Anemia is a frequent extraintestinal manifestation in IBD; about one-third of IBD patients have hemoglobin levels below 12 g/dL[96]. The anemic state correlates strictly with the quality of life and so is certainly an important problem in the therapeutic management of chronic patients[97]. Multiple pathogenic mechanisms often coexist in anemic patients leading to mixed features anemia. Chronic intestinal bleeding with iron loss (due to bowel inflammation) causes a hypochromic and microcytic anemia with associated hypoferremia and hypoferritinemia; the chronic inflammatory disease (typically characterized by hyperferritinemia) can cause anemia through the proinflammatory cytokine-dependent diversion of iron traffic to reticuloendothelial system and erythroid progenitor cell development interference[98]. The same inflammatory cytokines are able to inhibit erythropoietin production[99]. Recently, *in vitro* anti-TNF-α factors showed positive effects in preventing apoptosis of erythroid cells[100]. Other mechanisms implied in anemia are iron malabsorption (in duodenum or upper jejunum disease CD), vitamin B12 malabsorption (in terminal ileum and gastric CD), and folate deficiency (malabsorption, inadequate diet, and side effects of sulfasalazine and methotrexate). Vitamin B12 and folate deficient anemia is characteristically macrocytic. Myelosuppressive direct effects have been reported frequently for azathioprine/6-mercaptopurine and sometimes also for sulfasalazine and 5-aminosalycilic acid[101]. Correction of the anemic state is useful also in low-grade anemia. It is important to prevent and treat intestinal flares that are often the cause of anemia and to reintegrate the lacking of iron, B12, and folate.

In low-ferritin patients, prevention therapy with oral iron can be sufficient; in overt anemia iron intravenous (preferentially iron sucrose) supplementation should be preferred to oral route because of major efficacy and no collateral intestinal side effect. Epo therapy is useful in patients with no satisfactory response to iron therapy alone[101]. Low levels of Epo, soluble transferring receptors or transferrin have shown to predict iron sucrose resistance[102].

Urinary system manifestations

IBD is a risk factor for renal immune and non-immune mediated diseases.

The prevalence of nephrolithiasis in IBD varies from 2% to 6% and is more frequent in CD than in UC[103]. Calcium-oxalate stones are the most common and are caused by hyperoxaluria due to increased intestinal absorption of oxalate. In fact in the bowel that does not absorb fatty acids link calcium preventing calcium-oxalate precipitation with the consequent increased absorbable oxalate fraction. More than one lithogenic factors are often present in the same patient, more frequently during active disease. The main lithogenic risk factors are: low urinary volume, low urinary PH, increased excretion of lithogenic substances as oxalate, phosphate, uric acid, and decreased concentration of anti-lithogenic substances as citrate and magnesium. Colectomy in UC and ileo-colonic resection in CD seems to further increase the risk of lithiasis and oxalate stone formation occurs mainly in ileal CD[104].

Table 4 Drugs and their possible adverse side effects

Drugs	Possible adverse side effects
Corticosteroids	Acne, fluid retention, fat redistribution, hypertension, hyperglycemia, psycho-neurological disturbances, cataracts, growth failure in children, osteonecrosis[115]
Mesalazine	Nausea, dyspepsia, rare nephritis, rare idiosyncratic worsening of IBD[116]
Sulfapyridine	Headache, nausea, anorexia, rare hypersensibility hepatitis, hemolytic anemia, pancreatitis, reversible sperm abnormalities, worsening of IBD[116]
Azathioprine/mercaptopurine	Pancreatitis, bone marrow suppression, hepatotoxicity[115]
Methotrexate	Nausea, leucopenia, hepatic fibrosis, hypersensibility pneumonia[117]
Cyclosporin	Nephrotoxicity, hypertension, headache, gingival hyperplasia, paresthesias[115]
Tacrolimus	Nephrotoxicity[115]
Infliximab	Infusion reactions, delayed hypersensitivity-like reactions, drug-induced lupus, tuberculosis reactivation[118]
Metronidazole	Nausea, metallic taste, peripheral neuropathy[115]

Periodic sonographic examination is recommended for early diagnosis and for the prevention of complications. Furthermore, minimal signs of tubular damage have been found in about 20% of IBD patients but rarely they are clinically relevant[105].

A calculus uretheral obstruction, prevalently localized on the right, is also possible and is related to the mechanisms of adherence and compression by inflamed bowel (prevalently terminal ileum)[103]. Urinary tract fistulas occur in about 1.7-7.7% of patients. They can cause pneumaturia, dysuria, recurrent infections, and fecaluria. At the moment in most cases, the non-satisfactory response to medical therapy makes surgery the best option[106].

Clinical relevant renal amyloidosis has been reported in about 1% of IBD patients (more frequently in ileal CD). It is probably related to acute phase reaction proteins[107]. In IBD patients, cases of glomerulonephritis causing nephrotic syndrome and renal failure have also been reported. They are related to intestinal disease activity, are quite responsive to IBD therapy and can present many patterns at histology[108]. Moreover, it seems that mi nimal, clinically non significant, glomerular inflammatory changes are quite frequent in IBD patients as shown in a post mortem study (70% of subtle renal lesions *vs* 8% of controls)[109] but following data do not exploit this aspect.

Other rare extraintestinal manifestations

It has been reported in literature about the occurrence of other rare extraintestinal manifestations of IBD, such as, chronic recurrent multifocal osteomyelitis (CRMO), myositis[110], polyneuropathy, Guillain-Barre syndrome[111], lymphocytic encephalomyeloneuritis[112], myocarditis[113], and pleuropericarditis[114].

Drug-induced side effects

Many drugs used in IBD treatment can cause side effects involving various organs (Table 4). These effects that often need drug interruption enter in differential diagnosis with extraintestinal manifestations/complications of IBD; their early diagnosis is facilitated by periodical serum analysis exploring liver, pancreatic, renal, and hematological system integrity as for example is recommended in methotrexate and azathioprine use[115]. Furthermore, the limited use to short period of other drugs can prevent their effect as for example as it often happens for corticosteroids (Table 4).

CONCLUSION

IBD is a systemic disease, since its clinical manifestations can affect not only the bowel but also practically any other organ (eyes, liver, osteoarticular system, kidneys, and so on) through different (often not completely cleared) mechanisms. At the moment, awareness of the high incidence of extraintestinal manifestations is often inadequate. Therefore, prevention, early diagnosis, and adequate treatment of these pathological conditions, sometimes more dramatic than the intestinal disease, are necessary to increase patients' health. Clinical interventional trials in IBD patients should consider these conditions with more attention to indicate the best cost-effective method for clinicians.

Abstract

AIM: To clarify the efficacy and safety of three-dimensional conformal radiotherapy (3-D CRT) for this disease and to specify patient subgroups suitable for this treatment.

METHODS: Fifty-two patients with HCC received PVI-targeted radiation therapy from January 1995 through December 2003. Portal venous invasion (PVI) was found in the second or lower order branches of the portal vein in 6 patients, in the first branch in 24 patients and in the main trunk in 22 patients. Child classifications of liver function before radiation therapy were A, B, and C for 19, 24 and 2 patients, respectively. All patients received three-dimensional conformal radiotherapy with a total dose ranging from 39 to 60 Gy (57.0 Gy in average).

RESULTS: Overall survival rates at 1, 2, 3, 4, and 5 years were 45.1%, 25.3%, 15.2%, 10.1%, and 5.1%, respectively. Univariate analysis revealed that Child status, the number of tumor foci, tumor type, transcatheter arterial embolization (TAE) after radiation therapy were statistically significant prognostic factors. Multivariate analysis showed that the number of tumor foci and TAE after radiation therapy were statistically significant.

CONCLUSION: The results of this study strongly suggest the efficacy of 3-D CRT as treatment for PVI in HCC. 3-D CRT is recommended in combination with post-radiation TAE for PVI of HCC with 5 tumor foci or less in the liver and with Child A liver function.

Key words: Hepatocellular carcinoma; Portal venous invasion; Radiation therapy

INTRODUCTION

Patients with primary hepatocellular carcinoma (HCC) often develop portal venous invasion (PVI)[1-6]. PVI is associated with a high probability of extensive tumor spread and an elevation of portal vein pressure, which subsequently may cause esophageal varices and liver dysfunction. Transcatheter arterial embolization (TAE) which is performed frequently for advanced HCC is not indicated when portal blood flow decreases due to PVI. It is, therefore, associated with a poor prognosis[2-3]. No treatment strategy for PVI has been established, and the median survival has been reported to range only from 5 to 11 mo[7-12]. Notably, the 1-year survival rate is less than 50% and there are only a few 3-year survivors of PVI affecting the first branch and/or the main trunk of the portal vein[3, 13].

Few articles on the radiation therapy have been reported for the disease. The aim of the study is to clarify the efficacy and safety of three-dimensional conformal radiotherapy (3-D CRT) for PVI from HCC and to specify patient subgroups who are best benefited by this treatment strategy.

MATERIALS AND METHODS

Fifty-two patients with HCC received PVI-targeted radiation therapy from January 1995 through December 2003. The aim of the treatment was to prevent and/or improve liver dysfunction caused by PVI and re-actualize transcatheter arterial embolization (TAE) for intrahepatic tumors as well as to control PVI itself. All patients but one were male. A diagnosis of HCC was made using ultrasonography (US), computed tomography (CT), angiography, and liver biopsy, as previously reported. Histopathological diagnosis was confirmed in all the patients. Criteria of diagnostic imaging of PVT is a low-attenuation intraluminal mass that expanded the portal vein on enhanced CT or conventional US[14-16] and/or the detection of pulsatile flow in portal vein thrombi by Doppler US[17].

Table 1 List of size of intrahepatic tumor

Size of intrahepatic tumor (cm)	No. of patients
No HCC	1
1-1.99	2
2-2.99	21
3-3.99	11
4-4.99	7
5-5.99	3
6-6.99	2
⩾7	5

The observation period ranged between 17.4 mo and 123.6 mo (average, 60.4 mo; median, 58.4 mo). These patients ranged in age from 43 years to 82 years (average, 63.1 years; median, 64.0 years) when radiation therapy was started. Eight patients were hepatitis B virus (HBV) related, 40 patients were hepatitis C virus (HCV) related, and 45 had pathologically proven liver cirrhosis. Child classifications of liver function before radiation therapy were A, B, and C for 19, 24 and 2 patients, respectively. Values of the Karnofsky index ranged from 70 to 100 (average, 90.8; median 90). PVI was found in the second or lower order branches of the portal vein in 6 patients, in the first branch in 24 patients and in the main trunk in 22 patients. HCCs were classified as nodular, massive, and diffuse, according to the criteria of the Liver Cancer Study Group of Japan[18]. Thirty-six patients had nodular, 9 had massive, and 6 had diffuse HCCs. The size of the intrahepatic tumors varied patient to patient and no intrahepatic tumor was detected in one patient as summarized in Table 1. Thirteen patients had a single focus for the intrahepatic tumor, 7 had 2 to 5 foci, and 31 patients had 6 or more.

Regarding treatment for HCC before the detection of PVI, 31 patients had undergone percutaneous tumor ablation (PTA) such as percutaneous ethanol injection (PEIT) and percutaneous microwave coagulation therapy (PMCT), 40 patients had undergone TAE, and 22 patients had both procedures. Tumors were surgically resected in 7 patients.

All patients received 3-D CRT with a multi-leaf collimator (MLC) using 6 MV X-ray. Figure 1 is an example of dose distributions in one patient. Our goal to give a total dose of 60 Gy to each patient was achieved in 38 cases (mean total dose, 57.0 Gy, range: 39-60 Gy). A daily dose of 2 Gy was delivered 5 times a wk. Clinical tumor volume (CTV) was the tumor itself which was depicted on CT and/or US. Planning target volume (PTV) was defined as 1.5 to 2.0 cm beyond the enhanced lesion on CT scan. Radiation was performed while the patient was breathing shallowly without the use of breath control or respiratory gating. Initial effects of radiation therapy on PVI was evaluated 8 to 12 wk after the completion of radiation and expressed according to the WHO criteria[19].

After the completion of radiation therapy for PVI, 10 underwent PTA, 25 underwent TAE, and 8 patients had both procedures. No surgical operation was performed following radiotherapy for PVI.

The survival period was measured from first day of irradiation and the Kaplan-Meier technique was used to calculate the survival rate. The differences in survival rates were analyzed using the log rank test. Uni and multivariate analyses were performed by Cox's proportional hazard model. Statistical analyses were considered significant if the *P*-value was 0.05 or less.

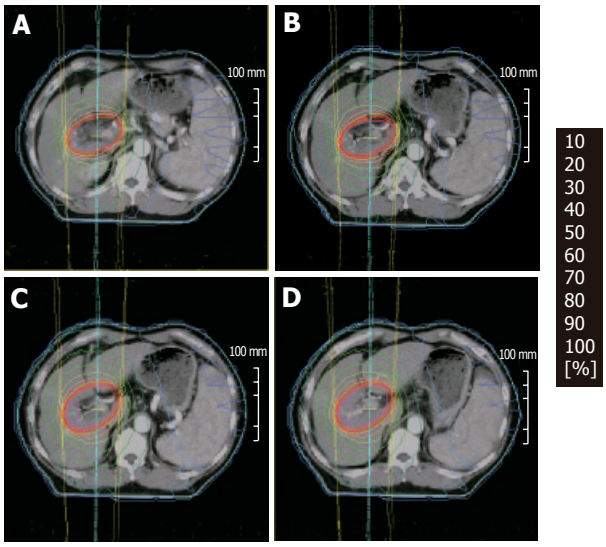

Figure 1 An example of dose distributions (**A, B, C, D**) in 3D-CRT.

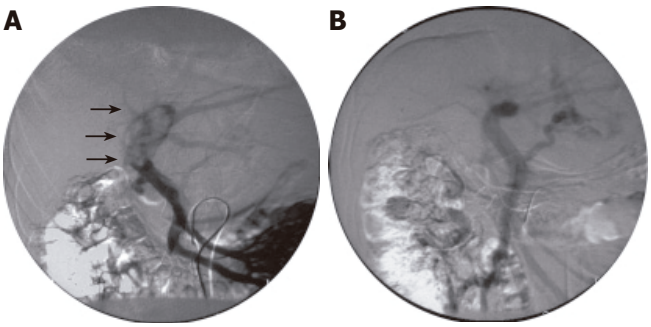

Figure 2 Angiographs of the portal vein showing disappearance of a tumoral embolus after irradiation therapy. Angiographs taken before and after treatment are shown to the left (**A**) and right (**B**), respectively.

Written informed consent was obtained in all the patients in this study.

RESULTS

The initial effects of radiation therapy on PVI were complete regression (CR) in 2 patients, partial regression (PR) in 24 patients, stable disease (SD) in 18 patients and progressive disease (PD) in 8 patients. Figure 2 shows angiographs of the portal vein before (A) and after irradiation (B). Defect of the portal blood flow which was marked with arrows (A) disappeared after the treatment (B). Intrahepatic tumors increased in 31 patients (59.6%).

Overall survival rates at 1, 2, 3, 4, and 5 years were 45.1%, 25.3%, 15.2%, 10.1%, and 5.1%, respectively (Figure 3). Neither age, nor Karnofsky performance index was related to the survival rate. Survival time greatly depended on

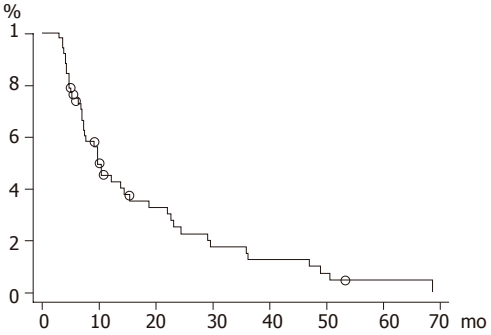

Figure 3 Overall survival curve.

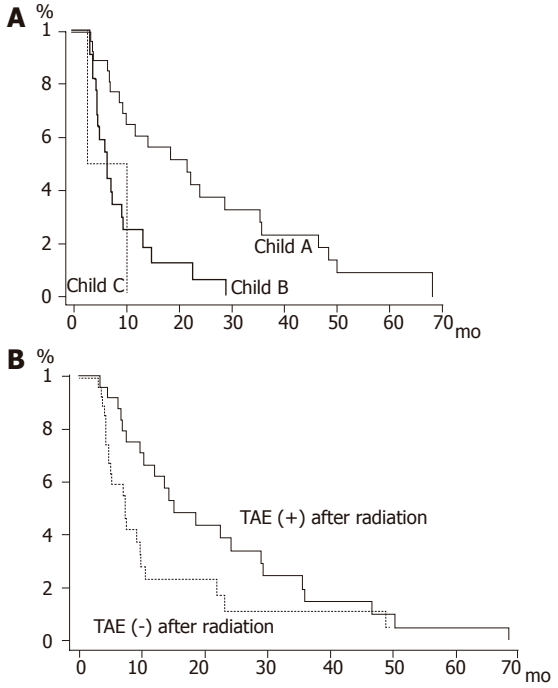

Figure 4 A: Survival curves according to Child classification. Solid line: Child A; bold line: Child B; dashed line: Child C; **B:** Survival curves for the patient group with and without post-radiation TAE. Solid line: post-radiation TAE (+); dashed line: post-radiation TAE (–).

the Child status as shown in Figure 4A (P = 0.0007). Diffuse type HCC showed a significant lower survival rate compared with nodular or massive type HCC (P = 0.0389). We also noted a higher survival rate in cases with 5 foci or less in the liver (P = 0.01). The spread of PVI (invasion of the main trunk, first branch, and second or lower order branches) was not relevant to the survival rate at all (P = 0.7679) (Figure 4B).

Treatment preceding irradiation, namely, surgical resection, PTA and TAE, was irrelevant to the prognosis as well. We noted a significant longer survival periods in cases with favorable primary effects following radiation therapy (P = 0.0419). Regarding the effect of treatments given after radiation therapy, PTA had no influence on the survival rate (P = 0.3987). On the other hand, the survival rate was higher, *albeit* marginally, in the TAE-treated group

Table 2 Univariate analysis

	Hazard ratio	95%CI	*P* value
Child classification (A)	0.217	0.048-0.978	0.0015

than in the TAE-untreated group (P = 0.0465).

Univariate analysis by the Cox proportional hazard model revealed that Child status, the number of tumor foci, tumor type, TAE after radiation therapy were statistically significant prognostic factors (Table 2). Multivariate analysis by Cox's proportional hazard model using five variables, namely, Child status, the number of tumor foci, tumor type, TAE after radiation therapy, initial effect showed that the number of tumor foci in the liver (P = 0.0285) were the most important factors contributing to the eligible prognosis of patients with HCC invading the portal vein, followed by TAE after radiation therapy (P = 0.0364) (Table 3).

Hepatic function, expressed using the Child classification, remained unaltered in 34 cases after radiation therapy. In the remaining 18 patients the classification changed from Child A to B in 13 cases, from Child B to C in two cases, and from Child B to A in three cases. A patient whose liver function deteriorated from Child B to C lapsed into a hepatic coma after radiation therapy. No other serious side effects of irradiation were observed.

DISCUSSION

PVI has been considered to be an important contributor to a poor prognosis in primary HCC, and no definitive treatment strategy has been established to it. The results of the present study demonstrated a relatively favorable survival following radiation therapy for PVI. The 3-year survival rate of 15.2 % among the present study patients

is excellent in comparison with survival rates reported previously[8-9]. In contrast to the surgical series[3,13], in the present study, 3-year survival did not depend on whether PVI invaded the first branch and/or the main trunk of the portal vein. The authors consider, therefore, that radiation therapy seems to be superior to surgical intervention for the patients who developed PVI in the proximal portal vein.

Survival rates did not differ significantly among groups of patients who received one of three different treatments prior to radiation therapy, namely surgical resection, PTA and TAE. On the other hand, a significantly favorable outcome of TAE after radiation therapy was found. The TAE was performed preferentially in patients whose PVI was controlled sufficiently and whose liver function was kept relatively normal; thus, this bias in selecting patients for TAE was probably the main reason for the favorable outcome. However, 6 of 7 patients who survived for more than 2 years had undergone TAE after radiation therapy. Therefore, it appears beneficial to perform TAE in cases in which PVI is under sufficient control.

Radiation therapy for hepatic carcinoma is not performed widely, and reports of such treatment are infrequent[20-23]. Reports of radiotherapy for PVI from HCC is even rare[24-26] Radiation therapy markedly damages normal hepatic cells when used with conventional large fields. According to the experience in the present paper, however, decreases in liver function were within the acceptable range if only PVIs of the patients classified into Child A and B were treated with 3-D CRT. With 3-D CRT, high doses of radiation are confined to the target region while surrounding areas of the liver are exposed only to lower doses. Although clinical data have accumulated concerning hepatic dysfunction after whole or partial irradiation of the liver, those data are not directly applicable to predict hepatic dysfunction after conformal radiotherapy. The biological effect on the liver of such inhomogenous irradiation has not been elucidated fully. Further accumulation of clinical experience is required to determine the most appropriate method of irradiation for this disease.

The results of this study strongly suggest the efficacy of 3-D CRT as treatment for PVI in HCC. From the present analyses, the authors will recommend 3-D CRT in combination with post-radiation TAE for HCCs with 5 tumor foci or less in the liver and with Child A liver function.

Needless to say, because this study was retrospective, the presence of bias in the selection of treatments for individual patients cannot be excluded completely. To more fully clarify the significance of this therapy, a prospective randomized trial should be performed. We hope that the outcomes reported here may contribute to designing future clinical trials and optimizing treatment for this disease.

Abstract

AIM: To investigate the effects of oral *Lactococcus lactis* (*L lactis*) containing endostatin on 1, 2-dimethylhydrazine (DMH)-induced rat colorectal cancer.

METHODS: Recombinant endostatin was produced by the expression of *L lactis* NZ9000. Sixty male Wistar rats were injected with DMH (40 mg/kg body weight) subcutaneously once a week for 10 wk to induce colorectal cancer. The rats were gavaged with 1 mL of endostatin at a dose of 1×10^8/d and fed with the basal diet. The animals were killed after 22 wk for histopathological examination. The total time of experimental observation was 58 wk.

RESULTS: Rat endostatin protein was expressed in *L lactis*. Recombinant endostatin exhibited a significant effect on colorectal cancer ($P<0.05$). Furthermore, the mean survival time of the rats treated with endostatin was longer than that of the animals treated with DMH. There was no statistically significant difference between the rats treated with endostatin and those treated with DMH. The results showed that endostatin could not result in complete cure.

CONCLUSION: Oral endostatin exerts an influence on the progression of chemically induced colon tumors.

Key words: Endostatin; DMH; Tumors

INTRODUCTION

There are lines of evidence that angiogenesis is essential for the growth and persistence of solid tumors and their metastases[1,2]. Tumor angiogenesis is regulated by the balance between proangiogenesis and antiangiogenesis factors, and this balance varies in different organ environments[3]. Systemic administration of recombinant endostatin potently inhibits angiogenesis and maintains metastases at a microscopic size, resulting in a strong anti-tumor activity[4-6]. Endostatin has been shown in some studies to inhibit the formation or growth of lung and liver metastases[7,8]. Endostatin, an angiogenesis inhibitor produced by hemangioendothelioma, is a 20 kDa carboxy-terminal fragment of collagen XVIII[5]. The efficacy of endostatin in colon environment is not well established. To our knowledge, there are no published reports on the efficacy of endostatin against chemically induced colon tumor progression.

An autochthonous colon cancer model is useful to evaluate the clinical therapeutic efficacy of drugs for colorectal cancer[9,10]. As DMH model is known to closely parallel the human disease in terms of disease presentation, gross and microscopic pathology[11], it is anticipated that DMH-induced colon tumors respond to chemotherapeutic drugs. Drugs such as 5-fluorouracil (5-FU) can inhibit the growth of DMH-induced colon tumors and prolong the survival of their rodent hosts[12]. Therefore, DMH-induced colon tumors at present are the most popular models to study the morphology, pathogenesis, prevention, and treatment of colorectal cancer[11,13]. Though 5-FU derivatives have been tested in the DMH model, whether this colon cancer model of rats can be applied to the evaluation of the effect of endostatin on colon tumors remains unknown. The aim of the present study was to investigate the effects of recombinant endostatin on the progression of DMH-induced colon tumors in rats.

MATERIALS AND METHODS

Animals and chemicals

Five-week-old male Wistar rats were provided by the Laboratory Animal Center, Chinese Academy of Medical Sciences, Beijing, China, and housed in plastic cages in a 12-h light/dark cycle at 22±2 ℃ and 44±5% relative humidity. Rats were fed with the basal diet with free access to water. Body weight and food consumption were measured weekly during the experiments. DMH was purchased from Tokyo Kasei Co. (Tokyo, Japan).

Preparation of recombinant endostatin

Endostatin expression experiments were performed with *L lactis* NZ9000 (donated by Institute National de la Research Agromique, France). All cloning steps were done with *E coli* Top 10. *E coli* (stored in our laboratory, China) was grown on Luria-Bertani (LB) medium and incubated at 37 ℃. *L lactis* was grown on M17 medium containing 0.5% (wt/vol) glucose and incubated at 30 ℃. When appropriate, chloramphenicol was added at a final concentration of 10 μg/mL and ampicillin was supplied at a concentration of 100 μg/mL. Expression of the endostatin gene was induced by nisin promotor. *L lactis* was cultured overnight and then transferred into a fresh medium at a dilution of 1:50. After 3-4 h of incubation, 1 μg/mL of nisin (Sigma) was added to the culture and incubated for 3-4 h.

Cloning and expression of rat endostatin in L lactis

Total RNA was extracted from rat kidney tissue using the SV total RNA isolation systems kit (Promega) and reverse-transcribed by reverse transcription system kit (Promega). The mixture was incubated at 25 ℃ for 10 min, at 42 ℃ for 60 min, at 95 ℃ for 5 min, and at 4 ℃ for 5 min. The two gene-specific primers were designed by the sequence encoding the carboxy terminal portion of rat collagen XVIII. The primer sequences were 5'-TTT GAA TTC GCC CAC ACC CAC CGC GAC TTC CAG CCG-3' and 5'-AAA AGC GGC CGC CTA CTT GGA GGC GGC AGT CAT GAA GCT-3'. PCR was performed in a total volume of 50 μL of reaction solution and 2 μL of RT template. The PCR conditions were as follows: denaturation at 94 ℃ for 5 min, then 25-35 cycles at 94 ℃ for 0.5 min, at 56 ℃ for 0.5 min, at 72 ℃ for 1 min, a final extension at 72 ℃ for 5 min and a DNA fragment was obtained. The amplified fragment was purified using the QIAquick PCR purification kit (QIAGEN Inc.) and digested with *EcoRI* and *Not*I. The resulting fragment was respectively ligated to nisin promotor plasmids pLA141 and pLA151 digested with *EcoRI* and *Not*I. The pLA141 plasmid carried a signal peptide Usp45. The recombinant plasmid DNA was transferred into *L lactis* NZ9000 by electroporation and transformants were plated on GM17 agar plates containing chloramphenicol according to the method of Wells *et al*.[15]. The recombinant plasmid DNA was isolated from *L lactis* as described previously[15,16] and the nucleotide sequence was further determined.

Western blotting

Total protein was prepared from exponentially growing cultures. The bacteria were harvested by centrifugation at 3 000 r/min for 10 min at 4 ℃, washed with PBS, resuspended in 1 mL of 10 mmol/L Tris-HCl (pH 7.5) and disrupted with a French press (Bioritech). The cell suspension was centrifuged at 10 000 g for 10 min at 4 ℃ to remove cell debris. The samples were mixed in *Laemmli* buffer and subjected to SDS-12% polyacrylamide gel electrophoresis. The protein was transferred onto nitrocellulose membranes with a Bio-Rad electroblotter. The blots were developed with BCIP/NBT developing buffer (Sigma).

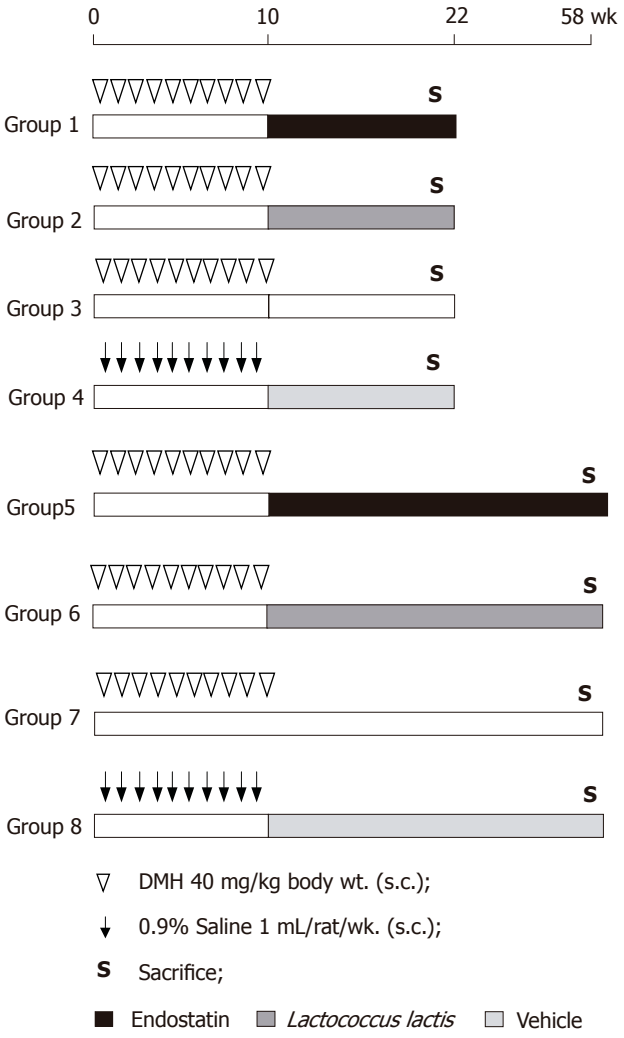

Figure 1 Experimental design.

Treatment protocol

The experimental design is shown in Figure 1. After 1 wk of acclimatization, 80 six-week-old rats were randomly divided into 8 groups (10 rats/group). Animals in groups 1-3 and 5-7 received subcutaneous injections of DMH dissolved in normal saline solution (40 mg/kg body weight) once a week for 10 wk. Rats in groups 4 and 8 were injected with 0.9% normal saline (vehicle) at the same time. After the last DMH treatment, the animals were additionally gavaged with 1 mL of *L lactis*-secreted endostatin protein (groups 1 and 5) and *L lactis* without endostatin gene but containing plasmids (groups 2 and 6) once a day for 12 wk or until they were killed after 58 wk. The dose of endostatin and *L lactis* was 1×10^8 daily. Groups 4 and 8 were gavaged with 1 mL of the solutions not containing *L lactis* (the vehicle control). Groups 3 and 7 served as a carcinogen control. The time of treatment differed slightly in each experiment. All animals that survived were killed under either anesthesia at wk 22 (groups 1-4) or to end of the experiment. The total time of experimental observation was 58 wk.

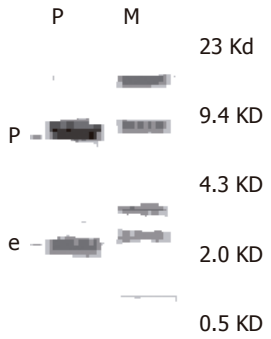

Figure 2 Expression plasmid obtained by restriction enzyme analysis. P: expression plasmid cut by *Eco*RI and *Not* I; e: endostatin gene; M: molecular weight marker.

Autopsy

The colons were removed, flushed with saline and opened along the longitudinal median axis. Tumor width (*W*) and length (*L*) were measured with calipers. The tumor volume (TV) was determined by the following formula: $TV = (L \times W^2)/2$[8]. After the gross pathologic changes (number, dimensions, and distribution of the tumors) were recorded, the colons were fixed flat in 10% phosphate-buffered formalin. The liver and kidneys were removed and weighed. Other major organs (stomach, small intestine, spleen, lungs, and lymph nodes) were also excised and fixed in 10% phosphate-buffered formalin. All tissues were embedded in paraffin, cut into sections and stained with hematoxylin and eosin. The proximal, intermediate and distal segments of the colon were examined for histopathological analysis.

Tumor staging

Animals with DMH-induced colon cancer developed multiple tumors and each tumor had a different histological stage[14]. Consequently, the animals were staged (Duke's stage) with reference to a single index tumor, defined as the largest macroscopically and histologically identifiable colon tumor.

Statistical analysis

Statistical analyses were completed with SPSS 9.0 software. The significance of differences between the average values of the groups was analyzed using Cochran's two-tailed Student's *t*-test. The significance of differences in lesion incidence between the groups was assessed by χ^2 test. Rat mortality was analyzed by the log-rank method of Peto *et al*.[17].

RESULTS

Construction of expression plasmid

The plasmid containing the endostatin gene was pla148, identified as the expression plasmid I. Recombinant *L lactis* was obtained by PCR and restriction enzyme analysis when the recombinant plasmid was transformed into *L lactis* by electroporation (Figure 2).

Expression of rat endostatin gene in L lactis

Recombinant lactic acid bacteria were incubated and induced by *nisin* in M17-Glu for 6 h. Endostatin protein was identified by SDS-PAGE and Western blot with the antibody prepared from rabbits immuned with human endostatin protein. Rat endostatin protein was expressed in *L lactis* (Figures 3A and 3B).

Lanes 1-6: engineered *L lactis* 1-6 h after induction; lane 7: *L lactis* without endostatin gene; lane 8: rat sera from groups after oral recombinant *L lactis*; lane 9: endostatin protein expression in *E coli* cells.

Animal experiment

All rats in groups 1-4 and 8 survived until the final termination and were relatively healthy throughout the experiment. No signs of severe toxicity were observed in all the animals that were given endostatin. No tumor was found in vehicle-treated animals. By the end of wk 22, the average body weights of the rats treated with DMH or endostatin or *L lactis* were significantly decreased compared to the vehicle control ($P<0.05$). Relative liver and kidney weights and food consumption did not significantly differ among the groups (Table 1). Macroscopically, the distribution of colon tumors in the proximal and middle colon at the end of wk 22 had no significant difference among the groups (data not shown).

Histopathological findings are summarized in Table 2. Colon epithelial lesions were divided into adenomas and carcinomas. At the end of wk 22, the incidence of colon tumors was not significantly affected by endostatin. The mean tumor incidence in a single tumor-bearing rat was 2.50 in group 1 and 4.00 in group 3. Tumor volume was decreased in rats receiving endostatin. However, it did not differ from that in DMH-treated group. In addition, there was a significant difference in Duke's stage between the animals treated with DMH and those treated with

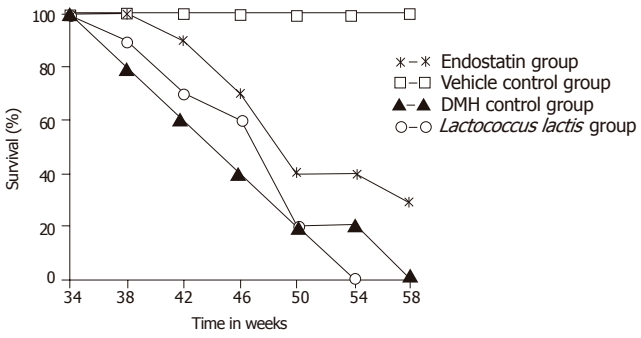

Figure 4 Survival rate of rats injected with DMH with or without endostatin and normal saline.

endostatin ($P<0.05$). Liver lesions and lymph node metastases were observed in about 30% of the animals in group 3.

The survival rates of rats in groups 5-8 are shown in Figure 4. The group that received endostatin had a survival rate of 30%. The survived rats were killed and metastases were found in their lungs and livers. All the saline-injected rats were alive at the end of the experiment. However, none of the DMH-treated rats survived the full duration of the experiment. The mean survival time of endostatin-treated animals was longer than that of DMH-treated rats. The range of ages at death in DMH-treated animals was 38-57 wk (Table 3).

DISCUSSION

Studies using preclinical models of nonhematologic malignancies indicate that antiangiogenic therapies may delay or even abrogate tumor growth[5,18,19]. Endostatin is one of the antiangiogenic drugs and our data indicate that the administration of endostatin after DMH treatment could prolong the survival time of rats. The Duke's staging system for human colorectal cancer provides accurate prognostic information. In other words, animals with less advanced disease (stage A) survive significantly longer than those with advanced disease (stages B and C) irrespective of the treatment. In our study, there was a significant difference in the levels of differentiation and metastases (Duke's stage) between the animals treated with DMH and those treated with endostatin. Endostatin-treated rats had an improved survival compared to untreated rats, indicating that the survival time of rats with colon cancer parallels to that of human beings with this disease. These results can at least in part explain the mechanism of the potent antiangiogenic and antitumor activities of endostatin. Furthermore, the improved survival is directly attributable to the effective induction of tumor stabilization and its ability to inhibit specifically endothelial proliferation in endostatin-treated animals. However, oral administration of endostatin could only prolong the survival time of tumor-bearing rats but not result in complete cure.

There are reports on endostatin against metastases in lung, stomach, and liver[7,8,20]. Recent studies showed that endostatin has an antiangiogenic action[21-24] and can

induce apoptosis in colon cancer cells by inhibiting tumor angiogenesis and inhibit tumor growth and metastases of human colon cancer xenograft in nude mice[24]. Some other mechanisms may be involved in endostatin stabilizing and maturating newly formed blood vessels[21]. Jia *et al*.[22] reported that endostatin could inhibit tumor growth and angiogenesis by blocking Vegf/Flk-1 pathway. In addition to its antiangiogenic activity, endostatin exerts a direct anticancer action that appears to be restricted to some tumor cell lines[25]. At the same time, endostatin has been demonstrated to induce regression of tumors in mice[7,26], but actual regression as opposed to growth inhibition has not been demonstrated in the colon environment. Though our study demonstrated that endostatin could influence rat colon tumor progression, the precise mechanisms by which endostatin exerts effects on colon carcinoma are not well understood.

Long-term administration of endostatin is needed because the inhibition of tumor metastases has not been observed after a shorter endostatin-treated period. The ultimate goal of antiangiogenic therapy is to induce long-term tumor stabilization[27] because data from studies in nonhuman primates indicate that endostatin may be administered for a long time without toxicity[28]. Furthermore, studies *in vitro* and *in vivo* suggest that endostatin gene therapy can effectively suppress angiogenic processes in model systems[29,30]. It was reported that endostatin treatment is not associated with any recognizable vascular changes in tumor samples[31].

Certain strains of lactic acid bacteria have been found to prevent putative preneoplastic lesions induced by carcinogens[32,33]. The antimutagenic activity of lactic acid bacteria is suspected to reside in the cell wall[34] as lactic acid itself has no antimutagenic effect[35]. The findings of the current study do not support the suggestion that the addition of *L lactis* may also prolong the survival time of DMH-treated rats. The reason for this is unclear, but might be explained by the differences in bacterial strains. The antitumor effect of lactic acid bacteria is still controversial[36]. Further study is needed to identify the antitumor effect of endostatin and the precise mechanisms by which these effects are mediated.

In conclusion, long-term administration of endostatin can inhibit the progression of chemically-induced colon tumors and prolong the survival time of rats.

Abstract

AIM: To explore the role of the adaptor molecule in liver regeneration after partial hepatectomy (PH).

METHODS: We used transgenic mice expressing an N-terminal truncated form of MORT1/FADD under the control of the albumin promoter. As previously shown, this transgenic protein abrogated CD95- and CD120a-mediated apoptosis in the liver. Cyclin A expression was detected using Western blotting. ELISA and RT-PCR were used to detect IL-6 and IL-6 mRNA, respectively. DNA synthesis in liver tissue was measured by BrdU staining.

RESULTS: Resection of 70% of the liver was followed by a reduced early regenerative response in the transgenic group at 36 h. Accordingly, 36 h after hepatectomy, cyclin A expression was only detectable in wild-type animals. Consequently, the onset of liver mass restoration was retarded as measured by MRI volumetry and mortality was significantly higher in the transgenic group.

CONCLUSION: Our data demonstrate for the first time an involvement of the death receptor molecule MORT1/FADD in liver regeneration, beyond its well described role as part of the intracellular death signaling pathway.

Key words: MORT1/FADD; CD95; TNF; Apoptosis; Liver regeneration

INTRODUCTION

Liver regeneration upon extensive liver damage is critical to survive diseases, such as fulminant hepatitis without liver transplantation. Beyond the cause of the underlying liver disease, it is well accepted that death receptor-mediated hepatocyte apoptosis is an important mechanism for liver damage[1,2]. The cascade of intracellular signaling events during apoptosis is reasonably well understood. Of critical importance is the activation of caspases, the subsequent cleavage of different death substrates and finally the disintegration of the cell. In this setting, MORT1/FADD is a central adaptor molecule for a number of death receptors to recruit and activate the initiator caspase-8 upon ligand-mediated aggregation[3,4]. Gene targeting of MORT1/FADD[5,6] or expression of a dominant negative mutant[7,8] confers resistance to CD95-mediated apoptosis in T cells. Recently, we have demonstrated that MORT1/FADD is also pivotal for CD95- and TNF-mediated apoptosis in hepatocytes *in vivo*[9]. In addition, emerging evidence suggests that death receptors and their intracellular signaling proteins have a dual role and may also be involved in the regeneration and repair mechanisms. TNF receptor I (CD120a) has been found to induce proliferation in a number of cells[10] and is involved in the initiation of liver regeneration[11]. Even the prototypical death receptor CD95 was described to exert non-apoptotic functions[12], e.g., stimulation of liver regeneration after partial hepatectomy (PH)[13]. In line with this observation, mice with the */pr* genotype and decreased expression of CD95 showed a delayed regenerative response after PH[13]. In addition, the most upstream signaling molecules of the intracellular death pathway MORT1/FADD and caspase-8 have been described to be critical for T-cell proliferation[5,6,14]. To our knowledge, the mechanism by which MORT1/FADD contributes to T-cell proliferation is not completely elucidated yet. The regulatory function of MORT1/FADD seems to be structurally independent of the death domain and its role in apoptosis, but to rely on phosphorylation at serine residue S191, which has been shown to be critical for the regulative role of MORT1/FADD in cell proliferation[15].

The role of MORT1/FADD in liver regeneration has not been described so far. We used transgenic mice expressing a dominant negative mutant of MORT1/FADD in a liver-specific manner to investigate a possible role of the adaptor molecule in liver regeneration. We observed a delayed onset of liver proliferation upon PH compared to wild-type littermates and found a higher early postoperative mortality in dnMORT1/FADD transgenic mice. The increased rate of mortality might be due to initially retarded liver regeneration and underlines the critical role of MORT1/FADD in the complex network of signaling proteins which orchestrate liver regeneration.

MATERIALS AND METHODS

Animal model of liver regeneration

Heterozygous transgenic mice (strain CB6F1) expressing liver-specific dominant negative mutant of the adaptor protein MORT1/FADD under the control of the albumin promoter were generated as previously described[9]. All animals were bred at the animal facility of the University of Mainz, had *ad libitum* access to water and food under standard conditions with 12-h dark/light cycle. All experiments were done in accordance with the Federal law and were approved by the Local Committee for Experimental Animal Research.

Partial hepatectomy

Male transgenic and wild-type animals at 6-8 wk of age were fasted overnight and operated in the morning. Mice were anaesthetized with subcutaneous injection of a solution containing 0.16% xylazinum and 1.2 mg ketamin (200 μL/20 g body weight). A 70% PH was performed by ligating and removing the left and median lobe at its root. The mice were killed at different time points and livers were harvested. The livers were either shock-frozen in liquid nitrogen and stored at -80 ℃ or fixed at 4 ℃ in 40 g/L paraformaldehyde overnight for further use. Serum was obtained by heart puncture.

DNA-synthesis measurement of BrdU incorporation and mitosis

After PH, the mice were treated at different time points with 1 mmol/L BrdU (10 g/kg body weight) 3 h prior to killing. The livers were harvested and shock-frozen. The livers were cut into 5-μm-thick slides with a microtome. BrdU incorporation was measured using the *In situ* Cell Proliferation Kit (Roche Diagnostics GmbH, 82372 Penzberg, Germany) according to the manufacturer's instructions. Results were presented as an average percentage of BrdU-positive cells counted in at least two fields of each slide under 10× high power field. Mitosis of the was counted by two independent observers in a blinded fashion.

Cytokine assays

Cytokine concentrations were assessed using ELISA, OptEIA Mouse IL-6 Set (Pharmingen, BD Biosciences, 69126 Heidelberg, Germany) following manufacturer's instructions. Samples were analyzed with an Elisa reader (MRX TC II, Dynex Technologies Lim., West Sussex BN).

Western blotting for cyclin A

Western blot analysis was performed with whole liver extract lysed in a lysis buffer. Protein concentration was equilibrated using Bradford assay reagent. The samples were boiled with sodium dodecyl sulfate sample buffer and electrophoresed on a 100 g/L sodium dodecyl sulfate-polyacrylamide gel. Following electrophoresis, the samples were blotted onto a PVDF-membrane (Pall, Germany), and the membrane was blocked with 20 g/L milk powder for 30 min, followed by an overnight incubation with a rabbit anti-cyclin A serum (Anti-rabbit polyclonal Cyc A C-19, # sc596, Santa Cruz) at 4 ℃ with phosphate-buffered saline/Tween (0.1%) with 20 g/L milk powder (PBSTM). After washing, the membranes were incubated for 45 min with horseradish peroxidase-conjugated goat-anti-rabbit serum (dilution 1:3 000) in PBSTM. Blots were developed using the Western Lightning Chemiluminescence Reagent (PerkinElmer Life Sciences, Boston, MA, USA).

Magnetic resonance imaging

Magnetic resonance imaging (MRI) was performed on a Magnetom Vision whole body scanner (Siemens Medical Solutions, Germany) at 1.5 T. The scanner was equipped with an experimental gradient system with maximum gradient field strength of 50 mT/m and a slew-rate of 160 mT/m/ms. A circular polarized small loop coil with 4 cm as diameter was used for imaging the mice.

For the imaging of the liver, a T1-weighed spinecho sequence with fat saturation and TR/TE/α = 640 ms/14 ms/90 ℃ was used. The experimental gradient system allowed a high resolution of 0.39 mm×0.39 mm with a slice thickness of 1 mm at a 50 mm×100 mm field of view. The gap between the slices was 0.8 mm.

Post processing was done using the Java-based free software ImageJ (National Institutes of Health, USA, download at http://rsb.info.nih.gov/ij). After drawing a region of interest (ROI) following the borders of the liver in every slice, the liver volume was calculated from the sum of pixels in each ROI over all slices with respect to the pixel size, the slice thickness and the slice gap is as follows:

$$\text{Volume}_{\text{liver}} = \sum_{\text{slice}} \sum_{\text{pixels}} \text{size}_{\text{pixel}}(\text{thickness}_{\text{slice}} + \text{gap}_{\text{slice}})$$

RT-PCR and light cycler

RNA was isolated from the cells using the First Strand cDNA Synthesis Kit for RT-PCR (Roche Diagnostics GmbH, 68305 Mannheim) according to the manufacturer's instructions. Primers for IL-6 were purchased from Metabion GmbH, D-82152 Planegg-Martinsried, Germany.

Duplicate PCR amplifications were carried out in a Light Cycler Fast Start DNA Master Green I™ (Roche Diagnostics GmbH, 68305 Mannheim) using Fast Start Light Cycler™ DNA Master containing Taq-polymerase, reaction buffer, and dNTPs (Roche). All reactions

were performed in 10 μL volumes and fluorescence quantification was calculated with the aid of built-in Light Cycler software, version 3.01 (Roche).

For quantification of the mRNA, we chose the method of relative quantification with external standards (HPRT-specific primers).

Liver enzymes

Liver enzymes in serum were measured with a Roche Hitachi 917.

Hematoxylin-eosin staining

Liver samples were fixed overnight at 4 ℃ with 40 g/L paraformaldehyde. The tissue was then dehydrated, embedded in paraffin, and 5-μm sections were stained with HE. Mitosis of the cells was counted by two independent observers in blinded fashion under 10×high power fields (about 50 cells/field).

RESULTS

A delayed proliferative response in dnMORT1/FADD mice after partial hepatectomy

As previously described, PH was performed by resection of around 70% of the total liver volume. DNA synthesis as a marker of the regenerative response was measured by BrdU staining. Kinetics of BrdU staining after PH obviously differed between transgenic and wild-type animals (Figure 1A). We observed a significantly more BrdU-positive cells in wild-type animals after 36 h, which was attenuated after 48 h (Figure 1A). In line with this observation, the number of mitoses differed in regenerating liver 48 h after PH (Figure 1B). Differences were also observed in expression levels of cyclin A at 36 h after hepatectomy (Figure 1C), when the expression was detected only in wild-type mice. These observations were further substantiated by MRI technique (Figure 1E), which allowed to follow closely the kinetic of liver mass restoration after hepatectomy. Here we could demonstrate that the delayed onset of liver regeneration was paralleled by a retarded gain of liver volume (Figure 1D). After all, surviving transgenic animals finally also reached complete volume restoration around at d 10 after PH, as did wild-type animals.

IL-6 levels after partial hepatectomy

IL-6 has been shown to be an essential factor during initial liver regeneration[16]. Wuestefeld *et al.*[17] specified the effect of IL-6 and demonstrated an important hepatoprotective role of IL-6 during the early phase of liver regeneration. We therefore investigated possible differences in IL-6 levels after PH. Serum IL-6 levels peaked around 24 h after PH (Figure 2A), however, did not significantly differ between wild-type and transgenic animals. Interestingly, a significantly higher IL-6 mRNA expression was detected in transgenic livers 36 h after hepatectomy (Figure 2B). This observation demonstrated a functional IL-6 deficiency to be unlikely and rather pointed to a compensatory reaction towards delayed

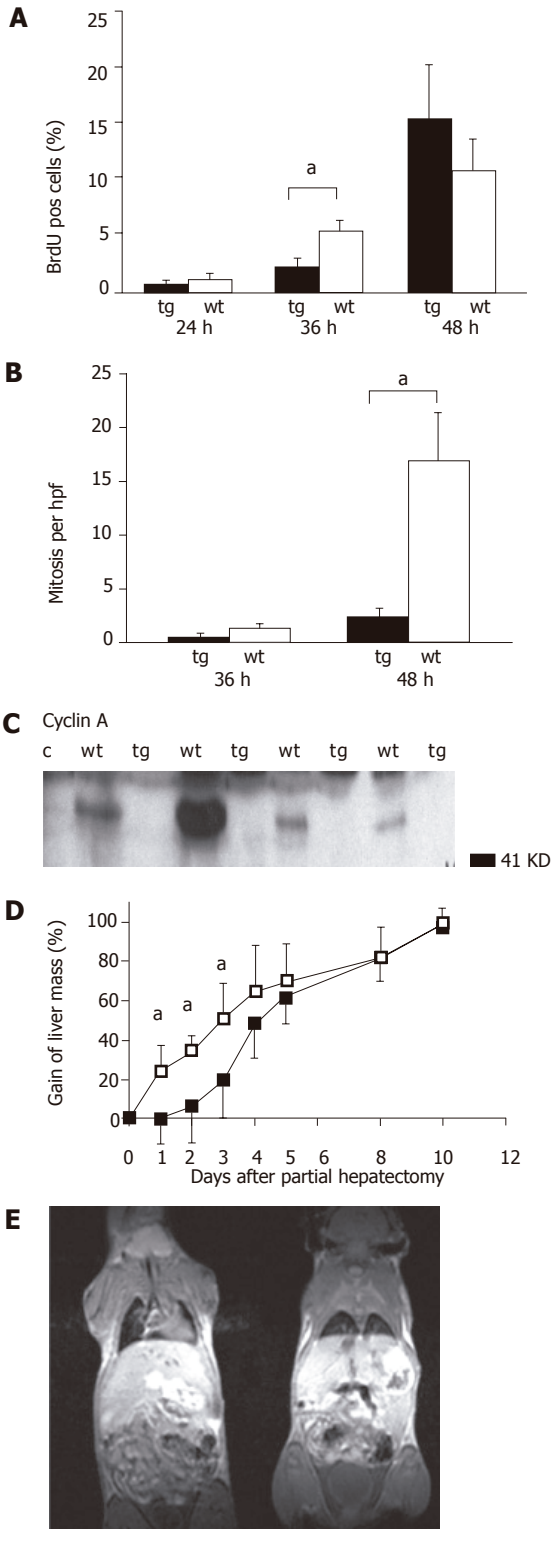

Figure 1 Retarded liver regeneration in dnFADD mice. **A:** Onset of DNA synthesis was delayed in transgenic animals; after 36 h of PH, the amount of BrdU-positive cells was significantly smaller compared to wild-type animals, while the numbers did not differ significantly later on; **B:** Showing a markedly higher number of mitosis per high power field in wild-type animals after 48 h ($^aP<0.05$); **C:** Cyclin A protein expression was not detectable in transgenic animals whereas, detectable in wild-type animals at 36 h after hepatectomy. **D:** Onset of liver mass restoration was retarded in transgenic animals ($^aP<0.05$) but surviving mice reached around 90% of the pre-operative volume as did wild-type animals. The average immediate postoperative liver volumes in the wild-type and transgenic group were 49% and 48% of the preoperative liver volume, respectively. **E:** MRI scans were used to determine liver mass during regeneration.

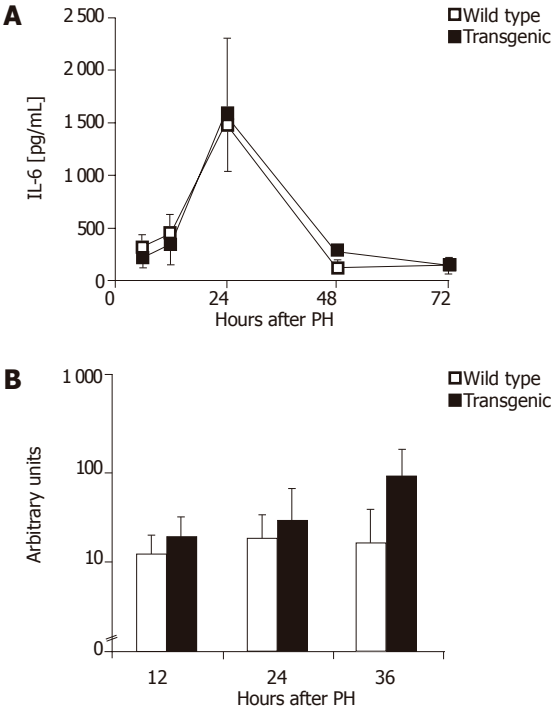

Figure 2 Expression of IL-6 in transgenic hepatocytes. **A:** Serum IL-6 levels peaked around 24 h after partial hepatectomy. There was no difference between wild-type and transgenic animals; **B:** After 36 h of PH, transgenic animals showed significant higher IL-6 mRNA expression in whole liver lysate as compared to wild-type animals, measured by Light Cycler analysis.

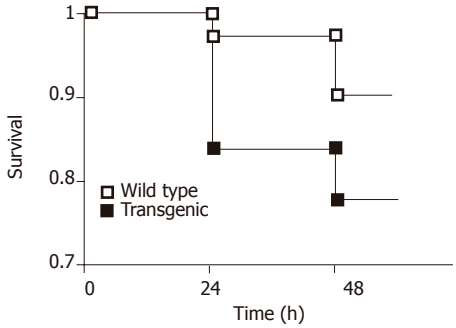

Figure 3 Differences in postoperative mortality. Within the first 24 h after PH, transgenic mice expressing the dominant negative FADD mutant showed a significant higher postoperative mortality (P<0.01). Within the first 24 h, 13 out of 81 transgenic mice died whereas only 2 out of 72 wild-type mice died. At later time points, no difference in postoperative mortality was detected.

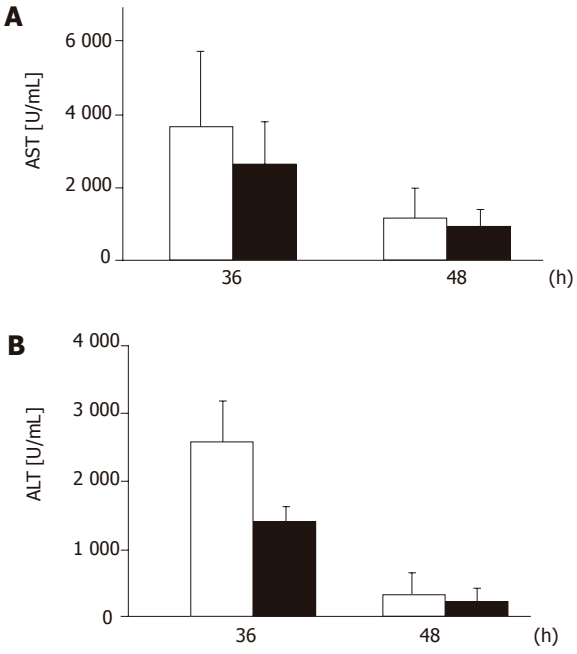

Figure 4 Liver enzymes test. Serum AST (left panel) and ALT (right) levels in wild-type and transgenic mice were not significantly different at 36 or 48 h after PH.

regeneration.

High mortality after partial hepatectomy in dnMORT1/FADD mice

Surprisingly, we observed significantly higher early postoperative mortality after resection of 70% of the liver mass among the transgenic mice expressing the dominant negative MORT1/FADD mutant (Figure 3) compared to the wild-type littermates. We found a significant difference in postoperative mortality during the first 24 h, when 16.49% (13/81) of transgenic animals whereas, only 2.77% (2/72) of wild-type mice died (P<0.01, Fisher's exact test). However, the mortality did not significantly differ later on. In order to elucidate the cause of different mortality rate, we measured liver enzymes during the early phase of regeneration. However, we did neither detect significant differences in liver function tests (Figure 4) nor differences in the degree of steatosis in liver sections at 36 or 48 h after PH (data not shown).

DISCUSSION

In the present study, we could show for the first time that MORT1/FADD acts as a multi-functional adaptor protein in the liver *in vivo*. In addition to its critical role in CD95- and CD120a-mediated liver failure[9], MORT1/FADD is involved in initiating liver regeneration upon PH. These results underline the dual role of MORT1/FADD, i.e., it was originally identified as an adaptor protein which is pivotal to convey death signals of the death receptors CD95 and CD120a[3,4] and the TRAIL receptors DR4 and DR5[18]. Initial evidence that the axis MORT1/FADD-caspase-8 has an additional role beside mediating apoptotic cell death revealed in the experiments with MORT1/FADD and caspase-8 knock out animals, showing that both genetic defects lead to embryonic lethality around d 11 *in utero* with similar pathology of cardiac malformation[5,6,19]. Interestingly, mice lacking functional flip/cash gene, a caspase-8 homolog without enzymatic activity, also died[20] *in utero* with a similarly impaired cardiac development. Later on, experiments with T-cells lacking MORT1/FADD or expressing a dominant negative mutant indicated an additional role of MORT1/FADD in

the regulation of cell proliferation[5-8,21].

The exact mechanism by which MORT1/FADD contributes to cell proliferation is still enigmatic, especially when the involved downstream molecules are not identified. Phosphorylation of MORT1/FADD at position serine 191 in mouse (corresponding to serine 194 in human beings) seems to be of crucial importance[15,22]. Current data have substantiated the idea of a bifurcation of the signal pathway at the level of MORT1/FADD by either sending a death signal via activation of caspase-8 or signaling towards cell proliferation. FLIP, which is also recruited to the receptor complex, has been reported to modulate caspase-8-mediated cell death and is a good candidate for further delivering a proliferation signal[23]. Indeed, FLIP has been shown to be involved in T-cell proliferation[23]. However, it has not been completely understood how FLIP further mediates the proliferation signal leading to the activation of ERK[23]. The molecular architecture of the intracellular bifurcation is complex, since the lack of caspase-8 does not only provide deficiency in death receptor apoptosis signaling but also confers an impaired T-cells proliferation[14]. According to data of Iimuro *et al*.[24] and Chaisson *et al*.[25], NF-κB is not involved in the orchestration of the initial DNA synthesis after PH.

A regenerating liver is protected against CD95-induced cell death[26]. This might partially be attributed to the downregulation of CD95 but resetting the function of proapoptotic molecules, such as MORT1/FADD during the initial proliferative response might also contribute. It is not obvious which receptor engages MORT1/FADD to contribute to liver regeneration. CD120a (TNF-receptor 1) and CD95 are both candidates since TNF-R1 knock-out mice[27] as well as mice with the decreased hepatic CD95 expression (*lpr*-genotype)[13] showed a pronounced delay of liver regeneration after PH. In our study, the cause of a high postoperative mortality in transgenic mice remains unclear. We could not find signs of liver dysfunction in the early postoperative phase and there was also presence of IL-6 expression. We even detected higher intrahepatic IL-6 mRNA levels in the transgenic mice. A previous study also reported no difference between wild-type and transgenic animals upon LPS or CpG-DNA challenge[28].

In conclusion, we provide further evidence for a complex role of the adaptor molecule MORT1/FADD which is also involved in death and proliferation pathways in hepatocytes. This observation should be taken into consideration while targeting anti-apoptotic as well as anti-proliferative therapies.

Abstract

AIM: To study the regulatory mechanisms of sinusoidal regeneration after partial hepatectomy.

METHODS: We investigated the expression of angiopoietin (Ang)-1, Ang-2, Tie-2, and vascular endothelial growth factor (VEGF) in regenerating liver tissue by quantitative reverse-transcription polymerase chain reaction (RT-PCR) using a LightCycler (Roche Diagnostics) and also immunohistochemical staining after 70% hepatectomy in rats. In the next step, we isolated liver cells (hepatocytes, sinusoidal endothelial cell (SEC), Kupffer cell, and hepatic stellate cells (HSC)) from regenerating liver tissue by *in situ* collagenase perfusion and counterflow elutriation, to determine potential cellular sources of these angiogenic factors after hepatectomy. Proliferation and apoptosis of SECs were also evaluated by proliferating cell nuclear antigen (PCNA) staining and the terminal deoxynucleotidyl transferase d-uridine triphosphate nick end labeling (TUNEL) assay, respectively.

RESULTS: VEGF mRNA expression increased with a peak at 72 h after hepatectomy, decreasing thereafter. The expression of Ang-1 mRNA was present at detectable levels before hepatectomy and increased slowly with a peak at 96 h. Meanwhile, Ang-2 mRNA was hardly detected before hepatectomy, but was remarkably induced at 120 and 144 h. In isolated cells, VEGF mRNA expression was found mainly in the hepatocyte fraction. Meanwhile, mRNA for Ang-1 and Ang-2 was found in the SEC and HSC fractions, but was more prominent in the latter. The PCNA labeling index of SECs increased slowly, reaching a peak at 72 h, whereas apoptotic SECs were detected between 120 h and 144 h.

CONCLUSION: Ang-Tie system, together with VEGF, plays a critical role in regulating balance between SEC proliferation and apoptosis during sinusoidal regeneration after hepatectomy. However, the VEGF system plays a more important role in the early phase of sinusoidal regeneration than angiopoietin/Tie system.

INTRODUCTION

The regenerative capacity of the liver is typically triggered by hepatic injuries, including partial hepatectomy or hepatocyte loss caused by viral or chemical injury[1-3]. Liver regeneration is a highly complex and organized process, but extensive studies have revealed that a number of cytokines and growth factors are involved in the regulation of hepatocyte proliferation[4-6]. Nonparenchymal cells (Kupffer cells, sinusoidal endothelial cells (SECs)) have both stimulatory and inhibitory influences on hepatocyte replication though a paracrine manner after hepatectomy[7]. As a consequence of hepatocyte proliferation, remodeling of the sinusoids has to be carried out for the supply of blood flow to the newly replicating hepatocytes in the process of liver regeneration, most probably with penetration of SECs into hepatocyte clusters. Presumably, SECs proliferate and assemble into tubes with cell-cell connections, followed by recruitment of hepatic stellate cells (HSCs) and Kupffer cells, to restore normal sinusoidal architecture. Lindahl *et al*.[8] reported that during vascular development and remodeling, endothelial cells initially proliferate, and recruit mural cell (pericytes or smooth muscle cells) precursors via secretion of platelet-derived growth factor-BB, and endothelial cell-mural cell contact is essential for vessel stabilization[9]. On the other hand, Martinez-Hernandez *et al*.[10] suggested that during liver regeneration, the laminin-containing Ito cells initially extend cell processes into the

hepatocyte clusters, followed by SECs, to form new sinusoids after hepatectomy, but at present the precise steps involved in sinusoidal regeneration remain poorly understood. However, recent studies including ours showed that vascular endothelial growth factor (VEGF) greatly contributes to the proliferation of SECs via up-regulated VEGF receptors during liver regeneration[11-15]. Moreover, we have clearly shown that newly replicated hepatocytes that are devoid of sinusoids are the major source of VEGF after hepatectomy[13]. However, the detail mechanisms of sinusoidal regeneration and remodeling are still open to discussion.

Recently, the angiopoietin (Ang)-Tie system has been identified as a second family of endothelial cell-specific growth factors[16-18], and has been reported to act in a complementary and coordinated fashion with VEGF, thus playing an important role in vascular maturation and remodeling[17,18]. The modulatory effect of angiopoietins on VEGF-induced angiogenesis is distinct[19-21], although angiopoietins alone are not mitogenic for endothelial cells *in vitro*[18], and do not promote neovascularization *in vivo*[19]. Angiopoietins include both receptor activators (Ang-1) and receptor antagonists (Ang-2)[18]. Binding of Ang-1 causes auto-phosphorylation of tyrosine kinase Tie-2 receptor, whereas Ang-2 binding conversely suppresses auto-phosphorylation of Tie-2. The Tie-2 signal is, therefore, defined by quantitative balance between Ang-1 and Ang-2 activities[19,20]. The Ang-1/Tie-2 pathway in the presence of VEGF is thought to mediate the vital functions of vascular stabilization and vascular maturation, via integration of peri-endothelial cells into the vascular wall. In contrast to Ang-1, Ang-2 induces vascular regression in the absence of VEGF but increases vascular sprouting in its presence[19-21]. Accordingly, it seems to be reasonable to assume that the Ang-Tie system and the VEGF system, participate in the process of sinusoidal regeneration and remodeling after partial hepatectomy.

In this study, we investigated the expression of Ang-1, Ang-2, Tie-2, and VEGF in regenerating liver tissue by quantitative reverse-transcription polymerase chain reaction (RT-PCR) using a LightCycler (Roche Diagnostics, Mannheim, Germany) and immunohistochemical staining after 70% hepatectomy in rats. In the next step, we isolated liver cells (hepatocyte, SEC, Kupffer cell, and HSC) from regenerating liver tissue by *in situ* collagenase perfusion and counterflow elutriation, to determine potential cellular sources of these angiogenic factors after hepatectomy. Proliferation and apoptosis of SECs were also evaluated by proliferating cell nuclear antigen (PCNA) staining and the terminal deoxynucleotidyl transferase d-uridine triphoshate nick end labeling (TUNEL) assay, respectively, to determine the putative role of VEGF and angiopoietins, especially their complementary and coordinated effects during sinusoidal regeneration after hepatectomy.

MATERIALS AND METHODS

Animals

Male Wistar rats, weighing 250 to 300 g, were used with the approval of the Chiba Animal Care Committee. The animals were housed in a temperature- and humidity-controlled environment with a 12-h light dark cycle. The study followed our institution's criteria for care and use of laboratory animals in research, which conform to the National Institutes of Health guidelines. Under ether anesthesia, 70% of the liver was resected as previously described[22]. The operative procedure was carried out by means of a clean, but not sterile technique. For the assessment of the Ang-1, Ang-2, Tie-2, and VEGF expressions, the right inferior lobe of the liver was carefully excised before and 12, 24, 48, 72, 96, 120, 144, and 240 h (n = 6 at each time point) after hepatectomy.

Quantitative RT-PCR analysis of VEGF, angiopoietins, and Tie-2 mRNA expressions

Total RNA was extracted from liver tissues or freshly isolated liver cells by the acid guanidium-thiocyanate/phenol/chloroform method, and 1 mg of extracted total RNA was subjected to a reverse transcription reaction, using Ready To Go™ T-primed 1st strand cDNA synthesis kit (Amersham Pharmacia Biotech, Buckinghamshire, England). The cDNA from 33 ng of total RNA was used as a template. VEGF, Ang-1, Ang-2, and Tie-2 mRNA levels were quantified by a LightCycler (Roche Diagnostics, Mannheim, Germany), using the double-strand-specific dye SYBE Green I. Details of the primers used in this study are summarized in Table 1. The PCR conditions were as follows: initial denaturation at 95 ℃ for 10 min, followed by 45 cycles of denaturation at 95 ℃ for 15 s, annealing for 10 s, and extension at 72 ℃ for 20 s. The expression level of each angiogenic factor was adjusted by the level of glyceraldehydes-3-phosphate dehydrogenase (GAPDH) mRNA, and expressed as a ratio to GAPDH mRNA. To confirm the specific amplification from the target mRNAs, some of the PCR products of each primer set were directly sequenced.

Liver cell isolation from regenerating liver tissue

In the next step, liver cells were isolated from the regenerating liver tissue at the peak periods of each angiogenic factor expression (at 48 and 72 h for VEGF, at 72 and 96 h for Ang-1, at 120 and 144 h for Ang-2, and at 72 and 96 h for Tie-2) after hepatectomy, to determine potential cellular sources of VEGF, Ang-1, Ang-2, and

Tie-2 mRNA. Rat hepatocytes were isolated according to the methods of Gumucio *et al*.[23] Briefly, the rat liver was portally perfused first with Mg^{2+}/Ca^{2+}-free Hanks' buffer at 37 ℃, and then with Eagle's minimal essential medium (EMEM) containing 0.05% collagenase (Type I, Sigma, St Louis, MO, USA). The liver was excised and placed in a petri dish containing fresh EMEM with 0.05% collagenase. Glisson's capsule was stripped, and cells were released by gentle manipulation. The resulting crude preparation was filtered though 250-mm and 100-μm nylon meshes. Hepatocytes were then separated by differential centrifugation. Cell viability and purity were >95%. The SECs, Kupffer cells, HSCs were also isolated by *in situ* collagenase perfusion and counterflow elutriation, as described by Knook *et al*.[24] with minor modifications. A JE-5.0 elutriator rotor (Beckman Instruments, Palo Alto, CA, USA) was used in a J6-MI Beckman centrifuge. The separation process was started by adding the nonparenchymal cell suspension to a sample-mixing chamber. The HSCs were eluted at a flow rate of 16 to 18 mL/min, and at a speed of 3 200 r/min. The SECs were then eluted at a flow rate of 23 to 26 mL/min, and Kupffer cells at a flow rate of 36 to 39 mL/min, and at a speed of 2 500 r/min. The purity of HSCs was >92%, as assessed 24 h after seeding by their typical light-microscopic appearance and their positive immunofluorescent staining for desmin[25]. The purity of SECs and Kupffer cells was >95%, >90%, respectively, as assessed 24 h after seeding by diacetyl-low-density lipoprotein incorporation[26], and positive immunofluorescent staining for ED-1[27]. To evaluate the expression of Ang-1, Ang-2, Tie-2, and VEGF mRNA in each cell fraction, freshly isolated cells were used for total RNA extraction.

Immunohistochemical examination of Ang-1, Ang-2 and Tie-2

For immunohistochemical examination of Ang-1, Ang-2, and Tie-2, the liver tissues excised after hepatectomy were fixed overnight in 2% paraformaldehyde solution at 4 ℃, embedded in tissue-tek compound (Miles Laboratories, Elkhart, IN, USA), and frozen in liquid nitrogen for preparation of cryostat sections. Sections (6 μm) were stained with Ang-1, Ang-2, and Tie-2 antibodies (dilution: 1:100, respectively, Santa Cruz Biotechnology Inc. Delaware, CA, USA) and incubated overnight at 4 ℃. Immunostained cells were detected out using LSAB kit (Dako, Copenhagen, Denmark) according to the manufacturer' s instructions. All sections were then lightly counterstained with 0.1% hematoxylin.

PCNA labeling index

Immunohistochemical staining for PCNA was performed on formalin-fixed and paraffin-embedded liver tissue with anti-PCNA antibody as previously described[28, 29]. The three-step immunoperoxidase method using streptavidin biotin complex (Dako, Copenhagen, Denmark) was performed, according to the procedure described by Hall *et al*.[29]. PC-10 monoclonal antibody (Dako, Copenhagen, Denmark) was used at a dilution of 1:100 and incubated overnight at 4 ℃. PC-10 immunostaining was evaluated based on the percentage of positive nuclei of 100 SECs at high power (400x), and expressed as a PCNA labeling index. In this study, the spindle-shaped sinusoid-lining cells in the open sinusoids at high power (400x) were regarded as SECs[30].

TUNEL assay

Regenerating liver tissue was evaluated using the TUNEL assay to identify SECs undergoing apoptosis. Portions of the liver were fixed with 4% paraformaldehyde and embedded in paraffin. Six micrometer thick sections were prepared, and stained by the TUNEL method using an *in situ* apoptosis detection kit (Takara Biomedicals Co., Osaka, Japan) according to the manufacturer' s instructions. Each stained section was examined at high power fields (200 x), and TUNNEL-positive cells in sinusoids were evaluated.

Statistical analysis

The results were expressed as mean±SD. Statistical analysis was made by the Mann-Whitney test for unpaired data. $P<0.05$ was considered significant.

RESULTS

Changes expression of VEGF, angiopoietin, and Tie-2 mRNA in regenerating liver tissue

The expression of VEGF mRNA was at very low levels before hepatectomy. However, VEGF mRNA in the regenerating liver tissue started to increase 24 h after hepatectomy, with a peak at 72 h. A significant increase was found at 48 and 72 h when compared to the prehepatectomy value ($P<0.05$, respectively). Thereafter, VEGF mRNA returned to baseline levels at 120 h (Figure 1A). The changes in Ang-1, Ang-2, and Tie-2 mRNA expressions are shown in Figure 1B. Ang-1 mRNA was present at detectable levels even before hepatectomy, and increased after 48 h of hepatectomy, with a peak at 96 h. A significant increase was seen at 72 and 96 h ($P<0.05$ *vs* 0 h, respectively). Meanwhile, Ang-2 mRNA was hardly detectable before hepatectomy, but was significantly up-regulated at 120 and 144 h ($P<0.03$ *vs* 0 h, respectively). The expression of Tie-2 mRNA was low before hepatectomy, but tended to increase between 72 h and 120 h after hepatectomy.

VEGF, angiopoietin, and Tie-2 mRNA in specific cell populations isolated from regenerating liver tissue

To determine the cellular sources of VEGF, Ang-1, Ang-2, and Tie-2 mRNA in the regenerating liver tissue, four types of liver cells were isolated at key time points: at 48 and 72 h for VEGF, at 72 and 96 h for Ang-1, at 120 and 144 h for Ang-2, at 72 and 96 h for Tie-2, because the expression of each was strongly induced at the indicated time points after hepatectomy (Figure 1). The results are shown in Figure 2. In cell isolates, the mRNA for VEGF was found mainly in the hepatocyte fraction, but in other

cell fractions, VEGF mRNA was hardly expressed. On the other hand, the mRNA for Ang-1 and Ang-2 was found mainly in the SEC and HSC fractions, but Ang-2 mRNA expression was more prominent in the latter. The mRNA for Tie-2 was found to be in the SEC fraction alone.

Immunohistochemical staining for angiopoietins and Tie-2

Ang-1 protein was detectable along sinusoids even before hepatectomy (Figure 3A), and was upregulated at 96 h after hepatectomy (Figure 3B). Meanwhile, Ang-2 protein was not detected before hepatectomy, but was remarkably up-regulated along sinusoids at 120 h after hepatectomy (Figure 3C). The Tie-2 protein was observed along sinusoids even before hepatectomy (Figure 3D).

PCNA labeling index and TUNEL staining

The PCNA labeling index was less than 5% in SECs before hepatectomy. However, a slow increase in the PCNA labeling index of SECs was observed after 24 h

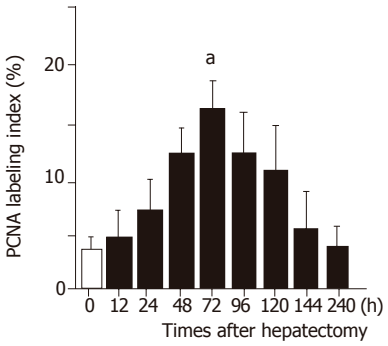

Figure 4 PCNA labeling index of sinusoidal endothelial cells (SECs) after 70 % hepatectomy in rats. [a]*P*<0.05 *vs* 0 h.

of hepatectomy, reaching a peak of 16 % at 72 h ($P< 0.05$ *vs* 0 h) after hepatectomy (Figure 4). Figure 5 shows TUNEL staining of the regenerating liver at 120 h after hepatectomy. Before hepatectomy, apoptotic cells in

sinusoids were uncommon in the liver, and even fewer such cells were detected within 72 h of hepatectomy. However, a few sinusoidal cells were found to be TUNEL stain-positive between 120 h and 144 h after hepatectomy.

DISCUSSION

In the present study, we showed that VEGF expression in the remnant liver started to increase 24 h after hepatectomy, with a peak at 72 h, which coincided with SEC proliferation, as assessed by PCNA staining. Moreover, in cell isolates from the regenerating liver tissue, VEGF mRNA expression was found mainly in the hepatocyte fraction, suggesting that VEGF secreted from hepatocytes may greatly contribute to SEC proliferation in a paracrine manner. Thereafter, Ang-1 and Ang-2 mRNA expression in the remnant liver increased, but the Ang-2 peak was much later than the Ang-1 peak. In isolated cells, both Ang-1 mRNA and Ang-2 mRNA were found to be abundant in nonparenchymal cells, especially in HSCs. Furthermore, apoptosis of SECs was only detected at 120 and 144 h after hepatectomy, which overlapped with elevated levels of Ang-2. Viewed from the standpoint of Ang-1 function as previously reported in angiogenesis, increased expression of Ang-1 might be related with maturation of sinusoids, presumably characterized by cell-cell contact between SECs and surrounding cells. Meanwhile, elevated Ang-2 in the absence of VEGF induction might be associated with the apoptotic changes in superfluous SECs for cessation of the regenerative process. On the other hand, their receptor, Tie-2 was constitutively expressed on SECs, and tended to increase in the later phase of regeneration, synchronized with up-regulation of Ang-1 and Ang-2. Altogether, these results strongly suggest that angiopoietins released from nonparenchymal cells may largely contribute to the later phase of sinusoidal regeneration and remodeling via Tie-2 receptor after hepatectomy.

In the present study, Ang-1 was constitutively expressed in the liver at the mRNA level and also at the protein level, but VEGF mRNA and Ang-2 mRNA were hardly detectable before hepatectomy. These results might be associated with the maintenance of stability and the maturation of existing sinusoids in the steady state of the liver. Meanwhile, Ang-2 mRNA expression was largely induced in the late phase of regeneration after hepatectomy. Furthermore, apoptotic SECs were detected between 120 h and 144 h, suggesting that SEC apoptosis might be associated with elevated levels of Ang-2 in the absence of VEGF induction. Since apoptosis is known to be a strategic biologic process of eliminating unnecessary cells under certain physiological conditions[31], the SEC apoptosis observed in this study might be related to the presence of superfluous SECs in the late phase of regeneration. Greene *et al.*[32] recently demonstrated that SECs play an important role in the regulation of regenerating hepatic mass by means of proliferation and apoptosis. Therefore, apoptosis of SECs in the late phase of regeneration in this study might be associated with cessation of the regenerative process of the liver.

In cell isolates from the regenerating liver tissue, Ang-2-produced cells were found to be nonparenchymal cells, mainly HSCs. HSCs are known to be located in the space of Disse, below the sinusoidal endothelial cell lining, in close to and partially intercalated between hepatocytes, with their long processes extending along sinusoids [33]. Under physiological conditions, HSCs embrace the sinusoids as "liver-specific pericytes"[34]. At present, the factors that initiate HSC activation are not yet fully understood, although platelet-derived growth factor and transforming growth factor-b (TGF-b) may play a key role in HSC activation and proliferation[35]. On the other hand, TGF-b, a potent inhibitor of hepatocyte proliferation has been reported to increase significantly in the later phase of regeneration, and is known to be mainly released from sinusoidal cells after 70% hepatectomy in rats[36-38]. That is, it would be reasonable to expect activation and proliferation of HSCs in a late phase of regeneration, and subsequent release of several growth factors, including angiopoietins, as well as induction of extracellular matrix, after hepatectomy.

In this study, we focused on the role of angiopoietins and VEGF, especially their complementary and coordinated role in the process of sinusoidal regeneration after hepatectomy, and clearly demonstrated that the Ang-Tie system, together with VEGF, played a critical role in regulating the balance between SEC proliferation and apoptosis during sinusoidal regeneration and remodeling after partial hepatectomy. Accordingly, it is clear that production of VEGF and angiopoietins in the liver must be coordinated both quantitatively and temporally to ensure appropriate sinusoidal regeneration after hepatectomy. However, the VEGF system plays a more important role in the early phase of sinusoidal regeneration than the angiopoietin/Tie system. In addition, close communications between different types of liver cells are clearly important in proceeding through these complex steps of regeneration. However, more detail studies are required to elucidate the regulatory mechanisms of sinusoidal regeneration and remodeling, which are only understood at a descriptive level at present, and

also to provide clues for treatment of impaired hepatic regeneration after major hepatectomy, from this point of view.

Abstract

AIM: To assess the usefulness of urinary trypsinogen-2 test strip, urinary trypsinogen activation peptide (TAP), and serum and urine concentrations of the activation peptide of carboxypeptidase B (CAPAP) in the diagnosis of acute pancreatitis.

METHODS: Patients with acute abdominal pain and hospitalized within 24 h after the onset of symptoms were prospectively studied. Urinary trypsinogen-2 was considered positive when a clear blue line was observed (detection limit 50 μg/L). Urinary TAP was measured using a quantitative solid-phase ELISA, and serum and urinary CAPAP by a radioimmunoassay method.

RESULTS: Acute abdominal pain was due to acute pancreatitis in 50 patients and turned out to be extrapancreatic in origin in 22 patients. Patients with acute pancreatitis showed significantly higher median levels of serum and urinary CAPAP levels, as well as amylase and lipase than extrapancreatic controls. Median TAP levels were similar in both groups. The urinary trypsinogen-2 test strip was positive in 68% of patients with acute pancreatitis and 13.6% in extrapancreatic controls ($P<0.01$). Urinary CAPAP was the most reliable test for the diagnosis of acute pancreatitis (sensitivity 66.7%, specificity 95.5%, positive and negative predictive values 96.6% and 56.7%, respectively), with a 14.6 positive likelihood ratio for a cut-off value of 2.32 nmol/L.

CONCLUSION: In patients with acute abdominal pain, hospitalized within 24 h of symptom onset, CAPAP in serum and urine was a reliable diagnostic marker of acute pancreatitis. Urinary trypsinogen-2 test strip showed a clinical value similar to amylase and lipase. Urinary TAP was not a useful screening test for the diagnosis of acute pancreatitis.

INTRODUCTION

Most patients with acute pancreatitis have mild and self-limited disease that resolves spontaneously, but about 20% of attacks are severe, with a mortality of about 10-25%[1]. Early diagnosis of acute pancreatitis is crucial to ensure rapid and appropriate treatment. However, the clinical features of acute pancreatitis can be difficult to distinguish from those of other acute abdominal conditions, and the diagnosis may be overlooked at first. Determination of amylase in serum or urine is the principal laboratory method for diagnosing acute pancreatitis. However, hyperamylasemia may be absent in 19% of cases[2], and increases in pancreatic enzyme levels can occur in patients with acute abdominal pain of extrapancreatic in origin[3-5]. The pathophysiology of acute pancreatitis involves the activation of the pancreatic proenzymes. The activation of trypsinogen followed by the activation of other pancreatic zymogens occurs early in the course of pancreatitis, in proportion to the extent of pancreatic injury[6]. Concentrations of the activation peptide of trypsinogen (TAP) in urine and of the activation peptide

of procarboxypeptidase B (CAPAP) in urine and serum have shown to be promise predictors of severity in acute pancreatitis[7,8]. However, the clinical value of these markers for the early diagnosis of acute pancreatitis is unclear. Until now, a previous study of urinary TAP levels[7] and three other studies of serum and urine CAPAP[9-11] have shown significantly higher concentrations of these peptides in acute pancreatitis compared to non-pancreatic abdominal pain, therefore, suggesting the usefulness of these assays for diagnosing acute pancreatitis. On the other hand, qualitative rapid urine trypsinogen-2 test strip is easy to perform and has been shown to be a reliable and useful screening test for acute pancreatitis in daily practice[12-16], particularly in healthcare units lacking laboratory facilities. This study was conducted to assess the usefulness of urinary trypsinogen-2 test strip, urinary TAP, and serum and urine CAPAP levels compared with conventional enzymes (serum amylase and lipase) for diagnosing acute pancreatitis.

MATERIALS AND METHODS

Patients

All consecutive patients with acute abdominal pain admitted to the Section of Gastroenterology of an Acute-care University Hospital in Alicante, Spain, in an 8-month period, participated in an observational, prospective, cohort study. Admission to the hospital within 24 h of symptom onset was the criterion for inclusion. The diagnosis of acute pancreatitis was based on (1) typical clinical symptoms and at least a threefold increase of serum amylase, once other causes of abdominal pain had been excluded, and (2) evidence of pancreatic inflammation by imaging studies and/or surgery. The severity of acute pancreatitis was assessed according to the criteria established at the International Symposium on Acute Pancreatitis in Atlanta in 1992[17]. According to our protocol, a CT scan was performed in patients with severe acute pancreatitis, with unknown etiology and whenever it was necessary to establish the diagnosis of acute pancreatitis. In all the patients, blood and urine samples were collected within the first 24 h of hospitalization. The Hospital General Universitario Ethic's Committee approved the protocol, and all patients gave their informed consent for the inclusion in the study. Patients were divided into two groups according to the origin of acute abdominal disease. There were 50 patients with acute pancreatitis (25 men, 25 women, mean age 62.5 ±16.5 years) and 22 patients (11 men, 11 women, mean age 50.8±22.4 years) whose acute abdominal pain turned out to be extrapancreatic in origin. A CT scan was performed in all the 22 patients with non-pancreatic abdominal pain to rule out the possibility of acute pancreatitis.

Laboratory tests

Serum amylase and lipase concentrations were measured by routine methods of our laboratory and for the remaining diagnostic markers, urine and serum samples were frozen immediately after collection and stored at (-20 °C) until analysis.

Serum amylase concentrations were measured using an enzymatic assay (Amyl, Boehringer Mannheim Systems, Mannheim, Germany). For this assay the limit of detection is 3 U/L and the range of the standard curve was comprised between 3 and 1 200 U/L. The reference range of serum amylase, previously established in our laboratory, was 26-100 U/L. Serum lipase was measured using a colorimetric enzymatic technique (Lip, Boehringer Mannheim Systems, Mannheim, Germany). For this assay the limit of detection was 3 U/L and the range of the standard curve was comprised between 3 and 300 U/L. The reference range of serum lipase, previously established in our laboratory, was 13-60 U/L.

Serum and urine CAPAP concentrations were measured using a radioimmunoassay method (CAPAP RIA kit, Euro-Diagnostica, Malmö, Sweden). The kit is based on a competitive radioimmunoassay using antibodies against human CAPAP. CAPAP both in standards and samples compete with ^{125}I-labeled CAPAP in binding to the antibodies. The ^{125}I-CAPAP binds to the antibodies in an inverse proportion to the concentrations of CAPAP both in standards and samples. Antibody-bound ^{125}I-CAPAP is separated from the unbound fraction using the double antibody solid-phase technique. The radioactivity of the pellets was then measured. For this assay, the lower limit of detection was about 0.4 nmol/L and the range of the standard curve was comprised between 0 and 20 nmol/L. When the results above this limit were obtained, serum samples were diluted at 1:5 and urine samples at 1:10 were processed again.

Urinary TAP was measured using a quantitative solid-phase ELISA based on the competition between free and immobilized peptide binding to an antibody to TAP (TAPKIT, Biotrin International Ltd, Dublin, Ireland). Urine samples were collected in sterile containers with EDTA (at final concentration 5-10 nmol/L) and diluted to a ratio of 1:4 in the assay buffer according to the manufacturer's instructions. TAP linked to a carrier protein is immobilized on the solid phase to which the peptide calibrator or diluted (1:4) urine sample, plus the TAP antibody, was added. After the reaction, the amount of antibody bound to the solid phase was measured spectrophotometrically (450 nm) after sequential addition of rabbit antibody to IgG-biotin conjugate, streptavidin-horseradish peroxidase, and tetramethyl-benzidine. The lower detection limit was 0.2 nmol/L (0.8 nmol/L in the 1:4 diluted samples) and the range of the standard curve was comprised between 0.14 and 200 nm.

The Actim Pancreatitis test strip (Medix Biochemica, Finland) for urinary trypsinogen-2 is an immunochromatographic test. After the test strip has been dipped into the urine sample, trypsinogen-2 is bound to monoclonal antibody-labeled blue latex particles, which migrate across a nitrocellulose membrane with a zone containing another antibody specific for another epitope on trypsinogen-2. At trypsinogen-2 concentrations higher than 50 μg/L, a blue line develops

Table 1 Clinical and outcome data in 50 patients with acute pancreatitis

	Number of patients	Percentage
Male/female	25/25	
Age, yr, mean (SD)	62.5 (16.5)	
Etiology		
Gallstones	30	60
Idiopathic	12	24
Alcohol	3	6
Post-ERCP	3	6
Hypertriglyceridemia	2	4
Severity		
Severe	15	30
Mild	35	70
Complications		
Local	12	24
Systemic	17	34
Death	5	10

ERCP, endoscopic retrograde cholangiopancreatography.

Table 2 Etiology in 22 controls with non-pancreatic acute abdomen

Etiology	Number of patients	Percentage
Acute cholecystitis	5	22.7
Acute appendicitis	3	13.6
Coliky pain	3	13.6
Intestinal obstruction	2	9.1
Active Crohn's disease	2	9.1
Acute cholangitis	1	4.5
Perforated peptic ulcer	1	4.5
Gastric carcinoma	1	4.5
Epiploic appendicitis	1	4.5
Abdominal abscess	1	4.5
Bleeding peptic ulcer	1	4.5
Mesenteric lymphadenitis	1	4.5

in this zone. The test was considered positive when a clear blue line was detected within 5 min. A control line was used to indicate proper functioning of the strip. If the control line was undetectable the assay was repeated.

Statistical analysis

Descriptive data were given as median with interquartile range (25th and 75th percentiles). The Mann-Whitney *U* test was used to compare the results between patients with acute pancreatitis and extrapancreatic controls. Statistical significance was set at $P<0.05$. Receiver operating characteristics (ROC) curves of serum and urine CAPAP levels and urinary TAP concentrations were used to determine the optimal cut-off levels. For serum concentrations of amylase and lipase, threefold increases in the reference values recommended by our laboratory were selected as cut-off values. Using these cut-off points, the sensitivity, specificity, positive and negative predictive values and positive likelihood ratio in establishing the diagnosis of acute pancreatitis were calculated. Comparison of different prognostic markers was made using the positive likelihood ratio for the different cut-off values that were selected. The SPSS/PC+10 statistical package on a personal computer was used for the analysis of data.

RESULTS

Of the 50 patients with acute pancreatitis, 15 (10 men and 5 women, mean age 66±16 years) had severe disease and 35 (17 men and 18 women, mean age 61±17 years) had mild disease. Etiology of pancreatitis and outcome are shown in Table 1. Local pancreatic complications included necrosis in 7 patients, pseudocyst in 4 and abscess in 1. Systemic complications consisted of renal failure in 6 patients, respiratory insufficiency in 6 and gastrointestinal hemorrhage in 5. Death occurred in 5 of 15 patients with severe pancreatitis. Diagnoses established in controls with non-pancreatic acute abdomen are shown in Table 2.

As compared with extrapancreatic controls, patients with acute pancreatitis had significantly higher values of amylase [942.20 (316.25-1 333.42) U/L *vs* 52 (29.50-91.20) U/L, $P<0.001$] and lipase [1 084 (228.75-2 133.75) U/L *vs* 22 (15.50-39) U/L, $P<0.001$] in serum. On the other hand, patients with acute pancreatitis showed significantly higher values of CAPAP in the serum and urine than controls with non-pancreatic acute abdomen, i.e., CAPAP in serum 5.05 (2.23-10.04) nmol/L *vs* 0.40 (0.40-1.14) nmol/L, $P<0.001$;

Table 3 Diagnostic accuracy of cut-off values of CAPAP in serum and urine and urinary TAP to distinguish severe acute pancreatitis from the mild form of the disease

Proenzyme, cut-off value within 24 h of admission	Pre-test probability %	Sensitivity %	Specificity %	PPV %	NPV %	Positive likelihood ratio	Post-test probability %
Amylase serum, >330 U/L	69.4	74	86.4	92.5	59.3	5.4	92.4
Lipase serum, >180 U/L	69.4	84	85.7	93.4	72	5.87	93
CAPAP serum, >1.53 nmol/L	69.4	85	90.9	95.2	74	9.3	95
CAPAP urine, >2.32 nmol/L	69.4	66.7	95.5	96.9	56.7	14.6	97
TAP urine, >10.01 nmol/L	69.4	68.8	40	73.3	34.7	1.13	71.9
Trypsinogen-2 urine, positive	69.4	68	86.4	91.9	54.3	5	91.9

PPV, positive predictive value; NPV, negative predictive value.

CAPAP in urine 7.05 (0.93-29.5) nmol/L *vs* 1.36 (0.80-1.85) nmol/L, $P<0.01$) (Figures 1A and B). However, there were no statistically significant differences in urinary TAP between patients and controls [15.45 (7.79-37.05) nmol/L *vs* 12.70 (7.03-20.27) nmol/L] (Figure 1C). The urinary trypsinogen-2 test strip was positive in 68% of patients with acute pancreatitis and 13.6% in extrapancreatic controls ($P<0.01$).

Sensitivity, specificity, predictive values, pre-test probability, post-test probability and positive likelihood ratio for the different cut-off values of CAPAP in serum and urine, urinary TAP and trypsinogen-2 test are shown in Table 3. Urinary CAPAP was the most reliable test for the diagnosis of acute pancreatitis (sensitivity 66.7%, specificity 95.5%, positive predictive value 96.6%, negative predictive value 56.7% and post-test probability 97%), with a 14.6 positive likelihood ratio for a cut-off value of 2.32 nmol/L.

DISCUSSION

This study demonstrates that CAPAP in serum and urine (especially urinary CAPAP) was a reliable diagnostic marker of acute pancreatitis providing slightly better results than serum amylase and lipase. Urinary trypsinogen-2 test strip showed a clinical value similar to amylase and lipase. Urinary TAP was not a useful screening test for the diagnosis of acute pancreatitis. In agreement with previous studies[18,19], we also found that serum amylase and lipase were adequate diagnostic markers of acute pancreatitis.

In respect to urinary TAP concentrations, the present results are consistent with other studies[20,21] in which this marker was not useful for diagnosing acute pancreatitis. However, in the study of Neoptolemos *et al*.[7], there were statistically significant differences in urinary TAP levels between patients with acute pancreatitis and controls both at 24-48 h of hospital admission and 24-48 h after the onset of symptoms. It may be possible that the increase in urinary TAP levels at 48 h compared to 24 h and the high rate of alcoholic pancreatitis included in the study of Neoptolemos *et al*.[7] may account for the differences observed with the present findings.

With regard to clinical value of serum and urine CAPAP concentrations, both assays were reliable early markers for diagnosing acute abdominal pain of pancreatic origin. These results are similar to previous findings by our group in a series of 22 patients[22] and confirm that this marker of acute pancreatitis is capable of both simultaneously diagnosing and assessing severity of disease at the time of admission to the hospital[8-11]. Certainly, we do not know why urinary TAP was not a useful screening test for the diagnosis of acute pancreatitis whereas urinary CAPAP levels were a reliable test, since both assays indicate an activation of pancreatic zymogens. Probably, the different kinetics of release and techniques of determination of both markers could explain this point. More studies are necessary to assess it. On the other hand, laborious and time consuming work are pitfalls of current CAPAP assays for rapid screening in a routine diagnostic setting. Moreover, it hardly improves the diagnostic accuracy of the routine markers (amylase and lipase).

Rapid urine trypsinogen-2 strip test has been introduced in an effort to decrease the number of misdiagnosed cases of acute pancreatitis in an emergency setting. In the present study, the test was positive in 68% of patients with acute pancreatitis and 13.6% in extrapancreatic controls, with a sensitivity of 68% and specificity of 86.4%. These results are slightly less favorable than those reported in other series[12-16], in which 90% sensitivity was almost reached. However, it should be noted that a high percentage of patients with non-pancreatic acute abdominal pain with a clinical profile similar to acute pancreatitis (cholecystitis five cases, biliary colic three cases) were included in our study. Therefore, the present results far from decreasing the clinical usefulness of urinary trypsinogen-2 test strip, contribute to delimit the true value of this rapid screening test in clinical practice. On the other hand, it has to be considered that the inclusion process of patients with abdominal pain in this investigation may be biased, since patients admitted to our department have been pre-selected by the emergency department, and this likely justifies the high proportion of patients with AP in our series (50/72).

In summary, in patients with acute abdominal pain, hospitalized within 24 h of symptom onset, CAPAP in serum and urine was a reliable diagnostic marker of acute pancreatitis, but it provided only slightly better results than serum amylase and lipase and, although we have not made a detailed economical analysis, it seems not to be cost-effective to use it as a routine diagnostic marker. On the other hand, urinary trypsinogen-2 test strip showed a clinical value similar to amylase and lipase. Urinary TAP was not a useful screening test for the diagnosis of acute pancreatitis.

Abstract

AIM: To find out the role of bacteria as a possible etiological factor in lymphocytic colitis.

METHODS: Twenty patients with histopathological diagnosis of lymphocytic colitis and 10 normal controls were included in this study. Colonoscopic biopsies were obtained from three sites (hepatic and splenic flexures and rectosigmoid region). Each biopsy was divided into two parts. A fresh part was incubated on special cultures for bacterial growth. The other part was used for the preparation of histologic tissue sections that were examined for the presence of bacteria with the help of Giemsa stain.

RESULTS: Culture of tissue biopsies revealed bacterial growth in 18 out of 20 patients with lymphocytic colitis mostly *Escherichia coli* (14/18), which was found in all rectosigmoid specimens (14/14), but only in 8/14 and 6/14 of splenic and hepatic flexure specimens respectively. In two of these cases, *E coli* was associated with proteus. Proteus was found only in one case, Klebsiella in two cases, and *Staphylococcus aureus* in one case. In the control group, only 2 out of 10 controls showed the growth of *E coli* in their biopsy cultures. Histopathology showed rod-shaped bacilli in the tissue sections of 12 out of 14 cases with positive *E coli* in their specimen's culture. None of the controls showed these bacteria in histopathological sections.

CONCLUSION: This preliminary study reports an association between *E coli* and lymphocytic colitis, based on histological and culture observations. Serotyping and molecular studies are in process to assess the role of *E coli* in the pathogenesis of lymphocytic colitis.

INTRODUCTION

Microscopic colitis is a syndrome consisting of chronic watery diarrhea, a normal or near normal gross appearance of the colonic mucosa, and a specific histological picture described as either lymphocytic or collagenous colitis[1]. The term microscopic colitis was first introduced by Read *et al*.[2] that was found in eight patients who were having idiopathic chronic diarrhea and normal colonoscopic findings. The diagnosis of microscopic colitis in such patients was based on the presence of excess amount of chronic inflammatory cells in the lamina propria of colorectal mucosa. A closely related term "lymphocytic colitis" was introduced by Lazenby *et al*.[3], who reported that the most distinctive histological feature of microscopic colitis is the presence of an excess amount of intraepithelial lymphocytes, and renamed microscopic colitis as "lymphocytic colitis". Recently, the histopathology of lymphocytic colitis has been more specified by Lamps and Lazenby[4].

The etiology of lymphocytic colitis is still unclear, and several factors have been claimed. First, it is induced by drugs especially non-steroidal-anti-inflammatory drugs (NSAIDs)[5]. However, subsequent studies found that there is no association between NSAID consumption and microscopic colitis[6]. Vascular tonics have also been suspected to play a part in the pathogenesis of lymphocytic colitis via chronic activation of the mucosal immune system by one or several components of such drugs[7]. Other drugs that claimed to be a cause of lymphocytic colitis include Lansoprazole[8] and Modopar[9]. The second concept is the reported association of microscopic colitis with celiac disease, which may indicate a common pathogenesis[1,10,11]. Nevertheless, many patients with celiac disease do not show colonic lymphocytosis[12]. Lastly it is the possible role of pathogenic organisms. Some investigators have found spirochetes in some patients with microscopic colitis, and suggested that these microorganisms are capable of inducing the disease[13]. Conversely, earlier studies reported that spirochetes have no clinical significance[14]. In a search for infectious causes, Afzalpurkar *et al*.[15] investigated 14 patients with chronic idiopathic diarrhea by stool examination and stool culture as well as a culture of the jejunal fluid. Although stool examination and culture were negative, abnormal growth

of bacteria in the jejunal fluid was noted in four patients. Similarly, the culture of the jejunal aspirate in 14 patients having chronic idiopathic diarrhea has revealed bacterial growth in one patient who was successfully treated with antibiotics[2].

The aim of the current preliminary study was to search for a possible role of the pathogenic bacteria in lymphocytic colitis. This has been achieved by thorough histologic examination as well as culture of the colonic tissue specimens, which is to the best of our knowledge not previously reported in the literature.

MATERIALS AND METHODS

Patients

The present study consisted of 20 patients fulfilling the classic definition of lymphocytic colitis, which is described as a triad of idiopathic chronic, watery diarrhea, normal or nearly normal colonoscopic findings, and colonic epithelial lymphocytosis without a thickened subepithelial collagen band[16]. The patients were chosen from the in- and outpatients of Ain-Shams University Hospital during the period between 1999 and 2001, after excluding all other causes of diarrhea by a thorough clinical examination, radiologic, endoscopic, and laboratory investigations. The exclusion criteria were autoimmune diseases, any systemic disease that could cause diarrhea as diabetes, history of food sensitivity, use of laxatives or other drugs that could cause diarrhea, presence of ova and parasites or occult blood in stools.

Ten age- and sex-matched healthy volunteers with no diarrhea or any other gastrointestinal diseases were used as negative controls. The endoscopic and histologic pictures of their colonic mucosae were normal. All patients and controls were not allowed to take antibiotics for 3 wk before the biopsy, since antibiotic treatment may affect the bowel microbial flora. Informed written consent was obtained from all the patients and volunteers.

Stool analysis

Microscopic examination of fresh unstained smears was done to exclude parasitic infestation.

Colonoscopic examination and biopsy

Using lower CF 100 L video colonoscope (Olympus), the whole colon was examined for any pathological lesions including the inspection of the terminal ileum if possible. Patients were selected on the basis of having normal or nearly normal colonoscopic findings. From each patient and control, four tissue samples were taken from each of the following sites: hepatic flexure (HF), splenic flexure (SF), and rectosigmoid region (RS). These biopsy specimens were collected separately, then each specimen was divided into two parts, the first part was put in normal saline and sent for culture, the other part was fixed in 10% buffered formalin and sent for histopathology.

Culture studies of biopsy samples

For all subjects, fresh colonic tissue specimens obtained from HF, SF, and RS regions were incubated separately on the media listed in Table 1 to detect bacterial flora. Specimens were crushed before incubation. The isolated intestinal bacteria were identified by colony morphology, microscopic examination of gram stained smears, conventional biochemical reactions and API20 E identification system (BioMerieux) for the identification of Gram-negative bacteria.

Histopathology

Formalin-fixed colonic tissue specimens obtained from the 20 patients and 10 controls (3 specimens from each subject) were processed separately for the preparation of paraffin blocks. The latter were sectioned at 5 μm and stained with hematoxylin and eosin (H&E) for routine examination, Masson trichrome for the demonstration of subepithelial collagen band, and modified Giemsa stain to search for bacteria (as followed in the cases of chronic gastritis) to detect *Helicobacter pylori*[17]. One pathologist (T.E.H.) examined all the tissue sections without the knowledge of the clinical or endoscopic findings. All 60 specimens were examined for the histologic criteria of lymphocytic colitis, which were modified by Lazenby *et al*.[3]. These criteria were simplified as follows. (1) Surface epithelial damage, which was seen as flattened or syncytial appearance of surface cells instead of the tall columnar cells that are normally observed. (2) Crypt distortion. Each of these two findings was graded according to severity into 1-3 scales (1+: mild, 2+: moderate, and 3+: marked). (3) Mononuclear cellular infiltrate in the lamina propria. This was graded into 1-4 scales (1+: normal, 2+: mild, 3+: moderate, and 4+: marked). (4) Intraepithelial lymphocytes. It was scored as the number of lymphocytes per 100 surface epithelial cells. It is worth mentioning that any case showing histologic features other than lymphocytic colitis was excluded from the study. These histologic exclusion criteria included features suggestive of inflammatory bowel disease[18], features of collagenous colitis[19], presence of ova or parasites, presence of viral inclusions, and melanosis coli.

Statistical analysis

Fisher's exact test was used to compare the patients and controls regarding the frequency of the bacterial growth.

Chi-square test was used to assess the association between the presence of bacteria and the severity of the histopathological features.

RESULTS

Clinical data

Patients with lymphocytic colitis included in the study consisted of 15 males and 5 females with a male to female ratio of 3:1. Ages ranged 20-67 years, with a mean of 36 ±10.3 years. All patients presented with chronic watery diarrhea of unknown cause for a period of 1-4.5 years with a mean of 2.5±0.76 years. The daily motions ranged 3-7 times (mean 4.5±1.3 times). All patients had associated mild to moderate abdominal discomfort. Five patients

had significant weight loss. No other gastrointestinal manifestations were found.

Culture results

Bacterial growth was observed in the colonic tissue specimens of 18 out of the 20 patients (90%). The most frequent isolated organism was *E coli*, which was demonstrated in 14 out of 18 culture positive cases (77.8%). These organisms were seen in the rectosigmoid specimens in all the 14 cases, splenic flexure growth was found in 8 of them, and hepatic flexure growth in 6 cases only. In 2 out of the 14 cases, *E coli* was associated with the growth of Proteus. Other isolated bacteria were Klebsiella (two cases) and *Staphylococcus* aureus (one case). Other organisms such as *Shigella, Salmonella, Campylobacter, Yersinia* did not grow on their specific media. In the controls, *E coli* was obtained from the rectosigmoid samples of two cases (20%). The frequency of the bacterial growth was significantly higher in the patients than in the controls (P = 0.0003) (Table 2).

Histopathological results

The most prominent feature in all 60 colonic biopsies obtained from the 20 patients was the increased number of mononuclear cells in the lamina propria (Figure 1A) observed in all the three regions examined (rectosigmoid, splenic, and hepatic flexures), indicating total colitis. The inflammatory cells were mainly lymphocytes with less number of plasma cells and histiocytes; few polymorphonuclear cells were present in two cases with no crypt abscess formation. A small number of eosinophils were seen in three patients. Epithelial damage was mild to moderate in the majority of colonic biopsies (Figure 1A). The average crypt distortion was mild to moderate in all colonic biopsies. Few lymphocytes could be seen between the crypt epithelial cells, but not in the crypt lumen (Figure 1B). No other inflammatory cells were present in the lumen or epithelial cells of the crypts.

The percentage of the inflammatory cells in the surface epithelium ranged 15-50% with a mean of 23%, 22%, and 28% in the rectosigmoid, splenic flexure and hepatic flexure, respectively. The intraepithelial inflammatory cells were lymphocytes only (Table 3 and Figure 1C).

In 12 out of 18 patients with bacterial overgrowth in their colonic tissue specimens, rod-shaped bacilli were seen in the histologic tissue sections obtained from various colonic sites. These bacilli were visible on H&E-stained sections, but were more easily demonstrated by Giemsa stain. They were closely applied to the surface epithelium (Figure 1D), or within the lumen of the crypts which showed destruction of their lining cells (Figure 1E). It is important to note that the intercellular and intracellular localization of the organisms could not be assessed because these modes of colonization could not be definitely identified by light microscopy alone. The presence of bacteria was significantly associated with the degree of epithelial damage (χ^2 = 9.9, P = 0.007) and the degree of the cellular infiltrate in the lamina propria

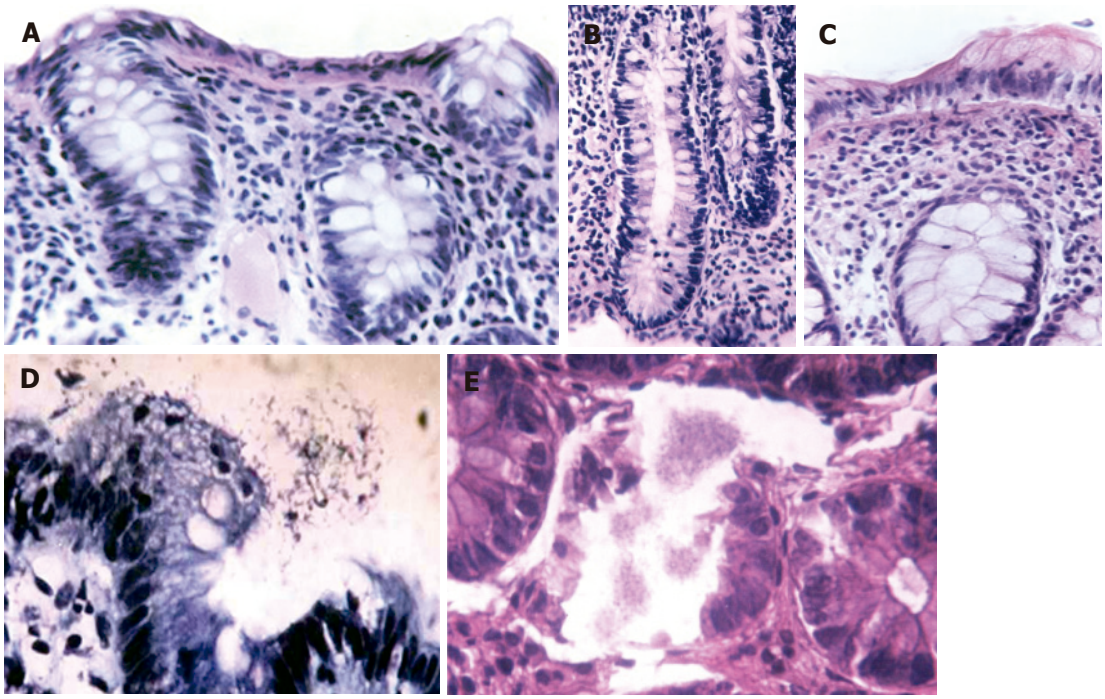

Figure 1 Cases of lymphocytic colitis showing respectively the damage of surface epithelium and increased mononuclear cells in lamina propria (H&E ×250) (**A**), few lymphocytes between crypt epithelial cells (H&E ×250) (**B**), intraepithelial lymphocytes (H&E ×250) (**C**), rod-shaped bacilli adherent to the surface epithelium (Giemsa stain ×400) (**D**), and bacilli within the lumen of transverse section of crypt (H&E ×400) (**E**).

(χ^2 = 6.0, P = 0.05). No significant relationship could be obtained between the presence of bacteria and the degree of crypt distortion (Table 4).

In all 30 colonic biopsies obtained from the 10 healthy controls, the colonic mucosa was nearly normal with no visible bacilli by H&E and Giemsa staining.

DISCUSSION

The main purpose of the present preliminary study was to investigate the possible role of bacteria in the pathogenesis of lymphocytic colitis. To achieve this aim, patients with definite diagnosis of lymphocytic colitis and normal controls were subjected to colonoscopy and biopsy. Specimens were examined in two ways. First, histopathological examination, including a thorough search for bacteria, similar to that for *H pylori* in gastric biopsies. Second, culture of colonic tissue specimens on specific media to isolate bacterial growth. Although some authors have investigated the possible role of infection in lymphocytic colitis or chronic idiopathic diarrhea, their methodology is limited to stool culture and/or culture of the jejunal fluid[2,15,19,20]. To the best of our knowledge, this is the first study, which attempted to search for bacteria in the colonic biopsies in cases of lymphocytic colitis by histologic examination of tissue sections as well as culture of the colonic tissue.

Microscopically, we could identify small or large number of rod-shaped bacilli closely related to the surface of the colonic mucosa and within the lumen of the crypts in 12 out of 14 patients with positive *E coli* in biopsy culture. It seems that *E coli* was most likely seen in the histologic sections of our tissue specimens, because these bacilli were seen in patients with positive *E coli* in biopsy culture.

The demonstration of these bacilli in the colonic mucosa of our patients with lymphocytic colitis raises several questions. The first question is why they have not been seen before in colonic tissue sections of such cases? We think that these bacteria have not been previously demonstrated because Giemsa stain is not routinely applied for colonic mucosal biopsy specimens and bacteria are easily overlooked on H&E-stained sections. The second question to be raised is whether these bacteria

are pathogenic or merely commensals in the colonic mucosa. From our point of view, we suggest that these bacilli, which have been demonstrated histologically, are pathogenic rather than commensals, since they are closely related to the mucosal surface and within the lumen of crypts, and not within the tissue debris. Moreover, they are always associated with prominent colonic pathology. It is worthy of notion that we could not demonstrate such bacteria in all colonic biopsies obtained from the healthy controls.

The relation between lymphocytic colitis and bacterial infection is still controversial. Gebbers and Laissue[13] reported the presence of spirochetes in some patients with microscopic colitis, and suggested that these microorganisms are capable of inducing the disease. On the other hand, earlier studies reported that spirochetes have no clinical significance[14]. Perk *et al*.[21] presented a patient who had chronic watery diarrhea and showed stool culture positive for *Campylobacter jejuni*. Examination of her colonic biopsies led to the diagnosis of lymphocytic colitis. The authors believed that the patient's disease is due to an infectious process. Also, Tremaine[22] reported that bismuth subsalicylate is effective in the treatment of some patients with lymphocytic colitis, a finding that supports the concept of infectious etiology in such disease.

It is interesting to note that the search for bacterial etiology in cases of chronic watery diarrhea has been expanded to include the type of bacteria responsible for this disease. The most common organism investigated in this regard is *E coli*[23-25].

Diarrheagenic *E coli* (*E coli* causing diarrhea) is divided into four groups: enteropathogenic (causing acute diarrhea in infants and children), enteroinvasive (causing Shigella-like dysentery), enterohemorrhagic (causing hemorrhagic colitis and bloody diarrhea) and enterotoxigenic (causing travelers' diarrhea)[26]. In addition to these groups, two other types, which were previously classified as enteropathogenic, have been recently identified. The first is enteroaggregative *E coli* (EaggEC), which is now considered as a cause of prolonged diarrhea[27]. Another recently described type of *E coli* is the diffusely adherent type which has been found to be significantly associated with chronic diarrhea[28]. It is important to note that many strains of *E coli* belonging to the classic enteropathogenic type are now found to be enteroaggregative by DNA hybridization or PCR. This indicates that routine culture studies and even serotyping are of limited value for the identification of various groups of diarrheagenic *E coli*[29].

These new types of *E coli* may be more likely the types seen in the tissue sections and biopsy culture of our patients, being associated with chronic diarrhea as mentioned above, and may be related to the pathogenesis of lymphocytic colitis, since it can colonize both in large and in small intestines. In a study by Kang *et al*.[30], strains of enteroaggregative *E coli* isolated from patients with diarrhea resulted in the colonization of both small and large intestines. In support to this suggestion is the study of Afzalpurkar *et al*.[15], who found that 4 out of 14 patients with chronic idiopathic diarrhea have abnormal growth of bacteria in aspirated jejunal fluid and the results of quantitative cultures are consistent with contamination. In addition, one of the four patients had steatorrhea, which is one of the hallmarks of bacterial overgrowth syndrome. These data have led the authors to speculate that *E coli* or other bacteria not identified by routine culture methods are involved in the etiology of chronic idiopathic diarrhea. It is worth mentioning that the lack of response to antibiotics in the four patients with bacterial overgrowth reported in the previous study should not be considered as evidence against bacterial etiology, since multiple drug resistance in EaggEC has been reported by some studies recommending quinolone treatment for EaggEC-associated diarrhea[31].

In conclusion, bacteria play a possible role in lymphocytic colitis in which rod-shaped bacilli adherent to the colonic mucosa can be seen as in cases of *Helicobacter* gastritis. Further studies are now in process to investigate the pathogenicity of these organisms in case of lymphocytic colitis.

Abstract

AIM: To investigate dose-response and time-course of the effects of ethanol on the cell viability and antioxidant capacity in isolated rat hepatocytes.

METHODS: Hepatocytes were isolated from male adult Wistar rats and seeded into 100-mm dishes. Hepatocytes were treated with ethanol at concentrations between 0 (C), 10 (E10), 50 (E50), and 100 (E100) mmol/L (dose response) for 12, 24, and 36 h (time course). Then, lactate dehydrogenase (LDH) leakage, malondialdehyde (MDA) concentration, glutathione (GSH) level, and activities of glutathione peroxidase (GPX), glutathione reductase (GRD), superoxide dismutase (SOD), and catalase (CAT) were measured.

RESULTS: Our data revealed that LDH leakage was significantly increased by about 30% in group E100 over those in groups C and E10 at 24 and 36 h, The MDA concentration in groups C, E10 and E50 were significantly lower than that in group E100 at 36 h. Furthermore, the concentration of MDA in group E100 at 36 h was significantly higher by 4.5- and 1.7-fold, respectively, than that at 12 and 24 h. On the other hand, the GSH level in group E100 at 24 and 36 h was significantly decreased, by 32% and 28%, respectively, compared to that at 12 h. The activities of GRD and CAT in group E100 at 36 h were significantly less than those in groups C and E10. However, The GPX and SOD activities showed no significant change in each group.

CONCLUSION: These results suggest that long-time incubation with higher concentration of ethanol (100 mmol/L) decreased the cell viability by means of reducing GRD and CAT activities and increasing lipid peroxidation.

Key words: Hepatocyte; Ethanol; Lipid peroxidation; Antioxidant capacity

INTRODUCTION

Ethanol is metabolized to acetaldehyde by some enzymes in the body, including alcohol dehydrogenase (ADH), cytochrome P450 2E1 (CYP 2E1), catalase (CAT), xanthine oxidase (XO), etc. Then acetaldehyde is decomposed to acetic acid by acetaldehyde dehydrogenase (ALDH) in mitochondria. Several studies have provided evidences for reactive oxygen species (ROS) generation during ethanol metabolism, including superoxide radical[1], hydrogen peroxide[2], hydroxyl radical[3], and 1-hydroxyethyl radical[4]. Numerous studies have indicated that excessive ethanol intake induces the mass production of free radicals in the body, which are considered to be associated with alcoholic liver disease[5]. Furthermore, a number of experimental studies demonstrated that either acute or chronic alcohol administration to experimental animals increases the formation of lipid peroxidation products, such as malondialdehyde (MDA), and decreases tissue levels of antioxidants, such as glutathione (GSH), in the liver[6]. Bailey and Cunningham also indicated that the exposure of hepatocytes to ethanol resulted in increased production of ROS, which correlated with decreased cell viability[7]. The impairment of cellular antioxidant defenses along with the formation of oxygen-derived radicals has been proposed to play a role in causing oxidative damage associated with alcoholic liver disease. Moreover, the individual differences in animals always makes the results inconsistent; therefore, the purpose of this study was to investigate and clarify the influences of different concentrations of ethanol on the

cell viability, antioxidant capacity, and antioxidant enzymes activities in the isolated liver parenchymal cells during different incubation times.

MATERIALS AND METHODS

Preparation of isolated rat hepatocytes

Hepatocytes were isolated from rats according to the two-step collagenase perfusion technique described by Berry and Friend[8]. Isolated cells were cultured as monolayers in William's medium E with 5% fetal bovine serum and 1 μmol/L dexamethasone at a density of 1×10^5 cells/mL. After 24 h of incubation at 37 ℃ in 50 mL/L CO_2, hepatocytes were treated with ethanol at concentrations between 0 (C), 10 (E10), 50 (E50), and 100 (E100) mmol/L (dose response) for 12, 24, and 36 h (time course). Then, the cells were collected using a scraper and resuspended in Tris buffer (50 mmol/L Tris-HCl, 5 mmol/L EDTA, and 1 mmol/L DTT, pH 7.5) for analysis as follows.

Lactate dehydrogenase (LDH) leakage

The viability of hepatocytes was expressed as the percentage of LDH leakage, which was the LDH activity in the culture medium relative to the total LDH activity including the culture medium and cytosolic fraction. The LDH level was determined using the method described by a previous study[9].

Lipid peroxidation of hepatocytes

The MDA concentration of hepatocytes was assessed colorimetrically at 586 nm using a commercial kit (Calbiochem 437634; Calbiochem-Novabiochem, La Jolla, CA, USA). The concentration was expressed as nmol/mg protein in hepatocytes.

Glutathione (GSH) concentration of hepatocytes

The concentration of reduced GSH in hepatocytes was measured spectrophotometrically at 400 nm using a commercial kit (Calbiochem 354102; Calbiochem-Novabiochem). The concentration was expressed as nmol/mg protein in hepatocytes.

Glutathione peroxidase (GPX) activity of hepatocytes

GPX activity of hepatocytes was determined with a commercial kit (RS 504; Randox Laboratories, Antrim, UK). Twenty microliters of the diluted sample was added to 1 mL of mixed substrate (4 mmol/L GSH, 0.5 U/L GRD and 0.34 mmol/L NADPH dissolved in 50 mmol/L phosphate buffer, pH 7.2, 4.3 mmol/L EDTA). Forty microliters of cumene hydroperoxide (diluted in deionized water) was added to the mixture and GPX activity was measured at 37 ℃ on a Hitachi U-2000 Spectrophotometer at 340 nm for 3 min. The activity was expressed as mU/mg protein in hepatocytes.

Glutathione reductase (GRD) activity of hepatocytes

GRD activity of hepatocytes was measured with a commercial kit (Calbiochem 359962; Calbiochem-Novabiochem). Two hundred microliters of the diluted sample was added to 400 μL of 2.4 mmol/L GSSG buffer (dissolved in 125 mmol/L potassium phosphate buffer, pH 7.5, 2.5 mmol/L EDTA). Four hundred microliters of 0.55 mmol/L NADPH (dissolved in deionized water) was added to the mixture and GRD activity was measured at 340 nm for 5 min on a Hitachi U-2000 Spectrophotometer. The activity was expressed as mU/mg protein in hepatocytes.

Superoxide dismutase (SOD) activity of hepatocytes

SOD activity of hepatocytes was measured with a commercial kit (SD 125; Randox Laboratories). Fifty microliters of the diluted sample was added to 1.7 mL of mixed substrate (50 μmol/L xanthine and 25 μmol/L 2-(4-iodophenyl)-3-(4-nitrophenyl)-5-phenyl tetrazolium chloride, INT). Two hundred and fifty microliters of XO was added to the mixture and SOD activity was measured at 37 ℃ on a Hitachi U-2000 Spectrophotometer at 505 nm for 3 min. The activity was expressed as U/mg protein in hepatocytes.

Catalase (CAT) activity of hepatocytes

CAT activity of hepatocytes was determined at 25 ℃ with Hitachi U-2000 Spectrophotometer UV-VIS Spectrophotometer according to the previous study[10]. Diluted sample was added to 59 mmol/L H_2O_2 (dissolved in 50 mmol/L potassium phosphate buffer, pH 7.0) and CAT activity was measured at 240 nm for 3 min. One unit of CAT activity was defined as the mmol of H_2O_2 degraded/min/mg protein. The activity was expressed as U/mg protein in hepatocytes.

Total protein concentration

In order to express the antioxidant enzymes activities per gram of protein, total protein concentration of hepatocytes was determined colorimetrically by using a Bio-Rad DC protein assay kit (Cat. No. 500-0116; Bio-Rad Laboratories, Hercules, CA, USA).

Statistical analysis

Values were expressed as mean±SD. To evaluate the differences between the groups studied, two-way analysis of variance (ANOVA) with Fisher's *post hoc* test was used. The SAS software (Vers. 8.2, SAS Institute Inc., Cary, NC, USA) was used to analyze all the data. Differences were considered statistically significant when $P<0.05$.

RESULTS

Effect of ethanol on LDH leakage

LDH leakage into the culture media of hepatocyte was used to assess the hepatotoxicity of ethanol (Figure 1). LDH leakage in group E10 was nearly the same as that in group C at 12, 24, and 36 h. In contrast, LDH leakage in group E100 was significantly increased by about 30% more than that in groups C and E10 at 24 and 36 h ($P<0.05$). Furthermore, the LDH leakage showed dose-dependent correlation with the ethanol concentrations ($P = 0.0026$). However, there was no significant correlation between LDH leakage and incubation time of ethanol ($P>0.05$).

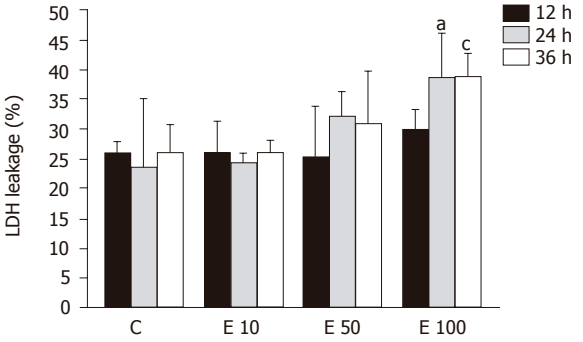

Figure 1 Lactate dehydrogenase (LDH) leakage of primary rat hepatocytes in each group. Data are mean±SD for 3 hepatocyte preparations. Cultures were incubated without ethanol (C), with 10 mmol/L ethanol (E 10), with 50 mmol/L ethanol (E 50), and with 100 mmol/L ethanol (E 100) for 12, 24, and 36 h, respectively. [a]*P*<0.05 *vs* 24 h of group C and E 10; [c]*P*<0.05 *vs* 36 h of groups C and E 10.

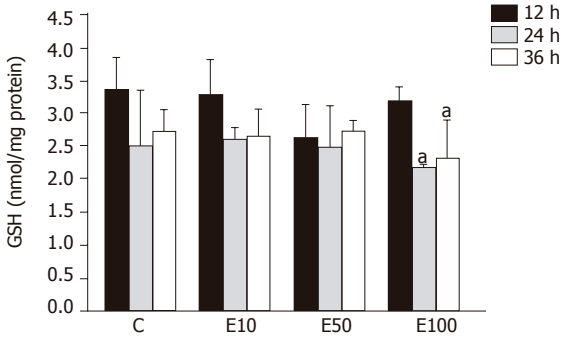

Figure 3 Glutathione (GSH) concentrations of primary rat hepatocytes in each group. Data are mean±SD for 3 hepatocyte preparations. Cultures were incubated without ethanol (C), with 10 mmol/L ethanol (E 10), with 50 mmol/L ethanol (E 50), and with 100 mmol/L ethanol (E 100) for 12, 24, and 36 h, respectively. [a]*P*<0.05 *vs* 12 h of group E 100.

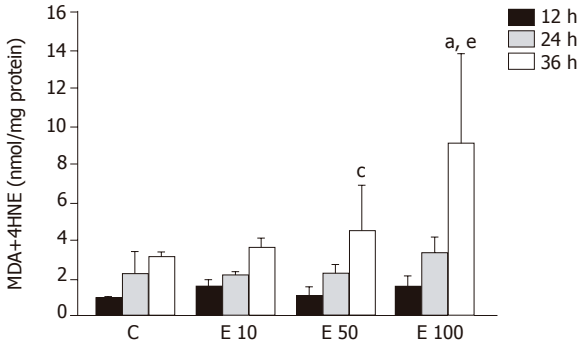

Figure 2 Lipid peroxidation of primary rat hepatocytes in each group. Lipid peroxidation was estimated by the measurement of MDA. Data are mean±SD for 3 hepatocyte preparations. Cultures were incubated without ethanol (C), with 10 mmol/L ethanol (E 10), with 50 mmol/L ethanol (E 50), and with 100 mmol/L ethanol (E 100) for 12, 24, and 36 h, respectively. [a]*P*<0.05 *vs* 36 h of groups C, E 10 and E 50; [c]*P*<0.05 *vs* 12 h of group E 50; [e]*P*<0.05 *vs* 12 h and 24 h of group E 100.

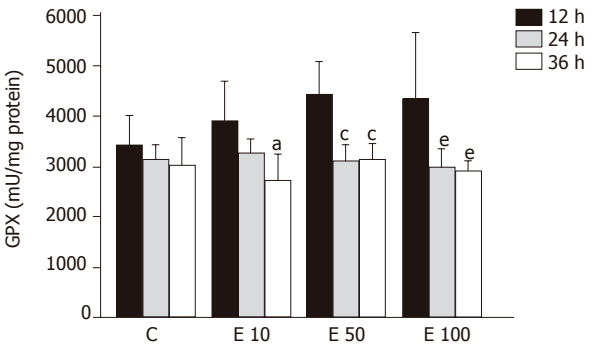

Figure 4 Glutathione peroxidase (GPX) activities of primary rat hepatocytes in each group. Data are mean±SD for 3 hepatocyte preparations. Cultures were incubated without ethanol (C), with 10 mmol/L ethanol (E 10), with 50 mmol/L ethanol (E 50), and with 100 mmol/L ethanol (E 100) for 12, 24, and 36 h, respectively. [a]*P*<0.05 *vs* 12 h of group E10; [c]*P*<0.05 *vs* 12 h of group E 50; [e]*P*<0.05 *vs* 12 h of group E 100.

Effect of ethanol on lipid peroxidation

The level of MDA in group E100 at 36 h was significantly increased by 1.9-, 1.5-, and 1.0-fold, respectively, over that in groups C, E10, and E50 ($P<0.05$, Figure 2). In group E50 and group E100, the lipid peroxidation product was significantly elevated at 36 h ($P<0.05$), by 2.9- and 4.5-fold, respectively, when compared to that at 12 h. In addition, there was no significant difference in group C and group E10. The level of MDA also showed significant correlation with the incubation concentration and time of ethanol ($P = 0.0105$ and $P = 0.0001$, respectively).

Effect of ethanol on antioxidant level

There was no significant difference across the groups at different times (Figure 3). However, in group E100, the GSH level was significantly decreased at 24 and 36 h, by 32% and 28%, respectively, over that at 12 h ($P<0.05$).

Effect of ethanol on antioxidant enzymes activities

There was no significant difference in GPX activity in each group at different times (Figure 4). However, in group E10, the GPX activity was significantly decreased at 36 h from that at 12 h ($P<0.05$). Furthermore, both in groups E50 and E100, GPX activities were significantly lowered at 24 and 36 h from those at 12 h ($P<0.05$). As a result, the activity of GPX was significantly correlated with the incubation time course ($P = 0.0004$).

After 36-h incubation, there were significantly fewer GRD activities in groups E50 and E100 than in groups C and E10 ($P<0.05$, Figure 5). However, both in group C and group E10 at 36 h, the activities of GRD were significantly increased over those at 12 and 24 h ($P<0.05$). On the other hand, the relation of GRD activity and the incubation time showed positive correlation ($P = 0.0002$).

There were no significant differences among the groups at different times in SOD activity (Figure 6). SOD activity of group E50 was significantly decreased at 36 h, by 45%, from that at 12 h ($P<0.05$). Furthermore, in group E100, the SOD activities were significantly decreased at 24 and 36 h, by 40% and 38%, respectively, from that at 12 h ($P<0.05$). In addition, the activity of SOD exhibited the reverse correlation with the incubation time ($P = 0.0018$).

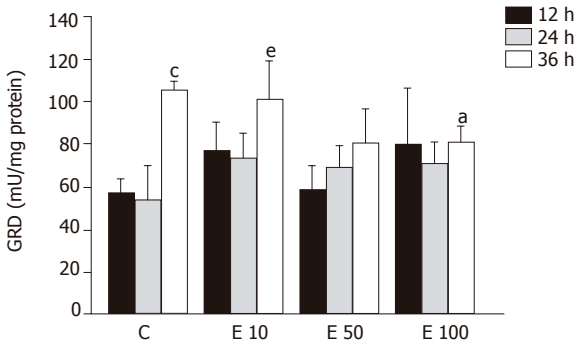

Figure 5 Glutathione reductase (GRD) activities of primary rat hepatocytes in each group. Data are mean±SD for 3 hepatocyte preparations. Cultures were incubated without ethanol (C), with 10 mmol/L ethanol (E 10), with 50 mmol/L ethanol (E 50), and with 100 mmol/L ethanol (E 100) for 12, 24, and 36 h, respectively. $^{a}P<0.05$ *vs* 36 h of groups C and E 10; $^{c}P<0.05$ *vs* 12 h and 24 h of groups C; $^{e}P<0.05$ *vs* 12 h and 24 h of group E 10.

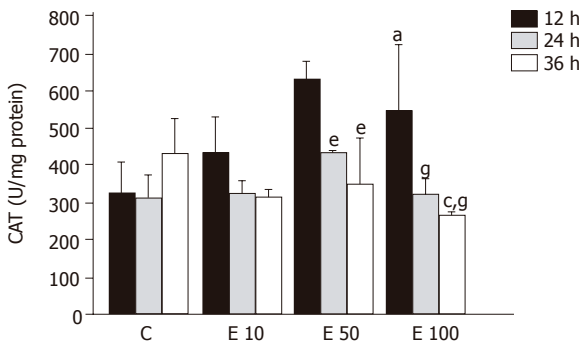

Figure 7 Catalase (CAT) activities of primary rat hepatocytes in each group. Data are mean±SD for 3 hepatocyte preparations. Cultures were incubated without ethanol (C), with 10 mmol/L ethanol (E 10), with 50 mmol/L ethanol (E 50), and with 100 mmol/L ethanol (E 100) for 12, 24, and 36 h, respectively. $^{a}P<0.05$ *vs* 12 h of groups C; $^{c}P<0.05$ *vs* 36 h of groups C and E 50; $^{e}P<0.05$ *vs* 12 h of group E 50; $^{g}P<0.05$ *vs* 12 h of group E 100.

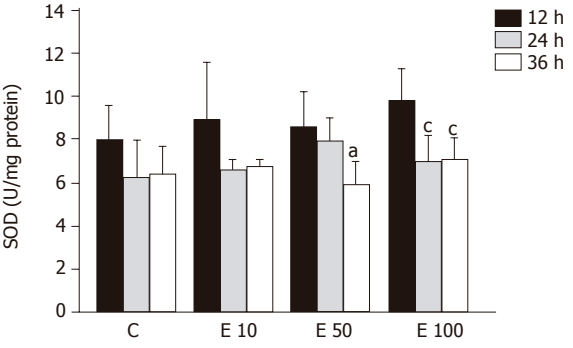

Figure 6 Superoxide dismutase (SOD) activities of primary rat hepatocytes in each group. Data are mean±SD for 3 hepatocyte preparations. Cultures were incubated without ethanol (C), with 10 mmol/L ethanol (E 10), with 50 mmol/L ethanol (E 50), and with 100 mmol/L ethanol (E 100) for 12, 24, and 36 h, respectively. $^{a}P<0.05$ *vs* 12 h of group E50; $^{c}P<0.05$ *vs* 12 h of group E 100.

After 12-h incubation, CAT activities in groups E50 and E100 were significantly increased, by 94% and 68%, respectively, over those in group C ($P<0.05$, Figure 7). On the contrary, CAT activity in group E100 at 36 h was significantly decreased from that in groups C and E50 ($P<0.05$). Moreover, both in groups E50 and E100, CAT activities were significantly lowered at 24 and 36 h from those at 12 h ($P<0.05$). There was a significant increase in correlation between CAT activity and incubation time ($P = 0.0003$).

DISCUSSION

LDH is an enzyme that exists in many tissues and organs, such as the heart, muscle, kidney, liver, etc. When those tissues or organs are damaged, LDH is released into the blood from the cells. Therefore, LDH leakage can be used to indicate cell viability. In this study, the viability of hepatocytes was monitored by the release of LDH into the medium. That is to say, higher LDH leakage was interpreted as lower viability of hepatocytes. The previous study has shown that ethanol increased the production of ROS and resulted in a decrease in hepatocyte viability[7]. Results in this study also suggest that high concentration of ethanol (100 mmol/L) may decrease cell viability of hepatocytes.

MDA was one of the main lipid peroxidation products, its elevated levels could reflect the degrees of lipid peroxidation induced injury in hepatocytes[11]. Many reports have demonstrated that ethanol exposure promotes the accumulation of lipid peroxidation *in vivo*[12] and *in vitro*[13]. Lipid peroxidation induced by ethanol administration results from not only increasing ROS production but also the mass generation of acetaldehyde[14]. Our data also indicated that the MDA concentration showed significant correlation with the incubation concentration and time of ethanol in isolated rat hepatocytes.

It has been reported that chronic ethanol feeding results in increased[15], decreased[16], or unchanged hepatic GSH contents[17] *in vivo*. The discrepancies in the total GSH levels in the livers of rats chronically fed with ethanol might have originated from the differences in the strains of rats used and the dose, duration, and route of ethanol administration among the different studies. On the other hand, the previous study has demonstrated that acute ethanol administration neither decreases nor increases the GSH level in hepatocytes, at least within 4 h after treating with 50 mmol/L ethanol *in vitro*[18]. Our results also showed that there was no significant difference in GSH content after 50 mmol/L ethanol treatment in hepatocytes. But the GSH concentration in hepatocytes significantly declined after 100 mmol/L ethanol treatment at 24 and 36 h. In this study, the reduction of GSH and the elevation of lipid peroxidation were simultaneously observed in the 100 mmol/L ethanol exposure. Thus, it could be speculated that ethanol-induced lipid peroxidation might contribute to decreased GSH contents in this study as previously shown by others[18].

Metabolism of ethanol is believed to result in the increased production of ROS, especially superoxide and

H_2O_2, and the removal of these toxic species is thought to be a vital initial step in ensuring cell survival during ethanol intoxication[6]. Four major antioxidant enzymes available to the cell during ethanol-induced oxidant stress include GPX, GRD, SOD, and CAT. The previous study has shown that GPX, CAT, and SOD activities showed an inverse correlation with the severity of pathological injury in rats fed with ethanol[12]. In contrast, Oh *et al.* reported that chronic ethanol feeding resulted in the lower activity of GPX with significantly higher activities of GRD and CAT[15]. However, there have been a few reports about the effects of ethanol on antioxidant enzymes activities in hepatocytes *in vitro*. Our data suggest that higher concentration of ethanol may reduce antioxidant enzymes activities of GRD and CAT after long-time incubation and contribute to decreased cell viability and increased lipid peroxidation.

In conclusion, this study indicates the direct relatedness between ethanol and hepatocytes and excludes the factor of gastrointestinal absorption. It was demonstrated that 100 mmol/L ethanol exposure diminished the cell viability because the lipid peroxidative product accumulated, which was caused by the decreased antioxidative status, including the reduction of GSH contents, GRD and CAT activities.

Abstract

AIM: To identify the bacterial flora in conditions such as Barrett's esophagus and reflux esophagitis to determine if they are similar to normal esophageal flora.

METHODS: Using broad-range 16S rDNA PCR, esophageal biopsies were examined from 24 patients [9 with normal esophageal mucosa, 12 with gastroesophageal reflux disease (GERD), and 3 with Barrett's esophagus]. Two separate broad-range PCR reactions were performed for each patient, and the resulting products were cloned. In one patient with Barrett's esophagus, 99 PCR clones were analyzed.

RESULTS: Two separate clones were recovered from each patient (total = 48), representing 24 different species, with 14 species homologous to known bacteria, 5 homologous to unidentified bacteria, and 5 were not homologous (<97% identity) to any known bacterial 16S rDNA sequences. Seventeen species were found in the reflux esophagitis patients, 5 in the Barrett's esophagus patients, and 10 in normal esophagus patients. Further analysis concentrating on a single biopsy from an individual with Barrett's esophagus revealed the presence of 21 distinct bacterial species. Members of four phyla were represented, including *Bacteroidetes, Firmicutes, Proteobacteria, and Actinobacteria.* Microscopic examination of each biopsy demonstrated bacteria in intimate association with the distal esophageal epithelium, suggesting that the presence of these bacteria is not transitory.

CONCLUSION: These findings provide evidence for a complex, residential bacterial population in esophageal reflux-related disorders. While much of this biota is present in the normal esophagus, more detailed comparisons may help identify potential disease associations.

Key words: Bacterial biota; Esophagus; 16S rDNA PCR

INTRODUCTION

Colonizing bacteria exist in each portion of the human digestive tract, from the oral cavity to the anus. Colonizing bacterial populations are essential for the development of the gastrointestinal mucosal immune system, for the maintenance of a normal physiological environment, and for the provision of essential nutrients[1,2]. Colonizing bacteria also play a role in a variety of disease conditions, as exemplified by the gastric colonizer *Helicobacter pylori* in relation to gastric cancer[3]. Conversely, loss of normal biota is responsible for the overgrowth of opportunistic pathogens that normally are inhibited, such as that occurs in antibiotic-associated colitis[4,5], or in candida vaginitis[6]. Microenvironment alterations may favor overgrowth of bacteria that produce carcinogenic metabolites[7-11], promoting tumorigenesis in inflammation-induced cancers, such as adenocarcinoma in experimental colitis mouse models[12].

A complex bacterial biota has been defined recently in the normal distal esophagus, estimated to be composed of approximately 140 species, of which 95 are identified[13].

Members of six phyla, *Firmicutes, Bacteroides, Actinobacteria, Proteobacteria, Fusobacteria,* and *TM7* are represented. *Firmicutes* represent the most commonly identified phylum in the distal esophagus, followed by phylum *Bacteroidetes*. Some of the phyla, including Spirochaetes and *Deferribacteres* that are commonly represented in the oral cavity, are not identified as esophageal flora, indicating that conditions in the distal esophagus are not ideal for the colonization of all oral flora. These are 14 species identified in the distal esophagus in all four persons studied[13], indicating that the esophageal biota are unique residents, and not identified simply as organisms transiting from the oral to the gastric cavity. Thus, although the esophagus is generally viewed as a conduit for food passage, the environment in which the bacteria reside is relatively stable.

The distal esophagus may be distinguished from other portions of the esophagus by the changes induced by the reflux of gastric and duodenal contents. Persistent untreated gastroesophageal reflux disease (GERD) can lead to a metaplastic and premalignant condition known as Barrett's esophagus, which carries an increased risk of esophageal adenocarcinoma. Repeated exposure of the distal esophagus to gastric acid and duodenal bile salts likely alters the biota present in the distal esophagus; as has been previously demonstrated in the stomach, changes in the microenvironment lead to alterations in colonizing bacterial populations[15]. One possibility is that perturbation of the normal esophageal biota could contribute to the progression from GERD to Barrett's esophagus towards the development of adenocarcinoma. Because little is known about the nature of bacterial biota in reflux esophagitis-related diseases, we sought to identify whether there exists a population of bacteria in patients with GERD and Barrett's esophagus. Our specific goal in this pilot study was to use broad-range 16S rDNA PCR to identify the presence of colonizing bacteria in patients with reflux esophagitis or Barrett's esophagus.

MATERIALS AND METHODS

Subjects

Patients presenting to the Department of Veterans Affair Medical Center, Nashville, TN, USA with gastrointestinal symptoms requiring upper gastrointestinal endoscopy were eligible for this study. Those who were willing to participate in the studies of upper gastrointestinal microbiology and who signed an informed consent form were recruited for this study[16]. Exclusion criteria included recent use of antibiotics, previous gastric/esophageal surgery, and active infection of the oral cavity[17]. Esophagogastroduodenoscopy was performed and endoscopic findings were recorded for 24 consecutive patients who met the above criteria. Esophageal biopsies were obtained 2 cm above the squamocolumnar junction or in the case of Barrett's esophagus, 2 cm above the gastroesophageal junction. Each biopsy was examined microscopically for morphological features of GERD and intestinal metaplasia (Barrett's esophagus). As described, features consistent with GERD included mucosal erosions/superficial ulcerations, epithelial hyperplasia, and inflammatory infiltrate of polymorphonuclear cells or eosinophils in the mucosal layer. Features of Barrett's esophagus included the presence of intestinal-type epithelium in the esophagus[18]. Tissue sections of esophageal biopsies from representative patients with normal esophagus, esophagitis, or Barrett's esophagus were examined by microscopy using Gram-Twort stain[19].

Specimen processing for molecular biological studies

Biopsies of 2 mm×2 mm×2 mm obtained for this study were placed in a 1.5-mL screw-top test tube and stored at -70 ℃. The specimens were coded so that the laboratorian performing the studies was blinded to the clinical information. DNA was extracted from the biopsy using a tissue DNA extraction kit (Qiagen) in a PCR-free clean-room and the DNA-enriched fractions were eluted in 200 microliters of buffer, as described by the manufacturer.

PCR

For each PCR amplification, 5 microliters of the DNA extracted from each biopsy was added to 45 μL of PCR reaction mixture containing 5 μL of 10× PCR buffer (Qiagen), 1.5 mmol/L $MgCl_2$, 200 μmol/L each dNTP, 50 pmol of each primer, and 5 units of Taq DNA polymerase. Reactions were run at 94 ℃ for 2 min, followed by 30 cycles of amplification at 94 ℃ for 30 s, 55 ℃ for 30 s, and 72 ℃ for 30 s and a 10-min extension at 72 ℃. Primers used were fPB7I (forward): 5' -GGIACTGAGACACIGICCIIACTCCT-3' and rPB10I (reverse): 5'-CGTATTACCGCIGCTGCTGGCAC-3', where I represents inosine, which was used at positions of nucleotide ambiguity, since it forms stable base pairs with A, G, T, and C. Use of inosine-containing primers significantly reduces the complexity accompanying the use of conventional degenerate primers[20-22]. As such, both inosine-containing primers perfectly match the consensus sequence-derived 16S rDNA pools composed of 21 evolutionarily-well diversified eubacterial groups including *Agrobacterium, Aquifex, Arthrobacter, Bacillus, Chlamydia, Chlorobium, Chloroflexus, Chloroplast, Clostridium, Desulfovibrio, Escherichia, Flavobacterium, Flexibacter, Gloeobacter, Heliobacterium, Leptonema, Planctomyces, Rhodocyclus, Synechococcus, Thermotoga,* and *Thermus*[23], but do not have significant 3' homology with human 18S rDNA, and human mitochondrial small subunit rDNA sequences. The expected PCR products are approximately 210 bp, depending on the species. In a study to determine the sensitivity, the above primer pair was able to amplify as little as one copy of an *Escherichia coli* genome (data not shown). An amplification control was designed to assess whether DNA extracted from the esophageal biopsy is of sufficient quality and quantity to be amplified by PCR. A primer pair specific for human 18S rDNA

was designed to serve this purpose: PBH (forward), 5' -TTGCCAAGAATGTTTTC-3' and rPBH (reverse), 5' -CGCGTAACTAGTTAGCA-3'.

Cloning and sequencing

The PCR products were separated from free PCR primers using a PCR purification kit (Qiagen), then ligated with the pGEM® T Easy (Promega) vector, and used to transform into *E coli* DH5α competent cells. The cloned inserts underwent sequence analysis using vector-based primers.

Phylogenetic analysis

Primer sequences were removed from all sequence files, and only inter-primer sequences were used in subsequent analyses. The sequences were analyzed using standard nucleotide BLAST (Blastn) search of GenBank for homology with known bacterial 16S rDNA sequences. In this study, 16S rDNA sequences with >97% identity with known sequences were considered as homologous with known bacterial species, as described[24]. 16S rDNA sequences were aligned using ClustalW[25] and phylograms of nucleotide alignments generated using Paup 4.0b10 (Paup 4.0b2. Phylogenetic Analysis Using Parsimony and Other Methods, Version 4, Sinauer Associates, Sunderland, MA, USA) neighbor-joining method based on HKY85 distance matrices[26]. All novel sequences were deposited in GenBank (accession numbers: AY212255-21225564).

RESULTS

Microscopic examination of bacterial flora in the distal esophagus

The 24 patients examined included 9 with normal esophagus, 12 with esophagitis, and 3 with Barrett's esophagus (Table 1). Because chronic gastritis is generally associated with the presence of overlaying *H pylori* in the lumen[27], we examined the inflamed distal esophagus to determine whether bacterial cells might be visible. Such a study, if positive, can provide morphological evidence for an indigenous esophageal biota, and provide a rationale for its further characterization. Of the 24 biopsies, 21 had sufficient tissue materials remaining for Gram-Twort stain, including 6 from patients with normal esophagus, 12 with esophagitis, and 3 with Barrett's esophagus. Bacteria were observed in 52% of the biopsies (from 4 of 6 with normal esophagus, 5 of 12 with esophagitis, and 2 of 3 with Barrett's esophagus). Bacteria appeared to be closely associated with the epithelial cell surfaces (Figure 1). All bacteria observed in the two biopsies with Barrett's esophagus were Gram-positive cocci, while in the 9 non-Barrett's biopsies, all were Gram-negative cocci or bacilli.

Bacterial 16S rDNA in esophageal biopsy specimens

To examine the nature of the bacterial populations present in the distal esophagus and to define their ancestry, we performed universal bacterial 16S PCR on biopsies

[1]None of the 24 patients had a history of recent use of antibiotics, previous gastric/esophageal surgery, active infection of the oral cavity[17].
[2]All 24 patients are males, reflecting the veterans population.
[3]NA, not available; Y, year; M, month.
[4]NP: no pathologic changes; BE: Barrett's esophagus; EO: eosinophils; CI: chronic inflammation; AI: acute inflammation.

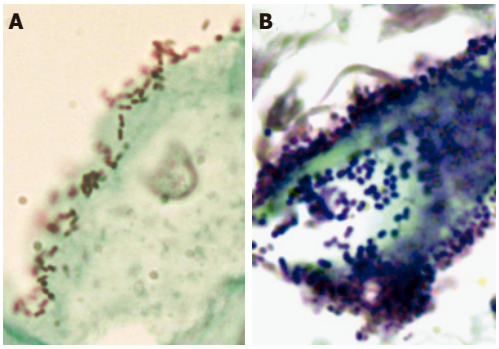

Figure 1 Microscopic examination of bacterial cells in the esophagus. Esophageal biopsies were fixed in formalin, paraffin-embedded, sectioned, and examined by using Gram-Twort stain. **A:** In the biopsy from patient #265 with a normal esophagus, Gram-negative cocci and coccobacilli were tightly associated with the surface of squamous epithelial cells. **B:** In the biopsy from patient #246 with Barrett's esophagus, Gram-positive cocci were highly concentrated within the lumen of an intestinal-type gland.

from each of the 24 studied patients. From each of the 24 biopsies, 2 clones of PCR products were randomly picked and sequenced. The 48 samples yielded 36 unique sequences belonging to 24 different species (97% identical), as established through GenBank BLAST searches. Of the 24 species identified, 14 represented known cultivation-defined bacterial species by sharing 97% identity, 5 shared 97% identity to 5 noncultured/unidentified bacterial species, and 5 did not share significant homology (<97% identity) with any existing bacterial 16S rDNA sequences in the GenBank (Table 2).

Of the 48 clones sampled, unidentified oral bacterium SH66 was the most prevalent species amplified, accounting for 22.9% (11 clones from 9 patients), followed by *Prevotella veroralis* (10.4%, 5 clones from 5 patients), members of the *Streptococcus genus* (10.4%, 5 clones from 5 patients), and *H pylori* (6.3%, 3 clones from 2 patients) (Table 2). None of the remaining species constituted more than 5% of

Colonization of the bacterial populations within a single esophageal biopsy

To characterize the bacterial populations within a single esophageal biopsy in the presence of esophageal disease, we further analyzed the biota from a patient with Barrett's esophagus (case 242; Table 3). From this biopsy, 99 clones were randomly picked and sequenced to allow a more in-depth analysis of the bacterial population in this biopsy. The 99 clones contained 36 unique 16S rDNA sequences comprising 21 species, including 10 homologous to cultivation-defined bacterial species, 5 homologous to unidentified/noncultured species, and 6 without significant homology (<97% identity) to any known 16S sequences at the species level (Table 4). Unidentified oral bacterium SH66 represented the most prevalent bacterial species (50.5% of the clones sequenced), followed by *Neisseria flavescens* (11.1%) and *Prevotella pallens* (6%).

Through combining the preliminary examination of the 24 patients, and the in-depth examination of a single patient with Barrett's esophagus, 147 sequences were obtained, belonging to 39 different species (Figure 2). Twenty-two of the sequences were homologous with cultivation-defined bacterial species, 7 with uncultivated species, and 10 were not homologous with any known bacterial species. The clones belonged to four phyla: *Bacteroidetes, Firmicutes, Proteobacteria,* and *Actinobacteria* (Figure 2).

DISCUSSION

Although 147 sequences from the biopsy specimens were analyzed, this study must be considered preliminary. Our strategy was to sample small populations of patients with reflux-related esophageal diseases to determine whether bacterial biota exist and ascertain any outstanding

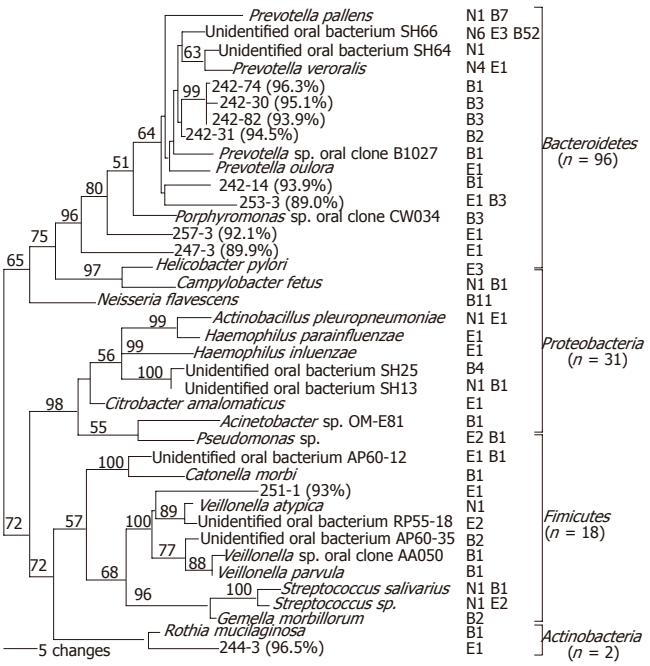

Figure 2 Phylogenetic analysis of bacterial 16S rDNA detected in the distal esophagus. Sequences were aligned using ClustalW, and subjected to phylogenetic analysis using Paup 4.0b10 neighbor-joining analysis, based on HKY85 distance matrices. Bootstrap values (based on 500 replicates) are represented at each node when >50%, and the branch length index is represented below the phylogram. Names of bacterial species closest in homology with the detected 16S rDNA are located at the termination of each branch. "Unidentified" oral bacterial clones are potential bacterial species whose phylogenetic positions were designated by PCR-amplified 16S sequences only, rather than based on cultured organisms. The serial number of a clone followed by percentage of homology with the closest DNA sequence in GenBank is used as the species name for 16S rDNA sequence with <97% identity with all known DNA sequences. The frequency that a species was detected and its sources are shown following the species name. 'N' represents normal esophagus, 'E' represents esophagitis, and 'B' represents Barrett's esophagus. The 39 species belong to four phyla, as shown at the right.

associations. The aim of these studies was thus hypothesis-generating, to establish parameters for more definitive studies. This approach was necessary because when this study was begun there was no prior information relating to bacterial populations in reflux-related disorders. We recognize the preliminary nature of this inquiry, but believe it can serve as a first approximation that can help guide future work.

Our findings suggest the existence of highly complex bacterial populations in the distal esophagus of patients with GERD-related disorders. Because many bacteria are fastidious, slow growing, or even uncultivable, simple culture methods often overlook a large number of bacteria, such as has been documented in the oral cavity and colon[14,28-30]. These drawbacks can be overcome by universal bacterial 16S rDNA PCR, since PCR does not discriminate bacteria based on their culture properties. However, PCR cannot distinguish living bacteria from naked bacterial genomes. In organs in which major digestive activities occur, such as the stomach and small intestine, bacteria brought downstream by peristaltic movement may be lysed and genomes released. Such DNA can be falsely interpreted by PCR as representing colonizing bacteria. Using microscopy in the present study, we observed a polymorphic population of bacteria in association with the epithelium of esophageal biopsies from patients with reflux-related diseases that included Gram-positive and Gram-negative bacilli, cocci, and coccobacilli. The variety of morphologically diversified esophageal bacteria is consistent with the highly diversified bacterial constituents identified using molecular techniques. The presence of intact bacteria closely associated with epithelial cells of the distal esophagus suggests that the 16S rDNA detected was from viable bacteria rather than from bacterial DNA only.

Because only a few PCR clones were sampled from each biopsy specimen, this study is not a quantitative comparison of the bacteria found in GERD-related disorders with those from normal esophagus or oral cavity[13,14,28-30], as the species identified may reflect chance rather than prevalence. However, the majority of bacterial species found in GERD-related disorders are shared with the previously identified bacteria in the normal esophagus[13], suggesting that certain bacterial species in the normal esophagus are resistant to the substantial environmental changes due to reflux. Finding *H pylori* 16S rDNA in the esophagus of two patients with GERD indicates that gastric bacteria can be brought into the distal esophagus by reflux, consistent with the previous detection of *H pylori* in Barrett's esophagus[31,32]. These observations suggest that the detected organisms (or DNA) may be transiently present, rather than persistent in the distal esophagus. Longitudinal studies of individual patients would help to address this question. Conversely, the microenvironment in the distal esophagus likely does not include all oral bacteria. Similar to our previous study of the normal esophageal biota[13], the most prevalent of the nine phyla identified in the subgingival crevice[14,28], *Spirochaetes*, was not found in the esophagus, consistent with the presence of endogenous bacterial populations unique to the distal esophagus.

In-depth study of a Barrett's esophagus case (Biopsy 242) revealed a single predominant species (unidentified oral bacterium SH66), representing 50.5% of the 99 clones sampled. SH66 was found in patients with or without the disease of the distal esophagus; whether there is overgrowth in Barrett's esophagus cannot be addressed without quantitative comparisons. SH66 was originally identified in the saliva by its 16S sequence, but never has been cultured[33]. Phylogenetic analysis indicates that SH66 resembles several members of the genus *Provotella* and belongs in the phylum *Bacteriodetes* (Figure 2).

Identifying complex bacterial populations in GERD-related disorders offers a new approach to understand bacterial roles as markers or as pathogenic factors in esophageal diseases. Bacterial populations in other portions of the digestive system, such as the oral cavity and colon, play important roles in the maintenance of local physiology as well as in disease pathogenesis[1-5,6-10,11-13]. The composition, transience, or stability of this complex bacterial biota in the distal esophagus and associations

with the disease remain to be determined. The results from this study justify large-scale comparisons of bacterial biota between normal and pathological conditions in the distal esophagus.

ACKNOWLEDGMENTS

We thank Dr. Kyi T. Tham for processing the specimens for histological examination and Mr. Joseph Szmulewicz for performing Gram-Twort stains.

Abstract

AIM: To demonstrate the ^{18}F-fluorodeoxyglucose positron emission tomography (^{18}F-FDG PET) findings in patients with non-Hodgkin's lymphoma (NHL) involving the gastrointestinal (GI) tract and the clinical utility of modality despite of the known normal uptake of FDG in the GI tract.

METHODS: Thirty-three patients with biopsy-proven gastrointestinal NHL who had undergone FDG-PET scan were included. All the patients were injected with 10-15 mCi FDG and scanned approximately 60 min later with a CTI/Siemens HR (+) PET scanner. PET scans were reviewed and the maximum standard uptake value (SUV_{max}) of the lesions was measured before and after the treatment, if data were available and compared with histologic diagnoses.

RESULTS: Twenty-five patients had a high-grade lymphoma and eight had a low-grade lymphoma. The stomach was the most common site of the involvement (20 patients). In high-grade lymphoma, PET showed focal nodular or diffuse hypermetabolic activity. The average SUV_{max}±SD was 11.58±5.83. After the therapy, the patients whose biopsies showed no evidence of lymphoma had a lower uptake without focal lesions. The SUV_{max}±SD decreased from 11.58±5.83 to 2.21±0.78. In patients whose post-treatment biopsies showed lymphoma, the SUV_{max}±SD was 9.42±6.27. Low-grade follicular lymphomas of the colon and stomach showed diffuse hypermetabolic activity in the bowel wall (SUV_{max} 8.2 and 10.3, respectively). The SUV_{max} was 2.02-3.8 (mean 3.02) in the stomach lesions of patients with MALT lymphoma.

CONCLUSION: ^{18}F-FDG PET contributes to the diagnosis of high-grade gastrointestinal non-Hodgkin's lymphoma, even when there is the normal background FDG activity. Furthermore, the SUV plays a role in evaluating treatment response. Low-grade NHL demonstrates FDG uptake but at a lesser intensity than seen in high-grade NHL.

INTRODUCTION

Non-Hodgkin's lymphoma (NHL) is known to arise from extranodal sites in 10-30% of cases[1,2]. Among the extranodal sites, the gastrointestinal tract is most frequently affected by NHL. It can involve the gastrointestinal tract partly or entirely[3]. Generally, the diagnosis of lymphomatous involvement of the gastrointestinal tract is based on clinical symptoms and imaging studies, such as double-contrast barium study, computed tomography (CT) and is confirmed by endoscopy with biopsy. CT has been widely used as the imaging modality for staging and restaging of lymphoma[4]. However, in evaluating lymphomatous involvement of the gastrointestinal tract, CT has some limitations. Examples are non-specific imaging patterns and findings that may be difficult to interpret such as wall thickening in a non-distended stomach or unopacified small bowel loops[5-7]. Gallium-67 citrate scintigraphy also plays an important role in patients with NHL for the detection of lesions, initial staging and assessment of therapeutic responses[8,9]. Gallium-67 citrate scintigraphy is known to be more sensitive for the detection of lesions in thoracic locations, but it is much less sensitive in the identification of infradiaphragmatic sites owing to physiologic hepatic and splenic uptake and excretion into the bowel[10]. Since Paul[11] first reported ^{18}F-FDG PET imaging in lymphoma, this modality has been increasingly used to examine patients with lymphomas. Many published articles have shown that ^{18}F-FDG PET is more sensitive in detect-

ing disease sites than gallium-67 scintigraphy. ^{18}F-FDG PET is at least as sensitive as CT, but more specific than CT, especially in patients undergoing restaging[12-15]. In addition, many studies have demonstrated that persistent FDG uptake after therapy may predict treatment failure or a high recurrence rate[16,17]. Most reported studies have assessed primarily patients with nodal NHL. A few studies have used ^{18}F-FDG PET to assess NHL in the gastrointestinal tract[18-21]. Rodriguez *et al.*[18] demonstrated that ^{18}F-FDG PET may have a novel application in the evaluation of gastric NHL and may complement endoscopy and CT in selected patients. However, in a study by Hoffmann *et al.*[19] in patients with mucosa-associated lymphoid tissue (MALT)-type lymphoma, no focal tracer uptake was demonstrated with ^{18}F-FDG PET in either gastric or extragastric lesions. In addition, there is concern that normal FDG accumulation in the gastrointestinal tract or abnormal uptake in patients with inflammatory bowel disease could cause confusion in the interpretation of ^{18}F-FDG PET images in patients with lymphoma[22-25]. Thus the clinical utility of ^{18}F-FDG PET imaging in the evaluation of lymphomatous involvement of the gastrointestinal tract has not been clearly established. This study aimed to demonstrate the ^{18}F-FDG PET findings in patients with NHL (high-grade *vs* low-grade) involving the gastrointestinal tract and the clinical utility of this modality through the normal uptake of FDG in the gastrointestinal tract was known.

MATERIALS AND METHODS

In this study, the electronic database of 907 consecutive patients with lymphoma who underwent PET imaging from October 2000 to June 2002 was retrospectively reviewed. Thirty-three patients with biopsy-proven NHL involving the gastrointestinal tract who underwent a ^{18}F-FDG PET scan were included in this study. There were 24 men and 9 women aged 34-80 years (mean 58 years). For scanning, all patients were injected with 10-15 mCi FDG and scanned approximately 60 min later with a CTI/Siemens HR (+) PET scanner (Siemens, Knoxville, TN, USA). Each scan was performed from the head to the pelvic floor with the total time of about 60 min for image acquisition. The acquired data were reconstructed using standard vendor-provided iterative reconstruction with segmented attenuation correction. Additional transmission scanning for attenuation correction was performed.

The PET scans obtained were reviewed by an experienced nuclear physician and a radiologist who together provided the consensus reading. Reviewing was done without patient's clinical data and the status of lymphoma. The SUV_{max} of the lesions was measured before and after the treatment in case the data were available. The SUV_{max} was measured in at least two orthogonal planes to demonstrate the best lesion appreciation. The CT scan obtained on the corresponding data was used as the guideline for demarcating those lesions when their boundaries were difficult to define. The highest SUV_{max} was used for each lesion. The ^{18}F-FDG PET results and the SUV measurements at each time point were compared with the histologic data from the corresponding data. The SUV_{max} was compared before and after the treatment using Student's *t*-test. $P<0.05$ was considered statistically significant.

Table 1 Sites of gastrointestinal involvement of NHL in 33 patients

Sites of GI involvement	Number of patients (%)
Stomach	21 (64)
Colon and rectum	12 (36)
Terminal ileum and cecum	9 (27)
Duodenum	8 (24)
Small bowel	6 (18)
Esophagus	2 (6)

RESULTS

Of the 33 patients with NHL involving the gastrointestinal tract, 25 had a high-grade lymphoma and 8 had a low-grade lymphoma as determined using the revised European-American classification of lymphoid neoplasm (REAL classification). The histologic subtypes included diffuse large cell lymphoma (n = 16), mantle cell lymphoma (n = 6), MALT-type lymphoma (n = 5), peripheral T-cell lymphoma (n = 3), follicular lymphoma (n = 2) and B-cell small lymphocytic lymphoma (n = 1). The stomach was the most common site of the involvement, followed (in order of decreasing prevalence) by the colon and rectum, cecum and terminal ileum, duodenum, small bowel, and esophagus (Table 1).

In high-grade NHL, ^{18}F-FDG PET showed focal nodular or diffuse hypermetabolic activity, which involved mainly the wall of the gastrointestinal tract. This activity's appearance was different from that of the normal activity in the bowel wall, which was less intense and uniform. Fifteen patients received ^{18}F-FDG PET for staging before the treatment. In these patients, ^{18}F-FDG PET identified 30 (100%) of 30 intestinal locations that had biopsy-proven lymphomatous involvement. These locations were the esophagus (n = 2), stomach (n = 11), duodenum (n = 5), small bowel (n = 6), cecum/terminal ileum (n = 3), and colon (n = 3). The SUV_{max} ranged from 3.64 to 25.10 (11.22±5.79). The SUV_{max}±SD in non-involved intestine was 3.09±2.34. After the therapy, uptake was absent or reduced without focal lesions in 14 patients who had complete responses and whose biopsies showed benign inflammation without evidence of lymphoma (Figure 1). The post- treatment SUV_{max} values were significantly lower ($P<0.05$), ranging from 0.89 to 4.30 (2.21±0.78). In three patients, the post-treatment biopsies still showed lymphoma (Figure 2) and the post-treatment SUV_{max} ranged from 3.44 to 21.90 (9.42 ±6.27).

In low-grade NHL, ^{18}F-FDG PET showed diffuse hypermetabolic activity in the bowel wall in two patients with follicular lymphoma of the colon and stomach (SUV_{max} 8.20 and 10.30, respectively). In one patient with follicular lymphoma of the stomach, the SUV_{max} after 5 wk of therapy decreased from 10.30 to 2.40. In four patients with

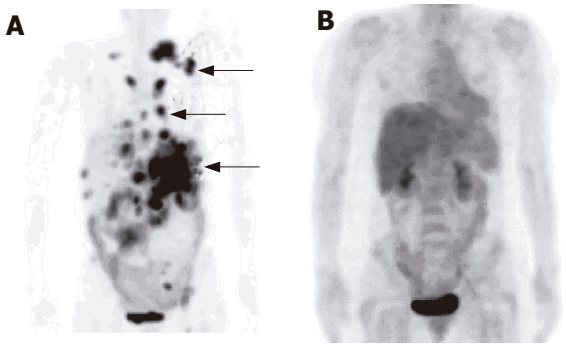

Figure 1 A 61-year-old woman with large cell lymphoma. **A:** Pre-treatment ^{18}F-FDG PET scan revealed multifocal hypermetabolic activity involving the neck, chest, and abdomen (arrow). The highest SUV_{max} was 20.3 in the left upper abdominal area, corresponding to a positive result of a gastric biopsy; **B:** Follow-up ^{18}F-FDG PET scan 5 mo later showed no evidence of residual FDG disease.

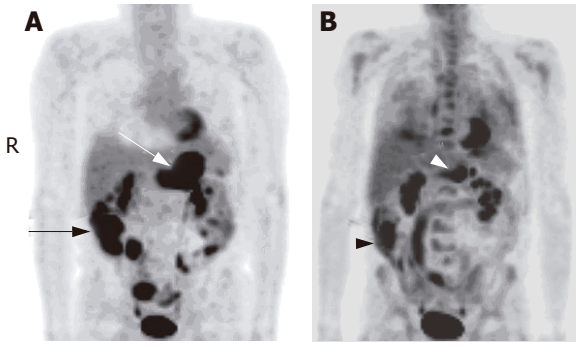

Figure 2 A 68-year-old man with large cell lymphoma. **A:** Base line ^{18}F-FDG PET scan showed hypermetabolic foci in the stomach (white arrow), cecum and terminal ileum (black arrow), and bowel loops (SUV_{max} = 12.7); **B:** ^{18}F-FDG PET scan obtained after therapy showed partial metabolic response of the activity in the stomach (white arrowhead) and cecum (black arrowhead, SUV_{max} = 10.7).

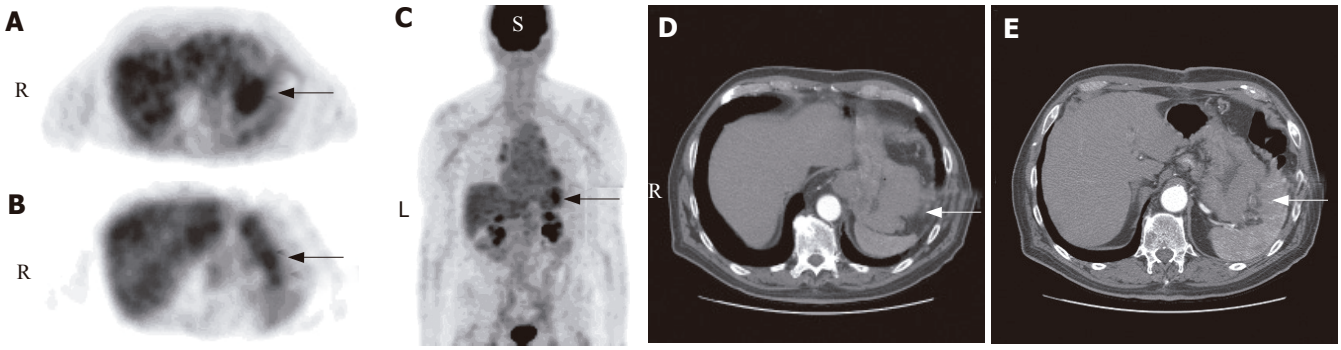

Figure 3 An 80-year-old man with MALT-type lymphoma. **A-C:** ^{18}F-FDG PET scans in transaxial and projection images showed a focal mild hypermetabolic activity (SUV_{max} = 3.8) in the region of stomach (black arrow); **D** and **E:** CT scans showed a bulky mass in the wall of gastric fundus and body (white arrow).

MALT-type lymphoma (Figure 3), lesions in the stomach and duodenum showed diffuse and low metabolic activity similar to that in the liver, and the SUV_{max} was 2.02-3.8 (average 3.02) at the time of the positive biopsy results. In another patient with MALT-type lymphoma involving the colon, the SUV_{max} was 6.82. However, follow-up biopsy in this patient showed high-grade transformation. The mean SUV_{max} in high-grade and low-grade NHL before and after the treatment is shown in Table 2. Negative post-treatment biopsy results corresponded to significantly decreased SUV_{max} in high-grade NHL (P<0.05). However, the SUV_{max} before and after the treatment was not significantly lower in low-grade NHL.

Table 2 SUV_{max} in high- and low-grade NHL before and after treatment (mean±SD)

NHL grade	SUV_{max} before treatment	SUV_{max} after treatment	
		Biopsy positive	Biopsy negative
High grade	11.22±5.79 (n = 15)	9.42±6.27 (n = 14)	2.21±0.78[a,c] (n = 3)
Low grade	8.57±2.47 (n = 2)	3.76±2.08 (n = 5)	3.03±0.89 (n = 2)

n, number of patients.
[a]P<0.05 *vs* SUV_{max} in high grade NHL before treatment; [c]P<0.05 *vs* SUV_{max} with biopsy positive after treatment.

DISCUSSION

The gastrointestinal tract is the most common extranodal site of NHL[1,3]. The stomach is most frequently involved (60-74% of cases), followed by the duodenum and small bowel (10-20%), ileocecal region (7-10%) and large bowel (<10%)[26,27]. Our results are consistent with these reports, except that the large bowel was involved in a greater percentage of patients in our study than the previous studies. Lymphomatous involvement of the gastrointestinal tract may be primary or secondary. The gastrointestinal tract is involved at autopsy in as many as 50% of patients with secondary lymphoma. However, most of these patients have subclinical disease while patients who have gastrointestinal symptoms are found to have primary gastrointestinal lymphoma[6,28].

Diagnostic imaging studies play an important role in documenting lymphoma, staging and re-staging the disease, evaluating treatment response and performing follow-up evaluations. Anatomical imaging modalities including computed tomography (CT) and magnetic resonance (MR) imaging have some limitations, especially when defining the viability of the residual mass, treatment

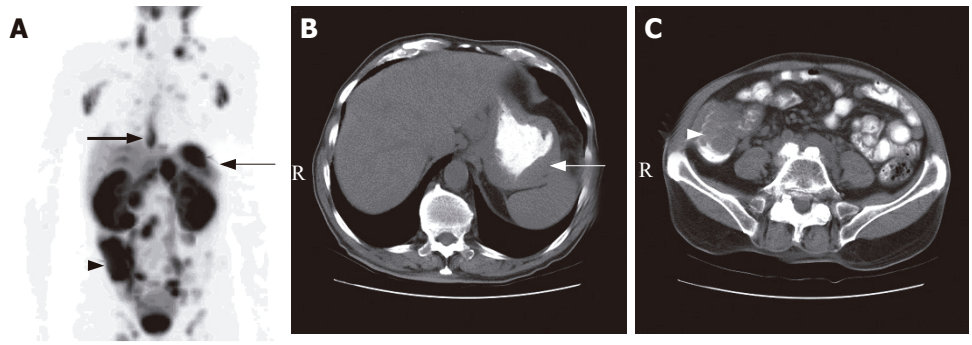

Figure 4 A 78-year-old man with mantle cell lymphoma. **A:** ^{18}F-FDG PET scan revealed multiple hypermetabolic foci involving the lower esophagus (thick arrow), gastric fundus (thin arrow), cecum and terminal ileum (arrow head); **B** and **C:** The corresponding CT scans of the abdomen showed wall thickening at the gastric fundus (white arrow) and the cecum and terminal ileum (white arrow head)

response or both[4,29]. Gallium-67 scintigraphy has been proposed as a functional imaging modality to assess remission and to evaluate the nature of residual masses in patients with lymphoma. However, gallium-67 scintigraphy is of little use in the abdomen because of the high hepatic uptake and excretion into the bowel and should be performed before treatment to determine whether the patient has a gallium-fixing tumor and whether the absence of fixation after treatment corresponds to a residual mass[8,9,30]. ^{18}F-FDG PET imaging has shown its clinical usefulness in patients with lymphoma. Several articles have reported that ^{18}F-FDG PET has a higher sensitivity in detecting disease sites than gallium-67 scintigraphy[11-13]. ^{18}F-FDG PET can also be used to assess the response after the therapy[16,17,31]. However, a limited number of studies have shown the utility of ^{18}F-FDG PET imaging for the evaluation of lymphomatous involvement of the gastrointestinal tract[18-21,32,33].

In our study, ^{18}F-FDG PET showed fixed focal nodular or diffuse hypermetabolic activity of all lesions in patients with high-grade non-Hodgkin's lymphoma, which was confirmed by histopathologic analysis. The appearance of focal intense hypermetabolic activity of the lesions was different from that of the normal activity in the bowel wall. Rodriguez *et al.*[4,18] evaluated CT, MRI, and PET in eight patients with primary gastric lymphoma and showed that ^{18}F-FDG PET can demonstrate both the presence and the extent of gastric NHL and is more accurate than endoscopy and CT for evaluating the extent of NHL in the gastric wall. In our study, ^{18}F-FDG PET clearly demonstrated the involvement of specific sites, particularly in the stomach (e.g. the fundus, body, antrum, lesser and greater curvature of the stomach), corresponding to endoscopic biopsy sites. However, extension outside the bowel wall was better appreciated when interpreted with the guidance of a CT scan. It should be noted that an evaluation of the extent of NHL in the gastric wall and careful assessment of multiplicities affect the selection of therapy, since radical surgery with lymph node dissection seems to be needed for most patients with high-grade and even low-grade NHL[34].

Ullerich *et al.*[20] and Sam *et al.*[21] showed that ^{18}F-FDG PET could find lesions in patients with small bowel lymphoma. Najjar *et al.*[32] also reported that ^{18}F-FDG PET could identify lymphoma of the colon. These results are consistent with the results in our study, in which pre-treatment ^{18}F-FDG PET showed pertinently high metabolic activity in the small bowel and colon in patients with high-grade NHL (Figure 4). It is difficult to differentiate high-grade non-Hodgkin's lymphoma from other neoplastic or inflammatory diseases. However, interpreting the results in the light of a careful clinical history, the extent of the disease and corresponding CT images, can contribute to the correct diagnosis. Moog *et al.*[33] showed that ^{18}F-FDG PET imaging could achieve 100% correct diagnoses of malignant lymphoma. In almost all cases of high-grade NHL in our study, CT scans also demonstrated the abnormal wall thickening or mass lesions. However, the results did not reveal the sensitivity of ^{18}F-FDG PET *vs* that of CT, because both modalities were interpreted together as complementary studies.

^{18}F-FDG PET can demonstrate diffuse hypermetabolic activity in patients with low-grade follicular NHL in the colon and stomach. The ability of gallium-67 scintigraphy and ^{18}F-FDG PET to detect MALT-type lymphoma of the gastrointestinal tract is controversial. Hsu *et al.*[35] showed that gallium-67 scintigraphy could not show abnormal uptake of radioactivity in patients with low-grade gastric MALT-type lymphoma. Hoffmann *et al.*[19] studied ^{18}F-FDG PET imaging in patients with MALT-type lymphoma and found that PET scans do not show focal tracer uptake in either gastric or extragastric lesions. Our study showed similar results of low activity in the stomach and duodenum. Even though it has been reported that CT scans may demonstrate gastric MALT-type lymphoma either as an infiltrative form or as a polypoid pattern[36,37], CT is limited in its ability to monitor the treatment response. Taken together, ^{18}F-FDG PET imaging in low-grade NHL seems to be able to monitor the treatment response and determine high-grade transformation.

Generally, in patients with NHL, histologic grade and disease stage are clearly identified as the two major prognostic factors and therapeutic determinants. Endoscopy with biopsy and histopathologic examination

are the gold standard for grading malignancies[38]. However, there have been attempts to differentiate high-grade from low-grade NHL by different methods (e.g. double-contrast radiography, CT scan and gallium-67 scintigraphy)[35,39]. ^{18}F-FDG PET imaging in our study showed that high-grade NHL of the gastrointestinal tract had high FDG activity in the lesions as was confirmed by high SUV measurements. Though the normal background FDG activity in the gastrointestinal tract was known, abnormalities were identified in this study. In low-grade NHL of the gastrointestinal tract, it was difficult to document existing disease, especially in patients with MALT-type lymphoma. However, there was a significant difference in the SUV_{max} measurement between high-grade and low-grade NHL.

This study also demonstrated the clinical utility of ^{18}F-FDG PET imaging for monitoring patients with NHL of the gastrointestinal tract especially those with high-grade lymphoma. The SUV_{max} measurements were significantly decreased after therapy and post-treatment biopsies were negative for lymphoma. In addition, benign inflammatory conditions such as gastritis showed significantly lower FDG activity. In patients whose post-treatment biopsies were positive for lymphoma, the SUV_{max} measurements were persistently high and even higher in patients with disease progression. Many studies have demonstrated that persistent FDG uptake after therapy may help to predict treatment failure or a high risk of recurrence[16,17].

In conclusion, ^{18}F-FDG PET contributes to the diagnosis of high-grade lymphoma involving the gastrointestinal tract, even when there is the normal background FDG activity. Furthermore, the SUV plays a role in evaluating treatment response especially when the PET images are interpreted with CT scans. Low-grade lymphoma demonstrates FDG uptake, but the intensity of the uptake is lower than that in high-grade lymphoma.

Abstract

AIM: To examine an increased risk of esophageal adenocarcinoma is restricted to patients who develop Barrett's esophagus or whether esophagitis *per se* is a risk factor for adenocarcinoma.

METHODS: A population-based cohort of patients with histological evidence of esophagitis without Barrett's esophagus was constructed using electronic pathology reports relating to all esophageal biopsies in Northern Ireland between 1993 and 1996. Person-years of follow-up and incident cases of esophageal cancer were calculated by linking the cohort to death files and the Northern Ireland Cancer Registry records. Standardized incidence ratios (SIR) were calculated for esophageal cancers (adenocarcinoma, squamous cell carcinoma (SCC), and histologically unspecified cancers).

RESULTS: A total of 2 013 patients in the cohort provided 13 559 patient-years of follow-up (mean follow-up 6.7 years). None of the patients developed adenocarcinoma. Three patients developed SCC, and six developed histologically unspecified cancers. The SIR for all esophageal cancers and for SCC were 2.73 (95%CI 1.25-5.19) and 2.93 (95%CI 0.61-8.59), respectively. In a sensitivity analysis in which all unspecified esophageal cancers were treated as adenocarcinomas, the SIR for adenocarcinoma was 2.64 (0.97-5.75).

CONCLUSION: The risk of adenocarcinoma is not elevated in patients with histological evidence of esophagitis without Barrett's esophagus; however, these patients may have a moderately increased risk of SCC. Further studies are required to confirm these findings, which suggest that Barrett's esophagus, not esophagitis, is the key precursor lesion in the development of adenocarcinoma.

Key words: Barrett's esophagus; Esophageal adenocarcinoma; Esophageal squamous cell carcinoma; Esophagitis; Population-based study

INTRODUCTION

The incidence of esophageal adenocarcinoma (OAC) is increasing at a rate faster than any other cancer in the Western world[1]. The most important risk factor for its development is Barrett's esophagus (BO), a metaplastic condition in which the native squamous epithelium of the esophagus is replaced by columnar epithelium, in response to chronic gastro-esophageal reflux[2]. OAC appears to result from a sequence of changes from esophagitis to non-dysplastic BO, to dysplastic BO, and finally to adenocarcinoma[3,4]. It is generally accepted that most, if not allpatients who develop OAC, pass through this sequence. It is on this basis that endoscopic surveillance of BO is recommended, in an attempt to reduce mortality from OAC[5]. However, some aspects of the relationship between BO and OAC remain unclear. While BO is the only known precursor to this tumor, there is a huge variation in the proportion of cases of OAC in which it is detectable, ranging from 23% to 100% of cases in different studies[6-12]. The difficulty in

identifying BO in patients with OAC is thought to result from tumor overgrowth of the Barrett's segment. However, in a large prospective case-control study in Sweden, Lagergren *et al.*[13] found that in patients with OAC, only 62% had evidence of BO identified by biopsy, despite extensive sampling by a rigorous protocol. They also found that symptoms of gastro-esophageal reflux *per se* were strongly associated with adenocarcinoma, and that the presence or absence of BO in cancer cases had no effect on the strength of this association. These findings have led to the speculation that gastro-esophageal reflux, rather than BO, is the crucial factor in the development of OAC. If that is the case, then esophagitis may be an important risk factor for its development. To our knowledge, there are no studies assessing the risk of OAC in patients with biopsy-proven esophagitis. We undertook a study to examine the incidence of OAC in a population-based cohort of patients who had histological evidence of esophagitis without BO.

MATERIALS AND METHODS

Patients and biopsies

This study is a follow-up study of a population-based cohort of patients with esophagitis. The cohort comprised every adult within Northern Ireland (NI), population 1.7 million, with histological evidence of inflammation of the esophagus that was not due to infection or radiation. The cohort was constructed by examining pathological reports relating to all esophageal biopsies undertaken within all the hospitals in NI between January 1993 and December 1996. Data were available for biopsies taken between 1993 and 1999, but only the first 4 years were used in order to maximize the period of follow-up. These reports were made available to the NI Cancer Registry (NICR) in an electronic format during the construction of the NI Barrett's Register[14]. The reports contained information on the nature and site of the submitted biopsy specimen, the clinical summary recorded by the endoscopist on the request form, the full text of the pathologist's report on the specimen, and the pathologist's diagnosis. The clinical summaries contained information relating to the site at which the biopsies were taken. All pathological reports in which the summary stated that the biopsies were taken from the esophagus, including the esophago-gastric junction (OGJ), were examined. A list of SNOMED (Systematized nomenclature of medicine)[15] codes indicating inflammation in the esophagus was compiled and biopsies were included in the study, if any of these codes appeared on the biopsy report (Table 1). The report which included more than one diagnostic code was considered if at least one of the codes indicated inflammation .

Exclusion criteria for biopsy reports

Biopsy reports were excluded, if patients were less than 16 years of age, or if the diagnostic codes included malignancy, fungal or viral infection, or radiation injury. The bodies of the reports were then examined and any reports in which the pathologist recorded the presence of columnar epithelium were excluded.

Table 1 SNOMED diagnostic codes used in study

Code	Diagnostic term	Number of patients
M40000	Inflammation	777
MZ0005	Non-specific inflammation	9
M40005	Active inflammation	88
M41000	Acute inflammation	31
M42100	Active chronic inflammation	62
M43000	Chronic inflammation	279
M76820	Inflammatory polyp	2
M36500	Edema	2
M36100	Congestion	52
M45020	Granulation tissue	11
M14110	Erosion	6
M38000	Ulcer/ulceration	570
MY0102	Reflux esophagitis	125

Identification and classification of individual patients

A substantial number of patients in the cohort had esophageal biopsies taken on more than one occasion. Individual patients were identified within the dataset by matching on surname, forename(s), and date of birth (and hospital numbers when they were available). The date of the earliest biopsy showing the inflammation was taken as the date of entry into the cohort.

Further exclusion criteria for patients with columnar epithelium

Some patients had an esophageal biopsy that contained columnar epithelium prior to their first biopsy showing inflammation (NB data only available from January 1993). These patients were excluded from the cohort. Other patients had an esophageal biopsy subsequent to their first biopsy showing inflammation that showed columnar epithelium. These patients were not excluded, unless the biopsy showing columnar epithelium occurred within 3 mo of the initial biopsy. These steps were taken to exclude prevalent cases of BO but to include incident cases in the cohort, the rationale being that if esophagitis leads to malignancy through the development of BO, excluding incident BO would potentially miss these patients.

Follow-up of patients

Members of the cohort were followed up for deaths and incident esophageal cancer OAC, squamous cell carcinoma (SCC), and histologically unspecified cancers and lung cancer till the end of December 2002. Lung cancer incidence within the cohort was determined as a proxy for smoking exposure. Deaths among the cohort were identified by matching with the death files from the Registrar General's Office (NI) using the patient's surname, forename(s), and date of birth. These files contained information on all the deaths that occurred within NI.

Incident cases of esophageal cancer with a date of diagnosis at least 6 mo after the date of entry into the cohort were identified by matching the cohort with the NICR database (using the patient's surname, forename(s), date of birth, and hospital numbers where available). This

population-based cancer registry had collected data on all cancers occurring in NI residents, since the beginning of 1993. When assessing lung cancer incidence, a threshold of 3 mo after the date of entry into the cohort was used.

Statistical methods

Person-years of follow-up were calculated for each member of the cohort with censoring either on the date of diagnosis of the esophageal or lung cancer, on the date of death, or on 31st December 2002. Incidences of OAC, SCC, histologically unspecified esophageal cancers, and lung cancer were calculated as the number of events divided by the person-years of follow-up. These incidences were expressed as events per hundred person-years of follow-up, which is equivalent to percentage incidence per year. The standardized incidence ratio (SIR) for these cancers was calculated by comparing the observed number of cancers in the cohort with the expected number, and by applying the relevant age-specific cancer incidence rates in the NI population to the cohort. Exact confidence intervals (CI) of rates and ratios were estimated using the Poisson distribution. Sensitivity analyses were performed in which histologically unspecified esophageal cancers were reclassified as OACs and then as SCCs and the corresponding SIRs were recalculated. This was done to illustrate the most extreme case scenarios, by assuming that all unspecified cancers were one or the other histological type of cancer. These analyses are secondary analyses of data collected during the construction of the NI Barrett's Register. Establishment of this Register received ethical approval from the Research Ethics Committee of the Queen's University, Belfast.

RESULTS

Figure 1 shows how the cohort was constructed and the effect of exclusion criteria. There were 2 013 patients in the cohort, comprising 996 (49.5%) men and 1 017 (50.5%) women. The mean age was 59.8 years, range 16.2-95.6 years. Men were substantially younger than women (56.6± 17.0 *vs* 63.0±16.2 years). The age and sex distributions of patients are shown in Figure 2. In 90 (4.5%) patients, the biopsies had been taken at the OGJ.

Members of the cohort were followed up for a mean of 6.7 years for a total of 13 559 person-years of follow-up. Nine patients developed esophageal cancer (4 men and 5 women), a mean of 3.1 years (range, 1.0-6.8 years) after the initial biopsy showing esophagitis. Mean age at diagnosis was 75.1 years (range, 60.8-86.3 years). None of the incident esophageal cancers were adenocarcinomas; three were SCCs and six were histologically unspecified. Two of the three patients who developed SCC were women. Histological confirmation of cancer was not possible in five of the six unspecified tumors, as biopsies were not taken. These diagnoses were based on the clinical opinion and in one case the registered causes of death did not include esophageal cancer. The pathological diagnosis in the single unspecified cancer case in whom biopsies had been taken was recorded as anaplastic carcinoma but in the body of the report the pathologist stated that it was 'probably squamous in type'.

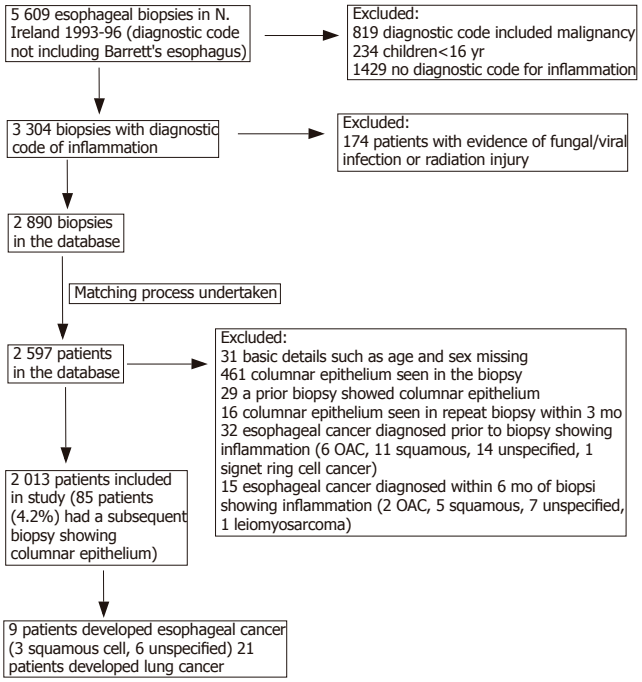

Figure 1 Flow diagram showing how cohort of patients with esophagitis was constructed.

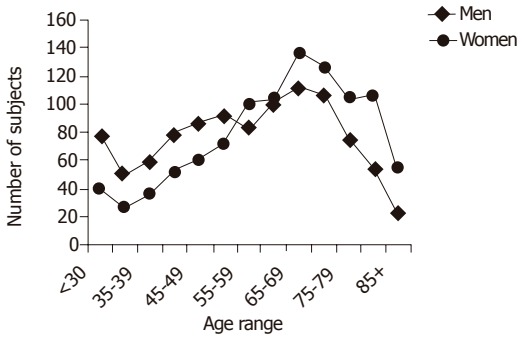

Figure 2 Age and sex distribution of patients with esophagitis.

The incidences and SIRs of esophageal cancers are shown in Table 2. The SIR (95%CI) for all esophageal cancers in the cohort was 2.73 (1.25-5.19), with a higher risk in women than men. The SIR (95%CI) for SCC was also raised at 2.93 (0.61-8.59) but this did not reach conventional statistical significance. The SIR for adenocarcinoma was 0 with an upper 97.5%CI of 2.73. None of the esophageal cancers occurred in patients whose biopsies were taken at the OGJ and exclusion of these patients had little effect on observed SIRs (data not shown). In the sensitivity analyses in which histologically unspecified cancers were reclassified as OACs and then as SCCs, the SIRs (95%CI) for OAC and SCC were 2.64 (0.97-5.75) and 4.64 (2.12-8.81), respectively. Dysplasia was noted in 20 (1%) patients; none of these patients

Table 2 Risk of esophageal and lung cancer in patients with histologically confirmed esophagitis and without Barrett's esophagus

		Number of cases	Incidence per 100 person-years of follow-up (95%CI)	Expected number of cases	Standardized incidence ratio (95%CI)

[1]One-sided 97.5%CI; [2]OAC+histologically unspecified cancers; [3]SCC+histologically unspecified cancers.

developed esophageal cancer.

Eighty-five (4.2%) patients in the cohort had a subsequent esophageal biopsy (after a minimum of 3 mo and before December 1999) showing columnar epithelium. None of the patients developed esophageal cancers in this group.

Twenty-one patients developed lung cancer, including 16 men and 5 women. Mean age at diagnosis of lung cancer was 71.3 years (range, 32.7-80.6 years). Overall, the SIR for lung cancer was not raised although a modest increase in risk was seen in men, which was not statistically significant (SIR 1.41, 95%CI 0.81-2.29).

DISCUSSION

This is the first population-based study to assess the risk of esophageal cancer in patients with histologically proven esophagitis that is not complicated by BO. We found that none of the 2 013 patients with esophagitis developed OAC after an average follow-up of 6.7 years. However, some of the six histologically unspecified tumors that occurred within the cohort might be adenocarcinomas.

This study has got many advantages. All patients had histologically confirmed esophagitis, and every patient in whom this diagnosis was made in NI between 1993 and 1996 was included in the study. The population-based nature of this study avoids selection biases that may operate when only patients attending specific centers are investigated. Also, patients who showed evidence of BO were excluded from the cohort, which allowed us to examine the risk of esophageal cancer in esophagitis uncomplicated by BO. Finally, follow-up of patients is likely to be near-completion for two reasons: firstly, population-based cancer and death registers were used to determine deaths and cancer incidence among the cohort; and secondly, emigration from NI is uncommon, averaging 1.1% of the population per year in the period 1991-2003[16].

This study also has limitations. A diagnosis of 'reflux esophagitis' was made in only a small proportion of cases because scant clinical details were provided on the pathology request forms. However, reflux of gastric contents was the most likely cause of esophagitis that was not due to infection or radiation. Also, patients with esophagitis were not routinely biopsied, so patients included in this cohort may represent a subset of patients with esophagitis who had suspicious features at endoscopy. Risk of esophageal cancer may, therefore, be exaggerated in this cohort but exclusion of prevalent cancers and cancers occurring within the first 6 mo reduces the effect of this problem. Accurate histological classification of the incident esophageal tumors occurring in the cohort was not available for 60% of tumors. Some of the unclassified tumors may be adenocarcinomas rendering the absolute incidence of OAC, an underestimate. However, classification of esophageal cancer incidence in the general population is subject to the same limitations, meaning that the SIRs presented for all cancers and for cancer subgroups should be valid comparisons between the cohort and the general population. Furthermore, we performed sensitivity analyses to estimate the maximum incidence of OAC and SCC, by assuming that all the histologically unspecified cancers were actually OACs or SCCs, respectively. Lastly, the modest size of the cohort and the period of follow-up have resulted in small numbers of incident cancers, which may render some of the estimates of cancer risk unstable. Another effect of the relatively short period of follow-up is that a late increase in the risk of OAC associated with esophagitis cannot be discounted.

When all histologically unspecified cancers were treated as OACs, giving a maximal possible risk of OAC, the risk in the cohort was approximately 2.5 times than that of the general population. This is undoubtedly an overestimate but the extent cannot be ascertained. We have previously demonstrated a 17-fold increase in risk of OAC in a cohort

of patients with BO (histologically confirmed specialized intestinal metaplasia) drawn from the same population and followed up in the same manner as in this study[14]. These data suggest that, unlike BO, esophagitis without BO is not an important risk factor for OAC.

