Table 2).

Table 2 Inhibitory effect of VES on DNA synthesis incorporated with ^{3}H-TdR ($\bar{x}\pm s$, n=6)

Group	Radioactive intensity / Bq·10^{4}cell^{-1})	
	24h(% of inhibition ratio)	48h(% of inhibition ratio)
UT control	64.1±10.2(0)	143.2±13.7(0)
VEH control	63.8±10.3(1)	141.9±14.7(0)
5 mg·L^{-1} VES	61.8±10.4(4)	137.1±16.3(4)
10 mg·L^{-1} VES	57.2±10.7(11)	79.3±10.0(45)^b
20 mg·L^{-1} VES	41.4± 8.0(35)^b	2.2±0.3(98)^b

$^b P$<0.01, *vs* UT control.

VES induction of apoptosis

Morphological changes Apoptotic characteristics including chromatin condensation, chromatin crescent formation/ margination, DNA fragmentation and apoptotic body formation were seen by electron microscopy (Figure 2) and by fluorescence microscopy of DAPI-labelled cells (Figure 3). The cells undergoing apoptosis evidently increased when the concentration of VES was elevated and reaction time was prolonged.

Flow cytometry VES-induced apoptosis was studied further in SGC-7901 cells using flow ctyometry. Cell cycle analysis after VES treatment revealed the presence of a sub-G1 apoptotic peak (Figure 4).

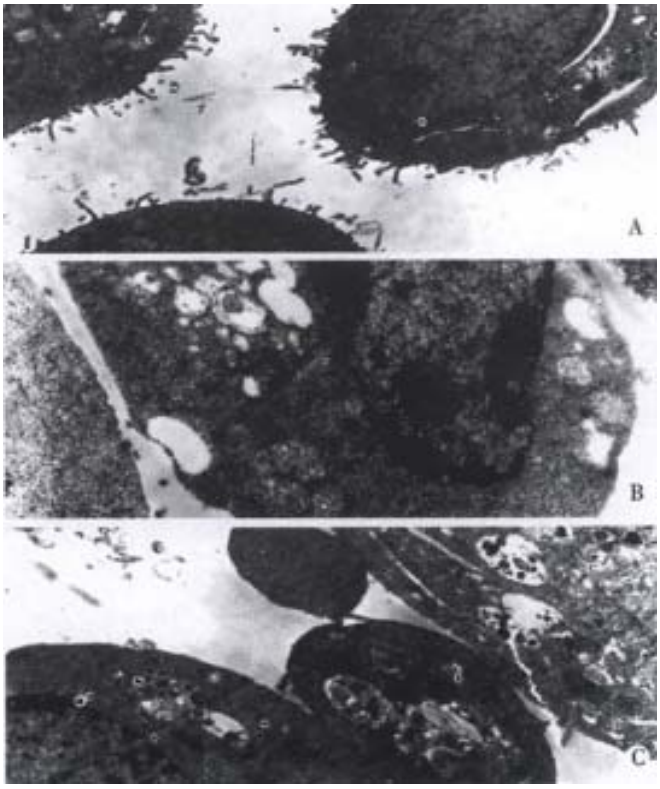

Figure 2 VES-induced apoptosis in SGC-7901 cells with transmission electron microscope
A: Normal cell; B: Apoptotic cell with chromatin condensation, chromatin crescent formation / margination; C: Cell with apoptotic body.

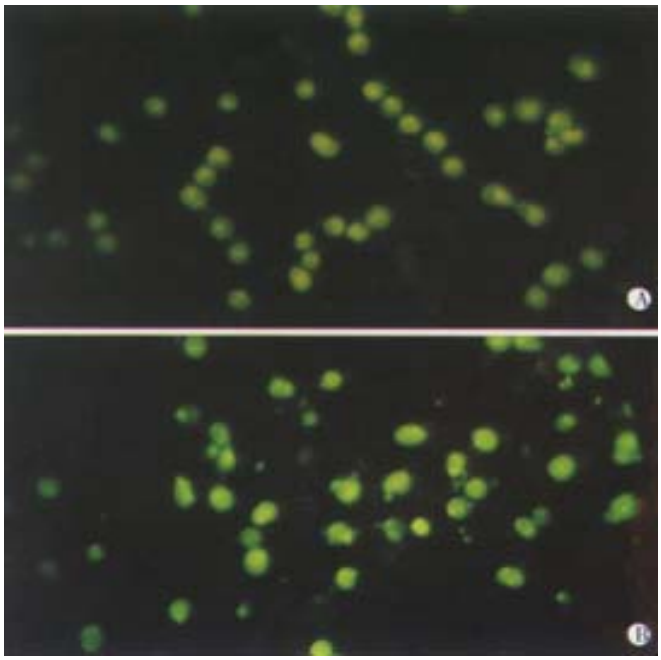

Figure 3 VES-induced apoptosis in SGC-7901 cells with DAPI staining UT control; VES at 20 mg·L^{-1}

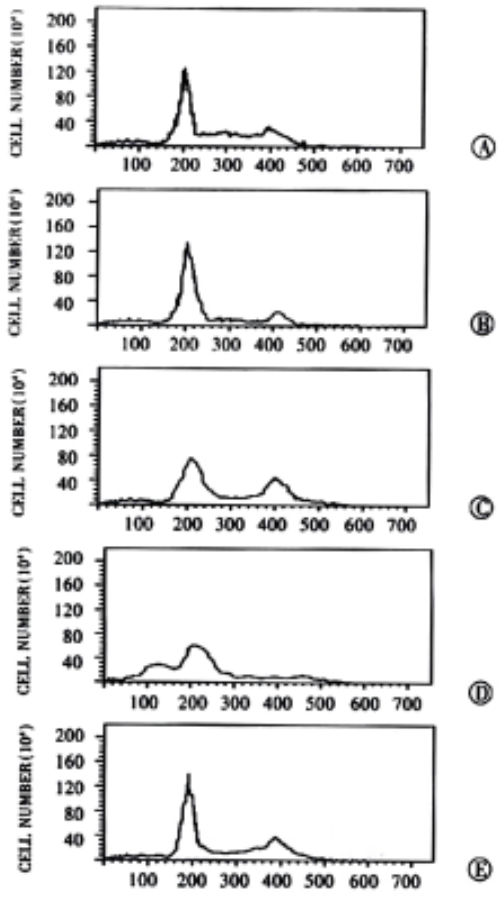

Figure 4 VES-induced apoptosis in SGC-7901 cells with flow cytometryA: UT control; B: VEH control; C: VES at 5 mg·L^{-1}; D: VES at 10 mg·L^{-1}; E: VES at 20 mg·L^{-1}.

TUNEL assay Apoptotic cell death was determined by TUNEL assay according to the manufacturer's instructions. The results showed that apoptotic cells increased with the increase of the concentration of VES in an obviously dose-dependent manner. The percentage of apoptosis was 90% after VES treatment at 20 mg·L^{-1} (Figure 5 and Table 3).

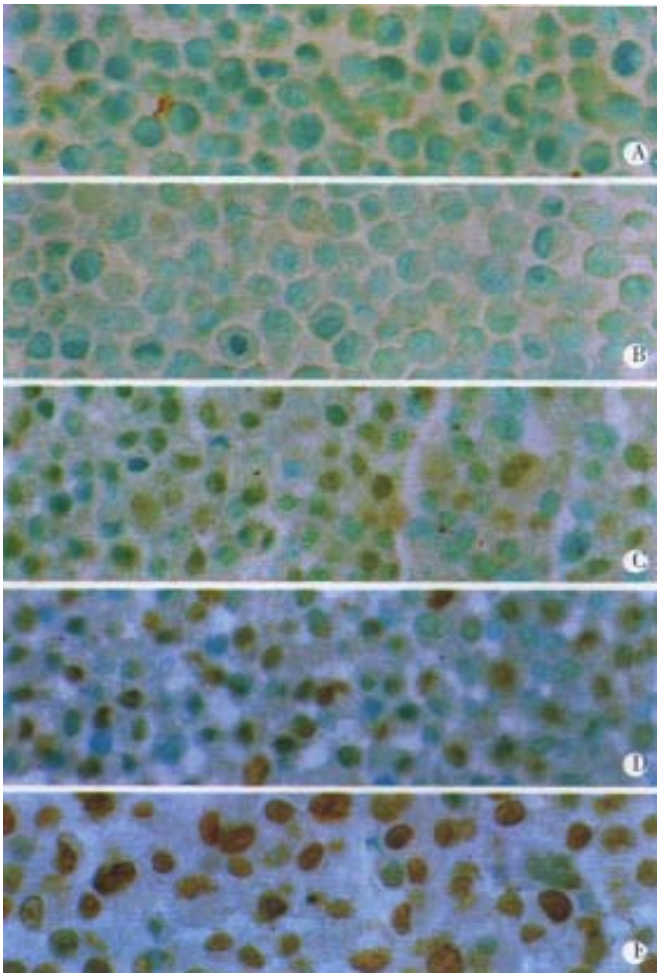

Figure 5 VES-induced apoptosis by TUNEL assay.
A: UT control; B: VEH control; C: VES at 5 mg·L^{-1}; D: VES at 10 mg·L^{-1}; E: VES at 20 mg·L^{-1}.

Table 3 Induction of apoptosis after 48h of VES treatment in SGC-7901 cells

Group	Apoptotic cells / 10^4 cells	Rate of apoptosis / %
UT control	6	0.06
VEH control	28	0.28
5 mg·L^{-1} VES	1248^b	12.48
10 mg·L^{-1} VES	5736^b	57.63
20 mg·L^{-1} VES	8996^b	89.96

$^b P<0.01$, *vs* UT control.

DISCUSSION

Cell growth is regulated by the interaction of cell proliferation and cell death. When cell growth is inhibited, the decrease of cell proliferation and increase of cell death will occur. Cell proliferation is performed by continuously proceeding into cell cycle and will be suppressed if cell cycle is disturbed[44-46]. The disorder of DNA synthesis, however, is a common reason for the disturbance of cell cycles[47,48]. Cell death is another principal reason for cell growth inhibition and is relevant to cell proliferation. Apoptotic cell death is a naturally occurring process of cell suicide which plays a crucial role in the development and homeostasis of metazons by eliminating superfluous or unwanted cells (reviewed by[49-53]).

Previous studies showed that VES can block DNA synthesis in tumor cells[43,54]. The percent of DNA synthesis arrest is more than 90% when human breast cancer cells are treated with VES at 10 mg·L^{-1}, similar to the rate of breast cancer cell growth inhibition which exceeds 80%[15]. A recent study shows that VES can function as an apoptosis inducer in tumor cells. In this study, VES was found to inhibit cell proliferation in human gastric cancer SGC-7901 cells by trypan blue exclusion analysis and MTT assay. Cell growth was inhibited by 100% with treatment of VES at 10 mg·L^{-1} on day 7 and at 20 mg·L^{-1} on day 4 in the former experiment, while on the 6th and 4th days in the latter one. Meanwhile, VES significantly suppressed cell growth by DNA synthesis arrest via preventing SGC-7901 cells from progressinginto S-phase, ultimately blocking the cell proliferation. In order to further elucidate the mechanisms of inhibitory effects of VES on cell growth, we determined the incidence of VES-mediated apoptosis in SGC-7901 cells by electron microscopy, DAPI staining, flow cytometry and TUNEL assay on the basis of morphological and molecular level. The results demonstrated that VES-treated SGC-7901 cells were characteristic by typical apoptotic alterations, including morphological changes by electron microscopy and DAPI staining, typical apoptotic sub-G_1 peak observed by flow cytometry; increase of apoptotic cells with the elevation of the concentration of VES in a clearly dose-dependent manner by TUNEL assay.The data above implicated that VES inhibits human gastric cancer SGC-7901 cell growth by inducing apoptosis and DNA synthesis arrest.

Apoptosis is a complex and programmed process which is regulated by a variety of factors[55-60]. The antiproliferative actions of VES may be due, in part, to the ability of VES to induce autocrine acting biologically active TGF-βs[9,14,17]. In addition, VES-mediated apoptosis is inhibited when c-Jun mutant is transfected into breast cancer cells[61]. JNK, mitogen-activated protein kinase (MAPK) family member, plays an important role in the course of VES-triggered apoptosis[31,61]. Although the exact mechanisms involved in VES-induced apoptosis have not been well known up to now, the ability of a compound to induce 90% apoptosis in a tumor cell population within 48h is noticeable. It is also noteworthy that VES can selectively inhibit the growth of tumor cells but not normal cells[8,62-64]. The research in our laboratory demonstrated that VES inhibited benzo (a)pyrene (B(a)P)-induced forestomach carcinogenesis in female mice[11], while the inhibition and inhibitory mechanisms of VES *in vivo* are worth further investigating.

Abstract

AIM: **To demonstrate that mitochondrial morphological and functional changes are an important intermediate link in the course of apoptosis in esophageal carcinoma cells induced by As_2O_3.**

METHODS: **The esophageal carcinoma cell line SHEEC1, established in our laboratory, was cultured in 199 growth medium, supplemented with 100mL·L^{-1} calf serum and 3μmol·L-1As_2O_3 (the same below). After 2, 4, 6, 12, 24 h of drug adding, the SHEEC1 cells were collected for light-and electron-microscopic examination. The mitochondria were labeled by Rhodamine fluorescence probe and the fluorescence intensity of the mitochondria was measured by flow cytometer and cytofluorimetric analysis. Further, the mitochondrial transmembrane potential (MTP, ΔΨm) change was also calculated.**

RESULTS: **The mitochondrial morphological change after adding As_2O_3 could be divided into three stages. In the early-stage (2-6 h) after adding As_2O_3, an adaptive proliferation of mitochondria appeared; in the mid-stage (6-12 h) a degenerative change was observed; and in the late-stage (12-24 h) the mitochondria swelled with outer membrane broken down and then cells death with apoptotic changes of nucleus. The functional change of the mitochondria indicated by fluorescent intensity, which reflected the MTP status of mitochondria, was in accordance with morphological change of the mitochondria. The fluorescent intensity increased at early-stage, declined in mid-stage and decreased to the lowest in the late-stage. 24 h after As_2O_3 adding, the cell nucleus showed typical apoptotic changes.**

CONCLUSION: **Under the inducement of As_2O_3, the early apoptotic changes of SHEEC1 cells were the apparent morphological and functional changes of mitochondria, afterwards the nucleus changes followed. It is considered that changes of mitochondria are an important intermediate link in the course of apoptosis of esophageal carcinoma cells induced by As_2O_3.**

INTRODUCTION

Esophagus cancer is common in China[1-11]. The treatment is still a focus of research[12-17]. Induction of cell apoptosis is a novel therapeutic strategies for cancer[18-25]. In our previous work, we used As_2O_3 to induce apoptosis of esophageal carcinoma cells [26]. The pathomorphological changes evinced that cells became smaller, the cells shrank, the nuclei rounded up, chromatin agglutinated and marginated, nuclear membrane broke down and then followed by the degenerative changes of the cells. All these changes indicated typical morphological changes of apoptosis[27]. The necrotic changes were also found with a large dosage of As_2O_3[28]. We discovered that in the early-stage of cell apoptosis, prior to the obvious change of cell nuclei, the mitochondria showed proliferation. The detailed morphological changes of mitochondria of esophageal carcinoma cells induced by As_2O_3 were firstly described in our paper[29]. We also found that nitric oxide (NO) was released from the cultured esophageal carcinoma cell line after administration of As_2O_3 with increasing amounts at the early apoptotic stage[30]. Furthermore, down regulated expression of bcl-2 and over expression of bax were always found in apoptotic cells induced by As_2O_3[31].

Some authors hold that apoptosis is a programmed cell death (PCD); the death signal originates from the inside of cells; the change chiefly involves the cell nucleus with no apparent changes seen in the cytoplasm and cell organelle[32-33]; making it different from cell necrosis[34]. In our studies, the morphological changes of apoptotic cells induced by As2o3 were different from the programmed cell death in which the latter showed the nuclear changes at first and then cytoplasm, and the former were vice versa[35]. In recent years, it has been explained that apoptosis is related to certain factors, such as Bcl-2/Bax,[36-39] Ca^{2+}[40]and cytochrome c[41-42], which are all located on mitochondria[43]. When they are released from mitochondria, they can inhibit or promote cell apoptosis. Therefore, mitochondria are thought to be the apoptosis regulation center[44]. Mitochondria are also an important organell. They are concerned with cell breathing, oxygen metabolism, enzyme activity and energy supply. All of those functions relate to the permeability of the mitochondria and mitochondrial transmembrane potential(MTP,ΔΨm). When MTP decreases, the mitochondria generate morphological and functional changes[45- 47].

Rhodamine 123 (Rho123), a kind of fluorescent dye, is traditionally used as a mitochondria probe[48]. Rho 123 can quickly gather on living cell mitochondria. The fluorescence intensity of Rho123 represents MTP which reflects the cell in a quiescent or active condition, and in a proliferative or differentiative manner[49]. Flow cytometer and fluorescent microphotometry are the satisfactory

instruments to measure Rho123 fluorescent intensity. The purpose of this paper is to study the mitochondrial morphological and functional changes during the cell apoptosis of esophageal carcinoma cell line induced by As_2O_3, thus demonstrating that mitochondrial changes play an important role in the course of cell apoptosis.

MATERIALS AND METHODS

Cell line and As_2O_3 adding

The esophageal carcinoma cell line SHEEC1 is the human embryonic esophageal epithelial cells malignantly transformed by HPV18 E6 E7 in synergy with TPA[50]. It is cultured in 199 growth medium, supplemented with 100mL·L^{-1} calfserum and antibiotics. In experiments, SHEEC1 cells were cultured separately in culture flasks and on 24-well culture plates (Corning Co.) with the cover slide inside the well, in every well 10^4 SHEEC1 cells were inoculated. As_2O_3 (Sigma, St. Louis, Mo; Lot A 1010) was prepared in concentration of 3μmol·L^{-1} with 199 growth medium. The experimental group and the control group without As_2O_3 administered were examined at definite times. The experiments were repeated once.

Examination under light-and electron-microscope

At 2,4,6,12,24 h after As_2O_3 adding, one culture flask of SHEEC1 cultured cells was taken for examination. The floating cells in the flasks were collected by centrifugation (CytospinIII, Shandon Co.), Giemsa stained and examined by light-microscope. Cells attached to flask were digested with 2.5g·L^{-1} trypsin, centrifuged, the cell pallet was fixed with 25g·L^{-1} glutaraldehyde, and were routinely prepared for electron-microscopic examination.

Rhodamine fluorescent probe labeling and cytofluorimetric analysis (CFA)[51, 52]

SHEEC1 cells were placed on the slide after reacting with As_2O_3 at various times, stained by Rhodamine 123 (Rho123, MW381, Molecular Probe Inc. Eugene) at the concentration of 10mg·L^{-1}, and the cells were incubated in 37℃, 50mL·L-1 CO_2 incubator for 15 min. It was examined by fluorescent microscopy and cytofluorimetry. Using the Nikon fluorescent microscope (Fluophot, Nikon) with Low-cost cooled digital CCD camera system and software STARI (Photometrics LTD. USA), the fluorescent image of mitochondria of SHEEC1 cells labeled by Rho123 were displayed on the screen of monitor, the fluorescent intensity of cells was measured by scanning method, and the average amount of cellular fluorescence was calculated by software.

Flow cytometer (FCM) examination[53]

Following As_2O_3 treatment, SHEEC1 cell cultured in flasks were harvested with trypsinization, washed once with PBS, resuspended in PBS, and incubated with Rho123 (10mg·L^{-1}) at 37℃ for 15 min, stained cells were wash twice with PBS, dispersed, filtered through a 360 mesh nylon net to make single cell suspension. 10^9 cell·L^{-1} were detected by flow cytometer (FACSort, B-D Co. USA) using exciting light 488nm and emission light 515nm to detect Rho123 fluorescent intensity. The histogram managed by the computer was drawn according to the fluorescent intensity value of one cell. Partial of SHEEC1 cells were fixed with 700mL·L^{-1} alcohol, stained with propidium iodide (Sigma) and analyzed with flow cytometer. The cell cycle and apoptotic cell rate were calculated.

Calculation of mitochondrial transmembrane potential (MTP. $\Delta\Psi m$)[46]

Examining 10^4 cells by FCM, the average fluorescent intensity of the cells labeled by Rho 123 before and after As_2O_3 adding were drawn as histograms for comparing. By cytofluorimetric analysis the average fluorescent intensity value (x±s) was calculated from one cell.

RESULTS

Cell apoptosis

Twenty-four hours after As_2O_3 acting on SHEEC1 cells, the apoptotic peak (28% of the cells) before G_1G_0 in DNA histogram of FCM examination appeared (Figure 1). Collecting the floating cells by cytospin and Giesma staining, the cell nuclei showed typical cell apoptotic changes with chromatin agglutinated and marginated (Figure 2).

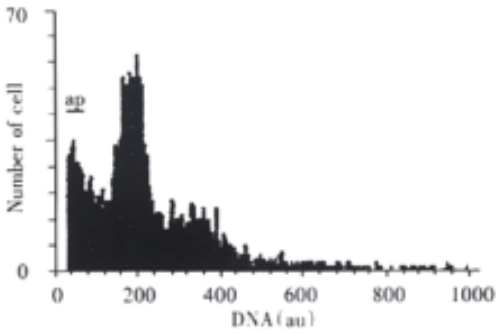

Figure 1 DNA histogram of SHEEC1 cells 24 h after Figure 2 Apoptotic changes 24 h after As_2O_3.

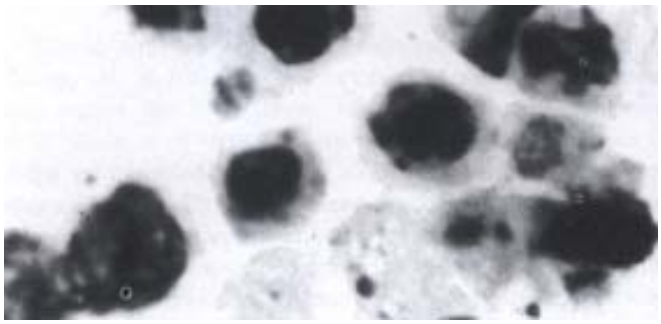

Figure 2 As_2O_3 adding. ap, apoptotic peak. adding, HE×400.

Morphological changes of mitochondria under transmission electron-microscope

Before adding As_2O_3 the mitochondria were located around the nucleus in one or two arrays (Figure 3A). There were fixed intervals between mitochondria, in which other organelles were present. When adding As_2O_3 2-4 h, the mitochondria increased, which showed either concentration in certain areas or in one pole of the cytoplasm or distributed in inner, middle or outer layer of the cytoplasm (Figure 3B). Mitochondria were oval in shape and different in size. The newly proliferated mitochondria were smaller with dense matrix. Some mitochondria were condensed with indistinct ridges and some mitochondria were crowded closely together. After 6 h, the high electron dense and irregular shaped substances precipitated in the mitochondrial matrix, even filled up the whole mitochondria (Figure 3C). The autophagosomes resulting from wrapping of condensed mitochondria by the lysosomes were frequently seen. After 12 h, the mitochondria swelled, its outer membrane broke down, left a single layer of membrane, which were seen like a balloon or a vacuole. After 24 h, the cell nucleus shrank and chromatin agglutinated locating near the nuclear membrane with mitochondria swelling, or becoming vacuole-like or broken down (Figure 3D).

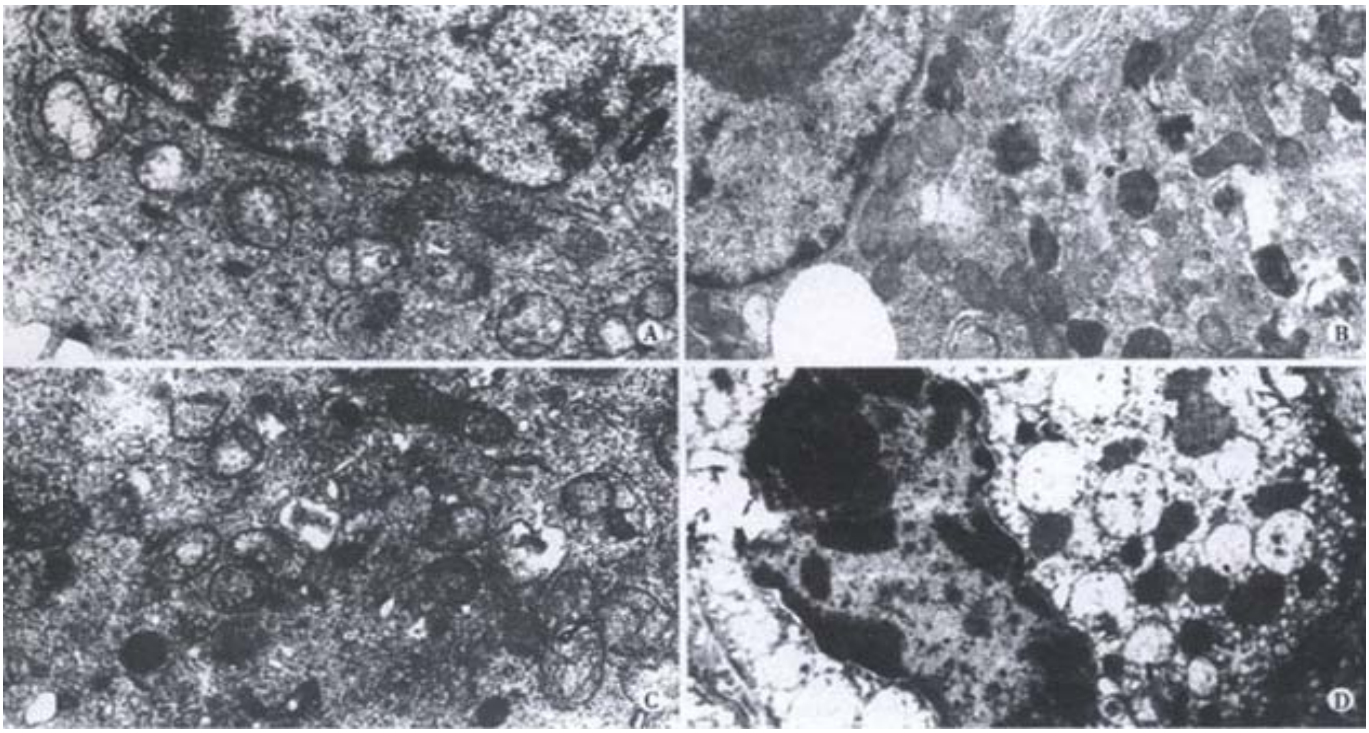

Figure 3 Apoptotic cells (EM x 15000). Mitochondria in 1-2 arrays located around the cell nucleus, not adding As_2O_3; Increment of mitochondria 2-4 h after As_2O_3 adding; Dense substances deposition in mitochondria 4-6h after As_2O_3 adding; Apoptotic cell showed cell nucleus shrank, chromatin agglutinated, mitochondria increased and swelled as balloon-like 24h after As_2O_3 adding.

Functional changes of mitochondria in cell apoptosis: the dynamic changes of MTP (ΔΨm)

Mitochondrial fluorescence intensity detected by FCM After As_2O_3 was added to SHEEC1 cells, the changes of mitochondria fluorescence intensity from different reacting times were seen in histogram (Figure 4 A,B,C,D). A slight increase of mitochondrial fluorescence intensity was observed at 2h after added As_2O_3. With treatment of As_2O_3 for 4-6h, fluorescent intensity of mitochondria was decreased sharply. After 12-24h fluorescent intensity was the lowest.

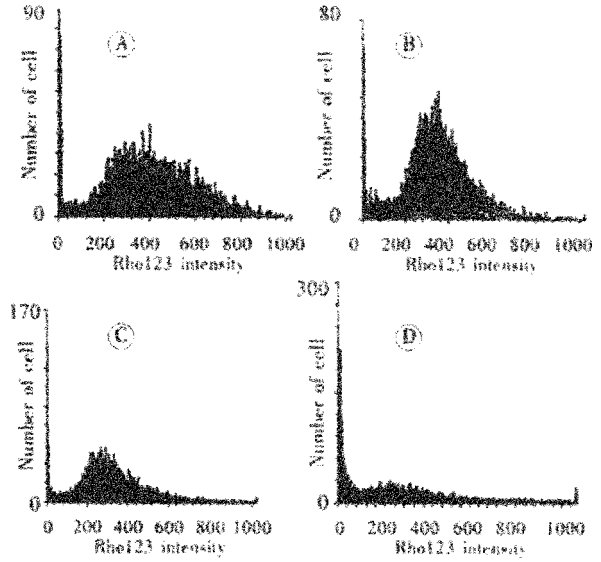

Figure 4 The histogram of mitochondrial fluorescent intensity by FCM after As_2O_3 adding.
A: Control; B: 2-4 h; C: 4-6 h; D: 12-24 h.

Fluorescent intensity by cytofluorimetric analysis Under fluorescent microscope, the number of mitochondria of cells was increased at first (Figure 5) and then decreased. The fluorescent intensity increased in 2h after As_2O_3 added, declined in 4-6h and decreased to the lowest in the 12-24h (Table 1). An increment of fluorescence intensity in partial early-stage apoptotic cells after 2 h of As_2O_3 adding and the intensity decreased hereafter. Following fluorescence associated with the uptake of dye Rho123 allows to evaluate ΔΨm modifications,the results showed the dynamic MTP changes in the apoptotic process induced by As_2O_3.

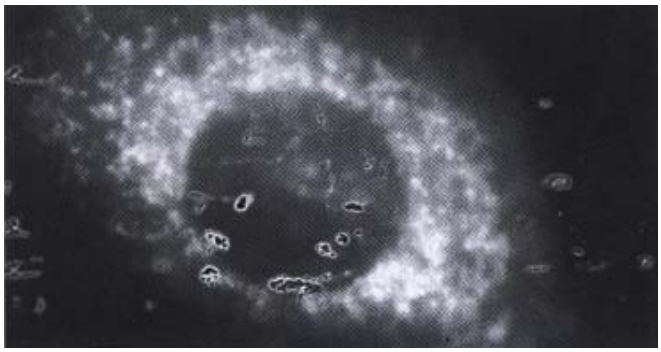

Figure 5 Increment of mitochondria with Rho123 labeled in cytoplasm of SHEEC1 after 2-4 h As_2O_3 adding. ×1000

The Rho123 fluorescence intensity of the labeled mitochondria differed from different reacting times after adding As_2O_3. At first fluorescent intensity increased and then the rapidly declining value of fluorescence intensity was in accordance with both results of FCM and CFA. It taking cell morphology into account, the fluorescence intensity changes may reflect the consequence of As_2O_3 stimulation to mitochondria for different times. 2 h after As_2O_3 was added, the mitochondria proliferated and the fluorescent intensity increased, soon after the

intensity swiftly declined and went to the lowest at 24 h, which indicated that morphological and functional changes of mitochondria induced by As_2O_3 represented the process cell apoptosis.

Table 1 Average fluorescence intensity value of SHEEC1 after As_2O_3 adding (arbitrary unit $x10^{-4}$/cell)

T (after As_2O_3) h	Fluorescence intensity ($\bar{x}\pm s$)
Control	180.3 ± 75.7
2	206.4 ± 93.2
4	170.2 ± 80.3
6	168.2 ± 72.2
12	114.4 ± 70.3
24	90.7 ± 85.6

DISCUSSION

Reports about As_2O_3 inducement of apoptosis of cancer cells have been seen frequently in hemopoietic stem cells and leukemia cells[54-60], but rarely in epithelial tumor cells[61-64]. We have tried to explore the possibility of curing esophageal carcinoma by using As_2O_3 treatment *in vitro*. The experimental results have shown that As_2O_3 can induce cancer cell apoptosis, large doses of As_2O_3 can even induce cell necrosis. Our previous works indicated that at the early-stage of cell apoptosis,morphological changes of the mitochondria might be an important phenomenon in the course of esophageal carcinoma cell apoptosis induced by As_2O_3[29, 31]. Our results showed that morphological and functional changes of mitochondria of SHEEC1 cells were induced by As_2O_3. It could divide into three stages. Two to four h after As_2O_3 administration, the mitochondria proliferated with a lot of new small mitochondria, distributing from the inner layer to the outer layer of cytoplasm. This was the early reaction of mitochondria of SHEEC1 cells to the effect of As_2O_3. 6 h after As_2O_3 inducement, many ridges on mitochondria were seen. The dense substances began to precipitate in the matrix of mitochondria and the condensed or damaged mitochondria were engulfed by lysosomes to form autophagosomes as seen in lymphocytes[65]. Twelve hours after As_2O_3 inducement, the mitochondria were swelling, or vacuolation with mitochondria ridges decreased or disappeared. Twenty-four h after As_2O_3 inducement, apoptotic cells appeared with coagulating chromatin in nucleus and shrinking in the whole cell. The mitochondria swelled like a balloon. During the whole course of cell apoptosis, changes of mitochondria preceded the changes in nuclei.

The fluorescent intensity value detected by CFA and FCM reflects the function of mitochondria[66]. The change of Rho123 fluorescent intensity under As_2O_3 treatment may be divided into 3 time phases: 2-4h after As_2O_3 inducement, mitochondria increased fluorescent intensity, but began to decline after 4-6 h and decreased to the lowest after 12-24 h. These functional changes of mitochondria were in accordance with mitochondrial morphological changes.

The functional changes of mitochondria may be accompanied with decreasing the formation of ATP, reducing the activity of dehydrogenase[67], thus influencing cell respiration, cell metabolism,energy supply and even the cell death. If the mitochondrial release cytochrome c or apoptotic inducement factors (AIF), they may activate the caspases enzyme system, which further act upon cell nucleus and cell keratinoprotein to induce irreversible apoptotic changes[68]. If the mitochondrial changes resulted in lowering of $\Delta\Psi m$, increase of oxygen free radical and blocking up the formation of ATP, the cells will be finally undergo necrosis, because they lose the ability of electron bond transmission. Therefore, the mitochondrial changes may induce cell apoptosis and also cell necrosis[69]. When the inducement factor is strong or highly concentrated it induces cell necrosis. If less in amount and strength, it may give times to activate the caspases enzyme system[70], the cell apoptosis will develop. Mitochondrial fluorescent probe Rho123 is a very useful tool, which may specifically conjugate with mitochondria to indicate cells living state or metabolic state[25]. Detecting Rho123 fluorescence intensity of mitochondria may reveal mitochondrial quantity and function under different kinds of stimuli. The Rho123 fluorescence intensity is stronger in proliferative cells than in quiescent cells, and the intensity decreases in damaged mitochondria caused by harmful stimuli[48]. The amount of Rho123 conjugated with mitochondria differs in different types of cells and in different cell functional status[66]. The mitochondrial changes of SHEEC1 cells induced by As_2O_3 occurred 2-4 h after drug adding. Under the same cultured conditions, mitochondria were supposed to be the firstly targeting site in the course of cell apoptosis. Therefore, under As_2O_3 inducement, the morphological and functional in mitochondria of SHEEC1 cells, which happened prior to cell nuclear DNA change, may be regarded as the important link in cell apoptosis.

Abstract

AIM: **To explore the correlation of the inherent cellular ROS level with the susceptibility of the digestive tract tumor cells to apoptosis inducted by As_2O_3.**

METHODS: **Two gastric carcinoma cell lines, SGC7901 and MKN45, and two esophageal carcinoma cell lines, EC/CUHK1(alternatively named EC1.71) and EC1867 with low concentration(2μmol·L^{-1})of As_2O_3 were cultured respectly, which confirmed the difference in apoptosis susceptibility between SGC7901 and MKN45, and between EC/CUHK1 and EC1867. The cells were incubated with dihydrogenrhodamine123 (DHR123), used as a ROS capture in absence of As_2O_3. The fluorescent intensity of rhodamine123, which was the product of cellular oxidation of DHR123, was detected by flow cytometry, and ROS was measured.**

RESULTS: **Apoptosis induced by a low concentration of As_2O_3 was more readily to occur in SGC7901 (22.4%±2.4%) and EC/CUHK1(27.0%±2.9%) than in MKN45(2.1%±0.5%) and EC1867(0.8%±0.5%). In other words, SGC7901 was more sensitive than MKN45 to As_2O_3, meanwhile EC/CUHK1 was more sensitive than EC1867 to As_2O_3. The level of inherent cellular ROS in SGC7901(650±37) was higher than that in MKN45(507±22)(P<0.01), and the level of inherent cellular ROS in EC/CUHK1(462±17) was higher than that in EC1867(187±12) (P<0.01).**

CONCLUSIONS: **The cellular sensitivity to apoptosis induced by As_2O_3 is associated with the difference in cellular ROS level. The inherent ROS level might determinate the apoptotic sensitivity of tumor cells to As_2O_3.**

INTRODUCTION

Arsenic trioxide (As_2O_3) has proved to be effective in the treatment of acute promyelocytic leukemia (APL)[1-7]. While many researchers aimed at the effectiveness of As_2O_3-induced apoptosis on the other leukemic cells and some solid tumor cells, a lot of evidence showed that some types of tumor cells were sensitive while others were insensitive to apoptosis-inducing effect of As_2O_3[2,8-20]. Unraveling the causes of such sensitivity difference in the tumor cells will benefit not only the clinical selection of patients,to which As_2O_3 can be given, but also understanding the mechanisms underlying the apoptosis induced by As_2O_3.

Previously we investigated the sensitivity of a series of digestive tumor cell lines to As_2O_3. We identified that there were difference of sensitivity to apoptosis inductied by low concentration (2μmol/L) of As_2O_3 between the gastric carcinoma cell line SGC7901 and MKN45, and between the esophageal carcinoma cell line EC/CUHK1(alternatively named EC1.71) and EC1867; SGC7901 was more sensitive than MKN45, and EC/CUHK1 was more sensitive than EC1867 to As_2O_3[15-16]. We found that As_2O_3 induced cell apoptosis via directly influencing mitochondrion, consequently causing decrease of transmembrane potential and increase of reactive oxygen species (ROS) level[17]. Recently it was evidenced that ROS participate the apoptosis induction of acute promylocytic leukemia[18,19,21,22]. But whether the difference of sensitivity of digestive tumor cells to apoptosis-inducing effect of As_2O_3 is associated with the inherent cellular ROS level is not clearly understood. In this study, we demonstrated the difference between SGC7901 versus MKN45, and EC/CUHK1 versus EC1867, thereby explored the ralation between the sensitivity of cell to apoptosis induction of As_2O_3 and the inherent cellular ROS level.

MATERIALS AND METHODS

Cell Lines and Culture Conditions

Gastric carcinoma cell line SGC7901 *vs* MKN45, and esophageal carcinoma cell line EC/CUHK1 *vs* EC1867(kindly provided by professor Shen, Shantou University) were cultured in DMEM medium supplemented with 100kU·L^{-1} pennicillin,100mg·L^{-1} streptomycin, and 100mL·L^{-1} fetal bovine serum(Gibco) in a fully humidified atomosphere with 50mL·L^{-1} CO_2 at 37℃. Cells were split when reached to 80% confluency.

Inducing Cell Apoptosis by As_2O_3

About 5×10^5 tumor cells in logarithmic stage were treated with 2μmol·L^{-1} concentration of As_2O_3 (Sigma) for 72h and analyzed by flow cytometry and electron microscopy for apoptosis[15-17]. As_2O_3 powder was dissolved in small amounts of 1.0 mol·L^{-1} NaOH, then diluted to 10.0 mmol·L^{-1} with phosphate-buffered saline(PBS) as stock solutions.

Detection Inherent ROS Level

The cells was incubated with 1μmol·L^{-1}dihydrorhodamine123 (DHR123,Sigma), as a ROS capture[23-25], for 1 or 24h. Blank and positive controls were set, in which DHR123 was either omitted or plus 50μmol·L^{-1} of hydrogen peroxide (H_2O_2). DHR123 could be oxidized intracellularly to form the fluorescent compound rhodamine123 (Rh123) by ROS, and be pumped into mitochondria and remained there. After incubated with DHR123, cells were trypsinized and harvested before an immediate detection of

fluorescence intensity of Rh123 by flow cytometry FACscan (Becton Dickinson), and the cellular ROS level was thus measured.

RUSULTS

Cell Apoptosis Induced by As_2O_3

A significant apoptosis was observed in EC/CUHK1 and SGC7901 cells with 2μmol/L of As_2O_3 for 3 days while no remarkable apoptosis could be seen in EC1867 and MKN45 cells with the equivalent As_2O_3. The characteristic morphological changes were displayed in the apoptotic cells, including the shrinkage of the nuclear membrane, condensation and margination of the chromatin, and nuclear breakage (Figure1). DNA flow cytometry showed that the some cells with fractional DNA, as typical display of apoptosis, appeared, (27.0±2.9)% and (22.4±2.4)% ($\bar{x}$±s,n=5)respectively in EC/CUHK1 and SGC7901 cells, but hardly visible in EC1867 (0.8±0.5)% and MKN45 (2.1±0.5)%. (Figure 2).

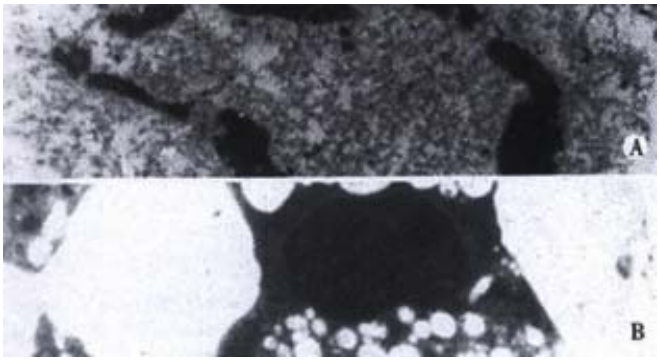

Figure 1 Apoptotic cells in EC/CUHK1 and SGC7901 with the condensation and margination of chromatin, and nuclear breakage EM×6000

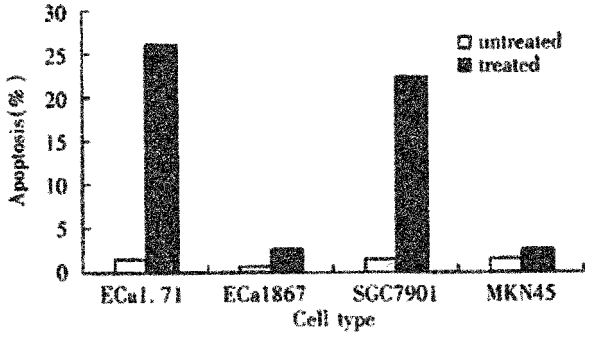

Figure 2 Flow cytometry with PI staining: apoptosis proportions in EC/CUHK1, EC1867, SGC7901 and MKN45

Inherent Cellular ROS Level

After incubation with DHR123 for 1 or 24h in absence of As_2O_3, the values ($\bar{x}$±s,n=3) of fluorescent intensity for Rh123 were 29±4. 1 and 650±37 in SGC7901 cells; 21±1.4 and 507±22 in MKN45 cells; 50±3.9 and 462±17 in EC/CUHK1; 46±6.4 and 187±12 in EC1867 cells. The fluorescent intensity in blank control was less than 3. The values for the positive controls (DHR123 plus hydrogen peroxide incubation for 1h) were 80±4.9 in SGC7901; 27±3.0 in MKN45; 72±5.8 in EC/CUHK1; and 19±2.1 in EC1867. Figure 3 displayed the fluorescence histograms for four types of cells after incubation with DHR123 for 24h. The data showed that,in absence of As_2O_3, the cellular ROS level was higher in SGC7901 than in MKN45, and higher in EC/CUHK1 than in EC1867. Such differences were augmented in 24h incubation as shown above, where the value in SGC7901 was as 1.3 times as in MKN45, and in EC/CUHK1 was 2.5 times as in EC1867.

DISCUSSION

ROS, including superoxide anion (O^-_2), hydrogen peroxide(H_2O_2), hydroxyl free radical (OH) and singlet oxygen ($^1O_2$), continuously generated from mitochondrial respiratory chain, have powerfully oxidative potential. ROS is capable of attacking lipids, nuclear acids and proteins, resulting in certain degree of oxidative damages[26-35]. It has been thought recently to involve in apoptosis triggering and signaling[36-43]. Cell possesses an efficient antioxidant defense system, mainly composed of the enzymes such as superoxide dismutase, glutathione peroxidase, and catalase, which can scavenge the ROS excessive to cellular metabolism, and make ROS level relatively stable under physiological conditions[26-35]. Though it has been noticed that ROS were involved in As_2O_3-induced apoptosis[18,19,21,22], evaluation of ROS level differences directly by a flow cytometric detection of ROS, to our knowledge, has not been frequently reported. Instead, H_2O_2, a kind of ROS, was adopted to represent the total ROS level, usually judged from a decrease in activity of glutathione peroxidase or catalase, or a decrease in ratio of reductive/oxidative glutathione[18,19]. The total ROS level in the resting cells, however, was directly measured in the present study, by flow cytometric detection of Rh123. The comparative investigation on the inherent ROS levels in the cells showed that there were different apoptosis susceptibility to As_2O_3. In this study, inherent ROS level signified the basal cellular level of ROS in absence of any drug or exogenous ROS.

Detecting ROS level by flow cytometry has been a novel approach with characteristic of rapidness, convenience and reproducibility. DHR123, one of common ROS captures, is membrane permeable. It is oxidized by ROS intracellularly to become fluorescent Rh123, and is pumped into mitochondria and remain there, then is detectable by flow cytometry after a period of accumulation[23-25]. 6-carboxy-2',7'-dichlorodihydrofluorescein diacetate (DCFH-DA) is another agent used to capture ROS. It is

cleaved by nonspecific esterases to form DCFH, which was further oxidized to form the fluorescent compound DCF and kept inside cells[19,44,45]. It proved important, as we realized in this study, to prolong the incubation time with the ROS capture in order to visualize the nuance in ROS, since the absolute quantity of ROS is scarce. We selected two time intervals to visualize the accumulation of Rh123 fluorescence, finding that difference began to display at 1 h and became much pronounced by 24 h. These parameters definitely represented the difference of ROS level inherently existed in the respective types of cells. A similar result was obtained by using DCFH-DA in our study. Recently it was evidenced that NB4 leukemia cell line, which is sensitive to low concentration of As_2O_3 (1-2μmol/L), had higher H_2O_2 level than the U937 leukemia cell line which is insensitive to As_2O_3, and exposure of cells to low concentration of As_2O_3 elevated the level of H2O2 in NB4 but not in U937[19]. Though these studies indicated that a higher H2O2 level in NB4 might link to its higher sensitivity to As_2O_3 -induced apoptosis[19], whether there existed a difference in total ROS level between cell lines which possessed different susceptibility to As_2O_3 -induced apoptosis, prior to As_2O_3 treatment, has not been documented.

Based on our previous work, we selected two pairs of digistive tract cell lines EC/CUHK1 versus EC1867, SGC7901 versus MKN45 in which one type of cell was susceptible and the other type was unsusceptible to As_2O_3 -induced apoptsis in this study, and measured the inherent levels of total ROS in these cells. The data on both pairs showed that the inherent ROS level was higher in sensitive cells. These results indicated that difference in apoptosis susceptibility of tumor cells to low concentration of As_2O_3, was associated with the difference in the inherent cellular level of ROS, and what's more, the inherent ROS level might be pivotal in determination of the cellular susceptibility to As_2O_3 -induced apoptosis. The difference of inherent ROS level between cells probably resulted from the differential expression of enzymes involved in ROS generation and elimination[46-51]. An interference to the expression of relevant enzymes or simply ROS is likely an approach by which an improved effect and expanded usage of arsenic trioxide can be achieved clinically.

Abstract

AIM: **To Quantitatively analyze the nitri oxide (NO) and Ca^{2+} in apoptosis of esophageal carcinoma cells induced by arsenic trioxide (As_2O_3).**

METHODS: **The cell line SHEEC1, a malignant esophageal epithelial cell induced by HPV in synergy with TPA in our laboratory, was cultured in a serum-free medium and treated with As_2O_3. Before and after administration of As_2O_3, NO production in cultured medium was detected quantitatively using the Griess Colorimetric method. Intracellular Ca^{2+} was labeled by using the fluorescent dye Fluo3-AM and detected under confocal laser scanning microscope (CLSM), which was able to acquire data in real-time enabling Ca^{2+} dynamics of individual cells *in vitro*. The apoptotic cells were examined under electron microscopy.**

RESULTS: **Intracellular concentration of Ca^{2+} increased from 1.00 units to 1.09-1.38 units of fluorescent intensity at As_2O_3 treatment and NO products subsequently released from As_2O_3-treated cells increased from 0.98-1.00 $\times 10^{-2}\mu mol \cdot L^{-1}$ up to 1.48-1.52$\times 10^{-2}\mu mol \cdot L^{-1}$ and maintained in a high level continuously. Finally apoptosis of cells occurred, chromatin being agglutinated, cells shrunk, nuclei became round and mitochondria swelled.**

CONCLUSION: **Ca^{2+} and NO increased with cell damage and apoptosis in cells treated by As_2O_3. The Ca^{2+} is an initial messenger to the apoptotic pathway. To investigate Ca^{2+} and NO will be a new direction for studying the apoptotic signaling messenger of the esophageal carcinoma cells induced by As_2O_3.**

INTRODUCTION

Arsenic trioxide (As_2O_3) has been proved to be a genotoxic and a carcinogenic agent[1-6]. Previous studies also showed that As_2O_3 induced cellular apoptosis in leukemia[7-15], in cancer cells of head and neck[16] and other cancer cells[17-22]. So As_2O_3 has antitumoral effect. We found that As_2O_3 induced apoptosis in esophageal squamous carcinoma cells[23]. The pathomorphological changes induced by As_2O_3 revealed that cells became smaller and shrank, nucleus rounded up, chromatin agglutinated and marginated, the nuclear membrane broke down followed by degenerative changes and cell mortality. All these changes indicated typical morphological changes of apoptosis[24, 25]. Mitochondria, an important cellular apparatus, is related to cell breathing, oxygen metabolism, enzyme activity and energy supply. Our data demonstrated that the primary target of As_2O_3 inducing apoptosis of esophageal carcinoma cells might be the mitochondria[26]. It is likely that As_2O_3 is a mitochondriotoxic agent[27, 28]. At the early stage of cellular apoptosis induced by As_2O_3, the mitochondria generated morphological and functional changes[29, 30].

NO exerts a wide range of its biological properties via its interaction with mitochondria and NO mediated mitochondria damage[31]. In our previous data, an increase level of nitrite, a stable product of NO, was detected in the culture medium of esophageal carcinoma cells in arsenite-treated apoptosis[32]. Calcium ions (Ca^{2+}) act as a universal second messenger in a variety of cells. Numerous functions of all types of cells are regulated by Ca^{2+} to a greater or lesser degree. Because of the importance of Ca^{2+} in biology, numerous methods of analyzing cellular Ca^{2+} activity have been established. Confocal laser scanning microscopy (CLSM) allows the precise spatial and temporal analysis of intracellular Ca^{2+} activity at the subcellular level. This optical technique has enabled scientists to document the dynamic changes of intracellular Ca^{2+} *in vitro*[33].

Arsenic may generate reactive oxygen species to exert its toxicity, which is implicated in DNA damage, signal transduction and apoptosis. What we are interested in is to see if NO and Ca^{2+} are involved in arsenic-induced apoptosis and to observe the changes of its target organelle—mitochondria. This study is to investigate which are the original messengers that initiate apoptosis and to detect quantitatively Ca^{2+} and NO in the apoptotic process of esophageal carcinoma cell line induced by As_2O_3.

MATERIALS AND METHODS

Cell line generation and cell culture

The esophageal carcinoma cell line (SHEEC1) was a malignantly transformed cell line of human embryonic esophageal epithelium induced by HPV18 E_6E_7 in synergy with TPA (12-O-tetradecanoyl-phorbol-13-acetate)[34]. Cells were cultured in 50ml flasks and 24-well plate (Corning) with serum-free medium. The culture medium contained of the basal medium (MCDB151) with trace elements (M-6645 Sigma) and added transferrin, hydrocorticosone, epidermal growth factor (EGF), insulin (Sigma Chemical Co.) and extracts of bovine hypophysis (Gibco, BRL), but without calf serum, nitrite and nitrate, while containing streptomycin and penicilline (50mg·L^{-1} for each).

The administration of arsenic

Arsenic trioxide (As_2O_3) obtained from Sigma Chemical Co. (St. Louis MO, Lot A 1010)at concertrations of 0, 1, 3 and 5$\mu mol \cdot L^{-1}$ was added into the culture flasks and 24-well plates, respectively, for

0, 2, 4, 8, 12 and 24 h. The experiment was repeated once.

Transmission electron-microscopy (EM) examination

At the endpoints of As_2O_3 (24h), cells of each group were digested with 0.25% trypsin, centrifuged, fixed with 2.5% glutaraldehyde, and routinely prepared for electron microscopic examination. The samples were observed under transmission electron microscope (Hitachi 300).

Cell cycle and apoptotic rate analyzed by flow cytometry (FCM)

Cells of repeated experiment were harvested to measure the ratio of apoptotic cells to survived cells. The cells were washed twice with PBS, dispersed, and filtered through 360 mesh nylon net to make a single cell suspension. It was fixed with 700mL·L^{-1} precooled alcohol in ice. Before analysis cells were suspended in PBS and stained with propidium iodide. 1×10^9 cells·L^{-1} were detected by flow cytometry (FACsort, B-D Co,USA). The DNA histogram was drawn according to the fluorescent intensity value of 10^4 cells.

Procedure of NO detection[35]

The nitrite/nitrate colorimetric method, using the kit purchased from Boehringer Mannheim Co, was used to detect NO in culture medium. The culture medium of 0.2 mL from flask was regularly deactivated at 80℃ for 5 min and deproteinated by centrifugation in 12000 r·min^{-1} for 30min, and the supernatant was determined. The procedure for NO determination was as follows: sample solution of 100μL, 50μL of nicotinamide adenine dinucleotide phosphate (NADPH) and 4μL of the enzyme nitrate reductase (NR) were placed in a 3mL test tube, mixed, incubated for 30 min at room temperature, and added 50μL color reagent I & II, respectively, mixed,and allowed to stand in the dark at room temperature for 10 to 15min. The NO content of the samples and the blank was estimated with Shimadzu UV/120 spectrophotometry by 450nm and was calculated by calibration curve of standard addition method. The standards were prepared from known amounts of stock NO_3 and NO_2 and run in parallel with test samples in each assay.

Determination of intracellular calcium level using CLSM[33, 36]

The cells were cultured on the coverslips within the glass bottom of a small cultured dish (No. 0, uncoated, and irradiated. MatTek Co., USA). At the exponential growth period, the cells were stained with 10μmol·L^{-1} fluo-3/AM (Molecular Probe) for 30min at 37℃, and washed with 135 mol·L^{-1} NaCl, 10 mol·L^{-1} HEPES, 0.4 mol·L^{-1} $MgCl_2$, 1mol·L^{-1} $CaCl_2$, 1g·L^{-1} D-glucose, 1g·L^{-1} bovine serum albumin, pH 7.3 at least 3 times. Then the cells were placed in the culture medium 199 to maintain them in living state. Before and after administration of As_2O_3 the fluorescence intensity was determined by CLSM in dynamic changes for up to 900 s. Using scan-time series menu, time series was used to scan some definite cells repeatedly to monitor the dynamic changes in fluorescent intensity of intracellular Ca^{2+} content over time. The parameters of the CLSM (Ultima 312, Meridian Instruments Inc., USA) were as follows: the excited light 488nm, the emission light 530 nm and pinhole 10-40nm. The fluorescent intensity of pixel was collected and managed with the software of the instrument.

RESULTS

Cell apoptosis

Ultrastructural morphological changes of mitochondria in As_2O_3 treated cells were described in the previous reports[25,26]. Cells treated with As_2O_3 at different concentrations for 24 h displayed an apoptotic appearance. Under electron microscope, condensed and marginated chromatins in most of the nuclei appeared accompanying swelling mitochondria (Figure 1). By flow cytometry, time course study on As_2O_3 induced apoptosis revealed that apoptotic peak can be observed as early as 12 h after the incubation of arsenic trioxide in 3μmol·L^{-1}. The apoptotic cells accounted for 5.0% of total cell population at 12 h and 28.3% at 24 h (Figure 2).

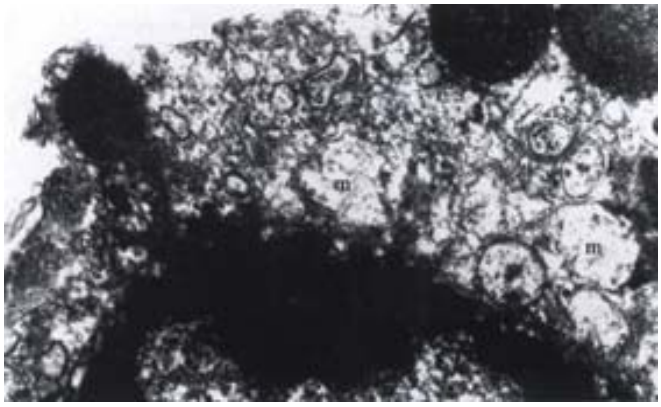

Figure 1 Ultrastructure of SHEEC1 cell treated with 3μmol·L^{-1} As_2O_3. Apoptotic appearance displayed with swelling of mitochondria and nuclear chromatin coagulating and merginating. m, mitochondria. n, nucleus. EM, ×7000

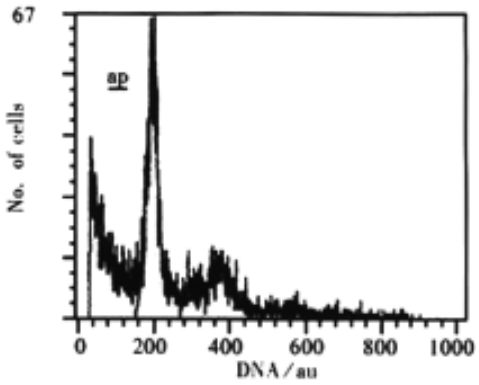

Figure 2 DNA histogram of SHEEC1 cell in 24 h after 3μmol·L^{-1} of As_2O_3 adding. ap, apoptotic peak.

NO determination

When As_2O_3 acted on the SHEEC1 for 2-24h, in 0, 1, 3 and 5μmol ·L^{-1} As_2O_3, NO in cultured medium was increased at the time points. The amount of NO released from SHEEC1 was increased from the basal condition (0.98-1.00×10^{-2}μmol·L^{-1}) up to the high level (1.48-1.52 ×10^{-2}μmol·L^{-1}) (8h) and maintained for 24h (Figure 3). The concentration of NO in different groupsvaried, high concentration of NO in 5μmol·L^{-1} of As_2O_3 and low concentration of NO in 1μmol·L^{-1} of As_2O_3.

Dynamic change calcium of intracellular calcium

To show the time course of changes in Ca^{2+} in individual cells, the changes in fluorescence intensity (arbitrary unit, au) at different representative cells were measured. Upon the initiation of stimulation by As_2O_3, all the cells responded with a rapid rise in [Ca^{2+}] from 1.00 au. to 1.09-1.38 au of fluorescent intensity. The peak levels of Ca^{2+} in all cells were consistently reached at about 900s after stimulation (Figure 4A). In the control group, without being treated with As_2O_3, the fluorescent intensity of cell, were remained on the basal line (Figure 4B).

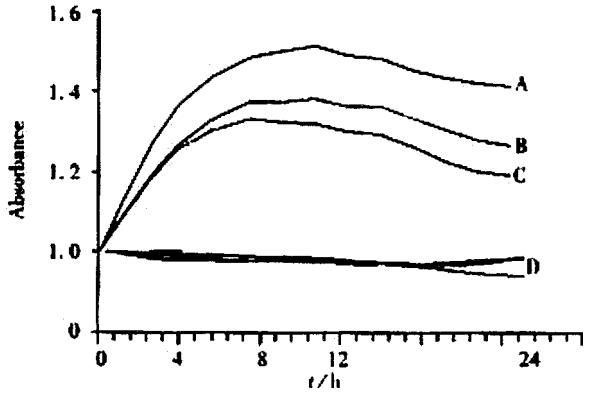

Figure 3 NO determination of SHEEC1 treated with different concentration of As_2O_3. NO increased markedly in 5μmol·L^{-1} of As_2O_3 group (A), intermediately in 3μmol·L^{-1} of As_2O_3 group (B) and lowly in 1μmol·L^{-1} of As_2O_3 group (C). The control group, 0μmol·L^{-1} of As_2O_3, were remained on the basal lines (D).

DISCUSSION

In general, the process of cell apoptosis involved three phases: the initiation phase, the effector phase and the degradation phase[37]. The initiation (or signal transduction) phase is the stage in which specific or non-specificpro-apoptotic signal transduction pathways are activated. The effecter (or central control) phase mainly occurs in the mitochondria[38] where mitochondria membranes are unstable as a result of the action of the permeability alternation. Some genes such as p53 and bcl-2, activate in this phase[39-41]. The degradation (or morphological and biochemical changes) phase manifest the postmitochondrial features of apoptosis, in which soluble intermembrane proteins released from mitochondria played an active role in the activation of proteolytic destruction. In our previous reports, we investigated the early changes of the apoptotic cells induced by As_2O_3 and defined the phase in which As_2O_3 was involved[26, 27]. Our results demonstrated that As_2O_3 acted directly on mitochondria for the early stage of apoptosis. The alteration of mitochondria in arsenic trioxide treated tumor cells could be observed as early as 2 h after the treatment[27, 30]. In this study we investigated signal messengers of apoptosis, by first selecting both messengers of NO and Ca^{2+} in the apoptotic pathway.

Experiments on the effects of various modulators (dose and time lag) of arsenic in the level of Ca^{2+} and NO were carried out. Nitric oxide (NO) is a free radical generated in cells by nitric oxide synthases (NOS)[42]. It is a gaseous inter- and intra-cellular messenger that plays as a signaling molecular in many physiological and pathological processes and it is also a cytotoxic agent involved in many diseases, whichhas been elaborated extensively during the last decade. Various intra- or extra-cellular factors act on mitochondria to produce NO. NO binds to cytochrome oxidase[43], blocks respiratory chain and induces apoptosis[44, 45].

Cells themselves control intracellular Ca^{2+} concentration ([Ca^{2+}]) strictly with several Ca^{2+} regulatory mechanisms, such as Ca^{2+} channels, Ca^{2+} pumps, and Ca^{2+} exchangers. The role of calcium is as the important intracellular signal element in regulating cell death[46]. As revealed by previous reports, it seems that calcium changes in apoptosis vary with stimuli and cell lines[47]. This data suggested that an early, gradual and sustained increase in intracellular Ca^{2+} is necessary for the appearance of apoptotic characteristics. In the examination of CLSM with Fuo-3 AM as a calcium indicator, we found that a rise in intracellular calcium was elicited at once after application of As_2O_3. The mechanism of how arsenic increases intracellular calcium levels was not clear at this moment. Arsenic has been shown to disrupt mitochondria and may elevate intracellular calcium via a signal transduction pathway. Arsenite has also been reported to activate protein kinase C and mitogen-activated protein kinase[48]. These kinases are known to be involved in the calcium signal transduction pathway.

According to the previous reports, the relationship between NO, Ca^{2+} and mitochondria in apoptosis is as follows:various extracellular factors can induce the increase of intracellular Ca^{2+} levels ([Ca^{2+}]$_i$), modulating cellular signaling and gene expression, and the increased ([Ca^{2+}]$_i$) effect on NO production through the iNOS pathway[49, 50]; mitochondria are a source of NO[51], the production of which may affect energy metabolism, O_2 consumption and O_2 free radical formation[52]; mitochondrial Ca^{2+} uptake in combination with NO production triggers the collapse of mitochondrial membrane potential, affecting mitochondrial respiration and culminating in delayed cell death[53].

In conclusion, our data proved that increased calcium ions and nitric oxide triggered by As_2O_3 may play an important role in arsenite-induced apoptosis in esophageal carcinoma cells. The demonstration of the involvement of Ca^{2+} and NO in arsenite-induced apoptosis suggests a new direction for studying the apoptotic pathway.

Abstract

AIM: **To investigate the effect of antisense RNA to vascular endothelial growth factor165 ($VEGF_{165}$) on human esophageal squamous cell carcinoma cell line EC109 and the feasibility of gene therapy for esophageal carcinoma.**

METHODS: **By using subclone technique, the full length of $VEGF_{165}$ amino acid cDNA, which was cut from pGEM-3Zf (+), was cloned inversely into the eukaryotic expression vector pCEP4 .The recombinant plasmid pCEP-AVEGF$_{165}$ was transfected into EC109 cell with lipofectamine. After a stable transfection, dot blot, enzyme-linked immunosorbent assay (ELISA), laser confocal imaging system analysis, transmission electron microscopy and flow cytometry were performed to determine the biological characteristics of EC109 cell line before and after transfection *in vitro* and whether there was a reversion in the tumorigenic properties of the EC109 cell *in vivo*.**

RESULTS: **The eukaryotic expression vector pCEP-AVEGF$_{165}$ was successfully constructed and transfected into EC109 cells. The expression of $VEGF_{165}$ was significantly decreased in the transfected cells while the biological characteristics of the cells were not influenced by the expression of antisense gene. The tumorigenic and angiogenic capabilities were greatly reduced in nude mice, as demonstrated by reduced tumor end volume (820±112.5)mm^3 *vs* (7930±1035)mm^3 and (7850±950) mm^3, *P*£¼0.01£½ and microvessel density(8.5±1.2) mm^{-2} *vs* (44.3±9.4)mm^{-2} and (46.4±12.6)mm^{-2}, *P*<0.01) in comparison between experimental groups empty vector transfected group and control group.**

CONCLUSION: **The angiogenesis and tumorigenicity of human esophageal squamous cell carcinoma were effectively inhibited by $VEGF_{165}$ antisense RNA. Antisense RNA to $VEGF_{165}$ can potentially be used as an adjuvant therapy for solid tumors.**

INTRODUCTION

Angiogenesis, which is defined as the formation of new blood vessel from the pre-existing vascular bed, is essential for solid tumor growth, for the entrance of tumor cell into the circulation, and for the subsequent establishment and growth of metastasis. Many studies demonstrated that tumor angiogensis is associated with patient outcome and is an independent prognostic marker in almost all solid tumors, including esophageal carcinoma[1-10]. Tumor angiogenesis is a complex process, involving growth factors and extracellular matrix enzymes. Among the many known triggers of tumor angiogenesis, vascular endothelial growth factor (VEGF), also known as vascular permeability factor, is an endothelial cell-specific mitogen and an angiogenesis inducer released by a variety of tumor cells and expressed in human tumors in situ. $VEGF_{165}$ is the most effective angiogenic factor in the VEGF family. Tumor cells engineered to express VEGF constitutively exhibit enhanced tumor growth and angiogenic phenotypes[11-13]. Conversely, inhibition of the expression of $VEGF_{165}$ was considered as a therapeutic strategy for the treatment of solid tumors[14-24].

In this report, we constructed antisense RNA to $VEGF_{165}$ eukaryotic expression vector and applied gene transfer technology to modulate the expression in stably transfected human esophageal squamous cell carcinoma cells. We assessed the effects of down-regulation of VEGF expression on the biological characteristics *in vitro*, microvessel density and turmorigenic capability in nude mice.

MATERIALS AND METHODS

Cell line and vector

The EC109 human esophageal squamous cell carcinoma cell line was generously provided by Dr. Sun (Department of Thoracic Surgery, Tangdu Hospital, Fourth Military Medical University). Cells were maintained in Dulbecco's modified Eagle's medium (DMEM), high glucose media (Life Technoligies) and supplemented with 100mL·L^{-1} fetal calf serum (HyClone Laboratories), penicillin, streptomycin, and nonessential amino acids (Life Technoligies). The vector pGEM-3Zf (+) (carrying the full length aminoacids cDNA of $VEGF_{165}$) was kindly provided by Dr. Abraham (Columbia University, USA) and vector pCEP4 was a gift from Dr. Li (Department of Infectious Disease, Tangdu Hospital, Fourth Military Medical University,China).

Plasmid construction

The expression vector for $VEGF_{165}$ antisense RNA was constructed by subcloning cDNA fragment that code for $VEGF_{165}$ into the eukaryotic expression vector pCEP4. pGEM-3Zf (+) was digested by *Kpn*I and *Hind* III. The fragment was purified by gel. The $VEGF_{165}$ amino acids cDNA was cloned inversely in the *Hind* III/*Kpn*I site of pCEP4 to generate plasmid pCEP-AVEGF$_{165}$ (Figure 1).

Transfection and selection

The transfection and selection of the EC109 cells were carried out in a 6-well plate. When the cells reached 70% confluence, the transfection process began. Briefly, solution A was prepared by diluting 10μg of pCEP-AVEGF$_{165}$ into 200μL serum-free medium, and solution B was prepared by diluting 20μL Lipofectimine 2000 (Life

Technoligies) into 200μL serum-free medium. The two solutions were combined for 20 min at room temperature, and then 0.6mL serum-free medium was added to the tube containing the complex, and subsequently added to the rinsed cells. The medium was replaced with fresh and complete medium 18 h after the start of transfection. Seventy-two hours after transfection, it was replaced again with the selective medium containing $200g \cdot L^{-1}$ hygromycin B (Boehrringer Mannheim). Once stable transfections were obtained, the cells were maintained in $100g \cdot L^{-1}$ of hygromycin B. The EC109 cells were transfected with either the empty pCEP4 vector or pCEP-$AVEGF_{165}$.

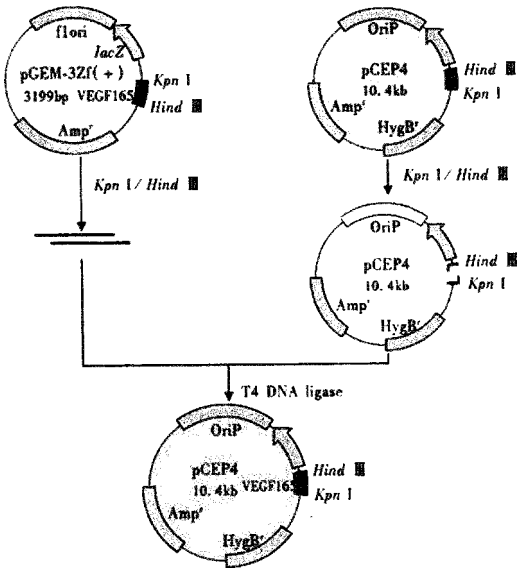

Figure 1 Diagram of the construction of the vector pCEP-$AVEGF_{165}$.

Dot blot analysis

Total cellular RNA was extracted from the cultured cells using the Trizol isolation kit (Life Technoligies) according to the manufacturer's instruction. The recovered total RNA was redissolved in diethyl pyrocarbonate-treated water and 20μg was immobilized onto a gene screen plus membrane (DuPont) by gentle suction with a blotting manifold (Bethesad Research Laboratories). The membrane was then probed with a 5'-end-radiolabeled synthetic oligodeoxyribonucleotide complementary.

Flow cytometry analysis

Approximately 5×10^6 centrifugal sedimentation cells were immediately fixed in $700mL \cdot L^{-1}$ ethanol and stored at 4℃ in PBS in preparation for fluorescent-activated cell sorting. Flow cytometry analysis was performed on a FACStar flow cytometer (Becton Dickinson). Histograms of cell number logarithmic fluorescence intensity were recorded for 10 000 cells per sample.

Transmission electron microscope examination

The centrifugalized cells were placed in $40g \cdot L^{-1}$ glutaraldehyde and then post-fixed in osmium tetroxide and embedded in Epon. Routine thin sections were stained with uranyl acetate and lead citrate. Thin sections were mounted on grids and examined under a transmission electron microscope (JEM-2000EX) at 60kV.

Laser confocal microscope analysis

Indirect immunofluorescence techniques were applied in the transfected EC109 cells and the parental cells. $VEGF_{165}$ protein was detected with mouse anti-human $VEGF_{165}$ antibody and sheep anti-mouse IgG-FITC (Dako A/S Denmark). FITC was activated by light with a wavelength of 488nm. The data of laser scanning were 3%. The expression of $VEGF_{165}$ was analyzed by confocal microscope system controlled by software obtained by Bio-Rad.

Tumorigenicity assay

Athymic Balb/c nude mice were obtained from the Animal Center of Fourth Military Medical University. The mice were maintained in a laminar airflow cabinet under specific pathogen-free conditions and used at 8-12 weeks of age. Cells used for injection were grown to subconfluence, trypsinized, washed once, and resuspended in serum-free DMEM. The cell suspensions were examined microscopically to ensure that they were composed of single-cell suspensions. Mice were injected s.c. on the hind leg with 5×10^6 single cells in 0.1mL. The mice were then separated into three groups, depending on whether they were injected with pCEP-$AVEGF_{165}$ transfected cells, pCEP4 empty vector transfected cells, or control cells. Each group contained five mice. Calipers was used for the calculation of tumor size. Microvessel density was determined under light microscopy after immunostaining of sections with anti-CD34 monoclonal antibody according to the strepto ABC kit (Dako A/S Denmark) instruction.

Statistical analysis

The data were analyzed for significance by ANOVA.

RESULTS

$VEGF_{165}$ antisense vector construction

After ligation, transformation and selection, three clones were found likely to contain the desired recombinant. These clones were digested by restriction enzymes *Kpn*I/*Hind* III or *Kpn*I/*Sfi*I.The 640bp or the 660bp fragment was found by using polyacrylamide gel electrophoresis. These recombinant plasmids were the eukaryotic expression vectors of antisense RNA to $VEGF_{165}$ (Figure 2).

Expression of $VEGF_{165}$ antisense RNA

Two weeks after being transfected and selected by hygromycin B, the EC109 cells transfected by pCEP-$AVEGF_{165}$ expressed antisense RNA to $VEGF_{165}$ which was confirmed by dot blot analysis, whereas the cells transfected by pCEP4 empty vector and control group cells were negative (Figure 3).

Expression of $VEGF_{165}$ in vitro

ELISA showed that a great number of $VEGF_{165}$ accumulated in the pCEP4 empty vector transfected group and control group cells, whereas in the pCEP-$AVEGF_{165}$ transfected group cells, the level of $VEGF_{165}$ was very low. The level of $VEGF_{165}$ expression was significantly lower in EC109 cells transfected by pCEP-$AVEGF_{165}$ than that in the pCEP4 empty vector transfected group and control group cells ($P<0.01$) determined under confocal microscope, as indicated in Figure 4.

The change of ultrastructrue and cell cycle

There was no substantial change neither in the ultrastructure examined under transmission electron microscope nor in the cell cycle determined by flow cytometer.

The change of tumorigenic capacity in vivo

The nude mice were sacrificed at week 5. Tumor volume was measured and morphological characteristics were assessed in HE stained sections. pCEP-$AVEGF_{165}$ transfected xenografts grew very slowly, pCEP4 empty vector transfected group and nontransfected control xenografts were significantly larger than pCEP-$AVEGF_{165}$transfected xenografts ($P<0.01$), and the mean tumor volumes were $(820\pm112.5)mm^3$,$(7930\pm1035)mm^3$ and $(7850\pm950)mm^3$,

respectively. pCEP-AVEGF$_{165}$ transfected xenografts had a relatively large area of central necrosis. Immunohistochemical staining for CD34 was performed to evaluate tumor microvessel density. The microvessel density was expressed as the average number of the five highest areas identified within a single×200 field, for the pCEP-AVEGF$_{165}$ transfected mice, pCEP4 empty vector group and nontransfected controls were (8.5±1.2)mm^{-2}, (44.3±9.4) mm^{-2} and (46.4±12.6) mm^{-2}, respectively (P<0.01).

DISCUSSION

Mammalian cells require oxygen and nutrients for their survival and are therefore located within 100μm-200μm blood vessels-the diffusion limit for oxygen. For multicellular organisms which grow beyond this size, they must recruit new blood vessels by angiogenesis and vasculogenesis. This process is regulated by a balance between pro- and anti-angiogenic molecules, and is derailed in various diseases, especially cancer. Without blood vessels, tumor can not grow beyond a critical size or metastasize to another organ[25-29]. In 1971, Folkman[30] proposed that solid tumor growth and metastasis are critically dependent on angiogenesis, the formation of new blood vessels from pre-existing vasculature, and hence, blocking angiogenesis could be a strategy to arrest tumor growth. The induction of angiogenesis is mediated by several factors released by both tumor and host cells. One of the key mediators of angiogenesis is VEGF, a multifunctional growth factor that is overexpressed and secreted by a majority of human and animal tumors. VEGF was purified by Ferrara *et al*[31] from the conditioned medium of bovine pituitary folliculo stellate cells. VEGF is a homodimeric 46ku heparin-binding glycoprotein with potent angiogenic, mitogenic, and vascular permeability-enhancing activities specific for endothelial cells. By alternative splicing of messenger RNA, VEGF may exist in at least four different homodimeric molecular species each monomer having 121, 165, 189 or 206 amino acids, respectively (VEGF$_{121}$, VEGF$_{165}$, VEGF$_{189}$, VEGF$_{206}$). Among this family, VEGF$_{165}$ is the most important effector. Antiangiogenic therapy targeting VEGF has been proposed as a means of inhibiting VEGF-dependent tumor growth and metastasis[32-40].

It has been suggested that antisense RNA could block the translation progress of aim protein effectively and inhibit expression [41-45]. DeFatta *et al*[46] found that reducing eIF4E express on *via* antisense RNA suppressed both the tumorigenic and angiogenic properties of the head and neck squamous cell cancers, cell line FaDu, as demonstrated by lowered capacity to grow in soft agar, reduced expression of angiogenic factors, and loss of tumorigenicity in nude mice. Oku and associates[47] transfected human SK-MEL-2 melanoma cells with antisense VEGF which resulted in substantial inhibition of intracerebral tumor growth in nude mice, and a decrease in tumor vascularity, blood flow, and permeability.

The prognosis of human esophageal squamous cell carcinoma after curative resection is dismal. Radiotherapy and several conventional chemotherapeutic agents have been tried to improve the prognosis, but the results are generally disappointing. In this regard, antiangiogenic therapy could be a promising and hopeful strategy for esophageal cancer[48-51]. In this study, an antisense RNA to VEGF$_{165}$ eukaryotic expression vector pCEP-AVEGF$_{165}$ was constructed successfully. We transfected it into human esophageal squamous cell carcinoma cell line EC109. Under immunohistochemistry and confocal microscopy, it was found that the expression of VEGF$_{165}$ decreased significantly in the cells transfected with VEGF$_{165}$ antisense RNA compared with the empty vector transfected and control group. Under transmission electron microscopy and flow cytometry, we observed that the ultrastructure

and cell cycle had no change among transfected and control groups. In the nude mice tumor model, the tumorigenicity, the rate of tumor growth, and microvessel density were significantly decreased for the tumors derived from antisense RNA transfected cells as compared with the empty vector transfected and parental cells. pCEP-A$VEGF_{165}$ transfected tumors had a very low initial growth rate with central necrosis. These results suggested that inhibition of tumor growth might be achieved by $VEGF_{165}$ antisense RNA's down-regulation of endogenous VEGF expression in tumor tissues. In the meantime, we found that the $VEGF_{165}$ antisense RNA therapy could slow the rate of tumor growth and not inhibit completely the tumorigenicity. This demonstrated that the process of angiogenesis and tumorigenicity is complex and involves multifactors. To the best of our knowledge, this is the first experimental report which shows that $VEGF_{165}$ antisense RNA suppresses the growth of human esophageal squamous cell carcinoma *in vivo* in association with decreased vessel number in the treated tumors.

Esophageal carcinoma is still common in China[52-58], and the treatment remains a big problem up to date[59-65]. Our present study suggests that antisese RNA to $VEGF_{165}$ can potentially be used as an adjuvant therapy for human esophageal squamous cell carcinoma. Further studies are needed to understand the details of the mechanisms for appropriate clinical application.

ACKNOLEDGMENTS We especially thank Dr. Xiao Yan Sun for providing us the EC109 cell line, Dr. Abraham for providing the pGEM-3Zf (+) vector, we also thank Dr. Zhi Pei Zhang for his assistance with the animal experiments, and Prof. Bo Rong Pan for improving the paper.

Abstract

AIM: **To analyze the association of tobacco smoking, polymorphism of CYP1A1 (7th exon) and GSTM1 genotype and esophageal cancer(EC) in Xi'an.**

METHODS: **A hospital based case-control study, with molecular epidemiological method, was carried out. Polymorphism of CYP1A1 and GSTM1 of samples from 127 EC cases and 101 controls were detected by PCR method.**

RESULTS: **There were no significant difference of age and gender between cases and controls. Tobacco smoking was the main risk factor(OR=1.97 ;95% CI=1.12-3.48) for EC in Xi'an. The proportions of CYP1A1 *Ile/Ile, Ile/Val* and *Val/Val* gene types in cases and controls was 19.7%,45.7%,34.6% and 30.7%,47.5%, 21.8% respectively(*P*=0.049).Individuals with CYP1A1 *Val/Val* genotype compared to those with CYP1A1 *Ile/Ile* genotype had higher risk for EC increased (OR=2.48, 95%CI=1.12-5.54). The proportions of GSTM1 deletion genotype in cases and controls were 58.3% and 43.6% (OR=1.81, 95%CI=1.03-3.18,*P*=0.028). Analysis of gene-environment interaction showed that tobacco smoking and CYP1A1 *Val/Val* genotype; tobacco smoking and GSTM1 deletion genotype had synergism interaction respectively. Analysis of gene-gene interaction did not find synergistic interaction between these two genes. But in GSTM1 deletion group,there was significant difference of distribution of CYP1A1 genotype between cases and controls (*P*=0.011).**

CONCLUSION: **CYP1A1 *Val/Val* and GSTM1 deletion genotypes are genetic susceptibility biomarkers for EC. The risk increases, when person with CYP1A1 *Val/Val* and/or GSTM1 deletion genotype. And these two-metabolic enzymes seem to have interactions with tobacco smoking, in which the mechanism still needs further study.**

INTRODUCTION

Esophageal cancer (EC) is one of the most common malignant tumors of human being. The incidence of EC varies in different countries. China is the country with highest incidence and mortality rate of EC. Research showed that risks for EC in different countries or different places were different[1-6].In western countries alcohol intake and tobacco smoking were studied deeply[7-12]. It was thought that besides tobacco smoking and alcohol drinking, nutrition factors, life style, viruses infection, heredity or exposure to nitrosamines, fungi or AFB1 maybe involved in the process of EC[1,3,13-19]. In China, researches showed risks for EC were different in areas with different incidence[1-5,16,18,20,21]. The mortality rate of EC of Xi'an city in Shaanxi province is about 24 per 100,000, which ranks first in all cancer mortalities. Previous studies showed that both of tobacco smoking and family history of EC were main risk factors for EC in Xi'an city[2,22,23].

EC is a multi-etiology disease; environmental risks exposures and genetic susceptibility may take the role part[2,22-24]. Almost all of the environmental carcinogens (procarcinogens) are activated to be ultimate carcinogens before initiate the process of carcinogenesis. Some metabolic enzymes are closely related to the activation and detoxification of procarcinogens. Alterations of the key oncogene or tumor suppress gene can disturb the cycle of cell proliferation, which can also initiate the process of carcinogenesis[23,25,26]. Susceptibility of cancer is associated with the genetics polymorphism of related metabolic enzymes. Both certain susceptibility related biomarkers and certain environmental carcinogens perhaps are indispensable factors for EC[20,23,27,28]. To explore the bio-basis of genetic susceptibility of EC in Xi'an, we carried out a hospital based case- control study to analyze the associations of tobacco smoking, CYP1A1, GSTM1 gene polymorphism and EC.

MATERIALS AND METNODS

Seletion of patients and controls

All cases with esophageal cancer (confirmed by pathological diagnosis) came from inpatients of Tandu Hospital during half a year period (December, 1999 to April, 2000). All controls were stratified randomly selected from non-cancer inpatients from different department of the same hospital during the same period. Both cases and controls were confined to residents with long-term living in Xi'an (with similar proportion of gender and age).

Collected data

Trained interviewers using a structured questionnaire interviewed cases and controls in the hospital. The questionnaire obtained detailed information on residence, occupation, tobacco smoking habit and so on. Here tobacco smoking was defined as smoking at least one cigarette per day and persisting for more than one year. 127 cases (male 97, female 30) and 101 (male 78,female 23) controls were included. Blood samples were also collected for extraction of DNA genome. All blood samples had been stored at -70℃ before started DNA extraction.

PCR methods to detect polymorphism of CYP1A1 and GSTM1

Digested by Proteinase K, DNA genomes were extracted from blood

clot of cases and controls with hydroxybenzene, chloroform method in a uninterrupted period. CYP1A1 and GSTM1 polymorphisms were identified by polymerase chain reaction (PCR) before which DNA samples were stored at 4℃. Primers for GSTM1(P1:5'-GTA CCC TAC TTG ATT GAT GGG-3'; P2:5' -CTG GAT TGT AGC AGA TCA TGC-3') and for CYP1A1 (P3: 5'-CGG AAG TGT ATC GGT GAG ACC A -3' P4: 5'- CGG AAG TGT ATC GGT GAG ACC G -3'; P5:5'-GTA GAC AGA GTC TAG GCC TCA-3') were synthesized by Shenggong bio-technical company of Shanghai. PCR condition for GSTM1 as follows, 50μL solution including 10×buffer 5μL, Mg^{2+} 2μL, P1,P2 1μL respectivly, template DNA1.5μL, dDNTPs 1μL and Taq DNA polymerase 3^{U}. After denaturation at 94℃ for 10 min, Taq DNA polymerase was added,followed by 30 cycles with 94℃ 1min, 60℃ 1min, and 72℃ 1min.20g·L^{-1} agar was used to electrophoresis PCR production, then observed under the violate light. GSTM1 exist genotype was characterized as had a 273bp fragment; while GSTM1 deletion genotype had no fragment (Figure 1).

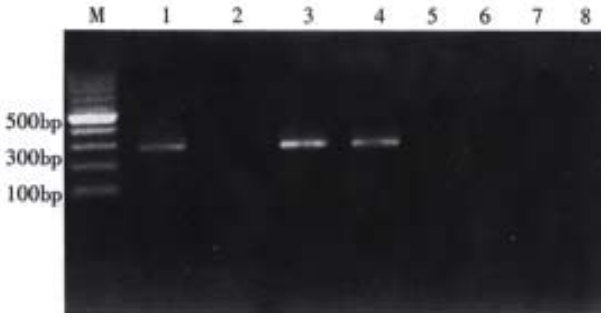

Figure 1 Identify the GSTM1 genotype
M:100bp DNA ladder, 3,4 were GSTM1 exist 2,5 were GSTM1 deletion; 1 positive control,6 negative control,7 was blank control (without DNA template)

We used two pairs of primers to detect the polymorphism of CYP1A1 (7^{th} exon). For each DNA sample two sets of PCR were carried out using P3, P5 (marked as tube A) and P4, P5 (marked as tube B) respectively. PCR conditions were the same:50μL solution including 10×buffer 5μL,Mg^{2+} 2μL, P3,P5 (or P4,P5) 1μL, template DNA 1.5μL, dDNTPs 1μL and Taq DNA polymerase 3^{U}, then 94℃ 10min followed by 94℃ 1min,55℃ 1min, 72℃ 1min, 35 cycles,72℃ extending 10 min. PCR products were observed. The PCR was conducted to detect the mutation of A-G in CYP1A1 7^{th} exon, the mutation can leads to change of one amino acid (Ile to Val). If there was only tube A had the specifically fragment (200bp), the DNA was regarded as CYP1A1 *Ile/Ile* genotype (pure wild genotype); if only tube B had the positive fragment, CYP1A1 *Val/Val* genotype (pure mutation) was considered; and CYP1A1 *Ile/Val* genotype was identified with both tube A and tube B had the fragment (Figure 2).

Quality control

DNA extraction and PCR were conducted in different period and places. The genotypes of DNA samples were identified blindly. Every PCR had were set controls as blanket control (without DNA template), positive control and negative control, and when any one of these controls was failure, PCR wasre-conducted.

Statistical analysis

Data were input into computer, then the values of χ^2, odds ratio (OR) and OR95% CI (confidence intermediate) were calculated. And ORs of gene-environment and gene-gene interaction were also estimated.

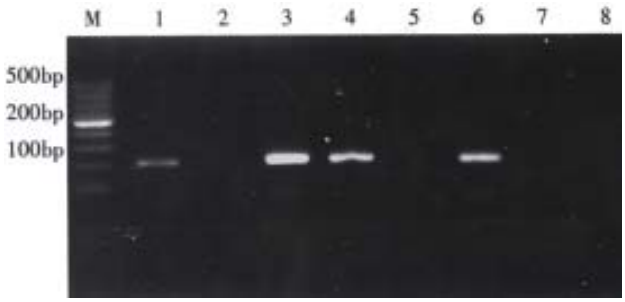

Figure 2 Identified the genotypes of CYP1A1
M: 100bp DNA ladder; 1(A),2(B) represent Ile/Ile genotype; 3(A),4(B) represent Ile/Val genotype; 5(A),6(B) represent Val/Val genotype; 7(A),8(B) as blank control(without DNA template).

RESULTS

Comparability between cases and controls

The age and gender in cases and controls were comparable(Table 1).

Table 1 Comparability of age and gender in cases and controls

Factor	Case	Control	χ^2	*P*
Age(year)				
<50	28	16		
50-	38	44		
⩾60	61	41	4.73	0.094
Gender				
Male	97	78		
Female	30	23	0.02	0.80

Risk factors for EC

The proportions of tobacco smoking, *GSTM1* deletion genotype and *CYP1A1* genotype (*Val/Val*) in cases and controls were significantly different ($P<0.05$) (Table 2).

Table 2 Distributions of smoking, GSTM1 deletion and CYP1A1 genotypes

Factors		Case	Control	OR	OR95%CI	χ^2	*P*
Smoking	Yes	69	38	1.97	1.12-3.48	6.28	0.012
	No	58	63				
GSTM1							
Deletion		74	44	1.81	1.03-3.18	4.85	0.028
Exist		53	57				
CYP1A1							
Ile/Ile		25	31	1.00		1.00	
Ile/Val		58	48	1.50	0.74-3.03	1.48	0.22
Val/Val		44	22	2.48	1.12-5.54	5.93	0.015

Interaction of tobacco smoking and GSTM1 deletion genotype or CYP1A1 Val/Val genotypes

Analysis showed that there was synergistic interaction between tobacco smoking and GSTM1 deletion genotype (Table 3).

Table 3 Interaction of smoking and GSTM1 deletion genotype.

Smoking	GSTM1 deletion	Case	Control	OR	OR95%CI	χ^2	*P*
No	No	25	37	1.00			
Yes	No	28	20	2.07	0.90-4.80	3.48	0.062
No	Yes	33	26	1.88	0.86-4.13	2.93	0.087
Yes	Yes	41	18	3.37	1.49-7.69	10.29	0.0013

SIA=3.37/(1.88+2.07-1.00)=1.14

Tobacco smoking and CYP1A1 *Val/Val* genotype also appeared synergistic interaction(Table 4).

Table 4 Interaction of tobacco smoking and CYP1A1 Val/Val genotype

Smoking	CYP1A1(*Val/Val*)	Case	Control	OR	OR95%CI	χ^2	*P*
No	No	36	47	1.00			
Yes	No	47	32	1.92	0.98-3.76	4.18	0.04
No	Yes	22	16	1.80	0.77-4.20	2.18	0.14
Yes	Yes	22	6	4.79	1.62-14.83	10.30	0.0013

SIM=4.79/(1.92×1.80)=1.39

But CYP1A1 mutation genotypes(*Val/Val, Ile/Val*)and GSTM1deletion genotype did not show significant interaction (Table 5).

Table 5 Interaction of CYP1A1mutation genotypes(Val/Val, Ile/Val)and GSTM1deletion genotype

GSTM1 deletion	CYP1A1 mutation	Case	Control	OR	OR95%CI	χ^2	*P*
No	No	10	20	1.00			
No	Yes	43	37	2.32	0.89-6.14	3.61	0.057
Yes	No	15	11	2.73	0.81-9.42	3.28	0.070
Yes	Yes	59	33	3.58	1.39-9.38	8.66	0.0033

OR of individuals with CYP1A1 mutation genotype and GSTM1deletion genotype was greater than those with of any other forms of the two genotypes. But there did not show any synergistic interaction between CYP1A1 mutation genotypes and GSTM1deletion genotype.

Stratified with GSTM1 deletion genotype to analyze the distributions of CYP1A1 genotypes in cases and controls. Results showed that there were significant different in cases and controls (*P*=0.011) in GSTM1 exist genotype CYP1A1 genotypes, whereas there were no significant difference (*P*=0.83) between cases and controls in GSTM1 deletion genotype (Table 6).

Table 6 Analysis of CYP1A1 genotypes in cases and controls with Stratified GSTM1deletion

CYP1A1 genotype	GSTM1 deletion		existing GSTM1	
	Case	Control	Case	Control
Ile/Ile	15	11	10	20
Ile/Val	35	19	23	29
Val/Val	24	14	20	8
χ^2	0.39		9.04	
P	0.83		0.011	

DISCUSSION

Under similar environmental carcinogens exposure only a few of individuals get neoplasm, for there were individual difference to environmental exposure. The different liability to cancer was called genetic susceptibility of cancer. Genetic susceptibility can affect on every step of carcinogenesis, including modify the effect of environmental carcinogens[24,29-35].Oncogenes and tumor suppressor genes can also affect individual's susceptibility to cancer.Cancer susceptibility genes includes typeI, typeII metabolism enzyme gene,DNA repair gene and those affect cell proliferation rate gene. In recent years evidence has accumulated to support the hypothesis that cancer susceptibility gene may be of importance in determining individual susceptibility to cancer[34,36-46].

EC is a multi-factor determined disease; including environmental risk factors and genetic factors. In recent years, more and more researches considered environmental and genetic susceptibility factors and their interactions in evaluating the risks of cancer[2,17,43,47-50]. Investigations showed the mortality rate of EC in Shaanxi province did not decreased during the late 20 years, and risks factors for EC in Xi'an city were discussed in several researches[2,22,23]. In this hospital based case- control study, the results showed that tobacco smoking was a risk factor;and tobacco smoking had interactions with GSTM1deletion genotype and CYP1A1 *Val/Val* genotype.

Most chemical carcinogens in environment are pro-carcinogens. And aromatic hydrocarbons (AHs) in tobacco smoking are pro-carcinogens, they need to be activated to reactive electrophilic forms by type ¢ñ metabolic enzymes (CYP450s), then initiate the carcinogenesis. On the other hand the reactive electrophilic forms of carcinogen can be detoxified and excreted by typeI metabolic enzymes such as GSTM1. Although theoretically the increase of activity of type II metabolic enzymes and/or decrease of activity of typeI metabolic enzymes can increase the risk for cancer, there were different results in different researches, some supported this hypothesis and others did not[27,34,35,37,40-42,51-56]. Our results showed that individuals with the GSTM1 deletion genotype or/and CYP1A1 *Val/Val* genotype had increased risks for EC.

P450 CYP1A1 gene located in chromosome 15q22 mainly metabolizes pro-carcinogens. There are three kinds of polymorphism of CYP1A1: MspI site, 7th exon (Ile-Val) and AA polymorphism. *MspI* polymorphism include three genotypes: without MspI enzyme cleavage site allele gene m1(*m1/m1*)as A genotype;having MspI cleavage site allele (*m2/m2*)as C genotype and *m1/m2* as B genotype. In different populations the distribution of these three genotypes were different. CYP1A1 Ile-Val polymorphism caused by 7th exon 4889th base difference (A or G), transition of A to G results in 462th amino turned from isoleucine to valine[13],then form three kinds of genotypes: homozygote wild genotype(*Ile/Ile*), mutation genotype(*Val/Val*)and heterozygote *Ile/Val* genotype. Polymorphism of 7th exon correlated with polymorphism of *Msp*I in Asia and Caucasian populations, and in Americans from Africa these two kind of CYP1A1 polymorphism were independent, CYP1A1 7th exon polymorphism and *Msp*I site were incomplete linkage. Research showed CYP1A1 *Val/Val* genotype have higher ability to activate pro-carcinogen than CYP1A1 *Ile/Ile* genotype. PAH-DNA adducts in leukocyte were higher in heavy smoking population with CYP1A1 *Val/Val* genotype than those with CYP1A1 Ilel/Val or Ile/Ile genotype. AA polymorphism was new special *MspI* polymorphism, which still under discussion.

Although evidence showed that CYP1A1 mutation genotype (*Val/Val*) had the strongest ability to activate pro-carcinogens, the associations between CYP1A1 genotype and susceptibility to cancers were varied[30-33,37,57,58]. Data from Guandong province in China showed that MspI C correlated with no-smoking population's lung cancer susceptibility[52]. Study in Shanghai and Haerbin no significant relation was discovered between CYP1A1 (*Ile-Val*) polymorphism and lung cancer susceptibility in non-smoking female patients[51].CYP1A1 *Val/Val* genotype only appear about 3.2%~5% in white population,while in Japanese it was about 19.8%,in Chinese it was 22.3%. Our study showed that distributions of CYP1A1 genotypes in cases and controls were different (*P*=0.049), CYP1A1 *Val/Val* genotype was associated with EC (OR= 2.48,95%CI=1. 12-5.54) and there was interaction of tobacco smoking and CYP1A1 *Val/Val* genotype.

GSTM1 can detoxify a number of reactive electrophilic compound substances, including the carcinogens PAHs. If

individuals with GSTM1 deletion genotype, the ability of detoxify the carcinogens decreased. Individuals with GSTM1 deletion can have the increased risk of cancers[24,43,46]. In China there were similar research on GSTM1 deletion genotype and the risks of lung cancer(OR=2.56)[53],and stomach cancer(OR=1. 90, 95%CI=1.01-3.56)[54].Researches showed that in Henan province, high incidence of EC in China, GSTM1 deletion gene polymorphisms had not significant relation with EC susceptibility[20]. Results of our study indicated GSTM1 deletion genotype was significant different in cases and controls (P=0.028) and the OR was 1.81(OR95%CI=1.03-3.18). GSTM1 deletion genotype had synergistic interaction with tobacco smoking.

In summary, we found tobacco smoking, CYP1A1 *Val/Val* genotype; GSTM1 deletion genotype had associations with EC in Xi'an area. Gene-environment interaction analysis showed that tobacco smoking had synergistic interactions with CYP1A1 *Val/Val* genotype, and with GSTM1 deletion genotype. Gene-gene interaction analysis did not find synergistic interaction between CYP1A1 mutation genotypes and GSTM1 deletion genotype, though individuals with these two genotypes had increased risk for EC. The synergistic interactions and their mechanisms of tobacco smoking with these two metabolic enzymes gene polymorphisms still need further study with large (population-based) samples and modified designs.

