**METHODS:** A total of 64 patients with gastric metastases from solid malignant tumors were retrospectively examined between 1990 and 2005. The clinicopathological findings were reviewed along with tumor characteristics such as endoscopic pattern, location, size and origin of the primary sites.

**RESULTS:** Common indications for endoscopy were anemia, bleeding and epigastric pain. Metastases presented as solitary (62.5%) or multiple (37.5%) tumors were mainly located in the middle or upper third of stomach. The main primary metastatic tumors were from breast and lung cancer and malignant melanoma.

**CONCLUSION:** As the prognosis of cancer patients has been improving gradually, gastrointestinal (GI) metastases will be encountered more often. Endoscopic examinations should be conducted carefully in patients with malignancies, and endoscopic biopsies and information on the patient's clinical history are useful for correct diagnosis of gastric metastases.

## INTRODUCTION

The stomach is an unusual site for metastasis. There have been several published reports on metastatic lesions in the stomach. However, information on gastric duodenal metastases is generally limited to single case reports. The present study examined the clinopathological features in a large series of patients with metastatic tumors in the stomach from distant sites.

## MATERIALS AND METHODS

We conducted a chart review of patients with metastatic tumors in the stomach detected endoscopically from January 1990 to December 2003. Patients with malignant lymphoma involving the stomach, or with direct invasion from neighboring organs, were excluded from this study.

Analysis of data included indication for endoscopy, endoscopic appearance, location, primary site and time interval between the diagnosis of primary tumors and diagnosis of metastatic lesions.

## RESULTS

The present study included 64 patients, including 36 men and 28 women, with a mean age of 56 years (range 28-82 years). The common indications for endoscopy were anemia or bleeding (19 cases, 10 of which had active bleeding), dyspepsia (15 cases) and epigastric pain (14 cases). Endoscopic findings mainly included small nodules with or without central ulceration, polypoid mass and ulcers. The other findings included peptic ulcer scar and small black spots, which were metastatic tumors from malignant melanoma. Solitary metastases (40 cases, 62.5%) were more common than multiple metastases (24 cases, 37.5%). The solitary lesions were mainly located in the middle third (43%) or the upper third (45%) of the stomach, and the proportion of solitary lesions was similar to that of multiple lesions. Forty percent of the solitary lesions and 35% of the multiple lesions were located on

the greater curvature (Table 1).

The diagnosis of metastatic tumors was confirmed pathologically by endoscopic biopsies in 59 out of 64 cases (92.2%). The remaining 5 cases were diagnosed during surgery for uncontrollable bleeding from the tumor. The primary sites of metastases are shown in Table 2.

The average time interval between the diagnosis of primary tumors and the diagnosis of metastatic lesions was 25.7 mo (1-40 mo), and varied in site of primary tumor (Table 3).

## DISCUSSION

The stomach is an unusual site for metastasis[1-8]. As the prognosis of cancer patients has been improving gradually, gastric metastases are encountered more frequently. In this series, lung, breast, and esophagus were the common primary metastatic sites, and malignant melanoma was associated with the highest rate of metastases. More than half of the metastatic tumors were found within a year of the diagnosis of a primary tumor. In particular, most of the gastric metastases from esophageal and lung cancer were detected within a year, since these cancers progress rapidly. On the other hand, breast cancer extended slowly, and it was sometimes more than three years before gastric metastases were diagnosed after the initial diagnosis of the primary tumor. It was noteworthy that metastatic tumors were detected before diagnosis of the primary tumors in 2 patients[8,9]. Symptoms of metastatic tumors including pain, nausea, vomiting, and signs of bleeding are nonspecific[4-9]. Endoscopy may be useful in the diagnosis and local treatment of gastric metastases, such us endotherapy that was performed successfully in 5 out of 10 patients with active gastrointestinal (GI) bleeding (endoscopic clipping in 4 cases and adrenaline injection in 1 case). In our series, more frequent endoscopic patterns included multiple nodules, bull's eye, extrinsic mass lesions, ulceration and polypoid tumor mass as previously reported[4-8,10-13].

Solitary metastases were more common than multiple metastases. The solitary lesions were mainly located in the middle third (40%) or the upper third (40%) of the stomach, and the proportion of the solitary lesions was similar to that of the multiple lesions. Forty percent of the solitary lesions and 35% of the multiple lesions were located on the greater curvature. About 90% of the metastatic lesions could be confirmed histologically by endoscopic biopsies. Tumor-negative biopsies may be mainly due to extrinsic mass rather than due to sampling error. It should be emphasized that the endoscopist should provide the pathologist with sufficient information about the patient's history to allow an accurate pathological diagnosis.

In conclusion, as the prognosis of cancer patients has been improving gradually, GI metastases will be encountered more often. Endoscopic examinations should be conducted carefully in patients with malignancies, and endoscopic biopsies. Information on the patient's clinical history is useful for the correct diagnosis of gastric metastasis.

## COMMENTS

### Backgrounds

The stomach is an unusual site for metastasis. There have been several published reports on metastatic lesion in the stomach and information on gastric duodenal metastases is generally limited to single case reports. The present study examined the endoscopic and clinopathological features in a large series of patients with metastatic tumors in the stomach.

### Research frontiers

As the prognosis for cancer patients has been improving gradually, GI metastases will be encountered more often.

### Innovations and breakthroughs

Metastasis to stomach is rare, hence no large series has been published so far. The current study is an improvement in terms of numbers of cases. It reemphasises the same results which have been published earlier.

### Applications

Endoscopic examinations should be conducted carefully in patients with malignancies, and endoscopic biopsies. Information on the patient's clinical history is useful for correct diagnosis of gastric metastasis.

### Peer review

The current paper gives a retrospective analysis of data on metastatic tumors in stomach over a period of 15 years at author's center. Metastasis to stomach is rare, hence no large series has been published so far. Oda et all have published a series of 54 cases of metastatic tumors in stomach in 2001. The current study provides a slight improvement in terms of numbers of cases. Authors have reported in the current article that 19 cases underwent endoscopy due to bleeding and 5 cases were diagnosed with metastatic tumors at the time of surgery due to uncontrolled bleeding.

## Abstract

**AIM:** To define the frequency of the C/T-13910 variant associated with lactase persistence/non-persistence trait and to analyze the milk consumption of lactase non-persistent subjects in Estonia.

**METHODS:** We genotyped 355 Estonians by polymerase chain reaction and direct sequencing. Milk consumption was analyzed by a questionnaire, specially developed to analyze milk consumption and abdominal complaints.

**RESULTS:** The frequency of the genotype of the C/C-13910 (lactase non-persistence) was found to be 24.8% in native Estonians. No other single nucleotide polymorphisms covering the region of 400 bp adjacent to the C/T-13910 variant were found. Lactase non-persistence subjects were found to consume less milk than lactase persistence subjects.

**CONCLUSION:** The frequency of lactase non-persistence defined by the C/C-13910 genotype confirms the results of the previous studies based on indirect methods of determining hypolactasia. Milk consumption of lactase non-persistence subjects is consistent with previously reported figures of adult-type hypolactasia in Estonia. However, lactase non-persistence does not prevent the intake of milk in many adults.

**Key words:** Lactase persistence; Milk; Estonia

## INTRODUCTION

Lactase enzyme hydrolyses lactose to glucose and galactose facilitating their absorption through the gut wall. Adult-type hypolactasia (lactase non-persistence, primary lactose malabsorption) is the most common enzyme deficiency in the world[1]. Clinically, hypolactasia is the main reason of milk intolerance in adults. Individuals with hypolactasia may develop symptoms of abdominal pain, borborygmi, flatulence and diarrhea if they drink milk[1,2]. The symptoms depend on the age of the subject. It has been reported that development of symptoms depends on the quantity of lactose in the diet and individual sensitivity. Individuals with hypolactasia can tolerate moderate quantities of milk without symptoms[3-5]. Many persons but not all with this condition avoid consuming large quantities of milk.

Normally, lactase activity declines after the weaning. However, a mutation has occurred in human history that maintains lactase activity high throughout life[1]. Specifically, a single nucleotide polymorphism (SNP) C/T (rs4988234) residing 13 910 bp upstream from the initiation codon of the lactase gene (LCT) has been shown to be associated with lactase persistence trait in Asian, European and Northern African populations[6-9]. Genotype CC of the C/T-13910 variant defines hypolactasia (lactase activity under 10 U/g per protein) and CT and TT genotypes' lactase persistence (lactase activity over 10 U/g per protein)[10-12]. More recent functional studies have shown that the C/T-13910 variant is associated with the regulation of the LCT gene at transcriptional level[10,11]. It has been shown that the T-13910 allele enhances LCT promoter activity 4 times more than the C-13910 allele[13,14]. A nuclear binding factor OCT-1 has recently been found to bind to the C/T-13910 region, more efficiently to the T- allele than to the C- allele. However, it seems that some other transcription factors are also needed for complete enhancer activity[15]. The excellent correlation of the C/T-13910 variant to the lactase activity[11] has made it a robust marker for routine clinical diagnostics. By using this SNP, hypolactasia can be diagnosed more easily and accurately than by other tests where environmental factors may interfere with and have

an impact on the results[16].

The prevalence of adult-type hypolactasia differs between ethnic groups. In Finland, the prevalence of adult-type hypolactasia is found to be 18% and in Sweden 10%[6,17]. Previously, the reported prevalence of adult-type hypolactasia in Estonians varies from 23% to 32%[1,18-20] and is 57% among Russians living in Estonia[20].

The aim of this study was to figure out the prevalence of adult-type hypolactasia in Estonians by genotyping of the C/T-13910 polymorphism and to find out if there are differences in milk consumption and intolerance in individuals with different genotypes of the C/T-13910 variant. We also studied if other SNPs exist adjacent to the C/T-13910 variant.

## MATERIALS AND METHODS

### Study population

The study was carried out in Väike-Maarja, Estonia. A random sample ($n$ = 434) of the population aged 25-70 years was drawn, the sample corresponded to the age and gender structure of the general population in Estonia. An informed consent was obtained from the subjects who participated in the study. The study was approved by the Ethics Committee of the Tartu University. Three hundred and sixty-six persons participated in the study (response rate 84%) and gave a blood sample, fulfilled a questionnaire about their health and personal data, including nationality of their grandparents, symptoms of milk intolerance and milk consumption habits. There were 167 males and 199 females, and their average age was 48.9 years. A blood sample was drawn for DNA analysis from each participant. DNA was isolated using the standard procedure. In statistical analysis chi-square test was used.

### Genotyping

The DNA fragment spanning the C/T-13910 variant was amplified by polymerase chain reaction (PCR) and analyzed by direct sequencing. The total volume of PCR was 50 μL containing genomic DNA (100 ng), reverse (5' -GTCACTTTGATATGATGAGAGCA-3') and forward (5'-CCTCGTTAATACCCACTGACCTA-3') primers (20 ng each), dNTPs (200 μmol/L) and 0.5 U of Taq polymerase in a standard buffer (Dynazyme, Finnzymes, Espoo, Finland). The PCR was initiated with denaturation at 95℃ for 10 min (during which enzyme was added), then 35 cycles were carried out in following conditions: denaturation at 94℃ for 30 s, annealing at 53℃ for 30 s, extension at 72℃ for 75 s and a final extension at 72℃ for 10 min. The size of PCR products was verified by 1.5% agarose gel electrophoresis with ethidium bromide. The purification of PCR products was done by 2.5 U of shrimp alkaline phosphatase (USB) and 5 U of exonuclease I (New England Biolabs) at 37℃ for 60 min, after which enzymes were inactivated at 80℃ for 15 min. The cyclic sequencing consisted of BigDye 3.1 terminator (Applied Biosystems) according to the manufacturer's instructions with a total volume of 10 μL. Sequencing reaction was as follows: at 96℃ for 1 min, then 25 cycles at 96℃ for 10 s, at 55℃ for 5 s and at 60℃ for 4 min. To remove unincorporated nucleotides, sequencing reaction products were purified by Millipore Multiscreen plates (Millipore, USA) with Sephadex G-50 superfine sepharose (Amersham Biosciences, Sweden). The sequenced products were at first electrophoresed on an ABI 3730 DNA analyzer (Applied Biosystems) and then Sequencing Analysis 5.2 software (Applied Biosystems) was used for base calling. The obtained sequence was analyzed by Sequencher 4.1.4 software (Gene Codes, USA).

| 8 and more | 1 (1) | 12 (8) | 8 (9) | 21 (7) | |
| Symptoms from milk | 17 (22) | 7 (5) | 5 (6) | 29 (9) | [b]$P < 0.001$ |

[a]$P < 0.05$ *vs* C/T-13910 and T/T-13910 in drinking milk; [b]$P < 0.001$ *vs* those without milk intolerance.

## RESULTS

The genotype was obtained from 355 subjects. According to their ethnic origin there were 314 Estonians (at least three grandparents being reported to be Estonians) and 41 other nationalities or mixed marriages (mostly Russians, Finns, but also Ukrainians, Swedes, Germans, Polish). In the final frequency analysis, the samples of the abovementioned 314 subjects were included. The frequencies of different C/T-13910 genotypes are presented in Table 1.

We found only two other single nucleotide mutations upstream of the C/T-13910 variant. One was C/T-variant (rs4988233), 101bp upstream of the C/T-13910 variant that was found in four subjects. The other was G/T variant 26bp upstream of the C/T-13910 variant that was found only in one subject. We did not find any polymorphisms downstream of the C/T-13910 variant.

Milk consumption and self-reported milk intolerance in the Estonian adult population with different genotypes are presented in Table 2. The subjects with the C/C-13910 genotype of adult-type hypolactasia drank less milk and reported more often milk intolerance as compared with those with the C/T-13910 or the T/T-13910 genotype.

## DISCUSSION

We found that the frequency of adult-type hypolactasia was 24.8% in Estonia. This confirmed the results of the previous studies based on indirect methods of determining hypolactasia, according to which the frequency of hypolactasia varies from 23% to 32%[1]. Our results may be more accurate because of the direct genotyping used for diagnosis in comparison with previously used lactose tolerance tests[16].

The prevalence of adult-type hypolactasia in Europe increases from west to east and from north to south, and is the lowest in Northern Europe[1]. The frequency of 25% is in agreement with this pattern. We have previously shown that the prevalence of the C/C-13910 genotype is 10% in Sweden and 18% in Finland[6,17].

The binding sites of transcription factors usually extend 100-200 bp. In the present study, we found only few other single nucleotide mutations adjacent to the C/T-13910 variant, indicating that the C/T-13910 variant is the only SNP in Estonian population affecting the binding of transcription factor at this binding site, thus confirming the previous findings that this SNP is the only SNP that affects transcription of the LCT gene in all studied populations.

As expected, we found that the consumption of milk was lower in lactase non-persistent subjects than in lactase persistent subjects, suggesting that lactase non-persistence does not prevent the intake of milk. Indeed, only 2/3 of subjects with lactase non-persistence get symptoms after consuming milk and most of the malabsorbers can consume couple of glasses of milk per day, especially during meals[3,21]. This may explain the fairly high rate of milk consumers among genotype CC-13910. Our results concerning milk consumption of CC-13910 genotype subjects are consistent with previously reported results[22,23]. Still, some individuals with hypolactasia may have severe abdominal complaints after milk consumption and it is of utmost importance to diagnose hypolactasia and give recommendations to restrict their fresh milk intake. The restriction of milk consumption is not indicated for those with hypolactasia but without any symptoms after drinking milk.

## ACKNOWLEDGMENTS

We thank Dr. Tiina Vilimaa and Dr. Mall Lepiksoo for their help in organizing the study in Väike-Maarja.

## Abstract

**AIM:** To evaluate the role of azathioprine (AZA) in Indian patients with ulcerative colitis over longer duration of time.

**METHODS:** One hundred fifty six patients with ulcerative colitis who were treated with AZA from January 1995 to December 2003 were reviewed. The indications for its use were as follows: (1) steroid dependent and steroid refractory disease; (2) Azathioprine monotherapy for naïve patients with severe disease; and (3) combination therapy (AZA + sulfasalazine or 5-aminosalicylates) for naïve patients with severe disease. The data included patient and disease demographics, efficacy and toxicity profile of AZA. Patients with a minimum duration of 6 mo use of AZA were included in this report.

**RESULTS:** Of a total of 156 patients treated with AZA, 45 were excluded from analysis for the following reasons- (follow up less than 6 mo, *n* = 9; poor follow up, *n* = 18; adverse affects, *n* = 18). In steroid refractory/dependent group the mean number of relapses prior to and post initiation of AZA therapy were 3.28 (± 0.81) and 0.94 (± 0.29) respectively. Discontinuation of steroids could be accomplished in 12 of the 15 steroid dependent patients. The proportion of patients with sustained remission of 1, 2, 3, 4 and 5 years duration were calculated. Eighteen patients experienced adverse effects necessitating withdrawal of AZA (pancreatitis, *n* = 7; hepatitis, *n* = 3; gastrointestinal intolerance, *n* = 2; alopecia, *n* = 2; and hematological, *n* = 4) while 13 patients needed dose reduction or temporary withdrawal of the drug.

**CONCLUSION:** Azathioprine is well tolerated and has therapeutic benefits lasting as long as 4 years. Adverse effects such as pancreatitis, hepatitis, cytopenias and gastrointestinal symptoms do occur but are controlled by drug withdrawal only.

**Key words:** Ulcerative colitis; Azathioprine; Immunosuppressive

Sood A, Midha V, Sood N, Bansal M. Long term results of use of azathioprine in patients with ulcerative colitis in India. *World J Gastroenterol* 2006; 12(45): 7332-7336

## INTRODUCTION

Immunosuppressive drugs were initially used clinically in the treatment of leukemias and solid organ transplantation. Over time, it was learned that these drugs were capable of long term modulation of the immune system in transplant recipients, a fact that was later extrapolated to change the course of many chronic diseases with presumed immune etiopathogenesis[1]. Based on the results of many controlled studies immunosuppressive drugs have obtained an obvious place in the medical armamentarium of ulcerative colitis in which there is growing evidence of dysregulation of the mucosal immune system[2].

Out of the various immunosuppressive drugs, the purine analogues, azathioprine (AZA) and 6-mercaptopurine (6-MP) have been most extensively used and are now considered as the first line of immunosuppressive agents for the maintenance of remission in patients with ulcerative colitis. Bowen and colleagues in 1966, first gave an encouraging report on the use of AZA in ulcerative colitis, which was followed by a number of uncontrolled observations in a series of patients. Finally, controlled double blind studies were done comparing AZA with placebo and other drugs[3-11]. These studies leave little doubt about the usefulness of AZA as a steroid sparing agent for maintenance of remission in chronic active disease. Its role in severe ulcerative colitis has been documented by our group earlier[11]. However, despite impressive data from clinical trials supporting the use of AZA, many clinicians may still be reluctant to use it

because of fear of drug toxicity in the long term. Often, patients are put on this drug either too late in the course of the disease, i.e. after multiple courses of steroids or not started at all even when unable to taper steroids after many months. Recently, some studies tried to evaluate the long-term benefit and tolerability of AZA in patients with inflammatory bowel disease (IBD)[12-16]. However, the optimal duration of AZA, 6-MP therapy is unclear and has not been studied in ulcerative colitis. We report results of our experience with AZA in patients with ulcerative colitis with particular attention to clinical response and adverse events and this is probably the first such study from India.

## MATERIALS AND METHODS

### Patients and methods

The analysis included 156 patients with ulcerative colitis who were treated with AZA from January 1995 to December 2003. Some of these patients have been the subjects of our previously published reports. The indications for AZA included (1) steroid dependent/steroid refractory disease and frequent relapses, (2) AZA monotherapy in naïve patients with severe disease and (3) combination therapy [AZA + sulfasalazine or 5-aminosalicylates (5-ASA)] in naive patients with severe disease. Steroid-dependence was defined as a requirement for corticosteroids at a prednisolone-equivalent dose of more than 10 mg/d on an average for at least 6 mos to control disease activity after failure of at least one attempt to withdraw corticosteroids. Steroid-resistance was defined as evidence of persistent active IBD despite 6 wk treatment with corticosteroids at a dose $\geqslant$ 30 mg/d during the 6 preceding months. Each patient had been regularly examined as an outpatient and a record had been maintained detailing drug tolerability, course of the disease and side effects, if any. Reasons for modifying the dose or stopping the drug have been recorded. Patients had been continuing other conventional drugs like SLZ or 5-ASA derivatives (oral and/or enema preparations). Each relapse had been diagnosed with routine stool and sigmoidoscopic examination showing evidence of active colitis and had been treated with steroids. Patients with a minimum of 6 mo of AZA treatment were eligible for inclusion in the study. Patients with no follow-up for 1 year were taken as lost to follow-up.

Medical information collected included the following: (1) patient characteristics such as age, gender, age at diagnosis, personal habits such as smoking, family history of IBD and extent of disease etc.; (2) Disease activity assessed at each visit; remission being defined as absence of symptoms of active disease as rectal bleeding and normal bowel frequency and hence no need for steroids for at least 6 mo. Relapse was defined as presence of blood and mucus in stools, increased bowel frequency, active colitis on sigmoidoscopy and need for reintroduction of steroids or the need for colectomy. (3) AZA related data including age at initiation, duration of disease prior to AZA initiation, indication of its use and drug adverse effects which included fever, gastrointestinal intolerance (recurrent nausea, vomiting), pancreatitis, hepatitis, infectious complications, hematological abnormalities and malignancies. Laboratory test results were reviewed for evidence of hepatic dysfunction based on increase in alanine aminotransferase (more than two times upper limit of normal), leukopenia (less than 2500/cumm) and thrombocytopenia (< 1 lac/cumm).

**Table 1 Baseline characteristics of the patients at initiation of azathioprine treatment**

| Characteristic | |
|---|---|
| Age (yr) (mean ± SD) | 34 (34.76 ± 11.70) |
| Sex (M/F) | 56/55 |
| Disease duration (yr) (range) | 0-7.3 |
| Disease extent *n* (%) | |
| Pancolitis | 51 (45.9) |
| Proctosigmoiditis | 29 (26.2) |
| Left sided | 31 (27.9) |
| Indication of use *n* (%) | |
| Steroid dependent/refractory | 54 (48.65) |
| Azathioprine monotherapy for naïve severe disease | 16 (14.41) |
| Combination therapy for naive severe disease | 41 (36.94) |

Recommendations for laboratory monitoring included complete hemogram, alanine aminotransferase at 2, 4 and 8 wk after initiation of treatment and then every 3 mo thereafter. In some cases, noncompliance, had resulted in blood tests being performed at 4-8 mo intervals. When investigation abnormalities were found, the dose reduction or discontinuation was done depending upon the values and the side effects reported.

### Statistical analysis

Data was analyzed as mean, median and range as suitable. Where appropriate, the median values (not the mean) were used to represent the data most accurately, given the limited sample size and survival curve analysis. A paired students t-test and standard deviation were used to compare the pre and post AZA change in the corticosteroid dose. The threshold of significance was set at 0.05. The probabilities of relapse were calculated using life table analysis. The effect of various variables on time to relapse was explored by Kaplan-Meier survival curves and compared using log rank test. Non-parametric Mann-Whitney test was used for comparing the mean relapse rate per year for the neutropenic and non-neutropenic group. The study was approved by the Hospital Drug Trial Ethical Committee.

## RESULTS

A total of 156 patients treated with AZA for ulcerative colitis were enrolled. Forty-five patients were excluded from analysis because of either of the following reasons: (a) follow up period of less than 6 mo, $n$ = 9; (b) poor compliance, $n$ = 18; (c) adverse effects, $n$ = 18. The study sample, thus, had 111 patients; 56 were males. The Median age of the patients was 34 years (range 11-73). The disease was pancolonic in 40%, left sided in 32% and proctosigmoiditis in 28%. The characteristics of the study patients are summarized in Table 1. The mean follow up

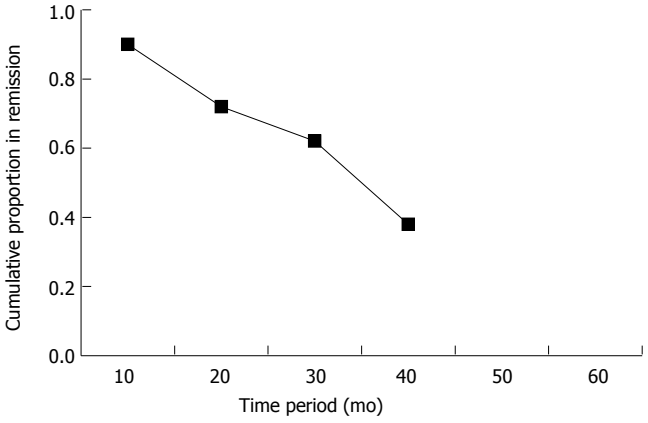

**Figure 1** Cumulative proportion of patients with ulcerative colitis in remission with azathioprine

period of patients on AZA was 18.70 ± 13.78 mo with a range of 6-73 mo.

In the steroid refractory steroid dependent and frequent relapsers group, the mean numbers of relapses prior and post initiation of AZA therapy were 3.28 (± 0.81) and 0.94 (± 0.29) respectively ($P < 0.01$). Discontinuation of steroids could be accomplished in 12 of the 15 patients who were on steroids for long time; in 1 patient the dose was decreased to half while the other two patients did not improve and underwent proctocolectomy.

Our analysis revealed that the proportion of patients in remission at 12, 24, 36, 48 and 60 mo were 0.91, 0.88, 0.76, 0.53 and 0.38 respectively. Life table analysis in our study showed that maintenance AZA treatment is effective for at least until 42 mo of treatment. Figure 1. As the number of patients on AZA beyond 42 mo is small we cannot comment on the efficacy beyond 42 mo. Various parameters, namely age, gender, disease activity at onset, extent of disease and indication of treatment were evaluated for predicting response by Kaplan Meier survival analysis. None of the above mentioned factors emerged as predictors of maintenance of remission. Thirteen patients became neutropenic (i.e. neutrophil count $\leqslant 2.5 \times 10^9$) while taking AZA. The mean number of yearly relapses for the neutropenic group was 0.2023 (± 0.3930) as compared to 0.1742 (± 0.3886) for the non-neutropenic group; the difference not being statistically significant ($P > 0.59$).

All patients necessitating drug withdrawal had experienced side effects within 6 mos of initial therapy. Hematological toxicity requiring drug withdrawal was seen in 4 patients; 3 had bicytopenia, 1 had thrombocytopenia. Dose reduction was required in 5 patients for bicytopenia and 5 for leukopenia. Persistent upper respiratory tract infection in 2 patients and pneumonia in 1 resulted in temporary discontinuation of the drug. Five patients had to undergo surgery, the indications being, unsatisfactory response resulting in chronic active disease, $n = 2$; malignancy, $n = 1$ and fulminant colitis, $n = 2$. The reasons for cessation of therapy included acute pancreatitis, $n = 7$; alanine aminotransferase, hepatotoxicity, in 3 gastrointestinal intolerance such as nausea, recurrent vomiting in 2 patients and alopecia in 2 patients.

## DISCUSSION

Ulcerative colitis treatment has undergone a significant change in the last 20 years. In particular, the use of immunomodulatory drugs like AZA and 6-MP has become widespread, as increasing familiarity and clinical trials have led to a clearer understanding of their benefits and potential risks. The results of our analysis show that AZA is efficacious and well tolerated in most patients with ulcerative colitis. Although ours is an analysis of results of all patients where AZA was used without randomization, it perhaps provides the 'best available' and the 'only' evidence of its use from our country to date. The scarcity of data on its use from our country is possibly related to fear of drug toxicity as AZA has been commonly viewed as a 'cancer drug' with high incidence of bone marrow toxicity, increased predisposition to infections, teratogenicity and malignancies, especially myeloproliferative disorders. However, it needs to be realized that this perception is derived in part from the side effect profile when the drug was originally used in preventing transplant rejection and in treatment of leukemia where significantly higher dosages were used.

Our analysis revealed that AZA is well tolerated as only 16.22% (18/111) experienced side effects requiring discontinuation of the drug. This frequency is comparable to the previously reported rate of approximately 15%. Pancreatitis, hepatitis, alopecia and gastrointestinal intolerance were the reasons for drug withdrawal. Nevertheless, all these adverse effects responded promptly to just drug withdrawal. Infections occurred in 3 cases resulting in temporary withdrawal of the drug; no patient died due to severe sepsis. In a large series by Connell *et al*[16] asymptomatic leukopenia was reported in 5% of patients and associated infections in only 1% patients with severe leukopenia. Fear of neoplasia, both intestinal and extraintestinal, has been cited as a major barrier for physicians choosing to use this drug in IBD[17,18]. We did come across one patient with rectal carcinoma who had been on AZA for 17 mo. However, an important confounding factor in the evaluation of the drugs oncogenic potential was the predisposition towards spontaneous neoplasm in ulcerative colitis. This patient had disease duration of 7 years and finally underwent surgery.

The spectrum of adverse events associated with AZA provides the most cogent argument for optimizing and individualizing drug dosing by determination of TPMT activity (phenotype or genotype) prior to initiation of therapy[19]. However, the validity of this recommendation still remains a debated topic. Nevertheless, careful regular clinical follow-up and monitoring of laboratory tests are fundamental to prevent and control adverse effects.

The effectiveness of AZA has been demonstrated by both uncontrolled and controlled trials in patients with ulcerative colitis. Our data corroborates previous clinical studies suggesting efficacy of AZA in maintenance of remission in steroid dependent and steroid refractory cases. Discontinuation of the steroids could be accomplished in 12 of the 15 patients who were taking low

doses of steroids as a maintenance dose; in one patient steroid requirement decreased and two patients who did not respond underwent proctocolectomy. There was a significant decline in the mean number of relapses pre and post initiation of AZA therapy. The most convincing controlled trial to date evaluating the maintenance benefits of AZA showed a 12 mo relapse rate of 36% for patients on AZA versus 59% for patients randomized to placebo. In a metaanalysis, AZA was found to be useful for maintenance of remission in ulcerative colitis, the pooled odd's ratio (OR) being 2.26 (95% CI: 1.27-4.01). The number needed to treat (NNT) to prevent one recurrence was 6 patients. For induction of remission, the pooled OR of the response to AZA therapy compared with placebo in active ulcerative colitis was 1.45 (95% CI: 0.68-3.08)[20]. In all these trials most patients were maintained on additional aminosalicylate therapy. However, the role of concurrent use of 5-ASA in patients effectively maintained on AZA has been questioned[21]. We reported earlier the role of AZA as monotherapy versus sulfasalazine monotherapy in the maintenance of disease remission. Although relapse rates were comparable in both groups, a trend towards earlier treatment failure was seen in patients on AZA monotherapy[22]. We have tried to shift the paradigm from 'step up' approach to combination therapy in naïve patients with severe ulcerative colitis[11]. Unfortunately the published experience with combination therapy in naïve patients is not large but we expect future studies to comment on this. It might be intuitive that early use of AZA may reset the immunostat of the body and influence the course of the disease. The results of our earlier study have demonstrated a trend in favor of combination therapy in preventing relapses but more information needs to be accrued over a longer follow-up. Life table analysis in our present study shows that AZA treatment is effective for as long as 42 mo of treatment. Although there is a gradual but variable decline in the proportion of patients who remained relapse free over the follow-up time period, it does not suggest that the effectiveness 'wears out' after this period. However, a recent retrospective study has suggested that the efficacy of AZA declines with time in patients with ulcerative colitis[20].

Over the past few years, great interest has surfaced in the potential therapeutic levels of leukopenia and neutropenia in achieving remission. Anecdotal reports have suggested that these may now be desirable end points of AZA therapy[23,24]. However, the cumulative remission percent determined by Kaplan Meier survival analysis showed no difference between neutropenic and non-neutropenic groups by log rank analysis in our study, suggesting that AZA dose titration to achieve neutropenia is not necessary for optimizing the dose.

Although a large array of therapeutic options exists, we have analyzed the therapeutic effects and toxicity of this not very new drug among patients with ulcerative colitis in the Indian population. We are of the opinion that the data is suggestive of the effectiveness of AZA in maintenance of remission and the drug, if indicated, should not be withheld for fear of toxicity.

## Abstract

**AIM:** To study the safety and efficacy of hepatitis A vaccine (HAV) in children with chronic liver disease of various etiologies.

**METHODS:** Eleven children with chronic liver disease and thirteen age- and sex-matched controls negative for HAV antibodies were vaccinated against hepatitis A after they gave their informed consent. Children with uncontrolled coagulopathy or signs of hepatic decompensation were excluded. The vaccine (Havrix: 720 ELISA units in 0.5 mL, from GlaxoSmithKline Biologicals) was given intramuscularly in the deltoid in 2 doses 6 mo apart. Children were tested for HAV antibodies one and six months after the 1st dose and one month after the 2nd dose. Total serum bilirubin, alanine aminotransferase (ALT), and aspartate aminotransferase (AST) were determined immediately before and after one month of the 1st dose of the vaccine.

**RESULTS:** Only 7 out of the 11 patients were positive for HAV antibodies after the 1st dose of the vaccine, as compared to 100% of the controls. One month after the 2nd dose, all patients tested were positive for HAV antibodies. No deterioration in liver functions of patients was noted after vaccination. No adverse events, immediate or late, were reported by the mothers after each dose of the vaccine.

**CONCLUSION:** Hepatitis A vaccine is both safe and effective in this small studied group of children with chronic liver disease. Given the high seroconversion rate, post-vaccination testing for HAV antibodies is not needed.

**Key words:** Children; Chronic liver disease; Hepatitis A; Hepatitis A vaccine

## INTRODUCTION

Hepatitis A virus (HAV) infection is common. In general, hepatitis A is a self-limited illness with a recovery time measured in months[1]. Young children are often asymptomatic, whereas adults are more likely to be symptomatic and may present with jaundice. Although most patients have a relatively quick recovery without long-term sequelae, about 15% may have a prolonged cholestatic syndrome or a relapsing course over 6-9 mo. A smaller subset will progress to fulminant hepatic failure and death or transplantation, with estimated case fatality rates ranging from 0.01%-0.03% to 0.2% of cases among hospitalized patients[2,3]. Two major risk factors have been identified in patients who developed fulminant hepatic failure: age over 40 years and the presence of underlying chronic liver disease (CLD)[2-4].

Apart from the growing evidence that acute hepatitis A has a more severe clinical course and a higher death rate in individuals with chronic hepatitis B[4-6], and that there is an increased risk of fulminant hepatitis A in patients with chronic hepatitis C[7], patients with other chronic liver diseases also appear to be at an increased risk of developing more severe disease[4,5,8,9].

As the pool of patients with CLD grows, and acute viral hepatitis continues to occur with only a slightly reduced incidence, it is inevitable that a greater number of individuals with CLD will be at risk of developing superimposed acute and chronic hepatitis[1]. To minimize the occurrence of acute hepatitis in patients with CLD, a variety of organizations have recommended hepatitis A and B vaccination in these patients[10,11].

Given the growing evidence that hepatitis A super-infection is probably worse in at least some and probably most patients with CLD, vaccination seems reasonable.

In evaluating HAV vaccination in patients with CLD, an effective strategy should include choice of vaccines, in addition to issues related to safety and efficacy of the vaccine[1].

The issue of pre-vaccination screening for hepatitis A in children with chronic liver disease has been discussed in details in a previous report[12]. The aim of the present study was to evaluate the safety and efficacy of hepatitis A vaccine (Havrix, GlaxoSmithKline Biologicals) in a group of Egyptian children suffering from CLD of various etiologies.

## MATERIALS AND METHODS

### Patients

We included 172 children: 101 children having CLD and 71 healthy age- and sex- matched brothers, sisters and contacts of the patients as a control group. Their age ranged between 2 and 18 years, with a mean of 7.8 ± 4 years. Parental consent was obtained for medical examination, venepuncture and vaccination. The etiological diagnoses of the 101 children with CLD included autoimmune hepatitis (14 children, 14%), cholestatic disorders of infancy (16 children, 16%), hepatitis B virus (HBV) infection (4 children, 4%) and hepatitis C virus (HCV) infection (9 children, 9%). The remaining 58 children (57%) had miscellaneous causes for their CLD.

Inclusion criteria of children with CLD were willingness to participate in the study, any CLD regardless of etiology, no previous history of vaccination against hepatitis A, children of both sexes. Exclusion criteria were children with uncontrolled coagulopathy, children with decompensated liver disease (hepatic coma, massive ascites, frequent bleeders from esophageal varices, repeated spontaneous bacterial peritonitis), children with known immunological deficiency, and infants below 2 years of age (those who will not be vaccinated).

All children were tested for anti-HAV antibodies by a competitive enzyme immunoassay (ELISA) using commercially available kits (Dia. Pro. Diagnostic Bioprobes Srl., Milano, Italy).

The test results were calculated by means of a cut-off value determined by the following formula: Cut-off = (NC + PC)/3 (NC: negative control; PC: positive control), and interpreted as a ratio of cut-off value and optical density ($A_{450\ nm}$) of the sample (or Co/S) (Table 1).

Out of the 101 children with CLD, only 15 cases were negative for hepatitis A (15%) and 11 consented to be vaccinated. Among the controls, only 16 were negative for hepatitis A (22.5%) and 13 consented to receive the vaccine. Among the 11 cases, 4 were diagnosed as cholestatic disorder of infancy, 3 as HCV infection, 2 as glycogen storage disease, 1 as HBV infection and 1 as Wilson's disease.

Two doses of the vaccine (Havrix: 720 ELISA units in 0.5 mL, from GlaxoSmithKline Biologicals) given intramuscularly in the deltoid 6 mo apart. The mothers were asked to report any immediate or late reactions after the vaccine was given.

Total serum bilirubin, alanine aminotransferase (ALT), and aspartate aminotransferase (AST) were determined immediately before and one month after the 1st dose of the vaccine. Testing for anti-HAV antibodies was done at 3 occasions: one and six months after the 1st dose of the vaccine and one month after the 2nd dose of the vaccine.

**Table 1 Ratio of cut-off value and optical density ($A_{450\ nm}$) of the sample (or Co/S)**

| Co/S | Interpretation |

HA: Hepatitis A.

### Statistical analysis

All patients' data were collected, tabulated and processed using SPSS 12.0 for Windows XP. Categorical variables were compared using Fischer's exact test. Continuous data were expressed as mean ± SD, range and median if appropriate. Repeated measures for HAV IgG were followed in the same group using Freidman test. These variables were compared in both cases and controls by analysis of variance of repeated measures using the general linear model. Paired variables before and after the vaccine was given were compared using Wilcoxon-Signed Rank test, while unpaired data were compared by Mann-Whitney $U$ test. In all tests, $P < 0.05$ was considered statistically significant.

## RESULTS

Testing for HAV antibodies in children with CLD, revealed that only 7 out of the 11 children with CLD were positive for HAV antibodies while 100% of the controls were positive for HAV antibodies one and six months after the 1st dose of the vaccine ($P$ = 0.07 and 0.09 respectively) (Table 2). However, all the children with CLD were positive for HAV antibodies one month after the second dose (booster).

**Table 3 Comparison of the mean value of seroconversion (Co/S) between patients and controls**

| Time | Patients ($n$ = 11) | | Controls ($n$ = 13) | |
|---|---|---|---|---|
| | Range | Mean ± SD | Range | Mean ± SD |
| 1 mo after the 1st dose of HA vaccine | 0.6-1.6 | 1.1 ± 0.4 | 1.5-3.6 | 2.5 ± 0.97 |
| 6 mo after the 1st dose of HA vaccine | 0.9-4.8 | 3 ± 1.3 | 2.3-6.9 | 4.7 ± 1.8 |
| 1 mo after the 2nd (booster) dose of HA vaccine | 3.2-5.3 | 4.6 ± 0.8 | 4.2-5.7 | 4.9 ± 0.7 |
| $P$ | [b]$P$ = 0.003 | | [a]$P$ = 0.02 | |

[a]$P$ = 0.02 within controls by Friedman test; [b]$P$ = 0.003 within patients by Friedman test.

**Table 4 Comparison of liver function tests before and after vaccination**

| | Before vaccination | | After vaccination | | $P$ |
|---|---|---|---|---|---|
| | Range | Median | Range | Median | |
| Patients | | | | | |
| Total Serum Bilirubin (mg/L) | 4-210 | 7 | 3-250 | 7.5 | 9.5 |
| ALT (IU/L) | 19-163 | 42 | 19-136 | 27.5 | 0.11 |
| AST (IU/L) | 28-299 | 38 | 30-288 | 43 | 0.07 |
| Controls | | | | | |
| Total Serum Bilirubin (mg/L) | 3-6 | 5 | 1-6 | 4 | 4.8 |
| ALT (IU/L) | 9-21 | 18 | 10-27 | 17 | 0.93 |
| AST (IU/L) | 21-39 | 27 | 21-57 | 31 | 0.01[b] |

[b]$P$ < 0.01 *vs* controls before and after vaccination (Wilcoxon Signed Ranks Test). ALT: alanine aminotransferase; AST: aspartate aminotransferase.

According to the interpretation of results in Table 1, a significant rise in HAV antibodies (Co/S) was noted both in the children with CLD and in the controls over the 3 readings ($P$ = 0.003 and 0.02 respectively) (Table 3).

No changes in liver function were noted after vaccination except for an insignificant rise in AST of the children with CLD ($P$ = 0.07) and a significant rise in AST of the controls ($P$ = 0.01), although which was within the normal AST range. No adverse events, immediate or late, were reported by the mothers after each dose of the vaccine (Table 4).

Comparison of the difference in liver functions before and after vaccination revealed a significant decrease in ALT of the children with CLD after vaccination as compared to the controls (Table 5).

**Table 5 Comparison of differences in liver functions before and after vaccination between patients and controls (mean ± SD)**

| | Bilirubin (mg/L) | ALT (IU/L) | AST (IU/L) |
|---|---|---|---|
| Patients | 0.8 ± 17 | -11.3 ± 26 | 14.8 ± 23.8 |
| Controls | -0.18 ± 0.9 | 0.54 ± 7.3 | 5.1 ± 6.8 |
| $P$ | 0.92 | 0.03[a] | 0.58 |

[a]$P$ < 0.05 *vs* controls before and after vaccination (Mann-Whitney $U$ test). ALT: alanine aminotransferase; AST: aspartate aminotransferase.

## DISCUSSION

HAV vaccine is currently recommended for three groups: communities with endemic HAV infection (> 20/100 000), individuals at an increased risk of HAV exposure, and individuals with an increased risk of developing severe disease[11]. Patients with CLD are considered to be at risk of developing severe disease, and also at an increased risk of HAV exposure. Patients with serological evidence of previous hepatitis A are considered to have probable lifelong immunity. As such, the seroprevalence of HAV markers plays a central role in determining a vaccination strategy[1]. To determine the need of our children with CLD for hepatitis A vaccination, pre-vaccination screening for HAV antibodies was carried out and vaccination was planned for those negative for HAV antibodies. Because of the high seroprevalence of HAV antibodies among our patients and controls, it seems cost-effective to pretest those above 5 years of age, while pre-vaccination screening would be cost-ineffective in those below 5 years of age[12]. In general, targeted vaccination strategies have been found to be the most cost-effective[13]. Even at the lowest estimated anti-HAV be seroprevalenced rates, selective or deferred vaccination is the most cost-effective strategy in patients with CLD, if the recommended HAV vaccination schedule is to be used[14]. The prevalence of anti-HAV must decrease to below 12% before universal vaccination becomes a more cost-effective strategy[1].

Among our studied children with CLD and controls, no immediate or late adverse effects after vaccination were noticed by the mothers. Liver functions were assessed immediately before and one month after the 1st dose of the vaccine. No significant changes were noted in the children with CLD apart from a significant decrease in ALT as assessed by comparing the mean difference (Table 5). Patients with CLD can receive HAV vaccination with little worry about the vaccine-related adverse effects. Since 1980s, hepatitis A vaccine has been studied extensively in individuals of all ages, and has been known to be safe[15-18]. No significant adverse events have been found to be associated with the use of hepatitis A vaccine in patients with CLD[19].

Only 7 out of 11 children with CLD were positive for HAV antibodies while 100% of the controls were positive for HAV antibodies one and six months after the 1st dose of the vaccine. However, one month after the booster dose all the children with CLD (100%) were positive for HAV antibodies. A rise in antibody level as calculated by Co/S was noted in both the children with CLD and the controls over the 3 readings. Similar seroconversion rates have been reported in children with chronic hepatitis B and C[20] and other chronic liver diseases[18]. A booster dose could induce seroprotection in all children[20]. Keeffe and co-workers[19] reported that the mean geometric titer of anti-HAV is significantly lower in patients with CLD than in healthy controls. However, seroconversion to an immune state has been found in approximately 95% of patients with CLD and 98% of healthy controls (seronegative patients can achieve anti-HAV titers of ⩾ 30 kIU/L as

previously defined). A smaller trial in Chinese patients also noted that the seroconversion rates are similar in 65 chronic HBV infection patients given HAV vaccine and healthy controls, although the anti-HAV titer is lower in patients with CLD[21]. Seroconversion in all patients after the 1st dose of the vaccine has been reported by Giacchino *et al*[22] in a group of children with a variety of metabolic liver diseases.

Although studies have demonstrated the immu-nogenicity of HAV vaccine in mild and moderate CLD, the efficacy of HAV vaccines in advanced or decompensated liver disease has not been thoroughly investigated. Smallwood *et al*[23] found that seroconversion can be achieved in only 48.6% of patients with end-stage liver disease awaiting liver transplantation following a normal HAV vaccination schedule. Patients with end-stage liver disease with uncontrolled coagulopathy and signs of hepatic decompensation were not included in our study.

In conclusion, hepatitis A vaccine is indicated for patients with CLD who are negative for HAV antibodies, and should be provided as early as possible in the course of CLD, as the immunogenicity is poor in advanced liver disease and after liver transplantation. In view of the high seroconversion rate for patients with mild to moderate disease, post-vaccination testing is not needed. The vaccine is both safe and effective in children with mild to moderate liver disease.

## Abstract

**AIM:** To analyze the results of ultrasound guided percutaneous needle aspiration (PNA) and percutaneous catheter drainage (PCD) in the treatment of splenic abscess.

**METHODS:** Thirty-six patients (14 females and 22 males, with an average age of 54.1 ± 14.1 years) with splenic abscess were treated with ultrasound guided PNA and/or PCD. Patients with splenic abscess < 50 mm in diameter were initially treated by PNA and those with abscess ⩾ 50 mm and bilocular abscesses were initially treated by an 8-French catheter drainage. The clinical characteristics, underlying diseases, organism spectra, therapeutic methods, and mortality rates were analyzed.

**RESULTS:** Twenty-seven patients had unilocular and 9 bilocular abscess. PNA was performed in 19 patients (52.8%), and 8 of them (42.1%) required PCD because of recurrence of abscess. In 17 patients (47.2%), PCD was performed initially. PCD was performed twice in six patients and three times in two. PNA was definitive treatment for 10 and PCD for 21 patients. One patient with PCD was referred for splenectomy, with successful outcome. In all 4 deceased patients, malignancy was the underlying condition. Twenty-one patients (58.3%) underwent 33 surgical interventions on abdomen before treatment. Cultures were positive in 30 patients (83.3%). Gram-negative bacillus predominated (46.7%). There were no complications related to the procedure.

**CONCLUSION:** Percutaneous treatmnet of splenic abscess is an effective alternative to surgery, allowing preservation of the spleen. This treatment is especially indicative for the patients in critical condition postoperatively. We recommend PNA as primary treatment for splenic abscesses < 50 mm, and PCD for those ⩾ 50 mm in diameter and for bilocular abscesses.

**Key words:** Interventional ultrasound; Needle aspiration; Catheter drainage; Spleen preservation

## INTRODUCTION

Splenic abscess is an uncommon entity with a reported frequency in autopsy series between 0.14% and 0.7%, and with high mortality rates because of delayed detection and treatment[1-3]. It often presents with either vague or nonspecific signs, thus making clinical diagnosis difficult. Current imaging modalities allow early diagnosis. Furthermore, splenic abscess often occurs in the patients with underlying diseases[1,4-6].

Many surgeons report that splenectomy is the best way for treatment of splenic abscess[2,4,6,7]. Although antibiotics and splenectomy are traditionally considered the treatment of choice, there is wide acceptance of important immunologic support of the spleen[8-10]. Recently, spleen-preserving management using medical treatment and percutaneous imaging-guided drainage were proved to be efficient methods for the treatment of splenic abscess[8-13]. Our study was undertaken to determine the current role of percutaneous ultrasound guided treatment of splenic abscesses as an alternative to surgery, with intention to analyze the role of needle aspiration and continous catheter drainage especially in patients in critical condition postoperatively.

## MATERIALS AND METHODS

### Subjects

From January 1, 1999 to December 31, 2004, all consecutive patients who were admitted to our hospital and subjected to percutaneous treatment of splenic abscess, were included in this study. All patients gave written informed consent. This study was approved by the local ethics committee.

### *Diagnosis and treatment*

The diagnosis of splenic abscess was made on the basis of clinical and imaging findings with ultrasound or computed tomography. Splenic abscess was defined as an intrasplenic pus collection. Case definition required patients to have one or more defects on spleen ultrasound examination or computed tomography along with the identification of pus. The demographic, clinical, and laboratory characteristics, underlying diseases, organism spectra, abscess number and size, and mortality rates were analyzed.

The size of abscess was recorded as the largest diameter in either solitary or bilocular abscess. The decision to select the method for percutaneous treatment between percutaneous needle aspiration (PNA) or percutaneous catheter drainage (PCD) was made on the basis of the longest diameter of abscess and number of abscesses. The patients with splenic abscess shorter than 50 mm in maximal diameter were initially treated with PNA. The reason for this is that the end of an 8-French pigtail catheter is a ring with 25 mm diameter and its insertion in a cavity shorter than its double length (50 mm in its longest diameter) would be difficult. In the case of the recurrence of abscess collection, an 8-French catheter for continous drainage was introduced. Patients with splenic abscess equal or greater than 50 mm in diameter were initially treated with PCD. All bilocular splenic abscess were treated with catheter regardless of the maximal diameter of the abscess. All surviving patients were followed up clinically for six months after percutaneous treatment. Patients' response to treatment in terms of clinical symptoms and laboratory test results were monitored. The criteria for successful treatment were if the infection had subsided clinically and if there had been sonographic evidence of abscess resolution (Figure 1). Patients were followed up in the out-patient clinic biweekly after they discharged from the hospital. Clinical examination, white blood cell count and neutrophillia, CRP and abdominal ultrasonography were performed at each follow-up visit.

**Antibiotics policy:** At present, all patients were treated with intravenous ampicillin 500 mg qid, cefuroxime 750 mg tid, and metronidazole 500 mg tid. The antibiotics were adjusted according to the results of the culture and sensitivity test of pus aspirated at the time of the drainage procedure. Antibiotics adjustment was done immediately when the sensitivity test was available. Patients with negative culture results were continuously treated with combination of ampicillin, cefuroxime, and metronidasole. Intravenous antibiotics were continued for 10 d. If antibiotic therapy was changed according to the results of sensitivity test, new antibiotics were administered for 10 d. Patients were discharged earlier with a percutaneous intravenous catheter inserted for a completion of therapy if fever had subsided for at least 48 h. The patients were then put on appropriate oral antibiotics for a total treatment period of 6 wk.

**Intervention:** All percutaneous interventions were performed under ultrasound guidance with a General Electric Logiq 400 machine and 3.5 MHz curvilinear transducer (General Electric, Chicago, USA). A free-hand technique using an 18 Gauge disposable trocar needle (Boston Scientific, Boston, USA) of varying lengths (10-16 cm) was employed for puncturing of abscesses. A sample of pus was routinely taken and sent for microbiological analyses, including microscopy, culture and antibiotics sensitivity tests.

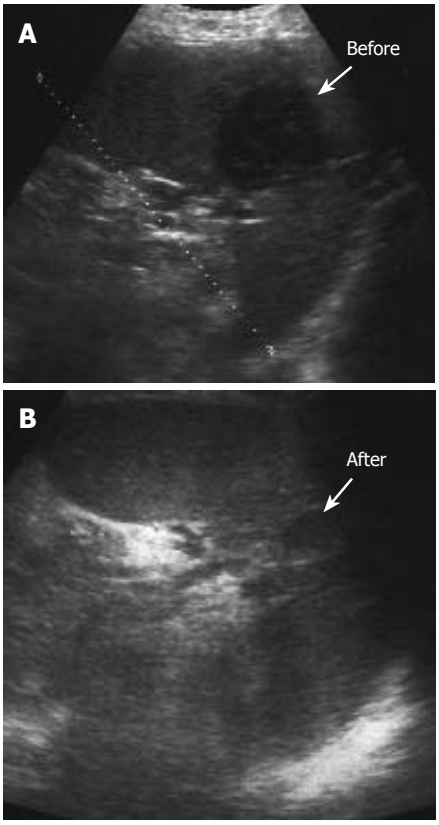

**Figure 1** Ultrasonographic appearance of splenic abscess before and after percutaneous treatment.

**Percutaneous drainage:** The applied drainage technique was the trocar method using an 8F multisidehole pigtail catheter (Boston Scientific, Boston, USA). by this method, reduction of catheter manipulations avoids damage of splenic tissues. Careful localization of the lesion and proper selection of the entry site were required. An optimal route of access must transverse the least possible amount of splenic parenchyma and avoid bowel and pleura.

Aspiration was then performed with the catheter until no more pus could be removed. The catheter was then secured to the skin for continuous external drainage and the patient was sent back to the ward. If after 24 h there was no catheter output, a follow-up sonography was performed. If the abscess cavity was absent, the catheter was removed. If a residual cavity was present, the catheter was flushed with saline and content aspirated until such time that the aspirated content is clear. Residual abscesses were treated with catheter repositioning and aspiration or introducing the new catheter. Subsequent sonography was performed three days later and the catheter was removed if the catheter remained unproductive. Otherwise, the catheter was left *in situ* until it stopped producing any content. Sonography was repeated every 3 d until the cavity either disappeared or showed significant reduction, along with clinical recovery.

**Needle aspiration:** Complete evacuation of pus from each cavity was attempted with 18G disposable trocar

**Table 1 Underlying pathology in patients with splenic abscess**

| Causes | *n* | % |
|---|---|---|
| Pancreatitis | 8 | 22 |
| Trauma | 8 | 22 |
| Stomach surgery | 8 | 22 |
| Deviscerated hydatid cyst | 2 | 6 |
| Nephrectomia | 2 | 6 |
| Liver cirrhosis | 1 | 3 |
| Spleen infarction | 1 | 3 |
| Unknown | 6 | 16 |

needle (Boston Scientific). The needle tip was inserted into the abscess for a complete pus removal. Sonography was performed every 3 d and the size of the abscess was recorded. If there was either no clinical improvement or no reduction in size of the abscess cavity, catheter for continuous drainage was introduced.

### *Statistical analysis*

Statistical analysis was done using statistical software Med Calc v. 8.0. Quantitative variables were compared using two-sample *t* test for independent samples, whereas categorical variables were analyzed by Fischer exact test. Statistical level of $P < 0.05$ was considered as significant for all performed tests.

## RESULTS

Splenic abscess was diagnosed in 41 patients during the study period. Five of them, who died within 6 wk after percutaneous treatment because of underlying diseases, were excluded. Out of the remaining 36 patients with splenic abscess, 14 were females and 22 males, with a mean (± SD) age of 54.1 ± 14.1 (range 7-69) years.

Prior to hospital admission, patients were symptomatic for a mean 16.83 ± 18.20 (range 1-72) d. The symptoms were fever in 33 patients (91.7%), left upper quadrant abdominal pain in 23 patients (63.9%), diffuse abdominal pain in 7 patients (19.4%), and shortness of breath in 6 patients (16.7%). The physical examination revealed splenomegaly in 24 patients (60%), left upper quadrant abdominal tenderness in 21 patients (58.3%), and generalized abdominal tenderness in 8 patients (22.2%). Leucocytosis over 10 000/mm$^3$ was revealed in 32 patients (88.8%), and CRP over 10 (normal up to 3.3) mg/L in 29 patients (55.6%). Among 36 patients, a potential underlying disease for splenic abscess was found in 30 (83.3%). Acute hemorrhagic necrotic pancreatitis, trauma and malignancy were the leading diseases (8 patients affected by each, covering 22.2%) (Table 1). Statistical analysis revealed that the presence of underlying disease did not correlate with the size and number of abscess, age, gender, and species of microorganism.

Frank pus was obtained from the abscesses in all 36 patients. A microbial pathogen was isolated in 30 patients (83.3%). Blood culture was positive in 11 of 30 patients (36.6%) and abscess culture in 23 of 30 patients (83.3%). All patients with both positive blood and abscess cultures had identical pathogens. The microorganisms of positive culture were predominantly gram negative (14 cases, 46.7%), with *K. pneumoniae* as the leading pathogen (20%). Gram positive microorganisms were isolated in 10 patients (33.3%). More than one organism was isolated in 16.7% of patients with positive culture (Table 2). All patients received appropriate antibiotic therapy. Twelve patients after pus culture and sensitivity test were obtained, had antibiotics changed, including imipenem ($n$ = 5), claritromycine ($n$ = 3), ciprofloksacin ($n$ = 2), and gentamycin ($n$ = 2). The mean hospital stay (± SD) was 20.1 ± 14 d. The shortest hospital stay was in the group with PNA (Table 3). The mean hospital stay (± SD) was significantly shorter ($P < 0.001$) in 19 patients of groups PNA + PNA/PCD (12.4 ± 7.7 d) than in 17 patients of PCD groups (28.7 ± 14.7 d).

The patients had either unilocular (27 cases) or bilocular (9 cases) splenic abscess. Sizes of abscess ranged from 26 to 97 mm, with a mean of 58.9 ± 8.6 mm. Size of abscess ranged from 26 to 49 mm, with a mean 40.2 ± 5.5 mm, in the PNA group and from 57 to 97 mm, with a mean 77.5 ± 11.7 mm, in the PCD group. Twenty-one patients (58.3%) underwent 33 surgical interventions on abdomen before percutaneous treatment. Six patients had two and three patients had three surgical interventions before percutaneous treatment was applied (Table 3).

Needle aspiration was performed in 19 patients (52.8%). In 10 patients, needle aspiration was a definitive and successful treatment, and one patient died 55 d after PNA and repeated surgery due to recurrence of stomach malignancy. Eight of 19 patients (42.1%) had recurrence of abscess collection and required continuous percutaneous drainage and instilled antibiotic therapy through the catheter. In 17 patients (47.2%) with abscess collection greater than 50 mm in diameter or bilocular abscess, percutaneous catheter drainage was initially performed.

Six patients with persistent abscess cavity or poor drainage underwent percutaneous catheter drainage twice

PNA: Percutaneous needle aspiration; PCD: Percutaneous catheter drainage.
[1]One patient underwent surgery after PCD.

and two patients for three times. PCD was a definitive and successful treatmnet for 21 patients, seven received it after PNA and PCD, five after two PCD and two after three PCD. One patient with percutaneous drainage was eventually referred for splenectomy, with a favorable outcome (Table 4). There was no statistically significant difference in the success of percutaneous treatment between unilocular and bilocular splenic abscesses ($P > 0.95$). As for the imaging techniques applied for splenic abscess, all patients underwent chest X-ray. Twenty-two patients (61.1%) had left lower lung infiltration (6 patients, 16.7%) or left pleural effusion (16 patients, 44.4%). The abnormalities revealed by chest X-ray disappeared after successful treatment of the splenic abscess. The mortality rate was 11.1% (Table 4). All 4 deceased patients died of predisposing factors such as malignancy rather than of splenic abscess itself.

## DISCUSSION

In the past, antibiotic therapy and splenectomy were cosidered the treatments of choice for splenic abscess[2,14]. Because of the increased number of immunocompromised patients within the general population, the incidence of splenic abscesses has increased over the last decade[15]. The spleen is important for proper immunologic function, and splenectomy carries an increased morbidity rate with the danger of postsplenectomic infections. Current therapeutic strategies established spleen-preserving treatment in cases of trauma and benign lesions. Thus, percutaneous drainage of splenic abscesses is used instead of surgical treatment with good results[9-13], provided that certain conditions were present. Contrary to these opinions, some new studies recommended splenectomy as the treatment of choice for splenic abscesses and splenic pseudocysts[2,16].

Our series revealed that gram negative bacilli were the leading pathogens causing splenic abscess. *K. pneumoniae* was the most frequently found pathogen. Some previous studies had similar[1], but other reports revealed different results (mailnly *Streptococcus* and *Staphylococcus* species)[4,6,7].

Percutaneous treatment is the most convenient when the abscess collection is unilocular or bilocular with a discrete wall and no internal septations, and when its content is liquid enough to be drained. As for the location, better results are obtained at the periphery and at the middle or lower pole of the spleen. The number of collections is another important factor. If there are more than two collections, surgical treatment should be considered[9]. All patients in our study had unilocoluar or bilocular abscess located at the middle or lower pole of the spleen.

Percutaneous treatment is indicated especially when patients are in critical condition postoperatively or when the risks of general anesthesia, surgical drainage, or splenectomy are substantial. Some authors report that percutaneous drainage or needle aspiration should be considered as the first line of treatment, reserving splenectomy for exceptional cases only[11-13]. More than half of patients enrolled in our study had surgical intervention in abdomen or retroperitoneum (9 after malignancy) earlier and percutaneous drainage or needle aspiration was the only available treatment for those patients. Percutaneous treatment was a successful and definitive treatment in almost all of our patients. All deceased patients died of underlying deseases of malignancies. The advantages of percutaneous treatment were compared with surgery, including external drainage without significant risks of intra-abdominal spillage and avoidance of perioperative complications, less time and cost, better acceptance by the patient, and easier nursing care. Also, immunologic disfunction after splenectomy is avoided, which is a desirable outcome, especially in young patients[9, 11-13].

We recommend needle aspiration, primarily in the treatment of splenic abscess with the maximal diameter less than 50 mm, since our experience with those cases showed that needle aspiration was sufficient to solve these splenic abscesses in more than 50% cases. Also, the method is much simpler and less aggressive than percutaneous catheter drainage, allowing shorter hospital stay and lower costs. If needle aspiration was insufficient, we subsequently used the drainage technique by the trocar method using pigtail an 8-French catheters. In patients with splenic abscesses longer or equal to 50 mm in maximal diameter, we initially introduced an 8-French catheter. As for the bilocular abscesses, we always introduced a single 8-French catheter to take the advantage of the hydrostatic pressure gradient created when one of the cavities was drained, thereby causing sometimes spontaneous drainage of other cavities. If persistence of clinical signs was combined with poor drainage, the correct location of the catheter should be verified. The possibility

of placing an additional catheter should always be explored if the abscess continues to exist. Complications associated with percutaneous drainage of splenic abscesses include hemorrhage, pleural empyema, pneumothorax and fistula formation[9,17]. These complications are rarely encountered if the exclusion criteria were carefully followed. In our study, all splenic abscesses were successfully drained without any complications.

In conclusion, ultrasound guided percutaneous treatment of splenic abscess is a safe and effective alternative to surgery, allowing preservation of the spleen, avoiding perioperative complications, ensuring better compliance and easier nursing care. This treatment is indicated especially when patients are in critical condition postoperatively or when the risks of general anesthesia, surgical drainage, or splenectomy are substantial. We recommend needle aspiration primarily in the treatment of splenic abscesses smaller than 50 mm and continuous percutaneous drainage for those larger than 50 mm in the longest diameter as well as for the bilocular abscesses.

## Abstract

**AIM:** To explore effects of huoxiangzhengqi liquid (HXZQ) on enteric mucosal immune responses in mice with Bacillus dysenteriae and Salmonella typhimurium induced diarrhea (BSD).

**METHODS:** BSD was induced in Balb/c mice by oral administration with Bacillus dysenteriae and Salmonella typhimurium. HXZQ was administrated from the day of diarrhea induction at dosages of 5.21 g/kg and 0.52 g/kg, respectively. The onset of diarrhea and lasting time were recorded. Peyer's patches and peripheral lymphocytes were prepared for flow cytometry, and levels of TNF-$\alpha$ in peripheral blood and enteric tissue homogenates were determined with ELISA. Student's *t* test was employed for statistics.

**RESULTS:** Mice in BSD group started showing continuous diarrhea on the day of induction until the fourth day when they were sacrificed. Diarrhea in the mice of HXZQ high and low dose groups lasted for 36 and 54 h, respectively. There were more $CD4^+$ and $CD8^+$ cells in peripheral blood, fewer $CD4^+$ cells in Peyer's patches in BSD mice compared to normal mice. Fewer $CD4^+$ and $CD8^+$ cells was shown in the mice in HXZQ high group compared to BSD mice. In Peyer's patch, there were more $CD8^+$ cells in mice in HXZQ high and low dose groups and more $CD4^+$ in mice in HXZQ high group. Higher levels of TNF-$\alpha$ in peripheral blood and intestinal tissue homogenates in BSD group were observed. Mice in HXZQ high group showed decreased levels of TNF-$\alpha$ in peripheral blood and enteric tissue homogenates.

**CONCLUSION:** The immune regulation of $CD4^+$ and $CD8^+$ cells in Peyer's patch and suppression of TNF-$\alpha$ levels in enteric homogenates may partially explain the effect of HXZQ on improvement of BSD.

**Key words:** Diarrhea; Peyer's patches; TNF-$\alpha$; Huoxiangzhengqi liquid

## INTRODUCTION

Huoxiangzhengqi liquid (HXZQ), consisting of Agastache rugosa, Ammi majus, areca peel, hoelen, beefsteak plant leaf, aurantii nobilis pericarpium, atractylodes macrocephala, magnolia bark, pinelliae tuber, platycodon root and Glycyrrhiza uralensis, has been used in China for thousands of years for the treatment of various diarrhea[1]. It is one of earliest marketed herbal medicines and is produced by China Tongrentang Pharmaceuticals Corp(GMP certificated), Beijing. Pharmacological research has shown that HXZQ has the activities of improving gastrointestinal dysfunction, anti-inflammation and immune regulation[1-3].

Enteric mucosal responses play an important role in anti-inflammation of the digestive tract[4,5]. However, the effects of HXZQ on enteric mucosal immune responses are largely unknown.

Dysenteriae and Salmonella typhimurium induced diarrhea (BSD) is one of widely used animal models for

human infectious diarrhea study[6,7]. In the present study, we investigated the effects of huoxiangzhengqi liquid on enteric mucosal immune responses in mice with BSD.

## MATERIALS AND METHODS

### Animals

Forty Balb/c mice, female and male in equal number, 8-10 wk old, were purchased from the Research Institute of Experimental Animals, Chinese Academy of Medical Science, Beijing. Mice were randomly divided into four groups with 10 in each group: control group (Control), BSD group, Huoxiangzhengqi liquid treated BSD groups at high dosage and low dosage (HXZQ high, HXZQ low). Mice were housed in a temperature-, humidity- and light-controlled environment with free access to rodent chow and water. The light-dark cycle was 12 h:12 h with the light phase from 06:00 am to 18:00 pm.

### Induction of BSD

BSD were induced by oral administration with sodium ampicillin (Northern China Pharmaceutical Limited Company, Guangzhou, China) at a dosage of 20 g/kg body weight, and 8 h later, were orally administered with Bacillus dysenteriae and Salmonella typhimurium (National Institute for Control of Drugs and Biological Products, Beijing, China) at the proportion of 1:1 with 0.2 mL/mouse (concentration at 1010 CFU/mL). Mice in BSD, HXZQ high, and HXZQ low groups were induced with BSD, and mice in Control group were treated with equal volume physiological saline. The onset of diarrhea and its lasting time were recorded as previously reported[6,7].

### Treatment of BSD with HXZQ

The administrations of HXZQ started from the day of induction of BSD, once a day for three days. The dosage of HXZQ was determined according to our *in vitro* tests, and the doses at 5.21 g (crude herbal drug)/kg body weight and 0.52 g/kg were used for the mice in HXZQ high and HXZQ low groups, respectively, in a volume of 10 mL/kg. The mice in control group and BSD group were administered with the same volume of saline.

### Preparation of Peyer's patch cell suspension

The mice were sacrificed on the fourth day after the treatment. Peyer's patch cells were separately harvested according to Lyscom's method[8]. Briefly, the tissues were mechanically dissociated into phosphate buffered saline (PBS). Lymphocytes were isolated by density centrifugation on Ficoll Hypaque (Lymphoprep, Nycomed, Olso, Norway). The lymphocytes were collected by repeated centrifugation at 463 rpm for 5 min after the tissues were washed twice with PBS and then suspended in PBS at a density of $1 \times 10^6$ cells/mL for flow cytometry.

### Preparation of peripheral lymphocytes

Whole blood samples were collected before the mice were sacrificed, and suspended in tubes containing 25 μL heparin (5000 IU/mL). Erythrocytes were lysed in a buffer containing 0.84% $NH_4Cl$ at pH 7.4 for 3-5 min. The remaining cells were then washed in saline twice, and resuspended for flow cytometry.

### Preparation of enteric tissue homogenates

Colons were washed and put into homogenate medium (dehydrated alcohol and saline at a ratio of 1:4) at 300 g/L. After mixed sufficiently, they were placed at 4℃ for 2 h, and centrifuged at 3500 rpm for 15 min. The supernatant was collected, and stored at 4℃ for ELISA.

### Flow cytometry for $CD4^+$ and $CD8^+$

Flow cytometry was performed on freshly isolated plasma lymphocytes and Peyer's patch cell suspension. Immunofluorescence staining of cell surface markers was performed using R-Phycoerythrin (PE)-conjugated OX-38 (BD Biosciences Pharmingen) for $CD4^+$ staining, Peridinin Chlorophyll-a Protein (PerCP)-conjugated OX-8 (BD Biosciences Pharmingen) for $CD8^+$ staining. Each sample of 0.1 mL peripheral lymphocytes or Peyer's patch cell suspension was incubated for 30 min at 4℃ in the dark, with a solution consisting of 6 μL PBS 0.01 mol/L and an appropriate concentration of antibodies. After washing in saline, the cells were resuspended and fixed. Flow cytometric analysis was performed using an FACS Caliburflow cytometer utilizing CELLQuest software (Becton Dickinson, San Jose, CA, USA). Analysis was carried out on $1 \times 10^4$ cells for each sample.

### ELISA for TNF-α

Detection of TNF-α in peripheral blood and intestinal tissue homogenates was conducted with ELISA kit (Cat. No.88-7340 eBioscience, Inc) according to instructions of the manuals.

### Statistical analysis

Data were expressed as mean ± SD. ANOVA was used to determine significance in the data set. Student-Newman-Keuls test was employed for variables between both groups when equal variances were assumed and Dunnetts's *t* test when equal variances not assumed. $P < 0.05$ was taken as significant.

## RESULTS

### Incidence and lasting time of diarrhea

After induction of BSD, all mice showed diarrhea within 6 h on the day of induction. The diarrhea in the mice in BSD group lasted until the fourth day when the mice were sacrificed. Diarrhea lasting time of the mice in HXZQ high and HXZQ low groups were 36 and 54 h, respectively.

### Changes of $CD4^+$ and $CD8^+$ cells in peripheral blood and Peyer's patch

Figure 1 shows that there were more $CD4^+$ and $CD8^+$ cells in BSD mice in periphery ($P < 0.05$ *vs* control group), less $CD4^+$ and more $CD8^+$ cells in Peyer's patch ($P < 0.05$ *vs* control group). Less $CD4^+$ and $CD8^+$ cells showed in the mice in HXZQ high group ($P < 0.05$ *vs* BSD group), and less $CD8^+$ cells in HXZQ low group ($P < 0.05$ *vs* BSD

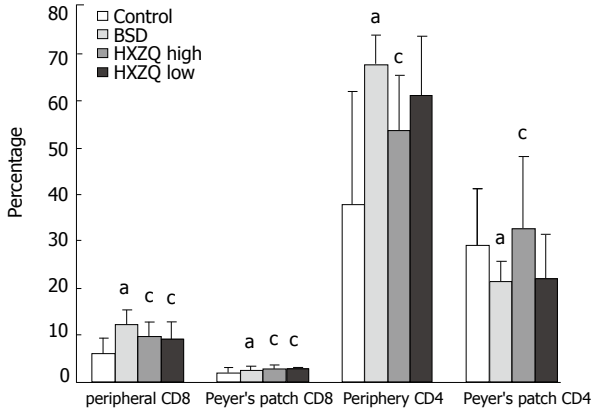

**Figure 1** $CD4^+$ and $CD8^+$ cells in peripheral blood and Peyer's patch were analyzed with flow cytometry. Data represent mean ± SE. $^aP < 0.05$ *vs* control group, $^cP < 0.05$ *vs* BSD group.

group) in periphery. In Peyer's patch, there were more $CD8^+$ cells in mice in HXZQ high and low groups ($P < 0.05$ *vs* BSD group), and more $CD4^+$ in mice in HXZQ high group ($P < 0.05$ *vs* BSD group).

### *TNF-α in peripheral blood and intestinal tissue homogenates*

Table 1 shows that there were higher levels of TNF-α in peripheral blood and intestinal tissue homogenates in BSD group ($P < 0.05$ *vs* control group). Mice in HXZQ high group showed decreased levels of TNF-α in peripheral blood and enteric tissue homogenates ($P < 0.05$ *vs* BSD group), and mice in HXZQ low group showed decreased levels of TNF-α in enteric tissue homogenates ($P < 0.05$ *vs* BSD group).

**Table 1 Changes of TNF-α in peripheral blood and enteric tissue homogenates**

| Group | Dosage (g/kg) | *n* | Peripheral blood (ng/mL) | Enteric tissue homogenates (ng/mL) |
|---|---|---|---|---|
| Control | - | 10 | 2.24 ± 0.26 | 1.83 ± 1 |
| BSD | - | 10 | 2.76 ± 0.26[a] | 4.13 ± 1.7[a] |
| HXZQ high | 5.21 | 10 | 2.31 ± 0.27[c] | 2.00 ± 0.6[c] |
| HXZQ low | 0.521 | 10 | 2.64 ± 0.54 | 2.7 ± 1.53[c] |

Data represent mean ± SE. $^aP < 0.05$ *vs* control group, $^cP < 0.05$ *vs* BSD group. TNF-α in peripheral blood and enteric tissue homogenates was analyzed with ELISA.

## DISCUSSION

HXZQ is one of ancient compound liquids of traditional Chinese herbal preparations. In China, it has been used for the effective treatment of various common gastrointestinal infectious diseases (GID), such as acute gastroenteritis, diarrhea and gastrointestinal type Frigorism[1]. It has been reported that HXZQ can promote gastroenteric motility, ameliorate myoelectricity of enteric smooth muscle and regulate gastrointestinal function[2]. Huoxiangzhengqi liquid has also been shown to have regulatory effects on specific immune responses[3]. Agastache rugosa is the essential component of huoxiangzhengqi liquid, and the extract of Agastache rugosa has been reported to have immune modulatory activities[9-15]. BSD in mice is induced by administration of attacking pathogenic bacteria, and shares similar pathogenesis and symptoms with GID[6,7]. Our study showed that HXZQ at 5.21 g/kg and 0.521 g/kg could significantly ameliorate diarrhea in BSD mice.

Although bacteria are usually regarded as harmful, it is now recognized that the breakdown or a failure of components of the indigenous microflora is responsible for allergic diseases or food enteropathies[8-10]. Intestinal microbial species and its product can partially modulate mucosal immune responses and influence the expansion and structure of lymphoid tissues, the activation of $TH_1$ and $TH_2$ T cells[11,12]. Intestinal bacteria are required for the development of gut-associated lymphoid tissues (GALT), which mediate a variety of host immune functions, such as mucosal immunity and oral tolerance[13]. Peyer's patch lymphocytes, as one important part of GALT, are considered to be the effectors in reacting with intestinal antigens, and mediate immune tolerance[14]. It has been known that some drugs can reestablish the microenvironment of the intestinal tract, thereby enhancing mucosal as well as systemic immune response[15-17]. Intestinal immunity has been evaluated with respect to $CD4^+$ cells armed with secretory intestine-derived IgA, and $CD8^+$ cells armed with IgG[18]. Down-regulation of immune responses by regulatory T cells is one of the major mechanisms involved in the induction of tolerance and self- and allo-antigen[19]. Microflora-associated antigens can drive antigen-specific $CD4^+$ T cells to cause intestinal inflammation. Therefore, the effectors $CD4^+$ T cells seem to regulate the development of intestinal inflammation[4]. Our results showed that there were significant changes in $CD4^+$ and $CD8^+$ cells both in Peyer's patch and peripheral blood in BSD mice, and HXZQ could regulate the proportion of $CD4^+$ to $CD8^+$. These results further supported that dysbacteria might take some active role in immune response in BSD mice, and HXZQ might have potential regulative activities on enteric mucosal immune responses in diarrhea. The results also indicate that $CD4^+$ and $CD8^+$ T cells in Peyer's patch may serve as one of the targets of the immunoregulatory activity of huxiangzhengqi liquid.

TNF-α is a pleiotropic cytokine with strong proinflammatory, immunomodulatory properties, and plays a critical role in inflammation and inflammatory bowel disease[20,21]. Anti-TNF therapy has been proven to be a milestone in the treatment of inflammatory bowel disease, and equally important in other inflammation-mediated conditions, including viral infections and mucosal inflammation[22,23]. Different strategies have been explored aiming at inhibiting TNF. Infliximab, a chimeric antibody to TNF-α, holds much promise for the treatment of Crohn's disease[24]. TNF-α levels in enteric tissue homogenates and peripheral blood in BSD mice were higher in our study, while HXZQ could decrease TNF-α. The results could partially explain the immunosuppressive activities of HXZQ in immune response of mice, and further support that dysbacteria could lead to increased inflammatory response in BSD mice.

In conclusion, enteric immune response might be actively involved in diarrhea and regulation of CD4 and CD8 T cells in Peyer's patch and suppression of TNF-α levels in enteric homogenates might be one of the mechanisms of HXZQ in the treatment of diarrhea.

## Abstract

**AIM:** To explore the effects of ketamine on hemodynamics, plasma proinflammatory cytokine (TNF-α and IL-6) levels and nuclear factor kappa B (NF-κB) activation during polymicrobial sepsis.

**METHODS:** Male Sprague-Dawlay rats were subjected to cecal ligation and puncture (CLP) or sham operation. The rats were randomly assigned into four equal groups: sham CLP group, CLP group, ketamine (KT) Ⅰ group and KTⅡ group. Thirty minutes before CLP, ketamine (5 mg/kg per hour and 10 mg/kg per hour, respectively) was infused continuously through the left femoral vein cannula in KTⅠ group or KTⅡ group. Sham CLP group and CLP group received 0.9% saline only (5 mL/kg per hour). The right femoral artery was cannulated to monitor mean arterial pressure (MAP) and heart rates (HR),and draw blood samples. The proinflammatory cytokine (TNF-α and IL-6) levels of plasma were measured using enzyme-linked immunosorbent assays (ELISA). The hepatic NF-κB activation was determined by Western blot and HPIAS 2000 image analysis system. Twenty hours after CLP, the rats were killed by right femoral artery phlebotomization.

**RESULTS:** CLP produced progressive hypotension, and a first increase followed by a decrease in HR. The hypotension was prevented, and the HR was slightly steady in ketamine treated rats. TNF-α levels of plasma reached a peak value at 2 h after CLP. Ketamine (KT Ⅰ group or KTⅡ group) caused a significant decrease compared with CLP group at 2, 5 and 9 h time points after CLP (14.3 ± 1.9 *vs* 4.3 ± 0.9, 9.7 ± 1.4 *vs* 4.3 ± 0.9; 9.3 ± 1.5 *vs* 4.3 ± 0.9, 8.7 ± 1.4 *vs* 4.3 ± 0.9; 6.0 ± 1.5 *vs* 5.0 ± 1.7, 5.3 ± 0.8 *vs* 5.0 ± 1.7; $P < 0.01$, respectively). The IL-6 levels of plasma firstly ascended and then descended in CLP group, and reached a peak value at 9 h after CLP. Ketamine (KTⅠ group or KTⅡ group) caused a significant decrease compared with CLP group at 5, 9 or 20 h after CLP (135.0 ± 52.6 *vs* 60.0 ± 16.3, 112.5 ± 52.6 *vs* 60.0 ± 16.3; 410.0 ± 68.7 *vs* 62.5 ± 12.5, 250.0 ± 28.0 *vs* 62.5 ± 12.5; 320.0 ± 25.9 *vs* 52.5 ± 10.1, 215.0 ± 44.6 *vs* 52.5 ± 10.1; $P < 0.05$, respectively). The IL-6 levels of plasma in KTⅡ group were lower than those of KTⅠ group at 9 h after CLP (250.0 ± 28.0 *vs* 410.0 ± 68.7; $P < 0.05$). In addition, CLP increased hepatic NF-κB expression compared with sham CLP. Ketamine suppressed NF-κB activation in a dose-dependent manner at 4 h after CLP (237.7 ± 3.5 *vs* 246.9 ± 3.1; $P < 0.05$).

**CONCLUSION:** Ketamine stabilizes the hemodynamics, attenuates the proinflammatory cytokine responses, and inhibits hepatic NF-κB activation. These findings suggest that ketamine has protective effects against polymicrobial sepsis in rats.

**Key words**: Ketamine; Sepsis; Hemodynamics; Tumor necrosis factor α; Interleukin 6; Nuclear factor kappa B

## INTRODUCTION

Sepsis/Septic shock is a complex pathophysiologic process characterized by profound hypotension, progressive metabolic acidosis, systemic inflammatory response syndrome (SIRS), multiple organ dysfunction syndrome (MODS), and even death. Although its pathophysiology is not well defined, that monocytes orchestrate the innate immune response to Gram-positive and Gram-negative bacteria by expressing a variety of inflammatory cytokines, especially tumor necrosis factor-α (TNF-α) is considered to play an important role in the pathogenesis of sepsis/septic shock[1,2].

It is known that nuclear factor kappa B (NF-κB) is an

inducible nuclear transcription factor that plays a central role in regulating the transcription of proinflammatory cytokines[3], such as TNF-α, interleukin 6 (IL-6), adhesion molecules, the other mediators involved in SIRS, severe sepsis, septic shock and MODS.

Recently, several investigators have reported that intravenous anesthetic ketamine has inhibitory effects on lipopolysaccharide (LPS)-induced TNF-α production in endotoxin-shock rats[4,5]. Others have documented that ketamine could suppress proinflammatory cytokine production in human whole blood *in vitro*[6,7]. Thus we hypothesized that ketamine could inhibit proinflammatory cytokine responses and NF-κB activation after cecal ligation and puncture (CLP, a model of polymicrobial sepsis) challenge during polymicrobial sepsis in rats.

## MATERIALS AND METHODS

### Establishment of rat model of polymicrobial sepsis

Polymicrobial sepsis was induced in male Sprague-Dawley (SD) rats (200-250 g) by CLP according to the method of Chaudry[8]. The rats were anesthetized with 20% ethyl carbamate (1 g/kg). Then the cecum was isolated and ligated with a 3-0 silk ligature just distal to the ileocecal valve, punctured twice at the opposite ends with a 9-gauge needle, and returned into the abdominal cavity. Following this, the abdominal incision was closed in two layers and the rats received normal saline solution (3 mL/100 g) subcutaneously.

### Experimental protocols

Rats were randomly assigned into four equal groups: CLP group, sham operation group, KT Ⅰ (ketamine Ⅰ) group and KT Ⅱ (ketamine Ⅱ) group. In CLP group, thirty minutes before CLP rats received 0.9% saline through the left femoral vein cannula. Polymicrobial sepsis was induced by CLP operation. In sham CLP group, rats were subjected to the same surgical procedure except that the cecum was neither ligated nor punctured. In KT Ⅰ and KT Ⅱ groups, ketamine (5 mg/kg per hour and 10 mg/kg per hour, respectively) was infused continuously through the left femoral vein cannula 30 min before CLP. The right femoral artery was cannulated to monitor the mean arterial pressure (MAP), heart rates (HR) and draw blood samples in all groups.

### Plasma cytokine levels

At 2, 5, 9 and 20 h after CLP or sham CLP operation, blood was drawn *via* the right femoral artery (1.0 mL each). The plasma was immediately separated by centrifugation at 3000 rotation per min for 15 min at 4℃, divided into aliquots and stored at -70℃ until assayed. The proinflammatory cytokine levels of plasma were quantified using enzyme-linked immunosorbent assays (ELISA)(American R & D and Bender).

### Preparation of nuclear extracts[9]

Fresh liver tissue of 0.1 g was homogenized in buffer A (10 mmol/L HEPES-NaOH pH 7.9, 1 mmol/L EDTA, 10 mmol/L KCl, 1.5 mmol/L $MgCl_2$, 1 mmol/L PMSF, 1 mmol/L DTT, 1 μg/mL Leupeptin), and the homogenates were incubated on ice (15 min) with gentle agitation. After lysis, nuclei were collected by centrifugation (14 000 rpm for 5 min). Nuclear proteins were extracted by incubation of nuclei on ice (30 min) in hypertonic salt buffer B (20 mmol/L HEPES-NaOH, pH 7.9, 0.2 mmol/L EDTA, 420 mmol/L NaCl, 1.5 mmol/L $MgCl_2$, 25% glycerin 0.5 mmol/L PMSF, 0.5 mmol/L DTT, 1 μg/mL Leupeptin). Extracts were centrifuged and nuclear extract supernatant was harvested and stored at -70℃. Proteins were quantified by the Lowry-Kalckar assays.

### Western blot analysis

The nuclear protein extracts of the liver tissue (20 μg) were boiled in Laemmli sample buffer and subjected to 12% sodium dodecyl sulfate polyacrylamide gel electrophoresis. Before transfer, gels were equilibrated for 15 min in cathode buffer. Proteins were transferred at 0.8 mA/cm for 2 h onto NC membranes, preequilibrated in methanol using a semidry blotting apparatus. Equal loading and transfer were monitored by immersing ponceau S staining of the membranes. Nonspecific binding sites were blocked by immersing the membrane into blocking solution overnight at 4℃. Membranes were washed three times (10 min each) in TBST and incubated in 1:200 dilution of rabbit-antirat NF-κB p65 polyclonal antibody in blocking solution for 1 h at room temperature, followed by extensive washing three times (10 min each) with TBST. Bound antibody was decorated with 1:1000 goat-antirabbit IgG diluted in blocking solution for 30 min at room temperature, after washing four times (10 min each). Immunocomplexes were detected using DAB staining, Western blotting reagents and determined using HPIAS 2000 image analysis system.

### Statistical analysis

Data were presented as mean ± SD. Analysis of variance (ANOVA) was used to evaluate whether values at the same time point were different for the control and ketamine groups and two-way analysis of variance for repeated measurements with multiple comparisons. A significant difference was presumed at a $P$ value < 0.05.

## RESULTS

### Hemodynamics (MAP and HR)

No significant differences were noted in baseline MAP among all groups. CLP challenge decreased MAP in CLP group, KT Ⅰ group and KT Ⅱ group but not in sham CLP group. At 20 h time point after CLP challenge, MAP decreased by 6.8%, 71.7%, 41.5% and 24.7% in sham CLP, CLP, KT Ⅰ, and KT Ⅱ groups, respectively. There were significant differences between CLP group and KT Ⅰ group at 14, 16, 18 and 20 h time points ($P$ < 0.05, respectively). At the same time significant differences in MAP were found between the CLP group and KT Ⅱ group at 8, 10, 12, 14, 16, 18 and 20 h time points after CLP challenge during polymicrobial sepsis ($P$ < 0.05, respectively) (Figure 1) .

There were no significant differences in baseline HR among all groups. First increased followed by a decrease in HR after CLP challenge, HR was slightly steady in

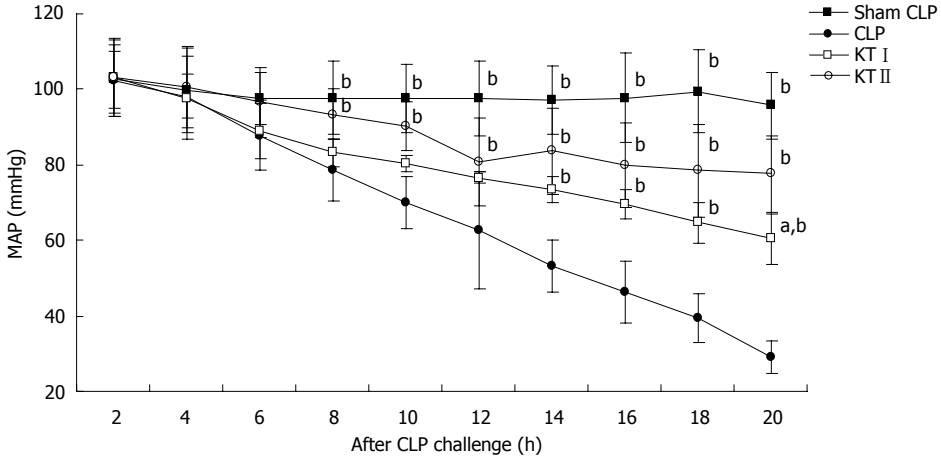

**Figure 1** Changes of MAP (mean ± SD). Closed squares, sham CLP group; Closed circles, CLP group; open squares, ketamine Ⅰ group; open circles, ketamine Ⅱ group, $^{b}P < 0.01$ *vs* CLP group, $^{a}P < 0.05$ *vs* ketamine Ⅱ group.

**Table 2 Changes of IL-6, (pg/mL, $n$ = 5, mean ± SD)**

| Group | Time point (after CLP) | | | |
|---|---|---|---|---|
| | 2 h | 5 h | 9 h | 20 h |
| Sham CLP | 50.0 ± 15.3 | 60.0 ± 16.3[b] | 62.5 ± 12.5[b] | 52.5 ± 10.1[b] |
| CLP | 52.5 ± 10.5 | 217.5 ± 25.9 | 882.5 ± 127.1 | 567.5 ± 144.9 |
| KT Ⅰ | 50.0 ± 8.8 | 135.0 ± 52.6[a] | 410.0 ± 68.7[b,c] | 320.0 ± 25.9[b] |
| KT Ⅱ | 45.0 ± 11.2 | 112.5 ± 52.6[b] | 250.0 ± 28.0[b] | 215.0 ± 44.6[b] |

$^{a}P < 0.05$, $^{b}P < 0.01$ *vs* CLP group; $^{c}P < 0.05$ *vs* ketamine Ⅱ group.

ketamine treated rats. There were significant differences in HR at 10, 12, 16, 18, and 20 h time points between CLP group and KT Ⅰ group ($P < 0.05$, respectively). Significant differences in HR were found between CLP group and KT Ⅱ group at 10, 12, 18 and 20 h time points after CLP challenge during polymicrobial sepsis ($P < 0.05$, respectively) (Figure 2).

### *Plasma cytokine levels of TNF-α and IL-6*

TNF-α levels of plasma were significantly increased after CLP challenge. In CLP group, TNF-α levels reached a peak level at 2 h after CLP operation (27.3 ± 3.1 pg/mL). Ketamine (KT Ⅰ group or KT Ⅱ group) caused a significant decrease compared with CLP group at 2, 5 and 9 h after CLP challenge ($P < 0.05$, respectively). TNF-α levels in KT Ⅱ group were lower than those of KT Ⅰ group at 2 h after CLP challenge ($P < 0.05$) (Table 1).

IL-6 levels of plasma were firstly increased followed by a decrease during polymicrobial sepsis in CLP group, and reached a peak level at 9 h after CLP (883 ± 127 pg/mL). Ketamine (KT Ⅰ group or KT Ⅱ group) caused a significant decrease compared with CLP group at 5, 9 and 20 h after CLP challenge ($P < 0.05$, respectively). IL-6 levels in KT Ⅱ group were lower compared with those of KT Ⅰ group at 9 h after CLP challenge ($P < 0.05$, respectively) (Table 2).

### *Activity of NF-κB p65*

Western blot analysis demonstrated that hepatic NF-κB activity was obviously increased in CLP group (266 ± 7, absorbency) compared with sham CLP group ($P < 0.05$) at 4 h after CLP. NF-κB activation in KT Ⅰ group or KT Ⅱ group was significantly decreased after ketamine treatment

**Table 3 Changes of NF-κB P65 absorbency, ($n$ = 5, mean ± SD)**

| Group | 4 h after CLP |
|---|---|
| Sham group | 215.5 ± 2.7[b] |
| CLP group | 264.5 ± 7.4 |
| KT I group | 246.9 ± 3.1[a,b] |
| KT Ⅱ group | 237.7 ± 3.5[b] |

[a]$P$ < 0.05 *vs* ketamine Ⅱ group; [b]$P$ < 0.01 *vs* CLP group.

($P$ < 0.05, respectively). By contrast, NF-κB activation in KT Ⅱ group was lower than those in KT I group ($P$ < 0.05) (Table 3 and Figure 3).

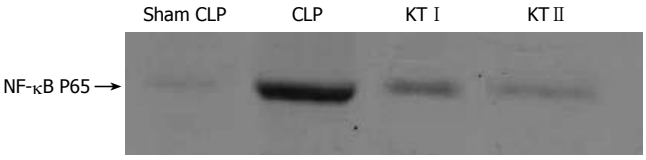

**Figure 3** Hepatic NF-κB activation.

## DISCUSSION

In our study, CLP produced progressive hypotension and obvious increase in plasma cytokine concentrations. Ketamine administration inhibited development of hypotension and increase of cytokine concentrations, which is in accordance with the literature[4-7]. It indicates that a subanesthetic dose of ketamine could inhibit endotoxin-induced expression of TNF-α and other proinflammatory mediators. We found that CLP provoked a transient elevation of TNF-α and IL-6 concentration in the plasma and enhanced the hepatic NF-κB activation in polymicrobial sepsis rats. In contrast, in the presence of ketamine, polymicrobial sepsis had inhibitory effects on the production of cytokines. Moreover, ketamine decreased the hepatic NF-κB activation during polymicrobial sepsis. This inhibitory effect of ketamine was the most important finding of the present study.

Since TNF-α is considered to play a key role in the pathogenesis of sepsis/septic shock, we detected TNF-α concentrations of plasma in rats. In addition, we also examined IL-6 concentrations. In 1994, Takenaka discovered that intravenous anesthetic ketamine had inhibitory effects on LPS-induced TNF-α production in endotoxin-induced shock in mice *in vivo*[3]. Following that more studies discovered that ketamine suppressed TNF-α mRNA expression and proinflammatory cytokine IL-6 and IL-8 production in human whole blood *in vitro*[10]. Our study demonstrated that ketamine had the same inhibitory effects on TNF-α and IL-6 expression during polymicrobial sepsis.

NF-κB is an inducible nuclear transcription factor that plays a central role in regulating the transcription of proinflammatory cytokines[3], including TNF-α, IL-6. However, the present study did not determine the cellular source of the cytokines. Numerous studies have implicated macrophages and other immunocompetent cells as important sources of proinflammatory cytokines in various models of shock and sepsis. Some investigators suggested that the hepatic Kupffer cells are a major source of proinflammatory cytokine release during acute phase of sepsis[11]. We attempted to identify the hepatic NF-κB activation during polymicrobial sepsis.

Until now, the effects of ketamine on NF-κB have been reported limitedly. In 2000, Sakai discovered ketamine inhibited endotoxin-induced NF-κB expression in brain cells *in vivo* and *in vitro*, in a dose-dependent manner[12]. In 2004, Sun discovered that ketamine suppressed endotoxin-induced NF-κB activation and TNF-α expression in the intestine, lung and liver[13]. In 2005, Suliburk found that ketamine attenuated liver injury attributed to endotoxemia: a role of cyclooxygenase-2[14]. In addition, Yang found that large dose ketamine inhibited LPS-induced acute lung injury in rats[15]. Our study indicated ketamine suppressed the hepatic NF-κB activation after CLP challenge during polymicrobial sepsis.

The doses of ketamine used in this study were 5 mg/kg per hour and 10 mg/kg per hour. Compared with the subanesthetic dose or the anesthetic dose, these doses of ketamine were relatively higher. It might be species-dependent. The two doses both inhibited proinflammatory cytokine responses and hepatic NF-κB activation, especially higher dose ketamine treatment group. It indicates that the effects of ketamine might be dose-dependent.

In summary, the current studies show that administration of ketamine has protective effects against polymicrobial sepsis in rats. Ketamine probably inhibits NF-κB activation, and attenuates the proinflammatory cytokine response. However, the precise mechanisms underlying the inhibitory effects are still unknown. Further investigations are needed, such as on toll-like receptors[16,17].

## Abstract

**AIM:** To investigate the expression of fragile histidine triad (FHIT) protein in 64 patients with ulcerative colitis (UC) and Crohn's disease (CD), and its relation with clinicopathological data.

**METHODS:** Rabbit-anti-FHIT antibody was used to detect FHIT protein expression in 64 formalin-fixed, paraffin-embedded tissue specimens of inflammatory bowel disease (IBD) by citrate-microwave-streptavidin (SP)-HRP immunohistochemical method.

**RESULTS:** The positive FHIT protein expression was 22.79% ± 16.16%, 42.14% ± 16.82% in active and remittent phases of UC, 36.07% ± 19.23% in CD, and 57.05% ± 8.86% in normal colon mucosa. Statistically significant differences in FHIT protein expression were observed between the active and remittent phases of UC, between the active phase of UC and normal colon mucosa, as well as between the remittent phase of UC and normal colon mucosa, and between CD and normal colon mucosa.

**CONCLUSION:** Our results show that FHIT protein expression is completely absent or reduced in IBD, suggesting that the FHIT gene might be associated with the oncogenesis and progression of IBD, an early event from inflammatory conditions to carcinoma in IBD.

**Key words:** Fragile histidine triad protein expression; Ulcerative colitis; Crohn's disease; Inflammatory bowel disease

## INTRODUCTION

Inflammatory bowel disease (IBD) is a collection of chronic idiopathic inflammatory disorders of the intestine and/or colon, including two independent diseases: ulcerative colitis (UC) and Crohn's disease (CD)[1]. Up to now, the complex etiology and pathogenesis of IBD are not known with certainty, but the growing theories suggest that many factors such as environment, genetic alteration, uncontrolled immune system, *etc*, can result in chronic gut inflammation[2-7]. However, none of the theories provides a sufficient explanation of either disease, indicating that their etiology is multifactorial. It has been well established that colorectal carcinoma is the most serious complication of patients with long-standing IBD who have an increased risk of developing colorectal carcinoma[8-11]. The cumulative risk of carcinoma in IBD patients is estimated to be 10-20 times greater in the small bowel and 4-20 times greater in the large bowel than that in the small and large bowel of general population. The mean duration of colitis before cancer diagnosis ranges 17-20 years. Dysplasia occurring in IBD constitutes a precursor stage of carcinoma[12,13]. Patients with IBD are characterized by recurrent acute mucosa inflammation, mucosal ulceration, epithelial necrosis and regeneration, all of which may result in DNA damage, genetic alterations including enhanced microsatellite instability of mucosa, activation of oncogene, inactivation of tumor suppressor gene, increasing susceptibility to mutagenesis and subsequent neoplastic transformation[8-18].

The fragile histidine triad (FHIT) gene was discovered at human chromosome 3p14.2 in 1996 by Ohta *et al*[19] using the exon trapping method, and has been identified as a candidate tumor-suppressor gene. This gene not only spans the translocation breakpoint of familial renal-cell carcinoma, but also encompasses the most active common human chromosomal fragile region, FRA3B[19,20]. The approximately 1-megabase FHIT gene includes 10 exons, encoding 1.1Kb mRNA transcript, 16.8 kDa, and 147 amino acid proteins[21]. FHIT protein is a member of the recently discovered histidine triad (HIT) family of nucleotide-binding proteins with a high specific hydrolysing activity for diadenosine 5', 5'''-P1, Pn-polyphosphate (ApnA), where $n$ = 3-6. The FHIT protein encoded by the FHIT gene can hydrolyze AP3A

and AP4A to ADP and AMP[20,22]. It was reported that the FHIT gene can facilitate deletions and aberrant transcripts and may play an important role in a variety of human malignancies[23-26], including cancers of lung[27], breast[28], pancreas[29], urinary bladder[30], head and neck[31] and gastrointestinal carcinomas[32-34].

Since the role of FHIT aberrations is unclear and results from different investigators are contradictory, the present study was to evaluate the expression of FHIT protein in patients with IBD and its relation with clinicopathological data.

## MATERIALS AND METHODS

### Patients

Biopsy specimens from 64 IBD patients including 47 UC and 17 CD patients were obtained from several hospitals in Hubei Province from 1990 to 2005. All the patients were diagnosed in the light of clinical, endoscopic, histological and radiological criteria. All IBD patients underwent sigmoidoscopy or colonscopy for routine clinical evaluation. Mucosal inflammation in active UC was classified as mild inflammation: mild-to-moderate small round-cell infiltration with formation of a few crypt abscesses in the lamina propria; severe inflammation: severe small round-cell infiltration with multiple crypt abscesses and partial granulation in the lamina propria. Remission was defined histologically as areas with branched or regenerated irregular crypts without acute inflammation but with chronic mild inflammation. Ten apparently normal colonic tissue sections were obtained. The mean age of 47 patients including 34 men and 13 women at the onset of UC was 36.9 years (averaged 13.4 years). The mean age of the remaining 17 patients including 10 men and 7 women at the onset of CD was 38.0 years (averaged 13.9 years).

### Reagents and antibodies

Rabbit anti-FHIT polyclonal antibody (Zymed Company, USA) was purchased from Beijing Zhongshan Biological Technology CO, Ltd. Immunohistochemical staining S-P kit (Zemed MAXIM, USA) was purchased from Maixin Co, LTD.

### Methods

All the biopsy specimens were fixed in 10% buffered formalin and embedded in paraffin wax. Four-μM thick sections were routinely prepared and stained with haematoxylin and eosin, while other sections were prepared with immunohistochemical SP staining method. In brief, the tissue sections were routinely dewaxed in xylene, rehydrated at graded concentrations of alcohol, and treated with 3% hydrogen peroxide for 10 min to block the endogenous peroxidase. The sections were immersed in citrate buffer (5 mmol/L sodium citrate, pH = 6.0), heated in a microwave oven for 2 min to enhance antigen retrieval, and then placed at room temperature for 10 min. The sections were blocked with normal goat serum for 15 min and incubated with rabbit anti-FHIT polyclonal antibody (1:100 dilution) overnight at 4℃. After washed three times in PBS, the binding of antibodies to their antigenic sites in the tissue sections was further amplified with biotinylated goat anti-rabbit antibody followed by reaction with streptavidin-biotin peroxidase. Antibody localization was detected with diaminobenzidine as a chromogen substrate. Sections prepared by substituting PBS for the primary antibody served as a negative control. The freshly prepared substrate DAB was added for color development. The sections were washed in distilled water and counterstained with haematoxylin and mounted for examination.

### Determination of FHIT expression

Negatively expressed FHIT manifested as blue-stained nuclei while positively expressed FHIT manifested as brown or dark brown cytoplasm and/or cell membrane mainly in epithelial tissues. Expressions of these target proteins were semi-quantitated with automatic image analyzer (Nikon,Japan) and HPIAS-2000 image analyzing program, in which the average value of positive cells in 10 randomly selected high power fields (× 400) for each section was used for the comparison of the target protein expressions.

### Statistical analysis

Quantitative variables were expressed as mean ± SD. Statistical comparisons between groups were made by one-way ANOVA. Differences in results between the two groups were tested with $t$ test. $P < 0.05$ was considered statistically significant. All analyses were performed using the SPSS version 14.0.

## RESULTS

The classification of IBD patients according to their clinicopathological characteristics and their association with FHIT protein expression are shown in Tables 1 and 2.

The pattern of FHIT protein expression was confined to the epithelial cells, especially cytoplasm. As shown in Figure 1A-1D, FHIT protein expression was unequivocal in normal colonic tissue and reduced or absent in UC and CD. The positive FHIT expression was 22.79% ± 16.16%, 42.14% ± 16.82%, respectively in active and remittent phases of UC, 36.07% ± 19.23% in CD, and 57.05% ± 8.86% in normal colon mucosa. Statistically significant differences in FHIT protein expression were observed between the active and remittent phases of UC ($P < 0.05$), between the active phase of UC and normal colon mucosa ($P < 0.01$), as well as, between the remittent phase of UC and normal colon mucosa ($P < 0.01$), and between CD and normal colon mucosa ($P < 0.01$).

## DISCUSSION

Recent studies showed that tumourigenesis is related to inflammatory conditions, such as IBD and pancreatitis, and inflammation has been considered as precancerosis, but the possible link between inflammation and tumourigenes is still unclear[14,35,36]. Chronic inflammatory conditions such as UC are thought as the risk factor for some carcinomas, the incidence of colon carcinoma in UC is estimated to be 5-7 times greater than what we have expected,

**Table 1 Clinicopathological data of patients with inflammatory bowel disease**

| Patient No. | Sex | Age (yr) | Disease extension |
|---|---|---|---|

**Table 2 Comparison of FHIT protein immunohistochemical expression in ulcerative colitis, Crohn's disease, and normal colon mucosa (mean ± SD)**

| Groups | *n* | Positive rate of FHIT protein expression (%) |
|---|---|---|
| Normal colon mucosa | 10 | 57.05 ± 8.86 |
| Ulcerative colitis | | |
| Active | 33 | 22.79 ± 16.16 |
| Remittent | 14 | 42.14 ± 16.82 |
| Crohn's disease | 17 | 36.07 ± 19.23 |

and colon carcinoma occurs in 20%-35% patients with IBD. Compared with sporadic colorectal cancers, such as adenomatous polyposis and hereditary non-polyposis colorectal cancer syndrome, the prognosis of UC-associated colorectal cancer is the worst, the 5-year survival rate of patients is the lowest (< 40%)[10,12]. In our study, the positive rate of FHIT expression was 31.88% ± 20.33%, 22.79% ± 16.16%, 42.14% ± 16.82% in initial, active and remittent phases of UC, and 36.07% ± 19.23% in CD, and 57.05% ± 8.86% in normal colon mucosa. Statistically significant differences in FHIT protein expression were observed between the active and remittent phases of UC, between the active phase of UC and normal colon mucosa, as well as between the remittent phase of UC and normal colon mucosa, and between CD and normal colon mucosa. The severer the inflammation (active phase) is, the more reduction the FHIT protein expression is.

The possible interpretations for these results are as follows. IBD is strongly related to environment, and microsatellite instability in 50% UC patients is enhanced during inflammation. Microsatellites are simple repetitive sequences of DNA that are scattered throughout the genome. These sequences are stably inherited, varying from individual to individual, and have a low alteration rate. Instability within these sequences has been recognized as a marker for genome mutations and DNA repair deficiency. Recently, there have been some reports on detecting microsatellite instability in non-neoplastic settings, including inflammatory mucosa of IBD[8]. Inflammation results in an increase in DNA damage, strengthening the ability of cells to repair the damage before replication[37]. Mutations of oncogene and tumor suppressor gene may be the initiating events in tumourigenesis arising from an inflammatory backgroud, and continuous production of mutations may be required for tumor progression[38]. Patients with IBD are characterized by recurrent acute inflammation of the mucosa, mucosal ulceration, and epithelial necrosis and regeneration. Various kinetic analyses have shown increasing epithelial cell proliferation or cell death in crypts and dysplastic glands in IBD, especially in UC[9,36]. Active inflammation and regeneration may increase epithelial cell turnover, susceptibility to mutagenesis, and neoplastic transformation[39,40]. The positive rate of FHIT expression in remission of UC was 42.14% ± 16.82%. The possible theoretical explanation is that the abnormal architecture after active ulceration might impair mucosal function and lead to increased cell turnover. Another possibility is that remission in UC is

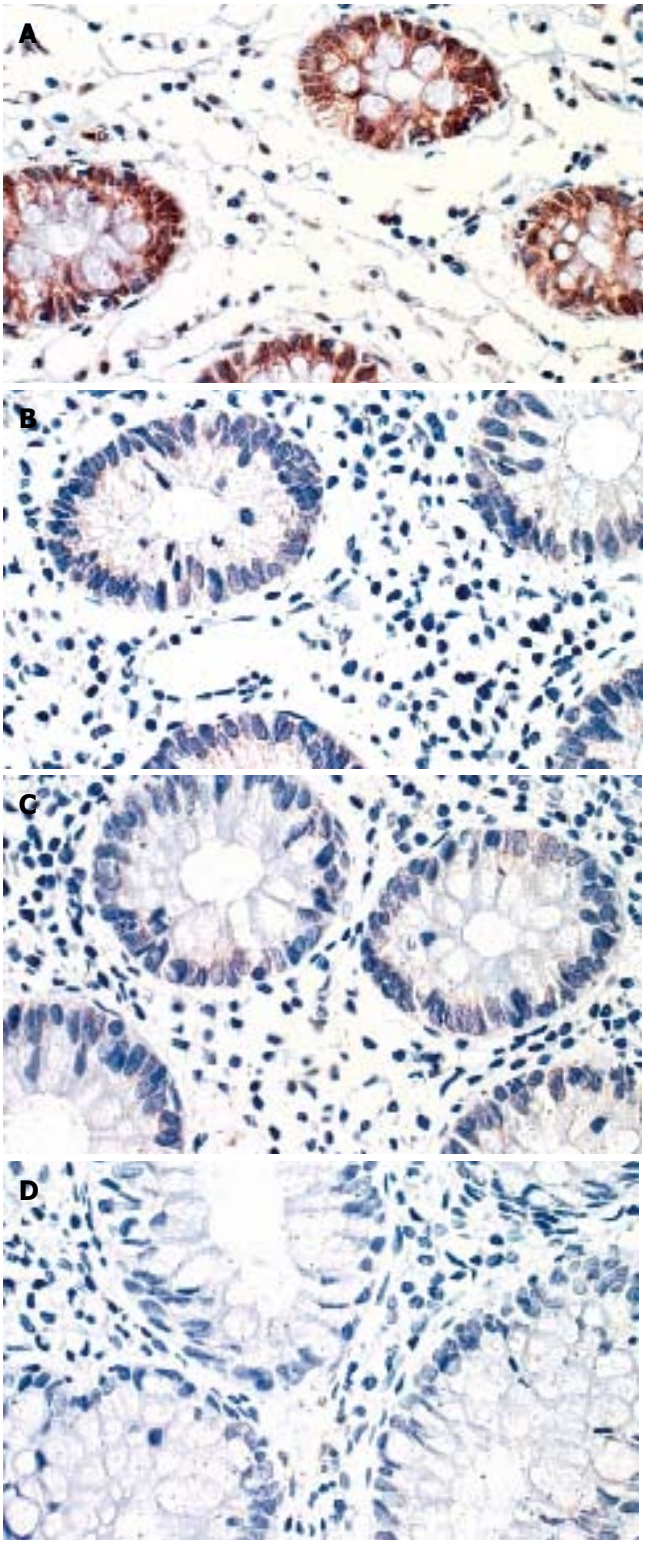

**Figure 1** FHIT protein expression in normal colonic epithelium (**A**), ulcerative colitis (**B**, **C**), and Crohn's disease (**D**) (SP × 400).

only relative with mucosal damage at a subclinical and subhistologic level between the time points of obvious relapse.