The literatures regarding the risk of adenocarcinoma in esophagitis are conflicting. Previous case-control studies have shown that esophagitis or esophageal ulcer is associated with a two- to fivefold increased risk of OAC[17-19]. However, the diagnosis of esophagitis was obtained from case-note review or questionnaire and was not histologically confirmed. Also, it was not possible to identify and exclude patients with BO in these studies. Ye *et al*.[20] reported a sixfold increase in the incidence of OAC in a large population-based cohort study of patients with a hospital diagnosis of gastro-esophageal reflux disease (GORD), but patients with BO were not excluded. A recent study utilizing data from the United Kingdom General Practice Research Database estimated that patients with esophagitis had a 4.5-fold increased risk of OAC compared to the normal population, whereas the risk in BO patients was increased 30-fold[21]. Moreover, following long-term follow-up of patients with GORD, Spechler *et al*.[22] found that patients with BO at baseline developed OAC at an annual rate of 0.4%, whereas the rate in patients without BO was only 0.07%. These data from patients with clinical diagnoses of esophagitis and BO appear to be in agreement with our findings from patients with histological confirmation of their diagnoses.

Only 4.5% of patients in our cohort had a subsequent esophageal biopsy showing columnar epithelium, suggesting that progression from esophagitis to BO may be uncommon. However, it must be borne in mind that there was no systematic recall of patients for endoscopy, so the incidence of BO in the cohort may be underestimated. Also, a systematic biopsy protocol was not employed, so columnar epithelium may have been missed in some patients, either in their initial biopsy or subsequent biopsies.

The low incidence of OAC in our cohort suggests that progression along a path from esophagitis to BO and to OAC may not be the normal sequence of events. Rather, an individual's response to reflux of gastric contents may result in either esophagitis or BO, with a future risk of OAC being confined to those who develop BO. Cameron and Arora[23] carried out a detailed study in which they mapped areas of damage seen at endoscopy in patients with esophagitis and in patients with BO. Their findings suggest that BO is unlikely to develop directly from areas of esophagitis, adding plausibility to the proposed pathway in Figure 3.

The incidence of SCC within the cohort was almost three times than that of the general population. There is limited evidence in the literature supporting a link between esophagitis and SCC. Munoz *et al*.[24] showed a very high prevalence of esophagitis (84%) in people living in the Linxian region of China, where there is a very high incidence of esophageal SCC. However, the authors stated that this esophagitis affected the middle and lower thirds of the esophagus as opposed to the distal esophagus; also, it was not accompanied by erosions or ulcers, features characteristic of esophagitis secondary to gastro-esophageal reflux. These patients are very different from the cohort that we had examined, particularly in terms of lifestyle and nutritional status and gastro-esophageal reflux may not be important in the etiology of esophagitis in China. Ribet *et al*.[25] found evidence of an association between reflux symptoms and SCC in the patients who underwent resection of esophageal cancers, but this was a small study involving a highly selected group. Ye *et al*.[20] found a moderately raised risk of SCC in a Swedish cohort of hospital patients with GERD. On the other hand, in a large Swedish case-control study, Lagergren *et al*.[13] found no association between symptoms of reflux and risk of SCC of the esophagus.

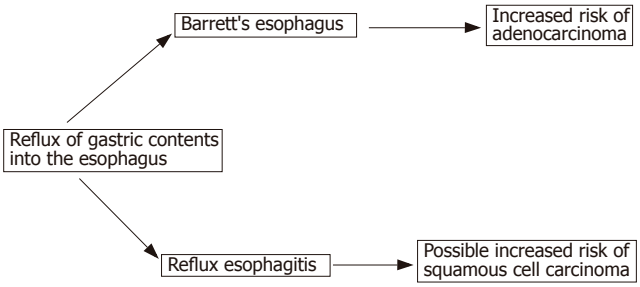

Figure 3 Potential pathways of cancer causation in the esophagus.

Our finding of increased SCC risk in patients with esophagitis could result from over-representation of smokers within the cohort, since smoking is associated with reflux symptoms[26,27]. However, this was unlikely because the risk of lung cancer was not raised in the cohort. It may also result from inclusion of patients with suspicious lesions seen at endoscopy, which might include dysplastic squamous epithelium; however, less than 1% of patients had evidence of dysplasia, and none of these developed SCC. Further research is required to examine the association we have seen between esophagitis and SCC.

In summary, our study shows that esophagitis that is not complicated by BO is not associated with an increased risk of OAC. This finding supports the view that BO, not esophagitis, is the key precursor of OAC. Further studies are required to see if these findings can be replicated. Determination of the relative importance of esophagitis in esophageal cancer causation is important because this has implications for the management of patients with gastro-esophageal reflux and for the prevention of OAC.

ACKNOWLEDGMENT

The authors thank Dr. Dermot Hughes, Consultant Pathologist at Altnagelvin Area Hospital, for advice relating to SNOMED codes used in the study. Thanks are also due to Mr. Colin Fox, Mr. Richard Middleton, and the Tumor Verification Officers of the NICR for their assistance with the processing of pathological records. We are also grateful to Dr. Anna Gavin, Director of the NICR

and to the administrative, medical and pathology staff of local Health Care Trusts and the staff of the Directorate of Information Services DHSSPS (NI) for assistance in the construction of the NI Barrett's Register.

Abstract

AIM: To check the utility of postcibal ultrasonography for the evaluation of reflux in relation to gastric emptying in infants with recurrent respiratory symptoms and to link imaging with clinical data.

METHODS: Esophageal reflux (hyperechoic retrograde filling) and gastric emptying (antral areas) were quantified before and after ingestion of a standard formula in 35 untreated infants (13 with chronic cough, 22 with recurrent bronchitis) and in 31 controls.

RESULTS: The prevalence of abnormal (≥8 episodes) postcibal refluxes was 74% in patients and 3% in controls. Number, duration of the longest episode and extent of refluxes were significantly higher in patients compared to controls. Number of refluxes was higher in patients with symptomatic refluxes than in those without. Infants with recurrent bronchitis had more refluxes than those with chronic cough and controls. Extent and timing of gastric emptying were similar in patients and controls.

CONCLUSION: Esophageal ultrasonography is a useful and physiological test in infants with recurrent respiratory diseases, which have a high prevalence of abnormal postcibal esophageal reflux and a gastric emptying similar to that of normal controls. Esophageal reflux is more severe in subjects with recurrent bronchitis than in those with chronic cough.

Key words: Ultrasonography; Gastro-esophageal reflux; Gastric emptying; Recurrent respiratory disease

INTRODUCTION

Gastro-esophageal reflux has been frequently linked to several acute and chronic respiratory diseases in infants[1-4]. As ultrasonography may allow direct visualization of gastro-esophageal junction and of retrograde reflux episodes[5,6], it has been used as an alternative to invasive techniques in pediatric age[5-9]. Validation studies reported high sensitivity and specificity for ultrasonography in diagnosing gastro-esophageal reflux, as compared to standard barium swallow examination[6], esophageal pH monitoring[8,10], and esophagomanometry[10]. The application of ultrasonography in pediatric age has major advantages due to its non-invasiveness, wide availability, and optimal compliance. Thus, in the present study, we aimed to: (1) employ ultrasound for the evaluation of gastro-esophageal reflux in relation to postprandial gastric emptying in infants with or without recurrent respiratory diseases; and (2) relate the gastro-esophageal imaging with clinical data in the postcibal period.

MATERIALS AND METHODS

Subjects

The ultrasonographic test was part of a routine work-up abdominal assessment. Informed consent was obtained from parents for each infant participating in the study and the study protocol was approved by an institutional review board. The study comprised 66 non-preterm infants (age range, 1-12 mo). Characteristics of the subjects are summarized in Table 1. Thirty-five inpatient or outpatient infants with a recent history of recurrent respiratory diseases were recruited. Patients had at least two episodes of asthmatic bronchitis requiring hospital admission (group A, $n = 22$) or unexplained chronic cough (group B, $n = 13$). Patients, who were referred only for respiratory problems, underwent *de novo* evaluation without prior investigations or therapies. Parents denied, in all cases, the consent to

invasive techniques. In all patients, immune deficiencies, cystic fibrosis, and allergopathies were excluded by clinical and biohumoral assessment. Parents were asked for the presence of daily regurgitation in all the patients.

Additionally, 31 inpatient or outpatient infants, who never experienced respiratory or gastrointestinal diseases, were considered as controls. Patients were not examined during acute respiratory disease. Neither patients nor controls were under medications able to influence gastrointestinal motility or secretion and were not affected by conditions known to alter gastrointestinal tract functions.

Study design

Each subject underwent a simultaneous ultrasonographic study of the esophagus and of the antrum with a Toshiba Capasee scanner and a 3.5-MHz convex probe. Ultrasonography was performed in a sitting position before and after the ingestion of a low volume liquid standard meal (10 mL/kg standard infant formula). Subjects were fed in the upright position. The observation was carried out continuously for at least 20 min and in all cases until complete antral evacuation was recorded. All tests started in the morning, in the fasting state (at least 4 h) and were performed by a single examiner who was unaware of patient's history and clinical examination. Ultrasonographic findings were analyzed while being done and events were recorded on a specific form. The infants were not burped after the feeding and pacifiers were not employed. All infants were awake during the examination. Subjects with excessive gas in the stomach or excessive crying time (able to interrupt the continuity of observation) were excluded by analysis due to technical limitations.

Gastro-esophageal reflux study

The employment of ultrasound in the diagnosis of gastro-esophageal reflux disease has previously been validated against other techniques[6,8,10]. The esophagus and the gastro-esophageal junction were studied by transverse and longitudinal scans at the epigastrium[5,6,11] at the level of the left lobe of the liver, slightly rotating up the probe. In all the subjects, this allowed the visualization of the esophagus like a three-layer canalicular structure posterior to the left lobe of the liver and anterior to the aorta, which were used as landmark points[11]. Immediately after the ingestion of the standard liquid meal, the esophageal lumen appeared dilated by hyperechoic content flowing towards the gastric lumen. First, a longitudinal scan was performed to show the emptying of the distal esophagus. Subsequently, a *"real time"* observation of the esophagus and the gastro-esophageal junction was performed[11] by splitting the image on the ultrasound monitor. In particular, the esophagus and the gastro-esophageal junction were imaged on one half of the monitor continuously during 20 min. At regular intervals (mentioned below), the observation was stopped shortly for 2-3 s to catch antral sections on the second half of the screen for subsequent antral area measurement.

Gastro-esophageal reflux, when present, was visible like a flow of hyperechoic material directed from gastric lumen to distal esophagus through gastro-esophageal junction.

In the present series, gastro-esophageal reflux was defined as abnormal when the total number of episodes lasting for more than 2 s was $\geqslant$8 (upper limit derived from mean+2SD in normal control group = 7.5). The presence/absence and the number of gastro-esophageal reflux episodes during 20 min were recorded and the frequency of gastro-esophageal reflux episodes (i.e., no. of episodes/time unit) was therefore calculated.

Immediately after the retrograde flow of hyperechoic material from gastric lumen to distal esophagus, the ultrasonographic image was frozen on one half of the monitor and the amount of gastro-esophageal reflux was subsequently quantified by measuring maximal esophageal lumen enlargement (distance between external esophageal layers). On the second half of the monitor (set as "real time" imaging), the duration of the reflux episode was counted by a timer. Maximal esophageal lumen enlargement and duration of the longest reflux episode for each examination were noted.

During the real-time continuous monitoring, all cough episodes were counted in both patients and controls. Cough episodes starting within 2 s from hyperechoic retrograde filling of esophageal lumen were therefore marked on a specific form and were considered related to reflux.

Gastric emptying study

Postprandial evacuation of the stomach was assessed by functional ultrasonography by monitoring antral areas, a well standardized technique in adults[11-15] and in infants[16-20]. Antral area was quantified in fasting infants and subsequently monitored at regular time intervals postprandially by longitudinal scans at the epigastrium at the level of antral-body connection in a single section. The superior mesenteric vein and the aorta were used as landmark points. Antral emptying was described by the following indices: (1) antral (basal) area (mean of two measurements between -5 and 0 min before meal, in cm^2); (2) maximal postprandial antral area, measured 2 min after meal ingestion; (3) postprandial antral areas each taken at 5-min intervals from meal ingestion; (4) minimal postprandial antral area observed throughout the emptying curve; and (5) half-emptying time.

Antral emptying curves were obtained by plotting antral areas *vs* time. In order to obviate interindividual variability of antrum size[13], postprandial areas were normalized to maximal areas after subtracting basal areas: $100\times(A_t\text{-}a)/(A_2\text{-}a)$, where A_t = postprandial area at any given time; a = basal area; A_2 = maximal antral area (measured at 2 min postprandially)[21]. Half-emptying time was the time at which 50% decrease of antral area occurred ($T_{1/2}$, min), and was calculated by linear regression analysis from the linear part of antral emptying curve. This index closely correlates with the scintigraphic half-emptying time[14].

Statistical analysis

All calculations were performed with the NCSS2001

Table 1 Characteristics of enrolled subjects

	Patients	Controls	*P*
N	35	31	
Age (mo)	5.6±2.9	4.5±3.6	NS
Weight (kg)	7.4±2.0	6.7±1.7	NS
Height (m)	0.7±0.07	0.6±0.01	NS

Data are expressed as mean±SD. NS: not significantly different.

Table 2 Ultrasonographic characteristics of gastro-esophageal reflux in infants with recurrent respiratory diseases and in healthy controls

	Patients	Controls	*P*
Number of reflux episodes	10 (2-21)	3 (1-9)	<0.01
Reflux frequency (reflux episodes/min)	0.5 (0.1-1.05)	0.15 (0.05-0.45)	<0.01
Maximal esophageal lumen enlargement (mm)	5 (1-17)	1.5 (1-9)	<0.01
Duration of the longest reflux episode (s)	11 (2-18)	4 (2-12)	<0.01

Results are expressed as median (range). Differences between groups were tested using Mann-Whitney *U* test.

software (Kaysville, UT, USA). Results were expressed as mean±SE or mean±SD or median and range, where appropriate. Data were statistically compared using two-tailed Student's t-test for unpaired data or by non-parametric Mann-Whitney *U* test, where appropriate. Analysis of variance followed by Fisher's LSD multiple comparison test was utilized to compare the differences among the groups. The χ^2 test was used to compare proportions of categorical data. Two-tailed *P* values less than 0.05 were considered statistically significant[22].

RESULTS

Patients and controls were similar in age-weight and height distribution (Table 1) and all subjects were below the 95th percentile for body weight. Overall, patients had significantly greater prevalence of abnormal postcibal reflux (74% in patients *vs* 3% in controls, $P<0.05$), number and frequency of reflux episodes, extent of refluxes and duration of the longest reflux episode as compared to controls (Table 2). Stratification of patients by age (0-6 mo, $n = 22$ and 7-12 mo, $n = 13$) showed similar results in the two age groups that were examined (Table 3).

The total number of cough episodes was significantly greater in patients than in controls (2.7±0.5 *vs* 0.03±0.03; $P<0.01$). Symptomatic reflux episodes (i.e., cough observed within 2 s from hyperechoic retrograde filling of esophageal lumen) were documented in 57% of patients (2.0±0.4 symptomatic refluxes in the observation period) and in none of the controls. Cough episodes not preceded by reflux were 0.5±0.3 in patients without symptomatic reflux episodes and 0.8±0.2 in patients with symptomatic refluxes.

The median number and frequency of gastro-esophageal reflux episodes were obviously higher in patients with symptomatic reflux episodes than in those without (Table 4).

Table 3 Ultrasonographic characteristics of gastro-esophageal reflux in patients with recurrent respiratory diseases in two age groups

	0-6 mo	7-12 mo	*P*
Number of reflux episodes	9.5 (3-21)	11 (2-18)	NS
Reflux frequency (reflux episodes/min)	0.5 (0.15-1.05)	0.6 (0.1-0.9)	NS
Maximal esophageal lumen enlargement (mm)	5.5 (1-17)	4 (1.6-11.5)	NS
Duration of the longest reflux episode (s)	11 (2-17)	7 (4-18)	NS

Results are expressed as median (range). Differences between groups were tested by Mann-Whitney *U* test; NS: not significantly different.

Table 4 Ultrasonographic characteristics of gastro-esophageal reflux in patients with or without symptomatic reflux episodes

	With symptomatic reflux	Without symptomatic reflux	*P*
Subjects	20	15	
Number of reflux episodes	11.5 (4-21)	7 (2-18)	<0.02
Reflux frequency (reflux episodes/min)	0.58 (0.2-1.05)	0.4 (0.1-0.9)	<0.05
Maximal esophageal lumen enlargement (mm)	5.5 (1.7-13.5)	3.0 (1-17)	NS
Duration of the longest reflux episode (s)	11 (6-18)	8 (2-17)	NS

Results are expressed as median (range). Differences between groups were tested using Mann-Whitney *U* test. NS: not significantly different.

The prevalence of abnormal refluxes was higher in patients with recurrent bronchitis (group A) and in patients with chronic cough (group B) as compared to controls (Table 5). Both subgroups of patients had more reflux episodes, higher reflux frequency, higher esophageal lumen enlargement and duration of the longest reflux episode as compared to controls ($P<0.01$, ANOVA, Figure 1 and Table 5). Patients with recurrent bronchitis also showed more reflux episodes, higher reflux frequency and higher duration of the longest reflux episode as compared to infants with chronic cough (Table 5). The number of symptomatic reflux episodes was similar in patients with recurrent bronchitis (2.6±0.6) and in those with chronic cough (1.2±0.4).

Daily regurgitation was present in 57% of patients with recurrent respiratory diseases, who showed a higher number, frequency, and duration of the longest reflux episode compared to patients without this symptom (Table 6). The number of symptomatic refluxes was similar in patients with (2.4±0.6) and without (1.7±0.6) daily regurgitation.

The study of gastric emptying showed a rapid and continuous decrement of the antral areas starting immediately after meal ingestion in both patients and controls (Figure 2). Patients and controls showed comparable fasting (1.3±0.01 and 1.2±0.1 cm^2, respectively) and maximal postprandial areas (5.7±0.3 *vs* 5.6±0.4 cm^2), and similar postprandial emptying indices, in terms of both minimal postprandial areas (1.4±0.1 *vs* 1.3±0.2 cm2; 4.6±1.9% *vs* 3.5±1.4%) and half-emptying time (9±0.6 *vs* 9±0.5 min, respectively). No significant difference was observed in time to maximal emptying between patients

Table 5 Ultrasonographic characteristics of gastro-esophageal reflux in patients with recurrent episodes of bronchitis (group A), chronic cough (group B), and in healthy controls

	Group A	Group B	Controls	ANOVA
Reflux prevalence (%)	82[a]	54[a]	3	
Number of reflux episodes (*N*)	12.0 (2-21)[a,c]	8.0 (2-12)[a]	3.0 (1-9)	<0.00001

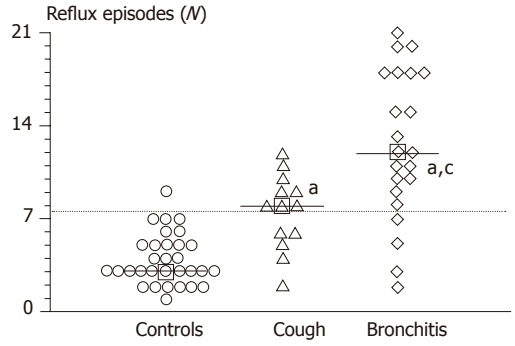

Figure 1 Number of postcibal gastro-esophageal reflux episodes, as determined by ultrasound, in controls (n = 31) and in infants with recurrent respiratory diseases (n = 35). Horizontal dotted line indicates the mean+2SD in the normal control group. Squares and continuous horizontal lines indicate medians. Differences between the groups were tested by using ANOVA, followed by Fisher's LSD multiple comparison test. [a]$P<0.05$ *vs* controls; [c]$P<0.05$ *vs* chronic cough.

(20±1 min) and controls (19±1 min). Invariably, gastric emptying was complete after 30 min in all cases. Gastric emptying speed was also similar in patients with and without symptomatic reflux episodes (half-emptying time 9±1 and 10±1 min, respectively) and in patients with and without daily regurgitation (half-emptying time 9±1 and 9±1 min, respectively).

DISCUSSION

The present study shows that ultrasonography is useful in providing important information about the presence, extent, and duration of postcibal gastro-esophageal reflux

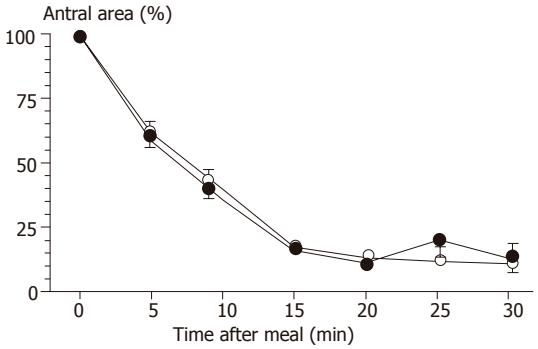

Figure 2 Postcibal gastric emptying curves, determined by ultrasound, in controls (n = 31) and in infants with recurrent respiratory diseases (n = 35). Symbols indicate means (○: controls; ●: patients), and vertical lines indicate SE. Differences between groups were tested by using ANOVA.

in infants with recurrent respiratory diseases.

Gastro-esophageal reflux is the effortless retrograde flow of gastric content in the esophageal lumen and, when abnormal, it is a recognized clinical problem in infancy, where it has been frequently associated with respiratory diseases[1-4,23].

Respiratory diseases and gastro-esophageal reflux disease have long been linked in childhood by both physiopathological and epidemiological studies, and the complex interplay between these two frequent clinical conditions is still under debate[24,25].

By prolonged pH-metry, a high prevalence of abnormal esophageal pH was reported in infants with recurrent bronchopulmonary infections, suggesting that this technique may be useful for diagnosing gastro-esophageal reflux and its association with recurrent bronchopulmonary diseases[26]. pH-metry, however, has several pitfalls, since it does not help with alkaline gastric content as seen in a number of conditions, namely after the ingestion of normal infant formula, achlorhydria or duodenogastric reflux[27,28], and alkaline reflux episodes[29,30]. In a recent study, intraluminal impedance has been used in infants with respiratory phenomena and it has been shown that gastro-esophageal refluxes accompanied by respiratory symptoms can be detected only in a minority of cases by pH-metry[29]. Similar findings were also evident in a large ultrasonographic study in symptomatic infants undergoing pH-metry[7].

Impedance monitoring is a pH-independent method for detecting bolus movement within the esophagus.

It might provide a valid alternative to esophageal pH-metry because it evaluates reflux occurring both in the interprandial and postprandial period, and it is sensitive to very small volumes of refluxate[29-33].

On the other hand, functional ultrasonography of the gastro-esophageal junction may allow direct visualization of lower esophageal sphincter relaxation and reflux episodes. The technique offers several advantages in that it has low costs, it is simple, non-invasive and is a more physiological alternative to invasive techniques[5,6,8-10]. In this respect, our results suggest that ultrasonography might represent a useful and physiological screening test in infants with recurrent respiratory diseases.

The importance of meal volume also needs to be addressed. We used a relatively low-volume liquid standard meal (i.e. of lower volume compared to that currently used during a physiological feeding). Such low volume would not affect the observed results, since in early studies, gastro-esophageal reflux was either unrelated to feed volume[17] or it was worsened by a high volume meal, through significant changes in lower esophageal sphincter pressure[20]. Here, we have observed several postcibal refluxes with a low-volume meal, suggesting that meal volume *per se* may not be a determinant in postcibal reflux occurrence.

The short postprandial observation period might be considered as a major pitfall of the ultrasonographic study. However, by using a 20-min postprandial time-window to check for persistence of intragastric content, we found significant differences for extent and timing of gastro-esophageal reflux between patients with recurrent respiratory diseases and controls, and an event/symptom relationship. Indeed, patients with recurrent involvement of lower respiratory tract (i.e. bronchitis) showed a higher number of postcibal reflux episodes compared to both patients with chronic cough and controls.

While interprandial refluxes could not be documented at ultrasonography, we underlined the importance of postcibal reflux in the pathogenesis of recurrent respiratory diseases in infants. Transient lower esophageal sphincter relaxation is the predominant mechanism of gastro-esophageal reflux[34] and postprandial reflux has been suggested to be a dynamic indicator of sphincter competency[20,35]; in this respect, postcibal ultrasonography allows direct visualization of both gastro-esophageal reflux and sphincter incompetency.

It has been reported that delayed clearance of refluxed material and clustering of reflux events may precipitate respiratory symptoms in infants[36,37]. Indeed, we found that amount, extent and number of postcibal gastro-esophageal reflux episodes were higher in subjects with symptomatic refluxes than in those without.

Although ultrasound visualization of reflux is limited to the distal esophagus, our results suggest the possibility that the involvement of the respiratory tract might be partly due to a greater chance for microaspiration of refluxed materials reaching the proximal esophagus. This possibility is more likely in subjects with a great amount and timing of gastro-esophageal reflux episodes. Interestingly, a recent study found a direct relation between incidence and duration of refluxes in the proximal and in the distal esophagus[38]. However, other mechanisms responsible for respiratory tract involvement secondary to gastro-esophageal reflux, particularly vagally mediated reflexes, may be taken into account[39].

The association of gastro-esophageal reflux disease and chronic cough in infants has been well demonstrated[2,23,40], and our results suggest that postcibal ultrasonography might be employed as a useful diagnostic approach also in patients with chronic cough.

Delayed gastric emptying has been frequently linked to gastro-esophageal reflux both in adults[41-43] and in pediatric age[16,44]. In a scintigraphic study in pediatric patients, it was found that delayed gastric emptying increased postprandial reflux by increasing the refluxate volume per episode of reflux through an underlying incompetent lower esophageal sphincter[44]. By using ultrasonography, we also performed the measurement of gastric emptying by a well standardized and validated procedure[11,16-20]. Our data demonstrated a similar extent and timing of postprandial gastric emptying in patients and controls. This is in accordance with a previous ultrasonographic study in infants with reflux disease, in which the speed of gastric emptying was unrelated to any interprandial or postprandial indices of gastro-esophageal reflux by a 24-h pH-metry[17]. Similar conclusions were also depicted by another recent study by (13)C-octanoic acid breath test, showing that gastric emptying was not delayed in infants with gastro-esophageal reflux[34].

In conclusion, postcibal esophageal ultrasonography is a useful and physiological screening test in patients with recurrent respiratory diseases, who show lower esophageal sphincter incompetence and high postprandial gastro-esophageal reflux prevalence, with a postprandial gastric emptying similar to controls. Subjects with recurrent bronchitis seem to have a greater amount of gastro-esophageal reflux episodes compared to those with chronic cough.

Abstract

AIM: To assess the associations of human leukocyte antigen (HLA) class II DQB1*0301 and/or DRB1*1101 allele with spontaneous hepatitis C virus (HCV) clearance by meta-analysis of individual dataset from all studies published till date.

METHODS: To clarify the impact of HLA class II polymorphisms on viral clearance, we performed a meta-analysis of the published data from 11 studies comparing the frequencies of DQB1*0301 and DRB1*1101 alleles in individuals with spontaneous resolution to those with persistent infection. As we identified the heterogeneity between studies, summary statistical data were calculated based on a random-effect model.

RESULTS: Meta-analyses yielded summary estimates-odds ratio (OR) of 2.36 [95%CI (1.62, 3.43), $P<0.00001$] and 2.02 [95%CI (1.56, 2.62), $P<0.00001$] for the effects of DQB1*0301 and DRB1*1101 alleles on spontaneous clearance of HCV, respectively.

CONCLUSION: These results support the hypothesis that specific HLA class II alleles might influence the susceptibility or resistance to persistent HCV infection. Both DQB1*0301 and DRB1*1101 are protective alleles and present HCV epitopes more effectively to $CD4^+$T lymphocytes than others, and subjects with these two alleles are at a lower risk of developing chronic HCV infection. Large, multi-ethnic confirmatory and well-designed studies are needed to determine the host genetic determinants of HCV infection.

INTRODUCTION

HCV infection presents with diverse clinical manifestations. Approximately 20% of infected patients successfully eliminate the virus, whereas the majority of patients develop chronic infection with a wide spectrum of liver lesions, ranging from minimal inflammation to cirrhosis and hepatocelluar carcinoma (HCC)[1]. The mechanisms underlying the spontaneous viral clearance or development of chronic HCV infection have not yet been identified[2]. Apart from viral characteristics (viral genotype, quasi-species distribution and viral load), it is generally accepted that cellular immune responses play an important role in viral clearance and disease resolution[3]. Clearance of the virus during acute infection has been shown to be associated with strong and sustained HCV-specific $CD4^+$ and $CD8^+$ T-cell responses[4-8]. Though $CD8^+$ T cells are primary effector cells directly eliminating HCV-infected cells, $CD4^+$ T cells play a central regulatory role, which modulates the $CD8^+$ T-cell responses and is crucial for the production of neutralizing antibodies. A number of recent studies have suggested that early sustaining vigorous and multi-specific $CD4^+$ T-cell responses might be a critical determinant for the primary HCV infection[9,10]. The importance to $CD4^+$ T-cell response is the presentation of HCV antigens in the context of HLA class II molecules. Therefore, the differences in HLA class II alleles may strongly influence the clinical course of hepatitis C.

HLA genes located on chromosome 6 encode peptides

Table 1 Characteristics of studies included in the meta-analysis

First author (year) [reference]	Country (ethnicity)	Spontaneous resolution	Persistent infection	Matching	Anti-HCV tests	HLA typing
Alric (1997) [21]	France (European)	25, M/F: 9/16 Age: 40.6±15.7 yr	103, M/F: 58/45 Age: 45.4±12.4 yr	Sex, age, source of HCV infection, HCV-serotype	2G EIA and RIBA	PCR-SSOP
Cramp (1998) [22]	UK (European)	49, M/F: 30/19 Duration: 15.5 (3-42) yr	55, M/F: 31/24 Duration: 14.2 (2-40) yr	Sex, age, source of HCV infection and duration	2G line immunoassay	PCR-SSOP
Minton (1998) [23]	UK (European)	35, M/F: 19/16 Age: 37.9±10.8 yr	138, M/F: 87/51 Age: 37.2±10.1 yr	Sex, age, source of HCV infection	2G ELISA and RIBA	PCR-SSOP
Mangia (1999) [24]	Italy (European)	35	149	Sex, HCV-serotype, not age, not duration	RIBA and 3G EIA	PCR-SSP
Thursz (1999) [25]	European	85, M/F: 37/48 Age: 45±14 yr	170, M/F: 74/96 Age: 50±16 yr	Sex, center, not age	ELISA and RIBA	PCR-SSP

Azocar (2003) [29]	Hispanic (European)	40,M/F: 33/7 Age: 37.9 yr	72, M/F: 54/18 Age: 39.2 yr	Age, sex	EIA and RIBA	PCR-SSOP PCR-SSP
Spada (2004) [30]	Italy (European)	10, M/F: 5/5 Age: 40.5 (20-61) yr	24,M/F:22/2 Age: 29 (20-56) yr	Not sex, age, source of HCV infection, HCV-serotype	3G ELISA and RIBA	PCR-SSP

EIA: enzyme-immunoassay; RIBA: recombinant immunoblot assay; ELISA: enzyme-linked-immunosorbent assay; 2G: second generation; 3G: third generation; SSOP: sequence-specific oligonucleotide probes; SSP: sequence specific primers; SSCP: single stranded conformational polymorphisms.

involved in host immune response. Moreover, the HLA loci display an unprecedented degree of diversity in human genome, presumably an evolutionary adoption to immune pressure from various infectious agents. Polymorphisms in HLA class II molecules can give rise to amino acid substitutions with different peptide-binding characteristics and determine antigenic specificities, the strength of immune response to HCV[11,12]. Consequently, distinct HLA class II alleles may be expected to exert an impact on the development of host immune responses against HCV infection. However, few studies have demonstrated consistency in different populations. In several Irish studies performed in women exposed to HCV genotype 1b from a single inoculum, DRB1*0101 and DQB1*0501 alleles are found to be associated with viral elimination[13–17]. One German study suggests that HLA-DR15 (B1*15011) might constitute an important genetic factor for the clearance of HCV[18]. Thio *et al*.[19] reported that HLA-A*1101, HLA-B*57, and HLA-Cw*0102 contribute to the spontaneous resolution of primary HCV infection. It was reported that the DQA1*03 and DQB1*0302 alleles promote viral clearance and confer protection against chronic HCV infection in Caucasians[20]. A number of studies have been conducted in different ethnic populations to investigate the associations of DQB1*0301 or DRB1*1101 allele with spontaneous HCV clearance[13,21-30]. However, the results from these molecular epidemiological studies are confusing rather than being conclusive. Single study might be underpowered to detect the association between DQB1*0301 and/or DRB1*1101 allele and HCV infection because of the limited sample size. The aim of this study was to assess the associations of HLA class II DQB1*0301 and/or DRB1*1101 allele(s) with spontaneous HCV clearance by meta-analysis of individual dataset from all studies published till date.

MATERIALS AND METHODS

Identification and eligibility of studies

PubMed was used to search for relevant reports published between 1997 and 2004 (using the key words: human leukocyte antigen, genetic polymorphism, hepatitis C virus, spontaneous clearance). The inclusion criteria for our analysis were as follows: studies reporting odds ratio (OR) or risk ratio (RR) calculated by comparing those with self-limiting infection to those with chronic infection as a measure of association; study designs such as cohort study, population-based case control study, hospital-based case-control study; studies using HLA class II molecular genotyping technique; studies including DQB1*0301 and DRB1*1101 alleles. A total of 11 candidate papers were identified.

Data extraction

Data were collected on the DQB1*0301 and DRB1*1101 allele frequencies, authors, journals, years of publication, country of origin, demographics, selection, definition of spontaneous viral clearance (anti-HCV positive and HCV-RNA negative at least for 6 mo), chronically persistent infection (anti-HCV positive and HCV-RNA positive for more than 1 year) and racial descents (categorized as Asian, European, and North American descents).

Table 2 Effect of DRB1*1101 allele on self-limiting HCV infection

Study	Spontaneous resolution *n/N*	Persistent infection *n/N*	OR (random) 95%CI
Alric	10/25	10/102	6.13 (2.18, 17.22)
Minton	11/35	11/135	5.17 (2.01, 13.27)
Cramp	9/49	6/55	1.84 (0.60, 5.60)
Mangia	7/35	24/149	1.30 (0.51, 3.32)
Thursz 1	26/85	29/170	2.14 (1.16, 3.94)
Thursz 2	14/57	15/152	2.97 (1.33, 6.65)
Fanning	4/68	4/64	0.94 (0.22, 3.92)
Alric	20/59	25/170	2.97 (1.50, 5.91)
Vejbaesya	2/43	3/57	0.88 (0.14, 5.50)
Thio	15/200	24/374	1.18 (0.61, 2.31)
Azocar	4/40	11/72	0.62 (0.18, 2.08)
Spada	2/10	2/24	2.75 (0.33, 22.92)
Total (95%CI)	124/706	164/1 524	2.02 (1.56, 2.62)

Test for heterogeneity: χ^2 = 19.38, df = 11 (P<0.05), I^2 = 43.2%. Test for overall effect: Z = 5.30 (P<0.00001).

Table 3 Effect of DQB1*0301 allele on self-limiting HCV infection

Study	Spontaneous resolution *n/N*	Persistent infection *n/N*	OR (random) 95%CI
Alric	21/25	28/91	11.81 (3.71, 37.61)
Minton	18/35	33/135	3.27 (1.51, 7.07)
Cramp	26/49	10/55	5.09 (2.10, 12.33)
Mangia	17/33	42/143	2.56 (1.18, 5.53)
Thursz 1	39/85	47/170	2.22 (1.29, 3.82)
Thursz 2	25/57	37/152	2.43 (1.28, 4.61)
Fanning	25/78	18/67	1.28 (0.63, 2.64)
Alric	38/59	45/157	4.50 (2.39, 8.50)
Vejbaesya	24/43	18/57	2.74 (1.20, 6.22)
Thio	49/200	71/374	1.38 (0.92, 2.09)
Azocar	6/40	13/72	0.80 (0.28, 2.30)
Spada	4/10	15/24	0.40 (0.09, 1.81)
Total (95%CI)	292/714	377/1 497	2.36 (1.62, 3.43)

Test for heterogeneity: χ^2 = 33.33, df = 11 (P = 0.0005), I^2 = 67.0%. Test for overall effect: Z = 4.48 (P<0.00001).

Furthermore, we examined whether matching was used and HLA class II molecular-typing assay was validated.

Statistical analysis

The OR of sustained HCV clearance associated with HLA class II polymorphisms (DQB1*0301 and DRB1*1101 alleles) was estimated for each study. The primary analysis was to estimate the allele frequencies between the groups with viral elimination and chronic infection. For each genetic group, we estimated the heterogeneity between the studies[31]. Data were combined using both fixed effect (Mantel-Haenszel) and random effect (DerSimonian and Laird) models[32]. In the absence of heterogeneity, the two methods provided identical results. Random effects were more appropriate, when heterogeneity was present. Analyses were performed by the software of SAS 8.0 (SAS Institute, Cary, NC, USA) and Review Manager 4.2 (Cochrance Collaboration, Oxford, UK). All P values were two-sided.

RESULTS

Characteristics of the studies are shown in Table 1. Multiple studies were conducted in the European population (n = 9). The number of individuals with spontaneous resolution and persistent infection in DRB1*1101 and DQB1*0301 studies was 706 and 1 524, 714 and 1 497, respectively. All the subjects of these studies were selected based on a histological diagnosis of strict criteria. With two exceptions[24,25] where the mean age of two groups differed and one where the age status was not stated[26], all other studies were matched for age. Most studies also stated the use of matching on sex status except for two[27,30]. Compared to other studies, only one was homogenous in terms of gender, source of HCV infection, HCV-serotype and ethnicity[13]. This subject population was derived from a cohort of females inoculated with anti-D immunoglobulin in 1977 that was contaminated with HCV from a single source.

With regard to the anti-HCV antibody testing, most studies used a combination of two tests, while only one used a single test[13]. Five studies used low resolution molecular typing (PCR-SSOP) for HLA, while others used high resolution molecular typing (PCR-SSP) for HLA[33]. Low resolution molecular typing methods for HLA could not identify the specific alleles. Accurate methods for HLA class II typing should involve the combination of PCR-SSOP, PCR-SSP, and PCR-SSCP[12].

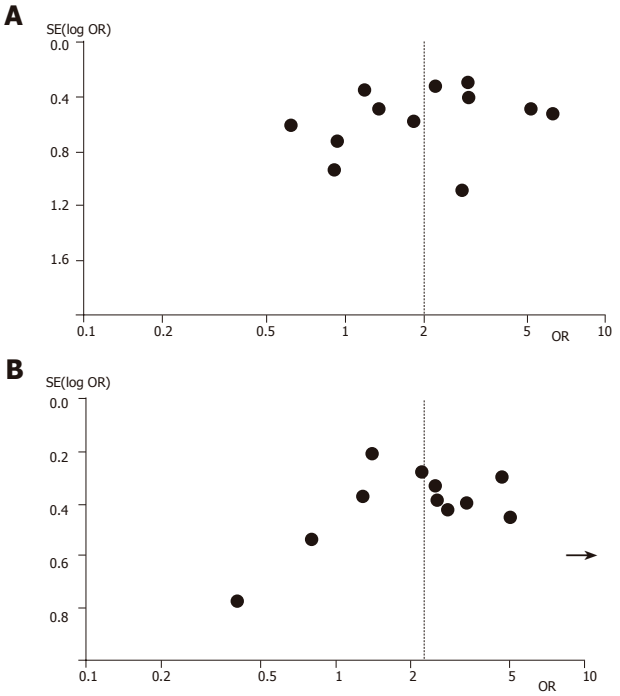

Figure 1 Funnel plot analysis of publication bias for DRB1*1101 allele (**A**) and DQB1*0301 allele (**B**). Each data point represents a separate study for the indicated association.

Table 2 shows the OR on HCV spontaneous clearance associated with DRB1*1101 allele. Overall, individuals with DRB1*1101 allele had a significantly reduced risk for chronic hepatitis C compared to individuals without it [OR = 2.02, 95%CI (1.56, 2.62) (P<0.00001)]. Similarly, subjects with DQB1*0301 allele appeared to be more

likely to clear the virus, while those lacking it were more prone to develop chronic infections [OR = 2.36, 95%CI (1.62, 3.43), $P<0.00001$] (Table 3). These analyses were based on the data from 11 studies regardless of ethnics.

We performed tests for homogeneity with respect to the studies of DRB1*1101 and DQB1*0301 alleles and viral clearance and obtained statistically significant results (DRB1*1101: $\chi^2 = 19.38$, $P<0.05$; DQB1*0301: $\chi^2 = 33.33$, $P = 0.0005$). Therefore, summary statistics were calculated based on a random-effect model.

Figure 1 shows the funnel plot analysis to detect publication bias of each study for DRB1*1101 and DQB1*0301, respectively. The shape of the funnel plot seemed to be asymmetrical, suggesting that publication bias might affect the findings of our meta-analysis. Furthermore, an Egger's test was used to provide statistical evidence for funnel plot symmetry[45]. In the linear regression analysis, the intercept value provided a measure of asymmetry, the larger the deviation the more pronounced the asymmetry. The intercept value in our study was 2.33 for DQB1*0301 and 2.03 for DRB1*1101, respectively, both of them were significantly deviated from zero ($P<0.0001$ for DQB1*0301 and $P<0.0022$ for DRB1*1101).

DISCUSSION

DQB1*0301 allele is reproducibly involved in spontaneous viral clearance of HCV in different populations[21-26,28,34-36]. Studies conducted in patients from France[21], Britain[22], Italy[24,35] with different genetic backgrounds have identified significant genetic associations with different DQB1*0301-bearing haplotypes, suggesting that DQB1*0301 might be one of the most prominent factors in HCV clearance[37,38].

Another allele correlated with self-limiting HCV is DRB 1*1101[21,23,25,27,34,39]. But disagreement exists over the allele. In Italy[24,35] BRB1*1104 correlates with HCV clearance, while in Japan[40] DR13 is linked to self-limiting infection.

It is difficult to determine whether HLA-DRB1*1101 or DQB1*0301 allele is the more relevant factor as HLA-DRB1*11 is associated with DQB1*0301. Some studies found that DRB1*1101 rather than DQB1*0301 is closely associated with viral elimination[23,30,41,42]. While some findings suggest that DQB1*0301 is dominant in determining the outcome of HCV infection[21,22,27,43,44]. In our meta-analysis, the OR for the two alleles was virtually identical, but which one is responsible for the viral elimination is not clear.

The outcome of HCV infection varies substantially among the individuals. Though the exact mechanisms involved in viral clearance have not been fully elucidated, there is evidence that cellular immune response, especially T-helper lymphocyte responses to HCV, plays an important role in the control of persistent HCV infection. DQB1*0301, DRB1*1101 alleles are closely associated with self-limiting HCV infection. Our meta-analysis demonstrated that subjects with HLA-DRB1*1101 allele reduced 102% risk of developing chronic HCV infection and those carrying HLA-DQB1*0301 allele reduced 136% risk of persistent infection. HLA-DQB1*0301 and DRB1*1101 alleles might act as the most prominent factors favoring the elimination of HCV and conferring protection against chronic evolution.

There are two possible explanations for these observations. (1) Because HCV is not cytopathic for infected cells, the immune response may play an important role in HCV infection. Binding to HCV peptides of HLA molecules is the first step for the initiation of this immune response. Due to the extensive polymorphisms of HLA, the strength of the response may vary among the individuals. It is assumed that DQB1*0301 and DRB1*1101 alleles may present HCV epitopes more effectively to $CD4^+$ Th cells than others, resulting in vigorous proliferative response to HCV and probably disease recovery[37,43,46-47]. $CD4^+$ Th responses have been characterized in patients with self-limiting infection and most immunodominant epitopes are present in the context of DQB1*0301 and DRB1*1101 molecules[48]. Therefore, individuals with these two alleles may present peptides derived from HCV in a more efficient manner than those without, thus clearing the infection spontaneously. (2) Another explanation for the association between the two alleles and viral elimination may be due to the other protective HLA loci[22,36]. Interpreting results of genetic studies can be complicated by linkage disequilibrium of the implicated gene linked to the true gene of interest[12]. Other candidate susceptible genes located in the HLA class II region also require antigen presentation. An excess of DQB1*0301 and DRB1*1101-restricted peptide-specific responses in individuals, who clear the virus, needs to be shown in order to prove conclusively whether the mechanism of the gene effect is direct or indirect.

While there are some consistent observations on DQB1*0301 and DRB1*1101 with self-limiting infection, many results are not uniform. These inconsistencies may be due to ethnic differences, patient selection, sample size, HCV-serotype, and HLA typing technique. Firstly, a primary cause for the difference in results by different authors may be related to the great variability of the frequency of HLA alleles in different populations. It is quite possible that one ethnic group may have the preferential use of different allele(s) in viral eradication compared to other ethnic groups. This DRB1*1101 association with viral clearance was not observed in the Irish anti-D population, which might be explained by the lower frequency of DRB1*1101 in Irish[16] (6.4%) than in French[21] control populations (25.2%). The association of DRB1*0101 and DQB1*0501 alleles with viral clearance has been documented in Caucasian Americans, whereas in African–American patients viral clearance is mainly associated with DQB1*0301[28]. Another study showed that there are marked differences in the frequency of viral clearance in Caucasians and African-Americans[49]. Racial heterogeneity has to be taken into account in the future studies[50,51]. Secondly, many studies were conducted on relatively smaller samples. Insufficient number of

individuals might decrease the power to detect a difference in the distribution of DQB1*0301 and DRB1*1101 alleles between patients with resolving infection and those with chronic evolution, though a true difference exists[52]. Lack of an association may not mean that associations do not exist. Thirdly, a number of HLA studies concerning the association between HLA class II and outcome of infection have compared allele frequency in HCV patients to that in healthy controls[20,53,54]. Studies including both HCV RNA positive and negative patients have failed to discover particular genetic associations[20]. Fourthly, effects of interactions in other environmental/behavioral and/or viral factors may be inevitable. There is a clear correlation between the HLA haplotype of individuals and outcome of HCV infection[55]. A complex interplay between various genes is likely to modulate the anti-HCV response rather than a single allele. Moreover, several variables including young age at infection and female sex have been suggested to determine HCV clearance[17,30,56]. Another possible reason for the discrepancy between these studies lies in the viral genotype.

In conclusion, large and well-designed studies should be carried out to investigate the host genetic determinants for HCV infection. Finding an association between specific alleles and favorable clinical outcomes in HCV patients might open new avenues to explore and understand the pathogenesis of HCV.

Abstract

AIM: To evaluate whether pyrrolidine dithiocarbamate (PDTC), an enhancer of HO production, attenuates intestinal IR injury.

METHODS: Eighteen male rats were randomly allocated into three groups: (a) sham; (b) IR, consisting of 30 min of intestinal ischemia, followed by 2-h period of reperfusion; and (c) PDTC treatment before IR. Intestinal microvascular perfusion (IMP) was monitored continuously by laser Doppler flowmetry. At the end of the reperfusion, serum samples for lactate dehydrogenase (LDH) levels and biopsies of ileum were obtained. HO activity in the ileum was assessed at the end of the reperfusion period.

RESULTS: At the end of the reperfusion in the IR group, IMP recovered partially to 42.5% of baseline ($P<0.05$ *vs* sham), whereas PDTC improved IMP to 67.3% of baseline ($P<0.01$ *vs* IR). There was a twofold increase in HO activity in PDTC group (2 062.66±106.11) as compared to IR (842.3±85.12) ($P<0.001$). LDH was significantly reduced ($P<0.001$) in PDTC group (585.6±102.4) as compared to IR group (1 973.8±306.5). Histological examination showed that the ileal mucosa was significantly less injured in PDTC group as compared with IR group.

CONCLUSION: Our study demonstrates that PDTC improves the IMP and attenuates IR injury of the intestine possibly via HO production. Additional studies are warranted to evaluate the clinical efficacy of PDTC in the prevention of IR injury of the small intestine.

Key words: Intestine; Ischemia-reperfusion injury; Heme oxygenase; Pyrrolidine

INTRODUCTION

Intestinal ischemia and subsequent reperfusion (IR) injury is encountered in a variety of clinical conditions, including hypovolemic shock[1], strangulation obstruction[2], cardiovascular surgery[3], abdominal aortic surgery[4], and small bowel transplantation[5]. The attenuation of IR injury is vital for intestinal graft function and survival after small bowel transplantation[6]. IR injury is associated with the breakdown of microvascular perfusion with subsequent impairment of tissue oxygenation[7]. The maintenance of microvascular perfusion is the ultimate determinant of viability of an organ[8]. IR injury of the intestine is a systemic phenomenon resulting in bacterial translocation[9], endotoxemia[10], acute respiratory distress syndrome[11], acute hepatic injury[12], which may eventually lead to multiple organ dysfunction syndrome[13].

Therapeutic strategies aimed at ameliorating IR injury have focused both on preventing the effects of reactive oxygen species and on downregulating the signal transduction cascades related to the expression of pro-inflammatory genes. Pharmacologic preconditioning based on enhancing the production or activity of endogenous protective molecules has also been proposed as an alternative therapeutic intervention. Among such agents, pyrrolidine dithiocarbamate (PDTC) has a variety of biochemical activities, such as redox state alternation, chelation of heavy metals, and enzyme inhibition[14]. PDTC was initially regarded as a potent inhibitor of nuclear factor-kappa B (NF-$\varkappa$B) and used as an antioxidant compound to counteract the toxic effects of free radicals[15]. PDTC is one of the most effective inducers of heme oxygenase-1 (HO-1), which also confers cytoprotection against oxidative stress[16]. HO is the rate-limiting enzyme in the conversion of heme into carbon monoxide (CO), biliverdin (which is rapidly converted to bilirubin) and free iron (Fe^{2+})[17]. Three isoforms of HO have so far been identified: inducible HO-1; constitutively expressed HO-2; and HO-3 which is related to HO-2, but is less well characterized[17]. The HO system is thought to

play a pivotal role in the maintenance of antioxidant and oxidant homeostasis during cellular injury. The HO system exerts four major beneficial effects broadly: (a) antioxidant function; (b) maintenance of the microcirculation; (c) anti-apoptosis; and (d) anti-inflammatory function[17]. The antioxidant function relies on heme degradation, production of bilirubin[18], and the formation of ferritin via Fe^{2+}[19]. The production of CO with its vasodilatory and anti-platelet properties maintains the microcirculation and may be involved in anti-apoptotic and cell arrest mechanisms. The HO system exerts anti-inflammatory effects via the modulation of endothelial adhesion molecules.

To the best of our knowledge, there are no previous studies exploring the effect of PDTC on IR injury of the intestine. Therefore, we have designed the present study to examine whether PDTC preconditioning induces HO expression in the small intestine and reduces the inflammatory response during reperfusion by focusing on the intestinal microvascular perfusion.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats, weighing 250-300 g, were used in this study. Rats were kept in a temperature-controlled environment with 12-h light-dark cycle and allowed tap water and standard rat chow pellets *ad libitum*. Animal care and experimental protocols were performed in accordance with the UK Government Guidance in the Operation of the Animals (Scientific Procedures) Act 1986.

Surgical procedures

Animals were anaesthetized using isoflurane (Baxter, Norfolk, UK) and allowed to breathe spontaneously via concentric mask connected to an oxygen regulator. The animal's body temperature was maintained at 36-38 °C using a heating pad (Harvard Apparatus Ltd, Kent, UK) and monitored with a rectal temperature probe. The arterial oxygen saturation (SaO_2) and heart rate (HR) were continuously monitored with a pulse oximeter (Ohmeda Biox 3740 pulse oximeter, Ohmeda Louisville Co., USA). The left carotid artery was cannulated with a polyethylene catheter (0.76 mm inner diameter, Portex, Kent, UK) and connected to a pressure transducer for the monitoring of mean arterial blood pressure (MABP). The right jugular vein was cannulated with a smaller polyethylene catheter (0.40 mm inner diameter, Portex, Kent, UK) for the administration of normal saline (1 mL/100 g body weight/h) to compensate for intra-operative fluid evaporation. All animals had an intravenous bolus of heparin (20 U/kg) to prevent potential thrombus formation in the ischemic segment of the intestine due to hemostasis.

Laparotomy was carried out through a midline incision. The superior mesenteric artery (SMA) was identified and dissected out from the mesentery to enable the passage of a 4/0 vicryl (Ethicon, Edinburgh, UK) suture loop. The SMA was occluded according to the method described by Arumugam *et al.*[20]. The free ends of the vicryl suture were then passed through a 5-cm segment of polyethylene tube (1.4 mm inner diameter). The tube was then gently advanced over the suture onto the mesentery and fixed in place with a hemostat. Reperfusion started when the hemostat was released. The animal's abdomen was covered with a plastic wrap (Saran wrap) to prevent fluid evaporation. At the end of the experiment, the animals were killed by exsanguination.

Experimental design

Rats were randomly allocated to three study groups ($n = 6$/group). Group 1: sham laparotomy, the SMA was identified and passage of vicryl suture was performed, but without vascular occlusion. Group 2: IR, the SMA was clamped for 30 min, followed by a 2-h period of reperfusion. Group 3: PDTC+IR, the animals received intramuscularly a single dose of 100 mg/kg of PDTC (Sigma Chemical Co., St. Louis, MO, USA) 30 min before IR.

Measurement of intestinal microvascular perfusion

Intestinal microvascular perfusion was measured by a surface laser Doppler flowmeter (LDF, DRT4, Moor Instruments Limited, Axminster, UK) in flux units. The Doppler signal varies linearly with the product of the total number of moving red blood cells in the measured volume of a few cubic millimeter multiplied by the mean velocity of these red blood cells. The numeric product is termed as perfusion units or blood cell flux units. LDF has been validated as a method for measuring gastrointestinal microvascular blood flow in animal models[21] and in clinical studies[22]. The LDF probe was placed on a fixed site on the serosa of the ileum and was held in place by a probe holder. Serosal blood flow has previously been shown to correlate well with mucosal flow[23].

Heme oxygenase assay

HO activity in ileal microsomal fractions was measured using a spectrophotometric assay of bilirubin production according to the method previously described by Motterlini *et al.*[24]. Briefly, tissue microsomes were added to the following mixture: $MgCl_2$ (2 mmol/L), phosphate-buffered saline (100 mmol/L, pH 7.4; Sigma, UK), rat liver cytosol as a source of biliverdin reductase (3 mg of total protein), hemin (10 μmol/L; Sigma, UK), glucose-6-phosphate (2 mmol/L; Sigma, UK), glucose-6-phosphate dehydrogenase (0.2 U; Sigma, UK) and NADPH (0.8 mmol/L; Sigma, UK). The reaction was conducted in the dark for 30 min at 37 ℃ and terminated by the addition of chloroform (Sigma, UK). The amount of the extracted bilirubin was calculated by the difference in absorption between 464 and 530 nm and an extinction coefficient of 40 mmol/L/cm was used for bilirubin. The total protein content of the samples was determined using a colorimetric assay according to the manufacturer's instructions (Bio-Rad, UK), and bovine gamma globulin was used as a standard.

Biochemical assays

Blood samples were taken at the end of the experiments from the carotid artery. The blood samples were

Table 1 Systemic hemodynamic parameters in three experimental groups at baseline, 5 min before, at the end of 30 min ischemia and at 1 and 2 h post-reperfusion

Hemodynamic parameters	Baseline	End of ischemia	1 h of reperfusion	2 h of reperfusion	*P* values
Heart rate (BPM)					
Sham	250±5	252±3	240±8	230±10	>0.05
IR	251±2	252±2	220±4	227±12	>0.05
PDTC	252±3	251±3	240±10	232±7	>0.05
SaO_2 (%)					
Sham	98±2	95±2	94±3	95±2	>0.05

PDTC	87±5	107±5[b]	79±4	73±6	<0.01

Values are expressed as mean±SE of six animals in each group. SaO_2: arterial oxygen saturation; MABP: mean arterial blood pressure. [b]P<0.01 *vs* baseline.

centrifuged at 2 000 g for 10 min at room temperature to sediment the erythrocytes. The serum was removed and analyzed on a Hitachi 747 auto-analyzer (Hitachi Ltd, Tokyo, Japan) by using commercially available enzymatic kits (Boehringer Mannheim Ltd, East Sussex, UK) for lactate dehydrogenase (LDH), aspartate aminotransferase (AST) and alanine aminotransferase (ALT).

Histological investigation

At the end of the experiment, tissue samples of ileum were taken, fixed in 10% neutral buffered formalin and embedded in paraffin, and 4-μm-thick sections were cut using a microtome and mounted on slides for hematoxylin and eosin staining. Ileal injury was assessed using a scoring system devised by Chiu *et al*.[25] under light microscopy without the knowledge of study groups.

Data collection and statistical analysis

Data from the pulse oximeter, pressure transducer and LDF were fed into a laptop computer and collected continuously at a sampling rate of 2 Hz. The data were calculated as 1-min averages at baseline and every 30 min till the end of the experiment. All values are expressed as mean±SE. ANOVA and Bonferroni adjustment for multiple comparisons were used unless otherwise stated, where unpaired Student's *t*-test was used for statistical analysis between groups. $P<0.05$ was considered statistically significant.

RESULTS

Systemic hemodynamic parameters

In all the animals in the experimental groups, the HR and the SaO_2 did not change significantly throughout the experiment (Table 1). In the sham group, MABP did not change significantly throughout the experiment. However, during ischemia, there was a transient increase in MABP from the baseline values in both IR (11.97±0.53 to 14.50 ±0.67 KPa, $P<0.01$) and PDTC groups (11.70±0.67 to 14.23±1.33 KPa, $P<0.01$). However, the MABP did not change significantly during the reperfusion period between the three groups (Table 1).

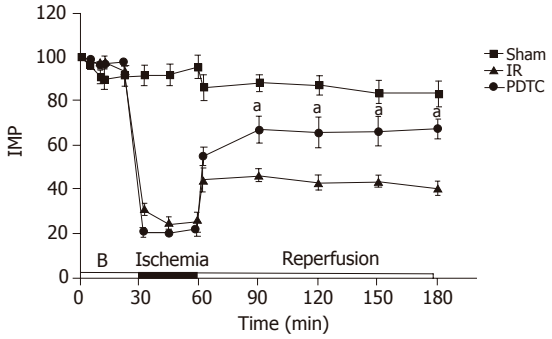

Figure 1 Intestinal microvascular perfusion in (% of baseline) during 30 min of ischemia and 2 h of reperfusion measured by L-DF. Values are expressed as mean±SE of six animals in each group ([a]$P<0.05$ *vs* IR). B: Baseline.

Intestinal microvascular perfusion

IMP did not alter significantly during the course of the experiment in the sham group. There were significant differences between IR and PDTC groups in IMP at 30 min of reperfusion (46.7±2.8% in IR *vs* 67.3±6.2% in PDTC, $P<0.01$). The increase in IMP persisted till the end of the 2-h reperfusion period (42.5±2.8% in IR *vs* 69.1± 4.5% in PDTC, $P<0.01$) (Figure 1).

HO activity assay

The mean HO activity in the sham group was 409.66±62.95 pmol bilirubin/(mg protein·h). PDTC led to a twofold increase in HO activity (2 085.83±158.65) as compared to IR (768.66±103.82) ($P<0.001$, Figure 2).

Biochemical analysis

LDH was significantly reduced in PDTC group (576.3± 98.7) as compared to IR group (1 866.0±267.5) ($P<0.001$, Figure 3). The LDH value in sham group at the end of the reperfusion was 335.23±77.7. Significant changes were not detected in serum indicators of liver function (AST and ALT) in any of the groups (data not shown).

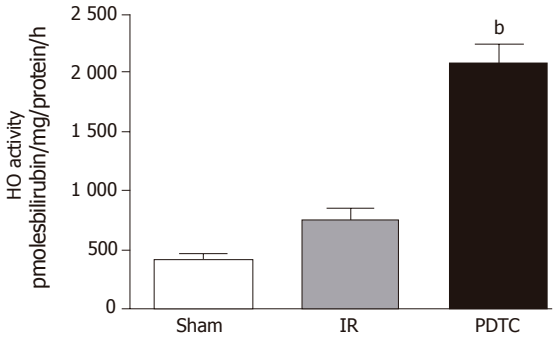

Figure 2 Ileal HO activity in all three experimental groups at the end of 2 h of reperfusion (^bP<0.01 *vs* IR).

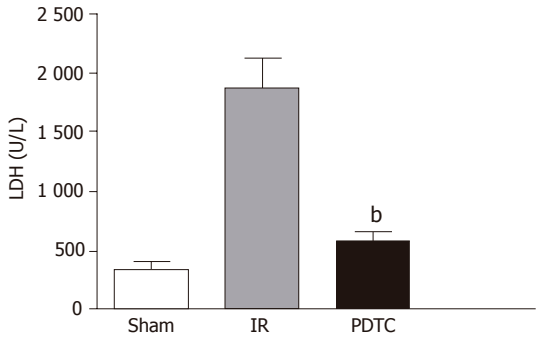

Figure 3 Serum LDH levels (U/L) at the end of 2 h reperfusion period. Values are expressed as mean±SE of six animals in each group. In PDTC group, LDH was significantly lower compared to the IR group (^bP<0.001 *vs* IR).

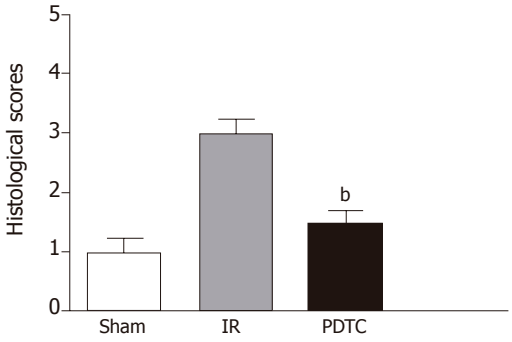

Figure 4 Comparison of histological scores of ileal mucosa between three experimental groups (^bP<0.01 *vs* IR).

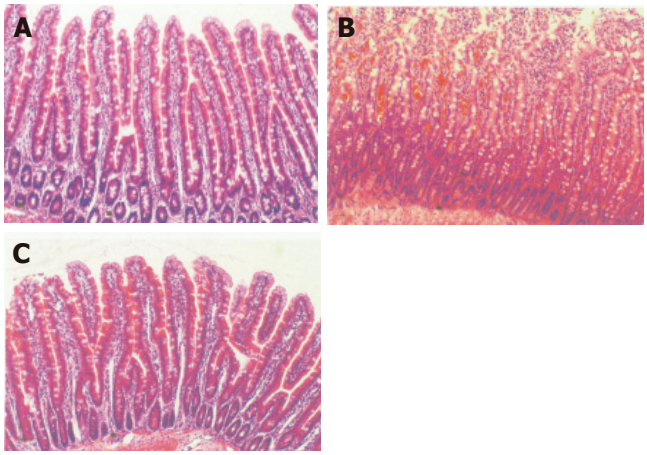

Figure 5 Representative photomicrographs of histological sections of ileum (a) in sham operated animals, (b) subjected to 30-min period of ischemia and 2-h period of reperfusion (IR) and (c) subjected to PDTC+IR (H&E, original magnification ×100).

Histological analysis

IR resulted in an increase in the histological score from a mean of 1.0±0.2 in sham-operated animals to 3±0.2. PDTC treatment improved the histological score significantly to 1.5±0.5 (P<0.01, Figures 4 and 5).

DISCUSSION

The present study clearly showed that PDTC improved the small bowel microvascular perfusion and increased HO activity, while ameliorating IR injury. Serum LDH levels, which is used as a marker for intestinal injury[6], reflected intestinal damage in IR group, whereas PDTC decreased these levels. IR injury resulted in villous and crypt damage, which attributed to hemorrhage and necrosis, whereas PDTC ameliorated this effect. These results suggest that PDTC protects small bowel from IR injury possibly via HO production.

The model of 30-min period of SMA occlusion with 2-h reperfusion was reliable with no procedure-related mortality, suggesting that 30 min of intestinal ischemia is non-lethal but induces substantial intestinal injury. A considerable number of experimental studies have indicated that IR injury of the intestine occurs in a biphasic manner characterized by different time frames and mechanisms: (a) an early phase that immediately follows the ischemia and lasts for 2-3 h; and (b) a late phase which begins 12-24 h from the ischemia and lasts for about 3-4 d[13]. Hence, a period of 2 h of reperfusion following ischemia was chosen to assess the changes in the early phase of reperfusion injury. One of the effective approaches for attenuating IR injury is to induce endogenous antioxidant genes, such as HO-1.

PDTC has been shown to be a potent inducer of HO-1 in many experimental models[16,14]. Whereas increasing evidences suggest that HO-1 induction may mediate cellular protection against oxidant injury in both *in vitro* and *in vivo* models, the role of HO in the intestinal microcirculation is poorly understood. In this study, the effects of PDTC on IR-induced intestinal microcirculatory changes were studied by continuously measuring intestinal blood flow with LDF, which has been used extensively in both animals and human beings[22]. It is non-invasive, safe, and easy to use[23]. This technique allows repeated measurements of blood flow without access to venous or arterial blood. In our study, the comparison of IMP between the groups at different time points showed that PDTC increased the IMP in the initial

30 min of reperfusion, suggesting that the mechanism of pharmacologic preconditioning by PDTC modulating flow in the microcirculation is an immediate phenomenon. Therefore, the effect of PDTC is likely to involve modulation of immediate microcirculatory events at the level of capillaries and postcapillary venules, because these are the primary sites of microcirculatory failure induced by IR injury.

The results of the present study clearly demonstrated that PDTC induced maintenance of adequate microvascular perfusion *in vivo*, and indicated that this protective effect might be mediated through the action of HO, which catalyzes the conversion of heme to CO, biliverdin and free iron. CO and its action on capillary pericytes may play a major role in this protection. It is well known that capillaries are associated abluminally with pericytes which protrude primary cytoplasmic processes running along the axes of the capillaries[26]. From these primary processes, lateral processes arise, which completely encircle the capillaries and form tight connections to the endothelial cells[26]. These pericytes contain muscle cytoskeletal proteins, in particular alpha-smooth muscle actin, which regulate microvascular blood flow[27]. In the liver, Ito cells, which are the sinusoids-associated pericytes, are primarily responsible for CO-mediated regulation in sinusoidal blood flow[28]. In addition, there is an increasing evidence that CO inhibits the aggregation of platelets[29], which could result in highly improved microvascular perfusion because of unhindered flow. Hence, tissue viability increases because of improved nutritional supply and better elimination of toxic residues of oxidative stress. Recently, Nakao *et al*.[30] demonstrated that inhalation of CO ameliorates IR injury in a model of bowel transplantation.

Biliverdin is subjected to further degradation to bilirubin by the cytosolic enzyme biliverdin reductase[31]. It acts as an antioxidant and is capable of scavenging oxygen free radicals that are thought to be primarily responsible for the tissue injury[18]. Iron, the last product of heme breakdown, acts as an oxidant like other transition metals and catalyzes the formation of reactive hydroxyl radicals (OH) by the Haber-Weiss reaction. Typically, the OH · causes biological damage by stimulating the free chain reaction known as lipid peroxidation, in which OH · attacks the fatty acid side chains of the membrane phospholipids and causes organelle and cell disruption[32]. Therefore, it seems to be of paramount importance to eliminate free iron from the tissue in order to maintain the cellular integrity after the stress event. To enable this process, an additional expression of ferritin, the iron-binding protein, is induced simultaneously by HO[33].

In summary, this study has demonstrated that intestinal IR injury induces rapid microcirculatory breakdown with tissue damage. Administration of PDTC maintains the intestinal microvascular blood flow and markedly attenuates the IR injury. PDTC may be of particular value in preventing IR injury to the small intestine and might help to improve the results of small bowel transplantation. Intestinal IR injury is also an obligatory component of numerous surgical procedures. The results of the present study may, therefore, prove beneficial in many areas of clinical research. Further studies are clearly warranted to evaluate the clinical efficacy of PDTC in the prevention of IR injury of the small intestine.

Abstract

AIM: To determine the concentrations of leptin and ghrelin, which have opposite effects on appetite, energy expenditure, and weight control, in the plasma of patients with Crohn's disease (CD), which is often associated with weight loss and malnutrition.

METHODS: Plasma leptin and ghrelin concentrations were determined in 28 outpatients with CD by radioimmunoassay. Age- and sex-matched controls with and without *Helicobacter pylori* (*H pylori*) infection (28 for each) were enrolled in the study. Circulating levels of these hormones were assessed with respect to CD activity, disease localization and medical treatment.

RESULTS: There were no significant differences in ghrelin levels between CD patients and *H pylori*-negative controls. However, circulating ghrelin levels were significantly lower in *H pylori*-infected subjects than in CD patients and uninfected controls. Plasma leptin levels were comparable among the groups. Localization and medication profile had no significant impact on circulating ghrelin and leptin levels.

CONCLUSION: Apart from *H pylori* infection, CD itself has no significant influence on circulating ghrelin and leptin levels in the outpatients who were mostly in inactive state.

Key words: Crohn's disease; Ghrelin; Leptin; *Helicobacter pylori*

INTRODUCTION

Crohn's disease (CD) is characterized by a relapsing inflammatory process throughout the digestive tract[1,2]. CD is frequently accompanied with malnutrition and weight loss[1,2]. Possible explanations for these complications include malabsorption of nutrients, intestinal losses during inflammatory process, and anorexia[3]. However, the exact etiology is not completely understood.

Leptin is mainly synthesized by the adipose tissue and plays a crucial role in the homeostasis of the body weight by reducing appetite and increasing energy expenditure[4,5]. Contrary to the initial reports, leptin production is not restricted to adipocytes. It is also detected in the human placenta, muscles, and gastric chief cells[6-10].

Ghrelin is a novel endogenous ligand for growth hormone secretagogue receptor[11,12]. It was originally isolated from the stomach and has been subsequently identified in various tissues including the small and large intestine[11,12]. In addition to its potent growth hormone-releasing activity, ghrelin displays metabolic effects opposed to those of leptin[11-13]. It stimulates food intake, enhances the use of carbohydrates and reduces fat utilization. In fact, circulating ghrelin levels are decreased in obesity and increased in anorexia nervosa or cachexia[11-14].

At present, no data on the interplay of ghrelin and leptin in CD are available. This is the first report to assess the circulating ghrelin and leptin concentrations in patients with CD simultaneously.

MATERIALS AND METHODS

Patients

Twenty-eight consecutive outpatients with CD were enrolled in the study between October 2002 and

Table 1 Plasma leptin and ghrelin levels in patients with CD and controls with or without *H pylori* infection (mean±SD)

	CD	Controls	
		H pylori-infected	*H pylori*-uninfected
Body mass index (kg/m^2)	20.5±0.4 (16.2-29.9)[1]	21.3±0.8 (16.4-28.5)	20.8±0.5 (16.4-26.7)
Plasma ghrelin levels (fmol/mL)	195.7±1.5 (45.7-368.7)	143.4±7.1 (53.2-481.0)	182.4±1.4 (75.7-322.2)
Plasma leptin levels (ng/mL)	3.8±0.4 (0.0-15.0)	4.3±0.6 (0.8-8.4)	3.8±0.6 (0.0-10.8)

[1]Mean±SD (range).

Table 2 Plasma leptin and ghrelin levels in terms of various parameters (mean±SD)

	Ghrelin (fmol/mL)	Leptin (ng/mL)	Body mass index
Disease activity			
Active (*n* = 5)	220.6±98.8	4.7±4.1	19.9±4.5
Inactive (*n* = 23)	202.3±86.4	3.6±2.4	20.6±2.7
Disease location			
Small intestine (*n* = 3)	186.3±68.6	2.8±2.3	18.5±1.6
Large intestine (*n* = 10)	246.8±83.3	4.2±3.3	20.9±2.4
Small and large intestine (*n* = 15)	186.8±92.4	4.1±3.1	20.5±4.0
Anal lesion			
Present (*n* = 7)	213.4±85.1	3.4±2.5	20.1±4.8
Absent (*n* = 21)	206.5±92.4	4.1±3.2	20.5±2.6
Medical treatment			
5-Aminosalicylates (*n* = 16)	185.5±86.5	2.8±1.5	20.1±2.4
5-Aminosalicylates and elementary diet (*n* = 7)	229.5±98.9	4.8±3.6	20.1±5.2
No medications (*n* = 5)	243.4±76.8	5.7±4.8	21.8±3.1
Helicobacter pylori status			
Positive (*n* = 5)	265.8±109.8	3.5±2.6	20.2±3.4
Negative (*n* = 23)	195.7±81.5	5.5±3.9	21.8±0.1

December 2004. The study was approved by Nagasaki University Human Ethics Committee. All samples were obtained with written informed consent of the patients prior to their inclusion, in accordance with the Helsinki Declaration. A diagnosis of CD is based on the generally accepted clinical, radiographic, endoscopic and histologic criteria[1,2]. The exclusion criteria were age <18 or >80 years, pregnancy, body mass index (BMI) >30 kg/m^2, diabetes mellitus, systemic infection, thyroid and liver diseases, renal impairment, use of medications against *H pylori* during the preceding 3 mo, alcohol abuse, drug addiction, and long-term corticosteroid or nonsteroidal anti-inflammatory drug use. None underwent gastrointestinal surgery. They included 16 men and 12 women, aged between 18 and 56 years (mean, 32 years). According to the CD activity index (>150), 5 patients suffered from active CD. As for disease localization, the disease process was limited to the small bowel in 3 patients, to the colon in 10 and affected both regions in 15. Seven had anal lesions and none had upper gastrointestinal involvement. Of those, 16 were treated with 5-aminosalicylates, 7 with 5-aminosalicylates and elementary diet, and 5 received no medications.

Since ghrelin is primarily produced by X/A-like cells in the gastric fundus[11,12], its production and release may be affected by inflammatory and atrophic events associated with *H pylori* infection[15,16]. Thus, *H pylori* status was assessed, as described below.

Age- and sex-matched 23 *H pylori*-negative healthy subjects served as controls. Moreover, age- and sex-matched 23 *H pylori*-infected patients with non-ulcer dyspepsia were enrolled in the study.

Plasma leptin and ghrelin concentrations

Blood samples were taken between 9 and 11 a.m. after an overnight fast, transferred into chilled tubes containing eth ylenediaminetetraacetic acid-2Na and aprotinin, stored on ice during collection and centrifuged. Then, the plasma was separated, and stored at -80 ℃ until assay. Plasma ghrelin concentrations were measured in-house in duplicate by radioimmunoassay (RIA), as described previously[17]. This assay system employs a rabbit polyclonal antibody against the C-terminal fragment of human ghrelin. Plasma leptin concentrations were measured in duplicate by commercial RIA kit (Linco Research Co., St. Charles, USA), based on the protocol provided by the manufacturer.

Detection of H pylori infection

H pylori status was assessed by anti-*H pylori* immunoglobulin G antibody (HELp TEST, an enzyme linked immunosorbent assay kit, AMRAD Co., Melbourne, Australia) using the stored plasma and ^{13}C-urea breath test (UBiT, Otsuka Pharmaceutical Co., Tokyo, Japan).

Statistical analysis

Statistical analyses were performed using Fisher's exact, χ^2, Student's *t*, Mann-Whitney *U*, Kruskal-Wallis, Spearman's rank, and Wilcoxon signed ranks tests, as appropriate. $P<0.05$ was considered statistically significant. Data were expressed as mean±SD.

RESULTS

There were no significant differences in ghrelin levels between CD patients and *H pylori*-negative controls (Table 1). However, circulating ghrelin levels were significantly lower in *H pylori*-infected subjects than in CD patients ($P<0.01$, Table 1) and controls negative for the infection ($P<0.05$, Table 1). On the other hand, circulating leptin levels were comparable between the groups (Table 1).

Other parameters such as disease activity, localization and medication profile and *H pylori* status had no significant impact on circulating ghrelin and leptin levels (Table 2).

There was a significant positive correlation between plasma leptin levels and BMI ($r = 0.61$, $P<0.005$). Plasma ghrelin concentrations tended to decrease with increase in BMI, *albeit* insignificantly. There was no significant correlation between circulating ghrelin and leptin levels.

DISCUSSION

Our results suggest that circulating ghrelin levels are not altered in CD patients who mainly consisted of those with the inactive disease. In our study, plasma concentrations of leptin, the opposing metabolic counterpart of ghrelin[10-13], were not affected by the disease. In addition, there were no significant association of such factors as localization and medication profile with circulating ghrelin and leptin. These findings suggest that alterations in these hormones involved in appetite and energy metabolism are unlikely to mediate nutrition state in CD. However, these results must be interpreted within the context of the limitations in our study. First, the sample size was relatively small. Second, severe patients with wasting symptoms or malnutrition were not enrolled in this study, as it was in the outpatient-based setting. Although our series were not associated with upper gastrointestinal lesions, where ghrelin is primarily produced[10,17], such involvement might have an impact on the circulating ghrelin levels.

Murch *et al*.[18] demonstrated that suppression of growth velocity in children with CD correlates with circulating tumor necrosis factor (TNF) alpha concentrations. In cachectic state, a positive correlation has been found between ghrelin and TNF alpha circulating levels[19]. On the other hand, there is a significant association between serum levels of leptin and TNF receptor 1[20]. We did not measure TNF alpha and TNF receptor 1 levels in the present series of CD, but accumulating evidence indicates that the TNF system is activated in CD[1,2].

Recently, Suzuki *et al*.[15] demonstrated that *H pylori* infection modifies gastric and plasma ghrelin dynamics in Mongolian gerbils. There are contradictory reports on the relationship between *H pylori* and ghrelin. A Turkish study reported that *H pylori* has no effect on plasma ghrelin levels[21], whereas a British study demonstrated that circulating ghrelin increases following the cure of *H pylori* infection[16]. In our series, the principal determinant of circulating ghrelin might be the *H pylori* status. The exact reason for such a discrepancy is not clear, but the following factors should be considered: differences in the study populations of diverse races, nutrient status and dietary habits, small sample size and inadequate assessment of *H pylori* status, i.e., only by histology, leading to underestimation of infection in their series[21]. In turn, circulating leptin concentrations are not associated with *H pylori* status, consistent with previous reports[22,23]. On the other hand, plasma leptin concentrations significantly correlate with BMI, as the primary contributor of circulating leptin is exclusively the adipose tissue[4,5].

In conclusion, CD itself has no significant influence on the circulating levels of leptin and ghrelin. Further evaluation of a larger population with the active disease or response to medical treatment including parenteral and enteric nutrition and infliximab is warranted. Plasma ghrelin dynamics may be affected by *H pylori* status in human beings.

Abstract

AIM: To assess the accuracy of a model in diagnosing severe fibrosis/cirrhosis in chronic hepatitis C virus (HCV) infection.

METHODS: The model, based on the sequential combination of the Bonacini score (BS: ALT/AST ratio, platelet count and INR) and ultrasonography liver surface characteristics, was applied to 176 patients with chronic HCV infection. Assuming a pre-test probability of 35%, the model defined four levels of post-test probability of severe fibrosis/cirrhosis: <10% (low), 10-74% (not diagnostic), 75-90% (high) and >90% (almost absolute). The predicted probabilities were compared with the observed patients' distribution according to the histology (METAVIR).

RESULTS: Severe fibrosis/cirrhosis was found in 67 patients (38%). The model discriminated patients in three comparable groups: 34% with a very high (>90%) or low (<10%) probability of severe fibrosis, 33% with a probability ranging from 75% to 90%, and 33% with an uncertain diagnosis (i.e., a probability ranging from 10% to 74%). The observed frequency of severe fibrosis/cirrhosis was within the predefined ranges.

CONCLUSION: The model can correctly identify 67% of patients with a high (>75%) or low (<10%) probability of cirrhosis, leaving only 33% of the patients still requiring liver biopsy.

Key words: Liver fibrosis; Ultrasonography; Bonacini score; Liver biopsy; Hepatitis C

INTRODUCTION

Hepatitis C virus (HCV) infection is a major cause of chronic liver disease worldwide: nearly 80% of HCV-infected patients develop chronic infection, and about 20% progress to cirrhosis[1]. Liver histology is currently considered as the "reference standard" for evaluating hepatic damage on the basis of the degree of necrotic inflammatory activity and fibrosis, with the latter having prognostic significance and playing a major role in therapeutic decision making[2,3].

However, liver biopsy is an invasive procedure with mild and severe complications of 20% and 0.5%, respectively[4,5]. Furthermore, its sensitivity in diagnosing liver cirrhosis is not absolute and the rate of false negative results is approximately 30%[6]. In addition, as it has been well evidenced by the recent studies, an adequate liver specimen should be at least 2.5 cm long[7] and 1.4 mm wide[8] including at least 6-8 portal tracts[9]. This has recently led various groups to investigate the non-invasive methods of detecting severe fibrosis/cirrhosis, including only biochemical (ALT, AST, GGT) tests[10-14] or in combination with hematological (platelet count) tests[15], test panels[16-25], serum "markers" of fibrosis (such as hyaluronic acid or procollagen peptides)[26-30] and ultrasonographic parameters (e.g., liver surface nodularity (LSN), portal blood flow)[31-34], but none of which have proved to be capable of avoiding liver biopsy.

The aim of this prospective study was to evaluate the accuracy of a model based on the sequential combination of a set of simple biochemical tests (Bonacini score, BS)[19,20] and liver surface ultrasound (US) examination[32] in diagnosing severe fibrosis/cirrhosis in a large series of consecutive patients with chronic HCV infection undergoing liver biopsy.

MATERIALS AND METHODS

All anti-HCV positive patients (EIA III, Abbott Laboratories, Chicago, IL, USA) with detectable HCV-RNA serum levels (Amplicor HCV kit, Roche, Molecular Systems, Basel, Switzerland) were evaluated for enrollment between September 2001 and June 2004.

The presence of decompensated liver disease (i.e., portosystemic encephalopathy, jaundice or ascites detected by means of US) and or an absolute contraindication to liver biopsy (PLT <60 000/mm^3, PT <60%) excluded patients from the study, whereas patients with an increase of ≥1.5 UNL in the serum alanine-aminotransferase (ALT) levels recorded twice in the previous 6 months, were included in the study, whose protocol was approved by the pertinent ethics committee after having obtained their written informed consent. Socio-demographic and clinical data were recorded as those on past and/or current alcohol intake for which a semi-quantitative questionnaire with three pre-defined levels of daily consumption (<30, 30-80 and >80 g) was used. At the time of liver biopsy, the laboratory data included AST, ALT (IU/L r.v. <40), platelet count (10^6/μL r.v. 130 000-400 000), the international normalized ratio (INR 0.8-1.2), level of albumin (g/dL r.v. 3.5-5.0), total bilirubin (mg/dL r.v. 0.3-1.0) and hemoglobin (g/dL r.v. 14-18 for men and 12-16 for women), as well as HCV genotyping by means of restriction fragment length polymorphism after amplification of the 5' non-coding region of the HCV genome[35]. As detailed in Table 1, the "cirrhosis discriminant score" (range 0-11) of each patient was calculated according to the method of Bonacini *et al.*[19], based on ALT/AST ratio, platelet count and INR. After an overnight fast, a US liver scan was performed using an ATL HDI 5000 equipment (Advanced Technology Laboratories, Bothell, WA, USA) and both 3.5 and a 5-12 MHz transducer by one of three gastroenterologists (AC, SM or MA) blinded to the clinical, biochemical and histologic data. A 5-12 MHz transducer was used to obtain multiple scans of the outer 2-3 cm of the liver parenchyma and of both lobes. LSN was considered positive when the liver surface appeared as a dotted or an irregular line and/or the liver parenchyma was not homogeneous, with areas of different echogenicity, reflecting an underlying nodularity. The interobserver agreement for this sign was calculated according to K statistics.

A US-guided transcostal or subcostal liver biopsy was performed (by AC or MF) using an 18-gauge needle (Biomol Hospital Service, Pomezia, Rome, Italy). We considered acceptable only specimens ⩾2.0 cm long including >12 portal tracts, that were fixed in formalin and stained with hematoxylin-eosin, silver impregnation for reticulin, and Masson's trichrome or picrosirius red for collagen. In case of inadequacy of the sample, a second biopsy was obtained.

The specimens evaluated by the same pathologist (VM) unaware of the patients' characteristics were staged according to METAVIR scoring system[36], where F0 indicates the lack of fibrosis, F1 corresponds to portal fibrosis without septa, F2 to the presence of few septa, F3 and F4 to the finding of numerous septa without or with cirrhosis, respectively. Histologic findings were considered as the reference standard for the presence and degree of fibrosis.

Table 1 Determinants of Bonacini score

Laboratory	Score						
parameters	0	1	2	3	4	5	6
INR	<1.1	1.1-1.4	>1.4				
ALT/AST ratio	>1.7	1.7-1.2	1.19-0.6	<0.6			
PLT ×1 000 /mm^3	>340	340-280	279-220	219-160	159-100	99-40	<40

Statistical analysis

The pre-test probability of severe fibrosis/cirrhosis (i.e., a staging score 3-4) was estimated to be about 35% on the basis of recent data from comparable series[2,32,37-39]. A predictive model was obtained by the sequential application of the BS and US liver surface examination, which could obtain the post-test probability of severe fibrosis/cirrhosis. As the BS and US signs of LSN could be considered conditionally independent, the probability of severe fibrosis/cirrhosis obtained by calculating the BS has been considered as the pre-test probability before the US examination. The post-test probabilities were calculated on the basis of post-test odds as previously described[40,41]. The values of sensitivity, specificity, positive and negative likelihood ratios (LR+ and LR-) of both BS and US in diagnosing severe fibrosis have been previously defined[19,32].

In detail, three possibilities had to be taken into account. Firstly, for a staging score 0-2, a BS ⩽3 had a sensitivity of 58% and a specificity of 85%, accounting for a LR+ of 4. Accordingly, in our model in the presence of a BS ⩽3, the probability of stage 0-2 increased from a pre-test one of 65% to 88%. Secondly, the sensitivity and specificity for severe fibrosis in the presence of a BS of 4-7 were 50%, making it impossible to modify the 35% pre-test probability of severe fibrosis/cirrhosis on the basis of a LR+ and a LR- of about one. Thirdly, the specificity of 100% for a BS >7 led to an almost absolute post-test probability of staging score 3-4, with a LR+ higher than 100. As far as the US finding of LSN was concerned, an inter-observer variability of 0.80 was reported. Our own previous data[32] demonstrated a sensitivity of 54% and a specificity of 95% for a staging score 3-4, with a LR+ and a LR- of 11.6 and 0.5, respectively. By combining the BS and the US signs of LSN, five groups of patients (I-V) were defined (Figure 1) with different post-test probability of severe fibrosis/cirrhosis. In the last group, with BS ≥7 the post-test probability of a staging score of 3-4 was close to 100% regardless of the US results. Finally, as detailed in Figure 1, to test the predictive accuracy and clinical usefulness of the model, four *clinically acceptable* ranges of post-test probability of severe fibrosis/cirrhosis were predefined based on BS and US findings*: low probability* (<10%), *not diagnostic* (10-74%), *high probability* (75-90%) and *almost absolute probability* (>90%).

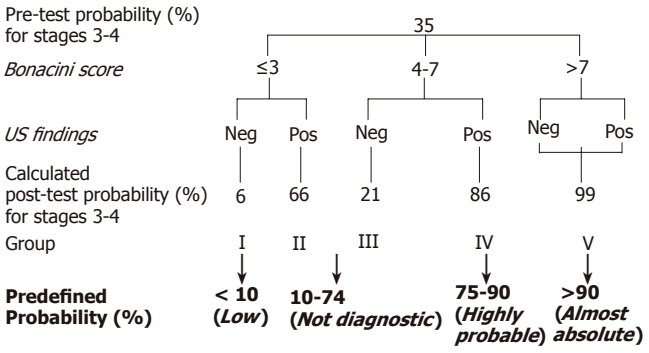

Figure 1 Post-test probability of severe fibrosis/cirrhosis calculated on the basis of both BS and US findings (starting from the pre-test value of 35%), and ranges of post-test probability for severe fibrosis/cirrhosis predefined as "clinically relevant" (in bold).

Bilirubin (mg/dL)			0.9±0.2

RESULTS

During the recruitment period, 1 089 patients were investigated for liver disease, and 363 were chronically infected with HCV. Of them, 184 were excluded for the refusal of liver biopsy (#11) because of already established cirrhosis with Child-Pugh score >5 (#67), or because of normal or slightly elevated ALT levels (<1.5 times the upper normal limit) or uncompleted ALT data (less than six distinct determinations) (#106). The remaining 179 fulfilled the inclusion criteria. Based on the inadequate US findings, three were excluded accounting for an overall recruitment of 176 patients, whose characteristics are detailed in Table 2. The inter-observer agreement for the detection of the LSN sign was 0.77. The average length of liver specimens was 4.1±0.4 cm and in 18 cases a second liver sample was obtained because of the inadequacy of the first one. At liver biopsy, well tolerated in all the cases, 67 patients (38%) had severe fibrosis (#52) or cirrhosis (#15, all in Child's A class). Of the remaining 109 (62%), fibrosis was absent in 6, mild (score 1) in 40 and moderate (score 2) in 63. LSN was present in 9 out of the 109 (8%) patients with a fibrosis score of 0-2 and in 40 out of 67 (60%) with F 3-4 with a sensitivity, specificity, LR+ and LR- of 60%, 92% and 7.5 and 0.5, respectively. Patients' distribution according to the BS and LSN, and corresponding observed frequency (%) of severe fibrosis/cirrhosis (stage 3-4) *vs* expected post-test probability calculated by the model, are shown in Table 3. Overall, the diagnostic accuracy of the model was 86.5% in groups I, IV, and V, accounting for 67% of the patients. Sixteen of one hundred and nineteen patients were incorrectly defined (1 in group I with fibrosis stage ⩾3, 15 in group IV with fibrosis stage <3). In groups II and III (33% of the total), the model did not show any predictive role and did not significantly modify the pre-test probability of severe fibrosis/cirrhosis.

DISCUSSION

In this prospective study, we have evaluated the accuracy of a non-invasive predictive model, consisting of the sequential combination of laboratory data score (BS) and US finding of a nodular liver surface, in detecting severe liver fibrosis or cirrhosis in patients with chronic hepatitis C. In clinical practice, it is easy to use the two elements with their operative characteristics individually validated in previous studies[19,20,32]. The BS is based on simple and widely available laboratory tests (ALT, AST, INR and platelet count) that assure its repeatability, and LSN can be easily detected using commercially available US equipment. Previous series using platelet count or ALT and AST level or BS or US can precisely predict the presence or absence of fibrosis but with a low discriminating power; thus, few patients have a very low or high probability of fibrosis, and most of them are in the gray zone of uncertainty[19,20,32]. On the contrary, the sequential model, which is applicable to the vast majority of enrolled patients (98%, because the US examination was technically inadequate in three cases), has been proved to have an adequate discriminating power and an accurate calibration. Its discriminating power is demonstrated by the fact that we were able to divide the patients into three comparable groups: 34% with a very

high (>90%) or low (<10%) probability of severe fibrosis, 33% with a probability ranging between 75% and 90%, and 33% with an uncertain diagnosis (i.e., with a fibrosis score 3-4 probability between 10% and 74%). The precise calibration of the model is demonstrated by the fact that the observed frequency of severe fibrosis/cirrhosis was within the predefined ranges for each group (Table 3).

The validity of the model is further supported by the finding that the 38% frequency of severe fibrosis/cirrhosis in the study population was similar to the theoretical value of 35% assumed by considering series of patients with comparable characteristics, represented by a $\geqslant$1.5 times increase in ALT levels recorded twice during a period of 6 months or more[2,32,37-39].

The operative characteristics of US are slightly different from those indicated by our own recent data[32], which were used for the model. However, the variations in LR+ and LR- remained within the broad confidence intervals of the original estimates and did not critically challenge the calibration of the model. Further studies are needed to assess the generalizability of the model, i.e. its reproducibility and transportability, for which independent validations are advisable.

Although our simple model could detect the presence or absence of severe fibrosis in nearly two-thirds of the patients, thus avoiding the need for liver biopsy, some limitations of the study require further discussion. Because of its intrinsic characteristics, the model was unable to detect moderate (stage 2) fibrosis, which together with grading is relevant in therapeutic decision making. Furthermore, the study seemed to underestimate the diagnostic role of liver biopsy, which was used not only to define staging and grading, but also to detect concomitant pathologies. However, the latter role which is already questionable in patients with liver disease of uncertain etiology[42] was irrelevant in our series of patients with chronic HCV infection. Conversely, liver biopsy still has some limitations in clinical practice, such as the difficulty in obtaining a liver sample of adequate size, as recently reported by some studies[7,8], and which can be considered as representative of the whole liver, given the patchy distribution of liver fibrosis in chronic hepatitis C. The above limitations in our opinion are a major issue in evaluating the diagnostic accuracy of non invasive diagnostic tests compared to liver biopsy. In fact in these types of studies, the major drawback is the imperfection of the reference standard itself, which can significantly affect the estimates of the operative characteristics of the test under investigation. To reduce the possible sample size effect, in the present study we obtained all the liver specimens >3 cm with >12 portal tracts from patients.

Previous studies assessing the individual role of BS and US findings of LSN in detecting severe fibrosis have found that they are inaccurate because their low power of discrimination means that a large proportion of patients still require liver biopsy[19,20,32]. It has recently been shown that the use of laboratory tests[10-16] and specific fibrosis markers, such as hyaluronic acid[26-30], is highly accurate in diagnosing cirrhosis. However, the considerable differences in the study design and the particularly high prevalence of symptomatic cirrhosis sometimes make it difficult to compare these data to our own. It has also recently been shown that relatively complex laboratory scores are accurate in discriminating stage 0-1 from stage 2-4, but fail to confirm severe fibrosis[17-25] although the aim of these studies was to detect patients with minimal or absent fibrosis with stage 3-4 found in only 15% (*vs* 37% in our series), possibly because they included patients with normal ALT levels and a younger age.

Recently, preliminary data from patients with chronic HCV liver disease[43] suggest a promising role of fibroscan [one-dimensional (1-D) transient elastography] in predicting the degree of liver fibrosis with a good accuracy in discriminating stage 0-2 from 3-4, and a LR+ and LR- of 5.7 and 0.16, respectively, similar to those observed in the present series for the US sign of LSN (LR+ and LR- of 7.5 and 0.5, respectively).

In conclusion, our data suggest that the use of liver biopsy to detect severe fibrosis can be avoided in about two-thirds of patients. Furthermore, the model can also be used in patients aged more than 65 years for whom liver biopsy could be questioned.

CONCLUSION: There is no evidence that the SNPs predispose to the need for IPAA surgery. The significant increase of the combined carriership of the *CD14* -260T and *TLR9* -1237C alleles in the chronic relapsing pouchitis group suggests that these markers identify a subgroup of IPAA patients with a risk of developing chronic or refractory pouchitis.

Key words: Pouchitis; Innate immunity; Single nucleotide polymorphisms; *CD14*; *TLR9*

Abstract

AIM: To investigate the single nucleotide polymorphisms (SNPs) in genes involved in bacterial recognition and the susceptibility to pouchitis or pouchitis severity.

METHODS: Analyses of *CD14* -260C>T, *CARD15/NOD2* 3020insC, Toll-like receptor (*TLR*)4 +896A>G, *TLR9* -1237T>C, *TLR9*+2848G>A, and *IRAKM* + 22148G>A SNPs were performed in 157 ileal-pouch anal anastomosis (IPAA) patients (79 patients who did not develop pouchitis, 43 infrequent pouchitis patients, 35 chronic relapsing pouchitis patients) and 224 Italian Caucasian healthy controls.

RESULTS: No significant differences were found in SNP frequencies between controls and IPAA patients. However, a significant difference in carriership frequency of the *TLR9*-1237C allele was found between the infrequent pouchitis and chronic relapsing pouchitis groups [$P = 0.028$, odd's ratio (OR) = 3.2, 95%CI = 1.2-8.6]. This allele uniquely represented a 4-locus *TLR9* haplotype comprising both studied *TLR9* SNPs in Caucasians. Carrier trait analysis revealed an enhanced combined carriership of the alleles *TLR9* -1237C and *CD14* -260T in the chronic relapsing pouchitis and infrequent pouchitis group ($P = 0.018$, OR = 4.1, 95%CI = 1.4 -12.3).

INTRODUCTION

Patients with ulcerative colitis may need surgery for their disease and proctocolectomy with ileal-pouch anal anastomosis (IPAA) is the surgical procedure of choice for the management of these patients[1,2]. Most patients undergoing IPAA for severe colitis or chronic continuous disease achieve good functional results, but some patients develop pouchitis, a non-specific idiopathic inflammation of the ileal reservoir. Frequency rates of pouchitis are highly variable, ranging 10-59% depending on the length of follow-up and the diagnostic criteria used[3]. Though the origin of pouchitis remains unknown, genetic and immunological factors are likely to be involved in addition to ileal mucosa that needs to adapt to its new role as a reservoir[4]. This is illustrated by the fact that pouchitis occurs almost exclusively in patients with IPAA for ulcerative colitis and not in patients with IPAA for familial adenomatous polyposis, a hereditary non-inflammatory disease of the colon with high risk of developing colon cancer. An important role of luminal bacteria in the development of pouchitis is underscored by various reports on bacterial overgrowth and dysbiosis in pouchitis[5] and is further confirmed by the efficacy of antibiotic and probiotic therapy[6,7].

Pattern recognition receptors (PRRs), including Toll-like receptors (TLRs), are essential components of the innate

immune system as recognition of microbial products occurs via PRRs that are expressed by innate effector cells. Microbial recognition results in a rapid and efficient immune response against invading microorganisms[8].

Given the role of luminal bacteria in driving the inflammatory response in pouchitis, identification and functional characterization of polymorphisms in innate immunity genes may provide insight in a possible genetically determined susceptibility to pouchitis and/or chronic relapsing pouchitis[9].

CD14 is part of the endotoxin/lipopolysaccharide (LPS) receptor complex[8] and is important in conjunction with TLR4 and with TLR2[10] in the recognition of LPS, a membrane glycolipid on Gram-negative bacteria. CD14 may also recognize cell membrane components of Gram-positive mycobacteria and viruses[11-15]. CD14 exists in a membrane form on monocytes and neutrophils and in a soluble form in serum[16-18]. The SNP at position -260C>T (also known as *CD14*-159C>T) in the promoter region of the *CD14* gene (located on chromosome 5q31) is associated with enhanced transcriptional activity[19] and significantly higher CD14 serum levels[20]. Increased expression of CD14 in macrophages has been found in inflammatory bowel disease (IBD)[21]. An association of the *CD14*-260C>T gene polymorphism with IBD[22,23] and atherosclerosis[24] has been described. Genetically determined variation in CD14 serum levels may have functional consequences given the ability of soluble CD14 to confer pathogen responsiveness to cells such as intestinal, epithelial and endothelial cells that do not express CD14 on their membranes[25].

The *TLR4* gene is located on chromosome 9q32-q33. The *TLR4*+896A>G SNP affects the leucine-rich repeat domain of TLR4 and is associated with hyporesponsiveness to LPS[26] with increased susceptibility to severe bacterial infections and IBD[27] and may predispose to septic shock with Gram-negative microorganisms[28,29].

TLR9 is required for the recognition of CpG motifs, short sequences of unmethylated DNA predominantly present in bacterial DNA. CpG motifs have immunostimulatory activity by inducing dendritic cell maturation, B-cell proliferation and production of cytokines, including interleukin-6 (IL-6) and interleukin-12 (IL-12)[30,31]. TLR9 signaling has been shown to mediate the resolution of intestinal inflammation in experimental colitis[32], suggesting that the release of bacterial DNA from the microflora might favor immune homeostasis. The promoter *TLR9* -1237T>C SNP located on chromosome 3p21.3 is associated with susceptibility to asthma in European Americans, but not in Hispanic or African Americans[33] and the marker D3S1076 in this region shows association with IBD in a classical TDT test[42]. Török and colleagues[34] studied the *TLR9* -1237T>C and *TLR9*+2848 G>A SNPs in German patients with Crohn's disease, ulcerative colitis and healthy blood controls and found that the allele *TLR9* -1237C carrier status is associated with Crohn's disease compared to controls. *TLR9* +2848 G>A allele frequencies are not different between the study groups.

CARD15/NOD2 is a cytoplasmatic bacterial PRR expressed in monocytes and intestinal epithelial cells and mediates response against muramyl dipeptide derived from peptidoglycan[35,36]. The *CARD15/NOD2* gene is located on chromosome 16q12. Three major polymorphisms in this gene (R702W, G908R, and L1007 frameshift mutation) are associated with susceptibility to Crohn's disease, possibly as a result of a defective response against muramyl dipeptide derived from peptidoglycan[37]. Recently, an increased frequency of the L1007 frameshift mutation has been observed in Italian patients with ulcerative colitis when compared to controls[38].

The intracellular domains of TLRs are homologous to the interleukin-1 receptor (IL-1R) type I intracellular domain and use a common pathway of intracellular signaling with shared components including the protein kinase IL-1R-associated kinase1 (IRAK1) and IRAK-M, as a negative regulator of TLR signaling. Cytokine production increases in IRAK-M-/- macrophages after TLR/IL-1 stimulation and bacterial challenge, while endotoxin tolerance reduces in these cells. Furthermore, IRAK-M-/- mice have increased inflammatory responses to bacterial infection and develop intestinal inflammation. These data suggest that IRAK-M has a regulatory function in TLR/IL-1R signaling and innate immune homeostasis[39]. The *IRAKM* (or *IRAK3*) gene is located at chromosome 12q14.2 within the IBD2 region associated with ulcerative colitis[40,41]. Genetic variation in the *IRAKM* gene may be involved in the development of chronic intestinal inflammation. For this reason, we chose to analyze a non-synonymous SNP in exon 5 resulting in an Ile/Val substitution.

A candidate gene approach, based on the determination of frequencies of functional SNPs, can be used to investigate the relevance of genes to the disease susceptibility and severity. Carrier trait analysis investigates combinations of SNPs and allows studying the implication of different SNPs in disease susceptibility and severity as a result of their synergistic action.

The aim of this study was whether SNPs in innate immunity genes could contribute to the susceptibility to pouchitis and/or severity of pouchitis. We chose candidate genes of *CD14, TLR4, TLR9, NOD2/CARD15*, and *IRAKM* for their involvement in bacterial recognition and intracellular signaling pathways.

MATERIALS AND METHODS

Patients

One hundred and fifty-seven unrelated patients with IPAA for ulcerative colitis and 224 healthy blood donors were studied. All individuals were Italian Caucasians. Consent was obtained and the local ethics committee approved the protocol. Their demographic and clinical information is described in Table 1. IPAA patients were subdivided into three test groups according to the pouchitis pattern. One group consisted of IPAA patients who had never developed pouchitis, another group consisted of IPAA patients who had up to two episodes of pouchitis during IPAA (infrequent pouchitis) and third group consisted of IPAA patients who developed three or more episodes of

pouchitis (chronic relapsing pouchitis).

DNA isolation

Venous blood (5-10 mL) was drawn and genomic DNA was isolated using standard protocols. Polymorphisms of the *CD14, TLR4, TLR9, CARD15/NOD2*, and *IRAKM* genes in these three groups were analyzed. Genomic DNA (5-100 ng) was used for each genotyping.

Analysis of gene polymorphisms

Polymerase chain reaction (PCR) for RFLP analyses was performed on a thermal cycler GeneAmp 9700 (Perkin-Elmer Cetus, Norwalk, CT, USA). Digested fragments were analyzed on a 4% agarose gel except for the *IRAKM* SNP analyzed on a 2% agarose gel and visualized with an UV-illuminator after ethidium bromide staining. SNPs were analyzed with the TaqMan assay (Applied Biosystems, Foster City, CA, USA). MGB TaqMan probes and primer pairs were designed with Primer Express software (version 2.0). TaqMan thermocycling consisted of an initial step at 50 ℃ for 2 min and denaturation at 95 ℃ for 10 min followed by 40 cycles of denaturation at 95 ℃ for 15 s and annealing/extension at 60 ℃ for 1 min. We used the ABI Prism 7000 sequence detector (Applied Biosystems) for data acquisition.

Genotyping

CD14-260C>T genotyping (NCBI SNP CLUSTER ID: rs2569190) was performed by PCR. Primers used were: forward primer 5'-TCA CCT CCC CAC CTC TCT T-3' and reverse primer 5'-CCT GCA GAA TCC TTC CTG TT-3'. The PCR conditions were initial denaturation at 95 ℃ for 5 min, followed by 35 cycles of denaturation at 95 ℃ for 30 s, annealing at 59 ℃ for 30 s, extension at 72 ℃ for 1 min and a final extension at 72 ℃ for 5 min followed by cooling to 4 ℃. The 107-bp amplicons were digested overnight with *HaeIII* (New England Biolabs, UK). Digestion resulted in two fragments of 83 and 24 bp (C allele) or 107 bp (T allele), respectively.

Genotyping of the *TLR4*+896 A>G SNP (NCBI SNP CLUSTER ID: rs4986790) was performed with forward primer 5'-TTT ACC CTT TCA ATA GTC ACA CTC A-3' and reverse primer 5'-AGC ATA CTT AGA CTA CTA CCT CCA TG-3'. PCR conditions were: initial denaturation at 94 ℃ for 5 min followed by 35 cycles of denaturation at 94 ℃ for 30 s, annealing at 55 ℃ for 30 s, extension at 72 ℃ for 30 s and a final extension at 72 ℃ for 5 min followed by cooling to 4 ℃. The 102-bp amplicons were digested overnight with *NcoI* (New England Biolabs, UK). Digestion resulted in two fragments of 80 and 22 bp (G allele) or 102 bp (A allele), respectively.

CARD15/NOD2 3020InsC (*CARD15 L1007fs*) (NCBI SNP CLUSTER ID: rs2066847) genotyping was performed with forward primer 5'-GGC AGA AGC CCT CCT GCA GGG CC-3' and reverse primer 5'-CCT CAA AAT TCT GCC ATT CC-3'. PCR conditions were: initial denaturation at 94 ℃ for 5 min followed by 35 cycles of denaturation at 94 ℃ for 30 s, annealing at 59 ℃ for 30 s, extension at 72 ℃ for 45 s and a final extension at 72 ℃ for 5 min followed by cooling to 4 ℃. The 150-bp amplicons were digested overnight with *ApaI*. Digestion resulted in a fragment of 150 bp (no insertion) or 128 bp and 22 bp (insertion C), respectively.

TLR9-1237T>C (NCBI SNP CLUSTER ID: rs5743836) genotyping was performed with TaqMan method. Primers used were: forward primer 5'-GGC CTT GGG ATG TGC TGT T-3' and reverse primer 5'-GGT GAC ATG GGA GCA GAG ACA-3'. Dual-labeled fluorogenic hybridization MGB-probes used were: CTGCCTGAAAACT 5' Fluor Label (FAM, 6-carboxyfluorescein) and CTGGAAACTCCCC 5' Fluor Label (VIC).

TLR9+2848G>A genotyping (NCBI SNP CLUSTER ID: rs352140) was performed with TaqMan method. Primers used were: forward primer 5'-CCG GTC TGC AGG TGC TAG AC-3' and reverse primer 5'-CCA AAG GGC TGG CTG TTG TA-3'. Dual-labeled fluorogenic hybridization MGB probes used were: AGCTACCGCGACTGG 5' Fluor Label (FAM) and AGCTACCACGACTGGA 5' Fluor Label (VIC).

Genotyping of the *IRAKM*+22148G>A exon 5 SNP (NCBI SNP CLUSTER ID: rs1152888) was performed by PCR with forward primer 5´-AGT GGA AC T GAT GTC CTG TGA CAG-3´ and reverse primer 5´-GCA ACA CAT TGA CCT AAT GAC CAG-3´.

The PCR conditions were: initial denaturation at 95 ℃ for 5 min, followed by 35 cycles of denaturation at 95 ℃ for 50 s, at 60 ℃ for 50 s, at 72 ℃ for 150 s and a final extension at 72 ℃ for 5 min followed by cooling to 4 ℃. Digestion overnight with RsaI (Invitrogen Life Technologies) of the 505-bp amplicons resulted in two fragments of 188+317 bp (allele G) or 505 bp (allele A).

Statistical analysis

Hardy-Weinberg equilibrium was determined in healthy controls to assess the Mendelian inheritance. Comparisons of the genotypes between control and different groups of IPAA patients were performed by Fisher's exact or χ^2 two-tailed tests where appropriate. Carrier trait analysis was performed to determine whether combinations of SNPs were acting synergistically on the risk of developing pouchitis or of predisposing to chronic relapsing pouchitis. Adjusted odd's ratio (OR) and 95% confidence intervals (95%CI) were calculated. $P<0.05$ was considered statistically significant.

Table 1 Demographic features of IPAA patients and healthy controls

controls are shown in Table 1. No statistical differences were found in the variables including gender and age between the IPAA group and healthy controls.

The clinical characteristics of patients with IPAA for ulcerative colitis were summarized. Information on the pattern of pouchitis within the group of IPAA patients for ulcerative colitis (patients who did not develop a pouchitis, patients who had infrequent pouchitis and patients who suffered from chronic relapsing pouchitis, respectively) is shown in Table 2. No statistically significant differences were found in gender and age between controls and IPAA patients as well as in the duration of pouch and the first episode of pouchitis after IPAA, respectively and among IPAA groups and between infrequent pouchitis and chronic relapsing pouchitis groups.

Genotyping

The genotype frequencies in the control group were in Hardy-Weinberg equilibrium for the *CD14, TLR4, TLR9, CARD15/NOD2,* and *IRAKM* gene polymorphisms. The genotype frequencies of these polymorphisms are described in Table 3. No significant differences in allele-, genotype- or carrier frequencies of the gene polymorphisms were found between the healthy controls and IPAA patients.

No significant differences in allele-, genotype- or carrier frequencies of the gene polymorphisms were found between the three subgroups of IPAA patients except that the carriership of allele *TLR9* -1237 C was more frequent in patients with chronic relapsing pouchitis (45.7%) as compared to those with infrequent pouchitis (20.9%) (P =0.028, OR = 3.2, 95%CI = 1.2-8.6). When the combined groups of infrequent pouchitis and chronic relapsing pouchitis (i.e. total pouchitis group) were compared to the patients without pouchitis, carriership of this allele was not significantly different (P = 0.87, OR = 1.1, 95%CI = 0.6-2.1).

TLR9 haplotype

The two analyzed *TLR9* SNPs were chosen based on the study of Lazarus *et al*.[33] in which a set of four frequent *TLR9* SNPs designated as *TLR9* -1486, *TLR9* -1237, *TLR9* +1174, and *TLR9* +2848, were described. Genotyping of both *TLR9* -1237 and *TLR9* +2848 could distinguish all four-locus haplotypes commonly present in the European American population. We therefore calculated the haplotypic genotypes in Italian Caucasians (Table 4). The haplotype frequencies in the healthy controls were identical to the European-Americans as reported by Lazarus *et al*.[33].

Table 4 Frequencies of *TLR9* haplotypes formed by -1237 T>C and +2848 G>A SNPs

TLR9 -1237	TLR9 +2848	Haplotype	Controls	No pouchitis	Infrequent pouchitis	Chronic relapsing pouchitis
			2*n* = 448	2*n* = 158	2*n* = 86	2*n* = 70
T	G	I	181 (40)	51 (32)	40 (47)	28 (40)

C	G	IV	3 (1)	1 (1)	0	0

[1]*P* = 0.018, OR = 3.0, 95%CI = 1.2-7.1.

Haplotype III was more frequent in chronic relapsing pouchitis as compared to infrequent pouchitis (*P* = 0.018; OR = 3.0, 95%CI = 1.2-7.1). This haplotype, however, did not show nucleotides uniquely present (tag SNPs) on position -1486 (allele T present in haplotypes I and III) or on position +1174 (allele G present in haplotypes II and III), indicating that allele *TLR9*-1237C could provide the strongest association.

Carrier trait analysis

To investigate if SNPs in different genes could act synergistically on disease susceptibility and/or severity, carrier trait analysis with the associated *TLR9* allele was performed. Simultaneous carriership of alleles *TLR9* -1237C and *CD14* -260T was more frequent in patients with chronic relapsing pouchitis as compared to those with infrequent pouchitis (*P* = 0.018, OR = 4.1, 95%CI = 1.4-12.3), which was more significant as compared to the analysis of allele *TLR9* -1237C alone (*P* = 0.028, OR = 3.2, 95%CI = 1.2-8.6). No other significant carrier traits were observed.

DISCUSSION

There is convincing evidence that enteric bacteria play a role in driving the inflammatory response in IBD and that genetic factors contribute not only to the pathogenesis but also to the course and extent of these disorders. Given these processes, we investigated whether polymorphisms in the following genes encoding for proteins involved in innate immunity, *TLR4* +896 A>G, *TLR9* +2848 G>A, *TLR9* -1237T>C, *CD14* -260C>T, *CARD15/NOD2* 3020insC, and *IRAKM* +22148 G>A, were associated with the development of pouchitis, disease frequency or severity.

Analysis of the three subgroups of IPAA patients (i.e. patients who never developed pouchitis, patients with infrequent pouchitis and patients with a chronic refractory form of pouchitis) revealed a positive association of allele *TLR9* -1237C with the risk of developing chronic refractory pouchitis, once these patients developed pouchitis. Haplotype analysis showed that out of the four SNPs defining *TLR9* haplotypes, this allele was uniquely responsible for this finding. Subsequently, we investigated whether interactions of allele *TLR9* -1237C with SNPs in the other candidate genes might strengthen this association. Carrier trait analysis revealed that an even stronger association was apparent with the combination of alleles *TLR9* -1237C and *CD14* -260T. These data suggest that this combination of alleles might be a valuable genetic marker to identify a clinical subgroup of IPAA patients with an enhanced risk of developing chronic pouchitis, compared to alleles of the SNPs *TLR4* +896 A>G, *TLR9* +2848 G>A, *CARD15/NOD2* 3020insC, and *IRAKM* +22148 G>A.

It cannot be excluded that the group of patients who did not develop pouchitis consisted of a mixture of patients who never developed pouchitis on the one hand and patients who proceeded to the infrequent or chronic relapsing pouchitis group on the other hand. This could explain why we did not detect an association of allele *TLR9* -1237C between the no-pouchitis and the chronic relapsing pouchitis groups. It should be noted that no significant differences were found in the mean duration of IPAA between the three groups.

At present it is unknown as to what effect of the *TLR9*-1237 T>C SNP exerts on the expression of *TLR9* given its location in the far promoter region where no DNA-binding site for known transcription factors is apparent. The association observed might therefore result from linkage disequilibrium with another polymorphism(s) in a nearby gene.

The mechanism underlying increased risk of developing chronic relapsing pouchitis by a combined carriership of alleles *TLR9* -1237C and *CD14* -260T might be a dysfunction in bacterial recognition or a lack of an adequate immune response to bacterial challenge. This could start at the level of the plasmacytoid dendritic cells, which play a central role in bacterial recognition, selectively express *TLR9* and have soluble *CD14* facilitating reactivity to a broad array of bacterial components[43] or at the level of the intestinal epithelium. Soluble *CD14* might confer epithelial cell responsiveness[25].

The regulatory role of dendritic cells is of particular importance in the intestine where the mucosal immune system is closely associated with the external environment[44]. Dendritic cells sample bacterial products either indirectly via M cells or directly by reaching between epithelial cells into the gut lumen[45]. In this perspective, it is noteworthy to mention a recent article that reported a lack of immature blood dendritic cells, which possibly migrate to the gut in IBD patients with active disease[46].

Recently, carriership of the *TLR9* -1237C allele has been associated with Crohn's disease[34]. Ileal involvement is present in about 60% of patients with Crohn's disease. Since the pouch is an ileal reservoir that is more vulnerable to the continuous contact with high bacterial titers, it could

be hypothesized that carriership of the allele *TLR9* -1237C (with or without *CD14* -260T) is associated with an impaired immune response at the level of the ileal tissue. Paneth cells are located in the crypts and are central in host defense to luminal bacteria by releasing antimicrobial substances[47,48].

If this is true, carriership of allele *TLR9* -1237C may become an important predictive marker to the enhanced risk of developing refractory chronic pouchitis and eventually pouch failure.

SNPs in different genes might work synergistically and constitute a small to moderate relative risk of developing diseases. Though the observations we described in this article were based on a relatively less number of patients, it should be realized that this study might represent one of the largest series available.

In conclusion, our data suggest that the alleles *TLR9*-1237C and *CD14*-260T synergistically enhance the risk of developing chronic relapsing pouchitis and eventually pouch failure in ulcerative colitis patients who need surgical intervention. Larger studies are required to determine whether this allelic combination becomes a valuable predictive marker and functional studies on the biological role of TLR9 and CD14 in pouchitis.

ACKNOWLEDGMENTS

We are indebted to Italian patients and healthy controls for their participation in this study. S.A. Morré was supported by Tramedico BV, the Netherlands, the Falk Foundation, Germany; the Foundation of Immunogenetics, The Netherlands; the Department of Internal Medicine of the VU University Medical Centre, the Netherlands. We thank Jolein Pleijster and Roel Heijmans for excellent technical assistance in the genotyping.

Abstract

AIM: To determine the utility of interferon (IFN) -α production capacity in patients with hepatitis C virus (HCV) infection for the measurement of immuno-surveillance potential and for the early detection of hepatocellular carcinoma (HCC) by investigating the Sendai virus (HVJ) stimulated IFN-α production capacity of patients with HCV infection.

METHODS: HVJ stimulated IFN-α production was determined in a large number of patients with HCV infection and the development of HCC was monitored for 3 years in patients with liver cirrhosis (LC).

RESULTS: IFN-α production capacity decreases gradually with the progression of liver disease from chronic hepatitis (CH) to HCC. A significant correlation between the duration of HCV infection and impaired IFN-α production capacity was observed. IFN-α production in patients who developed HCC within 3 years was significantly lower than that of patients who remained in LC without developing HCC.

CONCLUSION: Measurement of IFN-α production in LC patients may be useful for the early detection of HCC.

Key words: IFN-α production capacity; Hepatitis C virus; Hepatocellular carcinoma

INTRODUCTION

The natural history of chronic hepatitis C virus (HCV) infection entails a gradual progression from chronic hepatitis (CH) to liver cirrhosis (LC) over 10-20 years leading to hepatocellular carcinoma (HCC) within 30 years[1-3]. Some common factors influencing the development of HCC include the degree of liver fibrosis, old age, sex (male), high alanine aminotransferase (ALT) level and a history of diabetes and alcohol consumption[4,5]. In addition, the development of HCC is affected by viral factors[6] and host immune factors[7]. Although recent progress in hepatitis research has illustrated the role of viral factors, analysis of the role if any played by immune factors has been insufficient. Several investigators have discussed the impairment of NK cell function, cytotoxic T lymphocyte (CTL) function and dendritic cell (DC) function in hepatitis C patients[8-11].

In previous papers, we have reported about the impairment of HVJ induced IFN-α production in whole blood cultures of patients with lung cancer, mylodysplastic syndrome, pulmonary tuberculosis, HIV, diabetes mellitus and IgA nephritis[12,13]. Additionally, we mentioned that IFN-α production in patients with lung cancer gradually decreases with the progress of cancer[12]. In the present study, we examined the IFN-α production in a large number of patients with HCV infection and LC who were monitored for more than 3 years for the development of HCC. IFN-α production in patients who developed HCC within 3 years was significantly lower than that of patients who remained in LC without developing HCC. These results suggest that IFN-α production could be a parameter with promising anti-tumor immuno-surveillance potential, i.e., measurement of IFN-α production in patients with HCV infection may be useful for the early detection of HCC.

MATERIALS AND METHODS

Subjects

IFN-α production in whole blood cultures was measured

in 155 healthy individuals and 82 patients with chronic HCV infection including CH, LC and HCC. Blood was drawn after receiving informed consent.

The patients with HCV infection were all outpatients at Kyoto University Hospital, and were followed up at least once a month from 1994. All patients tested positive for anti-HCV (Abbot Japan, Tokyo) and/or HCV RNA by RT-PCR. The diagnoses of CH, LC and HCC were made by conducting a comprehensive analysis of liver histology, image analysis and blood tests. Patients underwent abdominal ultrasonography every 3-6 mo and/or contrast enhanced computed tomography every 6-12 mo. The CH group included 27 men and 12 women (age, 48.9±12.2 years). The LC group included 11 men and 10 women (age, 64.0±7.5 yeas). The HCC group included 13 men and 9 women (age, 64.1±5.4 years). Patients with HCV infection had not received interferon therapy for at least 3 mo prior to the measurement of IFN production capacity. In the case of patients with HCC, the IFN production capacity values of patients used were those determined at the point of first diagnosis of HCC.

We selected age-matched healthy persons as controls for comparison with the patients with HCV infection. Healthy subjects, 30 men (age, 53.6±8.9 years) and 95 women (age, 53.2±7.6 years), were selected from the people receiving medical examinations at the clinic of the Louis Pasteur Center for Medical Research who were over 40 years of age and had no acute and/or chronic disease and no abnormal values in blood tests.

Measurement of IFN-α production capacity in human whole blood

Two milliliters of heparinized blood was cultured with 500 HA U/mL Sendai virus (HVJ) within 5 h after the withdrawal of blood. The blood-virus mixture was incubated at 37 ℃ for 20 h. Supernatants were harvested by centrifugation at 3 000 r/min for 10 min. IFN-α activity in the supernatants was determined by bioassay as mentioned in a previous paper[12].

Statistical analysis

Results were expressed as mean±SD. Statistical significance was tested by Student's *t*-test. For multiple comparisons, one-way analysis of variance (ANOVA) or the χ^2 test was used, when appropriate.

RESULTS

IFN-α production capacity in patients with chronic HCV infection in the various stages

A previous study has reported that there was a significant difference in IFN-α production between men and women, but that the IFN-α production capacity per 1 000 leukocytes (WBC) did not differ significantly between men and women throughout various groups[12]. In this study, IFN-α production capacity in various stages is expressed as IFN-α production per 1 000 WBC for comparing each stage, normalized for any difference between men and women. We found that IFN-α production capacity per 1 000 WBC decreased with the progression of the disease (healthy control: 1.54±0.57, CH: 1.41±1.01; LC: 0.89±0.49; HCC: 0.87±0.45 IU/1 000 WBC) (Figure 1). Using ANOVA,we found that HCV groups showed a significantly lower IFN-α titer as compared with the control group.

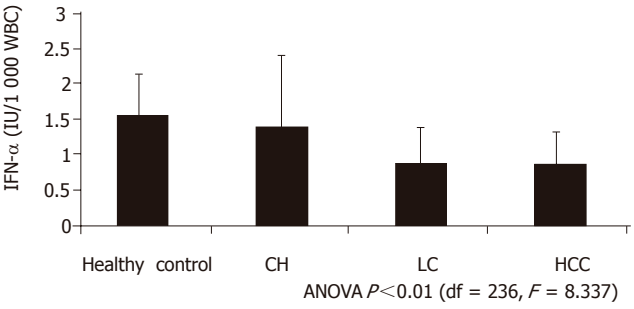

Figure 1 IFN-α production capacity per 1 000 WBC in patients with persistent HCV infection in various stages.

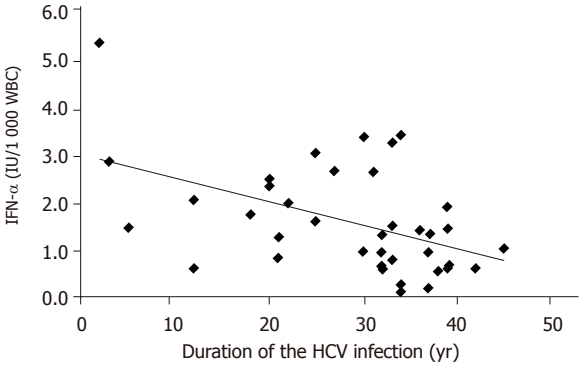

Figure 2 IFN-α production capacity per 1 000 WBC and duration of HCV infection.

IFN-α production capacity per 1 000 WBC and the duration from HCV infection by blood transfusion

It has been reported that a significant correlation exists between the incidence of HCC and the duration of HCV infection[1-3]. As the time of initial infection is precisely known for patients who were infected while undergoing transfusion, we chose HCV patients infected in this manner. We then looked at the relationship between the patient's IFN-α production capacity and the duration of the HCV infection (Figure 2). A significant correlation between the duration of HCV infection and impaired IFN-α production capacity per 1 000 WBC was observed (n = 39, r = 0.48, P = 0.0019). We could not find any significant correlation between platelet number, which was a surrogate marker for liver fibrosis, and ALT and AST levels, which were markers for the activity grade.

Table 1a IFN-α production capacity and the risk of HCC development within 3 years of LC

		Group A	Group B
n		11	10
Age	(yr)	63.6 ± 8.3	64.6 ± 6.7
IFN-α	(IU/mL	2 406 ± 1 239	3 936 ± 2 284

IFN-α production capacity and the risk of HCC development within 3 years of LC

We measured IFN-α production capacity in the LC group. After 3 years, we divided the original group into two, according to whether each patient developed HCC or not. We observed a significant difference ($P<0.05$) in the initial IFN-α production capacity per 1 000 WBC between the patients who developed HCC (Group A, $n = 11$) and those who remained in LC without developing HCC (Group B, $n = 10$). In addition, we observed significant differences in AST and ALT levels as well as IFN-α production capacity per 1 000 WBC between the two groups (Table 1a).

Since the mean IFN-α production value of the HCC patients was 0.87±0.45 IU/1 000 WBC, we divided the LC group into two sub-groups: patients with IFN-α production value greater or less than the mean value (0.87 IU/1 000 WBC) (Table 1b). After 3 years, we determined whether each patient had developed HCC or not. Compared to the 22% of patients in the high titer group, 75% of patients in the low titer group developed HCC. The c2 test showed significant differences between the two groups ($P<0.05$). These results indicated that LC patients with a low IFN-α production capacity (<0.87 IU/1 000 WBC) had a high risk of developing HCC within 3 years. Although low IFN-α production and high AST and ALT values, HCV copies and genotypes were demonstrated as risk factors of HCC development, no correlations were found between IFN-α production and these factors.

DISCUSSION

In this study, we have demonstrated that (1) HVJ-stimulated IFN-α production capacity decreased gradually with the progression of HCV infection from CH to LC to HCC; (2) the longer the duration of HCV infection was, the lower was the patient's IFN-α production capacity; and (3) IFN-α production capacity was lower in patients who developed HCC within 3 years as compared to those who did not develop HCC. Based on these results, a patient with lower IFN-α production capacity might be considered to be at a high risk for the development of HCC.

The progress of chronic HCV infection is one of slow progression from the early stages of CH without fibrosis to LC and HCC[1-3]. The disease progresses to its advanced stages over a period of 10-30 years, unless the viral infection is terminated by antiviral therapy[14]. In this study, we have demonstrated that the IFN-α production capacity of patients with HCV infection gradually decreased as the disease progressed, resulting in the development of HCC, suggesting that extended dysfunction of the type I IFN system may lead to an increased risk of HCC development.

Table 1b Relationship between IFN-α production capacity and incidence of HCC development of patients within 3 years

IFN-α IU/1 000 WBC	No of patients	No of patients who developed HCC within 3 yr	%
≥0.87	9	2	22.2
<0.87	12	9	75[a]

[a]$P<0.05$

In our previous studies, we have reported that IFN-α production was somehow decreased in patients with lung cancer, MDS, pulmonary tuberculosis, HIV infection, diabetes mellitus and IgA nephritis[12,13], suggesting that IFN-α production capacity is impaired by various diseases, including cancer, infections, and metabolic disorder. In addition, periodic measurements of IFN-α production revealed decreased IFN-α production capacities in patients with lung[12]. Consistent with these results, we demonstrated that LC patients who developed HCC within 3 years possessed a decreased capacity to produce IFN-α, suggesting that a low level of IFN-α production is associated with a higher incidence of HCC development in LC patients. In this study, 75% of LC patients with IFN-α production less than 0.87 IU/1 000 WBC developed HCC within 3 years. In the previous study, we have reported the mean values of IFN-α production in lung cancer and MDS to be 0.88±0.80 and 0.35±0.28 IU/1 000 WBC, respectively. These results suggest that patients with IFN-α production less than 0.87 IU/1 000 WBC need to be cautioned that they are at particularly high risk of cancer development. Consistently, MDS patients with low IFN-α production capacity developed cancer within several years[12,15,16]. Moreover, DM patients with low IFN-α production had a higher risk of developing cancer[6]. To clarify the utility of this IFN-α production capacity in the early detection of various types of cancers, further large scale clinical surveys are needed.

Why is impaired IFN-α production a risk factor for developing HCC? In our previous study, we have demonstrated that impairment of IFN-α production capacity in whole blood mainly depends not only on a defect in the number of mononuclear lymphocytes but also on the lower capacity of HVJ-stimulated IFN-α production from mononuclear lymphocytes. Mononuclear lymphocytes included monocytes, B cells, NK cells and plasmacytoid dendritic cells, all of which were producers of IFN-α[17,18]. Recently, there has been a new interest in type I IFN as a "bridge system" linking innate and adaptive immunity stemming from the identification of natural IFN producing cells, characterized as plasmacytoid dendritic cells[19,20]. Since IFN-α/β participate in cancer

immunosurveillance[21], IFN-α production capacity is considered to reflect a facet of individual cancer immunosurveillance potential. In fact, some studies have clearly demonstrated that metastatic tumor cells grow progressively in mice pre-treated with neutralizing antibodies to murine IFN-α/β, demonstrating the critical role of endogenous IFN-α/β in the inhibition of anti-tumor immune responses[20,22,23]. Furthermore, type I IFN is involved in the anti-tumor activation of NK cells and macrophages as well as the induction of anti-tumor CTLs[24-27].

IFN-α production capacity is determined by both the genetic background and by the physical condition of each individual, such as the presence/absence of infection, metabolic disorder and cancer[28]. It is therefore anticipated that periodic measurements of IFN-α production and the early detection of reduced IFN-α production capacity will contribute to the early detection of HCC as well as the early detection of cancer and infectious disease. Furthermore, intervention to increase and/or maintain IFN-α production capacity may be useful for the prevention of HCC development.

Abstract

AIM: To clarify the risk factors for bleeding after endoscopic mucosal resection (EMR).

METHODS: A total of 297 consecutive patients who underwent EMR were enrolled. Some of the patients had multiple lesions. Bleeding requiring endoscopic treatment was defined as bleeding after EMR. Odds ratios (OR) with 95% confidence intervals (CI), calculated by logistic regression with multivariate adjustments for covariates, were the measures of association.

RESULTS: Of the 297 patients, 57 (19.2%) patients with bleeding after EMR were confirmed. With multivariate adjustment, the cutting method of EMR, diameter, and endoscopic pattern of the tumor were associated with the risk of bleeding after EMR. The multivariate-adjusted OR for bleeding after EMR using endoscopic aspiration mucosectomy was 3.07 (95%CI, 1.59-5.92) compared with strip biopsy. The multiple-adjusted OR for bleeding after EMR for the highest quartile (16-50 mm) of tumor diameter was 5.63 (95%CI, 1.84-17.23) compared with that for the lowest (4-7 mm). The multiple-adjusted OR for bleeding after EMR for depressed type of tumor was 4.21 (95%CI, 1.75-10.10) compared with elevated type.

CONCLUSION: It is important to take tumor characteristics (tumor size and endoscopic pattern) and cutting method of EMR into consideration in predicting bleeding after EMR.

INTRODUCTION

Endoscopic mucosal resection (EMR) of early gastric cancers has been widely accepted as a standard procedure because of its low degree of invasiveness and the excellent quality of life in patients[1-3]. Bleeding is one of the major complications of EMR for gastric lesions. The reported bleeding rate after EMR for early gastric cancers is between 1.4% and 20%[4-8]. As indications for EMR expands, more complications such as bleeding may occur with it. It is reported that patients who required blood transfusion after EMR due to severe bleeding account for 4-14% of all patients undergoing EMR[7,13]. Several factors related to bleeding after EMR, such as tumor diameter, have been reported[9]. Our aim is to clarify the risk factors for bleeding after EMR in 297 patients with gastric lesions.

MATERIALS AND METHODS

Study population

A total of 297 consecutive patients who underwent EMR between April 1991 and December 1997 in the Department of Gastroenterology of Osaka City University Medical School were enrolled. Inclusion criteria were all gastric lesions confined to the lamina propria. The depth of tumor invasion was determined by endoscopic ultrasound. There was no bleeding tendency in any of the studied patient, and no patients used drugs such as anticoagulants.

Methods and measurements

The gastric lesions were removed by strip biopsy or endoscopic aspiration mucosectomy. We defined early gastric cancer using the Japanese Classification of Gastric Carcinoma[9,10], and we have defined the absolute indication

for endoscopic treatment as follows: elevated type mucosal cancer less than 2 cm or depressed type mucosal cancer without ulceration less than 1 cm in size. We have also carried out endoscopic treatment in cases extending beyond these criteria as a relative indication, when we could not perform surgery due to patient's refusal or due to significant heart, lung or kidney failure. Strip biopsy was performed with a two-channel scope (GIF2T-200; Olympus Optical Co., Tokyo, Japan), as described by Tanabe *et al*.[11]. Physiologic saline was injected locally to elevate the lesion. Endoscopic aspiration mucosectomy was performed as described by Torii[10]. A snare was introduced through a Teflon tube and tightened around the outer circumference of a transparent plastic cylinder cap (Olympus Optical Co., Tokyo, Japan). The Teflon tube, used as a snare introducer, was taped along the external axis of the endoscope. The snare was tightened by manipulating the handle, just as in polypectomy, and was fixed by taping it to the endoscope so that the snare loop remained at the tip of the cylinder cap. Physiologic saline was injected via an injection needle at the lesion to elevate the lesion. The snare was pushed over the tumor, while the lesion was aspirated along with the surrounding normal mucosa, and resection was performed by electrocauterization. A transparent cap was attached to the tip of an endoscope (GIFQ-200, GIFQ-230, GIFXQ-200, GIFXQ-230; Olympus Optical Co., Tokyo, Japan). The outer diameter of the transparent cap was 14.8 mm (MH-589) or 12.6 mm (MH-587).

Patients with a gastric lesion that required endoscopic treatment for bleeding after EMR were considered to have bleeding after EMR. We examined the patients with bleeding immediately after EMR, because they were treated with anti-ulcer drugs after EMR. Some of the patients had multiple lesions in our study in which the largest lesion per patient was selected as a representative lesion. Furthermore, when a patient had multiple tumors with the same largest diameter, we excluded the patient from analysis. We analyzed the data according to this rule.

The location of the lesion, tumor diameter, endoscopic pattern, histological findings for the tumor and cutting method were examined for their relationship to bleeding after EMR. After EMR, the removed mucosa was semifixed in formalin, and the lesion diameter was measured with a stereoscopic microscope (SZH-ILLB, Olympus Optical Co. Ltd., Tokyo, Japan). Based on the location, gastric lesions of the stomach was classified into an antrum group including the antrum and angle of the stomach, and a corpus group including the lower, middle, and upper body of the stomach. There were 158 lesions in the antrum group and 139 in the corpus group. By endoscopic pattern, lesions were classified into two types: elevated type and depressed type. There were 253 lesions of elevated type and 44 of depressed type. Histological examination revealed 139 early gastric cancers and 158 gastric adenomas[8]. We removed 177 lesions by the strip biopsy method and 144 lesions by endoscopic aspiration mucosectomy. Informed consent for EMR was obtained from all the patients.

Table 1 Baseline characteristics of study patients

	No bleeding after EMR (n = 240)	Bleeding after EMR (n = 57)	P
Age (yr)	65.3±9.3	66.0±8.4	0.582
Sex (M:F)	170:70	41:16:00	0.998

Strip biopsy	156 (88.1%)	21 (11.9%)	0.001
Endoscopic aspiration mucosectomy	84 (70.0%)	36 (30.0%)	

Values are mean±SE or no. of gastric lesions.

Statistical analysis

Values were expressed as mean±SD. Categorical variables were compared using the χ^2 test. Differences in mean values between the two groups were compared using the unpaired t test. $P<0.05$ were considered significant. Multiple logistic regression analysis was used to evaluate the simultaneous effects of age, location of lesion, diameter, endoscopic pattern, histology of the tumor and the cutting method of EMR. Linear trends in risk associated with the tumor diameter were evaluated by indicators for each categorical level of tumor diameter using the median value for each category. The 95%CI for each odds ratio (OR) was calculated, and all P values are two-tailed. Statistical analyses were made using the SPSS 10.0 software package.

RESULTS

Of the 297 patients, 57 patients (19.2%) were confirmed to have bleeding after EMR. Baseline characteristics of the patients are summarized in Table 1. There was no significant difference in age and gender of patients, tumor diameter or histological type of tumor between the groups. The bleeding incidence after EMR in the corpus group was significantly higher than that in the antrum group (P = 0.038). The bleeding rate for depressed type lesions was significantly higher than that for elevated type lesions (P = 0.012). The bleeding rate with endoscopic aspiration mucosectomy was much higher than that with strip biopsy ($P<0.001$).

Of the 57 patients with bleeding, 18 (31.6%) patients had spurting bleeding (12 patients underwent EMR by endoscopic aspiration mucosectomy, and 6 underwent EMR by strip biopsy). Of these 57 patients, 39 (68.4%) had oozing bleeding (28 patients underwent EMR by endoscopic aspiration mucosectomy, and 11 underwent EMR by strip biopsy). All bleeding, except in one case, was controlled by endoscopic treatment with endoscopic clipping (HX5LR-1, Olympus, Japan), ethanol injection,

and injection of hypertonic saline-epinephrine solution. No patient required blood transfusion in our study, only one patient underwent open emergency surgery because of severe bleeding after EMR.

Multivariate analysis of bleeding risk after EMR

The multivariate analysis of bleeding after EMR is summarized in Table 2. Cutting method of EMR was the strongest factor identified in this analysis. Location of gastric lesion, tumor diameter, and endoscopic pattern of the lesion were associated with an increased risk of bleeding after EMR, when the multivariate analysis was adjusted for age, location of gastric lesions, tumor diameter, endoscopic pattern of lesion and histological type. However, when cutting method of EMR was added to these factors in the multivariate analysis, location of the gastric lesion was no longer a significant factor. The multiple-adjusted OR excluding the factor of the cutting method for bleeding after EMR in the corpus group was 2.24 (95%CI, 1.20-4.18) compared with that in the antrum group. However, the multiple-adjusted OR including the factor of cutting method for bleeding after EMR in the corpus group was 1.69 (95%CI, 0.88-3.26) compared with that in the antrum group.

Tumor diameter and endoscopic pattern of the lesion were not significant factors in the multiple-adjusted analysis, either including or excluding the factor of cutting method. To examine in detail the risk of tumor diameter, tumor diameter was divided into four categories. The multiple-adjusted OR including the factor of cutting method for the highest quartile of diameter was 5.63 (95%CI, 1.84-17.23) compared with that for the lowest.

Concerning endoscopic pattern of lesions, the multiple-adjusted OR for depressed type lesions with the inclusion of the factor of cutting method was 4.21 (95%CI, 1.75-10.10) compared with that for elevated type lesions. The multiple-adjusted OR for bleeding after EMR with endoscopic aspiration mucosectomy was 3.07 (95%CI, 1.59-5.92) compared with that for strip biopsy.

On crude analysis, the histology of the lesion was also associated with the risk of bleeding after EMR, but in the multiple-adjusted analyses this association was not significant.

DISCUSSION

EMR is an established treatment for early-stage gastric cancers, and is an alternative to surgery for patients with superficial neoplastic lesions of the digestive tract. EMR can achieve a complete resection in a majority of patients, but is associated with a higher risk of bleeding than standard polypectomy[4-7,13,14]. Bleeding incidence, however, appears to vary according to how bleeding is defined. Bleeding during EMR of colorectal polyp is common, occurring in 24% of polypectomy of large colorectal polyps[15]. Morales *et al.*[15] defined procedural bleeding as a complication. Various forms of endoscopic treatment, such as multipolar electrocoagulation, use of heat probe, and injection therapy, are usually highly effective in stopping acute upper gastrointestinal ulcer bleeding[16-18]. Similarly, bleeding during the performance of EMR can almost always be controlled by the injection of saline epinephrine solution, thermal coagulation, or endoscopic clipping[25]. Endoscopic clipping is believed to be the safest therapeutic modality for controlling spurting bleeding after EMR[19,20,23]. However, it is reported that patients who required blood transfusion after EMR due to large bleeding accounted for 4-14% of patients undergoing EMR[7,13].

We came across one patient who underwent open emergency surgery because of severe bleeding after EMR.

Most bleeding occurs during the procedure, although delayed bleeding (up to 3 d in 10% of patients) has been reported[15]. In our study, patients with a gastric lesion that required endoscopic treatment for bleeding after EMR were considered to be cases to have bleeding after EMR.

The association of various factors with bleeding rates, such as tumor diameter[13], diameter of the removed mucosa, cutting method[6,12,13,21], location of gastric lesions, endoscopic pattern of lesions[13], and histological type of gastric tumor has been reported[6]. Those studies examined not only the risk of bleeding but also the rate of bleeding.

We found that tumor diameter, endoscopic pattern of lesions, and cutting method were associated with the increased risk of bleeding after EMR. These associations existed even on multivariate analysis.

It has been reported that larger diameter tumors bled readily after EMR[13]. We evaluated linear trends in risks of tumor diameter by indicators for each categorical level, and found that the findings were consistent with our results from the previous reports. We used tumor diameter determined by postfixation measurement as a predictor of post-EMR bleeding, because formalin fixation did not cause shrinkage of the specimens[22-23].

No significant relationship was found between bleeding incidence and the cutting diameter[12], and large cutting diameter was easy to bleed, because bleeding incidence may depend on the size of the cutting diameter[24]. We did not evaluate the diameter of the removed mucosa because this factor could not be measured before EMR was undertaken, and therefore could not be a predictor of bleeding.

Submucosal injection is an important part of the EMR procedure. Injection of fluid into the submucosa beneath a gastric lesion increases the distance between the base of the polyp and the deeper tissues of the gastric wall. It has been reported that a large submucosal cushion of saline solution increases the safety of polypectomy by preventing thermal injury to these deeper tissues[26,27]. Therefore, submucosal injection may influence bleeding after EMR. However, effects of the volume of physiologic saline solution injected were not investigated in our study, because the administration volume of physiologic saline solution was not routinely recorded. The endoscopic pattern of the lesion influences the risk of bleeding after EMR has not been reported. Depressed type lesion was a risk factor for bleeding after EMR in our study. However, the volume of submucosal injection used may have affected this result.

There is one report that bleeding incidence is higher with strip biopsy than with endoscopic aspiration mucosectomy, a finding inconsistent with our results[21]. It was reported that the size of resected specimens was significantly larger with endoscopic aspiration mucosectomy than with strip biopsy[11]. We did not evaluate the diameter of the removed mucosa in our study, though it might influence the bleeding rate associated with the cutting method.

Blood vessel diameter in the antral region of the stomach is smaller than that in the gastric corpus, and the number of blood vessels in the antral region is low[27]. In our study, no significant relationship was found between the locations of the lesion and cutting method in multivariate analysis. However, the bleeding incidence in the corpus group [24.5% (34/139)] was higher than that in the antrum group [14.6% (23/158)]. Therefore, if the sample size of our study was enlarged, a significant difference might be found.

Of the 297 patients, 64 (21.5%) patients underwent EMR by piecemeal resection, with a bleeding incidence of 15.6% (10/64). A total of 233 (78.5%) patients underwent EMR by en-bloc resection, with a bleeding incidence of 20.2% (47/233). There was no significant relationship between *en-bloc* resection or piecemeal resections and bleeding incidence after EMR.

In our study, ten endoscopists performed EMR for patients with bleeding after EMR. Categorical variables, such as location of the lesion, tumor diameter (four categories), endoscopic pattern, histology of the tumor and cutting method were compared among the 10 endoscopists using the χ^2 test. There was no significant difference among the endoscopists in the location of lesion ($P = 0.618$), tumor diameter ($P = 0.182$), endoscopic pattern ($P = 0.374$), histology of the tumor ($P = 0.395$) or cutting method ($P = 0.138$). Therefore, the particular endoscopist performing the procedure did not influence the risk of bleeding.

Conio *et al.* divided the definition of "bleeding after EMR" into three categories, i.e., intraprocedure (occurring during EMR), early (within 24 h), and delayed (≧24 h). In our study, "bleeding after EMR" was defined as intraprocedure.

In conclusion, our study indicated that tumor diameter, endoscopic pattern of lesions, and cutting method are risk factors for bleeding after EMR. It is important to consider these three factors in predicting bleeding after EMR.

Abstract

AIM: To evaluate two enzyme immunoassay-based stool antigen tests, Premier Platinum HpSA and Amplified IDEIA HpStAR, and one rapid test, ImmunoCard STAT! HpSA, in the primary diagnosis of *Helicobacter pylori (H pylori)* infection and after eradication therapy.

METHODS: Altogether 1 574 adult subjects were screened with a whole-blood *H pylori* antibody test and positive results were confirmed with locally validated serology and ^{13}C-urea breath test. All 185 subjects, confirmed to be *H pylori* positive, and 97 *H pylori*-negative individuals, randomly selected from the screened study population and with negative results in serology and UBT, were enrolled. After eradication therapy the results of 182 subjects were assessed.

RESULTS: At baseline, the sensitivity of HpSA and HpStAR was 91.9% and 96.2%, respectively, and specificity was 95.9% for both tests. ImmunoCard had sensitivity of 93.0% but specificity of only 88.7%. After eradication therapy, HpSA and HpStAR had sensitivity of 81.3% and 100%, and specificity of 97.0% and 97.6%, respectively. ImmunoCard had sensitivity of 93.8% and specificity of 97.0%. HpSA, HpStAR, and ImmunoCard had PPV 77%, 80%, and 75%, and NPV 98%, 100%, and 99%, respectively.

CONCLUSION: In primary diagnosis, the EIA-based tests performed well. After eradication therapy, negative results were highly accurate for all the three tests. HpStAR had the best overall performance.

INTRODUCTION

H pylori infection is one of the most common infections in human beings worldwide, strongly associated with peptic ulcer disease and gastric cancer[1,2]. There are several methods available to detect *H pylori* infection including invasive methods based on gastric biopsies and non-invasive methods like serology, urea breath tests (UBTs), and stool antigen tests[3,4]. Stool antigen tests have recently been welcomed with great expectations as they are convenient to the patients and can be easily performed even in small laboratories[5,6]. However, the accuracy of stool antigen tests in different clinical situations and outside of controlled studies is a matter of concern[7-9].

Several commercial stool antigen tests are available: enzyme immunoassays (EIAs) based on either polyclonal (Premier Platinum HpSA, Meridian Inc., Cincinnati, OH, USA) or mAbs (Amplified IDEIA HpStAR, also known as Femtolab, Dako, Glostrup, Denmark) and rapid bed-side tests like ImmunoCard STAT! HpSA (Meridian Bioscience Europe, Milan, Italy). HpSA is the most widely studied of these tests and it has shown acceptable performance in the primary diagnosis of *H pylori* infection but the accuracy in post-treatment setting and in special clinical situations (e.g. upper gastrointestinal hemorrhage, gastric surgery, PPI therapy) has been controversial[5,7,8]. The three stool antigen tests have rarely been compared in parallel in the same study. The differences in patient characteristics (e.g. peptic ulcer *vs* gastritis) and widely variable prevalence of *H pylori* in different studies make the comparisons between the tests difficult as the statistical parameters of the performance of the tests are often dependent on the prevalence of the infection.

Recently, we evaluated the three stool antigen tests in *H pylori*-positive patients before and after eradication therapy[10]. In the present study we also included *H pylori*-negative individuals. *H pylori* infection in all the subjects was verified by serology and ^{13}C-UBT.

MATERIALS AND METHODS

Subjects

Adults were invited with a newspaper announcement to participate in the study. Exclusion criteria were antibiotic treatment during previous 2 mo; use of H_2-receptor antagonists, bismuth or proton pump inhibitor therapy during previous 2 wk; *H pylori* eradication therapy during previous 5 years; gastric surgery; chronic gastrointestinal diseases; contraindications to drugs used in the study; pregnancy or lactation. Study subjects were screened for *H pylori* infection with rapid whole-blood antibody tests (Pyloriset Screen II, Orion Diagnostica, Espoo, Finland, or Biocard *Helicobacter pylori* IgG, AniBiotech Ltd, Vantaa, Finland). The present study was subsidiary to another study investigating the efficacy of probiotics in the eradication therapy of *H pylori*. Therefore, allergy to fruit juice containing the probiotics also belonged to the exclusion criteria.

The population screened comprised 1 574 subjects. Positive results in screening were confirmed with UBT and an in-house EIA-based serologic method. Of the 300 *H pylori*-positive subjects in screening, 196 were positive in both of the confirmatory tests, but 11 subjects met one of the exclusion criteria; thus 185 *H pylori*-positive subjects were included in the study (of the remaining 104 subjects positive in screening, 49 were negative in both of the confirmatory tests and for the rest either no confirmatory tests were performed or the results were discordant). From the subjects with *H pylori*-negative test result in screening, 114 (randomly selected by a computer program SPSS 12.0) were invited to bring the specimens for the confirmatory tests and 97 subjects followed this invitation. For these *H pylori*-negative study subjects, the infection was excluded with both of the confirmatory tests. Thus, the final study population consisted of 282 subjects: 185 were *H pylori* positive and 97 negative. The median age of the subjects was 52 years, range 23-71 years. The median age of *H pylori*-positive subjects was 55 years (range 25-71 years) and of *H pylori*-negative subjects 43 years (range 23-64 years). In total there were 186 females and 96 males.

H pylori eradication therapy

A total of 185 *H pylori*-positive subjects received the same eradication therapy: amoxicillin 1 g b.i.d., clarithromycin 500 mg b.i.d. and lanzoprazole 30 mg b.i.d. for 1 wk. Exclusion criteria for the therapy were penicillin allergy, prolonged QT-interval, and antifungal therapy for dermatophyte infection.

Serology

At baseline and 4 mo after the end of eradication therapy the subjects gave serum samples for locally validated in-house EIA[11]. At baseline, serum samples had been investigated in order to confirm the infection, and they were stored at -20 ℃ until further used. Serum samples before and after eradication therapy were analyzed in parallel for both immunoglobulin G (IgG) and IgA antibodies as described earlier[12]. *H pylori* eradication therapy was considered successful when antibody titers of at least IgG class had fallen 40% or more from the pre-treatment level[11].

UBT

UBT was performed at baseline and 4 wk after the end of eradication therapy. Diabact tablets were used (Diabact UBT, Diabact AB, Uppsala, Sweden) [13,14]. After overnight fast the subjects swallowed either one or two 50 mg Diabact tablets and blew into the test tube before and 10 min after ingesting the tablet(s). Results were analyzed by isotope ratio mass spectrometry (BreathMATPlus, Finnigan MAT GmbH, Bremen, Germany) and expressed as delta over baseline (DOB). Cut-off point for positive test result was DOB 2.2‰.

Stool antigen tests

All subjects gave stool specimens at baseline and those treated 4 wk after the end of eradication therapy. Stool specimens were stored at -20 ℃ before analysis and were thawed twice at most. Stool samples before and after therapy were always run in parallel in all three antigen tests.

The polyclonal antibody-based Premier Platinum HpSA test, later HpSA (Meridian Inc., Cincinnati, USA) was performed according to manufacturer's instructions. Diluted stool specimens were added to the microtiter wells with a peroxidase-conjugated polyclonal antibody. After washing, substrate was added. The results were read at 450 nm by a spectrophotometry (Titertek Multiskan analyzer, Eflab Oy, Helsinki, Finland). Optical density (OD) values <0.140 were negative, 0.140-0.159 equivocal (gray zone) and ⩾0.160 positive, as suggested by the manufacturer. In cases with gray zone values, the same stool samples stored at -20 ℃ were retested as recommended.

For the mAb-based Amplified IDEIA HpStAR test, later HpStAR (also known by name FemtoLab, Dako), the supernatant of stool suspension and peroxidase-conjugated mAbs were pipetted into the wells. After washing substrate was added, and the results were read by spectrophotometry. According to manufacturer's instructions, OD values ⩾0.190 (450 nm) were assessed as positive and <0.190 as negative.

ImmunoCard STAT! HpSA-test, later ImmunoCard (Meridian Bioscience Europe) is based on monoclonal *H pylori* antibodies and a lateral flow chromatography technique. The diluted stool sample was dispensed to the sample port of the test cassette, and after incubation of 5 min at room temperature, the appearance of a pink-red line in the reading window indicated a positive result.

The Ethics Committee of the Hospital District of Helsinki and Uusimaa approved the studies and all subjects

Table 1 Performance of the three stool antigen tests as compared with UBT and serology in 282 subjects at baseline

UBT, serology	HpSA		HpStAR	ImmunoCard
Positive 185	Positive	170[1]	178	172
	Negative	13[1]	7	13

[3]One subject originally had gray zone result.

gave their written informed consent.

RESULTS

The performance of the stool antigen tests at baseline is shown in Table 1 and after eradication therapy in Table 2. Four patients were treated with antimicrobials after eradication therapy before the 4 wk had elapsed and thus, stool specimens and UBTs of these particular patients were not collected until they gave the serum sample for serology 4 mo after the therapy. For all the other subjects, UBT was performed and stool specimens were collected 4 wk after therapy according to the study protocol.

The results after eradication therapy are presented for 182 subjects; 3 subjects had the results only at baseline. One patient died before the follow-up. Serum sample was collected and another subject discontinued the study during antimicrobial therapy because of severe headache, which later turned out to be viral meningitis as examined by a neurologist. After eradication therapy, the confirmatory tests (UBT and serology) showed concordant results in all but one subject, who had eradication failure according to the UBT and all three stool antigen tests but successful eradication according to the serology: his results after eradication therapy were excluded from the analysis.

The performance of the tests at baseline is presented in Table 3 and after eradication therapy in Table 4. The adjusting of the cut-off points would not have had any beneficial effect to the results either before or after eradication treatment (data not shown). The false-positive test results in stool antigen tests were randomly distributed between the individual tests. However, half of the false-negative HpSA test results at baseline were also negative with the other two stool tests.

The HpSA tests with gray zone values were re-examined using the same stool specimens according to manufacturer's recommendations. However, no new stool specimen was collected (although recommended by the manufacturer) if the result was in gray zone even in re-examination. Out of the 464 samples analyzed, 15 (3.2%) fell into the gray zone but only three were equivocal when re-tested. Gray zone results obtained after re-examination were considered neither true positive nor true negative in statistical calculations.

Table 3 Performance of the three stool antigen tests at baseline

	Sensitivity	Specificity	PPV	NPV	Accuracy
	(%)	(%)	(%)	(%)	(%)
HpSA	91.9	95.9	97.7	87.7	93.3
HpStAR	96.2	95.9	97.8	93.0	96.1
ImmunoCard	93.0	88.7	94.0	86.9	91.5

PPV, positive predictive value; NPV, negative predictive value.

	Sensitivity	Specificity	PPV	NPV	Accuracy
	(%)	(%)	(%)	(%)	(%)
HpSA	81.3	97.0	76.5	98.2	95.6
HpStAR	100	97.6	80.0	100	97.8
ImmunoCard	93.8	97.0	75.0	99.4	96.7

PPV, positive predictive value; NPV, negative predictive value.

DISCUSSION

In the primary diagnosis of *H pylori* infection, the EIA-based HpSA and HpStAR tests had high sensitivities in accordance with our previous study[10] and those of others[6,8]. Earlier the specificities of these tests have varied between 63% and 100% for HpSA and 87% and 100% for HpStAR in studies with high prevalence of *H pylori* infection[6,8,15-19] and are in line with the specificity of 96% in our present study population. ImmunoCard had a good sensitivity, 93.0%, but a low specificity, 88.7%, at baseline, leading to a high number of false-positive test results. In previous studies, ImmunoCard has shown variable results in the primary diagnosis with sensitivities between 83% and 96% and specificities between 82% and 94%[8,10,20-25].

The positive predictive values (PPVs) for all the three stool antigen tests were very high (94.0-97.8%) at baseline in our study population with a high prevalence (65.6%) of *H pylori*. However, if these stool antigen tests had been used to detect the infection in the original group of 1 574 screened study subjects with the prevalence of *H pylori* being 12% (in assuming that all the screened but not confirmed *H pylori*-negative subjects would have been negative also in the both confirmatory tests), the PPVs for these tests would have been only as follows: HpSA 76.6%, HpStAR 77.5%, and ImmunoCard 54.8%. It has been earlier suggested that at an *H pylori* prevalence of lower than 30%, the most cost effective diagnostic strategy would be to use stool antigen test and confirm positive results with UBT[4]. In our study, the ImmunoCard test had the lowest specificity and thus a high number of false-positive test results emphasizing the need for a confirmation of a

positive test result by UBT or serology.

In post-eradication setting, the position of these stool antigen tests is most controversial[7,8]. This is true especially for the most widely studied HpSA test, which also in our study showed a low sensitivity after eradication therapy. We had an exceptionally low eradication failure rate in this study, only 8.8%, and HpSA test was unable to find 19% of our eradication failures, which is in accordance with our previous endoscopy-based study, in which 25% of eradication failures were unidentified with this test[10]. For the HpStAR test, the sensitivity has varied after eradication therapy between 86% and 100%, specificity 95% and 100%, PPV 83% and 100%, and NPV 96% and 100%[8,18,19]. Our results fell well into this range. The performance of ImmunoCard after eradication therapy in the few published studies available has varied widely. In a study in adults ImmunoCard showed very low sensitivity both before (83%) and after (73%) eradication therapy but high specificity 98%[23] whereas in the study of Gatta *et al*.[21] the sensitivity was 92% and specificity 100%. In our study all the three stool antigen tests had false-positive results in 2.5%-3.1% of successfully eradicated subjects, figures comparable with UBT[3,26,27].

All patients except three in our study brought the follow-up UBT and stool specimens 4 wk after finishing the eradication therapy. In some previous studies using the HpSA test, it has been shown that the time elapsed after eradication therapy should not be less than 4 wk but extending the time beyond that would not clearly improve the results[8,10,19,28,29]. A positive HpSA test as early as 3 d after finishing eradication therapy has been highly predictive of eradication failure but a negative test result was reliable only after 3 wk[29]. Therefore, it is unlikely that after treatment a longer time before the collection of stool samples would have improved the results in our study.

In conclusion, in the primary diagnosis of *H pylori* infection, the EIA-based HpSA and HpStAR stool antigen tests performed well. However, in a population with a lower prevalence of *H pylori* infection, positive results even in these tests may be reasonable to confirm with UBT or serology. After eradication therapy, negative results were highly accurate for all the three tests and HpStAR even found all the subjects with an unsuccessful eradication. HpStAR had the best overall performance before and after eradication therapy.

ACKNOWLEDGMENTS

This study was in part presented at the XVI[th] International Workshop, European Helicobacter Study Group, Vienna, Austria 24th September 2004. Our deepest appreciation goes to Pirjo Kosonen, Leena Seppo, Anu Kosonen, Minna Hietala, and Tiina Vikstedt for their skillful and assiduous assistance.

Abstract

AIM: To analyze the effects of NF-κB inhibition by antioxidant pyrrolidine dithiocarbamate (PDTC) or TNF inhibitor pentoxifylline (PTX) on liver regeneration after partial hepatectomy (PH).

METHODS: Saline, PDTC or PTX were injected 1 h before PH and rats were killed at 0.5 and 24 h after PH. Several control groups were used for comparison (injection control groups).

RESULTS: Compared to saline injected controls, NF-κB activation was absent 0.5 h after PH in rats treated with PDTC or PTX. At 24 h after PH, DNA synthesis and PCNA expression were identical in treated and control rats and thus occurred irrespectively of the status of NF-κB activation at 0.5 h. Signal transducer and activator of transcription 3 (Stat3) activation was observed already 0.5 h after PH in saline, PDTC or PTX group and was similar to Stat3 activation in response to injection without PH.

CONCLUSION: These data strongly suggest that (1) NF-κB p65/p50 DNA binding produced in response to PH is not a signal necessary to initiate the liver regeneration, (2) Stat3 activation is a stress response unrelated to the activation of NF-κB. In conclusion, NF-κB activation is not critically required for the process of liver regeneration after PH.

Key words: Partial hepatectomy; Nuclear factor kappa B; Signal transducer and activator of transcription 3; Hepatocyte proliferation; Antioxidant

INTRODUCTION

The mechanisms initiating the regenerative response after partial hepatectomy (PH) remain controversial. Several lines of evidence point to the critical role of the activation of nuclear factor kappa B (NF-κB)[1,2]. This is one of the earliest events constantly detectable in the liver after PH and the previous findings have advocated NF-κB being a critical effector of the cascade initiating the regenerative process[3,4]. Some authors also emphasize an anti-apoptotic role of NF-κB during the regenerative process[5]. Mice lacking TNF receptor type 1 (TNF-R1) showed deficient NF-κB binding, low interleukin-6 (IL-6) production, decreased signal transducer and activator of transcription 3 (Stat3) activation and low levels of hepatocyte DNA replication after PH[6-8]. Based on this and similar observations, it has been proposed that activation of the NF-κB pathway is a critical step to usher cells into the cell cycle in response to PH. This process might also require the sequential activation of TNF/NF-κB/IL-6 and Stat3. However, recent studies using mice lacking the common signal transducer of all IL-6 family members gp130 showed only minor effects on the cell cycle and on the peak of DNA synthesis after PH despite an abolished acute phase response and inhibition of Stat3[9]. Moreover, recent studies in a model of transgenic mice, with specific inhibition of NF-κB at the hepatocyte level, did not impair DNA synthesis and did not increase liver apoptosis[10]. In order to clarify the importance of the activation of NF-κB in the liver regeneration process, we have evaluated the consequences of NF-κB inhibition on downstream activation of Stat3 and DNA synthesis after PH. Numerous exogenous and endogenous stimuli are capable of inducing NF-κB activity[11], but the pathways leading to NF-κB activation are complex. One of them involves oxidative stress with elevated level of reactive oxygen species[12,13]. We have therefore administered the anti-oxidant pyrrolidine dithiocarbamate (PDTC), a compound with metal chelator properties that has been used as a reversible inhibitor of NF-κB *in vitro* and *in vivo*[14-17]. Increased production of TNF-α is a potential activator of NF-κB after PH[4], although the source of TNF-α after

PH has not been entirely elucidated. To reduce TNF-α production, we administered pentoxifylline (PTX), a methylxanthine derivative, which has been demonstrated to suppress LPS-induced TNF-α production[18-20]. It may also modulate the expression of other cytokines like IL-6 and IL-1[21,22].

MATERIALS AND METHODS

Animals

Male Wistar rats (220-270 g body weight) were obtained from the Rat Breeding Facilities of the Catholic University of Louvain Medical School, Brussels, Belgium. All animals were kept in a temperature- and humidity-controlled environment in a 12 h light-dark cycle. At all times, they were allowed free access to water and standard food pellet diet (Usine d'Alimentation Rationnelle, Villemoisson-sur-Orges, France). The animals were handled according to the guidelines established by the Catholic University of Louvain.

Surgical procedures and experimental design

All animal manipulations were carried out under light ether anesthesia at room air between 9:00 a.m. and 12:00 noon with the use of a clean, but non-sterile technique. PH consisted in mid-ventral laparotomy and resection of the left lateral and median lobes (70% of the liver), according to Higgins and Anderson[23]. Saline, PDTC (100 mg/kg) and PTX (100 mg/kg) were injected intraperitoneally (i.p.) to the rats 1 h before PH. The rats were killed under ether anesthesia by exsanguination after the puncture of the abdominal aorta and transection of the inferior vena cava in the thoracic cavity, at 0.5 h after PH, i.e. 1 h 30 min after the initial injection of saline or the active compound, and 24 h after PH. Several additional control groups were used for comparison: (1) rats administered saline, PDTC or PTX without PH and killed 1 h after the injection (injection control group), (2) naïve rats that received neither injection not PH (true controls). The livers were removed, lobes were rapidly weighed, snap frozen in liquid nitrogen and stored at -80 ℃. A minimum of three rats was killed in each group at each of the indicated time points.

Preparation of nuclear extracts and electrophoretic mobility shift assays (EMSA)

Nuclear extracts were prepared as previously described[24]. Protein content was determined using a bicinchoninic acid (BCA) protein assay with serum albumin as a standard (Pierce Chemical, Rockford, IL, USA).

Six to ten micrograms of nuclear proteins were pre-incubated for 10 min at room temperature with 2 μg poly (dI-dC) in the following binding buffers: NF-κB (20 mmol/L Hepes, 60 mmol/L KCl, 5 mmol/L $MgCl_2$, 0.2 mmol/L EDTA, 0.5 mmol/L PMSF, 0.5 mmol/L DTT, glycerol 10%, Nonidet P40 1%); Stat3 (10 mmol/L Hepes, 50 mmol/L NaCl, 1 mmol/L EDTA, glycerol 10%). Double stranded oligonucleotides were ^{32}P end-labeled with γ-^{32}P ATP and added to the extracts (10^5 cpm). The mixtures were incubated for 30 min at room temperature and then electrophoresed (200 V, 2 h) on a 5% polyacrylamide gel in a 1× TBE buffer (25 mmol/L Tris-HCl, 25 mmol/L boric acid, 0.5 mmol/L EDTA). To confirm the identity of the protein/DNA complex, supershift analysis was performed: 4 μL of specific antibody (1 μg/μL) was added to the samples after 30 min of incubation with the labeled probe and incubated for a further 30 min. Polyclonal antibodies against NF-κB components p50 and p65, but also p52, c-rel, and rel-B, and anti-Stat3 were purchased from Santa Cruz (CA, USA). The following probes were used: chromatography-purified double stranded oligonucleotides from the class I major histocompatibility complex enhancer element H2κB; TCGAGGGCTGGGGATTCCC CATCTC (NF-κB) and from the serum-inducible factor binding element in the c-fos promoter; CCAGCATTTCCCGTAAATCCTCCAG; (Stat3). A rabbit reticulocyte (Promega Benelux, Leiden, Netherlands) and an EGF-stimulated A431 cell nuclear extract (Santa Cruz Biotechnology) were used as standards for NF-κB and Stat3, respectively. Gels were dried and exposed to a Kodak Biomax MS film (NEN™ Life Science Products, Inc., Boston, MA, USA) for 16 to 24 h.

Thymidine incorporation

One hour before being killed, 50 μCi of [^{3}H]-Thymidine (Amersham, Buckinghamshire, UK) was administrated into the femoral vein under light ether anesthesia. At the time of killing (24 h after PH), livers were removed, weighed and rapidly snap frozen in liquid nitrogen and stored at -80 ℃. Hepatic DNA synthesis was evaluated by measuring the incorporation of [^{3}H]-Thymidine into the DNA. Total hepatic DNA was extracted as previously described[25], and incorporation of radioactive nucleotide was measured in a liquid scintillation counter (Wallac 1409, Turku, Finland). Its value is expressed as disintegrations per minute (dpm) per μg of DNA. All samples were analyzed in duplicate.

PCNA labeling index

Sections from formalin fixed liver tissue (5 μm thick) were air-dried at 37 ℃ overnight and dewaxed. Slides were incubated for 30 min in H_2O_2 0.3% to inhibit endogenous peroxidases, then in TBS containing 10% normal goat serum (NGS, APP Products Ltd, West Midlands, UK) to block non-specific binding sites. Slides were incubated in a monoclonal primary anti-PCNA mouse antibody (PC10, Dako, Denmark; 1:100; overnight), and after washing, with the secondary antibody (anti-mouse antibody; Boehringer, Mannheim, Germany; 1:500; 30 min) followed by streptavidin peroxidase (Boehringer, Mannheim, Germany; 1:1 000; 30 min). Peroxidase activity was revealed by immersion of the slides for 10 min in a 3,3-diaminobenzidine hypochloride solution (DAB 50 mg/100 mL, pH 7.4, Amersham, Cardiff, UK) supplemented with 0.02% H_2O_2. All slides were treated simultaneously to ensure homogeneity of the technique. PCNA labeling index was obtained by examining 3-5 high-power fields in three rats per group. Each field was divided into four zones,

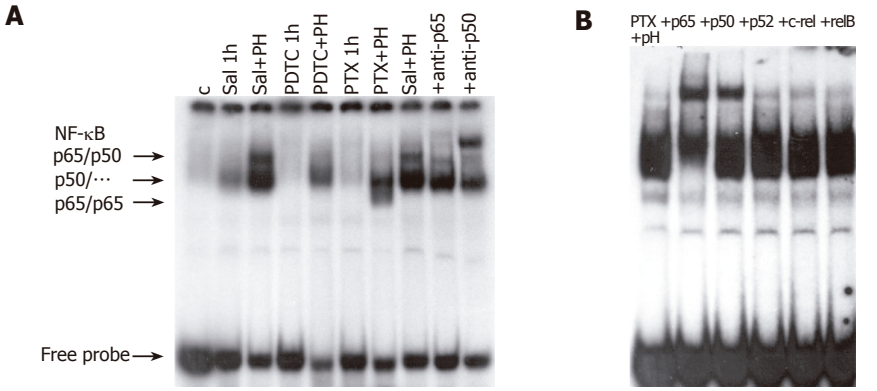

Figure 1 Effect of saline, PDTC, and PTX on NF-κB binding activity. **A:** Nuclear extracts were prepared from non-treated rats (control), from rats injected with saline, PDTC or PTX subjected or not to partial hepatectomy (PH). No NF-κB DNA binding activity was observed in the liver nuclear extracts of non-treated rats (controls) nor 1 h after injection of PDTC or PTX. Faint DNA binding was noticed 1 h after the injection of saline which mainly corresponds to NF-κB p50. Thirty minutes after PH, strong DNA binding was observed in saline-treated groups and two complexes were identified. Supershift experiments identified the upper complex in saline +PH as p65/p50. In the PTX group, a third complex was present 0.5 h after PH, which migrated faster than the dose obtained after saline; **B:** Detailed supershift experiments showed that this faster migrating complex in the PTX+PH group was completely supershifted with the p65 antibody. p52, c-rel and rel-B had no influence on the NF-κB DNA binding activity.

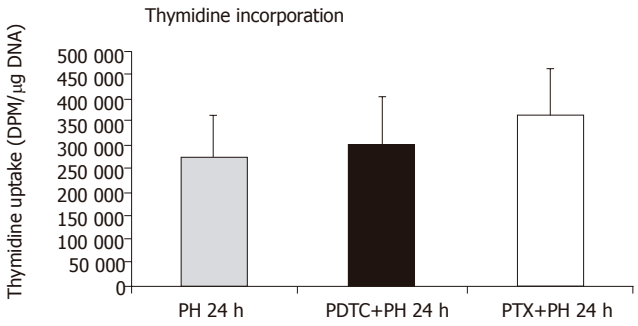

Figure 2 Thymidine incorporation. Similar thymidine incorporation was obtained 24 h after PH in rats pre-treated with an injection of PDTC or PTX compared to non-treated partial hepatectomized rats.

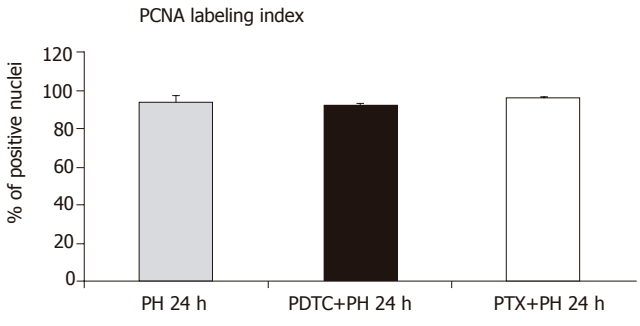

Figure 3 PCNA labeling index. Similar PCNA labeling index was obtained 24 h after PH in rats pre-treated with an injection of PDTC, or PTX compared to non-treated partial hepatectomized rats.

zone 1 being closest to the centrolobular vein and zone 4 corresponding to the periportal areas. Labeling index was defined as the ratio between marked cells and total counted cells.

The same experimented pathologist examined all the slides carefully to detect evidence of necrosis or apoptosis.

Statistical analysis

Results were expressed as mean±SE. The statistical differences between the groups were tested using the one-way analysis of variance (ANOVA), followed by Student-Newman-Keuls multiple comparison tests. Statistical significance was admitted for a P value of <0.05.

RESULTS

Effect of saline, PDTC, and PTX on NF-κB binding activity (Figure 1A)

NF-κB p65/p50 DNA binding activity was not detected in the liver of untreated rats (lane 1) nor in the livers from non-hepatectomized rats 1 h after i.p. injection of saline (lane 2), PDTC (lane 4) or PTX (lane 6). NF-κB was strongly activated 0.5 h after PH preceded by saline injection (lane 3), similarly to activation observed 0.5 h after PH alone[24]. Supershift analysis confirmed the binding of the heterodimer p65/p50 NF-κB complex (lanes 8-10). Injection of PDTC or PTX 1 h before PH prevented the occurrence of the expected p65/p50 DNA binding complex at 0.5 h after PH, since the upper complex was not observed on EMSA (lanes 5 and 7). However, two distinct faster-migrating complexes have been found after PTX (lane 7). The first one, also present after saline or PDTC injection, was partially supershifted by p50 antibody; the second one totally disappeared with p65 antibody. Supershift assays performed with p52, rel B, and c-rel had no influence on this lower complex (Figure 1B).

Effect of PDTC and PTX on hepatocyte proliferation 24 h after PH (Figures 2 and 3)

Hepatocyte proliferation was followed by PH peaks at 24 h. Pretreatment of rats with PDTC or PTX 1 h prior to PH had no effect on liver regeneration. Thymidine incorporation was indeed similarly elevated in all the groups (Figure 2). In untreated rats, 90% of hepatocytes

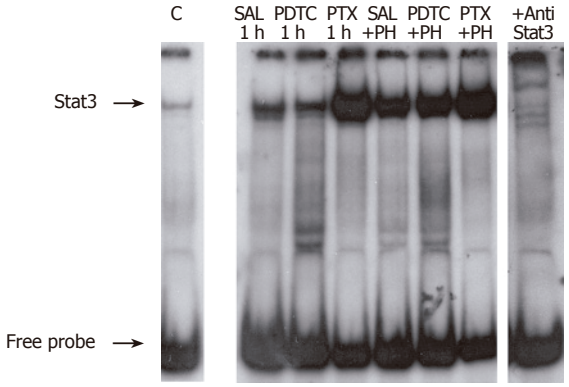

Figure 4 Effect of saline, PDTC and PTX on Stat3 DNA binding activity. No Stat3 DNA binding activity was identified in controls (C). Injection of saline, PDTC or PTX enhanced the binding at 1 h. At 0.5 h after PH, strong Stat3 DNA binding was observed in rats injected with saline, PDTC or PTX. Supershift experiments with a Stat3 specific antibody confirmed that Stat3 is the principal compound of these DNA-binding complexes.

nuclei expressed PCNA 24 h after HP. Pretreatment with PDTC or PTX did not modify the proportion of PCNA positive nuclei in agreement with the thymidine incorporation (Figure 3). No evidence of liver necrosis or massive apoptosis was observed by histological examination.

Effect of injection of saline, PDTC and PTX on Stat3 binding activity (Figure 4)

Stat3 DNA binding activity was not detected in the liver of untreated rats (lane 1), but a Stat3 DNA binding complex was present in the livers from non-hepatectomized rats receiving saline 1 h before being killed (lane 2), PDTC (lane 3) or PTX (lane 4). PH was associated with high Stat3 activity at 0.5 h in animals pretreated with saline (lane 5), PDTC (lane 6) or PTX (lane 7), contrasting with very low Stat3 activation after PH in non-injected rats at this time point. Indeed, as already reported by us and others, PH in non-injected rats was followed by slight Stat3 activation at 0.5 h after PH, peaked at 3 h and was still detected till 8 h[24,26]. Identity of Stat3 was confirmed by supershift analysis with a specific Stat3 antibody (lane 8).

DISCUSSION

PH induces an early cellular response involving pro-inflammatory cytokines like TNF-α or IL-6[27-29] and transcription factors molecules such as NF-κB and Stat3[3,4,30]. In the initiation of proliferating response following hepatic cell mass reduction, a key role seems to be attributed to the activation of the transcription factor NF-κB. The inducible NF-κB factor regulates the expression of numerous genes involved in immune, inflammatory and cellular growth control[11,31,32]. Migrating to the nucleus as soon as 0.5 h after PH[3], it induces the transcription of a large set of immediate-early genes[33]. The NF-κB p65 subunit, important for liver development[34], is responsible for the transcriptional activity of NF-κB[35] and also for its anti-apoptotic effects, preventing the cytotoxic effect of TNF-α and cell death[36,37]. Convergent data suggest that this mediator collaborates with other acute phase gene products in order to protect the cells during the regenerative process[5,38-40]. The most active form of NF-κB is a heterodimer consisting of subunits p50 or NF-κB1 and p65 also called RelA, which contains the transactivation domain necessary for the induction of target genes[41,43]. This active form has been identified after PH as the post-hepatectomy factor[3,30]. Although not consistently reported, the activation of NF-κB after PH has been supposed to be related to an increased expression of TNF-α, although not consistently reported, and/or to oxidative stress[2]. However, various other non specific stimuli are able to induce this activation[44]. Although the importance of the TNF-α pathway has been outlined[6-8], recent studies analyzing liver regeneration in different types of knockout mice suggest that a complete regenerative response may occur in the absence of early factors such as TNF-α, IL-6 or Stat3[43,45]. In order to investigate the role of NF-κB activation in determining the progression into the cell cycle and liver regeneration, we analyzed the effect of NF-κB inhibition on hepatocyte proliferation after PH in normal rat with otherwise normal cytokine expression, regulation and signaling capabilities. Two strategies have been used to prevent NF-κB activation. First, we administered an antioxidant molecule (PDTC) to reduce the oxidative stress, a known stimulus of NF-κB activation. Second, we aimed at decreasing the influence of TNF-α by reducing its production by the use of PTX. PTX and PDTC effectively prevented the activation of NF-κB p65/p50 complex observed 0.5 h after PH in non-treated and saline-treated animals. Despite this absence of NF-κB activation, the hepatocytes responded to the proliferation stimulus: PCNA expression as well as DNA synthesis analyzed 24 h post-PH were normal compared to a classical PH. At that time we did not observe any evidence of liver necrosis or massive apoptosis compared to livers from untreated animals (data not shown). This last observation is in contrast with the results obtained when NF-κB is inhibited by an adenoviral vector expressing a mutated form of IκB-α[5]. The inhibition of NF-κB using this adenoviral vector led to massive apoptosis but also failed to interfere with hepatocyte proliferation. This massive apoptosis could be induced by the adenovirus itself which causes increase of TNF levels and apoptosis before PH. More recently, it has been advocated that the activation of NF-κB in hepatocytes is not needed to induce liver regeneration after PH[10]. The authors also postulated that a preserved activation in non-parenchymal cells could be sufficient to drive both proliferative and anti-apoptotic effects of NF-κB during liver regeneration. This last assumption cannot be found in our experiments, since the inhibition of NF-κB was not targeted to a specific cell type in the liver and, in principal, the substances used in our experiments do act on all liver cell types including the non-parenchymal cells.

We observed that PTX induced another DNA binding

complex after PH, migrating faster, and partially supershifted by the p65 antibody. The functional role of such a complex is not elucidated but may constitute a compensatory response of the Rel family of transcription factors to substitute the usual factor. In a recent study using $p50^{-/-}$ mice[46], PH was associated with a normal regenerative response. P65 protein expression was elevated but without p65/p50 DNA binding activity suggesting that p65 could be part of other complexes, allowing normal regeneration. Considering our data and those obtained in p50 knockout mice, the p65/p50 DNA binding after PH does not seem to be absolutely required for proper liver regeneration. PTX is a potent inhibitor of TNF production which inhibited NF-κB activation but without reducing liver regeneration. These data further reinforce the absence of a link between NF-κB activation and hepatocyte proliferation. However, they do not bring any information concerning a role for TNF-α in the initiation of liver regeneration, since the expression of this factor was not investigated in the study. In contrast to the data demonstrating the quasi absence of Stat3 activation during the first hour after PH[24,26], an early activation of Stat3 was observed as soon as 0.5 h after PH preceded by saline, PDTC and PTX. This suggested that Stat3 was already induced in our model by the first stimulus, i.e. the injection and the required animal handling. This hypothesis was confirmed by the increased Stat3 DNA binding obtained after a single injection of saline, PDTC and PTX. It seems therefore that Stat3 is a component of the acute-phase response induced by stress procedures as minimal as the i.p. injection. This rather non-specific origin for Stat3 activation does not exclude that this factor may play an important role in liver regeneration as documented in studies conducted in IL-6 and TNFR-1 knockout mice in which the restoration of the Stat3 DNA binding following IL-6 supplementation corrected the impaired liver regeneration process[6,47]. It seems thus that Stat3 activation, which is a part of the priming process as described by Bucher *et al.*[48], can be produced by a great variety of stimuli and not necessarily by the PH itself.

As demonstrated previously, sham operation also induced activation of NF-κB and Stat3[24]. PH preceded by a sham operation was associated with a second activation of these transcription factors[49]. In this work, the i.p. injection is a minor stress compared to a sham operation. However, the i.p. injection procedure produced by itself an activation of Stat3 that persisted at the time of PH and probably for a longer period, possibly masking the effects induced by this second intervention. By contrast, a NF-κB response was clearly observed after PH when only saline was injected. When drugs able to inhibit NF-κB activation were injected, this response was indeed suppressed but the proliferation indices were not affected. An activation of liver NF-κB seems thus unnecessary to initiate liver regeneration in those conditions. In conclusion, and in complement to those of others using a transgenic model, our data strongly suggest that an increase of liver NF-κB p65/p50 DNA binding as an immediate response to PH is not essential for inducing liver cell proliferation.

Abstract

AIM: To investigate the relationship between serum paraoxonase (PON1), AST, ALT, GGT, and arylesterase (AE) activity alterations and the degree of liver damage in patients with chronic hepatitis.

METHODS: We studied 34 chronic hepatitis patients and 32 control subjects, aged between 35 and 65 years, in the Department of Infection and Clinical Microbiology at the Firat University School of Medicine. Blood samples were collected from subjects between 8:00 and 10:00 a.m. following a 12-h fast. Baseline and salt-stimulated PON1 activities were measured by the hydrolysis of paraoxon. Phenyl acetate was used as the substrate and formed phenol was measured spectrophotometrically at 270 nm after the addition of a 10-fold diluted serum sample in AE activity measurements.

RESULTS: The results of this investigation revealed that the levels of AE activity decreased from 132±52 to 94±36 (29%), baseline PON1 activity from 452±112 to 164±67 (64%), salt-stimulated PON1 activity from 746±394 to 294±220 (61%), HDL from 58.4±5.1 to 47.2±5.6 (20%), triglyceride from 133±51.2 to 86±34.0 (35%), while a slight increase in the level of LDL (from 163±54.1 to 177.3±56.0; 9%) and significant increases in the levels of AST (from 29±9.3 to 98±44), ALP (from 57.2±13.1 to 91±38.1), ALT (from 27.9±3.32 to 89±19.1), GGT (from 24.3±2.10 to 94±48.2), total bilirubin (from 0.74±0.02 to 1.36±0.06; 84%) and direct bilirubin (from 0.18±0.01 to 0.42±0.04; 133%) were detected. However, the levels of albumin, total protein, cholesterol, and uric acid were almost the same in chronic hepatitis and the control subjects.

CONCLUSION: Low PON1 and AE activity may contribute to the increased liver dysfunction in chronic hepatitis patients by reducing the ability of HDL to retard LDL oxidation and might be clinically useful for monitoring the disease of chronic hepatitis.

Key words: Paraoxonase; Arylesterase; Chronic hepatitis; Lipoproteins

INTRODUCTION

The paraoxonase (PON1), a 44-ku glycoprotein, is synthesized mainly in the liver, which hydrolyzes organophosphates like pesticides, neurotoxins, and arylesters[1-4]. PON1 activity exhibits a substrate-dependent activity polymorphism in human beings[4-6]. This polymorphism is related to two polymorphic sites at amino acid positions. One at position 192, which is a glutamine→arginine substitution, hydrolyzes paraoxon with a high enzyme activity, and the other at position 55, which is a leucine→methione substitution causes a low enzyme activity[7]. The activity of PON1 shows great inter-ethnic variability[8-11]. The gene frequency for $PON1_{R192}$ allele is 0.31 in Turkish population[11] and in Caucasian population[8], 0.41 in Hispanic populations, 0.66 in a Japanese population[8]. Three different phenotypes are reported based on the responses of the two isoenzymes to salt concentrations[6,12]. The ratio of salt-stimulated PON1 activity to arylesterase (AE) activity is used for the definition of phenotypes[6,12,13].

Environmental factors that change PON1 activity include tobacco consumption, which has been reported to depress PON1 activity and concentration[14]. Also, several studies have shown that PON1 level is tightly linked with HDL in the serum and contributes to the protection conferred by HDL against LDL oxidation. Human paraoxonase (PON), an HDL-associated enzyme carried on apo A-I, is believed to protect lipoproteins against oxidative modification[15,16].

As mentioned above, the role of PON1 and AE activity may be particularly meaningful as an index of liver func-

tion status because preliminary studies have revealed a remarkable decrease of serum AE activity in patients with liver cirrhosis[17,18], and AE and PON1 activities have been demonstrated to be a function of a single enzyme[19].

To the best of our knowledge, although AE and PON1 activities have been demonstrated to be a function of a single enzyme[19], both PON1 (only studied by Ferre *et al*.[20]), and AE activity (only studied partly[17,18]) in chronic HBV have not been studied together, as yet. The paucity of data on serum PON1 and AE does not allow for a conclusion about its role in chronic HBV. Therefore, we carried out this study aiming to compare PON1 and AE activities and traditional standard biochemical test of liver function parameters (such as, ALT, AST, and so on), and whether there were changes due to chronic hepatitis.

MATERIALS AND METHODS

We studied 34 chronic hepatitis patients and 32 control subjects, aged between 35 and 65 years, in the Department of Infection and Clinical Microbiology at the Firat University School of Medicine. Control subjects were healthy and evaluated for any symptoms of clinical or analytical evidence of diabetes, renal disease, cardiovascular disease, neoplasia, or hepatic damage and were matched for age and body mass index. Cirrhosis was graded according to Child-Pugh criteria[21]. Blood samples were collected from subjects between 8:00 and 10:00 a.m. following a 12-h fast. The extracted blood samples were then centrifuged at 4 000 r/min for 10 min and stored at -70 ℃ until the assay was performed. This study was performed with the approval of the ethics committee and all subjects volunteered for the study with informed consent.

Assay of paraoxonase activity

PON1 assays were done without additional NaCl (baseline activity) and with 1 mol/L NaCl included in the assay buffer (salt-stimulated activity), following the formation of *p*-nitrophenol by its absorbance at 405 nm for 5 min. Assay buffer contained 0.125 mol/L Tris-HCl (pH 8.5), 1.25 mmol/L $CaCl_2$, and 1 mol/L NaCl (pH 8.5)[4,12]. For each set of assays, 6 mmol/L freshly prepared paraoxon (*O,O*-diethyl-*O*-*p*-nitrophenylphosphate; Sigma Chemical Co.) substrate solution of 120 mmol/L paraoxon in acetone diluted with 0.125 mmol/L Tris-HCl was used. Paraoxon stock solution was handled very cautiously with protective measures. The assay tube contained 750 μL of Tris buffer, 50 μL of serum (1:2 diluted with water) and 200 μL of 6 mmol/L paraoxon. The reaction was initiated at 37 ℃ by the addition of the substrate solution, and using a Techcomp 8500 II Spectrophotometer, absorbance was continuously monitored at 405 nm and 25 ℃. The PON1 unit was defined as the enzyme quantity that disintegrates 1 μmol paraoxon substrate in one minute[4,12]. The percent stimulation of PON1 was calculated as follows[6]: [(PON1 activity with 1 mol/L NaCl)-(basal activity)/basal PON1 activity]×100.

Assay of arylesterase activity

AE activity was measured with phenylacetate as a substrate as previously described[17,18,22]. AE activity was affected with salt. The assay tube contained 750 μL of 0.1 mol/L Tris-HCl (pH 8.5), 1 mmol/L $CaCl_2$, 125 μL of 12 mmol/L phenylacetate and 125 μL of serum (1:10 diluted with water). The absorbance was continuously monitored at 270 nm and 37 ℃. The units were expressed as millimoles of phenylacetate hydrolyzed per minute.

Biochemical parameters of liver function

Serum AST, ALT, ALP, GGT, albumin, total protein, indirect bilirubin, total bilirubin and other biochemical parameters were analyzed with an auto analyzer (Olympus 600).

Statistical analysis

Statistical analysis was performed using Student's *t* test for group comparisons and data for biochemical analyses were expressed as mean±SD. Pearson's correlation coefficients were used to test the correlation between each of the two biochemical variables. Multiple linear regression analysis was used between PON1 and AE activity and possible determinants, such as AST, ALT, ALP, and GGT. A *P* value less than 0.05 was considered statistically significant.

RESULTS

Laboratory results of the standard liver functions tests are documented in Table 1, and provide evidence of the spectrum of disease. As expected, the levels of AST, ALT, ALP, and GGT in the chronic hepatitis patients were significantly increased as compared to the controls. Increased values of transaminase were also matched by a corresponding rise in serum bilirubin. The serum PON1 and AE were obviously correlated with each HDL parameter and triglyceride (TG) in chronic hepatitis patients compared to the controls.

In the present study, we also observed markedly elevated LDL (9%) and decreased HDL (20%) in chronic hepatitis patients as compared to the controls (Table 1). The activities of AE were significantly reduced (by 29%) in the chronic hepatitis group (94±36 U/mL) compared with the control group (132±52 U/mL, $P<0.001$, Table 1). Furthermore, PON1 baseline activity was significantly decreased (by 64%) in the chronic hepatitis group (164±98 U/mL) as compared with the control group (452±138 U/mL, $P<0.001$, Table 1). Also, salt-stimulated serum PON1 activity was decreased (by 61%) in chronic hepatitis group (294±220 U/mL) as compared with the control group (746 ±394 U/mL, $P<0.001$, Table 1).

Comparison of serum PON1/AE activity and traditional standard biochemical test of liver function

We observed negative correlations between ALT and AE activities ($r = -0.112$, $P<0.11$), as well as between the percent stimulation of PON1 and ALT ($r = -0.412$, $P<0.05$) in the chronic hepatitis patients, but not in the controls ($r = 0.142$). In addition, we found obvious negative

Table 1 Traditional standard biochemical test of liver function and some other parameters (mean±SD)

Parameters	Control (n = 32)	Chronic hepatitis (n = 34)
ALT (U/L)	27.9±3.12	89±19.1[b]
AST (U/L)	8±44	29±9.3
GGT (U/L)	24.3±2.10	94±48.2[b]
ALP (U/L)	57.2±13.1	91±38.1[b]
Albumin (mg/dL)	4.83±0.28	4.62±0.17
Total bilirubin (mg/dL)	0.74±0.02	1.36±0.06[b]
Direct bilirubin (mg/dL)	0.18±0.01	0.42±0.03[b]
Total protein (mg/dL)	7.3±0.18	7.3±0.42[a]
Cholesterol (mg/dL)	196±23.3	187±23.2[a]
Uric acid (mg/dL)	4.9±0.33	5.2±0.29[a]
HDL (mg/dL)	58.4±5.4	47.1±5.6[a]
LDL (mg/dL)	163±54.1	177.3±56.0[b]
TG (mg/dL)	133±51.2	86±34.0[b]
[1]Salt-stimulated PON1 (U/mL)	746±364	294±220[a]
Baseline PON1 (U/mL)	452±112	164±67[b]
AE (U/mL)	132±52	94±36[b]

[a]P<0.05, [b]P<0.001 *vs* control subjects; [1]salt stimulated activity.

correlations between GGT and AE activities (r = -0.901, P<0.01), as well as between the percent stimulation of PON1 and ALT (r = -0.412, P<0.05), but not such correlation in the controls (r = -0.122, not significant). We also previously reported similar correlations between AE and PON levels in severe pre-eclamptic women[23].

ALP activity was also correlated with PON1 (r = -0.41, P<0.05) and AE (r = -0.44, P<0.03) activities in the chronic hepatitis group, but not in the controls (r = 0.102). This moderate correlation might be a result of ALP demonstration in different tissues such as bone and small bowel when compared with ALT, which is demonstrated only in the liver.

DISCUSSION

Chronic HBV infection is one of the most important diseases leading to a high morbidity and mortality due to the development of liver failure, liver cirrhosis (LC), and liver cancer[24,25]. There are over 300 million people suffering from HBV infection worldwide[26]. The destruction of liver cells can be extensive, and death follows from liver failure in about 1% of cases. Many of those recover progress to shed the virus for years, while some develop a progressive degenerative liver disease called chronic active hepatitis[24,25,27]. Dramatic alterations in chronic hepatitis remain within laboratory values until gross disease becomes evident. To diagnose such a slow progressive liver disease (chronic hepatitis) before advancing hepatocellular necrosis and fibrosis, beside traditional biochemical tests needs alternative parameters to evaluate liver damage[20].

PON1 and AE activities have been demonstrated in different tissues, such as liver (including microsomes), kidney[28,29], brain[30,31] and lung[30], and it has been studied extensively in relation to cardiovascular diseases[2,3,5,16], whereas there are scarce data available on the hepatic enzyme. Some of these enzymes are released into the circulation and some portions are stored in the liver. Serum PON1, which is carried in circulation bound to HDL particles, protects LDL from peroxidation[2,3,10,14-16,32]. The putative function of PON1 in the liver is to provide hepatic protection against oxidative stress[33].

In the present study, the relation between serum PON1 and AE activity levels and chronic hepatitis was examined. We observed that PON1 and AE activities were obviously lower in the chronic hepatitis patients compared with the control subjects, and were significantly correlated with each HDL parameter, and consistent with reports that this enzyme is bound to a large apo A-I containing HDL subspecies and also confirmed previously reported results[10,15,34-36]. The decrease in PON1/AE activity in the serum was also correlated with serum AST, ALT, GGT, albumin, and bilirubin concentrations. It has been reported that the diagnostic accuracy of PON1 is equivalent to that of ALT in patients with chronic hepatitis and far superior to that of the other tests in patients with cirrhosis[20]. Our results are in agreement with some recent studies in cirrhotic patients[20], rats[33], and chronic hepatitis patients[17,18].

Serum PON1 and AE are mainly the result of liver activity[17]. We have some possible explanations for decreased PON1 and AE activities with chronic hepatitis. One is that even though hepatic PON1 and AE levels may be normal, serum PON1 and AE activity would be lowered as a result of changes in synthesis or secretion of the HDL secondary. This assumption is supported by other researchers[20,37-39]. Alterations in HDL structure and levels related to decreased serum PON1 activities in mice with LCAT deficiency are the consequence of LCAT gene-targeted disruptions. PON1 and AE have also been reported to play a role in the lipid transfer and assembly of VLDL particles in liver microsomes[39]. The other is that liver cells damaged via chronic hepatitis do not express the protein PON1 and AE. Both have been shown to be functions of single enzymes. Supporting this putative function is the report of inhibition of microsomal PON1 activity in rats with chronically administered CCl_4[32]. So, elevated LDL and decreased HDL might have a causal role in the pathogenesis of chronic hepatitis. It is known that PON1 is bound to HDL and acts as an antioxidant that protects LDL from oxidative modifications and can reduce oxidized lipids in oxidized lipoproteins[23].

In conclusion, a significant decrement in PON1 and AE is probably the consequence of liver dysfunction. For this reason, serum PON1 and AE activities could be a beneficial tool for chronic hepatitis patients. However, further research is needed to elucidate the mechanism leading to decreased serum PON1 and AE activities in liver diseases and potential pathophysiologic implications.

ACKNOWLEDGMENTS

We thank Dr. Mehmet Ozdin for help in the initial experimental stage.

Abstract

AIM: To investigate the effects of fermented soy milk powder on the antioxidative status and lipid metabolism in the livers of CCl_4-injected rats.

METHODS: Forty-five healthy male Sprague-Dawley rats were randomly assigned to five groups according to five different diets: control (AIN-76), AIN-76+high-dose fermented soy milk powder, AIN-76+low-dose fermented soy milk powder, AIN-76+high-dose milk yogurt powder and AIN-76+low-dose milk yogurt powder. The experiment lasted for 8 wk. After 4 wk, all the rats received intraperitoneal administration of CCl_4 (0.2 mL/100 g body weight) every week. Total cholesterol (TC), triglyceride (TG), TBARS, ALP, and antioxidative enzymes in the liver were evaluated.

RESULTS: There was also no significant difference in TBARS and antioxidative enzymes in the liver. TC and TG in the groups fed with fermented soy milk powder were generally lower than those fed with casein powder.

CONCLUSION: Consumption of fermented soy milk was positive in lowering total cholesterol and TG accumulation in the liver under CCl_4-induced oxidative stress.