Acknowledgment We would like to thank Bing-Quan Gu for their help in collecting blood sample.

Abstract

AIM: **To summarize the experiences of treating bile duct injuries in 40 years of clinical practice.**

MATHODS: **Based on the experience of more than 40 years of clinical work, 122 cases including a series of 61 bile duct injuries of the Southwest Hospital, Chongqing, and 42 cases (1989-1997) and 19 cases (1998-2001) of the General Hospital of PLA, Beijing, were reviewed with special reference to the pattern of injury. A series of cases of the liver and the biliary tract injuries following interventional therapy for hepatic tumors, most often hemangioma of the liver, were collected. Chinese medical literature from 1995 to 1999 dealing with 2742 traumatic bile duct strictures were reviewed.**

RESULTS: **There was a changing pattern of the bile duct injury. Although most of the cases of bile duct injuries resulted from open cholecystectomy. Other types of trauma such as laparoscopic cholecystectomy (LC) and hepatic surgery were increased in recent years. Moreover, serious hepato-biliary injuries following HAE using sclerotic agents such as sodium morrhuate and absolute ethanol for the treatment of hepatic hemangiomas were encountered in recent years. Experiences in how to avoid bile duct injury and to treat traumatic biliary strictures were presented.**

CONCLUSION: **Traumatic bile duct stricture is one of the serious complications of hepato-biliary surgery, its prevalence seemed to be increased in recent years. The pattern of bile duct injury was also changed and has become more complicated. Interventional therapy with sclerosing agents may cause serious hepatobiliary complications and should be avoided.**

Huang ZQ, Huang XQ. Changing patterns of traumatic bile duct injuries: a review of forty years experience. *World J Gastroenterol* 2002;8(1):5-12

INTRODUCTION

Since the first total cholecystectomy performed by Carl Langenbuch in 1882, there has been the likelihood of bile duct injury. But it was not mentioned until 1905 that Mayo reported the first two cases of bile duct stricture following cholecystectomy treated by choledocho-duodenostomy[1]. This might be due to the small number of operations performed by that time. However, the number of cases of bile duct injuries has been rapidly increased since then[2]. In China, the prevalence of cholelithiasis is increasing, and cholecystectomy has become one of the most frequent operations in daily surgical practice[3-5]. The victims of bile duct injuries often suffered from great misery and the fatality rate can be as high as 30%[6]. Efforts have been made in the training and standardization of conventional biliary operations such as cholecystectomy, the result being encouraging. Roslyn[7] (1993) revealed 42,474 cases of open cholecystectomy from 1988 to 1989 (8% of cholecystectomies performed in America at the same period of time), and the bile duct injury rate has been lowered to 0.2%. In China, however, the bile duct injury during conventional open cholecystectomy has been claimed to be low, in spite of the lack of statistical data. In recent years, the number of reports on bile duct injuries due to cholecystectomies has been rapidly increased in the Chinese medical literature. The seriousness of the problem caused great concern from the medical professionals[8]. Furthermore, the pattern of bile duct injuries at present also differed in some way from the traditional ones which imposed different methods of treatment. These may be complicated and unfamiliar to the practicing physicians and surgeons. In this report, we present our clinical experiences in the treatment of bile duct injuries over the past 40 years and specially the importance in laparoscopic, and bile duct injuries during liver resection and interventional therapy of hepatic lesions.

CLINICAL MATERIALS

Case records of traumatic bile duct injuries were reviewed. All patients in Group A and Group B series were the cases attended by the senior author either as the director or as senior surgeon of the department. Group A consisted of 61 cases of bile duct injury admitted to the South-west Hospital, Chongqing from 1963 to 1986;[9] and Group B were 61 cases admitted to the General Hospital of PLA in Beijing from 1989 to 1997[10] and from 1998 to 2001 (Tables 1,2).

Before 1990, the cases of traumatic bile duct stricture were mostly due to open celiotomy by conventional technique. Cases of bile duct stricture following laparoscopic cholecystectomy have been encountered since the turn of 1990 and cases of bile duct injuries resulting from the so-called 'mini-cholecystectomy' have been found in recent years. Up till now, bile duct injuries chiefly result from conventional surgery but not laporoscopic operations. Traumatic injuries and operations of the upper abdominal organs may cause bile duct injury, but biliary tract operations was the most common cause.

Table 1 Types of primary operations in 61 cases of traumaticbiliary strictures (Group A, 1963/1986, South-West Hospital Series)

Types of operation	Cases
Cholecystectomy	39
Cholecystectomy +choledochostomy	10
Gastrectomy (B-II)	7
Hepatic injury -Rt lobectomy	1
Suture +gauze packing	2
Suture + choledochostomy	1
Suture + repair of duodenum	1
Total cases	61

**29 of the 61cases were recognized by the operator during the primary operation

Table 2 Changing trend of primary operations in cases of traumatic biliary strictures (Group B: The General Hospital of PLA Series)

Types of operations	Cases	
	(1989-1997)	(1998-2001)
Cholecystectomy	27	8
Mini-cholecystectomy	2	
Laparoscopic cholecystectomy(LC)	4	5
Cholecystectomy + choledochostomy	9	
Hepatic resection	3	
Hepatic resection + HAE	1	
HAE		1
Gastrectomy(B-I)	1	
Total cases	42	19

In these 122 cases of traumatic bile duct injuries, cholecystectomy, especially simple cholecystectomies, was responsible for the majority of cases. As to the patterns of injuries, laparoscopic surgery, hepatic resection and interventional therapy for hepato-biliary diseases made a significant contribution in the Group B series.

Gastric resection The next common cause of extra-hepatic bile duct injury is gastric resection, which has been frequently employed for the treatment of chronic duodenal ulcer disease before the advent of the present anti-ulcer drugs. In series A, there were 2 cases of bile duct injury due to gastric resection probably through a not well- known mechanism which was differed from the ordinary direct operative injury. The first one was a male patient aged 42 years with a history of repeated hemorrhage from chronic duodenal ulcer for 7 years. On operation, a mass involving the posterior duodenal wall and the head of the pancreas was found and a Bancroft¡äs type of gastric resection was performed. Four years following the operation, the patient still suffered from episodes of massive G-I bleeding accompanied with low blood pressure. Therefore, another operation was undertaken. The operation consisted of vagotomy and resection of the remanding portion of the gastric antrum together with the duodenal "ulcer" so as to control bleeding. However, the patient experienced a very stormy postoperative course. Jaundice appeared on the 4th postoperative day associated with daily chills and fever, while the gastric aspiration showed no bile. The patient's general condition was thus rapidly deteriorated. Re-operation was performed on the 6th postoperative day. A large amount of blood and bile tinged fluid was found inside the peritoneal cavity, and fatty necrosis was found around the head of the pancreas. A cholecystostomy was performed to relieve jaundice and drainage of the abdominal cavity. After the operation, a large amount of bile mixed with pancreatic juice (amylase activity was 1280 Winslow's unit) was drained outdaily through the cholecystostomy tube. Subsequently, further additional operations were performed for intra-abdominal residual abscesses. Eventually, the patient died of sepsis and wide spread intra-cranial hemorrhage. At autopsy, left-sided residual suphrenic abscess and empyema of left thorax was found, the ruptured duodenal stump was healed, and obstruction of the common bile duct at the ampulla below the confluence of the bile and pancreatic ducts was found so that pancreatic fluid was drained through the cholecystostomy tube by retrograde flow. There was no evidence of direct surgical injury or suturing of the lower end of the bile duct as the cause of biliary obstruction, however.

Another case was a middle-aged patient who also suffered from chronic duodenal ulcer complicated with repeated G-I hemorrhage. He was also treated at first by Bancroft's gastric resection and followed by resection of the gastric remnant and the ulcer because episodes of G-I hemorrhage recurred. The patient developed disruption of the duodenal stump and obstructive jaundice. PTC showed bile duct obstruction at the ampulla of Vater. This patient was firstly treated by abdominal drainage and cholecystostomy followed by Roux-en-Y choledocho-jejunostomy and pancreatico-jejunostomy with an uneventful convalescence. This patient showed no excessive pancreatic drainage through the cholecystostomy tube because of the common bile and the pancreatic ducts were both obstructed at the ampullary level. In these two cases, the obstruction of the ampulla may be the result of operative interruption of blood supply to this particular region. However, the mechanism of such kind of bilio-pancreatic duct injury has not been well understood.

Interventional therapy and bile duct injury In recent years, a particular type of bile duct injury was noted[11], i.e., bile duct injuries following interventional treatment for hepatic tumors, most frequently for hepatic hemangiomas[12] (Table 3). But such kind of bile duct injuries was usually not categorized under the heading of traumatic bile duct injury in hospital files.

Table 3 Hepato-biliary complications following HAE for cavernous hemangioma of liver

Case No.	Embolizing agents	Complications	Operations	Results
1	Sod.mo.+Lip.	Rt,Lt.CHD,GB Necrosis Biliary cirrhosis	S-R shunt B-jejunostomy	Jaundice ↓

8	Sod.mo+Lip.	Rt liver abscess GB necrosis	Cholecystectomy Rt lobectomy Repair HD	Jaundice ↓
9*	Sod. Mo+Lip	Rt liver necrosis HD stricture Portal hypertension	No	Jaundice ↑ Repeated hematemesis

(Such type of bile duct injury was not included under the category of traumatic biliary injuries in the hospital records)

* Treated by consultation; Sod mo.=sodium morrhuate; Lip.=iodized oil; B=biliary; GB=gallbladder; CBD=common bile duct; HD=hepatic duct; S-R= spleno-renal;
PTBD=percutaneous transhepatic biliary drainage

Since interventional therapy was advocated for hepatocellular carcinoma in recent years with encouraging results, the method of percutaneous transarterial embolism (HAE) has also been advocated and used for the treatment of hepatic hemangioma[13,14]. The embolizing agent used was usually sodium morrhuate which is a strong sclerosing agent commonly employed for injection of varicose vein of the lower extremities. But in hepatic hemangioma, after HAE with sodium morrhuate, the patient usually experienced a chronic course of progressive sclerosis of the intrahepatic and extrahepatic hepatic bile duct, persistent jaundice, progression of hepatic fibrosis and portal hypertension[15].

A male patient aged 43 years, he was diagnosed having a hemangioma of the right liver after a routine physical examination with ultrasound scanning. He was advised to have a "catheter treatment" (HAE) for the tumor. According to the doctor's advice, he received a HAE treatment with injection of 10mL iodized oil and 4mL sodium morrhuate. He developed severe right upper abdominal pain, nausea and vomiting immediately after the injection. He was then admitted and treated in the hospital for one week, but he had constant upper abdominal discomfort after discharged from the hospital. Two years later, jaundice appeared which had been diagnosed as "viral hepatitis" and treated accordingly for 3 months. Exploratory celiotomy was

followed. A cholecystectomy was performed, exploring the common bile duct, in which a red-colored mucoid plug was found and removed. Three years later, a percutaneous transhepatic drainage of left intrahepatic bile duct was made because of persistent jaundice. A second operation of choledocho-jejunostony was then performed. Despite of the operations, jaundice still persisted. He was at last admitted to the General Hospital of PLA in 1999, 6 years after interventional therapy for the liver hemangioma. Preoperative evaluation revealed fibrosis and atrophy of the right liver with the hemangioma still in situ, extensive fibrosis and stricture of the right hepatic duct involving the hepatic duct confluence and the left hepatic duct, and, hypertrophy of the left lateral segment of the liver with dilated intrahepatic bile ducts (Figures 1,2). A third operation was then performed. The left lateral intrahepatic bile duct was chosen for biliary-intestinal anastomosis. Because of the sclerotic changes of the hepatic duct confluence, a trans-round ligament approach for left hepatic duct-jejunostomy of Roux-en-Y type with stent was adopted. Jaundice decreased following the last operation. The other cases of HAE biliary injuries showed more or less similar clinical courses (Table 3). The clinical course and type of subsequent surgical treatment depended on the extensiveness of hepatic and biliary damages and the progression of hepatic fibrosis. Portal hypertension secondary to hepatic fibrosis may be developed and complicated with G-I hemorrhage. In all the cases under this category, the caudate lobe of the liver was found to be much enlarged and in a state of functional compensation.

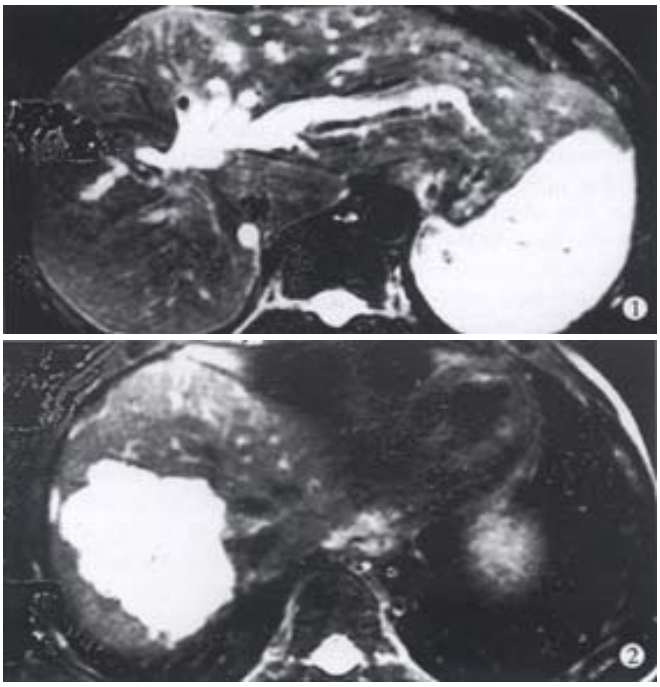

Figure 1 Hepatobiliary damages 6 years after HAE with sod. morrhuate:MRI showed atrophy of right liver, hypertrophy of the left lateral segment and obstruction of hepatic duct at the hila hepatis.
Figure 2 Hemangioma of right liver years after HAE.The same patient. MRI showed hemangioma still in place.

Hepatic trauma and bile duct injury Traumatic injury of the liver may be the cause of bile duct injury. Hepatic resections in daily surgical practice as one of the causes of bile duct injury is of increasing importance due to the rapid development of hepatic surgery in recent 20 years. In Group A series, we met a middle-aged male patient who sustained from severe laceration of the right lobe of the liver in a road accident. Resuscitation including emergency right hepatic lobectomy was undertaken in another hospital. However, injury to the left hepatic duct was inflicted and was recognized at completion of the operation. Hence, repeated operations to treat the bile duct stricture and its complications were necessary subsequently, such as spleno-renal shunt for the treatment of portal hypertension and G-I bleeding, and attempts to recreate a patent biliary-intestinal passage. But operative attempts failed repeatedly because of marked enlargement of the left hepatic lobe and the extreme right posterior rotating displacement of the hilum which became inaccessible to the operation through the conventional surgical approach. The thirteenth operation was performed for the patient to complete a mucosa-to-mucosa anastomosis between the left hepatic duct and a Roux-en-Y jejunal loop through a low thoraco-abdominal incision. The patient recovered from the operation uneventfully and reported to have a satisfactory outcome. There was a young male patient in Group A. He had a severe crushing injury of the liver in a road accident. An external biliary fistula developed following incision and drainage treatment of a subphrenic abscess in right side after the primary operation, and 200-300ml bile was drained from the wound every day. Reoperation revealed traumatic rupture and occlusion of the right hepatic duct. He was treated, during the operation, using the gallbladder to form a conduit bridging between the right hepatic duct and the common bile duct. The biliary fistula healed after the operation.
Bile duct injury and hepatic resection In the past 10 years, more and more cases of bile duct injury due to elective liver tumor resections were admitted to the General Hospital of PLA for further treatment. In the Group B series, 1 case of bile duct injuries as a result of hepatic resection was recorded from 1989-1997. From 1998-2001, 3 additional cases were admitted to the General Hospital of PLA. According to our knowledge, besides the above mentioned cases, more than 6 cases were actually caused by hepatic tumor excision in our hospital. Five of these 6 cases had injuries to the left hepatic duct during the resection of tumors involving the left medial segment of the liver (Figure 3). The history of a case of left hepatic duct injury as a result of extended right hepatic resection for neurilemmoma and gauze packing to check bleeding was very illustrative to show the complexity of bile duct injury following hepatic surgery.

Figure 3 Neurilemmoma of the right liver: Resection of the tumr with right-sided tri-segmentectomy resulted into injury ofthe left hepatic duct.

A male patient aged 32 years was admitted to the General Hospital of PLA on 4 January, 2000. He had operative bile duct in jury during resection of a neurilemmoma on 27 August,1998. The tumor, weighting 5.0kg, situated in the right liver, was resected with difficulty and complicated with profuse bleeding. The estimated blood loss was about 27 000 mL. Gauze packing was used to stop the hemorrhage from the liver hilum upon completion of the operation. There was clinical jaundice on the second post-operative day. The gauze packing was removed on the 5th postoperative day through the celiotomy wound. On October 21. 1998, PTCD of the left intrahepatic bile duct was performed because of persistent jaundice.

As the indwelling catheter was withdrawn accidentally later on, another PTCD of the left intrahepatc duct was performed on December 23, 1999 when the serum bilirubin level was 543μmol/L. The catheter was kept on draining of bile in the amount of 500-700mL·d^{-1}. Retrograde cholangiography showed complete obstruction of the left segmental bile duct (Figure 4). After admission to the General Hospital of PLA, the patient was reexamined and prepared for reoperation. During the operation, there was so dense fibrous adhesions and rich vascular communications in the hilar region that dissection of the extrahepatic bile duct was very difficult. Therefore, the left segmental bile duct was approached along the surface plane of the left external hepatic segment under the guidance of intraoperative ultrasound scanner. The site of the obstructed left intrahepatic duct was found posterior to the left portal vein. The operation was completed with a cholangio-jejunostomy over a U-typed silicone rubber tube. This case illustrated the changing scope of traumatic bile duct strictures at the present that restorative treatment in many cases may be very complicated, and this might be the reason why this patient carried on his PTCD tube for as long as 2 years before referral to our hospital without further surgical intervention. The use of intraoperative BU-scan was important for the success of the operation in this case. Since bile duct injuries inflicted from hepatic surgery may have a very complicated clinical feature, therefore, for one or another reason, such patients may be withheld from appropriate and timely surgical intervention. This was reflected from what happened to a male patient at 40 years of age in Group B.He was diagnosed as having a cavernous hemangioma of quadrate lobe of the liver by ultrasound. The tumor was resected in another hospital. Following the operation, the patient developed obstructive jaundice, biliary peritonitis, and a big "biloma" in the upper abdomen. Re-exploration of the abdomen was carried out, bile-like fluid of about 2500mL was evacuated,however, the extrahepatic bile duct could not be found. The patient suffered from obstructive jaundice and subphrenic abscess without further treatment for 7 months. At last, when the patient was admitted to the General Hospital of PLA, his general condition was very poor and cachectic, the serum bilirubin level was 600μmol/L. MRI examination showed a large subphrenic collection of fluid and markedly dilated intrahepatic bile ducts (Figure 5). Aspiration of the subphrenic abscesses showed infected bile collection. He was further treated by PTCD of the intrahepatic duct instead of reconstructive operation. In spite of the minimally invasive procedure, the patient developed hepatic coma and recovered only after a period of intensive medical treatment. He was waiting for further surgery when his condition was indicated for the operation. This was a typical case of negligence of medical profession. The difficult situations facing to the surgeon are the lack of knowledge and experience in handling bile duct injury following hepatic operations.

Figure 4 The same case as Fig 3.
Retrograde cholangiography of the intraphepatic duct through a PTBD catheter showing obstruction of left intrahepatic ducts and hypetrophy of the left hepatric segment.

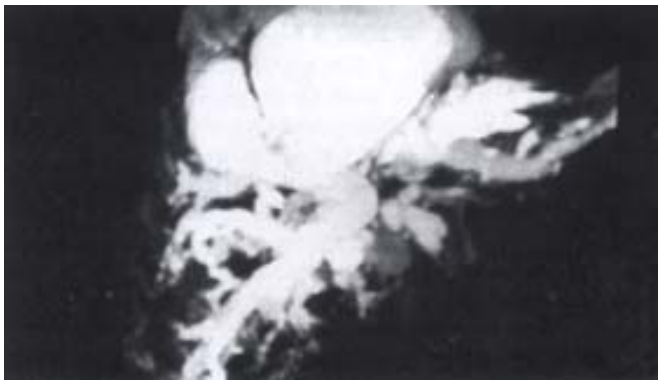

Figure 5 Bile duct injury in resection of quadrate lobe hemangioma: MRCP showing marked dilatation of the intrahepatic duct system with suphrenic collection of fluid. Extrahepatic bile duct not visualized.

DISCUSSION

Safety of cholecystectomy The current cholecystectomy should be a safe and effective operation. For example, in a review reported on the safety of laparotomic cholecystectomy for cholelithiasis[16], 4655 consecutive cases of cholecystectomies for gallstones one year before laparoscopic cholecystectomy (LC) was initiated were collected from 34 well equipped hospitals in China. Among these cases,postoperative complications which needed reoperative intervention occurred in 17 cases (0.36%), complications with lasting sequelae in 2 cases (0.05%), and death in 8 cases with a mortality rate of 0.18%. Most of the deaths were related to emergency operation in high risk patients[16]. More or less similar result was obtained by Roslyn[7] who revealed 42,474 open cholecystectomies performed in the year 1989 in America with a mortality rate of 0.17%. Injury to the bile duct is still a serious complication during cholecystectomy. Presently, incidence of bile duct injuries in open cholecystectomy has been decreased to a rather low level. Clavien *et al*[17] reviewed the result of open cholecystectomy in the hospitals in North America and in Europe, injuries to the extrahepatic bile duct was found in 0.2% of the 1, 252 operations. But, bile duct injuries occurred more frequently in laparoscopic cholecystectomy than in conventional open cholecystectomy[18-21]. The latest data about laparoscopic cholecystectomy collected by Huang *et al* showed that bile duct injuries occurred in 0.30% and biliary complications (including postoperative bile fistula which might be the result of minor bile duct injuries) occurred in 0.60% of the cases in China[22]. The reported incidence of operative injury of the bile duct may be much lower than actually existed, however. This is true in China and as well as in the other parts of the world. Therefore, the reported incidence of traumatic bile duct injury in laparoscopic cholecystectomy was around 0.15%(9/5680)[23] from a single hospital to 0.19% in a review series, but the result of about 0.5% in some western countries[24,25]. A review of recent Chinese medical literature (1995.1-1999.12) on trauma to the extra-hepatic bile duct[26] revealed that the spectrum of bile duct injuries occurring most frequently was the operations related to cholecystectomy, which accounted for 94% in 2,566 cases (Table 4).

Table 4 Bile duct injury and the type of operations in 2742 cases (Chinese literature review 1995-1999)

Type of operation	No. of cases	%
Cholecystectomy	1 933	70
Laparoscopic cholecystectomy	310	11
Cholecystectomy + choledochostomy	165	6
Gastrectomy	66	2
HAE*	16	0.6
Hepatic resection	10	0.4
Other operations	66	2
Unspecified	176	6

*HAE = Hepatic arterial embolization

There were cases of bile duct injuries from HAE and hepatic resections (0.6% and 0.4% respectively), and bile duct injuries due to laparoscopic cholecystectomy accounting for 11% of the total series. This variations in the disease pattern of benign biliary stricture were in accordance with the current changing practice of hepato-biliary surgery.

Surgical treatment of traumatic biliary stricture Since bile duct injury cannot be eradicated by biliary surgery as human beings are not exempt from errors. Therefore, prevention as well as treatment of bile duct injuries is still most important in biliary surgery [27-29]. In our experience, the long-term good results of reparative operation of traumatic bile duct stricture may be as high as 90% and 95%[9,10]. In average, especially when reconstructive surgery was performed in those hospitals lack of expertise in biliary surgery, the result may be far from satisfactory, the postoperative morbidity rate and reoperation rate was high, and the mortality rate may be as high as 30%. Many of the patients carried on a miserable life (so-called biliary cripple) and eventually died of hepatic failure. Option of methods of surgical treatment for traumatic biliary strictures is varied according to different authors. In our experience, the best result was obtained after bilio-enterostomy of Roux-en-Y type with application of plastic reconstructions of hilar bile duct remnant. Therefore, in the two series of cases in this report, satisfactory result was obtained in more than 90% of the treated cases. In our series, all of the patients were referred from elsewhere in our country, and most of them have had multiple unsuccessful operations and came to our hospital as the last resort. One patient with traumatic bile duct injury had been operated upon as many as 12 times. Secondary surgical repair of biliary stricture is more difficult than the primary reparation because of the much distorted local anatomy and, in many of the cases, the level of bile duct stricture may be extended above the hepatic confluence to involving both hepatic ducts (Bismuth classification type IV), which is the most difficult situation to be treated.

In the treatment of traumatic bile duct stricture, the type of surgery seems to have important influence on the outcome of the disease. We preferred cholangio-jejunostomy of the Roux-en-Y type for reconstruction, especially for those late cases and those high strictures in which one or both hepatic ducts may be involved. Therefore, we used such type of operative repair in 47 of the 61cases (77%) of Group A. Besides, in 4 cases with a functioning distal common bile duct, we adopted the principle of preservation of the sphincter of Oddi's function by using a pedicled gastric or jejunal patch for the repair. With an interposed jejunal loop with artificial nipple formation, hepatico-duodenostomy was employed in 2 cases. By such methods of management, we obtained good long-term result of 95.6% (including 2 reoperations 2 and 30 years after the first repair respectively). Two patients (4.4%) in Group A died of suppurative cholangitis 4 and 12 years respectively after the repair. Based on our experience in bile duct surgery, we have set up some guidelines for the surgery of biliary stricture which were proved to be important in clinical practice. They are: ① Strategy of traumatic biliary stricture repair : primary repair is critical, but early repair is more frequent, thus being, more important; though reoperations are difficult, they should be performed with confidence; operation should be staged in the presence of marked portal hypertension; operations should be a wait ted till marked biliary cirrhosis with liver dysfunction; ②. Technical essentials in reparative operation: side-to-side bilio-enterostomy is the first choice to minimize late stricture formation; single-layered anastomosis is essential; absorbable or single strand suturing materials should be provided; stent placement of 9 months or 1 year, if possible; good quality stenting tube should be selected to prevent accidental breakage; It should be kept in mind that there were '3 hepatic ducts' at the hilum of liver instead of only 2 as generally believed; ③ Alternatives: T-tube, Y-tube, and U-tube all have merits for stenting; straight-tube, and shape-memory tube may be used at special occasions; Trans-hepatic tube may also be used for prolonged stenting and instrumentation; Finally, bile duct surgery is more or less alike to cannel engineering.

LC bile duct stricture Treatment of traumatic injury of extrahepatic bile duct due to laparoscopic cholecystectomy is a special problem of current biliary surgery. Though the number of laparoscopic injuries was relatively low in comparison with the open technique, for example, 310 of 2742 cases of bile duct injuries (12%) in a literature survey[26] and 4 of 42 cases (9.5%) of bile duct injuries in the General Hospital of PLA from 1989-1997[10]. In a review of 182 cases of bile duct injuries from 4 medical centers (1999), 30 cases(17%) were due to LC[30]. Reports of LC bile duct injury have appeared since 1991 when the technique of laparoscopic cholecystectomy was first introduced to China mainland, but the number of patients rapidly increased as time went on. Therefore, LC bile duct injuries were found in 5 of the 19 cases treated in the General Hospital of PLA between the years 1998 and 2000, accounting for 26.3%. With accumulated experience of treatment of LC bile duct injuries,certain characteristic features were apparent. Most of the severe bile duct injuries of LC belonged to the so-called "classical injury" classified by Davidoff[31]. Usually there was loss of a segment of the upper bile duct and involvement of one or both hepatic ducts. Sometimes, one of the injured hepatic ducts in the hepatic hilum may be hidden from the operator's sight (the right posterior duct being the most often and also occasionally the left hepatic duct) (Figures 6,7). Retained foreign materials (usually a broken piece of plastic tube which was used for internal stenting) were found more often. Spontaneous biliary duodenal fistula may be found in cases with no clinical jaundice. On the other hand, in many cases, when secondary repair was undertaken, the degree of intra-abdominal inflammatory changes and extent of adhesions was less than in the operation after conventional open surgery, therefore, a repair operation for the injury or anastomosis with the gut can be considered. These characteristic features of LC bile duct injuries demanded a change of surgical policy in the management of bile duct injuries for a better result[32-34].

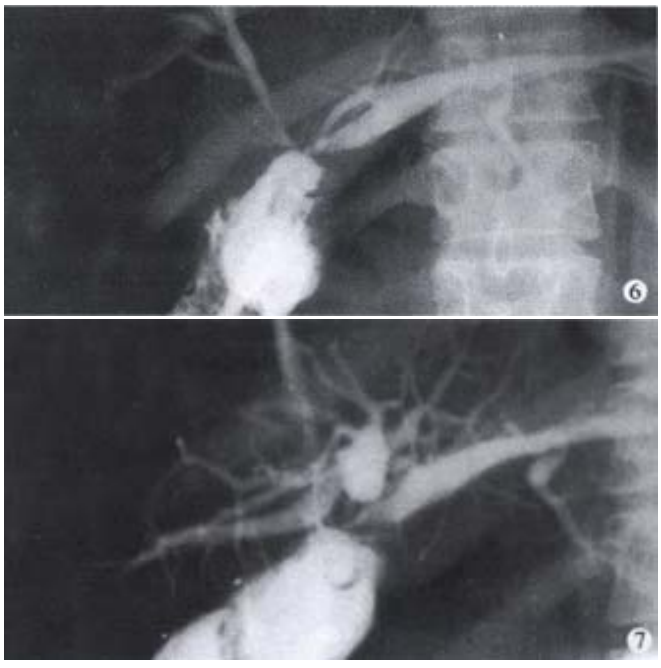

Figure 6 LC bile duct injury: Bile duct repair by hepatico-jejunostomy of Roux-en-Y tye. Postoperative retrograde cholangiography only the right anterior segmental duct and the left hepatic duct visualized.
Figure 7 The same case. PTC showing the dilated blind end of the right posterior segmental duct which was "missed" during the operation.

Gastric resection and bile duct injury Gastric resection is the next most common cause of operative bile duct injury. In a review of 2742 cases of bile duct injuries reported in Chinese literature by Huang *et al*[35], 66 cases occurred during gastric resection operation, accounting for 2.4% of the total. The most severe type of such kind injury was trans-section of the common bile duct together with the hepatic artery and the portal vein. Such type of injury gave a high fatality rate (11/11). Among the patients in series A, two incidences showed a similar clinical manifestations following gastric operation for bleeding chronic penetrating duodenal ulcer. The mechanism of such type of damages may be related to the disruption of blood supply to the duodeno-ampullary region. Disturbance of local blood supply resulted in the coexistence of disruption of the duodenal stump and fibrotic obstruction at the ampulla. Blood supply of the extrahepatic bile duct is segmental. The supra-duodenal portion of the common bile duct received arterial blood supply chiefly from branches sent by the hepatic artery proper, while the lower portion of the common bile duct including the ampullary region received blood supply chiefly from the posterior pancreatico-duodenal artery that was derived from the gastroduodenal artery[36,37]. Operation of excising the bleeding duodenal ulcer would inevitably result in the disruption of local blood supply and lead to the dishesion of the duodenal stump and fibrotic occlusion change of the ampulla.

Interventional therapy and bile duct injury Since bile duct injuries and its consequences are the ever existing problem of hepato-biliary surgery including interventional therapies of many hepato-biliary affections[38,39]. A kind of severe extensive damage of the intraand extra-hepatic bile duct as a result of inadvertent use of sclerosing agents in the treatment of liver tumors (most often hemangioma of the liver) was noted[11,13,14,40]. Six cases were admitted to our hospital on account of complications such as liver necrosis and abscesses, biliary intestinal fistula, extensive hepatic fibrosis complicated with portal hypertension, G-I bleeding, extensive destruction of the intra- and hilar bile duct with obstructive jaundice, etc. The sclerosing agents that most commonly employed were sodium morrhuate and absolute ethanol[13,14,41]. Furthermore, we have also attended 3 cases through consultation. One case of asymptomatic haemangioma of the right liver was treated in another hospital by injecting 19ml absolute alcohol through the hepatic arterial catheter. The patient suffered from severe abdominal pain soon after the injection and was operated upon because of signs of acute peritonitis on the third day after the procedure. During operation, necrosis of the right liver, the biliary tract and the duodenum was found. The patient developed biliary fistula, and eventually died of multiple organs failure on the 10th day after the therapy. The other 2 patients suffered from repeated G-I bleeding because of portal hypertension due to hepatic fibrosis. Trans-hepatic arterial embolization (HAE) is a kind of interventional therapy which was widely employed as the current non-surgical treatment for advanced hepatocellular carcinoma(HCC)[42-47]. In general, the embolizing agents consisted of lipoidal oil and small particles of gellform sponge. Particles of 1-2 mm in size would block the small intrahepatic arteriols about 50 μm in diameter, and caused necrosis of the tumor mass. The gellform sponge particles will be dissolved in a course of about 2 weeks. While, on the other hand, if liquid materials are used as embolizing agent, such as absolute ethanol and sodium morrhuate, the drug may reach the end of the hepatic arterioles, causing damages to the liver parenchyma whereever the drug reached. Therefore, liquid embolizing agents will cause more extensive liver necrosis and damages to the intrahepatic bile duct by way of the peribiliary plexus. The resulting complications will be necrosis of the gallbladder, destruction of the intrahepatic bile duct system, liver abscesses formation, sclerosis of intra- and extra-hepatic duct, necrosis of the gall bladder with biliary duodenal fistula formation, and hepatic fibrosis (Figures 8, 9). If a more caustic agent (such as absolute ethanol) is used, immediate coagulation necrosis of the bile duct and liver parenchyma will occure. If the drug was used in excessive amount or being injected too rapidly (as often the case when mechanical automatic injector is used), there will be retrograde flow of the drug causing extensive damage of extrahepatic intra-abdominal organs.

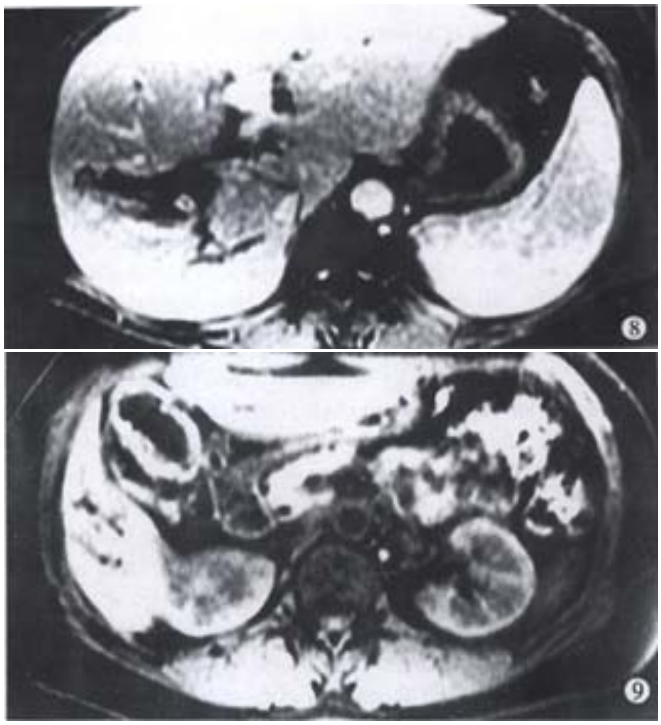

Figure 8 Fibrosis and obstruction of hepatic duct following HAE with injection of sodium morrhuate: 2 years after the procedure.
Figure 9 The same case. Necrosis of the gallbladder and the hepatic duct.

Liver receives double-sourced blood supply, arterial blood composed of 25%-30% of the hepatic blood inflow and supply 50% of the total oxygen expenditure of the liver. The hepatic artery, after entering into the liver parenchyma, sends branches to the hepatic duct, forming a complicated peribiliary plexus which by way of the portal vessels reaches hepatic sinusoids[48]. The intrahepatic bile duct system, differing from the hepatic cells, received blood supply exclusively from hepatic artery. Blood supply of the common hepatic duct and the right and left hepatic duct is derived directly from the right and left hepatic artery, forming a peribiliary vascular plexus in direct connection with the intrahepatic peribiliary vascular plexus [49]. Therefore, inadvertent intra-arterial injection of sclerosing agents into the hepatic artery will result in destruction of the intrahepatic bile duct, as well as sclerosis and obstruction of the right and left hepatic duct at the hilum hepatis. However, the common bile duct under such conditions was often found to be exempt except when retrograde flow of a large amount of the drug occurred. This is explained on the ground of vascular pattern of the common bile duct that the vascular plexus of the common bile duct is derived chiefly from the branches of gastroduodenal artery that connect with the vascular plexus of the intrahepatic bile duct indirectly. Furthermore, as we found in the reported cases of intrahepatic bile duct damage resulting from HAE that in spite of atrophy of the right and left hepatic lobes, the caudate lobe was usually markedly hypertrophied so as to take over the functional role of the liver. This phenomenon is also explained on the basis of blood supply of the caudate lobe. The caudate lobe of liver received bilateral hepatic arterial and portal venous blood supply, therefore, may be exempt from the injurious effect of HAE.

In recent years, HAE has been widely used as a therapeutic modality in the treatment of advanced HCC and was claimed to be safe and effective. However, serious biliary damage was found when

HAE was applied to treat cases of hepatic haemangiomas with sclerosing agents as shown in this report. There may be fundamentally different hemodynamic patterns between malignant and benign lesions of the liver. It was well known that arterial blood supply to HCC is much increased with dilatation and increased number of arterial branches to the tumor. Under such conditions, intra-arterial injection of sclerosing agents may be diverted from the accompanying intrahepatic bile ducts, While, in case of liver hemangioma, configuration of vascularity of the liver remained almost the same as found in the normal liver, therefore, more injected toxic agents will be directed to the intrahepatic biliary plexus and caused damages.A large volume of injected material (such as absolute ethanol) by high speed under pressure injection, and displacement of the intra-arterial catheter may render the situation worst as wide spread retrograde flow may occur as result of arterial spasm. Many cases of bile duct damage resulting from HAE employing sclerosing agents (generally not categorized under traumatic bile duct injury) may not be amendable to surgical treatment because of the extensiveness of the lesion. The authors have treated 11 such cases during the last 10 years (including 3 cases by consultation). Among these cases, 2 were not treated surgically because of extensive sclerotic cholangitis of the intrahepatic bile duct. One case of intrahepatic sclerosing cholangitis resulting from injection of absolute ethanol into a hydatic cyst of the right liver which happened to have a fistula communicating with the hepatic duct. One case of hemangioma of the liver died of multiple organs failure after the injection of absolute ethanol. The other 6 patients were treated by drainage of liver abscess, resection of damaged liver lobe, reconstruction of cholangio-enterostomy with an indwelling U-tube for stenting, and, in one case, a preliminary spleno-renal shunt was required before definite bile duct operation was attempted because of portal hypertension and G-I bleeding. One patient died of liver carcinoma 5 years after surgery. Because of the serious complications in HAE for benign hepatic lesions, re-evaluation of the rationale of such kind of treatment should be undertaken.

Hepatic resection and bile duct injury Injury to the extrahepatic bile duct during hepatic surgery occurred most frequently in operations for those lesions located in the perihilar region. Operations involving resection of tumors of quadrate lobe of the liver are most vulnerable because of the close proximity of these structures. Bile duct injury and stricture formation following hepatic resection should deserve more scrutiny because of its detrimental effect on the outcome of the surgery and the difficulty of repairing operation under such situation[50-52]. In our experience, bile duct stricture resulting from hepatic surgery has become more common over the past 10 years, the increase of number of patients kept pace with the development and propagation of hepatic surgery in our country. In this report, bile duct injury in hepatic surgery accounted for 0.82%-15.7% of the total bile duct strictures. Furthermore, bile duct injuries occurred only in cases of hepatic trauma in Group A. In Group B, the incidence of bile duct injuries rose to 15.7 % as a result of resection of hepatic tumors. In fact, to our knowledge, numbers of bile duct injury in hepatic surgery were much larger than what was reported. The apparent reason is that many cases were recorded and filed as 'operative complications' or 'bile fistulae' instead of the diagnosis of traumatic bile duct injuries[53-55]. Injury to the hilar bile duct is most vulnerable during resection of tumors, either benign or malignant, of the quadrate lobe of the liver. The transverse portion of the left hepatic duct courses along the underneath border of the quadrate lobe and with its peribiliary connective tissue fibers interwoven with that from the hilar plate. Identification and isolation of the left hepatic duct may be difficult especially when the normal anatomical relationship was distorted by local tumor growth. Furthermore, branches of bile duct to the left middle segment of the liver were difficult to be identified and individually divided, laceration injury of the left hepatic duct may occur when the hepatic tumor mass was mobilized. Therefore, we emphasized that technique of mobilizing the left hepatic duct with the hilar plate for the prevention of bile duct injury should be a safeguard measure in liver resection and should be followed in case of perihilar tumor resection.

In recent years, a kind of small incision (3cm-5cm) cholecystectomy (minilaparotomy) has been introduced[56-58]. The result of such type of operation is not different from that of conventional surgery so far as the probability of bile duct injury is concerned.

Abstract

AIM: **To isolate and clone the vincristine-resistine-related genes in gastric cancer SGC7901 cell line and to clarify the multidrug-resistant molecular mechanism of gastric cancer cells.**

METHODS: **The modified differential-display polymerase chain reaction (DD-PCR) was used to examine the differences in the mRNA composition of Vincristine-resistant gastric cancer SGC 7901 cells (SGC7901/VCR), induced by vincristine sulfate versus SGC7901cells. The differentially expressed cDNA fragments were confirmed by reverseNorthern analysis, sequencing, BLAST analysis and Northern bolt analysis.**

RESULTS: **DD-PCR identified that 54 cDNA fragments were preferentially expressed in SGC 7901/VCR cells. When these cDNA fragments were analyzed by reverse Northern blot, 20 were reproducibly expressed at a high level in SGC7901/VCR. Sequencing and BLAST analysis revealed that seven of the genes were known genes: ADP-ribosylation factor 4, Cytochrome oxidase subunit II, Ss-A/Ro ribonucleoprtein autoantigen 60kd subunit, ribosomal protein S13, galaectin-8 gene, oligophrenin 1 mRNA, ribosomal protein L23 mRNA; thirteen of the genes were unknown genes. The length and abundance of the four unknown genes mRNA were further confirmed by Northern blot analysis.**

CONCLUSION: **The twenty differential known and unknown genes may be related to the vincristine-resistant mechanism in human gastric cancer SGC7901 cell line.**

INTROUDCTION

The primary factor affecting the chemotherapy for gastric cancer is the resistance of cancer cells to anti-tumor drugs. This phenomenon is called multidrug-resistance (MDR). Previous studies have shown that the mechanisms of MDR involved P-glycoprotein (P-gp), multidrug-resistance related protein (MRP 1-5), lung drug-resistance related protein (LRP), and recently discovered breast cancer drug-resistance related protein (BCRP), GSH/GST, PKC, Topo DNA plerosis[1-3], genes related to apoptosis and changes of cellular environment (such as pH, hypoxia and temperature). However, over-expression of the genes encoding these proteins cannot completely account for MDR, nor can the treatment aiming at these mechanisms significantly revert MDR. Thus, it is most likely that MDR involves multi-genes. Little has been known about MDR of gastric carcinoma cells. Preliminary studies have shown specific features in MDR of gastric carcinoma cells[4-19], which cannot be completely explained by any known mechanisms of gastric carcinoma MDR[20-32]. We therefore used mRNA differential display to investigate the differential expression of the genes in MDR gastric cells in order to elucidate the molecular mechanism of gastric cancer MDR and to discover the related genes so as to lay the foundation for the eventual solution of the problem.

MATERIALS AND METHODS

Induction of vincristine-resistant gastric cancer SGC 7901 cells

Gastric cancer SGC7901 cell (preserved by the Institute), grown in RPMI1640 medium containing 100g·L^{-1} fetal bovine serum and cultured in incubator filled with 950mL·L^{-1} O_2, 50 mL·L^{-1} CO_2 at 37℃. The procedure of SGC7901/VCR cell induction was as follows[33]: SGC7901 cells were harvested at the mid log-growth phase, and then cultured in the medium containing 0.2 mg·L^{-1} vincristine; the medium exchanged every two or three days, and then the vincristine concentration was increased by 0.1 mg·L^{-1} every other week, until it reached0.8-1.0mg·L^{-1}. SGC7901/VCR cells with stable phenotype were obtained after three months of continuous culture.

DD-PCR[34-38]

Total RNA of gastric cancer SGC7901 and SGC7901/VCR cells was extracted and underwent RNA formaldehyde denatured agarose gel electrophoresis. The purity and RNA content of the samples were measured by OD260/280. Five μg of total RNA were taken from SGC7901 and SGC7901/VCR espectively, and combined with anchoring primers 5'-AAGCTTTTTTTTTTTA-3', 5'-AAGCTTTTTTTTTTG-3', and 5'-AAGCTTTTTTTTTTC to undergo RT-PCR. The procedure is as follows: to each 20μL reaction system, 5μg total RNA and 1.6μL anchoring primer were added, and the system was put at 70℃ for 5 min and then into ice bathing. Buffer of 5×RT 4μL, 10mmol·L^{-1} dNTP (each)2μL, RNase inhibitor 20U, M-MuLV retrotranscriptase (MBI) 2μL (40U) were added into the reaction system sequentially, and put in H_2O to get a total volum of 20μL. The reaction went at 37℃ for 1h, and for

10min at 70℃ to terminate.

Eight random primers AP1-8 were employed in PCR. Three kinds of cDNA products of retrotranscription were each combined with the eight random primers to form 24 PCR reaction systems.There were 48 PCR reactions for two kinds of cells. In each 20μL PCR reaction system, there were 2μL RT product cDNA,1μL anchoring primer (4μmol·L^{-1}), 1μL random primer (4μL),10×PCR buffer 2μL,$MgCl_2$ (25μmol·L^{-1})1.6μL, dNTP (5μmol·L^{-1})1.6μL, Taq plus I DNA polymerase (MBI) 0.15μL (0.4U), α-^{32}P-dNTP0.5μL(185kBq), and ion-free water. The conditions of PCR: 95℃ 3min; 94℃ 30s→40℃ 2min→72℃ 40s for 40 cycles; and then 70℃ 10min for termination. PCR product was 95℃ heat denatured for 3min, and underwent ice-bathing, and 60 g·L^{-1} urea denatured polyacylamine gel (sequencing gel) electrophoresis. The gel was preserved with membrane after electrophoresis and underwent X-ray film autoradiography at -70℃ in black box for 48h.

Cloning and restriction enzymatic cleavage identification of differential DNA bands

Differential bands were cut from the gel and the DNA was recovered and amplified with secondary PCR.The primers and conditions were identical to that of DD-PCR. The amplified product was separated with agarose gel electrophoresis, purified and retrieved, cloned into PUCm-T vector(Shanghai Shenggong Co.), and underwent restriction enzymatic cleavage identification.

Reverse Northern analysis

The plasmids were extracted from the bacteria with positive clones of the 46 differential DNA bands; the quantities were determined through 10 g·L^{-1} agarose gel electrophoresis. One μg plasmid was used to solve in 6(SSC buffer, boiled at 100℃ for 10min to denature, put into ice-water, and pointed onto two NC membranes, each NC membrane having 46 points, and 1μg plasmid. The location of the points on the two membranes were identical. The NC membranes were dried at room temperature. The samples were alkaline-denatured on the membranes; and the membranes were heated at 80℃ for 2h to fix the plasmid DNA and preserved at room temperature.

Preparation of radioactive cDNA probe: Total RNA was extracted from SGC7901 and SGC7901/VCR cells by the same method as in DD-PCR. Ten μg total RNA was taken; 2μL Olig dT_{18} (0.5mg·L^{-1}) were added, and put at 70℃ for 5min, and ice-water bathed for 5min. Buffer of 5×RT 10μL, dNTP(10mmol·L^{-1}/each) 2.5μL, RNase inhibitor 2.5μL(50U),α-^{32}P-dATP 5μL (1850kBq), α-^{32}P-dCTP 5μL(1850kBq), M-MuLV 4μL(80U), and water 50μL were added. The reaction was processed at 37℃ for 1h,and 70℃ for 5min to terminate. EDTA of 0.5 mol·L^{-1}(pH 8.0) 2μL, 100 g·L^{-1aa} SDS 2μL and 10 mol·L^{-1aa} NaoH1.8μL were put into the retrotranscription product, and incubated at 68℃ for 30min. Ten μL 1mol·L^{-1} Tris.Cl (pH7.4) and 3μL 2 mol·L^{-1} HCl were added to neutralize at room temperature. Pre-hybridization was made at 42℃ for 6h, and different cDNA probes were added onto the two membranes to hybridize at 42℃ for 20h. The membranes were washed, dried and underwent X-ray film autoradiography at -70℃ for 72h.

Sequencing and homologous analysis of cDNA clones

The cDNA fragments were sequenced and confirmed through reverse Northern blot to be highly expressed in SGC7901/VCR. BLAST program was used for homologic comparison in genetic library and FASTA was used to analyze the results.

Northern Blot analysis

The total RNA of the two kinds of cells was extracted by the method identical to that mentioned above. Sixteen μg total RNA of each sample was denatured; 10 g·L^{-1} formaldehyde denature agarose gel electrophoresis (16μg RNA/lane) was performed; the mRNA was transfered onto the NC membranes by capillary blot, and heated at 80℃ for 2h to fix the mRNA. Plasmids were extracted from positive clone bacteria; restriction endonuclease cleavage and electrophoresis were performed; the target cDNA fragments were recovered and purified; the cDNA probes were labeled by random primer method, and pre-hybridized on the NC membrane for 3h at 42℃.The probes were added and hybridized at 42℃ for 20h. the membranes were washed, dried and undergone for X-ray film autoradiography at -70℃ in black box for 48h.

RESULTS

DD-PCR separation of differential cDNA of SGC7901/VCR cell

The mRNA of SGC7901 and SGC7901/VCR cells was amplified by RT-PCR, each was divided into 24 groups, and each group was further separated into 150-200 cDNA fragments of diverted length (100-1500bp) after 60 g·L^{-1} polyacylamide gel electrophoresis. The comparison showed that the abundance of certain DNA bands in SGC7901/VCR cells was up-regulated, down-regulated, newly generated or lost. A total of 196 differential cDNA fragments were obtained (Figure 1).

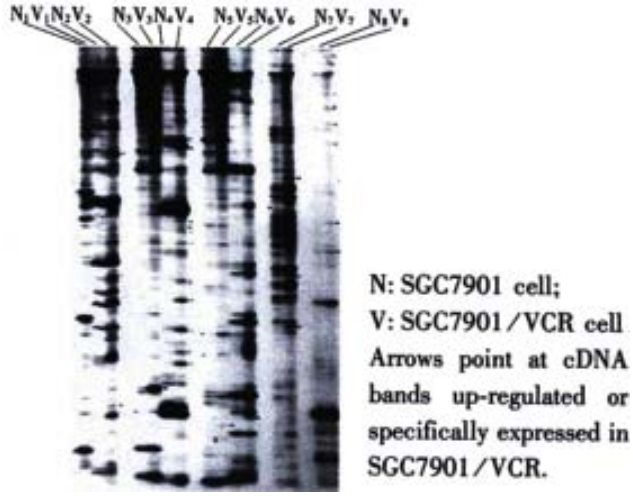

Figure 1 Differential display of mRNA of SGC7901/VCR.

Cloning and restriction enzymatic cleavage identification of differential cDNA fragments in SGC7901/VCR

Fifty-four of the 196 differential cDNA fragments were specifically or significantly highly expressed in SGG7901/VCR cells. Restriction enzymatic cleavage identification showed that 46 cDNA fragments were successfully cloned(Figure 2).

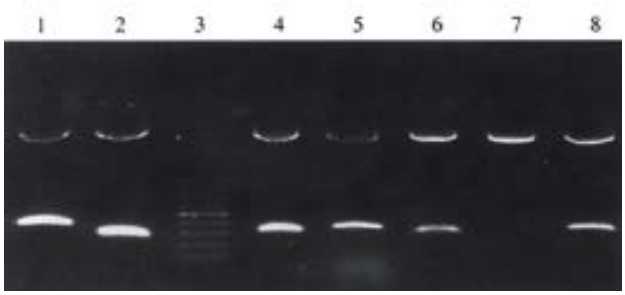

Figure 2 Restriction endonuclease cleavage identification of differential cDNA clones in SGC7901/VCR.

Reverse northern analysis of differential cDNA fragments

In order to confirm the abundance changes of the differential genes and exclude false positive, reverse Northern blot was performed and the high expression of the 20 cDNA fragments in SGC7901/VCR was further validated (Figure 3).

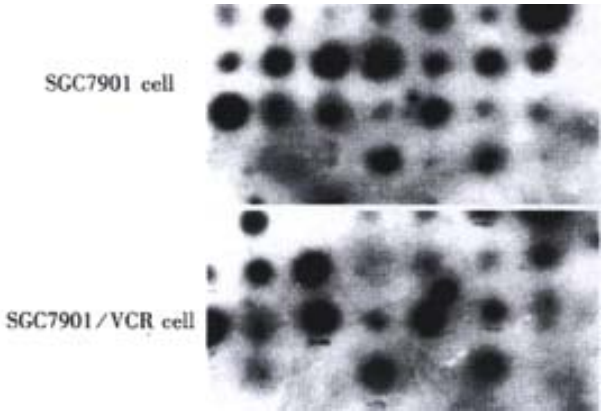

Figure 3 Reverse Northern analysis of genes significantly highly expressed in SGC7901/VCR.

cDNA sequencing and homologic analysis

Sequencing and homologic analysis of the 20 highly expressed genes in SGC7901/VCR cells, confirmed by reverse Northern blot, showed that 7 of the 20 positive clones were highly homologous with known gene sequences (Table 1), and 13 were unknown sequences: GRP-2, GRP-8, GRP-12, GRP-15,GRP-18,GRP-19,GRP-24,GRP-28,GRP-31,GRP-36, GRP-37, GRP-38, GRP-41.

Table 1 Up-regulated cDNA sequence in SGC7901/VCR homologous with known genes

Serial number	Homologous genes
GRP-44(168bp)	ADP-ribosylation factor4 (ARF4) mRNA (1610bp)
GRP-39(181bp)	Cytochrome oxidase subunit II mRNA
GRP-33(199bp)	Ss-A/Ro ribonucleoprtein autoantigen 60kd subunit mRNA
GRP-42(498bp)	Ribosomal protein S13 (RPS13) mRNA (530bp)
GRP-6 (390bp)	Galaectin-8 (LGALS 8) gene, exons4, mRNA
GRP-16(197bp)	Oligophrenin 1 (OPHN1) mRNA (7350bp)
GRP-1 (442bp)	Ribosomal protein L23 (RPL23) mRNA (490bp)

GRP:Gastric cancer drug-resistance related protein; serial numbers are numbering of positive cDNA clones.

Northern blot analysis of unknown differential genes in SGC7901/VCR cell

The cDNA fragments of four genes randomly selected from the 13 unknown genes mentioned above were used to produce probes for Northern blot, and the result was in agreement with that of DD-PCR and reverse Northern analysis. All the four genes were specifically (GRP-2) or highly expressed in SGC7901/VCR.

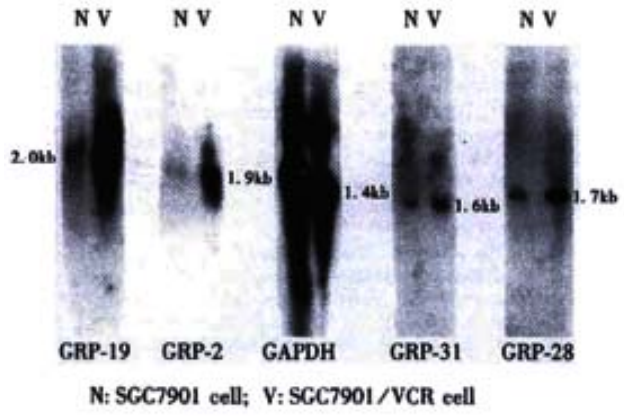

Figure 4 Northern analysis of unknown genes up-regulated in SGC7901/VCR cells.

DISCUSSION

MDR is a major obstacle to tumor chemotherapy. In recent years, progress has been made concerning the mechanism of MDR at the molecular level, which includes the separation and identification of some proteins encoded by MDR-related genes, including P-gp, MRP, LRP and BCRP. All of them are membrane proteins, which engender MDR by reducing the accumulation of chemotherapeutic drugs in the target cells or redistributing the drugs, which consequently reduce the drug concentration in the target organelles. Their expressions differ in different tumors. Certain anti-MDR drugs with some specific MDR mechanisms have been applied clinically. The first generation anti-MDR drugs require that the drug concentration to be high enough to revert MDR, so their side-effects often exceed the tolerance of patients. The second and third generation drugs (PSC833, GF 120918, VX-710, LY335979 etc) cannot revert MDR effectively, either. This phenomenon suggests that tumor cells may tolerate anti-tumor drugs through various mechanisms. The changes at the genetic level are usually more sensitive and prompt than those at the protein level, so screening MDR-related genes at the genetic level has great advantages. One method for screening differential expression genes is mRNA differential display, which contributes substantially in many researches. We employed this technique to screen 20 gene fragments that were highly expressed in gastric cancer MDR cells. This result indicates that MDR involves multi-genes, each playing its own role in the process.Among these genes, seven were separated and identified as known genes.

Human mitochondrial cytochrome C oxidase subunit II

Human mitochondrial cytochrome C oxidase consists of three subunits. It has essential functions in mitochondrial respiration. Higuchi[39]obtained two highly expressed genes in human head and neck squamous epithelium cancer cells that were cisplatin-resistant, using differential display, and one of the two encodes human mitochondrial cytochrome C oxidase subunit II. It is regarded as a sign of cisplatin-resistance. Denis-Gay *et al*[40] discovered that the concentration and activity of mitochondrial cytochrome C oxidase did not change in K562 leukemia cells that were adriamycin-resistant, while the concentrations of most other cytochrome oxidases declined significantly. A noteworthy phenomenon recently reported is that methamphetamine or 3,4-methylenedioxymethamphetamine (MDMA) could suppress the activity of mitochondrial cytochrome C oxidase, which implied that they could probably revert MDR[41].

Galectin-8 cDNA is closely related to PCTA-1[42]

If transferred into tumor 11299 cells, galectin-8 could suppress the formation of the clones by 75%. Galectin-8 is a binding protein of integrin, and has effects against tumor cell adhesion after binding. It can also induce apoptosis, too[43-45].

Human ribosomal protein L23(RPL23)

It is homologous with *E. coli* ribosomal protein L11. As the drug-resistant mutant strain of E. coli lacks L11, it is postulated that L23 may be related to drug-resistance[46].

Ss-A/Ro ribonucleoprotein autoantigen subunit

Its mRNA (1890 bp) has an open reading frame (ORF), encoding a polypeptide of 417 amino acid residues whose apparent molecular mass is 60ku. It is the antigen of several autoimmune diseases. In ultraviolet radiation resistant bacteria, an RNA-binding protein was recently discovered to mediate the resistance and to be highly homologous with Ss-A/Ro 60ku protein. Therefore, Ss-A/Ro ribonucleoprotein autoantigen 60ku subunit presumably has the similar function in the recovery of cells after UV radiation in higher eukaryotes[47].

Oligophrenin-1 (OPHN1)

Its gene covers 500 kb genomic DNA and is composed of 25 exons. It is highly expressed primarily in fetal brain, encoding a protein whose

molecular mass is 91ku. It has a typical Rho GTPase activation protein (rhoGAP) domain, the activation of which induces GAP to inactivate Rho and Ras. Therefore, the inactivation of rhoGAP can activate its target molecules and subsequently influence cell differentiation and migration. Its mutation can result in non-specific X-chromosome linked mental retardation, as its loss of function probably interferes with or affects cell signal transduction pathways, impeding cell migration and axonal growth in the development of cells in the neural system[48,49].

ADP-ribosylation factor 4 (ARF4)

It is a member of the G-protein family, with a molecular mass of about 20ku. It was first identified to activate cholera toxin ribosyltransferase, and was recently discovered to effect essentially in vesicular transport in cell, and to be an activator of phospholipase D[50]. Human ribosomal protein S13 (RPS13) is a translation initiation factor and is related to cell growth and differentiation[51]. Some of these seven genes are apparently related to MDR, and the relationship of others to MDR remains to be further studied.

Two cDNAs (GRP-24, GRP-41) which are highly expressed in SGC7901/VCR cells, are 100% homologous with human genomic clone fragments. The two genomic clones contain the genes of dynamin, neuroendocrine secretory protein 55 (NESP55), and GANS1. Dynamin is a membrane protein with GTPase activity; its alternative splicing produces six subtypes engaging in endocytosis, exocytosis, pinocytotic vesicle cycle, intracellular and Golgi complex vesicular transport, and cell membrane transport. NESP55 and GANS1 are both G-proteins, involved in cell signal transduction. Further confirmation of homologous genes of the two cDNA fragments is necessary.

We randomly selected 4 cDNA fragments (GRP-2,GRP-19, GRP-28,GRP-31) from the rest 11 unknown genes to do Northern analysis. The result was in agreement with that of reverse Northern analysis; and gave the lengths of the four genes and also confirmed the reliability of reverse Northern blot. The result is conducive to the cloning of the entire length of the genes.

To sum up, we managed to separate and clone 20 significantly highly or specifically expressed genes from drug-resistant gastric cancer SGC7901/VCR cells using DD-PCR. Some known genes are related to drug-resistance and others may enhance drug-resistance. It is necessary to conduct further research on the unknown genes.

Abstract

AIM: **To explore dysregulation of cyclin E in malignancies, and to further investigate the role of cyclin E in *Helicobacter pylori (H. pylori)*-induced gastric precancerosis.**

METHODS: **Four-week-old specific pathogen-free male Mongolian gerbils were employed in the study. 0.5mL 1×10^8 cfu·L^{-1} suspension of *H. pylori* NTCC11637 in Brucella broth was inoculated orally into each of 20 Mongolian gerbils, and a further 20 gerbils were inoculated with Brucella broth as controls. 10 of the infected gerbils and 10 of the non-infected control gerbils were sacrificed at 25, 45 wk after infection. The expression of cyclin E was analyzed by RT-PCR and immunohistochemical studies with monoclonal antibody to cyclin E in Mongolian gerbil of *H. pylori*-induced gastric precancerosis.**

RESULTS: ***H. pylori* was constantly detected in all infected animals throughout the study. At 25 wk after infection of *H. pylori*. ulcers were observed in the antral and body of stomach (n=6). Histological examination showed that all animals developed severe inflammation and multifocal lymphoid follicles appeared in the lamina propria and submucosa of gastric antrum. At 45 wk after infection of *H. pylori*, severe atrophic gastritis (n=10). intestinal metaplasia (n=8) and dysplasia (n=6) could be observed. Cyclin E mRNA levels were significantly more at 25 wk after infection of *H. pylori* (1.27±0.26), and at 45 wk after infection of *H. pylori* (1.82±0.39) than control-animals (0.59±0.20, P<0.01); cyclin E mRNA levels were evaluated by 2.2-fold at 25 wk (P<0.01) and 3.1-fold at 45 wk (P<0.01) precancerosis induced by *H. pylori*, when compared with control gastric epithelium of Mongolian gerbil. Immunohistochemical staining revealed exclusive nuclear staining of cyclin E. Furthermore, there was a sequential increase in cyclin E positive cells from normal epithelium to precancerosis.**

CONCLUSION: **Overexpression of cyclin E occurs relatively early in gastric tumorigenesis in this model.**

Yao YL, Xu B, Song YG, Zhang WD. Overexpression of cyclin E in Mongolian gerbil with *Helicobacter pylori*- induced gastric precancerosis. World J Gastroenterol 2002;8(1):60-63

INTRODUCTION

Gastric cancer is a major health problem[1-3] and remains the second most common cancer in the world[4-6]. Although epidemiological studies have indicated that *H. pylori* infection plays a crucial role in gastric carcinogenesis in humans[7-22], there is no direct proof that *H. pylori* is actually associated with gastric carcinogenesis[23-26]. The purpose of this study was to elucidate the relationship between *H. pylori* infection and gastric carcinogenesis by using an animal model of long-term *H. pylori* infection, and explore the role played by cyclin E in gastric tumorigenesis[27-29].

Cyclins are positive regulators of cell cycle progression. They function by forming a complex with and activating a class of protein kinases which are essential for cell cycle transitions. As the major regulatory events leading to cell proliferation occur in the G1 phase of the cell cycle, altered expression of cyclins involved in the G1 phase may be an important step in oncogenesis[30-33]. Among G_1 cyclins, an accumulating body of evidence suggests that over expression and rearrangement of cyclin E is associated with malignancy. Over expression of cyclin E has also been found in mouse mammary tumors and is associated iwth tumor development; altered expression of cyclin E can accelerate occurrence and early progression of colorectal cancer, and plays an important role in occurrence of breast cancer[34-37]. But cyclin D_1, over expression in esophageal cancer and breast cancer, has no over expression in gastric cancer, which suggests expression of cyclins has specificity of organs. To gain a further understanding of the role played by cyclin E in gastric tumorigenesis, the study investigates the role of cyclin E in *H. pylori*-induced gastric precancerosis[38-39].

MATERIALS AND METHODS

Animals and preparation

Four-week-old specific pathogen-free male Mongolian gerbils, weighing (20±5)g, were employed in the study. They were housed in individual metabolic cages in a temperature conditioned room (23±2)℃ with a 12 h light-dark cycle, allowed access to standard rat chow (provided by Experimental Animal Center, First Military Medical University) and water ad labium, and acclimatized to the surrounding for 7 d prior to the experiments. *H. pylori*(NTCC11637) was obtained from American Type Culture Collection and cultured on Brucella agar plates containing 70 mL·L^{-1} goat blood in a microaerobic condition (volume fraction; N_2:85%, O_2:5%,CO_2:10%, in aerobic globe box) at 37℃ for 3 d. The strain was identified by morphyology, Gram's stain, urease production and so on.

Experimental protocol

Suspension 0.5 ML 1×10^8 cfu·L^{-1} of *H. pylori* NTCC11637 in Brucella broth was inoculated orally into each of 20 Mongolian gerbils which had been fasted overnight, for 14 d continuously. A further 20 gerbils were inoculated with Brucella broth as controls. 10 of the infected gerbils and 10 of the non-infected control gerbils were sacrificed at 25, 45 wk after infection. The stomach of each animal was removed and opened for macroscopic observation. For half of each gastric antrum mucosa was dissected for RNA isolation. The remainders of the stomach samples were used for istological examination, which were fixed with neutral-buffered 100 mL·L^{-1}

formalin and processed by standard methods that embedded in paraffin, sectioned and stained with haematoxylin for analyzing histological changes, Giemsa stain for detecting for *H. pylori* and Alcian blue (AB)/PAS stain for examining intestinal metaplasia.

RNA isolation and RT-PCR analysis

Using Tripure isolation reagent (Boehringer Mannheim, Germany), total cellular RNA was isolated from previously frozen tissues according to the manufacturer's instruction. All RNA samples were analyzed for integrity of 18s and 28s rRNA by ethiding bromide staining of 0.5μg RNA resolved by electrophoresis on 12g·L^{-1} agarose-formaldehyde gels. RT-PCR analysis was performed as follows. RNA was incubated at 60℃ for 10 main and chilled to 4℃ immediately before being reverse transcribed. Reverse transcription of 1μg total RNA using antisense primers was performed in a volume of 20μL for 40 min at 50℃, containing 200 U MMLV reverse transcriptase, 1×buffer RT, 1 MU·L^{-1} Rnasin, 0.5mmol·L^{-1} dATP, dGTP, dCTP and dTTP respectively and 0.2μmol·L^{-1} antisense primers including cyclin E and β-actin respectively. The samples were heated to 99℃ for 5 min to terminate the reverse transcription reaction. By using a Perkin-Elmer DNA Thermocycler 4800 (Perkin-Elmer, Norwalk, CT), 5μL cDNA mixture obtained from the reverse transcription reaction was then amplified for cyclin E and β-actin. β-actin was used as the housekeeping gene and amplified with cyclin E as contrast. The amplification reaction mixture consisted of 10×buffer 5μL, 0.2 mmol·L^{-1} dATP, dGTP, dCTP and dTTP respectively, 2.5 U Taq DNA polymerase, and 0.2μmol·L^{-1} each of sense and antisense primers in a final volume of 50μL. The reaction mixture was first heated at 94℃ for 2 min and amplification was carried out for 29 cycles at 94℃ for 0.5 min, 53℃ for 1 min, 70℃ for 1.5 min, followed by an incubation for 7 min at 70℃. The number of amplification cycles was previously determined to keep amplification in the linear range to avoid the "plateau effect" associated with increased numbers of PCR cycles. The PCR primers used were: cyclin E, sense 5'-TAT GGC GAC ACA AGA AAA TG-3'and antisense 5'-GCA AGA GAA GAC AGA CAA CG-3'; β-actin, sense 5'-CCA AGG CCA ACC GCG AGA AGA TGA C-3' and antisense 5'-AGG GTA CAT GGT GGT GCC GCC AGA C-3'. The length of PCR products for cyclin E and β-actin was 770 bp and 587 bp. PCR products were run on a 15g·L^{-1} agarose gel in 0.5×TBE buffer and then analyzed by gel image analysis system. The level of cyclin E was reflected with the ratio of cyclin E/β-actin.

Immunohistochemical staining

Four micrometers paraffin-embedded tisue sections were deparaffinized and rehydrated. Endogenous peroxidase activity was ablated with 10 mL·L^{-1} hydrogenperoxide in methanol. The immunostaining for cyclin E was conduced using the StreptAvidin-Biotin-enzyme Complex kit (Boster, Wuhan). Immunostaining by replacing primary antibody with PBS was also conducted as a negative control. The staining was evaluated semiquantitatively on the basis of the percentage of positive cells, and classified as follows[40]: diffusely positive (+++) when positive cells accounted for more than 70% of the total cells, partially positive (++) when positive cells were 35%-70%, partially positive (+) when positive cells accounted for 5%-35%, and negative (-) when positive cells accounted for less than 5%.

Statistical Analysis

Experimental results were analyzed with Chi-square Tests and K Related Samples Test by SPSS software. Statistical significance was determined at $P<0.05$.

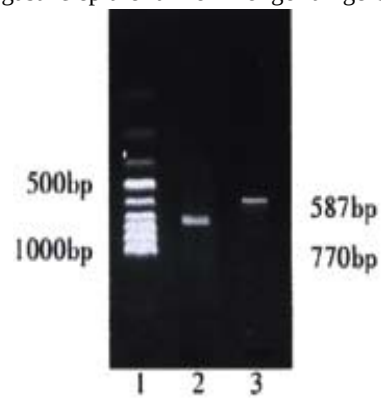
RESULTS

Histophathological findings

H. pylori was detected in gastric antrum and gastric body of all infected animals throughout the study, and more in gastric antrum than gastric body. By the 25th wk after infection of *H. pylori*, ulcers were observed in the antral and body of stomach (n=6). Histological examination showed that all animals developed severe inflammation in the area close to ulcers; multifocal lymphoid follicles appeared in the lamina propria and submucosa; and there were mild atrophic gastritis in all infected animals. By the 45th wk after infection of *H. pylori*, severe atrophic gastritis (n=10), intestinal metaplasia (n=8) and dysplasia (n=6) could be observed. Those metaplastic glands appeared more atypical than the surrounding nonmetaplastic and hyperplastic glands. Severe atrophic gastritis, intestinal metaplasia and dysplasia were gastric precancerosis. In the uninfected animals, there were no significant changes throughout the study.

RT-PCR analysis of cyclin E mRNA expression

There were cyclin E mRNA expression in gastric anturm mucosa of control-animals. cyclin E mRNA levels were significantly more at 25 wk after infection of *H. pylori*(1.27±0.26), and at 45 wk after infection of *H. pylori*(1.82±0.39) than control-animals (0.59±0.20,$P<0.01$); Cyclin E mRNA levels were evaluated by 2.2-fold at 25 wk ($P<0.01$) and 3.1-fold at 45 wk ($P<0.01$) precancerosis induced by *H. pylori*, when compared with control gastric epithelium of Mongolian gerbil (Figure 1-3).



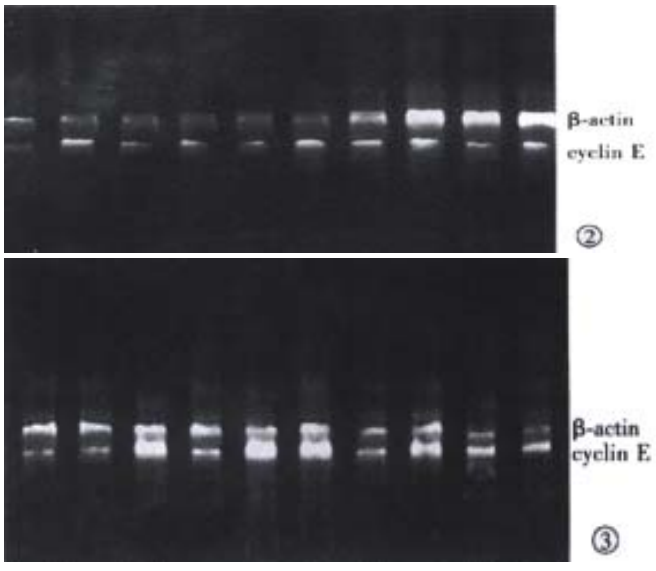


Figure 1 1:cyclin E; 2:PCR marker; 3:β-actin

Figure 2 RT-PCR analysis of cyclin E mRNA levels using β-actin as internal control. Total RNA was first reverse transcribed into cDNA and then amplified by PCR in control.

Figure 3 In 25 wk after infection of *H. pylori*.

Immunohistochemical analysis of cyclin E protein expression

To examine whether increased cyclin E mRNA expression were accompanied by increased expression of cyclin E protein, imunohistochemical analysis was performed. cyclin E protein expression lied in nuclei and cytoplasm. Cyclin E protein expressions were evaluated significantly at 25 wk(P<0.01) and at 45 wk (P<0.01) precancerosis induced by *H. pylori*, when compared with control gastric epithelium of Mongolian gerbil (Figure 4 and Table 1).

DISCUSSION

H. pylori infection is now know as a major cause of acute and chronic active gastritis, peptic ulcer disease and atrophic gastritis and is also suspected to be involved in the genesis of gastric adenocarcinoma and mucosa-associated lymphoid tissue lymphoma[41-49]. In 1994, the International Agency for Research on Cancer (IRAC), a branch of the World Health Organization (WHO), convened experts from 11 countries to examine the evidence linking a number of infectious agents with human cancer. Although there is no direct proof that *H. pylori* is actually associated with gastric carcinogenesis, epidemiological studies have indicated that *H. pylori* infection plays an important role in gastric carcinogenesis in humans; *H. pylori* was designated as a definite carcinogen (group I) to the human stomach based on prospective case-control studies reported in 1991. Several experiments were conducted in Japan that demonstrated that chronic *H. pylori*-infection models of Mongolian gerbils developed gastric carcinoma. These results will be extremely significant to elucidate the mechanism of gastric carcinogenesis due to *H. pylori* infection[5,50]. Apoptosis, a programmed cell death, was ignored, just like *H. pylori*, only to reappear recently. However, the number of current publications dealing with apoptosis of *H. pylori* has increased exponentially. Although gastric epithelial apoptosis is a programmed physiological event in the superficial aspect of the mucosa and is important for healthy cell turnover, *H. pylori* infection reportedly promotes such a cell death sequence[51-52]. Because apoptosis regulates the cycle of cell turnover in balance with proliferation, dysregulation of apoptosis or proliferation evoked by *H. pylori* colonization would be linked to the gastric carcinogenesis[53-56].

Cyclins are positive regulators of cell cycle progression, initially identified in early cleavage embryos of marine invertebrates as proteins that accumulated during interphase and were degraded at mitosis. Cyclins are now known to be positive regulatory subunits of a class of protein kinase termed cyclin-dependent kinases. These protein kinases have been shown in a number of diverse eukaryotic systems to be the master regulators of major cell cycle transitions[57-59]. Cyclin E is essential for the G1/S phase transitionin the cell cycle. Cyclin E gene amplification and altered expression has been reported in a variety of human cancers[60-61]. Now Cyclin E gene has been defected as oncogene[38]. Cyclin E was synthetized in the mid-term of the cell cycle, expressed the highest level when entering S phase, and degraded through S phase. The level of cyclin-dependent kinase2 kept constant during the cell cycle. Cyclin E, cyclin-dependent kinase2 and cyclin-dependent kinase inhibitor regulated G1/S phase transition by two-way at late stage of G1 phase, Cyclin E accelerated G1/S phase transition by composing and activating cyclin-dependent kinase2.

In the present study, to explore dysregulation of cyclin E in malignancies, and to further investigate the role of cyclin E in *H. pylori*-induced gastric precancerosis, cyclin E mRNA level was measured by quantitative RT-PCR analysis in Mongolian gerbil gastric antrum mucosa. In addition, the expression and localization of protein product was analyzed by immunohistochemistry. Sample size requirement for obtaining sufficient amounts of RNA for RT-PCR analysis did not allowdetection of either cyclin E mRNA level in any specific type of preneoplastic lesions. However, using immunohistochemical technique, cyclin E protein expression in preneoplastic lesions was observed from paraffin-embedded tissue sections. Cyclin E mRNA levels were increased 2.2-fold at 25 wk and 3.1-fold at 45 wk precancerosis induced by *H. pylori*, when compared with normal gastric epithelium of Mongolian gerbil. Immunohistochemical staining revealed exclusive nuclear staining of cyclin E. Furthermore, there was a sequential increase in cyclin E positve cells from normal epithelium to precancerosis. The present study indicated that expression of cyclin E increased from normal epithelium to precancerosis, dysregulation of cyclin E expression occurred relatively early in gastric tumorigenesis in this model and might participate in tumor progression. These findings suggested that *H. pylori*-induced gastric precancerosis was associated with dysregulation of gastric epithelial cell cycle. Further studies were needed to delineate the mechanism of these alterations.

Abstract

AIM: **To investigate the relationship between hepatocarcinogenesis and the expression of connexin32 (cx32), connexin43 (cx43) mRNAs and proteins *in vitro*.**

METHODS: **Gap junction genes cx32 and cx43 mRNA in hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal liver cell line QZG were detected by in situ hybridization (ISH) with digoxin-labeled cx32, and cx43 cDNA probes. Expression of Cx32 and Cx43 proteins in the cell lines was revealed by indirect immuno-fluorescence and flow cytometry (FCM).**

RESULTS: **Blue positive hybridization signals of cx32 and cx43 mRNAs detected by ISH with cx32 and cx43 cDNA probes respectively were located in cytoplasm of cells of HHCC, SMMC-7721 and QZG. No significant difference of either cx32 mRNA or cx43 mRNA was tested among HHCC, SMMC-7721 and QZG (P= 2.673, HHCC *vs* QZG; P = 1.375, SMMC-7721 *vs* QZG). FCM assay showed that the positive rates of Cx32 protein in HHCC, SMMC-7721 and QZG were 0.7%, 1.7% and 99.0%, and the positive rates of Cx43 protein in HHCC, SMMC-7721 and QZG were 7.3%, 26.5% and 99.1% respectively. Significant differences of both Cx32 and Cx43 protein expression existed between hepatocellular carcinoma cell lines and normal liver cell line (P= 0.0069, HHCC *vs* QZG; P= 0.0087, SMMC-7721 *vs* QZG). Moreover, the fluorescent intensities of Cx32 and Cx43 proteins in HHCC, SMMC-7721 were lower than that in QZG.**

CONCLUSION: **Hepatocellular carcinoma cell lines HHCC and SMMC-7721 exhibited lower positive rates and fluorescent intensities of Cx32, Cx43 proteins compared with that of normal liver cell line QZG. It is suggested that lower expression of both Cx32 and Cx43 proteins in hepatocellular carcinoma cells could play pivotal roles in the hepatocarcinogenesis. Besides, genetic defects of cx32 and cx43 in post-translational processing should be considered.**

INTRODUCTION

Carcinoma of the liver is one of the most common malignant tumors which seriously threatens to human life[1-14]. About 90% of carcinoma of the liver are hepatocellular carcinoma (HCC)[15-19]. In each year, more than 250 thousands of new cases of HCC were reported around the world, among which 110 000 cases (44.7%) occurred in China[20-24]. Due to the difficulty in early diagnosis and treatment, the tumor molecular mechanisms, early diagnosis and effective methods of clinical treatment for HCC have been a major research project all over the world.

Gap junctions are intercellular channels formed by the interaction of two hemichannels—connexons, one of which is composed of six protein subunits[25,26]. Connexins (Cx) are subunits of gap junctional channels[27,28], by which neighboring cells can exchange low molecular weight ions and molecules, i.e., gap junctional intercellular communication (GJIC)[29,30]. GJIC mediated via gap junctions plays important roles in embryogenesis, cell proliferation, tissue homeostasis and in carcinogenesis[31,32]. Connexins are encoded by a gene family of at least 16 members, which have been divided into two groups based on primary amino acid sequence homology. Connexin32 (Cx32) and connexin43 (Cx43) are the major gap junction forming proteins in liver tissues. Decreased expression of Cx genes and disordered signal transduction pathway of Cx genes contribute to abnormal gap junctional intercellular communication between contacting cells[33]. Uncontrolled tumor cell growth because of the loss of gap junctional intercellular communication due to the down-regulated expression of Cx genes appears to bean important event in cell transformation[34-37]. In this study, the hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal liver cell line QZG were employed to investigate the relationship between hepatocarcinogenesis and cx32, cx43 mRNA and their protein expression.

MATERIALS AND METHODS

Cell culture

Hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal liver cell line QZG, were kindly provided by Professor Chen in the 863 Research Group. The cells were cultured on slides in RPMI 1640 medium (Gibco BRL, USA), supplemented with 100mL·L^{-1} fetal bovine serum (Gibco BRL, USA), incubated in a humidified atmosphere of 950 mL·L^{-1} air and 50 mL·L^{-1} CO_2 at 37℃. The cells were passaged by trypsinization twice a week.

Probe labeling

pGEM-cx32 plasmid containing cx32 cDNA 1.5kb, pSG5-cx43 plasmid containing cx43 cDNA 1.1kb were gifts from Professor Li in Hunan Medical University. After amplification, isolation and purification, pGEM3-cx32 plasmid was digested by EcoR I (Gibco BRL, USA) and pSG5- cx43 by BamH I (Gibco BRL, USA). The digested plasmids were electrophorated on 7 g·L^{-1} agrose gel with DNA/Hind III + EcoR I Marker (Gibco BRL, USA). cx32, cx43 cDNAs from gel were extracted and purified as the protocol of PCR-pure kit (Clontech, USA), and labeled using Dig

DNA labeling and detection kit (Boehringer Mannheim, Germany).

In situ hybridization

Slides of varied cells were incubated in 0.2mL·L^{-1} DEPC at RT for 10 min , then in 0.2mL·L^{-1} HCl for 10 min, 5mg·L^{-1} PK at 37℃ for 10 min. The digestion reaction was stopped in 0.1mol·L^{-1} glycine and the slides were fixed in 40g·L^{-1} PFA for 10 min, dehydrated in ethanol and air dried in sequence. Prehybridization was performed at 42℃ for 30 min. The labeled cDNA probes were denatured in hybridization buffer at 100℃ for 10 min, then at -20℃ for 3 min, then added on tissues and coverslipped at 42℃ overnight. Washing of sections was done with 2×SSC, 1×SSC, 0.5×SSC and Buffer I. The slides were incubated in NSS at 37℃ for 30 min, and then Dig-Ap (Boehringer Mannheim, Germany, 1:500) for 2h, finally detected with NBT / BCIP of Dig DNA labeling and detection kit (Boehringer Mannheim, Germany). Positive signals were visualized as intensive blue granules in the cytoplasm. Control sections were used. All results were verified by χ^2 test.

Flow cytometry (FCM) analysis

Total 10^6·L^{-1} cells of HHCC, SMMC-7721 and QZG were collected, and blocked with normal serum (Vector, USA) for 30 min at 4℃, then added mouse-anti Cx32 McAb (Zymed, USA, 1:000) and mouse-anti Cx43 McAb (Zymed, USA, 1:1000) respectively for 30 min at 4℃, whereas IgG was added for control. FITC-IgG (Jackson,1:100) was added in the cells for 30 min at 4℃, precipitated and washed by 0.01mol·L^{-1} pH7.5 PBS. Detective rates and the fluorescent intensity of Cx32, Cx43 proteins in the cells were measured by ELITE ESP flow cytometer (Coulter, USA) and phoenix software (Coulter, USA).

RESULTS

Detect of cx32, cx43 mRNA in cell lines by ISH

The cx32, cx43 mRNA in hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal liver cell line QZG were detected by Dig-labeled cx32, cx43 cDNA probes. After in situ hybridization, blue positive hybridization signals of mRNA were located in cytoplasm of the cells. The results showed that bright blue specific hybridization signals of cx32 mRNA and cx43 mRNA were detected in hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal liver line QZG. χ^2 tests did not show any significant difference (P> 0.05) between them. The results were showed in Figure 1-3.

Expressions of Cx32, Cx43 proteins in hepatocellular carcinoma cell lines by FCM

Expression of Cx32, Cx43 proteins in cultured hepatocellular carcinoma cell lines HHCC, SMMC-7721 and normal liver cell line QZG were detected by FCM after immunoreaction with mouse-anti Cx32 McAb, mouse-anti Cx43 McAb. FCM examined both positive rates of Cx proteins expression and their quantities in each cell line.

FCM assay showed that positive rates of Cx32 protein expression in HHCC , SMMC-7721 and QZG were 0.7%, 1.7% and 99.0%, and those of Cx43 protein were 7.3%, 26.5% and 99.1% respectively. The fluorescent intensity of Cx32 protein and Cx43 protein in HHCC, SMMC-7721 were lower than those in QZG. QZG cells showed both higher positive rates for Cx32, Cx43 proteins and strong fluorescent intensity. The detection rates of Cx32, Cx43 proteins were showed in Figure 4-6 and Table 1.

Table 1 Positive expression rates of Cx32 and Cx43 proteins in various cell lines

Cell line	Positive rates %	
	Cx32	Cx43
HHCC	0.7[b]	7.3[b]
SMMC-7721	1.7[b]	26.5[b]
QZG	99.0	99.1

[b]$P<0.01$, *vs* QZG.

DISCUSSION

Gap junction intercellular communication (GJIC) mediated by gap junction channels[38,39] has been postulated to be an important tool for the maintenance of tissues homeostasis, metabolism, control growth and differentiation[40,41]. Carcinogenesis is one of the pathological processes in which disorders of GJIC may play an important role. The inhibited GJIC in many kinds of tumor cells has been found, which could make important contributions to neoplastic progression by allowing tumor cells to escape by either systemic or local control mechanisms[42-44].

Cx32, Cx43 are widely expressed in many tissues, especially in normal liver. This study revealed that Cx32 and Cx43 proteins expressed at a high level in normal liver cell line but at low level in hepatocellular carcinoma cell lines[45-47].

Hepatocarcinogenesis is dramatically enhanced in liver neoplasm tissues lacking of Cx32 and Cx43 proteins, as we shown previously[48]. The results showed that cx32 and cx43 mRNAs and their proteins were highly expressed in normal liver tissues and cell lines, and had significantly decreased in hepatocellular carcinoma tissues and cell lines except expression of Cx43 protein in hepatoma cell line SMMC-7721. cx32 is the specific expression gene in human normal liver tissues and cell line whereas cx43 is a kind of variable expressing gene in either normal liver or hepatoma cell lines.Decrease of Cx proteins related with abnormal function of GJIC between hepatocellular carcinoma cells and surrounding normal cells finally results in hepatocarcinogenesis. Aberrant localization of Cx32 and Cx43 may be not only essential for the reduced GJIC in HCC[49], but also disturb the mechanism of a bystander effect[50]. Expression of the gap junctional proteins is often decreased in tumor tissues, but recruited expression could suppress malignant phenotypes of the tumor cells. The mechanism is that enhanced GJIC on basis of normal gap junctional protein expression regulates homologous and heterologous communication between tumor cells, surrounding normal hepatocytes and other cells[51].

Many observations demonstrate that the lower expression of Cx32 and Cx43 may be involved in the development of hepatocellular carcinoma[52]. It is interesting, moreover, that our results have showed even lower expression of Cx32, Cx43 proteins in hepatocellular carcinoma cell lines HHCC, SMMC-7721 than that in normal liver cell line QZG, but ISH results have shown no decreases of cx32 and cx43 mRNA in hepatocellular carcinoma compared with normal liver cell line. Therefore, it appears that cx32 and cx43 genes transcription is not responsible for aberrant expression of Cx32 and Cx43 proteins during human liver tumorigenesis. Besides, the results have indicated that cx32 and cx43 genes, the specific genes expressing in normal liver tissues, are expected to be the potential unmutated tumor suppressor genes.

Some abnormal regulatory events promote carcinogenesis[55,56], through multiple mechanisms, including post translation process and other potential mechanisms[53-56]. The carcinogenesis and development of hepatocellular carcinoma are related with the abnormal expression of cx genes, signal transduction disorders[57, 58], such as reduce of $[Ca^{2+}]$[59,60] and post-translational phosphorylation on tyrosine of Cx proteins, which are associated with dramatic changes in gap junctional intercellular communication and carcinogenesis[61]. The possibility is that defects in post-translational processing of Cx32 and Cx43 proteins may be obstacle for their transportation to cell membranes[62]. Furthermore, phosphorylation on tyrosine of Cx protein can affect the structure of Cx proteins, which is related to channel properties[63]. Post-translational phosphorylation on tyrosine of Cx32 and Cx43 may be important factors controlling the GJIC in hepatocellular carcinoma and substantially responsible for the assembly and function of these proteins as well. Further investigation is expected to understand the mechanism in detail.

Abstract

AIM: **To label anti-hepatoma monoclonal antibody (mAb) fragment HAb18 F(ab')$_2$ was labeled with ^{188}Re for the pharmacokinetic model of ^{188}Re-HAb18 F(ab')$_2$ and to evaluate its pharmacokinetic parameters in hepatoma-bearing nude mice.**

METHODS: **HAb18 F(ab')$_2$ was directly labeled with ^{188}Re using 2-mercaptoethanol (2-ME) as reducing agents. Labeling efficiency and immunoreactivity of ^{188}Re-HAb18 F(ab')$_2$ were evaluated by Whatman 3MM paper chromatography and live cell assay, respectively. Biodistribution analysis was also conducted in nude mice bearing human hepatoma in which animals were sacrificed at different time points (1, 4, 18, 24 and 24h) after ^{188}Re-HAb18 F (ab')$_2$ was injected through tail-vein into hepatoma-bearing nude mice. The blood and radioactivity of organs and mass were measured. The concentrations of ^{188}Re-HAb18 F(ab')$_2$ were evaluated with apharmacokinetic 3P97 software.**

RESULTS: **The optimum labeling efficiency and immunoreactive fraction were 91.7% and 0.78% respectively. The parameters of ^{188}Re-HAb18 F(ab')$_2$ were: $T_{1/2}$, 2.29h; Vd,1.49×10^{-9}L·Bq^{-1};AUC, 20.49×10^{9}Bq·h·L^{-1};CL, 0.45×10^{-3}L·h^{-1}. ^{188}Re-HAb18 F(ab')$_2$ could locate specially in hepatoma with high selective reactivity of HAb18 F(ab')$_2$. ^{188}Re-HAb18 F(ab')$_2$ was mainly eliminated by kidney. The maximal tumor to blood ratio was at 48h, and maximal tumor to liver ratio was at 18h.**

CONCLUTION: **The pharmacokinetics of ^{188}Re-HAb18 F (ab')$_2$ fit a l-compartment model.^{188}Re-HAb18 F(ab')$_2$ can be uptaken selectively at the hepatoma site.**

INTRODUCTION

^{188}Re is a new radioisotope[1-16]. In the past,^{131}I was used as the main radioisotope for radioimmunotherapy(RAIT).^{131}I has its favour such as simple labeling, appropriate partical energy and path length,but the high energy of γ-ray produced harmness to the whole body, and β-energy(Emax,0.6MeV) was low[17-22]. So scientists have searched for more effective radioisotope. Rhenium-188 is of particular interest to this study as the ^{188}Re may be obtained from the ^{188}W/^{188}Re generator, and ^{188}Re decays by β- emission with energies (Emax=2.12MeV) similar to ^{90}Y and γ photons (Eγ=155keV; aboundance=15%) that are useful for dosimetry calculations and radioimmunoimaging, with a half-time of 17h. Furthermore, ^{188}Re has chemical properties similar to ^{99}Tc m, thus it can be conjugated to antibodies modeling on ^{99}Tc m labeling methods using direct or indirect method[23-29]. Direct methods require attaching the reduced form of Re to the endogenous thiols of antibodies, whereas indirect methods require the reduced Re to be complexed by a bifunctional chelator that is conjugated to the antibody[30-32]. There has been considerable interest in the direct labeling of mAb, which would result in the formation of an instant kit formulation for imaging or therapy.

^{188}Re can be provided at reasonable costs for routine preparation of radiopharmaceuticals for cancer treatment. ^{188}Re is an important therapeutic radioisotope which is obtained on demand as carrier-free sodium perrhentate by saline elution of the tungsten-188/rhenium-188 generator system.Because of its prominent physical characters, ^{188}Re will become a new therapeutic isotope.^{188}Re is a radioisotope currently under evaluation for a variety of therapeutic application, including that for metastatic bone pain and therapy in oncology.

The HAb18 antibody is a murine IgG_1 anti-hepatoma monoclonal antibody under investigation in our laboratory. It does not cross react with normal liver cells, and only rarely with other malignant tissues. Due to the smaller size, easier penetration into tumor tissues, rapid clearance from circulation, and less human anti-mouse antibody (HAMA) reaction, F(ab')$_2$ fragments showed that tumor localization is faster and better than the intact antibody. Previous studies of ^{99}Tcm labeled with HAb18 F(ab')$_2$ indicated that the conjugate is effective to detect hepatoma in the nude mice model[33]. The results encourage us to continue the radioimmunotherapy for hepatoma using ^{188}Re labeled with HAb18 F(ab')$_2$. we have studied the pharmacokinetics of ^{188}Re-HAb18 F(ab')$_2$ in hepatoma-bearing nude mice in order to prove if ^{188}Re-HAb18 F(ab')$_2$ was located specially in hepatoma, to establish the pharmacokinetical model and get the parameters of pharmacokinetics.

MATERIALS AND METHODS

Animals

Five-week Balb/c nude mice(derived from Experimental Animals Center of our university) were implated with 1×10^7(0.2mL) human hepatocellular carcinoma (HCC) cells in the right thigh. When the diameter of the tumors reached 1cm, the tumor bearing mice would be investigated further.

Monoclonal antibody fragment

HAb18 F(ab')$_2$ fragment was generated by pepsin digestion and phenyl-sepharose HP column purification with a relative molecular mass of 110,000. The solution containing the antibody fragment was concentrated by lypholization and reconstituted with distilled water.

Isotope

A 7.4GBq $^{188}W/^{188}Re$ generator was eluted with normal saline.

Radiolabeling

The antibody concentrated at 5g·L^{-1} was reduced by reaction with a molar excess of 2-ME at 4℃ for 20-30 min. The reduced antibody was isolated from reductant through a PD-10 column (Pharmacia) equilibrated with 0.05 mol·L^{-1} acetate-buffered saline.

For labeling, the reduced HAb18 F(ab')$_2$ was mixed with glucoheptonate (GH) solution, $SnCl_2$ solution, and 50-100μL perihenium solution for 2-3 h at 37℃ before it was analyzed by Whatman 3MM paper chromatography which was then developed in 100 g·L^{-1} trichloroacetic acid (TCA). R^a-f (distance of some composition moved/distance of extended reagent moved) values for 100 g·L^{-1} TCA are: mAb 0.0, ^{188}Re-GH 0.7, and ^{188}ReO-4 0.7. Labeled mAb was differentiated from ^{188}Re colloid by the method of Thrall *et al*[33]. The same strips impregnated with 10-20 g·L^{-1} human serum albumin before development with 5V:2V:1V; water: ethanol: 5 mol·L^{-1} NH_4OH(volum ratio). Colloid remained on the bottom of the strip while mAb-bound isotope migrated with the solvent front.

Immunoreactivity assessment

The *in vitro* immunoreactivity of the radiolabeled HAb18 F(ab')$_2$ was evaluated by a live cell assay[9]. Briefly, 5×10^9·L^{-1} HCC cells were centrifuged at 1000 r·min^{-1} for 5 min and washed twice with 1 g·L^{-1} bovine serum albumin (BSA) in PBS, then 5 serial 1:2 dilutions were made up in 10 g·L^{-1} BSA in Eppendorf tubes precoated with BSA. Radiolabeled HAb18 F(ab')$_2$ at a mass concentration of 40μg·L^{-1} in 10 g·L^{-1} BSA was added using a volume equal to half the volume of cell suspension. The total volume of cell-binding assay solution was 0.3 mL. After incubation for 2 h at 37℃, the total as well as the cell-bound radioactivity were counted in a gamma counter.

Study of biodistribution in nude mice

Fifteen hepatoma-bearing nude mice were divided into 5 groups randomly, the mice were tail-vein injected via tail vein with 1.85MBq^{188}Re-HAb18 F(ab')$_2$ in a volume of 0.1 mL and then they were sacrificed at 1, 4, 18, 24 and 48h (3 mice at each time). Samples of tumor, heart, liver, spleen, lung, kidney, large intestine, small intestine, muscle,bone were taken and weighed carefully. In addition, the blood sample was drawn from the heart. The radioactive concentrations in tissues were calculated and expressed as percent injected dose per gram(%ID·g^{-1}). The radioactivity of tumor/no tumor(T/NT) was also calculated.

Pharmacokinitics

The concentrations of blood and other organs were mounted by 3P97 software to get the parameters of pharmacokinetics and established the mode of pharmacokinetics was established.