Chronic inflammation and epithelial cell damage that characterize IBD result in increased cell proliferation and cell death[41]. At the same time, the accelerated cell turnover prediposes to genetic alterations in mucosa, which is in line with dysplasia and carcinoma in IBD. Nobuyasu Arai *et al*[9] suggested that P53 accumulation and high P21WAF1/CIP1 expression accelerate epithelial cell turnover and may result in an elevated risk of developing dysplasia and carcinoma in patients with IBD.

Chronic inflammation and epithelial damage might predispose to DNA damage in mucosa and accelerate the gene mutation. In the present study, FHIT-protein immunohistochemical expression was absent or reduced in IBD, which might be a precursor from inflammation to carcinoma transformation, suggesting that the alteration of FHIT-protein expression might remain long before any histological morphological change[10]. Skopelitou AS *et al*[42] showed that FHIT protein immunostaining is completely absent or reduced in most *H pylori*-related chronic gastritis, which may play a role in the development and progression of gastric cancer. The reduced or absent FHIT protein expression during inflammation is due to the direct exposure of the gastrointestinal tract to environmental factors that induce FHIT/FRA3B breakage and sustain FHIT damage as an early event or due to DNA damage and FHIT gene mutation induced by chronic inflammation[43].

Reduced or absent FHIT protein expression may play a role in accelerating epithelial cell turnover or carcinoma transformation in IBD. Diadenosine triphosphase is first sequestered and eventually hydrolyzed by FHIT to ADP and AMP, the balance between cellular AP3A level and FHIT enzymatic activity may affect cell death or survival. Reduced or absent FHIT protein expression can inhibit the enzymatic activity of FHIT and increase the cellular AP3A level.AP3A can strengthen the transmission of cellular survival signals and accelerate the epithelial cell turnover. It has been suggested that AP4A can also be hydrolyzed by FHIT to ADP and AMP. AP4A is an intracellular regulatory molecule which may regulate the ability of cells to adapt to metabolic stresses such as oxidation and DNA damage. When the function of FHIT protein is diminished, the normal level of AP4A is deviated, which may result in the inability of cells to adapt to environmental stresses and cause genetic damage. At the same time, the ratio of AP3A to AP4A is increased, which can also increase cellular survival[10,20-23,28,30,32-34]. FHIT protein is involved in the regulation of apoptosis in cell culture systems, which is independent of P53, Bax or Bcl-2 expression and has been considered as an independent mechanism for tumor suppression. FHIT-induced apoptosis comprises signaling processes of FHIT-caspase 8-caspase 9-Bid-PARP, which has two pathways: one is activated by caspase-8, the other involves bypassing mitochondria[31,32]. When FHIT protein is abnormal, apoptosis is disrupted and cellular proliferation is accelerated. FHIT is involved in the regulation of cell cycle and DNA retrieval, FHIT protein can transform damaged DNA into S phase[44]. When FHIT protein expression is reduced or absent, disruption of cell cycle regulation leads to uncontrolled proliferation and formation of tumors.

In conclusion, the high frequency of complete absence and/or reduced immunohistochemical expression of FHIT protein suggests that the FHIT gene might be involved in

most cases of IBD, which might be a precursor from the inflammatory conditions to carcinoma transformation.

## Abstract

**AIM:** To study the molecular forms of trefoil factor 1 (TFF1) in normal gastric mucosa and its expression in normal and abnormal gastric tissues (gastric carcinoma, atypical hyperplasia and intestinalized gastric mucosa) and the role of TFF1 in the carcinogenesis and progression of gastric carcinoma and its molecular biological mechanism underlying gastric mucosa protection.

**METHODS:** The molecular forms of TFF1 in normal gastric mucosa were observed by Western blot. The expression of TFF1 in normal and abnormal gastric tissues (gastric carcinoma, atypical hyperplasia and intestinalized gastric mucosa) was also assayed by immunohistochemical method. The average positive AO was estimated by Motic Images Advanced 3.0 software.

**RESULTS:** Three patterns of TFF1 were found in normal gastric mucosa: monomer, dimmer, and TFF1 compound whose molecular weight is about 21 kDa. The concentration of TFF1 compound was the highest among these three patterns. TFF1 was expressed mainly in epithelial cytoplasm of the mucosa in gastric body and antrum, especially around the nuclei. The closer the TFF1 to the lumen, the higher the expression of TFF1. The expression of TFF1 in peripheral tissue of gastric carcinoma (0.51 ± 0.07) was higher than that in normal gastric mucosa (0.44 ± 0.06, $P < 0.001$). The expression of TFF1 in gastric adenocarcinoma was positively related to the differentiation of adenocarcinoma. The lower the differentiation of adenocarcinoma was, the weaker the expression of TFF1. No TFF1 was expressed in poorly-differentiated adenocarcinoma. The expression of TFF1 in moderately-well differentiated adenocarcinoma (0.45 ± 0.07) was a little lower than that in normal mucosa ($P > 0.05$). The expression of TFF1 in gastric mucosa with atypical hyperplasia (0.57 ± 0.03) was significantly higher than that in normal gastric mucosa ($P < 0.001$). No TFF1 was expressed in intestinalized gastric mucosa. There was no statistically significant difference between the expressions of TFF1 in gastric mucosa around the intestinalized tissue (0.45 ± 0.07) and normal gastric mucosa ($P > 0.05$).

**CONCLUSION:** TFF1 is expressed mainly in epithelial cytoplasm of the mucosa in gastric body and antrum. Its main pattern is TFF1 compound, which may have a greater biological activity than monomer and dimer. The expression of TFF1 in peripheral mucosa of gastric ulcer is higher than that in mucosa 5 cm beyond the ulcer, indicating that TFF1 plays an important part in protection and restitution of gastric mucosa. The expression of TFF1 is increased in peripheral tissues of gastric carcinoma and gastric mucosa with atypical hyperplasia, but is decreased in cancer tissues, implying that TFF1 may be related to suppression and differentiation of carcinoma. The weaker expression of TFF1 in poorly-differentiated carcinoma may be related to the destruction of glands and cells in cancer tissues and the decrease in secretion of TFF1.

**Key words:** Trefoil factor 1; Gastric mucosa protection; Carcinoma suppression

## INTRODUCTION

Trefoil factor 1 (TFF1) is a member of the trefoil factor family, which is a group of small molecule polypeptides mainly secreted by gastrointestinal mucous cells. TFF1 is mainly expressed in epithelial cytoplasm of the mucosa in gastric body and antrum[1]. The specificity of expression disappears in case of gastrointestinal mucosa injury[2]. TFF1 can be expressed in the whole injured mucosa, and its expression in injured mucosa is much higher than that in normal mucosa[3]. The purpose of this experiment was to observe the expression and patterns of TFF1 in normal and abnormal gastric tissues (gastric carcinoma, atypical

hyperplasia, and intestinalization) and to investigate the role TFF1 in the carcinogenesis and progression of gastric carcinoma and its molecular biological mechanism underlying gastric mucosa protection.

## MATERIALS AND METHODS

### Materials

Gastric antral specimens were obtained from a cohort undergone upper gastrointestinal endoscopy without abnormal appearance at Zhongshan Hospital affiliated to Xiamen University in June 2003. Two specimens were taken from each person and preserved in liquified nitrogen.

Paraffin specimens were obtained from 160 patients who underwent gastroscopic biopsy or radical gastric carcinomectomy during January 2002-June 2003 in Zhongshan Hospital affiliated to Xiamen University. The age of the patients ranged from 40 to 70 (53.2 ± 6.5) years. Of these 160 patients, 35 had normal gastric antrum mucosa, esophageal, gastric and duodenal tissues in gastroscopy and normal gastric mucosa in pathologic examination; 38 were diagnosed as gastric adenocarcinoma by pathologic examination; 36 as atypical hyperplasia; 35 as intestinalized gastric mucosa; and 20 as esophageal squamous carcinoma.

### Reagents

Sheep anti-human TFF1 multiclonal antibody (first antibody) and second antibody were purchased from Beijing Zhongshan Jinqiao Biotechnology Company, Ltd. EDTA, SDS and β-mercaptoethanol were obtained from Sigma Company. Acrylamide, protein-determination reagent and NC film were bought from Bio-Rad Company. ECL Western blotting reagents were from Amersham Company. Mice anti-human TFF1 monoclonal antibody, S-P super sensitive kit and DAB display kit were from Fuzhou Maixin Biotechnology Development Company.

### Western blot

Normal gastric mucosa specimens were added into buffer solution (containing 0.2 mmol/L sucrose, 10 mmol/L Tris, 1.5 mmol/L EDTA, 20 mmol/L β-mercaptoethanol, 1% PMSF, 1% DTT) preset at 4℃. After the solution was uniformly mixed, protein was extracted and its concentration was measured. One hundred and twenty ug of protein from each specimen was added into buffer solutions of the same volume. The solutions were boiled at 100℃ for 5 min. The proteins were isolated by acrylamide gel electrophoresis (5% aggregation gel of 70 V and 20% isolation gel of 120 V) for about 5 h. NC films were metastasized by 250 mA electricity in icy water for 90 min by wet metastasis method. The proteins were kept in confining liquid at room temperature for 30 min, inoculated in 1:200 first antibody at room temperature for 3 h and cleansed by PBS-T, and then inoculated in 1:4000 second antibody for 3 h, cleansed by PBS-T, and exposed to ECL in dark room.

### Immunohistochemical method

Specimens from normal and abnormal gastric tissues (gastric carcinoma, atypical hyperplasia, and intestinalized gastric mucosa) were fixed in 10% formaldehyde, routinely dehydrated, cleaned, infiltrated with wax, embedded and made into serial 4 μm thick sections. The sections were dewaxed, stained with SP method, displayed by DAB, stained again with hematoxylin and blown dry. The specific operations were carried out following the instructions on the S-P test kit.

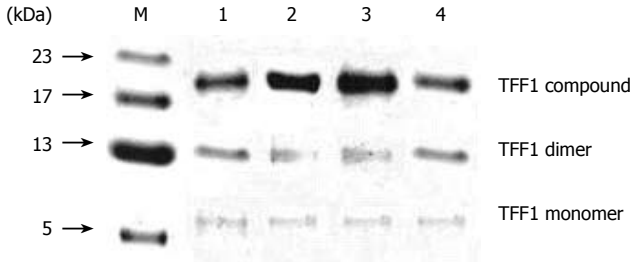

**Figure 1** Molecular forms of TFF1 in normal gastric mucosa by Western blot.

### Statistical analysis

All the data were analyzed by *t*-test using SPSS 10.0 software, and expressed as mean ± SD.

## RESULTS

### Western blot

Three patterns of TFF1 were found in normal gastric mucosa: monomer, dimer and TFF1 compound whose molecule weight is about 21 kDa. Among these three patterns, the concentration of TFF1 compound was the highest, followed by that of dimer, and monomer (Figure 1).

### Immunohistochemical method

Each section was photographed under 100 × high-power microscope. Motic Imaged Advanced 3.0 software was used to estimate the average positive *AO* of 20 glands randomly selected to reflect the intensity of TFF1 expression. The higher the *AO* was, the stronger the expression was.

TFF1 was expressed mainly in epithelial cytoplasm of the mucosa in gastric body and antrum, especially around the nuclei. The cytoplasm of positive cells was buffy after staining. The closer the TFF1 to the lumen, the deeper the color was. The expression of TFF1 in peripheral tissues of gastric carcinoma (0.51 ± 0.07) was higher than that in normal gastric mucosa (0.44 ± 0.06, $P < 0.001$). The expression of TFF1 in gastric adenocarcinoma was positively related to the differentiation of adenocarcinoma. The lower the differentiation of adenocarcinoma was, the weaker the expression of TFF1 was. No TFF1 was expressed in poorly-differentiated adenocarcinoma. The expression of TFF1 in moderately-well differentiated adenocarcinoma (0.45 ± 0.07) was a little lower than that in normal mucosa ($P > 0.05$). The expression of TFF1 in gastric mucosa with atypical hyperplasia (0.57 ± 0.03) was significantly higher than that in normal gastric mucosa ($P < 0.001$). No TFF1 was expressed in intestinalized gastric mucosa. There was no statistically significant difference between the expressions of TFF1 in gastric mucosa

**Table 1 Expression of TFF1 in gastric carcinoma and pathological changes prior to carcinogenesis (mean ± SD)**

| Classification | *n* | Average positive A |
|---|---|---|
| Normal | 35 | 0.44 ± 0.06 |
| Low-differentiated gastric carcinoma | 27 | None |
| Middle and highly differentiated gastric carcinoma | 11 | 0.41 ± 0.07[a] |
| Peripheral tissues of gastric carcinoma | 38 | 0.51 ± 0.07[b] |
| Atypical hyperplasia | 36 | 0.57 ± 0.03[b] |
| Intestinalization | 35 | None |
| Peripheral tissues of intestinalized mucosa | 35 | 0.45 ± 0.07[a] |
| Esophageal carcinoma | 20 | None |
| Peripheral tissues of esophageal carcinoma | 20 | None |

[a]$P > 0.05$ *vs* normal mucosa; [b]$P < 0.001$ *vs* normal mucosa.

around the intestinalized tissues (0.45 ± 0.07) and normal gastric mucosa ($P > 0.05$). No TFF1 was expressed in 20 specimens from patients with esophageal carcinoma (including peripheral tissues of carcinoma) (Table 1).

## DISCUSSION

Trefoil factor family (TFF) is a group of small molecule polypeptides and mainly secreted by gastrointestinal mucous cells. At present there are three kinds of trefoil peptides found in mammals, which are breast cancer-associated peptide (pS2 or TFF1), spasmolytic polypeptide (SP or TFF2) and intestinal trefoil factor (ITF or TFF3). These three patterns of TFF have a special structure, P-structure domain. This structure is composed of 38-39 amino acids sequenced by 6 highly conservative cysteine residues linked by three intramolecular disulfide bonds which make the whole peptide chain twisted and folded into trefoil-shaped structure[1]. Studies at home and abroad have proven that TFF plays an important role in protection and restitution of gastrointestinal mucosa[4-6].

TFF1, a member of TFF, was obtained from MCF-7 cell line of human mammary carcinoma by estrogen induction[7]. Each TFF1 molecule is composed of 60 amino acids and its molecular weight is 6674 kDa, including[8] cysteine residues, of which 6 take part in the constitution of P-structure domain and the 7th lies in the third base to the end of carboxyl side, i.e. $Cys^{58}$. Chadwick *et al*[5] replaced $Cys^{58}$ of recombinant TFF1 protein with $Ser^{58}$ and analyzed TFF1 containing $Ser^{58}$ by equilibrium ultracentrifugation, gel filtration, polyacrylamide gel electrophoresis, and mass spectrum. They found that homologous dimer could present in TFF1, but not in TFF1 analog containing $Ser^{58}$, suggesting that $Cys^{58}$ can form intermolecular disulfide bond and shape the dimer. In the present study, three patterns of TFF1 were found in normal gastric mucosa: monomer (6.5 kDa), dimmer and TFF1 compound whose molecule weight is about 21 kDa. The concentration of TFF1 compound was the highest among these three patterns, followed by that of dimer and monomer, indicating that the biological activity of TFF1 may be related to the formation of homologous dimmer or other oligomers composed of heterogenous proteins.

At present, there are two hypotheses concerning the mechanism underlying trefoil peptide protection in gastric mucosa. Trefoil peptide could bind to glycoprotein in mucus to form stable gel compounds, which could reinforce the mucous gel layer and decrease injury to mucosa by harmful substance in gastric surface and mechanical stress, *etc*. *In vivo* and *vitro* studies have shown that trefoil peptide can increase viscosity of mucous gel layer, decrease the ability of H+ to penetrate mucous gel layer and injuries to gastric mucosa[9]. Trefoil peptide is likely to accomplish its biologic function by binding to its receptor or transport protein. To find the possible receptor or transport protein and explore their mechanism are one of the hot topics in international studies on trefoil peptide[10-12]. TFF1 compound found in this study is likely composed of TFF1 and its receptor, transport protein or some glycoproteins. However, different molecules binding to TFF1 have been reported by different scholars. This diversity might be related to different experimental conditions, the ability of trefoil peptide to bind to different molecules, and the unstable structure of molecules binding to trefoil peptide. All the molecules are parts of the possible binding molecule. No consensus has been reached upon the real causes of the diversity. Moreover, no breakthrough has been made in finding the possible receptor or transport protein.

TFF1 is mainly expressed in epithelial cells of the mucosa in gastric body and antrum, but the specificity of expression disappears in pathological tissues[2]. TFF1 can be expressed in injured parts of gastrointestinal mucosa[3], much higher than that in normal mucosa. In the present study, the expression of TFF1 was higher in mucosa with peptic ulcer or gastritis, mucosa around gastric carcinoma and mucosa with stress ulcer induced by aspirin in rabbits than that in normal mucosa, which is consistent with other studies[13,14]. It has been proved that the expression of TFF1 is up-regulated in malignant carcinoma tissues. A hot topic of studies at home and abroad is whether carcinoma leads to the excessive expression of trefoil peptide. In mouse model of TFF1 gene knockout, all gastric epithelial cells showed severe hyperplasia, high dysplasia and adenoma in gastric antrum, which may develop into gastric infiltrative adenocarcinoma[15]. However, the excessive expression of TFF1 in mammal tissues of transgenic rat model does not lead to hyperplasia and dysplasia[16]. TFF1 could restrain proliferation of gastric adenocarcinoma cell line AGS and its inhibition is dose-dependent. TFF1 dimer has a much higher biologic activity than monomer[17], suggesting that TFF1 is a kind of tumor suppression factor. In our experiment, the expression of TFF1 in peripheral tissues of gastric adenocarcinoma was much higher than that in normal gastric mucosa, illustrating that TFF1 is relevant to tumor suppression. The formation of carcinoma promotes the secretion of TFF1 to restrain proliferation of carcinoma, leading to less or no expression of TFF1 in carcinoma tissues. The reasons why the lower the differentiation, the weaker the expression, might be as follows. The decreased expression of TFF1 may lead to formation of carcinoma, and destruction of glands and cells in carcinoma tissues may lead to decreased secretion of TFF1. The poorer the differentiation is, the

more seriously the glands and cells are destructed, the less the TFF1 is secreted and expressed. In our study, the expression of TFF1 in moderately-well differentiated adenocarcinoma was a bit lower than that in normal mucosa, but there was no statistically significant difference due to the limited specimens.

At present, more and more attention has been paid to the relationship between precancerous change and carcinogenesis. Intestinalized gastric mucosa and atypical hyperplasia are the most common pathological changes. Our study showed that the expression of TFF1 in atypical hyperplasia was much higher than that in normal mucosa. When the glands of gastric mucosa are not destroyed in early stage of gastric carcinogenesis, the secretion of TFF1 might be promoted to protect gastric mucosa against damage. in intestinalized gastric mucosa, TFF1 was expressed in peripheral tissues of intestinalized mucosa but not in intestinalized gastric. The possible reasons might be as follows. Goblet cells could not express TFF1, and lack of TFF1 induces intestinalization of epithelial cells in gastric mucosa, indicating that TFF1 might play a role in gastric carcinogenesis. Some studies showed that TTF1 can protect mucosa against damage and suppress carcinogenesis, while other studies showed that TTF1 can restrict cell adherence, promote cancer cell invasion, and block necrosis of cancer cells. These findings indicate that TFF1 may be an indicator of metastasis, carcinoma invasion, and poor prognosis[18,19]. Further study is needed to explore the relationship between trefoil peptide and carcinoma.

In addition, no TFF1 is expressed in esophageal carcinoma and its peripheral tissues, and TFF1 is irrelevant to esophageal carcinogenesis and suppression.

## Abstract

**AIM:** To rapidly quantify hepatitis B virus (HBV) DNA by real-time PCR using efficient TaqMan probe and extraction methods of virus DNA.

**METHODS:** Three standards were prepared by cloning PCR products which targeted S, C and X region of HBV genome into pGEM-T vector respectively. A pair of primers and matched TaqMan probe were selected by comparing the copy number and the Ct values of HBV serum samples derived from the three different standard curves using certain serum DNA. Then the efficiency of six HBV DNA extraction methods including guanidinium isothiocyanate, proteinase K, NaI, NaOH lysis, alkaline lysis and simple boiling was analyzed in sample A, B and C by real-time PCR. Meanwhile, 8 clinical HBV serum samples were quantified.

**RESULTS:** The copy number of the same HBV serum sample originated from the standard curve of S, C and X regions was $5.7 \times 10^4$/mL, $6.3 \times 10^2$/mL and $1.6 \times 10^3$/mL respectively. The relative Ct value was 26.6, 31.8 and 29.5 respectively. Therefore, primers and matched probe from S region were chosen for further optimization of six extraction methods. The copy number of HBV serum samples A, B and C was $3.49 \times 10^9$/mL, $2.08 \times 10^6$/mL and $4.40 \times 10^7$/mL respectively, the relative Ct value was 19.9, 30 and 26.2 in the method of NaOH lysis, which was the efficientest among six methods. Simple boiling showed a slightly lower efficiency than NaOH lysis. Guanidinium isothiocyanate, proteinase K and NaI displayed that the copy number of HBV serum sample A, B and C was around $10^5$/mL, meanwhile the Ct value was about 30. Alkaline failed to quantify the copy number of three HBV serum samples. Standard deviation (SD) and coefficient variation (CV) were very low in all 8 clinical HBV serum samples, showing that quantification of HBV DNA in triplicate was reliable and accurate.

**CONCLUSION:** Real-time PCR based on optimized primers and TaqMan probe from S region in combination with NaOH lysis is a simple, rapid and accurate method for quantification of HBV serum DNA.

**Key words:** Hepatitis B virus; Serum DNA; Real-time PCR; Extraction method

## INTRODUCTION

Hepatitis B virus (HBV) is a human hepadnavirus that causes acute and chronic hepatitis and hepatocellular carcinoma[1]. Although an effective vaccine has been available for two decades, an estimated 350 million people worldwide are chronically infected with HBV[2]. The conventional ways available for curing this disease are not very efficient. A significant proportion of chronic infections terminate in hepatocellular carcinoma, leading to more than one million deaths annually[3]. The diagnosis and clinical monitoring of HBV infection are based on the detection of viral antigens, antibodies to viral proteins, and circulating viral genome (HBV DNA)[4-6]. There is increasing evidence that measuring the level of HBV DNA in serum is useful in monitoring the efficacy of antiviral therapy, detecting the occurrence of drug-resistant mutants and relapse after discontinuing antiviral therapy[7-9]. An accurate quantitative assay for serum HBV

DNA may monitor residual viral load during treatment and allow the timely detection of flares of viral replication that accompany the emergence of variants.

In China, enzyme-linked immunosorbent assay (ELISA) is still a main detection method for HBV infection, but ELISA results neither efficiently reflect serum viral load or hepatitis activity nor monitor the efficacy of antiviral treatments. In recent years, real-time PCR detection assays based on SYBR Green I[10,11] and TaqMan probe[12-19] have been proposed for quantification of HBV DNA in serum. In the former assay, SYBR Green I can specifically bind to double-stranded DNA (dsDNA) rather than to single-stranded DNA (ssDNA). Fluorescence is monitored once each cycle after product extension and increases above background fluorescence at a cycle number that is dependent on the initial template concentration. Unfortunately, the dye detects all dsDNAs, including primer dimer and other nonspecific products.

The real-time PCR method based on the TaqMan probe uses a dual-labeled fluorescent probe containing a reporter dye that is quenched by a second fluorescent dye[20]. Hydrolysis of the probe by polymerase exonuclease activity separates the reporter from the quencher as the amplification proceeds, the fluorescence signal from the reporter increases cumulatively. The cycle at which fluorescence exceeds background, known as the threshold cycle, is inversely related to the initial copy number, thus allowing quantitative analysis.

The efficacy and accuracy of real-time PCR largely depend on the primers and probe[14,21], and are also related to the extraction method of HBV DNA[22,23]. A simple, rapid, efficient method for DNA extraction is crucial to the success of real-time PCR and the subsequent analysis. We describe here a rapid, convenient real-time quantitative assay for serum HBV DNA which combines optimized primers and probe with simple HBV DNA extraction method. The assay was designed to enable accurate quantification of clinical serum samples, which makes it a useful clinical test to monitor serially the efficacy of antiviral therapy.

## MATERIALS AND METHODS

### Preparation of standards

Serum HBV DNA was extracted by NaOH lysis as previously described[26]. In brief, 50 μL of HBV positive serum was mixed with an equal volume of 0.4 mol/L NaOH and then the mixture was incubated at 80℃ for 10 min, followed by centrifugation for 30 s at 15000 × *g*. After that the supernatant was carefully transferred to a new microcentrifuge tube and supplemented with 25 μL of 0.4 mol/L Tris-HCl (pH7.5). Two microliters of HBV DNA was used as a template in PCR.

Three pairs of primers were designed by software Beacon Designer 2.1 in the conserved region of S, C and X gene respectively and synthesized by Sangon Co., Ltd, Shanghai. The sequences of each pair of primers were as follows: RSU (5'-AGAATCCTCACAATACCGCAGAGT-3') and RSL (5'-CACACGGTAGTTCCCCCTAGAA-3'), RCU (5'-GTCTTTCGGAGTGTGGATTCG-3') and RCL (5'-CGGCGATTGAGACCTTCGT-3'), RXU (5'-ACTCCCCGTCTGTGCCTTCT-3') and RXL (5'-CATTCGGTGGGCGTTCAC-3').

Three amplified products were cloned into the pGEM-T vector (Promega, USA), and then the recombinant HBV plasmids pGEM-S, pGEM-C and pGEM-X were serially diluted from $10^7$ to $10^3$ copies/μL after identification by PCR. One microliter of each diluted recombinant plasmid was used as a standard PCR template.

### TaqMan probes

Taqman probes targeting S, C and X genes were designed by software Beacon Designer 2.1 and synthesized in Sangon Co., Ltd, Shanghai. The sequences of PS, PC, and PX were 5'FAM-AGACTCGTGGTGGACTTCTCTCAAT-TAMARA3', 5'FAM-TCCCCTAGAAGAAGAACTCCCTCGCCTC-TAMARA3', and 5'FAM-CCGGACCGTGTGCACTTCGCTT-TAMARA3', respectively.

### DNA extraction

Six methods (including guanidinium isothiocyanate, proteinase K, NaI, NaOH lysis, alkaline lysis, as well as boiling) were used to extract serum HBV DNA from three serum samples[24-28]. Two microliters of HBV DNA was used as a template in real-time PCR.

In the methods of GuSCN, proteinase K and NaI lysis, protocol after the lysis process was the same, though components of lysis were different. GuSCN lysate consisted of 1 mol/L Tris-HCl (pH8.0), 0.5 mol/L EDTA (pH8.0), 100 g/L SDS, 200 mg/L proteinase K[24]. Proteinase K lysate contained 10 mmol/L Tris-HCl (pH8.0), 10 mmol/L EDTA (pH8.0), 0.5% SDS, 150 mmol/L NaCl and 200 mg/L proteinase K[27]. NaI extraction buffer included 6 mol/L NaI, 0.5% SDS, 26 mmol/L Tris-HCl (pH8.0) and 13 mmol/L EDTA (pH8.0)[25]. First, 100 μL lysate was added into an equal volume serum, then the mixture was incubated at 37℃ for 1 h, 55℃ for 2 h and 60℃ for 15 min in GuSCN, proteinase K and NaI lysis methods respectively. After that, 200 μL chloroform/isoamyl alcohol (24:1) was added to extract products and the supernatants were removed into new eppendorf tubes after centrifugation at 15000 × *g* for 15 min, followed by alcohol precipitation and further washing[24,25,27]. At last, naturally dried DNA precipitates were dissolved in 30 μL 0.1 × TE.

The easily manipulated alkaline lysis and boiling extraction were similar to the above NaOH lysis, except for the lysate. The lysate used in alkaline lysis was composed of 1 mol/L NaOH, 2 mol/L NaCl and 0.5% SDS[26], while the boiling extraction consisted of an equal volume of PBS[28].

### Optimization of primers and probes

Real-time PCR amplification was performed in 20 μL

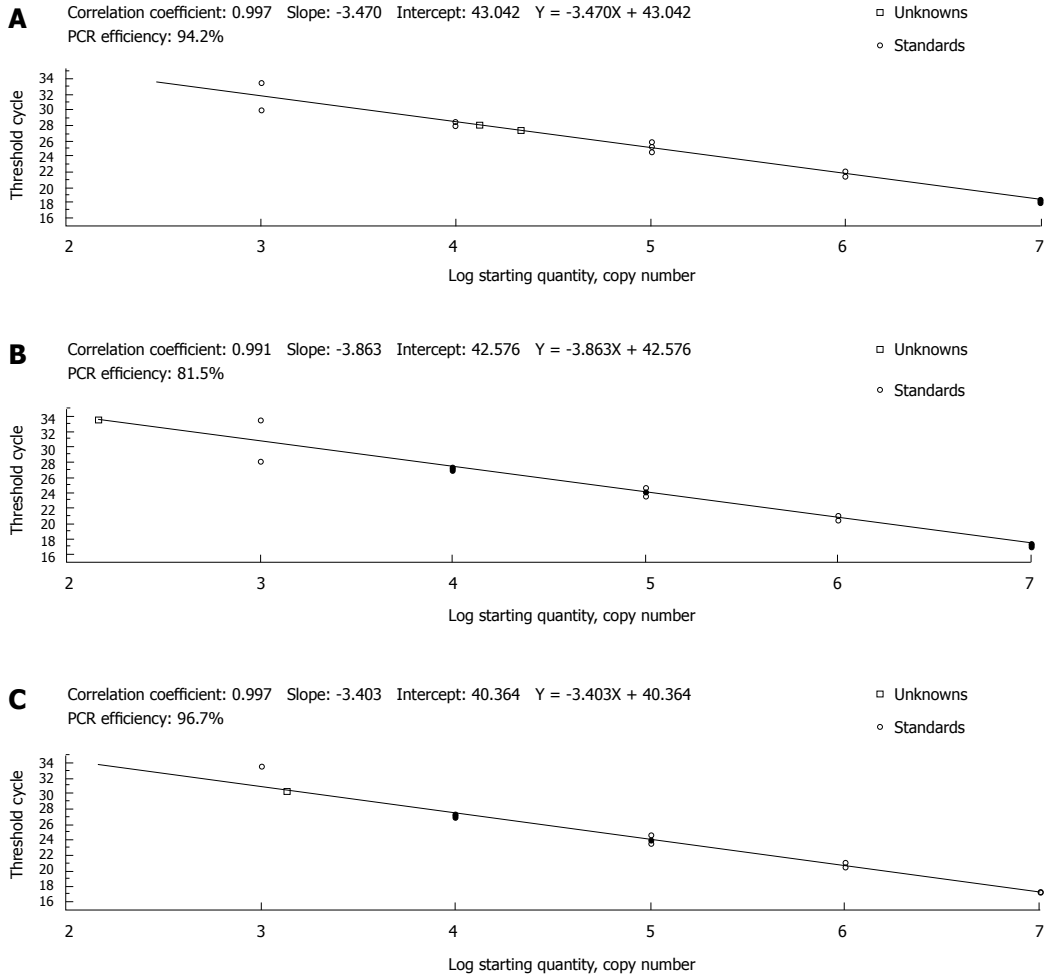

**Figure 1** Ct values and copy number of HBV serum samples originated from three standard curves corresponding to the S (**A**), C (**B**) and X (**C**) regions respectively. Each real-time PCR reaction was performed in triplicate.

reaction mixture containing 1 μL standard DNA or 2 μL isolated serum HBV DNA, 2 × PCR reaction buffer [100 mmol/L Tris-HCl (pH8.3), 100 mmol/L KCl, 7.0 mmol/L $MgCl_2$, 400 μmol/L each of the deoxynucleotide triphosphates (dNTP), 1U hot star DNA polymerase Takara, Japan], 5pmol of each pair of primers and 2.5 pmol of corresponding TaqMan probe. All amplification reactions were performed in triplicate. After preparation of the reaction mixtures in 96-well plates, amplification was performed as follows: initial denaturation at 94℃ for 3 min, followed by 40 cycles at 94℃ for 20 s, 60℃ for 40 s. Fluorescence readings were recorded at 60℃ in each cycle. Results were analyzed by the software iCycler$^{TM}$iQ 3.0a provided with the iCycler system (Bio-Rad, USA).

### *Evaluation of six DNA extraction methods*

To evaluate HBV DNA extraction methods, RSU, RSL primers and PS probe were used in real-time PCR. Amplification and analysis were performed as above.

### *Quantification of HBV viral DNA in sera by real-time PCR*

NaOH lysis was performed to extract serum HBV DNA from 8 clinical serum samples. The selected RSU, RSL and PS were used in real-time PCR. The procedures of real-time PCR and standard curve analysis were described as above.

**Table 1 Copy number and Ct values of HBV serum samples derived from three different standard curves (mean ± SD)**

| Standard curve | Ct | | Copy number ( /mL) | |
|---|---|---|---|---|
| | Mean ± SD | CV(%) | Mean ± SD | CV (%) |
| S | 26.6 ± 0.061 | 0.2 | $5.7 \times 10^4 \pm 2.29 \times 10^3$ | 4.0 |
| C | 31.8 ± 0.073 | 0.2 | $6.3 \times 10^2 \pm 2.73 \times 10^1$ | 4.3 |
| X | 29.5 ± 0.357 | 1.2 | $1.6 \times 10^3 \pm 1.77 \times 10^2$ | 11.1 |

CV: Coefficient variation.

## RESULTS

### *Linear standard curve and optimization of primers and TaqMan probes*

Three recombinant plasmids pGEM-S, pGEM-C and pGEM-X were used as standards to set up the real-time protocol and construct the standard curve. Forty cycles of amplification allowed us to obtain linear quantification between $1 \times 10^3$ and $1 \times 10^7$ copies/μL per reaction (Figure 1). The highest copy number ($5.7 \times 10^4$/mL) and the lowest Ct value (26.6) of the same HBV serum samples were observed from the standard curve originated from S region (Table 1). The lowest copy number ($6.3 \times 10^2$/mL) and the highest Ct value (31.8) were displayed from the

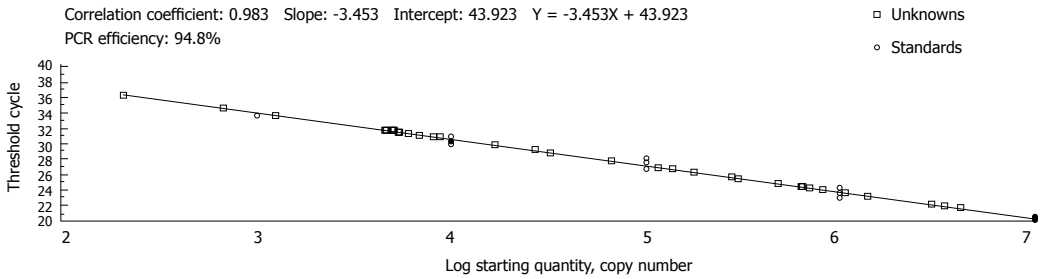

**Figure 2** A standard curve for evaluation of HBV DNA extraction methods.

**Table 2 Copy number and Ct values of HBV serum samples detected by six different extraction methods (mean ± SD)**

| Method | Copy number/mL and Ct value | | |
|---|---|---|---|
| | Sample A | Sample B | Sample C |
| Guanidinium isothiocyanate | $1.41 \times 10^5 \pm 1.23 \times 10^4$ | $1.92 \times 10^5 \pm 1.70 \times 10^4$ | $3.41 \times 10^4 \pm 3.65 \times 10^3$ |
| | 31.3 ± 0.16 | 30.9 ± 0.07 | 33.3 ± 1.59 |
| Proteinase K | $2.99 \times 10^5 \pm 2.88 \times 10^4$ | $2.21 \times 10^5 \pm 2.97 \times 10^4$ | $3.59 \times 10^5 \pm 5.10 \times 10^4$ |
| | 30.5 ± 0.19 | 30.3 ± 0.38 | 29.6 ± 0.38 |

CV: Coefficient variation.

standard curve of C region. The highest copy number from S region was about 90.5 and 35.6 multiple to the C and X regions. Hence, RSU, RSL primers and PS probe were chosen for further analysis because of the efficient amplification.

### *Different DNA extraction methods*

To explore a simple and fast method for serum HBV DNA extraction, six different methods were compared by real-time PCR in combination with selected primers and TaqMan probe from S region. The copy number and Ct values of three HBV serum samples on the standard curve (Figure 2 and Table 2) showed that NaOH lysis and boiling were predominately advantageous over the other methods. Adversely, alkaline lysis failed to detect any HBV DNA in all samples. There was no significant difference among the other three methods.

### *Quantitation of HBV viral DNA in sera by real-time PCR*

Table 3 indicated the copy number and Ct values of 8 positive HBV serum samples based on the optimized primers and TaqMan probe as well as DNA extraction. Their SD and CV unfolded that quantification of hepatitis B virus DNA in triplicate by real-time PCR was reliable and accurate.

## DISCUSSION

Detection and analysis of PCR products should be carried out simultaneously with temperature cycling during amplification. If the fundamental properties of DNA, such as product size, quantity, sequence, or melting profile can specifically identify the products during PCR, no further analysis is required.

Real-time PCR is a powerful diagnostic tool capable of rapidly generating reliable and reproducible results with reduced risks of cross contamination[29]. The amplification efficiency can be detected with fluorescent probes. All steps are accomplished automatically by computer except for sample preparation, which can monitor PCR reaction timely.

To make our assay more sensitive and efficient, we

optimized three pairs of primers and probes targeting the conserved S, C and X regions of HBV genome respectively. The highest copy number and Ct value of HBV serum samples were observed on the standard curve originated from S region. This indicated that the sensitivity of real-time PCR can be improved by adjusting primes and probe[21].

HBV DNA extraction from serum is a key step in real-time PCR, as it directly affects the accuracy of quantification of viral load. NaOH lysis showed that the highest copy number of HBV serum samples A, B, and C was $3.49 \times 10^8$/mL, $2.08 \times 10^6$/mL and $4.40 \times 10^7$/mL respectively. Boiling was as effective as NaOH lysis in DNA extraction from HBV serum samples A, B, and C. The copy number of HBV serum samples A, B, and C detected by boiling was $2.14 \times 10^8$/mL, $1.83 \times 10^6$/mL, and $1.48 \times 10^7$/mL, respectively. However, boiling was unsuitable for DNA extraction from serum with high viscidity[28].

Compared with the methods of NaOH lysis and boiling, guanidinium isothiocyanate, proteinase K and NaI decreased the copy number of HBV serum samples A, B and C to approximately $10^2$-$10^3$/mL. Proteinase K lysis was a bit better than the other two methods. In all three methods, the lysis was mixed with serum and extracted with chloroform/isoamyl alcohol (24:1), followed by precipitation and washing with absolute alcohol. A large quantity of DNA was lost due to the complicated process of these methods. DNA extraction with alkaline failed to detect serum DNA in our experiment, possibly due to the high concentration and pH value. On the contrary, 0.4 mol/L NaOH lysis followed by neutralization with 0.4 mol/L Tris-HCI (pH7.6) showed excellent efficacy because of a moderate alkaline concentration and lower pH value which may significantly improve the efficiency of PCR amplification.

In conclusion, real-time PCR based on the optimized primers, probe and DNA extraction is a simple, accurate, specific and sensitive method for the measurement of HBV viral load in serum. NaOH lysis for HBV serum DNA extraction is rapid, simple and efficient, making the assay suitable for handling a large number of clinical HBV serum samples. Since there are about 200 million HBV carriers in China, doctors need to know the HBV status of patients before starting any medical treatment. This assay may be especially useful for monitoring the therapeutic effects in chronically infected patients on antiviral therapy.

## ACKNOWLEDGMENTS

We thank Professor Xian-Rang Song from Shandong Cancer Hospital for his technical support.

## Abstract

**AIM:** To investigate the causes of small intestinal bleeding as well as its diagnosis and therapeutic approaches.

**METHODS:** A retrospective analysis was conducted according to the clinical records of 76 patients with small intestinal bleeding admitted to our hospital in the past 5 years.

**RESULTS:** In these patients, tumor was the most frequent cause of small intestinal bleeding (37/76), followed by Meckel's diverticulum (21/76), angiopathy (15/76) and ectopic pancreas (3/76). Of the 76 patients, 21 were diagnosed by digital subtraction angiography, 13 by barium and air double contrast X-ray examination of the small intestine, 11 by $^{99m}$Tc-sestamibi scintigraphy of the abdominal cavity, 6 by enteroscopy of the small intestine, 21 by laparoscopic laparotomy, and 4 by exploratory laparotomy. Although all the patients received surgical treatment, most of them (68/76) received part enterectomy covering the diseased segment and enteroanastomosis. The follow-up time ranged from 1 year to 5 years. No case had recurrent alimentary tract bleeding or other complications.

**CONCLUSION:** Tumor is the major cause of small intestinal bleeding followed by Meckel's diverticulum and angiopathy. The main approaches to definite diagnosis of small intestinal bleeding include digital subtraction angiography, $^{99m}$Tc-sestamibi scintigraphy of the abdominal cavity, barium and air double contrast X-ray examination of the small intestine, laparoscopic laparotomy or exploratory laparotomy. Part enterectomy covering the diseased segment and enteroanastomosis are the most effective treatment modalities for small intestinal bleeding.

## INTRODUCTION

Due to the lack of specific clinical symptoms and physical signs of small intestinal bleeding and the limitations in the present diagnostic methods for tumors inside the alimentary tract, early diagnosis of small intestinal bleeding is difficult[1-3]. In this article, we retrospectively reviewed and analyzed the diagnostic and therapeutic experiences with 76 cases of small intestinal bleeding patients admitted to our hospital between April 1999 and April 2004.

## MATERIALS AND METHODS

### *Clinical data*

A total of 76 patients with small intestinal bleeding (44 males and 32 females) were included in the present study. Their age ranged from 15 to 74 years with a mean of 43.5 years. Alimentary tract hematorrhea occurred in all 76 patients. Intermittent dark and bloody stools were found in 57 patients and recurrent dark and bloody stools in 19 with hemorrhagic shocks. Forty patients had accompanying abdominal pain, 4 had accompanying fever and 6 had tangible abdominal lumps.

### *Diagnosis procedures*

All the 76 patients underwent gastroduodenoscopy, colonscopy, barium meal examination or barium enema to exclude the possible lesions in the stomach, duodenum, colon or rectum. Barium and air double contrast X-ray examinations of small intestine were performed in 43 patients, of them 12 were diagnosed having small intestinal tumors including 1 having Meckel's diverticulum. $^{99m}$Tc-sestamibi scintigraphy of the abdominal cavity (ECT) was performed in 36 patients (Figure 1A and 1B). Of them, 16 were definitely diagnosed having small intestinal

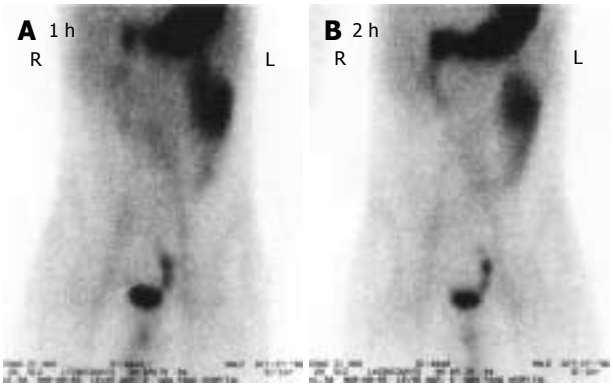

**Figure 1** ECT examination showing small intestinal bleeding at 1 h (**A**) and 2 h (**B**) after intravenous injection of the tracer. Serial planar imaging (1, 5, 15 and 30 min, 1 and 2 h) of the whole abdomen was performed. There was a radioactive accumulation at 5 min on the upper-left corner of the gall bladder, becoming increasingly dense till 2 h. Its emerging time was almost simultaneously as the image of the stomach with the density being slightly lower than that of the stomach image. During the whole period of imaging, its location was comparatively stable. The dynamic imaging of the whole abdomen showed an abnormal radioactive imaging near the upper-left corner of the gall bladder, which was considered the ectopic stomach mucous tissue inside the Meckel's diverticulum.

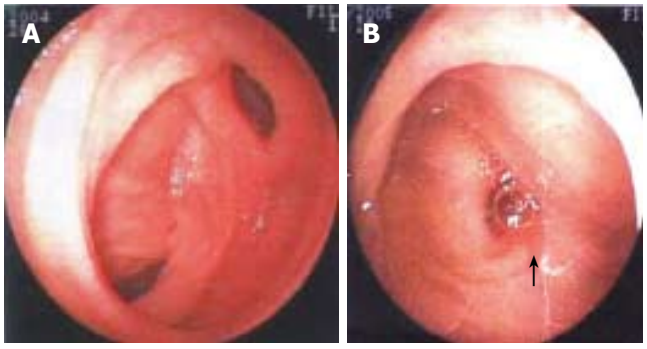

**Figure 2** Double-balloon enteroscopy showing small intestinal bleeding (**A**) and Meckel's diverticulum (**B**). Double-balloon enteroscope was pushed 200 cm into the ileum through the anus. There was a diverticulum in the ileum 90-100 cm away from the ileocecal valve, at the opening of which there was an ulcer (1.2 cm × 1.0 cm). The ulcer was covered by a thin lichenoid substance without active bleeding. No other abnormalities were found. The diagnosis of Meckel's diverticulum was established.

bleeding including 4 having Meckel's diverticulum and 2 having small intestinal tumor. Of the 25 patients who received small intestine enteroscopy, 11 had suspected small intestinal bleeding, and 6 had Meckel's diverticulum (Figure 2A and 2B). Of the 24 patients who received digital subtraction angiography (DSA), 18 were found to have definite small intestinal bleeding, 2 having Meckel's diverticulum and 6 having small intestinal tumor. Of the 21 patients who received laparoscopic laparotomy, 4 had Meckel's diverticulum, 4 had definite small intestinal bleeding (Figure 3A and 3B).

## RESULTS

Tumor was the major cause of small intestinal bleeding, which was found in 37 patients. Of these patients 29 were found to have benign stromal tumor, 3 had malignant stromal tumor and 5 had adenocarcinoma (Figure 4A and

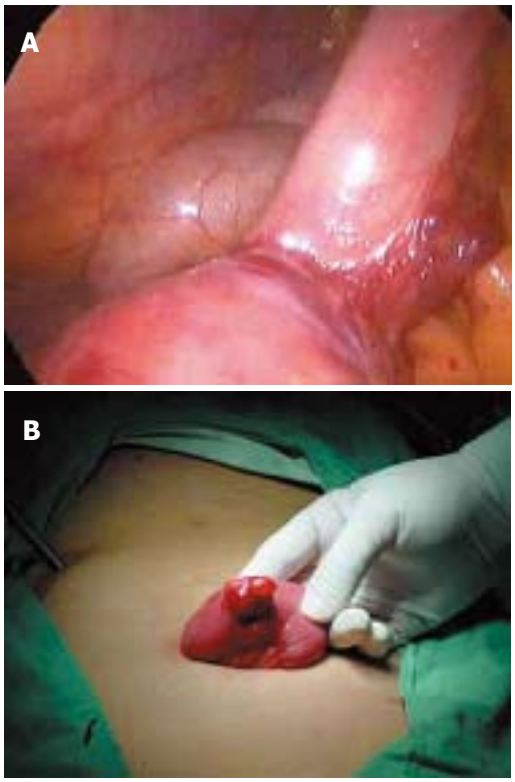

**Figure 3** Laparoscopic laparotomy showing small intestinal bleeding (**A**) and oval stromal tumor (**B**). An oval stromal tumor was found on the upper segment of jejunum with clear borderline and smooth surface but without adhesion to other tissues during laparoscopic laparotomy. Expansive abdominal excision was performed to draw out the tumor.

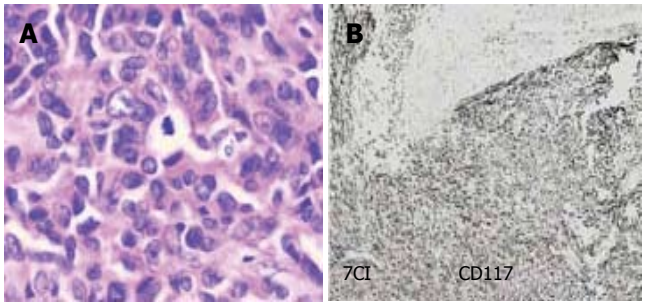

**Figure 4** Pathological and immunohistological examination of small intestinal bleeding caused by small intestinel stromal tumor. Arrangement of tumor cells in interlock weaving form with abundant cytoplasm, light staining, unclear borderline and diffused infiltration of chronic inflammatory cells but without necrosis and hemorrhage, karyokinesis could be seen (in the middle of **A**). Immunohistochemical findings were as follows: CD117 (+) (**B**), CD34 (-), S-100 (-), Vimentin (weak +) (HE × 200).

4B). Other causes of small intestinal bleeding included Meckel's diverticulum, angiopathy and ectopic pancreas, which were observed in 21, 15 and 3 patients, respectively. Jejunum bleeding in the small intestine was found in 38 (50%), ileum bleeding in 31 (40%) and multi-foci bleeding in 7 (10%) patients, respectively.

All the patients received surgical treatment, of them 49 received part enterectomy covering the diseased segment and enteroanastomosis, 12 had laparoscopic part enterectomy covering the diseased segment and enteroanastomosis, 9 had laparoscope-assisted

part enterectomy covering the diseased segment and enteroanastomosis, 3 had partial excision of ileum and half of the right colon for intestinal cancer, and 3 had conservative excision of intestinal cancer.

One patient with small intestine stromal tumor had recurrent bleeding 10 d after the operation. Stomal ulcer was confirmed by laparotomy and the stoma was then removed. Postoperative death occurred in 3 patients, of them 2 died of disseminated intravascular coagulation (DIC) and 1 of severe general infection. The rest 73 patients were cured and discharged from the hospital. Their follow-up time ranged from 1 year to 5 years with a mean of 2.8 years. By the time of this retrospective analysis, all these people were alive except for 2 deaths due to recurrent malignant stromal tumor of the small intestine and 3 deaths due to small intestinal adenocarcinoma. Those who were still alive at the time of this analysis had no alimentary tract bleeding or other complications.

## DISCUSSION

The 3-5 m long small intestine accounts for 75% of the whole gastrointestinal tract. The ansa intestinalis is long-winding and overlapping with active peristalsis and its position in the abdominal cavity varies greatly. Therefore, quick and accurate determination of the cause and foci of small intestinal bleeding is a great challenge for surgeons in clinical practice[1-4]. For unknown causes of alimentary tract bleeding, endoscopy should be first performed to exclude the possible lesions in stomach, duodenum, colon or rectum in order to confirm the bleeding originating from small intestinal segment inferior to duodenum. Subsequently, the bleeding causes can be diagnosed through related examinations.

Small intestine enteroscopy or barium and air double contrast X-ray examination of small intestine can be performed in patients with their bleeding arrested or with little bleeding and stable vital signs to determine the cause of bleeding[2,4]. ECT, DSA, exploratory laparotomy or laparoscopic laparotomy should be performed in patients with unstable vital signs and active bleeding as early as possible to determine the bleeding foci. B-mode ultrasonography or CT scanning should be carried out in patients with abdomen lumps to determine the origin and type of lumps as well as the interrelation with its neighboring organs.

Due to the lack of specific clinical symptoms and physical signs of small intestinal bleeding and the limitations of the present diagnostic approaches to finding lesions inside the alimentary tract, the early diagnosis of small intestinal bleeding is difficult. Barium and air double contrast X-ray examinations of small intestine are the most widely used methods for the diagnosis of small intestinal bleeding. However, since the foci of small intestinal bleeding usually grow outwards, it is difficult to show the tumor, thus resulting in false negatives. Of the 43 patients who received double-contrast radiology of small intestine, 13 were found to be positive for small intestinal bleeding, including 12 cases of small intestinal tumor and 1 case of Meckel's diverticulum.

Diagnosis of small intestinal bleeding by enteroscopy is time-consuming[5-7]. It is unpleasant for patients and may result in complications of bleeding and perforation or has a high rate of false negative, therefore, its clinical application is confined[8,9]. Recently, a capsule endoscope is under clinic experiment, but this examination cannot perform biopsy and make pathological diagnosis[10-12]. Of the 25 patients who received enteroscopy of small intestine more than once, 11 had suspected small intestinal bleeding and 6 had small intestinal bleeding. The diagnosis rate was less than 8%. Small intestine enteroscopy was performed 5 times in one stromal tumor patient with no positive findings. DSA is the most effective approach to diagnosis of alimentary tract bleeding which shows specific signs of tumor and angiopathy, while embolismic therapy can be performed during DSA diagnosis[3,4]. However, embolismic therapy for small intestinal bleeding has unsatisfying therapeutic efficacy. Even if the embolism is hyper-selective, hematorrhea could reoccur in several hours. Of the 24 patients who underwent DSA, 18 were found to be positive for small intestinal bleeding (including angiopathy in 3, small intestinal stromal tumorin 5, and small intestinal diverticulum in 2 patients). Hematorrhea reoccurred 4-6 h after the embolismic therapy in all the patients.

$^{99m}$Tc-marked erythrocytes for alimentary bleeding imaging are more sensitive to minor intestinal bleeding, and can only determine the position of the bleeding foci[4]. Of the 36 patients who received $^{99m}$Tc-sestamibi scintigraphy, 16 had positive findings of Meckel's diverticulum. Abdominal B-mode ultrasonography and CT scanning have limited diagnostic value because stromal tumor, angiocavernoma and Meckel's diverticulum of small intestine are usually small[13]. Of the patients who received CT scanning, only 4 were found to have abdominal lumps before the operation and none of them could be located. However, CT scaning can display the surrounding tissues of tumor and the involved organs, showing the origin and type of tumor as well as interrelation with its neighboring organs. Based on such findings, distant metastasis can be judged, suggesting that this diagnostic way provides valuable reference for surgical treatment.

Tumor is the major cause of small intestinal bleeding followed by diverticulum and angiopathy of small intestine. Most stromal tumors found in patients with intestinal bleeding caused by tumor are usually benign in nature. Stromal tumors are more common than small intestinal adenocarcinoma, which is not entirely consistent with other studies. Meckel's diverticulum and angiopathy are the second and third-frequent causes of small intestinal bleeding in such patients. The data reveal that jejunum bleeding often indicates small intestine stromal tumor, while ileum bleeding often originates from Meckel' s diverticulum. There is no definite location of small intestinal angiopathy, but most cases of angiopathy occur in the middle section of small intestine. Angiocavernoma is commonly restricted yet vascular malformation is usually multi-foci, distributing in segments or even spreading along the entire small intestine and its mesentery.

Because of the difficult location and diagnosis of small intestinal bleeding as well as the cautious attitude of surgeons, surgical treatment is only considered for patients with more-than-once negative test results,

recurrent hematorrhea and therapeutic failure. Exploratory laparotomy should be performed as early as possible for patients with unknown alimentary tract bleeding causes or for patients who have no specific cause discovered in various clinical examinations. However, patients with hematorrhea in small intestine are generally in poor conditions with unstable vital signs and are usually too vulnerable to receive major operation because they have missed the best time for operation. All the 3 deaths occurred due to the delayed operation. Once the diagnosis is made, different surgical procedures should be adopted according to the nature, location and area of the lesion. Part enterectomy covering the diseased segment and enteroanastomosis should be performed for patients with small intestinal stromal tumor, Meckel's diverticulum, ectopic pancreas, individual hemangioma and confined vascular malformation. The complete diseased segment of small intestine should be removed in patients with recurrent hemangioma and extensive vascular malformation. But excessive removal of small intestine lesion has to be prevented because short intestinal syndrome may occur.

Laparoscopic laparotomy can clearly and conveniently observe the small intestinal serosa and mesentery. It can assist in the management of discovered lesions. When the focus is discovered by laparoscopy, either laparoscope-assisted enterectomy covering the diseased segment and enteroanastomosis or laparoscopic enterectomy covering the diseased segment and enteroanastomosis can be performed[14-18]. Since December 2002, we have made efforts in applying laparoscope to examine unknown alimentary tract hematorrhea causes that were formerly imperative to laparotomy in 21 patients. The results show that laparoscope-assisted operation has the advantages of quicker location of the focus with noninvasive trauma, less pain and shorter recovery time. Therefore, laparoscope-assisted operation should be set up as the routine method for the treatment of small intestinal hematorrhea[13,15,17,18].

Patients whose bleeding causes could not be specified by laparoscopic laparotomy have only less bleeding from the small intestine that is mostly caused by ectopic pancreas or small intestinal stromal tumor, which is also difficult to locate by exploratory laparotomy. Alternatively, small intestinal enteroscopy during laparoscopy can be carried out by making use of the light-source atop the enteroscope to take fluoroscopy of the suspected area. This in combination with what is seen under the laparoscope usually leads to positive findings. Of the patients who received small intestinal enteroscopy during laparoscopy in this study, 4 had lesions which were cured.

In conclusion, tumor is the major cause of small intestinal bleeding followed by Meckel's diverticulum, angiopathy, and ectopic pancreas. The main diagnostic approaches are barium and air double contrast X-ray examinations of small intestine, DSA and ECT. Laparoscopic laparotomy or exploratory laparotomy should be performed for patients with long-term alimentary tract bleeding for unknown reasons as soon as possible. Enterectomy covering the diseased segment and enteroanastomosis are the most effective treatment modalities.

## Abstract

**AIM:** To investigate the therapeutic efficacy and complications of splenectomy with endoscopic variceal ligation (EVL) and splenectomy with pericardial devascularization (i.e. Hassab's operation) in patients with portal hypertension.

**METHODS:** A total of 103 patients with liver cirrhosis and portal hypertension were randomly selected to receive either splenectomy with EVL ($n$ = 53, group A) or Hassab's operation ($n$ = 50, group B).

**RESULTS:** The portal blood flow volume, the presence of portal vein thrombosis, gastric emptying time and free portal venous pressure (FPP) before and after the operation were determined. Patients were followed up for up to 64 mo with an average of 45 mo, and the Dagradi classification of variceal veins and the grading of portal hypertension gastropathy (PHG) were evaluated. It was found that all esophageal varices were occluded or decreased to grade Ⅱ or less in both groups. There was little difference in the recurrence rate of esophageal varices (11.9% *vs* 13.2%) and the re-bleeding rate (7.1% *vs* 5.3%) between groups A and B. The incidence of complications and the percentage of patients with severe PHG after the operation were significantly higher in group B (60.0% and 52.0%) than in group A (32.1% and 20.8%, $P < 0.05$). No patients died of operation-related complications. There was no significant difference in gastric emptying time, FPP and portal blood flow volume between the two groups.

**CONCLUSION:** The results suggest that splenectomy with EVL achieves similar therapeutic efficacy to that of Hassab's operation in terms of the recurrence rate of esophageal varices and the re-bleeding rate, but the former results in fewer and milder complications.

**Key words:** Portal hypertension; Splenectomy; Endoscopic varices ligation; Hassab's operation

## INTRODUCTION

Recurrent bleeding occurs in over 70% of portal hypertension patients with a variceal bleeding history[1]. It is a general consensus that all patients with a variceal bleeding history should accept further treatment to prevent re-bleeding. Surgical operations still play a role in this process[2]. Since hepatitis-induced cirrhosis is the main cause of portal hypertension in China, which is associated with increased hepatocellular damage and worsened liver function, splenectomy with pericardial devascularization (i.e. Hassab's operation) has been widely used because of its minor influence on liver function[3,4]. However, this operation has its limitations, including a high incidence of portal vein thrombosis, serious gastric mucosa damage and gastric emptying delay after operation[5-8].

The benefits of endoscopic management in preventing re-bleeding have been explicitly illustrated in a series of well designed randomized controlled trials[9,10]. Sclerotherapy significantly decreases the recurrence of bleeding and mortality, but it is associated with serious complications, the most common of which are esophageal strictures and bleeding from treatment-induced ulcers[11]. More recently, endoscopic variceal ligation (EVL) has been proven as an endoscopic therapy at least as effective as sclerotherapy, but with fewer complications. Meta-analyses have revealed that variceal ligation can more significantly reduce re-bleeding than sclerotherapy (POR = 0.53, 95% CI: 0.42 to 0.67), without significant heterogeneity amongst trials[12,13]. However, EVL still results in the re-bleeding rate as high as 30%, and does not help to relieve

portal hypertension and hypersplenism[14].

Theoretically, combining splenectomy with EVL should relieve not only portal hypertension but also hypersplenism, and thus prevent the bleeding of esophageal varices[15]. Meanwhile, avoiding the procedure of devascularization may overcome its associated limitations as mentioned above. In this study, we compared the therapeutic efficacy of splenectomy combined with EVL with that of Hassab's operation and their respective complications in patients with portal hypertension.

## MATERIALS AND METHODS

### Patients

From January 1999 to June 2002, 103 consecutive patients (61 males and 42 females) with portal hypertension caused by hepatitis-induced cirrhosis were admitted to the Third Affiliated Hospital of Sun Yat-Sen University Hospital. All these patients were recruited in this prospective study.

The inclusion criteria included clinically diagnosed portal hypertension caused by hepatitis-induced cirrhosis in patients with endoscopically confirmed esophageal varices and a history of upper gastrointestinal hemorrhage, and functional hepatic reserve of grade A or B according to the Pugh-modified Child's scales.

The exclusion criteria included portal hypertension caused by reasons other than hepatitis-induced cirrhosis in patients with functional hepatic reserve of grade C by the Child-Pugh classification, peptic ulcer or other gastrointestinal complications, severe diseases in major organs other than in liver and/or age over 70 years.

The recruited patients were randomly assigned to group A or B with the use of opaque, sealed envelopes that contained a treatment assignment derived from computer-generated random numbers. Randomization was stratified according to the severity of liver failure (assessed by the Child-Pugh classification system). All the patients were cared for at the Department of General Surgery, Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China. A written informed consent was obtained from all the patients, and the trial was approved by the Ethics Committee of Sun Yat-Sen University. The study protocol is shown in Figure 1.

### Pre-operative endoscopic examination

All the patients received a pre-operative endoscopic examination. The esophageal varix was evaluated by Dagradi classification[16,17], while the portal hypertensive gastropathy (PHG) was graded as mild, moderate or severe as previously described[18,19].

### Gastric emptying assessment

Gastric emptying was assessed with a standardized scintigraphy method[20]. In brief, a test meal was prepared by mixing sixty grams of fat-parched flour (16 g protein, 3.24 g fat and 80 g carbohydrate, 924.7 KJ per 100 g) with hot water containing 37-74 mBq of 99 mTc-DTPA to form a portion of semi-solid general meal. Each patient consumed a portion of the test meal within 5 min at a sitting position. Time to half-emptying of gastric contents, lag-phase calculation and residual gastric contents at 60, 120 and 240 min were calculated by a GENESYS SPECT system (ADAC, Laboratories, Milpitas, CA, USA).

### Splenectomy combined with endoscopic varices ligation

Patients assigned to group A ($n$ = 53) initially underwent routine splenectomy, and EVL was performed right after the splenectomy. After local application of lidocaine, an endoscope (GIF 240 or 260, Olympus Optical, Tokyo) was introduced, and ligation was carried out 6-12 times by placing a single rubber band (Bard Interventional Products, Tewksbury, Mass USA) over a varix each time. The ligation was repeated every 2 wk till the varices completely disappeared under the endoscope.

### Hassab's operation

Patients assigned to group B ($n$ = 50) underwent Hassab's operation as previously described in detail by Yang and Qiu[3]. In brief, extended left subcostal incision or L incision of the left upper abdomen was used for extreme splenomegaly. After routine splenectomy, the gastric branch and 5-8 small branches of the gastric coronary veins were disconnected. The esophageal branch was disconnected and suture-ligated. The gastric posterior vein was ligated by suturing, and then the left subphrenic vein was ligated as well[21]. In addition, the arteries accompanied by the veins including the left gastric artery, left gastroepiploic artery, gastric posterior artery and left subphrenic artery, were disconnected.

### Determination of portal vein hemodynamics

Free portal venous pressure (FPP) was measured before and after splenectomy (after the first EVL in group A) by inserting the measuring tube in the main portal vein through the right gastroepiploic vein during the operation, as described previously[22].

### Color Doppler ultrasound

Color Doppler ultrasound detection was performed 2 wk before and 3 wk after the operation by a color Doppler ultrasound system (Biosound AU 4, Esaote, Italy). For each measurement, at least 3 reproducible patterns were created to calculate the mean maximum portal blood velocity ($V_{max}$) to ensure the measurement accuracy. Mean portal blood velocity ($V_{mean}$) was calculated (cm/s) by the equation "$V_{mean} = 0.57 \times V_{max}$" as described by Moriyasu *et al*[23]. The cross-sectional area ($cm^2$) was also recorded at the site of the main portal vein where the portal blood velocity was measured. Portal blood flow volume (PBF) was obtained (mL/min) by the equation "PBF = Area × $V_{mean}$ × 60". The presence of portal vein thrombosis was examined as well[24,25].

### Follow-up of patients

All patients were followed up by endoscopy at wk 2, 4 and 12 after operation, and every 12 wk thereafter (Figure 1). Gastrointestinal symptoms such as refractory hiccup, bilious vomiting, hematemesis and dark stools were recorded. The Dagradi classification and PHG grading were evaluated at the follow-up endoscopy as described above.

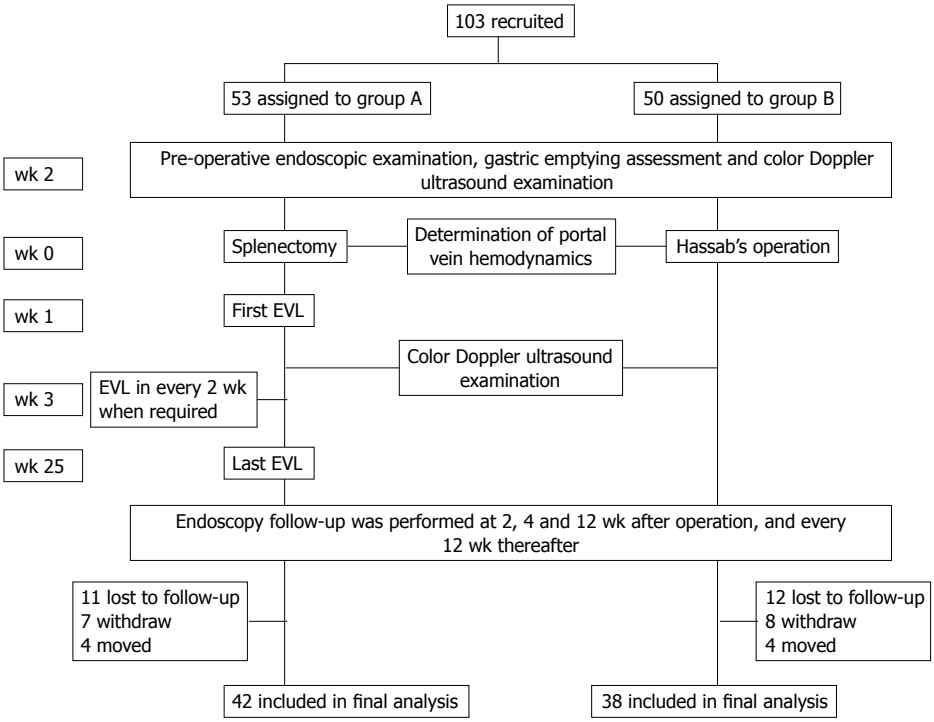

**Figure 1** The study protocol and the number of patients studied.

### *Statistical analysis*

Values were expressed as mean ± SD. Mean differences between the two groups were calculated by unpaired *t* test. Mann-Whitney test was used for the analysis of ranked data. The comparison of categorical data was performed by the $\chi^2$ test. $P < 0.05$ (2-tailed test) was considered statistically significant.

## RESULTS

### *Efficacy on esophageal varices*

A total of 154 EVLs were performed in group A, with a mean of 3.2 (2-5) EVL sessions per patient. All esophageal varices were occluded or decreased from grade Ⅲ to grade Ⅱ (Dagrade classification) in both groups.

A total of 80 patients were followed up for 24.5-64 mo with an average of 45 mo. Eleven patients in group A and 12 patients in group B were not followed up due to death or other reasons (3 died of liver cancer,5 died of hepatic failure, 15 lost contact). The recurrence rate of esophageal varices was 11.9% (5/42) in group A and 13.2% (5/38) in group B, while the re-bleeding rate was 7.1% (3/42) in group A and 5.3% (2/38) in group B ($P > 0.05$).

### *Complications*

No patients in both groups died of operation-related complications. The common complications included infection, worsened liver function (i.e. increasing jaundice), refractory ascites and pleural effusion. The incidence of complications in group B was higher than that in group A (60% *vs* 32.1%, $P < 0.01$). Mild pharyngodynia and/or retrosternal pain were found in most patients in group A, but they were relieved 3-5 d later without medical treatment. Esophageal ulcer-induced re-bleeding was found in 2 patients at 2 wk after the operation, but the bleeding was stopped by repeated EVL and medical treatment.

**Table 1 Incidence of complications after operation**

| Complications | Group A ($n$ = 53) | | Group B ($n$ = 50) | | Value | |
|---|---|---|---|---|---|---|
| | $n$ | % | $n$ | % | $\chi^2$ | $P$ |
| Total cases with complications | 17 | 32.1 | 30 | 60 | 4.85 | 0.01 |
| Refractory ascites | 3 | 5.7 | 9 | 18 | 4.65 | 0.03 |
| Pleural effusion | 5 | 9.4 | 16 | 32 | 5.63 | 0.02 |
| Esophageal ulcer | 2 | 3.8 | 0 | 0 | 6.56 | 0.03 |
| Portal vein thrombosis | 5 | 9.4 | 11 | 22 | 3.25 | 0.03 |
| Refractory hiccup | 2 | 3.8 | 15 | 30 | 5.46 | 0.02 |
| Bilious vomiting | 3 | 5.7 | 16 | 32 | 3.65 | 0.01 |

Incomplete portal vein thrombosis was found in 7 patients (13%) in group A as detected by color Doppler ultrasound, and disappeared after anticoagulation treatment. In group B, 14 patients (28%) suffered from portal vein thrombosis ($P < 0.01$, compared with group A), while one patient presented with widespread thrombi in the main portal vein and the portal vein branch, and died of sponge-like lesions in the portal vein and liver function failure 6 mo after the operation, despite thrombolysis treatment. Significant differences were found in the incidence of refractory hiccup, bilious vomiting and the degree of gastric motility between the two groups ($P < 0.05$) (Table 1).

### *Endoscopic follow-up of PHG*

The PHG grading increased significantly after the operation in patients of group B, but not in patients of group A (Table 2). The percentage of patients with severe PHG after the operation was 20.8% in group A and 52.0% in group B ($P < 0.05$) (Table 2). Three patients in group B suffered from hematemesis, which was evidenced by dark stools and/or a positive fecal occult blood test more than

**Table 2 PHG grading before and after operation *n* (%)**

| PHG grading | Group A (*n* = 53) | | Group B (*n* = 50)[a] | |
|---|---|---|---|---|
| | Pre-operation | Post-operation | Pre-operation | Post-operation |
| Normal | 3 (5.66) | 2 (37.74) | 5 (10.00) | 2 (4.00) |
| Mild | 25 (47.17) | 23 (43.40) | 27 (54.00) | 8 (16.00) |
| Moderate | 17 (32.08) | 17 (32.08) | 13 (26.00) | 14 (28.00) |
| Severe | 8 (15.09) | 11 (20.75) | 5 (10.00) | 26 (52.00)[c] |

[a]$P < 0.05$ *vs* post-operation; [c]$P < 0.05$ *vs* post-operation in group A.

**Table 3 Alteration of gastric emptying time after operation (mean ± SD)**

| Time points | Gastric emptying time (min) | |
|---|---|---|
| | Group A (*n* = 53) | Group B (*n* = 50) |
| Before operation | 55 ± 10 | 54 ± 8 |
| 3 wk after operation | 53 ± 8 | 64 ± 7 |
| 6 wk after operation | 51 ± 9 | 62 ± 6 |
| 12 wk after operation | 54 ± 8 | 58 ± 8 |

There was no significant difference in the gastric emptying time between the two groups at each time point, or among the four time points in each group.

**Table 4 Alterations of portal vein pressures and hemodynamic variables (mean ± SD)**

| | Group A (*n* = 53) | | | Group B (*n* = 50)) | | |
|---|---|---|---|---|---|---|
| | Pre-operation | Post-operation | *P* | Pre-operation | Post-operation | *P* |
| Free portal venous pressure ($cmH_2O$) | 37.1 ± 4.67 | 29.02 ± 4.34 | 0.02 | 38.1 ± 4.47 | 31.02 ± 4.3 | 0.02 |
| $V_{max}$ (cm/s) | 19.51 ± 4.30 | 15.90 ± 3.12 | 0.01 | 18.54 ± 3.30 | 14.90 ± 2.12 | 0.01 |
| Blood flow (mL/min) | 1100.84 ± 351.8 | 852.25 ± 292 | 0.02 | 1120.84 ± 341.84 | 852.25 ± 292.35 | 0.02 |

1 wk, and further confirmed as PHG-related hemorrhage by endoscopic examination.

### *Alteration of gastric empty time*

No significant difference was found in gastric emptying time between the two groups at each time point before and after the operation. Moreover, the gastric emptying time did not change after the operation in both groups (Table 3).

### *Alterations of portal vein pressure and hemodynamic variables*

In both groups after the operation, the directions of the portal venous flow were maintained towards the liver, but the FPP, $V_{max}$ and the blood flow were decreased significantly compared with those before the operation ($P < 0.05$). However, there was no significant difference in the changes of these variables between the two groups ($P > 0.05$) (Table 4).

## DISCUSSION

Portosystemic shunt and Hassab's operation are commonly used in the treatment of portal hypertension. Although both operations are effective in control of bleeding, portosystemic shunt has increasingly been replaced by devascularization in recent years in China because of its technical difficulty and poor long-term outcome[3,4]. A prospective study of 435 cases[3] showed that the 5- and 10- year survival rates of patients after devascularization are 94.1% and 70.0%, respectively, while the recurrent bleeding rate is 6.2% and 13.3%, respectively. The same study [3] also showed that the bleeding control rate of emergency operation is 96.9%, and the overall operative mortality rate is only 4.5%. However, the portal blood flow may decrease to some extent and re-bleeding is likely to occur because of the portal hyperdynamic state, and gastric congestion may exacerbate portal hypertensive gastropathy[4].

With the introduction of multishot band devices which allow the placement of 5-10 bands at a time, EVL has become a more effective method with fewer side effects compared with previous operations. After several repeated sessions at 2 wk intervals, obliteration of varices can be achieved in about 90% of patients[9]. However, since portal hypertension and hypersplenism cannot be eliminated by EVL resulting in the recurrence of varices after EVL, 20%-75% of patients require repeated EVL sessions[10]. As the hyperkinetic circulatory state of the splenic vein is a potential factor for the development of bleeding in esophageal varices, we believe that splenectomy in combination with EVL may eliminate not only hypersplenism but also the hyperkinetic circulatory state of the portal vein system, which may prevent the recurrence of esophageal varices after EVL.

In the present study, splenectomy in combination with EVL showed a similar efficacy to Hassab's operation in the treatment of esophageal varices and in the prevention of re-bleeding. However, the former demonstrated several advantages over the latter, including a lower incidence of overall and individual complications such as refractory ascites, pleural effusion, esophageal ulcer, portal vein thrombosis, refractory hiccup and bilious vomiting and lower percentage of patients with severe PHG.

EVL may cause fibrosis in the mucous layer where the esophageal varices are located, but has no effect on the formation of collateral circulation in the muscular layer. Moreover, EVL may not injure the collaterals of the portal vein near the esophagus, thus decreasing the portal vein pressure by keeping the natural portal azygous shunt. In addition, EVL is a safe operation with few mild complications that can be tolerated by patients even with poor liver functions, thus allowing the extension of the indications for such a surgical intervention.

Thrombosis in the portal vein is a major complication of

devascularization, which may be caused by the decreased blood flow in the portal vein system, porto-azygos disconnection, damage to the endangium and increased platelets after splenectomy. Acute thrombosis in the portal vein may lead to intestinal infarction, which is characterized by abdominal pain, hematochezia and diffuse peritonitis[3]. In our study, portal vein thrombosis was present in 28% (14/50) of patients receiving Hassab's operation and 13% (7/53) of patients receiving splenectomy in combination with EVL, indicating that the latter can offer a significant benefit for patients with portal vein thrombosis.

In addition to portal vein thrombosis, vagal nerve injury is another commonly reported complication of devascularization[3], which may greatly increase the incidence of gastric emptying delay and bilious vomiting by decreasing the gastric motivation. It is presumably a major cause for PHG. However, this kind of injury is likely to be related to the operational skills. Theoretically, devascularization may accompany a higher incidence of gastric emptying delay. However, no difference was found in the gastric emptying time between the two groups in the present study, suggesting that this phenomenon cannot be ascribed to any influence of EVL on gastric emptying.

Based on the observations of the present study, splenectomy in combination with EVL is as effective as Hassab's operation in preventing the recurrence of esophageal varices and the re-bleeding rate, but has a lower incidence of PHG than Hassab's operation. However, repeated EVL sessions (an average of 3.2 times) are necessary to maintain the occlusion of varices, which requires long-term follow-up and thus increasing the cost of therapy.

In conclusion, splenectomy in combination with EVL achieves a similar therapeutic efficacy to Hassab's operation in terms of the recurrence rate of esophageal varices and the re-bleeding rate, but the former results in fewer and milder complications.

## Abstract

**AIM:** To recognize cystic neoplasia of the pancreas and thus to identify a panel of curable diseases.

**METHODS:** Sixty-four cases of cystic neoplasia of the pancreas, including 28 cases of intraductal papillary mucinous neoplasia (IPMN), 12 cases of serous cystic neoplasia (SCN), 11 cases of mucinous cystic neoplasia (MCN), 11 cases of solid pseudo-papillary neoplasia (SPN), and 2 cases of solid tumor with cystic degeneration were examined immunohistochemically for their expression of MUC1, MUC2, MUC4, MUC5AC, and MUC6, as well as other related antigens.

**RESULTS:** Adenoma type of IPMN and borderline lesions exhibited high expressions of MUC2, and MUC5AC. In contrast, IPMN with invasive carcinoma component showed MUC1 immunoreactivity. SCN was mainly positive for MUC1 and MUC6, while negative for MUC2, MUC4 and MUC5AC. Noninvasive MCN, regardless of its cellular atypia degree, was positive for MUC5AC and negative for MUC1. MUC1 expression was only observed in patients with an invasive component. No mucin expression was found in SPN.

**CONCLUSION:** Mucin profile may, in conjunction with histologic study, provide important information on tumor types and patient treatment of cystic neoplasia of the pancreas.

**Key words:** Pancreas; Cystic neoplasm; Mucin; Differential diagnosis; Diagnosis

## INTRODUCTION

Cystic neoplasia of the pancreas accounts for about 10%-15% of all cystic pancreatic lesions[1]. The majority of cystic lesions of the pancreas are pseudocysts. Although cystic neoplasia of the pancreas is rare, it encompasses a spectrum of benign, borderline and malignant neoplasiae. In contrast to solid tumors of the exocrine pancreas, which are exclusively malignant (85%-90%), the clinical challenge is the differential diagnosis and management of cystic neoplasia.

The broad spectrum of pancreatic neoplasia and tumor-like lesions with cystic features has been recently reviewed[1-3]. The incidence or frequency of pancreatic cystic neoplasia varies among different institutes. Because there has been no comprehensive study in a large series of cases from China comparing the incidence and biology to Western series, we reviewed all cystic neoplasiae collected in pathological files of Zhongshan Hospital over five years. Most of the neolpasms in our series were well documented and have been included in the recent World Health Organization (WHO) classification[4]. The four most common cystic neoplasiae of the pancreas are intraductal papillary mucinous neoplasia (IPMN), serous cystic neoplasia (SCN), mucinous cystic neoplasia (MCN), and solid pseudo-papillary neoplasia (SPN).

Mucins are a group of high molecular weight glycoproteins that are widely expressed in epithelial cells. Fourteen mucin genes have been identified thus far[5-8]. They can be further grouped into two subfamilies: secreted and transmembrane mucin genes. Among these, MUC2, MUC5AC and MUC6, known as the gel-forming mucins, are expressed in the pancreas either under normal physiologic or tumoral conditions. Among membrane-bound mucins, MUC1 and MUC4 are the two main mucins

associated with pancreas[7,8].

In the present study, we examined the expression of the well-characterized MUCs (MUC1, 2, 4, 5AC and 6) in pancreatic cystic neoplasia and compared the expression profiles with those observed in adenocarcinoma and endocrine tumor of pancreas with cystic feature. The overall goal was to identify the mucin profile that is potentially a specific marker for the differential diagnosis of cystic neoplasia of the pancreas.

## MATERIALS AND METHODS

Pancreatic cystic tumors diagnosed between January 1999 and June 2005 in the Department of Pathology of Zhongshan Hospital, Fudan University were identified, reviewed, and classified according to the recent World Health Organization classification of pancreas neoplasia[6]. During this period, 248 patients were operated on in our hospital for pancreatic lesions. Clinical information was obtained from the patient records or the clinicians in charge. The tumors were removed surgically from all the patients. All specimens were fixed in buffered-formalin and embedded in paraffin. Deparaffinized sections were stained with haematoxylin and eosin, Alcian blue and periodic acid-Schiff. One or two representative blocks from each case were selected. Immunohistochemical analysis was carried out on serial sections cut from the cystic epithelial neoplasia using the Envision (DAKO, Carpiteria, CA) method with several antisera (Table 1).

All cases were analyzed by 2 pathologists in accordance with the WHO criteria. In the current study, SCN, MCN, IPMN were classified into three classes according to the degree of cytologic and structural atypia including increased nuclear-to-cytoplasmic ratio, loss of polarity, pleomorphism, hyperchromatism, prominent nucleoli, abnormal mitosis, cribriform pattern and multilayer, and presence of invasion. Immunohistochemical evaluation was independently performed by two authors (Ji Y, and Zhu XZ) without knowledge of the clinical data. For each marker, the positive cell distribution in tumor tissue and staining pattern (cytoplasmic, membranous, or nuclear) were recorded. For mucins, we evaluated the staining of cytoplasm and luminal surface. The cells were considered positive when at least one of the components was positive. Percentages of the positively stained neoplastic cells were as follows: -: < 5% of neoplastic cells stained; +: 5%-20% of neoplastic cells stained; ++: 20%-50% of neoplastic cells stained; +++: > 50% of neoplastic cells stained.

## RESULTS

This series was comprised of 64 cases, including 28 cases of IPMN, 12 cases of SCN, 11 cases of MCN, 11 cases of SPN, 1 case of ductal adenocarcinoma with cystic feature (cDAC), and 1 case of endocrine tumor with cystic feature (cPET). All cystic neoplasiae of the pancreas in order of their relative frequency are listed in Table 2.

The details of the cases included in the study are shown in Table 3. The immunostaining findings are listed in Tables 4 and 5.

**Table 1 Antibodies used for immunostaining of cystic neoplasia of the pancreas**

| Antibody | Clone | Type | Producer | Dilution | Commence |
|---|---|---|---|---|---|
| PanCK | AE1/AE3 | MoAb | DAKO | 1:100 | Membrane |

| Serous cystic neoplasia | | 12 | 18.8 |
| | Adenoma | 11 | |
| | Borderline | 0 | |
| | Carcinoma | 1 | |
| Mucinous cystic neoplasia | | 11 | 17.3 |
| | Adenoma | 8 | |
| | Borderline | 1 | |
| | Carcinoma | 2 | |
| Solid pseudo-papillary neoplasia | Borderline (Uncertain malignant potential) | 11 | 17.3 |
| Cystic ductal adenocarcinoma | High-grade malignant | 1 | 1.6 |
| Cystic pancreas endocrine tumor | Low-grade malignant | 1 | 1.6 |
| Total | | 64 | 100 |

### *IPMN*

Macroscopically, neoplasia could be classified as main pancreatic duct type in 15 (50.4%) patients (Figure 1A), and branch type in 5 patients, both main and branch duct types in 8 patients, respectively. On histologic analysis of the entirely resected specimens, IPMN showed simple hyperplasia (adenoma) in 5 patients, atypical hyperplasia

[1]Positive α-inhibin in MCN is limited in ovarian-like stromal cells. IPMN: intraductal papillary mucinous neoplasia; SCN: serous cystic neoplasia; MCN: mucinous cystic neoplasia; SPN: solid pseudo-papillary neoplasia; cDAC: cystic ductal adenocarcinoma; cPET: cystic pancreatic endocrine tumor.

(borderline lesion) in 4 patients, *in situ* carcinoma in 6 patients, and invasive carcinoma in 13 patients. The epithelial proliferative lesions in all patients involving the main or secondary pancreatic duct showed a papillary architecture (Figure 1B). Moderate to severe fibroatrophic changes of obstructive pancreatitis were observed in 21 patients.

Immunochemically, neoplasia could be classified as intestinal type (MUC1-, MUC2+) in 11 patients (Figure 1C), pancreaticobiliary type (MUC1+, MUC2-) in 9 patients, gastric type (MUC1-, MUC2-, MUC5AC+) in 6 patients (Figure 1D), and oncocytic type in 2 patients. Of the 13 IPMN patients with invasive carcinoma, 5 showed the features of mucinous carcinoma in their invasive component and 8 showed ductal carcinoma in their invasive component with MUC1+. The mucin profiles of the mucinous or ductal component corresponded to the intestinal or pancreaticobiliary type, respectively. All IPMN samples stained for CEA, CK8/18, and CK19 were negative for CK20, α1-AT. However, single endocrine cells were detected by SYN and CHG-A in 10 intestinal types and 4 pancreaticobiliary types of IPMN. They expressed both gastric hormones (serotonin and gastrin) and/or pancreatic hormones (glucagon, PP) focally.

**Table 5 Mucin profiles of cystic neoplasia of the pancreas**

| Type | IPMN *n* = 28 | SCN *n* = 12 | MCN *n* = 11 | SPN *n* = 11 | cDAC *n* = 1 | cPET *n* = 1 |

IPMN: intraductal papillary mucinous neoplasia; SCN: serous cystic neoplasia; MCN: mucinous cystic neoplasia; SPN: solid pseudo-papillary neoplasia; cDAC: cystic ductal adenocarcinoma; cPET: cystic pancreas endocrine tumor.

### SCN

The most common subtype of SCN was serous microcystadenoma (SMA, 8 cases), characterized by a central stellate scar, sharp demarcation from surrounding pancreatic tissue, and its predominant occurrence in women. SMA was comprised of numerous small cysts with a diameter ranging from 0.01 to 0.5 cm and a few larger cysts up to 1.5 cm in diameter. The cysts contained eosinophilic fluid and were lined by a single layer of cuboidal or flattened epithelial cells with pale to clear cytoplasm. The tumor cells were centrally located with round to oval nuclei. The cytoplasm was positive for granular periodic acid-Schiff. The usually thin fibrous septae were acellular. The central scar was composed of hyalinized tissue. Three cases of serous oligocystic ill-defined adenoma (SOIA) showed only a few, usually rather large cysts (0.2-2.5 cm in diameter) filled with clear or brown fluid (Figure 2A). The cyst epithelium was cytologically identical to that of SMA (Figure 2B). However, unlike SMA, SOIA was not well-defined due to the extension of small cysts into the adjoining pancreatic tissue. The tumors also lacked a central fibrous scar. One serous cystadenocarcinoma (SCC) was found to have a liver metastatic lesion during operation. The primary tumor of pancreas, which was similar to SMA, showed no distinct atypia.

Besides stained for CK8/18, CK19, the cells were also positive for neuron specific enolase (NSE) and negative for alpha-1-antitrypsin (α1-AT) and alpha-1-antichymotrypsin (α1-ACT). Of the mucins tested, MUC1 (75%) (Figure 2D) and MUC6 (66%) (Figure 2C) had the highest positive rates. MUC2 and MUC5AC staining was completely lacking. In

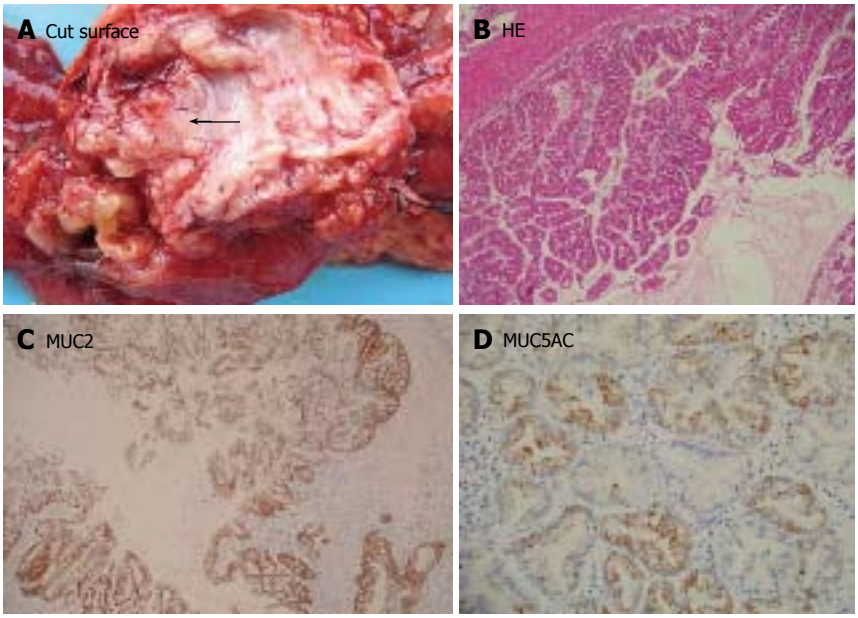

**Figure 1** Intraductal papillary mucinous neoplasia. **A**: Sectioning of the pancreas revealing papillary tumors (arrow) with sticky mucin in dilated main panceatic ducts; **B**: Epithelial proliferative lesions that involve the main or secondary pancreatic duct showing a papillary architecture (HE × 40); **C**: MUC2 diffuse expression in papillary epithelial cells of intestinal type (Envison × 40); **D**: Focally stained MUC5AC in cytoplasm of gastric subtype tumor cells (Envison × 100).

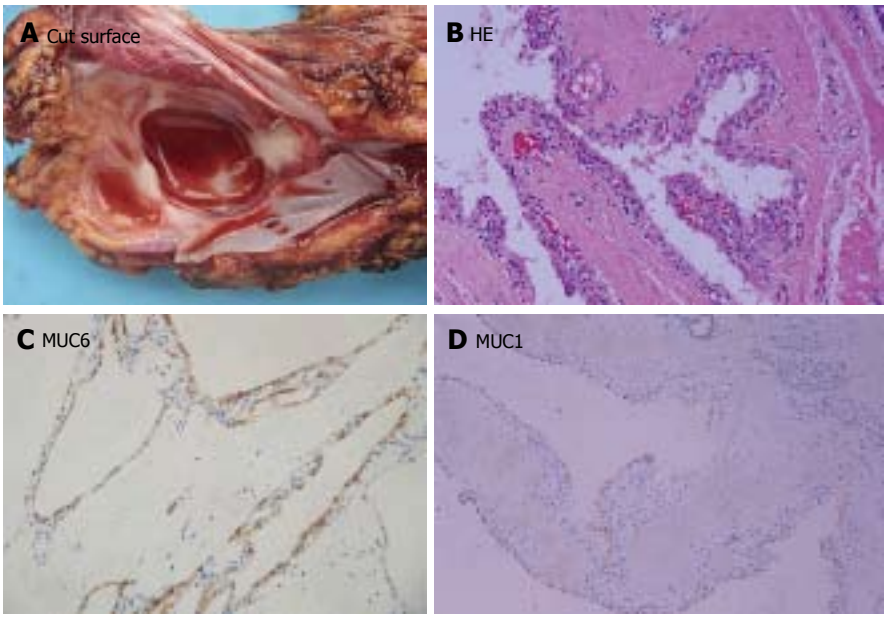

**Figure 2** Serous cystic neoplasm. **A**: Smooth and thin cyst wall on cut surface containing clear red-brown fulid; **B**: Cysts wall lined by a single layer of cuboidal or flattened epithelial cells with pale to clear cytoplasm, and centrally located tumor cells with round to oval nuclei (HE × 100); **C**: Tumor cells strongly positive for MUC6 (Envison × 100); **D**: MUC1 expression in some tumor cells (Envison × 40).

the normal pancreatic tissue entrapped into the tumors, small duct cells and centroacinar cells were apically positive for MUC6 and MUC1. In addition, the epithelial cells were stained for α-inhibin.

### *MCN*

MCN was studied in 11 patients. The tumors presented as a large round cystic mass with a unilocular or multilocular cut surface (Figure 3A). Micorscopically, the cysts were lined by mucin-producing epithelial cells with variant degrees of dysplasia supported by an ovarian-like stroma (Figure 3B). MCN was classified as adenomas (MCA) in 8 patients, borderline tumor (MCB) in 1 patient, and carcinomas (MCC) in 2 patients with invasive component. The epithelial component of MCN was stained for CK8/18, CK19, and CEA. MUC1 positivity was, however, found in the invasive components of MCC. All of our MCN patients were negative for MUC2, except for goblet cells, which were quite numerous in MCB and rare in MCA. MUC5AC expression was found in all the 11 MCN patients. The cytoplasmic staining intensity increased with progressive nuclear atypia and was the strongest in invasive carcinomas (Figure 3C). A few cells were stained faintly for MUC6 (Figure 3D). In addition, endocrine cells detected by CHG-A, were found in 3 MCN patients, of them 2 also had expression of gastrin and serotonin, 1 had expression of only serotonin.

### *SPN*

The extent of cystic changes in 11 SPN patients varied from tumor to tumor, affecting either part of the tumor tissue, or almost the entire tumor tissue. The cystic structures contained hemorrhagic debris and were usually surrounded by hemorrhagic-necrotic tissues (Figure 4A). Microscopically, SPN showing solid areas was composed of monotonous polygonal epithelioid cells, often

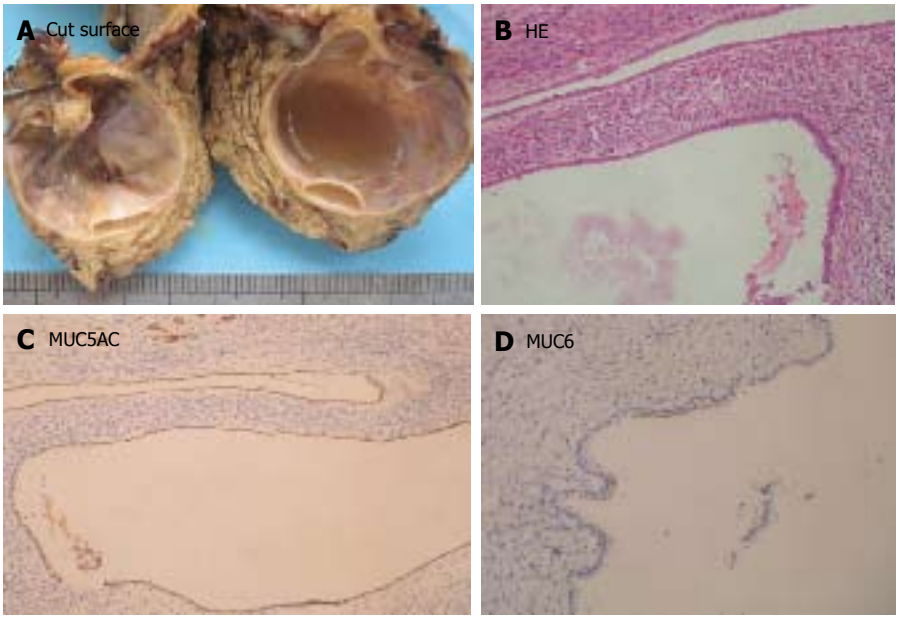

**Figure 3** Mucinous cystic neoplasm. **A**: Tumors presented as large round cystic masses with a unilocular cut surface; **B**: Cysts lined by mucin-producing epithelial cells with variant degrees of dysplasia supported by an ovarian-like stroma; **C**: MUC5AC expression in cytoplasm; **D**: Faint MUC6 expression in apical tumor cells (Envison × 100).

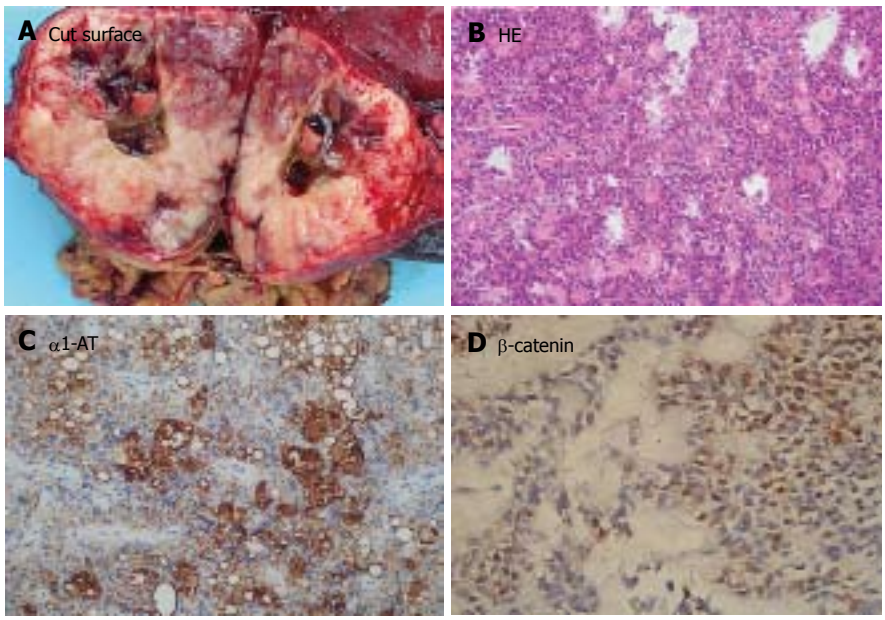

**Figure 4** Solid pseudo-papillary neoplasia. **A**: Cystic structures containing hemorrhagic debris surrounded by hemorrhagic-necrotic tissue; **B**: SPN showing solid areas consisting of monotonous polygonal epithelioid cells, often with minimal intervening stroma accompanied with innumerable capillary-sized vessels. In the pseudopapillary regions, the cells away from the small vessels appeared to have dropped away, leaving an irregular cuff of cells surrounding each vascular core (HE × 100); **C**: SPN showing a consistent pattern of reactivity for α-1-AT (Envison × 100); **D**: Positive β-catenin and progesteron receptor limited to the nuclei of tumor cells (Envison × 200).

with minimal intervening stroma accompanied with innumerable capillary-sized vessels (Figure 4B). Some areas showed more extensive stromal fibrosis, with round aggregates of perivascular hyalinized stroma imparting a cylindromatous appearance. In the pseudopapillary regions, the cells located away from the small vessels appeared to have dropped away, leaving an irregular cuff of cells surrounding each vascular core.

Immunohistochemical studies revealed that SPN showed a consistent pattern of reactivity for vimentin, α-1-antitrypsin (α-1-AT) (Figure 4C) and α-1-antichymotrypsin (α-1-ACT), but an inconsistent positive pattern for CD10 and S-100 protein. None of these proteins was reactive for mucins and pancreatic hormones. Staining of the pancreatic enzyme trypsin was consistently negative, as the specific endocrine marker chromogranin. Seven cases were focally positive for synaptophysin and the less specific marker NSE. Positive β-catenin (Figure 4D) and progesteron receptors were limited to the nuclei of tumor cells.

### *cDAC*

MUC1 and MUC4 were observed in invasive component. CEA, CK7, 19 and CA19-9 with focal staining of MUC5AC did not exceed 30% of the tumor, in which MUC2 was absent (Figure 5A-5D).

### *cNET*

The NET which was not encapsulated in the pancreatic head, infiltrated the duodenal wall and was considered malignant. As the typical NET had no cystic change, NET was diffusely stained for SYN, CHG-A and NSE, as well as pancreatic hormones and glucagons (Figure 6A-6D).

## DISCUSSION

Cystic tumor of the pancreas accounts for 10%-15%

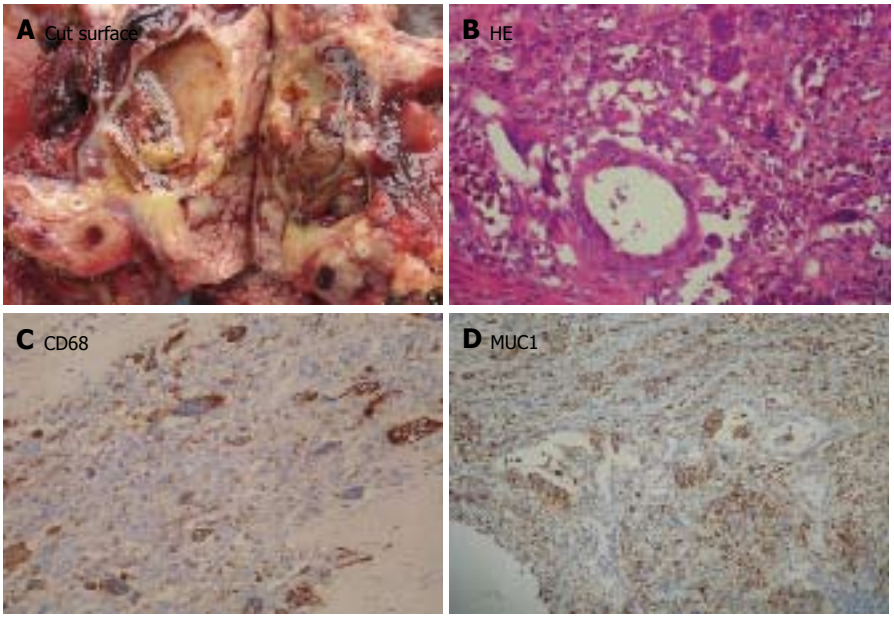

**Figure 5** Cystic ductal adenocarcinoma. **A**: Part of the tumor showing cystic wall with brown color; **B**: Cystic wall consisting of multinuclear giant cells (HE × 100); **C**: Giant tumor cells positive for CD68 (Envison × 100); **D**: Diffusely stained MUC1 in neoplastic cells, including duct and giant tumor cells (Envison × 100).

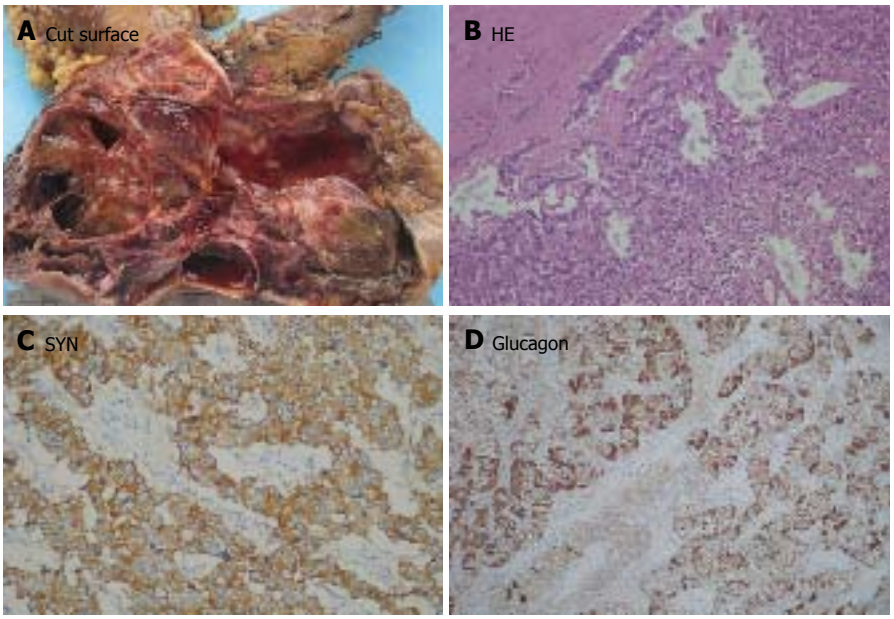

**Figure 6** Cystic pancreatic endocrine tumor. **A**: Cut surface of a large PET showing degeneration and cystic change; **B**: Tumor cells arranged as trabecular nests in the remnant area (HE × 100); **C**: SYN presented in all tumor cells (Envison × 200); **D**: Most tumor cells expressing glucagon in cytoplasm (Envison × 100).

of pancreatic cystadenomas and 1% of pancreatic carcinomas[1-3]. With the increased availability of imaging techniques and improved feasibility of surgical resection, an increasing number of cystic pancreatic neoplasiae have been identified in several institutions, thus their diagnosis can be established more easily.

The clinical challenge is the differential diagnosis and management of cystic neoplasm, which represents a wide range of biologic behavior. A variety of biochemical, genetic, and imaging techniques have been developed for the diagnosis and monitoring of the outcome of cystic neoplasia of the pancreas. In consideration of the potentials and limitations inherent in each of these methods, the need for efficient differential diagnostic markers that specifically discriminate pancreatic cystadenocarcinoma from pancreatic carcinoma cannot be overemphasized. In this regard, mucins may represent potential candidates for such a purpose, with respect to their biochemical properties relating to malignant conditions[9,10]. Analysis of mucin expression profiles in PCN patients has brought some light on their prognosis[5,6]. MUC1 is thought to have an inhibitory role in cell-cell and cell-stroma interactions as well as in immunoresistance[5]. MUC1also acts as a signal transducer, interacting with and promoting the activities of EGFR, MAP kinase and Wnt signaling pathway[11]. In pancreatic neoplasia, MUC1 has been found to be a marker of an aggressive phenotype expressed in high-grade PanINs, and more importantly, presents uniformly in infiltrating conventional ductal adenocarcinoma[5,6,9]. On the other hand, MUC2 functioning as a protective barrier in the intestinal epithelium[12,13], appears to be a marker of an indolent phenotype in the pancreas[5]. MUC2 is not expressed in the normal pancreas, PanINs or ductal adenocarcinoma, but is often detectable in IPMNs and uniformly presents in colloid carcinomas.

IPMN is a mucin-producing epithelial neoplasia in-

volving the main and/or branch pancreatic ducts. Recent data suggest that a more heterogeneous profile of IPMN has different mucin patterns and clinical prognosis[11,12]. In consistent with previous reports, the intestinal type of our IPMN patients expressed MUC2, MUC5AC and MUC4, but not MUC1. It had a lower invasive and metastatic potential in comparison to DACs and therefore had a better clinical outcome. The pancreatobiliary type of IPMN is MUC1 positive and MUC2 negative with an increased tendency to invade, and seems to be related to DAC[13,14]. The third group with a gastric foveolar differentiation which is MUC5AC positive but usually does not express either MUC1 or MUC2, was not identified in this study. The lack of this type in our series may be due to the misdiagnosis of MCN for their similar mucin profile.

Pancreatic SCN is usually considered benign. Whether SCN is malignant is still controversial. However, the malignancy of pancreatic SCN has been recognized since 3% of reported SCNs are cancerous in nature[15]. In many reported cases of malignant SCN, there are multifocal lesions in the liver or additional lesions, but pancreatic tumor itself shows no signs of malignancy. Amorphous nuclei, irregular nuclear margins, and coarse nuclear chromatin in SCN suggest that it has a malignant potential. In the present study, SCN exhibited a similar if not identical immunoprofile-positivity for MUC1 and MUC6, whereas no SCN expressed MUC5AC, although mucin production is not a histologic feature of SCN. The mucin profile of SCN that was positive for MUC6 supports the hypothesis of a direction of differentiation toward centroacinar cells, since the ultrastructural features of tumor cells are similar to those of centroacinar cells[15]. This hypothesis is further supported by the centroacinar localization of incipient serous cystic tumors observed incidentally[16]. In immunostaining, helpful markers for SCN are α-inhibin and MUC6.