Key words: Soy; Fermented soy milk; Antioxidative; Liver protection

INTRODUCTION

Soybeans contain valuable nutritional attributes. It has been found that the intake of soy foods is closely related to lowering the occurrences of chronic diseases[1]. There are many functional ingredients contained in soy foods such as soy protein, isoflavones, saponins, phytic acid, phytosterol, and phenolic acid[2-4]. Compared to casein, soy protein showed a greater antioxidative ability in preventing lipid oxidation[5]. Isoflavones have been found to increase the activities of some antioxidative enzymes in the liver[6]. Soy foods in Oriental countries can be divided into two categories: unfermented and fermented products. Fermented soy products have been greatly researched recently because their nutritional attributes may be changed due to the metabolism of microorganisms. Fermented soy milk, unlike fermented milk or yogurt drinks, contains no lactose or cholesterol and may have the health benefits from both soy itself and the fermentation. Cheng *et al*.[7] suggested that consumption of fermented soy milk was beneficial to human intestinal health. Our purpose was to investigate the effect of fermented soy milk on liver protection under induced oxidative stress.

MATERIALS AND METHODS

Fermented soy milk

Fermented soy milk was provided by Taiwan Tobacco & Liquor Cooperation (TTL, Taipei, Taiwan, China) Spray drying was applied to produce fermented soy milk powder.

Animals

Forty-five 6-wk-old healthy male Sprague-Dawley (SD) rats (National Laboratory Animal Center, Taiwan, China) were randomly assigned to five groups according to different diets. Guidelines for the ethical care and treatment of animals from the Animal Care Committee at Taipei Medical University were strictly followed. Rats were individually housed and maintained in a temperature-controlled (23±2 ℃) room with a 12-h light/dark cycle. They were fed a chow diet for 1 wk before switching to the experimental diet. Five rats were killed to acquire the baseline biological values of liver. Water and food were available *ad libitum*.

Treatment and sample collection

Fasting blood samples from the tail vein were collected in tubes containing heparin on the last day of wk 0, 2, 4, and 6.

Table 1 Composition of different diets (g/25 g)[1]

	CC[2]	HCS	LCS	HCM	LCM
Corn starch	13.2	4.8	9.0	6.7	9.8
Casein	5.0	4.4	4.7	2.1	4.0
Cellulose	1.6	1.1	1.4	1.1	1.4

Mineral mixture	1.5	0.9	1.2	0.9	1.2
Sucrose	1.5	0.9	1.2	0.9	1.2
Vitamin mixture	0.5	0.3	0.4	0.3	0.4
Methionine	0.1	0.1	0.1	0.1	0.1
Fermented soy milk		10.0	5.0		
Milk yogurt				10.0	5.0

[1]Diets were iso-caloric; [2]CC, control group; HCS, high-dose fermented soy milk powder; LCS, low-dose fermented soy milk powder; HCM, high-dose fermented milk powder; LCM, low-dose fermented milk powder.

The blood was then centrifuged for 15 min at 1 400 r/min to separate the plasma and erythrocytes and stored at -80 ℃. Starting from the 4th wk, rats received an abdominal injection of CCl_4 (0.2 mL/100 g body weight) once a week until the end of the experiment. The body weight of each rat was recorded every 2 d. At the end of wk 8, rats were killed, and liver samples were collected, weighed, and stored at -80 ℃.

Diets

The diets were iso-energetically formulated (Table 1). The control diet was AIN76 (CC). Four experimental diets were prepared by mixing 10 g (HCS), 5 g of fermented soy milk powder (LCS), 10 g (HCM), and 5 g of milk yogurt powder (LCM).

Preparation of liver homogenates and lipid extraction

For preparing liver homogenate, 1.5 g of liver samples was mixed with 2.5 mL of buffer (0.25 mol/L sucrose, 1 mmol/L EDTA, and 10 mmol/L Tris-HCl, pH 7.4) and blended at 4 ℃ (avoiding light), followed by centrifugation at 4 500 r/min for 6 min. The isolated liver cells were stored at -80 ℃.

For extracting liver lipid, 1 g of the liver samples was mixed well with 12 mL of chloroform/methanol (2:1) and then filtered. The filtrate was evenly distributed into two test tubes and chloroform/methanol/H_2O (3:48:47) was added to each tube to 10 mL. Then 2 mL of 0.05% $CaCl_2$ was added to each tube, followed by degassing for 15 min and centrifugation at 2 500 r/min and 4 ℃ for 3 min. The supernatant was removed and methanol was added to the sample to 10 mL. The sample in each tube was then mixed together, to which chloroform/methanol (2:1) was added to 25 mL.

Alkaline phosphatase (ALP) determinations

ALP was evaluated using commercial kits (ALP reagent L-type, Wako).

Activities of antioxidant enzymes in the liver

The activities of antioxidative enzymes were determined using commercial kits: superoxide dismutase (SOD, Calbiochem), glutathione peroxidase (GPx, Randox), and glutathione reductase (GR, Randox).

Thiobarbituric acid reactive substances (TBARS)

A blank (0.1 mL of water), a standard (0.1 mL of 4.2 μmol/L malonaldehyde), or 0.1 mL of the sample was mixed well with the reagent (a mixture of 4 mL of 22% sulfuric acid, 0.5 mL of 10% phosphotungstic acid, and 1 mL of 0.67% 2-thiobarbituric acid). Then the mixture was heated in a water bath to 95 ℃ for 1 h. After being cooled with ice water, 2 mL of butanol was added to the sample, followed by centrifugation at 3 000 r/min for 15 min. The optical density of the pinkish upper part was determined using a fluorescence spectrometer with excitation at 515 nm and emission at 555 nm.

Statistical analysis

All the results were presented as mean±SD. Two-way analysis of variance (ANOVA) and the least significant difference test were performed using SAS® 6.13 to analyze the time and diet effects.

RESULTS

Body weights of the animals

During the feeding period, body weights in each group of all the rats increased (Table 2). At the end of the feeding period, the body weights of rats fed with fermented soy milk powder (HCS and LCS) were significantly higher than those in the other groups (P<0.05). None of the rats showed any abnormal condition.

Alkaline phosphatase (ALP) determinations

ALP activity in the plasma was used to evaluate the liver function. Before injection (i.e. before wk 4) of CCl_4, the ALP (Table 3) in any group did not significantly differ. After injecting CCl_4, ALP activities in all the groups increased (P<0.05). HCS and HCM had higher ALP activities than did the other groups. After wk 6, the ALP activities in the HCS and HCM groups had significantly decreased (P<0.05). In wk 8, the ALP activity in the HCS

group had decreased even lower than those in the HCM group ($P<0.05$).

Antioxidative enzymes, TBARS, TC, and TG in the liver (Table 4)

Results showed that at the end of the feeding period, the catalase activity in the liver in all the groups decreased ($P<0.05$), while the activities in CC and HCS rats were significantly lower than those in the other groups ($P<0.05$). The activity of GPx in all the groups did not significantly change through the experiment. The activity of GR in the LCS group significantly increased at the end and was higher than those in the other groups ($P<0.05$), while those in the other groups did not differ from each other and from the baseline. The activities of SOD in all the groups decreased at the end but only those in the HCS and LCS groups were significantly lower than that in the baseline ($P<0.05$).

At the end of feeding period, the TABRS in all the groups did not differ from each other but tended to be lower or significantly lower (CC, LCS, and LCM; $P<0.05$) than that in the baseline. Rats in the LCS and HCS groups had lower TC value than did those in the HCM, LCM, and control groups ($P<0.05$). Rats in the LCS and HCS groups tended to have lower TG than did those in the HCM and LCM groups.

DISCUSSION

The isoflavone contents of HCS and LCS groups were 0.97 and 0.47 mg/d, respectively in our experiment. Converting the amounts for rats to that for a 70-kg adult, values were about 54 and 27 mg of isoflavones daily although the isoflavone contents in the plasma were either trace or undetectable. It has been pointed out that a daily intake of 50 mg of isoflavones is beneficial to health[8]. The reason why the isoflavones were not detected was due to that all rats were fasted for 8 h before their blood samples were collected. It was found that daidzein and genistein in the plasma were undetectable in rats after 8 h of ingestion[9-11]. The time might have been too long for the isoflavones to be detected.

We found that under such doses of CCl_4, all rats in this experiment had similar activities of GPx and GR in the liver no matter if they had consumed fermented soy milk powder or not. This could be due to a relatively high dose of CCl_4. Zavate[12] pointed out that injecting a dose of 0.2 g/100 g BW of CCl_4 in rats resulted in decreases or deactivation in the activities of catalase, SOD, and GPx, and increases in lipid oxidation in the liver. In addition, the CCl_4 injection produced acute damage to the liver. Protection of the liver through food consumption may not be effective enough in a short period.

In the diets of HCS and LCS groups, we found 3-hydroxyanthranilic acid (3-HAA; data not shown). 3-HAA is a by-product of soy fermentation[13]. It has been found as effective as α-tocopherol and was more effective than genistein[14,15] in inhibiting lipid oxidation *in vivo*. The effect of 3-HAA on protecting liver lipids from oxidation needs further research. Other than 3-HAA, many components in soy are antioxidative. Soy isoflavones, soy protein, and saponins all possess antioxidative abilities[16]. Our data did not clearly suggest that consumption of fermented soy powder was effective in reducing TBARS. This could be due to the limitation when applying TBARS to evaluate lipid oxidation in the liver. Massie *et al.*[17] pointed out that the storage time of liver samples before measuring TBARS affected the results. In addition, the antioxidants such as BHT and EDTA added to the test tubes during the preparation of the liver homogenate also affected the outcomes[18]. In our experiment, addition of EDTA was included in the procedure. In addition, Morrow *et al.*[19] found that under high oxidative stress, the oxidative damages to the liver resulted in an increase in F2-isoprostane (F2-IsoPs) which could not be evaluated with TBARS method.

Our result suggested that consumption of fermented soy milk powder slightly reduced the accumulation of TG in the liver caused by CCl_4. Pencil *et al.*[20] indicated that CCl_4 inhibited the secretion of lipoproteins in the liver and altered the metabolism of fatty acids and resulted in fatty livers.

In conclusion, consumption of fermented soy milk was positive in lowering total cholesterol and TG accumulation in the liver under oxidative stress. Fermented soy milk drink is relatively new to the market. The results open an opportunity to further research on the amount and formula of fermented soy milk needed to achieve health benefits.

Abstract

AIM: To investigate the changes of chaperonin60 (Cpn60) and pancreatic enzymes in pancreatic acinar cells, and to explore their roles in the development of experimental diabetes and acute pancreatitis (AP).

METHODS: Two different pathological models were replicated in Sprague-Dawley rats: streptozotocin-induced diabetes and sodium deoxycholate-induced AP. The contents of Cpn60 and pancreatic enzymes in different compartments of the acinar cells were measured by quantitative immunocytochemistry.

RESULTS: The levels of Cpn60 significantly increased in diabetes, but decreased in AP, especially in the zymogen granules of the pancreatic acinar cells. The elevation of Cpn60 was accompanied with the increased levels of pancreatic lipase and chymotrypsinogen in diabetes. However, a decreased Cpn60 level was accompanied by high levels of lipase and chymotrypsinogen in AP. The amylase level was markedly reduced in both the pathological conditions.

CONCLUSION: The equilibrium between Cpn60 and pancreatic enzymes in the acinar cells breaks in AP, and Cpn60 content decreases, suggesting an insufficient chaperone capacity. This may promote the aggregation and autoactivation of the premature enzymes in the pancreatic acinar cells and play roles in the development of AP.

Key words: Chaperonin60; Pancreatic enzymes; Immunocytochemistry; Diabetes; Acute pancreatitis

INTRODUCTION

Recently, a great deal of work has focused on a family of specific factors known as molecular chaperones. It has been established that molecular chaperones are involved in protein folding, assembly, disassembly, and degradation under normal conditions. It has also been established that molecular chaperones respond to stress states and certain disorders[1-4]. Previous studies demonstrated that Cpn60 was co-distributed with various secretory proteins in acinar cells of the mammalian exocrine pancreas and associated with pancreatic secretory proteins in the intracellular compartments involved in the secretion, such as the rough endoplasmic reticulum (RER), the Golgi (G), and the zymogen secretory granules (ZG). Cpn60 follows the RER →G→ZG pathway in an increasing gradient as pancreatic enzymes[1,5,6]. The association of Cpn60 and pancreatic enzymes along the secretory pathway was confirmed by immunoprecipitation assay on isolated zymogen granule extracts, where amylase and lipase co-precipitated with Cpn60[5]. However, to our knowledge, there is little information available in literature about the relationship between Cpn60 and the enzymes change and also their significance in pancreatic pathogenesis. Therefore, streptozotocin-induced diabetes and deoxycholate-induced acute pancreatitis (AP) models in the Sprague-Dawley (SD) rats were replicated in order to explore the possible alterations of Cpn60 and pancreatic enzymes in the pancreatic acinar cells under the two experimental pathological conditions.

MATERIALS AND METHODS

Chemicals

Rabbit anti-Cpn60 was purchased from Stressgen, Victoria, BC, Canada. Rabbit anti-lipase, rabbit anti-chymotrypsinogen and protein A-gold complex were prepared in the laboratory as previously described[7,8]. Rabbit anti-amylase, sodium deoxycholate (NaDc), urethane and some other chemical reagents were purchased from Sigma Chemical Co., St. Louis, USA.

Animals and preparation of pathological models

SD male rats (n = 15, part from St. Charles River, Quebec, Canada and part from the Animal Center, Shanghai Medical College of Fudan University, China) were randomly divided into three groups: normal control group (n = 4), AP group (n = 6) and diabetes group (n = 5). (1) AP model: Six rats (each weighing 250 g) were fasted overnight with free access to water. They were anesthetized by an intraperitoneal injection of urethane at 1 g/kg body weight. AP was induced by a retrograde injection of 4% NaDc into the biliopancreatic duct (BPD) using a modified method of Zhang *et al*.[9,10]. After a small median laparotomy, the BPD was temporarily closed at the liver hilum with a soft microvascular clamp to prevent reflux of the infused material into the liver. A retrograde injection of 4% NaDc into the distal BPD was performed (40 mg/kg body weight). The clamp was removed 5 min after the injection. The abdomen was closed and the rats were then kept for 5 h. (2) Diabetes model: Five rats were administered with a single intraperitoneal injection of streptozotocin dissolved in 10 mmol/L citrate buffer (pH 4.5), at 70 mg/kg body weight. The hyperglycemic state developed in the first 72 h after injection and remained throughout the 3 mo of the experiment.

Tissue processing

At the end of the experiments, all the rats were anesthetized with urethane and the splenic parts of the pancreases were removed and fixed by immersion with 10 g/L glutaraldehyde in 0.1 mol/L phosphate buffer (pH 7.4) for 2 h at 4 ℃. The tissue samples were washed with the phosphate buffer, dehydrated in a series of graded ethanol solutions, and embedded in Lowicryl K4M at -20 ℃ as described previously[7]. Ultrathin sections were cut, mounted on Parlodion-carbon-coated nickel grids, and processed for immunocytochemistry.

Immunocytochemistry

The ultrathin sections mounted on nickel grids were incubated by floating them on a drop of 1% ovalbumin in PBS (pH 7.2) for 10 min at room temperature (RT). They were then transferred separately to a drop of differently diluted primary antibodies for 2 h at RT (except 4 h for anti-amylase). The antibodies used here included rabbit anti-Cpn60 (1:10), rabbit anti-lipase (1:10), rabbit anti-chymotrypsinogen (1:10), and rabbit anti-amylase (1:500). The grids were rinsed with PBS, transferred to the ovalbumin solution for 10 min, and then incubated on a drop of the protein A-gold complex (10 nm in diameter)[6] for 30 min. They were then thoroughly washed with PBS and rinsed with distilled water. After staining with uranyl acetate, the sections were examined under a Philips 410 electron microscope. The specificity of each immunolabeling was tested effectively by two control experiments described previously[7].

Evaluation

Morphometrical evaluation of the labeling densities, as a reflection of the quantity, was performed using a Videoplan 2 image processing system. At least 30 micrographs, recorded at 28 000× final magnification, were analyzed for each animal tissue. Labeling densities were evaluated as described previously[6] and were reported as the mean of gold particles/μm^2±SE to the mean. Statistical analyses of the results were carried out using the Student's t-test. P<0.05 was considered statistically significant.

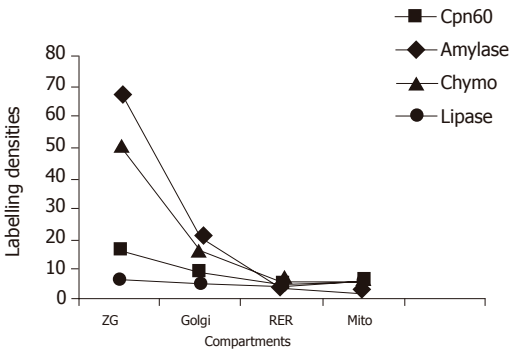

Figure 1 Distribution of Cpn60 and pancreatic enzymes in the compartments of the pancreatic acinar cells in normal rats. Labeling densities (gold particles/μm^2) were measured by immunocytochemistry. ZG: zymogen granules; RER: rough endoplasmic reticulum; Mito: mitochondria; Chymo: chymotrypsinogen.

RESULTS

Distribution of Cpn60 and pancreatic enzymes in the pancreatic acinar cells of rats

Immunocytochemistry labeling study on the sections of the pancreatic tissue revealed that in the acinar cells, both Cpn60 and the pancreatic enzymes, such as lipase, chymotrypsinogen, and amylase, co-existed in the RER, Golgi, and ZG. Increasing gradients of the labeling densities for both Cpn60 and the enzymes were present along the RER-G-ZG secretory pathway, with very low labeling in the mitochondria, in the normal rats and also in the experimental groups. (Figure 1).

Changes of Cpn60 and pancreatic enzymes in the pancreatic acinar cells of diabetic rats

Compared with the normal group, the sections from the diabetic rats showed a significant increase in the Cpn60 labeling density, and also in the lipase and chymotrypsinogen labeling densities, especially in the zymogen granules of the pancreatic acinar cells (Figures 2 and 3). In addition, the immunolabelings of Cpn60 increased nearly 3-fold, lipase 2.5-fold, and chymotrypsinogen was twice as high as the normal group (P<0.05), but amylase level decreased drastically to a very low level (P<0.01 *vs* normal group, Figure 3).

Changes of Cpn60 and pancreatic enzymes in the pancreatic acinar cells of AP rats

In AP, however, the labeling densities of Cpn60 declined through the secretory pathway (RER-G-ZG) of the

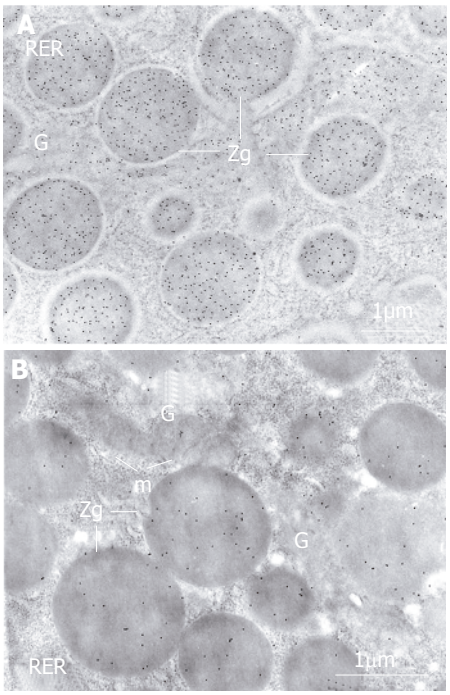

Figure 2 Changes of Cpn60 and pancreatic enzymes in the acinar cells of diabetic rats. The labeling by gold particles (black particles), reflecting Cpn60 antigenic sites, is more intense over the zymogen granules (ZG) in the pancreatic acinar cell in diabetic rat (**A**) compared with that in normal rat (**B**). RER: rough endoplasmic reticulum; G: Golgi; m: mitochondria.

pancreatic acinar cells (Figure 3), more significant in the zymogen granules where Cpn60 content decreased about 40% as compared with the normal group (P<0.05). However, lipase markedly increased and chymotrypsinogen was kept at a high level in the compartment, suggesting a nonparallel change with Cpn60 (Figure 3).

DISCUSSION

Molecular chaperones, including chaperonins (Cpn60 and Cpn10), heat shock proteins (Hsps) and other components are a large family of specialized proteins present in various cellular compartments. Some of them play important roles in enabling polypeptides to reach biologically active forms by serving as "detergents" and "proofreading apparatus" during protein synthesis and secretion[11]. In pancreatic acinar cells, like pancreatic enzymes, Cpn60 follows the well-characterized secretory pathway, sequentially increasing along the RER-G-ZG secretory pathway, and finally being discharged into the pancreatic juice[12-14]. In our former work, we have explored and analyzed the characteristic distribution of Cpn60 in the pancreatic acinar cells of rats, and an association of Cpn60 with lipase, amylase, and trypsinogen in the secretory pathway of normal rats[1,5,6].

The interesting finding, in this study, was that lipase and chymotrypsinogen increased to almost two to three times their normal levels in the acinar cells of the diabetic rats. However, the increased enzymes were not aggregated and autoactivated within the acinar cells like what happened in AP. The acinar cells and the pancreatic tissues were not damaged in this situation. The important protective mechanism may be associated with enough chaperon capacity where Cpn60 content increased significantly (nearly threefold) in the pathological condition. In this regard, it has been reported that Cpn60 is involved in successful folding, sorting, and assembly of pancreatic oligomeric polypeptides, and prevents aggregation of the premature polypeptides[15-17]. In addition, the increase of lipase and chymotrypsinogen and the decrease of amylase in diabetes may represent an adaptive process in which the diabetic body reduced starch digestion and then glucose absorption, and exhausted the fat and protein as the energy sources. In this regard, Nagy *et al.*[18] found a temporarily increased lipase content, when plasma free fatty acid concentration was elevated. The present results demonstrated that the pancreatic lipase and chymotrypsinogen were affected by the body metabolism, and confirmed the complicated correlation between the hormones, enzymes, and the metabolic situation of glucose, fat, and proteins in the body.

AP is caused by different etiologic factors, and each of them affects firstly the pancreatic acinar cells, resulting

in the intracellular activation of trypsinogen, and then the lipolytic enzymes which, in turn, injure the acinar cells and the whole pancreas[19,20]. The autodigestion of the pancreas by its own prematurely activated digestive proteases has been considered as an important event in the occurrence of AP[21,22], but the mechanism is under elucidation. Recently, Lee *et al*.[23] found that water immersion stress induced Hsp60 expression, prevented intrapancreatic trypsinogen activation, and then protected against cerulein-induced rat pancreatitis. Other reports also demonstrated that stresses, such as heat, acid, and osmotic shock, induced an increased transcription and production of Cpn60, and showed a protection for the pancreas, which was considered as an "adaptive cytoprotection"[24–26]. It is well known that in the early stage of AP, progressive increases of amylase, trypsin, and lipase levels are found in the ascites and the plasma (hyperenzymemia), and there is also an increase of enzyme content in the individual acinar cells[27,28].

In the present study, increased labeling densities of lipase and chymotrypsinogen were displayed in the AP sections. As an adaptive cytoprotection, the level of Cpn60 should increase; however, the data showed a decreased Cpn60 level and implied an insufficient chaperone capacity. This could in fact alter the steady-state equilibrium between some pancreatic secretory enzymes and chaperones, thus initiating premature enzyme aggregation and autoactivation in acinar cells. In this regard, Strowski *et al*.[29] found that the pancreas reacted to various kinds of stresses with different inductions of Hsp mRNAs during cerulein-induced AP, and they hypothesized that failure to appropriately increase Hsp levels in response to high doses of cerulein might be a factor involved in the development of pancreatitis. The results of our present study also support this hypothesis.

In summary, the changes in Cpn60 levels coincide with the changes of pancreatic enzyme levels, mostly with lipase, chymotrypsinogen in the pancreatic acinar cells. The equilibrium between Cpn60 and the pancreatic enzymes in the acinar cells breaks in AP, and Cpn60 content decreases, thereby suggesting an insufficient chaperone capacity. This may promote pancreatic premature enzyme autoactivation and play a role in the AP pathogenesis. The findings suggest that replenishing Cpn60 and increasing chaperone capacity may be a new therapeutic clue of AP.

Abstract

AIM: To detect the platelet-activating factor (PAF) and the plasma or serum levels of tumor necrosis factor-α (TNF-α) malondialdehyde (MDA), endotoxin (ET) and to discuss their significance in various types of viral hepatitis.

METHODS: PAF, TNF-α, MDA, and ET levels in 60 controls, 16 cases of acute viral hepatitis, 71 cases of chronic viral hepatitis, 19 cases of severe viral hepatitis were detected by reverse phase high-performance liquid chromatography (rHPLC), bio-assay, ELISA, thiobarbituric acid (TBA), and limulus lysate test (LLT), respectively.

RESULTS: The rHPLC was more sensitive and specific than bio-assay (r = 0.912, P<0.01). The plasma levels of PAF, TNF-α, MDA, and ET in patients with viral hepatitis were higher than those in controls (P<0.01).

CONCLUSION: rHPLC is more reliable and accurate for the detection of PAF.

INTRODUCTION

Platelet-activating factor (PAF) is an autocoid mediator which controls intra- and extra-cellular signal transduction[1]. PAF is produced by a variety of cells including platelets, macrophages, neutrophils, and endothelial cells. Intrahepatic PAF is mainly secreted from Kupffer cells and hepatic sinusoidal endothelial cells. It activates platelets, leukocytes, and smooth muscle contraction. It was reported that PAF, as a mediator of lipid, plays an important role in the occurrence of hepatocyte injuries[2]. Direct infusion of PAF into the liver can result in the rapid release of superoxide and direct damage to liver cells[3,4]. PAF is also a mediator necessary for the development of endotoxin (ET) damage[5]. In endotoxic shock, the production of PAF in tissues is significantly increased. When the concentration of PAF is extremely low in the body, PAF manifests a short half-life of only 30 s and is then transformed rapidly into lyso-PAF without biological activity. PAF is hard to link to the carriers of protein due to its low immunogenicity, which makes the explanation difficult in the antibody preparation. Consequently, the current biological and immunological techniques cannot meet the clinical requirements[6]. Based on the biological determination, we used reverse phase high-performance liquid chromatography (rHPLC) to determine plasma PAF, tumor necrosis factor-α (TNF-α), malondialdehyde (MDA), and ET in patients with viral hepatitis and further clarified their effect and significance in all types of viral hepatitis in order to study the mechanism of viral hepatitis.

MATERIALS AND METHODS

Study population

Between January 2001 and June 2002, 106 patients of both sexes diagnosed as viral hepatitis at the Department of Infectious Diseases of our hospital were recruited in the study. The patients consisted of 16 cases of acute hepatitis, 26 cases of chronic light hepatitis, 20 cases of chronic moderate hepatitis, 25 cases of chronic severe hepatitis (n = 25) and 19 cases of severe hepatitis, ranging in age from 40 to 61 years, with a mean age of 49.5±10.4 years. All the patients were diagnosed by the specialists of the Department of Infectious Diseases in accordance with the diagnostic criteria for viral hepatitis recommended on the 10th National Viral Hepatitis and Hepatopathy Conference in Xi'an 2000. All the patients did not receive

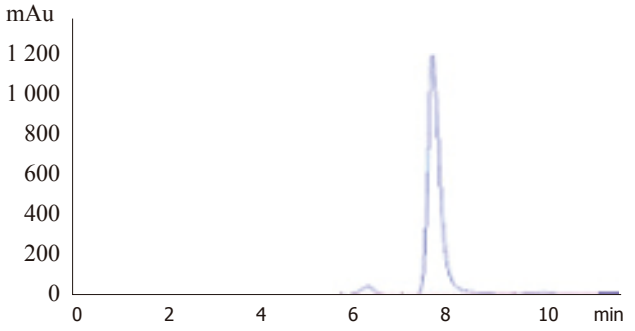

Figure 1 Standard C18 PAF. The horizontal and vertical axes represent the retention time (min) and milli-absorption unit (mAu) respectively, by which the peak area was calculated.

any immunomodulators and any drugs within 2 wk prior to this study.

Healthy control subjects (n = 60) without any thrombotic or communicable diseases were recruited from the blood center.

Blood PAF levels were measured in patients and normal volunteers. We also measured the plasma or serum levels of TNF-α, ET, and MDA.

Agents and devices for PAF analysis by rHPLC

Agilent 1100 series HPLC, water chromatographic column (3.9 mm×150 mm), Lab-line® Aquawave™ ultrasonic cleaner, standard lyso-PAF-C16 and PAF-C18 (chromatographic grade) were from Sigma Company.

Assay of ET, MDA and TNF-α

TNF-α was assayed with ELISA. The testing kits were from Jingmei Biological Engineering Co., Ltd.

ET was determined by limulus lysate test (LLT). The testing kits were from Shanghai Yi-Hua Clinical Medicine Technology Co., Ltd.

MDA was determined by thiobarbituric acid (TBA). The testing kits were from Nanjing Jian-Cheng Biological Engineering Research Institute.

PAF assay

Plasma was separated from whole blood by centrifugation at 3 000 r/min for 10 min and then stored at -70 ℃ until assay. PAF was assayed as previously described[7]. The mobile phase was required according to chromatographic condition, the velocity of flow was 1.0 mL/min, the column temperature was at 25 ℃ (Figure 1) and the determination wave was 208 nm. The PAF values of 20 randomly selected samples were determined by the biological technique established in our laboratory.

Statistical analysis

The descriptive values of variables were expressed as mean±SD. Categorical data were compared between the two groups with the Cochran's Q test. The correlations between laboratory results were evaluated by Pearson's correlation test. P<0.05 was considered statistically significant. All statistical analyses were performed by SPSS for Windows.

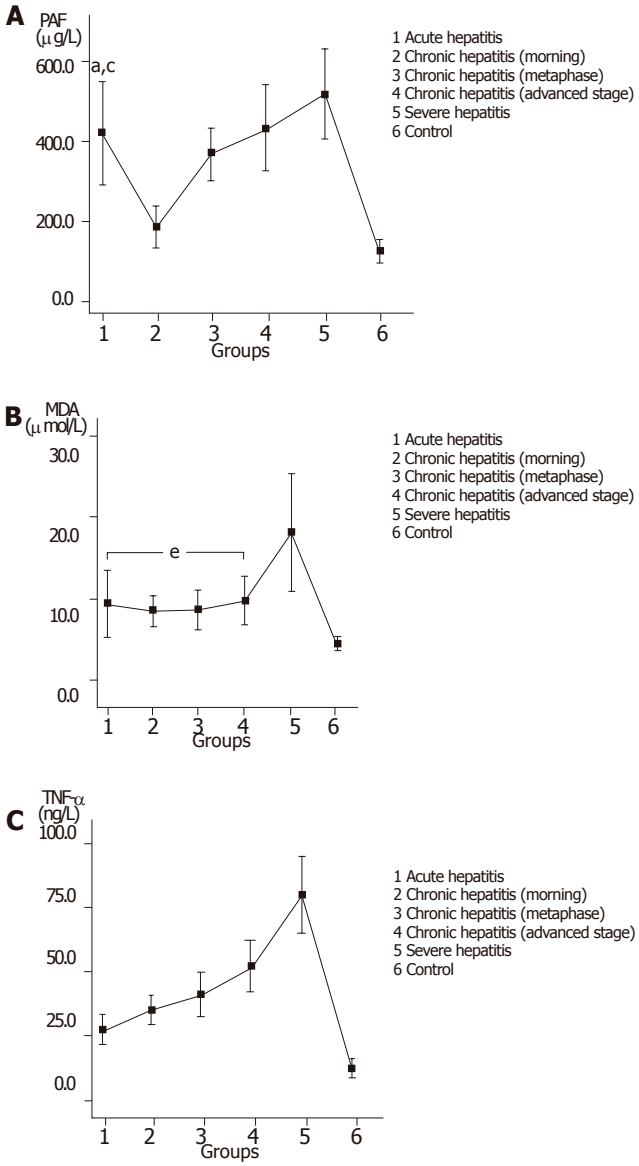

Figure 2 Plasma or serum levels of PAF (**A**), MDA (**B**) and TNF-α (**C**) in patients and controls. The values of PAF, TNF-α and MDA in patients with hepatitis were significantly higher than those in controls (P<0.01). [a]P<0.05 *vs* group 3, [c]P>0.05 *vs* group 4, [e]P>0.05 *vs* every two groups in groups 1-4.

RESULTS

In the assay of PAF by rHPLC, the retention times of lyso-PAF and C18 PAF were 6.2 and 7.8 min, respectively. The correlation analysis was performed for the results in the chromatography group and the biological technique group (r = 0.912, P<0.01).

The ET value of over 50 ng/L represented the positive finding in endotoxemia detection[6]. The detection rate of endotoxemia was 51.9%, 55.9%, 67.8%, and 0% in the patients with acute hepatitis, chronic hepatitis, severe hepatitis, and in the controls, respectively. The positive detection rate in the patients was significantly higher than that in the controls (P<0.01).

The values of PAF, MDA and TNF-α in the patients and controls are shown in Figures 2A-C.

DISCUSSION

The biological assay or radio immunoassay of PAF fails to manifest satisfactory specificity and sensitivity, because PAF in the body is rapidly transformed into lyso-PAF without biological activity[8]. In addition, the procedure is complicated and the results may be influenced by the individual difference of rabbit thrombocytes as well as the surgeon's skill in plate preparation and sample application[9]. The immunoassay may also be limited by antibody preparation that is actually difficult to complete. A desirable correlation is indicated between rHPLC and biological assay. The assay of PAF by rHPLC can lead to the effective separation and then the assay of PAF components (including C16 and C18) with different structures in the assayed sample not related to the biological activity of PAF. Thus, the reference values obtained are notably higher than those obtained by biological assay, contributing to a great increase in accuracy.

The liver plays an important role in removing ET by Kupffer cells and macrophages[10]. In our study, the detection rate of endotoxemia was 52.80%, 56.41%, and 69.57% in acute, chronic and severe hepatitis, respectively. Besides direct damage to the liver, ET is able to induce and release a large amount of inflammatory mediators including PAF and TNF-α by activating Kupffer cells, macrophages and hepatic sinusoidal endothelial cells. These mediators are not only involved in various biological effects of ET, but also exhibit their own biological effects by inducing generation of other inflammatory mediators, resulting in inflammation and tissue injuries in the body by various mechanisms[11,12]. PAF may cause many symptoms of endotoxic shock, including hypotension, cardiac function inhibition, and blood plasma exudation. The specific receptor antagonist of PAF has preventive and therapeutic effects on endotoxic shock. ET also has certain synergistic effect on PAF. Animal experiments showed that simultaneous use of ET and PAF could lead to severe endotoxic shock, granulopenia, and bowel necrosis. The TNF-α gene expression induced by ET is also related to PAF. The PAF antagonist can be used to effectively reduce the level of TNF in blood plasma and partially inhibit intrahepatic synthesis of TNF mRNA, indicating that TNF mRNA may be synthesized in a PAF-dependent manner or in a PAF-independent manner[13].

MDA is generated through lipid peroxidation. It can damage the complete membrane structure of hepatocytes and organelles, activate Kupffer cells, lead to endotoxemia and is closely correlated with the occurrence of hepatopathy[14]. In this study, PAF in patients with acute hepatitis was notably higher than that in patients with early- or medium-phase chronic hepatitis, suggesting that ET, PAF, TNF, and MDA may result in the aggravation of liver injury[15]. The PAF antagonist perfusion into the liver in advance can increase bile production in the affected liver, decrease the production of lipid peroxides (including MDA) and prevent energy damage by PAF. The value of blood MDA is remarkably increased in the early stage of severe hepatitis and returns to the normal levels during convalescence (data not shown)[16]. Therefore, MDA can be used as one of the indicators of diagnosis and prognosis of severe hepatitis.

Abstract

AIM: To explore the possibility of repression of chloromycetin (Cm) acyl transferase by using external guided sequence (EGS) in order to converse the clinical *E coli* isolates from Cm- resistant to Cm- sensitive.

METHODS: EGS directed against chloromycetin acetyl transferase gene (*cat*) was cloned to vector pEGFP-C1 which contains the kanamycin (Km) resistance gene. The recombinant plasmid pEGFP-C1+EGScat1+cat2 was constructed and the blank vector without EGS fragment was used as control plasmids. By using the $CaCl_2$ transformation method, the recombinant plasmids were introduced into the clinically isolated Cm resistant but Km sensitive *E coli* strains. Transformants were screened on LB agar plates containing Km. Extraction of plasmids and PCR were applied to identify the positive clones. The growth curve of EGS transformed bacteria cultured in broth with Cm resistance was determined by using spectrophotometer at A_{600}. Drug sensitivity was tested in solid culture containing Cm by using KB method.

RESULTS: Transformation studies were carried out on 16 clinically isolated Cm-resistant (250 μg/mL of Cm) *E coli* strains by using pEGFP-C1-EGScat1cat2 recombinant plasmid. Transformants were screened on LB-agar plates containing Km after the transformation using EGS. Of the 16 tested strains, 4 strains were transformed successfully. Transformants with EGS plasmid showed growth inhibition when grown in liquid broth culture containing 200 μg/mL of Cm. In drug sensitivity test, these strains were sensitive to Cm on LB-agar plates containing 200 μg/mL of Cm. Extraction of plasmids and PCR amplification showed the existence of EGS plasmids in these four transformed strains. These results indicated that the Cat of the four clinical isolates had been suppressed and the four strains were converted to Cm sensitive ones.

CONCLUSION: The EGS directed against Cat is able to inhibit the expression of Cat, and hence convert Cm-resistant bacteria to Cm-sensitive ones. Thus, the EGS has the capability of converting the phenotype of clinical drug-resistant isolates strains to drug-sensitive ones.

INTRODUCTION

Drug resistance in pathogenic bacteria is a problem of major clinical importance, which has not been effectively solved yet. The traditional approach to this problem is searching for novel antibiotics. However, this is expensive and time consuming, and the bacteria can quickly develop drug resistance to these novel antibiotics. With advances in gene therapy, ribozyme technology[1,2] appeared following antisense RNA technique[3-6], which though is abstract of the activity of catalysis and cleavage. Then, external guide sequence (EGS) technique[7] was found, with the advantages of both ribozyme and antisense RNA. EGS, a synthetic gene coding for small oligoribonucleotides, is able to form complexes with the mRNA encoded by target gene. The complexes are recognized as substrates of RNase P[8-11]. Then, EGS directs RNase P to cleave and inactivate the target mRNA. Therefore, the EGS technique is a method to block a particular gene by inhibiting the translation of its mRNA[12-14]. In 1997, by designing EGS directed against chloromycetin (Cm) acyl transferase (*cat*), Sidney Altman successfully applied EGS technique in engineered bacteria to convert the Cm-resistant bacteria into Cm-sensitive

ones, and hence paved a new way to solve the drug resistance problem[15]. In this study, we investigated the feasibility of applying EGS technique in converting the phenotype of clinically isolated *E coli* from Cm-resistant to Cm-sensitive.

MATERIALS AND METHODS

Materials

The *E coli* samples were clinically isolated from Affiliated Tongji Hospital of Huazhong University of Science and Technology between 2001 and 2002, from which 16 strains resistant to Cm 250 μg/mL and sensitive to kanamycin (Km) 50 μg/mL were selected as test strains. Plasmid pEGFP-C1 and pKB EGS cat1+cat2 were kindly provided by Dr. Sidney Altman (Yale University, USA). The plasmid pKB EGS cat1+cat2 was constructed according to the method in the literature[15].

Methods

Construction of pEGFP-C1-EGS cat1+cat2 recombinant plasmids A 510-bp EGS fragment directed against Cm acetyl transferase gene (*cat*) was cloned into pEGFP-C1 plasmid containing kanamycin-resistant gene between EcoRI and I sites. The EGS includes: M1RNA promoter, EGScat1, hammerhead sequence (HH1, HH2), EGScat2, HH3, and M1 terminator. The recombinant pEGFP-C1 plasmid containing EGScat1+cat2 was named K_3 plasmid, while pEGFP-C1 plasmid that had Km resistance gene but without EGS fragment was named as K plasmid.

Identification of partial phenotypes of clinically isolated *E coli*: (1) *Purification of the test bacteria* The clinically isolated bacterial strains were streaked on the LB plates and cultured for 6-8 h. A single colony on the plates was selected for Gram staining and its cellular configuration was checked under the microscope. Other single colony was then taken and diluted to 10^{-8}. The clone grown on plates with 30-300 colonies was taken for tests of Cm drug resistance and Km drug sensitivity again, and then Gram stained for morphology check. These steps were repeated until pure bacterium strains were obtained[16]; (2) *Extraction of plasmids of the test bacteria and determination of plasmid incompatibility* The methods for plasmid extraction and incompatibility determination were described by Huang[17]; (3) *Determination of spontaneous mutation rate of the test bacteria* The spontaneous mutation rate of testing bacteria to Km was determined for colonies grown on LB and LB+Km plates by using dilution plate counting method[18]; (4) *Determination of logarithmic growth stage of test* bacteria *Bacterial* growth curve were plotted based on bacterial optical density (A_{600})[19].

Transformation of test bacteria by pEGFP-C1-EGScat1+cat2 recombinant plasmids and identification: (1) *Transforming test* The competent cells of testing bacteria were prepared by using $CaCl_2$ method, and were transformed respectively with plasmids K3 and K[20]. The transformants that received K3 plasmid were designated as testing bacteria, and those transformed with K plasmid without EGS were used as plasmid controls. The competent cells from original testing bacteria were mock-transformed (without plasmid) and served as strain controls. Competent cells were inoculated on LB plates containing 50 μg/mL of Km after transformation, followed by incubation at 37 ℃ for 12-16 h; (2) *Extraction of plasmids and total DNA* Plasmid was extracted by using alkaline cleavage method[17] and total DNA was extracted by using the boiling method[21]. Positive clones were selected and transferred into Eppendorf tubes containing 20 μL sterilized water and boiled for 10 min. The supernatant was collected after centrifugation; (3) *PCR amplification* The primers were designed specifically for the inserted EGS on the vector. The amplified fragment containing EGScat1 and cat2 was 391 bp. The primer pairs used for PCR amplification were 5'-AGCCTGACCGATGATGTTG-3' and 5' -TCCTCACGGACTCATC AGAC-3'. The PCR reactions were performed at 94 ℃ for 1 min, 57 ℃ for 1 min, and 72 ℃ for 1.5 min, total 30 cycles. The PCR products were electrophoresed on a 1.5% agarose gel; (4) *Cm sensitivity test of the transformants* After transformation, the colonies grown on plates and the original colonies were re-inoculated on the LB plates containing 200 μg/mL of Cm and plates containing 50 μg/mL of Km, and incubated at 37 ℃ for 8-12 h. Then, their growth conditions on these two plates were checked and recorded; (5) *Growth determination of transformants in liquid broth* The colonies (K3, K plasmid transformants and original bacteria) were separately inoculated into 200 mL of broth culture containing Cm (200 μg/mL) with the inoculating concentration A_{600} = 0.05, and incubated in an orbital shaker at 37 ℃ and 200 r/min. A 0.5 mL bacterial suspension was sampled hourly and its A value was determined. Growth curve was plotted according to the constantly collected A values. The transformants were also incubated at the same concentrations into PA bottles at 37 ℃ and the bacterial growth was observed hourly as well.

RESULTS

Study of the partial phenotypes of the clinically isolated E coli strains' rates of spontaneous mutation

Sixty-one Cm-resistant but Km-sensitive *E coli* strains were clinically isolated. Of them, 16 strains were selected as test strains for their comparatively low simultaneous mutation rate. However, the test strains sensitive to Km were still suitable to present the spontaneous mutation and hence obtain Km resistance after culturing in a big scale. Among them, strains 16, 20, 3 900, and 6 470 showed the lowest mutation rate of Km drug resistance, being 8.85×10^{-6}, 3.36×10^{-6}, 6.57×10^{-7}, and 2.96×10^{-7}, respectively. The data of others were little higher than 10^{-5}.

Plasmids' profile of the test bacteria The plasmid profile of the test strains showed that each contained 2-3 plasmid bands. Introducing the plasmids extracted from test bacteria into *E coli* DH5α (no indigenous plasmids) indicated that Cm-resistant gene was located in the plasmids. The existence of resistance plasmids in the test strains may account for the difficulty of introducing EGS

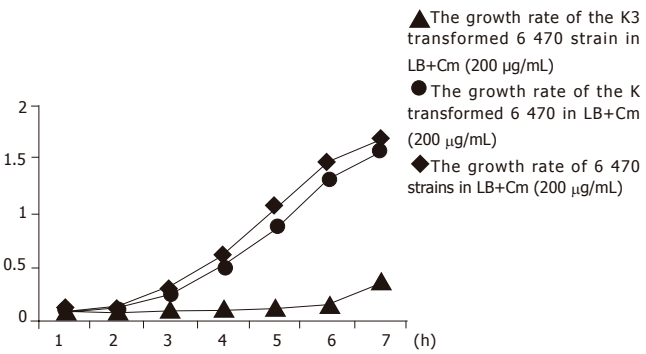

Figure 1 Growth curve of the transformants in the broth containing Cm after K3 plasmid and K plasmid were introduced into 6 470 strains of Cm-resistant *E coli*.

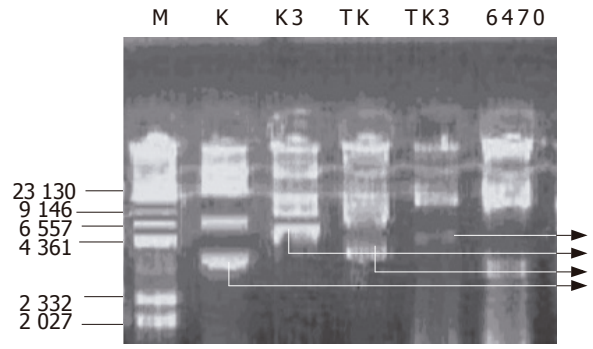

Figure 3 Results of rapid plasmid extraction after K3 plasmid and K plasmid were introduced into 6 470, K and TK, K3 and TK3 can be detected in similar bands.

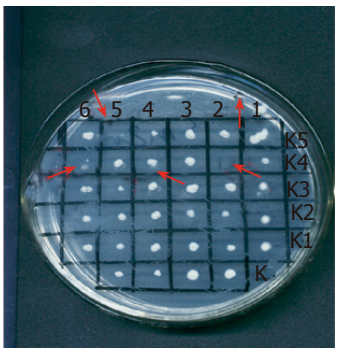

In the grids (red arrows), the K3 transformed 6 470 became sensitive to Cm in the LB-+Cm (200 μg/mL) plates. Up to low, the lines of 4 and 5 showed that the K transformed bacteria grew well in LB+Cm (200 μg/mL) plates. The last line showed the growth of the original 6 470 strains

Figure 2 Susceptibility test of the transformed bacteria in solid culture containing Cm (200 μg/mL) after K3 plasmids and K plasmids were introduced into 6 470

plasmid into the cells. Furthermore, the DH5α derivatives transformed with the plasmids extracted from test bacteria were hard to be transformed again with K3 and K. This suggested the plasmid incompatibility between original plasmids and K or K3 plasmids.

Determination of logarithmic phase The bacterial growth curve revealed that the logarithmic growth stage was from 4 to 8 h after being inoculated in the broth. In this study, the fresh culture of test strains was harvested in this period to prepare competitive cells.

Growth rate of the transformed bacteria in liquid broth culture

Four strains, 16, 20, 3 900, and 6 470 were transformed with K3 successfully. Kinetic growth study demonstrated that these four strains transformed with K3 plasmid exhibited growth inhibition in the broth containing 200 μg/mL of Cm (Figure 1). The growth inhibition became apparent at 2 h and peaked at 3 and 4 h, but active growth resumed at 5 h. In contrast, neither bacteria transformed with K plasmid nor original bacteria with mock-transformation showed any growth inhibition in the incubation condition described above. Their concentrations increased steadily as demonstrated by A_{600} values. Although the number of bacteria transformed with EGS began to elevate at 5 h, the degree of growth was much lower than that of the original bacteria. In PA bottles, the K3 plasmid transformed bacterial culture was still clear at 6 h to the naked eye and started to be turbid at 8 h, while the culture for K plasmid transformed bacteria or mock-transformed original bacteria started to be turbid at 3 h and was highly turbid at 6 h. The above findings demonstrated that EGS gene was able to convert bacteria from Cm-resistant to Cm-sensitive phenotype. All of the four strains that obtained their phenotypic conversion of drug resistance showed a lower spontaneous mutation rate, which may contribute to their easy transformation because of their stability. They exhibited very few variant strains when cultured on Km plates, and thus the transformants could be easily identified and collected.

Drug sensitivity test of transformed bacteria

Drug sensitivity test showed that the four strains transformed with K3 plasmid not only obtained sensitivity to Cm in liquid broth culture but also became sensitive to Cm in LB+Cm (200 μg/mL) solid culture (as indicated in Figure 2). The bacteria transformed with K plasmid and the original isolates grew well in LB+Cm (200 μg/mL) solid culture.

Determination of plasmid extraction from testing bacteria transformed by pEGFP-C1-EGS cat1+cat2 and identification of clones by PCR

Determination of the plasmids in transformed bacteria Four strains of transformed bacteria were subjected to the determination of the plasmid extraction. Figure 3 is the map of rapid extraction of plasmid and Figure 4 is the map of plasmid extraction after the transformants were cultured for 2 d. Figure 3 shows that the K and K3 can be detected in the strains transformed with K and K3, respectively. This indicated that K3 and K plasmids had been introduced into the cells successfully. In Figure 4, TK had the same bands as K, while TK3 had no similar bands as K3, indicating that the K3 plasmid was lost or had been degraded after 2 d of culturing. This may explain why the transformant retained its growing capacity gradually after several hours of culturing in the broth medium.

Identification of EGS gene by PCR The colonies transformed with K3, which did not grow on LB+Cm (200 μg/mL) plate (restoration of Cm sensitivity) but grew well in the corresponding LB+Km (50 μg/mL) plate, were

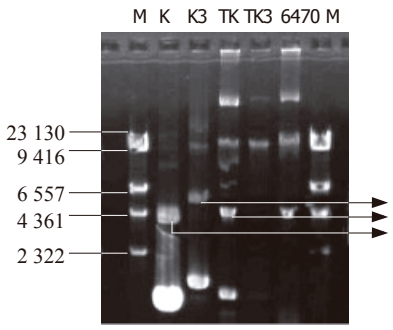

Figure 4 The map of plasmid extraction after the transformants were cultured for 2 d, K and TK can be detected in similar bands, while TK3 had no similar bands as K3, indicating the K3 plasmid was lost or had been degraded. M: Marker; lane K: control plasmid; K3; EGS plasmid; TK, 6 470 transformed with K plasmid; TK3, 6 470 transformed with K3; 6 470, original Cm-resistant 6 470.

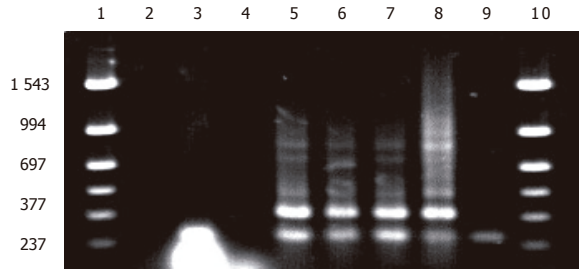

Figure 5 Electrophoresis of PCR amplification of EGS genes in the transformed bacteria after K plasmid and K3 plasmid introduced into 6 470. Lanes 1 and 10 Mmarker; Llane 2, blank control; lane 3, transformants cultured 2 d more; lane 4, original 6 470 strains; lanes 5, 6 and 7: 6 470 derivatives transformed with K3; lane 8: plasmid K3 (positive control); lane 9: K plasmid transformants (negative control).

used for PCR amplification of EGS fragments. K3 plasmid was used as positive control and clones transformed with K plasmid, original testing bacteria and DNA-free distilled water were used as negative controls. As shown in Figure 5, lanes 5, 6, and 7 were clones transformed with K3 plasmid that did not grow on LB+Cm plate, showing that these clones contained the EGS gene fragment (391 bp, lane 8). Lanes 4 and 9 were original test bacteria and K plasmid transformed bacteria, showing no EGS gene fragment in these strains. Lane 3 was the clone that initially resumed Cm sensitivity but lost the sensitivity 2 d later on LB+Cm plate. PCR amplification failed to detect any EGS band, suggesting the loss of EGS plasmid in this clone.

DISCUSSION

The problem of microbial drug resistance is growing severely year after year clinically. To cope with this problem, destroying the drug resistance gene is an effective and potential approach, in which no effective method has so far been achieved[22-24]. In 1997, Sidney Altman introduced EGS technique, which conversed the Cm resistance successfully. On the basis of the study on engineered bacteria by Altman, this study further introduced the EGS gene into the clinically isolated bacterial strains. Our study demonstrated EGS-mediated conversion of a Cm-resistant to a Cm-sensitive phenotype, and further showed the successful conversion of drug resistance by the introduction of EGS gene not only in laboratory bacteria but also in clinically isolated bacteria. This indicates a potential clinical utilization.

Mutation is a common phenomenon present in microorganisms. The clinically isolated bacterial strains are characterized with even higher spontaneous mutation rate than lab strains. In the early period of our experiments, it was found that the competent cells of the control bacteria sensitive to Km not transformed with plasmids and originally sensitive to Km still grew on the Km plates. At first, it was mistakenly rendered as the result of impurity of test strain. After further purification and spontaneous mutation study, we understood that it has resulted from high mutation rate of the clinically isolated bacteria. Mutated test strains obtained Km resistance, lost Km-sensitiveness, and therefore made selecting transformants difficult. To solve this problem, our efforts focused on selecting stable strains with low spontaneous mutation rate. At the end of the procedure, 16 comparatively stable strains were screened from the clinically isolated bacterial strains.

In this study, only 4 of 16 test strains were converted from drug-resistant to drug-sensitive phenotype. The low efficiency of conversion may be ascribed to the low transformation efficiency. Firstly, as *Enterobacteriaceae*, test strains were hard to be transformed for their native low transformation frequency[25]. Secondly, the low transformation rate can be contributed to the existence of host plasmids in test strain which may result in plasmid incompatibility. Thirdly, although the criteria for screening positive transformants in the culture medium containing Km were set up, not all of the transformed bacteria were desired transformants due to the spontaneous mutation of the testing bacteria. We believe that even if we select other sensitive antibiotics to testing bacterial strains, spontaneous mutation would also happen. So suitable methods to screen positive transformants were abstract. Km resistance in this study did not function as an effective selection marker due to the spontaneous mutation of the test strains. To increase the efficiency of conversion, we tried to apply one-step method[26] and electroporation transformation method, but the results were also not satisfactory. Although we can construct recombinant plasmids and insert a fluorescence enzyme's gene into the vector (EGFP site at pEGFP-C1 vector) to aid in screening, it may increase the transforming difficulty or render the transformed bacteria. In order to reduce the false positive clone in transformation assay, the original bacteria with high spontaneous mutation rate were excluded. At the same time, we found that the efficiency of transformation could be enhanced by using SOC medium and by collecting cell culture at early logarithmic phase. Transformation could be facilitated by washing cell culture with $CaCl_2$ solution for 2-3 times instead of once as well. This might be contributed to the increased permeability of the *E coli* wall.

PCR amplification was used to identify positive clones. In contrast to the spontaneously mutated bacterial strains, the transformants obtained through transformation grew slowly on the Km plates. On the other hand, long time culturing resulted in the loss of plasmids. Thus, it was difficult to identify the EGS transformants by plasmid extraction. In this study, PCR was applied to identify the presence of EGS in the EGS transformed bacteria and it worked effectively. Certainly, further study is to perform Northern blot to know the attenuation of mRNA transcribed from cat gene, which could further definitely verify the roles of EGS. As our conditions are limited, the experiment was not done.

EGS as a sort of synthesized oligonucleotides can combine the target RNA to form the substrate similar to pre-tRNA, which can be cleaved by RNase P and lose the ability of further gene expression. The targeted mRNA is cleaved but EGS itself is not cleaved[7]. EGS can function continuously. In this study, however, we found that the positive clones regained the Cm resistance after being cultured in broth containing Cm for 8 h and then on solid culture for 2 d. No EGS was detected and no plasmid could be extracted in clones that regained Cm resistance. This demonstrated that EGS plasmid had been lost in the host because of continuous culture. The reason might be due to an incompatibility between indigenous and exogenous plasmids.

Our experiments demonstrated that culturing on Km plates facilitated EGS plasmid inheritance, while culturing on the Cm plates was prone to result in the loss of EGS plasmid. This study also suggested the need for more effective methods to introduce EGS into the bacterial cells and to maintain its stability. Though a lot of challenges were involved in this study, transformants were still obtained. The results reflected the effectiveness of the EGS transforming drug-resistant bacteria, and provided a foundation for the clinical application of EGS.

In recent years, although RNA interference technique has been developed, no RNA interference phenomenon was observed in prokaryotes[27-30]. Thus, the EGS technique still is the most prospective way to solve bacterial drug resistance. As to the development of EGS technique, Sidney Altman put forward that enhancing the promoter, increasing the copy of EGS, augmenting the binding sites of EGS and stabling the EGS-mRNA complex are the potential methods. Furthermore, combined with nanotechnology, the EGS technology could be more promising. Conclusively, to improve this study, more measures should be explored for further investigation.

ACKNOWLEDGMENTS

We are deeply indebted to Professor Altman for kindly providing the plasmid and for his abundant help in this study.

Abstract

AIM: To evaluate the role of peritoneal lavage cytology (PLC) and carcinoembryonic antigen (CEA) determination of peritoneal washes (pCEA) in predicting the peritoneal metastasis and prognosis after curative resection of gastric cancer.

METHODS: PLC and radioimmunoassay of CEA were performed in peritoneal washes from 64 patients with gastric cancer and 8 patients with benign diseases.

RESULTS: The positive rate of pCEA (40.6%) was significantly higher than that of PLC (23.4%) (P<0.05). The positive rates of PLC and pCEA correlated with the depth of tumor invasion and lymph node metastasis (P<0.05). pCEA was found to have a higher sensitivity and a lower false-positive rate in predicting peritoneal metastasis after curative resection of gastric cancer as compared to PLC. The 1-, 3-, and 5-year survival rates of patients with positive cytologic findings or positive pCEA results were significantly lower than those of patients with negative cytologic findings or negative pCEA results (P<0.05). Multivariate analysis indicated that pCEA was an independent prognostic factor for the survival of patients with gastric cancer.

CONCLUSION: Intraoperative pCEA is a more sensitive and reliable predictor of peritoneal metastasis as well as prognosis in patients with gastric cancer as compared to PLC method.

INTRODUCTION

Peritoneal metastasis is the most common mode of relapse of gastric cancer after surgery and is the most frequent cause of death in patients with gastric cancer[1-3]. Peritoneal recurrence develops from micrometastasis originating from peritoneal free cancer cells. Therefore, it is very important to examine the presence or absence of free cancer cells in the peritoneal cavity at the time of surgery[4,5]. PLC is the gold standard for assessing the presence of peritoneal dissemination of gastric cancer, but its sensitivity is relatively low, ranging 14-21% in gastric cancer involving the serosa[6-8]. Recently, several new methods for detecting micrometastasis, including immunohistochemical and biological methods have been developed[9-11]. However, these diagnostic techniques are time-consuming and laborious compared to conventional cytological method. Therefore, a new and more sensitive method for the early detection of peritoneal metastasis is required.

In this paper, we have reported the clinical significance of a new method to detect peritoneal micrometastasis in combination with cytological method and measurement of pCEA level in peritoneal washes.

MATERIALS AND METHODS

Patients

Between December 1995 and December 1997, 64 patients with histologically confirmed gastric cancer underwent surgery at the Department of General Surgery of First Affiliated People's Hospital of Shanghai Jiaotong University. All patients underwent either a total or a partial gastrectomy with lymph node dissection and received no preoperative chemotherapy or radiotherapy before the surgery. These 64 cases included 42 male and 22 female patients with an average age of 59 (range 34-84 years) years. All specimens were histologically examined by HE staining according to the general rules of the Japanese Classification of Gastric Carcinoma[12]. Seven patients with

the maximum depth of tumor invasion at mucosal or submucosal level, were diagnosed as early gastric cancer. The other 57 cases were diagnosed as advanced gastric cancer with invasion deep into the gastric wall. In this study, eight patients with benign diseases such as peptic ulcer or cholecystolithiasis served as controls. The follow-up period ranged 9-74 mo and the median follow-up period was 39 mo.

Examination of peritoneal washes

The study consisted of 64 patients with gastric cancer and 8 patients with benign disease. After laparotomy, 50 mL physiological saline was introduced into the right upper quadrant or the Douglas pouch immediately and then 20 mL fluid was collected. The fluid sample was immediately centrifuged for 5 min at 1 500 r/min. The sediment of each fluid sample was smeared on a glass slide. The slide was fixed in 99% alcohol, stained with HE and examined for the presence of cancer cells by an experienced pathologist. The supernatant of each sample was concentrated by ultrafiltration. CEA levels of the concentrated supernatant (pCEA) were measured with a radiometric immunoassay kit (Delfia CEA kit, Wallac Oy, Turku, Finland) and expressed as ng/g of protein. The cut-off level was set according to Takayuki method (pCEA level ≥100 ng/g of protein was defined as positive)[13].

Statistical analysis

All the statistical analyses were done with SPSS statistical software. The χ^2 test was used to compare the positive results in CEA level and cytological examination. The survival rate was calculated by the Kaplan-Meier method and statistical difference was evaluated by the long-rank test. A Cox proportional hazard model was established to identify the independent prognostic factors.

RESULTS

Correlation between PLC or pCEA and clinicopathologic parameters

All the eight patients with benign diseases had a negative PLC finding or a pCEA level below the positive standard. Fifteen of sixty-four patients with gastric cancer had a positive PLC finding and an elevated pCEA level. Among the 49 patients with negative PLC findings, 11 had an elevated pCEA level. The overall pCEA positive rate in 64 patients with gastric cancer was 40.6% (26/64), which was significantly higher than that of PLC [23.4% (15/64), $P<0.05$]. We analyzed the correlation between PLC or pCEA positive rate and various clinicopathologic factors. The PLC and pCEA positive rates were significantly associated with the depth of tumor invasion and lymph node involvement. The patients with serosal invasion had a significantly higher PLC or pCEA positive rate than those without serosal invasion ($P<0.01$). The pCEA positive rate in patients with lymph node involvement was significantly higher than that in patients without lymph node involvement ($P<0.05$). Though the PLC positive rate in patients with lymph node involvement was also higher than that in patients without lymph node involvement, the difference did not reach statistical significance ($P>0.05$, Table 1).

Predicting values of PLC and pCEA for postoperative peritoneal recurrence of gastric cancer

Thirty-seven of sixty-four patients with gastric cancer had various postoperative recurrences (57.8%). Among the 37 patients with recurrence, 19 had peritoneal recurrence within 2 years after the surgery. The peritoneal recurrence rate was 29.7%. The accuracy, sensitivity, specificity, positive and negative predictive values, false negative and positive rates of PLC or pCEA in predicting peritoneal recurrence are shown in Table 2.

Correlation between PLC or pCEA and prognosis

The 1-, 3-, and 5-year survival rates were 53.3%, 13.3%, and 0.0%, respectively in patients with positive PLC findings, which were significantly lower than 87.8%, 71.4%, and 55.1% in those with negative PLC findings ($P<0.05$). Similarly, a significant difference in survival rates between pCEA-positive group and pCEA-negative group was observed. The 1-, 3-, and 5-year survival rates were 46.2%, 23.1%, and 15.4% in pCEA positive group and 89.5%, 73.7%, and 60.5% in pCEA negative group ($P<0.05$). Multivariate Cox survival analysis showed that PLC was not an independent prognostic factor, but pCEA was an independent prognostic factor with a relative risk rate of 9.046 ($P = 0.0092$).

Table 1 Correlation between the results of peritoneal washes and clinicopathological factors

Clinicopathological factors	*N*	PLC(+)		*P*	pCEA(+)		*P*
		n	%		*n*	%	
Tumor size							
≤4 cm	28	4	14.3	>0.05	9	32.1	>0.05

Table 2 Results of PLC and pCEA in predicting peritoneal recurrence of gastric cancer after surgery (%)

	Accuracy	Sensitivity	Specificity	Positive predictive value	Negative predictive value	False negative rate	False positive rate
PLC	90.6	73.7	97.8	93.3	89.8	26.3	2.2
pCEA	85.9	94.7	82.2	69.2	97.4	5.3	17.8

DISCUSSION

Though radical surgery is routinely practised, tumor recurrence is frequent in patients with gastric cancer. Peritoneal recurrence of gastric cancer is one of the most common patterns of recurrence and predicts a very poor prognosis for patients with gastric cancer[2,3,14,15]. Peritoneal dissemination was also prevalent in our current prospective study, which was observed in 19 of 64 patients (29.7%) following a potentially curative surgery. Peritoneal recurrence develops from peritoneal free cancer cells originating from primary lesion or metastatic lymph nodes[6,14,15]. However, it is difficult to identify these free cancer cells in the peritoneal cavity before or during the surgery[16]. In order to prevent postoperative peritoneal recurrence and increase the survival rate, it is important to find a more sensitive, accurate, and convenient method to detect the presence of free cancer cells in the peritoneal cavity and to eliminate these cells with effective measures such as adjuvant intra-peritoneal chemotherapy[17,18].

PLC is the gold standard for assessing the presence of free gastric cancer cells in the peritoneal cavity[6-8,19]. Cytology-positive patients are classified as stage IV of Union International Contrele Cancer (UICC) gastric cancer classification and curative surgery is impossible in such cases. The present study revealed that the PLC positive rate in patients with serosal invasion (35.1%) was significantly higher than that in patients without serosal invasion (7.4%), indicating that the PLC positive rate increases with the invasion of gastric serosa and the chance of peritoneal dissemination increases in case, the gastric serosa is infiltrated. However, 14 of 19 patients with postoperative peritoneal recurrence had a positive PLC finding and the other five cases were PLC negative. PLC showed an accuracy of 90.6%, a sensitivity of 73.7%, and a specificity of 97.8% in predicting peritoneal recurrence of gastric cancer. The positive and negative predicting value, the false negative and positive rates of PLC were 93.3%, 89.8%, 26.3%, and 2.2%, respectively, suggesting that PLC is a very useful method for predicting peritoneal recurrence of gastric cancer with a high accuracy and a high specificity. However, PLC lacks sensitivity and has a relatively high false negative rate. Some patients with negative PLC results may have recurrence in the form of peritoneal dissemination.

CEA is generally accepted as a specific marker of gastrointestinal tumor[20,21]. Recently, measurement of CEA level and CEA RT-PCR assay in peritoneal washes have been used to detect the existence of free cancer cells in the peritoneal cavity[10,22,23]. It was reported that RT-PCR based assay has a relatively high sensitivity but is time-consuming, relatively laborious and less practical[10,22]. In the present study, pCEA levels in peritoneal washes were measured in order to detect the presence of free cancer cells in 64 patients with gastric cancer. The results showed that all the 15 patients with PLC positive findings were pCEA positive. However, 11 of 49 patients with PLC negative findings were also pCEA positive. The total pCEA positive rate was 40.6%, which was significantly correlated with the presence of serosal invasion and lymph node metastasis. Thus, as a useful method for detecting the presence of free cancer cells in the peritoneal cavity and for clinical staging of gastric cancer, pCEA level determination is considered to be superior to PLC. In our study, 18 of 19 patients with postoperative peritoneal recurrence of gastric cancer were pCEA positive and only one patient who died of postoperative peritoneal recurrence was pCEA negative, suggesting that pCEA assay is a highly sensitive method to predict postoperative peritoneal recurrence with a relatively high accuracy and specificity as compared to conventional PLC method.

In addition, our results showed that the positive rates of PLC and pCEA assay were significantly correlated with survival. Patients with negative results in PLC or pCEA assay survived significantly longer than those with positive findings in PLC or pCEA assay. In a multivariate analysis, pCEA level was found to be an independent prognostic factor even when all the clinicopathological variables were considered.

In conclusion, pCEA is a potential predictor of peritoneal recurrence as well as poor prognosis in patients with gastric cancer. Intra-operative pCEA assay can be considered as a reliable method for patients with gastric cancer.

Abstract

AIM: To evaluate the recovery and function of isolated rat pancreatic islets during *in vitro* culture with small intestinal submucosa (SIS).

METHODS: Pancreatic islets were isolated from Wistar rats by standard surgical procurement followed by intraductal collagenase distension, mechanical dissociation and Euroficoll purification. Purified islets were cultured in plates coated with multilayer SIS (SIS-treated group) or without multilayer SIS (standard cultured group) for 7 and 14 d in standard islet culture media of RPMI 1640. After isolation and culture, islets from both experimental groups were stained with dithizone and counted. Recovery of islets was determined by the ratio of counts after the culture to the yield of islets immediately following islet isolation. Viability of islets after the culture was assessed by the glucose challenge test with low (2.7 mmol/L) and high glucose (16.7 mmol/L) solution supplemented with 50 mmol/L 3-isobutyl-1-methylxanthine (IBMX) solution. Apoptosis of islet cells after the culture was measured by relative quantification of histone-complexed DNA fragments using ELISA.

RESULTS: After 7 or 14 d of *in vitro* tissue culture, the recovery of islets in SIS-treated group was significantly higher than that cultured in plates without SIS coating. The recovery of islets in SIS-treated group was about twice more than that of in the control group. In SIS-treated group, there was no significant difference in the recovery of islets between short- and long-term periods of culture (95.8±1.0% *vs* 90.8±1.5%, $P>0.05$). When incubated with high glucose (16.7 mmol/L) solution, insulin secretion in SIS-treated group showed a higher increase than that in control group after 14 d of culture (20.7±1.1 mU/L *vs* 11.8±1.1 mU/L, $P<0.05$). When islets were placed in high glucose solution containing IBMX, stimulated insulin secretion was higher in SIS-treated group than in control group. Calculated stimulation index of SIS-treated group was about 23 times of control group. In addition, the stimulation index of SIS-treated group remained constant regardless of short- and long-term periods of culture (9.5±0.2 *vs* 10.2±1.2, $P>0.05$). Much less apoptosis of islet cells occurred in SIS-treated group than in control group after the culture.

CONCLUSION: Co-culture of isolated rat islets with native sheet-like SIS might build an extracellular matrix for islets and provide possible biotrophic and growth factors that promote the recovery and subsequent function of islets.

INTRODUCTION

In the last 10 years, both the prevalence and incidence of diabetes have increased sharply all over the world and this disease has already become one of the global health care problems. For example, there are 14 000 000 patients suffering from diabetes in USA and 1 000 000 of them suffer from type I diabetes mellitus[1]. Islet transplantation can control blood sugar effectively, reduce complications of diabetes and prevent hypoglycemia and insulin resistance caused by ectogenic insulin. Therefore, pancreatic islet cell transplantation may be an effective means for treating type I diabetes mellitus.

Human islet transplantation has been demonstrated to be a viable option for the treatment of type I diabetes mellitus[2]. However, there are still many difficulties hindering the transplantation alleviating complications of the disease. A major limitation for its use as a standard treatment is the lack of available viable islets for transplantation.

To maintain islets of Langerhans in tissue culture provides a chance for islet storage after being isolated from pan-

creas before clinical transplantation. The storage period can be utilized to assess the function of the islets and to confirm microbiologic sterility of the preparation. In addition, it can increase purity of the islet preparation and to reduce the immunogenicity of islets[3]. However, islet culture loses tissue mass over culturing time, which is one of its disadvantages[4]. Given the importance of transplanting sufficient islets to increase the chance of successful graft[5], any loss of islet tissue mass jeopardizes this possibility.

Both morphology and metabolic activities of cultured cells are affected by the composition of substrates on which they grow. Cultured cells may proliferate and/or perform their *in vivo* functions when cultured on substrates that closely mimic their natural environments. In fact, many commercially available matrices such as human extracellular matrix (ECM) derived from human placentas and matrigel (a soluble basement membrane extract from the Engelbreth-Holm-Swarm tumor) can be used in cell culture, which supports cell growth. Previous studies have showed that human islets cultured with bovine corneal endothelial cell matrix increase their ability to secrete insulin[6].

SIS is a relatively acellular collagen-based matrix derived from porcine small intestine by mechanical removal of the mucosal and smooth muscle layers[7]. The resulting cell-free translucent sheets are about 100 mm thick. The collagen-based matrix comprised highly conserved collagen, glycoprotein, proteoglycan, and glycoaminoglycan in their native configuration and concentration. In addition, SIS includes various growth factors such as fibroblast growth factor-2 (FGF-2), TGF-β and vascular endothelial cell growth factor (VEGF), which promote cell growth[8].

In 1966, Matsumoto *et al*.[9] reported that inverted small intestine could replace large veins in dogs. Improved processing of this biomaterial (SIS) has made it readily available for tissue engineering studies. Extensive *in situ* tissue remodeling from SIS has been shown in both rat and canine models. SIS has been used as a scaffold for proliferation, remodeling, and regeneration of a variety of host tissues including blood vessels[10], dura mater[11], urinary bladder[12], abdominal wall[13], and tendons[14]. Grossly and microscopically the remodeled tissue resembles the native tissue. Recently, SIS has been evaluated for its potential *in vivo* use in hepatocyte transplantation[15]. For these reasons, in this study we have investigated whether the use of SIS in co-culture with rat islets could improve islet survival and their *in vitro* function.

MATERIALS AND METHODS

Animals

Male Wistar rats (250-400 g body weight, Animal Laboratory of Xi'an Jiaotong University, China) were used for islet isolation. All animals received care in compliance with the guidelines of the local Animal Care and Use Committee following National Institutes of Health guidelines.

Design of study

Islets were isolated using a collagenase and purified by discontinuous Euroficoll gradient. The purified islets were separated into study group and control group. In study group, islets were cultured in plates coated with SIS. In control group, islets were cultured in plates not coated with SIS. The number of islets was counted after isolation and culture. Recovery of islets was determined by the ratio of counts after the culture to the yield of islets immediately following islet isolation. Islet function was determined by a static glucose challenge test after a short period of culture for 7 d and a long period of culture for 14 d. Glucose challenge test was performed in the absence and presence of IBMX. Apoptosis of islet cells following culture was measured by relative quantification of histone-complexed DNA fragments (mono- and oligonucleosomes) out of the cytoplasm of cells by ELISA.

Preparation of soluble SIS supplement

SIS was prepared as previously described[10]. In brief, freshly harvested porcine jejunum was obtained from a local slaughterhouse. The tube of intestinal material was rinsed, until it was free of contents and inverted. Superficial layers of the tunica mucosa were removed by scraping with a knife handle. The tissue was then reverted to its original direction, serosa and tunica muscularis were removed. The resulting membrane was approximately 80-100 μm thick consisting of tunica submucosa and basilar portion of the tunica mucosa. The prepared intestinal submucosa tube was split open longitudinally and rinsed extensively in water to get rid of any of the cells associated with the matrix to eliminate cell degradation products. The sheets of SIS were sterilized by exposure to 1 g/L per acetic acid. To make multilayered SIS, five sheets of SIS were mechanically compressed by vacuum pressing and dried. The multilayered SIS was then terminally sterilized with ethylene oxide and kept until ready to use. Re-soaking in saline prior to use made the SIS sheets pliable and soft.

Islet isolation and culture

Islets were isolated and purified from the rat pancreas as previously described[16]. Briefly, rats were anesthetized with intraperitoneal pentobarbital. Pancreas was infused via the common bile duct with Hanks' balanced salt solution, set apart, and minced on ice. Digestion was performed with type V collagenase (7.5 g/L; Sigma) for 25 min at 37 ℃. Islets were purified on a discontinuous Euroficoll gradient (Sigma), handpicked under an inverted light microscope, pooled and then separated into study group and control group. In study group, islets were cultured in plates coated with suitable size multilayer SIS. In control group, islets were cultured in plates not coated with SIS. Islets were cultured in RPMI 1640 medium (Gibco) supplemented with 100 mL/L fetal calf serum (Gibco), 200 kU/L penicillin, 100 mg/L streptomycin, and 2 mmol/L L-glutamine (Gibco) at 37 ℃ in a humidified 50 mL/L CO_2 atmosphere for a period of 7 or 14 d.

Islet quantification and recovery

Islets from both groups were stained with dithizone and counted in accordance with the criteria established at

the 1989 International Workshop on Islet Assessment after isolation and culture. The number of islets was determined using an optical graticule attached to the eyepiece of a dissecting microscope and converted to the standard of islet equivalent (IE). Recovery of islets following culture was determined by the ratio of counts after the culture to the yield of islets immediately following islet isolation.

Islet viability

For each group, 6 separate samples of 20 islets each were tested simultaneously for their stimulated insulin secretion. Islets (150±50 μm in diameter) were first pre-incubated for 45-50 min in 2 mL RPMI 1640 solution containing 2.7 mmol/L glucose. Insulin secretion was then assessed by three consecutive incubations with RPMI 1640 solution containing 2.7, 16.7, and 16.7 mmol/L glucose with 1 g/L IBMX (Sigma), each for 45 min. At the end of incubation with each solution, the supernatant was completely removed and used to test the insulin secretion level by radioimmunoassay (Department of Isotope, China Institute of Atomic Energy). Insulin secretory responses of 20 islets to glucose stimulation were expressed as milliunit per liter. To eliminate variation of islet size causing differences of insulin response, the stimulation index for each group of islets was determined by the ratio of insulin secretion stimulated by high glucose solution containing IBMX to the basal insulin secretion stimulated by low glucose solution.

Evaluation of apoptosis of islet cells

Apoptosis of islet cells was measured by relative quantification of DNA/histone fragmentation (mono- and oligonucleosomes) in culture supernatants. After 7-14 d of incubation, culture medium was collected from each well of two groups. The supernatants were analyzed to measure cytoplasmic histone-associated DNA fragments generated by cell death based on mouse monoclonal antibodies against DNA and histones, respectively. The cultured supernatant sample (20 μL) was mixed with 80 μL of immunoreagent containing two monoclonal antibodies, antihistone (biotin-labeled) and anti-DNA (peroxidase-conjugated) in the well coated with streptavidin of a 96-well plate. Antibody–nucleosome complexes were bound to the microplate by streptavidin. The solution mixture was incubated by gently shaking (300 r/min) for 2 h at room temperature. The solution was then collected and the well was completely rinsed thrice with 150 μL of an incubation buffer and 100 μL of premixed 2, 2'-azino-di-3-ethylbenzthiazoline sulfonate (ABTS) substrate solution was added to each well. The mixed solution was agitated on a plate shaker for 20 min at room temperature and the solution absorbance was measured at a wavelength of 405 nm. The enrichment of nucleosomes due to apoptosis of islet cells was calculated from these absorbance values by the following formula: enrichment factor of nucleosomes=(values of the sample-the background values)/values of the negative control. The assay was done independently thrice for each experimental group. This method could permit us to specifically determine mono- and oligonucleosomes released into culture supernatants accompanying apoptosis and necrosis of islet cells. Accumulation of mono- and oligonucleosomes in the cytoplasm of apoptotic and necrotic cells caused DNA degradation, occurring several hours before the breakdown of plasma membrane.

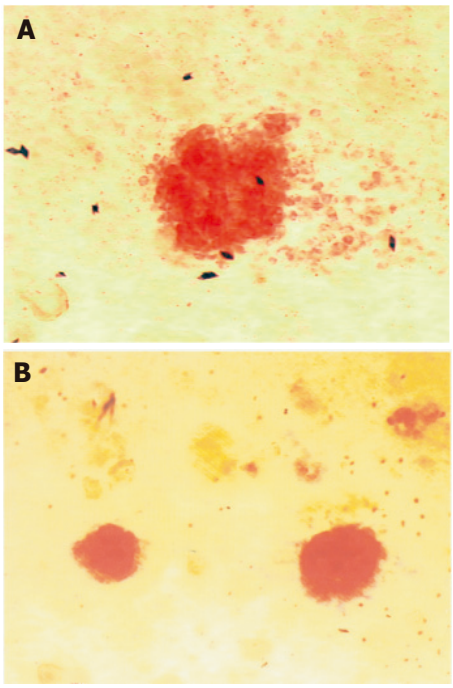

Figure 1 Morphology of islets after culture. **A:** Loose appearance of islets after 14 d of culture under standard condition; **B:** excellent morphology of islets after 14 d of culture on SIS (×400).

Statistical analysis

Results were expressed as mean±SE. Differences between the two groups were analyzed by *t*-test using SPSS10.0. $P<0.05$ was considered statistically significant.

RESULTS

After 7 and 14 d of *in vitro* tissue culture, SIS-treated group indicated a significantly higher ($P<0.05$) recovery of islets than control group (Table 1). The recovery in SIS-treated group was about twice more than that in control group. In SIS-treated group, there was no statistical difference in the recovery between the short and the long periods of culture (95.8±1.0% *vs* 90.8±1.5%, $P<0.05$). Most islets cultured in control group lost their initial morphology, becoming "loose" in appearance at the end of culture. Islets cultured with SIS exhibited excellent morphology (Figure 1).

In vitro viability of the islets was assessed using the glucose challenge test. There was no statistical difference in the basal level of insulin secretion between SIS treated group and control group (9.1±0.3 mU/L *vs* 7.8±0.6 mU/L after 7 d of culture, 5.9±0.4 mU/L *vs* 7.1±0.4 mU/L after

	SIS culture	1.08±0.02[a]	1.12±0.09[a]

[a]P<0.05 *vs* standard culture.

Table 2 Stimulated insulin secretion of rat islets cultured for 7 and 14 d during static incubation assay (n = 6, mean±SD)

Group	T (d)	Low glucose solution (2.7 mmol/L)	High glucose solution (16.7 mmol/L)	High glucose solution +50 μmol/L IBMX	SI[1]
Standard culture	7	9.1±0.3	18.3±1.1	51.3±3.4	5.7±0.4
SIS culture	7	7.8±0.6	21.8±1.9	75.8±2.1[a]	10.2±1.2[a]
Standard culture	14	5.9±0.4	11.8±1.1	20.5±1.8	3.6±0.4
SIS culture	14	7.1±0.4	20.7±1.1[a]	66.9±3.7[a]	9.5±0.2[a]

[1]SI (stimulation index)=insulin secretion during incubation with 16.7 mmol/L high glucose solution+50 μmol/L IBMX/insulin secretion during incubation with 2.7 mmol/L low glucose solution. [a]P<0.05 *vs* standard culture.

14 d of culture, P>0.05). There was a two- to threefold increase in insulin secretion in both groups upon stimulation by high glucose solution (16.7 mmol/L). After 14 d of culture, SIS-treated group showed a significantly higher increase in insulin secretion than control group (20.7±1.1 mU/L *vs* 11.8±1.1 mU/L, P<0.05). When islets were placed in the high glucose solution containing IBMX, the stimulated insulin secretion was significantly higher in SIS-treated group than in control group. Similar results occurred when the stimulation index was used as a reference (a ratio of insulin secreted upon stimulation by high glucose solution plus IBMX to basal insulin secreted). The stimulation index of SIS-treated group was about 2-3 times than that of the control group. In addition, the stimulation index of SIS-treated group were statistically equivalent to that of the group cultured for 7 and 14 d group (9.5±0.2 *vs* 10.2±1.2, P>0.05) (Table 2).

Apoptosis of islet cells was measured by relative quantification of DNA/histone fragmentation (mono- and oligonucleosomes) in culture supernatants using ELISA. The enrichment factor of nucleosomes was significantly lower in SIS-treated group than in control group, suggesting that much less apoptosis of islet cells occurred in SIS-treated group (Table 1).

DISCUSSION

Islet transplantation is a viable option of treatment for insulin-dependent diabetes mellitus. Maintaining islets in culture is important to increase the safety, practicality and efficacy of successful clinical results. In addition to reducing the immunogenicity of islets[3,17], islet culture simplifies the procedure of transplantation, which can be scheduled during regular hospital hours, and the patient is not necessary to move from a distant location to the transplantation center before a donor is available. Culture may facilitate novel immunosuppressive techniques[18]. Moreover, improved methods and supplementation of islet culture provide a unique opportunity to optimize recovery of islet mass for transplantation. Islets do not form monolayers, fail to replicate and contain multiple cell types, making them similar to a tiny organ. All these are the unique challenges for maintaining islets in culture. Procedures related to isolation and *in vitro* culture can lead to a considerable loss of islet tissue. Apoptosis and anoikis may be the mechanisms involved in tissue loss[19,20].

It has been reported that binding of ECM to integrin, a protein located on cell membrane, stimulates intracellular signaling pathways to prevent cells from their entry into the cascade of apoptosis[21], suggesting that interaction between cells and ECM plays an important role in the subsequent cell behaviors. It is possible that cell–ECM interaction is disrupted by the procedures related to islet isolation and purification. As a consequence, functions of isolated islets could be damaged. A recent study showed that the viability of porcine islet cells embedded in fibrous skeleton of pancreas is higher viability which may be due to cellular adhesion and ligation of ECM to integrins as opposed to their isolated counterparts. Further studies of these embedded cells demonstrated that the viability of the cells is sustained for 30 days or more and islet function is excellent 30 days after the isolation[22].

Frisch *et al.*[23] and Thomas *et al.*[22] have shown that anoikis resulted from a death signal induced by MEKK-1 group of caspases[23,24]. As a critical safeguard of nature, anoikis can prevent cells from taking up residence and growth in ectopic positions as in tumor metastases. Thomas *et al.*[22] reported that the apoptotic rate is markedly reduced when cells are attached to ECM, suggesting that ECM plays an essential role in the maintenance of differentiated cells. Preparation of islet isolation especially enzymatic digestion of pancreas can result in the loss of peripheral basement membrane or interstitial membrane of islets, suggesting that purity is not essential to achieve engraftment. The presence of other cellular elements may be critical for engraftment and long-term maintenance of graft function and survival[25]. The fact that transplantation of purified preparations of autologous islets loses islet function in early periods also supports this hypothesis[26].

A number of novel approaches have been developed to create a favorable physiological microenvironment for islets in culture to limit anoikis. The major method is to use ECM. Studies indicate that ECM can increase islet survival time and/or insulin secretion[21,27,28]. As a natural ECM, SIS is obtained from the intestine using a process that retains the natural composition and configuration of matrix molecules such as collagen (Types I, III and VI), glycosaminoglycans (hyaluronic acid, chondroitin sulfate A and B, heparin and heparin sulfate), proteoglycans,

glycoproteins (fibronectin), and growth factors (FGF-2, TGF-β, and VEGF), which play an important role in host tissue repair, remodel, and cell growth[8]. Mapping of the distribution of significant proteins and proteoglycans in small intestinal submucosa by fluorescence microscopy indicates that heparan sulfate proteoglycans (HSPG) is extensively distributed but concentrated in vessels. FGF-2 is diffusely distributed and associated with fibrous structures. VEGF is distributed mainly around the vessels. Collagen fibrils are distinctly present in the background. This anatomic structure of SIS is likely to play an important role in the regeneration of tissues and factors in remnant vessels may facilitate penetration of the matrix along these avenues[29].

SIS has excellent mechanical properties (high compliance, a high burst pressure point, and an effective porosity index), satisfactory histocompatibility, non-immunogenicity and safety for human use, allowing it to be used for vascular and connective tissue graft construct[7,10-14]. The porous nature and three-dimensional microarchitecture of SIS allow diffusion of cell nutrients and induce proliferation, remodeling and regeneration of host tissues when implanted in microenvironments *in vivo* (e.g. artery, tendon, bone, and articular cartilage)[10,14,30,31]. The same situation occurs in the cells during in vitro culture. In a recent study, several cell lines, including NIH Swiss mouse 3T3 fibroblasts, NIH 3T3/J2 fibroblasts, primary human fibroblasts, primary human keratinocytes, human microvascular endothelial cells (HMECs) and rat osteosarcoma (ROS) cells were cultured in the presence of sheet form SIS. All cell types showed the ability to attach and proliferate. All fibroblast cell lines and keratinocytes proliferated and/or migrated into the three-dimensional scaffold of SIS matrix. Co-culturing of NIH 3T3/J2 fibroblasts and primary human keratinocytes with SIS resulted in a distinctive spatial orientation of the two cell types. Fibroblasts populated the mid-substance of the three-dimensional matrix and keratinocytes formed an epidermal structure with rete ridge-like formation and stratification, when the composite was lifted to an air liquid interface in culture[32]. For these reasons, we hypothesize that SIS with native sheet-like configuration can imitate the natural growth environments of islets and improve islet survival and function *in vitro*, thus decreasing loss of tissue mass during culture.

We observed a higher recovery and stimulation index of islets and a lower enrichment factor of nucleosomes in SIS-treated group than in control group. These results may prove our hypothesis and are comparable to previous studies in different cell lines[32] and islets[6]. In pancreas, ECM is composed of interstitial matrix and basement membrane, the latter is composed of fibronectin, laminin and collagens IV and V[33]. These submucosal cell growth substrates provide islet cells with a collagenous matrix environment *in vitro*, resembling that in *in vivo*. We think that the unique configuration and composition of SIS may contribute to such improvements for islet culture. Firstly, the porous nature of SIS allows diffusion of cell nutrients, thus decreasing the central cell damage of isolated islets of Langerhans[34]. Secondly, SIS provides a substratum with a three-dimensional scaffold allowing for cell migration and spatial organization[35]. Thirdly, abundant collagen and various growth factors activate the signaling pathways, which induce attachment, proliferation, and differentiation of the cells[36].

In conclusion, co-culture of isolated rat islets with native sheet-like SIS can provide an ECM and possible biotrophic and growth factors, which promote the recovery and subsequent function of islets during *in vitro* tissue culture. In view of the rapid degradation of SIS *in vivo*[37], whether SIS improves the recovery and subsequent function of islets *in vitro* and the effect of SIS on islets *in vivo* needs to be further studied.

Key words: MALT lymphoma; Trisomy 3; Trisomy 18

Krugmann J, Tzankov A, Dirnhofer S, Fend F, Wolf D, Siebert R, Probst P, Erdel M. Complete or partial trisomy 3 in gastro-intestinal MALT lymphomas co-occurs with aberrations at 18q21 and correlates with advanced disease stage: A study on 25 cases. *World J Gastroenterol* 2005; 11(46): 7384-7385
http://www.wjgnet.com/1007-9327/11/7384.asp

TO THE EDITOR

Taji *et al*.[1] have reported in their study on 13 patients with gastric mucosa-associated lymphoid tissue (MALT) lymphomas an aggressive tumor course in trisomy 3 positive cases. The authors analyzed only stage I patients with classical low-grade marginal zone lymphoma of the MALT type and detected the trisomy 3 using an alpha-satellite DNA probe directed to the centromere. Their data support the observation that trisomy 3 is the most frequent cytogenetic aberration in MALT lymphomas[2,3].

In our previous published series[4] of 29 surgically resected gastrointestinal (GI) *t*(11;18) negative MALT lymphomas, we have described an adverse prognostic impact of trisomy 18q21 detected by a *MALT1*-specific fluorescence *in situ* hybridization (FISH) probe, especially in the lymphomas with high grade component. We have additionally studied 25 of the previously reported GI lymphomas including 7 low grade marginal zone lymphomas and 18 GI diffuse large B-cell lymphomas (DLBCL, including 3 cases with low grade lymphoma component) diagnosed in stage I (n = 8) and in stage >II (n = 17) for complete and partial trisomies 3 using FISH probes for the centromere of chromosome 3 (Vysis, Downer's Groove, IL, USA) as well as for the BCL6 gene at 3q27 (flanking BAC clones RP11- 528E8 and 690C8)[5]. The latter double-color assay was selected because it targets the critically gained band of chromosome 3 in MALT lymphomas and can detect breakpoints affecting the BCL6 locus, which are recurrent in extranodal DLBCL. For each hybridization, we evaluated 100 cell nuclei. The cut-off level, defined as mean false positive rate (determined in normal gastric mucosa and samples from *Helicobacter pylori* gastritis) plus three standard deviations, was 5.4% for the centromere 3 probe (trisomy). For the BCL6 probe mix no split or gain of signals was observed in the control samples, but according to the literature, the cut-off level for the detection of trisomy 3q27 or BCL6 breaks was set to 3%[5].

In agreement with the previously published studies, we detected trisomy 3q27 as the most frequent aberration in GI MALT lymphomas, occurring in 9/25 (36%) of the cases. In three of these nine cases, trisomy 3 was indicated by the presence of supernumerary signals for both the centromeric region and the *BCL6* locus, whereas in the remaining six cases, a gain of 3q27/*BCL6* was detected without a change in the number of centromere signals (partial trisomy 3q27). The only positive stage I lymphoma showed a partial trisomy 3q27. In three cases of the DLBCL subset, one with trisomy 3 and two with partial trisomy 3q27, a separation of the *BCL6* signal pair was additionally detected indicating both a *BCL6* translocation (two cases potentially with *BCL6*/IGH rearrangement) and overrepresentation of proximal/distal 3q27.

Trisomies 3q27 were present in 1/8 (13%) stage I and 8/17 (47%) stage >II diseases indicating a significant ($P<0.01$; χ^2 test) association of trisomy 3q27 with

lymphoma dissemination. There was a strong correlation between the occurrence of trisomies 18q21/*MALT1* and 3q27/*BCL6* in the present series of GI MALT lymphomas with 5/6 (83%) 18q21 positive tumors carrying both aberration and only 1/6 (17%) case showing trisomy 18q21 without trisomy 3q27 ($P<0.05$). We have previously reported that trisomy 18q21/*MALT1* to be associated with an unfavorable prognosis in the same series of surgically resected GI MALT lymphomas, which was particularly pronounced in the DLBCL subset[4]. With regard to trisomy 3q27, we observed a trend towards an inferior survival too, $P = 0.0727$.

Our data highlight that partial trisomies of chromosomes 3 and 18 have to be taken into account when evaluating the course of GI MALT lymphomas. Roughly two-thirds of the gains on the respective chromosomes might not include the centromeric region. Moreover, the co-occurrence of trisomies 3q27 and 18q21 in our group of surgically resected GI MALT lymphomas points to a possible interaction of both loci, especially in patients with an advanced stage disease.

World J Gastroenterol 2005;11(46):7388-7389
World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*WJG,* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc*., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Published jointly by
The WJG Press and Elsevier Inc.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297×210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures and Figure Legends. Neither the Editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Elsevier Inc., and may not be reproduced by any means, in whole or in part without the written permission of both the Authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations.

Online submission
Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com for assistance. If you submit manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission
Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4(297×210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

World Journal of Gastroenterology
Apartment 1066 Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors originating from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page
Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be involved. Titles should be concise and informative (removing all unnecessary words), emphasize what is NEW, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initials and/or first name, middle name or initial(s) and full family name.

Abstract
An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc*. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

Key words
Please list 3-10 key words that could reflect content of the study.

Text
For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or Figures and Tables, not both.

Illustrations
Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should add into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) and not RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126× 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by Freehand and Illustrator, or TIFF from Photoshop. EPS files must be accompanied by a version in native file format for editing purposes. Scans of existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size at which they will appear when printed, not smaller. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...;C: ...; D: ...; E: ...; F: ...; G: ...

Tables
Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be involved under the tables. This part should add into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations
Data which is not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used; Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or some other symbols with a superscript (Arabic

numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

References

Cited references should mainly be drawn from journals covered in the Science Citation Index (http://www.isinet.com) and/or Index Medicus (http://www.ncbi.nlm.nih.gov/PubMed) databases. Mention all references in the text, tables and figure legends, and set off by consecutive, superscripted Arabic numerals. References should be numbered consecutively in the order in which they appear in the text. Abbreviate journal title names according to the Index Medicus style (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=journals). Unpublished observations and personal communications are not listed as references. The style and punctuation of the references conform to ISO standard and the Vancouver style (5th edition); see examples below. Reference lists not conforming to this style could lead to delayed or even rejected publication status. Examples:

PMID requirement

From the full reference list, please submit a separate list of those references embodied in PubMed, keeping the same order as in the full reference list, with the following information only: (1) abbreviated journal name and citation (e.g. *World J Gastroenterol* 2003;9(11):2400-2403; (2) article title (e.g. Epidemiology of gastroenterologic cancer in Henan Province, China; (3) full author list (e.g. Lu JB, Sun XB, Dai DX, Zhu SK, Chang QL, Liu SZ, Duan WJ; (4) PMID (e.g. 14606064). Provide the full abstracts of these references, as quoted from PubMed on a 3.5 inch disk or CD-ROM in Microsoft Word format and send by post to The *WJG* Press. For those references taken from journals not indexed by *Index Medicus*, a printed copy of the first page of the full reference should be submitted. Attach these references to the end of the manuscript in their order of appearance in the text.

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean±SD and mean±SE.

Statistical expression

Express *t* test as *t*(in italics), *F* test as *F*(in italics), chi square test as χ^2(in Greek), related coefficient as *r*(in italics), degree of freedom as γ (in Greek), sample number as *n*(in italics), and probability as *P*(in italics).

Units

Use SI units. For example: body mass, m(B) = 78 kg; blood pressure, p(B)=16.2/12.3 kPa; incubation time, t(incubation)=96 h, blood glucose concentration, c(glucose) 6.4±2.1 mmol/L; blood CEA mass concentration, p(CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2 not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23,243,641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italicization

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc*.

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.

Biology: *Helicobacter pylori, H pylori, E coli, etc*.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the WJG Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

It is the policy of WJG to acquire copyright in all contributions. Papers accepted for publication become the copyright of WJG and authors will be asked to sign a transfer of copyright form. All authors must read and agree to the conditions outlined in the Copyright Assignment Form (which can be downloaded from http://www.wjgnet.com/wjg/help/9.doc).

Final check list for authors

The format is at: http://www.wjgnet.com/wjg/help/13.doc

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: http://www.wjgnet.com/wjg/help/10.doc

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Publication fee

Authors of accepted articles must pay publication fee.

Abstract

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors worldwide. The major etiologies and risk factors for the development of HCC are well defined and some of the multiple steps involved in hepatocarcinogenesis have been elucidated in recent years. Despite these scientific advances and the implementation of measures for the early detection of HCC in patients at risk, patient survival has not improved during the last three decades. This is due to the advanced stage of the disease at the time of clinical presentation and limited therapeutic options. The therapeutic options fall into five main categories: surgical interventions including tumor resection and liver transplantation, percutaneous interventions including ethanol injection and radiofrequency thermal ablation, transarterial interventions including embolization and chemoembolization, radiation therapy and drugs as well as gene and immune therapies. These therapeutic strategies have been evaluated in part in randomized controlled clinical trials that are the basis for therapeutic recommendations. Though surgery, percutaneous and transarterial interventions are effective in patients with limited disease (1-3 lesions, <5 cm in diameter) and compensated underlying liver disease (cirrhosis Child A), at the time of diagnosis more than 80% patients present with multicentric HCC and advanced liver disease or comorbidities that restrict the therapeutic measures to best supportive care. In order to reduce the morbidity and mortality of HCC, early diagnosis and the development of novel systemic therapies for advanced disease, including drugs, gene and immune therapies as well as primary HCC prevention are of paramount importance. Furthermore, secondary HCC prevention after successful therapeutic interventions needs to be improved in order to make an impact on the survival of patients with HCC. New technologies, including gene expression profiling and proteomic analyses, should allow to further elucidate the molecular events underlying HCC development and to identify novel diagnostic markers as well as therapeutic and preventive targets.

Key words: HCC resection; Liver transplantation; Percutaneous ethanol injection; Radiofrequency thermal ablation; Transarterial embolization or chemoembolization; Chemotherapy; Gene therapy; Immune therapy; Prevention

INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common malignant tumors worldwide[1-10]. The incidence ranges from <10 cases per 100 000 persons in North America and Western Europe to 50-150 cases per 100 000 persons in parts of Africa and Asia, where HCC is responsible for a large number of cancer deaths. However, a rise in the incidence and mortality of HCC, most likely reflecting the increased prevalence of hepatitis C virus (HCV) infection, has recently been observed in most industrialized countries[11-14].

The major etiologies of HCC are well defined (Table 1). An elevated body mass index, especially in men[15], and diabetes mellitus[9] are included among the well-known factors. Some of the steps involved in the molecular pathogenesis of HCC have been elucidated in the recent years. As for most types of cancer, hepatocarcinogenesis is a multistep process involving different genetic alterations that ultimately lead to the malignant transformation of hepatocytes. While significant progress has been made in recognizing the sequence of events involved in other forms of cancer, most notably in colorectal cancer and certain hematopoietic malignancies, the molecular contribution of the multiple factors and their interactions in hepatocarcinogenesis are still poorly understood. HCCs are phenotypically (morphology and microscopy) and genetically heterogenous tumors, possibly reflecting in part the heterogeneity of etiologic factors implicated in HCC development, the complexity of hepatocyte functions and the late stage at which HCCs usually become clinically symptomatic and detectable. Malignant transformation of hepatocytes may occur regardless of the etiologic agent through a pathway of increased liver cell turnover, induced by chronic liver injury and regeneration in a context of inflammation, immune response, and oxidative DNA damage. This may result in genetic alterations, such as activation of cellular oncogenes, inactivation of tumor suppressor genes, possibly in cooperation with genomic instability, including

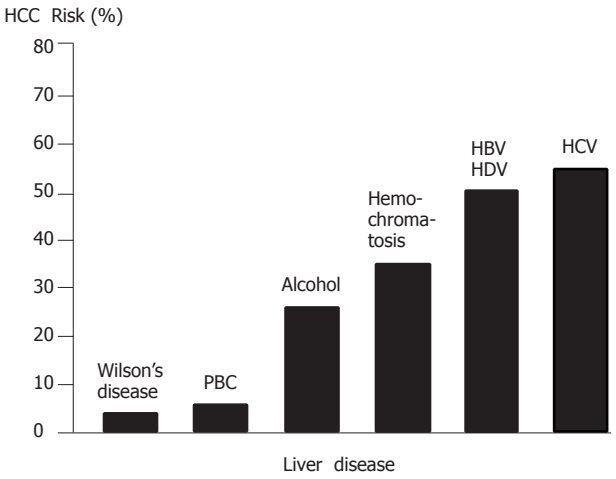

Figure 1 HCC Risk in Liver Cirrhosis

DNA mismatch repair defects and impaired chromosomal segregation, overexpression of growth and angiogenic factors, and telomerase activation[16-23]. Chronic viral hepatitis B, C, and D, alcohol, metabolic liver diseases such as hemochromatosis and α-1-antitrypsin deficiency as well as non-alcoholic fatty liver disease may act predominantly through this pathway of chronic liver injury, regeneration and cirrhosis. Accordingly, the major clinical risk factor for the development of HCC is liver cirrhosis since 70-90% of HCCs develop into a cirrhotic liver. Most HCCs occur after many years of chronic hepatitis that provides the mitogenic and mutagenic environments to precipitate random genetic alterations resulting in the malignant transformation of hepatocytes and HCC development.

The HCC risk in patients with liver cirrhosis depends on the activity, duration and etiology of the underlying liver disease (Figure 1). Clinical and biological variables (age, anti-HCV positivity, PTT and platelet count) allow to further identify a subset of cirrhotic patients with the highest risk of HCC development[24]. Coexistence of etiologies, such as hepatitis B virus (HBV) and HCV infection, HBV infection and aflatoxin B1[23,25], HBV/HCV infection and alcohol or diabetes mellitus[26], or HCV infection and liver steatosis[27], increases the relative risk of HCC development. Also, occult HBV infection (anti-HBc positive only) carries a significant HCC risk[28,29]. In general, HCCs are more frequent in males than in females and the incidence increases with age. On the other hand, there is evidence that HBV and possibly HCV under certain circumstances play an additional direct role in the molecular pathogenesis of HCC. Finally, aflatoxins can induce mutations of the p53 tumor suppressor gene, thus pointing to the contribution of an environmental factor to tumor development at the molecular level. Furthermore, in a transgenic mouse model it has been shown that chronic immune-mediated liver cell injury without environmental or infectious agents is sufficient to cause HCC[30] and that inhibition of cytotoxic T lymphocyte-induced apoptosis and chronic inflammation by neutralization of the Fas ligand and prevents HCC development in this model[31]. In addition, in a transgenic mouse model it has been demonstrated that NF-κB may be the link between inflammation and HCC development[32,33]. Finally, individual polymorphisms of drug-metabolizing enzymes, such as cytochrome P450 oxidases, N-acetyltransferases and glutathione-*S*-transferase, may contribute to the genetic susceptibility to HCC development[34].

HCC screening, staging, and natural course

For the staging of HCCs, five systems have been proposed for the assessment of the extent and prognosis of the disease[35,36]: the Okuda staging system (Table 2)[37], the TNM classification and its modification by the Union International Contre Cancer (UICC), the Barcelona Clinic Liver Cancer (BCLC) classification[38] and the Cancer of the Liver Italian Program (CLIP) score[39]. The Okuda staging system is very effective for the identification of a subgroup of patients (Okuda III) with a very good prognosis of patients who should be treated with best supportive care (BSC) only. The BCLC classification appears especially useful for the selection of treatment but has not been independently validated. The CLIP score is superior to the Okuda staging system but has not been systematically assessed in patients undergoing resection or liver transplantation. Thus, one staging system is not clearly superior to the others. The natural course of the disease and the median survival of patients with HCC depend on the stage of the disease at the time of diagnosis. In patients with CLIP score 0 or Okuda stage I, the median survival is in the range of 23-69 mo, while in patients with CLIP score 3-5 or Okuda stage III, the median survival is only 1-14 mo[4]. The staging system is clinically most important for the appropriate choice of therapeutic strategy for individual patients.

Treatment of HCC

Therapies for HCC can be divided into four categories: surgical interventions (tumor resection and liver

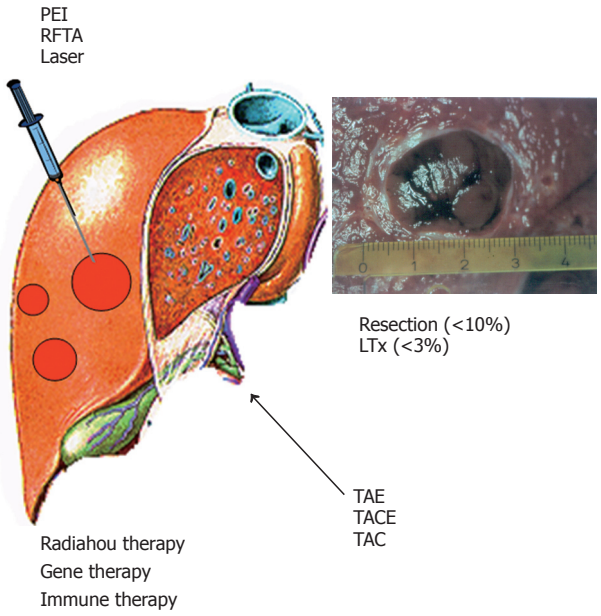

Figure 2 HCC treatment.

transplantation), percutaneous interventions (ethanol injection, radiofrequency thermal ablation), transarterial interventions (embolization, chemoperfusion, or chemoembolization) and drugs including gene and immune therapy (Figure 2). Potentially curative therapies are tumor resection, liver transplantation, and percutaneous interventions that can result in complete responses and improved survival in a large number of patients. In selected cases, transarterial interventions result in palliation with good response rates and improved survival in some cases. Drugs as well as conventional radiotherapy have no proven efficacy.

Till date, surgical, percutaneous and transarterial interventions have not been compared in randomized controlled trials. Tumor resection and transplantation can achieve a 5-year survival rate of 60-70% in selected patients transplantation is the best treatment for patients with single lesions and advanced liver diseases, such as decompensated cirrhosis and multicentric small tumors. Percutaneous interventions, again in selected patients, result in a 5-year survival rate of 40-50%. The following different therapeutic options as well as primary and secondary HCC prevention are discussed in detail.

Surgical interventions

Resection in patients without concomitant liver cirrhosis (5% in Western countries, 40% in Sub-Sahara Africa and Asia), HCC resection is the treatment of choice with a low rate of life-threatening complications. By comparison, in the majority of patients with cirrhosis, strict selection is required to avoid resection-related complications, especially postoperative liver failure[40]. Apart from bilirubin and albumin concentration as well as platelet count and indocyanine green clearance[14,42], a recent study has identified an elevated serum concentration of 7s-collagen as an independent risk factor for postoperative liver failure[43].

Resection-related mortality should be <1-3%, and the 5-year survival rate should be >50%. In patients with normal liver function (normal indocyanine green retention rate and bilirubin level), absence of clinically relevant portal hypertension (hepatic venous pressure gradient <1.33 kpa, no esophageal varices, no splenomegaly, platelet count $>100\times10^9$/L) and one asymptomatic HCC lesion only, the 5-year survival rate of 70% can be achieved. By comparison in patients with clinically relevant portal hypertension, the 5-year survival rate is about 50% only and in patients with portal hypertension and evidence of impaired liver function, the 5-year survival rate is even lower.

After successful HCC resection, tumor recurrence in the cirrhotic liver (local recurrence as well as *de novo* tumors) in about 70% of patients after 5 years is a major clinical problem. The risk of recurrence is especially high in patients with microvascular invasion and/or additional tumor nodules[41,44]. Therefore, strategies aimed at secondary HCC prevention are of paramount importance.

Liver transplantation Liver transplantation is in principle the optimal therapeutic option for HCCs, because it simultaneously removes the tumor and the underlying cirrhosis, including the risk of HCC recurrence[40,45-47]. While broad selection criteria applied previously led to poor results with the recurrence rate of about 50% and the 5-year survival rate <40%, the current criteria for liver transplantation in patients with HCC (1 lesion <5 cm in diameter or maximum 3 lesions <3 cm in diameter) result in the 5-year survival rate of 70% or more and the recurrence rate <15%[48-50]. Possibly these criteria can be extended in future, depending on more experiences based on the stage of the disease, macrovascular invasion, histopathological characteristics (histopathology, aneuploidy, microvascular invasion) as well as DNA and RNA chip data (molecular signature, proteomic signature and others)[51,52].

Clinically, it is most important to shorten the waiting time for transplantation to <6 mo. This is difficult to achieve with cadaveric liver transplantation due to the shortage of donors. With a waiting time of >12 mo in some Western countries, the drop-out rate of patients is 20-50%. To bridge the time to transplantation and to prevent tumor progression, neoadjuvant treatments, such as percutaneous and transarterial interventions may lead to an improved outcome[53]. While marginal livers, domino donors, and split liver transplantation have no major impact, living donor liver transplantation has been shown to be an alternative to cadaveric liver transplantation. Around 3 000 interventions have been done worldwide. However, living donor liver transplantation is a complex procedure with a morbidity of 20-40% and a donor mortality of 0.3-0.5%[50,54,55]. Therefore, a very careful selection of patients and donors, including consideration of ethical, societal and legal issues is central to the successful implementation of living donor liver transplantation for the treatment of HCC patients[56].

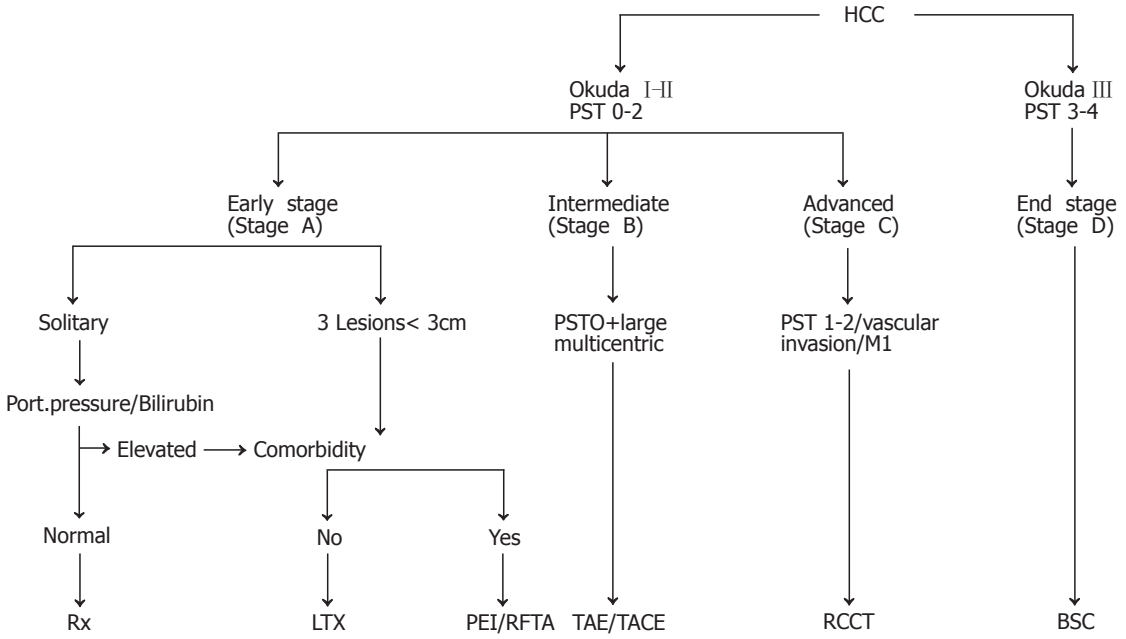

Figure 3 Stage-Dependent HCC Treatment.

Percutaneous interventions

Percutaneous intervention is the best option for small unresectable HCCs[57-59]. Tumor ablation can be achieved chemically by percutaneous ethanol injection (PEI) or acetic acid injection (PAI) or thermally by radiofrequency thermal ablation (RFTA), microwave heat-induced thermotherapy (HiTT), laser-induced thermotherapy (LiTT), or cryoablation. Apart from percutaneous interventions, these techniques can be applied also laparoscopically or after laparotomy.

Percutaneous ethanol injection PEI is the most widely used technique[60,61]. It is safe, easy to perform, inexpensive and can achieve complete tumor response rate of 90-100% in HCCs smaller than 2 cm in diameter, 70% in HCCs (3 cm in diameter) and 50% in HCCs (5 cm in diameter). Patients with liver cirrhosis Child A with complete responses can achieve a 5-year survival rate of 50% or more. Therefore, PEI is the procedure of choice for patients with a single HCC lesion smaller than 5 cm in diameter or with up to three lesions smaller than 3 cm in diameter (Figure 3).

Radiofrequency thermal ablation RFTA is an alternative to PEI[58,59,62,63]. Several devices are available that can be applied percutaneously, laparoscopically, or during laparotomy. The efficacy of RFTA is similar to that of PEI but requires generally only a single session. While being more expensive than PEI, RFTA offers a better local tumor control and a potential advantage of allowing the ablation of tumors larger than 5 cm in diameter especially when newer generation devices are used. However, the 5-year survival rate after complete response to RFTA is currently similar to that of PEI (around 30-40%) depending on the child stage of the underlying liver cirrhosis. In a review of 3 670 patients treated with RFTA, the mortality is 0-5% and the complication rate is 8-9%[64]. Predictors of treatment response are tumor size and morphology (well encapsulated *vs* invasive).

Percutaneous HCC ablation by PEI and/or RFTA when considered together is an effective treatment for patients with HCCs that prolongs the tumor-free and overall survival time, especially if surgery is not feasible. This strategy has been evaluated also for the treatment of liver metastases[65].

Transarterial interventions

Transarterial embolization and chemoembolization are the most widely used treatments for HCCs which are unresectable or cannot be effectively treated with percutaneous interventions[66-69]. Embolization agents may be administered alone (embolization) or after selective intra-arterial chemotherapy (generally doxorubicin, mitomycin or cisplatin) or in combination with lipiodol (chemoembolization). Transarterial embolization or chemoembolization results in partial responses in 15-55% of patients, delays tumor progression and vascular invasion, and prolongs the survival time compared to conservative management. The most important aspect is the selection of patients, i.e., patients should have preserved liver function (Child A) and asymptomatic multinodular tumors without vascular invasion or extrahepatic spread[67,69]. In patients with advanced liver disease (Child B or C), treatment-induced liver failure may offset the antitumor effect or survival benefit of the intervention. As has been shown recently, postoperative adjuvant TACE may improve survival in patients with risk factors for residual tumor[70].

Radiation therapy

While radiotherapy plays only a minor role in the treatment of primary HCC, selective intra-arterial

injection of ^{131}iodine-labeled lipiodol has been performed in some patients[71] but needs further clinical evaluation before a recommendation can be made. Furthermore, high dose proton beam radiotherapy and external beam radiation as well as Yttrium-90 microsphere treatment have been recently explored in clinical trials in patients with unresectable HCC[72-74]. These strategies will certainly be further explored in clinical studies and may become a treatment option in future.

Drugs

A number of chemotherapeutic, hormonal and other drugs (Table 3) have been evaluated in clinical trials[75-77]. While most chemotherapeutic agents, such as tamoxifen[78], octreotide[79] and interferon[66], have not been shown to be effective in randomized controlled clinical trials, there are a number of substances that may deserve further clinical evaluation, such as gemcitabine[80,81], thymostimulin[82], α-1-thymosin[83], pravastatin[84], thalidomide[85] and megestrol acetate[86], antiangiogenic small molecules, Cox-2 inhibitors in combination with capecitabine and possibly others. Till date, however, none of these drugs can be recommended outside clinical studies.

Experimental strategies

In view of the limited therapeutic options for advanced HCCs, a number of experimental strategies are being evaluated (Figure 4), including gene and immune therapies based on suicide, cytokine and antiangiogenic genes or DNA vaccination with tumor-specific genes[87-90], oncolytic viruses[91] as well as novel drugs such as 3-bromopyruvate[92].

HCC prevention

HCC prevention falls into two categories. Primary prevention that is aimed at the prevention of HCC development in patients with chronic liver diseases of different etiologies and secondary prevention that is aimed at preventing the recurrence and/or the development of new HCC lesions after successful surgical or non-surgical HCC treatment[93,94].

Primary HCC prevention Primary prevention is aimed at the interference with HCC development at four stages (Figure 5).

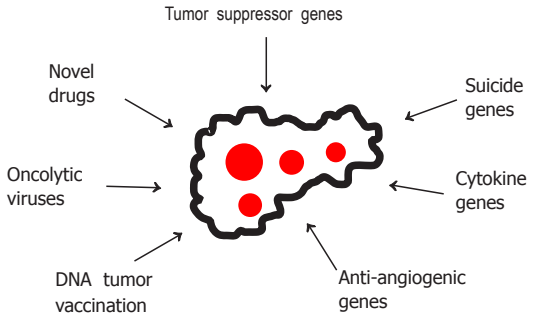

Figure 4 HCC Experimental Therapeutic Strategies

Stage 1: Interventions at this step are aimed at the prevention of acquired liver diseases. Apart from avoiding liver toxins, including alcohol and certain drugs, or infections with HBV or HCV by hygienic measures, avoiding parenteral exposure to blood, blood products or contaminated needles etc., a prime example is vaccination against HBV infection using commercially available active and passive vaccines. Several HBV vaccines using natural or recombinant hepatitis B surface antigen (HBsAg) from different sources are well introduced in clinical practice and universal vaccination in Taiwan has indeed already resulted in a decline of the incidence of HCCs[95]. In addition, novel HBV vaccination strategies are being explored, including a novel triple HBsAg recombinant vaccine[96], epidermal HBsAg powder immunization[97] as well as oral immunization using HBsAg transgenic plants[98-100]. Furthermore, DNA vaccination has been shown in animal models to induce antibodies against HBsAg/anti-HBs[101,102] even after topical application to the skin. For the prevention of HCV infection, however no effective vaccine is available till date. While several HCV vaccination concepts are being evaluated, including HCV proteins[103], HCV-like particles[104] as well as intravenous, intrahepatic, intraepidermal, intramuscular or oral cDNA immunization[105-109], it is not expected that a vaccine against HCV infection will become commercially available within the next few years.

Stage 2: Interventions at this step are aimed at the early treatment of acute liver diseases, thereby blocking their transition into chronic hepatitis that carries the risk of developing liver cirrhosis and its sequelae, including HCC development. While the principles mentioned above regarding liver toxins can also be applied here, the early diagnosis and treatment of inherited liver diseases, such as Wilson's disease and hemochromatosis, are of paramount importance. Furthermore, recent studies suggest that early treatment of acute HCV infection prevents its progression to chronic hepatitis C[110-112].

Stage 3: Interventions at this step are aimed at the prevention of the progression of chronic hepatitis to liver cirrhosis that carries a high risk of HCC development. Apart from avoiding liver toxins and long-term use of high dose androgens or other anabolic steroids, the treatment

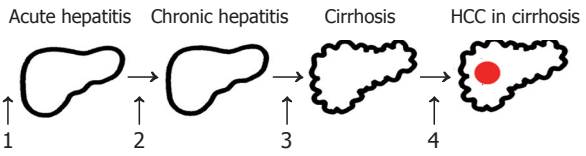

Figure 5 Primary HCC Prevention.

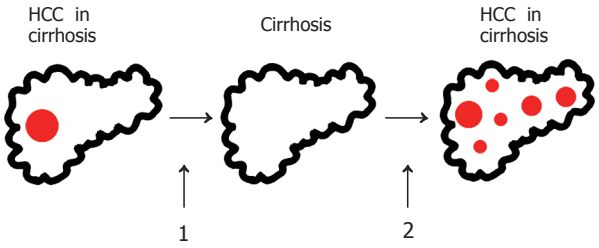

Figure 6 Secondary HCC Prevention.

of chronic hepatitis is of paramount importance. This includes the treatment of inherited, cholestatic or autoimmune liver diseases as well as the treatment of chronic viral hepatitis B or C. Reduction of iron overload by phlebotomy, for example, has been shown to stop the progression of hemochromatosis to liver cirrhosis and HCC. Treatment of chronic hepatitis B with interferon alpha or nucleoside analogs[113-118] and chronic hepatitis C with interferon alpha and now the combination of interferon alpha and ribavirin has demonstrated biochemical, virological, and histopathological improvements[119-123] and a lower incidence of HCC development[124-126].

Stage 4: Interventions at this step are aimed at interfering with the molecular events leading to HCC development, usually in a cirrhotic liver. These strategies include all treatment modalities detailed above (stage 3) as far as they can be implemented in patients with compensated or decompensated liver cirrhosis. In addition, some of the measures to prevent HCC recurrence after successful HCC treatment (secondary prevention) should in principle be useful for HCC prevention at this stage of the disease. Furthermore, some concepts of molecular therapy of HCCs should be applicable also in the prevention of HCCs. Without experimental pre-clinical data on these issues, it would be premature to discuss their potential clinical impact.

Secondary HCC prevention The prevention of a local recurrence and/or the development of new HCC lesions in patients after successful surgical or non-surgical HCC treatment (Figure 6) is of paramount importance and can significantly improve disease-free and overall patient survival.

After successful HCC resection or non-surgical ablation, HCC recurrence in the remaining cirrhotic liver is the major limitation of life expectancy of these patients. The probability of recurrence is about 50% within 3 years after successful treatment[38,127]. Strategies to prevent HCC recurrence are therefore central to the improvement of survival of HCC patients after initial cure. Apart from liver transplantation after successful resection[44], the strategies explored to date include administration of polyprenoic acid (an acyclic retinoid)[128] interferon alpha[129] and interferon beta[130]. Furthermore, adoptive immunotherapy[131] and intra-arterial injection of ^{131}iodine-labeled lipiodol[132,133] have been evaluated in clinical studies. All these interventions can result in lower HCC recurrence rates. These findings have to be confirmed in larger randomized controlled studies, demonstrating that a clear clinical benefit before secondary prevention with one of the strategies mentioned above should enter clinical practice.

Summary and perspectives

HCC is one of the most common malignant tumors in some areas of the world with an extremely poor prognosis HCC treatment is based on randomized controlled trials and many observational studies. Treatment options fall into four main categories: surgical interventions including tumor resection and liver transplantation, percutaneous interventions including ethanol injection and RFTA, transarterial interventions including embolization and chemoembolization, and drugs as well as gene and immune therapies. Though surgery as well as percutaneous and transarterial interventions are effective in patients with limited disease (up to three lesions smaller than 3 cm in diameter or one lesion smaller than 5 cm in diameter) and compensated underlying liver disease (cirrhosis Child A), at the time of diagnosis more than 80% patients present with multicentric HCC and advanced liver disease or co-morbidities that restrict the therapeutic measures to BSC.

In order to reduce the morbidity and mortality of HCC, early diagnosis and the development of novel systemic therapies for advanced disease, including drugs, gene and immune therapies as well as primary HCC prevention are of paramount importance. Furthermore, secondary HCC prevention after successful therapeutic interventions needs to be improved in order to achieve better survival of patients with HCC. New technologies, including gene expression profiling and proteomic analyses, should allow to further elucidate the molecular events underlying HCC development and to identify novel diagnostic markers as well as therapeutic and preventive targets.

Abstract

AIM: To study the relationship between the expression of human chorionic gonadotropin (HCG), CD44v6, CD44v4/5 and the infiltration, metastasis of esophageal squamous cell carcinoma.

METHODS: By labeled streptavidin-biotin technique, the expressions of HCG, CD44v6, and CD44v4/5 in 42 patients with esophageal squamous cell carcinoma were examined.

RESULTS: The positive rate of HCG expression in patients with lymph node metastasis was 85.71% (18/21), higher than that (57.14%, 12/21) in those without lymph node metastasis (P<0.05). The positive rate of CD44v6 expression was 71.43% (15/21) in lymph node metastasis group, and 38.09% (8/21) in non-metastasis group; there was a significant difference between the two groups (P<0.05). The positive rate of CD44v4/5 expression was 76.19% (16/21) in lymph node metastasis group, and 42.86% (9/21) in non-metastasis group; there was also a significant difference between them (P<0.05). From grade Ⅰ to grade Ⅲ in differentiation, the positive rate of HCG expression was 84.62% (11/13), 70.59% (12/17) and 58.33% (7/12), respectively; there was no significant difference among them (P>0.05). The positive rate of CD44v6 expression in grades Ⅰ-Ⅲ of cancer tissues was 76.92% (10/13), 52.94% (9/17), and 33.33% (4/12) respectively; there was no significant difference among them. The positive rate of CD44v4/5 expression in grades Ⅰ-Ⅲ of cancer tissues was 69.23% (9/13), 64.71% (11/17), and 41.67% (5/12) respectively; there was no significant difference among the three groups. There was no correlation between the positive rates of HCG and CD44v6, CD44v4/5 expression. Cancer cells in carcinomatous emboli and those infiltrating into vascular wall strongly expressed HCG, CD44v6, and CD44v4/5.

CONCLUSION: Expression of HCG, CD44v6, and CD44v4/5 in esophageal squamous cell carcinoma is related to its infiltration and metastasis. HCG, CD44v6, and CD44v4/5 have different effects on the infiltration and metastasis of esophageal squamous cell carcinoma.

INTRODUCTION

Human chorionic gonadotropin (HCG) is a glycoprotein molecule. Ectopic HCG produced by malignant tumors is one of the indexes of early diagnosis[1]. Researchers have studied the expression of HCG in malignant tumors, such as tumor of lung, bladder, breast[1-4], and found that HCG expression has a close correlation with the differentiation, infiltration, and metastasis of tumors. Expression of CD44 gene and its relation with metastasis of tumors are the hotspots of tumor study in recent years[5]. It has been found that expressions of mutant CD44 molecules exist in many tumors, such as stomach, lung, and cervix tumors, and have an obvious relation with metastasis of tumors[6-8]. In order to explore the relationship between the expression of HCG, CD44v6, and CD44v4/5 and the infiltration and metastasis of esophageal carcinoma, labeled streptavidin-biotin (LSAB) was used to detect the expression of these three proteins in 42 patients with esophageal squamous cell carcinoma.

MATERIALS AND METHODS

Selection of cases

Specimens were excised from 42 esophageal carcinoma patients in Tumour Hospital of Anyang city. There

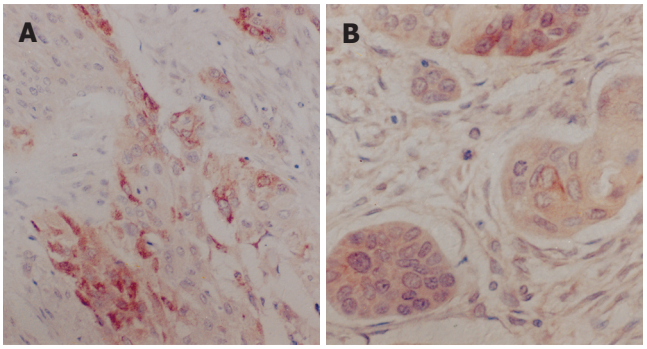

Figure 1 Spot or focus (**A**) and diffuse (**B**) distribution of HCG positive cells.

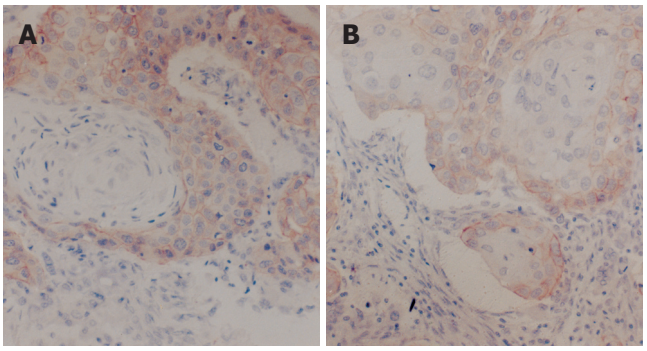

Figure 2 Diffuse distribution of CD44v6 (**A**) and CD44v4/5 (**B**) positive cells.

were 23 male patients and 19 female patients. Their age range was 33-73 years, averaged 55.7 years. None of the patients received chemotherapy, radiation therapy, or immunotherapy before surgery. All the formalin-fixed and paraffin-embedded specimens were sectioned and stained with hematoxylin-eosin. The sections were carefully diagnosed under light microscope. All the specimens excised from the patients proved to be squamous cell carcinoma by histopathology and 13 cases were grade Ⅰ, 17 cases were grade Ⅱ, and 12 cases were grade Ⅲ. Lymph node metastasis was found in 21 cases.

Detection of HCG, CD44v6, and CD44v4/5 proteins

Immunohistochemical LSAB technique was applied. Rabbit anti-human HCG antibody was purchased from DAKO (Denmark), mouse anti-human CD44v6 and CD44v4/5 mAb was the product of R&D (USA). LSAB immunohistochemical reagent kit was purchased from Zymed (USA). Human placental chorion was taken from pregnant women as HCG positive control. Squamous basal cells were taken from normal people as CD44v6 and CD44v4/5 positive control. Antibody I was replaced with normal goat serum as negative control group. Antibody I was replaced with PBS as blank negative control group.

The criteria were established as previously described[9]. The positive cells were stained brown-yellow. The positive expression of HCG mainly displayed on cytoplasm, while CD44v6 and CD44v4/5 mainly appeared on cell membrane. The positive cells of 10 high power fields were counted and the positive expression was categorized as follows: weakly positive (+), with positive cells less than 10%; moderately positive (++), with positive cells 10-50%; strongly positive (+++), with positive cells more than 50%.

Table 1 Correlation between expression of HCG and differentiation degree, lymph node metastasis of esophageal squamous cell carcinoma

Pathologic characteristics	*n*	Positive expression				Positive rates (%)	χ^2	*P*
		-	+	++	+++			
Differentiation Degree								
Ⅰ	13	2	3	3	5	84.62		
Ⅱ	17	5	4	2	6	70.59	2.122	>0.05
Ⅲ	12	5	2	3	2	58.33		
Lymph node metastasis

Metastasis	21	4	7	6	4	80.95	0.171	>0.05

Statistical analysis

Microsoft SPSS10.0 was applied. Comparison between two and multiple specimens was made by χ^2 test. Difference and correlation were analyzed by coupled χ^2 test and Spearman's correlation test.

RESULTS

Distribution features of HCG and CD44v6, CD44v4/5 positive cells

There were three patterns in the distribution of HCG and CD44v6, CD44v4/5 positive cells, namely spot, focal and diffuse distribution. In squamous cell carcinoma tissues of grade I, the distribution of HCG and CD44v6 was focal and diffuse (Figures 1A, 1B and 2A), while that of CD44v4/5 was spot, focal or diffuse. In grade II, the distribution of HCG, CD44v6, and CD44v4/5 was focal and diffuse (Figure 2B). In grade III, staining of HCG was focal or diffuse, while CD44v6 was multi-focal, CD44v4/5 was focal or spot. In carcinoma tissues with lymph node metastasis, the distribution of HCG and CD44v6, CD44v4/5 was multi-focal. The expression of keratinous pearl in grade I was negative. Tumor cells in emboli or tumor cells invading the vascular wall were frequently stained and highly positive for HCG, CD44v6, and CD44v4/5. The tumor cells at periphery of carcinoma nests with interstitial or intermuscular infiltration and mitosis were highly positive for CD44v6, CD44v4/5.

Correlation between expression of HCG, CD44v6, CD44v4/5, and differentiation degree, lymph node metastasis of esophageal squamous cell carcinoma

The correlations between expressions of HCG, CD44v6,

Negative	21	12	6	3	0	42.86	4.842	<0.05
Tumor focus								
Primary	21	5	10	4	2	76.19		
Metastasis	21	6	12	3	0	71.43	0.123	>0.5

CD44v4/5 and differentiation degree, lymph node metastasis of esophageal squamous cell carcinoma are listed in Tables 1-3.

Expression of HCG, CD44v6, and CD44v4/5 in primary and metastatic carcinoma

According to Tables 1-3, if the expression of HCG, CD44v6, and CD44v4/5 was positive in primary tumor, it could be negative in metastasis tumor. If both of them were positive, the expression was similar or lower in metastasis tumor compared to primary tumor, but there was no statistically significant difference.

Positive rate of HCG, CD44v6, and CD44v4/5 expressions in esophageal squamous cell carcinoma

The positive rate of HCG, CD44v6, and CD44v4/5 expression was 71.43%, 54.76%, and 59.52% respectively. There was no significant difference among them ($P>0.05$), nor was there any correlation ($P>0.05$).

DISCUSSION

HCG is a glycoprotein hormone. Recent studies found that HCG can be expressed in many tumors, such as the tumor of lung[2], bladder[3], breast[4], HCG is related with tumor differentiation degree, infiltration and metastasis. According to our study, there is a significant difference between lymph node metastasis and non-metastasis groups in terms of the positive expression of HCG, indicating that HCG plays an important role in lymphatic metastasis of esophageal squamous cell carcinoma. The stained tumor cells in emboli or invading the vascular wall were highly positive for HCG, suggesting that HCG also has a relationship with hematogenous metastasis of esophageal squamous cell carcinoma. Most tumor cells with positive expression of HCG in esophageal squamous cell carcinoma were well differentiated and had plenty of cytoplasm. The expression of HCG was mainly in central tumor cells of carcinoma nests, and in peripheral cells. But the keratinous pearls were not stained. All of these are in accordance with the study of Li[2] on lung squamous cell carcinoma. The expression of HCG was mainly in cytoplasm, and the amount of cytoplasm of the central tumor cells was more than that in periphery of carcinoma nests, suggesting that the different expression levels of HCG of these two types of carcinoma cells result from different amounts of cytoplasm. The tumor cells with positive expression of HCG infiltrated the vascular wall, suggesting that the expression of HCG has some relationship with infiltration and metastasis of esophageal squamous cell carcinoma.

Previously it was found that the expression of HCG is negatively related with the differentiation degree of carcinoma of bladder[3] and squamous cell carcinoma of lung[2]. These discrepancies may be due to the following reasons. Types of the tumor tissues are different (the difference between squamous cell carcinoma and transitional cell carcinoma). The expression of HCG is mainly in cytoplasm, while the quantity of cytoplasm is correlated with the differentiation degree of tumor cells (there is more cytoplasm in squamous cell carcinoma of grade I, less in grade II, and the least in grade III). The positive rate of HCG in the 42 cases of esophageal squamous cell carcinoma (71.42%) was much higher than that in carcinoma of bladder[3], and also higher than that in squamous cell carcinoma of the lung (60%)[2]. All of these indicate that HCG may become a new and more sensitive biological marker.

There was a close correlation between the expression of CD44v6, CD44v4/5, and the infiltration and metastasis of tumors. The study showed that the tumor cells at the periphery of carcinoma nest with interstitial or intermuscular infiltration and the stained tumor cells with mitosis were highly positive for CD44v6 and CD44v4/5, suggesting that CD44v6 and CD44v4/5 play a role in the infiltration of esophageal squamous cell carcinoma. The results are consistent with other studies[6-8]. There was a significant difference in the positive rate of CD44v6, CD44v4/5 expression between lymph node metastasis group and non-metastasis group, indicating a correlation

between the positive expression of CD44v6, CD44v4/5, and lymph node metastasis of esophageal squamous cell carcinoma. The stained tumor cells in the emboli or invading the vascular wall were highly positive for CD44v6 and CD44v4/5, suggesting that there is some relationship between the expression and risk of hematogenous metastasis of human esophageal squamous cell carcinoma.

The correlation between CD44v and metastasis of tumors was identified, while studies on relationship between CD44v and differentiation are few. This study showed that the expression rate of CD44v6, CD44v4/5 reduced with decline of the differentiation degree of esophageal squamous cell carcinoma. Yokozaki *et al*.[10] reported that if the differentiation of carcinoma is poor, the expression of CD44v is much lower.

There was no significant difference or any correlation among HCG, CD44v6, and CD44v4/5 in the 42 cases of esophageal squamous cell carcinoma. All these indicate that although HCG, CD44v6 and CD44v4/5 are related with the infiltration and metastasis of esophageal squamous cell carcinoma, their pathogenesis may be different.

Abstract

AIM: To examine the gene expression profile of gastric cancer (GC) by combination of laser capture microdissection (LCM) and microarray and to correlate the profiling with histological subtypes.

METHODS: Using LCM, pure cancer cells were procured from 45 cancerous tissues. After procurement of about 5 000 cells, total RNA was extracted and the quality of RNA was determined before further amplification and hybridization. One microgram of amplified RNA was converted to cDNA and hybridized to cDNA microarray.

RESULTS: Among 45 cases, only 21 were qualified for their RNAs. A total of 62 arrays were performed. These included 42 arrays for cancer (21 cases with dye-swab duplication) and 20 arrays for non-tumorous cells (10 cases with dye-swab duplication) with universal reference. Analyzed data showed 504 genes were differentially expressed and could distinguish cancerous and non-cancerous groups with more than 99% accuracy. Of the 504 genes, trefoil factors 1, 2, and 3 were in the list and their expression patterns were consistent with previous reports. Immunohistochemical staining of trefoil factor 1 was also consistent with the array data. Analyses of the tumor group with these 504 genes showed that there were 3 subgroups of GC that did not correspond to any current classification system, including Lauren's classification.

CONCLUSION: By using LCM, linear amplification of RNA, and cDNA microarray, we have identified a panel of genes that have the power to discriminate between GC and non-cancer groups. The new molecular classification and the identified novel genes in gastric carcinogenesis deserve further investigations to elucidate their clinicopathological significance.

INTRODUCTION

Gastric cancer (GC) is the second most common cause of cancer-related deaths in the world[1]. In Taiwan, GC ranks the fourth cancer-related death and caused more than 2 000 deaths annually[2]. The prognosis of GC depends mainly on early detection and adequate surgical resection. Although endoscopy with biopsy has been effectively used since 1980s for early diagnosis, the proportion of early to advanced GC being found through this method has not appreciably increased in recent years[3]. In spite of the current surgical techniques and chemotherapy that have made significant improvements, the cure rate for advanced GC remains low and the morbidity remains high[4]. Thus, to improve its detection and therapy, understanding of the pathogenesis and biologic features of GC is crucial.

Gastric carcinogenesis is a multi-factorial and multi-step process accompanied by accumulation of alterations of critical growth regulatory genes[5]. Delineating these genes involved may lead to important new insights into carcinogenesis[6]. Despite the fact that some interesting and promising genetic alterations have been elucidated[7], previous studies of gastric carcinogenesis were incomprehensive and inconclusive. The overall information of the genetic alterations is scanty due to technical problems of analyses. Firstly, the value of even the most sophisticated genetic testing methods will be limited if the inputs of genetic materials are not derived from pure populations or are contaminated by the wrong cells. In solid neoplasm such as GC, stromal and inflammatory cells usually intermingled with cancer cells. Therefore, special procedures to isolate cancer cells from heterogeneous tissues are mandatory. Secondly,

most of previous studies on genetic alterations of GC have focused on selected genes or chromosomal regions known in other cancers. These obstacles may be overcome using the recently developed techniques of laser capture microdissection (LCM) and microarray. LCM allows for the rapid, reliable, and accurate procurement of cells from specific microscopic regions of tissue sections under direct visualization[8]. It affords the opportunity to perform molecular genetic analysis of pure populations of malignant cells in their native tissue environment. On the other hand, the advent of high-density cDNA microarray technology with its capacity for simultaneous monitoring of thousands of genes, provides a unique opportunity for high-throughput genetic analysis of cancer[9]. For GC, several investigators have demonstrated the use of DNA microarray is beneficial for elucidation of gastric carcinogenesis[10-24]. However, to our knowledge, combined analyses of LCM and microarray in GC remain scanty[22-24]. Therefore, we aimed to examine gene expression profiles of GC by these two techniques.

MATERIALS AND METHODS

Tissues samples for LCM and RNA isolation

A total of 45 cancerous tissues and their respective non-cancerous tissues obtained at operation from patients with GC were collected and immediately frozen in liquid nitrogen. Gastric cancer and normal cells were stained by HistoGene LCM Frozen Section Staining Kit and laser capture microdissected by using a Pix Cell II LCM system (Arturus, USA). Malignant and normal cells were captured in a number of about 5 000 cells and their total RNAs were isolated by using PicoPure RNA extraction kit (Arturus, USA). The quality of RNA was determined by Bioprocessor before further amplification and hybridization.

RNA amplification, probe labeling, and hybridization

Linear RNA amplification was performed by using the RiboAmp kit (Arturus, USA). Two rounds of RNA amplification were performed to obtain enough amplified RNA (aRNA) for a microarray experiment. To serve as reference in cDNA microarray comparison, a human reference RNA pooled from 9 cell lines (Stratagene, USA) was amplified identically. cDNA was transcribed from aRNA at a quantity of 1.5 μg per channel in the presence Cy3- or Cy5-dUTP by using Cyscribe First-Strand cDNA Labelling kit (Amersham Biosciences, USA). Free conjugated dUTP was removed by Millipore Microcon YM-30 column. Cy3-labeled cDNA was pooled with Cy5-labeled reference probe in 30 μL of hybridization solution and hybridized to an Agilent human 1 cDNA microarray (Agilent Technology, USA). Hybridization was carried out at 65 ℃ for 17 h in a humidified dark chamber (Genetix, UK). After hybridization, slides were washed at the following condition: 2 X SSC/0.1 g/L SDS at 60 ℃ for 10 min, 2X SSC at room temperature for 10 min, and 0.2X SSC at room temperature for 10 min.

Scanning, image analysis, and data processing

Washed microarrays were scanned with a Virtek fluorescence reader (Virtek, CA, USA) at 535 nm for Cy3 and 625 nm for Cy5. Scanned images were analyzed by using Array-Pro image acquisition software (Media Cybernetics, USA), an image analysis algorithm was used to quantify the signal and background intensity for each target element. Data normalization was performed by Iowess method using R package (written by Terry Speeds Microarray Data Analysis Group, University of Berkerley, USA). Measurements from dye-swap replicates were average after normalization. A software developed by researchers in Stanford University-Prediction Analysis of Microarray (PAM) and Spotfire software was utilized to analyze the data.

Immunohistochemistry

Immunostaining for trefoil factor 3 protein was performed by using a standard avidin-biotin-peroxidase complex detection system[25]. The monoclonal antibody used for this study was purchased from Signet Laboratory (Bedham, MA, USA). In brief, 5-μm sections were dewaxed, microwaved, and rehydrated. Endogenous peroxidase activity and non-specific bindings were blocked by incubation with 30 mL/L hydrogen peroxide (H_2O_2) and non-immune serum, respectively. The slides were then incubated sequentially at 4 ℃ with the primary mouse monoclonal antibody overnight, a biotinylated goat anti-mouse secondary antibody for 30 min, peroxidase-conjugated streptavidin for 10 min and finally diaminobenzidine tetrachloride/H_2O_2 chromogen substrate for 10 min. Slides were then counterstained with Mayer's hematoxylin. Negative control sections were prepared by substituting the primary antibody with buffered saline. The percentage of positively stained cells was determined for each tumor section as well as its adjacent intestinal metaplasia and non-metaplastic epithelium. The immunostaining for trefoil factor 3 was registered as negative only if less than 5% of the cells showed a positive staining.

RESULTS

Among the 45 subjects with GC, only 21 (12 intestinal and 9 diffuse subtypes by Lauren classification; 19 advanced and 2 early gastric cancer by depth of invasion) of their respective RNAs were qualified for further analyses after capture of malignant cells by LCM. Figure 1 shows a representative example of LCM. A total of 62 arrays were then performed, including 42 arrays for cancer (21 cases with dye-swap duplication) and 20 arrays for non-tumorous cells (10 cases with day-swap duplication) with universal reference. PAM analyses showed differential expression of 504 genes (Tables 1 and 2) could distinguish the cancerous and non-cancerous groups with more than 99% accuracy. Of the 504 genes, trefoil factors 1, 2, and 3 were in the list and their expression patterns (down-regulation of trefoil factors 1 and 2, and up-regulation of trefoil factor 3 in cancer cases) were consistent with

Table 1 Up-regulated genes noted in gastric cancer

Biosynthesis

Argininosuccinate synthetase [BC009243], hydroxymethylbilane synthase [BC000520], hypothetical protein CL640 [BC008804], methylenetetrahydrofolate dehydrogenase ($NADP^+$-dependent), methenyltetrahydrofolate cyclohydrolase, formyltetrahydrofolate synthetase [BC001014]

Cell adhesion

Collagen, type XVIII, alpha 1 [AF01808], mesothelin [U40434], CD9 antigen (p24) (X60111), collagen, type VI, alpha 3 [X52022], thrombospondin 2 [L12350], immunoglobulin superfamily containing leucine-rich repeat [AB003184]

Cell death

Nerve growth factor receptor (TNFR superfamily, member 16) [M14764], phosphoprotein enriched in astrocytes 15 [AF153274], programmed cell death 5 [AF014955]

Cell growth and/or maintenance

Cell division cycle 25B [S78187], cyclin D2 [D13639], hippocalcin [BC001777], anillin, actin binding protein (scraps homolog, Drosophila) [AF273437], afamin [L32140], chromosome 14 open reading frame 58 [AK000378], C1q and tumor necrosis factor related protein 1 [AF32984], low density lipoprotein receptor-related protein 8, apolipoprotein e receptor [D86407], enhancer of rudimentary homolog (Drosophila) [U66871], tissue inhibitor of metalloproteinase 1 (erythroid potentiating activity, collagenase inhibitor) [D11139], insulin receptor substrate 2 [AF073310], low density lipoprotein receptor-related protein 8, apolipoprotein e receptor [D50678], thyroid hormone receptor interactor 10 [AJ000414], collagen, type I, alpha 1 [Z74615], ATPase, Na^+/K^+ transporting, beta 3 polypeptide [AF005896], T-LAK cell-originated protein kinase [AB027249], platelet-derived growth factor receptor, beta polypeptide [J03278], nucleolar protein 1 120 ku [BC000656], keratin 7 [BC002700], oncostatin M receptor [BC010943], tissue inhibitor of metalloproteinase 1 (erythroid potentiating activity, collagenase inhibitor) [BC000866], insulin-like growth factor 2 (somatomedin A) [S77035], karyopherin (importin) beta 1 [L38951], nuclear transport factor 2 (NTF-2) (Placental protein 15) (PP15) [X07315], nucleolar protein 1 120ku [X55504], thymosin beta-10 [S54005]

Cell motility

Hyaluronan-mediated motility receptor (RHAMM) [AF03286], sorcin [M32886], troponin T1, skeletal, slow [BC010963]

Cell-cell signaling

Ephrin-A2 [U92896], midkine (neurite growth-promoting factor 2) [X55110], prostaglandin I2 (prostacyclin) receptor (IP) [D25418]

Immune response

Carcinoembryonic antigen-related cell adhesion molecule 1 (biliary glycoprotein) [X14831], Human 1-8D gene from interferon-inducible gene family [X57351], GTP binding protein over-expressed in skeletal muscle [U10550], indoleamine-pyrrole 2,3 dioxygenase [M34455], interferon induced transmembrane protein 1 (9-27) [J04164]

Macromolecule metabolism

Cathepsin L2 [AB001928], PAK2 [AF09213], ribosomal protein, large P2 [M17887], hypothetical protein FLJ22761 [AK026414], KIAA0205 [D86960], proteasome (prosome, macropain) subunit, alpha type, 1 [D00759], protein tyrosine phosphatase type IVA, member 1 [U48296], peptidylprolyl isomerase (cyclophilin)-like 1 [BC003048], ribosomal protein L14 [BC009294], pyruvate kinase, muscle [BC007952], proteasome (prosome, macropain) subunit, alpha type, 7 [BC001895], isocitrate dehydrogenase 3 (NAD+) alpha [U07681], transglutaminase 4 (prostate) [U31905]

Organogenesis

Secreted protein, acidic, cysteine-rich (osteonectin) [M25743], caudal type homeo box transcription factor 2(CDX2) [AJ278434], transcription factor AP-2 alpha (activating enhancer binding protein 2 alpha) [M36711]

Regulation of metabolism

Homeo box B7 [BC015345], B-cell receptor-associated protein 37 [AF126021], Mediterranean fever [AJ003147], homeo box B7 [M16937], homeo box D4 [X17360], TIP49 [AB012122], sin3-associated polypeptide, 18 ku [AF153608]

Response to stress

Complement component 2 [X04481], complement component 3 [K02765], inhibin, beta A (activin A, activin AB alpha polypeptide) [X57579], serine (or cysteine) proteinase inhibitor, clade A (alpha-1 antiproteinase, antitrypsin), member 1 [K02212], serine (or cysteine) proteinase inhibitor, clade H (heat shock protein 47), member 1, (collagen binding protein 1) [D83174], meiotic recombination (*S. cerevisiae*) 11 homolog A [AF073362], RecQ protein-like 4 [BC013277]

Signal transduction

Secreted frizzled-related protein 4 [AF026692], lymphocyte antigen 6 complex, locus E(RIG-E) [Z68179], dimethylarginine dimethylaminohydrolase 2 [BC001435]

Unclassified

Angiotensin I converting enzyme (peptidyl-dipeptidase A) 1 [BI826471], apolipoprotein C-I [AV709433], argininosuccinate synthetase [BF305206], ATPase, Ca^{++} transporting, plasma membrane 4 [AI885833], ATPase, Na^+/K^+ transporting, beta 3 polypeptide [AU151263], B-cell associated protein [BG771222], BTG family, member 2 [BG750101], cadherin 3, type 1, P-cadherin (placental) [NM001793], calcium modulating ligand [AW474551], carbonyl reductase 3 [AI658832], cathepsin Z [AI913006], CDC-like kinase 2 [BG286233], cell division cycle 25B [BF976307], CGI-01 protein [AK027886], chloride intracellular channel 1 [AA291390], claudin 4 [BI760179], claudin 7 [AI279608], collagen, type I, alpha 1 [AW577407], collagen, type X, alpha 1 (Schmid metaphyseal chondrodysplasia) [NM000493], core-binding factor, beta subunit [NM001755], D123 gene product [BE792735], deoxythymidylate kinase (thymidylate kinase) [BF312526], diubiquitin [AW270961], DKFZP566C134 protein [BG621382], E2F transcription factor 3 [AU153511], epithelial protein lost in neoplasm alpha [AAF23756], exostoses (multiple) 1 [BF057267], FK506-binding protein 4 (59 ku) [NM002014], follistatin-like 3 (secreted glycoprotein) [NM005860], forkhead box M1 [AL525810], glutamine-fructose-6-phosphate transaminase 2 [AK001242], GTP-binding protein over-expressed in skeletal muscle [AW297828], guanylate cyclase 2C (heat stable enterotoxin receptor) [NM004963], heme oxygenase (decycling) 1 [BI596354], HMT1 (hnRNP methyltransferase, *S. cerevisiae*)-like 2 [BG167159], Homo sapiens cDNA FLJ11796 fis, clone HEMBA1006158, highly similar to Homo sapiens transcription factor forkhead-like 7 [FKHL7] gene [BI914918], homo sapiens mRNA for short form of beta II spectrin, partial [AA131993], human cDNA: FLJ22528 fis, clone HRC12825 [AK026181], human cDNA: FLJ22998 fis, clone KAT11985, highly similar to AB000712 Human hCPE-R mRNA for CPE-receptor [AK026651], human chromosome 20 clone h119, complete sequence [AF312913], human claudin 3 [CLDN3] gene, [AF007189], regenerating islet-derived family, member 4 [AF254415], human genomic DNA, chromosome 22q11.2, clone KB1125A3 [AP000350], likely ortholog of mouse membrane bound C2 domain containing protein [AB018290], KIAA0930 protein [AB02314], hypothetical protein LOC90499 [AL137712], fuse-binding protein-interacting repressor [AF190744], Thy-1 cell surface antigen [M11749], biglycan [BC002416], CK2 interacting protein 1; HQ0024c protein [BC010149], hypothetical protein FLJ12436 [BC011993], tissue inhibitor of metalloprotease 1 (erythroid potentiating activity, collagenase inhibitor) [BC000866], hypothetical protein FLJ20277 [M11749], hypothetical protein FLJ22393 [H45848],hypothetical protein PRO1489 [AI536671], interferon induced transmembrane protein 1 (9-27) [BG506643], interferon induced transmembrane protein 3 (1-8U) [BE886918], interleukin 13 [NM002188], interleukin 8 [BG777366], JM4 protein [BI818455], keratin 7 [BI094014], keratin 7 [AA307373], KIAA0747 protein [BG744628], low density lipoprotein receptor-related protein 8, apolipoprotein e receptor [BF110337], lymphocyte antigen 6 complex, locus E [BM101706], matrix metalloproteinase 7 (matrilysin, uterine) [NM002423], membrane protein of cholingeric synaptic vesicles [BG760616], mesothelin [AI813749], midkine (neurite growth-promoting factor) [AI784469], msh (Drosophila) homeo box homolog 1 [AI912103], MyoD family inhibitor [BG675569], neural precursor cell expressed, developmentally down-regulated 5 [AU131176], neuromedin U [BG661038], NIPSNAP, C. elegans, homolog 1 [BC006473], nucleolar and coiled-body phosphoprotein [AL553791], platelet-derived growth factor receptor, beta polypeptide [BI755841], procollagen-lysine, 2-oxogutarate 5-dioxygenase 3 [AL544817], proliferating cell nuclear antigen [AA523378], proliferation-associated 2G4, 38KD [BI088072], protein C receptor, endothelial (EPCR) [BG831881], pyruvate kinase, muscle [BF690275], rhoG [BG338917], regulatory factor X, 5 [AW027312], ribosomal protein L23 [AI349581], ribosomal protein L35 [BF310946], ribosomal protein L37 [BG032793], ribosomal protein S16 [BG765030], ribosomal protein S3 [AA593872], S100 calcium-binding protein A4 [AV713821], serine (or cysteine) proteinase inhibitor, clade A (alpha-1 antiproteinase, antitrypsin) [BG567810], sigma receptor (SR31747 binding protein 1) [AL571572], small inducible cytokine subfamily A (Cys-Cys), member 19 [W07401], superoxide dismutase 2, mitochondrial [BG773219], survival of motor neuron 1, telomeric [AA029190], thymosin, beta 10 [AV707021], thyroid hormone receptor interactor 10 [N98668], transKetolase [BI195990], translocase of outer mitochondrial membrane 34 [BE798732], trefoil factor 3 (intestinal) [AA633399], tumor suppressing subtransferable candidate 3 [BE670374], zinc finger protein 267 [AU128446]

[ ]: GeneBank accession number

Table 2 Down-regulated genes noted in gastric cancer

Biosynthesis

5-aminoimidazole-4-carboxamide ribonucleotide formyltransferase/IMP cyclohydrolase [D89976], adenosine monophosphate deaminase 1 (isoform M) [M60092], histidine decarboxylase [D16583], Human histidine decarboxylase (HDC) [M60445]

Catabolism

Human bilirubin UDP-glucuronosyltransferase isozyme 1 [M57899], Human placental cDNA coding for 5'nucleotidase (EC 3.1.3.5) [X55740]

Cell adhesion

Collagen, type IV, alpha 6 [D21337], collagen, type XVII, alpha 1[U76585], tenascin C (hexabrachion) [X78565], dermatopontin [AL049455], Human pancreatitis associated protein [M84337], sialic acid binding Ig-like lectin 11 [AF337818], Macaque brain cDNA clone:QflA-14173, full insert sequence [AB062939]

Cell death

Baculoviral IAP repeat-containing 1 [U80017], CD3E antigen, epsilon polypeptide (TiT3 complex) [X03884], programmed cell death 4 (neoplastic transformation inhibitor) [U96628]

Cell growth and/or maintenance

Core-binding factor, runt domain, alpha subunit 2; translocated to, 1; cyclin D-related [S69002], ATPase, Ca++ transporting, ubiquitous [Z69881], ATP-binding cassette, sub-family C (CFTR/MRP), member 5 [AB005659], B-cell CLL/lymphoma 3 [M31732], CDC7 (cell division cycle 7, S. cerevisiae, homolog)-like 1 [AF015592], gastrokine 1 [AB039886], Human chondroadherin mRNA, complete cds [AF371328], CDC28 protein kinase regulatory subunit 2 [X54942], solute carrier family 39 (zinc transporter), member 6 [U41060], ATPase, H^+/K^+ exchanging, alpha polypeptide [M63962], golgi autoantigen, golgin subfamily a, 4 [U31906], ATPase, H^+/K^+ exchanging, beta polypeptide [M75110], solute carrier family 7 (cationic amino acid transporter, y+ system), member 8 [AB037669], transcription factor-like 5 (basic helix-loop-helix) [AF070992], kinesin family member 11 [U37426], cholecystokinin B receptor [D13305], choline kinase alpha [D10704], sodium channel, nonvoltage-gated 1, gamma [X87160], MCM7 minichromosome maintenance deficient 7 (S. cerevisiae) [D28480], sodium channel, nonvoltage-gated 1 alpha [X76180], oxysterol binding protein-like 7 [AF323729], zinc finger protein 145 (Kruppel-like, expressed in promyelocytic leukemia) [AF060568], solute carrier organic anion transporter family, member 2A1 [U70867], aurora kinase B [AF004022], CDC-like kinase 1 [M59287], trefoil factor 1 [X52003], quiescin (Q6) [U97276], signal recognition particle receptor ('docking protein'), clone MGC:1609 IMAGE:3528505, mRNA, complete cds [BC001162], villin-like, clone MGC:656 IMAGE:3356294, mRNA, complete cds. [BC000243], inhibitor of DNA binding 1, dominant negative helix-loop-helix protein [S78825], insulin-like growth factor binding protein 2 36 ku [S37730], Macaque somatostatin I mRNA, complete cds. solute carrier family 9 (sodium/hydrogen exchanger), isoform 1 (antiporter, Na^+/H^+, amiloride sensitive) [S68616], platelet-derived growth factor receptor, alpha polypeptide [M21574], SH3-domain GRB2-like 2 [AF036268], solute carrier family 9 (sodium/hydrogen exchanger), isoform 1 (antiporter, Na^+/H^+, amiloride sensitive) [M96067], thiosulfate sulfurtransferase (rhodanese) [BI820468], thrombomodulin [M16552]

Cell-cell signaling

NAD(P)H dehydrogenase, quinone 1 [J03934], dopamine receptor D5 [BC009748], monoamine oxidase A [M69226]

Digestion

Japanese Macaque (Macaca fuscata) mRNA for pepsinogen A-2/3. [X59755]

Electron transport

Cytochrome P450, family 4, subfamily F, polypeptide 12 [AY008841], cytochrome P450, family 2, subfamily C, polypeptide 18 [M61853], cytochrome P450, family 4, subfamily F, polypeptide 11 [AF23608], cytochrome P450, family 2, subfamily S, polypeptide 1 [AF33527], dual oxidase 1 [AF21346], cytochrome c oxidase subunit Vic [BC000187]

Immune response

Diacylglycerol kinase, delta 130 ku [D63479], Fc fragment of IgG, high affinity Ia, receptor for (CD64) [X14356], beta-site APP-cleaving enzyme 2 [AL163285], X-box binding protein 1 [L13850]

Macromolecule metabolism

Sphingomyelin phosphodiesterase, acid-like 3A [Y08136], calpain 9 (nCL-4) [AB038463], carboxypeptidase A2 (pancreatic) [BC007009], 2,4-dienoyl CoA reductase 2, peroxisomal [AE006463], protein kinase (cAMP-dependent, catalytic) inhibitor beta [AF225513], calpain 13 [AK027176], calpain 9 (nCL-4) [AF022799], fructose-1,6-bisphosphatase 1 [L10320], fructose-1,6-bisphosphatase [Y10812], gastric lipase [X05997], heat shock 10 ku protein [AJ250915], progastricsin (pepsinogen C) [M23077], protein tyrosine phosphatase, receptor type, N polypeptide 2 [U66702], carboxypeptidase A2 (pancreatic) [U19977], prostaglandin-endoperoxide synthase 1 (prostaglandin G/H synthase and cyclooxygenase) [M59979], hyaluronoglucosaminidase 1 [U03056], galactose-4-epimerase, UDP-[L41668], chaperonin containing TCP1, subunit 3 (gamma)[BC008019], proprotein convertase subtilisin/kexin type 7 [BC010696], ubiquitin specific protease 14 (tRNA-guanine transglycosylase), [BC003556], Kallikrein 11 [AB013730], KIAA0089 protein [BC006168], prostaglandin-endoperoxide synthase 1 (prostaglandin G/H synthase and cyclooxygenase) [S36219], prostaglandin-endoperoxide synthase 1 (prostaglandin G/H synthase and cyclooxygenase) [U63846]

Metabolism

Aldo-keto reductase family 1, member C1 (dihydrodiol dehydrogenase 1; 20-alpha (3-alpha)-hydroxysteroid dehydrogenase) [AB032150], alcohol dehydrogenase 7 (class IV), mu or sigma polypeptide [X76342], carbonic anhydrase II [J03037], carbonic anhydrase IX [Z54349], transcription termination factor, mitochondrial [Y09615], hydroxyprostaglandin dehydrogenase 15-(NAD) [L76465], dehydrogenase/reductase (SDR family) member 9 [AY017349], sulfotransferase family, cytosolic, 1C, member 1 [AF186261], ribonuclease, RNase A family, 4 [BC015520]

Organogenesis

GATA binding protein 4 [L34357], aldehyde dehydrogenase 3 family, member A2 [U46689], tropomyosin 4 [BC002827]

Regulation of blood pressure

Chromogranin A (parathyroid secretory protein 1) [BC009384]

Regulation of coagulation

Annexin A10 [AJ238979]

Regulation of metabolism

Estrogen-related receptor gamma [AB020639], zinc finger protein 345 [X78933], Kruppel-like factor 2 (lung) [AF134053], RAR-related orphan receptor C [U16997], PEPP subfamily gene 2 [AL590526]

Response to stress

Checkpoint suppressor 1 [BC007506], CHK1 (checkpoint, S.pombe) homolog [AF016582], for protein disulfide isomerase-related [D49490], glutathione S-transferase A3 [BG573805], glutathione synthetase [AK000947], glutathione S-transferase A4-4 (GSTA4) [AF025887], cathepsin E (CatE gene), [AJ250716], glutathione peroxidase 3 (plasma) [D00632], RAD51 homolog (RecA homolog, *E. coli*) (*S. cerevisiae*) [D14134], RAD51 (*S. cerevisiae*) homolog C [BC000667]

Signal transduction

G protein-coupled receptor 30[U63917], hypothetical protein FLJ22595[AK026248], G protein-coupled receptor 30[AF015257], RAP1, GTPase activating protein 1[M64788], active BCR-related gene[U01147], G protein-coupled receptor, family C, group 5, member B[AL137684], G protein-coupled receptor, family C, group 5, member C[AF207989], RAS protein activator like 1 (GAP1 like)[AF086713], regulator of G-protein signaling 17 [RGS17] mRNA, complete cds. [AF202257], histidine triad nucleotide-binding protein, [BC007090], RAB26, member RAS oncogene family, [BC007681]

Unclassified

Actin binding LIM protein 1 [NM006719], activated leucocyte cell adhesion molecule [AI050952], adrenergic, beta-2-, receptor, surface [NM000024], alcohol dehydrogenase 1C (class I), gamma polypeptide[NM000669], aldehyde dehydrogenase 1 family, member A1 [AV649527], aldehyde dehydrogenase 3 family, member A2 (BF679509), aldo-keto reductase family 1, member C1 (dihydrodiol dehydrogenase 1; 20-alpha (3-alpha)-hydroxysteroid dehydrogenase)

previous reports. In addition, we verified expression status of trefoil factor 3 in GC by immunohistochemical staining (Figure 2). Comparison of the tumor group and non-cancerous group with these 504 genes showed that there were 3 subgroups of GC (Figure 3) that did not correspond to any current classification system, including Lauren's classification.

DISCUSSION

The completion of human genome sequencing has facilitated high-throughput quantitative analysis of gene expression alterations. Such transcriptome analyses utilizing DNA microarray offer a new avenue to understand the biological diversity of human cells and

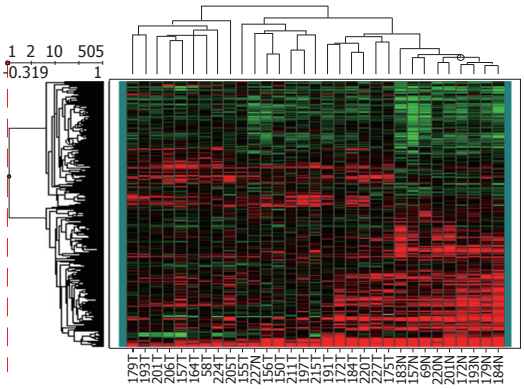

Figure 3 Molecular classification of gastric cancer into 3 subgroups by 504 differentially expressed genes found by microarray.

tumors. Microarray analysis of malignancies from other organ sites has revealed molecular subtypes of tumors that are histologically indistinguishable and clinically informative[26-29]. To elucidate the molecular portrait of GC, we extracted RNA from microdissected normal gastric epithelium and corresponding tumor cells for examining gene expression profiles in the cells as they exist *in vivo*. Coupling with common "reference" sample as an internal standard, we found this strategy is a rapid and efficient way to identify differentially expressed genes and can readily distinguish GC into 3 molecular subtypes.

Most previous gene expression studies on GCs have used whole tumor tissues[10-21]. The overall information of genetic alterations with this approach was comprehensive but might be hampered by the fact that stromal and inflammatory cells usually intermingled with cancer cells. Therefore, special procedures to isolate cancer cells from heterogeneous tissues are mandatory. To overcome the obstacles of the contamination of cancer cells with wrong cells, we adopted LCM. LCM allows for the rapid, reliable and accurate procurement of cells from the specific microscopic regions of tissue sections under direct visualization. The proportion of contaminated cells with this method is estimated to the less than 0.3%[30]. It thus affords the opportunity to perform molecular genetic

analysis of pure populations of malignant cells in their native tissue environment.

However, the RNAs obtained from procured cancer cells were not sufficient to hybridize with cDNA microarray. The recent advances of amplification techniques have provided the key to resolve this problem[31]. In particular, linear RNA amplification could not only provide sufficient RNAs for further analyses but also preserve the overall genetic information.

By the successfully developed techniques of LCM, linear amplification of RNA and cDNA microarray, we found that 504 genes could distinguish cancerous and non-cancerous groups with more than 99% accuracy. Of the genes discovered, some have known association with gastrointestinal cancers. Among them, trefoil factors 1, 2, and 3 were in the list. Furthermore, the expression patterns of these 3 genes were in agreement with previous reports in GCs[32]. These results confirmed our microarray data indirectly. Moreover, we selected trefoil factor 1 for further verification by immunohistochemical staining and the data were also consistent. The remaining novel genes differentially expressed in cancerous and non-cancerous tissues provided a starting point for identification of new biomarkers in GC and are worthy of future in-depth studies to elucidate their roles in GCs.

By comparing expression patterns of the identified 504 genes in individual tissues, we noticed a phylogenetic tree that not only showed clear segregation between normal and cancerous gastric tissues but also assorted GC into 3 subtypes. Although most previous studies suggested classification of GC based on gene expression largely recapitulate that based on histology[33], we did not find such correlation in our system. This discrepancy may be, in part, due to methodological differences and small case numbers in our study. In addition, one intriguing possibility is that tumors sharing similar genes expression profile arise from a common molecular genetic lesion but present with different histological appearances[16,18]. Enrollment of a larger number of tumor samples with well-documented information is under way to further clarify the clinicopathological significance of this molecular classification.

Another unique feature distinct from previous

microarray studies of GC is that we hybridized each tumor or normal mRNA against a "universal reference" of mRNA. This concept was advocated by investigators from Stanford University, who prepared cDNA for microarray experiments from a pool of mRNA isolated from 11 different cells lines[29]. Although normal epithelium from a spectrum of histological changes from atrophy to metaplasia could be easily microdissected by LCM, the so-called normal epithelium adjacent to tumor may not be similar to epithelium distant from the tumor at the molecular level. Therefore, the definition of control normal tissue will need to be carefully assessed in future global analysis of gene expression.

In conclusion, combined LCM and cDNA microarray is a rapid and efficient way to identify differentially expressed genes and can readily distinguish GCs by their molecular portraits. Further characterization of the genes identified in this study and prospective translational studies to determine their potential clinical value may lead to a deeper insight into the pathogenesis of GCs and facilitate the development of novel biomarkers for diagnostic and therapeutic applications.

Abstract

AIM: To investigate the effect of synbiotics, i.e. probiotics and prebiotics mixture, on the gut microbial ecology and digestive enzyme activities in rats.

METHODS: Forty-eight SD rats weighing about 280 g were used in this study. Rats were divided into three groups according to the contents of probiotics and prebiotics mixture in the feed as control, low and high dose groups. The duration of the experiment was 8 wk.

RESULTS: Compared with the control group, the fecal *Lactobacillus* and *Bifidobacterium* counts were significantly increased and the fecal Coliform organism counts were markedly reduced in the low and high dose groups. Concerning the digestive enzyme activity of jejunum, only lactase activity increased in low dose group. However, significant increase of lipase, lactase, sucrase, and isomaltase activities were observed in high dose group.

CONCLUSION: Intake of low and high dosages of probiotics and prebiotics mixture significantly improved the ecosystem of the intestinal tract by increasing the probiotics population and digestive enzyme activities in rats.

Key words: Synbiotics; Intestinal microflora; Digestive enzyme activity

INTRODUCTION

Gastrointestinal microfloras contain hundred different types of microorganisms and are a biologically important component of the body. According to the effect of microbial ecosystem of the human gastrointestinal tract on health, they are divided into two groups: one is probiotics and the other is harmful bacteria. Probiotics, defined as a live microbial food supplement, benefits the host by improving its intestinal microbial balance[1]. Modern perspectives on consumption of probiotics supplements are aimed at consumer well-being, using products enriched with acid bacteria (*Lactobacilli*), particularly *Bifidobacteria*, *Lactobacillus acidophilus* and *Lactobacillus bulgaricus,* and *Streptococcus thermophilus*. Through a process of fermentation, the metabolites of these complex microbes produce varying consequences on host health[2,3]. Health claims associated with probiotics supplements include prevention of diarrhea and colitis, antitumorigenic effects, and cholesterol reduction[4-8].

In contrast, prebiotics is a nondigestible nutritional compound (e.g. inulin, oligosaccharide, dietary fiber) that selectively stimulates the growth of endogenous lactic acid bacteria and *Bifidobacteria* to improve the health of the host[9]. The fermentability and bifidogenic effect of prebiotics have been confirmed with *in vitro* and *in vivo* studies[10-13].

The concept of synbiotics has been proposed recently to characterize colonic food with probiotics and prebiotics properties as health enhancing functional food[14]. Research and development of synbiotic products have been increasingly focusing on evidence of functional benefits including resistance to infection, antibacterial activity, and improved immune status[14].

Although there are numerous researches of biotic products focusing on balanced colonic microflora, few reports investigated into the intestinal digestive enzyme activities. Therefore, the role of enteric feeding and the microenvironment in host defense, the effect of synbiotics, i.e. probiotics and prebiotics mixture, on the gut microbial ecology and digestive enzyme activities in rats were investigated in this study.

Table 1 The composition of synbiotics powder[1]

	Amount/7.5 g
Thiamin (as thiamin hydrochloride)	0.375 mg
Riboflavin	0.425 mg
Niacin (as niacinamide)	5 mg
Vitamin B_6 (as pyridoxine hydrochloride)	0.5 mg
Folate (as folic acid)	100 μg
Vitamin B_{12} (as cyanocobalamin)	1.5 7 μg
Biotin	75 μg
Pantothenic acid (as d-calcium pantothenate)	2.5 mg
Inulin from chicory, powdered extract (root)	250 mg
Proprietary blend culture count	10 billion[2]
Lactobacillus acidophilus and *Lactobacillus bulgaricus*	2.7 billion
Bifidobacterium bifidum and *Bifidobacterium longum*	6.7 billion
Streptococcus thermophilus	0.6 billion

[1] FloraGuard®, Viva Life Science, Costa Mesa, CA, USA. [2] The viable count of each bacterium in powder was checked once a week.

MATERIALS AND METHODS

Animals and experimental diets

Forty-eight male SD rats (6 wk old) were purchased from the laboratory animal sources of the National Taiwan University College of Medicine. Rats were fed with a standard laboratory diet and distilled water *ad libitum*, and housed in an air-conditioned room at 23±2 °C with 12 h of light per day. Experiments were started after the rats reached a weight of about 280 g each and adapted to the individual stainless-steel cages. Rats were randomly divided into three groups of 16 animals: control, low dose and high dose groups. The control group was given 20 g laboratory rodent diet 5001 (PMI Feeds, St. Louis, MO, USA) per day. The low and high dose groups were fed with the synbiotics-containing diets, which contained 20 g/d laboratory rodent diet 5001 and low (1.5 g/kg body weight/day) or high (7.5 g/kg body weight/day) dosages of synbiotics powder (FloraGuard®, Viva Life Science, Costa Mesa, CA, USA). The composition of synbiotics powder is described in Table 1. The duration of the experiment was 8 wk.

Assessment of fecal weights and moisture

Before the rats were killed, feces were collected from each rat on the final 7 d of the experimental period. The feces were freeze-dried and weighed. The wet weight, dry weight, moisture content, and physical appearance of the feces were recorded.

Analysis of microbial ecosystem in the intestine

At 10:00 a.m., the day before the end of the experiment, all rats were anesthetized by ethyl ether inhalation and fecal samples were collected in sterile centrifuged tubes containing 9 mL of anaerobic dilution buffer (0.2% gelatin, 0.05% cysteine, and 0.0002% resazurin). Samples were brought to the laboratory within 2 h after defecation. Additionally, each sample was duplicated and inoculated onto the agar by the spread plate method for plate count determination. Ten-fold serial dilutions of the fecal samples (10^{-1}-10^{-6}) were m-ade in sterile physiological saline (9 g/L) and 50 μL was inoculated onto the following agar plates.

Total anaerobic bacteria counts

CDC anaerobe blood agar plates (Oxoid CM271, Basingstoke, Hants., UK) was used for the detection of total aerobic bacterial flora. Blood agar plates were incubated aerobically at 37 °C for 24 h.

Probiotics

Detection of *Lactobacillus* *Lactobacillus* anaerobic MRS with vancomycin and bromocresol green (LAMVAB) was used for the detection of *lactobacilli*. LAMVAB (pH 5) was prepared with MRS broth (104.4 g/L), cysteine-HCl (0.5 g/L), bromocresol green (0.05 g/L), agar (40 g/L) and vancomycin hydrochloride (>95% purity, 2 mg/mL) according to the method described previously[15]. LAMVAB agar plates were pre-reduced in the anaerobic cabinet for 24 h before the inoculation and were incubated in the anaerobic cabinet at 37 °C for 48 h after inoculation.

Plate count of viable *Bifidobacteria* Modified *Bifidobacterium* iodoacetate medium-25 (BIM-25) was used for the enumeration of bifidobacteria. All plates were incubated for 72 h at 37 °C.

Harmful bacteria

Detection of Coliform organisms Detection of Coliform organisms in fecal samples collected from rats were directly inoculated onto the Endo agar plates and incubated anaerobically in McIntosh Fildes jar at 37 °C for 48 h. Fourteen grams of dehydrated Endo agar media was dissolved in 500 mL of water and brought to a rolling boil. The media were then autoclaved at 121 °C for 15 min. Twenty milliliters of the agar was poured into the Petri plates that were sterilized under UV light and allowed to cool. The Endo agar plates were capped and stored upside down in the refrigerator for future use.

Analyses of digestive enzymes activities

Preparation of tissues After 8 wk, all rats were anesthetized by ethyl ether inhalation and killed. Blood was collected via the abdominal aorta. The small intestine was immediately removed, and then washed in ice-cold physiological saline (9 g/L NaCl). The length of the small intestine was measured. The mucosal cells of the jejunums (about 10 cm), where sucrase activity is most highly concentrated, were scraped off with a piece of glass and homogenized in ice-cold distilled water. The homogenates were centrifuged at 7 000×*g* for 10 min at 4 °C. Supernatants were transferred into new Eppendorf tubes and stored at -80 °C for further analysis.

Measurement of lipase and disaccharidase activities Lipase activity was measured with a commercial kit (lipase assay kit, LI-186, Randox Laboratories Ltd, Co.).

Sucrase, isomaltase and lactase activities from mucosal extracts were measured according to the modified method of Dahlqvist with some modifications[16]. Substrate

Table 3 Effect of synbiotics on intestinal microorganisms in rats[1]

	Control	Low dose	High dose
Total anaerobic bacteria counts (log CFU/g)	9.26±0.30	8.95±0.37	8.95±0.18
Lactobacillus (log CFU[2] /g)	7.42±0.44	9.35±0.64[a]	9.41±0.55[c]
Bifidobacteria (log CFU/g)	8.52±0.59	9.60±0.26[e]	9.40±0.39[g]
Coliform organisms (log CFU/g)	8.44±0.74	6.70±0.57	7.13±0.51

[1]Mean±SD of 16 rats for each group. [a]P<0.05 *vs* control, [c]P<0.05 *vs* control, [e]P<0.05 *vs* control, [g]P<0.05 *vs* control. [2]CFU: colony forming unit.

buffer solution containing maltose, sucrose, or lactose was incubated with a diluted sample for 60 min at 37 °C. The reaction was terminated by adding *O*-dianisidine, and released glucose was determined by means of a Tris glucose-oxidase (TGO) procedure (Tris-HCl, 100 mL, 0.5 mol/L, pH 7.0; glucose oxidase, 1.7 mg; peroxidase, 0.5 mg and Triton X-100, 1 mL) and the samples were analyzed by spectrophotometry at 420 nm. One unit of disaccharidase activity was defined as the amount of the enzyme that can hydrolyze 1 μmol/L of substrate equivalent per minute under the assay conditions. The specific disaccharidase activities were expressed as units/g protein.

Total protein concentrations Total protein concentrations of samples were spectrophotometrically estimated by the method of Biuret with bovine serum albumin as a standard.

Statistical analysis

All data were expressed as the mean±SD. One-way analysis of variance and Fisher's least significant difference test were used to compare the differences of means using the SAS software (version 8.2, SAS Institute, Cary, NC, USA). Statistical significance was assigned at the 0.05 level.

RESULTS

Feed intake and body weight changes

There was no difference in the feed intake in each group (Table 2). Body weight changes are shown in Figure 1. There were no changes in body weight among the three groups until 5 wk. However, the rats of high dose group showed significantly decreased body weights, as compared with the rats of control or low dose groups at the 6th, 7th and 8th wk.

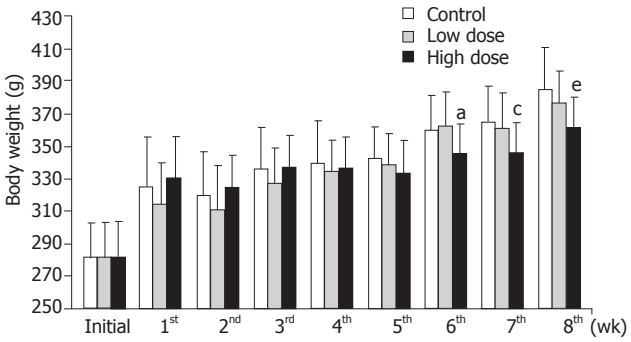

Figure 1 Effect of synbiotics on body weight changes in rats. All results are expressed as mean and standard errors of 16 rats. [a]P<0.05 *vs* control, [c]P<0.05 *vs* control, [e]P<0.05 *vs* control.

Fecal weight and moisture

The fecal weight and moisture in the low dose group did not differ at the 4th and 8th wk, in contrast to those of the control group (Figure 2). Although, the fecal weight and moisture in high dose group did not change at the 4th wk, they significantly increased at the 8th wk (Figure 2).

Microbial ecosystem in the intestine

Table 3 presents the intestinal microorganisms in each group. There was no change in anaerobic bacteria counts in each group. In addition, the *Lactobacillus* and *Bifidobacteria* counts were significantly increased in low and high dose groups as compared with the control group. On the contrary, the count of Coliform organisms was significantly decreased in low and high groups.

Digestive enzymes activities in jejunum

As shown in Figure 3, lipase, sucrase and isomaltase activities did not change, but lactase was significantly higher in low dose group, than in control group. On the other hand, not only lipase but also disaccharidase activities significantly increased in high dose group as compared with control group (Figure 3).

DISCUSSION

In this study, the effect of synbiotics containing probiotics and prebiotics on gut microbial ecology and digestive enzyme activities were investigated.

Many researches proved that consumption of prebiotics, such as inulin, could stimulate intestinal peristalsis by means of increasing fecal bulk and moisture[9,17]. The mechanism of action has been observed that indigestible water-soluble dietary fiber may incorporate a lot of water in the intestine[9]. Inulin consists of 2-60 fructose units linked by a β-(2→1)-glycosidic linkage often with a terminal glucose unit[9]. These fructans are not hydrolyzed by the digestive enzymes in the small intestine; they reach the colon unabsorbed and are utilized selectively

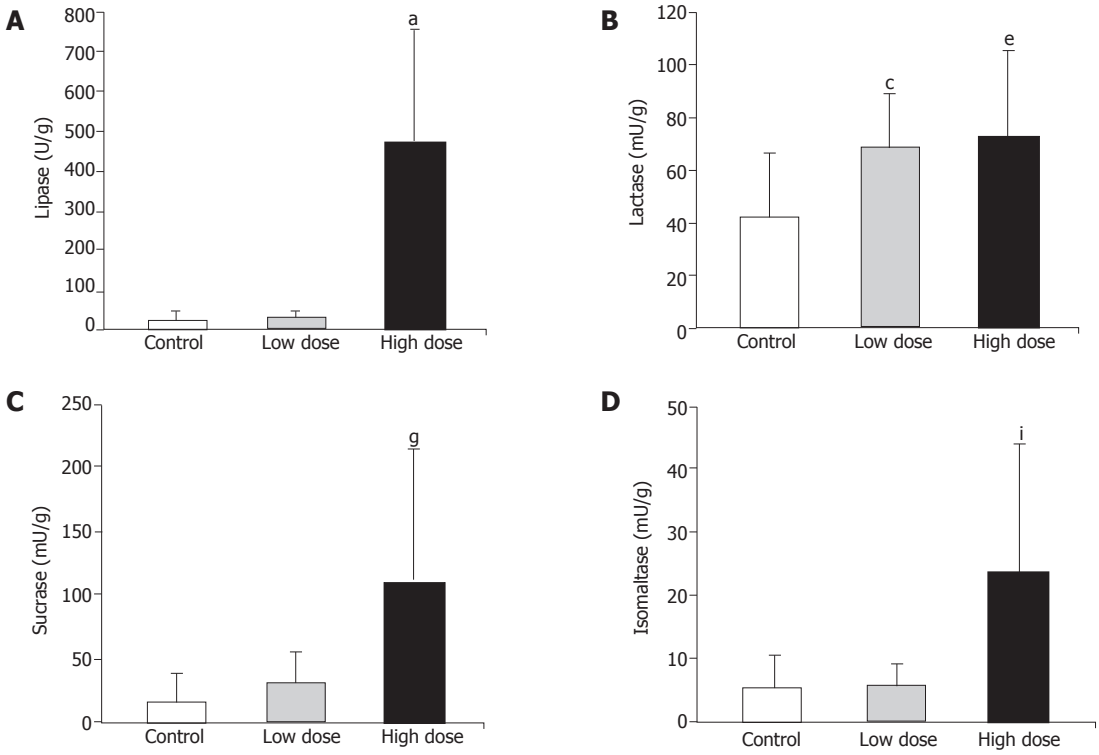

Figure 3 Effect of synbiotics on jejunal digestive enzyme activities in rats. All results are expressed as mean and standard errors of 16 rats. $^{a}P<0.05$ *vs* control, $^{c}P<0.05$ *vs* control, $^{e}P<0.05$ *vs* control, $^{g}P<0.05$ *vs* control, $^{i}P<0.05$ *vs* control (**A, B, C, D**).

as a substrate for the growth of *bifidobacteria*. The most widely accepted effect of inulin is to enlarge both the number and the proportion of fecal *bifidobacteria*[18]. These bacteria are recognized for creating conditions unfavorable for the growth of potentially pathogenic organisms, such as Coliform organism[19,20]. However, there seems to be no increase in the total bacteria number or a change in the anaerobe number[21].

In this study, rats that ingested high dose synbiotics showed lower body weight after 6 wk and higher fecal weight after 8 wk (Figures 1 and 2). Thus, it was speculated that consumption of synbiotics containing inulin may reduce body weight by means of improving the fecal bulk and moisture. Furthermore, the intestinal side-effect of synbiotics powder consumption, including diarrhea or constipation, was not observed in rats during the experimental period. This result may support the clinical application of synbiotics to weight management. In addition, it was also observed that the *Lactobacillus* and *Bifidobacteria* counts were significantly increased, but there was no change in the anaerobic bacteria counts in rats fed with low and high dose synbiotics, while the count of Coliform organisms, the harmful bacteria, were significantly reduced in rats fed with low and high dose synbiotics in this study (Table 3). These results were similar to our previous researches. There are two possibilities to explain the results. The first is the fermentation of inulin that provided short-chain fatty acids, stimulating the proliferation of *Lactobacillus* and *Bifidobacteria* and suppressing potential pathogenic organisms in the gut; and the second was the supplement of probiotics, including *Bifidobacteria*, *Lactobacillus acidophilus*, that directly improved the total number of these bacteria.

Some reported advantages of bifidobacterial proli-

feration in the human gut included the production of digestive enzymes. However, these reports were limited in *in vitro* testing[2]. Jiang *et al*[22]. proved that *Bifidobacterium longum* improved the lactose intolerance in human beings by secreting the lactase to the gut. In this study, jejunal lactase activity was improved in both low dose and high dose intake of synbiotics, and furthermore, lipase, sucrase and isomaltase activities were also increased in rats fed with high dose synbiotics (Figure 3). The causes for the improvement of digestive enzyme activity possibly are that synbiotics created the healthy gastrointestinal microbial ecology or modified the secretion of bacterial enzyme. Delzenne *et al*[23]. also suggested that polyamines may be synthesized from dietary fermentable substrates such as inulin or guar gum by bacteria. The exogenous sources of polyamines seemed to be essential for small intestinal and colonic mucosal growth and development[23]. Thus, the high digestive enzyme activities in rats fed with synbiotics powder were possibly caused by the well growth and high turnover rate of intestinal mucosa.

In conclusion, intake of low and high dose of synbiotics, which was the combination of probiotics and prebiotics, significantly improved the ecosystem of intestinal tract by increasing the probiotics population and jejunal digestive enzyme activities in rats. Based on this study, another possibility in the benefits of synbiotics is the weight management, and the clinical trial is still necessary in future.

Abstract

AIM: To determine functional consequences of this activation, whereby we focused on a potential regulation of the hepatocyte cytoskeleton during ischemia and reperfusion.

METHODS: For *in vivo* experiments, animals received ANP (5 μg/kg) intravenously. In a different experimental setting, isolated rat livers were perfused with KH-buffer ±ANP (200 nmol/L)±SB203580 (2 μmol/L). Livers were then kept under ischemic conditions for 24 h, and either transplanted or reperfused. Actin, Hsp27, and phosphorylated Hsp27 were determined by Western blotting, p38 MAPK activity by *in vitro* phosphorylation assay. F-actin distribution was determined by confocal microscopy.

RESULTS: We first confirmed that ANP preconditioning leads to an activation of p38 MAPK and observed alterations of the cytoskeleton in hepatocytes of ANP-preconditioned organs. ANP induced an increase of hepatic F-actin after ischemia, which could be prevented by the p38 MAPK inhibitor SB203580 but had no effect on bile flow. After ischemia untreated livers showed a translocation of Hsp27 towards the cytoskeleton and an increase in total Hsp27, whereas ANP preconditioning prohibited translocation but caused an augmentation of Hsp27 phosphorylation. This effect is also mediated via p38 MAPK, since it was abrogated by the p38 MAPK inhibitor SB203580.

CONCLUSION: This study reveals that ANP-mediated p38 MAPK activation leads to changes in hepatocyte cytoskeleton involving an elevation of phosphorylated Hsp27 and thereby for the first time shows functional consequences of ANP-induced hepatic p38 MAPK activation.

INTRODUCTION

Ischemia/reperfusion injury (IRI) remains a serious problem after liver surgery or liver transplantation, as it is a major cause of primary nonfunction or dysfunction of the graft[1-3]. In previous studies, we could demonstrate that atrial natriuretic peptide (ANP) has protective effects on the liver *ex vivo,* as reperfusion damage in ANP-preconditioned organs after cold and warm ischemia was significantly reduced[4-6]. Recently, Cottart *et al*[7]. also demonstrated beneficial properties of the peptide on the liver after ischemia *in vivo*. We have previously shown that preconditioning with ANP increases p38 mitogen activated kinase (MAPK) activity in the liver[8]. Enhanced p38 MAPK activity was reported to contribute to the protection against hepatic IRI in models of ischemic preconditioning (IPC)[9,10]. Furthermore, other groups assigned an important role to p38 MAPK in protection against IRI in the heart[11,12].

In contrast, ANP's cytoprotective effects in post-ischemic livers are independent of an activation of the p38 MAPK but are mediated via an activation of protein kinase A[13]. Accordingly, the functional significance of an ANP-

mediated p38 MAPK activation in the liver after ischemia/reperfusion (I/R) remains unknown. We therefore studied a potential functional role of p38 MAPK in the regulation of the hepatocyte cytoskeleton following I/R.

Structural alterations of the cytoskeleton, such as changes of cell shape of hepatocytes, sinusoidal endothelial cells (SEC), and platelets have been reported to cause disturbances of intracellular transport processes, cell motility, and microcirculation following I/R leading to dysfunction of the organ (for review see Refs.[14-16]). The subcellular distribution of filamentous actin (F-actin), being an important component of the cytoskeleton, as well as the balance between F-actin and monomeric G-actin seem to largely determine the functional outcome[17-19]. In liver cells F-actin forms microfilaments, which are involved in intracellular transport processes, exo- and endocytosis, maintenance of cell shape, and canalicular motility responsible for bile flow[14,18,19]. They are located particularly around the bile canaliculi exhibiting regulatory functions on bile secretion[17,20], but also in the apical membrane region of hepatocytes ensuring stability and mobility[21]. In hepatocytes, a decrease in hepatic F-actin content determines inhibition of store-operated calcium-channels (SOCs), disruption of the organization of the endoplasmic reticulum, and functional disturbances of tight junctions[19,22,23]. Cytoskeletal disruption caused by the administration of phalloidin or by chemical hypoxia results in decreased bile flow and plasma membrane breakdown in liver cells[15,24]. Shinohara *et al*[25]. proved that after warm ischemia *in vivo*, F-actin is reduced in rabbit livers resulting in the loss of cell-integrity and cytoplasmic transport in the liver causing damage to organelles and changes in cell morphology. The small heat shock protein Hsp27, which corresponds to Hsp25 in rodents and is able to interact with the cytoskeleton, plays an important role in the regulation of actin dynamics in other cell types[26-30]: Its phosphorylation leads to an increased conversion of monomeric G-actin into actin filaments (F-actin)[31], while unphosphorylated Hsp27 inhibits the polymerization of actin by binding to the capping end of actin filaments[32,33]. Its functions have been thoroughly investigated in the heart, suggesting an involvement of the heat shock protein in cardioprotection after IPC *in vitro* and *in vivo*[12,34].

The phosphorylation of Hsp27 is exhibited by the p38 MAPK/MAPKAPK2 pathway in different cells and organ systems, but has as yet been unknown in the liver[35-38]. As mentioned above, ANP activates the p38 MAPK in the liver. Due to the lack of knowledge about the downstream targets and functional consequences of this hepatic p38 MAPK activation by ANP, we aimed to determine a potential link to cytoskeletal alterations during I/R. Since the reported activation of p38 MAPK by ANP was detected as an early signaling event after preconditioning[8], we focused on early pre- and post-ischemic events.

MATERIALS AND METHODS

Materials

Rat ANP and SB203580-HCl were purchased from Calbiochem/Novabiochem (Bad Soden, Germany). Complete® was from Roche Diagnostics GmbH (Mannheim, Germany), recombinant murine Hsp25 and rabbit anti-Hsp25 polyclonal antibody from StressGen Biotechnologies (Victoria, Canada), rabbit anti-phospho-Hsp27 polyclonal antibody from New England Biolabs GmbH (Frankfurt, Germany), mouse anti-actin monoclonal antibody from Chemicon International (Hofheim, Germany), rabbit anti-p38 polyclonal antibody from Calbiochem-Novabiochem (Bad Soden, Germany), peroxidase conjugated goat anti-rabbit-IgG antibody from Dianova (Hamburg, Germany), and goat anti-mouse-IgG1 antibody conjugated to horseradish peroxidase from BIOZOL (Eching, Germany).

All other materials were purchased from either Sigma (Deisenhofen, Germany), or VWR international™ (Munich, Germany).

Animals

Male Sprague-Dawley rats weighing 200-300 g or male Lewis rats (donors: 207±12 g; recipients: 276±18 g body mass) were purchased from Charles River Wiga GmbH (Sulzfeld, Germany) and housed in a climatized room with a 12-h light-dark cycle. The animals had free access to chow (Sniff, Soest, Germany) and water up to the time of experiments. All animals received humane care according to the guidelines for care and use of laboratory animals. The study was registered with the local animal welfare committee.

ANP treatment

Under anesthesia Lewis rats received an intravenous infusion of ANP (5 μg/kg) or NaCl for 20 min. Thereafter, livers were excised, kept in cold UW solution (4 °C) for 24 h, transplanted into the recipient animal and reperfused for up to 2 h. At the indicated times (after 20-min perfusion, 24-h ischemia, 2-h reperfusion), livers were frozen in liquid nitrogen. Bile was collected during perfusion and reperfusion and quantified volumetrically. The bile flow was calculated per minute and gram liver tissue.

For isolated perfused rat liver experiments, Sprague-Dawley rats were anesthetized with Narcoren® (Merial, Hallbergmoos, Germany, 50 mg/kg body weight, intraperitoneally), 250 IU heparin were administered, the portal vein was cannulated, and the liver was perfused *in situ* with hemoglobin-free and albumin-free bicarbonate buffered Krebs-Henseleit (KH) solution (pH 7.4, 37 °C) gassed with 95% O_2 and 50 mL/L CO_2. The perfusion medium was pumped through the liver with a membrane pump at a constant flow rate in a non-recirculating fashion[5]. After 10 min of perfusion, ANP (200 nmol/L) was added to the perfusion buffer (depending on the treatment group), followed by an additional perfusion for 20 min. In some groups, SB203580 was added to the perfusion buffer from the beginning of perfusion followed by 30 min of perfusion. After these pretreatment procedures, livers were perfused with 30 mL of cold (4 °C) University of Wisconsin (UW) solution (DuPont Pharma

GmbH, Bad Homburg, Germany) for 1 min and stored in UW solution (4 °C) for 24 h. After this period of ischemia, the liver was reperfused with KH solution for up to 45 min. At the indicated times (after 30-min perfusion, 24 h ischemia, 45-min reperfusion), livers were frozen in liquid nitrogen.

Homogenization and fractionation of liver tissue for Western blot analysis

A fractionation protocol was employed according to published methods with minor modifications[39,40]. Briefly, 50 mg of liver tissue were homogenized in 1.5 mL of lysis buffer (50 mmol/L Tris-HCl pH 7.0, 5 mmol/L EGTA, 1 mmol/L PMSF, 1 mmol/L sodium vanadate, 40 μL Complete®) containing 1% Triton® X-100 (Roth, Karlsruhe, Germany) with a dounce homogenizer. Centrifugation at 15 000×*g* (15 min, 4 °C) delivered the cytoskeletal fraction in the pellet; supernatants representing the cytosolic fraction were cleared by ultracentrifugation (100 000×*g*, 2.5 h, 4 °C). The pellet was resuspended in SDS-containing sample buffer and the cytosolic fraction was diluted with the same sample buffer. Samples were stored at -20 °C until use for Western blot analysis.