RESULTS

Table 1 shows the biodistribution of ^{188}Re-HAb18 F(ab')$_2$. The blood concentration was measured by 3P97 software, which fits the 1-compartment model(Table 3). Figure 1 shows the curve of concentration-time in nude mice, and Table 2 shows the parameters of pharmacokinitics. The half-time(h) of each tissue was: tumor (32.99), blood (2.99), lung (5.67), bone (11.76), muscle (9.22), small intestine (7.47), large intestine (15.08), heart (2.29), liver (5.67), spleen (19.76),and kidney (11.53). Table 4 illustrates the influence of various concentrations of $SnCl_2$ and GH on the free $^{188}ReO_4^-$ amounts, colloid amounts and labeling efficiency. Optimal complexation with labeling efficiency of 91.7% was achieved in 0.8 mol·L^{-1} GH and 2 g·L^{-1} $SnCl_2$ solution. As shown in Figure 2, the immunoreactive fraction, 0.78 was determined by plotting the inverse of the bound fraction as compared with the inverse of the cell concentration, which is based on the assumption that the total antigen concentration (i.e., cell density) is a good approximation for the free antigen concentration.

DISCUSSION

The occurrence of hepatoma is high in Southeast Asia, East Africa and Middle Africa. In China, hepatoma is one of the most three common cancers related death, but there is no effective treatment[34-45]. The therapy of hepatoma includes surgical operation, chemotherapy and radiotherapy. Targeting diagnosis and therapy of hepatoma with anti-hepatoma Mab have been developed quickly,giving a hopeful prospect to hepatoma treatment. Our reaserch focuses on the targeting therapy of hepatoma.[46-48]^{188}Re is a generator-produced radioistope which can be obtained. There were some studies on the biodistribution and pharmacokinetics of ^{188}Re-mAb. Safavy *et al*[49]have reported biodistribution of ^{188}Re-labelded trisuccin-HuCC49 and tisuccin-C49deltaCh2 conjugates in athymic nude mice bearing intraperitoneal coloncer xenografts.^{188}Re-labeled mAb was injected,and the mice were sacrificed 24h postinjection. Biodistribution of the radiolabeled mAb at 24h after injection showed median tumor uptake values of 23.5%ID·g^{-1} and 17. 6%ID·g^{-1} for the ^{188}Re-C49deltaCh2 and ^{188}Re-HuCC49, respectively. Yang *et al*[50] have prepared the conjugate of staphylococcal exterotoxin A(SEA) protein which is a bacterical Sag and the F(ab')$_2$ fragment of HAb18. The F(ab')$_2$ fragment of mAb HAb18 was prepared by papainic digestion method. The conjugate of mAb HAb18 F(ab')$_2$ fragment and SEA was prepared with chemical conjugating reagent N-succinimidy1-3-(2-pyirdyldithio) propionate (SPDP) and purified through chromatography column Superose 12 with FPLC system. The molecular mass was identified with SDS-PAGE assay,the antibody activity of in the conjugate was determined by indirect immunocytochemical ABC method. SEA is a protein, the method of labeling is indirect, SEA and antibody are conjugated by SPDP. ^{188}Re's labeling method is direct,it is more convienient and quicker than indirect method. In the animal experiment, ^{188}Re -HAb18F (ab')$_2$ can inhibit the growth of tumor, but the pharmacokinetics of ^{188}Re- HAb18F(ab')$_2$ in animal is seldom reported.

^{188}Re- HAb18F(ab')$_2$ can last a long time at a high level (Table 1). The maximal ratio of tumor: bLood was at 48h, and maximal ratio of tumor: liver was at 18h. From Table l, we can also find that after 1, 4, and 24 h(iv) injection, the radio percent of tumor is 3.83%, 6. 48%, and 9.74%, the liver is 1.64%,2.59% and 3.19%, the kidney is 76.24%, 78.8% and 76.3% respectively, showing that the antibody and its fragments were eliminated from kidney[51-52]. The half-time of ^{188}Re- HAb18 F(ab')$_2$ in the tumor was 32.99h, it was longer in tumor than that in other organs, this indicated that ^{188}Re- HAb18 F(ab')$_2$ was located in tumor, the rate of decay was low. It also showed that the mAb was specifically combined with tumor tissues and its harmness to normal tissues was low. Pharmacokinetic parameters (AUC, blood clearance, half-life, etc) were generated using the 3P97 software.

From 3P97 software, we can see the pharmacokinecs of conform to a 1-compartment model.Table 3 shows the criteria for goodness of fitting. we can judge the compartments from R squares, goodness of fit and AIC.1,1/C,1/C/C represented three weights.To the same weight,when the F test has marked significance (P<0.05 or P<0.01),we should choose the compartment of small AIC,and when the F test has not prominent significance (P>0.05),we should choose the small compartment. [53] From Table 3, it can be seen that the 1- compartment model is the best. ^{188}Re-HAb18 F(ab')$_2$ can distribute to the whole body instantly.The elimination rate was corresponded to the concentration of the drug. The higher the concentration was, the higher the speed of elimination was.

The half-time was 32.99h in tumor, being much longer than that in any other organs.It showed that ^{188}Re- HAb18 F(ab')$_2$ was located specifically in hepatoma and the elimination was low. It also showed the higher selective reactivity of HAb18 F(ab')$_2$ with hepatoma, the

harmness to other organs was small. The half-time was 2.29h in blood, and was 32.99h in tumor,the radioation of blood can decrease more rapidly than that of the tumor. The half-time of ^{188}Re was 17h, which was also lower than that in blood, so the ^{188}Re can be eliminated through the blood. It has excellent value in the clinical therapy.[54-62]

Carrier-free ^{188}Re is one of β emitting radionuclides recommended for RAIT because of suitable decay characteristics and availability from ^{188}W/^{188}Re generator. Some methods are reported in the literature for labeling mAb with ^{188}Re which imitate the labeling method of ^{99}Tcm. ^{188}Re eluted from generator will not bind to organic ligands without reduction to a lower oxidation state. We selected $SnCl_2$ as reductant and GH as transfer ligand and stablizer to avoid Sn- or Re-collide formation. Table 1 shows that the concentration of $SnCl_2$ and GH solutions is an important parameter to obtain good labeling results. The low percentage of free $^{188}ReO^-_4$ and radiocolloid shows that 0.8 mol·L^{-1} GH and 2g·L^{-1} $SnCl_2$ are the optimal values. Under these conditions, the labeled HAb18 F(ab')$_2$ keeps its immunoreactivity (Figure 2).

We believe that a variety of factors make ^{188}Re a potential alternative to other β-emitting radionuclides for RAIT. They include an efficient generator system and the direct labeling of IgG at high specific activity. The enchanced clearance of ^{188}Re-IgG from the circulation and the retention of immunoreactivity and tumortargeting of the Re-mAb conjugate are also important factors. In addition, the low-energy(155keV,15%) γ emission for imaging and the lack of accretion of metabolic products in nontarget tissues are important characteristics for further evaluation of ^{188}Re-labeled antibodies for tumor therapy.

Abstract

AIM: **To conduct a randomized trial to evaluate the role of using high-dose iodized oil transcatheter arterial chemoembolization(TACE) in the treatment of large hepatocellular carcinoma (HCC).**

METHODS: **From January 1993 to June 1998, 473 patients with unresectable hepatocellular carcinoma were divided into two groups: 216 patients in group A received more than 20mL iodized oil during the first TACE treatment; 257 patients in group B received 5-15mL iodized oil in the same way. The Child's classification and ICG-R15 for evaluating the liver function of the patients were done before the treatment. During the TACE procedure the catheters was inserted into the target artery selectively and the tumor vessels were demonstrated with contrast medium in the hepatic angiography. The anticancer drug mixed with iodized oil (Lipiodol) were Epirubicin and Mitomycin. In group A, 112 cases received 20-29mL Lipiodol in the first procedure, 85 cases 30-39mL, 19 cases more than 40mL. The largest dose was 53 mL and the average dose was 28.3mL. In group B, 119 cases received 5-10mL Lipiodol, 138 cases received 11-15mL, and the average dose was 11.8mL.**

RESULTS: **High-dose Lipiodol chemoembolization caused tolerable side effects and a little hurt to the liver function in the patients with Child grade A or ICG-R15 <20. But the patients with child grade B or ICG-R15> 20 had higher risk of liver failure after high-dose TACE. More type I and type II lipiodol accumulations in CT scan after 4 weeks of TACE were seen in the group A patients than those in the group B patients (P<0.01). The resection rate and complete tumor necrosis rate in group A were higher than those of group B (P<0.05). The 1-,2-,3-year survival rates of group A patients with Child grade A were 79.2%, 51.8% and 34.9%, respectively, better than those of group B (P<0.001).**

CONCLUSION: **High-dose Lipiodol can result in more complete tumor necrosis by blocking both arteries and small portal vein of the tumor. High-dose TACE for treatment of large and hypervascular hepatocellular carcinoma is practically acceptable with the better effect than the routine dose. For the patients with large and hypervascular tumor of Child grade A liver function or ICG-R15 less than 20%, oily chemoembolization with 20-40mL Lipiodol is recommended.**

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors in human beings. It was estimated that in 1985, about 315, 000 new cases of primary liver cancer occurred worldwide, accounting for 4.1% of all human cancer cases[1]. In the same year, 312,000 patients died as a consequence of the disease. In China, HCC is responsible for 130,000 deaths every year and is the second cause of the cancer deaths[2]. The crude mortality of HCC was 20.4 per 100,000 population, accouning for 18.8% of the total cancer deaths in 1990-1992[3].

About 80% of HCC are associated with cirrhosis that makes treatment more difficult[4]. Surgical resection is the best options for the treatment of HCC and the 5-year survival rate after hepatectomy was about 20%-40%[5]. But in only 20% of HCC patients the surgical resection is feasible. About 60%-70% HCC were in late stages at the time of diagnosis and had lost the chance of operation[6-8]. Transcatheter arterial chemoembolization (TACE) is one of the most common method for the treatment of the unresectable HCC[9,10]. The results achieved by using TACE were much better than those of systemic or regional chemotherapy[11,12]. TACE with anticancer agent suspended in an oily substance has become one of the standard forms of treatment for advanced HCC. In the treatment, iodized oil is used as an embolic agent and carrier of anticancer drugs[13,14]. After entering into the small arteries and peritumoral sinusoid of HCC through a catheter, the iodized oil can be retain there to block the terminal blood flow. The more iodized oil entering into the small arteries and peritumoral sinusoid of HCC, the more complete blocking of the terminal blood supply to the cancer will occur[15,16]. But in such ease more iodized oil may flow into the portal vein causing infarction or necrosis in the noncancerous hepatic tissue, and thus lead to the more liver dysfunction. Generally the amount of iodized oil recommended is about 5-15 mL at each procedure for fear that more iodized oil could lead to liver dysfunction[17,18]. In clinical practice, most patients who received TACE were those with large HCC. For the large and hypervascular liver tumor, using 5-15 mL iodized oil is not enough to attain complete filling of tumor vessel bed. To get a full blocking of the tumor vessels, a larger volume of iodized oil is necessary. Basing on the experience of our clinical practice and the good evaluation of liver function, we conducted a high-dose (more

than 20mL) iodized oil TACE for the large HCC.

MATERIALS AND METHODS

Eligibility of patients

From January 1993 to June 1998, 473 patients with large HCC who were eligible for this study were treated at the Tumor Hospital of Sun Yat-sen University of Medical Sciences. The eligibility criteria for entering this study were as follows: ① a diagnosis of HCC was established on the basis of the patient's high serum alpha-fetoprotein (AFP) value, findings obtained at computed tomography(CT) scan and clinical manifestations; ② the largest diameter of the tumor exceeded 5 cm; ③ there was no evidence of portal trunk occlusion by thrombosis, extrahepatic metastasis, jaundice or ascites; ④ during the TACE procedure the catheter was successfully inserted into the target artery selectively as proved by angiography. We excluded patients who had Child's C grade liver function or ICG-R15 (indocyanine green retention rate in 15 min)>30%. All patients were randomly divided into two treatment groups. In Group A, 216 patients received more than 20mL of iodized oil in the first TACE, and in Group B, 257 patients received 5-15mL.

Clinical Characteristics of the patients

The clinical characteristics of the patients including age, sex, size of tumor, thrombosis in portal branch, AFP, serum alanine aminotransferase(ALT), Child's grading, ICG-R15 were collected before the treatment. The patients in the two groups did not differ significantly with respect to these clinical characteristics (Table 1).

Methods of chemoembolization

During the hepatic angiography that demonstrated the tumor vessels and tumor contour, the catheter was inserted selectively into the targetartery. The catheter tip was placed as close as possible to the tumor for attaining the high-selective embolization[19]. The first 5-10 mL iodized oil (Lipiodol, Laboratorie Guerbet, Aulnay-sous-Bois, France) were mixed with anticancer drugs, Epirubicin(50 $mg \cdot m^{-2}$) and Mitomycin(8$mg \cdot m^{-2}$), to form an emulsion. The emulsion was slowly injected under fluoroscopic control. The remainder Lipiodol was added according to the state of accumulation of the emulsion within the tumor at the first injection, speed of blood flowing to the tumor, and appearance of portal vein around the tumor (Figure 1). Gelatin sponge impregnated with contrast medium was injected into the tumor, if the blood flow to the tumor wasn't slowed down enough after the Lipiodol injection[20]. Any embolization was terminated when the blood flow to the tumor had slowed down.

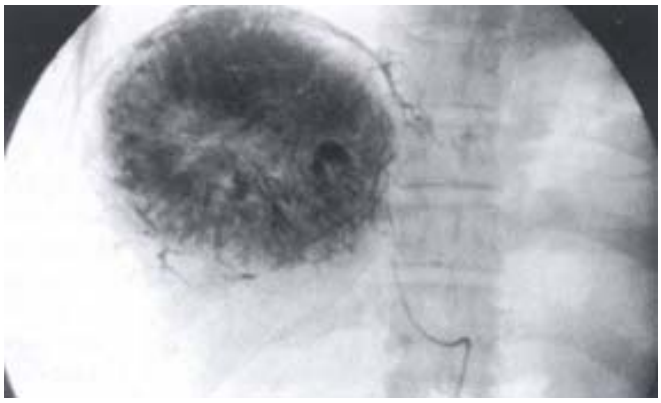

Figure 1 Portal vein branches around the tumor as visualized by high-dose iodized oil

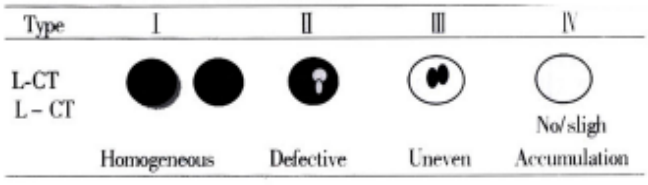
In group A, 112 cases received 20-29mL Lipiodol in the first procedure, 85 cases 30-39mL, 19 cases more than 40mL; the largest dose was 53 mL and the average dose was 28.3mL. In group B, 119 cases received 5-10mL Lipiodol and 138 cases received 11-15mL; the average dose was 11.8mL.

Follow-up

Four weeks after TACE, the therapeutic effect was assessed by double phase CT scan and AFP test. The CT was performed after a bolus administration of 50-100mL of contrast material[21]. The pattern of Lipiodol accumulation on CT were classified into following four kinds according to Nishimine[22]: type I, homogeneous; type II, defective; type III, inhomogeneous; and type IV, only slight accumulation, if any (Table 2). Type I was further subgrouped into type I a (with accumulation around the tumor) and type Ib (without accumulation around the tumor). AFP was tested at 4 wk intervals after first TACE.



A repeat TACE and other therapies were performed depending on the conditions of the patient after the first TACE. 11 patients underwent totally 5 times TACE; 32 underwent 4; 139 underwent 3; 207 underwent 2; 84 underwent 1. 59 patients underwent percutaneous ethonal injection(PEI) after TACE and 46 patients received surgical

resection. Survival was measured from date of the first treatment until death. The causes of death were determined for 347 patients during the follow-up period. When a patient died from advanced carcinoma, hepatic failure or a deterioration of his or her general condition shortly after the procedure, the patients death was considered to be due to treatment failure.

Statistical analysis

The changes of liver dysfunction and CT type was analyzed by chi-square test. Cumulative survival rates were estimated by the Kaplan-Meier method. The relationship between each of the variable and survival was assessed by log rank test. "Significant" indicated a calculated two-tailed value of <0.05.

RESULTS

Side Effects

The most frequent side effects of TACE were fever and abdominal pain. In Group A abdominal pain occurred in 53.7% of the patients, fever in 71.3%, vomiting in 20.8%, appetite loss in 41.7% and upper digestive tract breeding in 0.93%. In group B, abdominal pain occurred in 49.8% patients, fever in 47.5%, vomiting in 14.8%, appidit loss in 42.8% and upper digestive breeding in 1.17%. The toxic effect of the drugs on the hemopoietic system reflected in slight decreases in the white blood cell counts, platelet counts, and hemoglobin levels of peripheral blood in both groups. Elevations in the serum alanine aminotransferase, alkaline phosphatase, or total bilirubin levels were seen in the patients of both groups, but the changes were not severe and no significant differences were found between the two groups. Liver dysfunction occurred in 24 patients of group A and in 28 patients of group B. The patients with child's grade B or ICG-R15>20 had higher risk of liver failure after high-dose TACE (Table 2).

Table 2 The comparison of liver dysfunction** in two group

Group	Child-Pugh Classification		ICG-R15		
	A	B	<10%	10-19%	≥20%
Group A	5.9%(12/203)	92.3%(12/13)	1.4%(1/71)	7.9%(10/127)	72.2%(13/18)
Group B	5.5%(13/238)	84.2%(15/19)	2.2%(2/89)	5.8%(8/137)	58.1%(18/31)

**Liver dysfunction is refereed to ascites, jaundice(Tbil>34.2umol/L), or hepatic encephalopaphy

CT and AFP

CT scan was done four weeks after TACE: In group A there were 77 cases of type I, 130 cases of type II, 9 cases of type III; whereas in group B there were 27 cases of type I,108 cases of type II,90 cases of type II and 32 cases of typeIV (group A *vs* group B $P<0.001$, Figure 2). In group A, the AFP level in 78 of 91 AFP-positive patients ($\geqslant 400\mu g \cdot L^{-2}$) had decreased and in 12 of them down to normal; in group B, 81 of 114 AFP-positive patients had their AFP decrease and in 9 down to normal ($P<0.01$).

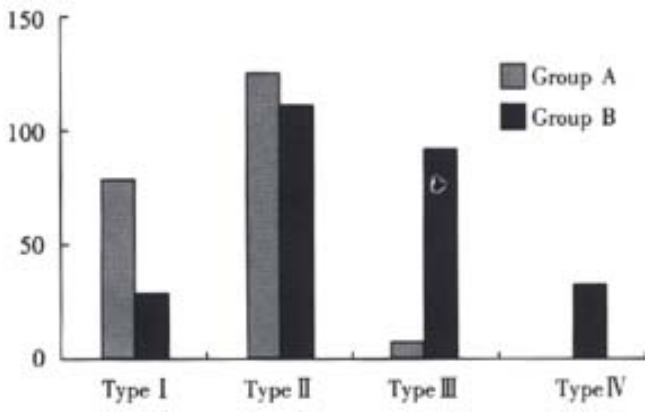


Figure 2 Comparison of CT type between the two groups.

Resection

After TACE, 47 cases achieved surgical resection in group A, and 19 of them were found to have complete tumor necrosis pathologically. In group B, 25 patients received surgical resection and only 4 cases were found to have complete tumor necrosis. The resection rate and complete tumor necrosis rate of group A were higher than those of group B ($P<0.05$).

Survival Rates

The 1-,2-,3-year cumulative survival rates of the patients with Child's grade A in group A were 79.2%, 51.8%, 34.9% and in group B was 59.1%, 26.7%, 14.9%, respectively (Figure 3). The cumulative survival rates were significantly better in group A than in groupB($P<0.001$). The 1-,2-,3-year cumulative survival rates of the patients with Child's grade B in group A were 42.1%, 21.1%, 7.7% and in group B was 46.8%, 23.7%, 0%, respectively (no significantly difference in between the two groups).

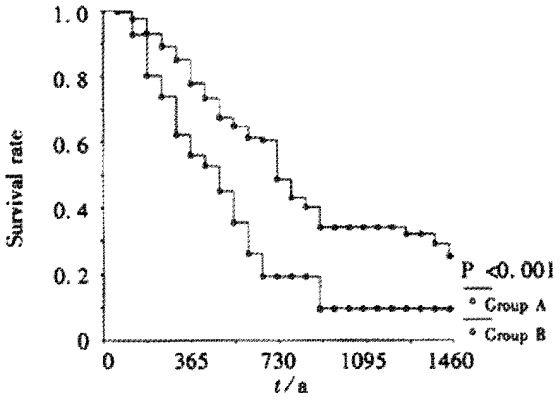

Figure 3 Cumulative survival rates of patients with Child's A in two groups.

DISCUSSION

For use in TACE, Iodized oil (mostly lipiodol) mixed with anticancer drugs has been reported to be one of the most effective agents[23,24]. Iodized oil plays an important role as an embolic agent. It not only occludes the small arteries supplying the tumor but also acts as the carrier bringing the drug to the tumor. The lipiodol can enter into the microcirculation of the tumor and stay there to stop the blood flow[25]. The experimental investigations in animal and human resected specimens revealed that the lipiodol could stay in the small artery, sinusoid, and small portal vein within the tumor. In general, the recommended amount of lipiodol is 5-15mL. The use of Iarge volume of iodized oil is more prone to invade the normal liver parenchyma, causing more live injury[26]. Matsuo[27] reported the relationship between the lipiodol dose and the tumor necrosis rates in 198 HCC cases. He found that the prognosis was better in the group of patients with bigtumors in which the doses of lipiodol were correspondingly larger tumor diameter, but the total dose must not be more than 10mL in small HCC. Other authors[28,29] comfirmed that the dose of iodized oil played an important role in TACE. A sufficiently high dose of Lp-TACE would be a factor of good tumor response, if the tumor was large. Therefore the volume of lipiodol is an important a factor influencing the antitumor effect of TACE. The large and hypervascular liver tumors have vast vessel bed. So it is necessary to inject high-dose lipiodol to attain complete filling of tumor vessel bed. While the tumor 5cm in diameter needs 5mL lipiodol to fill the vessel bed, the 10cm tumor would need at least 8 times of lipiodol to do the same work. In this situation a high-dose of iodized oil must be used for complete filling of the large tumor[30,31]. Some portal branches around the tumors are displayed after the high-

dose lipiodol pooled into the tumor; this is considered to be the sign of complete arterial block. After a certain amount of lipiodol is pooled into the hepatic microcirculation and sinusoid, any additional volume of lipiodol enter into the branches of portal vein via the sinus between hepatic artery and portal vein. And then some lipiodol is seen in the small branches of portal vein around the tumor. As the amount of lipiodol delivered into artery increase, the portal vein branches become more prominent[32]. Prominent portal vein appearances were seen in 29% patients given 10 mL or less of lipiodol, in 67% with 10-20 mL,and in 86% with more than 20 mL. It was known that infiltrating portion and nonencapsulated daughter nodules of the tumor are nourished by both the portal vein and the hepatic artery. So even if the tumor arteries are successfully embolized, some tumor cells can survive because the portal vein blood supply still exists. This may be the reason for incomplete tumor necrosis with subsequent tumor recurrence[28,15]. High-dose lipiodol fully fills the sinus and stops the portal vein supply to tumor cells after the arteries are embolized. Embolization of both hepatic artery and small portal veins may cause complete necrosis of the tumor infiltrating portion and nonencapsulated daughter nodules[13,14]. The visualization of some portal vein tributaries around the tumor may be a sign of complete embolization.

After Lp-TACE it is important to estimate the amount and state of iodized oil accumulating within the tumor, because this has much bearingon the prognosis of the patients[33]. Matsuo[27] found that the volume of lipiodol infusion correlated with the CT type. If the lipiodol volume is greater than the tumor mass in the small HCC, more type I lipiodol accumulation will be seen in the CT scan after Lp-TACE. He suggested that the lipiodol volume should be greater than the tumor mass, but the maximum dose should be less than 10 mL for fear of liver dysfunction even in the large HCC. Nishimine[22] reported that tumors of CT type I have the highest cumulative survival rates and those of the typeI have higher cumulative survival rates than type III and type IV. The iodized oil retention was again evaluated by using CT scan one month after TACE. It was found that the patients with iodized oil retention in the tumor greater than 50 per cent of tumor size survived longer than patients with retention of less than 50 per cent[34-36] . Our study showed that high-dose lipiodol could bring about more type I and type II lipiodol accumulation than a routine dose. Pathological sgudy of resected specimen after TACE showed that the area of lipiodol retention in CT was the necrotic area of the tumor. The high-dose lipiodol would lead to more lipiodol retention in the necrotic tumor[37,38].

For preventing severe side effects, attention must be paid. The liver reserve function must be evaluated by Child's grading and ICG-R15[39,40,41,42]. Our data showed that the liver dysfunction most frequently occurred in the patients with child's B or ICG-R15>20. The patients with Child's A or ICG-R15<20 were usually tolerant of 20-40mL lipiodol. Nonetheless, a high-dose lipiodol is contraindicated for the patients with child's B or ICG-R15>20. Second, to avoid normal liver parenchyma damage a high-selective placement of the catheter is crucial for injecting high-dose lipiodol. We mainly used the 5F Yasilo catheter or 5F RH catheter to perform the high selective catheterization. Subsegemental or segmental embolization is necessary for the high-dose lipiodol infusion[43,44]. If the tip of catheter can't pass over all the arteries that flow to normal tissue and organ, high-dose lipiodol injection should be done with caution. Finally, slow injection under fluorescopic guidance is also important to let all the lipiodol flow clearly into the tumor vessels. Whenever the lipiodol flows to the outside of tumor, injection should be stopped immedialely. In the condition that all the lipiodol selectively enters into the tumor and doesn't flow to the normal liver tissue, the hepatic function will not be deteriorated[45,46]. We safely injected 53mL into a large HCC with a diameter >20cm. If the blood flow is still fast toward the tumor after lipiodol infusion, Gelatin sponge should be prescribed[47]. High-dose lipiodol TACE can bring about more tumor necrosis. So high-dose lipiodol TACE results in higher survival rate.

It is concluded that high-dose lipiodol can bring about more completely tumor necrosis by blocking both the arteries and small portal veins of the tumor. High-dose TACE for treatment of large and hypervascular hepatocellular carcinoma is practically acceptable and gives a better effect than those using a routine dose. For the patients with large and hypervascular tumors and with Child A or ICG-R15 less than 20%, chemoembolization with 20-40mL lipiodol is recommended.

Abstract

AIM: **To study the anti-tumor effect of resveratrol alone and the synergistic effects of resveratrol with 5-FU on the growth of H22 cells line *in vitro*.**

METHODS: **The number of cells was measured by MTT method,the morphological changes of H_{22} cells were investigated under microscopy and electron microscopyq.**

RESULTS: **Resveratrol inhibited the growth of hepatoma cells line H_{22} in a dose- and time-dependent manner. IC_{50} of the resveratrol on H_{22} cells was 6.57mg·L^{-1}. The synergistic anti-tumor effects of resveratrol with 5-FU increased to a greater extent than for H22 cells treated with 5-FU alone (70.2% *vs* 28.4%)(P<0.05).Under microscope and electron microscope, characteristics of apoptosis such as typical apoptotic bodies were commonly found in tumor cells in the drug-treated groups.**

CONCLUSION: **Resveratrol can suppresses the growth of H_{22} cells *in vitro*, its anti-tumor activity may occur through the induction of apoptosis.**

INTRODUCTION

Hepatoma is common in China[1-20],but only a few chemotherapeutic drugs hold a high place in the treatment of human primary hepatocellular carcinoma (PHC).Resveratrol, a phytoalexin found in grapes, fruits, and root extracts of the weed Polygonum cuspidatum, has been an important constituent of Japanese and Chinese folk medicine. Indirect evidence suggests that the presence of resveratrol in white and rose wine may explain for the reduced risk of coronary heart disease associated with moderate wine consumption.This effect has been attributed to the inhibition of platelet aggregation and coagulation, in addition to the antioxidant and anti-inflammatory activity of resveratrol[21-28].Moreover, a recent report shows that resveratrol is a potent cancer chemopreventive agent in assays representing three major stages of carcinogenesis[29-35].The ability to inhibit cellular events associated with tumor initiation, promotion, and progression has been attributed to the anticyclooxygenase activity (COX-1) of resveratrol[36]. We report here the results of our findings showing that resveratrol inhibited the growth of hepatoma cells line H_{22}.

MATERIALS AND METHODS

Reagents

Resveratrol was kindly provided by Prof Li(Environment and Chemical Engineering School,Xi'an Jiaotong University)and dissolved in dimethylsulfoxide (DMSO);MTT was obtained from Sigma. PRMI1640 containing 100 mL·L^{-1} fetal bovine serum (FBS) was bought from Gibco. All other chemicals were standard commercial products of analytical grade.

Cell culture

H_{22} cells were obtained from Center of Molecular Biology of First Hospital, Xi'an Jiaotong University and routinely cultured in RPMI 1640 containing 100 mL·L^{-1} FBS at 37℃ in an atmosphere with 50mL·L^{-1} CO_2.

Assay of cell proliferation

H_{22} cells were plated in 96-well plates (2×10^4/well) for 24 h before the addition of resveratrol. Medium was then aspirated and replaced with fresh RPMI 1640 + 100 mL·L^{-1}FBS containing resveratrol for 48 h. Different compositions to be tested were added according to designed groups: group A (cell control group) with nothing added, group B (DMSO control group) with DMSO 5 mL·L^{-1}, group C1-5 with Resveratrol (1.25,2.50,5.0, 10.0 and 20.0 mg ·L^{-1}),group D 1-25-FU (2400 and 1200 mg·L^{-1}), group E with Resveratrol 5.0 mg ·L^{-1}+5-FU 1200 mg ·L^{-1} .Each group had 4 wells and was cultured for 48 h. The number of cells was determined by MTT (3-[4,5-dimethylthiazol-2-yl]-2, 5-diphenyl tetrazolium bromide) method as described in Sigma Technical Bulletin (Sigma, MO). Absorbance at 570nm (A) was assayed at different time points.The A value was adjusted with the living cell number. Each sample was assayed three times. Inhibition rate(%)=(1-experimental A/control A)×100%.

Morphologic observation

After the cellular culture for 48h, cells in groups A,C and E were observed and photographed with an Olympus BH-I microscope and a Hitachi-600 electron microscope.

RESULTS

Growth inhibition of H_{22} cells

H_{22} cells at 2×10^4/well were incubated with different concentrations of resveratrol for 8 - 48 h and the effect of resveratrol on the cells growth was examined by MTT assay. The growth of H_{22} cells was markedly inhibited by resveratrol with the IC50 value of 6.57 mg·L^{-1}. Moreover,the cytotoxicity of resveratrol was in concentration-dependent and time-dependent manners (Table 1) . The inhibition ability of 5-FU was 49.2%(2400mg·L^{-1}),28.4% (1200 mg·L^{-1}) respectively;The inhibiting ability of resveratrol (5.0 mg·L^{-1})combined with 5-FU(1200mg·L^{-1}) was higher than that of 5-FU alone(70.2% *vs* 28.4%,P<0.05).

Morphology observation

Apoptotic cells were found in cells incubated with resveratrol. Light microscopic observation showed that apoptotic cells were characterized with cytoplasmic condensation, vacant bubbles, and condensed nuclei(Figure 1). Under electron microscope, H_{22} cells exhibited the characteristics of apoptosis including cytoplasmic condensatin, pyknotic nuclei, condensed chromatin and apoptotic bodies(Figures 2,

3). Compared with control groups, groupC and E had much more cells with the apoptotic characteristics.

Table 1 Effect of various concentrations of resveratrol on the growth of hepatoma cells H_{22}

c(resveratrol) / mg ·L^{-1}	8h	12h	24h	48h
0.00	-	-	-	-

DISCUSSION

To date, only a few chemotherapeutic drugs hold a high place in the treatment of human primary hepatocellular carcinoma (PHC) and there is clearly a need for evaluation of new anti-hepatoma drugs. Resveratrol (3,5,4'-trihydroxystibene), a natural compound present in grapes and other food, has been shown to provide cancer chemopreventive effects in different systems based on its striking inhibition of diverse cellular events associated with tumor initiation, promotion, and progression[29-35,37]. At the molecular level, these effects were related to the inhibition of free radical formation and cyclooxygenase activity[36], as well as induction of differentiation. In addition, resveratrol was shown to be a remarkable inhibitor of ribonucleotide reductase and DNA synthesis with cellular arrest in the S phase or the S-G2 phase transition[38-40]. In the present study, MTT assay was used to observe the effect of resveratrol on the growth of H_{22} mouse hepatoma cells *in vitro*, indicating that the drug could inhibit the growth of hepatoma cells. Its concentration- and time-effect relationships were also significant. Compared with control groups, group C had much more cells with apoptotic characteristics. The plausible mechanisms that could account for the anti-tumor activity of resveratrol might be related to induce apoptosis of tumor cells[41-48].

Resveratrol combined with 5-FU inhibited the cell growth much more strongly than each agent used alone. At a certain concentration, resveratrol inhibits H_{22} cell growth with the same effect as using 5-FU alone. Combination of resveratrol and 5-FU could have a cooperative effect. Both drugs inhibit cell growth at different phases of the cell cycle, i.e, resveratrol mainly causes G2/M arrest[39-40] and 5-FU mainly inhibits DNA synthesis(S phase) which naturally decreases the cellular growth more significantly. Our study indicates that combined use of resveratrol and 5-FU at low concentration that is used to treat hepatoma may be more efficient than using a single drug at higher concentration.The side-effects produced by 5-FU at the high doses can be avoided by its combination at lowdoses. These results suggest that resveratrol, may be potentially useful as a biochemical modulator to enhance the therapeutic effects of 5-FU in cancer chemotherapy.

Abstract

AIM: **To evaluate the value of superparamagnetic iron oxide (SPIO) enhanced MRI in characterizing focal hepatic lesions.**

METHODS: **Forty-three patients (32 men, 11 women, mean age 51 years, age range 25-74 years) with previously identified focal hepatic lesions were enrolled into this study. All the patients underwent plain,Gd-DTPA enhanced MRI and the SPIO enhanced MRI 1-7 d later. The surgico-pathologic diagnosis was aestablished in 31 cases and the diagnosis in other 12 cases was made on the basis of clinical findings and biochemical tests. The signal changes of lesions were analyzed and the CNRs of lesion-to-liver were measured before and after SPIO enhancement. The data were analyzed by paired *t* test.**

RESULTS: **Focal hepatic lesions included primary hepatocellular carcinoma (HCC, *n*=22), hemangioma (*n*=5), cyst (*n*=4), metastases (*n*=5), cirrhotic nodule (*n*=4), focal nodular hyperplasia (FNH, *n*=5) and other miscellaneous lesions (*n*=6). After SPIO enhancement HCC demonstrated iso- or slight hyperintensity on T1WI and moderate hyperintersity on T2WI, hemangioma showed moderate hyperintensity on T1WI and obvious hyperintensity on T2WI, the SI of cyst had no change either on T1WI or on T2WI, cirrhotic nodules revealed iso-intensity on T2WI, and the SI of FNH decreased significantlyon T2WI. No specific manifestations were found in the other 6 miscellaneous lesions after SPIO enhancement.**

CONCLUSION: **SPIO enhanced-MRI can improve the characterization confidence for diagnosis of focal hepatic lesions.**

INTRODUCTION

Superparamagnetic iron oxide (SPIO) is a newly developed tissue-specific contrast material. Intravenously administrated SPIO particles can be specifically taken up by reticulo-endothelial system, and the signal intensities of normal hepatic and splenic parenchyma are significantly decreased on MR images. Therefore, it has been widely applied for lesion detection in the liver[1-6]. After SPIO-enhancement the detectablity of focal hepatic lesions smaller than 1cm could be increased from 65.9% to 97.5%. However, to our knowledge, the previously reported studies were mainly concerned about the detection of hepatic metastatic lesions and only a few studies focused on the characterization of focal hepatic lesions[4-13]. Thus, the purpose of this study is to evaluate the diagnostic value of superparamagnetic iron oxide in demonstrating benign and malignant focal hepatic lesions.

MATERIAL AND METHODS

Patients

Forty-three patients (32 men, 11 women, mean age 51 years, age range 25-74years) with previously identified focal hepatic lesions were enrolled into this study. The pathologically proven diagnosis was achieved in 31 cases and the other 12 cases were diagnosed on the basis of clinical findings and biochemical tests. Most lesions were smaller than 3cm. Three cases previously suspected of having focal hepatic lesion were finally confirmed as cirrhotic nodules after SPIO-enhancement. In the remaining 40 patients showed multiple hepatic lesions were found in 22 and solitary in 18, including malignant lesions in 29 cases and benign lesions in 11 cases. The malignant lesions included: primary hepatocellular carcinoma (HCC, *n*=22) associated with hemangioma or cyst in 4, cholangiocarcinoma with cysts (*n*=1),and cholangiohepatocarcinoma (*n*=1), metastases (*n*=5). The benign lesions included: multiple hemangiomas (*n*=2), focal nodular hyperplasia (FNH, *n*=5), angiolipoleiomyoma (*n*=1), inflammatory pseudotumor with hemangioma and cysts (*n*=1), multiple abscess (*n*=1) and focal inflammation with hemangioma (*n*=1).

Contrast agent

Gadopentetate dimeglumine (Magnevist; Schering, Berline, Germany) was manually administered through antecubital intravenous bolus of 0.1mmol/kg. Feridex (Advanced Magnetics, USA) is an iron oxide preparation coated with low-molecular-weight dextan available in 5mL vial containing 11. 2mg iron and 61.3mg mannitol/mL. Feridex at a dose of 0. 05mL·kg^{-1} (0.56mg Fe·kg^{-1}) was diluted with 100mL of 5g·L^{-1} glucose and infused intravenously at a rate of 3mL·min^{-1}.

Imaging procedure

The GE Signa 1.5T MR imaging system was used. The whole procedure including: ① non-enhanced images: SE T1-weighted (TR/TE=540ms/15ms), FSE T2-weighed with fat suppression (TR/TE=3000-4000ms/98ms); ② Gd-DTPA enhanced images: FMPSPGR with dynamic enhancement; and ③ SPIO-enhanced images: 1-7 d later, SE T1-weighed, FSE T2-weighed, FSE T2-weighed with fat suppressed sequences, were performed after SPIO administration. Transverse images were obtained with a slice thickness of 8mm, a section gap of 1-2mm, a field of view of 360mm and matrix size of 256×160.

Imaging analysis

The images were reviewed by 3 experienced radiologists. The signal intensities (SI) of normal hepatic parenchyma, hepatic lesions and

signal change of lesion-to-liver were measured before and after administration of SPIO. Regions of interest (ROI) with at least 50 pixels on homogeneous background free of artifacts. ROI were chosen to be representative of the tissue being evaluated. Measurements were made at the same anatomic level for unenhanced and enhanced images in each patient. If patient had multiple lesions with the homogeneous character, the typical one was selected, otherwise the lesions were analyzed individually.

RESULTS

Totally 12 kinds of benign and malignant diseases were observed in 43 patients. The CNR of lesion-to-liver was evaluated on each sequence (Tables 1 and 2). After SPIO-enhancement the ratios of lesion-to-liver were significantly raised on T1-weighed images except that of cyst, while on T2-weighed images the hepatic cirrhoticnodules and FNH's ratios of lesion-to-liver showed no significant difference before and after SPIO-enhancement.

Table 1 The CNR of lesion-to-liver on T_1WI

Lesion (cases)	T_1WI	SPIO-enhancedT_1WI	*P*
HCC (22)	-10.2±8.3	19.9±23.8	<0.001

HCC was found in 22 patients. The lesions were iso- or hypointense on T1-weighed images and slightly hyperintense on T_2-weighed images before enhancement. After SPIO administration, 11 cases of the lesions became slightly hyperintense, 10 were isointense and 1 was hypointense on T_1WI, while on T_2WI all lesions appeared hyperintense. The mean CNRs of lesion-to-liver on T1WI and T_2WI were greatly improved from -10.2±8.3, 98.4±58.6 to 19.9±23.8, 465.8±272.7 respectively after SPIO administration. The difference had statistical significance (P<0.001). After Gd-DTPA administration, 17 cases showed obvious enhancement while the other 5 cases enhanced mildly in early phase. Characteristically, the signal intensity or enhancement of the lesions decreased significantly in portal and delayed phases (Figure 1A-C).

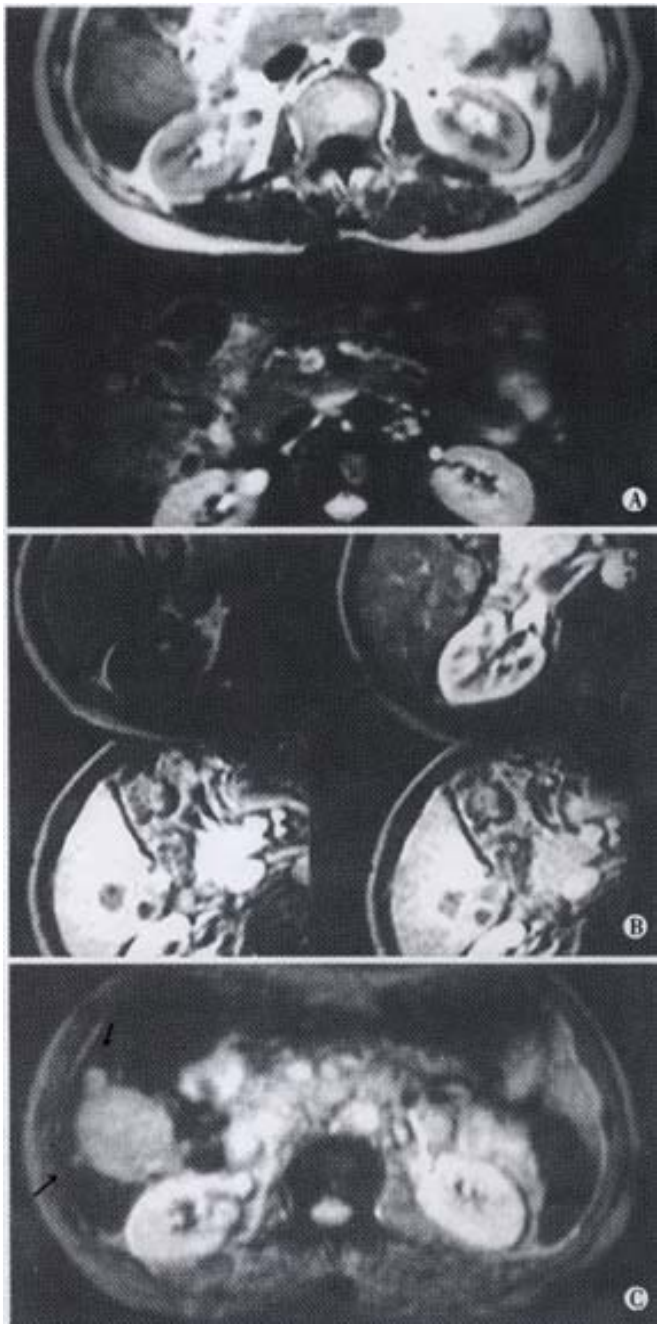

Figure 1 Primary hepatocellular carcinoma in posterior right lobe. The lesions appear hypointenity on T_1WI and mildly hyperintensity on T_2WI (A). On Gd-DTPA enhanced images, early enhancement can be seen in arterial phase and appear relatively hypointensity in portal phase.(B) On SPIO-enhanced image, the conspicuity is clearer than pre-contrasted and Gd-DTPA enhanced images. Two micro-lesions(arrow) are obviously showed (C).

Hepatic hemangioma was revealed in 5 cases. The lesions were iso- or hypointense on T_1WI and markedly hyperintense on T_2WI in pre-contrast images. After SPIO-enhancement distinct SI increase was noted and the CNR of lesion-to-liver increased from -16.4±8.6 to 71±33 (P<0.05) on T1WI. The signal intensity showed no perceivable change on T_2WI ,but the CNR of lesion-to-liver was greatly increased because of the signal loss of the background after SPIO administration (Figure 2A, B). After Gd-DTPA enhancement, the lesions were gradually filled by the contrast from peripheral to central area and were kept hyperintense in portal and delayed phases.

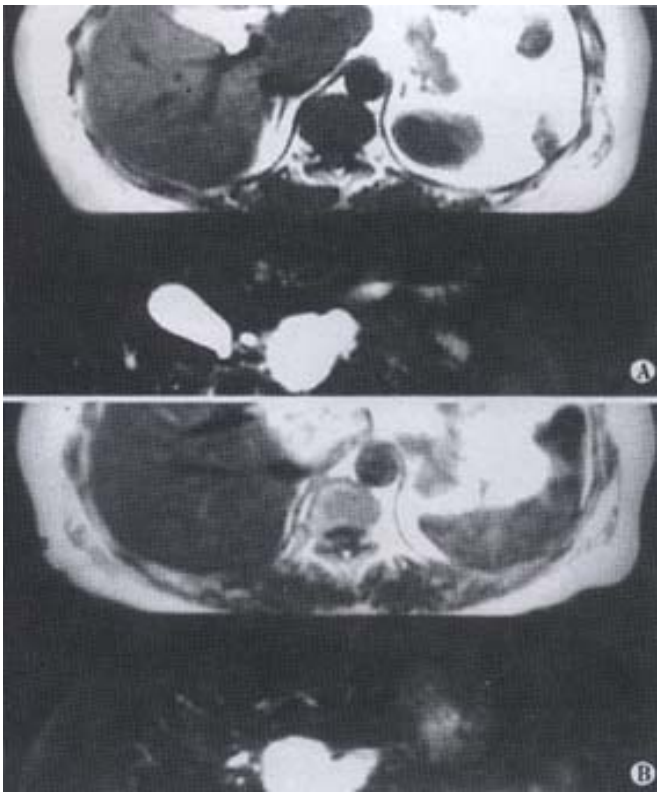

Figure 2 Hepatic hemangioma. (A) The lesion shows hypointensity on T_1WI and hyperintensity on T_2WI on pre-contrast images.(B) After SPIO administration, the lesion become hyerintense on both T1WI and T2WI (arrow).

Hepatic cyst was found in 4 patients. The SI of the cyst had no change after SPIO-enhencement. The hypointensity of cystic lesions on T1WI after SPIO-enhancement was characteristic,thus it could be distinguished from other focal hepatic lesions. The hepatic cyst showed no enhancement after Gd-DTPA administration.

Metastasis was observed in 5 cases. The lesions were hypointense on T_1WI pre-enhancement and iso- or hypointense during post-enhancement. On T_2WI they were mildly hyperintense before enhancement and relatively hyperintense after enhancement because of obvious signal decrease of adjacent normal liver parenchyma. Such change of SI had no diagnostic value because many other focal hepatic lesions could have the similar appearance after SPIO enhancement. The appearance of lesions varied after Gd-DTPA administration, most of them showed peripheral enhancement, or with " bull eyes" sign, or only slightly enhanced.

Cirrhotic nodule was found in 4 patients, which was associated with HCC in one patient. On pre-contrast T_1WI cirrhotic nodules appeared slightly hyperintense differing from other focal hepatic lesions. That the cirrhotic nodule contained Kupffer cells which could take up SPIO particles made it have the same SI as that of the surrounding liver parenchyma after SPIO administration. The cirrhotic nodules showed no early enhancement after Gd-DTPA administration and pertained iso- or hypo-intense in portal and delayed phases.

Focal nodular hyperplasia (FNH) was observed in 5 cases. The lesions were slightly hypointense on unenhanced T_1WI. The appearances of FNH on T_2WI were variable and could be hyperintense(n=2), heterogeneously intense(n=2) and iso-intense(n=1) which was unable to be detected. After SPIO-enhancement, SI of the lesion decreased markedly and appeared iso- or slightly hyper-intense on T_2WI,which was characteristic for FNH. On Gd-DTPA enhanced image, the manifestation was also characteristic: it was obviously enhanced in early phase and continuously kept hyperintense in portal and delayed phases (Figure 3A-C).

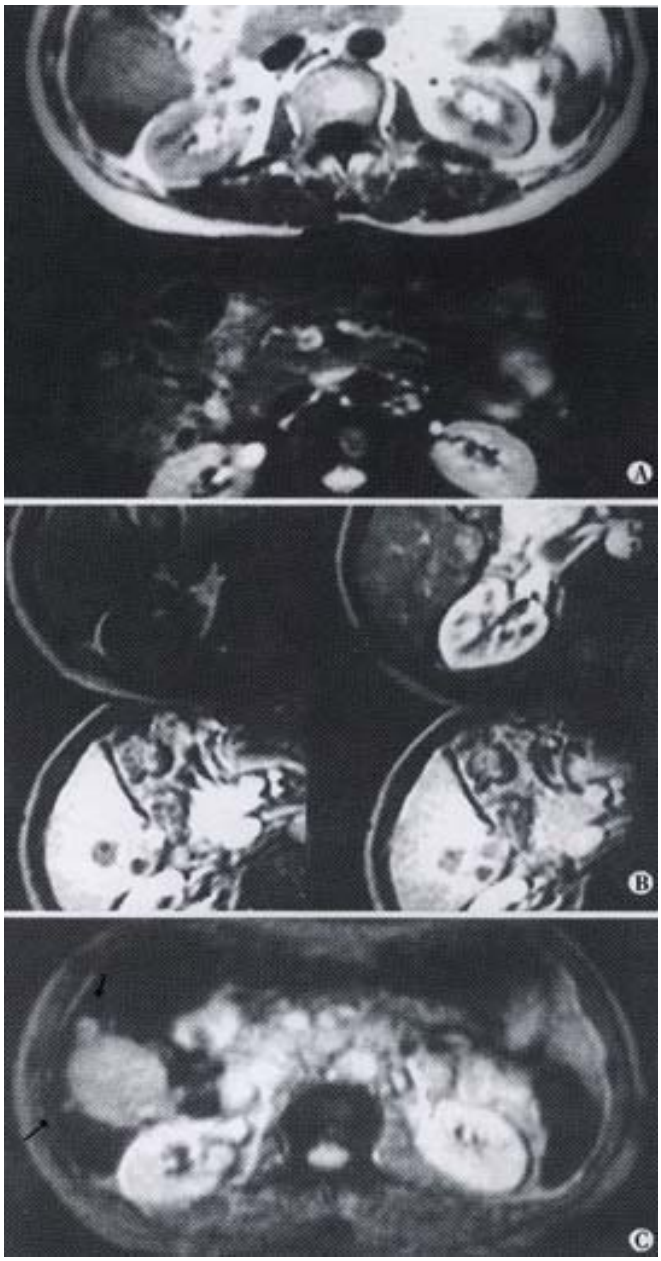

Figure 3 Focal nodular hyperplasia(FNH). Before enhancement, the lesion (arrow) presents hypointensity on T_1WI and heterogeneous hyerintensity on T_2WI (A). After Gd-DTPA administration, the lesion is obviously enhanced in arterial phase and remains hyperintense in portal and delayed phase (B). On T_2WI after SPIO enhancement, the lesion(arrow) has focal signal loss compared with the un-enhanced image (C).

Other focal hepatic lesions were found in 6 cases including cholangiocarcima (n=1), inflammatory pseudotumor (n=1), hepatic abscess (n=1), focal inflammatory lesion (n=1), angiolipoleiomyoma (n=1), and cholangiohepatocarcinoma (n=1). These lesions were hypointense on T1WI and slightly or moderately hyperintense on T2WI before enhancement. The appearances were non-specific after SPIO-enhancement although the contour of lesions was clear and the CNR of lesion-to-liver increased, which was helpful in improving the detectablity or conspicuity. The appearances of these lesions on Gd-DTPA enhanced images were also diversified.

DISCUSSION

As a non-specific extracellular contrast material, Gd-DTPA has been widely used in MR imaging of the liver. Dynamic Gd-DPTA-

enhanced MR images can provide much useful information of the blood supply of lesions and thus highly improving the accuracy of diagnose of focal hepatic lesions. However, Gd-DTPA has several disadvantages such as non-specific distribution, quickly reaching equilibrium throughout extracellular compartment and having slightly nephrotic toxicity. As a negative contrast material, namely reticulo-endothelial system specific contrast agent, the particles of SPIO can be taken up primarily by the hepato-splenic Kupffer cells. The collection of SPIO particles can produce a focal heterogeneous magnetic field which shortens T2 relaxation time predominantly, leading to a significant decrease of SI of normal hepatic parenchyma and remarkable improvement for the focal lesion detection. The prolonged half-life time and widened scanning time-window are also helpful in making examination more convenient[1,4,5,13-15,17].

The signal intensity of normal hepatic parenchyma decreased both on T_1WI and T_2WI after SPIO-enhancement, especially on T_2WI. The SI of HCC changed a little due to lack of Kupffer cells, but the signal loss of background inversely makes the HCC appear hyperintense. As a result ,the CNR of lesion-to-liver increased and the detection of HCC after SPIO-enhancement being improved. There are a few of reports dealing with the appearance of HCC on SPIO-enhanced MR images[9,14,17-22]. Grangier described HCC's feature in 10 cases after SPIO enhancement and concluded that the HCC presenting iso-intensity on TIWI was the key point for differentiating HCC from hemangioma and cyst[11]. However, we believe that it might be inappropriate because the appearances of HCC in our 22 cases on enhanced-T_1WI were slightly hyper-intense, isointense and hypointense which were 50% (11/22), 45. 5% (10/22) and 4.5% (1/22) respectively. This might be attributed to more examples in our study or the difference of HCC's differentiation between the two studies.The non-characteristic appearances of HCC on pre- and post-SPIO-enhanced T_2WI made it difficult to distinguish from other malignant lesions. Moreover, the signal changes on pre- and post-enhanced T_1WI can exclude the possibility of hemangioma and cyst. Accordingly, the accurate diagnosis of HCC must not merely rely on the appearance of lesion on SPIO-enhanced MRI but on the combination with the clinical findings and biochemical tests. After Gd-DTPA administration, the precise diagnosis in most cases can be made according to the enhancement pattern of the lesion. Typically, HCC is enhanced rapidly in arterial phase and the contrast agent is soon washed out in portal phase. So we believe that, only for those the diagnoses are indefinite or the appearances of lesion are untypical on Gd-DTPA-enhanced images, SPIO-enhanced MRI could be a method of choice to make further diagnosis[17-21].

The hemangioma had high SI on unenhanced T_2WI and showed no change on SPIO-enhanced T_2WI. The hemangioma presenting moderate hyper-intensity on T_1WI after SPIO-enhancement is a key point to distinguish it from cyst and other focal hepatic lesions. However, such typical appearance did not present, owing to the partial volume effect in tiny hemangioma in our study ,manifesting iso- or slight hyper-intensity on post-enhanced T_1WI which might make the diagnosis confused. Grangier and Hahn *et al* reported that on SPIO-enhanced T_2WI, the SI of hemangioma could decrease significantly and its enhancement pattern was as the same as that on Gd-DTPA enhanced T1WI (the lesion was filled with contrast agent gradually)[10,11]. Although the signal of lesion decreased a little, 11 lesions of 5 patients in our study had no such appearance and remained hyper-intensitive namely "Bright Bulb" on SPIO-enhanced T_2WI. Whether such difference is attributed to the different dosage of contrast agent used in studies (10(mol $Fe \cdot kg^{-1}$ in our group vs 15(mol $Fe \cdot kg^{-1}$ in others) needs further investigations.

SPIO has unique advantages in diagnosing liver cirrhotic nodules and FNH. Both contain Kupffer cells which can take up the SPIO particles. Accordingly, on post-contrast T_2WI, the former showed identical intensity to that of adjacent normal hepatic parenchyma and the latter had signal loss of different degree. Hepatic cirrhotic nodule and FNH were the only two diseases that had signal loss in our study.As hepatic cirrhotic nodules usually have a cirrhosis background, the lesion presented the SI similar to that of surrounding liver parenchyma after SPIO-administration and no early enhancement after Gd-DTPA administration is the key factorto make the accurate diagnosis. In our study there were 3 liver cirrhotic nodules, which had difficulty in characterization on pre- and Gd-DTPA enhanced MR images, accurate diagnoses were made after SPIO-administration. Thus, SPIO-enhanced MRI is supposed to be the first choice when the cirrhotic nodule is suspected to be associated with early stage of canceration and has no obvious early enhancement after Gd-DTPA administration[15]. FNH has no cirrhotic background with abnormally arrayed lobuli hepatis. The various appearances on pre-contrast T_2WI might be corresponding to its different cellular components. Most lesions were iso- or slightly hyperintense on T_2WI and had signal loss on SPIO-enhanced image. The CNR of lesion-to-liver had no statistical significance between pre- and post-contrast images in our study. This can exactly demonstrate that Kupffer cell in FNH uptake the contrast media and decrease the SI while the background has signal loss at the same time (the mean SI of lesion and liver decreased from 138.6 to 43 and 85.3 to 23.6 respectively on pre- and post-contrast images). The change of SI was different from other diseases and had statistical significance (P<0.05). The central scar was reported to present as mildly hyperintense and 2 cases in our study had this appearance. The characterized appearance of FNH on Gd-DTPA enhanced MR image demonstrated markedly early enhancement as homogeneous hyperintense and iso- to slightly hyperintense in portal or delayed phase. Central scarin 3 lesions enhanced in delayed phase. The results in our study were consistent with other report[24-29].

Cyst had no signal change on both pre- and post-contrast T_1W, and T_2W images. There were 4 inflammatory cases and 1 case of abscess in our study which had no visible difference on pre- and post- SPIO enhanced images. Diagnoses were made only by Gd-DTPA enhanced images and confirmed after clinical antibiotics treatment and follow-up. One case of inflammatory pseudotumor was pathologically proven[30]. One case of cholangiocarcinoma was diagnosed mainly on Gd-DTPA enhanced images which provided more information of the blood supply of lesions. Another case of angiolipoleiomyoma was misdiagnosed as HCC before surgery on both Gd-DTPA and SPIO-enhanced images because it had early enhancement and no SPIO uptake. When retrospectively reviewed, the patchy hyperintensity on T_1W and T_2W images corresponding to fatty component might suggest the diagnosis. Since there was no obvious difference of SI, SPIO-contrasted image had little specificity in diagnosing such hepatic inflammation, cholangiocarcinoma and angiolipoleiomyoma[30-33]. To characterize these lesions, SPIO-enhanced image was inferior to Gd-DTPA image although the lesions showed better circumscription.

As a specific MR contrast media, there is no doubt that SPIO has superiority in detection of hepatic micro-lesions. It is also useful in characterization of somelesions and is superior to unenhanced MR with Gd-DTPA enhanced image when differential diagnosis of HCC, FNH and cirrhotic nodule is needed. As most hepatic lesions could be precisely diagnosed by conventional MR combined with Gd-DTPA dynamic contrast enhancement, SPIO-enhanced image would be a supplementary modality to those which are difficult to be defined.

Abstract

AIM: **To observe the biological specialization of human peripheral blood dendritic cells (DC) and cord blood derived DC and its effects on effector cells killing human hepatocarcinoma cell line BEL-7402 *in vitro*.**

METHODS: **The DC biological characteristics were detected with immunohistochemical and MTT assay. Two antitumor experimental groups are: peripheral blood DC and cord blood DC groups. Peripheral blood DC groups used LAK cells as the effector cells and BEL-7402 as target cells, while cord blood DC groups used CTL induced by tumor antigen twice pulsed DC as effector cells and BEL-7402 as target cells, additional peripheral blood DC and cord blood DC are added to observe its stimulating activities to effector cells. The effectoriäs cytotoxicity to tumor cells were detected with neutral red colorimetric assay at two effector/target ratios of 5:1 and 10:1.**

RESULTS: **Peripheral blood DC and cord blood DC highly expressed HLA-ABC, HLA-DR, HLA-DQ, CD54 and S-100 protein. The stimulating activities to lymphocyte proliferation were compared between experimental groups (DC added) and control group (no DC added), in six experiment subgroups,the DC/lymphocyte ratio was sequentially 0.25:100, 0.5:100, 1:100, 2:100, 4:100 and 8:100, A values($\bar{x}\pm s$) were 0.75396±0.009, 0.84916±0.010, 0.90894±0.012, 0.98371±0.007, 1.01299±0.006 and 1.20384±0.006 in peripheral blood DC groups and 0.77650±0.005, 0.83008±0.007, 0.92725±0.007, 1.05990±0.010, 1.15583±0.011, 1.22983±0.011 in cord blood DC groups. A value was 0.59517±0.005 in control group. The stimulating activities were higher in experimental groups than in control group ($P<0.01$), which were increased when the DC concentration was enlarged ($P<0.01$). Two differently derived DCs had the same phenotypes and similar stimulating activities ($P>0.05$). In peripheral blood DC groups, the cytotoxicity (x±s) of the LD groups (experimental groups) and L groups (control group) was 58.16%±2.03% (5:1), 46c18%±2.25% (10:1) and 38c13%±1.29% (5:1) and 65.40%±1.56% (10:1) respectively; in cord blood DC groups, TD groups (experimental groups) and T groups (control groups) were 69.71%±2.33 % (5:1), 77.64%±1.94% (10:1) and 56.89%±1.82% (5:1) and 60.99%±1.42% (10:1) respectively. The cytotoxicity activities were enhanced with increased effector/target ratio ($P<0.01$). At the same effector/target ratio, the cytotoxicity of experimental groups were bigger than that of control groups ($P<0.01$). The cytotoxicity activities of cord blood DC groups were higher than that of peripheral blood DC groups ($P<0.01$).**

CONCLUSION: **Peripheral blood DC and cord blood DC are mature DC in morphology and function, both can enhance the effector cell killing activities to hepatocarcinoma cells. DC pulsed with tumor antigen can induce higher specific CTL activity than unpulsed DC.**

INTRODUCTION

Dendritic cells (DC) is a potent professional antigen presenting cell, the only one that can stimulate the naive T cell[1-4]. DC can present exogenous antigen to $CD4^+$ cell by MHC-II antigen presenting pathways as well as to $CD8^+$ cell by MHC-I pathways. It also provides plenty of costimulating signals, so that it plays a key role in antitumor immunity[5-9]. Although the peripheral blood DC is easily separated, DC weas able to enhance the killing activity of Lymphkine and PHA activated killer (LAK) cells *in vitro*[10-12], but in some patients with tumors, especially some patients with advanced tumors, autogenous DC may be defective.In this article, two differently derived DCs are studied on their induction of anti-hepatocarcinoma cell activity. It provides experimental evidence for clinical application of DC directed tumor immunotherapy.

MATERIAL AND METHODS

Blood

Human peripheral blood provided by young volunteers, and cord blood provided by Shantou University MedicalMollege FirstAffiliated Hospital.

Tumor cell line

BEL-7402 tumor cell line was bought from Experimental Animal Center,Sun Yat-Sen University of Medical Sciences.

Main reagents

Percoll was purchased from Pharmacia.Mini-MACS(magnetic activated cell sorter) and CD34 cell separation kit were purchased from Miltenyi GmbH Biotec, a kit including the following reagents: A1-human Ig (FcR), A2-haptin coupled CD34 monoclonal antibody, B-colloid anti-haptin antibody and microbead. rhSCF, rhGM-CSF and rh TNF-α were obtained from Pepro Tech Ltd or Institute of Basic Medicine Sciences,Chinese Military Medical Academy.Mouse anti-human antibody CD54, HLA-ABC, HLA-DR, HLA-DQ, S-100 protein and SABC immunohistochemical kit were obtained from Biotec, Boehringer Mannheim and Boster, respectively. MTT was from Amresco.

Isolation of human blood DC

Isolation of Human Peripheral blood DC[9] Four step method of our laboratory was used.Peripheral blood mononuclear cells from

healthy volunteers were prepared using Ficoll-Hypaque (ρ=1077 g·L^{-1}) centrifugation method. Interface cells were collected and washed three times to remove platelets. Discontinuous Percoll density gradient centrifugation was employed, and interface cells between 35% and 50% called preliminary enrichment of DC were collected, cultured in PRMI 1640 with 100mL·L^{-1} inactivated fetal calf serum (100 mL·L^{-1} FCS PRMI 1640) at 37℃, in a saturation humidity, atmosphere of 50mL·L^{-1} CO_2 for 36 hours, then panned on Ig coated petri dish for further purification, nonadhesive cells were collected as the mature DC.

Isolation of human cord blood DC The $CD34^+$ stem cells, were seperated using $CD34^+$ stem cell separation kit and microbead, Mini-MACS cell sorter, cultured with rhGM-CSF, rhTNF-α and rhSCF for 14 d, mature DC was acquired.

Immunohistochemistry method for DC phenotypes

Peripheral blood DC smear and cord blood DC smear were prepared and incubated with mouse anti human HLA-ABC, CD54, HLA-DQ, HLA-DR and S-100 protein primary antibody. ABC staining and DAB were used to display the result.

DC stimulating activity to homogenous lymphocyte

DC stimulating activity to homogenous lymphocyte proliferation Human peripheral blood lymphocytes were obtained by Ficoll separation method. Two groups of peripheral blood DC and cord blood DC were divided. In each group, six subgroups were divided according to the DC/lymphocyte ratio of 0.25:100, 0.5:100, 1:100, 2:100, 4:100 and 8:100 respectively. Lymphocyte concentration was 8×10^8·L^{-1}, PHA was 50mg·L^{-1}. Control group as DC^+PHA served as control in each subgroup. Additional lymphocyte+PHA and PHA also served as control groups. Each subgroup set three wells on 96 multiwell culture plates. Each experiment repeated 4 times.

MTT colorimetric method detecting the lymphocyte proliferation Add 20 μl MTT (5g·L^{-1}) to each well of multiwell culture plate, incubate for 4 hours, then add 150μL DMSO, mixed about 10 min until the crystal completely dissolved. The absorption value (A value) of each well was immediately read by Bio-Rad 3550-UV type automatic enzyme linked detector at 490nm wavelength. The minus of A value in experimental group and A in DC+PHA shows the proliferative response. The minus of A value in lymphocyte $^+$ PHA group and A in PHA shows the lymphocyte proliferation of control group. SPSS software was applied for analysis of variation.

Effector cells induced

LAK cell induced The human peripheral blood mononuclear cells were prepared by the same procedure above, cultured at 2×10^9·L^{-1} population with the final concentration of rhIL-2 1000kU·L^{-1} and PHA 20mg·L^{-1} in 100mL·L^{-1} FCS PRMI-1640 at 37℃ in a full humidified 50mL·L^{-1} CO_2 atmosphere for 7 d. Half volume of solution was replaced by fresh culture medium at d4.

CTL induced twice by antigen pulsed DC The whole culture system included human peripheral mononuclear cells 1×10^8·L^{-1}, cord blood DC 5×10^6·L^{-1}, ultrasonic disrupted BEL-7402 cells 1×10^9·L^{-1}, IL-2 80 kU·L^{-1}. They were cultured for 5 d and pulsed again at d3. Control culture system (no DC added) was set.

Antitumor experiment

DC induced CTL killing activity to hepatocarcinoma cells The experiment was conducted two groups: peripheral blood DC group and cord blood DC group, each group being divided into two subgroups. Peripheral blood DC groups: BEL-7402+LAK (L group) as control group, BEL-7402 +LAK +DC (LD group) as experiment group. BEL-7402 cell concentration was 8×10^8·L^{-1}, DC was 8×10^6·L^{-1}, two LAK /BEL-7402 ratio of 5:1 and 10:1 were applied.Cord blood DC groups: BEL7402+CTL (T group) as control group, BEL7402+DC-CTL (TD group) as experimental group. Cell concentration and ratio were the same as above. Additional BEL- 7402 culture media was set as control group. Each group set three paralleled wells, cultured in 96 multiwell culture plate for 48 hours, the effetor cell killing activities were detected. The procedure above was repeated for 4 times.

Neutral red uptake method **Neutral** red uptake method was applied to detect the cytotoxicity activities of effetor cells,0.1 mL neutral red solution 0.3g·L^{-1} was added to each well, incubated at 37¡æ for 1 h, rinsed with PBS, solution of hydrochloride ethanol 0.1 mL was added, and absorbance was detected at 570 nm by Bio-Rad automatic enzyme linked detector. Formula for cytotoxicity calculation is below:

$$(1-\frac{A \text{ value of experiment group-A value of medium control group}}{A \text{ value of control group-A value of medium control group}})\times100\%$$

SPSS for windows statistic software are used for data variation analysis.

RESULTS

DC phenotypes analysis

Immunohistochemical ABC method showed that human peripheral blood DC and human cord blood DC had high expression of HLA-ABC, HLA-DR, HLA-DQ and CD54. S-100 protein was also positive. Positive cells were big and irregular in shaped and filled with diffuse brown-yellow particles in cytoplasm, the neucleus was also big and irregular. However, the phenotype difference between peripheral blood DC and cord blood DC was not distinct.

DC stimulating activity to lymphocyte

In human peripheral blood DC and human cord blood DC groups, lymphocyte proliferation activities were significantly higher than control groups (P<0.01), which was increased when DC concentration was enlarged (P<0.01). Human peripheral blood DC and human cord blood derived DC had no significant difference in lymphocyte stimulation (P>0.05, Figure 1).

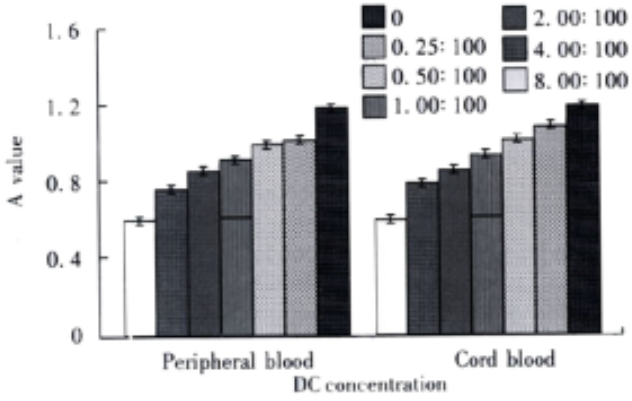

Figure 1 Lymphocyte proliferation response by different DC concentrations.

DC induced effector's cytotoxicity activities

In groups of human peripheral blood DC and human cord blood DC, cytotoxicity activities enhanced with the increased effector/target ratio (P<0.01). Within the same ratio, cytotoxicity activities of experimental groups were higher than control groups (P<0.01). Cytotoxicity activities of human cord blood DC groups were bigger

than human peripheral blood DC groups (P<0.01, Figure 2)

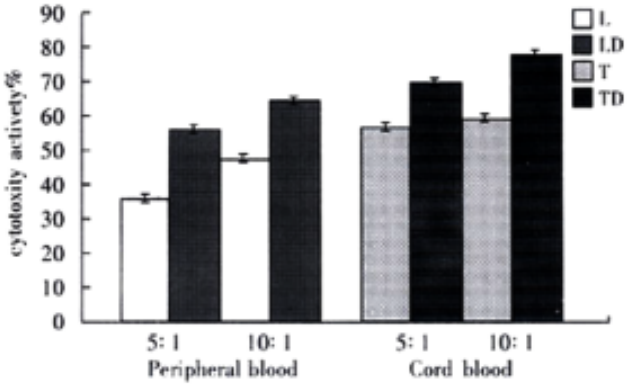

Figure 2 DC's effect to cytotoxity activity of effector against BEL7402.

DISCUSSION

DC is a potent antigen presenting cells, mainly takes part in cell immunity and T cell dependent humoral immunity, and plays a key role in antitumor immunity[13-21]. Recently, with the construction of DC isolation method and expanding culture *in vitro*, research has transfer red from the relationship between tumor infiltrating DC and the prognosis to DC application in tumor immunotherapy, especially how to improve the tumor cell immunogenocity and enhance the DC antigen presenting efficacy and stimulating activity to CTL[22-30]. In this experiment, DC of human peripheral blood and cord blood were studied on its potential in clinical application.

Human peripheral blood DC isolation was made according to four step method modified in this laboratory. This method is easy to operate, low in cost and reliable, and has been used in this laboratory for many years, and high purity of DC can be obtained by this method[31,32]. Another method is used in cord blood DC isolation: $CD34^+$ cell isolation kit combined with cell factor expanding culture for preparation of cord blood derived DC. This is an advancing method. The principle of $CD34^+$ cell isolation kit is as follows: $CD34^+$ monoclonal antibody recognizes the specific antigen of stem cell membrane, by which the antibody coupled magnetic microbead binds to cells, when the cells pass through column in the magnetic field, the $CD34^+$ can be acquired by positive selection. Three reagents comprises in $CD34^+$ isolation kit: A1, human Ig, used as blocking reagent to FcR for preventive non specific binding of $CD34^+$ monoclonal antibody to $CD34^-$ cells. A2, hapten coupled CD34 monoclonal antibody, can specifically bind with CD34 molecule. B, anti-hapten antibody linked with microbead, can link the microbead with $CD34^+$ cells. When the cells pass through MACS (magnetic cell sorter) column in magnetic field, negative cells can pass through the column, while positive cells were absorbed to column. When the column was token away from magnetic field, the elution from column included the positive cells. MACS cell isolation has been verified by immunofluorescent PCR, FISH and FACS method. It has the characteristics of high purity (93%-99.9%)[14], large number of cells processing ability in a single time, and easy operating, simple procedure. When cell factors such as rhGM-CSF, rhTNF-α and SCF are added to stem cell culture media, most of $CD34^+$ cells differentiate to DC[33]. Though the GM-CSF can stimulate cell growth of both the DC progenitor and monocyte or macrophage, for high purity of $CD34^+$ cell in initiate couture system, clearance most of monocyte and macrophage by its adherence to flask by replacing media and culture plate.Cell factor secreted by monocyte and macrophage also benefits DC development.

In this article, a series of antibodies were used for immunohistochemical staining of DC, results showed that human peripheral blood DC had and $CD34^+$ derived cord blood DC high expression of CD54, HLA-ABC, HLA-DR, HLA-DQ, and S-100 protein.The positive cells accounted for above 95% and 90% respectively, demonstrating that DC here is mature[34,35].

For DC functional analysis, MTT assay was used to detect the DC activity of stimulating the allogenious lymphocyte.The principle of MTT assay is that the living proliferating cells can deoxidize the MTT (thiazoyl blue tetrazolium bromide) to purple crystal formazan and deposit in cytoplasm, so we can use the colorimetric method to detect the cell proliferation. With continuous modification, it has become a very consummate method with characteristics of sensitivity, simple procedure, safety and no radioactivity. In this experiment, DC can clearly stimulate the lymphocyte response to PHA. It shows that the DC has potent MLR stimulating activity which contributes to DC expression of adherence and MHC-Ⅱ molecule. Phenotype and functionally mature DC of high purity provided primitive condition for DC application in antitumor.

Tumor cells expressed low level antigen and has antigen modulation, so tumor antigen can not be efficiently presented and the T cell mediated immune response can not be activated, by which tumor can escape the surveillance of immune system. As a nonprofessional APC, tumor cells with no expression of costimulator often leads to T cell anergy. Special attention has been paid to DC for its present exogenous antigen to $CD8^+$ cell by MHC-Ⅰ antigen presenting pathway as well as its expression of costimulating signal[36-40]. In this article, peripheral and human cord blood DC can significantly improve effector's cytotoxicity, due to a large quantity of dendrites, and many kindsof surface molecules and receptors and cytokine secreted[41,42]. LAK cells induced for 7 days chiefly demonstrated CTL's characteristic of $CD16^-$, $CD8^+$ and $CD3^+$,which can efficiently kill the target cells[43-46]. It has been found recently that DC secretion of exosome can present antigen and induce immune response. This is another path for effector activation[47]. In general,from patients in well condition, autogenous peripheral blood DC and LAK cells can be acquired, for it is low in cost; while in patient in bad condition, cord blood DC can be used as an alternative.

Cord blood DC can more efficiently induce effector's cytotoxicity than peripheral blood DC, due to the following factors: ① Cord blood DC comprises some immature DC,the coexistence of mature and immature DC can be synergetic, immature DC can ingest and process antigen, while mature DC can present antigen and activate T cells, therefore, coexistence of mature and immature DC is better than single mature DC[48]. ② Both cord DC and CTL were pulse twice with tumor antigen, and specific antitumor activity improved. LAK cells induced7 days can secrete perforin and granular particles nonspecific to ally kill target cells while human cord blood DC pulsed *in vitro* by tumor antigen can efficiently present tumor antigen to effector which occupy the TCR of CTL, and activate the specific CTL, with the help of costimulator such as CD80,CD86 and CD40. Furthermore, DC can secrete nave T specific chemotactic factor DC-CCK. Some other cell factors such as MCP-1, RANTES and IL-8 also can also play a chemotactic role in DC emigrant. DC can form a cluster of cells and secrete a large number of IL-12 which bind with IL-12R of CTL and enhance CTL proliferating response and cytotoxicity. IL-12 mediates T_H1 immune response and inclines to tumor killing activity[42,49-51].If permitted, twice antigen pulsed DC should be used.

Summary, human blood DC and cord blood DC have a potential application in the clinical therapy of hepatocarcinoma, especially late hepatocarcinoma.

Abstract

AIM: **To study the preparation and cleavage activity of HpRz directed against the transcript of HBV core gene *in vitro*.**

METHODS: **HpRz gene designed by computer targeting the transcript of HBV core gene was cloned into the vector p1.5 between 5′-cis-Rz and 3′-cis-Rz. ^{32}p-labeled HpRz transcript proved whether the vector fit for the preparation of hairpin ribozyme *in vitro*. ^{32}p-labeled pKC transcript containing HBV core region as target-RNA was transcribed using T_7 RNA polymerase and purified by denaturing PAGE. Cold HpRz transcript was incubated with ^{32}p-labeled target-RNAs under different conditions and radio autographed after denaturing polyacrylamide gel electrophoresis.**

RESULTS: **HpRz has the specific ability of cleavage of target RNA at 37℃ and 12 mM $MgCl_2$. K_m=26.31nmol/L, K_{cat}=0.18/min. These results revealed that the design of HpRz was correct.**

CONCLUSION: **HpRz prepared in this study possesses specific catalytic activity from the identification of cleavage activity. These results indicate that hairpin ribozyme may intracellularly inhibit the replication of HBV, therefore it may become a novel potent weapon for the treatment of hepatitis B.**

INTRODUCTION

Hepatitis B is a major worldwide health problem[1-5]. Hepatitis B virus is a small hepatotropic DNA virus, causing acute and chronic B-type hepatitis in man. Chronic infection is associated with a high risk of liver cirrhosis and primary liver carcinoma[6-14]. Currently available therapies are of limited efficacy[15-33]. Ribozyme is a kind of catalytic RNA which can catalyze the cleavage of sequence-specific RNA. Compared with antisense RNA, ribozyme may be a more effective experimental tool to suppress the gene expression. Possessing both antisense and RNA cleavage activity, the enzymatic nature of ribozyme may facilitate effectiveness even at low level of expression[34]. Hepatitis B virus is a DNA virus that replicates through reverse transcription of a RNA intermediate (pregomic RNA). So engineered anti-HBV ribozyme can potentially be multifunctional, targeting pregenomic RNA and viral mRNA to suppress the replication of hepatitis B virus. Since previous attempt to use hammerhead ribozyme for the intracellular inhibition of HBV replication have been largely unsuccessful in intact cell[35,36], however engineered hairpin ribozymes have been shown to inhibit replication of human immunodeficiency virus, hepatitis C virus and human papilloma virus *in vivo*[37-44]. So we designed hairpin ribozyme to inhibit HBV replication. It is well known that HBV C region is associated with viral replication. In this report we have designed hairpin ribozyme targeting core gene of HBV by computer, prepared hairpin ribozyme by transcription of recombinant plasmid *in vitro*, and proved its ability to cleave HBV *in vitro* from identification of activity of anti-HBV hairpin ribozyme.

MATERIALS AND METHODS

Materials

E. coli DH5α has been maintained in our laboratory. The ribozyme vector p1.5 (kind gift of Qi GR, Shanghai Institute of Biochemistry), Plasmid pKC[45] for target-RNAs (constructed by Dr Lian JQ, the Forth Military Medical University) has been maintained in our laboratory. DNA sequence Kit, *in vitro* transcription kit, restriction endonucleases, T4 DNA ligase, RNase A free DNase I were purchased from Promega Company; and RNase inhibitor, T4 DNA polymerase from Takara Company, α^{32}p dATP and α^{32} UTP from Beijing Yahui Company, Materials were used all of analytical purification.
Oligonucletides of HpRz: R1 5’-CTA GAT CCG GAA GAA CTA AAC CAG AGA AAC AGA TCT CTT CGG AGA TCG TAC ATT ACC TGG TAG GTA C-3’; R2 5’-CTA CCA GGT AAT GTA CGA TCT CCG AAG AGA TCT GTT TCT CTG GTT TAG TTC TTC CGG AT-3’. They were chemically synthesized in Beckman Oligo-1000 DNA synthesizer.

Methods

***In vitro* transcription and purification of target RNA** The template PKC was linearized with BstXI, the 3’-overhangs of linearized pKC was blunted with T4 DNA polymerase. *in vitro* transcription was carried out at 37℃ for 90 min in a 20 ìL final volume containing 40 mmol·L^{-1} Tris·Hcl (pH 7.5),50 mmol·L^{-1} DTT, 2 mmol·L^{-1} spermidine,8 mmol·$L^{-1}Mgcl_2$, 0.25 mmol·L^{-1}ATP, GTP,CTP, 0.05 mmol·L^{-1}UTP,370 KBq alpha ^{32}p-UTP,80 U T_7 RNA polymerase and 4 μg linearlized template. Target RNA was purified by 60g·L^{-1} denaturing gel electrophoresis by cutting off the autoradiograph bands. Labeled target RNA was dissolved in DEPC H_2O and reserved under -20℃.
Construction of recombinant plasmid for ribozyme and preparation of ribozyme *in vitro* The hairpin ribozyme HpRz for HBV was designed according to the computer software pcFOLD combiled by Professor Zuker (Canadian Academy of Science). The

homologous possibility with the gene of human being was excluded by consulting with RNA sequence of human cell from NCBI Genbank. Synthesized ribozyme fragments were cloned into XbaI/KpnI sites of p1.5 as pHpRz. Recombinant plasmid was identified by being digested with EcoRI and HindIII, then the DNA sequence of recombinant plasmid was analyzed through the dideoxy method developed by Sanger(Figure 1). The template pHpRz was linearized with EcoRI and *in vitro* transcription and purification of ribozyme were the same as those of target RNA. To get a large amount of transcribed HpRz without isotope, the transcription of HpRz was set up according to manufacture's instruction, then template was digested with RNAse A free DNase I, the RNA was dissolved in DEPC H_2O and measured by spectrophotomer containing 3'-cis-Rz and 5'-cis-Rz.

Figure 1 Structure of HpRz plus 5'-cis-Rz and 3'-cis-Rz.

***In vitro* cleavage reaction of HpRz** The cold hairpin ribozyme and target RNA labeled by alpha-^{32}p UTP were quantified. The cleavage reaction of ribozyme was performed in ribozyme buffer (40 mmol·L^{-1} Tris·Hcl pH7.5/ 12 mmol·$L^{-1}$$Mgcl_2$) at 37℃ with 10 nmol·L^{-1} ^{32}p-labeled substrate and 10 n mol·L^{-1} cold ribozyme. In this condition the cleavage mixture was incubated at different time points.The volume of the reaction is 5μL.One μL loading buffer (2.5g·L^{-1} Bromophenol Blue, 2.5g·L^{-1}Xylene cyanol FF, 20 mmol·L^{-1} EDTA and saturated Urea) was added to stop the reaction. The result could be analyzed after running a 60g·L^{-1} denaturing polyacylamide gel electrophoresis. The cleavage efficiency was calculated from Bq values of the bands of substrate (S) and products (P) CE=[P/(P+S)]·100%.

Kinetics of the cleavage reaction The procedure was described by Uhlenbeck[46].The cleavage reactions were done and the results were analyzed as above. K_m and K_{cat} were calculated by Lineweaver-Burk method (double- riciprocal plot).

RESULTS

Identification of recombinant plasmid pHpRz

The result of digested recombinant plasmid by EcoRI and HindIII was analyzed by running 20g·L^{-1} agrose gel elrctropheries(Figure 2).This result and the DNA sequence analysis showed that the clone was correct.

Identification of transcription of ribozyme

The transcription of ribozyme from EcoRI-linearized template should include three bands: 50nt, 63nt and 83nt. The resultshowed our design was correct (Figure 3).

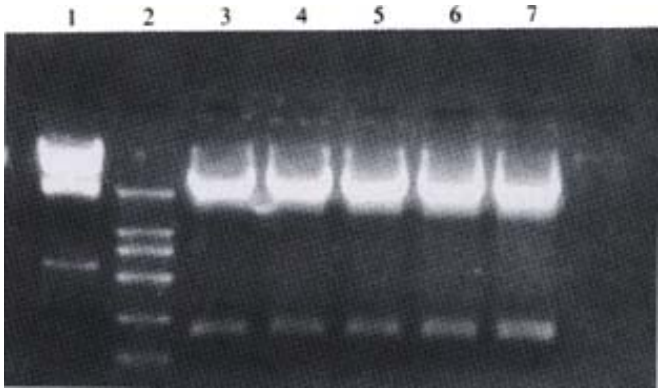

Figure 2 The analysis of HpRz digested by EcoRI and HindIII(20g·L^{-1} agrose gel). lane 1:λ DNA / HindIII marker; lane 2: DL2000 DNA marker; lane 3-7: HpRz digested by EcoRI and HindIII.

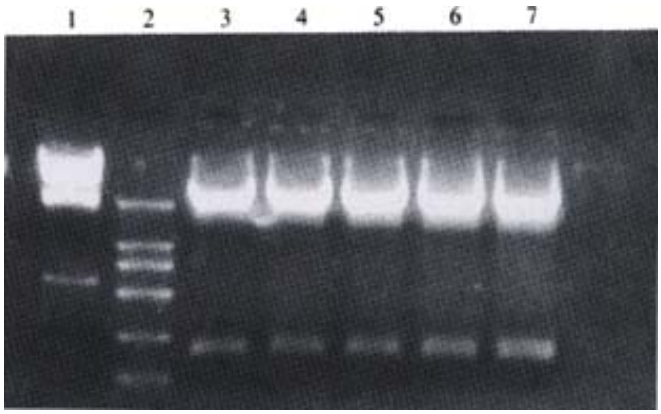

Figure 3 *in vitro* transcript of pHpRZ. HpRz is 83nt. 5'-cis-Rz is 63nt, 3'-cis-Rz is 50nt.

In vitro cleavage reaction of ribozyme and kinetics of the cleavage reaction

Time course The cleavage mixture (Rz :substrate=1:1 mol·L^{-1}) were incubated at 37℃ for different time points,it was shown that the reaction product increased with the increase in incubation time and within 60 min it was linear, CE=32.67% (Figures 4 and 5).

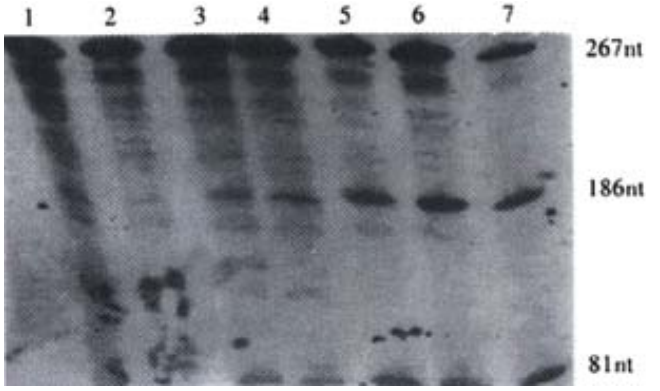

Figure 4 Time course. Specific cleavage of HBV RNA target molecules by HpRz *in vitro*. Lane 1:substrate control; lane 2:incubated for 6 min; lane 3: 10 min; lane 4:20 min; lane 5:40 min; lane 6:60 min; lane 7:90min.

The kinetics of cleavage reaction Under the condition of 37℃ and 40-minute reaction time, the cleavage efficiency was calculated at Rz:S=1:1,1:2,1:4,1:8 and 1:16(mol/L)ratio. K_m and K_{cat} were obtained by the Lineweaver-Burke method (Figure 6) K_m =26. 31nmol·L-1, K_{cat}=0.18·min^{-1}.

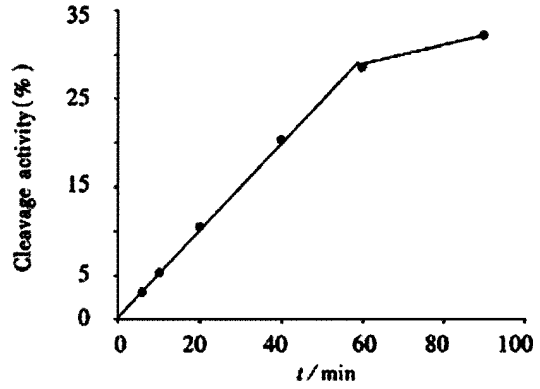

Figure 5 Time curves of cleavage reactions of HpRz prepared *in vitro*.

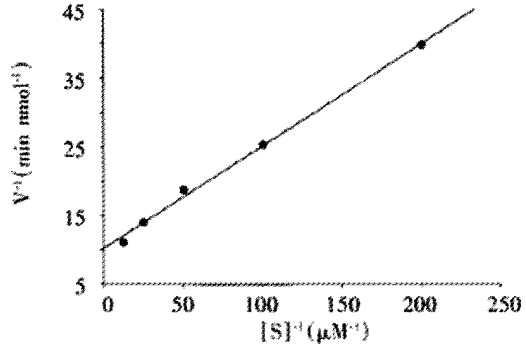

Figure 6 Lineweaver-burk kinetic plots of the specific cleavage of HBV RNA target molecules by HpRz prepared *in vitro*. HpRz concentration is 5 nmol·$^{-1}$, substate concentration is 80,40,20,10 5nmol·L^{-1}. Reaction is at 37℃ for 40 min.

DISCUSSION

Ribozyme is classified into six kinds. Hammerhead ribozyme and hairpin ribozyme have been studied extensively as experimental tools for trans suppression of gene expression and possible therapeutic application. Hammerhead ribozyme is small and easy to design and there is less restriction of selection of target site, so its application is extensive. Although hammerhead ribozyme was used to suppress HBV replication, and hammerhead ribozyme-mediated cleavage of target RNA could be achieved *in vitro* and in cell extract, they showed poor effect in intact cells[35, 36]. Cellular protein and low Mg^{2+} concentration limited intracellular ribozyme activity. It will be difficult to raise the intracellular Mg^{2+} level. Protein can influence the ribozyme intracellular performance. However, cellular protein may also have positive effect on ribozyme-mediated catalysis. Because of limited knowledge on mechanisms of protein modulation of catalytic RNA activity and the complex formed by ribozyme and ribonucleoprotein are frequently large, poorly defined and difficult to study, it is hard for us to use protein to enhance ribozyme activity. Compared with hammerhead ribozyme, hairpin ribozyme has complex structure, hard to design and there is too much restriction of target site and its application is limited. It possesses the better cleavage activity under physiological condition from *in vitro* assays done under standard condition at 37℃ and low Mg^{2+} concentration. PJ Welch[47] designed three hairpin ribozymes against the pgRNA (pregomic RNA) encoding HBV surface antigen, the polymerase and the X protein and demonstrated that two of them can cleave target RNA *in vitro* and reduced the level of HBV expression and suppressed HBV replication *in vivo*. Zu *et al*[48] used hairpin ribozyme library to identify accessible target sites within HBV progenomic RNA, four hairpin ribozyme targeting conserved region in subtypes of HBV can inhibit HBV replication in intact cell. Until now no report on hairpin ribozyme directed against core gene of HBV has available. In this report we have designed and constructed hairpin ribozyme to cleave transcripts of HBV core gene *in vitro*. Our experiment was the study of preparation and cleavage activity of hairpin ribozyme-HpRz by means of the computer design, cloning the ribozyme gene into the vector that possessed cis-cleavage ribozymes and labeled it with isotope. The *in vitro* transcription effect of ribozyme was satisfactory, 5'-cis-Rz and 3'-cis-Rz cut themselves and released the purposed ribozyme. The ribozyme flanking sequences could be shortened and ribozyme structure induced by the secondary structure of long flanking sequences would be eliminated. That would affect ribozyme turnover ratio/binding activity in the result of an accurate hybridization and better cleavage for ribozyme. Moreover isolation of ribozyme is very convenient by cutting off autoradiograph bands. Ribozyme is quantified more accurately.In this paper the number of nucleotide of hairpin ribozyme was similar to that of the cleavage product, so we can not use transcribed HpRz labeled by isotope. The ribozyme vector was proved to fit for preparation of hammerhead ribozyme[49-51], In our study we also used the preparation of hairpin ribozyme and its efficacy is similar to that of hammerhead ribozyme. So the vector possesses wide applicability in the study of preparation of ribozyme *in vitro*,not only hammerhead ribozyme, but also hairpin ribozyme.

HBV is a double-stranded DNA virus replicates through pregenomic RNA intermediate, which provides a therapeutic opportunity for a novel antiviral gene therapy based on ribozyme RNA cleavage. In our experiment, we have designed and constructed hairpin ribozyme directed against HBV core region. The kinetics of hairpin ribozyme showed that HpRz possessed specific ability of cleaving the HBV transcripts *in vitro*. These results indicated that HpRz is worthy of being further studied in intact cells and developed as a nucleic acid drug in the future. However the *in vitro* result can not completely reflect *in vivo* performance. The total HBV mRNA transcript in cell forms the secondary and tertiary structure which affect ribozyme combination with the substrate and cleavage activity. The subcellular compartment where the ribozyme is located, degradation of ribozyme, the complexes which are formed by ribozyme and ribonucleoprotein within cell and gene delivery system, affect the combination with substrate and cleavage of ribozyme. So *in vivo* effect of the ribozyme should be investigated as soon as possible. The ribozyme fragments would be cloned into eucaryotic vectors and transfected into HepG2 cell or Huh7 cell. Experimental analysis of the anti-HBV ribozyme activity *in vivo* is in progress and should help determine its potential use as antiviral agents against HBV.

Abstract

AIM: **To seek the X associated protein (XAP) with the constructed bait vector pAS2-1X from normal human liver cDNA library.**

METHODS: **The X region of the HBV gene was amplied by PCR and cloned into the eukaryotic expression vector pAS2-1.The reconstituted plasmid pAS2-1X was transformed into the yeast cells and the expression of X protein (pX) was confirmed by Western blot analysis. Yeast cells were cotransformed with pAS2-1X and the normal human liver cDNA library and were grown in selective SC/-trp-leu-his-ade medium, the second screen was performed with the LacZ report gene. Furthermore, segregation analysis and mating experiment were performed to eliminate the false positive and the true positive clones were selected for PCR and sequencing.**

RESULTS: **Reconstituted plasmid pAS2-1X including the anticipated fragment of X gene was proved by auto-sequencing assay. Western blot analysis showed that reconstituted plasmid pAS2-1X expressed BD:X fusion protein in yeast cells. Of 5×10^6 transformed colonies screened, 65 grew in the selective SC/-trp-leu-his-ade medium, 5 scored positive for β-gal activity, and only 2 remaining clones passed through the segregation analysis and mating experiment. Sequence analysis identified that two clones contained similar cDNA fragment: GAACTTGCG.**

CONCLUSION: **The short peptide (glutacid-leucine-alanine)is a possible required site for XAP binding to pX. Normal human liver cDNA library has difficulties in expressing the integrated XAP on yeast cells.**

INTRODUCTION

Modern biological investigations indicate many proteins have relationship with the development of hepatocellular carcinoma[1-8]. More and more evidences have demonstrated hepatitis B virus (HBV) X protein which encoded by the smallest open reading frame (ORF) of the HBV genome plays an important role in the carcinogenesis[9-13]. At a molecular level, several endogenous genes critical for cell proliferation or apoptosis and the inflammatory response seemed interacted with HBx, such as c-Fos, c-Jun, CREB, CD44,TNF-α,p21 and p53[14-21]. In addition, DNA transfection approaches have clearly demonstrated that pX is a transactivator of a wide variety of viral and cellar promoters[22-24],but the underlying mechanism of transactivation is currently obsure. Since HBx has no ability to bind DNA, protein- protein interaction seems to be crucial for HBx transactivation[25-28]. One most direct way to identify the mechanism of HBx transactivation is to find out host proteins that interact specifically with HBx. We use the yeast two -hybrid system, a genetic approach to search the clone genes that interact with a protein of interest by *in vivo* complementation in yeast cells, to seek XAP from normal human liver cDNA library.

MATERIALS AND METHODS

Plasmid Construction

To make the bait plasmid, the X region of the HBV gene was amplified by PCR using as forward and reverse primers XF and XR, which contain an EcoRI and Pst I site respectively for ease of cloning.The sequence of the primers, with the restriction enzyme site underlined are: XF: ACGGAATTCATGGCTGCTAGGCTGTG, XR: ATCCTGCAGAGGTGAAAAAGTTGCAT. These bind to nucletide positions 1374 and 1838 on HBV genome. The templates for this reaction were sera of HBV DNA posistive patients. The 464bp product was cloned into the respective restriction enzyme sites of plasmid pAS2-1 (Clontech) and this plamid was subsequently named pAS2-1X.

Westem Blot analysis

Saccharomyces cerevisiae AH109(Clontech) was grown in YPD medium($10g\cdot L^{-1}$ yeast extract, $20\ g\cdot L^{-1}$ peptone, $20\ g\cdot L^{-1}$dextrose). This yeast strain carries LacZ. HIS3 and ADE2 reporter genes under the control of Gal4-binding sites was used to screen the liver cDNA library. Yeast cells were transformed with pAS2-1X using lithium acetate method previsously published by Gietz *et al*[29] and were grown in selective SC/-trp medium. Cells were collected by centrifugation and lysates were prepared according to Urea/SDS method. A part of protein exact were resolved on a $120g\cdot L^{-1}$ SDS-polyacrylamide gel and transferred onto polyvinylidene difluride membrane. After blocking with nonfat dried milk, the membrane was treated with 1:3000 diluted Gal4 DNA-BD monoclonal antibody(Clontech) followed by 1:1000 dilured alkaline phosphatase-conjugated goat anti-mouse IgG. Subsequently the blot was developed by 5-bromo-4-chloro-3-indolyl phosphate and nitro blue tetrazolium. The untransformed yeast cells were used for negative control.