MCN was first considered as a premalignant or overtly malignant cystic neoplasia. Because of the reputed difficulty in classifying MCN as a "benign" cystadenoma, some pathologists classify MCN of the pancreas with only small areas of epithelial hyperplasia or dysplasia as grade 1 cystadenocarcinoma, thereby implying a more aggressive natural history and predetermining their future management and follow-up as a malignancy despite successful resection. When these neoplasiae become malignant, only portions of the tumor dedifferentiate (i.e., become proliferative, develop nuclear dysplasia, and eventually invade the stroma). These areas may not be sampled unless the entire neoplasm is examined. In addition, separation of cystic mucinous neoplasia from non-invasive IPMN and high-grade ductal adenocarcinoma that incidentally have cystic areas (related to necrosis or ductal obstruction) requires both adequate sampling and clinicoradiologic and pathologic correlation. Mucin gene expression may discriminate between MCN and DAC[7]. In this study, noninvasive MCN, regardless of the degree of cellular atypia, was positive for MUC5AC and negative for MUC1. MUC1 expression was observed only in patients with an invasive component. MUC2 perinuclear expression was restricted to goblet cells scattered within the epithelium of MCN, often accompanied with endocrine cells, a further indication of intestinal differentiation. As MUC5AC is a gastric foveolar mucin, and expressed during intestinal ontogenesis, further investigation is required before we understand the role of MUC5AC in MCN. In addition, the expression of α-inhibin in stromal cells of MCN may be useful in the diagnosis of cystic pancreatic lesions.

SPN of the pancreas is a rare neoplasia with distinctive pathologic features and low-grade malignant potential that preferentially affects young women. SPN is composed of uniform and polygonal epithelioid cells, which are arranged in a discohesive pattern. SPN can be readily diagnosed by routine histologic examination, but immunohistochemical studies are frequently performed to confirm the diagnosis. Tumor cells of SPN are characteristically positive for vimentin and α-1-antitrypsin, and may also show focal immunoreactivity for cytokeratin and synaptophysin and abnormal nuclear localization of β-catenin. Staining of chromogranin and the acinar markers trypsin and chymotrypsin is consistently negative. SPN is composed of monomorphous cells with uncertain lineage or histogenesis[17]. The phenotype of SPN surprisingly does not resemble that of any normal epithelial cell lines of the pancreas.

Cystic NET is relatively easy to be distinguished from other epithelial cystic neoplasiae by the lack of mucin expression and presence of neuroendocrine markers[18].

In general, mucins follow a defined spatial and temporal pattern of expression throughout the development of an organ. However, recent studies demonstrate that deregulated expression of mucins is associated with various types of neoplasia. In the normal adult pancreas, MUC1 expression is confined to the apical membrane of intralobular ductules, possibly a manifestation of the "lumen maintenance" role of MUC1. MUC1 expression is not detectable in larger ducts or other pancreatic elements (islets or acini)[19]. MUC6 mRNA is also detectable in acini, in which the signal is largely restricted to centroacinar cells (Table 5). MUC2 or MUC5AC is not expressed in normal adult pancreas[20,21]. In pancreatic adenocarcinoma, tumors and tumor cell lines can overexpress MUC1. Additionally, an aberrant expression of MUC4 in pancreatic tumor and cell lines has been reported, a MUC that is usually undetectable in normal pancreas.

It is important to distinguish between a pseudocyst tumor and a cystic tumor because they are frequently confused with one another and the management of these entities is entirely different.

In summary, mucin profile may lead not only to the early diagnosis of pancreatic tumors but also to the accurate diagnosis of neoplasia. Mucin alteration may, in conjunction with histologic study, provide important information on tumor type and patient treatment.

## Abstract

**AIM:** To investigate the protein and mRNA expression of semaphorin 6D in gastric carcinoma and its significance.

**METHODS:** The protein and mRNA expression of semaphorin 6D was detected by semi-quantitative reverse transcription PCR and Western blotting respectively in 30 cases of gastric carcinoma and normal gastric mucosa.

**RESULTS:** The protein and mRNA expression of semaphorin 6D in gastric carcinoma was significantly higher than that in normal gastric mucosa (0.24 ± 0.06 *vs* 0.19 ± 0.07, 0.26 ± 0.09 *vs* 0.20 ± 0.10, $P < 0.05$).

**CONCLUSION:** Semaphorin 6D may play an important role in the occurrence and development of gastric carcinoma, and is related to tumor angiogenesis.

**Key words:** Semaphorin 6D; Gastric carcinoma; Normal gastric mucosa; Angiogenesis

## INTRODUCTION

The semaphorin family is characterized by a phylogenetically conserved sema domain in the extracellular region[1]. This family has been subdivided into eight groups, which play a crucial role in formation of nervous system, embryogenesis, angiogenesis, immunoreaction, and carcinogenesis[1-5]. Semaphorin 6D is a novel member of class 6 semaphorin gene, mapped on the chromosome 2, and it is grouped into five isoforms through different splicing[6]. At present, little is known about the function of semaphorin 6D in carcinogenesis. Therefore, we detected the protein and mRNA expression of semaphorin 6D in gastric carcinoma and normal gastric mucosa by semi-quantitative RT-PCR and Western blotting in order to explore the expression of semaphorin 6D in gastric carcinoma and its significance.

## MATERIALS AND METHODS

### *Patients*

Thirty fresh gastric carcinoma specimens and thirty normal gastric mucosa specimens were obtained from patients who underwent surgery for gastric carcinoma between April 2006 and August 2006 in General Hospital of Chinese PLA and analyzed. The diagnosis of gastric carcinoma was confirmed by pathological examination. The patients with gastric carcinoma consisted of 11 women and 19 men. Their mean age was 54 years and ranged from 32 to 74 years. Of the 30 patients, 13 showed moderate differentiation, 17 poor differentiation.

### *Reverse transcription PCR (RT-PCR)*

Total mRNA was isolated by Trizol reagent according to the procedure of supplier (BioDev-tech, Beijing, China). The concentration was determined by measuring the absorbance at 260 nm and using the following equation: one optical density unit = 40 mg of RNA/mL. A 1.5 μg aliquot of total RNA from each specimen was reverse-transcribed into single-strand cDNA using oligo (dT)16 primer for 2 h at 37℃. Each single-strand cDNA was used for subsequent PCR amplification of semaphorin 6D and β-actin with the latter used as a quantitative control. PCR was carried out in a reaction volume of 50 μL: an initial denaturation for 5 min at 95℃, followed by 37 cycles at 94℃ for 50 s, at 55℃ for 50 s, and at 72℃ for 1 min, then a final extension at 72℃ for 10 min on the authorized thermal cycler for PCR. The primer sequences used for amplification were 5'-CTCAGTCGCTGTGAGCGTTAT-3' and 5'-CAGATGTTGGACCGCCAAATA-3' for samephorin 6D, 5'-CGCACCACTGGCATTGTCAT -3' and 5'-TTCTCCTTGATGTCACGCAC -3' for β-actin. The primer sequences were synthesized by Beijing Genomics Institute (China). The PCR products were resolved in 2% agarose gels and visualized by staining with

ethidium bromide. To quantify the PCR products, the bands representing amplified products were analyzed by Quantity One Analysis Software (BIO-RAD Co., USA).

### *Western blotting*

Expression of the semaphorin 6D protein was detected using the Western blot method. After washed in ice-cold PBS, the samples were finely minced and suspended in ice-cold homogenization buffer (2 mL/g of tissue) containing protease inhibitors to minimize protein degradation. The suspension was homogenized, then centrifuged at 12000 × *g* for 30 min at 4℃ to remove nuclei and cell debris. The supernatant (total protein extract) was collected. An equal amount (50 μg) of proteins was run on a 10% SDS-PAGE gel and electrotransferred onto hybond-polyvinylidene difluoride membranes (Amersham, Arlington Heights, USA). The membranes were blocked for 2 h at room temperature, followed by incubation with 3 μg/mL primary anti-semaphorin antibody (R&D system, Minneapolis, USA) at 4℃ overnight. The primary antibody was diluted in TBST containing fat-free milk. After three washes (10 min each time) in TBST, membrane was incubated in peroxidate-conjugated second antibody (Sigma, St. Louis, USA) diluted 1:800 at room temperature for 1 h. Immunoreactive proteins were visualized on autoradiogram using ECL Western blotting detection reagents (Amershan Pharmacia, Uppsala, Sweden) and exposed to X-Omat BT film (Kodak, New York, USA). Bands were analyzed by Quantity One Analysis Software normalized with respect to β-actin as an internal control.

### *Statistical analysis*

Results were expressed as mean ± SD. The statistical differences between different groups were analyzed by paired *t*-test. $P < 0.05$ was considered statistically significant. All analyses were performed by SPSS12.0 statistical software.

## RESULTS

### *Expression of semaphorin 6D mRNA*

Two percent of agarose gel electrophoresis showed a 232bp semaphorin 6D fragment by RT-PCR amplification from gastric caner and normal gastric mucosa specimens (Figure 1). The semaphorin 6D mRNA amplification was successful in all tissues. The expression level was 0.24 ± 0.06 in tumor, much higher than that in normal gastric mucosa (0.19 ± 0.07, $P < 0.05$).

### *Expression of semaphorin 6D protein*

The affinity-purified anti-semaphorin 6D antibody detected a major band at 100 kDa in protein extracts from all samples tested (Figure 2). The expression was 0.26 ± 0.09 in tumor, much higher than that in normal gastric mucosa (0.20 ± 0.10, $P < 0.05$), which was consistent with that of RT-PCR.

## DISCUSSION

The semaphorin family is characterized by a phylogenetically conserved sema domain in the extracellular region.

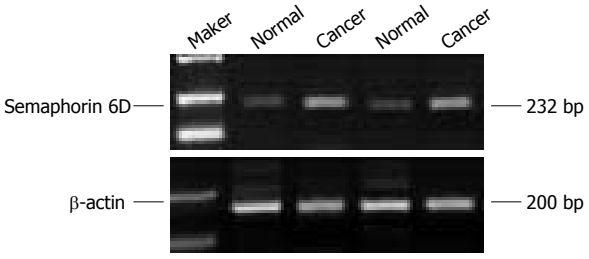

**Figure 1** Expression of semaphoring 6D mRNA detected by RT-PCR. The expression of semaphoring 6D mRNA was significantly higher in gastric cancer than in normal gastric mucosa ($P < 0.05$).

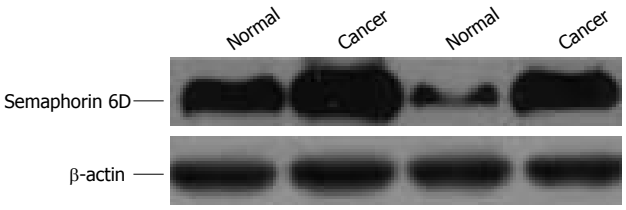

**Figure 2** Protein expression of semaphoring 6D detected by Western blot. The protein expression of semaphoring 6D was significantly higher in gastric cancer than in normal gastric mucosa ($P < 0.05$).

On the basis of additional structural features, such as the presence or absence of transmembrane domains, Ig-like domains, thrombospondin repeats, and glycophosphatidy linositol linkage sites, the family has been subdivided into eight groups, including virally derived proteins[1]. Despite the fact that a number of semaphorins have been known to play a crucial role in the hard wiring of the nervous system, including fasciculation, axon branching, and target selection as axonal guidance cues[2,3]. There is increasing evidence that semaphorins play a significant role in angiogenesis. For example, secreted class Ⅲ semaphorins, regulating axonal growth during the development of central nervous system[7,8], can initiate signaling events in a variety of tissues that influence vascular morphogenesis and endothelial cell motility[9-11]. It was reported that semaphorin 4D is highly expressed in endothelial cells and promotes endothelial cell migration and tubulogenesis[12].

Gastric carcinoma is one of the most common malignant tumors. As other malignant tumors, its growth and metastasis require induction of angiogenesis (the growth and remodeling of new blood vessels from a preexisting vascular network) to ensure the delivery of oxygen, nutrients, and growth factors to rapidly divide transformed cells and to provide tumor cell access to systemic circulation[13-15]. Without the ability to induce angiogenesis, most neoplasms would fail to grow (> 2 mm in diameter) or metastasize[15]. Semaphorin 6D is a novel class 6 semaphorin gene, mapped on the chromosome 2, and can be grouped into five isoforms through different splicing, including one short isoform (only consisting of extrocellular domain) and four long isoforms[6]. It was reported that semaphorin 6D can inhibit axonal extension of NGF-differentiated PC12 cells and to collapse growth cones of chick DRG and rat hippocampal neurons[6]. It was also reported that semaphorin 6D also can attract or

inhibit epithelial cell migration depending on different special regions through different receptor complex in cardiac morphogenesis of chick embryos[16], suggesting that semaphorin 6D may regulate angiogenesis *in vivo*, and increase the intriguing possibility, thus playing a role in tumor-induced angiogenesis, including gastric carcinoma. Therefore, we detected the protein and mRNA expression of semaphorin 6D in gastric carcinoma and normal gastric mucosa by semi-quantity RT-PCR and Western blotting. The results showed that the expression of semaphorin 6D was significantly higher in gastric carcinoma than in normal gastric mucosa, suggesting that semaphorin 6D plays an important role in the development of gastric carcinoma. Semaphorin 6D may induce tumor angiogenesis, thereby enhancing tumor growth, survival, and metastasis.

In conclusion, this is the first time to investigate the expression of semaphorin 6D in gastric carcinoma and its clinical significance. The results of our study shed some light on the pathogenesis of gastric carcinoma, and may represent a new therapeutic target for gastric carcinoma treatment.

## Abstract

Rituximab has been associated with the development of cytomegalovirus enterocolitis in immunosuppressed patients. A 51-year-old patient with diffuse large B-cell lymphoma who received a conditioning chemotherapy regimen (RCVP and RICE) consisting of rituximab before bone marrow transplantation went on to develop cytomegalovirus enterocolitis. This supports evidence from previously described cases that rituximab may be associated with cytomegalovirus enterocolitis.

## TO THE EDITOR

In response to Unluturk *et al*'s letter to the editor entitled 'Cytomegalovirus gastritis after rituximab treatment in a non-Hodgkin's lymphoma patient[1], a similar case of cytomegalovirus (CMV) enterocolitis after treatment with rituximab has been described in a similar patient.

Rituximab, a monoclonal antibody targeting CD20 molecules on B-lymphocytes, can be given in combination with the chemotherapy regimen CVP (cyclophosphamide, vincristine and prednisolone), as the first treatment for people who have advanced (stage three or four) follicular lymphoma when first diagnosed or for people with advanced (stage three and four) follicular lymphoma, whose lymphoma has come back after initial chemotherapy[2].

A 51-year old patient diagnosed with follicular lymphoma in August 2004 was treated with a splenectomy and eight courses of RCVP (rituximab, cyclophosphamide, vincristine and prednisolone) combined chemotherapy, which led to a partial remission. In March 2006 the follicular lymphoma transformed to diffuse large B-cell lymphoma (DLBCL) and he was then treated with three courses of RICE (rituximab, ifosfamide, cytosine-arabinoside and etoposide) combined chemotherapy, which again led to only a partial remission.

It was decided to proceed with an autologous peripheral blood stem cell transplant in August 2006. In the week preceding transplant he was treated with a conditioning chemotherapy regimen consisting of carmustine, etoposide, cytarabine, and melphalan. His pre-tansplant CMV PCR status was negative. In the immediate days post-transplant he developed conditioning chemotherapy-related mucositis affecting his whole gastrointestinal tract, which was treated symptomatically. Faecal microscopy and stool cultures at the time were negative. The mucositis resolved two weeks post transplant but then in the third week he developed profound diarrhoea passing two litres of liquid faeces per day. CMV was detected by PCR, but bacteriological analysis of the faeces was otherwise negative. With a provisional diagnosis of CMV enterocolitis, a colonoscopy was performed and biopsies were taken from the terminal ileum and colon. Histological analysis of the biopsy material revealed evidence of CMV inclusions. He was started on ganciclovir with marked symptomatic improvement and resolution of his diarrhoea.

This case supports Unluturk *et al*'s case that CMV enterocolitis may occur after treatment with rituximab in patients with non-Hodgkin's lymphoma. Whether this is an opportunistic reactivation infection related to rituximab-induced immunosuppression needs further research.

# Meetings

## MAJOR MEETINGS COMING UP

First Biennial Congress of the Asian-Pacific Hepato-Pancreato-Biliary Association
March, 2007
Fukuoka, Japan
http://www.congre.co.jp/1st-aphpba

American College of Gastroenterology Annual Scientific
20-25 October 2006
Las Vegas, NV

14th United European Gastroenterology Week, UEGW
21-25 October 2006
Berlin, Germany

APDW 2006: Asian Pacific Digestive Week 2006
26-29 November 2006
Lahug Cebu City, Philippines

## EVENTS AND MEETINGS IN THE UPCOMING 6 MONTHS

Falk Symposium 151: Emerging Issues in Inflammatory Bowel Diseases
24-25 March 2006
Sydney - NSW
Falk Foundation e.V.
symposia@falkfoundation.de

10th International Congress of Obesity
3-8 September 2006
Sydney
Event Planners Australia
enquiries@ico2006.com
www.ico2006.com

Easl 2006 - the 41st annual
26-30 April 2006
Vienna, Austria
Kenes International

Prague hepatology 2006
14-16 September 2006
Prague
Foundation of the Czech Society of Hepatology
veronika.revicka@congressprague.cz
www.czech-hepatology.cz/phm2006

12th International Symposium on Viral Hepatitis and Liver Disease
1-5 July 2006
Paris
MCI France

# Instructions to authors

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*WJG, World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

### *Indexed and abstracted in*

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### *Published by*

The WJG Press

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

### *Online submission*

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

### *Postal submission*

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

### Editorial Office

***World Journal of Gastroenterology***
Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com
Telephone: +86-10-85381901
Fax: +86-10-85381893

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### *Title page*

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

### *Abstract*

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

### *Key words*

Please list 5-10 key words that could reflect content of the study mainly from *Index Medicus*.

### *Text*

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

### *Illustrations*

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

### *Tables*

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### *Notes in tables and illustrations*

Data that are not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ should be noted ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used. Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under

illustrations should be expressed as $^1F$, $^2F$, $^3F$; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

### *Acknowledgments*

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### *Coding system*

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24 ], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### *PMID requirement*

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (http://www.wjgnet.com/cgi-bin/index.pl), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### *Style for journal references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (http://www.aushome.cn/cgi-bin/index.pl)

### *Style for book references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### *Format*

**Journals**

*English journal article (list all authors and include the PMID where applicable)*

### *Inappropriate references*

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### *Statistical data*

Present as mean ± SD or mean ± SE.

### *Statistical expression*

Express $t$ test as $t$ (in italics), $F$ test as $F$ (in italics), chi square test as $\chi^2$ (in Greek), related coefficient as $r$ (in italics), degree of freedom as $\gamma$ (in Greek), sample number as $n$ (in italics), and probability as $P$ (in italics).

### *Units*

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, $p$(B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; $CO_2$ volume fraction, 50 mL/L $CO_2$ not 5% $CO_2$; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

***Abbreviations***

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

***Italics***

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori, E coli, etc.*

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

***Language evaluation***

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

***Copyright assignment form***

Please downloaded CAF from http://www.wjgnet.com/wjg/help/9.doc.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to WJG all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The WJG requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1)direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3)supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The WJG does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to WJG if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

## Abstract

Acute fatty liver of pregnancy (AFLP) is a serious maternal illness occurring in the third trimester of pregnancy with significant perinatal and maternal mortality. Till recently, it has been considered a mysterious illness. In this editorial, we review the recent advances in understanding the pathogenesis of AFLP and discuss the studies documenting a fetal-maternal interaction with a causative association between carrying a fetus with a defect in mitochondrial fatty acid oxidation and development of AFLP. Further, we discuss the impact of these recent advances on the offspring born to women who develop AFLP, such that screening for a genetic defect can be life saving to the newborn and would allow genetic counseling in subsequent pregnancies. The molecular basis and underlying mechanism for this unique fetal-maternal interaction causing maternal liver disease is discussed.

**Key words:** Acute fatty liver of pregnancy; HELLP syndrome; Mitochondrial Trifunctional Protein; Mitochondrial fatty acid oxidation

Ibdah JA. Acute fatty liver of pregnancy: An update on pathogenesis and clinical implications. *World J Gastroenterol* 2006; 12(46): 7397-7404

http://www.wjgnet.com/1007-9327/12/7397.asp

## INTRODUCTION

Acute fatty liver of pregnancy (AFLP) is a maternal liver disease unique to pregnancy. It was first described in 1934 as "yellow acute atrophy of the liver[1]" and was described as a specific clinical entity in 1940[2]. AFLP is a rare, but serious condition that occurs in the third trimester. It carries a significant perinatal and maternal mortality[3,4]. AFLP can lead to hepatic failure and encephalopathy and, if diagnosis is delayed, death for the fetus and mother. Clinical findings in AFLP vary and its diagnosis is complicated by a significant overlap in clinical and biochemical features with the HELLP (hemolysis, elevated liver enzymes, and low platelets) syndrome. The cause for AFLP is unknown. Recent molecular advances suggest that AFLP may result from mitochondrial dysfunction. Some of the clinical and pathological features of AFLP are similar to those found in certain autosomal, recessively inherited disorders of fatty acid oxidation, and hence, it was suggested that AFLP may result from defects in the β-oxidation of fatty acids[5-7]. Below, we review recent advances that link AFLP to disorders of fatty acid oxidation and the clinical impact for both the mother and the newborn.

## CLINICAL FEATURES OF ACUTE FATTY LIVER OF PREGNANCY

AFLP has an incidence of 1 per 13 000 deliveries[4]. It affects women of all ages and races and there is no distinctive epidemiologic feature that has been related to geographic areas or ethnic groups. The onset of AFLP is between the 30$^{th}$ and 38$^{th}$ wk of gestation although an early occurrence at 26 wk has been reported[8]. There are rare reports of AFLP diagnosis in the second trimester[9-11]. It is more frequent in primaparous than multiparous women but can occur after multiple uneventful pregnancies[12]. Several reports have documented recurrence of AFLP in subsequent pregnancies[13,14].

The initial manifestations of AFLP are nonspecific and include headache, fatigue, nausea and vomiting[15,16]. Seventy percent of patients present with nausea and vomiting, whereas 50%-80% complain of right upper quadrant or epigastric pain. AFLP can be complicated at an early stage by an upper gastrointestinal hemorrhage due to coagulation abnormalities, acute renal failure, infection, pancreatitis, or hypoglycemia[15,16]. Hepatic encephalopathy occurs later in the disease and should immediately alert the physician to the possibility of AFLP. Most patients improve 1-4 wk postpartum[17].

## DIAGNOSIS OF ACUTE FATTY LIVER OF PREGNANCY

The diagnosis of AFLP is suggested by the clinical setting,

which can be confirmed by a liver biopsy[17]. Since AFLP is a medical and obstetric emergency, early recognition and prompt treatment improves both maternal and fetal survival. In most cases, reliance on clinical and laboratory findings and physician experience to make a differential diagnosis and therapeutic decisions are critical, even without a liver biopsy. Although the gold standard for a definitive diagnosis of AFLP is through a liver biopsy, it is not routinely done for the obvious reasons of urgent delivery and coagulopathy. Thus, in most cases, reliance on laboratory data without waiting for a histologically proven diagnosis is made.

Patients with AFLP have elevated serum aminotransferase levels. White-cell count can be elevated and peripheral blood smears may demonstrate thrombocytopenia and normoblasts[18]. Disseminated intravascular coagulopathy (DIC) is relatively common[19,20]. Prothrombin time (PT), partial thromboplastin time (PTT) and fibrinogen may be abnormal. Blood urea nitrogen and creatinine may be elevated with uric acid increased. Alkaline phosphatase is 3-4 times normal. Ammonia level may be elevated and hypoglycemia may occur. Ultrasound, computerized tomography scan, and magnetic resonance imaging have been considered as noninvasive tools for diagnosis of AFLP but their value remain limited[21]. Histologically, AFLP is characterized by microvesicular hepatic steatosis. On Oil Red O staining, one observes the cytoplasmic vesiculation as a result of microvesicular fat[22,23].

Although there are many causes of hepatic disease in pregnancy, a few disease states pose difficulty in the differential diagnosis. AFLP is often difficult to distinguish clinically from fulminant viral hepatitis since both may present suddenly and may progress to hepatic failure[24]. Severe HELLP syndrome may be impossible to distinguish from AFLP in some cases. HELLP syndrome is a severe form of preeclampsia that threatens the patient and her fetus occurring in 4%-20% of women with severe preeclampsia[25]. Typically, hypoglycemia, and prolongation of prothrombin time may distinguish AFLP from HELLP syndrome. Histological examination of liver biopsies from HELLP syndrome cases reveal periportal hemorrhage and fibrin deposition while those from AFLP cases are characterized by microvesicular fatty infiltration of the liver[27].

## PATHOGENESIS OF ACUTE FATTY LIVER OF PREGNANCY

Until recently the pathogenesis of AFLP was unknown and still has not been fully elucidated. Recent molecular advances suggest that AFLP may result from mitochondrial dysfunction. As we discuss below, several reports have documented a strong association between AFLP and a deficiency of the enzyme long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) in the fetus, a disorder of mitochondrial fatty acid beta-oxidation.

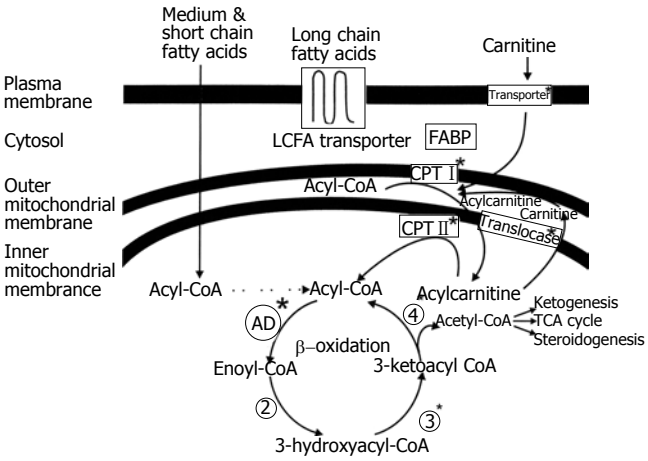

**Figure 1** Fatty Acid Import into the Mitochondria and Fatty Acid β-oxidation. Long chain fatty acids are actively transported across the plasma membrane, esterified to coenzyme A, carried by fatty acid binding proteins through the cytoplasm to the mitochondria and translocated across the mitochondrial membranes by the carnitine shuttle into the mitochondrial matrix. The fatty acid is subsequently cleaved into two shorter carbon entities by the β-oxidation spiral.

## MITOCHONDRIAL FATTY ACID BETA-OXIDATION

The β-oxidation of fatty acids is the major source of energy for skeletal muscle and the heart, while the liver oxidizes fatty acids primarily under the conditions of prolonged fasting, during illness, and at periods of increased muscular activity. Fatty acid oxidation (FAO) also plays an essential role in the intermediary metabolism in the liver. The oxidation of fatty acids in the liver fuels the synthesis of ketone bodies, 3-hydroxy butyrate and acetoacetate, which are utilized as alternative sources of energy by extrahepatic organs, like the brain, when blood glucose levels are low[18].

Mitochondrial β-oxidation of fatty acids is a complex process that consists of multiple transport steps and four enzymatic reactions resulting in the sequential removal of two-carbon, acetyl-coenzyme A units. Plasma long chain fatty acids are transported actively across the plasma membrane, esterified to coenzyme A, carried by fatty acid binding proteins through the cytoplasm to the mitochondria, and translocated across the mitochondrial inner membrane by the carnitine shuttle to the mitochondrial matrix (Figure 1). Once in the mitochondrial matrix, the fatty acid is sequentially cleaved, two carbons shorter, by the four reactions of the β-oxidation spiral. Each step in the spiral is catalyzed by 2-4 distinct enzymes, encoded by separate nuclear genes that exhibit different overlapping substrate specificities. The first step in the spiral, as shown in Figure 2, is an acyl-CoA dehydrogenase reaction, catalyzed by very long-chain acyl-CoA dehydrogenase (VLCAD) and its homologous enzymes, long-chain acyl-CoA dehydrogenase (LCAD), medium-chain acyl-CoA dehydrogenase (MCAD) or short-chain acyl-CoA dehydrogenase (SCAD). The second step in the pathway adds a water across the double bond and is catalyzed by either a long-chain 2,3-enoyl-CoA hydratase

(LCEH) or a short-chain 2,3-enoyl-CoA hydratase (SCEH) which hydrates the 2,3 enoyl-CoA across the double bond. The third step is catalyzed by a long-chain 3-hydroxyacyl-CoA dehydrogenase (LCHAD) or a short-chain 3-hydroxyacyl-CoA dehydrogenase (SCHAD) which oxidizes the 3-hydroxy position producing a 3-ketoacyl-CoA. The fourth and last step in the spiral is mediated by a long-chain 3-ketoacyl-CoA thiolase (LKAT), medium-chain 3-ketoacyl-CoA thiolase (MKAT), or short-chain 3-ketoacyl-CoA thiolase (SKAT), that shortens the fatty acyl-CoA substrate by two carbons by cleaving off acetyl-CoA. The shortened acyl-CoA can then reenter the fatty acid β-oxidation spiral until the fatty acid is completely broken down into a 2-carbon or 3-carbon specie. The acetyl-CoA produced can be used for ketogenesis, steroid genesis and as a substrate for the tricarboxylic acid cycle. For long chain length fatty acids, the last three steps are mediated by an enzyme complex called trifunctional protein[29,30].

In 1992, two groups of investigators, independent of each other, reported that LCHAD is part of an enzyme complex, the mitochondrial trifunctional protein (MTP) which is associated with the inner mitochondrial membrane[31,32]. MTP, also known as trifunctional protein (TFP), is a heterooctamer of 4α- and 4β- subunits. The α-subunit amino-terminal domain contains the long-chain 3-enoyl-CoA hydratase enzymatic activity while the LCHAD enzymatic activity resides in the carboxy-terminal domain. The β-subunit has the long-chain 3-ketoacyl-CoA thiolase enzymatic activity. The association of the α and β subunits to form the enzyme complex is necessary for membrane translocation and for the catalytic stability of the 3 enzymes[33,34]. The human cDNAs encoding both α and β subunits have been isolated and characterized[29,35]. Both subunit genes, HADHA and HADHB, have been localized to chromosome 2p23 using fluorescence *in situ* hybridization (FISH)[36]. Figure 3 shows a schematic representation of the exons of the α- and β-subunits composing the MTP subunit cDNAs and the corresponding functions of the encoded protein. Both genes have been found to be arranged in a head-to-head manner and share a promoter that is bidirectional[37].

## FATTY ACID OXIDATION DISORDERS

Fatty acid oxidation disorders have become an important group of inherited metabolic disorders characterized by a wide array of clinical presentations and as important causes of pediatric morbidity and mortality. The first documented inherited disorder of fatty acid oxidation was described in 1973 of a muscle carnitine palmitoyl transferase (CPT) deficiency[38]. Since then, more than 20 different disorders that affect β-oxidation have been identified. LCHAD deficiency was first described in 1989[39]. MTP deficiency was first reported in 1992[40], which cleared the confusion of interpreting the combined defects of LCEH, LCHAD, and LKAT.

Fatty acid oxidation disorders, if unrecognized and untreated, can cause sudden unexpected death. Such deaths can be certified as sudden infant death syndrome (SIDS), if fatty acid oxidation defects are not suspected.

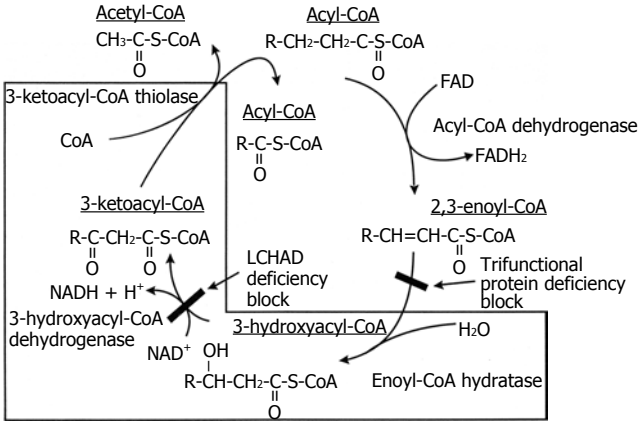

**Figure 2** The Biochemistry of TFP and LCHAD Deficiencies. The last three reactions of the mitochondrial fatty acid β-oxidation spiral where the trifunctional protein catalyzes long chain fatty acids substrates. In isolated LCHAD deficiency, the pathway is blocked after the enoyl Co-A hydratase reaction and before the 3-hydroxyacyl Co-A dehydrogenase reaction, causing the accumulation of medium- and long-chain 3-hydroxy fatty acids and their metabolites. In complete TFP deficiency, the pathway is blocked after the acyl Co-A dehydrogenase reaction and before the enoyl Co-A dehydrogenase reaction causing the accumulation of straight chain fatty acids and their metabolites.

Postmortem studies on SIDS victims attributed a small, but significant, number of SIDS to undiagnosed fatty acid oxidation disorders at the time of the sudden infant death[41].

## MITOCHONDRIAL TRIFUNCTIONAL PROTEIN DEFECTS

MTP defects have recently emerged as an important group of errors of metabolism because of their clinical implications. Human defects in the MTP complex are recessively inherited and cause either isolated LCHAD deficiency, with normal or partially reduced thiolase and hydratase activity, or complete MTP deficiency with markedly reduced activity of all 3 enzymes. Patients have been described with either an isolated LCHAD deficiency or MTP deficiency. In the literature, the majority of patients reported have been described as having isolated LCHAD deficiency[42].

A few hours or several months after birth, children with these recessively inherited disorders present with nonketotic hypoglycemia and hepatic encephalopathy, which may progress to coma and death if untreated[43]. They can also present with cardiomyopathy, slowly progressing peripheral neuropathy, skeletal myopathy, or sudden, unexpected death[44,45].

## MOLECULAR BASIS OF MTP DEFECTS

With the explosion in human molecular genetics over the last decade, we and others began to characterize normal and mutated MTP genes using molecular approaches to delineate disease-causing MTP mutations. Two teams, independent of each other, delineated the G1528C mutation in exon 15 of the α-subunit which alters amino acid 474 from glutamic acid to glutamine (E474Q) and

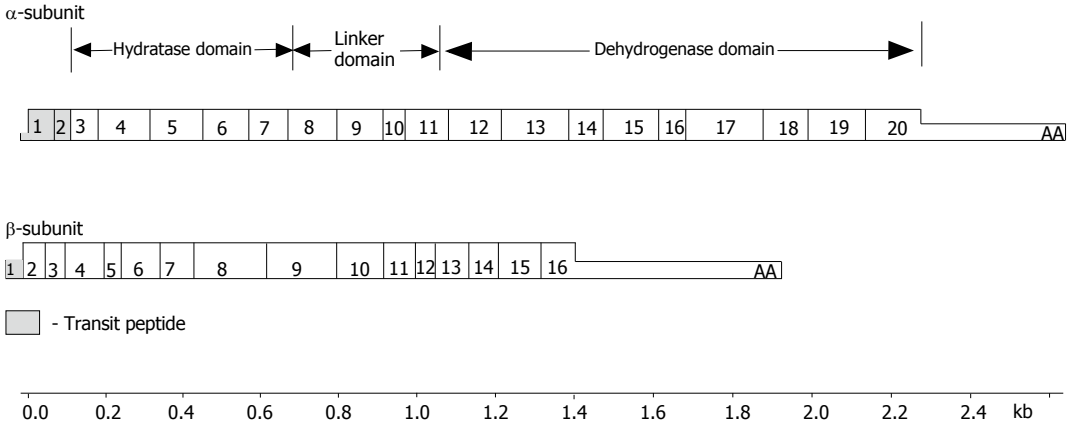

**Figure 3** The structure of MTP subunit cDNA's. The MTP α-subunit contains 20 exons. Exons 1 and 2 encode the transit peptide that directs uptake into the mitochondria which is proteolytically cleaved during translocation into the mitochondria. Exons 3-8 encode the N-terminus of the mature α-subunit containing the long-chain 2,3-enoyl-CoA hydratase activity. Exon 9 encodes the region known as a linker domain. Exons 11-20 encode the C-terminus of the mature α-subunit containing the LCHAD activity. The MTP β-subunit has 16 exons that encode the long-chain 3-keto-acyl CoA thiolase activity.

**Table 1 Genotypes and phenotypes in 24 families with MTP defects**

| Number of families | Biochemical phenotype | Pediatric phenotype | Protein expression | Pediatric phenotype | Maternal phenotype |
|---|---|---|---|---|---|
| 19 | LCHAD | Homozygous G1528C (8) | Normal | Hepatic (7)<br>Mixed (1) | AFLP (6)<br>Normal (1)<br>HELLP (1) |
| | | Compound heterozygous (11)<br>G1528C/splice site (3)<br>G1528C/stop codon (7)<br>G1528C/?[1] | Reduced | Hepatic (9)<br>Mixed (1)<br>Unknown (1) | AFLP (7)<br>HELLP (1)<br>Normal (3) |
| 5 | MTP | Homozygous (1)<br>(A→7G missplice), exon 7 | Absent | Cardiac | Normal |
| | | Compound Heterozygous (2)<br>(G + 1A missplice/A<br>+ 3G missplice), exon 3<br>( C2026T/C2027A), exon 19 | Absent<br>Absent | Cardiac<br>Cardiac | Normal<br>Normal |

[1]Unknown mutation; AFLP–acute fatty liver of pregnancy; HELLP–hemolysis, elevated liver enzymes and low platelets syndrome.

replaces the acidic and negatively charged side-chain with a neutral, amide-containing residue[35,46]. In a subsequent study, we have reported the α-subunit molecular defects and phenotypes in 24 patients with documented isolated LCHAD deficiency or complete MTP deficiency[42]. Of the 24 patients, 19 were diagnosed with isolated LCHAD deficiency and presented with the hepatic phenotype, 5 were diagnosed with complete trifunctional protein deficiency where three displayed the cardiac phenotype and the other two presented with the neuromuscular phenotype. Patients with isolated LCHAD deficiency presented predominantly with a Reye-like syndrome of liver dysfunction and carried the prevalent G1528C missense mutation on one or both alleles. Of the 19 subjects, 8 were homozygous for the common mutation G1528C while 11 were compound heterozygotes, where one allele carried the common mutation and the other allele had a mutation other than the common G1528C mutation[42]. The genotypes and phenotypes of these 19 patients are presented in Table 1.

The likely mechanism by which the E474Q mutation causes isolated LCHAD deficiency is that the mutation inactivates LCHAD directly within the catalytic domain, and hence, preserves the other MTP enzyme activities. The likely mechanism has been elucidated by Barycki and colleagues[42] based on the crystal and structural analysis of x-ray diffraction data from the human SCHAD which is highly homologous to the LCHAD domain. E170 in SCHAD, a residue that is analogous to LCHAD E474, is located in the NAD-binding domain within the active catalytic site. E170 is also in a position to interact with another residue, H158 which serves as a base abstracting a proton from the 3-hydroxy group of the substrate. Substitution of E170 in SCHAD with glutamine disrupts the electrostatic interaction between E170 and H158, which is essential for catalysis. Similar to what happens to

E170Q mutation in SCHAD, the E474Q mutation causes isolated LCHAD deficiency and blocks the β-oxidation resulting in the accumulation of 3-hydroxy fatty acid metabolites.

All the five patients with the complete MTP deficiency presented with cardiomyopathy or neuromyopathy and carried mutations other than the E474Q mutation (Table 1). Three of the five patients with MTP deficiency presented with cardiomyopathy. All three patients had splice site and missense mutations that caused the absence of the MTP protein complex[42]. This condition blocks the second step of the β-oxidation spiral that results in the accumulation of long-chain 3-enoyl fatty acid metabolites. The other two patients with complete MTP deficiency presented with neuromyopathy. These two patients carried mutations in exon 9 that allowed stable MTP expression[43]. Exon 9 in the MTP α-subunit encodes a region described as a linker domain that may be important in subunit interaction and octamer complex formation as suggested by crystallographic data from short-chain enoyl-CoA hydratase[43]. The exon 9 mutations in the α-subunit seem to result in defective subunit interactions and octamer formation.

## FETAL MITOCHONDRIAL TRIFUNCTIONAL PROTEIN DEFECTS AND MATERNAL LIVER DISEASE

Several studies document strong and somewhat unique causative association between fetal MTP defects and AFLP.

Shoeman and colleagues were first to report an association between recurrent maternal acute fatty liver of pregnancy with a fetal fatty acid oxidation disorder in two siblings who both died at 6 mo of age[43]. The authors speculated that due to the finding of similar hepatic pathology of microvesicular steatosis, AFLP and fatty acid oxidation defects might share a common pathogenesis.

Other case reports in the early 90's have also associated affected infants with LCHAD deficiency to the occurrence of severe preeclampsia, HELLP syndrome or AFLP in the infant's mother during pregnancy. Wilcken *et al*[14] reported 11 pregnancies in 5 mothers where 6 babies had confirmed LCHAD deficiency by enzymatic analysis of cultured skin fibroblasts and that the mothers had either AFLP or HELLP syndrome in all six pregnancies with the LCHAD-deficient fetuses. Treem *et al*[49] reported an LCHAD deficient child born to a pregnancy complicated by AFLP.

In a subsequent report published in 1995, Sims *et al* delineated the molecular basis of pediatric LCHAD deficiency and its association with AFLP in 3 families with LCHAD-deficient infants[35]. The mothers suffered maternal HELLP syndrome or AFLP during pregnancies with the affected children. Molecular analysis in 2 affected children revealed the G1528C mutation on both alleles and the third child was a compound heterozygote with one allele carrying the G1528C.

Another report documented an association between pediatric LCHAD deficiency and occurrence of AFLP in the mother, Isaacs *et al*[35] reported a compound heterozygosity for MTP mutations in an affected child born to a pregnancy complicated by AFLP, with a novel mutation in exon 16 on one allele and the common G1528C mutation on the other allele.

In a study where we examined the association between MTP defects in children and liver disease in their mothers during pregnancy[42], 15 of 24 women (62%) were diagnosed to have had maternal liver disease, while 9 of the 24 women had normal pregnancies, as summarized in Table 1. In 5 of the normal pregnancies, the affected infant did not have the G1528C mutation, but rather other MTP mutations. The remaining four normal pregnancies were associated with fetal LCHAD deficiency. Thus 15/19 pregnancies associated with fetal LCHAD deficiency were complicated by maternal liver disease and none of the pregnancies associated with complete MTP deficiency were complicated by AFLP or HELLP syndrome. The results in this study suggest that when carrying an LCHAD-deficient fetus, there is a 79% chance that the pregnancy will be complicated by AFLP or HELLP syndrome.

In a subsequent study, we evaluated fetal genotypes and pregnancy outcomes in 83 pregnancies in 35 families with documented pediatric MTP defects, 24 pregnancies were complicated by AFLP, HELLP syndrome or severe preeclampsia[51]. Of the 24 pregnancies, 20 were complicated by AFLP, 2 with HELLP syndrome and 2 with preeclampsia and all the LCHAD-deficient fetuses carried the G1528C mutation on one or both alleles. Five pregnancies had fetuses with complete MTP deficiency (none of the mutations were G1528C) but there were no associated maternal complications in those pregnancies.

The above studies provide strong evidence that carrying a fetus with LCHAD deficiency is associated with a high risk for developing AFLP during pregnancy. With the growing evidence suggesting that carrying an LCHAD-deficient fetus is associated with AFLP, we have recommended that neonates born to pregnancies complicated by AFLP be tested for the common G1528C mutation and that this testing when done early after birth can be life saving as it may identify LCHAD-deficient children before they manifest the disease allowing early dietary intervention by institution of a diet low in fat, high in carbohydrate, and by substitution of the long chain fatty acids with medium chain fatty acids.

To further assess the significance of the association between maternal AFLP and fetal LCHAD deficiency, we prospectively screened for MTP mutations in mothers who developed AFLP or HELLP syndrome and their newborn infants[52]. The molecular screening was based solely on the maternal history. We prospectively screened 27 pregnancies complicated by AFLP and 81 pregnancies complicated by HELLP syndrome. Out of the 27 women that developed AFLP, 5 carried fetuses with MTP mutations. Three were homozygous for the G1528C mutation and two were compound heterozygotes with one mutant allele carrying the common G1528C and the other mutant allele carrying a novel mutation. Only one woman diagnosed with HELLP syndrome was heterozygous for the G1528C mutation which was not detected in her infant. None of the children born to the 81 women diagnosed with HELLP syndrome carried MTP mutations. This study

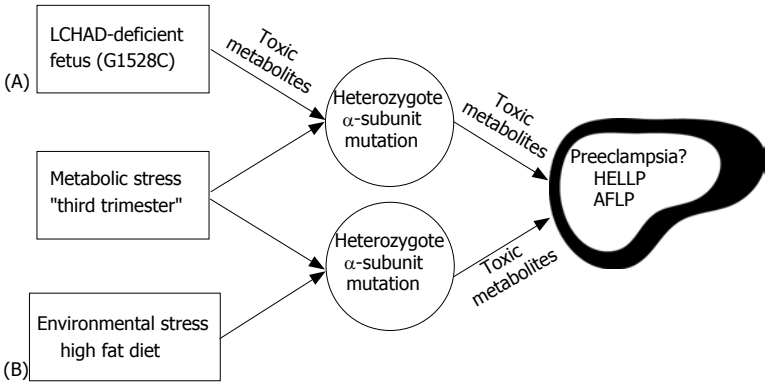

**Figure 4** Hypothesis illustrating the possible role of fetal and maternal MTP mutations in developing AFLP. Carrying an LCHAD deficient fetus (**A**) is the major determining factor in the development of maternal illness. Hepatotoxic metabolites produced by the fetus and/or placenta may cause liver disease in the obligate heterozygous mother when combined with the metabolic stress of the third trimester. Environmental stress (**B**) may lead to the further accumulation of toxic metabolites in the genetically susceptible mother causing maternal liver disease.

documents that in approximately one of five pregnancies complicated by AFLP, the fetus is LCHAD-deficient. This strong association between AFLP and the common G1528C mutation in the fetus is significant and hence screening the offspring of women who develop AFLP at birth for this mutation can be life saving.

In addition, identification of MTP mutations in the offspring of pregnancies complicated by AFLP allows genetic counseling for the mothers. Prenatal diagnosis can be performed in subsequent pregnancies to identify pregnancies at risk for development of AFLP. We performed molecular prenatal diagnosis in 11 pregnancies using chorionic villous samples and successfully identified the fetal genotype in these pregnancies confirmed by biochemical and molecular testing of the newborn or aborted fetuses[53].

## POSSIBLE HYPOTHESIS FOR THE ASSOCIATION BETWEEN FETAL LCHAD DEFICIENCY AND ACUTE FATTY LIVER OF PREGNANCY

The precise mechanism by which an LCHAD-deficient fetus causes AFLP in a heterozygote mother is still unclear. However, several factors appear to contribute to this fetal-maternal interaction as illustrated in Figure 4. First, the heterozygosity of the mother for an MTP defect reduces her capacity to oxidize long-chain fatty acids. Second, the stressful nature of pregnancy with its accompanying changes in metabolism, the increased lipolysis, and the decreased β-oxidation. We speculate that in the presence of the G1528C mutation, potentially hepatotoxic long-chain 3-hydroxyacyl fatty acid metabolites, produced by the fetus or placenta, accumulate in the maternal circulation. There is evidence for fatty acid oxidation in a normal human placenta including LCHAD and SCHAD activity[54]. Another study reported significant expression of fatty acid β-oxidation enzymes in human placenta as assessed by immunohistochemical and immunoblot analyses[55]. A recent study also showed high activity of fatty acid oxidation enzymes in human term placenta and chorionic villus samples[56].

The role of other FAO defects in the development of AFLP is not clear and remains controversial. Few case reports describe possible association between maternal liver disease and fetal fatty acid oxidation defects other than those in MTP. Maternal liver disease consistent with AFLP was associated with carnitine palmitoyl transferase Ⅰ (CPT-1) deficiency. In Innes *et al*[57], the patient developed liver disease consistent with AFLP and in a successive pregnancy, hyperemesis gravidarum. Both children were subsequently shown to have CPT-1 deficiency. In Ylitalo *et al*[58], the patient experienced complications that included a HELLP-like syndrome. She was later diagnosed to be CPT-1 deficient but her child was unaffected. Another report linked AFLP to fetal SCAD deficiency. In Matern *et al*[59], an infant born to a mother who developed AFLP was diagnosed with SCAD deficiency. A report of a pregnancy complicated with HELLP syndrome and associated with fetal MCAD deficiency has also been published[60].

## CONCLUSION

Acute fatty liver of pregnancy is a serious maternal disorder that has been for long considered of mysterious pathogenesis. Recent evidence suggests a fetal-maternal interaction causing acute fatty liver of pregnancy. Approximately one in five women who develop AFLP may carry an LCHAD-deficient fetus. Screening the newborn at birth in pregnancies complicated by AFLP for this fatty acid oxidation disorder can be lifesaving and may allow for genetic counseling in subsequent pregnancies.

## Abstract

Intracranial hypertension is a major cause of morbidity and mortality of patients suffering from fulminant hepatic failure. The etiology of this intracranial hypertension is not fully determined, and is probably multifactorial, combining a cytotoxic brain edema due to the astrocytic accumulation of glutamine, and an increase in cerebral blood volume and cerebral blood flow, in part due to inflammation, to glutamine and to toxic products of the diseased liver. Validated methods to control intracranial hypertension in fulminant hepatic failure patients mainly include mannitol, hypertonic saline, indomethacin, thiopental, and hyperventilation. However all these measures are often not sufficient in absence of liver transplantation, the only curative treatment of intracranial hypertension in fulminant hepatic failure to date. Induced moderate hypothermia seems very promising in this setting, but has to be validated by a controlled, randomized study. Artificial liver support systems have been under investigation for many decades. The bioartificial liver, based on both detoxification and swine liver cells, has shown some efficacy on reduction of intracranial pressure but did not show survival benefit in a controlled, randomized study. The Molecular Adsorbents Recirculating System has shown some efficacy in decreasing intracranial pressure in an animal model of liver failure, but has still to be evaluated in a phase Ⅲ trial.

**Key words:** Intracranial hypertension; Fulminant hepatic failure; Brain edema

## INTRODUCTION

Fulminant hepatic failure (FHF) is an infrequent but dreadful disease, defined by the appearance of hepatic encephalopathy within 8 wk after the onset of jaundice in patients with no known chronic liver disease[1]. Most FHF patients rapidly develop electrolyte, metabolic, and coagulation abnormalities[2]. They frequently suffer from acute renal insufficiency and/or adult respiratory distress syndrome (ARDS), leading to multiple organ failure (MOF)[3]. They are very sensitive to infection, and frequently develop a sepsis-like syndrome, with systemic hypotension, low peripheral resistance and increased cardiac output. Modern intensive care units (ICU) have learned to treat all these conditions, and have prolonged FHF patient survival. However, in absence of liver transplantation (LT), the mortality rate of FHF patients remains high (60%-80%). Causes of death of these patients are mainly MOF, sepsis, and/or brain edema leading to intracranial hypertension and secondary brain death.

Brain edema in FHF patients is a relatively recent concept. In a 1944 report of 125 autopsies of military patients dying from what was called fatal hepatitis (previously named idiopathic acute yellow atrophy of the liver), Lucké noted little alteration in the brain, except edema, but he did not describe cerebral herniation[4]. He hypothesized that the cerebral changes of fatal hepatitis might be attributed to loss of detoxifying function of the liver. The first reports of brain edema and cerebral herniation as complications of FHF were published in the 1970's[5,6] and were criticized at that time. Widespread recognition that brain edema and intracranial hypertension are complications of FHF only occurred in the 1980's[7,8]. It is also very interesting to note that brain edema and intracranial hypertension are not recognized common features of terminal chronic liver failure, despite some case reports or small series[9,10]. The recent recognition of brain edema in FHF patients could be due to the advances in FHF patient care. Previously, FHF patients were dying from early hepatocellular insufficiency complications, mainly hemorrhage or sepsis[4]. Improvements in ICU techniques have lengthened the survival of FHF patients. The longer course of the disease may have allowed the development of brain edema, possibly a later complication of FHF (Figure 1). Significant advances in the understanding of FHF brain edema have been made this last decade, but the exact pathophysiological mechanisms underlying development of brain edema and intracranial hypertension in FHF are still not entirely clear and are

likely to be multifactorial[11]. The aim of this paper is to review the pathophysiology of intracranial hypertension in FHF in order to improve understanding and management of this complication.

## PATHOPHYSIOLOGY OF INTRACRANIAL HYPERTENSION IN FHF

Normal intracranial pressure (ICP) is 5 to 10 mmHg and intracranial hypertension becomes clinically relevant when ICP exceeds 20 mmHg. The main complication of severe intracranial hypertension in FHF patients is transtentorial herniation[12]. This herniation may induce (1) compression of the posterior cerebral artery, leading to medial temporal, thalamic, and occipital lobe infarction; (2) cerebral aqueduct and subarachnoid space compression, causing obstructive hydrocephalus; and (3) brain stem compression, resulting in brain stem ischemia, haemorrhage, and death[12]. Additionally, severe intracranial hypertension compromises cerebral perfusion pressure (CPP). By definition, CPP is the difference between mean arterial pressure (MAP) and cerebral venous pressure. As cerebral venous pressure can be approximated by ICP, CPP equals MAP minus ICP[12,13]. An increase in ICP reduces CPP, and thus a decrease in cerebral blood flow (CBF). This reduction in CBF may cause cerebral ischemia or infarction, resulting in neurological deficits in FHF survivors.

A rise in ICP is the mechanical consequence of an increase in the intracranial volume. The central nervous system (CNS) is protected by the skull, which is rigid and incompressible. Inside the skull, 3 different compartments can be defined: the brain, the cerebrospinal fluid (CSF) and the blood. If the volume of one of these elements increases, the volume of another compartment might decrease, resulting in some intracranial compensation capacity or compliance. If the increase in volume exceeds this compliance, any further addition of volume leads to a rise in ICP.

It is generally accepted that CSF volume is not expanded in FHF. During episodes of intracranial hypertension in FHF, ventricular spaces measured by computed tomography (CT) were either unchanged or compressed, suggesting an increase in the brain tissue or blood volume[14,15]. In animal models and in FHF patients there is increased brain volume, secondary to edema[5,16,17]. In this environment even a small increase in cerebral blood volume could significantly increase ICP. In fact, these two phenomena have been proposed to account for intracranial hypertension in FHF: (1) brain edema due to osmotic astrocyte swelling secondary to ammonia-induced accumulation of glutamine (ammonia-glutamine hypothesis); (2) alteration of CBF regulation with increase of the intracranial blood volume.

### *Brain edema in FHF (Figure 2)*

Both vasogenic and cytotoxic mechanisms are implicated in the development of cerebral edema. Vasogenic brain edema occurs as a result of the disruption of the blood-brain barrier (BBB), allowing uncontrolled access of plasma components and water to the extracellular cerebral compartment. Cytotoxic edema is the consequence of impaired cellular osmoregulation in the brain, resulting in an increase of cellular water. In FHF, evidence from experimental animals and postmortem human brain supports aspects of each of these mechanisms, but it is now well established that brain edema in FHF is mainly cytotoxic[18]. In several models of FHF, compounds to which the BBB is normally impermeable (Evans Blue or a-aminoisobutyric acid) were detected in the brain in increased concentrations[19-21]. These observations suggest that BBB permeability is altered in FHF, which is consistent with a vasogenic mechanism. However, the ability of mannitol to reduce ICP in patients with FHF indicates that the BBB remains largely intact[8]. Furthermore, electron microscopic studies of human brain tissue in FHF revealed no alteration in the integrity of tight junctions[22]. Moreover, consistent with cytotoxic edema, marked intracellular swelling of perivascular astrocytes was observed. Recent magnetic resonance imaging of brain of FHF patients confirmed the predominant cytotoxic character of FHF brain edema[23]. This suggests that FHF brain edema primarily develops within the cellular component of the brain as a cytotoxic edema, and changes in the permeability of the BBB may represent secondary events that could exacerbate edema or intracranial hypertension.

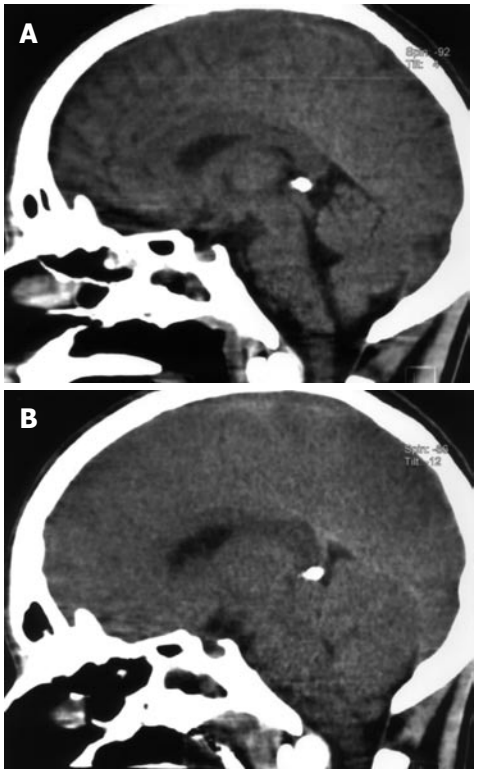

**Figure 1** Computed tomography (CT) (sagittal sections) of the brain of a 17-year old man who developed fulminant hepatic failure. **A**: First CT performed in encephalopathy stage Ⅳ; **B**: Control CT performed when the patient developed unilateral fixed midriasis, showing diffuse edema, compression of the fourth ventricle and of the brain stem. The patient developed brain stem death while waiting liver transplantation, despite medical therapy and MARS treatment.

**The ammonia-glutamine hypothesis:** Cortical astrocyte swelling is the most common observation

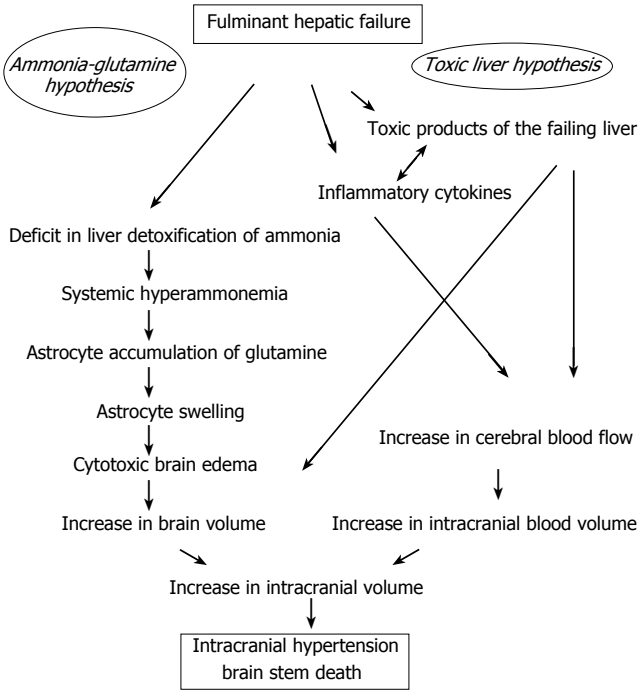

**Figure 2** Schematic representation of the hypotheses explaining intracranial hypertension and brain stem death in fulminant hepatic failure.

in neuropathological studies of brain edema in FHF. Astrocytes are the most numerous cell type in the brain and occupy about one-third of the cortical volume[24]. Astrocytes have several critical metabolic functions involved in the maintenance and regulation of the extracellular microenvironment. They participate in water regulation in the brain, detoxify ammonia and maintain normal levels of extracellular glutamate. Hyperammonemia is prevalent in acute liver failure. In the brain, ammonia is detoxified to glutamine via the amidation of glutamate by an astrocytic enzyme, glutamine synthetase. Glutamine leaves the astrocyte by passive diffusion into the extracellular space where it is taken up by neurons and converted to glutamate. There is clear evidence of increased brain glutamine concentrations in animal FHF models[25] and in postmortem samples of FHF[26]. Brusilow first proposed that this glutamine accumulation is the link between hyperammonemia and edema via altered osmoregulation[27]. In astrocyte cultures, ammonia induces cell swelling[17,28]. Brain swelling and intracranial hypertension have been documented in humans with hyperammonemic conditions[29]. In rats, a continuous infusion of ammonia is associated with brain edema or intracranial hypertension[30] which is reduced by inhibition of glutamine synthesis with methionine-sulfoximine[31-33]. The relationship between hyperammonemia, glutamine and ICP was recently demonstrated in humans[34]. Although there is much clinical and experimental evidence in support of the glutamine hypothesis, prevention of brain edema in FHF by inhibition of glutamine synthesis has not been successful in humans.

### *Increase in cerebral blood flow and intracranial blood volume*

Another phenomenon that has also been involved in intracranial hypertension in FHF is the increase of intracranial blood volume and CBF. Some reports describe decreased CBF in patients suffering from acute liver failure[35,36], but most have found high CBF associated with intracranial hypertension in FHF[37,38]. Paulson suggests that an impairment of vascular autoregulation in the brain could be responsible for this increase in CBF and blood volume[39]. Impaired autoregulation of CBF has been reported in animal models of FHF[40] and in patients with FHF[41]. The exact cause of this increase of CBF in FHF is not known. Nitric oxide (NO) has been implicated but it is possible that the increased NO in the brain of FHF patients is secondary to an increase in CBF, rather than a primary event[18,42]. Inflammation markers (IL-1 $\beta$, TNF $\alpha$, IL-6) and systemic inflammatory response have been associated with increased CBF and ICP in FHF[37,43], with poor outcome[44]. The association of systemic inflammation and impaired regulation of CBF might be related to the role of the necrotic liver in intracranial hypertension in FHF. The observation that brain edema and intracranial hypertension are complications of FHF and not of chronic liver disease lead to the hypothesis that these phenomena may in part result from products of the acutely necrotic liver. There is experimental and clinical evidence to support this theory, the "toxic liver hypothesis". In a rat model, cerebral edema was significantly lower in anhepatic than FHF animals[45]. In pigs, no elevation of ICP was observed after total hepatectomy, whereas a rise in ICP was observed in pigs with FHF secondary to ischemia[46]. Several human observations reinforced this hypothesis. During LT for FHF, it was established that ICP normalizes during the anhepatic phase and may increase during the dissection of the diseased liver and during graft reperfusion[47,48]. The removal of the diseased liver has been linked to ICP normalization and to marked and sustained reduction of several pro-inflammatory cytokines in a case report[49]. Moreover some patients underwent a prolonged period (up to 72 h) of an anhepatic state without neurological sequelae[50,51]. Although these findings are suggestive, the role of products from the necrotic liver in cerebral edema and intracranial hypertension is still unknown.

The respective roles of all of these phenomena in the development of intracranial hypertension in FHF remains to be determined. It can be hypothesized that brain edema (increase in brain volume) secondary to osmotic effect of glutamine in astrocytes, and cerebral hyperemia (increase in blood volume) secondary to vasodilation (cytokines, products of the necrotic liver, glutamine, others…) may contribute to intracranial hypertension leading to brain stem herniation and brain stem death in FHF. During all these FHF phenomena, the brain may respond by altering the expression of genes coding for various proteins whose role may be critical to some CNS functions, including the maintenance of cell volume and neurotransmission. Cerebral gene expression during FHF is modified as demonstrated by differential display in rat models[52,53]. Some genes have been more specifically studied, as GLUT-1[54], aquaporin IV[55], GLT-1[52,56] and others[57]. The exact role of this gene expression observed during FHF is still to be determined.

## DIAGNOSIS OF INTRACRANIAL HYPERTENSION IN FHF PATIENTS

Intracranial hypertension should be clinically suspected in FHF patients with systemic hypertension (sustained ⩾ 160 mmHg or paroxysms ⩾ 200 mmHg), aggravation of hepatic encephalopathy, abnormal pupillary signs, or signs of decerebration. However, most of these clinical signs are not specific, and may be developed by patients in hepatic grade IV encephalopathy without intracranial hypertension. It was reported that brain CT is unreliable in the diagnosis of intracranial hypertension in FHF patients[14], and there have been no reports of the value of brain magnetic resonance imaging in FHF patients for confirming the diagnosis of intracranial hypertension. The most accurate method of diagnosing intracranial hypertension is ICP monitoring. Although the advantages of this monitoring in FHF patients have not yet been demonstrated by a randomized study, ICP monitoring may be very helpful in establishing the presence of intracranial hypertension and in guiding specific therapy. Intracranial hypertension in FHF patients may suddenly rise from normal to life threatening levels within minutes. In this situation, continuous ICP monitoring may allow rapid and specific management. Several groups have included ICP monitoring in the protocol of FHF patient management[14,47,58]. The main argument against ICP monitoring is the enhanced risk of complications in FHF patients, mainly infection and hemorrhage. In a national survey of 262 FHF patients, the complication rate of ICP monitoring was 10%. In this series, intracranial hemorrhages were the cause of death in 7 patients and the epidural transducers had the lowest complication rate (3.7%)[59]. The complication rate of ICP monitoring in FHF patients was reported to be lower in a recent multicenter report, but is still significant[60].

## MANAGEMENT OF INTRACRANIAL HYPERTENSION IN FHF PATIENTS

General management of FHF patients is beyond the scope of this review and was presented elsewhere[2]. The goal in the medical management of FHF patients with intracranial hypertension is to maintain ICP below 20 mmHg and CPP above 70 mmHg. Cerebral ischemia occurs if CPP is less than 40 to 50 mmHg, and LT should be contraindicated if CPP remains below 40 mmHg for two hours[61]. This goal requires intense medical management and nursing. FHF patients should be admitted to the ICU in an institution with an active liver transplant program. FHF patients should be monitored with peripheral arterial catheters. Vital signs, urinary output, arterial blood gases and central hemodynamic parameters should be continuously monitored. FHF patients are treated with standard supportive measures to correct electrolyte, metabolic, respiratory and hemodynamic abnormalities. Hypovolemia may exacerbate hypotension, and may reduce CPP, inducing brain ischemia. Systemic hypertension may also be deleterious by increasing ICP[62]. In this case, β-blockers may be more useful than nitroprusside or calcium-channel inhibitors, because of their potential risk of brain blood vessel dilatation. Patient positioning and nursing is also important in the care of FHF patients with intracranial hypertension. The head should be in the midline because neck rotation or flexion may compromise jugular venous drainage and increase ICP. Head and chest elevation may lower ICP by enhancing CSF drainage and maximizing cerebral venous output[12]. However, the efficacy of this positioning in FHF patients is yet to be proven and further elevations to 40° and 60° may paradoxically increase ICP[63]. Environmental stimulation should be maintained at a minimal level. Most of the FHF patients with encephalopathy grade Ⅲ/Ⅳ are endotracheally intubated to provide airway protection and/or ventilation support. This ventilation may promote some ICP fluctuation. Moreover, positive end-expiratory pressure (PEEP) may increase ICP when mean airway pressures are increased and should be used carefully[12]. Straining against the mechanical ventilator may increase intrathoracic pressure and reduce venous outflow from the head. Coughing, which is a frequent reflex to tracheal tube aspiration, should be avoided for the same reason. Therefore, if necessary, the patient is sedated and/or paralyzed with nondepolarizing neuromuscular blockers.

Specific treatment of intracranial hypertension in FHF patients is aimed at the culprit underlying pathophysiology, for example therapy to reduce brain volume or lower ICP by reducing intracranial blood volume and CBF.

### *Treatments to decrease brain volume*

As hyperammonemia is considered responsible for the cytotoxic brain edema, it seems logical to try to reduce ammonia in FHF patients. There is no randomized study on the effects of lactulose in FHF. In a retrospective study, lactulose administration did not change the outcome of treated patients, and the routine use of lactulose is not recommended[64]. The use of intravenous *mannitol* improved the survival and decreased the ICP level in a controlled trial[8]. Mannitol (0.5 to 1 g/kg iv every 6 h, blood osmolarity < 310 mosmol/L) increases blood osmolarity, thereby inducing fluid movement from brain to blood. Therefore, the efficacy of mannitol depends on an intact BBB. The efficacy of mannitol to reduce ICP may be affected by acute renal failure and oliguria. In order to be able to use mannitol repeatedly, fluid can be taken off with *hemofiltration* (up to 500 mL), which by itself reduces ICP[64]. *Hypertonic saline* has also been evaluated in a small controlled trial to prevent the occurrence of intracranial hypertension. Intravenous hypertonic saline (30%) to maintain serum sodium between 145-155 mmol/L was compared with an untreated group. The treated group suffered smaller increases of ICP[65]. By extension, hyponatremia should be avoided in FHF patients.

### *Treatments to decrease cerebral blood flow and intracranial blood volume*

*Hyperventilation:* In non-FHF patients, hyperventilation induces ICP reduction through vasoconstriction of the brain blood vessels[12]. The duration of this ICP reduction varies, and ICP usually returns to baseline within hours of hyperventilation. In FHF patients, this effect of hyperventilation on intracranial hypertension is not clear[7] but may help to restore cerebral blood flow

**Table 1 Liver transplantation criteria in patients with fulminant hepatic failure**

| |
|---|
| Clichy criteria *(Hepatology* 1991; 14: 49A*)* |
| Grade Ⅲ or Ⅳ encephalopathy and |
| - Factor Ⅴ level < 20% (patients younger than 30) |
| - Factor Ⅴ level < 30% (patients older than 30) |
| King's College criteria *(*Modified from *Gastroenterology* 1989; 97: 439-445*)* |
| Paracetamol intoxication: |
| - pH < 7.3 or |
| - INR > 4 and serum creatinin > 300 μmol/L (> 34 mg/L) and grade Ⅲ or Ⅳ encephalopathy |
| Other causes: |
| - INR > 4 or |
| - 3 of the following criteria: |
| - Age < 10 or > 40 yr |
| - Etiology: NonA nonB hepatitis, halothane hepatitis, idiosyncratic drug reactions |
| - Delay between jaundice and encephalopathy > 7 d |
| - INR > 3.5 |
| - Bilirubin > 300 μmol/L (> 175 mg/L) |

autoregulation[66]. From these observations, it can be stated that hyperventilation may reduce ICP acutely but should not be used over a prolonged period[64]. *Indomethacin* induces cerebral vasoconstriction through inhibition of the endothelial cyclooxygenase pathway, alterations in extracellular pH and reduction in cerebral temperature[64]. Indomethacin has been shown to reduce ICP in an animal model[67] and a small cohort of 12 patients[68], and should be evaluated in a randomized controlled study before wider use. *Thiopental sodium* has also been studied in FHF patients. Its administration results in cerebral vasoconstriction possibly by inhibition of nitric synthase. There is only one small study in the literature involving 13 patients, that showed beneficial effects of thiopental on ICP but its efficacy and side effects have to be evaluated in further randomized studies[69]. *Propofol* in a dose of 6 mg/kg per hour reduces CBF through metabolic suppression[64] and was used in a small report[70]. It could be the sedative of choice in FHF patients.

### *Liver transplantation*

LT has emerged as the most important advance in the treatment of FHF[58,71-74]. To date, transplantation of a functioning graft is the best treatment to achieve control of brain edema and intracranial hypertension. For this reason, every FHF patient should be referred to a transplant center and listed for LT if transplant criteria are met (Table 1)[75,76]. However, some FHF patients in Grade Ⅳ encephalopathy may develop severe cerebral injury or brain death during the perioperative period, and these complications are believed to be secondary to perioperative ICP elevation or CPP reduction. For example, in a study from Paul Brousse's group, 13 patients among 116 (11.2%) who underwent LT for FHF developed brain death during or after the procedure, and 2 others suffered from neurological sequelae[74]. It was demonstrated that during LT, the dissection phase and the graft reperfusion are particularly at risk of ICP elevation, and that the anhepatic phase seems to be more favorable with ICP normalization[47,48].

## FUTURE PROSPECTS IN THE TREATMENT OF INTRACRANIAL HYPERTENSION OF FHF

### *Hypothermia*

The effects of moderate hypothermia (32-34℃) on ICP in FHF patients are currently being investigated. In rat models of FHF, hypothermia lowered brain edema measured by a gravimetric technique, and prolonged survival[77,78]. Several reports have demonstrated that hypothermia causes a significant decrease of ICP in FHF patients[79,80]. Hypothermia could be a very efficient therapy for patients with uncontrolled intracranial hypertension[81] and a multicenter, randomized, controlled trial should be conducted to definitively assess the role of hypothermia in FHF patient management.

### *Liver assist systems*

For more than 50 years, many research groups have attempted to support patients in acute liver failure as a bridge to LT or to recovery of adequate native liver function. Development of such a system presents a unique challenge as it has to reproduce an array of complex liver functions. Moreover, the results of this system have to be evaluated in very sick and unstable patients, in whom large, randomized, controlled trials are very difficult. Plasma exchange, plasmapheresis, blood exchange, hemodialysis, hemofiltration, cross-circulation, and cross-hemodialysis have all been tried without any benefit to patient survival[82]. *Ex vivo* whole (animal and/or human) liver perfusion might be promising in small series, but is limited by several drawbacks that are beyond the scope of this review[82]. Recent advances in semipermeable membranes and hollow-fiber technologies, as well as improved techniques of hepatocyte isolation, have allowed the development of new liver support systems, that may be classified as non-biological blood detoxification systems and liver assist systems with biological components[82]. Two systems have achieved relatively large use in humans. The Molecular Adsorbents Recirculating System (MARS), which is based on the selective removal of albumin-bound toxins from the blood, is commercially available. In a small, randomized trial MARS was shown to improve survival of patients suffering from acute-on-chronic liver failure[83], but controlled clinical data for the use of MARS in FHF patients is lacking, especially its effect on ICP. Recently, it was demonstrated that MARS may attenuate (but not normalize) ICP in a pig model with ischemic liver failure[84]. MARS has still to prove its value in FHF patients in controlled trials.

Multiple liver assist systems with biological components have been tried, in order to construct a liver support that may provide not only detoxification, but also biotransformation and missing liver synthetic function[82]. A lot of systems were based on isolated or cultured hepatocytes and liver tissue slices placed in a variety of perfusion bioreactors[82]. Only one system has completed a controlled trial, the bioartificial liver (BAL). The BAL design is based both on a detoxification part and on a cartridge containing porcine hepatocyte and is explained elsewhere[82]. The BAL has shown some

efficacy to decrease ICP in FHF patients[85] and in patients suffering from acetaminophen-induced liver failure[86]. However a controlled, randomized trial did not show any improvement in survival in the BAL treated group[87] and the Circe company that produced the BAL, has stopped its activity. In conclusion, despite years of scientific efforts, there is no (bio)artificial system that has proved its efficacy on ICP control. The MARS seems promising but has still to prove its role on ICP in FHF patients.

### *Hepatocyte transplantation*

Transplantation of isolated hepatocytes has been shown to provide metabolic support and improve survival in various experimental models of acute liver failure including 90% hepatectomy[88,89], D-galactosamine[90], acetaminophen[91] and ischemic models[92]. Hepatocyte transplantation has also been shown to improve chronic encephalopathy, induced by an end-to-side portocaval shunt in rats[93]. In a pig model of ischemic liver failure, the intrasplenic transplantation of hepatocytes allowed the transplanted animal to maintain normal ICP, compared to the treated group[46].

In two clinical reports, 12 patients were transplanted with a very small number of hepatocytes (0.01%-0.4% of the liver mass) which were infused either intraperitoneally or intrasplenically[94,95]. Although both studies reported improvement in neurologic status and survival of the transplanted patients, the limited number of patients and the lack of appropriate controls do not allow reliable conclusions to be reached. More experiments in large animal models are needed in order to investigate the "neuro-protective" potential of transplanted hepatocytes. In addition, three major problems need to be solved before clinical application of hepatocyte transplantation can be established: (1) how to harvest and store the maximum number of functional hepatocytes from human liver (e.g. hepatic resection specimens, organs rejected for transplantation, *etc*); (2) how to safely perform transplantation of a significant amount of hepatocytes (at least 5% of the liver mass) considering the anatomic limitations and the severe metabolic disturbances of FHF patients (e.g. coagulopathy); (3) how to determine the optimal timing of hepatocellular transplantation in the course of FHF.

## Abstract

Kupffer cells, the resident liver macrophages have long been considered as mostly scavenger cells responsible for removing particulate material from the portal circulation. However, evidence derived mostly from animal models, indicates that Kupffer cells may be implicated in the pathogenesis of various liver diseases including viral hepatitis, steatohepatitis, alcoholic liver disease, intrahepatic cholestasis, activation or rejection of the liver during liver transplantation and liver fibrosis. There is accumulating evidence, reviewed in this paper, suggesting that Kupffer cells may act both as effector cells in the destruction of hepatocytes by producing harmful soluble mediators as well as antigen presenting cells during viral infections of the liver. Moreover they may represent a significant source of chemoattractant molecules for cytotoxic CD8 and regulatory T cells. Their role in fibrosis is well established as they are one of the main sources of TGFβ1 production, which leads to the transformation of stellate cells into myofibroblasts. Whether all these variable functions in the liver are mediated by different Kupffer cell subpopulations remains to be evaluated. In this review we propose a model that demonstrates the role of Kupffer cells in the pathogenesis of liver disease.

**Key words:** Kupffer cells; Liver disease; Hepatic injury; Liver fibrosis; Hepatocellular carcinoma; Hepatitis; Steatohepatitis

## INTRODUCTION

The sinusoidal lining of the liver contains the nonparenchymal cell populations which consist of Kupffer cells (KCs), sinusoidal endothelial cells (SEC) and stellate cells (SC). All three cell-types seem to play a crucial role in liver homeostasis and in the pathogenesis of liver disease[1]. KCs constitute 80%-90% of the tissue macrophages in the reticuloendothelial system and account for approximately 15% of the total liver cell population[2]. They are mainly found in the periportal area of the lobule (43%), but KCs also exist in the midzonal (28%) and in the central area (29%)[2]. Despite the view that KCs are fixed tissue macrophages of the liver, there is evidence that they have the ability to migrate along sinusoidal walls with a mean speed of 4.6 ± 2.6 (SD) microns/min[3]. Since the description of these resident liver macrophages in 1876 by von Kupffer various theories have been proposed with regard to their origin and involvement in liver homeostasis and injury. It should be noted that almost all available evidence for the role of Kupffer cells comes from animal models.

KCs are the first cells to be exposed to materials absorbed from the gastrointestinal tract. Their ability to eliminate and detoxify microorganisms, endotoxins, degenerated cells, immune complexes, and toxic agents (e.g. ethanol) is an important physiological function. Due to their key location, KCs might function as antigen-presenting cells[4] and participate in tumour surveillance[5] and the regeneration processes of the liver[6]. They also seem to play a key role in innate immune responses and host defence through the expression and secretion of soluble inflammatory mediators[7]. There is accumulating evidence that the interaction between KC and lipopolysaccharide (LPS) may be the initiating event leading to hepatotoxicity in various types of liver injury including endotoxinaemia, alcoholic liver injury and ischemia/reperfusion injury[8,9] and systemic viral infections[10].

## THE ROLE OF KUPFFER CELLS IN HEPATIC INJURY

Kupffer cells are involved in the pathogenesis of liver injury mediated by chemical substances, toxins and pharmacological agents[7,9] such as carbontetrachloride ($CCl_4$)[11], endotoxin[12], galactosamine[13] and acetaminophen[14] through the release of biologically active substances that promote the pathogenic process[9]. In liver injury and hepatocellular necrosis activated Kupffer cells are a major source of inflammatory mediators including cytokines, superoxide, nitric oxide, eicosanoids, chemokines, lysosomal and proteolytic enzymes and demonstrate increased cytotoxicity and chemotaxis[7,14-16].

Reactive oxygen radicals are released by hepatic mac-

rophages after activation with cytokines, LPS and prostaglandins as a defence against bacterial invasion. These molecules have been implicated in the pathogenesis of liver injury induced in a rat model by sequential administration of endotoxin and *Corynebacterium parvum*[17]. In this model, the products of oxidation of hepatocellular membrane lipids were detected in the systematic circulation and were related with the degree of liver necrosis. Administration of superoxide dismutase, a reactive oxygen radical scavenger, significantly reduced the liver injury and animal mortality[12]. Isolated Kupffer cells from *Corynebacterium parvum*-treated rats demonstrated significantly increased release of superoxide that was further enhanced following administration of endotoxin[17]. The toxicity of reactive oxygen intermediates on hepatocytes has also been demonstrated *in vitro* using cultured rat hepatocytes[18]. However, LPS-treated Kupffer cells are cytotoxic to hepatocytes in co-culture experiments only in the presence of L-arginine, probably in response to simultaneous secretion of nitric oxide by Kupffer cells or induction of production by hepatocytes[19].

Nitric oxide is produced in the liver by Kupffer cells and hepatocytes. Its role in the pathogenesis of hepatic injury is controversial. A protective role has been detected in various conditions such as endotoxemia or $CCl_4$-induced damage where it protects hepatocytes *via* the inhibition of caspases and apoptosis. In other conditions like ischemia/reperfusion injury, shock, and galactosamine induced liver injury, nitric oxide increases oxidative stress *via* its interaction with reactive oxygen species leading to the formation of peroxynitrite or it induces the expression of inflammatory mediators such as TNF-$\alpha$ and IL-1[20]. Adiponectin suppresses TNF-$\alpha$ production and induces IL-10 production by Kupffer cells and administration of galactosamine in adiponectin knock-out mice significantly increases mortality rate compared with wild type animals[21]. It has been suggested that the hepato-protective activity of adiponectin is due, at least in part, to a direct anti-inflammatory effect of adiponectin on Kupffer cells[22].

Cytokine and chemokine production by activated Kupffer cells is involved in the pathogenesis of liver damage. It has been reported that alcohol-induced liver injury is accompanied by increases in the portal concentration of endotoxin, leading to activation of Kupffer cells and subsequent TNF-$\alpha$ production[23]. Other studies have shown a role for the increased production of the chemokine MCP-1 by Kupffer cells in the pathogenesis of acute liver injury due to $CCl_4$[24] or acetaminophen[25] administration. Proteolytic enzymes released by recruited and activated liver macrophages were also found to promote hepatic injury in a rat model of hepatic damage[26].

The pivotal role of Kupffer cells in the initiation of hepatocellular damage is supported by experimental models that have demonstrated a correlation between the degree of activation of Kupffer cells and the degree of hepatocellular destruction[14]. Administration of endotoxin to rats with activated Kupffer cells due to liver resection induced damage of endothelium, sinusoidal fibrin deposition, and lethal massive hepatic necrosis[27]. In another rat model, activation with endotoxin enhanced $CCl_4$-induced liver damage, while pretreatment with polymyxin B or administration of endotoxin in low doses induced immune tolerance which protected the liver from $CCl_4$-induced damage[27]. Other studies demonstrated that activated Kupffer cells express CD95L and could induce apoptosis in $CD95^+$ T lymphocytes and hepatocytes[28].

However, Kupffer cells also participate in protective mechanisms *via* the production of mediators that induce synthesis of the antioxidant agent glutathione[29], or the production of nitric oxide[30,31]. The production of ELR-CXC chemokines such as MIP-2, which induce hepatocyte proliferation also has a protective role in models of hepatotoxicity such as acetaminophen-induced injury[32-34]. This protection is also possibly mediated by the production of IL-10 and IL-18 by Kupffer cells, since depletion of Kupffer cells increases susceptibility of the murine liver to acetaminophen in parallel with a reduction in IL-10 and IL-18[35]. On the other hand, hard evidence for the protective role of Kupffer cells is missing since depletion of Kupffer cells by the traditional method of administration of gadolinium chloride ($GdCl_3$) intraperitoneally might not deplete the liver from Kupffer cells. Instead $GdCl_3$ might change the acinar distribution and phenotype of Kupffer cells promoting the production of TNF-$\alpha$ and IL-6[36-38]. Therefore interpretation of experiments using $GdCl_3$ is difficult. In conclusion, Kupffer cell-induced hepatotoxicity is not only a result of the reaction to hepatotoxins[39], but it might also be a response to an excessive activation or a suppression of hepatoprotective mechanisms[40].

## THE ROLE OF KUPFFER CELLS IN LIVER FIBROSIS

Liver fibrosis is a complex process that involves many cells of the hepatic sinusoid and is characterized by disturbance of the architecture and composition of extracellular matrix in the liver[41,42]. The extracellular matrix in the subendothelial space of Disse mainly consists of collagen type Ⅳ, laminin, and proteoglycans that are progressively replaced during fibrosis by collagen type Ⅰ and Ⅲ. This excess deposition disrupts the normal architecture of the hepatic lobule[43,44].

Ito or stellate cells are the main cellular source of extracellular matrix proteins in the liver[45,46]. The initiation and maintenance of fibrogenesis in the liver is characterized by two processes. The former is characterized by the activation and transformation of Ito cells to myofibroblasts resulting in increased production of collagen types Ⅰ and Ⅲ[47]. In parallel, there seems to be a disturbance of the homeostatic mechanisms involved in extracellular matrix deposition due to reduced expression of the proteolytic enzymes that degrade the extracellular matrix and increased expression of their inhibitors. Thus, maintaining fibrosis involves decreased production of matrix metalloproteinases (MMPs) and increased production of specific (tissue inhibitors of matrix metalloproteinases, TIMPs) or non specific metalloproteinase inhibitors (alpha1-antitrypsin)[48].

Kupffer cells are involved both in processes *via* the production of cytokines and growth factors that induce Ito cell myofibroblastic transformation and also *via* regulation of the production of metalloproteinases and their inhibitors[49]. Kupffer cell-derived TGF-$\beta_1$ has been suggested

to drive Ito cell transformation and to induce production of collagen and proteoglycans by these cells[50]. TGF-$\beta_1$ is considered as the main cytokine that drives fibrosis in various animal models of hepatic damage, including alcoholic liver fibrogenesis[51], schistosomiasis and $CCl_4$-induced fibrosis[52], and one of the major factors involved in fibrosis in patients with chronic liver disease[53].

*In vitro* studies have also shown that Kupffer cells can induce expression of platelet-derived growth factor (PDGF) receptors on Ito cells, thus enhancing Ito cell proliferation in response to PDGF[54]. TNF-α, IL-1 and MCP-1, that are produced by activated Kupffer cells, are also mitogenic and chemoattractant for Ito cells[55,56]. In addition, TGF-β1 and IL-6 were found to induce mRNA expression of metalloproteinases (MMPs) and also their specific inhibitors TIMPs (mostly TIMP-1, in hepatocytes, Kupffer cells and Ito cells in rat liver[57].

Finally another mechanism that could lead to the phenotypic change of Ito cells is the production of gelatinases by Kupffer cells. It has been demonstrated that extracellular matrix proteins play a crucial role in the maintenance of normal function of hepatocytes and Ito cells. Culture of Ito cells on type I collagen or plastic resulted in activation of cells and transformation to myofibroblasts. In contrast, culture of Ito cells in collagen type Ⅳ did not result in phenotypic change[58]. It has been suggested that activation of Kupffer cells and secretion of gelatinase degrades collagen type Ⅳ and therefore triggers the phenotypic change of Ito cells[7,59].

## THE ROLE OF KUPFFER CELLS IN LIVER DISEASES

### *The role of Kupffer cells in liver infections*

Kupffer cells are involved in the defence against infections of the liver. Their major role in the host defence and the prognosis of liver infection is indicated by studies in experimental models of sepsis. LPS pre-treatment has been shown to increase Kupffer cell numbers leading to a reduction of bacterial load and improvement of prognosis in a Salmonella septicemia model[60]. Impairment of the phagocytic function and the production of superoxide by Kupffer cells in models of obstructive jaundice leads to increased susceptibility to infection[61].

Infection of mice with Listeria monocytogenes is a well studied liver infection model. In this model, the accumulation of bacillus in the liver depends on recognition of bacillus surface sugars and lectins by cognate receptors on Kupffer cells. On the other hand, production of inflammatory mediators such as IL-6, IL-12, IL-1β, TNF-α, and nitric oxide by infected Kupffer cells inhibits proliferation of the microorganism[62,63]. At the same time Kupffer cell derived chemokines such as MIP-1α, MIP-1β, MCP-1, and MIP-2, drive monocyte and neutrophil recruitment into the liver in order to control infection[64-66]. Thus as expected, Kupffer cell inactivation results in impaired infection clearance[67]. Being the first line of defence, Kupffer cells also represent the portal of entry for viruses such as cytomegalovirus[68] and parasites such as *Plasmodium berget*[69] and *Leishmania*[70], which enter and proliferate in Kupffer cells and then infect the rest of the liver cells.

In humans, phenomena like the increased frequency of septicaemia and septic shock from Gram negative bacteria that are observed in patients with acute hepatic failure, have been attributed to the inability of Kupffer cells to clear the portal circulation of micro-organisms and endotoxin[71]. Various studies have shown that a large percentage of patients with chronic hepatic disease present with a systematic endotoxinaemia and high titres of antibodies against intestinal bacteria.In contrast, in normal individuals endotoxin is detected only in the portal circulation[72].

Very recently a direct contribution of Kupffer cells to the pathogenesis of hepatitis has been reported[73]. Influenza hepatitis was associated with absence of virus from the liver and foci of CD8+ virus specific T cells in close contact with Kupffer cells. Moreover, elimination of Kupffer cells abrogated the hepatocellular necrosis, despite persistence of CD8+ reactive cells. It seems that activated T cells are trapped and retained in the liver through an antigen-independent mechanism as a possible interaction between activated integrins like LFA-1 on the T cells and constitutively expressed integrin ligands like VCAM and ICAM-1 on sinusoidal endothelium[74,75]. In this model, Kupffer cells are possibly the effector cells killing hepatocytes in an as yet unidentified manner. Kupffer cells can kill hepatocytes either directly *via* activation of fas-dependent or CD95-dependent apoptotic pathways[76] or indirectly by interacting with CD8+ (and possibly CD4+) lymphocytes with the stimulation of cytokine secretion[77] and other mediators like phospholipases and nitric oxide, as previously reported. Although such a mechanism as that proposed in the paper by Polakos *et al*[73] might explain the hepatitis observed in measles, SARS and CMV infection (where the virus is not identified in the liver), a similar mechanism could well operate in the pathogenesis of hepatitis due to hepatotropic viruses like HBV, HCV and HEV. The only difference would be that the generation of CD8+ virus specific cells would take place in either the portal tracts or the sinusoids per se, with Kupffer cells and dendritic cells being the antigen presenters.

### *Kupffer cells and hepatocellular carcinoma*

The liver is a frequent site of hematogenous metastasis particularly for cancers of the gastrointestinal system. Isolated Kupffer cells were found to be cytotoxic against human colon adenocarcinoma cells and this cytotoxicity was increased significantly when the KC were stimulated with INF-γ and endotoxin[78,79]. It has been suggested that this effect is related to TNF-α expression by Kupffer cells as it is inhibited by anti-TNF-α[80,81]. Other studies have demonstrated that Kupffer cells induce Fas expression in colon cancer cells[82] and malignant glioma cells[83] leading to Fas-mediated apoptosis and death in the presence of tumour infiltrating lymphocytes or TNF-α.

Data from *in vivo* studies show that the degree of activation or repression of Kupffer cells influences the number and the size of hepatic metastases following injection of colon carcinoma cells in portal circulation[84]. Administration of $GdCl_3$, which is reported to deplete and block the function of Kupffer cells, resulted in increased size of metastases, while activation of Kupffer cells with Zymosan and *Corynebacterium parvum* decreased the size of

metastases[85].

*In vivo* microscopy has shown that Kupffer cells are attracted to tumour cells in the hepatic circulation and have the ability to phagocytose these cells[86]. Nitric oxide produced by Kupffer cells after stimulation with endotoxin, TNF-α and prostaglandin $E_2$[16,87] may also be an effective weapon of the Kupffer cell machinery against tumor cells[88]. Moreover, an indirect mechanism of defence by Kupffer cells against hepatic tumours is the induction of natural killer cell (NK-cell) cytotoxicity *via* the production of IL-12[84] and a possible anti-tumour effect of octreotide in hepatocellular carcinoma[89,90] might, in part, be explained by its antiapoptotic effect on Kupffer cells[91].

### Alcohol-related liver disease and Kupffer cells

Alcohol-related liver disease is a chronic inflammatory disease of the liver parenchyma due to chronic ethanol ingestion with the end result being alcoholic fibrosis and cirrhosis. Kupffer cells have been suggested to participate in this process mainly through the increased production of inflammatory mediators. Indeed, increased circulating levels of pro-inflammatory cytokines like TNFα and IL-6, and chemokines like IL-8, MCP-1 and MIP-1α have been detected in patients with alcoholic liver disease, which could potentially be related to Kupffer cell activation[92-95]. Increased numbers of Kupffer cells in the portal tracts have been observed in patients with acute alcoholic hepatitis or chronic alcoholic liver disease[96].

Animal studies have shown that acute or chronic ethanol administration is associated with an increase in numbers of Kupffer cells that exhibit morphologic signs of cell activation[97], up regulation of CD14 expression[98] and increased production of inflammatory mediators such as IL-1, TNF-α[99] and oxygen free radicals[100]. Kupffer cell depletion with $GdCl_3$ has been found to prevent early alcohol-induced liver inflammation and necrosis[101].

One of the current hypotheses about the pathophysiology of alcohol induced liver damage is that ethanol increases the proportion of Gram negative bacteria in the bowel flora and therefore the intraluminal production of LPS. Concurrently, the increase in the intestinal permeability due to alcohol-induced alterations of the epithelial barrier function results in portal vein endotoxinemia. This activates Kupffer cells leading to production of inflammatory mediators, which in turn activate the endothelium and induce neutrophil and mononuclear cell recruitment and infiltration resulting in liver damage. Furthermore, it has been suggested that ethanol may also have a direct effect on Kupffer cell activation by altering cell membrane calcium channels[102].

A synergistic effect of LPS with ethanol has been described. Recent evidence indicates that chronic ethanol administration decreases the cellular cAMP levels of Kupffer cells and this leads to enhanced NF-κB activation by LPS and TNF-α production[95]. Interestingly an increase in cAMP does not affect NF-κB activation but it decreases its transcription capability.

### Kupffer cells and liver transplantation

There is indirect evidence indicating that Kupffer cells may play a role in the process of graft rejection following liver transplantation mainly though their ability to act as antigen presenting cells (APC). Kupffer cells express MHC class Ⅱ and have been found to be effective APC *in vitro*[103]. Animal studies have shown that following liver transplantation Kupffer cells up-regulate MHC class Ⅱ expression and this has been associated with the initiation of the rejection process[104]. In humans the rate of reconstitution of the graft with recipient-derived Kupffer cells has been found to increase during the rejection phase[104]. Finally, graft rejection and the vanishing-bile duct syndrome occur more frequently in cases of MHC class I incompatibility accompanied by a MHC class Ⅱ partial or complete match, which suggests that presentation of MHC I antigens of the billiary epithelium by donor Kupffer cells may also take place[105].

Ischemia-reperfusion injury during the extracorporal preservation of the graft may often result to primary graft dysfunction[106]. There is accumulating evidence to suggest a major role for Kupffer cells during this process through the activation and production of oxygen free radicals resulting in alteration of the microcirculation of the graft[107]. Kupffer cell inactivation using $GdC_{13}$ has been found to prevent ischemia-reperfusion injury, whereas administration of latex particles that induce Kupffer cell activation through phagocytosis, accelerates ischemia-reperfusion injury of the graft[108]. Kupffer cell derived TNF-α, MIP-2 and keratinocyte chemoattractant chemokine have also been found to play a role in the microcirculatory failure that accompanies ischemia-reperfusion. Increased expression of TNFα, MIP-2 and keratinocyte chemoattractant both systemically and in the liver parenchyma have been observed in animal models during the reperfusion phase injury, and they have been associated with endothelial activation and β2-integrin up-regulation[109] and infiltration of the graft by neutrophils[110] respectively.

### Kupffer cells and portal hypertension

Kupffer cells have been shown to be the main source of thromboxane A2 production in the liver and this production is mediated by COX-1 and COX-2[111]. Recently it was demonstrated that the infusion of endothelin-1 significantly increased portal pressure in animal models. This increase was mediated by the production of thromboxane A2 by the Kupffer cells[112], since both thromboxane synthase inhibition and thromboxane A2 receptor antagonists blocked the effect of endothelin-1 on portal pressure[113]. Whether this is relevant to the situation in humans remains to be established.

### Kupffer cells and non alcoholic steatohepatitis

Recently a connection between Kupffer cells and the progression of non alcoholic steatosis to steatohepatitis and fibrosis was reported[114]. Interestingly, this report is one of the few that are based on human data. The enzyme chitotriosidase (CHIT), a member of the chitinase family, was found exclusively expressed in Kupffer cells in liver biopsies from patients with NASH. The levels of this enzyme were significantly higher in NASH than in simple steatosis and CHIT overexpression influenced hepatic stellate cell activation. A significant correlation was also observed between CHIT, TNF-α and lipid peroxidation in both

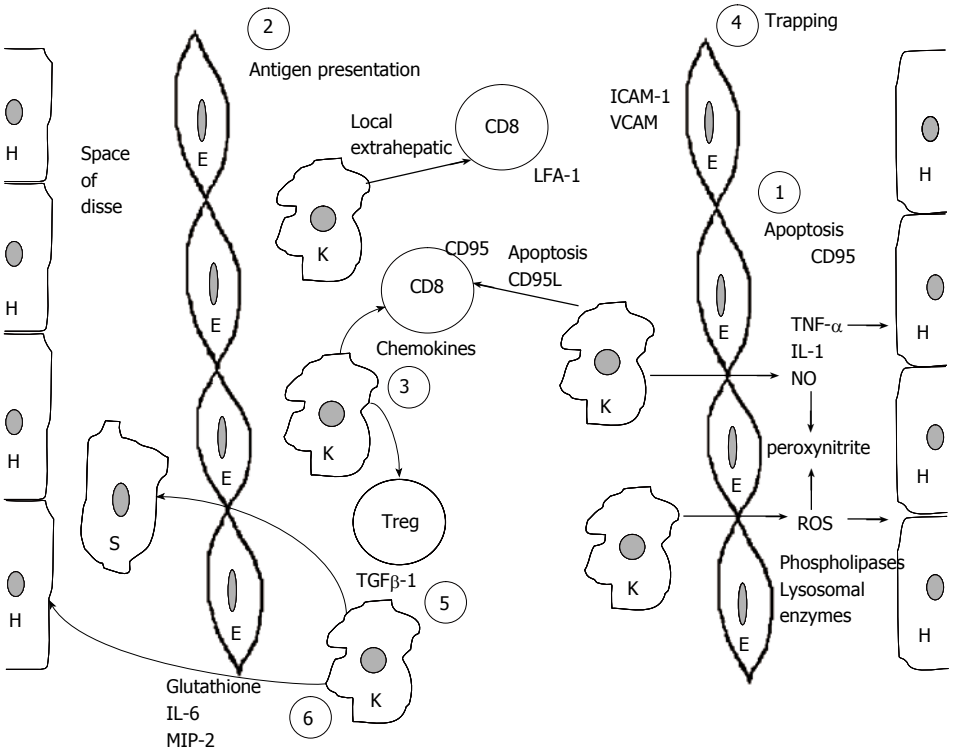

**Figure 1** Schematic representation of the proposed model for the role of Kupffer cells in the pathogenesis of liver disease. H: hepatocytes; E: endothelial cells; K: Kupffer cells; S: stellate cells. For numbers (1-6), please see text explanation.

NASH and simple steatosis. Since CHIT is increased in the liver in other forms of lipid storage disease it is postulated that Kupffer cells are implicated in the pathogenesis of NASH. Another study using an animal model has shown an enhancement of the TNF-α/TNFR mediated signalling pathway *via* activation of Kupffer cells in an autocrine or paracrine manner which might be critically involved in the pathogenesis of liver fibrosis in this NASH[115].

### *Kupffer cells and intrahepatic cholestasis*

Recently Kupffer cells have been implicated in the pathogenesis of intrahepatic cholestasis following hepatic ischaemia-reperfusion injury. Many hepatic canalicular transporters were reduced in parallel to the production of cytokines by Kupffer cells in an experimental model. Moreover, depletion of Kupffer cells abolished the reduced expression of transporters[116]. However, the role of Kupffer cells in cholestasis remains controversial. Recently, in bile duct ligated rats, selective anti-inflammatory blockade of Kupffer cells increased fibrosis and deposition of collagen I and Ⅲ[117]. More recently, in a bile duct ligated mouse model, depletion of Kupffer cells by intravenous inoculation of dichloromethylene diphosphonate resulted in high serum alanine transaminase levels and serious histologic portal inflammation and hepatocellular necrosis, indicating that Kupffer cells abrogate cholestatic liver injury in mice[118]. Moreover it seems that the abrogation of liver injury in this model might be cytokine dependent, mostly through the production of IL-6 by Kupffer cells[118].

## A PROPOSED MODEL FOR THE INVOLVEMENT OF KUPFFER CELLS IN THE PATHOGENESIS OF LIVER DISEASE

Based mostly on the presented data from experimental animals, we propose a model to demonstrate the role of Kupffer cells in the pathogenesis of various liver diseases. According to this model Kupffer cells are responsible for six major functions that are vital for the development of liver disease. Kupffer cells are the main effector cells, killing hepatocytes in various forms of hepatitis. This is achieved by the production of proinflammatory cytokines, reactive oxygen species, nitric oxide, phospholipase and lysosomal enzymes. Kupffer cells may harm hepatocytes by initiating their apoptosis through the CD95L-CD95 pathway (1). This effect is possibly accentuated by CD8 positive antigen restricted T cells and is stopped by $CD4^+CD25^+$ regulatory T cells. In this respect, Kupffer cells are acting as antigen presenting cells of either extrahepatic viruses like influenza[10,73] or intrahepatic viruses like HBV and HCV (2). Following antigen presentation Kupffer cells attract both CD8+ T cells and regulatory T cells by producing chemokines (3). T cells expressing LFA-1 are trapped as a result of endothelial cell overexpression of adhesion molecules like ICAM-1 and VCAM (4), while CD8 positive cells might be driven to apoptosis by direct contact with Kupffer cells. Moreover, TGF-β1 production by Kupffer cells drives stellate cells to be transformed into myofibroblasts eventually leading to fibrosis (5). Finally, by producing glutathione, IL-6 and MIP-2 Kupffer cells may protect hepatocytes from further damage (6). One vital question remains. Are all these six different functions mediated through the same Kupffer cells or are there different Kupffer cell subpopulations in the liver? A schematic presentation of this model is presented in Figure 1.

## Abstract

Use of alcohol is a worldwide habit regardless of socio-economic background. Heavy alcohol consumption is a potential risk factor for induction of pancreatitis. The current review cites the updated literature on the alcohol metabolism, its effects on gastrointestinal and pancreatic function and in causing pancreatic injury, genetic predisposition of alcohol induced pancreatitis. Reports describing prospective mechanisms of action of alcohol activating the signal transduction pathways, induction of oxidative stress parameters through the development of animal models are being presented.

**Key words:** Alcohol; Metabolism; Pancreatic function; Pancreatitis; Mechanism of action

## INTRODUCTION

Alcohol abuse and dependence are the major cause of morbidity and mortality in the United States. About three-fourths of individuals of 18-26 years of age and two-thirds of those 26 and older are current drinkers. The age related pattern for concurrent alcohol and tobacco dependence was similar to that found for tobacco dependence[1,2]. In a recent survey it was found that approximately 17.6 million adult Americans abuse alcohol or is alcoholic. Alcohol related problems cost society approximately $185 billion per year. In a study conducted at the population level, mortality from pancreatitis due to alcohol addiction was reported[3]. The mechanism of induction of alcoholic pancreatitis is not well understood.

Pancreatitis due to alcohol abuse is a very painful and potentially fatal condition. About one-third of acute pancreatitis cases in the United States are alcohol induced and 60%-90% of pancreatitis patients have a history of chronic alcohol consumption. It is estimated that drinking more than 80 gm of alcohol/d or about 10-11 standard U.S. drinks for a minimum of 6-12 years is required to produce symptomatic pancreatitis[4]. The risk of developing the disease increases with both amount and duration of alcohol consumption. Only 5% of clinically documented alcoholics develop disease but at autopsy only 5%-10% of alcoholics are found to have evidence of chronic pancreatitis[5-7]. Chronic pancreatitis is mostly caused by heavy alcohol consumption and is characterized by onset of symptoms in the 4$^{th}$ or 5$^{th}$ decade[8]. Due to this discrepancy in data of alcoholic and diseased patients, it is thought that other factors like environmental, genetic, race and concomitant risk factors are also involved.

Cigarette smoking might have an additive effect with alcohol in inducing pancreatitis. In the rat model of alcohol-induced pancreatitis, ethanol induces pancreatic ischemia while cigarette smoke potentiates the impairment of pancreatic capillary perfusion caused by ethanol[9]. Cigarette smoking accelerates progression of alcoholic chronic pancreatitis[10,11]. A dietary component may also interact and modify effects of alcohol on the pancreas. A protein and fat rich diet along with continued consumption of alcohol exacerbate the course of chronic pancreatitis[12,13]. African Americans are affected more than Caucasians and this could be due to differences in diet, type or quantity of alcohol consumption[14]. It can be due to differences in metabolism of alcohol in liver and pancreas. Alcohol consumption at intoxicating concentrations induces pancreatic cellular injury that may involve class Ⅲ isoenzymes of ADH[15].

## ALCOHOL METABOLISM

It is well known that alcohol is metabolized *via* an oxidative and a non-oxidative pathway in the liver. Various studies have been conducted to demonstrate alcohol metabolism in isolated pancreatic acini and cultured acinar cells. Haber *et al*[15] have studied oxidative metabolism of alcohol using cultured pancreatic cells. His findings corroborate a study reported by Gukovskaya *et al*[16], conduced with isolated pancreatic acini. In the cytosol of acini, ethanol is oxidized to acetaldehyde by alcohol dehydrogenase. At physiological

blood alcohol concentrations, cytochrome P-450 accounts for approximately 20% of ethanol metabolism[17,18]. The presence of cytochrome P-450 CYP2E1 has been demonstrated in rat pancreas[19] as well as human pancreas[20]. Chronic use of alcohol has been shown to induce the expression of CYP2E1 in rat pancreas[19] similar to that in liver[21].

The non-oxidative pathway of ethanol metabolism involves the formation of FAEE using FAEE synthase[22]. Gukovskaya *et al*[16] have confirmed the presence of FAEE synthase activity in pancreas that may explain the accumulation of FAEE in pancreas after ethanol exposure. Werner *et al*[23,24] studied correlation between oxidative and non-oxidative pathways of ethanol metabolism in the pancreas. Their studies show that ethanol causes a dose-dependent injury to pancreas due to a shift to non-oxidative metabolism following inhibition of the oxidative pathway. This results in an increase of FAEE. Carboxyl ester lipase (CEL) has been known to catalyze FAEE synthesis from fatty acids and ethanol. CEL gene polymorphism, especially an increase in the frequency of the L-allele, was found to be associated with alcohol induced pancreatitits[25]. The aspect that inhibition of the oxidative pathway can cause an increase in flux of ethanol metabolism *via* the non-oxidative pathway needs to be clarified further.

## GENETIC PREDISPOSITION OF ACUTE AND CHRONIC PANCREATITIS: ROLE OF ALCOHOL

In alcoholic pancreatitis, mutations of the cationic trypsinogen gene and of pancreatic secretory trypsin inhibitor (SPINK-1) have been implicated in its pathogenesis[26]. The discovery of genetic cause of hereditary pancreatitis has renewed interest in genetic predisposition to alcoholic pancreatitis. Various gene mutations like cationic trypsinogen (especially at codon 29 and 1220), SPINK1 mutation, and CFTR gene mutation are associated with development of chronic pancreatitis[27]. In idiopathic pancreatitis, both variants of SPINK1 (N 291 and R 122H) and CFTR were identified. Alteration of both genes was found in patients with alcoholic chronic pancreatitis and the increase of those genes is related to higher levels of alcohol consumption[27]. The SPINK1 inhibits the autoactivation of premature trypsinogen within the pancreas[28]. The most frequent mutation in the SPINK1 gene was the N34S mutation in Exon-3. Kuwata *et al*[29] detected intronic polymorphism in the SPINK1 gene in 4 alcoholic patients but found no differences when the data were compared with other patients. Similar findings have been reported in five other alcoholic chronic pancreatitis patients with an N34S mutation[30]. Truninger *et al*[31] and Monaghan *et al*[32] screened 58 and 46 alcoholic pancreatitis patients respectively for cationic trypsinogen gene mutation activation but no mutations have been found.