Immunoprecipitation

Liver tissue was homogenized as described above, but not fractionated. Protein concentration was determined by the bicinchoninic acid assay method[41]. Five hundred micrograms of protein in 500 μL lysis buffer was incubated with 5 μL of primary antibody (rabbit anti-Hsp25) with shaking overnight at 4 °C. The antibody-antigen complex was precipitated by incubation with 50 μL of washed agarose-A-beads (Sigma, Deisenhofen, Germany) for 2 h, followed by centrifugation. The beads were washed thrice with cold lysis buffer and resuspended in 25 μL of 3× SDS-containing sample buffer. After addition of 25 μL 1× sample buffer, samples were boiled for 5 min at 95 °C followed by centrifugation to remove the beads. Thirty-five microliters of the supernatant for phosphorylated Hsp27 and 10 μL for total Hsp27 were used for protein detection by Western blot analysis.

Western blot analysis

Livers were homogenized, fractionated, and treated as described above. Proteins in total liver homogenates, fractionated liver samples, or immunoprecipitates were separated by SDS-PAGE[42] and, after electrophoretical transfer, visualized via binding of specific first and HRP-conjugated secondary antibodies followed by chemoluminescent detection (NEN, Cologne, Germany). Detection and quantification was performed with a Kodak image station (NEN, Cologne, Germany).

Quantification of actin content in liver fractions

After detection of either F- or G-actin in liver samples via Western blot analysis, the densitometric intensity of the corresponding bands was used to evaluate the ratio of F-resp. G-actin referred to total actin signal (F- + G-actin) in the respective sample.

Staining of tissue sections

At the indicated times, livers were snap-frozen in liquid nitrogen and cut into 6-μm sections. Slices were dried overnight at room temperature. Before staining, samples were fixed in 3% formaldehyde for 15 min, rinsed thrice with PBS (phosphate buffered saline, pH 7.4, with calcium and magnesium), and stained with 1 U of rhodamine-conjugated phalloidin (stock solution: 200 U/mL; MoBiTec, Göttingen, Germany) and Hoechst 33342. Staining was performed for 1 h by gentle shaking in a dark room (room temperature). After two more washing steps, stained liver sections were covered with Mounting Medium (DakoCytomation GmbH, Hamburg, Germany), dried overnight, and observed by confocal laser microscopy (LSM 510 Meta, Zeiss, Jena, Germany).

Kupffer cell depletion

For Kupffer cell (KC) depletion, male Sprague-Dawley rats weighing 200-300 g were anesthetized with diethyl ether. Then 900 μL of a solution containing liposome-encapsulated Cl_2MBP were administered 48 h before perfusion experiments via a single intravenous injection into the tail vein. Animals of the control group received 900 μL NaCl instead. After injection, Cl_2MBP accumulates and induces KC apoptosis. Free Cl_2MBP released from dead macrophages has an extremely short half life in the circulation and is removed by the renal system. After 2 d, the livers of Cl_2MBP- and NaCl-pretreated rats were perfused for 30 min±ANP (200 nmol/L; 20 min), snap-frozen, and stored at -85 °C until further analysis.

Immunohistological analysis

Liver slices were fixed for 24 h in buffered formalin solution, embedded in paraffin and cut into 2 μm sections. Paraffin was removed and samples were pretreated by boiling in TRS 6 (Dako, Hamburg, Germany) in the microwave. Endogenous peroxidase was blocked by treatment with aqueous H_2O_2 solution. To verify KC depletion, ED2 as KC marker (antibody from Serotec, Oxford, England) was used. Blue staining of ED2-positive cells was realized with the ChemMate™ APAAP Kit (Dako, Hamburg, Germany) based on the alkaline phosphatase-anti-alkaline phosphatase method. The Alkaline Phosphatase Substrate Kit III (Linaris, Wertheim, Germany) served as a substrate for the alkaline phosphatase. Samples were counterstained in hematoxylin solution.

In vitro phosphorylation assay

Tissue samples (100 μg) were homogenized in ice-cold lysis buffer (containing 2 mmol/L EDTA, 137 mmol/L NaCl, 10% glycerol, 2 mmol/L tetrasodium pyrophosphate, 20 mmol/L Tris, 1 % Triton® X-100, 20 mmol/L sodium glycerophosphate, 10 mmol/L sodium fluoride, 2 mmol/L sodium vanadate, 1 mmol/L PMSF, 1× Complete). Samples were centrifuged at 11 180r/min and 4 °C for 10 min and aliquots of the supernatant were used for the determination of protein concentration by the bicinchoninic acid assay method[41]. Equal amounts

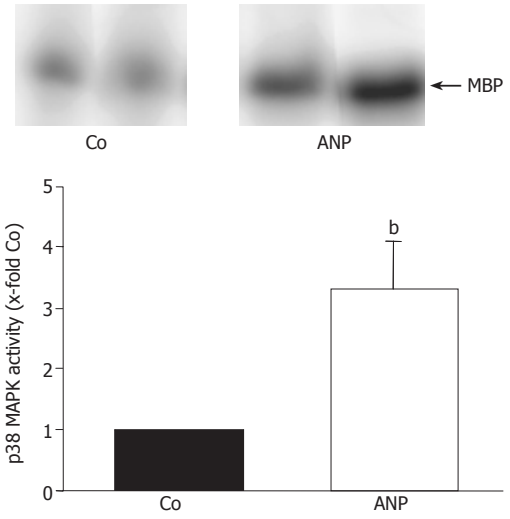

Figure 1 Effect of ANP pretreatment on p38 MAPK activity. After intravenous infusion of ANP (5 μg/kg) or NaCl (Co) for 20 min livers were snap-frozen and homogenized in lysis buffer. Following immunoprecipitation, the assay was performed as described in "Materials and methods", and samples were separated by SDS-PAGE. One representative kinase activity assay specific for p38 MAPK is shown with $n = 2$ (out of $n = 4$) for each treatment group. p38 MAPK activity in the liver homogenates is presented as 10-fold control (30-min perfusion), and is expressed as mean±SE of $n = 4$ experiments in each treatment group. $^{b}P<0.01$ *vs* control.

of protein were incubated with 1.5 μL of anti-p38 antibody shaking for 2 h. Afterwards immunoprecipitation was performed with 15 μL protein A agarose shaking overnight at 4 °C. Samples were centrifuged at 11 180×*g* (4 °C, 10 min) and pellets were washed thrice with lysis buffer and once with kinase buffer (20 mmol/L Hepes pH 7.5, 20 mmol/L $MgCl_2$, 25 mmol/L sodium glycerophosphate, 100 μmol/L sodium vanadate, 2 mmol/L DTT). Precipitates were resuspended in 20 μL kinase buffer, before 3 μL substrate solution (1 mg/mL of recombinant MBP, Sigma, Deisenhofen, Germany) and 10 μL of an ATP mix were added, the latter containing kinase buffer with 10 mCi/mL [γ^{32}P]-ATP, (3 000 Ci/mmol, Amersham, Braunschweig, Germany), 5 mmol/L ATP and 2 mol/L $MgCl_2$. The reaction mixture was then incubated for 20 min at 30 °C shaking. Phosphorylation was stopped by adding 6 μL 5× Laemmli buffer and heating for 3 min at 90 °C. Samples were separated by SDS-PAGE and band intensities quantified by phosphor-imaging (Packard, Meriden, USA). The ratio of digital light units (DLU) of respective values *vs* controls was determined.

Statistical analysis

All experiments were performed at least thrice per treatment group (5 animals per treatment). Results were expressed as mean±SE (n = number of organs). Statistical significance between the groups was determined with one sample or Student's t-test using GraphPad Prism® Version 3.02 for Windows (GraphPad Software Inc., San Diego, USA). $P<0.05$ were considered statistically significant.

RESULTS

ANP pretreatment causes increased p38 MAPK activity

In order to confirm our previous findings that preconditioning with ANP increases p38 MAPK activity in the liver[8], rats were treated intravenously with 200 nmol/L ANP or NaCl and livers were excised and homogenized in lysis buffer. Homogenates were analyzed by *in vitro* phosphorylation assay to determine the activity of p38 MAPK. As shown in Figure 1, hepatic p38 MAPK activity in livers of ANP-preconditioned rats was significantly increased compared to NaCl treated animals. These data confirm the stimulatory effect of ANP on p38 MAPK *in vivo,* with increased p38 MAPK activity after 20 min perfusion representing an early signaling event in ANP preconditioning.

ANP preconditioning leads to increased F-actin content after ischemia

As an activation of p38 MAPK has been shown to be connected with alterations of the cytoskeleton in other cells and organ systems, we investigated the polymerization state of actin in untreated *vs* ANP-perfused livers. Liver tissue was fractionated into a cytosolic (G-actin) and a cytoskeletal (F-actin) fraction in order to discriminate between the hepatic content of G- and F-actin, respectively. In untreated livers, F-actin content did not change during ischemia and reperfusion (Figures 2A and B). In contrast, ANP-preconditioned livers exhibited an obvious augmentation of F-actin after 24 h ischemia accompanied by a decrease in hepatic G-actin, which prolonged during reperfusion (Figures 2A and B). Neither I/R nor ANP preconditioning altered total hepatic actin content. This was examined by homogenizing liver tissue and analyzing samples by Western blotting without prior fractionation (Figures 2C and D).

Perfusion with SB203580 abrogates ANP-mediated increase of hepatocyte F-actin

In order to study the correlation between activation of p38 MAPK and cytoskeletal changes in untreated and ANP-preconditioned livers, we used the specific p38 MAPK inhibitor SB203580. Perfusion with 2 μmol/L SB203580 together with ANP completely abolished the enhanced hepatic F-actin content after ANP preconditioning (Figure 3A). Similarly, inhibition of p38 MAPK by SB203580 abrogated the decrease of G-actin in ANP pretreated liver homogenates, so that G-actin content in these samples resembled untreated controls (Figure 3B). Perfusion with the inhibitor alone did not affect the distribution of cytosolic G- and cytoskeletal F-actin in the liver (Figures 3A and B).

Changes in F-actin by ANP detected by Western blot analysis were confirmed by staining of tissue sections. Staining with rhodamine-conjugated phalloidin, which specifically binds to F-actin, showed a low fluorescence in tissue sections of untreated livers, which correlated with a marginal F-actin content (Figure 4A). Pretreatment

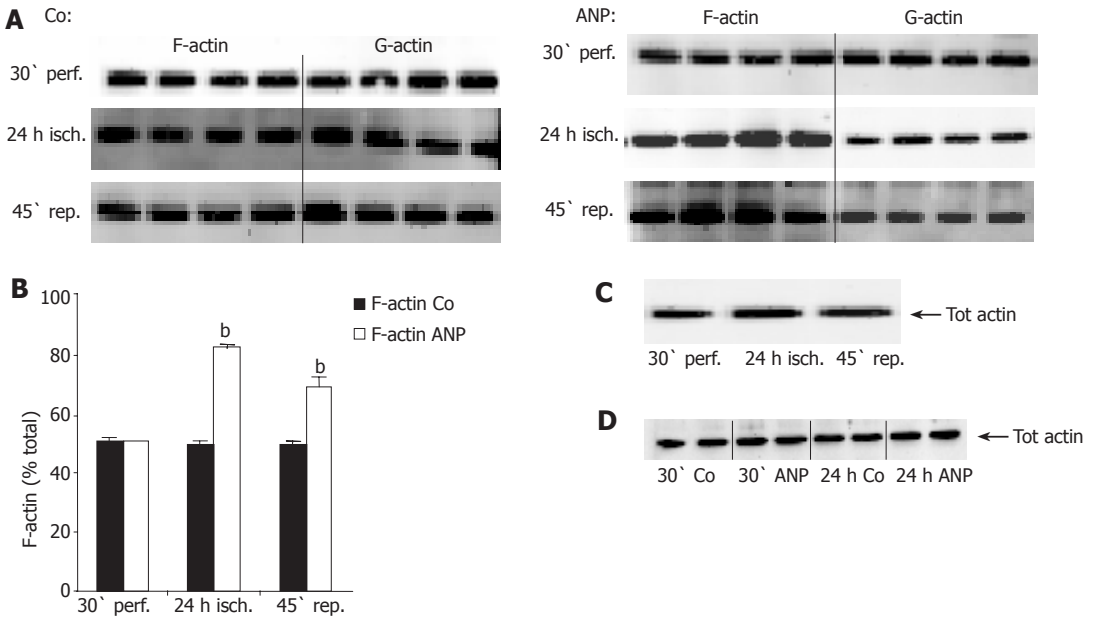

Figure 2 Influence of ANP preconditioning and ischemia on total actin and F-actin content. Livers were perfused for 30 min in the absence or presence of 200 nmol/L ANP, which was added 20 min prior to ischemia. Afterwards, livers were kept under ischemic conditions for 24 h (4 °C) in UW solution. At the indicated times, livers were snap-frozen, homogenized, and analyzed by Western blot using an anti-actin antibody. For differentiation between F- and G-actin (cytoskeleton and cytosol, respectively), liver homogenates were fractionated before Western blot analysis according to "Materials and methods" (**A** and **B**). One representative Western blot is imaged for each experimental setting. (**A**) Western blots representing hepatic F- and G-actin content during IR in untreated (Co) and ANP-preconditioned livers after 30-min perfusion (30' perf.), 24-h ischemia (24-h isch.), and 45-min reperfusion (45' rep.). (**B**) Quantitative/densitometric analysis of F- and G-actin content during IR in untreated (Co) or ANP-preconditioned livers. Data are expressed as percent of total actin content (F-actin+G-actin=100%) as mean±SE of n = 4 experiments in each treatment group. $^{b}P<0.001$ *vs* appropriate control. (**C**) Western blot showing total actin in untreated liver homogenates after 30-min perfusion, 24-h ischemia, and 45-min reperfusion. (**D**) Total hepatic actin content after perfusion (30') and ischemia (24-h) in ANP treated or untreated (Co) livers detected by Western blot analysis.

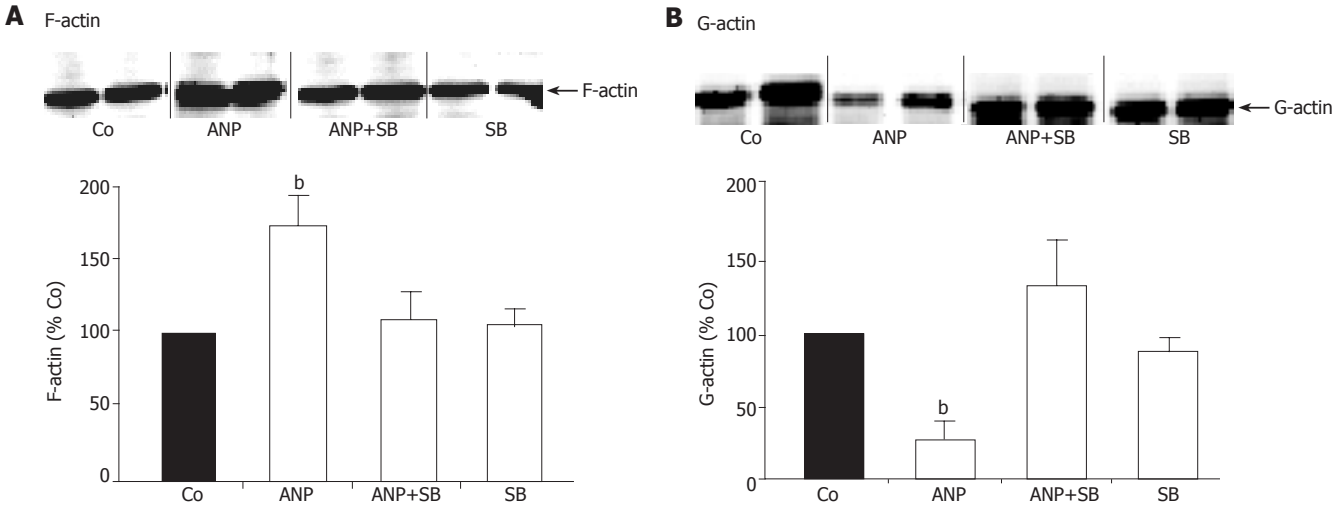

Figure 3 Effect of p38 MAPK inhibition on distribution of F- and G-actin. 20 min prior to ischemia livers were preconditioned with 200 nmol/L ANP or left untreated (Co) followed by 24-h ischemia at 4 °C. In different experiments, livers were perfused with SB203580 (2 μmol/L) or with a combination of SB203580 (2 μmol/L) and ANP (200 nmol/L). After ischemia livers were snap-frozen, homogenized and divided into cytoskeletal (**A**) and cytosolic (**B**) fraction by fractionation as described above. Samples were analyzed by Western blotting using an anti-actin antibody for detection of F-actin (**A**) in the cytoskeletal fraction and G-actin (**B**) in the cytosolic fraction. One representative Western blot is shown for each fraction. Bars show percentage of hepatic F-actin (**A**) or G-actin (**B**) in ANP, ANP+SB203580 and SB203580 treated livers referring to untreated control livers. Results are expressed as mean±SE of n = 4 experiments in each treatment group. $^{b}P<0.01$ *vs* control after 24-h ischemia.

with ANP caused very intensive staining of liver slices, representing an obvious increase in hepatic F-actin content (Figure 4B).

When stained with rhodamine-conjugated phalloidin, slices of ANP pretreated livers showed very intensive staining, representing an obvious increase in hepatic F-actin content especially at apical membranes of hepatocytes (Figure 4B) confirming the results obtained by Western blot analysis. Again, perfusion of the livers with SB203580 abolished the effect of ANP preconditioning on

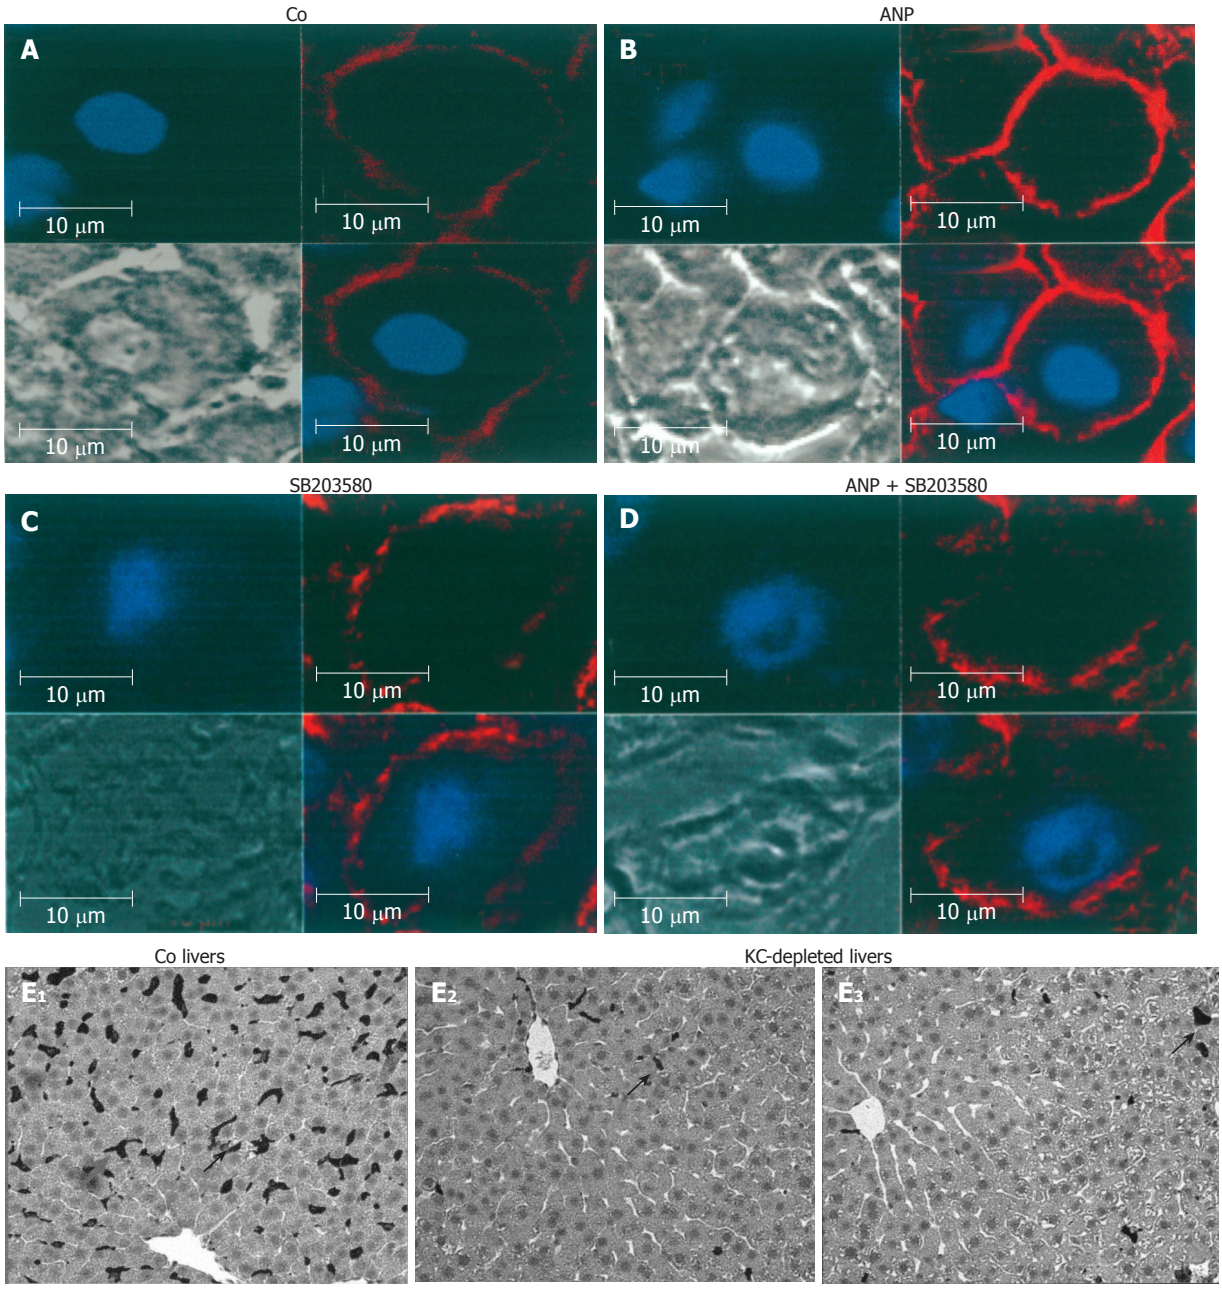

Figure 4 Analysis of the influence of ANP preconditioning on localization of F-actin in the liver by confocal microscopy. Livers were left untreated (**A**): preconditioned with 200 nmol/L ANP (**B**): 2 μmol/L SB203580 (**C**): or perfused with a combination of ANP (200 nmol/L) and SB203580 (2 μmol/L) (**D**): After ischemia (24 h, 4 °C), livers were snap-frozen, cut into 6-μm slices and stained with rhodamine-conjugated phalloidin (red, F-actin) and Hoechst 33342 (blue, nuclei) as described in "Materials and methods". Liver sections were observed by confocal laser microscopy (63-fold amplification). Immunohistological staining of KCs in untreated (Co) and KC-depleted livers (**E**): rats received an intravenous injection of 900 μL NaCl (Co) or 900 μL liposomes (12 mmol/L Cl_2MBP) into the tail vein. After 48 h rat livers were perfused, snap-frozen and liver slices were stained with an antibody against the KC-specific surface marker ED2 (see "Methods") to verify the Cl_2MBP-dependent depletion of the KCs. Dark staining represents KC (hallmarked with arrows). (**F**): KCs were depleted with Cl_2MBP as described under "Methods". After 48 h control organs (Co) or KC-depleted livers (12 mmol/L Cl_2MBP) were perfused ±ANP (200 nmol/L) for 20 min. Then p38 MAPK activity was investigated by *in vitro* phosphorylation assay (see "Methods"). Determination of density light units was performed by phosphorimaging and values of ANP-pretreated cells were divided by mean values of the respective control group. Columns show mean±SE of 4-5 independent perfusion experiments with $^bP<0.01$ being statistically different from the respective control group.

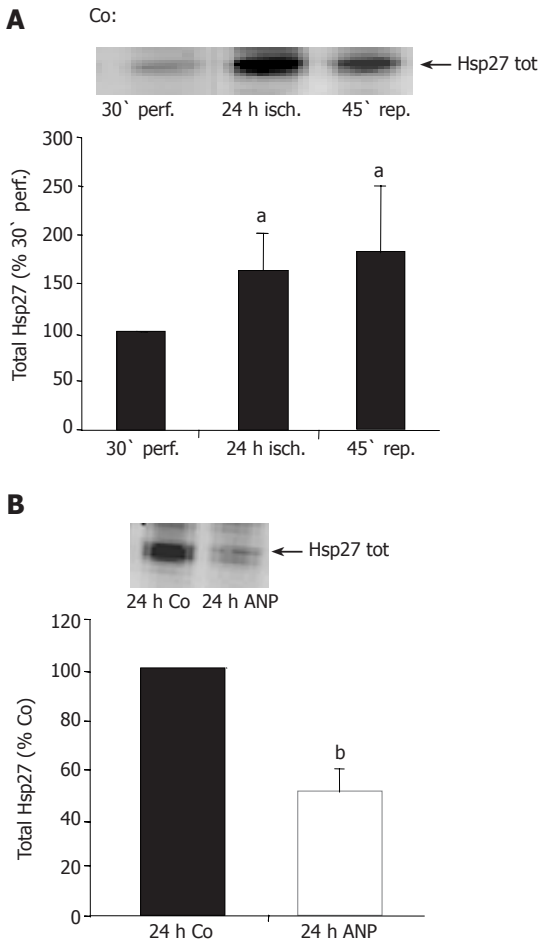

Figure 5 Changes in hepatic total Hsp27 during ischemia – influence of ANP pretreatment. Livers were perfused for 30 min in the presence or absence of ANP followed by 24-h ischemia at 4 °C in UW solution and reperfusion for 45 min. Afterwards, livers were snap-frozen at the indicated times, homogenized and analyzed via Western blot using an anti-Hsp27 antibody for detection of total Hsp27. One representative Western blot is shown for each experimental setting (untreated controls: (**A**), ANP pretreated livers: (**B**)). (**A**) Effect of IR on total Hsp27 in the liver. The graph shows percentage of values for untreated livers (Co) after 30-min perfusion (30' perf.) as means±SE of $n = 4$ experiments in each group. [a]$P<0.05$ *vs* untreated control after 30-min perfusion. (**B**) Influence of ANP preconditioning on total Hsp 27 after 24-h ischemia. Bars represent total Hsp27 as % Co after 24-h ischemia. Data are expressed as means±SE of $n = 4$ experiments in each treatment group. [b]$P<0.01$ *vs* control after 24-h ischemia.

F-actin, as it yielded a marginal staining intensity matching the intensity of untreated livers (Figure 4D), linking the effect to an activation of p38 MAPK.

Confocal data showed that changes in hepatic cytoskeleton occurred in parenchymal cells. The localization of p38 MAPK activation, however, has yet to be determined. We, therefore, measured p38 MAPK activation in both isolated Kupffer cells as well as in isolated hepatocytes. This experiment revealed no activation of p38 MAPK upon ANP treatment in KC, but a significant activation in hepatocytes (data not shown). Since the extent of activation was lower than that observed in whole livers[8] and since ANP has been reported as a regulator of Kupffer cell functions[43], we hypothesized that activation might occur in whole livers as a paracrine effect of Kupffer cells on hepatocytes.

To verify this potential cell interaction, we investigated the ANP-mediated effect on p38 MAPK in KC-depleted livers. For this purpose, we first audited the Cl_2MBP-dependent KC depletion via immunohistological staining of the macrophages with ED2 antibody (Figure 4E). In fact, Cl_2MBP led to a depletion of the KCs compared to NaCl-treated livers (Figure 4F). Furthermore, LDH efflux into the perfusate was determined to exclude Cl_2MBP-induced liver damage. The measurement indicated no increase in LDH-activity and thus no liver toxicity of Cl_2MBP (data not shown).

Subsequently, ANP-induced p38 MAPK activity was measured by determination of the radioactive labeled kinase substrate MBP. Surprisingly, liver perfusion with ANP exhibited no differences in kinase activity in KC-depleted or non-depleted livers (Figure 4F). Due to this observation we suggest that ANP mediates p38 MAPK activation not via hepatocyte-KC interaction.

Changes of total Hsp27 content and translocation of the heat shock protein

As the small heat shock protein Hsp27 has been demonstrated to be an important downstream target of p38 MAPK, which plays a critical role in the regulation of F-actin polymerization in different systems, we focused on a possible influence of ischemia on the expression of Hsp27 in the liver. Liver homogenates were analyzed by Western blot analysis without prior fractionation in order to investigate the hepatic content of total Hsp27. At the end of ischemia, Hsp27 levels in untreated livers were significantly higher than after 30-min perfusion (Figure 5A). This increase persisted during 45 min reperfusion.

To prove whether changes in total Hsp27 content are accompanied by a translocation of the heat shock protein towards the cytoskeleton, as described in previous studies[31,32], we investigated its subcellular distribution in liver tissue after ischemia. Liver tissue was fractionated, Hsp27 content in the cytosolic and cytoskeletal fraction was determined by Western blot analysis, and band intensity was considered proportional to the content of Hsp27 in the respective fraction. We were able to demonstrate that ischemia caused a translocation of the heat shock protein towards the cytoskeleton, as the content of total Hsp27 in cytoskeletal fractions accelerated after 24 h ischemia (Figure 6A). At this time more than 80% of the heat shock protein was localized in the cytoskeletal fraction of untreated liver homogenates (Figures 6A and B). This translocation seemed to decline during reperfusion (Figure 6A).

Interestingly, Western blot analysis of the whole tissue samples revealed that after 24 h ischemia ANP-pretreated livers showed significantly lower levels of total Hsp27 compared to untreated samples (Figure 5B). Surprisingly, the translocation of the heat shock protein detected in control livers was completely missing, so that the content of total Hsp27 in cytoskeletal and cytosolic fraction after ischemia was very similar (Figure 6B). Thus, pretreatment with ANP apparently both attenuates Hsp27 protein rise induced by I/R and prevents the translocation of Hsp27 to the cytoskeleton after ischemia.

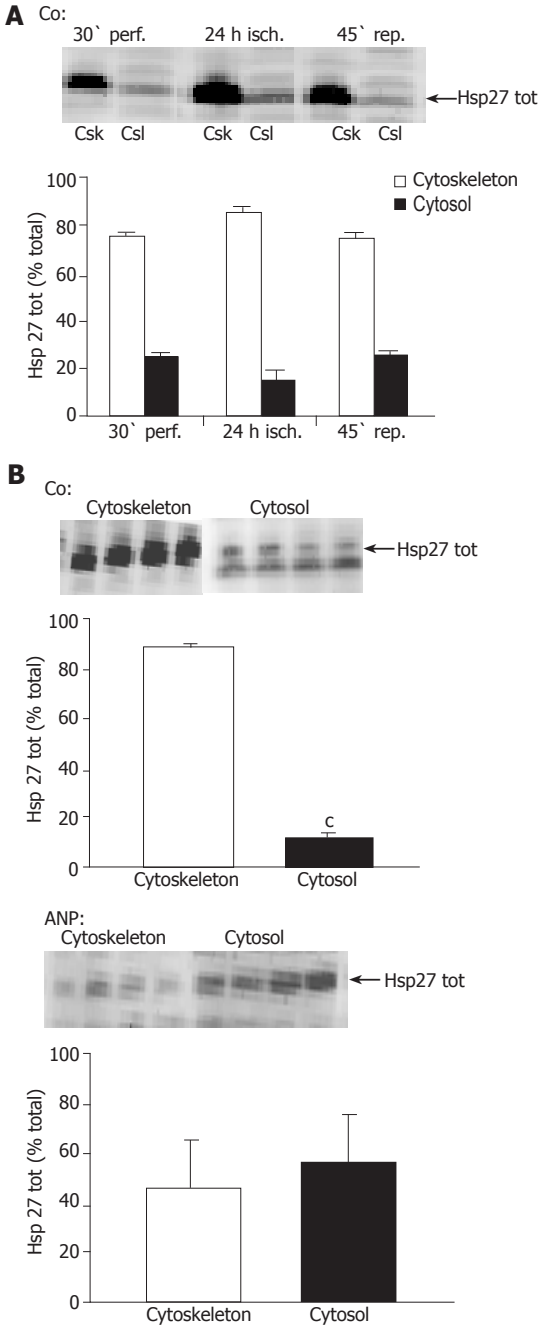

Figure 6 Influence of ischemia and ANP pretreatment on Hsp27 distribution. After perfusion for 30 min in the absence (**A** and **B**) or presence (**B**) of ANP, 24-h ischemia in cold UW solution, and reperfusion for 45 min, livers were snap-frozen, homogenized and fractionated as described in "Materials and methods". Samples were taken at indicated times and total Hsp27 in cytoskeletal (Csk) and cytosolic (Csl) fraction was detected via Western blot analysis using an anti-Hsp27 antibody. One representative Western blot is shown for each treatment group. (**A**) Effect of ischemia and reperfusion on the distribution of total Hsp27 in the liver. Quantification of total Hsp27 in the liver samples was verified via densitometric analysis of the corresponding bands, which was used to evaluate the ratio of Hsp27 in the cytoskeletal fraction (Csk) resp. cytosolic fraction (Csl) referring to total Hsp27 signal (cytoskeleton+cytosol) in the respective sample. Data are expressed as percent of total Hsp27 in cytoskeletal (F-actin) and cytosolic (G-actin) fraction as mean±SE of n=4 experiments in each treatment group. [a]P<0.05, *vs* Hsp27 content in cytoskeletal fraction in untreated livers after 30-min perfusion. (**B**) Distribution of total Hsp27 in untreated (control) and ANP-preconditioned livers after 24-h ischemia. Results are shown as percent of total Hsp27 in cytosolic and cytoskeletal fraction. Data are presented as mean±SE of n=4 experiments in each treatment group. [c]P<0.001 *vs* Hsp27 content in cytoskeletal fraction of untreated livers after 24-h ischemia. In ANP treated livers the differences in the values were not significant.

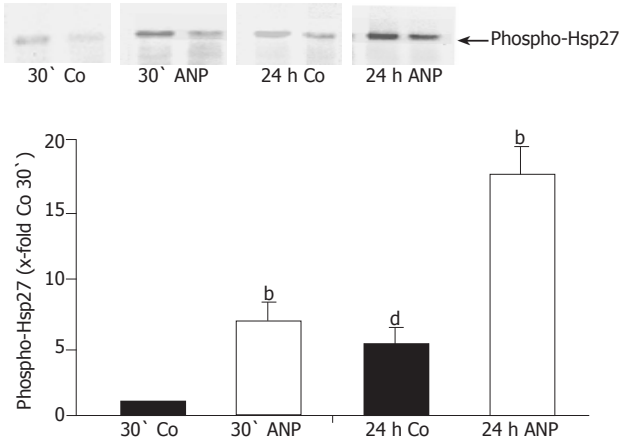

Figure 7 Influence of pretreatment with ANP on phosphorylation status of Hsp27. After perfusion for 10 min with KH-buffer livers were preconditioned with ANP for 20 min or left untreated, followed by 24-h ischemia (4 °C) according to the study protocol. Samples were taken after 30-min perfusion and 24-h ischemia. Livers were snap-frozen and homogenized, followed by immunoprecipitation with an anti-Hsp27 antibody and Western blot analysis using an anti-phospho-Hsp27 antibody. One representative Western blot is shown. Content of phospho-Hsp27 in the liver homogenates is presented as 10-fold control after 30-min perfusion, using the respective control as reference value and expressed as mean±SE of n = 4 experiments in each treatment group. Statistical analysis of ANP pretreated samples: [b]P<0.001 *vs* phospho-Hsp27 in respective control (after 30-min perfusion or 24-h ischemia). Statistical analysis of untreated control samples: [d]P<0.01 *vs* phospho-Hsp27 in control after 30-min perfusion.

ANP preconditioning causes increased phosphorylation of Hsp27

The influence of Hsp27 on actin polymerization depends on its phosphorylation status. Hence it was important to analyze the effect of ischemia and ANP preconditioning on the phosphorylation status of Hsp27. Detecting phospho-Hsp27 by Western blot analysis we obtained a significant increase of phosphorylation of the heat shock protein after ischemia in homogenates of untreated livers (Figure 7). In ANP-preconditioned samples phosphorylation seen after 30-min perfusion was already more intense than in untreated livers but increased even more after 24 h ischemia. Resuming these results, ANP seems to enhance the phosphorylation status of Hsp27 after 30-min perfusion and 24-h ischemia (Figure 7).

Inhibition of p38 MAPK prevents phosphorylation of Hsp27 in ANP pretreated livers

Pretreatment with ANP leads to an enhanced activation of p38 MAPK both in the isolated perfused liver as well as *in vivo* (Ref.[8] and Figure 1). We, therefore, investigated a possible connection between p38 MAPK activation and phosphorylation of its downstream target Hsp27 by using the specific p38 MAPK inhibitor SB203580. This treatment in fact completely abrogated the increase of Hsp27 phosphorylation induced by ANP (Figure 8). Pretreatment with SB203580 alone exerted no significant effect on phosphorylation of Hsp27 (Figure 8). Thus, activation of p38 MAPK is essential for the phosphorylation of the heat shock protein.

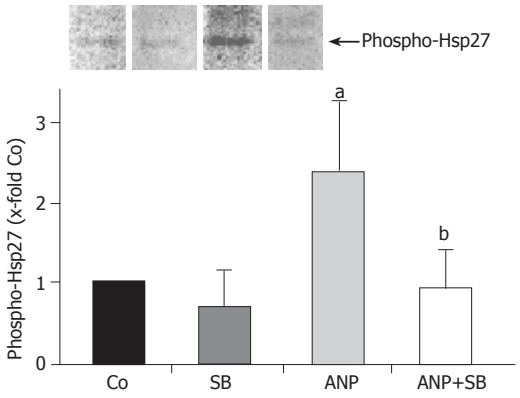

Figure 8 Effect of p38 MAPK inhibition on phosphorylation status of Hsp27. Livers were perfused for 30 min in the absence (Co) or presence of 200 nmol/L ANP, which was added 20 min prior to 24-h ischemia (4 °C). In different experiments, livers were perfused for 20 min with SB203580 (2 μmol/L) or with a combination of SB203580 (2 μmol/L) and ANP (200 nmol/L). After ischemia, livers were snap-frozen and homogenized. Total Hsp27 was precipitated as described and the content of phosphorylated Hsp27 was determined by Western blotting and detection with anti-phospho-Hsp27 primary antibody. One representative Western blot is shown. In the graph hepatic content of phospho-Hsp27 is expressed as percent of control samples after 24-h ischemia as mean±SE of n = 4 experiments in each treatment group. [a]P<0.05 *vs* control after 24-h ischemia, [b]P<0.01 *vs* phospho-Hsp27 content in ANP pretreated livers.

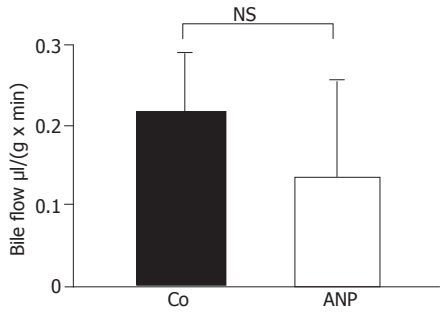

Figure 9 Effect of ANP preconditioning on bile flow. Bile was collected during perfusion and reperfusion and quantified volumetrically. Bile flow is expressed as μL per min and g liver tissue. Results show mean±SE of n = 4 experiments in each treatment group. The differences between untreated (Co) and ANP-preconditioned group were not significant.

ANP preconditioning shows no effect on bile flow

The cytoskeleton, more precisely F-actin, plays an important role in the maintenance of liver function[14,18,19]. In order to investigate a functional significance of an increase in F-actin after treatment with ANP, we studied the bile flow in transplanted organs of ANP- and NaCl-treated rats. Bile was collected as described during infusion and reperfusion. As shown in Figure 9, no significant differences between livers from NaCl-treated and from ANP-preconditioned rats could be detected. Thus, ANP-mediated increase of hepatic F-actin content does not cause an improvement of bile flow after ischemia.

DISCUSSION

This paper provides an important insight into the changes in hepatic cytoskeletal structures during I/R, signaling mechanisms in their modulation, and the interference of ANP preconditioning with these mechanisms.

Besides its vasodilating, hypotensive, and natriuretic activities[44], ANP has been described to protect against IRI *ex vivo* in the liver and *in vivo* in the heart[7,5,8,45], and to strongly activate p38 MAPK[8]. Interestingly, this activation has no influence on ANP's potential to protect from hepatic cell death, as previously shown by Kulhanek-Heinze *et al*[13]. In the present work, we therefore aimed to elucidate other potential functional consequences of ANP-induced p38 MAPK activity. In this context, we were able to demonstrate a clear coherence between ANP-mediated activation of p38 MAPK in the liver after ischemia and structural changes of the hepatocyte cytoskeleton. Interestingly, however, no functional correlation to improved bile flow could be established.

Cytoskeleton of hepatocytes during IR

Due to the evidence that activation of p38 MAPK leads to cytoskeletal changes in other systems[46] and the lack of knowledge about similar pathways in the liver, we investigated cytoskeletal changes during IR. We were able to show that hepatic content of total actin was affected neither by IR alone nor in combination with preconditioning of livers with ANP. Surprisingly, F-actin levels were not impaired by ischemia in control tissue after I/R. This result does not correspond to the findings of Cutrin *et al*[47]. who demonstrated structural changes of actin filaments after cold ischemia (120 min) and particularly after reperfusion (60-90 min) in transplanted human livers. Besides different species that were investigated, especially the much longer ischemic period employed in our model might account for these differences. In the kidney, Schwartz *et al*[30]. found a distinct increase of G-actin, paralleled by apical actin disruption after 30 min of warm ischemia. Again, the length, and also the temperature of ischemia cannot be compared to our experimental settings. Moreover, mechanisms in the kidney might differ from that in the livers. To the best of our knowledge, our data for the first time describe no significant cytoskeletal alterations in rat livers after prolonged hypothermic storage.

Cytoskeletal changes in ANP pretreated livers

Recently Gomes *et al*[28]. proved that IPC preserves rat kidneys from IRI by upregulation of genes coding for cytoskeletal proteins. The demonstrated increase in mRNA of these proteins, which have an F-actin-stabilizing function, is discussed to contribute to the tolerance of preconditioned tissue to ischemia. This effect, which was observed already after 30 min of preconditioning, goes along with our findings of an augmentation of F-actin in ANP-preconditioned livers confirming the influence of protective preconditioning (IPC or ANP pretreatment) on F-actin content of the affected tissue. Based on the findings that ANP preconditioning as well as IPC protects against IRI and due to the importance of F-actin for regulating cell morphology, intracellular processes, and bile secretion in liver cells, we hypothesized

that an augmentation of hepatic F-actin after ischemia might be a feature of the cytoprotective activities of ANP. Interestingly, however, although F-actin content increased in pretreated organs, we found no improvement of bile flow. Therefore, other functional parameters depending on the demonstrated F-actin formation in ANP pretreated livers need to be further investigated.

Involvement of p38 MAPK

As there are no data concerning a possible connection between p38 MAPK activation and cytoskeletal changes in liver tissue, we focused on the effect of p38 MAPK inhibition on hepatic F-actin content after ANP pretreatment. We applied the p38 MAPK inhibitor SB203580 at a concentration of 2 μmol/L to assure its specificity[48]. We demonstrated that perfusion with the inhibitor alone does not cause any cytoskeletal changes in liver tissue, but completely abolishes the ANP-induced effect of increased F-actin content in pretreated livers. Thus, we showed for the first time that ANP-mediated p38 MAPK activation leads to hepatic cytoskeletal changes by increasing the hepatocyte F-actin content in rat livers. To investigate a possible paracrine effect of KC on hepatocytes, p38 MAPK activity was determined in KC-depleted livers. Since KC depletion did not alter the activation of p38 MAPK, we suggest that an interaction between hepatocytes and KCs is not involved in ANP-mediated p38 MAPK activation.

Changes in total Hsp27

Analyzing total Hsp27 protein levels, we were able to show that the hepatic content of total Hsp27 increases during ischemia. It is a known fact that Hsp27 accumulates after cellular stress like hyperthermia[36], but also bacterial lipopolysaccharide (LPS) and Cyclosporine A enhance Hsp27 levels[49,50]. Thus, cellular stress can lead to an increase of Hsp27 content in the affected tissue elucidating the augmentation of the heat shock protein in the liver, which we observed during ischemia in untreated livers. This increased expression of the heat shock protein has been discussed to be a protective response, as it provides prevention from simulated IRI in canine myocytes[51]. Although our results of an augmentation of Hsp27 expression during ischemia, representing a situation of cellular stress, confirm these published data, our findings are surprising, as energy-dependent processes such as protein synthesis seem rather unlikely at 4 °C during a period of 24 h. Interestingly, however, such incidents have been observed before: Gerwig *et al*[6]. demonstrated an increase of caspase-3 precursor CPP 32 during an ischemic period and Wilhelm *et al*[52]. proved that cold ischemia induces upregulation of endothelin-1 in the kidney.

Detection of total Hsp27 in ANP-pretreated livers, however, yielded a rather astonishing result, as these organs showed markedly decreased levels of the heat shock protein. Interestingly, an increase of Hsp27 after cellular stress and decrease of the heat shock protein after treatment with a substance possessing protective properties has been described before for the kidney by Stacchiotti *et al*[50]. Hsp27 overexpression was seen after oxidative stress but disappeared after administration of an antioxidant[50]. This effect was ascribed to the cytoprotective effect of the antioxidant, which made additional protective Hsp27 response unnecessary. As ANP has been shown to protect against IRI[7,5], the effects seen in pretreated livers could be similar to the results of Stacchiotti *et al*. Thus, ANP might contribute to a protection of the liver tissue, so that higher levels of total Hsp27 as an additional protective response are no longer necessary.

It has to be noted that the functional consequences of changes in Hsp27 expression largely depend on its phosphorylation status and on its subcellular distribution, which will be subsequently discussed.

Translocation of total Hsp27

Sakamoto *et al*[34]. demonstrated that in rat hearts ischemia induces translocation of Hsp27 to the cytoskeleton and Aufricht *et al*[26]. showed the same effect in rat kidneys. Therefore, we investigated the subcellular distribution of the heat shock protein in isolated perfused rat livers after ischemia. In fact, significant augmentation of total Hsp27 in the cytoskeletal liver fraction could be detected after 24 h ischemia, suggesting a translocation of the heat shock protein towards the cytoskeleton. Pretreatment with ANP, however, completely abolished translocation of Hsp27 after ischemia. This observation enforces the assumption that ANP radically alters the response of liver cells to ischemia in isolated rat livers.

Phosphorylation status of Hsp27

As functional consequences of changes in Hsp27 protein expression and subcellular distribution largely depend on the phosphorylation status of the heat shock protein, we focused on this parameter next.

We proved that ischemic conditions cause phosphorylation of Hsp27 in isolated perfused rat liver, confirming the results of Huot *et al*[53]. who demonstrated an increased content of phosphorylated Hsp27 in vascular endothelial cells after oxidative stress. As the heat shock protein in its phosphorylated form is able to enhance F-actin formation, we expected a higher F-actin content in livers after ischemia. Interestingly, we could not detect an increase in hepatic F-actin in these organs. Since the augmentation of phosphorylation in untreated livers was not excessively high, the resulting effect on the cytoskeleton might not be sufficient to induce F-actin formation in liver tissue after ischemia.

In contrast, pretreatment with ANP resulted in a much stronger increase of the phosphorylation of the heat shock protein, which could be seen already after perfusion and obviously accelerated during ischemia (up to almost 20-fold of untreated controls). These findings correlate with data presented by Sanada *et al*[12]. showing changes in the phosphorylation status of Hsp27 after protective pretreatment of organs before ischemia *in vivo* in terms of an increased phosphorylation of the heat shock protein

after IPC. As Sanada *et al*. furthermore demonstrated coherence between Hsp27 phosphorylation and activation of p38 MAPK, we investigated this possible connection by perfusion of the livers with SB203580 in combination with ANP. An inhibition of p38 MAPK reduced the phosphorylation status of Hsp27 to basal levels. Thus, our results clearly prove the dependency of Hsp27-phosphorylation in the liver on prior activation of p38 MAPK.

Alterations of the cytoskeleton, particularly of F-actin content, are often discussed as a consequence of changes in the phosphorylation status of Hsp27 in other cell/organ systems[54]. We were able to confirm for the first time this correlation in the liver by showing an ANP-mediated increase of Hsp27 phosphorylation, which results in an accumulation of hepatic F-actin after ischemia. This effect is mediated via p38 MAPK, as an increase of F-actin in the liver after ANP preconditioning was abrogated by the p38 MAPK inhibitor SB203580.

Higher hepatic F-actin levels are thought to stabilize the cytoskeleton and to improve contractility resulting in improved bile flow after ischemia[15]. Our own data, however, do not show improved bile flow upon ANP pretreatment. Functional parameters other than improved bile flow are therefore hypothesized to be mediated by cytoskeletal changes, which need further investigation.

In summary, we were able to show for the first time the dependency of F-actin content in the liver on activation of p38 MAPK and that ANP preconditioning mediates changes in the cytoskeleton via an activation of p38 MAPK and phosphorylation of Hsp27 in the liver.

ACKNOWLEDGMENTS

We thank Dr. Stefan Zahler for his excellent support in confocal microscopy and processing of images, Kathrin Ladezki-Baehs for determination of p38 MAPK activity, and Dr. H. Meißner and Andrea Sendelhofert (both Institute of Pathology, University of Munich, Germany) for performing immunostaining. Clodronate was a gift of Roche Diagnostics GmbH, Mannheim, Germany.

Abstract

AIM: To investigate the therapeutic effects of DA-9601 on sodium taurocholate (TCA)-induced chronic reflux gastritis in SD rats.

METHODS: In this study, we have investigated the therapeutic effects of DA-9601 on chronic erosive and atrophic gastritis induced by 6 mo of TCA administration (5 mmol/L in drinking water) in SD rats.

RESULTS: Four weeks of DA-9601 administration (0.065%, 0.216% in rat chow), following the withdrawal of TCA treatment, resulted in a significant decrease in total length of erosions in rats in a dose-dependent manner. Furthermore, the indicators of atrophic gastritis, such as reduced mucosal thickness and reduction in the number of parietal cells, were improved by the administration of DA-9601 in a dose-related manner. DA-9601 also attenuated inflammatory cell infiltration and the proliferation of collagenous fiber in the gastric mucosa. The improvement in the reduction of the gastric mucus was observed in the rats receiving a high dose of DA-9601 (0.216%). The therapeutic effect of DA-9601 on experimental chronic erosive gastritis was superior to that of rebamipide (1.08% in rat chow). Biochemical analyses showed increased mucosal prostaglandin E_2 and reduced glutathione levels by DA-9601 treatment.

CONCLUSION: We suggest that DA-9601 is a promising agent for the treatment of chronic erosive and atrophic gastritis with an etiological factor of bile reflux. Increased mucosal prostaglandin E_2 and reduced glutathione by DA-9601 treatment may be therapeutic mechanisms for chronic erosive and atrophic gastritis.

Key words: DA-9601; Reflux gastritis; Erosive gastritis; Atrophic gastritis; Sodium taurocholate

INTRODUCTION

Reflux gastritis is a chronic disease in which the duodenal contents, particularly bile acid, are flown back into the stomach. It is associated with various symptoms, such as epigastric pain, dyspepsia, loss of appetite, nausea or vomiting[1,2]. While reflux gastritis is an occasional occurrence, it is primarily found in patients with pyloric insufficiency or delayed gastric emptying. It can also be found in patients who have previously undergone cholecystectomy or gastrectomy[3]. The reflux of intestinal fluid containing bile juice to the residual stomach has been considered as a primary pathogenic factor in this type of gastritis[4].

Although a number of treatments, such as improved gastric emptying, reduction of hydrochloric acid secretion and bile salt binding are available, a considerable portion of patients do not achieve the complete mucosal healing or suffer from sustained symptoms. Some studies have suggested the possible participation of bile acid in the development of erosive and atrophic gastritis[1,2]. Sodium taurocholate (TCA), a component of bile acid, induces erosive and atrophic gastritis, and is increasingly utilized in animal models for the study of bile reflux gastritis because of its simplicity and reproducibility[5]. Chronic exposure of the gastric mucosa of rats to TCA induces chronic erosive gastritis characterized by mucosal erosions, inflammatory cell infiltration, decreases in the number of parietal cells and mucosal thickness, and interstitial fibrosis. These characterizations are similar to those observed in human chronic erosive and reflux gastritis[6].

DA-9601 was developed for the treatment of gastritis[7-9]. DA-9601 was demonstrated to possess cytoprotective actions in various experimental models, including ethanol-induced gastric mucosal damage, and trinitrobenzene sulfonic acid (TNBS)-induced colitis[10]. Recently, DA-9601 has been reported to be effective in reflux esophagitis[11,12]. Although the mechanism via which DA-9601 exerts its mucosal protective effect has

not been fully elucidated, stimulation of the mucus, mucosal prostaglandins (PG), and reduced glutathione (GSH) are thought to play crucial roles in producing the gastric mucosal protective effect. The present study was undertaken to evaluate the effects of DA-9601 on TCA-induced chronic and atrophic gastritis in rats.

MATERIALS AND METHODS

Animals

Male Sprague-Dawley rats (weighing 210-230 g, aged 7 wk) were purchased from Charles River Japan (Kanagawa, Japan). Experimental procedures were performed in conformity with the Institutional Standard Procedure for Animal Care and Experiment (SOP-ANC) of Dong-A Pharmaceutical Company. The animals were kept under standard laboratory conditions and allowed free access to rodent chow (Cheil, Korea) and UV-sterilized tap water *ad libitum* in standard wire cage under a 12:12-h light-dark (LD) cycle. After a 5 d acclimation period, rats were treated according to the experimental protocols. Each group contained 20 rats, of them 10 rats were used for histological evaluation and the other rats were used for molecular assay.

Materials

DA-9601 was produced by Dong-A Pharmaceutical Co. Ltd. (Yongin, Korea). TCA was purchased from Sigma (St. Louis, USA), and rebamipide was obtained from Korea Otsuka (Seoul, Korea). DA-9601 (0.065% and 0.0216%) and rebamipide (1.08%) were mixed with rodent chow and then administered to the rats.

Sodium taurocholate (TCA)-induced gastritis and administration of DA-9601

Chronic gastritis was induced in rats by the administration of 5 mmol/L TCA dissolved in distilled water for 6 mo[13,14]. After discontinuation of TCA treatment, rats were allowed to drink plain tap water. To investigate the effects of the treatment, rats were divided into five groups, each consisting of 10 rats. In group 1, rats were fed a standard pellet meal and tap water for 7 mo. In group 2, rats were treated with TCA for 6 mo and then given the same standard pellet meals as used in the previous 6 mo and tap water alone for 1 mo. In groups 3, 4, and 5, rats were treated with TCA for 6 mo and then fed a standard pellet meal which was formulated to contain 0.065%, 0.216% of DA-9601 and 1.08% of rebamipide, respectively for 1 mo. Group 3 (0.065% of DA-9601), group 4 (0.216% of DA-9601), and group 5 (1.08% of rebamipide) all received tap water, following discontinuation of TCA treatment.

Histological evaluation

Rats were fasted for 24 h prior to the experiment and killed by decapitation under light ether anesthesia. The abdomen was opened and the stomach was then excised, opened along the greater curvature, laid flat so as not to cause any damage, and examined carefully for any evidence of macroscopic damage. The flattened stomach was divided into five parts, and each part was rolled in a Swiss manner for observation from the cardiac to the pyloric region. The Swiss-rolled tissue specimens were fixed in Bouin's solution for 6 h at 4 °C, and paraffin-embedded blocks were prepared by the routine method. After sectioning, each specimen was stained with H&E and Masson's trichrome and examined under a light microscope (BH-2, Olympus, Japan) by a pathologist who was blinded to the study. The length of mucosal surface injury was measured on the entire length of each tissue section in a visual field of 100-fold magnification. The total length of mucosal surface injury for the five parts per stomach was expressed as a measured length. The mucosal thickness was measured in a visual field of 100-fold magnification. The number of parietal cells per unit area (mm^2) in a visual field of 400-fold magnification was counted. The extents of inflammatory cell infiltration, the proliferation of collagenous fiber and stained gastric mucosa were evaluated in a visual field of 100-fold magnification.

Tissue malondialdehyde (MDA) and reduced glutathione (GSH)

The content of hepatic MDA was determined using the method described by Ohkawa *et al*[15]. In brief, after mincing and trimming, the pieces of liver were homogenized with four volumes of an ice-cold 0.1 mol/L potassium phosphate buffer (pH 7.4) solution. Then, the reaction mixture containing 0.2 mL of the homogenate, 81 g/L sodium dodecyl sulfate, 200 g/L acetate buffer (pH 3.5), and 8 g/L thiobarbituric acid (TBA) solution was mixed well for 3 min and incubated at 95 °C for 60 min. TBA reactive substance, MDA, was extracted with a butanol-pyrimidine mixture solution. The absorbance measured at 532 nm was expressed as nmol/mg protein. The content of hepatic glutathione (GSH) was determined by the spectrophotometric method of Griffith and expressed as nmol/mg protein[16]. Protein content was determined by the method described by Lowry *et al*[17]. using BSA as the standard.

Level of prostaglandin E_2

Using a commercially available EIA kits (Amersham, UK), gastric mucosal PGE_2 levels were measured. Immediately after biopsy and gross observation, mucosal specimens were frozen in liquid nitrogen and stored at -70 °C until the measurement of PGE_2. Tissue specimens were processed for the assay according to the method described previously by Lipscomb and Rees[18]. The final PGE_2 level was expressed in pg/mg of wet biopsy weight.

Statistical analysis

All data were expressed as mean±SE. Scheffe's *t*-test was used for comparing body weight, tissue MDA, tissue GSH, and endoscopic scores between the control group and experimental groups. Rank transformation and Kruskal-Wallis test were performed to determine the inter-group difference of non-parametric data, and Bonferroni's test was used for multiple pair-wise comparison. A $P<0.05$ was considered statistically significant.

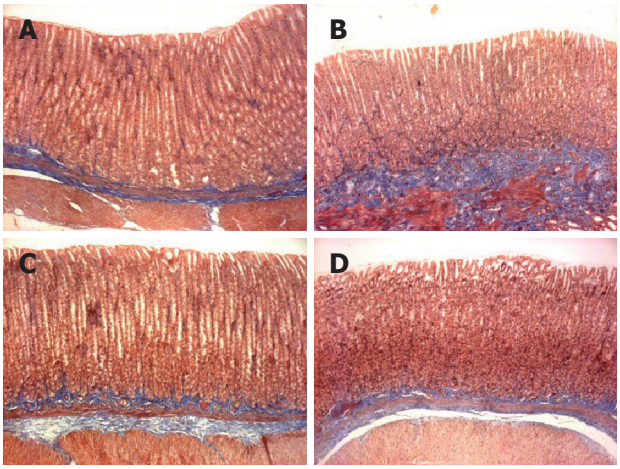

Figure 1 Microscopic appearance of gastric mucosa showing the effect of DA-9601 and rebamipide on sodium taurocholate (TCA)-induced erosive and atrophic gastritis in rats (×100). Rats were administered with 5 mmol/L TCA for 6 mo (given along with drinking water). **A:** Normal; **B:** control; **C:** 0.216% DA-9601; **D:** 1.08% rebamipide.

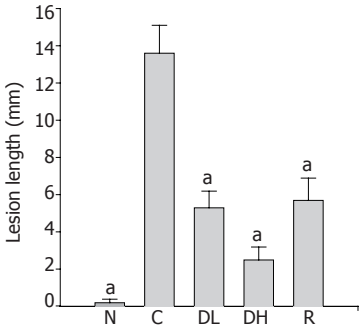

Figure 2 Inhibitory effects of DA-9601 and rebamipide on the length of mucosal lesion of TCA-induced erosive and atrophic gastritis in rats. DA-9601 (0.065% and 0.0.216%) and rebamipide (1.08%) were mixed with rodent chow and then administered to the rats. N: Normal; C: control; DL: 0.065% DA-9601; DH: 0.216% DA-9601; R: 1.08% rebamipide. Data are expressed as mean±SE. $^{a}P<0.05$ *vs* controls.

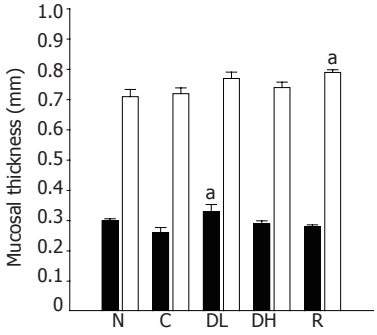

Figure 3 Effects of DA-9601 and rebamipide on the mucosal thickness of TCA-induced erosive and atrophic gastritis in rats. N: Normal; C: control; DL: 0.065% DA-9601; DH: 0.216% DA-9601; R: 1.08% rebamipide. Data are expressed as mean±SE. $^{a}P<0.05$ *vs* controls.

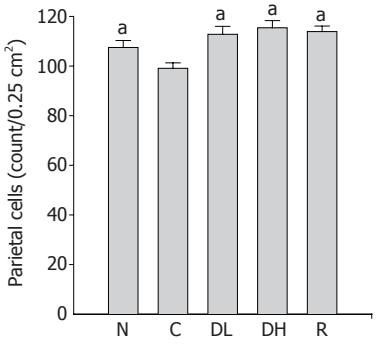

Figure 4 Effects of DA-9601 and rebamipide on the number of parietal cells in TCA-induced erosive and atrophic gastritis in rats. N: Normal; C: control; DL: 0.065% DA-9601; DH: 0.216% DA-9601; R: 1.08% rebamipide. Data are expressed as mean±SE. $^{a}P<0.05$ *vs* controls.

RESULTS

Inhibitory effect of DA-9601 on chronic gastritis

Macroscopic lesions were not observed on the surface of mucosa in any of the groups, while marked changes were observed microscopically in the gastric mucosa of the rats treated with TCA for 6 mo (Figure 1). A significant increase in the length of erosion was observed in the control animals as compared to normal level (Figure 2). However, the microscopic appearance of the gastric mucosa taken from group 3 or 4, treated with 0.065% and 0.216% DA-9601, respectively, showed a significant decrease in the length of erosion. DA-9601 significantly decreased the length of erosion in a dose-dependent manner. Although treatment with rebamipide also caused a significant decrease of erosive lesion, this protective effect by rebamipide was not as prominent as observed in group 4 (treated with 0.216% DA-9601). To explore the mechanism underlying DA-9601-induced protection against gastric lesions, the thickness of the gastric mucus layer was measured (Figure 3). We observed that 0.065% DA-9601 ameliorated the TCA-induced reduction of mucosal thickness in the antrum, while 1.08% rebamipide significantly thickened the mucus layer in the fundus.

Effect of DA-9601 on parietal cells, infiltration of inflammatory cells and intestinal fibrosis

The number of parietal cells in the controls (99.1±2.2 cells/0.25 cm^2) was significantly lower than that of the normal level (107.5±2.8 cells/0.25 cm^2). Furthermore, 0.065% DA-9601 (112.8±3.2 cells/0.25 cm^2), 0.216% DA-9601 (115.4±2.9 cm^2) and 1.08% rebamipide (113.9 ±2.9 cm^2) significantly increased the number of parietal cells in TCA-induced chronic gastritis as compared to the control (Figure 4).

The number of infiltrating inflammatory cells in the gastric mucosa of animals in the control group (4.7±0.86) was compared to the normal level (0.9±0.11). We observed significantly decreased number of infiltrating inflammatory cells in the gastric mucosa of the animals treated with 0.065% DA-9601 (1.4±0.27), 0.216% DA-9601 (2.0± 0.35) and 1.08% rebamipide (3.0±0.37) as compared to the controls ($P<0.05$) (Figure 5).

In addition, 0.065% DA-9601 (0.4±0.1) significantly

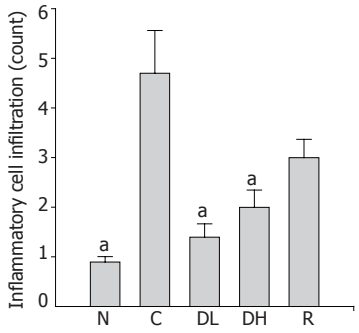

Figure 5 Effects of DA-9601 and rebamipide on the infiltration of inflammatory cells induced by TCA. N: Normal; C: control; DL: 0.065% DA-9601; DH: 0.216% DA-9601; R: 1.08% rebamipide. Data are expressed as mean±SE. [a]*P*<0.05 *vs* controls.

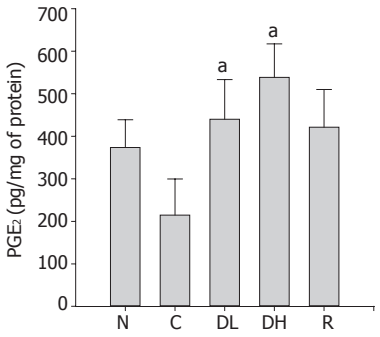

Figure 8 Effects of DA-9601 and rebamipide on PGE_2 induced by TCA in rat gastric mucosa. N: normal; C: control; DL: 0.065% DA-9601; DH: 0.216% DA-9601; R: 1.08% rebamipide. Data are expressed as mean±SE. [a]*P*<0.05 *vs* controls.

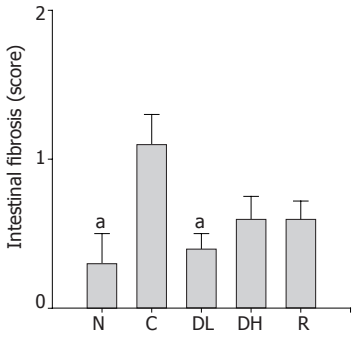

Figure 6 Effects of DA-9601 and rebamipide on the proliferation of collagenous fiber induced by TCA in rats. N: Normal; C: control; DL: 0.065% DA-9601; DH: 0.216% DA-9601; R: 1.08% rebamipide. Data are expressed as mean±SE. [a]*P*<0.05 *vs* controls.

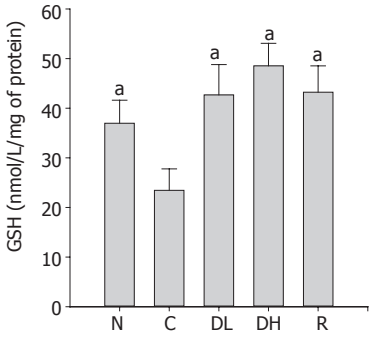

Figure 9 Effects of DA-9601 and rebamipide on glutathione (GSH) induced by TCA in rat gastric mucosa. N: Normal; C: control; DL: 0.065% DA-9601; DH: 0.216% DA-9601; R: 1.08% rebamipide. Data are expressed as mean±SE. [a]*P*<0.05 *vs* controls.

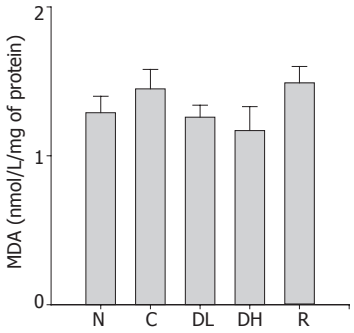

Figure 7 Effects of DA-9601 and rebamipide on malondialdehyde (MDA) induced by TCA in rat gastric mucosa. N: Normal; C: control; DL: 0.065% DA-9601; DH: 0.216% DA-9601; R: 1.08% rebamipide. Data are expressed as mean±SE. [a]*P*<0.05 *vs* controls.

reduced TCA-induced intestinal fibrosis (Figure 6). We found an obvious increase in the score of intestinal fibrosis in controls (1.1±0.2) as compared to normal level (0.3±0.2). On contrary, 0.216% DA-9601 (0.6±0.1) and 1.08% rebamipide (0.6±0.1) showed a decreasing tendency in the score of intestinal fibrosis (Figure 6).

Effects of DA-9601 on gastric mucosal MDA, PGE_2, and GSH

Lipid peroxidation is a well-established mechanism of cellular injury, and the accumulation of MDA is used as an indicator of oxidative stress in cells and tissues. The mean level of MDA in animals treated with DA-9601 and rebamipide was not significantly different from that of controls (Figure 7).

PGE_2 plays an important role in the regulation of gastric mucus secretion. As shown in Figure 8, we detected a significant decrease in PGE_2 contents in the controls (215.2±84.4 pg/mg of protein) as compared to the normal level (374.0±64.9 pg/mg of protein). The treatment with 0.065% DA-9601 (440.3±93.0 pg/mg of protein) and 0.216% DA-9601 (538.7±78.5 pg/mg of protein) could significantly increase the PGE_2 contents in a dose-dependent manner, and 1.08% rebamipide (421.6±88.4 pg/mg of protein) could significantly ameliorate the PGE_2 production (Figure 8).

As shown in Figure 9, we found a significant decrease in the GSH contents in the controls (23.5±4.3 nmol/mg of protein) as compared to normal level (37.0±4.6 nmol/mg of protein). We observed that the treatment with 0.065% DA-9601 (42.7±6.1 nmol/mg of protein) and 0.216% DA-9601 (48.5±4.5 nmol/mg of protein) significantly increased the GSH contents in a dose-dependent manner, and 1.08% rebamipide (43.2±5.3 nmol/mg of protein) significantly ameliorated the GSH production.

DISCUSSION

In the present study, 6 mo of DA-9601 administration resulted in a significant improvement of the experimental chronic erosive and atrophic gastritis induced by 6 mo of TCA treatment. The therapeutic effects of DA-9601 on experimental gastritis were superior to those of rebamipide observed in clinical practice for the treatment of gastritis. Six months of oral administration of TCA solution as drinking water induced the mucosal surface erosions and gastric mucosal thinning, and decreased parietal cell numbers, inflammatory cell infiltration in the lamina propria of the mucosa and mucosal fibrosis in rats. These characterizations were similar to those observed in chronic gastritis caused by bile reflux in human beings[19,20]. DA-9601 ameliorated the reduction in mucosal thickness and the decrease in the number of parietal cells induced by TCA treatment. Furthermore, DA-9601 increased the stimulation of PGE_2 and GSH in the gastric mucosa. These results suggest that DA-9601 promotes the healing of TCA-induced chronic erosive and atrophic gastritis with an etiological factor of the bile reflux.

The TCA-induced infiltration of inflammatory cells in the gastric mucosa was ameliorated by the administration of DA-9601. Tissue damage causes the infiltration of inflammatory cells that have migrated from the capillary vessels. Therefore, this amelioration of inflammatory cell infiltration by DA-9601 may be due to a decreased inflammatory response against damaging tissues through the healing of gastric surface injury. The interstitial space in the gastric mucosa may play an important role as a regulative factor in local microcirculation, and changes in this area may influence the gastric gland, particularly the glandular portion and the cell proliferative zone. Mizumachi *et al*[21]. reported that interstitial fibrosis was associated with decreased gastric mucosal blood flow. In this study, DA-9601 markedly ameliorated the TCA-induced proliferation of collagenous fiber. This change appears to be associated with the improvements in microcirculation via DA-9601-induced increased PGE_2 level.

In fact, reactive oxygen species has been suggested to be involved in the pathogenesis of gastric lesion caused by indomethacin[22,23]. In addition, previous studies have reported that the levels of scavengers and mucosal SOD activity were decreased and the lipid peroxide concentration was increased in the gastric mucosa before the sign of tissue injury appeared[24,25]. Some drugs that are capable of scavenging or inhibiting the generation of ROS have been introduced as effective agents to prevent the gastric mucosal injuries induced by various agents[26,27]. Recently, DA-9601 has been demonstrated to inhibit xanthine oxidase, a major source of ROS generation[28].

One of the causes of TCA-induced gastric lesions is that taurocholate selectively inhibits the synthesis of the vasodilator, PGI_2, an endogenous gastroprotector[29]. The suppression of PGI_2 production decreases the PGI_2/TXA_2 ratio, suggesting that the action of TXA_2 overcomes the action of PGI_2. This decreased ratio may reflect the pathogenesis of gastric ischemia due to vasoconstriction[30,31].

The mechanism by which DA-9601 produces such a therapeutic effect is possibly through its actions that elevate mucosal concentrations of PGE_2, increase the gastric mucosal blood flow, and stimulate re-epithelization and the formation of glandular tissue. PGE_2 has been reported to exert its cytoprotective effect on gastric mucosal epithelial cells by increasing gastric mucus secretion and stimulating cell proliferation in pyloric glands in rats[32]. It has been suggested that DA-9601 promotes the compensatory elevation in proliferative activity of generative cells through the possible increase in PG, which would be available to repair the gastric mucosa in erosive and atrophic gastritis. Gastric mucosal blood flow is essential for the homeostasis of the mucosal structure and function[33]. Whittle *et al*[30]. reported that the administration of (15s)-15-methyl PGE_2 decreased acid back diffusion, increased mucosal blood flow, and significantly reduced the lesions formed by topical TCA plus HCl and indomethacin administration. Kishimoto *et al*[5]. reported that mucosal blood flow was decreased by the administration of TCA. DA-9601 may improve the decreased mucosal blood flow induced by TCA administration although the mucosal blood flow was not measured in this study.

Another possible mechanism is that DA-9601, an antioxidant, neutralizes reactive free oxygen metabolites in the mucosa and attenuates the inflammation. Our results demonstrated that gastric mucosal GSH concentrations were depleted in TCA-induced chronic erosive and atrophic gastritis. The depletion of gastric mucosal GSH in rats with chronic gastritis is likely to render the gastric mucosa more susceptible to oxidative damages and the injurious effects of reactive oxygen species. GSH acts as a scavenger of free radicals and toxic substances ingested with foods or produced directly in the gastrointestinal tract[34].

Reflux gastritis, which occasionally occurs after gastrectomy, is associated with various symptoms, such as abdominal pain, nausea, emesis, and loss of appetite. However, the pathogenic mechanism responsible for the development of gastritis due to bile regurgitation in the stomach has not been fully elucidated. Treating patients exhibiting alkaline reflux symptoms with bile acid binding agents, such as cholestyramine or sucralfate, has been reported to be successful in some cases, but not uniformly successful. It is possible that the presence of lysolecithin, pancreatic enzymes, and cholic acids is responsible for causing erosive changes in the stomach wall[11]. A study has suggested that these factors destroy the mucosal barrier and increase its permeability to hydrogen ions, which can initiate inflammation through a mechanism similar to the one attributed to the erosive effects of salicylates[12].

In conclusion, DA-9601 is a promising agent for the treatment of chronic erosive and atrophic gastritis with an etiological factor of bile reflux. Increased mucosal PGE_2 and reduced glutathione levels by DA-9601 may be its therapeutic mechanisms for chronic erosive and atrophic gastritis.

Abstract

AIM: To test whether antioxidant treatment could prevent the progression of Barrett's esophagus to adenocarcinoma.

METHODS: In a rat model of gastroduodenoesophageal reflux by esophagojejunal anastomosis with gastric preservation, groups of 6-10 rats were randomized to receive treatment with superoxide dismutase (SOD) or vehicle and followed up for 4 mo. Rat's esophagus was assessed by histological analysis, superoxide anion and peroxinitrite generation, SOD levels and DNA oxidative damage.

RESULTS: All rats undergoing esophagojejunostomy developed extensive esophageal mucosal ulceration and inflammation by mo 4. The process was associated with a progressive presence of intestinal metaplasia beyond the anastomotic area (9% 1st mo and 50% 4th mo) (94% at the anastomotic level) and adenocarcinoma (11% 1st mo and 60% 4th mo). These changes were associated with superoxide anion and peroxinitrite mucosal generation, an early and significant increase of DNA oxidative damage and a significant decrease in SOD levels (P<0.05). Exogenous administration of SOD decreased mucosal superoxide levels, increased mucosal SOD levels and reduced the risk of developing intestinal metaplasia beyond the anastomotic area (odds ratio = 0.326; 95%CI: 0.108-0.981; P = 0.046), and esophageal adenocarcinoma (odds ratio = 0.243; 95%CI: 0.073-0.804; P = 0.021).

CONCLUSION: Superoxide dismutase prevents the progression of esophagitis to Barrett's esophagus and adenocarcinoma in this rat model of gastrointestinal reflux, supporting a role of antioxidants in the chemoprevention of esophageal adenocarcinoma.

Key words: Barrett's esophagus; Esophageal adenocarcinoma; Free radicals; Oxidative damage; Superoxide dismutase

INTRODUCTION

The incidence of esophageal adenocarcinoma (EAC) has increased dramatically in Western countries in recent years[1]. Today, the existence of a cause-effect relationship between gastroesophageal reflux disease (GERD) and EAC is firmly accepted. In order to design preventive strategies that might stop/delay the malignant transformation of the esophageal epithelium under the impact of chronic gastroesophageal reflux, it is important to define the mechanisms and mediators of the inflammatory process driving the esophageal mucosa from chronic inflammation to adenocarcinoma. Recent studies have implicated reactive oxygen species (ROS) in the pathogenesis of GERD, Barrett's esophagus (BE) and esophageal cancer. Increased levels of ROS have been found in esophageal tissues of patients with esophagitis and Barrett's epithelium[2]. Furthermore, a positive correlation between the severity of esophagitis and ROS levels has been demonstrated, with the highest levels in patients with BE. At the same time, the free-radical scavenger superoxide dismutase (SOD) level is decreased in esophageal tissue of patients with gastroesophageal reflux, being lowest in patients with severe esophagitis and BE[3,4]. Studies performed in animal models of both acute and chronic reflux esophagitis have

suggested a pathogenic role of ROS, especially superoxide anion, in the development of esophageal mucosal damage. Moreover, administration of SOD has been shown to either prevent or reduce mucosal damage[5-8]. However, it is not known whether SOD is effective in preventing the development of BE and EAC. In order to answer this question, we used an experimental model of gastroenteroesophageal reflux in rats that could lead to the development of EAC, to determine the temporal sequence of development of intestinal metaplasia (IM) and EAC and to assess the involvement of superoxide anion as a mechanism of damage. Finally, we tested whether administration of SOD was able to prevent the development of BE and/or EAC.

MATERIALS AND METHODS

Rat experimental model

All animal studies were carried out in the Service of Biomedicine and Biomaterials of the University of Zaragoza, officially inscribed as a "Research Establishment" for the adequate husbandry and use of all research animals under the "Good Laboratory Practices" norms and Spanish laws (RD 223/1988). The Ethics Committee approved all the procedures. Wistar rats weighing 250-300 g were studied. Rats underwent esophagojejunostomy with gastric preservation, allowing the gastroduodenal content to flow back into the esophagus. In a clean operating field, a midline abdominal incision was made and the liver was retracted to expose the stomach and intra-abdominal portion of the esophagus. Bilateral vagus nerves were preserved and the abdominal esophagus was transected proximal to the cardia and the distal cut end was closed with sutures. The esophagus was anastomosed end-to-side to an enterostomy performed in a jejunum loop distal to Treitz's ligament with 12 interrupted stitches of all layers using 7/0 silk sutures. Sham operation consisted of laparotomy and blunt manipulation of abdominal contents. After the operation, rats were housed in hanging cages to prevent bed ingestion and fasted until d 3 with free access to drinking water. Buprenorphine was used as an analgesic.

Study design and drug administration

For the first purpose of the study, groups of animals (6-10 rats/group) were killed at 1 mo intervals up to 8 mo after esophagojejunostomy or sham operation. Since a high incidence of EAC and IM was found 4 mo after surgery, this follow-up was considered for the second part of the study, where the effect of SOD administration on the development of BE and EAC was tested. SOD (Orgotein-Ontosein®, Tedec-Zambaletti, Madrid, Spain) was administered at a dose of 3 mg/kg (10 000 U/kg) every 3 d subcutaneously. The SOD used was a liver bovine metalloprotein which has been shown to be highly effective in the treatment of secondary effects of radiotherapy on human head and neck tumors[9] and in reducing acid and pepsin-induced esophagitis in rabbits[5,6]. Previously, we have confirmed that the dose of SOD administered to rats increased blood levels of SOD activity for several hours, which returned to basal levels approximately 24 h after SOD administration. However, given the duration of the study and the need for long-term parenteral treatment, we decided to administer SOD to rats once in every 72 h, mimicking the dosage used in patients receiving radiotherapy. Groups of rats (6-10 rats/group) with esophagojejunostomy receiving SOD treatment were killed at 1 mo intervals. Control rats with esophagojejunostomy were administered vehicle following the same pattern as that of SOD treatment.

Rats were killed by CO_2 inhalation. The esophagus was removed and opened longitudinally. More than half of the esophageal specimen was prepared for pathological study. The rest of the esophagus was cut into two slices: the lower and the upper half of the esophagus. For superoxide anion measurements, samples were processed immediately. For the rest of the determinations, samples were frozen immediately in liquid nitrogen and then kept at -70 °C until biochemical studies were performed.

Macroscopic and microscopic evaluation

The tissues were examined by two independent pathologists who were unaware of the experimental conditions. Changes of the squamous epithelium were classified into the following four categories. *Reactive changes*: characterized by the presence of basal cell hyperplasia, papillomatosis and hyperqueratosis with areas of inflammation and ulceration; *Barrett's esophagus*: squamous epithelium was replaced with columnar-lined epithelium comprising occasional and incomplete differentiation of goblet cells, the length must be superior to 3 mm from the anastomosis site or intercalated with squamous epithelium and metaplasia of cells beyond the anastomosis or containing areas of dysplasia; *Dysplasia*: characterized by nuclear atypia, partial loss of mucosecretory function and cell polarity, and an increase in mitotic figures; *Adenocarcinoma*: glandular structures of epithelial cells with architectural dysplasia and cytologic atypia with stromal invasion and deep infiltration. In general, the two pathologists showed a high concordance (kappa coefficient >0.8). However, in case of disagreement, a third pathologist was required to resolve the diagnosis.

Measurement of superoxide anion, peroxynitrite, and SOD activity

The presence of superoxide anion was determined by chemiluminescence using lucigenin (*N*-methyl-acridinium nitrate) as previously described[10]. Results were expressed as counts per minute per milligram of fresh tissue (CPM/mg). Total SOD activity was measured according to a previously described method[10] based on the inhibition of nitro blue tetrazolium (NBT) mediated by superoxide anion. Results were expressed as units of SOD per gram of fresh tissue (U/g). The presence of peroxynitrites was indirectly measured by nitrotyrosine immunohistochemistry using a monoclonal anti-

nitrotyrosine antibody (Chemicon, Temecula, CA, USA). Slides were examined microscopically and scored for relative staining intensity of nitrotyrosine: 0 (negative), 1+ (weak), 2+ (medium), 3+ (strong).

Nitrotyrosine immunoprecipitation

In order to purify the proteins containing tyrosine-nitrated residues, immunoprecipitation was performed using a monoclonal anti-nitrotyrosine antibody as previously described[11,12]. For this purpose, total protein was extracted from rat's esophagus and protein concentrations were measured by Bradford assay (Bio-Rad, Hercules, CA, USA). Extracted proteins (500 μg) were precleared (3 h at room temperature) with 25 μL of protein G-agarose (Roche Applied Science, Mannheim, Germany). After a brief centrifugation, the supernatants were collected and incubated (2 h at room temperature) with 20 μL of anti-nitrotyrosine agarose conjugate (Alexis Biochemicals, Lausen, Switzerland). After the incubation, beads were collected, resuspended in 25 μL of 1× Laemmli sample buffer and boiled for 5 min. Then, the supernatants were immediately subjected to electrophoresis in 12% SDS polyacrylamide gels.

Western blot analysis

For analysis of Cu, Zn-SOD and Mn-SOD expression and detection of nitrated Mn-SOD, Western blot analysis was performed in both total protein extracts (60 μg of total protein) and immunoprecipitated fractions, respectively. After separation by SDS/PAGE, proteins were transferred electrophoretically to PDVF membranes, which were blocked (4 °C, overnight) with 5% non-fat dry milk in 50 mmol/L Tris-HCl, pH 7.4/150 mmol/L NaCl/0.05% Tween 20 (TBST). For detection of Mn-SOD, blots were incubated (1 h, room temperature) with a rabbit polyclonal anti-MnSOD antibody (1:1 000 dilution, Upstate, Charlottesville, VA, USA). For the detection of Cu, Zn-SOD, blots were incubated (1 h, room temperature) with a rabbit polyclonal anti-Cu, Zn-SOD antibody (1:1 000 dilution, Santa Cruz Biotechnology Inc., Santa Cruz, CA, USA). After incubation with primary antibodies, membranes were probed (1 h, room temperature) with 1:3 000 dilution of peroxidase-conjugated secondary antibody in TBS with 0.1% of blocking agent. Immunoreactive proteins were detected using enhanced chemiluminescence (ECL Western blotting analysis system, Amersham Biosciences, Buckinghamshire, UK).

Measurement of 8-hydroxy-2'-deoxyguanosine levels in esophagus

Genomic DNA was extracted from the lower half of the esophagus and digested with DNAse I, alkaline phosphatase, nuclease P1 and phosphodiesterases I and II (Roche Molecular Bio-Chemicals, Indianapolis, IN, USA), in order to obtain free nucleosides according to previously described methods[13]. The nucleoside samples were used for the determination of the amount of 8-hydroxy-2' -deoxyguanosine, which was measured using a competitive enzyme-linked immunosorbent assay kit (Bioxytech 8-OHdG-EIA kit, OXIS Health Products, Portland, USA). Thirty micrograms of digested DNA was added to each well. Each sample was performed in triplicate. Results were expressed as nanograms of 8-OHdG per milligram of total DNA.

Statistical analysis

Data management and statistical analysis were performed using the SPSS software v.10.1. Results from biochemical assays were expressed as mean±SE. Data were compared between groups by non-parametric tests (Kruskall-Wallis and Mann-Whitney). $P<0.05$ was considered statistically significant.

Covariance analysis was used for the analysis of the drug on the quantitative variables, introducing the number of months as covariant. Multiple comparisons were corrected by means of the Bonferroni method. Logistic models were adjusted for the qualitative variables, evaluating in turn the effect of the drug and the months passed.

RESULTS

Pathological findings

Macroscopically, all rats with esophagojejunostomy showed dilatation and thickening of middle and lower esophagus. The inner surface of the esophagus showed ulcerations, which were larger the closer they were to the distal esophagus. Macroscopically, no esophageal tumors were identified. Microscopically, in most animals, the upper and the middle parts of the esophagus showed squamous hyperplasia. Squamous epithelium also showed extensive defects, in the form of erosions in the upper third or ulcers in the proximity of the anastomosis. In all rats with esophagojejunostomy, columnar-lined metaplasia was found in the area of anastomosis, in continuity with the jejunal epithelium (Figures 1A and 1B) after 5 mo. A second type of metaplasia was found far above the anastomosis in some animals. This metaplasia consists of isolated or grouped goblet cells, which formed authentic mucus glands in some cases (Figures 1C and 1D). In all cases an important inflammatory infiltrate was present. Neoplastic transformation of the epithelium was always found near the anastomosis, surrounded by columnar epithelium. Histologically, all tumors were adenocarcinomas, most of them mucinous (70.37%) (Figure 1E).

Incidence of lesions over time

Only rats that were killed in the protocol time were included in the study of the sequence esophagitis-BE-dysplasia-adenocarcinoma. The outcome of the rats included in different groups is shown in Table 1. Sham-operated rats did not show any esophageal change after 8 mo of follow-up. Inflammation, basal cell hyperplasia, hyperqueratosis and ulceration were present in mo 1. Columnar metaplasia was present in the first month,

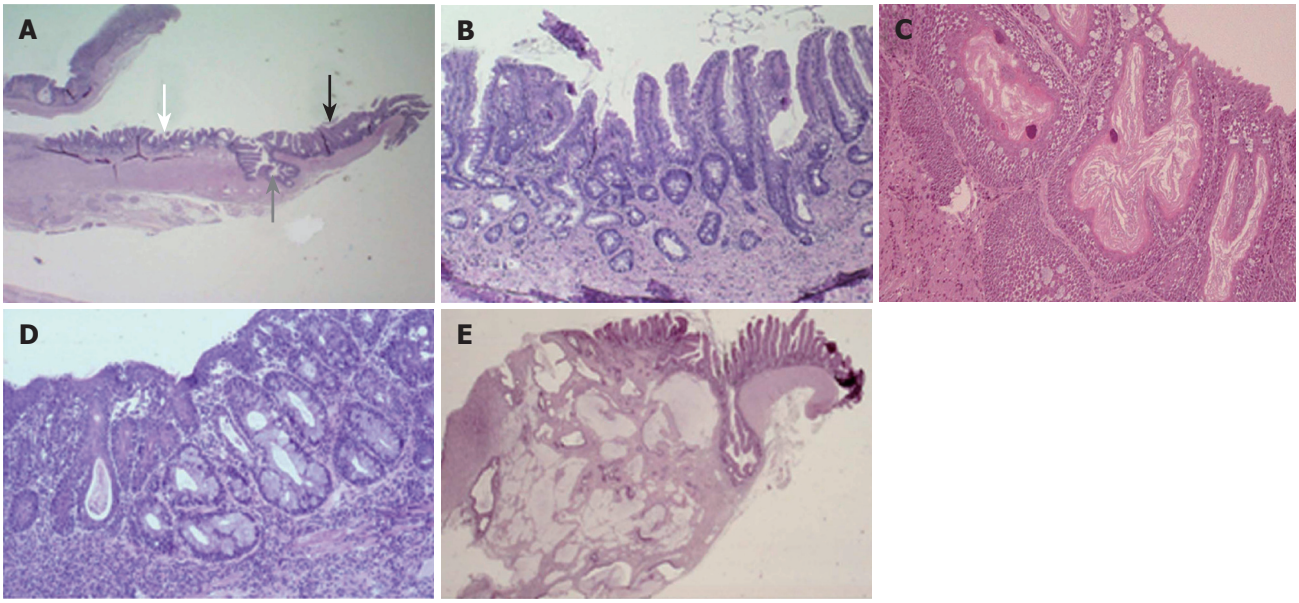

Figure 1 Pathological findings in the esophagus of rats with esophagojejunostomy. (**A**) Development of intestinal metaplasia in the area of anastomosis contiguous to the jejunal epithelium. Characteristic jejunal epithelial villi (white arrow) contrast with blunt villi of metaplastic areas (black arrow). The gray arrow shows the site of anastomosis (H&E staining, ×12.5); (**B**) A higher magnification of (**A**) shows the metaplastic epithelium in detail, with incomplete development of villi and crypts lined by absorptive cells with brush borders and goblet cells (H&E, ×100); (**C**) Intestinal metaplasia developed distant from the anastomosis, consisting of isolated goblet cells immersed within squamous epithelium (H&E, ×100); (**D**) Formation of mucus glands in squamous epithelium; (**E**) Development of mucinous adenocarcinoma from metaplasia in continuity, infiltrating the esophageal wall in depth. The site of anastomosis is shown by the gray arrow (H&E, ×12.5).

reaching an incidence of 100% in mo 2. The length of metaplasia increased progressively over time, with an average length of 1.61 mm in the first month to 6.75 mm in mo 8. Metaplasia also showed a progressive differentiation over time. Metaplasia beyond the anastomosis was identified in the first month, but increased substantially after 2 mo. Dysplasia and adenocarcinoma rates increased dramatically in the second month.

Superoxide anion generation, SOD activity and nitrotyrosine immunohistochemistry

An early and significant increase in superoxide anion generation and a significant decrease in SOD activity were evident in the second month after esophagojejunostomy (Figures 2A and 3A). When grouping the animals according to the highest lesion found in the sequence BE-dysplasia-adenocarcinoma, all groups showed higher superoxide anion levels than control rats (P<0.05), reaching the highest level in those rats with BE (Figure 2B). In parallel to these changes, a significant decrease in SOD activity was observed in all groups of rats with mucosal lesions when compared to control rats (Figure 3B).

In sham-operated rats, nitrotyrosine staining was absent or weak in the esophagus (Figure 4A). In contrast, in rats with esophagojejunostomy, a positive nitrotyrosine staining was found in all rats (55% grade 2, 45% grade 1). Interestingly, the intensity of staining was stronger in squamous epithelium, while weaker positive staining was seen in columnar epithelium (Figure 4B).

SOD expression

The expression of MnSOD and Cu, Zn-SOD was analyzed in total protein extracts. Immunoblot analysis of anti-Cu, Zn-SOD antibody revealed a unique immunoreactive band at 16 ku, corresponding to the molecular mass of monomeric Cu, Zn-SOD. This band was present in rats performed either with sham operation or with esophagojejunostomy and no significant differences were observed among them (Figure 5A). When blots were probed with an anti-MnSOD antibody, the band of 24 ku corresponding to monomeric MnSOD was detected in all cases, though the intensity was progressively increased

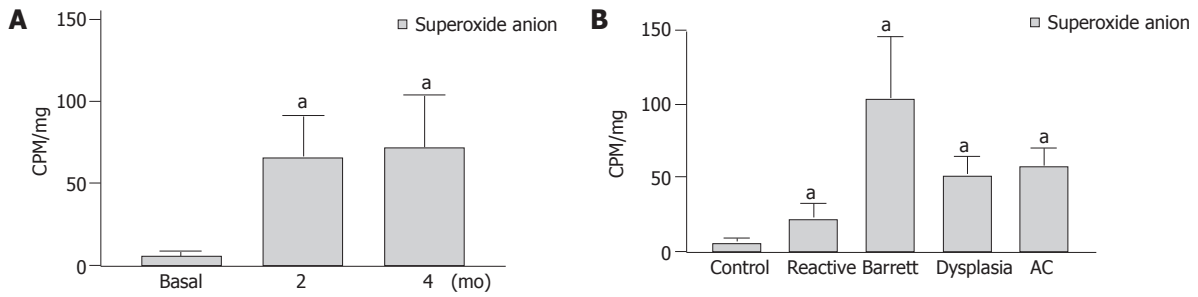

Figure 2 Superoxide anion levels in distal esophagus at different time points (**A**) and in different types of lesion (**B**) after esophagojejunostomy. $^{a}P<0.05$ *vs* control group (sham-operated rats) (n = 6-10).

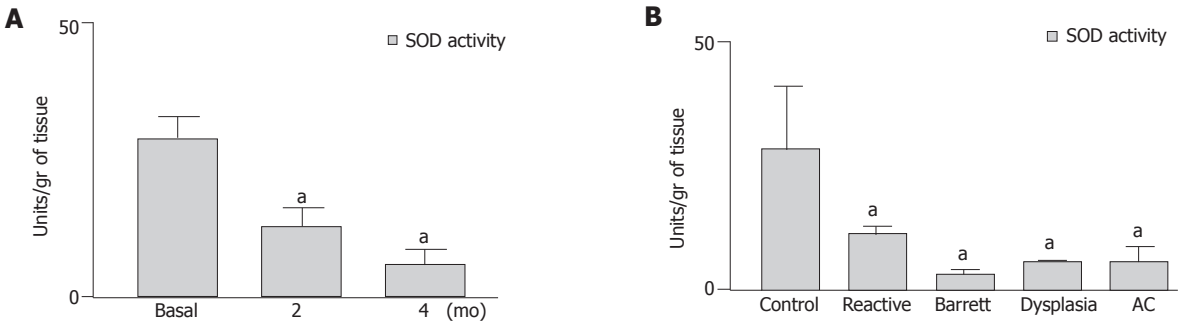

Figure 3 Superoxide dismutase levels in distal esophagus at different time points (**A**) and in different types of lesion (**B**) after surgery. $^{a}P<0.05$ *vs* control group (sham-operated rats) (n = 6-10).

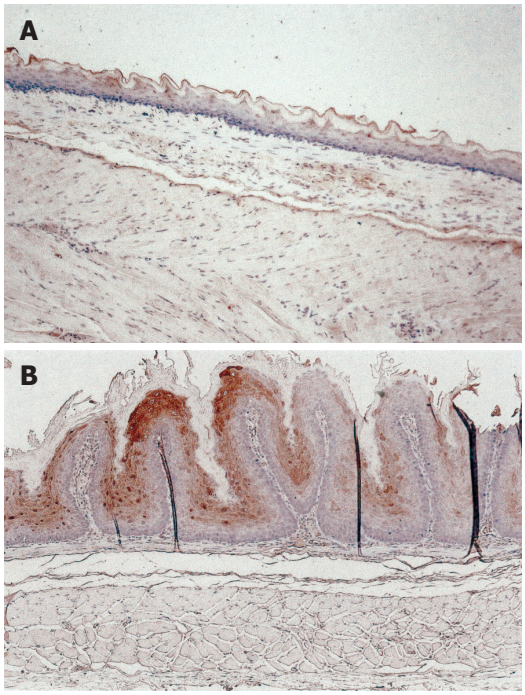

Figure 4 Representative nitrotyrosine immunohistochemical staining in the distal esophagus of rats without reflux (sham operation), showing weak and superficial staining (**A**) and stronger staining (**B**) in the cytoplasm of squamous epithelial cells of rats after 8 weeks of reflux (esophagojejunostomy).

in the esophagus of rats with esophagojejunostomy when compared to sham-operated rats (Figure 5B). Western blot analysis of MnSOD was also performed for nitrotyrosine immunoprecipitates from the rat's esophagus. Immunoblots demonstrated very low but detectable levels of tyrosine-nitrated MnSOD in some of the control tissues. In contrast, the intensity of the band was increased in the esophagus of rats with esophagojejunostomy, especially 4 mo after surgery (Figure 5C).

8-OHdG contents in rat esophagus

When compared to the sham-operated controls, rats with esophagojejunostomy had significantly higher levels of 8-OHdG (8.07±1.08 ng/mg of DNA in sham-operated rats *vs* 15.86±2.34 1st mo, $P<0.05$; 14.4±1.07 2nd mo, $P<0.01$; 14.63±0.63 4th mo, $P<0.01$). However, we did not find a time-dependent increase of 8-OH-dG content in rats with esophagojejunostomy.

Effect of SOD treatment

The exogenous administration of SOD did not significantly affect the development of inflammation, erosions, ulcers or metaplasia in continuity. However, SOD significantly reduced the risk of IM beyond the anastomotic level (odds ratio = 0.326, 95%CI = 0.108-0.981, P = 0.046) (Figure 6A). SOD also significantly decreased the risk of EAC (odds ratio = 0.243, 95%CI = 0.073-0.804, P = 0.021) (Figure 6B). In addition, esophageal mucosal levels of superoxide anion and SOD activity in rats with and without treatment were determined, confirming that administration of SOD significantly decreased superoxide anion production (53.7±10.11 cpm/mg *vs* 22±5.67 cpm/mg protein, $P<0.01$) and significantly increased SOD

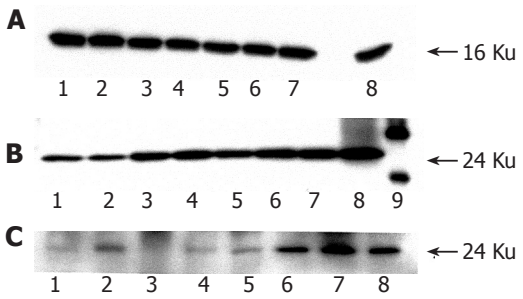

Figure 5 Cu, Zn-SOD and MnSOD expression in total protein extracts from sham-operated rats and rats with esophagojejunostomy. (**A**) A band of 16 ku corresponding to Cu, Zn-SOD observed in both normal rats and rats with enteroesophageal reflux; (**B**) Esophagojejunostomy-induced progressive increase of MnSOD expression; (**C**) Absent or weak nitrated MnSOD in control esophagus and its increase after esophagojejunostomy. Lanes 1-3: sham-operated rats; lanes 4-6: esophagojejunostomy 2 mo of evolution; lanes 7-8: esophagojejunostomy 4 mo of evolution; lane 9: molecular weight marker.

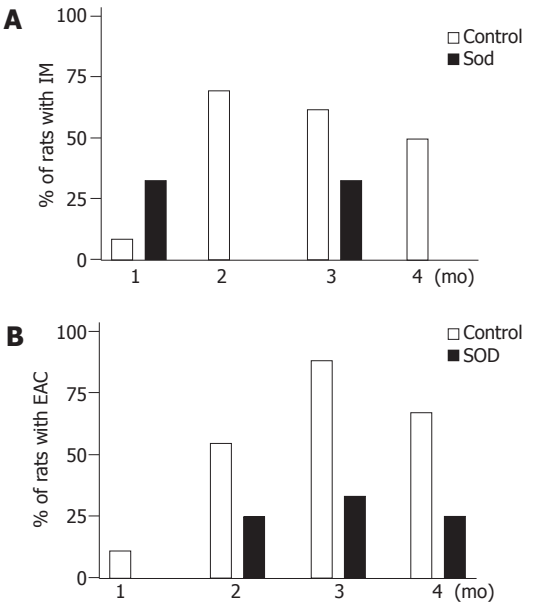

Figure 6 Incidence of intestinal metaplasia distant from the anastomosis site (**A**) and esophageal adenocarcinoma (**B**). The risk of both intestinal metaplasia and adenocarcinoma was significantly lower in the SOD-treated group than in the control group ($P = 0.046$ and $P = 0.021$, respectively) ($n = 6$-10).

activity in rats that received treatment when compared to non-treated rats (28.2±4.72 U/g *vs* 13.4±1.82 U/g tissue, $P<0.05$).

DISCUSSION

Surgical models allowing gastro-duodeno-esophageal reflux or duodeno-esophageal reflux in rats are commonly used to produce experimental BE and EAC[14-17]. Most studies using these models analyzed the prevalence of BE and AC only at one point, but the sequence esophagitis-BE-dysplasia-AC has not been analyzed. The present study established the chronology of this sequence, which is especially useful for analyzing the effect of treatments. Thus, reactive changes and intestinal metaplasia in continuity to the anastomotic site appeared at high rates in the first month, while the prevalence of metaplasia distant from the anastomosis increased considerably in mo 2. High rates of AC were found in mo 4, so we considered this time of follow-up to be sufficient for the second part of the study, which evaluated the efficacy of exogenous administration of SOD in preventing different lesions. The next step of the study was to evaluate the involvement of free radicals, especially superoxide anion as a mechanism of damage in this model. Thus, we showed that the progression of normal mucosa to AC in the esophagus was associated with a parallel increase in superoxide anion mucosal levels. Superoxide anion remained increased until the end of the follow-up, suggesting that superoxide anion plays a pathogenic role in the development of EAC. Furthermore, in the present study we avoided administration of iron, since it has been shown to promote oxidative stress in similar models[18-20]. Therefore, our results provide evidence that gastroduodenal reflux *per se* induces oxidative stress and the development of EAC. Apart from superoxide anion, the involvement of other ROS in this model cannot be excluded. Superoxide anion is scavenged by SOD, generating hydrogen peroxide and oxygen. In this experimental study, a significant and progressive decrease of SOD activity was found, which was parallel to the increase of superoxide anion levels. When SOD activity was analyzed by different degrees of lesion, all groups showed a significantly lower SOD activity than control rats. These data suggest that the decrease of SOD activity may be in part responsible for the accumulation of superoxide anion observed and makes unlikely the generation of hydrogen peroxide in substantial amounts. Since nitric oxide is a natural scavenger of superoxide anion and overexpression of the inducible nitric oxide synthase has been reported in a similar model of EAC in rats[20], the search for generation of the $ONOO^-$ radicals in the mucosa is the next logical step. In the current study, substantial amounts of peroxynitrites analyzed by nitrotyrosine immunostaining were found in the esophagus of rats with esophagojejunostomy, suggesting that peroxynitrite formation is a common event in the presence of excess superoxide anion radicals in this model.

DNA damage resulting from exposure to ROS is believed to play a significant role in carcinogenesis. Though the spectrum of ROS-induced DNA lesions is quite extensive, the modified base 8-hydroxy-2'-deoxyguanosine (8-OHdG) is the most abundant and extensively studied because it can be easily measured[21]. In the present study, 8-OHdG levels were significantly increased at all the time points (1, 2, and 4 mo after esophagojejunostomy), though there were no differences between the different periods. These data indicate that oxidative DNA damage is a very early event and may explain why AC appears so fast in this model. Our results agree with previous studies showing an early increase of oxidative damage to DNA both in an EDA model in rats[22] and in the human esophagitis-metaplasia-dysplasia-AC sequence[23].

The progressive decrease of SOD activity may be due to two main causes: decrease in SOD expression and/or enzyme inactivation. Therefore, we investigated SOD expression by Western blot at different time points of follow-up. Blots revealed that Cu, Zn-SOD expression remained unchanged after esophagojejunostomy, while a progressive increase of MnSOD expression was found, which agrees with previous reports showing higher levels of MnSOD in esophageal carcinomas in comparison to normal tissue[24,25]. The observed increase in MnSOD expression may reflect a compensatory mechanism against the decrease of activity[11]. Therefore, enzyme inactivation is the more plausible mechanism underlying the low SOD activity found in this model. Since tyrosine nitration by peroxynitrite has been shown to inhibit the activity of MnSOD[11], we studied this possibility. We showed that MnSOD was partially tyrosine-nitrated in esophagi exposed to chronic reflux and the amount of nitrated MnSOD increased with time. The low level of nitrated MnSOD observed in some of the control esophagi may reflect the post-mortem ischemia or the basal tyrosine nitration levels under normal physiological conditions. Therefore, we suggest that nitration of MnSOD contributes to partially decrease the SOD activity, but other mechanisms known to inactivate SOD isoforms[26] such as oxidation are likely to be involved in this model.

Administration of various free-radical scavengers can prevent esophageal mucosal damage in different animal models of reflux esophagitis[5-8,27,28], where the most pronounced scavenging effect can be achieved with SOD. However, there is no information about the effect of SOD on the progression of esophageal mucosal damage to BE and EAC. In the present study, administration of SOD significantly reduced the risk of developing IM beyond the anastomotic level and also decreased the risk of EAC, being associated with a relative risk reduction of 68% and 76% respectively. The fact that SOD had no effect on inflammation is in discordance with previous studies demonstrating its effectiveness in preventing esophageal damage in experimental models of esophagitis. However, these studies evaluated the effect of SOD for a short period of time, just hours or at most a few days. Thus, it is possible that the scavenging effect of SOD might be sufficient to decrease mucosal damage in the short term but the magnitude of injury induced by continuous reflux extending over a much longer period of time overwhelms the ability of SOD to avoid mucosal inflammation and ulceration. However, the reduction of IM and AC achieved with the administration of SOD in this study suggests that SOD might be a therapeutic tool for preventing the development of BE and AC in patients with esophagitis. Though administration of SOD in such basis could not completely eliminate the generation of superoxide anion, treatment with SOD significantly lowered superoxide anion levels and increased SOD activity in rat esophagi, indicating that ontosein thus administrated can reach the esophageal mucosa and effectively scavenge superoxide anion at this level.

In conclusion, gastrointestinal reflux induces esophageal IM and AC in most animals undergoing esophagojejunostomy in mo 4. The development of these lesions is associated with esophageal superoxide anion and peroxynitrite generation, reduction of endogenous SOD activity due in part to MnSOD inactivation by nitration and early oxidative damage to DNA. Exogenous administration of SOD reduces the risk of IM and AC in this rat model of gastrointestinal reflux, which constitutes the first evidence showing that antioxidant treatment is effective in preventing BE and EAC.

Abstract

AIM: To investigate the *in vivo* effects of NK2 on liver regeneration after partial hepatectomy (PH).

METHODS: Survival after PH was observed with 21 NK2 transgenic mice and 23 wild-type (WT) mice over 10 d. Liver regeneration was analyzed using histology and immunohistochemistry. Expressions of genes were analyzed using Northern blot analysis, immunoprecipitation and immunoblotting, and reverse transcriptase polymerase chain reaction assay. Kaplan-Meier method and the log-rank test were used for analyzing the survival after PH. Differences in the results of immunohistochemistry and percentage of liver regeneration was determined by the Student's *t*-test.

RESULTS: More than half of NK2 transgenic mice died within 48 h after PH. After PH, increased deposition of small lipid droplets in hepatocytes was evident and hepatic proliferation was inhibited in NK2 transgenic mice. The hepatic expression and kinase activity of HGF receptor, c-Met, were unchanged among WT mice and NK2 transgenic mice after PH. The expression of tumor necrosis factor-α (TNF-α) and interleukin-6 (IL-6) in liver tissues were prolonged in NK2 transgenic mice that died after PH.

CONCLUSION: Our findings indicate that overexpression of NK2 inhibits liver regeneration after PH.

INTRODUCTION

Hepatocyte growth factor (HGF) is a multifunctional cytokine involved in proliferation, motility, and morphogenesis[1]. The effects of HGF are mediated through the tyrosine kinase receptor, c-Met[2]. HGF is reportedly the most potent mitogen for hepatocytes and acts as a trigger for liver regeneration[3,4]. Indeed, HGF knockout mice died *in utero* and the embryonic liver was reduced in size and had extensive loss of parenchymal cells[5]. In c-Met conditional knockout mice produced by using the Mx-cre transgene to introduce the mutation in the adult, liver regeneration after PH was impaired[6,7]. In c-Met conditional knockout mice produced by Cre/loxP-mediated gene targeting, recovery from necrosis induced by carbon tetrachloride (CCl_4) was impaired[8]. These data indicate that the HGF/c-Met signaling pathway plays an important role in liver regeneration and repair.

HGF is a heterodimeric glycoprotein consisting of an α chain of 60 ku and a β chain of 30 ku[9]. The α chain has an N domain and four kringle domains. HGF mRNA can undergo alternative splicing to create a truncated isoform, NK2, which consists of an N domain and the first two kringle domains of HGF[10]. NK2 is also able to bind to c-Met with relatively high affinity and is thought to be an HGF antagonist of a variety of biological activities *in vitro*[1,11-13]. *In vivo*, it has been reported that NK2 acts as an antagonist of HGF in cellular proliferation and protective effect on CCl_4 induced hepatotoxicity[14,15].

Here we have reported that NK2 inhibits hepatocyte proliferation and impairs liver regeneration after PH in our transgenic model.

MATERIALS AND METHODS

Animals

NK2 transgenic mice were generated on an albino FVB

genetic background as previously described[14]. Expressions of human NK2 cDNA was under the control of the mouse metallothionein-1 (MT-1) promoter and associated locus control regions as previously described[16]. Wild-type (WT) mice were littermates of NK2 transgenic mice. All studies were performed using 6-wk-old female mice. PH, consisting of removal of the median and left lateral hepatic lobes, was performed as previously described[17]. Survival was observed with 21 NK2 transgenic mice and 23 WT mice over 10 d. Percentage of liver regeneration was defined as follows: [wet weight of regenerating liver/body weight (g/g mouse)]/[wet weight of original liver/body weight (g/g mouse)]×100%[18]. The animal experiments were conducted in compliance with the guidelines for animal care and use established by Gunma University Graduate School of Medicine.

Histology

Mice were injected with 50 μg/g of 5-bromo-2' -deoxyuridine (BrdU, Becton Dickinson, San Jose, CA, USA) 1 h before being killed. Livers were removed before and 48 h after PH. The tissues were fixed in 10% formalin, embedded in paraffin and stained with hematoxylin-eosin (H-E) and Oil-red-O. For immunohistochemistry, slides were stained with monoclonal antibody to BrdU. At 48 h after PH, the labeled hepatocyte nuclei were scored by counting 30 high-power light microscope fields (×1 000) for each animal.

Northern blot analysis

Total RNAs from liver tissues were prepared using TRIzol (Gibco BRL, Gaithersburg, MD, USA) according to the instructions provided by the manufacturer, and 20 μg of total RNA was loaded per lane onto a 1% agarose-formaldehyde gel and transferred to a nylon membrane (Amersham Pharmacia Biotech, Piscataway, NJ, USA). As described previously, transcripts of the NK2 transgene and endogenous c-Met were detected with a 2.2-kbp mouse HGF cDNA probe and a 1.5-kbp mouse c-Met cDNA probe, respectively[15]. The membrane was rehybridized with a mouse β-actin probe (generously provided by Kojima I) to control for RNA loading and transfer variation.

Immunoprecipitation (IP) and immunoblotting (IB)

Quantification of c-Met and c-Met tyrosine phosphorylation was performed as described previously[19]. Briefly, frozen liver tissues were solubilized in RIPA buffer consisting of 50 mmol/L Tris (pH 7.4), 50 mmol/L NaCl, 1% Triton X-100, 5 mmol/L ethylenediaminetetraacetic acid, 10 mmol/L sodium PPi (Sigma, St. Louis, MO, USA), 50 mmol/L sodium fluoride (Sigma), 1 mmol/L sodium orthovanadate (Sigma), 1 mmol/L phenylmethylsulfonyl fluoride (Boehringer Mannheim, Mannheim, Germany), 10 μg/mL leupeptin (Boehringer Mannheim), 10 μg/mL pepstatin (Boehringer Mannheim, Tokyo, Japan) and 10 μg/mL aprotinin (Boehringer Mannheim). Protein concentration in the resulting lysates was determined using Albumin Standard (Pierce, Rockford, IL, USA) and equivalent amounts of lysate (200 μg) were incubated with anti c-Met antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA) for 2 h on ice. After the addition of GammaBind G Sepharose (Boehringer Mannheim) and washing in RIPA buffer, samples were fractionated on 10% polyacrylamide gels (Biocraft). After electrophoretic transfer to nitrocellulose membranes (Bio-Rad, Richmond, CA, USA), filters were blocked and then incubated with anti c-Met antibody overnight. c-Met was visualized by incubation with anti-goat antibody conjugated to horseradish peroxidase (Santa Cruz Biotechnology, CA, USA) by using enhanced chemiluminescence (Santa Cruz Biotechnology, CA, USA) according to the instructions supplied by the manufacturer. Subsequently, filters were stripped with buffer consisting of 100 mmol/L 2-mercaptoethanol (Sigma), 2% sodium dodecyl sulfate, and 62.5 mmol/L Tris-HCl (pH 6.7) at 50 ℃ for 30 min. Filters were reblocked and incubated overnight with anti-phosphotyrosine (PY) antibody (Transduction Laboratories, Lexington, KY, USA) overnight. PY was visualized using an anti-rabbit antibody conjugated to horseradish peroxidase (Santa Cruz Biotechnology, CA, USA) and enhanced chemiluminescence (Santa Cruz Biotechnology, CA, USA) according to the instructions obtained from the manufacturer.

Reverse transcriptase polymerase chain reaction (RT-PCR) assay

RT-PCR was used to measure the expression of liver TNF-α mRNA and liver IL-6 mRNA. Total RNAs from liver tissues were prepared using TRIzol as previously described[15]. cDNA was prepared from 1 μg of total RNA from each liver sample by the SuperScript Preamplification System for First Strand cDNA Synthesis kit (GIBCO BRL) according to the manufacturer's instructions. The PCR reaction contained, in the same buffer as the reverse transcriptase reaction, cDNA corresponding to 50 ng of input RNA and 2.5 U AmpliTaq DNA polymerase. It was performed at 94 ℃ for 1 min, 55 ℃ for 1 min, 72 ℃ for 1.5 min for 35 cycles. Amplified products were electrophoresed in 2% agarose gels and stained with ethidium bromide. The primer pairs used were as follows[20]. TNF-α sense, 5'-AGCCCACGTCGTAGCA AACCACCAA-3'; antisense, 5'-ACACCCATTCCCTT CACAGAGCAAT-3' (448-bp product size), IL-6 sense, 5'-TATGAAGTTCCTCTCTGCAA-3'; antisense, 5' -CTTTGTATCTCTGGAAGTTT-3' (285-bp product size), β-actin sense, 5'-GCACCACACCTTCTACAATGA G-3'; antisense, 5'-AAATAGCACAGCCTGGATAGCAA C-3' (150-bp product size).

Statistical analysis

All experimental data are shown as mean±SD. Cumulative survival was plotted by the Kaplan-Meier method, and the significance of differences was examined by the log-rank test. Differences in the index of BrdU-labeled hepatocytes and percentage of liver regeneration were determined by

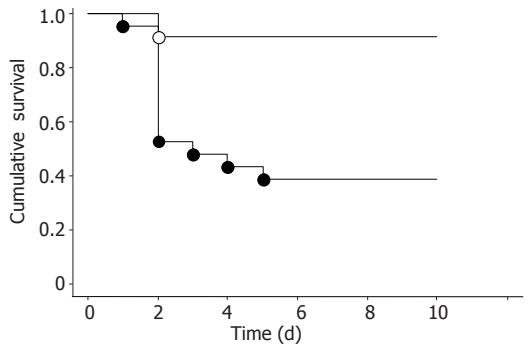

Figure 1 Cumulative survival after PH.Survival of WT mice (n = 23, open circles) and NK2 transgenic mice (n = 21, closed circles) after PH. The survival rate was significantly low in NK2 transgenic mice (^bP<0.01 *vs* WT mice).

the Student's t-test for each group. The level of significance for all statistical analyses was set at P<0.01.

RESULTS

Survival after PH

We examined the effect of NK2 on mortality of mice after PH (Figure 1). Ten of 21 NK2 transgenic mice (47.6%) died within 2 d. In contrast, 2 of 23 WT mice (8.7%) died within 2 d. Survival of NK2 transgenic mice after PH was significantly decreased compared with that of WT mice (P<0.01). Sham operation was performed using four mice per group. All four NK2 transgenic mice and all four WT mice survived until experiments were terminated after 10 d (data not shown).

Morphological alteration in liver and hepatocyte proliferation after PH

The liver structure of regenerating livers of WT mice after PH was normal (Figure 2A). NK2 transgenic mice that died during the first 48 h after PH had smooth and yellow livers. Histological examination revealed that livers of the dying NK2 transgenic mice contained a very large amount of intracellular small droplets at 48 h after PH (Figure 2B). These vesicles were readily identifiable as lipid by Oil-red-O stain (Figure 2C). BrdU staining was performed to analyze hepatocyte proliferation of each mouse at 48 h after PH (Figures 2D and E). The labeling index of the dying NK2 transgenic hepatocytes was significantly decreased relative to that of WT at 48 h after PH (WT, 18.0±6.6; dying NK2, 0.8±1.0, P<0.01) (Figure 2F). On the other hand, the percentage of liver regeneration of healthy NK2 transgenic mice and that of WT mice at 48 h after PH were 69.0±8.6% (n = 5) and 66.1±5.0% (n = 4), respectively (P = 0.59).

Expression of the transgene, endogenous c-Met and activation of c-Met in the liver after PH

High expression of transgene was detected at each time point in NK2 transgenic livers (Figure 3A). There was no difference of endogenous c-Met expression among WT mice, dying NK2 transgenic mice and healthy NK2 transgenic mice (Figure 3A). We next investigated the expression and phosphorylation of c-Met protein. The levels of c-Met protein were in accordance with the c-Met transcription findings and there was no difference of tyrosine phosphorylation of c-Met among the WT mice, dying NK2 transgenic mice and healthy NK2 transgenic mice (Figure 3B).

Hepatic expression of TNF-α and IL-6 after PH

We next examined the expressions of TNF-α and IL-6 mRNAs before PH and 48 h after PH in the livers of WT mice, dying NK2 transgenic mice and healthy NK2 transgenic mice by RT-PCR (Figure 4). TNF-α mRNA was increased in the livers of the dying NK2 at 48 h after PH. In contrast, the level of TNF-α mRNA expression at that point was similar to that before PH in WT mice and healthy NK2 transgenic mice. IL-6 mRNA was detected in the livers of the dying NK2 at 48 h after PH but not detected in WT mice and healthy NK2 transgenic mice at that point.

DISCUSSION

HGF is a potent mitogen for hepatocytes and appears to act on hepatocytes during liver regeneration after PH[3]. Indeed, HGF stimulates liver regeneration after PH in HGF transgenic mice[18,21]. NK2 is a naturally occurring HGF alternative splice variant and acts as an antagonist of HGF *in vitro*[1]. However, very little is known about the *in vivo* role of NK2 in the modulation of HGF activity. When NK2 transgenic mice, created using a mouse MT-1 promoter and associated locus control regions, were treated with zinc sulfate in water, a small reduction in liver size was observed[14]. This finding indicated that NK2 was able to inhibit endogenous HGF-mediated hepatocyte proliferation *in vivo*. Recently, we have demonstrated that overexpression of NK2 does not inhibit hepatocyte proliferation after liver damage induced by CCl_4 administration using NK2 transgenic mice[15]. In this study, we have investigated the effects of NK2 on liver regeneration after PH using NK2 transgenic mice. After PH, about half of the NK2 transgenic mice died within 2 d, whereas almost all WT mice survived that period. NK2 transgenic mice did not exhibit overt abnormal phenotypes, including the liver[15]. However, the NK2 transgenic mice that died after PH showed massive intracellular accumulation of lipid in hepatocytes at 48 h after PH. Moreover, the BrdU leveling index of hepatocytes in NK2 transgenic mice at 48 h after PH demonstrated their poor capacity to enter the S phase. Because DNA replication after PH starts at 20 to 34 h and reaches a peak at 36 to 44 h in mice[22,23], these results indicate that overexpression of NK2 inhibited DNA replication of hepatocytes after PH. The plasma HGF level was reported to peak at 48 h after PH[24]. Hepatic expression of the NK2 transgene transcript was very high at each time point after PH. This suggested that overexpression of NK2 inhibited the proliferative effect of endogeneous HGF after PH. On the other hand, the

(**F**) Data are mean±SD of the mean. Hepatocyte proliferation was significantly reduced in NK2 transgenic mouse liver ($^bP<0.01$ *vs* WT mouse liver).

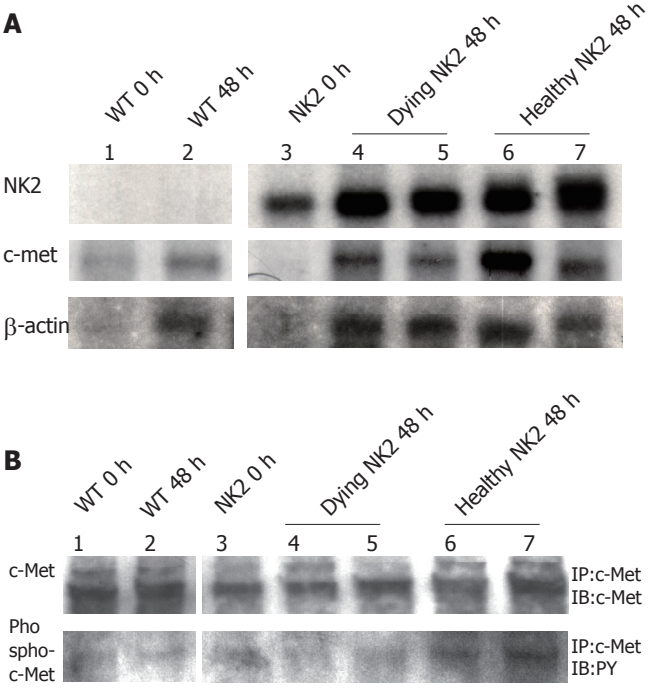

Figure 3 Expressions of RNAs and proteins of transgene and c-Met after PH. RNA expression of transgenic NK2 and c-Met, and c-Met protein levels and activity in livers from WT and NK2 transgenic mice after PH. Lane 1, WT mouse before PH; lane 2, WT mouse at 48 h after PH; lane 3, NK2 transgenic mouse before PH; lanes 4 and 5, dying NK2 transgenic mice at 48 h after PH; lanes 6 and 7, healthy NK2 transgenic mice at 48 h after PH. (**A**) Each RNA sample was subjected to Northern blot analysis. Expression levels of all transgenes were high at each time point and endogeneous c-Met expression was unaltered in each group. β-actin RNA expression was also examined as a control. (**B**) Each protein sample was subjected to IP and then IB with an anti c-Met antibody or an anti PY antibody. c-Met expression and the kinase activity were unaltered in each group.

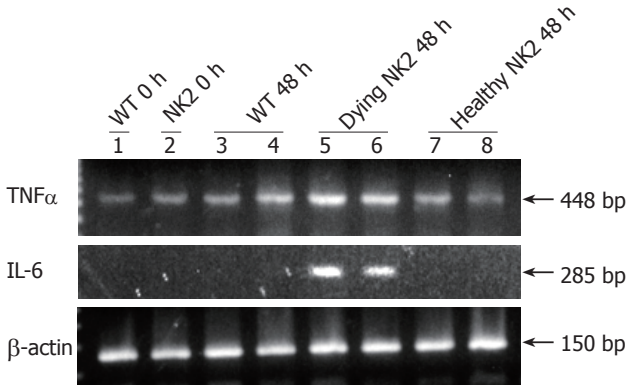

Figure 4 RNA expression of TNF-α and IL-6 after PH. TNF-α mRNA and IL-6 mRNA expression in livers of WT mice and NK2 transgenic mice. Lane 1, WT mouse before PH; lane 2, NK2 transgenic mouse before PH; lanes 3 and 4, WT mice at 48 h after PH; lanes 5 and 6, dying NK2 transgenic mice at 48 h after PH; lanes 7 and 8, healthy NK2 transgenic mice at 48 h after PH. The expression of TNF-α mRNA was increased in NK2 transgenic mice that died at 48 h after PH. IL-6 mRNA expression was detected in NK2 transgenic mice that died at 48 h after PH. β-actin mRNA expression was also examined as a control.

expression of endogenous c-Met RNA and c-Met protein, and phosphorylation of c-Met in the livers of WT and NK2 transgenic mice was unchanged at each time point after PH. Although we did not understand why only half of NK2 transgenic mice died, there could be differences in circulating levels of NK2 or critical local changes in the transgene expression[25].

Hepatocyte proliferation after PH occurs first in periportal cells, and then in perivenous cells[26]. This indicates that HGF is produced from endothelial and

Kupffer cells, and stimulates hepatocyte proliferation via a paracrine mechanism. In addition, HGF acts on hepatocytes located around the central vein by an endocrine mechanism. On the other hand, after CCl_4 administration, hepatocyte proliferation occurs randomly in the lobulus[27]. This indicates that HGF is produced by a paracrine mechanism. HGF may therefore have a differential role in hepatocyte proliferation in the PH and CCl_4 administration models. That is, NK2 overexpression might be inhibitory to hepatocyte proliferation after PH but not after CCl_4-induced acute liver injury.

TNF-α and IL-6 are known to be initiators of liver regeneration after PH[22]. Studies in TNF receptor 1 and IL-6 knock out mice demonstrated the sequence in which TNF-α is induced first after PH, followed by induction of IL-6[22]. Hepatic IL-6 mRNA expression peaked at 4 h after PH in WT mice[28]. TNF receptor 1 knock out mice showed massive lipid accumulation in hepatocytes at 40 h after PH[29] and IL-6 knock out mice showed poor hepatocyte DNA synthesis at 36 h after PH[30]. The observations in these mice are similar to those in NK2 transgenic mice after PH. We have investigated hepatic expression of TNF-α and IL-6 mRNA in NK2 transgenic mice after PH. TNF-α mRNA was increased and IL-6 mRNA was detected in the dying NK2 at 48 h after PH. This result indicates that liver regeneration was impaired in NK2 transgenic mice.

In conclusion, our study demonstrates that overexpression of NK2 prevents liver regeneration after PH.

Abstract

AIM: To examine the effect of DA-9601, a new gastroprotective agent, on the vulnerability of ethanol-treated rat's stomach to naproxen (NAP).

METHODS: Male Sprague-Dawley rats were pretreated with 1 mL of 50% ethanol twice a day for 5 d and then NAP (50 mg/kg) was administered. DA-9601 was administered 1 h before NAP. Four hours after NAP, the rats were killed to examine gross injury index (mm^2), histologic change and to determine mucosal levels of malondialdehyde (MDA), prostaglandin E_2 (PGE_2), glutathione (GSH) and myeloperoxidase (MPO).

RESULTS: Pretreatment of ethanol significantly increased NAP-induced gastric lesions, as well as an increase in MDA and MPO. On the contrary, mucosal PGE_2 and GSH contents were decreased dramatically by ethanol pretreatment, which were aggravated by NAP. DA-9601 significantly reduced NAP-induced gastric injury grossly and microscopically, regardless of pretreatment with ethanol. DA-9601 preserved, or rather, increased mucosal PGE_2 and GSH in NAP-treated rats ($P<0.05$), with reduction in mucosal MDA and MPO levels.

CONCLUSION: These results suggest that repeated alcohol consumption renders gastric mucosa more susceptible to NSAIDs though, at least in part, reduction of endogenous cytoprotectants including PGE_2 and GSH, and increase in MPO activation, and that DA-9601, a new gastroprotectant, can reduce the increased vulnerability of ethanol consumers to NSAIDs-induced gastric damage via the mechanism in which PGE_2 and GSH are involved.

INTRODUCTION

The prevalence of gastrointestinal (GI) disease is increasing in subjects aged 65 years and above. Among them, gastroesophageal reflux disease (GERD) and peptic ulcer are the most important and common GI disorders[1]. Peptic ulcer is one of the most common gastrointestinal diseases with 4-5% prevalence in the human society. Although it was speculated that food or stress was a main causative factor in the early 20th century, genetic and environmental factors are considered most relevant and it is generally accepted that their complicated correlation has a great role in the occurrence of peptic ulcer at present[2].

The number of patients with peptic ulcer is increasing as a result of complicated social activity and the continued advance of civilization. Whereas people over the middle age were predisposed to have peptic ulcer in the past, even teenaged group is also susceptible recently. Major etiologic factors of peptic ulcer include *Helicobacter pylori* (*H pylori*) infection, excessive use of drugs such as non steroidal anti-inflammatory drugs (NSAIDs), irregular eating habits, food containing causative materials such as linoleic acid, smoking, alcohol consumption, psychological, and physiological stress[3]. Chronic medication of NSAIDs often evokes dyspepsia, ulcer, hemorrhage, and perforation of upper gastrointestinal tract[4].

These side effects that arise from NSAIDs are augmented by the suppression of prostaglandin (PG) synthesis and neutrophil-mediated injury secondary to the production of inflammatory mediators such as tumor necrosis factor alpha (TNF-α) and leukotrienes (LTs)[5,6]. The risk factors responsible for the aggravation of gastrointestinal lesion by NSAIDs are believed to be age[7], gender[8], dyspepsia[9], clinical history ulcer and complicated ulcer disease[10] as well as heavy usage of alcohol and smoking[11] and *H pylori* infection[12].

Especially, NSAIDs and alcohol consumption increase the risk for major upper GI bleeding. Alcohol-induced disorders of the GI tract are very common[13]. Alcoholic gastritis subsequently leads to the impairment of the integrity of gastric mucosal barrier, contributing to acid reflux into the subluminal layers of the mucosa and submucosa. The underlying mechanism of mucosal lesions such as petechiae, hemorrhage, and erosion elicited by alcohol is similar to various NSAIDs[14].

In this connection, this study was carried out to investigate the effect of NSAIDs on the susceptibility of gastric lesion sensitized by serial administration of alcohol and preventative effect of DA-9601 (Stillen™), *Artemisia asiatica* extract, on the progression of gastric lesion and finally to reveal the underlying mechanism of action. DA-9601 is now on the market in South Korea and will be on sale in other Asian countries in the near future. It is reported to be effective to erosive gastritis[15] and to possess antioxidative and cytoprotective actions in models of gastric mucosal damage[16,17]. The active ingredient of DA-9601 is eupatilin, which is reported to prevent experimental gastric damage induced by a variety of noxious agents.

MATERIALS AND METHODS

Test materials and experimental animals

DA-9601 (Lot No. DA-9601-L-07) with 0.42% of active ingredient, eupatilin, was extracted from *Artemisiae herba* and supplied to this study after HPLC analysis in Dong-A pharmaceutical institute. (*S*)-6-methoxy-α-methyl-2-napthaleneacetic acid (Naproxen), 10% neutral formalin, sodium phosphate monobasic, sodium phosphate dibasic, ferric chloride ($FeCl_3$), thiobarbituric acid (TBA), trichloroacetic acid (TCA), malondialdehyde (MDA), sulfosalicylic acid, DTNB, β-nicotineamide adenine dinucleotide phosphate reduced form (β-NADPH), glutathione reductase, hexadecyltrimethylammonium bromide (HTAB), *O*-dianisidine dihydrochloride, bovine serum albumin (BSA) were obtained from Sigma (USA). Prostaglandin (PG) E_2 [^{125}I] radioimmunoassay kit (NEN) was obtained by DuPont (USA) and *p*-nitrothiophenol was obtained from TCI (Japan). Absolute ethanol, ether, and hydrochloric acid were purchased from Duksan (Korea). DA-9601 was suspended in 5% hydroxypropylmethylcell ulose (HPMC) dissolved in sterilized saline (v/v). Seven-week-old SPF male Sprague-Dawley rats were obtained from Charles River (Kanagawa, Japan) and acclimatized at least 1 wk under standard laboratory conditions [temperature: 23±2 ℃, humidity range: 40-70%, ventilation: 15-20/h, luminous intensity: 150-300 lux, 12 h light/dark cycle (lighting: 7:00 to 19:00)]. The rats were given regular chow and UV-sterilized tap water *ad libitum*.

Preventative effect of DA-9601 on ethanol-induced acute experimental gastric lesion

Rats fasted for 24 h were given 50% ETOH orally twice a day (8:00 a.m. and 4:00 p.m.) for 5 d. After body weight changes and clinical signs such as diarrhea and mortality were carefully examined, DA-9601 and naproxen (NAP) were administered orally after the last administration of ethanol and fasting animals. Rats were assigned to one of six experimental groups; group Ⅰ: normal age-matched control, group Ⅱ: alcohol administration, group Ⅲ: NAP 50 mg/kg without alcohol administration, group Ⅳ: alcohol+NAP, group Ⅴ: DA-9601 100 mg/kg pretreatment+NAP without alcohol administration, group Ⅵ: alcohol administration+DA-9601 100 mg/kg+NAP. Four hours after NAP administration, rats were anesthetized with ether and total extirpation of the stomach was performed. Thirteen milliliters of 4 ℃ saline was injected into the lumen of isolated stomach and maintained for 30 min. Surface area (mm^2) of gastric lesion was measured using optical microscope (Olympus ×10) following gastrotomy along with greater curvature. Small portion of tissue was fixed in 10% formalin solution and mucosal fluid collected from gastric mucosa stored at -74 ℃ refrigerator.

Homogenization of gastric mucosal fluid

Frozen mucosal fluid was thawed at room temperature and diluted with 1 mL Tris-HCl buffer (pH 7.4) per 100 mg and homogenized at 3 000 r/min for 10 min. Supernatant was stored at -20 ℃.

Measurement of the level of malondialdehyde in gastric mucosal fluid

TBA method was applied to accomplish MDA measurement. Two millimole per liter of $FeCl_3$ was added to 100 μL supernatant, which was agitated and incubated in 37 ℃ water bath for 30 min. Then 30% TCA, 0.75% TBA and 5 mol/L HCl were added as well and boiled for reaction in water bath for 15 min. Reacted mixture was cooled down to room temperature and centrifuged at 3 000 r/min for 10 min. Supernatant was assigned to measure absorbance at 550 nm thereby the amount of MDA (nmol/L/mg protein) was generated from standard curve of MDA.

Measurement of PGE_2 in gastric mucosal fluid

The amount of PGE_2 was measured with [^{125}I] RIA kit. After sample and tracer were added to the assay buffer, they were mixed with anti-serum and incubated at 2-8 ℃ for 24 h. Precipitating reagent was added to the sample, agitated well and then incubated for 30 min at 2-8 ℃. The amount of PGE_2 (pg/mg protein) was measured with gamma counter using pellet obtained from centrifugation at 3 000 r/min for 30 min.

Measurement of the amount of glutathione in gastric mucosal fluid

Sample added to 4% sulfosalicylic acid was centrifuged at 3 000 r/min for the elimination of protein and reacted with 0.1 mol/L sodium phosphate buffer (pH 7.5) containing 6 mmol/L DTNB, 0.3 mmol/L NADPH,

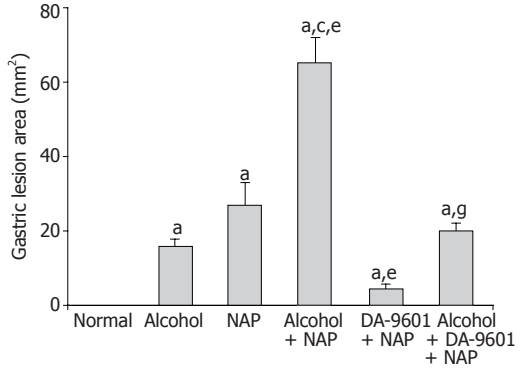

Figure 1 The effect of DA-9601 on the area of gastric lesion induced by alcohol and NAP. Data are expressed as mean±SD. [a]*P*<0.05 *vs* normal control, [c]*P*<0.05 *vs* alcohol group, [e]*P*<0.05 *vs* NAP, [g]*P*<0.05 *vs* alcohol + NAP.

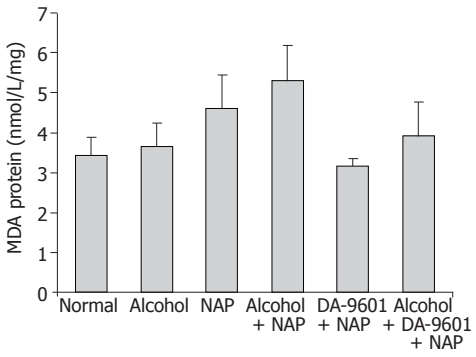

Figure 2 The effect of DA-9601 on MDA levels in gastric mucosal fluid. There were no statistical significances among all groups.

50 unit glutathione reductase at room temperature. The amount of GSH (nmol/L/mg protein) was generated by the absorbance of *p*-nitrophenol measured at 412 nm using the supernatant from centrifugation at 3 000 r/min for 10 min.

Measurement of the amount of myeloperoxidase in gastric mucosal fluid

The amount of myeloperoxidase (mU/mg protein) was measured at gastric mucosa modifying the method of previous reports. After gastric mucosa was homogenized in 0.5% HTAB solution containing 50 mmol/L potassium phosphate (pH 6.5), homogenized samples were freezed and thawed thrice and homogenized. Supernatant was added to the reaction buffer containing *O*-dianisidine dihydrochloride and H_2O_2 and the amount of myeloperoxidase was calculated from the absorbance of the reaction buffer at 460 nm at every 1 min.

Protein assay

Protein assay was performed by means of measuring absorbance at 535 nm compared using standard curve of BSA.

Statistical analysis

Data were expressed as the mean±SD and all statistical analyses were performed using SigmaStat® for Windows 2.0 software (Jandel Corporation, USA). Statistical significance was evaluated by one-way analysis of variance (ANOVA) followed by Bonferroni *post hoc* test or Dunnett's test for a multiple comparison. $P<0.05$ were considered significant.

RESULTS

Preventative effect of DA-9601 on ethanol-induced acute experimental gastric lesion

There was an apparent linear lesion on gastric mucosa of group Ⅱ (alcohol) with area of gross lesion (mm^2) of 16.0±1.8 (Figure 1). Group Ⅲ (NAP) had a petechial lesion on gastric mucosa and area of gross lesion was 27.0±6.0. Group Ⅳ (alcohol+NAP) exhibited hemorrhage on gastric mucosa with a significantly different area of hemorrhagic lesion (65.3±6.7, $P<0.05$), which was more severe than groups Ⅱ and Ⅲ. Group Ⅴ (DA-9601+NAP) significantly inhibited gross gastric lesion in comparison to group Ⅲ (4.5±1.2, $P<0.05$). The area of gross gastric lesion of group Ⅵ (alcohol+DA-9601+NAP) was 20.0±2.1 which was significantly different from group Ⅳ ($P<0.05$).

MDA level in gastric mucosal fluid

MDA levels (Figure 2) of groups Ⅰ (normal control) and Ⅱ (alcohol) indicating lipid peroxidation were 3.43±0.44 (nmol/L/mg protein) and 3.66±0.58 with no significant difference between them. It was found that groups Ⅲ (NAP) and Ⅳ (alcohol+NAP) had 4.61±0.83 and 5.30±0.89, respectively. There was a tendency to increase MDA levels of groups Ⅲ and Ⅳ without statistical significance. Group Ⅴ (DA-9601+NAP) exhibited MDA level of 3.16±0.18 which was reduced by 31.5% compared with group Ⅲ (NAP), but there was no significant difference between them. In case of group Ⅵ (alcohol+DA-9601+NAP), MDA level was 3.92±0.84 (nmol/L/mg protein) with 15.0% reduction compared to group Ⅳ, but no significance was found.

Prostaglandin E2 level in gastric mucosal fluid

PGE_2 level as a cytoprotection marker in group Ⅰ (normal control) was determined to be 194.5±21.5 (pg/mg protein) (Figure 3), group Ⅱ (alcohol) showed 159.5±30.2 which was reduced to the extent of 18.0% compared to group Ⅰ (normal control) but did not produce significance. Group Ⅲ (NAP) represented 62.0±13.8 indicating significant difference due to 68.1% reduction ($P<0.05$). PGE_2 level of group Ⅳ (alcohol+NAP) was 47.1±11.9 which produced 70.5% reduction which was significantly different ($P<0.05$) from group Ⅱ (alcohol) and 24.0% reduction without significance compared to group Ⅲ (NAP). 307.2±27.3 was determined as the PGE_2 level of group Ⅴ (DA-9601+NAP) and it was 57.9% higher than normal ($P<0.05$) and 395.5% higher than group Ⅲ (NAP) ($P<0.05$). Group Ⅵ (alcohol+DA-9601+NAP) showed 180.3±18.3 similar to group Ⅰ (normal control) normal control but 282.8%

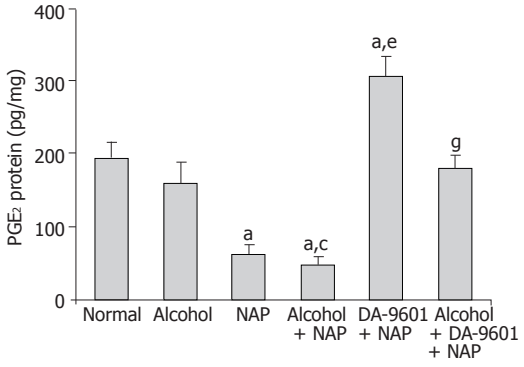

Figure 3 The effect of DA-9601 on PGE_2 levels in gastric mucosal fluid. Data are expressed as mean±SD. [a]*P*<0.05 *vs* normal control, [c]*P*<0.05 *vs* alcohol group, [e]*P*<0.05 *vs* NAP, [g]*P*<0.05 *vs* alcohol + NAP.

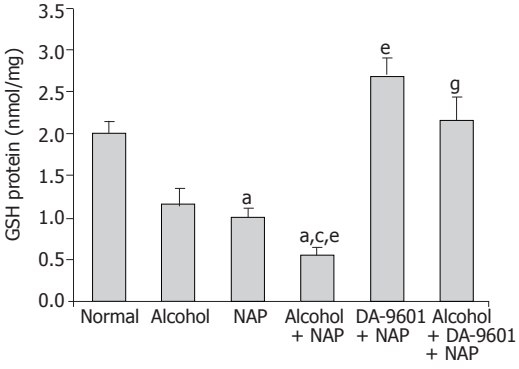

Figure 4 The effect of DA-9601 on GSH levels in gastric mucosal fluid. Data are expressed as mean±SD. [a]*P*<0.05 *vs* normal control, [c]*P*<0.05 *vs* alcohol group, [e]*P*<0.05 *vs* NAP, [g]*P*<0.05 *vs* alcohol + NAP.

increase with a significant difference (*P*<0.05) compared to group Ⅳ (alcohol+NAP).

Glutathione level

The levels of GSH in gastric mucosa (Figure 4) were 2.01±0.14 (nmol/L/mg protein) in group Ⅰ (normal control) and 1.18±0.17 in group Ⅱ (alcohol) and there was no significant difference between them. 1.01±0.21 of group Ⅲ (NAP) produced 49.8% reduction with significant difference (*P*<0.05). GSH level of group Ⅳ (alcohol+NAP) was 0.55±0.10 which generated 53.4% and 45.5% reduction and was significantly different (*P*<0.05) from group Ⅱ (alcohol) and group Ⅲ (NAP), respectively. Group Ⅴ (DA-9601+NAP) exhibited 2.68±0.22 with significant increase compared with group Ⅲ, and that was even higher than group Ⅰ (normal control). The level of GSH in group Ⅵ was 2.16±0.28 which was significantly higher than group Ⅳ (*P*<0.05).

Myeloperoxidase level

The level of MPO in group Ⅰ (normal control) was 0.78±0.11 (mU/protein) (Figure 5). Whereas group Ⅱ (alcohol) exhibited significant increase of MPO (1.19±0.27) compared to normal (*P*<0.05), there was an increase of MPO in group Ⅲ (NAP) without significance.

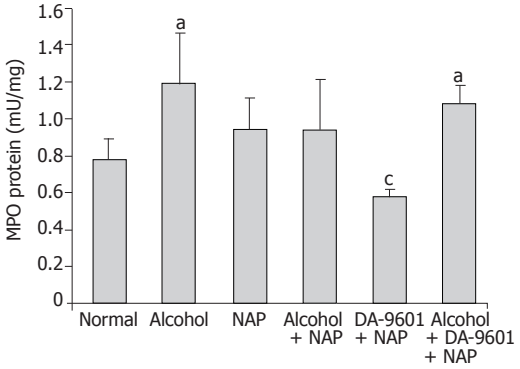

Figure 5 The effect of DA-9601 on MPO levels in gastric mucosal fluid. Data are expressed as mean±SD. [a]*P*<0.05 *vs* normal control, [c]*P*<0.05 *vs* NAP group.

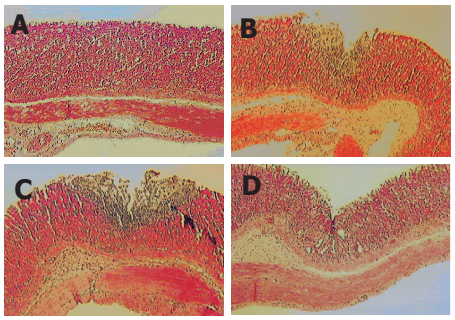

Figure 6 Histopathological changes induced either by alcohol, NAP and alcohol + NAP administration and its inhibition by DA-9601. **A:** Minimal inflammatory change in gastric mucosa in group Ⅱ (alcohol); **B:** Focal epithelial erosion and inflammatory cell infiltration in gastric mucosa and submucosa of group Ⅲ (NAP); **C:** Multifocal and diffuse epithelial erosion and severe inflammatory change in gastric mucosa and submucosa of Group Ⅳ (alcohol + NAP); **D:** DA-9601 treatment ameliorates the pathological changes of gastric mucosa and submucosa induced by NAP in alcohol pre-treated group Ⅵ (alcohol + DA-9601+NAP).

0.94±0.27 of group Ⅳ (alcohol+NAP) generated 21.1% reduction compared to group Ⅱ, but was similar to group Ⅲ. Group Ⅴ (DA-9601+NAP) showed 0.58±0.04 which produced 25.6% reduction in comparison to group Ⅰ (normal control) and was significantly decreased compared to group Ⅱ (alcohol) and group Ⅲ (NAP) (*P*<0.05). The level of MPO in group Ⅵ (alcohol+DA-9601+NAP) was 1.08±0.10 similarly to group Ⅱ (alcohol) and group Ⅲ (NAP).

Histopathological examination

Histopathological changes are depicted in Figure 6. In group Ⅱ (alcohol), there was a minimal inflammatory change in gastric mucosa; however, it was found that group Ⅲ (NAP) had focal epithelial erosion and inflammatory cell infiltration in gastric mucosa and submucosa. Whereas group Ⅳ (alcohol+NAP) aggravated the gastric lesion by forming multifocal and diffuse epithelial erosion and severe inflammatory change in gastric mucosa and submucosa, DA-9601 treatment ameliorates the pathological changes of gastric mucosa and submucosa induced by NAP in alcohol pre-treated group (group Ⅵ).

DISCUSSION

Considering the outcomes from this experiment, it was demonstrated that co-administration of alcohol and naproxen, one of the currently available NSAIDs, augmented the gastric mucosal lesion in comparison to the administration of alcohol or naproxen alone. Subsequently, treatment of DA-9601 that is being developed for targeting a new gastric mucoprotectant was shown to account for the preventative effects on gastric mucosa effectively against the lesion caused by alcohol and naproxen. Besides the effects on quantified gastric lesion, the level of MDA and MPO in DA-9601 treated group exhibited similar level to that in normal control and it was also revealed that DA-9601 contributed to intact maintenance of the gastric mucosa at the extent of normal control on histopathological examination.

The well-known etiologies for peptic ulcer can be categorized as follows: eating habits, environmental factors, stress by social life, drinking behavior, smoking, and drugs. Among these causative factors, drug-induced peptic ulcer is increasing dramatically with respect to the overuse of NSAIDs and increased susceptibility of gastric mucosa by single or co-administration of oral anti-coagulants (warfarin, phenindione, phenprocoumon, acenocoumarol, anisindione, diphenadione, *etc*.) and corticosteroid hormones (triamcinolone, dexamethasone, cortisone, hydrocortisone, prednisolone, prednisone)[18]. It is reported that alcohol is responsible for the hemorrhage of gastric mucosa and edema in submucosal muscle layer by means of direct irritation[19] and also leads to acute gastritis associated with microcirculer stasis[20]. Once gastric mucosa is injured, thereby ischemia and decreased level of ATP in gastric mucosa and intervention of microcirculation occurs[21]. Gastric mucosal damage due to chronic ingestion of low concentration of alcohol is generally not discernible on gross examination; however, if gastric mucosa is exposed to an external mucosal irritant, gastric lesion becomes more extensive and consistent with increased susceptibility as well as persistent submucosal microcircular stasis[22]. It was demonstrated that DA-9601 100 mg/kg treatment exerted excellent preventative or therapeutic effects on gastric mucosal lesion with action of duration being effective for more than 2 h. It was also well documented that these effects were in accordance with the facilitation of the synthesis of PG by DA-9601.

Since aspirin was first synthesized in the year of 1899, a variety of NSAIDs has emerged so far and they are being used as antipyretic analgesics and anti-inflammatory drugs. Nowadays, the market size of NSAIDs is more than 60 billion/year, in addition, more extended indications are making the need for NSAIDs to increase[23]. Despite these facts, NSAIDs were reported to cause gastric lesion since 1930s and underlying mechanism was related to the fact that NSAIDs inhibit cyclooxygenase (COX) thereby block the synthesis of PG[24]. More specifically, NSAIDs elicit gastromucosal lesion not only by reducing the physiological role of PG, but also by directly inducing neutrophilic infiltration in gastric capillaries causing subsequent stasis and free radical formation by extravasated neutrophil[25]. Several methods are suggested to alleviate the adverse effects of NSAIDs until recently. First of all, aspirin is administered in the form of enteric-coated tablet or direct irritation to gastric mucosa is prevented by administration of prodrug[26]. Secondly, NSAIDs are administered to patients being chemically modified with nitric oxide that is known to act as a gastric mucosal protectant similarly to PG[27,28]. Lastly, NSAIDs with high sensitivity to COX Ⅱ are designed[29,30]. Despite these efforts, 62.2% of patients treated with NSAIDs on a long-term basis complained of upper gastrointestinal clinical signs of which gastritis (38.5%), gastric ulcer (15.5%), duodenal ulcer (1.9%) were most prevalent; however, it appears that more patients suffered from these adverse effects due to complicated drug administration or eating habits. The underlying mechanisms that result in gastrointestinal symptoms can be classified as follows: firstly, it is generally accepted that NSAIDs inhibit COX responsible for the synthesis of PG. Secondly, NSAIDs have a direct effect on gastric mucosa and lastly it is also proposed that overproduction of LTs, especially for LTB4, by 5-lipoxygenase (5-LO) resulting from compensation for the inhibition of COX is a causative factor[31,32]. LTs are known to be mediators that induce inflammatory process and take part in the formation and infiltration of neutrophils[33]. The most commonly prescribed formula considering NSAIDs treatment is the co-administration of extrinsic or intrinsic PG. Whereas Misoprostol, one of the extrinsic PG synthetics, has the advantage in the aspect of potency, and it exhibits adverse effect such as diarrhea. The intrinsic PG derivative, ornoprostil, is known to be not effective in the patients with gastric ulcer or gastritis because of the fact that NSAIDs inhibit COX[34]. It was revealed that DA-9601 increased the level of PGE_2 and GSH dose-dependently in normal state as well as alcohol or ammonia-induced gastric lesion. Moreover, DA-9601 elevated the level of PGE_2 protecting gastric mucosa without affecting the efficacy of NSAIDs, when DA-9601 was co-administered with NSAIDs in arthritis-induced rats. Oxygen free radical and lipid peroxidation are regarded as the crucial etiologies leading to gastric mucosal lesion by oxidative stress[35]. Once oxygen free radical triggers and maintains ischemic status in gastric mucosa, hydroxyl radical generated from superoxide anion results in gastric lesion by virtue of decreasing the velocity of blood flow subsequently[36].

In this present study, we measured not only the level of MDA and MPO in order to quantify the materials contributing to gastric mucosal lesion but also the level of PGE_2 and GSH that are produced as protective markers. As a whole, it was demonstrated that the level of MDA and MPO were decreased similarly to the level of normal control, whereas PGE_2 and GSH were increased in DA-9601 treated group. In the previous report, DA-9601 treatment alone had the ability to facilitate the production of mucosal PGE_2[17]. From the findings of this study, DA-9601 treatment was proven to protect effectively against the NSAIDs-induced lesion of gastric

mucosa which was more susceptible to NSAIDs by the administration of alcohol in rats. On closer inspection of results, the underlying mechanism of the action of DA-9601 can be centered on the cytoprotective effect by normalizing the production of PG, additional improvement of gastric mucosal function by elevating GSH content, alleviation of inflammation by decreasing the level of MDA and MPO. Bearing all these in mind, it is worth making a conclusion that DA-9601 treatment has a protective effect on gastric mucosa of patients who are accustomed to drinking alcohol regularly and will be of great value in human clinical study.

Abstract

AIM: To investigate the release of cyclodextrin-5-aminosalicylic acid (CyD-5-ASA) in cecum and colon.

METHODS: An anti-inflammatory drug 5-ASA was conjugated onto the hydroxyl groups of α-, β- and γ-cyclodextrins (CyDs) through an ester linkage, and the *in vivo* drug release behavior of these prodrugs in rat's gastrointestinal tract after the oral administration was investigated.

RESULTS: The 5-ASA concentration in the rat's stomach and small intestine after the oral administration of CyD-5-ASA conjugate was much lower than that after the oral administration of 5-ASA alone. The lower concentration was attributable to the passage of the conjugate through the stomach and small intestine without significant degradation or absorption, followed by the degradation of the conjugate site-specific in the cecum and colon. The oral administration of CyD-5-ASA resulted in lower plasma and urine concentration of 5-ASA than that of 5-ASA alone.

CONCLUSION: CyD-5-ASA conjugates may be used as prodrugs for colon-specific drug delivery system.

Key words: Cyclodextrin; 5-Aminosalicylic acid; *In vivo*; Colon-specific

INTRODUCTION

Ulcerative colitis and Crohn's disease are recurrent disorders chronically involving the mucosa and submucosa of the colon. 5-Aminosalicylic acid (5-ASA) is an active ingredient of agents used for the long-term maintenance therapy to prevent relapses of Crohn's disease and ulcerative colitis[1-3]. However, when 5-ASA is administered orally, a large amount of the drug is absorbed from the upper gastrointestinal tract (GIT), and causes systemic side effects. Therefore, it is preferable to deliver the drug site-specifically to the colon. Various approaches have been developed, including coating with biodegradable polymers[4,5], coating with pH-sensitive polymers[6,7], time-dependent formulations[8,9], forming biodegradable matrices[10,11], and forming prodrugs.

Azo prodrugs of 5-ASA are the most effective prodrugs used for the treatment of inflammatory bowel disease (IBD). Polymeric prodrugs of 5-ASA have not been used in clinics[12,13]. Natural polysaccharides have been used as tools to deliver the drugs to the colon. These polysaccharides remain intact in the physiological environment of the stomach and small intestine, but once the dosage form enters into the colon, it is acted upon by polysaccharides, which release the drug into the colon[14-16]. Cyclodextrins are cyclic oligosaccharides that consists of 6-8 glucose units. They are known to be barely capable of being hydrolyzed and only slightly absorbed in the passage through the stomach and small intestine, and are fermented by colonic microflora into small saccharides. The present study aimed to clarify the *in vivo* release behavior of 5-ASA from its CyD ester prodrugs in rat's intestines.

MATERIALS AND METHODS

Materials

α-, β-, γ-CyDs and carbonyldiimidazole (CDI) were obtained from Sigma Chemical Co (St. Louis, USA). 5-ASA was purchased from Acros Organics Ltd (NJ, USA). CyD-5-ASA and Ac-5-ASA were prepared according to the method reported in a previous paper[17].

All other chemicals and solvents were of analytical reagent grade, and deionized double-distilled water was used throughout the study.

Analytical methods

The HPLC system that consisted of LC-10ADvp pumps, SPD-10ADvp detector, and SIL-10ADvp autoinjector was purchased from Shimadzu. Reversed-phase HPLC conditions[18,19] for the determination of 5-ASA and its metabolites were as follows: a mobile phase of 5.0 mmol/L pH 6.0 phosphate buffer/acetonitrile/ 0.1 mol/L tetrabutyl-ammonium chloride (90:10:0.5 v/v/v), a flow rate of 1.0 mL/min, and a detection of wavelength 330 nm for 0-9 min, 240 nm after 9 min.

Release of 5-ASA in rat's gastrointestinal tract and tissues

Male SD rats, weighing about 200 g, were fasted for 8 h prior to drug administration while water was allowed *ad libitum*. 5-ASA or CyD-5-ASA (equivalent to 50 mg of 5-ASA) was orally administered to the rats and then the rats were placed in metabolic cages. At appropriate intervals (4, 8, 12, and 24 h), blood samples (about 3 mL) were taken from the jugular vein, and the rats were killed by ether anesthesia, followed by thoracotomy. The blood was centrifuged at 10 000 *g* for 5 min, and serum was frozen at -20 °C and stored until analysis. The GIT was isolated and divided into stomach, small intestine, cecum, and colon. The intestinal contents were removed by gently squeezing the gastrointestinal segments, which were then rinsed with a small amount of phosphate buffer (about 10 mL) to remove the adherent materials. The separated contents and tissues were quickly frozen at -20 °C and stored until analysis. Urine and feces samples were collected and frozen at -20 °C.

The frozen intestinal contents were thawed, weighed, and diluted with 1.5 mL of 0.1 mol/L HCl. They were vortexed for 3 min, centrifuged at 5 000 r/min for 5 min, then 2.5 mL of methanol was added to 0.8 mL of the supernatant, vortexed for 2 min. The mixture was centrifuged for 10 min at 5 000 r/min. The supernatant of 3.0 mL was transferred into another cleaning tube and evaporated under N_2 at 40 °C. The remaining supernatant was dissolved in mobile phase and filtered through 0.2-mL membrane. The frozen tissues were thawed, weighed, cut into small pieces and homogenized with five volumes of cold 0.1 mol/L HCl using a tissue homogenizer (Polytron PT-MR3100, Kinematica, Switzerland) at 0 °C.

RESULTS

Recovery of CyD-5-ASA, 5-ASA and its metabolite

In a previous paper[17], we have reported that the hydroxyl propyl cellulose/5-ASA (HPC-5-ASA), chitosan/5-ASA (ChT-5-ASA) conjugate are stable in rat's GIT, where CyD-5-ASA liberates 5-ASA site-specifically in rat's cecum and colon. In this study, the distribution of CyD-5-ASA prodrugs, 5-ASA and its metabolites were investigated.

Tables 1-3 show the recovery percentage of the intact prodrugs, 5-ASA and *N*-acetyl-5-ASA (Ac-5-ASA), a metabolite of 5-ASA in GIT, blood, liver, feces, and urine after the oral administration of CyD-5-ASA to rats. The sampling time was chosen on the basis of the time necessary for CyD-5-ASA to reach the cecum after oral administration. The total recovery was defined as the sum of the intact prodrugs, 5-ASA and Ac-5-ASA in the entire GIT and tissues, blood (assuming that the blood volume is 6.5% of body weight), urine and feces, and expressed as a percentage of the dose administered. The recovery from the stomach, small intestine, cecum, colon, blood, urine, feces, and liver was expressed as a percentage of the total recovery described above.

Four hours after dosing, about 60% of 5-ASA and Ac-5-ASA were recovered in intact form from the stomach and small intestine and about 40% in the cecum and colon. Eight hours after dosing, 20% of the prodrugs were located in the stomach and small intestine and a large portion (>70%) was recovered from cecum and colon. After 12 h, the major portion of the prodrugs was recovered from the cecum, colon, and feces. There was only a negligible amount of 5-ASA and Ac-5-ASA in blood and urine. These results indicated that the CyD prodrugs survived passage through the rat's stomach and small intestine and were subjected to the ring-opening process in the cecum and colon.

Release behavior in rat's gastrointestinal tract and tissues

In this study, 5-ASA, α-CyD-5-ASA, β-CyD-5-ASA and γ-CyD-5-ASA (equivalent to 50 mg/kg 5-ASA) were administered to the rats. There was no or a very small amount of 5-ASA detected in the tissues after the oral administration. The results of β-CyD-5-ASA and γ-CyD-5-ASA were similar to those of α-CyD-5-ASA.

Figure 1 shows the concentrations of 5-ASA and Ac-5-ASA in rat's blood, urine, feces, liver homogenates after the oral administration of 5-ASA (50 mg/kg) and α-CyD-5-ASA (equivalent to 50 mg/kg 5-ASA). With the oral administration of 5-ASA, 5-ASA being absorbed in the upper GIT, the concentration in cecum and colon was very low. Whereas during the oral administration of α-CyD-5-ASA, the levels of 5-ASA and Ac-5-ASA in the plasma and urine were very low in the whole experimental period, which might indicate the limited oral absorption of α-CyD-5-ASA. α-CyD-5-ASA was not degraded to release 5-ASA in the GIT, and 5-ASA was detected in the cecum and colon. A portion of the released 5-ASA might be absorbed in the large intestine and appeared in the plasma concentration of Ac-5-ASA.

DISCUSSION

In this study, formation of prodrugs has improved the delivery properties of the parent drug molecule. Activated by the microbial enzymes in the large intestine, CyD-5-ASA released 5-ASA at a controlled rate. These results suggest that after the oral administration of prodrugs there is no or a very small amount of 5-ASA in the tissues of rats. Oral administration of 5-ASA gives much higher

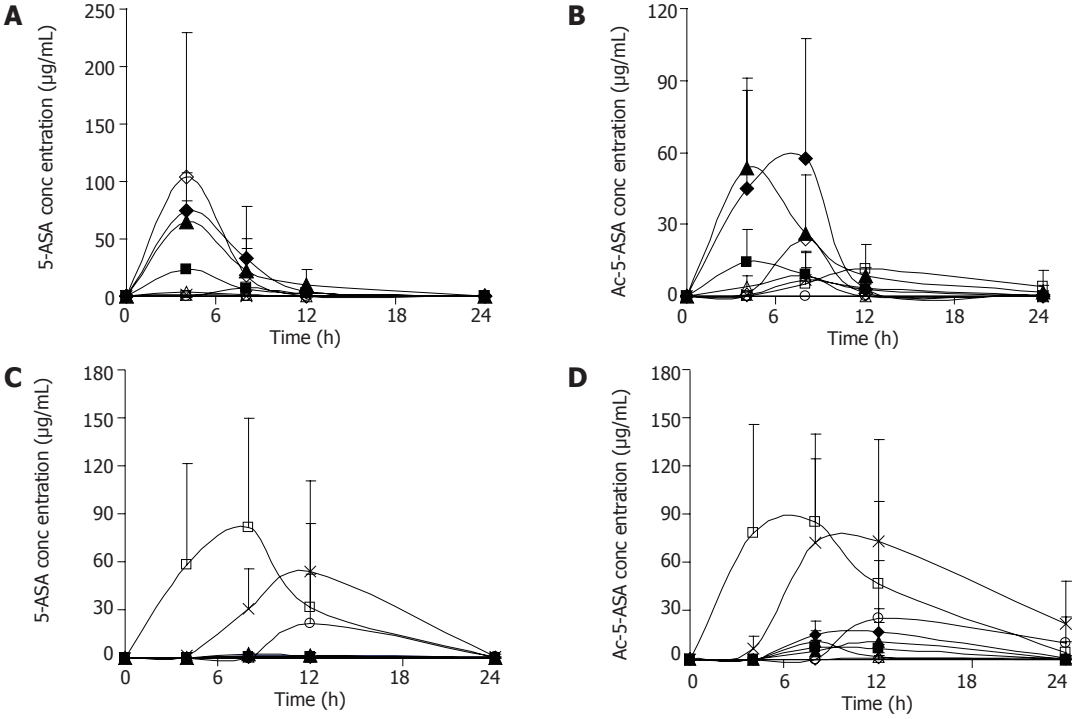

Figure 1 Concentration of 5-ASA and Ac-5-ASA in serum (◆), urine (■), feces (○), liver homogenates (△), stomach contents (◇), small intestinal contents (▲), cecal contents (□), colonic contents (×) after the oral administration of 50 mg/kg 5-ASA or α-CyD-5-ASA (equivalent to 50 mg/kg 5-ASA) to rats. **A:** Concentration of 5-ASA after oral administration of 5-ASA; **B:** concentration of Ac-5-ASA after oral administration of 5-ASA; **C:** concentration of 5-ASA after oral administration of 10 α-CyD-5-ASA; **D:** concentration of Ac-5-ASA after oral administration of α-CyD-5-ASA.

plasma and urine concentrations of 5-ASA than CyD-5-ASA and the conjugate can lower the plasma concentration of 5-ASA. The lower concentration is attributable to the passage of the conjugate through the stomach and small intestine without significant degradation or absorption, followed by the degradation of the conjugate site-specifically in the cecum and colon. Therefore, CyD-5-ASA conjugates may be useful as prodrugs for colon-specific delivery system.

Abstract

AIM: To investigate the differentiation of human umbilical cord blood (HUCB)-derived mesenchymal stem cells (MSCs) into hepatocytes by induction of fibroblast growth factor-4 (FGF-4) and hepatocyte growth factor (HGF), and to find a new source of cell types for therapies of hepatic diseases.

METHODS: MSCs were isolated by combining gradient density centrifugation with plastic adherence. When HUCB-derived MSCs reached 70% confluence, they were cultured in Iscove modified Dulbecco medium (IMDM) supplemented with 10 mL/L FBS, 20 ng/mL HGF and 10 ng/mL FGF-4. The medium was changed every 4 d and stored for albumin, alpha-fetoprotein (AFP) and urea assay. Expression of CK-18 was detected by immunocytochemistry. Glycogen storage in hepatocytes was determined by PAS staining.

RESULTS: By combining gradient density centrifugation with plastic adherence, we could isolate MSCs from 25.6% of human umbilical cord blood. When MSCs were cultured with FGF-4 and HGF, approximately 63.6% of cells became small, round and epithelioid on d 28 by morphology. Compared with the control, the level of AFP increased significantly from d 12 to 18.20±1.16 μg/L (t = 2.884, P<0.05) in MSCs cultured with FGF-4 and HGF, and was higher (54.28±3.11 μg/L) on d 28 (t = 13.493, P<0.01). Albumin increased significantly on d 16 (t = 6.68, P<0.01) to 1.02±0.15 μg/mL, and to 3.63±0.30 μg/mL on d 28 (t = 11.748, P<0.01). Urea (4.72±1.03 μmol/L) was detected on d 20 (t = 4.272, P<0.01), and continued to increase to 10.28±1.06 μmol/L on d 28 (t = 9.276, P<0.01). Cells expressed CK-18 on d 16. Glycogen storage was observed on d 24.

CONCLUSION: HUCB-derived MSCs can differentiate into hepatocytes by induction of FGF-4 and HGF. HUCB-derived MSCs are a new source of cell types for cell transplantation therapy of hepatic diseases.

Key words: Mesenchymal stem cell; Differentiation; Hepatocyte

INTRODUCTION

Cell transplantation therapy is an alternative to the treatment of liver conditions that sustain significant liver injury. It has been reported that bone marrow-derived MSCs can differentiate into mesoderm cells such as osteoblasts[1-3], adipocytes[4-6], neural and brain cells[7-10],cardiomyocytes[11-13] and hepatocytes[14,15] *in vivo* or *in vitro*. However, it has been demonstrated that the number and the differentiating potential of bone marrow MSCs decrease with age [16]. Therefore, search for alternative sources of MSCs is of significant value.

Studies have shown that human umbilical cord blood (HUCB) contains hematopoietic stem cells and MSCs, both of them can be used as alternative sources to bone marrow for cell transplantation therapy. Hematopoietic stem cells of HUCB have already been proven to be useful for the treatment of various hematological disorders. On the other hand, identification of the MSCs remained elusive until they were recently isolated as a homogeneous cell population by a number of different laboratories[17,18]. The extensive characterization of these cells has revealed

that they are similar to bone marrow-derived MSCs not only with respect to cellular properties and multi-lineage differentiation potential, but also with respect to their molecular context[19,20]. It was reported that HUCB-derived MSCs could differentiate into mesoderm cells such as osteoblasts, adipocytes[21], neuron-like cells[19, 22], and cardiomyocytes[23, 24]. Schwartz *et al*[14]. and Kang *et al*[15]. reported that FGF-4 and HGF could induce differentiation of bone marrow MSCs into functional hepatocyte-like cells. We hypothesized that FGF-4 and HGF could also induce differentiation of HUCB-derived MSCs into functional hepatocyte-like cells.

Using a relatively simple method, namely gradient density centrifugation in combination with adherence, we isolated HUCB-derived MSCs and cultured them in plastic culture flasks by induction of FGF-4 and HGF.The results showed that HUCB-derived MSCs could differentiate into hepatocytes *in vitro*.

MATERIALS AND METHODS

Materials and reagents

Human cord blood was obtained from Department of Obstetrics and Gynecology, First Hospital of Xi' an Jiaotong University. Fetal bovine serum (FBS) was purchased from Hangzhou Sijiqing Biological Engineering Material Co.Ltd. Albumin RIA kit and alpha-fetoprotein RIA kit were purchased from Beijing Atom High-tech Co.Ltd. Mouse anti-human monoclonal antibody cytokeratin 18(CK-18) was purchased from Chemicon Company. Iscove modified Dulbecco medium (IMDM) was purchased from GIBCO. Acid fibroblast growth factor-4 (FGF-4) and hepatocyte growth factor (HGF) were purchased from R&D Systems, Inc. Ficoll-Paque (1.077 g/mL) was pursed from Amersham-Pharmacia.

Isolation and culture of MSCs from HUCB

Ten mL of umbilical cord blood was taken from each patient (n = 49).The blood sample was diluted with an equal volume of D-Hanks. The diluted umbilical cord blood was layered over an equal volume of Ficoll-Paque (1.077g/mL). Mononuclear cells (MNCs) were recovered from the gradient interface and washed twice with D-Hanks after centrifugation at 800r/min for 20 min. The MNCs were suspended in 5 mL IMDM supplemented with 100 mL/L FBS, 100 U/mL penicillin, 100 U/mL streptomycin, at last plated in 25 cm^2 plastic cell culture flasks at the density of 10^6 /mL. The cells were maintained at 37 ℃ in 50 mL/L CO_2 in fully humidified air. The medium was changed for the first time on d 5 and then changed every 4 d. Because of limited time, 27 blood samples were treated within 3 h, 22 samples within 3-6 h, 8 samples within 6-12 h, and 2 samples after 12 h.

Hepatocyte differentiation

The cultured cells were harvested from the culture bottles with 0.25g/L trypsin. Cultured cells at passage 3 were seeded in six- well cell culture clusters. When the cells grew at 70% confluence, the control group was continuously cultured in IMDM supplemented with 10 mL/L FBS, 100 U/mL penicillin, 100 U/mL streptomycin. The hepatocyte differentiation group was cultured in IMDM supplemented with 10 ml/L FBS, 20 ng/mL HGF, 10 ng/mL FGF-4,100 U/mL penicillin and 100 U/mL streptomycin. Each well was added 2 mL of the medium, and changed every 4 d. The medium was stored at -20 ℃ for albumin, alpha-fetoprotein (AFP) and urea assay.

Radioimmunoassay

Concentrations of AFP and albumin in the changed medium were determined by radioimmunoassay on d 4, 8, 12, 16, 20, 24, and 28. Since there might be a very small amount of AFP and albumin in the changed medium, the medium was condensed 5 times by freeze drying before radioimmunoassay.

Urea assay

Cell culture media at the indicated time points after the induction of hepatogenic differentiation were collected, analyzed for urea as previously described by Buga *et al*[25]. and optical densities were measured at 492 nm using a spectrophotometer. The control group was used as a negative control, which was cultured in IMDM supplemented with 10 mL/L FBS, 100 U/mL penicillin and 100 U/mL streptomycin.

Immunocytochemistry

A slide was put in each well. Cells on the slides were fixed with 4% paraformaldehyde at 20 ℃ for 10 min and permeabilized with 0.3% Triton X-100 in PBS for 10 min. Cells were incubated with 3 mL/L hydrogen peroxide in methanol for 10 min to block endogeneous peroxidase activity and then washed twice in PBS for 5 min. Nonspecific binding sites were blocked with 3 mL/L normal goat serum. Cells were incubated overnight at 4 ℃ with primary antibody (mouse anti-human monoclonal antibody of CK-18, 1:200). After washed twice for 15 min in PBS, slides were incubated at 37 ℃ for 30 min with secondary antibody (goat anti -mouse IgG marked by biotin), with streptoavidin marked by horseradish peroxidase, and then developed color with DAB, 0.01 mol/L PBS was substituted for primary antibody as the negative control. The positive cells presented as brownish yellow.

Periodic acid-Schiff treatment for glycogen

In the hepatocyte differentiation group, on d 16, 20, 24, and 28, we took out the medium from the flasks, rinsed cells 3 times with PBS , fixed them with 100 mL/L formaldehyde for 30 min. The cells were oxidized in 10 g/L periodic acid for 10 min and rinsed three times in dH_2O. Then, the cells were treated with Schiff's reagent for 10 min, rinsed in dH_2O for 10 min, stained with hematoxylin for 2 min, differentiated by 1% alcohol/ HCL, rinsed in dH_2O again and observed under an invert

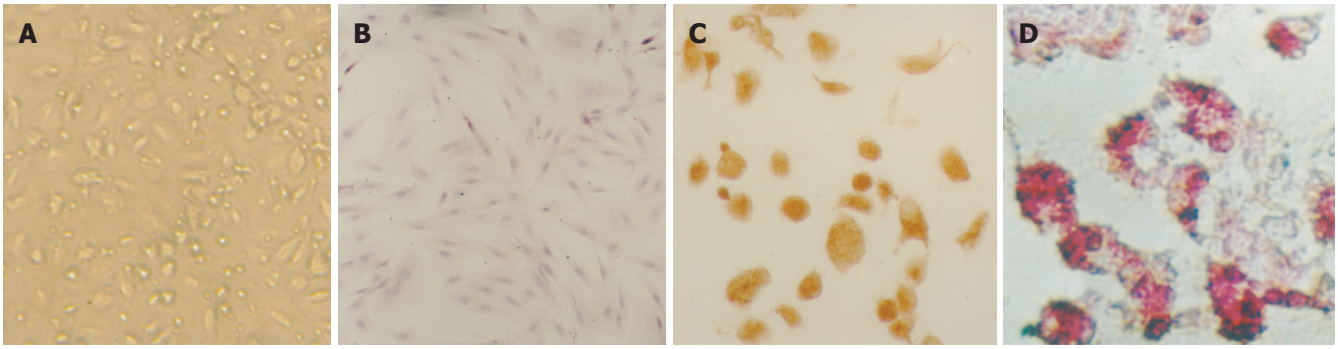

Figure 1 Different morphology and differentiation of HUCB-derived MSCs. **A**: morphology of primary cultured HUCB-derived MSCs. MSCs are spindle-like and osteroclasts are big and round; **B**: morphology of sub-cultured HUCB-derived MSCs stained with HE. The fibroblast-like cells are growing as a whirlpool (×100); **C**: representative immuocytochemistry showing expression of CK-18 on HUCB-derived MSCs on d 28 (SABC×200); **D**: cells stained by PAS. Glycogen storage is seen as accumulated magenta staining, the round and epithelioid cells show magenta staining in the region (×400).

microscope.

Statistical analysis

The data of AFP, albumin and urea were expressed as mean±SE. The statistical software SPSS12.0 was used. The results were analyzed by t-test. P<0.05 was considered statistically significant.

RESULTS

Isolation and culture of MSCs from HUCB

The cells isolated by gradient density centrifugation showed heterogeneity during the first five days. Adherent cells were observed on d 9-12. Spindle-shape cells appeared at the bottom of culture flasks. In addition, some big and round osteroclasts were observed among the spindle-like cells. Many round cells were suspended in the medium (Figure 1A). By changing the medium, the suspending cells became less and less. After the medium was changed twice, the suspending cells were completely removed from the medium, but osteroclasts still existed in the cells. The adhered cells were fibroblast-like and grew as a whirlpool. The sub-cultured cells were much pure and fibroblast-like, the osteroclasts disappeared (Figure 1B). The primary culture cells reached confluence 10-12 d later, the cells sub-cultured at a ratio of 1:3 reached confluence 8-10 d later. Using the method, we isolated HUCB-derived MSCs from 10 samples of 39, which were isolated within 6 h. The rate of separation was 25.6%. MSCs could not be isolated from the other sample.

MSCs became small, round and epithelioid cells after cultured with FGF-4 and HGF

When the cultured cells reached 70% confluence, they were treated with hepatocyte differentiation medium, containing IMDM supplemented with 10 mL/L FBS, 20 ng/mL HGF, 10 ng/mL FGF-4, 100 U/mL penicillin and 100 U/mL streptomycin. Before the 8-d treatment they did not show any change compared to the controls. After treatment, small round cells appeared in the treatment group, epithelioid cells were also observed. The diameter of the cells was 12-16 μm. On d 28, approximately 63.6% of the cells were small, round and epithelioid. The control cells were still fibroblast-like, the density of the cells increased. The cells were overlapped in some regions.

Radioimmunoassay

By radioimmunoassay, albumin and AFP production was measured at various time points throughout the differentiating process. We could detect low levels of AFP on undifferentiated HUCB-derived MSCs, but not of albumin. However, there was a small amount of albumin in the medium, which was hardly detected by

albumin RIA. Compared to controls, the levels of AFP increased significantly from d 12 with a concentration of 18.20±1.16 μg/L ($P<0.05$) in MSCs cultured with FGF-4, and HGF continued to increase and was higher on d 28 ($P<0.01$) with a concentration of 54.28±3.11 μg/L. The level of albumin could not be detected by radioimmunoassay before d 12, albumin increased significantly on d 16 with a concentration of 1.02±0.15 μg/mL ($P<0.01$), and to 3.63±0.30 μg/mL on d 28 ($P<0.01$). According to the data, increasing time points were different between AFP and albumin (Table 1).

Urea assay

Urea production and secretion by hepatocytes were detected at various time points throughout the differentiating process. Following treatment with FGF-4 and HGF, urea produced by MSCs was detected with a concentration of 4.72±1.03 μmol/L on d 20, and increased to 10.28±1.06 μmol/L on d 28 (Table 1).

Immunocytochemistry

On d 8, 16, 24, and 28, we took out the cells on the slides respectively. The cells expressed CK-18 on d 16 (Figure 1C). The control group was negative.

Periodic acid-Schiff treatment for glycogen

We analyzed the levels of glycogen storage by periodic acid-Schiff (PAS) staining of FGF-4 and HGF-induced MSCs on d 20, 24, and 28. Glycogen storage was seen on d 24, being positively stained for PAS (Figure 1D).

DISCUSSION

There are many hematopoietic stem cells and MSCs in HUCB. Many methods can isolate MSCs from HUCB[26-28]. In this study, we used the Ficoll (1.077 g/mL) to isolate MSCs from HUCB, we combined the gradient density centrifugation with plastic adherence and changed the medium many times to purify MSCs after gradient density centrifugation. This method is relatively simply, and can easily get pure MSCs. We isolated MSCs from 10 of 39 samples, which is in accordance with the previous study[28]. MSCs should be isolated from the sample as soon as possible. Our results showed that it was difficult to isolate MSCs from the samples, because the activity of MSCs is low, even loses with time prolonged.

During the 28 d of differentiation, FGF-4 and HGF induced MSCs into cells with morphological and functional characteristics of hepatocytes. In our study, the cells that differentiated into hepatocyte-like cells could produce urea, secrete albumin, AFP and Ck-18, and store glycogens. Urea production was characterized by hepatocyte activity, although kidney tubular epithelium also produced urea. In contrast, albumin, AFP and Ck-18 production is a specific test for the presence and metabolic activity of hepatocytes. Only hepatocytes can generate and store glycogens. In our research, we found that AFP could be detected throughout the differentiating process because the medium contained a low level of AFP. From d 12, the level of AFP increased significantly compared to controls, suggesting that MSCs can secrete AFP. It was reported that AFP is produced by immature hepatocytes. That is to say, hepatocytes are immature on d 12. Before d 12, the concentration of albumin could not be measured by radioimmunoassay because the amount of albumin was small in the medium. When MSCs differentiated, albumin was significantly secreted by MSCs from d 16, CK-18 was expressed by cells from d 16, and urea was significantly secreted from d 20. By periodic acid-Schiff (PAS) staining, the differentiated cells could store glycogens. The data suggest that HUCB-derived MSCs can differentiate into hepatocytes by induction of FGF-4 and HGF.

HGF was first identified as a blood-derived mitogen for hepatocytes. HGF and its receptor c-Met are the key factors for liver growth and function. After cultured with only HGF, adult human bone marrow MSCs could also differentiate into hepatocytes *in vitro*[29]. FGF-4 is mitogenic for fibroblasts and endothelial cells. Mouse embryonic stem cells grown in medium supplemented with FGF-4 could differentiate into cells expressing hepatocyte-specific genes and antigens[30]. By cooperation of HGF and FGF, the differentiation of MSCs could be triggered and MSCs could develop into hepatocytes.

Our experimental data showed the hepatic differentiation potential of HUCB-derived MSCs. HUCB-derived MSCs have more advantages over bone marrow MSCs. It is suggested that HUCB-derived MSCs are a source of cell types for cell transplantation therapy of liver diseases.

Abstract

AIM: To investigate the influence of fish oil enriched enteral diet on intestinal tissues taken from Crohn's disease (CD), ulcerative colitis (UC) and non-inflamed non-IBD control patients *in vitro*.

METHODS: Colonoscopic biopsies from patients with active CD (n = 4), active UC (n = 7), and non-inflamed non-IBD control patients (n = 4) were incubated (three dilutions of 1:20, 1:10, and 1:5) with Waymouth's culture medium and enteral elemental diet (EO28, SHS, Liverpool, UK) modified in the fatty acid composition with fish oil (EF) in an organ culture system for 24 h. In each experimental set-up, incubation with Waymouth's medium alone as control was included. Tissue viability was assessed by adding bromodeoxyuridine (BrdU) to the culture fluid and immunohistochemically staining for BrdU uptake. Cytokine ratio of IL-1ra/IL-1β (low ratio indicative of inflammation) and production of those cytokines as a percentage of medium control were assayed in the culture supernatant.

RESULTS: Incubation of CD-affected tissue with EF (1:20, 1:10, and 1:5) modestly and non-significantly increased IL-1ra/IL-1β ratio as compared with medium control (CD 39.1±16.1; 26.5±7.8, 47.1±16.8 *vs* control 13.0±2.2), but incubation of UC-affected tissues increased IL-1ra/IL-1β ratio significantly in all three dilutions (UC 69.1±32.2, P<0.05; 76.1±36.4, P = 0.05; 84.5±37.3, P<0.02; *vs* control 10.2±3.7). Incubation of non-inflamed non-IBD control tissue did not increase the IL-1ra/IL-1β ratio in any dilution compared to medium control (69.3±47.0, 54.1±30.6, 79.4±34.0 *vs* control 76.1±37.3). Average percentage production of IL-1β indexed against medium control was significantly less in UC after EF incubation as compared with CD (UC 24.0±4.8 *vs* CD 51.8±8.1; P<0.05). Average percentage production of IL-1ra was markedly higher in UC (135.9±3.4) than that in control patients (36.5±4.3) (P<0.0001).

CONCLUSION: IBD tissues, after incubation with elemental diet modified in its fatty acid composition with fish oil, show an increase in IL-1ra /IL-1β cytokine ratio. This effect of ω-3 fatty acid modulation is significantly more marked in UC compared with CD and is accompanied by both a reduction of IL-1β and increase of IL-1ra. The positive direct anti-inflammatory effect of elemental diet with fish oil in tissue affected with UC suggests dietary treatment of UC may be possible.

INTRODUCTION

Enteral defined formula nutritional therapy is currently an option only in Crohn's disease (CD), and this may result in an improvement in clinical inflammatory parameters[1], histological appearance[2], and disease activity[3]. Hypotheses about how elemental diet might work include withdrawal of food antigens, decrease and alteration in luminal bacteria, reduction in pancreatic and biliary secretion, bowel rest (or medical bypass), alteration of dietary lipids and improvement in nutritional status[3]. Increased production of IL-1β during active inflammatory bowel disease (IBD)[4] and an imbalance of IL-1β and its receptor antagonist (IL-1ra) are now well-known features of IBD[5-7], and ratio of anti-inflammatory to pro-inflammatory cytokines IL-1ra/IL-1β may be used as an index of inflammatory status. The possible influence and modulation of cytokine balance by dietary fatty acids are of interest and might have clinical implication[8,9].

The main fatty acids of fish oil are the long-chain-polyunsaturated fatty acids (FA) of eicosapentaenoic acid

(EPA, C20:5 ω-3) and docosahexaenoic acid (DHA, C20:6 ω-3). The use of these FA in inflammatory conditions has been explored in other inflammatory disorders, such as rheumatoid arthritis[10,11] and inflammatory skin disorders[12,13]. In IBD, especially in ulcerative colitis (UC), treatment with fish oil preparations may have a better impact than in CD, though this is still controversial. Studies have shown a decrease in clinical activity and some morphological improvements in UC but no change was observed in CD after 7-mo treatment with 3.2 g of ω-3 FA per day in active IBD[14]. Stenson *et al*[15]. reported the effect of oral fish oil treatment in UC in a double-blind placebo controlled crossover trial of 18 patients. Fish oil supplementation resulted in a significant decrease in rectal dialysate of LTB_4, and significant improvement in the histological appearance of the colon. Furthermore, they reported a significant increase in body weight, averaging 1.74 kg, as compared to controls who had no change in body weight[15]. Clinical improvement in 11 patients with mild to moderate UC after ingestion of ω-3 FA was reported by Aslan and Triadafilopoulos[16]. Six months of supplementation with ω-3 FA in patients with proctocolitis resulted in a significant improvement in sigmoidoscopic and histologic appearance in the distal colon. Blood analysis showed a decreased natural killer (NK) cell activity and markedly reduced LTB_4 serum levels, which correlated with a decrease in IL-2[17,18]. In contrast, Hawthorne *et al*[19]. reported only limited clinical benefit despite increased synthesis of LTB_5 and suppression of LTB_4 in ω-3-supplemented UC patients.

These studies, although controversial and differing in the delivery system and dose, demonstrate that dietary modulation via FA, especially of ω-3 and ω-6, can modulate and influence the inflammatory mediator production and response in IBD.

A theoretical advantage of dietary intake of ω-3 FA is that these FA do not have to go through the processes of elongation and saturation, and can therefore be immediately incorporated into the plasma membrane.

The aim of this study was to investigate the direct effect of fish oil containing enteral diet *in vitro* on cytokine response of IL-1ra/IL-1β ratio and on cytokine production as a percentage of medium control in tissue affected with CD, UC, and non-inflamed non-IBD control patients. Such *in vitro* experiments, though reductionist may provide indirect evidence of the alteration in inflammatory profile after the ingestion of defined formulae diet, which rapidly changes tissue levels of nutrients. In CD, it is clear that local effect cannot explain the benefit of such therapy in distal ileum and colon as most of elemental diet is absorbed in proximal small intestine. We specifically aimed to explore whether such modification of enteral diet used in CD might show evidence of efficacy in UC.

MATERIALS AND METHODS

Subjects

Fifteen patients were included in this study. Four patients with CD (mean age 41±14 years), seven patients with UC (mean age 56±6 years) and four patients as non-inflamed non-IBD control group (mean age 36±9 years). The latter group included patients with a final diagnosis of irritable bowel syndrome. The patients attended routine colonoscopy and gave consent to obtain additional biopsies along with the biopsies taken for clinical management. Ethical approval was obtained from Research Ethics Committee.

Biopsies were taken from the following anatomic areas: in CD (2 sigmoid, 1 rectum, 1 ileocolonic anastomosis), UC (5 sigmoid, 2 rectum) and control group (4 sigmoid). Disease duration for IBD patients was as follows: (1) 1-3 years (1 CD, 2 UC); (2) 4-6 years (1 CD, 1 UC); and (3) >6 years (2 CD, 4 UC). Medications at the time of biopsy were (1) in CD with azathioprine (n = 2), steroids and azathioprine (n = 1), steroids and 5-ASA (n = 1) and (2) in UC with steroids (n = 1), azathioprine (n = 1), 5-ASA (n = 3).

The biopsies in IBD patients were taken from macroscopically affected areas but avoiding frankly ulcerated areas, and histologically confirmed active inflammation and the diagnosis of IBD. The biopsies in control patients showed no evidence of inflammation. All biopsies were taken with identical biopsy forceps by the same surgeon (SG) to ensure uniform size of the biopsies.

Methods

Biopsies obtained from endoscopy were incubated for 24 h with elemental diet EO28 (SHS, Liverpool, UK), specially modified in its FA composition for fish oil (EF), as previously described[20]. Tables 1 and 2 show the details of diet composition regarding general composition of diet and FA profile, respectively. Briefly, enteral diet was diluted in distilled water in three dilutions of 1:5, 1:10, and 1:20 with Waymouth's medium (MB752/1, Flow-labs 12-52-54). The medium was supplemented with 100 mL/L heat-inactivated fetal calf serum (Ako Tech), 200 mmol/mL L-glutamine (Gibco 43-8030), 300 μg/mL ascorbic acid (Sigma A 4544), 0.45 μg/mL ferrous sulfate (Sigma F 8633), 50 μg/mL gentamycin (Flow-labs 16-760-45), 5 000 IU/mL penicillin and 5 000 μg/mL streptomycin (Flow-labs 16-700-49).

From each patient, one biopsy was always incubated with only medium as control. Tissue viability over culture period was confirmed by adding 10 μL/mL BrdU (Sigma B5002) to the culture fluid. After the culture period, supernatant was stored and frozen at -70 °C for immunoassay and tissue was processed for BrdU immunohistochemistry and validated as described previously[20,21]. All explants were examined in a blinded fashion under a light microscope (100× and 250×). The explants were considered viable only if the morphology of the tissue was considered intact with well-defined crypts, epithelial surface and adequate and strong uptake of BrdU with labeled cells in horizontal and vertical crypts. Formal scoring to determine labeling index was not performed as the focus of this study was not on colonic epithelial proliferation.

Cytokine assay for IL-1ra and IL-1β

After 24 h incubation, IL-1ra and IL-1β were measured in culture supernatants by ELISA using matched antibody pairs (R&D Systems, UK) as previously described[20]. Capture antibody was supplied by R&D Systems (IL-1ra MAB280, IL-1β MAB601, R&D Systems). Standard proteins for IL-1ra (280-RA-010) and for IL-1β (201-LB-005) were also supplied by R&D Systems. Biotinylated detection antibodies, IL-1ra (BAF280) and IL-1β (BAF201), were purchased from R&D Systems. Streptavidin-horse-radish peroxidase conjugate (Zymed Laboratories, UK) and substrate TMB (R&D Systems) were used for IL-1ra and OPD substrate for IL-1β. Plates were read at 450 nm for IL-1ra, and at 490 nm for IL-1β.

Preliminary experiments showed that cytokine recoveries after incubation in defined formula diet for both IL-1ra and IL-1β were satisfactory. Formula diet spiked at low concentration (100 pg/mL) showed that more than 50% of IL-1ra cytokine was detected over the entire 24-h incubation period and that in diet spiked with IL-1ra at high concentration (1 000 pg/mL), a steady decrease of detectable cytokine was measured from 100% recovery at 0 h to 52% after 24 h.

Defined formula diet spiked with IL-1β at low concentration (10 pg/mL) showed that IL-1β was 100% detectable at all time points (0, 3, 6, and 24 h), and at a high concentration (100 pg/mL), 100% recovery at time points 0, 3, and 6 h but only 60% at 24 h.

As IL-1ra and IL-1β were continually secreted into the supernatant, the actual recovery in these experiments is likely to be higher than the recovery 24 h after spiking with cytokines. Standard curves in EF diet for IL-1ra and IL-1β showed no evidence of interference with the ELISA as compared with curves performed with medium alone, which again confirmed the reproducibility of the obtained data.

Statistical analysis

Statistics was performed using the Minitab 10 program. Mann-Whitney test and one-way analysis of variance (ANOVA) were performed to detect differences between diet incubations. Differences were considered significant at $P<0.05$. Data for IL-1ra/IL-1β ratio were compared with medium control, if not otherwise stated and presented as mean values and standard error of the mean (SEM). The numbers were too low to perform any subgroup analysis depending on the duration of disease or concurrent medications.

RESULTS

A total of 59 biopsies were included in the final analysis as follows: (1) CD medium ($n = 4$), EF diet ($n = 12$); (2) UC medium ($n = 6$), EF diet ($n = 21$); and (3) control patients' medium ($n = 4$), EF diets ($n = 12$). All the explants fulfilled the criteria of intact morphology and BrdU uptake in order to be included in this final analysis. BrdU-labeled cells occurred in vertical crypts at the base of the crypts and along the sides of the crypts and intact epithelium.

Cytokine response determined by IL-1ra/IL-1β ratio

IL-1ra/IL-1β ratio is indicative of the inflammatory status of the tissue and is independent of the tissue weight. We have reported this ratio previously in organ culture of

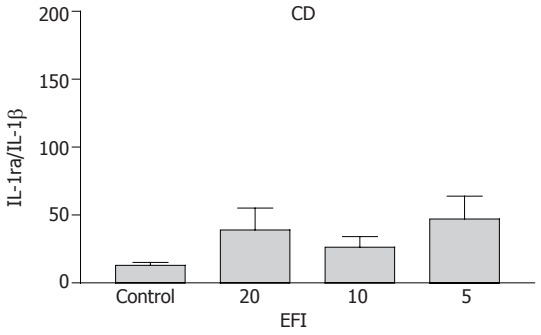

Figure 1 IL-1ra/IL-1β ratio in CD patients after incubation with elemental diet fish oil (EFI).

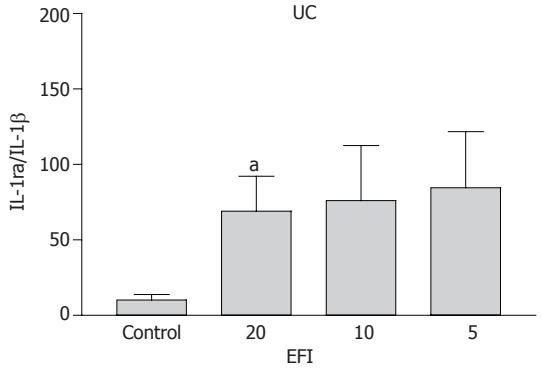

Figure 2 IL-1ra/IL-1β ratio in UC patients after incubation with elemental diet fish oil (EFI). [a]*P*<0.05 *vs* control; *P* = 0.05 (1:10 dilutions of EFI); *P*<0.02 (1:5 dilutions of EFI).

IBD-affected tissue as sensitive to changes after incubation with defined formula diets of different compositions[20]. As the tissue is inflamed, the ratio tends to decrease and vice versa.

Crohn's disease A trend towards an increase in IL-1ra/IL-1β ratio was observed for 1:20, 1:10, and 1:5 dilutions of EFI (39.1±16.1; 26.5±7.8; 47.1±16.8 *vs* medium control 13.0±2.2), respectively, but this did not reach statistical significance (Figure 1).

Ulcerative colitis A significant increase in IL-1ra/IL-1β ratio for 1:20, 1:10, and 1:5 dilutions of EFI (69.1±32.2, *P*<0.05; 76.1±36.4, *P* = 0.05; 84.5±37.3, *P*<0.02 *vs* medium control 10.2±3.7) was noted (Figure 2). The ratio was similar in CD and UC patients for medium control alone and significantly lower than non-inflamed non-IBD control patients (shown below), confirming the inflammatory status of these tissues.