Screening of the liver cell cDNA library by the yeast two-hybrid system

The screening procedure used was a modification of the method

described by Gietz *et al*[29]. Yeast cells AH109 were transformed with pAS2-1X and pACT2-cDNA library (Clotech) by Liac-mediated transformation and were grown in selective SC/-trp-leu-his-ade medium for 7 days. After about 3 days at 30℃, the growing colonies were assayed for α-gal activity by replica plating the yeast transformants onto Whatman filter papers, the filters were snap frozen in liquid nitrogen for 10s twice and incubated for 1-8h at 30℃ in a buffer containing 5-bromo-4-chloro-3-indolyl-α-D-galactopyranoside(X-gal) solution. Positive interactions were detected by the appearance of blue colonies. Segregation analysis and mating experiment were done to exclude the type I ,II, III false positive and true positive colonies were obtained.

Sequence analysis of pACT2-cDNA

The pACT2-cDNA plasmid genome was isolated following the standard protocol. Briefly, the true positive clones were grown in SC/-leu medium, cells were collected by centrifugation and resuspended in lysis buffer (20g·L^{-1} Triton 100, 10g·L^{-1}SDS, 10mmol L^{-1} NaCl, 10mmol·L^{-1} Tris-HCl pH8.0, 1mmol·L^{-1} Na_2EDTA) and phenol, chloroform and isoamyl alcohol(volume fraction 25:24:1). After addition of acid-washed glass beads (Sigma), samples were centrifugated and plamid DNA recovered. The pACT2-cDNA plasmid DNA was purified by CsCl gradient centrifugation to permit PCR using the Matchmaker AD LD-Insert Screening Amplimers (Clotech) which anneals to GAL4-AD. Auto-sequencing assay was performed in Shanghai Shenggong Biological Corporation.

RESULTS

Plasmid construction

The HBV X fragment was successfulily generated by PCR(figure 1) and cloned into plamsid pAS2-1. Reconstituted plasmid pAS2-1X including the anticipated fragment of X gene was proved by digesting with resticted endonuclease and auto-sequencing assay as follows:

Westem Blot analysis

Westem Blot Analysis proved that yeast cells transformed with pAS2-1X have positive signal which can not be seen in the control, pAS2-1X can express BD:X fusion protein yeast cells(figure 2). Besides, The colony-lift assay showed that the reconstruted plasmid could not active LacZ reporter gene in yeast. pAS2-1X can be used as bait vector in yeast two-hybrid system.

Screening of the liver cell cDNA library

Of 5×10^6 transformed colonies screened, 65 grew in the selective SC/-trp-leu-his-ade medium. Out of these HIS+ ADE+ prototrophs, 5 scored positive for β-gal activity, only 2 remaining clones passed through the segregation analysis and mating experiment.

Sequence analysis

PCR (Figure 3) and sequence analysis identified that two clones contained the same cDNA sequence: GAACTTGCG, which encodes glutacid-leucine -alanine.

DISSCUSION

Persistent Hepatitis B virus infection is strongly associated with the development of hepatocellular carcinoma(HCC). The viral X gene encodes a 17-kd protein, termed pX, fuctions a transcriptional activator of a variety of viral and cellular genes, it is capable of interacting with a wide variety of cellular protein, including cell-cycle control and apoptosis protein. There are well documented that pX acts through apoptosis pathway involving Fas and caspase 3[30-33], it also

interacts with p53, a wellknow tumor suppressor gene[34-36] and inhibits nucleotide excision repair[37-39]. However, ample evidences showed that pX may function by additional profound mechanisms in HCC[40-43].

Identification and characterization of proteins in a cell with which a given protein interacts is often helpful for understanding the function and mechanisms of action of that protein.The yeast two-hybrid system is a molecular genetic test for protein interaction, which is firstly established by Fileds *et al* in 1989[44].It's a powerful and sensitive technique for the identification of genes that code for proteins which interact in a biologically significant fashion with a protein of interest. The assay is performed in the yeast cells so as to reflect the real situations *in vivo* and has the potential to identify the weak and transient interaction between two protein. In addition, since the cDNA libiary can be constructed according to various type of tissues,organs and cells, many proteins interact with transcription factors, protein kinases, phosphatases, receptors, cytoskeletal proteins as well as proteins involved in cell cycle regulation and apoptosis can be study by this elegant approach. Although the yeast two-hybrid system has become a standard procedure for molecular biologists, it remains some deficiency. The most important problem is different types of false positives, fortunately, they can be eliminated by other method such as segregation analysis and mating experiment[29,45].

Our study successfully constructed the bait vector pAS2-1X, HIS and ADE independent growth and blue -colony formation in the α-gal assay by yeast cells harboring both pAS2-1X and pACT2-cDNA recombinant plasmids and the behaviors of cells in false-positive elimination tests suggested the isolated clones can specifically interact with pX and the results were reliable.

It should be greatly concerned that XAPs studied by the yeast two-hybrid system in the past were different in size, structure and biological functions[46]: Lee *et al*[47] indentified an XAP1 that is a human homolog of the monkey UV-damaged DNA-binding protein in 1995; Kuzhandaivelu *et al*[48] discovered an XAP2 which is known as the p38 subunit of the aryl hydrocarbon receptor complex (ARA9) in 1996; Huang *et al*[49] reported an XAPC7 contained a polypeptide with high sequence homology to the PROS-28.1 subunit of proteasome of Drosophila melanogaster and the α proteasome subunit of Arabidopsis thalinna in 1996; Cong *et al*[50] isolated an XAP3 which is a human homolog of the rat protein kinase C-binding protein in 1997; Melegari *et al*[51] proved an XIP incluing two consensus phosphorylation sites for protein kinase C and Casein kinase II in 1998; Sun *et al*[52]demonstrared a p55sen appeared to be related to the family of EGF-like protein in gengeral in 1998; Rahmani *et al*[53,54] identified an HVDVC3 which is a third member of the family of human genes that encode the voltage-dependent anion channel. The reasonable explantation for these distinct results has not been obtained yet. Whether there exists different kinds of XAP or funtional fragment interacting with pX or the repetitive results depend on the high transformation efficiency remains obscure. One of the possible mechanism may be a specific fragment can interact with pX specially and the proteins containing this fragment thus can bind to pX. Sequence analysis shown that both two true positive clones we isolated contained the sequence encodes glutacid-leucine -alanine, therefore, it's rational to deduce this short peptide is a required site for XAP binding to pX.

The interaction of proteins shall locate at nucleus in yeast two-hybrid system. However, some proteins require modification such as glycosylation outside the necleus after the expression, and others are only correctly folded and actived in the cooperation of some particular proteins which don't exist in yeast cells, so not all proteins can obtain normal structure and biological function in yeast cells. The cDNA library used for seeking XAP in the past research including Epstein-Barr virus transformed human peripheral lymphocyte cDNA library, Hela λ gt11 cDNA library or senescent human liver cDNA library, were all library consititued from abnormal cells.Our study had not isolated integrated cDNA sequence of XAP partly owing to the difference between normal human liver cDNA library and abnormal cells cDNA library in protein's expression, modification and activation.

In conclusion, the short peptide(glutacid-leucine-alanine) is a possibly required site for XAP binding to pX. Normal human liver cDNA library has difficulties in expressing the integrated XAP on yeast cells.

Abstract

AIM: **To examine the molecular mass and identify the bioactivity of MG_7 scFv for its application as a targeting mediator in gene therapy of gastric cancer.**

METHODS: **Two strongly positive recombinant phage clones screened from MG_7 recombinant phage antibody library were separately transfected into *E.coli* TG1. Plasmid was isolated from the transfected *E.coli* TG1 and digested by EcoR I and Hind Ⅲ to examine the length of exogenous scFv gene. Then, the positive recombinant phage clones were individually transfected into *E.coli* HB2151.The transfectant was cultured and induced by IPTG. Perplasmic extracts was prepared from the induced transfectant by osmotic shock. ELISA was used to examine the antigen-binding affinity of the soluble MG_7 scFv. Immunodoting assay was adopted to evaluate the yield of soluble MG_7 scFv produced by transfected *E.coli* HB2151. Western blot was used to examine the molecular mass of MG_7 scFv. Finally, the nucleotide sequence of MG_7 scFv was examined by DNA sequencing.**

RESULTS: **two positive recombinant phage clones were found to contain the exogenous scFv gene. ELISA showed that MG_7 scFv had strong antigen-binding affinity. Immuodoting assay showed that transfected *E.coli* HB2151 could successfully produce the soluble MG_7 scFv with high yield via induction by IPTG. The molecular mass of MG_7 scFv was 30 kDa by western blot. DNA sequencing demonstrated that the V_H and V_L genes of MG_7 scFv were 363bp and 321bp, respectively.**

CONCLUSION: **We have successfully developed the soluble MG_7 scFv which possessed strong antigen-binding affinity.**

INTRODUCTION

Gastric cancer takes the leading place in the incidence of various tumors in china[1]. Many conventional approaches, including surgical, chemical and physical treatments, appear palliative in most advanced cases. Because these conventional approaches cannot selectively target at the tumor cells and completely eradicate them, and recurrence and metastasis of tumor may develop due to the existence of residual tumor cells. Therefore, targeting therapy for tumor is badly needed to achieve a greater curative effect and overcome the obstacle existing in the conventional approaches[2-13]. Recent studies showed that the targeting therapy had a promise in the treatment of gastric cancer[14-29]. In the present study, we produced the soluble MG_7 scFv and evidenced that MG_7 scFv is a favorable mediator for targeting therapy of gastric cancer.

MATERIALS AND METHODS

Restriction analysis of the strong recombinant phage clones

The strong positive recombinant phage clones (3 μL containing 2×10^9 pfu) were separately added into 5mL log-phase *E.coli* TG1 and incubated for 1 h at 37℃ with shaking at 250 $r\cdot min^{-1}$. Plasmid was isolated from the culture product and digested by *Eco*R I and *Hind* Ⅲ. Electrophoresis was performed to check the digested product.

Production and antigen-binding affinity test of the soluble MG_7 scFv

The strongly positive recombinant phage clones (3 μL containing 2×10^9 pfu) were separately added into 5mL log-phase *E.coli* HB2151 and incubated for 1 h at 37℃ with shaking at 250 $r\cdot min^{-1}$. 10 μL IPTG (isopropyl β-D-thiogalactopyanoside) were added and incubated overnight at 37℃ with shaking at 250 $r\cdot min^{-1}$. Cells were precipitated by centrifugation and supernatant was also collected. The precipitated cells were subjected to osmotic shock for preparation of soluble MG_7 scFvs. KATOⅢ cells in log phase were transferred into a 96 wells-plate and immobilized on the wall by centrifiguation at 1000g for 10min, and finally fixed in 0.25$mL\cdot L^{-1}$ glutaraldehyde. 0.2 mL perplasmic extracts and supernatant were applied to each well and incubated at 4℃ overnight. 0.2 mL anti-E tag antibody were applied to each well and incubated at 37℃ for 2 h. 0.1 ml HRP-labeled goat anti-mouse (HRP-GAM) Ig solution was added into each well. The absorbance value (A) at 450nm of reactant in each well was measured after incubation for 1 h at 37℃ and staining with TMB.

Immunodoting test of the yield of soluble MG_7 scFv

40 μL of perplasmic extracts and supernatant were separately dotted on the Hybond-C super membrane and dried at 60℃ for 30 min. After being blocked by 50 $mL\cdot L^{-1}$ nonfat milk for 2 h, the Hybond-C super membrane was incubated in 5mL diluted anti-E tag antibody solution at 37℃ for 2 h. 5 mL HRP- labeled goat anti-mouse (HRP-GAM) Ig solution were added for another incubation at 37℃ for 1 h and eventually stained by DAB.

Western blot test of the molecular mass of soluble MG_7 scFv

40 μL of perplasmic extracts and supernatant were firstly analysized by SDS-PAGE and then transferred onto the Hybond-C super membrane. After being blocked by 50 $mL\cdot L^{-1}$nonfat milk, the Hybond-C super membrane was incubated in 5mL diluted anti-E tag antibody solution at 37℃ for 2 h. 5 mL of HRP- labeled goat anti-mouse (HRP-GAM) Ig solution were added for another incubation at 37℃ for 1 h and

eventually stained by DAB.

DNA sequencing of MG_7 scFv

DNA sequencing was performed by ABI PRISM™ 377 DNA sequencer.

RESULTS

Restriction analysis of the strong positive recombinant phage clones

Two strongly positive clones were found to be recombinant clones which contained the exogenous gene. One of the two strongly positive clones contained a 450bp fragment of exogenous gene (Lane 1)and the other one contained a 750bp fragment of exogenous gene(Lane 2, Figure 1).

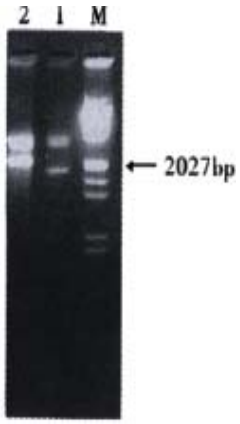

Figure 1 Restriction analysis of the strong positive recombinant phage clones. M: λ/EcoR I and Hind II; 1,2: Recombinant clones

Antigen-binding affinity of the soluble MG_7 scFv by ELISA

One of the strong positive clones was shown to produce soluble form of MG_7 scFv with Antigen-binding activity (Table 1). This clone was confirmed to contain a 750bp fragment of exogenous gene by restriction analysis above and chosen for later use.

Table 1 ELISA of the soluble MG_7 ScFv for binding with KATOIII cells (*A* value)

ELISA	Number of strong positive clones		Neg. ctrl
	1	2	
First round	0.287	0.776	0.201
Second round	0.346	0.802	0.223

The yield of soluble MG_7 scFv

The positive signal displayed on the dotting site with perplasmic extracts from induced *E.coli* HB2151 was significantly stronger than that from non-induced *E.coli* HB2151 (Figure 2). It implied that *E. coli* HB2151 had successfully produced the soluble MG_7 scFv via induction by IPTG.

Figure 2 Immunodoting of soluble MG_7 scFv.1: Perplasmic extracts from induced *E.coli* HB2151; 2: Supernatant from induced *E.coli* HB2151; 3: Perplasmic extracts from non-induced *E.coli* HB2151

The molecular mass of MG_7 scFv

A protein band with positive signal was found at *Mr* 30 indicating that the soluble MG_7 scFv was a protein of *Mr* 30 (Figure 3).

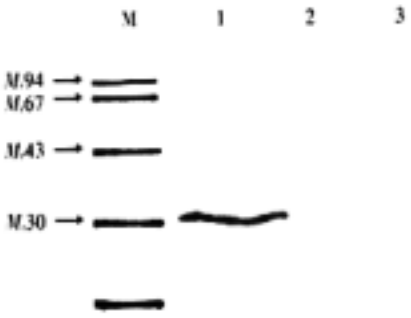

Figure 3 Western blot of the molecular mass of soluble MG_7 scFv. M: Protein marker; 1: Perplasmic extracts from induced *E.coli* HB2151; 2: Supernatant from induced *E.coli* HB2151; 3: Perplasmic extracts from non-induced *E.coli* HB2151

DNA sequence of MG_7 scFv

The V_H and V_L genes of MG_7 scFv were respectively 363 bp and 321 bp in length. The V_H gene has two conserved codon for cysteine at 67-69bp and 289-291bp.The V_L gene has two conserved codon for cysteine at 472-474bp and 664-666bp. Both of the V_H and V_L genes are highly homologous with the variable fragment of some known antibodies (Figure 4).

Figure 4 Nucleotide sequence of MG_7 scFv

DISCUSSION

MG_7, a monoclonal antibody against human gastric cancer, was proved to possessa quite high specificity and sensitivity to gastric cancer associated antigen. It was successfully used in experimental targeting therapy in nude mice bearing transplanted human gastric cancer[30]. But owing to its murine origin, like many other similar antibodies, MG_7 antibody can elicit anti-mouse immunoreaction in man and thus its use in clinical practice is restricted[31,32]. One of the efficient strategies to this problem is to remove the constant region of antibody which makes main contribution to the immunogenicity of the murine antibody to human being[33-38]. On the other hand, antibody without constant region, termed scFv, is less antigenic and induces weaker repulsive reaction. In addition, it is a smaller molecule and comprises 1/6 of its original antibody in molecular mass which ensure that scFv can more readily penetrate into the tumor tissue *in vivo* and be easily cleared up from the normal tissue[39,40]. Besides, the scFv is more available than its original antibody by gene engineering technology which can provide an economical means for diagnosis of gastric cancer[41-47].

As mentioned above, the scFv is advantageous to its original antibody in clinical practice. Therefore, developing the MG_7 scFv is of great significance in both early diagnosis and therapy of gastric cancer. For example, MG_7 scFv fused with avidin can be used as a reagent in immuno-PCR for early diagnosis of gastric cancer. Additionally, a new immunotoxin for treatment of gastric cancer can be developed by fusing the MG_7 ScFv and A subunit of ricin together. MG_7 ScFv can direct the A subunit of ricin to MG_7 positive gastric cancer cells[48-50]. In our previous study, the MG_7 recombinant phage antibody derived from MG_7 hybridoma was constructed and subsequently two strong positive phage antibody clones were screened out from this library[51].

Targeting therapy for tumors in the last decade has become a highlight in the field of tumor therapy[52-57]. In past, the discoveries of many tumor specific antigen (TSA) and tumor associated antigen (TAA) assured the practicability of antibody as a tool in tumor targeting therapy[58-69]. Ascribed to its high specificity and sensitivity in recognizing associated antigen, antibody is the optimal candidate for targeting mediator. Therefore, targeting therapy mediated by antibody still remains as a promising curative modality among the ways of tumor therapy and attracts worldwide attention[70].

This study was conducted with the purpose to produce the soluble MG_7 scFv, identify its antigen-binding affinity, determine its molecular mass and get an understanding of its nucleotide sequence. We first examined the length of exogenous MG_7 scFv gene harbored in the two strong positive phage antibody clones by restriction analysis and found that one of the phage antibody clones contained a 750bp fragment of exogenous gene which was identical to many discovered scFvs in length. Secondly, we prepared the perplasmic extracts (containing majority of the soluble scFv) from IPTG-induced *E.coli* HB2151 and detected the antigen-binding affinity of MG_7 scFv by ELISA. One of the soluble MG_7 scFvs was shown to possess apparent antigen-binding activity. Subsequently, immunodoting test exhibited that *E.coli* HB2151 had successfully produced the soluble MG_7 scFv with high yields via induction by IPTG. Meanwhile, western blot suggested that the molecular mass of soluble MG_7 scFv was *Mr* 30. Finally, DNA sequencing unraveled that the MG_7 scFv had the common characteristics shared by other known scFvs in nucleotide sequence. Collectively, we have successfully developed the soluble MG_7 scFv and created an opportunity to study its application in targeting therapy of gastric cancer.

Abstract

The prognosis of patients with HCC still remains dismal. The life expectancy of HCC patients is hard to predict because of the high possibility of postoperative recurrence. Many factors, such as patient's general conditions, macroscopic tumor morphology, as well as tumor hitopathology features, have been proven of prognostic significance. Female HCC patient often has a better prognosis than male patient, which might be due to the receptor of sex hormones. Younger patients often have tumors with higher invasiveness and metastatic potentials, and their survival and prognosis are worse than the older ones. Co-existing hepatitis status and hepatic functional reserve have been confirmed as risk factors for recurrence. Serum alpha-fetoprotein (AFP) is useful not only for diagnosis, but also as a prognostic indicator for HCC patients. AFP mRNA has been proposed as a predictive marker of HCC cells disseminated into the circulation and for metastatic recurrence. Many pathologic features, such as tumor size, number, capsule state, cell differentiation, venous invasion, intrahepatic spreading, and advanced pTNM stage, are the best-established risk factors for recurrence and important aspects affecting the prognosis of patients with HCC. Marked inflammatory cell infiltration in the tumor could predict a better prognosis. Clinical stage is still the most important factor influencing on the prognosis. Extratumor spreading and lymph nodal metastasis are independent predictors for poor outcome. Some new predictive systems have recently been proposed. Different strategies of treatment might have significant different effects on the patients' prognosis. To date, surgical resection is still the only potentially curative treatment for HCC, including localized postoperative recurrences. Extent of resection, blood transfusion, occlusion of porta hepatis, and blood loss affect the survival and prognosis of HCC patients. Regional therapies provide alternative ways to improve the prognosis of HCC patients who have no opportunity to receive surgical treatment or postoperative recurrence. The combination of these treatment modalities is hopeful to further improve the prognosis. The efficacies of neoadjuvant (preoperative) or adjuvant (postoperative) chemotherapy or chemoembolization in preventing recurrence and on the HCC prognosis still remain great controversy, and deserves further evaluation. Biotherapy, including IFN-alpha therapy, will play more important role in preventing recurrence and metastasis of HCC after operation.

Qin LX,Tang ZY.The prognostic significance of clinical and pathological features in hepatocellular carcinoma. *World J Gastroenterol*/2002;8(2):193-199

INTRODUCTION

The outcome for patients with hepatocellular carcinoma (HCC) still remains dismal, although it has been proven much in the past few decades, a definitive subset is cured by surgery only, and encouraging long-term survival of patients have been obtained in some clinical centers. The high possibility of intrahepatic and/or extrahepatic recurrence postoperatively remains one major obstacle for further improving the survival and prognosis of HCC patients. The life expectancy of HCC patients is hard to predict, making it difficult to decide the patient's prognosis. Many factors, such as the patient's general conditions (age, sex, co-existing hepatitis, liver function, AFP level), macroscopic tumor morphology (tumor size, number, capsule status, intra- or extrahepatic spreading, vessel invasion,), tumor pathohistology features, as well as effective treatment and adjuvant therapies, have been proven of prognostic significance. In recent years, as the understanding of tumor biology and the development of molecular biology techniques, many molecular factors (biomarkers) have been shown related to prognosis[1-11]. In this review, we will focus on the prognostic significance of clinical and pathological features of HCC.

PATIENTS'SEX AND AGE

Sex and sex hormone related factors

Many reports indicate that female HCC patient more frequently has a well-encapsulated, less invasive tumor, and longer survival, lower recurrent rate, and better prognosis than male patient. These might be due to the receptor of sex hormones[5,12]. Both androgen receptor (AR) and estrogen receptor (ER) are found closely related to the prognosis of HCC patients. The 5-year survival rates of AR negative, ER negative, ER positive, or AR positive HCC patients were 55%,

24%, 10%, and 0%, respectively. ER positive HCC has less malignant biologic behavior and a better prognosis than ER negative ones, with higher percentages of single nodule, complete encapsulation, and lower PCNA labeled index. And the ER positive rate of small HCC (62.5%) is higher than that of large HCC (30.4%). The presence of variant liver ER transcripts in the tumor is the strongest negative predictor of survival in inoperable HCC, with spontaneous survival significantly worse than that of patients with wild-type ER. HBsAg-positive patients with variant receptors have a even worse survival[12]. But there is still controversy with the relationship between the better prognosis of female HCC patients and the sex hormone receptors.

Age

Younger HCC patients often have tumors with higher invasiveness and metastatic potentials, higher recurrence possibility, and their survival and prognosis are worse than the older ones. However, Chedid found male, older patients often had poorly differentiated tumors, and poorer survivals, and age younger than 45 years was a good prognostic factor[13]. In authors' institute, no significant difference between the younger and older patients was found[14].

CO-EXISTING HEPATITIS STATUS AND LIVER CIRRHOSIS

Co-existing hepatitis status and liver cirrhosis are other important factors influencing the prognosis of HCC patients. The inflammatory activity and hepatic reserve have been confirmed as risk factors for recurrence. Longer disease-free survival (DFS) is found in patients without active hepatitis, and suppression of co-existing hepatitis is necessary to achieve better DFS[15]. The postoperative overall and disease-free survival rates of patients without hepatitis viral infection (N-HCC) are better than those hepatitis B virus-related HCC (B-HCC) and HBV-HCV double infection HCC(D-HCC)patients. The postoperative long-term survival rate of patients seronegative for HBsAg is greater than that of patients seropositive for HBsAg[16]. This is due to N-HCC cases have a good liver function reservation, and have no synchronous and metachronous multicentric occurrence[17]. D-HCC often has a higher surgical complication rate and hospital mortality, and recurred earlier after hepatectomy[18].

A high viral load is an independent risk factor for recurrence. The HBeAg, wild-type HBV are more likely to be found in patients with a high viral load, while precore mutant-type HBV is useful for estimating a patient's prognosis after resection of B-HCC[19]. Patients infected with genotype 1b of HCV may have a relatively high risk of ongoing hepatocarcinogenesis and more aggressive progression of associated liver dysfunction, resulting in a poorer outcome than with other genotypes[20, 21].

Functional reserve of the remnant cirrhotic liver is another independent prognostic factor. Hepatic functional damage immediately after hepatectomy is a significant risk factor for early intrahepatic recurrence[22]. Some liver functional markers, such as alanine transaminase (ALT), gamma-glutamyl transpeptidase (GGT), serum albumin level, the preoperative indocyanine green (ICG) retention value at 15 minutes after injection, particularly the Child-Pugh classification, are important predictive markers for DFS of HCC patients[23-25]. According to the scoring of hepatitis activity index (HAI), the histologic activity of hepatitis was closely related to the HCC recurrence, the HCC patients with middle hepatitis activity (HAI score of 6-9) in the non-tumor liver tissue had a higher 2-year intrahepatic recurrent rate[26]. Recurrence hardly could be avoided in the patients with liver dysfunction[27,28]. The serum albumin level of patients was also an independent risk factor of early recurrence, while liver cirrhosis and serum bilirubin were independent prognostic factors for late recurrence after HCC resection[29]. Patients with Karnofsky index <80%, serum bilirubin >50micromol/l, serum alkaline phosphatase at least twice the upper limit of normal range, and prothrombin time <70% of normal level have been found to have a poor prognosis[14,30].

TUMOR MAKERS

Serum alpha-fetoprotein (AFP) is useful not only for diagnosis, but also as a prognostic indicator for HCC patients. Patients with high AFP levels at diagnosis tended to have greater tumor size, bilobar involvement, massive or diffuse types, and portal vein thrombosis. The median survival rates with normal AFP (<20IU/mL), or with moderately elevated AFP (20-399IU/mL) (6-7 months) were significantly longer than that with markedly elevated AFP (> or =400IU/mL) (3months)[31]. Nonetheless, a correlation could not be established between increased AFP and Okuda's stages, degree of tumor differentiation, or extrahepatic metastasis.

AFP mRNA has been proposed as a predictive marker of HCC cells disseminated into the circulation and for metastatic recurrence in many reports[32-37], but its clinical significance remains controversial[38-40]. The patients with positive AFP mRNA in peripheral blood were found to have a higher possibility of extrahepatic metastasis than those negative. Some of them could change to negative after adjacent treatment, whose overall and disease-free survival rates are much better than those with permanent positive AFP mRNA. So, AFP mRNA in peripheral blood of HCC patients in perioperative period might be a predictive marker for the early intrahepatic recurrence and distant metastasis after HCC resection[32,33]. In a recent report, circulating AFP mRNA was transiently detected in cirrhosis with no predictive value for HCC development.

Lens culinaris agglutinin A-reactive fraction of alpha-fetoprotein (AFP-L3) is found to be a useful indicator of distant metastasis and a poor prognosis for HCC. Patients with AFP-L3-positive had worse liver function and larger tumors compared to the negative group. They also had more advanced cancer with poor tumor histology compared to the negative group. Distant metastasis was diagnosed significantly more often in the positive group than that in the negative group[41].

Although DCP was not an independent prognostic factor, its measurement was effective in predicting HCC recurrence and had the advantage that it can be assessed before operation[42]. However, albumin mRNA in peripheral blood has no confirmed value for predicting circulating spread of HCC cells.

PATHOLOGICAL FEATURES OF TUMOR

Many pathologic factors of tumor itself, such as tumor size, number, capsule state, cell differentiation, venous invasion, presence of satellite nodules, and advanced pTNM stage, are the best-established risk factors for recurrence and important aspects affecting the prognosis of patients with HCC[43-46]. Assal *et al*. proposed an invasiveness scoring system to predict recurrence and survival after curative HCC resection, which consists of six variables including portal venous invasion, intrahepatic spreading, hepatic venous invasion, membrane invaded, and no tumor capsule, or capsule invaded. According to this system, HCC could be divided into three groups: low invasiveness HCC (A): 0-1 score, middle invasiveness (B): 2-4, and high invasiveness HCC (C): 5-11 scores. The recurrent rate increased as the score became higher. The prognosis of Group B and C patients were much worse than Group A[47].

Tumor size

Many studies have confirmed that tumor size is one independent

prognostic factor[46,50]. Both of the 5-year overall survival (OS) and disease-free survival (DFS) rates of small HCC(tumor largest diameter≤5cm) are better than that of large HCC (tumor diameter >5cm)[3,4-8,14,48].

Tumor number and capsule status

The prognosis of patient with single tumor nodule is much better than those with multiple nodules. However, there was still a different result, no significant difference between their overall and DFS rates could be found[49].

The patients with well-encapsulated HCC have a better prognosis than those with poor encapsulated. However, well-encapsulated and nonnecrotic HCCs have a significantly higher tumor pressure (TP) and great pressure gradient (TP-PVP), both of them are found to associate with venous invasion or intrahepatic metastasis[50].

Venous invasion and intra-or extrahepatic spreading

Venous invasion and intrahepatic metastasis (IM) might strongly reflect the invasiveness of HCC. They are also important independent factors for poor prognosis[45, 49, 51,52]. In Authors' institute, the 5-year survival rate of the HCC patients without portal vein thrombi (PVT) (63.9%) after operation is much higher than that of patients with PVT (40.8%). Ouchi K, *et al*. defined portal vein invasion (Vp) and IM as the extratumor spread, and found it was the only significant variable influencing recurrence in multivariate analysis. As a predictive factor for recurrence after resection of HCC, the extratumor spreads was found to be more accurate than is any single invasiveness parameter such as Vp or IM[53]. The patients with macroscopic portal vein invasion, microscopic vascular invasion, intrahepatic metastasis, poor differentiation, pleomorphism, sarcomatous change, vascular lake, and angiographic condensed pooling were more frequently found to have extremely poor prognosis[54]. The prognosis of patients with lymph nodal metastasis from HCC is generally poor, even if hepatic resection with regional LN dissection is performed[52,55].

Inflammatory cell infiltration

Marked inflammatory cell infiltration in the tumor could predict a better prognosis, which could attribute to the anti-tumor effect induced by cellular immunity of CD8+ and CD4+ T lymphocytes. Wada found the patients with HCCs less than 3 cm in diameter with marked inflammatory cell infiltration had a much lower recurrence rate after resection (9.1%) (compared with 47.7% in the controls), and a higher 5-year survival rate (100%) (compared with 65.1% in the controls). The tumor invasion into the portal vein in the vicinity of the tumor was much lower. Varying degrees of piecemeal necrosis of cancer nests produced by infiltrating lymphocytes were observed in all patients with marked inflammatory cell infiltration in the tumor[56].

CLINICAL STAGING

It is well known that clinical stage is the most important factor influencing on the prognosis of HCC patients. The most common used staging system is UICC's TNM (tumor, nodes, metastases). Okuda system is also used in some regions. Based on the current TNM staging system for human HCC, a new T staging system has been proposed to correlate the staging group with patient outcome after curative liver resection. In this new system, T1 is defined as no vascular invasion, small size (< or = 5cm), and solitary tumor; T2 as the presence of one of the following factors: size greater than 5cm, vascular invasion, or multiple tumors; T3 as the presence of two of the above three factors; and T4, the presence of all three factors. The new T staging system shows good correlation between the staging group and patient outcome. But this modified TNM system is not superior to the UICCpTNM system in predicting survival of HCC patients[43]. Portal vein invasion (Vp) and intrahepatic metastasis (IM) strongly reflect the invasiveness of HCC, and are predictive factors for recurrence and prognosis after resection of HCC[53]. Lymph nodal metastasis is one independent predictor for poor outcome[55].

A new score system, the Cancer of the Liver Italian Program (CLIP) score, recently is proposed, which includes the parameters involved in the Child-Pugh stage, plus macroscopic tumor morphology, AFP levels, and the presence or absence of portal thrombosis. The CLIP score is able to predict survival better than the Okuda or TNM staging system, accurately identify patients with different prognoses, particularly in the early phases of HCC[57]. Besides, Schoniger-Hekele developed a multivariate Cox proportional hazard model (Vienna survival model for HCC=VISUM-HCC) predicting survival, and found patients with serum bilirubin > 2mg/dl, portal vein thrombosis, prothrombin time <70%, AFP> 180mg/l, tumour mass >50%, and enlarged lymph nodes were independent predictors of survival. Applying the VISUM-HCC survival model to patients in Okuda stage 2 identified subgroups with an excellent and very poor prognosis for which different treatment modalities should be offered[52].

TREATMENT STRATEGIES RELATED

Effective treatment is important for prolonging the survival and improving the prognosis of HCC patients. Different strategies of treatment might have significant different effects on the patients' prognosis.

At present, surgery is still the only potentially curative treatment for HCC, including either partial hepatectomy or total hepatectomy with orthotopic liver transplantation (OLT). Although the survival rates of selected patients for transplantation and partial hepatectomy are comparable, the use of OLT is limited by the difficulty of obtaining donor livers, the expensive cost (particularly in developing countries)[58]. So, surgical resection is still the most important way to obtain long-term survivals. In recent years, regional cancer therapies, such as transcatheter arterial chemoembolization (TACE), and vary kinds of liver tumor ablation therapies (including percutaneous ethanol injection-PEI, percutaneous microwave coagulation therapy-PMCT, radiofrequency ablation-RF, etc.) have been developed. These regional therapies are hopeful in further improving the prognosis of HCC patients who have no opportunity to receive surgical treatment or postoperative recurrence. The combination of these treatment modalities is hopeful to further improve the prognosis of HCC patients[59,60].

OPERATION RELATED

Many operation-related factors, such as extent of resection, blood transfusion, occlusion time of porta hepatis, blood loss, affect the survival and prognosis of HCC patients.

Surgical margin

The significance of the extent of surgical resection remains controversial. Some reports indicated it had no significant influence on the OS and DFS rates. No significant difference between the major hepatectomy (2 segments or more) and a minor hepatectomy group (one segment or less) could be observed in patient OS and DFS. So, a major hepatectomy is therefore not recommended for patients with solitary small HCC[61,62]. However, many other reports emphasized the importance of surgical margin in the prognosis of HCC patients. Anatomical resection appeared to have a beneficial effect on recurrence-free survival after hepatectomy for HCC. If the liver

functional reserve is good, the extent of surgical resection should be big enough to increase the DFS[63,64]. Some reports indicated that surgical margin might have some effect on the survival rate of patients with small HCC, while no obvious influence on the overall survival of HCC patients[65]. However, in China, co-existing liver cirrhosis is found in most of the HCC patients, which limits the extent of surgical resection. If major liver resection is performed in the patients with severe liver cirrhosis, the patients could be died of the poor remnant liver function. And more, when tumor locates in the porta hepatis or is closed to the important vessels (blood vessels and bile duct), it is impossible to have the surgical margin >1cm. In authors' institute, no significant difference in the survival rates between the HCC patients received different extensions of liver resection was found. So, it is not necessary to try to have an extended surgical margin for the patients with obvious liver cirrhosis.

Blood transfusion

Many reports indicate perioperative blood transfusion enhances the risk of intrahepatic recurrence of HCC, and is a significant independent factor that influence cumulative survival rate of patients[48,66]. Cox regression analysis for recurrence revealed that blood transfusion was the most significant prognostic indicator for recurrence in stage I-II patients but not in stage III-IV patients[67].

ADJUVANT THERAPIES

Adjuvant therapies are hoped to decrease or elimination of intrahepatic recurrence of HCC after liver resection and satisfactory OS. However, in 2000, Chen *et al*. reviewed all of the eight truly randomized and quasi-randomised clinical trials (totaling 548 patients) (RLT) that compared HCC patients who were given and not given neoadjuvant/ adjuvant therapy as a supplement to curative liver resection. Both pre- (neoadjuvant) and post-operative (adjuvant), systemic and locoregional (+/- embolization), chemo- and immunotherapy interventions were tested. Seven of the eight trials reported no survival benefit from adjuvant therapy. Only one trial reported a statistically significant difference for survival and DFS for the treatment arm, but the results of both its arms were very poor when compared to other studies. So, there is no evidence for efficacy of any of the adjuvant protocols reviewed on the survival and prognosis of HCC patients[68]. Little and Fong also thought as yet there were no evidence demonstrated benefit from the various neoadjuvant and adjuvant therapies investigated[58].

Preoperative adjuvant therapy (neoadjuvant therapy)

The value of preoperative TACE on the prognosis still remains great controversy. Many reports indicated that it could increase the possibility of recurrence and lung metastasis, showed no contribution to prognosis, should be avoided for the resectable HCC, particularly in patients with advanced cirrhosis of the liver[69,70]. Partial tumor necrosis caused by preoperative TACE might facilitate postoperative disease recurrence. The possible reason is that the remaining tumor cells might become more aggressive, and less firmly attached, more likely to be dislodged into the bloodstream during hepatic resection [71]. And more, preoperative TACE for resectable HCC results in delayed surgery and operational difficulty, without any benefit. It might also increase the possibility of liver failure in those with severe liver cirrhosis[32]. Preoperative TACE should only be performed to reduce tumor bulk in patients with HCC with borderline resectability, and increased the resectability. Peng *et al*. found preoperative TACE might only benefit patients with tumors >8cm but not those with tumors 2 to 8cm[72]. Yoshida found preoperative TACE could not improve DFS after liver resection, but preoperative transarterial immunoembolization (TIE), a newly developed arterial embolization technique using OK-432 and fibrinogen, seemed to be more effective than conventional TAE against extracapsular invasion and intrahepatic metastasis, could improve the disease-free survival[73]. However, Wu *et al*. found effective preoperative TACE might be one of the best methods for resectable HCCs including small HCCs for improving disease-free survival after hepatectomy[74].

Preoperative portal vein embolization could improve prognosis after right hepatectomy for HCC in patients with impaired hepatic function, but cannot prevent tumor recurrence after HCC resection[75]. Main portal branch transection combined with major liver resection and neoadjuvant and adjuvant locoregional immunochemotherapy could increase the resectability rate and the overall survival and DFS[76]. Preoperative administration of 5-FU and interferon LFN-beta may prevent recurrence of co-existing hepatitis B and C virus infections[77].

Postoperative adjuvant therapy

Effective postoperative adjuvant treatment might also be helpful in further improving the prognosis of HCC patients[78].

The effectiveness of postoperative chemotherapy and chemoembolization on the prognosis of HCC patients still remains controversial. Some reports indicated TACE or hepatic arterial infusion chemotherapy (HAIC) was an effective in preventing recurrence after radical hepatectomy for HCC, it could suppress residual liver recurrence from intrahepatic micrometastases rather than multicentric carcinogenesis[79-82]. This was confirmed by one RCT[83]. However, another RCT indicated that TACE after radical resection for HCC could increase the possibility of extrahepatic metastasis, and the prognosis would be even worse[84]. And more recently, Ono *et al*. summarized three RCTs of postoperative chemotherapy, and found postoperative chemotherapy was associated with significantly worse disease-free and overall survival rates, enhanced the cancer recurrence in the remnant liver is enhanced and deteriorated the long-term outcome in patients with cirrhosis[85].

According to authors' institute data, postoperative adjuvant TACE or HACE or combined IFN-alpha therapy, or autologous lymphocytes activated vitro with recombinant interleukin-2 (LAK) therapies could decrease significantly the 3-year recurrent rate of patients received radical liver resection for HCC[3,86,87]. Postoperative TACE is useful for prevention and treatment of HCC recurrence, particularly in treating the postoperative residual tumor[88,89].

Biotherapy plays more and more important role in the prevention of recurrence and metastasis of HCC after operation[33]. Adoptive immunotherapy can lower recurrence and improve recurrence-free outcomes of HCC[78].

Postoperative IFN-alpha therapy can decrease recurrence after resection of hepatitis C virus-related HCC[90]. This result was further confirmed by two pilot RCTs[91,92]. A similar effect was obtained by preoperative IFN-alpha therapy, it might due to IFN can prevent the recurrence of hepatitis B and C virus, and decrease the incidence of HCC in patients with HCV[48,93]. We found high-dose and long-term therapy with IFN-alpha dose-dependently inhibited tumor growth and recurrence after resection of HCC. The result of RCT carried in authors' institute also showed that IFN-alpha therapy could decrease the postoperative recurrence rate of HCC and prolong the DFS after HCC resection. This might be attributed to antiangiogenesis effect of IFN-alpha[94].

Recently, one RCT indicated that a single 1850 MBq dose of intra-arterial ^{131}I-lipiodol given after curative resection significantly decreased the rate of recurrence and increased the 3-year overall survival rate from 46.3% to 86.4%[95].

TIME OF RECURRENCE

Recent studies have shown that the prognosis of recurrent HCC after resection was dependent on the time of recurrence. Based on the time of recurrence, Poon *et al*. classified the intrahepatic recurrences into early (</= 1 year) and late (> 1 year) recurrences, and found that early and late intrahepatic recurrences were associated with different risk factors and prognostic factors. By multivariate analysis, preoperative tumor rupture and venous invasion were independent risk factors for early recurrence, whereas cirrhosis was the only significant risk factor for late recurrence. The prognosis for patients with early recurrence was worse than that of patients with late recurrence. Independent prognostic factors for early recurrence were serum albumin level and initial tumor pTNM classification, whereas only serum bilirubin level was found to be an independent prognostic factor for late recurrence. Early recurrences appear to arise mainly from intrahepatic metastases, whereas late recurrences are more likely to be multicentric in origin[29]. Prognosis was determined by the interval to recurrence, number of recurrent tumors, any concurrent extrahepatic recurrence, and type of treatment[24, 30,45].

SUMMARY AND PERSPECTIVE

In summary, the prognosis of patients with HCC is still dismal. In addition to clinical stage, age, sex, hepatitis activity in the nontumorous liver, treatment strategies, and perioperative transfusion also appear to have some prognostic significance. Pathologic factors indicative of tumor invasiveness such as venous invasion, presence of satellite nodules, large tumor size, and advanced pTNM stage, are the best-established risk factors for recurrence.

Effective treatment is important for prolonging the survival and improving the prognosis of HCC patients. Different strategies of treatment might have significant different effects on the patients' prognosis. To date, surgical resection is still the only potentially curative treatment for HCC, including localized postoperative recurrences. There is a lack of convincing evidence for the efficacy of neoadjuvant or adjuvant chemotherapy in preventing recurrence, which deserves further evaluation. Regional therapies, such as TACE, PEI, RF, etc, are alterative modalities for the nonresectable HCC and nonresectable recurrences. Combination of regional therapy modalities, may offer additional benefit. Biotherapy, particularly IFN-alpha therapy, will play more important role in the preventing recurrence.

Abstract

AIM: **Esophageal cancer remains a significant health problem worldwide. It is important to investigate alterations in expression of retinoic acid receptor-β, *p*53 and Ki67 proteins in esophageal carcinogenesis.**

METHODS: **To find biomarkers for early identification of esophageal cancer, we analyzed the retinoic acid receptor-β, *p*53 protein and the proliferation marker Ki67 in surgical specimens of normal, mildly, and severely dysplastic and malignant esophageal tissues by *in situ* hybridization of RNA and immunohistochemistry.**

RESULTS: **RAR-β was expressed in 94.3%(33/35) of normal mucosae, 67.8%(19/28) of the mild, 58.1% (18/31) of the severe lesions and 53.2%(116/218) of tumor samples. RAR-β mRNA was expressed in 62.7%(42/67), 55.1%(43/78) and 29.2%(7/24) of well, moderated and poorly differentiated SSCs. The *p*53 and Ki67 proteins were 5.9%(2/34) of the normal mucosa. P53 and Ki67 stained positively in 10.7% (3/28) and 21.4% (6/28) of mild dysplasia, and 51.6% (16/31) and 58.1% (18/31) of severely dysplasia respectively. Samples from esophageal cancer showed no higher levers of *p*53 and Ki67 expression than seen in severely dysplastic lesions. There was significant difference of RAR-β, *p*53 and Ki67 expression between normal mucosa and dysplatic tissue or esophageal cancer.**

CONCLUSION: **Loss of RAR-β expression and accumulation of *p*53 and Ki67 proteins may serve as biomarkers for early identification of esophageal cancer in the high-risk populations.**

INTRODUCTION

Esophageal cancer remains a significant health problem in the world because the 5-year survival rate is low[1]. Chemoprevention is very important for the esophageal cancer. But it remains a problem to identify the premalignant esophageal tissues in the people with high risk. In this study, we investigate the expression of retinoic acid receptor-â (RAR-â), Ki67 and *P*53 protein in normal, premalignant, and maligant esophageal tissues to find biomarkers for early identification of the disease.

Retinoids, a group of nature and synthetic analogues of vitamin A, can modulate cell growth and differentiation[2]. Retinoids are known to exert their biological effects by binding to specific nuclear retinoid receptors, which belong to a steroid/thyroid hormone-receptor superfamily. The nuclear retinoid receptors are divided into retinoic acid receptors (RARs) and retinoid X receptors (RXRs), both with three subtypes (α,β,γ)[3]. Retinoids can suppress or reverse epithelial carcinogenesis and to prevent the development of invasive cancer in many animal models[4-6]. In a Chinese clinical trial using the synthetic retinoid N-4-(ethoxycarbophenyl) retinamide, the incidence of cancer in the treatment group with severe esophageal dysplasia was 43.2%, that was lower than of the group treated with placebo[7]. Our previous study demonstrated that all-trans RA can induce esophageal cancer cell lines to undergo apoptosis, which was associated with the expression and upregulation of RAR-β[8]. In this study, we tried to explore the earliest loss of RAR-β expression.

Deletion or mutation of tumor suppressor genes may be a key event in carcinogenesis. The human *p*53 gene encodes a nuclear protein that may be vital in the regulatory control of cell proliferation[9,10]. Loss of wild-type *p*53 function is considered to be a key event in the induction of malignant transformation in many cancers,including esophageal cancers[11-14].

Ki67 is a nuclear antigen expressed during G1, S, M and G2 periods of cell cycle. The expression level of Ki67 indicated the status of cell proliferation. Some studies have showed that Ki67 protein could be a biomarker to identify the high-risk precancerous tissue[15,16]. The present study was undertaken to determine the accumulation of *p*53 and Ki67 protein in normal, premalignant, and malignant esophageal tissues to gain insight into the possible involvement of them in the early stage of esophageal carcinogenesis.

MATERIALS AND METHODS

Tissue specimens

Three hundred and twelve tissue specimens were obtained from the Ci County, Hebei Province and the Cancer Hospital, China, respectively. The esophageal specimens of normal mucosae (*n*=35) used in this study were obtained from a clinical chemopreventive trial in Ci County with a high prevalence of esophageal cancer. These samples were reviewed by pathologists and considered to be morphologically normal epithelium. There were 59 specimens of dysplatic lessions and 218 specimens of esophageal cancer from the Cancer Hospital, China. Of these dysplastic lessions, there were 28 cases of mild dysplastic lessions and 31 cases of severe dysplastic lesions. Of these esophageal cancers, there were 169 cases of squamous cell carcinoma (SCC), 29 cases of adenocarcinoma (AC) and 20 cases of adenosquamous cell carcinoma (AC-SSC). There were 67 well differentiated SSCs, 78 moderately differentiated and 24 poorly differentiated SSCs among the SSCs. All samples were

routinely fixed in 10% buffered formalin, embedded in paraffin, and cut into 4ìm sections. One of each of these sections was stained with hematoxylin and eosin for classification.

In Situ Hybridization of RNA

Levels of RAR-β expression were measured by using a previously described method of nonradioactive *in situ* hybridization. The quality and specificity of the digoxigenin-labeled anti-sense and sense riboprobes were determined using Northern blotting, and the specificity of the binding of antisense riboprobes was verified using negative control sections. Briefly, the tissue sections were treated with 0.2 N HCl and proteinase K, respectively, after deparaffinization and rehydration. The slides were then postfixed with 4% paraformaldehyde and acetylated in freshly prepared 0.25% acetic anhydride in a 42℃ for 1h with a hybridization solution containing 50% deionized formamide, 2X standard saline citrate, 2X Denhardt's solution, 10% dextran sulfate, 400μg/ml yeast tRNA, 250μg/ml salmon-sperm DNA, and 20mm dithiothreitol in diethylpyrocarbinate-treated water. Next the slides were incubated in 50μl per slide hybridization solution containing 20ng of a freshly denatures dig-cRNA probe at 42℃ for 4h. After that, the slides were washed for 2h in 2XSSC containing 2% normal sheep serum (NSS) and 0.05% Triton X-100 and then for 20minutes at 42℃ in 0.1XSSC. For color reaction, the slides were incubated for 30min at 23℃ in 0.1mol/L maleic acid and 0.15mol/L NaCl (PH 7.5, buffer 1) containing 2% NSS and 0.3% Triton X-100 and then incubated overnight at 4℃ with a sheep anti-digoxigenin antibody. After being washed in buffer 1 twice, the color was developed in a chromogen solution (45μl of nitroblue tetrazolium and 35μl of an X-phosphate solution in 10ml of buffer 2, which consisted of 0.1M Tris, 0.1M NaCl, and 0.05M $MgCl_2$ (PH9.5)) for 6h with occasional observation for color development. The slides were then mounted with cover glass in Aqua mounting medium.

Immunohistochemistry

The immunohistochemical detection of *p*53 protein and the proliferation marker Ki67 was performed using a modified ABC technique. Briefly, tissue sections were deparaffinized in xylene and rehydrated in a series of ethanol solutions (100-50%). The sections were then microwaved for 15min to retrieve antigens in 0.02M citric acid solution. The endogenous peroxidase activity was blocked by incubation in a 1% methanolic hydrogen peroxide solution for 30min. This was followed by preincubation with 20% normal horse serum to minimize nonspecific binding of the second antibody. The sections were then incubated at 23℃ for 4h with monoclonal mouse anti-*p*53 or Ki 67 antibody from Vector Laboratories (Burlingame, Calif., USA) both diluted at 1 ∶ 50 in PBS. After being washed three timed in PBS, the sections were incubated with biotinylated horse anti-mouse IgG (H+L) (Vector) for 30min at 23℃ and then incubated with the ABC kit (Vector) for 30min in the dark. This was followed by incubation with 3-amino-9-ethylcarbazole (Sigma Chemical, St. Louis, Mo., USA) solution were finally mounted with Aqua mount medium under coverslips. Control sections were incubated with normal mouse IgG instead of primary antibodies or with the second antibody only.

Review and scoring of the sections

The stained sections were reviewed and scored independently by two investigators using an Olympus microscope. The sections stained for nuclear retinoid receptors were assigned to positive or negative staining categories only. Positively staining means that 10% or more epithelial cells stained positively. Sections stained for *p*53 protein and Ki67 were assigned scores of 0-3, with 0 meaning no staining; 1, weak positive, the mounts of positive cells are less than 10%; 2, positive, the mounts of positive cells are more than 10% but less than 50%; and 3, strong positive, the mounts of positive cells are more than 50 %. Scores 0 and 1were counted as negative and scores 2 and 3 as positive cases. Statistical analysis was performed using fisher's exact test to determine the association between normal or dysplastic tissues and tumors. P values were generated using Statistica version 3.0a for a Macintosh computer (StatSoft, Tulsa, Okla., USA).

RESULTS

RAR-β expression

Our priliminary study showed that RAR-α, RAR-γ and RXR-α were expressed in all of the esophageal samples without significant difference, so we excluded RAR-α, RAR-γ and RXR-α from this study and only investigate the expression of RAR-β. In 33 of 35 samples of normal mucosae, RAR-β was expressed, whereas RAR-β were detected in only 67.8%(19/28) and 58.1% (18/31) of the mild and severe lesions, respectively. In 116 of 218 tumor samples, RAR-β was expressed (Table 1). The expression of RAR-β decreased significantly between normal mucosae and dysplastic tissues or esophageal cancers (Table 2). But it was similar among the three subtypes of esophageal cancer (Table 1). However RAR-β expression was associated with the degree of squamous cell differentiation: RAR-β mRNA was expressed in 62.7%(42/67) of well differentiated SSCs, but in only 55.1%(43/78) of moderated differentiated SSCs, and in 29. 2%(7/24) of poorly differentiated SSCs (Table 3).

Table 1 Expression of the biomarkers in all kinds of esophageal tissues

Biomarker	%(positive/total)					
	Normal	Mild Dysplasia	Severe dysplasia	SSC	AC	AC-SSC
RAR-β	94.3	67.9	58.1	54.4	51.7	45.0

Tumor differentiation	%(positive/total)
Well differentiated SCC	62.7(42/67)
Moderately differentiated	55.1(43/78)
Poorly differentiated	29.2(7/24)[a]

[a]$P<0.005$ *vs* χ^2 test between well differentiated and poorly diffentiated SSCs.

P53 and Ki67 expression

In contrast to RAR-β expression, the *p*53 tumor-suppressor gene and the proliferation marker Ki67 were only detected immunohistochemically in two cases each in the normal mucosa. P53 and Ki67 stained positively in 10.7%(3/28) and 21.4% (6/28) of mild dysplasia, respectively. A dramatic increase in their expression, however, was seen in 51.6%(16/31) and 58.1% (18/31) of

severely dysplastic esophageal lesions. Samples from esophageal cancers showed no higher levers of *P*53 and Ki67 expression than seen in severely dysplastic lesions. And there was no significant alteration found in the three subtypes of esophageal cancers (Table 1). However, there was significant accumulation between normal mucosae and dysplastic tissues or esophageal cancers. (Table 2).

DISCUSSION

In this study, we first analyzed the expression of RAR-β by using *in situ* hybridization, and then the *p*53 tumor-suppressor gene product and proliferation marker Ki67 protein using immunohistochemistry in normal, mild dysplastic, severely dysplastic, and cancerous mucosae. We found that RAR-β expression was progressively lost as early as in the mildly dysplastic stage of esophgeal mucosae. And RAR-β expression was significantly lost with esophageal squamous differentiation. *p*53 and Ki67 were also accumulated in the later precancerous stage of the esophagus. These results suggest that the detection of RAR-β expression and of *p*53 and Ki67 protein may be biomarkers for early identification of esophageal cancer in the high-risk populations.

It is well established that retinoids can modulate epithelial cell growth, differentiation, and apoptosis *in vitro* and *in vivo*. Retinoids can prevent abnormal squamous differentiation of epithelial cells in nonkeratinizing tissues physiologically. Retinoids can also reverse squamous metaplasia, which develops during vitamin A deficiency[2]. The abrogation in the retinoid signal pathway may be due to the loss of expression of RAR-β[17]. Indeed, in our recent study, we demonstrated that the sensitivity of esophageal cancer cells to RA was correlated not only with the constitutive expression but also with RA-induced upregulation of RAR-â[17]. Cell lines that failed to express RAR-β were resistant to RA and could form colonies in soft agar[17]. Thus, loss of RAR-β expression could contribute to the resistance to treatment with 13-cis RA in esophageal cancer. In addition, a more recent study demonstrated that RAR-β 2 knockout in F9 cells resulted in the loss of RA-associated growth arrest[18]. Various studies have clearly demonstrated that altered expression of retinoid receptors is associated with malignant transformation in human cells. Alter expression of RAR-β is a common event in different types of tumors, including head and neck, lung, and breast tumors[8,17,19,20]. In our previous study, RAR-β was expressed in all of the distant normal epithelia from esophageal cancer patients[21]. In this study, RAR-β expression is just a little low in the histologically normal mucosa. Taken together, it could be inferred that RAR-β serves as a biomarker for the early identification of esophageal cancer for chemoprevention strategy.

Previous studies demonstrated that lots of genetic alterations existed in specimens from esophageal cancer patients. For instance, *p*53 and *p*16 mutations were revealed to be early events during esophageal carcinogenesis[22, 23]. Loss of *p*53 activity could lead to malignant transformation of normal human cells[24,25]. The studies by Dr. Yang's group demonstrated that accumulation of *p*53 protein was due to *p*53 gene mutation, which occurred at very early stages of esophageal carcinogenesis[26]. Some studies have also showed that Ki67 protein could be a biomarker to identify the high-risk precancerous tissue[15,16]. In our study, both Ki67 and *p*53 proteins accumulated at early stages of esophageal carcinogenesis.

Since the RAR-β, *p*53, Ki67 expression showes significant changes at the early stage of esophageal carcinogenesis, then they could be biomakers to identify the high-risk precancerous tissue. The combination of them may improve the accuracy of identification greatly. But the underlying mechanism of the change is largely unknown, therefore more additional work is needed to investigate the mechanism and the correlation of lost expression of RAR-β, *p*53 gene protein mutation and Ki67 protein expression in esophageal cancers.

Abstract

AIM: **The transcription factor EGR-1 (early growth response gene-1) plays an important role in cell growth, differentiation and development. It has identified that EGR-1 has significant transformation suppression activity in some neoplasms, such as fibrosarcoma, breast carcinoma. This experiment was designed to investigate the role of *egr-1* in the cancerous process of hepatocellular carcinoma (HCC) and esophageal carcinoma (EC), and then to appraise the effects of EGR-1 on the growth of these tumor cells.**

METHODS: **Firstly, the transcription and expression of *egr-1* in HCC and EC, paracancerous tissues and their normal counterpart parts were detected by *in situ* hybridization and immunohistochemistry, with normal human breast and mouse brain tissues as positive controls. *egr-1* gene was then transfected into HCC (HHCC, SMMC7721) and EC (ECa109) cell lines in which no *egr-1* transcription and expression were present. The cell growth speed, FCM cell cycle, plate clone formation and tumorigenicity in nude mice were observed and the controls were the cell lines transfected with vector only.**

RESULTS: **Little or no *egr-1* transcription and expression were detected in HCC, EC and normal liver tissues. The expression of *egr-1* were found higher in hepatocellular paracancerous tissue (transcription level *P*=0.000; expression level *P*=0.143, probably because fewer in number of cases) and dysplastic tissue of esophageal cancer (transcription level *P*=0.000; expression level *P*=0.001). The growth rate of *egr-1*-transfected HHCC (HCC cell line) cells and ECa109 (EC cell line) cells was much slower than that of the controls. The proportion of S phase cell, clone formation and tumorigenicity were significantly lower than these of the controls' (decreased 45.5% in HHCC cells and 34.1% in ECa109 cells; 46.6% and 41.8%; 80.4% and 72.6% respectively). There were no obvious differences between SMMC7721 (HCC) *egr-1*-transfected cells and the controls with regard to the above items.**

CONCLUSION: **The decreased expression of *egr-1* might play a role in the dysregulation of normal growth in the cancerous process of HCC and EC. *egr-1* gene of transfected HHCC and ECa109 cells showed obvious suppression of the cell growth and malignant phenotypes, but no suppression in SMMC7721 (HCC cell line) cells.**

INTRODUCTION

The tumor suppressorgene therapy research has become increasingly interested. Tumor suppressor genes have two categories: Type 1, they undergo mutation or deletion, such as *p*53, Rb, WT1 and BRCA1 etc. Type 2, they express little or nil and with rare mutation or deletion, such as cx34, maspin and integrin α6 etc[1]. In designing the tumor gene therapy, the type IItumor suppressor genes are evidently more advantageous. We only need to induce or to promote more expression of the genes to get rid of many technical difficulties such as replacing the deleted gene or knocking out the mutated gene.

The early growth response gene, *egr-1* (Zfp-6 in standardized genetic Nomenclature for mice[2], also known as NGFI-A, Krox-24, Zif-268, or TIS-8) is one of the important members of the immediate early gene family. It encodes a protein EGR-1 with 3 adjacent zinc-finger motifs, and structures that are present in many DNA-binding transcription factors. Its special zinc-finger structure can bind with "GC-rich" DNA regulatory elements and can control that particular gene to transcribe[3]. The expression of *egr-1* is closely related to cell growth[4] and differentiation[5]. Some researching results have revealed that EGR-1 can reverse the malignant phenotype of HT-1080 fibrosarcoma and ZR-75-1 mammary carcinoma cell lines, and can also EGR-1 inhibit the tumorigenicity and transforming growth of these cells[6-8]. *egr-1* may act as a type II tumor suppressor gene.

Both hepatocellular carcinoma (HCC) and esophageal carcinoma (EC) are common malignant tumors in China. Many research works on HCC and EC[9-24], especially on the effects of the tumor suppressor genes such as *p*53, *p*16 and *p*21 etc[25-38] had been reported, but the reports about *egr-1* for these two cancers are still lacking. In this paper, the transcription and expression of *egr-1* in HCC,EC tissues and their normal counterparts were detected by *in situ* hybridization and immunohistochemistry in order to investigate the role of *egr-1* in the cancerous process of HCC and EC. The constructed *egr-1* eukaryo-expressing vector was transfected into HCC and EC lines, where there was absence of expression of *egr-1*, with a view to observe how the high level of exogenous expression of EGR-1 in the cancer cell influenced their growth, clone formation and tumorigenicity. The inhibitory action of *egr-1* on HCC and EC is to be probed so as to provide an experimental evidence for the study of gene therapy of the two cancers.

MATERIALS AND METHODS

Materials

The plasmids, pAC-h-*egr-1* (fragment of single and double enzyme digestion by BamH I and/or SalI was determined by $10g \cdot L^{-1}$ agarose gel electrophoresis. The size of the fragments was identical to that of

plasmid map), containing the whole cDNA fragment of human wild-type *egr-1* gene and pAC-Φ eukaryo-expressing vectors, were kindly granted by Dr. JG Monore, Pennsylvania University School of Medicine[39].

Human hepatocellular, esophageal carcinomas and breast tissue specimens were collected from the Pathology Department of Fourth Military Medical University and Medical College of Shantou University. All patients providing the specimens were not treated by radiotherapy or chemotherapy before operation. The specimens were fixed with 40g·L^{-1} formaldehyde solution (for*in situ*hybridization) and Carnoy solution (for immuno-histochemistry). Mouse brain tissues were from Balb/c mice.

The cell lines HHCC and SMMC7721 of HCC were purchased from Shanghai Cytology Institute, China. The EC cell line ECa109 was from Cytology Institute of Chinese Medical Academy. All the cell lines were cultured in RPMI 1640 medium supplemented with 100mL·L^{-1} new born bovine serum and grown in the circumstance of 37℃, 50mL·L^{-1} CO_2 and saturated humidity. Cell numbers were determined by Coulter counting method.

The Lipofectamine™, G418 and TRIzol™ total RNA extraction kit were purchased from Gibco/BRL Co. The Wizard™ plus Minipreps DNA purification kit was the product of Promega Co. The polyclonal rabbit anti-human EGR-1 (C$^{\#}$-19) antibody was from Santa Cruz Co.*in situ*hybridization (POD) detection kit and SABC immunohistochemistry kit were from Boster Co, Wuhan,China. The Advantage™ PCR purification kit was from Clontech Co, and γ-^{32}P-dATP was provided by Yahui Biomedical Engineering Co, Beijing.

Methods

Probe preparation and labeling

The plasmid pAC-h-*egr-1* was digested by both *Sal* I and *Bam*H I, and the products were determined by agarose gel electrophoresis; the 400 bp DNA fragments were recovered by promega DNA purification kit. The recovered DNA was dissolved in 20ul sterile three-distilled water and ultraviolet spectrophotometry was taken for quantitation analysis. γ-^{32}P-dATP 5'end Label method was used for probe labeling. After alcohol precipitation, the probe was dissolved in TE; the specific radiation activity was determined by TAC method, and stored at -20℃.

In situ hybridization and Immunohistochemistry

In situ hybridization was performed according to the kit instructions on the formaldehyde-fixed and paraffin-embedded sections. Human normal breast and mouse brain tissue sections were used as positive controls. According to the SABC stain instructions, immunohistochemistry was done on the Carnoy-fixed or frozen section. Positive control was frozen section of human normal mammary adenosis, and negative control was primary antibody-blank.

Gene transfection and identification after transfection

Transfection was performed according to the legend of Lipofectamine™ kit, and 48h later selective culture was added with 600mg·L^{-1} G418.2 weeks later, the cells and clones appeared all (the cells of blank control died). The concentration of G418 was changed to 400mg·L^{-1} G418 for maintenance. The clones were digested *in situ*, and transferred to a 6-well plate for amplification, which were used for detection of every item.

mRNA dot hybridization: 2×10^6 cells were collected and total RNA was extracted according to TRIzol™ total RNA extraction kit. The extracted RNA was dissolved in the RNase-free water. A absorbance value was determined, RNA quantity was calculated and purified was identified; stored at -80℃; procedures of RNA dot blot was according to the directions.

Western blot hybridization and immunohistochemistry: Western blot hybridization was performed according to the directions. The "cell crawling slide" in logarithm stage was collected, rinsed with PBS×2, fixed in 700mL·L^{-1} alcohol and stained by SABC kit. The positive control was frozen section of mammary adenosis, and the negative control was primary antibody-blank.

Assay of cell phenotype

FCM cell cycle examination: The transfected cells were digested by 2.5g·L^{-1} trypsin to a single cell suspension when they were 80% confluent, counted, 1×10^6 cells were fixed in 700mL·L^{-1} alcohol and FCM was performed.

Cell growth curve: cells of transfected and blank vector groups were digested by trypsin and counted in 1×10^3 cells. Each group was inoculated in 24-well plate, and 1ml RPMI 1640 medium containing 100mL·L^{-1} FCS was added. In the culture period, cells of 3 wells were digested and counted every day, and the mean values were also calculated. Of the remainder, the medium was changed every 3-4d and counted every 6-7d according to the cell growth conditions, growth curves were then made.

Examination of plate cloning: HCC and EC lines, which had been transfected with *egr-1* gene, G418 selected and amplified were digested to a single cell suspension. Cells counted were inoculated into 6-well tissue culture plates; each well contained 100 cells. The control cells were transfected with blank vector. Changing the medium 1～2 times per wk; by about 2 wk plates were taken out to observe the clone formation; fixed in methyl alcohol, Giemsa stained, clones over 50 cells were counted, and the mean value was adopted and clone formation rates were made.

Nude mice tumorigenicity: After trypsin digestion, the cells of the experimental and control groups were inoculated into nude mice subcutaneously with 1×10^7 cell (about 0.1-0.2mL) for each mouse. About 3wk later the mice were killed according to the tumor growth, and then pictures were taken. The tumor mass was separated carefully and weighed, and the daily growing mass was calculated then. Tumor tissues were fixed, paraffin embedded, HE stained and observed microscopically.

Statistical analysis

Results were expressed as mean±SE. To compare the mean values, Stata statistical software was used. $P<0.05$ was considered significant.

RESULTS

Egr-1 mRNA and protein expression in HCC and EC

In situ hybridization and SABC immunohistochemistry staining for *egr-1* mRNA and protein in human HCC, EC tissues and their normal counterparts were performed. Little or no *egr-1* transcription was detected in HCC and normal liver tissues. Higher transcription of *egr-1* was detected in hepatocellular paracancerous tissues such as large cell hyperplasia (LCD) and "atrophic-like liver plate (reluctant LCD)". *egr-1* mRNA signal was present in the cytoplasm. EGR-1 expression in HCC, normal liver and hepatocellullar paracancerous tissues was consistent with the transcription (When EGR-1expression in HCC compared with the expression in the paracancerous tissue, P=0.143. Table 1, Figure 1). EGR-1 protein signal was in the nucleus. Little or no *egr-1* transcription was detected in the aggressive EC and normal esophageal epithelial tissues (not including basal layer cells). Higher transcription of *egr-1* was detected in dysplastic esophageal epithelium. EGR-1 expression in aggressive EC, normal esophageal epithelium and dysplastic tissues was also consistent with the transcription (Table 2, Figure 2).

Table 1 *egr-1* transcription and expression in HCC tissue and its normal counterparts

Tissue	*n*	mRNA (%)	*n*	Protein (%)
Normal liver	8	0(0.0)	2	0(0.0)
Hepatic paracancerous tissue	22	21(95.5)	5	4(80.0)
Liver carcinoma	24	6(25.0)[a]	3	0(0.0)[b]

[a]*P*=0.000, [b]*P*=0.143, *vs* hepatic paracancerous tissue

Table 2 *egr-1* transcription and expression in EC tissue and its normal counterparts

Tissue	*n*	mRNA(%)	Protein (%)
Agressive carcinoma	47	8(17.0)[a]	6(12.8)[b]
Dysplasia	29	18 (62.1)	14 (48.3)
Normal epithelium	28	9(32.1)	2(7.1)

[a]*P*=0.000, [b]*P*=0.001, *vs* dysplasia

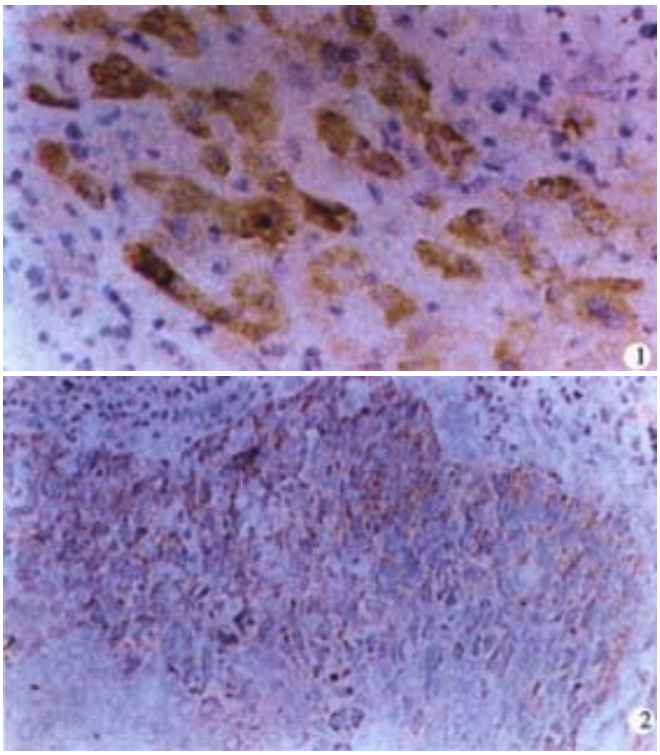

Figure 1 Positive signal of *egr-1* mRNA in the cytoplasm paracancerous "atrophic-like liver plate" tissue of HCC. SP×400
Figure 2 Positive signal of EGR-1 mRNA in the cytoplasm of moderately dysplastic esophageal epithelium. SP×400

Egr-1 mRNA and protein detection in transfected tumor cells

mRNA level (mRNA dot blot): The total RNA of *egr-1* and vector transfected HCC and EC cells were dot hybridized by ^{32}P labeled egr-1 probe. The result revealed that *egr-1* group had stronger signals than that of the control.

Western blot and immunohistochemistry: The proteins of *egr-1* and vector transfected HCC and EC cells were extracted and quantitatively analyzed. Then both groups with identical quantitative proteins were determined by SDS-PAGE; electrical transfer onto the nitro-cellulose membrane was made, and Western blot hybridization was performed. The results revealed that in *egr-1* transfected groups of both HCC and EC cells, there were strongly stained bands just at the molecular mass of 59ku, which was identical to that of EGR-1, whereas in all the controls there were no such bands present. This suggested that the tumor cells transfected by *egr-1* could strongly express EGR-1 protein. The results of immunohistochemistry by primary antibody EGR-1 and SABC method showed 50-70% positive staining of *egr-1* transfected cells were, while in the controls the results were all negative; which was consistent with that of the Western blot.

Malignant phenotype examination

Curves of cell growth

The growth rates of the *egr-1* transfected HHCC liver carcinoma cells and EC109 esophageal carcinoma cells were obviously slower than that of the controls. But the difference was not significant in the SMMC7721 liver carcinoma cell line (Figure 3).

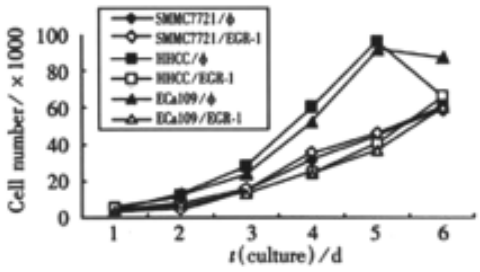

Figure 3 Cell growth curve of liver and esophageal carcinoma cells transfected *egr-1* and vector

FCM cell cycle assay

In *egr-1* transfected HHCC, the number of fraction of S phase accounted for 0.15, lower than that of the controls (0.28, *P*=0.038); i. e., the proportion of S phase was 0.46 lower than that of the control (Table 3). In ECa109, the number of fraction of S phase accounted for 0.18 (control 0.27, *P*=0.048), and was 0.34 lower than that of the control. In SMMC7721 (HCC), there was no marked difference between the experimental and the control groups (0.21 to 0.22, *P*=1.000). As for the G_1 and G_2/M phases, there were neither significant differences between experiment groups and control groups.

Table 3 Cell cycle of HCC and EC cells expressing EGR-1 with FCM (number of fraction)

Cell clone	G_1	G_2/M	S
HHCC/EGR-1	0.77	0.08	0.15[a]
HHCC/φ	0.64	0.08	0.28
SMMC7721/EGR-1	0.70	0.09	0.21[b]
SMMC7721/φ	0.70	0.09	0.22
ECa109/EGR-1	0.73	0.11	0.18[c]
ECa109/φ	0.64	0.10	0.27

[a]*P*=0.038, [b]*P*=1.000, [c]*P*=0.048, *vs* their controls

Plate cloning formation

In HHCC cell line, the clone forming rate of transfected cells was 49.0±10.6%, 42.7% lower than that of control 91.7±6.1%. In ECa109 line, the clone forming rate of transfected cells was 45.0±5.3%, 32.3% lower than that of control 77.3±3.1%. In SMMC7721, There were no statistical difference between the experimental group 26.0±2.6% and the control group 23.3±2.1% (Figure 4).

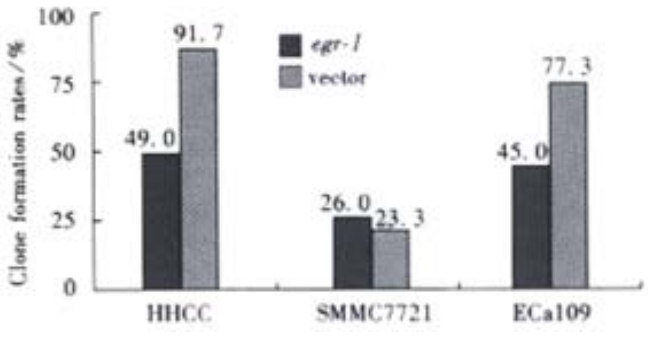

Figure 4 Clone formation rates of exogenous high EGR-1 expression HCC and EC

Nude mice tumorigenicity

All the inoculated nude mice had tumor mass growth except in one case (one of the three SMMC7721/φ inoculated mice). In HHCC cell line, the tumor growth rate of transfected group was 80.7%, lower than that of the control (P=0.001). In ECa109 cell, the growth rate of transfected group was 72.6%, also lower than that of the control (P=0.001). In SMMC7721, there was no growth rate difference between the experimental and the control group(P=0.681)(Table 4).

Table 4 Nude mice tumorigenicity of gene transfected groups in HCC and EC cells

Cell clone	n	Tumorigenicity rate	Tumor growth rate ($x\pm s$, mg·d^{-1})
HHCC/EGR-1	3	3/3	13.9±5.2[a]
HHCC/φ	3	3/3	70.9±7.8
SMMC7721/EGR-1	3	3/3	18.7±4.3[b]
SMMC7721/φ	3	2/3	15.2±13.0

ECa109/φ	4	4/4	47.1±11.3

[a]P=0.001, [b]P=0.681, P=0.001, *vs* their controls

DISCUSSION

Althrough *egr-1* is a member of immediate early genes, its expression is also elevated during the process of growth[4] and differentiation[5]. Observations suggest that EGR-1 have pleiotropic roles such as growth, development, differentiation etc. This is Supported by the finding that the GC-rich DNA-binding element for *egr-1* (GCE) is present in a large number of gene regulating regions, including growth factors, signal transduction genes, other transcription factors and oncogenes. In this report, we showed that *egr-1* transcription and expression decreased obviously in HCC and EC tissues compared with their paracancerous tissues. Another (large) study also indicated that human small cell lung tumors express little or no *egr-1* mRNA compared with adjacent normal tissues[40], further supporting our findings. Except that the *egr-1* gene was deleted only in all 5q$^-$ syndrome cases[41], *egr-1* expression was profoundly decreased in a number of other human tumor cell lines such fibroblastoma, glioblastoma, osteosarcoma and lung cancer[6].Therefore it seems likely that the inactivation of *egr-1* expression is a generalized phenomenon in the developmental process of a number of tumors.

Egr-1 is ubiquitously expressed at low levels but accumulates to relatively high levels in only a few adult organs as brain, heart, lung, kidney[42] and breast[1]. We showed here that normal liver and esophageal epithelial tissues expressed undetectable level of *egr-1*, but the *egr-1* gene was activated in the tissues of hepatic paracancerous tissue such as LCD and "atrophic liver plate" (reluctant LCD) and dysplastic tissue of esophageal carcinoma. During regeneration of normal liver tissue, increased *egr-1* expression is induced[43]. In mouse fibroblast NIH3T3 cells, *egr-1* expression increases two-fold 10min after UV irradiation, which rises to a maximum (eightfold induction) after 2h[6]. Human HT1080 fibrosarcoma subclone, cells H4, express little or no *egr-1*. Phorbol ester treatment only can elicit a small increase in *egr-1* expression in H4, in contrast to the normally rapid, high transient expression of *egr-1* observed after the addition of a wide range of stimulating agents to normal or immortalized cell lines[7]. Therefore, the meaning of little or no *egr-1* expression in liver and esophageal carcinomas is different to their counterparts. *egr-1* gene in the hepatic paracancerous tissue such as LCD and dysplasia of esophageal carcinoma can be activated when they are stimulated, but the stimulations is invalidated in carcinomas. The decreased expression of *egr-1* may play a role in the dysregulation of normal growth in the cancerous process of HCC and EC.

To confirm the development of liver and esophageal carcinomas involves the inactivation of *egr-1*. It would deserve further investigation of the effects of exogenous EGR-1 on the growth and malignant phenotypes of the cancer. Like tumor suppressor gene WT1, EGR-1 can also bind with GCE elements[44], this suggests that EGR-1 might have inhibitory activity on cancer growth. In the experimental report[8], EGR-1 could reverse the malignant phenotype of *v-sis* transformed NIH3T3 cells. The results of this paper also showd that stably expressed EGR-1 could inhibit the cancer's growth rate, reduce the number of fraction of S phase, decrease the plate clone formation rate and reduce the tumorigencity of HHCC and ECa109 cell lines. In recent years, studies have revealed that in human tumors, EGR-1 expression suppressing tumor cell growth is a common phenomenon. In human HT-1080 fibrosarcoma cells, the growth rates in 6 groups of expressing different EGR-1 level are inhibited proportionately and are dose-dependent. The total inhibition rate of these cells' tumorigencity is over 50%. The growth of human ZR-75-1 breast carcinoma, U251 glioblastoma and SAOS-2 osteosarcoma cells has also been demonstrated to be suppressed by EGR-1 in different degree[6]. However, in this experiment EGR-1 did not suppress the malignant phenotypes of SMMC7721, HCC cell line, this might be due to different transformation mechanism in this cell line, which needs investigation further.

The mechanism of EGR-1 inhibition on cancer growth is complicated, which interacts with TGF-β1, PDGF and WT1. TGF-β1 specifically inhibits PDGFβ-dependent cells' growth[4], while EGR-1 inhibits the malignant phenotype and growth of the PDGFβ/v-sis that were transformed from NIH3T3 cells. This suggests that EGR-1 is closely related with TGF-β1 and PDGF. Meanwhile, EGR-1 can also activate the transcription of TGF-β1 in a dose-dependent manner, this activation might be one of the potential mechanisms of EGR-1 of inhibiting tumor growth[45]. Interestingly, WT1 can bind with the GC element of TGF-β1 promoter, and then inhibit the activity of that promoter (but this reaction is weaker than that of inhibition on PDGFβ). One recent study has shown that the inhibitory reaction of EGR-1 on cancer growth is also by inducing the expression of TGF-β1, fibronectin, p21 and focal adhesion kinase (FAK) in human fibrosarcoma cell line[46]. EGR-1 may also regulate cell interaction with the extracellular matrix by synergistic induction of TGF-beta1, FN, and PAI-1 in human HT-1080 glioblastoma cells[47] and directly transactivates the fibronectin gene and enhances attachment of human glioblastoma cell line U251[48]. Other reports show that the suppression by *egr-1* also involves down-regulation of bcl-2[49] and stimulates apoptosis by transactivation of the p53 gene[50].

Recent studies[6, 8, 50] as well as this experiment suggest that EGR-1 can act as a tumor suppressor factor. EGR-1 has been identified to be little or no expression in several human malignant tumors such as fibroblastoma, glioblastoma, osteosarcoma, lung cancer, breast carcinoma (including cancer cells and tumor tissues)[1,6], as well as hepatocellular carcinoma and esophageal carcinoma in this experiment. Another (larger) study also indicates that human small cell lung tumors express little or no *egr-1* mRNA compared with adjacent normal tissues[40]. Furthermore, 5q-syndrome is the exclusive tumor with *egr-1* gene deletion[41]. Hence we suspect that *egr-1* might be belonged to typeII tumor suppressor genes as mentioned above. The reintroduction of *egr-1* gene products by drugs might be a promising approach to normalize growth regulation, which can avoid the difficult problem of replacing defective gene DNA.

AKNOWLEDGEMENT

Abstract

AIM: **To elucidate molecular mechanism of chemopreventive efficacies of garlic against human gastric cancer (HGC).**

METHODS: **HGC cell line BGC823 was treated with Allitridi (a kind of garlic extract) and Allitridi-treated and parental BGC823 cDNA libraries were constructed respectively by using λZAP II vector. cDNA Representational Difference Analysis (cDNA RDA) was performed using *Bam*H I cutting-site and abundant cDNA messages provided by the libraries. Northern blot analysis was applied to identify the obtained difference products.**

RESULTS: **Two specific cDNA fragments were obtained and characterized to be derived from homo sapiens folate receptorα (FRα) gene and calcyclin gene respectively. Northern blot results showed a 4-fold increase in FRα gene expression level and 9-fold increase in calcyclin mRNA level in BGC823 cells after Allitridi treatment for 72h.**

CONCLUSION: **The method of cDNA RDA based on cDNA libraries combines the high specificity of cDNA RDA with abundant cDNA messages in cDNA library; this expands the application of cDNA library and increases the specificity of cDNA RDA. Up-regulation of FRα gene and calcyclin gene expressions induced by Allitridi provide valuable molecular evidence for the efficacy garlic in treating HGC as well as other diseases.**

Li Y, Yang L, Cui JT, Li WM, Guo RF, Lu YY. Construction of cDNA representational difference analysis based on two cDNA libraries and identification of garlic inducible expression genes in human gastric cancer cells. *World J Gastroenterol* 2002;8(2):208-212

INTRODUCTION

Gastric cancer is common in China[1-38]. Garlic has been used for over three thousand years in traditional Chinese medicine and is widely used in preventing manifold diseases all over the world. Epidemiological studies indicated that garlic in diet had remarkable antithrombotic, hypolipidemic, hypocholesterolemic and antineoplastic effects[39-41]. Both Chinese and Italian scholars reported protective efficacies of garlic in cases of human gastric cancer (HGC)[40]. Allitridi is an important constituent of garlic oil mainly containing diallyl trisulfide (DATS) and diallyl disulfide (DADS), which are widely used in cancer chemoprevention and anti-cardiovascular disease research[42]. Our data also indicated that Allitridi could arrest HGC cell line BGC823 in G1 phase and induce morphological changes of such cells (data not shown). Recent studies suggested that garlic may exert its chemopreventive effects by modulating lipid peroxidation, enhancing the levels of glutathione (GSH), glutathione peroxidase (GPx), glutathione S-transferase (GST) and NAD(P)H:quinone oxidoreductase (NQO)[43,44]. However, a definitive molecular mechanism of anticarcinogenic activities of garlic has not been established.

The cDNA Representational Difference Analysis (cDNA RDA) method with high specificity is widely used in identifying differentially expressed genes in different developmental stages and cell cycle phases or in following the progression of expression in proceeding with a particular event, for example, stimulation of cells with a growth factor[45-47]. Enough double stranded cDNA will be available in cDNA libraries for subtractive cloning. In order to detect the feasibility of cDNA RDA based on cDNA libraries and to identify Allitridi inducible expression genes at the same time, Allitridi-treated and parental BGC823 cell cDNA libraries were constructed respectively by using λZAP II vector. We further took advantage of restriction site harbored in the vector and replaced four-cutting restriction endonuclease *Dpn* II used in classical cDNA RDA with six-cutting enzyme *Bam*H I to select representations and to perform cDNA RDA following the classical procedure.

MATERIALS AND METHODS

Cell culture and cDNA library construction

The HGC cell line BGC823 was grown at 50mL·L^{-1} CO_2 in DMEM medium supplemented with 50mL·L^{-1} fetal calf serum. Allitridi used in our experiments contained 97.98% DATS and 0.85% DADS. BGC823 cells were incubated in medium containing 25mg·L^{-1} Allitridi for 72h. Total RNA isolated from parental and Allitridi-treated BGC823 cells was separated by using guanidinium thiocyanate acid-phenol-chloroform method, followed by purification of poly(A)+ mRNA with the Poly(A)+ Quik mRNA Isolation Kit (Stratagene). 5μg mRNA were collected and λZAP-cDNA Gigapack III Gold Cloning Kit (Stratagene) was used to construct two cDNA libraries which were Allitridi-treated and parental cell cDNA libraries respectively.

Establishment of cDNA RDA based on cDNA libraries

By using Allitridi-treated BGC823 (Alli823) library DNA as tester and parental cell (BGC823) library DNA as driver, we performed cDNA RDA following the protocol supplied by classical cDNA RDA. Library DNAs (40μg) of the two cDNA libraries were prepared respectively and digested with *Bam*H I, phenol extracted, ethanol

precipitated and resuspended in 20μL 1×TE. 12μL (about 24μg) digested DNAs were then conjugated to 18μL R-Bam-24 (10μmol·L^{-1}) and R-Bam-12 (10μmol·L^{-1}) adapters. PCRs were set up to generate the initial representations by using R-Bam-24 as a primer. Afterward the R-adapters were removed from the representation of BGC823 with *Bam*H I to form the driver. Representation of Alli823 was also digested with *Bam*H I and the product was purified using Qiaex resin (Qiagen). This formed the tester, of which 2μg was conjugated to the J-Bam-12/24 adapters. For the first subtractive hybridization, 0.4μg J-conjugated tester was mixed with 24μg driver, and the mixture was allowed to anneal 20h at 67℃. The annealing products were used as templates and 25 cycles of PCR were performed to generate the first difference product (DP1). J-adapters on DP1 were changed for N-Bam-12/24 adapters. The ratio for subtractive hybridization was changed for 50ng：40μg and the processes were repeated to generate the second difference product (DP2). To generate the third difference product (DP3), 400pg J-conjugated DP2 was mixed with 40μg driver and the process repeated. Sequences of oligonucleotides used in cDNA RDA were as follows: R-Bam-24 5'-AGCACTCTCCAGCCTCTC ACCGAG-3'; R-Bam-12 5'-GATCCTCGGTGA-3'; J-Bam-24 5'-ACCGACGT CGACTATCCATGAACG-3'; J-Bam-12 5'-GATC CGTTCATG-3'; N-Bam-24 5'-AGGCAACTGTGCTATCCGA GGGAG-3'; N-Bam-12 5'-GATCCTCCCTCG-3'. The 5' end of 12-mer adapters was dephosphorylated. cDNA RDA based on cDNA libraries is showed schematically in Figure 1.

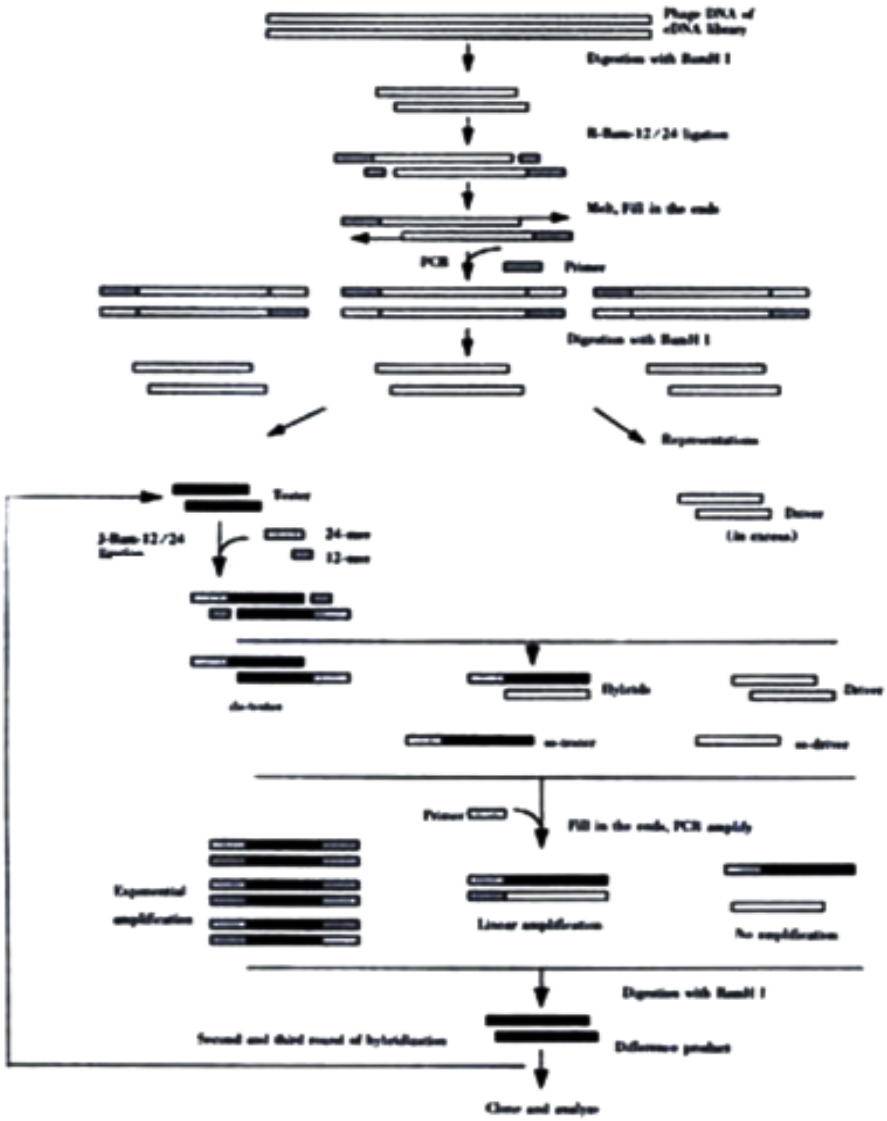

Figure 1 Schematic diagram of cDNA RDA based on cDNA libraries, illustrating the subtractive hybridization and amplification steps following the representation stage and preparation of amplicons. Gray boxes (24-mer,12-mer) represent R (or J, N)-Bam adapters

Northern blot hybridization

Total RNA extracted from parental and Allitridi-treated BGC823 cells for 72h (10μg for each sample) were fractionated on formaldehyde agarose gel and transferred onto Nitrocellulose filters (S&S Company), then cross-linked by using a UV Stratalinker. Probes (DP3s) were labeled by random primer extension and hybridization carried out in 1mmol·L^{-1} EDTA, 0.25mmol·L^{-1} Na_2HPO_4 and 70g·L^{-1} SDS solution for 16h at 60℃. Following hybridization, the filters were washed twice in 1mmol·L^{-1} EDTA, 40mmol·L^{-1} Na_2HPO_4 and 50g·L^{-1} SDS for 25min at 60℃ and twice in 1mmol·L^{-1} EDTA, 40mmol·L^{-1} Na_2HPO_4 and 10g·L^{-1} SDS for 25min at 60℃ again. Filters were exposed to a phosphor screen for 48h and analyzed.

Sequencing and Database Searching

Final difference products were amplified and cloned into pGEM-T Easy Vector (Promega). Double stranded plasmid DNA was prepared using miniprep columns (Promega) and sequenced with Ultra VGI 1280 (applying User Manual version 3.0). Resulting sequences were compared to the GenBank database by using the BLAST program.

RESULTS

Parental and Allitridi-treated BGC823 cell cDNA libraries

Morphological changes were observed in BGC823 cells after exposure to 25mg·L^{-1} Allitridi for 96h. The cells after treatment dramatically changed to an elongated shape with filamentous protrusions. Neurite-like structures outgrew from the cell bodies and formed interconnections (Figure 2). Titer for Allitridi-treated BGC823 (Alli823) cDNA library was 1.1×10^{13} clones·L^{-1}, and titer for parental cell (BGC823) cDNA library 2.0×10^{13} clones·L^{-1}. The size of insert sequences for those two cDNA libraries ranged from several hundred base pairs to several kilobase pairs (kb), and the average length was about 2 kb (Figure 3).

cDNA RDA based on two cDNA libraries

cDNA RDA based on cDNA libraries is an extension of classical cDNA RDA in application and follows the protocol of the latter. λZAP II vector used to construct cDNA libraries has three *Bam*H I restriction sites with one site located very near the 5'-end of insert sequence. Thus *Bam*H I adapters can be introduced into the 5'-end of insert sequence. The shortest fragment cleaved from library vector DNA is 6.4kb in size, unable to compete with insert sequence during subsequent PCR amplification. Therefore, we could replace four-cutting restriction endonuclease Dpn II used in classical cDNA RDA with six-cutting enzyme *Bam*H I to select representations and perform cDNA RDA. With same copies three distinct fragments appeared in the digestion products of library DNA (about 22.1, 11.3 and 6.4kb in size respectively). We saw a stepwise reduction of complexity of the products in each successive difference product, until two clear bands with little background were visible by ethidium staining in the third difference products (DP3). The larger band named as DP3-1 is about 340 bp and the shorter one DP3-2 about 180bp in size. The amplicons and difference products obtained after the first, second and third round hybridization-amplification steps are showed in Figure 4.

Identification of differentially expressed genes in parental and Allitridi treated BGC823 cells

The third difference products, DP3-1 and DP3-2 were cloned into pGEM-T Easy Vector and resulting sequences were compared to the GenBank database using the BLAST program. Results showed that: DP3-1 had remarkable homology with FRα mRNA as high as 98%; DP3-2 sequence showed a remarkable homology of 97% with human calcyclin mRNA. Northern blot results using DP3-1 and DP3-2 as probes showed a 4-fold increase in FRα gene expression level and 9-fold increase in calcyclin mRNA level in BGC823 cells after Allitridi treatment for 72h (Figure 5).

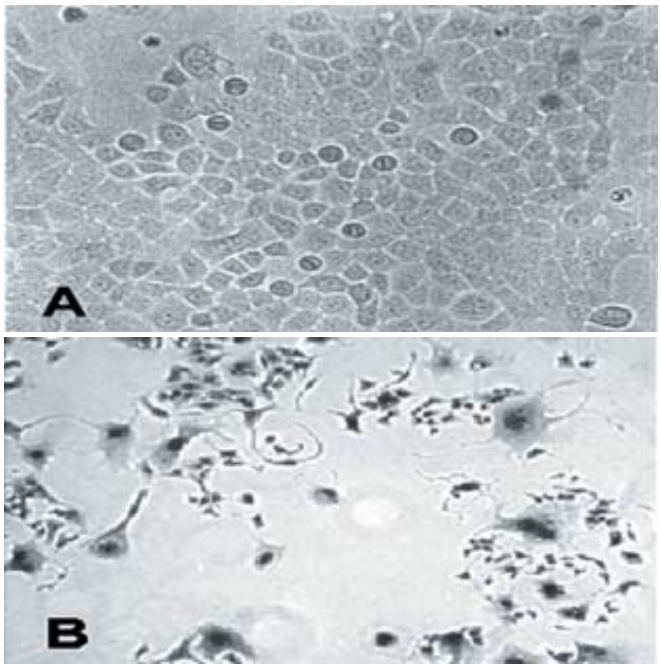

Figure 2 Morphological changes of human gastric cancer cell line BGC823 after Allitridi treatment. A: The parental cells (used as control); B: Neurite-like structures outgrew from the cell bodies and formed interconnections after exposure to 25mg·L^{-1} Allitridi for 96h (5×40).

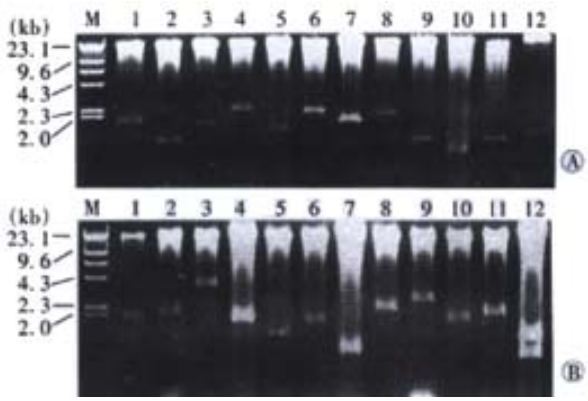

Figure 3 Insert sequences released from randomly selected clones (Lanes 1-12) of parental cell (BGC823) cDNA library (A) and Allitridi-treated cell (Alli823) cDNA library (B) by digestion with *Eco*$_R$ I and *Xho* I. λPhage/*Hin*d III size marker was indicated in Lane M.

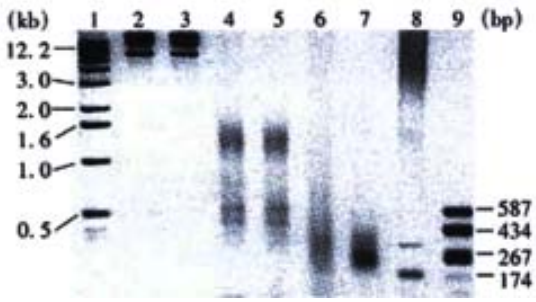

Figure 4 Agarose gel electrophoresis of difference products obtained after the first, second and third round hybridizations. *Bam*H I-digested library DNA extracted from Alli823 and BGC823 cDNA libraries respectively (Lanes 2,3); Amplicons of cDNA population prepared from Allitridi-treated and parental groups (used as tester and driver respectively) (Lane 4,5); First, second and third difference products respectively (Lanes 6,7,8); 1 kb size marker (Lane 1) and PUC18/Hae III DNA size marker (Lane 9).