Alcohol metabolizing enzymes such as aldehyde dehydrogenase (ADH), metabolizing alcohol to acetaldehyde, exist as different isoenzymes. ADH polymorphism has been identified in ADH-2 and ADH-3[33]. Increased prevalence of ADH-1 isoenzyme in patients with alcoholic pancreatitis has been reported[34]. With regard to ADH-2 isoenzyme, results are not conclusive and further studies need to be done. Kimura *et al*[35] and Frenzer *et al*[36] found no correlation between ADH-2 polymorphism and chronic pancreatitis in Japanese and Austrian patients respectively while Maruyama *et al*[37] demonstrated elevated risk for chronic alcoholic pancreatitis for different genotypes of ADH-2. Cytochrome P-450 is involved in metabolizing alcohol in endoplasmic reticulum. Several studies have been done to evaluate the association between polymorphism of enzyme Cyto-P4502E1 (CYP2E1) and alcoholic pancreatitis with no success[36,38,39]. Verlaan *et al*[40] analyzed DNA samples from chronic pancreatitis -alcoholic, idiopathic and hereditary. They observed that the frequency of ADH-3 and CYP2E1C1C2 genotypes did not differ between chronic pancreatitis patients, alcoholic and healthy controls. But they conclude that the presence of CYP2E1 intron 6DD genotype might confer a higher risk of alcoholic chronic pancreatitis. Kim *et al*[41] compared the genotype and allele frequencies of ADH-2, ADH-3, ALDH-2, Cyto P450-2E1, IL-1, IL-6, IL-8 and TNF-alpha in patients with chronic pancreatitis and alcoholic liver cirrhosis with those from controls. No difference in frequencies of genotype and allele of enzymes and cytokines amongst three groups were found. Frequency of ADH-2 was significantly higher and those of CYP2E1 and ALDH-2 were significantly lower than control.

Polymorphism of other enzymes involved in free radical stress and acinar cell damage, such as glutathione -S-transferase (GST) family has also been investigated[42]. Bartsch *et al*[43] found a moderate increase in susceptibility of pancreatitis due to polymorphism of GSTM1 but Frenzer *et al*[36] and Scheider *et al*[44] were not able to confirm it. The enzymes GSTM1, GSTT1, GSTP1, CYP1A1 and CYP2E1 are involved in bioactivation and detoxification of a variety of xenobiotics present in smoke, alcoholic drink among others. A higher frequency of the Val/Val genotype in alcoholics and pancreatitis in comparison to alcoholics without the disease was found[45]. In the same study the investigators found an association between the occurrence of Val/Val GSTP1 genotype and chronic pancreatitis and also an association between m2/m2, CYP1A1 and alcoholic liver cirrhosis suggesting that these genotypes are genetically more prone to the development of alcoholic pancreatitis and alcoholic cirrhosis respectively.

## EFFECT OF ETHANOL ON GASTROINTESTINAL AND PANCREATIC FUNCTION

Ethanol had a stimulatory effect on gastric acid secretion[46]. Singer *et al*[47] found that the effect of ethanol on gastric acid secretion is concentration dependent. Gastric instillation of 1.4% and 4.0% (v/v) of ethanol has a small stimulatory effect while higher concentrations (up to 40% v/v) have either no effect or an inhibitory one. Different studies under controlled conditions have been conducted to determine the action of pure ethanol on gastric acid secretion but results were very different from each other[48-54]. Alcohol is oxidized by ADH enzyme

present in all parts of the gut[55,56]. Ethanol has a direct toxic effect on the mucosal epithelium leading to loss of epithelium and hemorrhagic erosions in the duodenum[57,58]. In large bowel, gut flora plays an important role in ethanol metabolism[59]. Due to increased amounts of conversion of ethanol to acetaldehyde, than to further oxidize to acetate, the toxic acetaldehyde accumulates thereby damaging colonic mucosa and after being absorbed into the portal blood may contribute to liver injury. Alcohol when taken orally is known to increase mucosal perfusion[60] and also to stimulate production of secretin[61]. Both can affect pancreas microcirculation indirectly. Ethanol is also known to affect pancreatic blood flow when given intravenously[62,63] and *via* intragastric route[64]. McKim *et al*[65] investigated the effect of chronic intragastric ethanol administration which induced pancreatic hypoxia and oxidative stress *in vivo*. Pancreatic hypoxia induced by chronic alcohol appears to be secondary to increase in oxygen consumption by pancreas or to decrease in local blood supply without alteration of hemodynamic patterns. Chronic ethanol ingestion was associated with dose related inhibition of basal pancreatic protein secretion which was reversed upon alcohol withdrawal[66]. Increased susceptibility to chronic alcoholic pancreatitis may be through a hyperstimulation mechanism due to combination of neurohormonal factors. In exocrine pancreas, alcohol induces secretory alteration which varies by manner and duration of alcohol exposure. Ethanol effects on pancreatic secretion appear to be primarily caused by systemic cholinergic mechanisms of the vagus nerve[67].

## ROLE OF ETHANOL METABOLISM IN PANCREATIC INJURY

Various studies have been done to understand the mechanism of ethanol induced pancreatic injury but till now the exact mechanism is not clear. Earlier it was thought that the Sphincter of Oddi spasm induced by alcohol may be one of the mechanisms responsible but due to a lack of consensus, the later proposal includes the Ductal-Plug hypothesis by Sarles and his colleagues[68]. The secretion of pancreatic juice rich in protein may "plug" the small ductules leading to acinar atrophy and fibrosis. It was not clear whether protein precipitation within pancreatic ducts precedes acinar damage. So protein plugs may be a cause or an effect of pancreatic injury. Saluja and Bhagat[69] investigated the mechanism by which alcohol may induce pancreatitis in an animal model. Ethanol administration resulted in a transient increase of pancreatic amylase output and plasma cholecystokinin (CCK) levels. This phenomenon was mediated by a trypsin-sensitive CCK-releasing factor from the duodenum. The studies suggest that ethanol-induced stimulation of pancreatic digestive enzyme secretion plays an important role in the development of pancreatic injury. Chronic ethanol exposure alone in animals inhibits apoptosis through an intrinsic pathway and the downstream apoptosis executor caspase-3 when compared with the controls[70]. Alcohol exposure accelerates pancreatic necrosis in response to endotoxin. The results from this study showed that the pancreas exposed to alcohol is more sensitive to LPS-induced damage because of increased sensitivity to necrotic cell death rather than apoptotic cell death suggesting that this mechanism may occur in acute alcoholic pancreatitis patients[70].

Due to inability to explain the pathogenesis of alcoholic pancreatitis by theories as mentioned above the focus was directed to pancreatic acinar cells. It is now believed that acinar cells are capable of metabolizing alcohol and the toxic effect may predispose the gland to injury in the presence of an appropriate triggering factor. The characteristics of pancreatic stellate cells showing the involvement of acinar cells in pancreatic fibrosis may be another possible link[71] . It is speculated that metabolites of ethanol like acetaldehyde and FAEEs have direct effects on acinar cells/or induce metabolic alterations within cells indirectly. Acetaldehyde is believed to interfere with the binding of secretagogue to their receptors[72] and thereby inhibit stimulated secretion from isolated pancreatic acini[72]. It also causes microtubule dysfunction thereby affecting exocytosis from acinar cells[73].

During oxidation of ethanol, hydrogen ions and reducing equivalents are released[74]; increase NADH, thereby leading to an imbalance between free radicals and antioxidant defense mechanism. It leads to a loss of mitochondrial glutathione and inactivation of GPx and other respiratory complexes[75]. Also, chronic ethanol ingestion upregulates CYP2E1[19] and catalase[76] for metabolism These pathways will require increased oxygen that will compete with mitochondrial electron transport system leading to localized and transient hypoxia in tissues. These transient conditions of hypoxia and re-oxygenation would further enhance ROS formation through the respiratory chain.

FAEEs, products of non-oxidative ethanol metabolism, have been shown to induce pancreatic injury *in vivo*[77] and *in vitro*[78]. FAEE undergo hydrolysis to FFA which impairs mitochondrial function by uncoupling of mitochondrial and oxidative phosphorylation[79]. Also its direct binding to the intracellular membrane leads to alteration in function and permeability of cell membrane[80]. The generation of cholestryl esters is responsible for the increase in lysosomal fragility releasing hydrolase's which act on the zymogen granule membrane and increase release of trypsin[81,82].

Impairment of blood flow to pancreas by ethanol causes hypoxia without any change in hemodynamic parameters. McCord[83] explained reoxygenation induced injury following hypoxia. Hypoxia can decrease the ability of cells to detoxify free radicals[84] and secondarily, hypoxia/reoxygenation causes more free radical formation leading to formation of α-hydroxyethyl radical and subsequent tissue damage and functional impairment. McKim *et al*[65] found 4-hydroxy nonenal protein adduct accumulation and increasing hypoxia in the pancreas following chronic intragastric alcohol administration in rats. These studies support the hypothesis that hypoxia contributes to oxidative stress caused by alcohol.

## EFFECT OF ALCOHOL ON CELL SIGNALING PATHWAY

The mechanism of acute and chronic ethanol mediated

pancreatic injury is unclear in the literature. Feeding alcohol to animals could not reproduce pancreatitis, suggesting that alcohol alone is not sufficient to induce pancreatitis. It sensitizes pancreas to other risk factors, thereby injuring pancreas[85]. Studies using CCK or its analog are done to induce pancreatitis both *in vivo* and *in vitro*[86]. CCK at supra-physiological doses causes pancreatitis with increased blood levels of amylase and lipase and acute inflammatory response along with parenchymal cell damage[87-89]. Katz *et al*[90] showed that ethanol with low dose CCK-8 caused 6-fold more zymogen conversion than that caused by CCK alone**.** To evaluate a mechanism for the development of alcoholic pancreatitis, Pandol *et al*[91] fed animals intragastrically with ethanol diet followed by infusion of CCK-8. Ethanol exposure in the presence of CCK-8 resulted in activation of pro-inflammatory transcription factors, NF-κB, AP-1 and other cytokine and inflammatory molecules thereby resulting in increased trypsin release. On the other hand alcohol when given alone causes less activation of NF-κB as compared to that given with CCK alone indicating that ethanol has inhibitory effects on the inflammatory response alone. $Ca^{2+}$ and PKC contribute to NF-κB activation induced by CCK-8 in acinar cells. Ethanol differentially affects the Ca $(2^{+})$/calcineurin- and PKC-mediated pathways of NF-kappaB activation in pancreatic acinar cells[16,92]. These effects may play a role to sensitize pancreas to the inflammatory response and pancreatitis. Acute oxidative stress modulates secretion and repetitive $Ca^{2+}$ spiking in rat pancreas[93]. Thus perturbations in $Ca^{2+}$ signaling do not fully explain the secretory block caused by oxidative stress in acute pancreatitis.

## CIGARETTE SMOKING AND PANCREATITIS: EFFECT OF ALCOHOL

Cigarette smoking is a known risk factor for alcoholic and chronic pancreatitis. About 80%-95% of people who abuse alcohol also smoke while 25%-30% of smokers do not drink alcohol[94]. The incidence of alcoholism is 10 times more likely in smokers than nonsmokers. Cigarette smoking accelerates the progression of alcohol induced pancreatitis[10,11]. Blomqvist *et al*[95] reported that intermittent nicotine administration to rats enhances ethanol intake and preference to ethanol in a free choice between ethanol and water. He suggested that subchronic nicotine doses increased the responsiveness of mesolimbic dopamine neurons to both nicotine and alcohol. Potthoff *et al*[96] found similar results in their experiments in rats administering chronic nicotine. Ericson *et al*[97] reported the involvement of nicotinic acetylcholine receptors (nAChR) in nicotine induced increased uptake of ethanol. He gave antagonist to peripheral nAChR to mice and rats subchronically for 15 d and after stopping drug, ethanol intake and preference as well as ethanol induced locomotor stimulation increased. This may be due to compensatory enhanced autonomic ganglionic and/or muscarinic neurotransmission. The mechanism (hormonal or metabolic) by which increased peripheral neuronal activity affects the brain dopaminergic system in the brain is not known.

The mechanism by which alcohol causes the pancreatic injury is not entirely clear. Metabolic as well as microcirculatory changes and other theories were proposed to explain this phenomenon. Cigarette smoking is known as a potentiating factor in the development of alcohol induced pancreatic injury. Hartwig *et al*[9] investigated the effect of cigarette smoke on alcohol induced pancreatic injury. They gave cigarette smoke alone or with ethanol intravenously to rats. Ethanol alone impairs pancreatic blood flow without any change in systemic hemodynamic parameters and inflammatory change. Cigarette smoke potentiates pancreatic microcirculatory impairment by ethanol and also induces leukocyte aggregation and adhesion.

Nicotine is metabolized by cytochrome P450 into cotinine[98,99]. Tissue distribution of $^{3}$H-nicotine in rats demonstrated that nicotine is distributed and accumulated significantly in the pancreas and parts of the gastrointestinal tract[100]. But nicotine metabolism in pancreas has not been reported yet. In liver, low doses of nicotine and ethanol induces CYP2E1 activity as reported by Howard *et al*[101]. The study suggests that nicotine may increase CYP2E1-induced toxicity and contribute to cross-tolerance in smokers and people treated with nicotine. It may be possible that nicotine might have some effect on pancreatic CYP2E1 induction leading to increased metabolism of ethanol in pancreas by cytochrome and thereby potentiate the damage caused by ethanol.

## CONCLUSIONS

Alcohol abuse/alcoholism are a major cause of pancreatitis. Combining alcohol abuse with smoking aggravates the condition further. Despite numerous reported studies the pathogenesis of alcoholic pancreatitis remains obscure. During recent years it has been possible to evaluate the mechanism of development of alcoholic pancreatitis in the animal model and in *in-vitro* acinar cell cultures. The summary of events relating to alcohol exposure that may lead to induction of alcoholic pancreatitis is shown in the flow diagram below (Figure 1).

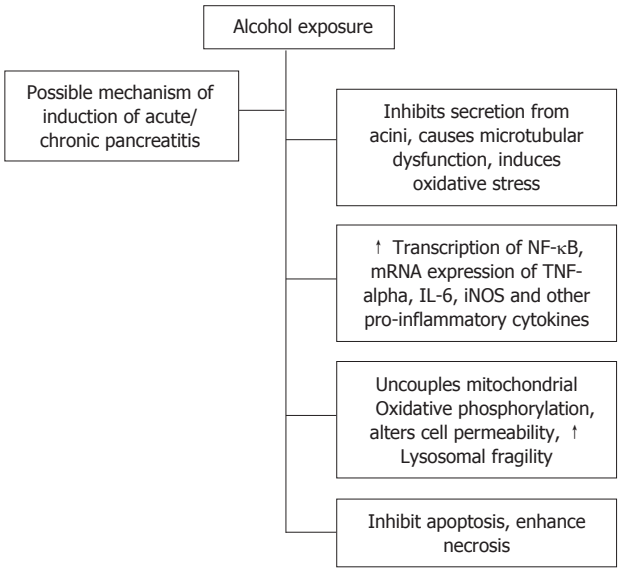

**Figure 1 The summary of events relating to alcohol exposure that may lead to induction of alcoholic pancreatitis.**

## Abstract

Cell proliferation is an important process in life for growth of normal and cancer cells. The signal transduction pathways activated during this process are strictly regulated. This editorial focuses on the role of nicotine, a mitogen, in the induction of signaling pathways resulting in proliferation of pancreatic tumor cells and compares these events with those in normal acinar cells isolated from the rat pancreas. The data shows striking similarities between these two cellular systems. In addition, the editorial reviews very recent literature of the contribution of MAPK signaling in cell lines associated with human diseases. A prospective cellular model of nicotine induced activation of MAPK cascade is presented.

**Key words**: Cell Proliferation; Nicotine; AR42J cells; Pancreatic acinar cells; ERK activation

## INTRODUCTION

Cell proliferation is a strictly regulated event. The rate of cell division depends upon instructions by which the cell responds to mitogenic or other stimuli in order to enter the cell cycle substantiated by cyclin dependent kinases (CDKs) which are activated by cyclins. In a normal resting cell the intracellular signaling proteins and genes, activated by extracellular growth factors, are quiescent. However, when stimulated by growth factors, the cells undergo proliferation. In cancer cells, intracellular signaling proteins and oncogenes activated by the growth factors remain constitutively active[1]. In response to growth factors or other mitogenic stimuli, three major types of signal transduction pathways are activated in a cell: mitogen activated protein kinase (MAPK) pathways, protein kinase C (PKC) pathways and JAK/STAT pathways. Activation of each of these pathways requires a phosphorylation step that regulates cell proliferation and differentiation[1].

Understanding of the complex molecular mechanisms involved in the regulation of cell proliferation in normal and cancer cells will provide us with tools to intervene in the regulation and control of the cell cycle in the presence of a mitogen. Qualitatively speaking, the biochemistry of growth of tumor and normal cells appear similar[2]. The fundamental difference most probably lies in a relaxation of regulation of cell growth[3,4]. Here we will discuss the role of nicotine in cell proliferation in reference to AR42J cells (a rat pancreatic tumor cell line) and look further into extended observations from our recent findings using primary cells derived from the normal rat pancreas when exposed to nicotine in culture.

Nicotine is a major component of cigarette smoke and is a known risk factor for the development of numerous diseases[5-9]. The role of nicotine/smoking as a risk factor for the induction of pancreatic inflammation and pancreatic cancer has been reported recently[10,11]. The mechanism by which nicotine induces such pathologies is as yet unknown. Understanding of the proliferative potential of nicotine in primary and tumor cells of the pancreas will allow us to develop measures that will ultimately lead to intervention, prevention and treatment.

## AR42J CELLS: CHARACTERISTICS AND ASSOCIATION WITH MAP KINASES

AR42J is a stable, rat pancreatic tumor cell line derived from the hyperplastic pancreatic nodules of male rats following the administration of azaserine[12]. Because of

their unique properties of stability, secretory capacity, and growth potential[13], these cells have been extensively used as an *in vitro* model for studying exocytotic secretory processes and activation of signal transduction pathways[14-16]. In response to regulatory peptides, AR42J cells can be stimulated to secrete enzymes and induce proliferation[13,17,18].

MAPK enzymes play critical roles in the regulation of cell proliferation, differentiation, and apoptosis, and are comprised of a ubiquitous family of tyrosine/threonine kinases that include the extracellular signal-regulated kinases (ERK1/2), c-jun $NH_2$-terminal kinases (JNK1/2), and p38 MAPK. Cytokines and mitogens trigger signaling cascades that lead to the activation of MAPK, as reported in studies with different cell lines[19-24].

Activation of ERK has been primarily implicated in cell proliferation and survival, whereas activation of JNK and p38 are associated with growth arrest and apoptosis[25-27]. Induction of MAPK's leads to the phosphorylation and activation of a variety of proteins, including a number of transcription factors involved in regulating the expression of genes controlling cellular proliferation[28-30]. ERK1/2 is found in most tumors and is involved in gastric carcinogenesis[31]. Differential activation of MAPK by cholecystokinin (CCK) and bombesin has been reported in AR42J cells[17].

## ACTIVATION OF SIGNALING PATHWAYS BY NICOTINE

Nicotine is known to activate several MAPK signaling pathways in a variety of tissue and cell types[32-37]. It also behaves like a growth factor promoting survival of human lung cancer cells[38]. Studies show that nicotine can increase the cell numbers of certain cancer cell lines[39-41]. This suggests that nicotine exposure can lead to the disruption of the dynamic balance between cell death and proliferation, which is required for normal functioning of cells.

In pulmonary neuroendocrine cells, nicotine binds to nicotinic receptors, resulting in the phosphorylation of ERK and stimulation of DNA synthesis[32,42]. Furthermore, nicotine induces $Ca^{2+}$ influx and stimulates the Ras/ERK cascade that promotes cell survival in neuronal cells[43]. Thus, ERK1/2 is one of the possible signaling pathways involved in nicotine-induced cell proliferation. Studies by Bose *et al*[44] on the mitogenic effect of nicotine on AR42J cells show that nicotine activates ERK1/2 in AR42J cells and induces proliferation without affecting basal and stimulated enzyme secretion. These data suggest that MAPK signaling by nicotine in AR42J cells is independent of the secretory response.

## ACTIVATION OF SIGNALING PATHWAYS BY NICOTINE IN PRIMARY CELLS: EFFECTS ON PROLIFERATION

Primary cells are normally derived from intact rat pancreas. The functional status of the primary acinar cells exposed to nicotine under basal and stimulated conditions has been reported[45,46]. However, the ability of nicotine to activate MAPK signaling pathways and subsequent proliferation has not yet been reported. It has been shown that p42 MAPK is fully activated at 5 min by cholecystokinin (CCK) in freshly isolated pancreatic acini, and JNK is activated maximally at 30 min and remains significantly elevated at 60 min[47,14]. Unpublished studies from our laboratory show that exposure of primary cells to nicotine in short term culture activates ERK1/2 MAPK with very little or no effect on JNK and p38 MAPK. The results on primary cells from this study and the studies cited above thus demonstrate that some parallelism in the time-dependent activation of ERK by CCK and nicotine exists, although these two secretagogues are completely different from one another in terms of their biological actions on the pancreas[15,14,48]. Further, cell proliferation studies conducted and monitored with three independent methods (MTT assay, BrdU assay and flow cytometry) confirmed the proliferative ability of primary cells in the presence of nicotine. This response is reversed in the presence of the ERK1/2 inhibitor UO126, suggesting that the proliferation induced by nicotine in primary cells is MAPK-dependent. Activation of these signals and application of their inhibitors in the presence of nicotine had no effect on the stimulated enzyme secretion by these cells (unpublished observations). The proliferation of primary cells by nicotine thus appears to be independent of the stimulus-secretion coupling response of amylase secretion.

## ACTIVATION OF MAPK SIGNALING PATHWAYS IN CELL LINES DERIVED FROM HUMAN DISEASES

MAPKs are known to exert several complex functions, such as regulation of cellular growth, proliferation, and differentiation[29,49,50]. It has also been shown that activation of ERK1/2 MAPK is associated with cell proliferative signals whereas activations of c-jun $NH_2$-terminal kinases 1/2 (JNK1/2) and p38 MAPKs are associated with stress-response signaling[51,52]. Zhao *et al*[53] have shown that in the human T lymphoma cell line Molt-4, ERK and p-38 mitogen activated protein kinase (MAPK) signaling are induced in response to hepatitis C virus E2 envelope protein resulting in alterations in cell behavior. In human squamous cell carcinomas (SCC) of the larynx, the potential derangement of MAPK pathways which showed decreased activity of ERK1/2 p44/42 reflecting alterations in tumor suppressing activity, has been reported[54]. Application of low power laser irradiation (LPLI) has been shown to promote cellular proliferation of human dental pulp derived fibroblast-like cells (dental pulp cells) inducing the activation of ERK 1/2 with no induction pf p38 MAPK or c-Jun N-terminal kinase (JNK) phosphorylation[55]. Hepatocyte growth factor (HGF) also enhanced proliferation and differentiation of dental pulp cells by partial activation of the ERK/MAPK pathway[56].

Recently Li *et al* have shown that anti-apoptotic human phosphatidylethanolamine-binding protein (hPEBP4) silencing, promotes tumor necrosis factor

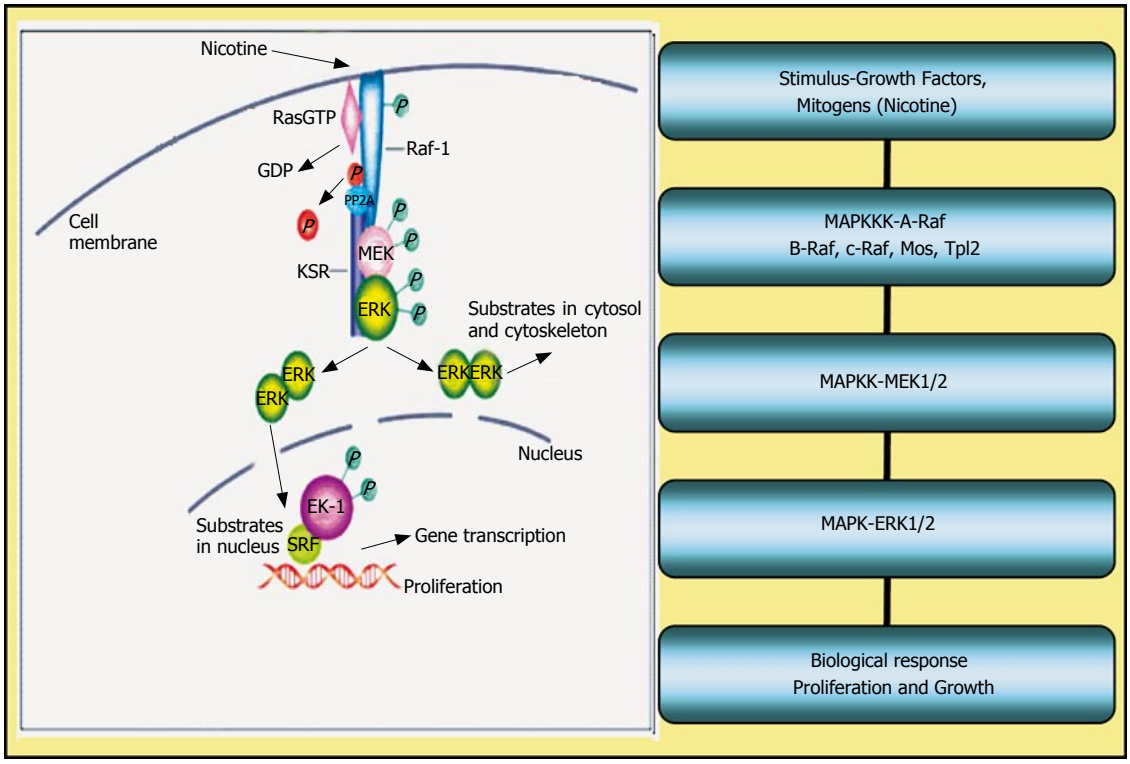

**Figure 1** The possible organisation of the Ras-Raf-MEK-ERK pathway by nicotine.

related apoptosis-inducing ligand (TRAIL)-induced apoptosis of human ovarian cancer cells by activating ERK and JNK pathways[57]. Mutant huntingtin, a protein derived from Huntington disease (HD) affects signaling at upstream points activating ERK and JNK, suggesting that pharmacological intervention of MAPK pathways may be an appropriate approach to HD therapy[58]. ERK 1 expression has been shown to be an early marker of cervical carcinogenesis[59]. In human glomerulopathies, activation of ERK pathways has been correlated with cell proliferation, histologic lesions, and renal dysfunction[60]. In human neutrophils, Rac/Cdc-dependent activation of MAPK/ERK is a critical event in the immediate phagocytic response of PMNs to microbial challenge[61]. IL-1 beta stimulated human airway smooth muscle cells demonstrate activated p38 MAPK, JNK kinase and p42/p44 ERK suggesting their role in the inflammatory process in asthma[62]. In the human myeloma cell line SKO-007, activation of ERK in the Ras/MAPK signaling pathway has been shown to play important differences in their responsiveness to IFN-alpha[63]. Signaling through SAPK/MAK pathways is shown to be a typical feature of chronic synovitis in rheumatoid arthritis, but not in degenerative joint disease. SAPK/MAPK signaling is found at distinct sites in the synovial tissue and is induced by proinflammatory cytokines[64].

## CONCLUSIONS

The possible signaling pathways leading to cell proliferation by nicotine are shown in Figure 1 below. The schematic shows that nicotine enters the cell either by diffusion or *via* a calcium regulated pathway as demonstrated earlier[65]. Entry of nicotine induces the activation of Ras-Raf-MEK-ERK pathways inducing phosphorylation of the MAP kinase cascade. Substrates of ERK in the cytosol include tyrosine kinase receptors among others. Substrates of ERK in the nucleus include transcription factors such as ELK-1 and others. The endpoint of ERK phosphorylation leads to the assembly of transcription factors which stimulate the production of proteins causing cells to proliferate and grow.

The parallelism observed in nicotine-induced cell proliferation studies conducted in a mutant pancreatic cell line and freshly isolated pancreatic acinar cells suggest the possibility that this stable mutant line can be used for extensive evaluation of signal transduction pathways mediating oncogenesis. The data gathered from these studies can be extended to assess the mechanisms of development of pancreatic diseases induced in animal models exposed to chronic/sub-chronic exposure to nicotine or cigarette smoking.

## Abstract

Smoking of tobacco products continues to be a major cause of worldwide health problems. Epidemiological studies have shown that tobacco smoking is the greatest risk factor for the development of pancreatic cancer. Smokers who are able to quit smoking can reduce their risk of pancreatic cancer by nearly 50% within two years, however, their risk of developing pancreatic cancer remains higher than that of non-smokers for 10 years. Nicotine is the major psychoactive substance in tobacco, and is responsible for tobacco dependence and addiction. Recent evidence suggests that individuals have genetically based differences in their ability to metabolize nicotine, as well as genetic differences in the psychological reward pathways that may influence individual response to smoking initiation, dependence, addiction and cessation. Numerous associations have been reported between smoking behavior and genetic polymorphisms in genes that are responsible for nicotine metabolism. In addition, polymorphisms in genes that encode neurotransmitters and transporters that function in psychological reward pathways have been implicated in differences in smoking behavior. However, there is a large degree of between-study variability that demonstrates the need for larger, well-controlled case-control studies to identify target genes and deduce mechanisms that account for the genetic basis of inter-individual differences in smoking behavior. Understanding the genetic factors that increase susceptibility to tobacco addiction may result in more effective tobacco cessation programs which will, in turn, reduce the incidence of tobacco related disease, including pancreatic cancer.

## INTRODUCTION

The use of tobacco products constitutes the most preventable cause of premature death worldwide. It is estimated that half of all Americans who continue to smoke will die of smoking-related diseases[1], including cancer, emphysema and heart disease. The U.S. Surgeon General reported in 2004 that cigarette smoking has caused more than 12 million premature deaths in the United States since the publication of the Surgeon Generals report on smoking and health in 1964[2]. Although the dangers inherent in smoking are well known, the use of tobacco continues because these products are delivery systems for nicotine, an extremely addictive drug. Long term smoking is the most established risk factor for lung cancer, however smoking also increases the risk of developing cancers of the esophagus, uterine cervix, kidney, bladder, stomach and pancreas[2]. This review will briefly discuss the effects of cigarette smoke components on the pancreas, and then focus on the genetic basis for nicotine addiction that is responsible for tobacco product use.

Pancreatic cancer is a relatively rare tumor; the lifetime risk of dying from pancreatic cancer is between 1% to 2% of the general population. However, pancreatic tumors are extremely aggressive, with a 5-year survival rate of less than 5% and a mortality rate of nearly 100%[3,4]. Since there are presently no tests for early screening, and once detected, therapeutic choices are limited, the best hope for reducing mortality from pancreatic cancer is prevention. Smoking of tobacco products is the most important risk factor for developing pancreatic cancer[3-6], with risk increasing with higher levels of tobacco use and more years of exposure. A 40 year epidemiological study of British physicians

determined that the pancreatic cancer rate for smokers was 35 per 100 000 person years, while the risk for ex-smokers and non-smokers was reduced to 23 and 16 per 100 000 person years respectively[7]. A large prospective study by Fuchs *et al*[8] determined that current smokers had a 2.5 times greater relative risk of developing pancreatic cancer compared to study subjects who had never smoked. They also found that although smoking cessation reduces the risk of pancreatic cancer by 48% within 2 years, smokers who quit have an increased risk for approximately 10 years compared to non-smokers. Smoking, as a single risk factor or in combination with alcohol, increases the risk of idiopathic pancreatitis, a precancerous condition[3,5,9,10]. Clearly, one way to reduce the risk of pancreatic cancer is to develop more effective smoking cessation strategies; however, smoking is a complex behavior, which is likely influenced by both environmental and genetic factors. There is wide inter-individual variation in the risk of becoming dependent on nicotine. Genetic factors that influence nicotine metabolism and the psychological reward system of nicotine use are both thought to be important in the development of nicotine dependence.

## MECHANISMS OF TOBACCO INDUCED PANCREATIC CANCER

Cigarette smoke is a complex mixture of carcinogenic compounds and nicotine, many of which have deleterious effects on the exocrine pancreas. Nicotine forms carcinogenic *N*-nitroso compounds during processing[11-14], which induce pancreatic cancer in the Syrian golden hamster model of pancreatic carcinogenesis[15,16]. A particular component of tobacco smoke, 4-(methylnitrosamino)-1-butanone (NNK), is implicated in pancreatic carcinogenesis by its ability to form DNA adducts[17] which have been associated with activating RAS mutations that are found in most human pancreatic adenocarcinomas[18]. NNK also induces proliferation in pancreatic ductal epithelial cells by stimulating EGF mediated signal transduction pathways through binding to β-adrenergic receptors[19,20].

Nicotine, although not carcinogenic, exerts toxic effects on the pancreas. Exposure of rat pancreatic acini to nicotine results in increased protein secretion[21]. We have demonstrated that nicotine induces cytoplasmic vacuolization, cellular edema and increases the cellular amylase content in the exocrine pancreas[22]. We also demonstrated that the increase in pancreatic enzymes in nicotine treated rats was accompanied by reduced CCK mediated enzyme secretion, which may be the causative factor in nicotine induced pancreatic cell pathology. Exposure of rats to tobacco smoke produced fibrosis and scarring of pancreatic acinar structures, characteristic of chronic pancreatitis[23]. In humans, nicotine inhibits the secretion of bicarbonate and affects the composition of pancreatic secretions[24,25], and in patients with pancreatitis, nicotine exposure resulted in increased pancreatic enzyme secretion, including amylase[26] and lipase[27].

## THE GENETICS OF NICOTINE DEPENDENCE

Nicotine is the major psychoactive component of tobacco that is responsible for dependence through a nicotine stimulated reward system that is thought to be mediated by the dopaminergic system of the brain. Recent research has identified behavioral, environmental and genetic factors that influence the various stages of smoking behavior, including smoking initiation, development of addiction and smoking cessation. Early evidence for the influence of heredity on tobacco dependence came from studies of tobacco use among families[28], adopted siblings and among mono and dizygotic twins[29,30]. In a study of mono and dizygotic twins, True *et al*[31] found that 50% of the risk of smoking initiation and 70% of the risk for continuing to smoke were due to genetic factors.

## POLYMORPHIC GENES INVOLVED IN NICOTINE METABOLISM

Individuals with increased tolerance to nicotine because of a greater capacity to metabolize the drug may experience fewer adverse reactions to their first encounter with nicotine, and therefore may have a greater propensity to continue using tobacco products. Conversely, slow metabolizers of nicotine would be expected to smoke less and would be less likely to become nicotine dependent. Smokers tend to adjust their smoking behavior in order to maintain a certain level of nicotine in the brain[32], so that an individual's capacity to metabolize nicotine will influence their intake and exposure. Polymorphic expression of genes that are responsible for nicotine metabolism may be responsible for the wide variability in nicotine tolerance between individuals.

The hepatic enzymes cytochrome P450 2A6 (CYP2A6) and cytochrome P450 2D6 are the major isoforms responsible for the metabolism of nicotine to cotinine, however hepatic CYP2A6 is responsible for 90% of the first pass metabolism of nicotine[33,34]. Both of these enzymes are polymorphic in the human population, with genetic differences that are responsible for high and low activity alleles.

## CYTOCHROME P450 2A6 (CYP2A6)

The CYP2A6 gene is polymorphic in the human population, with large inter-individual differences in the levels of hepatic CYP2A6 protein and enzyme activity[34-36]. A deletional allele was found to be responsible for low or non-existent CYP2A6 activity[36]. A number of studies have found that individuals with genetically determined slow or absent CYP 2A6 activity have a reduced risk of becoming smokers, and those who do smoke tend to smoke fewer cigarettes per day and have a higher smoking cessation success rate[37-40]. Pianneza *et al*[41] reported that a tobacco dependent population had an under representation of low activity CYP2A6 alleles, and that those smokers who had low activity alleles tended to smoke fewer cigarettes per week, suggesting a role for CYP2A6 in nicotine tolerance and dependence. However, other studies have failed to detect an association between genetically low CYP2A6 activity and nicotine use or dependence[42,43]. One reason for this discrepancy was the use in early studies of a

genotyping protocol that overestimated the number of low activity alleles in the study population[44,45]. A meta-analysis by Carter *et al*[46] also failed to find a significant association between CYP2A6 genotype and smoking behavior. In another meta-analysis, Munafo *et al*[47] concluded that the influence of individual genes on smoking behavior may be subtle, and that larger studies that have the power to detect the effects of multiple genes on smoking behavior will be necessary. However, in a number of studies, they found strong evidence that the reduced activity allele of CYP2A6 was associated with smokers who were able to quit smoking.

Recently, the use of CYP2A6 inhibitors has been explored as a chemoprevention strategy for smoking cessation. A study by von Weymarn *et al*[48] reported that the benzyl and phenylethyl isothiocyanates that are found in cruciferous vegetables such as broccoli and cabbage, were effective competitive inhibitors of both CYP2A6 and CYP 2A13. CYP2A13 is the enzyme responsible for the activation of the tobacco procarcinogen NNK to its ultimate carcinogenic form. This report suggests that inhibition of CYP2A6 may convert the phenotype of smokers to one which confers less metabolic tolerance to nicotine, leading to fewer cigarettes smoked per day. The resultant reduction in nicotine metabolism may possibly increase success with smoking cessation. At the same time, inhibition of CYP2A13, which is found primarily in the lung, may result in less activation of NNK, potentially protecting individuals who continue to smoke from developing lung cancer. Sellers *et al*[49] reported that another CYP2A6 inhibitor, methoxsalen, was effective in increasing the bioavailability of nicotine in smokers, resulting in a decrease in the number of cigarettes they smoked per day. These studies demonstrate that the use of CYP2A6 inhibitors may be a useful strategy to reduce tobacco exposure and may have the potential to increase the success rate of smoking cessation programs.

## CYTOCHROME P450 2D6 (CYP2D6)

Caporaso *et al*[50] determined inter-individual differences in CYP2D6 phenotype by measuring the metabolism of dextromethorphan, a CYP2D6 substrate. They concluded that polymorphisms in CYP2D6 were not major determinants of nicotine metabolism in smokers except in ultrametabolizers. These are individuals who have a duplication of the CYP2D6 gene that is present in 3%-8% of Caucasians and up to 30% of other ethnic groups[51]. This duplication results in the production of high levels of functional CYP2D6 protein and results in the increased metabolism of CYP2D6 substrates, including nicotine. In a case-control study of lung and larynx cancer, the CYP2D6 gene duplication was found in 13% of cancer patients compared to 6% of healthy control subjects. The frequency of a genetic polymorphism that codes for a high activity CYP2D6 allele called CYP2D6*9 was also higher in cases compared to controls[52]. Approximately 3%-10% of Caucasians are CYP2D6 poor metabolizers, due to inheritance of two defective alleles. Saarikowski *et al*[53] found the same proportion of poor metabolizers in groups of smokers and never-smokers, however among men, a trend toward more poor metabolizers in the non-smoking group was observed. They also found twofold more ultrametabolizers among heavy smokers compared to non-smokers. Overall, the results of these studies suggest that CYP2D6 affects nicotine metabolism among individuals who have high activity due to gene duplication, however the influence of the low activity allele remains controversial.

## GENES INVOLVED IN NICOTINE DEPENDENCE

Nicotine is thought to induce a euphoric state in users and by that is thought to be the result of activation of the mesolimbic dopaminergic reward system in the nucleus accumbens of the brain[54-56]. Nicotine binds to nicotinic receptors that, when activated, enhance dopamine release in areas of the brain that are thought to be involved in reward[55,57]. The involvement of the dopaminergic system in the reinforcement activity of nicotine may be related to the highly addictive properties of the drug[56]. Genetic polymorphisms in genes that affect this reward system, including dopamine receptors and transporters, nicotinic receptors and serotonin receptors may modulate an individual's risk of becoming nicotine dependent.

## DOPAMINE RECEPTOR GENE POLYMORPHISMS

The human dopamine $D_2$ receptor (DRD2) has a *Taq*I polymorphism with two minor alleles termed the *Taq*IA allele ($A_1$ and $A_2$) and the *Taq*IB allele ($B_1$ and $B_2$). The *Taq*I*A1 allele has been shown to be associated with reduced expression of dopamine $D_2$ receptor in the striatum[58-61]. It has been hypothesized that subjects with reduced numbers of dopamine receptors may compensate for this deficiency by using nicotine to increase brain dopamine levels. The presence of the DRD2 *Taq*I allele has been associated with an earlier age of smoking initiation[62], increased risk of being a current smoker, and reduced duration of smoking abstinence[63]. Spitz *et al*[64], conducted a case control study of lung cancer patients and found that a greater percentage of chronic smokers had the $B_1B_2$ genotype compared with non-smokers, whether they were cancer cases or controls. The least common $A_1$ or $B_1$ alleles were associated with individuals who were younger when they started smoking and had attempted to quit smoking fewer times compared with smokers with the more common DRD2 alleles. Other studies have failed to find an association between the DRD2 *Taq*I allele and smoking behavior. Bierut *et al*[65] analyzed a family study by the transmission disequilibrium test and found no difference in the frequency of DRD2 alleles transmitted to habitual smokers. In a small British study, Singleton *et al*[66] found no increase in the DRD2 *Taq*I allele in smokers compared to non-smokers, and Johnstone *et al* duplicated these findings in a larger study[67]. Munafo *et al*[47] conducted a meta-analysis of the genetic basis for smoking behavior and concluded that there is some evidence for an association between the DRD2 *Taq*I*A1 allele and smoking behavior, but larger, better designed

studies in a variety of populations are needed to confirm this relationship.

Other dopamine receptors are genetically polymorphic, but have received less attention than the DRD2 gene with respect to smoking behavior. A 5' polymorphism of no known function, located in the dopamine $D_1$ receptor gene (DRD1), has been associated with smoking[68]. The DRD3 receptor is genetically polymorphic and is highly expressed in the nucleus accumbens, however, no association with smoking behavior has been reported[69].

A polymorphism characterized as a variable number of tandem repeats has been reported in the dopamine D4 receptor (DRD4)[70,71]. The receptor containing 7 repeats has been characterized as having a reduced response to dopamine binding[72]. Shields *et al*[73] compared DRD4 genotype for a population of smokers compared to non-smokers and found that African American smokers had a higher incidence of the DRD4 allele containing 7 repeats than African American non-smokers. In addition, African American smokers with this allele had an earlier age of smoking initiation and less success at smoking cessation than African Americans with shorter repeat sequences. The same analysis of a Caucasian population showed no association with smoking status. This data suggests that individual genotypes may be a factor in the success of smoking cessation strategies, and more effective strategies may need to be tailored to an individual's genetic background. The human DRD5 gene has at least 4 missense or nonsense polymorphisms, however, no association with smoking behavior has been reported[74].

## DOPAMINE TRANSPORTER POLYMORPHISMS

The dopamine transporter gene (*SLC6AC*) has a variable number of tandem repeats polymorphism in the 3' noncoding region of the gene[75] that is associated with reduced transporter levels in the brain[76]. The role of this polymorphism in determining smoking behavior is not clear, however, in some studies, the polymorphism containing 9 repeats was found to be associated with greater levels of cigarette craving among African American smokers[77]. Other studies found that individuals with the *SLC6AC* 9 repeat allele were less likely to be smokers, especially if they also had the DRD2 Taq1 $A_1$ allele[78]. These individuals were less likely to start smoking at an early age, and those who did smoke had greater periods of smoking cessation. Sabol *et al*[79] confirmed these findings in a diverse population of smokers, non-smokers, and ex-smokers, however Vandenbergh *et al*[80] failed to replicate these results in spite of another report on the function of the 9 repeat sequence as a transcriptional enhancer[81, 82].

## CATABOLISM OF DOPAMINE

The action of dopamine is terminated by the action of catabolic enzymes, primarily catecholamine-*O*-methyltransferase (COMT) with lesser roles for monoamine oxidase A and B (MAO) and dopamine β hydroxylase (DBH). Genetic polymorphisms have been discovered in these enzymes, and the effects on smoking behavior have been tested in a number of studies. In a study of smokers, McKinney *et al*[83] reported that polymorphisms in DBH and MAO were related to maintenance of nicotine levels and predicted the quantity of cigarettes smoked. No association between the amount of tobacco consumed and the functional COMT A1947G single nucleotide polymorphism (SNP), which results in the substitution of a methionine for valine at codon 108 (Met108Val) in the COMT protein, was detected in this study. These results were unexpected in light of a report that the G allele at this locus results in a three to fourfold increase in COMT activity[84], and a reported association of this allele with addiction to other drugs[85]. The lack of association between this SNP and smoking initiation, persistence and cessation was replicated in a larger study of current smokers, ex-smokers and lifetime non-smokers[86]. More recent studies include the finding of a positive association between the high activity COMT allele and nicotine dependence in a Caucasian population, however, these results were not replicated in a second independent study by the same researchers[87]. In a case-control study of women, those who were homozygous for the lower activity Met allele were more likely to be ex-smokers rather than current smokers, and in a nicotine replacement clinical trial reported by the same group, Met homozygotes at the COMT locus had more success at smoking cessation[88]. Bueten *et al*[89] analyzed five allelic variants in the COMT gene, including the Met108Val SNP, and found a significant association with nicotine dependence. The lack of reproducibility of this data, even when the same researchers analyze independent study populations, may be due to the lack of power to detect relatively small effects of COMT on smoking behavior. These results demonstrate the need for large, adequately powered replication studies to determine the genetic basis of smoking behavior and nicotine addiction.

## SEROTONIN TRANSPORTER PROMOTER POLYMORPHISMS

Nicotine increases the secretion of serotonin in the brain[90] therefore, the serotonergic system may have a function in determining smoking behavior. Lower serotonin reuptake has been associated with an increased risk of depression as well as increased impulsive or aggressive behavior[91]. This combination of behavioral traits is termed neuroticism, and has been associated with increased incidence of smoking, nicotine dependence, and difficulty in quitting smoking[92]. Evidence for a genetic link to neuroticism and smoking behavior centers around a 44-bp deletion/insertion polymorphism that corresponds to short (S) and long (L) versions of the serotonin transporter gene (5-hydroxytryptamine transporter or 5-HTT) promoter[93]. Functional characterization of this polymorphism has demonstrated that the short promoter variant reduces the transcriptional activity of the gene and results in decreased 5-HTT expression and decreased serotonin uptake[94]. Hu *et al*[92] found a relationship between the genotype for the 5-HTT promoter polymorphism and degree of

neuroticism and smoking behavior. This finding was confirmed by another study which reported that smokers who were heterozygous or homozygous for the 5-HTT S-allele were more likely to be dependent on nicotine than subjects who were homozygous for the L allele[95]. However in a Japanese population, the presence of the S allele was associated with non-smokers or ex-smokers, indicating that individuals who were homozygous for the S allele were less likely to begin smoking, or were more successful at smoking cessation[96]. Other studies were unable to detect any association between the 5-HTT promoter polymorphism and smoking behavior in Caucasian or African American populations, in spite of significant differences in the distribution of 5-HTT promoter alleles between racial groups[97].

## CONCLUSIONS

The variability of results reported for most candidate genes that are hypothesized to affect smoking behavior demonstrates the need for larger, well controlled studies designed to define the genetic basis for inter-individual differences in nicotine and dopamine metabolism as they relate to smoking behavior and nicotine dependence. Results of these future studies will be useful in identifying individuals who are at increased risk of becoming dependent on nicotine and will also facilitate the development of smoking cessation strategies that are targeted to individual differences in nicotine and neurotransmitter action and metabolism. Considering that smoking is the greatest risk factor for pancreatic cancer, reduction of tobacco use through both abstinence programs and successful smoking cessation is the best hope for reducing the risk of developing this devastating disease.

## Abstract

Members of the receptor tyrosine kinase family, that include EGFR, ErbB-2/HER-2, ErbB-3/HER-3 and ErbB-4/HER-4, are frequently implicated in experimental models of epithelial cell neoplasia as well as in human cancers. Therefore, interference with the activation of these growth factor receptors represents a promising strategy for development of novel and selective anticancer therapies. Indeed, a number of inhibitors that target either EGFR or HER-2, with the exception of a few that target both; have been developed for treatment of epithelial cancers. Since most solid tumors express different ErbB receptors and/or their ligands, identification of inhibitor(s), targeting multiple EGFR family members may provide a therapeutic benefit to a broader patient population. Here we describe the significance of an ErbB family of receptors in epithelial cancers, and summarize different available therapeutics targeting these receptors. It also emphasizes the need to develop pan-ErbB inhibitors and discusses EGF-Receptor Related Protein, a recently isolated negative regulator of EGFR as a potential pan-ErbB therapeutic for a wide variety of epithelial cancers.

**Key words:** Gastrointestinal cancers; Carcinogenesis; Targeted therapies; Pan-ErbB family; EGF-Receptor Related Protein

## EPIDEMIOLOGY

Gastrointestinal cancers account for 21% of all cancers incidences and 25% of the cancer mortality in the United States[1]. Despite recent advances in diagnosis and treatment, gastric carcinoma, ductal carcinoma of the pancreas and colorectal cancer are the leading causes of cancer-related deaths worldwide. The pathogenesis of these cancers remains elusive and the available treatment options are limited. Among the GI cancer-related deaths, carcinoma of the stomach ranks seventh in the USA. However, stomach cancer is the leading cause of cancer-associated mortality in Japan, China and India[2]. Gastric cancer ranks number 2 worldwide, second to lung cancer and thus is a major international health concern[2]. Colorectal cancer is the third most common malignancy among men and women in the USA and ranks second for cancer related deaths[3]. In terms of global incidence, colorectal cancer ranks third in frequency, but fourth in cancer related mortality[2]. Adenocarcinoma of the pancreas is the second most common gastrointestinal malignancy in the USA[4]. However, pancreatic cancer is the fourth leading cause of cancer-related mortality among American men and women[5]. GastroIntestinal Stromal Tumor (GIST) is a rare stomach and intestinal cancer with unknown global incidence that spreads rapidly and the survival rate for patients is quite low. GIST is resistant to most known therapies and the available ones have much harsher side effects.

## CURRENT TREATMENT MODALITIES

Different treatments are available for gastrointestinal (GI) cancers. These may be employed alone or in combination with other therapeutic/adjuvant therapy. The available treatments for GI tract cancers are (1) Surgery: resection of the solid tumor whenever possible (2) Chemotherapy: employing cytotoxic drugs to kill cancers cells (3) Radiation therapy: to treat localized solid tumors, (4) Hormonal therapy: systemic treatment that targets cancer cells through out the body. Different analogs of GI hormonal peptides and endogenous growth factors are utilized to inhibit the progression of tumor. Such analogs target gastric releasing peptide (GRP), bombesin, somatostatin, as well as peptide receptors and antagonists of growth hormone releasing hormone (GH-RH)[6]. However, the successful treatment of cancer often requires the combination and coordination of several different

treatment approaches. This is referred to as multi-modality treatment and may consist of surgery, chemotherapy, radiation therapy, and/or hormonal therapy. It is important to emphasize that surgery is a local treatment and is only capable of removing cancer cells from a defined area. By the time a cancer is diagnosed, many patients will already have experienced spread of cancer cells through the blood and lymph system to other locations in the body. They are referred to as micrometastases. Currently available tests cannot always detect micrometastases. Information obtained during surgery and from other tests determines the likelihood of the cancer having spread and whether additional treatments with chemotherapy, radiation, or hormonal therapy is necessary.

## TARGETED THERAPIES

With the recent advances towards understanding of the molecular basis of carcinogenesis, different cell signaling pathways have been implicated in aberrant growth of cells. Direct or indirect interference with signaling pathways often results in modulation of cellular growth. The modalities that target single or multiple signaling pathways, referred to as "Targeted therapies" have been developed and are currently being utilized in clinics as anti-cancer therapeutics. A targeted therapy is designed to treat the cancer cells and minimize damage to normal, healthy cells. Treatments that "target" cancer cells specifically offer the advantage of reduced treatment-related side effects and improved outcome. Conventional cancer treatments such as radiation therapy, do not distinguish between cancer cells and healthy cells. Consequently, healthy cells are commonly damaged in the process of treating the cancer, which results in side effects. Chemotherapy damages rapidly dividing cells, a hallmark trait of cancer cells. In the process, healthy cells that are also rapidly dividing (such as blood cells and the cells lining the mouth and GI tract) are also damaged. Many chemotherapy drugs, which damage DNA of both malignant cells and normal cells, frequently cause toxicity. Treatment-related damage to healthy cells leads to complications of treatment, or side effects. These side effects may be severe, reducing a patient's quality of life, compromising their ability to receive their full, prescribed treatment, and sometimes, limiting their chance for an optimal outcome from treatment.

A number of genes/proteins have been identified to be abnormally expressed in tumors and thus serve as targets for therapeutic intervention. Among the known targets for treatment of GI cancers, Epidermal Growth Factor Receptor and its family members (EGFRs) form the most attractive candidate. EGFR sits across the outer membrane of the cell, receiving and transmitting growth signals from the cell surface to the nucleus. EGFRs have been implicated in variety of epithelial cancers and are generally overexpressed or aberrantly activated in one third of all the cancers. The overexpression of the receptor has been reported in cancers of the stomach (33%-74%), colorectum (25%-77%), esophagus (43%-89%), and pancreas (30%-50%)[7]. Increased EGFR or some of its family members expression is normally associated with poor prognosis with more advanced disease, increased metastasis and decreased survival[8-10]. For the sake of simplicity, the current article will focus on different clinically approved and ongoing developing therapeutics that target EGFR or its family members.

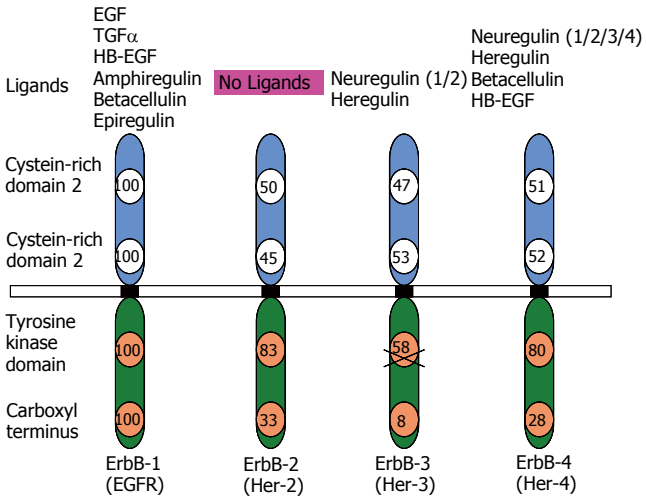

**Figure 1** Schematic representation of the four ErbB family members and their respective ligands. The numbers depict percentage homology of each domain relative to EGFR/ErbB-1. There are no known ligands for ErbB-2 and the tyrosine kinase domain is non-functional in ErbB-3, as marked with a cross.

### *ErbB family of tyrosine kinase receptors*

The EGFR family of RTKs is comprised of four members in mammals but containing one member of the EGFR family in *C.elegans* and *D. melanogaster*. The four members are called: EGFR (also ErbB-1 or HER-1), ErbB-2/HER-2, ErbB-3/HER-3 and ErbB-4/HER-4[11,12]. The signaling transduced by these members is crucial for the development of mice, fruitflies and nematodes[13-17]. The best-characterized functions of the ErbB family of receptors are regulating aspects of replication, migration and survival of cells. In this regard, these receptors interact with multiple signaling molecules and pathways, transmitting and receiving both stimulatory and inhibitory signals[18-20].

All members of the ErbB family are cell surface allosteric enzymes consisting of a single transmembrane domain that separates the extracellular ligand binding domain from the intracellular kinase domain (Figure 1). Under normal physiological conditions, activation of ErbB receptors is regulated by the specific spatial and temporal expression of their ligands which are members of the EGF family of growth factors[11,20]. Ligand binding initiates homo/hetero dimerization of the receptors, leading to auto and trans- tyrosine phosphorylation of the receptors. Tyrosine phosphorylation/activation of the kinase domain leads to recruitment of different proteins initiating a downstream signal cascade. Protein phosphorylation and dephosphorylation, catalyzed by protein tyrosine kinases and protein phosphatases respectively represent the two fundamental biochemical events for downstream intracellular signal transduction[21]. Autophosphorylation of tyrosine residues within the C-tail terminus of EGFR in the cytoplasm following activation of the receptor initiates a cascade of intracellular signaling pathways[22,23].

The receptor tyrosine kinase signaling may be terminated by the endocytosis of the receptor-ligand complex[24]. The downstream signaling by ErbB receptors results in transcriptional regulation of various genes including proto-oncogenes like jun, fos and myc in addition to some zinc-finger containing transcription factors[25].

### Complexity of ErbB signal transduction

Signaling by ErbB receptors is quite diversified and finely tuned at two levels of regulation. These include the specific binding of the ligand to the receptor(s) and the ability of each receptor to form homo/hetero dimers[20,26]. The peptide ligands are produced as transmembrane precursors and their ectodomains are processed by proteolysis, which leads to shedding/secretion of the soluble form of growth factors[27]. There are several ErbB specific ligands, all sharing an EGF-like motif of 45-55 amino acids, including six cysteine residues that interact covalently to form three loops. Depending on the binding specificity conferred by this region, the ligands may be categorized into three groups (Figure 1). The first group includes EGF, amphiregulin and transforming growth factor α (TGF-α) that bind specifically to EGFR/ErbB-1. The second group includes betacellulin (BTC), heparin binding EGF (HB-EGF) and epiregulin that exhibit dual specificity for ErbB-1 and ErbB-4[24]. The third group includes neuregulins (Neu also called Neu differentiation factors or Heregulins). This group is further divided into two sub-groups depending on their ability to bind to ErbB-3 and ErbB-4 or only ErbB-4[28,29]. The second level of regulation depends on the homo-hetero dimerizing partners. Although, a total of nine possible homo- and hetero-dimeric receptor combinations can occur, EGFRs often display preference for their dimeric partners. In this network, ErbB-2 is the most preferred partner and thus plays a co-ordinating role[30,31]. The ErbB-2 containing dimers are known for their high signaling potency as ErbB-2 drastically reduces the rate of ligand receptor dissociation and allows for strong and prolonged activation of the downstream signaling pathways[32,33]. Also, each homo/hetero dimer has been shown to possess unique specificity for the ligand that would stimulate the ErbB activation[34-39]. Within the same heterodimer, the signaling properties of a receptor can be significantly modulated by specific ligand binding. In context of EGFR/ErbB-4 heterodimer, EGF induction is quite fast and recruits both Grb2 and p85 for downstream signaling. On the other hand, addition of NDF stimulation of the receptor heterodimer is relatively slow and recruits only p85 to activate downstream pathways.

### ErbB signaling and integration with other cell signaling pathways

Each of the seven ligands (Figure 2) has a preferred receptor homo/hetero dimer. The ligand-bound receptor homo/hetero dimer, in turn, has a different set of tyrosine phosphorylation sites, which serve as docking sites for specific SH2 containing proteins and recruit different combinations of intracellular signaling molecules[20,40,41]. This is despite the fact that there is a considerable overlap in the molecules recruited to the active receptors. For example, tumor cells that over express EGFR with kinase domain mutations preferentially activate the pro-survival PI3K-Akt pathway and Signal Transducer and Activator of Transcription (STAT) pathways. EGFR has no consensus sequence for the p85 adaptor subunit of PI3K; it couples to this pathway via GAB1. GAB1 in turn binds the Growth Factor Receptor Bound protein 2 (GRB2), which docks at the phosphorylated tyrosine of the kinase domain of the activated EGFR. Similarly, there is no evidence for direct binding of STAT to the EGFR. But it is proposed that this coupling is mediated via tyrosine 1068 and tyrosine 1086 of the EGFR kinase domain[42]. ErbB-2 couples to the Mitogen-Activated Protein Kinase (MAPK) pathway through GRB2, SHC, downstream of Kinase Related (DOK-R)[43] and CRK. PhosphoLipase C γ (PLCγ) binding has recently been implicated in transducing signals by EGFR[44]. Although ErbB-3 is able to bind neuregulins (NRGs), it has impaired kinase activity owing to substitutions in crucial residues in the tyrosine-kinase domain. Therefore, ErbB-3 gets phosphorylated and functions as a signaling entity only when it heterodimerizes with another ErbB receptor[45], ErbB-2 being the preferred partner. ErbB-3 contains six docking sites for the p85 adaptor subunit of PI3K[37,46] and couples very efficiently to this pathway[41].

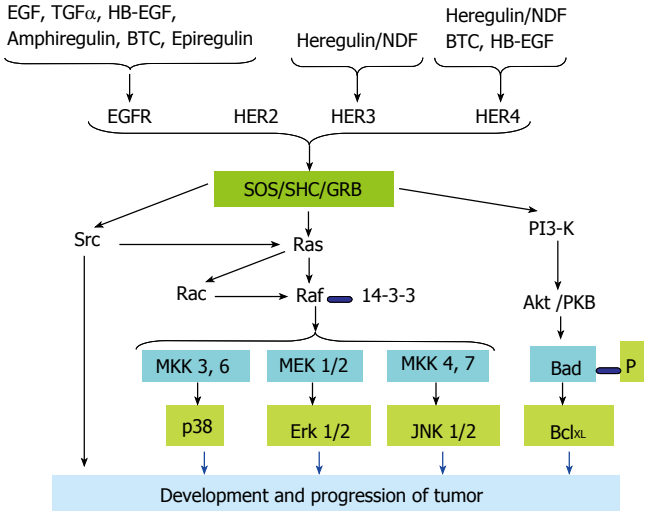

**Figure 2** Schematic representations of different ErbBs/EGFRs ligand-induced signaling pathways leading to development and progression of tumors. BTC: betacellulin; EGF: Epidermal growth factor; EGFR: Epidermal growth factor receptor; ERK: Extracellular signal regulated protein kinase; HB-EGF: heparin binding-EGF; Grb: Growth factor receptor receptor binding protein; JNK: c-Jun N-Terminal kinase; MEK: Mitogen activated protein kinase kinase; NDF: neu differentiation factors (also called neuregulins); PI3K: Phosphoinositide-3-kinase; PKB: Protein kinase B; SOS: Son of sevenless;TGF-α: transforming growth factor α.

### Functions of ErbB members

The ErbB family of RTK plays a crucial role in the development of the cardiovascular system, nervous system, mammary gland, and probably others[47]. Expression patterns of ErbB receptors and their ligands, as well as targeted inactivation of components of the ErbB signaling network highlight the importance of short-range ligand-receptor interactions, especially in mid-gestation processes. ErbB receptors regulate different developmental processes

by fine-tuning of apoptosis and proliferation. In light of data from *in vivo* and *in vitro* studies, it may be concluded that the primary role of ErbB receptor signaling is to promote growth and proliferation. This is achieved in two ways (1) suppressing apoptotic signals and (2) promoting pro- survival signals. ErbB receptor signaling has the ability to antagonize the activation of extrinsic apoptosis signals by Fas receptor and TNFR-1[48]. On the other hand, ErbB-1 signaling can increase Bcl-$X_L$ transcription through STAT-3[49,50] or the mitogen-activated protein kinase kinase (MEK) protein of the mitogenic Ras pathway[51]. Thus, ErbB receptors function at both the transcriptional and post-transcriptional levels to modulate the expression and localization of Bcl family proteins to promote cell survival.

### *Significance of ErbB receptors in oncogenesis*

**ErbB receptors and clinical studies:** In head and neck cancer, the vast majority of tumors are strongly EGFR-positive[10]. Studies have also reported EGFR overexpression in the following cancers: bladder, brain, breast, cervical, uterine, colon, esophageal, glioma, non-small-cell lung cancer (NSCLC), ovarian, pancreatic and renal cell[52-54]. ErbB-2 overexpression, generally attributable to gene amplification, occurs in 25%-30% of breast cancers and correlates with shorter time to relapse and lower overall survival[55]. Overall, about 30% of invasive ductal carcinomas overexpress ErbB-2, but no ErbB overexpression is seen in benign breast disease[56]. ErbB-3 overexpression was linked to several negative prognostic factors, including lymph node involvement, invasion, and patient survival[57]. Involvement of ErbB-4 in breast cancer remains controversial. Some reports indicate that increased ErbB-4 expression or signaling is associated with tumorigenesis. ErbB-4 overexpression has been observed in a variety of cancers, including tumors of the thyroid, breast, and gastrointestinal tract[58-61]. However, other reports indicate that increased ErbB-4 expression or signaling correlates with tumor cell differentiation and reduced tumor aggressiveness. ErbB-4 overexpression in breast tumors is associated with progesterone receptor and estrogen receptor expression and is often a favorable factor in prognosis[62,63]. In one study of common solid human cancers, the loss of ErbB-4 expression was seen in a significant percentage of breast, prostate, and head and neck malignancies[64,65]. These findings raise the intriguing possibility that ErbB-4 is unique to the ErbB family of receptors in that ErbB-4 expression and signaling may couple to reduced tumorigenesis or tumor cell proliferation. However, due to presence of the conflicting evidence, it remains unclear what general or specific roles ErbB-4 plays in differentiation, tumor suppression, or proliferation.

**Elevated Co-expression of partners and ligands:** In many cases EGFR is co-expressed with other members of the ErbB family, leading to the formation of highly transforming dimers such as EGFR//ErbB-2 and EGFR//ErbB-3. It is also well known that other dimers such as ErbB-2//ErbB-3 play a key role in various cancers such as breast carcinoma. ErbB-3 is frequently overexpressed than ErbB-2 in gastric cancers and was widely detectable, making it a potential marker for postgastrectomy recurrence. It was further demonstrated that ErbB-3 functions as an indispensable ErbB-2 dimerization partner and is required for proliferation of ErbB-2-overexpressing tumor cells in ErbB-2 overexpressing breast tumor cell lines[66]. There was a correlation between ErbB-3 expression and sensitivity to ErbB-2 directed inhibitors. For above reasons, the prognostic significance of any ErbB expression in tumors also depends on the expression of other ErbB members being co-expressed. For instance, in childhood medulloblastoma patients with tumors overexpressing both ErbB-2 and ErbB-4 have worse prognosis than patients with tumors that express either receptor alone[67]. Moreover, the levels of ligands like TGF$\alpha$ also significantly correlated with advanced disease, suggesting that elevated levels of ligand and its receptor might create an autocrine signaling loop[68].

**Deregulation of ErbB signaling:** Enhanced activity of the receptors resulting from overexpression, coexpression of the receptor, and their ligands, as well as activating mutations, is the hallmark of many human carcinomas[24]. However, the most common is the overexpression of the receptor along with the expression of the respective ligands like TGF$\alpha$, EGF, amphiregulin and HB-EGF leading to persistent autocrine stimulation. Another common occurrence is the activating mutation in the EGFR extracelluler domain; where the exons 2-/7 are deleted, leading to a persistently active receptor EGFR$\Delta$[69-74], that is persistently active in the absence of a ligand[73,74]. This activating mutation is the hallmark of many tumors that overexpress EGFR. Activation of the EGFR stimulates tumor growth and progression, including the promotion of proliferation, angiogenesis, invasion, metastasis and inhibition of apoptosis[18,75,76]. The emergence of this mutation represents the most aggressive form of the tumor. ErbB receptors appear to have the potential to acquire novel survival signaling pathways when overexpressed and/or mutated within certain tumor cell types. ErbB survival signals can also prevent tumor cells from responding to chemotherapeutic agents[77-81], which often function by activating apoptotic pathways within targeted tumor cells[82,83]. Studies by Yu *et al*[78,79] have demonstrated that overexpression of ErbB-2 permits the MDA-MB-435 breast cancer cell line to withstand ten times the usual dose of the chemotherapeutic agent Taxol before undergoing apoptosis. Similarly, studies by Nagane *et al*[77], indicate that expression of a mutated version of ErbB-1 in human malignant gliomas results in tumor cell resistance to the apoptosis-inducing chemotherapeutic drug cisplatin. Enhanced tumorigenicity and escape from cisplatin-induced apoptosis have been correlated with mutant ErbB-1 induced upregulation of the anti-apoptotic Bcl-$x_L$ protein.

### *Strategies for inhibition of ErbB receptors*

Over the years, different strategies have been developed that inhibit signaling by ErbB receptors. These agents with degrees of receptor specificity include monoclonal antibodies, tyrosine kinase inhibitors, immunotoxin conjugates, antisense oligonucleotides, and bispecific antibodies (Figure 3). Among the classes of agents targeting ErbB receptors, the monoclonal antibodies and tyrosine kinase inhibitors are furthest in development. In general, monoclonal antibodies against the extracellular domain target an individual ErbB receptor, whereas

**Table 1 Selected ErbB-targeted monoclonal antibodies**

| Drug/agent | Type | Target | Company/institution | Stage of development |
|---|---|---|---|---|
| Trastuzumab (Herceptin) | Humanized mAb | ErbB-2 | Genentech/Roche | Approved for ErbB-2 over expressing breast cancer in 1998 |
| Cetuximab (Erbitux/IMC-225) | Human-mouse Chimeric mAb | EGFR | ImClone/Merck KGaA Bristol-Myers Squibb | Approved for colorectal cancer, Phase Ⅲ trials ongoing for HNSCC and NSCLC in 2004 |
| Panitumumab (ABX-EGF) | Fully Human mAb | EGFR | Abgenix | Phase Ⅲ trials for renal cancer, prostate cancer, pancreatic cancer, colorectal and NSCLC, esophageal cancer |
| Pertuzumab (Omnitarg/2C4) | Humanized mAb | ErbB-2 | Genentech | Phase Ⅱ trials for ovarian cancer, breast cancer, prostate cancer and NSCLC |
| Matuzumab (EMD-72000) | Humanized mAb | EGFR | Merck KGaA | Phase Ⅱ trials ongoing for gynaecological cancer, pancreatic cancer and esophageal cancer |
| Thera CIM (hR3) | Humanized mAb | EGFR | YM Biosciences/CIM | Phase Ⅱ trials for HNSCC |
| HuMab-Mouse (MDX-447) | Humanized mAb | EGFR | Medarex/Merck KGaA | Preclinical trials ongoing. Phase Ⅱ trials ongoing for HNSCC |
| Mab 806 | - | EGFR(del 2-7)/ EGFR vⅢ | Ludwig Institute | Preclinical trials ongoing. |

EGFR: Epidermal growth factor receptor; mAb: Monoclonal antibody; NSCLC: Non-small-cell lung cancer; HNSCC: Head and neck squamous-cell cancer.

tyrosine kinase inhibitors that compete with the ATP binding site of the intracellular kinase domain[84-92]. The first ErbB-targeted compound approved for use in human malignancies was trastuzumab (Herceptin), a monoclonal antibody directed against ErbB-2. Subsequently, cetuximab (Erbitux), a monoclonal antibody directed against EGFR; and gefitinib (Iressa), an EGFR tyrosine kinase inhibitor were approved by the FDA for treatment of a number of epithelial cancers. Individually, they target a single ErbB receptor (Table 1). However, because members of the ErbB receptor family cooperate in signal transduction and malignant transformation, the efficacy of these agents has been limited. As mentioned earlier, the ErbB signaling is quite diverse due to different combinations of ligand binding and ErbB partners and the cross talk with other pathways. Preclinical studies have shown that cancer cells can escape the antiproliferative activity of an agent directed against one ErbB receptor by overexpressing ligand for another ErbB receptor. For these reasons there is an ever-increasing requirement for the development of therapies that can induce concurrent inhibition of two or more receptors/pathways. Using both *in vitro* and *in vivo* models, strategies that employ a dual ErbB approach seem to have a greater antitumor efficacy than agents targeting an individual ErbB receptor[93-99].

### *Therapies targeting inhibition of dual /pan Erb B*

Different multi-target therapies can be categorized in the following three groups:

**Combinations of agents that target individual ErbB receptors:** As an ErbB-targeted approach, the combination of a monoclonal antibody together with a small-molecule tyrosine kinase inhibitor uses two agents with different sites of action (Table 2). A phase II clinical study is currently underway to test the dual therapy with trastuzumab (mAb to ErbB-2) and EGFR tyrosine kinase inhibitors. The potential mechanisms of action of trastuzumab combined with an ErbB tyrosine kinase inhibitor include receptor down-regulation, signaling perturbation, angiogenesis inhibition, and antibody-dependent cell-mediated cytotoxicity[54,100,101].

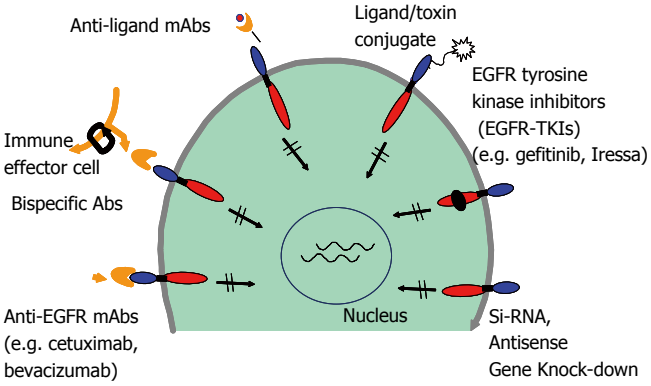

**Figure 3** Different strategies to inhibit EGFRs signaling. mAbs: monoclonal antibodies; siRNA: small interfering ribonucleic acid.

**Single agents that target multiple ErbB receptors:** They are either dual or pan-ErbB tyrosine kinase inhibitors (Table 2). Most tyrosine kinase inhibitors compete with the ATP binding site to inhibit phosphorylation. Among these agents, canertinib, targeting EGFR, ErbB-2, and ErbB-4, and lapatinib, targeting EGFR and ErbB-2, are the furthest in development. Lapitinib (GW2016) is a quinazoline derivative that functions as a reversible, dual ErbB tyrosine kinase inhibitor.

**Agents that interfere with ErbB receptor interactions:** Another approach to inhibiting multiple ErbB receptors is provided by pertuzumab (Omnitarg, 2C4), a monoclonal antibody against ErbB-2 that interferes with ErbB receptor interactions. Pertuzumab binds to a different epitope of the ErbB-2 extracellular domain than trastuzumab[102,103] and seems to differ from trastuzumab in its mechanism of action. Trastuzumab is only active in cells that overexpress ErbB-2, and it does not directly affect the ability of ErbB-2 to function as a coreceptor[104,105]. In contrast, pertuzumab is active in cells that do not overexpress ErbB-2, and it inhibits ligand-mediated signaling by preventing the recruitment of ErbB-2 into ligand/ErbB

**Table 2 Selected ErbB-targeted small molecule inhibitors**

| Drug/agent | Molecular properties | Target Selectivity | Clinical activity in cancer type | Company/Institution | Stage of development |
|---|---|---|---|---|---|
| Gefitinib (ZD 1839; Iressa) | Reversible TKI | EGFR inhibitor | NSCLC, HNSCC, colorectal cancer and breast cancer | AstraZeneca | Approved for NSCLC in 2003, ongoing Phase Ⅲ Trials for other cancers |
| Erlotinib (OSI-774; Tarceva) | Reversible TKI | EGFR inhibitor | NSCLC, HNSCC, colorectal cancer and pancreatic cancer | Genentech/ OSI pharmaceuticals | Approved for NSCLC in 2005, ongoing Phase Ⅲ Trials for other cancers |
| Canertinib (CI-1033)/(PD183805) | Irreversible TKI | EGFR/ErbB-2 inhibitor | NSCLC, HNSCC, Ovarian cancer, breast cancer | Pfizer | Phase Ⅱ |
| Lapatinib (GW2016) | Reversible TKI | EGFR/ErbB-2 dual inhibitor | Breast cancer | GlaxoSmithkline | Phase Ⅲ |
| EKB-569 | Irreversible TKI | EGFR inhibitor | Colorectal cancer, cancer, HNSCC, and NSCLC | Wyeth-Ayerst | Phase Ⅱ |
| AEE788 | TKI | EGFR/ErbB-2/VEGFR | Anti-proliferative effects in tumor cell lines and animal models of cancer | Novartis | Phase I |
| EXEL 7647/EXEL 0999 | TKI | EGFR/ErbB-2/VEGFR | | EXELIXIS | Phase I |
| PKI-166 | Reversible TKI | EGFR/ErbB-2 | Thyroid, Renal, colorectal, HNSCC, and NSCLC | Novartis | Phase I |
| PD 168393 | Irreversible TKI | EGFR | - | Calbiochem | Preclinical |
| AG-1478 | Irreversible TKI | EGFR | - | Calbiochem | Preclinical |
| CGP-59326A | Reversible TKI | EGFR | - | Novartis/ | Preclinical |
| BIBX 1382 | TKI | EGFR | - | Boehringer/Ingelheim | Preclinical |

EGFR: epidermal growth factor receptor; TKI: tyrosine-kinase inhibitor; NSCLC: non-small-cell lung cancer; HNSCC: head and neck squamous-cell cancer, VEGFR: vasculo-endothelial growth factor receptor.

receptor complexes[105,106]. In this manner, pertuzumab provides a unique opportunity to study the contribution of individual heterodimers to the activation of specific signaling pathways.

### *EGF-Receptor Related Protein (ERRP), a novel pan ErbB inhibitor*

Several strategies have been developed to inhibit EGFR and other members of the ErbB family receptors. As mentioned above, usually more than one ErbB member may be involved in a given type of cancer. Thus, in such a scenario it becomes imperative that strategies are developed to target multiple members of the EGFR family. EGFR Related Protein (ERRP) recently isolated from the rat gastro-duodenal mucosa, was found to be a pan-ErbB inhibitor that targets multiple members of the EGFR family. ERRP, a 53-55 kDa protein, possesses three of the four extracellular domains of EGFR, which are responsible for the ligand binding, and subsequent homo/hetero dimerization of various ErbB members. The ERRP cDNA shows 85%-90% homology to the external domain of EGFR and 50%-60% homology to ErbB-2, ErbB-3 and ErbB-4[107]. Though the human counter part of the rat ERRP remains to be isolated, the rat ERRP shows approximately 85% homology to the extracellular domain of human EGFR. Nevertheless, immunohistological analyses in conjunction with anti-rat ERRP polyclonal antibodies revealed that ERRP expression changes in the gastrointestinal tissues (as discussed below) of the rat and human during carcinogenesis as well as aging. These data suggest the presence of an ERRP like molecule in humans.

Garrett *et al*[108] has reported that a truncated EGFR, lacking the extracellular domain Ⅳ of the receptor that binds EGF and TGF-α with higher affinity than the full-length extracellular domain of EGFR. ERRP, a naturally occurring molecule, lacking most of the extracellular domain Ⅳ, also binds TGF-α and is expected to be effective in preferentially binding/sequestering other ligands of ErbBs. In addition, recent biochemical studies utilizing EGFR mutant lacking exons 2-7 of the receptor extracellular domain demonstrated intermolecular inhibitory function of EGFR extracellular domains[109]. Such mutants dimerize with EGFR and cause phosphorylation of wild type EGFR in the absence of ligands[108]. In the light of these findings and the available experimental data, it is suggested that loss of such subdomains is associated with constitutive activation of EGFR, while the truncated EGFRs containing only the extracellular domains serve as repressors of EGFR functions. Ectopic expression of recombinant ERRP causes increased binding/sequestration of EGFR ligand(s) resulting in decreased availability of the ligand(s) for binding to and activation of EGFR with a subsequent attenuation of EGFR signaling pathways. A schematic representation of our hypothesis is depicted in Figure 4. This is further supported by experimental data. Marcinaik *et al*, have demonstrated that exposure of HCT-116 cells to recombinant ERRP and TGF-α results in the formation of heterodimers of EGFR and ERRP with molecular weight of about 220 kDa[110]. TGF-α also induces the

formation of a 340 kDa homodimer of EGFR[110].

**ERRP and carcinogenesis:** In order to investigate the correlation between expression of ERRP protein and carcinogenesis, benign and neoplastic tissues from the pancreas, liver and gastric and colonic mucosa were examined. Expression of ERRP was found to be high in benign human colonic and gastric mucosa as well as in the liver and pancreas but low in the respective carcinomas of these tissues[110-118]. It was further observed, that in colorectal and pancreatic cancers, expression of ERRP decreases progressively with decrease in differentiation[112,113]. In the colon, ERRP expression became more attenuated in polyps with increasing grades of dysplasia. Expression of EGFR inversely related to ERRP in representative samples of normal and neoplastic colon[112]. In light of these observations it is speculated that the loss of ERRP may partly be responsible for induction of EGFR, and may play a causative role in the development of carcinogenesis.

To further evaluate the role of ERRP in the development of cancer, colonic mucosa from rats treated with the colonic carcinogen dimethylhydrazine (DMH) or vehicle (controls) was analyzed for ERRP and EGFR expression. ERRP expression was significantly lost in early stages of chemically induced colon cancer[113]. These observations suggest a potential role for ERRP in the development and progression of carcinogenesis. Supporting data for this inference was further obtained when EGFR and ERRP expression was analyzed in the gastric mucosa of rats during advancing age. In the rat model, it is generally accepted that aging is associated with increased proliferation of colonic mucosal cells that frequently involves the enhanced activity and expression of EGFRs. It has been postulated that age-associated enhanced EGFR activity is due in part, to loss of ERRP which acts as a negative modulator of EGFRs. Immunohistochemical studies revealed that ERRP expression decreased in the gastric mucosa with aging in contrast to increasing expression of EGFR[117].

**ERRP as a potential pan-ErbB inhibitor:** Our hypothesis that ERRP could be a potential therapeutic agent for epithelial cancers came from initial observation that transfection of ERRP cDNA into colon cancer cells inhibited proliferation in the matrix-dependent and -independent systems. This inhibition was associated with attenuation of tyrosine phosphorylation and tyrosine kinase activity of EGFR[107]. The similar phenomenon was also noted in prostate cancer cells (PC-3) following transfection with ERRP cDNA (unpublished data).

To further determine the therapeutic potential of ERRP, we generated and purified recombinant ERRP using the drosophila expression system (Invitrogen)[110]. The affinity-purified recombinant protein was utilized to investigate its effects on the growth of colon and other epithelial cancer cells *in vitro* and *in vivo*. ERRP was reported to inhibit proliferation of colon, and prostate cancer cell lines in a dose-dependent manner. These changes included the inhibition of EGFR signaling and attenuation of downstream signaling involving activation of Akt, mitogen activated protein kinase (MAPK) and nuclear factor (NF-κB)[110,118]. The similar effects were observed in other studies involving non-small cell lung cancer (NSCLC) cell lines,

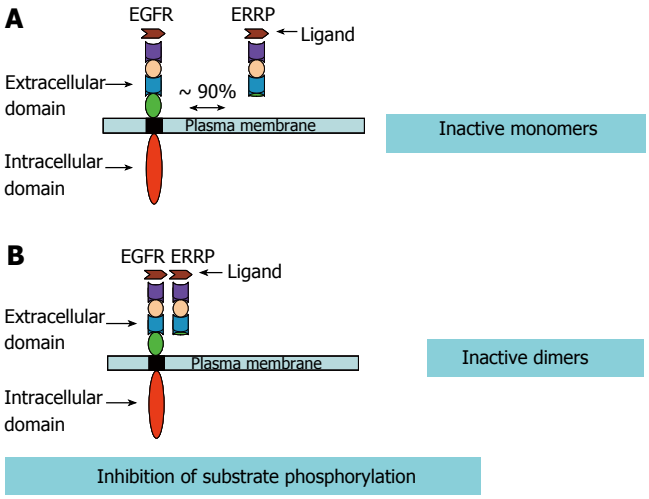

**Figure 4** Schematic representation of the comparison of ERRP structure with EGFR (**A**) and hypothetical mechanism of action of ERRP (**B**). EGFR: Epidermal growth factor receptor; ERRP: Epidermal growth factor receptor-related protein.

breast cancer and pancreatic cancer[119-121]. These epithelial cancer cells express varying levels of EGFR and other ErbB receptors. Thus, a pan-ErbB inhibitory role of ERRP was suggested. The results from efficacy trials using SCID mice have further shown tumor regression in some and arrested growth in other animals[110,122]. ERRP was effective at dose levels of 25 μg/kg and could be tolerated up to 100 μg/kg without producing signs of toxicity in the SCID mice. Although the withdrawal of ERRP administration leads to reappearance of the tumors, the growth rate was significantly reduced afterwards.

Immunohistochemical analysis of ERRP-treated tumors revealed that ERRP-induced inhibition of growth, accompanied by a marked stimulation in expression of active caspase-3 and reductions in phosphorylated (activated) forms of Akt and ERKs[122]. This suggests that ERRP inhibits tumor growth, in part by inducing apoptosis, which was further supported by *in vitro* experiments[122]. ERRP induced apoptosis follows arrest of the cells in the Go/G1 phase of the cell cycle[122]. In order to test the therapeutic value of ERRP, its immuno-reactivity in humans has been further investigated. *In vitro* studies in human peripheral blood lymphocytes have shown marginal activation of the immune response (unpublished data). In an attempt to understand the mechanisms underlying ERRP induced growth inhibition and apoptosis of the tumors, further *in vitro* studies have been conducted. Rishi *et al* observed that ERRP inhibits the processes of cell invasion and blood vessel formation by colon cancer cells. Further, ERRP also inhibited tubule formation by aortic endothelial cells and invasion by colon cancer cells through matrigel[123]. This finding suggests that ERRP inhibits different processes of invasion, metastasis and angiogenesis that are critical in the progression of carcinogenesis. Thus, ERRP, a novel pan-ErbB inhibitor, has a potential utility as a therapeutic for a wide variety of epithelial cancers.

## CONCLUSION

Limited success of chemotherapy/adjuvant therapies in

cancer treatment has necessitated the development of novel targeted therapies. A number of pharmacologic as well as biologic agents have been developed that target specific aspects of intracellular processes and interfere with development and progression of tumors. In light of the fact that the ErbB family of receptors plays an important role in epithelial cancers, a number of inhibitors that target these receptors have been developed. In particular, the monoclonal antibodies Cetuximab and Herceptin, as well as small molecule inhibitors gefitinib and tarceva have shown some promise in the treatment of cancer. However, these agents target EGFR or Her2 but not both. Since most cancers over-express multiple ErbBs, targeting a single receptor often leads to activation and signaling by other ErbBs resulting in development of resistance. In this regard, the agents/inhibitors that target multiple ErbBs are anticipated to display superior efficacy. In our pursuit to develop a pan-ErbB inhibitor, we have recently isolated and characterized ERRP. ERRP have been shown to inhibit proliferation and induce apoptosis of the prostate, colon, gastric, pancreatic, breast and lung cancer cells in *in vitro* models. ERRP attenuates the basal and ligand induced (TGF-$\alpha$, HB-EGF and heregulin) activation of EGFR and Her-2 in a variety of epithelial cancers, suggesting a pan-ErbB inhibitory property. Recombinant ERRP also inhibits growth of colon and pancreatic cancer cell-derived xenografts in SCID mice. ERRP, is unlikely to initiate an immune response as it is an endogenous, secretory protein. ERRP thus is a potential therapeutic for a wide variety of epithelial cancers.

## Abstract

Discoveries in the first few years of the 21st century have led to an understanding of important interactions between the nervous system and the inflammatory response at the molecular level, most notably the acetylcholine (ACh)-triggered, α7-nicotinic acetylcholine receptor (α7nAChR)-dependent nicotinic anti-inflammatory pathway. Studies using the α7nAChR agonist, nicotine, for the treatment of mucosal inflammation have been undertaken but the efficacy of nicotine as a treatment for inflammatory bowel diseases remains debatable. Further understanding of the nicotinic anti-inflammatory pathway and other endogenous anti-inflammatory mechanisms is required in order to develop refined and specific therapeutic strategies for the treatment of a number of inflammatory diseases and conditions, including periodontitis, psoriasis, sarcoidosis, and ulcerative colitis.

**Key words**: α7-nicotinic acetylcholine receptor; Inflammation; Mucosa; Nicotine; Nicotinic anti-inflammatory pathway; Tobacco smoking

## INTRODUCTION

Tobacco smoke appears to affect susceptibility to and the severity of various skin and mucosal diseases differently. For example, tobacco smoking is associated with an increased incidence and clinical severity of psoriasis[1-3] and Crohn's disease[4-6] but is associated with a lower incidence of pouchitis[6,7], celiac disease[6,8] and ulcerative colitis[6] as well as improved symptoms of ulcerative colitis[6]. While smokers are more susceptible to developing inflammatory periodontal diseases, smoking masks overt signs of gingival inflammation, which represents a clinical conundrum for dental professionals[9,10]. In order to explain these associations, and to harness any therapeutic potential of tobacco components, it will be necessary to better understand the cellular and molecular mechanisms by which tobacco smoke and smoke components influence epithelial inflammation in the skin and mucosa. This review describes the nicotinic anti-inflammatory pathway and provides some insight into the possible exploitation of this pathway for the treatment of epithelial inflammation and other inflammatory conditions.

In addition to observations of associations between tobacco use and specific inflammatory diseases, the use of nicotine delivery systems, for reasons other than tobacco cessation therapy, has received attention. However, such studies have been essentially limited to inflammatory bowel and neurodegenerative diseases. Clinical trials using transdermal nicotine have shown that nicotine can improve symptoms in individuals with ulcerative colitis[11-14]. Additionally, several studies suggest that nicotine treatment may be useful in improving learning and attention, but importantly, probably not memory function in subjects with Alzheimer's disease and other neurodegenerative diseases associated with a loss of neuronal nAChR protein or function[15-18]. However, an increasing understanding of the mechanisms by which nicotine interacts with the inflammatory system may soon open up further avenues for the therapeutic use of nicotine and other cholinergic agonists in the combat of several inflammatory disease processes.

## KEY INFLAMMATORY CELLS EXPRESS NICOTINIC ACETYLCHOLINE RECEPTORS

Monocytes and macrophages are key innate response cells that, when appropriately activated, potentiate inflammation. Lipopolysaccharide (LPS), a cell wall component of Gram negative bacteria, is a potent inducer of the inflammatory response and the best studied pro-inflammatory stimulus.

LPS recruits, activates, and promotes degranulation events in the most numerous inflammatory leukocyte; i.e., the neutrophil. LPS and neutrophil degranulation products each recruit monocytes and macrophages to the locus of infection. While neutrophils are, in relative terms, short-lived and transcriptionally quiescent, activated monocytes/macrophages are longer-lived cells that produce large amounts of pro-inflammatory cytokines *de novo*, including TNF, IL-1, IL-6, IL-12/IL-23 p40, IL-18, and HMGB-1, when stimulated by inflammatory mediators. Such macrophage-derived mediators amplify and direct inflammation and link the innate and adaptive immune responses. In addition to the pro-inflammatory cytokine functions of HMGB-1, the continued production of this protein is a requisite for survival in monocytes, with apoptosis occurring when HMGB-1 translation is suppressed[19-22].

The ability of the host's immune system to initially recognize and respond to bacteria and other insults is largely mediated by the innate immune system *via* the expression of a family of type I transmembrane receptors; i.e., the Toll-like receptors (TLRs)[23-26] that signal the production of pro-inflammatory cytokines when stimulated by their cognizant ligands. For example, LPS activation of TLR4 on monocytes and macrophages triggers the biosynthesis of diverse mediators of inflammation, such as TNF and IL1-β, and activates the production of costimulatory molecules (B7, CD40, MHCII) and the immunoregulatory cytokine IL-12 required for the adaptive immune response[23,27-29]. These inflammatory events are critical for clearing bacterial pathogens locally and surviving systemic infections. However, inflammation is a leading cause of morbidity and mortality in humans. Pro-inflammatory cytokines, such as TNF, have been found to be key mediators of chronic inflammatory diseases, including periodontitis[30]; rheumatoid arthritis[31]; and inflammatory bowel diseases[31,32]. Additionally, the onset of sepsis has been associated with a predominant production of multiple pro-inflammatory cytokines, including IL-1, TNF, IFN-γ and IL-12[33]. There is a subsequent set of cytokines, including HMGB1, that play a predominant role in mediating mortality in the latter phase of septic shock[32]. Therefore, there is great interest in learning how to control the production and activity of immune cell-derived inflammatory mediators[30,34] and the potential of their targeted suppression is enormous.

Cholinergic agonists act *via* either muscarinic (G-protein coupled) or nicotinic receptors. Nicotinic acetylcholine receptors are ligand-gated ion channels, but have additional functions unrelated to ion-channeling. Functional AChRs are pentameric, are composed of multiple combinations of a possible 16 monomer subtypes (α1-7; α9-10; β1-4; δ; ε; and γ), and exhibit divergent pharmacological behaviors[32,35,36]. Thus, identifying the exact type of nAChR involved in specific events can be difficult. It has been known for 25 years that phagocytic cells express nAChRs[37], yet this knowledge has not been significantly explored until recently. Neutrophils are known to express multiple nAChR subtypes. nAChR expression on monocytes and macrophages, in contrast, is much more restricted and may be limited solely to the α7 subtype in humans[35]. Certainly, of the α-bungarotoxin sensitive human nAChRs (α1, α7, and α9), monocytes and macrophages appear to express only α7 receptors that are functional[21,35,38,39]. nAChR expression on human macrophages is shown in Figure 1.

Of the known AChRs, α7 nAChR exhibits a number of unusual features[40]. First of all, it can assemble and function as a homopentamer[40,41]; the ion channel exhibits high permeability for calcium ions in preference to sodium[42]; and it is widely expressed in the central and peripheral nervous system[36] as well as on leukocytes[32]. The last few years have seen a great expansion of our knowledge of how nicotine interacts with α7 nAChRs on monocytes and suppresses pro-inflammatory activities in these cells. The most extensively studied signaling mechanism involved in nicotine-induced inflammatory suppression in monocytes is the cholinergic, or nicotinic, anti-inflammatory pathway.

## THE NICOTINIC ANTI-INFLAMMATORY PATHWAY

In order to limit self-damage, excessive inflammation is normally controlled by several endogenous anti-inflammatory mechanisms. One such mechanism is the nicotinic anti-inflammatory pathway. It has been known for some time that products of the central nervous system, such as adrenocorticotropic hormone, glucocorticoids, substance P, and melanocyte-stimulating hormone, are immunomodulatory[21,43,44]. In 2000, Borovikova *et al* first showed that synthesis of TNF by macrophages was under the control of the vagus nerve[45]. The vagus nerve is part of the parasympathetic system, is finely branched, and because it is composed of sensory (input) and motor (output) fibres can theoretically react to cytokines and suppress their production[31]. Furthermore, the vagus nerve is the longest of the cranial nerves and innervates most peripheral organs in humans. Recently, it has been shown that vagus nerve stimulation does not block TNF production in splenectomized animals dosed with LPS and the cholinergic pathway is functionally hard-wired to the spleen *via* the celiac nerve[46]. It has been dramatically shown that electrical stimulation of the vagus nerve prevents TNF production from macrophages and protects against death from LPS-induced shock[45]. The same authors have also shown that severance of the vagus nerve increases LPS-sensitivity in mice. Recently, it has been shown by using (1) α-bungarotoxin, an inhibitor of the α7 AChR, in wild type mice and (2) α7 AChR-deficient mice, that acetylcholine (ACh) or nicotine interaction with the α7 AChR is critical in the suppression of TNF release in response to LPS[32,39]. α7 AChR-deficient mice are not only hypersensitive to LPS and produce high amounts of TNF, but they also exhibit an exaggerated production of the pro-inflammatory cytokines IL-1 and IL-6[31,32]. It is currently known that the nicotine-dependent suppression of TNF release from primary macrophages is abrogated by α7 nAChR-specific, but not α1- or α10-specific, anti-sense oligonucleotides surrounding the translation-initiation codon of the α7 nAChR gene[32,39]. It is important to note that suppression of TNF and other cytokine release from macrophages

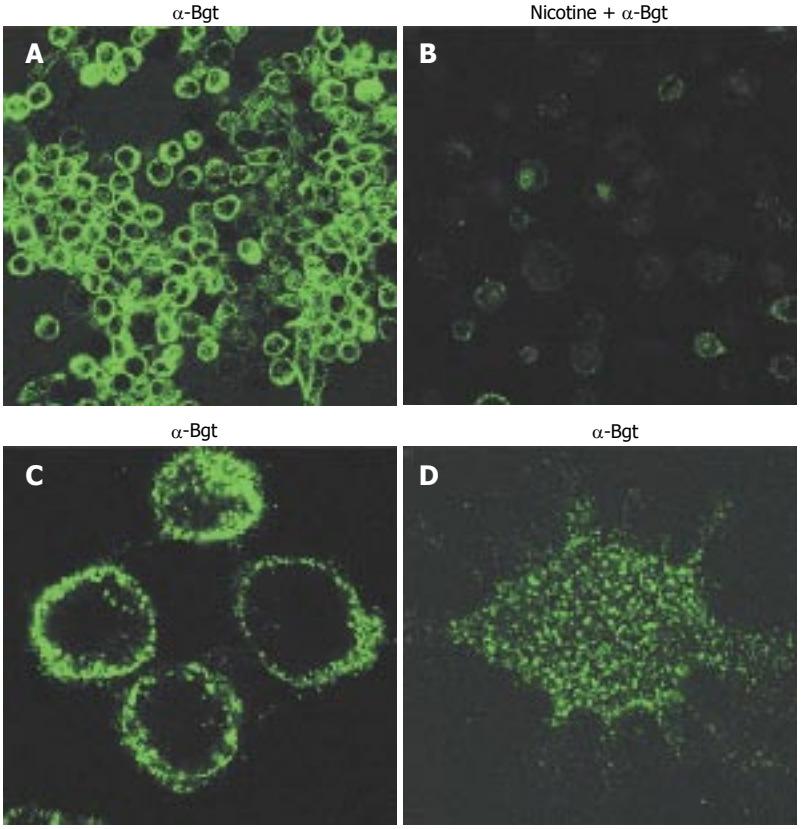

**Figure 1** α-Bungarotoxin-binding nicotinic receptors are clustered on the surface of macrophages. Primary human macrophages were stained with fluorescein isothiocyanate (FITC)-labelled α-bungarotoxin (1.5 μg /mL) and viewed by fluorescent confocal microscopy. **A**: Cells were stained with α-bungarotoxin alone; **B**: Nicotine was added to a final concentration of 500 μmol before addition of α-bungarotoxin. **C**, **D**: Higher magnification reveals receptor clusters. **C**: Focus planes are on the inside layers close to the middle (three lower cells) or close to the surface (upper cell) of cells; **D**: Focus plane is on the surface of the cell. Magnifications: **A**, **B**, x 50; **C**, x 200; **D**, x 450.

by the cholinergic anti-inflammatory system is extremely rapid, acting *via* a post-transcriptional mechanism[32,39,45,47,48], further enhancing the attractiveness of this pathway as a therapeutic target for mucosal inflammatory conditions, endotoxemia and sepsis, for example. The cholinergic anti-inflammatory pathway is presented in Figure 2.

A critical intracellular pathway involved in the production of pro-inflammatory cytokines in innate immune cells is the NF-κB pathway[19,20]. Nicotine prevents or inhibits the degradation of the inhibitory IκB protein that masks the nuclear localization signal of NF-κB and thus prevents NF-κB translocation and activation in monocytes/macrophages, in a dose-dependent manner[32,45,49], as may also be the case for other cell types, such as TNF-stimulated endothelial cells[50]. Therefore, the nicotinic anti-inflammatory pathway may not be limited to cells of monocyte lineage. As a further example, nicotine has been shown to inhibit LPS-induced TNF production by microglia cells[49,51]. Laan *et al* have shown that nicotine dampens the inflammatory response to LPS in bronchial epithelial cells and suggested that the down-regulation of the LPS-induced transcription factor, AP-1, may be of importance in regulating this phenomenon[52]. Thus, we are beginning to understand that, while tobacco smoke exerts a plethora of negative effects on the immune and inflammatory system, tobacco appears to have the potential to protect against highly specific pathological conditions; e.g. inflammatory bowel diseases[53], perhaps neurodegenerative diseases[54] and overt periodontal inflammation[9]. Obviously, the negative effects of smoking are likely to significantly outweigh any "positive" health impacts and given the enormous epidemiological and mechanistic data linking tobacco use and disease this must remain the primary public health message. Nevertheless, identification of mechanisms by which tobacco smoke components suppress certain aspects of inflammation may lead to the identification of novel therapeutic targets and may drive the future development of non-tobacco-derived agonists and antagonists. In this regard, much recent attention has focused on the translation of the anti-inflammatory agent, CNI-1493 (semapimod). CNI-1493 suppresses TNF production in multiple environments; e.g. retinopathy[55], ischemic heart failure and stroke[21,56], inflammatory bowel disease[57], Haemophilus influenza type b and LPS-induced sepsis[58-60]. While its precise mode of action is unclear, it now seems that CNI-1493 activates vagus nerve electrical activity and acts *via* the cholinergic anti-inflammatory pathway[21].

In macrophages, the nicotine-induced suppression of pro-inflammatory cytokine release may involve recruitment of the tyrosine kinase Jak2 to the α7 nACh receptor, the subsequent phosphorylation of the transcription factor STAT3, and the activation of STAT3 and SOC3 signaling cascade[61], which is known to interact with the NF-κB system[62-64], and to inhibit the expression of IL-1, IL-6, and TNF[62]. There is an obvious need to further elucidate the signaling mechanisms activated on interaction of nicotine with the α7 nAChR.

## A NON-α7nAChR-DEPENDENT ANTI-INFLAMMATORY PATHWAY

Matsunaga *et al*[65] have shown that a non-α7nAChR-dependent, nicotine-induced anti-inflammatory pathway may also function in macrophages. Nicotine-treated,

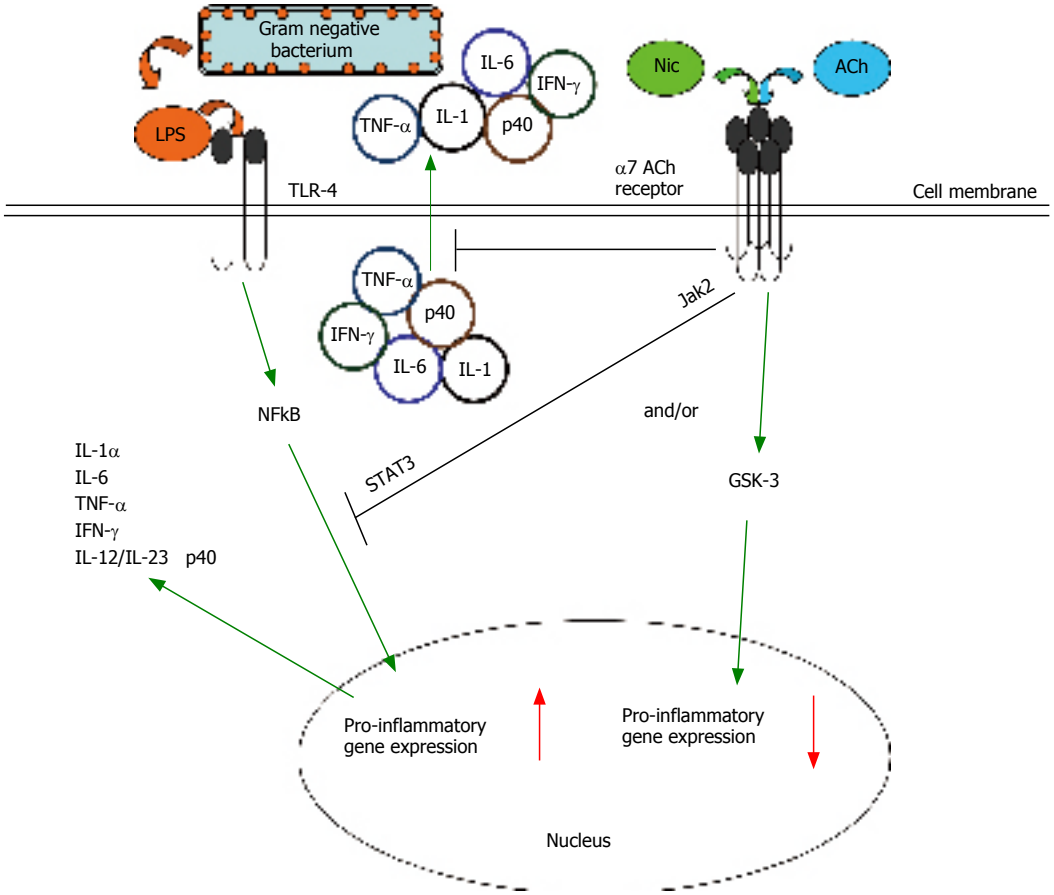

**Figure 2** The cholinergic anti-inflammatory pathway. Multiple inflammatory stimuli activate the NFκB system and lead to the release of pro-inflammatory cytokines from innate immune cells. For example, interaction of bacterial LPS with Toll-like receptors (TLRs) on the monocyte surface induces a pro-inflammatory response characterized by the production and release of several key pro-inflammatory cytokines[88]. The α7 nAChR-dependent cholinergic anti-inflammatory pathway, triggered endogenously by acetylcholine or exogenously by nicotine, can suppress the production of several pro-inflammatory cytokines in activated monocytic cells (see Figure 4)[21,22,32,39,45]. Such nicotine-mediated suppression of TNF *in vivo* protects mice from endotoxic shock[32,46]. The cholinergic anti-inflammatory pathway acts at both the transcriptional and post-translational levels. Engagement of the α7 nAChR results in the rapid suppression of the release of pre-formed pro-inflammatory cytokines[32,39,45-47]. Engagement of the α7 nAChR also results in inactivation of the NFκB system, preventing the upregulation of pro-inflammatory gene activity[32]. There is a need to further explore the signaling within the cholinergic anti-inflammatory pathway. In macrophages, the nicotine-induced suppression of pro-inflammatory cytokine release involves recruitment of the tyrosine kinase Jak2 to the α7 nACh receptor, the subsequent phosphorylation of the transcription factor STAT3, and the activation of STAT3 and SOC3 signaling cascade[61]. We have shown the potential convergence of the nicotinic anti-inflammatory and an endogenous, GSK-3-dependent anti-inflammatory pathway[88] in monocytes (see Figure 5).

*Legionella pneumophila*-infected murine alveolar macrophages exhibit enhanced intracellular bacterial replication and down-regulation of key pro-inflammatory cytokine release (IL-6, IL-12, and TNF) but not the anti-inflammatory cytokine IL-10. This inflammatory suppression was unaffected by a selective antagonist; i.e., α-bungarotoxin. Thus, the suppression of macrophage cytokine production in the pulmonary environment may help to explain the increased susceptibility for respiratory infections in smokers.

## THE NICOTINIC ANTI-INFLAMMATORY PATHWAY AND SPECIFIC DISEASES AND CONDITIONS

### *Periodontitis*

Smoking is the primary environmental factor associated with increased susceptibility and severity of periodontitis in western populations, and more than 50% of periodontitis cases in the USA can be attributed to tobacco use[66]. However, as we have previously reported, smoking reduces overt, clinically apparent, periodontal inflammation (edema; gingival index; bleeding on probing)[10,67], which is not due to any acute vasoactive effect of tobacco smoke (unlike the obvious tobacco-induced vasodilatation and vasoconstriction known to occur in forehead skin and the thumb, respectively)[68], but rather is a chronic tobacco-induced angiogenic suppression[69] that is reversed within weeks of tobacco cessation[10]. A representative case of chronic periodontitis in a smoker is shown in Figure 3.

While conflicting data has been presented for TNF[70,71], several studies have shown reduced gingival crevicular fluid (GCF) levels of major pro-inflammatory mediators, such as IL-1[72-74] in smokers with periodontitis compared to non-smokers with periodontitis, whereas anti-inflammatory cytokines are increased in the GCF of smokers, including IL-10 and TGF-β1[72,75]. This agrees well with recent and exciting data showing that nicotine activates the nicotinic anti-inflammatory pathway and suppresses pro-inflammatory cytokine production by monocytes and macrophages at the transcriptional and/or post-translational levels[21,39,45,56,61]. Thus, the inflammatory response to plaque bacteria is altered in periodontitis, and

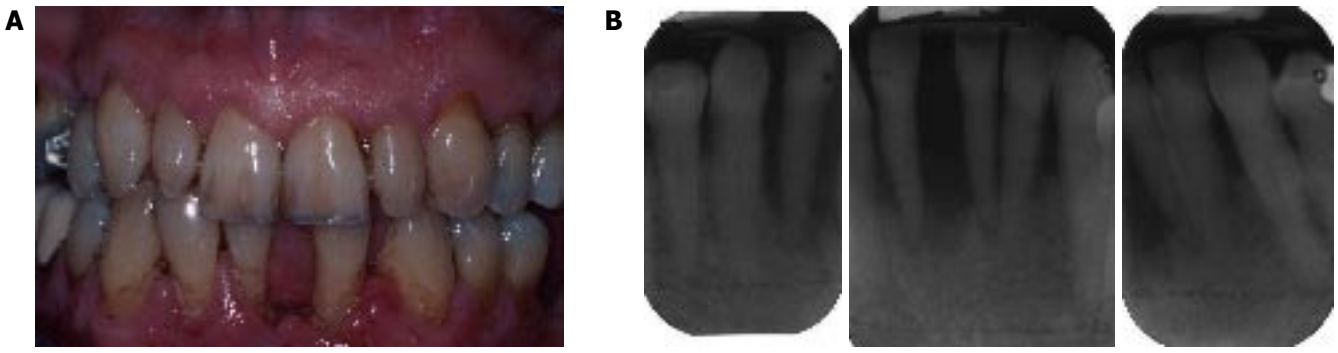

**Figure 3** Periodontitis in a male smoker, age 55. **A**: An anterior view of the mouth of a male smoker, age 55. The teeth have some staining and visible plaque. The gingivae are receded and some root surfaces are exposed. The gingivae in the upper jaw are relatively uninflamed and appear pink and fibrous in contrast to the red and swollen appearance in the lower anterior jaw; **B**: Radiographs of the lower anterior teeth. One tooth exfoliated a few months before. The remaining incisor teeth have advanced bone loss almost to the apices. Loss of these teeth is almost inevitable.

further understanding of the interactions between tobacco components, the immune system and the development of periodontitis are needed.