Control patients No increase in the IL-1ra/IL-1β ratio was detectable for 1:20, 1:10, 1:5 dilutions of EFI (69.3±47.0; 54.1±30.6; 79.4±34.0 *vs* 76.1±37.3). This is mainly due to the fact that the ratio in the medium control was high (as expected in non-inflamed tissues) and this did not increase any further with EF incubation.

Cytokine response of IL-1β and IL-1ra as percentage of medium control

Interleukin-1β Percentage production of IL-1β in UC (as a proportion of medium control) was lower at all the three dilutions as compared with CD and this reached statistical significance for 1:20 dilution (UC 32.6±9.8% *vs* CD 62.1±19.1%; *P* = 0.02). The average production (in all three dilutions of EF) of IL-1β was significantly more suppressed in UC than that in CD (24.0±4.8% *vs* 51.8±8.1%; *P*<0.05). In UC patients, the decrease in production of IL-1β was also significant as compared with control patients at 1:20 dilution (32.6±9.8% *vs* 117.3±87.3%; *P* = 0.02). In control patients, there was a little suppression of IL-1β after incubation with EF except at the highest concentration of 1:5 (Figure 3).

Interleukin1-receptor antagonist In UC patients, secretion of IL-1ra (as percentage of medium control) tends to be higher when compared with CD patients at 1:10 and 1:5 dilutions (UC 142.3±33.2% and 130.5±50.3% *vs* CD 104.9±13.2% and 70.1±35.9%), respectively. Compared with control patient, secretion of IL-1ra was increased for 1:20, 1:10, and 1:5 dilutions of EF [UC (134.9±66.1%; 142.3±33.2%; 130.5±50.3%) *vs* control (44.1±16.2%; 29.4±13.2%; 35.9±10.1%)], respectively, and average production of IL-1ra for all dilutions was significantly increased (UC 135.9±3.4% *vs* controls 36.5±4.3%; *P*<0.0001).

In CD patients, there was an increase in IL-1ra secretion (as percentage of medium control) at all three dilutions as compared with control patients (in whom IL-1ra decreased) (CD 146.3±45.6%; 104.9±13.2%; 70.1±35.9%; control 44.1±16.2%; 29.4±13.2%; 35.9±10.1%), reaching significance at 1:10 dilution (*P* = 0.03). The average increase in IL-1ra in CD patients for all three dilutions was significant *vs* control patients (CD 107.1±22.0% *vs* 36.5±4.3%; *P* = 0.03).

In control patients, IL-1ra production tends to decrease after incubation with EF as a proportion of medium control, unlike CD and UC (Figure 4).

DISCUSSION

Fish oil preparations in the form of gelatin-coated fish oil capsules have been used to treat UC in several studies. Hawthorne *et al*[16,19]. Stenson *et al*[15]. and Loeschke *et al*[22]. investigated (in placebo-controlled trials) the influence of ω-3 FA, EPA and DHA derived from fish oil on prostaglandin and leukotriene synthesis in patients with UC. These studies illustrated that treatment with fish oil led to a corticosteroid sparing effect and a reduction in LTB_4 measured in colonic mucosa, rectal dialysate and suppression in synthesis of LTB_4 in peripheral blood neutrophils[15,16,19]. Contrary to these studies, we investigated, in the *in vitro* organ culture model, the direct influence of fish oil containing enteral diet (EFI) on pro- and anti-inflammatory cytokine production assayed in the culture supernatant. We found a significant increase in IL-1ra/IL-1β ratio in UC patients as compared with medium control as a result of enteral diet-fish oil incubation. This increase was not found in non-inflamed non-IBD control patients and was less marked in CD patients. This might be as a result of an increased production of IL-1ra and decreased pro-

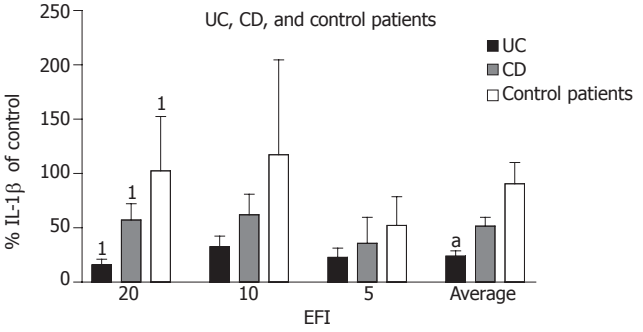

Figure 3 Percentage production of IL-1β of medium control in UC, CD, and non-inflamed non-IBD patients after incubation with EFI. [1]*P* = 0.02, UC *vs* CD and UC *vs* control patients (1:20 dilution of EFI); [a]*P*<0.05, UC *vs* CD (average of all dilutions).

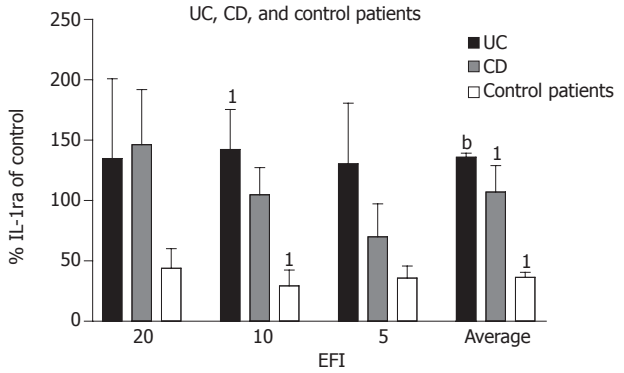

Figure 4 Percentage production IL-1ra of medium control in UC, CD, and controls (non-inflamed non-IBD patients) after incubation with EFI. [1]*P* = 0.03, CD *vs* control patients (1:10) and CD *vs* control patients (average of three dilutions); [b]*P*<0.0001, UC *vs* control patients (average of all dilutions).

duction of IL-1β. Average percentage of IL-1ra release in UC patients was higher than in CD and significantly higher compared with control patients after the incubation with EF. The percentage of IL-1β production of medium control showed, in all three dilutions of EF, a more marked decrease in UC compared with CD and control patients. In this model of intestinal tissue incubation for 24 h period, it would appear that enteral diets containing ω-3 FA have a direct *in vivo* anti-inflammatory and immunomodulatory impact, especially in UC. It seems that fish oil not only increases IL-1ra production, but also inhibits the production of IL-1β. This modulation of cytokine response by fish oil containing defined formula diet EF in UC patients is possibly due to the modified fatty acid profile with increased ω-3 FA. This preferentially favors the production of prostaglandins and thromboxanes of series 3 and leukotrienes of series 5, with decreased pro-inflammatory properties.

Mahida *et al*[23]. also used a similar organ culture model similar to that used by us in their study. Colonic biopsies of patients with UC were incubated with and without 5-aminosalicylic acid (5-ASA). Significantly higher IL-1β was detected in inflamed colonic biopsies compared to normal controls. After the incubation with 5-ASA, there was a significant dose-dependent decrease of IL-1β production as a percentage of controls. It also showed a significant correlation of IL-1β and TXB_2 synthesis in culture medium of inflamed tissue as compared with controls. A significant decrease in LTB_4 was found in inflamed tissue treated with 5-ASA. It is known that 5-ASA can inhibit the synthesis of PGE_2, LTB_4 and their products of the 5-lipoxygenase pathway. It is likely that these ω-3 FA affect the IL-1β synthesis either by altering the eicosanoid synthesis or by having a direct influence of FA on gene expression. The two major polyunsaturated fatty acids (PUFAs) in fish oil are EPA and DHA, which are also major PUFAs incorporated into the cell membrane. EPA is a substrate for eicosanoid production via cyclooxygenase pathway for PG_3 and lipoxygenase pathway for TX_3, both known as having less inflammatory properties. Watanabe *et al*[24]. showed that in LPS stimulated mice lymphocytes, where mice had been fed with beef tallow, the two fish oil FA, DHA and EPA, produced different IL-1β mRNA expression. Decreased production of IL-1β mRNA after EPA and DHA was significant in DHA *vs* tallow and slightly lower in EPA as compared with DHA. Production of PGE_2 was significantly decreased in EPA and DHA, though DHA is not a precursor for eicosanoids[25]. As IL-1β mRNA response differed between EPA and DHA, though the PGE_2 production was similar, it seems that the balance of EPA/DHA in cellular lipids might be important in affecting intracellular signaling through modifications of specific gene transcription[24]. FA in the cell are bound on fatty acid binding proteins (FABP), which exist in the cytosol and nucleus, in the form of fatty acid acyl-CoA (FA-CoA). The nuclear receptors peroxisome proliferator-activated receptors (PPARs) occur in three identified subtypes of α, β, and γ, which are regulated by FA. It is likely that some FA or their metabolites may act as hormones to control specific transcription factors. For example, PPARα is required for fish oil-mediated induction of $mRNA_{AOX}$ (mRNA - acyl-CoA oxidase). Nuclear transcription factor, NFκB, is required in genes, which are involved in pro-inflammatory responses, such as cyclooxygenase 2 and cytokines IL-1β and TNF-α. The effect of ω-3 FA might be attributed to the PPARα activation and the regulation of NFκB-mediated transcription[26]. As incubation with fish oil resulted in marked and divergent anti- and pro-inflammatory cytokine response, it is possible that ω-3 PUFA result in different cytokine production in various cell types[24]. It may also reflect a different response in IBD subtypes, as IL-1ra/IL-1β was not significantly increased in CD after incubation with EF. Furthermore, as EPA and DHA act differently in eicosanoid and IL-1β production, both of these ω-3 FA in fish oil may contribute to the anti-inflammatory effect of fish oil.

Biopsies incubated with EF, as a major source of ω-3 FA in the present study, have shown a significant positive response towards an anti-inflammatory effect only in UC. In the current literature, the immunomodulatory properties of fish oil manifests as a decrease of LTB_4 or increased synthesis of LTB_5[16,27]; however, a change in IL-1β mRNA expression after LPS stimulation in mouse spleen lymphocytes has also been reported[24]. The actual increase

in IL-1ra/IL-1β ratio could be interpreted as a reaction of eicosanoid-modulated cytokine production through G proteins and/or FA-modulated gene transcription via transcription factor. Which of these factors may have the predominant impact on immunomodulatory properties of fish oil is not defined as yet. Several studies have demonstrated that DHA might be superior as compared with EPA in immunomodulatory activity[24,28]. This suggests that the effects of fish oil might be a response of FA-induced gene transcription, as eicosanoids are derivatives of dihomo-γ-linolenic acid (DLGA, 20:3 ω-6), arachidonic acid (AA C20:4 ω-6) and eicosapentaenoic acid (EPA C20:5 ω-3)[25] and not of docosahexaenoic acid (DHA C22:6 ω-3).

In this study, the results of the supernatant cytokine concentration were presented predominantly as a ratio of anti-inflammatory to pro-inflammatory cytokine (IL-1ra:IL-1β) as this was independent of the weights of the biopsies. The cytokine concentrations were not indexed against the protein or DNA content of the biopsies as the biopsies were processed for the uptake of BrdU and determination of tissue viability after 24 h incubation. The ratio of cytokines, which is independent of the explant weights, has been used in our previous publication on the effect of elemental diet alone[20]. Each individual set of biopsies from one patient was simultaneously put in organ culture at the different dilutions of EI as well as a medium control, within 10 min of collection of the biopsies. All biopsies in this study were taken with identical biopsy forceps by the same surgeon, and therefore were uniform in size. This enabled representation of the results of EF incubation as a proportion of the cytokine concentration produced by incubation in medium control alone without any added defined formula diet. The results of the changes in cytokine ratios were consistent with the changes in individual cytokines indexed as a proportion of the medium control incubation. All explants included in the analysis were considered viable by morphology and BrdU uptake.

We have previously reported on the results of incubation of IBD (CD and UC) affected explants with elemental diet (EO-28) as well as modified elemental diet with altered nitrogen source (casein and whey). These experiments were identical in design to the present study and showed direct anti-inflammatory effect of elemental diet on CD but not UC-affected tissues. This anti-inflammatory effect was manifested by a rise in IL-1ra/IL-1β ratio, and persisted when elemental diet was modified with casein and whey. In this study, we have showed that when elemental diet was modified by fish oil, but the rest of its composition including amino acids were kept unaltered, the anti-inflammatory effect could be observed on UC-affected tissues. It is striking that by modifying the composition of elemental diet, the anti-inflammatory effect could be made to be more pronounced in CD (conventional EO-28) or in UC patients (fish oil modified EO-28). This raises the possibility that such modifications could provide the option of nutritional therapy for UC patients, and again illustrates the difference between CD and UC patients in nutritional modulation and immunology.

The *in vitro* model is reductionist and local delivery of fish oil could be a problem by the oral delivery of fish oil modified enteral diet. Rectal delivery or enteric coated preparations would be necessary. Systemic effects of oral delivery are also possible and almost certainly mediate part of the beneficial effects of elemental diet especially on terminal ileum and colon. Nevertheless, these experiments suggest that enteral defined formula diet may have direct anti-inflammatory effects, and the composition may determine whether it is effective in CD or UC patients. Absorption after oral administration will alter the nutrient milieu of cells and possibly their inflammatory response.

In conclusion, we have shown a positive anti-inflammatory effect on tissues incubated with enteral diets modified with fish oil, which is significant only in UC, but much more modest in CD. This study provides a rationale for exploring dietary therapies for UC patients.

ACKNOWLEDGMENTS

We thank SHS, Liverpool UK for supplying us with the specially prepared enteral diet modification and MC Aldhous for technical assistance.

Abstract

AIM: To evaluate the surface expression of triggering receptor on myeloid cell 1 (TREM-1), class II major histocompatibility complex molecules (HLA-DR), and the expression of the splicing variant (svTREM-1) of TREM-1 in septic patients and those subjected to major abdominal surgery.

METHODS: Using flow cytometry, we examined the surface expression of TREM-1 and HLA-DR in peripheral blood monocytes from 11 septic patients, 7 elective gastrointestinal surgical patients, and 10 healthy volunteers. svTREM-1 levels were analyzed by RT-PCR.

RESULTS: Basal expression of TREM-1 and HLA-DR in healthy volunteers was 35.91±14.75 MFI and 75.8±18.3%, respectively. In septic patients, TREM-1 expression was 59.9±23.9 MFI and HLA-DR expression was 44.39±20.25%, with a significant difference between healthy and septic groups (P<0.05) for both molecules. In the surgical patients, TREM-1 and HLA-DR expressions were 56.8±20.85 MFI and 71±13.8% before surgery and 72.65±29.92 MFI and 72.82±22.55% after surgery. TREM-1 expression was significantly different (P = 0.0087) between the samples before and after surgery and svTREM-1 expression was 0.8590± 0.1451 MF1, 0.8820±0.1460 MF1, and 2.210±0.7873 MF1 in the healthy, surgical (after surgery) and septic groups, respectively. There was a significant difference (P = 0.048) in svTREM-1 expression between the healthy and surgical groups and the septic group.

CONCLUSION: TREM-1 expression is increased during systemic inflammatory conditions such as sepsis and the postoperative phase. Simultaneous low expression of HLA-DR molecules correlates with the severity of illness and increases susceptibility to infection. Additionally, TREM-1 expression is distinctly different in surgical patients at different stages of the inflammatory response before and after surgery. Thus, surface TREM-1 appears to be an endogenous signal during the course of the inflammatory response. svTREM-1 expression is significantly increased during sepsis, appearing to be an indicator of severity of illness. Together, these data indicate that TREM-1 may play an important role in establishing and amplifying the systemic inflammatory response. TREM-1, HLA-DR, and svTREM-1 expression analysis can provide useful diagnostic and prognostic indicators during SIRS, CARS, and sepsis.

Key words: TREM-1; HLA-DR; SIRS; CARS; Sepsis

INTRODUCTION

Inflammation constitutes the initial and essential response of the host against infection and injury. In the presence of infection, inflammation is triggered through the recognition of microorganism-associated molecular structures by Toll-like receptors (TLRs)[1,2], which are expressed in a nonclonal manner on the surface of innate immune cells such as monocytes, macrophages, and dendritic cells[3,4]. This interaction leads to the activation of nuclear factor κB (NF-κB) and to the release of pro-inflammatory (tumor necrosis factor α (TNF-α), interleukin (IL-12, IL-1, IL-6, IL-8, *etc.*) and anti-inflammatory (IL-10 and TGF-β) cytokines[3,5-7]. In the absence of infection, injuries such as trauma, burns, pancreatitis, and major surgery also induce an inflammatory response. In most cases, inflammation is a local response, but in some situations, it becomes a systemic phenomenon and leads to the development of systemic inflammatory response syndrome (SIRS), characterized by the massive release of pro-inflammatory mediators in the absence of infection[8-10]. On the other hand, the excessive release of anti-inflammatory mediators leads to the development of compensatory anti-inflammatory response syndrome (CARS)[8,11]. During this phase, patients frequently suffer from temporary impairment of immunological functions, which in its most severe form is referred to as immunoparalysis[8-10]. This diminished the ability to respond to stimuli is paralleled by a strong downregulation of MHC class II (mainly HLA-DR, invariant chain) expression on the surface of monocytes. Such monocytes produce only minor amounts of pro-inflammatory cytokines, as well as NO[12,13]. Very similar alterations of monocyte function exist with experimental endotoxin tolerance and in patients after trauma, burns, pancreatitis, and major surgery[10,14-17]. These alterations often predispose patients to life-threatening infections and to the development of sepsis. Furthermore, it has been reported that immunoparalysis correlates with the severity of sepsis and injury as well as the postoperative course[15,17-19].

However, progress has been made in sepsis research improving the knowledge of the basic pathophysiological processes of sepsis, in daily intensive care unit (ICU) practice, it remains difficult to adequately identify and treat sepsis and its related conditions[20]. In some cases, measurement of serum proteins such as interleukin 6 (IL-6) has been demonstrated to be useful in evaluating the severity and in predicting the outcome for patients with SIRS/sepsis, but not in CARS and susceptibility to infection[21,22]. Therefore, it is essential to search for and identify endogenous mediators of inflammatory response suitable for use as early indicators of infection in cases of sepsis and as prognostic indicators during SIRS and CARS[20,23-27].

TREM-1 is an activating receptor of the Ig superfamily exclusively expressed on blood neutrophils and monocytes[28]. Expression of TREM-1 on these cells is induced by TLR ligands such as lipopolysaccharide and lipoteichoic acid[29]. Though its natural ligand has not been identified, engagement of TREM-1 on monocytes with agonist monoclonal antibodies results in the production of pro-inflammatory cytokines (TNF-α and IL-1β) as well as chemokines such as IL-8 and monocyte chemoattractant protein-1. When monocytes are stimulated with lipopolysaccharide, leading to a pro-inflammatory response, engagement of TREM-1 dramatically enhances this effect when used as a costimulus, showing that TREM-1 can amplify inflammatory responses initiated by TLRs[28-30].

TREM-1 surface expression is greatly increased on infiltrating neutrophils isolated from the peritoneal cavity of patients with septic shock due to bacterial peritonitis. In contrast, peritoneal lavage cells of patients with SIRS caused by nonmicrobial peritoneal inflammation show normal levels of TREM-1, and it has been proposed that TREM-1 is upregulated in the presence of infection[30]. At the mRNA level, an alternative splicing variant of TREM-1 (svTREM-1) has been described, which might encode a soluble form[31], as it has been detected in patients receiving mechanical ventilation. Rapid detection of soluble TREM-1 in bronchoalveolar lavage fluid has been proposed for establishing or excluding a diagnosis of bacterial or fungal pneumonia[32,33], and TREM-1 mRNA upregulation correlates with the severity of acute pancreatitis[34].

In this study, we aimed to explore the expression of TREM-1, svTREM-1, and HLA-DR as early indicators of infection or as prognostic indicators during systemic inflammation, using surgical and septic patients as models of the inflammatory response.

MATERIALS AND METHODS

Patients

Samples were obtained from 11 septic patients, 7 elective gastrointestinal surgical patients (pre- and post-surgery) and 10 healthy volunteers who gave their informed consent, according to the protocol approved by the Institute Ethics Committee (reference number 034/2004, IMSS 2004-3601-0064). Sepsis diagnosis was determined by the presence of at least two of the following signs: hypothermia or hyperthermia, tachycardia, tachypnea or hyperventilation as defined by $PaCO_2$ of 4.256 Kpa and leukocytosis, bandemia or leukopenia.

Blood samples

Blood (15 mL) was collected from healthy volunteers, septic patients (at their admission to gastro surgery service with sepsis diagnosis) and surgical patients (first sample 30 min before surgery and second sample 12-24 h after surgical procedure ended) and heparinized (10 U/mL).

Flow cytometry

Peripheral blood mononuclear cells were obtained from the heparinized samples by centrifuging at 800 r/min for 30 min over a Ficoll-Hypaque gradient. Cells were washed thrice with isotonic solution at 150 r/min for 10 min, the

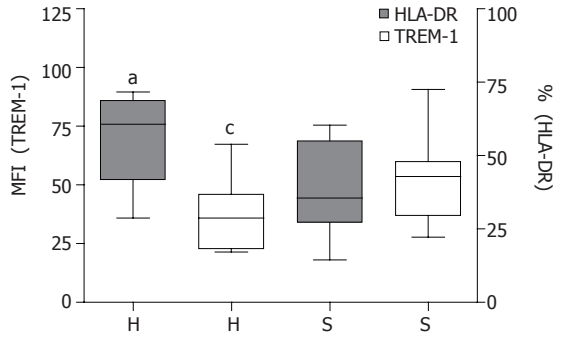

Figure 1 TREM-1 and HLA-DR expression in healthy volunteers and septic patients. Comparison of expression levels of TREM-1 (mean of fluorescence intensity) and HLA-DR (percentage of CD14+HLA-DR+cells) between healthy volunteers (H) and septic patients (S). [a]*P*<0.05 healthy *vs* septic for HLA-DR expression, [c]*P*<0.05 healthy *vs* septic for TREM-1 expression.

supernatant was discarded, and the pellet was resuspended in an isotonic solution. Trypan blue staining was done on an aliquot of the cell suspension to determine cell numbers and to assess their viability. Cells were transferred to a 96-well conical well plate (1×10^6 cells/well). Cells were blocked with a 20 g/L human gamma globulin solution (Beriglobina®, Aventis) for 1 h at 4 °C and washed by centrifuging at 800 r/min for 3 min at 4 °C. The supernatant was discarded and the pellet was resuspended. Cell staining for flow cytometry was done by adding anti-CD14/FITC, anti-HLA-DR/PE (BD Biosciences), anti-TREM-1/PE (R&D Systems) and an isotype control. The contents in each well were transferred to flow cytometry tubes in 400 μL of sheath fluid. Finally, samples were analyzed in a BD FACScalibur flow cytometer.

Total RNA extraction, RT-PCR and semiquantitative analysis

Total RNA was extracted from peripheral blood mononuclear cells using TRIzol reagent (Invitrogen). The concentrations and purity of the extracted RNA were determined spectrophotometrically at 260 and 280 nm (Beckman DU640, USA). Single-stranded cDNA was synthesized by mixing 1 μg RNA with 1 μL oligo-dT (0.5 g/L, Promega), 1 μL dNTP mix (10 mmol/L, Promega), 4 μL reaction buffer (Promega), 2 μL DTT (0.1 mol/L, Promega), 1 μL SuperScript II RNase H reverse transcriptase (200 U/μL, Promega) and DEPC-treated water to 20 μL. The reaction mixture was incubated at 42 °C for 50 min, followed by 70 °C for 15 min to inactivate the reverse transcriptase. cDNA (1 μg) was used as the template for PCR amplification of TREM-1. The mixture consisted of 0.5 μL dNTP mix (10 mmol/L, Promega), 1.5 μL $MgCl_2$ (25 mmol/L, Promega), 5 μL primers (5'-GGACGGAGAGATGCCCAAGACC-3' and 5'-ACCAGCCAGGAGAATGACAATG-3' for TREM-1 or 5'-GTGGGGCGCCCCAGGCACCA-3' and 5'-CTCCTTAATGTCACGCACGATTTC-3' for β-actin)[31], 0.25 μL DMSO, 0.25 μL Taq DNA polymerase (5 U/μL, Promega), 2.5 μL PCR buffer (Promega) and DEPC-treated water to 25 μL. The reaction was performed using a programmable thermocycler (Techne, Progene). The DNA was predenatured at 94 °C for 15 s, followed by 32 cycles of denaturation (94 °C for 15 s), annealing (60 °C for 15 s), and extension (72 °C for 20 s). The mixture was finally extended for 5 min at 72 °C. β-Actin served as an internal control in each experiment. PCR products (10 μL) were electrophoresed using 20 g/L agarose gels in TAE at 70 V for 60 min. The samples were stained with ethidium bromide (0.1 mg/L) and observed by ultraviolet illumination. The images were photographed and analyzed with an IS-1000 digital imaging system (Alpha Innotech Corporation). The pixel densities of TREM-1 and β-actin bands were determined and the ratios of TREM-1/β-actin were calculated. These ratios were represented as the relative expression levels (expression index) of TREM-1 mRNA and were used for semiquantitative analysis.

ELISA

Sera levels of IL-6 were measured using a commercial kit (BD-Pharmingen) according to the manufacturer's instructions.

Statistical analysis

Due to the sample size, we performed qualitative analysis with the data expressed as medians and quartiles. For comparison between each group, the nonparametric Mann-Whitney *U*-test was used. $P\leqslant0.05$ was considered statistically significant.

RESULTS

Twenty-eight subjects were included: 11 septic patients, 7 elective gastrointestinal surgical patients (pre- and post-surgery) and 10 healthy volunteers. The age range was 20-83 years and the average age over each group was 52.7, 52.25, and 35.4 years for the surgical, septic and healthy groups, respectively. Demographic data for all the subjects included in this study, as well as diagnostic and disease evolution data, are shown in Table 1.

Expression levels of TREM-1 and HLA-DR

Surface expression levels of TREM-1 and HLA-DR were measured by flow cytometry. Results were expressed as mean fluorescence intensity (MFI) related to the entire monocyte population for TREM-1 and as the percentage of HLA-DR-positive monocytes in the total monocyte population[35].

The expression of TREM-1 and HLA-DR in healthy volunteers was 35.91±14.75 MFI and 75.8±18.3%, respectively. We considered this group as showing the basal level of expression of both molecules. In septic patients, the TREM-1 expression level was 59.9±23.9 MFI and HLA-DR expression was 44.39±20.25%. There was a significant difference between healthy and septic groups ($P<0.05$) for both molecules (Figure 1).

In the surgical patients, TREM-1 and HLA-DR expressions were 56.8±20.85 MFI and 71±13.8% before

A = years; M = masculine; F = feminine; AP = acute pancreatitis; GRD = gastroesophageal reflux disease; L=live; D=death; [1]mixed papillary neoplasm of the pancreas; [2]gastro-gastro-anastomosis; [3]H-J = hepatico-jejunostomy; [4]ARS = anti-reflux surgery; [5]EC = emphysematous cholecystitis; NA = not applicable; pre-s = pre-operative; post-s = post-operative.

surgery and 72.65±29.92 MFI and 72.82±22.55% after surgery, respectively. There was a significant difference ($P<0.05$) in TREM-1 expression between the samples before and after surgery (Figure 2).

svTREM-1 expression levels

svTREM-1 expression was 0.8590±0.1451 in the healthy group, 0.8820±0.1460 in the surgical group (after surgery; pre-surgical value was 0.377±3.7) and 2.210±0.7873 in the septic group. There was a significant difference ($P<0.05$) when svTREM-1 in both the healthy and surgical groups was compared to the septic group (Figure 3).

Serum interleukin-6 levels

Serum level of IL-6 was 0.0±28.49, 0.1320±1.547, 24.53±51.94, and 155.5±124.5 (pg/mL) in the healthy surgical (before and after surgery) and septic groups, respectively. There was a significant difference ($P<0.05$) when the serum IL-6 levels in the healthy and surgical groups were compared to the septic group. There was also a significant difference between the surgical patients before and after surgery (Figure 4).

DISCUSSION

The SIRS concept is valid to the extent that a systemic inflammatory response can be triggered by a variety of infectious and noninfectious conditions. Sepsis is a clinical syndrome defined by the presence of both infection and a systemic inflammatory response. However, these definitions are also considered nonspecific in clinical diagnosis or prognosis[9,20,36,37]. Here we have demonstrated that both low levels of HLA-DR and high levels of TREM-1 expression were related with sepsis and its resolution.

Major injuries such as extensive abdominal surgery, which involves stress and tissue necrosis, could lead to immunoparalysis as a consequence of CARS and get infected independent of their surgical and medical treatment, developing sepsis[15,38]. In addition to the massive release of pro- and anti-inflammatory mediators such as cytokines, acute phase proteins, heat shock proteins, and intracellular molecules such as HMGB1[19,24,25,39-43] there is a modification of expression of surface receptors such as TLRs, TREM-1 and HLA-DR in monocytes during the evolution of inflammatory response (SIRS, CARS, and sepsis)[15,30,35,38,44,45].

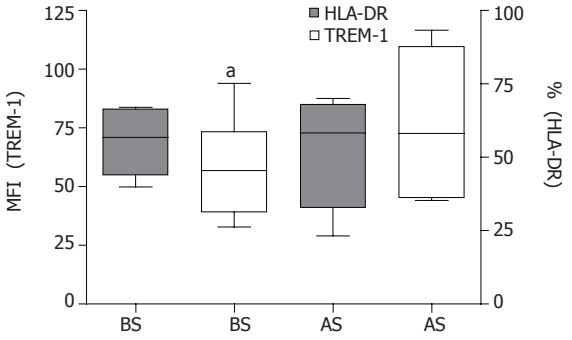

Figure 2 TREM-1 and HLA-DR expression in surgical patients. Comparison of expression levels of TREM-1 (mean of fluorescence intensity) and HLA-DR (percentage of CD14+HLA-DR+cells) in surgical patients before (BS) and after surgery (AS). [a]*P*<0.05 before surgery *vs* after surgery for TREM-1.

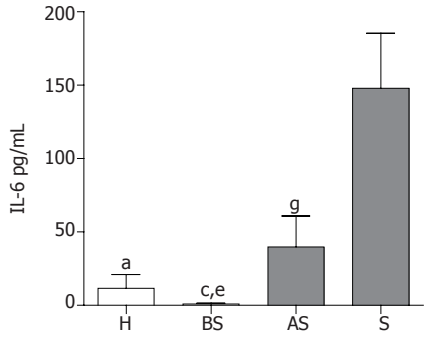

Figure 4 Serum interleukin-6 levels. Serum levels of IL-6 in healthy volunteers (H), surgical patients before surgery (BS) and after surgery (AS), and septic patients (S). [a]*P*<0.05 healthy *vs* septic groups; [c]*P*<0.05 surgical groups before *vs* after surgery; [e]*P*<0.05 before surgery *vs* septic groups; [g]*P*<0.05 after surgery *vs* septic groups.

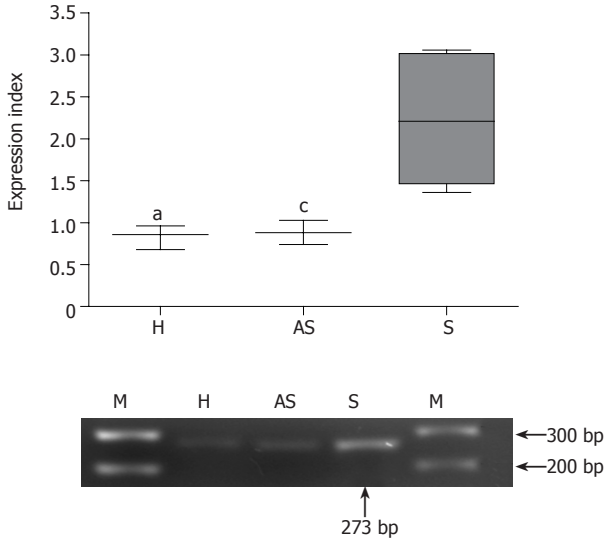

Figure 3 mRNA expression of svTREM-1. **A:** Expression index of svTREM-1/β-actin in each group. HLA-DR expression level in septic patients was strongly diminished compared to pre-surgical patients and healthy volunteers. This correlates with studies in which low expression of HLA-DR is considered as a sign of immunoparalysis and is related to the presence of infection in septic patients[12,13,35]. The relationship between high levels of TREM-1 and low HLA-DR expression correlates with the severity of illness. On the other hand, healthy volunteers showed low levels of TREM-1 and high levels of HLA-DR, as the surgical patients did before and after surgery, indicating that the immunocompetence of these subjects correlates with their optimal outcome and recovery.

During the onset of an infection, monocytes and neutrophils trigger inflammation in response to the recognition of microorganism-associated molecular structure by pattern recognition receptors, which may lead to the upregulation of surface TREM-1 expression[29]. Subsequently, stimuli through TREM-1 may amplify the inflammatory response by the release of TNFα, IL-1β, and IL-8, as well as the upregulation of co-stimulatory molecules[28,30].

In our study, the TREM-1 expression level in septic patients was significantly higher than in healthy volunteers. This correlates with previous reports where TREM-1 surface expression is strongly increased in infiltrating neutrophils isolated from the peritoneal cavity of patients with septic shock due to bacterial peritonitis[30].

Among the surgical patients, TREM-1 expression before surgery increased when compared to healthy volunteers, while after surgery there was a statistically significant upregulation as compared to the pre-surgical and healthy volunteer groups. This increase without clinical signs of infection might be the result of the inflammatory status due to the disease that led to operation and/or to surgical stress, instead of other factors such as age or gender. Thus, TREM-1 appears to be an endogenous signal reflecting the course of the inflammatory response.

We also measured the svTREM-1 mRNA level in mononuclear cells of each group, since this molecule might encode soluble TREM-1, which has been proposed as a marker for establishing the diagnosis of bacterial or fungal pneumonia[33]. svTREM-1 could serve as a soluble receptor for a yet unknown ligand, and its upregulation at the transcriptional, translation and secretion level may be a negative regulation mechanism by preventing surface TREM-1 engagement and pro-inflammatory activity during severe inflammatory processes such as SIRS and sepsis. We speculate that the increased svTREM-1 expression observed in septic patients compared to both healthy and surgical groups may correlate with the presence of pathogens that activate the immune response leading to complications such as sepsis.

We measured serum IL-6 in each group as an indicator of disease severity and for prediction of patient outcomes. IL-6 increased as previously described[21,46].

We found a correlation between the upregulation of surface TREM-1 and svTREM-1 and the downregulation of surface HLA-DR in critically ill patients.

In conclusion, TREM-1 may play an important role in establishing and amplifying the systemic inflammatory response. In the future, with the support of epidemiological data, TREM-1, HLA-DR and svTREM-1

expression may be used as diagnostic and prognostic indicators to identify different phases of the inflammatory response, such as in SIRS, CARS and sepsis.

Abstract

AIM: To analyze the relationship between perisinusoidal stellate cell (PSC) activation and the dietary fat quantity and composition in the treatment of hepatic steatosis.

METHODS: Using an experimental rat model of steatosis based on the intake of a hyperlipidic diet (14% fat as olive oil or sunflower oil, HL-O and HL-S, respectively), we analyzed the liver's capability of recovery after the treatment with a normal-lipidic diet (5% fat as olive oil or sunflower oil, NL-O and NL-S, respectively) by immunocytochemical and Western blot analysis of glial fibrillary acidic protein (GFAP) expression in PSCs, collagen quantification and serum aminotransferase determination.

RESULTS: The fatty infiltration in the steatotic livers decreased after the treatment with both NL diets, indicating liver recovery. This decrease was accompanied with a lower collagen deposition and aminotransferase level as well as changes in the PSC population that increased the GFAP expression. The above-mentioned effects were more pronounced in animals fed on NL-O based diet.

CONCLUSION: Treatment with a balanced diet enriched in olive oil contributes to the liver recovery from a steatotic process. The PSC phenotype is a marker of this hepatic-recovery model.

Key words: PSCs; GFAP; Steatosis; Collagen; Hyperlipidic diet; Liver recovery; Olive oil

INTRODUCTION

Hepatic steatosis is associated with obesity[1,2], toxic injury by toxins such as alcohol[3] or thioacetamide[4], and intake of high quantities of dietary fat[1,4]. Particularly, high-fat diets lead to biochemical and morphological hepatic changes, including steatosis and collagen deposition as well as alterations in the levels of plasma lipoproteins and serum aminotransferases (ALT, AST)[1,4,5]. These features are affected not only by the quantity but also by the composition of the dietary fat [1,5,6].

Perisinusoidal stellate cells (PSCs), also known as Ito cells or fat-storing cells, are liver pericytes that are involved in the hepatic metabolism of lipoproteins[7], synthesis of extracellular matrix proteins[8] and release of some hepatocyte growth factors[9], thus playing a key role in different pathologies such as hepatic fibrosis[10] and non-alcoholic steatohepatitis[11]. In addition, these cells due to their privileged location among hepatocytes, endothelial cells and nerve endings, have been proposed to be the main cell type responsible for the microcirculation control at the sinusoidal level[12].

In the normal liver, PSCs show a quiescent phenotype characterized by the presence of numerous intracytoplasmic fat droplets[13]. Nevertheless, in different hepatic pathologies, these cells are detected without lipid droplets showing an activated phenotype that implies changes in their antigenic composition[14,15] as well as in their morphology and functions[15,16].

PSCs share several features with astrocytes[16,19] and contain the glial fibrillary acidic protein (GFAP), a type of intermediate filament protein like these glial cells[20]. The plasticity in the expression of this cytoskeletal protein in PSCs has been proposed to be an instrument

to discriminate between quiescent and activated phenotypes[20].

The aim of the present study was to analyze the relationship between PSC activation and dietary fat quantity and composition in the treatment of hepatic steatosis. For this, an evaluation of the expression and distribution of the liver glial fibrillary acidic protein was made, and the liver collagen and the aminotransferase serum level were quantified in a rat model. These diets were prepared with olive or sunflower oils to compare the efficacy of the two fats on steatosis recovery.

MATERIALS AND METHODS

Animal diet and experimental design

Semipurified and balanced high-lipidic (HL; 14% fat) and normal-lipidic (NL; 5% fat) sunflower oil and olive oil diets were prepared as previously described[1,4]. The only difference between HL and NL diets was that the fat energy content was reduced from 14% to 5%, with a corresponding increase in the carbohydrate energy content. To avoid auto-oxidation, the oils were added to the diets on a daily basis immediately before feeding. All the animals had free access to the diet and water.

A total of 32 weaned Wistar rats were divided into two groups of 16 rats each and fed *ad libitum* on high-lipidic olive (HL-O) or high-lipidic sunflower (HL-S) oil diets for 1 mo. This time period was long enough to induce steatotic pathology[1,4]. Half of the rats of each HL oil group (n = 8 olive, n = 8 sunflower) were killed, and the other half were fed on a normal-lipidic (NL-O, NL-S) diet without changing the type of oil for an additional month.

The experiments followed the European Union guidelines on the use of animals for biomedical research (86/609/EU).

Histopathological examination

Four rats from each group were intraperitoneally anaesthetized with Ketolar (15 mg/100 mg body weight), and heparin was injected through the penis dorsal vein (500 IU/kg body weight) to avoid blood coagulation. The livers were perfused with 20-30 mL of carbogenated 0.01 mol/L phosphate buffer saline (PBS), and then with 100-120 mL of 4% paraformaldehyde-0.1 mol/L phosphate buffer (PB). After this, the organ was dissected out, cut into small blocks and immersed in the same fixative for 3 h at 4 ºC, and then immersed in 30% sucrose-0.1 mol/L phosphate buffer overnight at 4 ºC. The blocks were covered with OCT compound and frozen with 2-methylbutane at liquid-nitrogen temperature.

Histological study for the analysis of fatty infiltration was performed on 20-μm-thick sections stained with 1% OsO_4 0.1 mol/L phosphate buffer for 1 h at 4 ºC and mounted in PBS:glycerol (1:1).

Free-floating sections (40-μm thick) were obtained for collagen quantification by the colorimetric method described elsewhere[21].

Immunohistochemistry

For immunohistochemical analysis, free-floating (40-μm thick) sections were incubated overnight with a rabbit polyclonal anti-bovine GFAP (1:100; DAKO A/S, Z334) antiserum diluted in PBS containing 0.2% Triton X-100 at 4 °C. After several washes in PBS, the sections were incubated with biotinylated goat anti-rabbit IgG (Vector Laboratories Ltd) followed by peroxidase-linked ABC. The peroxidase activity was demonstrated following the nickel-enhanced diamino-benzidine procedure[24]. The sections were then mounted on slides, dehydrated in ascending grades of ethanol series, and covered using DPX. Controls for background staining, which was usually negligible, were performed by replacing the primary antiserum with normal rabbit serum.

Western blotting

Four rats from each group were killed by cervical dislocation and the livers were individually triturated with liquid nitrogen. The resulting powder was kept at -80 ºC and used for the preparation of crude extracts. Frozen liver powder (0.3 g) was homogenized (Polytron, PT 1200) in 30 mmol/L Tris-HCl buffer, pH 7.4, containing 0.5 mmol/L DTT, 1% SDS, 1 mmol/L EDTA and 1 mmol/L PMSF (1:3 w/v). The resulting homogenates were centrifuged for 60 min at 100 000 *g*. All the procedures were performed at 0-4 ºC. Protein concentrations in the supernatants were determined by the Bradford method[23].

For Western blot analysis, equal amount of the denatured proteins per lane (30 μg) were loaded and separated on an 8% SDS-polyacrylamide gel (Mini Protean II, BioRad), and transferred to a PVDF membrane (Hybond-P, Amersham). The membrane was blocked with 5% defatted milk powder in Tris-buffered saline buffer (25 mmol/L Tris-HCl, pH 7.6, 137 mmol/L NaCl, 2.6 mmol/L KCl, 0.2% Tween-20) and incubated at room temperature with diluted rabbit polyclonal anti-cow GFAP antibody (1/1 000) in a blocking buffer. Bound antibodies were revealed with an enhanced chemiluminescence kit (ECL, Amersham) according to the manufacturer's instructions. After immunodetection, membranes were probed with anti α-tubulin (Sigma) as a loading control. The relative expression of GFAP in each sample was quantified by densitometric scanning.

Serum aminotransferase levels

Blood samples were taken from the mesenteric vein of the same animals used for Western blot analysis. Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) activities were automatically analyzed with a multifunctional biochemistry analyzer (Autoanalyzer Hitachi 917, Roche).

Statistical analysis

Data were expressed as mean±SD. Student's t-test was performed to evaluate significant differences between groups. $P<0.05$ was considered statistically significant.

Table 1 Body weight and liver weight (mean±SD)

	Body weight (g)	Liver weight (g)
HL-O	307.44±18.61	14.66±0.36
NL-O	255.33±23.58	12.05±0.87[a]
HL-S	310.55±16.48	
NL-S	207.16±32.83[a]	14.85±0.41

HL-O, high-lipidic olive oil; NL-O, normal-lipidic olive oil; HL-S, high-lipidic sunflower oil; NL-S, normal-lipidic sunflower oil. [a]P<0.05 *vs* HL-S, P<0.02 *vs* NL-O.

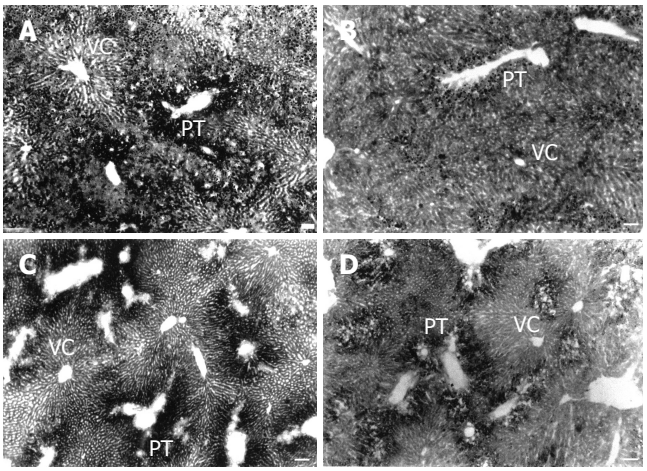

Figure 1 Light micrographs of representative liver sections from rats of each dietary group stained for fat with OsO_4. **A:** High-lipidic olive oil; **B:** normal-lipidic olive oil; **C:** high-lipidic sunflower oil; **D:** normal-lipidic sunflower oil. PT: portal triad; CV: central vein. Scale bar, 100 μm.

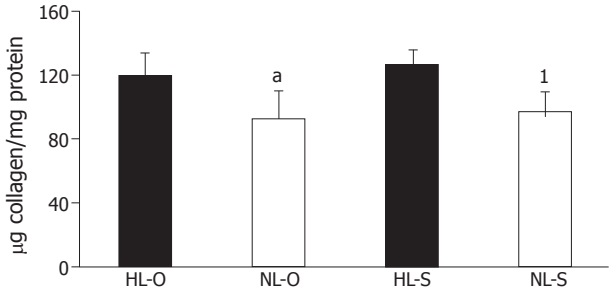

Figure 2 Collagen quantification in the high fat-induced steatotic liver (HL-O, HL-S) after its treatment with a normal-lipidic diet (NL-O, NL-S). Data are mean ±SD of four determinations. HL-O, high-lipidic olive oil; NL-O normal-lipidic olive oil; HL-S, high-lipidic sunflower oil; NL-S normal-lipidic sunflower oil. Significantly greater than in corresponding HL group: [a]P<0.05 *vs* HL-S, [1]P<0.02 *vs* NL-O.

RESULTS

Body and liver weights

Table 1 lists the body weight and liver weight before and after hyperlipidic and normal-lipidic diets.

Histopathological manifestations

Sections stained with OsO_4 revealed steatosis in the HL groups[4], characterized by the accumulation of many fat droplets inside the hepatocytes, mainly in those from the portal zone. After treatment with NL diets, steatosis was reduced principally in the NL-O group (Figure 1).

Regardless of the type of diet, the collagen quantification significantly decreased in rats after treatment with NL diets (Figure 2).

Table 2 Serum alanine aminotransferase (ALT) and aspartate aminotransferase (AST) levels (mean±SD)

	ALT (IU/L)	AST (IU/L)
HL-O	39±1.41	83.50±12.02
NL-O	27±5.66[1]	60±2.83[a]
HL-S	52±1.41	75±4.24
NL-S	26±14.14[b]	57.50±16.26

HL-O, high-lipidic olive oil; NL-O, normal-lipidic olive oil; HL-S, high-lipidic sunflower oil; NL-S, normal-lipidic sunflower oil. [a]P<0.05, [1]P<0.02 *vs* HL-S, [b]P<0.01 *vs* HL-O.

Distribution of GFAP immunoreactive PSCs

In all experimental groups, glial fibrillary acidic protein immunoreactive (GFAP-IR) cells were uniformly distributed in the liver parenchyma throughout the hepatic lobule (Figure 3A). These cells had a stellate shape with a large nucleus surrounded by a cytoplasm that exhibited many long processes (Figures 3B-D). Most of the cells contained numerous lipid droplets in their cytoplasm (Figure 3C), though some cells lacked fat droplets (Figure 3B).

The GFAP-IR cells had their cytoplasmic processes preferentially circumscribed to the Disse's space, running along or encircling the hepatic sinusoids (Figure 3B). Nevertheless, some cells, probably those called the "second layer cells"[24] located near the vascular network of the liver, sent out some processes towards the wall vessel, where they formed structures resembling the end-feed of astrocytes (Figures 3B and 3D).

When different dietary groups were compared, a lower frequency of GFAP-IR cells was found in the steatotic liver of animals fed on HL diets (sunflower or olive oil) in relation to the group receiving NL balanced diets (sunflower or olive oil) (Figure 4). No differences were found when diets with the same lipid content but with a different oil were compared.

Semiquantification of GFAP expression

Western blot analysis of denatured hepatic homogenates from HL and NL groups revealed a 51-ku protein detected by the GFAP antibody (Figure 5). The densitometric semiquantification showed that, after the normalization of the fat level in the diets (5%), GFAP expression was significantly increased but only in the olive oil diet (P<0.001).

Changes of aminotransferase levels

Serum ALT and AST levels are shown in Table 2. Compared with the HL groups, serum ALT activity significantly decreased after the treatment with NL diets. This decrease was more significant in the sunflower oil group (P<0.01). AST activity decreased only in the olive oil group after the treatment with NL diet (P<0.05).

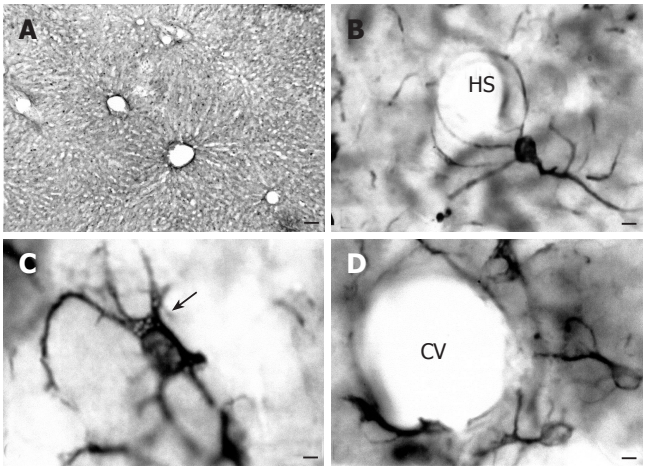

Figure 3 Distribution and location of GFAP immunoreactivity. **A:** GFAP-positive cells were distributed evenly in the lobule; **B:** GFAP-IR cells with processes circumscribing a hepatic sinusoid; **C:** GFAP-IR cell showing lipid droplets in its cytoplasm; **D:** GFAP-IR cell sending processes towards the vascular vessel. HS, hepatic sinusoid. CV, central vein; black arrow, lipid droplets; scale bar A: 100 mm; scale bars **B-D:** 10 μm.

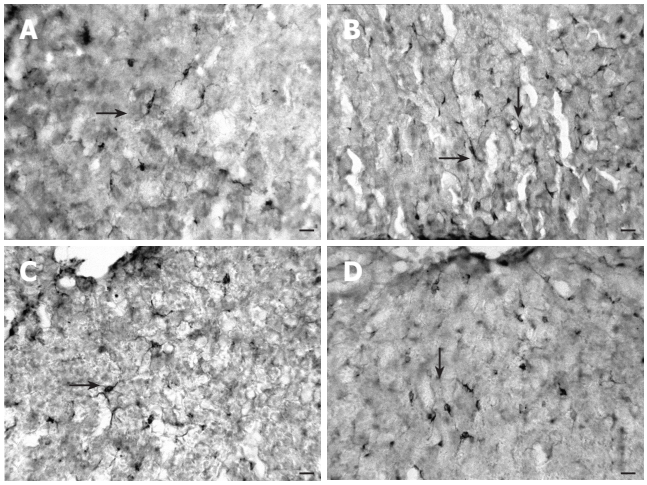

Figure 4 Light micrographs of representative liver sections from rats of each dietary group immunostained with GFAP antiserum. **A:** High-lipidic olive oil; **B:** normal-lipidic olive oil; **C:** high-lipidic sunflower oil; **D:** normal-lipidic sunflower oil. Scale bar, 10 μm.

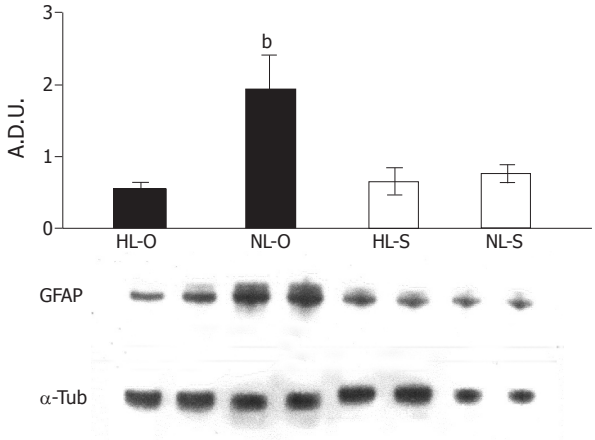

Figure 5 Western blot analysis of GFAP expression. Top panel: densitometric quantification of GFAP in the high-fat-induced steatotic liver (HL-O and HL-S), and after its treatment with a normal-lipidic diet (NL-O, NL-S). Results were average values of four experimental animals in each group. HL-O, high-lipidic olive oil; NL-O, normal-lipidic olive oil; HL-S, high-lipidic sunflower oil; NL-S, normal-lipidic sunflower oil. Bottom panel: representative autoradiography of the corresponding GFAP band. α-Tubulin immunodetection was also included as a protein-loading control. Protein expression is significantly greater than in HL-O group ($^bP<0.001$).

DISCUSSION

Several studies have emphasized the importance of dietary composition in the treatment of fatty liver[5,24]. Our results based on the induction of a steatotic process by diets of 14% fat and its recovery by diets of 5% fat demonstrated that these NL diets could reduce the collagen deposition and aminotransferase serum level as well as changes in the PSC population that increased the GFAP expression. In addition, taking into account that both HL and NL diets were prepared with sunflower or olive oils, we found that the above-mentioned effects were more pronounced in animals fed on NL olive oil-based diet.

No information is available on the involvement of PSCs in the regenerative potential of steatotic liver induced by high-lipidic diets, even though it is well known in other models of liver injuries. GFAP is the most reliable marker for testing the functional status of these liver cells[20]. In this sense, we used the immunohistochemical study of GFAP as well as its expression by Western blot to evaluate the dynamics of the PSC changes. Our results showed a significant increase in the GFAP expression after the treatment of steatotic animals with a NL-O diet.

The GFAP is an essential molecule for the formation and maintenance of the characteristic cytoplasmic processes[12]. Moreover, the role of PSCs in lipid storage and metabolism[7,17], synthesis of growth factors, and particularly in regulation of the hepatic microcirculation[10] is crucial in the development of and recovery from steatosis. In fact, the location of GFAP-IR cells surrounding the hepatic sinusoids, and also forming a peculiar barrier with their processes ending in the vascular wall of the periportal and pericentral vessels, allows us to suggest the participation of PSCs not only in the lipoprotein metabolism but also in the lipoprotein exchange between the Disse's space and the blood stream. Indeed, it has been reported that during hepatocyte proliferation after partial hepatectomy, PSCs send out their processes between hepatocytes and in vascular spaces, allowing the restoration of hepatic vascularization[25]. Thus, the present results showing GFAP increases in the PSCs population after the treatment with NL-O may be correlated with the recovery from the steatotic process.

It was reported that the type of fat in the diet affects serum lipid levels[1,4], as well as the quantity and spatial distribution pattern of the fat stored in hepatocytes[4]. It is noteworthy that, under our experimental conditions, both the doses and the type of dietary fat effectively influenced GFAP expression and the activation degree of PSCs. It has been shown that activation of PSCs by peroxidation

reactions is induced by free radicals[26,27]. In this sense, polyunsaturated fatty acids (PUFAs) from sunflower oils can be more easily affected by oxidative stress. Consequently, given that NL-S diet does not significantly augment GFAP expression in the liver, we might conclude that PSCs from animals fed on the sunflower-oil diet are more strongly activated than those from animals fed with olive oil containing mainly monounsaturated fatty acids (MUFAs), which are less sensitive to peroxidation.

Hepatic steatosis due to excessive dietary fat contents is characterized by an increased collagen deposition, like other hepatic pathologies such as cirrhosis and fibrosis[28,29]. Previous studies carried out in fibrotic rats showed that olive oil, in contrast to polyunsaturated oils, could protect against the development of fibrosis[30] though this depends on the experimentally induced fibrotic model that was employed[4]. It is therefore interesting to determine how the quality of fat in the diet affects this parameter. The present study showed that the restoration to a NL diet in animals previously fed on the HL diet significantly reduced hepatic collagen, this reduction being greater in the olive oil group (with a diet rich in MUFAs) than in the sunflower oil group (with a diet rich in PUFAs). These results agree with the observations of Fernandez *et al*[31].

It is well known that hepatic steatosis raises the serum aminotransferase level[28,32,33], which is decreased after the treatment with hypocaloric diets[5,32]. Our results showed that treatment with a NL diet (olive or sunflower oil) could reduce the aminotransferase level. However, the decrease was more significant in the olive oil group. Since sunflower oil is more susceptible to oxidative stress due to its PUFA content, its hepatic recovery ability is presumably lower. Polavarapu *et al*[34]. and Grattagliano *et al*[35]. found that ALT activity increases in alcoholic subjects fed on high PUFAs diets, which also supports our results.

In short, the results of the present work indicate that a balanced diet enriched in olive oil contributes to the recovery from hepatic steatosis.

Abstract

AIM: To compare the effectiveness, patient acceptability, and physical tolerability of two oral lavage solutions prior to colonoscopy in a Taiwanese population.

METHODS: Eighty consecutive patients were randomized to receive either standard 4 L of polyethylene glycol (PEG) or 90 mL of sodium phosphate (NaP) in a split regimen of two 45 mL doses separated by 12 h, prior to colonoscopic evaluation. The primary endpoint was the percent of subjects who had completed the preparation. Secondary endpoints included colonic cleansing evaluated with an overall assessment and segmental evaluation, the tolerance and acceptability assessed by a self-administered structured questionnaire, and a safety profile such as any unexpected adverse events, electrolyte tests, physical exams, vital signs, and body weights.

RESULTS: A significantly higher completion rate was found in the NaP group compared to the PEG group (84.2% *vs* 27.5%, $P<0.001$). The amount of fluid suctioned was significantly less in patients taking NaP *vs* PEG (50.13±54.8 cc *vs* 121.13±115.4 cc, $P<0.001$), even after controlling for completion of the oral solution ($P = 0.031$). The two groups showed a comparable overall assessment of bowel preparation with a rate of "good" or "excellent" in 78.9% of patients in the NaP group and 82.5% in PEG group ($P = 0.778$). Patients taking NaP tended to have significantly better colonic segmental cleansing relative to stool amount observed in the descending (94.7% *vs* 70%, $P = 0.007$) and transverse (94.6% *vs* 74.4%, $P = 0.025$) colon. Slightly more patients graded the taste of NaP as "good" or "very good" compared to the PEG patients (32.5% *vs* 12.5%; $P = 0.059$). Patients' willingness to take the same preparation in the future was 68.4% in the NaP compared to 75% in the PEG group ($P = 0.617$). There was a significant increase in serum sodium and a significant decrease in phosphate and chloride levels in NaP group on the day following the colonoscopy without any clinical sequelae. Prolonged (>24 h) hemodynamic changes were also observed in 20-35% subjects of either group.

CONCLUSION: Both bowel cleansing agents proved to be similar in safety and effectiveness, while NaP appeared to be more cost-effective. After identifying and excluding patients with potential risk factors, sodium phosphate should become an alternative preparation for patients undergoing elective colonoscopy in the Taiwanese population.

Key words: Colonoscopy; Bowel preparation; Sodium phosphate; Polyethylene glycol

INTRODUCTION

Colonoscopy has become an essential procedure for the detection and treatment of colonic lesions; therefore, cleansing the bowel for adequate visualization of the colonic mucosa during colonoscopic examination is important. In the past two decades, various bowel preparation methods have been proposed including castor oil, anthroquinones, diphenylmethanes, phenolphthalein, and magnesium citrate, in combination with a low residue diet[1-5]. Along with these bowel-cleansing agents, cleansing enemas formed the "traditional" bowel preparation[6-10]. The introduction of polyethylene glycol (PEG) in 1980, an osmotically balanced solution, gradually replaced the

rigorous traditional 2 d preparation of enemas, a clear liquid diet, and laxatives in various combinations[11-15]. Although PEG provided safe and effective bowel cleansing, the patient was required to take 3-4 L of a salty tasting solution within a short period of time[16-19]. As reported, 5-15% of patients were unable to finish the prescribed dosage[8,16], potentially resulting in a poorly cleansed colon and inadequate colonoscopic assessment[17,19].

Oral sodium phosphate (NaP), a highly osmotic cathartic containing monobasic and dibasic sodium phosphate, was first evaluated by Vanner *et al*[19]. in 1990 by comparing it with PEG solutions. The mechanism of NaP is through the osmotic effect of phosphate. This draws large amounts of water into the bowel, creating a flushing action and a laxative effect within 30 min after ingestion and lasting an average of 2-3 h[19,20]. Several studies have been conducted to compare both NaP and PEG solutions, the majority of which have suggested a superiority or equivalence of NaP for adequate mechanical bowel preparation and safety[16-18,21,22]. Moreover, NaP was proven more cost-effective and has since been used worldwide[18,21,23]. With few studies being conducted in Singapore and Hong Kong[24-26], the effectiveness and safety of NaP for bowel preparation has not been prospectively assessed within the confines of a trial in the Taiwanese population. Due to the National Health Insurance (NHI) policy in Taiwan, only one bottle of magnesium citrate solution (MagVac, Pfizer Inc., USA) combined with six tablets of Bisacodyl (Durolax®, Boehringer-ingelheim GmbH, Ingelheim, Germany) are covered by NHI for bowel preparation; however, the results of bowel cleansing are often unsatisfactory. Other agents such as Klean Prep (Helsinn Birex Pharmaceuticals Ltd, UK), a PEG solution, and Fleet® Phospho-soda® (C.B. Fleet Company, Inc., Lynchburg, VA, USA), a NaP solution licensed after this trial, may be available at patients' own expense, if the hospitals carry such products. Most of the elective colonoscopic evaluations were performed at outpatient practice in Taiwan. Patients were scheduled for the examination on the day of consent, and bowel preparation agents were dispensed off on the same day along with both written and oral instructions. Patients were advised to start the preparation at home on the evening before the day of colonoscopy and only clear liquids were allowed after the procedure. The price of regular use of Klean Prep is NT$800 (about US$25) for four sachets (to be diluted to 4 L solution for use), while a 90 mL Fleet® Phospho-soda® costs NT$380 (about US$12). Since Fleet® Phospho-soda® had not been licensed by the Department of Health (DOH), Taiwan, until the results of this bridging study were available, and most of the doctors here do not have much experience with it, it becomes essential to provide effectiveness and safety data in this population along with cost-effective concerns. This study was undertaken to prospectively compare the effectiveness, patients' acceptability, and physical tolerability between the NaP and PEG in the Taiwanese population.

MATERIALS AND METHODS

Patients and methods

From August 2003 to December 2003, 80 consecutive patients who underwent elective colonoscopy were enrolled in this study. Eligible patients who had given written informed consent were randomized to receive either the standard 4 L of PEG (Klean Prep solution; Helsinn Birex Pharmaceuticals Ltd, UK) or 90 mL of NaP (Fleet® Phospho-soda®; C.B. Fleet Company, Inc., USA), in a split regimen of two 45 mL doses separated by 12 h, prior to the colonoscopic evaluation. Colonoscopy was scheduled after 8:00 a.m. for all the subjects, and study subjects were asked to report to the endoscopy room by 8:00 a.m. on the day of examination. Both groups were instructed to start the preparation around 6:00-7:00 p.m. the day before the colonoscopy. One sachet of Klean Prep should be diluted in 1 L of water (repeat for all four sachets) and one glassful (250 mL) of the solution would be taken every 10-15 min until the entire solution was consumed. The first 45 mL dose of Fleet® Phospho-soda® (diluted with a cold clear liquid or water by 1:16) was taken at 6:00-7:00 p.m. on the previous evening, and the second dose was taken at 6:00-7:00 a.m. on the day of the colonoscopy. A clear liquid diet was allowed during the bowel preparation. This study was approved by both the Health Department of Taiwan and the Institutional Review Board of ChangHua Christian Hospital, Taiwan. Exclusion criteria included symptomatic congestive heart failure, myocardial infarction, serum creatinine greater than 1.5 mg/dL, abnormal liver function defined as glutamic-oxaloacetic transaminase (GOT)/glutamic-pyruvic transaminase (GPT) greater than 120 U/L, ascites, electrolyte abnormalities, gastrointestinal obstruction, gastric retention, bowel perforation, obstructive or paralytic ileus, uncontrolled hypertension, unstable angina pectoris, pregnancy or breast feeding, and severe chronic constipation.

Demographic characteristics such as age, gender, prior bowel preparation experience, indication for colonoscopy, and medical history were obtained for all the patients. Laboratory assessment including blood urea nitrogen (BUN), GOT, GPT, sodium (Na), potassium (K), chloride (Cl), calcium (Ca), and phosphate (P), were done for all patients at baseline (the day of screening and consent, within 15 d prior to colonoscopy) and on the day following colonoscopy. In addition, a pregnancy test was performed on all the female patients and an electrocardiogram was performed on all the patients if no data were available within the prior 6 mo, during the initial screening visit. Body weight and routine vital signs, including pulse rate, blood pressure, and temperature were obtained at baseline, on the day of colonoscopy, and on the following day. Blood pressure and pulse rate were measured with the patient in both the supine (after resting for 5 min) and standing (after standing for 1 min) positions.

A self-administered structured questionnaire was completed by the patients to assess the tolerance, acceptability, and palatability of the bowel preparation

Table 1 Grades of bowel cleansing

Score	Stool amount	Stool consistency	Percent wall visualized	Overall assessment
0	None	None	⩾90%	
1	Small	Clear lavage	75-89%	Excellent (small volume of clear liquid)
2	Moderate	Liquid stool	50-74%	Good (large volume of clear liquid)
3	Large	Particulate stool	⩽49%	Fair (some semi-solid stool that could be suctioned or washed away)
4		Semi-solid stool		Poor (semi-solid stool that could not be suctioned or washed away)
5		Solid stool

method. The taste of the oral solutions was graded as very poor, poor, fair, good, and excellent. The ease of taking or swallowing, convenience, and the entire preparation process were graded as very difficult, difficult, tolerable, easy, and very easy. The occurrence and severity of several adverse events commonly associated with bowel preparation, the percentage of the solution ingested, and willingness to repeat the assigned preparation in the future were also addressed in the questionnaire. Patients were instructed to complete and return the questionnaire prior to the colonoscopy.

A single surgeon who was blinded to the type of preparation performed all of the colonoscopies. The time to reach the cecum, the scope of insertion and removal time, the volume of fluid irrigated and suctioned, and the level of the colon reached were recorded. Colonic cleansing was evaluated as to the amount and consistency of stool and the estimated percentage of the bowel wall visualized at the level of the rectum, descending colon, transverse colon, ascending colon, and cecum, as well as the overall assessment rated by the colonoscopist and scored according to the scale shown in Table 1.

[1]Mantel–Haenszel χ^2 test and *t*-test when appropriate. [2]SD: standard deviation.

Statistical analysis

The Mantel-Haenszel χ^2 test and Fisher's exact test were used to compare the ordinal scores of the global and segmental assessment of bowel cleansing and patient index of experience, preference, and acceptability between the two groups. The Cochran-Mantel-Haenszel χ^2 was used to compare these categorical variables between the two groups, controlling for the completion of oral solution. General linear regression analysis was conducted by SAS Proc GLM procedure (SAS v.8.12, SAS Institute Inc., Cary, NC, USA) for the comparison of continuous variables between the two groups, controlling for the completion of oral solution. Changes from baseline of the laboratory tests and vital signs were analyzed across the treatment groups by the paired *t*-test. With a one-sided test, type I error rate of 0.05, power of 80% and a drop out rate of 7.5%, 40 patients for each group are needed to distinguish the difference of completion rate between a 62% for Klean Prep and 87% for Fleet® Phospho-soda® Solution.

RESULTS

Among the 80 patients who were prospectively randomized and completed the study, two NaP subjects were excluded from effectiveness analysis due to invalid laboratory tests at screening visit. The demographic characteristics and prior bowel preparation experience of all the 80 patients are summarized in Table 2. No significant differences in any of these variables were observed between the two groups. The major indications for colonoscopic evaluation were change in bowel habits (34/80; 42.5%), history of polyps (11/80; 13.8%), bleeding (11/80; 13.8%), family history of colorectal cancer (10/80; 12.5%), and cancer surveillance (9/80; 11.3%). There were four patients (three from NaP, and one from PEG group) in whom the cecum was not reached due to a surgical history of colorectal cancer. None of the baseline variables for the laboratory assessment/vital sign measurements were significantly different between the two groups. However, the NaP group had a significantly higher preparation completion rate than the PEG group (84.2% *vs* 27.5%, respectively; P<0.001) (Table 3).

Assessment of bowel cleansing

The amount of fluid suctioned was significantly less in patients taking NaP than those taking PEG (50.13±

[1]One patient in NaP group and 1 in PEG group did not have this data. [2]Three patients in NaP group and 1 in PEG group did not have this data.

54.8 cm^3 *vs* 121.13±115.4 cm^3, respectively; $P<0.001$), even after controlling for the completion of oral solution ($P = 0.031$). The two groups showed a comparable overall assessment of bowel preparation with a grade of "good" or "excellent" in 78.9% in the NaP and 82.5% in the PEG group ($P = 0.778$) (Table 4). Patients taking NaP tended to have significantly better colonic segmental cleansing as assessed by the colonoscopist in the amount of stool observed in the descending ($P = 0.007$) and transverse ($P = 0.025$) colon, even after controlling for the completion of oral solution ($P = 0.006$ for descending and $P = 0.048$ for transverse colon). Twenty-two (57.9%) patients in the NaP group had the stool amount graded as "none" for the descending and 22 (59.5%) for the transverse colon, while only 11 (27.5%) and 16 (41%) patients in the PEG group had perfect visibility in the descending and transverse colon, respectively. Furthermore, more patients in the NaP group had a grade of "none" in terms of stool consistency and ≥90% of the colonic wall visualized throughout the entire colon, although this difference was not statistically significant. A slightly better grade in the rectum ($P = 0.057$) relative to stool amount and in the descending colon for percent of wall visualized ($P = 0.055$) was also observed in the NaP group (Table 5).

Patient acceptability and preference

When assessing for the taste of the bowel preparation, four patients disliked the NaP and did not wish to have this preparation again, while slightly more patients enjoyed the taste and rated it as "good" or "very good" compared to patients taking PEG (13/40, 32.5% *vs* 5/40, 12.5%, respectively; $P = 0.059$). No differences were observed relative to ease of taking or swallowing, convenience, and ease of the entire preparation process, although slightly more patients in our study taking PEG rated these variables as "good/easy" or "very good/easy". When asked whether the patient would take the same preparation in the future, 26 (68.4%) in the NaP group and 30 (75%) in the PEG group replied "yes" ($P = 0.617$). Among the patients who had previous experience with bowel preparation, 8 (66.7%) of the 12 receiving NaP and 11 (78.6%) of the 14 receiving PEG would have the same preparation in the future ($P = 0.665$).

Adverse events

A total of 33 patients had 117 adverse events in the NaP group and 33 had 91 adverse events in the PEG group. These are summarized in Table 6. Although patients who received NaP had a slightly higher incidence than those who received PEG, no significant differences between the two groups were observed. One 32-year-old female patient in the NaP group who had a history of allergies to seafood was taking Lorazepan (Ativan, Wyeth, USA) for insomnia during the study period. Consequently, the patient experienced severe nausea, dizziness, and chills after taking the entire NaP solution. The patient's follow-up electrolytes were normal and all the symptoms subsided on the day following the colonoscopy.

Serum electrolyte changes

Comparison of baseline and post colonoscopy laboratory assessment revealed a significantly elevated Na, while Cl

[1]Change: value obtained at the visit – value obtained at baseline visit. [2]SD: standard deviation. [3]SBP: systolic blood pressure.

and P were decreased in both groups (P<0.001; Table 7). The changes from baseline for both K and P were significantly different (P<0.05), while the changes of Na, Cl, and Ca were comparable between the two groups. Most of the laboratory values remained within the normal range and none of the patients complained of any discomfort during the follow-up period.

Hemodynamic profile and body weight

Hemodynamic profile is summarized in Table 8. Change from baseline in pulse rate (≥10 beats/min) and systolic blood pressure (SBP≥10 mmHg) were observed in 27.5-32.5% subjects from each group on the day of colonoscopy after the preparation, and were seen in 17.5-35% subjects on the day following the colonoscopic evaluation, though only <10% of the subjects had a change of >20 beats/min (mmHg) at the follow-up visit. Following the colonoscopy, after rest and resumption of a normal diet, most of the average values of vital signs, including body temperature, body weight, and pulse rate returned to baseline level except blood pressure (change from baseline of SBP for all subjects: -2.8±12.3, P = 0.042; diastolic BP: -3.5±7.9, P<0.001). None of these hemodynamic fluctuations were clinically significant

and no patients reported a syncopal episode or postural dizziness.

DISCUSSION

A "clean" colon is essential in colonoscopic examination for the early diagnosis of colonic neoplasia. A higher compliance rate for a bowel preparation agent will help to achieve this goal. In this study, 84% of the patients who received NaP completed the entire bowel preparation regimen compared with only 27.5% of the PEG group ($P<0.001$). All four patients in the PEG group who reported a "poor" grade for overall assessment were associated with poor compliance. Consistently more patients in the NaP group had perfect cleanliness in terms of the stool amount, stool consistency, and percent of colonic wall visualized in the majority of the colonic segments compared to those patients in the PEG group. In our study, although significantly better performance was found in some of the colonic segmental evaluations, NaP did not demonstrate a dramatic superiority over PEG in terms of the overall assessment. Our results differ from those of previous studies that have reported a 10-40% difference in favor of NaP[16,17,19,21,22]. In addition to these studies, two Asian studies conducted in Singapore and Hong Kong[24,25] also indicated a significantly higher proportion of patients reporting good or excellent grades with the NaP compared to the PEG solutions (22% and 20% difference, respectively for each study; $P<0.05$). However, this study did not demonstrate any statistically significant difference between patients receiving PEG who were graded as "good" or "excellent" in terms of overall assessment by the physician, compared to those who took NaP (82.5% *vs* 78.9%, respectively; $P = 0.78$). Although some of the studies used less amount, i.e., 3 or 2 L, instead of 4 L for PEG preparation[18,27-29], most of the trials adopted a standard amount of 4 L recommended by the manufacturer for a better cleansing result. The Hintertux study group even demonstrated that the 4 L PEG group was significantly superior to the 3 L PEG group[28]. However, a remarkably low completion rate of PEG solution (27.5%) was observed in this study. Using 75% as the cut-off for the completion rate, i.e., 3 L of PEG solution, there were still 14 (35%) subjects who failed to complete the PEG preparation in this study, which indicated a cultural difference in terms of the practice of bowel preparation. Instead of getting admitted to the hospital the day prior to the colonoscopic evaluation as did in some other trials[19,30], all of our subjects initiated the preparation at home without assistance. With the large amount (4 L) of the solution, some subjects tended to stop drinking PEG when they felt that they were already clean. Others stated that they were afraid of having the needs to go to the restroom on a bus or a train to the hospital and therefore stopped taking the rest of the solution after going to bed in the night before the colonoscopy. This kind of stress and inconvenience are less likely to happen to inpatients, subjects who have their own vehicles or those who live close to the hospital. Contrary to the results reported by Cohen *et al*[17]. in which significantly more fluid was suctioned from the colon after NaP, while more irrigation was necessary to cleanse the bowel after PEG, our data show that significantly more fluid was suctioned in patients who took PEG than those taking NaP, while the amount of irrigation did not differ between the two groups. More fluid in the colon may result in missed colonic lesions or tumors while the use of suction may cause more mucosal injury.

There were four patients who disliked the NaP and did not wish to have this preparation again. The same situation was mentioned by some studies[22,24,31], although some patients reported discomfort with the NaP solution due to its salty and unpalatable taste, still found it easier to complete than the PEG solution due to the smaller volumes. Although the 4 L required for the PEG solution is much greater than that required for NaP, none of the patients in the PEG group complained about taking or swallowing the large amount of solution. Furthermore, none of them rated the convenience of taking or ease of the entire preparation as "very poor", though the completion rate was also much lower than expected. In contrast to most of the other studies, slightly more patients in our study taking PEG rated the ease of taking or swallowing, convenience of taking, and ease of the preparation as "good/easy" or "very good/easy", and answered "yes" to the question "would you take the same preparation in the future" compared with the NaP group, although these differences were not statistically significant. The majority of our patient population lived in rural areas and tended to unquestionably follow physician's instructions more than their urban counterparts, which may explain the high satisfaction rates with the PEG preparation.

The patients in our study reported a consistently higher incidence of several anticipated adverse events than cited by other studies[17,18,24,25], although there was no significant difference between the two groups. Nevertheless, the NaP group had a slightly higher overall occurrence of these symptoms than did the PEG group. The majority of the adverse events were graded as mild-to-moderate and had subsided by the day following the colonoscopy. One patient in the NaP group who suffered from severe nausea, dizziness, and chills was taking Lorazepan (Ativan, Wyeth, USA) for insomnia during the bowel preparation. This observation might be just a coincidence or a result from multiple factors, i.e., the concomitant use of NaP and Lorazepan along with the patient's history of allergy, which will need further investigations. A transient hypophosphatemia was observed in the NaP group the day following the colonoscopy, compared to baseline. Hyperphosphatemia is a recognized consequence of sodium phosphate. According to the reports by Kolts *et al*[22]. and Huynh *et al*[30]. serum phosphate rose significantly 2 h after NaP consumption, but subsequently returned to normal within 26 h. Since the preparation was done at the subjects' residence, instead of continuous monitoring the electrolytes during the preparation, only the value on the day after the colonoscopy was obtained to compare the baseline level, and therefore we failed to observe the elevation phase of serum phosphate but observed only the decrease phase at more than 24 h after the preparation. The same pattern was also observed by Vanner *et al*[19]. in which serum phosphate of seven patients in NaP group elevated from 3.7±0.2 mg/dL on the day of admission to 7.2±0.6 mg/dL at 8:00 a.m. on the

day of colonoscopy, then dropped to 3.7±0.3 mg/dL at 4:00 p.m. in the evening and to 3.1±0.3 mg/dL at 8:00 a.m. on the following day. Consistent with known effect of oral sodium phosphate solution, serum sodium levels remained higher and potassium levels were lower than baseline on the day following the colonoscopy. Although different from baseline, most of the values were still within normal ranges and none of the subjects developed any clinically relevant adverse events that accompanied these metabolic changes after the cessation of the preparation.

Contraindications to the use of NaP have been emphasized, and serious electrolyte disturbances have been reported in individual patients taking oral sodium phosphate[20,32,33]. Some studies have indicated that NaP should not be used in women who are pregnant or breast-feeding, or patients with renal failure, congestive heart failure, ascites, or congenital megacolon[34,35]. Furthermore, hypokalemia resulting from the ingestion of NaP can increase the risk of cardiac arrhythmias in patients who are taking diuretics or digitalis[30,36]. The proportion of subjects (27.5-32.5%) with a hemodynamic change greater than 10 beats/min in pulse rate or 10 mmHg in systolic blood pressure on the morning of colonoscopy compared to baseline levels are slightly higher than reported studies, i.e., 14-28% of oral sodium phosphate solution recipients with decreases in SBP >1.33 Kpa and 15-30% with changes in postural pulse $\geqslant$10 beats/min from baseline[19,30,34]. Without taking any solid food since the previous afternoon, suffering from the preparation process and insufficient sleep, along with an early commute to the hospital (some had a commute longer than 30 min), most of the subjects appeared weak on arrival at the endoscopic station. It might explain why the outpatient subjects had a larger hemodynamic change on the day of colonoscopy compared with those who were admitted to the hospital on the previous day[19]. One study reported that 12% NaP patients had changes in SBP>20 mmHg[34], which was higher than what we observed (7.5%). Hemodynamic changes suggest that intravascular volume decreases during the bowel preparation, and it is considered to be transient unless contraindications are encountered. Patients in both the groups were instructed to take adequate amounts of fluid during the preparation, therefore, no significant body weight changes were observed in either group.

CONCLUSION

Both bowel cleansing agents were found to be equally safe and effective for bowel preparation prior to colonoscopy. Although NaP was more effective in some of the colonic segmental cleansing, both solutions were found to be equally acceptable and had the same overall assessment. However, the high completion rate related to NaP may prevent inadequate bowel preparation and facilitate colonoscopic evaluation. Taking its more affordable price into consideration (about half price of PEG), NaP demonstrates its cost effectiveness. Severe adverse events were observed in only one patient who was taking medication for insomnia during the NaP preparation, which implies that caution should be taken relative to concomitant medications. Although not clinically significant, some hemodynamic and electrolyte changes were prolonged more than 24 h. After identifying and excluding patients with potential risk factors, NaP should become an alternative bowel preparation for patients undergoing colonoscopy in the Taiwanese population.

Abstract

AIM: To evaluate health-related quality of life (HRQOL) in Chinese patients with chronic hepatitis C (CH-C), and the impact of antiviral treatment.

METHODS: Short Form 36 (SF-36) Health-related Quality of Life Questionnaires to interview CH-C patients, and age- and sex-matched control subjects at outpatient clinics of a medical center in Taiwan were used. Data were transformed to scores for comparisons of eight major SF-36 domains. We also enrolled consecutive CH-C patients who completed one course of antiviral treatment (interferon α with ribavirin), and measured the HRQOL before, at the 12th wk of treatment, at the end of treatment, and at mo 6, after stopping the treatment to evaluate the impact of antiviral treatment.

RESULTS: A total of 371 outpatients were enrolled, including 182 with CH-C and 189 age- and sex-matched subjects without CH-C. CH-C subjects had obviously lower educational status ($P<0.01$). Mean scores of domains in general health, physical functioning, role-physical, role-emotional, vitality, and mental health of the SF-36 were significantly lower in subjects with CH-C than those without CH-C ($P<0.05$). In an analysis of 47 CH-C patients who received and completed the whole course of antiviral treatment, mean scores of all domains were significantly lower at wk 12 of treatment compared to baseline. The scores returned to pretreatment values by the end of treatment, but were significantly increased at mo 6 after stopping the treatment. Among the 47 CH-C patients, 21 had sustained responses and 26 had non-sustained responses to antiviral treatment. Compared to pretreatment values, subjects with sustained responses had significantly lower social functioning scores at wk 12 of treatment, and scores for all SF-36 domains returned to pretreatment values, and increased significantly at mo 6 after stopping the treatment. For non-sustained virological responders, scores of all SF-36 domains significantly decreased at wk 12 of treatment, and did not increase significantly by the end of treatment, or at mo 6 after stopping the treatment when compared to the pretreatment values.

CONCLUSION: HRQOL in CH-C patients is significantly impaired in most SF-36 domains. Antiviral treatment impaired HRQOL of CH-C subjects during early treatment, mainly in non-sustained virological responders, and improved at mo 6 after stopping the treatment, mainly in sustained virological responders.

Key words: Hepatitis C; Quality of life; Questionnaire

INTRODUCTION

Hepatitis C virus infection (HCV), previously known as non-A, non-B hepatitis, has become an important health issue worldwide in the last 15 years. Its chronic sequelae, liver cirrhosis and hepatocellular carcinoma, have had a significant impact on the health of the population worldwide[1,2]. Antiviral treatments, including interferon with or without ribavirin, have been used in treating chronic hepatitis C (CH-C) patients to prevent the development of liver cirrhosis and hepatocellular carcinoma. In Taiwan, the prevalence of CH-C has been reported to be around 2-5% in urban populations. High HCV endemic villages with 20-60% positive rates of serum antibody to HCV have been found in central and southern parts of Taiwan[3,4]. Interferon α therapy with and without ribavirin for 6 mo has been used to treat CH-C patients since 1991 in Taiwan. The sustained virological response rate at the end of

the treatment ranged from 12% to 76%, but the sustained virological response rate at the 6th mo after stopping the treatment ranged only from 12% to 43%[5-8].

Health-related quality of life (HRQOL), which reflects what patients are concerned with and what they experience, has been widely researched in patients with CH-C in the West. Indeed, the impact on HRQOL and the adverse effects of antiviral treatment have been documented for Western populations. However, to our knowledge, such studies have not been done for HRQOL in Chinese patients with CH-C.

For evaluation of HRQOL in Chinese CH-C patients, the Short Form 36 (SF-36) Questionnaire is most commonly used. The aims of our study were to understand the characteristics of HRQOL in Chinese CH-C patients compared with age- and sex-matched subjects without CH-C, and to evaluate the impact of antiviral treatment on HRQOL in Chinese CH-C patients.

MATERIALS AND METHODS

We used questionnaires to conduct interviews of CH-C patients at the Outpatient Clinics of Taipei Veterans General Hospital, a medical center in Taipei City, Taiwan. CH-C patients were defined as those who had sustained elevation of serum transaminase and positive tests for serum antibody to HCV for more than 6 mo, and/or pathological changes consistent with the diagnosis of CH-C on liver biopsies. CH-C patients who showed decompensated cirrhosis or hepatocellular carcinoma were excluded from the study. Age- and sex-matched subjects without CH-C were interviewed at the same places and at the same times as CH-C patients. The enrolled outpatients were randomly selected and interviewed from January 1, 2002 to December 31, 2002. Demographic data, including subjective difficulty in completing the questionnaire, acute illness within the last 2 wk, combined chronic systemic diseases such as hypertension, coronary artery disease, chronic obstructive pulmonary disease, diabetes mellitus and osteoarthritis, were obtained for each subject. We trained senior-grade medical students and nurses to interview the subjects and to assist them in filling out the questionnaire.

We used the SF-36 HRQOL questionnaire, Taiwan version, as a tool for our study. The SF-36, developed by John E. Ware Jr. in late 1980s, has been widely used in different fields for health evaluations all over the world. Translated into several languages, the SF-36 has shown similar reliability and validity in studies conducted in different countries[9-15]. For the SF-36 Taiwan version, the norms and internal consistency have been validated by local researchers[16,17]. It measures eight main domains: (a) general health (GH); (b) physical functioning (PF); (c) limitation of roles due to physical problems, known as role-physical (RP); (d) limitation of roles due to emotional problems, known as role-emotional (RE); (e) social functioning (SF); (f) bodily pain (BP); (g) vitality (VT); and (h) mental health (MH). We recorded demographic data, summarized the original scores of each SF-36 domain, and translated them into final scores from 0 to 100 linearly via the formulas of the SF-36. A score of "0" indicates the least favorable health status; a score of "100", the most favorable health status.

Table 1 Demographic characteristics of 371 study subjects with and without chronic hepatitis C (CH-C)

	CH-C patients (n = 182)	Controls (n = 189)	P
Mean age (yr)	59.9±12.9	58.8±13.9	0.302
Sex (male:female)	91:91	106:83	0.254
Educational status (below high school:high school or above)	97:85	62:127	<0.001
Subjective difficulty to questionnaire(difficult: non difference:easy)	0.146	0.362	0.118
Acute illness during recent two weeks (yes:no)	47:135	47:142	0.905
Combined chronic diseases (yes:no)	94:88	115:74	0.076

[1]Mann-Whitney U test or χ^2 test.

We also enrolled and collected data from 47 consecutive CH-C patients who had completed one course of antiviral treatment. This included: (a) 24 patients who received pegylated interferon α-2a subcutaneously at a dose of 180 μg per week plus oral ribavirin (1 000 mg/d if body weight <75 kg, and 1 200 mg/d if body weight ⩾75 kg) for 6 mo; and (b) 23 patients receiving interferon α-2b subcutaneously 3 million units thrice a week plus oral ribavirin (1 000 mg/d if body weight <75 kg, and 1 200 mg/d if body weight ⩾75 kg) for 6 mo. We interviewed the subjects and recorded their SF-36 scores before the initiation of treatment, at the 12th wk of treatment, at the end of treatment, and at the 6th mo after the stopping treatment. The sustained virological responders were defined as those whose serum HCV RNA was detected to be negative by branched chain signal amplification assay (VERSANT HCV RNA 3.0 Quantitative Assay, Chiron Corporation, Tarrytown, NJ, USA) with a sensitivity of 3 200 copies/mL and reverse transcription-nested polymerase chain reaction with a sensitivity of 100 copies/mL at the 6th mo after stopping the treatment[18-21].

The data in the text and tables are expressed as mean ±SD. Mann-Whitney U tests, χ^2 tests, Fisher's exact tests, and paired t- tests were done appropriately depending on the type of data analyzed by using SPSS software (SPSS version 11.0, SPSS Inc., Chicago, IL, USA). Cronbach's α expressed both internal consistency of each domain and overall consistency of the SF-36. A two-tailed P<0.05 was considered statistically significant.

RESULTS

Three hundred and seventy-one subjects, including 182 CH-C patients and 189 age- and sex-matched control subjects without CH-C, received interviews and filled out questionnaires during the period of study. The internal consistency of each domain of the SF-36 shown by Cronbach's α was greater than 0.6 (GH: 0.75, PF: 0.87, RP: 0.90, RE: 0.88, SF: 0.69, BP: 0.81, VT: 0.83, MH: 0.67), and the

[1]Mann–Whitney *U* test and Fisher's exact test.

overall consistency of the SF-36 (Cronbach's α) was 0.91. The demographic data for the 371 study subjects are listed in Table 1. Subjects with CH-C showed lower educational status than those without CH-C (P<0.01). The subjects with subjective difficulty in completing the questionnaire, with acute illness within the previous 2 wk, or combined chronic diseases showed no significant differences than the subjects without these characteristics.

The original scores of the SF-36 in 371 study subjects were translated to linear scores from 0 to 100, which are listed in Table 2. Subjects with CH-C had significantly lower scores in GH, PF, RP, RE, VT, and MH domains than those without CH-C (P<0.05). The domains of SF and BP showed no significant differences between subjects with or without CH-C.

Of the 47 CH-C patients who received antiviral treatment and completed the whole course of therapy, all had significantly lower mean HRQOL scores in all SF-36 domains at the 12th wk of treatment as compared with pretreatment values, but mean scores returned to pretreatment values by the end of treatment and significantly increased at the 6th mo after stopping the treatment (Figure 1). Among the 47 CH-C patients who received antiviral treatment, 21 were sustained virological responders and 26 were non-sustained virological responders. Sustained virological responders and non-sustained virological responders showed no significant difference for mean age, gender, and treatment modality. Mean scores for the SF-36 in all domains before antiviral treatment showed no significant difference between the two groups except that mean scores for MH was significantly higher in sustained virological responders than in non-sustained virological responders (Table 3).

Mean SF-36 scores at different time points of antiviral treatment in both sustained virological responders and non-sustained virological responders are listed in Tables 4 and 5, respectively. Compared to pretreatment values, subjects with sustained virological response showed significantly lower SF scores at the 12th wk of treatment. Mean scores of all SF-36 domains returned to pretreatment values by the end of treatment, and increased significantly by the 6th mo after stopping the treatment (P<0.05). For non-sustained virological responders, mean scores for all domains of the SF-36 significantly decreased at the 12th wk of treatment compared to pretreatment values, and did not increase significantly at the end of treatment and at the 6th mo after stopping the treatment.

DISCUSSION

Chronic HCV infection has become an important health issue in Taiwan and worldwide. Moreover, the chronic sequelae of liver cirrhosis and hepatocellular carcinoma have led to considerable morbidity and mortality in CH-C patients, and a negative impact on HRQOL in CH-C patients has been well documented for Western populations[22,23]. In Asia, impaired HRQOL in Korean patients with chronic viral hepatitis has been reported[24]. Till now, however, there have been no reports on HRQOL in Chinese patients with CH-C.

To the best of our knowledge, our study is the first study investigating HRQOL and the impact of antiviral treatment in Chinese CH-C patients. Our results showed

that HRQOL in Chinese CH-C patients in outpatient clinics was significantly impaired compared to non-CH-C subjects. This finding may reflect the fact that chronic viral hepatitis is more commonly seen in Chinese nationals than in Caucasians and the chronic sequelae of chronic viral hepatitis, such as cirrhosis and hepatocellular carcinoma, may have greatly affected the health of Chinese patients. We propose that Chinese patients with CH-C should be paid more attention regarding their HRQOL, health education and disease management.

Interferon was introduced for the antiviral treatment of CH-C in the late 1980s[25,26]. Due to the poorer sustained response rate using interferon therapy alone, combined treatment of interferon and ribavirin has been widely used in treating CH-C patients, which recently had 40-60% sustained virological response rate. However, the side effects of interferon with or without ribavirin, such as fatigue, malaise, flu-like symptoms, anemia, itching, skin rash or eruption, arthralgia, myalgia, depression, impaired sleeping quality, and loss of concentration, have been notable and have bothered CH-C patients during antiviral treatment[27]. Previous reports from Western countries had focused on comparison of HRQOL before and after antiviral therapy in CH-C patients, and they revealed that the HRQOL of CH-C patients could be improved through aggressive antiviral therapy, and sustained virological responders showed greater improvement[28-32]. Our results for Chinese CH-C patients were consistent with reports from Western countries that sustained virological responders to antiviral treatment have improved HRQOL.

Our results also revealed that all regimens of antiviral therapy impaired HRQOL of the subjects at early therapeutic stages, and especially bothered non-sustained virological responders. Initially therapeutic discomfort would impair patients' compliance and willingness to continue antiviral therapy. We suggest that active explanations of possible side effects and discomforts to patients before antiviral therapy are needed. If patients have insights into and are aware of possible adverse side effects, the compliance and continuity of antiviral therapy should be improved.

The limitations of our research are the different regimens of antiviral treatment. Therefore, we did not perform comparisons of the therapeutic effects and impact on HRQOL among the different kinds of antiviral regimens. Further evaluations and comparisons of the impact of different therapeutic regimens on HRQOL in CH-C patients are now indicated.

In conclusion, our study suggests that CH-C patients have a lower HRQOL than those without CH-C in Chinese populations visiting outpatient clinics. Antiviral treatment reduced HRQOL of CH-C patients at the early phase of treatment, mainly in non-sustained virological responders. The HRQOL may return to pretreatment values at the end of treatment and improve significantly at the 6th mo after stopping the treatment, mainly in sustained virological responders.

ACKNOWLEDGMENTS

The author wishes to thank Miss Jia-Ling Lin, Wei-Lin Chen, and senior students of the Department of Medicine, National Yang Ming University for selection of the subjects. The author especially expresses his thanks to Dr. Ming-Wei Lin for statistical assistance and Dr. Jui-Feng Rachel Lu for allowing us to use the SF-36 HRQOL Questionnaire, Taiwan version.

Abstract

AIM: To investigate the bactericidal and anti-adhesive properties of 25 plants against *Helicobacter pylori* (*H pylori*).

METHODS: Twenty-five plants were boiled in water to produce aqueous extracts that simulate the effect of cooking. The bactericidal activity of the extracts was assessed by a standard kill-curve with seven strains of *H pylori*. The anti-adhesive property was assessed by the inhibition of binding of four strains of FITC-labeled *H pylori* to stomach sections.

RESULTS: Of all the plants tested, eight plants, including Bengal quince, nightshade, garlic, dill, black pepper, coriander, fenugreek and black tea, were found to have no bactericidal effect on any of the isolates. Columbo weed, long pepper, parsley, tarragon, nutmeg, yellow-berried nightshade, threadstem carpetweed, sage and cinnamon had bactericidal activities against *H pylori*, but total inhibition of growth was not achieved in this study. Among the plants that killed *H pylori*, turmeric was the most efficient, followed by cumin, ginger, chilli, borage, black caraway, oregano and liquorice. Moreover, extracts of turmeric, borage and parsley were able to inhibit the adhesion of *H pylori* strains to the stomach sections.

CONCLUSION: Several plants that were tested in our study had bactericidal and/or anti-adhesive effects on *H pylori*. Ingestion of the plants with anti-adhesive properties could therefore provide a potent alternative therapy for *H pylori* infection, which overcomes the problem of resistance associated with current antibiotic treatment.

Key words: *H pylori*; Inhibition; Adhesion; Killing; Plants

INTRODUCTION

Over half the human population is colonized by *Helicobacter pylori* (*H pylori*), a Gram-negative, microaerophilic bacterium. If untreated, infection is usually life-long and leads to chronic active disease[1]. Although most infected people are asymptomatic, 5-10% of those infected with this bacterium develop severe gastroduodenal diseases, including gastric and duodenal ulcers, gastric lymphomas, and gastric adenocarcinomas[2].

The current and most effective treatment for peptic ulcer disease is a triple therapy regimen consisting of a proton pump inhibitor, such as omeprazole, and two antibiotics, clarithromycin and either amoxicillin or metronidazole. However, there is an increase that disturbs due to the prevalence of antibiotic resistance, which is high in some areas of the world. Metronidazole resistance is more common than clarithromycin, the latter particularly having an adverse effect on the eradication rate. Second line therapies following failure of one of the initial regimes include triple and quadruple regimens containing antibiotics, such as levofloxacin or furazolidone, or even regimens containing five agents. Although the use of molecular methods can rapidly detect antibiotic resistance and host polymorphisms, which may lead to reduced efficacy of treatment and thus eradication failure[3,4], this is not a long-term solution to the rising trend of antibiotic resistance.

Resistance to antibiotics is not limited to *H pylori* and has been an increasing problem for many years. There is therefore a constant need for new antimicrobial agents and novel approaches to treatment, ideally preventing disease, such as inhibition of adhesion or vaccination[5]. Plants are known to be the source of phytochemicals which are beneficial for health and could also prevent diseases[6]. Among these phytochemicals, two are of particular interest in the case of infectious diseases: antimicrobial and anti-adhesive agents.

Numerous studies have been undertaken in order to find antimicrobial agents from plants against organisms ranging from viruses to protozoa[7]. The major concern is the validation in human beings with well-designed clinical trials, and this has also been true for *H pylori* infection. Several *in vitro* studies have looked at the effect of plant extracts on *H pylori*. Anti-microbial effects have been reported for garlic[8,9], green tea[10], honey[11], thyme[12], some Iranian plants[13] and the essential oils from several species of mint[13]. Some of these studies have been validated in animals and confirmed the potential benefit of using plants as the source of anti-microbial agents against *H pylori*. Although garlic and cinnamon have been tested in human clinical trials with no significant effect[14], a recent study has shown that consumption of broccoli sprouts is associated with the eradication of *H pylori* in some patients[15], but more work needs to be done in determining the active ingredients of broccoli as well as performing studies on a larger number of patients.

The search for anti-adhesive agents represents the second alternative to antibiotic therapy, which has received less interest, although studies in animals and human beings have proved its potential as a new therapy[16]. Successful inhibition of adhesion has been shown *in vitro* with cranberry juice against *H pylori*[17] and for the seaweed *Cladosiphon fucoidan*[18]. Recently, Shibata *et al*.[19] have demonstrated that *Cladosiphon fucoidan* inhibits adhesion of *H pylori* to porcine gastric mucin. By adding the plant to the drinking water of infected Mongolian gerbils, the prevalence of animals with infection was shown to be markedly reduced. Lengsfeld *et al*.[20] have shown that adhesion of *H pylori* to human stomach sections was almost completely inhibited by pre-incubating *H pylori* with a fresh juice preparation of the fruit of the okra plant [*Abelmoschus esculentus* (L.) Moench]. Lengsfeld *et al*.[21] have also demonstrated that acidic high molecular weight galactans from blackcurrant seeds could inhibit adhesion of *H pylori* to human gastric mucosa tissue sections. Moreover, Lee *et al*.[22] have demonstrated the inhibition of *H pylori* adhesion by polysaccharide fractions of *Panax ginseng* and *Artemisia capillaris* to a human gastric adenocarcinoma epithelial cell line.

As mentioned earlier, many plants have been shown to kill microorganisms but rarely have been studied for their anti-adhesive properties. We have therefore investigated both the bactericidal and anti-adhesive properties of 25 plants against *H pylori*. Sixteen of them have never been tested before against *H pylori* and are plants that are frequently used in cooking as well as in medicine in Sri Lanka, Iran, and the Middle East. Moreover, we have used an *in situ* adhesion assay[23], with stomach tissues expressing either the Lewis a (Le a) or Lewis b (Le b) antigen, in order to determine whether the plant extracts inhibit adhesion by blocking the major *H pylori* adhesin BabA (which binds to Le b) or have an effect on other adhesins.

MATERIALS AND METHODS

H pylori isolates

H pylori NCTC 11637 and six fresh clinical strains from Italian patients with peptic ulcer disease [obtained by one of the authors (DV)] were used in the study. All strains were stored on beads at -80 ℃ until use. Bacteria were grown for 2 d on Columbia agar plates supplemented with 5% horse blood (Oxoid, UK) at 37 ℃ under microaerobic conditions. The number of bacterial cells was determined by obtaining viable counts of serial dilutions and measurement of the optical absorbance at 600 nm (Ultrospec II, LKB, UK) of a suspension of bacterial cells to prepare a standard curve for *H pylori*. All studies thereafter used the same concentration of organism based upon its absorbance.

Fluorescent labeling of H pylori isolates

Suspensions of 1×10^9 cells/mL were prepared from 1 mL carbonate buffer (0.15 mol/L NaCl/0.1 mol/L Na_2CO_3, pH 9.0). Five microliters of a 10 mg/mL fluorescein isothiocyanate (FITC, Isomer I, Sigma, UK) solution in dimethyl sulfoxide (DMSO, Sigma, UK) was added to each bacterial suspension and then incubated for 1 h with continuous shaking. The suspensions were then washed three times with phosphate buffered saline (PBS, 8.0 g/L NaCl; 1.21 g/L K_2HPO_4; 0.34 g/L KH_2PO_4, pH 7.4) containing 0.5 g/L Tween 20 (PBST; Sigma, UK), and resuspended in PBS. Labeling was confirmed by using flow cytometry (FACSCalibur, Becton Dickinson, UK). All incubation and washing steps were carried out in the dark at room temperature.

Plants

Twenty-five plants were obtained from different sources and are described in Table 1. Extracts from the plants were prepared as follows: for turmeric, ginger, fenugreek, cumin, fennel, coriander, and chilli, plants were boiled to 100 ℃ in sterile distilled water (100 mg/mL), filtered through sterile gauze, neutralized to pH 7.0 and then sterilized. Extracts from all the other plants were prepared as follows: plants were boiled in sterile distilled water (100 mg/mL) for 10 min, allowed to cool and filtered through sterile filter paper (Grade 1, Whatman, UK). Fresh garlic, black peppercorns and cinnamon sticks were finely chopped before being boiled. All extracts were stored in the dark at -20 ℃ until use. Before the experiments of adhesion, plant extracts were filtered again (Grade 1 filter paper, Whatman, UK).

Stomach sections

H pylori-negative biopsies of human stomach were obtained by one of the authors (DV), with the consent of the Ethics Committee, St Orsola Hospital, Bologna. Two

Table 1 Plants used in the study

English name	Sri Lankan name	Scientific name	Part of the plant used	Source	Use
Bengal quince	Belly	*Aegle marmelos*	Root	Sri Lanka	In cooking & medicine
Black caraway (Europe)/Black Cumin (USA)		*Nigella sativa*	Seeds	UK, Supermarket	In cooking & medicine
Black pepper	Gammiris	*Piper nigrum*	Seed berries/fruit	UK, Supermarket	In cooking & medicine
Black tea	Thee	*Camellia sinensis*	Leaves and shoots	Sri Lanka	In cooking
Borage (Starflower)		*Borago officinalis*	Flowers	Iran	In cooking & medicine
Chilli	Mirise	*Capsicum anunum*	Fruit	Sri Lanka	In cooking & medicine
Cinnamon	Curundu	*Cinnamomum verum*	Bark	UK, Supermarket	In cooking & medicine
Columbo weed	Veneval	*Coscinium fenestratum*	climbing root	Sri Lanka	In medicine
Coriander	Kottamalli	*Coriandrum sativum*	Seeds	Sri Lanka	In cooking & medicine
Cumin (small cumin)	Suduru	*Cuminum cyminum*	Seeds	Sri Lanka	In cooking & medicine
Dilla	Sududurru	*Anthum graveolens*	Leaves	UK, Supermarket	In cooking & medicine
Fenugreek	Mathe seeds	*Trigonella foenum-graecum*	Seeds	Sri Lanka	In cooking & medicine
Garlica	Sudulunu	*Allium sativum*	Bulb	UK, Supermarket	In cooking & medicine
Ginger	E'guru	*Zingiber officinale*	Rhizome	Sri Lanka	In cooking & medicine
Liquorice	Val'mee	*Glycyrrhiza glabra apofosa*	Stem	Sri Lanka	In cooking & medicine
Long pepper	Tiphili	*Piper longum*	Seeds	Sri Lanka	In cooking & medicine
Nightshade	Ela battu	*Solanum surattense*	Fruit and root	Sri Lanka	In medicine
Nutmeg	Sadikka	*Myristica fragans*	Kernel	UK, Supermarket	In cooking & medicine
Oreganoa	Oregano	*Origanum vulgare*	Leaves	UK, Supermarket	In cooking & medicine
Parsleya	Parsley	*Petroselinum crispum*	Leaves	UK, Supermarket	In cooking & medicine
Sagea	Minchi	*Salvia officinalis*	Leaves	UK, Supermarket	In cooking & medicine
Tarragona	Tarragon Path	*Artemisia dracunculoses/ dracunculus*	Leaves	UK, Supermarket	In cooking & medicine
Threadstem carpetweed	Paradagam	*Mollugo cerviana*	Seeds	Sri Lanka	In medicine
Turmeric	Kaha	*Curcuma longa*	Rhizome	Sri Lanka	In cooking & medicine
Yellow-berried nightshade	Katu val batu	*Solanum xanthocarpum*	Whole plant	Sri Lanka	In medicine

These plants were bought as both fresh and dried material.

sets of formalin-fixed stomach biopsies were used: those whose epithelial cells expressed the Lewis a blood group antigen (Le a stomach) and those expressing the Lewis b blood group antigen (Le b stomach). Five-micrometer thick sections of the stomach were cut using a Leica SM2400 rocking microtome. Sections were collected on polished glass slides coated with Vectabond (Vector Laboratories, UK). An antigen retrieval step was used by boiling for 5 min in an 800-W microwave in plastic Coplin jars containing 15 mL of citrate buffer (pH 6.0, 100 mol/L sodium citrate tribasic dihydrate, Sigma, UK). The Lewis phenotype of the tissue was determined by standard immunohistochemical staining using the DAKO EnVision Plus HRP kit (DAKO, UK) with anti-Le a and anti-Le b antibodies generously donated by Dr. J Bara, Hôpital St-Antoine, Paris, France. Both antibodies were supplied at a concentration between 1 and 5 μg/mL and diluted 1:10 for the anti-Le a antibodies and 1:50 for the anti-Le b antibodies.

Viable colony count

Bactericidal activity of the plant extracts was determined by a viable colony count. One hundred microliters of a suspension of 10^8 bacteria/mL was added to 900 μL of plant extract for 60 min. The control consisted of *H pylori* incubated with sterile distilled water. Serial 10-fold dilutions were made, and 100 μL of each dilution was plated onto 50 g/L horse blood agar (Oxoid, UK). These were incubated in gas jars under microaerophilic conditions using CampyPak (Oxoid, UK) for 3 d, and colonies were counted (colony forming units per milliliter, CFU/mL). Plant extracts that killed 100% of *H pylori* cells at 60 min (i.e. no colonies grew) were further tested at 0-, 15-, 30-, and 60-min intervals. All experiments were performed three times. The effectiveness of the plants at killing *H pylori* was expressed as percentage inhibition of colony growth (i.e. percentage of bacteria killed) compared to the control.

Microscopic examination

In order to validate the inhibition of adhesion by the plant extracts, any lytic effect of the extracts on the bacterial cells was first examined. FITC-labelled and non-labelled bacteria (1×10^8 cells/mL) were centrifuged (9 000 *g* for 3 min), re-suspended in 500 μL of undiluted plant extract (100 mg/mL) and incubated with continuous shaking for 1 h at room temperature in the dark. After incubation, bacteria were centrifuged, washed in PBST and re-suspended in 500 μL sterile distilled water. One drop of the bacterial suspension was Gram stained. Using a Zeiss light microscope, the slides were observed for bacterial lysis. All the plant extracts were examined, except long pepper and threadstem carpetweed, which were not tested due to their limited supply. The negative control consisted of *H pylori* incubated with sterile distilled water and the positive control of *H pylori* incubated with Puregene PCR

Table 2 Bactericidal activity of plants against *Helicobacter pylori*, determined using viable colony count. '% inhibition of growth' indicates the percentage of bacteria that were killed by the plants, (i.e. the colonies did not grow), compared to the control.

cell lysis solution (Flowgen, UK). The lysis experiments were performed twice.

Adhesion and adhesion-inhibition assay

Tissue sections were incubated for 30 min in a humidified atmosphere with 200 μL of blocking buffer (PBST+20 g/L BSA) per slide. Next, the sections were washed three times, by placing in a slide rack in a glass trough containing 350 mL of PBST, on a rotator for 10 min. Suspensions of FITC-*H pylori* were centrifuged and re-

Images taken using x100 objective.

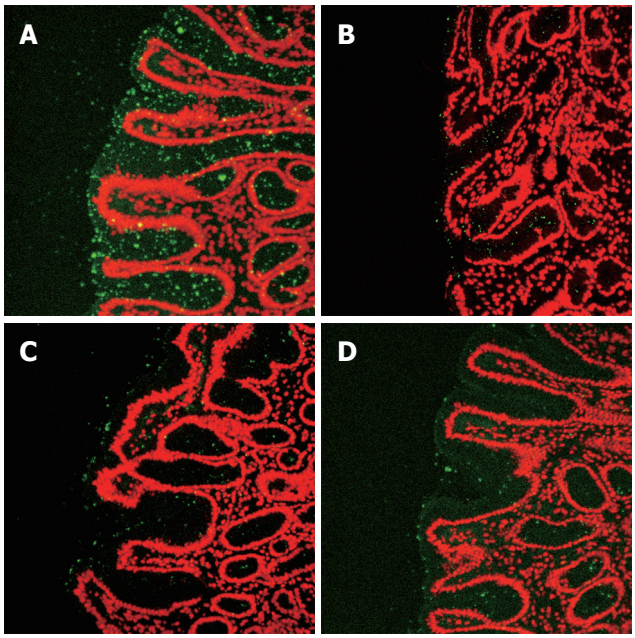

Figure 2 Confocal images showing inhibition of *H pylori* adhesion by **A**: distilled water (control); **B**: turmeric (0.05 g/mL); **C**: borage (0.05 g/mL) and **D**: parsley (0.05 g/mL); to stomach sections expressing the Lewis b blood group antigen.

suspended in plant extract to give 1×10^8 bacteria/mL. This was incubated with continuous shaking for 2 h, and then washed with the blocking buffer. For the controls, bacteria were re-suspended in sterile distilled water. The bacterial suspension (200 μL) was then added to each of the stomach sections and incubated in a humidified atmosphere for 1 h. After incubation, slides were washed in PBST as previously, and 200 μL of propidium iodide (PI, 5 μg/mL, Sigma, UK) was added and each slide was incubated for 3 min. Slides were then washed twice in PBST, air-dried and mounted with Vectashield (V-1000, Vector Laboratories, UK). All incubation and washing steps were carried out in the dark at room temperature. Two tissue sections were used for each plant that was tested.

All plant extracts were initially screened for inhibition of adhesion properties at a concentration of 50 mg/mL (diluted in sterile distilled water) and incubated with *H pylori* strain 11 637 and Le b stomach sections. For those plants which had an anti-adhesive effect, the inhibition assay was repeated using Le a and Le b stomach sections, and the plants were diluted to concentrations of 5, 10, and 50 mg/mL. Because 50 mg/mL was found to give a good inhibition of adhesion, for all further inhibition experiments, all plants were used at this concentration. Inhibition of adhesion experiments were then performed on three clinical strains. All experiments were performed three times.

Quantification of binding

Sections were observed using a Laser Scanning Confocal Microscope (Zeiss: Axiovert 100 TV) with a ×20 Zeiss LD-ACHR objective. The excitation wavelengths were 488 nm (for FITC) and 568 nm (for PI). We used 522- and 605-nm band-pass filters to acquire FITC emission and PI emission, respectively. Digital images (512×512 pixels) of the sections were captured using a Biorad Lasersharp 2000 Confocal Laser Scanning System. Images were converted to TIF files for processing. Two photographs showing adjacent areas of the tissue were taken for each tissue section. Using these digital images, the number of adherent *H pylori* were quantified as previously reported (Region of Interest method with standard area method of counting) using Metamorph Image analysis software (version 4.5r, Universal Imaging Corporation, USA)[23]. Using the Mann-Whitney (non-parametric) test, the difference between the number of adherent cells for each plant was compared statistically to the controls (0 μg/mL plant extract).

RESULTS

Bactericidal properties of plants

Among the 25 plants tested for their bactericidal activity against *H pylori*, eight showed no activity after 60 min of incubation, these were Bengal quince, nightshade, garlic, dill, black pepper, coriander, fenugreek and tea (data

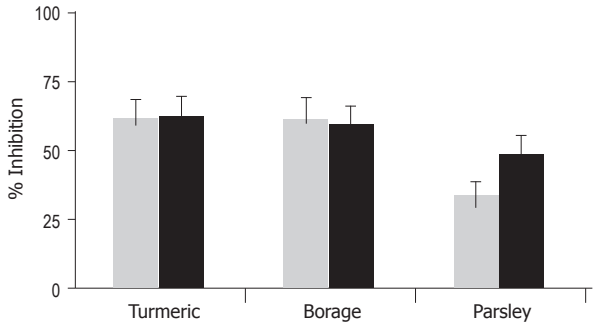

Figure 3 Inhibition of *H pylori* adhesion by turmeric, borage and parsley to stomach sections expressing either the Lewis a or Lewis b blood group antigen. Experiments were performed three times using four strains of *H pylori*. Mean percentage of inhibition is shown for each plant. Gray bar, Lewis a stomach; Black bar, Lewis b stomach.

not shown). The other 17 plants had activity (results are summarized in Table 2). Turmeric was the most efficient in killing the seven strains within 15 min. Ginger, cumin, and chilli were able to kill all the strains within 30 min, whereas liquorice, oregano, black caraway, and borage killed the strains within 60 min. Cinnamon had a bactericidal activity against *H pylori,* although the seven bacterial strains differed in their sensitivity. Moreover, the bacterial colonies were very small, reflecting some resistance to cinnamon. Finally, the following plants showed a bactericidal activity against *H pylori* but without achieving a complete inhibition of growth (i.e., killing all the colonies) within 60 min: columbo weed, yellow-berried nightshade, long pepper, threadstem carpetweed, sage, tarragon, nutmeg, and parsley. Small colonies were seen with yellow-berried nightshade, threadstem carpetweed, and sage.

Morphological studies

None of the 23 plant extracts that were tested caused lysis of *H pylori* cells, as the organisms that remained were spiral and intact like the negative control. Bacterial cells incubated with Puregene PCR cell lysis solution were lysed and no intact spiral shaped bacteria could be observed (Figure 1).

Anti-adhesive properties of plants

Of the 23 plants screened for anti-adhesive properties, turmeric, borage, and fresh parsley (50 mg/mL) were found to inhibit adhesion of *H pylori* 11637 to the stomach sections expressing the Le b antigen (Figure 2). Further testing of these three plant extracts using *H pylori* 11637 and three clinical isolates confirmed that they were able to inhibit *H pylori* adhesion to stomach sections expressing either the Le b antigen or the Le a antigen (Figure 3). Mean inhibition rates of the four strains to the stomach sections expressing the Le a antigen were 61.9%, 61.1%, and 33.9% for turmeric, borage and parsley, respectively. The differences between the number of adherent bacteria compared to the controls (0 μg/mL) were: highly significant ($P<0.01$) for turmeric; not quite significant ($P = 0.07$) for borage; and not significant ($P>0.05$) for parsley. For sections expressing the Le b antigen, inhibition rates were 62.3%, 59.5%, and 48.5% for turmeric, borage and parsley, respectively. The differences between the number of adherent bacteria compared to the control (0 μg/mL) were: not quite significant ($P = 0.07$) for turmeric; significant ($P<0.05$) for borage; and not significant ($P>0.05$) for parsley. There was no significant difference between the number of adherent bacteria (to Le a or Le b stomach sections) when comparing each of the plant-treatments, except for adhesion of bacteria to Le a sections where there was a highly significant difference ($P<0.001$) between turmeric and parsley.

DISCUSSION

Investigations into plant materials as alternative sources of antimicrobials have become more common over the past few years, due to the increased rate of development of antibiotic resistant organisms. New strategies to combat infection are also being sought and one such strategy is the use of 'anti-adhesive' molecules, targeting the primary step of infection - adhesion of the organism to host tissue[5]. In this study, we therefore examined both the anti-microbial and anti-adhesive properties of 25 plant extracts against *H pylori*, obtained simply by boiling, as would occur during the normal cooking process.

Of the eight plants that were not able to kill *H pylori* after 60 min of incubation (Bengal quince, nightshade, garlic, dill, black pepper, coriander, fenugreek, and black tea), two had been tested previously against *H pylori*. Several studies have shown that garlic does kill *H pylori in vitro* and *in vivo*[8,9]. It is probably due to the boiling method of extraction that this effect was not observed in this study, since boiling has been shown to reduce the inhibitory activity of garlic against *H pylori*[24,25]. Fenugreek sprouts have been shown to have high anti-microbial activity against *H pylori*[26]. In the present study, fenugreek appeared inactive but the seeds were examined rather than sprouts, which may account for the difference in results. Green tea catechins have previously been reported to have antibacterial effect against *H pylori*, which was confirmed in Mongolian gerbils[27]. Moreover, Chinese tea has been shown to reduce *H pylori* infection in patients[28]. In this study, black tea was tested, but no bactericidal activity against *H pylori* was observed.

Columbo weed, long pepper, parsley, tarragon, nutmeg, yellow-berried nightshade, threadstem carpetweed, sage, and cinnamon had bactericidal activity against *H pylori*, but total inhibition of growth was not achieved within 60 min. Moreover, a reduced colony size was observed with some of them, such as yellow-berried nightshade, threadstem carpetweed, sage, and cinnamon. Nutmeg[29], tarragon[30], and cinnamon[31] have previously been reported to inhibit the growth of *H pylori in vitro*. When tested in clinical trials, however, cinnamon was found to be ineffective at eradicating *H pylori*[32].

Among the plants that killed *H pylori*, turmeric was the most efficient, followed by cumin, ginger, and chilli. These results confirmed what has been published before

regarding turmeric[33], chilli[34], and ginger[35], but cumin has not been previously tested. Other plants, such as borage, black caraway, and oregano, which have never been tested before against *H pylori*, were also found to have bactericidal effects. Finally, the previous reported bactericidal effect of liquorice has been confirmed[36,37].

As well as looking at their bactericidal activity, all these plants were also tested for their anti-adhesive effects, using an *in situ* adhesion assay. Stomach tissues expressing either the Le a or Le b antigen were used. This was in order to determine whether the plant extracts inhibit adhesion by blocking the major *H pylori* adhesin BabA, which binds to Le b, or have an effect on other adhesins. Most studies have not attempted to determine which adhesin is being blocked, and this may be important because combinations of plants targeting several different adhesins may provide a more potent therapeutic treatment.

Extracts of turmeric, borage, and parsley were able to inhibit the adhesion of *H pylori* strains to both Le a and Le b stomach sections. Turmeric was the most effective at inhibiting *H pylori* adhesion to both Le a and Le b stomach sections, followed by borage and fresh parsley. From these results, it seems that both turmeric and borage could inhibit adhesins other than BabA, because the percentage of inhibition was almost exactly the same for Le a and Le b stomach sections. Parsley possibly inhibited BabA as well as other adhesins, because inhibition occurred on Le a and Le b stomach sections, but was higher for Le b stomach sections, indicating that it had a greater effect at inhibiting BabA. The morphological studies demonstrated that the reduction in adhesion caused by these plant extracts was due to the true inhibition of adhesion, but not because the plants caused the bacteria to lyse. Tarragon is the only plant in this study that has been tested previously for its anti-adhesive effects, where it was found to inhibit *H pylori* adhesion to human gastric adenocarcinoma cells[22]. However, in the present study, tarragon failed to inhibit *H pylori* adhesion to human stomach sections. This discrepancy is probably due to the differences between using cell-lines and whole-tissue.

Plants contain multiple organic components including phenols, quinones, flavones, tannins, terpenoids, and alkaloids all of which are known to have bactericidal effects[7]. These substances are also water-soluble and therefore very likely to be present in the plant extracts produced in this study, and are likely candidates responsible for the killing effect of the extracts on *H pylori*. Plants also contain many water-soluble proteins, lectins and carbohydrates which may bind specifically to sugar residues, polysaccharides, glycoproteins or glycolipids, such as the adhesins present on the cell surface of *H pylori*. In the event of such interactions occurring, the result would be to block the availability of the adhesin to its receptor and hence prevent adhesion of the bacterium to the stomach sections.

Despite the success of many plant materials at killing organisms, resistance can develop to these too, as shown in this study. The present work is of importance because plant extracts were shown to inhibit adhesion of *H pylori* to the stomach - an alternative strategy to bactericidal compounds. Because inhibition of adhesion works on the principle of sterically blocking bacteria from attaching to host tissue, the likelihood of resistance developing in organisms, which occurs when the organism is killed, is less likely.

Although the majority of individuals colonized by *H pylori* are asymptomatic, a proportion of patients develop peptic ulcers (duodenal and gastric), and an even smaller proportion develop gastric cancer. Globally, *H pylori* is the major cause of gastric cancer and has been classified as a Class I carcinogen by the WHO. Some plants are known to have anti-ulcerogenic and anti-cancer effects. Most of the plants tested here, which have bactericidal and/or anti-adhesive properties, also have anti-ulcerogenic or anti-cancer effects, for example, turmeric[38,39], ginger[40,41], cumin[42,43], borage[44], liquorice[45], and parsley[46]. Chilli has recently been shown to have detrimental effects on the gastric mucosa[47]. The anti-cancer and anti-ulcerogenic effects of ginger, cumin, liquorice, parsley, turmeric, and borage combined with their bactericidal and anti-adhesive properties, as shown in this study, suggests that ingestion of these six plants could have important therapeutic implications for patients with *H pylori*-induced peptic ulcer disease or gastric cancer. As turmeric killed 100% of organisms within 15 min, it could therefore be a useful anti-*Helicobacter* agent *in vivo*, because, if given orally, it would be able to kill *H pylori* despite the short amount of time that it would remain in the stomach during digestion. Moreover, these plants could be used in combination with antibiotics, possibly increasing the success of eradication, as has been shown *in vitro* for cranberry juice[48].

Most studies have used plant extracts that are obtained by chemical processing, for example, ethanol extracts. In developing countries where antibiotics are less freely available, such processing methods of plants would be impractical and/or expensive. This present study is therefore of importance because it has demonstrated that several plant extracts are effective against *H pylori* and are obtained simply by boiling the plants. Such a method may provide a treatment that is simple, relatively inexpensive and could be incorporated into the normal diet of the patient, which is highly favorable. Herbal treatments are usually unregulated and the safety of plants consumed is often unknown. The plants used and shown to be effective in this study are already commonly consumed, and thus they are already known to be safe.

Although the cidal and anti-adhesive effects of ginger, cumin, liquorice, parsley, turmeric, and borage have been shown *in vitro,* further studies are needed to be carried out to investigate their effects *in vivo,* to see whether the extracts are able to remain effective despite the harsh process of digestion.

ACKNOWLEDGMENTS

We are grateful to Martin Avedian for the idea of testing borage and for its supply and Ms A. Al-Dossary (School of Hygiene and Tropical Medicine, UK) for providing black caraway.

Abstract

AIM: To evaluate the nature of the "learning curve" for laparoscopy-assisted distal gastrectomy (LADG) with systemic lymphadenectomy for early gastric cancer.

METHODS: The data of 90 consecutive patients with early gastric cancer who underwent LADG with systemic lymphadenectomy between April 2003 and November 2004 were reviewed. The 90 patients were divided into 9 sequential groups of 10 cases in each group and the average operative time of these 9 groups were determined. Other learning indicators, such as transfusion requirements, conversion rates to open surgery, postoperative complication, time to first flatus, and postoperative hospital stay, were evaluated.

RESULTS: After the first 10 LADGs, the operative time reached its first plateau (230-240 min/operation) and then reached a second plateau (<200 min/operation) for the final 30 cases. Although a significant improvement in the operative time was noted after the first 50 cases, there were no significant differences in transfusion requirements, conversion rates to open surgery, postoperative complications, time to first flatus, or postoperative hospital stay between the groups.

CONCLUSION: Based on operative time analysis, this study show that experience of 50 cases of LADG with systemic lymphadenectomy for early gastric cancer is required to achieve optimum proficiency.

Key words: Laparoscopic gastrectomy; Systemic lymphadenectomy; Learning curve

INTRODUCTION

In Korea, an aggressive surgical approach of gastrectomy with systemic lymphadenectomy has long been the standard treatment, even for superficial cancers, because of the limitations of preoperative assessment for the depth of tumor invasion[1,2] and imaging technique for the detection of regional lymph node metastasis[3-5]. Since its introduction in 1992, laparoscopy-assisted distal gastrectomy (LADG) has become a viable treatment alternative for patients with early gastric cancer[6-8]. Many studies have been conducted on the safety, efficacy, and feasibility of this procedure[9-14]. Surgeons who are seeking to undertake, or who are currently practicing this procedure, should be aware that it is considered as an advanced laparoscopic procedure and it is associated with a significant learning curve. Although many reports have been issued on the learning curves of laparoscopic cholecystectomy[15], laparoscopy-assisted colectomy[16], and laparoscopic urologic procedures[17], no report has been issued on the learning curve of LADG with systemic lymphadenectomy for early gastric cancer.

We hypothesized that the point at which proficiency is reached (as defined as the learning curve plateau) would be associated with improvements in perioperative outcomes, including transfusion requirement, conversion rates to open surgery, postoperative complications, time to first flatus, and postoperative hospital stay. The purpose of this study was to define the nature of the "learning curve" for LADG with systemic lymphadenectomy for early gastric cancer.

MATERIALS AND METHODS

Patients

The Dong-A University Medical Center's stomach cancer database and the medical records of 90 consecutive patients with early gastric cancer who underwent LADG with systemic lymphadenectomy by a single surgeon (MC Kim) between April 2003 and November 2004 were reviewed. The review board of the Dong-A University Medical Center approved the protocol used for LADG with systemic lymphadenectomy in early gastric cancer patients and written informed consent was obtained from every patient that

agreed to LADG with systemic lymphadenectomy.

Patients' characteristics, pathologic findings, and postoperative outcomes were evaluated. Cases with mucosal lesions suitable for endoscopic mucosal resection (EMR) and with a history of upper abdominal surgery were excluded. The indication for EMR at our hospital is a Tm lesion with a size of <2 cm with no ulcer.

Surgical technique

A periumbilical trocar (10 mm) was inserted using the open surgical method, and four trocars were introduced under laparoscopic guidance. A rigid electrolaparoscope (25 °, Panoview plus telescope, Richard Wolf, Germany) was then introduced through the umbilical port. Under pneumoperitoneum of 10-14 mmHg, the greater omentum was divided proximally at about 4 cm from the gastroepiploic arcade towards the lower pole of the spleen, using a new hemostatic device (The Ligasure™ Vessel Sealing System, Valleylab, Boulder, CO, USA). The roots of the left gastroepiploic vessels were then exposed using an ultrasonic dissector (Autosonix™, Tyco/US Surgical Inc., Norwalk, CT, USA) and a hook-type bovie, and divided with double Ligasure™ clamps. Their perforating branches were dissected away from the greater curvature using an ultrasonic dissector (Autosonix™, Tyco/US Surgical Inc., Norwalk, CT, USA), and the right gastroepiploic vein and artery were divided individually at their roots with double clips. The right gastric artery was then exposed and divided at its origin with double clips, thus creating room for the dissection of the suprapyloric lymph nodes (No. 5 lymph nodes). The duodenum was then transected 1 cm distal to the pylorus, using an endoscopic stapling device (Endo cutter 45 staple; Ethicon, OH, USA). After switching to an electrolaparoscope (50°, Panoview plus telescope, Richard Wolf, Germany), no. 8a (the common hepatic artery, anterosuperior group), and no. 9 (the celiac axis) lymph nodes were dissected along each artery, by using ultrasonic dissection and a hook-type bovie. In some cases, no. 11p (the proximal splenic artery), 12a (the hepatic artery), and 14v (the superior mesenteric vein) lymph nodes were dissected. The left gastric vein was then divided, and the root of the left gastric artery was exposed and divided with double clips, allowing dissection of the left gastric artery (No. 7 lymph nodes). The perigastric lymph nodes were dissected along the upper lesser curvature up to the esophagogastric junction. A 5-cm upper transverse skin incision that separated three fingers from the substernal angle, was made from the midline to the right side for the Billroth I reconstruction or to the left side for the Billroth II reconstruction. The distal two-thirds of the stomach were resected using a stapler (Proximate linear cutter 100 mm; Ethicon, OH, USA). Billroth I gastroduodenostomy was performed using a circular stapler (Proximate CDH 25; Ethicon, OH, USA), and Billroth II gastrojejunostomy with side to side jejunojejunostomy using two endoscopic stapling devices (Endo cutter 45 staple; Ethicon, OH, USA) or by hand sewing. Irrigation and observation of the operative field were achieved under pneumoperitoneum after closing the 5-cm minilaparotomy wound. Each trocar wound was closed after a closed suction drain had been placed around the anastomosis.

Table 1 Characteristics and pathologic results of patients

	Total	1–50 cases	51–90 cases	*P*
Total number of patients	90	50	40	
Age (yr, mean±SD)	55.7±12.0	56.3±11.3	54.9±12.9	0.6907

Perioperative management

All patients were managed routinely using a standardized postoperative protocol as follows: (1) No nasogastric intubation or preoperative mechanical bowel preparation; (2) the use of one closed suction drain; (3) sips of water at 48 h after the operation; (4) clear liquid diet after first flatus; (5) the discharge of the patients after tolerance of a soft diet for 2 d; and (6) no postoperative transfusion unless the hemoglobin level fell to or below 80 g/L and the patient complains of anemic symptoms. All patients received a continuous intravenous infusion of mixed analgesics (butorphanol 20 mg, ketorolac 300 mg, metoclopramide 30 mg, saline 100 mL) at 1 mL/h for 3-4 d after surgery.

Calculation of the learning curve

To define the learning curve, the 90 patients were divided into 9 sequential groups of 10 cases in each group and the average operative time of these 9 groups were determined. Other learning indicators, such as transfusion requirements, conversion rates to open surgery, postoperative complication, time to first flatus, and postoperative hospital stay, were evaluated for statistical significance. Statistical analysis was performed using the unpaired Student's *t*-test and the Mann-Whitney *U*-test for continuous variables, and the χ^2 and ANOVA tests for categorical variables. For all the three tests, $P<0.05$ was considered statistically significant. Data were expressed as mean±SD.

Table 2 Overall postoperative outcomes

	Total	1–50 cases	51–90 cases	*P*
Operative time (min, mean±SD)	227.2±48.0	251.3±47.3	227.2±48.0	<0.0001
No. of transfused patients (%)	5 (5.6)	3 (6.0)	2 (5.0)	0.837
Time to first flatus (d, mean±SD)	3.1±0.8	3.1±0.9	3.1±0.6	0.805
Postoperative hospital stay (d, mean±SD)	7.5±1.2	7.6±1.4	7.4±1.0	0.610
Postoperative complication (%)	13 (14.4)	6 (12.0)	7 (17.5)	0.663

Table 3 Comparison of postoperative outcomes (first 50 patients *vs* last 40 patients)

	Operative time (min)	Open conversion	Transfusion requirement	Time to first flatus (d)	Hospital stay (d)	Complication (patients)
First 50 patients	251.3±47.3	1	3	3.1±0.9	7.6±1.4	7
Last 40 patients	197.0±27.7	1	2	3.1±0.6	7.4±1.0	6

P<0.0001

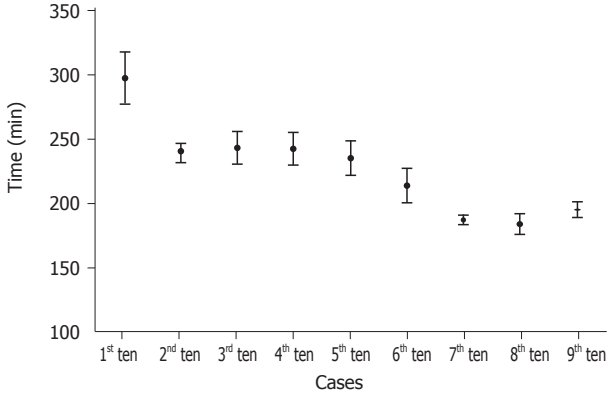

Figure 1 LADG with systemic lymphadenectomy (operative time *vs* number of cases experienced).

RESULTS

Patients' characteristics and pathologic findings are summarized in Table 1. The mean patient body mass index was 22.8 kg/m^2. Of the 22 patients with a submucosal lesion, two patients had one metastatic lymph node. There were no significant differences in patients' characteristics, oncological radicality, and pathology between the two groups.

Mean operative time was 227.2 min (Table 2). Open conversion was required intraoperatively in two cases due to excessive intra-abdominal fat (n = 1) or intra-abdominal adhesion (n = 1). The body mass index of the patient with excessive intra-abdominal fat was 29.3 kg/m^2. Fifteen complications occurred in 13 patients. These complications included wound complications, intra-abdominal bleeding, anastomotic bleeding, dumping syndrome, subcutaneous emphysema, intra-abdominal abscess, and anastomotic stricture. All these complications were treated by conservative management without reoperation. No deaths occurred in this series.

Defining the learning curve

Figure 1 shows two plateaus in operative time *vs* cumulative case number plot for LADG with systemic lymphadenectomy. After the first 10 LADGs, the operative time reached its first plateau (230-240 min/operation) and then reached a second plateau (<200 min/operation) for the final 30 cases, which was between 30 and 40 min/operation faster than that for the first 10-50 cases. We considered that learning was complete at the second plateau, and not at the first. When we compared the postoperative outcomes of the first 50 cases with the last 40 cases, no significant difference was observed despite the fact that mean operative time had been obviously reduced for the last 40 cases (Table 3).

DISCUSSION

The proportion of cancers invading the mucosa or submucosa represents about a half of surgical gastric cancer cases in Korea. Recently, many gastric surgeons have expressed a high level of interest in laparoscopic surgery for early gastric cancer, because laparoscopic surgery has been proven to have substantial advantages over conventional open surgery[14,18-20]. However, LADG with systemic lymphadenectomy is considered technically more complicated than other laparoscopic procedures (e.g., cholecystectomy, Nissen fundoplication, colon resection, or splenectomy) because many great vessels must be identified and extensive lymph node dissection is necessary for radical gastrectomy.

The definition of the completion of learning is clearly arbitrary. To determine that learning has occurred, some have used the minimization of operative complications or the reaching of a steady mean operative time as measures. According to the learning curves of other laparoscopic procedures, surgeons who have performed more than 20 laparoscopic cholecystectomies[15] or 8 laparoscopic urologic procedures[17] have lower complication rates. As for colorectal surgery, approximately 11-15 completed laparoscopic colectomies were found to be needed to comfortably learn this procedure[21]. We hypothesized that the point at which learning has been achieved (as defined by the operative time plateau) would be associated with an improved postoperative outcome. However, though a significant improvement in operative time was noted after the first 50

cases, this did not correspond with a significant reduction in other postoperative outcomes, including transfusion requirements, conversion rates to open surgery, postoperative complications, time to first flatus, or postoperative hospital stay. This finding may be attributed to, firstly, regardless of operative time, transfusion requirement or conversion to open surgery which was rare, and postoperative complications occurred evenly in each of the nine groups. Second, time to first flatus was not proportioned to operative time. The mean time to first flatus in the present study was 3.1 d, although flatus has been reported to return at a mean 2.5 d after laparoscopic gastrectomy and 3.5 d after conventional open gastrectomy[22,23]. However, the previous result of 2.6 d may have been caused by less extensive lymphadenectomy (D1+α).

Although Kitano *et al*.[11] reported that the mean operative time of 116 cases for LADG with D1+α lymphadenectomy (perigastric and no. 7 lymph nodes dissection) was 234 min, Noshiro *et al*.[13] found a mean operative time for 79 cases of LADG with D1+β lymphadenectomy of over 300 min. In another study of 43 LADGs was performed for 2 years, the mean operative time was 225 min despite LADG with D1+β lymphadenectomy[24]. We performed 90 LADGs with D1+β lymphadenectomy for 20 mo, and mean operative time of the present study was 227.2 min. We believe that the operative time required for LADG in gastric cancer is related to the extent of the lymphadenectomy, constant LADG practice, the experience of open radical gastrectomy, information and familiarity with the laparoscopic system and instruments, and the skill of the operative team.

In conclusion, based on operative time analysis, our study shows that experience of 50 cases of LADG with systemic lymphadenectomy for early gastric cancer is required to achieve optimum proficiency.

Abstract

AIM: To characterize the baseline profiles of patients aged 70 years and above with hepatocellular carcinoma (HCC).

METHODS: A series of 127 consecutive patients with HCC were enrolled between 2000 and 2004, and none of them had been diagnosed as having HCC previously. Baseline profiles, including parameters of hepatic function such as serum transaminase and prothrombin time [PT (% activity)] were compared between patients aged ⩾70 and <70 years.

RESULTS: Patients ⩾70 years old showed significantly lower levels of aspartate aminotransferase ($P = 0.04$) and alanine aminotransferase ($P = 0.01$), and significantly higher PTs ($P = 0.04$) and platelet counts ($P = 0.02$). Concomitantly, among ⩾70-year-old patients, HCC was more common in non-cirrhotics, whereas among patients <70 years old, HCC was more common in cirrhotics. There was no significant difference between the groups in the number or size of tumors.

CONCLUSION: Older HCC patients showed less inflammation and better preservation of hepatic function, indicating that not only cirrhotic patients but also non-cirrhotic patients should be considered as a high-risk group among the elderly.

Key words: Hepatocellular carcinoma; Elderly patients; Baseline profile; Non-cirrhosis

INTRODUCTION

Hepatocellular carcinoma (HCC), one of the most common forms of tumors, is increasing in frequency worldwide[1-4]. The increase is attributable to the spread of hepatitis C virus (HCV) infection in the population. HCV-related HCC is more common among the elderly patients, whereas hepatitis B virus (HBV)-related HCC is more common among the younger patients[3,5]. In Japan, fatalities from HCC are higher among patients who are aged 70 years and above[3]. However, the baseline profiles of such patients, including various parameters of hepatic function, have not been thoroughly investigated. In this study, we have evaluated the baseline profiles, including parameters of hepatic function such as alanine aminotransferase (ALT), aspartate aminotransferase (AST), and prothrombin time [PT (% activity)] in HCC patients aged ⩾70 and <70 years.

MATERIALS AND METHODS

A total of 127 consecutive patients with HCC, who had not been diagnosed with HCC previously, were admitted to our department at Kyushu University Hospital between 2000 and 2004 (Table 1). HCC was diagnosed by computed tomography (CT), ultrasonography, angiography and tumor biopsy, and treated with transcatheter arterial chemoembolization (TACE), percutaneous ablation [percutaneous ethanol injection therapy (PEIT) or radio frequency ablation (RFA)], and/or hepatic resection. Liver cirrhosis (LC) was diagnosed based on liver biopsy, laboratory data, ultrasonography, and/or computed tomography. Variables were compared between patients aged ⩾70 and <70 years, which included parameters of hepatic function (albumin, total bilirubin, AST, ALT, PT, and platelet number), serum levels of alpha-fetoprotein (AFP), tumor size and number (solitary or multiple), existence of liver cirrhosis, etiology [HBV, HCV, or non-HBV-non-HCV (NBNC)], and treatment.

Data were presented as mean±SE for quantitative variables. Differences in characteristics between patients aged ⩾70 and <70 years were analyzed by Wilcoxon rank sum test and Fisher's exact test for qualitative variables.

RESULTS

The number of older patients (aged ⩾70 years) and younger patients (aged <70 years) with HCC was 49 and 78, respectively. There was no difference in the proportion

Table 1 Comparison of baseline profiles between elderly patients and younger patients with HCC

Age (yr)	<70	≥70	*P*
n	78	49	
Male/female	56/22	34/15	0.772
Age (yr)	60.4±0.8	74.3±0.5	0.002
Platelet (mm^3)	10.3±0.7	13.9±0.9	0.002
PT (%)	66.8±3.2	76.6±3.1	0.036
Albumin (g/dL)	3.6±0.1	3.8±0.1	0.146
TBil (mg/dL)	1.5±0.2	1.2±0.2	0.298
AST (U/L)	86.4±6.0	66.3±7.9	0.044
ALT (U/L)	79.6±7.1	53.0±6.1	0.010
AFP (ng/mL)	1 651±839	1 006±390	0.562
HBV/HCV/NBNC	11/69/5	2/42/3	0.629
Non-LC/LC	35/44	36/13	0.001
HCC: solitary/multi	61/17	39/10	0.868
HCC: size diameter (mm)	36.0±4.0	28.6±3.0	0.184

of males and females between the two groups (Table 1). The prevalence of HBV and HCV in older and younger patients was 4% and 86%, and 14% and 88%, respectively. A comparison of hepatic function parameters showed differences in the platelet counts, PT (%), and the levels of AST and ALT (Table 1). Platelet counts and PT were significantly higher in older patients ($P = 0.016$ and $P = 0.0355$, respectively). The serum levels of AST and ALT were significantly lower in older patients ($P = 0.0443$ and $P = 0.0100$, respectively). The incidence of HCC among older patients was higher in those without LC than in those with LC, whereas in the younger patients, HCC developed more frequently in those with LC than in those without LC. There was no difference between the age groups in tumor number (solitary or multiple), tumor size, or serum levels of AFP. Resection was performed in 14% of the patients aged ≥70 years and in 13% of those aged <70 years. There was no difference between the groups in the types of treatment received.

DISCUSSION

This study demonstrated that older patients (aged ≥70 years) had higher PTs and platelet counts, and lower levels of AST and ALT as compared with younger patients (aged <70 years). The higher platelet counts and PTs indicate that liver function was better preserved, since platelet counts have been reported to correlate inversely with the degree of liver fibrosis[6]. In our study, 73% (36/49) of the older patients were diagnosed as having chronic hepatitis (non-LC), whereas only 45% (35/78) of the younger patients were diagnosed as having non-LC. Furthermore, the lower levels of AST and ALT indicate that hepatitis (inflammation) was less active. These results indicate that HCC in elderly patients tends to occur more frequently among those with non-LC and mild hepatic inflammation.

HCC is generally thought to be more common among LC patients, and the prevalence of cirrhosis in those with HCC is estima e EUROHEP group demonstrated that the 5-year risk of HCC was increased by 25% for a 60-year-old man with cirrhosis, mild elevation in total bilirubin (TBil) levels, and a low platelet count, whereas the risk was only increased by 3% for a 50-year-old man with cirrhosis, normal TBil levels, and normal platelet counts[8]. Tarao *et al*. also reported that the incidence of HCC in LC patients with ALT ≥80 U/L was much higher than in those with ALT <80 (13%/year *vs* 3%/year)[9]. These results are similar to our observations in patients <70 years old. However, in contrast with the previous studies, we found that the development of HCC in older patients was not strongly associated with LC, ALT levels, or the duration of disease. Although the precise reasons for this difference remain unknown, aging itself might be an important factor, independent of the duration of disease, since older people generally have a higher risk of cancer, regardless of the type[10]. It is possible that the patients with cirrhosis and HCC have died before reaching the age of 70 and those survived patients had well preserved hepatic function. To clarify this point, a Kaplan-Meier survival analysis of the two groups over the 5-year period of observation is needed. Comparison of the two groups of patients (<70 and ≥70 years) with chronic viral liver disease without HCC is also needed to know whether our present findings are indeed unique for HCC patients or a common profile in all patients with chronic viral disease.

Recently, the importance of surveillance for HCC among older LC patients has been recognized[11], due to the increasing life expectancy of cirrhotic patients as well as of the general population[1,12], and because surveillance among the older subjects can facilitate early detection and more effective treatment[13-15]. Trevisani *et al*. reported that surveillance for HCC in elderly LC patients improves their survival by identifying certain cancers earlier when they are more amenable to the treatment[11]. Better preservation of hepatic function as well as an early diagnosis can allow for more effective treatment such as hepatic resection. In our study, 14% of older patients received hepatic resection, which was similar to the percentage among younger patients. Therefore, we suggest that elderly non-LC patients should also be included in the surveillance to facilitate both early diagnosis and effective treatment.

Another significant finding in our study is that most of the patients (86%) suffered from HCV infection. It was recently reported that interferon treatment lowered the incidence of HCC[16,17], suggesting that interferon therapy would be advisable for preventing the development of HCC, even in elderly patients.

In conclusion, our study demonstrated that patients ≥ 70 years old with HCC had baseline clinical profiles that differed considerably from those of patients <70 years old; that is, HCC was more likely to develop among non-LC patients with well-preserved hepatic function and mild inflammation. Our results suggest that elderly non-LC patients, as well as LC patients, should be recognized as a high-risk group for HCC.

Abstract

AIM: To evaluate the efficacy of CT-maximum intensity projection (CT-MIP) in the detection of gastric varices and their inflowing and outflowing vessels in patients with gastric varices scheduled to undergo balloon-occluded retrograde transvenous obliteration (B-RTO).

METHODS: Sixteen patients with endoscopically confirmed gastric varices were included in this study. All patients were evaluated with CT-MIP using three-dimensional reconstructions, before and after B-RTO.

RESULTS: CT-MIP clearly depicted gastric varices in 16 patients (100%), the left gastric vein in 6 (32.5%), the posterior gastric vein in 12 (75.0%), the short gastric veins in 13 (81.3%), gastrorenal shunts in 16 (100%), the hemiazygos vein (HAZV) in 4 (25.0%), the pericardiophrenic vein (PCPV) in 9 (56.3%), and the left inferior phrenic vein in 9 patients (56.3%). Although flow direction itself cannot be determined from CT-MIP, this modality provided clear images of the inflowing and the outflowing vessels. Moreover, in one patient, short gastric veins were not seen on conventional angiographic portography images of the spleen, but were clearly revealed on CT-MIP.

CONCLUSION: We suggest that CT-MIP should be considered as a routine method for detecting and diagnosing collateral veins in patients with gastric varices scheduled for B-RTO. Furthermore, CT-MIP is more useful than endoscopy in verifying the early therapeutic effects of B-RTO.

Key words: Gastric varices; CT-MIP; Portal hypertension

INTRODUCTION

Gastric varices have been increasingly recognized as a major cause of gastrointestinal bleeding in patients with portal hypertension[1,2]. These varices are appreciably less common than their more usual esophageal counterparts, but are associated with a poor prognosis.

Recent technical advances offer us increasingly greater imaging clarity of gastric varices. However, diagnosing this type of varices is problematic, mostly due to the absence of data on the hemodynamic features of such patients. Moreover, a non-invasive imaging modality is preferable in these high-risk patients. CT is currently reported to be superior to angiography in the detection of paraumbilical and retroperitoneal varices[3]. Furthermore, CT-MIP as a rendering method for visualizing the portal system provides superior visualization of portal collaterals.

The purpose of this study was to assess the accuracy and utility of CT-MIP in evaluating the collateral veins in patients with gastric varices before and after B-RTO. We also evaluated the detection of gastric varices and their inflowing and outflowing vessels by CT-MIP.

MATERIALS AND METHODS

Patients

Sixteen consecutive patients with gastric varices confirmed by endoscopy at the Saiseikai Niigata Second Hospital were enrolled in this study between April 1999 and April 2004. Both CT-MIP and transarterial portography were performed in these patients before and after B-RTO. Patients [8 men and 8 women, aged 45-72 years (mean 59.31 years)] were selected for routine endoscopic screening for esophago-gastric varices. The cause of portal hypertension was liver cirrhosis in 14 patients, and cirrhosis coupled with hepatocellular carcinoma in two patients. Cirrhosis was diagnosed through imaging, and regarding stage, 13 patients were classified as Child-Pugh class B and 3 as Child-Pugh class C. The etiology of liver disease was hepatitis B virus (HBV); in 1 patient

(surface antigen (HBs)-positive), hepatitis C virus (HCV) in 7 (anti-HCV antibody-positive), alcoholic liver disease in 5, and autoimmune hepatitis in 3. Endoscopic findings of gastric varices were evaluated according to the general rules proposed by the Japanese Research Society for Portal Hypertension. Variceal form (F) was classified as small and straight (F1, n = 0); enlarged and tortuous (F2, n = 7), or large and coil-shaped (F3, n = 9). Variceal location (L) was classified as: cardiac (Lg-c; located adjacent to the cardiac orifice, n = 0); fundal (Lg-f; located far from the cardiac orifice, n = 11); or cardiofornical (Lg-cf; located between the cardiac orifice and the fornix, n = 5). Patient parameters and characteristics of varices are shown in Table 1.

Follow-up endoscopic examination was performed to evaluate the size of gastric varices at 1 wk, 1 mo, and 3 mo after B-RTO, with CT-MIP also performed at these times together.

Computed tomography

All CT studies were performed using an SD-CT scanner (HiSpeed LX/i; General Electric Medical Systems, Milwaukee, WI, USA). Gantry rotation time was 0.8 s. Initially, non-contrast enhanced images were obtained for localization with 10.0 mm beam collimation. Subsequently, after placing a 20-gauge plastic cannula in an antecubital vein, a bolus of 100 mL of iopamidol (Omnipaque; Daiichi Pharmacy Co., Ltd, Tokyo, Japan) was injected with an automated power injector (Auto Enhance A-50; Nemoto Kyorindo, Tokyo) at the rate of 3 mL/s. Scan delays were empirically set at 25, 50, and 200 s after contrast material injection for the arterial, portal, and equilibrium phases, respectively. The entire liver was scanned with a slice thickness of 2.5 mm and table feed of 15 mm (pitch of 6) in a cranio-caudal direction in the arterial phase. In the portal phase, scanning was performed at a slice thickness of 2.5 mm and table feed of 7.5 mm (pitch of 3) in a cranio-caudal direction. In the equilibrium phase, slice thickness was set at 5 mm and table feed at 15 mm (pitch of 3) in a cranio-caudal direction.

Three-dimensional reconstructions

Sources with 50% overlap were obtained from the raw data of the portal phase, and a total of 250-350 images were generated. These images were transferred to a workstation [Advantage Workstation 3.1; General Electric Medical Systems, Milwaukee, WI, USA), and three CT portographic models (volume rendering [VR], MIP, and surface shade display (SSD)] were reconstructed. In MIP and VR, voxels over -200 HU were selected. CT portography was reconstructed using the VR algorithm with lower thresholds of 70-90 HU. Display parameters including width, level, opacity, and brightness were chosen subjectively to best visualize the portal vasculature. For MIP, a slab of some 3-10 cm was applied to avoid interference of the vertebral bodies, and the overlying skeletal structures were carefully removed if necessary. Voxel data over the threshold level of 70-90 HU were extracted and applied for SSD images.

Transarterial portography

Transarterial portography was performed with the digital subtraction angiography technique (DSA, General Electric Medical Systems, Milwaukee, WI, USA) in all the 16 patients to evaluate portosystemic collaterals by the Seldinger method. In all cases, transarterial portography was performed through both the superior mesenteric and splenic arteries using the standard angiographic technique. After the administration of prostaglandin E1 (Palcus, Taisho Pharmacy Co., Ltd, Tokyo), a total of 25 mL of contrast material was injected by power injector at a rate of 5 mL/s via the superior mesenteric artery. Portography via the splenic artery was also obtained with 20 mL of contrast material at a rate of 5 mL/s. Balloon-occluded retrograde transvenous venography (B-RTV) was performed using a DSA device, and was done with selective injection of contrast material into the gastrorenal shunt in all the patients.

After confirming complete visualization of the gastric varices, the sclerotic agent (a mixture of equal amounts of 10% ethanolamine oleate and contrast medium) was injected through the balloon catheter until stasis was obtained in the gastric varices. Eradication of all gastric varices was achieved in all the patients.

RESULTS

All CT-MIP studies were of diagnostic quality, identifying the main portal veins and clearly delineating gastric varices in all the 16 patients (100%). Inflowing vessels to gastric varices were revealed by CT-MIP in all the patients (100%) and comprised the left gastric vein in 6 (32.5%), the posterior gastric vein in 12 (75.0%), and short gastric veins in 13 (81.3%) (Table 2). Regarding outflowing vessels from gastric varices, CT-MIP identified gastrorenal shunts in 16 patients (100%), the hemiazygos vein (HAZV) in 4 (25.0%), the pericardiophrenic vein (PCPV) in 9 (56.3%), and the left inferior phrenic veins in 9 patients (56.3%) (Table 2).

HAZV	4	4

Pericardiophrenic V. (PCPV); hemiazygos V. (HAZV); Lt. inferior phrenic V. (LIPV); gastrorenal shunt (G-R shunt)

We then investigated collateral imaging, comparing CT-MIP with angiographic findings (conventional arterial portography) in all the patients. Gastric varices were delineated in all the 16 patients by both CT-MIP and angiography. Both CT-MIP and angiography depicted the gastrorenal shunt in all patients who were studied. Findings of CT-MIP and angiography agreed for the left gastric vein in six patients, for the short gastric vein in one, for the left gastric vein and short gastric vein in one, and for the left gastric vein and the posterior gastric vein in one. In two patients, CT-MIP revealed the short gastric vein as an inflowing vessel to gastric varices, while angiography failed to identify these veins (Table 3). However, CT-MIP failed to reveal the outflowing blood vessels in two patients, while angiography identified the left inferior phrenic vein and PCPV as outflowing vessels in these cases (Table 4). No statistically significant difference between CT-MIP and conventional angiography was apparent in the detection rates of gastric varices and their inflowing/outflowing vessels.

In case 5, in a 53-year-old woman, the endoscopic view revealed Lg-f, F3 type varices (Figure 1A). Using CT-MIP, clear images of gastric varices were obtained and agreed with those of angiographic findings (Figures 2A and B). The short gastric vein and the posterior gastric vein were identified as inflowing, and the gastrorenal shunt and left inferior phrenic vein as outflowing. One week after the procedure, endoscopy revealed unchanged variceal size, although the gastric varices had developed bronze discoloration (Figure 1B). One month after B-RTO therapy, complete disappearance of the varices was observed and this persisted for about 3 mo (Figure 1C).

CT-MIP at 1 wk after the treatment revealed disappearance of the gastrorenal shunt (Figure 2C). CT-MIP was therefore superior to conventional angiography in evaluating treatment of gastric varices in all cases.

DISCUSSION

The increasing numbers of patients being treated for portal hypertension has led to a growing demand for radiographic examination of the portal venous system. Several methods including endoscopy and intravascular interventional techniques such as balloon-occluded retrograde transvenous obliteration (B-RTO) are available for treating esophageal and gastric varices[4]. Evaluation of the portosystemic collateral pathways in patients with portal hypertension is essential and potentially helpful for clinical management.

For many years, transcatheter portography via the superior mesenteric or splenic arteries has been considered as a standard technique for visualizing the portal vein. However, it is gradually being challenged by non-invasive means of portal venous assessment. Several reports have demonstrated the usefulness of CT for examining the patency of the portal venous system for assessing portosystemic collaterals and evaluating the presence and patency of portosystemic shunts[5,6]. Studies have shown the clinical usefulness of CT-MIP in various diagnostic fields. Particularly in assessing intracranial vessels, CT-MIP has become a non-invasive alternative to conventional angiography for depicting aneurysms and arteriovenous malformations[7]. In contrast, CT-MIP has seldom been used in evaluating abdominal veins, particularly portosystemic collaterals. Recently, however, CT-MIP has been reported to be useful for evaluating the portal venous system in patients with portal hypertension[8] and it is possible that this modality is more sensitive than conventional angiography in detecting esophageal and gastric varices. To the best of our knowledge, no attempt has been made to evaluate whether CT-MIP might yield useful information on gastric varices, and only a few

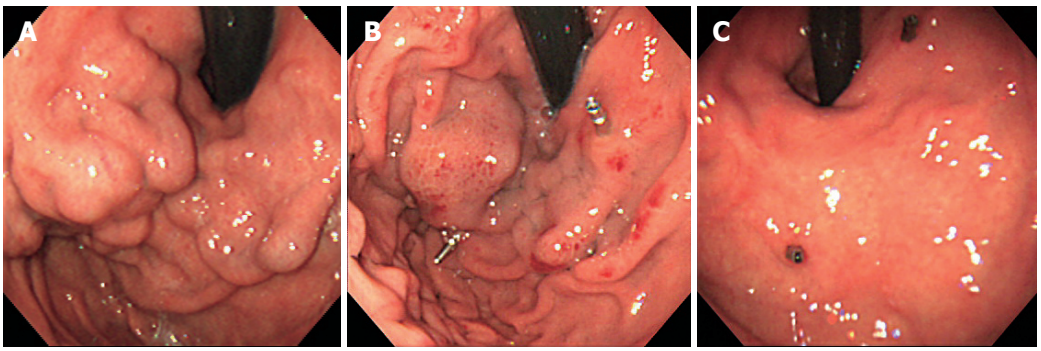

Figure 1 Case 5, a 53-year-old woman. (**A**) The endoscopic view revealed Lg-f F3 type varices. (**B**) One week after the procedure, endoscopic findings revealed varices to be unchanged in size, although the gastric varices had developed bronze discoloration. (**C**) One month after B-RTO therapy, complete disappearance of the varices was observed, and this persisted for about 3 mo.

reports have compared the results of CT-MIP with those of conventional angiographic portography regarding visualization of portosystemic collaterals[9].

We compared CT-MIP for portal venous phase images and DSA. We observed the hemodynamics of the gastric varices before and after B-RTO by means of CT-MIP. The inflowing vessels to gastric varices generally consist of the short gastric veins, the posterior gastric vein, and the left gastric vein, while the outflowing vessels are commonly gastrorenal shunts. In this study, CT-MIP more thoroughly delineated gastrorenal shunts, the left gastric vein, and gastric varices than did angiography and CT. Unlike DSA, CT-MIP is unable to demonstrate direction of the flow within the portal venous system. However, CT-MIP proved so effective that it can be considered as a less invasive alternative to conventional angiographic portography for assessing portosystemic collaterals.

CT-MIP was associated with the following limitations. Small vessels were not defined as well with CT-MIP as with retrograde venography performed during balloon occlusion. The modality is also prone to certain artifacts, such as those due to surrounding tissue and marking clips. In addition, it was difficult to distinguish between intramural gastric varices and extramural collateral veins using CT-MIP.

On the other hand CT-MIP has certain advantages. Firstly, it is a non-invasive modality. Furthermore, CT-MIP is useful for detecting the entire length of gastric varices, which is not always possible with B-RTV due to the limitations of venography. This study has emphasized that CT-MIP may be useful for the treatment of patients with gastric varices[10]. Moreover, the technique may be useful for evaluating the effect of embolization therapy[11]. Endoscopic findings of gastric varices after B-RTO are particularly limited, owing to the depth of submucosal or extramural collateral veins. On endoscopic findings following B-RTO, gastric varices gradually become reduced in size, disappearing completely after some months. Hence, CT-MIP revealed disappearance of gastrorenal shunts and gastric varices after B-RTO.

CT-MIP enabled us to detect the blood flow from gastric varices to other collateral shunts and is therefore useful in the follow-up after therapeutic procedures[12].

We suggest that CT-MIP can be used as a routine method for detecting and diagnosing collateral veins in patients with gastric varices and that it is effective for use with embolization therapy for gastric varices. Moreover, CT-MIP may also be useful for the assessment of therapeutic effect of B-RTO and could potentially demonstrate residual gastric varices after B-RTO, better than endoscopy.

We conclude that CT-MIP is a useful method for the

assessment of therapeutic effect following treatment of gastric varices. Although further evaluation and the development of alternative therapies for the treatment of gastric varices are warranted, it would seem that CT-MIP has a valuable role in this situation.

When considering B-RTO for the treatment of patients with gastric varices, CT-MIP is useful for selecting the patients as candidates, for planning the procedure, and finally for evaluating the results. Furthermore, CT-MIP may be useful for detecting collateral vessels by portal hypertension.

Abstract

AIM: To investigate the effect of probiotic bacterium, *Clostridium butyricum* MIYAIRI 588 strain (CBM) on the changes of the fecal flora in *Helicobacter pylori* (*H pylori*) treatment.

METHODS: Thirty-five patients with gastric or duodenal ulcers positive for *H pylori* were randomized either to 1 wk amoxicillin, clarithromycin, lansoprazole (Group 1) or to the same regimen supplemented with CBM 7 d ahead of the triple therapy (Group 2). Stool samples were collected before and 2, 4, 7, 15, and 22 d after the starting eradication therapy, and were examined intestinal flora. Patients were required to keep a diary record of their condition.

RESULTS: Obligate anaerobes decreased significantly on d 2, 4, 8 and 15 in Group 1. On the other hand, they did not decrease significantly in Group 2. The *Escherichia coli* was dominant bacterium in *Enterobacteriaceae*, but that was replaced by other species such as *Klebsiella* and *Enterobacter* after eradication in Group 1. The change was suppressed in Group 2. Abdominal symptoms were less frequent in Group 2 than in Group 1.

CONCLUSION: The combined use of CBM reduced the changes in the intestinal flora and decreased the incidence of gastrointestinal side effects.

INTRODUCTION

Antibiotic therapy causes loose stools and/or diarrhea quite frequently, probably because of changes in the intestinal flora. Super infection arising from the alterations of the normal intestinal flora is a factor in the onset of infectious enteritis.

Helicobacter pylori (*H pylori*) is deeply involved in gastroduodenal ulcer disease and *H pylori* -positive patients are generally treated with antibiotics to eradicate this bacterium[1]. Triple therapy with a proton pump inhibitor and two antibiotics selected from among the following three: amoxicillin, clarithromycin and metronidazole, is now considered to be the standard therapy, and it is reported that a bacterial eradication rate of about 80-90% can be achieved[2-4]. Although such therapy causes few serious adverse reactions, gastrointestinal side effects like diarrhea and loose stools occur at a high incidence[5].

It is known that probiotic supplementation prevents or reduces of antibiotics-induced diarrhea. Recent studies have shown that probiotics were effective against gastrointestinal symptoms associated with *H pylori* eradication therapy[6]. Probiotics are defined as viable microorganisms which, when ingested, have a beneficial effect on human health, including amelioration or prevention of specific pathologic conditions[7].

Clostridium butyricum is a butyric acid producing Gram-positive anaerobe which is found in soil and the intestines of healthy animals and humans, and the MIYAIRI 588 strain of *C. butyricum* (CBM) has been used as probiotics for treating and preventing non-antimicrobial induced diarrhea, antimicrobial associated diarrhea and constipation in human beings[8-10]. MIYA-BM® tablets (Miyarisan pharmaceutical Co., Ltd., Tokyo, Japan) containing CBM were approved from Japanese Ministry of Health and

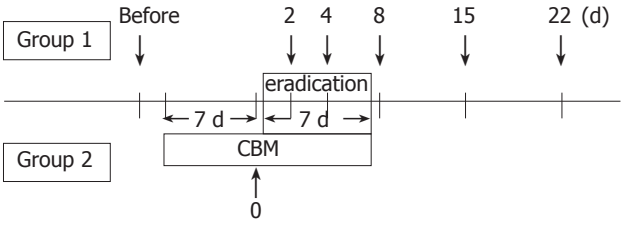

Figure 1 Study design. Fecal sample collection(↓).

Welfare for human clinical use since 1970 in Japan.

However, the preventive effect of CBM preparation on the abnormalities of intestinal microflora due to *H pylori* eradication therapy was unknown. Therefore, in the present study, we have examined the changes of fecal flora and gastrointestinal symptoms frequently during *H pylori* eradication therapy, and evaluated the utility of CBM supplementation to prevent the disturbance of the intestinal flora.

MATERIALS AND METHODS

Patients

Of the patients diagnosed as having gastric or duodenal ulcers at the outpatient clinic of the First Department of Medicine of Chiba University, 35 patients (male/female: 28/7; mean age 52.7±11.3 years) were enrolled in this study. They were all positive for *H pylori* by culture method, microscopical examination and the rapid urease test (PyloriTek® test kit, Serim Research Corp., Elkhart, IN, USA).

The patients were blindly and randomly allocated to two groups. Seventeen patients were assigned the 1 wk triple therapy consisting of amoxicillin 1 500 mg b.i.d., clarithromycin 400 mg b.i.d. and lansoprazole 60 mg b.i.d. (Group 1). Alternatively, eighteen were assigned to the same regimen supplemented with CBM (120 mg t.i.d.), which was started 1 wk prior to the eradication therapy for 14 d (Group 2). The patients had not been treated with any drugs that might have influenced intestinal bacteria, and had no known underlying gastrointestinal disorders. They were all given a full explanation of the contents of the study and they provided their informed consent in writing.

Six weeks after the completion of the therapy, the ^{13}C-urea breath test was performed to check whether eradication had been achieved.

Collection of stool samples

Stool samples were collected the day before the start of the therapy, and on d 2, 4, 8, 15, and 22 after the start of *H pylori* eradication therapy in Group 1. In Group 2, stools were also collected 1 wk after the administration of CBM (Figure 1). Fresh samples were placed in a transporter filled with CO_2 (Kenkiporter® II, Clinical Supply, Gifu, Japan), and were transferred under refrigeration for culture within 24 h of the collection.

Examination of intestinal flora

Intestinal flora was investigated according to Mitsuoka's method[8]. Any bacterium detected was identified at the level of species or genus, and counted. The microorganisms were classified into sub groups of bacteria according to morphology of the colonies, Gram staining and cell shapes. Isolation of *Clostridium difficile* was also attempted.

The nonselective media used for isolation included TS, EG, and BL agar, while selective media included DHL, TATAC, P, PEES, LBS, NBGT, ES, BS, and CCMA agar. A stool sample (0.5 g) was placed into an anaerobic glove box (N_2 80%, H_2 10%, CO_2 10%) and was diluted with a diluent for anaerobic bacteria from 10-fold to 10^8-fold in 10 steps. Aliquots (0.05 mL) of each dilution were cultured anaerobically in an incubator in the glove box at 37 ℃ for 3 d. When TS, DHL, TATAC, P, or PEES agar was used the culture plates were removed from the glove box after the bacteria were seeded and were cultured aerobically at 37 ℃ for 1 to 2 d. Any colony that grew during anaerobic culture was also examined for aerobic growth. Smears were prepared on slide glasses for any colony that grew and the smears were subjected to Gram staining for microscopic observation. Then each organism was classified on the basis of its characteristics, including colony morphology, growth under aerobic conditions, and growth in selective culture media. The number of live bacteria of each genus per 1 g of feces was calculated from the number of colonies and converted into a logarithmic equivalent for each bacterial species identified; log colony forming unit/g feces (logCFU/g feces). The detection limit was 2.3 logCFU/g feces. The total count of viable bacteria was calculated from the sum of the counts of each bacterial species. Species in the Enterobacteriaceae were identified by the kit of Enterotube® Ⅱ (Becton Dickinson, USA).

Assessment of symptoms

Each patient was required to keep a daily record of the conditions of their stools and any abdominal symptoms, from before the therapy to 2 wk after the completion of *H pylori* eradication therapy.

Statistical analysis

Bacterial counts were expressed as the mean±SD. Statistical evaluation of changes within groups was carried out using the Wilcoxon signed-rank test. The Mann-Whitney *U* test was used for comparison between groups. Fisher's exact test was performed to compare the detection rates. Differences of $P<0.05$ were considered to be statistically significant.

RESULTS

Intestinal flora before H pylori eradication therapy

The levels of obligate and facultative anaerobes in the groups did not differ significantly. The predominant bacteria were obligate anaerobes, such as Bacteroidaceae,

Table1 Level of obligate and facultative anaerobes in Group1 and Group2, before *H pylori* eradication therapy (mean±SD)

Population	LogCFU/g			
	Group 1 (n = 17)		Group 2 (n = 18)	
Total counts	10.4±0.4		10.2±0.5	
Obligate anaerobes	10.4±0.4		102±0.6	
Bacteroidaceae	10.1±0.4	(100)	9.3±1.6	(100)
Bifidobacteria	9.8±0.6	(93.8)	9.6±0.6	(93.8)
Peptococci	8.9±0.8	(62.5)	9.0±0.5	(62.5)
Clostridia	7.5±1.9	(93.8)	7.9±1.5	(100)
Micrococci	3.0±1.2	(25)	3.5±1.8	(37.5)
Facultative anaerobes	8.3±0.7		8.1±1.0	
Enterobacteriaceae	7.2±1.7	(93.8)	6.7±1.5	(100)
E.coli	7.3±1.4	(81.3)	6.4±1.6	(93.8)
Others	6.9±1.8	(18.8)	5.7±1.0	(31.3)
Enterococci	7.3±1.1	(93.8)	7.9±1.0	(93.8)
Lactobacilli	7.2±1.6	(100)	6.9±1.0	(93.8)
Bacilli	7.6±0.9	(37.5)	7.4±0.6	(25)
Yeasts	5.0±2.0	(75)	4.8±1.8	(56.3)

There are no significant differences between the two groups using Mann-Whitney *U* test. Figures in parentheses are detection rates.

Table 2 Detection rates of fecal flora

			Detection rates (%)				
Population	Group	Before	D2	D4	D8	D15	D22
Bacteroidaceae	1	100	100	93.8	100	100	93.3
	2	100	94.4	100	100	100	94.4

[a]P<0.05, [b]P<0.01, [d]P<0.001 *vs* before, Fisher's exact test.

Bifidobacteria and in both groups (Table 1). As for the viable counts and detection rates of all species, there was not significant difference between the two groups. The viable counts and detection rates of all species did not change significantly between before and 1 wk after CBM administration in Group 2 (data not shown). None of the patients was positive for *C. difficile* as assessed by culture.

Counts of CBM and detection rate

Counts of CBM increased and averaged 6.7 logCFU/g on the day before eradication therapy. The detection rate was the highest on d 2 (90%); it gradually decreased. On d 15, CBM became under detectable.

Table 3 Clinical symptoms observed during and after *H pylori* eradication therapy

	Group 1 (n = 17, %)		Group 2 (n = 18, %)	
Loose stool	8	(47.1)	4	(22.2)
Water diarrhea	2	(11.8)	1	(5.6)
Abdominal pain	2	(11.8)	0	(0)
Abdominal distention	2	(11.8)	0	(0)

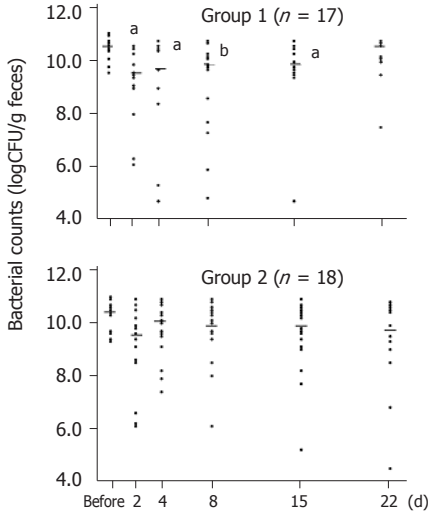

Figure 2 Obligate anaerobes during and after *H pylori* eradication therapy There are no significant differences between the two groups before therapy. Statistically significant changes are noted as [a]P<0.05, [b]P<0.01 before using the Wilcoxon's signed-rank test.

Intestinal flora after starting H pylori eradication therapy

Obligate anaerobes decreased significantly on d 2, 4, 8, and 15, and returned to their pretreatment levels on d 22 in Group 1. On the other hand, the number of obligate anaerobes did not change significantly at any time in Group 2 (Figure 2). The number of facultative anaerobes did not decrease significantly in either group.

The detection rates of intestinal flora are shown in Table 2. Bacteroidaceae, the dominant bacteria, did not change after starting eradication of *H pylori* in either group. *Bifidobacterium* was significantly lower on d 2, 4, and 8 in Group 1, in the other, only on d 4 in Group 2. As for each group of facultative anaerobes, *E.coli* was significantly lower on d 4, 8 and other species such as *Klebsiella* and Enterobacter in Enterobacteriaceae were significantly higher on d 2, 4, 8, and 15 in Group 1. On the other hand, either Enterobacteriaceae did not change significantly in Group 2. Lactobacilli significantly lower in either group.

Yeasts was significantly higher on d 4 in Group 1. No significant alterations in Yeasts were observed in Group 2. All bacterial groups recovered to pretreatment levels d 22 after completion of the drug administration. No patients were colonized with *C.difficile* at any time.

Clinical symptoms

As for abdominal symptoms, in Group 1, loose stools were noted in 8 of 17 patients (47.1%): diarrhea in 2 of 17 patients (11.8%): abdominal pain and distention in 2 of 17 patients (11.8%), each. In Group 2, loose stools were noted in 4 of 18 patients (22.2%) and diarrhea in 1 of 17 patients (5.6%). The rates were lower in Group 2, although the differences were not significant (Table 3). Treatment was successful in 13 out of 17 patients in Group 1 (76.5%) and in 17 out of 18 patients in Group 2 (94.4%).

DISCUSSION

The intestinal flora in our subjects before the treatment was similar to that detected in normal adults by Mitsuoka[11]. It is known that the normal fecal flora is almost the same as that of the recto-sigmoid colon. Intestinal flora is reported to remain stable in each individual, although it differs among individuals[12-13]. However, it has been shown that the administration of antimicrobial agents, which are excreted in the bile, in the intestinal mucosa or are incompletely absorbed, causes changes in the normal intestinal flora.

Buhling *et al*[14]. have shown that infrequent detection of Clostridia, *Veillonela, Eubacteria, Actinomyces,* Bifidobacteria and *E.coli* with simultaneous more frequent growth of other Enterobacteria and *Yeasts* on d 8 of starting *H pylori* treatment, and after 4 wk of therapy, the microflora returned to normal.

When they collected stool samples for three times (d 0, 8, 35-40), we examined the chronological changes of the intestinal flora were followed 6 or 7 times at short intervals during and after *H pylori* treatment in this study.

Then we found that the total bacterial counts started to decrease as early as on d 2 of therapy. Especially, obligate anaerobes, which are the dominant bacteria, were markedly reduced. And it took 3 wk for them to return to their pretreatment levels after starting of therapy.

These bacteria are known to produce short-chain fatty acids (SCFA). Such SCFA are considered to promote proliferation of colonic epithelial cells, provide energy for colonic epithelial cells and to stimulate the absorption of water and sodium[15-19].

Previous studies have demonstrated a close correlation between a decrease in the viable count of anaerobes and a reduction in SCFA content. The drastic reduction of intestinal SCFA associated with the decrease in anaerobes during the diarrheal stage and the increase of the pH thought to be due to these changes, result in increase of the fecal water content[20-22].

Probiotics are known to prevent or lower the antibiotic-related gastrointestinal side effects. It is reported that CBM together with germinated barley foodstuff effectively increased the level of SCFA in feces and suppressed dextran sulfate sodium-induced experimental colitis in rats[23]. Butyric acids, which is produced by CBM has stronger stimulatory effects on epithelial cell proliferation than other SCFA, such as acetic acid or propionic acid[24].

Tanaka *et al*[25]. reported that the effect of CBM on the side effect of *H pylori* eradication triple therapy *in vivo*. These results have shown that obligate anaerobe and Lactobacillus decreased in the rat intestine and then SCFA in intestinal contents were decreased. However, administration of CBM preparation with *H pylori* eradication triple therapy was increased SCFA and resident fusiform bacteria in the mucous layer were more frequently observed in rats administered with CBM preparation than *H pylori* eradication triple therapy.

Our present findings show that CBM preparations prevent the decrease of obligate anaerobes and reduce the frequency of gastrointestinal side effects. These result similar to the pervious *in vivo* result. However, we did not examine the concentration of SCFA in this study but it is possible that the one of mechanism of action of CBM preparation to prevent the side effect induced by not only maintenance of intestinal flora but also increased SCFA contents by CBM.

In our study, *H pylori* eradication therapy caused a significantly greater decrease of *E.coli* , as a results, Enterobacteriaceae, except of *E.coli,* such as *Klebsiella* and *Enterobacter* that are known to potential cause of diarrhea was rising in Group 1.

Our results showed that CBM suppressed the replacement of *E.coli* by other species in Entero-bacteriaceae and superinfection.

In conclusion, intestinal flora with an eradication treatment of *H pylori* not a little changed. The change was reduced by supplementation of CBM, and the frequency of gastrointestinal side effects decreased. Furthermore CBM may have some beneficial effects on *H pylori* infection.

ACKNOWLEDGMENT

We would like to express our gratitude to Mamoru Tanaka, Miyarisan pharmaceutical Co., Ltd. for his technical help.

Abstract

AIM: To validate novel single nucleotide polymorphisms (SNPs) in Greek patients with Crohn's disease (CD).

METHODS: A total of 120 patients with CD, 85 patients with UC, and 100 unrelated healthy controls were genotyped. Genotyping was performed by allele-specific PCR or by PCR-RFLP analysis.

RESULTS: Our results showed that the 1672T and -207C alleles were obviously over-represented in CD patients only ($P<0.01$ and $P<0.05$, respectively) compared to the control population. The G113A polymorphism was completely absent in our studied population. The odds ratio for the carriage of the TC haplotype was 2.21 for CD patients as compared with controls. Additionally, the frequency of the TC haplotype was increased in patients with ileocolitis or colitis, and was mainly associated with the fibrostenotic phenotype of the disease. Furthermore, when the TC haplotype was compared jointly with the carriage of at least one mutation of the *NOD*2/*CARD*15 gene, there was an increased risk for CD, but not for UC, compared to controls. Regarding the location of the disease, the concomitant presence of the TC haplotype and *NOD*2/*CARD*15 mutations was mainly associated with ileocolitis or ileitis.

CONCLUSION: Collectively, our results suggest that the 1672T variant of the *OCTN*1 gene and the -207C variant of the *OCTN2* gene represent risk factors for CD in the Greek population.

Key words: Crohn's disease; SNPs; *OCTN1*; *OCTN2*; *DLG5*

INTRODUCTION

The inflammatory bowel diseases (IBD), Crohn's disease (CD) and ulcerative colitis (UC), represent common chronic relapsing and remitting inflammatory disorders of the intestine. The pathogenesis of IBD is complex and both environmental and genetic factors contribute to its etiology. A series of genetic and epidemiologic studies have provided conclusive evidence for the presence of genetic determinants of disease susceptibility and progression[1]. Genome-wide linkage studies of IBD families that were affected by multiple factors have been remarkably successful in identifying a number of susceptibility loci, with convincing replication shown for at least 7 loci (IBD1-7)[2]. In 1996, Hugot *et al*[3]. identified the first susceptibility locus for CD adjacent to the centromere on chromosome 16 (IBD1)[3]. This has been further corroborated in several independent Caucasian populations[4-6]. In 2001, three independent CD mutations within the *NOD*2/*CARD*15 gene, mapping to chromosome 16, were discovered. These mutations are strongly associated with CD in populations of European descent[7-11].

Very recently, Peltekova *et al*[12]. reported on two novel functional single nucleotide polymorphisms (SNPs) in the carnitine/organic cation transporter (OCTN) cluster on 5q31 (designated as the IBD5 locus) that were associated with CD[12]. The cation transporters are expressed in the liver, kidney, intestine, brain, heart and placenta, and maintain physiological cation environments in the organism.

A C1672T substitution in exon 9 of the *OCTN*1 gene and a G-207C in the *OCTN*2 promoter region have been suggested as causative mutations to increase susceptibility to CD. Additionally, Stoll *et al*[13]. reported that a G113A SNP in exon 3 of the *DLG*5 gene was also associated with susceptibility to IBD. This gene is located on the long arm of chromosome 10 (10q23) and encodes a scaffolding protein involved in the maintenance of epithelial integrity. Genetic variants in *DLG*5 could therefore interfere with the epithelial barrier.

Table 1 Demographic characteristics and clinical features of 120 patients with Crohn's disease and of 85 patients with ulcerative colitis

	Crohn's disease	Ulcerative colitis
Total number	120	85
Sex (male/female)	58/62	42/43
Age of diagnosis (mean±SD yr)	29.82±14.00	33.36±14.24
Family history in first-degree relative (%)	4 (3.3 %)	5 (5.9%)
Smoking habit (%)		
Never	50 (41.7%)	48 (56.5%)
Ex-smoker	11 (9.2%)	14 (16.5%)
Current	59 (49.2%)	23 (27.1%)
Localization of disease		
Ileal	39 (32.5%)	
Colonic	11 (9.2%)	
Ileocolitis	67 (55.8%)	
Upper gastroenteric	3 (2.5%)	
Disease features		
Inflammatory	78 (65%)	
Fibrostenotic	32 (26.7%)	
Fistulizing	10 (8.3%)	
Extra-intestinal manifestations		
Arthritis	16 (13.3%)	
Erythema nodosum	5 (4.2%)	

To investigate whether the above mentioned SNPs in *OCTN*1, *OCTN*2, and *DLG*5 genes contribute to the predisposition to IBD, as well as whether the interaction of specific haplotypes of the *NOD*2/*CARD15*, *OCTN*1, *OCTN*2, and *DLG*5 genes could increase the risk for IBD in the Greek population, we genotyped 120 patients with CD, 85 patients with UC, and 100 healthy controls. Our studies documented that mutations of the *OCTN1* and *OCTN*2 genes were obviously associated with CD. Furthermore, the combination of the OCTN-TC haplotype was found to be significantly associated with ileocolitis or colitis and the fibrostenotic phenotype, while the combination of the TC haplotype with the *NOD*2/*CARD15* variants was associated with ileocolitis or ileitis.

MATERIALS AND METHODS

Subjects

Blood samples from 120 patients with CD, 85 patients with UC and 100 age- and sex-matched healthy individuals were collected at the IBD Outpatient Clinic of the Evagelismos Hospital, between September 2002 and February 2003. The vast majority of these patients had been diagnosed at our institutions (open-access visit to the IBD Outpatients Clinic or as emergency cases), but there were also some referrals by other physicians. All groups were matched with regard to sex and age, and all subjects were of Greek origin. The diagnosis of either CD or UC was based on standard clinical, endoscopic, radiological, and histological criteria[7,14]. For CD, the vast majority of the patients (102, 85%) had newly diagnosed disease that was classified according to the Vienna System. The records of CD patients were systematically reviewed for the following demographic and clinical characteristics: age, sex, smoking habits, age at diagnosis, disease localization (ileal, colonic, ileocolonic or upper gastroenteric), disease behavior (inflammatory, fibrostenotic or fistulizing), presence of extra-intestinal clinical manifestations (e.g., arthritis, erythema nodosum), and familial IBD (Table 1). Before the commencement of the study, the ethics committee at the participating centers had approved the recruitment protocols. Informed consent was obtained from all the participants.

Genotyping

DNA was isolated from blood with the NucleoSpin blood kit (Macherey-Nagel, Germany). To confirm the integrity of DNA, initially a 430-bp sequence in the human glyceraldehyde-3-phosphatate dehydrogenase gene was amplified.

The genotyping for the three casual *NOD*2/*CARD*15 variants (L1007fsinsC, R702W, and G908R) in the studied group of patients and controls has been previously performed[7].

The C1672T substitution in exon 9 of the *OCTN*1 was genotyped by a PCR amplification of specific allele assay, using two allele-specific reverse primers: octn1C, 5' TCTGACTGTCCTGATTGGAATCC 3' for the wild type allele and octn1T: 5' TCTGACTGTCCTGATTGGAATCT 3' for the mutant allele, in combination with a common forward primer octn1F: 5' AGATGAGGTTTCACTATGTTGGC 3' in two separate PCR reactions. The 3'-ends of the reverse primers were able to anneal to the regions that differed between the two alleles. The PCR profile included initial denaturation at 95 ℃ for 5 min, followed by 35 amplification cycles of denaturation at 94 ℃ for 45 s, annealing at 58 ℃ for 40 s and extension at 72 ℃ for 30 s and a final incubation at 72 ℃ for 10 min.

The mutation G-207C in the *OCTN*2 promoter region resulted in the abolishment of a restriction site for NlaIV and was genotyped by a combined PCR-RFLP method using primers 5' TCAGGTGCACTCCCGGCCCG 3' (forward) and 5' GACCAGGCAAGCCAGGCAGC 3' (reverse). The presence of a wild-type allele resulted in the generation of three fragments (42, 44, and 122 bp), whereas the RFLP profile of the -207C variant was characterized by two fragments of 42 and 167 bp, analyzed by 30 g/L agarose gel electrophoresis. The PCR conditions included initial denaturation at 95 ℃ for 5 min, followed by three cycles of denaturation at 94 ℃ for 40 s, annealing at 58 ℃ for 1 min and extension at 72 ℃ for 2 min, by two cycles of denaturation at 94 ℃ for 40 s, annealing at 56 ℃ for 1 min and extension at 72 ℃ for 2 min, and by 28 cycles of denaturation at 94 ℃ for 40 s, annealing at 54 ℃ for 1 min and extension at 72 ℃ for 2 min, and a final incubation at 72 ℃ for 10 min.

The G113A SNP in exon 3 of the *DLG*5 gene creates a restriction site for *Msp*I and was also genotyped by a combined PCR-RFLP method using a primers 5' TCACTTTCAGTTCTACCTGCTAC 3' (forward) and 5' TCTAGGAGACAGTGGTAGGG 3' (reverse). The

presence of a wild-type allele resulted in five fragments of 40, 51, 65, 124, and 360 bp, whereas the RFLP profile of the 113A variant was characterized by four bands of 65, 91, 124, and 360 bp. The PCR conditions included initial denaturation at 95 ℃ for 5 min, followed by 35 cycles of denaturation at 94 ℃ for 45 s, annealing at 58 ℃ for 40 s and extension at 72 ℃ for 30 s, and a final incubation at 72 ℃ for 10 min.

All PCR assays were performed in a 50-μL volume reaction containing 10 mmol/L Tris-HCl (pH 8.3), 50 mmol/L KCl, 2 mmol/L $MgCl_2$, 250 μmol/L dNTPs, 0.20 μmol/L of each primer, 200 ng of genomic DNA and 2.5 U of Taq DNA polymerase (Platinum Invitrogen). The specificity of PCR products was confirmed by sequencing analysis using a Dye Terminator Cycle Sequencing Ready Reaction kit (Applied Biosystems, Darmstadt, Germany), and an ABI 377 automated sequencer.

Statistical analysis

Frequency and susceptibilities of mutations among the patients and controls were compared using χ^2 test. Odds ratios (OR) were calculated with the corresponding χ^2 distribution test and 95% confidence intervals (95%CI). The two-tailed $P<0.05$ were considered statistically significant. Hardy-Weinberg equilibrium was verified by the calculation of expected frequencies and numbers, and significance testing was based on the 1 df χ^2. The hypothesis that there is no linkage disequilibrium (LD) was also tested using the 1 df χ^2. Allele frequency independent estimators of LD were used: the $D' = D/D_{max}$, where D_{max} is the maximum possible D (i.e., for border frequencies p_1, p_2, q_1, q_2, the lesser of p_1q_2 or p_2q_1 if D is positive or lesser of p_1q_1 or p_2q_2 if D is negative). Inference was aided by GraphPad InStat (version 3.00, GraphPad Software, Inc., San Diego, CA, USA).

RESULTS

We genotyped 120 patients with CD, 85 patients with UC and 100 healthy individuals in order to investigate a possible association of the genetic substitutions in the *OCTN*1, *OCTN*2 and *DLG5* genes with a susceptibility to CD in the Greek population. These mutations were reported to have significant association with CD in the Caucasian population[13,14].

The C1672T of the *OCTN*1 genotype carrier frequencies are summarized in Table 2. The distribution of genotypes was consistent with the Hardy-Weinberg equilibrium. The 1672T allele frequencies were 25%, 11.17%, and 15% in CD, UC and healthy controls, respectively. The frequency of the 1672T allele was significantly higher in CD patients compared to the controls ($P<0.05$). The 1672T allele was not found to be significantly associated with UC.

Allele and genotype frequencies of the mutations G-207C of the *OCTN*2 gene are presented in Table 3. The

distribution of genotypes was consistent with the Hardy-Weinberg equilibrium. C allele frequencies were markedly increased in only CD patients compared to the controls ($P<0.05$).

The G113A SNP of the *DLG5* gene was completely absent in the Greek IBD cases as well as in the Greek healthy population.

The C1672T and G-207C were in strong linkage disequilibrium and created a two-allele risk haplotype (TC) (Table 3). The TC haplotype was significantly overrepresented in patients with CD (13.3%) as compared to the controls (6.5%) ($P<0.05$, Table 4). Odds ratios conferred by allele 1672T, allele -207C or the TC haplotype were similar. The risk for CD was much greater in the presence of both the TC haplotype and at least one of the three main alleles of *NOD*2/*CARD*15 gene (Table 5).

A significant association was found between ileocolitis and colitis and possession of TC haplotype. Twenty-three out of the thirty carriers of the TC haplotype had ileocolitis or colitis, whereas only seven TC carriers had exclusively ileal disease ($P<0.01$). Notably, when the presence of TC haplotype was evaluated jointly with the presence of one or more of the common *NOD*2/*CARD*15 variants, a significant association was observed with ileocolitis and ileitis. Seventeen of the nineteen carriers of both TC haplotype and at least one of the *NOD*2/*CARD*15 variants had ileocolitis or ileitis, whereas only two patients presented exclusively colitis ($P<0.05$).

In CD patients, disease behavior in 32 (26.7%) was defined as fibrostenotic, in 10 (8.3%) as fistulizing and in 78 (65%) as inflammatory. A significant association was observed between the presence of the TC haplotype and fibrostenotic *vs* inflammatory phenotype of disease in our population. Twenty out of the thirty TC carriers presented a fibrostenotic phenotype since only 10 patients had inflammatory disease ($P<0.05$).

DISCUSSION

The precise etiology of CD and UC is uncertain, although it is widely accepted that IBD develops in a genetically predisposed individual following exposure to environmental stimuli[15]. The genetic basis of IBD is adequately documented, since genetic factors that affect susceptibility to IBD have been disclosed through genetic linkage and population-based association studies[9-11]. *NOD*2/*CARD*15 was the first gene which was found to be associated with IBD, specifically with CD[9,10]. Through the candidate gene approach, various genes were identified as candidate genes to predispose to IBD in some populations[16]. Very recently Peltekova *et al*[12]. reported on two functional mutations in the *OCTN* cluster on 5q31 (the IBD5 locus) that were associated with CD, while Stoll *et al*[13]. reported the association of IBD with mutations in the *DLG*5 gene.

Regarding the *OCTN*1 and *OCTN*2, it has been recently shown that mutations in these genes are associated with lower carnitine uptake rate and increased transport of xenobiotics[14,17]. It is known that carnitine deficiency could be related with a disorder of fatty acid oxidation and consequently with insufficient fatty acid β-oxidation[17]. On the other hand, there are some evidences that the inhibition of fatty acid oxidation in the epithelium of the colonic mucosa is associated with UC and inflammation[18]. Taking all these into consideration, it seems reasonable that the *OCTN* cluster might have an active role in IBD pathogenesis.

Our case-control study for *OCTN*1 and *OCTN2* genes showed that the frequency of the 1672T and -207C alleles was significantly higher in CD patients compared to UC patients and controls. Both mutations were, as expected from the previous studies on IBD5 haplotype, in strong linkage disequilibrium (LD) and created a two-allele risk haplotype, i.e. TC which in our cases had a frequency of 13.3% in CD patients compared to 6.5% in healthy individuals. Although the TC haplotype frequency that was observed was lower than that reported by Peltekova *et al*[12]. our results confirmed an association between the *OCTN* cluster and CD. The TC haplotype was not increased in UC in our population, which was in agreement with Peltekova *et al*[12]. but in contrast with several previous studies on IBD5[19,20]. It has to be pointed out that our results differed from those of a recent study in CD patients in a Japanese population, where other genetic variants have been associated with CD pathogenesis[21]. Furthermore, it is known that variants in the IBD5 haplotype appear to be very rare in the Japanese population[19].

It has been hypothesized that the third member of the *OCTN* cluster, the *OCTN*3 gene, in the *OCTN*1-*OCTN*2 interval, is also associated with IBD[22]. The *OCTN*3 gene might represent a homolog to the mouse gene Slc22a9 and several research groups were unable to identify a human counterpart or any other gene within this region[12,22].

Interestingly, the risk for CD was even greater in the presence of both TC haplotype and at least one of the *NOD*2/*CARD*15 variants, confirming the previously reported interaction between IBD5 haplotype and *NOD*2/*CARD*15[23]. Notably, in agreement with our results, very recently, Torok *et al*[24]. reported that TC haplotype was associated with an increased CD risk, which increases even more in the presence of *NOD*2/*CARD*15 mutations.

Patients with CD clinically present heterogeneous disease characteristics, including differences in disease behavior, localization and severity. Defining the relationship between *OCTN*-TC haplotype and disease phenotypic variation is not only crucial in probing the clinical diversity in disease presentation and behavior, but may also assist in defining rational treatment strategies. Concerning the disease location in the intestine, we found that the possession of the TC haplotype was associated mainly with colitis or ileocolitis, which was in agreement with previous findings that demonstrated the IBD5 association with colonic CD[24-27]. However, when the TC haplotype was combined with the presence of at least one of the *NOD*2/*CARD*15 variants, a significant association with ileitis or ileocolitis was observed, which was in agreement with the results of a recent study by Newman *et al*[28]. This observation suggests that these variants have a

biological involvement in CD pathogenesis. When disease behavior was examined, the presence of the TC haplotype was found to be associated with the fibrostenotic phenotype.

Concerning the *DLG*5 gene, which is important in maintaining the epithelial structure, the 113A variant was completely absent in our studied population. Our observations concerning the *DLG*5 gene were strongly in contrast with previous data reported by Stoll *et al*[13]. but were in full agreement with the studies by Torok *et al*[24]. and Noble *et al*[29]. in German and Scottish populations, respectively. These findings are not unexpected in a polygenic disease model, and imply significant differences in the genetic background for CD susceptibility among the different populations.

Collectively, our study confirms recent findings suggesting that the mutations in *OCTN*1 and *OCTN*2 genes are associated with CD[12]. Additionally, our results indicate that the carriage of the *OCTN*-TC haplotype is significantly associated with ileocolitis or colitis and the fibrostenotic phenotype, but the TC haplotype combined with the presence of *NOD*2/*CARD*15 variants, associates with ileocolitis or ileitis. However, further studies involving a larger number of cases and controls in a worldwide scale are needed to elucidate the complex biological mechanisms underlying IBD susceptibility.

Abstract

AIM: To evaluate the efficacy and safety of gastric varices injection with cyanoacrylate in patients with gastric variceal bleeding.

METHODS: Twenty-four patients (15 males, 9 females) with gastric variceal bleeding underwent endoscopic treatment with cyanoacrylate injection. Successful hemostasis, rebleeding rate, and complications were retrospectively reviewed. Followed up endoscopy was performed and repeat cyanoacrylate injection was given until gastric varices were obliterated.

RESULTS: Seventeen patients achieved definite hemostasis. Of these, 14 patients had primary success after initial endoscopic therapy. Ten patients developed recurrent bleeding. Repeated cyanoacrylate injection stopped rebleeding in three patients. Transjugular intrahepatic portosystemic shunt (TIPS) was performed to control rebleeding in one patient which occured after repeat endoscopic therapy. Six patients died (three from uncontrolled bleeding, two from sepsis, and one from mesenteric vein thrombosis). Minor complications occurred in 11 patients (six epigastric discomfort and five post injection ulcers). Cyanoacrylate embolism developed in two patients. One of these patients died from mesenteric vein thrombosis. The other had pulmonary embolism which resolved spontaneously. Advanced cirrhosis and hepatocellular carcinoma (HCC) were major risk factors for uncontrolled bleeding.

CONCLUSION: Endoscopic treatment for bleeding gastric varices with cyanoacrylate injection is effective for immediate hemostasis. Repeat cyanoacrylate injection has a lower success rate than the initial injection. Cyanoacrylate embolism is not a common serious complication.

INTRODUCTION

The source of variceal bleeding can be esophageal varices (EVs) or gastric varices (GVs). Generally, about 20% of patients with portal hypertension harbor GVs, but only a few bleed from these[1-3]. Unfortunately, bleeding GVs is catastrophic and usually present with massive UGI bleeding. Many endoscopic techniques have been applied to control GVs related bleeding. Rubber band ligation and sclerotherapy are the most preferred procedures for EVs treatment but neither of them seem to be effective enough to control GVs related bleeding[8-11]. Unlike EVs, GVs related bleeding is very difficult to control by routine band ligation since retroflex position of the scope has to be used in order to reach GVs. This in turn leads to difficult band deployment. Non-endoscopic methods, such as transjugular intrahepatic portosystemic shunt (TIPS) and surgical portosystemic shunts are effective but require experienced specialists[4-7]. Moreover emergency shunt carries a high rate of post operative mortality[6,7]. The discovery of tissue adhesive chemical has changed the management of gastric variceal bleeding. Cyanoacrylate (Histoacryl^{TM}), a tissue adhesive, was first applied for endoscopic treatment of bleeding GVs in 1980s. Thereafter, cyanoacrylate has become popular for this purpose in many countries. However, it is not available for use in the United States. We have retrospectively reviewed the safety and efficacy of endoscopic injection of cyanoacrylate for the treatment of UGI bleeding from GVs at King Chulalongkorn Memorial Hospital.