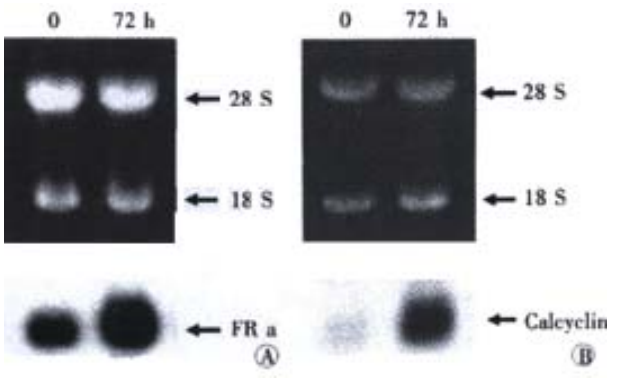

Figure 5 Northern blot analysis of FRαgene and calcyclin gene expression in BGC823 cells. FRα mRNA (A) and calcyclin mRNA (B) level was elevated after exposure to 25mg·L^{-1} Allitridi for 72h.

DISCUSSION

cDNA RDA based on cDNA libraries shares the chief merits of classical cDNA RDA, and has in addition several distinct advantages: Firstly, enough double stranded cDNAs needed for subtractive hybridization can be obtained from cDNA libraries and thus expand the application of cDNA libraries. Next, with same copies, three distinct fragments (about 22.1, 11.3 and 6.4kb in size respectively) appear in the products of library DNA digestion with *Bam*H I and act as good marks indicating the appropriate digestion degree for library DNA and thus increasing the specificity and reproducibility of cDNA RDA. Thirdly, by replacing four-cutting enzyme *Dpn* II with six-cutting enzyme *Bam*H I to digest library DNA, longer difference products can be obtained; this will increase the specificity of subsequent Northern blot analysis, Database homology searching and library screening. Finally, through replacing or combining *Bam*H I cutting site with other restriction sites (for example, *Eco*$_r$ I or *Xho* I) harbored in library vector, more difference products including low abundant messages can be obtained.

FRα functions as a membrane receptor to mediate the high-affinity internalization and delivery of folate and 5-methyltetrahydrofolate to the cytoplasm of the cell[48]. Deficiency of folate has already been linked with increased incidence of neural tube defects and of cardiovascular disease through elevated plasma homocysteine levels[49]. Recent studies showed that folate deficiency may cause an imbalance in DNA precursors, uracil misincorporation into DNA, and chromosome breakage. By reducing intracellular S-adenosylmethionine (SAM), it can also cause global DNA hypomethylation, leading to inappropriate activation of proto-oncogenes and induction of malignant transformation[50-52]. Folate deficiency is reported to be associated with increased risk of colorectal carcinoma and breast cancer[53-55]. Our findings suggested that up-regulation of FRα gene expression by Allitridi may compensate for folate deficiency and correspond with the preventive efficacy of garlic against HGC as well as other human diseases. Calcyclin gene, as a member of the S100 family for generating small calcium-binding proteins, was reported to be a cell cycle-dependent gene and to be associated with cell differentiation[56-59]. Our results showed that calcyclin gene expression in BGC823 cells was up-regulated by Allitridi treatment before the neurite-like structures generated in the cells, and this would suggest the impact of garlic on regulating calcium metabolism and the involvement of calcyclin gene in HGC cell differentiation.

In conclusion, cDNA RDA based on cDNA libraries combines the high specificity of cDNA RDA with the abundant cDNA messages in cDNA library, and thus expands the application of cDNA library and increases specificity of cDNA RDA. Our findings suggest that up-regulation of FRα gene and calcyclin gene expression induced by Allitridi may play an important role in HGC cell differentiation and may provide valuable molecular evidence for demonstrating the important preventive efficacy of garlic against HGC.

Abstract

AIM: **To develop and optimize cDNA representational difference analysis (cDNA RDA) method and to identify and clone garlic up-regulated genes in human gastric cancer (HGC) cells.**

METHODS: **We performed cDNA RDA method by using abundant double-stranded cDNA messages provided by two self-constructed cDNA libraries (Allitridi-treated and paternal HGC cell line BGC823 cells cDNA libraries respectively). *Bam*H I and *Xho* I restriction sites harbored in the library vector were used to select representations. Northern and Slot blots analyses were employed to identify the obtained difference products.**

RESULTS: **Fragments released from the cDNA library vector after restriction endonuclease digestion acted as good marker indicating the appropriate digestion degree for library DNA. Two novel expressed sequence tags (ESTs) and a recombinant gene were obtained. Slot blots result showed a 8-fold increase of glia-derived nexin/protease nexin 1 (GDN/PN1) gene expression level and 4-fold increase of hepatitis B virus x-interacting protein (XIP) mRNA level in BGC823 cells after Allitridi treatment for 72h.**

CONCLUSION: **Elevated levels of GDN/PN1 and XIP mRNAs induced by Allitridi provide valuable molecular evidence for elucidating the garlic's efficacies against neurodegenerative and inflammatory diseases. Isolation of a recombinant gene and two novel ESTs further show cDNA RDA based on cDNA libraries to be a powerful method with high specificity and reproducibility in cloning differentially expressed genes.**

INTRODUCTION

cDNA representational difference analysis (cDNA RDA), with high specificity by eliminating those fragments present in two compared populations and leaving only the differences, has been employed with some degree of success[1-6]. While cDNA RDA, like other PCR-based difference screening methods, is prone to produce false positive results[7,8]. In our study, we used cDNA RDA method to isolate garlic inducible differentially expressed genes in human gastric cancer (HGC) cells. Allitridi is a critical constituent of garlic oil, mainly containing diallyl trisulfide (DATS) and diallyl disulfide (DADS), which is widely used in cancer chemoprevention and anti-cardiovascular disease research[9-16]. Differences between two double-stranded cDNAs populations derived from Allitridi-treated and paternal HGC cell line BGC823 cells cDNA libraries were identified by using cDNA RDA. *Bam*H I and *Xho* I restriction sites harbored in the library vector were employed to select representations. We found another major source of false positives in cDNA RDA, which was inappropriate enzyme digestion of sample DNAs, and introduced improvements to minimize their production.

MATERIALS AND METHODS

Allitridi-treated and paternal HGC cell line BGC823 cells cDNA libraries

Allitridi is a critical constituent of garlic oil, containing 97.98% diallyl trisulfide (DATS) and 0.85% diallyl disulfide (DADS) in concentration. BGC823 cells were incubated in medium containing 25mg·L^{-1} Allitridi for 72h. Total RNA isolated from paternal and Allitridi-treated BGC823 cells were extracted, followed by synthesis of double stranded cDNAs using λZAP-cDNA Gigapack III Gold Cloning Kit (Stratagene). cDNAs derived from Allitridi-treated and paternal BGC823 cells, with *Eco*$_r$ I cutting site at 5'-end and *Xho* I site at 3'-end, were unidirectionally cloned into λZAP II vector for cDNA library construction.

cDNA RDA based on cDNA libraries: generation of representations

Difference between Allitridi-treated BGC823 (Alli823) cDNA library DNA (used as tester) and paternal cell (BGC823) library DNA (used as driver) was identified by using cDNA RDA to isolate Allitridi up-regulated genes. Library DNAs of the two cDNA libraries were prepared and digested with *Bam*H I respectively in a mixture containing 40μg library DNAs, 8μL *Bam*H I (10kU·L^{-1}, Promega), and 10μL 10×Buffer H in a final volume of 100μL. The digestions were carried out at 37℃ for 2, 4, and 12h respectively to obtain the most appropriately digested fragments. After phenol extraction and ethanol precipitation, digested DNAs (about 24μg) were then ligated to 18μL R-Bam-24 (10μmol·L^{-1}) and 18μL R-Bam-12 (10μmol·L^{-1}) adapters. PCR reactions were set up to generate the initial representations by using R-Bam-24 as primer.

In order to expand the content of messages in the representations, we further employed *Bam*H I and *Xho* I together to digest the library DNAs. Library DNAs (about 40μg) of Alli823 and BGC823 cDNA libraries were digested with *Xho* I respectively. Digested DNAs were then ligated to *Xho* I Linker-15 (5'-TCGAGGATCCATTCA-3') and *Xho* I Linker-13 (5'-ACTGAATGGATCC-3'). Resulting ligations were digested with *Bam*H I and then ligated to R-Bam-12/24 adapters (10μmol·L^{-1}),

followed by PCR amplification to generate amplicons.

Using *Bam*H I alone or *Bam*H I and *Xho* I together to digest library DNAs and to prepare representations is showed schematically in Figure 1.

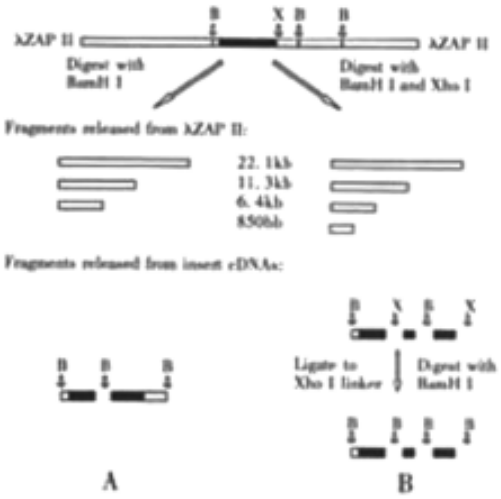

Figure 1 Schematic diagram of preparing representations for cDNA RDA based on cDNA libraries. Using *Bam*H I alone (A) or *Bam*H I and *Xho* I together (B) to digest library DNAs. Black boxes represent insert cDNAs of cDNA libraries. White boxes represent two arms of cDNA library vector (λZAP II vector)."B"represents *Bam*H I and"X" *Xho* I.

The followed three rounds of hybridizations and selective amplifications were performed according to the protocol supplied by typical cDNA RDA. Sequences of adapters used here are as follows:R-Bam-24 5'-AGCACTCTCCAGCCTCTCACCGAG-3'; R-Bam-12 5'-GATCCTCGGTGA-3';J-Bam-24 5'-ACCGACGTCGACTATCC ATGAACG-3'; J-Bam-12 5'-GATCCGTTCATG-3'; N-Bam-24 5'-AGGCAACTGTGCTATCCGAGGGAG-3'; N-Bam-12 5'-GATCCTCCCTCG-3'.

Slot and Northern blots analyses

Reamplified difference products (100ng each) were mixed with 2.5μL 3mmol·L^{-1} NaOH respectively and incubated for 1h at 65℃, and then transferred onto Nitrocellulose filters (S&S Com) by using Slot Minifold® II (Schleicher&Schull). Two same filters were prepared and then cross-linked using a UV Stratalinker. Reverse transcription products (the first stranded cDNAs) of 5μg total RNA of Allitridi-treated and paternal BGC823 cells were used as probes respectively. Probes were labeled with ^{32}P using a Random-Primer labeling kit (Promega) and hybridization carried out in 1mmol·L^{-1} EDTA, 0.25mmol·L^{-1} Na_2HPO4 and 70g·L^{-1} SDS solution for 16h at 60℃. Following hybridization, the filters were washed twice in 1mmol·L^{-1} EDTA, 40mmol·L^{-1} Na_2HPO4 and 50g·L^{-1} SDS for 25min at 60℃ and twice in 1mmol·L^{-1} EDTA, 40mmol·L^{-1} Na_2HPO_4 and 10g·L^{-1} SDS for 25min at 60℃ again. Filters were exposed to a phosphor screen for 48h and analyzed.

Total RNA (10μg each) isolated from HGC cell lines BGC823, MGC803, PAMC82, SGC7901 and MKN45 were transferred onto Nitrocellulose filters. Probe (the third difference product, DP3) was labeled by random primer extension and Northern blots hybridization carried out in the same manner described above.

Sequencing and Database Searching

Difference products were amplified and cloned into pGEM-T Easy Vector (Promega). Double stranded plasmid DNAs were prepared using miniprep columns (Promega) and sequenced with Ultra VGI 1280 (applying User Manual version 3.0). Resulting sequences were compared to the GenBank database by using the BLAST program.

RESULTS

Generation of representations for cDNA RDA based on cDNA libraries

Double stranded cDNAs, with Eco_r I cutting site at 5'-end and *Xho* I site at 3'-end, were unidirectionally cloned into λZAP II vector for cDNA library construction. Library vector (λZAP II vector) has three *Bam*H I restriction sites with one site located very near to 5'-end of insert cDNAs. Thus *Bam*H I adapters can be introduced into the 5'-end of insert cDNAs. With the same copies three distinct fragments appeared in the products of library DNA digested with *Bam*H I at 37℃ for 4h (about 22.1, 11.3 and 6.4kb in size respectively), which indicated appropriate digestion degree. However, library DNAs were not fully digested at 37℃ for 2h, and the smears of library DNAs after digestion for 12h showed excessive reactions. When *Bam*H I and *Xho* I were used together to digest library DNAs (1 cut/2 kb insert cDNAs in average), another vector-derived fragment (850 bp in size) was released from 3'-end of insert cDNAs. We further designed *Xho* I Linker-15/13 to convert *Xho* I cutting site to *Bam*H I site. Thus the content of cDNA messages available for difference analysis was expanded. The results for library DNAs after digestion with different enzymes or different conditions are showed in Figure 2. Subsequently, PCR reactions were set up to generate the initial representations (amplicons) (Figure 3).

Identification of differentially expressed genes in Allitridi-treated BGC823 cells

Results of Slot blots analysis showed that expression of 4 cDNAs was up-regulated by Allitridi treatment and the degree to which each cDNA was up-regulated ranged from 3- to 8-fold (Figure 4). Sequencing and GenBank database searching results showed that two isolated

difference fragments (SH2 and SH3) had remarkable homology over 97% with glia-derived nexin/protease nexin 1 (GDN/PN1) mRNA and hepatitis B virus x-interacting protein (XIP) mRNA respectively. No homology was found in fragment SH1, which indicated SH1 to be a novel EST. SH4 showed remarkable homology as high as 98% with a piece of human DNA sequence on chromosome 20 and was also showed to be a novel EST. The sequences of SH1 and SH4 were showed in Figure 5.

Figure 5 Sequences of two novel ESTs (SH1 and SH4) isolated by cDNA RDA based on cDNA libraries.

Northern blots analysis was employed to detect the expression level of another obtained difference product (derived from calcyclin mRNA) and a novel transcript about 2 kb in size appeared only in the hybridization result of BGC823 total RNA (Figure 6). Further cDNA library screening and database searching showed this novel transcript to be a recombinant gene merged from calcyclin gene and homo sapiens heterogeneous nuclear ribonucleoprotein A0 (HNRPA0) gene.

DISCUSSION

When cDNA RDA[1-6] or RDA[17-19] is performed, sample cDNAs or genome DNAs are digested into fragmented populations to prepare representations, and the digestion products showed as smears by agarose gel electrophoresis. Therefore, it is difficult to determine the most appropriate digestion degree. However, deficient or excessive enzyme digestion of sample DNAs can undoubtedly result in false positive results. In our study, cDNA RDA was performed based on cDNA libraries. Our data showed that time for enzyme digestion affected the digestion degree obviously. With the same copies, three or four fragments released from library vector after enzyme digestion acted as good marks indicating appropriate digestion, which increased the specificity and reproducibility of cDNA RDA. Moreover, when *Bam*H I and *Xho* I were used together to digest library DNAs, the content of cDNA messages available for difference analysis was expanded and more specific products were obtained.

Thrombin, as the principal component of the blood coagulation cascade, also prevents neurite outgrowth and modulates morphologic changes in both neurons and astrocytes[20-22]. Recent studies have showed that thrombin mediates polyneuronal synapse elimination, both *in vivo* and *in vitro*[23]. Glia-derived nexin/protease nexin 1 (GDN/PN1) is the most potent vertebrate inhibitor for thrombin, which, acting as neurite-promoting factor, plays an important role in neurotrophic and neuroprotective properties[24-29]. Garlic extract contains antioxidant phytochemicals that prevent the oxidant-mediated brain cell damage and produce neurotrophic effects[30-33]. Our results showed the potential effect of garlic on reducing the risk of neurodegenerative disease through up-regulation of GDN/PN1 expression.

The hepatitis B virus (HBV) has been reported to be a risk factor in the development of hepatocellular carcinoma[34-42]. The HBV X protein (HBx) is a small transcriptional activator and has been showed capable of transactivating many different viral and cellular promoters. It is essential for virus infection and is implicated in the development of hepatocellular carcinoma[43-49]. An HBx-interacting protein that specifically binds to the carboxy terminus of wild-type HBx was identified in 1998 and designated as HBx interacting-protein (XIP), which could inhibit HBx activity and thus decrease HBV replication[50]. Elevated level of XIP mRNA induced by garlic extract provided valuable molecular evidence for elucidating the garlic's efficacies against inflammatory diseases.

Identification of recombinant gene in our study showed the feasibility of employing cDNA RDA method to the discovery of probes for anonymous loci that suffered genetic rearrangements. Cloning of two novel ESTs further showed cDNA RDA based on cDNA libraries to be a powerful method in isolating novel genes.

Abstract

AIM: **To investigate the role of the mitochondrial pathway in JTE-522-induced apoptosis and to investigate the relationship between cytochrome C release, caspase activity and loss of mitochondrial membrane potential (△Ψm).**

METHODS: **Cell culture, cell counting, ELISA assay, TUNEL, flow cymetry, Western blot and fluorometric assay were employed to investigate the effect of JTE-522 on cell proliferation and apoptosis in AGS cells and related molecular mechanism.**

RESULTS: **JTE-522 inhibited the growth of AGS cells and induced the apoptosis. Caspases 8 and 9 were activated during apoptosis as judged by the appearance of cleavage products from procaspase and the caspase activities to cleave specific fluorogenic substrates. To elucidate whether the activation of caspases 8 and 9 was required for the apoptosis induction, we examined the effect of caspase-specific inhibitors on apoptosis. The results showed that caspase inhibitors significantly inhibited the apoptosis induced by JTE-522. In addition, the membrane translocation of Bax and cytosolic release of cytochrome C accompanying with the decrease of the uptake of Rhodamin 123, were detected at an early stage of apoptosis. Furthermore, Bax translocation, cytochrome C release, and caspase 9 activation were blocked by Z-VAD.fmk and Z-IETD-CHO.**

CONCLUSION: **The present data indicate a crucial association between activation of caspases 8, 9, cytochrome C release, membrane translocation of Bax, loss of △Ψm and JTE-522-induced apoptosis in AGS cells.**

INTRODUCTION

Previous studies have showed that non-steroidal anti-inflammatory drugs (NSAIDs) can induce apoptosis in several cell type, including human colorectal tumor cell lines[1,2], human breast cancer cells[3], human lung cancer cells[4], B cell chronic lymphocytic leukemia cells[5] and myeloid leukemia cell line[6]. JTE-522 is a novel NSAIDs, which is a specific inhibitior of cyclooxygenase-2 with significant anti-inflammatory and analgestic properties[7]. In a previous study, we have demonstrated that JTE-522 induced apoptosis in human gastric adenocarcinoma AGS cells, but the detail mechanism is not clear.

Caspase, a family of cysteine protease, is the common executor of apoptosis induced by various stimuli[8,9]. Caspase 8 and caspase 9 are recognized as upstream apoptosis initiators, which activate downstream caspases 3, 6 and 7[10]. The apoptotic action of NSAIDs was inhibited by the caspase inhibitor Z-VAD.fmk, demonstrating the involvement of caspases[5]. However, the pathway leading to caspase activation remains unknown. Caspases play a central role in the execution of apoptosis. The two most well-studied pathways of caspase activation include the surface death receptor pathway and the mitochondrion-initiated pathway. In the mitochondrion pathway, cytochrome C and other apoptogenic proteins (e.g apoptosis-inducing factor) are released from the intermembrane space to the cytosol[12]. Once released, cytochrome C binds to apoptotic protease-activating factor-1 (Apaf-1) and induces activation of caspase 9[12]. Recently, it was shown that bax, a proapoptotic member of bcl-2 family, promoted apoptosis by triggering the release of cytochrome C from mitochondria[13-18]. In the present study, our aims are to investigate the role of the mitochondrial pathway in JTE-522-induced apoptosis and to investigate the relationship between cytochrome C release, caspase activity and loss of mitochondrial membrane potential (△Ψm).

MATERIALS AND METHODS

Cell line and reagents

AGS, a gastric adenocarcinoma cell line, was provided by Cancer Institute, Sun-Yet Sen University of Medical Sciences (China). The cells were grown in RPMI-1640 medium and supplemented with 10% fetal calf serum, penicillin G (100kU/L) and kanamycin($0.1g \cdot L^{-1}$) at 37℃ in a 5% CO_2. Antibodies used in this study were obtained from Santa Cruz. All other chemicals were purchased from Sigma Chemical Co (St. Louis, MO, USA).

Determination of cell proliferation rate

AGS cells (1×10^5) were seeded in 12-well plates and cultured for 24h. The cultures were divided into two groups: the girst group (control) was cultured in the RPMI1640 medium, and the second was cultured in the continuous presence of 1mmol/L JTE-522. The cells were then harvested every 24h by trypsinization and cell numbers counted with a hemocytometer. Three cultures were used for experiments at each time point.

Detection of apoptotic DNA fragmentation

AGS cells were grown in 96-well culture plates. The cells were incubated with various doses of JTE-522 for 6h. Apoptotic DNA fragmentation was determined using a commercially obtained enzyme-linked immunosorbent assay (ELISA) kit from Sigma. This assay was based on a quantitative sandwich enzyme-immunoassay directed against cytoplasmic histone-associated DNA fragments. Briefly, the cells were incubated in 200μL of lysis buffer provided in the kit, the lysates were centrifuged, and 20μL of the supernatant containing cytoplasmic histone-associated DNA fragments were reacted overnight at 4℃ in streptavidin-coated microtitrator wells with 80μL of the immunoreagent mixture containing biotinylated anti-histone antibody and peroxidase-conjugated anti-DNA antibody. After washing, the immunocomplex-bound peroxidase was probed with 2,2'-azino-di[3-ethylbenzthiazoline sulfonate] for spectrophotometric detection at 405nm.

TUENL

TUNEL assay was performed using the apoptosis detection system. Cells were fixed by 4% paraformaldehyde in PBS overnight at 4℃. The samples were washed three times with PBS and were permeabilized by 0.2% Triton X-100 in PBS for 15min on ice. After washing twice, cells were equilibrated at room temperature for 15 to 30min in equilibration buffer (200mmol/L potassium cacodylate, 0.2mmol/L dithiothreitol, $0.25g\cdot L^{-1}$ bovine serum albumin, and 2.5mmol/L cobalt chloride in 25mmol/L Tris-HCL, PH 6.6) and then incubated in the presence of 5μmol/L pluorescein-12-dUTP, 10μmol/L dATP, 100μmol/L ethylenediaminetetraacetic acid (EDTA), and terminal deoxynucleotidyl transferase at 37℃ for 1.5h in dark. The tailing reaction was terminated by 2×standard saline citrate (SSC). The samples were washed three times with PBS and were analyzed by fluorescence microscopy. At least 1000 cells were counted, and the percentage of TUNEL-positive cells was determined.

Ladder detection assay

After induction of apoptosis, cells (5×10^6/sample, both attached and detached cells) were lyzed with 150μL hypotonic lysis buffer (10mmol/L EDTA, 0.5% Triton X-100 in 1mmol/L Tris-HCL, Ph7.4) for 15min on ice and were precipitated with 2.5% polyethylene glycol and 1mol/L NaCl for 15min at 4%. After centrifugation at 16000g for 10min at room temperature, the supernatant was incubated in the presence of proteinase K ($0.3g\cdot L^{-1}$) at 37℃ for one hour and precipetated with isopropanol at -20℃. After centrifugation, each pellet was dissolved in 10μL of Tris-EDTA (pH 7.6) and electrophoresed on a 1.5% agarose gel containing ethidium bromide. Ladder formation of oligonucleosomal DNA was detected under ultraviolet light.

Cytosolic release of cytochrome C and membrane translocation of Bax

The analysis was performed according to the method of Euguchi *et al*[19], with minor modifications. Briefly, cells were collected and suspended in mitochondria isolation buffer [20mmol/L Hepes-KOH, PH 7.5; 210mmol/L sucrose; 70mmol/L mannitol; 1mmol/L EDTA; 1mmol/L dithiothreitol (DTT); 1.5mmol/L $MgCl_2$, 10 mmol/L KCl_2; and protease inhibitor cocktail supplemented with 10μmol/L digitonin]. The suspensions were incubated at 37℃ for 5min and centrifuged at 15000g for 15min. The supernatants and pellets were collected for Western blotting according to the method described by Tsuchida *et al*[20].

Caspase activity assay

Activities of caspase 8 and caspase 9 were determined by using a fluorometric assay kit according to the method described by Gao *et al*[20]. Briefly, 5×10^5 cells were collected and lysed in 50μL lysis buffer and incubated with fluorochromic caspase substrate, Ile-Glu-Thr-Asp-7-amino-4-trifluoromethylcoumarin (IETD-AFC) and Leu-Glu-His-Asp-7-amino-4-trifluoromethylcoumarin (LEHD-AFC) for caspase 8 and caspase 9, respectively. After incubation at 37.5℃ for 1h, the fluorescence was measured by a spectrofluorphotometer with excitation at 400nm and emission at 550nm.

Mitochondrial membrane potential analysis

Rhodamine 123, a cationic fluorescent dye whose mitochordrial fluorescence intensity decreased quantitatively in response to dissipation of $\triangle\Psi m$, was used to evaluate perturbations in $\triangle\Psi m$. Cells were incubated with 5μmol/L rhodamin 123 for 30min, and then were collected, washed, and stained with 10μmol/L PI. The uptake of rhodamin 123 was measured by flow cytometry.

Statistics analysis

The data shown were mean value of at least three different experiments and expressed as mean±SD. Student's test was used to compare data. A *P* value of less than 0.05 was considered as statistically significant.

RESULTS

Effect of JTE-522 on cell proliferation and apoptosis in AGS cells

In order to understand the potential role of JTE-522 in the induction of apoptosis and its possible contribution to AGS cell loss in human gastric adenocarcinoma, the inhibitory effect of JTE-522 on cell proliferation was studied in AGS cells. As shown in Figure 1.

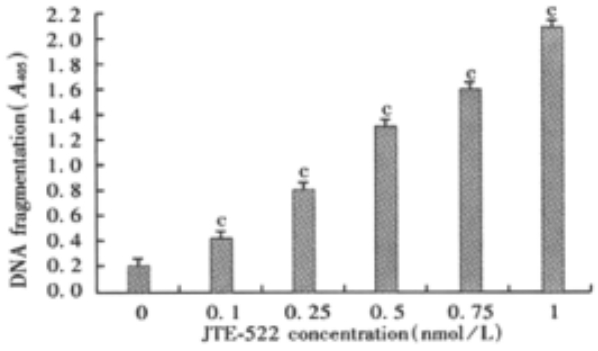

Figure 1 Effect of JTE-522 on AGS cell proliferation. Cells were incubated in the absence or presence of 1mmol/LJTE-522 and cell numbers determined at the time replicates at each time point ($^cP<0.01$).

The cells were cultured in the presence or absence of JTE-522 and cell numbers determined over three days. AGS cell proliferation was markedly inhibited by 1 mmol/L JTE-522. In the absence of JTE-522, the number of control cells doubled approximately every 24h in RPMI1640 medium supplemented with 10% fetal calf serum. The effect of JTE-522 at concentrations from 0.1mmol/L to 1mmol/L on DNA fragmentation in AGS cells was shown in Figure 2.

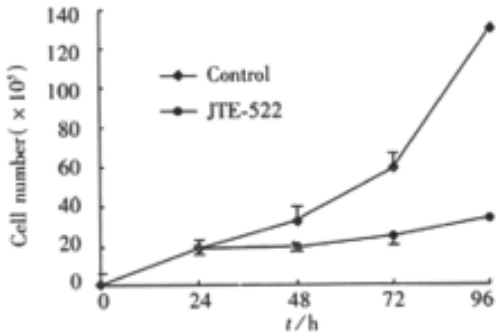

Figure 2 Effect of JTE-522 on DNA fragmentation in AGS cells. Cytoplasmic histone-associated DNA fragments were determined using a commercial ELISA kit. Results were representative of four independent determinations.

JTE-522 was found to significantly induce DNA fragmentation after the onset of incubation and this effect was in a dose-dependent manner. The same results were obtained by TUNEL assay. The number of TUNEL-positive cells was dramatically increased after treatment with JTE-522 for 48h, that is, the percentage of TUNEL-positive cells increased from 19.3±1.7% to 59.8±2.6% (Figure 3).

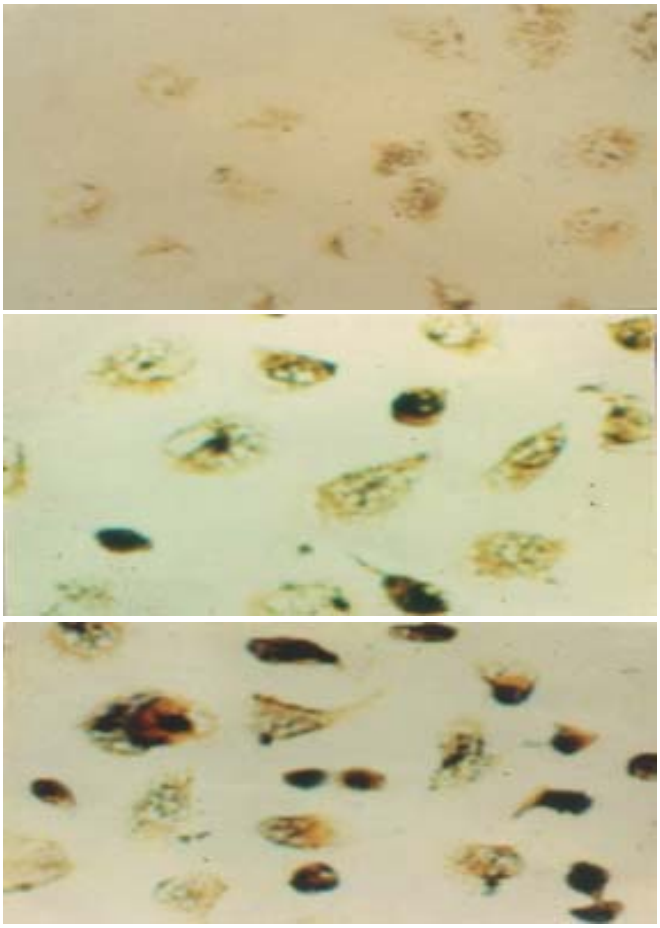

Figure 3 TUNEL assay demonstrating marked morphological changes in AGS cells after treatment with different concentrations of JTE-522. A: control; B: 0.1mmol/L JTE-522; C: 1mmol/L JTE-522

Effect of JTE-522 on caspases 8, 9 in AGS cells

In order to demonstrate the role of caspase 8 and caspase 9 in JTE-522-induced apoptosis, we examined the activities of caspase 8 and caspase 9 after treatment with JTE-522 for indicated time. The results showed that caspase 8 activity increased at 9h after JTE-522 treatment in AGS cells (Figure 4A), and the activity of caspase 9 also increased. To further confirm the activation of these two caspases, we conducted Western blot analysis (Figure 4B). The results showed that both caspases were activated, as judged by the decrease of the procaspases and the increase of their cleavage products. These experiments clearly showed that caspase 8 and caspase 9 played an important role during apoptosis induced by JTE-522. To investigate whether the activation of caspases 8 and 9 was required for the apoptosis induction, we examined the effect of caspase-specific inhibitors on apoptosis. The results showed extensive DNA fragmentation after treatment with JTE-522, while the treatment of Z-VAD.fmk, Ac-IETD-CHO or Ac-LEHD-CHO significantly blocked it (Figure 4C). These results suggested that both caspase 8 and caspase 9-like activity was required for JTE-522 apoptosis during the apoptotic process.

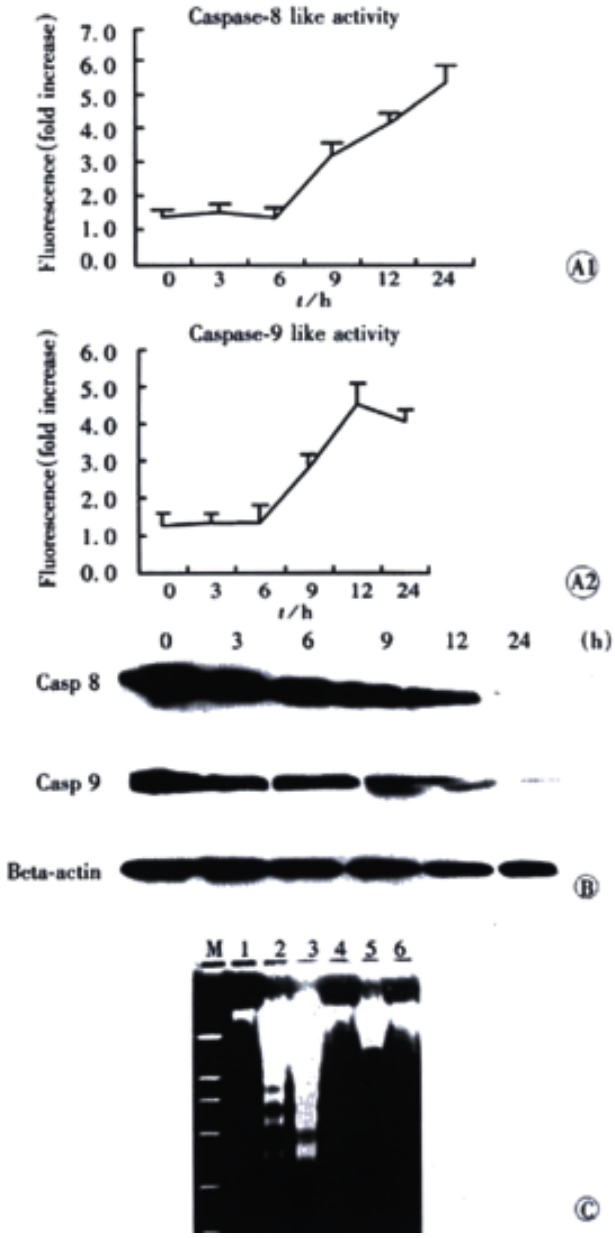

Figure 4 The role of procaspase 8 and procaspase 9 in JTE-522 induced apoptosis for indicated time. 4A: Effect of JTE-522 on caspase activities for indicated time. Data presented are the mean value of three separate experiments. 4B: Western blot shows the cleavage of procaspase 8 (Casp 8) and procaspase 9 (Casp 9). AGS cells were treated with JTE-522 for the indicated times. 4C: Effect of caspase inhibitor on JTE-522 induced DNA fragmentation. AGS cells were treated with: 1:control; 2: 1mmol/L JTE-522; 3: 0.5mmol/L JTE-522; 4: 50μmol/L Z-VAD.fmk+1mmol/L JTE-522; 5: 50μmol/L Ac-IETD-CHO +1mmol/L JTE-522; 6: 50μmol/L Ac-LEHD-CHO+1mmol/L JTE-522 for 24h.

Effect of JTE-522 on cytosolic release of cytochrome C and membrane translocation of bax

Cytochrome C, which is released from mitochondria, has recently been identified as a key factor that could activate caspase in a cell-free system[19]. In fact, it has been reported that levels of cytosolic cytochrome C were increased in response to various apoptotic stimuli such as staurosporine, *P*53, etoposide, and ultraviolet-B irradiation[20-22]. We therefore performed Western blotting to examine the distribution of cytochrome C in cytosol and membrane fractions before and after apoptosis induction. AGS cells were treated with JTE-522 for 24h, and the cells treated with 0.1μmol/L staurosporine for 24h were used as a positive control. After treatment, the cells were collected and suspended in the mitochondrial isolation buffer containing digitonin. Treatment with digitonin made small pores on cell membranes that allow the releases of cytosolic cytochrome C to the buffer fraction[19]. The supernatant and the pellet that represented cytosol and membrane fractions, respectively, were collected separately and subjected to Western blot analysis (Figure 5A). The result showed that cytochrome C in membrane fractions decreased significantly in both staurosporine and JTE-522 treated cells, while in cytosol fractions, high levels of cytochrome C were detected in both treated cells but not in control cells. On the contrary, bax protein increased in membrane fractions and decreased in cytosol fractions after treatment with staurosporine or JTE-522. Bcl-2 protein, as well as cytochrome C oxidase subunit IV (cyto oxi, as a control for mitochondrial protein loading), which were located in mitochondria and not released to cytosol. This result indicated that the cytosolic release of cytochrome C was specially triggered by apoptotic stimuli, but not due to the experimental manipulation.

There was a growing evidence for two pathways of cytochrome C release from mitochondria during apoptosis: rupture of the outer membrane following swelling, or through a specific pore in the outer membrane[23]. In liposomes and yeast Bax and Bak interacted with voltage-dependent anion channel (VDAC) to cause selective cytochrome C release[21]. Addition of recombinant Bax to isolated mitochondria induced cytochrome C loss without swelling. However, others had shown that Bax did induce the permeability transition in isolated mitochondria and within cells[24]. Therefore, we questioned whether the cytosolic release of cytochrome C and membrane translocation of Bax in JTE-522-induced apoptosis were caspase-dependent or not. The cells were pretreated with Z-VAD.fmk at 50μmol/L for 1h before treatment with staurosporine or JTE-522. Levels of cytochrome C and Bax in cytosol were examined by Western blotting (Figure 5C). The results showed that the increase of cytochrome C and the decrease of Bax in cytosol induced by staurosporine or JTE-522 were blocked by Z-VAD.fmk. The cleavage of procaspase 3 and 8 was also blocked. These results indicated that the Bax translocation and cytochrome C release were dependent on the activation of caspases.

Since it has been well documented that caspase-8 was the first caspase activated in Fas-, *P*53-, TRAIL- and TNF-induced apoptosis[20, 25, 26], we sought to determine whether caspase-8 activation occurs prior to, as in Fas-, *P*53- and TNF-induced apoptosis or after caspase-9, caspase 3 activation and cytochrome C release, and examined the effects of Ac-IETD-CHO on cytochrome C release and caspase 9 activation. The results showed that Ac-IETD-CHO effectively blocked cytochrome C release and the processing of caspase 8. The caspase 9-like activity was also blocked by both Z-VAD.fmk and Ac-IETD-CHO (Figure 5D). This result suggested that caspase 8-like caspase might work as an initiation caspase that triggered the release of cytochrome C and caspase 9 activation in this system.

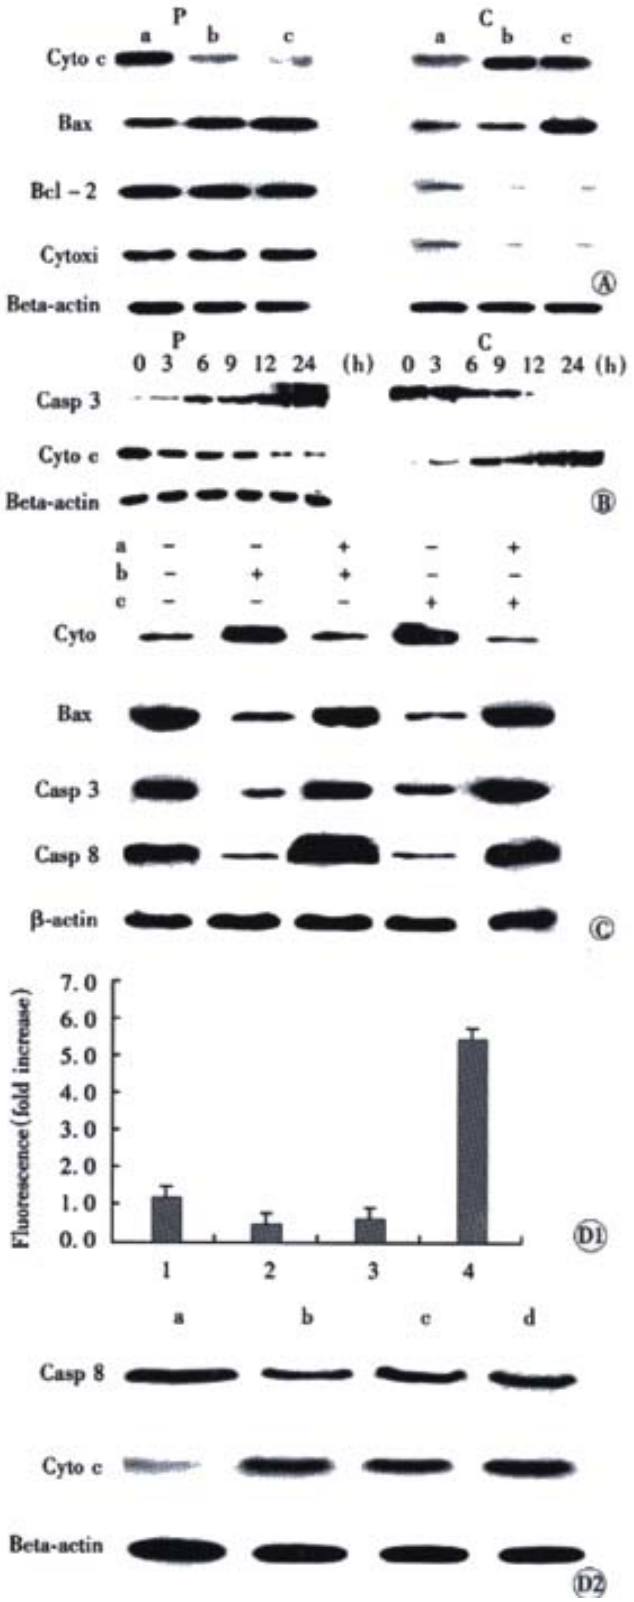

Figure 5 Effect of JTE522 on the activation of caspase, cytochrome C release and membrane translocation of Bax. Figure 5A: AGS cells were treated with: RPMI 1640 medium for control (a) or 0.1μmol/L staurosporine (b) or 1mmol/L JTE-522(c). After 24h, the cells were collected and suspended in mitochondria isolation buffer. Cytosol (C) and pellet (P) fractions were separated and subjected to Western blotting as described in Materials and Methods. Cytochrome C (cyto c), cytochrome C oxidase subunit IV (Cyt oxi); Figure 5B: Effect of JTE522 on the changes of cytosolic cytochrome C release and procaspase 3 (casp-3); Figure 5C: Effect of caspase inhibitors on cytochrome C release and translocation of Bax. AGS cells were treated with 50

μmol/L Z-VAD.fmk (a) for 1h or 0.1μmol/L staurosporine(b) or 1mmol/L JTE-522(c) or without any treatment. The cytosol was prepared as in (A) and analyzed by Western blotting with indicated antibodies, Casp 3 (procaspase 3), Casp 8 (procaspase 8); Figure 5D: AGS cells were cultured at RPMI 1640 medium or treated with caspase inhibitors: Figure 5D1: Effect of caspase inhibitor on the activity of caspase 9: 1: control; 2: Z-VAD.fmk+1mmol/L JTE-522; 3: Ac-IETD-CHO+1 mmol/L JTE-522; 4: 1mmol/L JTE-522 for 24h; Figure 5D2: Effect of caspase inhibitor on caspase 8 cleavage, cytochrome c release: 1: control(a); 2: Z-VAD.fmk+1mmol/L JTE-522 (b); 3: Ac-IETD-CHO+1mmol/L JTE-522(c); 4: Ac-LEHD-CHO +1 mmol/L JTE-522(d). Cells were collected and analyzed for caspase 8 cleavage, cytochrome C release, or caspase-like acitivity as described in Materials and Methods.

Effect of JTE-522 and Z-VAD.fmk on mitochondria membrane potential

It had been described that cytochrome C release could be induced by mitochordrial permeability transition (PT) characterized by loss of $\triangle\Psi m$[27]. As salicylates induced mitochondrial PT and loss of $\triangle\Psi m$ in isolated mitochondria and hepatocytes, we analyzed the effect of JTE-522 on $\triangle\Psi m$ in AGS cells using rhodamin 123 dye. As shown in Figure 6, JTE-522 had no significant effect on $\triangle\Psi m$ at 3h and decrease the uptake of rhodamin 123 at 6h, 9h and 12h, earlier than mitochondrial cytochrome C release and caspases 8 and 9 processing. In addition, Z-VAD.fmk blocked loss of $\triangle\Psi m$ induced by JTE-522 at 9h and had a marked inhibitory effect at 12h, indicating that loss of $\triangle\Psi m$ was caspase-dependent and this loss was in a time-dependent manner.

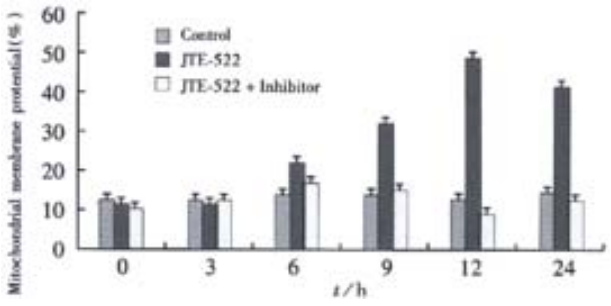

Figure 6 Time-lapsed changes of mitochondrial $\triangle\Psi m$ in AGS cells under the treatment of JTE-522. The data were the means of three experiment±SD

DISCUSSION

NSAIDs have another interesting effect which is seemly unrelated to their anti-inflammatory action. Administration of some NSAIDs to patients and animals suffering from colonic polyps and colon cancer causes regression of the aberrant growth, while epidemilolgical studies have shown that long-term consumption of NSAIDs, greatly reduces the risk of developing colon cancer and gastric adenocarcinoma[28-33]. However, the mechanism remains unclear. Many studies showed that apoptosis was likely to play an extremely important part in the pathogenesis of NSAIDs-induced ulcerogenesis, and also likely to be involved in regression of colon cancer and other neoplasms[34]. The mechanism underlying the inducting of apoptosis by JTE-522 and other NSAIDs is unknown and currently under research. So far, several pathways have been implicated inducing cyclooxygenase inhibition[32-35], arrest of cell cycle[36]and nuclear factor-kB inhibition[37,38]. Although several groups have demonstrated the involvement of caspases[5], the pathways leading to caspase activation remain unknown. In this study, we observed for the first time the caspase-dependent membrane translocation of Bax and cytosolic release of cytochrome C and the loss of $\triangle\Psi m$ in JTE-522-induced apoptosis. These results indicate that mitochondria play an important role in JTE-522-induced apoptosis.

A number of pro- and anti-apoptotic members of the Bcl-2 protein family regulate the release of cytochrome C and apoptosis inducing factor (AIF) from the mitochrondrial intermembrane space into the cytosol[39-43]. Cytochrome C then interacts with pro-caspase 9 and Apaf-1 to activate caspase 9 and thus switch on caspase 3, 6 and 7, leading to apoptosis. The cytosolic release of cytochrome C has been reported in apoptosis induced by various stimuli, including NSAIDs[43]. In this study, we observed the cytosolic release of cytochrome C, as well as the activation of caspase 9. In contrast to the caspase-independent release of cytochrome C in Raji cells induced by aspirin[44] the release of cytochrome C was almost completely blocked by caspase inhibitor in our system, suggesting that different mechanisms are involved in cytochrome C release in these two systems.

Disruption of mitochondrial function is a critical event in the apoptotic process leading to the elimination of cells treated with chemptherapeutic agents. Opening of the mitochondrial megachannel has been implicated as a key event in the disruption of mitochondrial membrane integrity during apoptosis. Many intrinsic factors can induce opening if the megachannel including members if the Bcl-2/Bax family, cellular redox status, and cytosolic Ca^{2+} levels[45]. Disruption of mitochondrial membrane integrity involves the loss of metabolic functions and release of proteins from the mitochondrial intermembrane space into the cytosol. Cytochrome C and AIF represent two such proteins, which are released into the cytosol, and promote caspase and/or nuclease activation. However, there are considerable uncertainties about how cytochrome C and AIF are released from mitochondria and about the events leading up to their appearance in the cytosol. One of them is that the pro-apoptotic proteins Bax and Bak that accelerate opening of the voltage-dependent anion channel (VDAC) in the outer membrane and thereby specifically release cytochrome C[46,47]. Bax is a proapoptotic member of Bcl-2 family proteins, which can form channels in synthetic membrane[48-50] and induce cytochrome C release from isolated mitochondria[51]. However, the mechanism by which Bax stimulates cytochrome C release is unclear. Bax contains the hydrophobic membrane-anchoring domain at its C-terminus, but the membrane-anchoring potential is repressed by its N-terminal domain, allowing Bax to distribute typically in cytosol[52]. Upon apoptotic stimulation, Bax inserts into mitochondria membrane, where it exerts its function[53,54]. The overexpression[55], enforced dimerization[56], and Bid-induced conformation change[57] trigger the redistribution of Bax. In this study, we observed JTE-522-induced membrane translocation of Bax and this translocation was not associated with the increase of Bax protein level, but dependent on caspase activity. Caspase 8 has been shown to cleave Bid and the cleaved Bid is reported to be more efficient for triggering the oligomerization and insertion of Bax into mitochondria membrane. In agreement with these observations, we detected caspase 8 activation by cleavage activity of a caspase 8-specific fluorogenic substrate, as well as cleavage of caspase 8 in our system. In addition, the caspase 8-preferential inhibitor effectively blocked cytochrome C release and caspase 9 activation, suggesting caspase 8 to be an upstream caspase.

The most informative measure of the changes associated with cytochrome C release is the mitochondrial membrane potential. However, such measurement in apoptotic cells has produced conflicting results, with reports of no decrease in potential until after cytochrome C release, a decrease in membrane potential associated with cytochrome C release[50], and an initial increase in potential followed by cytochrome C release without loss of membrane potential[58]. These measurements rely on the uptake of fluorescent dyes, which gives a qualitative indication of the membrane potential. In this study, our results indicate that JTE-522-induced decrease in $\triangle\Psi m$ precedes the release cytochrome C at an early phase of apoptosis. This result is different from the report that aspirin induced cytochrom c release precedes the decrease of $\triangle\Psi m$ in Raji cells. This

discrepancy might reflect that multiple pathways mediated NSAIDs-induced apoptosis depending on experimental systems.

In summary, The present data indicate a crucial association between activation of caspases 8 and 9, cytochrome C release, membrane translocation of Bax, loss of mitochondrial membrane potential and JTE-522-induced apoptosis in AGS cells.

ACKNOWLEDGEMENTS

We gratefully acknowledge Prof Geng-Tao Lui, Institute of Material Medica, Chinese Academy of Medical Sciences for the many helpful discussion and suggestions relating to this work; Special thanks to Chris Simmet and Pasricha Jerriment for proofreading the manuscript and for useful suggestions; Dr Cheng Wei He for technical advice and helpful discussion; Dr Gang Fei Peng for FCM; Dr Wang Tao for Western blot; Dr Guo Qing Xie and Mr Hai Nan Wang for photo processing.

Abstract

AIM: **To determine the effect of *cis-9,*trans-11-conjugated linoleic acid (*c9,t*11-CLA) on the cell cycle of gastric cancer cells (SGC-7901) and its possible mechanism in inhibition cancer growth.**

METHODS: **Using cell culture and immunocytochemical techniques, we examined the cell growth, DNA synthesis, expression of PCNA, cyclin A,B_1,D_1,$p16^{ink4a}$ and $p21^{cip/waf1}$ of SGC-7901 cells which were treated with various *c9,t*11-CLA concentrations (25,50,100 and 200μmol·L^{-1})of *c9,t*11-CLA for 24 and 48h, with a negative control (0.1% ethane).**

RESULTS: **The cell growth and DNA synthesis of SGC-7901 cells were inhibited by *c9,t*11-CLA. SGC-7901 cells. Eight day after treatment with various concentrations of *c9, t*11-CLA mentioned above, the inhibition rates were 5. 92%,20.15%,75.61% and 82.44%,respectively and inhibitory effect of *c9,t*11-CLA on DNA synthesis (except for 25μmol/L,24h) showed significantly less ^{3}H-TdR incorporation than that in the negative controls ($P<0.05$ and $P<0.01$). Immunocytochemical staining demonstrated that SGC-7901 cells preincubated in media supplemented with different *c9,t*11-CLA concentrations at various times significantly decreased the expressions of PCNA (the expression rates were 7.2-3.0%,24h and 9.1-0.9% at 48h, respectively), Cyclin A (11.0-2.3%, 24h and 8.5-0.5%,48h), B_1 (4.8-1.8% at 24h and 5.5-0.6% at 48h)and D_1 (3.6-1.4% at 24h and 3.7%-0 at 48h) as compared with those in the negative controls(the expressions of PCNA, Cyclin A, B_1 and D_1 were 6.5% at 24h and 9.0% at 48h, 4.2% at 24h and 5.1% at 48h, 9.5% at 24h and 6.0% at 48h,respectively)($P<0.01$), whereas the expressions of $p16^{ink4a}$ and $p21^{cip/waf1}$, cyclin-dependent kinases inhibitors(CDKI), were increased.**

CONCLUSION: **The cell growth and proliferation of SGC-7901 cell is inhibited by *c9,t*11-CLA via blocking the cell cycle, with reduced expressions of cyclin A,B_1 and D_1 and enhanced expressions of CDKI($p16^{ink4a}$ and $p21^{cip/waf1}$).**

INTRODUCTION

Gastric cancer is common in China[1-12], and it is currently thought to be caused by environmental factors, with diet being an important modifying agent[13-17]. Its mechanism of prevention and treatment still makes it become a hot spot in this area[18-39]. Its anticancerous potential Dietary fat has been implicated as an enhancing agent in carcinogenesis by both epidemiological and animal studies. Consumption of meat, specifically animal fat, has been implicated in a number of disease processes[40-42]. However, several epidemiological studies have suggested an association between increased consumption of meat and fat and decreased risk of stomach, mammary and esophageal cancers[43,44]. Among the fatty acids, only the essential fatty acid, linoleic acid (LA), has been clearly shown to enhance mammary tumorigenesis[43]. However, isomeric derivatives of *cis*-9,*cis*-12-octadecadienoic acid (linoleic acid, LA) containing a conjugated double-bond system (conjugated linoleic acid, CLA) showed inhibitory effect on carcinogenesis in animal studies[45,46]. CLA has a mixture of positional (9/11 or 10/12 double bonds) and geometric (various cis/trans combinations) isomers of LA formed by rumen and colon bacteria. The ability of CLA to prevent mammary and other tumors in rodents has been identified and has been the subject of several reviews[43]. There are eight potential isomers of CLA, but the *cis*-9, trans-11 and trans-9, *cis*-11 isomers are thought to be active as potential antioxidant and anticarcinogenic agents. Therefore, it is of interest to investigate more extensively the anticancer activities of CLA.

In the present study, we investigated the effect of *cis*-9, trans-11-CLA(*c9,t*11-CLA) on the cell cycle of human gastric adenocarcinoma cells (SGC-7901).

MATERIALS AND METHODS

Materials

*c9,t*11-CLA, a monoisomer of *c*-9,*t*11-octadecadienoic acid with 98% purity, was obtained from Dr. Rui-Hai Liu(Food Science and Toxicology, Department of Food Science, Cornell University, Ithaca, NY, USA). The *c9,t*11-CLA was dissolved in 96ml·L^{-1} ethanol, and was then diluted to the following concentrations: 0,25,50,100 and 200μmol·L^{-1}.

Methods

Cell culture Human gastric adenocarcinoma cells(SGC-7901), purchased from Cancer Research Institute of Beijing (China), were cultured in RPMI 1640 (Gibco) medium, supplemented with calf serum 100ml·L^{-1}, penicillin (100×103u·L^{-1}) and streptomycin (100mg·L^{-1}). The pH was maintained at 7.2-7.4, by equilibration with 5% CO_2.The temperature was maintained at 37℃. The cells were sub-cultured with a mixture Ethylenedinitrile tetraacetic acid (EDTA) and trypsin.

Cell growth curve The SGC-7901cells were seeded in six 24 well plates (Nuc,Co.); each well contained 2×10^4 cells. After 24h, the medium of different plates was replaced with media supplemented with *c*9, *t*11-CLA at different concentrations. On the next day, the numbers of cells of 3 wells from each plate were determined daily by using the trypan blue staining. The means were obtained on each of

eight days and were used to draw a cellular growth curve. The inhibitory rates(IR) on the 8th day was calculated, as follows:

$$IR(\%)=\frac{\text{Total Number of cells in negative control (8d)}-\text{Number of cells in test groups(8d)}}{\text{Total number of cells in negative control(8d)}}\times 100\%$$

[^{3}H]-Labeled precursor incorporation SGC-7901 cells (5×10^4/well in 24 well plate) were cultured in appropriate medium for 24h prior to beginning the experiment. The medium was, then, replaced with different concentrations *c9, t*11-CLA. After 18 and 42h, the cells were incubated with [^{3}H] thymidine (China Nucleus Institute, 0.5μci/mL, 1.0μci/well). After 6h the cells were harvested with trysin/EDTA. Cells were collected in an acetic fiber filter with cellular collector and washed three times with PBS. The filter was dried overnight at 37℃. The filter was transferred into liquid of scintillation(containing 1% po and 2% pop in xylene) and cpm value determined by liquid Scintillation Counter (LS6500, Beckmen Co.).

Cell samples

SGC-7901 cells were treated for 24 and 48h with various concentrations of *c9,t*11-CLA and collected by centrifugation. Specimens were fixed immediately in 40g·L^{-1} formaldehydum polymerisatum and embedded in paraffin. Gastric cancer tissue from a patient served as a reference.

Primary antibodyies

To examine the proliferating cell nuclear antigen(PCNA) in cell proliferation and to determine cyclins (A,B_1 and D_1) and cyclin-dependent kinases inhibitors ($p16^{ink4a}$ and $p21^{waf1}$) in cell cycle of SGC-7901, we used six primary antibodies: corresponding mouse monoclonal antibodies for cyclin B_1 and D_1, PCNA and $p21^{waf1}$ and corresponding rabbit polyclonal antibodies for cyclin A and $p16^{ink4a}$. PCNA, $p16^{ink4a}$, and cyclin D_1 were purchased from Calbiochem Co. USA; others from Zhongshan Co. China.

Immunocytochemistry

Immunocytochemical staining was performed on serial sections at room temperature, using the horseradish peroxidase method. The sections were deparaffinized in xylene and rehydrated through graded alcohol. The sections were incubated for 10min at 95℃ in 10mmol·L^{-1} sodium citrate(pH 6.0) buffer for PCNA staining. Endogenous peroxidases were inactivated by immersing the sections in hydrogen peroxide for 10min, and then were incubated for 10min with 100ml·L^{-1} normal goat serum in PBS to block non-specific binding. The sections were subsequently incubated overnight at 4℃ with relevant antibodies (1∶50 dilution) respectively. The next day, the sections were incubated with biotinylated anti-mouse or anti-rabbit IgG(Zhongshan Co. China) for 30min, followed by peroxidase-conjugated streptavidin(Zhongshan Co.China) for 30min. The chromogenic reaction was developed with DAB (diaminobenzidine) for 10min, and all sections were counterstained with hematoxylin. Controls consisted of omission of the primary antibody. The Positive Rate(PR) was calculated as follows:

$$PR(\%)=\frac{\text{Number of positive cells}}{\text{Total number}(2\times10^4)}\times 100$$

Statistical analysis

Analysis of data was performed using the student's *t* test or χ^2 test. A value of $P<0.05$ is considered to be statistically significant.

RESULTS

Effect of c9,t11-CLA on SGC-7901 cell growth

As shown in Figure 1, Growth of the cells in various concentrations of *c9, t*11-CLA did not differ from the negative control within 3d. After 3d, SGC-7901 cells incubated in 25 and 50μmol·L^{-1} of *c9,t*11-CLA grew at a lower rate than the negative control. While in 100 and 200μmol·L^{-1} concentrations of *c9, t*11-CLA, cell proliferation was significantly inhibited. The inhibitory rate of various *c9, t*11-CLA concentrations were 5.9%, 20.2%, 75.6% and 82.4%, respectively.

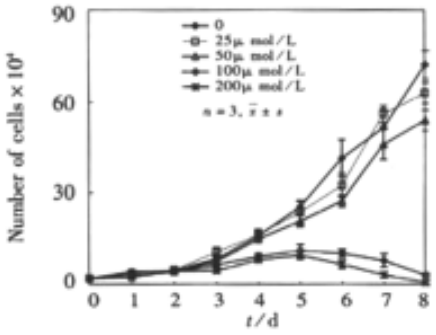

Figure 1 Growth curve of SGC-7901 cells cultured in various concentration of *c9, t*11-CLA

Effect on DNA synthesis

The effect of CLA on isotope incorporation into SGC-7901 cells are presented in Table 1. SGC-7901 cells preincubated in media supplemented with various *c9, t*11-CLA concentration (except for 25μmol/L, 24h) incorporated significantly less ^{3}H-TdR than did the negative control ($P<0.05$ and $P<0.01$, Table 1). The inhibitory rate (IR) displayed a dose-response relationship as the concentration of *c9, t*11-CLA increased.

Cell proliferation

As shown in Figure 2, expression raues of PCNA (Figure 3.1) on SGC-7901 cells gradually decreased after SGC-7901 cells were incubated with different concentrations of *c9,t*11-CLA at various times. Moreover, SGC-7901s cell expressed significantly less PCNA than did the negative control ($P<0.01$). The expression rate displayed a dose-response relationship as the concentrations of CLA increased.

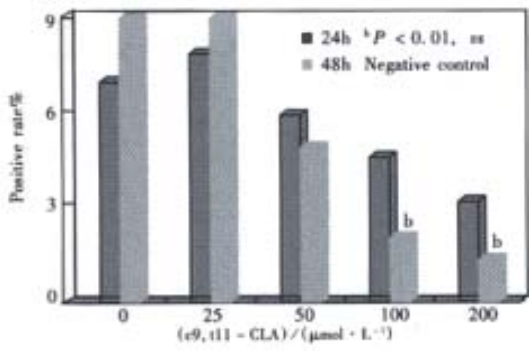

Figure 2 Expression of PCNA on SGC-7901 cells treated with *c9, t*11-CLA

Expressions of cyclin A,B_1 and D_1 and p16^{ink4a}, p21^{waf1}

The the expression of rates cyclin A, B_1, and D_1 (Figure 3.2-4)on SGC-7901 cells was decreased (Table 2) after SGC-7901 cell were incubated with different concentrations of *c9, t*11-CLA for 24h and 48h while cyclin-dependent kinases inhibitors (*P*16^{ink4a}, and *P*21^{waf1}) increased (Table 3; Figure 3.5-6).

DISCUSSION

CLA is a naturally occurring fatty acid in animal's food. Dietary sources of CLA include grilled beef, cheese, and related foods[47]. Another source of CLA is its endogenous generation via the carbon centered free radical oxidation of linoleic acid[45]. Over the past ten years, a number of research works of animal experiments have supported the observation that CLA is an effective chemopreventive agent of cancer, and that it can inhibit carcinogenesis of different tissues at different stages of induction by chemical agents[44,45]. Several investigators in our group have reported that *c9, t*11-CLA is an effective agent to prevent carcinogenesis[48,49] and cancer[50-52]. Zhu's study[48] demonstrated that *c9,t*11-CLA could significantly inhibit the mice forestomach neoplasia induced by B(a)P(50mg·kg^{-1}) in post-initiation in short term(23weeks).The incidences of tumors of mice in the B(a)P group, B(a)P with high dose CLA(5μL·g^{-1}) group and B(a)P with low dose CLA(2.5μL·g^{-1}) group were 100%, 60% and 69% respectively (P <0.05). Xue's research[49] also indicated that the incidence of neoplasm in mouse forestomach in the B(a)P group,75% pure *c9,t*11-CLA group, 98% pure *c9,t*11-CLA group and 98% pure t10,c12-CLA group were 100.0%, 75.0%, 69.2%, and 53.8%, respectively. This maybe due to an inhibition mitogen of activated protein kinase(MAPK)-a way to reduce carcinogenesis. The data from our research group suggested that *c9,t*11-CLA could inhibit proliferation of cancer cells, i.e. SGC-7901 cells[50] and MCF-7 cells[51,52], and induced cancer cell (SGC-7901) apoptosis [53]. Moreover, the inhibiting effect of *c9,t*11-CLA on SGC-7901 cell proliferation may be related to cell cycle.

As shown in Figure 1, *c9, t*11-CLA at various concentrations in 8 days reduced the proliferative activity of SGC-7901 cells and its inhibitory rates were from 5.92% to 82.44%, but the mechanism of such inhibition of *c9,t*11-CLA has not been clarified. However, we discovered that SGC-7901 cells supplemented with *c9,t*11-CLA incorporated significantly less [^{3}H] thymidine than negative controls (shown in Table I). The inhibitory rates of, from 16.4% to 78.2% after incubating with *c9,t*11-CLA for 24h and from 14.0% to 97.5% after 48h displayed a dose-response relationship.In the meantime, we investigated further the expressions of PCNA and protein from cell cycle such as cyclins and cyclin-dependent kinase inhibitors (CDKI) on SGC-7901 cells treated with various concentrations of *c9,t*11-CLA. PCNA (proliferating cell nuclear antigen) plays an essential role in both the replication and repair of DNA, and is an essential component of the DNA replication machinery, acting as the processing factor for polymerases äandå.In addition to its role in replication, PCNA is not only required for base excision-repair of nucleotides, but also binds to cell cycle regulatory proteins such as *p*21 and Gadd45 [54]. In this study, we discovered that the expression of PCNA on SGC-7901 cells gradually decreased with increasing concentrations of *c9,t*11-CLA in comparison with negative controls(showed in Figure 2). In other words, DNA replication lessens, thereby resulting in slower on SGC-7901 cell proliferation.

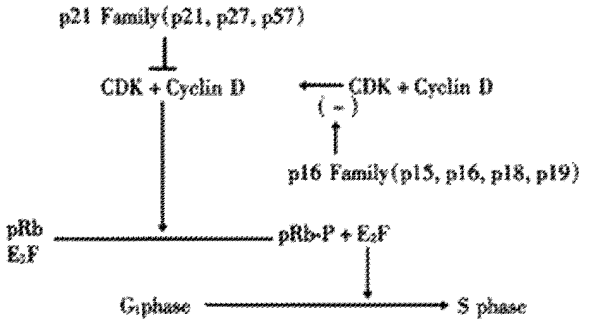

Figure 4 The relationship between CDKI(*p*16 and *p*21) and cyclins in G_1/S transition

The fundamental task of the cell cycle is to ensure that DNA is faithfully replicated once during S phase and that identical chromosomal copies are distributed equally to two daughter cells during M phase. The cell cycle is a complex process, regulated by many factors, which can be divided into three groups: cyclins(A,B, D,E....H); cyclin-dependent kinases (CDK, including CDK_1-CDK^a-7); CDK inhibitors (CDKI, including *p*16 family and *p*21 family). They are balanced through mutual interactions. Uncontrolled cell proliferation is the hallmark of cancers which are the result of damage to genes that directly regulate their cell cycles. Using immunocytochemical technique to detect expressions of cyclins and CDKI, we demonstrated that the expressions of cyclin A,B_1 and D_1 on SGC-7901 cells treated with various concentrations *c9,t*11-CLA were reduced, whereas expressions of CDKI($p16^{in4a}$ and $p21^{waf1}$) increased, as compared with those of negative controls. Successive actions of CDKs promote cell-cycle progression in mammalian cells. Various cyclins bind and activate CDKs at specific times during the cell cycle.

Mammalian cyclin A activates CDK_2[55] in S-phase and CDK_1 (Cdc_2) in G_2- and M-phases. One important mechanism that enables sequential activation of cyclin-CDK complexes is the periodic synthesis and destruction of cyclins. Cyclin A expression starts late in G_1-phase and is increasing through S- and G_2-phase before the protein is degraded in M-phase. The cell cycle-dependent expression of cyclin B_1 is critical for the proper timing of a cell's entry into mitosis which is dependent both upon the binding of CDK_1 to cyclin B_1, as well as a series of phosphorylation and dephosphorylation events. The cyclin B_1 protein accumulates during interphase and peaks at the G_2-M phase transition [56]. One of the crucial substrates of G_1 phase CDK, including CDK_4 in the complex with D-type cyclins(cyclin D_1,D_2 and D_3), is Rb protein (pRb), which is the product of the retinoblastoma susceptibility gene. Rb protein plays an important role in the regulation of the G_1 to S phase progression in normal cells and the function of pRb is regulated by phosphorylation. Thus, during the G_0 and G_1 phase, Rb protein is in an un- or underphosphorylated stage and binds to E_2F family transcription factors. Cylin Ds/CDK_4 becomes activated around the mid G_1 phase, resulting in the accumulation of increasingly phosphorylated, inactive forms pRb. This causes the release of E_2F family transcription factors which induce the expression of S-phase genes by positive regulation through E_2F-binding sites(see Figure 4) [57]. It is also known that abrogation of the functions of Cylin A prevents entry into the S phase. From the beginning of the S phase Rb protein remains in the hyperphosphorylated inactive state until the end of M phase; such condition is thought to be due to both cylin A/CDK_2 and Cylin A,B_1/Cdc_2 in catalyzing the phosphorylation reaction [58]. $p16^{ink4a}$ is the founder member of a family of proteins with the ability to inhibit CDK_4 and the CDK_4-related kinase CDK_6.

The INK4 family is composed of four members in mammalian organisms: $p16^{ink4a}$, $p15^{ink4b}$, $p18^{ink4c}$, and $p19^{ink4d}$. The four mammalian INK4 proteins have similar biochemical properties: all of them bind to CDK_4 and CDK_6 and inhibit the kinase activity of the $CDK_{4\text{-}6}$/Cylin D complexes(Figure 4)[59]. The INK4 inhibitor causes G_1 arrest indicating that the phosphorylation of pRb on residues specific for CDK_4(and possibly CDK_6) is critical for G_1/S progression. While $p21^{CIP1/waf1}$ family, comprising $p21^{Cip1/waf1}$, $p27^{CIP1}$ and $p57^{CIP2}$, bind to a variety of CDKs and cyclins, preferentially to cyclin/CDK complexes rather than monomeric forms and also inhibit performed active cyclin/CDK complexes(see Figure 4)[59]. In addition to its role as a CDKI, $p21^{Cip/waf1}$ has been shown to block DNA replication by direct interaction with PCNA mentioned above. However, $p21^{CIP1/waf1}$ does not inhibit the PCNA-dependent nucleotide excision-repair of DNA. In deed, DNA damage leads to an increase in the level of *p*53, and result in *p*21-mediated cell cycle arrest in the G_1 phase, which persists

until DNA repair is completed[60].Thus, it is proposed that $p21^{Cip/waf1}$ plays an important role under such conditions as terminal differentiation and cell senescence.

In conclusion, *c9,t*11-CLA may inhibit cell growth and proliferation by a decrease in the expressions of cyclin A,B_1 and D_1 and an increase in that of CDKI($p16^{ink4a}$ and $p21^{Cip1/waf1}$) on SGC-7901 cells in comparison with the negative controls. This result suggested that the inhibition effect of *c9,t*11-CLA on SGC-7901 cell proliferation is related to the cell cycle. The whole mechanism of the action of *c9,t*11-CLA on SGC-7901 cell cycle further research.

Abstract

AIM: **To elucidate whether human primary gastric cancer and gastric mucosa epithelial cells *in vitro* can grow normally in a methionine (Met) depleted environment, i.e. Met-dependence, and whether Met-depleting status can enhance the killing effect of chemotherapy on gastric cancer cells.**

METHODS: **Fresh human gastric cancer and mucosal tissues were managed to form monocellular suspensions, which were then cultured in the Met-free but homocysteine-containing (Met^-Hcy^+) medium, with different chemotherapeutic drugs. The proliferation of the cells was examined by cell counter, flow cytometry (FCM) and microcytotoxicity assay (MTT).**

RESULTS: **The growth of human primary gastric cancer cells in Met^-Hcy^+ was suppressed, manifested by the decrease of total cell counts [1.46±0.42 ($\times10^9\cdot L^{-1}$) in Met^-Hcy^+ *vs* 1.64±0.44 ($\times10^9\cdot L^{-1}$) in Met^+Hcy^-, $P<0.01$], the decline in the percentage of G_0G_1 phase cells (0.69±0.24 in Met^-Hcy^+ *vs* 0.80±0.18 in Met^+Hcy^-, $P<0.01$) and the increase of S cells (0.24±0.20 in Met^-Hcy^+ *vs* 0.17±0.16 in Met^+Hcy^-, $P<0.01$); however, gastric mucosal cells grew normally. If Met^-Hcy^+ medium was used in combination with chemotherapeutic drugs, the number of surviving gastric cancer cells dropped significantly.**

CONCLUSION: **Human primary gastric cancer cells *in vitro* are Met-dependent; however, gastric mucosal cells have not shown the same characteristics. Met^-Hcy^+ environment may strengthen the killing effect of chemotherapy on human primary gastric cancer cells.**

INTRODUCTION

Gastric cancer is common in China and abroad[1-20], and chemotherapy is still a main method for advanced cancer so far[21-30]. Up to now, quite a few studies have elucidated the property of methionine (Met) dependence of cancer cells[31-34]. If that property was utilized in combination with specific chemotherapeutic drugs, the proliferation of tumor cells would be suppressed. This study intended to culture the human primary gastric cancer cells in diverse environments to judge whether the gastric cancer cells were Met-dependent and whether Met^-Hcy^+ could enhance the effect of chemotherpy.

MATERIALS AND METHODS

Study on Met-dependence

Human primary gastric cancer cells were collected from gastric cancer tissues of 37 advanced gastric cancer patients in our hospital, and human gastric mucosal epithelial cells were simultaneously obtained in 31 patients. Based on the Met-free RPMI-1640 medium, dialyzed bovine serum, and other ingredients necessary for cell growth, Met-free but homocysteine-containing (Met^-Hcy^+) medium and Met-containing but Hcy-depleting (Met^+Hcy^-) medium were prepared[31]. Fresh gastric cancer and mucosa tissues were obtained during operations. After being clipped into pieces and digested, the samples were made into monocellular suspensions, which were then shared out equally in the Met^-Hcy^+ medium (test group) and Met^+Hcy^- medium (control group) separately. The cell concentration was adjusted to $5\times10^8\cdot L^{-1}$. Seeded in the bottles the inside of which was covered with mouse tail collagen, the cells were incubated at 37℃ in an atmosphere containing $50mL\cdot L^{-1}$ CO_2. After being cultured continuously for 96h, the cells were digested by protease to monocellular suspensions, which were then examined by cell counter and phase-contrast microscope and submitted to FCM study for cell kinetics.

Study on Met^-Hcy^+ environment in combination with chemotherapeutic drugs

Human primary gastric cancer cells were sampled from gastric cancer tissues of 40 advanced gastric cancer patients. The methods and conditions of gastric cancer sampling, treatment, and culture were the same as mentioned above. Human primary gastric cancer cells were inoculated in 96-well plates, in which any one of adriamycin (ADM), cisplatin (DDP), 5-fluorouracil (5-FU), mitomycin C (MMC) and methotrexate (MTX) was then added. The concentrations of those drugs were 0.4, 3.0, 10.0, 3.0 and $4.0mg\cdot L^{-1}$ respectively. Each drug group was designed to be repeated for 3 times, and the concentration of 0 was the empty control. Tetrazolium salt was added after the cells were incubated at 37℃ in a $50mL\cdot L^{-1}$ CO_2 atmosphere for 48h. The cell suspensions were centrifuged, added with dimethyl sulfoxide (DMSO), shaken and aspirated until crystals dissolved completely. Microcytotoxicity assay (MTT) was applied, and the cells were colorimetrically analyzed by Bio-tek Instruments at 490nm to obtain the A (absorbance) value, which reflected the amount of surviving cells.

Statistical analysis

Paired *t* test was used.

RESULTS

Human primary gastric cancer cell cycle and amount

After a 96-h culture, the proliferation of human primary gastric cancer cells in the test group was affected, showing bad adherence and cytolysis; however, the cancer cells in the control group did not show

the similar phenomenon. The percentage of cells in G_0G_1 phases in the test group was significantly lower than that in the control group while the percentage of S phase cells in test group was obviously higher than that in the control group. There was no statistical significance between the percentage of G_2M cells in the test group and that in the control group. The result of cell counting was that human primary gastric cancer cells in the test group were apparently less than those in the control group (Table 1).

Table 1 The distribution of human primary gastric cancer cell cycle and the amount of cells ($\bar{x}\pm s$, n = 37)

Groups	Fractions in different phases			Amount of cells ($\times10^9\cdot L^{-1}$)
	G_0G_1	S	G_2M	
Met^+Hcy^-	0.80±0.18	0.17±0.16	0.04±0.06	1.64±0.44
Met^-Hcy^+	0.69±0.24[b]	0.24±0.20[b]	0.07±0.13	1.46±0.42[b]

[b]P<0.01, *vs* Met^+Hcy^- group.

Human gastric mucosa cell cycle and amount

Gastric mucosa epithelial cells grew well both in the test group and in the control group. There was no obvious difference in the percentages in various phases in cell cycle between the two groups. The amount of cells in the test group was slightly higher than that in the control group but without statistical significance (Table 2).

Table 2 The distribution of human gastric mucosa epithelial cell cycle and the amount of cells ($\bar{x}\pm s$, n = 31)

Groups	Fractions in different phases			Amount of cells ($\times10^9\cdot L^{-1}$)
	G_0G_1	S	G_2M	
Met^+Hcy^-	0.90±0.13	0.07±0.11	0.02±0.02	1.70±0.44
Met^-Hcy^+	0.90±0.14	0.08±0.11	0.03±0.04	1.75±0.45

Different media in combination with chemotherapeutic drugs

The surviving gastric cancer cells in the test group without chemotherapeutic drugs were fewer than those in the corresponding control group, with lower A value. The proliferation of gastric cancer cells in the Met^-Hcy^+ group was suppressed much more strongly than that in the Met^+Hcy^- group, no matter which drug was added. The former group had the manifestation of the decrease in surviving gastric cancer cells to various extents, with lower A value (Table 3).

Table 3 The influence of Met^+Hcy^- or Met^-Hcy^+ in combination with chemotherapeutic drugs to gastric cancer cells ($\bar{x}\pm s$, A)

Drug	Met^+Hcy^-	Met^-Hcy^+
ADM	0.3807±0.3114	0.3175±0.2003[a]
DDP	0.3878±0.3050	0.3189±0.1848[b]
5-FU	0.3657±0.2597	0.3182±0.2049[a]
MMC	0.3861±0.2734	0.3105±0.2103[b]
MTX	0.3649±0.2811	0.3120±0.2003[b]

DISCUSSION

Met-dependence and Met starvation

Methionine is an essential amino acid containing an S-methyl, which is used to synthesize through methylation quite a few important physiological active substances. Homocysteine is the direct precursor of Met. Hcy and Met may be converted into each other *in vitro*, but it is not as such *in vivo*. Hcy is continuously consumed with the need of metabolism, and hence is transformed and supplied by Met. Met depletion *in vivo* is easily produced once Met supply is stopped, as there is no pathway *in vivo* of Hcy transforming to Met, which is an essential amino acid. Normal cells can grow well in the environment containing Hcy instead of Met. The proliferation of tumor cells, however, may be suppressed under such condition. This phenomenon is called Met-dependence. It is one of research focuses in the past decades that Met starvation is made artificially in tumor-bearing body to inhibit the tumor growth based on the therapy of Met-dependence. There are several methods to produce Met starvation[32-34]: (1)degradation of Met by methioninase; (2)fast plus Met-depleting total parenteral nutrition (Met^--TPN).Due to its unsatisfactory specificity methioninase can degrade Met irreversibly,but it can also degrade Hcy,homocystine, cysteine and cystine during a short period of time so that the normal cells are hard to survive.Only through fast and Met^--TPN may Met starvation be produced and have little impact on normal tissue cells.

Met-dependence of tumor cells

Studies *in vivo* and *in vitro* can be used to judge whether tumor cells have the property of Met-dependence and to explore the impact of Met starvation on the proliferation of tumor cells. The research *in vivo* is not easy to conduct because of many inevitable factors. The prominent characteristic of the research *in vitro* is that the cells cultured are not influenced by complex internal environment and the rule of cell life activity can be studied. The change of cell physiological functions under the influence of single or multi-factors may be further observed when culture conditions such as physical, chemical and biological factors are altered artificially. Goseki *et al* explored the relationship of tumor growth and Met-dependence by animal experiment. We have also done such work in the past years[35,36]. The studies suggested that Met starvation in tumor-bearing animals could inhibit the proliferation of tumor cells. In the experiment *in vitro* of gastric cell line SGC-7901, we found that the percentages of SGC-7901 cells in S and G_2M phases in the Met^-Hcy^+ medium were both obviously elevated and the percentage of G_0G_1 cells significantly declined in comparison with those in the Met^+Hcy^- medium. The results meant that the cell cycle of SGC-7901 was inhibited in the G_2M phase. The present study showed again that *in vitro* the proliferation of human primary gastric cancer cells in the environment of Met^-Hcy^+ had the similar results to that of human gastric cancer cell line SGC-7901. The cell cycle of tumor cells was disturbed and the amount of cancer cells decreased significantly; however, no same phenomenon was observed in the gastric mucosa epithelial cells. The results suggested that human gastric cancer cells were Met-dependent. The cause of Met-dependence of tumor cells remains unclear. As far as we know now, the causes include: (1)decreased amount and activity of Met synthetase; (2)deficiency of 5-methyltetrahydrofolate reductase; (3)inability to make use of endogenous Met; (4)rise in the rate of basal transmethylation; (5)activated EJ/T24HRAS1 oncogene leading to the expression of Met-dependence.

Significance of Met starvation in combination with chemotherapeutic drugs

Chemotherapy can not be replaced by surgery and radiotherapy in the treatment of malignancies. At present most chemotherapeutic drugs are phase-specific, despite some without phase-specificity, all of which are hard to kill tumor cells completely. So the aim of tumor therapy is to take measures to improve the effect of chemotherapy. It is a new trial to drive the G_0 cells to enter into the proliferating phase. Our previous clinical study and tumor-bearing rat experiment[37-39] showed that after the treatment of parenteral nutrition, the percentages of S and $S+G_2+M$ gastric cancer cells increased obviously while that of G_0G_1 cells decreased dramatically. Met deprivation can produce Met starvation in Met-dependent tumor cells, then metabolism of cancer cells is suppressed and more cells remain in the phases of S and G_2. As a result, the effect of phase-specific chemotherapeutic drugs is enhanced significantly. This provides a new way to improve the therapeutical effect on tumors by using Met^--TPN combined with chemotherapeutic drugs. Many authors[40-44] have made the researches, both experimentally and clinically, on Met^--TPN in

combination with chemotherapeutic drugs to improve the effect of chemotherapy. They confirmed that Met-TPN in combination with 5-FU, DDP and ADM respectively can enhance the sensitivity of chemotherapy of gastric cancer, breast cancer and Yashida sarcoma. Our present study supported the above results. It is hypothesized that Met starvation could make primary gastric cancer cells blocked in the phases of S/G_2M. Theoretically, the more numerous are the cells in the proliferating phase, the stronger effect of phase-specific chemotherapeutic drugs have been produced.

Abstract

AIM: **To improve the preparation of adherent lymphokine-activated killer (A-LAK) cells and to study the effects of cryopreservation and phenylacetate (PA) on biological characters of A-LAK cells.**

METHODS: **A-LAK cells were obtained from peripheral blood mononuclear cells (PBMCs) of the patients with hepatocellular carcinoma (HCC) by using L-phenylalanine methyl ester (PME) to deplete immunosuppressive monocytes. Proliferative activity of SMMC7721 cell line after treatment with phenylacetate (PA) was observed. A-LAK cells were treated with the supernatant of SMMC7721 cells that had been pretreated with PA. The changes of proliferation, cytotoxicity and phenotype of A-LAK cells were investigated after cryopreservation.**

RESULTS: **The expansion of A-LAK cells (96.79±69.10 folds on Day 14) was significantly higher than that of non-adherent LAK (NA-LAK) cells (22.77±13.20) as well as conventional LAK cells (4.64±0.91). PA significantly suppressed the growth of SMMC7721 cells, and the inhibitor ratio was 46%. The supernatant of cultured tumor cells intensively suppressed the proliferation and cytotoxicity of A-LAK cells, but the suppressive effect of the supernatant was previously decreased after treatment with PA. Impairments in proliferation and cytotoxicity of A-LAK cells immediately after thawing of cryopreservation and recovery after reincubation with IL-2 were observed. The cytotoxicity of thawed A-LAK cells on Day 5 was significantly higher than that of fresh A-LAK before freezing (54.8±10.2% *vs* 40.5±6.4%). No significant change in the percentage of lymphocyte subsets was identified in frozen A-LAK cells as compared with that in the fresh control cells.**

CONCLUSION: **A-LAK cells can be simply prepared by using PME, and showed a synergistic anti-tumor effect with the combination of PA. Cryopreservation can increase the immunoactivities of A-LAK cells from the patients with hepatocellular carcinoma.**

INTRODUCTION

Biotherapy of cancer, as the forth modality of tumor treatment, has been accepted[1-4]. Adoptive transfer of LAK cells together with IL-2 has been found to be an effective immunotherapeutic modality for eradication of several tumors[5-8]. However, some reports indicated that clinical responses have been infrequent and transient, and that severe toxicity was associated with the administration of high doses of rIL-2[6,9,10]. Adherent-lymphokine activated killer (A-LAK) cells have significantly higher cytolytic activity on a per cell basis and greater proliferative capacity than LAK cells[9-14]. But the usage of A-LAK cells was limited by the complex traditional preparation by using nylon wool columns[15-17]. To harvest a large number of actively immunocompetent cells at the right time now becomes an important point of adoptive immunotherapy. The freezing of peripheral blood mononuclear cells (PBMCs)is a common practice, and does not significantly alter the functional activities of immunocompetent cells [18]. The recent reports showed that frozen PBMCs produced significantly larger quantities of IL-1, IL-2, IL-6, and IFN-ã than the fresh cells[19]. These results indicated that cryopreservation could increase the immunoactivities of immunocytes. We improved the preparation of A-LAK cells and studied the effects of cryopreservation and phenylacetate (PA) on biological characters of A-LAK cells from the patients with hepatocellular carcinoma.

MATERIALS AND METHODS

Cell lines and Reagents

A human hepatocellular carcinoma cell line, SMMC7721, was maintained in RPMI1640 medium supplemented with 10% heat-inactivated fetal calf serum (FCS, Gibco) at 37℃ in a 5% CO_2 humidified atmosphere. Phenylacetate (PA, Sigma) and L-phenylalanine methyl ester (PME, Sigma) were dissolved in RPMI1640 medium, brought to PH7.0 and 7.4, respectively and stored in aliquots at 4℃.

Preparation of A-LAK cells

PBMCs were isolated from the patients with hepatocellular carcinoma (HCC) by using a cell separator (CS-3000 plus, Baxter), and then by centrifugation on Ficoll-Hypaque gradients. Cells collected from the gradient interface were washed twice in RPMI 1640 medium (GIBCO) and incubated in medium containing PME (5mmol/L) for 40min at room temperature to remove monocytes. After two washes with complete tissue culture medium (TCM) containing RPMI 1640 medium supplemented with 10%(v/v) heat-inactivated pooled AB human serum. The monocyte-depleted PBMCs were adjusted to the concentration of 2×10^6/ml and incubated in TCM containing rIL-2 (1000U/ml) in a plastic culture flasks positioned on its flat side for 24hr at 37℃ in humidified atmosphere of 5% CO_2. Following 24hr of activation in rIL-2, supernatants containing cells that did not adhere to plastic were decanted from the flasks, collected, and centrifuged. The recovered non-adherent cells (NA-LAK cells) were resuspended in fresh TCM plus rIL-2 (1000U/L) and cultured for 8-12 days. The cell-free supernatant of the non-adherent cell population was collected

and used as autologous conditioned medium (AuCM). The cells adherent to plastic (A-LAK cells) were washed twice with prewarmed TCM to remove cells that were not firmly attached to plastic, and then were supplemented with TCM containing 50% (v/v) of AuCM and rIL-2 (1000U/ml). These A-LAK cells were also cultured for 8-12 days and maintained at a concentration of 2×10^6 cells/ml by supplying fresh TCM containing rIL-2 (1000U/ml) as needed. PBMCs were also established in cultures with rIL-2 (1000U/L) and cultured for 4 days as standard, regular LAK cells.

Procedures of freezing and thawing

After 10 days of incubation with rIL-2, A-LAK cells were washed and counted. Then the cells were diluted in the cold freezing medium in an ice bath to give a final concentration of 5×10^6cells/ml. The freezing medium consisted of 10% (v/v) heat-inactivated pooled AB human serum, 10% dimethyl sulfoxide (DMSO), and 80% RPMI-1640 containing rIL-2 (1000U/ml). The cells were distributed in precooled plastic vials. The vials were frozen according to the routine procedure: at 4℃ for 30min→ at 0℃ for 30min → at -20℃ for 30min → at -80℃ for 60min → transferred to liquid nitrogen for storage.

The frozen cells were thawed in a 37℃ water bath, and washed at 1000rpm in phosphate-buffered saline twice to remove DMSO. Cell recovery and viability were calculated by trypan blue exclusion. After thawing, the cells were cultured in complete media as described above with 1000U of rIL-2/ml at the concentration of 2×10^6cells/ml for 7~10 days.

Tumor cell culture and PA treatment

The SMMC7721 cells growing in logarithmic phase were seeded into flasks at a concentration of 2×10^5cells/flask. The following day, the medium was changed, and PA was added to the medium at 0 and 5mmol/L for 7days. After cell counts,the mediums were changed. Twenty-four hours later, the cell-free supernatants of SMMC7721 cells with PA pre-treatment and non-treatment were collected.

Proliferative activity of A-LAK cells

Fold expansions of fresh A-LAK cells, NA-LAK cells, regular LAK and frozen A-LAK cells were determined by cell counts performed in the presence of trypan blue on day 1,4,7,10,and 14,respectively.

On the other hand, A-LAK cells were incubated by supplying fresh TCM containing 10% (v/v) cell-free supernatant derived from SMMC7721 cells with and without PA administration previously for 14 days. Cell numbers were calculated by hemocytometer cell counts in trypan blue.

Cytotoxicity Assays[20]

The fresh A-LAK cells, frozen A-LAK cells and A-LAK cells treated with SMMC7721 cell supernatant administered with or without PA were tested as effector cells for cytotoxicity against cultured SMMC7721 cells in MTT assays. SMMC7721 cells as target cells were seeded 2×10^4cells/well in wells of U-bottomed 96-well plates and incubated for 24hr. Effector cells were added to target cells in effector-to-target ratio of 10 ∶ 1. After 48-hour incubation at 37℃, stock MTT solution (50μl/well) was added to all wells of an assay, and plates were incubated at 37℃ for 6hr. Acid-isopropanol was added to all wells and mixed thoroughly to dissolve the dark blue crystals. After a few minutes at room temperature to ensure that all crystals were dissolved, the plates were read on a Microplate Reader (3550-UV, Bio-Rad), using a test wavelength of 570nm, a reference wavelength of 630nm.

Analyses of phenotype

The surface phenotype of cells was analyzed before freezing, after thawing and after 3 days of restimulation with rIL-2 using monoclonal antibodies CD3, CD4, CD8, CD16, and CD25. Analyses were performed on a flow cytometer (EPI CV-V, Culter Corp.).

Statistics

Statistics analysis of the data was performed using the Student's *t*-test; $P<0.05$ was considered statistically significant.

RESULTS

Proliferation of A-LAK cells

A-LAK cells expanded better and faster than autologous non-adherent cells or regular LAK cells under the same growth conditions (Table 1). For HCC patients, the expansions of A-LAK cells varied from 23- to 243- fold by 14 days in culture, which were much higher than those of NA-LAK cells and regular LAK cells.

Table 1 Proliferative capacity of A-LAK cells

Culture Days	Cells expansion folds		
	A-LAK	NA-LAK	Regular LAK
1	1.35±0.39	0.87±0.21[a]	0.83±0.09[a]
4	2.22±0.85	1.09±0.33[a]	0.99±0.03[a]
7	4.42±2.05	2.13±0.83[a]	1.55±0.14[b]
10	22.52±10.47	8.49±3.91[a]	3.25±0.64[b]
14	96.79±69.10	22.77±13.20[a]	4.64±0.91[a]

[a]$P<0.05$, *vs* compared with A-LAK cells of the same day; [b]$P<0.01$, *vs* compared with A-LA cells of the same day

The recovery rate after thawing of the cryopreserved A-LAK cells was 84.3±4.2%. The viability of frozen cells was 96.4±3.8%. The length of storage in liquid nitrogen (ranged from 1 day to 6 months) did not have any detectable effect. The frozen A-LAK cells after thawing maintained a high ability of proliferation. After 3 days of reculture with rIL-2, the expansion folds of thawed A-LAK cells was in the same range as A-LAK cells before freezing (Figure 1).

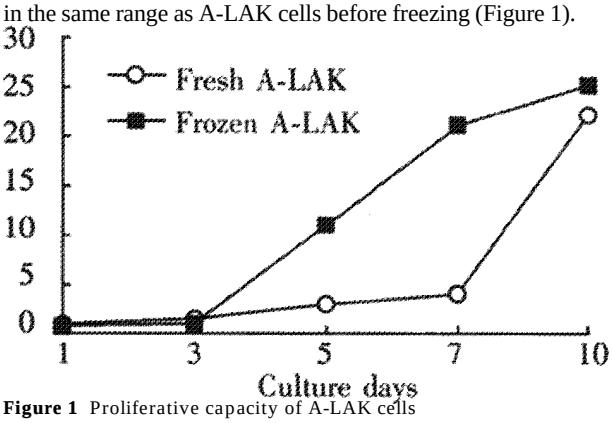

Figure 1 Proliferative capacity of A-LAK cells

Effect of PA on SMMC7721 cell proliferation

Having treated with PA at 5mmol/L for 7 days, the SMMC7721 cells propagated from 2.0×10^5 cells/flask to 1.54×10^6 cells/flask. At the same time, the tumor cells without PA treatment proliferated to 2.86×10^6 cells/flask. The inhibitory ratio of PA affecting SMMC7721 proliferation was 46%.

Effect of PA and supernatant of Tumor cells on A-LAK propagation

On day 14 of cell culture, the expansion folds of A-LAK cells treated with the supernatant of SMMC7721 cells were only 55.22±42.37, which were significantly lower than those of normal cultured A-LAK cells (96.79±69.10, $P<0.01$). However, the expansion folds of A-LAK cells treated with the supernatant of SMMC7721 cells with PA administration previously recovered to 84.72±58.98, which had no

significant statistical difference from those normal cultured A-LAK cells (P>0.05).

Effect of PA and supernatant of tumor cells on A-LAK cell cytotoxicity

The cytotoxicity of A-LAK cells treated with the supernatant of SMMC7721 cells 31.2±9.01% was significantly lower than that of normal cultured A-LAK cells 68.4±8.82% (P<0.001). However, the cytotoxicity of A-LAK cells treated with the supernatant of SMMC7721 cells with PA administration previously approached the normal level 57.1±10.1% (P>0.05).

Effect of cryopreservation on A-LAK cell cytotoxicity

Immediately after thawing, there was a significant decrease in cytotoxic activities. This impairment in activity was temporary, and the complete cytotoxicity could be restored by reincubation of the thawed A-LAK cells with rIL-2 for 1 day (Figure 2). After 5 days of postthaw culture with rIL-2, the cytotoxicity of the thawed A-LAK cells (54.8±10.2%) was significantly higher than that of fresh A-LAK cells before freezing (40.5±6.4%, P<0.05).

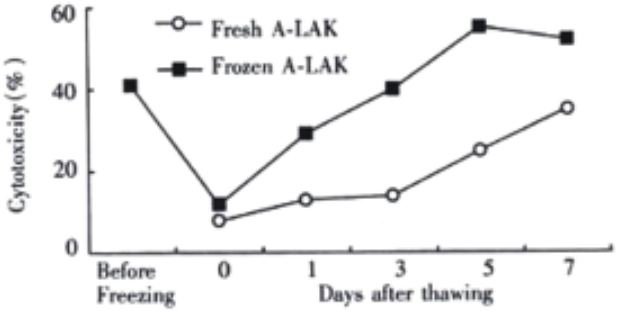

Figure 2 Effect of cryopreservation on A-LAK cells cytotoxicity

Change of phenotype of frozen A-LAK cells

As shown in Table 2, no significant change in the percentage of lymphocyte subpopulations of A-LAK cells before freezing, immediately after thawing, and 3 days after thawing was identified (P>0.05).

Table 2 Changes of phenotype of cryopteserved A-LAK cells

	Case No.	CD3	CD4	CD8	CD4/CD8	CD16	CD25
Before freezing	6	76.5±10.3	41.4±7.5	40.3±5.3	1.03±0.31	10.4±3.1	52.3±5.9
Day 0 after thawing	6	80.5±11.4	35.9±6.4	36.5±4.9	1.07±0.38	14.1±4.3	49.7±3.1
Day 3 after thawing	6	86.3±8.9	33.1±7.5	42.6±6.0	0.78±0.19	15.4±2.7	46.5±4.7

DISCUSSION

The application of LAK cells in immunotherapeutic treatment of cancer began in the past decade. The biotherapy may be the most effective method in delayed treatment of residual neoplastic diseases after classic reductive therapy (i.e. chemotherapy and bone marrow transplantation). A large number of immunocompetent cells are required for each adoptive immunotherapy. In some patients, because of the complexity of the preparation of immunocytes, such as LAK cells and A-LAK cells, the immunosuppressive status of the tumor host, and the procedures of the treatment of malignant tumor (i.e. the side effects of chemotherapy on the immune system of the host), it is difficult to obtain sufficient effector cells when they are needed. Therefore, we have carried out experiments to improve the preparation of A-LAK cells, and to determine the effects of cryopreservation and PA on the immunologic function of A-LAK cells obtained from the patients with HCC.

A major contributor to host immunity and immune surveillance against infection, tissue or cell damage and malignancy is the monocyte/macrophage system. The monocytes/macrophages play both positive and negative regulator roles in immune responses[21-23]. They can secret some kinds of cytokines (i.e. IL-1, IL-6), which may lead to an enhancement effect on both humoural and cellular immunity of human bodies[24,25]. Meanwhile, they can also produce some chemotactic factors (such as prostaglandin E2, lipocortin) to intensively suppress the immune responses[26,27]. In addition, some reports indicated that monocytes/macrophages could inhibit the proliferation and cytotoxicity of LAK cells[28]. Thus, the therapeutic effects of LAK cells would be improved by removing monocytes/macrophages from PBMC. The monocyte-depleted PBMC cells could be incubated with rIL-2 in a plastic flask and the plastic-adherent cells could be harvested as adherent LAK cells. There are several methods that can be used to get rid of monocytes/macrophages from peripheral blood. The routine one is to load PBMC onto prewarmed nylon wool column to remove monocytes/macrophages by adherence to nylon wool. But the complexity of this procedure limited the usage of A-LAK cells. Some reports demonstrated that PME could remove the monocytes/macrophages efficiently without changing the phenotype and cytotoxicity of lymphocytes. Triozzi and colleagues used this procedure to harvest A-LAK cells with efficient anti-tumor activities from the patients with renal cancer[15]. Our results using the same method to prepare A-LAK cells from patients with HCC are similar to those reports.