### *Psoriasis*

Like periodontitis, tobacco smoking is associated with an increased clinical severity of psoriasis, with up to 95% of subjects with a genetically-determined localized variant of psoriasis; i.e., palmoplantar pustulosis, being smokers[1-3]. Smoking can influence nAChR expression in skin epidermis and, in palmoplantar pustulosis, skin epidermal $\alpha$7-nAChR expression is abolished, whereas $\alpha$7-nAChR staining of the endothelium is stronger, compared to controls. Such findings have led to the hypothesis that there is an abnormal inflammatory response to nicotine, or other tobacco smoke constituents, in subjects with palmoplantar pustulosis[3]. These findings suggest that patients with palmoplantar pustulosis may not be able to activate the endogenous nicotinic anti-inflammatory pathway due to a lack of $\alpha$7nAChR, and thus treatments that activate this pathway, or other anti-inflammatory pathways, may prove efficacious in such subjects.

### *Sarcoidosis*

Sarcoidosis is a systemic granulomatous disease that can present in any organ but primarily involves the lungs and can lead to respiratory failure. In sarcoidosis, macrophages release multiple inflammatory mediators favoring an initial accumulation of Th1 cells and the generation of a polarized Th1-type environment (IL-12, TNF and IFN-$\gamma$), which has led to the targeting of specific cytokines as potential therapeutics with which to prevent the reduction in pulmonary function that accompanies granuloma formation[76-78]. A higher frequency of sarcoidosis in non-smokers than in smokers has been reported by several authors[79-83]. Thus, therapeutic activation of the nicotinic anti-inflammatory pathway represents a theoretical intervention with which to prevent progression of sarcoidosis.

### *Ulcerative colitis*

While smokers may be at increased risk of Crohn's disease[13], increasing evidence suggests that the risk for ulcerative colitis is significantly reduced in smokers, and that smoking itself may reduce disease symptoms[21]. This has led to clinical trials that show potential therapeutic efficacy in nicotine treatment for this specific inflammatory bowel disease[11-14,84]. Thus, the suppression of cytokine production and/or release by nicotine appears to contribute to a dampening of intestinal inflammation and an improved disease course. There is some evidence that ulcerative colitis may be a Th2-type inflammatory disease[6], and it is known that nicotine suppresses the production of the IL-12/IL-23 sub-unit p40, which is critical in promoting Th1 responses (our unpublished data, see Figure 4). This implies that refined targeting of the nicotinic anti-inflammatory pathway may allow the development of therapeutic interventions that are as successful in reducing the symptoms of ulcerative colitis as nicotine but that may not induce the side-effects, such as nausea, lightheadedness, headache, tremor, sleep disturbance, contact dermatitis, nausea and acute pancreatitis[11-13,84], that compromise the attractiveness of nicotine delivery as a treatment for ulcerative colitis.

### *Crohn's disease*

Tobacco smoking is associated with an increased incidence and clinical severity of Crohn's disease[4-6]. Considering that pro-inflammatory cytokines, particularly TNF, are considered to be key mediators of Crohn's disease[85], it seems counter intuitive to suggest that activation of the nicotinic anti-inflammatory pathway may exacerbate this disease. It has, however, been hypothesized that tobacco-induced suppression of the normal inflammatory response of macrophages, by $\alpha$7 and non-$\alpha$7 nAChR-dependent mechanisms, impairs the macrophage response to intestinal bacteria, leaving smokers more prone to developing Crohn's disease[6,65]. Therefore, a better understanding of the nicotinic anti-inflammatory pathway may allow pharmaceutical manipulation of this pathway, the counteraction of nicotine-dependent inflammatory suppression, and the recovery of the inflammatory response to a level sufficient for rescue macrophage effector function.

### *Septic shock*

Severe sepsis, the organ dysfunction that occurs during

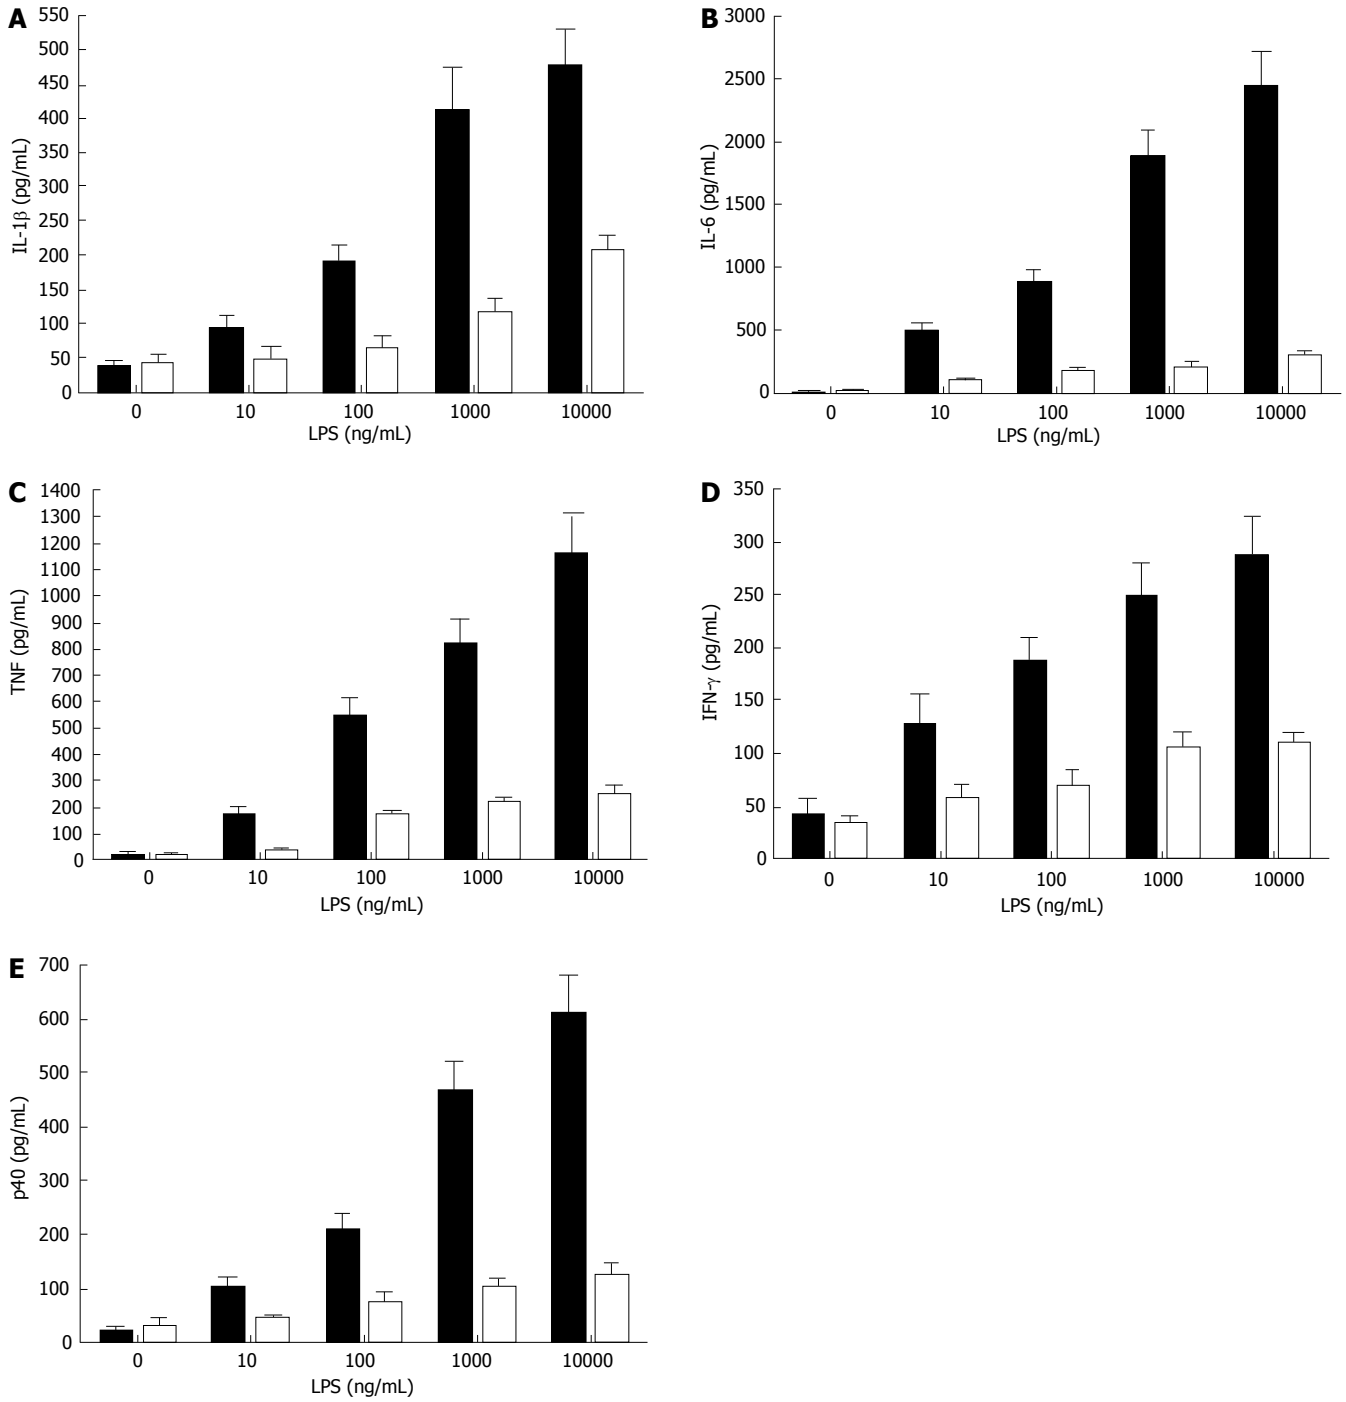

**Figure 4** Nicotine inhibits the release of multiple cytokines (TNF, IFN-γ, IL-1β, IL-6, and the common IL-12/IL-23 subunit, p40) under the control of the NF-κB pathway. Cells were pre-treated with nicotine (100 ng/mL) for 2 h then stimulated with purified LPS (0 to 1 x $10^4$ ng/mL) for 24 h. Cell-free supernatants were harvested by centrifugation and levels of pro-inflammatory cytokines were determined by ELISA. Data represents the mean (SD) of triplicate experiments.

systemic inflammation, is a major cause of mortality in developed nations, contributing to 9.3% of the total annual deaths in the United States. It is characterized by the rampant production of multiple pro-inflammatory cytokines, including TNF, IL-1β, HMGB-1, and IL-12[21,86,87]. Therapies designed to combat individual pro-inflammatory mediators in order to prevent septic shock have not been as successful as hoped and it has thus been hypothesized that inhibition of several or all pro-inflammatory mediators may be required[21]. Alternatively, it is recognized that HMGB-1, which is a late mediator of sepsis, is critical in the disease process and can be inhibited by nicotine[21,22]. Therefore, there is now a great deal of interest in using nicotine as an inducer of the nicotinic anti-inflammatory pathway as a potential treatment for severe sepsis[21,22,31,32,39].

## FUTURE DIRECTIONS

Cholinergic strategies have been suggested as potential treatments for multiple diseases. In this review we have largely limited ourselves to the discussion of the relevance

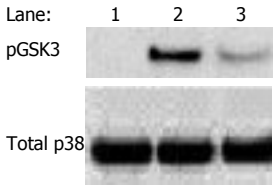

**Figure 5** Nicotine-treated human monocytes exhibit augmented levels of phosphorylated (Ser9) GSK3-β in monocytes stimulated with the Gram negative bacterium, *Porphyromonas gingivalis*. Monocytes were pre-treated for 2 h with 100 ng/mL of nicotine and stimulated for 60 min with *P. gingivalis* (MOI = 10). Western blot was performed using whole-cell lysates (20 μg) and probing for GSK3 using a phospho-specific GSK3-β (Ser9; denoted pGSK3) antibody. Blot was stripped and re-probed for total p38 to ensure equivalent loading. Lane 1: Nonstimulated; Lane 2: *P. gingivalis* + Nicotine; Lane 3: *P. gingivalis*. Data are representative of three experiments.

of the nicotinic anti-inflammatory pathway to skin and mucosal pathologies.

It is essential to point out that the use of nicotine as an anti-inflammatory agent, while supported by the current evidence, nevertheless represents a "sledgehammer" strategy. It must be envisaged that non-nicotinic (and, indeed, non-tobacco-derived) cholinergic agonists will be developed and explored in order to avoid the psychoactive, vascular, and other actions of nicotine on multiple nAChR-initiated pathways and to avoid the side-effects and adverse reactions associated with nicotine delivery. As recently pointed out by Ulloa, better structural characterization of nAChRs will be crucial in designing such nicotinic agonists[21].

Furthermore, it must be expected that targets downstream of the nAChRs will be identified allowing therapeutic refinement and an avoidance of blanket targeting of nAChRs.

Finally, the nicotinic anti-inflammatory pathway is unlikely to exist as a single, self-contained entity, but rather it is anticipated that the nicotinic anti-inflammatory pathway interacts and converges with multiple other pathways, including the NF-κB pathway and others. For example, we have shown the convergence of the nicotinic anti-inflammatory and an endogenous GSK-3-dependent anti-inflammatory pathway[88] in monocytes (our unpublished data, see Figure 5). As our knowledge of these signaling interactions increases, we are likely to identify further attractive anti-inflammatory targets and refined selectivity. In conclusion, the manipulation of nAChR-initiated signaling pathways likely represents a potentially fruitful area for inflammation research in the coming years and the currently expanding literature suggests that the number of diseases in which the pathway is relevant, for example, pancreatitis[47] and various vascular pathologies will increase[50,89,90].

## Abstract

Erythropoietin (Epo) is the regulator of red blood cell formation. Its receptor (EpoR) is now found in many cells and tissues of the body. EpoR is also shown to occur in tumor cells and Epo enhances the proliferation of these cells through cell signaling. EpoR antagonist can reduce the growth of the tumor *in vivo*. In view of our current knowledge of Epo, its recombinant forms and receptor, use of Epo in cancer patients to enhance the recovery of hematocrit after chemotherapy treatment has to be carefully evaluated.

## INTRODUCTION

Erythropoietin (Epo) is a hormone which regulates the red blood cell formation. Epo is produced in the kidney and delivered to the target organ, bone marrow, *via* circulation[1]. The circulatory levels of Epo is usually at a very low level but in response to the loss of red blood cells or during hypoxic exposure its level is increased within a few hours due to the enhanced production in the kidney. The elevated Epo level acts on the bone marrow erythroid cell precursor population to augment the erythroid cell production resulting in the increase of red blood cell mass. Thus EPO acts in a tightly regulated system for the maintenance of red blood cell volume. Action of Epo on the responding cells is mediated through its receptor, EpoR.

The signal provided by Epo and its receptor, EpoR are essential for erythroid cell proliferation and differentiation[2]. Studies have revealed that there is an unique mechanism of Epo binding and activation of EpoR-Jak2 kinase complexes. Erythroid cell populations collected from humans or mice and enriched by various techniques have been used for these studies[3]. Purified human blood erythroid burst forming units, mice fetal liver cells or spleen cells from mice made anemic by two consecutive injections of phenyhydrazine have been used for such investigations[3]. Studies indicated that Epo binds to EpoR and induces a signal for proliferation and survival similar to other cells.

## STRUCTURE AND CHARACTERISTICS OF Epo

Epo is a glycoprotein with a molecular weight of approximately 34 000 daltons[4]. The protein backbone of the mature hormone consists of 165 amino acids. The alpha form of the hormone consists of 31% carbohydrate while the beta form consists of 24% carbohydrates. These two forms of Epo have similar biologic and antigenic properties. The carbohydrate moiety of Epo plays an important role in the mediation of its overall effect *in vivo*. Sialic acid, which comprises 30% of carbohydrates, represents the critical component of the carbohydrate moiety for *in vivo* biological activity. The desialation of Epo, while fully functional *in vitro*, results in significant loss of *in vivo* activity due to the rapid clearance by the liver of disialated Epo[5]. The importance of glycosylation of the Epo molecule in the mediation of its *in vivo* effect also became evident when it was found that the recombinant Epo produced in *E. coli* was not effective *in vivo*. Expression of the Epo gene in mammalian cells that provided sugars was needed to attain its full biological effect *in vivo*. Epo is a single chain polypeptide and is resistant to denaturation by heat, alkali or reducing agents. The Epo gene is located on chromosome 7 and unlike other hormones like insulin or ACTH, it is fully synthesized in its active form prior to secretion into circulation.

## Epo AND EpoR FUNCTION

Effect of Epo on erythroid cells is mediated through the EpoR similar to other hormones. One single class of EpoR with an apparent molecular weight of about 100 000 daltons occurs and it binds to the hormone with a dissociation constant of about 300 pM[6]. Erythroid cells display between 1000 and 3000 EpoR sites per cell. Only a small percentage of these receptor sites have to be populated with Epo to initiate cell division and this process is dependent largely on $Ca^{2+}$.

Previously it was thought that EpoR and Epo are required for the survival and proliferation of erythroid cells alone. However, recent investigations have indicated the presence of EpoR in normal cells of other tissues as well. Epo is now known to be important in function and development of the brain. Furthermore the brain makes its own Epo which is slightly smaller in size than Epo produced by the kidney[7]. Epo is needed for the development of new blood vessels in the muscles of athletes training at high altitude. A greater oxygen demand by the exercised muscle tissue is supplemented by the presence of Epo. Requirement of Epo is also shown in ovary, oviduct, uterus, and testis and in all of these organs the presence of EpoR has been shown[4].

## PRESENCE OF Epo AND EpoR ON TUMOR CELLS

Presence of EpoR is shown in the breast cancer cells while adjacent normal cells have no such receptors[8]. Authentic EpoR transcripts and protein have been detected in human renal-cell carcinoma and the cell lines derived from these are shown to enhance proliferation by the presence of Epo[9]. Presence of Epo and EpoR has also been shown in breast carcinoma but not in normal breast, benign papilloma or fibrocystic tissues[10]. EpoR is also found in epithelial ovarian carcinoma as detected by Western blot analysis[11]. Using the immunoblot technique, Belenkov *et al* have confirmed the presence of EpoR in the human malignant glioma cell line, U87 and the primary cervical cancer cell line, HT100[12]. Examination of breast cancer biopsies has revealed a high level of EpoR expression in cancer cells in 90% of tumors while Epo expression has been found in 60% of tumors[13]. Wollman *et al* have demonstrated the presence of EpoR in the human neuroblastoma cell line using the RT-PCR technique[14]. Occurrence of EpoR in human prostatic epithelial cells and prostate cancer cells has been demonstrated and in this instance Epo serves as a growth factor for these cells[15]. Yasuda *et al* have reported that signaling pathways of Epo and EpoR are involved in the tumorigenesis of ovarian and uterine cancers[16]. Hepatic tumors, chemically induced in rats, showed the presence of Epo while in normal cirrhotic liver tissues Epo was not detected[17]. EpoR was present in such tumors. Table 1 summarizes the publications which have looked into the occurrence of EpoR and Epo in various tissues. Our own observation on rat pancreatic tumor cell line, AR42J cell, has indicated the presence of EpoR on the surface of these cells and Epo induces proliferation of these cells (unpublished observation). Hence it is now well established that EpoR is present in most of the cancer cells and Epo has a significant effect upon these cells.

**Table 1 Presence of Epo and EpoR in the tumors of different tissues of the body. Symbol + in the columns indicate the presence of particular item in the tumor and - indicate either it is not tested or it is absent**

## FUNCTIONAL SIGNIFICANCE OF EpoR ON TUMOR CELLS

Question naturally arises what is the function of the EpoR present in cancer cells? Attempts have been made in many investigations to find the role of EpoR in light of induction of signal transduction and cell growth. Some studies, as described earlier, have noted the induction of proliferation of tumor cell lines in the presence of Epo. Transplanting several tumor cell lines into nude mice Yasuda *et al* have confirmed the presence of Epo-responsive sites in xenografts in which phosporylation of the STAT5 (signal transducer and activator of transcription) is detected[16]. In these nude mice when Epo signaling is blocked by EpoR antagonist, angiogenesis and tumor cell survival are inhibited leading to the destruction of tumor mass and the disturbance of phosphorylation of STAT5. Epo mimetic peptide, on the other hand, has promoted angiogenesis and tumor cell survival. Hence Epo is indispensable for the growth and viability of malignant tumor[16].

EpoR on prostate cells is functional and exhibited a dose-dependent proliferative response to Epo and triggered STAT5 phosphorylation[15]. Epo mediated invasion of head and neck squamous cell carcinoma cells in Epo-treated head and neck cancer patients has been shown to be due to induction of limited proliferation effect by the pharmacological dose of Epo[18]. Epo activates the mitogen activated protein kinase, extracellular signal regulated kinase (ERK), and promotes migration in breast cancer cells. This migration can be inhibited by the inhibitor MEK[19]. Further, hypoxia induced Epo mRNA and EpoR expression in breast cancer cells is followed by the activation of ERK and cell migration[19]. When rat mammary adenocarcinoma cells were implanted into rats

in a tumor Z-chamber model and administered with a neutralizing anti-EPO antibody or soluble Epo receptor or an inhibitor of Jak2, all resulted in a delay in tumor growth with 45% reduction in tumor depth in a dose dependent manner[13]. Renal carcinoma cells have been shown to have increased proliferation in the presence of Epo[9]. Several effects of Epo described above with various tumors and carcinoma indicates a compelling proof that cancer cells have EpoR and Epo has an effect on these cells despite the fact that a recent study has indicated that all anti-EpoR antibodies do not always predict the EpoR expression[20]. An exception to this is an early study by Wollman *et al*[14] who have found no proliferative effect of Epo on nerve tumor cells in spite of the presence of EpoR on these cells.

## CONCLUSIONS

The reports on studies of Epo and EpoR indicate that they are not specific to erythroid cell proliferation and differentiation alone. They have an active role in other cells as well, normal as well as tumor cells. Use of Epo in cancer patients has to be monitored carefully for its side effects related to its proliferation potential of the tumor for which chemotherapy is given. It is important as more and more patients are being treated with Epo for a rapid hematocrit recovery after chemotherapy treatment. Knowledge is emerging in this regard and further studies are needed to sort out the beneficial effect of Epo from its harmful effect.

## Abstract

Apoptosis is necessary for maintaining the integrity of proliferative tissues, such as epithelial cells of the gastrointestinal system. The role of apoptosis in post mitotic tissues, such as skeletal muscle, is less well defined. Apoptosis during muscle atrophy occurs in both myonuclei and other muscle cell types. Apoptosis of myonuclei likely contributes to the loss of muscle mass, but the mechanisms underlying this process are largely unknown. Caspase-dependent as well as -independent pathways have been implicated and the mode by which atrophy is induced likely determines the apoptotic mechanisms that are utilized. It remains to be determined whether a decrease in apoptosis will alleviate atrophy and distinct research strategies may be required for different causes of skeletal muscle loss.

## INTRODUCTION

Apoptosis, or programmed cell death, is an important process in multicellular organisms both during development, where it ensures the elimination of superfluous tissues, and in adulthood, where it is critical for maintenance of tissue homeostasis. The early stage of apoptosis involves death-inducing signals, such as reactive oxygen and nitrogen species, ligands for the death receptors, imbalances in calcium regulation, and alterations in the composition and abundance of B-cell lymphoma (Bcl)-2 family proteins, such as Bax, Bad, Bcl-2, Bcl-xl (see[1] for review). After this induction phase, nuclear activators, cell surface receptors, or mitochondrial pathways become activated in the commitment to cellular death followed by cytoplasmic and nuclear events. During apoptosis, protein-cleaving enzymes, i.e., caspases (cysteine-dependent aspartate-directed proteases), become activated in the cytosol and are responsible for proteolytic cleavage of a broad spectrum of cellular targets[2]. Caspase-independent mechanisms also exist, such as the release of apoptosis-inducing factor (AIF) and endonuclease G (EndoG) from mitochondria (Figure 1), inducing large scale DNA fragmentation and apoptosis after translocation to the nucleus[3-5]. In the nucleus, DNA fragmentation caused by activated endonucleases, chromatin condensation, and the breakdown of the nuclear envelope occurs and eventually the cell itself disintegrates into apoptotic bodies and is phagocytosed by surrounding cells or macrophages[6]. Both extrinsic or intrinsic stimuli can be responsible for the induction of apoptosis, with some cross-talk between signaling pathways[1,7,8].

## ROLE OF APOPTOSIS

In highly proliferative tissues, such as the intestinal epithelium, apoptosis serves to maintain a constant number of cells and consistent tissue architecture, counterbalancing the rapid proliferation. Indeed, cell loss in the normal intestine can largely be explained by apoptosis[9]. In addition, in the small intestine apoptosis serves to stabilize the stem cell population by removing excess, or perhaps compromised, stem cells[10]. Decreased rates of apoptosis have been observed during tumor progression in colon carcinomas[11] and the overall decrease in apoptosis in proliferative tissues may predispose the cells in those tissues to accumulate genetic changes characteristic of tumorigenesis.

In contrast, in post mitotic tissues such as skeletal muscle, the role of apoptosis is less clear. Also, with respect to cell death, skeletal muscle is a unique tissue because muscle cells, i.e., myofibers, are multinucleated. This aspect of skeletal muscle has led to the concept of the myonuclear domain, which is defined as the theoretical amount of cytoplasm supported by a single muscle fiber nucleus, which is called a myonucleus (protein/DNA)[12].

Even though muscle size can vary considerably under different conditions, the myonuclear domain size remains relatively constant, implying a fairly strict regulation of myonuclear number (for review[13]). Myonuclear number decreases in muscles undergoing atrophy in a variety of experimental conditions, such as spinal cord isolation and transection, microgravity, hind limb suspension, and chronic denervation[14-20] and the process by which nuclei are eliminated from muscle fibers resembles apoptosis. Since destruction of the entire cell does not necessarily follow the elimination of a nucleus, as occurs with apoptosis in mononucleated cells, this process is called 'apoptotic nuclear death'. The mechanisms underlying apoptotic nuclear death in muscle are likely distinct from those involved in apoptosis in mononucleated cells.

The fact that apoptosis plays an important role in skeletal muscle atrophy can be deduced from the observation that it is increased in skeletal muscle in a number of pathological and under some physiological circumstances. Chronic heart failure, motor neuron disorders, skeletal muscle denervation, spinal cord injury, muscular dystrophy, and skeletal muscle atrophy due to hind limb suspension or immobilization are all associated with an increase in apoptosis in affected skeletal muscles, as measured by terminal deoxynucleotidyl transferase-mediated deoxyuridine triphosphate nick end-labeling (TUNEL) or by DNA fragmentation in gel electrophoresis[16,21-26]. In addition, exercise was shown to increase apoptosis when assayed acutely after a bout of exercise[24], but by contrast, exercise training for a period of 8 weeks decreased apoptosis[27]. Interestingly, we and others have shown that exercise training attenuated the apoptosis induced by disuse (spinal cord injury or hind limb suspension)[16,26]. This exercise-associated decrease in apoptosis under atrophy-inducing conditions may depend on the mode or intensity of exercise, since recently we found that gravity-independent resistance exercise did not decrease apoptosis during hind limb suspension[28]. Therefore, apoptosis in skeletal muscle seems to be a highly regulated process that may serve distinct functions under different physiological and pathological conditions and a better understanding of pathways involved in the apoptotic response in muscle is warranted.

## APOPTOTIC PATHWAYS IN SKELETAL MUSCLE

Caspases are thought to be the main enzymes involved in both the initiation (caspase-8, -9, -12) and execution of apoptosis (caspase-3, -6, -7) (Figure 1). Internal as well as external signals can activate caspases and this is under the control of the balance between pro-and anti-apoptotic proteins of the Bcl-2 family, heat shock proteins, and inhibitors of apoptosis proteins (IAPs)[29]. However, apoptosis can ensue in the absence of caspase activation, whereas caspase activation does not always necessarily trigger cell death[30]. Caspase-3 is often used as a surrogate for apoptosis, but in muscle, in particular, this may not be justified. We and others found that caspase-3 activity did not increase with atrophy induced by hind limb suspension[31,32], even though apoptosis was increased concurrently, indicating that other pathways, besides caspase-3 activation, may be involved. In contrast, denervation-induced atrophy was associated with an increase in caspase-3 activity[33] as well as caspase-8[34], indicating that the activation of caspases may serve a different role in distinct models of muscle atrophy or that the mode by which atrophy occurs determines the involvement of different pathways. Indeed, caspases have been found to play non-apoptotic roles in pathways such as the inflammatory response, immune cell proliferation and differentiation of various cell types (e.g. skeletal muscle)[35]. In skeletal muscle, caspase-3 was found to be involved in protein degradation, in particular of filamentous actin[36], and it contributed to muscle weakness in response to endotoxin[37]. Similarly, in cardiac muscle caspase-3 was shown to be involved in post-ischemic contractile dysfunction (cardiac stunning), apparently independent of apoptosis[38]. Therefore, classical apoptotic pathways, as observed in mononucleated cells, may not be as important in muscle and other molecules may take on the role of apoptosis inducers.

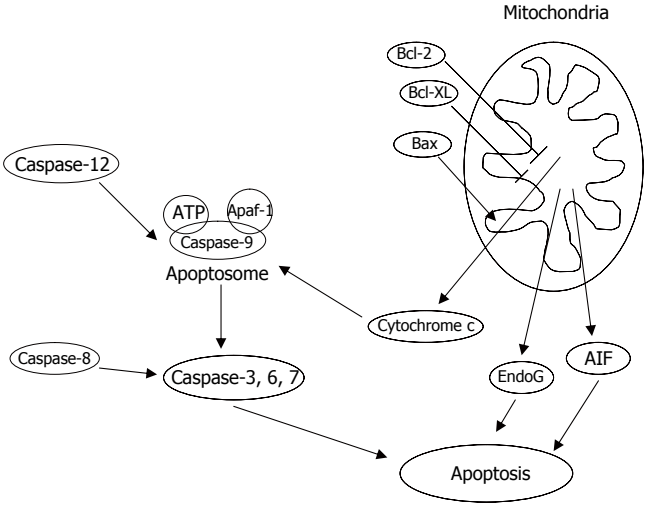

**Figure 1** Pathways involved in apoptosis in skeletal muscle. Caspase-dependent and -independent pathways are likely involved in apoptotic nuclear loss during atrophy in skeletal muscle. Caspase-3 activation and subsequent apoptosis occurs through the release of cytochrome-c from mitochondria in response to changes in the ratio of pro- and anti-apoptotic members of the Bcl-2 family of proteins, or through the activation of initiator caspases, such as caspase-8 or -12. Caspase-independent pathways such as the release of EndoG and/or AIF may be more important in skeletal muscle as they directly induce DNA fragmentation.

In this light, we have investigated the role of EndoG during skeletal muscle atrophy[31,39]. EndoG is a protein released from mitochondria upon pro-apoptotic stimulation and is capable of inducing DNA fragmentation independent of caspase activation[40-42] (Figure 1). We found that EndoG co-localization with nuclei was increased in muscles atrophied in response to both hind limb suspension and age[31,39] and that EndoG protein was increased in muscles of aged rats undergoing disuse-induced atrophy[31]. Moreover, EndoG translocation was very specific for myonuclei and did not seem to be involved in the apoptosis of interstitial cells, which also occurs during muscle atrophy[39]. In contrast, caspase-3 activation was observed more in interstitial cells and therefore different cell types within

the same tissue may be undergoing apoptosis through different mechanisms. Another protein released from mitochondria upon pro-apoptotic stimulation and capable of inducing apoptosis independent of caspases is apoptosis inducing factor (AIF)[43]. Siu and Alway[33] showed that AIF release was elevated in denervated muscle, in concert with cytochrome-c, Smac/DIABLO and a subsequent upregulation of caspase-9 and -3. Therefore, the atrophy-inducing stimulus, the time point after onset of disuse, or the different cell types undergoing apoptosis may be important in the activation of distinct apoptotic pathways. Finding interventions to counteract the increase of apoptosis with muscle atrophy will be challenging, considering the many different pathways used to induce apoptosis in skeletal muscle.

## INHIBITION OF APOPTOSIS

The question arises whether inhibiting apoptosis in skeletal muscle will also decrease atrophy induced by disuse or due to aging. Recently, Siu and Alway[44] showed that inhibition of apoptosis somewhat attenuated muscle atrophy induced by denervation in a Bax knock out mouse model. Interestingly, DNA fragmentation after denervation was much lower in the knock out mice compared to the wild type and caspase activation was also lower. However, mitochondrial AIF release was not decreased, possibly implying that caspase-independent mechanisms were not affected. In this study, the effect on different cell types was not investigated, but it is plausible that the minimal effect on muscle mass could be due to the fact that myonuclear apoptotic loss was not affected by the Bax-/- phenotype. Therefore, it remains to be determined whether inhibition of myonuclear apoptosis will decrease muscle atrophy.

## CONCLUSION

Recently a number of studies have implicated an important role for apoptosis in the development of skeletal muscle atrophy. It is likely that atrophy induced by different conditions, such as denervation, microgravity, aging, cachexia, and spinal cord injury, initiates different apoptotic signals and indeed the role of apoptosis may be distinct among the conditions. It will be important to investigate, at the cellular level, which signals are responsible for the loss of myonuclei, interstitial cells, or stem cells in skeletal muscle in order to develop strategies to decrease apoptosis and atrophy.

## Abstract

The incidence of hyperbilirubinemia is high clinically, which is difficult to cure by medication, surgery or interventional therapies. Non-bioartificial liver is the main alternative in the blood purification for hyperbilirubinemia, which includes plasma exchange, hemoperfusion, hemodialysis, molecular adsorbent recycling system and so on. The research results and clinical experiences in China show that these methods are effective in lowering high levels of bilirubin with fewer side effects. The hyperbilirubinemias of different causes, with different complications or accompanying different diseases can be treated by different methods. Bioartificial liver, hybrid artificial liver support system and adsorbent membrane material have also been studied and their development in reducing hyperbilirubinemias has been achieved. This article gives a brief overview on the actuality and research improvement in blood purification for hyperbilirubinemia in China.

## INTRODUCTION

Hyperbilirubinemia, namely jaundice, is a common clinical manifestation, and it may be life threatening. Many diseases result in hyperbilirubinemias, some are refractory, and cannot be cured by medication or surgery. Though some obstructive jaundice related to the common bile duct can be relieved quickly and temporarily with the recent development of interventional therapies, there is a paucity of effective methods for those lesions occurring in small or capillary bile ducts such as primary biliary cirrhosis of the liver, and for some other hyperbilirubinemias that need to be cured in a short time such as an obstructive jaundice that cannot be relieved or does not have an indication for operational or interventional therapy temporarily, an acute or chronic hepatic failure, a portal hypertension associated with serious icterus in liver cirrhosis and a quite severe jaundice before liver transplantation. So, how to reduce the high concentration of bilirubin in the blood of these patients has always been a focus of study for many researchers. Blood purification has been used for treating hyperbilirubinemia in the recent two decades, and it is also called non-bioartificial liver (non-BAL) for distinguishing bioartificial liver (BAL), a recent research hotspot. Non-bioartificial liver could temporarily improve the status of patients with end-stage liver diseases and help by extending time and increasing opportunity for further treatment despite lack of synthesis and metabolic function. Especially at present when research of the artificial liver is still at its initial phase in China, non-bioartificial liver is applied widely and further research is being performed for higher efficacy. In this paper, reports by Chinese researchers on these aspects are reviewed.

## APPLICATION AND CURATIVE EFFECT OF BLOOD PURIFICATION FOR DEPRESSING HIGH LEVEL OF BILIRUBIN

Non-bioartificial blood purification applied in China currently includes plasma exchange (PE), hemoperfusion (HP), hemodialysis (HD), molecular adsorbent recycling system (MARS)[1], of which PE is used most frequently.

### *Plasma exchange (PE)*

In the process of PE, plasma is separated and discarded, while cells, as well as some supplied albumin, plasma and balance solution are reinfused back so as to remove the causative agents. PE not only removes bilirubin, endotoxin and complement activator, but also replenishes albumin, coagulation factor and hepatic regenerative stimulating substance, which can correct metabolic disorder.

Shang *et al*[2] compared treatments in two different groups: 116 patients with chronic severe hepatitis and

hepatic failure were categorized as a therapy group with 142 instances of blood purification using an artificial liver support system (ALSS, 800 PE) and medication therapy; 118 patients with the same illnesses as mentioned above were categorized as a control group which was given only supportive care and observed. All cases were consistent with virus hepatitis diagnostic criteria enacted at the China Virus Hepatitis Conference in 2000 (2000CVHC). After treatment, total bilirubin (TBIL) decreased 62.96% in the therapy group, and the clearance rate was much higher than that in the control group. The statistical difference was significant. Ming *et al*[3] also treated 32 cases of severe hepatitis diagnosed according to 2000CVHC by PE (HP200 blood purification equipment, YT-50PP PE, Yatai Company, Ningbo, China; plasma separation rate, 20-30 mL/min; blood flow rate, 60-100 mL/min; infused fresh plasma, 2000 mL), and the result showed TBIL descended 25.17%, icterus faded and symptoms improved. PE could alleviate hyperbilirubinemia, decrease mortality, and prolong survival time. However, by use of PE, large amounts of fresh plasma are consumed and there is a paucity of safety issues such as hepatitis, HIV, anaphylaxis and other complications addressed for regulatory approval. Zou *et al*[4] utilized Plasauto IQ PE instrument (OP-08W plasma segregator) for 116 times in 93 patients with severe hepatitis (consistent with 2000CVHC). After treatment, the short-term total effective rate was 80.2% (93/116), 51 were cured, 18 died, and 24 were discharged from hospital. During the treatment, adverse reactions occurred in 64 patients including erythema in 24 (22.41%), hypotension in 21 (1.72%), anesthesia accompanied hemifacial spasm in 15 (12.93%) and alimentary tract hemorrhage in 2, both of whom died, one died of intracranial hemorrhage. Besides, the drop of serum bilirubin level after PE treatment might rise again. Even so, PE is still a relatively mature method. Yang *et al*[5] reported that in the treatment of viral hepatitis hyperbilirubinemia, fewer amounts and more numbers of albuminpheresis could decrease hyperbilirubinemias more effectively in refractory hepatitis, especially in Types non-B and non-C. Meanwhile it could avoid blood contamination, providing a relative security. Long-term effects with low incidence of adverse reaction were confirmed.

### HP

The accurate meaning of hemoperfusion is blood adsorption, i.e., pathogenic medium dissolved in the blood is adsorbed to a solid matter with an ample surface for removing various toxins in a perfusion apparatus. Based on blood or plasma flowing through the perfusion apparatus, blood perfusion or plasma perfusion was named. Blood perfusion is rarely used clinically because the adsorbent may hurt or activate blood cells, so usually plasma perfusion is used for hemoperfusion. There is no incidence of cross infection, protein susceptibility or other side effects because fresh plasma, albumin and other blood products do not need to be supplied in the process of hemoperfusion. There are mainly two kinds of adsorbents used in hemoperfusion, activated charcoal and resin. Activated charcoal, is a kind of broad-spectrum adsorbent, which can effectively clear endotoxin, leukocyte inhibitory factor, cytotoxin of inhibition liver cell regeneration agent, aromatic amino acid, hydroxybenzene, indole and short chain fatty acids, and also can availably adsorb bilirubin in the blood[6]. Clinically resin is used more frequently than activated charcoal. Sorbents are macroreticular resins including uncharged resin and ion exchange resin. Although the adsorption capacity of resin is inferior to that of activated charcoal, it has a higher clearance rate towards all kinds of lipophilic and hydrophobic substances such as bile acid, bilirubin, free fatty acid and amine. Du *et al*[7] treated 2 cases of severe obstructive jaundice with carcinoma in pancreas head by HB-H-6 resin (Liver and Gall Disease Research Center, the Third Center Hospital of Tianjin, China) before surgery. TBIL, direct bilirubin (DBIL) and indirect bilirubin (IBIL) decreased more than 340 μmol/L, 230 μmol/L and 98 μmol/L, respectively. Bilirubin adsorption in the perfusion was at the highest speed from 15 to 45 min. HB-H-6 resin consisted of macroporous anion exchange resin and cation exchange resin. Anion adsorbed IBIL while cation adsorbed DBIL. Two patients were bridged successfully to surgery on the following day. It indicated that perfusion by HB-H-6 is safe and effective as a bridging option for malignant obstructive jaundice during the waiting time for transplantation. Zhang *et al*[8] identified bilirubin binding capacities of ten different kinds of resin (Tianjin Jinlin Biochemistry Development Company, China) and found that the clearance rates of both resins No.5 and No.9 towards DBIL were more than 70%; however, resin No.9 was superior to resin No.5 in regard to IDBIL. It indicated that No.9 had the best bilirubin removal efficiency among the ten kinds of resins, and No.5 was next to it. Resin No.9 had polyvinyl alcohol as a matrix and amino acid as a ligand, while No.5 was constituted by polystyrene resin and polar reactive groups coupled on it. Among the ten kinds of resin with pretreatment for the experiments of bilirubin adsorption in a solution, only one kind was selected, which had a higher capacity for bilirubin removal, constituted by hydrophilic crosslinked polyvinyl alcohol matrix, and amino acid as a ligand. The clearance rates of TBIL and DBIL in the solutions were 68.16% and 58% respectively, and those of TBIL and DBIL were 68% and 70% in the sera of patients. Furthermore, its blood compatibility was superior. In addition, resin could adsorb molecules with a molecular weight between 500 and 5000 Daltons, which covered the molecular weight of bilirubin, 548.67 Daltons. Accordingly, HP could treat hyperbilirubinemia effectively, and showed an applicable foreground[9].

### HD

As a safe and simple technique of blood purification, HD has been applied extensively in renal failure. Dialysis means the solute passing through a semipermeable membrane from high concentration to low in solution, which includes the movement of solute and water. A routine application of HD cannot effectively clear a high concentration of serum bilirubin. It has been reported that the clearance rate could be raised using plasma as the dialysate or associated with other purification methods. In the report by Liu *et al*[10], 21 cases of

hyperbilirubinemias received different alternatives: high volume hemofiltration, HE (HP200 blood purification equipment, YP-50PP membrane type plasma separator, Yatai Company, Ningbo, China; total amount of plasma exchange, 3000-3600 mL; plasma exchange rate, 25-30 mL/min; displacement with homeotype fresh refrigerated plasma), MARS (ALSS-MARS, Germany; blood flow, 150 mL/min; time of treatment, 6 h) and hemodialysis with plasma-based dialysate (HD-PBD) (AV600 filter, Diapact CRRT, CVVHD mode; blood flow, 250 mL/min). After treatment, the clearance rates of TBIL were 19.1%, 39.9%, 36.6% and 38.2%, respectively, while that of DBIL were 2.7%, 41.0%, 33.9% and 28.5%. The results indicated that there were no significant differences among HD-PBD, PE and MARS in removals for TBIL, DBIL, serum ammonia and bile acid. Lin *et al*[11] treated 26 severe hepatitis patients with a combination of PE and high-flow hemodiafiltration (HDF), there was obvious improvement of symptoms, with 49.46%, 48.77% and 47.98% decrease in levels of TBIL, DBIL and ammonia with low incidences of severe hemorrhage, shock or other complications. The common adverse effect was still hypersensitivity to plasma. You *et al*[12] treated 8 cases of severe hepatitis complicated with renal failure by a combined therapy of hemoperfusion and hemodialysis (330 mL HA blood perfusion equipment coupling F6 blood dialyzor; F-4008E Hemodialysis machine, Germany; carbonic acid dialysate; blood flow, 200-220 mL/min; dialysate flow, 500 mL/min; time of treatment, 4-5 h), and the patients had good tolerance with a decrease of TBIL by 15.6%-45.8% and no severe complications occurred.

#### *Molecular adsorbent recycling system (MARS)*

MARS is composed of an albumin recycling system, activated charcoal or resin, dialysis and so forth. It combines blood purification techniques of HD and a molecular adsorbent to selectively clear lipophilic albumin-bound toxin and hydrosoluble toxin. It can also adjust water and electrolyte disturbance, as well as acid-base disequilibrium. Yang *et al*[13] treated 30 patients with chronic severe type B hepatitis by MARS (MARS equipment, AKLIN Company, Germany; AK95 hemdialysis machine, Jinbo Company, China). The diagnosis of each patient was consistent with revised criteria at a Beijing academic conference in 1995, and their TBIL and DBIL were 369.77 ± 112.17 μmol/L and 114.75 ± 38.98 μmol/L, respectively. The levels lowered to 293.19 ± 99.16 μmol/L and 95.00 ± 31.41 μmol/L and symptoms of patients were improved after treatment of MARS. Chen *et al*[14] reported 28 patients with acute or chronic liver failure, who received 56 intermittent MARS treatments (Teraklin, Germany; time of therapy, 6-8 h) based on medicinal treatment, the TBIL, DBIL and total bile acid decreased by 31.47%, 29.15% and 35.91%, respectively after a single treatment of MARS, and the process was smooth except one ended having acute upper gastrointestinal bleeding; 8 cases of hypokalemia were corrected in time by infusing kalium intravenously. In Sun's study on treatment of 27 patients with severe hepatitis (the diagnosis was consistent with 2000CVHC) by MARS, he evaluated the degree of severity of disease by the MELD system[15,16], and reported that MARS could effectively alleviate hyperbilirubinemia, cure hepatorenal syndrome and decrease mortality obviously. Anyhow, MARS is an effective alternative for acute or chronic liver failure and their complications.

## COMPARISON AND SELECTION OF BLOOD PURIFICATION METHODS FOR REDUCING BILIRUBIN

The research of non-bioartifical liver is relatively mature and it is safe and easy to gain ground. Based on medicinal treatment, the hyperbilirubinemias caused by different pathogenic factors should be treated by different blood purification methods, or by a combination of these methods according to the accompanying symptoms, complications, concomitant diseases, existing equipment and conditions as well. Liu *et al*[1] treated 161 cases of severe hepatitis or liver failure with different blood purifications. The results indicated that PE(variant homeotype plasma exchange; 2000-2500 mL plasma; plasma segregating rate, 25-30 mL/min; blood flow, 30-40 mL/min), HP(microcapsule activated charcoal perfusion column; total time, 1.5-3 h) and MARS (NCU-11 blood dialysis machine and MARS mainframe, Germany) could reduce TBIL by 46.53%, 21.20% and 37.69% respectively, and blood ammonia by 19.04%, 15.35% and 44.13%. PE showed a superior ability in removing bilirubin, and at the same time it could supply albumin, coagulation factors and other biological active substances. MARS reduced blood ammonia effectively, so it would be a good option for patients complicated with hepatic encephalopathy to reduce icterus and correct hepatic coma simultaneously. Patients who had ascites and renal failure could be treated by HD. HP was able to correct alkalosis and hypokalemia, so it could be applied to patients with these complications. In addition, combination of MARS, PE, HP and HD can treat abdominal dropsy and renal inadequacy[11,12]. Recently it was reported that PE (SP1 or SP2, Fresenius Company), HP (BR-350, Asahi Company; Japan) and HD could be used in combination. Firstly, PE was performed (blood flow ⩽ 100 mL/min), subsequently bilirubin was adsorbed. Excessive water was dialysed out in those patients with complicating hepatorenal syndrome or being infused with redundant water during PE[17].

## RESEARCH FOCUS AND ADVANCEMENT OF BLOOD PURIFICATION FOR CLEARING BILIRUBIN

The study of bioartificial liver is a new hotspot recently. The so-called bioartificial liver is loaded with a combination of liver, tissues, cells and other things that are obtained from homologous or heterogeneous animals with special materials and equipment. It simulates the main functions of the liver: detoxification, synthesis and regulation[18]. Liver cells form a crucial part of BAL, and the cell type that can be used on humans is limited. It includes normal adult hepatocytes, fetus stem cells, liver tumor cells, swine hepatocytes, human stem cells,

reversible immortalized hepatocytes and so on[19]. Several liver support systems have been described, but no system has gained widespread clinical acceptance[20]. Chen *et al*[21] used a high concentration of L-02 human hepatocytes (Shanghai Institute of Biochemistry and Cell Biology, China) into hollow fiber bioreactor( YT-PP/F50 grate Ⅱ plasma separator, Yatai Company, Ningbo, China) and constituted extracorporeal BAL with another assisting circulation device. An extracorporeal-circulation test was performed later and the effect on bilirubin was observed simultaneously. The result showed that TBIL decreased by 35.78% after 4 h of treatment. Heterogenic or heterologous hepatocytes and tumor cells of liver cultured *in vitro* are used in BAL, so it has risks of xenogenic rejection, potential xeno-zoonosis and morbigenous. The hollow fiber bioreactor was also given attention because of its vital function for containing hepatocytes in BAL. The limitation of cultured cells substituting natural livers and the culture techniques, as well as the limitation of large-scale production, preservation and transportation of biologic materials make it difficult for BAL to be popularized clinically.

Recently, the combination of non-BAL and BAL was proposed, namely hybrid ALSS. It consisted of plasma separator, activated charcoal adsorber, level detector, attemperater and hollow fiber bioreactor and so on[22]. Li *et al*[23] used hybrid ALSS (Chinese experimented small porcine, Experiment Animal Research Center of Beijing Agriculture University; D-hanks perfusate and TECA- Ⅰ hollow fiber bioreactor, USA) to treat 15 chronic severe hepatitis patients (the diagnosis was consistent with 2000CVHC) and found that hybrid ALSS had an effect of reducing bilirubin. The TBIL decreased 240 μmol/L while DBIL decreased 110 μmol/L after treatment. Ten patients improved and were discharged from the hospital and one case was bridged to transplantation successfully and is living till now. Although 4 cases died, cure rate and survival rate of severe hepatitis had already increased without severe complications. Hybrid ALSS will be improved constantly with the development of ALSS. Consequently, for the time being the application of non-BAL is still the main alternative as a clinical treatment method for hyperbilirubinemia.

Though the technology of blood purification has improved gradually, a great deal of problems still exist. The main problems include low removal efficiency, long therapeutic time and expensive treatment costs. One key limitation of PE is bulk supplement of plasma and costly price, while the single application of HD is rare because of its low clearance. Further improvement and study on HP and MARS was brought into a focus by modified adsorbent materials. The ideal method of solving these vital problems is using the best membrane material and an optimally modified method, and increasing removal efficiency to the best advantage. Many scholars in the world are further groping for membrane modification for specific adsorption based on investigating bead affinity adsorbents. Yu *et al* immobilized guanidine on cross-linked polyvinyl alcohol gel, and coated cyclodextrin and glucose to polymer for adsorbing bilirubin in the blood[24-26]. At present, the most advanced affinity membrane is CA/PEI affinity membrane. The basic component of the membrane-cellulose acetate (CA) has favorable blood compatibility. Wei *et al*[27] used cellulose acetate as a compatible membrane matrix and made polylysine and quaternary ammonium salt as a ligand to prepare two kinds of modified affinity membranes after grafting. It was used to remove bilirubin from the HSA solution. Polyethyleneimine (PEI) has been widely used in the field of biochemistry and medicine now. CA/PEI membrane could be used directly to clear endotoxin or adsorb heavy metal[28,29], to prepare a metal chelating affinity membrane, to further covalently link other specific ligands on the membrane, and to work out a modified affinity membrane that could possess better adsorption performance for bilirubin in serum. Otherwise, favorable immune compatibility, i.e., ability to reduce immunoreaction was a precondition of the biomaterial being applied in clinics[30]. Now it is known that structure character of material is related to activating rejection of body fluid, cell and host[31]. Peng *et al*[32] evaluated the immunocompatibility of propylene-acidamide grafted polypropylene membrane (PP-g-AAm) *in vitro* on peripheral blood mononuclear cells (PBMCs) and confirmed that PP-g-AAm had preferable immunocompatibility.

Blood purification for hyperbilirubinemia is not an etiological therapy but strives for the opportunity to cure. So many patients can obtain surgery and liver transplantation finally. With the development of medicine, molecular biology, biochemistry and chemical engineering, blood purification will improve continuously and will make new breakthroughs for treatment of hyperbilirubinemia.

## Abstract

**AIM:** To determine the inhibitory effect of the vector-generated small interfering RNAs (siRNAs) on the expression of the Bcl-$X_L$ gene in established human esophageal cancer cells, and to investigate the effect of the Bcl-$X_L$ siRNAs on cell growth and apoptosis in esophageal cancer cells.

**METHODS:** Three siRNA-expressing vectors targeting different sites of the Bcl-$X_L$ gene were constructed from pTZ-U6+1 vector. Cultured esophageal cancer cells were transfected with the siRNA-expressing vector (or the control vector) using lipofectamine 2000. Bcl-$X_L$ gene expression was determined with semiquantitative RT-PCR assay and Western blotting. Among the three siRNA-expressing vectors, the most highly functional vector and its effect on cell growth and apoptosis in esophageal cancer cells was further analyzed.

**RESULTS:** Of the three siRNA-expressing vectors, siRNA-expressing vector No.1 was the most potent one which suppressed Bcl-$X_L$ mRNA production to 32.5% of that in the untreated esophageal cancer cells. Western blotting analysis showed that siRNA-expressing vector No.1 markedly down-regulated the expression of Bcl-$X_L$ in human esophageal cancer cells. Treatment of esophageal cancer cells with siRNA-expressing vector No.1 resulted in inhibition of cell growth and induction of apoptosis.

**CONCLUSION:** Down-regulation of Bcl-$X_L$ by vector-generated small interfering RNAs can suppress cell growth and induce apoptosis in human esophageal cancer cells.

**Key words:** Esophageal cancer; Bcl-$X_L$; RNA Interference; Apoptosis

## INTRODUCTION

Esophageal cancer is one of the most common malignant tumors of mankind. About 300 000 people died of esophageal cancer each year in the world. The incidence and mortality of esophageal cancer are unusually high in China, especially in the areas of Henan, Shanxi, Hebei and Sichuan provinces[1]. Even though a small number of esophageal cancer patients survive longer than 5 years after initial surgical treatment, over 60% of patients still die of metastasis and local recurrence[2]. It is therefore imperative to investigate new therapeutic strategies in the treatment of esophageal cancer. Due to genetic abnormalities observed in esophageal cancer cells, the application of gene therapy has attracted the attention of many researchers. Activation of the cellular apoptotic program is a current strategy for the treatment of human cancer. It has been demonstrated that radiation and standard chemotherapeutic drugs kill some tumor cells through induction of apoptosis[3,4]. Upon apoptosis stimulation, several key events occur in mitochondria, including the release of cytochrome c. The mitochondrial cytochrome c release can be inhibited by expression of an antiapoptotic Bcl-2 family member (such as Bcl-2 or Bcl-$X_L$) and induced by expression of a proapoptotic member of the Bcl-2 family (such as Bax or Bid)[5]. In fact, an increased expression of Bcl-$X_L$ has been found in a variety of cancers[6-9]. In many neoplastic cells, high expression of Bcl-$X_L$ also correlates with resistance to conventional chemotherapy[10-13]. Bcl-$X_L$ is considered to be a highly promising molecular target to design new molecular targeted anticancer therapies.

Small interfering RNAs (siRNAs) are double-stranded RNA molecules that induce sequence-specific degradation of homologous single-stranded RNA. It has been verified as a powerful tool to knock down the expression of a

target protein in mammalian cells. siRNA technology has several major advantages over other posttranscriptional gene silencing techniques, such as antisense and gene knockout technology. It is easier to deliver, requires only small doses of siRNA to produce its silencing effect, and can inactivate a gene at almost any stage in development[14]. siRNA can be synthesized *in vitro*, but a specific gene silencing induced by synthetic siRNA might not be maintained long enough to achieve a phenotypic change[15]. In order to solve this problem some investigators have developed several vector-based expression systems to produce endogenous, functional siRNA molecules *in vivo*[16,17].

In this study, we present data showing that RNAi technology can be used to down-regulate Bcl-$X_L$ expression, resulting in suppression of cell growth and induction of apoptosis in esophageal cancer cells Eca109. It can be concluded that Bcl-$X_L$ is an alternative target in developing new therapeutic strategies for the treatment of esophageal cancers.

## MATERIALS AND METHODS

### Preparation of siRNA-expressing vector

siRNA-expressing vector was constructed from pTZ-U6+1 vector (Provided by Rossi JJ, Division of Molecular Biology, Beckman Research Institute of the City of Hope, Duarte, California 91010, USA) according to the instructions of the manufacturer. Briefly, a pair of oligonucleotides were synthesized *in vitro*. Each oligonucleotide contained a 21 nucleotide target sequence followed by a short loop sequence, the reverse complement of the target sequence, and five thymidines as a RNA polymerase Ⅲ transcriptional stop signal. The oligonucleotides were annealed in a buffer (potassium acetate 100 mmol/L, 30 mmol/L HEPES-KOH pH 7.4, and magnesium acetate 2 mmol/L) and the mixture was incubated at 95℃ for 5 min and then at 37℃ for 1 h. The double stranded oligos were cloned into the *Sal*Ⅰ and *Xba*Ⅰ sites of the pTZ-U6+1 vector where short hairpin RNAs were expressed under the control of the U6 promoter. The target sequences, corresponding oligonucleotides and resulting siRNA-expressing vectors in this study are shown in Table 1.

### Cell culture and transfection

The human esophageal cancer cell line Eca-109 was obtained from Shanghai Institute of Cell Biology, Chinese Academy of Sciences. Eca-109 cells were cultured in medium RPMI-1640 (Invitrogen) supplemented with 10% fetal bovine serum (FBS) and penicillin (100 kU/L) and streptomycin (100 mg/L) at 37℃ in a humidified incubator with 5% $CO_2$. For cell transfection, lipofectamine 2000 (Invitrogen) was used for transfecting the siRNA-expressing plasmids (or the control plasmids) following the manufacturer's instructions. The transfected cells were cultured for 5 h and then transferred to fresh medium with 10% FBS.

### Semiquantitative RT-PCR analysis for Bcl-$X_L$ gene expression

Cells were harvested 48 h after transfection. Total RNA was purified using the Total RNA Isolation System (Qiagen). Reverse transcription-PCR was performed with the isolated total RNA (100 ng) using the Omniscript RT kit and HotStarTaq PCR kit (Qiagen) according to the manufacturer's instructions. The primers were bcl-xl: 5'-GGCCTGAAGCCGGTGCAC -3', 5' -CACGGCGATACC GCTGGA -3'; β-actin: 5'-CTGG ATGCGATTCCAAGCAC-3', 5'-GAAGGACTTGGG ATCGTCCGG-3'. When RT-PCR was finished, 1 μL from the reaction mixture was withdrawn and analyzed by agarose gel electrophoresis followed by ethidium bromide staining. The 500 bp bcl-xl bands were cut from the gel and extracted using a DNA gel extaction kit (Qiagen). DNA concentration was determined using the GeneQuant *pro* RNA/DNA Calculator (Biochrom Ltd). Bcl-$X_L$ gene expression was calculated by dividing the concentration of the RT-PCR product of the treated cells by the concentration of the RT-PCR product of the untreated cells (taken as 100%). Each point represents the average of triplicate tests.

### Western blotting analysis

Seventy-two hours after the transfection, cells were washed twice in PBS and total protein was extracted in 150 mmol/L NaCl, 50 mmol/L Tris·HCl (pH 7.5), 1% sodium deoxycholate, 0.1% SDS, 1% Triton X-100, 5 mmol/L EDTA, 10 mg/mL leupeptin, 1% aprotinin and 2 mmol/L PMSF. Ten micrograms of protein sample was loaded onto a 10% SDS-PAGE and electroblotted onto a PVDF nylon membrane (Millipore, Bedford). Membranes were blocked in 0.05% Tween 20 (v/v) PBS containing 5% skim milk， and then incubated with rabbit polyclonal Bcl-$X_L$ antibodies and rabbit polyclonal β-Actin antibodies (Santa Cruz Biotechnology). Membranes were then incubated with a HRP-linked goat anti-rabbit IgG secondary antibody (Santa Cruz Biotechnology). Finally, the membrane was reacted with DAB reagent and washed with PBS once protein bands had appeared.

### Cell growth assay

Untreated cells or the transfected cells were harvested and reseeded at $1 \times 10^4$ cells/well in a 12-well, flat-bottomed plate. Cells were cultivated with RPMI 1640 medium in the $CO_2$ incubator at 37℃. The total cell number was determined every two days with a hematocytometer and under an inverted microscope (Olympus). Cell viability was determined by trypan blue staining. Each value represents the average of triplicate wells.

### Analysis of apoptosis

Cell apoptosis was assessed under an inverted fluorescence microscope (Olympus).The green fluorescent DNA intercalant dye YO-PRO-1 was purchased from Invitrogen Company. Dual staining with YO-PRO and PI made it possible to detect early apoptotic cells that have undergone initial changes in permeability to small molecules. At 72 h post cell transfection, YO-PRO-1 dyes were added to the culture medium at 0.1 μmol/L for 30 min. Cell apoptosis was quantified by determining the percentage of cells that were YO-PRO-1-positive in every 200 cells. Each value represents the average of triplicate wells.

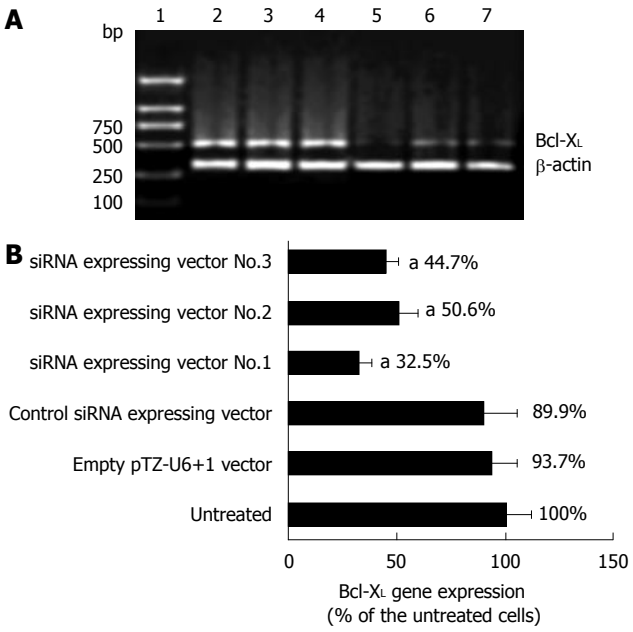

**Figure 1** RT-PCR analysis of the effect of siRNA-expressing vector on Bcl-XL gene expression. **A:** Argarose gel electrophoresis of the RT-PCR products. L1: DNA marker; L2: RT-PCR product of the untreated cells; L3: RT-PCR product of the empty pTZ-U6+1 vector treated cells; L4: RT-PCR product of the control siRNA-expressing vector treated cells; L5: RT-PCR product of the siRNA-expressing vector No.1 treated cells; L6: RT-PCR product of the siRNA-expressing vector No.2 treated cells; L7: RT-PCR product of the siRNA-expressing vector No.3 treated cells. **B:** Quantification of the RT-PCR products (mean ± SD, $n = 3$, $^aP < 0.05$ *vs* untreated esophageal cancer cells).

### *Statistical analysis*

Statistical analysis was performed by the Student's $t$ test or $\chi^2$ test. $P < 0.05$ was considered statistically significant. Data are expressed as mean ± SD. All statistical calculations were performed using SPSS10.0 statistical software package.

## RESULTS

### *siRNA-expressing vector inhibiting Bcl-XL mRNA expression*

We examined three siRNA-expressing vectors which target human Bcl-XL as shown in Figure 1A. Of the three siRNA-expressing vectors, siRNA-expressing vector No.1 potently suppressed the synthesis of Bcl-XL mRNA in human esophageal cancer cells. RT-PCR product quantification showed that siRNA expressing vector No.1 suppressed Bcl-XL mRNA production to 32.5% of that in the control as shown in Figure 1B. On the basis of these results, we selected siRNA-expressing vector No.1 as the most highly functional siRNA-expressing vector in further studies.

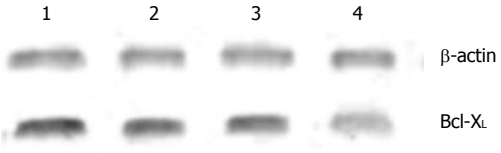

**Figure 2** Western blotting analysis and effect of siRNA-expressing vectors. L1: Untreated esophageal cancer cells; L2: Esophageal cancer cells were transfected with empty pTZ-U6+1 vector; L3: Esophageal cancer cells were transfected with control siRNA expressing vector; L4: Esophageal cancer cells were transfected with siRNA-expressing vector No.1.

### *Effect of siRNA-expressing vector on Bcl-XL protein expression*

We evaluated the effect of siRNA-expressing vector No.1 on target protein Bcl-XL by Western blotting analysis. Figure 2 shows that siRNA-expressing vector No.1 markedly down-regulated the expression of Bcl-XL in human esophageal cancer cells as compared with untreated cells. However, treatment with control siRNA-expressing vector and empty pTZ-U6+1 vector did not change the expression of Bcl-XL in human esophageal cancer cells as compared with untreated cells.

### *Effect of siRNA-expressing vector on cell proliferation*

We have analyzed siRNA-expressing vector No.1 on the cell proliferation of Eca-109 esophageal cancer cells. Figure 3 shows that siRNA-expressing vector No.1 target Bcl-XL significantly inhibited the cell growth in esophageal cancer cells as compared with the untreated cells ($P < 0.05$). Cells treated with control siRNA expressing vector and empty pTZ-U6+1 vector showed only slight cell growth inhibition and had no difference as compared with the untreated cells.

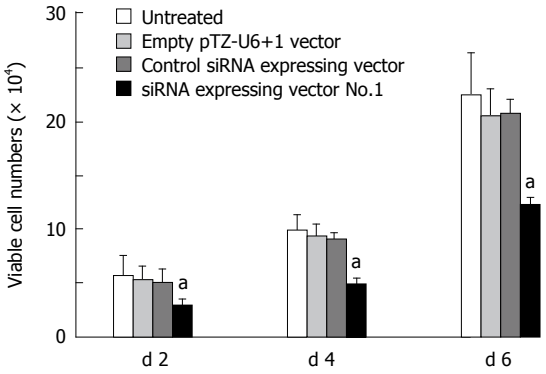

**Figure 3** Effect of siRNA-expressing vector on cell growth post transfection (mean ± SD, $n = 3$, $^aP < 0.05$ *vs* untreated esophageal cancer cells).

### *Bcl-X$_L$ siRNA-expressing vector potentiating apoptosis of esophageal cancer cells*

YO-PRO-1 is a membrane-impermeable DNA-binding dye and is generally excluded from variable cells, whereas early-stage apoptotic cells are YO-PRO-1-positive. Typical photographs of YO-PRO-1 staining are shown in Figure 4A. The nucleus of early-stage apoptotic cell was stained green under the inverted fluorescence microscope. Figure 4B shows that the apoptotic cells significantly increased in siRNA-expressing vector No.1 treated cells compared to untreated cells ($P < 0.05$). However, treatment with control siRNA expressing vector and empty pTZ-U6+1 vector did not significantly affect the apoptosis of esophageal cancer cells.

## DISCUSSION

Members of the Bcl-2 family of proteins play important roles in regulating cell survival and apoptosis. The Bcl-2 family includes pro-apoptotic members and antiapoptotic proteins such as Bcl-2 and Bcl-X$_L$ that inhibit apoptosis by blocking the release of cytochrome C. Bcl-X$_L$ is over-expressed in numerous types of cancer including myelomas, lymphomas, hepatomas, gastric carcinomas and ovarian cancers[6,7,9,18,19]. This over-expression of Bcl-X$_L$ is associated with decreased apoptosis in tumors, resistance to chemotherapeutic drugs and a poor clinical outcome. In esophageal cancer, some investigators observed that Bcl-X$_L$ expression correlated well with depth of tumor invasion, lymphatic invasion, and lymph node metastasis in superficial squamous cell carcinoma of the esophagus. Patients with high Bcl-X$_L$ expression showed significantly shorter survival than those with low Bcl-X$_L$ expression[20,21]. However, the precise role of Bcl-X$_L$ in the development of esophageal cancer remains to be elucidated. Thus, the performance to specifically reduce Bcl-X$_L$ level by genetic means in established esophageal cancer cell lines should be helpful for a better understanding of its role in maintaining the malignant phenotype. Several approaches have been developed to inhibit the function of Bcl-X$_L$ including antisense, peptide nucleic acid, small organic compounds[22-24]. Most of these antagonists of Bcl-X$_L$ were reported to elicit spontaneous apoptosis of cancer cells *in vivo* as well as *in vitro* and to enhance the sensitivity to chemotherapy in cancer cells. Bcl-X$_L$ has been successfully

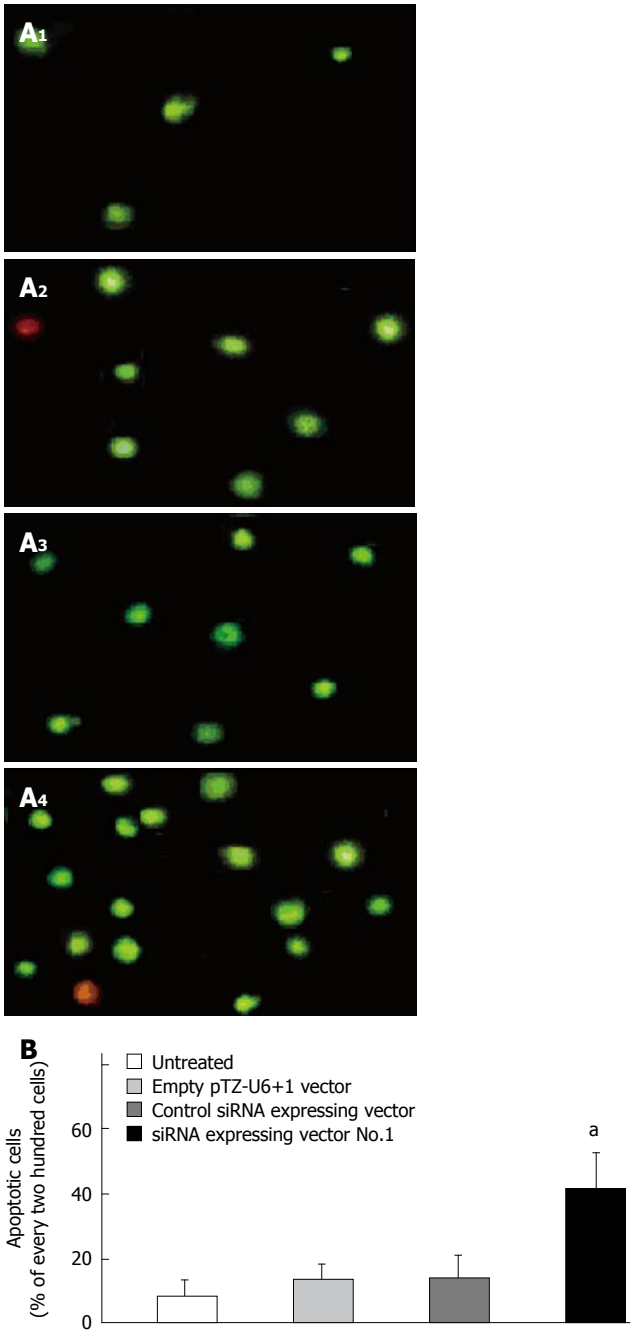

**Figure 4** Effect of siRNA-expressing vector targeting Bcl-X$_L$ on apoptosis of esophageal cancer cells. **A**: Photographs of YO-PRO-1 staining under the inverted fluorescence microscope at 72 h after transfection. 1: Untreated esophageal cancer cells; 2: Esophageal cancer cells were transfected with empty pTZ-U6+1 vector; 3: Esophageal cancer cells were transfected with control siRNA-expressing vector; 4: Esophageal cancer cells were transfected with siRNA-expressing vector No.1. **B**: Percentage of apoptotic cells in every 200 cells (mean ± SD, $n = 3$, $^aP < 0.05$ *vs* untreated cells).

down-regulated by RNAi in some previous studies, but the down-regulation of Bcl-X$_L$ expression by siRNA-expressing vector or other approaches in esophageal squamous cell carcinoma has not been performed until now.

In this study, we constructed three siRNA expressing vectors targetting human Bcl-X$_L$. Down-regulation of Bcl-X$_L$ gene expression was observed in the esophageal carcinoma cell line Eca109 transfected with these three siRNA-expressing vectors. Of the three siRNA-expressing

vectors, siRNA-expressing vector No.1 potently suppressed the synthesis of Bcl-$X_L$ mRNA in semiquantitative RT-PCR assay. RT-PCR product quantification showed that siRNA-expressing vector No.1 suppressed Bcl-$X_L$ mRNA production to 32.5% of that in the untreated esophageal cancer cells. Western blotting analysis showed that siRNA-expressing vector No.1 decreased the synthesis of Bcl-$X_L$ protein in esophageal cancer cells. To further investigate the role of Bcl-$X_L$ in the pathogenesis of esophageal cancer, cell growth and apoptosis were analyzed to determine the functional consequence of the siRNA-expressing vectors mediated decrease of Bcl-$X_L$ in established esophageal cancer cells. Our data showed that knockdown of Bcl-$X_L$ by siRNA-expressing vector suppressed cell growth and potentiated apopotosis in established esophageal cancer cells in a stable manner. These results were consistent with previous reports, Zhu *et al*[25] found that knockdown of Bcl-$X_L$ protein expression by small interfering RNA inhibited the proliferation of 5-FU-resistant human colon cancer cells. Lei X *et al*[26] demonstrated that siRNA targeting Bcl-$X_L$ genes specifically suppressed Bcl-$X_L$ expression and increased spontaneous apoptosis in the human gastric cancer cell line MGC-803. All these investigations suggest that Bcl-$X_L$ may serve as a potential target in cancer therapy. In summary, our study indicates that down-regulation of Bcl-$X_L$ by siRNA-expressing vectors can suppress cell growth and induce apoptosis in human esophageal cancer cells and siRNA technique may provide a novel therapeutic approach in the treatment of human esophageal cancer.

## ACKNOWLEDGMENTS

We thank Dr. John J. Rossi (Division of Molecular Biology, Beckman Research Institute of the City of Hope, Duarte, California 91010, United States) for providing the pTZ-U6+1 vector.

## Abstract

**AIM:** To elucidate the localization of vasodilator stimulated phosphoprotein (VASP), a cytoskeletal organizing protein and a substrate of protein kinases A and G in mitotic gastric cancer cells.

**METHODS:** Immunofluorescence microscopy was used to observe the localization of α-tubulin, VASP and Ser157 phosphorylated VASP (p-VASP) in interphase of mitotic gastric cancer of the cell line SGC-7901.

**RESULTS:** Immunofluorescence staining showed that p-VASP but not VASP was co-localized with α-tubulin on spindle poles and fibers in prophase, metaphase and anaphase of the mitotic process of the gastric cancer cell line SGC-7901. H89, an inhibitor of protein kinases A and G, had no effect on the localization of p-VASP on the spindles.

**CONCLUSION:** VASP may play a role in assembling and stabilizing the mitotic spindle of cells, and phosphorylation of the protein is the precondition for it to exert this function.

**Key words**: Phosphorylated vasodilator-stimulated phosphoprotein; Localization; Mitotic spindle; Gastric cancer cell

## INTRODUCTION

The spindle is a vital apparatus of mitotic cells. The mechanism of its formation has attracted great research attention. In centrosome-containing cells, centrosomes are thought to be instrumental for organization of the spindle poles and determination of both the microtubule polarity and the spindle axis[1]. The spindle poles often contain widely different amounts of known spindle-pole components, such as γ-tubulin. At the beginning of mitosis, γ-tubulin is recruited to the poles and forms a γ-tubulin ring complex (γTuRC), which can collect both α and β tubulins to form spindle fibers[2,3]. At the same time, accessory proteins also join the process. One of these types is microtubule-associated proteins (MAPs). Three major neural MAPs (MAP1, MAP2 and tau) and one non-neural MAP (MAP4) have been identified and well characterized at the biochemical level[4,5]. These MAPs possess the ability to stimulate tubulin polymerization and to bind to microtubules *in vitro* and are believed to play an important part in the regulation of microtubule formation and stabilization *in vivo*[6].

Vasodilator-stimulated phosphoprotein (VASP) is a proline-rich founding member of the Ena (drosophila enabled)/VASP family, a group of multifunctional proteins associated with regulation of actin. VASP was first found in platelets and is known to be a substrate for cAMP dependent protein kinase (PKA) and cGMP dependent protein kinase (PKG) in a variety of cells, such as vascular smooth muscle cells and endothelial cells[7,8]. It is also known to be actin cytoskeletal regulatory proteins. In a variety of cells like vascular endothelial cells, platelets, smooth muscle cells, and fibroblasts, VASP has been found to be highly expressed where it can be found in focal adhesions, along stress fibers, and in the areas with highly dynamic membrane activity, such as extending lamellipodia and filopodia[9-12]. *In vivo* evidence indicates that VASP is a crucial factor in the formation of actin filaments and the integration of signals transmitted between

cytoskeleton, cytoskeleton-membrane interface and the two cyclic nucleotide signal transduction pathways[9]. Even though increasing data address the importance of VASP, the biological role of this protein still remains largely unknown. We have recently found that phosphorylated VASP (p-VASP) is co-located with α-tubulin on the spindles of mitotic cells, indicating that this cytoskeletal organizing protein may also have a role in assembling and stabilizing the mitotic spindles.

## MATERIALS AND METHODS

### Cell line

Human gastric epithelial cell line SGC-7901 was provided by Institute of Cell Biology of China (Shanghai, China).

### Reagents

Dulbeccos's modified Eagle's medium (DMEM) was from GiBco (Grand Island, NY). Newborn calf serum (NBCS) was from Minhai Bio-engineering Co., LTD (Lanzhou, China). Antibodies against VASP (Cat. No. sc-46668) and phosphorylated VASP (Cat. No. sc-23506-R) were from Santa Cruz Biotechnology (Santa Cruz, CA). Antibody against α-tubulin (BM1452) was from Wuhan Boster Biological Technology Ltd (Wuhan, China). FITC- and TRITC- conjugated secondary antibodies were from Jackson ImmunoResearch Laboratories (West Grove, PA). Protein kinase A inhibitor H89 (Cat. No. 371963) was from Calbiochem (San Diego, CA). Nuclear fluorochrome Hoechst 33342 was from Sigma (St. Louis, Missouri).

### Immunofluorescent microscopy

The cells grown on cover slips were incubated to reveal nuclei with 0.2 μmol/L Hoechst 33 342 for 10 min. Then, the cells were fixed with freshly prepared 40 g/L paraformaldehyde in PBS at 4℃ overnight (o/n). After being penetrated with 30 mL/L Triton × 100 and blocked with 30 g/L BSA, the cells were incubated with primary antibodies at 4℃ o/n, and then with FITC- or TRITC- conjugated secondary antibodies for 1 h at room temperature (RT), and washed three times after each time of incubation. For immunofluorescence co-staining of α-tubulin and p-VASP, the cells on cover slips were subsequently incubated with mouse monoclonal antibody against α-tubulin at 4℃ o/n, rabbit polyclonal antibody against p-VASP for 2 h at RT, goat anti-mouse IgG conjugated with FITC for 1 h at RT, and finally TRITC-conjugated goat anti-rabbit IgG for 1 h at RT, and washed three times after each time of incubation. The cover slips were mounted in 900 mL/L glycerol and 100 mL/L Tris-HCl (25 mmol/L, pH 7.5). The fluorescence of FITC (green), TRITC (red), and Hoechst 33 342 (blue) was observed under a fluorescence microscope with a CCD camera (Leica).

## RESULTS

### Distribution of p-VASP and α-tubulin in interphase of SGC-7901 cells

Immunofluorescence staining showed that both p-VASP and α-tubulin were mainly distributed in the cytoplasm of the cells in interphase (Figure 1A and B)

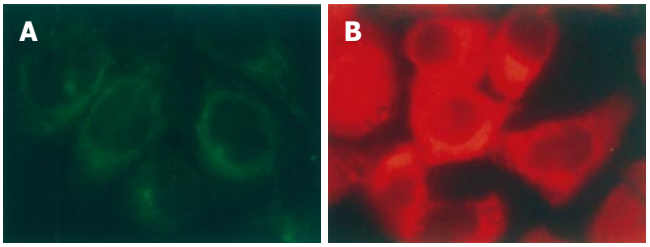

**Figure 1** Distribution of α-tubulin (**A**) and p-VASP (**B**) in interphase of SGC-7901 cells (immunofluorescent staining × 200). α-tubulin was stained with monoclonal antibody against the protein. p-VASP was stained with polyclonal antibody specifically against VASP phosphorylated at Ser157. Both α-tubulin and p-VASP were located in cytoplasm of the cells.

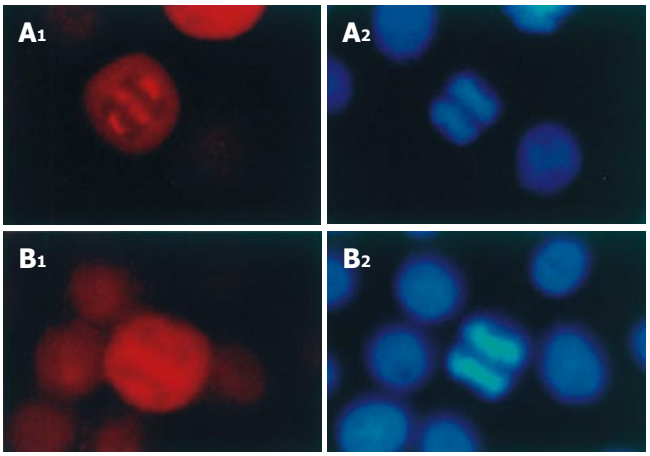

**Figure 2** Distribution of p-VASP (**A**) and VASP (**B**) in mitotic SGC-7901 cells (× 200). p-VASP and VASP in mitotic SGC-7901 cells were immunofluorescently stained with polyclonal and monoclonal antibodies respectively. The chromosomes were stained with Hoechst 33342.

### p-VASP but not VASP was located with α-tubulin on the spindle of mitotic cells

Immunofluorescence staining showed that p-VASP but not VASP was localized both on the spindle poles and on the spindle fibers of mitotic cells (Figure 2A and B). In prophase, the chromosomes became condensed with formation of p-VASP-containing spindle poles (Figure 3A). In metaphase, the chromosomes converged at the metaphase plate (Figure 3B) and the p-VASP-containing spindle poles were located at the opposite sides of chromosomes and the p-VASP-containing spindle fibers irradiated to the chromosomes (Figure 3B). In anaphase, daughter chromosomes were separated and moved toward the opposite p-VASP-containing spindle poles (Figure 3C). Both p-VASP-containing spindle poles and fibers could be seen in this phase (Figure 3C). In telophase, p-VASP-containing spindle disappeared and new daughter nuclei formed (Figure 3D). However, p-VASP could be detected at the cleavage furrow between two separating cells (Figure 3D). Immunofluorescence co-staining showed that α-tubulin was co-localized with p-VASP throughout all phases of mitosis (Figure 3A-D).

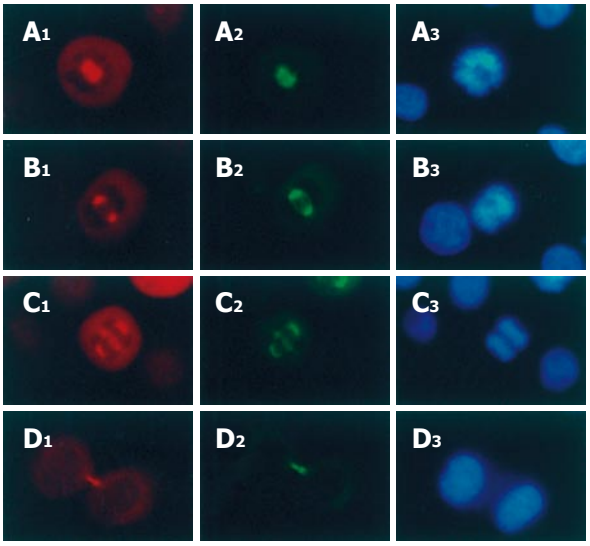

**Figure 3** p-VASP co-localization with α-tubulin and chromosomes on spindles of mitotic SGC-7901 cells (× 200). p-VASP and α-tubulin were stained with polyclonal and monoclonal antibodies respectively. **A1-D1**: p-VASP localization in prophase, metaphase, anaphase and telophase respectively; **A2-D2**: α-tubulin localization in the same phases; **A3-D3**: chromosomes of the cells were stained with Hoechst 33342.

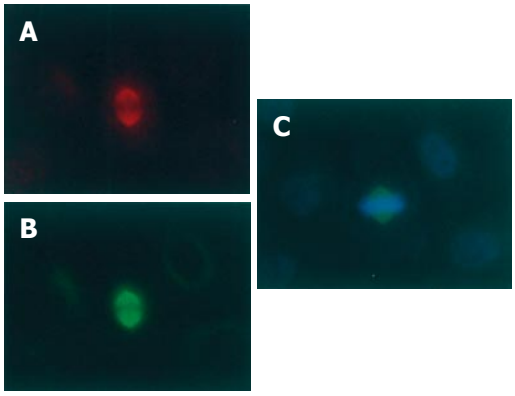

**Figure 4** No effect of PKA and PKG inhibitor H89 on location of p-VASP on spindles of mitotic SGC-7901 cells (× 200). SGC-7901 cells were treated with H89 (10 μmol/L) for 6 h and immunofluorescently stained for p-VASP (**A**) and α-tubulin (**B**). The chromosomes were stained with Hoechst 33342 (**C**).

### *PKA and PKG inhibitor had no effect on the distribution of p-VASP in mitotic spindle*

H89, an inhibitor of PKA and PKG, had no obvious effect on the localization of p-VASP on the mitotic spindle. Immunofluorescent staining of p-VASP could still be seen on the spindles of mitotic cells treated with H89 (10 μmol/L) for different periods of time (Figure 4).

## DISCUSSION

Mitosis is an important event of the cell cycle. During this process, duplicated DNA genetic material is condensed to chromosomes moving into two daughter cells with high fidelity. In eukaryotic cells, the accurate segregation of chromosomes during cell division occurs on the spindle. The formation of the spindle is a complicated process that requires the participation of several types of proteins such as tubulins, spindle-microtubule motor proteins, and microtubule-associated proteins (MAPs)[13,14]. Even though accumulating data address the dynamic process of spindle formation, the exact mechanism and process still need to be further clarified.

In this experiment, we showed for the first time that p-VASP was localized both on spindle poles and on spindle fibers of the mitotic cells. The localization of p-VASP exerted a dynamic change associated with stages of the cell cycle. In interphase, p-VASP was detected in the cytoplasm. In mitotic cells, p-VASP was localized on the mitotic spindle from prophase to anaphase. In prophase, p-VASP was localized on the poles of the spindle. p-VASP could be detected on both the poles and fibers of the spindles from metaphase to anaphase. The localization of p-VASP in mitotic cells was exactly coincident with the localization of alpha tubulin, suggesting that p-VASP might play a role in the formation of mitotic spindles, which is associated with tubulin.

Microtubule-associated proteins (MAPs) play an important role in the formation of spindles, and can bind to tubulin and assist the assembling and stabilizing of spindles. The microtubule-binding domains of MAPs are divided into three sub-domains: a proline-rich region, an AP sequence region and a short hydrophobic tail[4]. The importance of the proline-rich region in *in vitro* MAP-induced microtubule assembly has been widely recognized[15-18]. Tokuraku *et al*[6] showed that this proline-rich region plays a new role as the protofilament linker in *in vitro* MAP-induced microtubule assembly. Since microtubules consist of tubulin as its major component, the proline-rich region of MAPs may be one of the structural features that permit the protein be able to bind to tubulin. Interestingly, VASP also has a proline-rich region in its structure. This protein is organized in three domains, an Ena-VASP-homology 1 (EVH1) $NH_2$-terminal domain, a proline-rich central domain, and an EVH2 COOH-terminal domain. The proline-rich region comprises a $(GP_5)_3$ sequence presenting as a single or repeated motif in different proteins. It has been confirmed that profilin binds to VASP *in vitro* and cell extracts probably *via* the $(GP_5)_3$ repeats[19]. Considering this structural feature of VASP, it is reasonable to speculate that p-VASP may be able to bind to tubulin and the possible function of the p-VASP-tubulin binding is to stimulate the polymerization of tubulin on spindle fibers and increase the stability of microtubules of the spindles, a role similar to that of MAPs.

Research data indicate that phosphorylation is necessary for the accessory proteins to exert their role in forming and stabilizing the spindles. For example, mutations that cause loss of function of the protein kinase aurora prevent centrosome separation in Drosophila[20], while phosphorylation of Eg5 has been shown to be necessary for its localization on spindle poles[21]. Since our results showed that p-VASP was a form of this protein detected on spindles, it is possible that phosphorylation is the precondition for VASP to exert its role in spindle formation and stabilization. VASP has a peptide chain containing 380 amino acid residues. Three of them are known as phosphorylation sites, of which two

serine residues are Ser157 and Ser239 respectively and the threonine residue is Thr278. Phosphorylation of VASP at these sites is directly regulated by PKA and PKG, and VASP has also been shown to be directly phosphorylated on Ser157 by protein kinase C (PKC)[22]. It has been confirmed that VASP phosphorylation is a modulatory event for VASP-dependent regulation of the actin cytoskeleton. The phosphorylation can affect the cytoskeleton structure and may induce morphological changes of cells[23-25]. Research data also indicate that phosphorylation of VASP on different amino acid residues has different functions. For example, serum-induced VASP phosphorylation at serine157 by both PKA and PKC promotes smooth muscle cell (SMC) proliferation, whereas VASP phosphorylation at serine239 induced by nitric oxide (NO)/PKG is required to induce the inhibitory effects of NO on SMC proliferation[26]. One interesting phenomenon observed in our experiment was that PKA (also PKG) inhibitor H89 could not prevent the localization of p-VASP on the mitotic spindles, suggesting that VASP on the spindle is not the substrate of PKA and PKG.

In conclusion, p-VASP might play a role in mitotic spindle formation and stabilization, which implies a potential target for controlling the division and proliferation of gastric cancer cells. The exact mechanism and which protein kinase is responsible for the phosphorylation of VASP on the mitotic spindle need to be further investigated.

## Abstract

**AIM:** To explore the effect of gastrin 17 (G17) on β-catenin/T cell factor-4 (Tcf-4) signaling in colonic cancer cell line Colo320WT.

**METHODS:** The pCR3.1/GR plasmid, which expresses gastrin receptor, cholecystokinin-2 receptor (CCK-2R), was transfected into a colonic cancer cell line Colo320 by Lipofectamine ™2000 and the stably expressing CCK-2R clones were screened by G418. The expression levels of gastrin receptor in the Colo320 and the transfected Colo320WT cell line were assayed by RT-PCR. Colo320WT cells were treated with G17 in a time-dependent manner (0, 1, 6, 12, 24 and 48 h), then with L365,260 ($Gastrin_{17}$ receptor blocker) for 30 min, and with G17 again for 12 h or L365,260 for 12 h. Expression levels of β-catenin in a TX-100 soluble fraction and TX-100 insoluble fraction of Colo320WT cells treated with G17 were detected by co-immuniprecipation and Western blot. Immunocytochemistry was used to examine the distribution of β-catenin in CoLoWT320 cells. Expression levels of c-myc and cyclin D1 in Colo320WT cells treated with G17 were assayed by Western blot.

**RESULTS:** Expression levels of β-catenin in the TX-100 solution fraction decreased apparently in a time-dependent fashion and reached the highest level after G17 treatment for 12 h, while expression levels of β-catenin in the TX-100 insoluble fraction were just on the contrary. Immunocytochemistry showed that β-catenin was translocated from the cell membranes into the cytoplasm and nucleus under G17 treatment. Expression levels of c-myc and cyclin D1 in the G17-treated Colo320WT cells were markedly higher compared to the untreated Colo320WT cells. In addition, the aforementioned G17-stimulated responses were blocked by L365,260.

**CONCLUSION:** Gastrin17 activates β-catenin/Tcf-4 signaling in Colo320WT cells, thereby leading to over-expression of c-myc and cyclin D1.

**Key words:** Gastrin17; Cholecystokinin-2 receptor; Colorectal carcinoma; β-catenin/Tcf-4 pathway

## INTRODUCTION

Gastrin is a hormone produced by G-cells in the normal gastric antrum. As a peptide hormone and trophic factor, in addition to regulating gastric acid secretion, gastrin exerts a growth-promoting action on gastrointestinal malignancy[1,2]. And there is substantial evidence that gastrin can stimulate the growth and proliferation of some colorectal cancers *in vivo* and *in vitro*[3-6]. Colorectal carcinoma cells may also aberrantly produce gastrin. Thus, gastrin may act as an autocrine/paracrine or endocrine factor in initiation and progression of colorectal carcinoma[1]. As yet, some research has shown that gastrin exerts its effect in promoting proliferation and growth by binding its receptor CCK-2[7-11]. We have demonstrated that G17 can cause tyrosine phosphorylation of focal adhesion kinase (FAK), paxillin, and $p130^{Cas}$ in human colon cancer cells. We have also confirmed that G17 may promote colon cancer cell invasion and metastasis by phosphorylating FAKTyr397 and activating FAK pathway[12,13].

The β-catenin/Tcf-4 signaling pathway plays a critical role in gastrointestinal malignancy. As an effector to transmit a receptor-mediated signal from cytosol to the nucleus in the β-catenin/Tcf-4 pathway, β-catenin interacts with and activates the Tcf/Lef transcription factor in the nucleus. The activation of β-catenin/Tcf-4 transcriptional complex can result in expression of multiple target genes,

such as c-myc, cyclin D1 and matrilysin, which induce tumor cells invasion and metastasis[14-18]. However, till now, little research has been carried out on whether gastrin exerts its effects on β-catenin/Tcf-4 pathway in colorectal carcinoma cells. We, therefore, aimed to explore the effects of gastrin on β-catenin/Tcf-4 pathway in human colorectal carcinoma cells.

## MATERIALS AND METHODS

### Materials

Gastrin-17 amide was purchased from Sigma. The gastrin receptor antagonist L-365,260 and eukaryotic expression vector pCR3.1/GR were kindly provided by St. Josef-Hospital, Ruhr-University Bochum, Germany. Mouse monoclonal antibodies for β-catenin (E-5), E-cadherin (G10), c-myc (9E10), cyclin D1 (A-12) and enhanced chemoluminescence (ECL) reagents were purchased from Santa Cruz Biotechnology. Mouse polyclonal antibodies for Tcf-4 (6H5-3) were obtained from Upstate Biotechnology. Protein G Sepharose 4 Fast Flow and nitrocellulose membranes were obtained from Amersham Pharmacia. Horseradish peroxidase-conjugated anti-mouse secondary antibody was obtained from PIERCR.

### Cell culture

Culture of the human colon cancer cell lines Colo320 (ACTCC) was maintained at 37℃ in RPMI-1640 medium, supplemented with 100 mL/L fetal bovine serum (FBS) in a humidified atmosphere containing 50 mL/L $CO_2$ and 950 mL/L air. For experimental purposes, cells were plated in 35-mm dishes at a density of $1 \times 10^5$ cells per dish and grown in RPMI 1640 medium containing 100 mL/L FBS for 5-7 d.

### Stable transfection

Colo320 cells were stably transfected with wild-type CCK2 receptor cDNA cloned into the eukaryotic expression vector pCR3.1/GR using the Lipofectamine$^{TM}$2000 according to the manufacturer's instructions. Following transfection, cells were seeded at very low density to obtain a single cell in an individual well of 96-well plates and further expanded in the presence of 500 mg/mL G418. G418-resistant clones were screened for CCK2 receptor expression by RT-PCR.

### RNA extraction and reverse transcription polymerase chain reaction

Total RNA was extracted from Colo320 and Colo320WT cells by using Trizol reagent. The first strand cDNA was synthesized from 1 μg of total RNA using murine moloney leukemia virus (MuMLV) reverse transcriptase and the first strand cDNA synthesis kit (MBI Fermants) in a total volume of 20 μL. One microliter of each product was subjected to PCR for 30 cycles, each amplification cycle consisting of denaturation at 95℃ for 30 s, primers annealing at 60℃ for 45 s, and extension at 72℃ for 60 s. The primers used were as follows: CCK2, 5'-GTGACAG CGACAGCCAAAGCAG-3' (sense) and 5'-CGAGGCGT AGCTCAGCAAGTGA-3' (antisense); β-actin, 5'-CGAC GGGAAATCGTGCGTGACATTAAGGAGA-3' (sense) and 5'-CGTCATACTCCTGCTTGCTGATCCACATCT GC-3' (antisense). The PCR products were visualized on ethidium bromide-stained 7 g/L agarose gels.

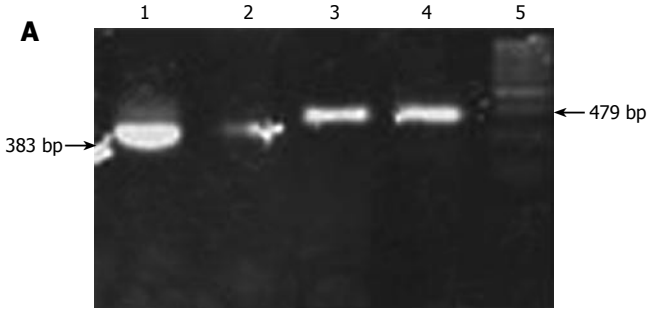
### Cell fractionation and co-immunoprecipitation

The following procedures were carried out at 4℃ as previously described[19-21]. Cells were extracted in the tissue-culture dish with 1 mL of cytoskeleton extraction buffer [CSK: 300 mmol/L, sucrose, 10 mmol/L pipes (pH 6.8), 50 mmol/L NaCl, 3 mmol/L $MgCl_2$, 5 mL/L Triton X-100, 1.2 mmol/L PMSF, 0.1 mg/mL DNase, 0.1 mg/mL RNase]. Cells were harvested with a rubber policeman from the tissue-culture dish, centrifuged at 14 000 *g* for 10 min and the TX-100-soluble fraction separated from the pellet. The TX-100-insoluble pellet was resuspended in 100 μL of SDS immunoprecipitation buffer [10 g/L SDS, 10 mmol/L Tris-HCl (pH 7.5), 2 mmol/L EDTA, 0.5 mmol/L DTT, 0.5 mmol/L PMSF] and boiled for 10 min. SDS concentration was reduced to 0.1% by the addition of 900 μL of CSK buffer prior to immunoprecipitation. For total cell extract immunoprecipitation, cultures were extracted with 1 mL of lysis buffer [10 mmol/L Tris-HCl (pH 7.5), 1 mmol/L EDTA, 1 mmol/L EGTA, 2 mmol/L PMSF and 5 mL/L Triton X-100] for 10 min and harvested as described above.

The soluble and insoluble fractions were precleared for 1 h by incubation with 1 μg of purified mouse serum IgG and 5 μL of 50% protein G Sepharose at 4℃. Following centrifugation at 3000 r/min for 15 min, the TX-100-soluble fraction was processed for immunoprecipitation with 1 μg of E-cadherin antibodies and 20 μL of 50% protein G Sepharose overnight at 4℃. TX-100-insoluble fractions were processed for immunoprecipitation with 1 μg of β-catenin antibodies and 20 μL of 50% protein G Sepharose overnight, because TX-100-insoluble fractions have to be solubilized prior to immunoprecipitation and the solubilization conditions (10 g/L SDS at 100℃) caused dissociation of the complex. Purified mouse serum Ig was used as a negative control. The beads were washed sequentially with high stringency buffer [15 mmol/L Tris-HCL (pH 7.5), 5 mmol/L EDTA, 2.5 mmol/L EGTA, 10 mL/L TX-100, 10 g/L sodium deoxycholate, 1 g/L SDS, 120 mmol/L NaCl and 25 mmol/L KCl], high-salt buffer [15 mmol/L Tris-HCl (pH 7.5), 5 mmol/L EDTA, 2.5 mmol/L EGTA, 10 mL/L TX-100, 10 g/L sodium deoxycholate, 1 g/L SDS and 1 mol/L NaCl] and low-salt buffer [15 mmol/L Tris-HCl (pH 7.5), and 5 mmol/L EDTA]. The beads were then resuspended in an equal volume of sample buffer, boiled for 5 min and centrifuged at 14 000 *g* for 5 min, and the supernatant was dissolved by SDS-PAGE on an 80 g/L polyacrylamide gel and transferred by electroblotting onto nitrocellulose membrane and probed with anti-β-catenin antibodies. For β-catenin/Tcf-4 complex coimmunoprecipitation, the total cell extract was precipitated with anti-Tcf-4 antibody and the immunoprecipitated proteins were subjected to probe with anti-β-catenin or anti-Tcf-4, respectively.

### Immunocytochemistry

Cells were grown to approximately 80% confluence on tissue-culture multispot glass microscope slides at 37℃



Lane 1: CCKR-2 from Colo320WT; Lane 2: CCKR-2 from Colo320; Lane 3: β-actin from Colo320WT; Lane 4: β-actin from Colo320; Lane 5: DNA marker.

Lane 1: Colo320 cells; Lane 2: Colo320WT cells.

**Figure 1** Expression and receptor binding characteristics of CCK2 receptor in Colo320 and Colo320 WT cells. **A**: RT-PCR using RNA extracted from Colo320 and Colo320WT cells; **B**: Immunoblotting using protein extracted from Colo320 and Colo320WT cells. Blotting result of β-actin was used to show the equal loading.

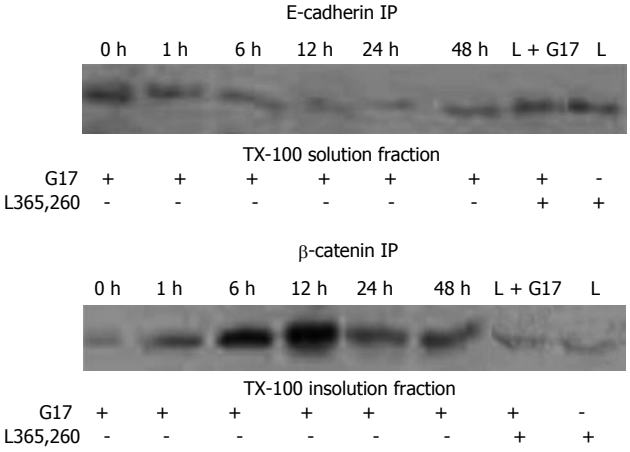


**Figure 2** Immunoprecipitation of β-catenin in TX-100 solution fraction and the insoluble fraction of Colo320WT cells treated with G17 ($10^{-8}$ mol/L). TX-100 solution fraction was immunoprecipitated with anti-E-cadherin antibody, while TX-100 insoluble fraction was immunoprecipitated with anti-β-catenin antibody. E-cadherin immunoprecipitate and β-catenin immunoprecipite were separated on 100 g/L SDS/PAGE gel and probed with β-catenin antibody. Stimulation with G17 induced an increase in the level of β-catenin protein extracted from TX-100 -insoluble fraction and reached the highest at 12 h, while a reduction in the level of β-catenin protein extracted from TX-100 solution fraction. But the responses stimulated by G17 were blocked by L365,260 (Right lane: L).

in an incubator containing 50 mL/L $CO_2$ in absence of serum. The next day, cells were treated with $10^{-8}$ mol/L G17 or with $10^{-6}$ mol/L CCK2 receptor antagonist L365,260 for 30 min, followed by treatment with G17 for 12 h. The cells were then fixed in acetone for 10 min at 4℃. Endogenous peroxidase was blocked by incubating the slides in 3 mL/L hydrogen peroxide ($H_2O_2$) in phosphate-buffered saline (PBS) for 15 min. The slides were incubated in normal goat serum for 20 min to block the non-specific binding. Primary antibody was added to the cells (β-catenin, 1:50), and the slides were incubated overnight at 4℃. The cells were washed in PBS and then appropriate biotinylated secondary antibody was added to each well. The slides were incubated for 30 min at room temperature, washed in PBS, and then incubated with streptavidin-HRP for 30 min at room temperature. The slides were examined by a conventional light microscope, and cellular distributions of the proteins between the membrane, cytoplasm and nucleus were assessed.

### *Western blot*

Cells were grown to approximately 80% confluence and then serum-starved for 24 h. Then the cells were treated with $10^{-8}$ mol/L G17 or with $10^{-6}$ mol/L CCK2 receptor antagonist L365,260 as described above. The stimulation was terminated on ice by aspirating the medium and solubilizing the cells in 1 mL of ice-cold RIPA buffer (10 mL/L NP-40, 1% DOC, 1 g/L SDS, 150 mmol/L NaCL, 10 mmol/L Tris-HCl, 1 μmol/L PMSF, 1 μg/mL leupeptin, 1 μg/mL Aprotinin, 1 μg/mL Pepstatin). Cell lysates were centrifuged at 14 000 *g* for 5 min. The supernatants were transferred into new ice-cold micro-centrifuge tubes. Following SDS-PAGE, proteins were transferred onto nitrocellulose membranes. For detection of proteins, membranes were blocked using 50 g/L non-fat dried milk in Tris buffer containing 1 g/L Tween (TBST) and then incubated overnight at 4℃ with specific antibodies diluted in TBS-T containing 50 g/L non-fat milk. Bound primary antibodies to immunoreactive bands were visualized by ECL detection with horseradish peroxidase-conjugated anti-rabbit or anti-mouse antibodies.

## RESULTS

### *Expression of CCK2 receptor in Colo320WT cells*

The transfection efficiencies in Colo320 and Colo320 WT cells were evaluated by RT-PCR and immunoblotting. Although no method is capable of discriminating between endogenous and transfected CCK2 receptor expressions, our results of RT-PCR and immunoblotting showed that Colo320 cells expressed low levels of CCK2 receptor mRNA and protein, and that stable transfection with CCK2 receptor cDNA led to a 4-fold over-expression of the CCK2 receptor at protein and mRNA levels (Figure 1A and B).

### *Immunoprecipitation of β-catenin*

β-catenin in the TX-100 solution fraction was precipitated with anti-E-cadherin antibody. Expression of β-catenin in the TX-100 solution fraction increased in a time-dependent fashion under G17 treatment, and the expression level reached the highest when treated for 12 h. While the expression of β-catenin in the TX-100 insoluble fraction was obviously decreased, and β-catenin in free pool increased (Figure 2).

### *Coimmunoprecipitation of β-catenin/Tcf-4*

β-catenin interacts with Tcf-4 and forms a complex in the nuclei. We used anti-Tcf-4 antibody to precipitate the complex in the total cell extract, and then go on to probe by anti-β-catenin or anti-Tcf-4 antibody, respectively. As a result, we found that the expression levels of β-catenin

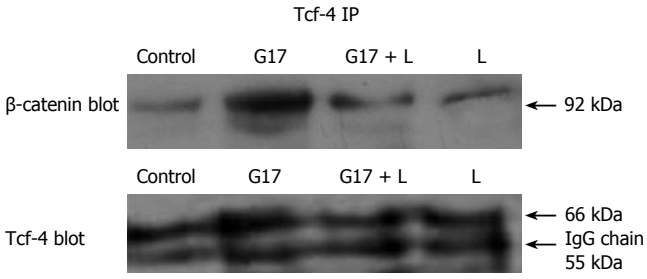

**Figure 3** Immunoprecipitation of β-catenin/Tcf-4 transcription complex in cell protein fraction treated with G17 ($10^{-5}$ mol/L). Cells were stimulated with G17 ($10^{-8}$ mol/L) for the times indicated and lysed. Whole cell lysates were immunoprecipitated with anti-Tcf-4 antibody and Tcf-4 immunoprecipitate was probed separately with anti-β-catenin or anti-Tcf-4 antibody. The results showed that the level of Tcf-4 and β-catenin from immunoprecipitation with Tcf-4 increased under G17 stimulation.

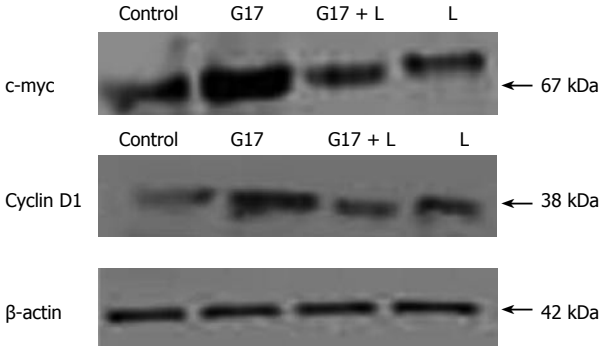

**Figure 5** Over-expression of c-myc and cyclin D1 in Colo320WT cells stimulated by G17. Expression levels of c-myc and cyclin D1 were determined by immunoblotting. The results showed that expression levels of both proteins increased markedly under G17 stimulation for 12 h. But L365,260 could abrogate the responses stimulated by G17.

and Tcf-4 proteins in the complex increased greatly after G17 stimulation, which confirmed that more β-catenin translocated into the nucleus where it bound and interacted with Tcf-4. The active β-catenin/Tcf-4 transcriptional complex further resulted in the expression of the target genes, such as c-myc and cyclin D1 (Figure 3).

### *Immnodetection of β-catenin*

Before treatment with gastrin, scattered Colo320WT cells showed cytoplasmic and little nuclear immunoreactivity for β-catenin in the absence of serum. When confluent, Colo320WT cell membrane localization of β-catenin was at sites of cell-cell contact, but free borders of the cells showed little membranous staining. After G17 stimulation, distribution of β-catenin in the cells changed greatly and β-catenin was translocated from the membrane to the cytoplasm and nucleus, especially to scattered cells. In cohesive cells, staining decreased at sites of cell-cell contact. But after application of L365,260, straining of β-catenin in the cells was the same as that of the cells untreated by G17 (Figure 4).