Patients

There were 143 patients who presented with esophagogastric varices bleeding identified by endoscopy at King Chulalongkorn Memorial Hospital between January 2000 and 2003. Twenty-four patients (15 men and 9 women), mean age 48 years (29-75 years), had gastric variceal bleeding and all underwent endoscopic injection

of N-butyl-2-cyanoacrylate for hemostasis. Among these patients, nine had active bleeding (spurting or oozing) and the remaining 15 patients had evidence of recent variceal bleeding by demonstrating clot on gastric varices without any other potential source of bleeding.

Methods

Commercially flexible sclerotherapy injectors with a 6 mm/21-guage needle were used for gastric variceal injection. *N*-butyl-2-cyanoacrylate (Histoacryl™, B. Braun, Melsungen, Germany), was mixed with Lipiodal ™ (Laboratoire Guerbet, Aulnay-Sous-Bois, France) in 5:8 ratio and injected as a bolus dose of 2.6-5.2 cc, depending on the size of the GVs. Lipiodal was used to flush the needle before and after each injection. Generally injections

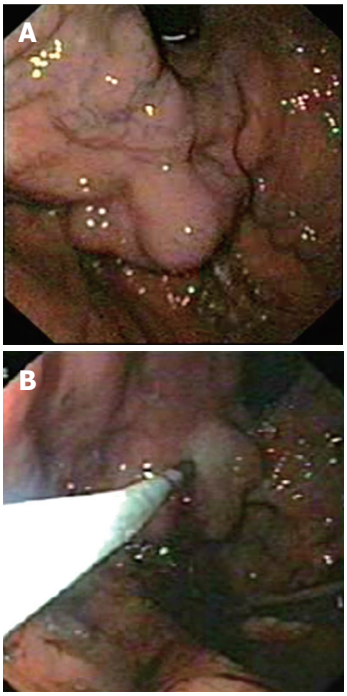

Figure 2 (**A**) (top) GVs at fundus, (**B**) (bottom) cyanoacrylate injection into the GV.

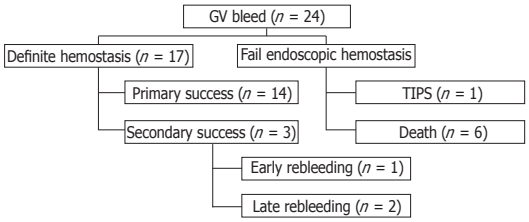
were directly delivered into gastric varices with active bleeding or containing stigmata of recent bleeding. Most procedures were performed by senior gastroenterologists under the supervision by experienced staff. At two week-follow-up endoscopy, reinjection was performed, if GVs were still detectable by palpation with the tip of biopsy forceps. An X-ray was taken after the injection to check the contour of the cyanoacrylate cast only in patients whom were suspected to have cyanoacrylate embolism. If there was recurrent bleeding during the follow-up period, reinjection with cyanoacrylate was also performed. Follow up endoscopy was performed in all the patients every two weeks and were followed up for a minimum of 4 wk. All patients who underwent endoscopic therapy received intravenous broad spectrum antibiotics prophylactically. Primary success was defined as an absence of recurrent bleeding after the first cyanoacrylate injection and during the follow-up period. Secondary success was defined as an absence of recurrent bleeding after reinjection of cyanoacrylate for recurrent bleeding. Definite hemostasis denotes primary or secondary success. A failure to achieve definite hemostasis was considered to be endoscopic failure. According to the classification proposed by Sarin *et al*[2]. (Figure 1) gastric varices were classified by their location: varices in the esophagus and lesser curvature (GOV1); varices in the esophagus and gastric fundus (GOV2); varices in the fundus only (IGV1); or varices at other sites in the stomach or in the first part of the duodenum (IGV2). Status of cirrhosis was classified according to Child-Pugh classification[12].

Statistical analysis

Data were expressed as percent, mean±SD, or median and range as appropriate. The prevalence of HCC and



Early rebleeding: rebleeding occurred within 24 h after endoscopic treatment. Late rebleeding: rebleeding occurred after 24 h after endoscopic treatment.

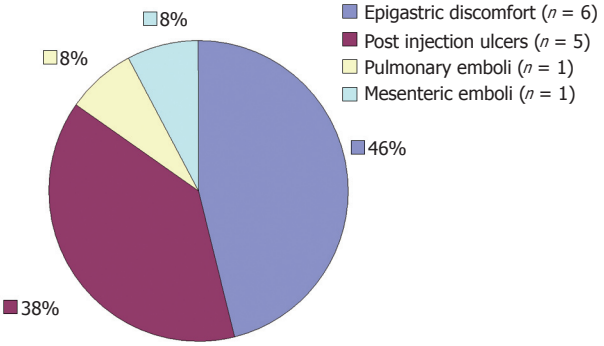

Figure 4 Complications of cyanoacrylate glue injection.

Child A, B or C cirrhosis in definite hemostasis group was compared to failed hemostasis group using Fisher's exact test. $P<0.05$ was considered statistically significant.

RESULTS

All patients who had gastric varices bleeding underwent endoscopic injection of *N*-butyl-2-cyanoacrylate. Patients characteristics are shown in Table 1 (The mean duration of follow-up was 8.3 mo, range 1-34 mo). Figure 2 shows gastric varices in one of the patients. Intra gastric variceal cyanoacrylate injection was performed (Figure 2B) and the GV was disappeared at 4-wk follow up endoscopy. Seventeen patients (71%) achieved definite hemostasis. Primary success was achieved in 14 patients (58%) (Figure 3). The remaining three (12%) were classified as secondary success after repeat endoscopic injection of cyanoacrylate. The mean number of sessions to achieve definite treatment was 1.4. Seven patients (29%) failed to achieve definite hemostasis despite multiple sessions of endoscopic treatment (1 IGV 1, 2 GOV 2). In one patient, the bleeding was successfully controlled by TIPS procedure. The remaining six patients had conditions unsuitable for TIPS procedure. None of them were treated with sclerotherapy. Three patients died from refractory gastrointestinal hemorrhage with severe coagulopathy, two died from sepsis, and another died from cyanoacrylate induced mesenteric embolism and bowel infarction (Table 2). Six of the seven patients (85.7%) who failed to achieve definite hemostasis had higher prevalence of

HCC compared to patients who had definite hemostasis ($P<0.01$) (Table 3). Child C cirrhosis was presented more often in patients who failed definite hemostasis (71.6%) compared to patients who achieved hemostasis (11.7%, $P<0.01$) (Table 3). Eighteen patients did not have serious adverse effects from cyanoacrylate injection. Six patients complained of epigastric discomfort which resolved spontaneously. Follow up endoscopy in five patients revealed asymptomatic post-injection ulcers at injection site from cyanoacrylate. Two patients developed serious complication from cyanoacrylate emboli. One patient died from small bowel infarction and peritonitis. This was found to be related to cyanoacrylate emboli since lipiodal stain was detected in the territory of mesenteric vein. The other patient developed chest pain and tachypnea 2 h after endoscopic treatment. Lipiodal stain was detected by a chest film. Fortunately, this patient survived after conservative treatment (Figure 4).

DISCUSSION

In asymptomatic portal hypertensive patients who underwent endoscopic surveillance for varices, GVs were detected less commonly than esophageal varices (EVs). The risk of GVs bleeding is also less but whenever bleeding occurs, it is dangerous and may be fatal[2]. Unlike

EVs, endoscopic technique to control gastric variceal bleeding is very difficult due to the awkward position of the scope. All therapeutic devices have to come from retroflex position. In addition, blood in the fundus may obscure the view. Apart from endoscopic treatment, TIPS is the best alternative treatment for gastric variceal bleeding. Unfortunately, TIPS is not widely available. Endoscopic obliteration of bleeding gastric varices to achieve hemostasis has been reported from many centers around the world. Variety of sclerosing agents were used including alcohol, tissue thrombin, and cyanoacrylate. There have been reports that cyanoacrylate injection could control GV bleeding with excellent results[13]. Generally, endoscopic variceal ligation (EVL) is one of the preferred treatments for EVs. Applying this technique for GVs is possible. However, there is a significant limitation due to the position of the scope and size of GVs. Gastric varix that is larger than 2 cm in diameter may be difficult to suck in to the tip of the scope while performing EVL. Therefore, incomplete endoscopic ligation may occur. The residual varix with high pressure may be prone to recurrent bleeding. A recent study reported by Lo *et al*[14]. concluded that endoscopic obliteration using band ligation is less effective and more difficult than cyanoacrylate injection in the management of bleeding gastric varices. Endoscopic variceal injection by other agents beside cyanoacrylate such as alcohol appeared to be less effective. This has been confirmed by Sarin *et al*[15]. who showed that cyanoacrylate injection was significantly more effective in achieving variceal obliteration than alcohol injection. Furthermore, complete obliteration was achieved within a few weeks by injection of a smaller volume of the agent. In addition they also found that cyanoacrylate injection was able to stop acute GV bleeding more often than alcohol injection and the need for rescue surgery was less.

Our study has shown that bleeding GVs was controlled by the first session of cyanoacrylate injection in 14 of 17 patients (82.3%) who achieved definite hemostasis (Figure 5). Second injection was less effective resulting in definite hemostasis in only 30% of patients (3/10) who failed initial injection. The mean number of session for endoscopic therapy to achieve hemostasis in our series was lesser than a series from UK (1.4 *vs* 2±1)[16]. In our series, large volume of cyanoacrylate injection was used during the initial treatment and majority of GVs were obliterated. This in turn may lead to a less number of endoscopic sessions. The overall success rate is usually determined by definite hemostasis. Our success on definite hemostasis is lower than the previous study by Lo *et al*[14]. (71% *vs* 87%).

We found that patients who failed definite hemostasis had more advanced stage of liver disease than patients who achieved definite hemostasis. In addition, HCC was found more often in failure group (6 of 7 patients) compared to success group (1 of 17 patients) (Table 3). Endoscopic related complications from cyanoacrylate injection are generally minor and spontaneously resolved such as epigastric discomfort, nausea, vomiting, and ulcer at the injected site.

However, fatal complication may occur. The most dangerous complication is glue embolism. There have been many reports regarding this type of complication. For example, there was a case report of cerebral embolism after glue injection. Glue was found in the left atrium by echocardiography. Cardiac surgery was performed and intracardiac glue was removed[17]. A retrospective study from UK reported pulmonary embolism after glue injection in 1 of 23 cases[16]. Another larger study from Taiwan reported no case of pulmonary embolism after glue injection in 90 patients with bleeding gastric varices[18]. Unfortunately, one of the patients in our series developed generalized peritonitis, 8 h after glue injection. The lipiodal stain was detected from abdominal X-ray. This patient expired 2 d later without undergoing laparotomy due to his poor condition. During the period of our study, all patients received prophylactic antibiotics. Despite this protocol, there were two patients who died from septicemia. Sarin *et al*[15]. reported that 9 of 17 patients developed fever following glue injection for GVs. A case report from Malaysia showed that a patient developed multiple systemic emboli with septicemia after elective glue injection for fundic varices[19]. Fortunately, the patient recovered completely after intensified supportive treatment. Prophylactic administration is becoming a standard protocol for cirrhotic patient with active upper gastrointestinal hemorrhage[20]. However, antibiotic prophylaxis for elective glue injection is still controversial. Our recent unpublished data did not discover any bacteremia in the patient who underwent elective glue injection for GVs.

In conclusion, the results of the present study demonstrated that endoscopic injection of cyanoacrylate is effective to control majority of GVs related bleeding within the first session of treatment. Repeat endoscopic treatment is less effective than the initial injection. Advanced staged cirrhosis and HCC are major risk factors for failed hemostasis after cyanoacrylate injection of GVs.

Abstract

AIM: To explore the inducing effect of human mutant p27 gene on the apoptosis of the human gastric cancer cell line MKN-45 and its associated mechanisms.

METHODS: The recombinant adenovirus Ad-p27mt was constructed to infect the human gastric cancer cell line MKN-45. Using flow cytometry, TUNEL assay and DNA fragment analysis, we measured the apoptotic effect of Ad-p27mt on the human gastric cancer cells.

RESULTS: Ad-p27mt was successfully constructed and the infection efficiency reached 100%. After 18 h of infection, we observed an apoptotic hypodiploid peak on the flow cytometer before G_1-S and apoptotic characteristic bands in the DNA electrophoresis. The apoptotic rate detected by TUNEL method was significantly higher in the Ad-p27mt group (89.4±3.12%) compared to the control group (3.12±0.13%, $P < 0.01$).

CONCLUSION: Human mutant p27 can induce apoptosis of the human gastric cancer cells *in vitro*.

Key words: Gastric cancer; Human mutant p27; Cell line MKN-45

INTRODUCTION

Apoptosis plays a crucial role in the proliferation and turnover of cells in various malignant tumors. Studies have proved that apoptosis is enhanced in tumor by many anticancer drugs, such as cytotoxic drug, hormone, or some recombinant gene, medicine, etc. However, there is a lack of an effective therapy for advanced gastric cancer at present. Gastric cancer is a disease with not only abnormal cell proliferation and differentiation, but also abnormal apoptosis. So, the enhanced induction of apoptosis in human gastric cancer cell needs to be explored. Human mutant p27 gene is a kind of multifunctional cyclin-dependent kinase inhibitor, playing a negative role in cell cycle regulation by inhibiting transformation from G_0/G_1 phase to S phase. Similarly, a recombinant p27mt presents cell proliferation and tumorigenesis. Based on the previous studies, we examined the apoptotic effect and its associated mechanisms in human gastric cancer implanted into nude mice after the treatment with human mutant p27 gene.

MATERIALS AND METHODS

Materials

BALB/C-nu/nu mice (weight 18-22 g, 36-37 wk old) and human gastric carcinoma cell line MKN-45 were obtained from Shanghai Tumor Institution (No. 01842). The animals were subcutaneously grafted with the MKN-45 cell line.

RPMI 1640 culture medium and TRIzol total RNA isolation kit were purchased from Gibco BRL. The rat anti-human p27 kip1 multi-antibody was purchased from Santa Cruz Co. The liposome, trypsin, DMEM culture medium, Hepes and Csc1, 200-bp DNA ladder, dNTP, tag enzyme and the restriction endonuclease were obtained from Sigma Co. PORF9-hp27mt plasmid (human mutant p27 gene) was obtained from InvivoGen Co. The recombinant adenovirus (Ad-lac2) and Ad-LacZ (medium of the recombinant adenovirus) were provided by Dr. Robert, Huston University, USA.

Cell culture

Human gastric cancer cell line MKN-45 was routinely cultured in RPMI 1640 medium supplemented with heat-inactivated 100 mL/L fetal calf serum, 100 kU/L penicillin, 100 mg/L streptomycin and 2 mmol/L glutamine, and incubated at 37 ℃ in a humidified atmosphere containing 50 mL/L CO_2 in air until the gastric carcinoma cells were 80-90% confluent.

Construction and identification of human mutant p27 recombinant adenovirus

After pORF9-hp27mt was digested with *Age*I and *Nhe*I

enzymes, the 619-bp fragment was recycled and subcloned into pBluescript II SK (+), which was digested with *Xma*I and *Xba*I enzymes, resulting in pBluescript-hp27mt. pBluescript-hp27mt was digested with *Not*I and *Kpn*I enzymes, and then the 699-bp fragment was recycled and inserted into shuttle plasmid vector pShuttle-CMV-hp27mt, which was digested with the same enzyme, resulting in the transfer plasmid vector pShuttle-CMV-hp27mt. The competence *E. coli* was transformed by adenoviral framework plasmid pAdeasy-1. According to ampicillin-resistant gene, the BJ5183 containing pAdeasy-1 was picked out and prepared as the ultra-competent BJ5183 containing pAdeasy-1. Then the ultra-competence BJ5183 containing pAdeasy-1 was transformed by transfer plasmid pShuttle-CMV-hp27mt, which was digested with *Pme*I enzyme and dephosphorylated by alkaline phosphatase. A little DNA of the transformed clone bacterial plasmid was taken out and the suspect DNA of the recombinant adenovirus plasmid was chosen according to the size of plasmid on agarose electrophoresis. If the chosen DNA was identified as the proper DNA by digestion with *Pac*I enzyme, the recombinant adenovirus plasmid pAdeasy-1-hp27mt could be massively prepared, and then used to perform liposome PolyFect-mediated infection of Ad293 cells, thereby resulting in the preparation of human p27mt recombinant adenovirus (Ad-p27mt). The amplification, identification and titer determination of the recombinant adenovirus were carried out as previously described[3].

Chemical staining of X-gal

The MNK-45 cells taken from the 15-cm culture flask was infected with Ad-lacZ according to MOI of 20, 40, 50, and 100 and then incubated for another 48 h. After the cells were fixed by 0.5% glutaral pentanediol for 15 min and washed thrice with PBS, X-gal staining solution (20:1) was added, followed by incubation at 37 ℃ for 4-25 h in a humidified atmosphere containing 50 mL/L CO_2 in air. The blue-staining cells, i.e. the positive cells in which LacZ gene was expressed, were observed under microscope and the percentage of the positive cells was calculated.

Detection of expression of p27mt gene

The MKN-45 cells taken from the 75-cm culture flask was infected with Ad-p27mt (MOI) and Ad-LacZ (MOI), respectively. After being incubated at 37 ℃ for 48 h in a humidified atmosphere containing 50 mL/L CO_2 in air, all cells were digested with 0.5 g/L trypsin. The cells were collected and washed twice with PBS. After the cells were lysed with 500 μL of SDS-PAGE cell lysis solution and boiled for 5 min, they were centrifuged and the supernatant was collected for Western blot detection.

Flow cytometric detection of cells infected by Ad-p27mt

The MKN-45 cells taken from the 75-cm culture flask was infected with Ad-p27mt (MOI 100). After incubation for 48 h, they were digested with 0.5 g/L trypsin. The cells were collected and washed twice with PBS. Proper amount of PBS was added, until the cell concentration reached 10^9/L. Then 100 μL of cell suspension was mixed with 200 μL of DNA-PREP™ LPR, followed by detection using Coulter Epics XL flow cytometer after 15 min. The cell cycle and cell apoptosis rate were analyzed. The Ad-LacZ (MOI 100) group and the normal control group (MKN-45 cells cultivated without adenovirus) were used as control groups.

DNA fragment analysis

MKN-45 cells, after being infected with Ad-p27mt and Ad-LacZ for 48 h, and the normal control cells were separately collected and centrifugated at 1 000 r/min for 5 min. The supernatant was thrown away, and 500 μL of cell lysis solution [10 g/L NP40, 20 mmol/L EDTA, 50 mmol/L Tris-HCl (pH 7.5)] and 10 μL of protease K were added into the cell sediment, followed by heating in 56 ℃ water bath for 1-2 h and then extraction with phenol/chloroform and DNA precipitation with dehydrated alcohol. After the DNA precipitate was washed once with 700 mL/L alcohol, 200 μL of TE was added to lyse the DNA, followed by incubation with RNase (final concentration 50 mL/L) overnight at 37 ℃. The final DNA was electrophoresed on 10 g/L agarose gel and observed with the aid of an ultraviolet light lamp.

Detection of cell apoptosis by TUNEL method

Cell suspensions ($1x10^4$ cells) of each Ad-p27mt group and normal control group were inoculated separately into 60-mm dishes containing six cover glasses (washed and high-pressure sterilized), followed by incubation for 24 h. Then the glasses were taken out and washed twice with 1× PBS and fixed in methanol:freezing acetic acid (3:1) for 30 min. The following procedures were carried out according to the instructions of the kit. The average number of apoptotic cells was determined by counting 1 000 cells on each glass. Then the apoptotic index (AI), i.e. the number of apoptotic cells per 100 cancer cells, was calculated.

Statistical analysis

All statistical analyses were performed using SPSS 11.5 for Windows. The data were analyzed using *t*-test. A $P<0.05$ was considered statistically significant.

RESULTS

PCR identification of recombinant adenovirus Ad-p27mt

The pathological change of multi-drug resistant MKN-45 cells and their culture fluid were collected and centrifuged. Five milliliters of the supernatant was mixed with 1 mg of protease K, 2 mL of 10 g/L SDS, 10 mmol/L EDTA, and 20 mmol/L Tris-HCl to digest for 2 h. After being precipitated by dehydrated alcohol, the viral DNA was collected. PCR reaction was carried out after adding the forward and reverse primers. Finally, a 275-bp target gene was amplified, which showed that the recombinant adenovirus had already possessed p27mt target gene.

Detection of gene transfer rate by X-gal chemical staining

The adenovirus-mediated gene transfer rate was evaluated

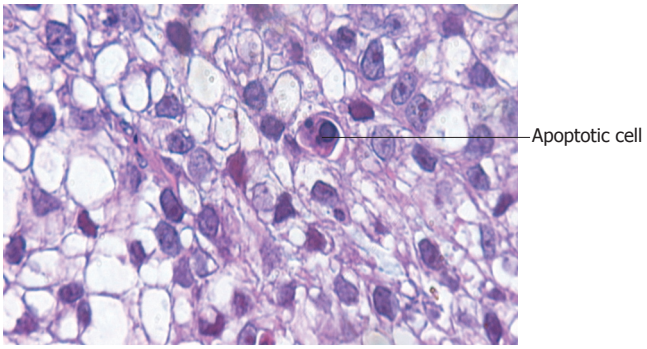

Figure 1 Detection of apoptotic cells by TUNEL method. The nuclei of apoptotic cells appeared blue in Ad-p27mt group.

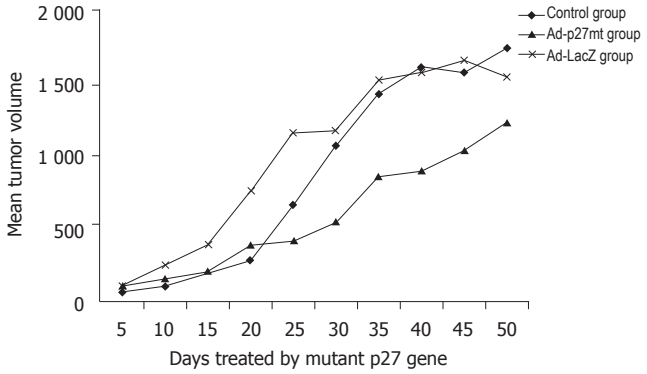

Figure 2 Growth curves of human gastric cancer implanted in nude mice.

by X-gal staining. The results showed that the infection efficiency could reach 100% when MOI was larger than 50, which indicated that recombinant adenovirus could effectively transfer to MKN-45 cells *in vitro*.

The expression of p27 protein was evaluated after MKN-45 was infected with human mutant p27 recombinant adenovirus *in vitro*. After MKN-45 cells were infected with Ad-p27mt (MOI 100) for 24 h, the cells were collected and lysed with 1x SDS-PAGE cell lysis solution, boiled at 100 ℃ for 5 min, and then centrifuged. The supernatant was collected and the protein was detected by using TMB system Western blot kit (KPL, USA). We found a high expression of 27-ku protein in Ad-p27mt group, while only slight trace expression (endogenous expression) in Ad-LacZ group and normal control group, indicating that the human mutant p27 recombinant adenovirus constructed in the present study could express p27 gene properly in MKN-45 cells and the protein product could be expressed at a high level in the cells.

After the MKN-45 cells were treated with Ad-p27mt, Ad-LacZ and without virus for 24 h, the apoptosis rate was detected in the different groups using flow cytometry. Reproducibility was confirmed by processing all samples at least six times. The average values of hypodiploid in Ad-p27mt, Ad-LacZ, and non-infected groups were 41.0%, 4.67%, and 1.96%, respectively, showing significant differences between these three groups.

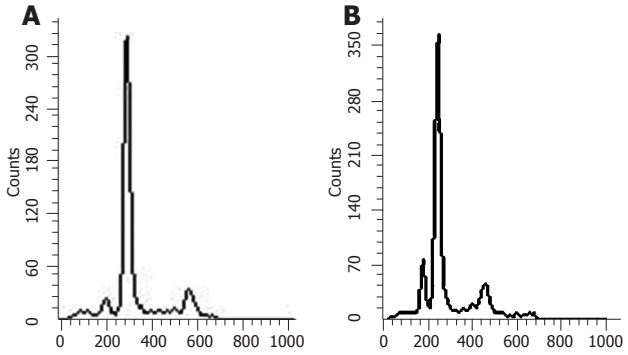

Figure 3 Detection of multi-drug resistant MKN-45 cells' apoptosis by flow cytometry. **A**: Non-infected MKN-45 cells; **B**: Ad-p27mt-infected MKN-45 cells.

Table 1 Effect of Ad-p27mt on the cell cycle of MKN-45 cells (mean ±SD)

Groups	G_0/G_1	S	G_2/M
Control	25.29±1.04	41.12±1.19	33.34±1.55
Ad-LacZ	27.57±0.45[a]	38.21±0.44[a]	34.22±0.92[a]
Ad-P27mt	77.96±2.20[b]	8.98±0.17[b]	13.06±2.35[b]

[1]$P>0.05$ *vs* control group; [b]$P<0.01$ *vs* Ad-LacZ group.

Detection of DNA fragment

The result of DNA electrophoresis showed that the gene bands were intact in Ad-LacZ group and normal control group, while there were obvious 180-200 bp diploid 'trapezia' bands in Ad-p27mt group, which was in concordance with the characteristic changes of apoptosis (Figures 1 and 2).

Detection of cell apoptosis by TUNEL method

The apoptotic cells had concentrated cytoplasm with shrunk and dark-stained nuclei. AI of Ad-p27mt group (82.6±3.2%) was significantly higher compared to the control group (5.0±3.5%, $P<0.05$), showing that Ad-p27mt could obviously induce apoptosis of gastric cancer cells (Figure 3).

The cell cycles of different groups of MKN-45 cells are shown in Table 1. We found that the number of G_0/G_1 phase cells decreased gradually and the percentage of S-phase cells increased in Ad-LacZ group and control group, which indicated that the transition time of cell cycle was shortened and cell proliferation was active. However, the percentage of G_0/G_1 phase cells significantly increased and the cell cycle was obviously arrested in G_0/G_1 phase in Ad-p27mt group as compared to the control group and Ad-LacZ group ($P<0.01$).

DISCUSSION

Human mutant p27 protein is a kind of heat stable protein, which was first found by Polyak and colleagues in a research on cell contact inhibition with TGF-β[4]. It has been found that p27 mainly inhibited the activity of cyclin E-CDK2, cyclin D-CDK4, and cyclin A-CDK2

complexes. In addition, the arrest of cells at G_0/G_1 phase was mainly caused by p27 accumulation induced by exogenous signal, and tumorigenesis was closely correlated with translocation, deletion and mutation of p27 gene and changes of expression and activity of p27 protein[5]. If the expression level of p27mt was downregulated, the inhibition of cyclin E-CDK2 complex by p27 would decrease and thus the DNA damaged cells could transform from G_1 to S phase directly.

The degradation of p27 protein is mainly caused by phosphorylation of the 187th threonine of p27 which is mediated by ubiquitin[6-8]. Kudo *et al*[9]. found that the 187th threonine of p27 was mediated by p27 protein, and thereby obviously inhibited the cell growth, and these inhibitive effects were more obvious on mutant p27 (T187A) than on wild-type p27.

In this study, we constructed a replication-deficient recombinant adenovirus, which carried p27mt, to investigate the apoptotic rate of gastric cancer cell line MKN-45, expecting for a more effective p27 gene to treat gastric cancer. Koguchi *et al*[11]. reported the prohibition of the viability of astrocytes, resulting from transfection with adenovirus-mediated exogenous p27 gene. Zhang *et al*[12]. reported that the upregulation of p27 expression by retinoic acid significantly inhibited the growth of the oophoroma cells. In addition, Koh *et al*[13]. found that high expression of p27 and raised expressions of cyclin D1 and cyclin E in cephalocervical squamous cell carcinoma cell lines SUN-1066, SUN-1041, and SUN-1076 after transfection with adenovirus-mediated p27kip1 could significantly inhibit the proliferation of the cancer cells by arresting the cells mainly at G_1-S stage. All these data showed that p27 gene might have a significant impact on the onset, development and prognosis of tumor.

Nowadays, functional reconstruction of anti-oncogene has been a reasonable strategy of gene therapy for tumor. Sasaki *et al*[14]. showed that compared with p27wt, p27mt had stronger inhibitive effects on the apoptosis of cholangiocarcinoma cells. Park *et al*[15,16]. reported similar results when they performed adenovirus-mediated transfection of p27mt and p27wt genes into lung cancer cell lines NCI H460, NCI H1264, NCI H358, and NCI H157. In our study, adenovirus-mediated transfection of mutant p27 gene could upregulate its expression in gastric cancer cell line MKN-45, suggesting that adenovirus with reconstructed p27mt can transfect the target gene into tumor cells. We also observed that the apoptotic rate was markedly higher in Ad-p27mt group as compared to the control group. DNA analysis showed 180-200 bp DNA ladder. Moreover, TUNEL assay showed obviously higher AI up to 82.6% in Ad-p27mt group as compared to the control group. These results revealed that p27 gene might play an important role in gastric carcinoma and its downregulation may be the main cause of cell differentiation dysfunction and apoptosis dysfunction. Thus, upregulating the expression of p27 by transfection of mutant p27 may serve as a new therapy on gastric carcinoma by exerting its apoptosis-inducing effect. The cell cycle analysis showed that the cleavage of tumor cells was stopped at G_1 stage via suppressing the activity of the cyclin/CDK kinase by p27mt. Winteringham *et al*[17]. have found that the accumulation of p27 plays a crucial role in the gastric cell cycle arrest at the initiation of cell differentiation.

In recent studies[18], although the gastric cancer cells apoptosis was successfully induced by the application of NM-3 and other gene therapies, Ad-p27mt-induced apoptosis of human gastric cancer cell line MKN-45 has not yet been reported in nude mice model. Our study showed a very useful experimental evidence for human gastric cancer suppression by using p27 gene therapy *in vivo*. The efficacy of p27 gene therapy and the mechanisms of apoptosis may provide an important theoretical evidence in the treatment of advanced gastric cancer.

Abstract

A 34-year-old male with hereditary non-polyposis colon cancer with a mutation in hMSH2 line is reported. Despite regular colonoscopic follow-up, he developed cecal cancer involving the extraluminal area. Due to sub-occlusive symptoms, the patient was submitted to further colonoscopy, however with no clear evidence of neoplasia. Thin slice multiplanar reconstruction computed tomography CT scan performed thereafter revealed a transmural mass 2.5 cm in size localized near the cecal valve. Discussion is made on the reliability of colonoscopic examinations as well as the need for further investigations in the follow-up of patients at very high risk of right-sided colon cancer, such as male hMSH2 carrier affected by hereditary non-polyposis colon cancer.

Key words: Hereditary non-polyposis colon cancer; Spiral CT scan; Colonoscopy; hMSH2 carrier

INTRODUCTION

Hereditary non-polyposis colorectal cancer (HNPCC or Lynch syndrome) is a disease of autosomal dominant inheritance, accounting for 3-5% of all colorectal cancers[1]. This disorder predisposes to the development of colorectal cancer (CRC) at an early age (mean age 45 years), as well as other cancers mainly of the gastrointestinal and genitourinary tract. HNPCC is caused by defects in one of the mismatch repair (MMR) genes such as hMLH1, hMSH2, hMSH6, hPMS1 or hPMS2, all of which are important in the detection and repair of base pair mismatches during DNA replication[2]. The presence of this syndrome is suspected on the basis of specific diagnostic guidelines known as "Amsterdam I and II, original Bethesda and revised Bethesda criteria" and on the clinical features of colorectal adenomas and/or cancers[1]. Genetic tests, to detect MMR gene mutations, are usually used to confirm the diagnosis.

Even when the more stringent clinical criteria are met, germline mutations are detected only in 40-60%[3-5]. Patients who met the family history and clinical criteria or who have inherited MMR gene mutations are at high risk of developing cancer and should undergo specific surveillance and follow-up, particularly colonic endoscopic surveillance[6,7].

Herein, we describe a case of a man with HNPCC who developed a right-sided colon cancer at the age of 34 despite regular colonoscopic examinations.

CASE REPORT

A 34-year-old man was admitted to our department with pain in the right lower quadrant of the abdomen, abdominal distension, and signs of pseudo-obstruction. The patient, with a family history of HNPCC, was regularly attended for surveillance at a well-known international center for diagnosis, treatment, and surveillance of HNPCC patients. A germline mutation in the hMSH2 gene was detected at the age of 17. A substitution at codon 383, changing CGA (Arg) to TGA (stop codon), was found which resulted in the formation of a truncated protein. No alteration was identified in the hMLH1 line. The last full endoscopic colon examination was carried out almost 2 years before and the colonic mucosa was reported with no alteration. The patient's family pedigree is outlined in Figure 1. His father was diagnosed as having CRC at the age of 37, jejunum cancer at the age of 48 and at the age of 58 he died of cholangiocarcinoma. His older

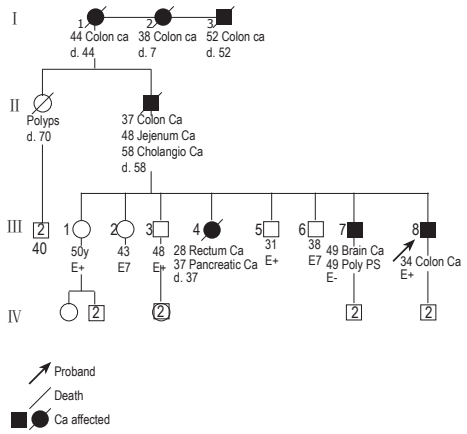

Figure 1 Pedigree of proband. d indicates age at death. E indicates evaluation for hMSH2 mutations.

sister presented rectal carcinoma at the age of 28 and died of pancreatic cancer at the age of 37. His older brother developed colonic polyps, three times consecutively, diagnosed during colonoscopic surveillance and also presented a glioblastoma at the age of 49, although he was negative for hMSH2 mutations upon DNA analysis.

This patient had been on a semi-liquid diet for 2 d, and was treated with 20 mg of i.v. *N*-butylbromide for the abdominal pain. Laboratory data revealed no abnormality. Complete blood count, hemoglobin, hematocrit, ferritin, urinalysis and electrolyte panel were all within the normal range. Liver function tests, carcinoembryonic antigen (CEA) and tissue polypeptide antigen (TPA) were also normal. An abdominal X-ray showed mild colonic and ileal distension in the absence of air-fluid levels or free air below the diaphragm. Complete abdominal ultrasonic investigations revealed normal kidney, urinary tract, liver, and biliary system. A chest X-ray was also negative.

The next day colonoscopy was performed. No alteration was detected, except in the mucosa around the ileocecal valve, an irregular and protuberant appearance, above which a small sessile polyp, 7 mm in diameter was visible. Multiple biopsies were collected. Histological examination revealed only the presence of a non-specific inflammatory submucosal infiltration.

A routine spiral-CT scanning (16 slices-Mx8000 IDT, Philips, Cleveland, OH, USA) was performed and simple axial reconstructions 5 mm thick were obtained. No alterations were detected at the first examination. However, after consultation with the radiologist, a thin slice (2 mm) multiplanar reconstruction (MPR) of the right colon was performed and a 2.5-cm mass was revealed extrinsically localized to the fundus of the cecum, well visualized in the coronal planes (Figures 2A and B). Before the surgery, the patient was informed about the surgical options and the related risks and/or potential benefits. The patient agreed to undergo a right hemicolectomy, but not total colectomy. At surgery, ascites was found locally and the mass was macroscopically transmural. The surgeon, therefore, had no choice but to carry out terminal ileum resection, resection of the ileocecal valve, hepatic flexure, part of the transverse colon and dissection of related lymph nodes.

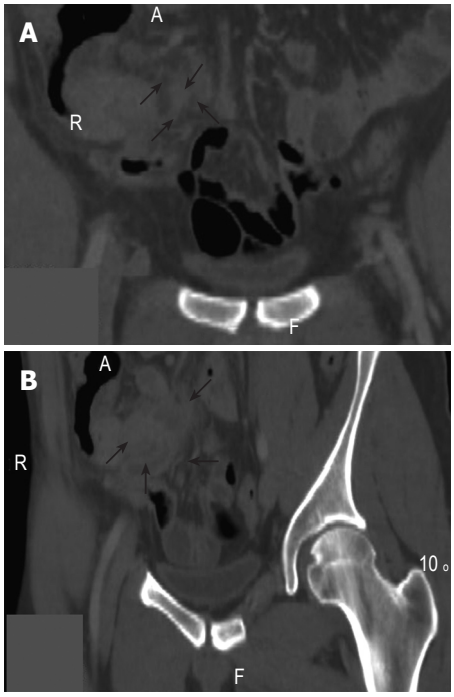

Figure 2 Spiral CT scan with multiple planar reconstruction, in coronal (**2A**) and oblique (**2B**) views, showing extrinsic localization of neoplasia. Soft tissue density mass is visible attached to the wall of cecum (black arrows) which is compressed without clear evidence of mucosal infiltration. Air distension of cecum (**A**) contributes to better visualization of the mass.

Upon histological examination, the neoplasia was found to contain moderately differentiated adenocarcinoma with transmural involvement and mucinous foci, covering 30% of the entire mass. The neoplasia was classified as T3N1MX, corresponding to Dukes' stage C. The patient rapidly recovered after surgery.

DISCUSSION

CRC is the third most frequently diagnosed cancer and the second leading cause of cancer-related deaths in the world. The lifetime risk, in the general population, is approximately 5-6%. The cancer develops sporadically in 80% of these patients, while 20% have an inherited predisposition to the disease[8,9]. HNPCC is the most common hereditary form of CRC accounting for 3-5% of all CRCs[10,11].

HNPCC is an autosomal dominant condition that predisposes to a lifetime risk of approximately 80% of the development of CRC, localized predominantly in the proximal colon. Adenomas, in these patients, tend to have a villous component and most of them present dysplasia, compared with the more common sporadic type. The aggressive behavior of HNPCC adenomas has been demonstrated with an accelerated adenoma-carcinoma sequence (2-3 years) compared to the sporadic forms[12], which are diagnosed at a mean age of 45 and are characteristically localized in the right colon in 60-70% of these patients[13]. HNPCC mutation carriers also have a 60% lifetime risk of developing cancers in other sites of the body, predominantly the uterus, ovary, urinary tract, small bowel, and bile duct[13]. Germline mutations in hMSH2

and hMLH1 account for 90% of the mutations identified in HNPCC patients. These are scattered throughout the entire coding region without a clear phenotype-genotype correlation. However, specific sex and genotype/phenotype associations in HNPCC mutation carriers have been reported. In fact, CRC risk is reported to be higher in males than in females[14]. In one study, the CRC risk is reported to be 96% in males with a hMSH2 mutation compared with 39% in females with the same mutation[15], whereas the risk of extracolonic cancers is reported to be 48% as compared with 11% reported in hMLH1 mutation carriers[14,15]. Based on these considerations, male hMSH2 mutation carriers should receive a tailored program of cancer surveillance. Colonoscopy is the most important tool in the surveillance for CRC; in all individuals, especially patients who are at high risk of developing a CRC, complete colonoscopy in examinations with scrupulous exploration of the cecum is always recommended[16]. Although, colonoscopy is a method of choice in colon cancer surveillance, concerns about its sensitivity and specificity in many clinical settings still remain. Complete colonoscopy refers to the passage of the colonoscope to the cecum and can be assessed by various landmarks[17]. The most reliable are the identification of the cecal valve and/or intubation of the terminal ileum[17]. The rate of colonoscopies considered to be complete decreases significantly (56.9%) when either or both of these landmarks are applied[17]. Moreover, it has been reported that only experienced endoscopists can reach the cecum in almost 97% of colonoscopies, whereas completion of the colonoscopic procedure, by self-trained endoscopists, is reported to be as low as 54%[18,19]. Various factors may cause this discrepancy, one of which might be related to the professional experience of the endoscopist who may erroneously believe that the cecum has been reached. The other factor may be related to bowel preparation that may not offer clear visualization of the cecum. The size of the cancer is also an important factor. If the neoplastic mass is very small or located in close proximity to the ileocecal valve, in an area which is difficult to explore, the cancer can be very easily missed. However, even if colonoscopy is complete, the extension of the neoplasia may be mainly extraluminal, as in the case described here.

All these factors suggest that additional diagnostic examinations, besides colonoscopy, should be made in the follow-up of very high-risk patients, such as the hMSH2 male mutation carriers, in order to complete right colon evaluation, in the event of incomplete or dubious colonoscopy. Spiral CT scan is currently used for the detection of extra-colonic cancers, which is frequently encountered in HNPCC patients. In this particularly high-risk patient, due to the specific sub-occlusive symptoms, a spiral CT scan, with thin slice multiplanar reconstruction, was used for complete visualization of the right colon, detecting a cecal cancer lesion with a predominantly extraluminal development missed at colonoscopy.

In conclusion, given the very high risk of developing a right-sided colon cancer in hMSH2 male carrier HNPCC patients and the possibility that colonoscopy may not completely visualize the cecal region, spiral CT scan should, in our opinion, be included in the follow-up of these patients. At present, due to the relative rarity of this disease, it is difficult to evaluate when, for these specific reasons, a spiral CT scan should be performed. However, besides evaluation of the clinical symptoms, surveillance of right colonic cancer with a thin slice multiplanar reconstruction spiral CT scan is advisable and should always be performed in hMSH2 male carriers in dubious cases or when colonoscopy is thought to be incomplete for any reason.

Abstract

A 53-year-old man with a history of blood transfusion at the age of 20 was admitted to our hospital because of liver dysfunction. He had bronchial asthma when he was 18 years old, which naturally resolved within 2 years. However, his bronchial asthma recurred at the age of 45 and was treated with oral theophylline. He was diagnosed as having chronic hepatitis C based on the histological and clinical findings, and then interferon (IFN) therapy was administered. The frequency of bronchial asthma attack was gradually decreasing after IFN therapy with marked improvement of hypereosinophilia. He achieved sustained viral response (SVR) and his bronchial asthma did not worsen even after the cessation of IFN. Hepatitis C virus (HCV) infection and IFN therapy were considered in the remission of asthma in this case. HCV infection could be the cause of bronchial asthma, especially in patients with late appearance of asthma.

Key words: Bronchial asthma; Chronic hepatitis C; IFN therapy

INTRODUCTION

Hepatitis C virus (HCV) infection is sometimes associated with extrahepatic diseases, such as cryoglobulinemia[1,2] and lichen planus[2,3]. These extrahepatic diseases are considered as part of immune responses against HCV. We have presented a case of chronic hepatitis C with bronchial asthma which improved after interferon (IFN) therapy.

CASE REPORT

A 53-year-old man with a history of blood transfusion at the age of 20 was admitted to our hospital because of liver dysfunction. He had bronchial asthma when he was 18 years old, which naturally resolved within 2 years. However, his bronchial asthma recurred at the age of 45 and has been treated with oral theophylline. Asthma occurred 5-10 times a week before IFN therapy which needed inhalation of β_2 stimulators in addition to daily treatment of theophylline therapy. They were all minor attacks and the patient was easily relieved after a few inhalations of β_2 stimulators. On admission, physical examinations revealed mild wheezing at bilateral lung fields, but no hepatosplenomegaly was observed. Laboratory findings were as follows; white blood cell counts: 5 500/mm^3 (eosinophils 11.2%); platelet counts: 169 000/mm^3, alanine aminotransferase (ALT): 171 IU/L; and aspartate aminotransferase (AST): 81 IU/L, albumin: 42 g/L. HCV-RNA (Genotype 1b, 500 KIU/mL) was positive, but HBsAg, anti-HBc and anti nuclear antibody were all negative. IgE level was within the normal limit (55 IU/mL) and immune complex was negative (Table 1). Abdominal ultrasonography showed chronic liver injury. Liver biopsy revealed moderate portal inflammation and fibrous expansion (A2F2). Based on these findings, he was diagnosed as having chronic hepatitis C. IFN-α2b (10 MU daily for 2 wk, followed by 10 MU thrice a week for another 22 wk) was started on September 2000 with careful observation because asthma exacerbation during IFN therapy was reported[4]. Surprisingly, the frequency of asthma attack was gradually decreasing after IFN therapy with marked improvement of hypereosinophilia (Figure 1). Furthermore, during IFN therapy, asthma attack never recurred even after the cessation of daily theophylline. HCV-RNA became negative after IFN therapy and he achieved sustained virological response (SVR). After the cessation of IFN therapy, he needed inhalation of β_2 stimulators for asthma occasionally. However, he did not require theophylline or steroid any more since the frequency of attack per month was well reduced and the degree of asthma attack was very mild. Interestingly, the eosinophil counts slightly increased after the cessation of IFN, but remained within the normal level (Figure 1).

DISCUSSION

Chronic HCV infection can be associated with various immune mediated extrahepatic manifestations, including porphyria cutanea tarda[1,2], membranoproliferative

glomerulonephritis[1,2], oral lichen planus[2,3], mixed cryoglobulinemias[1,2], vitiligo[2], B-cell non-Hodgkin lymphoma[2], etc. The response of bronchodilator against asthma was significantly better in the IFN responder group than in the IFN non-responder group[5]. Remission of asthma after the clearance of HCV by IFN therapy in our case could be considered from two points of view. Cytotoxic T cells induced by chronic HCV infection might be a trigger for the development of airway inflammation in patients with bronchial asthma[5] since latent viral infections may be an important cofactor causing airway inflammation[6]. In patients with chronic hepatitis C, the responses of inhaled corticosteroid therapy[5] or bronchodilator for bronchial asthma are impaired, which are recovered in IFN responders[5]. Peripheral B-cell markers such as CD81 and CD5 are correlated with HCV viral load and autoimmunity[7]. The response of antiviral therapy is correlated with the downregulation of these markers. These observations suggest that immune responses by HCV, including cytokines from lymphocytes, may contribute to chronic airway inflammation, and the clearance of HCV by IFN may improve it. The other cause is IFN itself. Injected IFN or released IFN induced by cytotoxic T cells against HCV may improve bronchial asthma by suppressing the chronic airway inflammation since IFN-γ acts as Th1 paracrine inflammatory cytokine. On the contrary, IFN-γ producing T cells may induce the migration of Th2 cells to the airways and IFN may worsen bronchial asthma[8]. Furthermore, IFN increases histamine release from basophilic cells, which is an important trigger for asthma attack[9]. The effect of IFN on bronchial asthma is still controversial.

This is, to our knowledge, the first case in which bronchial asthma improved after the clearance of HCV by IFN. HCV infection could be the cause of bronchial asthma, especially in patients with late onset of asthma.

Abstract

The etiology of inflammatory bowel disease is multifactorial and appears to combine both genetic and environmental factors. We experienced here a rare occurrence of woman monozygotic twins with ulcerative colitis (UC). A 45-year-old woman (the elder monozygotic twin) was admitted to our hospital because of bloody diarrhea occurring over 10 times per day, abdominal pain and fever. She was diagnosed as UC at the age of 22, and repeated the relapse and remission. She was diagnosed as relapse of UC and total colitis type. Her younger monozygotic twin sister also suffered from UC at the age of 22. Human leukocyte antigen was examined serologically with DNA type in both patients. DRB1*1502, which was previously shown to be dominant in Japanese patients with UC, was not observed in this case. Although the concordance in monozygotic twin in UC is reported to be 6.3-18.8%, the concordant case like this is relatively rare. We report this rare case of UC and the previously reported cases are also discussed.

Key words: Ulcerative colitis; Inflammatory bowel disease; Monozygotic twin; Human leukocyte antigen

INTRODUCTION

Ulcerative colitis (UC) is an idiopathic inflammatory bowel disease, which is thought to be multifactorial and appears to combine both genetic and environmental factors. A number of studies have demonstrated aggregation of cases of UC in families, suggesting that patients share a genetic background. The concordance in monozygotic twin in UC is reported to be 6.3-18.8%[1-4]. Although the concordance rate is not so low, patients with twin pairs suffering from UC are relatively rare[5-9] and few observations of the twin pairs with UC have been reported[10-14]. In addition, although previous studies on the associations of UC and human leukocyte antigen (HLA) genes suggest that HLA play a role in this disease, the associations of various HLA loci with UC have yet to be fully elucidated. We experienced here a rare monozygotic twin with UC and determined their HLA serological and DNA type.

CASE REPORT

A 45-year-old Japanese woman (the elder monozygotic twin) was admitted to Gunma University Hospital with episodes of bloody mucous diarrhea occurring over 10 times per day and associated crampy lower abdominal pain and fever. She had a past history of UC at the age of 22, and was followed up by her primary physician. UC repeated the relapse and remission. Bloody diarrhea, abdominal pain and fever worsened from September 2004, and caused the admission. Physical examination was unremarkable and laboratory examination showed 105 g/L hemoglobin, 7 200 /mm^3 WBC count, 15.7×10^4/mm^3 platelets, 56 mm/h erythrocyte sedimentation rate, 52 g/dL serum total protein, 27 g/L albumin, 33 U/L alanine transaminase, 35 U/L aspartate transaminase, 67 U/L γ-glutamyl transferase, and 5.3 mg/L C-reactive protein. Perinuclear pattern of antineutrophil cytoplasmic antibodies (p-ANCA) was negative. Stool cultures for bacteria showed negative findings. Computed tomography of abdomen showed no abnormalities of liver, pancreas or biliary tract. Colonoscopy revealed a total colitis with diffusely reddish, edematous and erosive lesions, being consistent with the relapse of UC (Figure 1). Histological examination of biopsy specimen revealed depletion of goblet cells, crypt abscesses and severe lymphoplasmacytic infiltration in the mucosa, which was also consistent with UC. There were no extra-bowel complications such as primary sclerosing cholangitis. Because sulfasalazine failed to control her colitis, she was treated with intravenous prednisolone and granulocyte and monocyte adsorptive apheresis, which led her to a remission state.

Her younger sister was also diagnosed as UC at the age of 22, and was followed-up by her primary physician. She had a similar course of UC disease as her elder

Table 1 HLA alleles in the case

sister. Although she was not admitted to the hospital, her colitis worsened in October 2004, and was treated at the outpatient clinic. She was also negative for p-ANCA and had no extra-bowel complications.

The twins were born as full-term normal deliveries and the pregnancy was not complicated. No differences in dietary habits were observed between the twins. They were non-smokers. Their parents, husbands, and daughters had no history of UC or chronic diarrheal diseases. Both twins shared the same home for 24 years, but they lived in different places since the younger sister was married and left home. For the purpose of genetic search, HLA was revealed with serological and DNA types after informed consent was obtained from each patient. HLA was identical and A2, A33, B44, B75, DR13, DR15, DQ1 were detected serologically. DRB1*1501, *1302, DQB1*0602, *0604 were observed by DNA typing (Table 1).

DISCUSSION

The pathogenesis of UC and Crohn's disease is still unknown, but the importance of genetic susceptibility has been clearly shown by epidemiological data from family and twin studies[1-4]. Several twin studies reported that the concordance rate in monozygotic twin with UC is 6.3-18.8%[1-4]. Tysk *et al*[1]. used the Swedish twin registry and inpatient hospital records to identify twins affected by inflammatory bowel disease. Among 25 000 pairs of twins identified from the Swedish twin registry, 80 twin pairs suffering from inflammatory bowel disease were found. In the UC group, 1 of 16 monozygotic pairs was concordant with the disease and the proband concordance rate among monozygotic twins was 6.3% for UC. It was reported that the pair concordance rate in monozygotic twins increases from 6.3% to 18.8% in a Swedish study[2]. Thompson *et al*[3]. also traced 144 twin pairs with inflammatory bowel disease from 16 000 members of the National Association for Colitis and Crohn's Disease, and found that 15.8% monozygotic twins with UC are concordant with the disease. These studies and case reports all indicate a higher concordance with inflammatory bowel disease in monozygotic twins than in dizygotic twins[1-4]. The prevalence and incidence of UC are much lower in Japan than in Europe and North America[15]. Although inflammatory bowel diseases are increasing also in Japan as in European countries, hospital-based investigation in 1991 revealed that the prevalence of UC is 18.12/100 000 and

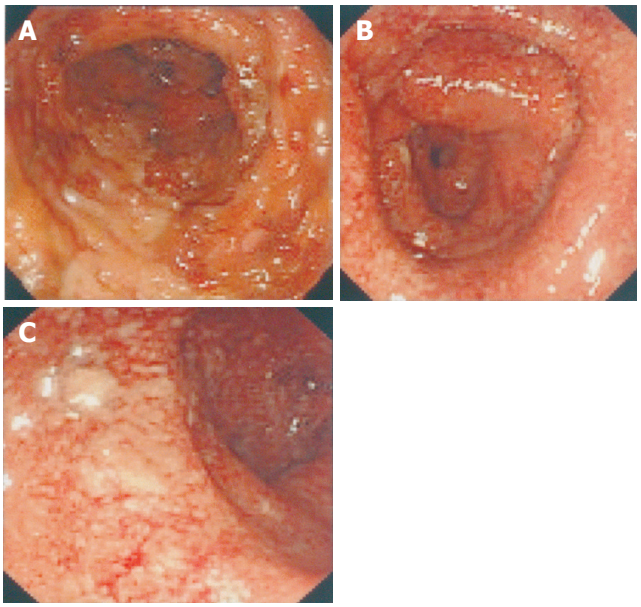

Figure 1 Colonoscopic findings in elder twin sister with UC.

the incidence is 1.95/100 000 in Japan[15]. Delivery with monozygotic twins is reported to be about 4/1 000. The twin study with UC reported that the concordance rate in monozygotic twins with UC is 6.3-18.8%[1-4]. If prevalence of UC is estimated to be 18.12/100 000, concordance rate to be 18.8% and twin delivery rate to be 4/1 000, concordance twin with UC like this case is estimated to be about 13.6/100 000 000. Thus, concordance twins with UC like this case are about only 13.6 cases in Japan. We searched concordant twins with UC using PubMed by key words ulcerative colitis and twin, and found only 22 cases (Table 2) including our case which was reported.

The apparently conflicting data on the HLA system in different studies from around the world may be explained by differences in ethnics, cases and genetic heterogeneity[16]. Replicated class II HLA includes HLA DRB1*0103 and DR2 (DRB1*1502) involved in UC susceptibility, and HLA DRB1*03 and DR4 as resistant alleles for Crohn's disease and UC respectively[16]. The strong association between HLA DR2 and UC has been reported in Japan[17], India[18], and Israel[19]. However, these alleles were not observed in our case. HLA could not explain the occurrence of UC in our case.

The role of environmental factors in the pathogenesis of inflammatory bowel disease is still controversial. The lack of complete concordance in monozygotic twin studies underlines the crucial role played by external factors in the determination of disease expression in patients with genetic susceptibility to inflammatory bowel disease. Non-smoking or a cessation of smoking is a proven risk factor for developing UC[20]. Neither of the twins in our case has ever smoked. Inversely, it has been suggested that appendectomy offers protection against the development of UC[21]. Neither of the twins in our case has received appendectomy.

Our case (Japan)	Case report			1		

Total number of concordant cases of ulcerative colitis in monozygotic twins. IBD[1]: number of twins, one or both pair suffered from inflammatory bowel disease Ulcerative colitis[2]: number of twins, one or both pair suffered from ulcerative colitis. UK: United Kingdom, USA: United States of America.

In summary, we have explained here a rare monozygotic twin with UC. HLA serological and DNA typing were determined. Similar twins are reported to be concordant with inflammatory bowel disease; however the concordant rate is only 6.3-18.8% and the accurate number of these cases is rare. Further accumulations of these cases are needed to clarify the contribution of genetic factors to the development of UC.

Abstract

AIM: To examine the effect of pseudolaric acid B on the growth of human gastric cancer cell line, AGS, and its possible mechanism of action.

METHODS: Growth inhibition by pseudolaric acid B was analyzed using MTT assay. Apoptotic cells were detected using Hoechst 33258 staining, and confirmed by DNA fragmentation analysis. Western blot was used to detect the expression of apoptosis-regulated gene Bcl-2, caspase 3, and cleavage of poly (ADP-ribose) polymerase-1 (PARP-1).

RESULTS: Pseudolaric acid B inhibited the growth of AGS cells in a time- and dose-dependent manner by arresting the cells at G_2/M phase, which was accompanied with a decrease in the levels of cdc2. AGS cells treated with pseudolaric acid B showed typical characteristics of apoptosis including chromatin condensation and DNA fragmentation. Moreover, treatment of AGS cells with pseudolaric acid B was also associated with decreased levels of the anti-apoptotic protein Bcl-2, activation of caspase-3, and proteolytic cleavage of PARP-1.

CONCLUSION: Pseudolaric acid B can dramatically suppress the AGS cell growth by inducing apoptosis after G_2/M phase arrest. These findings are consistent with the possibility that G_2/M phase arrest is mediated by the down-regulation of cdc2 levels. The data also suggest that pseudolaric acid B can trigger apoptosis by decreasing Bcl-2 levels and activating caspase-3 protease.

Key words: Pseudolaric acid B; Apoptosis; AGS cells

INTRODUCTION

Extracts from the root and trunk barks of the Chinese tree *Pseudolarix kaempferi* containing pseudolaric acids are used in traditional Chinese medicine for the treatment of fungal infections[1]. Pseudolaric acid B is the major cell-permeable constituent that displays potent antifungal, antifertil, and anti-angiogenic properties[2-7]. Pseudolaric acid B has cancer chemopreventive activity and inhibits *in vitro* growth of a number of human cancer cell lines, including KB, A-549, HCT-8, P-388, and L-1210 tumor cells[8]. However, no information is at present available on the chemopreventive potentials of pseudolaric acid B on gastric carcinoma.

Apoptosis, a mode of cell death, is a physiologic event that regulates cell number and eliminates damaged cells. Recent studies implicated that apoptosis is a common mechanism through by which chemotherapeutic agents exert their cytotoxicity and that the efficiency of anti-tumor agents is related to the intrinsic propensity of target tumor cells to respond to these agents by apoptosis[9]. *In vitro* studies have shown that pseudolaric acid B treatment can induce apoptosis in human HeLa cells via the activation of c-Jun N-terminal kinase and caspase-3[10]. In order to exploit the chemotherapeutic potentials of pseudolaric acid B on gastric carcinoma, we treated human gastric cancer cell line, AGS, with pseudolaric acid B to examine its antiproliferative effect and apoptosis-inducing activity. Our results suggest that pseudolaric acid B can inhibit the growth of AGS human gastric cancer cells by inducing cell cycle arrest, which correlates with a marked decrease in the expression of key G_2/M-regulating proteins cdc2. The data also suggest that pseudolaric acid B can trigger apoptosis by decreasing Bcl-2 levels and activating caspase-3 protease. Pseudolaric acid B may be used as an effective chemotherapeutic agent against gastric carcinoma.

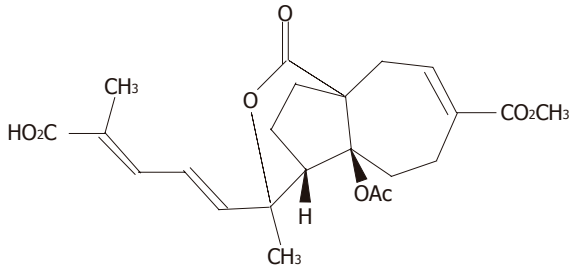

Figure 1 Chemical structure of pseudolaric acid B ($C_{23}H_{28}O_8$, MW = 432.5).

MATERIALS AND METHODS

Materials

Gastric adenocarcinoma cell line (AGS) was obtained from the Shanghai Institute of Cancer Research. Pseudolaric acid B was purchased from Calbiochem Company (La Jolla, CA, USA). The chemical structure of pseudolaric acid B is shown in Figure 1. Hoechst 33258, RNase A, proteinase K and MTT [3'-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrazolium bromide] were purchased from Sigma Chemical Company (St. Louis, USA). Monoclonal antibodies to Cdc2, Bcl-2, caspase-3, and PARP were purchased from Santa Cruz Biotechnology Incorporation (Santa Cruz, CA, USA). PVDF membrane was obtained from Bio-Rad (CA, USA).

Cell culture and treatment with pseudolaric acid B

AGS was maintained in RPMI 1640 supplemented with 10% fetal calf serum, penicillin G (100 kU/L) and kanamycin (0.1 g/L) in a humidified atmosphere of 95% air and 50 mL/L CO_2 at 37 °C. The medium was changed twice a week. A 10 mmol/L stock solution of pseudolaric acid B was prepared in DMSO and stored at -20 °C. Final concentrations of pseudolaric acid B used for different experiments were prepared by diluting the stock with DMEM.

Assay for cell proliferation inhibition (MTT assay)

AGS cells were subcultured in a 96-well plate with 1×10^4 cells/well in 100 μL medium. After 24-h incubation at 37 °C, the medium in each well was discarded and replaced with a fresh medium at various concentrations of pseudolaric acid B in a final volume of 200 μL. Cells were incubated at 37 °C for 6, 12, 24, and 48 h, respectively. At the end of incubation, 50 μL of PBS solution containing 1 mg/mL MTT was added to each well, and further incubated for 4 h. The cell suspension was then centrifuged at 720 r/min for 5 min, and the formazan precipitate in each well was dissolved in 100 μL DMSO for optical density reading at 570 nm.

Flow cytometric analysis

Control and pseudolaric acid B-treated cells were harvested by trypsinization (0.5% trypsin/2.6 mmol/L EDTA), washed twice with ice-cold PBS and fixed in methanol/PBS (9/1, v/v) at 22 °C for at least 30 min. The fixed cells were then washed twice with ice-cold PBS and stained with 50 mg/mL of propidium iodide in the presence of 25 mg/mL of RNase A. Cell cycle phase distribution was determined by flow cytometry (FACSCalibur, Becton Dickinson) and the data were analyzed by multicycle DNA content and cell cycle analysis software (Modfit LT 2.0).

Nuclear damage observed with Hoechst 33258 staining

After being treated with pseudolaric acid B, AGS cells were collected by centrifugation at 1 000 r/min for 5 min and washed twice with PBS. The cells were fixed with 3.7% paraformaldehyde at room temperature for 2 h, centrifuged and washed with PBS, stained with Hoechst 33258 (167 μmol/L) for 30 min at 37 °C. At the end of incubation, the cells were washed and resuspended in PBS for the observation of nuclear morphology under fluorescence microscope (Nikon, Japan).

DNA fragmentation analysis

After being treated with pseudolaric acid B for 12, 24, or 48 h, the cells were harvested and incubated in 0.2 mL lysis buffer containing 10 mmol/L Tris–HCl (pH 8.0), 1 mmol/L EDTA, 1% sodium dodecyl sulfate, and 100 μg/mL proteinase K at 37 °C for 24 h. RNase A (0.5 mg/mL) was added and further incubated at 55 °C for 18 h. Genomic DNA was extracted by phenol/chloroform, precipitated with ethanol and dissolved in TE. Integrity of the DNA was analyzed by electrophoresis on 1.7% agarose gels with ethidium bromide staining.

Western blot analysis

After being treated with pseudolaric acid B for the indicated periods, the cells were washed with PBS and lysed in a buffer containing 20 mmol/L Tris–HCl, 150 mmol/L NaCl, 1% Triton X-100, 1.5 mmol/L $MgCl_2$, 1 mmol/L $NaVO_3$, 100 mmol/L NaF, 10% glycerol, 1 mmol/L EGTA, 10 mmol/L sodium pyrophosphate, and 1 mmol/L phenylmethylsulfonyl fluoride, pH 7.5. Cell lysates were centrifuged at 12 000 *g* for 125 min at 4 °C. The protein concentrations were determined using Bio-Rad protein assay (Bio-Rad Laboratories, USA). After SDS-PAGE, proteins were transferred to PVDF membranes for 2 h at 80 mA. Blots were probed with mouse monoclonal antihuman anti-Bcl-2, anti-caspase-3, and rabbit monoclonal anti-human anti-PARP antibodies. Immunoreactivity was detected using either an anti-mouse (Santa Cruz) or an anti-rabbit (Amersham) peroxidase-conjugated secondary immunoglobulin G antibody followed by enhanced chemiluminescence (ECL, Amersham). Experiments were repeated at least thrice.

Statistical analysis

Data analysis was performed using Student's *t* test. $P<0.05$ was considered statistically significant.

RESULTS

Pseudolaric acid B inhibited AGS cell proliferation

The effects of pseudolaric acid B on cell growth in AGS cell lines were tested. As shown in Figure 2, pseudolaric

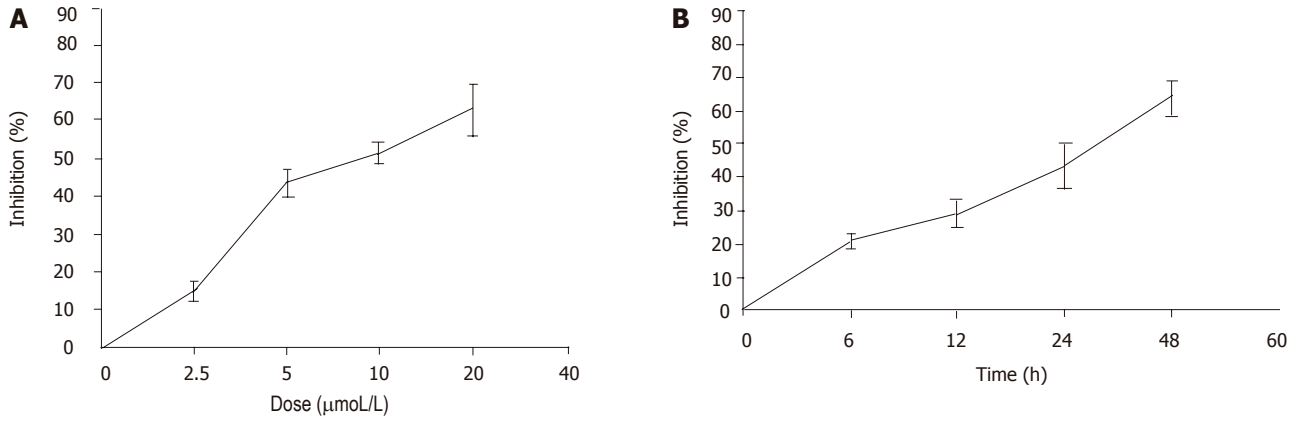

Figure 2 Dose- and time-dependent inhibitory effect of pseudolaric acid B on growth of AGS cells. **A:** AGS cells were treated with various doses of pseudolaric acid B for 24 h; **B**: AGS cells were treated with 5 μmol/L pseudolaric acid B for various time periods. Each point indicates mean±SD of three independent experiments.

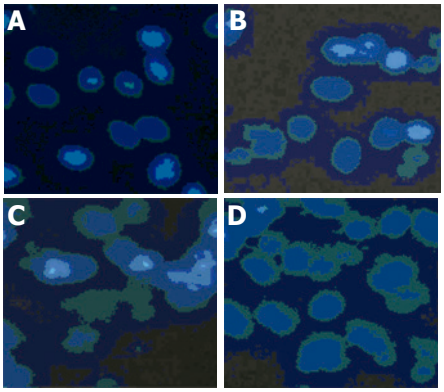

Figure 3 Time-dependent effect of 5 μmol/L pseudolaric acid B on morphological changes in AGS cells. **A:** 0; **B:** 12; **C:** 24; **D:** 48 h.

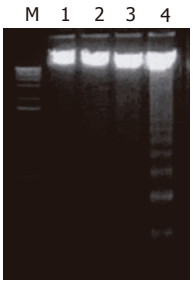

Figure 4 Time-dependent effect of 5 μmol/L pseudolaric acid B on internucleosomal DNA fragmentation in AGS cells. M: Marker; lane 1: 0 h; lane 2: 12 h; lane 3: 24 h; lane 4: 48 h.

acid B inhibited AGS cell proliferation in a time- and dose-dependent manner. Only a minor inhibition of AGS cell growth was observed in the presence of 2.5 μmol/L pseudolaric acid B. Growth was inhibited by more than 40% in cells exposed to 5 μmol/L pseudolaric acid B after 24 h. A concentration of 5 μmol/L pseudolaric acid B was used in all further experiments.

Changes of cell cycle detected by flow cytometric analysis

We further investigated the effects of pseudolaric acid B on the progression of AGS cells throughout the cell cycle. AGS cells were cultured for various lengths of time in the presence or absence of 5 μmol/L pseudolaric acid B and analyzed by flow cytometry. As shown in Table 1, pseudolaric acid B induced a time-dependent accumulation of AGS cells in the G_2/M phase accompanied with a decreased percentage of cells in S and G_0/G_1 phases of the cell cycle.

Table 1 Time course analysis of the cell cycle in pseudolaric acid B-treated cells

0 (control)	56.23	33.42	10.35
12	50.64	31.49	17.87[a]
24	43.56	30.81	25.63[b]
48	33.54	28.45	38.01[b]

[a]P<0.05 , [b]P<0.01 *vs* control. Results were representative of three independent experiments.

Morphological changes and DNA fragmentation in AGS cells

To determine the mode of cell death induced by pseudolaric acid B, morphologic alterations in the AGS cells after treatment with 5 μmol/L pseudolaric acid B for up to 48 h were examined under fluorescent microscope after Hoechst 33342 staining. In the control group, AGS cells were round in shape and stained homogeneously. After 24 h of treatment with pseudolaric acid B, blebbing nuclei and granular apoptotic bodies appeared (Figure 3). We analyzed chromosomal DNA from control and pseudolaric acid B-treated cells. Compared to DNA from control cells, treatment with pseudolaric acid B induced apoptosis, as shown by the formation of distinct internucleosomal DNA fragments (Figure 4). The intensity of the DNA banding ladder progressively increased in a time-dependent manner. An early DNA fragmentation was observed after 12 h of incubation with pseudolaric acid B.

Down-regulation of cdc2 levels in response to pseudolaric acid B

Because pseudolaric acid B arrested AGS cells at the

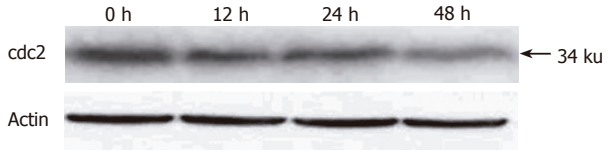

Figure 5 cdc2 levels in AGS cells down-regulated by pseudolaric acid B treatment.

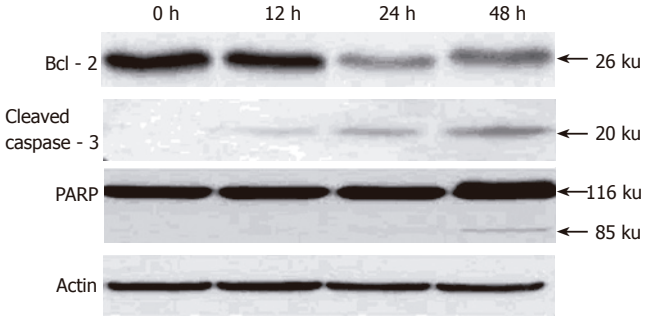

Figure 6 Time-dependent down-regulation of Bcl-2, activation of caspase-3, and PARP cleavage in cultured AGS cells induced by pseudolaric acid B.

G_2/M phase, it was of interest to test the effect of this compound on cdc2 levels, which plays an important role in the G_2 to M progression of the cell cycle. A time-dependent reduction in cdc2 protein level was evident in cells treated with pseudolaric acid B for 48 h (Figure 5).

Down-regulation of Bcl-2, activation of caspase-3, and cleavage of PARP induced by pseudolaric acid B treatment

To investigate the mechanism underlying apoptosis induced by pseudolaric acid B, we tested the effect of this compound on Bcl-2 level, an important regulator of apoptotic signaling pathways[19]. As shown in Figure 5, Western blot analysis revealed that pseudolaric acid B treatment decreased Bcl-2 protein levels. We also found that pseudolaric acid B induced proteolytic processing of caspase-3 in a time-dependent manner. Activation of caspase-3 led to the cleavage of a number of proteins, including PARP-1. Pseudolaric acid B treatment also induced a time-dependent proteolytic cleavage of PARP-1, with concomitant accumulation of the 85 ku and the disappearance of the full-size 116 ku molecule (Figure 6). These findings suggested that pseudolaric acid B could induce apoptosis by down-regulating Bcl-2 and activating caspase-3.

DISCUSSION

Gastric cancer is the second most common cause of cancer death worldwide. Though extensive clinical research has been carried out with numerous combinations of cytotoxic agents, the overall prognosis of advanced gastric cancer still remains poor[11]. Thus, there is considerable interest in identifying more effective cancer chemotherapeutic agents. Pseudolaric acid B, the diterpenoid isolated from the root and trunk bark of *Pseudolarix kaempferi* Gordon tree, has been recently reported to exert an antiproliferative effect on several cancer cell lines[10,12,13]. Since there is no report about its effect on human gastric cancer, we treated human gastric cancer cell line, AGS, with pseudolaric acid B to examine its antiproliferative effect and apoptosis-inducting activity. MTT assay showed that pseudolaric acid B could significantly inhibit growth of AGS cells in a dose- and time-dependent manner. In addition, flow cytometric analysis further revealed that pseudolaric acid B induced a time-dependent accumulation of AGS cells in the G_2/M phase which was coupled with a parallel depletion of the S and G_0/G_1 phase. To further analyze the molecular mechanism by which pseudolaric acid B causes cell cycle arrest, we evaluated cdc2 protein levels. The cdc2/cyclin B complex is one of the major regulatory elements governing the G_2 to M progression[14]. Cdc2 is activated by phosphorylation of and binding to cyclin B, which is synthesized during the S and G_2 phases of the cell cycle[15]. In our study, pseudolaric acid B treatment reduced cdc2 protein levels, suggesting that cell cycle arrest is mediated by the limitation of the supply of cdc2 to cdc2/cyclin B complex formation, which is an essential step in regulating passage into mitosis.

Cell cycle checkpoints are activated to ensure orderly and timely completion of critical events such as DNA replication and chromosome segregation. It is widely accepted that activation of checkpoints in response to DNA damage leads to cell cycle arrest, but in the case of severe damage, the cell cycle arrest leads to cell apoptosis[16,17]. The effects of pseudolaric acid B are compatible with this model. Our present investigation clearly demonstrated that pseudolaric acid B could induce apoptosis of AGS cells, which appears to account for its growth inhibitory and antiproliferative activities. The induction of cell apoptosis was accompanied with characteristic morphological changes, such as chromatin condensation and nuclear fragmentation. Internucleosomal DNA fragmentation as determined by agarose gel electrophoresis also supported the progress of apoptosis of pseudolaric acid B-treated AGS cells.

Apoptosis is a closely regulated process, involving changes in the expression of distinct genes. One of the major genes involved in regulating apoptosis is the protooncogene Bcl-2 encoding a 26-ku mitochondria-associated protein[18,19]. Bcl-2 functions as an intracellular apoptosis suppressor by controlling the mitochondrial membrane permeability with its pro-apoptotic relative, Bax. Diminished expression of Bcl-2 has been observed in certain types of cells undergoing apoptosis[20]. In line with these findings, pseudolaric acid B treatment decreased Bcl-2 protein levels in AGS cells, suggesting that down-regulation of Bcl-2 may be required for AGS cell apoptosis induced by pseudolaric acid B, thus increasing mitochondrial permeability and cytochrome *c* release, which initiates the progress of apoptosis. In addition, involvement of caspase 3 was also examined in pseudolaric acid B-induced AGS cell apoptosis. Caspase-3, a cysteine protease that exists as an inactive proenzyme in cells, is activated by proteolytic processing at internal aspartic

acid residue when cells receive an apoptosis-inducing signal[21]. Activation of caspase-3 leads to degradation and inactivation of key cellular proteins such as DNA repair, signaling, and structural proteins[22,23]. Among these, the cleavage of PARP represents a well described response of cells undergoing caspase-mediated apoptosis[24]. AGS cells treated with pseudolaric acid B exhibited time-dependent activation of caspase-3 and proteolytic cleavage of PARP, indicating that apoptosis of AGS cells is induced by pseudolaric acid B and caspase cascade process.

In conclusion, naturally occurring diterpenoid, pseudolaric acid B, is a potent inhibitor of the growth of human gastric cancer cells. Growth inhibition of the compound is highly related to the induction of cell cycle arrest and apoptosis.

Abstract

AIM: To evaluate the safety and efficacy of chronic administration of losartan on hepatic fibrosis in chronic hepatitis C patients.

METHODS: Fourteen patients with chronic hepatitis C non-responders (n = 10), with contraindications (n = 2) or lack of compliance (n = 2) to interferon plus ribavirin therapy and liver fibrosis were enrolled. Liver and renal function test, clinical evaluation, and liver biopsies were performed at baseline and after losartan administration at a dose of 50 mg/d during the 6 mo. The control group composed of nine patients with the same inclusion criteria and paired liver biopsies (interval 6-14 mo). Histological activity index (HAI) with fibrosis stage was assessed under blind conditions by means of Ishak's score. Subendothelial fibrosis was evaluated by digital image analyses.

RESULTS: The changes in the fibrosis stage were significantly different between losartan group (decrease of 0.5±1.3) and controls (increase of 0.89±1.27; P<0.03). In the treated patients, a decrease in fibrosis stage was observed in 7/14 patients *vs* 1/9 control patients (P<0.04). A decrease in sub-endothelial fibrosis was observed in the losartan group. No differences were found in HAI after losartan administration. Acute and chronic decreases in systolic arterial pressures (P<0.05) were observed after the losartan administration, without changes in mean arterial pressure or renal function.

CONCLUSION: Chronic AT-II type 1 receptor (AT1R) blockade may reduce liver fibrosis in patients with chronic hepatitis C.

Key words: Hepatitis C; Liver fibrosis; Losartan; AT1R; Chronic liver disease; Angiotensin II

INTRODUCTION

The hepatitis C virus (HCV) is one of the leading causes of chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma. Although major progress has been made in the treatment of chronic HCV infection, the current treatment regimens, including Peginterferons in association with ribavirin, appear capable of eradicating HCV in only 30-50% of the treated patients[1]. In this scenario, alternative medical strategies to reduce hepatic fibrosis are under investigation, since drugs with antifibrotic effects may be an option in the treatment of patients with chronic hepatitis C who do not respond to the standard antiviral therapy.

Much evidence suggests that hepatic stellate cells (HSCs) play important roles in the pathogenesis of liver fibrosis, since they were shown to undergo a transformation during the injury that is termed as activation[2]. Furthermore, *in vitro* studies have shown that angiotensin II (ANGII) is a mitogenic protein for a number of cell types and between them the HSCs undergo a MAPK-dependent pathway. In these cells, ANGII upregulates the transforming growth factor beta 1 expression *via* AT-II type 1 receptor (AT1R) *in vitro*. Additionally, proliferation of activated HSCs was found in chronic liver diseases taking part in the development of liver fibrosis[3]. The fact that the actions of ANGII are mediated through AT1R is related to the therapeutic interventions, since AT1R can be completely blocked by losartan, a specific ANGII receptor antagonist. For instance, ANGII stimulated mRNA expression of TGF-beta and fibronectin can be reversed by saralasin and losartan, a nonselective and specific antagonists for AT1R receptors, respectively[4]. Lastly, in animal

models of fibrosis, chronic administration of losartan prevented the development of hepatic fibrosis and portal hypertension[3,5,6].

The purpose of this study was to investigate the safety and efficacy of chronic administration of losartan on hepatic fibrosis in chronic hepatitis C patients.

MATERIALS AND METHODS

Fourteen outpatients (10 men and 4 women) aged 49.6±13 years, with both chronic hepatitis C infection and biopsy proven liver fibrosis, were enrolled in a pilot study.

Ten patients were previous non-responders to a 12-mo combined therapy of interferon and ribavirin, two had contraindications and two showed lack of compliance to the mentioned treatment.

In the control group, nine sex- and age-matched untreated chronic hepatitis C patients with the same inclusion and exclusion criteria who underwent paired liver biopsies (interval 6-14 mo) were included. No patient had a previous history of autoimmune disease, alcohol intake, current intravenous drug use or other chronic liver diseases. All were negative for hepatitis B surface antigen and anti-human immunodeficiency virus. Their clinical characteristics are shown in Table 1.

Written informed consent was obtained from all patients, and the local ethical committee approved the study protocol, based on the 1975 Declaration of Helsinki.

Systolic, diastolic, and mean arterial blood pressures were taken by an automatic sphygmomanometer (VR 12, Electronics for Medicine). Liver and renal function tests and liver biopsies were performed at baseline and after the losartan administration at a dose of 50 mg/d during 6 mo (Losacor, kindly donated by Roemmers, Buenos Aires, Argentina). During the losartan administration, patients did not receive any other medication. Clinical and biochemical follow-ups were assessed and blood pressure was monitored during the first hours, at 1 wk and monthly after the losartan administration.

Liver histology

Ultrasound-assisted liver biopsy was performed using modified Menghini needle of 1.4 mm diameter (Hepafix, Braun, Germany). Liver specimens, previously fixed in formalin, were stained with hematoxylin and eosin, Masson trichrome, silver impregnation for reticular fibers, Perls blue and Prussian blue, and examined by a liver pathologist who was blinded to the clinical data of the patients. Histological activity index (HAI) and fibrosis stage were assessed by means of Ishak's score.

Digital image analysis

Selected areas for fibrosis quantification included the hepatic lobule but without the portal, periportal, septal, and pericentral vein areas. Histological slides stained for reticular fibers were evaluated for sub-endothelial deposit of types III collagen[7] by a digital image analysis. A previous study of our group using this method showed a high correlation between image analysis and fibrosis stage[8]. Images were obtained using a video camera (Sony CCD Iris camera) attached to a light microscope and converted to digital format on a computer by CAP VIEW Leadtek Winfast 2000 PAL device (Leadtek Research Inc.). Standardization of the images was performed with software Adobe Photoshop 7.0 (Adobe Systems Inc.). The quantification of the selected color areas of the digitalized, standardized, and processed images was performed in a 256 gray tones scale with software Scion image for Windows (2000 Scion Corporation), and expressed in pixels/inch^2.

Statistical analysis

Results were expressed as mean±SD. Differences between

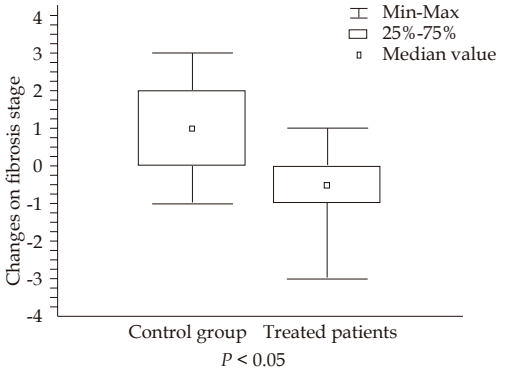

Figure 1 Changes in fibrosis stage in control group and treated patients.

Table 2 Histological changes in liver biopsies

	Treated group (n = 14)		Untreated group (n = 9)	
	Baseline	Post losartan	Baseline	Second biopsy

Fibrosis stage	3.29±1.44	2.64±1.22	2.67±2	3.56±2.13
Sub-endothelial fibrosis (pixels/inch^2)	2.48±1.04	1.00±0.53[a]	1.65±0.43	1.55±0.27

Results are expressed as mean±SD. [a]P<0.01 *vs* baseline.

Table 3 Changes in arterial pressure after losartan administration

	Baseline	3 h	1 mo
Systolic arterial pressure (mmHg)	134±22.7	125±17.4[a]	124±18.1[a]
Diastolic arterial pressure (mmHg)	80.8±14	81.2±14.2	82.5±13.7
Mean arterial pressure (mmHg)	98.4±16.3	95.7±14.8	100±15.8

Results are expressed as mean±SD. [a]P<0.05 *vs* baseline.

Table 4 Orthostatic variations in arterial pressure after losartan administration

	Supine position	Sitting position	
Baseline (10:00 am)			
Systolic arterial pressure (mmHg)	132.7±22.1	132.2±16.8	
Diastolic arterial pressure (mmHg)	80.7±13.4	87.8±8.93	(P<0.0001)
Mean arterial pressure (mmHg)	98±15.7	102.6±11.1	(P<0.01)
Three hours post losartan			
Systolic arterial pressure (mmHg)	124. 7±17.4	127.3±14.9	
Diastolic arterial pressure (mmHg)	81.1±14.2	83.5±11.1	
Mean arterial pressure (mmHg)	95. 7±14.8	98.1±12	

proportions were analyzed by χ^2 test and the Fisher's exact test. Differences between the groups were analyzed by paired and unpaired Student's t- test, by Mann–Whitney U or Wilcoxon matched paired tests, according to the distribution and the scale of measurement. Spearman's ρ coefficient was utilized for correlations. Significance was established at P<0.05.

RESULTS

Effects of losartan

The changes in fibrosis stage were significantly different between losartan group and controls (a decrease of 0.64± 1.3 *vs* an increase of 0.89±1.27, respectively; P<0.02) (Table 2). In the treated patients, a decrease in fibrosis stage was observed in 7/14 patients *vs* 1/9 control patients (P<0.04). Three of the seven patients showed a reduction of two or more points in fibrosis stage. No differences were observed in HAI after losartan administration. Sub-endothelial fibrosis evaluated by image analysis of lobular areas was significantly reduced after losartan administration, without changes in the control group (Table 2 and Figure 1). A significant correlation was found between fibrosis stage and sub-endothelial fibrosis (Spearman's ρ 0.36, P<0.03). A significant increase was observed in albumin level and platelet counts in the treated patients.

Additionally, no significant differences were found in any clinical or biochemical parameters between responders and non-responders to losartan, except that patients who responded to losartan had higher baseline serum alkaline phosphatase than non-responders (309±132 IU/L *vs* 194± 25 IU/L, P = 0.009).

Safety

Acute (3 h) and chronic (1 mo) decreases in systolic arterial pressures in supine position, and a loss of physiologic increase in diastolic pressures from supine to sitting position were observed after losartan administration (Tables 3 and 4). Nevertheless, only one treated patient had a single episode of mild orthostatic hypotension. No differences were observed in renal function tests after losartan administration.

DISCUSSION

It is well known that, at present, the most effective therapy for treating hepatic fibrosis is the removal of the causative agent. In chronic hepatitis C, this goal may be achieved with standard antiviral therapy in a great proportion of patients. Nevertheless, non-responder patients may obtain a benefit from the emerging antifibrotic therapies.

Since renin-angiotensin system blockers are promising drugs in reducing the accumulation of scar tissue in experimental models of chronic liver injury, we performed a pilot study with chronic losartan administration in 14 chronic HCV non-responder patients or with contraindications to interferon plus ribavirin regimen.

Liver biopsy is considered the gold-standard method for the assessment of liver fibrosis[9]. In our study, paired biopsy specimens taken at baseline and at the study completion were compared by means of the standard Ishak score and by an image analysis method for quantification of liver fibrosis. Histopathological scores showed that losartan had an inhibitory effect on the progression of hepatic fibrosis stage. Subendothelial fibrosis evaluated by image analysis of lobular areas was significantly decreased after losartan administration in comparison with the untreated control group.

Regarding biochemical evaluation of the patients, liver

and renal function tests, and blood cells content did not change in either group, except for the platelet content and the albumin concentration in the losartan treated patients, who evidenced a significant improvement in comparison with the control group. Additionally, serum HCV-RNA levels had no change after the study in both groups (data not shown).

Several authors, including us, demonstrated in randomized controlled trials that losartan had equal or greater effects in lowering portal pressure than propranolol, without serious adverse effects[10-13]. The effects of losartan on portal pressure may be explained by the effect of the blockade of AT1R on the contractility of hepatic activated stellate cells, by means of a decrease in intrahepatic vascular resistance. In addition to these events, antifibrotic effects of AT1 blockade may have actions on the structural component of portal hypertension.

With regard to the safety of this treatment, no serious side effects were noted during the study. Nonetheless, an overall decrease was observed in systolic arterial pressures in supine position.

The pathogenesis of HCV-induced liver fibrosis is poorly understood due to the lack of a rodent model of persistent HCV infection. However, since liver fibrosis is the excessive accumulation of extracellular matrix proteins including collagen, it is rational to assume that any chronic damage of the liver may lead to the same final outcome.

Experimental and human studies have consistently shown that ANGII is involved in the development of fibrosis in cardiac and renal tissues in conditions associated with chronic inflammation. Besides, *in vivo* studies have shown that ACE inhibitors and AT1 receptors antagonists can limit the progression of cardiac, renal and pulmonary fibrosis.

In human beings, their efficacy has been tested in a few preliminary pilot studies in patients with NASH[14] and in chronic HCV infection[15], suggesting that renin–angiotensin blocking agents may have beneficial effects on fibrosis progression.

In conclusion, this study shows that administration of an AT1R antagonist may improve liver scores of fibrosis stage in patients with chronic hepatitis C, suggesting that losartan may provide an effective new approach to the treatment of non-responders to antiviral therapy. However, a randomized, controlled trial seems to be necessary in order to confirm the benefit of AT1R blocking for hepatic fibrosis in chronic HCV infection. Lastly, one may speculate that the combination treatment of the clinically used Peginterferons and AT1R blocker may provide a new strategy for anti-liver fibrosis treatment in HCV.

Abstract

AIM: To compare the gene expression profile in a pair of HBV-infected twins.

METHODS: The gene expression profile was compared in a pair of HBV-infected twins.

RESULTS: The twins displayed different disease outcomes. One acquired natural immunity against HBV, whereas the other became a chronic HBV carrier. Eighty-eight and forty-six genes were found to be up- or down-regulated in their PBMCs, respectively. Tumor necrosis factor-alpha-induced protein 1 (TNF-αIP1) that expressed at a higher level in the HBV-immune twins was identified and four pairs of siblings with HBV immunity by RT-PCR. However, upon HBV core antigen stimulation, TNF-αIP1 was downregulated in PBMCs from subjects with immunity, whereas it was slightly upregulated in HBV carriers. Bioinformatics analysis revealed a K+ channel tetramerization domain in TNF-αIP1 that shares a significant homology with some human, mouse, and *C elegan* proteins.

CONCLUSION: TNF-αIP1 may play a role in the innate immunity against HBV.

Key words: TNF-α; HBV; Immunity

INTRODUCTION

Though substantial advances have been made in understanding of the pathogenesis of hepatitis B virus (HBV), HBV infection remains a global health threat with currently more than 350 million carriers and causes about one million deaths worldwide. The situation is particularly severe in high-endemic areas like southeastern Asia. For instance, a study of 16 334 subjects in 1978-1979 in Hong Kong suggested that 43% of the local population have evidence of past infection and 10% are HBs Ag carriers[1].

The major spread mode of HBV in most high endemic areas, such as Hong Kong and China, is perinatal transmission, which accounts for 40%-50% of chronic HBV infection[2,3]. The reason for the preponderance of perinatal transmission among Orientals is at least in part related to the high prevalence of HBV infection among the Asian carriers of reproductive age[2]. Though the incidence of perinatal transmission is high in China, not all siblings in the same family with HBV-infected mothers remain persistently infected with HBV as some acquired natural immunity against the virus. We are among the first group to demonstrate that the use of HLA-matched donor marrow from siblings with natural immunity could enable serological clearance of HBV in their HBsAg positive recipient siblings[4-7]. This indicates that the transfer of certain molecules from the donor's immune system is sufficient to confer the recipient immunity against HBV. However, the identities of these molecules are unknown.

In this study, Affymetrix cDNA mircroarray was employed to investigate the differential gene expression patterns in PBMCs in an identical twin pair who had different outcomes to HBV infection. Use of the twin pair could eliminate the potential confounding factors like age, gender, and living environment, etc. A novel cytokine signaling-related gene, TNF-αIP1, is significantly downregulated in chronic HBV carriers. Moreover, we have confirmed that this gene is indeed differentially expressed in several groups of HBV-infected siblings who display different disease outcomes by reverse transcription-polymerase chain reaction (RT-PCR). We also found that upon HBcAg stimulation, TNF-αIP1 exhibited different

responses between PBMC isolated from subjects with immunity and chronic infection. These results suggest that TNF-αIP1 may be involved in immunity against HBV infection. An understanding of the immunological and genetic differences in PBMCs of these sibling pairs should provide insight into the molecular mechanisms of the protection and enable a more rationale design of therapeutic regimen for chronic HBV infection in Chinese.

MATERIALS AND METHODS

Patient sample information

Eight groups of HLA-A, B and DR identical Chinese siblings (including pair of identical twins) who differed in their outcomes to HBV infection were used in this study. RNA was isolated from PBMC of the siblings with spontaneous recovery (anti-HBs and anti-HBc positive) and their corresponding HLA-matched HBV-infected siblings (HBsAg positive).

PBMC preparation, RNA extraction, and labeling

Heparinized venous blood was collected and PBMC was separated by density-gradient centrifugation over Ficoll-Hypaque. Total RNA was extracted from PBMC using RNeasy kit (Qiagen, Valencia, CA, USA) following manufacturer's instructions. For each sample, 60 mg of total RNA was reverse transcribed using Superscript II (Invitrogen, Carlsbad, CA, USA) according to manufacturer's instructions.

DNA microarray

Generation of antisense RNA (aRNA) probe for cDNA microarray analysis was carried out as described previously[8]. Briefly, mRNA was amplified using two or three rounds of cDNA synthesis followed by aRNA synthesis. T7-promoter-oligo-dT [5'-GCCAGTGAATTGTAATAC GACTCACTATAGGGAGGCGG-$(dT)_{24}$-3'] was used for cDNA synthesis and T7 RNA polymerase was used for aRNA synthesis. Ten micrograms of starting total RNA was used to obtain 10 mg of final aRNA. During the process of the final aRNA synthesis, biotinylated UTP and CTP were used for labeling purpose (Enzo, Farmingdale, NY, USA). Detection of the hybridized probe using streptavidin-phycoerythrin fluorescent conjugate was done according to manufacturer's protocol (Molecular Probes, Eugene, OR, USA).

The labeled aRNA probe from PBMC was hybridized to a HU 95A gene chip representing 12 000 full-length human genes (Affymetrix, Santa Clara, CA, USA). The threshold for significant up- or down-regulation was 2.0- and 0.5-fold, respectively. Hybridizations were typically carried out for 16 h at 45 ℃ followed by washing, staining and using Affymetrix fluidic stations. Stained arrays were scanned in the G2500 A Hewlett-Packard Gene Array Scanner (Hewlett-Packard, Palo Alto, CA, USA) at the excitation wavelength of 488 nm. The amount of emitted light was proportional to the bound target at each location on the probe arrays.

RT-PCR

Total RNA was reverse transcribed using the Superscript II (Invitrogen) according to the manufacturer's instructions. PCR conditions for pre-B-cell colony-enhancing factor (PBEF), IL-18 receptor accessory protein (IL-18 RAP), TNF-αIP1 and GADPH were as follows: at 94 ℃ for 30 s, at 57 ℃ for 30 s, at 72 ℃ for 1 min for 35, 35, 35, and 32 cycles, respectively. The primer sequences of the genes tested were PBEF (sense: 5'-AAAAGCTGTTCCTGAGG GCTTTG-3'; anti-sense: 5'-TGACCACAGATACAGGCA CTGATG-3'); IL-18RAP (sense 5'-CCAGAGCCACAGA AATCACATTTC-3'; anti-sense 5'-CAAGAAATAGAGCC AGTGCTCCCA-3'); TNF-αIP1 (sense: 5'- TTACCTCCG AGATGACACCATCAC-3'; anti-sense: 5'-TCCTCATCTT CACTGGGGGAA-3').

RESULTS AND DISCUSSION

Perinatal transmission is the most common spread mode of hepatitis B infection in Chinese. Yet not all the siblings infected with HBV from mothers become chronic HBV carriers. It appears that different disease outcomes of these siblings represent success and failure of their immune systems in controlling HBV infection. In this study, we attempted to explore this phenomenon by investigating gene expression profiles in PBMCs of two identical twins who displayed diverse disease outcomes.

The differences in PBMC gene expression between two identical twins were analyzed using a DNA microarray chip containing 12 000 human expressed genes. Eighty-eight genes were expressed at a higher level and 46 genes were expressed at a lower level in twins with immunity (HBV resistant) compared to the HBV carrier twins [HBV susceptible). These genes were grouped on the basis of their predicted functions into 12 major groups (metabolism, cell signaling, transcription, transport physiology, growth, and differentiation, immune system, cell adhesion, house keeping, cell cycle, translation, apoptosis, and unknown genes (ESTs)] (Figure 1). We found that genes with unknown functions represented the major portion of genes with altered expression levels in the HBV immune twin.

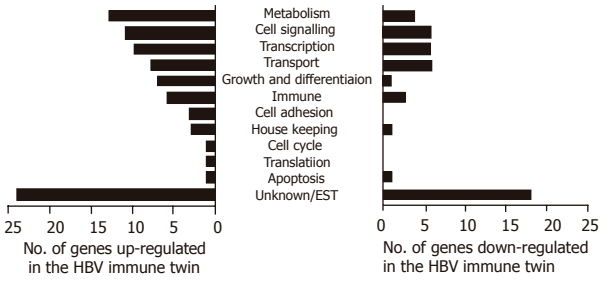

Figure 1 Number of genes upregulated or downregulated in the immune twin compared to the HBV carrier twin. PBMCs from two HBV infected twins with different disease outcomes were analyzed for gene expression using DNA microarray. Eighty-eight genes were identified as upregulated and 46 downregulated. They were further divided into 12 groups based on their presumed functions.

Table 1 Differential expression of immunity-related genes in PBMCs of HBV identical twin patients

UniGene ID	Gene name	Known function(s)	Fold change
Hs.244613	Signal transducer and activator of transcription 5b (STAT 5b)	Signal transducer of IL-2, IL-4, CSF1, and different growth hormones. I mportant for TCR signaling, apoptosis, adult mammary gland development, and sexual dimorphism of liver gene expression	–4.2
Hs.239138	Pre-B-cell colony-enhancing factor (PBEF)	A cytokine that increases the expression of IL-6 and IL-8 in fetal membrane and may be important in both normal spontaneous labor and infection-induced preterm labor	2.2
Hs.158315	Interleukin 18 receptor accessory protein (IL-18RAP)	An accessory subunit of the heterodimeric receptor for IL-18 enhances the IL-18 binding a ligand binding subunit of IL-18 receptor. The coexpression of IL-18R1 and this protein is required for the activation of NF-κB and MAPK8 (JNK) in response to IL-18	3.0
Hs.76090	Tumor necrosis factor-alpha-induced protein 1 (endothelial) (TNF-αIP1)	Unknown	2.3
Hs.225948	Chemokine (C-C motif) ligand 27 (CCL27)	Cytokine that plays a role in mediatinghoming of lymphocytes to cutaneous sites. It specifically binds to chemokine receptor 10 (CCR10). Studies of murine protein indicate that these protein-receptor interactions have a pivotal role in T-cell-mediated skin inflammation	-2.5
Hs.301921	C-C chemokine receptor type 1 (C-C CKR-1)	Cytokine receptor important for host protection from inflammatory response and susceptibility to virus and parasite	-2.7
Hs.57735	Scavenger receptor class F, member 1 (SCARF1)	Scavenger receptor that has roles in the binding and degradation of acetylated low density lipoprotein and may be involved in atherosclerosis	-2.2
Hs.4930	Low density lipoprotein receptor-related protein 4 (LRP4)	A membrane protein which may be involved in calcium ion binding	-2.8

[1]Fold changes between the HBV immune twin pair. Positive number indicates upregulation, whereas negative number denotes downregulation.

We are interested in the immune system-related genes that are putative candidates for conferring HBV immunity. Among the up- or down-regulated genes, eight genes were related to immune responses including several cytokine/chemokine signaling-related genes (Table 1). Three genes, namely cytokine PBEF, interleukin IL-18 receptor (R) accessory protein and TNF-αIP1 were upregulated in the immunity twin. PBEF is a cytokine transcribed in human bone marrow, liver tissue and muscle[9,10] and synergized with stem cell factor (SCF) and IL-7 activating pre-B-cell colony formation[11]. IL-18R accessory protein enhances the IL-18 binding activity of IL-18R1 and is required for the activation of nuclear factor-kappa B (NF-κB) and mitogen-activated protein kinase 8 (MAPK 8) in response to IL-18. TNF-αIP1 is first identified as a primary response gene in human umbilical vein endothelial cells towards TNF-α stimulation[12], but yet with no known function.

Five genes were downregulated in the HBV-immuned twins. They are the signal transducer and activator of transcription 5b (Stat5b), which is crucial for normal immune function and T-cell-mediated mitogenic signals and is a key signal transducer of T-cell receptor[13]. The chemokine (C-C motif) ligand 27 (CCL27) and C-C chemokine receptor type 1 (C-C CKR-1) are important for host inflammatory response. We also observed the downregulation of the scavenger receptor class F member 1 (SCARF1) and low-density lipoprotein receptor-related protein 4. Scavenger receptors encompass a broad range of molecules involved in receptor-mediated endocytosis of selected polyanionic ligands, including modified low-density lipoproteins (LDL)[14]. Further investigating the role of these genes and the molecular differences between immune siblings and HBV chronic carrier siblings may help us in designing therapeutic measures that modulate the immune system of patients in controlling HBV infection.

Of the eight immune system-related genes, TNF-αIP1 demonstrated the highest frequency of differential expression among the other groups of HBV-infected HLA-matched siblings with different disease outcomes as determined by semi-quantitative RT-PCR (Figure 2A). As shown in Figure 2B, the expression level of TNF-αIP1 was

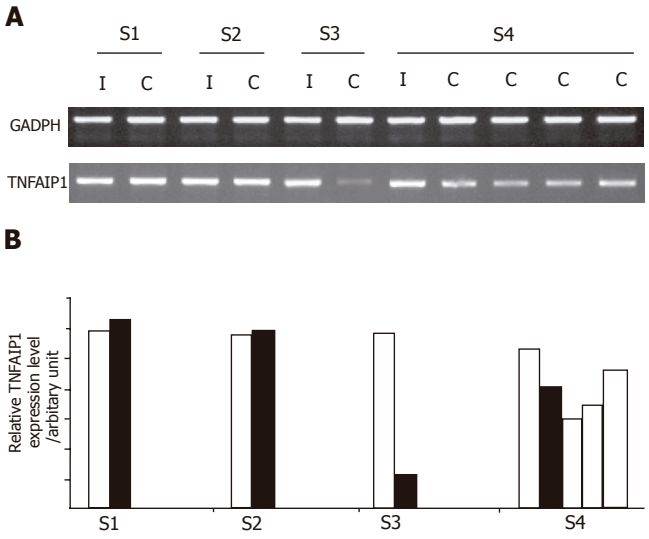

Figure 2 Expression levels of TNF-αIP1 gene in HBV-infected siblings with different disease outcomes. **A:** RT-PCR analysis of TNF-αIP1 in four sibling pairs; **B:** Fold changes of band intensity of TNF-αIP1 in different sibling groups. Open bar: HBV immune patients; black or patterned bars: HBV carrier; S1: sibling group 1; S2: sibling group 2; S3: sibling group 3; S4: sibling group 4.

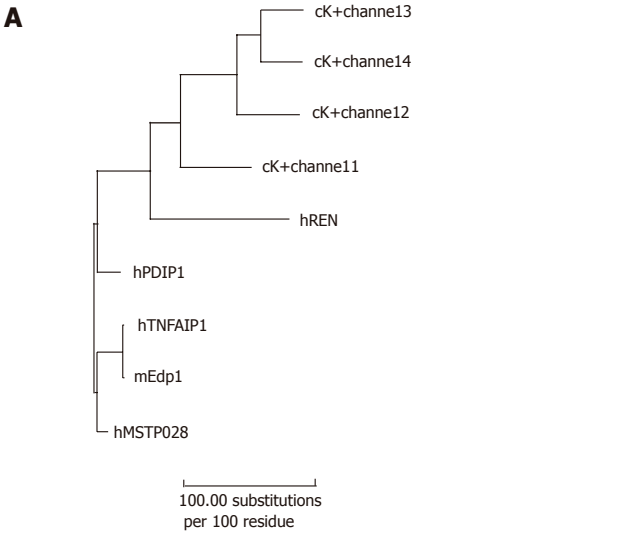
lower in HBV carriers than in their HBV immune siblings in two siblings groups. Noticeably, the expression of TNF-αIP1 was significantly downregulated in HBV carrier siblings of group 3 and all four carrier siblings displayed down-regulation of TNF-αIP1. Suggesting that TNF-αIP1 may be a gene differentially expressed in PBMCs of HBV immune and carrier patients.

Recent studies suggest that cytokine response plays an important role in successful host defense against HBV infection. In transgenic mouse and chimpanzee model, cytotoxic T lymphocytes do not directly kill HBV-infected hepatocytes, but inhibit the viral replication through the actions of TNF-α and interferon (IFN-γ)[15,16]. Romero and Lavine[17] demonstrated that TNF-α and IFNs can downregulate the activity of HBV core/pregenomic (C/P) promoter, hence contributing to viral clearance. Moreover, activated intrahepatic antigen-presenting cells can inhibit liver HBV replication by secreting IL-12 and TNF-α[18]. One of the downstream mechanisms of how TNF-α modulates HBV infection is via the activation of NF-κB, which can inhibit HBV replication[19]. Interestingly, we have shown that TNF-αIP1 (a TNF-α inducible gene) expresses at a higher level in HBV immunized twin. TNF-αIP1 was first identified as an endothelial primary response gene towards TNF-α (then named B12), which induces TNF-αIP1 expression rapidly and transiently. Biochemical characterization suggests that TNF-αIP1 is a 36 ku protein, which may play a regulatory role and locate intracellularly[12]. The role of TNF-αIP1 in TNF-α-mediated NF-κB activation and HBV replication inhibition is of interest for further study.

Phylogenetic analysis showed that TNF-αIP1 could evolve into human and mouse endothelial protein 1 (Edp1), reflecting the fact that Edp1 is likely the mouse ortholog of TNF-αIP1 (Figure 3A). Predicted from the



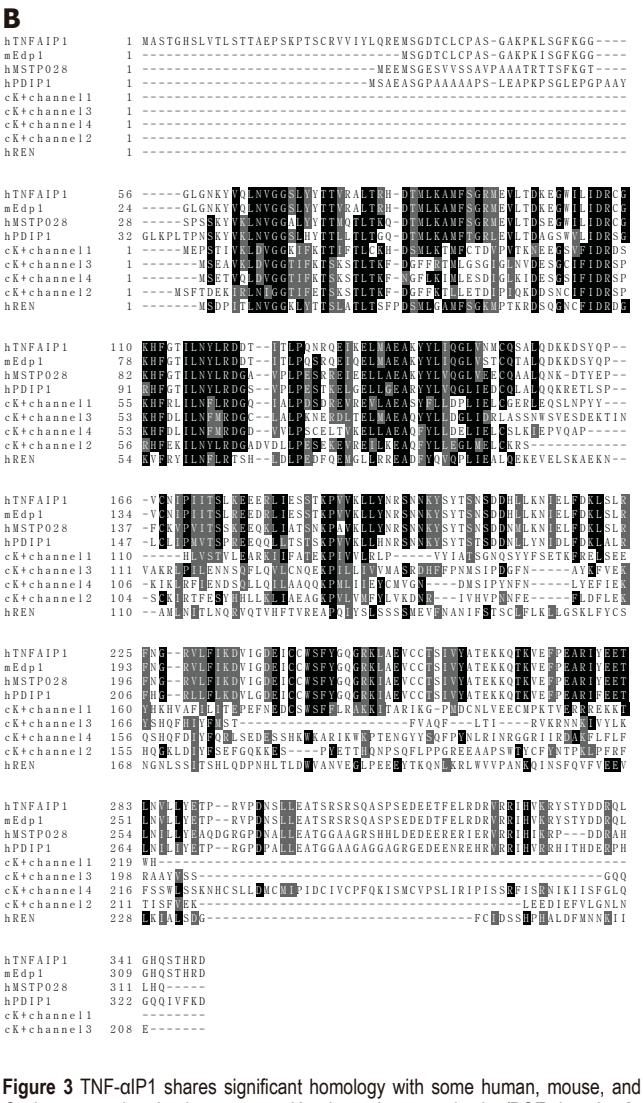


Figure 3 TNF-αIP1 shares significant homology with some human, mouse, and *C elegan* proteins, having common K+ channel tetramerization/POZ domain. **A:** Phylogenetic analysis of evolutionary distance of the protein sequences. The protein sequences were analyzed by the Growtree program provided by the GCG package. Kimura distance was adopted as the distance correction method. **B:** Amino acid sequence alignment of TNF-αIP1 (A41784) with mouse Edp1 protein (AAC78826), human MSTP028 protein (NP_114160), PDIP1 (AAL14962), human REN protein (XP_208568), and four C elegan K+ channel family members and with highest homology to TNF-αIP1 (NP_499312, NP_494320, NP_494476 and NP_494315). Black line: K+ channel tetramerization/POZ domain.

amino acid sequence of TNF-αIP1 (A41784), there is a K+ channel tetramerization domain in the middle of the sequence. This N-terminal, cytoplasmic tetramerization domain (T1) of voltage-gated K+ channels encodes molecular determinants for subfamily-specific assembly of alpha-subunits into functional tetrameric channels[20]. It is distantly related to the BTB/POZ domain which plays an oligomerization role in the function of this protein. Interestingly, the K+ channel tetramerization domain is the common domain feature shared by many TNF-α inducible proteins. For instance, mouse TNF-α inducible proteins such as Edp1 share high homology with the entire amino acid sequence of TNF-αIP1 (97% identity) (Figures 3A and B). It is also noticed that there was a group of C elegan proteins containing the K+ channel tetramerization domain. However, the function of this group of proteins is unknown.

Among the proteins containing K+ channel tetramerization domain, polymerase delta-interacting protein 1 (PDIP1) is best characterized[21]. PDIP1 is a TNF-α inducible protein and plays a role in linking cytokine activation and DNA replication in the liver as well as in other tissues. It localizes inside the nuclei and interacts with DNA polymerase δ small subunit (p50) and proliferating cell nuclear antigen (PCNA). In addition, it modulates DNA polymerase δ activity in a PCNA dependent manner. Importantly, it shares high homology (62% identity) with TNF-αIP1 (B12). PDIP1 is involved in TNF-α-mediated hepatocyte regeneration and stimulates hepatocyte proliferation upon TNF-α signal[21]. It is of interest to know whether this is also true for TNF-αIP1 using cell proliferation assay.

Abstract

AIM: Passive immunotherapy using antibody against hepatitis B surface antigen (HBsAg) has been advocated in certain cases of Hepatitis B infection. We had earlier reported on the cloning and expression of a high affinity scFv derived from a mouse monoclonal (5S) against HBsAg. However this mouse antibody cannot be used for therapeutic purposes as it may elicit anti-mouse immune responses. Chimerization by replacing mouse constant domains with human ones can reduce the immunogenicity of this antibody.

METHODS: We cloned the V_H and V_L genes of this mouse antibody, and fused them with CH1 domain of human IgG1 and C_L domain of human kappa chain respectively. These chimeric genes were cloned into a phagemid vector. After initial screening using the phage display system, the chimeric Fab was expressed in soluble form in *E. coli*.

RESULTS: The chimeric Fab was purified from the bacterial periplasmic extract. We characterized the chimeric Fab using several *in vitro* techniques and it was observed that the chimeric molecule retained the high affinity and specificity of the original mouse monoclonal. This chimeric antibody fragment was further expressed in different strains of *E. coli* to increase the yield.

CONCLUSION: We have generated a mouse-human chimeric Fab against HBsAg without any significant loss in binding and epitope specificity. This chimeric Fab fragment can be further modified to generate a full-length chimeric antibody for therapeutic uses.

INTRODUCTION

Hepatitis B virus (HBV) infection is the 10th leading cause of death worldwide, with 2 billion people infected by it and 350 million suffering from chronic HBV infection[1]. Protective antibodies that appear after natural infection are mostly directed against the major antigenic 'a'determinant of Hepatitis B surface antigen (HBsAg)[2]. The immunodominant 'a' epitope is a part of a large antigenic area of HBsAg, called the major hydrophilic region[3] and this epitope is present in all serotypes[4]. Antibodies against HBsAg are thus advocated for passive immunotherapy against Hepatitis B infection in cases of accidental needle stick injuries, for liver transplant patients and to prevent vertical transfer of HBV infection from mother to child[5-8]. Presently, human anti-HBs immune globulin (HBIG) collected from the blood of hyperimmune donors is used for postexposure prophylaxis. Being a blood derived product anti-HBs HBIG is costly and can cause cross-contamination. Therefore a recombinant antibody to HBsAg can be a suitable alternative to such a practice.

Although several recombinant antibodies against HBsAg have been reported in literature, none is available for clinical use[9–12]. In our previous work we had expressed and characterized a recombinant anti-HBs scFv cloned from a mouse monoclonal 5S[13]. This antibody binds to HBsAg with high affinity (K_D = 0.889 nmol/L). It tested positive in an *in vitro* surrogate test for seroconversion and protective antibodies (Hepanostika anti-HBs kit, Organon Teknika, The Netherlands). The scFv generated from this hybridoma retained the high affinity and epitope specificity[13]. However this mouse monoclonal cannot be used for therapeutic purposes as it may trigger human anti-mouse antibody response, especially when multiple infusions are required to obtain therapeutic efficacy[14,15]. It is well known that immunogenic reactions are predominantly directed towards constant domains of

murine antibodies[16]. Problems associated with the HAMA response can be reduced by creating mouse-human chimeric antibodies, where mouse constant regions are replaced by human ones[17-19].

The exact mechanisms of antibody-mediated virus neutralization are not clear till date. A few of the principal mechanisms, which have been postulated for virus neutralization, are virus aggregation, inhibition of attachment of virus to cell receptors and inhibition of events after attachment to cell receptors[20,21]. Though high affinity binding to viral epitopes is a pre-requisite for antibody-mediated virus neutralization, the importance of antibody constant domains is not clear. Apart from full-length antibodies, antibody Fab fragments have been shown to neutralize viruses[22-26]. It has been shown that $F(ab)_2$ fragments derived from HBIG is effective for the prevention of vertical transfer of HBV infection in neonates[27]. In comparison to a full-length antibody, a Fab fragment can be easily expressed in bacterial expression systems[28]. A recombinant Fab can be further modified for increase in affinity[29], for chimerization/humanization[30] and can be linked with antibody Fc region to generate a full-length antibody[31,32].

In the present work, we have fused the variable regions of the mouse monoclonal 5S (IgG1/κ) with the corresponding human constant regions (C_H1 of IgG1/C_L of κ) to generate a mouse-human chimeric Fab. This chimeric Fab was expressed using a phage display expression system. After initial screening of functional clones, the chimeric Fab was expressed in *E. coli* in soluble form. It was purified by affinity chromatography and characterized for antigen binding. We observed that the chimeric Fab fragment retained the high affinity binding and epitope specificity of the original mouse monoclonal. This chimeric molecule can be further modified for generation of a therapeutically useful full-length chimeric antibody.

MATERIALS AND METHODS

Materials

The phagemid vector pCOMB3H was provided by The Scripps Research Institute, La Jolla, USA. Shanta Biotech (India) provided purified recombinant HBsAg expressed in a *Pichia* system. *E. coli* XL1-Blue and TG1 cells and helper phage M13 KO7 were obtained from MRC, Cambridge, UK. *E. coli* strains AD494 and BL 21 CodonPlus were procured from Novagen. 5S hybridoma cells were maintained in RPMI (Sigma, USA) with 10% FCS (Sigma, USA). Anti-M13 mouse antibody was provided by Dr. Vijay Chaudhary, University of Delhi, South Campus, New Delhi, India.

Construction of the chimeric light chain and Fd fragment

The strategy for generation of the chimeric Fd and light chain is shown in Figure 1. The variable region genes of 5S hybridoma were amplified by reverse transcription followed by PCR. Primers used for all reverse transcriptions and PCRs are listed in Table 1. Total RNA was isolated from 5S cells using TRI reagent (Sigma, USA) and cDNAs for the V_H and V_L fragments were generated by reverse transcription using Omniscript RTase (Qiagen). Primers used for reverse transcriptions were Fd3 and K3 for V_H and V_L respectively. These primers have overhangs complementary to the 5' regions of the respective human constant domains. The V_H fragment was further amplified by PCR using primers 5H23M and Fd3. Similarly, the V_L fragment was amplified by PCR using primers 5L35 and K3. Conditions for both the PCRs were: 30 cycles at 94 °C for 1 min, 50 °C for 1 min, 72 °C for 2 min, followed by a final extension for 10 min at 72 °C.

For amplification of human constant domains, RNA was isolated from human peripheral blood lymphocytes (PBLs) using TRI reagent. cDNAs for the C_H1 region of human IgG1 and the C_L region of human kappa chain were generated by reverse transcription using Omniscript RTase (Qiagen). Primers used for reverse transcriptions were CG1Z and Ck1d for C_H1 and C_L respectively. The C_H1 fragment was further amplified by PCR using primers Fd5 and CG1Z. Human C_L was amplified by PCR using primers K5 and Ck1d. Fd5 and K5 carry overhangs complementary to the 3' end of variable regions of 5S. Conditions for both these PCRs were: 30 cycles at 94 °C for 1 min, 60 °C for 1 min, 72 °C for 2 min, followed by a final extension for 10 min at 72 °C.

PCR amplified fragments were resolved in 1.5% agarose gel and respective bands were eluted out using QIAquick gel extraction kit (Qiagen). PCR amplified C_H1 (human IgG1) and mouse V_H were used as templates for generation of the chimeric Fd by overlap PCR. Initial assembly of equimolar amounts of the mouse V_H and human C_H1 was done by PCR for 20 cycles at 94 °C for

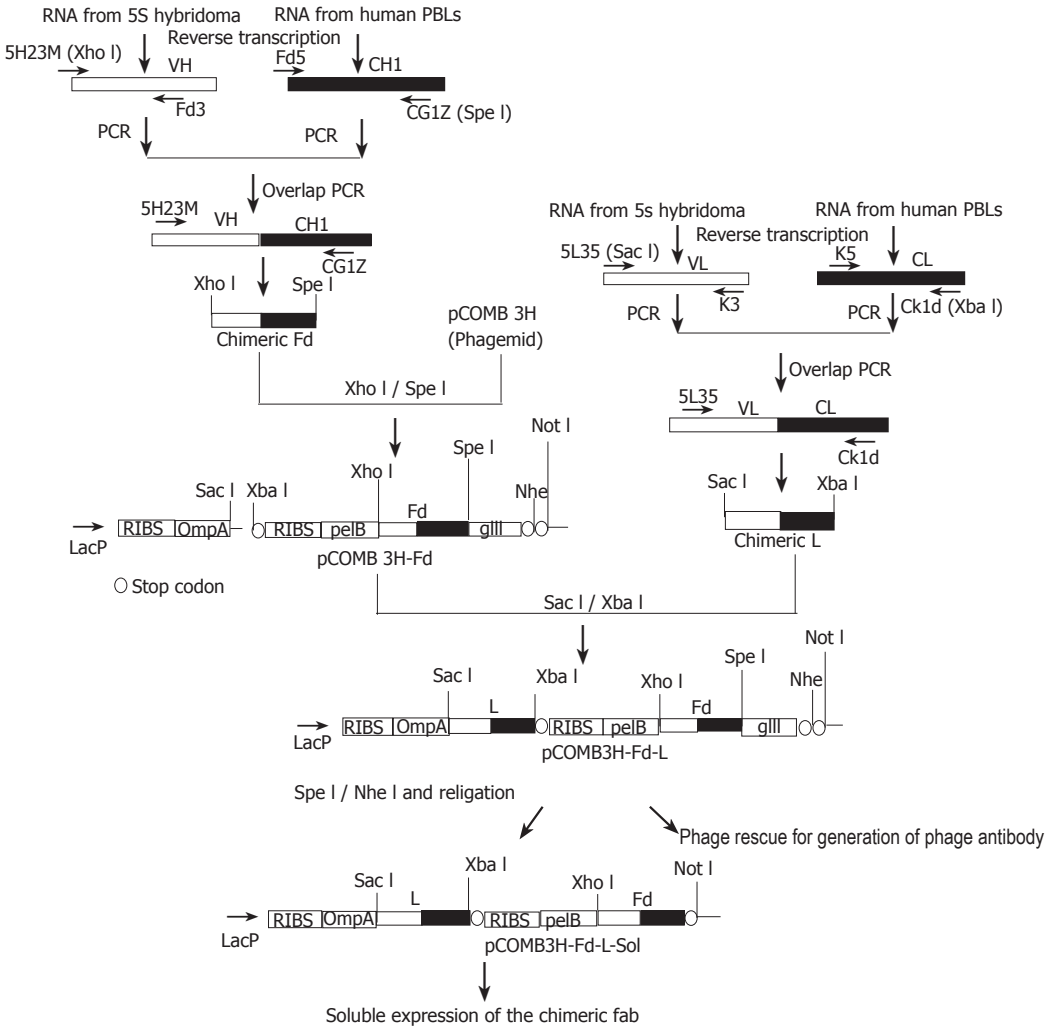

Figure 1 Schematic representation of the strategy for cloning and expression of the anti-HBs chimeric Fab. The V_H and V_L fragments of 5S hybridoma were fused with human C_H1 and C_L by overlap PCR. The resulting chimeric fragments were cloned in the bi-cistronic phagemid vector pCOMB3H. Both the fragments are under the control of a single *LacZ* promoter. *ompA* and *pelB* are two leader sequences, provided for directing the light chain and Fd fragment to the bacterial periplasm. Two ribosome-binding sites are present in the vector for stable expression of both the fragments. The Fd fragment was cloned upstream to the phage gIII sequence, for surface display of the chimeric Fab. This *gIII* fragment was removed by digestion with *Spe I/Nhe I* and after self-ligation of the vector, the Fab fragment was expressed in soluble form.

1 min, 60 °C for 1 min and 72 °C for 2 min, followed by final extension of 10 min at 72 °C. The product of the initial assembly reaction was diluted 10 times and used as the template for pull through PCR using primers 5H23M and CG1Z. Similarly human kappa C_L and mouse V_L fragment were joined to generate the chimeric light chain. Primers used for this reaction were 5L35 and Ck1d.

Construction of the phagemid construct

We used the bi-cistronic phagemid vector pCOMB3H, a variant of the phagemid pComb3[33], for the expression of the chimeric Fab. The essential features of this vector system and our cloning strategy are shown in Figure 1. The chimeric Fd was digested with *Xho1* and *Spe1* and cloned into the phagemid vector pCOMB3H. The resulting construct (pCOMB3H-Fd) was transformed into chemically competent *E. coli* XL1-Blue cells by standard chemical method ($CaCl_2$/heat shock)[34]. Transformed cells were grown on Amp-Agar plates. Colonies were picked up after overnight incubation and screened for the presence of the insert by colony PCR and restriction digestion (*Xho1*/*Spe1*). The recombinant phagemid pCOMB3H-Fd was isolated by alkali-lysis method and digested with *Sac1* and *Xba1*. The chimeric light chain digested with these two enzymes was cloned into pCOMB3H-Fd to generate the phagemid construct pCOMB3H-Fd-L. This construct was transformed into chemically competent XL1-Blue cells by standard chemical transformation method and after overnight incubation, recombinant clones were checked for the presence of the chimeric light chain by colony PCR and by restriction digestion (*Sac1*/*Xba1*).

Expression of the phage antibody and selection of antigen binding clones

Cells transformed with the construct pCOMB3H-Fd-L were used for expression of the chimeric Fab on phage surface. Phage displaying chimeric Fab was rescued by infection with helper phage M13-KO7 as described by

Barbas *et al*.[33]. Phage was precipitated from the culture supernatant by incubating with PEG/NaCl (20% PEG/2.5 mol/L NaCl) for 8 h on ice. After centrifugation, precipitated phage was resuspended in PBS and titrated to determine phage concentration[35].

Clones displaying functional Fab fragment were selected by biopanning over antigen-coated plates. The method for biopanning has been discussed in detail in our earlier article[13]. Essentially this method involves incubation of phage in uncoated ELISA plate followed by incubation of unbound phage in antigen-coated plate. After thorough washing, bound phage was eluted out at low pH. Eluted phage was passed through two more rounds of selection over coated and uncoated wells with increasing number of washing.

Identification of antigen binding clones by phage-ELISA

Phage obtained after three rounds of selection, was reinfected in XL1-Blue cells and amplified by standard phage rescue protocol as mentioned earlier. Antigen binding clones were identified by phage-ELISA. Maxisorp ELISA plates were coated with HBsAg (250 ng/well) in bicarbonate buffer (pH 9.5). After blocking with 2% non-fat milk in PBS (MPBS), phage (~10^{12}/well) was added and incubated for 1 h at room temperature. Bound phage was detected by incubation with 1:1 000 dilution of anti-M13 mouse antibody for 1 h at room temperature, followed by 1 h incubation with 1:2 000 dilution of anti-mouse antibody-HRP conjugate (Promega, USA). ELISA was developed by using 100 μL of 0.4 mg/mL *o*-phenylenediamine and 0.8 μL/mL of H_2O_2 in citrate-phosphate buffer (pH 5). The same amount of helper phage (M13-KO7) was used as negative control in phage-ELISA.

The phagemid construct was isolated from the clone showing maximum binding and the nucleotide sequences of the chimeric Fd and light chain were determined by sequencing using ABI-Prism automatic DNA sequencer. Primers used for sequencing the light chain were 5'-ATGAAAAAGACAGCTATCGC-3' and 5'-TAATAAC AATCCAGCGGCTG-3'. Primers used for sequencing the Fd fragment were 5'-TCTTTTCATAATCAAAATCACC G-3' and 5'-AAATGAAATACCTATTGCC-3'.

Soluble expression of the chimeric Fab

The antigen binding clone selected by phage ELISA was further processed for soluble expression of the anti-HBs chimeric Fab. For soluble expression of the chimeric Fab, the phage *gIII* sequence was removed from the recombinant phagemid construct pCOMB3H-Fd-L by double digestion with *Spe I* and *Nhe I*. Digestion by these two enzymes provides compatible ends for self-ligation of the vector. Double digested phagemid was self-ligated to generate the construct pCOMB3H-Fd-L-Sol and transformed in chemically competent XL1-Blue cells. For soluble expression of recombinant chimeric Fab, 1 L Super Broth with 20 mmol/L $MgCl_2$ and ampicillin (100 μg/mL) was inoculated with 10 mL of overnight culture of the recombinant clone and grown at 37 °C till the A_{600} reached approximately 0.6, when overexpression of the chimeric Fab was induced by 1 mmol/L IPTG. After overnight growth at 30 °C, cells were harvested by centrifugation at 4 000 r/min. Cell pellet was re-suspended in 20 mL PBS/ 1 mmol/L EDTA and kept on ice for 40 min. Clarified periplasmic extract was obtained by centrifugation of the re-suspended product at 10 000 *g*. The same method was used to express the soluble chimeric Fab in three other *E. coli* strains (AD494, BL21 CodonPlus and TG1).

Purification of the recombinant chimeric Fab

The periplasmic extract was concentrated (~10 times) using Centriprep YM-30 centrifugal filter (Millipore, USA). The recombinant chimeric Fab was purified from the periplasmic extract by affinity chromatography using HiTrap Protein G HP column (Amersham) as per the manufacturer's protocol. In brief, the protein G column (1 mL) was washed thoroughly with double distilled water (five column volumes) and equilibrated with five column volumes of equilibration buffer (pH 7.0). The concentrated periplasmic extract was allowed to pass through the column using a syringe at a speed of 2 mL/min. The column was washed thoroughly by 10 volume of equilibration buffer and bound chimeric Fab was eluted out by 5 volume of elution buffer (pH 2.7). Eluted fractions were immediately neutralized using neutralization buffer (77 μL/mL, pH 9). The eluted fractions were concentrated by Centriprep YM-30 centrifugal filter and checked on SDS-PAGE.

Electrophoresis and Western blot analysis

The purified chimeric Fab was resolved by 12% SDS-PAGE, separately in reducing (with βME) and non-reducing conditions (without βME or DTT). The resolved protein was stained by silver staining.

For Western blot analysis, the concentrated periplasmic extract was resolved by 12% SDS-PAGE in non-reducing conditions and electroblotted on nitrocellulose membrane. After blocking with 4% MPBS for 2 h, the chimeric Fab was detected by Rabbit anti-Human IgG-HRP conjugate (1:1 000 dilution; Dako). The blot was developed using DAB/H_2O_2 system. An equal amount of concentrated periplasmic extract of untransformed XL1-Blue cells was used as the negative control for the Western blot experiment. A separate Western blot experiment was performed under reducing conditions for the detection of the monomeric Fd and light chain. Whenever required, intensity of bands in Western blots was measured densitometrically using ChemiImager 4400 (Alpha Innotech Corp., USA).

Antigen binding assays for the chimeric Fab

Binding of the chimeric Fab was checked by solid phase ELISA. Maxisorp ELISA plate was coated with 250 ng/well of HBsAg in bicarbonate buffer (pH 9.5). After blocking with 4% MPBS, different dilutions of the chimeric Fab was added to antigen coated wells and bound antibodies were detected by Rabbit anti-Human IgG-HRP conjugate (1:2 000 dilution; Dako). Hybridoma supernatant of the original mouse monoclonal 5S was

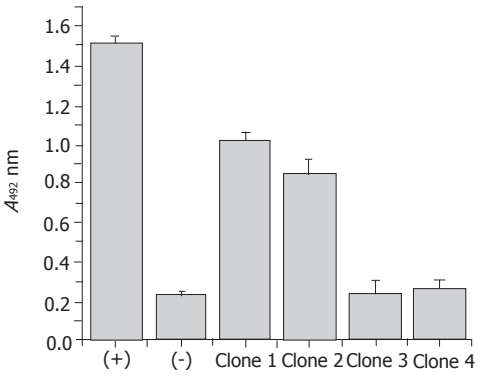

Figure 2 Phage ELISA to identify antigen binding clones. After three rounds of biopanning, selected phage was rescued and antigen-binding clones were detected by phage ELISA. In this experiment 5S hybridoma supernatant and helper phage M13 KO7 were used as positive (+) and negative (–) control respectively. Clone 1 was used for soluble expression of the chimeric Fab.

used as a positive control for this experiment. The extract of untransformed XL1-Blue cells was used as a negative control and corresponding readings were deducted from the readings of the chimeric Fab. This ELISA method was also used to study the levels of expression the chimeric Fab in different *E. coli* strains.

For competitive ELISA, plates were coated with HBsAg (100 ng/well) in bicarbonate buffer and blocked with 4% MPBS. Different amounts of the chimeric Fab were mixed with 1:80 dilution of 5S hybridoma supernatant and added to antigen-coated wells. After one hour incubation at room temperature, bound mouse antibody was detected by anti-mouse-HRP conjugate (Bangalore Genei, India). Periplasmic extract of untransformed XL1-Blue cells was used as the negative control and binding of the mouse monoclonal in its presence was taken as the maximum binding to calculate the percent inhibition.

Determination of the dissociation constant of the chimeric Fab

The dissociation constant (K_D) of HBsAg and chimeric Fab interaction was determined in solution phase by an ELISA method as described by Friguet *et al*.[36]. Essentially the technique involves incubation of a fixed amount of the antibody with different amounts of the antigen in solution phase for a prolonged period so that the equilibrium is reached. This is followed by detection of unbound antibody by conventional ELISA. This ELISA data is then used to calculate the K_D value, by using an equation derived from the law of mass action. The advantage of this technique is that it can be used to determine the affinity of an antibody without prior purification.

For this experiment we used crude periplasmic extract of the clone expressing the chimeric Fab in soluble form. A fixed amount of the periplasmic extract (1:300 dilution, in 100 μL of 4% MPBS) was incubated with varying concentrations of HBsAg (3-10 nmol/L) for 16 h at 4 °C. This equilibrated solution was incubated in antigen coated ELISA plates (250 ng antigen/well) for 20 min at room temperature to capture the free Fab. Bound chimeric Fab was detected by Rabbit anti-human IgG-HRP conjugate (Dako).

Protein estimation

Protein concentrations were estimated by Bradford assay[37].

RESULTS

Generation of a phagemid construct for the expression of phage antibody: Variable regions of the light chain and heavy chain of the mouse monoclonal 5S were amplified by RT-PCR. The $C_{H}1$ region of human IgG1 and C_L of human kappa chain were amplified by RT-PCR using RNA extracted from human PBLs. After the fusion of the mouse V_H and human $C_{H}1$, resulting chimeric Fd was cloned into the phagemid vector pCOMB3H to generate the recombinant construct pCOMB3H-Fd. Similarly, the chimeric light chain, generated by joining the mouse V_L and human C_L, was cloned into pCOMB3H-Fd to generate the recombinant construct pCOMB3H-Fd-L. This construct was transformed in XL1-Blue cells and phage displaying the chimeric Fab was generated by phage rescue using helper phage.

Selection of antigen binding clones and phage ELISA: The anti-HBs chimeric Fab was first expressed as phage antibody and antigen-binding clones were enriched by bio-panning over antigen coated plate. Selection was done on uncoated and antigen coated wells alternatively, thereby removing plastic binding clones, which can interfere in subsequent ELISAs. After three rounds of selection, functional clones were amplified and rescued to generate phage particles displaying the chimeric Fab and antigen-binding clones were detected by phage ELISA (Figure 2). As shown in Figure 2, clone 1 had the maximum binding and was used for soluble expression of the chimeric Fab. Nucleotide sequences of the chimeric Fd and light chain of this clone were submitted to the EMBL Nucleotide Sequence Database (EMBL accession numbers: AJ878860 and AJ878861). Sequence analysis indicated that the variable regions in these chimeric genes are identical to the variable regions of the mouse monoclonal 5S (data not shown).

Soluble expression of the chimeric Fab: Phage *gIII* sequence was removed from pCOMB3H-Fd-L for soluble expression of the chimeric Fab. The anti-HBs chimeric Fab was expressed in *E. coli* XL1-Blue cells by inducing overnight with 1 mmol/L IPTG. The leader sequences, present upstream to the chimeric genes, drag both the chains to the bacterial periplasm, where they form inter- and intra-chain disulphide bonds. The periplasmic extract was concentrated and the chimeric Fab was purified using Protein G column. Yield of the purified chimeric Fab when expressed in XL1-Blue cells was ~40 μg/L of culture. The purified product was resolved by SDS-PAGE in non-reducing (without βME/DTT) as well as in reducing conditions (with βME). As shown in Figure 3A, the chimeric Fab is expressed as a heterodimer (~50 ku) of the chimeric Fd and light chain. In reducing conditions, both the chains were detected in monomeric form (~25 ku).

Expression of the heterodimeric chimeric Fab was further confirmed by Western blot in non-reducing

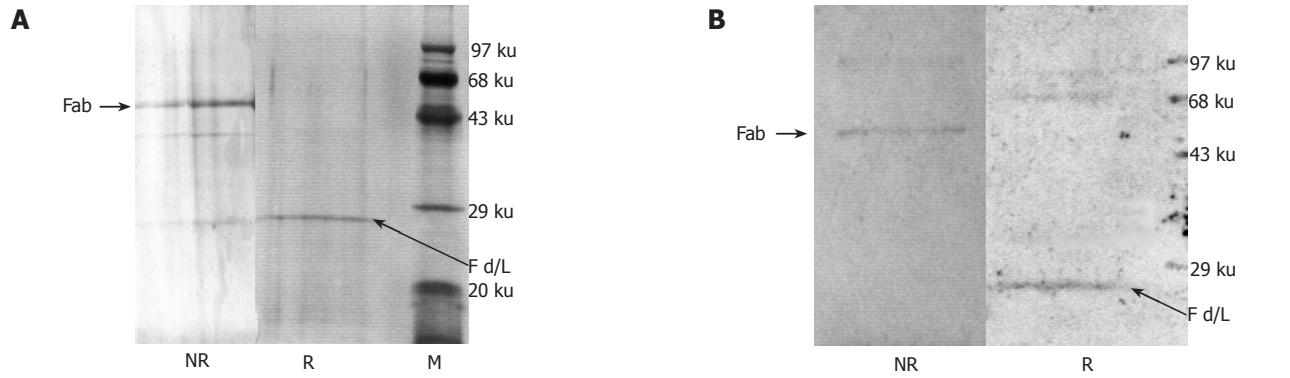

Figure 3 SDS-PAGE (**A**) and Western Blot (**B**) analysis of the chimeric Fab. The purified chimeric Fab was resolved in 12% SDS-PAGE under reducing (R) and non-reducing conditions (NR). In non-reducing conditions the Fab is a heterodimer of molecular weight ~50 ku. In reducing conditions the heterodimer dissociates into chimeric light chain (~25 ku) and Fd (~25 ku). Both the gels were stained by silver staining. M is the lane for the protein marker. Similar observations were made in Western Blots (**B**) of the chimeric Fab in reducing (R) and non-reducing (NR) conditions. Electroblotted antibody fragments were detected by Rabbit anti-Human IgG-HRP conjugate (1:1 000 dilution; Dako).

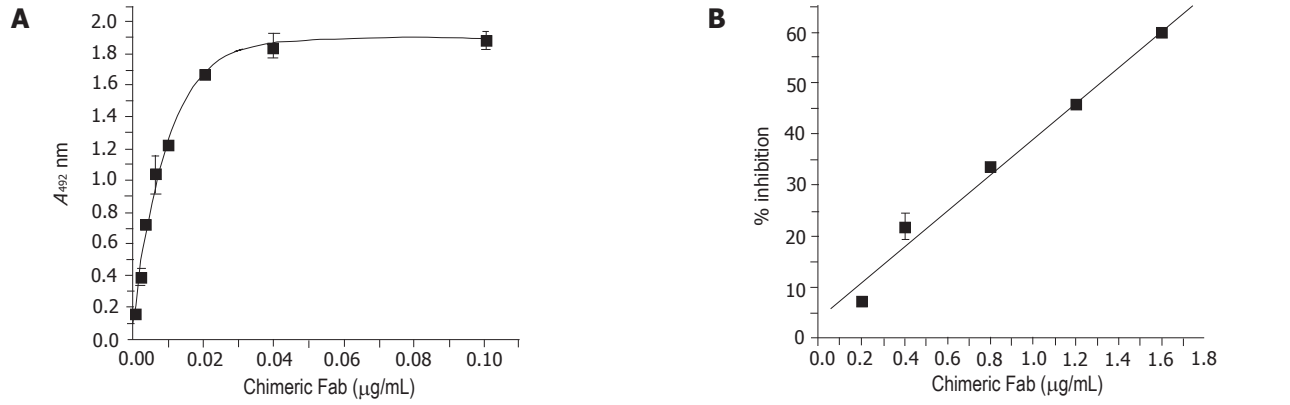

Figure 4 Binding properties of the anti-HBs chimeric Fab. 1 Solid phase ELISA was performed with different dilutions of the soluble chimeric Fab. The result of the competitive ELISA between the chimeric Fab and the mouse monoclonal 5S is shown in Figure (**B**). Different amounts of the chimeric Fab were allowed to compete with 1:80 dilution of the 5S-hybridoma culture supernatant for binding to HBsAg. Bound mouse monoclonal was detected with anti-mouse HRP and the % inhibition of binding was calculated.

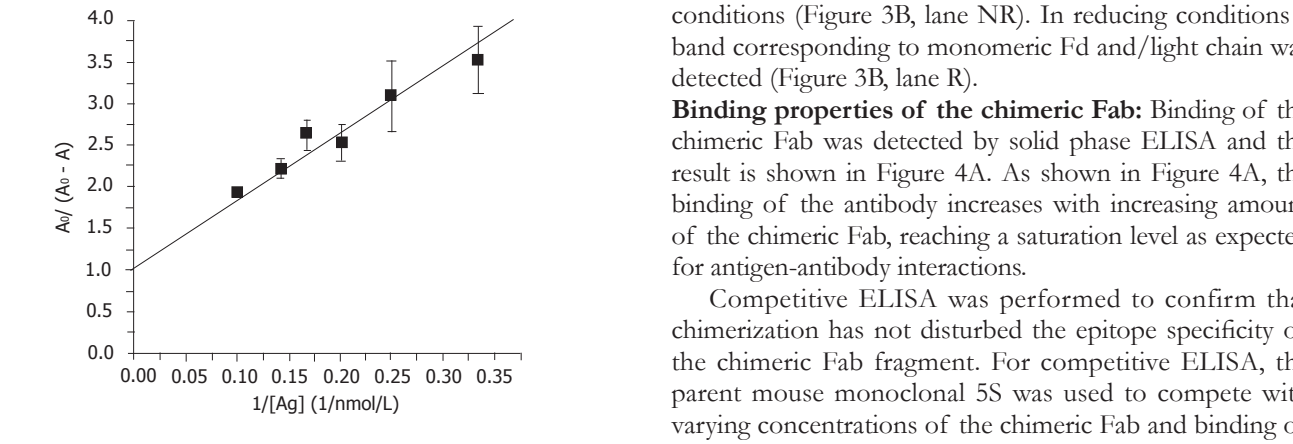

Figure 5 Dissociation constant (K_D) of the chimeric Fab. The K_D was determined using an ELISA based method. Different amounts of HBsAg were incubated with concentrated periplasmic extract of the clone expressing the anti-HBs chimeric Fab for 16 h and unbound antibody was detected by ELISA using rabbit anti-human antibody-HRP (Dako). The data was fitted to the equation $A_0/(A_0–A) = K_D*1/[Ag]+1$, where Ao = absorbance when the antibody was incubated without any antigen, A = absorbance corresponding to free antibody after incubation with the antigen. Dissociation constant of the chimeric Fab was determined from the slope of the straight line (K_D = 8.166±0.14 nmol/L).

conditions (Figure 3B, lane NR). In reducing conditions a band corresponding to monomeric Fd and/light chain was detected (Figure 3B, lane R).

Binding properties of the chimeric Fab: Binding of the chimeric Fab was detected by solid phase ELISA and the result is shown in Figure 4A. As shown in Figure 4A, the binding of the antibody increases with increasing amount of the chimeric Fab, reaching a saturation level as expected for antigen-antibody interactions.

Competitive ELISA was performed to confirm that chimerization has not disturbed the epitope specificity of the chimeric Fab fragment. For competitive ELISA, the parent mouse monoclonal 5S was used to compete with varying concentrations of the chimeric Fab and binding of the mouse antibody was detected using anti-mouse-HRP conjugate. Figure 4B shows that the chimeric Fab inhibits the binding of the mouse antibody, indicating that both of these bind to the same epitope.

Dissociation constant of the chimeric Fab: The dissociation constant of the chimeric Fab in solution phase was determined using an ELISA based technique developed by Friguet *et al.*[36]. As calculated from the slope

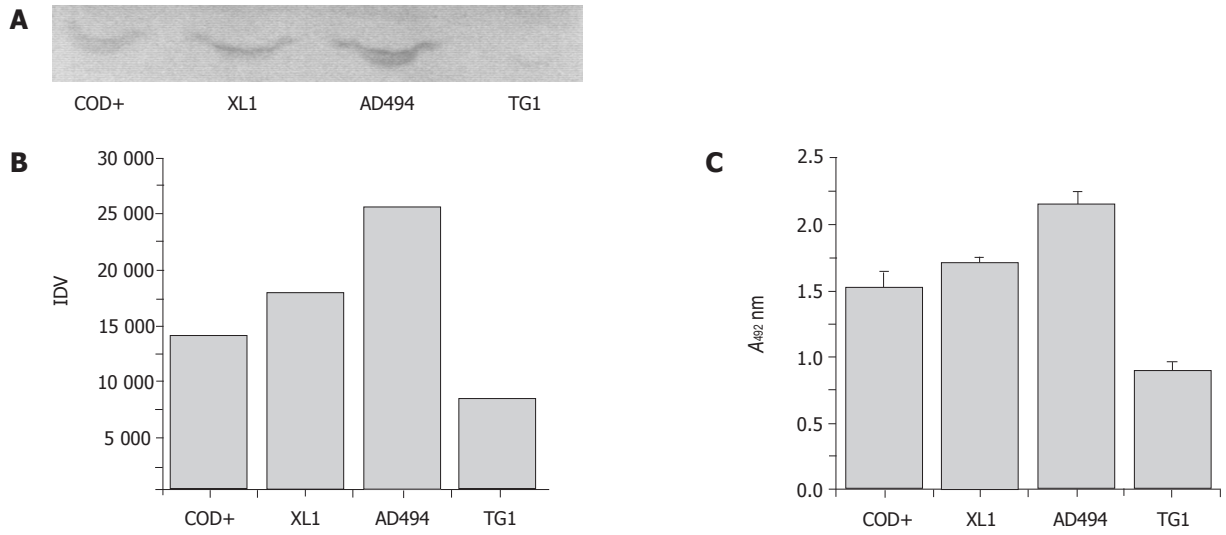

Figure 6 Expression profile of the chimeric Fab in different strains of *E. coli*. The chimeric Fab was expressed in soluble form in different *E. coli* strains in identical conditions. Levels of expression of the chimeric Fab were checked by Western blot in non-reducing conditions (**A**). Intensities of bands were measured densitometrically (**B**). Levels of expression were also checked by ELISA (**C**). Equal amount of the periplasmic extracts were allowed to bind to HBsAg coated on ELISA plate and bound chimeric Fab was detected. (XL1 = XL1-Blue, AD494 = AD494, COD+ = BL21 Codon Plus, TG1 = TG1, IDV = integrated density value).

Table 2 Yields of the anti-HBs chimeric Fab in different *E. coli* strains

E. coli strain	Yield (μg/L)[1]
XL1-Blue	40
AD494	62
BL21 Codon Plus	40
TG1	8

[1]Estimated by Bradford assay, after purification by protein G column

of the line in Figure 5, the K_D of the chimeric anti-HBs Fab is 8.166±0.14 nmol/L, (r^2 = 0.914).

Expression of the chimeric Fab in different *E.coli* strains: Yield of this chimeric Fab in *E. coli* XL1-Blue cells was found to be low (~40 μg/L). The recombinant construct pCOMB3H-Fd-L-Sol was transformed into three other strains of *E. coli*, (AD494, BL21 CodonPlus and TG1) to check the yield of the chimeric Fab in soluble form. The chimeric Fab was expressed in these cells in the same fashion as stated above for XL1-Blue cells. The levels of expression of the chimeric Fab in different *E. coli* strains were checked by Western Blot and compared densitometrically (Figures 6A and B). The levels of expression of the chimeric Fab in different strains of *E. coli* were further confirmed by ELISA using crude periplasmic extracts. The result of the ELISA is shown in Figure 6C. Yields of the purified chimeric Fab expressed in different *E. coli* strains are shown in Table 2. As shown in Figure 6 and Table 2, maximum yield of the chimeric Fab was observed in case of *E. coli* AD494 cells.

DISCUSSION

5S is a mouse monoclonal that binds to HBsAg with high affinity[13]. However, like any other mouse monoclonal, this antibody can give rise to HAMA response and cannot be used clinically. HAMA may neutralize the injected mouse antibody directly by immune complex formation, which could lead to rapid clearance or to hypersensitivity reactions[38,39]. As immunogenic reactions are predominantly directed towards the Fc region of murine antibodies[16], creation of mouse-human chimeric antibodies by swapping murine constant regions with the human ones can address the problem of HAMA response, at least in part[17-19]. But such domain swapping can alter the immunological and pharmacokinetic properties of an antibody, making the task of generation of chimeric antibodies quite tricky[40].

One of the crucial aspects in generation of chimeric antibodies is the selection of human isotypes for domain swapping. Effector functions of antibody constant domains are broadly dependent on the antibody classes and subclasses[41]. Usually human IgG1 is the preferred choice for chimeric antibodies in situations where activation of effector functions is the desired outcome[42]. Rath and Devey[43] had observed that the subclasses of antibodies associated with HBsAg in circulating immune complexes of patients with either acute or chronic HBV infections were predominantly IgG1 and IgG4. A study involving children, who have recovered from acute hepatitis B, has shown that after natural seroconversion, specific antibodies were highly restricted to IgG1[44]. It has also been observed that anti-HBs IgG1 is predominant after vaccination with recombinant vaccines[44,45].

Apart from being important for effector functions, the choice of isotype can also affect the antigen binding of a chimeric molecule. It has been observed that changes in constant domains can affect the functional affinity and specificity of antibodies[46]. Pritsch *et al*.[47] have shown that Fab fragments of antibodies sharing identical variable regions but C_H1 of different isotypes have significant differences in affinities. A molecular dynamic study

involving anti-HEL Fab has shown that, the interactions between C_L and C_H1 domains may have influence not only around the local interface between C_L and C_H1 but also around the interacting regions between HEL and Fv[48].

In the present work, the variable region genes of 5S (IgG1/κ) were fused with the C_H1 region of human IgG1 and human kappa chain constant region, to generate a mouse-human chimeric Fab. The C_H1 region of IgG1 and kappa C_L were amplified using RNA extracted from human PBLs and linked with respective variable regions of 5S hybridoma by overlap PCR. The chimeric fragments were subsequently cloned into the phagemid vector pCOMB3H and phage antibodies were expressed. Functional clones were selected by biopanning over antigen coated plate and selected clones were checked for binding by phage ELISA. It is well known that cloning of antibody genes by PCR may introduce mutations and may amplify truncated antibody genes, generating clones that are non-functional[49,50]. Use of a phagemid expression system allows the initial expression of antibody molecules as phage antibodies, which can be easily selected for antigen binding and then be further processed for soluble expression. As shown in Figure 2, two of the four clones checked by phage ELISA after three rounds of biopanning showed high binding. Clone 1 was further processed for soluble expression of the chimeric Fab. SDS-PAGE and Western blot in both reducing and non-reducing conditions confirmed that the chimeric Fab was expressed in the form of a heterodimer (Figures 3A and B). The chimeric Fab was further characterized by ELISA and competitive ELISA. Competitive ELISA confirmed that the chimeric Fab and the original mouse monoclonal bind to the same epitope (Figure 4B). The dissociation constant of the chimeric Fab as determined by the ELISA based method was found to be high (8.166±0.14 nmol/L). The dissociation constant for the original mouse monoclonal is 0.8899 nmol/L[13]. Given the level of accuracy of the method used for the determination of K_D values, one can consider both of these values to be in the same broad range. An anti-human antibody was used in the ELISA to calculate the K_D of the chimeric Fab; whereas an anti-mouse antibody was used in case of the mouse monoclonal. Such a difference in experimental setup can also be attributed for the difference in K_D values.

Though it seems simple, high yield expression of heterologous proteins in bacterial systems sometimes proves to be problematic. Multiple factors like codon usage[51], DNA/RNA/Protein interaction[52], regulatory factors for transcription and translation and nucleotide usage in the leader peptide[53] affect the yield of heterologous proteins in bacteria. The yield of Fab depends upon the relative levels of expression of the light chain and Fd. The light chain-heavy chain balance depends upon codon usage in the signal peptides and 5' sequence of coding regions[54]. In this present work, the yield of soluble recombinant Fab in XL1-Blue cells was low (~40 μg/L). Such a low yield of Fab fragment expressed in *E. coli* using pCOMB3H vector system has been reported earlier[55]. To optimize the yield of the soluble chimeric Fab, the recombinant construct was transformed in different *E. coli* strains — TG1, AD 494 and BL21 CodonPlus. *E. coli* BL21 CodonPlus-RP (Novagen) cells contain extra copies of the *argU* and *proL* genes. These genes encode tRNAs that recognize the arginine codons AGA, AGG and the proline codon CCC, respectively. *E. coli* BL21 has been used for high-level expression of several antibody fragments[56,57]. *E. coli* AD494 cells are thioredoxin negative (*trxB*$^-$), thereby providing an oxidizing environment in the cytoplasm. Proper folding and assembly of antibody domains require inter- and intra-chain disulphide bond formation. Therefore bacterial periplasm is suitable for the assembly of functional Fab fragments. An oxidizing environment in the cytoplasm may also help to increase the yield of properly folded soluble antibody fragments. We expressed the anti-HBs chimeric Fab in soluble form in different *E. coli* strains under identical conditions. As shown in Figure 6 and Table 2, there was a slight increase in the expression of the chimeric Fab in AD494 cells; whereas the expression in BL21 was equivalent to that in XL1-Blue cells. Though Raffai *et al*.[55] had observed increased yield of soluble Fab fragment in TG1 in comparison to XL1-Blue cells, we could not detect any such increase in yield.

Though chimerization and humanization are essential to reduce immunogenicity of non-human antibodies before they can be used clinically such genetic engineering can alter functional capabilities of the molecule, often leading to loss of binding or reduction in affinity. Our results show that the chimerization of the 5S mouse monoclonal did not disturb its binding to the antigen and the chimeric Fab binds to the same epitope as that of the original mouse monoclonal. Though chimeric and monovalent in nature, the affinity of the recombinant chimeric Fab remained in the same range as the mouse monoclonal 5S. The high affinity binding of this chimeric Fab fragment indicates that it can be further modified to generate a clinically applicable full-length chimeric anti-HBs antibody, with out any significant loss of binding affinity.

ACKNOWLEDGMENTS

We are thankful to Dr. Dennis R. Burton and The Scripps Research Institute, La Jolla, USA for providing the vector pCOM3H. We thank Dr. Vijay Chaudhary for his gift of anti-M13 antibody. We are also thankful to M/s. Mathura Prasad and Satish for their technical and secretarial assistance.

Abstract

AIM: To develop a simplified and efficient method for the preparation of hepatitis C virus (HCV) cDNA microarray probes.

METHODS: With the technique of restriction display PCR (RD-PCR), restriction enzyme *Sau3A* I was chosen to digest the full-length HCV cDNAs. The products were classified and re-amplified by RD-PCR. We separated the differential genes by polyacrylamide gel electrophoresis and silver staining. Single bands cut out from the polyacrylamide gel were isolated. The third-round PCR was performed using the single bands as PCR template. The RD-PCR fragments were purified and cloned into the pMD18-T vector. The recombinant plasmids were extracted from positive clones, and the target gene fragments were sequenced. The cDNA microarray was prepared by spotting RD-PCR products to the surface of amino-modified glass slides using a robot. We validated the detection of microarray by hybridization and sequence analysis.

RESULTS: A total of 24 different cDNA fragments ranging from 200 to 800 bp were isolated and sequenced, which were the specific gene fragments of HCV. These fragments could be further used as probes in microarray preparation. The diagnostic capability of the microarray was evaluated after the washing and scanning steps. The results of hybridization and sequence analysis showed that the specificity, sensitivity, accuracy, reproducibility, and linearity in detecting HCV RNA were satisfactory.

CONCLUSION: The RD-PCR technique is of great value in obtaining a large number of size-comparable gene probes, which provides a speedy protocol in generating probes for the preparation of microarrays. Microarray prepared as such could be further optimized and applied in the clinical diagnosis of HCV.

INTRODUCTION

Hepatitis C virus (HCV) is a RNA virus with a high rate of genetic mutation[1]. HCV has a linear genome approximately 10 kb in length, which consists of a positive sense single-stranded RNA (ssRNA)[2]. Consistent with related members of the family *Flaviviridae,* HCV demonstrates a high degree of sequence variation throughout its genome. Sequence analysis of multiple strains of HCV has demonstrated that the nucleotide sequence can differ by as high as 30%[3]. Infection with HCV has been identified as the major cause of post-transfusion non-A, non-B hepatitis, and is a major public health problem in most areas of the world, raising the issues of its diagnosis, treatment, and prevention[4-6].

In the present study, we utilized the technique of restriction display PCR (RD-PCR) to prepare HCV cDNA chip probes. Restriction enzyme *Sau3A* I was chosen to digest the full-length HCV cDNAs. The products were classified and re-amplified by RD-PCR. We separated the differential genes by polyacrylamide gel electrophoresis and silver staining. The cDNA microarray was prepared by spotting RD-PCR products to the surface of amino-modified glass slides using a robot. The specificity, sensitivity, accuracy, reproducibility, and linearity in detecting HCV RNA were evaluated.

MATERIALS AND METHODS

Probe template

The full-length plasmid of HCV pCV-J4L6S was presented

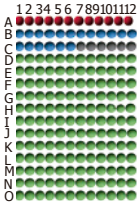

Figure 1 Arrangement of all spots on gene chip. Positive controls, negative controls, empty controls, HCV probes.

by Dr Jens Bukh of NIH (USA)[7].

Chemicals and reagents

Premix Taq, dNTP, *Eco*RI, *Not*I, *Xba*I, *Sau*3A I, pMD18-T vector, and T4 DNA ligase were obtained from Takara Corp. (Japan). Dimethyl sulfoxide (DMSO) was bought from Sangon (Shanghai, China). Plasmid Miniprep kits, 3S PCR purification kit V20 were purchased from Shen Neng Bo Cai Corp. (China). PCR primers of HCV and the primers in pMD18-T vector were synthesized by BioAsia Corp. (China). Universal primer (U) cy3-GTTTG GCTGGTGT GGATC, selective primers (similar with U but with one "nesting" base overhanging at 3'-end, UA, UT, UC, UG) and the adapter (SIP, SIR) were purchased from GIBCO Corp. (USA).

Instruments

GenePix 4000B scanner and ScanArray Lite were provided by GSI Lumonics (Billerica, USA). GS Gene Linker ultraviolet chamber was obtained from BioRad (Hercules, USA). PixSys 5500 gene chip printing machine was purchased from Cartesian Technologies (Irvine, USA). CMT-GAPSTM coated slides and Corning CMT-Hybridization™ chambers were ordered from Corning Microarray Technology (Acton, USA).

Bacterial strains

The *E. coli* strain XL-1 used in experiments was maintained in our laboratory.

Probe preparation

To isolate HCV genomes, plasmid pCV-J4L6S was digested with *Not*I and *Xba*I. The plasmid (1-2 μg) was added to a total volume of 20 μL mixture at 37 °C for 4 h. The target HCV gene was isolated and recovered with UNIQ-5 column DNA extraction kit (Sangon, China). RD-PCR was performed as previously described[8-10]. The recovered HCV cDNAs were digested with 2 μL *Sau*3A1 (5'↓ GATC3') (10 U/μL) in a total volume of 20 μL mixture at 37 °C for 3 h. The two ends of each *Sau*3AI-digested fragment were linked to an adapter that was prepared by annealing the 2 oligonucleotides containing the sequences of 5'-GATCCACACCAGCCAAACC CA (SIP) and 5' -GGTTTGGCTGGTGTG (SIR) in a ligation reaction containing 1 μL T4 DNA ligase (350 U/μL), 1 μL 10× DNA ligation buffer, 1 μL adapter (50 μmol/L), 20 pmol of digested HCV cDNA fragments of *Sau*3AI, and then UPW was added for a total of 10 μL. After 4 h of ligation at 16 °C, PCR was performed in a 9700 thermocycler with an initial denaturation at 94 °C for 5 min, followed by 35 cycles at 94 °C for 30 s, at 60 °C for 30 s, at 72 °C for 1 min, and a final extension at 72 °C for 7 min. PCR primers were designed to match the universal adapters, including the restriction site sequence, but with one "nesting" base overhanging at the 3'-end, and the reactions were divided into 10 subgroups. To check for positive PCR results, 7 μL of the PCR products was loaded onto 5% polyacrylamide (Takara, Japan) gel electrophoresis at 90 V for 5-6 h and the technique of DNA silver staining[11] was used to separate different target gene fragments.

DNA microarray printing

The final concentration of each probe was adjusted to 0.3 mg/mL with DMSO and water. The DMSO concentration was 50% (v/v). The probes were spotted onto a CMT-GAPS aminosilane-coated glass microscope slide at 25 °C and 60% relative humidity, using the ArrayIt ChipMaker2™ microspotting pins (TeleChem International, Sunnyvale, USA) and a Cartesian PixSys 5500 robot. A microarray of 12×15 spots was printed. The arrangement of all spots on the gene chip is shown in Figure 1. After printing, the slide was rehybridized and snap-dried in a plate at 80 °C for 5 min. A BioRad UV crosslinker was used to immobilize the DNAs onto the slide with 125 mJ of energy. The slide was treated with blocking solution (335 mL 1-methyl-2-pyrrolidinone, 6 g succinic anhydride and 15 mL 1 mol/L sodium borate, pH 8) and stored for later use.

Fluorescent labeling

The samples of HCV were digested at 37 °C with the restriction enzyme *Sau*3AI. T4 DNA ligase was used to link gene fragments with universal adapters (SIP, SIR). After 3 h of ligation at 16 °C, 25 μL 2×premix, 2 μL of linkage products, 2 μL of Cy3 labeled universal primer matched with the adapter, and 21 μL of water were added for a total volume of 50 μL. Reactions were performed in a GeneAmp PCR 9700 system with an initial denaturation at 94 °C for 10 min, and then subjected to 30 thermal cycles at 94 °C for 30 s, at 60 °C for 30 s, at 72 °C for 1 min, followed by a final incubation at 72 °C for 5 min. Finally, the reaction was stopped by cooling down the solution to 4 °C. After this labeling reaction, the sample DNA fragments of hundreds of base pairs were labeled with fluorescent Cy3. The labeled PCR products were further purified using a 3S PCR product purification kit V20. Of the 30 μL purified products, 5 μL was used for hybridization with the microarray probes.

Pre-hybridization and hybridization

The slide was incubated in 25% formamide, 5×SSC, 0.1% sodium dodecyl sulfate (SDS) in a jar for 45 min at 42 °C, rinsed 5 times in distilled water, immersed in isopropyl alcohol for 1 s, and then dried in the air. Five microliters of Cy3 labeled samples was mixed with 1 μL Cot-1 DNA (20 μg/μL, Life Technologies) and 6 μL 2×hybridization

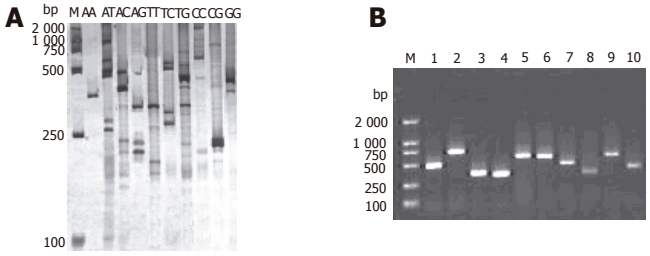

Figure 2 RD-PCR patterns of HCV genes (**A**) and 1.5% agarose gel electrophoresis of RD-PCR products from the white clones of HCV genomic fragments (**B**). M: MDL2 000 standard DNA ladder; lanes 1-10: PCR products of positive clones.

buffer (50% formamide, 10×SSC, 0.2% SDS) that was preheated at 42 °C, then heated to 95 °C for 5 min and centrifuged at 14 000 *g* for 2 min. This mixture was completely pipetted onto the pre-hybridized lambda phage DNA microarray slide and covered with a glass coverslip pretreated with Sigmacote® (Sigma, St. Louis, USA) to keep the sample from evaporating. The slide was put into a sealed hybridization box, 10 μL UPW was added to each well at the two ends of the chamber. The sealed chamber containing the DNA microarray slide was placed in a 42 °C water bath. After 4 h of incubation, the slide was taken out and washed in low-stringency washing buffer containing 1 ×SSC and 0.2% SDS at 42 °C for 5 min, in high-stringency washing buffer containing 0.1×SSC and 0.2% SDS at room temperature for 10 min, in 0.1×SSC and Milli Q water and ethanol, respectively. Finally, the air-dried slide was scanned using the ScanArray® Lite MicroArray Analysis System.

Scanning and analysis

The hybridized microarrays were scanned using GenePix 4000B scanner under the conditions of 90% laser power and 70% photo-multiplier tube (PMT). The results were analyzed using the QuantArray array analysis software. The criteria for positivity included the average fluorescence signal of Cy3 being three times as great as the value of the negative point, with a retro value of 2.7-3.3.

Probe optimization and printing

Ten HCV gene fragments were selected from the high value of the hybridized fluorescence signals to low fluorescence signals as microarray probes. The probes were spotted onto a CMT-GAPS aminosilane-coated glass microscope slide at 25 °C and 60% relative humidity, using the ArrayIt ChipMaker2™ microspotting pins and a Cartesian PixSys 5500 robot. A microarray of 12×8 spots was printed. The arrangement of all spots on the gene chip was similar to that shown in Figure 1. After printing, the slide was rehybridized and snap-dried in a plate at 80 °C for 5 min. A BioRad UV crosslinker was used to immobilize the DNAs onto the slide with 125 mJ of energy. The slide was treated with blocking solution and stored for later use.

Evaluation of microarray in sample detection

The specificity, sensitivity, accuracy, reproducibility, and linearity of this assay system were evaluated.

Identification of microarray probes and positive serum samples

After purification using the 3S PCR purification kit V20, the RD-PCR products (for probe preparation) and real-time RT-PCR products (for clinical serum sample detection) were inserted into the pMD18-T vector. The ligation mixture containing 4 μL of PCR products, 1 μL of pMD18-T vector (50 ng/μL) and 5 μL of loading buffer solution was incubated at 16 °C for 3 h, and then transferred into 100 μL of XL-1 *E. coli* competent cells treated with solutions containing Ca^{2+} ions (0.1 mol/L). To transform *E. coli*, the mixture of DNA formed in a ligation reaction was combined with a suspension of competent cells for 30 min, then heat-shocked at 42 °C for 1-2 min. The cells were then incubated in a growth medium and finally spread on an agar plate and incubated until single bacterial colonies were grown. Then the clones containing target fragments were selected and identified with the pMD18-T vector primer (primer A 5'-GTAAAACGACGGCC AGT-3', primer B 5'-CAGGAAACAGCTATGAC-3'). To check for positive PCR results, 5 μL of the PCR products was analyzed by 1.5% agarose (Takara, Japan) gel electrophoresis at 75 V for 45 min with a DNA marker DL2000 (Takara, Japan) as reference. Then the sequence was analyzed with ABI Prism™ 3730 DNA sequencer, and GenBank Blast sequence alignments were done.

RESULTS

Probe preparation

Twenty-four gene fragments of HCV were found in each subgroup by RD-PCR amplification with the expected size. The products were separated by electrophoresis on 5% polyacrylamide gel, and cDNA bands were stained with a silver solution (Figure 2A). Each subgroup produced 1-5 single cDNA bands with their length ranging from 200 to 800 bp. These bands could be used as probes for chip manufacture. Figure 2B shows the 1.5% agarose gel electrophoresis results of the clones.

Microarray design

The clinical diagnostic microarray was prepared by immobilizing the captured target genes of pathogens on a slide specifically treated. The DNA or RNA extracted from the patient's serum was labeled with fluorochrome and hybridized to the target DNA. In this study, the microarray was prepared by spotting RD-PCR products of HCV onto the surfaces of glass slides using a Cartesian 5500 MicroArrayer. Controls were immobilized at the same time. The control system was composed of empty controls which were DMSO without gene fragments, negative controls which were gene fragments of plants (rice) (B1-6) and an eukaryocyte (K562 cell) (B7-12) and a prokaryocyte (*E. coli*) (C1-6) not homologous with HCV, positive controls which were the reconstructed gene fragments.

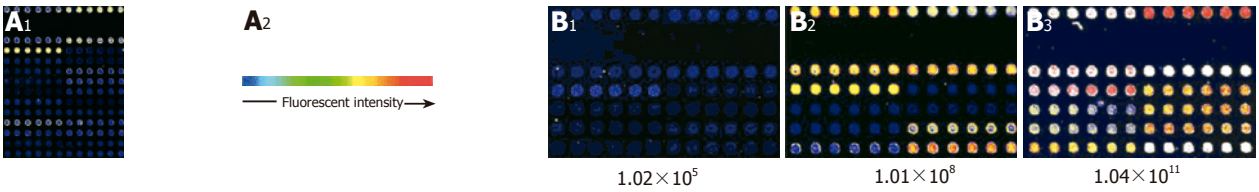

Figure 3 Scanning plots of hybridizing signals on gene chip of HCV (**A**) and modified gene chip (**B**). The samples were serially diluted (1.02×10^5, 1.01×10^8, 1.04×10^{11} copies/mL) and used in microarray analysis.

Eight of the 12×15 microarrays could be simultaneously immobilized on a glass slide.

Detection and analysis of hybridization

Based on the hybridizing signals under 90% laser energy and 70% GMT on the gene chip, the specificity and sensitivity in detecting HCV were satisfactory (Figure 3A). There was no signal on the empty control spots (printing 50% DMSO) and negative control spots (printing gene fragments of eukaryotic cells). The signal of spots hybridized to HCV positive controls and samples of HCV was strong and clear, but the analysis of variance showed that the density of signal was different in different probes (F = 8.325, P<0.001).

Optimization of microarray probes

Ten HCV gene fragments selected from the high- to low-density signals of hybridization were prepared for HCV gene chip probes. To obtain further information about the ten probes, we sequenced and analyzed the probes and found that nearly all of them had a similar length ranging 250-700 bp and a high GC content (≥40%) and T_m values (≥82 °C). The microarray was prepared by spotting the probes with Cartesian 5500 MicroArrayer. A microarray of 12×8 spots was printed. The arrangement of all spots on the gene chip is shown in Figure 1. The hybridization results indicated that the positive signal was strong compared to the hybridization signal (Figure 3B). There was no signal on the empty control spots and negative control spots.

Evaluation of microarray in sample detection

There was a strong linear relation between the concentrations of target cDNA and the fluorescence intensities obtained from microarray assay (r = 0.9819). The detection range of the microarray was 10^4-10^{11} copies/mL. The lower detection limit of HCV cDNA by microarray was 1.03×10^4 copies/mL, which was 2 log units lower than that by real-time RT-PCR. The reproducibility and accuracy of this assay system were evaluated by repeated measurement, and the within-run coefficient of validation was 6.6%, while the between-run coefficient of validation was 7.6%. Seventeen serum samples from hepatitis C patients (positive for anti-HCV, ALT≥80) were analyzed, and 15 patients (88.2%) were positive by microarray assay. Ten serum samples from healthy people were also evaluated and the results were all negative. The obtained sequences were verified and each sequenced PCR product was confirmed to be a HCV genome fragment using the basic local alignment search tool (BLAST) and the GenBank database.

DISCUSSION

HCV is the most important cause of transfusion-associated and community-acquired non-A, non-B hepatitis. Chronically infected individuals have a relatively high risk of developing chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma. No effective vaccine therapy is available at present for HCV. Detection of HCV is essential for the correct diagnosis of HCV infection. Antibody-based methods have been considered as a practical way to detect infection of HCV. However, these methods cannot diagnose patients with hypoimmunity. Nucleic acid hybridization may have an excellent specificity, but its sensitivity is not satisfactory. In the protocol of PCR, cross contamination and false negative and positive incidents often occur. DNA microarray offers a solution to these problems and has the potential for the diagnosis of HCV infection. Compared to traditional diagnostic techniques, it has a number of advantages such as integration, micromation, and automatization[12,13]. The use of multiple independent gene fragments with a suitable size (ranging from 200 to 800 bp) for the probes to detect the same molecular targets can greatly enhance the signal-to-noise ratio and reduce the false-positive rate[14]. The gene chip also offers a dependable basis for the diagnosis and treatment of hepatotropic viral infections[15-17].

Probe preparation is a key step for microarray. One of the major difficulties in the development of microarray is to collect or prepare sufficient probes[18]. A few methods can be used to prepare microarray probes, including PCR amplification of DNA fragments with a molecular clone[19], artificial synthesis of oligonucleotide arrays by a DNA synthesizing machine[20] and light direction of *in situ* synthesis[21]. We prefer the first method because of its rapidity, simplicity, and effectiveness. However, conventional PCR is conducted with specific primers. RD-PCR provides an efficient and a simple way to obtain probes, since cDNA gene fragments digested by 4-cutter restriction endonuclease can be ligated with adapters at the same restriction site. In the present study, a PCR universal primer (U) was designed to match the sequence of both the adapters and the restriction site, but there were too many fragments amplified with universal primers (U). Using the selective primers with one or more

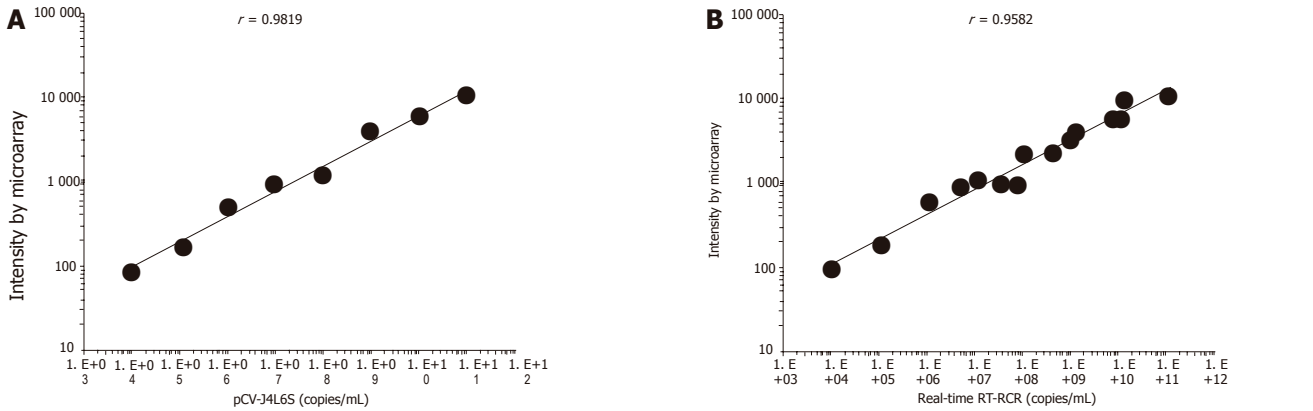

Figure 4 Fluorescence intensity from cDNA microarray analysis as a function of serial dilution from 10^4 to 10^{11} copies of plasmid pCV-J4L6S (r = 0.9819, ^bP<0.01)/mL (**A**) and comparison of the HCV RNA levels in 15 serum samples determined by cDNA microarray analysis and RT-PCR (Taqman) assays (**B**).

"nesting" bases at the 3'-end of universal primer, 10 or more subgroups of PCR reaction were performed for various single selective primers or primer combination, in which gene fragments were widely distributed in different groups and their isolation was achieved. We separated the differential genes by polyacrylamide gel electrophoresis and silver staining. Single bands cut out from polyacrylamide gel were isolated. Using the single bands as PCR template, we performed the third-round PCR and a total of 24 different cDNA fragments ranging from 200 to 800 bp were obtained and sequenced, which were the specific gene fragments of HCV. These fragments could be further used as probes in microarray preparation, suggesting that RD-PCR technique is of great value in obtaining a large number of size-comparable gene probes, thus providing a swift protocol in generating probes for the preparation of microarrays.

In general, the density of hybridization signal is correlative to the length of probes, GC contents and T_m value under the same experimental conditions. A further sequence analysis of the 10 probes, GC contents, and T_m value showed that these probes were 250-700 bp in length, and had a high GC content (≥40%) and T_m values (≥82 °C).The probes were widely distributed in the full HCV genome. The results of hybridization and sequence analysis showed that the specificity, sensitivity, accuracy, reproducibility, and linearity in detecting HCV RNA were satisfactory. There was a linear correlation between the concentrations of pCV-J4L6S target cDNA and the signal intensities (correlation coefficient = 0.9819). The detection range of the microarray was 10^4-10^{11} copies/mL. The lower detection limit of HCV RNA was 1.03×10^4 copies/mL, which was 2 log higher than that by RT-PCR (Taqman method). But the assay was as sensitive as the conventional RT-PCR in HCV detection. The chip we developed is cost-effective, and the procedure required to prepare the chip is straightforward and convenient. When results are verified by molecular hybridization, PCR cross contamination can be overcome. By incorporating negative and positive controls, the detection results can be reduced greatly using analytic software[22]. Seventeen serum samples from hepatitis C patients (positive for anti-HCV, ALT≥80) were analyzed, and fifteen patients (88.2%) were positive by microarray assay. Within the detection range of 10^4-10^{11} copies/mL, there was a good correlation between the two assay systems (n = 15, r = 0.9582) (Figure 4B). Ten serum samples from healthy people were also detected by this assay and no specific signal intensities were obtained from the samples. Finally, the reproducibility and accuracy of this assay system were evaluated by repeated measurement, and the within-run coefficient of validation was 6.6%, while the between-run coefficient of validation was 7.6%. However, further work should be done. It took about 10 h to complete our assay. Modifying the DNA extraction procedure could reduce this time. The sensitivity of the assay could be enhanced by increasing the amount of captured cDNA on the slide, or by pretreatment of the sample RNA. A large number of serum samples should be tested to verify the reliability of microarray assay in the detection of HCV.

In conclusion, cDNA microarray technology can be applied to other pathogens and is a useful diagnostic method for HCV infection.

Abstract

AIM: To observe the effects of plasma from patients with severe viral hepatitis (SVHP) on the growth and metabolism of porcine hepatocytes and the clinical efficiency of bioartificial liver device.

METHODS: Hepatocytes were isolated from male porcines by collagenase perfusion. The synthesis of DNA and total protein, leakages of AST and LDH, changes in glutathione (GSH), catalase and morphology of porcine hepatocytes exposed to SVHP were investigated to indicate the effect of plasma from patients with severe hepatitis on the growth, injury, detoxification, and morphology of porcine hepatocytes.

RESULTS: The synthesis of DNA and protein was inhibited in the medium containing 100% SVHP compared to the controls. The leakages of LDH and AST increased in porcine hepatocytes following exposure to 100% SVHP for 5 h. The difference between 100% SVHP and 10% newborn calf serum (NCS) was significant in t-test (LDH: t = 24.552, P = 0.001; AST: t = 4.169, P = 0.014). After exposure to SVHP for 24 h, alterations in GSH status were significant (F = 2.746, P<0.05) between porcine hepatocytes in 100% SVHP and 10% NCS, but no alteration occurred in the culture medium after 48 h (F = 4.378, P<0.05). A similar profile was observed in catalase activity. Many round vacuoles were observed in porcine hepatocytes cultured in SVHP. The membranes of these cells became indistinct and almost all the cells died on d 5.

CONCLUSION: Plasma from patients with severe hepatitis inhibits the growth, injures membrane, disturbs GSH homeostasis and induces morphological changes of porcine hepatocytes. It is suggested that SVHP should be pretreated to reduce the toxin load and improve the performance of porcine hepatocytes in extracorporeal liver-support devices.

INTRODUCTION

A bioartificial liver (BAL) support system, composed of artificial materials and biological components such as hepatocytes, acts as a bridge to provide patients with prolonged time of survival until a donor organ becomes available for the transplantation or their own liver can regenerate[1]. The performance of a BAL depends on the viability and functional activities of hepatocytes in the system. Many laboratories are currently investigating the factors influencing the viability and functional activities of hepatocytes. It has been demonstrated that serum or plasma from liver failure patients interferes extensively with cellular metabolism[2-6]. When the patient's blood is detoxified by the BAL device, there is contact between the patient's plasma and cells in the device. It is thus important to assess the direct interactions between plasma and hepatocytes.

Porcine and human hepatocytes have similar physiological characteristics and metabolic functions and are considered to be the best candidate for use in a BAL[7-11]. They have been applied in clinical trials based on their easy source and excellent functions for the synthesis of protein, glucose, and urea as well as lower lactate dehydrogenase release. *In vitro*, porcine hepatocytes in the bioreactor can clear most conjugated bile acid species from pooled patient plasma[6]. Furthermore, it can be immobilized on a "hepatocyte/gold colloid" interface at which hepatocytes proliferate quickly[12].

In China, HBV infection rate has been estimated to be 10% or higher, and severe hepatitis caused by HBV is common[13,14]. BAL also provides temporary support for these patients when acute or chronic severe viral hepatitis (SVHP) develops. However, there are few reports on

how SVHP interferes with the growth and function of hepatocytes in primary culture. Therefore, we investigated the direct interactions between SVHP and porcine hepatocytes.

MATERIALS AND METHODS

Materials

Cell culture reagents, including RPMI-1640, sodium pyruvate, and L-glutamine were purchased from GIBCO, Life Technologies, Ltd. (Paisley, Scotland, UK). Type IV collagenase was a product of Sigma Chemical Co, Ltd (St. Louis, MO, USA). Reagents for the measurement of reduced glutathione (GSH), catalase (CAT) and total protein (TP) were from Nanjing Biological Technology Co, Ltd. Methyl thiazolyl tetrazolium (MTT) was from Fluka Chemic AG (Switzerland). TriPure isolation reagent was from Roche (Switzerland). Plasticware was from Nunc (Denmark). All solutions were prepared with twice-distilled water.

Hepatocyte preparation

Healthy Chinese experimental miniature male pigs aged 1-4 d were provided by Experimental Animal Center of Third Military Medical University. The research protocol was in compliance with Chinese guidelines for the humane care of experimental animals. Porcine hepatocytes were isolated by modified two-step *in situ* collagenase perfusion method[15,16]. The viability of freshly isolated suspensions determined by trypan blue exclusion was 85-95%. Porcine hepatocytes were cultured at 37 °C for 24 h in RPMI-1640 medium supplemented with 10% (vol/vol) newborn calf serum (NCS) at a density of 2×10^5 cells/mL in a 50 mL/L CO_2 incubator. The cultures were washed twice in warm phosphate-buffered saline (PBS) and cultured in a medium containing 10% (vol/vol) NCS, normal plasma (NP) anti-coagulated by heparin, and SVHP. Porcine hepatocytes were prepared for assay as described below.

Plasma from patients with severe virus hepatitis

Plasma was obtained from six patients with SVHP (3 females, 3 males, aged 34-60 years) at the onset of plasmapheresis and stored at -80 °C until use. Diagnosis of these patients was in accordance with the criteria of severe hepatitis described in the Viral Hepatitis Protection and Cure Guideline established by the Chinese Infection and Hepatology Association. In these six patients, total bilirubin (TB) averaged 611.8 μmol/L, prothrombin time (PT) averaged 32 s, total bile acids (TBA) averaged 309.8 μmol/L and PTa averaged 29%. Hepatitis B surface antigen (HBsAg) was positive and HBV-DNA was greater than 10^5 copies/mL in all the 6 patients. All patients suffered from hepatic encephalopathy, grade II in two patients, grade III in three patients, and grade IV in one patient. Normal serum was obtained from normal individuals.

Cell viability determination

Cells were seeded in 24-well plates in 500 μL medium. The viability was assessed by tetrazolium bromide assay (MTT) on d 0-5 after exposure to the culture medium containing 10% (vol/vol) NCS, 100% NP, and 100% SVHP.

DNA synthesis

After being cultured in six-well plates for 24 h, the media were discarded, and DNA was isolated as the procedures of TriPure isolation reagent description. DNA content was determined using a spectrophotometer (SmartSpec 3000, BioRad, USA).

Protein content

After being incubated for 24 and 48 h, monolayer cells were washed and dissolved. Total cellular protein was digested in 0.5 mol/L NaOH and measured by micromodification as previously described[17].

Leakage of LDH and AST

Porcine hepatocytes were exposed to 100% SVHP and 10% (vol/vol) NCS in RPMI-1640 for 5 h. The media were washed thrice with PBS and replaced with RPMI-1640 without plasma and serum. After 24 h of culture, the leakage of LDH and AST from hepatocytes into the supernatant was measured using an automated chemical analyzer (Model 7020 Hitachi Co., Tokyo, Japan)[18].

Oxidative status

After being incubated for 24 and 48 h, the medium containing 10% NCS, 100% NP, 100% SVHP was removed, the wells were washed with PBS, and GSH was added into 0.2 mL 10% (w/v) trichloroacetic acid for 10 min at room temperature. Samples were frozen at -20 °C until measurement of GSH by fluorimetry. CAT activity was measured.

Morphology

Cultured hepatocytes were observed daily under phase contrast microscope (IX70, Olympus, Tokyo, Japan), and the morphological changes were compared.

Statistical analysis

Data were expressed as mean±SD. Statistical analysis was carried out by analysis of variance and *t*-test. $P<0.05$ was considered statistically significant.

RESULTS

Viability of porcine hepatocytes cultured in SVHP

The viability of porcine hepatocytes cultured in 100% SVHP was significantly lower than that cultured in the medium containing 10% NCS ($F = 6.328$, $P<0.01$). The viability of porcine hepatocytes in 100% NP group was not higher than that in 10% NCS group. The viability of porcine hepatocytes in all the groups tended to decrease from the third day (Figure 1).

DNA content

After being cultured for 24 h, the DNA level in three

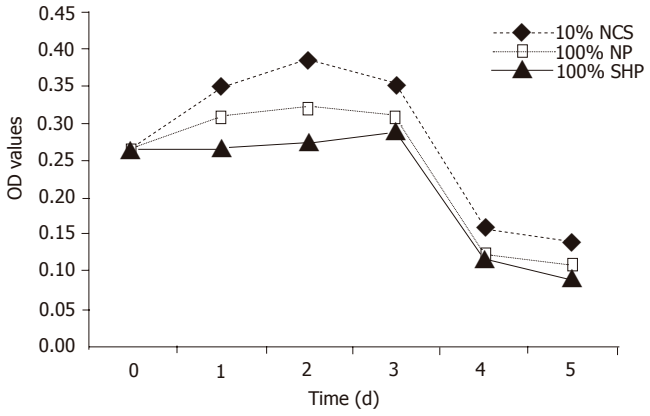

Figure 1 Viability of porcine hepatocytes cultured in ♦ medium containing 10% NCS, □ 100% NP, ▲ 100% SVHP. Results were expressed as mean±SD for six samples.

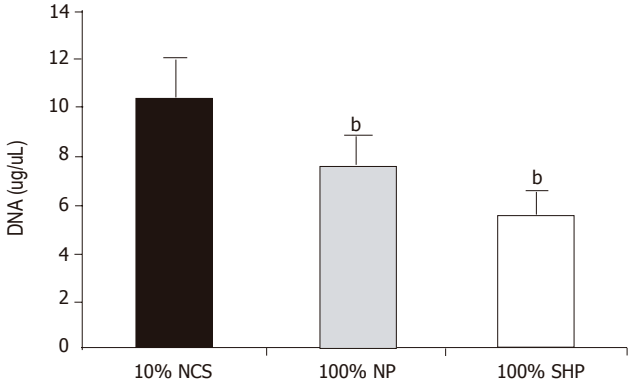

Figure 2 DNA content in porcine hepatocytes grown in three different media. DNA synthesis in 100% SVHP and normal plasma was compared to that in the medium containing 10% NCS (^bP<0.01 *vs* 10% NCS group, by ANOVA followed by multiple comparisons). Results were expressed as mean±SD for six samples Black oblique line: 10% NCS, black small point: 100% NP; black small square: 100% SVHP.

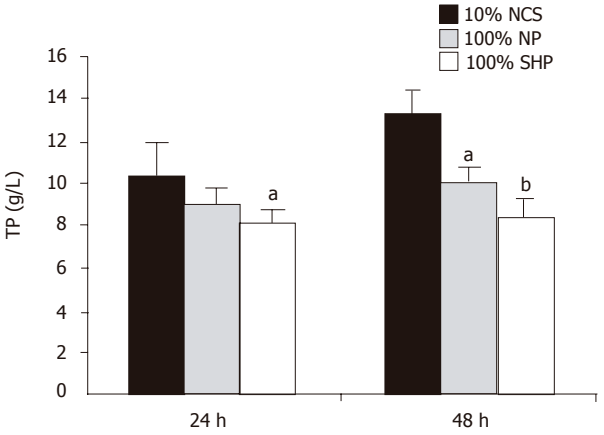

Figure 3 TP content in porcine hepatocytes grown in three different media. TP synthesis in 100% SVHP and NP was compared to that in the medium containing 10% NCS (^aP<0.05, ^bP<0.01 *vs* 10% NCS group, by two-way variance analysis). Results were expressed as mean±SD for six samples. Black bar: 10% NCS; gray bar: 100% NP; white bar: 100% SVHP.

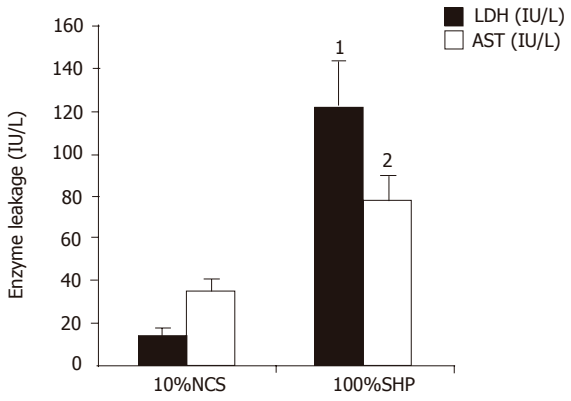

Figure 4 Leakage of LDH and AST after 5 h of culture (black bar: LDH; white bar: AST). The levels of LDH and AST in 100% SVHP were significantly higher than those in the medium containing 10% NCS. Results were expressed as mean±SD (1: t = 24.552, P = 0.001 and 2: t = 4.169, P = 0.014, compared to the10% NCS group, n = 6).

different media was significantly different (F = 20.107, P<0.01). The level was the lowest in 100% SVHP and lower in 100% NP than in 10% NCS. The inhibitory effect of porcine hepatocytes on DNA synthesis is shown in Figure 2.

Total protein synthesis

During the course of culture, the amount of TP in three different media was significantly different (F = 9.281, P<0.01, Figure 3). Multiple comparison showed that the TP level in 100% SVHP was lower than that in 10% NCS (P<0.01). The TP level in 100% NP was also significantly lower than that in 10% NCS (P<0.05).

Leakage of LDH and AST

LDH and AST elevations were observed in 100% SVHP group after 5 h of culture. The LDH level in 100% SVHP group was significantly higher than that in 10% NCS group (t = 24.552, P = 0.001). The AST level in 100% SVHP group was also significantly higher than that in 10% NCS group (t = 4.169, P = 0.014, Figure 4), indicating that hepatocytes cultured in plasma from patients with SVHP had damage in the cell membrane.

GSH content and CAT activity

GSH concentration in porcine hepatocytes decreased in SVHP and NP as compared to that in the culture medium containing 10% NCS (Figure 5A). A significant decrease in GSH content was observed in SVHP compared to that in the medium containing 10% NCS within 24 h (F = 2.746, P<0.05). After 48 h the GSH level declined slightly. There was no difference between 100% SVHP and 10% NCS (F = 4.378, P>0.05). A similar profile was observed in CAT levels following incubation with SVHP and NP (Figure 5B). The only difference between GSH and CAT was that the CAT content was dramatically decreased after being cultured for 48 h.

Morphological study

The dramatic change of porcine hepatocyte morphology

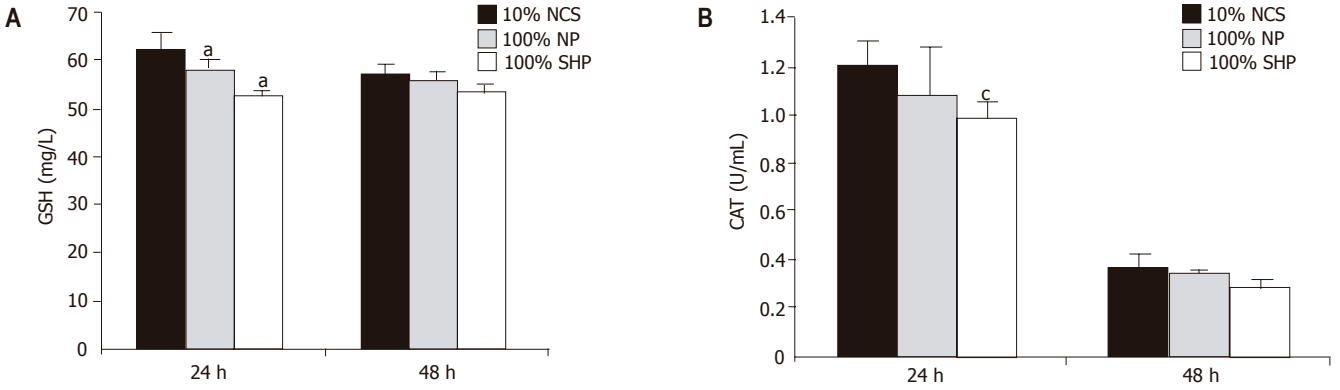

Figure 5 GSH content in porcine hepatocytes grown in three different cultures (**A**) ($^{a}P<0.05$ *vs* 10% NCS, by two-way variance analysis, compared to 10% NCS) and CAT activity of porcine hepatocytes grown in the three different cultures (**B**) ($^{c}P<0.05$ *vs* 10% NCS by two-way variance analysis, compared to 10% NCS). Black bar: 10% NCS, gray bar: 100% NP; white bar: 100% SVHP.

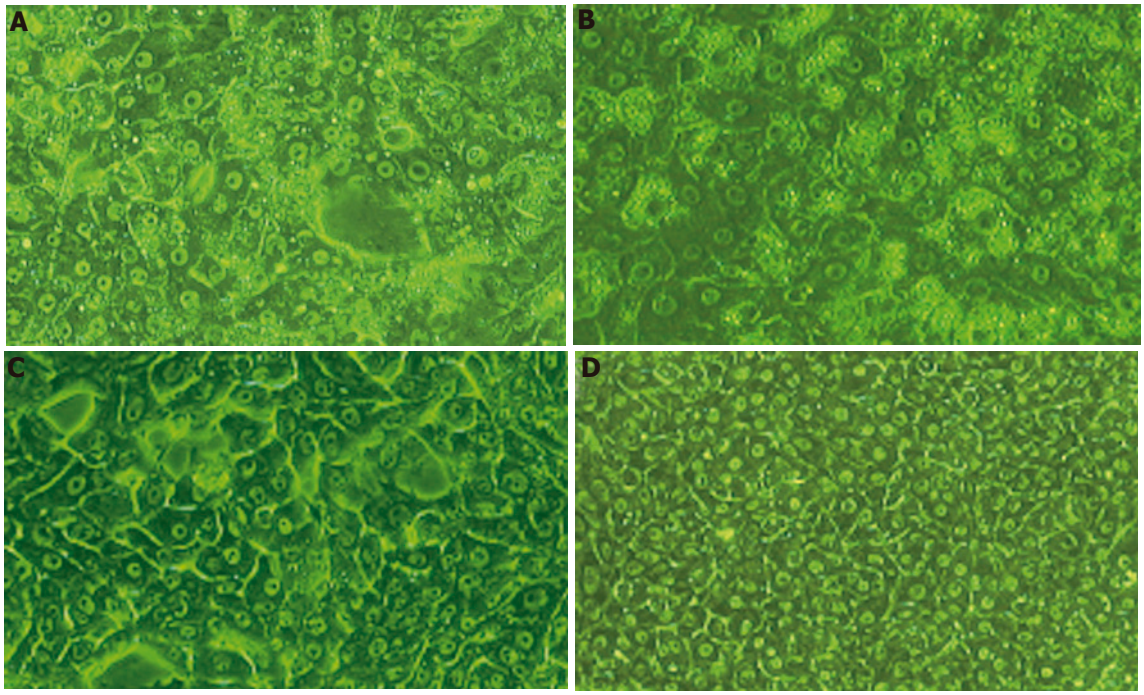

Figure 6 Morphological changes of porcine hepatocytes cultured in 100% SVHP **(A** and **B**) and media containing 10% NCS (**C** and **D**). After 24 h of culture, hepatocytes in the100% SVHP group were detached from the dishes, vacuolization in the cytoplasm and deformities were more commonly observed. The membranes of cells became indistinct (**A**); after 48 h of culture, vacuoles were more and mainly concentrated around cell nuclei (**B**); after 24 h of culture, hepatocytes in the 10% NCS group constituted confluent monolayers with an intact morphology throughout the culture (**C**); after 48 h of culture, hepatocytes in the 10% NCS group constituted confluent monolayers with an intact morphology throughout the culture (**D**).

after 24 h exposure to 100% SVHP was observed under phase contrast microscope. As shown in Figures 6A-D, most of the cells became detached and deformed. Vacuolization in cytoplasm and necrosis were more commonly observed. Membranes of the cells became indistinct. These morphological changes became marked after 48 h of culture. Vacuoles were mainly concentrated around cell nuclei and detached from their dishes. During the 48-h culture, hepatocytes in groups of 100% NP and 10% NCS spread and formed a clear confluent monolayer. Detachment, deformity, and vacuolization were not observed in the cytoplasm. There was no obvious difference between the two groups. After 5 d of culture, necrosis was observed in the two groups and almost all hepatocytes were dead in 100% SVHP group.

DISCUSSION

Experimental studies[3-5] have demonstrated that plasma from patients with fulminant hepatic failure (FHF) or liver failure (LF) can inhibit the growth of hepatocytes and synthesis of macromolecules in hepatocytes. McCloskey *et al*.[5] found that plasma from patients with liver failure could diminish DNA and protein synthesis.

Shi *et al*.[4] reported that serum from patients with FHF inhibits the growth rate and synthesis of DNA, RNA, and protein. In our study, the plasma was from patients with SVHP. Inhibition of growth and macromolecule synthesis, reduction of viability of porcine hepatocytes were demonstrated. The inhibition mechanism might be related to endogenic materials such as bile acids, growth factors, and cytokines in SVHP. There are more bile acids, hepatic growth factor (HGF) and tumor growth factor-β (TGF-β)[19] in SVHP. Accumulation of intracellular bile acids causes damage to intracellular organelles, such as mitochondria[20]. Bile acids in nuclei cause DNA injury by changing chromatin structure or by activating nuclear nuclease, thus resulting in conversion into a metabolite that could directly damage DNA[21,22]. HGF does not always accelerate the growth of hepatocytes. Sometimes there are converse results[23]. It was reported that HGF inhibits cell growth at a cell cycle phase and growth of cells is impaired with the increasing HGF concentration, while elevated serum TGF may lead to an increase in p21, a cyclin-dependent kinase inhibitor that can inhibit the activation of G1-associated cyclins such as Cdk2[24,25]. In this study, the viability of porcine hepatocytes cultured in 100% NP was decreased compared to that in 10% NCS, which may result from cytokine- and antibody-mediated damage.