There are evidences that the immune system of tumor hosts has been destroyed, and that the immune function of hosts is suppressed[29-32]. Thus, LAK cells and A-LAK cells prepared from peripheral blood of tumor hosts were different from those of normal individuals. Melden *et al* reported that for normal individuals, the expansion of A-LAK cells varied from 190- to 800- folds by 14 days in culture[9], whereas the numbers of A-LAK cells harvested from HCC patients in our study were only increased by 23- to 243- folds. We also indicated that the human HCC cell line (SMMC7721) intensively suppressed the proliferation and cytotoxic activity of A-LAK cells by secreting some immunosuppressive factors. The suppression of immune system of tumor host caused by secretion of immunosuppressive factors from tumor cells has become one reason for the limitation of the usage of the adoptive immunotherapy such as LAK/rIL-2.

The cryopreservation of human mononuclear cells is a common practice, but the effect of the cryopreservation of the effector cells on the functional activities is not well documented. Some reports indicated that high concentration of DMSO, rapid cooling rate, and rapid diluting after thawing could injure the hemopietic stem cells and lymphocytes[33]. Recent results showed that freezing not only did not significantly affect the functional activities of immunocompetent cells, but also increased the secreting abilities of some cytokines of these cells[19]. In our tests, optimal proliferation and cytotoxicity of A-LAK cells from the patients with HCC were generated after 10 days of culture with rIL-2. Cryopreservation was performed on cells after 10 days of culture. Our results demonstrated that impairments in proliferation and cytotoxicity of A-LAK cells immediately after thawing of cryopreservation and recovery after reincubation with IL-2 were observed. The cytotoxicity of thawed A-LAK cells on Day 5 was significantly higher than that of fresh A-LAK before freezing. The results indicated that cryopreservation could increase the immunoactivities of A-LAK cells from the patients with hepatocellular carcinoma. The difference of the immunologic activities of A-LAK cells during the distinct periods after thawing may explain the

divergence of views from different investigators.

Phenylacetate (PA) is a member of a class of aromatic fatty acids and common metabolite of phenylalanine that is present in human plasma and cerebrospinal fluid in micromolar concentrations[34]. Experimental data indicated that PA was able to promote differentiation, growth inhibition, tumor maturation, and apoptosis *in vitro* and in vivo of various human leukemia cells, prostate carcinoma cells, breast cancer cells, brain tumor cells and renal cancer cells[35-38]. The phase I clinical trials at the National Cancer Institute with phenylacetate as a novel, nontoxic differentiation inducers have been finished[39]. Currently in clinical trials, PA was examined for its ability to modify tumor immunogenicity and revealed that it was able to reduce biosynthesis and secretion of TGF-â2, the tumor-derived T-cell suppressor factor, and reverse the tumor associated inhibition of IL-2 secretion by PHA-treated peripheral blood lymphocytes[40]. In our study, PA could significantly inhibit the growth of tumor cells, and the suppressive effect of the supernatant of tumor cells with pre-treatment of PA on the proliferation and cytotoxicity of A-LAK cells was decreased. Our data indicated that PA could decrease the immunosuppressive factors derived from tumor cells, antagonize the inhibition of tumor in biotherapy, and coordinate to attack tumor cells.

Abstract

AIM: **The survival time of patients with hepatocellular carcinoma (HCC) after resection is hard to predict. Both residual liver function and tumor extension factors should be considered. A new scoring system has recently been proposed by the Cancer of the Liver Italian Program (CLIP). CLIP score was confirmed to be one of the best ways to stage patients with HCC. To our knowledge, however, the literature concerning the correlation between CLIP score and prognosis for patients with HCC after resection was not published. The aim of this study is to evaluate the recurrence and prognostic value of CLIP score for the patients with HCC after resection.**

METHODS: **A retrospective survey was carried out in 174 patients undergoing resection of HCC from January 1986 to June 1998. Six patients who died in the hospital after operation and 11 patients with the recurrence of the disease were excluded at 1 month after hepatectomy. By the end of June 2001, 4 patients were lost and 153 patients with curative resection have been followed up for at least three years. Among 153 patients, 115 developed intrahepatic recurrence and 10 developed extrahepatic recurrence, whereas the other 28 remained free of recurrence. Recurrences were classified into early (</=3 year) and late (>3 year) recurrence. The CLIP score included the parameters involved in the Child-Pugh stage (0-2), plus macroscopic tumor morphology (0-2), AFP levels (0-1), and the presence or absence of portal thrombosis (0-1). By contrast, portal vein thrombosis was defined as the presence of tumor emboli within vascular channel analyzed by microscopic examination in this study. Risk factors for recurrence and prognostic factors for survival in each group were analyzed by the chi-square test, the Kaplan-Meier estimation and the COX proportional hazards model respectively.**

RESULTS: **The 1-,3-,5-,7-,and10-year disease-free survival rates after curative resection of HCC were 57.2%,28.3%, 23.5%,18.8% and 17.8%,respectively. Median survival time was 28,16,10,4, and 5mo for CLIP score 0,1,2,3, and 4 to 5, respectively. Early and late recurrence developed in 109 patients and 16 patients respectively. By the chi-square test, tumor size, microsatellite, venous invasion, tumor type (uninodular, multinodular, massive), tumor extension (</= or >50% of liver parenchyma replaced by tumor), TNM stage, CLIP score, and resection margin were the risk factors for early recurrence, whereas CLIP score and Child-Pugh stage were significant risk factors for late recurrence. In univariate survival analysis, Child-Pugh stages, resection margin, tumor size, microsatellite, venous invasion, tumor type, tumor extension, TNM stages, and CLIP score were associated with prognosis. The multivariate analysis by COX proportional hazards model showed that the independent predictive factors of survival were resection margins and TNM stages.**

CONCLUSION: **CLIP score has displayed a unique superiority in predicting the tumor early and late recurrence and prognosis in the patients with HCC after resection.**

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the major causes of death in the world[1-4]. In China, HCC ranked second of cancer mortality since 1990s[5]. Within the past decade, as a result of advances in the diagnosis and disease management of HCC, significant improvement of overall and disease-free survival rates after resection of HCC have been achieved[6-9]. However, even when curative resection is performed, a considerable number of patients develop intrahepatic and/or extrahepatic recurrence postoperatively[10-16]. The recurrence and prognostic assessment of patients with HCC after resection is an important clinical issue[13,14,17-21].

After Okuda made a suggestion of clinical stage system[22], UICC introduced the tumor node metastasis (TNM) stage that was widely used in China for predicting the prognosis of HCC[17,18,23]. TNM stage took into account of the tumor extension alone and it did not deal with liver function. HCC mainly arose in patients already affected with chronic hepatitis or cirrhosis[12,24]. The prevalence of hepatitis B surface antigen (HbsAg) and antibody to HCV in HCC patients were reported to be 63.2% and 11.2% respectively in China[25], and coexisting cirrhosis occurred in 88.8% (888/1000 patients) for patients with small HCC[14]. The liver damage in patients with HCC after resection is also a risk factor for recurrence and prognosis[26-32]. Hence, a new stage accounting for both liver function and tumor extension is necessary to predict HCC prognosis.

In 1998, by a retrospective evaluation of 435 Italian patients, the Cancer of the Liver Italian Program (CLIP) had proposed a new prognostic system that included four parameters involved in the Child-Pugh stag, plus macroscopic tumor morphology, alpha-fetoprotein (AFP) levels, and the presence or absent portal thrombosis and confirmed that the CLIP score, compared with the Okuda staging system, gave more accurate prognostic information, was statistically more efficient, and had a greater survival predictive power[33,34]. After that, Farinati *et al*[35] pointed that the CLIP score was able to

predict survival better than TNM staging system, especially in the subgroup of patients undergoing chemoembolization. However, the number of patients with HCC after resection in these two studies was small and limited. Correlation between CLIP score and prognosis of patients with HCC after resection was not reported. The aim of this study is to validate the prognostic value of CLIP score in the patients with HCC by means of disease-free survival rate and time to recurrence for patients enrolled between 1986 and 1998 in our department.

MATERIALS AND METHODS

Patients

From January 1986 to June 1998, 174 patients underwent resection of HCC at our department. The mean age was 49.8 (range, 9-75) years old and the ratio of male to female was 156 to 18. Six patients who died in the hospital after operation and 11 patients were excluded because of the disease detected in the remnant liver by a routine ultrasound or CT scan or arteriography performed at 1 month after hepatectomy, which was considered residual disease. By the end of June 2001, 4 patients were lost and 153 patients with curative resection have been followed up for at least three years. Among 153 patients, 115 developed intrahepatic recurrence and 10 developed extrahepatic recurrence, whereas the other 28 remained recurrence free after a mean follow up period of 60 months. Figure 1 showed the patients distribution of the time to recurrences or death after operation. There were two peaks at 6 months and 15 months among those with early recurrence. Our data indicated that 3-year' survival after hepatectomy was a distinctive point of early from late recurrence when compared with other time intervals such as 1 and 2 years.

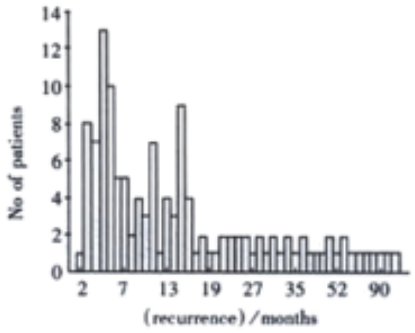

Figure 1 The recurrent time distribution of patients with HCC after complete resection

Methods

The CLIP score system included Child-Pugh stage[36], tumor morphology and extension, AFP levels, and the presence or absence of portal thrombosis (Table1).

Table 1 CLIP score system

Variable	Scores		
	0	1	2
Child-Pugh stage	A	B	C
Tumor morphology	Uninodular and extension ≤50%	Multinodular and extension ≤50%	Massive or extension >50%
AFP(ng/Dl)	<400	≥400	
Portal vein thrombosis	No	Yes	

The scores was calculated by addition of each individual value of the four items[34]. What was the difference from the CLIP data, that portal vein thrombosis was defined as the presence of tumor emboli within vascular channel analyzed by microscopic examination in this study.

Disease-free survival rate was defined as the time relapsed from the date of image diagnosis and either the date of death or the date of the latest follow-up visit, with final evaluation at June 30, 2000. Recurrences were classified into early (</=3 year) and late recurrence (>3 year) after the date of hepatectomy. Patients with early or late recurrences were compared respectively with patients who did not develop any recurrent disease during the follow-up periods to identify risk factors.

Statistical Analysis

Comparisons between groups were performed by the chi-square test (Pearson's methods or Fisher's exact test). Univariate survival curves were evaluated using the Kaplain-Meier method and compared by using the Long-rang test. The COX proportional hazards model was used to determine the significance of each significant univariate variable in multivariate analysis of prognostic factors. All analyses were performed using SPSS 8.0 for windows software. All *P* values of less than 0.05 in two-tailed were considered statistically significant.

RESULTS

The 1-, 3-, 5-, 7-, and 10-year cumulative disease-free survival rates were 57.2%, 28.3%, 23.5%, 18.8% and 17.8% respectively after hepatectomy. Among the 125 patients with recurrence, 109 had early recurrences and 16 had late recurrences. 28 patients were recurrence free within follow-up period.

Risk factors for early and late recurrence

The characteristics of the host-and treatment-related factors were showed in Table 2. Among of six host-related factors, age, gander, hepatitis B surface antigen status, tumor family history and cirrhosis were associated with neither early nor late recurrence.

Table 2 Characteristics of host-and treatment-related factors in patients with HCC after resection

Characteristics	Early recurrence (*n*=109)	Late recurrence (*n*=16)	No recurrence (*n*=28)
Age	50.7±9.8	49.2±8.5	48.3±10.2

Child-Pugh stage had not correlation with early recurrence, whereas it had significant correlation with late recurrence [Child stage B: 37.5% (6/16) in late recurrence versus 7.1% (2/28) in no-recurrence, P=0.019]. The four treatment-related factors, preoperative transcatheter arterial embolization (TAE), postoperative chemotherapy, with or without splenectomy, were associated with neither early nor late recurrence. The proportion of resection margin less than one centimeter in early recurrence was significant higher than that in no-recurrence (P=0.000), but had not correlated with late recurrence. Eight tumor-related factors except serum AFP levels were associated with early recurrence, namely tumor size >5cm (P=0.001), presence of microsatellite (P=0.000), venous invasion (P=0.001), tumor type (P=0.024), tumor extension (P=0.013), advanced TNM stages (P=0.000), and CLIP scores (P=0.005). In contrast, only CLIP score has significant correlation with late recurrence [CLIP score 0-1: 92.9% (26/28) in no-recurrence versus 56.2% (9/16) in late recurrence, P=0.006] (Table 3).

Survival curve analysis

Univariate survival curve analysis showed that Child stage (P=0.0358), resection margin (P=0.0000), tumor size (P=0.0000), presence of microsatellite (P=0.0000), venous invasion (P=0.0000), tumor type (P=0.0000), tumor extension (P=0.0000), TNM stage (P=0.0000), and CLIP score (P=0.0000) were associated with prognosis. The multivariate analysis by COX proportional hazards model revealed that the independent prognostic factors for survival were resection margin (P=0.0000) and TNM stage (P=0.0035). Figure 2 and 3 demonstrated cumulative disease free survival curves of TNM stage and CLIP score respectively. Table 3 showed 1-, 3-, and 5-year disease free survival rates and median survival time of TNM stage and CLIP score.

DISCUSSION

Recurrences of HCC in the remnant after surgical resection could originate from either intrahepatic metastasis from the primary tumor or multicentric occurrence[19,32,37,38]. Some authors have been found that recurrence was mainly associated with adverse tumor factors such as tumor size, vascular invasion, and microsatellite[10-14,17,18]. Others demonstrated a liver function status[26-32,38]. Poon *et al* showed that

tumor factors were linked to early recurrence, whereas the nontumorous liver status was linked to late recurrence[19]. Thus, a good stage system should include both tumor-related factors and host-related factor. In 1998, a retrospective analysis of 435 cases of HCC diagnosed at 16 Italian institutions was performed by CLIP[33]. Four independent predictive factors of survival were Child-Pugh stage, tumor morphology, AFP, and portal vein thrombosis by multivariate analysis. Adding each individual value for the four items, the CLIP score was produced. The median survival time for CLIP score 0, 1, 2, 3, 4, and 5 to 6 were 42.5, 32.0, 16.5, 4.5, 2.5, and 1.0 months respectively. Compared with Okuda stage Ⅰ (32.5 months), Ⅱ (12.0 months), and Ⅲ(1.5 months), the CLIP score has a higher number of categories and a greater discriminating ability, and gives more precise information[33,34]. After that, 154 patients with histologically ascertained HCC and cirrhosis were recruited by Farinati *et al*[35] and found that the median survival rate in patients with CLIP stages 0, 1, 2, 3, 4, and 5 to 6 were 31, 27, 13, 8, 2, and 2 months respectively. The TNM staging was much less effective in distinguishing patients with respect to median survival (TNM stage Ⅰ, 34 months; stage Ⅱ, 25 months; stage Ⅲ, 20 months; and stage Ⅳ, 14 months) and TNM was not significantly correlated with survival rate in patients undergoing a single treatment (TACE). In conclusion, Farinati *et al* confirmed that the CLIP score was currently the best way to stage patients with HCC, it could accurately identify patients with different prognosis, particularly in the early phases(CLIP0-3)of HCC[35]. However, in those data, the major treatment of the HCC were not surgical resection, 12 of 435 patients in the CLIP group[33] and 17 of 154 patients in Farinati group[35] were surgical treatment. The CLIP score was based on prognostic parameters of unresectable patients. This study introduced the CLIP score into the patients with HCC after resection and studied its prognostic value. The results suggested that CLIP score were significantly associated with early and late recurrence, but TNM stage was only associated with early recurrence. It meant that the risk of early recurrence was dependent on the primary tumor factors, but the late recurrence was dependent on the underlying liver status. The CLIP score has a unique superiority for predicting recurrence, because of that accounting for both liver function and tumor extension. The survival analysis showed that the CLIP score was associated with prognosis in the univariate survival and did not associated with that in the multivariate survival. Otherwise, the TNM stage was associated with prognosis in the both univariated and multivariated survival analysis. We had reported before[18] that the TNM stage was inefficient for multicentric origin and Long-term survival patients because the TNM stage depended only on tumor characteristics, but not on patient factors[32]. In addition, CLIP score also solved out a problem of TNM stage, that is HCC with two nodes located in both lobes of the liver may be a multicentric origin and the patient after complete resection will have a good prognosis, which was identified stage Ⅳ in TNM stage. Recently, Ueno *et al*[39] investigated the value of CLIP score in 662 Japanese patients with HCC at 4 Japanese institutions from 1990 and 1998. Compared with the Okuda and AJCC staging systems, the CLIP score revealed a class of patients with an impressively more favorable prognosis and another class with a relatively shorter life expectancy. Moreover, the likelihood ratio test showed that the CLIP score had additional homogeneity of survival within each score above that of the Okuda stage or the AJCC stage. This was true for 3 subgroups of patients who received surgery, TAE, and percutaneous ethanol injections.

The patients with portal vein tumor thrombosis (PVTT), which was one of the most important predictive factor identified with the multivariated analysis[10-12,14,17,18,40-42] showed higher recurrence rate and a poor prognosis, as has been found previously. However, unlike the resectable cases, the PVTT had been a relatively rare condition prevalently in unresectable patients[43]. With the development of image technology, the CT and Doppler ultrasound characteristics of benign and malignant PVTT have been described[43,44]. But the PVTT detected by image examination were either located in the main and/or the first portal branch or large thrombosis[43,44]. For the resectable HCC, macroscopic tumor thrombus rate was 4.9%[14]. Cong *et al*[45] reported the rate of microscopic vascular embolus was 28% in 93 hepatectomies of <3cm small HCC. In the 336 patients with HCC reported by Sithinamsuwan *et al*[40], the PVTT was 50%. Liver Cancer Study Group of Japan[11] reported that image TVPP positive rate was 23%, whereas microscopic PVTT rate was 72.8%. Thus, whether the portal thrombosis was benign or malignant, and PVTT was defined by image or pathology, those all would affect patient's prognosis, and result in the difference of scores of CLIP stage. Under similar circumstances, it will effect predictive capacity of CLIP score.

AFP level is the most effective marker for HCC diagnosis and recurrent surveillance[11,46-48]. The prognostic significance of AFP level is still a controversial issue[11,12,14,17,18,33,40,46,48]. The large series data (Liver Cancer Study Group of Japan in 1995, 9099 patients[11], Zhang in 2000, 1725 patients[17]) showed that AFP level was associated with prognosis, and the higher AFP was, the poorer patient's prognosis was. To our knowledge, no study has been reported that AFP level has correlated with prognosis in multivariate analysis in China[17,18,49,50], and the literature also did not show any relationship between AFP level and prognosis. Rabe *et al*[12] reported that while AFP positivity itself was not associated with lower survival, AFP-level greater than $100ug\cdot L^{-1}$ was associated with a median survival of 3 months, and lower AFP-level was associated with a survival of 12.5 months ($P<0.01$). Hanazaki *et al*[51] reported that AFP > or= $1000ug\cdot L^{-1}$ and the presence of vascular invasion were independent unfavorable prognostic factors affecting overall survival and that AFP > or = $1000ug\cdot L^{-1}$ was an independently significant factor of poor disease-free survival. Thus, the both all were inefficient and need to be considered that the critical value of AFP was more than $400ug\cdot L^{-1}$ and the prognostic weight of preoperative variable AFP level was defined zero or one score in CLIP, which was the same as present or absent portal vein thrombosis.

Tumor morphology, including the microsatellite, tumor size, uni- or multinodular and tumor extension, can be regarded as indices of tumor burden and was defined as prognostic factors previously for patients with HCC[9,18,33-35,41,49]. Recently, the literature regarding the correlation of remnant liver function status and prognosis after operation, increased gradually. 246 patients with curative resection of HCC were observed. Intrahepatic recurrences were classified into early (</= 1 year) and late (> 1 year) recurrences. By multivariate analysis, preoperative tumor rupture and venous invasion were independent risk factors for early recurrence, whereas cirrhosis was the only significant risk factor for late recurrence. By comparing histological features of resected recurrent and primary tumors, 8 of 9 resected early recurrent tumors (89%) were classified as intrahepatic metastases, whereas all 6 resected late recurrent tumors (100%) were multicentric occurrences[19]. For resectable cases of HCC, the most patients have a good liver function in preoperation, whereas the late recurrence or death only associated with Child stage in this study, which suggest that liver function damage is the one of reasons which result in late death(no-tumor factors) beside early operative mortality or easy to recurrence. Ariizumi *et al*[52] showed that multicentric HCC tended to grow in more damaged segments of the liver. Thus, influence of tumor-related factors to patients who survived more than three years with no recurrence decreased gradually, meanwhile the influence of host-related factors, including liver functional status and multicentric in origin increased gradually[18,32]. Consequently, a question occurs: why HCC only found some patients but not all The answer only is that the liver background with or without HCC is different from each other. In other word, some livers have a predisposition to cancer. Donato *et al*[53] have studied risk factors and clinical significance of high liver cell proliferative activity in 208 well-compensated cirrhotic patients with immunostaining for proliferating

cell nuclear antigen (PCNA). The overall PCNA labeling index (LI) ranged from 0.1% to 12.5% (mean, 2.1%), being significantly higher in the 50 patients who developed HCC during 88+/-42 months of follow-up than in the 158 patients who remained cancer-free (3.6%+/-2.4% *vs* 1.6%+/-1.5%; $P<0.0001$). In conclusion, development of HCC in patients with compensated cirrhosis seems to be reliably predicted by liver cell proliferation status. Sangiovanni *et al*[54] assessed whether hepatocyte proliferation is an independent risk factor for HCC when considered together with clinical and demographic characteristics. Total 97 consecutive patients with a histological diagnosis of cirrhosis and preserved liver tissue function were retrospectively evaluated, Hepatocyte proliferation was evaluated by flow-cytometric analysis in liver samples collected at the time of histological diagnosis of cirrhosis. The results showed that S-phase fraction of 1.8% or higher significantly correlated with the development of HCC. To study the liver status of patients with HCC have important role in clarification of histogenesis of HCC.

In summary, CLIP score, because of giving consideration to both tumor and patients, has displayed a unique superiority in predicting the tumor recurrence and prognosis in patients with HCC.

Abstract

AIM: **To study the viscoelastic properties of human hepatocytes and hepatocellular carcinoma (HCC) cells under cytoskeletal perturbation, and to further to study the viscoelastic properties and the adhesive properties of mouse hepatoma cells (HTC) in different cell cycle.**

METHODS: **Micropipette aspiration technique was adopted to measure viscoelastic coefficients and adhesion force to collagen coated surface of the cells. Three kinds of cytoskeleton perturbing agents, colchicines (Col), cytochalasin D (CD) and vinblastine (VBL), were used to treat HCC cells and hepatocytes and the effects of these treatment on cell viscoelastic coefficients were investigated. The experimental results were analyzed with a three-element standard linear solid. Further, the viscoelastic properties of HTC cells and the adhesion force of different cycle HTC cells were also investigated. The synchronous G_1 and S phase cells were achieved through thymine-2-desoryriboside and colchicines sequential blockage method and thymine-2-desoryriboside blockage method respectively.**

RESULTS: **The elastic coefficients, but not viscous coefficient of HCC cells (K_1=103.6±12.6N.m^{-2}, K_2=42.5±10.4N.m^{-2}, μ=4.5±1.9Pa.s), were significantly higher than the corresponding value for hepatocytes (K_1=87.5±12.1N.m^{-2}, K_2=33.3±10.3N.m^{-2}, μ=5.9±3.0Pa.s, P<0.01). Upon treatment with CD, the viscoelastic coefficients of both hepatocytes and HCC cells decreased consistently, with magnitudes for the decrease in elastic coefficients of HCC cells (K_1: 68.7 N.m^{-2} to 81.7N.m^{-2}, 66.3% to 78.9%; K_2: 34.5N.m^{-2} to 37.1N.m^{-2}, 81.2% to 87.3%, P<0.001) larger than those for normal hepatocytes (K_1: 42.6N.m^{-2} to 49.8N.m^{-2}, 48.7% to 56.9%; K_2: 17.2N.m^{-2} to 20.4N.m^{-2}, 51.7% to 61.3%, P<0.001). There was a little decrease in the viscous coefficient of HCC cells (2.0 to 3.4Pa.s, 44.4 to 75.6%, P<0.001) than that for hepatocytes (3.0 to 3.9Pa.s, 50.8 to 66.1% P<0.001). Upon treatment with Col and VBL, the elastic coefficients of hepatocytes generally increased or tended to increase while those of HCC cells decreased. HTC cells with 72.1% of G_1 phase and 98.9% of S phase were achieved and high K_1, K_2 value and low μ value were the general characteristics of HTC cells. G_1 phase cells had higher K_1 value and lower μ value than S phase cells had, and G_1 phase HTC cells had stronger adhesive forces [(275.9±232.8)×10^{-10}N] than S phase cells [(161.2±120.4)×10^{-10}N, P<0.001].**

CONCLUSION: **The difference in both the pattern and the magnitude of the effect of cytoskeletal perturbing agent on the viscoelastic properties between HCC cells and hepatocytes may reflect differences in the state of the cytoskeleton structure and function and in the sensitivity to perturbing agent treatment between these two types of cells. Change in the viscoelastic properties of cancer cells may affect significantly tumor cell invasion and metastasis as well as interactions between tumor cells and their micro-mechanical environments.**

INTRODUCTION

Current advances in oncology have shown that the continuous growth of malignancy, invasion and metastasis are a multi-step pathophysiological process, which consists of successive steps of tumor cell deformation and locomotion[1-3]. For an understanding of the mechanisms involved, advanced methodologies of cellular and molecular biology have been extensively used in the study of the related oncogenes and anti-oncogenes, as exemplified in hepatocellular carcinoma (HCC)[4-8], and in the elucidation of the interaction between tumor cells and vascular endothelial cells[9,10]. These studies have already led to considerable knowledge in the event involved in tumor metastasis.

The mechanical properties are very important for biologic behaviors of tumor cells in following reasons. Firstly, tumor cells are destined to experience shear-induced deformation in blood flow if they metastasize through the blood vasculature. The mechanical properties determine whether tumor cells can pass through the microvasculature to form metastases, and probably whether they can survive in the blood shear environment.Secondly, the mechanical properties are related to active pseudopod formation and motility,in which they probably have a similar structural basis and are the main cellular events of tumor cell invasion, and a relationship between active pseudopod formation and cytoskeletal structures has already been demonstrated[11-13]. To the aim of this study was to try to understand how the viscoelastic properties of HCC cells are altered compared to those of normal hepatocytes, how the viscoelastic properties of these two types of cells respond to treatment with cytoskeleton perturbing agents [cytochalasin D(CD), colchicines (Col) and vinblastine(VBL)] and what changes occur in viscoelastic properties and the adhesive properties of hepatoma cells in different phases.

MATERIALS AND METHODS

Cell sample preparation

HCC cells (SMMC 7721) were obtained from the 2nd Military Medical University (Shanghai, China); HTC cells were kindly given by department of clinical biochemistry of Chongqing Medical University. Normal hepatocytes were prepared from human fetal liver tissue by a combination of 0.5g·L^{-1} collagenases IV (Sigma) digestion and density gradient centrifugation[14-17]. Cells were maintained in an incubator at 37℃ in an atmosphere of 950mL·L^{-1} humidified air and 50mL·L^{-1} carbon dioxide. The final concentration of the cells for micropipette experiment was of the order of 10^9cells·L^{-1}.

Preparation of synchronous G_1 an d S phase HTC cells

The synchronous G_1 phase cells were achieved through thymine-2-desoryriboside and colchicines sequential blockage method[18].

Micropipette system and analysis of the viscoelastic properties of cells

The structure of micropipette system and experimental procedures were described in literatures[19-21]. Micropipettes were pulled from capillary glass tubes in a micropipette puller (P87, Sutler Instrument Co, USA). The weighted average values of the internal radius of the pipette used in the present investigation were 2.47±0.91μm.

Experimental results were analyzed with a three-element standard linear solid model[22], in which an elastic element, K_1, was in parallel with a Maxwell element composed of another elastic element, K_2, in series with a viscous element, μ. Viscoelastic coefficients were expressed as $\bar{x}\pm s$. Student's *t*-test was used for statistical analysis.

Analysis of the adhesive properties of HTC cells in different cycle

The adhesive model used was schematically shown in Figure 1, Fa was adhesive force of cell, R_p was the inner radius of micropipette, △P was negative pressure pulled the adhesive cell away from basement membrane coated by collagen Ⅳ, and θ was the angle of micropipette between basement membrane, F a can be calculated from the following equation: $F_a=R_p^2\times\triangle P\times Cos^{\theta}$

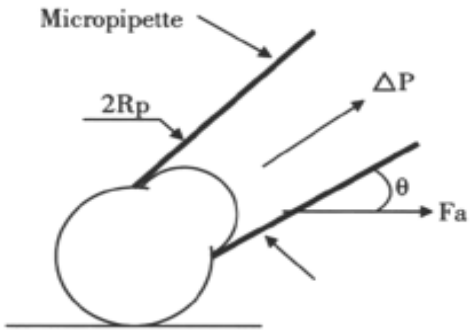

Figure 1 Geometry of adhesive model

RESULTS

Viscoelastic properties of HCC cells and hepatocytes and effects of cytoskeleton inhibitions

The values of the viscoelastic coefficients of hepatocytes and HCC and the effects of treatment with CD, Col and VBL were shown in Tables1-3, respectively. The results were summarized as follows: (1) Compared to those of normal hepatocytes, the values of the elastic coefficients K_1 and K_2 of HCC cells were significantly higher (P<0.01). However, the viscous coefficient, μ, of the HCC cells was not significantly different from that of hepatocytes. (2) Treatment with 1-60mg·L^{-1} of Col resulted in a little but significant increase in K_1 for hepatocytes with independent of [Col], whereas in the case of K_2 there appeared to be no significant change. In the case of the viscous coefficient, there was a significant decrease with independent of [Col]. In contrast to hepatocytes, the HCC cells resulted in a significant decrease in all 3 coefficients with dependence on [Col] (Table 1). (3) Treatment of the hepatocytes with VBL in the concentration range of 0.05-2.00mg·L^{-1} resulted in a marked increase in the elastic coefficients at all concentrations, whereas the viscouscoefficient only increased significantly at 0.25mg·L^{-1} and 0.75mg·L^{-1} of VBL. In the case of the HCC cells, K_1 exhibited a little but significant increase at 0.05mg·L^{-1} of VBL, but then decreased continuously with increasing [VBL], whereas the values of K_2 and ì decreased monotonously with increasing [VBL] (Table 2). (4) Upon treatment with 0.25 to 5.00mg·L^{-1} of CD, the coefficients K_1, K_2 and μ decreased significantly from the control values, but the decrease exhibited no significant dependence on the perturbing agent concentration. In the case of the K_1 and K_2, the magnitude of the above decrease was significantly greater for the HCC cells. For μ, the magnitude of the decrease for HCC cells was less than that of the hepatocytes (Table 3).

Viscoelastic and adhesive properties of HTC in different cycle

The synchronization results detected with flow cytometer showed that it could meet the requirements of the experiments nicely. HTC with 72.1% of G_1 phase and 98.9% of S phase were achieved. The values of the adhesive force of HTC on different concentration of artificial basement membrane (collagen Ⅳ coated) were shown in Table 4. The adhesive force of G_1 phase HTC on basement membrane coated by collagen Ⅳ 5mg.L^{-1} was (275.9±232.8)×10^{-10}0N, and the corresponding value of S phase HTC was (161.2±120.4)×10^{-10}0N. Difference between them was considered significant (P<0.001). The viscoelastic coefficients of HTC cells in different cycle were shown in (Table 5).

DISCUSSION

Viscoelasticity is an important mechanical property of a cell that is related to its motility and deformability[23-25]. For HCC cells, the viscoelasticity has probably significant bearing on tumor cell invasion and metastasis, in which it determines the flowing behavior of tumor cells in the circulation and whether such cells can be arrested to form metastasis. In addition, mechanical stiffness is closely related to cell adhesion behavior[26,27], which is the first step in tumor cell invasion. With the three-element standard linear solid viscoelastic model, we clearly showed that HCC cells have higher values for the elastic coefficients but not the viscous coefficient than hepatocytes. This result indicated that HCC cells were more rigid than normal hepatocytes under the experimental conditions. One possible explanation of this result is that, in HCC cells, interconnections between microfilaments and microtubules might have changed as compared to those in normal hepatocytes, and thus microfilaments are affected upon disorganization of microtubules.

As the primary force-bearing structure of a cell, the cytoskeleton may be very important in determining cell mechanical behavior[28-30]. We used three microfilament- or microtubule- targeting perturbing agents (Col, VBL and CD) to treat hepatocytes and HCC cells and found the effects of agents on viscoelastic properties of HCC cells were different obviously in both pattern and extents from those on hepatocytes. Such differences might reflect differences in the state of the cytoskeleton structure and organization, and in the cell's sensitivity to agents. These results also suggested that cytoskeleton play a role in the maintenance of cell viscoelasticities.

Our results of the viscoelastic properties of HTC in different cycle indicated that high K_1, K_2 and low μ were the general characteristics of HTC, and these were coincided with the result of HCC cells. G_1 phase cells had higher K_1 value and lower μ value than S phase cells had, but there was no obviously difference in K_2 between two phase cells, which reflected the discrepancies of cytoskeletal protein assemble and synthesis in different cell cycle. Those resultson relevance of cytoskeletal structure to viscoelastic coefficient of HCC cells suggested that microfilaments could play a major rule in the maintenance of cell viscoelasticity, especially in G_1 phase cells. In contrary to these, synthesis of microtubules in S phase cells increased, and more microtubules took part in determination the cells viscoelasticity, which could endow G_1 phase cells with higher elasticity and lower viscosity than S phase of cells. These characteristics evidently contributed to G_1 phase cells survival from the blood shear environment and arrest to form metastases.

The adhesive properties of HTC in different cycle

Current study has shown that action of tumor cells on basement membrane is a multi-step pathophysiological process[31]. Our results showed the adhesive force of HTC cells on basement membrane coated by collagen Ⅵ had the obvious correlation with the concentration of collagen. Wang *et al*[32] reported that the content of collagen Ⅳ and laminin in basement membrane increased along with the growth of tumor, but basement membrane became to decrease, even damaged when tumor transferred. So, the different thickness of basement membrane could reflected the different interaction between tumor cells and the membrane. Increased thickness of basement membrane might play the important rule in tumor cell invasion, which was conducive to the chemotactic motion of tumor cell, active orientation movement, and supplied strong adhesive force and adhesive site for tumor cell.The adhesive force of G_1 phase of HTC was obviously greater than that of S phase cells. In general, expression of fibronectin receptor in transferred tumor cell would decrease and laminin receptor would increase. Fibronectin play a more important rule in improving tumor cell spreading and increasing the synthesis and proliferation of DNA in S/G_2 phase. Laminin has many functions on the tumor cell adhesion and movement[33]. So, the difference of adhesive force between G_1 phase cell and S phase cell could reflect the difference of expression of adhesive molecule receptor on the cell surface, especially the difference of periodic distribution of fibronectin receptor and laminin receptor. In addition, a strong affinity existed between laminin and thrombolysin, and both of them binded together to form thrombolysin by activating profibrinolysin and hydrolyzing laminin and fibronectin, and finally activation of procollagen and degradation of basement membrane occured. The phenomenon of high adhesive force value in G_1 phase cell may be also relevant to these changes, which made G_1 phase cells in active condition in adhesion and movement. In the course of tumor invasion and metastasis, G_1 phase cell were more capable of adhering to and getting through basement membranes than S phase cells.

Abstract

AIM: **To investigate the action of apoptosis in occurrence of liver cacinomas *in vivo* and the biological effect of Solanum lyratum Thumb on BEL-7404 cell line inducing apoptosis *in vitro*.**

METHODS: **The apoptosis in the liver carcinoma was detected with terminal deoxynucl neotidyl transferase mediated dUTP nick end labelling (TUNEL); the cancer cells cultured in DMED medium were treated with extract of Solanum lyratum Thumb and observed under microscope, and their DNA was assayed by gel electrophoresis.**

RESULTS: ***In vivo* apoptotic cells in the cancer adjacent tissues inceased; *in vitro* treatment of liver cancers with extract of Solanum lyratum Thumb could induce the cells to manifest a typical apoptotic morphology. Their DNA was fractured and a characteristic ladder pattern could be found using electrophoresis.**

CONCLUSION: ***In vivo* the apoptosis of carcinomas was lower; maybe the cells divided quickly and then the cancers occurred. In the cancer adjacent tissues,the apoptosis pricked up, and *in vitro* Solanum lyratum Thumb could induce the apoptosis of BEL-7404 cells.**

INTRODUCTION

The balance between cell proliferation and apoptosis is essential for the development and maintenance of normal organs. The occurrence of cancers is purportedly due to the smother of normal apoptosis process, which caused the imbalance between cell proliferation and apoptosis[1,2]. To investigate the action of apoptosis in the occurrence of liver carcinomas *in vivo*, the apoptosis in the cancers was detected with terminal deoxynuclneotidyltransferase mediated dUTP nick end labelling (TUNEL). Solanum lyratum Thumb is usually used as an anticancer drug to treat liver cancers, lung cancers, esophagus cancers and so on. Modern scientific research revealed that Solanum lyratum Thumb can promote the formation of cycle adenocine monophosphate (cAMP) and the activity of protein kinase A(PKA) in the gastric cancer cells[3]. Yet, there has been no report as to whether Solanum lyratum Thumb could induce the apoptosis of cancer cells. This paper studied the apoptosis-inducing action of the extracts of Solanum lyratum Thumb on human hepatoma cell line BEL-7404.

MATERIALS AND METHODS

Selection of samples

20 liver tissue samples were collected from the patients of liver cancer hospitalized in Department of Pathology of Affiliated Hospital to Binzhou Medical College as the liver cancer group(12 from males,8 from females). Their tissues adjacent to the cancer were used as the cancer adjacent tissue group. The preparation of tissue block and slices: the samples obtained surgically were fixed with 10% formalin, dehydrated by conventionality, embedded by paraffin, cut into slices 5ìm thick. One slice for each sample was stained by HE; it was used for pathological identification.

In vivo detection of apoptosis

TUNEL staining was used to detect DNA degradation*in situ*in the relatively late stage of apoptosis. Apoptotic cells were labelled by the TUNEL reaction using an*in situ*Cell Apoptosis Detection Kit. *In situ* Cell Apoptosis Detection Kits were purchased from WUHAN BOSTER Biological Technology Co, Ltd. The detailed manipulation were conducted according to introductions for users. Negative controls consists of the process except that the labelling buffer was substituted for TdT and DIG-dUTP. positive controls were hypothyroid cancer samples. Result identification: After DAB staining the cells whose nuclei were orange counted as positive. Photomicrograghs were taken with an Olympus microphoto-microscope (see Figure 1).

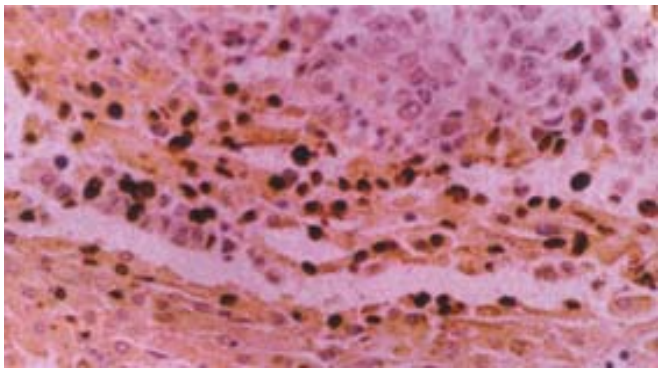

Figure 1 shows apoptotic cells in liver carcinomas and in cancer adjatent tissues(positive).TUNEL ×200

Data processing

The positive rates for each group were calculated.Four visual fields were randomly selected from each tissue section and analyzed under 10×20 fold statistics microscope with the imaging analysis system of CMIAS. The integrated optical density (IOD) was measured, and data were expressed as means±s.e.m, and analyzed with t-test by software Microsoft Excel 97.*P* volume less than 0.05 was regarded as representing significant difference.

Drug preparation

Solanum lyratum Thumb is the whole plant of Solanum lyratum Thumb deadly nightfade. After extraction using ethanol, and there after using acetidine, the fat-soluble extracts of Solanum lyratum Thumb.were distilled in DMSO and then diluted in RPMI 1640 medium to different concentrations for later use.

Cell culture and drug application

Human hepatoplastoma cell line BEL-7404 was purchased from Institute of Materia Medica, Chinese Academy of Medical Science, Beijing. BEL-7404 cells were seeded at 37℃ in a humidified incubator under 5% CO2/95% air in RPMI1640 supplemented with 200IU/ml penicillin, 200μg/ml streptomycin, and cultured for 24h. This medium was replaced by another medium containing extracts of Solanum lyratum Thumb 10μg·ml^{-1},5μg·ml^{-1},2.5μg·ml^{-1} respectively. The cells went on to be cultured for 24, 48,72h.

In vitro detection of apoptosis

Cellular morphological observation: First the cell shapes were observed and apoptosis was detected and photomicrograghs were taken with an Olympus microphoto-microscope.DNA isolation and electrophoresis: After the cells were cultured in deferent concentrations of the drug for deferent time lengths, DNA isolation was done as follows: After they were washed twice with RPMI1640 medium and resuspended ,the cells (5×10^5 or 2×10^6 cells)were collected by centrifugation (200×g,10min), and then 50μl of cell cracking liquid was added to resuspend the cells. They were incubated at 37℃ until the lysates containing liquid became clear, and then centrifuged at 12000r·min^{-1} 5min at 4℃. DNA fragments were extracted from the supernatant with phenol-chloroform(1:1) phenol-chloroform-isoamyl alcohol(25:14:1), precipitated by addition of 2 volumes of absolute ethanol and 0.1 volume of 3mol·L^{-1} sodium acetate at -20℃ for 24h, centrifugated at 12000r·min^{-1} -10℃, for 10min. The precipitate was dissolved in 20μl TE with 1μl RNase and kept at 37℃ for 1h. The pattern of DNA fragmentation was visualized by electrophoresis (at room temperature,75mA,1-2h) in 1% agarose gel containing ethidium bromide and photographed under UV light.

RESULTS

In vivo detection of apoptosis

It was found with TUNEL technique that the partial tissues in the liver cancer group were positive; its positive rate was lower than in the tissues adjacent to cancers. The IOD in the cancer group was lower than in the cancer adjacent tissue group. There was significant deference between the two groups (see Table 1).

Table 1 Cell apoptosis in liver carcinoma

Group	Number of cases	Positive rate	IOD number ($\bar{x}\pm s$)
Cancer	20	2/20	2.9±10.85
Cancer adjacent tissue	20	20/20	266.8±536.7

t=2.2011, P<0.05

In vitro morphological observation of cells and production of apoptotic body

The morphological changes took place in BEL-7404 cells exposed to extracts of Solanum lyratum Thumb (2.5μg·ml^{-1},5μg·ml^{-1},10μg·ml^{-1}) for 24h. As is shown in Figure 2, a lot of cells became round; their cytoplasm and chromatin became condensed; their membranes became crooked, and vesicles shaped. The nuclei cracked and typical apoptotic bodies formed. BEL-7404 cells exposed to extracts of Solanum lyratum Thumb (2.5μg·ml^{-1},5μg·ml^{-1},10μg·ml^{-1}) for 48h showed an increase in the number of apoptotic cells, and a decrease in the number of normal cells. The cells came off and suspended in the medium. In BEL-7404 cells exposed to extracts of Solanum lyratum Thumb (2.5μg·ml^{-1},5μg·ml^{-1},10μg·ml^{-1}) for 72h, most cells suspended, the apoptotic bodies of a few cells enlarged. Their membrane bursted, exhibiting the death state of these cells.

DNA ladder production

In BEL-7404 cells exposed to extracts of Solanum lyratum Thumb (2.5μg·Ml-、5μ·ml^{-1},10μg·ml^{-1}) for 24h,48h and 72h, the DNA changed obviously. Just as shown in Figure 3, they showed ladder bands after electrophoresis. It proved that cellular apoptosis happened, which was significantly different from the controls.

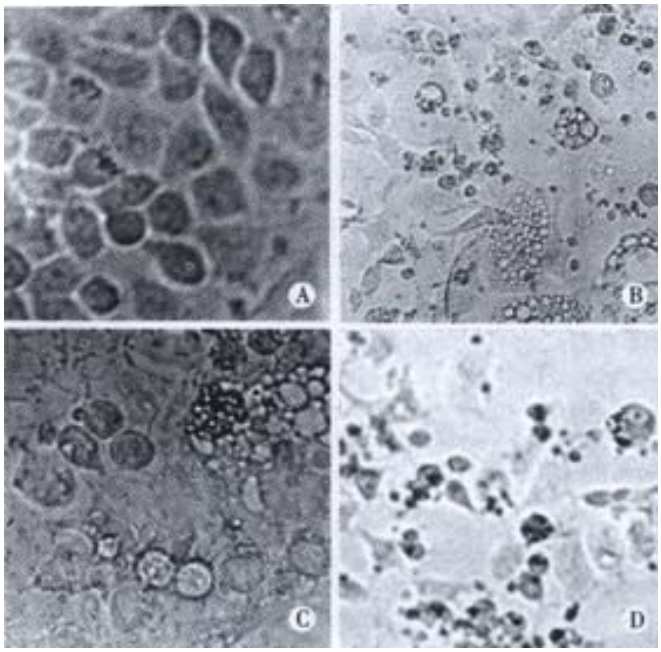

Figure 2 Morphological change in BEL-7404 cells exposed to the extract of Solanum lyratum Thumb. 5μg·ml^{-1} for untreated (2A),24h(2B),48h(2C),72h (2D). ×100

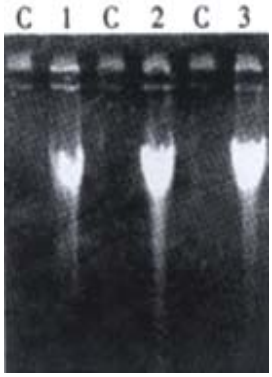

Figure 3 DNA ladder in agarose gel after BEL-7404 cells treated with extract of Solanum lyratum Thumb 5μg·ml^{-1} for 24,48,72h. Column C: control; 1, 2, 3, column: the cells treated with extract of Solanum lyratum Thumb for 24h,48h,72h respectively.

DISCUSSION

The term 'apoptosis' was introduced into modern science by Kerr *et al*. in 1972 to describe the special morphology of physiological cell death. The word itself is an ancient Greek word meaning the 'falling off' of leaves from a tree or petals from a flower and was originally used in the medical and philosophical writings of classical Greek and Roman times. Apoptosis or 'programmed cell death' represents the regulated activation of a pre-existing death program encoded in the genome. It is a highly orchestrated form of cell death and plays a central role in the control of tissue cell numbers in organs' development, homeostasis and normal functioning, such as cell proliferation and differentiation. Dysregulation of apoptosis may be involved in the pathogenesis of human diseases[4,5].

There are two central pathways that lead to apoptosis: (1) positive induction by ligand binding to a plasma membrane receptor and (2) negative induction by loss of a suppressor activity. Each leads to activation of cysteine proteases with homology to IL-1b converting enzyme (ICE) (i.e., caspases). Positive-induction

involves ligands related to TNF. The ligands are typically trimeric and bind to cell surface receptors causing aggregation (trimerization) of cell surface receptors. The intracellular portion of these receptors contains an 80 amino acid death domain (DD) that through homophilic interactions recruits adaptor proteins to form a signaling complex on the cytosolic surface of the receptor. The bringing together of the three receptors, thereby orienting the intracellular DDs, appears to be the critical feature for signaling by these receptors. The adaptor complex then recruits caspase-8; caspase-8 is activated, and the cascade of caspase-mediated disassembly proceeds[6,7]. Cytosolic Aspartate-Specific Proteases, called CASPases, are responsible for the deliberate disassembly of a cell into apoptotic bodies. Caspases are present as inactive pro-enzymes, most of which are activated by proteolytic cleavage. Caspase-8, caspase-9, and caspase-3 are situated at pivotal junctions in apoptotic pathways. Caspase-8 initiates disassembly in response to extracellular apoptosis-inducing ligands and is activated in a complex associated with the receptors' cytoplasmic death domains. Caspase-9 activates disassembly in response to agents that trigger release of cytochrome c from the mitochondria and is activated when complexed with dATP, APAF-1, and extramitochondrial cytochrome c. Caspase-3 appears to amplify caspase-8 and caspase-9 signals into full-fledged commitment to disassembly. Both caspase-8 and caspase-9 can activate caspase-3 by proteolytic cleavage and caspase-3 may then cleave vital cellular proteins or activate additional caspases by proteolytic cleavage[8-10].

Negative induction of apoptosis by loss of a suppressor activity involves the mitochondria. Release of cytochrome c from the mitochondria into the cytosol serves as a trigger to activate caspases[11]. Permeability of the outer mitochondrial membrane is essential to initiation of apoptosis through this pathway. Proteins belonging to the Bcl-2 family appear to regulate the membrane permeability to ions and possibly to cytochrome c as well. Although these proteins can themselves form channels in the membrane, the actual molecular mechanisms underlying the regulation of mitochondrial permeability and the release of solutes remain to be elucidated. The Bcl-2 family is composed of a large group of anti-apoptosis members that when overexpressed prevent apoptosis and a large group of pro-apoptosis members that when overexpressed induce apoptosis. The balance between the anti-apoptotic and pro-apoptotic Bcl-2 family members may be critical to determining whether a cell undergoes apoptosis. Thus, the suppressor activity of the anti-apoptotic Bcl-2 family appears to be negated by the pro-apoptotic members[12]. Many members of the pro-apoptotic Bcl-2 family are present in cells at levels sufficient to induce apoptosis. However, these members do not induce apoptosis because their activity is maintained in a latent form. Bax is present in the cytosol of living cells. After an appropriate signal, Bax undergoes a conformational change and moves to the mitochondrial membrane where it causes release of mitochondrial cytochrome c into the cytosol. BID is also present in the cytosol of living cells. After cleavage by caspase-8, it moves to the mitochondria where it causes release of cytochrome C possibly by altering the conformation of Bax. Similarly, BAK appears to undergo a conformational change that converts it from an inactive to an active state. Thus, understanding the molecular mechanisms responsible for regulating the Bcl-2 family activities creates the potential for pharmaceutical intervention to control apoptosis[13-16].

Liver cancinoma is one of the most common cancers. Further progress has been made in its diagnoses, treatments and the mechanism of its occurrence. The study of its apoptosis is very important[17,18]. It has been proved that occurrence of cancers is due to the loss of control of normal apoptosis and the disturbance of balance between cell apoptosis and cell proliferation[1,2]. The apoptosis related genes (bcl-2 family) is divided into two categories: apoptotic repressor and apoptotic promoter. Bcl-2 is an important apoptotic repressor, while Bax is one of the most important apoptotic promoters. The protein it encodes can combine with Bcl-2 to form compounds which resist the action of repressing apoptosis. But it has a positive regulatory action[19-21].Recant studies indicate that the regulation of apoptosis by bcl-2 and bax is not only based on the level of either of the two regulatory proteins but also based on the ratio of them. If the ratio is high, the cells go to apoptosis[22-24]. In our experiment the *in vivo* apoptosis in liver cancers was detected by TUNEL technique. The result showed that IOD in the liver cancer group was lower than in the cancer adjacent tissue group, which was a significant difference (t=2.2011, P<0.05). Our results were consistent with that of Peng *et al* [25].We found that apoptotic cells in the cancer adjacent tissue were more and there were less in the cancer. This showed that apoptosis in the cancer adjacent tissue is more active. The apoptosis may be caused by a negative induction of apoptosis. First the level of BAX can increase. Its conformations can change, and then move to the outer membrane of mitochondria thus making cytochrome c to release from mitochondria. There after CASPASE is activated, and then the cascade of CASPASE -mediated disassembly proceeds. Thus apoptosis emerges. The pathway may be blocked in liver cancers, and apoptosis slow down, so proliferation of the cells cannot balanced, and the cancers occur.

Some drugs(e.g. adriamycin, doxorubicin, propolis)can induce apoptosis, repress the division of liver cancer cells and thus treat cancers[26-28]. Tamoxifen can induce apoptosis of HepG2 hepatoblasma cells, because Tamoxifen activates Ca^{2+} influx pathways. After the human hepatocellular SK-HEP-1 carcinoma cells were treated with methylglyoxal bis (cyclopentylamidinohydrazone) (MGBCP), their cell morphology changed, and the cell growth rate decreased. It may induce cell apoptosis [29,30]. Human hepatoma cell line (HepG2) were treated with Sodium selenite. Selenite-induced DNA alterations in apoptosis were studied, and characteristic apoptotic morphological alterations were observed. The results clearly show that Se-induced cell death occurs predominantly in the form of apoptosis[31]. Apoptosis in human hepatoma BEL-7402 cells can be induced by Octreotide, which may be related to the mechanism of antineoplastic action of Octreotide in hepatoma[32]. It has been proved that baicalein, chlorinated fatty acids, troglitazone (an antidiabetic agent) and cisplatin could respectively induce apoptosis in hepatoma cells HepG2[33-36]. Their results were similar to ours. The apoptostic characteristics, DNA fragment, cellular morphological changes emerged in the hepatoma cells treated with deferent agents.

Solanum Lyratum is one of Chinese anticancer herbals .The damage effect of Solanum Lyratum on different phases of PC chromosomes in CHO cells was studied by cell fusion technique. The result showed that obvious damage were observed in G2-PCC in cells treated with the drug at 0.5-1.0g·ml^{-1} for 45min at 37℃. The obvious damage of PC chromosomes indicated that Solanum Lyratum may markedly block the G2 phase of cell cycle. But treatment with different doses of the drug showed no effect on the progression of cells in M phase. A study found that Chinese Herbal Mixture containing Solanum Lyratum has a stronger killing action on Human Tumor Cells BGC-823 and MCF-7 in Vitro. Flowcytometric analysis showed that the drug can stop the cell cycle of BGC-823 at G1 phase and cause a significant decrease in the number of S phase cells. It was found that the drug can inhibit DNA synthesis, expressions of antioncogenes Rb, *p*21 and enhance the expresion of oncogene c-myc in BGC-823 cells[37]. Apoptosis of cancers is induced with the Chinese herbal medicine[38-40]. Solanum Lyratum can suppress the proliferation of hepatoma cells via G0/G1 arrest and inhibition of DNA synthesis followed by apoptosis. Arsenic trioxide has significant selective apoptosis-inducing effect on human hepatocarcinoma cells, which is regulated by several genes. Bcl-2 gene expression down-regulated,Bax and Fas gene expressions up-regulated[41]. A Chinese herb-magnolol can also inhibit the proliferation of tumor cells and activate apoptosis *in vitro* and *in vivo*[42].

In our experiment, after BEL-7404 human hepatoblasma cell line was cultured in the medium containing Solanum Lyratum extract

(concentration: 2.5μg·ml^{-1},5μg·ml^{-1},10μg·ml^{-1}) for 24h, the morphologic change took place in these cells, and the apoptotic bodies and DNA ladders appeared. After 48h,72h they changed acutely. This indicated that Solanum Lyratum may exert an anticancer action through promoting apoptosis and resulting in the death of the liver cancer cells. it may stimulate the cells to bring out a positive gene directed apoptosis. It probably induce overexpression of gene bax and inhibit expression of gene bcl-2, making the ratio of proteins of bax/bcl-2 increase and then promoting the cell apoptosis.This may be a positive induction of apoptosis. First Solanum Lyratum as a ligand binds to cell surface receptor. It causes aggregation of cell surface receptors. The signaling complex on the cytosolic surface of the receptor forms. CASPASE is activated, and then the cascade of CASPASE -mediated disassembly proceeds.

Several genes, factors and TNF receptor family are involved in the apoptosis of liver cancer cells. In the human hepatocellular carcinoma cell line, Hep3B, an increased level of bax expression mediates apoptosis[43]. It was found that bcl-2-positive cells did not show apoptosis, and *p*53 protein (stimulative) may regulate apoptosis in some cases of human liver tumors, the mutant *p*53 protein may inhibit the cancer cells going to the apoptosis, whereas c-myc, Fas and Lewisy are not relevant to apoptosis[25,44,45].Bcl-2 was focally expressed in hepatic tumor epithelium[21]. Using immuno-histochemical methods, the expression of Bcl-2, an anti-apoptotic protein was studied in hepatocellular tumors of B6C3F1 mice. Normal mouse hepatocytes did not express detectable amounts of Bcl-2, whereas most diethylnitrosamine-induced tumors were positive for this protein. This explained that expression of bcl-2 might inhibit the normal proliferation of cells, and result in the occurrence of tumors[46]. In the BEL-7404 cells where apoptosis was mediated by AFP, Fas apoptosis signals and Bcl-2 survival signals from apoptosis were expressed[47]. the proapoptotic protein Bax is translocated from the cytosol to mitochondria, where a potent proapoptotic 18-kDa fragment (Bax/p18) at its N-terminus of Bax was cleaved. It promotes release of cytochrome c, a caspase-activating protein, activation of caspase-3, cleavage of poly(ADP-ribose) polymerase, and fragmentation of DNA and apoptosis. On the contrary Bcl-2 overexpression inhibited etoposide-induced calpain activation, Bax cleavage, cytochrome c release, and apoptosis[48].In human hepatoma cells ,Bcl-2 may protect cells from TGF-beta-F-induced apoptosis by interfering TGF-beta generated signals leading to the production of reactive oxygen species[49]. Ethanol could induce apoptosis in liver cells ,which was initiated by the intracellular $Ca^{(2+)}$ elevation in the cytoplasm. N-p-tosyl-l-lysine chloromethyl ketone (TLCK)-sensitive serine proteases was activated[50].

Combination of drugs can increase the pharmacotherapeutic effect on liver cancers. Co-administration of the chemosensitizer verapamil increased the antitumor efficacy of paclitaxel by up to five-fold. cyclin A and cdc2 kinase accumulated in paclitaxel-treated cells. Exposure to paclitaxel decreased [^{3}H]thymidine incorporation into DNA in cells at 24h but this significantly increased at 72h, that was most likely due to DNA repair mechanisms related to cell cycle restriction[51].Glutathione-doxorubicin (GSH-DXR) effectively induced apoptosis in rat hepatoma cells (AH66) at a lower concentration than DXR.DXR and GSH-DXR induce apoptotic DNA fragmentation via caspase-3 activation, but not via caspase-1 activation, and GSH-DXR enhances the activation of caspase-3 approximately 100-fold more effectively than DXR used alone. An upstream apoptotic signal that can activate caspase-3 is activated within 6 h by treating AH66 cells with the drug[52]. Internucleosomal DNA fragmentation, a biological hallmark of apoptosis, was detected in hepatoma cells after continuous incubation with a combination of sodium butyrate and interferon-alpha (IFN-alpha) for 72h. Sodium butyrate potently enhances the anti-tumour effect of IFN-alpha *in vitro* and a rational combination of these two drugs may be useful for the treatment of liver cancer[53]. After 96h in HepG2, Hep1B, Hepa1-6 and MH1C1 hepatoma cells,combination therapy of an acyclic retinoid and tamoxifen (TAM) on proliferation and apoptosis of hepatoma cell enhanced apoptosis from a maximum of 60% after monotherapy to more than 90%. Apoptosis increased p27, bax, caspase 3 expression was accompanied by upregulation of caspase 3 and 8 activity, while the levels of p21cip/waf and bcl-2 were unchanged or decreased[54]. The combination of human peripheral blood dendritic cells (DCs) and lymphokine and phytohaemagglutininum (PHA) activated killer (LPAK) cells could induce apoptosis of BEL-7402 cells effectively, with some LPAK cells manifesting the characteristics of autophagic apoptosis[55].

Clinical resistance to chemotherapeutic drugs is a major problem in the treatment of cancers. Increased bcl-2 expression in epithelium adjacent to tumors represents a genetically variation in the morphologically normal epithelium because it occurs without the corresponding high proliferative state seen in the normal crypt-regenerative compartment. Heterogeneity may provide a mechanistic explanation for chemotherapeutic resistance in tumors with cells having high bcl-2[22]. Treatment with taxol can induce apoptosis of HepG2 thus killing liver cancer cells. DNA ladder of 200bp emerged. In the meantime bcl-xl, or bad and bax were expressed in HepG2 cells;and the expression levels of bcl-xl and bak remained unchanged, whereas the level of bad was down-regulated. It was thought that the change of bcl-2 family proteins caused by anticancer drugs in liver cancer cells may be involved in chemoresistance[56]. A new somatostatin analogue, TT-232 has a pronounced antiproliferative effect on differentiated and dedifferentiated, drug-sensitive and multidrug-resistant hepatocellular carcinoma cell lines. TT-232 induces apoptosis at comparable levels in all these hepatoma variants, which demonstrats that the multidrug resistance of hepatomas does not correlate with a reduced susceptibility to apoptosis induction. The mechanism involved in apoptosis is functional in both drug-sensitive and resistant hepatoma variants and can be activated by the somatostatin analogue TT-232[57].

The gene therapeutics to liver cancer is a new technique. Human genes *p*53, B7-1,GM-CSF,IL-2 were transduced into liver cancer cells by adenovirus. The ad-multigenes can induce apoptosis and elevate sensitivity of liver cancer cells to chemotherapy drug-cisplatin[58]. After gene therapy with HSV thymidine kinase, inhibition of enhanced glucose transport in ganciclovir -treated Morris hepatoma cells increased apoptosis[59].For gene therapy of hepatocellular carcinoma (HCC), the Escherichia *coli* purine nucleoside phosphorylase (PNP)/ fludarabine suicide gene system may be more useful than the herpes simplex virus thymidine kinase/ganciclovir (HSV-tk/GCV) system. Human HCC cells of the cell lines, HepG2 and Hep3B were transduced with PNP or HSV-tk using adenoviral vectors, followed by prodrug incubation. Both systems predominantly induced apoptosis in HepG2 and Hep3B cells. The results showed that cell line-specific differences in response to treatment with PNP/fludarabine and HSV-tk/GCV, respectively. PNP/fludarabine may be superior to HSV-tk/GCV for the treatment of human HCC because of its independence from p53 and the Fas/FasL system[60].

Abstract

AIM: **To construct a stable transfectant of human liver carcinoma cell line SMMC7721 that could secret human endostatin and to explore the effect of human endostatin expressed by the transfectant on endothelial cell proliferation.**

METHODS: **Recombinant retroviral plasmid pLncx-Endo containing the cDNA for human endostain gene together with rat albumin signal peptide was engineered and transferred into SMMC7721 cell by lipofectamine. After selection with G418, endostatin-transfected SMMC7721 cells were chosen and expanded. Immunohistochemical staining and Western blot were used to detect the expression of human endostatin in transfected SMMC7721 cells and its medium. The conditioned medium of endostatin-transfected and control SMMC7721 cells were collected to cultivate with human umbilical vein endothelial cells for 72 hours. The inhibitory effect of endostatin, expressed by transfected SMMC7721 cells, on endothelial proliferation *in vitro* was observed by using MTT assay.**

RESULTS: **A 550 bp specific fragment of endostatin gene was detected from the PCR product of endostatin-transfected SMMC7721 cells. Immunohistochemistry and Western blot analysis confirmed the expression and secretion of foreigh human endostatin protein by endostatin-transfected SMMC7721 cells. *in vitro* endothelial proliferation assay showed that 72 hours after cultivation with human umbilical vein endothelial cells, the optical density (OD) in group using the medium from endostatin-transfected SMMC7721 cells was 0.51±0.06, lower than that from RPMI 1640 group (0.98±0.09) or that from control plasmid pLncx-transfected SMMC7721 cells (0.88±0.11). The inhibitory rate for medium from endostatin-transfected SMMC7721 cells was 48%, significantly higher than that from empty plasmid pLncx-transfected SMMC7721 cells (10.2%, $P<0.01$).**

CONCLUSION: **Human endostatin can be stably expressed by SMMC7721 cell transferred with human endostain gene and its product can significantly inhibit the proliferation of human umbilical vein endothelial cell *in vitro*.**

INTRODUCTION

Recent studies have shown that angiogenesis is essential for tumor growth and metastases[1-9]. Hanahen *et al*[10,11]noted that angiogenesis is regulated by a balance between factors of proangiogenesis and antiangiogenesis. The pathological formation of new blood vessel could be generated if the balance was undermined[12]. This provides the rationale for antiangiogenic therapy for cancer. Endostatin, a specific inhibitor of endothelial cell proliferation, first isolated as a M_r22000 protein from the conditioned medium of a murine hemangioendothelioma cell line (EOMA), is a C-terminal fragment of collagen 18a consisting of 184 amino acids. Its potent antiangiogenic effect can specifically inhibit the proliferation and migration of endothelial cell and subsequently promote the development of apoptosis and atrophy of tumor without direct influence on tumor cell or nonneoplastic cell growth[13-21]. To explore the inhibitory effect of human endostain expressed by SMMC7721 on endothelial cell proliferation, retroviral pLncx carrying human endostatin gene was used to transfect human liver carcinoma cell line SMMC7721, and the supernatant of transfected SMMC7721 was collected to incubate with human umbilical vein endothelial cell (HUVEC) *in vitro*.

MATERIALS AND METHODS

Plasmids

The plasmid pUC19-Endo containing the cDNA for human endostain was generously provided by Professor Genxin Xu (Nanjing Military Medical College, Nanjing, China). In this plasmid, human endostain cDNA was put downstream from rat serum albumin signal peptide and influenza virus HA tag. Plasmid pUC19-Endo and retroviral pLncx were digested with HindIII and Cla Ⅰ respectively, and resulting products were ligated. The recombinant plasmid was designated as pLncx-Endo. Correct in-frame insertion of human endostatin cDNA was confirmed by electrophresis showing the pattern of pLncx-Endo digested with restriction enzyme.

Cell lines

Virus packaging cell PA317 and NIH3T3 cell lines were provided by Dr. Qian (Second Military Medical University, Shanghai, China). PA317 and NIH3T3 cells were maintained in DMEM supplemented with 100mL·L^{-1}fetal bovine serum, 100units/ml penicillin and 100ug/ml streptomycin. HUVEC was purchased from Shanghai Cellular Research Institute. SMMC7721 and HUVEC were maintained in 1640 medium.

Tranfection of PA317 cells and determination of viral titre

Plasmids of pLncx-Endo and pLncx were transferred into PA317 cells respectively by lipofectamine (Gibco) following the manufacturer's instructions. G418 selection at 500mg·L^{-1} was added at the same time. Two weeks after transfection, G418-resistant colonies emerged and were expanded. The supernatant of G418-resistant PA317 colony was collected and diluted to infect NIH3T3 cells with a final

concentration of polybrene at 2mg·L^{-1}. After transfection, NIH3T3 cells were also placed under G418 selection. Two weeks later, G418-resistent NIH3T3 colonies were counted for determination of viral titre.

Generation of stable transfectant

Total of 5×10^5 SMMC7721 cells were plated on 6-well plate and incubated for 24h. The cells were rinsed with serum-free 1640 medium twice, and 100μL supernatant of endostatin-transfected PA317 colony was added and incubated for 3h. Another 3mL 1640 medium was added with the final concentration of polybrene at 2mg·L^{-1} and G418 at 500mg·L^{-1}. Four weeks after transfection, G418-resistent cells were expanded for preservation and detected for endostatin-HA fusion protein by immunohistochemistry and Western blot analysis. The G418-resistent colony was designated as SMMC-Endo. Control transfectant (SMMC-pLncx) was generated in a similar way except that the parent plasmid pLncx-Endo was replaced by pLncx.

PCR amplification of endostatin gene

SMMC-Endo and SMMC-pLncx cells were harvested and DNA was extracted. The primers used were: 5'CCG GAA TTC ATG CAC AGC CAC CGC GAC TTC CAG CCG and 5'GCC GGA TCC CTA CTT GGA GGC AGT CAT GAA GCT based on human endostatin sequence. PCR was performed in 50μL reactive volume containing 2μL cDNA, 2uL 10×PCR buffer, 2μL 4×dNTP (2mmol·L^{-1}), 50pmol·L^{-1} primer, and 1μLTag DNA polymerase. The samples were subjected to 30 thermal cycles, consisting of 5min at 94℃ for predenaturation, 1min at 94℃ for denaturing, 1min at 60℃ for annealing, 1min at 72℃ for extension, and 10min at 72℃ for final extension after the last cycle. PCR products were run on 10g·L^{-1} agarose gels (containing 0.5mg·L^{-1} ethidium bromide) and visualized under UV light.

Immunohistochemical staining

Immunohistochemical staining was accomplished utilizing an avidin-biotin technique. Anti-HA monoclonal antibody was purchased from Jing Mei Biotechnology Co. Ltd. SMMC-Endo and SMMC-pLncx cells were grown on six-well glass slides and fixed in acetone. After washing in PBS, the cells were incubated with a 10m·L^{-1} H_2O_2 solution at room temperature for ten minutes to quench endogenous peroxidases. Nonspecific binding was blocked with 50mL·L^{-1} normal horse serum at room temperature for five minutes. The cells then were incubated with anti-HA at a 1:300 dilution at 4℃ overnight. Following washing in PBS, the secondary antibody, biotinylated anti-rat Ig G, was added and the cells were incubated at room temperature for an hour. After washes in PBS, Vectastain reagent (a solution containing strepavidin-horseradish peroxidase) was added and then incubated at room temperature for ten minutes. 3,3-diaminobenzidine was used as the chromagen. After ten minutes, the brown color signifying the presence of antigen bound to antibodies was detected by light microscopy and photographed at ×400.

Western blot analysis

SMMC-Endo and SMMC-pLncx cells were plated in six-well plates at 2.5×10^5 cells/well respectively and incubated for 24h. The medium was replaced with 1ml serum-free RPMI 1640 and collected after 48h. One mL of conditioned medium was concentrated in a microconcentrator (Amicon, Berverly, MA) to 20μL and subjected to a 120g·L^{-1} reducing SDS/PAGE gel. Protein were transferred to a nitrocellulose membrane and incubated overnight in 50mL·L^{-1} nonfat milk in PBS at 4℃. After briefly washing in 10mL·L^{-1} nonfat milk, the membrane was incubated with anti-HA mouse monoantibody diluted 1:500. After three 10min washes in 10mL·L^{-1} nonfat milk, the membrane was incubated in horseradish peroxidate-conjudated antimouse immunoglobulin diluted 1:1000. After three 10min washes in TBS, the proteins were detected using the Amersham ECL kit.

Endothelial cell proliferation assay

SMMC7721, SMMC-Endo and SMMC-pLncx cells were plated onto six-well culture plates at a density of 2.5×10^5 cells/well and incubated for 24h. The cells were washed with PBS, and 1.5mL of serum-free 1640 were added and incubated for another 48h. The total of 9mL serum-free RPMI 1640 were collected and concentrated to 1.8mL using Centriplus 10 concentrator (Amicon), and stored at -80℃ for usage. HUVEC cells were plated at a density of 4000 cells/well onto gelatinized 40-well culture plates and incubated (37℃, 50mL·L^{-1}CO_2) for 24h in 100μL RPMI 1640 medium. The medium was replaced with 20μL of above concentrated conditioned medium and incubated for 30min. 80μL of 1640 supplemented with 10mL·L^{-1} fetal bovine serum and 1μg·L^{-1} bFGF (Sigma) was then added for 72h. The numbers of cells were quantified using a colorimetric MTT assay. Tests were conducted in quadruplicate.

RESULTS

Identification of a recombinant retroviral pLncx-Endo and determination of the recombinant virus titre

The plasmid pLncx and the recombinant retroviral pLncx-Endo were digested by Hind III and Cla Ⅰ respectively. Only in recombinant retroviral pLncx-Endo contained a 640-bp endostatin gene fragment separated by electrophoresis in 10g·L^{-1} agarose gel (Figure 1). It proved that the foreign endostatin gene together with signal peptide and HA-tag was correctly inserted in retroviral pLncx. After transfection of NIH3T3 cells with supernatant of endostatin-transfected PA317, NIH3T3 cells were maintained in DMEM supplemented with G418 500mg·L^{-1}. Two weeks later, total 34 colonies were detected under microscopy and the titre of the recombinant virus (pLncx-Endo) was 1.36×10^{8}cfu·L^{-1}.

Generation of stable transfectants

The PCR products amplified from DNA of SMMC-Endo and SMMC-pLncx cells were analyzed under ultraviolet light after 10g·L^{-1} agarose gel electrophoresis. A 550-bp fragment was seen in the PCR product from DNA of SMMC-Endo cells, but not from the control (Figure 2). It indicated that endostatin was successfully transferred into SMMC7721 cells by way of retroviral pLncx-Endo. The expression of endostatin in the transfected SMMC-Endo cells was also detected by immunohistochemical staining. A lot of brown granules were seen in endostatin-transfected SMMC-Endo cell cytoplasms while control SMMC-pLncx cells showing negative. Thus, it proved that endostatin

gene can be expressed stably in SMMC7721 cells (Figure3). Transgene expression was also tested by Western blot for the expressed protein. On a reducing 120g·L^{-1} SDS/PAGE gel, a distinct band at around M_r22000,corresponding to the size of endostatin, was visualized in the supernatant of SMMC-Endo cells but not in the supernatant of SMMC-pLncx cells. Monoclonal mouse anti-HA antibody reacted positively in a Western blot with the M_r22000 protein only. It was confirmed that endostatin could be efficiently secreted into the supernatant of cells transduced by retroviral pLncx-Endo (Figure 4).

Human endostatin inhibits endothelial cell proliferation

Three days after incubation with conditioned medium, cell number, as measured by absorance (OD), was quantified by using a colorimetric MTT assay. The results showed that the optical density in groups using concentrated conditioned medium from SMMC7721 cells, RPMI1640 and SMMC-pLncx cells were 1.01±0.09,0.98±0.09 and 0.88±0.1 respectively. It revealed that conditioned medium both from SMMC7721 cells and empty plasmid pLncx-transfected SMMC7721 cells did not have inhibitory effect on the growth of HUVEC, compared with 1640 medium (P>0.01). While the optical density in group using conditioned medium from endostatin-transfected SMMC-Endo cells was 0.51±0.06, significantly lower than that from SMMC-pLncx group (0.88±0.1). It meant that inhibitory rate on endothelial proliferation for conditioned medium from endostatin-transfected SMMC7721 group was 48%, significantly higher than that from control pLncx-transfected SMMC7721 group (10.2%, P<0.01), (Figure5).

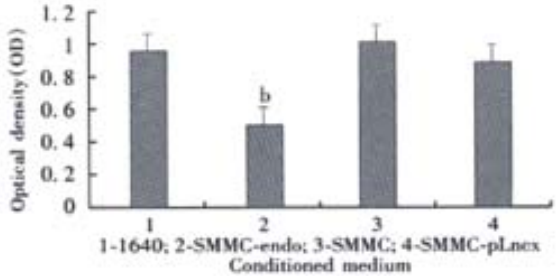

Figure 5 Inhibition of endothelial cell proliferation by conditioned medium from transfected and untransfected cells. Conditioned medium from endostatin-transfected SMMC-Endo cells (2), conditioned medium from SMMC7721 cells (3), and conditioned medium from SMMC-pLncx cells (4) were concentrated and applied to cultivate with HUVEC cells grown in 40-well plate. Three days later, cell number, as measured by absorbance (OD), was then quantified by using a colorimetric MTT assay. Bars, SD. ^bP<0.01, compared with conditioned medium from control SMMC-pLncx cells.

DISCUSSION

It is well known that the growth and metastases of tumor is dependent on the formation of new blood vessel. The new blood vessel provides not only nutrient for tumor, but also the ways for excretion and metastases. Numerous studies have proven that tumor cells will stop growing or die when it exceeds 2mm to 3mm in diameter if new blood vessel for tumor is not formed[5,6]. So, anti-angiogenesis is one of the effective ways to inhibit and control the development of tumor by inducing tumor dormancy or apoptosis.

Endostatin is a new kind of potent antiangiogenic factor

consisting of 184 amino acids in C- terminal fragment of endogenous collagen 18a. It was isolated as a M_r22000 protein from conditioned medium of the EOMA murine hemangioendothelioma cell line by Professor O'Reilly in 1997[22-27]. *In vivo* and *in vitro* experiments have demonstrated that endostatin have specific inhibitory effect on tumor metastases and primary tumor with no observed sign of toxicity[6,28-33]. Furthermore, the genome of endothelial cell, targeted by endostatin, has a stable inherent property and rare mutation. So, there is no acquired resistance to endostatin during endostatin therapy. But the production of functional polypeptide has proven difficult because of its unstable physical property. In addition, antiangiogenic therapy with endostatin in cancer requires prolonged administration and high doses of the recombinant protein. It will result in heavy economic burden and inconvenience to recipients by repeated administrations. Therefore, transfer of foreign endostatin gene into host cells represents an alternative method to treat tumor by generating high efficient endostatin in areas around tumor[34-36]. The aims of generating a high efficient protein with no toxin and keeping a long time and relatively high expression of endostatin can be achieved by single administration[37]. A few groups have demonstrated that antiangiogenic gene therapy with viral vectors is a potentially useful approach for inhibiting tumor growth in mouse model[35,38-44]. By the way, gene transfer mediated by retroviral vectors is most commonly used among the various ways of transducing methods[45]. As retroviral vectors can be integrated into chromosome of host cells, gene transferred by retrovirus can be inherited to next generation and stably expressed in host cells. In this experiment, in order to explore the effect of endostatin on endothelial cell proliferation expressed by SMMC7721, endostatin gene was inserted into retroviral vector pLncx by recombinant technology and subsequently used to infect human liver carcinoma cell line SMMC7721. After transfection, PCR products and immunohistochemical staining showed that endostatin gene had been successfully transferred into and expressed in endostatin-transfected SMMC7721 cells. For the purpose of the protein expressed by SMMC7721 cells being excreted outside the cell, rat albumin signal peptide, which can lead to the expressed protein being secreted outside cell while without any effect on the activity of the protein, was put into the upstream of endostatin gene during the construction of recombinant plasmid[6,28,46]. The effect of signal peptide was also demonstrated by Western blot analysis, which revealed that endostatin protein did exist in the concentrated supernatant of endostatin-transfected SMMC7721 cells. The endothelial cell proliferation assay indicated that conditioned medium from endostatin-transfected SMMC7721 cells significantly inhibited the proliferation of endothelial cell by 48%, compared to conditioned medium from control SMMC7721 cells transferred with empty plasmid pLncx. In another word, endostatin expressed by SMMC7721 cells can remarkably inhibit the proliferation of endothelial cell. In conclusion, gene therapy with endostatin mediated by retrovirus is effective *in vitro*,and perhaps it might also have a significant inhibitory effect on tumor growth *in vivo*, but that remains to be confirmed by further experiments.

Abstract

AIM: **To generate soluble single chain variable fragments (ScFv) of monoclonal antibody MC3 recognizing colorectal and gastric carcinomas.**

METHODS: **mRNA was isolated from the hybridoma cell line producing MC3 and the DNAs encoding variable domains of heavy and light chains (VH and VL) of the antibody were amplified separately by RT-PCR and assembled into ScFv DNA with a linker DNA.The ScFv DNA was ligated into the phagemid vector pCANTAB5E and the ligated sample was transformed into *E.coli* TG1.The transformed cells were infected with M13KO7 helper phage to yield recombinant phages. After two rounds of panning with gastric carcinoma cell line AGS highly expressing MC3-binding antigen, the phage clones displaying ScFv fragments of the antibody were selected by ELISA. 4 phage clones showing strong signal in ELISA were used to infect *E.coli* HB2151 to express soluble ScFvs. The soluble ScFvs were identified by Dot blot and Western blot, and their antigen-binding activity was assayed by ELISA. The VH and VL DNAs of the ScFv DNA derived from phage clone 19 were sequenced.**

RESULTS: **The VH,VL and ScFv DNAs were about 340 bp, 320 bp and 750 bp respectively. After two rounds of panning to the recombinant phages, 18 antigen-positive phage clones were selected from 30 preselected phage clones by ELISA. All the soluble ScFvs derived from the 4 out of the 18 antigen-positive phage clones were about *M*,32000 and concentrated in periplasmatic space under the given culture condition. The soluble ScFvs could bind the antigen, and they shared the same binding site with MC3. The sequences of the VH and VL DNAs of the MC3 ScFv showed that the variable antibody genes belonged to the IgG1 subgroup, κ-type.**

CONCLUSION: **The soluble ScFv of MC3 is successfully produced, which not only provides a possible novel targeting vehicle for *in vivo* and *in vitro* study on associated cancers, but also offers the anuibody a stable genetic source.**

INTRODUCTION

Progress in the use of murine monoclonal antibodies (McAbs) for the *in vivo* study on diagnosis and treatment of human tumors is limited by a number of factors, including poor penetration of the intact antibody molecule into the tumors, their inability to reach the tumor in sufficient quantities without significant toxicity to normal tissue, and the development of a human anti-mouse antibody response to the injected McAb[1-5]. One possible way to alter the pharmacology of antibody is via the use of smaller molecular weight antibody fragment called ScFv. ScFv molecules offer several advantages as carriers for the selective delivery of radionuclides and toxins to tumors, including rapid blood clearance, low kidney uptake, small size suitable for rapid penetration through tumor tissue and less possibility of developing antimouse antibody response[6-18]. Colorectal and gastric carcinomas are frequent causes of death of the cancers of digestive system. MC3 is a specific monoclonal antibody directed against colorectal and gastric carcinomas[19], which has a potential use for *in vivo* diagnosis and therapy of the corresponding carcinomas. In order to overcome the disadvantages of the intact McAb applied *in vivo* and to offer the antibody a stable genetic source, soluble ScFv of MC3 was generated by advanced recombinant phage antibody technique, which may provide a novel tumor-targeting vehicle for *in vivo* study on the diagnosis and treatment of colorectal and gastric carcinomas.

MATERIALS AND METHODS

Materials

The hybridoma cell line producing McAb MC3 (isotype IgG1,κ) was generated by the Institute of Digestive Disease,Xijing Hospital,Fourth Military Medical University, Xi'an, China[19]. Mouse ScFv DNA construction kit, phage-displayed ScFv expression and detection kits, anti-E tag antibody and pCANTAB5 Sequencing Primer Set were purchased from Pharmacia, Sweden. mRNA isolation kit, Taq DNA polymerase, T4 DNA ligase, SfiIand NotIrestriction enzymes were bought from Promega,USA. The gastric carcinoma cell line AGS highly expressing MC3-binding antigen was from ATCC, USA.Horseradish peroxidase (HRP)-labeled goat anti-mouse IgG was from Sino-American Biotechnology Company, China.

Preparation of the phage-displayed ScFv

Total RNA was extracted from guanidine thiocyanate homogenates from 5×10^6 MC3-producing hybridoma cells[20], and the mRNA was isolated from the total RNA using mRNA isolation system according to the protocal supplied by the manufacturer. Subsequently the phage-displayed ScFvs were generated using the Mouse ScFv DNA construction kit and ScFv expression kit[21-27]. The purified mRNA was transcribed into cDNA using random primers, and the VH and VL DNAs were separately amplified through PCR program 1 (30 cycles: 94℃×1min, 55℃×2min, 72℃×2min). Gel-purified VH and VL DNAs were mixed with linker primers at an equimolar ratio and assembled inuo ScFv DNA in fill-in reaction, designed

program 2 (7 cycles: 94℃×1min, 63℃×4min). In a second PCR reaction (same as program 1), the ScFv DNA was amplified and provided with a SfiI site at the 5'end and a NotI site at the 3'end. After digestion with restriction enzymes SfiI and NotI, the ScFv DNA was ligated into the phagemid vector pCANTAB5E, and the ligated sample was transformed into competent *E. coli* TG1 cells to express phage-displayed ScFv. The transformants were grown in 2×YT medium containing ampicillin and glucose (2×YT-AG medium) up to an OD_{600}=0.5. Bacteria were infected with M13KO7 helper phage for 1 h at 37℃ with shaking. The cells were sedimented by centrifugation, and the supernatant was carefully removed and discarded. The pellet was gently resuspended in 2×YT medium containing ampicillin and kanamycin (2×YT-AK medium) and incubated overnight at 37℃ with shaking.The supernatant containing the recombinant phages was harvested by centrifugation and the phages were precipitated with PEG8000 and NaCl and resuspended in 2×YT medium, filtered through a 0.45ìm filter and store at 4℃.

Panning to select for antigen-positive phage-displayed ScFvs

Recombinant phage expressing the MC3 ScFv were selected by panning[25-27]. The AGS cells highly expressing MC3-binding antigen were grown as an attached monolayer in 25-cm^2 flasks until almost confluent, washed with PBS, and fixed with 0.25% glutaraldehyde for 8min at room temperature(RT). The fixed cells were washed with PBS and blocked with 50g/L nonfat dry milk in PBS for 2h at RT. The cells were washed 3 times with PBS and the PEG-precipitated recombinant phages diluted 8:7 with 100g/L nonfat dry milk in PBS containing 0.1g/L sodium azide were added to the fixed cells. The culture flask was shaken gently for 2h at 37℃ and the cells were washed 20 times with PBS and 20 times with PBS containing 0.1% Tween20 (PBST). Log phase *E. coli* TG1 cells were incubated with bound phages for 1h at 37℃ with shaking. Ampicillin, glucose and M13KO7 were added to the bacterial suspension, and the culture was incubated for 1h at 37℃ with shaking. Subsequently, preparation of PEG-precipitated recombinant phage was completed as above, and the second round of panning was performed as described for the first panning step. After the second round of panning, the reinfected TG1 bacteria were plated on SOBAG plates and grown overnight at 30℃, and single colonies were grown in 2×YT-AG medium overnight at 30℃ with shaking. 40μL of the saturated culture of single clone was infected with 400μL of M13KO7 helper phage in 2×YT-AG medium for 2h at 37℃ with shaking. Cells were pelleted by centrifugation, resuspended in 400μL of 2×YT-AK medium and grown overnight at 37℃ with shaking. After centrifugation, phage supernatants were harvested and screened by ELISA.

Detection of phage-displayed MC3 ScFv by ELISA

Phage supernatants obtained from single recombinant cell clones were screened for binding to the AGS cells by ELISA[25,26,28-33]. The AGS cells were grown in 96-well plates, fixed and blocked as described in the panning step. Phage supernatants obtained from single recombinant cell clones were diluted 4:1 with 20g/L nonfat dry milk in PBS and incubated for 10min at RT, then added to the cell-grown wells (100μL/well) and shaken gently for 1.5h at RT. The cells were washed 6 times with PBST, and the bound phages were detected by incubation for 1 hr at RT with 1:5000 diluted HRP-labeled mouse McAb directed against major coat protein(gene 8 protein) of M13(100μL/well). Plates were washed 6 times, ABTS substrate was added and incubated for 40min in the dark at RT with shaking, and the *A* value was measured at 405 nm(A_{405}). M13KO7 helper phage served as a negative control, and the phage antibodies were regarded as antigen-positive when A_{405} was at least 2×higher compared to the negative control.

Expression of soluble MC3 ScFv

Log-phase *E. coli* HB2151 cells were infected separately with phage clones12, 19, 23 and 30(which previously showed strong signal in phage ELISA, clone 19 showed the strongest signal) for 30min at 37℃ with shaking and the infected cells were plated on SOBAG plates containing 100mg/L of nalidixic acid. Single colonies were grown in 5mL of SB-AG medium overnight at 30℃ with shaking and diluted with 50mL of fresh SB-AG medium for further incubation for 1h at 30℃ with shaking. After centrifugation, the sedimented cells were resuspended in 50mL freshly prepared SB-AI(I:IPTG, 1mmol/L) and incubated for 5h at 30℃ with shaking to induce the expression of soluble ScFv. Bacterial culture was divided into two separate centrifuge tubes and centrifuged and supernatants (extracellular fraction) were stored at -20℃ until use. One of the two cell pellets was resuspended in 0.5mL of ice-cold 1×TES (0.2mol/L Tris-HCl, pH8.0, 0.5mmol/L EDTA, 0.5mol/L sucrose) followed by adding 0.75mL of 1/5×TES. After incubation for 30min on ice, the supernatant containing the periplasmatic fraction was centrifugated and stored at -20℃. Whole-cell extract was prepared by resuspending the second pellet in 0.5mL PBS and boiling for 5 min following centrifugation.

Detection of soluble ScFv by Dot blot

Extracellular fraction and its concentrate precipitated by ice-cold 200g/L trichloroacetic acid (TCA)(to 1/5 of the original volume), periplasmatic extract diluted 1:4 with PBS, and whole-cell extracts were spotted onto the nitrocellulose membrane separately (2μL/spot). The membrane was blocked for 2h at RT with PBS containing 100g/L nonfat dry milk(blocking buffer, BB)followed by incubation for 1h at RT with anti-E tag antibody (directed against the E tag-peptide fused to the VL region of the ScFv) diluted to a final concentration of 8mg/L with an equal volume mixture of PBS and BB containing 0.05% Tween20 (PBS/BBT). After being washed once with PBS containing 0.05% Tween20 and 4 times with PBS and followed by a 5min soak in PBS, the membrane was incubated for 1h at RT with HRP-labeled goat anti-mouse IgG diluted 1:150 with PBS/BBT,and washed as above and developed using diaminobenzidine (DAB) substrate.

Detection of soluble ScFv by Western blot

Routine method was applied[34,35]. Periplasmatic extract diluted 1:4 with PBS and TCA-concentrated extracellular fraction were loaded into the wells (10μL/well) of 120g/L SDS polyacrylamide gels and followed by electrophoresis, and the fractionated proteins were then transferred onto a nitrocellulose membrane. The membrane was blocked and developed as discribed in Dot blot.

ELISA for assay of the reactivity with antigen of soluble ScFv

The AGS cells were grown in 96-well plates, fixed and blocked as described in phage ELISA followed by incubation with 50μL of periplasmatic and extracellular fraction for 1 at RT. After washed 6 times with PBST, anti-E tag antibody diluted 1:1000 with PBS/BBT was added (50μl/well) and incubated as above. The plate was washed and 50μL of HRP-labeled goat anti-mouse IgG diluted 1:1000 with PBS/BBT was added and incubated as above. After being washed, ABTS substrate was added and A_{405} was measured. PBS was as a negative control, and the ScFv was considered as a binder when the ELISA response was at least 2×higher compared to the negative control.

ELISA for assay of the competition of soluble ScFv with MC3 in antigen-binding

It was done as described in references[36-38].The AGS cells were

grown in 96-well plates, fixed and blocked as described in phage ELISA followed by incubation with 50μL of periplasmatic fraction for 1h at RT, with PBS as a negative control. After washed 6 times with PBST, MC3 was added to the plate (50μL/well) at a final concentration of 20mg/L, and incubated for 1h at RT. After washed as above, HRP-labeled goat anti-mouse IgG diluted 1:1000 was added (50μL/well) and incubated and washed as above. Then TMB substrate was added and A_{450} was measured. Binding of MC3 with the cells was inhibited by the soluble ScFv, which was described as the inhibition rate: Inhibition rate (%)=1-(A_{450} of the tested sample/A_{450} of the control) ×100%.

DNA Sequencing

The phagemid derived from phage antibody clone 19 was used for DNA sequencing of VH and VL DNAs of the ScFv DNA, based on the dideoxy method, with the primers taken from the pCANTAB5 Sequencing Primer Set.

RESULTS

Cloning of MC3 ScFv DNA and Screening of phage-dispalyed ScFv

The amplified VH, VL and ScFv DNAs were about 340 bp, 320 bp and 750 bp respectively. After two rounds of panning to the recombinant phages, 18 antigen-positive phage clones were selected from 30 preselected phage clones by ELISA. 4 out of the 18 clones (clones 12, 19, 23 and 30), which showed strong signal (clone 19 showed the strongest signal), were selected for expression of soluble MC3 ScFv in *E. coli* HB2151.

Identification of soluble MC3 ScFv

After expression of soluble ScFv in *E. coli* HB2151, extracellular, periplasmatic, and whole-cell fractions were checked for the presence and reactivity of ScFv by Dot blot, Western blot and ELISA. In a Dot blot, no visible signal was achieved for the whole-cell extracts, and only weak signal was shown for the extracellular extracts, while a strong signal for periplasmatic and TCA-precipitated extracellular extracts. Based on the results in the Dot blot, Western blot analysis was performed only with periplasmatic and TCA-precipitated extracellular extracts, and ELISA for reactivity of soluble ScFv with antigen was performed only with periplasmatic and extracellular fractions. Western blot showed that in both periplasmatic and TCA-precipitated extracellular extracts, a distinct band of M_r32000, lying within the expected molecular weight range of soluble ScFv, was visualized, and the periplasmatic fractions showed stronger reactivity in comparison to the TCA-precipitated extracellular extracts (Figure 1 and Figure 2). The results displayed in Dot blot and Western blot indicated that most of soluble ScFv was secreted into the periplasm under the given culture condition.

ELISA showed that MC3 ScFv secreted into the periplasm could react with AGS cells expressing MC3-binding antigen at a high level, whereas no significant binding signal was obtained in extracellular extracts. The periplasmatic fraction containing soluble ScFv derived from the phage clone 19 showed the strongest signal in ELISA.

Based on the above result in ELISA, the competition ELISA was performed only with periplasmatic fraction, and the result showed that all the soluble ScFv-containing periplasmatic extracts derived from the clones 12, 19, 23 and 30 could inhibit the binding of MC3 with its corresponding antigen, and the inhibition rates were 36.9%, 41.2%, 31.9% and 33.8% respectively, which indicated that the soluble ScFvs shared the same antigen binding site with McAb MC3.

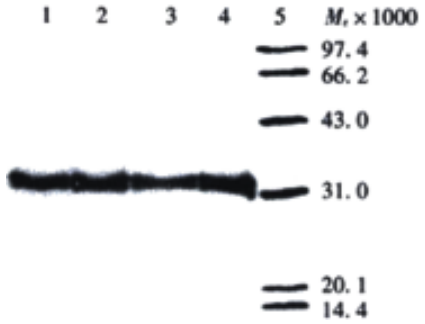

Figure 1 Detection of soluble MC3 ScFv in periplasmatic extract by Western blot. Lanes 1-4: periplasmatic extracts derived from phage clones 12, 19, 23 and 30 respectively, diluted 1:4 with PBS; Lane 5: low molecular weight protein marker.

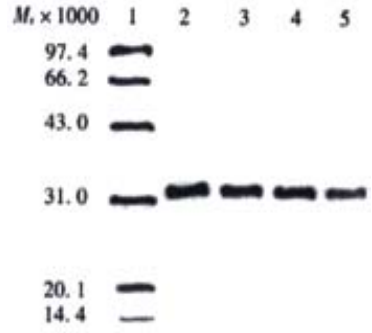

Figure 2 Detection of soluble MC3 ScFv in TCA-precipitated extracellular fraction by Western blot. Lane 1: low molecular weight protein marker; Lane 2-5: TCA-precipitated extracellular fractions (to 1/5 of the original volume) derived from the phage clones 12, 19, 23 and 30 respectively.

DNA Sequence analysis

The phagemid derived from clone 19 was used for DNA sequencing, and the result showed that the VH and VL DNAs of MC3 ScFv DNA were 336 bp and 312 bp respectively, and they were identified as variable antibody genes belonging to the IgG1 subgroup, κ-type. The detail sequence of the VH and VL DNAs were listed as follows.

DISCUSSION

Recent progress in antibody engineering have been directed toward the expression of antibody fragments in bacterial and phage display systems, leading to increase of various applications in biology, clinical diagnosis and therapy.The power of the phage display system to express antibody fragments offers several advantages over hybridoma technology, allowing quick, economical production and generation of antibodies with increasing affinity and specificity by mimicking affinity maturation in the normal immune system, and offering the antibody a stable genetic source which can be easily manipulated[39-51]. Antibody fragments showed less possibility of developing anti-antibody response in comparison to the intact antibodies when applied *in vivo*. In this study, the ScFv of murine McAb MC3 directed against colorectal and gastric carcinomas was successfully produced by advanced phage antibody technology, which offered it the above advantages of the engineering antibody. MC3 ScFv was displayed on the surface of M13 phage as a fusion protein with gene Ⅲ protein (g3p) and additionally expressed in a soluble form secreted in the bacterial periplasm. Both expression forms retained their reactivity to the antigen. Because of the advantage of MC3 ScFv compared to the intact MC3 for *in vivo* diagnosis and therapy of the associated carcinomas, we have focused on the production of soluble ScFv.

A critical step in cloning of the ScFv DNA was the assembly of VH and VL DNAs with linker DNA. The linker primers consist of two 93-base oligonucleotides which are complementary to each other and have homology with the 3'end of the VH gene and the 5'end of the VL gene. 24 bases on either end of the linkers are complementary to the ends of the VH and the VL. The central 45 bases of the linkers encode the flexible $(Gly^a\text{-}4Ser)^a$-3 linker which joins the VH and the VL to form a ScFv fragment. In the assembly and fill-in reactions, an exact quantification of purified VH and VL products and linker DNA was very essential. Even slight deviations of the equimolar ratio VH: VL:linker lead to either no visible ScFv product or to the formation of VH-linker or VL-linker dimers, apparently 450bp in size.

McAb MC3 was prepared by immunizing mice with human colorectal carcinoma cells, but immunohistochemical detection indicated that the MC3-binding antigen was highly expressed in both colorectal and gastric carcinomas[19]. Because no purified antigen was available so far, the recombinant phages were selected in a panning reaction with AGS cells highly expressing MC3-binding antigen. After two rounds of panning, 18 antigen-positive phage clones were selected by ELISA, and 4 clones showing strong signal were used to express soluble ScFv. Clone 19, which showed the strongest signal in ELISA, was used for DNA sequencing and identified as variable antibody genes belonging to the IgG1 subgroup, κ-type.