### *Immumoblot of c-myc and cyclin D1 protein*

After stimulating Colo320WT cells by G17, expression levels of c-myc and cyclin D1 protein were greatly

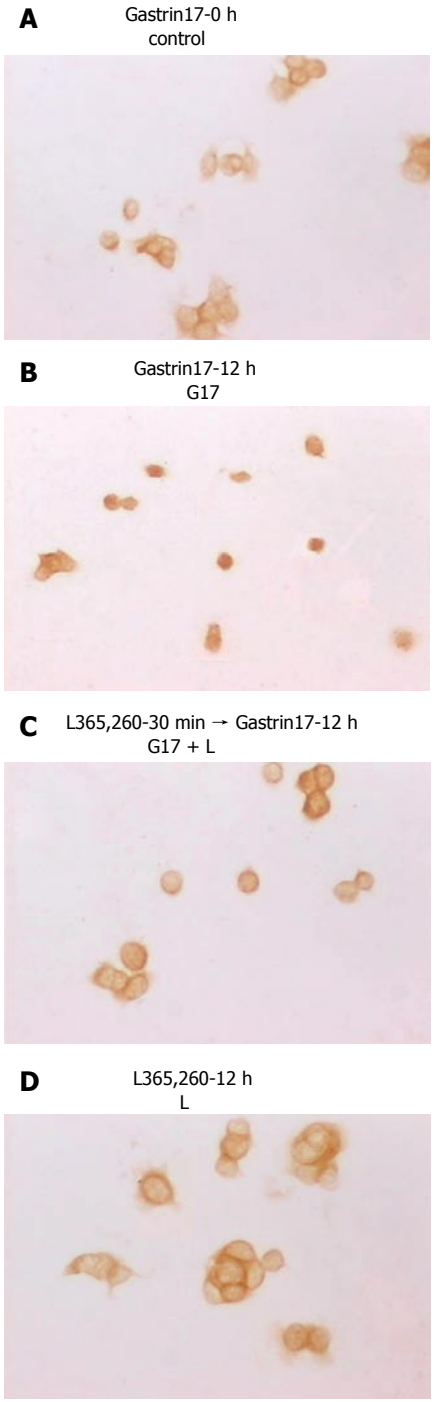

**Figure 4** Immuno-cytochemical staining of β-catenin in Colo320WT cells treated with G17. **A**: Expression of β-catenin in Colo320WT cells stimulated for 0 h by G17 ($10^{-8}$ mol/L); **B**: Expression of β-catenin in Colo320WT cells stimulated for 12 h by G17 ($10^{-8}$ mol/L); **C:** Expression of β-catenin in Colo320WT cells stimulated for 12 h by L365,260 ($10^{-6}$ mol/L); **D**: Expression of β-catenin in Colo320WT cells stimulated for 30 min by $10^{-6}$ mol/L L365,260 and then for 12 h with G17 ($10^{-8}$ mol/L).

increased, showing that gastrin can translocate β-catenin into the nucleus where it interacts with Tcf-4, resulting in over-expression of downstream molecules c-myc and cyclin D1, which may cause tumor cell invasion and metastasis (Figure 5).

## DISCUSSION

The gastrointestinal (GI) peptide hormone gastrin has

been shown to regulate multiple cellular functions, including growth, apoptosis and secretion[22]. Many studies have also shown that gastrin can stimulate the growth and proliferation of colorectal cancer cells from animals and human[3-6] and gastrin exerts its effects in promoting proliferation and growth by binding its high affinity receptor CCK-2, which belongs to the family of G protein-coupled receptors[7-11]. The gastrin receptor antagonist can abrogate responses stimulated by gastrin[23,24]. We have confirmed that G17 may increase invasion of human colorecatal cancer cell by activating the FAK pathway[12,13]. Recently, we have also found that G17 can lead to phosphorylated FAKTyr397 to accumulate at lamellipodia and to form the FAK-Src-p130Cas-Dock180 signaling complex in human colorectal cancer cells (unpublished data).

β-catenin is a member of the catenin family as a proto-oncogene. Adenomatous polyposis coli (APC) can compete with E-cadherin to bind and interact with β-catenin. β-catenin binds the intracellular domain of E-cadherin and forms a complex, which keeps low levels of β-catenin in the cytoplasm. Alpha-catenin mediates the anchorage of the E-cadherin/β-catenin complex to actin filaments of the cytoskeleton and participates in cytoskeleton remodeling[25-28]. Cytosolic β-catenin is degraded by the ubiquitin-proteasome pathway, requiring active glycogen synthase kinase-3β (GSK-3β), APC and axin[25,29-31].

Our study showed that G17 could stimulate redistribution of β-catenin in human colon cancer cells Colo320WT, which is different from the results achieved by Song *et al*[32] that gastrin can lead only to high expression of β-catenin, but not redistribution of β-catenin in mouse colorectal cells. The different results probably resulting from different genus cells (mouse and human) are to be studied in our following research. Our coimmunoprecipation results showed that the expression level of β-catenin in the TX-100 insoluble fraction markedly increased in a time-dependent manner, and the expression level of β-catenin reached the highest when G17 was exogenously applied for 12 h. But the expression level of β-catenin in the TX-100 soluble fraction was the other way around. It indicates that free cytosolic β-catenin increases greatly under G17 treatment, because G17 may inhibit activation of APC, axin, PTEN (the phosphatase and tensin homologue) and GSK-3β, and further inhibit β-catenin phosphorylation. As a result, free β-catenin in the cytoplasmic pool increases on gastrin stimulation. When we used L365,260 (gastrin receptor antagonist) to block effects caused by G17, expression level of β-catenin changed a little in the TX-100-insoluble fraction and the TX-100-soluble fraction, which confirmed that G17 exerts its effects on Colo320WT cells by binding and interacting with its high-affinity receptor CCK-2R.

Immunocytochemistry demonstrated a link between cell-cell contact and the distribution of β-catenin. Without G17 stimulation, scattered Colo320WT cells showed cytoplasmic and little nuclear immunorectivity for β-catenin, and the confluent Colo320WT cells membrane localization of β-catenin was at sites of cell-cell contact, but free borders of the cells showed little membranous staining. But after G17 stimulation, distribution of β-catenin in the cells changed greatly and β-catenin was translocated from the membrane to the cytoplasm and nucleus, especially to scattered cells. In cohesive cells, staining decreased at sites of cell-cell contact. Taken together, G17 can affect redistribution of β-catenin in Colo320WT cells and decrease cell-cell cohesion, resulting in cell invasion and metastasis.

G17 leading to redistribution of β-catenin in Colo320WT cells resulted in an increase of the cytoplasmic pool of β-catenin. The increased free β-catenin was translocated into the nucleus, where it bound and interacted with Tcf-4 transcription factor. Thus, activated β-catenin/Tcf-4 pathway led to the up-regulation of downstream target genes c-myc and cyclin D1.

In conclusion, G17 can cause redistribution of β-catenin and activate β-catenin/Tcf-4 pathway which leads to high expression of c-myc and cyclin D1, thereby promoting invasion and metastasis of Colo320WT cells.

## COMMENTS

### Background

Colorectal cancer is one of human malignant tumor, and tumor metastasis affects therapeutic effect and prognosis, playing a key role in death to a patient with cancer. But the biologic mechnism of tumor cells' motility, invasion and metastasisis to be studied as yet.

### Research frontiers

Gastrin may mediate intracellular signal transduction in human colon cancer cells, and can increase invasion and metastasis of tumor cells by binding to its receptor CCK-2.

### Innovations and breakthroughs

Our study shows that Gastrin17 may induce redistribution of β-catenin in human colon cancer cells Colo320WT, which is different from the results achieved by Song DH *et al* that gastrin can lead only to high expression of β-catenin, but not redistribution of β-catenin in mouse colorectal cells.

### Applications

The research explores the mechanism of colorectal cancer invasion and metastasis in order to provide a new thinking of preventing and curing tumor invasion and metastasis.

### Terminology

Beta -catenin in the TX-100 solution fraction is cytoplasmic beta -catenin, while beta -catenin in TX-100 insoluble fraction is cytoskeleton bound beta -catenin.

### Peer review

Gastrin is a peptidic hormone essentially secreted by gastric antrum and proximal duodenum, which belongs to the same family as cholecystokinin (CCK). More recent findings suggest that gastrin can mediate proliferative effects in digestive tract neoplasia by the CCK2 receptor. And some clinical evidence and animal experiments have shown that gastrin may promote tumor's invasivness and metastasis, regrettably, its mechanism is still to be explored as yet.

The experiment aims to explore the mechanism by which gastrin increases tumor's invasion and metastasis by plasmid transfection, RT-PCR, coimmunoprecipitation and Western blot methods. The results showed that G17 induced redistribution of β-catenin and increased free cytoplasmic β-catenin which translocated into the nucleus, where it was bound and interacted with Tcf-4 transcription factor. G17 activated the β-catenin/Tcf-4 pathway, and further upregulated downstream target genes c-myc and cyclinD1.

This article is clear-cut and easy to understand. The paper provides new thoughts on how gastrin affects gastrointestinal tract tumorigenesis, development, invasion and metatasis.

## Abstract

**AIM:** To investigate the effect of human apolipoprotein B mRNA-editing enzyme catalytic-polypeptide 3G (APOBEC3G) and its N-terminal or C-terminal cytosine deaminase domain-mediated antiviral activity against hepatitis B virus (HBV) *in vitro* and *in vivo*.

**METHODS:** The mammalian hepatoma cells HepG2 and HuH7 were cotransfected with APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain expression vector and 1.3-fold-overlength HBV DNA as well as the linear monomeric HBV of genotype B and C. For *in vivo* study, an HBV vector-based mouse model was used in which APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain expression vectors were co-delivered with 1.3-fold-overlength HBV DNA *via* high-volume tail vein injection. Levels of hepatitis B virus surface antigen (HBsAg) and hepatitis B virus e antigen (HBeAg) in the media of the transfected cells and in the sera of mice were determined by ELISA. The expression of hepatitis B virus core antigen (HBcAg) in the transfected cells was determined by Western blot analysis. Core-associated HBV DNA was examined by Southern blot analysis. Levels of HBV DNA in the sera of mice as well as HBV core-associated RNA in the liver of mice were determined by quantitative PCR and quantitative RT-PCR analysis, respectively.

**RESULTS:** Human APOBEC3G exerted an anti-HBV activity in a dose-dependent manner in HepG2 cells, and comparable suppressive effects were observed on genotype B and C as that of genotype A. Interestingly, the N-terminal or C-terminal cytosine deaminase domain alone could also inhibit HBV replication in HepG2 cells as well as Huh7 cells. Consistent with *in vitro* results, the levels of HBsAg in the sera of mice were dramatically decreased, with more than 50 times decrease in the levels of serum HBV DNA and core-associated RNA in the liver of mice treated with APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain as compared to the controls.

**CONCLUSION:** Our findings provide probably the first evidence showing that APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain could suppress HBV replication *in vitro* and *in vivo*.

## INTRODUCTION

Hepatitis B virus (HBV) infects more than 350 million people worldwide and is a leading cause of end-stage liver disease and of hepatocellular carcinoma[1]. HBV is non-cytopathic for hepatocytes; however, most newly HBV-

infected adult patients develop acute hepatitis because of a strong immune response that clears HBV from the liver, whereas approximately 5% of newly HBV-infected adult patients generate insufficient immunity and become chronically infected[1,2]. HBV and other hepadnaviruses replicate their partially double-stranded DNA genome within cytoplasmic core particles by reverse transcription of encapsidated pregenomic RNA and thus are related to retroviruses[3].

The cytidine deaminase APOBEC3G (A3G), which is encoded within a cluster of seven related editing enzymes (APOBEC3A-G) on chromosome 22, provides a broad innate immunity against exogenous and endogenous retroelements[4-10]. It has been shown that the propagation of HIV-1 strains lacking the accessory protein virion infectivity factor (VIF) is suppressed in non-permissive cells due to expression of the cytidine deaminase APOBEC3G[5,11]. Encapsidated into the retroviral particle, APOBEC3G induces massive C→U deamination of single-stranded retroviral DNA, resulting in DNA degradation or lethal G→A hypermutation[6-8]. HIV overcomes this innate defense barrier in T-cells with the help of the HIV-encoded VIF protein that specifically targets A3G to proteosomal degradation[12-14]. In addition, APOBEC3F (another cytidine deaminase of APOBEC family) is a potent retroviral restrictor, but its activity, unlike that of APOBEC3G, is partially resistant to HIV-1 VIF and results in retroviral hypermutation. Moreover, APOBEC3F and APOBEC3G appear to be coordinately expressed in a wide range of human tissues and are independently able to inhibit retroviral infection. Thus, APOBEC3F and APOBEC3G are likely to function alongside one another in the provision of an innate immune defense, with APOBEC3F functioning as the major contributor to HIV-1 hypermutation *in vivo*[15]. Recent evidence suggests that some of the HIV restriction exerted by A3G may be independent of its cytidine deaminase activity[16-18].

Interestingly, APOBEC3G can also interfere with the HBV life-cycle in co-transfected cells[19,20]. However, reduced levels of encapsidated viral pgRNA rather than extensive editing was found to be the major contributing factor[19], APOBEC3G-mediated editing did occur but was only detected in a minority of clones produced in the transfected HepG2 hepatoma cells[20]. In addition, the C-terminal cytosine deaminase domain catalytically inactive APOBEC3G derivatives no longer inhibited VIF-defective HIV-1 but did conserve wild-type levels of activity on HBV[19]. As a result, the mechanisms of APOBEC3G blocking HBV production are unclear.

A previous study shows that APOBEC family members contain a domain structure characteristic of cytidine deaminases[21]. A short a-helical domain is followed by a catalytic domain (CD), a short linker peptide and a pseudocatalytic domain (PCD). In APOBEC3G, the entire unit is duplicated to form the domain structure helix1- CD1-linker1-PCD1-helix2-CD2-linker2-PCD2. Each catalytic domain contains the conserved motif H-X-E-(X)27-28-P-C-X-X-C in which the His and Cys residues coordinate $Zn^{2+}$ and the Glu serves as a proton shuttle in the deamination reaction[22]. Based on the molecular structure of APOBEC3G and recent research results, we speculated that the N-terminal or C-terminal cytosine deaminase domain of APOBEC3G could also display HBV inhibition activity.

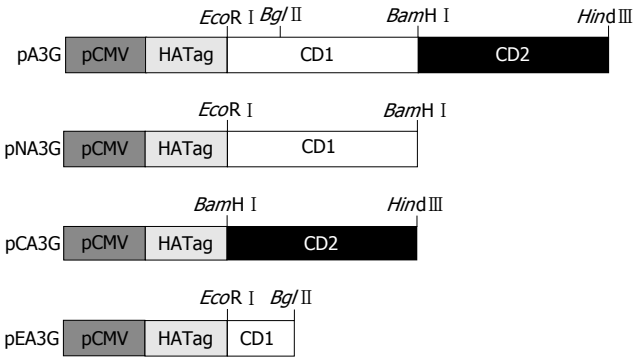

**Figure 1** Construction of APOBEC3G and its N-terminal and C-terminal cytosine deaminase domain expression plasmids. Full-length APOBEC3G sequence was cloned into *Eco*R Ⅰ/*Hind*Ⅲ restriction sites of the CMV-driven expression vector fused with a hemagglutinin fusion epitope tag at its N- terminal end (pXF3H) to construct APOBEC3G expression plasmid (pA3G). pA3G was digested with *Eco*R Ⅰ/*Bam*H Ⅰ and *Bam*H Ⅰ/*Hind*Ⅲ, these fragments were inserted into pXF3H to construct the N-terminal and C-terminal cytosine deaminase domain expression plasmids (pXFNA3G and pXFCA3G), respectively. pA3G was digested with *Eco*R Ⅰ/*Bgl*Ⅱ, and used for the construction of the N-terminal region of APOBEC3G which did not contain any cytosine deaminase domain plasmid (pXFEA3G). pCMV: CMV promoter; CD1: N-terminal cytosine deaminase domain; CD2: C-terminal cytosine deaminase domain.

In the present study, we performed a detailed analysis of the inhibitory effect of APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain on hepatitis B virus replication in cell culture and in an HBV vector-based mouse model.

## MATERIALS AND METHODS

### Plasmid constructs

For construct expression vectors coding for human APOBEC3G (pXFA3G), total RNA was extracted from the peripheral blood mononuclear cells (PBMCs). RT-PCR amplification of human APOBEC3G sequence was carried out using forward primer 5'-CGGAATTCAAGCCTCACTTCAGAAACAC-3' and reverse primer 5'-CGAAGCTTTCTGCCTTCCTTAGAGACTG-3'. The PCR product was cloned into *Eco*R Ⅰ/*Hind*Ⅲ restriction sites of the CMV-driven expression vector fused with a hemagglutinin fusion epitope tag at its carboxy terminal end (pXF3H). For construction of the N-terminal and C-terminal cytosine deaminase domain expression plasmids, the unique restriction enzyme site *Bam*H Ⅰ in the linker area of APOBEC3G, two cytosine deaminase domains were used. pXFA3G was digested with *Eco*R Ⅰ/*Bam*H Ⅰ and *Bam*H Ⅰ/*Hind*Ⅲ, these fragments were inserted into pXF3H to construct the N-terminal and C-terminal cytosine deaminase domain expression plasmids (pXFNA3G and pXFCA3G), respectively. Next, pXFA3G was digested with *Eco*R Ⅰ/*Bgl*Ⅱ, and used for construction of the N-terminal region of APOBEC3G which did not contain any cytosine deaminase domain plasmid (pEA3G) (Figure 1). Replication competent of wild-type HBV 1.3-fold-overlength plasmid (subtype, ayw) and linear monomeric HBV genomes of

genotype B and genotype C with *Sap* I ends have been constructed previously in our laboratory.

### Cell culture, transfection and harvesting

HepG2 and Huh7 cells were grown in Dulbecco's modified Eagle medium (DMEM) supplemented with 100 mL/L fetal calf serum (Invitrogen, CA, USA) at 37℃ in a humidified atmosphere containing 50 mL/L $CO_2$. The cells were plated at a density of $4.5 \times 10^5$ cells per well in 6-well plates 18 h prior to transfection. Transfecion of cells was performed with lipofectamine 2000 (Invitrogen, USA) following the manufacturer's guidelines. On d 3 after transfection, the cells were removed from the culture dish *via* treatment with trypsin-EDTA, resuspended in culture medium, washed with phosphate-buffered saline (PBS), pelleted, and resuspended in 1 mL chilled lysis buffer (140 mmol/L NaCl, 1.5 mmol/L $MgCl_2$, 50 mmol/L Tris-HCl [pH 8.0]) containing 5 mL/L NP-40. Nuclei were removed *via* centrifugation for 5 min at 2000 r/min in an eppendorf centrifuge, and the supernatant was cleared of cell debris by centrifugation for another 5 min at 14 000 *g*.

### HBV vector-based mouse model

For the *in vivo* experiments, 6 to 8-wk-old female BALB/c mice were used. A total of 30 mice were randomly divided into 5 groups (6 mice/group). Replication-competent pHBV1.3 (10 μg) and APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain expression vectors (10 μg) or pXF3H (10 μg) control plasmid DNA were co-injected into the tail vein of mice in a volume of Ringer's injection equivalent to 9% of the mouse body weight[23,24], the total volume was delivered within 5 s. The mice sera were collected at an indicated time after hydrodynamic injection, and secreted hepatitis B virus surface antigen (HBsAg) levels and HBV DNA content were measured. All mouse experiments were carried out according to the guidelines established by the Institutional Animal Care and Use Committee at the Tongji Medical College, Huazhong University of Science and Technology.

### HBsAg and HBeAg assays and Western blot analysis

Levels of HBsAg and HBeAg in the media of the transfected cells, and in the sera (1:100 dilution) of the treated mice were determined using an ELISA kit (Shanghai Shiye Kehua Company, China). For Western blot analysis, cytoplasmic lysates were incubated with 1 vol 2 × loading buffer containing 100 mL/L beta-mercaptoethanol for 10 min at 95℃ before loading on a 125 g/L SDS-PAGE. Proteins were transferred onto a nitrocellulose membrance via electroblotting. The membranes were incubated with HBV core-specific rabbit antiserum (Santa Cluz, USA) or with anti-hemagglutinin fusion epitope monoclonal antibody (Santa Cluz, USA), followed by horseradish peroxidase-conjugated mouse anti-rabbit antibody. Proteins were visualized by Enhanced Chemiluminescene (Roche, Germany).

### HBV DNA purification and analysis

The method for purification of cytoplasmic core-associated HBV DNA was adapted from Pugh *et al*[25]. Briefly, HepG2 cells were disrupted in lysis buffer (100 mmol/L Tris-HCl, pH 8.0, 2 mL/L NP-40). The cell lysate was clarified by centrifugation at 13 000 *g* for 1 min to pellet nuclei and insoluble material. The supernatant was adjusted to 6 mmol/L $MgOAC_2$ and incubated for 2 h at 37℃ with 200 μg/mL DNase I and 100 μg/mL RNase A. Following digestion, the lysate was centrifuged for 1 min at 13 000 *g*. The supernatant was incubated for 1 h at 55℃ after addition of 10 mmol/L EDTA, 10 g/L SDS, 100 mmol/L NaCl and 200 μg/mL proteinase K. Finally, the sample was extracted with phenol:chloroform. The DNA was ethanol precipitated, resuspended in TE at pH 8 (10 mmol/L Tris-HCl, pH 7.5; 1 mmol/L EDTA) and digested with 100 μg/mL RNase A for 30 min at 37℃. The purified DNA was subjected to Southern blot analysis. DNA samples were loaded onto 13 g/L agarose gels, blotted onto nylon membranes, and probed with a Dig-labeled full-length HBV genome in EasyHyb hybridization solution (Roche, Germany).

For quantitative PCR, 100 μL of mouse serum was adjusted to 6 mmol/L $MgOAC_2$ and incubated for 2 h at 37℃ with 200 μg/mL DNase I and 100 μg/mL RNase A. Following proteinase K digestion, the sample was extracted with phenol:chloroform. HBV DNA levels were analyzed with the Light Cycle real-time PCR system (Roche, Germany), using the primer sequences as follows: 5'-TCACAATACCGCAGAGTC-3' (nt231-248, forward) and 5'-AGCAACAGGAGGGATACA-3' (nt569-552, reverse). The pHBV1.0 vector containing the full-length HBV genome was used as a standard curve to calculate HBV copies per milliliter of serum.

### RNA isolation and analysis

For quantitative RT-PCR, approximately 20 mg of liver tissue was obtained from each mouse for total RNA extraction with RNeasy Total RNA kit (QIAGEN, Germany), according to the manufacture's protocol. cDNA was synthesized from 2 μg of total RNA with oligo$(dT)_{18}$ primer in a total volume of 20 μL. Quantitative RT-PCR was performed with the Light Cycler real-time PCR system (Roche, Germany). The PCR primers were as follows: GAPDH, 5'-GTTGTCTCCTGCGACTTCA-3' (forward) and 5'-GGTGGTCCAGGGTTTCTTA-3' (reverse); HBV, 5'-TCACAATACCGCAGAGTC-3' (nt231-248, forward) and 5'- AGCAACAGGAGGGATACA-3' (nt569-552, reverse). A standard curve was constructed by the simultaneous amplification of serial dilutions of the expression plasmid encoding HBV used as templates. Target cDNAs were normalized to the endogenous RNA levels of the DAPDH. Quantitative amplification was carried out using the SYBR Green kit (Invitrogen, USA). Gene expression was determined using the relative quantification: $\Delta\Delta C_T$ = $(C_{THBV}\text{-}C_{T\ GAPDH})$Test -$(C_{T\ HBV}\text{-}C_{T\ GAPDH})$ Control. $C_T$ is the fractional cycle number that reaches a fixed threshold, $C_{Test}$ is the test of interest, and $C_{Control}$ is the reference control (RNA from control group). ΔCT is the difference between gene expression in the treated cells and the reference control cells. The fold increase was calculated using $2^{\Delta\Delta CT}$[26].

## RESULTS

### Inhibitory effect of APOBEC3G on HBV DNA replication in cell culture

Various amounts of a CMV-driven expression vector

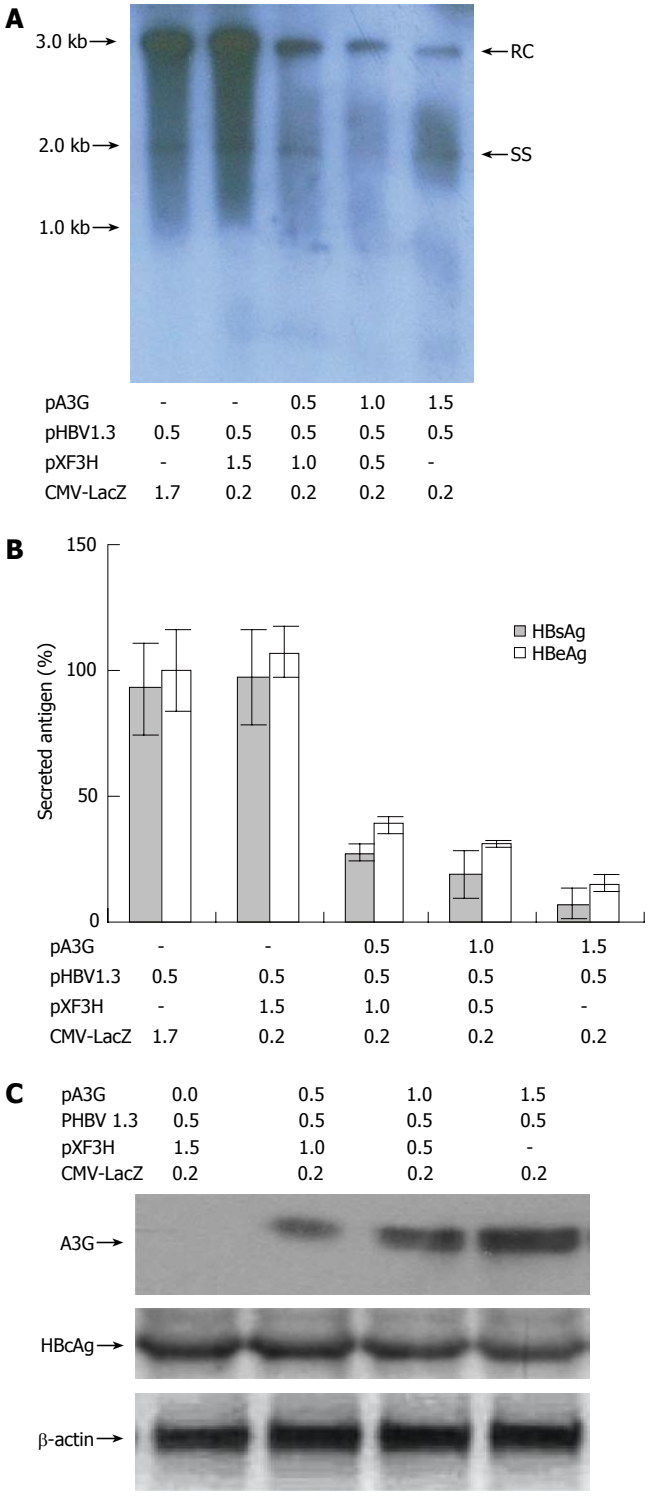

**Figure 2** Effect of APOBEC3G on HBV replication in co-transfected HepG2 cells. (**A**) Human hepatoma HepG2 cells were transiently co-transfected with pHBV1.3 and various amounts of a CMV-driven expression vector encoding A3G or with empty vector pXF3H and pCMV-LacZ using Lipofectamine 2000 reagents. The cells were harvested 3 d after transfection. HBV core-associated viral DNA was prepared from nuclease-treated cytoplasmic lysates. Viral replicative DNA intermediates were analyzed by Southern blotting using a Dig-labeled full-length HBV DNA probe. (**B**) HBsAg and HBeAg levels were determined in the media of co-transfected HepG2 cells by ELISA, normalized to the activity of co-tansfected β-galactosidase in the cell lysates. The mean ± SE of six independent experiments is shown (error bar indicates standard error). (**C**) Western blot analysis of cytoplasmic extracts from HepG2 cells co-transfected with the indicated plasmids. Numbers at the end or top of the lines indicate the amount of transfected plasmid DNA in micrograms. HBV: hepatitis B virus; pA3G: APOBEC3G expression plasmids; RC: relaxed circular DNA; SS: single-stranded DNA; HBcAg: hepatitis B virus core antigen; HBsAg: hepatitis B virus surface antigen; HBeAg: hepatitis B virus e antigen.

encoding A3G (pA3G) and empty vector (pXF3H) were co-transfected into the human hepatoma cells HepG2 together with replication-competent 1.3-fold-overlength HBV and with pCMV-LacZ to normalize for the transfection efficiency. Three days after transfection, core-associated viral DNA was prepared from nuclease-treated cytoplasmic lysates and analyzed with Southern blotting. HBsAg and HBeAg levels in the media of co-transfected cells were determined by ELISA. As shown in our previous study[27], A3G reduced the level of HBV-replicative intermediates in a dose-dependent manner (Figure 2A). In a series of six independent experiments, the expression of A3G resulted in a dose-dependent decrease in the levels of extracellular production of HBsAg and HBeAg even after correction for transfection efficiency by determination of the co-transfected β-galactosidase (Figure 2B). However, the expression of core protein did not change (Figure 2C).

### *Suppression of the replication of HBV clinical isolates of different genotypes by APOBEC3G*

Based on sequence divergence, HBV can be classified into at least 8 genotypes[28]. These results, in agreement with our and other's results[19,27], showed that APOBEC3G inhibited the replication of a laboratory clone of genotype A (subtype ayw). Further testing concerned whether or not APOBEC3G could also inhibit the replication of HBV with different genotypes from clinical isolates. As genotypes B and C are the most prevalent genotypes in China, this study mainly focused on these 2 genotypes. A previous study has demonstrated that linear monomeric HBV genomes with *Sap* I ends can initiate a full replication cycle, leading to viral replication and antigen expression[29].

In order to examine the effect of APOBEC3G on different genotypes of clinical isolates, a full-length HBV genome of genotype B or C was amplified from the patient's serum by PCR and cloned into pUC19 vector. After digestion with *Sap* I , the linear monomeric HBV genomes were transfected into HepG2 cells with APOBEC3G expression plasmid (pA3G) or the control plasmid (pXF3H). Three days after transfection, HBV core-associated DNA was analyzed by Southern blot. As shown in Figure 3, pA3G could also inhibit the replication of HBV genotypes B and C from clinical isolates to a similar extent as on genotype A (pHBV1.3).

### *Inhibitory effect of N-terminal and C-terminal cytosine deaminase domain of APOBEC3G on HBV DNA replication in cell culture*

APOBEC family members contain a domain structure characteristic of cytidine deaminases[21]. A short a-helical domain is followed by a catalytic domain (CD), a short linker peptide and a pseudocatalytic domain (PCD). In APOBEC3G, the entire unit is duplicated to form the domain structure helix1-CD1-linker1-PCD1-helix 2-CD2-linker2-PCD2. Each catalytic domain contains the conserved motif H-X-E-(X)27-28-P-C-X-X-C in which the His and Cys residues coordinate $Zn^{2+}$ and the Glu serves as a proton shuttle in the deamination reaction[22]. A recent study has shown that APOBEC3G can interfere with the HBV life-cycle, but APOBEC3G-mediated

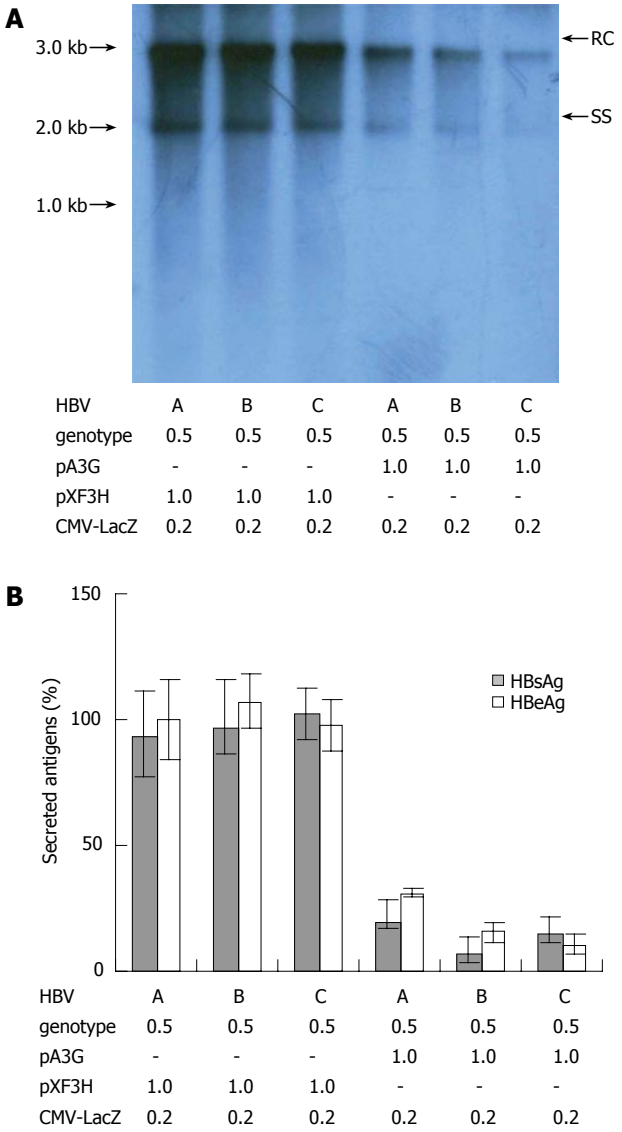

**Figure 3** Suppression of replication of HBV clinical isolates of different genotypes by APOBEC3G. (**A**) pHBV1.3 or the linear monomeric HBV genomes of genotype B and C were transiently co-transfected into HepG2 cells with the CMV-driven expression vector encoding A3G or empty vector pXF3H and pCMV-LacZ using Lipofectamine 2000 reagents. The cells were harvested 3 d after transfection. HBV core-associated viral DNA was prepared from nuclease-treated cytoplasmic lysates. Viral replicative DNA intermediates were analyzed by Southern blotting using a Dig-labeled full-length HBV DNA probe. (**B**) HBsAg and HBeAg levels were determined in the media of co-transfected HepG2 cells by ELISA, normalized to the activity of co-tansfected β-galactosidase in the cell lysates. The mean ± SEM of six independent experiments is shown (error bar indicates standard error). pA3G: APOBEC3G expression plasmids; RC: relaxed circular DNA; SS: single-stranded DNA.

editing of nucleic acids does not seem to represent the major contributing factor[10]. We speculated that the N-terminal or C-terminal cytosine deaminase domain of APOBEC3G could also display HBV inhibitory activity.

To verify this hypothesis, APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain expression plasmids were co-transfected with replication-competent 1.3-fold-overlength HBV DNA into HepG2 and HuH7 cells, and with pCMV-LacZ to normalize for the transfection efficiency. HBV core-associated viral DNA was prepared 3 d after transfection and analyzed by Southern blotting. HBsAg and HBeAg levels were determined by ELISA. As expected, N-terminal or C-terminal cytosine deaminase domain of APOBEC3G expression plasmid (pNA3g and pCA3g) could also reduce the level of replicative HBV intermediates and HBsAg and HBeAg levels in the media of co-transfected HepG2 cells, while the N-terminal region of APOBEC3G, which did not contain any cytosine deaminase domain (pEA3G), had no inhibitory effect on HBV production, and the same results were observed in another human hepatoma cell Huh7 (Figures 4A and 4B). In a series of six independent experiments, the expression of A3G and its N-terminal or C-terminal cytosine deaminase domain, but not of pEA3G, resulted in a consistent decrease of secreted HBsAg and HBeAg even after correction for transfection efficiency by determination of the co-transfected galactosidase (Figure 4C). Compared with the empty vector control and normalized to the amount of secreted HBsAg, the N-terminal or C-terminal cytosine deaminase domain decreased the formation of intracellular HBV-replicative intermediates in this series to approximately 60% and thus achieved a similar level of inhibition as A3G (Figure 4D). In all of these experiments, pEA3G showed no apparent inhibition of HBV replication (Figure 4D). However, Western blot analysis, using the polyclonal anti-HBV core antibody, indicated that the levels of core protein were unaffected by APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain (Figure 4E).

### *Inhibition of HBV replication in mice by N-terminal or C-terminal cytosine deaminase domain of APOBEC3G*

To examine whether the N-terminal or the C-terminal cytosine deaminase domain of APOBEC3G could also display HBV inhibition *in vivo*, replication-competent HBV plasmid (pHBV1.3) was co-transfected with the expression plasmids of N-terminal or C-terminal cytosine deaminase domain of APOBEC3G or the empty control plasmid (pXF3H) to mouse liver by hydrodynamic injection. As previously shown[30], hydrodynamic injection of pHBV1.3 into mouse resulted in HBV replication in the liver and secretion of viral antigens to the serum. Consistent with *in vitro* experiments, serum HBsAg and viral DNA in mice that received pHBV1.3 were suppressed dramatically at different time points by the N-terminal or the C-terminal cytosine deaminase domain of APOBEC3G compared to the mice treated with control plasmid (Figures 5A and 5B). Real-time PCR quantification of core-associated HBV RNA in the liver of mice treated with APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain of APOBEC3G expression plasmid showed approximately 50 times decrease compared to the controls (Figure 5C).

## DISCUSSION

Our study describes the inhibitory effects of human APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain on HBV DNA production in mammalian hepatoma cells as well as in HBV vector-based mouse model. Our data confirm and extend the recent results by Turelli *et al*[19] who reported A3G-mediated inhibition of HBV DNA production in human

**Figure 4** Inhibitory effect of the N-terminal and C-terminal cytosine deaminase domain on HBV production in the co-transfected cells. (**A** and **B**) Human hepatoma HepG2 and HuH7cells were transiently co-transfected with the pHBV1.3 and CMV-driven expression vector encoding A3G and its N-terminal or C-terminal cytosine deaminase domain or with the empty vector pXF3H and pCMV-LacZ using Lipofectamine 2000 reagents. The cells were harvested 3 d after transfection. HBV core-associated viral DNA was prepared from nuclease-treated cytoplasmic lysates. Viral replicative DNA intermediates were analyzed by Southern blotting using a Dig-labeled full-length HBV DNA probe. (**C**) HBsAg and HBeAg levels were determined in the media of co-transfected HepG2 cells by ELISA, normalized to the activity of co-tansfected β-galactosidase in the cell lysates. The mean ± SE of six independent experiments is shown (error bar indicates standard error). (**D**) The hybridized HBV DNA from the replicative intermediates was quantified by radiophosphorimaging, normalized to the amount of secreted HBsAg (normalized for co-transfected β-galactosidase activity) and calculated relative to the empty vector control (pXF3H). The mean ± SE of six independent experiments is shown. (**E**) Anti-HA monoclonal antibody for Western blot analysis of cytoplasmic extracts from HepG2 cells co-transfected with the indicated plasmids. Numbers at the end or top of the lines indicate the amount of transfected plasmid DNA in micrograms. pXF3H: empty vector; pA3G: APOBEC3G expression plasmids; pNA3G: N-terminal cytosine deaminase domain of APOBEC3G expression plasmids; pCA3G: C-terminal cytosine deaminase domain of APOBEC3G expression plasmids; pEA3G: N-terminal region of APOBEC3G which does not contain any cytosine deaminase domain plasmid; HBV: hepatitis B virus; RC: relaxed circular DNA; SS: single-stranded DNA; HBcAg: hepatitis B virus core antigen; HBsAg: hepatitis B virus surface antigen; HBeAg: hepatitis B virus e antigen.

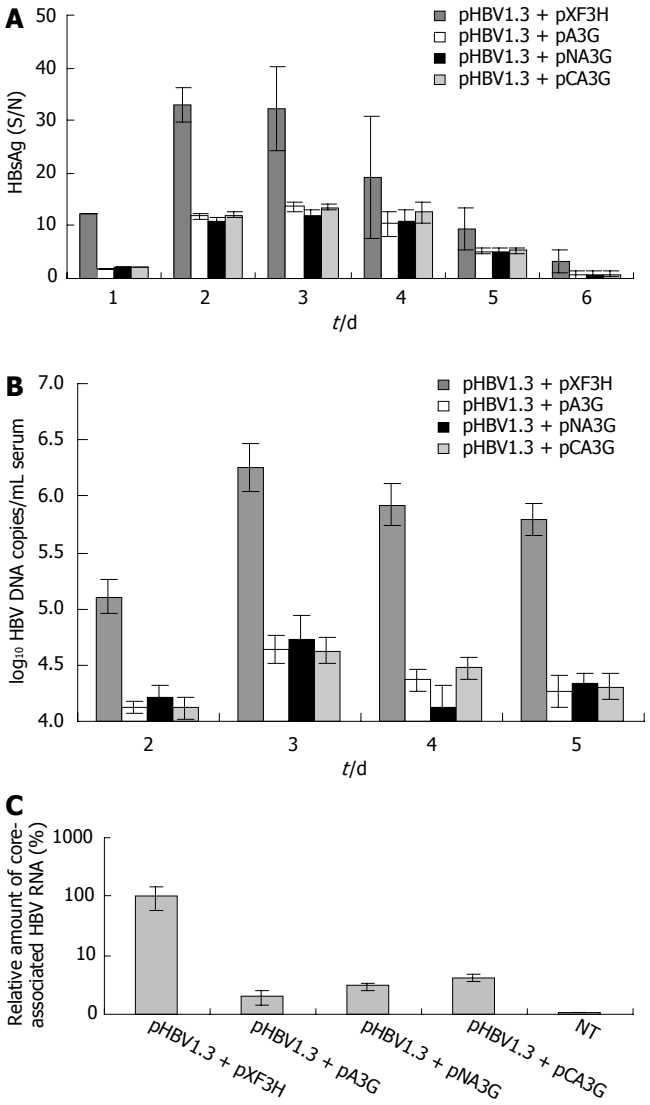

**Figure 5** The N-terminal or C-terminal cytosine deaminase domain of APOBEC3G inhibits HBV replication and gene expression in mice. (**A**) Serum HBsAg levels in the mice treated with APOBEC3G and its N-terminal and C-terminal cytosine deaminase domain expression vector. HBsAg levels (S/N, S: absorbance of the sample, N: absorbance of the negative control) in the sera of BALB/c mice were significantly reduced after treatment with APOBEC3G and its N-terminal and C-terminal cytosine deaminase domain expression plasmids (error bar indicates standard error) in the indicated time points. (**B**) Real-time PCR quantification of HBV DNA in the sera of mice treated with APOBEC3G and its N-terminal and C-terminal cytosine deaminase domain expression plasmid. BALB/c mice were co-injected with pHBV1.3 vector (10 μg) and the indicated expression plasmids (10 μg). HBV DNA levels of sera were determined by quantitative PCR ($n$ = 6 per treatment group). (**C**) Real-time PCR quantification of core-associated HBV RNA in the liver of mice treated with APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain expression plasmids. BALB/c mice were co-injected with pHBV1.3 vector (10 μg) and the N-terminal or C-terminal cytosine deaminase domain expression vector of APOBEC3G (10 μg) 3 d after injection, and the levels of the liver HBV RNA were determined by quantitative RT-PCR, normalized to GAPDH mRNA and reported as a ratio of HBV mRNA/GAPDH mRNA (± SD) ($n$ = 6 per treatment group). NT: non-treated group; pXF3H: empty vector; pA3G: APOBEC3G expression plasmids; pNA3G: N-terminal cytosine deaminase domain of APOBEC3G expression plasmids; pCA3G: C-terminal cytosine deaminase domain of APOBEC3G expression plasmids; HBsAg: hepatitis B virus surface antigen.

HuH-7 hepatoma cells. Previous studies suggested that G-to-A hypermutation could influence HBV pathogenesis. Specific G-to-A changes yielded HBeAg-negative HBV variants, often isolated from patients with acute fulminant hepatitis, as well as HBV vaccine escape mutants[31,32]. However, there is no evidence so far that APOBEC3G-induced lethal hypermutation represents an important innate defense mechanism down-regulating hepadnavirus production.

APOBEC3G site-directed mutation experiments showed that both the N- and the C-terminal cytosine deaminase domains were required for inhibiting the infectivity of HIV-based retroviruses[6,7], and the C-terminal cytosine deaminase domain of APOBEC3G governed the catalytic activity and the retroviral hypermutation specificity, while the N-terminal deaminase domain was to perform other aspects of retroviral restriction[33]. Another study suggested that the N-terminal deaminase domain of APOBEC3G mediates encapsidation and RNA binding, while the C-terminal cytosine deaminase domain mediates cytidine deaminase activity[17].

Although APOBEC3G could inhibit HBV replication, extensive editing was not found to be the major contributing factor[19,20]. Each catalytic domain contains the conserved motif in which the His and Cys residues coordinate $Zn^{2+}$ and the Glu serves as a proton shuttle in the deamination reaction[22]. In this study, we found the N-terminal and C-terminal cytosine deaminase domain of APOBEC3G could inhibit HBV DNA replication and gene expression in cell culture and the HBV vector-based mouse model. Together with the fact that catalytically inactive APOBEC3G derivatives no longer inhibited VIF-defective HIV-1 but did conserve wild-type levels of activity on HBV, confirming the hypothesis that APOBEC3G might act on HBV and retroviruses through different mechanisms. As a result, we speculated that the RNA binding activity might play a role in these processes, for example, APOBEC3G might bind to the pregenome RNA or interfere with the binding of the ε subunit and RT domain of HBV DNA polymerase, but this needs further investigation.

Given the high heterogeneity of HBV sequences, HBV can be classified into 8 genotypes according to the sequence divergence[28]. Our results and other group showed that APOBEC3G inhibited the replication of genotype A. Whether APOBEC3G could also inhibit the replication of HBV with different genotypes (genotypes B and C) from clinical isolates is a great concern. As we expected, pXFA3G could also inhibit the replication of the most prevalent genotypes B and C from clinical isolates to a similar extent as on pHBV1.3, thereby indicating the inhibitory effect of APOBEC3G is different than that of the siRNAs which is sequence-specific.

The hydrodynamic delivery of nucleic acids in the mouse was described by Liu *et al*[23], who showed that the vast majority of the injected nucleic acid was delivered to the liver by this technique. Yang *et al*[30] first demonstrated that hydrodynamic injection of a replication-competent HBV vector resulted in high levels of HBV replication in the livers of the injected mice. In the vector-based model, HBV replicates in the liver of immunocompetent mice for 7-10 d, resulting in detectable levels of HBV RNA and antigens in the liver and of HBV DNA and antigens in the serum. Several reports have documented the use of the HBV vector model to examine the *in vivo* activity

of co-HDI-administered HBV-targeted unmodified siRNAs[34,35] or vector-expressed short hairpin RNAs[36] in silencing HBV gene expression. Most notably, we have demonstrated *in vivo* activity of APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain expression vector via standard intravenous administration. This is probably the first demonstration of APOBEC3G *in vivo* activity in a hepatitis animal model with a clinically viable route of administration. Although we observed a more than 50 times reduction in serum HBV levels after treatment with APOBEC3G and its N-terminal or C-terminal cytosine deaminase domain in an HBV mouse model, the potential contribution of toxicity from the APOBEC3G has not been ruled out and will need to be investigated further.

During the course of an acute infection, HBV DNA clearance apparently occurs through noncytopathic mechanisms in which interferon γ (IFN-γ) and tumor necrosis factor α (TNF-α) play an important role[37,38]. APOBEC3G might participate in this type of antiviral response. Although APOBEC3G is not normally expressed in the liver, but a recent study has shown that APOBEC3G is induced by IFN-α stimulation in human hepatocytes[39]. It is possible that it is induced by IFN in the course of HBV infection. Several studies have shown that IFNs inhibit HBV replication *in vitro* and *in vivo* in human hepatoma cells and HBV transgenic mice[40-42]. Currently, IFN-α is an approved treatment for chronic hepatitis B. We speculate that APOBEC3G might be responsible for the anti-HBV action of IFNs under hepatic inflammation. Further analyses will be necessary to determine whether APOBEC3G plays roles in the human innate defense against hepatitis viruses *in vivo*.

Our study demonstrated that APOBEC3G and its N-terminal and C-terminal cytosine deaminase domain effectively inhibited HBV replication in the culture cells and mammalian liver, showing that such an approach could be useful in the treatment of HBV infection. However, whether suppression of viral replication by APOBEC3G plays a role during natural HBV infection seems speculative at present, because expression of APOBEC3G in human liver tissue has not yet been shown. Nevertheless, a better understanding of the mechanisms of A3G action may help identify new therapeutic strategies against chronic hepatitis B.

## Abstract

**AIM:** To evaluate the pharmaceutical safety of a Chinese herbal formula, Chunggan extract (CGX), traditionally prescribed as a hepatotherapeutic drug *via* systemic acute and subacute toxicological study.

**METHODS:** Twenty male dogs and 20 female dogs were fed doses 50 times and 4 times greater than the clinically-recommended drug dosages in an acute and a subacute toxicological study, respectively. Adverse effects were examined by comparing the differences between normal and drug-administered groups using clinical signs, necropsies, histopathologic findings, haematology, urinalysis, and biochemical analysis.

**RESULTS:** In the acute study no change in the body weight, diarrhoea, apetite, mortality rate and histopathology of major organs was observed in male or female dogs with a single administration of CGX at 5 g/kg. No drug-induced abnormalities at analysis of histopathology, haematology, urinalysis, and biochemistry were found with any dose of this drug.

**CONCLUSION:** CGX is supposed to be very safe when used in a clinical application with a wide therapeutic index.

**Key words:** Hepatotherapeutics; Herbal remedy; Chunggan extract; Safety; Toxicological study

## INTRODUCTION

Worldwide use of complementary and alternative medicines, including herbal products for various health benefits, has recently increased[1,2]. Botanical compounds and medical plants have also attracted attention among drug investigators and the pharmaceutical industry. Many herbal formulae have been traditionally prescribed for patients with hepatic disorders, and researchers have recently studied many compounds from natural resources as potential hepatotherapeutic candidates[3-5].

However, many issues related to a lack of scientific evidence about the efficacy and safety of herbal remedies remain unresolved[6,7]. Many reports and warnings have been published, particularly about the potential hepatotoxicity of herbal products, because the liver is a prime target for the toxic effects of general drugs[8-10].

Chunggan extract (CGX) is a potentially hepatotherapeutic drug derived from natural herbs. It has hepatoprotective effects on alcohol-, dimethylnitrosamine (DMN)-, and D-galactosamine-induced liver injury, a therapeutic effect on chronic liver disease, and an inhibitory effect on intestinal absorption and storage of cholesterol[11-14]. However, no animal-based high-dose toxicological study has been performed in conjunction with tests to confirm the drug's safety and efficacy in the appropriate dosages.

This study applied acute and subacute toxicological tests using beagle dogs to evaluate the wide-range tolerance and safety of Chunggan extract. This report aims to provide vital information about the efficacy and safety of multi-herbal plant-derived traditional Chinese medicine.

## MATERIALS AND METHODS

### *Components of CGX and fingerprinting analysis*

The ingredients of CGX include 5 g each of Artemisia capillaris Herba, Carapax Trionycis, Semen Raphani; 3 g each

of Rhizoma Atractylodis Macrocephalae, Poria, Alismatis Rhizoma, Atractylodis Rhizoma, Salviae Miltiorrhizae Radix; 2 g each of Polyporus, Amomi Fructus, Aurantii Fructus, and 1 g of Glycyrrhizae Radix or Helenii Radix. The 10.71% (w/w) lyophilized water-extract was obtained from the initial dried mixture according to the Korean standard over-the-counter (OTC) monographs, and its high-performance thin layer chromatography (HPTLC)-based fingerprint was produced by the CAMAG application system (Muttenz, Switzerland) (Figure 1A-D). For the HPTLC analysis, water extracts of CGX, Artemisia capillaris Herba, Aurantii Fructus, Glycyrrhizae Radix, Poria cocos and their standard components, 6,7-dimethoxycoumarin (Sigma Chemical Co., St. Louis, MO, USA), Poncirin (Fluka, St. Louis, MO, USA), Glycyrrhizic acid ammonium salt (Sigma Chemical Co., St. Louis, MO, USA) and Pachyman (Megazyme Co., Wicklow, Ireland) were dissolved in HPLC-grade methanol and applied to pre-washed silica gel 60 F254 HPTLC plates (size 20 cm × 10 cm, thickness of the silica gel 0.2 mm; Merck, Darmstadt, Germany) with an automated applicator (Linomat IV; CAMAG). The samples were then separated (migration distance 80 mm) using HPLC-grade ethyl acetate/formic acid/acetic acid/water (15:1:1:2) except for Poria cocos (migration distance 70 mm, n-butanol/methanol/water as 50:25:20). The migrated components were visualized under UV radiation at 366 nm or 254 nm using Reprostar 3 with a digital camera (CAMAG). Only Poria coco was visualized under white light after derivatization with aniline-diphenylamine-phosphoric acid solution.

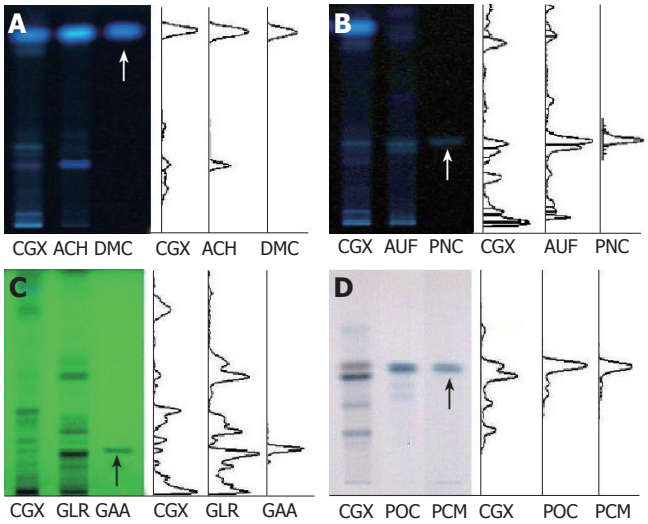

**Figure 1** High-performance thin layer chromatography method-based fingerprint for Chunggan extract. HPTLC analysis was performed to characterize CGX and its three major components (extracts from Artemisia capillaris Herba, Aurantii Fructus, Glycyrrhizae Radix and Poria cocos) with reference components, 6,7-dimethoxycoumarin, Poncirin, Glycyrrhizic acid ammonium salt and Pachyman (indicated by arrows). **A**: 2 μL of CGX (200 mg/mL) and 1 μL of the extract from Artemisia capillaris Herba (50 mg/mL) were subjected to HPTLC with 1 μL of 6,7-dimethoxycoumarin (0.1 mg/mL), then visualized under UV radiation at 366 nm; **B**: 2 μL of CGX (200 mg/mL) and 1 μL of the extract from Aurantii Fructus (50 mg/mL) were subjected to HPTLC with 1 μL of Poncirin (5 mg/mL), then visualized under UV radiation at 366 nm; **C**: 4 μL of CGX (200 mg/mL) and 4 μL of the extract from Glycyrrhizae Radix (50 mg/mL) were subjected to HPTLC with 4 μL of Glycyrrhizic acid ammonium salt (1 mg/mL), then visualized under UV radiation at 254 nm; **D**: 2 μL of CGX (40 mg/mL) and 1 μL of the extract from Poria cocos (10 mg/mL) were subjected to HPTLC with 10 μL of Pachyman (100 mg/mL), then visualized under white light after derivatization.

### *Animals*

In total, 40 beagle dogs (20 males and 20 females) were obtained from Jung-Ang Lab Inc. (Seoul, Korea). Each dog was acclimatized to conditions in kennel units (1.08 $m^2$) and was subjected to routine examination and acceptance procedures for 6 wk. Animal housing was maintained at 22 ± 3℃ with a 12-h light/dark cycle, and air was exchanged approximately 13-18 times/h. Each dog was fed 400 g/d of a standard dry diet (Gold Pet; Agribrands Purina Korea Inc., Seoul, Korea) and had free access to automatically filtered tap water that was checked using routine chemical monitoring (Korea Chemicals Inspection & Testing Institute). At the beginning of treatment, the dogs averaged approximately 5 mo of age and 8.5-11.5 kg in weight.

Prior to the experiment, a veterinarian performed an animal health review. This study complied with the Testing Guidelines of the Korea Food and Drug Administration (KFDA; notification no. 1999-61).

### *Acute toxicity*

After 12 h of fasting, two males and two females in each of four groups received oral doses (5 000, 2 500, 1 250, and zero mg/kg respectively) of CGX dissolved in distilled water through a catheter. Clinical observations were performed hourly for 6 h, after which mortality or clinical signs of toxicity were monitored daily for the following 2 wk. Body weight was measured weekly, and necropsy-gross findings were recorded on the final day.

### *Subacute toxicity*

Over 4 wk, three male and three female dogs received orally administered CGX in one of four dosages: 400, 200, 100, and zero mg/kg as a control. They were subsequently checked and measured carefully for mortality and clinical signs of toxicity (daily), body weight and food intake (weekly), ocular fundus examination, and slit lamp examination (before drug administration and 2 d before the final day). On the final day, all dogs were deprived of food, but not water, for 16 h. Urinalysis, hematologic, and various biochemical parameters of all dogs were measured using blood samples after collection via the jugular vein (before and on the final day of the experiment). After necropsy, organs (brain, hypophysis, heart, liver, spleen, kidneys, adrenal glands, prostate, testes, and ovaries) were weighed. Microscopic examination of the following organs was also done: lungs, trachea, heart, thymus, liver, kidneys, pancreas, spleen, thyroid, adrenal glands, testes, epididymes, ovaries, uterus, esophagus, stomach, duodenum, jejunum, ileum, cecum, colon, urinary bladder, aorta, brain, pituitary, prostate gland, and tongue. A histopathologist performed a complete examination of the tissue samples after they were stained with haematoxylin-eosin (H&E) following a 10% formalin fixation and embedded in paraffin wax.

### *Statistical analysis*

Distributions of body and organ weight, food intake, and

**Table 1 Summary for clinical observation and histological examination**

| CGX (mg/kg per day) | 0 | 100 | 200 | 400 |
|---|---|---|---|---|
| Mortality | - | - | - | - |
| Clinical signs | NAD | NAD | NAD | NAD |
| Anorexia | - | - | - | - |
| Soft feces | - | - | - | - |
| Food intake | NAD | NAD | NAD | NAD |
| Ophthalmologic findings | NAD | NAD | NAD | NAD |
| Relative organ weight | NS | NS | NS | NS |
| Necropsy findings | NAD | NAD | NAD | NAD |
| Histopathological findings | Rarely in some samples | Rarely in some samples | | |
| Liver | Focal necrosis | Subcutaneous necrosis | | |
| Lung | Yellow pigmentation | Yellow pigmentation | | |
| Kidney | Glomerular hyperemia | Glomerular hyperemia | | |
| Spleen | White pulp atrophy | White pulp atrophy | | |
| Stomach | *Helicobacter* | *Helicobacter* | | |

Three male and three female beagle dogs in each group were fed CGX, and the clinical symptoms including mortality were monitored for 4 wk. At the end of the experiment, ophthalmologic, necropsy-based, and histopathological examinations were performed. NAD: No abnormality detected; NS: Not significant; -: Absent.

haematological and biochemical parameters were analysed using Levene's test of equality of variance. When variance was homogenous, a one-way ANOVA was applied. Statistical differences in the means among groups were analysed using Dunnett's multiple comparison test[15,16]. When variance was not homogenous, Dunnett's *t*-test was performed. Statistical analyses were conducted using SPSS Base 10.0 (SPSS, Inc., Chicago, IL, USA).

## RESULTS

### *Acute toxicity*

After administration of CGX and distilled water (DW) as a control, all dogs exhibited decreased activity for 1 h. No clinical symptoms including diarrhoea, anorexia, or death were observed in any of the dogs during the remaining 2 wk of the experiment. Each group exhibited a normal range in weight gain (Figure 2A), and no abnormal findings were seen at necropsy in the major organs of males or female dogs treated with CGX (data not shown).

### *Subacute toxicity*

**Food consumption and body weight:** Food consumption did not appear to markedly differ in any CGX-treated group compared to the control over 4 wk (Figure 2B), although females in the CGX-treated groups consumed less food than the control group. This result may have been due to a lower body weight among females at the starting point, leading to reduced food consumption. Similarly, no groups exhibited significant gains or losses in body weight during the 4-wk experimental period (Figure 2C and D).

**Clinical signs, necropsy, and histopathological findings:** No clinical signs including anorexia or soft faeces were observed in any dogs during the 4 wk of the experiment. No tested groups exhibited any changes in ophthalmologic signs (summarised in Table 1). Macroscopic autopsy

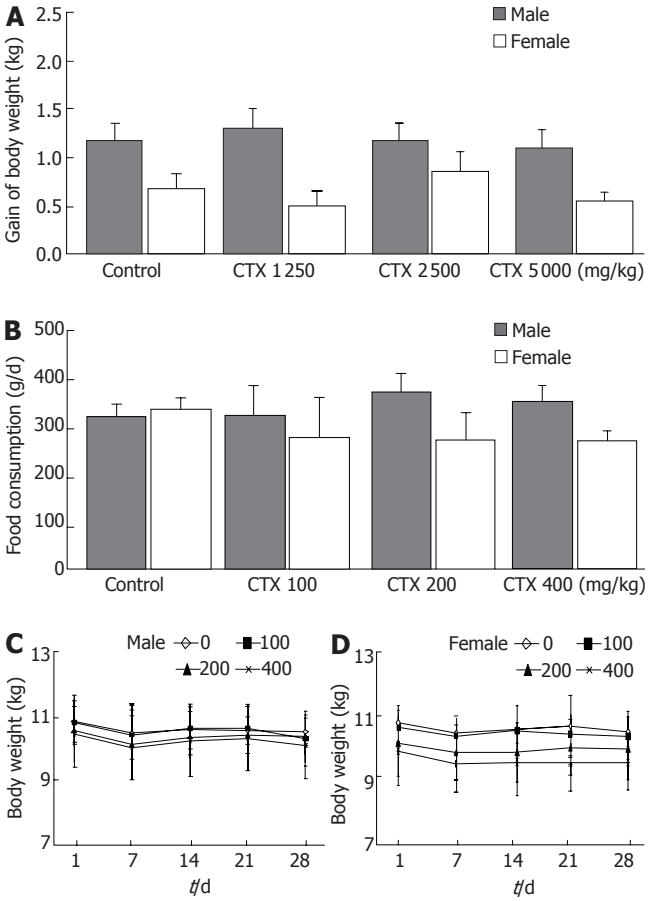

**Figure 2** Body weight and food consumption. **A**: Final gains in body weight for each group administered with indicated Chunggan extract (CGX) after 2 wk of the acute toxicity experiment ($n$ = 2 males and 2 females); **B**: Average daily food consumption for each group ($n$ = 3 males and 3 females) during the subacute toxicity experiment; **C**: Change in body weight during 4 wk of the subacute toxicological experiment, shown separately for males ($n$ = 3) and females ($n$ = 3). Values represent the mean ± SD.

examination did not reveal any pathological findings in any organs, and no significant changes to body weight ratio were found in any of the 13 tested organs of either treated or control groups: liver, kidneys, spleen, adrenals, ovaries, brain, pituitary gland, lungs, heart, thymus, thyroid, uterus, and urinary bladder (data not shown). However, microscopic examination detected rare pathological findings, such as focal necrosis with macrophage, lymphocyte, plasma cells, hyperaemia, and subcutaneous edema in livers, bronchopneumonia in lungs, glomerular hyperaemia in kidneys, white pulp atrophy in spleens, and *Helicobacter* in stomachs; similar findings were exhibited by groups treated with CGX and the control group. However, no systematic histopathological differences were observed between groups. Figure 3 presents the only observed focally pathological features in kidneys and livers between the control group and the group treated with the highest levels of CGX (400 mg/kg per day).

**Haematology and urinalysis:** Before the experiment began, tests indicated that all dogs (12 males and 12 females) had normal haematological values (data not shown). Haematology was measured again on the final day of the experiment, and results revealed a significant decrease in mean corpuscular haemoglobin concentration (MCHC)

After administration of Chunggan extract (CGX) for 4 wk, haematology was analysed to compare CGX-treated groups to the control group. MCV: Mean corpuscular volume; MCH: Mean corpuscular haemoglobin; MCHC: Mean corpuscular haemoglobin concentration; RDW: Red cell distribution width; MPV: Mean platelet volume; PT: Prothrombin time; APPT: Activated partial thromboplastin time. aindicates a significant difference at a level of $P < 0.05$.

only in male dogs treated with 100 mg/kg per day CGX compared to control dogs; 200 or 400 mg/kg per day male and all female dogs produced normal values (Table 2). No other haematological indicators revealed any significant change.

No other unusual results were revealed by urinalysis before and after administration of CGX (data not shown).

**Serum biochemistry:** The serum chemistry in all dogs (12 males and 12 females) was checked before beginning CGX administration. Another chemistry analysis was conducted on the final day. Results did not reveal any significant changes to biochemistry values between the control and CGX groups, except the BUN levels in female dogs who were administered 400 mg/kg per day CGX when compared to the control group (Table 3).

## DISCUSSION

Among the variety of complementary and alternative medicines, Asian doctors have prescribed herbal mixtures to treat various diseases according to traditional Oriental pharmacology. Since this traditional treatment is based on extensive knowledge gathered from applications of natural resources to humans, people have usually assumed that the treatment is safe. However, as Oriental remedies have been rapidly growing in popularity worldwide, researchers are paying as much attention to safety issues as to their therapeutic efficacy[17-21]. Many studies have therefore been conducted to evaluate the safety of Oriental herbal medicines or the associated risk of adverse effects[22-25].

This study applied a systemic acute and subacute toxicological examination using beagle dogs to investigate the possibility of adverse effects associated with Chunggan extract, a modified-traditional hepatotherapeutic herbal drug.

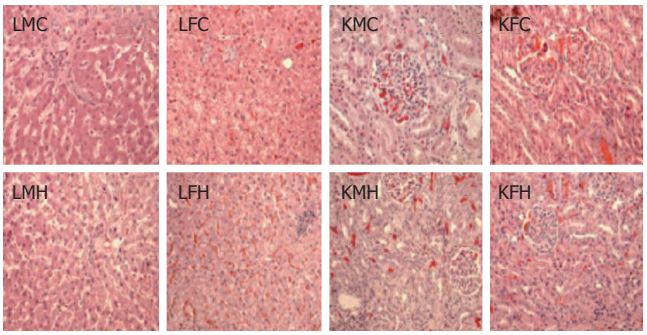

**Figure 3** Histopathological findings. On the final day of the subacute toxicological experiment, 13 main organs (indicated in the text) were removed from each dog, and microscopic examinations were carefully performed after a general H&E staining process. Livers, lungs, kidneys, spleens, and stomachs from the control and the group fed CGX revealed uniformly rare focal pathological findings. This figure presents the only pathological findings among livers and kidneys from the control and the group treated with the highest level of CGX, such as focal necrosis and hyperemia in livers, and glomerular hyperemia in kidneys (HE stain, X 200). LMC: liver from male control; LFC: liver from female control; LMH: liver from male high dose (400 mg/kg); LFH: liver from female high dose (400 mg/kg); KMC: kidney from male control; KFC: kidney from female control; KMH: kidney from male high dose (400 mg/kg); KFH: kidney from female high dose (400 mg/kg).

In clinical application, the therapeutic dosage of CGX is 100 mg/kg per day, usually divided into three daily doses. We treated dogs with 50 times the clinically recommended dosage of CGX, but observed no clinical signs of adverse effects except slightly decreased activity for 1 h in every group including the control. The decrease in activity might have resulted from the forced administration of a high volume of CGX (or water in the control group) via a catheter. Typical adverse signs of any drug include changes in appetite or faeces; even a 50-fold increase in CGX did

| Chloride (mmol/dL) | 116 ± 1.1 | 115 ± 2.5 | 115 ± 2.3 | 116 ± 0.6 | 117 ± 1.5 | 114 ± 1.5 | 114 ± 3.2 | 114 ± 1.5 |

After administration of Chunggan extract (CGX) for 4 wk, serum chemistry was analysed to compare CGX-treated groups to the control group. AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; ALP: Alkaline phosphatase; BUN: Blood urea nitrogen; AG ratio: Albumin globulin ratio; LDH: Lactate dehydrogenase; GGT: Gamma glutamyl transferase. [a]$P < 0.05$ among BUN in female grops treated with 0 mg, 100 mg, 200 mg and 400 mg CGX.

not affect appetite or faeces in any group, nor did it affect body weight changes in any group (Figure 2A). A similar pattern was exhibited over repeated CGX administration for 4 wk with dosages ranging from 100 to 400 mg/kg (Table 1). However, no dog in any group (male or female) gained body weight during the 4 wk, which may have resulted from the daily repeated stress of drug or water administration. The variations in body weight on the final day corresponded to the differences in initial body weight at the starting point (Figure 2C and D).

During the subacute toxicological study, no groups exhibited changes in clinical signs. Ophthalmologic examination, analysis of organ weights, and autopsy findings on the final day revealed dogs were free of pathologic states. Because the microscopic examination revealed that every group including the control exhibited focally pathological findings in livers, kidneys, lungs, stomachs, and spleens (Table 1, Figure 3), they were not caused by CGX administration. Furthermore, the positive results for *H pylori* in all groups might be related to statistics showing that this disease has infected 78% of dogs in Korea[26].

Haematology and chemistry analysis revealed that groups treated with CGX showed no significantly changed values except MCHC in males treated with 100 mg (41.7 ± 0.6) and BUN in females treated with 400 mg (24.4 ± 2.8), shown in Tables 2 and 3 respectively. However, the significance of these changes is doubtful since the values were within the normal range for dogs and the results did not exhibit a dose-dependent or histopathological correlation. It is important to examine potential hepatotoxicity in herbal products because therapeutic and toxic properties apply similar biological processes, especially in the liver[27]. Serum values of aspartate aminotransferase (AST), alanine aminotransferase (ALT), alkaline phosphatase (ALP), and bilirubin are among the most sensitive markers of liver damage[28]. As expected, treatment with CGX during this study resulted in normal values identical to the control group.

In conclusion, this study verifies that CGX could be safely used in a clinical application with a very large therapeutic index.

## Abstract

**AIM:** To characterize and evaluate the therapeutic efficacy of bioartificial liver (BAL) as compared to that of continuous hemodiafiltration (CHDF) with plasma exchange (PE), which is the current standard therapy for fulminant hepatic failure (FHF) in Japan.

**METHODS:** Pigs with hepatic devascularization were divided into three groups: (1) a non-treatment group (NT; $n$ = 4); (2) a BAL treatment group (BAL; $n$ = 4), (3) a PE + CHDF treatment group using 1.5 L of normal porcine plasma with CHDF (PE + CHDF, $n$ = 4). Our BAL system consisted of a hollow fiber module with 0.2 μm pores and 1 x $10^{10}$ of microcarrier-attached hepatocytes inoculated into the extra-fiber space. Each treatment was initiated 4 h after hepatic devascularization.

**RESULTS:** The pigs in the BAL and the PE + CHDF groups survived longer than those in the NT group. The elimination capacity of blood ammonia by both BAL and PE + CHDF was significantly higher than that in NT. Aromatic amino acids (AAA) were selectively eliminated by BAL, whereas both AAA and branched chain amino acids, which are beneficial for life, were eliminated by PE + CHDF. Electrolytes maintenance and acid-base balance were better in the CPE + CHDF group than that in the BAL group.

**CONCLUSION:** Our results suggest that PE + CHDF eliminate all factors regardless of benefits, whereas BAL selectively metabolizes toxic factors such as AAA. However since PE + CHDF maintain electrolytes and acid-base balance, a combination therapy of BAL plus CPE + CHDF might be more effective for FHF.

## INTRODUCTION

Fulminant hepatic failure (FHF) has been one of the most challenging problems in clinical medicine. Although plasma exchange (PE) is still a main therapeutic modality in Japan, PE was found not to affect mortality in cases of liver failure[1]. Therefore, recently the combination of continuous PE and continuous hemodiafiltration (CHDF) has been proposed, and its initial clinical results have been encouraging[2-4]. In fact, however, no studies have compared CHDF with other therapeutic modalities.

We have developed a BAL system utilizing porcine hepatocytes cultured on collagen-coated beads and reported on its efficacy[5]. Although many studies have reported the efficacy of CPE + CHDF or BAL treatment, little is known about how these two modalities compare with each other.

The purpose of the present study is to compare the therapeutic efficacy of BAL support for ischemic FHF with that of CPE + CHDF treatment in pigs. In addition, a characterization of the benefit of each treatment was attempted.

## MATERIALS AND METHODS

All study protocols were reviewed and approved by the University of Nagasaki Research Animal Resources Animal Care Committee and met both institutional and national guidelines.

### *Hepatocyte isolation*

Hepatocytes were harvested from outbred female white pigs weighing 8 to 10 kg, according to the method described by Seglen with our modification[6]. Briefly, under isoflurane anesthesia, the portal vein was cannulated with a silicon tube and the liver was perfused *in situ* with 4 L of oxygenated 2 mmol/L ethylenediaminotetraacetic acid

(EDTA) solution at the rate of 400 mL/min at 37℃. Immediately after the perfusion, the liver was removed and placed in a sterile basin. Ten minutes later, the EDTA solution was replaced with a $Ca^{2+}$-enriched Leffert's buffer solution containing 0.05% type P collagenase (Sigma Chemical Co. St. Louis, MO). The solution was re-circulated through the liver in the basin at a rate of 400 mL/min for 20 min under a clean air-filtered hood. After the collagenase perfusion, the digested liver was manually disrupted in cold DMEM (Nissui Pharmaceutical, Tokyo, Japan) containing 10% heat-inactivated fetal calf serum (FCS, Pharmacia LKB Biotechnology, Piscataway, NJ) and 1% penicillin-streptomycin (Life Technologies, Grand Island, NY). The crude liver cells were filtered through a Mesh Filtration Unit (mesh space, 105 μm; Spectrum, Laguna Hills, CA), and the enriched fractions of the hepatocytes were separated by low-speed centrifugation (at 50 g for 2 min, at 4℃). Centrifugation was performed three times. The initial viability of the hepatocytes was determined using the trypan blue dye exclusion test.

### Preparation of the bioreactor

Isolated hepatocytes with a viability of better than 90% and collagen coated dextran microcarrier beads (Cytodex 3, Pharmacia LKB Biotechnology, Piscataway, NJ) were incubated with DMEM with 10% FCS in a cell culture bag (Si culture bag, Wako, Tokyo, Japan) for 4 h at 95% air and 5% $CO_2$ at 37℃. After washing with normal saline, ten billion microcarrier-induced hepatocytes were inoculated into the extra-fiber space (185 mL) of the hollow fiber module with 0.8 $m^2$ of total external fiber surface (Plasmaflo OP-08, Asahi Medical, Tokyo, Japan). The hollow fibers were made from polyethylene materials with an internal diameter of 340 mm, a pore size of 0.2 μm, and membrane thickness of 50 μm.

### Animal model of fulminant hepatic failure

Under general anesthesia with mechanical ventilation via an endotracheal tube, pigs (weighing 27 to 30 kg) underwent hepatic devascularization consisting of dissection of the biliary tract, hepatic arteries, and ligaments after creation of an end-to-side portocaval shunt according to the method described by Mazziotti *et al*[7]. This model was reported to reproduce the many pictures of FHF including, encephalopathy, coagulopathy and brain edema. A femoral artery was cannulated for sampling blood and monitoring blood pressure. A jugular vein was also cannulated with a double lumen catheter for blood access. The volume of the replacement fluid was adjusted over the range of 3-6 L, with 5% dextrose lactate Ringer solution depending on the response of the FHF pigs.

### Circulation system of BAL

The BAL system consisted of a hollow fiber module inoculated with microcarrier-attached porcine hepatocytes, a plasmapheresis unit (Plasauto 2500 and Plasmaflo OP-2, Asahi Medical, Tokyo, Japan), a roller pump, and a plasma reservoir (Figure 1). The system was oxygenated and warmed at 37℃ using a membrane-type oxygenator. Whole blood was removed at a rate of 35-45 mL/min from the jugular vein and was separated to plasma at a rate of 15 mL/min. The separated plasma was perfused through the bioreactor at a rate of 400 mL/min and was recirculated through the whole system with the transmission reservoir (Figure 1).

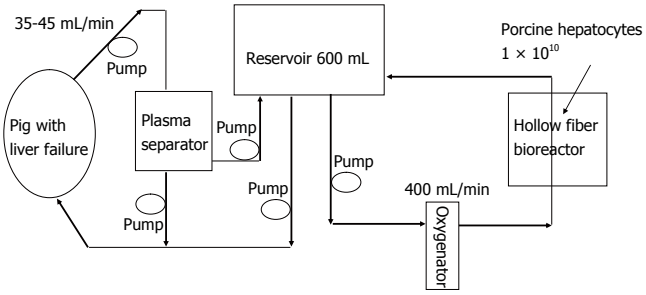

**Figure 1** Schematic drawing of our bioartificial liver (BAL) system. It consists of 1 × $10^{10}$ cultured allogeneic hepatocytes in the outer space of a hollow fiber.

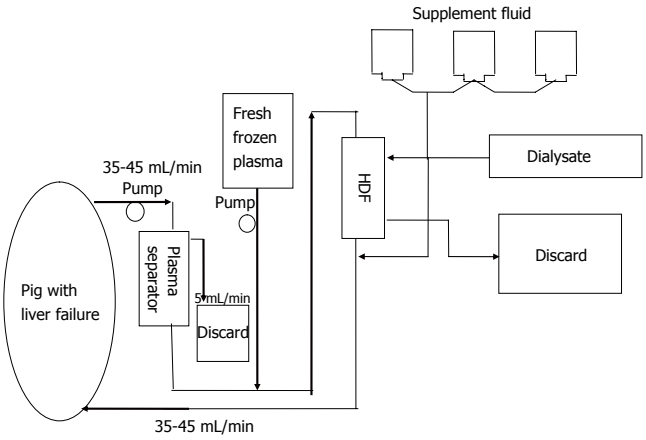

**Figure 2** Schematic drawing of continuous plasma exchange (CPE) with allogeneic plasma and continuous hemodiafiltration system (CHDF).

### Circulation system of PE + CHDF

The PE + CHDF system consisted of the plasmapheresis unit mentioned above, a high performance hemodiafiltration unit (Panflo, APF-03S, Asahi Medical,Tokyo, Japan) and three roller pumps (Figure 2). In this system, the apparatuses were connected in a series. PE + CHDF was performed for 6 h. An average of 1.5 L fresh porcine frozen plasma was used during PE treatment. Dialysis was performed concomitantly at a flow rate of 50 mL/min using a dialysis fluid containing bicarbonate buffer (Sublood B; Fuso Pharmaceutical, Tokyo, Japan).

### Experimental design

Animals undergoing hepatic devascularization were divided into three groups as follows: a non-treatment group (NT; only plasma separation, $n$ = 4), a BAL treatment group (BAL; $n$ = 4), and a CPE + CHDF treatment group (CPE + CHDF; $n$ = 4). The BAL or CPE + CHDF treatments were initiated at 4 h after completion of hepatic devascularization. The pigs in both the BAL and CPE + CHDF groups were treated for 6 h and were given 800 U/h of heparin as an anticoagulant. After 6 h BAL or CPE + CHDF was stopped and the pigs were observed until their death.

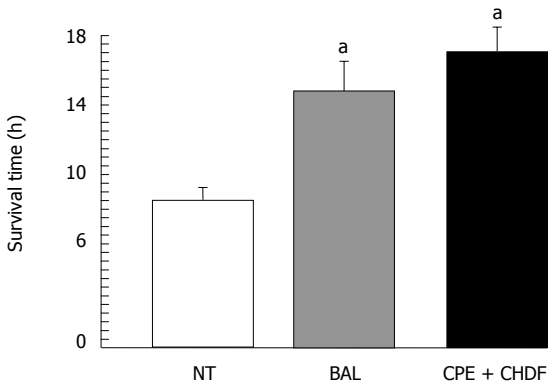

**Figure 3** Survival after induction of hepatic failure. $^{a}P < 0.05$ *vs* NT group.

### *Assessments*

Conventional liver function tests including aspartate aminotransferase (AST) and alanine aminotransferase (ALT), the plasma levels of branched chain amino acids (BCAA), aromatic amino acids (AAA), the ratios of the BCAA to the AAA (Fischer's ratio) after each treatment, and the changes in plasma ammonia were determined. Plasma levels of electrolytes, blood urea nitrogen (BUN), creatinine, and pH were measured. Survival time was also observed.

### *Statistical analysis*

Data were expressed as mean ± SD, and were analyzed statistically using a non-parametric test. $P < 0.05$ was considered to indicate a significant difference.

## RESULTS

### *Survival*

Although the pigs in the BAL and the CPE + CHDF groups survived significantly longer than those in the NT groups, there were no significant differences between the BAL group and the CPE + CHDF group (Figure 3; control: 10.3 ± 1.1 h; BAL: 18.0 ± 1.3 h; CPE + CHDF: 19.2 ± 0.7 h).

### *Liver functions*

Plasma levels of AST and ALT showed no significant differences among the three experimental groups. The Fischer's ratio was highest in the BAL group (NT: 0.8 ± 0.1; BAL: 1.5 ± 0.3; CPE + CHDF: 1.1 ± 0.2). In the NT group, plasma levels of both AAA and BCAA increased gradually during the treatments. In the BAL groups, whereas AAA levels in plasma decreased significantly, BCAA levels remained unchanged. In contrast, in the CPE + CHDF group, both AAA and BCAA levels in plasma decreased during the treatments (Figure 4).

The elimination capacity of ammonia in both the BAL and CPE + CHDF groups was significantly higher than that in the NT group, but there were no significant differences between the BAL and CPE + CHDF groups (Figure 5).

### *Electrolytes and pH*

As for electrolyte status, serum potassium level increased with time in both the NT and BAL group. In the CPE + CHDF group, the increase in potassium level was kept within the normal range (Figure 6). As for acid-base balance acidosis deteriorated with time in the NT and BAL group but was rather maintained in the CPE + CHDF group (Figure 6). Although the same pattern among the three groups was also seen, there were no statistical differences between the groups.

## DISCUSSION

Although most nonbiological or biological liver support systems rely on blood detoxification, the removal of medium-sized molecules, which cause hepatic coma, does not improve the survival rate of patients with severe encephalopathy[1]. This implies that the replacement of biotransformation and of liver synthetic functions is also needed in order to maintain life. At present, only intact hepatocytes seem to be able to achieve it[8-10].

In this experiment, the most striking findings for BAL were its effects on changes in plasma ammonia and on amino acids. The elimination capacity of plasma ammonia in BAL and CPE + CHDF was significantly higher than that in NT, although there were no significant differences between BAL and CPE + CHDF. These results indicated that hepatocytes in BAL functioned well and that its ammonia elimination capacity was not inferior to that of the CPE + CHDF treatment. The improvement of Fischer's ratio in BAL treatment was attributable to the decrease in AAA, which is one of the toxic substances in hepatic failure and which is metabolized by intact hepatocytes[11]. It is noteworthy that AAA was selectively eliminated in BAL, whereas both AAA and BCAA, which are beneficial amino acids, were eliminated in CPE + CHDF. This implies that CPE + CHDF eliminated all factors regardless of toxicity or necessity, whereas BAL selectively metabolized toxic factors such as AAA in the blood. To the best of our knowledge, the present results are the first to report the characteristics of two different liver support systems *in vivo*.

However, as for the maintenance of acid-base balance and electrolytes, CPE + CHDF was superior to BAL. That is, in the model of FHF in pigs, CPE + CHDF outperformed BAL in the maintenance of general status such as acid-base balance and electrolytes abnormalities. In addition, although there were no significant differences between these two groups, the pigs in the CPE + CHDF group survived slightly longer than those in the BAL group. We attributed this to better renal functions and maintenance of acid-base balance in the CPE + CHDF group.

Also, it was possible that CPE + CHDF removed all growth factors that might be needed for a diseased liver to regenerate. This kind of nonselective removal of the indispensable factors has been reported previously by researchers, including ourselves[12]. We showed that, in the rat model undergoing partial hepatectomy, blood exchange therapy reduced the serum level of hepatocyte growth factor significantly, resulting in better liver regeneration with a PCNA labeling index. In this sense, BAL might be valuable in light of its bio-transforming activity, which does not remove all factors needed.

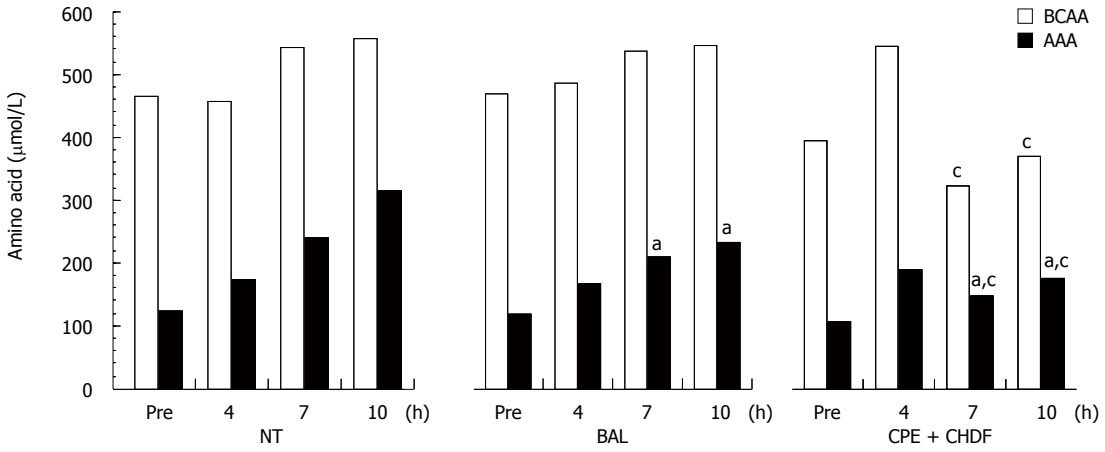

**Figure 4** Time transition of the levels of amino acid after induction of acute liver failure in (**A**) NT group, (**B**) BAL group and (**C**) CPE+CHDF group. $^{a}P < 0.05$ *vs* NT group, $^{c}P < 0.05$ *vs* NT group and BAL group.

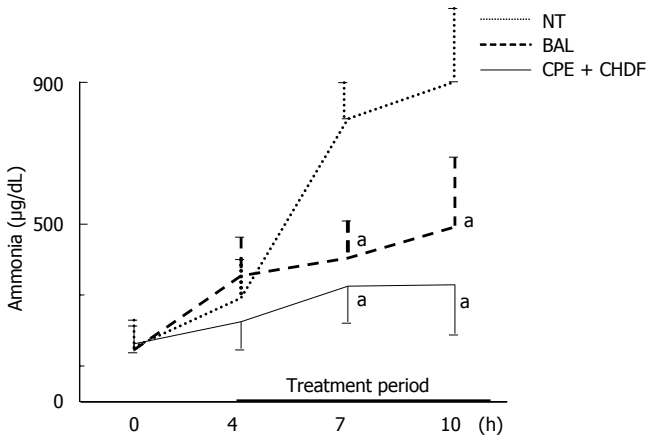

**Figure 5** Time transition of the levels of ammonia in the blood after induction of acute liver failure. $^{a}P < 0.05$ *vs* NT group.

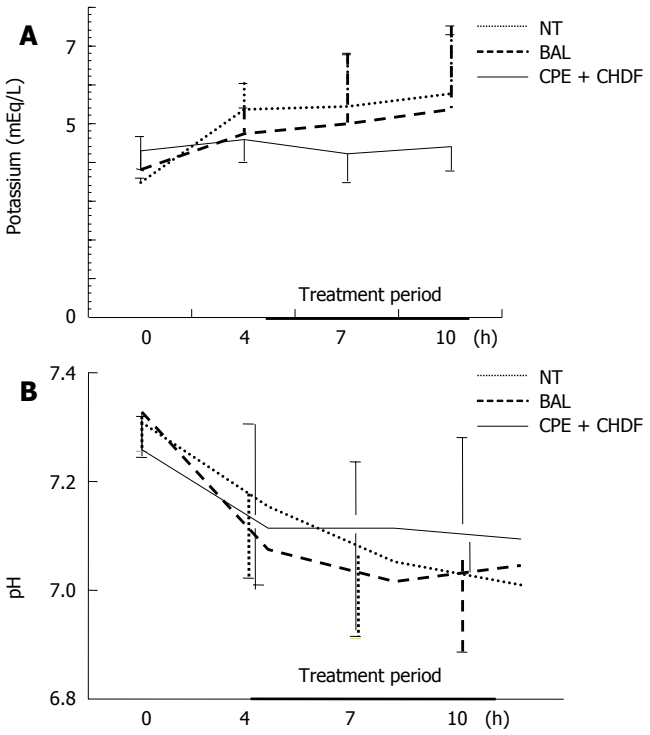

**Figure 6** Time transition of the serum levels of (**A**) potassium and (**B**) pH after induction of acute liver failure.

As to survival time, we did not find the difference between the BAL and CPE + CHDF, although both treatments prolonged the survival of pigs with ischemic liver. Therefore, it would be possible to use other models of liver failure such as the one recently published, since our model of liver failure was too aggressive with no chance of spontaneous liver regeneration[13].

In conclusion, we have compared the BAL and CPE + CHDF treatments, especially concerning their elimination capacity. We expect that the combination of BAL and CPE + CHDF would serve as an effective bridging therapy to liver transplantation or liver regeneration in patients with liver failure.

## Abstract

**AIM:** To explore the effects of ultrasound exposure combined with microbubble contrast agent (SonoVue) on the permeability of the cellular membrane and on the expression of plasmid DNA encoding enhanced green fluorescent protein (pEGFP) transfer into human umbilical vein endothelial cells (HUVECs).

**METHODS:** HUVECs with fluorescein isothiocyanate-dextran (FD500) and HUVECs with pEGFP were exposed to continuous wave (1.9 MHz, 80.0 mW/cm$^2$) for 5 min, with or without a SonoVue. The percentage of FD500 taken by the HUVECs and the transient expression rate of pEGFP in the HUVECs were examined by fluorescence microscopy and flow cytometry, respectively.

**RESULTS:** The percentage of FD500-positive HUVECs in the group of ultrasound exposure combined with SonoVue was significantly higher than that of the group of ultrasound exposure alone (24.0% ± 5.5% *vs* 66.6% ± 4.1%, $P < 0.001$). Compared with the group of ultrasound exposure alone, the transfection expression rate of pEGFP in HUVECs was markedly increased with the addition of SonoVue (16.1% ± 1.9% *vs* 1.5% ± 0.2%, $P < 0.001$). No statistical significant difference was observed in the HUVECs survival rates between the ultrasound group with and without the addition of SonoVue (94.1% ± 2.3% *vs* 91.1% ± 4.1%).

**CONCLUSION:** The cell membrane permeability of HUVECs and the transfection efficiency of pEGFP into HUVECs exposed to ultrasound are significantly increased after addition of an ultrasound contrast agent without obvious damage to the survival of HUVECs. This non-invasive gene transfer method may be a useful tool for clinical gene therapy of hepatic tumors.

**Key words:** Microbubble; Ultrasound; Gene transfer; Human umbilical vein endothelial cell; Enhanced green fluorescent protein

## INTRODUCTION

Tumor angiogenesis plays a critical role in the development and progression of hepatocellular carcinoma (HCC)[1]. The emerging success of anti-angiogenic therapy for other cancers, such as colorectal cancer[2,3] and lung cancer[4], suggests that it may be useful for HCC because of its hyper-vascularity. To the best of our knowledge, the delivery method targeting the vascular endothelial cells of HCC has not been used in gene therapy as yet. As an effective strategy, gene therapy is largely dependent on the development of a vector or vehicle that can selectively and efficiently deliver a gene to cells or target tissues with minimal toxicity. There has been a great deal of attention paid to the development of different gene carriers to more effectively deliver DNA[5]. In addition to naked DNA, both viral (e.g., adenovirus) and non-viral (e.g., liposome) vectors have been used[6,7]. DNA may also be incorporated into nanospheres with biopolymers, such as chitosan and gelatin[8]. Ultrasound exposure has been proven to permeabilize plasma membranes[9] and reduce the thickness of the unstirred layer at the cell surface[10] because of the remarkable ability of ultrasound to produce cavitation activity[11]. Cavitation is the interaction between an ultrasonic field in a liquid and gaseous inclusion (i.e., microbubbles) within the insonated medium, which disrupts the structure of the carrier vesicle and releases the drug and also makes the cell membranes and capillaries more permeable to drugs. Cavitating gas bodies, such as microbubbles, are the mediators through which the energy of relatively non-interactive pressure waves is concentrated

to produce forces that permeabilize cell membranes and disrupt the vesicles that carry the gene[12,13]. SonoVue, as a microbubble contrast agent, associated with the gene on the surface, under ultrasound exposure, can lower the threshold for cavitation by acting as a cavitation nucleus and boosts the cavitation which alters cell membrane permeability without significantly affecting cell viability in biological tissue[10], which can be used to enhance gene transfer even further. In this study, we attempted to evaluate the effect of microbubble-enhanced ultrasound exposure in improving the transfection of enhanced pEGFP into HUVECs. The aims of the study were to elucidate the mechanism of microbubble-enhanced transfection and to construct a novel gene therapy that might be used to treat HCC.

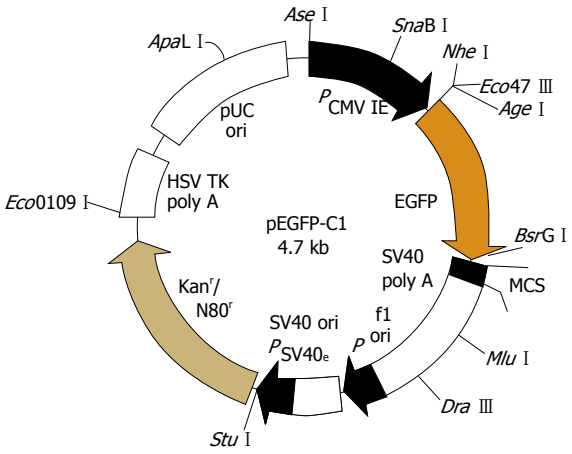

**Figure 1** Map of pEGFP-C1, showing the restriction sites.

## MATERIALS AND METHODS

### Cell culture

Primary human umbilical vein endothelial cells (HUVECs), separated with 0.2% collagenase (Sigma, St. Louis, MO, USA) from newborn aseptic umbilical cords after abdominal delivery from the healthy pregnant women who had normal routine urinalysis and blood tests (women with any complications of pregnancy or viral infections were excluded), were maintained in Human Endothelial-SFM (Gibco, California, USA) supplemented with 100 mL/L fetal bovine serum (Gibco), 2 ng/mL vascular endothelial cell growth factor (Sigma), 90 μg/mL heparin (Sigma), 100 U/mL penicillin and 50 μg/mL streptomycin. HUVECs were cultured in a 50 ml/L $CO_2$ incubator at 37℃[14], and the cellular viability was determined by counting the cells stained with trypan blue (Sangon Biological Engineering technology, Shanghai, China). The HUVECs were identified by detecting rabbit anti-human von Willebrand factor (Boshide Company, Wuhan, China), as well as by performing the acetylated low-density lipoprotein color reagent test (DiI-Ac-LDL) (Molecular Probes, Novato, Canada, Europe BV). Further experiments were performed only when the purity of the HUVECs was above 95%.

### Preparation of microbubble contrast agent and plasmid DNA

The microbubble-based ultrasound contrast agent SonoVue™ (Bracco SpA, Milan, Italy) was used in this study, which consists of 59 mg of sulfur hexafluoride gas (SF6) and 25 mg of a freeze-dried white powder. After adding 5 mL of normal saline into the vial and then shaking for several seconds, phospholipid-stabilized microbubbles filled with sulfur hexafluoride with a diameter of less than 8 μm (mean, 2.5 μm) were generated[15,16].

The EGFP plasmid DNA (donated by Doctor Zhangge, Laboratory of Molecular Medicine, Sun Yat-Sen University, China) was prepared with a special reagent (E.ZN.A Plasmid Miniprep Kit Ⅱ, Omega Bio-tek Company, Doraville, GA, USA). The purity of extract EGFP plasmid DNA was more than adequate given that the value of 260 was 1.8 as measured on ultraviolet spectrophotometry (DU800, BeckMan, Miami, USA). EGFP plasmid DNA was identified by enzyme digestive (*Sal* Ⅰ or *Xho* Ⅰ) and subsequent electrophoresis. The map of pEGFP was analyzed (Figure 1), two restriction sites *Sal* Ⅰ and *Xho* Ⅰ were included which proved that the obtained plasmid was EGFP.

### Analysis of cell membrane permeability

HUVECs were counted and resuspended in 24-well plates at a density of $1.5 \times 10^5$ cells/well. Fifty microliters of FD500 (25 mg/mL, Sigma, St. Louis, MO, USA) was added to the 24-well plates. The 24-well plates were randomly assigned into four groups, each consisting of six samples: group A (control group), sham-exposure to ultrasound without addition of SonoVue; group B, sham-exposure to ultrasound with the addition of SonoVue (600 μg/well); group C, exposure to ultrasound without addition of SonoVue; and group D, exposure to ultrasound with the addition of SonoVue (600 μg/well). Ultrasound was delivered using an HP-Viewpoint 2500 scanner (Hewlett-Packard Company, NY, USA). An E94K213 transcranial vector transducer (12 mm in diameter) with transmission gel (thickness, 10 mm) was placed on polyester film (thickness, 6 μm) that covered the 24-well plate, and the cells were exposed to 1.9 MHz continuous ultrasound at an 80.0 mW/cm$^2$ output intensity for 5 min (Figure 2). The cells were incubated for another 4 h. Subsequently, a flow cytometer (Elite, Beckman-Coulter, Miami, USA) was used to detect the percentage of FD500-positive cells in 5 wells from each group (10 000 cells in each well were detected). The other wells from each group were observed for fluorescent staining of HUVECs under the fluorescent microscope (Leica, Danaher Corporation, Wetzlar, Germany).

### Detection of gene transfection efficiency

HUVECs, at a density of $1.5 \times 10^5$ cells/well, were resuspended in 24-well plates, and 15.0 μg of pEGFP (280 μg/mL) was added to the 24-well plates. The total amount in each well was approximately 300 μL. The mixture of the HUVECs and pEGFP was incubated for 20 min at 37℃. The 24-well plates were divided into 4 groups, each consisting of 6 samples: group A, no ultrasound exposure and no SonoVue; group B, SonoVue (600 μg/well) only;

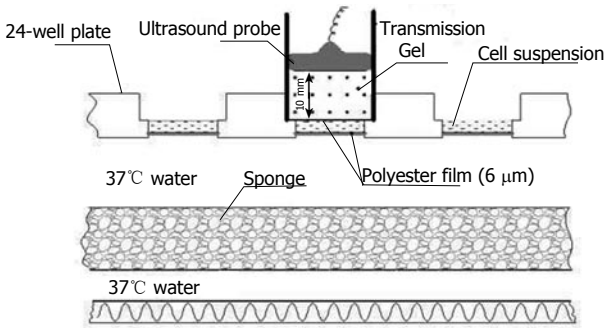

**Figure 2** Experimental setup for the ultrasound exposure. Ultrasound probe with transmission gel was placed on the cell suspension covered with polyester film, a 24-well plate covered by a 6-μm polyester film was kept in a water bath at 37℃, and also a sponge mat was placed in the water bath.

group C, ultrasound exposure only; and group D, both SonoVue (600 μg/well) and ultrasound exposure. The cells were exposed to 1.9-MHz of continuous waves at an 80.0 mW/cm$^2$ output intensity for 5 min. The cell viability was tested immediately with trypan blue after the exposure was completed. The cell suspensions were harvested from the wells, separated by centrifugation, and resuspended in medium. After 48-h culture, the pEGFP transfection efficiency was detected with fluorescent microscopy and flow cytometry.

### *Statistical analysis*

Data were expressed as mean ± SD. ANOVA was used to analyze the differences among the different groups. $P < 0.05$ was considered statistically significant.

## RESULTS

### *Examination of FD500-positive HUVECs*

Samples were evaluated with fluorescent microscopy and flow cytometry. Faint fluorescent staining in the cytoplasm was observed in few HUVECs in group A (control group) and group B (stimulated by SonoVue only). A few dispersed fluorescent-stained HUVECs were observed in group C (stimulated by ultrasound only), whereas an increased number and high concentration of fluorescent-stained HUVECs were detected in group D (stimulated by both ultrasound and SonoVue) (Figure 3). The percentages of FD500-positive HUVECs detected by flow cytometry are presented in Table 1.

### *Expression of EGFP in HUVECs*

In group D (stimulated by both SonoVue and ultrasound exposure), fluorescent microscopy revealed that the HUVECs transfected by the EGFP gene had an obviously green fluorescence in the cytoplasm, while the cells in other groups had almost no coloration (Figure 4). Flow cytometry showed that HUVECs with ultrasound exposure only barely expressed EGFP, whereas a little more than 16% of HUVECs with both ultrasound exposure and SonoVue expressed EGFP (Figure 5).

### *Cell survival rate*

The percentage of surviving cells was examined by trypan

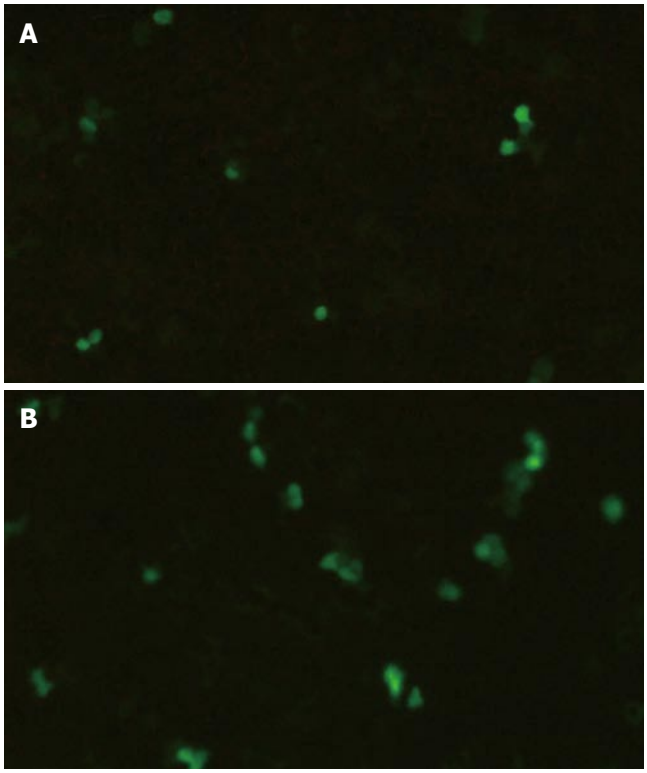

**Figure 3** Fluorescent microscopy showing FD500-positive HUVECs (200 ×). **(A)** A few FD500-positive HUVECs with ultrasound only; **(B)** significant increase in FD500-positive HUVECs after the addition of SonoVue.

**Table 1 The percentage of FD500-positive HUVECs**

| | Percentage of positive cells | Fluorescence intensity |
|---|---|---|

## DISCUSSION

Gene therapy has made significant progress in the therapy of liver neoplasms[17]. Hepatocellular carcinoma (HCC) is a typical malignancy characterized by neovascularization. Recent studies have shown that the angiogenic activity in HCC is correlated with metastasis and tumor recurrence after resection[18,19]. Angiogenesis provides a target for therapeutic approaches to HCC and may show clinical potential.

The success of gene therapy is largely dependent on the development of the gene delivery vector which is safe, easy to apply and give efficient transgene expression. DNA molecules are large, negatively charged molecules and have major difficulties in entering the cell or cell nucleus. DNA

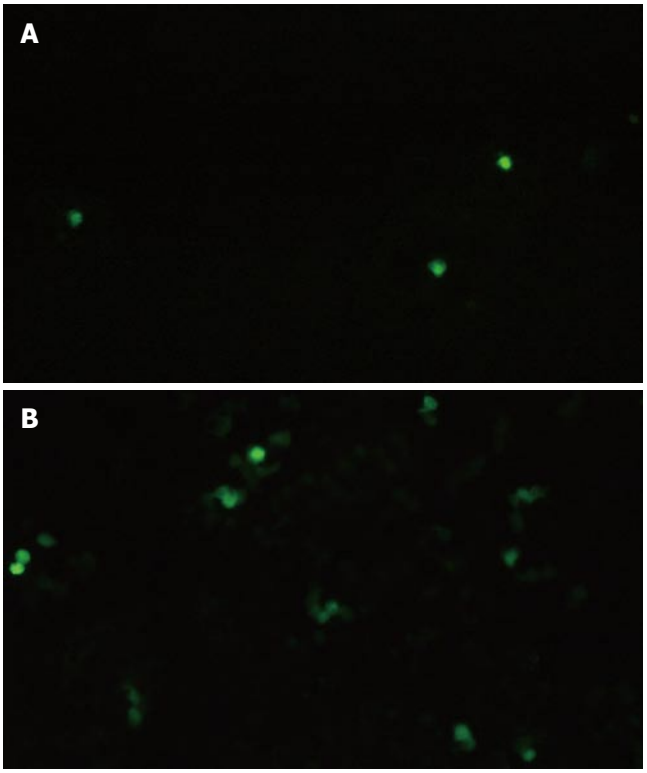

**Figure 4** Fluorescent microscopy after EGFP gene transfection (200 ×). (**A**) EGFP expression 48 h after ultrasound exposure only; (**B**) significant increase in EGFP expression in HUVECs 48 h after the addition of SonoVue.

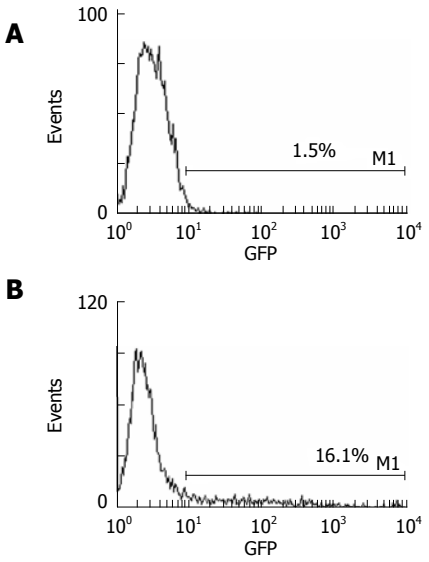

**Figure 5** Detection of EGFP gene transfection by flow cytometry. (**A**) Cells exposed to ultrasound only showed 1.5% of HUVECs within $M_1$ area; (**B**) cells exposed to both the ultrasound and SonoVue showed 16.1% of HUVECs within $M_1$ area.

becomes rapidly degraded by extra- and intra-cellular nucleases[20]. Therefore, suitable DNA delivery systems are under development. Viral vectors have been developed as highly efficient carriers for gene delivery to a variety of tissues; the efficiency of these vectors is due to the presence of viral proteins that interact with cell surface receptors. However, viral gene carriers have some major disadvantages: they often provoke an immune response and severe inflammation reactions. Additionally, the risk for insertional mutagenesis and the size

Limitations of the DNA that they can accommodate are other drawbacks of viral gene carriers[21]. Therefore, non-viral transfection systems based on cationic lipids or cationic polymers have gained more and more attention[22]. Although non-viral carriers may be safer and cheaper, they have, especially *in vivo*, a much lower transfection efficiency than viral gene carriers. To overcome the limitations of non-viral gene therapy, ultrasound energy, alone or in combination with gas-filled microbubbles, has recently been proposed to enhance the intracellular delivery of DNA, RNA, and proteins[23,24].

Microbubbles and ultrasound have been investigated with a view to improve the transfection efficiency of non-viral delivery systems. Ultrasound can create transient non-lethal perforations in cells and other membranes, which allow large molecules from the surrounding medium to enter into the cell, without remarkable damage so that the cell can reseal its membrane and survive[25,26]. Microbubbles, by acting as cavitation nuclei, applied in combination with the use of ultrasound, are thought to potentiate this effect, particularly effectively for gene delivery[27]. FD500 is the conjugate of fluorescein FITC and dextran with a molecular weight of 500 000, which makes it difficult for FD500 to penetrate the cellular membrane under normal conditions. In this study, HUVECs containing FD500 were treated with ultrasound alone and ultrasound with SonoVue, and the results showed that ultrasound exposure alone induced FD500 (24.0%) into HUVECs, as detected by flow cytometry, and the FD500-positive HUVECs increased to 66.6% after addition of SonoVue. Under ultrasound exposure, microbubbles suspended in liquid can be collapsed intentionally by insonation, and this collapse creates a mechanical force on the cell membrane and destroys the integrity of the adjoining cellular membrane.