Membrane damage and enzyme leakage have been detected in the culture medium[5,26,27]. McCloskey *et al*.[5] reported that after HHY41 hepatocytes are exposed to plasma from patients with LF containing $Na_2{}^{51}CrO_4$ for 16 h, the leakage of ^{51}Cr is about 20 times higher than that in controls. However, Uchino *et al*.[28] demonstrated that the function of pig hepatocytes does not deteriorate when they are exposed to the serum from the patients with FHF[28]. In this study, LDH and AST leakage from porcine hepatocytes cultured in SVHP was significantly higher than that from porcine hepatocytes cultured in 10% NCS. Morphological changes of hepatocytes also suggested severe cell membrane damage, indicating that SVHP can lead to hepatocellular membrane impairment. Endogenic toxins may originate either from cellular necrosis debris and breakdown products released into the blood stream or from accumulation of an agent that is normally eliminated by metabolism in hepatocytes. Bile acids play an important role in the toxicities and can form micelles with cholesterol and phospholipids on the surface of hepatocyte membranes, which produce apparent hepatocellular membrane injury[22]. Virus-mediated damage involves immune-mediated and direct viral cytopathic effects.

The highest cytotoxicity values have been found in the plasma from patients with FHF, indicating the utmost importance of detoxification by BAL. Intracellular GSH content often reflects the fate of potentially harmful substances, and examination of GSH status may provide information on the mechanisms of toxicity. Previous experimental studies revealed that exposure of hepatocytes to the serum from patient with FHF results in increase or decrease in GSH content. The changes are related to plasma concentration, culture time, hepatocyte type[4,5]. Previous studies have shown that Hep G2 cells respond to abnormal culture conditions and toxic concentrations of bile. GSH of HHY41 in plasma from patients with LF is decreased[5]. In our study, the pronounced decrease in GSH levels was observed following incubation with SVHP. As a main member of anti-oxidizing system, GSH plays an important role in relieving the tissue depression due to electrophilic reactive toxins or oxidative stress because it can react directly with reactive oxygen free-radicals and conjugate bile acids[29].These factors lead to a depletion of cellular GSH store. The activity of CAT changes as GSH, which requires further investigation.

Abstract

AIM: To elucidate the role of the peroxisome proliferator-activated receptor α (PPARα) and its target gene carnitine palmitoyl acyl-CoA transferase 1A (CPT1A) in the pathogenesis of hepatitis C virus (HCV) infection.

METHODS: Liver samples were collected from the patients with chronic HCV infection and controls. HepG2 cells were transfected with vector pEF352neo carrying. Two independent clones (clone N3 and N4) stably expressing HCV core protein were analyzed. Total RNA was extracted from cells and liver tissues. PPARα and CPT1A mRNAs were quantified by real-time polymerase chain reaction (PCR) using SYBR Green Master. Total extracted proteins were separated by polyacrylamide gel electrophoresis, and electroblotted. Membranes were incubated with the anti-PPARα antibody, then with a swine anti-rabbit IgG conjugated to horseradish peroxidase for PPARα. Protein bands were revealed by an enhanced chemiluminescence reaction for PPARα. For immunohistochemical staining of PPARα, sections were incubated with the primary goat polyclonal antibody directed against PPARα at room temperature.

RESULTS: Real-time PCR indicated that the PPARα level and expression level of CPT1A gene in hepatitis C patients lowered significantly as compared with the controls (1.8±2.8 *vs* 13±3.4, $P = 0.0002$; 1.1±1.5 *vs* 7.4±1, $P = 0.004$). Western blot results showed that the level of PPARα protein in the livers of hepatitis C patients was lower than that in controls (2.3±0.3 *vs* 3.6±0.2, $P = 0.009$). The immunohistochemical staining results in chronic hepatitis C patients indicated a decrease in PPARα staining in hepatocytes compared with those in the control livers. The *in vitro* studies found that in the N3 and N4 colon stably expressing HCV core protein, the PPARα mRNA levels were significantly lower than that in the controls.

CONCLUSION: The impaired intrahepatic PPARα expression is associated with the pathogenic mechanism in hepatic injury during chronic HCV infection. HCV infection reduced the expression of PPARα and CPT1A at the level of not only mRNAs but also proteins. PPARα plays an important role in the pathogenesis of chronic HCV infection, but the impaired function of this nuclear receptor in HCV infection needs further studies.

Key words: Hepatitis C virus; Infection; PPARα; CPT1A

INTRODUCTION

Hepatitis C virus (HCV) infection is a major health care problem around the world[1]. It is estimated that there are about 170 million chronic carriers worldwide with four million in the USA[2-4] and five million in the western Europe[5-6]. HCV infection accounts for 20% of cases of acute hepatitis, 70% of chronic hepatitis, 40% of end-stage cirrhosis, 60% of cases of hepatocellular carcinoma, and 30% of liver transplantation[7-10]. Liver lesions are thought to be mainly related to immune-mediated mechanisms[5] but the exact mechanisms during HCV infection are still unclear[8,9,11]. However, the HCV core protein is a major component of viral nucleocapsid and it is a multifunctional protein that affects transcription and cell growth[12]. HCV core protein plays an important role in the HCV pathogenesis[13].

The ability of peroxisome proliferators to activate a receptor in the steroid receptor superfamily was first discovered in 1990[14], and the cognate protein was designated as peroxisome proliferator-activated receptors (PPARs). The PPARs are soluble transcription factors that are activated by a diverse class of lipophilic compounds[15].

With the activation of PPAR, a concomitant induction of a number of genes that code for peroxisomal fatty acid metabolizing enzymes was observed in mouse liver. There are three PPAR subtypes: PPARα (NR1C1), PPARβ (NR1C2), and PPARγ (NR1C3); and each subtype is capable of binding to DNA after heterodimerizing with RXR (NR2B1). PPARα is highly expressed in the liver, kidney, and cardiac smooth muscles. Many of the genes regulated by PPARα are involved in fatty acid metabolism[16]. PPARα could influence fatty acid import into hepatocyte mitochondria by up-regulating the expression of the liver-predominant mitochondrial carnitine palmtoylacyl-CoA transferase 1 (CPT1) gene[17].

Three CPT1 isoforms with various tissue distributions and encoded by distinct genes have been identified: CPT1A or L-CPT1 (liver isoform), CPT1B or M-CPT1 (muscle isoform), and CPT1C (brain isoform). CPT1A is expressed in the liver, the neonatal heart, and a number of other tissues, and has been the most investigated member of the acyltransferase family. It is anchored in the mitochondrial outer membrane by two transmembrane segments (TM1 and TM2), its N terminus (residues 1-47) and C-terminal catalytic domain (residues 123-773) being located on the cytosolic face of mitochondria. The N-terminal domain (1-147 residues) was shown to be essential for mitochondrial import and for the maintenance of a folded active and malonyl-CoA-sensitive conformation[18].

Until now, the role of PPARα and its target gene CPT1A in liver diseases is still limited to animal studies. In order to elucidate the mechanism of PPARα during the pathogenesis of HCV infection, PPARα and CPT1A expression levels were studied *ex vivo* and *in vitro,* respectively in this study.

MATERIALS AND METHODS

Subjects and liver samples processing

Chronic hepatitis C infection was defined by increased serum alanine transaminase activity (>35 IU/L), positive serum HCV replication determined by polymerase chain reaction (PCR; Amplicor Monitor v2.0; Roche, Indianapolis, IN, USA), and histological hepatic injury quantified by the METAVIR score evaluating the intensity of fibrosis (F1-F4) and necroinflammatory activity (A1-A3)[19]. The subjects were excluded if their body mass index was greater than 30 or if they suffered from diabetes or dyslipidemia.

Patient liver samples were collected from 46 patients with chronic HCV infection (41 transcutaneous needle liver biopsy samples from chronic hepatitis C patients and 5 surgical liver samples from HCV-related cirrhotic patients when they underwent transplantation). Non-HCV-infected liver tissues as controls were collected from 40 patients (29 normal tissue samples from patients who underwent surgery because of hepatic carcinoma, 5 biopsy samples from patients with alcoholic cirrhosis, and 6 samples from patients with alcoholic hepatitis). Both patients and controls did not receive any therapy (antiviral therapy, hepatotoxic drugs, corticosteroids, or immunosuppressive drugs) before or during liver sample collection.

The liver samples collected from hepatitis C patients or controls were divided into two parts: one part was fixed in 4% paraformaldehyde/phosphate-buffered saline and embedded in paraffin wax, and routinely processed for pathological analysis and for immunostaining[20]. Specimen slides were incubated for 48 h at 37 °C and then deparaffinized by dimethylbenzene and rehydrated by graded alcohol series, then stained with H&E, safran, and Masson's trichrome. The other part was frozen immediately in the liquid nitrogen and stored at -80 °C for mRNA and protein analysis.

HepG2 cell culture and transfection

Human hepatocellular carcinoma cell line HepG2 was used for this study. Cells were maintained in Dulbecco's modified Eagle's medium (Sigma-Aldrich, St. Louis, MO, USA) supplemented with 10% heat-inactivated fetal bovine serum (Eurobio, Les Ulis, France) in a humidified atmosphere of 50 mL/L CO_2 in air at 37 °C.

In order to analyze the effect of the HCV core protein on PPARα expression, HepG2 cells were transfected with vector pEF352neo carrying, under the control of the elongation factor-1α promoter, an HCV complementary DNA including 1b HCV sequences from core to NS3 region as previously described[21]. Two independent clones (clone N3 and N4) stably expressing HCV core protein were analyzed. The clone transfected with the empty vector acted as negative control. Cells were resuspended in lysis buffer with 10% β-mercaptoethanol for RNA isolation[22]. All studies were performed in triplicate samples for three separate experiments.

RNA extraction and the real-time PCR analysis

Total RNA was extracted from cells and liver tissues by RNeasy kit (Macherey Nagel, Hoerdt, France) and TRIzol reagent (Life Technologies, Cergy Pontoise, France) following the protocols provided by the manufacturers with some modification[20]. RNA quantification was performed using spectrophotometry. After treatment at 37 °C for 30 min with 20-50 U of RNase-free DNase I (Roche Diagnostics Corporation), oligo-dT primers (Roche Diagnostics Corporation) were used to synthesize single-stranded complementary DNA. PPARα and CPT1A mRNAs were quantified using SYBR Green Master Mix (Applera, Courtaboeuf, France) with specific primers in a GeneAmp ABI prism 7000 (Applera). The primers used were as follows: PPARα anti-sense 5'-CCA CCA TCG CGA CCA GAT-3', PPARα sense 5'-GAC GTG CTT CCT GCT TCA TAG A-3'; CPT1A anti-sense 5'-TGT GCT GGA TGG TGT CTG TCT C-3', CPT1A sense 5' -CGT CTT TTG GGA TCC ACG ATT-3'; TBP anti-sense 5'-TTT TCT TGC TGC CAG TCT GGA C-3', TBP sense 5'-CAC GAA CCA CGG CAC TGA TT-3'. Calibrated and nontemplate controls were included in each assay. Each sample was run in triplicate. SYBR Green dye intensity was analyzed using the ABI prism 7000 SDS software (Applera). All results were normalized to the

TATA box-binding protein, an unaffected housekeeping gene[23]. All quantifications were performed in triplicate samples for three separate experiments.

Western blotting analysis

Protein preparation and immunoblotting were performed in liver specimens as described before. Total protein extracts were obtained by homogenization of tissues in an extraction buffer containing phosphate-buffered saline with 1% tergitol NP-40, 0.5% sodium desoxycholate, 0.1% sodium dodecyl sulfate, and a classic protease inhibitor cocktail. One hundred micrograms of total proteins were then separated by 10% polyacrylamide gel electrophoresis and electroblotted. Blots were blocked for 1 h at 4 °C with 5% milk Tris-Tween buffered saline 1×, and were incubated overnight at 1:1 000 with the anti-PPARα (Geneka Biotechnology Inc., Montreal, Canada). Membranes were incubated for 1 h with a swine anti-rabbit IgG conjugated to horseradish peroxidase for PPARα (dilution 1:1 000, Dako Laboratories, Trappes, France). Protein bands were revealed by an enhanced chemiluminescence reaction for PPARα. The results were expressed as units of optical density per quantity of total protein[20,24,25].

Immunohistochemical staining in liver tissues

Serial sections of paraffin embedded liver tissues were cut at 4 μm by Leica RM2145 rotary microtome (Leica Instruments GmbH, Germany). Glass slides were treated with poly-L-lysine in advance. Specimen slides were incubated for 48 h at 37 °C and then deparaffinized by xylene and rehydrated by graded alcohol series. An immunohistochemical staining was performed[20,24,25] for the detection of PPARγ expression. Liver sections were incubated in 3% H_2O_2 in methanol to deactivate endogenous peroxidase activity for 20 min. Then slides were incubated with 0.05% Saponin (ICN Biomedicals, OH, USA) for 30 min at room temperature to permeablize the tissues. After being washed, sections were pre-treated with Avidin D, followed by Biotin (Vector Laboratories) to block non-specific binding of Biotin/Avidin system reagents. Non-specific antibody binding was blocked with 1.5% goat serum in PBS for 15 min. Slides were incubated with 5% milk and 0.1% bovine serum albumin (BSA) in PBS for 15 min. Sections were incubated with the primary goat polyclonal antibody directed against PPARγ at room temperature (dilution 1:50, TEBU International) for 30 min, and were processed for peroxidase immunostaining using the Dako Laboratories system following the manufacturer's instructions. Sections were incubated for 30 min at room temperature in rabbit anti-goat IgG (dilution 1:100, Dako Laboratories), and then under the same conditions in an avidin-biotinylated peroxidase complex (Dako, Denmark) that was prepared at least 30 min before use. Staining was developed with 3,3'-diaminobenzidine in chromogen solution for 1 min, and the reaction was stopped in distilled water. Sections were counterstained with hematoxylin. As a negative control experiment, the primary antibody was omitted and replaced with a non-specific antibody[20].

Statistical analysis

All results were expressed as mean±SD. Comparisons were analyzed by the nonparametric Mann-Whitney *U* test. Differences were considered statistically significant, if the *P* value was less than 0.05.

RESULTS

Patients' ALT, HCV load, histological scores, and genotype

In this study, the body weights of the chronic hepatitis C patients were within the normal range and homogeneous. Before and during the study, they did not receive any treatment which could have influenced the results. Their mean serum alanine transaminase value was 119±27 IU/L, mean peripheral blood HCV RNA level was $747\pm267\times10^3$ IU/mL, and their histological lesions were consistent at the time of liver biopsy examination. Half of the patients had fibrosis scored F1, 24% F2, and 26% F3-F4. Seventy-two percent of the cases had an inflammatory activity scored A1 and 28% A2. Fifty-two percent of patients were genotype 1, 31% were genotype 3, 12% were genotype 2, and 5% were genotype 4.

HCV infection reduced the expression of PPARα and CPT1A

The real-time PCR analysis indicated that the housekeeping gene TATA box-binding protein concentrations were similar in patients and controls. But the level of PPARα in hepatitis C patient livers lowered by 86% compared with controls (1.8±2.8 *vs* 13±3.4, $P = 0.0002$) (Figure 1A). And the reduction in CPT1A mRNA was similar to the reduction in PPARα in the livers of patients in the study (Figure 1B). Compared with the 40 controls, the expression level of the CPT1A gene in the 46 hepatitis C patients lowered by more than 80% (1.1±1.5 *vs* 7.4±1, $P = 0.004$).

In a similar pattern, the Western blot also proved the results of real-time PCR analysis. Because of the limited amount of the liver biopsy samples, the Western blot analysis of PPARα was performed only in the surgically obtained liver specimens of patients with HCV infection ($n = 5$) and controls ($n = 7$). The analysis revealed a band with a molecular weight of approximately 55 ku corresponding to PPARα in all surgical liver specimens, and significantly lower levels of PPARα protein in HCV patients than in controls (2.3±0.3 *vs* 3.6±0.2 OD of PPARα protein/5 ng total protein, $P = 0.009$) (Figure 1C).

PPARα protein expression decreased in hepatocytes

The immunohistochemical staining was performed in all hepatitis C patients' and controls. Cell staining was positive for PPARα mainly in hepatocytes and by perinuclear staining (Figure 2, left). However, the results of stained cells in chronic hepatitis C patients indicated a decrease in PPARα staining in hepatocytes compared to those in control livers (Figure 2, right). Negative control staining was performed by omitting the primary antibody or the use of an irrelevant antibody. These results suggested that hepatocytes were the major sources of PPARα and they expressed low levels of PPARγ during HCV infection.

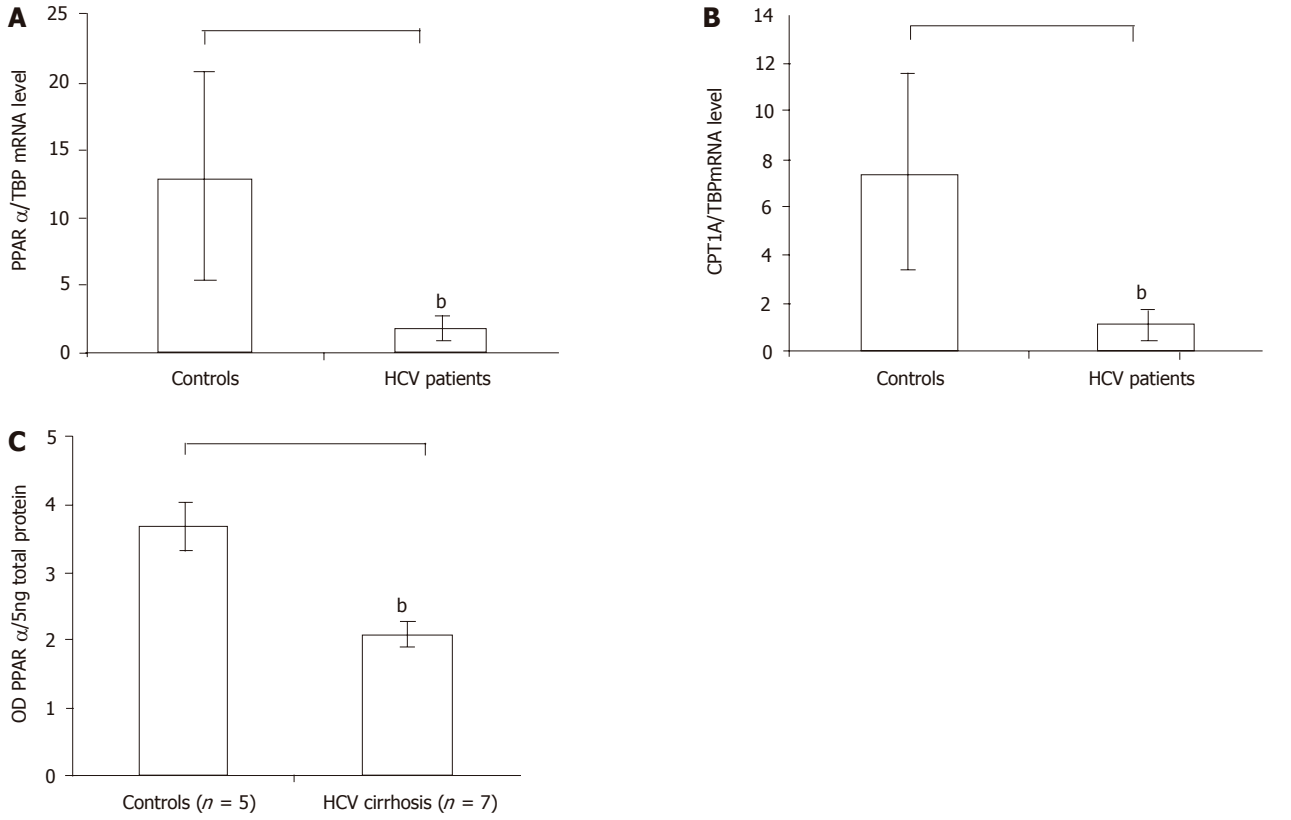

Figure 1 **A:** The PPARα mRNA level in the HCV patients reduced compared with controls by real-time RT-PCR, $^{b}P<0.01$ *vs* control; **B:** The PPARα target gene CPT1A mRNA level in the HCV patients also reduced compared with controls by real-time RT-PCR, $^{b}P<0.01$ *vs* control; **C:** The PPARα protein level in the HCV cirrhotic patients reduced compared with controls by Western blot. Results were expressed as mean±SD, $^{b}P<0.01$ *vs* control.

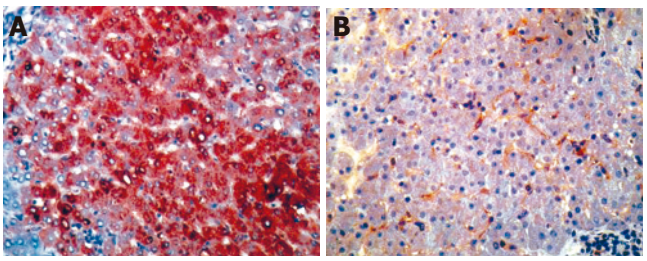

Figure 2 Representative PPARα immunostainings in liver specimens. The left: a control liver, PPARα staining was detected in the majority of hepatocytes (magnification ×160); The right: a severe hepatitis patient liver, the number of PPARα-stained hepatocytes was decreased markedly (magnification ×160).

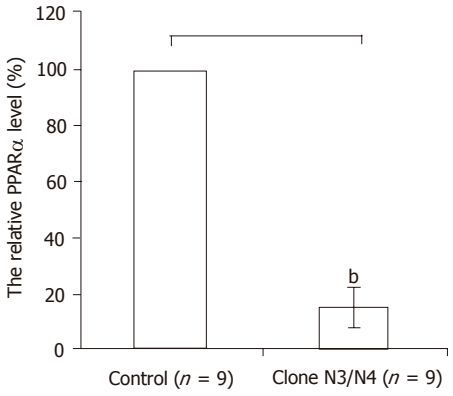

Figure 3 In the N3 colon and N4 colon which were stably expressing the HCV core protein PPARα mRNA levels decreased more than 80% compared with controls by real-time RT-PCR. Results were expressed as mean±SD, $^{b}P<0.01$ *vs* control.

HCV core protein reduced the expression of PPARα

Because hepatocytes were the parenchymal component in the liver that were prone to be infected by HCV, and HCV core protein regulated the transcriptional activity of several genes, the PPARα expression in HepG2 cells stably expressing HCV core protein were also quantified with the real-time PCR. In the N3 and N4 colons which were stably expressing the HCV core protein, PPARα mRNA levels were found to be similar, but decreased more than 80% compared with controls (Figure 3).

DISCUSSION

Because the morbidity and mortality of hepatitis C is high and the natural history is generally long and slow, many patients develop complications[6-8]. It is difficult to find an effective treatment if the exact mechanism of HCV is not clear, so it is a very important task to elucidate the pathogenesis of hepatitis C[2,4]. The results in this study demonstrated for the first time that the expression of PPARα was impaired in the livers of chronic hepatitis C patients. Both *in vitro* studies and the transgenic mouse model suggested that the HCV core protein is possibly responsible for lipid accumulation[12,26]. It was reported

that HCV core protein expression in transgenic mice could inhibit microsomal triglyceride transfer protein activity and very low density lipoprotein secretion causing steatosis[13]; and the mechanism postulated seemed to be related to mitochondrial toxicity with the production of reactive oxygen species. In this study, it was also found that in the N3 colon and N4 colon stably expressing the HCV core protein, the PPARα mRNA levels lowered significantly compared with controls. These results indicated the involvement of the HCV protein in the regulation of PPARα expression and activation.

PPARα plays a fundamental role in regulating energy homeostasis through controlling lipid metabolism[14]. PPARs belong to the type II steroid receptor family, including members such as RXR and thyroid hormone receptor[27]. These receptors are generally considered to localize to the nucleus and appear not to be bound to other proteins in inactive complexes, as has been extensively described for type I receptors (e.g. glucocorticoid receptor, progesterone receptor, androgen receptor). PPARα is a fatty acid-activated transcription factor that up-regulates the expression of a variety of genes encoding proteins involved in β-oxidation and lipoprotein metabolism[16]. PPARα plays a central role in fatty acid homeostasis by regulating the degradation of fatty acids by mitochondrial as well as by peroxisomal and microsomal fatty acid oxidation[28]. In addition, PPARα contributes to the maintenance of energy balance by regulating the expression of enzymes that participate in mitochondrial fatty acid oxidation and the formation of ketone bodies from fatty acids. Lack of this transcriptional factor in PPARα–/– mice results in the inability to up-regulate hepatic fatty acid oxidation and ketogenesis in the face of increased concentrations of free fatty acids in the circulation[15]. In this study, both the real-time PCR and Western blot analysis indicated that PPARα expression level was down-regulated in HCV infection; and the immunohistochemical staining also showed that the decreased expression was mainly in hepatocytes. So it suggests that HCV injures the liver partly through down-regulation of PPARα.

The PPARα-responsive human genes include CPT1A, the long chain fatty acyl-CoA synthase (ACS), and the mitochondrial HMG-CoA synthase (HMGCS2). Several aspects of fatty acid oxidation are disrupted in PPARα null mice that include a diminished, constitutive expression of several components of the mitochondrial fatty acid oxidation pathway. These results suggest that in mice, PPARα is a significant regulator of the mitochondrial capacity for fatty acid β-oxidation. The flux of long chain fatty acids through the mitochondrial γ-oxidation pathway is regulated by CPT1, a component of the long chain fatty acylcarnitine translocases. The activity of CPT1 is modulated by the concentration of malonyl-CoA, a potent inhibitor of the enzyme formed in the first committed step of fatty acid synthesis. Because CPT1 is induced by peroxisome proliferators in the liver, the target gene CPT1A of PPARα was also studied in order to understand the possible mechanisms of reduced expression of PPARα in the HCV infection. The human CPT1A gene is PPARα-responsive[17,18,29-31]. The fatty acyl-CoA substrates for CPT1 are formed by the esterification of free fatty acids to CoA by ACS. ACS is induced by peroxisome proliferators in rat liver, and PPRE has been identified in the promoter of the rat gene. In this study, the expression levels of the CPT1A gene in the livers of hepatitis C patients decreased significantly. It indicated that HCV core protein was possibly responsible for lipid accumulation by CPT1A, which was regulated by the transcriptional factor PPARα that was also the major isoform required for mediating the responses resulting from the actions of peroxisome proliferators in liver.

It was reported that human genes encoding key enzymes for mitochondrial fatty acid oxidation and ketogenesis could be regulated by human PPARα. In these tissues malonyl-CoA may act as a sensor or hormone and fuel through its ability to inhibit mitochondrial outer membrane CPT I[17]. This enzyme catalyzes the transesterification of long-chain fatty acyl-CoAs to long-chain acylcarnitines, which are carried into the mitochondrial matrix where acyl-CoA is regenerated for β-oxidation[18,30,31]. The role of PPARα in cell proliferation[32,33], tumor promotion[34,35] and in the prevention/reversal of liver injury has been studied by different researchers before[34-36].

To sum up, this report showed that the reduced intrahepatic PPARα expression level was associated with the HCV core protein. HCV infection down-regulated the expression of PPARα and CPT1A not only at mRNA level but also at the protein level. Correspondingly, the reduced PPARα level induced the low expression of CPT1A. The immunohistochemical analysis also proved that expression level of PPARα decreased in the hepatocytes. The function impairment of PPARα and CPT1A during the HCV infection still needs further investigation. The results in this study indicated that PPARα played an important role in the pathogenesis of chronic HCV infection, and this nuclear receptor could be a potential therapeutic target[34-36] in the treatment of HCV infection in the future.

Abstract

AIM: To evaluate the interplay between gliadin and LoVo cells and the direct effect of gliadin on cytoskeletal patterns.

METHODS: We treated LoVo multicellular spheroids with digested bread wheat gliadin in order to investigate their morphology and ultrastructure (by means of light microscopy and scanning electron microscopy), and the effect of gliadin on actin (phalloidin fluorescence) and the tight-junction protein occludin and zonula occluden-1.

RESULTS: The treated spheroids had deep holes and surface blebs, whereas the controls were smoothly surfaced ovoids. The incubation of LoVo spheroids with gliadin decreased the number of intracellular actin filaments, impaired and disassembled the integrity of the tight-junction system.

CONCLUSION: Our data obtained from an "*in vivo*-like" polarized culture system confirm the direct noxious effect of gliadin on the cytoskeleton and tight junctions of epithelial cells. Unlike two-dimensional cell culture systems, the use of multicellular spheroids seems to provide a suitable model for studying cell-cell interactions.

Key words: Celiac disease; Gliadin; Cytoskeleton; Multicellular spheroids

INTRODUCTION

Celiac disease (CD) is an immunomediated intestinal disorder that is triggered by dietary gluten and related cereal proteins in genetically susceptible individuals[1,2]. Gluten consists of a complex mixture of gliadin monomers and large polymeric glutenin polypetides. A number of *in vitro* studies of two-dimensional cell cultures have shown that gliadin has direct cytotoxic effects on epithelial cells[3], but the early steps allowing the start of the immunoreaction are largely unknown.

CD is characterized by enhanced paracellular permeability across the intestinal epithelium, a "leaky gut" condition that allows the passage of macromolecules through the paracellular spaces[4-6]. Moreover, it has also been demonstrated that cytoskeleton involved in the pathogenesis of CD as a gluten challenge rapidly causes the disappearance and disorganization of actin filaments in the intestinal mucosa of CD patients[7]. The actin filaments in epithelial cells are associated with tight junctions (TJs), appearing as a series of discrete sites of apparent membrane fusion (so called "kissing points") involving the outer leaflets of the plasma membranes of adjacent cells. The integrity of the barrier function is important for the separation of two different compartments, and TJs play a major role in controlling paracellular transport between the luminal and basolateral fluid compartments[8].

Almost all the proteins associated with TJs are peripheral membrane proteins that form part of the submembrane plaque (Figure 1). The first TJ-associated protein to be identified is zonula occluden-1 (ZO-1) whose C-terminal half contains an actin-binding site and mediates interactions between transmembrane proteins and cytoskeleton elements[9]. Occludin, a 60 ku integral membrane protein in TJ strands[10], is involved in TJ barrier and fence functions through its four transmembrane domains, three cytoplasmic domains and two extracellular

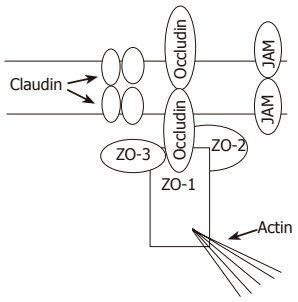

Figure 1 Tight junction (TJ) structure with emphasis on proteins of the TJ membrane domain: ZO family members and their interaction with actin filaments.

loops[8]. Claudin-1 and claudin-2 are 23 ku integral membrane proteins that function as major structural components of TJ strands[11]. Junctional adhesion molecules (JAMs) have only one putative transmembrane sequence. The intracellular domain consists of 45 residues, and the extracellular portion (215 residues) contains two domains with intra chain disulfide bonds[12].

The cytoskeletal network generates tension and transmits stress within and among the cells[13]. The formation of multicellular tumor spheroids (MCTSs) involves cell translocations and morphological changes that are indicative of the organization of the cytoskeleton. The cells grown in MCTSs are interconnected by the means of TJs that form a seal between adjacent cells, thus defining their apical and basolateral surfaces, and creating a model similar to *in vivo* tissue. This is very different from the organization of two-dimensional cell cultures[14,15].

The aim of this study was to evaluate the interplay between gliadin and LoVo MCTSs, with specific emphasis on the direct effect of gliadin on cytoskeleton patterns and reorganization.

MATERIALS AND METHODS

Cell line

Cells from the human colon adenocarcinoma cell line (LoVo, ATCC, Rockville, USA) were grown in T75 flasks (PBI, Italy) at 37 °C in an atmosphere containing 95% air and 50 mL/L CO_2. The medium consisted of Ham's F-12 medium (GIBCO, Italy), supplemented with 10% fetal bovine serum (GIBCO, Italy), 1% MEM vitamin solution 100× (GIBCO, Italy), and 3% L-glutamine 200 mmol/L (GIBCO, Italy).

After one week, the cells were removed using solution containing 0.25% (w/v) trypsin and 0.02% (w/v) EDTA (Sigma-Aldrich, Italy), and the cell suspensions were cultured again. Mycoplasma contamination was regularly searched for and excluded using the Hoechst method[16].

Gliadin digestion

Gliadin was purified from *Triticum aestivum* flour (Hereward Cultivar, UK) according to Capelli[17]. Pepsin (3.2-4.5 U/mg) was supplied by Sigma (Italy), and the pancreatin (0.1 mAnson/mg) by Merck (USA). All the chemicals were of analytical grade. Digestion was performed as previously described by our group[18]. Briefly, the gliadin was first incubated with pepsin at 37 °C for 24 h, and then with pancreatin at 37 °C for 3 h, adjusting to a pH of 8. The digested protein was analytically controlled by means of RP-HPLC, SE-HPLC, and SDS-PAGE, freeze-dried and stored.

Three-dimensional cell cultures and gliadin treatment

Three-dimensional cell cultures were initiated by seeding 4×10^5 cells/mL in 25 mL of complete medium supplemented with penicillin (100 U/mL) and streptomycin (100 Ug/mL) (GIBCO, Italy) in Erlenmeyer flasks (Corning, Italy), and incubated in a gyratory rotation incubator (60 rev/min) at 37 °C in air (Colaver, Italy). Homotypical aggregations were visible after 4 d of culture, and the MCTSs were usually complete within 7 d (average diameter±SD, 370±48.5 μm).

On the seventh day, the MCTSs were exposed to PT-digested gliadin (500 μg/mL) in a completely renewed medium for further 4 d and subsequently taken for microscopic examination. The PT-digested gliadin greatly inhibited cell growth (50% inhibitory concentration: 390 μg/mL) and the dose used was selected from four different concentrations (125, 500, 750, 1 000 μg/mL) on the basis of previous data obtained in our laboratory[18,19].

Scanning electron microscopy (SEM)

Three-dimensional cell cultures were washed twice in PBS, and then fixed in 2.5% glutaraldehyde in phosphate buffer at room temperature for 24 h at 4 °C. At the time of analysis, a representative sample of spheroids was recovered, immediately placed on a paper filter and observed in low vacuum modality at a high voltage of 10 kV. SEM analysis was performed using a Philips Scanning Electron Microscope (Mod. ×L20).

Confocal laser scanning microscopy of intracellular F-actin

LoVo MCTSs were washed twice in PBS, fixed in 4% paraformaldeyde for 1 h, permeabilized with 0.4% Triton X-100 (Sigma-Aldrich, Italy) for 20 min, washed thrice for 5 min in PBS and stained for immunocytochemistry by means of incubation with fluorescein TRITC-phalloidin (Sigma-Aldrich, Italy) (1:200 PBS) in a humid chamber at room temperature for 6 h. After washing thrice in PBS each for 5 min, 10 spheroids were transferred onto slides, and each slide was mounted with 90% glycerol in PBS. The results were analyzed using a confocal laser scanning microscope (Leica TCSNT, Germany).

Confocal laser scanning microscopy of occludin

LoVo MCTSs were washed twice in PBS and fixed in ethanol for 30 min at 4 °C. After the first incubation, the samples were incubated with acetone (previously stored at -20 °C) for an additional 3 min at room temperature. They were then blocked and incubated for immunocytochemistry overnight with anti-occludin-FITC (Zymed, CA, USA) before being analyzed by means of confocal laser scanning microscopy (Leica TCSNT, Germany).

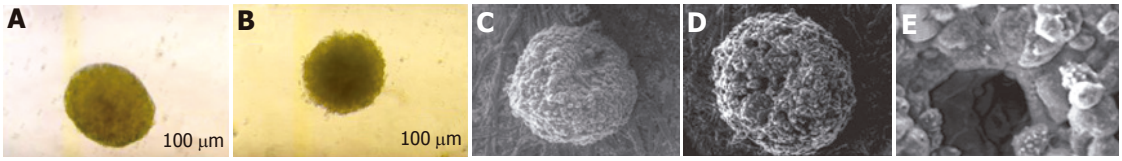

Figure 2 Phase-contrast micrographs (10×) showing control (**A**) and gliadin-treated multicellular tumor spheroids of the human colon adenocarcinoma LoVo cell line (**B**) after 11 d of culture; Scanning electron micrographs: showing the ovoid control spheroids (**C**) and their very compact, densely organized and tightly packed structure that they can be clearly distinguished from each other; The surface of gliadin-treated spheroids (**D**) focally interrupted by irregularly distributed holes, and loss of their structural thickness and organization (**E**).

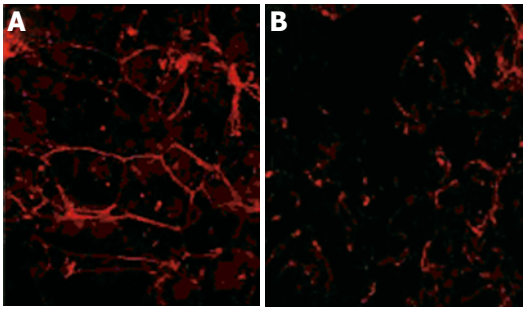

Figure 3 Confocal laser scanning micrograph in which TRICT-phalloidin highlights the organization of F-actin in multicellular tumor spheroids. The control spheroids (**A**) have a "chicken-wire" distribution under the plasma membrane, whereas the treated spheroids (**B**) show a reorganized actin cytoskeleton.

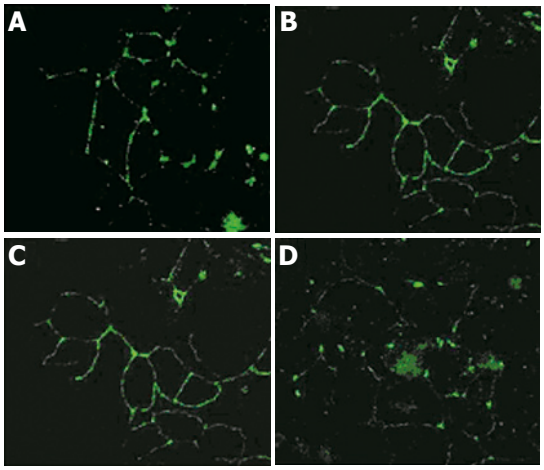

Figure 4 Confocal microscopy immunolocalization of occludin and zonula occluden-1 (ZO-1) in LoVo multicellular tumor spheroids. In the control spheroids, occludin and ZO-1 localized sharply in the apical region of the lateral membrane are visualized en face as a ring pattern (**A** and **C**), whereas the distribution of occludin and ZO-1 in the spheroids exposed to gliadin for 4 d is far from the lateral TJ membrane (**B** and **D**).

Confocal laser scanning microscopy of zonula occluden-1

LoVo MCTSs were washed twice in PBS and fixed in ethanol for 30 min at 4 °C. After the first incubation, the samples were incubated with acetone (previously stored at -20 °C) for an additional 3 min at room temperature. They were then blocked and incubated overnight with anti-ZO-1-FITC (Zymed, CA, USA) before being analyzed by means of confocal laser scanning microscopy (Leica TCSNT, Germany).

RESULTS

Light microscopy and SEM

The untreated MCTSs appeared bright and round at phase-contrast microscopy (Figure 2A). SEM showed that they were well-defined and compact, with smooth boundaries and a regular surface. Their structure was compact, densely organized and tightly packed (Figure 2C).

The MCTSs treated with PT-digested gliadin were loosely connected and irregularly shaped (Figure 2B). They were less bright than the controls and had frayed borders. SEM revealed an altered surface, with deep and irregularly distributed holes (Figures 2D and E).

Confocal laser scanning microscopy

The untreated MCTSs stained with TRITC-phalloidin had regular perijunctional actin rings and showed organized distribution at the cell boundaries (Figure 3A), whereas those treated with PT-digested gliadin had reorganized intracellular actin filaments and disassembled F-actin (Figure 3B).

In comparison with the normal subapical honeycomb pattern typical of TJs (Figures 4A and C), treatment with PT-digested gliadin led to their structural dissociation (Figures 4B and D). The morphologically characteristic ring structure of occludin and ZO-1 immunolocalization in the en face confocal images had sharp boundaries in the untreated spheroids, but was partially or completely lost in the treated spheroids.

DISCUSSION

CD is a chronic intestinal inflammatory disorder characterized by mucosal changes including lymphocyte infiltration, crypt hyperplasia and villous atrophy. Furthermore, intestinal permeability is increased and TJs appear open[20]. As TJs form a barrier against the diffusion of molecules from the lumen to the tissue parenchyma (barrier function), and restrict the diffusion of lipids and proteins between the apical and basolateral plasma membranes (fence function)[21], the loss of permeability allows the translocation of antigenic molecules from the intestinal lumen to the lamina propria, thus creating a condition for an immune response.

Traditional tissue culture methods have been based on growing cell lines as monolayers, but a new three-

dimensional culture system (Figure 2A) has been investigated as a mean of modeling a solid tumor under *in vitro* conditions that simulates its *in vivo* biological properties. Given the fundamental differences between monolayer and three-dimensional cultures, spheroids should become mandatory test systems in oncological therapeutic screening programs[22]. Furthermore, cells grown in three-dimensional cultures are oriented and polarized[23,24], and often express a gene repertoire that is different from that of the monolayer cultures[25]. Previous studies from our laboratory have confirmed the polarized structure, and the presence of microvilli and tightly connected epithelial junctional complexes[18].

The interaction between TJ proteins and actomyosin cytoskeleton in MCTSs is a primary target for physiological and pathological signals. Circumferential actomyosin contraction and cytoskeleton interaction modulate TJ permeability, thus contributing to the formation of the TJ fence[21]. Pizzuti *et al*.[26] have recently demonstrated that the intestinal mucosa of celiac patients has an altered TJ system during gluten exposure, and decreased ZO-1 expression is associated with a disrupted F-actin organization and the loss of normal distribution at cell-cell contact sites.

Our SEM morphological examinations confirmed that gliadin treatment could affect spheroid structure, causing a loss of cell thickness and organization, and the formation of hole-like surface structures (Figures 2C-E). Confocal laser scanning microscopy showed that gliadin could induce cytoskeleton reorganization (Figures 3A and B), and specifically act on TJ structural proteins.

Though our results have confirmed that the expression of occludin correlates with barrier properties, the decreased intensity or disappearance of occludin staining at cell–cell borders in gliadin-treated spheroids (Figures 4A and B) do not presuppose the absence of TJ structural integrity. Knockout experiments in mouse embryonic stem cells have demonstrated that occludin is not necessary to form functionally competent TJs[27], and ZO-1 has a wild-type localization in apical junctional regions of the outermost layer of epithelial cells in the absence of occludin[28]. We found that the immunolocalization of ZO-1 in TJ ring structures was severely disrupted by gliadin exposure, leading to almost complete lack of continuity, and *en face* confocal images showed a breakdown of junctional complexes (Figures 4C and D). Taken together, these findings suggest that ZO-1 lies at the centre of a network of protein–protein interactions and may be critical in recruiting the proteins necessary to establish TJs.

Our preliminary data showed that TJ permeability might be regulated directly as a result of TJ protein modifications, or indirectly as a result of the effects of xenobiotics on the cytoskeleton. New insights into the molecular architecture of TJs and their regulation have given rise to a new concept of TJ modulation based on peptides from the first extracellular domain of occludin[29]. We can speculate that gliadin peptides also act as modulators on the extracellular loops of TJ transmembrane proteins, mediating TJ opening and the consequent cytoskeletal redistribution. According to the "tensegrity model"[30,31], the cells are in prestressed structures in which cytoskeletal elements are major determinants of deformability, and so a local stress can cause global structural rearrangements. The cell response to xenobiotic exposure leads to the retraction of submembranous actin filaments from junctional complexes, thus determining the disappearance of organized TJs. Furthermore, this alteration of internal balance of tensile stress compromises the stability of cell shape: the cells become rounded and stimulate an apoptotic process. The correlation of apoptosis with a disrupted cytoskeleton and junctional system may explain the SEM images: the blebs and holes visible on the surface of treated spheroids are the results of an apoptotic process initiated by the deregulation of internal cell balance. Ojakian *et al*.[32] reported that gliadin has an apoptotic effect on Caco-2 colon carcinoma cells directly stimulated by digested gliadin.

Understanding the events of this process will throw light onto the changes in paracellular permeability caused by gliadin and identify novel therapeutic targets in celiac disease. Though the intricacies of this process *in vivo* have not yet been fully elucidated, our results indicate that a pivotal role is played by the disarrangement of the "belt-like" structure of perijunctional F-actin affiliated with TJs. This highlights the importance of the cytoskeleton network in the ultrastructural architecture of enterocytes, given that a gluten challenge in CD patients rapidly distorts the microvillous structure, thus disorganizing the actin network on the intestinal mucosa.

If the early steps of gliadin-induced mucosal damage in patients with CD concern intestinal permeability, which is directly altered by gliadin before the immunological response, MCTSs could become essential for testing the cytotoxic effects of new chemically, enzymatically or genetically modified gliadins studied as alternative therapies to a gluten-free diet.

ACKNOWLEDGMENTS

The authors would like to thank Kevin Smart (Link srl, Milan), "Centro per lo Studio della Celiachia" of the University of Milan, for his help in preparing the English version of the manuscript, Maria Letizia Falini and Rosita Caramanico for their help in preparing peptides, and San Paolo Bank for financial support.

The study was conceived and designed by E. Dolfini, R. Colombo, L. Roncoroni, C. Fumagalli, L. Elli, and M.T. Bardella. L. Roncoroni and C. Fumagalli were responsible for the cell cultures. V. Lorusso and S. Ramponi undertook the morphological investigations and F. Forlani prepared the digested gliadin.

Abstract

AIM: To investigate the effect of cyclosporine A (CsA), FK-506, and mycophenolate mofetil (MMF) and 40-0-[2-hydroxyethyl]rapamycin (RAD) on proliferation of human intrahepatic biliary epithelial cells (BECs) *in vitro*.

METHODS: BECs were isolated from six human liver tissuespecimens with the immunomagnetic separation method and treated with different concentrations of CsA, FK-506, RAD, and MMF *in vitro*. Proliferation of the cells was measured by MTT assay at 24 and 48 h after treatment, respectively. One-way analysis of variance was used to analyze the results. Expression of CK 19 in BECs was monitored by flow cytometry and Western blot.

RESULTS: Six lines of BECs were established. They survived for 4-18 wk *in vitro*. Flow cytometry analysis showed that these cells always expressed CK19. CsA, FK-506, RAD, and MMF inhibited proliferation of BECs in a dose-dependent manner. The lowest concentration of CsA, FK-506, RAD, and MMF to inhibit proliferation of BECs ($P<0.05$) was 500, 100, 0.25, and 100 μg/L, respectively. However, the expression of CK19 by BECs was not changed.

CONCLUSION: CsA, FK-506, RAD, and MMF have an antiproliferative effect on human intrahepatic BECs *in vitro*, while RAD has the strongest growth-inhibitory effect. Their possible effects on liver regeneration and bile duct injury in transplant patients should be further investigated.

Key words: Cyclosporine A; FK-506, Rapamycin; Mycophenolate mofetil; Biliary epithelial cells

INTRODUCTION

Within the last decade, living donor liver transplantation (LDLT) has become an accepted treatment for adult patients with end-staged liver disease and it provides a viable alternative to many recipients who would otherwise die while on the waiting lists. Part of the donor liver used for adult LDLT is small in size when transplanted into the recipient. The liver has the unique ability to regenerate and adjust its size according to the requirement of the recipient. Therefore, liver regeneration is crucial for a successful LDLT. The volume and quality of the graft, ischemic time, portal flow, venous outflow, and immunosuppressive agents are among the factors affecting liver regeneration after adult LDLT.

Cyclosporine A (CsA), FK-506, and MMF can augment liver regeneration after hepatectomy or orthotopic liver transplantation in rats[1-6]. However, in vitro experiments indicate that CsA and FK-506 have an antiproliferative or cytotoxic effect on adult human hepatocytes[7,8]. During liver regeneration after partial hepatectomy, both mature hepatocytes and BECs are induced to proliferate. Human hepatocytes and intrahepatic BECs can be isolated from the liver tissue and maintained *in vitro* for a certain time. *In vitro*, mature hepatocytes have a very limited ability to replicate, while BECs have a great potential to proliferate[9,10]. In this study, the effect of CsA, FK-506, MMF, and 40-0-[2-hydroxyethyl]rapamycin (RAD) on the proliferation of human intrahepatic BECs *in vitro* was investigated.

MATERIALS AND METHODS

Liver tissue

All liver specimens were taken from the patients who

underwent hepatectomy or liver transplantation at University Hospital Essen, Germany. The procedure confirmed to the local ethical guidelines and followed the ethical guidelines of the 1975 Declaration of Helsinki. All patients or their relatives gave informed consents. Three diseased liver tissues were obtained from explanted livers, including one case of primary biliary cirrhosis (64 years old), one case of oxalosis (one year old) and one case of carbamoyl-phosphate-synthetase deficiency (one year old). Two normal liver tissues were obtained during hepatectomy, including one case of hepatoblastoma (1.5 years old) and one case of hepatocellular carcinoma (67 years old). Another normal liver tissue was obtained from a donor (10 years old) when the graft exceeded surgical requirement. All tissues were stored in Dulbecco' s minimum essential medium (PAA Laboratories, Coelbe, Germany) at 4 ºC and used within 36 h after hepatectomy.

Isolation and culture of human intrahepatic BECs

Human intrahepatic BECs were isolated with an immunomagnetic separation method employing an antibody against human epithelial antigen (HEA) as reported[11,12]. BECs were cultured with the plating medium in a 25-cm^2 flask (Greiner, Frickenhausen, Germany) pre-coated with collagen G (Biochrom KG, Berlin). The cell culture was maintained in a humidified atmosphere composed of 95% air and 50 mL/L CO_2. About 24-72 h after plating, the growth medium containing hepatocyte growth factor (HGF, R&D systems, UK) was used to culture the cells. The composition of the plating medium and growth medium was similar to the reported[13]. At confluence, BECs were detached with a solution containing 0.1 g/L trypsin and 1.0 g/L EDTA (Sigma, Taufkirchen, Germany) and maintained in a culture or used for the experiment.

Flow cytometry analysis of cytokeratin (CK) 19 expression

The expression of CK19 by BECs was investigated using flow cytometry with a FACS-Scan machine (Becton Dickinson, Heidelberg, Germany). Cells were pre-treated with the Fix & Perm cell permeabilization kit (Dianova, Hamburg, Germany). The monoclonal antibody against CK19 (IgG2b, Progen, Heidelberg, Germany) was used in a three times dilution according to the manufacturer's instructions. The FITC-labeled second antibody (Dianova, Hamburg, Germany) was diluted fifty times.

In vitro exposure to drugs

During passage, BECs were seeded at the density of 1×104 viable cells/well in 24-well plates with the plating medium. One day later, the medium was changed to the growth medium containing the drugs. CsA (MW 1203, Sandoz, Switzerland), FK 506 (MW 822, Fujisawa, Japan), RAD (MW 958.25, Sandoz, Switzerland) and MMF (MW 433.5, Sandoz, Switzerland) were diluted with a phosphate-buffered solution (PBS, PAA Laboratories, Coelbe, Germany). The concentrations of CsA, FK 506, RAD, and MMF in the medium ranged from 10 to 1 000 μg/L, 10 to 1 000 μg/L, 0.05 to 10 μg/L, 0.05 to 500 μg/L, respectively. Each concentration of the drug was determined in eight wells per experiment. The vigorously proliferating BECs derived from each liver tissue were used in the study and each drug was investigated eight times. Negative control cultures only received the growth medium.

MTT assay of cell growth

Dimethylthiazol-diphenyl-tetrazolium (MTT) assay was performed at 24 and 48 h after addition of the drugs, respectively. Fifty microliters of 4 mg/mL MTT (Sigma, Taufkirchen, Germany) was given to each well (containing 0.5 mL medium) in the 24-well plate. Four hours later, the medium was removed and 250 μL dimethyl sulfoxide (DMSO) was added into each well to solubilize the formazan dye converted from MTT by the cells. Five minutes later, the plates were shaken to make a homogenous dye solution and measured immediately with an ELISA reader (Lambda E, MWG-Biotech, Ebersberg, Germany) at a wavelength of 550 nm minus 690 nm. The cell number in each well was recorded in the form of optical density (OD).

Western blot analysis of CK19 expression

BECs were passaged into six-well plates pre-coated with collagen G. After 24 h, CsA or FK-506 was added into the growth medium and the cells were cultured for 48 h. The concentrations of both CsA and FK-506 in the medium were 500, 1 000 and 2 000 μg/L, respectively. BECs were detached by the use of 0.05% collagenase XI (Sigma, Taufkirchen, Germany), washed with PBS and stored at –20 °C. Protein amount was determined with the Bradford method (Biorad, Munich, Germany) after the cell pellet was boiled 10 times with 40 μL of 0.1% Triton/PBS. Extracted protein (1 μg/lane) was electrophoretically separated on a 10% SDS-PAGE and transferred to nitrocellulose. For the staining, blots were blocked with 1.2% gelatin in PBS and washed with 0.05% Tween 20 in PBS. First antibody against CK19 (IgG2b, Progen, Heidelberg, Germany) was diluted 1:80 in PBS and incubated for 1 h at room temperature. Anti-mouse Ig AP-conjugate as second antibody was diluted 1:1 000 in PBS and also incubated for 1 h at room temperature. Finally, the color was developed using BCIP and NBT (Gerbu, Gaiberg, Germany).

Statistical analysis

The average OD measured at different concentrations of each drug was compared using one-way analysis of variance (ANOVA) with the software SPSS 11.0 (SPSS, Inc., Chicago, IL, USA). Proliferation of the cells exposed to the drugs was compared to the negative control. $P<0.05$ was considered statistically significant.

RESULTS

Isolation and culture of intrahepatic BECs

The freshly isolated cells were small and round in shape and most of them formed clusters. Magnetic beads could

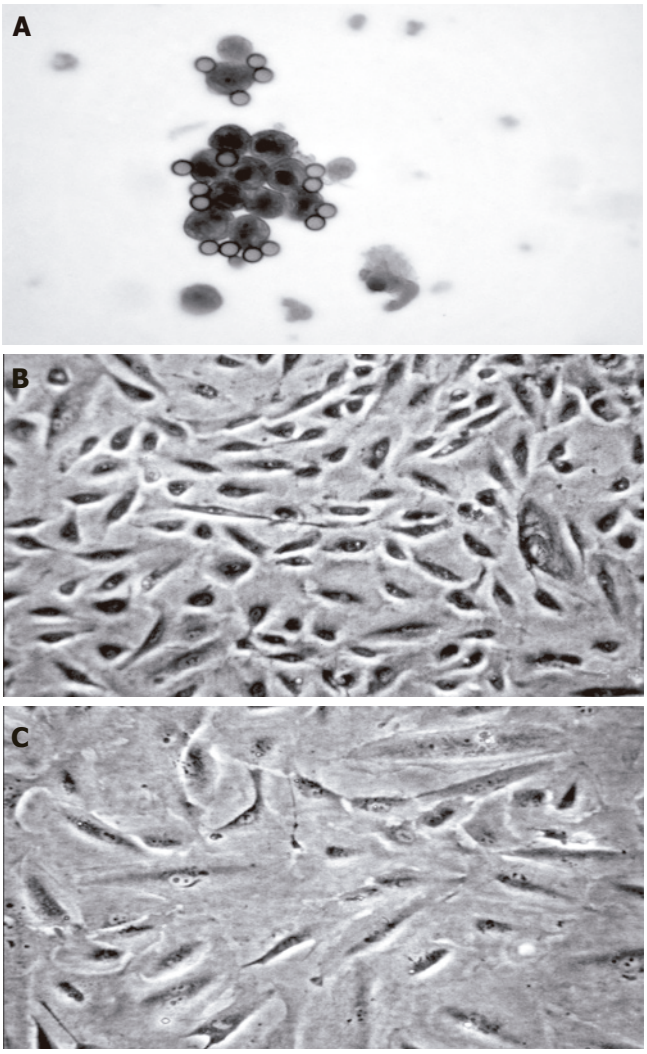

Figure 1 Freshly isolated (**A**) and proliferating human intrahepatic BECs (**B**) as well as BECs exposed to immunosuppressive agents (**C**).

be seen on the cell surface (Figure 1A). Intrahepatic BECs isolated from six liver tissues proliferated for 4-18 wk *in vitro* and were passaged 3-12 times. The proliferating BECs were small and oval in shape (Figure 1B). Flow cytometry analysis showed that the proliferating BECs consistently expressed CK19 (Figure 2).

Growth of intrahepatic BECs exposed to drugs

The vigorously proliferating BECs which represented passage (P) 1–6 BECs derived from different liver tissues, were exposed to the drugs. In this set of experiments, all the four immunosuppressive agents had no growth-promoting effect on BECs at any concentration *in vitro*. On the contrary, they inhibited the proliferation of BECs and this could be clearly shown at 48 h after the addition of the drugs (Figure 3A). All the four drugs inhibited the proliferation of BECs in a dose-dependent manner (Figure 3B) and this was repeatedly demonstrated with BECs derived from different liver tissues and in different passages. The lowest concentration for CsA, FK-506,

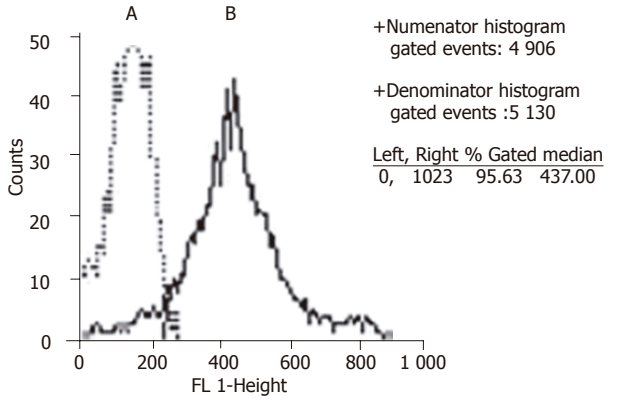

Figure 2 Flow cytometry analysis of CK19 expression. **A:** negative control. **B:** with antibody against CK19.

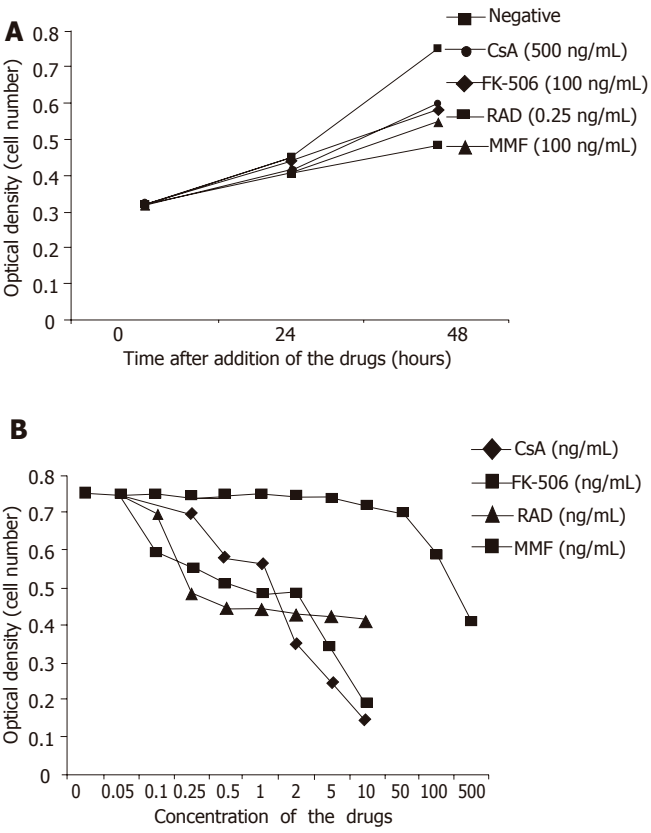

Figure 3 MTT analysis of proliferation of BECs exposed to drugs. **A:** BECs exposed to the drugs for 24 and 48 h. At 48 h, CsA (500 μg/L), FK-506 (100 μg/L), RAD (0.25 μg/L), and MMF (100 μg/L) inhibited proliferation of BECs (P<0.05). **B:** BECs exposed to the drugs for 48 h. CsA, FK-506, RAD, and MMF inhibited the proliferation of BECs in a dose-dependent manner.

RAD, and MMF to inhibit the proliferation of BECs (P<0.05) was 500, 100, 0.25, and 100 μg/L, respectively (Figures 3A and B). RAD had the strongest growth-inhibiting effect. Microscopically, the BECs treated with the drugs became larger than the cells in negative control (Figure 1C). However, Western blot analysis showed that CsA and FK-506 did not change CK19 protein expression by BECs (Figure 4).

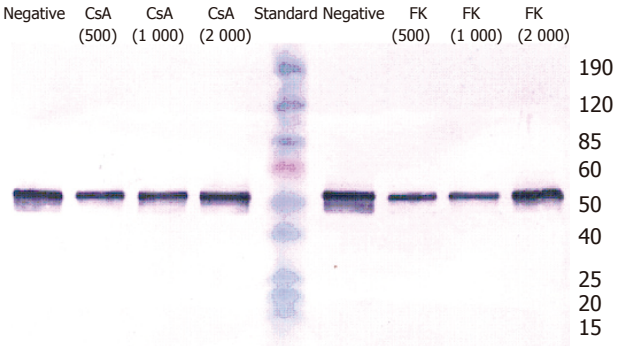

Figure 4 Western blot analysis of CK19 expression. BECs were treated with 500, 1 000, 2 000 μg/L CSA, and FK-506, respectively for 48 h. CsA and FK-506 did not change the protein expression of CK19 in BECs.

DISCUSSION

Intrahepatic BECs represent about 5% of total cell population in the liver. In the human liver, human epithelial antigen (HEA) is the cell surface antigen that only exists in intrahepatic BECs. With the immunomagnetic isolation technique employing anti-HEA monoclonal antibody, intrahepatic BECs can be purified after density-gradient centrifugation[11]. The purity of isolated human intrahepatic BECs is more than 99%[12]. The specific markers for biliary cells include CK7 and CK19. All the cells used in this experiment expressed CK19 (Figure 2), indicating that they are intrahepatic BECs.

In liver transplantation, the damaged liver cells caused by ischemia-reperfusion injury are repaired by liver regeneration. In adult LDLT, liver regeneration is of particular importance to meet the necessary metabolism requirement of the recipient. An immunosuppressive agent is one of the factors affecting liver regeneration after liver transplantation.

Generally speaking, CsA and FK-506 exert their immunosuppressive effect by blocking the production of interleukin-2 (IL-2) by T helper cells, while MMF and RAD exert their immunosuppressive effect by inhibiting proliferation of lymphocytes. CsA, FK-506, and MMF can enhance liver regeneration after hepatectomy or small-for-size liver transplantation in animals. The augmented liver regeneration might be an indirect effect, as CsA and FK-506 have anti-proliferative or cytotoxic effect on hepatocytes[7,8]. The possible mechanism for CsA and FK-506 on enhanced liver regeneration is through inhibition of production of IL-2 production and activation of natural killer (NK) cells[6]. The mechanism of MMF underlying accelerated liver regeneration is not fully understood.

In this study, all the four immunosuppressive agents inhibited human intrahepatic BECs in a dose-dependent manner *in vitro*, indicating that they have a direct inhibiting effect on liver regeneration and this direct effect should not be neglected, especially in adult LDLT. Our results showed that RAD had the strongest inhibiting effect on human intrahepatic BECs *in vitro*. The minimal concentration of RAD to inhibit proliferation of BECs (0.25 μg/L) *in vitro* was much lower than that of target serum through RAD level in patients undergoing immunosuppression (8-12 μg/L) after liver transplantation. Though the results obtained from an *in vitro* experiment were not identical to the results *in vivo*, it may indicate the importance of the direct effect of RAD on liver regeneration. Also, as an immunosuppressive agent, RAD has been reported to attenuate liver regeneration in a rat hepatectomy model[14]. Moreover, immunosuppressant-induced bile duct damage has been reported in azathioprine[15-18]. RAD and azathioprine share the similar immunosuppressive mechanism and it should be alerted that RAD might also cause bile duct damage in transplant patients.

In conclusion, CsA, FK-506, RAD, and MMF have an anti-proliferative effect on human intrahepatic BECs *in vitro*, while RAD has the strongest growth-inhibitory effect. Their possible effects on liver regeneration and bile duct injury in transplant patients should be further investigated.

Abstract

AIM: To evaluate the antioxidant and phase II detoxification enzyme inducing ability of green leaf vegetables consumed in Asia.

METHODS: The antioxidant properties of six commonly consumed Asian vegetables were determined using the ABTS, DPPH, deoxyribose, PR bleaching and iron-ascorbate induced lipid peroxidation assay. Induce of phase II detoxification enzymes was also determined for each respective vegetable extract. Protection against authentic ONOO- and HOCl mediated cytotoxicity in human colon HCT116 cells was determined using the MTT 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyl tetrasodium bromide) viability assay.

RESULTS: All of the extracts derived from green leaf vegetables exhibited antioxidant properties, while also having cytoprotective effects against ONOO- and HOCl mediated cytotoxicity. In addition, evaluation of the phase II enzyme inducing ability of each extract, as assessed by quinone reductase and glutathione-S-transferase activities, showed significant variation between the vegetables analyzed.

CONCLUSION: Green leaf vegetables are potential sources of antioxidants and phase II detoxification enzyme inducers in the Asian diet. It is likely that consumption of such vegetables is a major source of beneficial phytochemical constituents that may protect against colonic damage.

Key Words: Cruciferous vegetables; Lipid peroxidation; Free radicals; Isothiocyanates

INTRODUCTION

Reactive oxygen, nitrogen and chlorine species are generated *in vivo* by a diverse array of mechanisms including inflammatory responses, aerobic metabolism, and exposure to ionizing radiation. For example, the interaction of nitrogen monoxide (·NO) and superoxide ($O_2^{\cdot -}$) forms the cytotoxic product peroxynitrite, ($ONOO^-$) (Eq. 1)[1]. $NO + O_2^{\cdot -} \rightarrow ONOO^-$ (1)

Under physiological conditions ONOO- is converted to its protonated form peroxynitrous acid, ONOOH, which in turn decays to generate multiple toxic products with reactivities resembling those of the nitryl cation (NO_2^+), nitrogen dioxide radical ($^{\cdot}NO_2$), and hydroxyl radical (·OH). Similarly, at sites of chronic inflammation, neutrophils secrete hydrogen peroxide (H_2O_2) and the enzyme myeloperoxidase (MPO) which catalyzes the formation of hypochlorous acid (HOCl) (equation 2).

$H_2O_2 + Cl^- \rightarrow HOCl + OH^-$ (2)

Up to 80% of the H_2O_2 generated by activated neutrophils is used to form 20-400 μmol/L HOCl an hour[2-4]. Throughout this paper we use the term "hypochlorous acid" (pKa = 7.46) to refer to the approximately 50% ionized mixture of HOCl and OCl- species that exists at physiological pH 6[5]. Both peroxynitrite and HOCl and species derived from it can oxidize lipids, proteins, DNA, and carbohydrates[6-11]. Indeed, the addition of ONOO- or HOCl to biological fluids leads to the depletion of antioxidants including ascorbate, urate, and thiols. Depletion of *in vivo* antioxidant level by RS can initiate and promote cellular damage leading to genotoxicity and disease progression[12]. For example, RS may participate in the carcinogenesis by inducing genetic mutations. Therefore, due to the cytotoxicity of RS considerable interest in identifying chemical agents or dietary constituents that can interfere with RS mediated damage has been sought[13,14]. Plant derived antioxidants have been proposed to fulfill this role[15,16] and much research has focused on the potential antioxidant and cytoprotective or anti-carcinogenic properties of numerous phytochemical compounds[17,18]. These studies have been further supported by epidemiological investigations indicating that dietary habits

Table 1 Total phenolic content and inhibition of PR bleaching mediated by ONOO- and HOCl by green leaf vegetables used in this study.

play a significant role in the risk of developing cancer[19]. High consumption of fruits and vegetables, reduced red meat intake and low alcohol consumption appears to be inversely correlated with colon cancer development. In Asia the lower prevalence of degenerative disease like cancer and heart disease are thought to be due to the high consumption of fruits and vegetables[20]. However, little information is available on the antioxidant properties of green vegetables that are widely consumed in Asia. These food stuffs are perhaps a major source of antioxidants and antioxidant like compounds in the Asian diet. Therefore, in this report, we determined the antioxidant properties and phase II enzyme inducing the ability of several green vegetables commonly consumed in Asia. In addition, each vegetable was evaluated for its protective effects against both authentic ONOO- and HOCl mediated cellular toxicity in human colon cells.

MATERIALS AND METHODS

Chemicals

Glutathione (GSH, reduced form), 4-nitrobenzaldehyde (4-NBA), h-nicotinamide adenine dinucleotide (NAD), NADP, NADPH, NADH, 1-chloro-2,4-dinitrobenzene (CDNB), flavin adenine dinucleotide (FAD), 2,6-dichloroindophenol (2,6-DCIP), were purchased from Sigma Chemical Co. (St. Louis, MO, USA). Protein assay kit was purchased from Bio-Rad labs (Hercules, CA, USA).

Plant material and extract preparation

Individual vegetables, broccoli (B), *Rorripa* (R), Sio Pek (SP), Pa Po (PP), Pheuy leng (PL) and Choi Sum (CS) were collected over a 3 mo period from the local supermarkets (Table 1). *Rorripa* and watercress are used interchangeably through the current text. All individual varieties were placed on dry ice and freeze dried immediately to preserve freshness. All individual representative vegetable samples were then pooled, this being conducted to eliminate variation. Extracts were then prepared using the procedure detailed[23,24]. In brief, 100 mg of freeze-dried tissue was weighed into a 50 mL polypropylene tube, hydrated with 2.0 mL of deionised water and homogenized for 15 s (Ultraturrax homogeniser) and left at room temperature for 1 h with occasional vortexing. Boiling 700 mL/L methanol (3.0 mL) was added to the mix and incubated for a further 15 min at +70 °C. The mixture was cooled to room temperature, and centrifuged at 3 000 r/min for 5 min. After centrifugation 1 mL aliquots were removed and vacuum condensed to 200 μL volumes. The resultant concentrates were filtered through sterile non-pyrogenic filters (0.2 μm; Millipore) and stored at -70 °C prior to testing. Extracts gave an equivalent concentration of 100 mg/mL for each sample. All extracts were analyzed for their respective ITC composition using a Finnigan- LCQ LC-MS system using the method previously described.

Cell culture and treatments

Human HCT116 cells were obtained from the American Type Culture Collection (ATCC, Manassas, VA, USA). Cells were grown in complete DMEM (containing 100 mL/L FBS, 100 000 U/L penicillin, 100 mg/L streptomycin, pH 7.4) in 75/cm^2 culture flasks at 37 °C in 50 mL/L CO_2. HOCl concentration was quantified immediately before use spectrophotometrically at 290 nm (pH 12, ε = 350 mol/L/cm). HOCl was diluted in ice cold EBSS to a concentration of 10 mmoL/L and stored on ice for no longer than 1 min. To expose the cells to HOCl, cells were washed twice with PBS and once with EBSS warmed to 37 °C. Fresh EBSS was then added followed by oxidant addition as described. The addition of HOCl did not significantly alter the pH of the reaction mixture. Hydrogen peroxide-free peroxynitrite (ONOO-) was synthesized as described[24], respectively. ONOO- solution was quantified immediately before use using a molar absorption coefficient of 1670/cm/mol/L[5].

ABTS assay

This was carried out as described in Ref.[25] 2,2'-Azinobis[3-ethylbenzothiazoline-6-sulfonate] (ABTS) in water (7 mmol/L final concentration) was oxidized using potassium persulfate (2.45 mmol/L final concentration) for at least 12 h in the dark. The ABTS$^+$ solution was diluted to an absorbance of 0.8±0.05 at 734 nm (Beckman UV-VIS spectrophotometer, Model DU640B) with phosphate-buffered saline (PBS). Absorbance was measured every 1 min for 5 min after initial mixing of extracts of different concentrations or Trolox standard with 1 mL of ABTS$^+$ solution. Trolox was used as a reference standard. Antioxidant properties of extracts were expressed as Trolox equivalent antioxidant capacity (TEAC).

Ascorbate-iron induced lipid peroxidation

Peroxidation of bovine brain extract was performed as described[26]. Briefly, bovine brain extract (BBE, 100 mg) was dissolved with PBS, and sonicated in an ice bath until dissolved. The BBE (0.2 mL) was preincubated with vegetable extracts in the presence of PBS and $FeCl_3$ (1 mmol/L). Lipid peroxidation was initiated by adding ascorbate (1 mmol/L), and the mixture was then incubated

for 1 h at 37 °C. The reaction was stopped by adding butylated hydroxytoluene (2 g/L in 950 mL/L ethanol), followed by the addition of trichloroacetic acid (28 g/L) and 2-thiobarbituric acid (TBA, 1 g/L). The mixture was heated at 80 °C for 20 min in a water bath. The (TBA) 2-MDA (malondialdehyde) chromogen formed was measured at 532 nm after extraction into 1-butanol using a SpectraMax190 microplate reader (Molecular Devices). Results were expressed as percentages of control.

Scavenging of 2,2-diphenyl-1-picrylhydrazyl

Scavenging activity was determined as described in Ref.[27]. DPPH solution (200 µmol/L in 800 mL/L ethanol) was mixed with an equal volume of extracts, and the absorbance at 520 nm was measured after 20 min at room temperature using the microplate reader. Results were expressed as percentages of control (100%).

Assessment of pyrogallol red bleaching by peroxynitrite

Bleaching of PR was performed as described in Ref.[28], respectively. PR (100 µmol/L final concentration) was dissolved in K_2HPO_4-KH_2PO_4 buffer. Compounds to be tested were added into the PR solution and incubated at room temperature for 10 min; addition of ONOO- (200 µmol/L) or HOCl (125 µmol/L) followed and the mixture was vortexed immediately for 10 s. The decrease in absorbance at 542 nm was determined using a microplate reader.

Total phenolic content

Total phenolic content of extracts was assessed approximately by using the Folin-Ciocalteu phenol reagent as described in Ref.[29]. The extracts (100 µL) were mixed with the Folin-Ciocalteu phenol reagent (0.2 mL), water (2 mL), and Na_2CO_3 (15 g/L, 1 mL), and absorbance at 765 nm was measured 2 h after incubation at room temperature using the microplate reader specified above. Gallic acid was used as a reference standard, and the total phenolics were expressed as milligrams per milliliter of gallic acid equivalents (GAEs).

Determination of phase II enzymatic induction and cellular glutathione

Glutathione-S-transferase and quinone reductase activities were determined as previously described[30]. Reduced glutathione levels in HCT116 cells were determined using the procedure described[31]. The formation of the GSH-phthalaldehyde conjugate was measured fluorometrically (excited at a wavelength of 350 nm, and the fluorescence measured at 420 nm).

Statistical analysis

All statistical analysis of data was conducted using MINITAB version 10.1 software package. ANOVA analysis was performed to determine the variation within and between selected populations.

RESULTS

Total phenolic content

The amounts of total phenolics varied widely in the vegetable extracts evaluated, these ranging between 56.2 to 163.7 mg GAE/g dry weight material (Table 1). Among the vegetable extracts, Choi Sum (*B. chinensis var. parachinensis*) contained the highest total amount of phenolics (163.2 mg GAE/g), whereas lower levels were found in Pa Po (*B. chinensis*), broccoli (*Brassica oleracea. var. italica*), and Pheuy leng (*Amaranthus tricolor*), (65.7, 61.0, and 56.2, respectively).

An additional assay, pyrogallol red (PR) bleaching, was used as an initial screening for the protective effects of each vegetable extract (10 mg/mL concentration) against ONOO- and HOCl induced PR bleaching. As shown in Table 1, all extracts showed some degree in preventing both ONOO- and HOCl mediated bleaching.

Radical scavenging by Asian green leaf vegetable extracts

The antioxidant activities of each vegetable extract were determined using four different chemical assays, ABTS, DPPH, deoxyribose and iron ascorbate lipid peroxidation assay. All the methods have been extensively used for the screening of antiradical activities of fruit and vegetable juices and extracts.

The antioxidant properties of each individual vegetable extract are represented in Figure 1A and F. Extracts of each vegetable were examined and compared for their free radical scavenging activities against radical cation ABTS+. The ABTS assay has been widely used to determine the radical scavenging ability of both synthetic chemicals and plant extracts. All extracts showed ABTS+ scavenging capacity as determined by the reduction in absorbance at 734 nm, as previously reported (Figures 1A and B). In addition, comparison with the water soluble analog Trolox allowed us to determine the total antioxidant capacity TEAC value for each extract, none of the extracts were more effective than Trolox alone (Figure 1C). Likewise, as demonstrated in Figure 1D, all vegetable extracts showed antioxidant scavenging potential in the DPPH assay. In additional assays, we also examined the effects of extracts on hydroxyl radicals and lipid peroxidation (Figures 1E and F). Again all extracts showed some positive inhibition in each assay however, we were unable to show any correlation between phenolic acid content and scavenging ability. Kahkonen *et al.* and Shahidi *et al.* reported that differences in antioxidant activities of plant extracts are a likely result of differences in the types of phenolic acids and flavonoid compounds and their derivatives present with in the plant extracts[32,33]. For example, the antioxidant activities of phenolic acids and their esters are dependant on the number of hydroxy groups in the molecules. Perhaps such limitations are also apparent in our study.

Protection Against ONOO- and HOCl mediated cytotoxicity in HCT116 cells by asian green leaf vegetables

Incubating HCT116 colon cells in the presence of each vegetable extract (0.2-10 mg/mL extract) for 1 h did not result in any significant cytotoxicity measured using the MTT assay (data not shown) whereas the addition of 200 µmol/L ONOO- or 125 µmol/L HOCl led to

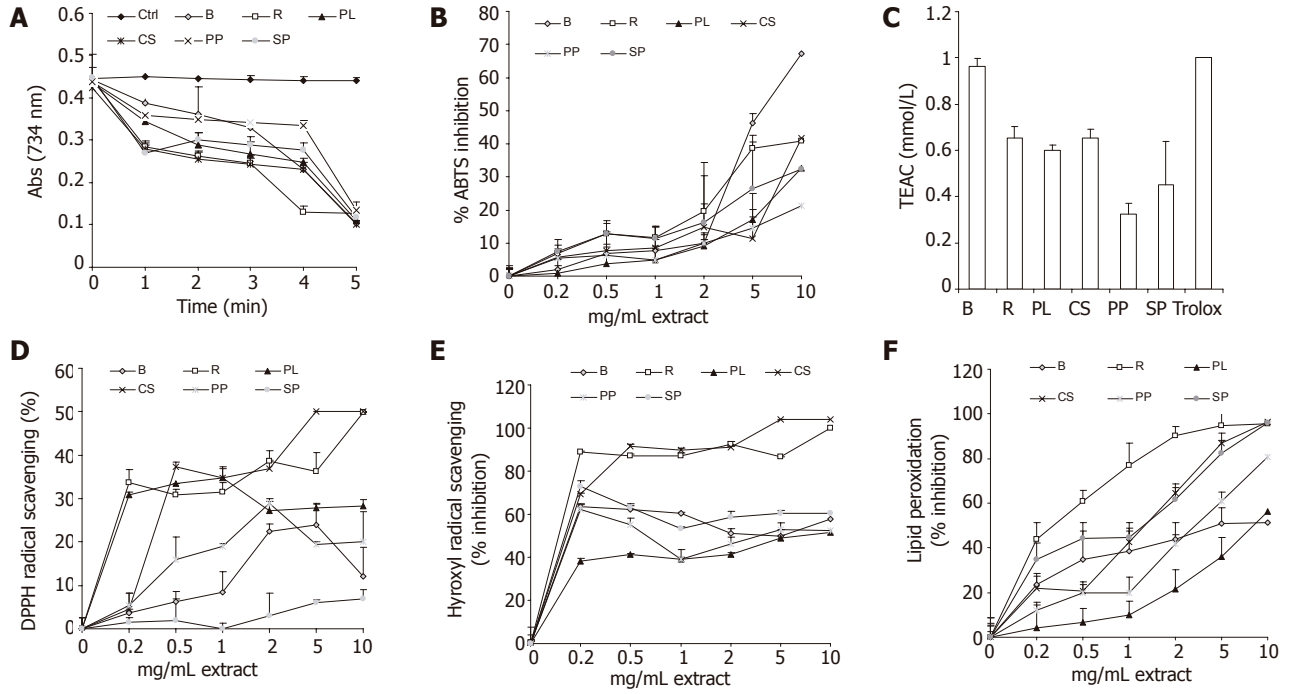

Figure 1 Kinetics of reactions of ABTS radicals in the presence of 10 mg/mL of each vegetable extract (**A**), (**B**) the effects of increased concentration of the vegetable extracts on the inhibition of the ABTS radical represented as % ABTS inhibition, (**C**) total antioxidant activity of extracts from green leaf vegetables as compared to trolox, (**D**) DPPH radical scavenging, (**E**) hydroxyl radical scavenging, and (**F**) iron-ascorbate induced lipid peroxidation. Values are presented as means±SD (n = 6).

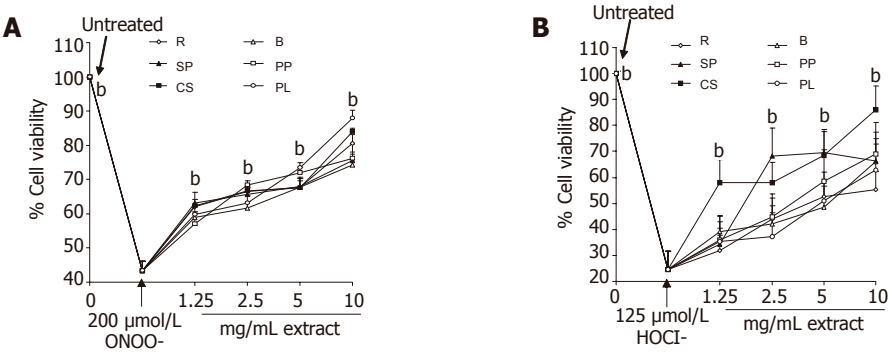

Figure 2 Concentration dependant inhibition of ONOO–- and HOCl mediated cytotoxicity by green leaf vegetable extracts. HCT116 cells were treated with each extract for 5 min and ONOO– or HOCl added. Cell viability was assayed using MTT and measurement of the solubilized formazan dye at Abs 595 nm. Experiments were conducted as described in Materials and methods and data are expressed as mean±SD (n = 6). ^{b}P<0.01 comparing extracts to ONOO– or HOCl treatment alone.

substantial decrease in viability (Figures 3A and B). All extracts significantly inhibited ONOO–- and HOCl mediated cytotoxicity in a concentration-dependent manner.

Induction of phase II detoxification enzymes by Asian green leaf vegetable extracts inhibits ONOO- and HOCl mediated cytotoxicity

The induction of phase II detoxification enzymes QR and GST varied widely among the vegetable extracts evaluated. As shown in Figures 3A and B, both the broccoli and watercress extracts, two species previously been shown as potent inducers of phase II enzymes, showed the most significant induction of QR and GST at 0.02-0.1 mg/mL extract in human HCT116 cells. In contrast, only extracts of Choi Sum (*B. chinensis var. parachinensis*) and Pheuy leng (*Amaranthus tricolor*), showed any potential in inducing QR and GSTs in the current study, all be it at a 10 fold higher concentration (0.1-10 mg/mL extract) than that of broccoli or watercress. Neither Pa Po (*B. chinensis var. parachinensis*) nor Sio Pek (*B. chinensis var. parachinensis*) showed any ability to induce QR or GST (Figure 3C and D). In addition, analysis of each vegetable extract using LC-MS, we were unable to find any putative ITCs present except in any extracts except for broccoli (4-methylsulfinylbutyl ITC) and *Rorripa* (7-methylsulfinylheptyl ITC), respectively. All LC-MS data corresponded to that previously published[23-24]. This may suggest that the other vegetable extracts did not contain any ITCs or that the levels were below the level of detection in our method (Figures 3E and F). To

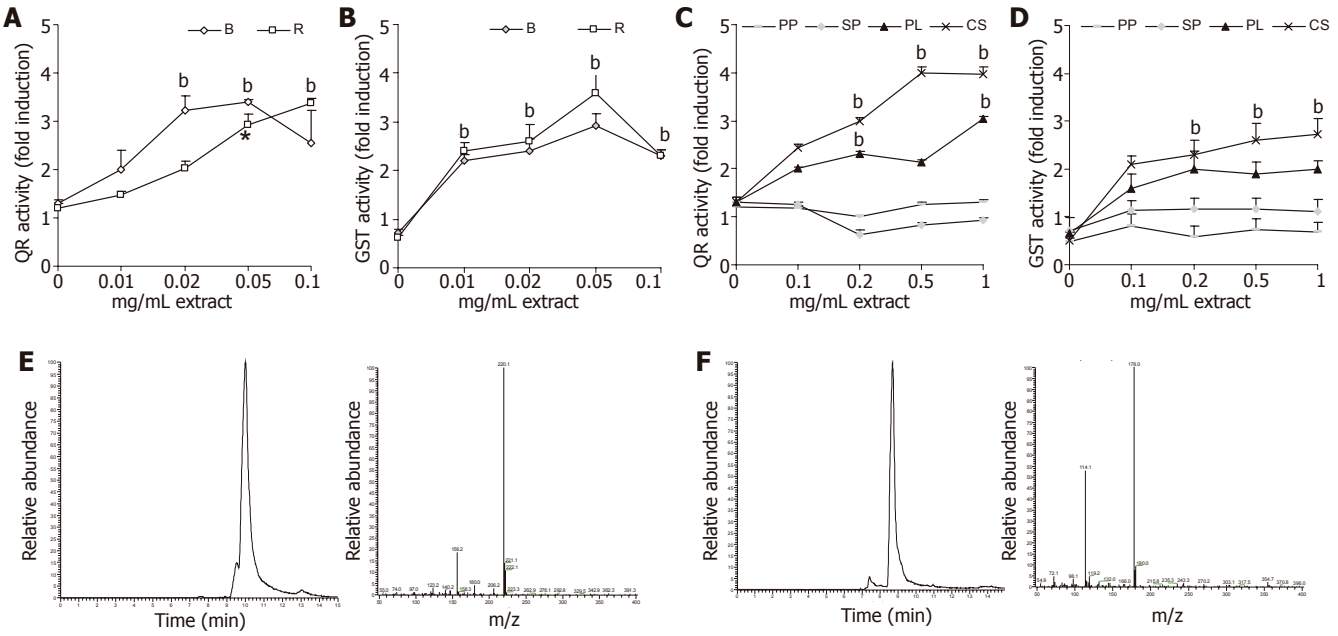

Figure 3 Effect of green vegetable extracts on QR and GST induction in the human colon HCT116 cell line. Cells were treated with each respective extract at 0.01-1 mg/mL (broccoli and *Rorripa*) and 1-10 mg/mL Choi Sum, Pa Po, Pheuy leng and Sio Pek for 24 h. (**A**) induction of QR and (**B**) GST induction by broccoli and *Rorripa*, (**C**) and (**D**) induction of QR and GST by Choi Sum, Pa Po, Pheuy leng and Sio Pek, (**E**) *Rorripa* ITC, 7-methylsulfinylheptyl ITC and (**F**) broccoli ITC, 4-methylsulfinylbutyl ITC as determined using LC-MS. Each data point represents the mean±SD for four separate experiments. $^{b}P<0.001$ *vs* the control cells.

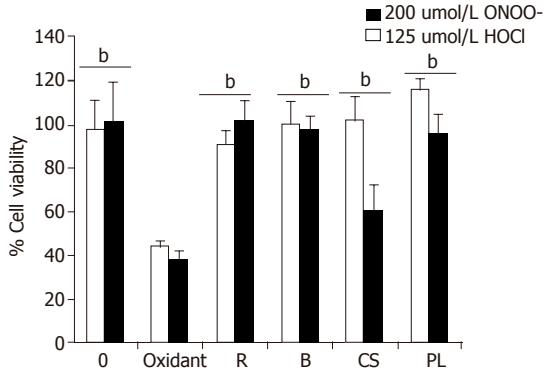

Figure 4 Protective effects of vegetable extracts on ONOO-- and HOCl mediated cytotoxicity in HCT116 cells. Cells were pre-treated with each extract for 24 h to induce phase II detoxification enzymes prior to the addition of ONOO- or HOCl for 30 min. Cell viability was assayed using MTT and measurement of the solubilized formazan dye at Abs 595 nm. Experiments were conducted as described in Materials and methods and data are expressed as mean±SD (n = 6). $^{b}P<0.001$ *vs* extracts to ONOO- or HOCl treatment alone.

examine whether the induction of phase II enzymes could protect against oxidative stress, human HCT116 cell were pre-incubated for 24 h with each respective extract at a concentration that induced a 2 fold induction of QR and GST [(0.01mg/mL) broccoli or *Rorripa* and 1 mg/mL for Pheuy leng, and Choi Sum)], respectively. Consequently, intracellular glutathione was determined prior to the addition of the oxidants ONOO- and HOCl. In all the treatment groups particularly broccoli, Rorripa and Choi Sum, intracellular GSH was elevated (Table 2). Moreover, pre-treated cells were more resistant against ONOO- and HOCl mediated toxicity (Figure 4A).

Table 2 Pre-treatment with green leaf vegetables increases intracellular glutathione levels in HCT116 cells. $^{b}P<0.01$ comparing treated to control cells (mean±SD).

Vegetable	Total GSH ($nmol^{-1}/mg^{-1}$protein)

Watercress "*Rorripa*"	33.2±2.7^{b}
Broccoli	28.7±0.5^{b}
Choi Sum	25.1±1.9^{b}
Pheuy leng	25.2±2.2^{b}

DISCUSSION

In the present investigation we evaluated green leaf vegetables that are commonly consumed in Singapore, this being a representative group of vegetables commonly consumed in the region. Recent epidemiological studies have highlighted a protective effect of vegetable consumption, particularly cruciferous vegetables, on colon cancer development[34-37]. Thus, knowledge of the antioxidant properties of local vegetables may partly explain their beneficial health effects.

The generation of $ONOO^{-}$ and HOCl *in vivo* is implicated in a wide range of human diseases ranging from cancer and cardiovascular diseases to chronic inflammation[12]. The *in vivo* formation of ONOO- in patients with colorectal cancer and a corresponding reduction in plasma antioxidant status has been reported[38]. While increased expression levels of inducible nitric oxide sythase and the formation of ONOO- is observed in patients with ulcerative colitis[39]. Similarly, HOCl produced by inflammatory phagocytic leukocytes reportedly contribute to gastrointestinal mucosal damage[40]. These data being suggestive that

oxidative stress contributes to the pathogenesis of colonic inflammation and cancers. Indeed, supplementation with antioxidants in numerous gastrointestinal model systems has been shown to reduce oxidant induced damage[41-45]. Therefore, agents that are able to protect against ONOO- and HOCl dependent damage may be particularly useful in the diet.

Till date, much is known about the dietary sources and antioxidant properties of vegetables commonly consumed in the Western diet however, much less is known about the antioxidant properties of green leaf vegetables consumed in Asia. In our study, we examined six local vegetables, five being members of the family Cruciferae, and an additional specimen being a spinach substitute used in the region, a member of the genus *Amaranthus* (Table 1). Analysis of total phenolic content using the Folin–Ciocalteu phenol reagent method showed considerable variation among the vegetables studied. Chye Sim had the highest total phenolic content (163.7±2.1 mg/g sample) whereas Pheuy leng had the lowest (56.2±3.0 mg/g sample). Dietary derived phenolic compounds like flavonoids, phenolic acids and condensed tannins are all reported to function as antioxidants. Indeed, in all the antioxidant assays used in the current study, PR bleaching, lipid peroxidation, ABTS, DPPH and hydroxyl radical scavenging; all vegetable extracts, to a varying degree, possessed antioxidant properties. Moreover, co-treatment of human colon cancer HCT116 cell line with individual vegetable extract inhibited both ONOO- and HOCl mediated toxicities in a concentration dependant manner. Several investigators have correlated the antioxidant potential of plant extracts with the content of individual compounds. As well as phenolic constituents many vegetables also contain fat-soluble vitamins and precursors, such as tocopherols and carotenoids, along with the water-soluble vitamin ascorbic acid that also poses antioxidant properties. Indeed, the antioxidant potential of Broccoli has been partially attributed to both flavonoid as well as hydroxycinnamic acid constituents[46]. Flavonoids along with other phenolic constituents are widely distributed in higher plants and exhibit diverse biological activities. For example, the antioxidant action of flavonoids in the GI tract could be mediated by the suppression of ROS formation either by inhibition of enzymes or chelating trace elements involved in free radical production, direct scavenging ROS or the upregulation of antioxidant defense system. Structure function analysis has revealed that the antioxidant properties are dependant upon the extent, type and position of functional group substitutions on the ring structures. In our study we were unable to find any correlation between the antioxidant potential of individual vegetable extracts and their total phenolic content. Our findings are in-agreement with that of Kurilich *et al.* 2002, who demonstrated that the antioxidant properties of different broccoli cultivars did not correlate with their respective ascorbic acid or flavonoid composition[47]. We propose that such discrepancies are a likely result of differences in the chemical composition of each vegetable and that such effects may influence the antioxidant properties as observed in the current study. Also, given that recent evidence suggests that many phenolic compounds such as flavonoids are not absorbed to any appreciable levels *in vivo*, perhaps the major site of action is in the lumen of the GI tract as has previously been suggested[48]. We assume that the observed variation in antioxidant properties and cytoprotective effects are perhaps due to the composition of phenolic compounds present in each vegetable, although this requires further study.

In contrast to direct antioxidant scavenging properties, a secondary mechanism that may protect against oxidative stress is the stimulation of cellular protective pathways. The co-ordinate induction of phase 2 detoxification enzymes provides protection against electrophilic and oxidant induced cellular damage. Interestingly, cruciferous vegetables contain phytochemicals known as glucosinolates that under the action of plant or bacterial myrosinases (thioglucoside glucohydrolase; EC 3.2.3.1) following tissue disruption, are converted to bioactive isothiocyanates (ITC)[49]. ITCs are potent inducers of phase II detoxification enzymes in mammals[23-52]. Indeed, induction of phase II enzymes by the ITC sulforaphane has recently been shown to protect human adult retinal pigment cells, epithelial keratinocytes and murine leukemia cells against oxidant induced damage[50]. Mechanistic studies have also indicated that, depending upon the specific structure of the ITC, these compounds can act at three stages of carcinogenesis. Firstly, they can prevent carcinogen activation through inhibition of phase I enzymes such as cytochrome P450s[51]. Secondly they can induce phase II enzymes such as quinone reductase (QR) [NAD(P)H: (quinone-acceptor) oxidoreductase, EC 1.6.99.2], glutathione S-transferases (GSTs) [EC 2.5.1.18] and UDP-glucuronosyltransferases [EC 2.4.1.17] , resulting ultimately in the excretion of the potential carcinogens[52]. Thirdly, they can induce apoptosis[53-56]. The putative anticarcinogenic activity of ITCs is consistent with the results of epidemiological studies, which have suggested a reduction in risk of cancer, particularly of the gastrointestinal tract, through the consumption of cruciferous vegetables[34,36]. In our, study, we found a 10 fold difference in the ability of the vegetables examined to induce both QR and GSTs in human colon HCT116 cells. Both broccoli and *Rorripa* were the strongest enzyme inducers, this previously being attributed to there ITC composition[23-24]. Of the local vegetables only Choi Sum and Pheuy leng induced any significant increase in QR and GST activity. We assume that such variation in phase II enzyme induction is likely to be a result of the composition and content of ITCs present within each vegetable. Jiao *et al.* 1998, previously demonstrated that considerable variation exists between local cruciferous asian vegetables (low ITC content) when compared to broccoli or *Rorripa* (High ITC content)[57]. Moreover, Hecht *et al.* 2004, also reported that cruciferous vegetables collected in Singapore contained high levels of glucobrassicins (70-90%) and relatively low levels of alkyl GSLs, the progenitor compounds of chemicals like sulforaphane[58]. Glucobrassicins, upon tissue disruption form indole-3-carbinols, these compounds have previously been shown to be poor inducers of phase II detoxification enzymes[59].

In summary, our data supports the finds that cruciferous vegetables can decrease *in vitro* and *in vivo* oxidant induced genotoxicity[60] by being potent source of antioxidants that may offer protection against oxidant induced damage in human beings. Moreover, we also found that the phase II enzyme inducing ability varied considerably among the vegetables analyzed, these data suggesting that biomarkers of exposure to cruciferous vegetables may be a more important inclusion into epidemiological studies than previously thought.

Abstract

AIM: To detect the common intestinal pathogenic bacteria quickly and accurately.

METHODS: A rapid (<3 h) experimental procedure was set up based upon the gene chip technology. Target genes were amplified and hybridized by oligonucleotide microarrays.

RESULTS: One hundred and seventy strains of bacteria in pure culture belonging to 11 genera were successfully discriminated under comparatively same conditions, and a series of specific hybridization maps corresponding to each kind of bacteria were obtained. When this method was applied to 26 divided cultures, 25 (96.2%) were identified.

CONCLUSION: *Salmonella sp*., *Escherichia coli*, *Shigella sp*., *Listeria monocytogenes*, *Vibrio parahaemolyticus*, *Staphylococcus aureus*, *Proteus* sp., *Bacillus cereus*, *Vibrio cholerae*, *Enterococcus faecalis*, *Yersinia enterocolitica*, and *Campylobacter jejuni* can be detected and identified by our microarrays. The accuracy, range, and discrimination power of this assay can be continually improved by adding further oligonucleotides to the arrays without any significant increase of complexity or cost.

INTRODUCTION

Intestinal pathogenic bacteria exert a great threat upon human health. It is still a challenge to detect and identify bacterial pathogens quickly and accurately from the samples. Since intestinal bacterial pathogens involve a wide range of genera and species, few existing methods can meet the requirement of quick and parallel detection of these bacterial pathogens. Classical diagnostic methods, including culture and biochemical identification, immunological assay, nucleotide probe hybridization, and PCR amplification, share a common shortcoming: only one or few kinds of bacteria can be identified in a complete cycle of experiment. These serial procedures are hard to use for quick and simultaneous detection of multiple pathogenic bacteria. To meet the demands of rapid and parallel detection and identification of many common pathogenic bacteria in one experiment, we present here a new approach based on the epoch-making gene-chip (microarray) technology.

Gene chip technology is based upon the reversed solid hybridization of oligonucleotides[1,2]. The major advantages of gene chip technology, including miniature, high performance, parallelism, automation, have expanded its application in this decade[3]. Since the efficacy of gene chip technology depends heavily upon the oligonucleotide probes, careful selection of target genes and wise design of oligonucleotide probes with variable kind, sequence and amount, are cardinal factors for a good gene chip. The target genes may be species-specific. For example, the pathogenic genes[4] can be easily identified by simple PCR. However, it is impractical to use different primers for different species in gene chip technology, especially in the case where a specimen of one or more possible bacteria is given. Either a complex PCR with a mixture of many primers or a series of PCRs performed in parallel or sequential are necessary to amplify the target genes. However, the time, complexity and expense of experiment will also increase. On the contrary, if a consensus gene among many pathogenic bacteria is chosen, a single pair of carefully designed universal primers may be used to amplify the conserved stretches of DNA, which are then detected and identified by the wisely designed oligonucleotide probes. The conserved consensus genes usually chosen by many researchers are 16S ribosomal DNA (rDNA),

Table 1 Standard strains used in the present study

Genus or species	Standard strain(s)[1]
Salmonella	50 001, 50 004, 50 009, 50 013, 50 014, 50 018, 50 019, 50 020, 50 021, 50 023, 50 029, 50 041, 50 042, 50 043, 50 047, 50 051, 50 073, 50 082, 50 083, 50 086, 50 093, 50 096, 50 098, 50 099, 50 100, 50 104, 50 105, 50 106, 50 109, 50 112, 50 115, 50 120, 50 124, 50 128, 50 145, 50 191, 50 200, 50 201, 50 220, 50 304, 50 306, 50 307, 50 309, 50 310, 50 313, 50 315, 50 320, 50 321, 50 322, 50 326, 50 327, 50 333, 50 335, 50 337, 50 338, 50 354, 50 355, 50 358, 50 360, 50 362, 50 402, 50 707, 50 708, 50 709, 50 710, 50 711, 50 712, 50 718, 50 719, 50 730, 50 731, 50 732, 50 733, 50 735, 50 736, 50 739, 50 746, 50 761, 50 774, 50 783, 50 825, 50 835, 50 846, 50 853, 50 854, 50 864, 50 913

[1]Except that one strain of Vibrio sp. was obtained from the Beijing Institute of Microbiology and Epidemiology, all other strains used in the present study were purchased from the National Center for Medical Culture Collection.

23S rDNA[5,6], 16S-23S rDNA spacer region[7], ERIC, while 16S rDNA[8] is the most popular one. Among the eubacterial 16S rDNA genes, the highly conserved sequences compose the constant regions, and the relatively less conserved sequences compose the variable regions, both interlace along the linear genes. Therefore, the pair of universal primers was carefully designed based upon the constant regions of 16S rDNA, so that they were capable of amplifying the 16S rDNA genes of all bacteria under certain circumstances. Meanwhile, the oligonucleotide probes were wisely designed based upon the variable regions of 16S rDNA at the species or genera level.

MATERIALS AND METHODS

Materials

The standard strains used in this study including a wide range of species and many of the common organisms causing intestinal disease are listed in Table 1. These organisms were identified by conventional methods.

Extraction of bacterial DNA from standard cultures

One colony from a fresh culture was resuspended in 100 μL distilled water in Eppendorf tubes. Then the tubes were transferred to a thermal cycler (Techgene, Techne Ltd.) and heated to 95 °C for 10 min. Finally, they were spun at 10 000 *g* for 1 min in a microcentrifuge, and 2 μL of the supernatant was used in PCR described below.

Sample preparation

Strains divided from Hai River, Luan River, municipal sewage, and food samples from markets were used in this study. All the divided strains were identified by conventional methods and the VITEK test system (BioMerieux SA, France). Extraction of DNA from divided bacterial cultures was performed as above.

Design of primers to amply bacterial 16S rDNA

We downloaded 113 bacterial 16S rDNA sequences from the GenBank database. Then, we used the program ClustalW alignment of the software MacVector 6.5.1 to analyze these sequences and showed the conserved regions of 16S rDNA. The primers were based on the conserved regions 8 and 10 of the 16S rDNA. The sequences of forward primer 1169U20 (5'-AACTGGAGGAAGGTGGGGAT) and reverse primer 1521L19 (5'-AGGAGGTGATCCAACCGCA) were used to amply bacterial 16S rDNA. The forward primer 1169U20 was labeled with 5'-Cy3 fluorescence.

Design of primers to amply specific pathogenic genes of Salmonella and Shigella

Sequences of forward primer invA-139 (5'-GTGAAA TTATCGCCACGTTCGGGCAA) and reverse primer invA-141 (5'-TCATCGCACCGTCAAAGGAACC) were used to amplify the invA gene of *Salmonella*. Sequences of forward primer virA-1 (5'-CTGCATTCTGGCAATCTC TTCACATC) and reverse primer virA-2 (5'-TGATGAG CTAACTTCGTAAGCCCTCC) were used to amplify the virA gene of *Shigella*. The forward primers invA-139 and virA-1 were labeled with 5'-Cy3 fluorescence.

PCR amplification to get hybridization targets

Each 50 μL reaction contained 33 μL sterile water, 5 μL 10 ×buffer (Takara Biotechnology Co., Ltd.), 2 μL supernatant from the extraction of bacterial DNA, 200 μmol/L dNTP mixture (Takara), 0.02 U/μL Takara Taq (Takara, 5 U/mL) and 0.1 μmol/L each primer (1169U20, 1521L19, invA-139, invA-141, virA-1, and virA-2). The PCR mixtures were subjected to 95 °C for 5 min, followed by 35 cycles at 94 °C for 25 s, at 55 °C for 30 s, and at 72 °C for 25 s. The PCR products were checked using 2% agarose electrophoresis and visualized with ethidium bromide staining.

Making oligonucleotide microarrays

All the oligonucleotide probes were chosen based on the variable regions between PCR primers using the alignment information. They were synthesized and modified with

3'-NH_2 in order to increase their binding to the glass slide surface and their hybridization intensity.

Before use, the glass slides for microscopy must be cleaned as described by Brown (http://cmgm.stanford.edu/pbrown/protocols.html). Then the oligonucleotide probes were bound to the slides as follows: 5 μL of 50 μmol/L oligonucleotide drop was spotted on the glass slide by an arrayer (PixSys 5500 Workstation, Cartesian Technologies), 5 mm between each oligonucleotide spot. When all the oligonucleotide probes were applied, the glass slides were left at room temperature for 24 h to permit thorough drying of the DNA on the slide surface. After drying, the slides were washed twice in 0.2% SDS for 5 min each and twice in distilled water for 5 min each. Subsequently, the slides were washed in sodium borohydride solution (1.3 g Na_2BH_4 was dissolved in 375 mL phosphate buffered saline, and then 125 mL pure ethanol was added) for 5 min, in 0.2% SDS for 2 min, and twice in distilled water for 2 min each.

Hybridization

The fluorescent-labeled amplicons were hybridized to the oligonucleotide microarrays using the following protocol: 1 μL of amplicons was added into a tube containing 4 μL hybridization solution (UniHyb™, TeleChem International, Inc.), and the tube was heated to 95 °C for 10 min and was put on ice immediately. Mixture in the tube was then transferred onto the microarray, kept at 50 °C for 1 h in a hybridization cassette (TeleChem International, Inc.). After hybridization, unbound fluorescent amplicons were washed with washing buffer A (1×SSC+0.2% SDS) for 1 min, B (0.1×SSC+0.2% SDS) for 1 min, C (0.1×SSC) for 1 min, respectively.

Scanning the microarray for fluorescent signals

We used the ScanArray 3000 (GSI Lumonics) to scan the area of the slide containing the microarray. The laser power and PMT were set at 80%.

Scoring hybridization results

The resolution of the ScanArray 3000 scanner is 10 μm, and the fluorescent density of each pixel is saved into the TIFF image file, facilitating further process and analysis of software. We uploaded the scanned image TIFF file into the ImaGene 4.0 software (BioDiscovery) to examine each feature for fluorescence intensity.

RESULTS

Under the same conditions for PCR amplification and hybridization, all the 170 strains produced PCR products, showing bands at approximately 370 bp, being equivalent to the fragment of 16s rDNA. Besides, strains belonging to *Salmonella* sp. produced another band of 285 bp, and strains belonging to *Shigella* sp. produced a 215-bp band. After the hybridization between PCR products and oligonucleotide probes, respective hybridization maps were built through the signal acquisition step using the ScanArray 3000 scanner. The original images generated by ScanArray 3000 scanner are shown in Figure 1. Monochrome fluorescent signals were mapped into pseudocolor spectrum according to their density in ascending order, e.g. black, dark blue, blue, green, yellow, red, white. Twelve typical hybridization maps corresponded to nine genera or species of bacteria, specifically.

The wisely designed oligonucleotide probes could be classified by their efficacy into six categories (Table 2).

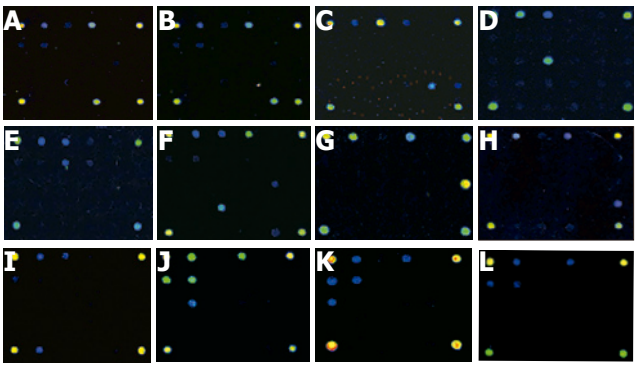

Figure 1 Typical hybridization results from *Vibrio parahaemolyticus* (**A**), *Yersinia enterocolitica* (**B**), *Listeria monocytogenes* (**C**), *Bacillus cereus* (D), *Staphylococcus aureus* (**E**), *Proteus sp.* (**F**), *Campylobacter jejuni* (**G**), *Vibrio cholerae* (**H**), *Enterococcus faecalis* (**I**), *Salmonella sp.* (**J**), *Shigella sp.* (**K**) and *Escherichia coli* (**L**).

[1]Negative control (3×SSC).

Figure 2 Layout of oligonucleotide probes.

Category one, including oligonucleotide probe 1, a universal probe targeting the portion of 16S rDNA shared by all known eubacteria, was used to detect all kinds of known eubacteria. Category two, including oligonucleotide probes 2 and 3, the specific probes targeting the portion of 16S rDNA shared by both Gram-positive (G^+) and negative (G^-) bacteria, was used to distinguish between G^+ and G^- bacteria. Category three, including oligonucleotide probes 4 and 5, targeting the portion of 16S rDNA shared by all enteric bacteria, was used to identify intestinal bacteria at the family level. Category four, including oligonucleotide probes 6, 7, 9, 11, and 15-28, a cluster of genus or species-specific probes targeting the portion of 16S rDNA shared by their respective bacteria, was used to identify bacteria at genus or species level. Category five, including oligonucleotide probes 31 and 32, targeting the portion of the specific pathogenic genes of *Shigella* and *Salmonella*, was used to discriminate between bacteria of these two genera. Category six, including oligonucleotide probe 30, a positive control probe, was used both as a gauge to reflect the effectiveness of this hybridization system and as a reference coordinate for scanning. From hybridization signals of the five categories of oligonucleotide probes, it was easy to identify the target pathogenic bacteria in a given specimen. For instance, strong hybridization signals at the sites corresponding to the oligonucleotide probes 1, 3, and 23 were found, so the pathogenic bacteria in the given specimen could be sequentially identified as eubacteria, G^- bacteria, and strains of *Vibrio parahaemolyticus* (Figure 1G). Some slightly weaker signals due to unspecific hybridization were also found. By means of multiple experiments, a hybridization signal was regarded as a specific signal if it meets the following criterion: the foreground fluorescent signal at an oligonucleotide probe spot was stronger than its background fluorescent signal with a signal-noise ratio larger than 100 calculated by ImaGene 4.0. Since the fluorescent signals of specific hybridization were three-fold stronger compared to those of unspecific hybridization, it was easy to identify the specific hybridization signals from the hybridization maps directly (Figure 2).

Twenty-six unselected divided cultures were also processed and hybridized as described above, and then identified according to the specific hybridization maps (Table 3). Among them, 25 strains were distinguished according to their hybridization maps, but only one strain was indistinguishable due to its weak signal. The comprehensive identification results by classical methods were regarded as the final standards. Except for sample 7, all other results were consistent with those detected by hybridization assay and conventional method, the consistency was 96.2% (25/26).

DISCUSSION

Our study showed that the gene chip-based method could identify a wide range of intestinal pathogenic bacterial species. The genus or species specific probes on the microarray are targeted at the 16S rDNA, while two discriminative probes are targeted at special pathogenic genes. Sample DNA was labeled with fluorescence by PCR, then hybridized to the probes on the chip, thus a couple of genus or species-specific hybridization patterns could be generated and used to discriminate the bacteria[9].

When the oligonucleotide probes for 16S rDNA were designed, we preferred a longer oligonucleotide segment with multiple mutation sites over a shorter one, which is also suitable for detecting single-nucleotide mutation[10-12]. The advantages are obvious: the amount of essential oligonucleotides is less, the cost of experiment is lower, and the identification of hybridization map is easier. However, the shortcoming is somewhat less discriminative to those sequences where only minor differences are present.

The 16S rDNA sequences of *Shigella*, *Salmonella,* and *Escherichia coli* are similar, and share almost identical sequences of the target 16S rDNA genes. Thus, these three genera can hardly be identified by only 16S rDNA[13,14].

Besides, intestinal pathogenic bacteria belonging to *Listeria monocytogenes*, *Vibrio parahaemolyticus*, *Proteus* sp., *Vibrio cholerae*, *Enterococcus faecalis*, *Yersinia enterocolitica,* and *Campylobacter jejuni*, could be detected and identified using the gene chip.

Compared to the classic microbial assay, immunological assay, PCR-based assay, the method based upon the gene chip technology could detect and identify a given strain of bacterium within 3 h. It is a fundamental start point to develop other methods for a large-scale assay. The target spectrum of this gene chip may be gradually expanded

[1]The results from hybridization assay and conventional methods are consistent. [2]The results are inconsistent. [3]No signal was detected.

by adding newly designed oligonucleotide probes into the oligonucleotide microarray, and the accuracy may also be improved by increasing and readjusting the oligonucleotide probes in the oligonucleotide microarray. The arrangement of the oligonucleotide microarray may be rearranged according to its end usage. This method for intestinal pathogen assay using gene chip technology can be used for the diagnosis of infectious diseases, environmental supervision, food quality surveillance, etc.

Abstract

AIM: To study the morphological and serum hyaluronic acid (HA), laminin (LN), and type IV collagen changes in hepatic fibrosis of rats induced by dimethylnitrosamine (DMN).

METHODS: The rat model of liver fibrosis was induced by DMN. Serum HA, type IV collagen, and LN were measured by ELISA. The liver/weight index and morphological changes were examined under electron microscope on d 7, 14, 21, and 28 by immunohistochemical alpha smooth muscle actin α-SMA staining as well as Sirius-red and HE staining.

RESULTS: The levels of serum HA, type IV collagen and LN significantly increased from d 7 to d 28 (P = 0.043). The liver/weight index increased on d 7 and decreased on d 28. In the model group, the rat liver stained with HE and Sirius-red showed evident hemorrhage and necrosis in the central vein of hepatic 10 lobules on d 7. Thin fibrotic septa were formed joining central areas of the liver on d 14. The number of α-SMA positive cells was markedly increased in the model group. Transitional hepatic stellate cells were observed under electron microscope. All rats in the model group showed micronodular fibrosis in the hepatic parenchyma and a network of α-SMA positive cells. Typical myofibroblasts were embedded in the core of a fibrous septum. Compared to the control group, the area-density percentage of collagen fibrosis and pathologic grading were significantly different in the model group (P<0.05) on different d (7, 14, and 28). The area-density percentage of collagen fibrosis in hepatic tissue had a positive correlation with the levels of serum HA, LN, and type IV collagen.

CONCLUSION: The morphological and serum HA, type IV collagen, and LN are changed in DMN-induced liver fibrosis in rats.

INTRODUCTION

In China, the incidence of liver cirrhosis is still high[1]. Hepatic cirrhosis results from fibrosis[2-4]. Many factors can lead to chronic liver disease and hepatic fibrosis[5-9]. Hepatic fibrosis is associated with a number of morphological and biochemical changes leading to structural and metabolic abnormalities in the liver. Hepatic stellate cells (HSCs) play a major role in various types of liver fibrosis through initial myofibroblast transformation. Transformed HSCs can actively synthesize extracellular matrix and then change morphology and function of the liver. Dimethylnitrosamine (DMN)-induced hepatic fibrosis in rats appears to be a good and reproducible model with decompensating features of human disease[10,11]. This study was to observe the morphological and serum hyaluronic acid (HA), laminin (LN), and type IV collagen changes in DMN-induced hepatic fibrosis of rats.

MATERIALS AND METHODS

Animals and experiment protocol

Male Wistar rats weighing 175-200 g were obtained from the Experimental Animal Center of Yanbian University College of Medicine. The rats were divided into two groups. The model group (n = 40) received 1% DMN (10 μL/kg

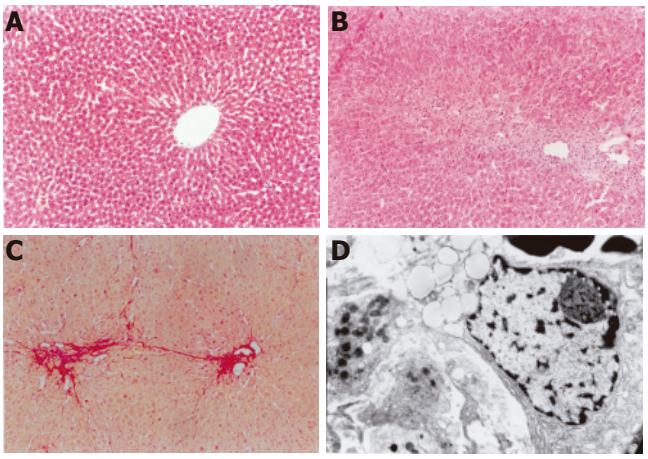

Figure 1 Changes after DMN treatment. **A:** Livers in the control group showed normal lobular architecture with central veins; **B:** after 7 d of DMN treatment, extensive necrosis was observed in portal areas; **C:** after 14 d of DMN treatment, thin fibrotic septa were formed joining central areas; **D:** after 21 or 28 d of DMN treatment, thick intralobular septa were evident.

body weight, i.p.) thrice a week for 4 wk, while the control group (n = 12) received an equivalent amount of saline. The animals were killed on d 7, 14, 21, and 28 (10 treated with DMN at each time interval). Blood was taken from the left ventricle. Serum samples obtained from all study subjects were frozen at -70 °C and aliquots were thawed when needed for specific tests. The liver was examined by light and electron microscopy.

Serum HA, type IV collagen, and LN levels testing

A quantitative ELISA was used to determine serum HA, type IV collagen, and LN levels according to the manufacturer's instructions.

Sirius-red and HE staining

Formalin-fixed tissues were paraffin-embedded and cut into 4-μm thick sections from the right lobe of rat's liver for HE and Sirius-red staining. HE staining was used to observe liver pathologic structures, Sirius-red staining was used to grade liver fibrosis from 0 to 4[16]: grade 0 = no fibrosis, grade 1 = portal area fibrosis, grade 2 = fibrotic septa between portal tracts, grade 3 = fibrosis septa and structure disturbance of hepatic lobule, grade 4 = cirrhosis. At the same time, Sirius-red staining and CMIAS image analysis system (Beijing, China) were used to determine the area-density percentage of collagen fibrosis in hepatic tissue. At least five high-power (×400 field) fields were chosen and positive collagen fibrosis (red staining) was determined. Area-density percentage of collagen fibrosis was calculated by dividing the number of positive collagen fibroses (positive optical density) over the total number of collagen fibroses (integrated optical density).

Immunohistochemical staining

α-SMA for the detection of activated HSCs was studied by immunohistochemical staining. Sections (5-μm) were deparaffinized, rehydrated and incubated with 0.3% hydrogen peroxidase in methanol for 15 min at room temperature to block endogenous peroxidase activity. After being washed twice with phosphate-buffered saline (PBS) for 5 min, tissue sections were incubated at 37 °C for 20 min with blocking solution, then incubated at 37 °C for 2 h with rabbit anti-rat α-SMA antibody (Dako, Denmark) at dilution 1:100. After being washed twice with PBS (0.01 mol/L, PH 7.4) for 10 min, tissue sections were incubated at 37 °C for 30 min with biotin-anti-rabbit IgG. After being washed twice with PBS for 5 min, the sections were incubated with streptavidin-HRP for 30 min. Then the sections were washed twice with PBS for 5 min and incubated with metal-enhanced 3, 3-diaminobenzidine solution for 15 min, washed twice in distilled waster and counterstained with hematoxylin. Negative control sections were incubated with normal rabbit serum instead of primary antibody. The positive staining for α-SMA positive cells was expressed as red brown granules and photomicrographed (Olympus PM-10AD).

Electron microscopy

Fresh fragments of 1 mm^3 liver tissue were fixed in 10% paraffin, dehydrated and embedded in Epon-812 resin. Sections were stained with uranyl acetate for 15 min and then lead citrate for 15 min. Transitional HSCs were observed under JEM-1200EX, 80 kV electron microscope (JEOL, Japan).

Statistical analysis

Data were expressed as mean±SD. The two-tailed χ^2 test was used to examine the correlation between the area-density percentage of collagen fibrosis in hepatic tissue and serum HA, LN, and type IV collagen levels. Statistical significance was estimated by t-test. $P<0.05$ was considered statistically significant. All calculations were made by SPSS 11.0 for Windows.

RESULTS

Serum HA, type IV collagen, and LN levels change

When compared to control values, a significant increase ($P<0.05$) was observed in serum levels of HA, LN, and type IV collagen on d 7, 14, 21, and 28 after administration of DMN. The maximum increase in serum levels of HA, LN, and type IV collagen was observed on d 28 after DMN treatment (Figure 3).

Change in the weight of body and liver as well as liver and body ratio

An increase in liver weight was observed on d 7 after DMN treatment, with a decreased liver weight on d 28. The maximum liver and body weight ratio increased on d 14 and decreased on d 28 (Table 1).

Changes after DMN treatment

The rat liver stained with Sirius-red and HE showed an extensive accumulation of collagens. Fibrotic septum increased from port to port and from port to central

vein in some parts of lobules. The livers of the rats in the control group showed normal lobular architecture with central veins and radiating hepatic cords (Figure 1A). After 7 d of DMN treatment, extensive necrosis occurred in portal area and hemorrhage was prominent (Figure 1B). After 14 d, hemorrhagic necrosis and formation of thin fibrotic septa joining central areas were found (Figure 1C). After 21 d, thick intralobular septa were evident (Figure 1D). After 28 d, the pattern was similar with that after 21 d. At the same time, fibrotic septum increased the area-density percentage of collagen fibrosis in hepatic fibrosis. Compared to control values, a significant increase ($P<0.05$) was observed in area-density percentage of collagen fibrosis on d 7, 14, 21, and 28 after administration of DMN. The maximum increase in the levels of the area-density percentage of collagen fibrosis was observed on d 28 after DMN treatment (Figure 2). Liver fibrosis was graded from 0 to 4 (Table 2)

Distribution of α-SMA positive cells

Activated HSCs characterized by the expression of α-SMA increased in the liver of rats that received DMN. The distribution of α-SMA positive cells was similar to that of collagen in the liver. After 14 d, linear immunoreaction for α-SMA was scattered along the sinusoidal wall (Figure 4A). After 21 d, a network of α-SMA cells was evident (Figure 4B). After 28 d, a dense network of α-SMA cells was evident (Figure 4C). Transitional HSCs were observed under electron microscope, showing features of lipid-containing myofibroblasts and bundles of connective tissue after 14 d of DMN treatment (Figure 4D). Typical myofibroblasts were embedded in the core of fibrous septa after 21–28 d of DMN treatment. The elongated cell body contained a nucleus and numerous microfilaments outlined by a lamina-like structure. Collagen fibers of variable size were seen around the myofibroblasts (Figure 4E).

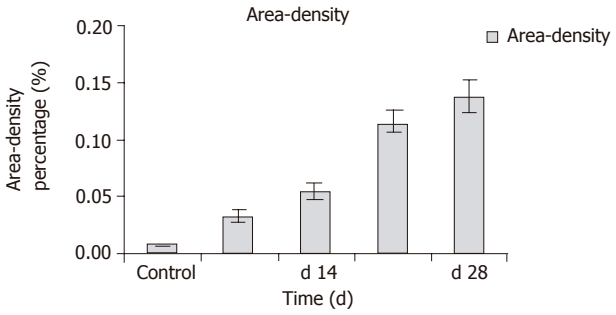

Figure 2 Area–density percentage of collagen fibrosis in hepatic tissue. *P*<0.05 *vs* control; *P*<0.05 *vs* d 7.

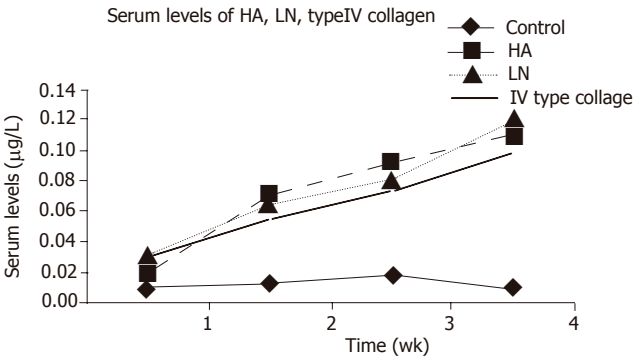

Figure 3 Serum levels of HA, LN, and Type IV collagen in DMN-induced fibrosis of rats and control, *P*<0.05 *vs* control.

Relationship between area-density percentage of collagen fibrosis and serum HA, type IV collagen, and LN levels

A positive correlation ($r = 0.707$, $P<0.01$) was noticed between the area-density percentage of collagen fibrosis and serum levels of HA, LN, and type IV collagen during the course of DMN administration.

DISCUSSION

Liver fibrosis is common in most chronic liver diseases regardless of their etiology[12-15]. The incidence rate of chronic liver disease in China is high[16]. Hepatic fibrosis is the intermediate and crucial stage of cirrhosis. If treated properly in this stage, cirrhosis could be successfully prevented[17], but it remains a problem to prevent cirrhosis or to control its progression in patients with chronic liver disease[18]. HSCs play a central role in the pathogenesis of liver fibrosis. After liver injury, HSCs become activated and express a wide variety of extracellular matrixes. It was reported that hepatic fibrosis is induced in rats by low doses of DMN and morphological changes of hepatic fibrosis are associated with cells bearing 'transitional' features of HSCs, myofibroblasts and fibroblasts[19]. Activated but not quiescent HSCs have a high level of collagen and express α-SMA. HSCs play a key role in the pathogenesis of hepatic fibrosis[20]. To evaluate the distribution of α-SMA positive cells in various liver diseases, Yu *et al*.[21] undertook an immunohistochemical

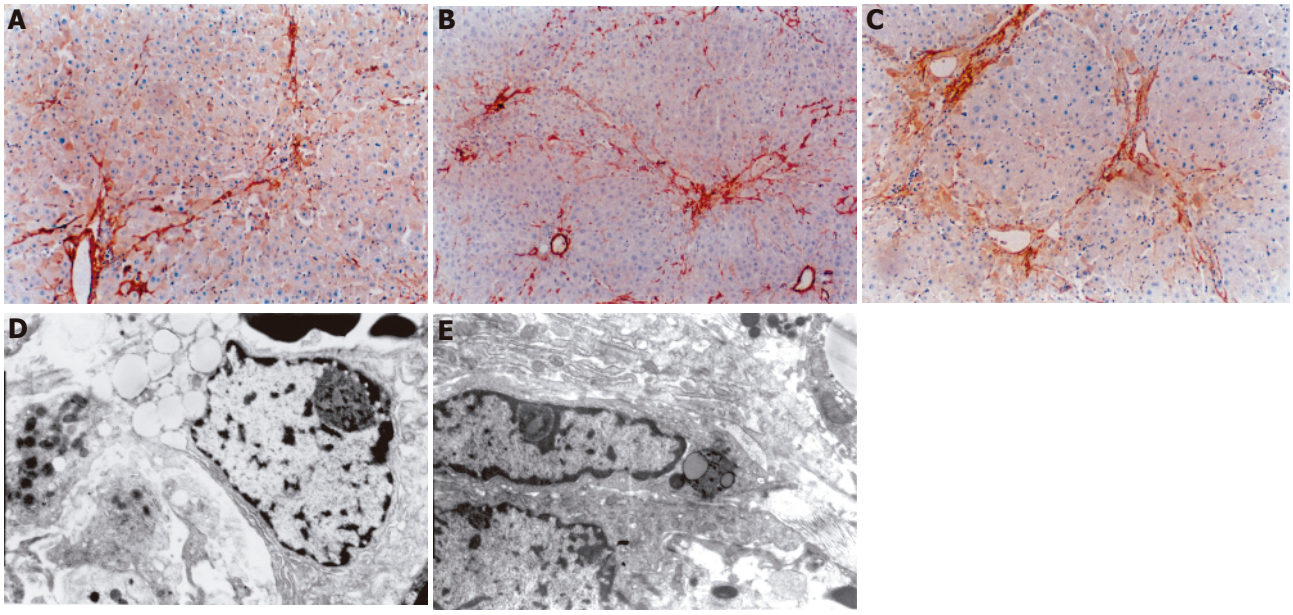

Figure 4 Distribution of α-SMA positive cells after DMN treatment. **A:** After 14 d, linear immunoreaction for α-SMA was scattered along the sinusoidal wall; **B:** after 21 d, a network of α-SMA cells was evident; **C:** after 28 d, a dense network of α-SMA cells was evident; **D:** after 14 d, transitional hepatic stellate cells were observed under electron microscope; **E:** after 21 or 28 d, typical myofibroblasts were embedded in the core of fibrous septa.

study of liver diseases including chronic persistent hepatitis, chronic active hepatitis, liver cirrhosis, intrahepatic cholelithiasis and hepatocellular carcinoma, and found that expression of α-SMA may be related to the fibrotic process[22]. DMN-induced experimental model may contribute to the understanding of the relationship between liver injury and hepatic fibrosis[23] and is used to detect different degrees of hepatic fibrosis[24,25]. In our study, serum levels of HA, LN, and type IV collagen increased significantly in hepatic fibrosis, suggesting that detection of HA, LN, and type IV collagen level is an optimal choice[26]. In this study, a positive correlation was noticed between the area-density percentage of collagen fibrosis and serum levels of LN, HA, and type IV collagen during the course of DMN administration, indicating that DMN is a potent hepatotoxin that can cause fibrosis of the liver. DMN can be administered to adult male albino rats in order to document sequential pathological and biochemical alterations[27].

In conclusion, HSCs play a central role in the pathogenesis of liver fibrosis and can regulate degradation of matrix in the liver.

Abstract

AIM: To assess the management and outcome of hilar cholangiocarcinoma (Klatskin tumor) in a single tertiary referral center.

METHODS: The notes of all patients with a diagnosis of hilar cholangiocarcinoma referred to our unit for over an 8-year period were identified and retrospectively reviewed. Presentation, management and outcome were assessed.

RESULTS: Seventy-five patients were identified. The median age was 64 years (range 34-84 years). Male to female ratio was 1:1. Eighty-nine percent of patients presented with jaundice. Most patients referred were under Bismuth classification 3a, 3b or 4. Seventy patients required biliary drainage, 65 patients required 152 percutaneous drainage procedures, and 25 had other complications. Forty-one patients had 51 endoscopic drainage procedures performed (15 failed). Of these, 36 subsequently required percutaneous drainage. The median number of drainage procedures for all patients was three, 18 patients underwent resection (24%), nine had major complications and three died post-operatively. The 5-year survival rate was 4.2% for all patients, 21% for resected patients and 0% for those who did not undergo resection (P = 0.0021). The median number of admissions after diagnosis in resected patients was two and three in non-resected patients (P<0.05). Twelve patients had external-beam radiotherapy, seven brachytherapy, and eight chemotherapy. There was no significant benefit in terms of survival (P = 0.46) or hospital admissions.

CONCLUSION: Resection increases survival but carries the risk of significant morbidity and mortality. Percutaneous biliary drainage is almost always necessary and endoscopic drainage should be avoided if possible.

INTRODUCTION

Cholangiocarcinoma is a relatively rare tumor, accounting for approximately 2% of all diagnosed cancers. Its prevalence in England and Wales is approximately 2.0/100 000; however, the mortality rate has risen sharply in the past 30 years[1]. Upper third or perihilar (Klatskin) tumors make up 40-60% of cases[2,3] and are the main subjects of this paper. Klatskin tumors may be categorized as suggested by Bismuth classification into:

- Type I: tumors below the bifurcation of the common hepatic duct;
- Type II: tumors involving the bifurcation, but not extending into the main right or left duct;
- Type III: tumors infiltrating the right (IIIa) or the left (IIIb) hepatic duct;
- Type IV: tumors involving both the right and left hepatic ducts.

Cholangiocarcinoma is a slowly growing tumor and tends to spread longitudinally along the bile ducts with neural, perineural, and subepithelial extensions[4]. Lymph node invasion, particularly to the portal and peripancreatic regions, can be found in 46% of patients at the time of diagnosis[5]. Blood-born metastasis is rare and occurs at later stages of the disease. The prognosis for patients with unresectable tumors is poor and the majority of them die within 6 mo to a year of diagnosis[3].

Most patients present with obstructive jaundice. Preoperative investigations help establish the cause of obstruction, determine the extent of local disease and any evidence of distant metastasis, and evaluate the hepatic vasculature.

Treatment options for Klatskin tumors may be primarily surgical - either curative resection or palliative bypass, or non-surgical using modalities such as chemotherapy,

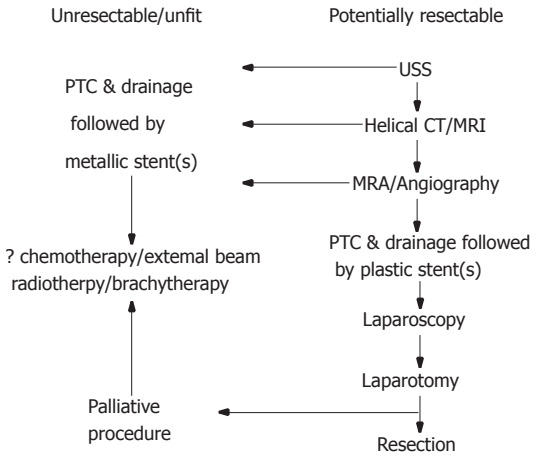

Figure 1 Flow chart demonstrating management options for hilar cholangiocarcinoma. USS, ultrasound scan; CT, computed tomography; MRI, magnetic resonance imaging; MRA, magnetic resonance angiography; PTC, percutaneous transhepatic cholangiography.

radiotherapy (external or endoluminal), a combination of the two or more recently photodynamic therapy and gene therapy. The use of biliary endoprosthesis is common either as the primary modality in palliation or for relieving jaundice or sepsis prior to more definitive treatment.

The aim of our study was to assess the management and outcome of hilar cholangiocarcinoma in a single tertiary referral center in the United Kingdom.

MATERIALS AND METHODS

Patients

Our unit is a cancer center recognized for the treatment of hepatobiliary malignancy and covers a population of approximately 3.5 million people across the North of England. The notes of all patients with hilar cholangiocarcinoma presenting to our unit during an 8-year period from June 1995 to June 2003 were identified and assessed retrospectively. Seventy-five patients were identified. Male to female ratio was 1:1 with a median age of 64 years (range 34-84 years). Thirty-seven patients had confirmed histological diagnoses with the remainder being diagnosed on strong radiological evidence. In each case, tumors were categorized using the Bismuth classification. A schematic representation for the treatment of these patients is shown in Figure 1.

Investigations

All patients were assessed using triple phase helical CT or magnetic resonance imaging. Scans performed at referring hospitals were repeated, if deemed to be of insufficient quality. Vascular involvement of hilar vessels by tumors was assessed using magnetic resonance angiography (MRA) or transfemoral angiography if MRA could not be performed or was inadequate for accurate assessment. No percutaneous or endoscopic cholangiography was performed for purely diagnostic reasons. Further imaging and laparoscopic assessment were performed if clinically indicated. Staging procedures were completed, wherever possible, before biliary drainage.

Biliary drainage

It is our policy, to drain all obstructed segments of the bile ducts in all jaundiced patients with hilar cholangiocarcinoma wherever possible. Many patients referred from other units attempted endoscopic stenting of hilar strictures. In our experience, this is often inadequate and therefore staged percutaneous drainage was performed in the majority of cases with the initial placement of internal/external or external biliary catheters being followed by the placement of single or multiple stents. When the possibility of resection was excluded, self-expanding metallic stents were used, otherwise plastic stents were inserted.

Surgical procedures

Tumors were deemed to be unresectable on pre-operative staging in the presence of extra-hepatic metastases, occlusion of main hepatic vessels, or bilateral invasion of secondary biliary radicals into the liver parenchyma. On laparotomy or laparoscopic assessment, evidence of extensive lymph node involvement and peritoneal deposits were also taken to indicate unresectability. Curative resections involved complete removal of all gross and microscopic diseases to achieve negative histological margins with eradication of all metastatic lymph nodes restricted to the scope of dissection (Ro) and restoration of bilio-enteric continuity. Caudate lobectomy was also performed in the majority of cases. For all surgical procedures, duration, blood loss, utilization of critical care beds, and complications were recorded.

Other treatment modalities

Palliative chemotherapy, external beam radiotherapy, and brachytherapy were utilized in selected cases after consultation with clinical oncologists.

Follow-up

For all patients, the last consultation date as well as dates and causes of death were recovered from patient records. For those who lost their follow-up, data were completed by consulting the patients' general practitioners or collected from the local health authority records.

Statistical analysis

Data were analyzed using Minitab statistical software. Numbers of admissions and drainage procedures were compared using the Student's *t*-test and Bismuth classification. Breakdown was made using the χ^2 test. Survival analysis was made using the log-rank test. In all cases, $P<0.05$ was considered statistically significant.

RESULTS

Management for the 75 patients is shown in Figure 2. Of these, 67 (89%) patients presented with obstructive jaundice. Although there was an incidence of type IV tumors in the non-resected group, there was no significant difference in Bismuth classification between resected and

Table 1 Bismuth classification

non-resected groups (χ^2 test, Table 1).

Investigations

All patients received transcutaneous ultrasonography, of them 72 patients (96%) underwent assessment with CT scanning, 42 (56%) had MRI scans, and 18 (24%) received transfemoral angiography.

Biliary drainage

Biliary drainage was necessary in 70 patients, of them 65 (93%) required percutaneous drainage. A total of 51 endoscopic biliary drainages were performed in 41 patients, of which 15 (29%) failed. Percutaneous drainage was subsequently required in 36 of the 41 patients who underwent ERCP, due to failure or inadequate drainage or stent occlusion. Of the 199 drainage procedures performed, 49 (24.6%) had complications including 20 failures, 20 episodes of biliary sepsis, and 3 cases of pancreatitis. The median number of drainage procedures for all patients was three.

Surgical procedures and complications

A total of 27 surgical procedures were performed in 26 patients (Table 2). Eighteen patients underwent resection (24%) and three underwent portal vein resection. Major complications occurred in nine (50%) including three post-operative deaths (16.7%). The breakdown of complications is shown in Table 3. The median blood loss (range) in resected cases was 2.4 L (range 1-12 L), the median duration of procedure was 8 h (6-18) and the median critical care stay was 6 d (range 2-40d).

Follow-up

The median follow-up time was 9 mo. The 5-year survival rate was 4.2% for all patients, 21% for resected patients and 0% for those who did not undergo resection (P = 0.0021, log-rank test, Figure 2). The number of admissions after diagnosis was significantly lower (P<0.05, Student's t-test) in resected patients (median = 2) than in non-resected patients (median = 3).

Table 3 Complications of resection

Complication	*n*
Death	3 (17%)
Sepsis	9 (50%)

Wound infection	4 (22%)
Bleeding	3 (17%)
ARDS	1 (6%)
Hepatic artery thrombosis	1 (6%)
GI obstruction	1 (6%)
Pleural effusion	1 (6%)
Renal failure	1 (6%)
Respiratory arrest	1 (6%)
Wound dehiscence	1 (6%)

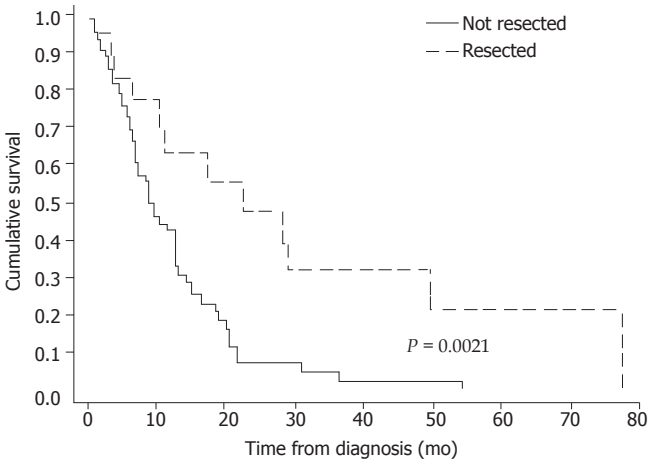

Figure 3 Kaplan–Meier survival plots for all patients with breakdown in resected and non-resected groups.

Other treatment modalities

In 23 patients who did not undergo resection, radiotherapy or chemotherapy was employed (Figure 3). These conferred no significant benefit in terms of survival (P = 0.46, log-rank test) (Figure 4), number of drainage procedures, or total hospital admissions.

Resected specimen pathology and staging

R0 resections were reported in 13 of 18 resected cases (72%). The pathological breakdown of resected cases by

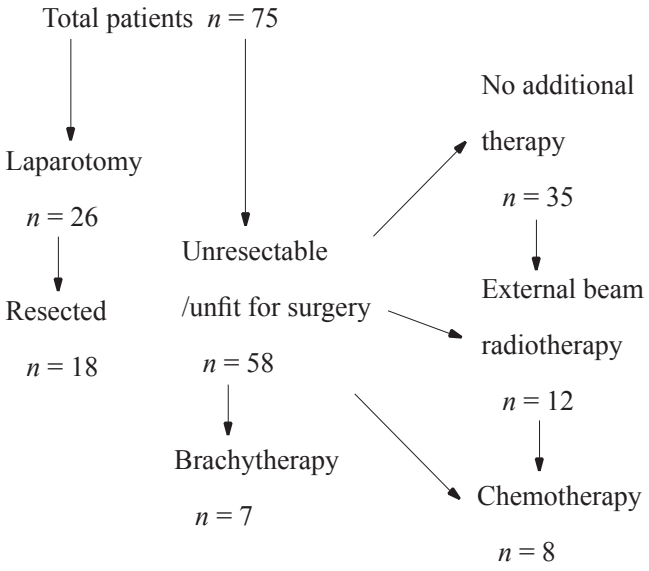

Figure 2 Flow chart showing management outcomes.

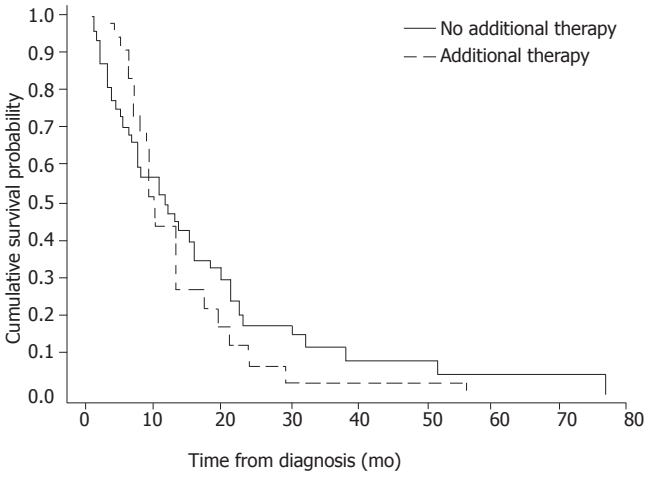

Figure 4 Kaplan-Meier survival plots for non-surgical therapeutic modalities in non-resected patients.

TNM classification is shown in Table 4. Vascular invasion was present in 9 cases (50%), perineural invasion in 13 cases (72%) and lymphatic invasion in 7 cases (39%). Patients who had node-negative resections tended to have a better survival than those who had node-positive resections (Figure 5) but this did not reach statistical significance ($P = 0.1$, log-rank test).

DISCUSSION

Our study is one of the few UK studies, documenting experienc-es in the management of hilar cholangiocarcinoma. The disease generally has a dismal prognosis; however, our findings demonstrate that an aggressive approach to the resection of these tumors results in prolonged survival. Resection is the only potentially curative treatment, and many patients do develop recurrence; however, these still benefit in terms of survival, fewer hospital admissions and decreased necessity for

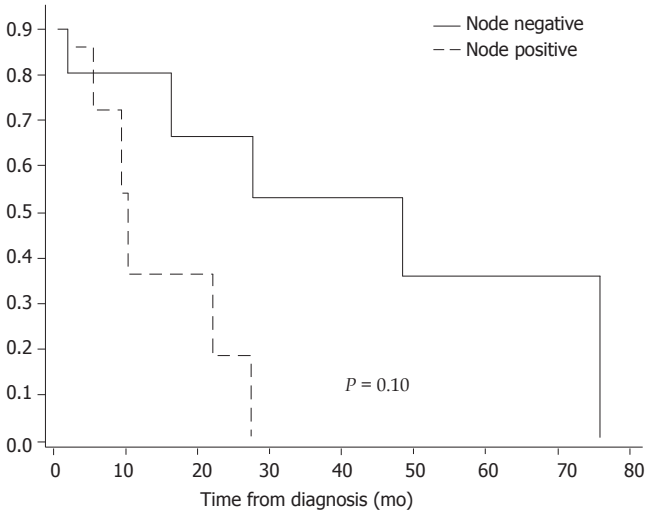

Figure 5 Kaplan-Meier survival plots for node positive and node negative resections.

biliary drainage. Our results are comparable with several reported series of surgical resections for Klatskin tumors, with 5-year survival of 8-56%, in-hospital mortality of 6-17% and morbidity of 30-50%[2,3,6-11]. Negative resection margins have been shown to be important in prolonging survival although this could not be independently assessed in our study due to small numbers[3,8,12-14].

Major resection of a cholestatic liver is associated with an increased risk of serious complications due to impairment of liver function, including reticuloendothelial cells, mitochondrial and microsomal functions, impaired protein synthesis, wound healing and cell medicated immunity. All obstructed segments of the bile ducts in all patients undergoing preoperative assessment for surgical resection are therefore drained in our center. This facilitates not only the relief of jaundice, but also provides valuable information regarding the proximal extent of the tumor. In addition, it identifies the most common organisms isolated from the bile cultures to formulate the most appropriate perioperative antibiotic regimen.

In our study, endoscopic biliary drainage of hilar lesions had a high failure rate and almost all patients had to have subsequent percutaneous procedures in order to achieve adequate drainage. This is comparable with previously published data. Success rates for adequate endoscopic

biliary drainage for hilar tumors has been reported to be between 55% and 81%[15-18]. Even in studies supporting this modality, stent occlusion requiring further drainage procedures has been reported between 33% and 94% with morbidity of 22% and 44%[15,20]. Rerknimitr[15] describes an 81% rate for successful endoscopic drainage for Bismuth type II, III or IV tumors; however, 54% developed cholangitis and 30 of the 32 who did not undergo resection required further procedures within a mean of 47 d from initial drainage. Liu[18]describes a cohort of 55 patients undergoing endoscopic biliary drainage. Of these, only 73% had successful prosthesis insertion (16% required multiple procedures) with only 20 having satisfactory drainage. Of the 16 patients treated with palliative intent only, only 3 were successfully palliated by endoscopic means with the remainder requiring percutaneous drainage. Finally, Nomura[20]describes a significantly higher risk of cholangitis in patients treated endoscopically when compared to percutaneous drainage. Biliary obstruction due to hilar cholangiocarcinoma should therefore be ideally managed with percutaneous biliary drainage. Plastic internal-external catheters are placed initially and are then internalized. The majority of patients present with unresectable disease and in these cases, effective and reliable relief of the primary symptom - usually obstructive jaundice is paramount. For these patients also, percutaneous drainage is the method of choice. Self-expanding metallic Wallstents are preferred over plastic stents that have been shown to have longer duration of patency (6-8 mo), are more cost-effective, and are associated with a shorter hospital stay[21-23].

The use of palliative non-surgical treatment modalities conferred no benefit in our study. To date, there is no chemotherapeutic regimen that markedly improves survival in patients with advanced Klatskin tumors. Almost all phase II trials using single agents failed to demonstrate any beneficial effects with partial response rate of less than 10%[24-27]. Using combination therapy, however, the overall response rate has generally been shown to be slightly better at around 27%[28-32]. Radiotherapy may be delivered as an external beam irradiation using linear accelerator or by intraluminal brachytherapy. Trials assessing the palliative radiotherapy have generally been disappointing although a few have shown promising results. Shinchi *et al*. have shown in a retrospective review of 51 patients that external radiotherapy combined with metallic stents can offer a mean survival rate of 10.6% mo, which was significantly longer than stenting alone (4-6 mo), with a much improved quality of life[33]. Kuvshinoff *et al*. also reported similar encouraging results in 12 patients managed with intra-ductal brachytherapy and external beam radiation; the mean survival being 14.5 mo[34].

In conclusion, resection of hilar cholangiocarcinoma, when possible, increases survival although it carries the risk of significant morbidity and mortality. Percutaneous biliary drainage is almost always necessary and ERCP should be avoided. There is no evidence of benefit from chemotherapy or radiotherapy in non-resected patients, although there is data from other studies suggesting some beneficial effects.

Abstract

AIM: Chemokines and their receptors are crucial for immune responses in HCV and HIV infection. RANTES gene polymorphisms lead to altered gene expression and influence the natural course of HIV infection. Therefore, these mutations may also affect the course of HIV/HCV coinfection.

METHODS: We determined allele frequencies of RANTES-403 (G→A), RANTES-28 (C→G) and RANTES-IN1.1 (T→C) polymorphisms using real-time PCR and hybridization probes in patients with HIV (n = 85), HCV (n = 112), HIV/HCV coinfection (n = 121), and 109 healthy controls. Furthermore, HIV and HCV loads as well as CD4+ and CD8+ cell counts were compared between different RANTES genotypes.

RESULTS: Frequencies of RANTES-403 A, RANTES-28 G and RANTES-IN1.1 C alleles were higher in HIV infected patients than in healthy controls (-403: 28.2% *vs* 15.1%, P = 0.002; -28: 5.4% *vs* 2.8%, not significant; IN1.1: 19.0% *vs* 11.0%, P = 0.038). In HIV/HCV coinfected patients, these RANTES alleles were less frequent than in patients with HIV infection alone (15.4% P = 0.002; 1.7%; P = 0.048; 12.0%; not significant). Frequencies of these alleles were not significantly different between HIV/HCV positive patients, HCV positive patients and healthy controls.

CONCLUSION: All three RANTES polymorphisms showed increased frequencies of the variant allele exclusively in patients with HIV monoinfection. The finding that the frequencies of these alleles remained unaltered in HIV/HCV coinfected patients suggests that HCV coinfection interferes with selection processes associated with these alleles in HIV infection.

Key words: RANTES polymorphism; HIV/HCV-coinfection; HCV

INTRODUCTION

Coinfection with human immunodeficiency virus (HIV) and hepatitis C virus (HCV) is common among certain risk groups such as hemophiliacs and intravenous drug abusers (IVDA)[1]. Unfortunately, HIV/HCV coinfection is associated with an accelerated course of HCV infection leading to progressive liver disease, cirrhosis, and hepatic failure[2,3].

Chemokines and their receptors play a central role in HIV infection. During the initial steps of viral infection chemokine receptors, such as the chemokine receptor 5 (CCR5), are used as co-receptors by HIV to enter monocytes and CD4 positive T-helper cells. A mutation in the encoding region of CCR5, CCR5-△32, abrogates HIV cell entry of m-tropic HIV strains, and thus prevents HIV infection in CCR5-△32 homozygous patients[4]. Heterozygosity for the CCR5-△32 mutation is associated with delayed progression of HIV infection to AIDS[4]. Recently, we have reported that the CCR5-△32 mutation was more prevalent in hemophiliac patients with chronic hepatitis C virus infection and was associated with increased hepatitis C viral loads[5]. A study on liver biopsies of patients with chronic hepatitis C revealed that this mutation may be associated with reduced portal inflammation and fibrosis[6]. Furthermore, we have found epidemiological evidence that the CCR5-△32 mutation is a predictor of treatment failure in interferon-α monotherapy

of chronic HCV infection, possibly indicating that the CCR5 receptor may also play an important role in the immune response to HCV infection[7].

The natural ligands of CCR5 are the chemokines RANTES (regulated on activation normal T cell expressed and secreted; CCL5), MIP-1α (macrophage inhibitory protein-1α; CCL3) and MIP-1β (macrophage inhibitory protein-1β; CCL4), all of which are potent inhibitors of HIV-1 cell entry[8]. Importantly, RANTES blocks the CCR5 receptor via receptor binding and down-regulation of CCR5 on T cells and macrophages. Furthermore, RANTES was reported to be critically involved in the recruitment of T cells to the liver[9]. Several single nucleotide polymorphisms in the RANTES gene have been reported to influence the natural course of HIV infection by up- or down-regulating RANTES gene activity. The most frequent of those polymorphic sites comprise RANTES-403 (G→A) and RANTES-28 (C→G) in the promoter region and RANTES-IN1.1 (T→C) in the first intron region[10,11]. Both promoter polymorphisms increase RANTES transcription and may delay HIV disease progression[11,12]. Conversely, the RANTES-IN1.1 C allele seems to decrease RANTES transcriptional activity and is probably associated with an increased risk for HIV infection and progression to AIDS[10].

Since RANTES seems to be involved in the pathogenesis of both HIV and HCV infection, we studied the effects of the RANTES gene polymorphisms in patients with HIV/HCV coinfection as compared to patients with HIV infection. To exclude that HCV infection or allele frequency in the background population contributed to our results we also included patients with HCV monoinfection as well as a group of healthy blood donors into the study.

MATERIALS AND METHODS

Design and study populations

All anti-HCV or anti-HIV positive patients of Caucasian descent attending our outpatient department between May 1999 and August 2000 were enrolled into one of the three study groups (HCV monoinfection = group I, HIV monoinfection = group II, HIV/HCV double infection = group III). None of the anti-HCV positive and anti-HIV/HCV positive patients had received interferon therapy at the time of the study. Type and duration of antiretroviral therapy and risk factors for infection were recorded in groups II and III. One hundred and nine healthy Caucasian blood donors of the Bonn University transfusion center (females 37, males 72, median age 27 years, range: 12-58 years) served as a reference group. In this reference group, HIV and HCV infection had been excluded by serology and PCR.

EDTA blood samples were obtained from each patient for genotyping of RANTES-403, -28 and -IN1.1 alleles. HCV genotype, HCV, and HIV viral loads, aminotransferase serum levels, CD4+ and CD8+ cell counts were determined in HIV, HCV, and HIV/HCV coinfected patients, respectively.

Serum aminotransferase levels were determined by routine biochemical procedures. Serologic markers of hepatitis B virus infection (HBs antigen, anti-HBs, and anti-HBc) were assessed by commercially available assays according to the manufacturer's instructions (Abbott, Wiesbaden, Germany). CD4 and CD8 cell counts were analyzed on a FACSort™ (Becton Dickinson, Heidelberg, Germany) flow cytometer using the Simulset™ test kit (Becton Dickinson, Heidelberg, Germany). The study conformed to the ethical guidelines of the Helsinki declaration as approved by the local ethics committee.

Diagnosis of HIV infection

Serum samples were analyzed for anti-HIV antibodies and p24 antigen with commercially available test kits (Abbott, Wiesbaden and Coulter, Hamburg, Germany) according to the manufacturer's instructions. A positive ELISA result was confirmed by immunoblot (Biorad, Munich, Germany).

HIV DNA was amplified from peripheral blood leukocytes by nested PCR according to Saiki *et al*.[13]. Amplification of the HIV-1 proviral DNA was carried out as nested PCR with the following primers for the first PCR (sense: 5-ATTTGTCATCCATCCTATTTGTTCCTGAA GGGT-3, antisense: 5-AGTGGGGGGGACATCAAGC AGCCATGCAAAT-3) and with the following primers for the second PCR (sense: 5-TGCTATGTCACTTCCCCTT GGTTCTCT-3, antisense: 5-GAGACTATCAATGAGGA AGCTGCAGAATGGGAT-3). The amplified product was detected by agarose gel electrophoresis.

HIV load was determined quantitatively using the NucliSens HIV-QT assay (Organon Teknika, Boxtel, the Netherlands). Amplified patient and calibrator RNA were quantified with different electrochemiluminescent probes in the NASBA QR system (Organon Teknika, Boxtel, the Netherlands) based on competitive internal linear standard curves[14]. This assay had a detection limit of 80 copies/mL.

Diagnosis of HCV infection

HCV antibodies were detected with a microparticle enzyme immunoassay (MEIA, Axsym, Abbott, Wiesbaden, Germany). Positive results were confirmed by dot immunoassay (Matrix, Abbott, Wiesbaden, Germany). HCV RNA was detected after nucleic acid purification kit (Viral Kit, Qiagen, Hilden, Germany) followed by reverse transcription and nested polymerase chain reaction as described elsewhere[15]. The detection limit was 100 copies/mL. Quantitative determination of HCV load was done via branched DNA technology (Quantiplex HCV RNA 2.0 assay, Chiron, Emeryville, CA, USA), which has good linearity for all genotypes above its detection limit of 200 000 copies/mL serum. HCV genotypes were determined by the Innolipa II line probe assay (Innogenetics, Zwijndrecht, Belgium) according to the manufacturer's instructions.

Genotyping of the RANTES-403, -IN1.1, and -28 single nucleotide polymorphisms

Genomic DNA was extracted from 200 μL EDTA-

treated blood samples using the QIAamp Blood Mini Kit (Qiagen, Hilden, Germany) according to the manufacturer's protocol.

Light Cycler PCR and hybridization probes: RANTES genotyping was performed using lightcycler and "fluorescence resonance energy transfer" (FRET) technology[16,17]. For amplification 2 μL light cycler-DNA master hybridization probes (Roche Diagnostics, Mannheim, Germany), 2 μL $MgCl_2$ (25 mmol/L), 8 μL PCR-grade water were used. For genotyping of the amplified DNA, 4 pmol of each hybridization probe (TIB MolBiol, Germany) was added to the reaction mixture. Sequences of oligonucleotide primers and hybridization probes for RANTES-403 were: sense *CACCTCCTTTGGGGACTGTA* and antisense *CCTCCGGAAATTCGAGTCTC*, anchor *GAGTCACTG AGTCTTCAAAGTTCCTGCTTA-F* and sensor *LC640-CATTACAgATCTTACCTCCTTTCCp*. The sensor hybridization probe was specific for the RANTES-403G allele at a melting temperature of 62.5 ℃.

Sequences of oligonucleotide primers and hybridization probes for RANTES-28 were: sense *CACCTCCTTTGGGGACTgTA* and antisense *TGGGATGGGGTAGGCATTCTA*, anchor probe *GTTGCTATTTTGGAAACTCCCCTTAGG-F* and sensor probe *LC705-ATGCCCCTGAACTGGCCp*. The sensor hybridization probe was specific for the RANTES-28G allele at a melting temperature of 60.0 ℃. Sequences of oligonucleotide primers and hybridization probes for RANTES-IN1.1 were: sense *CCTGGTCTTGACCACCACA* and antisense *GCTGACAGGCATGAGTCAGA*, anchor probe *LC640-CCCTCAAGGCCTACAGGTGTTCACp* and sensor probe *TCAGTTTTTCTGTCTTCAAGTCTAC-F*. The sensor probe was specific for the C allele at a melting temperature of 65 ℃.

An initial denaturation step at 95 ℃ (60 s, ramp rate 20 ℃/s) was followed by amplification for 40 cycles of denaturation (95 ℃, 0 s, ramp rate 20 ℃/s), annealing (63 ℃, 10 s, ramp rate 20 ℃/s) and extension (72 ℃, 15 s, ramp rate 20 ℃/s). For RANTES-IN1.1, the annealing temperature was lowered to 55 ℃. After DNA amplification a melting curve was generated at 95 ℃ (5 s, ramp rate 20 ℃/s) followed by 45 ℃ (15 s, ramp rate 20 ℃/s) and 75 ℃ (0 s, ramp rate 0.1 ℃/s, acquisition mode: continuous) for RANTES-403 and RANTES-IN1.1 and 95 ℃, 35 ℃, and 70 ℃ for RANTES-28. After a final cooling step for 30 s at 40 ℃ melting curve analysis could be performed. Representative genotyping results are given in Figures 1A-C.

Statistical analysis

RANTES genotypes and allele frequencies were compared to the healthy reference population via contingency tables using χ^2 statistics and Fisher's exact test where appropriate. Based on gene frequencies, the expected phenotype frequencies were calculated according to the Hardy–Weinberg equation and compared to the observed frequencies using χ^2statistics[18]. Haplotype analysis for combined RANTES-403 and -28 genotypes as in Table 3 was performed according to Gonzalez *et al*.[19]. In each group, different genotypes of each RANTES polymorphism were compared with respect to HIV and HCV loads, CD4+ and CD8+ cell counts using parametric (unifactorial ANOVA with Bonferroni's correction) or non-parametric statistical analysis as appropriate (Kruskal-Wallis test followed by the Mann-Whitney test for pairwise comparison of the groups), if the number of patients with the particular genotype exceeded five. Results are given as median and range unless indicated otherwise.

In all statistical tests, $P<0.05$ were regarded as significant. All calculations were performed on a personal computer with SPSS 11.0 software (SPSS, Chicago, IL, USA).

RESULTS

Patient groups

One hundred and twelve anti-HCV positive, 85 anti-HIV positive, and 121 anti-HIV/HCV double-positive Caucasian patients were recruited into this study. The characteristics of these patient groups are summarized in Table 1. Hemophilia was the major risk factor for infection in HCV and HIV/HCV coinfected patients, whereas sexual transmission was the main risk factor in HIV infected patients. Rates of persistent HBs antigenemia was low in each study group (<5%), although the high prevalence of anti-HBc antibodies in the anti-HCV and the double infected groups indicated significant exposure to HBV (Table 1).

Distribution of RANTES-403, -28, and -IN1.1 genotypes

The distribution of RANTES-403, -28, and -IN1.1 alleles is shown in Table 2. The RANTES-403 A, RANTES-28 G, and RANTES-IN1.1 C alleles were more frequent in HIV monoinfected patients than in healthy controls as has been previously described[10]. The distribution of RANTES-403 genotypes in HIV infected patients differed significantly from controls ($P = 0.004$), whereas the RANTES-28 and RANTES-IN1.1 genotypes did not differ between the groups.

Unexpectedly, these higher frequencies of distinct RANTES alleles and genotypes were not observed in patients with HIV/HCV coinfection. RANTES-403 A, RANTES-28 G, and RANTES-IN1.1 C alleles were significantly less frequent than in HIV monoinfected patients ($P = 0.002$; $P = 0.048$; not significant). In contrast, the frequencies of the different RANTES alleles did not differ between HIV/HCV coinfected and HCV infected patients or healthy controls. This also held true for RANTES-403, -28, and IN1.1 genotype distribution ($P = 0.005$; $P = 0.045$; not significant). There was no deviation from the Hardy-Weinberg equilibrium in any of the groups.

Interestingly, the frequency of the combined RANTES wildtype (-403 G/G; -28 C/C; IN1.1 T/T) was lowest in HIV infected patients (49.4%) compared to healthy

controls (69.9%; $P = 0.007$), but also compared to HCV (63.4%; not significant) and HIV/HCV coinfected patients (70.4%; $P = 0.004$). The [-403 G/A; -28 C/G; IN1.1 T/C] combination genotype had the highest prevalence in HIV infected patients (9.6%) differing significantly from HCV (0.9%; $P = 0.005$) and HIV/HCV coinfected patients (1.7%; $P = 0.015$) as well as controls (4.9%; not significant).

When haplotype analysis for RANTES promoter polymorphisms was performed as described previously by Gonzalez *et al*.[19], the RANTES high producer haplotype (-403A, -28G) was most frequent in HIV monoinfected patients, whereas in HIV/HCV coinfected patients the frequency of this haplotype was similar in HCV infected patients and healthy controls (Table 3). The same finding also applies when the frequency of the (-403A, -28G) haplotype was compared between HIV and HIV/HCV infected patients ($P = 0.006$), between HIV and HCV infected patients ($P = 0.002$) and between HIV infected patients and controls ($P = 0.019$).

Effects of the RANTES-403, -28 and -IN1.1 mutations on parameters of HIV and HCV infection

HCV and HIV viral loads as well as the numbers of CD4+ and CD8+ cell counts are given in Table 4 stratified according to RANTES genotypes. There was a trend towards higher HIV loads in HIV infected patients with the RANTES-403 G/G genotype (wildtype) compared to subjects with the G/A and A/A genotype. Furthermore, HIV infected patients with the RANTES-28 C/G genotype tended to have lower HIV loads than patients with the C/C genotype (wildtype), whereas the RANTES-IN1.1 polymorphism did not affect HIV or HCV viral loads. However, statistical analysis could not be performed for RANTES-403 A/A and RANTES-IN1.1 C/C genotypes in HCV and HCV/HIV coinfection, because these genotypes were rare in each of the groups. CD4+ and CD8+ cell counts were not affected by any of the different RANTES genotypes. Finally, HIV and HCV viral loads did not differ significantly between the different haplotypes (Figure 1).

DISCUSSION

RANTES polymorphisms have been proposed to modify susceptibility to HIV infection and progression to AIDS[10,11,19]. In this study, the prevalence of all three polymorphic RANTES alleles (RANTES-403 A, RANTES-28 G, and RANTES-IN1.1 C) was higher in HIV monoinfected patients compared to healthy blood donors. In contrast, in HIV/HCV coinfection the frequency of the studied RANTES alleles did not differ from HCV monoinfection or healthy controls. Since we included patients with HCV monoinfection as well as a cohort of healthy blood donors into the study to exclude biased results as a consequence of HCV infection or allele frequency of the background population, the influence of RANTES alleles on HIV infection seems to be neutralized by concomitant HCV infection.

The increased frequency of distinct polymorphic RANTES alleles in HIV infection is in line with McDermott *et al*., who observed increased susceptibility to HIV infection in patients with RANTES-403 G/A -28 C/C haplotypes[20]. The prevalence of the RANTES-28 G allele in all groups was as low as previously described by An *et al*.[10], and none of our patients was homozygous for the RANTES-28 G allele[11].

The RANTES-IN1.1 C allele has been reported to be associated with an increased susceptibility for infection with HIV, which would explain the significantly increased frequency of the C allele in our HIV monoinfected patients[10]. However, none of the different RANTES alleles was significantly associated with altered HIV viral loads or CD4+ cells counts. In this context, we cannot rule out that we have missed an association between viral loads or CD4 counts and the polymorphic RANTES alleles, because our study group was rather small and not well balanced for antiviral therapy. To exclude that the presence of the CCR5-△32 allele which probably also affects susceptibility to HCV infection has influenced our findings, we tested whether any of the RANTES polymorphisms was associated or in linkage disequilibirum with CCR5-△32[5]. However, we could not find any associations between CCR5-△32 and the RANTES alleles.

The low frequency of the RANTES alleles -403A and -28G in our HCV infected patients is in accordance with Promrat *et al*., who also could not find any association of RANTES-403 and –28 polymorphisms with susceptibility to HCV infection or laboratory parameters of chronic

n.d. = not detectable

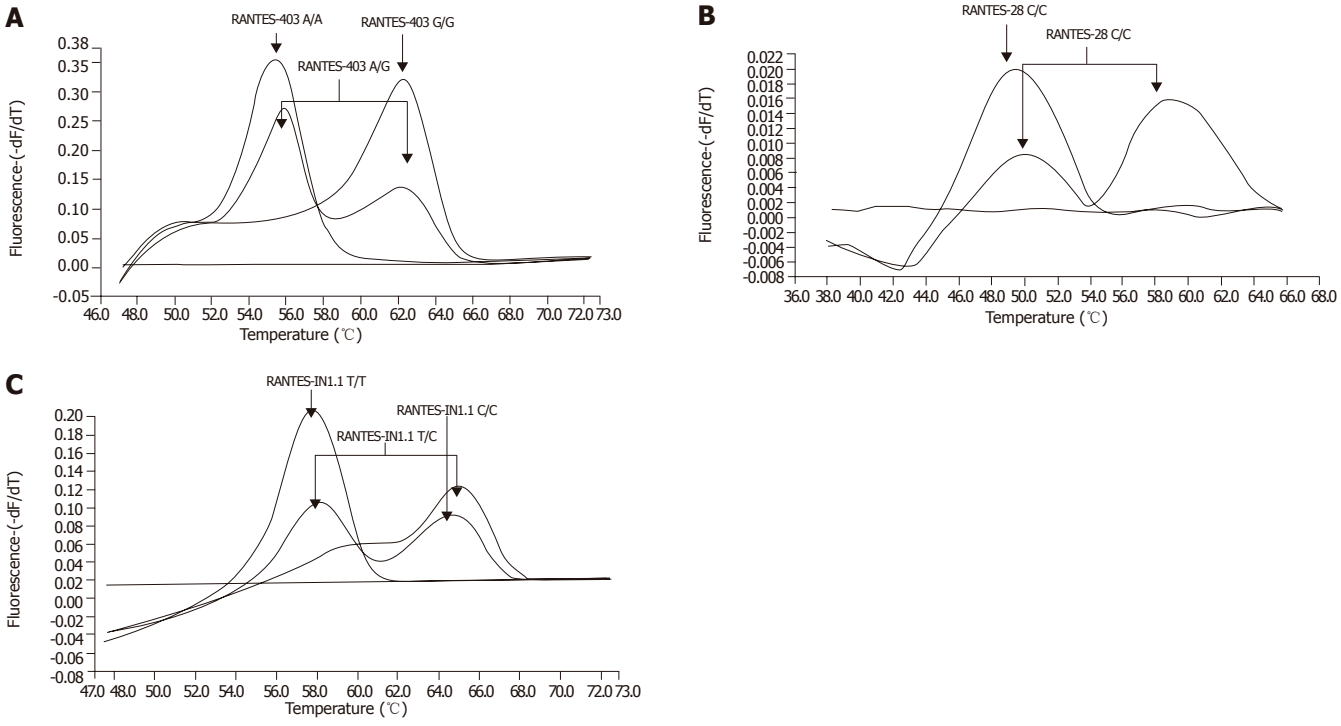

Figure 1 Shows the melting curve analysis (first order derivate) for different genotypes of the RANTES-403 (**A**), RANTES-28 (**B**), and RANTES-IN1.1 (**C**) polymorphisms. When the PCR product is melted, the probe-DNA binding will break up at a hybridization probe-specific temperature, which causes a loss in emitted fluorescence energy. This can be seen as a peak in the first order derivate of the melting curve. As the sensor probe is specific for only one of the two possible alleles in each PCR, binding of the probe to the other allele will cause a mismatch and therefore a weaker coupling and disengagement of probe and DNA at lower temperatures.

hepatitis C[21]. In contrast, Hellier *et al*. reported the RANTES-403 A/A genotype to be associated with mild portal inflammation[6]. However, the frequency of the A/A genotype in the study of Hellier (1.9%) was not different from the frequency in our patients[6]. Therefore, it was unexpected that the prevalence of RANTES alleles known to be increased in patients with HIV monoinfection was significantly lower in our HIV/HCV coinfected patients. Additionally, prevalence of these alleles was similar to HCV monoinfected patients and controls.

Several explanations may account for these divergent results: First, none of the studies so far was controlled for differences in transmission routes. Therefore, it is unclear whether disease modifying effects of the RANTES polymorphisms are equally operative in patients with sexual transmission *vs* parenteral transmission.

Alternatively, our patients with HIV/HCV coinfection could represent long time survivors: The RANTES-IN1.1 C allele has been described to be associated with rapid progression to AIDS, whereas both the RANTES-403 A and the RANTES-28 G allele have been reported to delay HIV disease progression[10,11,19]. However, frequency of these polymorphic RANTES alleles did not differ from our background population. Finally, differences in genotype and allele frequencies between HIV and HIV/HCV coinfected patients might reflect differences in the physiological roles of the single polymorphisms. RANTES-403 A and RANTES-28 G alleles have been shown to up-regulate RANTES transcription, whereas RANTES-IN1.1 C has been reported to be associated with the down-regulation of RANTES promoter activity[10-12]. Thus, RANTES expression should be characterized in terms of haplotypes, defined by the combination of the various alleles, giving the possibility to explain selection effects on the course of HIV infection[10]. However, only haplotypes AC and AG were more prevalent in patients with HIV infection, whereas their frequencies in patients with HCV and HIV/HCV coinfection were identical to the healthy background population.

The selection effect of the RANTES alleles in HIV infection may be lost in patients with HCV coinfection, because interactions of HCV-specific proteins such as core and NS5A may interact with host genes to augment RANTES promotor activity[22]. Binding of the HCV-specific protein E2 to CD81 is associated with increased RANTES serum levels resulting in CCR5 internalization[23]. Therefore, HCV infection is likely to trigger increased RANTES serum levels, which in turn decrease CCR5 expression on the cell surface due to receptor internalization. This hypothesis is further supported by a recent study that shows reduced CCR1 and CCR5 surface expression on peripheral blood cells in chronic HCV infection[24]. Thus, it is intriguing to speculate that the effects of RANTES polymorphisms on RANTES expression in HIV infection are abrogated in HIV/HCV coinfection due to induction of RANTES by HCV-specific proteins. In line with this assumption, we observed reduced frequencies of patients carrying the putatively up-regulating (RANTES-403 and RANTES-28) as well as down-regulating RANTES polymorphisms (RANTES-IN1.1) in our patients with HCV and HIV/HCV coinfection.

In summary, deviations in polymorphic RANTES allele frequencies seen in HIV infection could not be confirmed in HIV/HCV coinfection. Functional studies will be required to further analyze the differences in RANTES regulation between HIV and HIV/HCV coinfection at a molecular level.

Abstract

AIM: To evaluate the plasma von Willebrand factor (vWF) levels in patients with ulcerative colitis (UC) and to investigate their relationship with disease activity, systemic inflammation and coagulation activation.

METHODS: In 46 patients with ulcerative colitis (active in 34 patients), clinical data were gathered and plasma vWF levels, markers of inflammation (ESR, CRP, and fibrinogen) and thrombin generation (TAT, F1+2, and D-dimers) were measured at baseline and after 12 wk of treatment. Plasma vWF levels were also determined in 52 healthy controls (HC). The relationship of plasma vWF levels with disease activity, disease extent, response to therapy, acute-phase reactants (APRs) and coagulation markers (COAGs) was assessed.

RESULTS: The mean plasma vWF concentrations were significantly higher in active UC patients (143.38 ±63.73%) than in HC (100.75±29.65%, P = 0.001) and inactive UC patients (98.92±43.6%, P = 0.031). ESR, CRP and fibrinogen mean levels were significantly higher in active UC patients than in inactive UC patients, whereas there were no significant differences in plasma levels of D-dimers, F1+2, and TAT. UC patients with raised APRs had significantly higher mean plasma vWF levels than those with normal APRs (144.3% *vs* 96.2%, P = 0.019), regardless of disease activity. Although the mean plasma vWF levels were higher in UC patients with raised COAGs than in those with normal COAGs, irrespective of disease activity, the difference was not significant (141.3% *vs* 118.2%, P = 0.216). No correlation was noted between plasma vWF levels and disease extent. After 12 wk of treatment, significant decreases of fibrinogen, ESR, F1+2, D-dimers and vWF levels were noted only in UC patients with clinical and endoscopic improvement.

CONCLUSION: Our data indicate that increased plasma vWF levels correlate with active ulcerative colitis and increased acute-phase proteins. Elevated plasma vWF levels in ulcerative colitis possibly reflect an acute-phase response of the perturbed endothelium due to inflammation. In UC patients, plasma vWF levels may be another useful marker of disease activity or response to therapy.

INTRODUCTION

The etiology and pathogenesis of inflammatory bowel diseases (IBD), ulcerative colitis (UC) and Crohn's disease (CD), are still unclear[1]. "Vascular" theory supports that intestinal vascular injury is involved in CD and UC pathogenesis[2,3].

There is evidence that a hypercoagulable state exists in IBD, which might play a role in IBD pathogenesis[3-5]. This theory is further supported by the observation of Gaffney *et al*.[6] that patients with hemophilia and von Willebrand's disease have a lower risk in developing IBD and by the beneficial effects of heparin in the treatment of refractory ulcerative colitis[7,8]. The hypercoagulable state has been found to exist both in active and in inactive disease[9-15]. Furthermore, endothelial dysfunction, due to effects of

increased proinflammatory cytokines (IL-1, TNF-α), seems to play a central role in the hypercoagulant state production in IBD and also provides an evidence of interrelation between coagulation and inflammation pathways[16-18].

von Willebrand factor (vWF) is a large glycoprotein which circulates in human plasma or is deposited into the vascular subendothelium. Approximately 85% of circulating vWF is synthesized by the vascular endothelial cells, which are the main source of synthesis and secretion of this coagulation factor. vWF is also synthesized by megakaryocytes and is contained in platelets, which derive the remaining 15% of the circulating protein in blood. vWF serves as a stabilizing carrier protein of the coagulation factor VIII in circulation. vWF also mediates platelet to platelet interactions and platelet adhesion to the subendothelium in response to endothelial injury during the first step of thrombus formation[19]. Increased circulating levels of vWF in serum are considered as a marker of endothelial dysfunction or injury[19,20]. Increased levels of vWF are also observed as an acute-phase response in various inflammatory conditions[21].

vWF serum levels have been reported to be increased in patients with IBD, but it is not clear whether they reflect primary endothelial damage[17,22–25] or they are a manifestation of acute-phase response due to inflammation[22,23,26].

In this study, in order to clarify the meaning of elevated vWF levels in ulcerative colitis, we measured the circulating plasma vWF levels in a group of patients with ulcerative colitis and investigated their relationship with clinical activity and endoscopic severity of disease, markers of systemic inflammation and thrombin generation. We also monitored the changes of these variables during 12 wk of therapy and estimated their relationship with the clinical outcome.

MATERIALS AND METHODS

Patients and controls

Forty-six patients with ulcerative colitis (30 males and 16 females, mean age 41.8 years, range 17-73 years) and 52 healthy individuals (healthy controls, HC) (30 males and 22 females, mean age 40.9 years, range 19-65 years) were consecutively included in the study. All patients and controls were from the same geographical area (Northern Greece) and had a Greek ancestry.

Methods

The diagnosis of UC was based on the standard clinical, endoscopic and histological criteria. A complete medical history was obtained and physical examination was performed in all UC patients. During baseline evaluation, disease activity in patients with UC (active or inactive) was assessed with the simple clinical colitis activity index (SCCAI), taking into account five clinical criteria: day and night stool frequency, urgency of defecation, blood in the stool, general well being and presence of extracolonic manifestations[27]. A SCCAI score of ≤2 points was defined as clinical remission. Baseline colonoscopy with biopsy sampling was performed in all patients with UC, in order to assess the endoscopic severity and extent of disease. Endoscopic severity was measured by a modified endoscopic score with an 18-point scale[28] involving nine parameters: erythema, vascular pattern, friability, granularity, spontaneous bleeding, occurrence and severity of ulcers, extent of ulcerated surface, and presence of mucopurulent exudates. All parameters were scored from 0 to 2 points. Four grades of activity were considered according to the sum of all parameters: inactive disease (0-3), mild disease (4-7), moderate disease (8-12), and severe disease (13-18). Grading of endoscopic severity was done from the most inflamed part of the bowel. The extent of disease was recorded as rectosigmoiditis, left-sided colitis, and pancolitis. Patients with severe hepatic, renal and cardiac disease were excluded from the study.

Healthy control subjects were visitors in the outpatient clinic of Haematology Department and had no known diseases, or clinical or laboratory evidence of metabolic, neoplastic or inflammatory disease. They also had no history of thromboembolic disease.

All patients and control subjects gave their informed consent to participate in the study, which was approved by the Hospital's Scientific Committee.

Laboratory studies

Blood samples were collected at baseline from UC patients and control subjects for the quantitative determination of von Willebrand factor antigen (vWFAg) in plasma with an immuno-turbidimetric assay (STA-Liatest vWF, Diagnostica Stago, France; normal values 50-160%). Additional blood samples were obtained from UC patients in order to determine variables of inflammation (ESR, CRP and fibrinogen) and parameters reflecting thrombin generation (thrombin–antithrombin complex [TAT], prothrombin fragments 1+2 [F1+2], and D-dimers [D-Di]).

ESR was measured by standard laboratory technique (normal values <20 mm/h) and CRP was measured with ELISA (normal values <5 mg/L). Plasma fibrinogen concentration was measured by the Claus method using bovine thrombin (bioMerieux sa, France) on OPTION coagulation analyzer (normal values 2-4 g/L).

TAT levels in plasma were measured by sandwich enzyme immunoassay (Enzygnost TAT micro, Dade Behring, Marburg, Germany; normal values 1-4.1 μg/L). F1+2 levels in plasma were measured by sandwich enzyme immunoassay (Enzygnost F1+2 micro, Dade Behring, Marburg, Germany; normal values 0.4-1.1 nmol/L). D-dimers levels in plasma were measured by immuno-turbidimetric assay (STA-Liatest D-Di, Diagnostica Stago, France; normal values <500 μg/L).

All venipunctures were performed using a butterfly 18-gauge needle between 08:00 and 10:00 a.m. The first 10 mL of blood was not used for determination of hemostatic variables. Venous blood samples for hemostatic variables were collected in trisodium citrate tubes and platelet-poor plasma was prepared by one-stage centrifugation at 2 000 r/min for 20 min at 4 °C. Plasma was removed and assayed immediately for fibrinogen and stored at -20 °C until assayed, within one month, for vWF, TAT, F1+2, and D-dimers.

All UC patients were considered to have increased acute-phase reactants (APRs) if an increase in at least one of the two inflammation variables (ESR, CRP) was noted, as previously described[26]. Likewise, all UC patients were considered to have increased coagulation markers (COAGs) if an increase in at least one of the three hemostatic variables (TAT, F1+2, and D-dimers) was noted.

Treatment and course

Patients with active UC were treated for attenuation of disease activity with high-dose corticosteroids and mesalazine orally and rectally. Azathioprine was continued if already used. Patients were set into a follow-up program with regular visits every 2nd wk for 12 wk. Corticosteroids were tapered off with a weekly based schedule throughout the study period. At the end of the study (12th wk), complete clinical, endoscopic and laboratory evaluation, similar to baseline week, was performed in all patients with active colitis. Complete response to therapy (remission) was considered, if a SCCAI score of ≤2 and endoscopic remission was achieved after 12 wk of therapy. Partial response was considered if a 50% reduction of SCCAI score was noted together with a reduction of endoscopic activity by at least one grade.

Statistical analysis

Statistical analysis was performed using the SPSS for Windows package (version 11.0, SPSS, Chicago, IL, USA). Data were presented as mean±SD. Baseline comparisons were performed between the three main groups (healthy controls, patients with inactive UC and patients with active UC). A detailed analysis and multiple comparisons were performed between different subgroups of patients with UC according to disease activity, raised APRs or raised COAGs. Comparisons between groups were performed with Student's *t* test or ANOVA when appropriate. Student's *t* test for paired samples was used to compare baseline and follow-up measurements in patients with active disease. Associations between continuous variables were tested with Pearson's correlation. Differences in frequencies were studied with Fisher's exact test. $P<0.05$ was considered statistically significant.

RESULTS

During baseline evaluation, 12 patients with ulcerative colitis were found to be in remission and 34 patients had active disease. Demographic and clinical data of patients are shown in Table 1. There were no significant differences in sex, age and extent of disease between patients with active and inactive disease.

Table 1 Demographic and clinical data of ulcerative colitis patients (mean±SD)

	Active UC (n = 34)	Inactive UC (n = 12)
Male/female	22/12	8/4
Age (yr)	41.5±14.6 (17–73)	42.8±15.2 (18–65)
Extent of disease

5-ASA compounds	30	12
Azathioprine	11	2
None	2	0
Smoking	7	5

SCCAI: simple clinical colitis activity index; 5-ASA: 5-aminosalicylates.

Elevated plasma vWF concentrations were found in 1 patient with ulcerative colitis in remission and in 11 patients with active disease. None of the healthy subjects had an elevated value of plasma vWF. Mean plasma vWF concentrations were significantly higher in active ulcerative colitis patients (143.38±63.73%) than in healthy controls (100.75±29.65%, $P = 0.001$) and inactive UC patients (98.92 ±43.6%, $P = 0.031$). There was no difference in mean plasma vWF concentrations between HC and inactive UC patients (Table 2).

Mean levels of ESR, CRP and fibrinogen were significantly higher in active UC patients than in inactive UC patients. There were no significant differences in plasma levels of coagulation markers (D-dimers, F1+2 and TAT) between patients with active and inactive UC (Table 2).

UC patients with raised APRs (n = 34), irrespective of disease activity, had significantly higher mean plasma vWF levels than those with normal APRs (n = 12) (144.3 ±62.4% *vs* 96.2±45.8%, $P = 0.019$). Mean plasma vWF levels were also higher in UC patients with raised COAGs (n = 27), irrespective of disease activity, than in those with normal COAGs (n = 19), but did not reach statistical significance (141.3±64.8% *vs* 118.2±56.3%, $P = 0.216$). However, when all UC patients were divided into four subgroups according to raised or normal APRs and COAGs,

Table 2 Acute phase reactants and coagulation factors in patients with ulcerative colitis and healthy controls (mean±SD)

	Active UC (n = 34)	Inactive UC (n = 12)	Healthy controls (n = 52)
vWF (%)	143.38±63.73 (49-278)	98.92±43.6[a] (25-188)	100.75±29.65[b] (51–160)
ESR (mm/h)	40±21 (10-97)	16±12[a] (4-40)	
CRP (mg/L)	24.7±40.2 (3.1-175.5)	4.1±1.7[a] (3.1-7.3)	
Fibrinogen (g/L)	4.86±1.21 (2.93-7.3)	3.48±1.14[a] (1.25-5.61)	
D-dimers (μg/L)	873±1 308 (32-3 993)	608±1 149 (19-4 038)	
F1+2 (nmol/L)	3.71±6.09 (0.21–22.53)	3.72±6.41 (0.28-21.52)	
TAT (μg/L)	6.91±15.18 (0.09–85.9)	3.99±4.2 (0.85-13.2)	

vWF: von Willebrand factor; ESR: erythrocyte sedimentation rate; CRP: C-reactive protein; F1+2: prothrombin fragments 1+2; TAT: thrombin–antithrombin complexes. [a]$P<0.05$ active UC *vs* inactive UC. [b]$P<0.001$ active UC *vs* HC.

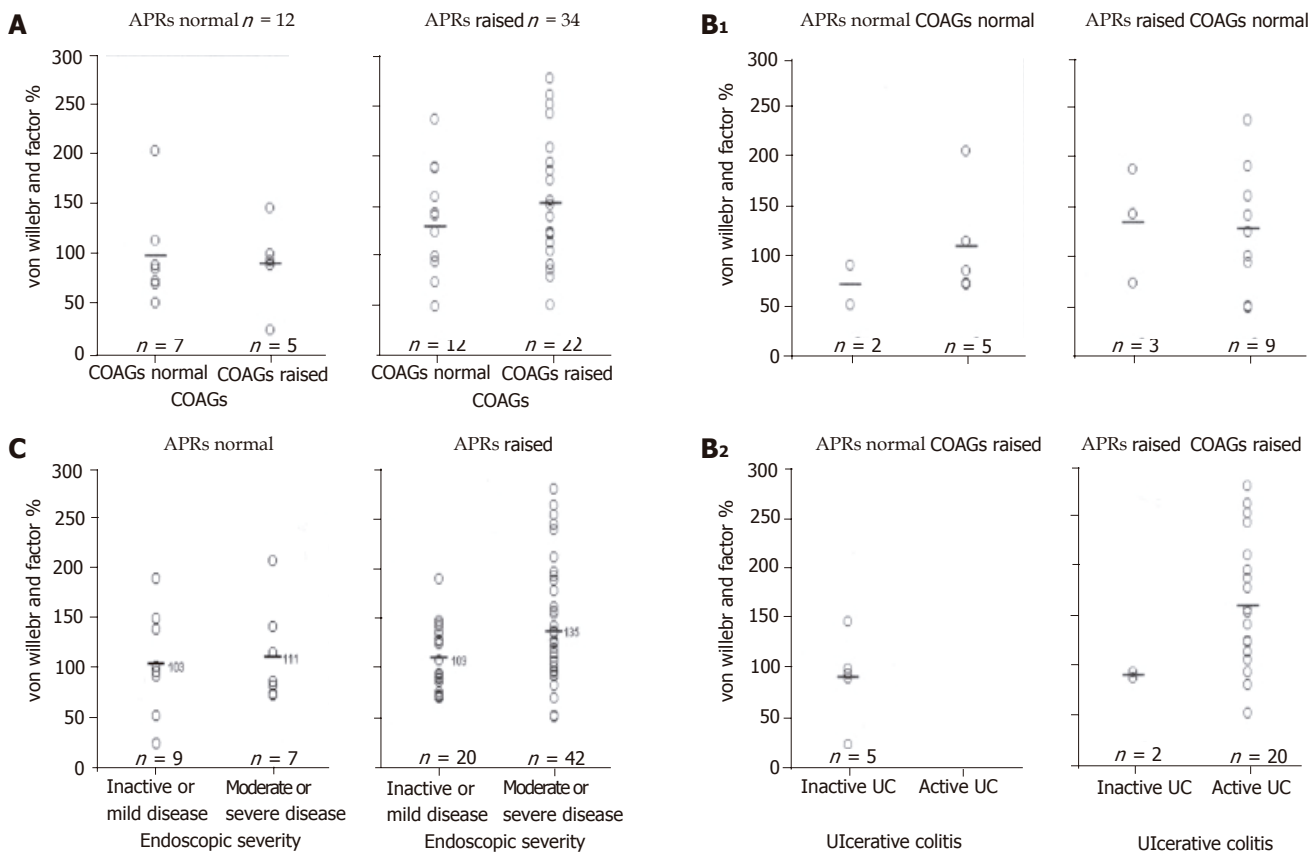

Figure 1 Mean plasma von Willebrand factor (vWF) levels in UC patients (**A**), their subgroups were divided according to disease activity, APRs and COAGs (**B1**, **B2**), as well as according to endoscopic severity and APRs(**C**). Open circle black dots (o) represent individual values and horizontal black lines (-) represent mean values. APRs: acute-phase reactants; COAGs: thrombin generation coagulation markers.

irrespective of disease activity, it was noted that patients with raised APRs had significantly higher mean plasma vWF levels than those with normal APRs, regardless of COAGs status (Figure 1A).

Furthermore, when UC patients were divided into subgroups according to disease activity and raised or not APRs and COAGs, there was a trend towards higher mean plasma vWF levels in almost all subgroups of patients with raised APRs (especially to those with active disease) compared to the patients with normal APRs. However, there were no significant differences between subgroups (Figure 1B1, B2).

In patients with ulcerative colitis (active and inactive), Pearson's correlation analysis revealed that there was a significant positive correlation of plasma vWF levels with clinical activity index (SCCAI) (r = 0.41, P = 0.004), endoscopic score (r = 0.3, P = 0.041), ESR (r = 0.39, P = 0.006), fibrinogen (r = 0.42, P = 0.003) and D-dimers (r = 0.36, P = 0.015). No correlation was noted between plasma vWF levels and extent of the disease or smoking status.

In all patients with UC, analysis of the percentages of high plasma vWF levels between subgroups revealed that raised APRs were the main factors influencing the plasma vWF levels (data not shown).

Thirty-two patients with active UC completed the study after 12 wk of treatment. Two patients did not show up at the final date of the follow-up schedule (12th week). There were no complications of the disease or adverse events from the treatment during the study period. Twenty-two patients showed response to therapy (complete or partial) and 10 patients were non-responders. A significant decrease of the inflammatory parameters (fibrinogen and ESR), the coagulation markers (F1+2 and D-dimers) and von Willebrand factor levels was noted only in the "responders" group (Table 3).

We pooled all patients in respect of endoscopic severity, before and after the therapy for active disease plus patients in remission at baseline week, and found that mean plasma vWF levels in patients with active disease at endoscopy (n = 54, 131.2±56.2%) were significantly higher than those in patients with endoscopic remission (n = 24, 103.1±36.7%, P = 0.028). There were no significant differences in plasma vWF levels between the groups of endoscopic severity grades (mild to severe) in patients with active disease. However, when we divided the patients in respect of APR status, we found that patients with raised APRs and moderate or severe endoscopic activity had significantly higher mean plasma vWF levels than the other subgroups (Figure 1C).

DISCUSSION

This study showed that mean plasma vWF levels were significantly raised in patients with active UC compared

vWF: von Willebrand factor; ESR: erythrocyte sedimentation rate; CRP: C-reactive protein; F1+2: prothrombin fragments 1+2; TAT: thrombin–antithrombin complexes.

to healthy controls and patients with UC in remission. Since elevated circulating von Willebrand factor levels are regarded as markers of both endothelial dysfunction and acute phase response to inflammation, we tried to investigate the relationship between vWF and markers of inflammation and coagulation, in order to clarify the meaning of elevated vWF levels in our patients with active ulcerative colitis. APRs were significantly higher in patients with active UC than in those with inactive disease. On the other hand, there were no significant differences in markers of thrombin generation between patients with active and inactive UC (Table 2). These observations are in accordance with previous studies, suggesting that a hypercoagulable state exists in both active and inactive UC[29-31]. In contrast, intense inflammatory response to elevated APRs is a prominent feature of active UC[32,33].

In our study, UC patients were divided into subgroups according to disease activity (active and inactive) and APRs or COAGs status (raised or not). The analysis of data revealed two main findings. The mean plasma vWF levels were significantly higher in patients with active disease (Table 2) and higher in patients with raised APRs irrespective of disease activity or COAGs status (Figure 1).

In a recent study, Meucci *et al*.[26] reported that elevated vWF levels in a group of patients with IBD are related to increased APRs, regardless of disease activity and concluded that elevated plasma vWF levels are a secondary manifestation due to systemic inflammation. In our study, we had similar findings with Meucci *et al*.[26], suggesting that elevated plasma vWF levels in patients with UC correlate mainly with the inflammatory response and to a lesser degree with hypercoagulability. However, in the most recent study, Xu *et al*.[25] had the opposite findings in a group of patients with UC, reporting that plasma vWF levels are significantly higher in patients with ulcerative colitis than in controls, with no differences between active and inactive disease. They also reported that D-dimers levels are higher in patients with active disease than in those in remission and D-dimers levels are positively correlated with vWF levels. The authors concluded that elevated vWF levels both in active and inactive UC reflect the fact that endothelial cell damage is a feature of UC and that D-dimers levels can be used as a marker of inflammation to distinguish active from inactive UC.

Inflammation, coagulation and endothelial dysfunction correlations have been studied in many other clinical conditions[34-37]. Inflammation as measured by CRP has been found to be associated with prothrombotic status and endothelial dysfunction as reflected by elevated vWF in acute coronary syndromes[38]. Plasma vWF has been reported as an APR in patients with acute infectious diseases which parallels CRP levels during illness and recovery phase[21]. The inflammatory and coagulation abnormalities observed in patients with ulcerative colitis possibly represent combined and cross-linked manifestations of the inflammation and coagulation systems, which are interrelated in a bidirectional way with the endothelium being the interface between inflammation and coagulation[18].

Inflammation is undoubtedly a key component in the pathogenesis of ulcerative colitis[39] and proinflammatory cytokines (IL-1, IL-6, IL-8, TNF-α, and IFN-γ) operate as a cascade and network in stimulating the production of acute-phase proteins and induction of acute-phase manifestations[40]. Inflammation can also lead to activation of coagulation system with the endothelium playing a central role in all major pathways involved in the pathogenesis of hemostatic derangement[18]. Proinflammatory cytokines induce a procoagulant profile with thrombin production,

through their effects on the vascular endothelial cells[18] and can also stimulate vWF secretion from Weibel-Palade storage granules of the endothelial cells[19,41,42]. A small fraction of the elevated plasma vWF levels can also be derived from platelets, since reactive thrombocytosis and *in vivo* activation of platelets are observed in active ulcerative colitis[15], consisting acute-phase phenomena due to systemic inflammation[40], but it seems that the contribution of platelet-derived vWF to elevated plasma levels is minor[23]. We can assume that, like other coagulation factors which are synthesized in liver cells and behave as acute-phase proteins (fibrinogen, factor VIII) during inflammation, elevated plasma vWF concentrations represent an endothelial component of the acute-phase response[23].

Glucocorticoids are known to increase plasma concentrations of factor VIII (FVIII) and von Willebrand factor (vWF), and their administration is associated with an increased thrombotic tendency[43,44]. In our study, patients with active ulcerative colitis were treated with high doses of corticosteroids for attenuation of disease activity and had no thromboembolic complications during the study period. Follow-up measurements after 12 wk of treatment showed that patients who responded to therapy had a significant improvement of all the variables of inflammation and hemostasis, including von Willebrand factor. Inflammation is undoubtedly the main feature of UC and the attenuation of inflammatory process due to the potent anti-inflammatory properties of corticosteroids is the principal mechanism that contributes to the improvement of disease severity and its clinical or laboratory manifestations. It is likely that hepatic and endothelial acute-phase responses have a parallel course during inflammatory process since they may be regulated in a similar manner by the same cytokines.

In our study, we investigated the relationship of plasma vWF levels with disease activity, parameters of inflammation and hemostasis in a group of patients with ulcerative colitis (active and inactive), before and after therapy. It is the first study to our knowledge which combines the assessment of all these variables in a time course manner and represents an extension of the two most recent studies[25,26]. The small number of patients in our study did not allow us to generalize our findings and give a possible explanation for any discrepancies of data among all relative studies. However, the general trend from the data is that plasma vWF levels are correlated with systemic inflammation.