The E. *coli* strain HB2151 was used to express soluble MC3 ScFv because in this strain the amber stop codon interposed between the E-tag sequence and g3p gene prevented the expression of a ScFv-g3p fusion protein. The soluble ScFv is secreted into the periplasm via the g3p leader sequence, where it is folded in its native form. Dot blot, Western blot, and ELISA verified that soluble ScFv was concentrated in periplasmatic fraction under the given culture condition. Location of functional ScFv in the periplasm is preferred for large-scale preparation because of smaller volume in comparison to the extracellular fraction. The soluble ScFv-containing extracts (such as periplasmatic fraction) may be used directly for some immunoassays. Alternatively, the soluble ScFv may be purified from *E. coli* proteins if the components of the bacterial extract interfere with the immunoassay or/and when the ScFv is for *in vivo* use. In conclusion, the preparation of soluble ScFv of MC3 may provide a promising targeting vehicle for *in vitro* and potential *in vivo* imaging and therapeutic applications to colorectal and gastric carcinomas, and also offer the antibody a stable genetic source.

Abstract

AIM: **To analyze the diagnosis and treatment of 16 hereditary nonpolyposis colorectal cancer (HNPCC) kindreds, and to report the first kindred with hMLH1 germline mutation in Mainland China.**

METHODS: **The diagnosis, treatment and follow-up study of 16 HNPCC kindreds were retrospectively reviewed. Data concerning site of the malignant tumor, age at the diagnosis, history of synchronous and/or metachronous cancer, and histopathology of tumors were recorded. All treatments had won formal consent. PCR and SSCP were used to screen the coding region of hMLH1 and hMSH2 genes. Variant bands were sequenced by a 377 DNA sequencer.**

RESULTS: **Among sixteen kindreds, sixty-eight patients had a mean age of 50.8 years, including twenty-one multiple cancer patients and forty-six colorectal cancer patients (metachronous colorectal cancers in sixteen). A total of one hundred and one malignant neoplasms were found in these sixty-eight patients, including 50 colonic, 17 rectal, 11 gastric, 7 endometrial, and 4 esophageal cancers. 39.5% colorectal patients had metachronous cancers within ten years who needed reoperations. A germline G265T nonsense mutation was found in the third exon of hMLH1, resulting in a stop codon and truncated protein. Three phenotypically normal family members were also found to carry the mutated gene.**

CONCLUSION: **HNPCC is a typical auto-dominant hereditary disease, the main characteristics include early onset and frequency of cancers; predominance of colorectal, especially right-sided colon cancers; frequency of multiple primary cancers (especially colorectal cancers). Segmental resection for colorectal cancers is not eligible for colorectal cancer patient in HNPCC kindreds. Intensive follow-up is essential for all patients and possible gene carriers. The first HNPCC kindred with hMLH1 gene germline mutation was identified in Mainland China, and three phenotypically normal family members were found to be carriers of the mutated gene. The G265T germline (nonsense) mutation in the third exon of hMLH1 found here had not been reported previously in the literature.**

INTRODUCTION

Hereditary nonpolyposis colorectal cancer, or Lynch syndrome, is an autosomal, dominantly inherited disease characterized by an exess of early age onset colorectal cancers. It is estimated that hereditary nonpolyposis colorectal cancer may account for 5 to 10 percent of the total colorectal cancers worldwide[2]. There are two main variants of the disorder[1,3], Lynch syndrome I, which is susceptible to colorectal carcinoma only, and the more common Lynch syndrome Ⅱ,which is characterized by excessive colorectal carcinoma and malignancies of extracolonic tissue, especially the endometrium in the western world. Other tumors belong to the spectrum of this syndrome include those of the stomach, esophagus, ovaries, pancreas, and urinary tract[3,4]. HNPCC has no premonitory symptoms, and the cancer is usually found at an advanced stage at around 50 years of age.

Five causative mismatch repair genes for HNPCC(hMSH2, hMLH1, hPMS1, hPSM2, and hMSH6/GTBP) have been identified, and a germline mutation in one of them predisposes carriers to early onset cancers[5-10]. hMSH2 and hMLH1 genes contribute at least 40 and 35 percent of all HNPCC germline mutations, respectively. Mutational analysis of the two main genes not only permit diagnosis of most cancer families or patients, but also earlier detection of cancer through targeted surveillance and chemoprevention of the gene carriers.

Despite the fact that China might have the biggest HNPCC population, the disease is rare reported. And also the mismatch repair gene mutation of HNPCC families from Mainland China has not been reported. We retrospectively reviewed the clinical characteristics and treatments of 16 HNPCC kindreds registered in our hospital, and report the first hMLH1 gene mutation family in Mainland China.

MATERIALS AND METHODS

Diagnotic criteria of HNPCC family

Kindreds of independent Chinese families that included multiple patients with colorectal cancer were clinically reviewed. The strict criteria for HNPCC were the Amsterdam criteria[11]. The criteria are (1) three or more relatives with histologically verified colorectal cancer, with one of them being a first-degree relative to the other two relatives; (2) at least two successive generations were affected; (3) one or more colorectal cancer cases diagnosed under 50 years of age; and (4) familial polyposis of colon is excluded. Japanese clinical diagnotic criteria for HNPCC[12] was used for highly suspected families that did not fully met the Amsterdam criteria. Families that met either A or B were clinically diagnosed as HNPCC. The criteria include A: a case with three or more colorectal cancers within the first-degree relatives; B: a case with two or more colorectal cancers within the first-degree relatives meeting the following criteria (1)age onset of colorectal cancers being earlier than 50 years old; (2) with right colon involvement; (3) with synchronous or metachronous multiple colorectal cancers; (4) associated with synchronous or metachronous extracolonic malignancies.

Family investigation

The diagnosis is made upon the compilation of a detailed family history. The family history of cancer was thoroughly reviewed when a

patient was admitted with the diagnosis of colorectal cancer. Suspected families were further reviewed by a specific surgeon (Wang ZJ). The history covered at least all first-degree relatives and selected second-degree relatives. Families fulfilling the Amsterdam criteria or Japanese clinical diagnotic criteria were registered and family members were reviewed by telephone or outpatients visits. Before this review, all patients were reinvestigated by follow-up records or telephone interviews.Data concerning the site of cancer, age of diagnosis, history of synchronous and/or metachronous cancers, and histopathology of cancers were documented. The Clinical characteristics, diagnosis, treatments and follow-up study of sixteen HNPCC pedigrees were retrospectively analyzed in this report.

Germline hMLH1 gene mutation analysis

Peripheral blood was obtained from the affected and unaffected normal family members, all of whom signed the formal consent. Genomic DNA was extracted by standard organic methods. The coding regions of hMLH1 and hMSH2 gene were PCR amplified according to Weber methods[13] with minor modifications. SSCP was used to screen the cording regions and variant bands were then sequenced by a 377DNA sequencer. After a mutation was found, specific regions of DNA from their offspring were PCR amplified and sequenced.

RESULTS

HNPCC families

A total sixteen kindreds were diagnosed, among there, eleven met Amsterdam criteria and five met the Japanese clinical diagnosis criteria. There were three Lynch syndrome I families, and thirteen Lynch syndrome II families respectively. HNPCC constituted about 5.2% of colorectal cancer patients within the same period in our hospital.

Tumor spectrum

One hundred and one malignant neoplasms were found in sixty-eight patients (multiple cancer in twenty-one) with a mean age of 50.8 years in sixteen kindreds, including fifty colonic, seventeen rectal, eleven gastric, seven endometrial, and four esophageal, two each skin, pancreatic, lung and cervical,one each breast, ovarian cancer, gastric leiomyosarcoma and brain glioblastoma, respectively.There were forty-six colorectal cancer patients (including sixteen metachronous colorectal cancers). In the present group, 67.6% patients and 66.3% cancers are of colorectal ones. Right-side colon cancers constitute 47.8% of total cancers and 74.6% of colorectal cancers. 34.8% of colorectal cancers were metachronous ones.

Patient treatment and follow-up

81.6% patients received radical operations; other patients received chemotherapy, irradiation and traditional Chinese medicine treatment. 39.5% colorectal cancer patients had metachronous colorectal cancers within 10 years and required re-operations. A multiple primary cancer patient, after rectal cancer was resected, developed subsequently ascending colon cancer 12 years later, stomach cancer 18 years later, transverse colon cancer 19 years later, and descending colon cancer 28 years after the first operation.

hMLH1 mutation RESULTS

In one large HNPCC family, a germline G265T nonsense mutation was found in the third exon of hMLH1 gene. The mutation turned GAG in codon 89 to a stop codon TAG, resulting in a truncated protein. The normal family member over 50 years old did not have the same germline mutation. Three phenotypically normal family members were also found to carry the mutated gene. Two of them subsequently received colonoscopy examinations. One was found to have an adenoma of 2cm and was resected endoscopically. We searched the Human Gene Mutation Database (HGMD) (uwcm.web.cf.ac.uk/uwcm/mg/hgmdo.html), and found this mutation had not been reported previously in the literature.

DISCUSSION

Hereditary nonpolyposis colorectal cancer is a typical auto-dominant hereditary disease[14], constituting about 5.2% of colorectal cancer patients within the same period in our hospital,which is consistent with the published reports[14,15]. Early onset of the colorectal cancer is an important feature of HNPCC patients[16]. The average age onset of colon cancer in the general population in China is around 60 years of age. Patients with HNPCC in our group developed colorectal cancer at an average of 49 years, 10 years earlier than the general population. Colorectal cancers occur most frequently in HNPCC kindred. In the present group, 67.6% patients and 66.3% cancers are colorectal ones, consistent with previously published reports[17,18]. Colon cancers are more often right-sided,constituting 47.8% of total cancer and 74.6% of colorectal cancers, whereas in sporadic colon cancer, the opposite is true[17,18]. The next most frequently seen cancer is gastric cancer, about 10.8% in this group, well above the reported frequency in the literature[19,20]. It is interesting that gastric cancer occurred at a higher frequency and ovarian cancer at a lower frequency in our group[21,22]. More research study should be done to clarify if this is just a reflection of case selection bias or the difference is related to ethnic or geographical groups[23,24]. Endometrium is the third predisposing organ, and about 6.9% cancer is in the endometrium[21]. A small number of other cancers included pancreatic, esophageal, skin, lung, cervical, and breast cancers. There was one gastric leiomyosarcoma and glioblastoma, respectively.

Two breast and two lung cancers in our small group of patients are worthy of particular comment. Controversy exists whether these two kinds of cancers belong to the spectrum of HNPCC[25,26]. In China, breast and lung cancers are much less prevalent than those in the western worle, and it is interesting that the incidence of these two cancers among those families is far above the average level in China. One breast cancer occurred in the index patients of a Lynch syndrome II kindred (Figure 1) that received sequence analysis in this study. The patient developed ascending colon cancer at 37 years of age, breast cancer at 38, rectum cancer at 52, descending colon cancer at 57. The possibility of a sporadic breast cancer in this patient is small. The two lung cancers occurred in two patients of classical Lynch syndrome II kindred, but they developed rather late. More cases and studies are needed to clarify if these two cancers are integral to cancer spectrum of this syndrome[27].

Figure 1 A Lynch syndrome II pedigree with hMLH1 gene germline mutation

Another cardinal features of the HNPCC in this group and in the medical literature is the occurrence of metachronous colorectal cancer[28,29]. In our group, 39.5% colorectal cancer patients developed metachronous colorectal cancer within ten years after their initial colorectal cancer resection. But in contrast to the literature, none of the patients were found to have synchronous colorectal cancers. Although it is quite possible that small benign adenomas were not recorded or missed during the colonoscopic or barium examination, but the possibility of missing a cancer is quite small. The reason for the lack of synchronous cancer remains unclear.

81.6% our patients received routine radical resection. Among colorectal patients who received routine segmental resections, 39.5% developed metachronous colorectal cancer, and needed re-operations. After segmental resection, a multiple primary cancer patient developed ascending colon cancer twelve years later, gastric cancer eighteen years later, transverse colon cancer nineteen years later, and descending colon cancer twenty eight years later after the first operation. Therefore, the most eligible choice is subtotal or total colectomy with ileorectal anastomosis or with ileopouch anal anastomosis[30,31], which removes the colonic segment as much as possible, and avoids permanent ileostomy. Two patients, one had primary cancer, the other had metachronous colon cancer, both received total coloproctectomy with ileopounch anal anastomosis. A short term follow-up of the patients showed good life quality. In literature[30-33], different views exist regarding prophylactic coletomy for gene carriers of HNPCC. Firstly, not all carriers of the germline hMSH2 and hMLH1 gene mutations develop colorectal cancer; Vasen *et al* reported that up to 60 years of age, 92% of the carriers developed colorectal cancers in affected families[32]. Secondly, complications even mortality occurred around 8% and 1% respectively in these operations[30]. The timing of prophylactic operation in an HNPCC gene carrier is unknown. The median age at diagnosis of colorectal cancer is around 45 years, but Rodriguez-Bigas showed that 27% of their patients were diagnosed before 39 years and 88% by 69 years of age[33]. Other uncertainties include: the optimal procedure has yet to be considered, the psychologic impact of the invasive procedure on body image and sexuality in young adult carriers.

Colonoscopy remains the most important surveillant measure in revealing synchronous and metachronous cancers or polyps in the follow-up of patients and in symptomatic gene-carriers. polypectomy should performed if present[34]. J vinen *et al*[35] reported a 62 percent decrease of colorectal cancer in HNPCC patients who underwent colonoscopic screening vs. those who did not.

The first family with hMLH1 gene mutation from Mainland China was identified in our study. In the large HNPCC kindred, a germline G265T nonsense mutation was found in the third exon of hMLH1, resulting in a stop codon and truncated protein. The mutation segregated with the disease in the family. We made a search in the Human Gene Mutation Database (HGMD) (uwcm.web.cf.ac.uk/uwcm/mg/hgmdo.html), and found this to be a new mutation previously unreported in the medical literature. In three phenotypical normal family members, the same mutated gene was found in the germline. Two of them subsequently received colonoscopy examinations, and one was found to have an adenoma of 2cm which was resected endoscopically. These carriers are now needed an intensive follow-up regime.

ACKNOWLEDGMENT

We appreciate the invaluable technical assistance and great help of Dr. Ding-fang Bu from Experimental Center of our hospital.

Abstract

AIM: **To improve the prevention and treatment of senile patients with colorectal cancer by evaluating the importance of colonoscopy in clinical screening and follow-up.**

METHODS: **Clinical screening of colonoscopy was performed for 2196 patients aged 60-90 years old according to the protocol,and 1740 of them (79.2%) were followed-up.**

RESULTS: **Colorectal cancer was found in 52 patients, and the detectable rate was 2.4%. Among them, 19 were diagnosed as early colorectal cancer, accounting for 36.5% of the detected colorectal cancer. Among the followed-up patients, early colorectal cancer was found in 9, accounting for 45.0% of the detected colorectal cancer. The resectable rate and 5 years survival rate of colorectal cancer were 97.7% and 80.9% respectively. The incidence of complication was 0.05%, and the successful rate of cecum intubation was 98.9%.**

CONCLUSION: **Colonoscopic screening and follow-up of the elderly for colorectal cancer and pre-cancerous lesion (adenomatoid polyp) can increase the detectable rate of early colorectal cancer and improve its prevention and treatment.**

INTRODUCTION

Sequential method is usually used in clinical screening of colorectal cancer[1-3], but some experts hold that direct sigmoidoscopy should be performed for the screening of large intestinal cancer[4-6]. Colonoscopy screening of large intestinal cancer is advocated abroad due to the significant incidence of proximal cancer of colon in the past 10 years[7-14]. Colonoscopy screening and follow-up were conducted for 2196 old patients who had not received barium enema contrast radiography from September 1985 to July 1998 in this study.

MATERIALS AND METHODS

All the 2196 patients to be screened were retired or veteran officers in active service. Age ranged from 60 to 90 (averaged 70.5) years old, 2067 male and 129 female. Enteroscopy was performed for 8298 with times, and 1740 of the 2196 patients(79.2%) were followed-up for 1-12 years. The number of follow-up per patient was 4.5 times and the time of follow-up per patient was 5.9 years. Among the screened patients, 1618 (73.7%) were asymptomatic. The main symptoms of the remainder were anorexia, abdominal uncomfortableness, constipation, irregular feces and loss of body weight. Among the 2196 patients, heart disease, encephalopathy, lung disease and nephrosis were found in 1911 (87.0%),in which more than 3 vital organ diseases were found in 534 (24.3%). 639 patients(29.1%) were found to have a history of abdominal operation such as subtotal gastrectomy, cholecystectomy, appendectomy, abdominal exploratory operation and colon cancer operation.

Colonoscopy screening was performed by using Olympus CF-MB3W,CF-IBM, PCF-10, CF-1T20I, CF-V10L, CF-200L colonoscopes made in Japan, and colonoscopic follow-up was conducted according to the patients' physical conditions every years.

RESULTS

The detectable rate of colorectal polypus

Among the 2196 patients, 9893 polypi were found in 1364 (62.1%), in which 8587 polyps were detected in 1618 asymptomatic patients (86.8%). 3435 and 6458 polypi were found in the first diagnosis and follow-up respectively, which accounted for 65.3% of the total detected polypi. Among the 8537 polypi confirmed by pathologic examination, 1841 (21.6%) were inflammatory polypi, and 5801 (67.9%) were adenomatoid polypi, and 895 (10.5%) were hyperplastic and hamartoma. 21 were adenomatoid polypi with malignant transformation, accounting for 0.2% of the detected colorectal polypi.

The detectable rate and follow-up of colorectal cancer

Among the 2196 patients, colorectal cancer was found in 52 patients, and the detectable rate was 2.4%. Among the 52 patients with colorectal cancer, early colorectal cancer and early multiple colorectal cancer were found in 19 (36.5%) and in 3 (5.8%) respectively, and 22 early cancerous foci were found as well. Among the asymptomatic patients, colorectal cancer was found in 24, which accounted for 46.2% of the total detected colorectal cancer, and early colorectal cancer was found in 13 asymptomatic patients, which accounted for 54.2% of the total asymptomatic colorectal cancer. Colorectal cancer was found in 20, and early colorectal cancer in 9 of them (45.0%) during the follow-up, which was higher than that (31.3%) by colonoscopic screening. Surgical treatment was performed for 24 of the 32 patients with colorectal cancer found in the screening. The Duck's pathologic staging was as follows:7 patients (29.2%) were in stage A, 15 (62.5%) in stage B, and 2 (8.3%) in stage C.

Treatment and prognosis of the patients with colorectal cancer

Treatment of the 52 patients with colorectal cancer was shown in Table 1. Surgical operation and or electric coagulation resection under colonoscope was performed according to the patient's condition. Among the 44 patients who received surgical treatment,

colorectostomy was performed for 43 (97.7%) with all the early colorectal cancer removed(100.0%). 22 survived for more than 5 years, and 5 years survival rate was 80.9% (Figure 1).

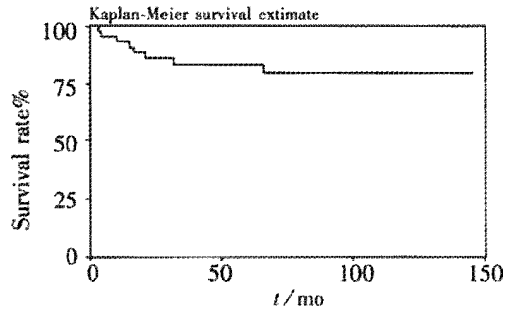

Figure 1 The survival curve of 44 operated patients with colorectal cancer

Table 1 Treatment of 52 patients with colorectal cancer

Type of cancer	*n*	Treated by endoscope	Operation		Not operated	Not followed up
			Removed	Not removed		
Early	19	6	12	0	1	0
Progressive	33	0	31	1	0	1

Complication and successful rate of intubation

8298 times of colonoscopy were performed, in which the incidence rate of complication was 0.05%, complication was found in 4 patients (bleeding in 2 and collapse in 2), and the successful rate of intubation was 98.9%. Colonoscopy was not performed in the ileocecum of 91 patients due to their poor tolerance, history of abdominal operation, long and tortuous intestinal canal, obstruction by tumors, and poor preparation of intestinal tract.

DISCUSSION

Colonoscopic clinical screening and follow-up is an ideal method for the detection of early colorectal cancer and pre-cancerous lesion (adenoma). In this study, clinical screening and follow-up by colonoscopy were performed for patients over 60 years old, and the detectable rate of colorectal cancer was 2.4%, and the detectable rate of early colorectal cancer was 36.5%, which was higher than that (21.0%) reported by using screening method[15,16]. The detectable rate of early colorectal cancer was 15.2-16.8% in this country[17,18], and 45.0% in our follow-up by colonoscopy. It indicates that persistent follow-up by colonoscopy is of great importance for the detection of early colorectal cancer. Among the 2196 screened patients, colorectal polypi was found in 1364 (62.1%), and 67.9% of them were adenomatoid polyps confirmed by pathologic examination. The detected polypi by colonoscopy in the follow-up accounted for 65.2% of the total detected polypi. Therefore, we hold that colonoscopic screening should be performed for the patients over 60 years old including those with no symptoms, and those with their adenomas removed. The latter should be followed up every year. Experts[14,19]also advocated that colonoscopic screening should be performed for the ordinary population every year, because they believed that it was more economic and effective for the patients over 60 years old.

Clinical screening and follow-up by colonoscopy lead to the prompt treatment of colorectal cancer and improve the excision rate and 5 years survival rate of the patients with colorectal cancer, which are higher than those (71-92.8% and 62-74%)[20-24] reported in other countries and are significantly higher than those(84.8% and 53.0%) reported in China[25]. The treatment of pre-cancerous lesion (adenomatoid polyp) under colonoscopy reduced the incidence of colorectal cancer and improved its prevention and treatment. 9566 of the 9893 (96.7%) colorectal polypi were treated under colonoscopy. Among the 21 cancerous polypi, surgical operation and excision under colonoscopy were performed for 20 patients respectively, except one case due to the patient's condition. Researchers found that the incidence of colorectal cancer can be decreased by 76-90% by removing adenomatoid polypus under colonoscopy with the recurrent and regenerated adenomas resected in the follow-up by colonoscopy[26-28]. The colorectal polypi were treated when clinical screening and follow-up by colonoscopy were performed in this study. It would greatly decrease the expected incidence of colorectal cancer.

In this study 87% of the patients suffered from multiple organ diseases such as heart disease, encephalopathy, and nephrosis, and 24.3% of them had diseases in more than 3 vital organs, but the incidence of complication was significantly lower than that (0.4-1.4%)[29-31] with no occurrence of death and perforation[31]as a result of the improvement of intestinal canal preparation, simplification of colonoscopy intubation, and the appropriate measures taken for them according to the changes of their blood pressure and ECG when colonoscopy was performed. 29.2% of the patients in this study had a history of abdominal operation, but the successful rate of intubation was 98.9%. Therefore, we hold that clinical screening and follow-up by colonoscopy for old patients can lead to early diagnosis and treatment of patients with colorectal cancer and pre-cancerous lesion (adenomatoid polypus), and it is a safe and effective method to detect early colorectal cancer and decrease the death rate of colorectal cancer.

Abstract

AIM: **To kill CEA positive colorectal carcinoma cells specifically using the *E coli* cytosine deaminase (CD) suicide gene, a new replication-deficient recombinant adenoviral vector was constructed in which CD gene was controlled under CEA promoter and its *in vitro* cytotoxic effects were evaluated.**

METHODS: **Shuttle plasmid containing CD gene and regulatory sequence of the CEA gene was constructed and recombined with the right arm of adenovirus genome DNA in 293 cell strain. Dot blotting and PCR were used to identify positive plaques. The purification of adenovirus was performed with ultra-concentration in CsCl step gradients and the titration was measured with plaque formation assay. Cytotoxic effects were assayed with MTT method, The fifty percent inhibition concentration (IC_{50}) of 5-FC was calculated using a curve-fitting parameter. The human colorectal carcinoma cell line, which was CEA-producing, and the CEA-nonproducing Hela cell line were applied in cytological tests. An established recombinant adenovirus vector AdCMVCD, in which the CD gene was controlled under CMV promoter, was used as virus control. Quantitative results were expressed as the mean ± SD of the mean. Statistical analysis was performed using ANOVA test.**

RESULTS: **The desired recombinant adenovirus vector was named AdCEACD. The results of dot blotting and PCR showed that the recombinant adenovirus contained CEA promoter and CD gene. Virus titer was about 5.0×10^{14}pfu/L^{-1} after purification. The CEA-producing Lovo cells were sensitive to 5-FC and had the same cytotoxic effect after infection with AdCEACD and AdCMVCD (The IC_{50} values of 5-FC in parent Lovo cells, Lovo cells infected with 100 M.O.I AdCEACD and Lovo cells infected with 10 M.O.I AdCMVCD were >15000, 216.5±38.1 and 128.8±25.4μmol·L^{-1}, $P<0.001$, respectively), and the cytotoxicity of 5-FC increased accordingly when the m.o.i of adenoviruses were enhanced (The value of IC_{50} of 5-FC was reduced to 27.9±4.2μmol.L^{-1} in 1000 M.O.I AdCEACD infected Lovo cells and 24.8±7.1 μmol·L^{-1} in 100 M.O.I AdCMVCD infected Lovo cells, $P<0.05$, $P<0.01$, respectively). The CEA-nonproducing Hela cells had no effect after infection with AdCEACD, but Hela cells had the cytotoxic sensitivity to 5-FC after infection with AdCMVCD (The IC_{50} of 5-FC in parent Hele cells and Hela cells infected with AdCMVCD at 10 M.O.I was >15000 and 214.5±31.3μmol·L^{-1}, $P<0.001$). AdCEACD/5-FC system also had bystander effect, and the viability was about 30 percent when the proportion of transfected cells was only 10 percent.**

CONCLUSION: **The recombinant adenovirus vector AdCEACD has the character of cell type-specific gene delivery. The AdCEACD/5-FC system may become a new, potent and specific approach for the gene therapy of CEA-positive neoplasms, especially colon carcinoma.**

INTRODUCTION

Gene therapy is a novel approach that might lead to improved treatments of some types of cancer[1-9]. A suicide gene is a gene encoding a protein, which under appropriate conditions (i.e., exposure to prodrugs) is toxic to the genetically modified cell (i.e., tumor cell). Apart from the direct killing effects, further investigation led to the fundamental discovery, termed the "bystander effect", which allowed a therapeutic application of suicide gene therapy. The bystander effect demonstrated that a tumor population could be killed if only a fraction of the tumor expressed the suicide gene, and thus was a seminal finding that overcame the limitations of gene therapy technology, i.e., the inability to genetically modify an entire tumor mass[10,11]. The gene for herpes simple virus-thymidine kinase (HSV-1 TK) has been the subject of many investigations *in vitro* and *in vovo*[12-19]. The Escherichia *coli* gene coding for the cytosine deaminase (CD) enzyme is another suicide gene. CD transforms nontoxic prodrug 5-fluorocytosine (5-FC) into an antitumor chemotherapeutic agent 5-fluorouracil (5-FU). This gene has already been tested *in vitro* as well as in several animal models; most of them being based on colorectal carcinoma cells[20-24].

If suicide gene wese delivered into cells, these cells, either target cells or normal cells, might be killed. The ability to direct suicide gene to transfer to particular cell will be important not only to achieve a therapeutic effect but also to limit potential adverse effects. But gene targeting continues to be a major obstacle to the overall success of gene therapy. For such strategies to have clinical applications the therapeutic gene should be expressed in the cells of interest, while avoiding expression in non-target cell population. In the case of cancer therapy, one such method would be uhe use of tumor cell-specific or tissue-specific promoters capable of directing expression of a heterologous gene in the cells[25-27]. Systemic delivery

of a vector, which contains a tumor- or tissue-specific expression cassette, would then be feasible since expression of the transgene would be limited to these cells exclusively[28,29].

Previously we constructed a replication-deficient recombinant adenovirus vector containing CD gene controlled under cytomegalovirus (CMV) promoter, termed AdCMVCD, and confirmed that AdCMVCD/5-FC system presented direct killing and bystandes effect for many kinds of neoplasms *in vitro* and *in vivo*[30]. In the present study we constructed a new replication-deficient recombinant adenovirus vector, termed AdCEACD, containing CD gene under control of the carcino-embryonic antigen (CEA) promoter, and investigated its *in vitro* effects.

MATERIALS AND METHODS

Cells and ceml culture

Ad5-transformed human embryonic kidney (293) cell line, human colorectal carcinoma (Lovo) cell line and human cervix carcinoma (Hela) cell line were grown in Dulbecco's modified Eagle's medium (DMEM) (Gibco) supplemented with 100mL·L^{-1} fetal bovine serum (FBS) (Gibco) in a 50mL·L^{-1} CO_2 atmosphere at 37℃.

Plasmid and virus

Expression plasmid pCEACD contained whole length CD gene sequence and CEA promoter sequence. Shuttle plasmid pAdE1CMV contained the E1A enhancer linked to the cytomegalovirus (CMV) promoter. The recombinant adenoviral vector AdCMVlacZ carried the *E. coli* lacZ gene for β-galactosidase under control of the CMV enhancer/promoter. We constructed a recombinant adenoviral vector, termed AdCMVCD, containing CD gene under CMV promoter.

Shuttle plasmid containing CEA promoter and CD gene

A fragment of CEA promoter (about 0.4kb) and CD gene (about 1.3kb) was obtained from pCEACD by digestion with HindIII and BamHI (Promega), then the terminal of BamHIwas treated with Klenow fragment of *E. coli* DNA polymerase (Promega), finally the fragment was subcloned into pAdE1CMV with XbaIand HindIII (Promega). The resulting plasmid was named pAdCEACD.

Preparation of the "right arm" of adenovirus genome and recombination of adenovirus vector AdCEACD

Preparation of the "right arm" of adenovirus genome DNA and construction of recombinant adenovirus by homologous recombination AdCEACD were conducted according to methods we had reported[31].

Identification of AdCEACD

Adenovirus supernatant of each clone were degraded by boiling, ten minutes later the supernatant was laid on ice. CEA fragment, 0.3kb, obtained from pCEACD by digestion with HindIII and Eco_RI, was used to prepare [α-^{32}P]-labeled probe according to product instruction (Amersham Pharmacia Biotech). The probe was used to dot blotting with DNA of all clones on nylon membrane (Amersham Life Science) in Rapid-hyb buffer (Amersham Pharmacia Biotech).

For positive clones with dot blotting, polymerase chain reaction (PCR) assay was applied to determine CD gene. The sense sequence of CD primer was 5'-TATGGATCCTCAACGTTTGTAATCGA TGGCTT-3', while the antisense sequence was 5'-ATAGAATTAAGGCTAACAATGTCGAATAACGCTT-3'. Each 50μL PCR system contained 3μL DMSO, 1.5μL dNTP (10mmol·L^{-1}), upstream primer 20pmol, downstream primer 20pmol, adenovirus supernatant 2μL, 4u pfu DNA polymerase (Sangon, Shanghai), 5μL 10×pfu DNA polymerase buffer. PCR was performed for 30 cycles (94℃ 1min, 60℃ 1.5min, 72℃ 1.5min) in an automated DNA Thermal Cycler (Perkin-Elmer Cetus).

Propagation, purification and titration of AdCEACD

AdCEACD was propagated in 293 monolayer cells. The purification of adenovirus was performed with ultra-concentration in CsCl step gradients for 2h at 20℃ and 22000r.min^{-1}. The titration of AdCEACD was measured with plaque formation assay.

CEA secretions of Lovo and Hela cells

Lovo cells or Hela cells were subcultured in 60-mm cell culture dishes respectively. After determining the number of cells on a dish that was about over 90% confluent, we removed the medium, and added 3ml fresh complete media and continue to incubate for 24h, then collected the supernatant to test the concentration of CEA with radioimmunologic assay.

The sensitivity of cells infected by adenovirus to 5-FC

Lovo or Hela cells were seeded at a concentration of 2000 cells/well on 96-well, flat-bottom microplates in medium supplemented with 100ml·L^{-1} FBS. After 12h, cells were infected by adenoviruses in different multiplicity of infection (M.O.I). After 12h, cells were cultivated in fresh medium containing various concentrations of 5-FC (0, 0.15, 1.5, 15, 150, 1500 and 15000μmol·L^{-1};Sigma). After 48h of incubation with the drug, cell viability was measured using MTT (Huamei Corporation) assay. The fifty percent inhibition concentration (IC_{50}) of 5-FC was calculated using a curve-fitting parameter, and the results were represented as the means±SD from three independent experiments.

The bystander effect of AdCEACD/5-FC

After tumor cells had been infected by adenovirus for 12h in 1000 M.O.I, the bystander effect was measured by co-culturing different proportions of transfected cells and untransfected cells at a concentration of 2×10^5 cells/well on 6-well, flat-bottom plates in 5-FC-containing medium that was replaced every day. After 5d of incubation with the drug, cell viability was measured by counting live cells with typan blue staining.

Statistical Analysis

Quantitative results were expressed as the mean ± SD of the mean. Statistical analysis was performed using ANOVA test. $P<0.05$ was considered statistically significant.

RESULTS

Construction of shuttle plasmid pAdCEACD

The structure of pAdCEACD is depicted in Figure1. The map of pAdCEACD after treatment with restriction endonuclease is showed in Figure 2.

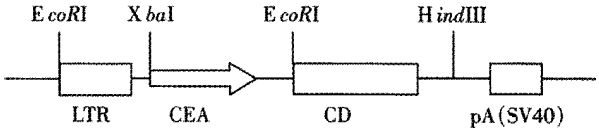

Figure 1 Schematic representation of the adenovirus shuttle plasmid, LTR, left inversed terminal repeats; pA, polyadenylation signal.

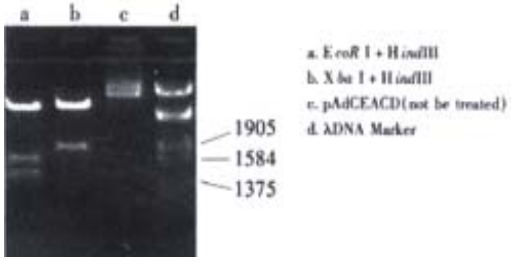

Figure 2 Map of pAdCEACD. There was a fragment of 1.8kb containing CEA and CD after being digested with XbaIand HindIII; As there were two co_RIrestriction sites, there were three fragments after treatment with $Eco_RI$and HindIII, 0.9kb for LTR and CEA, 1.3 kb for CD, 2.2kb for LTR and CEA and CD.

Identification of AdCEACD

The result of dot blotting:There were 36 clones after recombination, 11 of which were hybridized. The result is showed in Figure 3.

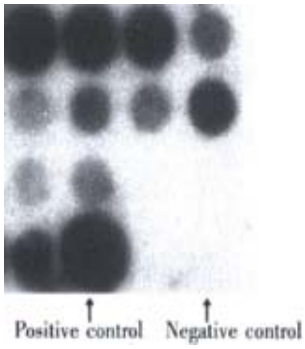

Figure 3 The identification of the recombinant adenovirus AdCEACD by dot blotting

During dot blotting the expression plasmid CEACD was used as positive control while virus AdCMVLacZ was used as negative control. The three well around negative controls were vacancy. The result showed that 6 of 11 clones were positive(over 50 percent). The left upper clone was to be further identified. The result of PCR Figure 4.

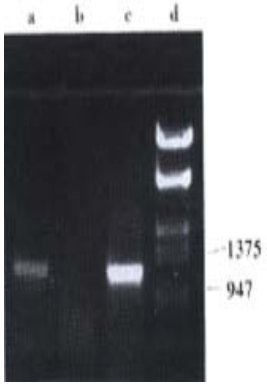

Figure 4 The identification of the recombinant adenovirus AdCEACD by PCR. a, PCR product using AdCEACD as templet; b, PCR product using pAdE1CMV as templet; c, PCR product using pAdCMVCD as templet; d, λDNA Marker.

During identification by PCR, pAdCMVCD was used as positive control while pAdE1CMV as negative control. The result showed that the recombinant adenovirus (left upper clone) contained CD gene in its genome.

The titration of AdCEACD

After purification the titration of the recombinant adenovirus AdCEACD was 5.0×10^{14}pfu/L^{-1}.

CEA secretions of Lovo or Hela

The concentration of CEA in the supernatant of Lovo cells was estimated to be 100μg·L^{-1},while lower 0.5μg·L^{-1} (beyond test) in the supernatant of Hela cells. So we consider that Lovo cell is CEA-producing and Hela cell CEA-nonproducing.

Sensitivity of the cells infected with AdCMVCD to 5-FC (Figure 5)

CMV promoter is ubiquitously strong, and effective in a variety of cells and tissues. As showed in Figure 5, after infected with AdCMVCD, the sensitivity of both Lovo cells (CEA-positive) and Hela cells (CEA-negative) to 5-FC had been enhanced, the IC_{50} values of 5-FC for Lovo cells and Hela cells infected with AdCMVCD at 10 M.O.I were 128.8±25.4 and 214.5±31.3μmol·L^{-1}, respectively, while the value of IC_{50} for parent cells of these two cell lines was more than 15000μmol·L^{-1} (P<0.001, respectively). The cytotoxicity of 5-FC increased accordingly when the m.o.i of adenovirus was enhanced, the value of IC_{50} was reduced to 24.8±7.1 and 23.9±5.2μmol·L^{-1}, respectively, when the adenovirus concentration was 100 M.O.I(P<0.01, respectively).

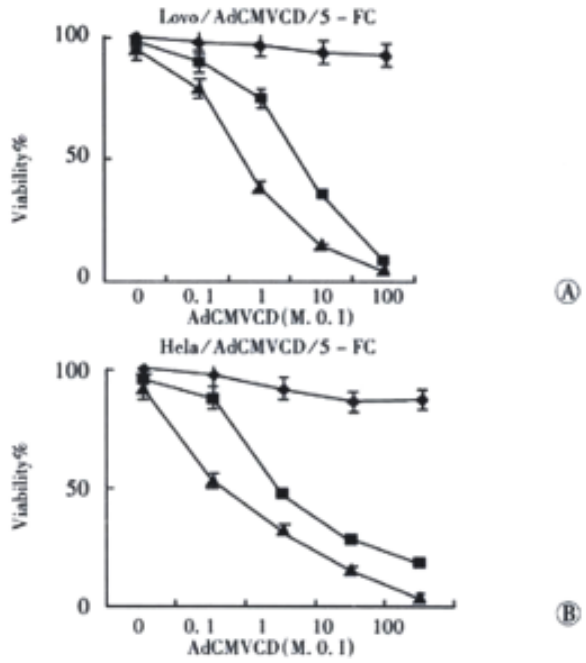

Figure 5 Sensitivity of cells infected with AdCMVCD to 5-FC.◆:5-FC 0;■: 5-FC,15μmol·L^{-1};▲:5-FC,150μmol·L^{-1}.

Sensitivity of the cells infected with AdCEACD to 5-FC (Figure 6)

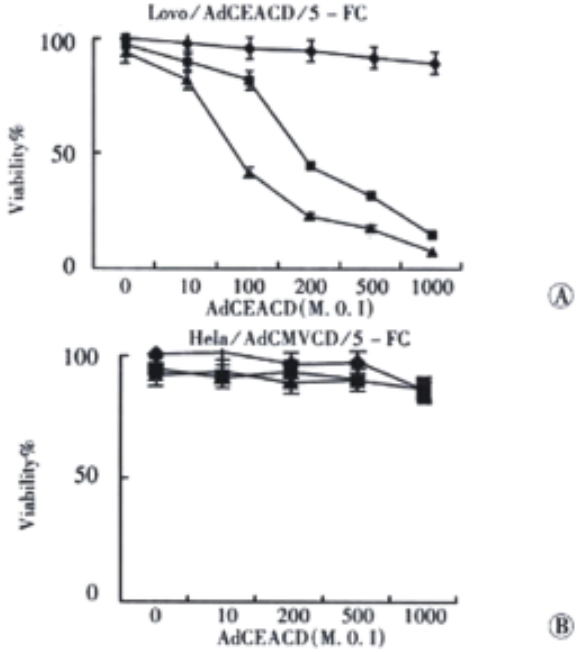

Figure 6 Sensitivity of cells infected with AdCEACD to 5-FC. ◆:5-FC 0;■: 5-FC,15μmol·L^{-1};▲:5-FC,150μmol·L^{-1}.

CEA promoter is cell- or tissue- specific, so it makes CD gene express only in CEA-producing cells. Figure 6 shows that, human colorectal carcinoma cell strain Lovo cells (CEA-positive) became sensitive to 5-FC significantly when they were infected with AdCEACD, the IC_{50} of 5-FC for Lovo cells infected with AdCEACD

at 100 M.O.I was 216.5±38.1μmol·L^{-1} (P<0.001,compared with the IC_{50} of 5-FC in parent Lovo cells). The cytotoxicity of 5-FC increased accordingly when the m.o.i of adenovirus was enhanced, the value of IC_{50} of 5-FC was reduced to 27.9±4.2μmol·L^{-1} in Lovo cells infected with 1000 M.O.I AdCEACD(P<0.05). However, the sensitivity of Hela cells (CEA-negative) infected with AdCEACD to 5-FC was not enhanced (the IC_{50} of 5-FC in 100 M.O.I AdCEACD infected Hela cells and 1000 M.O.I AdCEACD infected Hela cells was more than 15000μmol·L^{-1} too, P>0.05, compared with the IC_{50} of 5-FC in parent Hela cells, respectively), indicating that AdCEACD/5-FC system can result in specific killing of CEA-producing cells.

The bystander effect of AdCEACD/5-FC system (Figure 7)

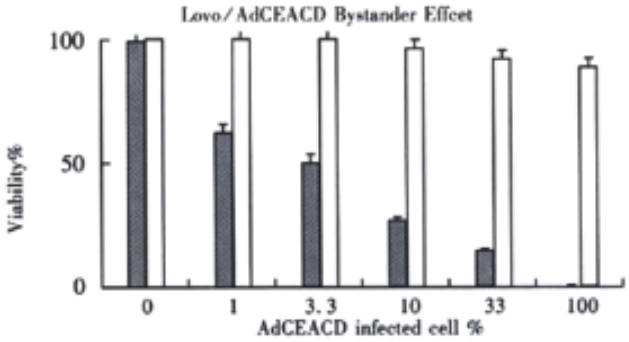

Figure 7 The bystander effect of AdCEACD/5-FC system.□:without 5-FC;■:5-FC 150μmol·L^{-1}

After tumor cells had been infected by AdCEACD for 12h in 1000 M.O.I, the bystander effect was measured by co-culturing different proportions of transfected cells and untransfected cells at a concentration of 2×10^5 cells/well on 6-well, flat-bottom plates in 5-FC-containing medium that was replaced every day. After 5d of incubation with the drug, cell viability decreased significantly. The viability was 24.7±3.4% when the proportion of transfected cells was only 10 percent, while the value of according control was 98.7±8.9%(P<0.05), indicating that the AdCEACD/5-FC system had excellent bystander effect.

DISCUSSION

Gene therapy has made rapid progress during the past few years and appears to be approaching clinical application in medical practice[32-35]. Cancer is one of the most common causes of death in many countries and conventional treatments have not been able to cope with cancer adequately. Advances in our knowledge of molecular biology of cancer have brought a better understanding of the pathomechanism, as well as the development of molecular diagnostics and the basics of gene therapy. Cancer protocols (both marker and therapy) constitute about 70 percent of all current gene therapy protocols. Suicide gene therapy is one of these protocols and has a promising perspective. The purpose of this study is to apply CD gene, one of suicide genes, to treat colorectal carcinoma. One of the most important techniques of gene therapy is the choice of certain vector for gene transfer. Vectors are carriers or delivery vehicles for therapeutic genetic materials. There are two kinds of vectors available, non-viral vectors and viral vectors, the former contains liposomes, ligand-polylysine-DNA-complexes, dendrimers, cochleates, synthetic peptide complexes, electroporation and microinjection, etc, while the latter is composed of retroviral vectors, adenoviral vectors and adeno-associated virus vector.

Adenovirus vector system has many advantages. Adenovirus vectors can be prepared at much higher titres than retroviral vectors and have a high efficiency gene transfer regardless of the proliferative state of the tissues whereas retroviral vectors insert their genes only into dividing cells. Adenovirus genomes usually do not integrate into the host cell chromosome[36-42]. Although the duration of *in vivo* gene expression with adenovirus vector is short, the level of therapeutic gene expression is much higher. The purpose of suicide gene therapy is to kill transfected cells, so we choose adenoviral vector for suicide gene transfer. Suicide gene with efficient expression disappears rapidly after transfected tumor cells are killed, resulting in minimizing the underlying side effects of suicide gene. The adenovirus can infect a wide range of different cells, making it impossible to deliver genes to special target cells by intravenous administration. CD gene encodes cytosine deaminase which can transform 5-FC to cytotoxic 5-FU. 5-FU is often used for the treatment of colorectal carcinoma in combination with another chemotherapeutic agent. It causes cell death by inhibiting both RNA and DNA syntheses. If CD gene is delivered into normal cells, it maykill them when 5-FC is administrated.

The ability to target gene transfer to a particular class of cells is an important aspect of improving efficacy of gene therapy and limiting undesirable side effects. Ideal gene therapy vectors would be delivered intravenously to transfect only specific cells. Exiting vectors only transfect cells *in vivo* in a manner determined by blood flow and the site of introduction. Various strategies for targeted gene therapy have been designed, one of which is transcriptional targeting[43-46]. For certain procedures it may be necessary to deliver genes under the control of appropriate tissue- or cell-specific promoters, perhaps for the lifetime of the individual[47-50]. Transcriptional targeting of vectors is important for gene therapy of cancer because of the requirement to limit toxic therapies to the malignant target cells. It may be possible to identify and use transcriptional control elements that drive expression of proteins unique to, or overexpressed in malignant cells. These genes would reduce collateral expression of the transgene, and hence toxicity to healthy cells. For colorectal carcinoma, carcino-embryonic antigen (CEA) is one of such elements. CEA is a tumor-associated marker for human colorectal carcinoma and CEA is transcriptionally silent in adult normal tissues but over-expressed in approximate 60 to 80 percent human colorectal carcinomas[51-54]. Therefore we have used CEA as a transcriptional element to construct a new replication-deficient recombinant adenoviral vector containing CD gene controlled under CEA promoter in this study, and we have constructed the desired adenovirus vector, AdCEACD, successfully. We have applied dot bloting and PCR to identify CEA gene and CD gene in the vector respectively. *in vitro* experiments have showed the vector delivers CD gene only to CEA-producing cells, and only CEA-producing cells can be killed by 5-FC.

Currently available *in vivo* gene transfer vectors are not capable of transferring a gene to all tumor cells; however, successful application of suicide gene therapy in vivo relies on the bystander effect, where the active chemotherapeutic agent diffuses in the tumor cells and neighboring malignant cells in sufficient concentrations to suppress growth. In this study we also demonstrated that the AdCEACD/5-FC system presented bystander effect, as did AdCMVCD. The correction between CEA secretion and induction of CD activity and 5-FC/5-FU sensitivity is not straightforward. It is presumed that transcriptuional targeting is due to transcriptional activation. There are transcriptional activators in CEA-producing cells, which can activate CEA promoter, hence can drive the expression of CD gene, whereas CEA-nonproducing cells lack certain activators and CD gene can not express. The current results suggest that the recombinant adenovirus transfer of the CD gene under control of CEA promoter could theoretically be a useful vector for the CEA-producing tumors, such as colorectal carcinoma. It is not perfect that

Hela cells had been used as CEA-nonproducing cell control, but we lack cell lines of normal intestinal mucosa or normal bone marrow. We will continue this research in vivo to further investigate the specificity of the recombinant adenoviral vector AdCEACD.

Abstract

AIM: **To establish a convenient immunoassay method based on recombinant antigen preS1(21-119aa) to detect anti-preS1 antibodies and evaluate the clinical significance of antibodies in hepatitis B.**

METHODS: **The expression plasmid pET-28a-preS1 was constructed, and a large quantity of preS1(21-119aa) fragment of the large HBsAg protein was obtained. The preS1 fragment purified by Ni^{2+}-IDA affinity chromatography was used as coated antigen to establish the indirect ELISA based on streptavidin-biotin system for detection of the anti-preS1 antibodies in sera from HBV-infected patients. For follow-up study, serial sera were collected during the clinical course of 21 HBV-infected patients and anti-preS1 antibodies, preS1 antigen, HBV-DNA and other serological HBV markers were analyzed.**

RESULTS: **preS1(21-119aa) fragment was highly expressed from the plasmid pET-28a-preS1 in a soluble form in *E.Coli* (30mg·L^{-1}), and easily purified to high purity over 90% by one step of Ni^{2+}-IDA-sepharose 6B affinity chromatography. The purity and antigenicity of the purified preS1(21-119aa) protein was determined by 150g·L^{-1} SDS-PAGE, Western blot and a direct ELISA. Recombinant preS1(21-119aa) protein was successfully applied in the immunoassay which could sensitively detect the anti-preS1 antibodies in serum specimens of acute or chronic hepatitis B patients. Results showed that more than half of 19 acute hepatitis B patients produced anti-preS1 antibodies during recovery of the disease, however, the response was only found in a few of chronic patients. In the clinical follow-up study of 11 patients with anti-preS1 positive serological profile, HBsAg and HBV-DNA clearance occurred in 6 of 10 acute hepatitis B patients in 5-6 months, and seroconversion of HBeAg and disappearance of HBV-DNA occurred in 1 chronic patients treated with lavumidine, a antiviral agent.**

CONCLUSION: **The high-purity preS1(21-119aa) coated antigen was successfully prepared by gene expression and affinity chromatography. Using this antigen, a conveniently detective system of anti-preS1 antibodies in sera was established. Preliminarily clinical trial the occurrence of anti-preS1 antibodies in acute hepatitis B patients suggests the clearance of HBV from serum in a short-term time, and anti-preS1 positive in chronic patients means health improvement or recovery from the disease.**

Wei J, Wang YQ, Lu ZM, Li GD, Wang Y, Zhang ZC. Detection of anti-preS1 antibodies for recovery of hepatitis B patients by immunoassay. *World J Gastroenterol* 2002;8(2):276-281

INTRODUCTION

Human hepatitis B virus (HBV) is a small enveloped DNA virus which causes acute and chronic hepatitis in humans[1]. Worldwide, the number of infected persons is predicted to reach 400 million during 2000. Areas with high prevalence of HBV include China[2,3], Southeast Asia and Africa, where approximately 10% of the population are chronic carriers[4]. The envelope of HBV contains three related proteins, encoded by the S open reading frame (ORF) of the viral genome, composed of three regions: preS1, preS2 and S. The major protein, termed small HBs protein (SHBs), is encoded by the S gene, whereas the two minor envelop proteins, termed the middle protein (MHBs) and the large protein (LHBs), are encoded by the preS2+S and preS1+preS2+S region, respectively[5]. The preS1 region contains epitopes that elicit immune responses at the B-cell and T-cell level over a broader range of MHC haplotypes than those on the preS2 and S protein[6-8]. The preS1 domain also contains potential viral attachment sites to hepatocytes[9] and elicit antibodies capable of neutralizing HBV in the chimpanzee[10].

The preS1 epitopes has been extensively analyzed using synthetic peptides, anti-peptide sera and anti-preS1 monoclonal antibodies. B cell epitopes have been mapped to residues 27-35aa, 72-78aa, 32-47aa, 41-53aa, 94-105aa and 106-117aa in the preS1 region[11-13]; and T cell epitopes mainly located in residues 12-21aa, 21-30aa, 29-48aa and 94-117aa of the preS1 region[13, 14]. These findings explain why the preS1 region has good immunogenicity and can easily elicit the anti-preS1 responses[15]. Additionally, nearly all preS1 epitopes concentrate on residues 21-119aa in the preS1 region (ad subtypes of HBV LHBs carry a 119aa-residue preS1, and HBV in most Chinese belong to adr subtype; 8 residues on N-terminus of preS1 are absent in ay subtype). Because the preS1 region locates on the outside of the mature virion and has many overlapping epitopes, anti-preS1 immune response occurred early in the course of the disease and is involved in the clearance and neutralization of HBV. As anti-preS1 antibodies have been mainly detected early during acute hepatitis B[16, 17], the anti-preS1 antibodies could represent an early serological marker for HBV clearance[18]. About 1/2 of subjects in the convalescence phase of acute hepatitis B were serological positive for anti-preS1 antibodies, whereas persistence of preS1 antigen and lack of corresponding antibodies have been the predict of the evolution of a chronic course of disease[19]. In this study, preS1(21-119aa) peptide was chosen and highly expressed in a soluble form. Using this protein as the antigen, an effective enzyme-linked immunosorbent assay was established. The sensitive test can provide a basis for monitoring anti-preS1 in sera of patients with hepatitis B and offers a prognostic implication for patients.

MATERIALS AND METHODS

Materials

Plasmids, *E.Coli* strain The plasmid pADR-1 containing HBV genome (adr subtype) was constructed by Wu *et al*[20]. Expression vector pET-28a(+) was purchased from Novagen. *E.Coli* strain BL21 (DE3)plysS was used for the production of the preS1(21-119aa) peptide.

Enzymes and Reagents Restriction enzymes and T_4 DNA ligase were purchased from New England Biolabs, Boehringer Mannheim and GIBCO BRL. DNA sequence kit was from USB. Agrose and LMP agarose were from GIBCO BRL. Acrylamide, bisacrylamide, isopropylthio-β-D-galactoside (IPTG), imidazole and iminodiacetic acid (IDA)-Sepharose 6B, biotinamidocaproate-N-hydroxy-succinimide ester (BNSE) and 3,3',5,5'-tetramethylbenzidine (TMB) were from Sigma. Protein A was from Pharmacia. Diaminobenzidine (DAB) and streptavidin-horseradish peroxidase (HRP) conjugate were from Sino-American Biotech. Anti-preS1(21-47aa) monoclonal antibody (mAb) 125E11 and 125E11 conjugated with HRP were made in our lab[21]. Tetrabutyl ammoniumborohydride (TBABH) was from Fluka.

Serum specimens and kits for HBV markers Serum specimens were collected from patients admitted to the Rui-Jin Hospital with clinical and biochemical evidence of hepatitis B. As a control, sera of healthy persons with normal liver function and without any markers of HBV infection were used. HBsAg and anti-HBs, HBeAg and anti-HBe, anti-HBc were determined by commercially available ELISA kits from Abbott laboratories. PreS1 protein were detected by a double mAb sandwich ELISA[22]. HBV-DNA level in serum samples was assayed by HBV PCR fluorogence diagnostic kit from PJ (Shenzhen,China).

Methods

Construction of expression plasmid containing preS1(21-119aa) DNA sequence.

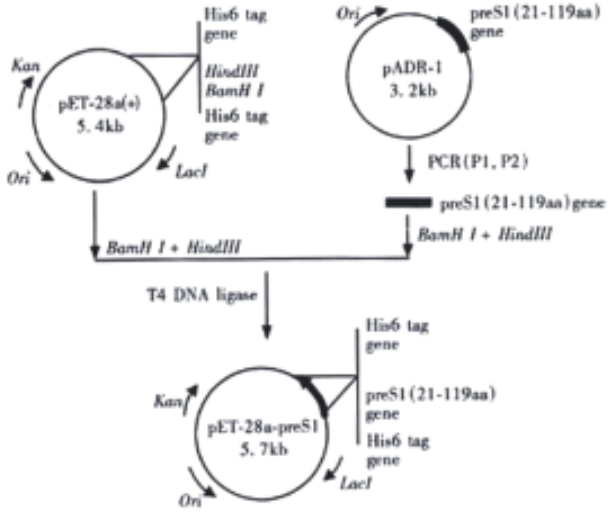

Figure 1 Construction of expression plasmid pET-28a-preS1

Figure 1 depicts the steps leading to the final construction of the expression plasmid pET-28a-preS1 which expresses a fusion protein containing preS1(21-119aa) peptide with His6 tags. PCR primers were designed as follows:

Forward primer P_1: 5'-CATAGGATCCCCTCTGGGATTCTTT-3'
*Bam*HI
Reverse primer P_2: 5'-ATCG AAGCTTGAATTC GGCCTGAGGATGACT-3'
*Hin*dIII *Eco*RI

Preparation of plasmid DNA, PCR, digestion of DNA with restriction enzymes, agarose gel electrophoresis, recovery and purification of DNA fragment, ligation of terminus created by restriction enzymes and transformation of competent *E.Coli* were performed according to Sambrook[23].

Cell culturing and harvesting *E.Coli* strain BL21(DE3)plysS cells harboring the expression plasmid pET-28a-preS1 were inoculated into LB medium containing kanamycin (50mg·L^{-1}). The seed culture was inoculated into 100-fold volume of fresh LB medium (kanamycin, 50mg·L^{-1}) and cultured at 37℃ up to 0.4-0.6 of A_{600}. To this culture IPTG was added to give a final concentration of 0.2mmol·L^{-1}, and incubation was continued at 37℃ for 6h or 22℃ for 24h. The induced cells, as well as the uninduced cells, were harvested by centrifugation, and cell lysates were analyzed by 150g·L^{-1} SDS-PAGE.

Western analysis of the preS1(21-119aa) fusion protein After SDS-PAGE, proteins were transferred to nitrocellulose membrane (Schleicher & Schuell), and the membrane was incubated with a murine monoclonal antibody 125E11 (1:1000, volume ratio), which recognizes preS1(21-47aa) fragment within the preS1 region, followed by goat anti-mouse IgG peroxidase conjugate (1:1000, volume ratio). After washing, substrate solution containing DAB (0.5g·L^{-1}) and H_2O_2 (0.02mL·L^{-1}) was added to have 125E11 specific binding protein bands visualized.

Purification of the preS1(21-119aa) fusion protein In order to characterize whether the expressed fusion protein is soluble or insoluble, the cell pellet from 100ml culture was resuspended in 4ml buffer A (20mmol·L^{-1} Tris-HCl pH7.9, 0.5mol·L^{-1} NaCl, 100g·L^{-1} glycerol, 1mmol·L^{-1} PMSF, 25mmol·L^{-1} imidazole), and sonicated in ice bath. Then the sonicate was centrifuged at 18000r.min for 15min, and the resulting supernatant was concentrated to 2mL and the pellet was resuspended in 2mL buffer A as the insoluble protein sample. The soluble and insoluble samples were subjected to 150g·L^{-1} SDS-PAGE and Western blot analysis.

2mL supernatant was applied to 2mL Ni^{2+}-IDA sepharose 6B column (2mL) preequilibraed with buffer A at 4℃. The column was washed with 30ml buffer B (20mmol·L^{-1} Tri-HCl pH7.9, 0.5mol·L^{-1} NaCl, 100g·L^{-1} glycerol, 1mmol·L^{-1} PMSF, 45mmol·L^{-1} imidazole), and the bound protein was eluted with 4mL buffer C (20mmol·L^{-1} Tri-HCl pH7.9, 0.5mol·L^{-1} NaCl, 100g·L^{-1} glycerol, 1mmol·L^{-1} PMSF, 100mmol·L^{-1} imidazole) and the elution samples were collected[24, 25]. The fractions enriched for preS1(21-119aa)-His_6 tag fusion protein was identified by 150g·L^{-1} SDS-PAGE and Western blot analysis.

Biotin labeling of protein A The procedure is essentially the same as that described by Kittigul *et al*[26]. Protein A (2.0g·L^{-1}) is dialyzed against 0.01mol·L^{-1} $NaHCO_3$ at 4℃. After dialysis, 1mL of the protein A solution was mixed with 120μL of BNSE (1.0g·L^{-1} in dimethyl sulfoxide). The mixture was incubated at 4℃ overnight and dialyzed overnight against PBS at 4℃ with several changes of PBS.

Antigenicity analysis of preS1(21-119aa) domain of the fusion protein The antigenicity of preS1(21-119aa) fusion protein was analyzed by a direct ELISA. The microtiter plate was coated with preS1(21-119aa) fusion protein from 10 to 2500ng/well, and mAb 125E11 labeled with HRP was added to each well and incubated at 37℃ for 1h. The plate was washed, and substrate solution containing TMB (7.5g·L^{-1}) and H_2O_2 (0.3mL·L^{-1}) was added to each well to develope a color change, then the reaction was stopped with 1.0mol·L^{-1} H_2SO_4 and A (absorbance) value was measured at 450nm in an ELISA reader (Labsystem Multiscan, Finland).

Establishment of indirect ELISA for detecting anti-preS1 antibodies in serum The optimal dilutions of the reagents are

determined by checkerboard titration. Mirotiter plates (Nunc, Denmark) were coated by incubation overnight at 4℃ with 2mg·L^{-1} preS1(21-119aa) protein in 100μL volume of per well in carbonate buffer (15mmol·L^{-1} Na_2CO_3, 35mmol·L^{-1} $NaHCO_3$, pH9.6). The microplates were then washed three times with a washing solution (20mmol·L^{-1} Tris-HCl pH7.4, 0.5mL·L^{-1} Tween-20), and postcoated with 5g·L^{-1} bovine serum albumin (BSA) in PB (2.7mmol·L^{-1} KCl, 0.5mmol·L^{-1} KH_2PO_4, 6.5mmol·L^{-1} Na_2HPO_4, pH7.5) for 1h at 37℃. After washing, 100μL diluted serum samples [1:30 in PBFST (100mL·L^{-1} fetal calf serum(FCS), 0.5mol·L^{-1} NaCl and 0.5g·L^{-1} Tween-20 in PB] were added and incubated for 2h at 37℃. After washing, 100μL biotin labeled protein A solution (2mg·L^{-1} in PBFST) diluted in PBFST was dispensed into wells, and the plates were incubated for 1h at 37℃. After washing 4 times, streptavidin-HRP conjugate diluted in PBFST was added into each well of the plates, and the plates were incubated for 1h at 37℃. Finally, after washing, 100μL of the substrate mixture (1.0mmol·L^{-1} TMB, 0.2mmol·L^{-1} TBABH, 0.2mol·L^{-1} potassium citrate and 0.5mL·L^{-1} H_2O_2)[27] was added and incubated for 20min at 37℃. The reaction was stopped by the addition of 50μL of 1.0mol·L^{-1} H_2SO_4. The optical density was measured at 450nm (A_{450}) with the ELISA reader. To determine cut-off value for the established ELISA, A_{450} value of negative control for anti-preS1 antibodies was evaluated by testing a serum mixture from 100 normal individuals. The cut-off value was defined as 2.1 folds of mean of negative control. Specimens were considered to be positive when the obsorbance value exceeded the cut-off value.

Specificity of established ELISA for detection of anti-preS1 antibodies Twenty-five μL anti-preS1 antibodies positive serum with the same volume of 0.15g·L^{-1} preS1(21-119aa) protein or PBS was incubated at 37℃, and mixture was stepwise diluted and added to wells coated by preS1(21-119aa), and then indirect ELISA was performed. A parallel test with normal human serum was also performed in the same experiment.

Follow-up study The serum specimens from 11 anti-preS1 positive patients and 10 anti-preS1 negative patients with hepatitis B were collected at monthly intervals and their HBV markers[28], including HBV-DNA[29-31], HBsAg, anti-HBs, HBeAg, anti-HBe, anti-HBc, preS1[32] and anti-preS1 were analyzed.

RESULTS

Construction of expression plasmid pET-28a-preS1

PreS1(21-119aa) gene fragment was synthesized by PCR using the primers P_1, P_2 and the plasmid pADR-1 containing HBV genome (adr subtype) as the template. The PCR product was digested with *Bam*HI and *Hin*dIII and then subcloned into the *Bam*HI-*Hin*dIII sites of pET-28a(+) to yield expression plasmid pET-28a-preS1 (Figure 1). Two His tag fragments which coded a stretch of six histamine residues located in both terminus of inserted fragment, respectively. This made it easy to purify preS1(21-119aa) fusion protein by Ni^{2+}-IDA-sepharose 6B affinity chromatography. DNA sequence analysis confirmed that the expression plasmid coded the correct nucleotide sequence. The nucleotide sequence and deduced amino acid sequence of the preS1(21-119aa) region gene fragment inserted in the pET-28a-preS1 is shown in Figure 2.

Expression of preS1(21-119aa) fusion protein

In order to express the preS1(21-119aa) fusion protein, the expression plasmid pET-28a-preS1 was transformed into *E.Coli* BL21(DE3) plysS, and the cells were cultured and induced by IPTG. The expressive levels were determined by SDS-PAGE and Western blot analysis of the cell lysates. As show in lane 2 of Figure 3, more than 30% of total stainable proteins was about 17000 fusion protein. The analysis of solubility showed that about 80% of the fusion protein was soluble (lane 3 of Figure 3). Thus, the soluble form was convenient for the followed purification and clinical application.

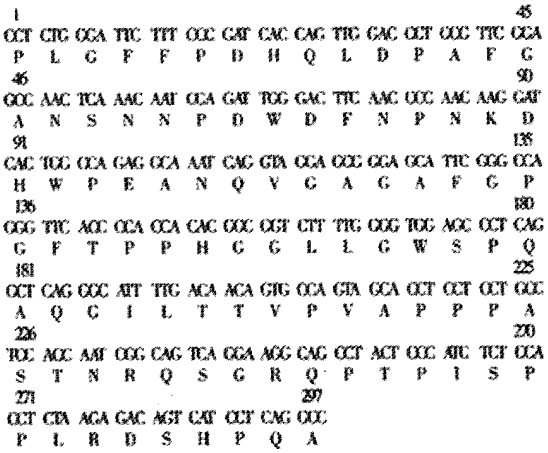

Figure 2 Nucleotide and derived amino acid sequence of PreS1(21-119aa) region gene fragment inserted into the expression vector pET-28a-preS1.

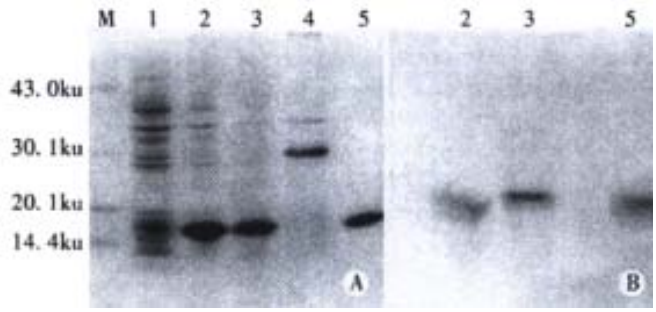

Figure 3 Expression and intracellular location of preS1(21-119aa) in *E.Coli*. BL21(DE3)plysS cells. Protein samples were subjected to 15% SDS-PAGE and stained with Commassia brilliant blue (A), and the duplicate gel was electroblotted onto a nitrocellulose membrane for western analysis (B). Lane M: molecular mass standards. Lane 1-2 are culture lysates of uninduced BL21 cells (lane 1) and induced BL21 cells (lane 2). Lane 3,4: Supernatant (soluble) and precipitate (insoluble) fractions, respectively; Lane5: purified fusion protein by Ni^{2+}-IDA-sepharose 6B.

Purification and antigenicity analysis of the preS1(21-119aa) fusion protein

The fusion protein was purified by affinity chromatography on Ni^{2+}-IDA sepharose 6B column as described in Materials and Methods. The purity of purified fusion proteins was evaluated to be over 90% (Lane 5, Figure 3). In order to analyze antigenicity of the fusion proteins, microtiter plates were coated with stepwise diluted solutions (from 2500ng to 10ng per well) of purified preS1(21-119aa) protein, GST-preS1(21-47aa) or artificially synthesized preS1(21-47aa) peptide. Direct ELISA showed that they all reacted well with the preS1-specific mAb 125E11 in a dose-dependent manner, meanwhile the antigenicity of preS1(21-119aa) protein was better than GST-preS1(21-47aa) and much better than synthesized preS1(21-47aa) peptide (Figure 4).

Detection of anti- preS1(21-119aa) antibodies in sera from hepatitis B patients

In order to observe specificity of established indirect ELISA, anti-preS1 antibodies positive serum (confirmed by Western Blotting) was preincubated with preS1(21-119aa) fusion protein and used to test. The result showed in a drop of the extinction to a value close to the negative control, thus demonstrating specificity of the method (Figure 5).

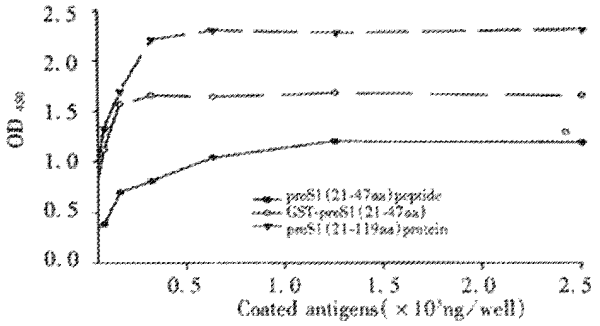

Figure 4 Immunoreactivity of preS1(21-119aa), GST-preS1(21-47aa) peptide. Microtiter plate was coated with different amount (10-2500ng) of the purified preS1 proteins or peptide. Then direct ELISA was performed.

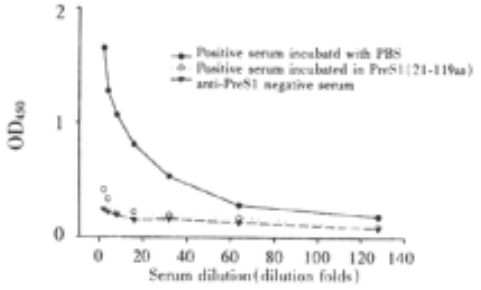

Figure 5 Specificity test of indirect ELISA for detection of anti-preS1 antibodies

In order to inspect established indirect ELISA, 192 serum specimens were collected from patients admitted to the Rui-Jin Hospital, Shanghai Second Medical University. Among them, there were 92 serum specimens with clinical and biochemical evidence of hepatitis B; and 100 sera of individuals without any markers of HBV infection and with normal liver function were assigned as negative controls. Additionally, 3 sera known to contain antibodies against preS1(21-119aa) with different level tested by Western analysis were used as positive controls. Through the indirect ELISA based on recombinant preS1(21-119aa) fusion protein, anti-preS1 antibodies were detected in none of 100 HBV negative controls. In HBsAg positive individuals (Table 1), anti-preS1 antibodies were noted in more than half of patients with acute hepatitis before or after recovery, but only found in a few of patients with chronic hepatitis, and the level of anti-preS1 antibodies had significant difference between acute hepatitis patients and chronic hepatitis patients (*t* test, $P<0.01$).

Table 1 Anti-preS1 antibodies in HBV-infected patients detected by indirect biotin-labeled protein A ELISA

Subjects	*n*	anti-preS1 Ab(+)	positive/%
Acute hepatitis			
Before recovery(HBsAg+)	16	10	62.5
After recovery (HBsAg-)	17	9	52.9
Chronic carriers			
Healthy chronic carriers	30	1	3.3
Chronic hepatitis	29	2	6.9
Total	92	22	23.9
Control (negative forall HBV markers)	100	0	0.0

Follow-up study

Diagnosed by clinical symptoms and serological profile, the inpatients for follow-up study were assigned to 10 acute hepatitis patients and 11 chronic hepatitis patients. Sera from 21 hepatitis B inpatients were collected at monthly intervals in half a year and anti-preS1 antibodies were detected by indirect ELISA. In Figure 6A, a typical profile of an acute episode of hepatitis B followed by seroconversion to anti-preS1 are presented. HBV-DNA and preS1 antigen were detectable simultaneously in the acute phase of the disease. Anti-preS1 developed early in infection, still in the presence of low level of preS1 antigen, and climbed the highest with disappearance of HBV-DNA and preS1 antigen. The results of detection of the other serological markers showed that anti-HBe and antiBs in sera of patients was followed by appearance of anti-preS1 antibodies.

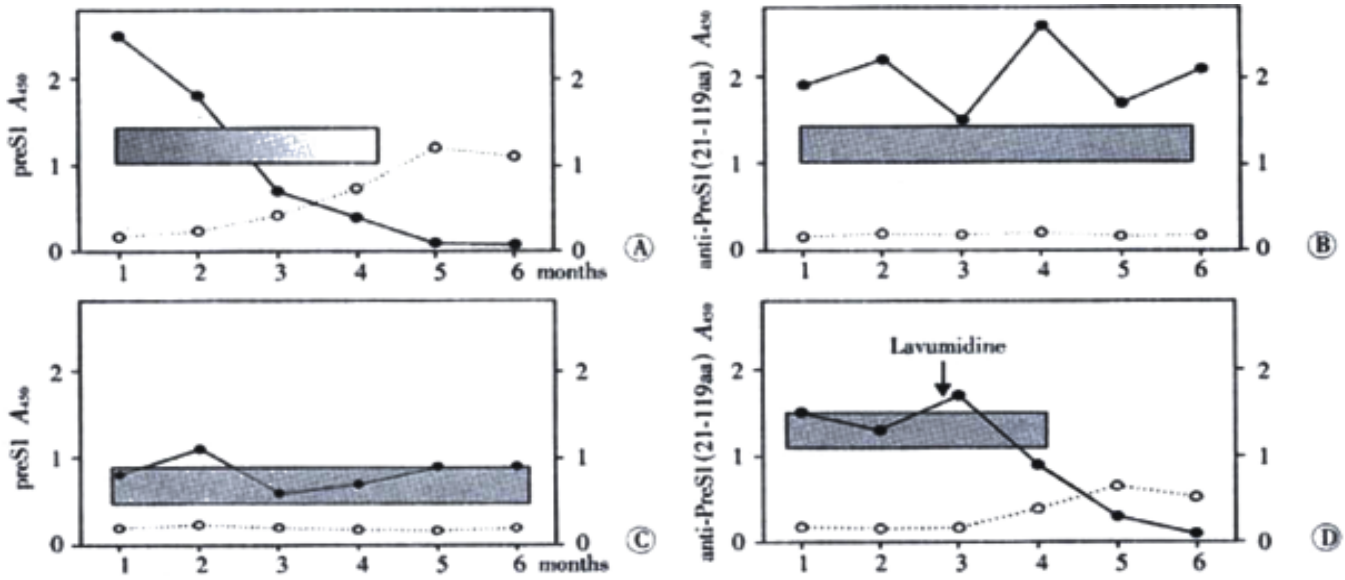

Figure 6 The profiles of serologic markers during acute chronic HBV infection with immuno-diagnosis for preS1 antigen and anti-preS1 (21-119aa) antibodies. A: Typical serologic profile of HBV markers during acute infection, with disappearance of preS1 antigen and seroconversion to anti-preS1(21-119aa) antibodies; elimination of HBV-DNA in 2-4 months from the appearance of antibodies. B: Chronic patients with HBeAg+ serologic profile; high level of preS1 antigen and HBV-DNA but absence of anti-preS1(21-119aa) antibodies. C: Chronic patients with anti-HBe+ serologic profile; low level of preS1 domain and HBV-DNA and absence of anti-preS1(21-119aa) antibodies. D:One patient persisting of HBsAg, HBeAg and preS1 for almost 3 years until treated with Lamivudine. Appearance of anti-preS1(21-119aa) antibodies with simultaneous health improvement; disappearance of HBV-DNA and declining level of preS1 antigen in serum. OD_{450} value of Y axis ('•'preS1 antigen and '。' anti-preS1 antibody) was mean value of inpatients in every group; different shade (■) in the rectangle (A) represented different level of HBV-DNA in patients.

Ten chronic hepatitis B inpatients were divided into two groups: one group was healthy chronic carriers (Figure 6B) who were seropositive HBeAg and high level of HBV-DNA and preS1 antigen; the other group was chronic hepatitis B patients (Figure 6C) who had seropositive anti-HBe and low level of HBV-DNA and preS1 antigen during the course of the disease. During follow-up period, anti-preS1 antibodies were not found and there were no apparent improvement in both groups. Interestedly, a patient (Figure 6.D) treated with lavumidine, a anti-HBV-DNA replication agent, was different from the other chronic patients. Seroconversion of preS1 antigen to anti-preS1 antibodies was observed after lavumidine treatment. Although no elimination of HBsAg was observed in this patient, the development of anti-preS1 response correlated well with improvement in health.

DISCUSSION

The PreS1 domain is found exclusively in LHBs, which is a major component of the envelope of mature virions, but it is significantly less represented in subviral particles of HBV[5]. These findings suggest that PreS1 domain is located on the out surface of the virion and thought to be involved in virus-host cell interaction[33-35]. Moreover, a sequence between amino acid residues 21 and 47 of the PreS1 domain was found to be the dominant binding site for hepatocytes[9, 36-38]. PreS1 domain induces an immune responses in patients recovering from HBV infection and are considered to be essential in initiating the clearance of the infectious virus for recovery from HBV infection[19, 39]. Above materials indicate that the anti-preS1 antibodies in the serum of hepatitis B patients may well be a new serological marker for clinical diagnosis of hepatitis B. Previous experimental data showed that none of important epitopes were found in preS1(1-20aa) fragment. Therefore, in present study preS1(21-119aa) sequence of HBV (adr subtype) envelope protein was chosen for recombinant expression and application for detection of anti-preS1 antibodies.

Under the control of inducible T_7 promoter, preS1(21-119aa) fusion protein was highly expressed in soluble form by the expression plasmid pET-28a-preS1 transfected BL21(DE3)plysS cells, and was easily purified by single step of affinity chromatography, owing to His6 tags on both terminus of preS1(21-119aa) sequence.The antigenic properties of the recombinant preS1(21-119aa) protein were determined by the reactivity with anti-preS1 monoclonal antibody 125E11, which recognizes a linear preS1 sequence between 21aa and 47aa[21], and it is suitable for identification of preS1 proteins containing preS1(21-47aa) fragment.

Recently, Wei *et al*[40] reported that they have expressed preS1 (21-47aa) fusion proteins, which were successfully used in preliminary trial to detect anti- preS1(21-47aa) antibody. Because there are more epitopes in preS1(21-119aa) sequence, ELISA established in this study was much better in sensitivity compared with the assay based on preS1(21-47aa) fusion proteins as coated antigen. In this study, streptavidin-biotin system was introduced into ELISA, and this system has been used widely to detect immunoglubin[41, 42]. Protein A is known to bind IgG in human and several species of animals via the Fc portion of the IgG molecule[43]. In our experimental condition, the sensitivity and specificity of ELISA based on biotin labeled protein A were much improved than ELISA based on anti-human IgG.

Clinical follow-up results showed that appearance of anti-preS1 antibody in the course of most acute hepatitis patients could predict the clearance of HBeAg and disappearance of preS1 dominants and HBV-DNA[44, 45] followed by elimination of HBsAg and seroconversion to anti-HBs. The antibodies directly against preS1 region are distinct from anti-HBs, and anti-preS1 response developed after onset of the symptom in-patients and early than other HBV-related immune-responses[46, 47]. The role of anti-preS1 antibodies might be neutralization of HBsAg with preS1-coded epitopes (particularly infective HBV virions), as the antibodies were found in most cases of acute hepatitis followed by recovery[48]. Anti-preS1 antibodies were hardly observed in patients with acute hepatitis progressing to chronic disease and in chronic hepatitis patients with continuing presence of preS1 domain and seropositive of HBeAg or anti-HBe[49, 50]. But anti-preS1 antibodies was detected in a few patients with chronic aggressive hepatitis undergoing treatment with antiviral agents, and the appearance of the antibodies correlated well with healthy improvement[51, 52]. The apparent prognostic implications of anti-preS1 antibodies are of interest in screening for this marker in hepatitis B patients.

In conclusion, the study suggested that presence of antibodies against preS1(21-119aa) region in serum during acute infection may indicate subsequent recovery. Through detection of anti-preS1(21-119aa) antibodies based on biotin-labeled protein A indirect ELISA and follow-up study, it afforded some information about the state and future prognosis of hepatitis B patients. The detection system has potential to be developed to a new kit for diagnosis and prognosis of hepatitis B patients.

Abstract

AIM: **To set up a new method to detect tissue inhibitors of metalloproteinase-1 and -2(TIMP-1 and TIMP-2) in sera of patients with hepatic cirrhosis, and to investigate the expression and location of TIMP-1 and TIMP-2 in liver tissue of patients with hepatic cirrhosis, and the correlation between TIMPs in liver and those in sera so as to discuss whether TIMPs can be used as a diagnosis index of hepatic fibrosis.**

METHODS: **The monoclonal antibodies (McAbs) of TIMP-1 and TIMP-2 were used to sensitize erythrocytes, and solid-phase absorption to sensitized erythrocytes (SPASE) was used to detect TIMP-1 and TIMP-2 in the sera of patients with hepatic cirrhosis. Meanwhile, with the method of *in situ* hybridization and immunohistochemistry, we studied the mRNA expression and antigen location of TIMP-1 and TIMP-2 in the livers of 40 hepatic cirrhosis patients with pathologic diagnosis.**

RESULTS: **With SPASE, they were 16.4% higher in the acute hepatitis group, 33.3% higher in the chronic hepatitis group, and the positive rates were 73.6% and 61.2% respectively in sera of hepatic cirrhosis patients, which were remarkably higher than those in chronic hepatitis and acute hepatitis group ($P<0.001$). In 40 samples of hepatic cirrhosis tissues, all of them showed positive expression of TIMP-1 and TIMP-2 mRNA detected with immunohistochemistry or *in situ* hybridization (positive rate was 100%). Expression of TIMPs in different degrees could be found in liver tissue with cirrhosis. TIMPs were located in cytoplasm of liver cells of patients with hepatic cirrhosis. There was a significant correlation between serum TIMPs level and liver TIMPs level.**

CONCLUSION: **SPASE is a useful method to detect the TIMP-1 and TIMP-2 in sera of patients with hepatic cirrhosis, and TIMP-1 and TIMP-2 can be considered as a useful diagnostic index of hepatic fibrosis, especially TIMP-1.**

Nie QH, Cheng YQ, Xie YM, Zhou YX, Bai XG, Cao YZ. Methodologic research on TIMP-1, TIMP-2 detection as a new diagnostic index for hepatic fibrosis and its significance. *World J Gastroenterol* 2002;8(2):282-287

INTRODUCTION

SPASE (solid-phase absorption to sensitized erythrocytes) is an immunological detecting method possessing the similar principle with ELISA(enzyme-linked immunosorbent assay) and SPRIA(solid-phase radioimmunoassay)[1]. Erythrocytes sensitized by antibodies are used as the indicator, taking the place of enzyme or isotope labeled antibody. The result is judged by the hemagglutination phenomena. SPASE has the same sensitivity and specificity as ELISA and SPRIA, and is so simple and rapid as RPHA (reverse passive hemagglutination)[2,3]. The monoclonal antibodies (McAbs) of TIMP-1 and TIMP-2 were used to sensitize erythrocytes. SPASE was used to detect TIMP-1 and TIMP-2 in the sera of patients with hepatic cirrhosis, and proved pretty well. At the same time, with the method of *in situ* hybridization and immunohistochemistry, the mRNA expression and antigen location of TIMP-1 and TIMP-2 in the livers of 40 hepatic cirrhosis patients diagnosed by pathology were studied.

MATERIALS AND METHODS

Materials

The U shape 96 well plexiglass microhemagglutination plate was used as the solid phase support. The solid-phase antibody (McAbs of TIMP-1 and TIMP-2) was purchased from Maxim Biologic Technology Corp, America, (No: MAB-0282, MAB-0283). Formaldehyde-chicken or sheep erythrocytes were sensitized by TIMP-1 and TIMP-2 McAb, according to the method introduced by Han[4] to prepare for sensitized erythrocytes. The concentration of McAbs was 50-100mg·L^{-1}. The positive samples that simulated positive sample were obtained from the sera of hepatic cirrhotic patients pathologiclly diagnosed, and normal human sera were used as the negative control, and PBS as the blank control. To test the thermal stability, McAb was bathed at 60℃ water with different time, and its activity was detected by RIA.

We collected 408 serum samples from Tangdu Hospital and Xijing Hospital affiliated to the Fourth Military Medical University, and Southwest Hospital affiliated to the Third Military Medical University, The First and Fourth Hospitals of Chinese PLA. The diagnosis of viral hepatitis accorded with the diagnosis standard revised by the Fifth National Academic Conference[5] for Infectious and Parasitic Diseases. According to the standard, there were 128 serum samples of acute hepatitis, 174 of chronic hepatitis, and 106 of hepatic cirrhosis. 40 liver samples were collected from the pathologic departments of Tangdu and Xijing Hospitals affiliated to the Fourth Military Medical University. All the 40 samples were proved pathologiclly with nodular hepatic cirrhosis. Male,40; female,8;the mean age, 50 years.

Methods

Procedure of SPASE 50mg·L^{-1} McAb were added into U shape 96 well plexiglass micro hemagglutination plate (100 μL·well), to make one layer and the unnecessary solution should be removed, the sparing solution could be reused, and then dried under room

temperature, fixed at 56℃, washed with PBS 3-4 times, to get rid of the unfixed McAb molecule. 100μL per well of the prepared serum sample (diluted at the ratio volume of 1:10) was added, reacted at 37℃ for 1h, washed with PBS 3-4 times, and then 50μL per well of McAb sensitized erythrocytes were added. After shaking mixed, they were standing for 1h at 37℃ or 2h at room temperature. The results were determined according to the absorbed condition of erythrocytes (like RPHA). The erythrocytes depositing on the bottom of the well was considered as negative result, showing a spot or a little circle in the center of the well without scattered erythrocytes around. The positive result was determined when the erythrocytes were absorbed and a layer spread on the bottom of the well.

Immunohistochemical staining The laboratory procedure referred to references 6-12.SP immunostaining was performed as described by streptomycin avidin-peroxidase immunochemistry kit (purchased from Maxim Biological Technology Company). Briefly, the liver samples were embedded with paraffin, and serial sections at 4μm thickness were prepared. Paraffin was removed from the sections with xylene and rehydrated with graded ethanol. After the antigens were repaired, unspecific immunoglobulin-binding sites were blocked by a 20min preincubation with 100mL·L^{-1} normal human sera. The sections were then incubated with monoclonal antibody against TIMP-1 or TIMP-2 at 4℃ overnight, and then secondary antibody was added at 37℃ for 30-40min, avidin-peroxidase at 37℃ for 20min, and finally DAB was added to be stained. After the sections were washed several times, they were counterstained with hematoxylin, dehydrated with ethanol, rinsed in xylene, and the sections were mounted with gum for microscopic examination and photography. To make sure of the reliability and specificity of the result of immunohistochemical staining, rabbit sera and PBS were used to replace the first antibody in our control test. 10 normal liver tissues were also used as the normal control samples.

Liver tissue *in situ* hybridization The investigation procedure referred to related references[13-17]. The *in situ* hybridization kit was purchased from Boshide Biological Technology Limited Company (Wuhan, China, No. MK1549). *In situ* hybidization was performed according to the manufacturer's direction. Briefly, the paraffin embedded serial sections(thickness 4μm), were dried at 80℃, and their paraffin was removed by xylene and rehydrated with graded ethanol. The sections were acidified in HCl for 30min, and blocked in 3mL 300mL·L^{-1}H_2O_2 for 10min before digestion in proteinase K for 30min, and then dehydrated with graded ethanol. After prehybridization at 37-40℃ for 2h, the labeled cDNA probes of TIMP-1 and TIMP-2 were denatured in hybidization buffer at 95℃ for 10min,then -20℃ for 10min, added on tissues which had been prehybridized at 37℃ overnight. Sections were washed in turn with 2×SSC, 1×SSC, 0.2×SSC, and Buffer I, blocking water was added at room temperature for 20min, and then rabbit anti-digoxin serum at 37℃ for 60min, biotinylated goat anti-rabbit serum at 37℃ for 30min, SABC at 37℃ for 30min, finally DAB was added to be stained. After several times of washing, the sections were counterstained with hematoxylin, dehydrated with ethanol, rinsed in xylene, and mounted with gum for microscopic examination and photography. (1) Blank control: prehybridization solution was replaced by the cDNA probes of TIMP-1 and TIMP-2 to be hybridized with the positive liver sections; (2) Negative control: the *in situ* hybridization was performed with 10 normal liver sections.

Semi-quantitative index was used to determine the results of immunohistochemistry and *in situ* hybridization: no positive cells (-); positive cells occupied hepatocytes of hepatic lobulfe less than than1/3(+); 1/3~2/3(++); more than 2/3(+++).

RESULTS

Methodologic Optimization

The best laboratory condition and influence factors To study the related factor of sensitivity and specificity of this technique, the simulated positive samples were used, and we concluded that there were two main factors might directly influence the experiment condition. One was the concentration of coated antibodies and the other the density of sensitized erythrocytes. Much higher or less concentration of coated antibodies would decrease the sensitivity, while 50-100mg·L^{-1} might be the best (Table 1). There was a close relation between the density of sensitized erythrocytes, which is the indicator, and at 2.5·L^{-1} the sensitivity appeared to be the best (Table 2).

Degree of accuracy and repetitive test The coefficient of variation (CV) in one lot of samples in the same plate was 6.06%. The coefficient of variation (CV) in different lot of samples in different plate was 7.65%. Both of them were less than 10% (Table 3), which showed that this technique was provided with good degree of accuracy and repetition.

Table 1 Relationship between coated McAb and the sensitivity of SPASE

Coated McAb (mg·L^{-1})	Serum titer							Negative control
	1:1	1:10	1:20	1:50	1:100	1:200	1:500

	Well numbers	($\bar{x}$±s)	CV(%)
In the same lot	15	0.642±0.0389	6.06
In different lot	5	0.575±0.044	7.65

Table 4 Results of detecting TIMP-1 and TIMP-2 in different sera

Clinical type	*n*	TIMP-1		TIMP-2	
		Positive number	%	Positive number	%
Acute hepatitis	128	21	16.4	16	12.6
Chronic hepatitis	174	59	33.9	48	27.6
Hepatic cirrhosis	106	78	73.6	65	61.3

Clinical Application

Serum samples The 408 serum samples of patients with liver disease were used to detect TIMP-1 and TIMP-2 with SPASE. The

positive rates were 73.6% and 61.2% respectively, which were remarkablly higher than those in chronic hepatitis and acute hepatitis group. There was a significant statistical difference (P<0.001, Table 4).

Immunohistochemistry By immunohistochemistry detection, the positive signal as brown particles were scattered or diffused only in cytoplasm other than nuclei in liver cells. Table 5 represented the result of detecting TIMP-1 and TIMP-2 of 40 liver samples of hepatic cirrhosis, in which, for TIMP-1, 28 samples were (+++), 70.0% of cytoplasma; 4 were (++), 10.0%; 8 were (+), accounted for 20.0%. For TIMP-2, 22 samples were (+++), 55.0% of cytoplasma; 10 were (++), 25.0%; 8 were (+), 20.0%. 10 normal liver tissues were negative. There was no positive signal after abridging the first antibody or the second one, and there was no positive signal when the first antibody replaced by rabbit serum or PBS, which proved that the results of immunohistochemistry detecting were specific.

***In situ* hybridization** The positive signal of *in situ* hybridization showed brown particles, and distributed in the cytoplasm, scattered or diffused. There was no positive signal in nuclei. All the 40 samples of hepatic cirrhosis tissues showed positive expression of TIMP-1 and TIMP-2 mRNA, and the positive rate was 100%. Table 6 showed the intensity of TIMP-1 and TIMP-2 mRNA expression in the liver samples. For TIMP-1 mRNA, 32 samples were (+++), 80.0% of cytoplasma; 6 were (++), 15.0%; 2 were (+), 5.0%. Of TIMP-2 mRNA, 22 samples were (+++), in which 55.0% of cytoplasma; 16 were (++), accounted for 40.0%; 2 were (+), 5.0%. The expression intensity of TIMP-1 mRNA was stronger than that of TIMP-2 mRNA. There was no positive signal when TIMP-1 cDNA probes or TIMP-2 cDNA probes were replaced by the prehybridization solution, and when the 10 normal liver tissues were hybridized with TIMP-1 cDNA probes or TIMP-2 cDNA probes, all were negative. These proved that the results of*in situ*hybridization were specific.

Table 5 Expressing of TIMP-1 and TIMP-2 in liver

Group	*n*	TIMP-1				TIMP-2			
		-	+	++	+++	-	+	++	+++
Normal group	10	10	0	0	0	10	0	0	0
Hepatic cirrhosis	40	0	8	4	28	0	8	10	22

Table 6 Expressing of TIMP-1 mRNA and TIMP-2 mRNA in liver of hepatic cirrhosis

Group	*n*	TIMP-1				TIMP-2			
		+++	++	+	-	+++	++	+	-
Hepatic cirrhosis	40	32	6	2	0	22	16	2	0
Normal liver	10	0	0	0	10	0	0	0	10

DISCUSSION

SPASE is a new method used to detect the TIMP-1 and TIMP-2 in sera of patient with hepatic cirrhosis. During the setting up of this technique, we preliminarily tried to find out how to treat the influence factors and choose the condition. We consider that this method can not only possess both the advantages of SPA and IHT (indirect hemagglutination test), but also avoid the radiation pollution of RIA or cancer-causing danger of ELISA. Meanwhile, this method possesses many other advantages, such as wider range of usage, less influence factors, saving McAb, being easy to operate and judge detecting results. In a word, this is a specific, sensitive, rapid and economic method. There are two main factors that may influence the laboratory condition. Firstly, lower concentration of coated antibodies may result in fewer antibodies combined on the surface of support, which won't be able to catch antigens, while higher density may result in overlap of antibodies on the surface of support, which will have effect on the space position of conjunction of antigens and antibodies, and then antigens can't be effectively caught. Secondly, acting as the indicator system, a reverse correlation exists between the density of sensitized erythrocyte and sensitivity of detection. When the density of sensitized erythrocyte is higher than $3\cdot L^{-1}$, the detection sensitivity will be significantly decreased, while clarity of the result would be impaired if the density is lower than $1\cdot L^{-1}$. Because the erythrocytes can only react with one layer of the agent on the surface of solid support, excessive erythrocytes didn't combine with agents and would deposit at the bottom of wells, then the judgment of the results would be affected. For this reason, a layer of the sensitized erythrocytes with adequate density is better. The density we used in practice is about $2.5\cdot L^{-1}$, which is lower than that used in RPHA. In present study, the way of coating the antibodies was improved, and proved that the method of heating-fixed antibodies was feasible. Sheep erythrocytes and chicken erythrocytes sensitized by formaldehyde were detected with sensitization test, and no specific difference was observed except a little faster sedimentation rate of the former. This insured the source of erythrocytes.

The occurrence and progress of hepatic cirrhosis were the result of the interaction between hepatocytes and extracellular matrixes (ECM)[18-25]. The increase of ECM synthesis and decrease of ECM degradation will result in excess deposition of ECM in liver. More important reason of the excess deposition of ECM is the decrease of ECM degradation in the late stage. The metrical metalloproteinases played a leading role during the degradation of ECM[26-35]. MMPs were a group of zinc-ion dependent enzymes, which created conditions for further degradation of other proteinases though reducing the stability of helical structure of collagen and changing the secondary structure of substrates. TIMPs were a group of polypeptides with the ability of inhibiting the function of MMPs. TIMPs would inhibit the degradation of ECM through two main ways, which is non-covalent modification or conjugated with proenzyme. Research work showed that TIMP could be divided into four classes: TIMP-1, TIMP-2, TIMP-3, and TIMP-4. However, only TIMP-1 and TIMP-2 could be detected in liver[37-44]. All the 40 samples of hepatic cirrhosis tissues, showed positive expression of TIMP-1 and TIMP-2, and the positive rate was 100%. TIMP-1 and TIMP-2 were expressed at the same time, and were located in the liver cytoplasm, not in the nuclei. The expression of TIMP-1 was more obvious than that of TIMP-2. No expression of related antigens of TIMP-1 and TIMP-2 were detected. All these indicated that TIMP-1 did play an important role in the development of liver fibrosis and liver cirrhosis. The inhibitory effect of MMPs was enhanced with the high level expressing of TIMP-1 and TIMP-2 which resulted in the decrease of degradation of ECM, the deposit of ECM and the development of liver fibrosis and liver cirrhosis. The cause of the higher expression of TIMP-1 probably lay in two main reasons. First, the different classes of MMP resulted in the different inhibition activity of TIMP to MMP. TIMP-1 to procollagenase (MMP1) and TIMP-2 to gelatinase -A (MMP2),and gelatinase -B (MMP9) had assumed stronger inhibition activity. During the degradation of ECM, the main one was MMP1, and collagens Ⅰ,Ⅲ were the main object of MMP1. Second, the promotion of TIMP-1 was 10 times more than TIMP-2 to the proliferation of cells (including fibroblast, epithelial cells, endothelial cells, and smooth muscle cells). Furthermore, this action had no relation with the inhibition action of TIMP to MMP[45-59].

In situ hybridization was mainly used to observe the characteristics and accurate location of gene expression. The high sensitivity and strong specificity of this technique will be preferable to

study the pathogenesis of hepatic fibrosis and to demonstrate the diagnosis. Recently, digoxin has become a widely used non-isotope labeled compound characterized by its perfect specific and stability. Its sensitivity is almost the same as isotope, but without pollution. So, it is easily accepted and used to label TIMP-1 and TIMP-2 cDNA probe to detect the paraffin sections of liver. The results showed that this technique was high sensitive and specific. The rates of positive expressions of TIMP-1 and TIMP-2 were 80.0% and 55.0% respectively. The location of TIMPs expression was in cytoplasm of hepatocyte, except nuclei, and the mRNA expression of TIMP-1 was stronger than that of TIMP-2, which was in accordance with the results of immunohistochemistry, and further proved that the TIMPs played a key role in the development of hepatic fibrosis and hepatic cirrhosis.

It is now known that there is a noticeable increase of TIMP-1 in the injured liver, which takes place earlier and increases faster, therefore, more and more researchers has regarded it as the diagnostic index of hepatic fibrosis. Detecting TIMP-1 and TIMP-2 with SPASE was used as a quick labortory diagnosis of hepatic fibrohosis. The sera from hepatic cirrhosis patients pathologically confirmed and normal people served as positive and negative control respectively. The results of detecting TIMP-1 and TIMP-2 in the sera of 408 patients with hepatic disease showed that positive rate of TIMPs was higher in sera of hepatic cirrhosis patients than that of acute or chronic hepatitis(P<0.001). TIMPs in sera of chronic hepatitis patients were apparently higher than those of acute hepatitis patients. This conclusion enumerated above was Supported by the detecting results of TIMP-1 and TIMP-2 by using immunohistochemistry and in situ hybridization.

Recently, Murawaki *et al*[60-62] has detected TIMP-1 and TIMP-2 in sera of patients with chronic liver disease by means of ELISA, and found a good relation between TIMP-1 and TIMP-2 in sera and in liver. The sensitivity and specificity of TIMP-1 were higher than those of TIMP-2. In injured liver, especially in fibrotic liver, TIMP-1 predominated, and the degree of TIMP-1 was remarkably related to the severity of hepatic fibrosis. Compared with TIMP-1, the specificity and sensitivity of TIMP-2 were inadvisable for diagnosis of hepatic fibrosis. So, TIMP-1 was more important than TIMP-2 in the determination of histological change of hepatic fibrosis[63-70]. This was proved by our study of the expression of related antigens and the location of mRNA of TIMP-1 and TIMP-2. The expression of related antigens in liver could be reflected through detecting TIMPs in sera. So, TIMP-1 and TIMP-2 could be considered as useful diagnostic index of hepatic fibrosis, especially TIMP-1. Because viral hepatitis is common in China[71-99], liver fibrosis is the focus of research[18-24,100,101]. So serum TIMP-1 and TIMP-2 will find wide use in practice in the future.