Based on the aforementioned findings, we chose the pEGFP to examine the feasibility of gene transfer. GFP, as a report molecule, is used for detecting cytogene expression and protein location. EGFP is the optimized mutant of GFP; the fluorescence it emits is brighter and more sensitive than GFP[28]. The expression of plasmid

EGFP in HUVECs was just 1.5% in the group exposed to the ultrasound only, whereas the expression rate significantly increased to 16.1% ($P < 0.001$) when SonoVue was added, as detected by flow cytometry. The increase in transfection efficiency might be due to the transient holes that are produced in the cell membrane by the spreading of microbubbles. Several studies have reported that gas-body-based contrast agents enhance the non-thermal effects of ultrasound that induce cell membrane porosity[29]. SonoVue seemed to be rapidly destroyed by the sonication, which implies that most of the effects seen were not caused by any direct effect of SonoVue, but by ultrasonic-induced cavitation, which is used to mediate the transfection of the exogenous gene[30]. In the group with the addition of SonoVue only, there was no expression of plasmid EGFP in HUVECs. Compared to the cells treated with ultrasound alone, the addition of SonoVue did not significantly affect cell viability; more than 85% of the cells were viable.

In conclusion, our study demonstrates that ultrasound exposure combined with microbubble significantly improves the transfection efficiency of pEGFP in HUVECs, and the mechanism is based on the enhanced cellular membrane permeability caused by acoustic cavitation with no adverse effect on cellular viability. This method can be used as a new strategy for target gene therapy of HCC.

## ACKNOWLEDGMENTS

We thank Dr. Ge Zhang for providing the pEGFP.

## COMMENTS

### *Background*

It has been shown that ultrasonic waves may increase cell membrane permeability by inducing transient holes in the membrane and facilitate thereby the transfer of DNA into cells and ultrasound-mediated gene transfer is principally due to acoustic cavitation.

### *Research frontiers*

Ultrasound-mediated gene transfer can be further enhanced in the presence of microbubble contrast agents.

### *Innovations and breakthroughs*

Tumor angiogenesis plays a critical role in the development and progression of HCC, which is associated with a high propensity for vascular invasion. We attempted to evaluate the effect of microbubble-enhanced ultrasound exposure in improving the transfection of enhanced pEGFP into HUVECs.

### *Applications*

The gene therapy method of Microbubble¬-enhanced Ultrasound Exposure on targeting the vascular endothelial cells of HCC has not been used. The aims of the study was to elucidate the mechanism of microbubble-enhanced transfection and to construct a novel gene therapy that might be used to treat HCC.

### *Peer review*

HUVECs: Human umbilical vein endothelial cells; pEGFP: plasmid DNA encoding enhanced green fluorescent protein.

## Abstract

**AIM:** To study the cellular immune response during rat liver regeneration (LR) at a transcriptional level.

**METHODS:** Genes associated with the cellular immune response were obtained by collecting the data from databases and retrieving articles. Gene expression changes during LR were detected by rat genome 230 2.0 array.

**RESULTS:** A total of 127 genes were found to be associated with LR. The number of initially and totally expressing genes in the initial phase of LR [0.5-4 h after partial hepatectomy (PH)], transition from $G_0$-$G_1$ (4-6 h after PH), cell proliferation (6-66 h after PH), cell differentiation and structure-function reconstruction (66-168 h after PH) was 54, 11, 34, 3 and 54, 49, 70, 49 respectively, illustrating that the associated genes were mainly triggered at the initiation of LR, and worked at different phases. According to their expression similarity, these genes were classified into 41 up-regulated, 21 predominantly up-regulated, 41 down-regulated, 14 predominantly down-regulated, 10 similarly up-regulated and down-regulated genes, respectively. The total up- and down-regulated expression times were 419 and 274, respectively, demonstrating that the expression of most genes was increased while the expression of a small number of genes was decreased. Their time relevance was classified into 14 groups, showing that the cellular physiological and biochemical activities were staggered during LR. According to the gene expression patterns, they were classified into 21 types, showing the activities were diverse and complicated during LR.

**CONCLUSION:** Antigen processing and presentation are enhanced mainly in the forepart, prophase and anaphase of LR. T-cell activation and antigen elimination are enhanced mainly in the forepart and prophase of LR. A total of 127 genes associated with LR play an important role in cellular immunity.

**Key words:** Partial hepatectomy; Rat genome 230 2.0 array; Cellular immune response; Genes associated with liver regeneration

## INTRODUCTION

After antigenic stimulus, antigens are processed and presented to lymphocytes by antigen-presenting cells, and lymphocytes are activated[1] to proliferate and differentiate into effector cells that eliminate antigens[2]. This process is called immune response which is the self-protective mechanism of organisms developed during a long evolutionary history, closely associated with high animal survival[3]. Usually, the immunoreactions are classified into cellular and humoral immune responses according to different effectors[4]. The cellular immune response performs in brief as following: firstly the antigens were specifically recognized and presented by T-cells[5], then the effector cells, including T-cells, macrophages *etc.*, work by clearing the antigens. Injured cells and cell remnants caused by partial hepatectomy (PH)[6] are harmful to the organism[7], and wound areas are also susceptible to infection with antigen and xenobiotics[8]. Whether the cellular immune system plays a part in this process is worthy of an in-depth study.

In addition, PH[9] also activates the remnant hepatocytes to enter into the cell cycle to compensate for the lost liver mass, which is called liver regeneration (LR)[10]. Usually, based on the cellular physiological activities, the process

is classified into 4 phases: initiation (0.5-4 h after PH), transition from $G_0$ to $G_1$ (4-6 h after PH), cell proliferation (6-66 h after PH), cell differentiation and structure-function reorganization (66-168 h after PH)[11]. According to a time course, it is divided into 4 phases: forepart (0.5-4 h after PH), prophase (6-12 h after PH), metaphase (16-66 h after PH), and anaphase (72-168 h after PH)[12], in which many physiological and biochemical events, such as cell activation, de-differentiation, proliferation and its regulation, re-differentiation, reorganization of structure-function[13], are involved and regulated by many factors such as cellular immune response[14]. The relevance between cellular immune and liver regeneration has been studied at the transcriptional level[12,15,16]. The expression changes of genes in regenerating liver after PH can be detected by rat genome 230 2.0 array[17,18] containing 213 genes participating in the cellular immune response. A total of 127 genes have been identified to be associated with LR[19]. Their expression changes, patterns and action were primarily analyzed in the present study.

## MATERIALS AND METHODS

### Regenerating liver preparation

Healthy SD rats weighing 200-250 g were obtained from the Animal Center of Henan Normal University. The rats were randomly divided into groups, 6 rats in each group (male: female = 1:1). PH was performed as previously described[9], the left and middle lobes of liver were removed. The rats were killed by cervical vertebra dislocation at 0.5, 1, 2, 4, 6, 8, 12, 16, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 96, 120, 144 and 168 h after PH and the regenerating livers were observed at corresponding time points. The livers were rinsed 3 times in PBS at 4℃, 100-200 mg was taken from the middle parts of the right lobe. Six samples were collected from each group, mixed into 1-2 g (0.1-0.2 g × 6) liver tissue, and stored at -80℃. The sham-operation (SO) groups underwent the same PH without removal of liver lobes. The animal protection laws of China were strictly followed.

### RNA isolation and purification

Total RNA was isolated from frozen livers according to the manual of the Trizol kit (Invittrogen)[22] and purified the guide for the RNeasy mini kit (Qiagen)[21]. Agarose electrophoresis (180V, 0.5 h) showed that the total RNA samples had a 2:1 ratio of 28S to 18S rRNA intensities. Total RNA concentration and purity were estimated by optical density measurements at 260/280 nm[22].

### cDNA, cRNA synthesis and purification

Total RNA (1-8 μg) was used as a template for cDNA synthesis. cDNA and cRNA synthesis was proceeded as previously described[17]. cRNA labeled with biotin was synthesized using 12 μL synthesized cDNA as a template, and cDNA and cRNA were purified[17]. Measurement of concentration, purity and quality of cDNA and cRNA was conducted as previously reported[22].

### cRNA fragmentation and microarray detection

Fifteen μL (1 μg/μL) cRNA incubated with 5 × fragmentation buffer at 94℃ for 35 min was digested into 35-200 bp fragments. The hybridization buffer was added to the prehybridized rat genome 230 2.0 microarry produced by Affymetrix, and then hybridization was carried out for 16 h at 45℃ on a rotary mixer at 60 rpm. The microarray was washed and stained by GeneChip fluidics station 450 (Affymetrix Inc., USA). The chips were scanned with GeneChip Scan 3000 (Affymetrix Inc., USA), and the signal values of gene expression were observed [18].

### Microarray data analysis

The normalized signal values, signal detections (P, A, M) and experiment/control (Ri) were obtained by quantifying and normalizing the signal values using GCOS1.2[18].

### Normalisation of microarray data

To minimize errors in microarray analysis, each analysis was performed 3 times by rat genome 230 2.0 array. Results with a maximal total ratio (Rm) and an average of three housekeeping genes β-actin, hexokinase and glyceraldehyde-3-phosphate dehydrogenase approaching to 1.0 (Rh) were taken as a reference. Modified data were generated by applying a correction factor (Rm/Rh) multiplying the ratio of each gene in Rh at each time point. To remove spurious gene expression changes resulting from errors in microarray analysis, the gene expression profiles at 0-4 h, 6-12 h and 12-24 h after PH were reorganized by a normalization analysis program (NAP) software according to the cell cycle progression of regenerating hepatocytes. Data statistics and cluster analysis were done using GeneMath, GeneSpring, Microsoft Excel software[18,23,24].

### Identification of genes associated with liver regeneration

First, nomenclature of the cellular immune response was adopted from the GENEONTOLOGY database (www.geneontology.org) and inputted into the cellular immune response at NCBI (www.ncbi.nlm.nih.gov) and RGD (rgd.mcw.edu) to identify the rat, mouse and human genes associated with the activities mentioned above. According to the maps of biological pathways embodied by GENMAPP (www.genmapp.org), KEGG (www.genome.jp/kegg/pathway.html#amino) and BIOCARTA (www.biocarta.com/genes/index.asp), genes associated with blood coagulation were collated. The results of this analysis were codified and compared with those obtained in humans and mice in order to identify human and mouse genes which are different from those of rats. Comparing these genes with the analysis output of the rat genome 230 2.0 array, genes showing more than twofold change in expression level as meaningful expression changes[19], were referred to as rat homologous genes or rat specific genes associated with cellular immune response. Genes displaying reproducible results in three independent analyses with the chip and more than twofold change in expression level at least at one time point during LR with a significant difference ($P \leqslant 0.01 < 0.05$) or an extremely significant difference ($P \leqslant 0.01$) between PH and sham operation (SO), were referred to as genes associated with LR.

[1]Reported genes associated with liver regeneration; Associated with others: involved in other process of cellular immune response.

## RESULTS

### *Expression changes of genes associated with cellular immune response during liver regeneration*

According to the data from databases at NCBI, GENMAPP, KEGG, BIOCARTA and RGD, 468 genes were involved in the cellular immune response, of which 213 were contained in the rat genome 230 2.0 array. The expression of 127 genes displayed meaningful changes at least at one time point after PH, showing significant or extremely significant differences in expression compared with those after PH and SO, and reproducible results detected by three analyses of rat genome 230 2.0 array, suggesting that the genes were associated with LR. Ranges of the expression of up-regulated and down-regulated genes were respectively 2-37 fold and 2-10 fold of the control (Table 1). Up-regulated, down-regulated and up-/down-regulated expressions were observed in 41, 41 and 45 genes, respectively during LR. The up- and down-regulated expression times were 419 and 274, respectively (Figure 1A). At the initial phase (0.5-4 h after PH), 32 genes displayed up-regulated expression, 19 down-regulated expression, and 2 up-/down-regulated expression. At the transition phase from $G_0$ to $G_1$ (4-6 h after PH), 29 genes showed up-regulated expression, and 11 down-regulated expression. At the cell proliferation phase (6-66 h after PH), 43 genes exhibited up-regulated expression, 44 down-regulated expression, and 29 up-/down-regulated expression. At the cell differentiation and structure-functional reorganization phase (66-168 h after PH), expression was up-regulated in 49 genes, down-regulated in 46 genes, and up-/down-regulated in 15 (Figure 1B).

### *Initial expression time of genes associated with cellular immune response during liver regeneration*

At each time point of LR, the number of initially up-regulated and down-regulated as well as the total number of up-regulated and down-regulated genes were 15 and 6 at 0.5 h; 7, 10 and 17, 13 at 1 h; 7, 1 and 21, 3 at 2 h; 5, 3 and 27, 6 at 4 h; 1, 3 and 19, 10 at 6 h; 0, 0 and 17, 6 at

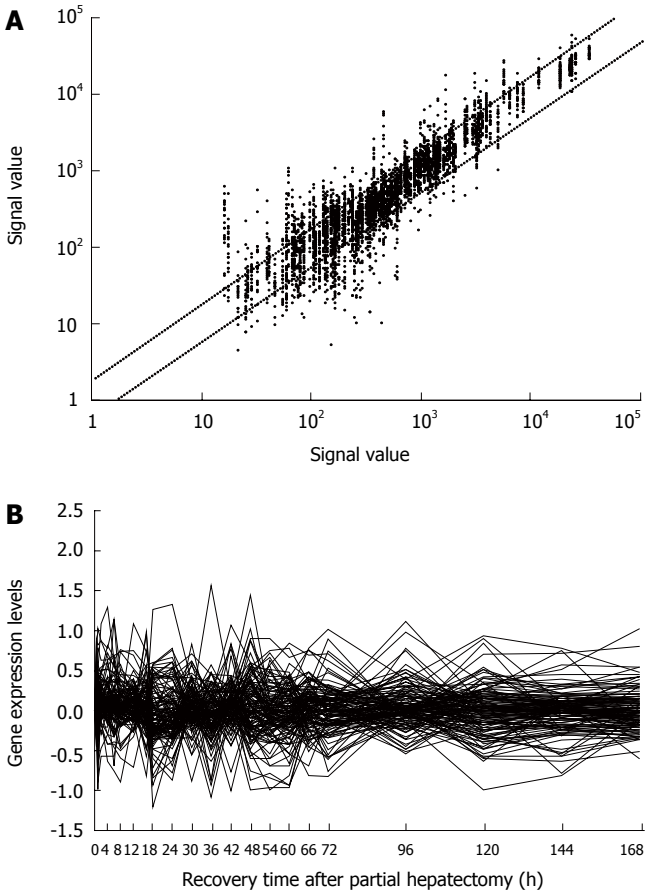

**Figure 1** Expression frequency (**A**) and changes (**B**) of 127 cellular immune response-associated genes during rat liver regeneration. Detection data of rat genome 230 2.0 array were analyzed and graphed by Microsoft Excel. The dots above bias represent the expression of genes up-regulated more than two fold, those under bias represent down-regulated more than two fold; the total times of up-regulated, down-regulated expression under bias are 419, 274, respectively. The ones between biases have meaningless alteration.The expression of 88 genes is up-regulated 2-37 fold and that of 86 genes is down-regulated 2-10 fold.

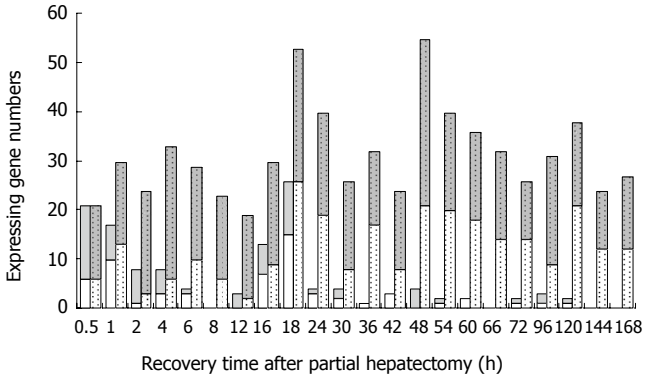

**Figure 2** Initial and total expression profiles of 127 cellular immune response-associated genes at each time point of liver regeneration. Grey bars: up-regulated genes; white bars: down-regulated genes; blank bars: initial expressing genes in which up-regulated genes are predominant in the forepart and prophase and down-regulated genes in the metaphase, whereas very few genes in the anaphase; dotted bars: total expressing genes in which some genes are up-regulated and others are down-regulated during the whole LR.

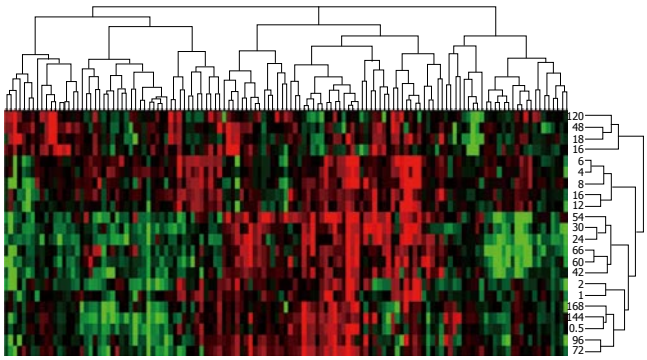

**Figure 3** Expression similarity and time relevance clusters of 127 cellular immune response-associated genes during liver regeneration. Detection data of rat genome 230 2.0 array were analyzed by H-clustering. Red represents up-regulated genes chiefly associated with antigen processing and presentation; green represents down-regulated genes mainly associated with antigen elimination; black represents the genes whose expressions are meaningless. The upper and right trees showing the expression similarity cluster and time series cluster respectively, by which these genes can be classified into 5 and 14 groups, respectively.

8 h; 3, 0 and 17, 2 at 12 h; 6, 7 and 21, 9 at 16 h; 11, 15 and 27, 26 at 18 h; 1, 3 and 21, 19 at 24 h; 2, 2 and 18, 8 at 30 h; 0, 1 and 15, 17 at 36 h; 0, 3 and 16, 8 at 42 h; 4, 0 and 34, 20 at 48 h; 1, 1 and 20, 20 at 54 h; 0, 2 and 18, 18 at 60 h; 0, 0 and 18, 14 at 66 h; 1, 1 and 12, 14 at 72 h; 2, 1 and 22, 9 at 96 h; 1, 1 and 17, 21 at 120 h; 0, 0 and 12, 12 at 144 h; 0, 0 and 15, 12 at 168 h (Figure 2). Generally, gene expression changes occurred during the whole LR. The up- and down-regulated expression times were 419 and 274, respectively. The initially up-regulated genes were predominant in the forepart and prophase and the down-regulated genes were predominant in the metaphase, whereas only a few of down-regulated genes were found in the anaphase.

### *Expression similarity and time relevance of genes associated with cellular immune response during liver regeneration*

A total of 127 genes could be characterized based on their similarity in expression: 41 up-regulated, 21 predominantly up- regulated, 41 down-regulated, 14 predominantly down-regulated, 10 up-/down-regulated genes, respectively (Figure 3). According to the time relevance, they were classified into 14 groups ( 0.5 and 144 h, 1 and 2 h, 4 and 6 h, 8 h, 12 and 16 h, 18 and 48 h, 24 and 30 h, 36 h, 42 h, 54 h, 60and 66 h, 72 and 96 h, 120 h, 168 h). The up- and down-regulated expression times were 21 and 7, 64 and 22, 42 and 8, 72 and 16, 32 and 9, 37 and 34, 62 and 49, 69 and 55, 54 and 28, 57 and 32, 41 and 35, 27 and 25, 20 and 16, 16 and 20, respectively (Figure 3). The up-regulated expression genes were chiefly associated with antigen processing and presentation, and the down-regulated genes were significantly associated with antigen elimination.

### *Expression patterns of genes associated with cellular immune response during liver regeneration*

A total of 127 genes were categorized into 21 patterns according to the changes in their expression: 11 up-regulated genes at one time point (i.e. 4, 18, 30, 48, 54, 96, 120 h) after PH (Figure 4A); 5 up-regulated genes at two

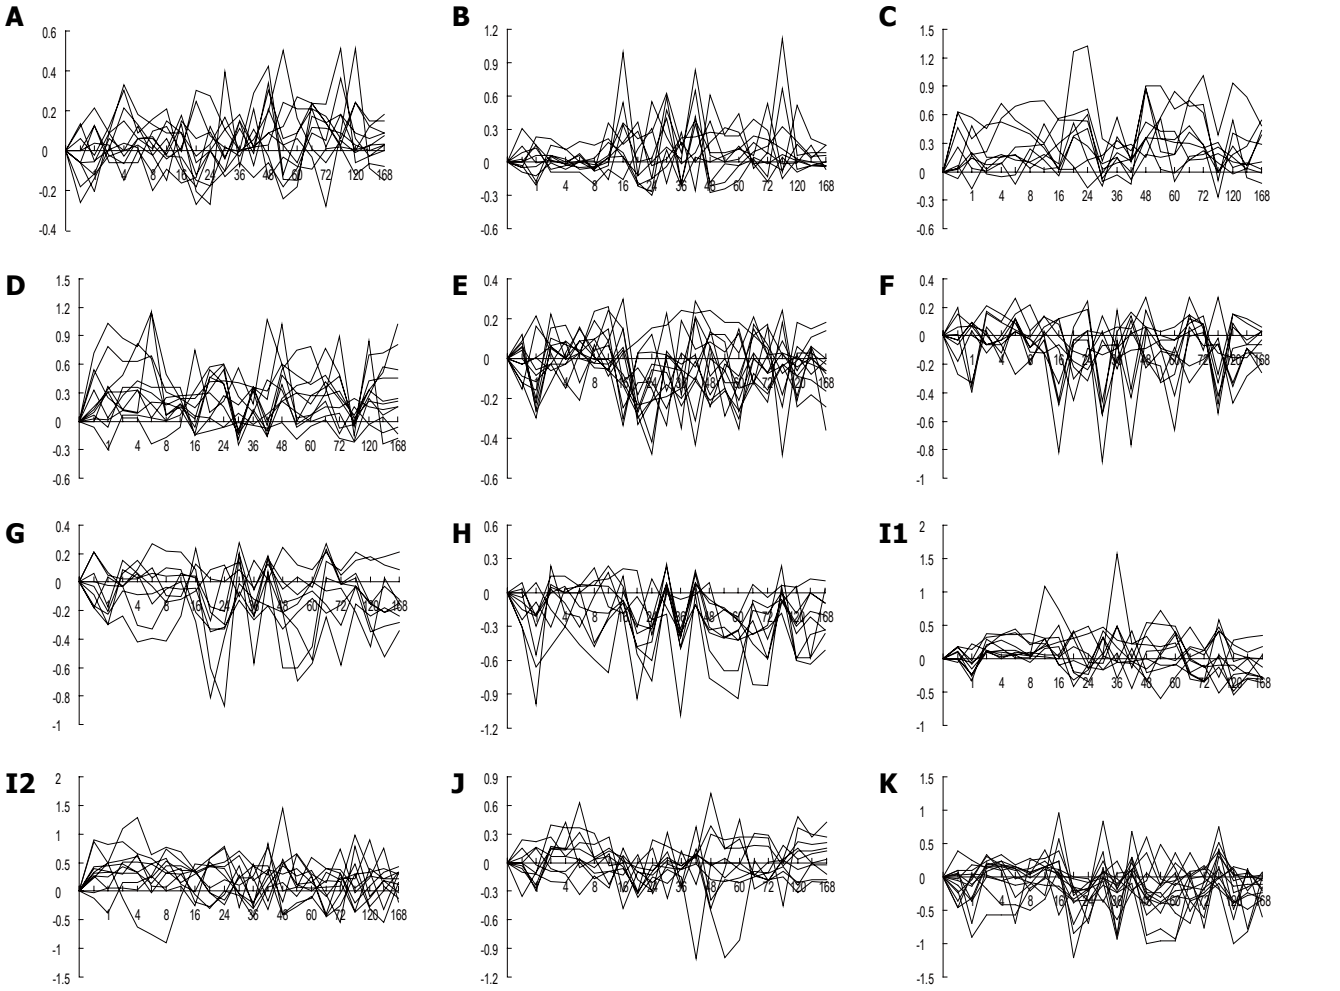

**Figure 4** Twenty-one gene expression patterns of 127 cellular immune response-associated genes during liver regeneration. Expression patterns were obtained by analysis of detection data with rat genome 230 2.0 array using Microsoft Excel. **A-D**: 41 up-regulated genes; **E-H**: 41 down-regulated genes; **I-K**: 45 up/down-regulated genes. X-axis represents recovery time after PH (h); Y-axis shows logarithm ratio of the signal values of genes at each time point to control.

time points (i.e. 12 and 60 h, 18 and 54 h, 24 and 48 h, 30 and 42 h, 72 and 120 h) (Figure 4B); 2 up-regulated genes at three time points (Figure 4B); 3 up-regulated genes at four time points (Figure 4B); 2 up-regulated genes at one time point/two phases (Figure 4C); 4 up-regulated genes at two time points/one phase (Figure 4C); 3 up-regulated genes at two time points/phases (Figure 4C); 4 up-regulated genes at multiple time points/phases (Figure 4D); 13 down-regulated genes at one time point (i.e. 16, 18, 24, 30, 36, 42, 60, 96, 168 h) (Figure 4E); 4 down-regulated genes at two time points (i.e. 16 and 30 h, 18 and 54 h, 30 and 96 h, 42 and 60 h) (Figure 4F); 3 down-regulated genes at three time points (Figure 4F); 3 down-regulated genes at four time points (Figure 4F); 4 down-regulated genes at one phase (i.e. 4-6 h, 4-8 h, 54-60 h and 120-168 h) (Figure 4G); 3 down-regulated genes at one time point/phase (i.e. 48 and 18-24 h, 72 and 120-144 h, 120 and 18-24 h) (Figure 4G); 2 down-regulated genes at one time point/two phases (Figure 4G); 2 down-regulated genes at two time points/one phase (Figure 4H); 2 down-regulated genes at two time points/phases (Figure 4H); 5 down-regulated genes at multiple time points/phases (Figure 4H); 21 predominantly up regulated genes (Figure 4I); 14 predominantly down regulated genes (Figure 4J); 10 similarly up-/down-regulated genes (Figure 4K).

## DISCUSSION

Cellular immune response is a self-protection mechanism formed during the long-term evolutionary processes, closely associated with higher animal. Of the proteins associated with antigen processing and presentation, five proteins including toll-like receptor 2 (TLR2) can activate the immune response by recognizing many kinds of pathogens[25]. Five proteins including lectin galactoside-binding soluble 3 binding protein (LGALS3BP) activate antigen presenting cells[26]. Transporter 1 ATP-binding cassette subfamily B (TAP1) speeds up antigen translocation[27]. The meaningful expression profiles of the genes encoding the above proteins are identical or similar at some time points while different at other time points, indicating that they may co-regulate antigen processing and presentation. In the present study, *tlr2* and *lgals3bp* were all up-regulated at multiple time points, reaching their peaks that were both 10.6 fold of the control respectively at 168 h and 48 h after PH. It is suggested that these genes play a

key role in antigen processing and presentation during LR.

Of the proteins associated with T-cell activation and proliferation, 6 proteins including granzyme B (GZMB) can activate T-cells[28], 4 proteins including transforming growth factor beta 1 (TGFB1) can activate CD4+T cells[29], 10 proteins including Rho GDP dissociation inhibitor beta (ARHGDIB) increase connection between antigen presenting cells and T-cells by promoting T-cell proliferation[30], 16 proteins including protein kinase C alpha (PRKCA) increase cytokine synthesis and expression of IFNγ and IgG[31], apolipoprotein E (APOE) facilitates endocytosis[32], 6 proteins including T-cell receptor beta chain (TCRB) activate the T-cell-dependent signaling pathway[33], 5 proteins including DEAD (Asp-Glu-Ala-Asp) box 58 (DDX58) promote the immunologic response[34]; intercellular adhesion molecule 1 (ICAM1) facilitates leucocyte transport[35]; interferon-gamma (IFN-γ) interacts with IL-12 and TNFα to augment immunological competence [36]; insulin-like growth factor I receptor (IGF1R) conducts signals of autoimmune inflammation[37]; integrin beta 2 (ITGB2) promotes leucocyte adherence and phagocytosis[38]; 4 proteins including Fyn proto-oncogene (FYN) suppress the Th2-mediated immune response[39], 7 proteins including kit oncogene (KIT) inhibit T lymphocyte proliferation[40]; vasoactive intestinal peptide receptor 1 (VIPR1) combines T-cell to enhance HIV infection[41]. In the present study, the meaningful expression profiles of the genes encoding the above proteins were identical or similar at some time points while different at other time points, indicating that they may co-regulate T-cell activation and proliferation. *gzmb* expression was up-regulated at 0.5-8, 36, 48-66 and 168 h and reached 7.5 fold at 48 h after PH. *arhgdib* expression was up-regulated at 16, 42 and 96 h and reached 13 fold at 96 h after PH. *prkca* expression was up-regulated at 16, 30, 42 and 96 h and reached 4.6 fold at 96 h after PH. *ddx58* expression was up-regulated at 1, 16, 30 and 42-48 h, reached 11.8 fold at 42 h after PH. *ifng* expression was up-regulated at 1-6, 18-24, 36, 48-66 and 144-168 h and reached 6.5 fold at 4 h after PH, indicating that they are crucial in T-cell activation and proliferation during LR.

Of the proteins associated with antigen elimination, profilin 1 (PFN1) accelerates antibody processing and modification [42]; 9 proteins including E2F transcription factor 1 (E2F1) and pancreatic lipase-related protein 2 (PNLIPRP2) increase immune response by speeding up the activities of lymphocytes and cytokines[43,44]; zinc finger protein 148 (ZFP148) accelerates the differentiation of monocytes into macrophages by inhibiting the activity of integrin CD11b[45]; complement factor H (CFH) promotes complement activation[46]; cathepsin κ (CTSK) promotes immunologic response *via* bactericidal action[47]; 6 proteins including superoxide dismutase 2 (SOD2) inhibit tumor cell proliferation and migration[48]; lymphocyte specific 1 (LSP1) and uromodulin (UMOD) suppress chemotaxis of macrophages and neutrophils[49,50]; chemokine receptor 1 (CCR1) conducts signals of inflammatory response[51]; 3 proteins including connective tissue growth factor (CTGF) accelerate wound repair by increasing expression of chemotactic factors[52]; transforming growth factor beta 2 (TGFB2) combines IL-10 to suppress immunologic response induced by bacterial infection[53]; myeloid cell nuclear differentiation antigen (MNDA) blocks combination of ligands and receptors[54]; 8 proteins including adrenomedullin (ADM) control the activity of effector lymphocytes and cytokines[55]; plasminogen activator urokinase receptor (PLAUR) promotes cancer cell spread[56]. The meaningful expression profiles of the genes encoding these proteins are identical or similar at some time points while different at other time points, indicating that they may co-regulate antigen elimination. In the present study, *ctsk* expression was up-regulated at 1, 18-24, 48 and 66-168 h and reached its peak at 72 h, which was 10.3 times that of the control and is basically in line with the result reported by Dransfeld[15]. *e2f1* expression was up-regulated at 18-30, 54-72 and 120 h, and reached its peak at 24 h, which was 21.2 times that of the control. *pnliprp2* expression was up-regulated at 12-18 and 36 h, and reached its peak at 36 h, which was 36.8 fold that of the control. *sod2* expression was up-regulated at 0.5, 4-24 and 48 h, and reached its peak at 12 h, which was 5.6 times that of the control. *ctgf* expression was up-regulated at 0.5-8, 18-24, 36, 54 and 72 h, and reached its peak at 1 h, which was 10.7 fold that of the control. *adm* expression was up-regulated at 0.5-24, 36, 48-72 and 168 h, and reached its peak at 54 h, which was 8-fold that of the control. *plaur* expression was up-regulated at 1, 6, 18-24, 48, 72 and 120 h, and reached its peak at 6 h, which was 13.9 times that of the control. These findings suggest that the seven genes are of importance in antigen elimination during liver regeneration.

In conclusion, the expression changes of cellular immune response-associated genes after rat partial hepatectomy can be investigated by high-throughput gene expression analysis. Cellular immune response is enhanced during liver regeneration. Rat genome 230 2.0 array is a useful tool for analyzing the response at the transcriptional level. However, DNA→ mRNA→ protein→ function is influenced by many factors including protein interaction. So we will further analyze the results using such techniques as Northern blotting, protein chip, RNA interference, protein-interaction *etc.*

## Abstract

**AIM:** To investigate the referred pain area in patients 2-7 years after cholecystectomy in order to test the hypothesis that neuroplastic changes could give rise to post cholecystectomy pain.

**METHODS:** Forty patients were tested. Twenty five were cholecystectomized due to uncomplicated gallbladder stones and 15 because of acute cholecystitis. Sensitivity to pinprick, heat, cold, pressure and single and repeated electrical stimulation was studied both in the referred pain area and in the control area on the contra lateral side of the abdomen.

**RESULTS:** Five patients still intermittently suffered from pain. But in the objective test of the 40 patients, no statistical significant difference was found between the referred pain area and the control area.

**CONCLUSION:** This study does not support the hypothesis that *de novo* neuroplastic changes could develop several years after cholecys-tectomy.

**Key words:** Referred pain; Hyperalgesia; Cholecystitis; Post cholecystectomy syndrome

## INTRODUCTION

Cholecystectomy in patients with gallstone disease usually relieves the symptoms. However, it has repeatedly been demonstrated that 5%-10% of the patients still suffer from severe pain, and even more patients (25%-40%) have milder symptoms[1,2]. The explanations for continuing symptoms are multiple. An underlying organic disorder can be demonstrated in some patients, but no well-defined diagnosis can be identified in a substantial number of patients. Previous studies have shown that some of the patients suffer from sphincter of Oddi dysfunction (SOD). This condition can be relieved by endoscopic sphincterotomy[3-5]. Others have suggested a more generalized intestinal motor disorder in which SOD may be a component[6-8]. In previous studies we have demonstrated that patients with uncomplicated gallstone disease or acute cholecystitis have an increased sensibility in the referred pain area (RPA), probably reflecting neuroplastic changes and hyperexcitability in the central nervous system[9,10]. Animal studies have shown that such changes are frequently persisting even though the initial cause is eliminated[11]. We therefore hypothesized that continuing central neuronal changes could be the cause of continuing pain in some of the patients. However, we were not able to support this hypothesis in subsequent investigations[12]. Since these studies were carried out shortly after cholecystectomy, the possibility still remains that neuroplastic changes could occur at a later point of time.

Accordingly, the aim of the present study was to evaluate the sensibility in the referred pain area in patients who underwent cholecystectomy some years earlier, and to correlate possible abnormalities to the clinical condition of the patients.

## MATERIALS AND METHODS

### Patients

Two groups of Fifty-five patients were included in this study and divided into two groups. These were patients from the previous gallbladder stones and acute cholecystitis studies[9,10]. The first group consisting of 36 patients was tested prior to their cholecystectomy and then approximately 4 wk following the surgery. These patients were contacted and asked to participate in the follow-up study. Twenty-five entered the study, one man and 24 women, with a median age of 48 years (range 25-68 years). The reason for not entering the study was either that they did not want to (six patients) or we were not able to locate

and thereby get in contact with the patients (five patients). The second group consisting of 19 patients was all cholecystectomized after acute cholecystitis. Two of these patients were excluded and two did not want to participate in the study. The remaining 15 patients who entered the study were seven men and eight women with a median age of 60 years (range 37-84 years). Thus, follow-up testing was done in 40 patients (25 following uncomplicated gallbladder stones and 15 following acute cholecystitis).

### Protocol

The patients were interviewed focusing on any relevant pain or medication. Each patient was asked to express the degree of pain during any attacks similar to what they knew as gallstone-attacks from their experience prior to the cholecystectomy. The pain was described in terms of intensity, localization, number of attacks, duration, physical activity, accompanying symptoms, and use of the visual analogue scale (VAS) anchored at 0 (no pain) to 10 (worst imaginable). After the interview the patients were tested with the same equipment to evoke pain as in the previous studies[9,10]. For testing of somatosensory sensitivity the patients were asked to assign the area under the right curvature/epigastrium where the pain was referred to during the previous disease. This area was assumed to be the area of initial referred pain (RPA). Then a symmetrical area was marked under the left costal margin to represent the control area (CA). The subsequent sensory assessment was performed at the centre of these areas. The experimental sensory testing with different modalities (see below) was used for measuring superficial/deep and sensory/pain thresholds in the RPA and CA. The sensory testing was first applied in the CA and then in the RPA.

### Pinprick

The sensitivity to touch was determined using a Von Frey hair with a bending force of 6.6 g (SenseLab, Somedic AB, Stockholm, Sweden), which was pressed against the skin until bending of the hair occurred. The two skin areas were stimulated consecutively, and the patients were asked if it was painful or if they felt any difference between the two areas. The perception of the pinprick was rated as 'similar', 'greater', or 'painful'.

### Pinching

The sensitivity of pain to the pinching stimulation was determined bilaterally using an electronic pressure algometer (Somedic AB, Stockholm, Sweden) mounted with a 1 $cm^2$ probe, connected to a plastic clamp. A skin fold was placed and pinched between the clamp. The pinching was gradually increased at 10 kPa/s, and the patients pushed a stop button when the pain detection threshold was reached. The mean of three trials, with an interval of a minimum of 20 s between each trial was used in the subsequent calculations.

### Thermal stimuli

The sensitivity to thermal stimuli was tested in the two areas using two 4 $cm^2$ metal rollers, which prior to testing were placed in water baths with temperatures of 0℃ and 40℃, respectively. The cold and warm rollers were held in contact with the skin for 3 s in the two areas, and immediately after the stimulus the patients were asked to rate possible differences in sensation (lesser, similar, greater, or painful) between the two zones. The cold stimulus was applied first.

### Electrical stimuli

A constant current electrical stimulator controlled by a computer (Aalborg University, Denmark) was attached to two electrodes (Neuroline, Disposable Neurology Electrodes, type: 720-01-K; Medicotest A/S, Ølstykke, Denmark). The electrodes were applied to the RPA and CA. Five constant currents, 1ms rectangular pulses applied at 200 Hz, were defined as a 'single burst stimulus'. When this single stimulus was repeated five times at 2 Hz, it was defined as a 'repeated burst stimulus'. This repeated paradigm was used to measure temporal summation [13-15]. The patients were instructed to indicate when the single and repeated stimuli could be felt (sensation threshold), and when pain was perceived (pain detection threshold). The stimulation was started at 0.2 mA, and the current was gradually increased in steps of 0.1-1.0 mA until the actual threshold was reached. The patients could interrupt the stimulation at any time during the experiment.

### Pressure stimuli

The sensitivity of pain to the pressure stimulation was determined bilaterally using an electronic pressure algometer (Somedic AB, Stockholm, Sweden) mounted with a 1 $cm^2$ probe. The pressure was gradually increased at 50 kPa/s, and the patients pushed a stop button when the pain detection threshold was reached. The mean of three trials, with an interval of a minimum of 20 s between each trial, was used in the subsequent calculations.

### General hypersensitivity

Hypersensitivity in general was defined as three or more pain-modalities showing hypersensitivity in the RPA compared to the CA and no modalities demonstrating hypersensitivity in the CA compared to the RPA. All patients were tested in the pain free period.

### Statistical analysis

Data were described as median (range). For comparison of the sensation to pinprick, heat and cold in the RPA and CA, the McNemar test for dichotomous paired data was used. The sensation and pain thresholds for pinching, electrical and pressure stimuli in the two areas were compared using the Mann-Whitney test. Correlation analysis was performed with Pearson's test. $P < 0.05$ was considered statistically significant.

### Ethics

The study was conducted in accordance with the Helsinki Declaration. All patients gave their verbal and written consent following verbal and written information.

## RESULTS

The median time interval between cholecystectomy and the investigation was 35.6 (27.7-58.1) mo for the first group

**Table 1 Characteristics of the 5 patients still intermittently suffering from pain**

| Patient (*n*) | Pain localization | Attack frequency | Pain duration | Physical activity | Accompanying symptoms | VAS | Pain-killers | Anti-depressive |
|---|---|---|---|---|---|---|---|---|
| C (4) | Epigastriel | Daily | h | Depending on activity | Feeling ill and nausea | 9 | Paracetamol | No |
| C (5) | Under the right costal margin | Every 3rd wk | 20-30 s | Sitting down | No | 7 | | SSRI |
| C (14) | Under the right costal margin | Approximately 3 every week | min | Sitting down | No | 4 | No | No |
| C (17) | Epigastriel and under the right costal margin | 2-3/mo | h | Depending on activity | Nausea and reflux for 1-2 d | 7 | NSAID and paracetamol | TCA |
| AC (15) | Under the right costal margin | 2-3/yr | min | Standing | No | 6 | No | |

C: Cholecystholithiasis study[10]; AC: Acute cholecystitis study[9]; VAS: Visual analogue scale; NSAID: Non steroid anti-inflammatory drug; SSRI: Selective serotonin reuptake inhibitor; TCA: Tricyclic anti-depressants.

of patients and 74.9 (62.2-87.8) mo for the second group. The majority of patients no longer had pain in the relevant region. Five patients (12.5%) still intermittently suffered from pain similar to the pain they remembered during the precholecystectomy period localized to the original region (Table 1). The general picture showed some diversity in terms of pain description. One patient had daily attacks of pain and another only two to three attacks every year. One patient had attacks lasting seconds and in another case the duration of pain was days. The mean VAS-score under attacks was 6.6.

Only three patients had general hypersensitivity in the RPA compared to the CA (Table 2). There were no overlaps between the five patients informing of actual intermittent pain and the three patients who had generalised hypersensitivity in the RPA.

### Sensory test

Using Von Frey hair the presence of increased sensitivity in the RPA was detected in three patients (7.5%) but three other patients (7.5%) experienced increased sensitivity in the CA ($P > 0.05$). No patient had allodynia (painful response to a stimulus that does not normally provoke pain).

When cold stimulation was applied increased sensitivity was found in the RPA in 12.5% of the cases and again 12.5% experienced increased sensitivity in the CA ($P > 0.05$). No patient had allodynia. Using heat stimulation, increased sensitivity was found in the RPA in 10% of the cases and 12.5% experienced increased sensitivity in the CA ($P > 0.05$). None of these patients reported that pain was evoked.

### Quantitative assessment

The pinching pain threshold was 176.5 kPa (4-1057 kPa) in the RPA and 213.5 kPa (7-660 kPa) in the CA ($P > 0.05$).

**Sensation to electrical stimuli:** The sensation detection threshold for single burst electrical stimuli was 0.6 (0.3-2.5) mA in the RPA and 0.6 (0.2-1.4) mA in the CA ($P > 0.05$). The pain threshold for single burst electrical stimuli was 13 (0.9-56) mA in the RPA and13.5 (0.7-46) mA in the CA ($P > 0.05$). There was no statistical difference in the pain threshold for single burst electrical stimuli between the RPA and CA ($P > 0.05$). The sensation detection threshold for repeated burst electrical stimuli (temporal summation) was 0.6 (0.2-2.2) mA in the RPA and 0.6 (0.3-1.3) mA in the CA ($P > 0.05$). The pain threshold for repeated burst electrical stimuli was 9 (1.0-30.5) mA in the RPA and 9.3 (0.9-35.4) mA in the CA ($P > 0.05$). Table 3 shows the comparison of results from the present study with result from the initial study.

**Table 2 Sensory findings in the three patients showing generalized hypersensitivity**

| Patient (*n*) | Pinprick | Cold | Heat | Pinching | SES | RES | Pressure |
|---|---|---|---|---|---|---|---|
| AC (2) | - | - | - | ↑ | ↑ | - | ↑ |
| AC (24) | - | - | - | ↑ | ↑ | ↑ | ↑ |
| AC (30) | - | - | - | ↑ | ↑ | ↑ | ↑ |

AC: Acute cholecystitis study[9]; SES: Single electrical stimulus; RES: Repeated electrical stimulus; "-": No difference between referred pain area (RPA) and control area (CA); "↑": Hypersensitivity in the RPA.

**Sensation to pressure:** Pressure gave no indication that the patient still had significant hyperalgesia in the RPA. The pressure pain threshold was 267 (60-890) kPa in the RPA and 270.5 (87-856) kPa in the CA ($P > 0.05$).

## DISCUSSION

In the present study, no evidence for long lasting or *de novo* central neuronal changes were found 2-7 years after uncomplicated gallbladder stones or acute cholecystitis. Somatosensory hyperalgesia in the referred pain area (RPA) has previously been reported in different groups of patients[9,16,10,13]. The phenomenon is the result of direct or indirect convergence of nerve fibres from visceral and somatic tissue at the spinal and/or even the supraspinal levels[17], and the RPA therefore, most likely, reflects central changes in neurons receiving convergent afferent information from both the visceral and somatic systems[18]. Hyperexcitability of neurons in the central nervous system (CNS) may theoretically explain why some patients suffer from pain although the original disease has resolved. In other words, continuous visceral pain stimuli can lead to a hypersensitive cutaneous area, where a stimulus that does not usually cause pain is perceived as painful (allodynia). This central sensitization is characterized by neuroplastic findings such as increased spontaneous activity, decreased firing threshold, and expansion of the receptive fields of

**Table 3 Comparison of results regarding electrical stimuli from the present study with result from the initial study, mean (range)**

| | Present study in mA | | Initial study in mA | |
|---|---|---|---|---|
| | RPA | CA | RPA | CA |
| The sensation detection threshold for single burst electrical stimuli | 0.6 (0.3-2.5) | 0.6 (0.2-1.4) | 0.7 (0.3-1.2) | 0.7 (0.4-1.5) |
| The pain threshold for single burst electrical stimuli | 13 (0.9-56) | 13.5 (0.7-46) | 12.4 (2.6-30.6) | 13.9 (3.7-28.6) |
| The sensation detection threshold for repeated burst electrical stimuli | 0.6 (0.2-2.2) | 0.6 (0.3-1.3) | 0.7 (0.25-1.2) | 0.7 (0.4-1.6) |
| The pain threshold for repeated burst electrical stimuli | 9 (1.0-30.5) | 9.3 (0.9-35.4) | 7.6 (1.5-17.2) | 7.7 (2.7-25) |

RPA: Referred pain area; CA: Control area.

spinal neurons[19,20,16].

The primary objective of this study was to investigate a group of patients who tested twice during and after acute cholecystitis or uncomplicated gallbladder stones. We searched for any persisting changes in the RPA reflecting central hyperexcitability in exactly the same way as in the initial studies shortly after surgery. In these studies, hyperalgesia in the RPA was found and the abnormal sensation disappeared after surgery[9,10]. Other studies have shown that muscular hyperalgesia tends to persist for a long time, outlasting the duration of the initial pain and that muscular hyperalgesia in the RPA could be experienced several years after elimination of renal stones[16,11,18]. These findings by Italian colleagues were not confirmed in our work, where the experimental findings in the RPA in patients with uncomplicated gallstone disease in the pain free period were not dependent on intensity or duration. The statistical analysis showed no significant correlations between the pain thresholds to single and repeated electrical or mechanical stimuli in the RPA. This absence of correlation between hyperalgesia in the RPA in the pain free period, can therefore be caused by too short duration and relatively low intensity of the painful episodes. The duration of the pain attacks was much shorter and the intensity was lower than in above-mentioned studies with unilateral renal/ureteral colics (where the duration was around 5-10 d with high intensity). An alternative explanation for the lack of correlation could be that our method was insufficient for measuring chronic pain caused by neuroplastic changes at the supraspinal level. The method was, however, sufficient to demonstrate abnormalities prior to surgery.

All but five patients no longer suffered from pain similar to the pain they remembered during the preoperative interval. These patients were classified as having postcholecystectomy syndrome[21,22]. In these patients no evidence for hyperalgesia in the RPA was found, reflecting that any neuronal changes at the spinal cord level have resolved. Hence the reason for their symptoms could be either peripheral changes[23,24] relating to the surgical incision of the nerves or more complex supraspinal changes as reorganization in the CNS which have been demonstrated in patients suffering from chronic pancreatic pain[25]. The pathogenesis of chronic pain is poorly understood, but there is a growing body of evidence that neuroplastic changes as seen in neuropathic pain and other chronic pain disorders may be of importance in understanding chronic pain disorders, including post cholecystectomy syndrome.

In conclusion, initial studies in this patient group showed that hypersensitivity is present in the RPA after acute cholecystitis and gallbladder stones[9,10]. After the immediate recovery from the cholecystectomy the hypersensitivity returns to normal[9,10]. The current study has confirmed that the hypersensitivity does not reappear, which does not support the hypothesis that the occurrence of neuroplastic changes could explain pain some years after cholecystectomy. Since five patients in the present study suffered from pain, central changes in a small subset of patients with post cholecystectomy syndrome cannot be ruled out. Therefore, in the future, it would be interesting to study a large group of patients with post cholecystectomy syndrome. Further studies with more advanced equipment for measuring peripheral changes and reorganization in the CNS, along with alternative ways of testing, should be carried out to further explain post cholecystectomy syndrome.

## COMMENTS

### Background

Cholecystectomy in patients with gallstone disease usually relieves the symptoms. However, it has repeatedly been demonstrated that 5%-10% of the patients still suffer from severe pain, and even more patients (25%-40%) have milder symptoms. Accordingly, the aim of the present study was to evaluate the sensitivity in the referred pain area in patients who underwent cholecystectomy some years earlier, and to correlate possible abnormalities to the clinical condition of the patients.

### Research frontiers

In previous studies we have demonstrated that patients with uncomplicated gallstone disease or acute cholecystitis have an increased sensitivity in the referred pain area (RPA), probably reflecting neuroplastic changes and hyperexcitability in the central nervous system. Animal studies have shown that such changes are frequently persisting even though the initial cause is eliminated. Could this increased sensitivity indicate a later development into post cholecystectomy syndrome?

### Innovations and breakthroughs

There is no indication that changes in the central nervous system persist in patients treated with cholecystectomy after several years of follow-up.

### Applications

This study strips away the hypothesis that central neuronal changes may be responsible for the post cholecystectomy syndrome. Although it does not give sufficient information on the post cholecystectomy syndrome, it is definitely a future puzzle.

### Terminology

Referred pain: Physical pain in a location other than the site of origin. Somatosensory sensitivity: The somatosensory system includes multiple types of sensation from the body-light touch, pain, pressure, temperature, and joint and muscle position sense (also called proprioception). However, these modalities are lumped into three different pathways in the spinal cord and have different targets in the brain.

### Peer review

In order to test the hypothesis that neuroplastic changes give rise to post cholecystectomy pain, the referred pain area after cholecystectomy was studied in 40 patients. However, no statistical significant differences were found between the referred pain area and the control area. Thus, this study does not support the hypothesis that de nova neuroplastic changes cause post cholecystectomy syndrome. The description of materials and methods is sound. However, a major drawback of this study is the small number of patients.

## Abstract

**AIM:** To study the protective effect of a natural antioxidant, melatonin, against multistress condition induced lipid peroxidation *via* determination of gastric damage and plasma malondialdehyde (MDA) level by high performance liquid chromatography in rats.

**METHODS:** We compared indomethacin-induced gastric damage and MDA plasma level in three groups of rats: unoperated, bile duct ligated and sham-operated and evaluated the role of the melatonin on gastric damage and plasma MDA level. Indomethacin and melatonin were injected intraperitoneally in doses of 50 mg/kg and 20 mg/kg, respectively. Animals were killed 4 h after indomethacin injection.

**RESULTS:** Indomethacin induced more severe gastric damage and plasma MDA level in bile duct ligated animals was significantly higher (3.1 ± 0.04 μmol/L) than sham (2.8 ± 0.04 μmol/L) and unoperated animals (1.4 ± 0.08 μmol/L). Pretreatment with melatonin reduced indomethacin-induced gastric damage and plasma MDA level.

**CONCLUSION:** Considering the results of this study, we suggest that in multistress conditions the intensity of gastric damage and the plasma MDA level are great and melatonin reduces the negative effect of lipid peroxidation and cell damage by oxidative stress in multistress conditions due to its antioxidizing activity.

**Key words:** Melatonin; Oxidative stress; Gastric ulcer; Cholestasis; Malondialdehyde; High performance liquid chromatography; Rat

## INTRODUCTION

It has been accepted that the pathogenesis of ulcer is complex and related to different pathogenic factors. The most common side-effect of indomethacin (NSAID) is gastric mucosal damage. The inhibition of the biosynthesis of gastric prostaglandins is accepted as a main mechanism implicated in NSAID-induced gastropathy[1,2]. Oxidative stress is involved in this pathology and it has been suggested that active oxygen metabolites play an important role in gastric damage induced by aspirin[3]. The focal ischemic areas produced as a result of inhibition of prostaglandin synthesis, may eventually produce tissue-damaging mediators such as oxygen-derived free radicals[1]. The break down of lipid peroxide in the biological system produces a number of aldehydes such as malondialdehyde (MDA), which are cytotoxic by reacting with lipids, protein and nucleic acids[4]. It has been shown that gastric mucosa of cholestatic rats is more vulnerable than that of normal animals to NSAIDs and this has been referred to different factors such as increased gastric acid secretion, decreased prostaglandins and increased free radical formation and accumulation of endogenous opioids[5].

Melatonin, a pineal secretory product, was recently found to be a potent free radical scavenger and antioxidant, especially hydroxyl radical (•OH) and peroxyl radical. In *in vitro* and *in vivo* experiments melatonin in different models of oxidative stress has been found to protect tissues against oxidant damage induced by various free radical generating agents[6-9]. It has been shown that melatonin exerts protective and therapeutic effects against cholestatic liver injury and its associated oxidative stress in rats subjected to BDL through its direct and indirect antioxidant actions as well as its anti-inflammatory effects[10-14].

The aim of this study was to investigate the antioxidant effect of melatonin on multistress conditions *via* assessment of gastric lesion and determination of MDA concentration in plasma as a lipid peroxidation biomarker.

We compared gastric damage and plasma MDA level in 3 groups of rats: unoperated (UNOP), bile duct ligated (BDL) and sham-operated (SHAM) and evaluated the antioxidative effect of melatonin in these groups.

## MATERIALS AND METHODS

### Chemicals

The following chemicals were used: 1,1,3,3- tetramethoxypropane (Sigma), butylated hydroxytoluene (Sigma), 2-thiobarbituric acid (Serva), high performance liquid chromatography (HPLC) grade methanol and ethanol (Merck), melatonin (Nature's Bounity), ketamin HCl (Rotex Medica) and Promethazine HCl (Sigma).

### Reagent preparation

Chemical solutions were prepared using distilled deionized water. Butylated hydroxytoluene (BHT) solution was prepared in ethanol to a final concentration of 0.05% BHT. An 0.44 mol/L phosphoric acid solution was obtained by diluting 1 mL concentrated phosphoric acid to 100 mL final volume. 2-thiobarbituric acid (TBA) was dissolved in water on a stirring hot-plate at 50-55℃ to a concentration of 42 mmol/L.

### Experimental design

Male Sprague-Dawley rats weighing 200-250 mg were used in this experiment. All animals were given free access to food and water. The animals were handled in accordance with the criteria and recommendations of the ethics committee on animal experiments of the Medical School Tehran University of Medical Sciences. Animals were divided into three groups.

First group (UNOP, $n$ = 5), second group (BDL, $n$ = 10), third group (SHAM, $n$ = 10). Animals in BDL and SHAM groups were divided randomly into sham plus saline plus indomethacin, bile duct ligation plus saline plus indomethacin, sham plus melatonin plus indomethacin and bile duct ligation plus indomethacin plus indomethacin subgroups, respectively; each subgroup consisted of 5 rats.

### Surgery

Laparotomy was performed under general anesthesia induced by intraperitoneal (IP) injection of ketamin (60 mg/kg) and chlorpromazine (20 mg/kg) in BDL rats, the common bile duct was isolated and doubly ligated. In SHAM rats the bile duct was identified, manipulated and left *in situ*. Then the abdominal wall was closed in two layers[15]. Five days after surgery animals were fasted but with access to water and during this period were housed in individual cages with a wire-mesh floor to prevent coprophagy. Experiments were performed 7 d after surgery, when the BDL group had shown overt jaundice. Rats were divided into 5 groups.

**UNOP group**: which were injected with saline at 0 and 30 min and were killed under ether anesthesia 4 h after last injection and 2 mL blood were drawn from the heart ventricle into a syringe containing EDTA (ethylenediaminetetraacetic acid) with a final EDTA concentration 1 mg/mL and transferred to plastic tubes and centrifuged for 10 min at 4000 rpm at room temperature. The aliquots were kept frozen at -80℃ until analysis. Plasma samples in this temperature are stable for at least one year[16]. Then the stomachs were immediately removed and cut along the greater curvature and the stomach contents were washed out with saline and gastric lesions were fixed with 20% formaldehyde for 5 min.

**BDL group:** which were injected with saline (1 mL/kg, ip) and 30 min later treated with indomethacin (50 mg/kg, ip) and were killed under ether anesthesia 4 h after last injection. Plasma samples and stomachs were prepared like the UNOP group.

**BDL group:** which were pretreated with melatonin (20 mg/kg, ip)[17] and 30 min later treated with indomethacin (50 mg/kg, ip) and were killed under ether anesthesia 4 h after last injection. Plasma samples and stomachs were prepared like the UNOP group.

**SHAM group:** which were injected with saline (1 mL/kg, ip) and 30 min later treated indomethacin (50 mg/kg, ip) and were killed under ether anesthesia 4 h after last injection. Plasma samples and stomachs were prepared like the UNOP group.

**SHAM group:** which were pretreated with melatonin (20 mg/kg, ip) and 30 min later treated with indomethacin (50 mg/kg, ip) and were killed under ether anesthesia 4 h after last injection. Plasma samples and stomachs were prepared like the UNOP group.

### Measurement of gastric lesions and malondialdehyde levels

Gastric lesions were assessed macroscopically and evaluated according to J-score[18]. The J-score was calculated by classifying the lesions by diameter; 0-1 mm = 1; 1-2 mm = 2; greater than 2 mm = 3. The score was defined as the sum of these points in each rat[19]. Plasma analysis was performed immediately after thawing the plasma samples and lipid peroxidation was monitored by MDA measurement by HPLC-based assay of MDA-TBA adduct.

### Standards

Standards and control samples were prepared using TMP with the stock standard solution containing 100 μmol/L TMP in a 40% ethanol solution. Standards were prepared through serial dilution of stock standards with ethanol solution to obtain concentrations of 4, 3, 2, 1, 0.5 and 0 (blank) μmol/L TMP. The concentration of TMP solution did not change after three months at 4℃ (refrigerator)[7]. The standard curve was prepared freshly for analysis each day as well as control samples of 4, 3, 2, 1, 0.5 and 0 (blank) μmol/L TP.

### Sample preparation

Sample derivatization was carried out in 2 mL capacity plastic centrifuge tubes fitted with screw-on caps. To a 150 μL aliquot of sample or TMP standard, 50 μL BHT, 400 μL $H_3PO_4$ and 100 μL TBA solution were added. Sample tubes were capped tightly, vortexed, and then heated for 1 h in a 100℃ water bath. Following heat derivatization, samples were placed on an ice-water (0℃) water bath for 5 min to cool, with 250 μL n-butanol subsequently added to each tube for extraction of the MDA-TBA complex. Tubes were vortexed 5 min and then centrifuged 3 min at

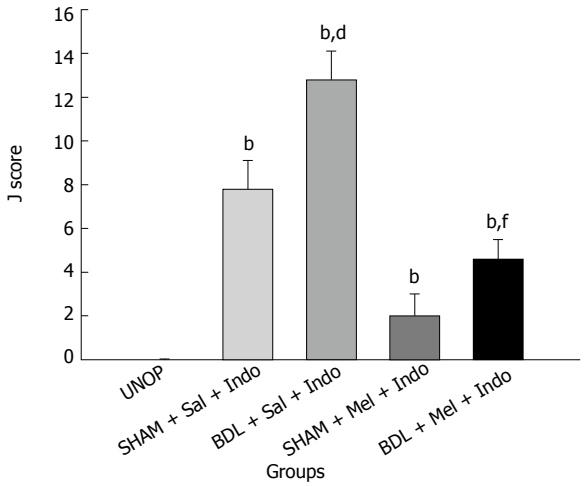

**Figure 1** Effect of melatonin (20 mg/kg) on indomethacin (50 mg/kg) induced gastric damage in BDL and SHAM animals. Five rats were used in each group. Data values are expressed as mean ± SD. $^{b}P < 0.001$ *vs* UNOP group; $^{d}P < 0.001$ *vs* Sham + Sal + Indo group; $^{f}P < 0.001$ *vs* Sham + Mel + Indo group.

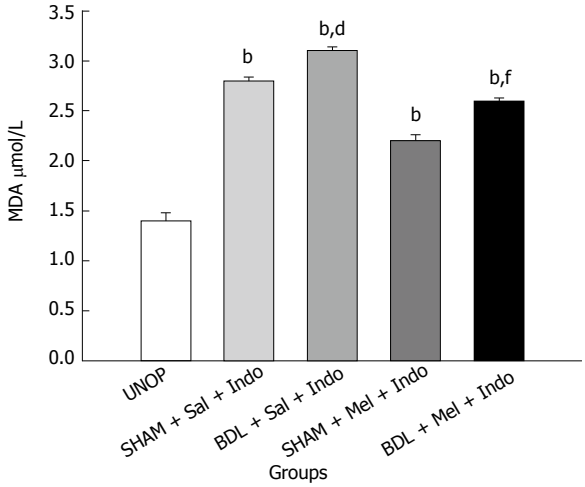

**Figure 2** Effect of melatonin (20 mg/kg) on indomethacin (50 mg/kg) induced plasma malondialdehyde (MDA) levels in BDL and SHAM animals. Five rats were used in each group. Data values are expressed as mean ± SD. $^{b}P < 0.001$ *vs* UNOP group; $^{d}P < 0.001$ *vs* Sham + Sal + Indo group; $^{f}P < 0.001$ *vs* Sham + Mel + Indo group.

14 000 rpm to separate the two phases[20]. Aliquots of 20 μL removed from n-butanol layers of each sample and injected in HPLC for analysis without evaporation[20]. Since MDA degrade approximately 10% per hour, the best performance of assay requires analyzing samples within an hour of derivatization[20].

### HPLC procedure

Chromatographic determination was performed on a Cecil 1100 series high performance- liquid chromatograph equipped with an 1100 series pump and a fluorescence detector which was set at an excitation wavelength of 515 nm and emission wavelength of 553 nm. A HP 3395 integrator was employed to record retention times, chromatograms and evaluate peak areas. The column was a Pefectsil Target (ODS, 150 mm × 4.6 mm, 3-5 μ particles). Elution was performed isocraticaly with a mixture of methanol-buffer (40:60 v/v) at a flow rate of 1.0 mL/min at room temperature. The buffer was 50 mmol/L potassium monobasic phosphate (anhydrous) with an adjusted pH of 6.8 using a 5 mmol/L potassium hydroxide solution. In this study, we used the Agarwal method for determination of MDA[20].

### Linearity

Calibration curves were created for 6 different concentrations (0-4 μmol/L) by plotting the peak areas versus the nominal MDA concentrations. There was a significant linear relationship between MDA concentration in water and plasma and peak area obtained by fluorescence (water: Y = 1 642 598X + 484 484; $r^2 = 0.999$; plasma: Y = 1 888 481X + 2 706 994; $r^2 = 0.999$). Furthermore the slopes of peak areas to MDA levels were parallel in plasma and water, and that no matrix effect existed when n-butanol was added as an extracting solvent, suggesting that n-butanol is superior as an extracting solvent.

### Accuracy and limit of detection

The accuracy was determined by evaluation of analytical recovery after addition of known amounts of standard solution to plasma. After homogenizing the samples, the MDA-TBA adduct was measured as described in the sample preparation section. The limit of detection was computed by standard method[21]. The average of recovery of MDA-TBA adducts was 99%.

### Statistical analysis

Data were analyzed statistically by one-way analysis of variance (ANOVA) and expressed as mean ± SD. The *P* values less than 0.05 were considered statistically significant. If a significant *P* value was obtained, the POST HOC analysis (Tukey-HSD multiple comparison tests) was performed to determine the effect of various treatments on gastric damage and MDA levels. Calculations were performed using SPSS software version 13.

## RESULTS

### J-scores in BDL and SHAM groups

Two days after laparotomy, BDL rats showed signs of cholestasis (jaundice, dark urine and steatorrhea) confirming rise in the level of plasma bilirubin. As shown in Figure 1, 50 mg/kg of indomethacin in BDL and SHAM rats produce gastric lesions with a J-score of 12.8 ± 1.3 and 7.8 ± 1.3, respectively. These results show that gastric mucosal damage is significantly more severe in BDL compared with SHAM and UNOP ($P < 0.001$) animals. This means that cholestasis increased the ulcerogenic effect of indomethacin and in multistress conditions; gastric mucosal damage is significantly more severe. The effect of melatonin on indomethacin-induced gastric damage in BDL and SHAM groups has been shown in Figure 1. As shown in Figure 1, 20 mg/kg of melatonin 30 min before indomethacin reduces the ulcerogenicity of indomethacin both in BDL and SHAM rats. The J-scores in this group were 4.6 ± 0.89 and 2 ± 1, respectively. These results show that the antioxidant effect of melatonin reduces cell damage mediated by oxidative stress.

### MDA levels in BDL and SHAM groups

Plasma MDA levels are shown in Figure 2. MDA level is

significantly higher in BDL compared with SHAM and UNOP rats (BDL = 3.1 ± 0.04; SHAM = 2.8 ± 0.04; UNOP = 1.4 ± 0.08; $P < 0.001$). These results show that the level of MDA is dependent on the number of stressful conditions. The effect of melatonin on MDA level in BDL and SHAM groups has been shown in Figure 2. As shown in Figure 2, 20 mg/kg of melatonin 30 min before indomethacin reduced the lipid peroxidation and MDA levels both in BDL and SHAM groups (BDL = 2.6 ± 0.03; SHAM = 2.2 ± 0.06; $P < 0.001$).

## DISCUSSION

Oxidative stress caused by reactive oxygen species (ROS) damaged cellular lipids, proteins and DNA and is widely recognized as one of the causes of the development of chronic disease. Under normal circumstances, the levels of ROS are low enough to be effectively removed by the natural defense mechanisms of the cell. There are, however, many conditions that enhance the production of ROS to such an extent that cellular defenses are overwhelmed and the cell injured[19]. The evaluation of biomarkers of cellular stress in conditions mediated by oxidative compounds could help to prevent appearance and development of oxidative stress-related diseases. Lipid peroxidation is considered to be important in the development of atherosclerosis, to be involved in aging and other clinical disorders, such as cancer, cardiovascular and liver diseases. An important step in the degradation of cell membranes is the reaction of ROS with double bound polyunsaturated fatty acids to yield lipid hydroperoxide (as primary products). On breakdown of such hydroperoxides a great variety of aldehydes can be formed (as secondary products). MDA, a three carbon compound formed by scission of peroxidized polyunsaturated fatty acids, is one of the main secondary products of lipid peroxidation[16,22]. MDA is reactive toward amino groups of protein and nucleic acid and have cytotoxic and mutagenic effects. Since MDA has been found elevated in various diseases thought to be related to free radical damage, it has been widely used as an index of lipid peroxidation in biological and medical sciences[20,22]. Determination of lipid peroxidation products in the body fluids can be used as a diagnostic tool for detecting increased levels of ROS. The most popular method of MDA detection is derivatization of MDA with different chemicals such as TBA and DNPH (2, 4-dinitrophenylhydrazine) and conversion into derivatives to allow more specific estimation of this compound. We used the HPLC method suggested by Agarwal, a rapid and reproducible method. In this method, protein was not precipitated and samples were derivatized after addition of BHT, and extraction of derivatized sample with n-butanol, found to be a suitable extracting solvent[20]. The plasma MDA levels and J. scores in both BDL animals treated with indomethacin and SHAM animals treated with indomethacin groups were greater than UNOP animals ($P < 0.001$). The plasma MDA levels and J-score in BDL rats treated with indomethacin were greater than SHAM animals treated with indomethacin ($P < 0.001$). The plasma MDA levels and J-score in BDL animals pretreated with melatonin and treated with indomethacin and SHAM animals with melatonin and treated with indomethacin were lower than BDL animals treated with indomethacin and SHAM animals treated with indomethacin. In conclusion, our results suggest that: cholestasis can increase the indomethacin-induced gastric mucosal damage and plasma MDA level. Melatonin is an efficient agent in reducing the negative effect of lipid peroxidation and reduces cell damage by oxidative stress in multistress conditions. According to the calculated detection limit (0.101 μmol/L) and average of recovery (99%) for MDA, sensitive methods for the determination of MDA level in plasma have been used.

## Abstract

**AIM:** To determine whether listening to music decreases the requirement for dosages of sedative drugs, patients' anxiety, pain and dissatisfaction feelings during colonoscopy and makes the procedure more comfortable and acceptable.

**METHODS:** Patients undergoing elective colonoscopy between October 2005 and February 2006 were randomized into either listening to music (Group 1, $n$ = 30) or not listening to music (Group 2, $n$ = 30). Anxiolytic and analgesic drugs (intravenous midazolam and meperidine) were given according to the patients' demand. Administered medications were monitored. We determined their levels of anxiety using the State-Trait Anxiety Inventory Test form. Patients' satisfaction, pain, and willingness to undergo a repeated procedure were self-assessed using a visual analog scale.

**RESULTS:** The mean dose of sedative and analgesic drugs used in group 1 (midazolam: 2.1 ± 1.4, meperidine: 18.1 ± 11.7) was smaller than group 2 (midazolam: 2.4 ± 1.0, meperidine: 20.6 ± 11.5), but without a significant difference ($P$ > 0.05). The mean anxiety level in group 1 was lower than group 2 (36.7 ± 2.2 *vs* 251.0 ± 1.9, $P$ < 0.001). The mean satisfaction score was higher in group 1 compared to group 2 (87.8 ± 3.1 *vs* 58.1 ± 3.4, $P$ < 0.001). The mean pain score in group 1 was lower than group 2 (74.1 ± 4.7 *vs* 39.0 ± 3.9, $P$ < 0.001).

**CONCLUSION:** Listening to music during colonoscopy helps reduce the dose of sedative medications, as well as patients' anxiety, pain, dissatisfaction during the procedure. Therefore, we believe that listening to music can play an adjunctive role to sedation in colonoscopy. It is a simple, inexpensive way to improve patients' comfort during the procedure.

## INTRODUCTION

Anxiety and pain are common problems associated with colonoscopy procedure and most endoscopy units prescribe some form of sedation and analgesia for patients undergoing this procedure[1]. Although the use of sedation is both risky and costly[2,3], performing colonoscopy without sedation may adversely affect both the outcome and patients' tolerance and is therefore not universally accepted practice[4-6]. It is imperative that ways be found to reduce the use of sedation without affecting patients' tolerance and satisfaction[1]. To reduce a patient's anxiety during invasive procedures like endoscopy, various approaches have been used to distract the patient's attention, such as therapeutic communication, visualization, aroma therapy, therapeutic touch, and listening to music[7,8].

Use of music to promote relaxation has a long history in medicine[1,9]. Music has been acknowledged as a cheap, safe and effective non-pharmacological anxiolytic agent due to its effect on the perception of pain and anxiety,

reducing the regular pharmacological sedative doses[10]. The role of music as an adjunct to standard treatment has been studied in several disorders[9]. There are a few studies that analyse the effect of music on the anxiety suffered by patients who undergo invasive procedures[10]. Some studies suggest that music alleviates anxiety and improves patients' tolerance during gastrointestinal (GI) endoscopy[9].

In this study, we aimed to assess whether listening to Turkish classical music may decrease the dose of sedative and analgesic medication requried during the colonoscopy procedure and improve anxiety and dissatisfaction of the patients.

## MATERIALS AND METHODS

Between October 2005 and February 2006, 60 patients scheduled for elective colonoscopy consecutively agreed to participate in the study. Patients aged below 18 or above 75 years, those who have hearing problems due to any cause, patients with overt or borderline psychiatric illnesses, presence of senile dementia, treatment with anxiolytic medication in the 72 h prior to the examination and those with considerable cardiopulmonary morbidities were excluded. Patients were randomized into two groups (group 1: listening to music, group 2: not listening to music) using computer-generated random numbers. All examinations were performed by an expert endoscopist who performed at least 200 full-length colonoscopic procedures previously using the Olympus CV-145 video-colonoscope. All patients provided written informed consent for participation in the study. The study protocol was approved by local ethical committee of Gaziantep University.

In this study, in the first part of the questionnaire in order to obtain demographic characteristics of the patients, questions related to age, gender, educational level, marital status, occupation, monthly income, having previous non-formal information about colonoscopy were asked. Doses of sedatives and analgesics were determined by the endoscopist performing the procedure according to patients' demand and anxiety status. Initial intravenous doses of meperidine at 10 mg and initial midazolam at 1 mg were given. Additional doses were titrated based on assessments of the patient by the endoscopist and nurse. Increments of meperidine (10 mg) and midazolam (1 mg) were given if patients showed signs of discomfort, pain, restlessness, or agitation that were not related to hypoxemia. After the procedure, the patients were asked several questions using a visual analog scale ranging from 0 (very much) to 100 (none) for pain (0 = Very much 100 = None), satisfaction (0 = none, 100 = very much), procedure evaluation (0 = unpleasant, 100 = pleasant) and willingness to do the procedure again (0 = never, 100 = happly)[1,11].

The State Trait Anxiety Inventory (STAI) was used to determine the anxiety level of the patients. STAI was developed by Spielberger *et al* in 1970 and adapted to Turkish population by LeCompte *et al* in 1976 and confirmed for reliability and validity by Oner in 1977[12]. This instrument has been used extensively in clinical settings to measure feelings of apprehension, tension, and nervousness. STAI is a two-part 40-item self-report. The Trait Portion (20 items) measures a person's general disposition and the State Portion (20 items) measures how a person feels at the time of the operation. The instrument is rated on a four-point scale. Scores are added to obtain an overall score (higher scores indicate higher levels of anxiety). The internal consistency alpha coefficients of the state portion range from 0.86 to 0.92. It is simple to use, generally taking < 5 min to complete, and easy to score[13,14].

Patients in the study group before and during the procedure were exposed to approximately 30 min of music therapy broadcasting from the central system of the endoscopy unit. The decision about the type of music was given by consultations with the specialist working in the Turkish Music Department of State Conservatory of Gaziantep University. During the research, music of a *ney* (reed flute) that is played using a traditional Turkish classical music instrument was found. It has been theorized that classical Turkish music, a slow and relaxing type of instrumental music, has the most recreative effect on people's psychological state[15] and ney is considered the most suitable instrument for this purpose. It has been known that Uygur Turks use music in the treatment of patients. Especially in the Mevlevi stories, it is told that psychologically ill people become relaxed when they listen to the sound of the ney. This application of music therapy was also seen in the Ottoman Empire period[16,17].

### *Statistical analysis*

Statistical Package for Social Sciences (SPSS 10.0 for Windows) was used for the analysis of the data. We performed Student's *t* test to compare means for two groups of cases. $P < 0.05$ was considered as significant.

## RESULTS

No significant difference was found between the two groups with respect to their age, gender, urban residence or not, educational and marital status, occupation, monthly income and having non-formal information about colonoscopy ($P > 0.05$) (Table 1).

Drug doses in group 1 (midazolam: 2.1 ± 1.4, meperidine: 18.1 ± 11.7) was lower than group 2 (midazolam: 2.4 ± 1.0, meperidine: 20.6 ± 11.5), but the difference was not statistically significant ($P > 0.05$) (Figure 1). Anxiety levels were significantly lower in the study group ($P < 0.05$) (Figure 2)

Patients in group 1 experienced less pain, were more willing to repeat the procedure, perceived the procedure more comfortable and were more satisfied with the procedure. All these parameters in group 1 and group 2 were significantly different ($P < 0.05$) (Figure 3).

## DISCUSSION

Colonoscopy is an uncomfortable and painful endoscopic procedure[4]. The use of various relaxing techniques to reduce pain and anxiety has been reported in medical literature[1]. Music therapy is one of the relaxing techniques and the benefical effects have been recognized for many years[18]. Several studies reported that the use of music

during endoscopy could alleviate anxiety and improve tolerance and compliance[7,18,19]. The results of clinical studies suggest that listening to music has a positive effect on psychological and physiologic status, and thus music has been used as an anxiolytic for relieving discomfort in stress-related interventions[20].

Lee *et al*[20] found that listening to music decreased the dose of sedative drugs that were used during colonoscopy. Harikumar *et al*[9] revealed that the dose of midazolam was lower in music group. In our study, we also found the dose of sedatives was lower; however, probably due to small

sample size, the difference was not statistically significant. Nevertheless, this prospective randomized controlled trial demonstrated that music can decrease the dose of sedative medication required for colonoscopy. The use of music as an adjuvant to sedation can potentially reduce dose-related complications associated with the use of sedative and analgesic drugs.

Many studies in different fields of medicine revealed beneficial effects of music on anxiety and discomfort[7,21-23]. Palakanis *et al*[18] determined that music decreased anxiety levels in sigmoidoscopy patients. Andrada *et al*[10] also found that anxiety levels were lower in music group in colonoscopy patients. In our study, we also clearly showed that listening to music decreased anxiety significantly. Many of the beneficial effects of music are linked to its anxiolytic capacity and its action on the perception of pain. This painful perception, however, is correlated with the levels of anxiety perceived during the procedure; therefore, an increase of this anxiety results in a more painful perception. Our study allows us to affirm that listening to music during colonoscopic procedures decreases the levels of anxiety linked to this invasive procedure.

Music therapy is widely used in treatment of acute and chronic pain[24]. Some studies showed decrease of pain by music[1,24-26]; however, some showed no effect[9,11,20]. In our study, pain perception was significantly decreased by listening to music.

Most studies revealed that music increased patients' satisfaction[1,19,27-29]. Our results are consistent with the literature. Although the doses of sedative drugs were not different between the two groups in our study, the satisfaction score was higher in group 1. The use of music in addition to sedative drugs had a favorable effect on patients' satisfaction. Moreover, most patients who underwent colonoscopy with a combination of music plus sedative drugs were willing to repeat the procedure. Thus, in the present study, music improved patients' acceptance of and tolerance to colonoscopy.

## CONCLUSION

This randomised trial demonstrates that music decreases the dose of sedative and analgesic medication required by patients undergoing colonoscopy, but not significantly. Listening to music decreases anxiety levels and pain scores significantly and increases satisfaction scores and patients' comfort and tolerance. Since it is a readily available, noninvasive, inexpensive, simple, and nonpharmacological method without any side effects, listening to relaxing music is highly recommended as an adjunct to sedatives and analgesics for patients undergoing elective colonoscopy.

## Abstract

**AIM:** To assess the clinical and economical validity of glutamine dipeptide supplemented to parenteral nutrition (PN) in patients undergoing abdominal surgery.

**METHODS:** A meta-analysis of all the relevant randomized controlled trials (RCTs) was performed. The trials compared the standard PN and PN supplemented with glutamine dipeptide in abdominal surgery. RCTs were identified from the following electronic databases: the Cochrane Library, MEDLINE, EMBASE and ISI web of knowledge (SCI). The search was undertaken in April 2006. Literature references were checked by computer or hand at the same time. Clinical trials were extracted and evaluated by two reviewers independently. Statistical analysis was performed by RevMan4.2 software from Cochrane Collaboration. A $P$ value of < 0.05 was considered statistically significant.

**RESULTS:** Nine RCTs involving 373 patients were included. The combined results showed that glutamine dipeptide has a positive effect in improving postoperative cumulative nitrogen balance (weighted mean difference (WMD = 8.35, 95% CI [2.98, 13.71], $P$ = 0.002), decreasing postoperative infectious morbidity (OR = 0.24, 95% CI [0.06, 0.93], $P$ = 0.04), shortening the length of hospital stay (WMD= -3.55, 95% CI [-5.26, -1.84], $P$ < 0.00001). No serious adverse effects were found.

**CONCLUSION:** Postoperative PN supplemented with glutamine dipeptide is effective and safe to decrease the infectious rate, reduce the length of hospital stay and improve nitrogen balance in patients undergoing abdominal surgery. Further high quality trials in children and severe patients are required, and mortality and hospital cost should be considered in future RCTs with sufficient size and rigorous design.

## INTRODUCTION

Glutamine (Gln) is the most abundant free amino acid in the body and plays a vital role in amino acid transport and nitrogen balance. Gln is also a primary fuel for rapidly dividing cells such as enterocytes and lymphocytes, which protect mucosa barricade and enhance immune functions[1]. Patients undergoing elective abdominal surgery usually have malnutrition and Gln concentration is low in blood due to several factors: mechanical obstruction, limitation of food intake, tumor-induced cachexia, obstruction of pancreaticobiliary, malabsorption and ongoing blood loss. Moreover, intravascular and free muscle glutamine pools become depleted in response to perioperative abrosia and operative stress. Free Gln is lack of stability in solution and intravenous adminitration is limited. Glutamine dipeptide (L-alanyl-L-glutamine) can be taken *via* vein and hydrolyzed into glutamine in circulation as Gln substitution. It was given to patients undergoing abdominal surgery in order to improve their postoperative nitrogen balance and immunonutrition[2]. Therefore, it is worth knowing whether routine supplementation of glutamine dipeptide in parenteral nutrition (PN) can amend clinical outcomes.

Meta-analysis has been applied in medical research to improve statistical efficiency, to evaluate the disadvantage of established studies and to draw reliable conclusions from various potentially relevant studies. It is the most promising approach for future research and a guideline for clinical treatment[3]. This meta-analysis aims to enhance our understanding of the clinical and economical validity of glutamine dipeptide for patients undergoing abdominal surgery.

## MATERIALS AND METHODS

### Identification of trials

The meta-analysis included clinical randomized controlled trials (RCTs) of patients undergoing abdominal surgery. The trials compared standard isonitrogen PN and PN supplemented with glutamine dipeptide.

### Search strategy

A computerized literature search was applied from the following electronic databases: the Cochrane Library (April 2006), MEDLINE (PubMed) (1966-April 2006), EMBASE (1980-April 2006) and ISI web of knowledge (SCI) (April 2006). The search was undertaken in April 2006. Literature reference proceedings were hand retrieved at the same time. The subject words for the search were glutamine dipeptide in addition to L-alanyl-L-glutamine. Other useful words were glutamine, parenteral nutrition, operation, surgery, postoperation or perioperation, RCT or clinical trials. Study literature includes abstracts at least in the English language and followed by full text.

### Data collection

Data were extracted independently by two reviewers and decided by the research team. Methodological quality of study was evaluated using the Jadad scale[4] and the trial with a score over 2 was included as high quality. Published studies were identified by the following selection criteria: study design-RCT, population-hospitalized adult patients undergoing abdominal surgery, intervention-parenteral nutrition with glutamine dipeptide and standard parenteral nutrition with isonitrogen and isocalorics. The following data were extracted: quantity and group dividing of patients, different doses and days of glutamine dipeptide used, and the baseline of trials. Outcome variables included: nitrogen balance, length of hospital stay, postoperative infection, immune effects, adverse events and mortality.

### Data analysis

The statistical analysis was performed by RevMan4.2 software, which was provided by the Cochrane Collaboration. $P$ value < 0.05 was considered statistically significant. Heterogeneity was checked by the Chi-square test Meta-analysis was done with fixed effects model when results of the trials had no heterogeneity. If the results had heterogeneity, random effects model was used and causes were analyzed. The result was expressed with an odds ratio (OR) for the categorical variable and weighted mean difference (WMD) for the continuous variables, and with 95% confidence intervals (CI). The Handbook for Cochrane Reviewer (v 1.8.0) from Cochrane Collaboration was used as a guideline for the meta-analysis.

## RESULTS

There were 454 papers relevant to the searching words. Through the steps of screening the title, reading the abstract and the entire article, only nine RCTs[5-13] involving 373 patients were included. Other two studies were excluded because of repeated reports[14-15]. Characteristics of studies included in meta-analysis are presented in Table 1. There were 7 papers published in English and 2 in Chinese. Five studies were done in Europe and 4 in Asia. In the trials, glutamine dipeptide was administered at 0.18-0.5 g/kg per day and lasted 5-7 d.

### Postoperative cumulative nitrogen balance

Six RCTs (involving 238 patients) reported postoperative cumulative nitrogen balance. The result was heterogeneous ($P$ < 0.00001) and the random effects model was used because of different preoperative general nutrition, different PN design and different doses and days of glutamine dipeptide supplementation. Combined analysis indicated that the use of glutamine dipeptide had a positive effect in improving the postoperative cumulative nitrogen balance (WMD = 8.35, 95% CI [2.98, 13.71], $P$ = 0.002) (Figure 1).

### Postoperative morbidity of infection

Five RCTs (involving 215 patients) reported the postoperative morbidity of infection. There was no heterogeneity ($P$ = 0.94). Combined analysis indicated that the use of glutamine dipeptide reduced infective events (OR = 0.24, 95% CI [0.06, 0.93], $P$ = 0.04) (Figure 2).

### Length of hospital stay

Six RCTs (involving 291 patients) reported length of hospital stay. The result was heterogeneous ($P$ < 0.00001) and the random effects model was used because of different severity of primary diseases, different levels of operational injury, different preoperative general nutrition and APACHE Ⅱ scores. Comprehensive analysis indicated that the use of glutamine dipeptide had a positive effect in shortening the length of hospital stay (WMD = -3.55, 95% CI [-5.26, -1.84], $P$ < 0.00001) (Figure 3).

## DISCUSSION

Before operation, abdominal diseases often led to lack of Gln, following malnutrition and immune dysfunctions. After operation, demand for Gln exceeded the supply from diet and from muscle as a response to injury. And it has been shown that intravascular and free muscle glutamine pools become deficient or depleted in response to operative stress[5,16,17]. The deficiency of glutamine is the main cause for protein metabolism disorder, intestinal mucosal injury, enteral wall permeability destruction, bacterial translocation and immunosuppression. All these increase the perioperative infection risk and hinder the postoperative recovery.

Meta-analysis indicates that the use of glutamine dipeptide could improve the postoperative nitrogen balance better than standard PN. Gln, accounting for approximately one third of the translocated nitrogen, plays a major role in supporting vital organ function and repairing wound[18]. Full supplementary glutamine dipeptide not only prevents protein lost, but also makes nutrition metabolism effective.

The study also gives us evidence that use of glutamine dipeptide decreases infective events. Gln is utilized at a high

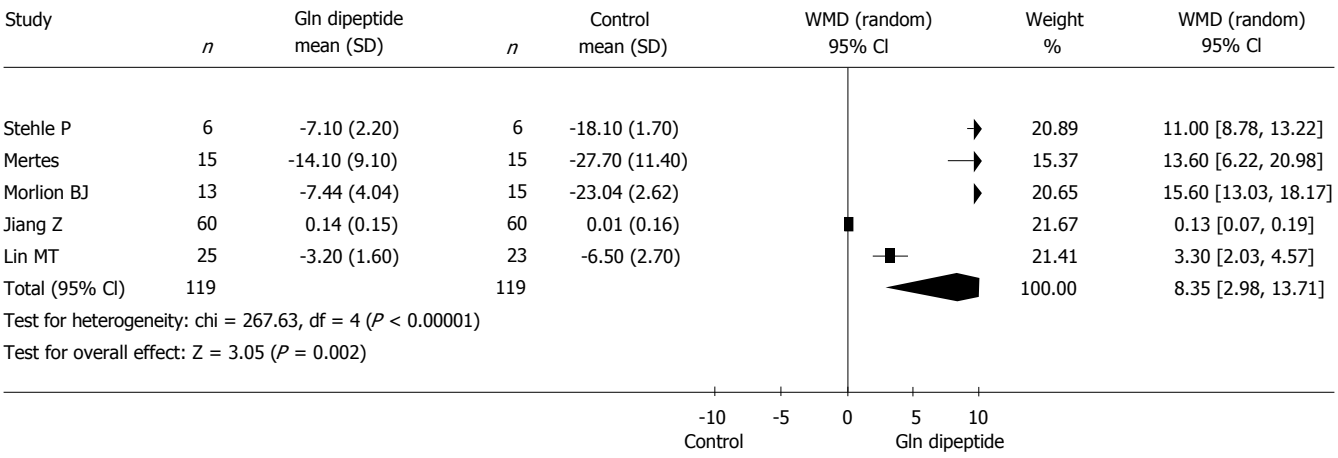

**Figure 1** Effect of glutamine dipeptide on postoperative cumulative nitrogen balance for abdominal surgery. Review: Clinical evidence of glutamine dipeptide for abdominal surgery; Comparision: Gln dipeptide *vs* control; Outcome: Postoperative cumulative nitrogen balance.

rate by cells of the immune system. It supports optimal lymphocyte proliferation, and production of cytokines by lymphocytes and macrophages. Macrophage-mediated phagocytosis is influenced by glutamine availability[1,19]. Hydrolysable glutamine dipeptide can substitute glutamine to support lymphocyte and macrophage functions *in vitro*. Animal studies have shown that intake of glutamine increases survival to bacterial challenge[19]. After operation, immunosuppression resulted in lowered plasma glutamine concentrations. If Gln or its precursors are provided to patients at risk of immunosuppression following surgery, sufficient maintenance of plasma glutamine concentration is of benefit to maintaining immune function. In clinical trials, glutamine dipeptide ameliorates restoration of plasma CD14 levels, improves lymphocyte recovery[6,9] and attenuates plasma IL-6 to relieve immunodepression[12,15]. Moreover, glutamine in circulation can also improve barricade function of gastroenteral mucosa to prevent bacterial translocation[9].

In those studies, mortality and hospital cost were seldomly reported. Length of hospital stay becomes a clinical end point as a surrogate for both clinical and economic efficiency. Meta-analysis shows that the use of glutamine dipeptide has a positive effect on shortening the length of hospital stay. Factors influencing hospital stay by Gln include accelerating wound repair and recovery of intestinal mucosal integrity, preventing potential delay of infection. It implies that such an approach is optimal in clinical practice, especially for severe surgeries[15]. At the same time, no serious adverse effects were found in all the

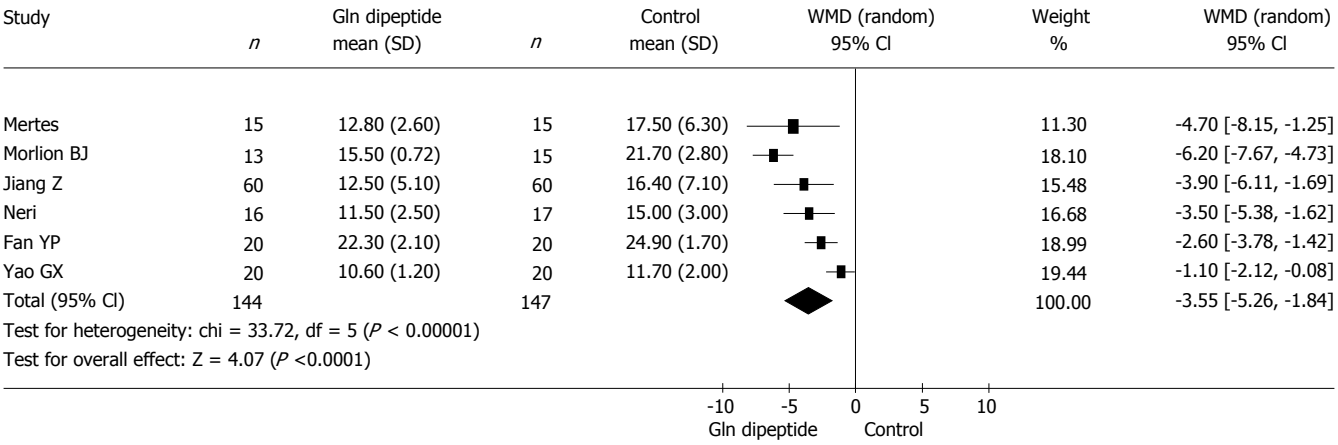

**Figure 3** Effect of glutamine dipeptide on length of hospital stay for abdominal surgery. Review: Clinical evidence of glutamine dipeptide for abdominal surgery; Comparison: Gln dipeptide *vs* control; Outcome: Length of hospital stay.

included studies.

In conclusion, postoperative PN supplemented glutamine dipeptide is effective and safe to decrease the infectious rate, reduce length of hospital stay and improve nitrogen balance in patients undergoing abdominal surgery. Further high quality trials in children and severe patients are required; Mortality and hospital cost should be considered in future RCTs with sufficient size and rigorous design.

## Abstract

**AIM:** To investigate the endoscopic findings and pathologic characteristics of gastric eosinophilic granuloma (GEG).

**METHODS:** A retrospective study of 18 cases of gastric eosinophilic granulomas was conducted. Gastroscopy was performed and all specimens of biopsies were stained by H&E and observed under light microscopy.

**RESULTS:** Ulcer was the most frequent endoscopic appearance. The others included deformed pylorus and/or duodenal bulb, esophagitis, mucous hyperemia and/or mucosal erosion. Eosinophilic cell infiltration and generous hyperplasia of arterioles, venules and lymph vessels were found in the lesions of the patients. Interstitium had massive eosinophilic infiltrates and was made up of collagen fibers and fibroblasts. Lymphoid follicles were revealed in some sections of biopsies.

**CONCLUSION:** GEG is lack of specific symptoms and physical signs. It can be misdiagnosed as gastric ulcer in most cases before biopsies. Endoscopy and endoscopic multiple deep biopsies in suspected areas are indispensable for correct diagnosis of GEG.

**Key words**: Gastric eosinophilic granuloma; Endoscopy; Pathology

## INTRODUCTION

Gastric eosinophilic granuloma (GEG) is characterized by pathological changes including eosinophil cells infiltrated into the submucous layer and muscular layer of the stomach. Its etiology is still unknown. The patients are prone to be misdiagnosed as having gastric carcinoma and gastric ulcer[1]. In order to investigate the endoscopic findings and pathologic characteristics so as to improve the diagnostic accuracy and therapeutic effect for GEG, 18 patients finally diagnosed by endoscopy and pathology are analyzed.

## MATERIALS AND METHODS

### Patients

From 2002 to 2006, a retrospective review of endoscopic mucosal biopsies and pathologic examinations was performed at the Digestive Endoscopic Center of Renmin Hospital of Wuhan University (Wuhan, China). In the routine gastroscopies performed during this period, 18 GEG patients (14 males, 4 females) were found among the 14 396 cases. Their mean age was 44.85 ± 11.70 years (range 22-65 years).

Endoscopic diagnoses were GEG (7 cases; including 5 definite cases and 2 suspected cases), gastric ulcer (5 cases), gastric ulcer accompanying esophagitis (1 case), gastric ulcer accompanying superficial gastritis (2 cases), superficial gastritis (1 case), and superficial gastritis accompanying duodenal ulcer (2 cases).

### Design

Gastroscopy was performed in the 18 cases. All the patients underwent endoscopic mucosal biopsies and pathologic examinations. All specimens of biopsies were stained by H&E and observed under light microscopy. Diagnostic criteria were used in accordance with the literature[2].

### Ethics

This is a retrospective study and data were collected by the common methods used in clinical practice.

## RESULTS

### Endoscopy

Ulcer is the most frequent endoscopic appearance. The endoscopic appearances include ulceration in 15 cases,

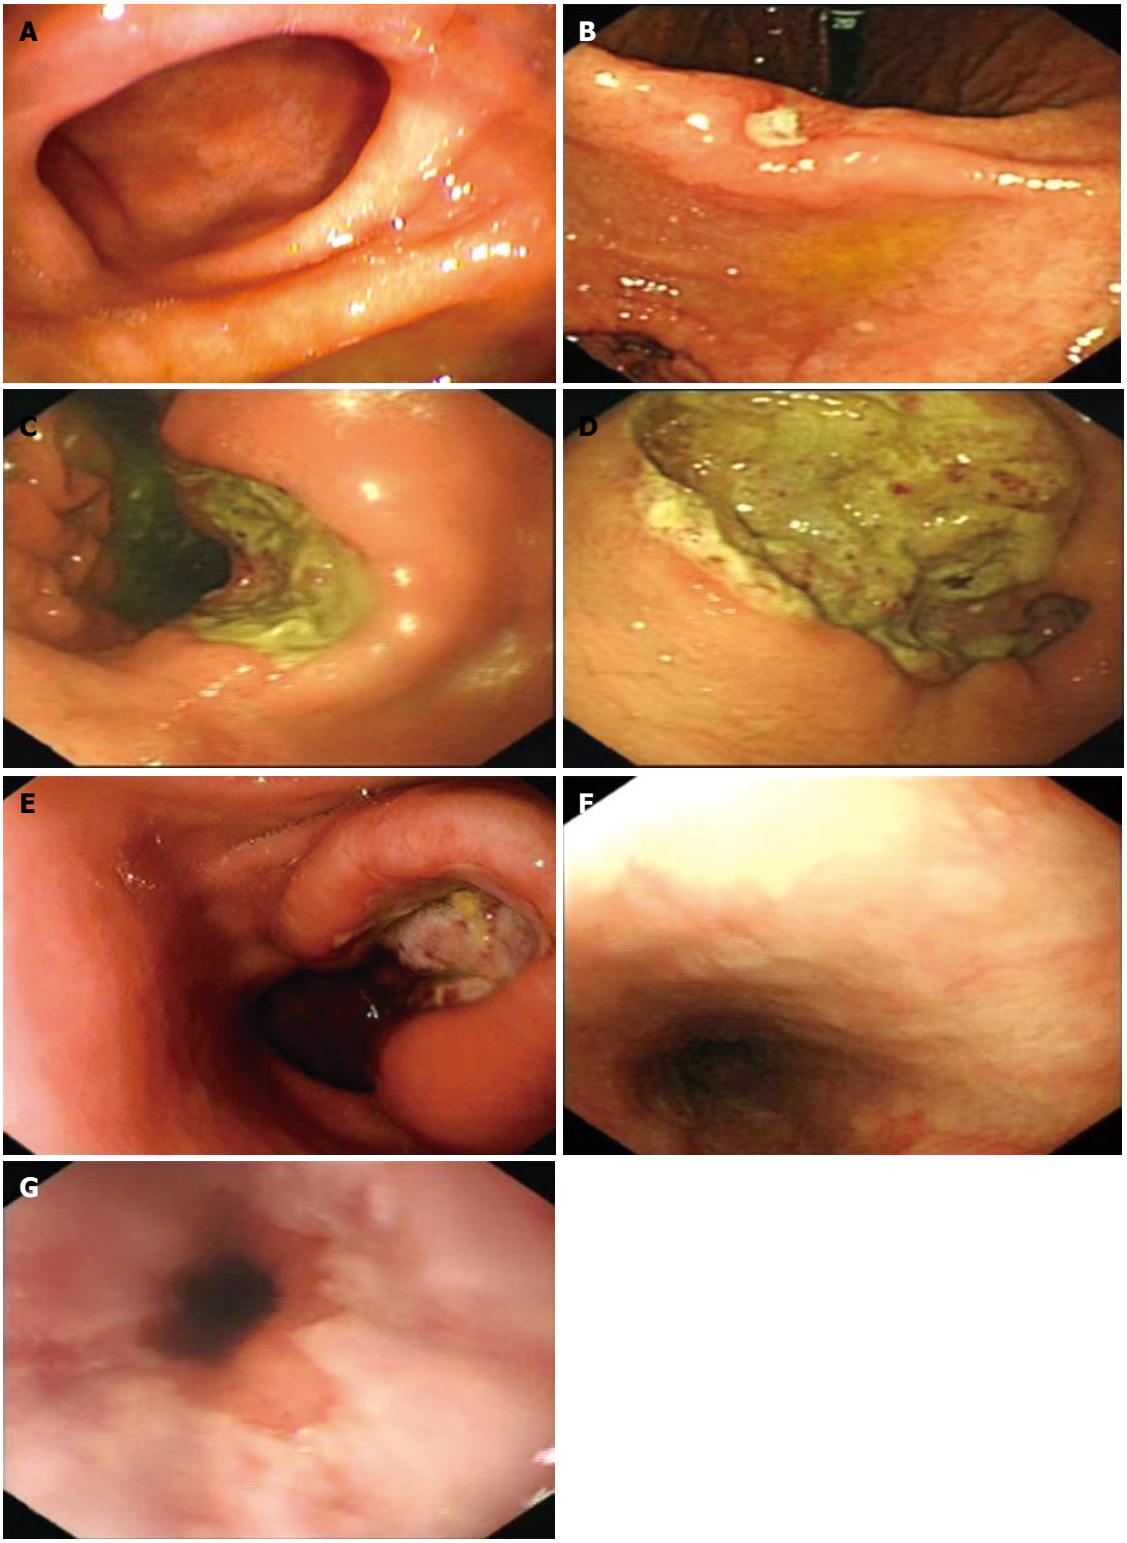

**Figure 1** Endoscopic photographs of GEG. **A**: Retracted ulcer scar on greater curvature and incomplete closure of pylorus; **B**: A 0.3 cm × 0.4 cm ulcer on gastric notch had whitish base; **C**: A 3 cm × 4 cm ulcer on inferior wall of gastric body and lesser curvature side. Yellowish green base and tumid ulcer margin; **D**: A 4 cm × 5 cm giant ulcer on lesser curvature side of gastric antrum and gastric notch had thickened and irregular base. Anterior wall of duodenal bulb was involved; **E**: The deformed gastric antrum and a 2 cm × 3 cm giant ulcer on gastric antrum and posterior wall of pylorus. The ulcer had mignonette base and black spots. The ulcer margin presented indentation-shaped appearance. Ulcer tissue was rigid and prone to bleed; **F**: Rough esophageal mucous membrane, blurred vascular net, clear-cut esophageal Z line; **G**: Higher esophageal Z line.

retracted scar tissue in 1 case (Figure 1A), and erosive gastritis in 2 cases.

**Sites of ulcers:** Gastric notch (3 cases), gastric body (3 cases), gastric antrum (5 cases), complex ulcer (1 case of gastric notch $H_1$+duodenal bulb $A_2$, 2 cases of gastric antrum $H_1$+duodenal bulb $A_1$), multiple ulcers on cardia and gastric antrum (1 case) and duodenal ulcer ( 2 cases).

**Morphologic characteristics of ulcers:** Besides 3 cases of giant peptic ulcers, the diameter of ulcers in most cases was less than 1 cm. Most ulcers were in active stage (7 cas-

es of $A_1$ stage and 3 cases of $A_2$ stage) and had whitish or greyish bases (Figure 1B). Merely 2 ulcers had mignonette bases (Figure 1C). Black spots were seen in the ulcer base in 1 case (Figure 1D). In addition, minute protuberances were frequently seen and caused by hyperplasia of granulation tissues. An irregular base was only found at a giant ulcer on the gastric antrum (Figure 1D). But malignant gastric ulcers, regardless of hemorrhage or not, showed dun or mignonette base, and no minute protuberances occurred. The margin of most ulcers was smooth and regular, and congestion and swelling of the surrounding mucosa were frequently seen, and symmetrically thickened (inflammatory) folds typically radiated to the ulcer base (Figures 1C and D). The surrounding mucosa of one giant ulcer presented with an indentation-shaped appearance (Figure 1E), one (posterior wall ulcer of central gastric body) presented with a crater-like appearance, and one (irregular ulcer of the gastric body) had an obscure boundary and nodular base. These cases should be differentiated from malignant ulcer. In contrast, malignant ulcers characteristically have irregular edges, and the surrounding, asymmetrical folds do not radiate to the ulcer base. Such folds may appear nodular or clubbed. An obvious mass often surrounds the malignant ulcer.

**Texture of ulcers:** Biopsied tissue was relatively rigid but had certain tenacity, ulcer tissues were not fragile, and the sites of biopsies bled less. Nevertheless, ulcer tissues of a giant ulcer on the gastric antrum was rigid and the sites of biopsies were prone to bleed during biopsies (Figure 1E). This case should be differentiated from malignant ulcer. Malignant ulcer is stiff and ulcer tissues are fragile. The sites of biopsies are prone to bleed. Multiple biopsies from the ulcer margin are apt to find malignant cells.

All patients had mucous hyperemia in the gastric fundus and gastric body, and mucosa-mottled congestion in the gastric antrum. Most patients had no gastroduodenal mucosal erosion, except one patient (endoscopic appearance indicative of a complex ulcer) who had mucosal erosion in the gastric notch.

Esophagus was not involved in most patients. Only in 5 cases, esophageal mucosa presented esophagitis-like appearance (Figure 1F). The mucous membrane of esophagus in 4 cases was gray, with blurred vascular net and scattered whitish granulations; 1 case had higher esophageal Z line (Figure 1G), but the mucous membrane of esophagus was normal.

These lesions included 2 cases of deformed pylorus (Figure 1E), 2 cases of incomplete closure of pylorus (Figure 1A) and mucous hyperemia, 1 case of swollen and deformed duodenal bulb, and 1 case of deformed pylorus and duodenal bulb. Anterior wall of duodenal bulb was involved and deformed by a giant ulcer from lesser curvature of gastric antrum to gastric notch in 1 case. Pylorus and duodenal bulb was normal in the rest of the cases.

### *Pathology*

Submucous layer of stomach presented significant inflammatory edema. Massive eosinophil cells and lymphocytes infiltrated into the stomach at full thickness, especially in submucous and muscular layers (Figure 2A-D). In granulated tissues, fibrous tissue proliferation around blood vessels, and fabric scars and hyalinization were found (Figure 2E). Arteriole, veinlets and lymph vessels abundantly proliferated (Figure 2F and G). The muscular layer was crushed and separated by eosinophilic cells, even the serous coat was involved. Lymphoid follicles formed and proliferated in the mucosal base. Intestinal metaplasia emerged in the epithelium of the gastric gland (Figures 2F and G). Chronic inflammation appeared in the peripheral lymph nodes. Ulcers emerged because of gastric mucosa necrosis around the lesions.

Fibroblasts and collagen fibers constituted interstitial substance of the lesions (Figure 2E). Massive eosinophilic cells and lymphocytes infiltrated into the interstitial substance. Occasionally, lymphoid follicles formed in the interstitial substance (Figure 2F and G). Arteriole, veinlets and lymph vessels also existed in the matrix.

## DISCUSSION

Kaijser[3] first described GEG in 1937. In 1950, Polayars formally denominated this syndrome as gastric eosinophilic granuloma. In 1961, Ureles, *et al*[2] systematically synthesized and categorized 47 cases of eosinophil cell infiltration in gastrointestinal tract and described the clinical characteristics of GEG extensively.

The cause of GEG is still unknown, and the pathogenesis is poorly understood. The etiological hypothesis of GEG mainly includes familial inheritance, allergic response, inflammation, foreign body reaction, *H pylori* infection, fungous infection, *etc*.[1,4-6].

There are more male patients than females, and middle-aged patients (11 cases) are frequently seen in this group. Clinical manifestations are lack of specificity and usually include stomachache, belching, abdominal distention, sour regurgitation and pyloric obstruction[7]. Compared with peptic ulcers, epigastric pain usually is irregular and is independent of eating. Abdominal pain is often severe and complicated with bleeding and chronic perforation, and antacids are ineffective. Many patients had anemia of different severities. Eosinophilic cells can increase in the peripheral blood of some patients[1].