In conclusion, increased plasma vWF levels in ulcerative colitis patients correlate with disease activity and increased acute-phase proteins. It seems that elevated plasma vWF levels in active ulcerative colitis patients reflect an acute-phase response of the perturbed endothelium due to inflammation and von Willebrand factor can be regarded as an endothelial APR. Further and larger studies are needed to show if plasma von Willebrand factor levels can be a useful and sensitive marker of disease activity or response to therapy.

Abstract

AIM: To analyze the serum levels of retinoids and Leiden mutation in patients with esophageal, gastric, liver, pancreatic, and colorectal cancers.

METHODS: The changes in serum levels of retinoids (vitamin A, α- and β-carotene, α- and β-cryptoxanthin, zeaxanthin, lutein) and Leiden mutation were measured by high liquid performance chromatography (HPLC) and polymerase chain reaction (PCR) in 107 patients (70 males/37 females) with esophageal (0/8), gastric (16/5), liver (8/7), pancreatic (6/4), and colorectal (30/21 including 9 patients suffering from *in situ* colon cancer) cancer. Fifty-seven healthy subjects (in matched groups) for controls of serum retinoids and 600 healthy blood donors for Leiden mutation were used.

RESULTS: The serum levels of vitamin A and zeaxanthin were decreased significantly in all groups of patients with gastrointestinal (GI) tumors except for vitamin A in patients with pancreatic cancer. No changes were obtained in the serum levels of α- and β-carotene, α- and β-cryptoxanthin, zeaxanthin, lutein in patients with GI cancer. The prevalence of Leiden mutation significantly increased in all groups of patients with GI cancer.

CONCLUSION: Retinoids (as environmental factors) are decreased significantly with increased prevalence of Leiden mutation (as a genetic factor) in patients before the clinical manifestation of histologically different (planocellular and hepatocellular carcinoma, and adenocarcinoma) GI cancer.

Key words: Human gastrointestinal cancer; Leiden mutation; Retinoids; Vitamin A; Zeaxanthin

INTRODUCTION

The number of patients with different gastrointestinal (esophageal, gastric, liver, pancreatic, and colorectal) cancer has increased about two- to threefolds in the last decades (except for gastric cancer which has decreased 50%) in Hungary. The number of patients who died of these malignant diseases represents the second highest population of the total mortality of patients in Hungary. The second highest mortality rate of gastrointestinal (GI) tumor takes place at the second place in our country.

The causes of GI tumors are not known. However, different genetic and environmental factors play a role in the development of GI cancer. It is generally accepted that different diseases such as acute and chronic inflammatory diseases, polyposis, can be taken as precancerous states of GI cancer.

Since the year of l980, we have studied the role of retinoids in protecting gastrointestinal mucosa in animal experiments and human observations[1-4]. Retinoids are chemical compounds of color materials from plants and are built up from C-20 and four isoprene units, while carotenoids are built up from C-40 and eight isoprene units located in about 600 plants, and about 50 from 600

Table 1 Patients with different gastrointestinal tumors

	Number of patients			
Types of tumors	Male	Female	Total	Histology
Esophageal	8 (60±10 yr)[1]	–	8	Planocellular carcinoma
Gastric	16 (64±12 yr)[1]	5 (68±10 yr)[1]	21	Adenocarcinoma
Liver	8 (60±8 yr)[1]	7 (57±13 yr)[1]	15	Hepatocellular carcinoma
Pancreas	6 (56±11 yr)[1]	4 (63±9 yr)[1]	10	Adenocarcinoma
Colorectal	30 (66±10 yr)[1]	23 (65±11 yr)[1]	53	Adenocarcinoma
In situ carcinoma in colon polyps	4 (60±5 yr)[1]	5 (61±5 yr)[1]	9	Adenocarcinoma
Total	70	37	107	
Healthy subjects	29 (50±12 yr)[1]	28 (49±10 yr)[1]	57	

600 blood donors (healthy controls) for Leiden mutation study. [1]Age of patients (mean±SD).

isolated compounds are precursors of vitamin A.

Vitamin A and β-carotene (and other retinoids) have gastric mucosal protective effects in rats provoked by intragastric administration of 1 mL from 0.6 mol/L HCl, 25% NaCl, 0.2 NaOH, and 960 mL/L ethanol, without the presence of any inhibition of gastric acid secretion[1]. Vitamin A has a higher ulcer healing effect than atropine, cimetidine DE-NOL (tripotassio–dicitrato) in patients with gastric ulcer[2-4] .The serum level of retinoids is decreased in patients with inflammatory bowel disease[5-8]. It was also demonstrated that the serum levels of vitamin A and zeaxanthin are also decreased in patients with GI cancer[9], but the possible correlation between the changes in other serum retinoids and the prevalence of Leiden mutation has not been studied.

The presence of Leiden mutation (replacement of Arg by Glu of residue 506 in the factor V molecule, FVR, 506 Q) has been proven in thrombophylia[10-13] as well as in Crohn's disease and ulcerative colitis[14-18], meanwhile no higher prevalence of Leiden mutation has been obtained in patients with acute gastritis and hepatitis[17]. The significant presence of Leiden mutation (APC) is responsible for blood coagulation abnormality in thrombophylia.

The aims of our present study were to evaluate the changes in serum levels of retinoids (as nutritional components of vitamin A, β-carotene, α-carotene, α- and β-cryptoxanthin, zeaxanthin, lutein) in patients with different gastrointestinal (esophageal, gastric, liver, pancreatic, and colorectal) cancer, to study the prevalence of Leiden mutation in the above mentioned patients, to find some correlation between the changes in Leiden mutation and serum level of vitamin A and zeaxanthin in GI cancer patients as well as between GI cancer development and chemical structure of retinoids, to obtain some correlation between serum levels of vitamin A and zeaxanthin in patients with different GI tumors.

MATERIALS AND METHODS

Observations were carried in 107 patients with esophageal (n = 8), gastric (n = 21), liver (n = 15), pancreatic (n = 10), colorectal (n = 53), and *in situ* colon (n = 9) cancer, including 70 males (50±12 years) and 37 females (49± 10 years). Fifty-seven healthy persons (in matched group) were used as control, and 600 healthy blood donors were used for the control of Leiden mutation (Table 1). A total of 764 patients with gastrointestinal cancer and healthy subjects were included in this study. The studies were approved by the Ethical Committee of University of Pécs, Hungary. Written informed consent was obtained from all participants and the nature of the study was fully explained (Table 1).

Physical, laboratory, iconographic, and histological examinations were carried out in the patients with gastrointestinal tumor. The diagnostic histology indicated planocellular carcinoma in esophagus, hepatocellular carcinoma in liver and adenocarcinoma in stomach, pancreas and colorectum. The control (healthy subjects) persons received physical and laboratory screening, and the medical histories were found to be negative (including the genetic backgrounds).

Measurement of serum retinoid levels

The serum levels of retinoids were measured by high performance liquid chromatography (HPLC). The serum levels of vitamin A, α- and β-carotene, α- and β-cryptoxanthin, zeaxanthin and lutein both in the control (healthy subjects) and in patients with GI tumors were measured. Blood samples were prepared for HPLC measurements: 2 mL of serum sample was shaken with 2 mL/L ethanol for 2 min, and extracted with 3 mL hexane for 2 min. The mixture was centrifuged for 5 min. As an internal standard, canthaxanthin was added to the removed homogenous organic phase, evaporated in vacuum. The residue was dissolved in 0.2 mL 1:4 dichloromethane/methanol and 0.125 mL of this solution was injected. The chromatographic system consists of a gradient former Model 250 B Glenco injector (Glycotec, Germany) and a time programmable UV-vis detector Model 166-2, equipped with Gold chromatography software (Beckmann, USA).The column is 150 mm× 4.6 mm in size packed with Chromsil-C 0.186 mm. The eluent was 30 mL/L water in methanol (A), methanol (B) and 20 v/v dichloromethane in methanol. The flow rate was 1.5 mL/min. The gradient program was 100% A for 30 s, 100% B for 3 min, to 100% for 4 min (linear steps). The time program of wavelength was 323 mm for 3.5 min (detecting vitamin A), then 450 mm (detecting other retinoids). The chromatograms were evaluated quantitatively by relating the peak areas of the individual components to canthaxanthin used as internal standard. The ratio of the molar extinctions of the authentic

samples to that of canthaxanthin was employed as a correction factor of the detector signals. The results were given in μmol/L, and expressed as mean±SE.

Determination of Leiden mutation

Leiden mutation was detected by polymerase-chain reaction (PCR)[12]. The DNA was isolated from 3 mL EDTA blood.

Statistical analysis

The changes in serum levels of retinoids were detected by the method of ANOVA. The prevalence of Leiden mutation was statistically analyzed by χ^2 test. P<0.05 (in the changes of serum retinoids and prevalence of Leiden mutation) was considered statistically significant.

RESULTS

The serum levels of vitamin A were decreased in all groups of patients with esophageal, gastric, hepatocellular and colorectal cancer meanwhile its level remained normal in patients with pancreatic cancer. The serum levels of α- and β-carotene, as provitamins of vitamin A, were normal in different groups of patients with GI cancer. Zeaxanthin level (without presence of any vitamin A property) was decreased significantly in patients with esophageal, gastric, hepatocellular, pancreatic, and colorectal cancer. No changes were obtained in the serum levels of α- and β-cryptoxanthin and lutein in the studied cancer patients (Table 2).

Prevalence of Leiden mutation accounted for 5.56% in 600 healthy blood donors, which was significantly higher in patients with esophageal (P<0.05), gastric (P<0.01), liver (P<0.01), pancreatic (P<0.05), colorectal (P<0.001) cancer. The higher prevalence of Leiden mutation (55%) was found *in situ* colorectal cancer (P<0.001, Figures 1 and 2).

DISCUSSION

Retinoids are chemical compounds of color materials from plants. Increased intake of plant foods can prevent different types of GI cancer. We studied the possible role of different retinoids (vitamin A, α- and β-carotene, α- and β-cryptoxanthin, zeaxanthin, and lutein) in patients with different GI cancer based on previous studies[5–9,19,20]. The location of GI tumor differed in organs (esophagus, stomach, pancreas, liver, and colon), suggesting that different etiological factors are involved in the development of different GI cancer (Barrett's esophageal metaplasia, chronic atrophic gastritis, viral infection in liver, chronic inflammatory bowel disease) in our everyday medical practice.

The serum levels of vitamin A and zeaxanthin were decreased significantly in all groups of GI cancer patients (not in patients with pancreatic cancer). Surprisingly the serum levels of provitamins were normal in patients with different GI tumor. These results indicate that transformation of provitamins into vitamin A is impaired by some factors at the level of liver, suggesting that the liver plays a key role in the development of tumor. Similar changes were observed in the serum levels of retinoids in patients with hepatocellular cancer, which offers a further proof for this hypothesis.

It is also interesting to evaluate the possible correlation between the terminal chemical structure, vitamin A activity and GI mucosal protection. Our results have clearly proved that there is no close correlation between the terminal chemical structure, vitamin A activity and GI mucosal protection (Table 3).

Similar results have been obtained in animal experiments[1,21-24] (Table 4). At present, no information is available on the correlation between the serum and tissue levels of retinoids in patients with different GI tumor. These observations cannot be done due to the obligatory necessity of histological evaluation of tumor tissues.

In animal experiments, β-carotene has been found in gastric mucosa of indomethacin-treated rats after

acute surgical vagatomy[25,26], however no gastric mucosal protection is found, indicating that intact vagal nerve is necessary for the development of β-carotene-induced gastric cytoprotection[26]. The mechanism of retinoids is very complex. Our earlier observations indicate that the GI mucosal protective effect of retinoids depends on intact vagal nerve and adrenals as well as on gastric mucosal biochemical changes (retinoids produce a dose-dependent inhibition on the extent of ATP-transformation into ADP in association with a simultaneous increase in the transformation of ATP into cAMP), intact function of sulfhydryl groups and scavenger properties[9,19-28].

Retinoid-induced GI mucosal protection does not depend on the inhibition of gastric acid secretory responses, vitamin A activity, number of unsaturated double bonds, presence of a characteristic chemical structure of their terminal components and modification of vascular permeability[20]. These results clearly indicate that the beneficial effect of retinoids is much more complex than that of their scavengers. The results of biochemical observations suggest that different cAMP-dependent cellular regulatory mechanisms exist (including the functions of retinoid receptors, gene expressions)[7,20,27].

The involvement of vascular events is suggested in the development of different acute inflammatory processes in the GI tract[20]. That is the reason why we studied the potential role of Leiden mutation in acute and chronic gastrointestinal inflammatory processes (*Helicobacter pylori*-induced gastritis, viral hepatitis, Crohn's disease, ulcerative colitis). The prevalence of Leiden mutation increased in chronic inflammatory bowel diseases, but no changes were obtained in gastritis and hepatitis. The prevalence of Leiden mutation was also significantly higher in patients with esophageal, gastric, hepatocellular, pancreatic, and colorectal cancer. These results indicate that only the increased prevalence of Leiden mutation does not take place directly in the tumor genesis of human GI cancer. We compared the different results in the examined parameters in patients with acute and chronic gastrointestinal inflammatory diseases, and found a time-sequence process between the inflammatory diseases and GI cancer in patients, suggesting that retinoids play a key role in the development of precancerous state to cancerous state[5,8,20].

In conclusion, the prevalence of Leiden mutation is significantly correlated with decrease in serum levels of vitamin A and zeaxanthin, suggesting that retinoids play a role in the human GI tumor genesis.

Abstract

AIM: Pathological prion protein (PrP^{sc}) is responsible for the development of transmissible spongiform encephalopathies (TSE). While PrPc enters the organism via the oral route, less data is available to know about its uptake and the role of gastrointestinal inflammation on the expression of prion precursor PrPc, which is constitutively expressed in the gastric mucosa.

METHODS: We studied PrPc expression in the gastric mucosa of 10 *Helicobacter pylori*-positive patients before and after successful *H pylori* eradication compared to non-infected controls using RT-PCR and Western blotting. The effect of central mediators of gastric inflammation, i.e., gastrin, prostaglandin E_2 (PGE_2), tumor necrosis factor alpha (TNF-α) and interleukin 1 beta (IL-1β) on PrPc expression was analyzed in gastric cell lines.

RESULTS: PrPc expression was increased in *H pylori*-infection compared with non-infected controls and decreased to normal after successful eradication. Gastrin, PGE_2, and IL-1β dose-dependently upregulated PrPc in gastric cells, while TNF-α had no effect.

CONCLUSION: *H pylori* infection leads to the upregulation of gastric PrPc expression. This can be linked to *H pylori* induced hypergastrinemia and increased mucosal PGE_2 and IL-1β synthesis. *H pylori* creates a milieu for enhanced propagation of prions in the gastrointestinal tract.

Key words: Prions; *Helicobacter pylori*; Gastrin; Pro-inflammatory cytokines

INTRODUCTION

Transmissible spongiform encephalopathies (TSE) are fatal neurodegenerative diseases affecting both animals and human beings[1]. They are characterized by typical cerebral histopathological findings such as amyloid deposition, neuronal loss, and spongiform changes. The prion protein (PrP) can exist in the normal cellular form (PrPc) or in an "infectious" form (PrP^{sc}) that causes disease by converting apathogenic PrPc into pathogenic PrP^{sc}[2]. Previous studies have demonstrated that PrPc is required for prion infection propagation and infectivity has been suggested to be a consequence of conformational modification of PrPc by the infectious PrP^{sc}. Experiment on animals shows that animals lacking the PrPc gene are not able to propagate prion infectivity and are not able to develop the disease[3]. Both the prion isoforms differ dramatically in their physicochemical properties. Whereas PrPc is soluble and easily digested by proteinase K, PrP^{sc} is rich in β-sheet structure, aggregates into fibrils, and is resistant to proteinase K.

The main entry for prions is the gastrointestinal tract. Recent animal studies have shown that after oral exposure to pathogenic prions, PrP^{sc} accumulates in gut lymphoid tissues or in the enteric nervous system prior to its appearance in the central nervous system[4,5]. It has been postulated that prions then propagate from the enteric nervous system along the nerve pathways to ventral and dorsal root ganglia and further through the spinal cord into the brain cortex[4-6].

However, the mechanisms of propagation of prions from the gut lumen, before they reach intestinal lymph follicles or the enteric nervous system remain unexplained. Recently, the 67-ku laminin, binding protein, which can act as a PrP^{sc} receptor was demonstrated on small intestinal epithelial cells[7-9], suggesting that individuals with a high expression of this receptor could be at greater risk of developing TSE after oral challenge with PrP^{sc}. There is also evidence of transepithelial transport of pathogenic prions via intestinal M cells to adjacent lymph follicles (Peyer's patches)[10]. However, it is unknown if and how far gastrointestinal inflammation may influence PrPc expression

and thus potentially PrP^{sc} propagation in the GI tract.

MATERIALS AND METHODS

Patients

Ten *H pylori* positive patients with non-ulcer dyspepsia (mean age 47 years, range 20-79 years) were included in this study. All patients underwent upper gastrointestinal endoscopy during which four biopsies from the antrum and corpus were obtained. Patients with *H pylori* gastritis were graded according to the updated Sydney classification[11]. All patients underwent a second endoscopy 4 wk after completing successful eradication therapy consisting of clarithromycine 500 mg twice daily, amoxicillin 1 000 mg twice daily and omeprazole 40 mg twice daily for 1 wk. *H pylori* was considered to be successfully eradicated, if histology was normal and silver stainable organisms were not detected anymore in the follow-up endoscopy, during which again four biopsies from the antrum and corpus were obtained.

Cell culture

MKN45 and KATO III cell lines were obtained from the American Type Culture Collection. Cells were cultured in RPMI medium containing 10% of fetal calf serum (FCS), 2 mmol/L L-glutamine and antibiotics (1% penicillin-streptomycin, 0.5% gentamycin) at 37 ℃ in a water-saturated atmosphere of 95% air and 50 mL/L CO_2. Subconfluent MKN45 cells were incubated in RPMI without FCS and antibiotics for 24 h. Following serum starvation, cells were exposed to the increasing amounts of gastrin (Clinalfa, Switzerland, C-210), prostaglandin E_2 (PGE_2), interleukin 1 beta (IL-1β) or tumor necrosis factor alpha (TNF-α) (all from Calbiochem, Bad Soden, Germany).

Extraction of mRNA and RT-PCR analysis

Total RNA was extracted from biopsy specimens and cultured cells using TRIzol reagent (Gibco, Karlsruhe, Germany). Single stranded cDNA was generated from 5 μg RNA using Moloney murine leukemia virus reverse transcriptase (MMLV-RT) and oligo-(dT)-primers (both Stratagene, Heidelberg, Germany). Briefly, 5 μg of total RNA was uncoiled by heating (65 ℃ for 5 min) and then reverse transcribed (37 ℃ for 1 h) into complementary DNA (cDNA) in a 50 μL reaction mixture that contained 50 U MMLV-RT, 0.3 μg oligo-(dT)-primer, 40 U RNase Block Ribonuclease Inhibitor, 2 μL of a 100 mmol/L mixture of dNTPs, and 5 μL of buffer (10 mmol/L Tris-HCl, 50 mmol/L KCl, 5 mmol/L $MgCl_2$, pH 8.3). The resultant cDNA (2 μL) was amplified in a 50 μL reaction volume containing 2 U Taq polymerase, dNTP (200 μmol/L each), 1.5 mmol/L $MgCl_2$, 5 μL 10× PCR buffer (50 mmol/L KCl, 10 mmol/L Tris-HCl, pH 8.3) and specific primers at a final concentration of 1 mmol/L (all reagents from Takara, Shiga, Japan). Reactions were carried out at the following conditions: denaturation at 94 ℃ for 45 s, annealing at 60 °C (for GAPDH) and 67 ℃ (for PrPc) for 45 s and extension at 72 ℃ for 2 min. Polymerase chain reaction (PCR) products were detected by electrophoresis on a 1.5% agarose gel containing ethidium bromide. Product size was confirmed by using a 100-bp ladder (Takara, Shiga, Japan) as standard. The gel was photographed under UV transillumination and the intensity of PCR products were measured using a video image analysis system (Kodak Digital Science). The signal for PrPc mRNAs was standardized against that of the GAPDH mRNA from each sample and the results were expressed as PrPc/GAPDH mRNA ratio. The following PCR primers were used based on published sequences: PrPc (sense) 5`- GGCAGTG ACTATGAGGACCGTTAC-3´; PrPc (antisense) 5´-GG CTTGACCAGCATCTCAGGTCTA-3´; GAPDH (sense) 5´-GTCTTCACCACCATGGAGAAGGCT-3´; GAPDH (antisense) 5´-CATGCCAGTGAGCTTCCCGTTCA-3´. Expected product lengths were 528 bp for PrPc and 392 bp for GAPDH. All primer sequences were based on the sequences of the published cDNAs[12,13] and synthesized by GIBCO BRL/Life Technologies (Eggenstein, Germany).

Real-time RT-PCR

PrPc transcript levels were quantified by real-time RT-PCR. Using the Primer Express software (Perkin Elmer, Tokyo, Japan) TaqMan probe and primer set were designed based on published sequences of human PrPc (GenBank accession no.: GI 11079225); PrPc sense (5´ -CGCGAGCTTCTCCTCTCCTC-3´), PrPc antisense (5´ -GCCCAGGTCACTCCATGT-3´) and beta-2-microglobulin (β2M, GenBank accession no.: XM_007650), β2M sense 5 ´-TGACTTTGT-CACAGCCCAAGATA-3´, β2M antisense primer 5´-AATCCA-AATGCGGCATCTTC-3´. Probes for PrPc (5´-TCGCCATAA-TGACTGCTCTGCCTCGGT-3´) and β2M (5´-TGATGCTG-CTTACAT GTCTCGATCCCA-3´) were synthesized and labeled with a reporter dye (FAM) at the 5' end and quencher dye (TAMRA) at the 3´-end at MWG Biotech AG (Ebersberg, Germany). For normalization of differences in RNA amounts and efficiencies in the reverse transcription reactions, the housekeeping gene β2M was amplified under the same conditions as PrPc. Real-time RT-PCR was performed on a LightCycler (Roche, Mannheim, Germany) in a reaction volume of 15 μL using the LightCycler FastStart DNA Master Hybridization Probes Kit (Roche Molecular Biochemicals, Mannheim, Germany). The reaction mix included FastStart Taq DNA-Polymerase, dNTP-mix, reaction buffer, $MgCl_2$ (3.0 mmol/L), primers (2 μmol/L of each) and probe (0.5 μmol/L). After pippeting 13.5 μL of this mixture into LC-capillaries and 1.5 μL template cDNA was added. The capillaries were sealed and placed into the thermal chamber of the LightCycler. Samples were amplified with a pre-cycling step at 95 ℃ for 10 min, followed by 40 cycles of denaturation at 95 ℃ for 10 s, annealing at 60 ℃ for 15 s and extension at 72 ℃ for 6 s.

Immunoblot

MKN45 cells were incubated with Gastrin 1-1 000 nmol/L, PGE_2 1-100 nmol/L, TNF-α 1-10 ng/mL or IL-1β 1-10 ng/mL) for 24 h. Cells were collected, washed

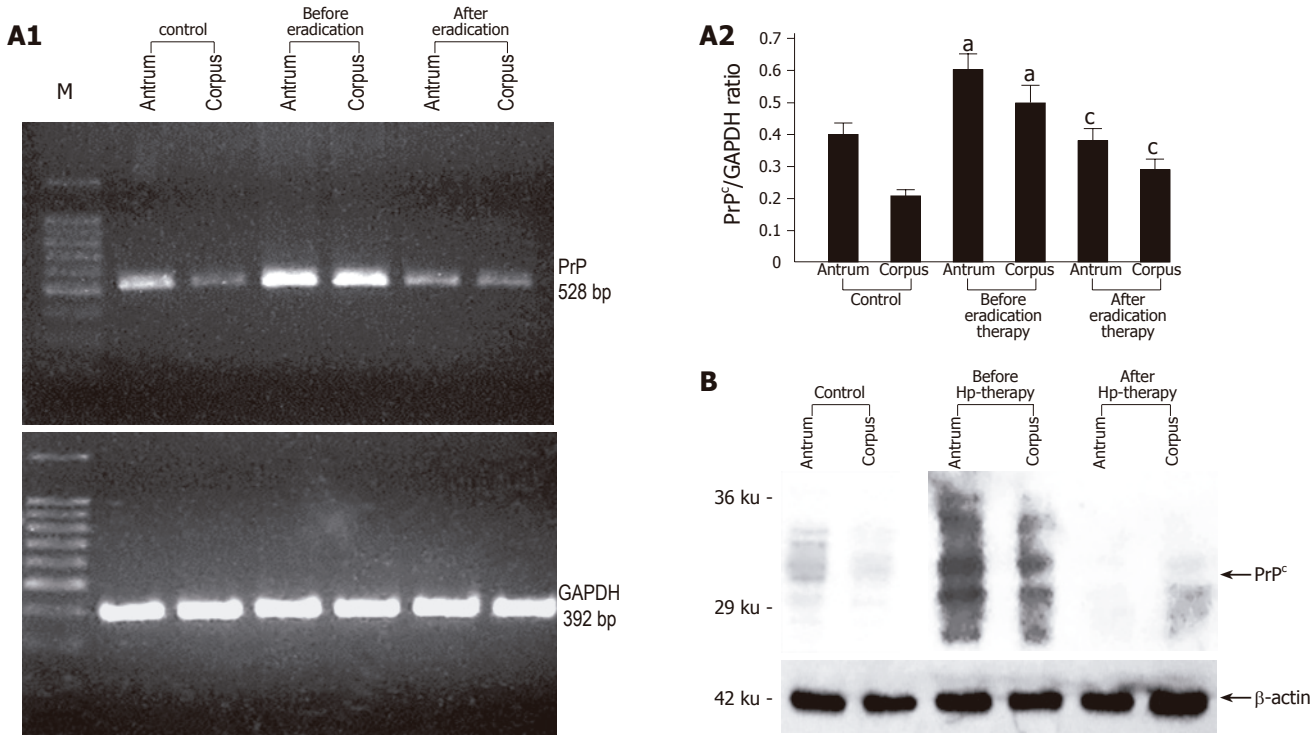

Figure 1 A: Representative RT-PCR and densitometric analysis showing PrPc mRNA expression in the gastric mucosa colonized with *H pylori* before and after successful eradication therapy (n = 10). Data are expressed as means ± SE. $^{a}P<0.05$ *vs* the control group, $^{c}P<0.05$ *vs* the expression before eradication therapy; **B**: Representative immunoblot analysis showing PrPc protein expression in the gastric mucosa colonized with *H pylori* before and after successful eradication therapy.

twice with PBS, and lysed in 0.4 mL of lysis buffer (0.06 mol/L Tris-HCl, pH 6.8, 10% glycerol, 2% SDS, 5% beta-mercaptoethanol, 0.0025% bromophenol blue). DNA was sheared by a needle, the solution heated at 95 ℃ for 5 min and centrifuged at 15 000 *g* for 2 min at 4 ℃. Twenty-five micrograms of the total protein was loaded on SDS-polyacrylamide gel, run at 40 mA and transferred to nitrocellulose (Protran, Schleicher&Schuell, Germany) by electroblotting. Filters were blocked with 3% bovine serum albumin (BSA, Sigma Aldrich, Germany) in TBS/Tween-20 buffer (137 mmol NaCl, 20 mmol Tris-HCl, pH 7.4, 0.1% Tween-20) before incubation with antibodies against PrPc (mouse monoclonal anti-PrP antibody 6H4, 1:2 000 dilution; Prionics, Switzerland), or β-actin (mouse monoclonal, dilution 1:5 000; Sigma Aldrich, Germany), followed by horseradish peroxidase-conjugated anti-mouse or anti-rabbit-IgG secondary antibody (dilution 1:20.000; Promega, WI, USA) dissolved in 1% non-fat milk in TBS/Tween-20. Immune complexes were detected by the SuperSignal West Pico Chemiluminescent Kit (Pierce, USA) and exposed to an X-ray film (Kodak, Wiesbaden, Germany).

Statistical analysis

Statistical analysis was performed using the Mann-Whitney Wilcoxon's test. The level of significance was set at $P<0.05$.

RESULTS

Analysis of gastric biopsy samples obtained endoscopically from patients infected with *H pylori*, which is found in approximately 50% of the world's population[14] and which causes gastric inflammation and ulceration[15] demonstrated highly increased PrPc expression compared to uninfected controls. After treatment with antibiotics which usually lead to *H pylori* eradication, PrPc mRNA and protein expression decreased to control levels (Figures 1A and B).

Using RT-PCR and immunoblotting we demonstrated the expression of PrPc mRNA and protein in two different gastric cell lines (MKN45 and KATO III) (Figure 2). In order to assess possible mechanisms responsible for the upregulation of PrPc during chronic *H pylori* gastritis, we analyzed the effect of increasing doses of key physiological modulators of the gastric mucosa on PrPc expression in these gastric cell lines. These modulators included gastrin (hypergastrinemia is a hallmark of chronic *H pylori* infection[16,17], PGE_2 chronic *H pylori* infection is accompanied by an increased mucosal production of PGE_2[18], and the pro-inflammatory cytokines TNF-α and IL-1β, which are implicated as key promoters of *H pylori*-induced gastritis and ulceration. When exposed to gastrin, cellular PrPc expression increased in a dose-dependent manner, reaching a peak value of 100 nmol/L (Figure 3A). Similarly, PGE_2 induced maximal PrPc mRNA and protein expression at 10 μmol/L (Figure 3B). While IL-1β increased PrPc expression in a dose-dependent manner at the mRNA and protein level (Figures 3C and D), TNF-α showed no effect (Figure 3E).

DISCUSSION

Considering the importance of the human gastrointestinal

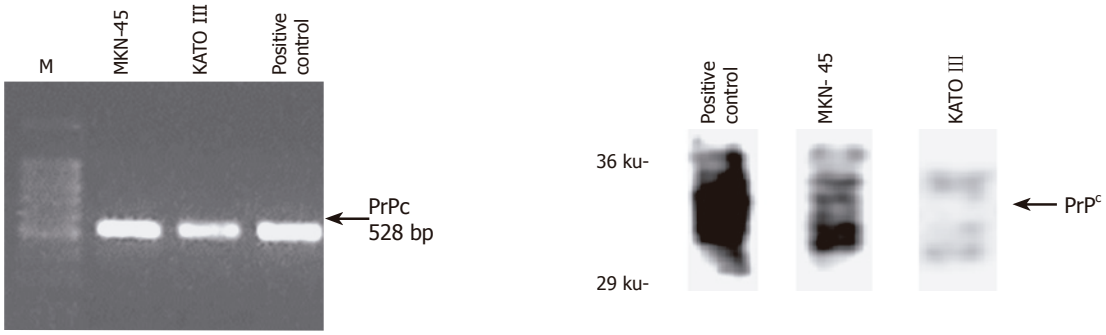

Figure 2 Protein expression of PrPc in two gastric cell lines (MKN45 and KATO III); the positive control is from bovine brain.

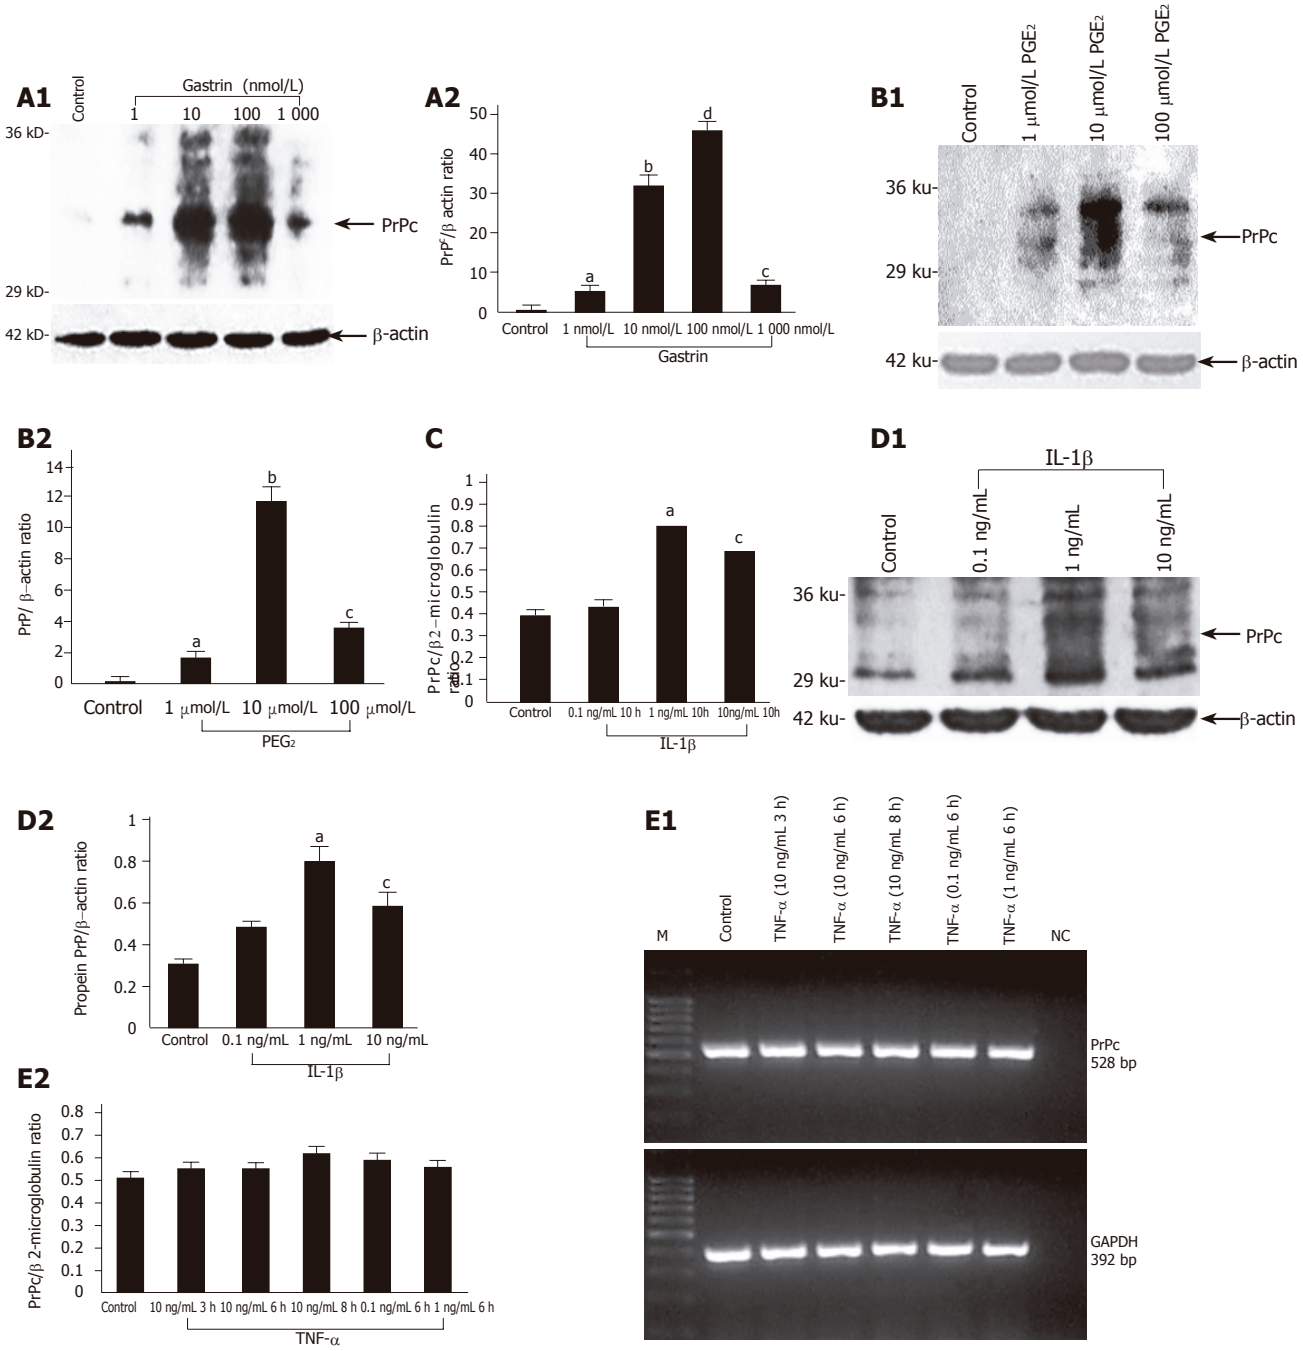

Figure 3 PrPc protein and mRNA expression in MKN45 cells incubated with increasing doses of gastrin (1-1 000 nmol/L) (**A**), PGE_2 (1-100 μmol/L) [a]*P*<0.05 *vs* control, [b]*P*<0.001 *vs* control, [c]*P*<0.05 *vs* control, [d]*P*<0.001 *vs* control (**B**), interleukin 1β (0.1-10 ng/mL) (**C** and **D**) or TNF-α (0.1-10 ng/mL) [a]*P*<0.05 *vs* control, [b]*P*<0.001 *vs* control, [c]*P*<0.05 *vs* control (**E**). Data represent means±SE of three independent experiments. At the mRNA level, the expression of PrPc was normalized to β2-microglobulin and at the protein level to β-actin.

tract for the propagation of prions from the gut to the central nervous system, we analyzed the expression of PrPc in human beings with *H pylori* infection (determined by histology) before and after eradication therapy. This study provides the first *in vitro* and *in vivo* evidence that *H pylori* infection is accompanied by a dramatic upregulation of PrPc expression in the gastric mucosa. The physiological importance of the observed PrPc overexpression in *H pylori* infected gastric mucosa remains elusive. However, multiple physiological functions of PrPc were identified only recently. Thus, PrPc is involved in signal transduction, from the extracellular space to cells, participates in intracellular signaling and regulation of cell survival, protects against oxidative stress, and interacts preferentially with some of the heat-shock-proteins[19-20]. Therefore, the main role of increased PrPc expression in the stomach appears to be the protection of the gastric mucosa against oxidative stress induced, for example by chronic *H pylori* infection[21]. This assumption is further supported by a previous study demonstrating that PrPc upregulates antioxidant enzyme activities[22]. Another possible role of PrPc in the gastric mucosa could be the modulation of apoptosis induced by *H pylori*[23], since PrPc was shown to protect cells against Bax-mediated cell death[24,25]. But this issue remains controversial, as other investigators demonstrated that PrPc may sensitize cells to apoptosis[26,27]. An explanation could be the preferential use of various neuronal cell lines[28] *in vitro* which necessitates further *in vitro* and *in vivo* studies on modulation of apoptosis gastric epithelial cells by PrPc.

In the present study, using quantitative RT-PCR and Western blot analysis we demonstrated an increased PrPc expression in the *H pylori* infected mucosa which significantly decreased after a successful eradication therapy. The mechanisms behind this phenomenon appears to be linked to the hypergastrinemia observed during *H pylori* infection which is supported by our *in vitro* data showing a dose-dependent increase in PrPc expression in gastric epithelial MKN45 cells after incubation with gastrin. According to previous studies, this finding shows that PrPc expression may be modulated by different growth factors[29,30].

Since *H pylori* infection is associated with an increased generation of prostaglandins in the gastric mucosa[18], we analyzed the effect of prostaglandin PGE_2 on PrPc expression in MKN45 cells. At the protein level, we observed a dose-dependent increase in PrPc expression which reached its maximum at the physiological concentration of 10 μmol/L. This could represent another mechanism by which the *H pylori*-induced inflammatory response triggers protective mechanisms in the gastric mucosa.

According to previous studies, chronic infection with *H pylori* is accompanied by a significantly increased generation of pro-inflammatory cytokines, especially IL-1β and TNF-α, in the gastric mucosa. Thus, both cytokines could be responsible for the upregulation of PrPc in the gastric mucosa colonized by *H pylori*. Here we have demonstrated a significant dose-dependent increase of PrPc expression in MKN45 cells incubated with IL-1β, while in contrast, TNF-α showed no effect. We did not further analyze the difference in the action of these two cytokines, but it has been shown by others that these two cytokines evoke different signaling cascades in gastric epithelial cells[31,32].

Gastrin, IL-1β and prostaglandins are not the sole candidates for stimulation of PrPc expression in *H pylori* infected gastric mucosa. Although not investigated in this study, heat shock proteins could represent additional important factors responsible for the upregulation of PrPc. Previous studies demonstrated that exposure of the gastric mucosa to *H pylori* lipopolysaccharide leads to a strong upregulation of heat shock proteins which could in turn stimulate the PrPc expression in gastric epithelial cells[33]. In a previous study, it was found that cellular stress upregulates PrPc expression through its interaction with the heat shock elements (HSE) on the PrPc gene promoter[34]. Together these findings suggest a regulation of PrPc expression by heat shock proteins. All these findings demonstrate the complexicity of the regulation PrPc expression and underscore the need to further analyze the precise link between *H pylori* infection and PrPc expression.

In conclusion, our results indicate that (1) *H pylori* infection is accompanied by a dramatic upregulation of PrPc expression in the gastric mucosa; (2) this is linked to *H pylori*-induced hypergastrinemia, increased mucosal prostaglandin synthesis and enhanced mucosal generation of IL-1β; (3) Thus, *H pylori* infection may promote uptake and propagation of alimentary prions from the gastrointestinal tract by upregulation of PrPc expression.

Abstract

AIM: To define the prevalence of gastroesophageal reflux disease (GERD) in mild persistent asthma and to value the effect of pantoprazole therapy on asthmatic symptoms.

METHODS: Seven of thirty-four asthmatic patients without GERD served as the non-GERD control group. Twenty-seven of thirty-four asthmatic patients had GERD (7/27 also had erosive esophagitis, sixteen of them presented GERD symptoms. An upper gastrointestinal endoscopy was performed in all the subjects to obtain five biopsy specimens from the lower 5 cm of the esophagus. Patients were considered to have GERD when they had a dilation of intercellular space (DIS)>0.74 μm at transmission electron microscopy. Patients with GERD were treated with pantoprazole, 80 mg/day. Forced expiratory volume in one second (FEV1) was performed at entry and after 6 mo of treatment. Asthmatic symptoms were recorded. The required frequency of inhaling rapid acting β2-agonists was self-recorded in the patients' diaries.

RESULTS: Seven symptomatic patients presented erosive esophagitis. Among the 18 asymptomatic patients, 11 presented DIS, while all symptomatic patients showed ultrastructural esophageal damage. Seven asymptomatic patients did not present DIS. At entry the mean of FEV_1 was 1.91 L in symptomatic GERD patients and 1.88 L in asymptomatic GERD patients. After the treatment, 25 patients had a complete recovery of DIS and reflux symptoms. Twenty-three patients presented a regression of asthmatic symptoms with normalization of FEV1. Four patients reported a significant improvement of symptoms and their FEV1 was over 80%.

CONCLUSION: GERD is a highly prevalent condition in asthma patients. Treatment with pantoprazole (80 mg/day) determines their improvement and complete regression.

Key words: Asthma; Gastroesophageal reflux disease; Pantoprazole; NERD; ERD; Dilated intercellular spaces; TEM

INTRODUCTION

The association of asthma with GERD has attracted particular attention because about half of the patients with asthma also have GERD[1–3]. Mechanisms by which esophageal reflux triggers asthma include acid aspiration, direct acid stimulation of the esophagus, or stimulation of vagal nerves which heightens bronchial responsiveness to extrinsic allergens. Clinicians are advised to treat GERD to improve and control asthma[1]. Endoscopic findings of the esophageal erosions (ERD) confirm the diagnosis of GERD. However, absence of macroscopic signs of damage does not rule out an endoscopy negative esophagitis (NERD) that may also be associated with asthma[4]. Recently, we have shown the presence of a highly sensitive and specific marker of damage, the dilation of intercellular spaces (DIS) in GERD with or without erosions, which permits us to define NERD with a strong accuracy[5].

The prevalence of GERD and effects of proton pump inhibitor (PPI) treatment on the decors of asthma are still uncertain and results obtained are often conflicting[6,7]. Bias in the selection of asthma patients or during PPI treatment and absence of highly sensitive parameters of morphology to define the presence of esophageal mucosa damage, may affect the reported results of studies. Moreover, several studies have a non-randomized poor quality design which leads to a further potential error on definition of treatment effects[8,9].

For this reason, the aim of the present study was to define the prevalence of GERD in patients with mild persistent intrinsic asthma and to estimate the effect of pantoprazole in relation with GERD, asthmatic symptoms and respiratory function in this subset of patients.

Table 1 Demographic data of 34 asthmatic patients with or without GERD symptoms

	Symptomatic	Asymptomatic	
		GERD	Non-GERD

DIS (mean±SD) (μm)	2.09±0.24	0.5±0.08	$P<0.001$
FEV_1 (L)	1.91±0.045	1.88±0.02	NS

MATERIALS AND METHODS

Among the 301 asthma patients, 34 consecutive asthma patients with intrinsic, mild persistent asthma[10] were enrolled and their diagnosis was made according to the diagnostic criteria recommended by American Thoracic Society (ATS). Patients were excluded if they had any of the following: past or present smoker, unequivocally extrinsic and/or occupational asthma, acids suppression therapy within 4 wk prior to recruitment, previous gastroesophageal surgery, professional voice users, previous glottal surgery or radiotherapy or malignancy, immune suppression therapy, age above 50 years.

For evaluation of ventilation function, FEV_1 was performed using the Jaeger Masterlab spirometer based on the guidelines of ATS[14]. Symptoms were recorded in each patient to rate the frequency and severity of asthmatic episodes. Symptom severity was rated on a scale of 0 (none) to 6 (severe). The required frequency of inhaling rapid acting β2-agonists was self-recorded in the patients' diaries. All the patients did not use systemic bronchodilators or corticosteroids.

For the diagnosis of GERD, the patients underwent gastrointestinal endoscopic (GE) examination and interviews according to the QUEST questionnaire[11]. Reflux esophagitis was graded according to the Los Angeles classification[12,13]. During endoscopy, five biopsy specimens were taken from the lower 5 cm of esophagus for ultrastructural evaluation. At transmission electron microscopy (TEM), ultrastructural signs of mucosal damage were considered to be the DIS>0.74 μm[5]. To obtain this measure, 10 photomicrographs of biopsy specimens of the supra-basal layer of the esophageal mucosa from each patient were taken. At least 10 randomly selected perpendicular trans-sections to adjacent membranes were drawn and measured in each image for a total of 100 measurements in each case. Measurements obtained were used to calculate the mean DIS score.

The endoscopists, pneumologists and pathologists were unaware of the clinical history of the patients. Data were collected separately by another physician (DZ) who assigned patients to different groups and established the therapy. Symptomatic and asymptomatic patients with or without endoscopic signs, were considered to have GERD when they had ultrastructural evidence of esophageal damage. Patients so defined with GERD were treated with pantoprazole, 80 mg once daily for 6 mo. After 6 mo, a new endoscopy with biopsies was performed and DIS was evaluated. Improvements in GERD symptoms according to the QUEST questionnaire were recorded. FEV_1 was valued.

Asthma patients without GERD were followed up for 6 mo and the use of anti-asthmatic treatment (inhaled glucocorticosteroid 200–1 000 μg BDP or rapid acting β_2-agonists) and symptoms were recorded. We considered them as the control group for the evaluation of asthmatic symptoms, respiratory function and drug assumption with time.

The study was conducted in accordance with the guidelines of the Declaration of Helsinki. The local research ethical committee approved the study protocol in 2002. The objective of the study was explained to each patient and written informed consent was obtained from each one.

For statistical analysis, one-way analysis of variance, paired and unpaired *t* test were performed. The results of the treatment were compared by χ^2 test or Fisher' s exact test. All statistical analyses were two-tailed. Data were analyzed with SPSS software. $P<0.05$ was considered statistically significant.

RESULTS

Among the 34 patients evaluated, 16 presented GERD symptoms (heartburn and/or acid regurgitation) and 18 were asymptomatic for reflux disease. At endoscopy, all asymptomatic subjects had no macroscopic signs of esophagitis. Seven symptomatic patients (43.75%) presented erosive esophagitis (ERD).

Among the 18 asymptomatic patients, 11 (61%) presented DIS, while all symptomatic patients showed ultrastructural esophageal damage. Seven asymptomatic patients (38.9%) did not present DIS (Table 1). At entry the mean of FEV_1 was 1.91 L in symptomatic GERD patients and 1.88 L in asymptomatic GERD patients. The two groups at baseline were not significantly different (P = NS) (Table 2).

All the 27 patients with GERD (79.4%) completed the study. They were treated for 6 mo with pantoprazole. At the end of this period erosive esophagitis was healed in seven patients with ERD. Among the 25 patients (92.6%), 6 with ERD and 19 with NERD, had a complete recovery of DIS and reflux symptoms (Table 3 and Figure 1A).

Twenty-three patients (85.18%) presented a regression of asthmatic symptoms (Table 4 and Figure 1B), including nocturnal asthma and FEV_1 (2.75 L, $P<0.01$), but there

was no statistical difference in respiratory parameters between patients with ERD and those with NERD. After 3 wk of treatment no more asthmatic symptoms occurred and no inhaler was needed.

Four patients (14.8%) reported a significant improvement in symptoms, including dyspnea, cough, wheeze, and expectoration with a significant reduction in the consumption of inhalers and FEV_1 over 80%.

DISCUSSION

Physicians mostly focus on the effects induced by gastroesophageal reflux into the esophagus. The anatomic proximity of the esophagus to the respiratory tract in some patients also leads to his involvement. Thus, the spectrum of symptoms of GERD includes also respiratory complications like chronic cough, laryngeal disorders, chest pain, and asthma. In this contest, GERD gains an additional fraction of significance and has been reported to occur in 30-89% of asthma patients[13,15-18].

Treatment with PPI can relieve the symptoms of GERD in up to 90% of patients. It has been tempted to investigate if treatment of GERD with PPI could improve also the respiratory symptoms of asthma patients[19].

It seems obvious that to achieve improvement in asthma symptoms and lung function, the treatment needs to be effective in controlling reflux as well as reducing acidity. However, this has been only objectively confirmed in few studies using high doses of omeprazole[19]. An optimal study design would establish if the esophageal damage is adequately treated as a prerequisite to assess the effects on asthma.

In this study, we analyzed the esophageal specimens from 31 consecutive asthmatic patients, 16 of them were symptomatic for GERD. We found that all symptomatic patients presented an ultrastructural pattern of damage and 73% of asymptomatic GERD patients had esophageal signs of ultrastructural damage, suggesting that GERD is a highly prevalent condition even in asymptomatic patients. Acid stress might initiate or exacerbate asthma in this contest. Electron microscopy is able to find out esophageal damage, especially in asymptomatic patients with NERD.

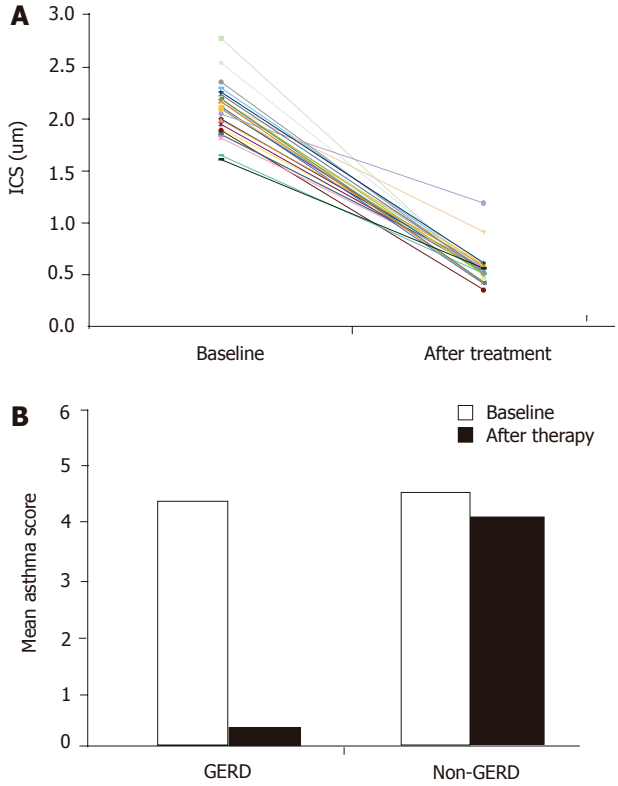

Figure 1 Effect of pantoprazole treatment on dilation of DIS (**A**) and asthma symptom scores (**B**) in GERD patients. The dashed line in Figure 1A corresponds to the mean score of DIS; its cut-off (0.74 μm) represents the presence of damage. Graphic is based on the data analyzed as mean value.

All patients with GERD so defined in our study were treated with a high dosage of pantoprazole for 6 mo. We observed that 93% of patients recovered DIS, 85% of them presented a regression of asthmatic symptoms with normalization of FEV_1, with no statistical difference in respiratory parameters between patients with ERD or NERD. Other patients improved markedly their symptoms and pulmonary function but sporadically presented asthmatic episodes.

We believe that the strong efficacy of PPI treatment in these patients is related to the characteristics of the carefully defined population. The young age of subjects and the mild-moderate asthma let us suppose the existence of an early "action" of treatment before the chronicity of the illness or the worsening to a severe status of asthma. In other words, PPI can suppress or delay the potential development of pulmonary tissue injury.

In conclusion, GERD-related asthma complications are highly prevalent in patients with mild-moderate intrinsic asthma. Treatment with pantoprazole (80 mg once daily for 6 mo) determines the improvement and complete regression of asthmatic symptoms and respiratory function in most patients.

Abstract

AIM: To evaluate the phagocytic activity and neutrophil oxidative burst in liver cirrhosis.

METHODS: In 45 patients with advanced postalcoholic liver cirrhosis (aged 45±14 years) and in 25 healthy volunteers (aged 38±5 years), the percentage of phagocytizing cells after *in vitro* incubation with *E. coli* (Phagotest Kit), phagocytic activity (mean intensity of fluorescence, MIF) and the percentage of neutrophil oxidative burst (Bursttest Kit), and the level of free oxygen radical production (MIF of Rodamine 123) were analyzed by flow cytometry. The levels of soluble sICAM-1, sVCAM-1, sP-selectin, sE-selectin, sL-selectin, and TNF-α were determined in blood serum.

RESULTS: The percentage of *E. coli* phagocytizing neutrophils in liver cirrhosis patients was comparable to that in healthy subjects. MIF of neutrophil - ingested *E. coli* was higher in patients with liver cirrhosis. The oxidative burst in *E. coli* phagocytizing neutrophils generated less amount of active oxygen compounds in liver cirrhosis patients (MIF of R123: 24.7±7.1 and 29.7±6.6 in healthy, $P<0.01$). Phorbol myristate acetate (PMA) - stimulated neutrophilsproduced less reactive oxidants in liver cirrhosis patients than in healthy subjects (MIF of R123: 42.7± 14.6 *vs* 50.2±13.3, $P<0.01$). A negative correlation was observed between oxidative burst MIF of PMA-stimulated neutrophils and ALT and AST levels (r -0.35, $P<0.05$; r-0.4, $P<0.03$). sVCAM-1, sICAM-1, sE-selectin concentrations correlated negatively with the oxygen free radical production (MIF of R123) in neutrophils after PMA stimulation in liver cirrhosis patients (r-0.45, $P<0.05$; r-0.41, $P<0.05$; r-0.39, $P<0.05$, respectively).

CONCLUSION: Neutrophil metabolic activity diminishes together with the intensification of liver failure. The metabolic potential of phagocytizing neutrophils is significantly lower in liver cirrhosis patients, which can be one of the causes of immune mechanism damage. The evaluation of oxygen metabolism of *E. coli*-stimulated neutrophils reveals that the amount of released oxygen metabolites is smaller in liver cirrhosis patients than in healthy subjects.

INTRODUCTION

Neutrophils play an important role in non-specific immune response and organism resistance, specifically in anti-bacterial resistance as effectors, inducing and regulating cells[1,2]. They reveal many features which are crucial in organism immunity: to produce and adhere towards vascular endothelial cells, migrate to inflammatory sites through the vessel walls, recognize and phagocytize opsonized molecules, and degradate and release proteins from granules[3,4]. These features are possible due to the presence of receptors distributed on the surface and inside of the cells such as cytokine-, neuromediator-, autocoid-, hormone receptors. Neutrophil chemotaxis occurs towards stimulus gradient, in response to chemotactic factors (chemotaxins) produced at the inflammatory site. Moreover, chemotaxins increase neutrophil metabolism, aggregation, and bactericidal abilities[5-7].

Phagocytosis is facilitated by specific (immunoglobulins IgG) and non-specific (complement components) opsonins, circulating in the plasma. On their surface, granulocytes have receptors that bind to Fc fragment of IgG1 and IgG2 immunoglobulins, and complement C3b fragment receptors[8]. Absorbed opsonized microorganisms are killed through both oxygen-dependent and independent mechanisms. Free oxygen radicals kill

absorbed bacteria in phagosomes and partially are released into the environment, intensifying killing microorganisms and simultaneously injuring the surrounding tissues. It is specifically intensified in acute inflammation, less in chronic course of the disease[1]. Microorganism killing is also possible by proteins present in azurophil granules, such as cathepsin G, lysozyme, interferons, and others.

Inflammatory mediators, cytokines (e.g. TNFα) and selectins increase the ability of granulocytes to localize at the site of inflammation. Phagocytic ability is elevated by intensification of hydroxylic radical production and lysosomal enzyme release[9,10]. TNFα is an important factor strengthening granulocyte phagocytic and cytotoxic activity. Activated granulocytes secrete cytokines. IL-1, which stimulates monocytes, endothelial cells, and fibroblasts to secrete IL-8, in turn increases the expression of CD11b/CD18 adhesive molecules and granulocyte oxygen metabolism[11]. Interferon gamma is a strong cytokine, which intensifies Fc receptor expression, stimulates oxygen changes, and strengthens granulocytic granule release.

The aim of the study was to evaluate the metabolic activity of oxidative burst *in vitro* and the production of active oxygen compounds stimulated by *E. coli* and phorbol myristate acetate (PMA). Determination of the percentage of phagocytizing cells and their ability to phagocytize opsonized bacteria is of great importance in the estimation of neutrophil functioning. We evaluated the neutrophil ability to phagocytize *E. coli in vitro* in advanced liver cirrhosis. We also tried to establish the relationship between the neutrophil ability and the concentration of soluble adhesive molecules in peripheral blood.

MATERIALS AND METHODS

Patients

The studies were conducted in the group of 45 patients with advanced postalcoholic liver cirrhosis (30 men and 15 women, aged 45±14 years) (Table 1). Liver cirrhosis was confirmed clinically and histologically. Patients with acute viral or bacterial disease and those in the course of corticosteroid therapy who did not drink alcohol for at least 6 mo were excluded from the study. Patients with liver cirrhosis were divided into groups B and C in accordance with the classification of liver failure according to Child-Pugh[12]. The control group consisted of 25 healthy volunteers (12 women and 13 men, aged 38±5 years), who had never suffered from liver diseases and those without registered immunity disorders. Ethical approval for research was obtained from local Ethics Committee in the Medical University.

Methods

Blood was collected in plastic testing tubes with EDTA K2 and the absolute number of leukocytes and neutrophils was evaluated. The blood was collected in lithium heparin plastic testing tubes for the evaluation of phagocytizing cells and phagocytic activity and the percentage of bursting cells as well as neutrophil oxygen metabolism.

Table 1 Clinical characteristics of patients with liver cirrhosis (mean±SD)

	Child–Pugh B	Child–Pugh C
Age, year	43±12	46±13
Male/female	15/10	15/5
Albumin, g/dL	3.2±0.3	2.8±0.6
AST/ALT, IU/mL	98±65/87±98	110±45/97±45
Bilirubin, mg/dL	4.5±3.8	9.7±6.5

The assessment of phagocytosis was performed using the Phagotest Kit (ORPEGEN Pharma, Germany) containing fluorescein-labeled opsonized Escherichia coli (*E. coli* - FITC). Samples of 100 μL of blood with heparin were cooled in an ice bath for 15 min mixed with 2×10^7 FITC-labeled *E. coli* and then put in a chamber thermostat at 37 °C for 10 min. Simultaneously, the control samples were put into an ice bath to inhibit phagocytosis. Afterwards, 100 μL of brilliant blue (Quenching solution) was added in order to suppress the fluorescence of bacteria connected to the leukocyte surface. After two washing steps (with 2 mL of washing solution, centrifuged at 2 000 r/min, supernatant was pumped out), erythrocytes were lysed using lysis fluid for 20 min at room temperature. At the end, 50 μL propidyne iodide was added to stain leukocytes and bacterial DNA.

Oxidative burst

Granulocyte oxidative burst was determined quantitatively with Bursttest Kit (ORPEGEN Pharma, Germany). Fresh heparinized blood was put in a water bath for 15 min. Then, four testing tubes were filled with 100 μL of blood each and 2×10^7 unlabeled opsonized bacteria *E. coli*, 20 μL of substrate solution (negative control), 20 μL fMLP (peptide *N*-formyl-MetLeuPhe) as chemotactic low physiological stimulus (low control) and 20. μL phorbol 12-myristate 13-acetate (PMA), a strong non-receptor activator (high control). All the samples were incubated for 10 min at 37.0 °C in a water bath, dihydrorhodamine (DHR) 123 as a fluorogenic substrate was added and incubated again in the same conditions. The oxidative burst occurred with the production of reactive oxygen substrates (ROS) (superoxide anion, hydrogen peroxide) in granulocytes stimulated *in vitro*. In ROS-stimulated granulocytes, nonfluorescent DHR 123 underwent conversion to fluorescent rhodamine (R) 123 registered in the flow cytometer. Erythrocytes were removed using lysing solution for 20 min at room temperature, centrifuged (5 min, 250 r/min, 4 °C), and supernatant was discarded. Samples were washed again (washing solution), centrifuged (5 min, 250 r/min, 4 °C) and the supernatant was decanted. An amount of 200 μL of DNA staining solution (centrifuged and incubated for 10 min at 0 °C in a dark place) was added to discriminate and exclude aggregation artifacts of bacteria and/or cells in cytometric flow analysis.

Cytometric analysis

The flow cytometer EPICS XL (Coulter, USA) equipped

with 488 nm argon-ion laser was used. The apparatus was calibrated every day using DNA check. Neutrophil populations were identified by the use of forward and right angle light scatter, and the fluorescence emission of 10^4 cells per sample was recorded on a logarithmic scale. Fluorescent measurements were conducted with identical settings as for the standard determination of cell phenotype with fluorochrome-stained mAb.

Phagocytic activity was determined as the percentage of phagocytizing neutrophils (one or more bacteria ingestion) and as the mean intensity of fluorescence (MIF) value, which equaled the mean number of bacteria phagocytized by the cells.

Granulocyte oxygen metabolism was determined with the percentage of cells phagocytizing *E. coli* producing reactive oxidants (cells undergoing bursts, the change from DHR 123 to R 123), and with the evaluation of granulocyte enzymatic activity (the amount of released active oxygen compounds – the amount of MIF R 123 per cell).

Adhesive molecules and TNFα

ELISA tests were used to determine the level of sICAM-1 (Human sICAM-1, R&D, UK), sVCAM-1 (Human sVCAM-1, R&D), and the level of tumor necrosis factor alpha (Human TNFα, R&D) in blood serum. Soluble forms of P- (Human soluble P-Selectin, R&D), E- (Human sE-Selectin, R&D), and L-selectins (Human sL-Selectin, R&D) were determined by ELISA tests simultaneously in blood serum.

Statistical analysis

The results were presented as mean±SD. Statistical analysis was performed by non-parametrical *U* (Mann-Whitney) test. The result of correlation was calculated by Spearman's correlation test. $P<0.05$ was considered statistically significant.

RESULTS

Phagocytic activity of neutrophils

The ability of neutrophils to phagocytize opsonized *E. coli* was assessed. No significant differences were found in phagocytizing neutrophils both in liver cirrhosis patients and in healthy subjects (Table 2). The MIF of absorbed *E. coli* was slightly higher in patients with liver cirrhosis (differences being statistically insignificant). A positive correlation was observed between the percentage of neutrophils-phagocytized *E. coli* and the percentage of neutrophils with oxidative burst after *E. coli* stimulation *in vitro* ($r = 0.37$, $P<0.05$, Table 3).

Neutrophil oxidative burst

Stimulation *in vitro* with a strong activator PMA causes a markedly lower production of reactive oxidants in neutrophils in liver cirrhosis patients than in healthy individuals (MIF 42.7±14.6 *vs* 50.2±13.3, $P<0.01$, Table 2). Incubation of neutrophils with non-opsonized *E. coli* induced oxidative burst in more neutrophils in patients with liver cirrhosis than in the control group. However, neutrophils phagocytizing *E. coli* showed markedly lower metabolic potential in liver cirrhosis patients than that in healthy subjects. The oxidative burst in neutrophils phagocytizing *E. coli* caused generation of smaller amounts of active oxygen compounds in the cells of patients with liver cirrhosis. Neutrophils with oxidative burst (MIF of rhodamine 123) were statistically lower in liver cirrhosis patients (24.7±7.1) than in healthy subjects (29.7±6.6, $P<0.01$). PMA neutrophil stimulation *in vitro* was more effective than a direct contact with *E. coli*.

The decrease in neutrophil metabolic and phagocytic activities was observed together with the intensification of liver damage. We noted a negative correlation of MIF of neutrophil oxidative burst after PMA stimulation and ALT and AST, which was $r = -0.35$, $P<0.05$ and $r = -0.4$, $P<0.03$, respectively.

Adhesive molecules and TNFα

The concentrations of adhesive molecules sVCAM-1 and sICAM-1 in blood serum were several times higher in patients with liver cirrhosis ($P<0.01$, Table 2). Soluble E-selectin concentrations in liver cirrhosis patients were also significantly higher than in healthy subjects ($P<0.01$). However, significant differences of sL-selectin concentrations were not present, while sP-selectin concentrations were lower in liver cirrhosis patients. The level of sVCAM-1, sICAM-1, sE-selectin correlated negatively with the activity of oxygen radical production (MIF) after PMA neutrophil simulation ($r = -0.45$, $P<0.05$, $r = -0.41$, $P<0.05$, $r = -0.39$, $P<0.05$, respectively). The concentration of TNFα was markedly higher in liver cirrhosis patients than in healthy individuals ($P<0.01$). No correlation was observed between neutrophil metabolic and phagocytic activities and TNFα concentration. On the other hand, there was a positive correlation between sVCAM-1 and sE-selectin concentration ($r = 0.4$, $P<0.05$) and between sL-selectin concentration and the production of free oxygen radicals in neutrophils (MIF of R123) ($r = 0.35$, $P< 0.05$).

DISCUSSION

Infectious and toxic factors and over reactivity of the immune system are crucial in the pathogenesis of chronic liver diseases. The essence of the disease is accumulation of natural killer cells and inflammatory cells as well as intensified fibrosis in the liver. Chronic failure of endothelial cells of hepatic vessels increases expression and concentration of adhesive molecules. It facilitates inflammatory cell activation, margination and accumulation of leukocytes in the liver[4,13-15]. Neutrophils are professionally phagocytizing cells, which play an important role in immunological processes of the organism. They participate mainly in non-specific response as they do not possess the properties for precise recognition of antigens. Chemotactic factors and cytokines (IL-1, IL-8, TNFα, TGF-β) induce migration of granulocytes and other cells to the inflammatory site.

Table 2 Phagocytic and oxidative burst activity of neutrophils, level of soluble form of adhesive molecules and TNFα in liver cirrhosis patients (mean±SD)

		Liver cirrhosis		Healthy
	Total	Child–Pugh B	Child–Pugh C	
Oxidative burst				
Percentage of neutrophils with oxidative burst after PMA stimulation (%)	98.3±1.2	98.4±1.5	98.2±1.6	98.8±2.8

[b]$P<0.01$ *vs* healthy subjects (Mann–Whitney *U* test).

Table 3 Correlation (*r*) of phagocytic activity of neutrophils with their oxidative burst level and biochemical tests of liver dysfunction (Spearman test)

Correlations	*r*	*P*
MIF oxidative burst neutrophils after PMA stimulation with ALT level	-035	0.05
MIF phagocytizing *E. coli* with prothrombin time	-0.47	0.03
Percentage of neutrophils phagocytizing *E. coli* with leukocyte number	0.35	0.05
Percentage of oxidative burst neutrophils after *E. coli* stimulation with MIF phagocytosis *E. coli*	0.37	0.05

The study showed a significant impairment of neutrophil immune mechanisms in liver cirrhosis as well as oxidative burst damage with diminished amount of generated free oxygen form in neutrophils. Stimulation *in vitro* with the strong stimulant PMA and non-opsonized *E. coli* induces less amount of released active oxygen compounds in neutrophils in liver cirrhosis patients than in healthy subjects. It should be assumed that it is a result of permanent stimulation of neutrophils by inflammatory factors or lipopolysaccarides (LPS). Observed disorders can be treated as dysfunctions of exhausted neutrophils, and oxygen exchange impairment (processes being important in the maintenance of organism immunity) has been confirmed in other studies[16,17]. The higher release of oxygen metabolites observed after PMA is probably due to different stimulation mechanisms. The neutrophil phagocytic activity in both groups was comparable. Cytometric examinations of the percentage of phagocytizing neutrophils and MIF of absorbed opsonized *E. coli* did not show differences in both groups.

Vascular endothelium has many important functions, and is a barrier against pathogens as well as the site of immunological and inflammatory process initiation with participating neutrophils[18]. Neutrophil accumulation at the site of inflammation depends on the adhesive molecule expression in endothelial cells. Neutrophil stimulation leads to activation of L-selectin and other molecules (β2-integrines) that participate in adhesion to the endothelium. In addition, increase in adhesive molecule expression directly activates antibacterial mechanisms, granule secretion and neutrophil oxygen metabolism. Activation of neutrophils (the main generators of free oxygen radicals in inflammatory processes) leads to elevation of active oxygen metabolites responsible for killing microorganisms[19]. In patients with end-stage liver disease, the ability of neutrophils to migrate to the inflammatory sites is impaired. It was observed that neutrophils present there have their phagocytizing activity reduced[16].

Adhesive molecules (ICAM-1, VCAM-1, selectins) play an important role in keeping neutrophils in liver sinusoids. Antibodies against anti-ICAM-1 and anti-VCAM-1 inhibit neutrophil accumulation in liver tissues and diminish their damage[9,20]. P- and E-selectin expressions in endothelial cells and L-selectin – in leukocytes – lead to slower flow of leukocytes and blood platelets in bloodstream, activation, rolling, and adhesion of these cells. In liver cirrhosis patients, adhesive molecule expression increases due to tissue hypoxia, deposits of immunological complexes, endogenic toxic compounds, LPS, bacteria, and viruses[21-23].

Fiuza *et al.*[16] have suggested that, in the end-stage liver disease, neutrophils have injured ability to migrate to the inflammatory sites and their phagocytic activity is diminished, which in turn, correlates with the severity of liver disease. It has been shown that chronic intravascular peripheral neutrophil activation occurs in vessels. Their results point to the fact that antibacterial early inflammatory immune response is damaged in liver cirrhosis. The increase in bacterial translocation and endotoxin absorption from the bowel is a stimulus for the reticuloendothelial system to produce proinflammatory cytokines[24,25]. Neutrophil activity and phagocytic ability failure may result in ascitic fluid microinfection and

subclinical SBP. On the other hand, a persistent stimulation of neutrophils by inflammatory factors can lead to the exhaustion of their functional potential. Proinflammatory factor elimination from peripheral blood is impaired in liver cirrhosis which facilitates persistent stimulation of peripheral blood neutrophils[25].

We observed high concentrations of soluble adhesive molecules VCAM-1, ICAM-1, and E-selectin, which can account for a marked vascular endothelium damage in liver cirrhosis. Endothelial cell failure or stimulation can occur due to high levels of proinflammatory cytokines (e.g. TNFα). Chronic endotoxemia may also stimulate adhesive molecule expression. High concentrations of VCAM-1, ICAM-1 and E-selectin stimulate inflammatory site to accumulate in terminal capillaries of the liver and other organs. In our studies, the increased expression and concentration of soluble adhesive molecules might result in exhaustion of oxygen metabolism of neutrophils in liver cirrhosis.

Neutrophils are an important host immune barrier against bacterial infections. A persistent stimulation of leukocytes that flow through the liver affected by inflammation leads to the exhaustion of mechanisms responsible for their immune properties.

Abstract

AIM: To investigate the expression of leptin and leptin receptor (ob-R) in intestinal-type gastric cancer and precancerous lesions, and to explore the possible mechanism and role of the leptin system in developing intestinal-type gastric adenocarcinoma.

METHODS: Immunohistochemistry was performed to examine the expression of leptin and leptin receptor in archival samples of gastric adenocarcinoma and preneoplastic lesions, including intestinal metaplasia and mild to severe gastric epithelial dysplasia. Positive staining was identified and percentage of positive staining was graded.

RESULTS: Dual expression of leptin and leptin receptor were detected in 80% (16/20) intestinal metaplasia, 86.3% (25/30) mild gastric epithelial dysplasia, 86.7% (26/30) moderate gastric epithelial dysplasia, 93.3% (28/30) severe gastric epithelial dysplasia, 91.3% (55/60) intestinal-type gastric adenocarcinoma and 30.0% (9/30) diffuse-type gastric carcinoma. The percentage of dual expression of leptin and leptin receptor in intestinal-type gastric adenocarcinoma was significantly higher than that in diffuse-type gastric adenocarcinoma ($\chi^2 = 37.022$, $P<0.01$).

CONCLUSION: Our results indicate the presence of an autocrine loop of leptin system in the development of intestinal-type gastric adenocarcinoma.

Key words: Leptin; Leptin receptor (ob-R); Intestinal-type gastric adenocarcinoma; Intestinal metaplasia; Gastric epithelial dysplasia

INTRODUCTION

Leptin, the product of the obesity gene (ob gene), is a cytokine-like peptide capable of signal transduction via interaction with its specific receptor (ob-R). It was initially found to be synthesized by adipocytes and act centrally in the hypothalamus to regulate food intake and energy expenditure[1]. Subsequently, expressions of leptin or ob-R were detected in a wide variety of tissues with multiple role in hematopoiesis, reproductive control, angiogenesis, cardiovascular medication, immunomodulation and carcinogenesis[2–6]. Recently, the presence of leptin has also been demonstrated in stomach and thought to be stomach-derived. This endogenous gastric leptin acts as a gastrointestinal hormone via autocrine and/or paracrine pathway in gastrointestinal tract and plays an important role in digestive physiological activities, including short-term meal size control, gastric mucosal cytoprotection and nutrition, regulation of gastric acid and gastric hormone secretion, and modulation of intestinal transport[7].

According to Lauren, gastric cancer can be divided into two histological types: diffuse and intestinal[8]. During the carcinogenesis of intestinal-type gastric adenocarcinoma, a stepwise process proposed by Correa has been widely accepted, which suggested that prolonged *H pylori* infection leads to atrophic gastritis, then with further mutational events leads to the development of intestinal metaplasia, epithelial dysplasia and finally intestinal-type gastric adenocarcinoma[9]. Gastrointestinal hormones and cytokines, including gastrin, epithelial growth factor, vasoactive intestinal peptide and IL-6, seem to play important roles in this transformation processes[10–16]. However, whether leptin, a cytokine-like gastrointestinal hormone that share similarity with aforementioned hormones or cytokines, is involved in the development of intestinal-type gastric adenocarcinoma remains unclear. In the present study, using immunohistochemistry, we examined the expression of leptin and ob-R protein in the tissues of intestinal metaplasia, gastric epithelial dysplasia and intestinal-type gastric adenocarcinoma. Their presence may suggest an autocrine/paracrine pathway of leptin system in gastric carcinogenesis.

MATERIALS AND METHODS

Samples

Formalin-fixed samples of 30 cases of intestinal

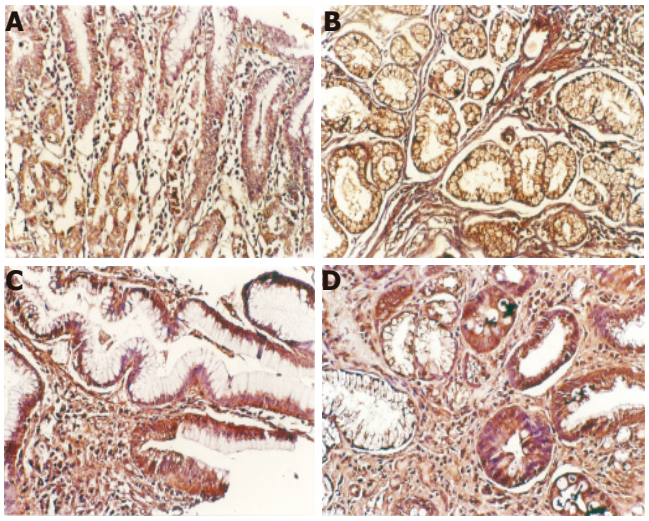

Figure 1 Immunohistochemical stainings of leptin located in cytoplasm (×200). **A:** Normal gastric mucosa; **B:** intestinal metaplasia; **C:** gastric dysplasia; **D:** intestinal-type gastric adenocarcinoma.

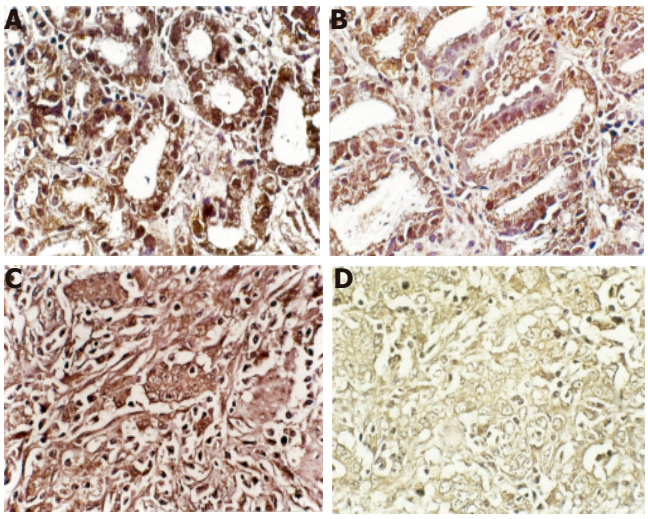

Figure 2 Immunohistochemical stainings of leptin receptor located at cell membrane (×200). **A:** Normal gastric mucosa; **B:** intestinal metaplasia; **C:** gastric dysplasia; **D:** intestinal-type gastric adenocarcinoma.

metaplasia, 90 cases of epithelial dysplasia (mild dysplasia, moderate dysplasia and severe dysplasia, each 30 cases), and 90 cases of gastric adenocarcinoma (60 intestinal-type, 30 diffuse-type) were obtained from pathology archives during 1995-2004 from Renmin Hospital, Wuhan University, Wuhan, China. Those patients had never received chemotherapy, radiation therapy or *H pylori* eradiation. For each case, a paraffin-embedded section with hematoxylin-eosin-safran staining was subjected to pathological identification by a consultant histopathologist on the basis of the Lauren's classification and WHO classification.

Immunohistochemistry

For immunohistochemistry analysis, paraffin-embedded tissue blocks were serially sectioned (4-μm thickness) and mounted onto histostick-coated slides and kept in an oven at 72 °C for 2 h. Sections were deparaffinized in xylene and rehydrated before analysis. Endogenous peroxides was quenched with 30 mL/L hydrogen peroxide in methanol for 10 min. Antigen retrieval was performed by means of microwave irradiation for 15 min and blocked for 15 min with normal goat serum, followed by incubation overnight at 4 °C with a rabbit polyclonal antibody (SC-842) against human leptin (Santa Cruz Biotechnology) and a rabbit polyclonal antibody (SC-1834) against human leptin receptor (Santa Cruz Biotechnology) both at a dilution of 1:70. Replacement of the primary antibodies by PBS solution was used as a negative control. Sections of normal gastric fundus mucosa that had previously shown expression of leptin and ob-R were used as positive

Table 1 Expression of leptin and ob-R in gastric cancer and precancerous lesions

	n	Leptin						Ob-R						Dual expression of leptinand ob-R

controls. Sections were washed thrice with PBS for 2 min each and incubated with biotin-labeled anti-rabbit IgG at room temperature for 1 h. After washing thrice with PBS for 2 min each, sections were stained by streptavidin-peroxidase detection system. Antibody binding was visualized using the diaminobenzidine as chromogen and counterstained with hematoxylin. The positive cells were counted in ten randomly selected fields under ×200 or × 400 microscopic magnification for each specimen and the mean positive percentage was calculated as the density of positive cells. Immunoreactivity was performed by two experienced histopathologists without knowledge of the background features. The abundance of positive stains was graded as follows: -, no cell stained; +, <25% of cells stained; ++, 25–50% of cells stained; +++, 50–75% of cells stained; and ++++, >75% of cells stained.

Statistical analysis

Data were analyzed using SPSS 10.0 software. The χ^2 test was used to compare binomial proportions. A P value less than 0.05 was considered statistically significant.

RESULTS

Immunostainings of leptin and ob-R in normal gastric mucosa, intestinal metaplasia, gastric epithelial dysplasia, intestinal-type gastric adenocarcinoma, diffuse-type gastric carcinoma are shown in Figures 1 and 2. Positive staining of leptin was identified as brownish-yellow granules in cytoplasm. Positive staining of ob-R was identified as brownish-yellow granule at cell membrane.

DISCUSSION

In the present study, the expressions of leptin and ob-R in intestinal metaplasia, gastric epithelial dysplasia, intestinal-type gastric adenocarcinoma and diffuse-type gastric cancer were determined using immunohistochemistry. Our results demonstrated that dual expressions of leptin and leptin receptor were detected in 83.3% (25/30) intestinal metaplasia, 87.7% (79/90) gastric epithelial dysplasia, and 83.3% (75/90) intestinal-type gastric adenocarcinoma without statistically significant difference among those groups. Moreover, no obvious difference among mild gastric dysplasia (83.3%, 25/30), moderate gastric dysplasia (86.7%, 26/30) and severe gastric dysplasia (93.3%, 28/30) was observed. The percentage of dual expression in intestinal-type gastric adenocarcinoma (91.7%, 55/60) was significantly higher than that in diffuse-type gastric carcinoma (30.0%, 9/30). These results indicated that dual expression of leptin and ob-R might be a tumor-specific phenomenon in the transformation from intestinal metaplasia to intestinal-type gastric adenocarcinoma. To the best of our knowledge, our study may be the first study demonstrating dual expression of leptin and ob-R in intestinal metaplasia, gastric epithelial dysplasia and intestinal-type gastric adenocarcinoma, which may play important roles in this transformation process.

As a growth factor, leptin exhibited simulative effect on the proliferation of a variety of malignant cell lines, including leukemia, breast cancer, esophagus adenocarcinoma, prostate cancer, colon cancer, and pituitary adenomas[6,17–21]. In addition, there had been increasing evidence that leptin plays an important role in tumor invasion, metastases, angiogenesis and resistance to chemotherapy[22–26]. Based on these results, leptin is considered to serve as a multi-functional growth factor in tumorigenesis and is capable of promoting an aggressive cancer phenotype. Recently, it has been shown that leptin induced the proliferation of human gastric adenocarcinoma AGS cell line in a dose-dependent fashion[27]. Therefore, it is reasonable to speculate that dual expression of leptin and ob-R may form an autocrine/paracrine stimulatory loop based on intestinal-type gastric adenocarcinoma and precancerous lesions, and play an important role in gastric carcinogenesis.

As a member of the class I cytokine receptor family, ob-R is identified as a single membrane-spanning protein with multiple isoforms (ob-Ra, ob-Rb, ob-Rc, ob-Rd). ob-Rb contains sequence motifs of janus-kinase (JAK)/signal transduction and activation of transcription signal transduction pathways. In addition, leptin activates mitogen-activated protein kinase (MAPK) signal transduction pathways through the ob-Rb receptor and also through the ob-Ra receptor in some cases[18,28]. Those downstream signal pathways of leptin system were verified to be implicated in the formation and progression of tumor. Proliferation of prostate cancer cells appeared to be working through the PI3K and MAPK leptin receptor-activated pathways, depending on cell type[21]. In colon cancer cell line, leptin was demonstrated to stimulate proliferation via P42/44 MAPK signal pathway and induce invasion via JAK/PI3K signal pathway[18,23]. Recently, Schneilder et al.[27] have also reported that leptin caused a moderate, significant proliferative effect on gastric adenocarcinoma cell line AGS proliferation through MAPK signal pathways.

On the other hand, the expression of leptin protein in intestinal-type gastric adenocarcinoma and precancerous lesions in our study can be viewed as "ectopic secretion"

of gastric leptin in those tissues. Similar "ectopic secretion" of gastrointestinal hormone such as gastrin, epithelial growth factor, cholecystokinin, vasoactive intestinal peptide in gastrointestinal tumors has been well documented in previous studies[13–16]. Those "ectopic secretion" of gastrointestinal hormone acted as a growth factor and promoter of angiogenesis in gastrointestinal tumors via interaction with its specific receptor in tumors. Taking into account that those ectopic-secreting gastrointestinal hormones exert similar function in gastrointestinal tumors to their physiological functions to normal gastrointestinal tract, we hypothesized that the ectopic-secreting leptin in intestinal-type gastric adenocarcinoma and precancerous lesions may have similar function with gastric leptin[13–16]. As gastric leptin has been found to mediate gastric cytoprotection and increase mucosal blood flow via overexpression of growth factors, such as EGF, TGF-α and VEGF[29,30], it can be anticipated that leptin may enhance growth and angiogenesis of intestinal-type gastric cancer via similar mechanism mentioned above.

What activates leptin expression in gastric adenocarcinoma remains unclear. Recently, it has been reported that *H pylori* infection significantly increases gastric leptin expression[31]. In addition, leptin expression and secretion were induced by chronic inflammation of inflammatory bowel disease in colonic epithelial cells that were unable to express leptin physiologically[32]. Therefore, we postulated that leptin might be induced as a pro-inflammatory mediator in chronic gastrointestinal inflammation, including *H pylori*-associated chronic gastritis. In addition, previous reports demonstrated that K-ras mutation or amplification of chromosome 17q12-q21 induced the amplification of gastrin gene in colon or gastric cancer[33,34]. Whether *H pylori* infection and chronic gastritis might induce some special biomolecular alterations to amplify leptin expression and its downstream signal pathways during gastric carcinogenesis needs further investigation.

In conclusion, our study demonstrates constitutive dual expression of leptin and ob-R in intestinal-type gastric adenocarcinoma and precancerous lesions. Based on these results, we suggest that leptin system might act as a growth factor and angiogenesis promoter via autocrine and/or paracrine pathway in gastric carcinogenesis. Further investigations are warranted to identify the exact role of leptin system and exact mechanism of its activation in gastric carcinogenesis.

Abstract

AIM: To examine the concentration of a new antigen SC6 (SC6-Ag) recognized by monoclonal antibody (MAb) in patients with pancreatic cancer and other malignant or benign diseases and to understand whether SC6-Ag has any clinical significance in distinguishing pancreatic cancer from other gastrointestinal diseases.

METHODS: Six hundred and ninety-five serum specimens obtained from 115 patients with pancreatic cancer, 154 patients with digestive cancer and 95 patients with non-digestive cancer were used and classified in this study. Serum specimens obtained from 140 patients with benign digestive disease and 89 patients with non-benign digestive disease served as controls. Ascites was tapped from 16 pancreatic cancer patients, 19 hepatic cancer patients, 16 colonic cancer patients, 10 gastric cancer and 6 severe necrotic pancreatitis patients. The samples were quantitated by solid-phase radioimmunoassay. The cut-off values (CV) of 41, 80, and 118 U/mL were used.

RESULTS: The average intra- and interassay CV detected by immunoradiometric assay of SC6-Ag was 5.4% and 8.7%, respectively. The sensitivity and specificity were 73.0% and 90.9% respectively. The levels in most malignant and benign cases were within the normal upper limit. Among the 16 pancreatic cancer cases, the concentration of SC6-Ag in ascites was over the normal range in 93.8% patients. There was no significant difference in the concentration of SC6-Ag. Decreased expression of SC6-Ag in sera was significantly related to tumor differentiation. The concentration of SC6-Ag was higher in patients before surgery than after surgery. The specificity of SC6-Ag and CA19-9 was significantly higher than that of ultrasound and computer tomography (CT) in pancreatic cancer patients. Higher positive predictive values were indicated in 92.3% SC6-Ag and 88.5% CA19-9, but lower in 73.8% ultrasound and 76.2% CT.

CONCLUSION: The combined test of SC6-Ag and CA19-9 may improve the diagnostic rate of primary cancer. The detection of SC6-Ag is valuable in the diagnosis of pancreatic cancer before and after surgery.

Key words: Tumor antigen SC6; Pancreatic neoplasm; Immunoradiometric assay

INTRODUCTION

Pancreatic cancer is the fourth or the fifth leading cause of cancer-related deaths in the Western world[1,2]. Approximately 50% of pancreatic cancer patients have metastatic disease at the time of diagnosis with a median survival of 3-6 mo[2,3]. However, even 70-80% of patients, whose tumor could be completely removed, suffer from an incurable local relapse, distant metastases, or peritoneal carcinosis[4,5]. The overall 5-year survival rate of pancreatic cancer patients is only 1%[6,7]. Ultrasound, computer tomography (CT), magnetic resonance imaging and other methods have made it easier to define the late-stage disease and to establish its diagnosis. Unfortunately, these imaging and diagnostic methods cannot detect the early-stage disease[8-11].

In recent years, there has been an increasing clinical attention to the role of tumor markers in the pathogenesis of pancreatic cancer[12-14]. The most widely used marker for pancreatic cancer is CA19-9[15-18]. CA19-9 has a mean sensitivity of 81% and a mean specificity of 90% for pancreatic cancer[19-23]. Other mucin-type markers such as CA50, CA242, DU-PAN2, CA195 and CAM17.1/WGA have also been described for pancreatic cancer[24-28]. These markers have been investigated less widely than CA19-9 but available evidence appears to provide similar data[29-33]. CA19-9 remains as the "gold standard marker"[10] against which tumor markers for pancreatic cancer are evaluated.

Antigen SC6 (SC6-Ag) recognized by monoclonal antibody SC6 (MAb SC6) against human colonic cancer is a relatively new marker compared with CA19-9, CA242, CEA, AFP, DU-PAN-2 and β_2-MG[34-36]. The antigen was purified by immunoaffinity chromatography using the MAb SC6 at our laboratory. The results of SDS-

PAGE, Western blotting and amino acid analysis indicate that SC6-Ag is a glycoprotein with a molecular weight of 67 kμ and contains 18 amino acids. An immunoradiometric sandwich assay of SC6-Ag has been established by us[37]. The diagnostic value of SC6-Ag was evaluated in patients with pancreatic cancer. The sensitivity and specificity of SC6Ag for patients with pancreatic cancer are similar to those of CA 19-9 detected by radioimmunodetection[38]. Therefore, in the present study, we analyzed and compared the pattern of SC6Ag expression in pancreatic cancer and other gastrointestinal cancers to evaluate whether it might be also of high biological strategy in the diagnosis of pancreatic cancer.

MATERIALS AND METHODS

Patients

Serum specimens were obtained from 115 patients with pancreatic cancer (41 females and 74 males, mean age 61 years, with a range of 39-80 years). Among them, 39 had well-and moderately-differentiated tumor, 55 had poorly-differentiated tumor and 21 had differentiated tumor with unknown reason. According to International Union Against Cancer criteria, 9 patients had stage I disease, 33 stage II, 46 stage III and 6 stage IV. Fifteen primary esophageal cancer specimens, 43 gastric cancers specimens, 11 specimens of cancer of papilla of Vater, 39 hepatocellular carcinoma specimens and 46 colonic cancer specimens were classified. Fifteen esophagitis patients (5 females and 10 males; mean age 41 years), 27 gastritis patients (11 females and 16 males; mean age 38 years), 16 papilla of Vater cancer patients (7 females and 9 males; mean age 43 years), 28 pancreatitis patients (15 females and 13 males; mean age 35 years), 23 cirrhosis patients (10 females and 13 males; mean age 44 years) and 31 colitis patients (17 females and 14 males; mean age 35 years) were obtained. The diagnosis of pancreatic cancer was made based on histology and clinical and radiological findings. We noted weight loss, duration of symptoms and tumor position. Other cancers were diagnosed by abdominal ultrasound and CT scan, surgery and pathology. Ninety-five cancers involving lung and bladder were determined. Fifteen out of 42 suspicious patients before surgery were diagnosed having pancreatic cancer after surgery. CA 19-9 was examined in the same samples. Ascites was tapped from 16 pancreatic cancer patients, 19 hepatic cancer patients, 16 colonic cancer patients, 10 gastric cancer and 6 severe necrotic pancreatitis patients.

Sample collection

Blood samples were obtained from all the subjects after an overnight fast. The plasma was immediately separated by centrifugation. The samples were frozen and stored at -20 °C until assay.

Radiolabeling of MAb SC6

MAb SC6 is a murine MAb of the IgG1 isotype against purified antigen SC6 from human colonic cancer tissues as described previously[34-36]. MAb SC6 was isolated from the ascitic fluid of BALB/C mice in which hybridoma cell line SC6 was injected intraperitoneally and purified by protein A-Sepharose 4B columns (Bioinstitute, Shanghai, China). Normal murine immunoglobulin (IgG1, Bioinstitute, Beijing, China) was used as nonspecific control antibody. The MAb was labeled with $Na^{125}I$ by the iodogen method. The average intra- and interassay CV of the method was 5.4% and 8.7% respectively. The recovery rate was 96.5-108.0%, average 102.3%.

Sandwich measurement by radioimmunoassay

After the MAb SC6 was labeled, ^{125}I uncombined with MAb SC6 was separated from bound iodine by gel filtration on a Sephadex G-25 column. Microtiterplates (96-well) were coated with MAb SC6 (20 ng/mL, 100 μL/well) overnight and then incubated with 100 μL/well of 3% bovine albumin in phosphate-buffered saline at 37 °C for 2.5 h. Standard SC6-Ag, various sera, quantity control sera and nonspecific control were incubated at 37 °C for 1 h. ^{125}I-MAb SC6 (25 ng/mL, 100 μL/well) was coated at 37 °C for 3 h and the radioactivity of each well was determined with a Gamma counter (Instrument Factory, Xian, China). After each step, the wells were washed four times with phosphate-buffered saline.

The cut-off values (CV) of SC6-Ag were determined and expressed as mean±SD. The SC6-Ag concentration in sera of controls was lower than CV. The CV of 41 U was mean±2SD, 80 U was mean±3SD, 118 U was mean±4SD. CA 19-9 kit (Abbott Diagnostics, USA) was quantitated by solid-phase radioimmunoassay, CV of 37 U/mL were used.

Statistical analysis

Analysis was performed using SPSS 10.0 software package. For the comparison of various tumor markers, CV representing 90% and 95% specificity levels in patients with relevant benign diseases were determined. The correlation between SC6-Ag and CA 19-9 concentrations was calculated by linear regression using the logarithms of the serum levels. The statistical comparison of multifactors was made and results were significant ($P<0.05$).

RESULTS

SC6-Ag levels in pancreatic cancer and other diseases

The characteristics of the 695 patients are presented in Table 1. Low concentration SC6-Ag was found in the sera from 102 healthy individuals and the cut-off of its normal upper limit was 41 U/mL (20.7±9.8). Among the 115 patients with pancreatic cancer, the cut-off was over the normal range in 73.3% patients, more than 118 U/mL in 48.7% patients and over 41 U/mL in 29.9% patients. The SC6-Ag level was mainly elevated in colonic cancer, hepatic carcinoma and gall bladder tract/bile duct cancers. Non-digestive cancers were mainly non-small cell lung cancer and renal carcinoma. Lower levels of SC6-Ag were observed in benign digestive and non-digestive diseases

Gastric Ca	10	38.1±23.4	3 (30.0)	1 (10.0)	0 (0.0)
Several pancreatitis	6	30.9±26.3	2 (33.3)	0 (0.0)	0 (0.0)

mainly including acute pancreatitis and obstruction of gall bladder/bile duct and acute renal impairment.

Relationship between SC6-Ag and clinicopathological factors

SC6-Ag was not significantly related with clinicopathological factors in patients with pancreatic cancer. Decrease of SC6-Ag in the pancreatic head was compared with that in its body and tail. However, the difference failed to reach statistical significance ($P>0.05$).

SC6-Ag concentration in ascites from patients with different digestive diseases

Among the 16 patients with pancreatic cancer, the concentration of SC6-Ag in ascites was over the normal range in 93.8% patients, over 41 U/mL in 33.3-52.6% patients and more than 118 U/mL in 43.8% patients (Table 2).

Parameters for SC6-Ag, CA19-9, ultrasound and CT in patients with pancreatic cancer

The sensitivity of SC6-Ag and CA19-9 was similar to that of ultrasound and CT, while the specificity of SC6-Ag and CA19-9 was significantly higher than that of ultrasound and CT in patients with pancreatic cancer. Higher positive predictive values were found in 92.3% SC6-Ag and 88.5% CA19-9, but lower positive predictive values were found in 73.8% ultrasound and 76.2% CT (Table 3).

Table 3 Comparison of parameters for SC6-Ag, CA19-9, ultrasound and CT in patients with pancreatic cancer

	SC6-Ag (%)	CA19-9 (%)	Ultrasound (%)	CT (%)
Sensitivity	73.0 (84/115)	84.3 (97/115)	82.6 (95/115)	83.5 (96/115)
Specificity	90.9 (70/77)	84.4 (65/77)	55.8 (43/77)	59.7 (46/77)
Positive predictive value	92.3 (84/91)	88.5 (92/104)	73.8 (96/130)	76.2 (99/130)
Negative predictive value	69.3 (70/101)	73.9 (65/88)	69.4 (43/62)	74.2 (46/62)

DISCUSSION

It is obvious that early diagnosis has the greatest impact on the survival of patients with pancreatic cancer. Clinically, fast spiral CT using dynamic intravenous contrast and the potential for improved MRI can provide high-resolution images of small masses[9-13]. Endoscopic retrograde cholangiopancreatography with improved cytology, brushes, and biopsy forceps should enhance preoperative diagnosis of this malignancy. Endoscopic ultrasound also may help detect small lesions and determine the depth of invasion and vascular involvement. Tumor markers are normally produced in low quantities by cells in the body. Detection of a higher serum level of tumor markers by radioimmunoassay or immunohistochemical techniques usually indicates the presence of a certain type of cancer. In some types of cancer, tumor marker levels may reflect the extent or stage of the disease and can be useful in its diagnosis. Recently, the most widely used marker for pancreatic carcinoma is CA19-9, but SC6-Ag has also been found in China[34-38].

In the present study, high levels of SC6-Ag over the normal upper limit (41 U/mL) were found in 73.0% patients with pancreatic cancer, and in 29.8% patients with other digestive tumors. Using a cut-off point of 80 U/mL, the proportion of patients with elevated levels was 59.2%. But over 118 U/mL SC6-Ag was detected in 48.7% patients with pancreatic cancer, in 5.8% patients with digestive cancers, in 4.2% patients with non-digestive carcinoma and in 2% patients with benign digestive diseases. Furthermore, patients with certain benign diseases such as jaundice and pancreatitis, may present with elevated levels of CA19-9[12-14], suggesting that SC6-Ag and CA19-9 may have similar value in the diagnosis of pancreatic cancer.

Increased SC6-Ag concentrations in ascites are not specific for adenocarcinoma of the pancreas when the CV is 41 U/mL, which was evaluated in other digestive tumors and pancreatitis in our study (Table 2). With a cut-off point of 118 U/mL, the respective specificities for patients with pancreatic cancer were high compared to patients with gastric cancer or pancreatitis, indicating that high SC6-Ag level can be used to distinguish pancreatic cancer from benign disorders. However, decreased level of SC-Ag in pancreatic head compared to that in its body and tail failed to reach statistical significance, and there was no relationship between SC-Ag and tumor stage, size and duration ($P>0.05$).

Up to now, it is difficult to diagnose pancreatic cancer using one of the tumor markers because tumor marker levels can be elevated in patients with benign conditions.

In the recent study, the sensitivity, specificity and positive predictive value of SC6-Ag were found to be 73.0%, 90.9% and 92.3%, respectively. By analyzing the four factors, we found that the sensitivity of SC6 and CA19-9 was lower than that of ultrasound and CT, but their specificity was significantly higher (Table 3). Positive predictive values in SC6-Ag and CA19-9 were 92.3% and 88.5%, which were distinctly higher than those of ultrasound (73.8%) and CT (76.2%). The lack of sensitivity and specificity also limits the diagnosis of pancreatic cancer although CA19-9 and SC6-Ag may be useful in differentiating benign from malignant pancreatic disease in non-jaundiced patients. However, combined measures are more useful in the diagnosis of pancreatic cancer.

In conclusion, detection of SC6-Ag is valuable in the diagnosis of pancreatic cancer before and after surgery. The combined test of SC6-Ag and CA19-9 may improve the diagnostic rate of primary cancer.

Abstract

Neuroendocrine tumors are divided into gastrointestinal carcinoids and pancreatic neuroendocrine tumors. The WHO has updated the classification of these lesions and has abandoned the term "carcinoid". Both types of tumors are divided into functional and non-functional tumors. They are characterized by slow growth and frequent metastasis to the liver and may be limited to the liver for long periods. The therapeutic approach to hepatic metastases should consider the number and distribution of the liver metastases as well as the severity of symptoms related to hormone production and tumor bulk. Surgery is generally considered as the first line therapy. In patients with unresectable liver metastases, alternative treatments are dependent on the type and the growth rate. Initial treatments consist of long acting somatostatin analogs and/or interferon. Streptozocin-based chemotherapy is usually reserved for symptomatic patients with rapidly advancing disease, but generally the therapy is poorly tolerated and its effects are short-lived. Locoregional therapy directed such as hepatic-artery embolization and chemoembolization, radiofrequency thermal ablation and cryosurgery, is often used instead of systemic therapy, if the disease is limited to the liver. However, liver transplantation should be considered in patients with neuroendocrine metastases to the liver that are not accessible to curative or cytoreductive surgery and if medical or locoregional treatment has failed and if there are life threatening hormonal symptoms. We report a case of liver transplantation for metastatic neuroendocrine tumor of unknown primary source and provide a detailed review of the world literature on this controversial topic.

Key words: Liver metastases; Neuroendocrine tumors; Liver transplantation

INTRODUCTION

Neuroendocrine tumors are divided into gastrointestinal carcinoids and pancreatic neuroendocrine tumors[1]. However, it is suggested that they may be grouped together and be categorized into functional and non-functional tumors[2] to indicate the clinical manifestations of syndromes caused by hypersecretion of neuropeptides and biogenic amines at supraphysiologic levels[2,3]. These tumors are very rare and occur with an incidence of 2 per 100 000/year (with a slight female predominance) for carcinoids[4-6] and 1-1.5 per 100 000/year for pancreatic neuroendocrine tumors[7].

Gastrointestinal carcinoid tumors originate from cells of the diffuse neuroendocrine system, which is composed of amine-and peptide-producing cells[1]. These cells are scattered throughout the body and predominantly occur in the submucosa of the large and small intestine, stomach and larger bronchi[1]. In 85% of all cases they arise in the lung, stomach, ileum, appendix and rectum[1]. Although the majority of these tumors are nonfunctional, certain primary site locations, such as the ileum and bronchi, have a predilection for producing the carcinoid syndrome[1]. This syndrome is characterized by flushing, diarrhea, abdominal pain and less often by wheezing and heart disease and is predominantly caused by the production of serotonin[1,8]. Other biological substances, produced by carcinoid tumors, such as kalikrein and prostaglandins also take part in the pathogenesis of the carcinoid syndrome[1]. Overall, the carcinoid syndrome develops in only 5% of all carcinoid tumor patients, but this figure rises to approximately 60% in cases with liver metastases[1]. Prior to metastasizing to the liver, carcinoid tumors are usually

silent because their secretory products are inactivated in the liver[1,8,9].

Pancreatic endocrine tumors arise from pleuropotential stem cells within the pancreas[9,10] and those that are functional produce biologically active peptides such as gastrin, insulin, glucagon, vasoactive intestinal polypeptide, somatostatin, growth hormone releasing factor, and pancreatic polypeptide which are responsible for distinct clinical syndromes[1,11]. Gastrinomas and the insulinomas are the most common functional pancreatic endocrine tumors whereas all others are rare[1,11]. Non-functional pancreatic neuroendocrine tumors (45-50% of all pancreatic neuroendocrine tumors) exhibit no specific syndromes; such tumors present only with symptoms due to tumor mass[3,11].

Liver metastases develop in 46-93% of patients with neuroendocrine tumors and can involve large portions of the liver before becoming symptomatic[12]. They exhibit a slow growth despite their multilocular and bilateral occurrence in most cases[13] and may be limited to the liver for long periods[14]. Surgery is generally the first line therapy for patients with liver metastases due to neuroendocrine tumors[15-17]. Potentially curative resection is considered in patients with solitary or unilobar hepatic metastases and without radiological evidence of systemic disease[18]. However, curative resection is possible only in approximately 20% of patients[19], because liver metastases frequently diffuse at the time of diagnosis[8]. In patients with bulky disease, preoperative hepatic artery embolization is recommended in order to decrease the blood flow and shrink tumors[18]. In patients with previously resected or resectable primary tumors, regional nodal disease and metastases confined to the liver, cytoreductive surgery is recommended, provided that preoperative imaging confirms that the primary and regional diseases are controlled or controllable and 90% or more of the bulk of the tumor can be removed[14]. In patients with unresectable liver metastases alternative treatments that can be considered include immunotherapy (somatostatin analogs and/or alpha-interferon) and chemotherapy (usually streptozocin-based). Additional therapy such as hepatic-artery embolization or chemoembolization, radiofrequency ablation and cryosurgery are pursued as needed[8,11,18,20]. Some studies report a tumoristatic effect of somatostatin analogs such as octreotide and lanreotide in 36.5-75% of treated patients lasting for 3-12 months[21-24]. Furthermore, treatment with high-dose somatostatin analogs may induce apoptosis in neuroendocrine tumors[25]. In addition, small liver metastases (diameter less than 1-2 cm) may respond to radiopharmaceutical agents such as Y (90)- and In (131)-labeled octreotide which involve insertion of radiotherapeutic agents directly into the tumor[26]. A recent study suggested that the administration of combinations of Y (90)- and Lu (177)-labeled octreotide in patients with tumors of different sizes may allow wider tumor penetration[27]. In patients with bilobar hepatic tumors, hepatic artery embolization combined with octreotide treatment has also been proposed[28].

Liver transplantation is considered in patients with neuroendocrine metastases to the liver which are not accessible to curative or cytoreductive surgery, tumors which do not respond to medical or interventional treatment and in tumors causing uncontrollable life-threatening hormonal symptoms (severe hypoglycemia, gastrointestinal hemorrhage, severe diarrhea, valvulopathy)[29,30] providing the disease has not extended beyond the liver, although certain hormonal symptoms (e.g. insulinoma) may be less amenable to transplantation than others.

We report herein a case of liver transplantation due to metastatic neuroendocrine tumor of unknown primary source. In addition, we present a comprehensive review of liver transplantation in patients with metastatic neuroendocrine tumors.

CASE REPORT

A 61-year-old white male with a prior history of hypertension and arteriosclerotic heart disease was referred in May 1999 for evaluation of multiple liver metastases from an unclear primary source. In the 4-5 years prior to referral, he described that he had flushing and cough. The flushing was primarily on his face, lasted for about an hour at a time and was precipitated by heat. In the few months prior to referral he developed episodes of fevers, chills and lassitude and had been treated briefly with antibiotics with a good response. The patient had lost about 16 pounds, which was attributed to dieting and anxiety. Physical examination revealed hepatomegaly. Ultrasound of the right upper quadrant and CT scanning of the chest and abdomen revealed multiple metastases in the liver but no other obvious primary tumor (Figure 1A). Laboratory data included a urinalysis which was negative, a serum albumin of 2.9 gm/dL (n.: 3.5-5.0), an elevated alkaline phosphatase of 197 IU/L (n.: 42-121), an ALT of 96 IU/L (n.: 10-60), an AST of 57 IU/L (n.: 10-42), a BUN of 18 mg/dL (n.: 6-20), a normal serum calcium and normal chloride and electrolytes. His total bilirubin was 1.0 mg/dL (n.: 0.2-1.0) and his total protein was 6.7 gm/dL (n.: 6.4-8.2). His CBC was within normal limits.

His serum gastrin level was 38 pg/mL (n.: 0-100), serum chromogranin A level was 275 ng/mL (n.<50) and serum pancreatic polypeptide was 258 pg/mL (n.<312). 24-h urine analysis for 5-hydroxydinoloacetic acid was normal. A transcutaneous liver biopsy was positive for neuroendocrine tumor. The tumor was strongly positive for neuron specific enolase, synaptophysin, insulin, S100 and chromogranin. An OctreoScan showed liver and midline abdominal foci of increased radiotracer uptake compatible with neuroendocrine lesions. There were no neuroendocrine lesions within the lungs and mediastinum. His small bowel enema was normal. An upper endoscopy revealed a few small prepyloric ulcers with no evidence of *Helicobacter pylori*. In addition, there was evidence of extrinsic antral compression from the left lobe of the liver. An echocardiogram was performed which showed a thickened and calcified aortic valve and mitral valve with mild mitral regurgitation. A diagnosis of metastatic

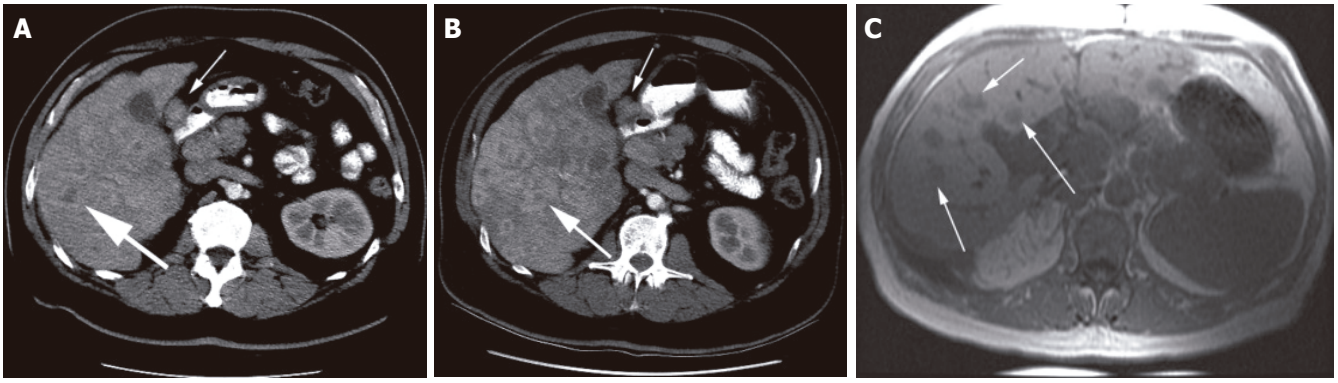

Figure 1 (A) Enhanced CT of the abdomen shows multiple hepatic metastases (big arrow) and lymphadenopathy of the gastrohepatic ligament (small arrow). **(B)** Follow-up CT, 2 mo later reveals an increase in size and number of liver metastases (big arrow) and persistent gastrohepatic ligament adenopathy (small arrow). **(C)** T1-weighed MR image performed 9 mo after transplantation shows the interval development of multiple liver metastases (arrows).

nonfunctional neuroendocrine tumor was eventually made. For the next six months the patient received somatostatin maintenance therapy at which point recurrent upper respiratory symptoms and severe abdominal discomfort developed. There were no carcinoid symptoms and the patient continued to work. A follow up CT scan of the abdomen revealed innumerable metastases throughout the liver (which had coalesced when compared to an examination performed 2 mo earlier) and increasing adenopathy within the gastrohepatic ligament (Figure 1B). Six months later, while on depot octreotide maintenance, he presented with bleeding esophageal varices, and frank hepatic encephalopathy. A metastatic work-up at that time revealed disease predominantly in the liver with additional sites of involvement in the pancreas (possibly an enlarging primary site) and questionable lesions in the chest.

His most recent MRI scan showed no change in tumor size although possibly there was more inferior vena cava obstruction.

The patient underwent orthotopic liver transplantation (OLT) without a pancreatic resection. His explant revealed a liver diffusely involved (approximately 60%) by low grade, neuroendocrine carcinoma with metastasis involving perihilar lymph nodes and cirrhosis. The patient was placed on Prograf and Ganciclovir. Octreotide was discontinued. The patient remained healthy for several months after the transplant and a follow up MRI at 3 mo did not reveal any malignancy until 12 mo later when he presented with pruritus, generalized fatigue and profound diminution in stamina. MRI of the liver confirmed metastasis (Figure 1C) as well as multiple pulmonary nodules and spinal lesions. He was retreated with somatostatin, initially subcutaneously and later by depot injections. However over the next 12 mo his condition deteriorated and despite treatment with Ytrium octreotide in an experimental protocol he ultimately expired 27 mo after liver transplantation.

DISCUSSION

Neuroendocrine tumors represent an unusual group of rare tumors due to their slow growth and ability to produce and secrete a multitude of peptide hormones and amines[30,31]. These substances give rise to different clinical syndromes related to the peptide production, such as the carcinoid syndrome, insulinoma syndrome, Zollinger-Ellison syndrome, glucagonoma syndrome, WDHA syndrome and somatostatinoma syndrome[31]. However, as in this case, many patients have nonfunctional tumors and present with hepatic metastases[30]. In most cases neuroendocrine metastases to the liver are located in both lobes. Gastrointestinal carcinoid tumors, especially those located in the small intestine or ascending colon, are the most common neuroendocrine tumors presenting with liver metastases. Gastrointestinal carcinoids and pancreatic neuroendocrine tumors have different degrees of malignant potential and frequency of liver metastases[32].

The therapeutic approach to hepatic metastases should consider the natural history of the disease and the progression and severity of symptoms caused by both hormone production and tumor mass[33]. In contrast to nonendocrine tumors, therapy for hepatic metastases from neuroendocrine tumors with liver transplantation is reasonable because the disease may be confined to the liver for extended periods and the growth is slow[13,34-36]. The presence of liver metastases from neuroendocrine tumors is a very important prognostic factor for decreased survival[37]. The 5-year survival rate in untreated patients is approximately 30%[38,39] and chemotherapy only prolongs life by a mean of 12-24 mo[40,41].

There have been several single-center (Table1) retrospective analyses and three multicenter restrospective studies[43,46,49] of liver transplantation in patients with liver metastases from neuroendocrine tumors. They are summarized in Table 1. However closer review of these reports reveals that some of the patients were part of more than one publication. Several tumor and patient characteristics influence the outcome following liver transplantation. A large retrospective study of 637 patients who underwent OLT between 1968 and 1991, observed that 67% of patients with carcinoid tumors had recurrence[42]. The authors concluded that patients with slowly growing metastatic neuroendocrine tumors might be suitable candidates for liver transplantation[42].

LT: liver transplantation; OLT: orthotopic liver transplantation; MVT: multivisceral transplantation; PNT: pancreatic endocrine tumors, nr: results not reported

These data were further supported by another experience on 30 patients from 14 centers who underwent OLT for metastatic neuroendocrine tumors[43]. It was noted that the actuarial survival, often combined with other upper abdominal resective procedures, for the entire group of patients was 52% after 1 year and remained stable for another 24 mo[43]. Overall, mortality during the first year after transplantation due to recurrent tumor was 17%[43]. The longest survival, 42 mo, was in a patient who died from recurrent carcinoid tumor[43]. Overall, at the time of this study 57% of patients were alive, 30% had developed recurrence, 43% had died and 70% did not have evidence of disease recurrence. Based on their observations they proposed that extrapancreatic primary neuroendocrine tumors be treated with radical hepatic resection followed by medical therapy and that the tumor response should be evaluated before considering liver transplantation[43]. Even the primary pancreatic primary tumors with slow growth that do not respond to medical therapy can be considered for liver transplantation but with a combination of a pancreatic resection procedure[43].

The role of abdominal cluster transplantation was best described in 57 patients presenting with primary or metastatic liver tumors[44]. Abdominal cluster transplantation for metastatic neuroendocrine liver tumors had a better 3-year survival rate (64%) than for patients who underwent this procedure due to sarcoma (44%), hepatocellular carcinoma (25%), cholangiocarcinoma (20%) and other adenocarcinomas (20%)[44]. OLT was found to be effective in controlling symptoms that were caused by carcinoid metastases to the liver[45]. The tumor recurrence was not necessarily associated with early recurrence of symptoms[45]. The patients with non-carcinoid tumors were found to have a higher likelihood of prolonged disease-free survival than those with carcinoid tumors[45]. On the other hand Le Treut *et al.* found significantly higher survival in patients with metastatic carcinoid tumors (80% after 1 year and 69% after 5 years) than in patients with non-carcinoid neuroendocrine tumors who underwent OLT (38% after 1 year and 8% after 4 years)[46]. However additional analysis of 37 cases of OLT for metastatic neuroendocrine tumors presented in the literature revealed significantly higher survival rates in patients with non carcinoid apudomas (83% after 2 years) than in patients with carcinoids (34% after 2 years)[46].

When liver transplantation was done only in cases with unresectable liver tumor, untreatable hormonal symptoms or massive tumor bulk[47] and without extrahepatic tumors at the time of transplantation, patients were observed to derive benefit from OLT[47]. A characteristic of the patients who did not have recurrence during follow up was that they had less than 40–50% tumor bulk in the explant. Thus, it has been suggested that OLT may be also regarded as curative treatment in some patients with neuroendocrine metastases who have relatively low tumor burden[47]. In contrast, Florman found only 1 rare case of 5-year disease free survival among 11 transplanted patients. Moreover, it was claimed that due to only few reports in the literature of 5-year disease free survival (4.6%), OLT cannot be considered as a curative procedure[48].

Other prognostic indicators that have been suggested include a limited operation and age of <50 years. Patients with such features had an overall 5-year survival of 65% and median survival of more than 8 years[49]. On the other hand, patients who underwent extended operations including upper abdominal exenteration or Whipple's operation had 1-year survival of 50% and 5-year survival of 31%[49]. Therefore, an extended operation (Whipple's operation, abdominal exenteration) and age≥50 years were considered as independent indicators of poor outcome and thus extensive surgery does not translate into better outcomes perhaps because of the high rate of post operative morbidity and mortality (10 of 11 patients with such features died after a median of 7 mo)[49]. Interestingly, location of the primary tumor, tumor histology and treatment with somatostatin were not found to be prognostic factors, although patients with primary tumors located in the pancreas or gastrinoma seemed to have poorer outcomes[49]. The outcome of liver transplantation showed a highly significant survival difference between patients with metastases from neuroendocrine tumors and other tumors such as colorectal carcinoma, melanoma, choriocarcinoma or pancreatic carcinoma[50]. The 5-year survival was 86.7% in patients with neuroendocrine metastases and 0% in patients with other malignancies[50].

Little is known about tumor markers as prognostic factors. It has been demonstrated that low tumor expression of the immunohistochemical marker, Ki67(<5%), and the adhesion molecule, E-cadherin, might be associated with a favorable outcome after liver transplantation for metastatic neuroendocrine tumors[51]. Patients (n = 12) with an increased expression of the markers, (Ki67≥5% positive cells and/or E-cadherin staining) showed decreased survival (median 46 mo) whereas patients (n = 5) with low expression of these markers showed increased survival (median 90 mo)[51]. It was also suggested that the combination of these two markers had an excellent specificity and sensitivity to predict a survival of 7 years after liver transplantation[51]. Further study showed that liver transplantation for metastatic well-differentiated neuroendocrine tumors with a low expression of protein Ki67 (Ki67<10%) resulted in relief of hormonal symptoms and long disease-free periods[14]. Another study suggested that MIB-1 antibody expression might have prognostic value in patients undergoing liver transplantation for metastatic carcinoid tumors[66]. The authors assessed the cell proliferative activity by MIB-1 antibody labeling in 14 patients with metastatic neuroendocrine liver tumors (7 carcinoids, 7 non-carcinoids) who underwent liver transplantation[66]. In this group, two patients remained alive and disease-free at 96 and 192 mo after liver transplantation[66]. MIB-1 index was calculated by dividing the number of tumor cells with positive staining for MIB-1 antibody by the total number of tumor cells[66]. It was shown that patients with a MIB-1 index of greater than 5% showed early tumor recurrence (median 11 mo) and shorter survival (median 13 mo)

whereas patients with a MIB-1 index of less than 5% showed late tumor recurrence (median 69 mo) and longer survival (median 80.5 mo)[66]. The low MIB-1 index (<5%) was found to have a sensitivity of 71% and a specificity of 83% for predicting survival of greater than 2 years[66].

Current knowledge about the role of liver transplantation for patients with neuroendocrine liver metastases indicates that liver transplantation should be considered only in selected individuals. Coppa *et al*. proposed that selection of patients with non-resectable metastatic neuroendocrine tumors for liver transplantation should be based on the Milan criteria: young patients (less than 50 years) with carcinoids confirmed by histology, with less than 50% of the liver replaced by metastases, with a primary tumor (originating from the gastrointestinal tract) drained by the portal venous system, an absence of extrahepatic disease and stable disease during the pretransplantation period[19]. In a group of nine patients who underwent liver transplantation based on these criteria the 5-year survival was 70% and the 5-year disease-free survival was 53%[19]. On the other hand, in the group of 20 patients who were treated by liver resection due to less advanced liver metastases, the 5-year survival was 67% and the 5 year disease-free survival was 29%[19]. Our patient had a 27 mo survival and the less than ideal outcome may have been because of some of the poor prognostic factors of age>50, tumor bulk exceeding 50%, and regional metastasis. Furthermore, whether immunosuppression after OLT has any effect on the rate of tumor recurrence or not is pure speculation. Thus, given the shortage of donor organs and the high rate of tumor recurrence, we currently believe that OLT should only be undertaken, when other therapeutic approaches including combinations of regional or systemic chemotherapy and hormone inhibitors together with partial hepatectomy have failed[64]. There is a need for prospective studies in large numbers of patients to fully evaluate the role of liver transplantation in patients with metastatic neuroendocrine tumors who may gain many years of effective palliation with careful selection. However, suboptimal outcomes may occur if case selection is compromised.

Abstract

Liposarcomas are rare soft tissue tumors, commonly affecting the lower limbs and less commonly the retroperitoneum. Although other organs can be affected, the pancreas is one of the rarest, and metastasis at presentation has never been reported. We describe the case of a 76-year-old gentleman presenting with abdominal pain and an abdominal mass. Imaging confirmed a primary tumor in the body and tail of the pancreas, with a metastatic deposit in the mesentery adjacent to the second part of the duodenum. Biopsy confirmed a liposarcoma, and subsequently a complete surgical excision was achieved. He then received adjuvant radiotherapy and has remained disease free for the next 26 mo.

INTRODUCTION

Primary retroperitoneal neoplasms account for only 0.1-0.2% of all malignancies. Liposarcoma is a rare mesenchymal tumor that occurs most commonly in the soft tissues of the extremities, but other sites such as the retroperitoneum can also be involved. Retroperitoneal liposarcomas grow slowly and silently. Prognosis is poor due to relapse, so only complete excision, which is often difficult, produces a 'cure'[1]. There are only four cases of pancreatic liposarcoma in the literature. To our knowledge, this is the first reported case of metastatic pancreatic liposarcoma at the time of presentation, with successful outcome following surgery.

CASE REPORT

A 76-year-old retired civil engineer presented with a 1-mo history of abdominal pain. He had anorexia associated with significant weight loss. His medical history was unremarkable. He was a smoker and drank a moderate amount of alcohol. On examination he was cachectic and had a large, firm, but non-tender, upper abdominal mass. All blood results including tumor markers (CEA, CA 19.9, AFP, CA125) were within the normal limits. Abdominal ultrasound showed two large masses adjacent to the pancreas. CT scan revealed a 20-cm mass in the mesentery adjacent to the second part of the duodenum, and an 8-cm tumor of the body and tail of the pancreas (Figure 1). The appearances were suggestive of liposarcoma, and this was confirmed by CT-guided core biopsy.

At laparotomy, he had a primary tumor (9 cm×6 cm ×2.5 cm) (Figure 2A) in the distal body and tail of the pancreas attached to the spleen and a further tumor (27 cm ×20 cm×10 cm) (Figure 2B) adjacent to the second part of the duodenum, not infiltrating the bowel or the pancreas. He underwent distal pancreatectomy with splenectomy and the second lesion, which was encapsulated, was completely enucleated. His post-operative recovery was slow with the development of sepsis and a pancreatic fistula, which was managed conservatively with drainage.

Histology of both masses demonstrated a well differentiated sclerosing liposarcoma (Figure 3A) with an area within the primary mass of dedifferentiation (Trojani grade 3) (Figure 3B). The patient received adjuvant radiotherapy and was under follow-up with abdominal CT every 6 mo. At 26 mo, there was no evidence of recurrence and he remained asymptomatic.

DISCUSSION

Liposarcomas are intermediate (locally aggressive) malignant mesenchymal tumor comprising 16-18% of all malignant soft tissue tumors in adults[2]. The incidence is the same in the USA and Europe, with a slight male preponderance[2]. These tumors can grow slowly by direct invasion and can metastasize to the lungs, liver and other viscera[3]. Histologically they can be classified into well differentiated (WD), myxoid, round cell poorly differentiated myxoid and pleomorphic[4,5].

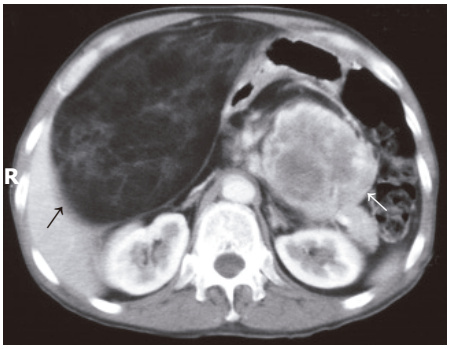

Figure 1 Abdominal CT showing the primary tumor in the body and tail of the pancreas (white arrow) and the solitary metastasis in the mesentery adjacent to the duodenum (black arrow).

Figure 2 The primary tumor (right) and its solitary metastasis (left) after removal.

WD liposarcomas are the commonest, accounting for approximately 40-45%[6]. WD liposarcomas can in turn be subdivided morphologically into four main subtypes: adipocytic, sclerosing, inflammatory and spindle cell. This case was a WD sclerosing liposarcoma, which ranks second in frequency, and is most often seen in retroperitoneal and paratesticular lesions[6].

WD liposarcomas show no potential for metastasis unless they undergo dedifferentiation. Dedifferentiation occurs in up to 10%, with 90% arising *de novo* and the rest in recurrences. Risk of dedifferentiation appears higher with deep-seated (particularly retroperitoneal) lesions and is markedly less in the limbs. This is probably a time-dependant phenomenon. However, it is often impossible to obtain a wide surgical resection margin and local recurrence is almost inevitable and often leads to death[6].

Retroperitoneal liposarcomas produce non-specific symptoms and are often extensive on diagnosis[1]. Most tumors occur at 40-60 years of age, though they may appear at any time. The etiology of these tumors is unknown, although trauma or radiation exposure has been suggested. CT scan is good at characterizing the lesions and aspiration cytology is recommended to differentiate from other pancreatic neoplasms[2]. Pancreatic liposarcomas are very rare with eventual metastases reported in 30-60% of cases[3]. Regardless of cell type, aggressive surgical excision offers the best chance of cure[3]. Some patients may benefit from adjuvant radiotherapy and less commonly chemotherapy. This patient had successful resection of the primary tumor and a giant metastasis followed by adjuvant radiotherapy, and had remained disease free. Prognosis depends on tumor location and histological type[2]. Reported 5-year survival following surgical excision varies from 41%[3] to 50%[4]. Radiotherapy can increase the duration of remission after incomplete excision and possibly achieve clinical cure[3].

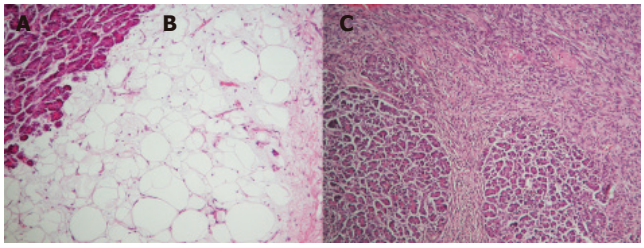

Figure 3 Microphotographs of the primary tumor. **A:** Normal pancreatic tissue; **B:** well-differentiated sclerosing liposarcoma; **C:** area of dedifferentiation.

CONCLUSION

Aggressive resection combined with adjuvant radiotherapy should be considered for metastatic pancreatic liposarcomas when feasible as this offers the best chance of cure and follow-up is essential.

Abstract

Dilatation of the colon and the rectum, which is not attributable to aganglionosis, is a rare finding and can be the result of intractable chronic constipation. We report a rare case of a 29-year-old male patient with impressive megacolon, in whom Hirschsprung's or Chagas disease was ruled out. In the present case, dilatation of the colon was most likely due to a behavioral disorder with habitual failure of defecation. Chronic stool retention led to a bizarre bulging of the large bowel with displacement of the other abdominal organs and severe occult blood loss. Because of two episodes of life-threatening gastrointestinal bleeding despite conventional treatment of constipation, a surgical approach for bowel restoration was necessary. Temporary loop ileostomy had to be performed for depressurization of the large bowel and the subsequent possibility for effective antegrade colonic lavage to remove impacted stools. Shortly after the operation, the patient was healthy and could easily manage the handling of the ileostomy. However, the course of the megacolon in this young adult cannot be predicted and the follow-up will have to reveal if regression of this extreme colonic distension with reestablishment of regular rectal perception will occur.

INTRODUCTION

Occult gastrointestinal bleeding is a frequent actuality in human beings, likewise is a temporary absence after drinking beer on the "Oktoberfest" in Munich. We report the case of a young male with the unusual combination of both conditions.

CASE REPORT

A 29-year-old male patient collapsed at the "Oktoberfest" after consumption of a small beer and was admitted to our emergency department. The patient was pale and displayed hemoglobin of 30 g/L despite normal blood pressure and heart rate. On clinical examination, cachexia and an obvious distension of the abdomen with slight pain in the epigastrium and the periumbilical region were noted. The digital rectal exam revealed black stools with positive guaiac testing, but the patient denied gross rectal bleeding in the past. The patient has seldom bowel movements (every third day) and denotes the absence of the urge for defecation. He has recently lost his job as a janitor because of permanent fatigue and decreasing tolerance to work. Furthermore, he reported an unclassified "bowel disease" since early childhood and a "dilatation" of the colon which had been performed during infancy. Two years ago, iron deficiency anemia had been treated at another hospital but repeated attempts for colonoscopy had failed because of stool residues in the colon despite lavage for several days at that time.

After transfusion, a diagnostic procedure was performed in addition to the severe anemia and the laboratory tests revealed significant iron deficiency with a ferritin level of 6 μg/L and transferrin saturation of 4.5%. Serum potassium and albumin were decreased to 2.13 mmol/L and 28 g/L, respectively. The abdominal CT scan showed massive dilatation of the rectum and the left-sided colon (Figures 1A and B) with displacement of the other organs. A colonoscopy could not be performed because of persistent masses of stools in the colon even after prolonged bowel lavage. An upper gastrointestinal endoscopy demonstrated regular mucosa without evidence for celiac disease or a bleeding source in the proximal gastrointestinal tract. A radionuclide bleeding

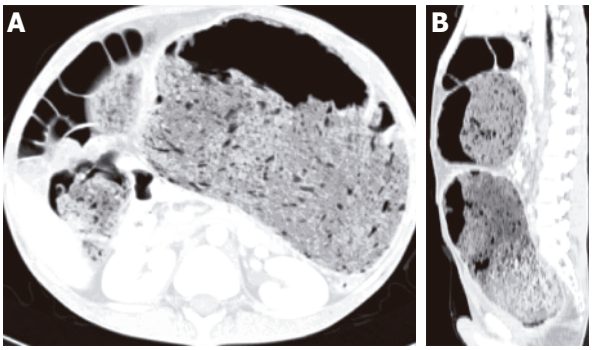

Figure 1 A: Axial CT image of the abdomen; **B:** Saggital CT reconstruction of the abdomen.

scan was negative for an apparent bleeding source. Rectal manometry demonstrated regular arbitrary contraction and a normal reflectory relaxation of the anal sphincter. A dynamic MR defecography revealed again a massive dilatation of the distal colon with complete failure of emptying on command. The histological examination of a rectal biopsy demonstrated chronic proctitis with pseudomelanosis and explicit verification of submucous ganglions excluding Hirschsprung's disease (aganglionosis). Chagas' disease was ruled out by serology. A pathological H2-glucose breath test showed signs for a bacterial overgrowth of the small bowel and significant osteopenia was documented by measurement of the bone density by dual X-ray densitometry.

Initially, we aimed at relieving the chronic constipation by regular administration of polyethylene glycol. However, distention of the colon was even progressive and gastrointestinal bleeding continued. Therefore, a temporary loop ileostomy was performed and about 12 kg of stools could be removed by antegrade colonic lavage. A CT scan 3 wk after surgery demonstrated declining of the colonic dilatation with a marked decrease of abdominal distension. The postoperative course was uneventful and the patient's fitness improved significantly. He received intravenous iron and vitamin supplementation and due to the bacterial overgrowth antibiotic treatment with metronidazole was initiated. Subsequently lower gastrointestinal bleeding subsided and a repeat colonoscopy showed regular mucosa in the right colon with atrophic appearance of the mucosa in the left colon. The patient was motivated to perform stool training aiming at the establishment of a normal rectal perception.

DISCUSSION

Dilatation of the colon and the rectum, which is not attributable to aganglionosis[1] is a rare finding and can be the result of intractable chronic constipation[2]. Herein we report a rare case of a young adult with impressive megacolon, in whom Hirschsprung's or Chagas disease was ruled out. In the present case dilatation of the colon is likely to be due to a behavioral disorder with habitual failure of defecation. Chronic stool retention led to a bizarre bulging of the large bowel with displacement of the other abdominal organs. Occult gastrointestinal bleeding has not been described in patients with megacolon, but in our patient dilation of the colonic wall presumably resulted in occult blood loss. The exact bleeding source could not be localized by a radionuclide bleeding scan, thus the intensity of bleeding was supposed to be low. The low hemoglobin value was well tolerated by the patient; therefore, the anemia was most likely due to a chronic blood loss. However, the patient had previously experienced two episodes of life-threatening gastrointestinal bleeding despite conventional treatment of constipation; consequently, a surgical approach for bowel restoration appeared feasible.

A further concern in this patient was the apparent malabsorption with low levels of albumin, severe iron deficiency and osteoporosis. Distension of the colon with subsequent stasis can lead to small bowel bacterial overgrowth, as demonstrated in patients with megacolon due to Chagas disease[3]. Restoration of the small bowel by antibiotic treatment would be a futile approach as long as the underlying stasis of the bowel is not corrected. Therefore, a temporary loop ileostomy was performed for depressurization of the large bowel and the subsequent possibility for effective antegrade colonic lavage to remove impacted stools[4].

In the present case, the indication for surgical intervention was delicate, because ileostomy does not affect the underlying behavioral disorder and includes the risk for a complete unlearning of defecation. Furthermore, the development of a diversion colitis is a possible sequelae[5]. Nevertheless, shortly after the operation the patient was healthy and could easily manage the handling of the ileostomy. However, the course of the megacolon in this young adult cannot be predicted and the follow-up will have to reveal if regression of this extreme colonic distension with re-establishment of regular rectal perception will occur.

Abstract

Immunologic response to acute hepatitis C is mainly a Th1 response, whereas fasciolopsiasis is associated with a diverse T-cell response. Interferon-alpha has immunomodulatory effects and enhances Th1 immune response. Fasciola infection could theoretically interfere with the Th1 immune response, even when acquired after an initial response to interferon-alpha treatment for acute hepatitis C virus (HCV) infection. We report here the case of a male patient who acquired *Fasciola hepatica* infection after an initial response to IFN-alpha therapy with a favorable outcome

Key words: Hepatitis C; Interferon; *Fasciola hepatica*

INTRODUCTION

Hepatitis C virus (HCV) infection is a common cause of hepatocellular injury associated with complex immunologic mechanisms including both humoral and cell-mediated responses. Acute hepatitis C infection especially produces a Th1 response[1]. Fasciolopsiasis, like other helminth infections, is associated with the induction of T-cell responses particularly the Th2 subtype[2]. Enhanced induction of Th2 cytokines and downregulation of Th1 responses during infection with *Fasciola hepatica* could be expected to interfere with the natural course of and the response to the treatment of acute viral hepatitis C. The concurrence of HCV and *F. hepatica* infection is uncommon and whether *F. hepatica* infection acquired during IFN-α therapy has any effect on HCV replication is unknown.

CASE REPORT

A 50-year-old male patient, with chronic renal failure began hemodialysis 3 mo ago. Prior to initiation of hemodialysis, liver function tests were normal and serological tests for hepatitis B and C were negative. During the 3rd mo of hemodialysis, laboratory evaluation showed elevations of 183 IU/L AST (normal, 5-45 IU/L), 394 IU/L ALT (normal, 5-45 IU/L), 141 IU/L GGT (normal, 0-50 IU/L), and 90 IU/L ALP (normal, 53-128 IU/L). Physical examination was normal. Abdominal ultrasonography showed normal liver size with grade II heterogeneity, normal portal vein size and no ascites. Anti-HCV antibody and HCV RNA were positive. Anti-HAV IgM, HBs Ag, and anti HIV were negative.

The patient was diagnosed with acute viral hepatitis C. IFN-α 2b (Intron A; Schering Plough Corporation, Kenilworth, NJ, USA) was started 3 MU thrice weekly subcutaneously for 12 mo. ALT levels normalized during the 4th wk of the therapy. HCV RNA was negative after 6 mo.

After 6 mo of treatment with IFN-α, the patient reported marked malaise and right upper quadrant abdominal pain. Physical examination revealed right hypochondrium tenderness. Repeated liver function tests showed elevations of ALT (51 IU/L), ALP (196 IU/L), and GGT (272 IU/L). WBC were 6 800/mm^3 with marked eosinophilia (20%). Abdominal ultrasonography showed hepatomegaly and a well-defined 9-mm hyperechoic round mass in the anterior–superior segment of the right hepatic lobe which raised the suspicion of hemangioma and the possibility of *F. hepatica*. The causes of eosinophilia were investigated in the 9th mo of IFN-α therapy. Serology for fasciolopsiasis revealed positivity by enzyme-linked immunosorbent assay (ELISA) prepared against a secretory antigen according to Carnevale *et al*.[3]. The assay was reported to have 100% sensitivity and 100% specificity. ELISA absorbance value of the patient's sera was 2 900 units, while the cut-off value was 380. Stool specimens were negative for ova and parasites of *F. hepatica*. Oral triclabendazole (10 mg/kg), twice daily

doses was initiated for fasciolopsiasis. One week after the initiation of triclabendazole (10th mo of IFN therapy), the patient reported to have right upper abdominal pain and was hospitalized. Physical examination showed abdominal tenderness on the upper right quadrant and a positive Murphy's sign. Laboratory tests showed elevations of serum total and direct bilirubin which were 2.28 mg/L (normal, 0.2-1 mg/L) and 2.24 mg/L (normal, 0.1-0.5 mg/L), respectively in addition to elevations of ALT (58 IU/L), AST (53 IU/L), GGT (333 IU/L), and ALP (399 IU/L). WBC were 11 700/mm^3 with 10% eosinophilia. Abdominal ultrasonography revealed no intraparenchymal lesion in the liver, thickening of gallbladder wall and a hyperechoic round mass measured 10 mm in the gallbladder. Intra and extrahepatic bile ducts were normal. The patient's condition improved after 48 h of intravenous fluids and antibiotics.

Twenty-four months after the initiation of IFN-α treatment, liver function tests and complete blood count were normal with 2% eosinophilia. Stool specimen for fasciola was negative. HCV RNA was negative. The patient continued his regular hemodialysis schedule.

DISCUSSION

An effective host response against a viral infection requires coordinated efforts by both nonspecific and antigen-specific immune responses. Cytokines play a key role in the cell-to-cell communication necessary for this process. Immediately after viral infection, several antigen nonspecific effector mechanisms are activated[4].

Among the individuals who recover from acute HCV infection, Th1 subtype responses predominate and are necessary for complete recovery in acute HCV infection[5,6]. Lechmann *et al*.[7] found that cellular immune responses against a panel of HCV core-derived peptides are stronger than humoral immune responses in individuals who have recovered from acute HCV infection. Also, experimental models reveal that rats with resolved acute hepatitis C have a higher proportion of cells producing Th1 subtype cytokines. Parasitic infections are frequently accompanied with a downregulation of cell-mediated immunity. Parasitic infections can exert bystander suppression of protective Th1 responses to infection and liver flukes may secrete molecules that down-regulate Th1 responses[2]. In an experimental model, Miriam *et al*.[8] showed that Th1 response to *Bordetella pertussis* antigens is markedly suppressed following infection with *F. hepatica*. Kamal *et al*.[9] showed that patients with acute hepatitis C and schistosomiasis coinfection cannot clear viremia and show rapid progression once chronic infection is established. In contrast, in the present case, the clinical and serological response marked by the clearance of HCV-RNA was maintained though the acquisition of *F. Hepatica*. This favorable outcome may be related to immunomodulatory effects of IFN-α therapy. IFN-α induces the production of certain cytokines and has been recognized as a cytokine promoting Th1 differentiation[10,11]. In addition, it increases cytotoxic activity of natural killer cells, cytotoxic T lymphocytes and macrophages[12]. Recent data suggest that early treatment of acute HCV infection with IFN-α may be highly effective in preventing chronic hepatitis C infection[13].

In conclusion, the present case illustrates that acute hepatitis C is responsive to the treatment even in the coexistence of fasciolopsiasis.

Abstract

Polycystic liver disease (PLD) is characterized by the presence of multiple bile duct-derived epithelial cysts scattered in the liver parenchyma. PLD can manifest itself in patients with severe autosomal dominant polycystic kidney disease (ADPKD). Isolated autosomal dominant polycystic liver disease (ADPLD) is genetically distinct from PLD associated with ADPKD, although it may have similar pathogenesis and clinical manifestations. Recently, mutations in two causative genes for ADPLD, independently from ADPKD, have been identified. We report here a family (a mother and her daughter) with a severe form of ADPLD not associated with ADPKD produced by a novel missense protein kinase C substrate 80K-H (PRKCSH) mutation (R281W). This mutation causes a severe phenotype, since the two affected subjects manifested signs of portal hypertension. Doppler sonography, computed tomography (CT) and magnetic resonance (MR) imaging are effective in documenting the underlying lesions in a non-invasive way.

Key words: ADPLD; Hepatic cysts; Hepatocystin; Inferior vena cava compression; Polycystic liver disease; Portal hypertension

INTRODUCTION

Proof of existence of autosomal dominant polycystic liver disease (ADPLD) as a distinct genetic entity, independently from autosomal dominant polycystic kidney disease (ADPKD), stems from three studies in which isolated familial polycystic liver disease (PLD) was shown to be unlinked to the PKD1 or PKD2 loci[1-3]. In 2000, Reynolds *et al*.[4] identified a locus for ADPLD on chromosome 19p13.2-13.1. In 2003, two independent groups demonstrated that mutations in *PRKCSH*, encoding the β-subunit of glucosidase II, a N-linked glycan-processing enzyme in the endoplasmic reticulum, cause isolated ADPLD[5,6]. Given its role in the pathogenesis of ADPLD, this protein has been renamed as hepatocystin[5]. Very recently, Davila *et al*.[7] found that mutations in *SEC63* (chromosome 6q21), encoding a component of the protein translocation machinery in the endoplasmic reticulum, also cause ADPLD. Mutations in *PRKCSH* and *SEC63* probably account for less than one-third of ADPLD cases, indicating that there is at least one more locus associated with this disease[7,8].

We have reported here the first Spanish family with a severe form of ADPLD not associated with ADPKD. The proband manifested displacement of abdominal structures by a massively enlarged liver causing portal hypertension and inferior vena cava compression.

CASE REPORT

A 36-year-old woman presented with a long history of abdominal enlargement. She had two pregnancies and live births at 29 and 34 years of age, respectively. Physical examination showed a bulging abdomen with a palpable mass extending from the right hemiabdomen to the left quadrant reaching 10 cm below the umbilicus. Laboratory data showed 0.9 mg/dL creatinine (normal range 0.6-1.2 mg/dL), 7.2 g/dL total proteins (normal range 6-8 g/dL), 137 mg/dL total cholesterol (normal range 140-220 mg/dL), 30 mg/dL triglycerides (normal range 50-128 mg/dL), 29 IU/L aspartate

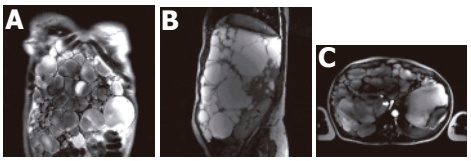

Figure 1 Massive polycystic liver disease on coronal MR imaging (**A**), caudal and posterior displacement of abdominal organs by the massively enlarged liver on sagittal MR imaging (**B**), and compression of the inferior vena cava (arrow) produced by the massively enlarged liver (**C**) on MR angiograph.

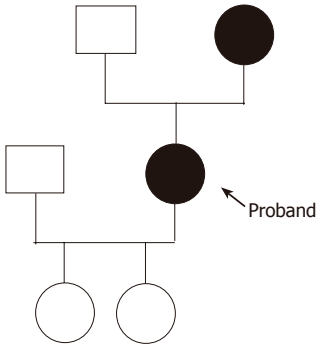

Figure 2 Family pedigree of the patient.

aminotransferase (normal range 10-40 IU/L), 22 IU/L alanine aminotransferase (normal range 10-40 IU/L), 135 IU/L gamma glutamyl transpeptidase (normal range 10-40 IU/L), 117 IU/L alkaline phosphatase (normal range 40-105 IU/L), 1.1 mg/dL total bilirubin (normal range 0.1-1.0 mg/dL), 82% prothrombin time and 394 mg/dL fibrinogen (normal range 200-400 mg/dL). Sonography and computed tomography (CT) of the abdomen were compatible with an increased liver volume caused by numerous hepatic cysts of various sizes. Magnetic resonance (MR) imaging of the abdomen revealed a massive polycystic liver with caudal and posterior displacement of the abdominal organs (Figures 1A and B). Doppler sonography and MR angiography demonstrated displacement of the kidneys and their vascular structures by the massively enlarged polycystic liver. The celiac axis was also displaced and the portal vein and a segment of the inferior vena cava below the hepatic veins were compressed by the hepatic cysts (Figure 1C). The kidneys were normal except for two small cortical cysts on the left kidney. There were signs of moderate portal hypertension with varices in the hepatic hilum. Seven years after the diagnosis, the patient was healthy and free of complications. Currently she is awaiting a liver transplantation.

Family history revealed that the patient's mother also had PLD without kidney disease. The father was not known to suffer from liver or kidney disease. The proband's daughters had no renal or hepatic cysts. The family pedigree is represented in Figure 2. The proband's mother (age 72 years) had a history of cholecystectomy in 1983 (performed in another hospital) and a diagnosis of heterozygous beta thalassemia minor in 1990. She had one daughter. Laboratory data showed 37% hematocrit (normal range 36-46%), 12.2 g/dL hemoglobin (normal range

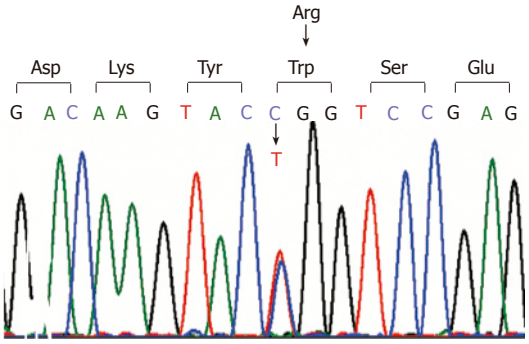

Figure 3 Sequence identification of the C>T changes in exon 10. This mutation, C841T which is predicted to change the amino acid composition of hepatocystin, changes arginine to tryptophan at codon 281 (R281W).

12-16 g/dL), 66.6 fL MCV (80-100 fL), 21.8 pg MCH (normal range 26-34 pg), 5.9% hemoglobin A2 (normal range 2-3.5%), 3 500/μL white blood cell with normal differentiation, 105 000/mm^3 platelet count, 0.6 mg/dL creatinine, 6.9 g/dL total proteins, 177 mg/dL total cholesterol, 101 mg/dL triglycerides, 31 IU/L aspartate aminotransferase, 19 IU/L alanine aminotransferase, 14 IU/L gamma glutamyl transpeptidase, 109 IU/L alkaline phosphatase, 2.1 mg/dL total bilirubin, 79% prothrombin time and 362 mg/dL fibrinogen. Ultrasonography and CT of the abdomen demonstrated PLD. There were signs of portal hypertension with varices in the hepatic hilum, gastrohepatic ligament, and lower esophagus. The spleen was enlarged, measuring 17.6 cm in length. The kidneys were normal. The patient was healthy and had no variceal bleeding. She refused any invasive procedure.

DNA sequencing and mutation detection

DNA was isolated from peripheral blood leukocytes by standard procedures. We performed polymerase chain reaction amplification using specific primer sets for all the 18 exons that constitute the open reading frame of *PRKCSH*. We determined the nucleotide sequences of the amplified fragments by fluorescence sequencing with dye-terminator chemistry on an ABI3700 capillary sequencer (Perkin-Elmer Applied Biosystems).

RESULTS

Sequence analysis of PRKCSH gene from DNA isolated from the proband demonstrated a base pair change (C>T) on one allele at position 841 (Figure 3). This mutation located in exon 10 resulted in a change of the amino acid composition of hepatocystin with the replacement of arginine to tryptophan at codon (R281W). The missense mutation was also present in the affected mother of the proband but not in her two children. Within hepatocystin, the mutation was located between the EF-hand calcium-binding domain, ending at codon 234 and the glutamic acid-rich region which starts at codon 299 (Figure 4). Hepatocystin, the protein product of PRKCSH, comprises 528 amino acid residues and has a predicted molecular mass of approximately 59 ku. This protein contains a signal peptide for translocation across the endoplasmic

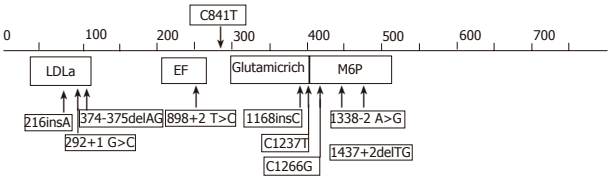

Figure 4 Schematic representation of hepatocystin. The position of *PRKCSH* mutations that have been associated with PCLD are superimposed on the structure of hepatocystin. The new mutation detected in our family is indicated on top. The numbers reflect the amino acid numbering of hepatocystin. LDLa: low-density lipoprotein receptor domain A; EF: EF-hand calcium-binding domains; MPR: mannose 6-phosphate receptor domain.

HS: *Homo sapiens*; BT: *Bos Taurus*; MM: *Mus musculus*, RN: *Rattus norvegicus*. The C841T *PRKCSH* mutation detected in this study is indicated in bold, and for comparison the corresponding nucleotides from various species are included. The numbers on top correspond with the codon numbering of hepatocystin, while Asp is aspartic acid; Lys is lysine; Tyr is tyrosine; Arg is arginine. Note that the C at position 841 is highly conserved among the species.

reticulum membrane, a low-density lipoprotein receptor domain class A (LDLa) domain, two EF-hand domains, a glutamic-acid-rich region, a mannose-6-phosphate receptor domain and a conserved C-terminal HDEL amino acid sequence for endoplasmic reticulum retention. Hepatocystin is an endoplasmic reticulum-resident enzyme that is involved in carbohydrate processing and quality control of newly synthesized glycoproteins.

DISCUSSION

ADPLD is a rare autosomal dominant disorder that has been described in fewer than 50 families from Finnish[8], Dutch[5], American[4], Belgian[2], and Spanish-Belgian[3] ancestry. The pathology of ADPLD consists of numerous cysts of biliary epithelial origin spread throughout the liver parenchyma. This disease is distinct from ADPKD1 and ADPKD2, in which affected individuals develop bilateral renal cysts and liver and pancreatic cysts in advanced cases[9-11]. Cystic liver disease occurs in a substantial portion of patients with ADPKD and end-stage renal disease. Factors influencing the prevalence of PLD in ADPKD include female sex, age (prevalence of PLD is 10% in the third decade, but 60% in patients older than 60 years), and pregnancy (multiparity is associated with increased size and number of cysts in ADPKD)[12].

The recent cloning of the gene involved in ADPLD has greatly facilitated the possibility of a firm molecular diagnosis in our family. Up to now, a total of nine different *PRKCSH* mutations have been described[13,14]. We detected a novel missense *PRKCSH* mutation (R281W) in our family. Several lines of evidence suggest that the R281W represents a bona fide disease causing mutation. First, there is segregation of the mutation with the disease in our family. Second, arginine, a positively charged amino acid is replaced by tryptophan which is neutral. Lastly, the C at position 841 is highly conserved among the species (Table 1).

As is the case for ADPKD, ADPLD is clinically and genetically heterogeneous[8-14]. Although isolated PLD is genetically distinct from PLD associated with ADPKD, both diseases may have similar pathogenesis and clinical manifestations. If ADPLD, like ADPKD[15], occurs by a cellular recessive, two-hit mechanism, then mutations in either *PRKCSH* or *SEC63* will result in loss of proper folding of integral membrane or secreted glycoproteins in bile duct cells that have undergone somatic second hits[7,13,14]. However, the two-hit model has not been investigated in isolated PLD.

The clinical profile of PLD has been defined by Qian *et al*.[16] who on the basis of a small series concluded that extra hepatic manifestations are infrequent but may include simple renal cysts, intracranial aneurysms, and mitral valve abnormalities. Genotype-phenotype relations remain speculative at this point. Liver cysts are usually asymptomatic, and as a consequence, the disease may go undetected and is likely to be underdiagnosed in the general population[17]. Symptoms occurred are caused by the mass effect of the cysts, or the development of complications such as hemorrhage, infection, or rupture of cysts. Symptoms caused by the mass effect of the cysts include vague abdominal distension, early satiety, dyspnea, and back pain. Rarely, ascites can form because of hepatic venous outflow obstruction by cysts. Lower extremity edema is secondary to extrinsic compression of the inferior vena cava, hepatic veins, or portal vein by large or by many small or medium size hepatic cysts. Compression of the bile ducts can cause jaundice. The symptoms of compression or thrombosis of the inferior vena cava may be obscure and a high index of suspicion is required for the diagnosis[18]. Liver metabolic and synthetic functions remain normal, although an increase in serum levels of alkaline phosphatase, bilirubin and gamma glutamyl transpeptidase, and a decrease in serum levels of total cholesterol and triglycerides have been described in some cases[16]. The factors that affect disease progression are unclear. However, some risk factors for the progression of the disease are age, sex, number of pregnancies, and use of estrogen[14,16].

The proband manifested a massively enlarged liver, which caused abdominal heaviness and progressive hemodynamic changes. She presented displacement of abdominal structures by the massively enlarged liver and hepatic cysts not only caused extrinsic compression of the inferior vena cava, but also were responsible for portal hypertension. Whereas laboratory studies in the proband disclosed a slight increase in the serum levels of alkaline phosphatase and gamma glutamyl transpeptidase, and a decrease in serum levels of total cholesterol and triglycerides, the proband's mother presented thrombocytopenia and a slight increase in total bilirubin.

As the proband's history shows, the disease may become highly symptomatic in young women. The more severe extensive development of the condition in the proband than in her affected mother contrasts with the reported greater severity of the liver involvement with age. The increased severity of the disease in the proband could be in relation, at least in part, with repeated pregnancies in this patient. However, other possible factors for the progression of the disease remain unknown. Screening of the at-risk members of the families of other affected patients could help to answer this question.

The presence of (few) renal cysts, as demonstrated in our proband who had 2 renal cysts does not preclude the diagnosis ADPLD. This is in accord with the data from another study that demonstrated *PRKCSH* mutations in four patients with polycystic livers who possessed at least one renal cyst[14].

Most patients with PLD require no treatment. In highly symptomatic patients, percutaneous cyst aspiration, sclerosis and cyst fenestration may be indicated[16]. In patients with diffuse cystic liver, hepatic resection[19] is often the only possibility but entails a high mortality rate. Stent placement in the inferior vena cava has been successfully applied in a few well-selected patients with only inferior vena cava compression. In patients with severe phenotype, liver transplantation should be considered[20]. In our patients, due to the size of their liver, resection of the lobes of their livers for decompression was deemed to be problematic and liver transplantation was considered as the better option in the proband.

In summary, we have described here a family with a severe form of ADPLD not associated with ADPKD, and a novel *PRKCSH* mutation that was vertically transmitted. The two affected subjects manifested signs of portal hypertension. This family underlines the need for a careful investigation of patients with otherwise unexplained liver cystic disease, focusing on whether other organ systems are involved. It also stresses the importance of accurate family investigation whenever possible. Doppler sonography, CT, and MR are effective in documenting the underlying lesions non-invasively.

ACKNOWLEDGMENTS

We thank the family members for their great cooperation.

Abstract

Minimally invasive surgery has revolutionized the treatment of gastrointestinal tumors. Submucosal tumors of the stomach can be resected using laparoscopic techniques. We report here a case of ectopic pancreas tissue in the gastric wall that was removed using robotic-assisted laparoscopic resection. The patient was a 15-year-old female who presented with abdominal discomfort and tarry stools. Laboratory analysis showed iron deficiency anemia. Preoperative endoscopy revealed a submucosal lesion in the posterior wall of the gastric high body. Intraoperative upper endoscopy clearly located the lesion. A robotic-assisted laparoscopic wedge resection of the putative gastric submucosal tumor was performed. The pathology results showed an ectopic pancreas. The patient had an uneventful recovery and we believe that this is a valid treatment option for this benign condition.

INTRODUCTION

Ectopic pancreas is relatively rare and is definite as abnormally situated pancreatic tissue has no contact with the normal pancreas, and has its own ductal system and blood supply[1]. It is a rare entity and is usually an incidental finding in clinical practice. Most patients with an ectopic pancreas are asymptomatic, and if present, symptoms are nonspecific and depend upon the site of the lesion and different complications are encountered. Heterotopic pancreatic tissue has been found in several abdominal and intrathoracic locations, most frequently in the stomach (25-60%) or duodenum (25-35%)[2]. We report here a successful robotic-assisted laparoscopic wedge resection of a putative gastric submucosal tumor in a 15-year-old female.

CASE REPORT

A 15-year-old adolescent girl presented with intermittent epigastric pain with tarry stools for about 10 mo. She did not have any history of gastrointestinal cancer. The familial and personal history was nothing special. Laboratory findings showed iron deficiency anemia that prompted further gastrointestinal evaluation. The results of abdominal sonography and colonoscopy were negative. Panendoscopy revealed a submucosal lesion in the posterior wall of the gastric high body (Figure 1). The submucosal lesion measured about 1.5 cm in diameter. Pathological evaluation of a biopsy sample revealed chronic gastritis and mucosal hyperplasia. Biopsies collected with endoscopic techniques often do not provide the representative histologic sample needed for further therapeutic decisions. Because a malignant etiology could not be ruled out, a laparoscopic-endoscopic approach was considered to be appropriate for a curative and definitive diagnosis and minimally invasive for the resection of a localized gastric submucosal tumor.

The initial trocar was inserted at the umbilicus, using the Hasson technique. A pneumoperitoneum was created with carbon dioxide. In total, four trocars were inserted in the upper abdomen. The abdominal cavity was fully explored, during which robotic-assisted laparoscopic procedures were performed using the Zeus robot system. The greater omentum was detached from the greater curvature of the stomach with a harmonic scalpel, and the lesser sac was entered (Figure 2).

A clearly localized tumor mass was identified with

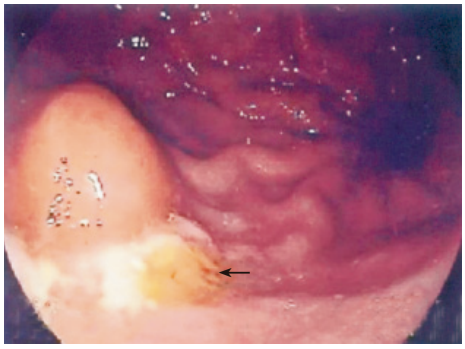

Figure 1 One submucosal lesion about 1.5 cm in diameter with a round surface on the area of the posterior wall of gastric high body with mucosal ulceration (arrow).

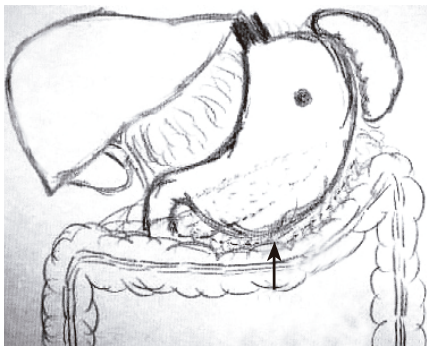

Figure 2 Detachment of greater omentum from the greater curvature of the stomach with a harmonic scalpel.

the assistance of intraoperative upper-tract endoscopy. A robotic-assisted laparoscopic wedge resection of the gastric high body was performed using the Endo-GIA roticulator (Figure 3). The resection margins were clear and the specimen was sent for pathological analysis. A layer of interrupted silk sutures was placed in the serosa surface to ensure the integrity of the staple line. A nasogastric tube was inserted into the stomach and a drain tube was placed near the staple line. The abdominal cavity was deflated and the trocar sites were closed.

The final pathology report revealed that the resected specimen was an ectopic pancreas (Figure 4). The patient was discharged on postoperative d 6, with no complications and normal gastrointestinal motility. She had an uneventful recovery.

DISCUSSION

Ectopic pancreas is a rare entity and is usually an incidental finding in clinical practice. Most patients with an ectopic pancreas are asymptomatic, and if present, symptoms are nonspecific and depend on the site of the lesion and the different complications are encountered[3-5]. About 75% of all pancreatic rests are located in the stomach, duodenum, or jejunum[6]. However, they have also been found in the ileum, Meckel's diverticulum, gall bladder, common bile duct, splenic hilum, umbilicus, lung, and in perigastric and periduodenal tissues[7]. In autopsy series, the frequency of ectopic pancreas is between 1% and 2%. The rate of recognition at the time of laparotomy is 0.2%.

A preoperative diagnosis of ectopic pancreas in the gastric wall is not easy. Although a radiological diagnosis of gastric ectopic pancreatic tissue is difficult, double-contrast barium meal may show a characteristic focally raised mucosal area with associated superficial ulceration. The role of endoscopic biopsies in identifying ectopic pancreas remains questionable because normal gastric mucosa covers the lesion. Recently, endoscopic ultrasound combined with fine-needle aspiration cytology has been reported to facilitate a definitive diagnosis by histological examination[8]. Surgical excision, either endoscopically or laparoscopically, provides symptomatic relief and is recommended if the diagnosis remains uncertain. Laparoscopic wedge resection of a presumed gastric submucosal tumor appears to have been a suitable treatment for our patient. This approach is more advantageous over a laparotomy because recovery is easier and morbidity is less.

With the advent of laparoscopy at the end of the 1980s, surgery has entered the computer age[9]. More recently, robotic-assisted laparoscopy has joined the general surgeon's armory to address some of the shortcomings of laparoscopic surgery. Magnified and computer-enhanced

video images provide surgeons with much better access to and visualization of the abdomen. The main advantages of robot-assisted laparoscopic surgery are the availability of three-dimensional visibility and easier instrument manipulation compared to standard laparoscopy. Initially, robotic-assisted laparoscopic cholecystectomy was deemed safe, and has been proved to be safe in foregut procedures.

In conclusion, ectopic pancreas in the posterior wall of gastric high body can be resected by robotic-assisted laparotomy. This procedure is minimally invasive for such benign lesions.

Abstract

The occurrence of rectal diverticula is very rare, with only sporadic reports in the literature since 1911. Symptomatic rectal diverticula are encountered even less frequently. Treatments of these complicated events range from conservative treatments to major surgical interventions. We present a hitherto unreported occurrence of isolated rectal diverticulum complicated with rectal prolapse and outlet obstruction. Delorme's procedure resulted in subsidence of symptoms and resolution of the diverticulum. It provides a minimal invasive surgical technique to successfully address the reported malady.

Key words: Rectal diverticula; Rectal prolapse; Delorme's procedure

INTRODUCTION

Cases involving complicated rectal diverticula are extremely rare[1]. But when they occur, they usually present with rectal pain and bleeding, or inflammatory lesions such as abscess formation[3,4]. The following report documents a patient who experienced outlet obstruction during defecation and episodic rectal prolapse as the initial presentation. Eventual diagnosis was complication arising from a rectal diverticulum. Surgical intervention utilizing Delorme's procedure was successful, and is novel for the treatment of this rare and complicated event.

CASE REPORT

A 71-year-old female was admitted with a chief complaint of the sudden onset of a prolapsed mucosa through the anus during defecation on the night before admission. The protruding mucosa was reduced manually. She was nulliparous and had undergone surgical intervention for a benign tumor of unknown origin within the pelvis by a gynecologist 35 years before. Records had been lost during the subsequent postoperative period. She had experienced chronic constipation for 20 years, primarily involving an outlet obstruction for the passage of stools. She had to push her left buttock manually with her fingers to let the stool pass through the anal canal.

Upon admission, the patient was normal in general appearance except for a longitudinal surgical scar at the lower abdomen courtesy of the previous surgery. Results of physical examination were essentially normal except for the rectum. A large out-pouched pocket situated at the left lateral aspect of the rectal wall approximately 3 cm from the anal verge was digitally palpable. Sigmoidoscopy was negative. Barium enema examination showed a marked solitary 5 cm diameter diverticulum with wide-orifice neck arising from the rectal wall (Figure 1). Thus, we considered that the rectal diverticulum resulted in the accumulation of stools, causing the symptom of outlet obstruction, and subsequently had appeared as a prolapsed rectum due to the inverted rectal diverticulum protruding through the anus after excessive straining during defecation. The diagnosis of rectal diverticulum complicating with rectal prolapse and outlet obstruction was made.

The patient underwent a 50-min Delorme's procedure under intravenous anesthesia. A circumferential incision was made through the mucosa near the dentate line. Using electrocautery, the mucosa was stripped to the apex of the prolapsed lump and excised. The denuded prolapsed muscle was then pleated with 2-0 prolene sutures and reefed up. The transected edges of the mucosa were sutured together using 3-0 chromic catgut (Ethicon, Johnson & Johnson, Medical Taiwan). The excised specimen consisted of the resected rectal mucosa with an out-pouched sacculation measuring 50 mm×70 mm in size.

Postoperatively, bowel movements occurred more than 10 times a day initially but rapidly improved to 3-4 times per day in the following days. She recovered uneventfully and obtained relief from the outlet obstruction. Repeated

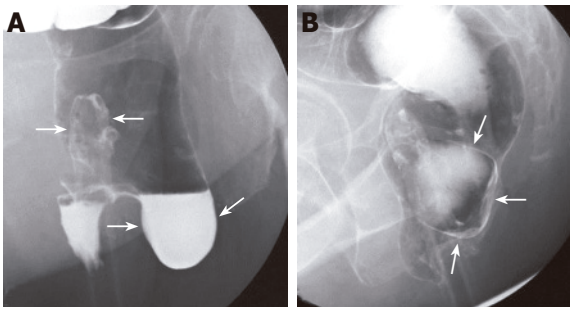

Figure 1 A and **B**. Double-contrast barium enema examination demonstrates a large diverticulum with wide-orifice arising from the left lateral rectal wall (large arrows). The rectal catheter is also seen (small arrows).

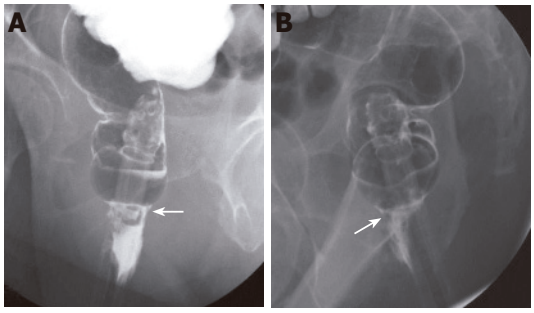

Figure 2 A and **B**. Postoperative barium study revealed the subsidence of the rectal diverticulum (arrows).

rectal examination revealed that the wide-orifice neck of the diverticular out-pouching had been tightly closed. She was discharged 6 d after the operation. A barium enema was repeated 2 mo later. (Figure 2) She defecated normally with 1–2 bowel movements per day during the 12 mo following the operation.

DISCUSSION

Diverticular disease occurs in the colon with great frequency. However, rectal involvement is very rare; being estimated to occur in less than 0.1% of cases[1,2]. Most patients with rectal diverticula are diagnosed by accident, as the malady is asymptomatic. Such uncomplicated rectal diverticula are clinically insignificant. However, complications associated with rectal diverticula can include rectal diverticulitis with perforation and abscess formation, diverticulitis of the midrectum, and a prolapsed rectum from an inverted rectal diverticulum[3-5]. Postinflammatory stenosis of the rectum, a rectal-vesical fistula, and an enormous fecaloma within a rectal diverticulum have also been reported as complications of rectal diverticula[6,7]. Erroneous diagnosis of carcinoma can prompt abdominal perineal resection[8].

Diverticulosis of the rectum typically occurs in the presence of colonic diverticula, especially the sigmoid segment. The factors that may contribute to rectal diverticula are still not completely understood. Possible predisposing factors include congenital anomalies such as weakness in the circumferential muscle that surrounds the rectum, primary muscle atrophy, or the absence of supporting structures such as the coccyx. Other acquired causes include relaxed rectal-vaginal septum, recurrent fecal impactions that exert pressure and cause distension of the rectum and pelvic trauma or infections leading to the weakening of the rectal wall[8,9]. In addition, Plavsic *et al*.[2] reported in 1995 that 2 of 27 patients with scleroderma had rectal diverticulosis without other diverticula in the rest of the colon. Loss of colonic haustrations has been reported in scleroderma and likely results in the development of colonic diverticula[10]. To our knowledge, the case we present is only the third reported case of isolated rectal diverticulum.

Rectal diverticula are typically situated along the lateral aspects of the rectum, since the complete longitudinal muscular layer of the rectum is thicker anteriorly and posteriorly compared to the lateral aspects of the wall[9]. Additionally, most rectal diverticula thus far described include all layers of the colonic wall as opposed to the more pseudodiverticula of the colon, suggesting the possibility that they occur at areas of focal weakness in the rectal wall caused by congenital or acquired origin[11]. The number of rectal diverticula per patient ranges from one to three with a diameter of 20 mm or greater compared with the remaining colonic diverticula, which typically measures less than 15 mm[9]. Rectal diverticula may also vary greatly in size with changes in intra-abdominal pressure[11].

Surgical treatments of the complicated rectal diverticula include drainage of the abscess, diverting colostomy, resection of the diverticular mass or abdominal perineal resection of the rectum. However, the Delorme's procedure has never been reported for these complicated events. This procedure is often used for small rectal prolapse but may also be used for large ones. Our case presented with rectal prolapse, which was considered to be the result of an inverted rectal diverticulum protruding through the anal canal. Delorme's procedure carries the advantage of a less invasive procedure that shortens the hospital stay. The patient recovered rapidly and uneventfully. Recurrence is the most common complication of this operation with an average incidence of 12% in different series[12]. Other complications such as hemorrhage, suture line dehiscence, stricture, and incontinence had ever been reported[13].

In conclusion, rectal diverticula are rare and can be easily missed by proctoscopy. They typically require no treatment because they are asymptomatic in most patients. Surgical intervention is only necessary in such patients with complicated events. Various approaches had been described in the management of different complications. Correct diagnosis preoperatively is required to prevent unnecessary surgery. In our presenting case, solitary rectal diverticulum was diagnosed by digital examination and barium enema preoperatively. Delorme's procedure provides a minimal invasive surgery and produces excellent results.

TO THE EDITOR

A 79-year-old man was hospitalized because of worsening upper abdominal pain which started two days before admission and was continuously present. His personal and family history was uneventful, he did not smoke and denied toxic habits or using any medications, including over-the-counter medications, herbal remedies or any vitamin supplements.

At admission, the patient was fully alert and oriented, afebrile, but distressed due to severe abdominal pain; his vital parameters were normal. On physical examination, there was abdominal guarding and rebound with hypoactive bowel sounds, rectal examination revealed no masses, liver and spleen were normal, and a stool sample was guaiac negative. The remaining physical examination was unrevealing.

Laboratory tests showed a leukocyte count of 12×10^9 cells/L, 90% of which were neutrophils; electrolytes, amylase, lipase, and liver and renal function tests were normal. An electrocardiogram and a chest X-ray were also normal. A color Doppler ultrasonography and an emergency contrast-enhanced computed tomography disclosed thrombosis with complete occlusion of both intra- and extra-hepatic branches of the portal vein and partial obstruction of the superior mesenteric vein; abundant intraperitoneal fluid was observed with no collateral venous vessels or any direct or indirect evidence of transmural intestinal infarction. Endoscopy of both the upper and lower gastrointestinal tract was negative.

A thrombophilic screening showed extremely elevated blood levels of homocysteine (91 and 88 μmol/L on the 1st and 5th d of hospital stay; normal values < 15); search for antiphospholipid antibody and lupus anticoagulant was negative and blood levels of antithrombin and protein C and S were normal. Circulating vitamin B_6, B_{12}, and folate concentrations were also normal.

The patient was treated with bowel rest, intravenous fluids, antibiotics, and enoxaparin (100 IU/kg twice daily) and he reported complete recovery from abdominal pain on the 2nd d after admission. We added folate and vitamin B_6 to his regimen and the patient was discharged free of symptoms on the 15th d; at this time blood homocysteine was 75 μmol/L. At a follow-up visit 2 mo later, while still on enoxaparin and folate, he was doing well with no clinical or laboratory evidence of active thrombosis. We received the results of molecular studies performed on blood samples taken at admission, which showed heterozygosity for factor V Leiden mutation; search for prothrombin G20210A and MTHFR C677T mutations was negative. Blood homocysteine concentration was < 15 μmol/L and imaging studies showed normal flow in the superior mesenteric vein along with a complete occlusion of the portal vein, which was unchanged; there were venous collaterals in the hilar area of the liver. Anticoagulant therapy was shifted to warfarin with a targeted international normalized ratio (INR) 2-3 and, when last seen six months after discharge, the patient was asymptomatic with INR 2.6, normal blood homocysteine and no active thrombosis.

Combined thrombosis involving one mesenteric vein and the portal vein is rare, difficult to diagnose and can be fatal, with diffuse abdominal pain, distension and tenderness being the most common symptoms and physical findings[1,2]. Stricture and bowel necrosis with peritonitis due to transmural intestinal infarction may complicate the course and are important causes of mortality among those patients[1,2]. The early initiation of anticoagulation using unfractionated heparin or low

molecular weight heparin has been shown to minimize the risk of serious complications [1,2], nonetheless spontaneous resolution of extensive superior mesenteric and portal vein thrombosis has been also reported [3]. Common causes include liver disease, pancreatitis, inflammatory bowel disease, cancer, sepsis, an underlying myeloproliferative disorder, surgery or trauma, and systemic thrombophilia [4,5].

The association of hyperhomocysteinemia with extremely elevated blood levels of homocysteine and heterozygosity for factor V Leiden mutation was the cause of such a severe abdominal venous thrombosis in the case we report on. No precipitating events of venous thromboembolism were recognized and the patient had none of the abdominal disorders that may trigger thrombosis of the mesenteric veins or the portal vein or any other inherited or acquired prothrombotic condition. Available data consistently suggest a moderate, positive, and dose-related relationship between blood levels of homocysteine and the risk of portal or mesenteric venous thrombosis [6]. However, almost all the patients so far described in whom portal or mesenteric venous thrombosis was linked with hyperhomocysteinemia also had at least one additional prothrombotic disorder [7-10]. Our Medline search yielded no case of combined mesenteric-portal vein thrombosis associated only with hyperhomocysteinemia and no other risk factors for venous thromboembolism. It is not surprising in our opinion that, despite being heterozygous for factor V Leiden mutation, our patient did not experience any thrombotic disorders until severe hyperhomocysteinemia developed. This adds weight to the relevance of hyperhomocysteinemia in the pathophysiological mechanisms as a trigger of venous thrombosis in this case.

The mechanisms of hyperhomocysteinemia in our patient remain unclear. The patient was not exposed before presentation to any folate or vitamin B_6 antagonists, i.e. methotrexate, phenytoin, estrogens, or theophylline, and we ruled out upon history and clinical examination atherosclerosis, smoking or elevated blood pressure, which are also associated with raised circulating concentrations of homocysteine [11]. An acquired nutritional deficiency of folate also sounds a non reliable cause. Even though blood levels of folate, vitamin B6 and vitamin B12 were normal, homocysteine concentrations returned to the normal range after eight weeks of treatment with folate and vitamin supplements. This apparent discrepancy is difficult to explain, however we could reasonably speculate that the exogenous supplementation of folate and vitamins did ultimately correct a subtle age-dependent impairment of folate metabolism.

We claim that patients with apparently unexplained combined thrombosis involving both one mesenteric vein and the portal vein should be screened for hyperhomocysteinemia. Outcome could be favorable, even in those carrying other prothrombotic conditions such as factor V Leiden mutation, with a complete recovery if appropriate treatment with anticoagulants, folate and vitamin supplements is timely started.

TO THE EDITOR

Fenofibrate is a member of such fibrate class agents as bezafibrate and it work as a ligand of PPARα, and also shows a potent triglyceride-lowering effect. The elevation of aminotransferase levels has been frequently observed after the administration of fenofibrate and this phenomenon is considered to be non-pathological because fenofibrate activates the gene expression of the aminotransferases. Recently, fenofibrate has been used not only for hypercholesterolemia but also for primary biliary cirrhosis (PBC)[1, 2]. However, the occurrence of liver injury induced by fenofibrate has not yet been reported written in the English literature. We herein report a rare case of liver injury due to the oral use of this drug.

A 66-year-old Japanese female patient was admitted to undergo a further examination with a nearly 20-year history of liver dysfunction. She had been previously treated with 600 mg of ursodeoxycholic acid (UDCA) for nearly 6 mo at another clinic. On admission her conjunctiva was neither anemic nor icteric. The laboratory data revealed white blood cell counts of 6 600/μL with a differential of neutrophils 50%, lymphocyte 38%, monocytes 6%, basophils 1%, eosinophils 5%. The C reactive protein level was less than 0.3 mg/dL. The hepatic function profiles showed the total bilirubin to be 0.8 mg/dL, aspartate aminotransferase (AST) 40 IU/L, alanine aminotransferase (ALT) 29 IU/L, lactate dehydrogenase (LDH) 183 IU/L, alkaline phosphatase (ALP) 367 IU/L and gamma-glutamil transpeptidase (γ-GTP) 272 IU/L. Regarding the hepatitis virus, hepatitis B virus surface antigen and hepatitis C virus antibody were both negative. Serology revealed a high level of IgM of 393 mg/dL, and the antinuclear antibody of 80-fold and antimitochondrial antibody (AMA) of 320-fold each and antibody of 176 U/mL were positive for pyruvate dehydrogenase complex-E2. Histopathologically, a damaged bile duct with aggregates of lymphocytes with a nonsuppurative inflammatory destruction of the small bile duct and granuloma was seen in the portal area, which was compatible with those of Scheuer's stage 1 of primary biliary cirrhosis.

Based on the diagnosis of primary biliary cirrhosis, the administration of fenofibrate 150 mg per day was initiated in addition to 600 mg of UDCA. A fever of over 37.5 ℃, anorexia and discomfort in the right hypochondrium appeared 11 d after the administration of fenofibrate. Liver injury such as elevations of total bilirubin of 1.8 mg/dL, AST 268, ALT 216, ALP 537, and γ-GTP 660 IU/L was confirmed, and both the CRP level and the ratio of eosinophils in the peripheral blood increased to 5.14 mg/dL and 14.4 %, respectively. She was diagnosed to have fenofibrate-induced liver injury based on the laboratory data and the clinical course. Therefore, fenofibrate was discontinued, however, UDCA continued to be administered continuously. Thereafter, the serum concentrations of AST, ALT, ALP, γ-GTP, CRP, and the rate of eosinophils rapidly returned to the pretreatment levels of 30, 27, 457, 399 IU/L, less than 0.3 mg/dL and 4.6 %, respectively, 12 d after the discontinuation of fenofibrate (Figure 1). Later, the lymphocyte stimulation index for fenofibrate for this patient was found to be positive, while showing a stimulation index of 212 % in comparison to normal samples.

Several clinical studies on lipoprotein-lowering agents such as simvastatin[3] and bezafibrate[4-7] on PBC patients who failed to respond to UDCA have so far been conducted, and the results have been found to be of value. In addition, fenofibrate, a member of such fibrate class agents as bezafibrate, has also recently been found to be a likely agent for PBC because of its stronger anti-inflammatory effect via PPARα, and its greater ability to reduce the levels of TG and LDL-C than that of bezafibrate. We previously found fenofibrate to effectively treat UDCA-resistant PBC in nine cases without any adverse effect[2].

Regarding the adverse effect of fenofibrate, a Diabetes Arteriosclerosis Intervention Study (DAIS) showed that micronized fenofibrate at 200 mg (equivalent to 300 mg of

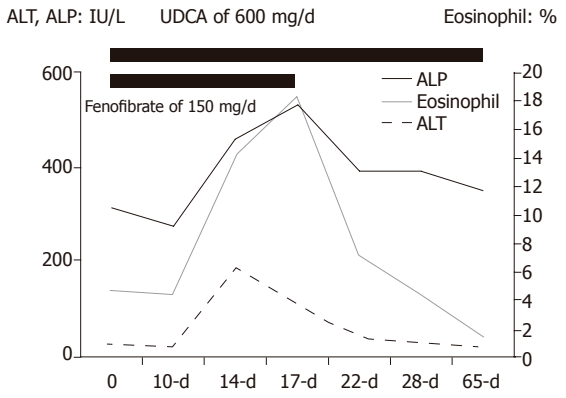

Figure 1 Clinical course.

the standard formulation) was administered for 3 years to type 2 diabetic patients in order to observe the inhibitory effect in the progression of coronary arterial stenosis. As a result, no difference in the safety between fenofibrate and placebo was observed[8]. In addition, studies of human first-generation cultured cells and HepG2 cells suggested the serum aminotransferase levels to be transiently elevated and normalized or returned to pretreatment levels[9]. The increase in the aminotransferase level which occurs after treatment with fenofibrate is not considered to be clinically significant although fenofibrate activates the aminotransferase gene expression, thus leading to a mild and transient elevation of aminotransferase via PPARα through mechanisms involving increased levels of reactive oxygen species and intracellular glutathion depletion, thus leading to mitochondrial dysfunction and a perturbation of intracellular Ca^{++} homeostasis and also cell death[9].

Since fenofibrate is a widely prescribed therapeutic agent world-wide for patients with hypercholesterolemia and recently for those with PBC[1, 2], the early recognition of any possible liver dysfunction especially in the case of PBC, and the immediate cessation of its administration, when positively identified are thus called for to avoid any dangerous clinical complications. Furthermore, our case shows that fenofibrate-induced liver injury might occur in addition to the transient elevations in the AST and ALT levels via PPARα.

World J Gastroenterol 2005;11(48):7704-7714
World Journal of Gastroenterology ISSN 1007-9327

Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those were published and those were rejected in this issue) during the last editing period of time. Arabic number in parenthesis stands for the number of the reviewer have reviewed this year.

1 **Christian Cormac Abnet, PhD, MPH**
Investigator, tritional Epidemiology Branch Division of Cancer Epidemiology and Genetics, 6120 Executive Blvd, EPS/320, MSC 7232 Rockville, MD 20852, United States

2 **Kyoichi Adachi, MD (12)**
Department of Gastroenterology and Hepatology, Shimane University, School of Medicine Shimane, 89-1 Enya-cho, Izumo-shi Shimane 693-8501, Japan

Department of Medicine and Clinical Science, Kyushu University, Maidashi 3-1-1, Higashi-ku, Fukuoka 812-8582, Japan

222 Nikolai V Naoumov, Professor
Department of Medicine, Institute of Hepatology University College London, 69-75 Chenies Mews, London WC1E 6HX, United Kingdom

223 John P Neoptolemos, Professor (2)
Divison of Surgery and Oncology, University of Liverpool, Royal Liverpool University Hospital, Daulby Street, Liverpool, L69 3GA, United Kingdom

224 James Neuberger, Professor (9)
Liver Unit, Queen Elizabeth Hospital, Birmingham B15 2TH, United Kingdom

225 Yaron Niv, Professor (3)
Department of Gastroenterology, Rabin Medical Center, Beilinson Campus, Tel Aviv University, 2 Hadekel St., Pardesia 42815, Israel

226 Masayuki Ohta, MD (7)
Department of Surgery I, Oita University Faculty of Medicine, 1-1 Idaigaoka, Hasama-machi, Oita 879-5593, Japan

227 Tetsuo Ohta, MD (2)
Department of Gastroenterologic Surgery, Kanazawa University Hospital, Takara-machi 13-1, Kanazawa 920-0934, Japan

228 Katsuhisa Omagari, MD (3)
Second Department of Internal Medicine, Nagasaki University School of Medicine, 1-7-1 Sakamoto, Nagasaki-city 852-8501, Japan

229 Giovanni D De Palma, Professor
Department of Surgery and Advanced Technologies, University of Naples Federico II, School of Medicine, Naples 80131, Italy

230 Bo-Rong Pan, Professor (2)
Departmant of Oncology, Xijing Hospital, Fourth Military Medical University, No.1, F. 8, Bldg 10, 97 Changying East Road, Xi'an 710032, Shaanxi Province, China

231 Julian Panes, Professor (2)
Department of Gastroenterology, Hospital Clinic of Barcelona, Villarroel 170, Barcelona 08036, Spain

232 Fabrizio R Parente, MD (2)
Department of Gastroenterology, L.Sacco University Hospital Via GB Grassi, 74, Milan 20157, Italy

233 Jae-Gahb Park, Professor (4)
Seoul National University College of Medicine, 28 Yongon-dong, Chongno-gu, Seoul 110-744, South Korea

234 Zhiheng Pei, Assistant Professor (3)
Department of Pathology and Medicine, New York University School of Medicine, Department of Veterans Affairs, New York Harbor Healthcare System, 6001W, 423 East 23rd street, New York NY 10010, United States

235 Amado Salvador Peña, Professor (2)
Department of Pathology, Immunogenetics, VU University Medical Centre, De Boelelaan 1117, PO Box 7057, Amsterdam 1007 MB, The Netherlands

236 Miguel Perez-Mateo, Professor (4)
Liver Unit, Hospital General Universitario Alicante, Pintor Baeza s/n, Alicante 03004, Spain

237 Raffaele Pezzilli, MD (6)
Department of Internal Medicine and Gastroenterology, Sant' Orsola-Malpighi Hospital, Via Massarenti, 9, Bologna 40138, Italy

238 Josep M Pique, MD
Department of Gastroenterology, Hospital Clínic of Barcelona, Villarroel, 170, Barcelona 08036, Spain

239 Gabriele Bianchi Porro, Professor
Gastroenterology Unit, "L. Sacco" University Hospital, Via G.B. Grassi 74, Milano 20157, Italy

240 Piero Portincasa, Professor
Internal Medicine – DIMIMP, University of Bari Medical School, Hospital Policlinico Piazza G. Cesare 11, Bari 70124, Italy

241 Jesus Prieto, Professor (5)
Clinica Universitaria, University of Navarra, Avda, Pio XII, 36, Pamplona 31080, Spain

242 Lun-Xiu Qin, Professor (3)
Liver Cancer Institute and Zhongshan Hospital, Fudan University, 180 Feng Lin Road, Shanghai 200032, China

243 Eamonn M Quigley, Professor (2)
Department of Medicine National University of Ireland, Cork, Cork University Hospital Clinical Sciences Building Wilton, Cork, Ireland

244 Massimo Raimondo, Dr
Division of Gastroenterology and Hepatology, Mayo Clinic, 4500 San Pablo Road, Jacksonville, FL 32224, United States

245 Bernardino Rampone, Dr

World J Gastroenterol 2005;11(48):7716-7717
World Journal of Gastroenterology ISSN 1007-9327

Instructions to authors

GENERAL INFORMATION

World Journal of Gastroenterology (*WJG,* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc*., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

Published jointly by
The WJG Press and Elsevier Inc.

SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297×210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, Acknowledgements, References, Tables, Figures and Figure Legends. Neither the Editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press and Elsevier Inc., and may not be reproduced by any means, in whole or in part without the written permission of both the Authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations.

Online submission
Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email describing the problem to wjg@wjgnet.com for assistance. If you submit manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

Postal submission
Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4(297×210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

World Journal of Gastroenterology
Apartment 1066 Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com

MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors originating from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

Title page
Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be involved. Titles should be concise and informative (removing all unnecessary words), emphasize what is NEW, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initials and/or first name, middle name or initial(s) and full family name.

Abstract
An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc*. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

Key words
Please list 3-10 key words that could reflect content of the study.

Text
For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include appropriate Figures and Tables. Data should be presented in the body text or Figures and Tables, not both.

Illustrations
Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should add into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) and not RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126× 76 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by Freehand and Illustrator, or TIFF from Photoshop. EPS files must be accompanied by a version in native file format for editing purposes. Scans of existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size at which they will appear when printed, not smaller. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...;C: ...; D: ...; E: ...; F: ...; G: ...

Tables
Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be involved under the tables. This part should add into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

Notes in tables and illustrations
Data which is not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used; Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under illustrations should be expressed as ^{1}F, ^{2}F, ^{3}F; or some other symbols with a superscript (Arabic

numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc*. in a certain sequence.

Acknowledgments

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

References

Cited references should mainly be drawn from journals covered in the Science Citation Index (http://www.isinet.com) and/or Index Medicus (http://www.ncbi.nlm.nih.gov/PubMed) databases. Mention all references in the text, tables and figure legends, and set off by consecutive, superscripted Arabic numerals. References should be numbered consecutively in the order in which they appear in the text. Abbreviate journal title names according to the Index Medicus style (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=journals). Unpublished observations and personal communications are not listed as references. The style and punctuation of the references conform to ISO standard and the Vancouver style (5th edition); see examples below. Reference lists not conforming to this style could lead to delayed or even rejected publication status. Examples:

Standard jounal article (list all authors and include the PubMed ID [PMID] where applicable)

1 **Das KM,** Farag SA. Current medical therapy of inflammatory bowel disease. *World J Gastroenterol* 2000; 6: 483-489 [PMID: 11819634]

2 **Pan BR**, Hodgson HJF, Kalsi J. Hyperglobulinemia in chronic liver disease: Relationships between *in vitro* immunoglobulin synthesis, short lived suppressor cell activity and serum immunoglobulin levels. *Clin Exp Immunol* 1984; 55: 546-551 [PMID: 6231144]

3 **Lin GZ,** Wang XZ, Wang P, Lin J, Yang FD. Immunologic effect of Jianpi Yishen decoction in treatment of Pixu-diarrhoea. *Shijie Huaren Xiaohua Zazhi* 1999; 7: 285-287 [CMFAID:1082371101835979]

Books and other monographs (list all authors)

4 **Sherlock S,** Dooley J. Diseases of the liver and billiary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

Chapter in a book (list all authors)

5 **Lam SK.** Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

Electronic journal (list all authors)

6 **Morse SS.** Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1):24 screens. Available from: URL: http//www.cdc.gov/ncidod/EID/eid.htm

PMID requirement

From the full reference list, please submit a separate list of those references embodied in PubMed, keeping the same order as in the full reference list, with the following information only: (1) abbreviated journal name and citation (e.g. *World J Gastroenterol* 2003;9(11):2400-2403; (2) article title (e.g. Epidemiology of gastroenterologic cancer in Henan Province, China; (3) full author list (e.g. Lu JB, Sun XB, Dai DX, Zhu SK, Chang QL, Liu SZ, Duan WJ; (4) PMID (e.g. 14606064). Provide the full abstracts of these references, as quoted from PubMed on a 3.5 inch disk or CD-ROM in Microsoft Word format and send by post to The *WJG* Press. For those references taken from journals not indexed by *Index Medicus*, a printed copy of the first page of the full reference should be submitted. Attach these references to the end of the manuscript in their order of appearance in the text.

Inappropriate references

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

Statistical data

Present as mean±SD and mean±SE.

Statistical expression

Express *t* test as *t*(in italics), *F* test as *F*(in italics), chi square test as χ^2(in Greek), related coefficient as *r*(in italics), degree of freedom as γ (in Greek), sample number as *n*(in italics), and probability as *P*(in italics).

Units

Use SI units. For example: body mass, m(B) = 78 kg; blood pressure, p(B)=16.2/12.3 kPa; incubation time, t(incubation)=96 h, blood glucose concentration, c(glucose) 6.4±2.1 mmol/L; blood CEA mass concentration, p(CEA) = 8.6 24.5 μg/L; CO_2 volume fraction, 50 mL/L CO_2 not 5% CO_2; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc*. Arabic numerals such as 23,243,641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

Abbreviations

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

Italicization

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.

Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc*.

Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc*.

Biology: *Helicobacter pylori, H pylori, E coli, etc*.

SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the WJG Editorial Office Online System is NOT available at present).

Language evaluation

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

Copyright assignment form

It is the policy of WJG to acquire copyright in all contributions. Papers accepted for publication become the copyright of WJG and authors will be asked to sign a transfer of copyright form. All authors must read and agree to the conditions outlined in the Copyright Assignment Form (which can be downloaded from http://www.wjgnet.com/wjg/help/9.doc).

Final check list for authors

The format is at: http://www.wjgnet.com/wjg/help/13.doc

Responses to reviewers

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: http://www.wjgnet.com/wjg/help/10.doc

Proof of financial support

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

Publication fee

Authors of accepted articles must pay publication fee.

21	1 M	1 mol/L	
22	10 μM	10 μmol/L	
23	1N HCl	1 mol/L HCl	
24	1N H_2SO_4	0.5 mol/L H_2SO_4	
25	4rd edition	4^{th} edition	
26	15 year experience	15- year experience	
27	18.5 kDa	18.5 ku,18 500u or M_r18 500	
28	25 $g.kg^{-1}/d^{-1}$	25 g/(kg·d) or 25 g/kg per day	
29	6900	6 900	
30	1000 rpm	1 000 r/min	
31	sec	s	After Arabic numerals
32	1 pg $\cdot L^{-1}$	1 pg/L	
33	10 kilograms	10 kg	
34	13 000 rpm	13 000 *g*	High speed; *g* should be in italic and suitable conversion.
35	1000 *g*	1 000 r/min	Low speed. *g* cannot be used.
36	Gene bank	GenBank	International classified genetic materials collection bank
37	Ten L	Ten liters	At the beginning of a sentence
38	Ten mL	Ten milliliters	At the beginning of a sentence
39	umol	μmol	
40	30 sec	30 s	
41	1 g/dl	10 g/L	10-fold conversion
42	OD_{260}	A_{260}	"OD" has been abandoned.
43	One g/L	One microgram per liter	At the beginning of a sentence
44	*A*260 nm	A_{260} nm	*A* should be in italic.
	$^bP<0.05$	$^aP<0.05$	In Table, no note is needed if there is no significance in statistics: $^aP<0.05$, $^bP<0.01$ (no note if $P>0.05$). If there is a second set of *P* value in the same table, $^cP<0.05$ and $^dP<0.01$ are used for a third set: $^eP<0.05$, $^fP<0.01$.
45	**F*=9.87, $^§F$=25.9, $^{\#}F$=67.4	^1F=9.87,^2F=25.9, ^3F=67.4	Notices in or under a table
46	KM	km	kilometer
47	CM	cm	centimeter
48	MM	mm	millimeter
49	Kg, KG	kg	kilogram
50	Gm, gr	g	gram
51	nt	N	newton
52	l	L	liter
53	db	dB	decibel
54	rpm	r/min	rotation per minute
55	bq	Bq	becquerel, a unit symbol
56	amp	A	ampere
57	coul	C	coulomb
58	HZ	Hz	
59	w	W	watt
60	KPa	kPa	kilo-pascal
61	p	Pa	pascal
62	ev	EV	volt (electronic unit)
63	Jonle	J	joule
64	J/mmol	kJ/mol	kilojoule per mole
65	10×10×10cm^3	10 cm×10 cm×10 cm	
66	N·km	KN·m	moment
67	$\bar{x}\pm s$	mean±SD	In figures, tables or text narration
68	– Mean±SEM	mean±SE	In figures, tables or text narration
69	*im*	im	intramuscular injection
70	*iv*	iv	intravenous injection
71	Wang et al	Wang *et al.*	
72	EcoRI	*Eco*RI	*Eco* in italic and RI in positive. Restriction endonuclease has its prescript form of writing.
73	Ecoli	*E.coli*	Bacteria and other biologic terms have their specific expression.
74	Hp	*H pylori*	
75	Iga	*Iga*	writing form of genes
76	*igA*	IgA	writing form of proteins
77	-70 kDa	~70 ku