Abstract

AIM: **To investigate the state of infection, replication site, pathogenicity and clinical significance of transfusion transmitted virus (TTV) in patients with hepatitis, especially in patients of unknown etiology.**

METHODS: **Liver tissues taken from 136 cases of non-A non-G hepatitis were tested for TT virus antigen and nucleic acid by *in situ* hybridization (ISH) and nested-polymerase chain reaction (PCR). Among them, TT virus genome and its complemental strand were also detected in 24 cases of autopsy liver and extrahepatic tissues with ISH. Meanwhile, TTV DNA was detected in the sera of 187 hepatitis patients by nested-PCR. The pathological and clinical data of the cases infected with TTV only were analyzed.**

RESULTS: **In liver, the total positive rate of TTV DNA was 32.4% and the positive signals were located in the nuclei of hepatocytes. In serus, TTV DNA was detected in 21.4% cases of hepatitis A-G, 34.4% of non-A non-G hepatitis and 15% of healthy donors. The correspondence rate of TTV DNA detection between liver tissue with ISH and sera with PCR was 63.2% and 89.3% in the same liver tissues by ISH and by PCR, respectively. Using double-strand probes and single-strand probes designed to detect TTV genome, the correspondence rate of TTV DNA detected in liver and extrahepatic tissues was 85.7%. Using single-strand probes, TTV genome could be detected in liver and extrahepatic tissues by PCR, but its complemental strands (replication strands) could be observed only in livers. The liver function of most cases infected with TTV alone was abnormal and the liver tissues had different pathological damage such as ballooning, acidophilia degeneration, formation of apoptosis bodies and focus of necrosis, but the inflammation in the lobule and portal area was mild.**

CONCLUSION: **The positive rate of TTV DNA among cases of hepatitis was higher than that of donors, especially in patients with non-A non-G hepatitis, but most of them were coinfected with other hepatitis viruses. TTV can infect not only hepatocytes, but also extrahepatic tissues. However, the chief replication place may be liver. The infection of TTV may have some pathogenicity. Although the pathogenicity is comparatively weak, it can still damage the liver tissues. The lesions in acute hepatitis (AH) and chronic hepatitis (CH) are mild, but in severe hepatitis (SH) , it can be very serious and cause liver function failure, therefore, we should pay more attention to TTV when studying the possible pathogens of so-called "liver hepatitis of unknown etiology".**

INTRODUCTION

In 1997, Nishizawa first found and reported a virus which was associated with post-transfusion hepatitis and named it transfusion transmitted virus. TTV is an unenveloped, single-stranded and circular DNA virus, which consists of 3852 nucleotides and most closely resembles the members of the Circoviridae family[1-3]. Meanwhile, different studies suggested that TTV genotypes were so much and could vary frequently[4-8]. It is believed that TTV belongs to hepadnavirus and replicates chiefly in the liver[9-11], however, some researchers think that the replication site is in the bone marrows rather than in the livers[12]. At present, epidemiological studies suggest that TTV is mainly transmitted by blood[13-15]; blood products[16] and body fluid routes[13,17], it can also be transmitted by mother-to-child vertical[18] and horizontal[19,20] route , fecal-oral route[9,15,21]and sexual route[22]. The infection rate of TTV DNA varies largely in healthy population and patients with liver diseases, but generally, it is higher in patients than in healthy donors[7,23-26]. The discovery of TTV once put a light on the etiological diagnoses of hepatitis cases of unknown etiology, unfortunately, the pathogenicity and clinical significance of TTV remain doubtful at this time[25,27-29]. To clarify the infection status, replication place, pathogenicity and clinical significance of TTV among hepatitis cases, especially in patients of unknown etiology, we conducted the research to test TTV DNA comprehensively among large-sample cases of hepatitis.

MATERIALS AND METHODS

Patients

We studied 136 hepatitis cases of unknown etiology, including 45 females and 91 males, aged 16-77 years. By serological screening, all the cases were proved to have not been infected by hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), hepatitis E virus (HEV), hepatitis G virus (HGV), cytomegalovirus (CMV) or Epstein-Barr virus (EBV). Meanwhile, alcohol hepatopathy, hepatopathy caused by drugs, autoimmunity hepatopathy and liver damage caused by other systemic diseases were eliminated on the basis of the history and other clinical indexes. According to the pathological diagnostic criteria set up at the 10th National Meeting of Infection Diseases in September 2000, Xi'an, China. there were 51 cases of acute hepatitis (AH), 41 chronic hepatitis (CH), 9 acute severe hepatitis (ASH), 11 subacute severe hepatitis (SSH), 5 chronic severe hepatitis (CSH), 11 liver cirrhosis (LC) and 8

hepatocarcinoma (HCC). The liver biopsies were performed in all patients except 28 who died of liver failure and autopsies were performed. Among the 28 cases, extrahepatic tissue samples (including pancreases, kidneys, spleens and hearts) were obtained from 24 cases. The control group consists of 31 patients who had undergone abdominal operations for other diseases except liver diseases. Paired sera were also obtained from 19 of 136 cases. Sera were collected from 42 cases of non-A non-G hepatitis and from 126 cases of hepatitis A-G. Sera of 20 donors from blood bank in Beijing You'an Hospital served as controls. All the specimens of the liver tissues and the extrahepatic tissues were fixed immediately in 100mL·L^{-1} neutral formalin and embedded in paraffin, and then sliced continuously to make 5ìm thick sections and stained with hematoxylin-eosin (HE). After that, the common pathological damages of virus hepatitis were observed under microscopy and the inflammation and fibrosis of the hepatic lobules were assessed according to the Histology Activation Index (HAI, Knodell Grade) and the pathological diagnoses were made.

Methods

Design and synthesis of primers The primers of PCR were contrived using the molecular biology software "Goldkey" (by the Chinese Academy of Military Medical Sciences, Beijing, China) and OLIGO 5.0 (USA), the sequence was based on the full-length TTV genome published in the Gen Bank (registry code: AF079173). The sequences were as follows: outer primers: P_1:5'-ACAGACAGAGGAGAAGGCAAC-3'; P_2:5'-AACAGGCACATTACTACTACC-3', inner primers: P_3: 5'-CCAGGAGCATATACAGAC-3', P_4:5'-TGTACTTCTTGCTGGTGAAAT-3'.

Label of double-strand TTV DNA probes Using the plasmid pGEM-ORF1 that contains the sequences of TTV genome as template (plasmid pGEM-ORF1 was provided by the Chinese Academy of Military Medical Sciences), the double-strand probes of TTV DNA were labeled with digoxigenin by PCR following the manual of Boehringer Mannhein digoxigenin kit. In the presence of template (3μL), 10×PCR buffer (6μL), labeling mixture with Dig-11-dUTP (2μL), primer P1 and P2 (1μL separately) and Taq DNA polymerase (1μL), PCR was performed for 30 cycles (94℃ for 40s with an additional 3min in the first cycle, 55℃ for 40s, and 72℃ for 50s) in a reaction volume of 60μL. The products were separated by electrophoresis to purify the probes. The labeled probes were homologous with the 1900-2208bp region of the TTV DNA that was a part of the TTV DNA ORF1. The total length of the probe was 309bp and the titer was 1mg·L^{-1}.

Label of single-strand TTV DNA probes The single-strand TTV DNA probes were labeled by asymmetric PCR, which was performed under the same conditions as the double-strand probes, except that the primer P1 and P2 were added in a rate of 1:100. The two primers were used to label the two single-strand probes. One could be used to detect the genome strand of TTV DNA (probe P37), the other could be used to detect its complemental strand (probe P38).

***In situ* hybridization** Paraffin embedded sections were first parched at 60℃ for 3-5h, deparaffined in xylene, digested by protease K, fixed in 40g·L^{-1} polyformaldehyde, dehydrated through graded alcohol, and prehybridized for 10min. Then hybridization liquid was added (5-10 drops/section). After denatured for 10min (95℃ in wet bin), the sections were subsequently incubated for 16-20h at 68℃ in water bath bin, washed by 2×SSC, blocked by goat serum/BSA, incubated with anti-Dig-Ap. At last, chromogenic reaction was developed with NBT, BCIP lucifugously.

The confirmation assays included: (1)blank controls: the positive sections were hybridized with prehybridization solution instead of Dig-TTV DNA probes; (2)replacement assays by other probes: the positive sections were hybridized with Dig-HBV DNA probes but not TTV DNA probes; and (3) the negative sections of normal liver tissues were rehybridized, using probes with higher titer.

Nested-PCR After the paraffin-embedded sections had been deparaffined and treated with alcohol, the liver tissues were homogenized and incubated in proteinase K-sodium dodecyl sulfate at 52℃ for 3h. And then,nucleic acids were extracted from them with phenol-chloroform and precipitated with ethanol.DNA species of chromosomal origin, which emerged as a cloudy precipate immediately after addition of ethanol, were removed. The remaining nucleic acids were collected by centrifugation and dissolved in 200μL Tris-HCl buffer (10mmol·L^{-1}, pH 8.0) containing 1m·L^{-1} EDTA (TE buffer). Sera (1mL) was diluted twofold with Tris-HCl buffer (50mmol·L^{-1}, pH 8.0) containing 150mmol·L^{-1} NaCl and 1mmol·L^{-1} EDTA and centrifuged in a TLA 100.3 rotor (Beckman Instruments, Inc., Palo Alto, Calif.) at 190583G for 1h. The pellet was suspended in Tris-HCl buffer (10mmol·L^{-1}, pH 8.0) containing 5mmol·L^{-1} EDTA and supplemented with 0.5mg proteinase K per mL as well as 5g·L^{-1} sodium dodecyl sulfate and incubated at 65℃ for 2h as the direction of the STG Kit (Biotronics Tech. Corp., USA). Then, nucleic acids were extracted with phenol-chloroform, precipitated with ethanol and dissolved in 100μL of TE buffer.

Using DNA (0.1ng) extracted from the sera or livers as a template, the first-round PCR was performed with P1 and P2 (100μmol·L^{-1} respectively) for 35 cycles (94℃ for 40s with an additional 3min in the first cycle, 55℃ for 40s, and 72℃ for 40s with an additional 7min in the last cycle) in the presence of 10×PCR buffer (3μL), dNTPs (100μmol·L^{-1}) and Taq DNA polymerase (1U) in 30μL of reaction volume (the reverse transcriptase, Taq DNA polymerase, dNTPs and T4 DNA Ligase were provided by Sino-American Biotech. Inc. Beijing). On the products of the first-round PCR (2μL), the second round was performed for 30 cycles under the same conditions as in the first round.

Detection of other pathogens The markers of hepatitis A-G viruses, CMV and EBV in sera were screened by ELISA, the steps were according to the directions of the Kits (anti-HAV IgM Kit, HBV-M Kit, anti-HCV IgM IgG Kit, HDV-M Kit and anti-HEV IgM Kit were purchased from Sino-American Biotech. Inc. Beijing, and anti-CMV IgM, anti-EBV IgM were the products of Delyea Inc., Italy). The antigens of HBV, HCV, HGV, EBV and CMV expressed in liver tissues were assayed by immunohistochemical staining using the streptavidin-peroxidase (S-P) method. The monoclonal antibody Kit against HBsAg and polycolonal antibody Kit against HBcAg were purchased from Maxim Biotech. Inc. Fuzhou, China. Purified rabbit monoclonal antibodies against HCV NS5-Ag, HGV NS5-Ag and EBV-Ag were provided by the Institute of virology of Chinese Academy of Preventive Medicine and Institute of Bacteriology & Epidemiology of Chinese Academy of Military Mmedical Sciences. Serum alanine aminotransferase (ALT) and total serum bilirubin (TSB) were assayed by automatic analyzer (COMBAS).

Statistical analysis

Aided by statistical software SPSS 10.0, statistical analysis was performed. χ^2 test was used for unpaired enumeration data and McNemar test for pairedenumeration data. If they were measurement data and normal distribution, we expressed them as $\bar{x}\pm s$ (standard deviation) and the comparison among groups were performed by unpaired Student's *t* test. *P* values less than 0.05 was considered significant.

RESULTS

TTV DNA in liver tissues

In all the 136 samples of liver tissues, the total positive rate of TTV DNA was 32.4% (44/136). It was 27.5% (14/51) in acute mild hepatitis group, 36.6% (15/41) in chronic hepatitis, 45.5% (5/11) in subacute severe hepatitis, 40.0% (2/5) in chronic severe hepatitis, 36.4% (4/11) in active liver cirrhosis and 50% (4/8) in primary hepatocarcinoma. No TTV DNA could be detected in the cases of acute severe hepatitis. The positive rate in chronic liver diseases (39.5%) was significantly higher than that in acute liver diseases (23.3%, P=0.046). However, there was no significant difference as compared with control group. After detection of other pathogen by immunohistochemical staining and *in situ* hybridization, 13 cases were confirmed to be infected by TTV alone, including 5 cases of acute hepatitis, 6 cases of chronic hepatitis and 2 cases subacute severe hepatitis (Table 1).

Table 1 TTV DNA in liver tissues of hepatitis

Type	*n*	TTV(+) *n*(%)	TTV(-) *n*(%)	TTV alone *n*(%)
AH	51	14(27.5)	37(72.5)	5(9.8)
CH	41	15(36.6)	26(63.4)	6(14.6)
ASH	9	0(0.0)	9(100.0)	2(18.2)
SSH	11	5(45.5)	6(54.5)	0(0.0)
CSH	5	2(40.0)	3(60.0)	0(0.0)
LC	11	4(36.4)	7(63.6)	0(0.0)
HCC	8	4(50.0)	4(50.0)	0(0.0)
Total	136	44(32.4)	92(67.6)	13(9.6)
Normal	31	8(25.8)	23(74.2)	

The positive signal of TTV DNA predominantly located in the nucleoli of the hepatocytes with an appearance of blue grain. It also could be found in the cytoplasm of the hepatocytes but much weaker than that in the nucleoli. In acute hepatitis, the positive cells were distributed diffusely in the interlobular areas, and in chronic hepatitis they were aggregated in the periportal areas and in active liver cirrhosis they clustered in the pseudolobules. The positive signals could also be found in the hepatocarcinoma cells.

TTV DNA in sera

TTV DNA could be detected in 21.4% (27/126) cases of hepatitis A-G, 34.3% (21/61) cases of non A non G hepatitis and 15% (3/20) healthy donors. There was no significant difference between the donors and the patients of hepatitis. Classified by the clinical diagnosis in AH, CH, SH and LC groups, the positive rates were 29.0% (18/62), 23.5 % (19/81), 52.9 % (9/17) and 7.4 % (2/27), respectively. The positive rate in SH group was significantly higher than in control group (P=0.014, Table 2).

Table 2 TTV DNA in sera of patients

Type	*n*	TTV(+) *n*(%)	TTV(-) *n*(%)
NA-NG	61	21(34.4)	40(65.6)
A-G	126	27(21.4)	99(78.6)
AH	62	18(29.0)	44(71.0)
CH	81	19(23.5)	62(76.5)
SH	17	9(52.9)	8(47.1)[a]
LC	27	2(7.4)	25(92.6)
Total	187	48(25.7)	139(74.3)
Control	20	3(15.0)	17(85.0)

[a]P<0.05, *vs* Control

In liver tissues and sera of patients of non-A non-G hepatitis, the positive rate of TTV DNA (33.0%) was significantly higher than that of hepatitis A-G (21.4%) (P=0.025).

Among the 19 paired samples of sera and liver tissues, 12 cases had the same results when testing liver tissues by ISH and testing sera by PCR, although 5 liver tissues were positive while the paired sera were negative and 2 sera were positive but the paired liver tissues were negative. However, there was no significant difference between them (P=0.453).

Fifty-six liver tissue specimens were assayed by PCR and at the same time by ISH. The coincidence rate of the results was 89.3% (50/56). Five cases were positive by PCR while negative by ISH and only 1 case was negative by PCR but positive by ISH. The difference was not statically significant either (P=0.219). Fifty-six specimens of liver, pancreas, kidney, spleen and heart tissues were tested by PCR using the two probes respectively. The results suggested that the total coincidence rate was 85.7% (48/56). The rest showed positive outcomes using one probe but negative outcomes using another probe in equal proportion. The difference using the two probes was not significant (P=1.000).

Paired specimens of liver, pancreas, kidney, spleen and heart tissues from 8 patients in whom TTV DNA had been found in the liver tissues by PCR using double-strand probes, were assayed again using P37 probes and P38 probes, respectively. The results showed that using P37 probes, 7, 7, 3, 5, 1 cases were positive in liver, pancreas, kidney, spleen and heart tissues, respectively. However, using P38 probes, only 5 specimens of liver tissues were positive and all the extrahepatic tissues were negative (Table 3).

Liver damage of cases infected with TTV alone

In AH group, serum ALT and TSB in patients infected with TTV alone (325±222nkat·L^{-1}, 91±115μmol·L^{-1}, respectively) were lower than that in patients infected with HBV only (931±630nkat·L^{-1}, 134±118μmol·L^{-1}, respectively), the difference of ALT being statistically significant (P=0.005). However, in SH group, there was no significant difference of ALT and TSB between cases infected with TTV alone (509±361nkat·L^{-1}, 304±125μmol·L^{-1}, respectively) and cases infected with HBV alone (435±239nkat·L^{-1}, 226±96μmol·L^{-1}, respectively) (P>0.05, Table 4).

Table 4 Liver function of cases infected by TTV alone and by HBV alone

	Pathogen	ALT(nkat·L^{-1})	TSB(μmol·L^{-1})
AH	TTV alone	325±222[b]	91±115
	HBV alone	931±630	134±118
SH	TTV alone	509±361	304±125
	HBV alone	435±239	226±96
CH	TTV alone	187±150	98±199

[b]P<0.01, *vs* HBV

In the liver tissues of patients with chronic hepatitis caused by TTV alone, some histological lesions could be found in hepatic lobule, including ballooning degeneration, acidophile degeneration, formation of apoptotic bodies, focus of necrosis,amplification of portal areas and infiltration of mononuclear cells, but the inflammation and fibrosis were mild. The histological activity index (3.23±1.86) was lower than that in cases infected by HBV only (5.69±1.34), the difference being statistically significant (P=0.001).

In cases without detectable pathogens in sera at present, after histological assay, 25.7% (35/136) were still of unknown etiology and 50.0% (68/130) could be explained to be the infection of HBV and/or HCV. Infection with TTV alone and with HGV only accounted for 9.6% (13/136) respectively, and the rate of coinfection with TTV and HGV was 5.1% (7/136) and the others were mixed infected with TTV/HGV and HBV/HCV.

DISCUSSION

Up to now, the epidemiological survey of TTV suggested that the infection of TTV globally distributed in all kinds of species. It was reported that the positive rate of TTV in healthy donors differed largely, ranging from 1% to 93%[30-34]. Nevertheless, in patients with hepatopathy it ranged from 20% to 80%[23-25,35]. These data show that the positive rate of TTV in population varies remarkably, it may be the result of the difference of the primers used in test or the imbalance of the different regions. However, it was higher in cases of liver diseases than that in healthy donors. These conclusions were chiefly drawn on the basis of serological studies, as the investigation of the liver tissues was scarce. In our study, we detected TTV DNA directly in liver tissue specimens by ISH. The results suggested that the total positive rate of TTV DNA was 32.4% in liver tissues of cases of unknown etiology, which was coincident with that in sera (34.4%). It could be conjectured that the results from serological screening can mirror the situation of TTV DNA in liver. Moreover, the positive rate of TTV DNA in AH group (27.5%) was similar to that in the normal controls(25.8%), but it was significantly higher in chronic hepatopathy (39.5%), especially in SSH, CSH and HCC groups, than in acute hepatopathy (23.5%) and control group. It indicated that TTV was common in population, and its infection could cause acute hepatitis and fulminant hepatitis and could develop to chronic hepatitis too. It may be one of the promoters of chronicity and deterioration of acute hepatitis and can affect the development of liver cirrhosis and hepatocarcinoma. It is worthy notice that no TTV DNA could be found in acute severe hepatitis group. We think that it might be due to the large portion of the necrosis areas.

In sera, the positive rate of TTV DNA in cases of unknown etiology was much higher than that of hepatitis A-G and the lowest in healthy donors, but the difference was not significant. We thought that it was because the samples were not enough, thus we merged the samples of liver tissues and sera to enlarge the samples and perform the statistical analysis again. The results showed the positive rate of TTV DNA in cases of non-A non-G hepatitis (33.0%) was significantly higher than that of hepatitis A-G. Therefore, when we search the pathogens of "hepatopathy with unknown etiology", we must pay more attention to the infection of TTV.

In our study, we used different methods to confirm the results. The data suggested that the positive rate in liver tissues by ISH was similar to that in sera by PCR, there were 5 cases in which TTV was positive in the liver by ISH but negative in sera by PCR, and only 2 cases were reversed. The reason might be the small number of cases or that the copies in liver tissues were higher than that in sera, and in some cases the replication of TTV DNA was so inactive that the corresponding viremia was absent. In the liver, the results of test by ISH were not significantly different from that by PCR and there was no significant difference between the results of test by PCR using the double-strand probes and single-strand probes which were complemented with the genome of TTV DNA. These methods could be used to supplement and verify each other.

TTV was once regarded as a particular hepadnavirus[36], but some studies suggested that TTV DNA could be detected in the bone marrows and the peripheral blood mononuclear cells (PBMC), and the hepatocytes were not the only site where TTV infected and existed[11,12]. In our study, we screened the paired tissues of liver, pancreas, kidney, spleen and heart by PCR using doubt-strand probes and P37 probes. The results showed that TTV DNA could be detected in livers as well as in extrahepatic tissues, but in extrahepatic tissues, the positive rate was lower, and the density and intensity of positive signals were much weaker than that in liver tissues. In general, only in cases with positive TTV in liver, were there positive signals in extrahepatic tissues and there was only one case was reversed. Furthermore, there was no obvious pathological damage in the extrahepatic tissues. In conclusion, TTV can infect not only the liver, but also extrahepatic tissues. Yet, the liver is still the mainly infected site and the infection in extrahepatic tissues is an accompanying status that may act as a refuge to escape the attack of the immunity system of the host. As a result, these places can reinfect the liver as a source of infection and might be responsible for the chronicity of TTV infection and the high prevalence in all populations.

Concerning the replication site of TTV, there are much disputations at present. Okamoto *et al*[11] discovered that separated by gel electrophoresis and characterized biophysically, TTV DNA in sera migrated in sizes ranging from 2.0 to 2.5kb. However, TTV DNA in liver tissues migrated at 2.0 to 2.5kb as well as at 3.5 to 6.1kb. Both faster and slower migrating forms of TTV DNA in the liver were found to be circular and the full genomic length being 3.8kb. The further study suggested that TTV DNA migrated at 3.5 to 6.1kb represents a circular, double-strand replication intermediates of TTV. The author concluded that TTV replicated in the liver via a circular double-strand DNA. However, Kikuchi *et al*[12] found that in hepatocytes there was only TTV DNA but no mRNA by PCR and Southern hybridization, while in bone marrow tissues, especially specimens coming from biopsy, there were high titers of TTV DNA. The author suggested that TTV replicates chiefly in bone marrows but not in liver, and Okamoto *et al*[37] found replication intermediates in marrows too. Furthermore,

Maggi *et al*[38] found that TTV can replicate in activated mononuclear cells, and recent studies[39,40] suggest that viral replication takes place in multiple tissues at distinct levels in infected individuals. In order to clarify the problem, we contrived and labeled 2 single-strand probes by asymmetric PCR. Because TTV is a single-strand DNA virus, in the process of replication the replication intermediates will appear. Detection of the genomes and its complemental chains using single-strand probes could explain the existence and replication of TTV DNA in different tissues. The results suggested that in positive cases using double-strand probes, positive signals could be detected in parts of the specimens of liver, pancreas, kidney, spleen and heart tissues using single-strand probes designed to detect the TTV genome. However, using single-strand probes designed to detect the replication chain of TTV DNA, positive signals could be seen in part of liver tissues but all the extrahepatic tissues were negative. These results showed again that TTV can infect extrahepatic tissues, but the infection belongs to an accompanying state and liver is still one of the main replication places. Although we have studied the bone marrow tissues and had not compared it to the liver, it is clear at least that TTV can replicate in liver and it is the prerequisite to investigate the pathogenicity of TTV.

Discovery of TTV once triggered the expectations to explain the cases of non-A non-G hepatitis, unfortunately, the pathogenicity and clinical significance of TTV remain doubtful at this time. Most studies suggest that TTV is not responsible for hepatitis and is not one of the chief pathogens of hepatitis[23,25,30,41-43], and in hepatitis B/C, TTV does not seem to cooperate with HBV/HCV and coinfection with TTV does not modify the clinical feature and exacerbate liver damage[44,45]. And TTV plays an insignificant role in acute fulminant and non-fulminant hepatitis[46]. But some researchers did not think so. They think that TTV may cause epidemic outbreak of hepatitis of unknown etiology by fecal-to-mouth route[28], and be responsible for some cases of non-A non-G hepatitis[47,48]. Some studies suggest that TTV can make other systems abnormal[49,50] and may be responsible for the development of hepatocellular carcinoma in patients with type C liver disease[51]. We selected the patients of non-A non-G hepatitis who had been screened by serological and histological assays by ISH and confirmed to be infected by TTV alone, and then we observed the pathological damages, assessed the damage degree of the liver tissues by the criterion of global "Knodell Grade" and analyzed the liver function. The results show that TTV DNA is mainly located in the nuclei or cytoplasm of the hepatocytes. In the liver tissues of cases infected with TTV only the common pathological damages and inflammation would be found in the interlobular and periportal areas. The positive cells scattered diffusely in the interlobular areas in acute hepatitis and aggregated in periportal areas in chronic hepatitis or in the form of cluster in pseudolobules in the liver cirrhosis. The grade of HAI of acute or chronic hepatitis caused by TTV only was much lower than that caused by HBV. Clinically, the patients might have a raised ALT and TSB in AH group, but the elevation was mostly moderate and ALT was significantly lower than that caused by HBV. However, in SH group, the liver function change caused by TTV was similar to that caused by HBV. In CH group, the grades of inflammation activity of all the cases with TTV alone were G1-2. Therefore, TTV may have some pathogenicity, but the pathogenicity is comparatively weak and the liver damage is not serious in AH or CH. The result is identical with that of the study performed by Ge *et al*[52]. However, when it caused fulminant hepatitis, the pathogenicity is not weaker than that of HBV and Yusufu's study[53] demonstrated that TTV may contribute to fulminant hepatic failure as a solitary infectious agent or a co-infectious agent with HCV. In addition, among these 136 cases of unknown etiology, the pathogen of 25.7% (35/136) patients was still unknown after the histological tests, 50% were caused by HBV and/or HCV, 9.6% were infected by TTV alone while 24.3% were contaminated by TTV and/or HGV, the others were coinfected with TTV/HGV and HBV/HCV. These results suggest that we ought to pay more attention to TTV when we study the possible pathogen of so-called "liver diseases of unknown etiology", although the conclusion should be verified by more data and more thorough studies.

On the whole, TTV is widespread in population. The positive rate of TTV DNA among hepatitis cases is higher than that of donors, especially in patients of non-A non-G hepatitis, but most of them are coinfected with other hepatitis viruses. TTV can infect not only hepatocytes, but also extrahepatic tissues. However, the chief replication place may be the liver. The infection of TTV may have some pathogenicity. Although the pathogenicity is comparatively weak, it can sill damage the liver tissues. The lesions in acute hepatitis (AH) and chronic hepatitis (CH) groups are mild, but in severe hepatitis (SH) group, it can be very serious and cause failure of liver function, therefore, we should pay more attention to TTV when studying the possible pathogens of so-called "liver hepatitis of unknown etiology".

Abstract

AIM: **To characterize the biochemical and immunological properties of an experimental ISCOMS vaccine prepared from a novel therapeutic polypeptide based on T cell epitopes of HBsAg, and a heptatis B-ISCOMS was prepared and investigated.**

METHODS: **An immunostimulating complexes(ISCOMS)-based vaccine containing a novel therapeutic hepatits B polypeptide was prepared by dialysis method, and its formation was visualized by electron microscopy and biochemically verified by SDS-polyacrylamide gel electrophoresis. Amount of the peptide within ISCOMS was determined by Bradford assay, and specific CTL response was detected by ELISPOT assay.**

RESULTS: **Typical cage-like structures of submicroparticle with a diameter of about 40nm were observed by electron microscopy. Results from Bradford assay showed that the level of peptide incorporation was about 0.33g·L^{-1}. At the paralleled position close to the sixth band of the molecular weight marker(3480kDa) a clear band was shown in SDS-PAGE analysis, indicating successful incorporation of polypeptide into ISCOMS. It is suggested that ISCOMS delivery system could efficiently improve the immunogenicity of polypeptide and elicit specific immune responses *in vivo* by the results of ELISPOT assay, which showed that IFN-γ producing cells (specific CTL responses) were increased (spots of ISCOMS-treated group: 47±5, *n*=3; control group: 5±2, *n*=3).**

CONCLUSION: **ISCOMS-based hepatitis B polypeptide vaccine is successfully constructed and it induces a higher CTL response compared with short polypeptides vaccine *in vivo*.**

INTRODUCTION

Infection of hepatitis B virus(HBV) is very common in China[1-25], and nearly 100 million people have a persistent infection with HBV who are at risk of developing chronic pepatitis leading to liver cirrhosis and hepatocellular carcinoma. Up to now, vaccination is a main way in prevention[26-36]. Based on our knowledge and work on epitopes of HBV natural nucleocapsids, using SGI O2 workstation and Insight Ⅱ software modeling the configuration of natural HBV PreS2, HBsAg and HbcAg, we have screened out several novel HBV therapeutic polypeptides containing immunodominant B-, T helper(Th) and cytotoxic T lymphocyte responses (CTL) epitopes of HBV PreS2, HBsAg and HBcAg. It is well known that natural antigens and their dominant epitope peptides can not induce sufficient antigen-specific CTL responses *in vivo*, although they could pulse antigen-specific CTLs *in vitro*. Therefore efforts should be made to potently promote or enhance their antigenicity so as to induce efficient immune responses including CTLs *in vivo*, among which utilization of appropriate adjuvants or delivery systems is a promising and useful strategy.

Elaborate work has demonstrated that ISCOMS, or immunostimulating complexes, first described by Sweden scientist Bror Morein and his colleagues in 1984, is a good vehicle for antigen presentation. Previously antigens used in earlier works in this complexes were isolated from crude molecular components of microbes while is prepared from phosphatidylcholine(or phosphatidylethanamine), cholesterol and glucoside Quil A(also called Spikoside) and antigen molecule now, which are approximately 40nm submicroscopic cage-like particles(the size is similar to virus particle). ISCOMS formed in the absence of antigen molecules is termed ISCOMS matrix or empty ISCOMS compared to ISCOMS formed in the presence of antigen(s). Elaborate work has demonstrated that ISCOMS is a good vehicle for antigen presentation. Incorporation into ISCOMS not only allows protein antigens to induce strong antibody, major histocompatibility complex(MHC) class II-restricted T cell responses and mucosal immunity, but also allow antigens to enter the endogenous pathway of antigen processing to induce MHC class I-restricted CTL *in vivo*[37-39]. Immunization with antigens in ISCOMS induces protective immunity against a number of experimental infections, including influenza, toxoplasmosis, measles, feline leukemia, EBV infection, and herpes simplex[40-42]. An ISCOMS-based vaccine against equine influenza was produced and sold by Iscotec AB in Sweden in 1988. Compared with liposomes, ISCOMS structure is much more rigid, three-dimensional with marked symmetry, which is extremely stable under many conditions, including in the intestine, and may be present for long periods of time intra- and extracellularly in lymphoid tissues. On the basis of our previous work on the design and synthesis of HBV epitope-based vaccines, choosing a polypeptide containing both Th and CTL epitopes of HBV as a model antigen, an experimental ISCOMS-based vaccine was constructed and prepared, and its biochemical and immunological properties were then investigated and discussed in this study.

MATERIALS AND METHODS

Reagents and preparation

Phosphatidylcholine, cholesterol, and decanoyl-N-methyl-glucamide (Mega-10) were all from Sigma. Quil A was kindly provided by Dr. Erik B Lindblad. SDS molecular mass marker(2500-17000u)was from Sigma (MWM-100). Hepatitis B polypeptide, glycopeptide and lipopeptide were synthesized by the solid-phase method with an automated peptide synthesizer(431A,Applied Biosystems,Foster City, CA).

Lipid mixture stock solution

Phosphatidylcholine and cholesterol(10g·L^{-1} each) were fully dissolved in 200g·L^{-1}(in distilled water) Mega10, aliquot and store at low temperature until required.

Bradford solution

Dissolve 100mg Coomassie blue G and 30mg SDS in 50mL 950mL·L^{-1} ethanol. Add 100mL of 850g·L^{-1} orthophosphoric acid and make up to 1L with water. Filter before use.

Preparation of an experimental ISCOMS-based vaccine from a therapeutic hepatitis B short polypeptide

To a solution of hepatitis B polypeptide(1g·L^{-1}) and Quil A(1g·L^{-1}), add 100μL of lipid mixture stock solution and mix thoroughly. After reaction at room temperature for 2h, the mixture was transferred to a dialysis bag, dialyzed 24h at room temperature, then at 4℃ for another 48h. To confirm the presence of typical structure of ISCOMS, a small aliquot(-80μL) was negatively stained and examined by electron microscopy analysis. Sterilize by filtration through a 0.22μm filter.

Amount of polypeptide incorporated into ISCOMS determined by Bradford method

To each 50μL sample of ISCOMS and to each 50μL dilution of BSA add 1mL Bradfords solution. Incubate 5min at room temperature. Measure the A595 of each sample and BSA standard. Plot a standard curve from the BSA values and determine the protein concentration of the ISCOMS by interpolation from this curve.

Incorporation of short peptide into ISCOMS examined by peptide SDS-PAGE analysis

Table 1 Formulation of gels

Components	Stacking gel (mL)	Spacer gel (mL)	Separating gel (mL)
Acrylamide solution	5.00	3.05	1.00
Gel buffer	5.00	5.00	3.10
Glycerol	1.60	—	—
Water	3.40	6.95	8.40
Total	15.00	15.00	12.50

Prepare gels as indicated in Table1. After the gel has set, allow to equilibrate by leaving overnight at 4℃. Remove the comb and rinse wells with water, then with Cathode Buffer. Load the samples and molecular weight marker. Electrophoresis condition: constant current at 20mA for 1h and 30mA for 4-6h (the marker dye is within 1cm of the anodic end of the gel). Immerse in the fixative solution for 30min. Transfer to staining solution for 1h and destaining solution for 2h, renewing the solution every 30 minutes. The gel now is ready for visualization, analysis or qhotography.

ELISPOT assay

Female Balb/c mice, obtained from the Animal Research Center of Academy of Military Medical Sceinces(Beijing, China) were sc injected to the hind footpad with hepatitis B polypeptide-ISCOMS and hepatitis polypeptide(5nmol each) alone. After 7d of the first priming, the animals were boosted and lymph nodes were removed 7d later to prepare single cell suspension for the ELISPOT assay, which was performed according to the instruction of the murine IFN-γ ELISPOT kit(Diaclone, France).

RESULTS

Typical structure of ISCOMS prepared from hepatitis B polypeptide by electron microscopy

Hepatitis B-ISCOMS unique structure was examined by electron microscopy, which showed uniform honeycomb-like open structure composed of several subunits and confirmed the formation of ISCOMS (Figure 1).

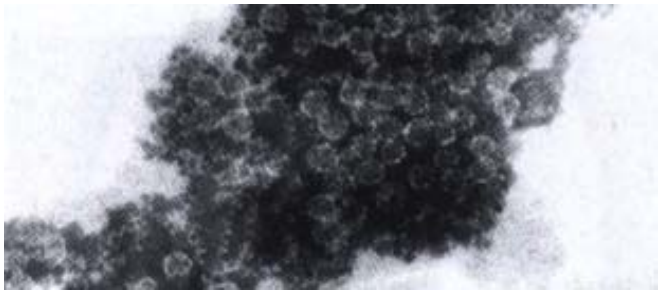

Figure 1 Visualization of hepatitis B-ISCOMS by electron microscopy.

Amount of hepatitis B polypeptide incorporated into ISCOMS

Standard curve was shown as Figure 2(r=0.9968). The mean A_{595} value of ISCOMS was 0.0835. According to the standard curve, the corresponding peptide concentration was about 0.33g·L^{-1}.

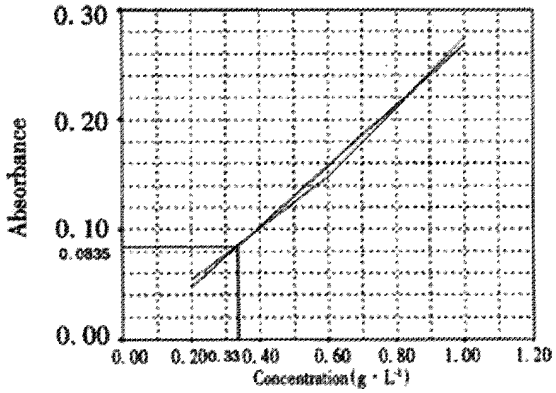

Figure 2 Standard curve of Bradford assay

SDS-PAGE analysis of ISCOMS

In the SDS-PAGE separation of ISCOMS prepared from different hepatitis B polypeptides we observed that at the paralleled position close to the sixth band of the molecular weight marker there was a clear band indicating the peptide incorporated into ISCOMS(Figure 3). Compared to the polypeptide sample, it was at the similar position but somewhat with a slight tailer, which might be affected by other components in the ISCOMS.

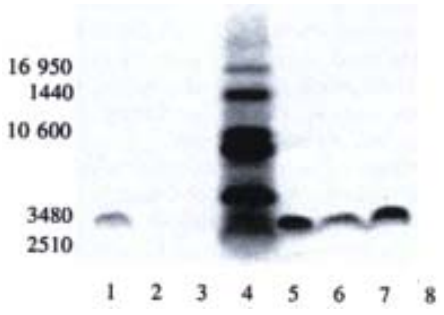

Figure 3 SDS-polyacrylamide gel separation of hepatitis B polypeptide-ISCOMS. 1.Heptatitis B peptide(30)-ISCOMS; 2.ISCOMS matrix; 3.Hepatitis B lipopeptide-ISCOMS; 4.Molecular weight marker; 5.Hepatitis B peptide(30)(as control); 6,7.Hepatitis B peptide(30)-ISCOMS; 8.Hepatitis B glycopeptide -ISCOMS.

IFN-γ linked-CTL activity of Hepatitis B polypeptide-ISCOMS determined by ELISPOT assay

Swelling of lymph nodes were obvious in ISCOMS treated group. In ELISPOT assay, significantly improved IFN-γ linked cytotoxic T lymphocyte(CTL) proliferation response to hepatitis B polypeptide was observed in HBP-ISCOMS group compared to the polypeptide control group(spots of B: 47±5, *n*=3; A: 5±2, *n*=3, respectively)(Figure 4).

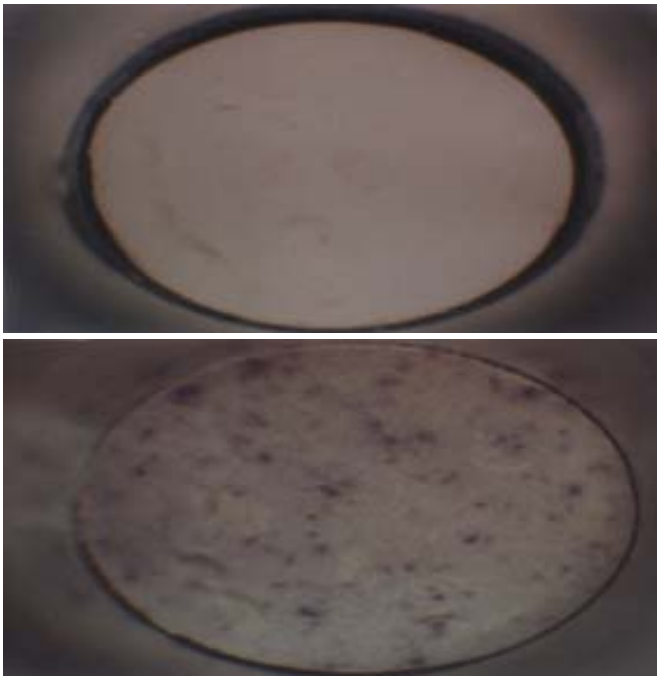

Figure 4 ELISPOT results showing improved specific CTL responses induced by hepatitis B polypeptide incorporated into ISCOMS (B) compared with the polypeptide (A)

DISCUSSION

Studies in immunological mechanisms and T cell function have demonstrated that class I major histocompatibility complex(MHC)-restricted cytotoxic T lymphocytes(CTL) play a critical role in the control of intracellular pathogens and tumor cells growth, but the problems of CTL responses induced *in vivo* and cell-medicated immunity have not been solved yet. Exogenous soluble antigens are not allowed to enter the endogenous pathway necessary for MHC class I-restricted presentation, therefore are not capable of stimulating MHC class I-restricted $CD8^+$ CTL responses. Obviously, intracellular expression and synthesis of antigens by infection or through pathological/physiological genes could lead to MHC class I restricted-representation pathway, but vaccination of infectants or transfected cells might lead to certain diseases, thus development of adequate novel vaccine adjuvants, especially those themselves are not immunogenic and could present non-replicable soluble antigens to the endogenous pathway and are capable of inducing MHC class I restricted-CTL responses, are badly in demand.

ISCOMS technique is just one of the novel adjuvanted-vaccine systems to meet this demand. Since the first description of ISCOMS appeared more than a decade ago, ISCOMS has been widely used to generate antigen-adjuvant complex in vaccine development, especially in viral antigen studies to promote immune responses. ISCOMS has a unique ability to provoke a full range of immune response to protein antigens, which is efficient after both parenteral and oral immunization. It has a unique ability to allow the antigen molecules to enter the endogenous pathway for antigen processing, which in turn to provoke MHC class I-restricted CTL. It is safe and stable, prepared in mild conditions. Furthermore, as ISCOMS is a non-viable adjuvant vesicle and is not immunogenic and antigenic itself, it could enhance antigen specific immune responses, but not unwanted immunity. Different antigen molecules are able to produce vaccine-adjuvant complex with ISCOMS matrix after proper modification, so are useful and promising in various vaccine design.

Preparations of experimental ISCOMS-based vaccines. have been done with large number of whole microbe or isolated from microbe, especially viruses such as HIV[43-46], influenza virus[38,47-49], EBV[41], HSV[42,50] and Measles[40,51]. The work with the major S gene products (HBsAg) of the hepatitis B virus genome has been reported, but not with epitope-based hepatitis B polypeptide. In our study, on the basis of the molecular design and synthesis of therapeutic heptatitis B peptides previously, different hepatitis B polypeptides were investigated for their abilities to incorporating into ISCOMS.

Formation of typical structure of ISCOMS was verified by electron microscopy. Adequate proportion of the components, extensive dialysis and purification by density gradient ultracentrifugation when necessary, are important factors involved in the preparation of ISCOMS. The presence of typical cage-like microparticles visualized by electron microscopy is a simple and direct method to examine the formation of ISCOMS, but ISCOMS matrix also shows similar structure as ISCOMS containing antigen molecules, so other methods are required to verify the presence of antigen component. Results from Bradford assay suggested that ISCOMS was successfully formed with polypeptide(30) and other components. In our study, polypeptide incorporated into ISCOMS was about 0.33g·L^{-1}(incorporation rate 33%). In addition, we observed that the short polypeptide which was easily degraded in a couple of days even at 4℃, was stable while stored at 4℃ for months without notable degradation, indicating markedly improved stability of antigen peptide after the formation of hepatitis B short polypeptide-ISCOMS.

SDS-PAGE separation of short polypeptide showed an apparent band close to 3480Da which confirmed the successful incorporation of hepatitis B polypeptide into ISCOMS(peptide failed to incorporate into ISCOMS was removed during dialysis). The peptide control showed a straight and regular band, while those for peptide-ISCOMS were broad which indicated effects of other components on SDS-PAGE separation. Specific CTL responses were markedly enhanced by ISCOMS-adjuvanted hepatitis B vaccine compared to antigen peptide control in mice visualized by ELISPOT assay. More work will be done to investigate the immunological properties and mechanisms underlying of this experimental ISCOMS-based vaccine from hepatitis B polypeptide *in vivo*.

Abstract

AIM: **To study the levels of membrane interleukin-2 receptor (mIL-2R) and T cell subsets in peripheral blood mononuclear cells (PBMC) from patients with hepatitis C and their role in the pathogenesis of hepatitis C.**

METHODS: **The levels of mIL-2R and T cells subsets in PBMC were detected by biotin- streptatividin (BSA) technique before and after stimulation with PHA in 203 patients with hepatitis C with HCV-RNA(+), anti-HCV(+), anti-HCV(-).**

RESULTS: **The total expressive levels of mIL-2R before and after stimulation with PHA(0.03±0.01, 0.03±0.02, 0.04±0.02, 0.36±0.03), and T cell subsets in PBMC (0.62±0.06, 0.37±0.05, 0.35±0.07) were all lower in patients with hepatitis C than those in normal controls (0.66±0.07, 0.41±0.06, 0.31±0.05, $P<0.01$). Among the patients, the levels of mIL-2R were lower in silence than those in situation of PHA inducting ($P<0.01$). However, the levels of mIL-2R were similar in acute hepatitis C to that in chronic hepatitis C ($P>0.05$). The levels of CD_3^+, CD_4^+, CD_4^+/CD_8^+ were lower and CD_8^+ was higher in patients with acute and chronic hepatitis C with anti-HCV(+) than those in normal controls (0.62±0.06, 0.37±0.05, 0.35±0.07, 1.18±0.30, 0.61±0.07, 0.37±0.05, 1.39±0.33, 0.31±0.05, $P<0.05$-$P<0.01$).**

CONCLUSION: **The cellular immunity is obviously changed in patients with hepatitis C. The levels of mIL-2R and activation of T cells are closely associated with chronicity of hepatitis C.**

INTRODUCTION

In acute and chronic hepatitis C virus (HCV) infection liver damage is thought to be the results of T-lymphocyte-mediated destruction of virus infected liver cells[1-51]. The factors that affected the immune response to viral antigens, particularly those that regulate the function of virus-specific cytotoxic T-lymphocyte-mediated lymphocytes, most likely play an important role in determining the states of liver injury. Interleukin-2 (IL-2) has a crucial role in several immunologic functions and its effect is dependent on the interaction with IL-2 receptors (IL-2R) expressed on surface of activated T lymphocytes and other immunocompetent cells[52-54]. Decreased IL-2 activity in supernatants of mitogen-activated peripheral blood mononuclear cells (PBMC) has been measured in patients with chronic HCV infection who had active liver disease, while normal levels have been detected in chronic HCV carriers with milder or no liver damage. The impaired IL-2 activity of PBMC, which has been claimed to be associated with high levels of virus duplication, has been interpreted as the reflection of an immune regulatory disorder of chronic active hepatitis C, which may be responsible for reduced differentiation of cytotoxic, virus-specific T cells and could explain the failure to eliminate all infected cells. Recently, methods for detecting membrane interleukin-2 receptor (mIL-2R), which exists on surface of T cells and can be released from activated lymphocytes, have been available, and high levels of these serum factors have been detected in a variety of pathologic conditions. To analyze IL-2R dependent immunoregulatory function in viral hepatitis, the levels of mIL-2R in the course of acute and chronic HCV infection in relation to the activity of liver disease and of virus replication have been investigated. The results suggest that in chronic active hepatitis C there is a state of activation rather than of depression of the IL-2 system, and the pathogenesis is related to the cellular immune function of the patients. PBMC are aggregation of immune cells,which have a lot of T lymphocytes, and play an important role in the anti-HCV infection. The cellular immune function of the patients may be the reflection of the level of T cell subsets and mIL-2R. The method of biotin-streptavidin (BSA) has higher specificity and sensitivity. In order to study the influence on the cellular immune function after being infected by HCV in PBMC and the effect on the mechanism of hepatitis C, the T cell subsets and mIL-2R of 203 patients with acute and chronic hepatitis C were detected by the above methods.

MATERIALS AND METHODS

Subjects

The 203 patients with confirmed diagnosis of hepatitis C (male 116 and female 87), aged 19-52 (average: 36.4 years), from our affiliated and teaching hospitals were chosen whose HCV-RNA in serum and PBMC were detected. Among them, the positive number of HCV-RNA in acute and chronic patients was 58 and 145 respectively. All diagnoses were made according to the diagnosis criterion of Chinese Hepatitis Conference 1995 (Beijing). The controls (n=20) were normal blood donors from the local Central Blood Bank.

Reagents and instruments

The antibodies against T cell subsets, Ficoll-Hypaque sedimentation gradient were produced by Shanghai Jingan Medical Institute, the Second Reagent Factory of Shanghai, and Huamei Bioengineering Company of Shanghai (No. 981010, 980215, 980422). Carbon dioxide gas incubator (MDF-135) was made in Japan.

Samples

The peripheral vein blood 5mL from each of the patients with hepatitis C was collected at 08:00, which was distributed 2.5mL in a sterile test tube and an anticoagulant test tube with heparin respectively.

Separation of PBMC and detection of T cell subsets, mIL-2R

After the anticoagulant heparinized blood was mixed with equal volume of Hanks' liquid without Ca^{2+} and Mg^{2+}, the PBMC were harvested from heparinized whole blood by centrifugation on Ficoll-Hypaque sedimentation gradient and diluted to $(1\text{-}3)\times10^9\cdot L^{-1}$ cells suspension with RPMI 1640 culture liquid. The 10μL suspension of

PBMC was smeared on sheet glass pores so that the cells with CD_3^+, CD_4^+, CD_8^+ could be detected. Of the PBMC suspension, 0.5mL was mixed with RPMI 1640 culture liquid, which had PHA 200mg·L^{-1}. The cells were grown in continuous culture (37℃, 50mL·L^{-1} CO_2 in atmosphere) for 72h and its mIL-2R induced by PHA could be measured by the antibodies against membrane of T cells.

Immunocytochemical method of Biotin- streptavidin system (BSA)

The different mAb against CD_3, CD_4, CD_8 and Tac with biotin and SA-HRP were smeared on different sheet glasses. These smears were left dry naturally and fixed with acetone for 15-20min. The cells were incubated in continuous culture (37℃, 50mL·L^{-1} CO_2 in atmosphere) for 30min. The immune sheet glass pores were measured after being stained with the color-developing agent and several washings with Tris Buffer Solution (TBS). The total number of 200 PBMC was counted and its positive cells were statistically analyzed with the help of high power lens. The positive criterion was that the color of endoplasm or cell membrane was brown, if not being negative.

Statistical analysis was made by using Student's *t* test.

RESULTS

The results showed that the absolute positive rates of CD_3^+, CD_4^+ and CD_4^+/CD_8^+ were lower and CD_8^+ was higher in patients with anti-HCV(+) than those in normal controls (P<0.01, Table 1). However, there was no significant difference between the patients with acute hepatitis C and normal controls (P>0.05). But there was a higher significant difference between the patients with chronic hepatitis C and normal controls (P<0.05). The reactivity of T cells in peripheral blood before and after being induced by PHA was all lower in acute, chronic hepatitis C than those in normal controls (P<0.01).

DISCUSSION

The chronicity of hepatitis is easier in patients with hepatitis C than that with hepatitis B[6,12,20,26,36]. The T cell subsets of the 203 patients with hepatitis C were detected by the method of BSA, and the results showed that the positive rate of T cell subsets and their mutual proportion were significantly different (P<0.01), and there were significant disorders of cellular immune function and obvious pathologic injury.

It seems probable that mIL-2R is an important symbol of active T cells and plays a key role in biologic effect and its expression level can reflect the course of T cells activity and immune situation. The expressive level of T cells in silence was lower in hepatitis C patients than in normal controls (P<0.01), which showed that the T cell activity was interfered. The possible reasons seemed to be as follows: (1)The mIL-2R on surface of T cells of the patients was inhibited by HCV; (2)The infection, duplication, proliferation of HCV in PBMC promoted the soluble interleukin-2 receptor to (sIL-2R) produced and released from T cells and inhibited the expression of mIL-2R[55-59]. This manifestation was caused by the low inducing cellular immune ability. Some active Tc cells could be combined tightly with the complex of HCV antigen-MHC-I molecule on the surface of liver cells by T cells receptor (TCR) and released perforin. This irrevocable and progressive injury was one of the important reasons for chronicity of hepatitis C; (3)sIL-2R and mIL-2R could competitively combine with IL-2, and sIL-2R, being an immunosupperssive factor (similar to blocking factor), which could activate the IL-2 around the T cells so that the self-secretion effect of T cells decreased and the disorder of cellular immune function was enforced and the infection of HCV would be persisted[60-62]. These conclusions were in agreement with the concept that both acute and chronic active hepatitis C liver cell damages were caused mainly by cytotoxic T lymphocytes directed against viral antigens expressed on the surface of infected cells and that CD_8^+ lymphocytes were abundant in the infiltrates of the liver.

The present study demonstrates that the receptor of PHA exists on the surface of T cells. The level of mIL-2R obviously increased after stimulation with PHA, which showed that mIL-2R could be induced by PHA and was significantly different between acute hepatitis C patients and chronic hepatitis C patients (P<0.05). The more serious the patient's condition, the longer the course of disease, and the lower the level of mIL-2R. The low level of mIL-2R was not beneficial for clearing away HCV and easy to reduce chronicity of hepatitis C.

CD_3^+, CD_4^+ and CD_8^+ are major function subsets of T cells and play a key role in response to HCV. Its counts and mutual relationship could be used to identify the cellular immune level and immunoregulation and is one of the valuable immunologic targets to forecast the change of patients' condition. The results showed that the lower positive rate of CD_3^+ in chronic hepatitis C and the immunity to HCV were partly deficient. The lower positive rate and poor activation of CD_4^+ are important reasons for the disorder of the immune function and can not clean HCV in time. Another key reason is the high level of CD_8^+ in chronic active hepatitis C, which can cause injury of liver cells and increase of ALT persistently. The proportion of CD_4^+/CD_8^+ could play an important role in the network of immunoregulation. The high level of CD_8^+ identified the injury of liver cells caused by CTL. These findings indicated that the immune response of the body to HCV was limited, and the infection of HCV existed persistently so that the patient's condition would change from acute to chronic.

Abstract

AIM: **This paper describes the procedure of detection of *Helicobacter pylori* (*H. pylori*) in bile specimens in patients suffering frombenign diseases of biliary ducts (lithiasis with/without nonspecific cholangitis).**

METHODS: **The group of 72 patients entering the study consisted of 32 male and 40 female (45% and 55%, respectively). Bile was obtained during ERCP in 68 patients, and during cholecystectomy in 4 patients. A fast urease test (FUT) to determine the existence of *H. pylori* in gastric mucosa was carried out for all the patients during the endoscopic examination. The existence of genetic material of *H. pylori* was determined by detection of ureA gene by the method of nested PCR. The results of this reaction were shown by electrophoresis on 10g·L^{-1} agarose gel in a band of 256bp.**

RESULTS: **The majority of the patients included in our study had biliary lithiasis without signs of cholangitis (48 patients, 67%), whereas other patients were complicated by cholangitis (17 patients, 24%). Seven patients (9%) had normal ERCP, forming thus the control group. In the group of patients with lithiasis 26 patients (54.2%) had positive PCR of *H. pylori* in bile and among the patients with associated cholangitis positive PCR was detected in 9 patients (52.9%). Among the seven patients with normal ERCP only one (14%) had positive PCR of *H. pylori*. A high percentage of *H. pylori* infection of gastric mucosa was observed (57 patients, 79%). It was also observed that its slightly higher positivity was in the patients with distinct bile pathology: 81% FUT positive patients in the group with choledocholithiasis alone and 76% in the group with choledocholithiasis associated with cholangitis. Seventy-one percent of the patients with regular findings had positive FUT.**

CONCLUSION: **The prevalence of *H. pylori* infection both in bile and in gastric mucosa in patients with benign diseases of biliary ducts does not show a statistically significant difference in relation to the prevalence of the same with the patients with normal ERCP. The existence of *H. pylori* infection possibly does not play a role in pathogenesis of benign biliary diseases.**

INTRODUCTION

Helicobacter pylori (*H. pylori*) is a microaerophilic and Gram-negative microorganism which could represent the main causative agent in the development of chronic antral gastritis, duodenal ulcer, or even gastric cancer[1-3]. In the last few years, the interests of scientists in the correlation between *H. pylori* infection and various extradigestive diseases[4] have been significantly increasing. Due to the complexity of pathophysiologic mechanisms of the infection with this microorganism, diagnostic procedures for the detection of *H. pylori* infection in extragastric specimens did not meet high standards. Fast urease test for the detection of *H. pylori* infection in stomach often had false negative or false postive results[5]. Microscopic analysis of the specimens by means of various staining also proved to be nonspecific without sufficient sensitivity to detect this organism. The incubation process takes even from 3 to 7 days in order to obtain cultures of *H. pylori*. This was the reason to undertake cloning of urease gene of *H. pylori*, which was specific for this species, thus obtaining high sensitivity and specificity[6]. Urease genes (EMBL acc. No. X17079)[7] were sequestrected and specific *H. pylori* oligonucleotid primers were synthesized. Having used fumes of these oligonucleotid primers for detection and identification of *H. pylori*, the method of PCR (polymerase chain reaction) permits the recognition of *H. pylori* even in a trace, by multiplying the aimed genetic sequence of a specific ureA gene[8].

This paper describes the procedure of *H. pylori* microorganism detection in specimens of bile with the patients subject to the test suffering from benign diseases of biliary ducts (lithiasis with/without nonspecific cholangitis).

MATERIALS AND METHODS

The study was carried out on 72 patients, admitted at the Institute for Digestive Diseases (the Clinic for Gastroenterology and Hepathology and First Surgical Clinic) of the University Clinical Centre of Serbia in Belgrade. Laboratory workup was accomplished at the Gastrointestinal Research Laboratory, University of Rostock. The group of 72 patients who were tested consisted of 32 male and 40 female (45% and 55, respectively). The age range was from 11-90 yrs. The average age of all the patients was 56.7 years with SD±16.45. Thirty two patients (44%) had undergone previous cholecystectomy.

The patients were examined at the University Clinical Centre of

Serbia from September 20, 1998 to October 5, 1999. Prior to this, the patients did not undergo any endoscopic biliary theraputical procedures. In 68 patients, the specimens of bile were obtained during endoscopic retrograde cholangio-pancreatography (ERCP) and in 4 patients during cholecystoctomy. In all the patients which underwent ERCP, endoscopic papillotomy (EPT) was carried out with a variety of subsequent extraction procedures (basket, mechanical lithotripsy, balloon). Sampling of bile in those cases was performed prior to EPT. The existence of *H. pylori* in gastric mucosa was checked by fast urease test in all the patients at the Clinic of Gastroenterology and Hepathology of the Clinical Centre of Serbia during endoscopic examination.

DNA was isolated from bile specimens by a sequence of procedures including respectively: centrifugation, followed by a 2-hour incubation in lysis buffer, extraction via phenol chloroform, precipitation with acid ethanol, and dissolution in Tris-EDTA buffer. The final DNA sample was tested in respect of the existence of ure A gene by means of PCR method. In order to detect *H. pylori* infection of bile ducts nested (two-step) PCR was used, with two pairs of primers: outer primer with its own sense and antisense as follows: 5'-GCCAATGGTAAATTAGTTCC-3' (*s*) 5'-TTACTCCTTAATTGTTTTTAC-3' (as) and the other pair is so-called inner primer with its own sense and antisense: 5'-TTCTTTGAAGTGAATAGATGC-3' (*s*) 5'-ATAGTTGTCATCGCTTTTAGC-3' (*as*)[9]. Taq polymerase, 5MU·L^{-1} (Perkin Elmer Biosystems) was used during the reaction. The master mix for the first reaction (outer primers) consisted of 5μL of DNA template, 3μL of $MgCl_2$, 5μL Taq reaction buffer II, 4μL dNTPs, 0.2μL Taq polymerase, 1.3μL of outer sense primer, 1.2μL of outer antisense primer, and H_2O up to the final volume of 50μL. The master mix for the second reaction (inner primers) differed from the first one in the amount of primers: 1.7μL of outer sense primer, 1.0μL of outer antisense primer. Both PCR reactions were performed in a DNA thermal cycler in three steps, 1min. at 94 , 1min. at 50 , and 1min. at 72 , for 25 cycles each. The *H. pylori* gene was presented by electrophoresis on 10g·L^{-1} agarose gel at the level of 258 base pairs.

RESULTS

Based on the clinical tests, we diagnosed biliary lithiasis in the patients included in our study. Forty-eight of them (67%) had no signs of cholangitis (Figure 1), and 17 cases were complicated by cholangitis (24%, Figure 2). Seven patients (9%) had normal ERCP findings and constituted the control group.

In the group of patients with lithiasis 54.2% patients had a positive PCR H. pylori in bile and in the group of patients with inflammation a positive PCR was detected in 52.9% of the patients (Table 1). Among the seven patients with regular findings only one patient (14%) was PCR positive. There was a statistically significant difference in the positivity of PCR *H. pylori* in the joint group of patients who had non-malignant diseases of bile ducts (gallstones and inflammation) in relation to the controls (Chi-square test, P=0.0467). After the tested group was diivided into two basic pathologies and the statistical analysis repeated, it was clear that only the patients with lithiasis alone had a significantly higher frequency of positive *H. pylori* in bile (P=0.0486), contrary to the ones with associated cholangitis (Fischer's precision test, P=0.0967).

Fast urease test revealed a high percentage of *H. pylori* of gastric mucosa (57 patients - 79%). There was a slightly higher positivity in patients with distinct biliary pathology - 81% FUT positive patients in the group with cholelithiasis and 76% in the group with associated cholangitis, compared to the controls, where FUT was positive in 71%. There was no statistical difference between the groups (Chi-square test, P=0.5957).

Finally, if we compare findings of *H. pylori* in bile (by PCR method) with the same in gastric mucosa (by FUT method), we come to the conclusion that there is no statistically significant difference between them. However, if we extract only the subgroup of patients with lithiasis then the difference becomes highly significant (Chi square, P=0.0045).

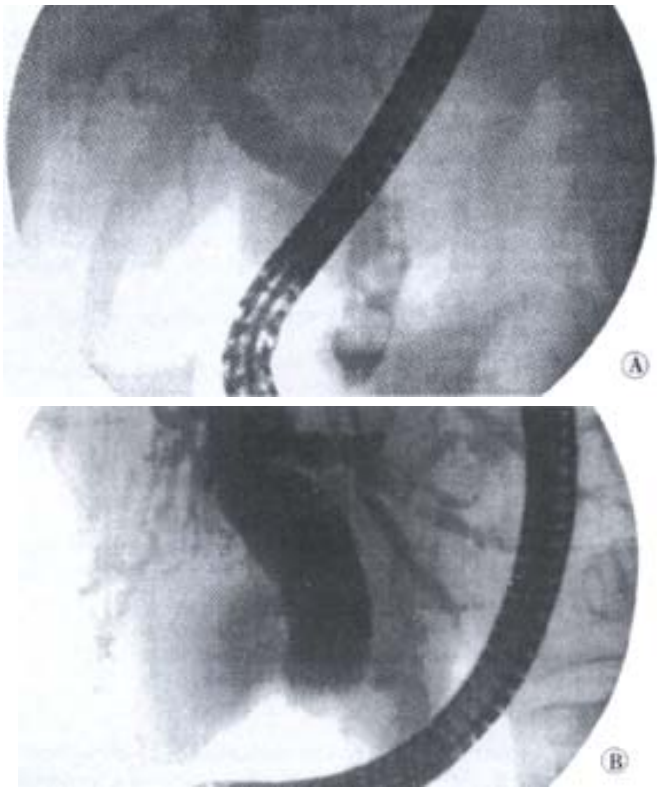

Figure 1 ERCP: Biliary calculosis
Figure 2 ERCP: Cholangitis

Table 1 *H. pylori* positivity in bile (PCR) and in gastric mucosa (FUT)

Test	Biliary lithiasis		controls
	without cholangitis	with cholangitis	
PCR +	26	9	1
PCR -	22	8	6
FUT +	39	13	5
FUT -	9	4	2

PCR: for ureA gene; FUT: Fast urease test

DISCUSSION

Bile acids in physiological concentrations inhibit the growth of various sorts of intestinal bacteria[10], including lactobacilli and clostridia, which are sensitive to unconjugated bile acids, such as cholic, deoxycholic and lithocholic acids. Since *H. pylori* is a Gram negative bacteria, it also shows sensitivity *in vitro* to deoxycholic and chenodeoxycholic acids[11]. They are the main free bile acids in human bile. However, under different pathological conditions, this inhibition factor of *H. pylori* growth can be changed: for example, the concentration of various matter in bile can be influenced by biliary obstruction[12]. Further, the *in vivo* inhibitory effect of bile acids to *H. pylori* has been proven by various studies through testing the role of *H. pylori* in biliary reflux gastritis, which, however, has given contradictory results[13], as some studies suggested that biliary reflux from the duodenum into the antrum did not affect the growth of *H. pylori* in antrum.

In our study, out of the total of 72 patients *H. pylori* was identified in bile of 36 patients (50%). This study demonstrates that there is a possibility to identify this microorganism by means of PCR method in the environment which is known to inhibit its growth under *in vitro* conditions. Since *H. pylori* infection was more frequent in the patients with the diseases of biliary ducts than in the controls (53.8% *vs* 14.3%), it is possible to suppose that under the pathological conditions there was a change of the conditions for the growth of this bacteria *in vivo* and this would be the subject of further research. Although it seems unlikely that *H. pylori* could grow in the environment which contains bile, it has been proven for some of Helicobacter species to be living in the gallbladder (H. hepaticus, H. bilis, H. pullorum and others)[14]. Fox *et al* detected H. bilis, H. pullorum and H. rappini by means of PCR method in 23 patients with the diagnosis of chronic cholecystitis although there were no cases where microorganisms had grown from bile cultures. Based on these data, it is possible that *H. pylori* caused certain idiopathic hepatobiliary diseases. *H. pullorum* is known to cause infection in people and chicken manifested with diarrhoea or increased hepathic enzymes and liver enlargement[15]. *H. rappini*, which causes abortion in sheep and acute insufficiency of liver of the sheep fetus, was isolated in people complaining of diarrhoea. Finally, *H. bilis* was proved to be a cause of hepatitis in mice[16].

Offner *et al*[17] announced in 1994 that the presence of M_r130 proteins caused crystalization of cholesterol. It was also found that CagA protein of *H. pylori* had this identical molecular weight, and also that both of these proteins had crossed reactions with human leucin-aminopeptidase[18]. Figura *et al*[19] found anti-CagA antibodies in 15 of 16 bile specimens in patients undergoing cholecystoctomy for stones and were proven to have CagA *H. pylori* within the stomach. All these findings support the role of these microorganisms in the initiation of crystalization of cholesterol which induces cholelithiasis. Recent researches devoted to the studies of Helicobacter sp. in different diseases of biliary ducts and liver show that Helicobacter can survive not only in stomach but also in human bile, and, additionally, that it can be the cause of various hepatobiliary diseases. For this reason, Roe *et al*[20] tested the survival of Helicobacter sp. in bile of the patients having various diseases of biliary system which contained changed bile acids or bile acids to which *H. pylori* was resistant. The study included 20 patients with intrahepatic lithiasis, three patients had pancreas cancer and two patients had common bile duct cancer. Bile was obtained by means of PTBD method and tested in respect of the presence of 16s rRNA specific gene of *H. pylori* by PCR method. The result of the PCR were the product of 375 bp. After the sequencing and analysis of sequences, 20 (80%) of PCR product were suited to *H. pylori* genome while the rest of 5 (20%) were suited to H. bilis genome. Based on the obtained results the authors concluded that H. pylori was the most important and the most frequent cause of infection among all sorts of *Helicobacter sp*. in diseases of biliary ducts. However, the authors did not give any explanation how the infection of biliary ducts with this bacteria happens but suggested further research in future.

In order to analyse the path and source of infection of biliary ducts utilizing the most senzitive methodology, we tested the positivity of *H. pylori* by PCR method (in bile) and FUT (in gastric mucosa) the result of which was a statistically very significant difference. This surprising finding could imply that the pathogenesis of biliary system and gastric mucosa are independent. In this difference the main portion belongs to lithiasis, since in the case of the subgroup with associated cholangitis no statistically significant difference was found. Taking into account that in the subgroup of lithiasis there were some deviations in the positivity of *H. pylori* towards the controls, it is clear that biliary pathogenesis is not uniform in all its forms. It has been pointed out earlier that H. sp. exist in the biliary system and gallbladder of the patients belonging to the Chilean population[13], being one of the main causes of chronic inflammation which can stimulate forming of biliary stones. Ponzetto *et al*[21] tested the presence of H. sp. in bile and mucosa of bile bladder of the patients having cholelithiasis and prevalence of *H. pylori* antibodies in serum of the patients. Sixty four patients were subjected to cholecystectomy and from whom bile was collected at operation as well as the mucosa of gallbladder. The specimens of serum were compared to the specimens of 610 blood donors. Serum was tested in respect of the presence of specific IgG antibodies in relation to *H. pylori* (ELISA). Bile and mucosa of bile bladder were tested by means of PCR method with respect to the presence of genetic sequence 16s rRNA H. sp. In 22 out of 64 tested specimens of bile PCR for H. sp. was positive. *H. pylori* infection was significantly more frequent in the patients with cholelithiasis than in the controls, and *H. pylori* DNA was also present in the bile of the patients.

Our clinical and molecular biological tests for *H. pylori* in patients with biliary diseases were undertaken in a larger population than that previously reported.

It is possible to conclude that PCR method can detect *H. pylori* infection of biliary ducts. Prevalence of *H. pylori* infection in the patients with benign diseases of bile ducts does not show a statistically significant difference in relation to the prevalence with the patients presentign with normal ERCP. However, in the patients with biliary lithiasis there is a certain difference which is on the borderline of statistical significance. The analysis of *H. pylori* in gastric mucosa by means of FUT method did not have a statistically significant difference either among the patients with benign biliary pathology and controls. Based on all the data stated above it can be said that the presence of *H. pylori* infection, either in bile or in gastric mucosa, does play a role in pathogenesis of benign biliary diseases although more explicit conclusions require a larger control group.

AKNOWLEDGEMENT

Warmest gratitude to the Department of Medicine, University of Rostock, and particularly to the Head and staff of the Gastrointestinal Research Laboratory for their kind help, support and contribution in this article.

Abstract

AIM: **To investigate the presence of *H.pylori* DNA within gastric epithelial cells in patients with *H.pylori* infection and its possible carcinogenic mechanism.**

METHODS: **Total 112 patients, with pathologically confirmed chronic superficial gastritis, chronic atrophic gastritis, intestinal metaplasia, atypical hyperplasia or gastric cancer were studied. Among them, 28 were *H.pylori* negative and 84 *H.pylori* positive. *H.pylori* DNA in gastric epithelial cells was detected by GenPoint catalyzed signal amplification system for *in situ* hybridization.**

RESULTS: **In the *H.pylori* positive group, zero out of 24 chronic superficial gastritis (0.0%), four out of 25 precancerous changes (16.0%) and thirteen out of 35 gastric cancers (37.1%) showed *H.pylori* DNA in the nucleus of gastric epithelial cells, the positive rates of *H.pylori* DNA in the nucleus of gastric epithelial cells were progressively increased in chronic superficial gastritis, precancerous changes and gastric cancer groups (χ^2=12.56, *P*=0.002); One out of 24 chronic superficial gastritis (4.2%), eleven out of 25 precancerous changes (44.0%) and thirteen out of 35 gastric cancers (37.1%) showed *H.pylori* DNA in the cytoplasm of gastric epithelial cells (χ^2=10.86, *P*=0.004). In the *H.pylori* negative group, only one patient with gastric cancer was found H.pylori DNA in the nucleus of gastric epithelial cells; Only two patients, one patient with precancerous changes and another with gastric cancer, showed H.pylori DNA in the cytoplasm of gastric epithelial cells. Furthermore, *H.pylori* DNA must have been in the cytoplasm as long as it existed in the nucleus of gastric epithelial cells.**

CONCLUSION: ***H.pylori* DNA exists both in the nucleus and the cytoplasm of gastric epithelial cells in patients with *H.pylori* infections. The pathological progression from chronic superficial gastritis, precancerous changes to gastric cancer is associated with higher positive rates of *H.pylori* DNA presence in the nucleus of gastric epithelial cells.**

INTRODUCTION

Gastric cancer is the second most common fatal malignancy in the world and is the cause of more than 750000 deaths annually[1-3]. Many studies have showed that *H.pylori* infection is closely related with gastritis, peptic ulcer and gastric cancer, and may play a causative role at the early phases of this chain[3-16]. *H.pylori* was classified as a class I carcinogen by the International Agency for Research on Cancer in 1994. So far the mechanism of *H.pylori* carcinogenesis has not been illuminated[3-7]. The *H.pylori* DNA must invade gastric epithelial cells first, and then exists chronically in gastric epithelial cell in an unknown manner before integration. The *in situ* hybridization technique has become an essential tool for detecting the localization of DNA transcripts on tissue sections[17-19]. The aims of our study are to investigate whether there is *H.pylori* DNA within gastric epithelial cells and the possible carcinogenic mechanism by GenPoint catalyzed signal amplification system for*in situ*hybridization in patients with *H.pylori* infections.

MATERIALS AND METHODS

Clinical data

By *H.pylori* diagnostic criteria, 112 patients, including 28 *H.pylori* that were negative and 84 *H.pylori* that were positive, were studied. There were 24 cases with chronic superficial gastritis, 25 cases with precancerous changes and 35 cases with gastric cancer among the *H.pylori* positive group, and 10, 16 and 2 cases, respectively among the *H.pylori* negative group. Histological examination was by routine haematoxylin and eosin stain, and by the *H.pylori* methylene blue staining kit as suggested by the manufacturer (Fujian Sanqiang, China). Rapid urease tests (Digestech, China),^{13}C-urea breath tests (Isodiagnostak, Canada) or ^{14}C-urea breath tests (Shenzhen Headway, China), and serological *H.pylori*-IgG tests (Orion Diagnostica,Finland) were carried out as suggested by each manufacturer. The positive criteria were randomly for two positive items among the following three items: (1) histology (routine haematoxylin and eosin stain, methylene blue stain), (2) urease dependent tests (rapid urease tests, ^{13}C- or ^{14}C- urea breath tests), and (3) serological *H.pylori*-IgG tests. Negative criteria were met if three items were negative.

In situ hybridization

The size of biotinylated Long DNA Probe for *H.pylori* M_r26000 Protein Gene (Maxim Biotech, USA.) is 303 base pair. 5μm sections were coated on single well slides and hot plated for 12h before deparaffination and rehydration with ethanol. The sections were treated sequentially with 2g·L^{-1} Triton-X100 for 15min, 1mM HCl for 10min and digested with 10g·L^{-1} pepsin (Sigma, USA) for 15min, and 20mg·L^{-1} proteinase K (Meack, Germany) for 30min. The enzyme was inactivated by treatment with 2g·L^{-1} glycine in pH7.4 phoshate-buffered saline (PBS) for 5min. Then the sections were incubated sequentially with 10g·L^{-1} RNase at 37℃ for 30min, 3ml·L^{-1} H_2O_2 in methanol for 30min and prehybridized with hybridization buffer solution at 37℃ for 60min. To denature the probe and cellular DNA, the sections were heated with hybridization buffer solution containing 1mg·L^{-1} of *H.pylori* probe at 95℃ for 15min. The sections were hybridized at 42℃ in a humidified chamber for 60min, then treated with Dako GenPoint catalyzed signal amplification system

for *in situ* hybridization as suggested by the manufacturer. The sections were counterstained with hematoxylin and examined under a light microscope.

Catalyzed signal amplification system for in situ hybridization

The Dako GenPoint system created an additional level of amplification for biotin detection. After an initial binding of streptavidin-peroxidase to the biotinylated probe, the peroxidase catalyzed the oxidation of biotinyl-tyramide, which immediately formed covalent bonds with aromatic groups in the specimen. This reaction deposited large amounts of biotin at the site of hybridization. The additional biotin was then used to capture more streptavidin-peroxidase. The signal was finally developed by adding the chromogenic indicator dye diaminobenzidine (DAB), which was oxidized by the precipitate at the site of hybridization.

RESULTS

In the *H.pylori* positive group, zero out of 24 chronic superficial gastritis (0.0%), four out of 25 precancerous changes (16.0%) and thirteen out of 35 gastric cancers (37.1%) showed *H.pylori* DNA in the nucleus of gastric epithelial cells, the positive rates of *H.pylori* DNA in the nucleus of gastric epithelial cells were progressively increased in chronic superficial gastritis, precancerous changes and gastric cancer groups (χ^2=12.56, P=0.002); One out of 24 chronic superficial gastritis (4.2%), eleven out of 25 precancerous changes (44.0%) and thirteen out of 35 gastric cancers (37.1%) showed *H. pylori* DNA in the cytoplasm of gastric epithelial cells (χ^2=10.86, P=0.004). In the *H.pylori* negative group, only one patient with gastric cancer was found *H.pylori* DNA in the nucleus of gastric epithelial cells; Just two patients, one patient with precancerous changes and another with gastric cancer, showed *H.pylori* DNA in the cytoplasm of gastric epithelial cells. Furthermore, *H.pylori* DNA must have been in the cytoplasm as long as it existed in the nucleus of gastric epithelial cells.

DISCUSSION

H.pylori has been acknowledged as a possible carcinogen[3-16]. Genome integration is the most important carcinogenic mechanism in some microorganisms[19-21]. However, there is no reliable evidence of integration of the *H.pylori* DNA in the human genome at this time[22-24]. Parsonnet proposed that *H.pylori* has a similar mechanism as virus carcinogenesis[4], viz, *H.pylori* DNA integrated into the gastric epithelial cells genome, which may induce transformation or malignancy of the normal cell. The *H.pylori* DNA must invade the gastric epithelial cells first, and then exists chronically in gastric epithelial cell in an unknown manner before integration. We found that the *H.pylori* DNA can exist both in the nucleus and cytoplasm of gastric epithelial cells in patients with *H.pylori* infections, predominately in cases with precancerous changes and gastric cancer by *in situ* hybridization technique that has been proved a powerful tool for *in situ* gene localization in individual cell[17-19]. *H.pylori* DNA can invade into host cells, even into the nucleus, and exist chronically within cells, which is indicated *H.pylori* DNA and genome of host cell would affect each other, even *H.pylori* DNA integrated into genome of host cell. Chiou and his colleagues[25] demonstrated that *H.pylori* infection caused an alteration of gene expression in AGS cells and identified 21 overexpressed genes and 17 suppressed genes from the cDNA expression arrays. Some other studies have also showed the alteration of gene expression, cell proliferation and apoptosis[14-16,26-38] in patients with gastric cancer or *H.pylori* infection.

We collected 84 *H.pylori* positive cases, including 25 precancerous changes and 35 gastric cancers, and significantly increased sensitivity by Dako GenPoint catalyzed signal amplification system. The rates of *H.pylori* DNA in the nucleus of gastric epithelial cells was progressively increased in chronic superficial gastritis, precancerous changes and gastric cancer, at 0.0%, 16.0% and 37.1%, respectively in the *H.pylori* positive group. So the progression from chronic superficial gastritis to precancerous changes and to gastric cancer was associated with the presence of *H.pylori* DNA in the nucleus of gastric epithelial cells. This may indicate that *H.pylori* DNA and the genome of the host cell may affect each other, as *H.pylori* DNA is integrated into genome of the host cell. As a result this may change the structure and function of the host cell genome, and thus destroy the stability of the genome. We also found there was *H.pylori* DNA in the *H.pylori* negative group. High sensitivity of *in situ* hybridization[17-19] and previous *H.pylori* infection may explain the result. *H.pylori* DNA was also located in the cytoplasm of gastric epithelial cells. *H.pylori* can be seen to invade gastric mucosa by electron or immunoelectron microscopy[39-42]. *H.pylori* was able to destroy the junction of cells, and even invade into the cytoplasm of stromal cells in the lamina propria. Yang and his colleagues[41] found that *H.pylori* could be engulfed and degraded by the human gastric cancer cell line SGC-7901 using transmission electron microscopy. Once the *H.pylori* DNA invaded the gastric epithelial cells, it could enter the nucleus when the karyotheca disappears during the metaphase of mitosis. If the *H.pylori* DNA was found in nucleus, it was also found in the cytoplasm in our study. In the *H.pylori* positive group, the positive rates of finding *H.pylori* DNA in cytoplasm in precancerous changes and gastric cancer were higher than that in chronic superficial gastritis, while there was no statistic significance in the rate between precancerous changes and gastric cancer.

ACKNOWLEDGEMENT

We thank Dr EB Holm for suggesting improvements to the manuscript.

Abstract

AIM: **To construct a recombinant vector which can express M_r26000 outer membrane protein (OMP) from *Helicobacter pylori* (*Hp*), and to obtain the vaccine protecting against *Hp* infection and a diagnostic reagent kit quickly detecting *Hp* infection.**

METHODS: **The gene encoding the structural M_r26000 outer membrane protein of *Hp* was amplified from *Hp* chromosomal DNA by PCR, and inserted in the prokaryotic expression vector pET32a (+), which was transformed into the Top10 E. *coli* strain. Recombinant vector was selected, identified and transformed into BL-21(DE3) E. *coli* strain. The recombinant fusion proteins were expressed. The antigenicity of recombinant protein was studied by ELISA or immunoblotting and immunized Balb/c mice.**

RESULTS: **The gene of M_r26000 OMP was amplified to be 594 base pairs, 1.1% of the cloned genes was mutated and 1.51% of amino acid residues was changed, but there was homogeneity between them. The recombinant fusion protein encoded objective polypeptides of 198 amino acid residues, corresponding to calculated molecular masses of M_r26000. The level of soluble expression products was about 38.96% of the total cell protein. After purification by Ni-NTA agarose resin columniation, the purity of objective protein became about 90%. The ELISA results showed that recombinant fusion protein could be recognized by patient serum infected with *Hp* and rabbit serum immunized with the recombinant protein. Furthermore,Balb/c mice immunized with the recombinant protein were protected against *H.pylori* infection.**

CONCLUSION: **M_r26000 OMP may be a candidate vaccine preventing *Hp* infection.**

INTRODUCTION

Helicobacter pylori (*Hp*) is a microaerophilic, spiral and gram-negative bacillus first isolated from human gastric antral epithelium in 1982. It is recognized as a human-specific gastric pathogen that colonizes the stomachs of at least half of the world's population[1]. Most infected individuals are asymptomatic. However, in some subjects, the infection is associated with the development of peptic ulcer, gastric adenocarcinoma, mucosa-associated lymphoid tissue (MALT) lymphoma and primary gastric non-Hodgkin's lymphoma[2-11]. Furthermore, this organism was recently categorized as a class I carcinoma by the World Health Organization[12], and direct evidence of carcinogenesis was recently demonstrated in an animal model[13,14]. Immunization against the bacterium represents a cost-effective strategy to reduce the incidence of global gastric cancer and would also have a major impact on *H. pylori*-peptic ulcer disease[15]. The selection of antigenic targets is critical in the design of an Hp vaccine. To date, this area is scarcely touched upon. The majority of studies focused on the urease enzyme, heat shock protein, VacA, and so on[1,16-19],but not M_r26000 outer membrane proteins. So, in this study, the recombinant plasmid of *H. pylori* M_r26000 outer membrane protein genes was constructed,and expressed for development of *Hp* vaccine.

MATERIALS AND METHODS

Materials

A well-characterized strain, *H. pylori* (*Hp*), was afforded by the Department of Microbiology, Chongqing University of Medical Sciences. Top10, BL21 E.coli strains and pET32a(+) plasmid were presented by the Institute of Viral Hepatitis of Chongqing University of Medical Sciences. Restriction enzymes (HindIII, BamHI) and T_4 DNA ligase were purchased from Promega, TagDNA polymerase was produced by Immunology Department of the former Beijing Medical University. Isopropyl-β-D-thiogalactopyranoside (IPTG), dNTP and oligonucleotide primers were obtained from Sigma Chemical Co. and so on.

Cloning of Hp M_r26000 OMP gene

Oligonucleotide primers were designed to amplify *H. pylori* open reading frame (ORFs) of M_r26000 outer membrane protein based on the published genome sequence[20]. The primers were designed with a *Bam*HI site incorporated into the 5' end and a *Hin*d III site at the 3' end as follows(5'-3'): GCGGATCCATGTTAGTTACAAAA CTTGCC (forward) and AAGCTTAATGGAATTTTCTTT (reverse). Genomic DNA prepared from Chongqing *H. pylori* strains was used as the template in the PCR. The PCR cycle consisted of 30 cycles of denaturation at 94℃ for 60s, annealing at 58℃ for 45s, with an extension step at 72℃ for 90s. Products were visualized on $10g \cdot L^{-1}$ agarose gel and purified using a PCR purification kit. After digestion with the restriction enzymes BamHI and Hind III simultaneously, the purified products were cloned into the compatible sites of the expression vectors pET32a(+) using T_4 DNA ligase at a molar ratio of 4:1 at 4℃ overnight.

Fifty μL Top10 incubated at 37℃ overnight was added into 2mL Luria-Bertani broths and routinely grew at 37℃, and shaken at $300r \cdot min^{-1}$ for 4h. When optical density at 600nm was 0.5, it was ultracentrifuged at $10000r \cdot min^{-1}$ at room temperature (RT) for 2min. The resulting deposits were suspended with $100mmol \cdot L^{-1}$ $CaCL_2$ 150μL and incubated at 0℃ for 2h. Ten μL connected products(aboved) was resuspended and incubated at 0℃ for 30min, at 42℃ for 2min and at 0℃ for 2min respectively. At last, it was incubated at 37℃ at $180r \cdot min^{-1}$ for 30min after the addition of 1mL LB broth, 200μL was collected and spred onto an LB plate containing $100mg \cdot L^{-1}$ ampicillin as the selectable marker and incubated at 37℃ overnight.

Extraction and expression of recombinant plasmid

The next day, the single cloned bacterial drop was selected, and cultured in 2mL LB broth containing 100mg·L^{-1} ampicillin at 37℃ overnight at 300r·min^{-1}, then recombinant plasmids were extracted and screened with plasmid extraction kit according to the manufacturer's instruction, in the meantime, identified by PCR and restriction enzyme digestion. The recombinant plasmids were selected and transformed into competent BL21(DE3) E.*coli* strains using standard procedures. BL21 E.*coli* strains containing recombinant plasmid were grown until mid-log phase (optical density at 600nm= 0.5 to 1.0), and expression of the fusion proteins was induced by addition of 0.5-4.0mmol·L^{-1} IPTG for 4h. Following induction, the bacteria were harvested by ultracentrifugation at 12000r·min^{-1}, resuspended in protein-buffer and seethed for 5min. Total protein was electrophoresed on SDS-PAGE gel and stained with coomassie.

Immunoblotting analysis

Briefly, the M_r26000 OMP was purified using Ni-NTA agarose resin after bacteria were cultured and broken down cy microwave with the energy of 600W×35% for 40min, ultracentrifuged (10000g, 15min, 4℃), and then quantified. *H.pylori* M_r26000 outer membrane protein-specific antibody was produced following subcutaneous immunization of the New Zealand rabbits, while age-matched control rabbits were immunized with PBS as described previously[17]. Serum antibody specificity was determined by ELISA or immunoblotting following electrophoretic transfer of SDS-PAGE-separated (150g·L^{-1} acrylamide) *H. pylori* M_r26000 outer membrane protein to 0.45μm pore size PVDF membrane. After a 30min wash in Tris-saline blotting buffer, antigen-impregated PVDF strips were incubated with the rabbit sera for 2h at RT. After washing, bound rabbit antibodies were detected by incubation of the strips in alkaline phosphatase-conjugated goat anti-rabbit IgG antibody for 1h at RT.

Prophylactic immunization

Six- to eight-week-old mice were immunized three times by subcutaneous immunization using emulsified M_r26000 OMP with Freund's adjuvant at intervals of 1, 14 and 21 days respectively, to produce antibody responded to M_r26000 outer membrane protein. The dose consisted of 1mL (100mg·L^{-1}) of purified M_r26000 OMP and 1mL complete Freund's adjuvant. Thereafter, the dose consisted of 0.5mL OMP and 0.5mL incomplement Freund's adjuvant. Age-matched control mice were immunized with PBS. The antibody titers in immunized mice were monitored by ELISA with purified fusion protein. Mice were challenged with a single dose of 10^8 *H. pylori* organisms 7 days after the last immunization. Twenty-eight days after challenge, the mice were killed by cervical dislocation. The stomach of each animal was removed,bisected longitudinally, and pinned out. Full-thickness tissue was taken from the antrum-body area of one-half of each stomach and placed into 0.2mL of urease test medium. Urease activity in the sample, identified by a distinctive color change in the medium, was assessed after 24h incubation at RT. The remainder of the stomach was fixed in 100mL·L^{-1} buffered formalin and embedded in paraffin. Longitudinal sections, stained with a modified May-Grunwald Giemsa stain, were scanned by full length under light microscopy. Mice were considered protected or not according to the previously report[17].

Statistical analysis

The Student test was used to evaluate the presence or absence of experimental infection in test and control animals as well as the anti-M_r26000 outer membrane protein response to immunization. *P* values <0.05 were considered as statistically significant.

RESULTS

PCR amplification of H. pylori M_r26000 OMP gene

According to the literature, the gene encoding the M_r26000 outer membrane protein, was amplified by PCR with Chongqing *H. pylori* strain's chromosomal DNA as the templates. The cloning products were electrophoresed and visualized on 10g·L^{-1} agarose gel(Figure 1). It revealed that M_r26000 OMP DNA fragment amplified by PCR contained a gene of approximately 594 nucleotides, which was compatible with the previous reports[21].

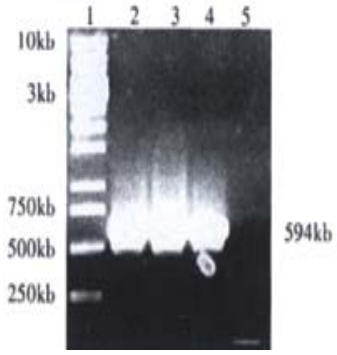

Figure 1 Ten g·L^{-1} agarose gel electrophoreses of M_r26000 OMP DNA fragment amplified by PCR from *Helicobacter pylori*. Lane1: Nucleotide marker; Lane2-4: PCR products; Lane 5: Negative control.

Identification of recombinant plasmid by restriction enzyme digestion

The recombinant plasmids pET32a(+) were all digested by *Hind*III or *Bam*HI, and by *Hind*III and *Bam*HI simultaneously, then digestive products were visualized on 10g·L^{-1} agarose gel eletrophoreses (Figure 2). It demonstrated that recombinant plasmid contained the objective gene.

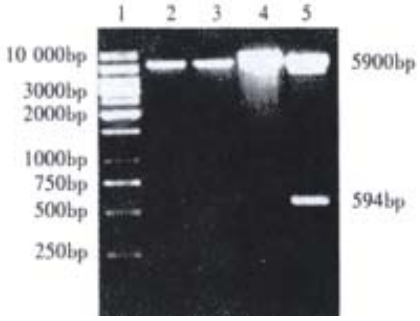

Figure 2 The identification of recombinant plasmid by restriction enzyme digestion. Lane1:Nucleotide marker; Lane2: pET32a(+) / *Hin*dIII; Lane3: pET32a(+) / *Hin*dIII, *Bam*HI; Lane4: Recombinant plasmid / *Hin*dIII; Lane5: Recombinant plasmid / *Hin*dIII, *Bam*HI.

Sequence analysis of cloned M_r26000 OMP nucleotide

The nucleotide sequence of the cloned genes inserted in pET32a(+) was analyzed by automated sequencing across the cloning junction, using the universal primer T_7. The results were: the cloned genes contained 594 nucleotides with a promoter and a start codon coding a putative protein of 198 amino acid residues with a calculated molecular mass of M_r26000. As compared with previously reports, 1.1% of the cloned genes were mutated, and 1.51% amino acid residues were changed. The homogeneity was about 98% between them. The cloned gene and mutative protein sequences were published in GenBank (AY 033499).

Analysis of the recombinant fusion protein

Following recombinant vector transformed into BL21 *E. coli* strains,

the fusion protein was amply expressed. Its molecular mass was M_r 46000 by 150g·L^{-1} SDS-PAGE gel analysis (the expression of the pET32a(+) vector, M_r20000). After the recombinant bacteria broken down by microwave and ultracentrifuged (10000r·min^{-1}, 15min, 4℃), the level of soluble fusion protein in the supernatant was about 38.96% of total cell protein. After purification by Ni-NTA agarose resin columniation, the purity of objective protein was about 90% (Figure 3).

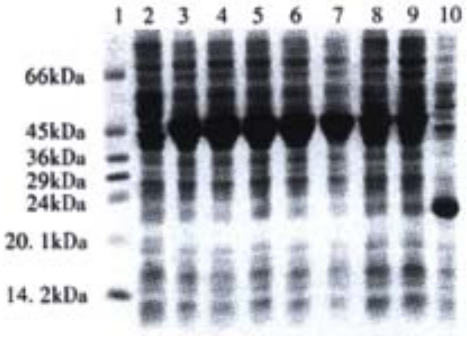

Figure 3 150g·L^{-1} SDS-PAGE analysis of the fusion protein expressed in BL21(DE3). Lane1: Molecular weight marker; 2Lane: BL21 after 4h induction with IPTG; Lane3-9: BL21/recombinant vector expression after 4h induction with 0.5,1,1.5,2,2.5,3,4mmol·L^{-1} IPTG respectively; Lane10: BL21/pET32a(+) vector expression after 4h induction with IPTG.

Antigenicity study of recombinant fusion protein

Sera were obtained from persons infected and not infected with *H. pylori* respectively. The recombinant fusion protein was recognized by the *H. pylori* positive sera, not recognized by the *H. pylori* negative sera, while the expressed protein of BL21/pET32a(+) not recognized by the *H. pylori* positive sera; the recombinant fusion protein was also recognized by the rabbit sera immunized with M_r26000 OMP, however the expressed protein of BL21/pET32a(+) not recognized by the rabbit sera immunized with M_r26000 OMP.

Prophylactic efficacy with H. pylori M_r26000 OMP

Subcutaneous immunization with *H. pylori* OMP and FA(Freund's adjuvant) conferred immune protection against *H. pylori* challenge in 19 (95%) of 20 mice. In contrast, 15 (100%) of 15 naive control animals were infected with *H. pylori*. These differences were statistically significant (P<0.05). The protection from infectious challenge was correlated with serum antibody reactivity to M_r26000 OMP by immunoblotting. Similar reactivity was absent in the sera collected from same animals prior to immunization, while sera from mice sham immunized with PBS and FA failed to display similar immune responsiveness.

DISCUSSION

The outer membrane is a continuous structure on the surface of gram-negative bacteria and an asymmetric bilayer with phospholipids in the inner monolayer and the bulky glycolipid lipopolysaccharide (LPS) in the outer monolayer, in bacterial pathogens, has bilateral particular significance as a potential target for protective immunity and avoiding the host's immune system. Outer membrane vaccines have been used with considerable success to induce protection against a number of organisms, including *H. pylori* the heat shock protein, urease A, B and so on. M_r26000 OMP is a low molecular mass Hor protein belonging to family I of *H. pylori*[20]. An earlier study showed that it was commonly expressed in all *H. pylori* strains examined so far. Furthermore, no cross-reaction is shown when antibodies (polyclonal and monoclonal) to *H. pylori* low-molecular outer membrane protein are used to immunoscreen closely related species of helicobacter, campylobacter, or a diverse range of other bacteria. *Hp* low molecular outer membrane protein is unique.

In our study, 1.1% of the cloned genes was mutated, 1.51% of amino acid residues was changed as compared with other reports[20]. The reasons of difference might be summarized as follows: (1)*H. pylori* chromosomal DNA as templates were different; (2) there is heterogeneity among strains; and (3) *H. pylori* was provided with the ability of transformation, which could lead to *H. pylori* variated and genome reseted[22]. But there was homogeneity between them. The purified recombinant M_r26000 OMP antigen could be recognized by the sera of patients infected with *H. pylori* and rabbit sera immunized with the recombinant protein. Moreover, in animal model, Balb/c mice immunized with the recombinant fusion protein were protected against *H. pylori* infection. These were consistent with previous reports[23-26]. While being an immunogenic marker, M_r26000 OMP showed a high sensitivity and specificity[27]. Moreover, a significant association was found between the serologic response to M_r26000 antigen and malignant outcome of *H. pylori* infection[28-31]. So the serum test for detecting antibody with low molecular weight proteins of *H. pylori* could be useful for identifying *H. pylori*-infected patients at risk of peptic ulcer or malignancy. The results showed that M_r26000 OMP is not only an immunogenic marker for detecting *Helicobacter pylori* infection and gastric carcinoma, but also a true vaccine candidate.

In addition to constructing the recombinant vector,we also tried to seek live carriers, because antigen delivery systems can influence the immune response qualitatively as well as quantitatively. Immunization via the mucosal route offers the advantage that it has the potential to stimulate both mucosal immunity and systemic immunity. It is simple, safe and can be used for the immunization of large population groups. Another advantage is the existence of the common mucosal immune system which induced protective immune responses at one mucosal site to be expressed at another[32]. So live carriers on oral route are ideal vaccine delivery systems and are being increasingly used to express large amounts of protective recombinant antigens. We are investigating live carriers to provide a mucosal vaccine vector to deliver M_r26000 OMP to antigen-presenting cells on the mucosal surface.

Abstract

AIM: **Residual stress and strain are important for gastrointestinal function and relate to the geometric configuration, the loading conditions and the zero-stress state of the gastrointestinal tract. The purpose of this project is to provide morphometric data and residual strains for the rat small intestine (n=11).**

METHODS: **To approach the no-load state, the intestine was surgically excised, transferred to an organ bath and cut transversely into short ring-shaped segments. Each ring was cut radially for obtaining the zero-stress state. The residual stress can be characterised by an opening angle. The strain difference between the zero-stress state and the no-load state is called residual strain.**