Gastric mucosa, thickened mucosal folds, and superficial erosion were seen prominently. Because the lesions were involved in the pylorus in some patients, pyloric deformity and obstruction occurred. A few patients still presented incomplete closure of the pylorus. Most patients have ulcers. The edge of most ulcers is usually smooth and regular, and the ulcers have sharp margins, congestion and hydropsia in the surrounding mucosa, which are frequently seen, and symmetrically thickened (inflammatory) folds typically radiated to the ulcer base. The areas of ulcerations in a few patients are comparatively large; the edges of ulcers are irregular or crater-like in appearance; ulcer tissue is relatively rigid but not fragile, and the sites of biopsies are not prone to bleed[8,9]. But bleeding occurred in the sites of biopsies in 1 patient, which should be differentiated from malignant ulcers. Besides the above-mentioned appearances, GEG still has congestion and swelling of the gastric body and gastric fundus; and a few patients involv-

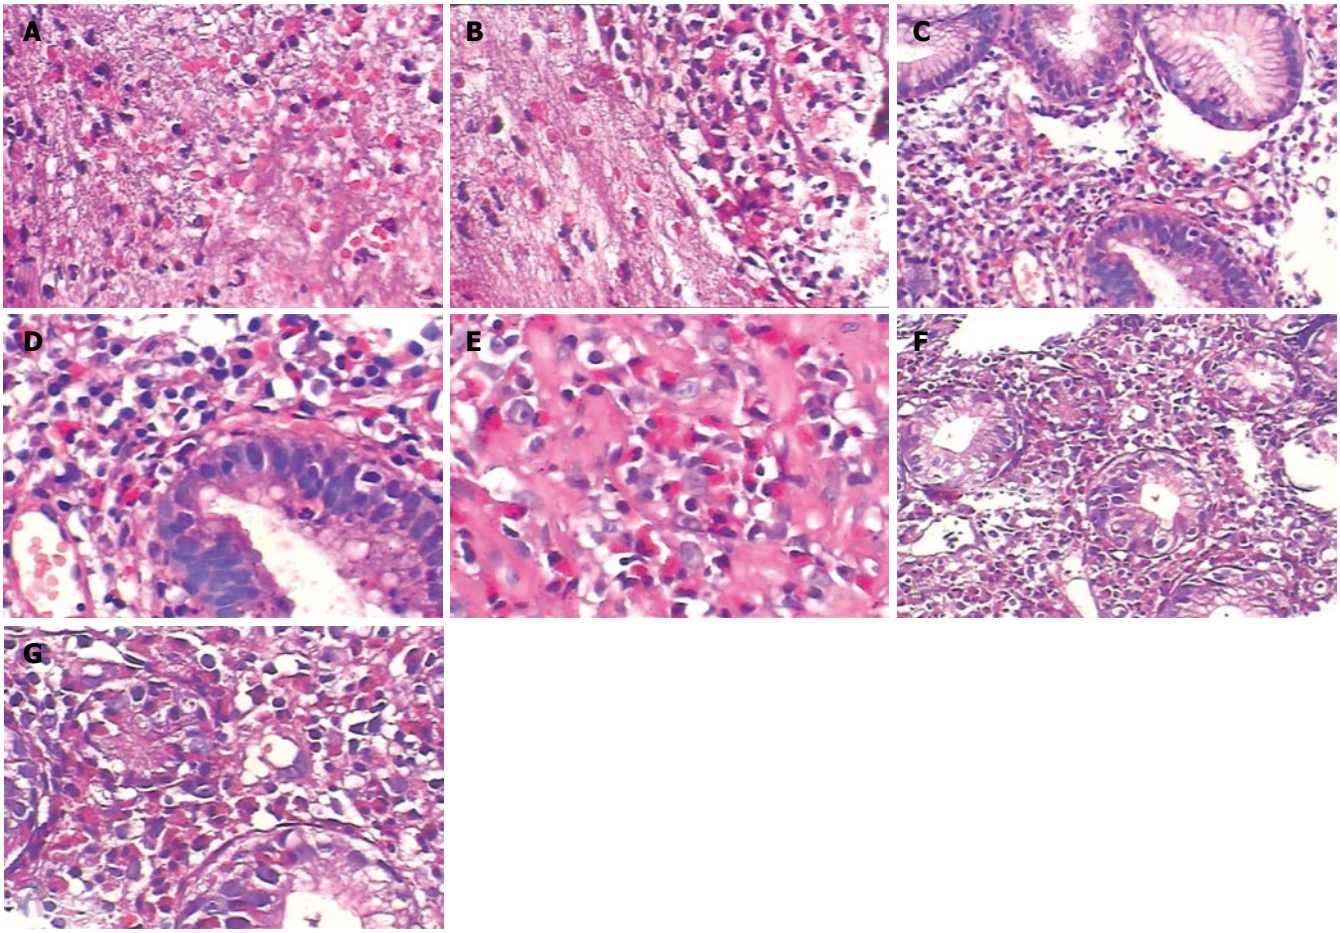

**Figure 2** Histologic photographs of GEG (H&E staining). **A**: Massive eosinophil cells and lymphocytes infiltrated (original magnification x 200); **B**: Same view as A, at different magnification (original magnification x 200); **C**: Massive eosinophil cells and lymphocytes infiltrated, especially surrounding the vessels. Intestinal metaplasia (original magnification x 100); **D**: Same view as C, at different magnification (original magnification x 200); **E**: Massive eosinophil cells and lymphocytes. Fibrous tissue proliferation, fabric scar, intestinal metaplasia and hyalinization (original magnification x 400); **F**: Massive eosinophil cells and lymphocytes. Arteriole, veinlets and lymph vessels abundantly proliferated. Lymphoid follicles (original magnification x 100); **G**: Same view as F, at different magnifications (original magnification x 400).

ing the esophagus present an esophagitis-like appearance.

In this group, all patients had lesions in the gastric antrum, and about 45% ulcers were located in the gastric antrum. The causes of GEG ulceration are suggested in four aspects: (1) Thickened stomach wall or localized masses can induce pylorus dysfunction and ulceration[10]. (2) Food deposition caused by gastric emptying disorder results in persistent food contacting with gastric antrum mucosa, which intensively stimulates gastrin and gastric acid secretion. Gastric mucosa is thus damaged and an ulcer forms. (3) Fibrous tissue proliferation surrounding blood vessels, fabric scars and hyalinization in granulation tissue cause insufficient blood supply to the gastric wall, myxasthenia and H-ion counter-diffusion, thus impairing the gastric mucosa. (4) As mucosa of the gastric antrum and lesser curvature is comparatively friable, mucosal defense to causative agents is weak, which increases the incidence rate of ulceration.

In order to increase the diagnostic accuracy of GEG, endoscopic multiple deep biopsies should be performed in suspected areas because of the eosinophilic cells which mainly infiltrate into the submucosal layer. Accordingly, most patients are firmly diagnosed by this method. With regard to the lesions of widespread infiltrating type, gastric carcinoma must be excluded. Endoscopic biopsies should be performed again when biopsies in suspected areas are negative, but these patients normally have chronic digestive system symptoms and simultaneously combine with increasing eosinophilic cells in peripheral blood, or had histories of hypersensitiveness or anaphylactic disease before. Recently, eosinophilic gastroenteritis is diagnosed by percutaneous puncture biopsies under ultrasound guidance[11].

Vanek[12] suggests the criteria for pathologic diagnosis of GEG as follows: (1) Interstitial substance is composed of fibroblasts and collagen fibers; (2) Eosinophilic cells and lymphocytes infiltrate into interstitium. Lymphoid follicles form occasionally; (3) Arteriole, veinlets and lymph vessels exist in interstitium; (4) Ulcers emerge around the pathologic lesions. While malignant lesions must be carefully precluded, GEG should be differentiated from plasma cell granuloma of the stomach when more plasma cells and Russell bodies are found in pathological lesions of some GEG patients. Exceptional granulomatous lesions such as mycetes, parasite, etc. should also be excluded. The pathological lesions of the 18 cases are consistent with the diagnostic criteria.

Therefore, in order to decrease the misdiagnosis rate, it is extremely important to have an intimate knowledge of endoscopic findings and pathologic characteristics of

GEG. Meanwhile, endoscopic examinations and endoscopic multiple deep biopsies in suspected areas are indispensable for accurate diagnosis. In addition, because endoscopic findings of some GEG patients are similar to that of gastric carcinoma, gastric lymphoma, gastric fibroma, gastric ulcer complicated with fungus infection, *etc*., these diseases must be attentively discriminated.

## Abstract

A 67-year-old woman underwent an orthotopic liver transplantation for end stage liver disease secondary to chronic autoimmune hepatitis. She developed sudden massive hematochezia on post-operative day 23 with hemodynamic compromise. The source of hemorrhage was found at colonoscopy after careful irrigation and inspection to be a dieulafoy lesion situated just proximal to the anorectal junction. Hemostasis was achieved with epinephrine injection and thermal coagulation.

**Key words:** Bleeding; Anorectal; Dieulafoy; Rectum

http://www.wjgnet.com/1007-9327/12/7547.asp

## INTRODUCTION

A dieulafoy lesion is a submucosal ectatic arterial lesion associated with a tiny mucosal defect. It is a rare cause of profuse, but intermittent upper or lower gastrointestinal bleeding. The bleeding is often unresponsive to conservative treatment and is associated with a high mortality rate. The exact process that results in the tortuousity of the superficial artery which erodes through the mucosa and which then may bleed is unknown. Most cases have occurred in the proximal stomach. Less commonly, lesions are encountered in the small intestine, colon and rectum. Cases of rectal dieulafoy-like lesion have been reported in literature. We report a case of massive lower gastrointestinal bleeding from a dieulafoy lesion of the rectum, immediately proximal to the anorectal junction post liver transplantation that was successfully treated with injection of 1:10 000 epinephrine followed by thermal coagulation. Without careful endoscopic examination, this lesion may have been mistaken as bleeding from hemorrhoids.

## CASE REPORT

A 67-year-old woman underwent a cadaveric orthotopic liver transplant for end stage liver disease secondary to chronic autoimmune hepatitis. Immunosuppression consisted of induction with basiliximab (Simulect, Novartis-Canada, Dorval QC) on post operative day 0 and day 4, delayed tacrolimus (Prograf, Astellas-Canada, Markham, ON) started on post operative day 6, mycophenolate mofetil (Cellcept, Hoffman LaRoche, Mississauga ON) and tapering doses of corticosteroids. Her post operative course was complicated and prolonged due to enterococcus faecalis septicemia, requiring intravenous vancomycin for 2 wk and disseminated varicella zoster virus reactivation which was treated with intravenous acyclovir for 10 d followed by oral valacyclovir for 3 mo to prevent recurrence.

On post-operative day 23, she developed sudden massive painless lower gastrointestinal bleeding with hemodynamic compromise. Her hemoglobin level dropped from 97 g/L to 72 g/L within several hours and she required a 2 unit transfusion of packed red blood cells which raised the hemoglobin level to 99 g/L. Her liver allograft was functioning well with a normal coagulogram and her liver blood tests remained stable. She also had normal serum urea and creatinine. There was no history of constipation, abdominal pain or previous gastrointestinal bleeding but occasional diarrhea while she was in the intensive care unit. There was no history of rectal enemas use, rectal digitation, rectal tube or foreign body insertion. On examination, she was not septic, but tachycardic with heart rate of 110/min and blood pressure of 115/70 mmHg and her abdominal examination was unremarkable except for mild tenderness around the incision site. A digital rectal examination revealed the presence of fresh blood with clot and no palpable masses. An urgent colonoscopy to the terminal ileum was performed on the same day and revealed the presence of blood throughout the colon but with abundant fresh clots in the rectum.

No obvious source of hemorrhage could be identified initially. After careful irrigation and inspection, a pulsatile active bleeding site was identified < 0.5 cm proximal to the anorectal junction, just above the dentate line (Figure 1). There was no obvious erosion or ulceration around the vessel and the surrounding mucosa appeared normal. Its appearance was consistent with that of a dieulafoy lesion. Hemostasis was achieved by injection with a total of 4 mL of 1:10 000 epinephrine around the bleeding lesion followed by bipolar electrocoagulation (BICAP). No further episodes of fresh bleeding were noted post-procedure. Passage of a normal brown stool was noted the following day with no further bleeding after a follow-up of 4 mo.

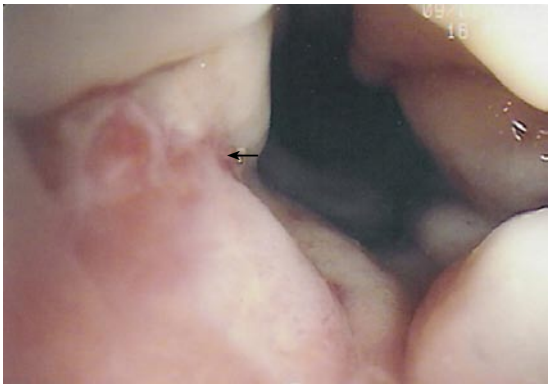

**Figure 1** Rectal dieulafoy (arrow) following injection of 1:10 000 epinephrine solution around the lesion.

## DISCUSSION

Dieulafoy's lesions are uncommon but well recognized life threatening sources of gastrointestinal bleeding. The majority of lesions occur in the stomach, and most lie in the lesser curvature within 6 cm of the gastroesophageal junction[1]. The lesion ruptures spontaneously and bleeds massively for reasons that are unclear. The typical endoscopic appearance of this lesion is a single, round mucosal defect with an artery protruding from its base in the absence of surrounding ulceration. The diagnosis now primarily depends on the endoscopic visual criteria that include active arterial spurting or micropulsatile streaming from minute (< 3 mm) mucosal defects or through normal surrounding mucosa, visualization of a protruding vessel with or without active bleeding within a minute mucosal defect or through normal appearing mucosa, and fresh, densely adherent clot with a narrow point of attachment to a minute mucosal defect or to normal appearing mucosa[2,3]. Microscopic examination of the lesion reveals a small mucosal defect with minimal inflammation and a large, tortuous, thick-walled artery at the base of the defect with rupture of the artery into the lumen with fibrin thrombus in the necrotic artery loop[4,5]. Although the original descriptions and early reports were of lesions in the proximal stomach, similar lesions have subsequently been reported in the esophagus, duodenum, jejunum, colon and rectum[4,6-10]. The unique aspect of this case was the fact that the dieulafoy lesion was immediately adjacent to the anorectal junction and without careful endoscopic lavage, could have been misdiagnosed as a hemorrhoidal bleeding with potentially disastrous sequelae. Since the colonoscopic diagnosis of rectal dieulafoy-like lesion may be difficult in the presence of large amount of luminal blood and clots, we would recommend rapid colonic lavage with a polyethyleneglycol solution either orally or *via* nasogastric tube if oral intake is not tolerated to enable adequate visualization which is crucial in making a diagnosis. A thorough and patient endoscopic examination with lavage is also necessary.

In terms of therapy, historically surgery had been the traditional treatment of dieulafoy lesions. However, the surgical approach has been superceded by endoscopic therapy. Several endoscopic methods have been successfully used including injection of epinephrine in conjunction with coagulation therapy or the application of a Hemoclip.

In summary, rectal dieulafoy lesions are unusual sources of rectal bleeding but must be included in the differential diagnosis of profuse painless rectal bleeding, especially when other definitive lesions are not found. Endoscopic therapy is safe and effective in the treatment of rectal dieulafoy lesions.

## Abstract

Primary aorto-colic fistula is rarely reported in the literature. Although infrequently encountered, it is an important complication since it is usually fatal unless detected. Primary aorto-colic fistula is a spontaneous rupture of abdominal aortic aneurysm into the lumen of the adjacent colon loop. Here we report a case of primary aorto-colic fistula in a 54-year old male. The fistulated sigmoid colon was repaired by end-to-end anastomosis. Despite inotropic support, the patient died of sepsis and multiorgan failure on the first postoperative day.

**Key words:** Aortocolic fistula; Abdominal aort aneurysm; Rupture; Lower gastrointestinal bleeding; Aneurysm

## INTRODUCTION

Primary aortocolic fistula is a very rare and catastrophic complication of infrarenal abdominal aortic aneurysms. The incidence of secondary aorto-enteric fistulae has increased to 1.5%-4.0% due to the increase in the frequency of aorto-iliac fistula reconstruction techniques[1]. However, the incidence of primary aorto-colic fistulae is reported to be as low as 0.69%-2.36%[2].

The most common etiology of aorto-colic fistulae is a previous aorto-iliac fistula reconstruction with a synthetic graft for abdominal aortic pathology. An abrasion of the graft or erosion of the wall of the adjacent bowel loop by the suture line may cause a connection between the lumen of both organs[2,3]. Primary aorto-colic fistula is a spontaneous rupture of abdominal aortic aneurysm into the lumen of the adjacent colon loop. Here we report a case of primary aorto-colic fistula.

## CASE REPORT

A 54-year old male was admitted to the Emergency Surgery Department of the Medical Faculty of Istanbul, Istanbul University, Turkey, with a diagnosis of an abdominal pulsatile mass. The patient suffered from hematochezia 4 d prior to admission. His past medical history did not reveal any abnormality besides heavy-smoking. During the physical examination he did not have any abdominal pain or tenderness. However, there was a pulsatile mass in the abdomen. There was blood upon rectal examination. The femoral pulses and lower extremity pulses were bilaterally palpable. The blood pressure was 90/70 mmHg, pulse rate was 112 beats/min, respiratory rate was 24 breaths/min, and the body temperature was 37.3℃. A laboratory investigation indicated hemoglobin of 7.4g/dL, hematocrit of 27%, white blood cells of 14000/mm$^3$, and a normal platelet count. The blood glucose was 160 mg/dL. Computed tomography (CT) scanning showed a 7 cm × 7 cm abdominal aortic aneurysm located infra-renal with gaseous images within the lumen of the aneurysm (Figure 1). Upon CT scanning, a loop of sigmoid colon was in close contact with the aorta at the level of the gaseous images. Emergency laparotomy showed a fistula between the aneurysm and the distal sigmoid colon. The aneurysm was resected and an axillo-bi-femoral bypass with ePTFE graft was carried out. In spite of inotropic support with dopamine and dobutamine, blood pressure was below 90 mmHg and a cardiac arrest (which responded to cardiopulmonary resuscitation) occurred during the operation. The fistulated sigmoid colon was repaired by end-to-end anastomosis. The patient was monitored at the Intensive Care Unit postoperatively. Despite inotropic support, the patient died of sepsis and multiorgan failure on the first postoperative day.

## DISCUSSION

Primary aorto-colic fistula is seldom reported in the literature. Although rarely encountered, it is an important com-

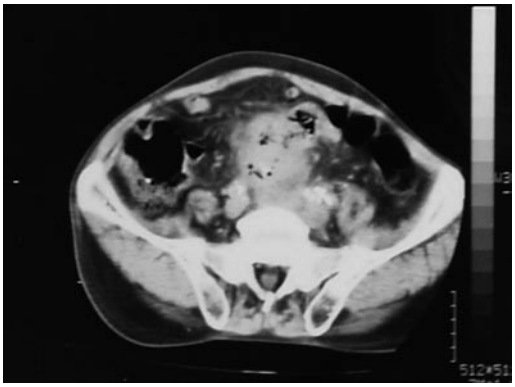

**Figure 1** CT scanning-revealed air bubbles in aortic lumen and fistula tract between the sigmoid colon and the aorta.

plication since it is usually fatal unless detected. Fistulization may occur in the jejunum, ileum, esophagus, stomach as well as colon[4-7]. Although the most frequent site of fistula is the third portion of the duodenum, a classic triad of symptoms including abdominal pain, gastrointestinal bleeding and a pulsatile abdominal mass may present in some cases regardless of the site affected[5,6]. The bleeding may be abundant or intermittent "herald" with hypotension and syncope. Our patient had a history of bleeding four days before he was admitted. However, it did not recur until the day he presented with shock at the Emergency Department. Despite the fact that certain definition of the pathogenesis of primary aorto-enteric fistulae is beyond our knowledge for the time being, mechanical erosion by aneurysms and inflammations such as diverticulitis is generally suggested to be the cause[8,9]. CT scanning and angiographies rarely demonstrate the fistula tract. However, CT scanning is of utmost importance in patients with an initial diagnosis of aorto-colic fistula. CT scanning may reveal an aortic aneurysm, deletion of the plane between the aorta and the adjacent organ, and gas in the wall or even within the lumen of the aorta as it was in this case (Figure 1).

The appropriate treatment of the entity consists of aneurysmectomy, repair of the fistula, and aortic reconstruction with synthetic grafts and omental wrapping or an extra-anatomical bypass. Aggressive antibiotic treatment is required as well to prevent an *in-situ* graft infection, which may be fatal[8]. The mortality rate still remains high and ranges from 30% to 75% depending on the time of surgery. The high mortality is mainly due to the sequelae of hemorrhagic shock and massive blood transfusion and sepsis. It has been stated that early death due to multisystem failure is to be expected and sepsis is an inevitable consequence of aorto-colic fistula[10].

This report emphasizes that rupture of aorto-iliac aneurysm into the sigmoid colon should be included in the differential diagnosis of lower gastrointestinal bleeding, and the high mortality of aorto-colic fistulae may be overcome with prompt diagnosis, immediate surgical intervention, and measures against sepsis. However, it may still cause death of patients in spite of all measures.

## Abstract

Cyproterone acetate (CPA) is a steroidal synthetic progestagen and anti-androgenic compound widely administered in prostate cancer which has been evidentially correlated with a severe hepatotoxic potency. Three male patients aged 78-83 years are presented, in whom severe hepatotoxic reactions emerged after CPA administration. Patients were treated with CPA at the doses of 200-300 mg/d for malignant prostate disease for 3-12 mo prior to the acute manifestation of the hepatic disease. Clinical features compatible with mixed hepatocellular and cholestatic liver disease including jaundice, white stools and dark urine, manifested in all three cases whereas encephalopathy and ascites were present in two of the patients. Other primary causes of hepatotoxicity (alcohol consumption and viral hepatitis) were also verified in two cases, and in those patients biopsy findings revealed the presence of cirrhotic lesions in liver parenchyma. Discontinuation of the therapeutic agent led to the amelioration of the clinical profile in all the patients whereas a patient died 40 d after hospital admission due to sepsis, despite acute liver disease improvement. The current article highlights the hepatotoxic potency of a widely administered therapeutic agent and illustrates the importance of clinical surveillance especially in patients with previous hepatic diseases. Three relevant cases are reported and a review of the published literature is made.

## INTRODUCTION

Androgen deprivation therapy in the form of either orchiectomy or treatment with endogenous estrogens or luteinizing hormone releasing hormone (LHRH) analogues alone or coupled with antiandrogens, produces regression of prostate cancer cells through suppression of serum testosterone levels, and is on that ground regarded as an effective adjuvant therapeutic option. Cyproterone acetate (CPA) is a steroidal synthetic progestagen and antiandrogenic compound widely administered not only in prostate cancer but also in breast cancer, severe acne, female hirsutism, precocious puberty, hyper sexuality and sexual deviation in men. CPA inhibits the peripheral actions of testosterone and suppresses gonadotropin secretion by maintaining the negative feedback on the pituitary. Hepatotoxicity is a serious adverse reaction potentially induced by both steroidal and nonsteroidal antiandrogens. The first case of CPA-induced fulminant hepatitis with a fatal outcome was described in 1989[1]. A variety of hepatotoxic reactions have been documented in the literature including immunoallergic cytotoxic reactions[2], cholestasis, autoimmune hepatitis[3], acute hepatitis[4-10] fulminant hepatic failure[1,2,11-17] cirrhosis[18] and finally CPA has been attributed a hepatocellular mutagenic potency leading to hepatocarcinogenesis[8,19-27]. Clinical features include jaundice, fatigue, nausea, elevated serum levels of liver enzymes, different types of necrosis (bridging, confluent, and centrilobular), inflammation and features of hepatic decompensation[19]. This article highlights the hepatotoxic potency of a widely administered therapeutic agent and illustrates the importance of clinical surveillance. Three relevant cases are presented and a review of the published literature is made.

We searched the database PubMed (1995-2005) using the following key words: "cyproterone acetate hepatotoxicity", "drug induced hepatotoxicity". We also included review articles, book chapters, or commonly referenced publications. We reviewed the reference lists of articles identified by the search strategy and selected those we judged relevant. The search was restricted to papers published in English.

## CASE REPORT

Three male patients aged 78-83 years with clinical features compatible with mixed hepatocellular and cholestatic liver diseases, including jaundice, white stools and dark urine were admitted to Hippocration University Hospital of Athens. Clinical manifestations including encephalopathy (Case 2) and ascites were documented in two of the patients (Case 1 and 2) (Table 1). The main characteristics of patients, as well as the values of bilirubin, aspartate (AST) and alanine aminotransferase (ALT), International Normalized Ratio (INR), albumin, and alkaline phosphatase (ALP) at the time of admission are depicted in Table 1. All three patients had been administered cyproterone acetate for 3-12 mo for prostate cancer without metastasis, at a dose ranging from 200-300 mg/d. Extensive clinical evaluation and exclusion of other potential hepatotoxic causes were performed. No serological evidence of recent acute viral hepatic infection was verified whereas in Case 3, pre-existing chronic inactive hepatitis B virus infection was justified based on compatible serological findings (hepatitis B virus surface (HBs) antigen was positive and hepatitis B virus DNA negative by hybridization assay). In addition, a history of excessive alcohol consumption was documented in Case 1. Autoimmunity markers were negative and no evidence of tumor in the liver or pelvis was seen on the computer tomography scan. Yet the presence of cirrhotic lesions was verified in Cases 1 and 3 on tomography. Liver biopsy was performed in all three Cases (Figure 1). In Cases 1 and 3, cirrhosis with fibrosis and loss of the normal lobular architecture were revealed and attributed to chronic hepatitis B and alcohol consumption. In all three cases, hepatocellular degeneration with ballooning of hepatocytes, portal and lobular inflammation and marked cholestasis with bile plugs were also demonstrated. Discontinuation of the therapeutic agent led to the restoration of the pathological clinical profile in Cases 1 and 3 whereas this was not accomplished in the second patient who died 40 d after hospital admission, due to sepsis, despite acute liver disease improvement. (Figures 2 and 3).

## DISCUSSION

The diagnosis of drug-induced hepatotoxicity is usually based on exclusion of other possible causes of hepatic dysfunction and on the temporal association between drug administration and the onset of liver disease while liver biopsy may allow a correct diagnosis[28,29]. Toxic hepatitis in our patients appeared to be causally related to the administration of cyproterone acetate based on a temporal relationship, negative serology for acute viral infection, negative autoantibody markers and exclusion of drugs or other potentially hepatotoxic agents. Proof is not possible in the absence of the rechallenge for ethical reasons. Pathophysiology of CPA-induced hepatotoxicity remains largely hypothetical. The histological features fit with an idiosyncratic reaction to the drug or its metabolites, or possibly an immunologically mediated reaction[2]. In many cases, a direct drug or metabolite effect is implied attributed to the hepatomitogen action of cyproterone, causing an increase of hepatocytes expressing placental glutathione S-transferase, which are considered preneoplastic elements[30-31]. The combination of Transforming Growth Factor-beta 1 (TGF) expression coupled with a strikingly enhanced sensitivity to the induction of apoptosis might be responsible for both the liver damage and the development of liver tumors observed after CPA supplementation since CPA shortens the lag phase of induction of apoptosis by shifting hepatocytes to a point before S phase, where they are highly susceptible to TGF-beta 1-induced apoptosis[19,32].

Hinkel *et al*[33] have conducted a retroprospective analysis of 89 patients who received cyproterone acetate for 4 years (50mg/d po range, 2-152 mo) for prostate cancer. Elevated liver enzymes were documented in 28.2% of the patients, yet CPA-induced liver toxicity and carcinogenesis were implied to be totally irrelevant considering the life expectancy of patients with advanced prostate cancer and the high-dose exposure of CPA required to possibly induce liver malignancies. Since then several large series have assessed the same issue with yet controversial results. In 1996, a retrospective study was conducted in 2506 patients receiving CPA (18-136 mg/d for less than 47.5 mo/patient) and a correlation with hepatocarcinogenesis could not be established. And 9.6% of the patients eventually presented with pathological liver profile, yet discontinuation of the therapeutic agent was not regarded necessary in any case[8]. Lin *et al*[34] assessed 229 patients by retrospective chart review submitted in orchiectomy or LHRH analogues plus antiandrogen for prostate cancer. In 105 patients administered with CPA (150 mg/d), hepatotoxity rates were 9.5%. Serious hepatic injury was documented in 3.8% (4/105) of the patients, mean latency period of hepatotoxity was estimated to be 5.8 ± 1.9 mo and in 9 out of 10 patients CPA-induced hepatotoxity got self resolution after discontinuation of the antiandrogen in an average period of 6.3 ± 4.7 mo[34]. In another study, patients with a preexisting chronic viral hepatitis were recognized as having a higher risk of developing antiandrogen hepatotoxicity[35]. Finally in a series assessing predictive utility of several clinical features, both age and therapeutic indication or the dose prescribed failed to depict with significant accuracy, those patients at risk for presenting hepatic disorders[36].

In the three cases of severe CPA-induced hepatotoxicity presented in this article patients were administered with CPA at the doses of 200-300 mg/d for malignant prostate disease for 3-12 mo prior to the manifestation of hepatic disease. In two of the patients, other primary causes of hepatotoxicity (excessive alcohol consumption and viral hepatitis) were also verified and in those patients, biopsy findings revealed the presence of cirrhotic lesions in liver parenchyma along with acute cholestatic hepatitis. Discontinuation of the therapeutic agent resulted in the amelioration of the hepatic injury in all the patients whereas Case 2 died 40 d after hospital admission from sepsis.

Eleven cases assessing CPA-induced fulminant hepatic failure are presented in the literature[1,2,11-17]. According to Friedman *et al*[13] adverse hepatic reactions occurred more commonly in elderly patients (range, 65-92 years) with malignant diseases who were treated with high doses (range, 100-300 mg) for a prolonged period. Fulminant hepatic failure developed a few weeks to several months after initiation of therapy (range, 2-15 mo). On admission, aminotransferases were 3-27 times that of normal, and a markedly elevated bilirubin of 9-30 times higher than normal were also documented, but the ALP was usually 2 times lower than normal. Clinical features of hepatotoxicity initially included nausea, anorexia and malaise; however, a progressive jaundice eventually ensued. The duration from the onset of jaundice to death was 2-7 wk[13]. Beside acute liver failure, a less severe hepatic reaction can emerge on the ground of CPA-administration. Eight cases of acute hepatitis complicating CPA-treatment have been documented in the literature[4-10]. Doses of 100-150 mg/d are correlated with mild hepatotoxic reactions, mainly elevated transaminase levels, whereas an association between the duration of CPA-treatment and the prevalence of liver enzymes could not be established[8]. Latency before the onset of hepatocellular carcinoma and cirrhosis after CPA therapy is estimated up to several years. Preexisting viral, metabolic, drug-induced or alcoholic liver diseases are found correlated with the development of more severe hepatotoxic reactions. Discontinuation of the antiandrogens results in the resolution of hepatotoxicity. A change to other antiandrogen may be the alternative strategy to CPA-induced hepatic injury although controversy exists upon that issue[9]. After the withdrawal of the causative agent, hepatocellular recovery is achieved within 2-3 mo[19]. Fourteen case reports involving CPA-induced hepatotoxicity are reviewed with regard to the patient's age, dose of CPA, latency before the onset of jaundice and duration between onset of jaundice and death[13,36] (Table 2). Descriptive statistics including means, medians and standard deviations were calculated, and are displayed in Table 2. Age and CPA doses were plotted in correlation with mortality (Figure 4). Relevant statistics were calculated and no statistically significant correlation was demonstrated between age and doses of CPA and the clinical outcome (death or survival) ($P$ = 0.241 and $P$ = 0.789 for CPA doses and age, respectively; not significant).

In conclusion, the aim of this report and review of

the literature is to underline the potential hepatotoxicity effect of CPA, which may prove fatal in some cases. Close monitoring of liver function tests is recommended, particularly on the setting of a pre-existing liver disease for which increased risk rate has been implied.

*ACKNOWLEDGMENTS*

# Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those were published and those were rejected in this issue) during the last editing period of time.

# Meetings

## MAJOR MEETINGS COMING UP

First Biennial Congress of the Asian-Pacific Hepato-Pancreato-Biliary Association
March 2007
Fukuoka, Japan
<http://www.congre.co.jp/1st-aphpba>/

American College of Gastroenterology Annual Scientific
20-25 October 2006
Las Vegas, NV

14th United European Gastroenterology Week, UEGW
21-25 October 2006
Berlin, Germany

APDW 2006: Asian Pacific Digestive Week 2006
26-29 November 2006
Lahug Cebu City, Philippines

## EVENTS AND MEETINGS IN THE UPCOMING 6 MONTHS

Falk Symposium 151: Emerging Issues in Inflammatory Bowel Diseases
24-25 March 2006
Sydney - NSW
Falk Foundation e.V.
symposia@falkfoundation.de

10th International Congress of Obesity
3-8 September 2006
Sydney
Event Planners Australia
enquiries@ico2006.com
www.ico2006.com

Easl 2006 - the 41st annual
26-30 April 2006
Vienna, Austria
Kenes International

Prague hepatology 2006
14-16 September 2006
Prague
Foundation of the Czech Society of Hepatology
veronika.revicka@congressprague.cz
www.czech-hepatology.cz/phm2006

12th International Symposium on Viral Hepatitis and Liver Disease
1-5 July 2006
Paris
MCI France
isvhld2006@mci-group.com
www.isvhld2006.com

Falk Symposium 152: Intestinal Disease Part I, Endoscopy 2006 - Update and Live Demonstration
4-5 May 2006
Berlin
Falk Foundation e.V.
symposia@falkfoundation.de

Falk Symposium 153: Intestinal Disease Part II, Immunoregulation in Inflammatory Bowel Disease - Current Understanding and Innovation
6-7 May 2006
Berlin
Falk Foundation e.V.
symposia@falkfoundation.de

ILTS 12th Annual International Congress
3-6 May 2006
Milan
ILTS
www.ilts.org

Internal Medicine: Gastroenterology
22 July 2006-1 August 2006
Amsterdam
Continuing Education Inc
jbarnhart@continuingeducation.net

6th Annual Gastroenterology And Hepatology
15-18 March 2006
Rio Grande
Office of Continuing Medical Education

# Instructions to authors

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*WJG, World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

### *Indexed and abstracted in*

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### *Published by*

The WJG Press

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

### *Online submission*

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

### *Postal submission*

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

### Editorial Office

***World Journal of Gastroenterology***
Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com
Telephone: +86-10-85381901
Fax: +86-10-85381893

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### *Title page*

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

### *Abstract*

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

### *Key words*

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

### *Text*

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

### *Illustrations*

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

### *Tables*

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### *Notes in tables and illustrations*

Data that are not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ should be noted ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used. Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under

illustrations should be expressed as $^1F$, $^2F$, $^3F$; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

### *Acknowledgments*

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### *Coding system*

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24 ], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### *PMID requirement*

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (http://www.wjgnet.com/cgi-bin/index.pl), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### *Style for journal references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (http://www.aushome.cn/cgi-bin/index.pl)

### *Style for book references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### *Inappropriate references*

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### *Statistical data*

Present as mean ± SD or mean ± SE.

### *Statistical expression*

Express $t$ test as $t$ (in italics), $F$ test as $F$ (in italics), chi square test as $\chi^2$ (in Greek), related coefficient as $r$ (in italics), degree of freedom as $\gamma$ (in Greek), sample number as $n$ (in italics), and probability as $P$ (in italics).

### *Units*

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, $p$(B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; $CO_2$ volume fraction, 50 mL/L $CO_2$ not 5% $CO_2$; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

***Abbreviations***

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

***Italics***

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori, E coli, etc.*

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

***Language evaluation***

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

***Copyright assignment form***

Please downloaded CAF from http://www.wjgnet.com/wjg/help/9.doc.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to WJG all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The WJG requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1)direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3)supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The WJG does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to WJG if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

## Abstract

The prognosis of patients with hepatocellular carcinoma (HCC) accompanied by portal vein tumor thrombus (PVTT) is generally poor if left untreated: a median survival time of 2.7-4.0 mo has been reported. Furthermore, while transcatheter arterial chemoembolization (TACE) has been shown to be safe in selected patients, the median survival time with this treatment is still only 3.8-9.5 mo. Systemic single-agent chemotherapy for HCC with PVTT has failed to improve the prognosis, and the response rates have been less than 20%. While regional chemotherapy with low-dose cisplatin and 5-fluorouracil or interferon and 5-fluorouracil via hepatic arterial infusion has increased the response rate, the median survival time has not exceeded 12 (range 4.5-11.8) mo. Combined treatment consisting of radiation for PVTT and TACE for liver tumor has achieved a high response rate, but the median survival rates have still been only 3.8-10.7 mo. With hepatic resection as monotherapy, the 5-year survival rate and median survival time were reportedly 4%-28.5% and 6-14 mo. The most promising results were reported for combined treatments consisting of hepatectomy and TACE, chemotherapy, or internal radiation. The reported 5-year survival rates and median survival times were 42% and 31 mo for TACE followed by hepatectomy; 36.3% and 22.1 mo for hepatectomy followed by hepatic arterial infusion chemotherapy; and 56% for chemotherapy or internal radiation followed by hepatectomy.

**Key words:** Hepatocellular carcinoma; Portal vein tumor Thrombus; Hepatic resection; Transcatheter arterial chemoembolization; Chemotherapy; Radiation

## INTRODUCTION

Recent progress in imaging techniques has permitted the diagnosis of hepatocellular carcinoma (HCC) at an early stage. However, portal venous invasion is still found in 12.5%-39.7% of patients with HCC[1-5]. According to the 16th National Survey for Primary Liver Cancer in Japan, 808 of 5130 patients (16%) who received hepatic resection had macroscopic portal venous invasion[6]. Portal venous invasion is a crucial factor that can worsen the prognosis of patients with HCC. It often leads to extensive spreading of the tumor throughout the liver, and can increase portal venous blood pressure, resulting in the fatal rupture of esophageal varices, and can decrease portal flow which causes ascites, jaundice, hepatic encephalopathy, and liver failure. Previous studies have reported that the median survival time of patients with portal venous invasion was 2.7-4 mo if left untreated[7,8]. To improve this short-term prognosis, various treatments have been applied, however, no standard treatment exists. In this paper, we review recent approaches to this disease.

## TRANSCATHETER ARTERIAL CHEMOEMBOLIZATION

Transcatheter arterial chemoembolization (TACE) is a widely used palliative treatment for HCC that is unsuitable for radical treatments. Some investigators have noted that TACE was contraindicated for patients with portal vein tumor thrombus (PVTT), because it carried a potential risk of ischemic liver damage[9]. In contrast, other authors suggested that TACE might be safely performed in patients with PVTT if they have good hepatic reserve and collateral circulation around the portal trunk[10-13]. Yamada *et al*[9] performed TACE in 9 patients with obstruction of the main portal vein. Five of these patients died of hepatic insufficiency within 1 mo after TACE. In autopsy studies of 3 patients who died of hepatic insufficiency, extensive necrosis of tumor tissue and surrounding liver parenchyma was observed[9]. Based on these results, they concluded that TACE was contraindicated in patients with HCC in which the tumor has invaded the major portal vein. This opinion

Vp2: 2nd order branches of the portal vein; Vp3: 1st order branches of the portal vein; Vp4: the main trunk of the portal vein.

is now supported by many clinicians even after some authors have shown that TACE is safe for these patients. One hundred sixty three patients with HCC accompanied by PVTT (48 at the 2nd portal branch, 56 at the 1st portal branch, and 59 at the main portal trunk) received TACE, and the median survival time and mortality rate within 1 mo for these patients were 4.3 mo and 6.5%, 4.0 mo and 8.0%, and 3.8 mo and 5.6% respectively[10]. The authors concluded that there was no difference in risk according to the location of portal invasion and the mortality rate was comparable to that of hepatic resection at the time[10] (Table 1). Based on these results, they suggested that the selection criteria for TACE in patients with HCC that invaded the main portal vein were the presence of cavernous transformation and a serum total bilirubin level of less than 2.0 mg/mL[10,11]. To avoid the interruption of hepatic arterial flow and subsequent hepatic insufficiency by TACE, Raoul *et al*[14] introduced internal radiation therapy using $^{131}$I-labeled Lipiodol in patients with these conditions. Twenty seven patients with HCC, stage Ⅰ or Ⅱ by the classification of Okuda, accompanied by PVTT in the 1st branches of the portal vein or the portal trunk were randomly assigned to an $^{131}$I-labeled Lipiodol group ($n$ = 14) or a Control group ($n$ = 13). The survival rates at 3, 6, and 9 mo were 71%, 48%, and 7% for the $^{131}$I-labeled Lipiodol group and 10%, 0%, and 0% for the Control group ($P < 0.01$): the response rate and median survival time of the treated group were 40% and 6 mo[14]. Chung *et al*[12] performed TACE in 110 patients with HCC that invaded the 1st branch of the portal vein or the main portal vein: the response rate was 28% and the median survival time was 6 mo. In their series, hepatic insufficiency developed in 10 patients and 3 of them died within 1 mo after TACE, and the tumor extended to more than 2 sectors in all 10 of these patients. This tumor extent was a significant factor in predicting the efficacy of therapy, and they concluded that TACE was effective and safe if the extent of the tumor was limited and liver function was preserved[12]. Georgiades *et al*[13] reported that TACE was safe and effective for these patients. Thirty two patients with unresectable HCC that completely occluded the main portal vein or the right, left, or both the right and left portal veins underwent TACE. The mortality rate within 1 mo was zero and there was no evidence of TACE-related hepatic infarction or liver failure. The median survival time was 9.5 mo and the Child-Pugh score was the prognostic factor that was most strongly related to survival[13].

Despite the widespread use of TACE for patients with unresectable HCC and the demonstration that TACE is safe for patients with PVTT, the efficacy of TACE in these patients has long been controversial. Randomized controlled trials performed in the 1990s have found that this approach does not confer any survival benefits compared to conservative management[15-19]. Although tumor growth has been shown to be inhibited, survival has not been shown to be prolonged by this treatment[17]. Llovet *et al*[20] published the results of a randomized controlled trial that was stopped early because TACE provided a statistically significant survival benefit in selected patients; survival rates at 1 and 2 years were 82% and 63% for TACE versus 63% and 27% for supportive care, respectively. Lo *et al*[21] also demonstrated a significant survival benefit in patients with unresectable HCC treated with chemoembolization. The 1-, 2-, and 3-year survival rates in TACE-treated patients were 57%, 31%, and 26%, compared with 32%, 11%, and 3%, respectively, in the controlled group[21]. In a meta-analysis of randomized controlled trials, patients treated with chemoembolization showed a significantly decreased 2-year mortality rate with an odds ratio of 0.53 (95% CI, 0.32-0.89; $P = 0.017$)[22].

## CHEMOTHERAPY

Many chemotherapeutic agents have been studied for their anti-HCC activity. The pyrimidine anti-metabolic agent 5-fluorouracil (5-FU) was the first reported chemotherapeutic agent tested in the treatment of HCC. However, an overall response rate of about 10% and a median survival of 3 to 5 mo have discouraged further use of 5-FU as a single agent[23,24]. Other agents tested include doxorubicin[23,25], which has a reported single-agent activity of 25% and yields a survival advantage when compared with no treatment[25]. There seems to be a general consensus that no single-agent systemic chemotherapy has an objective response rate of more than 25%. Okada *et al* reported the results of systemic chemotherapy in 71 patients with unresectable HCC (Table 2)[26]. The agents were changed from Tegafur to Doxorubicin, Tegafur plus Uracil, Etoposide, Mitoxantrone, Interferon-gamma, Cisplatin, and 5-FU over time and the response rate ranged from 0% to 20%[26]. Among these patients, 22 had tumor thrombus in the main portal vein. The median

survival time of these patients was 3.9 mo, while that of the 49 patients without this condition was 7.3 mo ($P < 0.05$)[26]. Since cisplatin and 5-FU have been reported to exhibit a synergistic effect, this combination has been widely used for various malignancies[27]. The results of the administration of low-dose cisplatin and 5-FU by repeated arterial infusion in nine patients with HCC and PVTT in the main portal trunk was reported by Ando *et al*[28]: the response rate was 44.4% and the median survival time was 9.2 mo. Seven patients with HCC and PVTT in the 1st branches of the portal vein or the main portal trunk received the same regimen: the response rate was 33%, and the median survival time was 7.5 mo[29]. Yamasaki *et al*[30] showed that the addition of leucovorin to this protocol significantly increased the survival time in a randomized study in 19 patients. Among them, 6 had PVTT in the major portal veins: their response rate and median survival time were 0% and 4.5 mo, respectively[30].

Recombinant interferon alpha has been found to be superior to doxorubicin for the treatment of inoperable HCC[31]. Combined treatment with 5-FU and alpha-interferon for HCC patients was first reported by Patt *et al* in 1993[32]. The response rate was reportedly 22%[32]. Urabe *et al*[33] treated 16 patients with HCC and PVTT in the main trunk or the major branches of the portal vein by intrahepatic infusion of methotrexate, 5-FU, and cisplatin, and administered alpha-interferon subcutaneously. The response rate and median survival rate were 46.7% and 7 mo, respectively[33]. The results of combined treatment using alpha-interferon, cisplatin, methotrexate, 5-FU, and leucovorin were reported by the same group: the response rate was 44% and the median survival time was 11 mo for 13 patients who had a complete response or partial response, and 3.5 mo for 16 patients who had stable or progressive disease[34]. Combined intra-arterial 5-FU and subcutaneous alpha-interferon therapy for 8 patients with HCC accompanied by PVTT in the major portal vein was reported by Sakon *et al*[35]: one patient died at 5 mo, the remaining 7 patients were alive after 3-15 mo, and the response rate was 63%. In another study by this group in 2005, 55 patients received this treatment, and 8 (14.5%) showed a complete response, 16 (29.1%) showed a partial response, 4 (7.3%) showed no response, and 27 (49.1%) showed progressive disease[36]. The median survival time and 5-year survival rate were 11.8 mo and 16.4%, respectively[36]. Using this combination protocol, Obi *et al*[37] treated 116 patients with unresectable HCC accompanied by PVTT in the main trunk or the 1st branches of the portal vein: the response rate was 52%, and the median survival time was 6.9 mo.

While the response rate for single-agent systemic treatment for unresectable HCC is less than 25%, combined treatment with cisplatin plus 5-FU or alpha-interferon plus 5-FU using hepatic arterial infusion remarkably increased the response rate from 33% to 63%, and the median survival time was prolonged to 11 mo in patients with an active response, although there appears to be no benefit in patients without an active response.

## RADIATION

Radiotherapy for HCC has been infrequently used in the treatment of HCC because the liver has a low tolerance to whole-organ irradiation[38,39]. However, some authors have reported that the tolerance dose for the liver depends on the volume of liver irradiated, and a small volume of liver tissue can tolerate a higher dose of radiotherapy[40]. Radiotherapy for patients with HCC and PVTT was first reported by Chen *et al* (Table 3)[41]. Ten patients with PVTT in the 1st branches of the portal vein received irradiation for PVTT and TACE for liver tumor, and the response rate was reportedly 100%[41]. The same protocol was used by Tazawa, Yamada, and Ishikura in 24, 8, and 20 patients[42-44]. Objective responses of PVTT ranged from 37.5% to 50%, and the median survival times were 9.7 mo in responders and 3.8 mo in non-responders[42-44]. With advances in three-dimensional planning tools, three-dimensional conformal radiotherapy (3-D CRT) allows clinicians to escalate radiotherapy doses to the tumor and minimize radiotherapy doses to normal tissue, such as normal liver parenchyma, small bowel, and spinal cord. Combined treatment consisting of 3-D CRT for PVTT

[a]Survival curves remain above a survival rate of 50%. PIAF: Doxorubicin, CDDP, 5-FU iv + Interferon-α sc; Hx.: Hepatic resection; HAI: Hepatic arterial infusion chemotherapy; Vv2: The main trunk of hepatic vein; Vv3: The inferior vena cava; B3: 1st order branches of bile duct; B4: The common hepatic duct; YSR: Year survival rate.

and TACE for liver tumor was reported by Yamada *et al*[45]: the response rate and median survival time were 57.9% and 7 mo. Nakagawa *et al*[46] treated 52 patients with HCC and PVTT at the 2nd and 1st branches of the portal vein or the main portal trunk followed by percutaneous ablation therapy, TACE, or both for liver tumor: the response rate was 50%, and the 3- and 5-year survival rates were 15.2% and 5.1%. Five or fewer liver tumors and TACE after radiation independently predicted a favorable prognosis[46]. The response rates of 3-D CRT for PVTT have reportedly ranged from 45.8% to 83%, and the median survival times ranged from 5.3 mo to 7 mo[47-49]. Kim *et al*[50] reported that the median survival time was 10.7 mo in responders and 5.3 mo in non-responders.

Since proton beam irradiation enables excellent dose localization to the target compared to conventional photon irradiation, Matsuzaki *et al* applied it to the treatment of HCC[51,52]. Twelve patients with HCC and PVTT at the 1st branches or the trunk of the portal vein received proton beam irradiation for PVTT and liver tumor: the response rate and median survival time were 100% and 27 mo[53].

## HEPATIC RESECTION

In the early days of a surgical approach for patients with HCC accompanied by PVTT, the goal was to prevent the rapid aggravation of portal hypertension and esophagogastric varices, and to improve the short-term prognosis. Reports of surgical therapy for these patients are shown in Table 4. Kumada *et al*[54] first reported surgical techniques in 13 patients who had tumor thrombus in the portal trunk. They described the resection

techniques; balloon catheter methods, an open method, and resection of occluded portal segment followed by portal reconstruction[54]. Yamaoka *et al*[55] performed tumor thrombectomy combined with hepatic resection in 29 patients with HCC and PVTT in the 1st branch or the portal trunk. While their primary purpose was to avoid impeding the rupture of esophageal varices, they reported an unexpectedly high 3-year survival rate of 11.6%[55]. Ikai *et al*[56] reported the outcome of 150 patients with stage Ⅳ-A HCC who underwent hepatic resection. The 5-year survival rate of 29 patients with tumor thrombi in the 1st branch of the portal vein was 11%, which was not significantly different from that of 29 patients with tumor thrombi in the portal trunk (4%)[56]. Ohkubo *et al*[57] reported the results of 47 patients with portal tumor thrombus in the 1st-2nd branches of the portal vein or the portal trunk who underwent hepatic resection. The 3- and 5-year survival rates were 33.2% and 23.9%, respectively, and the indicators of a favorable prognosis were curative hepatic resection, tumor size less than 10 cm, and absence of intrahepatic liver metastases[57]. Wu *et al*[58] reported that among 368 patients with HCC who underwent curative liver resection, 15 received concomitant liver resection and partial resection of the main portal vein because of apparent tumor thrombi extension to the portal bifurcation, and 97 had HCC which invaded intrahepatic portal branches, as confirmed on pathological examination, but did not involve the portal bifurcation. The 5-year survival rates of the former and latter groups were 26.4% and 28.5% ($P = 0.33$)[58]. They pointed out that intramural invasion was found at the site of thrombi adhesion to the portal vein cuff in 11 of 15 patients in the former group[58]. Minagawa *et al*[59] reported a high survival rate in these patients with the combination of TACE followed by hepatic resection. Eighteen patients who had HCC and gross portal tumor thrombus in the 1st-2nd branch or trunk of the portal vein showed a 5-year survival rate of 42% by preoperative TACE and hepatic resection, while none of the patients who received regional chemotherapy, TACE as monotherapy, or ligation of the portal vein survived more than 1.5 years[59]. The sole independent predictor of a favorable prognosis was hepatic resection[59]. Fukuda *et al*[60] reported that 19 patients with HCC and tumor thrombi in the 1st branch or trunk of the portal vein, inferior vena cava, or extrahepatic bile duct underwent hepatic resection with thrombectomy, and received hepatic arterial infusion chemotherapy after resection as adjuvant therapy. The 5-year survival rate of these patients was 36.3%[60]. Poon *et al*[61] reported that the prognosis of patients with HCC classified as stage Ⅳ in the tumor-node-metastasis classification of the International Union Against Cancer was not homogenous according to the 4 categories. In their paper, the 5-year survival rate of patients with HCC involving the 1st branches or trunk of the portal vein or major branches of the hepatic vein was 13.3%[61]. Lau *et al*[62] reported that 49 patients with initially unresectable HCC received nonsurgical treatment, such as systemic chemotherapy or intra-arterial yttrium-90 microspheres followed by salvage surgery. The 5-year survival rate of these 49 patients was 57%[62]. Their series included 7 patients with HCC involving the main portal vein, and the 5-year survival rate of these 7 patients was 56%[62]. Pawlik *et al*[63] analyzed the prognostic factors in 102 patients with HCC involving major portal or hepatic venous branches who were treated by hepatic resection in 5 hepatobiliary centers, and the significant predictors of a poor prognosis were moderate to severe fibrosis (Ishak grade 3 to 6) and high-grade neoplasm (Edmondson-Steiner grade Ⅲ and Ⅳ), and the operative mortality and 5-year survival rate of these 102 patients were 5.9% and 10%. Ikai *et al*[64] also analyzed the prognostic factors in 78 patients with HCC and tumor thrombus in the 1st branch or trunk of the portal vein, and the independent predictors of a favorable prognosis were absence of ascites, prothrombin activity >/= 75%, and maximal tumor diameter < 5 cm. In their series, the mortality rate and 5-year survival rate were 3.8% and 10.9%[64]. In 108 patients who underwent major hepatic resection for HCC, Le Treut *et al*[65] compared 26 who had HCC with PVTT in the portal or hepatic vein to 82 without PVTT: operative mortality and median survival time were 11.5% and 9 mo in the former group and 8.5% and 41 mo in the latter group. Zhou *et al*[66] reported a large series of hepatic resections: 381 patients with HCC and PVTT at the 1st-2nd branches or the trunk of the portal vein were treated by hepatic resection, and the 5-year survival rate of these patients was 12%.

## CONCLUSION

In these reports, the median survival times were less than 12 mo without hepatic resection. While we can not exclude the possibility that this is the result of a selection bias, the most promising results were obtained with combined treatments that included hepatic resection. This analysis suggests that this disease does not have a homogenous prognosis, and therefore it is important to select patients who have a good prognosis and to treat these patients with combined treatments.

## Abstract

Ulcerative colitis (UC) and Crohn's disease (CD) are the major forms of idiopathic inflammatory bowel disease (IBD). Both UC and CD are debilitating chronic disorders that afflict millions of individuals throughout the world with symptoms which impair function and quality of life. The etiology of IBD is inadequately understood and therefore, drug therapy has been empirical instead of being based on sound understanding of IBD pathogenesis. This is a major factor for poor drug efficacy and drug related side effects that often add to the disease complexity. The development of biologicals notably infliximab to intercept tumor necrosis factor (TNF)-α reflects some progress, albeit major concern about their side effects and lack of long-term safety and efficacy profiles. However, IBD seems to be perpetuated by inflammatory cytokines like TNF-α, interleukin (IL)-1β, IL-6 and IL-8 for which activated peripheral granulocytes and monocytes/macrophages (GM) are major sources. Further, in IBD, peripheral GMs are elevated with activation behavior, increased survival time and are found in vast numbers within the inflamed intestinal mucosa; they are suspected to be major factors in the immunopathogenesis of IBD. Hence, peripheral blood GMs should be appropriate targets of therapy. The Adacolumn is a medical device developed for selective depletion of GM by receptor-mediated adsorption (GMA). Clinical data show GMA, in patients with steroid dependent or steroid refractory UC, is associated with up to 85% efficacy and tapering or discontinuation of steroids, while in steroid naïve patients (the best responders), GMA spares patients from exposure to steroids. Likewise, GMA at appropriate intervals in patients at a high risk of clinical relapse suppresses relapse thus sparing the patients from the morbidity associated with IBD relapse. Further, GMA appears to reduce the number of patients being submitted to colectomy or exposure to unsafe immunosupressants. First UC episode, steroid naivety and short disease duration appear good predictors of response to GMA and based on the available data, GMA seems to have an excellent safety profile.

## INTRODUCTION

Ulcerative colitis (UC) and Crohn's disease (CD) are the major forms of idiopathic inflammatory bowel diseases (IBD) of the intestine. UC and CD are both debilitating chronic disorders that afflict millions of individuals throughout the world with symptoms which impair function and quality of life. Whereas UC is confined to the colon and the rectum, CD may affect any part of the gut from the mouth to the perianal[1-4]. A multitude of clinical manifestations represent the expressions of IBD. These include diarrhea, rectal bleeding, abdominal discomfort, fever, anemia, and weight loss[1-3]. Both UC and CD tend to run a remitting-relapsing course affected by diverse environmental factors[1,3-5].

Despite the recognition of a genetic background together with environmental factors, which at present are thought to translate into an inappropriate inflammatory response in patients with IBD[3,4,6], currently our understanding on the immunopathogenesis of IBD is inadequate. Hence, up to now drug therapy of IBD has been empirical rather than based on sound understanding of disease etiology. Accordingly, while drug therapy initially appears successful in the majority of patients, it comes at the cost of significant side effects[7,8]. Further, up to now, first line medications for exacerbation of IBD include 5-aminosalicylic acid (5-ASA) or sulphasalazine (SZ) in combination with a corticosteroid with consideration of azathioprine (or 6-mercaptopurine) and nutritional support for some patients[1,9-14]. Treatment failure in patients with severe disease has often been an indication for colectomy in up to 40% of steroid refractory patients[10,15] although in

recent years, cyclosporin A (CysA) has been introduced for corticosteroid refractory UC[15,16]. Despite being moderately effective in this clinical setting in reducing colectomy rates, there remain serious concerns over long-term efficacy and toxicity of CysA[17].

Currently, the view is that IBD is perpetuated by inflammatory cytokines like tumor necrosis factor (TNF)-α, interleukin (IL)-1β, IL-6, IL-8 and others[18,19]. Based on this perception, in recent years, anti-cytokine antibodies, notably the anti-TNF antibody, infliximab have been developed for the treatment of IBD[13], and the seemingly success of infliximab in CD[20,21] is hoped to be realized in patients with UC as well[22,23]. However, the enthusiasm towards biologicals is currently dampened by concerns about their long-term efficacy and safety profiles[24-29]. Taking infliximab as one example (that has been through extensive clinical evaluations), following the initial and subsequent administrations, antibodies to this agent emerge which potentially can reduce its efficacy[29]. Regarding their side effects, the literature on biologic therapy carries headlines like "Tumor necrosis factor antagonist therapy and lymphoma development;"[28] "Serious bacterial infections in patients with rheumatoid arthritis under anti-TNF-α therapy;"[27] "Treatment of rheumatoid arthritis with tumor necrosis factor inhibitors may predispose to significant increase in tuberculosis risk;"[26] "Adverse skin reactions to anti-TNF-α;"[24] "Anti-TNF antibody therapy in rheumatoid arthritis and the risk of serious infections and malignancies;"[30] "Anorectal carcinoma after infliximab therapy in Crohn's disease"[31]. There is no shortage of many more warnings.

In the face of the overwhelming evidence for the involvement of various cytokines in the immunopathogenesis of IBD and the fact that peripheral blood granulocytes and monocytes/macrophages (GMs) are major sources of these cytokines[32,33], GMs appear logical targets in the treatment of IBD. Indeed, histological examination of the mucosal tissue in biopsy specimens from patients with active IBD reveals a spectrum of pathologic manifestations among which presence of an abundance of neutrophils relates specifically to clinical disease activity and severity of the disease[1-3,34-36]. The circulating activated GMs are elevated with increased survival time in active IBD[35-44]. Paradoxically, corticosteroids[45] which are given to most patients with active IBD and inflammatory cytokines[46] increase neutrophil survival time. In this article, the author reviews the therapeutic application of selectively depleting peripheral blood GM by adsorption apheresis (GMA) in patients with IBD with a major focus on UC. The underlying rationale is that selective removal of these cells that are otherwise destined for migration to the intestine reduces the inflammatory intensity, which in turn allows healing to take place. The author also presents arguments why GMA should be likened to an effective and safe biologic therapy in IBD.

## THE STRATEGY FOR SELECTIVE LEUKOCYTAPHERESIS

The Adacolumn which is featured in this editorial is an example of a medical device that can selectively deplete activated myeloid leukocytes from peripheral blood in the GMA therapy of patients with IBD[39,40-58]. In essence, the treatment involves an extracorporeal approach in which patients' blood is passed through a column (Adacolumn) that is filled with specially designed cellulose acetate beads of 2 mm in diameter known as leukocytapheresis carriers. Pre and post column blood cell counts have shown that the carriers adsorb from the blood which passes through the column about 65% of granulocytes, 55% of monocytes and a very small fraction of lymphocytes[41]. These are the leukocytes that bear the so-called FcγR and complement receptors. They include GM, small subsets of $CD19^+$B lymphocytes and $CD56^+$NK (natural killer) cells[59-61]. One novel feature of this treatment is that it involves removing from the body the effector cells rather than administering drugs. It is therefore not expected to induce dependency or refractoriness and the treatment has not been associated with serious side effects in a significant number of patients[39,40,47-58].

## TREATMENT OF PATIENTS WITH SEVERE STEROID REFRACTORY UC

In our first major attempts (albeit without control groups)[39,40] we carefully selected patients with severe UC from a total of 285 patients with active UC who were first given salicylates as the first-line medication and those who did not improve (or worsened) were given intensive prednisolone (PSL) therapy and after a course of intensive PSL therapy, those who improved were not selected; 56 patients who could then be classified as steroid refractory were given GMA with the Adacolumn to deplete their peripheral blood GM. The study design is shown in Figure 1. The patients had a clinical activity index (CAI) of $\geqslant$ 12, a disease activity index (DAI) of $\geqslant$10[40,62,63] and were treated twice weekly for 2 to 3 consecutive weeks and then at one session per week for up to 11 GMA sessions. Assessments within one week after the last GMA session showed a response rate of 85% (Figures 1 and 2). No additional drug therapy was initiated while their ongoing PSL was tapered as symptoms improved. Figure 3 shows typical endoscopic improvements in steroid refractory patients. Pretreatment circulating neutrophil counts were very high, $9.3 \times 10^9 \pm 0.5 \times 10^9$/L, about 3 times the level seen in controls[40] and marked reductions were seen at wk 12 of treatment, $4.9 \times 10^9 \pm 0.4 \times 10^9$/L. Haemoglobin (Hb) at wk 12 relative to baseline increased by 25%, which may relate to the cessation of rectal bleeding following remission or improvements of clinical symptoms. Along with a fall in the patients' CAI and DAI and peripheral blood leukocytes counts, there was a comparable fall in C-reactive protein[40]. A total of 11 non-severe side effects in 7 patients were observed during leukocyte reduction therapy[40]. These were 3 incidences of flushing, 6 incidences of dizziness/light headache, nausea in 1 and mild fever in 1. However, no patient discontinued GMA therapy due to these side effects, all of which lasted from a couple of minutes to 3 h. Further, there was no evidence of opportunistic infection in any patient during or after GMA therapy.

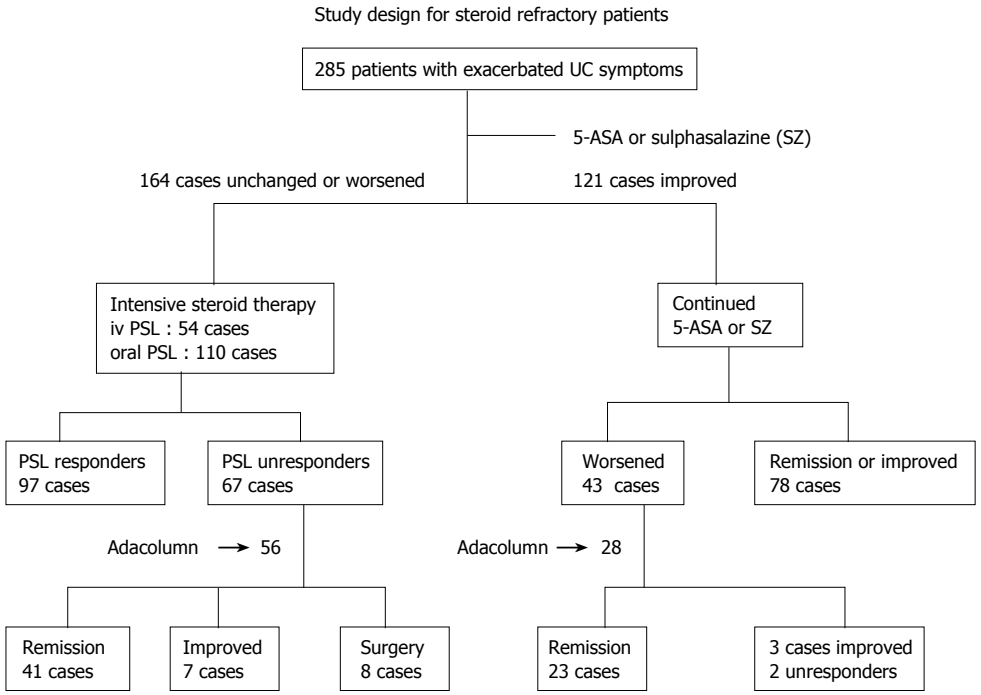

**Figure 1** Study design and patient selection for selective leukocytapheresis with the Adacolumn (GMA) in patients with steroid refractory and steroid naïve ulcerative colitis. iv prednisolone (PSL) indicates intravenous PSL (60 mg/d); oral PSL (40-60 mg/d). The dose of 5-ASA was 1.5-2.25 g/d while the dose of SZ was 2-3 g/d. During GMA course, PSL was tapered or discontinued in patients who improved. As shown, 56 steroid refractory and 28 steroid naïve patients were randomly selected for GMA, and the rest were treated according to Figure 5.

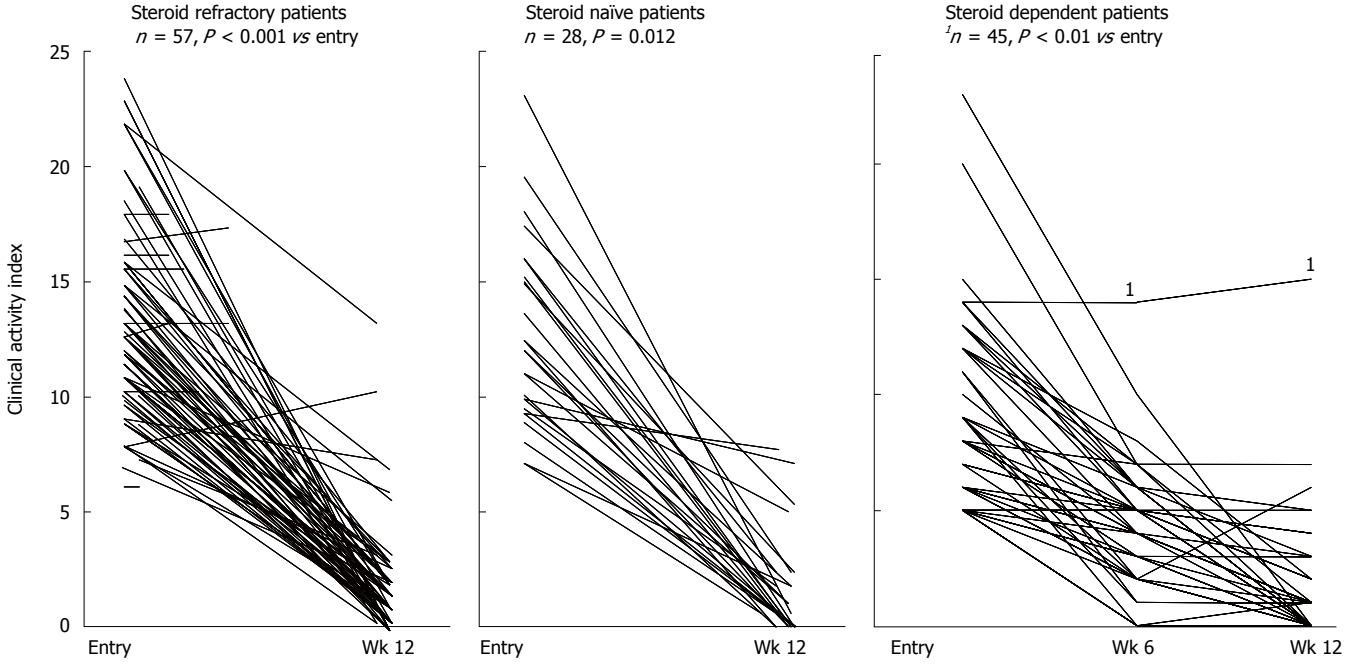

**Figure 2** Fall of clinical activity index (CAI) during the course of Adacolumn GMA in patients with steroid refractory, steroid naïve and steroid dependent ulcerative colitis.

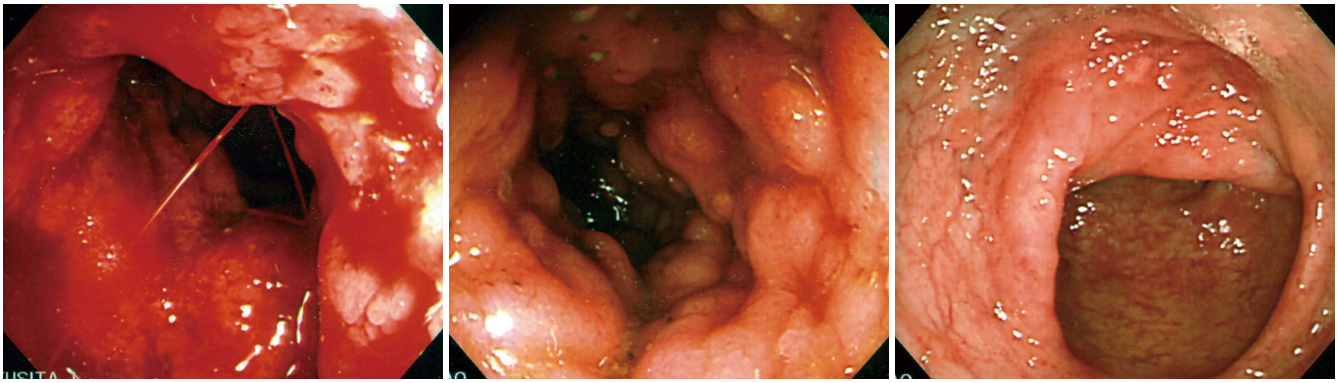
The aforementioned refractory cases represent a subgroup of patients with severe UC who are at a significant risk of serious complications. Indeed treatment failure after 5-10 d of intensive corticosteroid therapy is often considered to be an indication for colectomy, CysA or TNF-α antibodies. Only 8 (14%) patients underwent colectomy. At 12 mo, 79% of patients had maintained their remission. In contrast, the relapse rate in patients who initially respond to CysA has been 60% to 80%[64], and unlike CysA, GMA with the Adacolumn has been without major side effects[39,40-58]. These initial response rates have subsequently been reproduced both in Japan and in Europe[47-58].

## GMA AS A FIRST-LINE MEDICATION FOR STEROID NAÏVE PATIENTS

Together with our steroid refractory patients described above we had a subgroup of steroid naïve patients, all of whom achieved remission by GMA[40]. This has now increased to 28 patients (Figure 1). Most of these steroid naïve patients went into clinical remission by GMA and remained steroid naïve during the study and the 12-mo follow up period. Subsequently, Suzuki *et al* reported treating 20 steroid naïve patients with active UC by GMA[47,48]. The patients treated by Suzuki *et al*[47,48] had moderate to severe UC; mean CAI was 8.8. At entry, all



At entry

After 10 adacolumn sessions
(Vascular patterns visible)

**Figure 3** Typical endoscopic response in steroid refractory patients. Modified from Hanai *et al*, *Dig Dis Sci* 2002; 47: 2349-2353 with kind permission of Springer Science and Business Media.

patients were on 5-ASA (1.5 to 2.25 g/d). Each patient was to receive up to a maximum of 10 GMA sessions, at a frequency of 2 sessions/wk. Efficacy was assessed 1 wk after the last session. CAI fell to clinical remission levels (CAI $\leqslant$ 4) in the majority of patients after 6 sessions, and only 2 of the 20 patients required all 10 sessions. At post treatment, the mean CAI was 3, with a range from 0 to 12 and 17 of 20 patients (85%) were in clinical remission. The 3 non-responders had deep colonic ulcers at entry. There were significant changes in total peripheral white blood cell counts ($\times 10^9$/L), 9.8 $\pm$ 1.0 *vs* 7.0 $\pm$ 0.6 at post treatment. In contrast, lymphocytes increased dramatically from a pretreatment level of 19% to nearly 30%, attributable to the increase in absolute lymphocyte count[47]. During GMA therapy, 2 incidences of transient mild headache were reported. In both cases, the headache receded within 3 h without medication.

## GMA IN THE TREATMENT OF PATIENTS WITH STEROID DEPENDENT UC

Similarly, we used GMA to treat patients with corticosteroid dependent UC where GMA was used vs PSL[56]. A total of 261 consecutive patients who were initially evaluated were treated with a 5-ASA (1.5-2.25 g/d) or SZ (2-3 g/d). Patients who failed to respond were then treated with steroids and those patients who obtained remission, but relapsed during PSL tapering were given GMA or their steroid dose was increased. Both treatments were added to their ongoing conventional therapy. However, in both groups, PSL was to be tapered or discontinued in line with improvements of CAI. At wk 12, 83% in the GMA group and 65% in the PSL group were in remission (CAI $\leqslant$ 4)[56]. Further, in the GMA group, flushing was seen in 6 cases, nausea in 2 and mild fever in 2. This is in sharp contrast to 40 steroid side effects reported by Shimoyama *et al*[65] in a cohort of 52 patients who were given PSL. Typical remission rate in terms of CAI for GMA in steroid dependent patients is presented in Figure 2.

It is hard to overemphasize the clinical value of GMA in steroid dependent patients because patients in this group are exposed to steroids for most of their active disease lives and therefore, steroid side effects are often additional complications. Thus, one wary physician writes: How to do without steroids in inflammatory bowel disease[8]? Quotations from this article include the followings: "I believe physicians have fallen into an incorrect pattern of using steroids without considering other therapeutic options;" "The toxicity associated with oral steroids occurs so frequently and is so severe that physicians should take another look at administering these agents;" "At a meeting of Crohn's Disease and Ulcerative Colitis Foundation of America, a patient asked 'Why physicians use steroids when they are so destructive to the individual? '" Therefore, Adacolumn GMA might be a safe and perhaps most effective alternative therapy for these patients.

## GMA IN THE TREATMENT OF CD

The vast majority of clinical reports on GMA with the Adacolumn are in patients with UC. However, there is evidence to assume that GMA is effective in patients with CD as well. The first study in CD was reported by Matsui *et al*[54]. In that study, 7 patients with CD refractory to conventional medication including nutritional therapy, each received 5 GMA sessions. Five of seven patients achieved remission. In the study by Fukuda *et al*[55], 21 patients with refractory CD received 5 GMA sessions each. The efficacy rate was 52%. It is imperative to state that the patients Fukuda *et al*[55] included had received conventional medications including 2 wk of optimum nutritional therapy and only patients who remained with a high Crohn's disease activity index (CDAI) were given GMA. Therefore, 52% remission rate in these refractory patients was very encouraging. Domenech *et al*[53] reported treating 12 steroid dependent patients with CD. The remission rate in that clinical setting was 70%. Finally, Muratov and colleagues[66] reported treating 7 patients with CD who were refractory or had relapsed despite medication. Six had received infliximab, but without success. Adacolumn GMA was performed at one session per week for 5 wk. Efficacy was assessed at wk 7 and 12 mo. The median

value of CDAI decreased from 290 at wk 1 to 184 at wk 7 ($P = 0.031$). At the 12 mo follow-up, CDAI had decreased further to 128.5 ($P = 0.0156$).

## WHAT COULD BE THE MOST APPROPRIATE DOSAGE OF GMA?

Since the publications of first papers on GMA in the treatment of patients with UC, the following questions have often popped up in the community of IBD physicians: What is the most effective number of GMA sessions for a patient with severe IBD? What is the most appropriate frequency of GMA, one, two, three sessions per week or more? How long should be the duration of one treatment session and treatment course? The reality is that unlike drugs for which the dosage regimen has been defined, for a non-drug GMA, up to now treatment has been more or less arbitrary. In our centers, we have adopted a strategy of giving patients 2 treatment sessions per week in the first 2-3 wk and then 1 session per week up to 10 or 11 sessions[39,40,56]. We found that although patients with steroid naïve UC achieved remission or improved after 5 sessions, this was not seen in steroid refractory patients who responded better to 10 sessions[40]. Regarding duration of one GMA session, Kanke and colleagues[49], found that 90 min was significantly better than 60 min per GMA session. No data on the duration of one treatment course are available right now. However, the clinical response to Adacolumn GMA may not be immediately evident. For example, in patients with rheumatoid arthritis, there was a sustained increase in CD4+ T lymphocytes up to 12 wk following the last GMA session[41]. Similarly, there was a striking decrease in the expression of the chemokine receptor CXCR3 on leukocytes several weeks after the last GMA session[59,67]. Clearly it seems that much work has yet to be done before the optimum frequency and duration of treatment can be firmly established.

## PATIENTS WHO ARE MOST LIKELY TO RESPOND TO GMA

Currently available data suggest that steroid-naive patients respond particularly well to this treatment[40,47]. Characteristically they respond faster with fewer GMA sessions and have a higher cumulative rate of remission[40,47]. As reviewed above, most steroid naïve patients in our centers achieved remission[40], while the remission rate in the cohort reported by Suzuki *et al*[47] was 85%. In one of the most thorough and retrospective studies by Suzuki and colleagues[58], the authors attempted to determine the responders to Adacolumn GMA. Their findings are summarized as follows. Seven days after the last GMA session, 20 of 28 patients had achieved clinical remission including all 8 patients who had their first UC episode. The mean duration of UC in the 8 first episode cases was 3.4 mo compared with 40.2 mo for all 28 patients and 65.4 mo for the 8 non-responders. The response to GMA seemed to be independent of basal CAI. The 8 non-responders were given conventional medication (CM) or CysA if the former failed. Two patients responded to CM, 3 to CysA and 3 underwent colectomy. The authors' conclusions are as follows. First UC episode and short disease duration appear good predictors of response to GMA. Further, GMA might be an effective first line medication[57]. It would appear that the clinical response in patients with chronic continuous UC[40] and patients with deep colonic lesions[47] might be somewhat less satisfactory than in those experiencing their first UC.

## GMA IN PATIENTS AT A HIGH RISK OF CLINICAL RELAPSE

Bjarnason and colleagues in London (Guy's King's and St Thomas' Medical School) are currently evaluating the efficacy of GMA with the Adacolumn to suppress IBD relapse in patients at a high risk of experiencing one. The ongoing work was presented at the UEGW 2005 in Copenhagen[68]. The approach represents a fundamental change in the philosophy of treating IBD. Instead of treating active disease, asymptomatic patients are identified solely on the basis of a very high fecal calprotectin concentration, a neutrophil selective protein that provides quantitative measure of intestinal inflammatory activity[34-36]. The high calprotectin levels (over 250 μg/g) place them in a very high-risk group for clinical relapse[32]. This multi-center, prospective, randomized controlled study, assigned patients to Adacolumn, undergoing 5, once weekly, outpatient GMA sessions, or to unchanged treatment. Both patients with UC and CD were included. Follow up was monthly for 6 mo for a clinical relapse. In the Adacolumn group, 62% maintained their remission compared to 24% in the control group ($P < 0.04$, Pearson Chi squared test). Life table analysis demonstrated the mean survival in the Adacolumn group, 181 d *vs* 104 d in the control group ($P = 0.016$, Mantel Chi-squared test). This study represents a new approach to the treatment of IBD, namely targeting the inflammatory component of the disease at an asymptomatic stage. It seems likely that the 5 weekly sessions of GMA in such patients will have a significant effect and potentially avoid the morbidity associated with severe clinical relapses and the subsequent drug therapy in most patients.

## EFFECTS OF GMA ON LEUKOCYTE-DERIVED INFLAMMATORY AND ANTI-INFLAMMATORY FACTORS

Although the primary target of GMA with the Adacolumn is to deplete activated peripheral blood leukocytes principally granulocytes and monocytes/macrophages, it has been difficult to explain why some patients continue to improve long after the treatment has been ceased. Also the low relapse rate during follow-up we have reported[40] can not be fully explained by our current understanding of neutrophil function or the effects of GMA on peripheral blood levels of leukocytes *per se*. Alternative mechanisms of action have therefore been sought. Adacolumn is filled with cellulose acetate beads to which leukocytes that bear

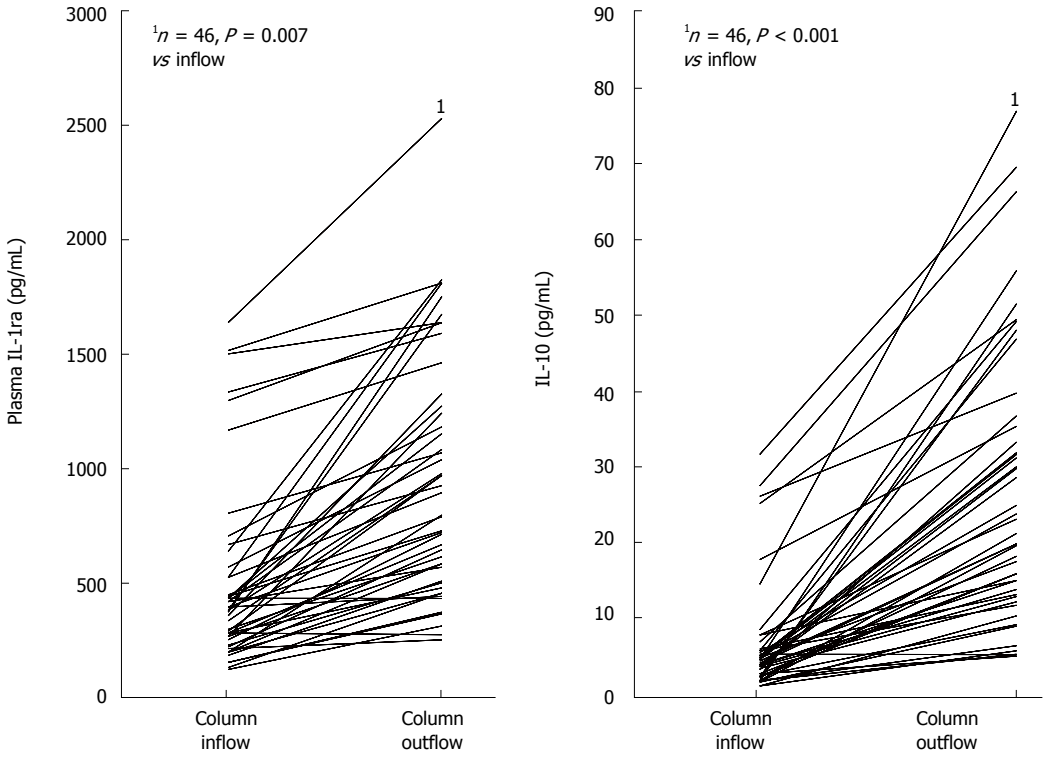

**Figure 4** Release of interleukin-1 receptor antagonist (IL-1ra) and IL-10 in the Adacolumn during Adacolumn GMA in patients with active ulcerative colitis. Column outflow returns to the patients. Elevated IL-1ra and IL-10 (both anti-inflammatory) in the column outflow is potentially very significant (see text for comments on IL-1ra and IL-10).

the FcγR and complement receptors adhere[59-61]. The adsorbed leukocytes release an array of active substances both toxic and non-toxic, but anti-inflammatory as well[47,69-71]. Some of these like cytokines, complement fragment C3a and C5a are of short half-life and may not reach the patients' circulation in fully active form. In view of this background, several investigators have carried out analysis on blood samples taken from the Adacolumn inflow and outflow (blood return line to patients) during GMA procedure. We[69,70] as well as Suzuki *et al*[47] found a significant increase in blood levels of soluble TNF-α receptors I, Ⅱ. Soluble TNF receptors are believed to neutralize TNF without invoking TNF-like actions[72]. Further, several studies report a marked decrease in the capacity of peripheral blood leukocytes to generate inflammatory cytokines (TNF-α, IL-1β, IL-6 and IL-8) following Adacolumn GMA[39,41,59,65,71,73,74]. Also, GMA procedure appears to produce a similar effect on leukocyte trafficking receptors. Thus the expressions of both L selectin[59,74] and the chemokine receptor CXCR3[59,67] were dramatically reduced, while the expression of the leukocyte integrin, Mac-1 (CD11b/CD18) was up-regulated[41,59,73]. These observations indicate that the procedure has a suppressive effect on leukocyte extravasation. Similarly, *in-vitro* studies showed that incubation of human whole blood with the Adacolumn leukocytapheresis carriers for 60 min resulted in the generation of significant amounts of IL-1 receptor antagonist (IL-1ra) and hepatocyte growth factor (HGF)[75]. However, the authors did not detect significant amounts of TNF or IL-1. IL-1ra has an essential role in the control of inflammation in the mucosa[76,77] while HGF is known to promote mucosal epithelial cell regeneration, which is an essential step in ulcer healing[78]. These observations on cytokines and adhesion molecules are perhaps of more academic significance than therapeutic value, but still are related to the effects of the GMA on neutrophils. Figure 4 shows elevated IL-1ra and IL-10, another major anti-inflammatory cytokine[79] in the blood at the Adacolumn outflow.

There is evidence that GMA suppresses cytokine profiles within the mucosal tissue as well. Thus, Muratov *et al*[66] found a very marked decrease in tissue interferon (IFN)-γ positive T-cells in clinical responders ($P = 0.027$) after GMA. In parallel, significantly lower levels of IFN-γ producing lymphocytes were detected in peripheral blood. IFN-γ positive cells in pretreatment biopsies completely disappeared or decreased in post-treatment biopsies sampled 2 wk after the last GMA session in responders ($P = 0.027$) and appeared to predict the maintenance of long-term remission or response after 12 mo. In another study by Yamamoto and colleagues[80] , the authors found that at entry the mucosal concentrations of IL-1β, IL-1, IL-1ra, IL-6, IL-8 and TNF-α were significantly higher compared with healthy persons, while IL-1ra/IL-1β ratio was significantly lower. In patients who achieved clinical remission by GMA, but not in those without remission, the mucosal tissue concentrations of IL-1β, IL-1ra, IL-6, IL-8 and TNF-α significantly decreased, whereas the IL-1ra/IL-1β ratio significantly increased.

## GMA INCREASES PERIPHERAL BLOOD LYMPHOCYTES

As stated above, the Adacolumn leukocytapheresis carriers selectively adsorb FcγR and complement receptors bearing leukocytes[59-61]. Indeed, Adacolumn not only spares the prevailing lymphocytes, it also induces an increase in *de novo* lymphocytes[41,47,81]. This is very intriguing and is in line with the original thinking for the design and development of the

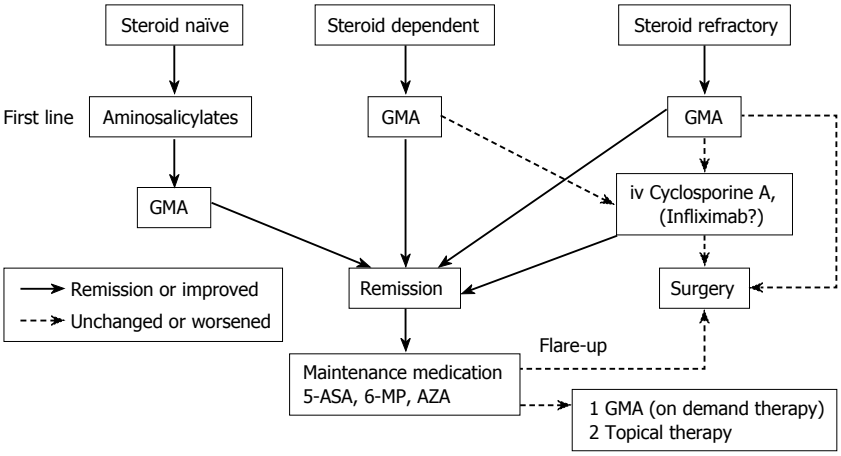

**Figure 5** Treatment algorithm for ulcerative colitis without corticosteroids. Based on this scheme, patients at any stage of their disease might benefit from GMA and avoid corticosteroids or other drug based medications. Intensive leukocytapheresis (2 or more GMA sessions per week in the first 3 wk) is recommended in severe or fulminating cases. GMA: Granulocyte and monocyte adsorption apheresis; 5-ASA: 5-aminosalicylic acid; 6-MP: 6-Mercaptopurine; AZA: Azathioprine.

present Adacolumn, to tame the exuberant immune system in patients in whom an elevated peripheral neutrophils level was thought to promote disease progression[41]. One likely question could be "What is the merit of sparing lymphocytes? " The precise role of lymphocytes in the relapse of IBD is uncertain and evidence presented below indicates that indiscriminately removing peripheral lymphocytes even for a short period might in fact be pro-inflammatory in patients with IBD[71,82]. The majority of patients with active IBD have very low lymphocyte counts[47,81,83] and a low lymphocyte count has been associated with relapse of CD[83]. Hence depleting the already compromised lymphocytes potentially could impair adequate immune function. To our knowledge, there is no published data showing elevated peripheral lymphocytes in patients with active IBD. Further, in one of the best controlled studies on lymphocytapheresis in IBD reported by Lerebours and colleagues[84], the authors selectively depleted peripheral lymphocytes in patients with CD with the aim of suppressing clinical relapse. At the end of an 18-mo follow-up, the rate of relapse was 83% in the lymphocytapheresis group and 62% in the control group; the clinical outcome in the lymphocytapheresis group being 21% inferior to that of control. The increase in lymphocytes associated with Adacolumn GMA indicated above is primarily attributable to an increase in CD4+ T cells. Of these, the CD4+CD25+ T-cell subset suppresses intestinal inflammation through mechanisms that involve interleukin 10 and transforming growth factor beta[85,86].

## CONCLUDING REMARKS

There have been significant recent advances in the medical therapy of IBD represented in part by the availability of biologicals which are developed to intercept the inflammatory cytokines or related inflammatory cells. However, the introduction of biologicals (albeit representing progress), has added new dimensions to the spectrum of treatment related adverse side effects like tuberculosis and lymphoma, to mention just two. Biologicals on which there rest great hope bear long term efficacy and safety concerns. Given that IBD is often associated with elevated and activated myeloid leukocytes which are major sources of inflammatory cytokines (the very agents that biologicals are expected to intercept), selective depletion of these leukocytes with the Adacolumn should represent a natural biologic therapy, and based on the available data, GMA seems to have an excellent safety profile. GMA in patients with steroid refractory UC (albeit mostly uncontrolled studies) has been associated with impressive clinical efficacy together with tapering or discontinuation of steroids, while in patients with steroid dependent or steroid naïve, GMA spares patients from exposure to steroids. Likewise, GMA at appropriate intervals in patients with IBD at a high risk of clinical relapse suppresses relapse thus sparing the patients from the morbidity associated with IBD relapse. Additionally, the procedure appears to reduce the number of patients being submitted to colectomy or exposure to potent immunosupressors like CysA. First UC episode, steroid naivety and short disease duration appear good predictors of response to GMA. This might be in line with the finding that corticosteroids support granulocytes. The author believes that GMA should be given as a first line medication. A treatment algorithm reflecting the author's current opinion for the medical therapy of UC is presented in Figure 5.

## Abstract

Over the lifetime of the animal, there are many changes in the function of the body's organ systems. In the gastrointestinal tract there is a general modest decline in the function of the esophagus, stomach, colon, pancreas and liver. In the small intestine, there may be subtle alterations in the intestinal morphology, as well as a decline in the uptake of fatty acids and sugars. The malabsorption may be partially reversed by aging glucagon-like peptide 2 (GLP2) or dexamethasone. Modifications in the type of lipids in the diet will influence the intestinal absorption of nutrients: for example, in mature rats a diet enriched with saturated as compared with polysaturated fatty acids will enhance lipid and sugar uptake, whereas in older animals the opposite effect is observed. Thus, the results of studies of the intestinal adaptation performed in mature rats does not necessarily apply in older animals. The age-associated malabsorption of nutrients that occurs with aging may be one of the several factors which contribute to the malnutrition that occurs with aging.

**Key words:** Aging; Gastrointestinal tract; Intestine; Absorption; Malnutrition

## INTRODUCTION

Although each and every one of us is familiar with inevitable age-related changes, the task of clearly defining the term is challenging. Aging is a multi-factorial process which includes both intrinsic and extrinsic factors. To further complicate matters, in humans the term can be considered from sociological, physiological, psychological and molecular perspectives.

While we tend to use the term "ontogeny" to describe development in early life, and "aging" to describe development or sometimes presumed degeneration in later life, it is likely that the better concept is that of development over the lifetime of the animal. Thus, "young" and "old" become descriptive terms describing a process over time. Aging then may be considered to be a continuum that begins at conception and proceeds until death. The definition of aging can be further refined as "chronological age" according to the passage of time. Although advancing age is associated with increases in morbidity and mortality in general, this approach fails to consider the health of the individual. Determining a specific age at which an individual becomes "old" is arbitrary, and the concept of aging has changed over the centuries with humans now experiencing increased longevity and quality of life.

"Biological age" reflects the presence or absence of disease. Because there is not always a direct relationship between age and disease, this definition is considered to be a better marker of health status. The term "functional aging" has also been used to emphasize the limitations of defining health based on chronological age. This definition characterizes people based on what they can do in relation to others in society, but may also be used to characterize the level of functioning of organs and systems in the elderly. Finally, the concept of "successful aging" takes this idea one step further, and suggests that the aging process is variable, and may be characterized as a balance between gains and losses[1]. The compression of morbidity and an enhanced quality of life are cornerstones of the concept of successful aging.

## THEORIES OF AGING

A number of theories have been proposed to describe the process of aging. Longevity genes have been identified in many species, suggesting that aging may be at least partially under genetic control. In yeast, overproduction of the enzyme Sir2 prolongs the life of yeast grown under normal nutrient conditions[2]. It has been suggested that increases in Sir2 (seen in response to caloric restriction or resveratrol, a polyphenol found in red wine) may increase gene silencing, and thereby result in greater genomic stability[2]. Research undertaken in Drosophila has identified single gene mutations that extend life span. These include the gene Methuselah (*mth*), a secretion-type receptor that provides resistance to stress[3], and *Indy*

(I'm Not Dead Yet), whose gene product is homologous to Kreb's cycle intermediates[4,5]. In humans, a genetic component to aging has also been suggested. Werner's syndrome, a disorder characterized by an apparent accelerated senescence, has been associated with a single gene locus on chromosome 8[6]. On the other hand, a genome wide scan of elderly subjects suggested that there is a locus on chromosome 4 which influences a person's genetic susceptibility to age well and to achieve exceptional longevity[7].

Cellular theories emphasize that the environment as well as intrinsic properties of the cell, often referred to as a "cellular clock", may limit survival. Pivitol research by Hayflick and Moorhead[8] found that normal human fetal cell strains were limited to 40-60 doublings before they entered senescence. From this finding, they developed the concept of the "Hayflick limit" to explain determination of longevity. From this early work, the concept of telomere shortening was then established as another mechanism of longevity determination. These repetitive DNA sequences found at the end of chromosomes are progressively depleted with age, and may represent a method by which cells enter senescence. However, this theory is not universally accepted, largely due to a lack of correlation between telomere length and life span in many animal species[9].

Aging may be the consequence of oxidative damage. Oxidative damage to DNA, protein, carbohydrates and lipids contribute to degenerative diseases in aging, due to a disruption in cellular homeostasis. The activation of specific stress signalling pathways results in alterations in gene expression mediated by a variety of transcription factors including NF-κB, p53, and heat shock transcription factor 1 (HSF1)[10]. While levels of antioxidants correlate with longevity in primates[11,12], there is no evidence that antioxidant supplementation affects life span. It has been suggested, but not proven conclusively, that the success of calorie restricted diets in extending the lifespan of rodents is related to a reduction in free radical formation[13-15].

The role of insulin/IGF-1 signalling in the regulation of lifespan has been studied. The gene *daf*2, an insulin/IGF-1 receptor homolog has been shown to affect the lifespan of *C. elegans*[16]. Similarly, a related tyrosine kinase receptor, InR, regulates lifespan in Drosophila[17]. Holzenberger *et al*[18] demonstrated the importance of this pathway in mammals. In this study, heterozygous knockout mice ($Igf1r^{+/-}$) were used, as null mutants were not viable. These $Igf1r^{+/-}$ mice had IGF-1 receptor levels that were half of those seen in wild-type animals. These mice lived an average of 26% longer than did their wild-type littermates, without developing dwarfism, or showing adverse changes in physical activity, fertility or metabolism. This suggests that the link between insulin signalling and longevity seen in lower order organisms may also exist in mammals. Furthermore, the $Igf1r^{+/-}$ mice showed a greater resistance to oxidative stress, a known determinant of aging[10]. This lends support to the theory that oxidative stress plays an important role in the aging process.

In addition to increasing resistance to oxidative stress, insulin/IGF-1 signalling may affect aging via effects on Forkhead transcription factors of the FOXO class. Overexpression of FOXO extends life span[19]. Insulin/IGF-1 receptor binding, and subsequent activation of the PI3K/Akt pathway, results in the phosphorylation of Akt, which inactivates FOXO by sequestering it in the cytoplasm[20]. This alters the effects of FOXO on resistance to stress, apoptosis and longevity, and provides another potential link between insulin/IGF-1 and aging.

Other theories of aging focus on neuro-endocrine changes, including reductions in the levels of the steroid hormone dehydroepiandrosterone (DHEA). Both animal and human studies have demonstrated that oral replacement of DHEA may prevent or reduce age-associated events such as cancer and cardiovascular disease, and may stimulate immune function[21-25].

## A SOCIETAL PERSPECTIVE

Seniors constitute the fastest growing segment of Canada's population. In fact, the proportion of seniors has risen from one in twenty in 1921, to one in eight in 2001. Within this group, the number of Canadians aged 85 or more is anticipated to increase substantially, up to 4% of the total population by the year 2041 (Health Canada, 2002). Women make up the majority of seniors, with gender differences becoming more pronounced in the oldest age groups.

The aging of the population may be thought of as a modern day success story. For the first time in history human beings have been afforded the opportunity to live an unprecedented number of years, with a reasonable quality of life. This accomplishment is not without challenges, however, as society struggles to adapt to a changing demographic, with a unique set of physiological, psychological, and social needs of the elderly themselves as well as their caregivers.

Several non-genetic factors may influence life expectancy, including improvements in sanitation and nutrition, as well as reductions in maternal mortality and the rates of infectious diseases (An Aging World: 2001, U.S. Census Bureau). These changes, coupled with lower fertility rates, result in a changing demographic that presents society with the challenges of providing quality health care to an aging population, and facilitating the social, economic and community involvement of seniors.

Although most seniors rate their health as "good" or "very good", seniors are more likely to visit health care professionals, to take medication, and to be hospitalized when compared to their younger counterparts. Therefore, increases in this population and the associated increased health care utilization may place a burden on the system. Indeed, health expenditures for seniors in 2000-2001 represented 43% of total health care expenditures (Health Canada, 2002). Of course we recognize that these persons have contributed greatly to our society, and it is our responsibility to provide ready access to quality of healthcare for these special persons, who must be treated with respect and allowed to age with dignity.

## MALNUTRITION IN THE ELDERLY

The elderly are at a high risk for malnutrition, yet

unfortunately it is often underdiagnosed[26]. Poor nutritional status is a key determinant of morbidity and mortality in the elderly[27-30]. Because nutrition is a modifiable risk factor, attempts should be made to design preventative nutritional strategies aimed at improving the quality of life and consequently minimizing the use of health care resources.

Why are the elderly malnourished? There are a number of contributing factors including: (1) inadequate intake, attributed to a lack of appetite, or difficulty in preparing food; (2) psychological factors, including depression; (3) social factors, including isolation and low income; and (4) physiological factors, such as reduced sense of smell and taste, drug-nutrient interactions and reductions in nutrient absorption[31]. Sullivan *et al*[29] demonstrated that hospitalization was a risk factor for inadequate food intake in seniors, possibly due to the unattractive and monotonous food choices, or due to the side effects of drug therapies. Reduced food intake is generally accepted as the main cause of undernutrition in the geriatric population, and as such therapies should be aimed at increasing food intake. Many researchers also feel that malnutrition in the elderly is indicative of prevailing social conditions, and that therapies should be aimed at alleviating poverty, isolation and depression in this age group.

Because one of these several factors which may contribute to malnutrition relates to possible age-associated changes in the physiology of the gastrointestinal tract, this topic will be reviewed.

## THE AGING PROCESSES AND THE GASTROINTESTINAL TRACT

The aging of the population, coupled with the potential impact on the health care system, has focused attention on the physiological processes associated with aging. Only with an increased understanding of the aging process can we work towards improving the quality of life for the elderly, and reducing disease morbidity in this population.

There are age-related alterations in the gastrointestinal tract but the difficulty lies in excluding concomitant pathological factors as the cause of these changes. Certainly with aging, conditions such as diabetes, pancreatic or liver disease, cancer, or drug-induced enteropathy will have potential adverse effects on the form and function of the intestine. It is necessary to exclude these pathological factors, to consider the physiological changes that occur in the healthy elderly, and to understand how these factors influence the nutritional status of this population.

Dysphagia is more common in the elderly than in younger persons[32]. Selective neurodegeneration may occur in the aging enteric nervous system (reviewed in Saffrey)[33], and may contribute to gastrointestinal symptoms such as dysphagia, gastrointestinal reflux and constipation. Interestingly, caloric restriction in rodents can prevent the neuronal losses that occur with aging, suggesting that diet may influence gastrointestinal aging[34]. Alterations in esophageal motility may be due to reductions in the number of neurons in the myenteric plexus of the elderly[35]. While gastric motility may be impaired with aging[36,37], small intestinal motility is unaffected[38-40]. Aging may affect the signal transduction pathways and cellular mechanisms controlling smooth muscle contraction, which may influence colonic motility and thereby contribute to the development of constipation (reviewed in Bitar and Patil)[41].

The data regarding aging and gastric acid secretion is inconclusive, as early studies were likely confounded by the presence of *H pylori* in some persons. Achlorhydria or hypochlorhydria may result from atrophic gastritis, as a result of the use of medications such as proton pump inhibitors, or as a result of *H pylori* infection[42-44]. This reduction in gastric acidity may increase the risk of small bowel bacterial overgrowth, potentially leading to malabsorption[45]. For example, McEvoy *et al*[46] found that 71% of patients in a general geriatric ward had bacterial overgrowth of the small intestine, while 11% were found to be malnourished. Indeed, bacterial overgrowth in older adults is associated with reduced body weight, which is paralleled by reduced intake of several micronutrients[47].

Although structural changes in the pancreas are seen with aging, no functional age-related alterations are seen using the fluorescein dilaurate test[48]. Some studies demonstrate reduced secretagogue-stimulated lipase, chymotrypsin and bicarbonate concentrations in pancreatic juice with aging[49]. Other research suggests that there is little evidence of reduced pancreatic secretions with age, independent of other factors including the presence of disease and the effect of drugs[50].

There are age-related reductions in liver mass and blood flow, yet microscopic changes are subtle[51-53]. While structural and functional changes do not correlate well, there is evidence that liver function declines with age. For example, Cao *et al*[54] used microarrays to show that aging in mice is accompanied by changes in the expression of genes in the liver involved in inflammation, cellular stress and fibrosis, all of which are linked to age-related liver pathologies. Interestingly, caloric restriction in mice starting at weaning reversed the majority of the age-related changes, once again emphasizing the ability of the diet to influence the aging process.

Holt *et al*[55] looked at age-related changes in the intestinal morphology of Fischer 344 rats. Increases in villous width were noted throughout the small intestine, while increases in villous height were limited to the ileum. Other studies in rats have shown age-related losses in villous and enterocyte heights[56]. Age-related declines in mucosal surface area have also been reported in rabbit jejunum[57]. Human studies generally show no changes in intestinal morphology, as determined from measurements of villous height, crypt depth, crypt-to-villous ratios and enterocyte size[58-60]. Warren *et al*[61] showed a decrease in villous height with age. Martin *et al*[62] described histological changes that occur in aging mice: when old mice were compared to young mice, there were larger villi, a reduced number of crypts, and fewer villi and crypts per mm along the small intestine. These changes were most pronounced in the distal, as opposed to the proximal small intestine. However, even if there are minor age-associated alterations in intestinal morphology with aging, there is not a clear association between intestinal morphology and nutrient

uptake with aging. For example, despite reductions in mucosal surface area, aged rats demonstrated increases in the jejunal uptake of saturated fatty acids[57]. So, while it remains controversial as to whether or not aging is associated with morphological changes, even if such changes were to occur, the impact on nutrient uptake may not be clinically relevant.

Ciccocioppo *et al*[63] suggested that intestinal architecture is maintained with aging by increases in proliferation and differentiation rates. This agrees with work done by Corazza *et al*[64] that showed increased expression of proliferating cell nuclear antigen (PCNA) in older subjects when compared to their younger counterparts.

## NUTRIENT DIGESTION AND ABSORPTION

Age-related alterations in the abundance of brush border malease (BBM) enzymes may also impact upon the digestion and subsequent absorption of nutrients. BBM lactase phlorizin hydrolase (LPH) and sucrase-isomaltase (SI) activities fall with age in rats[65]. Bacterial overgrowth, which is common in the elderly, may also negatively impact upon disaccharidase activity, and thereby possibly reduce carbohydrate absorption[66].

Hollander and colleagues demonstrated that intestinal permeability to medium sized probes (mannitol, polyethylene glycol) increased in 28-month old rats when compared to 3-month old rats[67]. However, the lactulose: mannitol (LTM) ratio was not different between young and old subjects, indicating that intestinal permeability to these sugars does not change significantly with age in humans[68]. A study using breath hydrogen analysis following a carbohydrate meal showed evidence of malabsorption with aging. Elderly patients (ranging from 65-89 years, mean age, 79 years) were compared to control subjects (ranging from 20-64, mean age, 35 years). Significantly more subjects in the elderly group (7 out of 21) excreted excess $H_2$ when compared to controls (0 out of 19)[69]. This suggests that there may be malabsorption of carbohydrates in the elderly. *In vitro* transport experiments using BBM vesicles also demonstrated a reduction in $Na^+$-dependent D-glucose uptake in patients over the age of 70[70]. In contrast, Wallis and co-workers[71] did not find changes in $Na^+$-dependent glucose transport in BBM vesicles isolated from duodenal biopsies from patients whose ages ranged from 55 to 91 years.

Experiments using rodent models of aging also demonstrate conflicting results. Several studies show reductions in D-glucose absorption in aged rats[72-74]. Depending upon the intestinal site studied, a normal or increased absorptive capacity was also found in a study using everted intestinal segments from old versus young rats[75]. Results from studies in mice also do not offer conclusive results on the effect of aging on nutrient absorption. Ferraris *et al*[76] showed in aged mice a reduction in uptake and site density of the $Na^+$-dependent glucose transport in the BBM, SGLT1. This is in contrast to the findings of Thompson *et al*[77] who showed an increase in intestinal glucose uptake in aged mice. Our lab has recently investigated the effect of age on intestinal glucose uptake in Fischer 344 rats using the *in vitro* intestinal sheet method[78]. Glucose uptake was reduced in 9 mo old and 24 mo old rats when compared to 1 mo old animals. When changes in mucosal surface area were accounted for, only ileal glucose uptake was reduced in the older animals. These age-associated changes in glucose uptake were not explained by alterations in the abundance of SGLT1, GLUT2 or $Na^+K^+$-ATPase.

The variations in the results from human, rat and mouse studies may be due to the differences in the methodologies that were used. While some investigators studied uptake using BBM vesicles[70-74], others used everted intestinal rings[75,77,79] or intestinal sheets[78]. As well, the method of expressing results may influence qualitative differences between studies. Uptake is often expressed on the basis of intestinal weight, and does not taken into account any potential age-associated changes in mucosal weight or surface area. The strain and ages of the animals, and the site of the intestine used also differ between studies, and may explain the variability in the results.

The uptake of fructose has been studied in aging mice. Ferraris and Vinnekota[79] showed that D-fructose uptake per milligram of tissue was higher in the jejunum of young as compared to old animals. Adaptive increases in uptake, in response to increases in carbohydrate levels, were blunted in these mice, and were restricted to more proximal regions of the small intestine

While it is reasonable to speculate that the complexity of lipid absorption may make it susceptible to the effects of aging, experimental findings do not consistently support this notion. While a number of animal studies demonstrate reduced *in vitro* lipid absorption with aging[80,81], others have shown increases in lipid absorption in aged rats using an *in vivo* perfusion model[82]. Aging is associated with a decrease in the thickness and resistance of the unstirred water layer[80], which could partially explain the finding of increased absorption with aging in the *in vivo* model.

Early work using human subjects demonstrated reductions in lipid absorption with age[83]. There also appears to be reduced intestinal absorption of bile acids with age[84], although it is not clear if this negatively impacts lipid absorption in the elderly. When healthy elderly human subjects were studied, however, no correlation between age and 72 h fecal fat excretion was found[85].

More recently, a study by Woudstra *et al*[86] showed that the ileal uptake of several fatty acids including 16:0, 18:0, 18:1 and 18:2, was reduced in 24 mo old rats, when compared to 1 mo old animals. However, when mucosal surface area was considered these differences disappeared, suggesting that the age-related changes in lipid uptake were largely due to non-specific reductions in intestinal surface area. After considering the results of all of these studies, Holt[87] suggested that no important changes in lipid absorption with aging have been described.

## MODIFICATION OF AGE-ASSOCIATED DECLINES IN INTESTINAL ABSORPTIVE FUNCTION

Holt *et al*[55] have shown that the intestine of elder rats is capable of adopting its function in response to changes

in dietary protein levels. In adult rats, a diet enriched with saturated fatty acids (SFA) results in increased intestinal sugar uptake when compared to an isocaloric diet enriched with polyunsaturated fatty acids (PUFA)[88-91]. Similarly, Vine *et al*[92] studied the effect of various fatty acids on the passive and active transport properties of rat jejunum, and found that an SFA diet increased $Na^+$-dependent glucose uptake when compared to a diet enriched with n6 PUFA. Of importance, Woudstra *et al*[93] showed that the intestinal response to dietary lipids may differ with age. In this study, in contrast to what is seen in younger animals, feeding a PUFA diet increased lipid uptake when compared to feeding a SFA diet. Drozdowski *et al* (unpublished observations) have also shown that PUFA rather than SFA increases intestinal sugar uptake in older rats. The mechanism responsible for the age-related alteration in adaptation to daily lipids is not known. But clearly, the results of adoptive studies in young rats do not necessarily apply to older animals. Other factors which may enhance the reduced uptake of sugars that occurs in older animals indicates glucagon-like peptide 2 (GLP2) at the glucocorticosteroid, dexamethasone (Drozdowski *et al*, unpublished observations, 2006).

## Abstract

**AIM:** To study the effect of CXC chemokine receptor-4 (CXCR4) expression on disease progression and prognosis in esophageal cancer.

**METHODS:** CXCR4 expression was evaluated in 37 patients with histologically confirmed esophageal squamous carcinomas (ESCC) undergoing preoperative chemoradiotherapy (CRT) by immunohistochemical staining.

**RESULTS:** Eleven out of 37 ESCC patients showed a pathological complete response (CR) after CRT. CXCR4 protein expression was observed in cell cytoplasms of 13 tumors, and null expression was seen in 13 tumors. Distant recurrence was significantly more common in patients with positive CXCR4 expression ($P$ = 0.0318). After a median follow-up time of 31.6 mo, 19 patients progressed (12 of 19 expressed positive CXCR4) and 11 died (10 of 11 expressed positive CXCR4). Overall survival was significantly correlated with lymph node metastasis (952.1 ± 53.8 d in negative group *vs* 475.1 ± 56.2 d in positive group, $P$ = 0.023), distant metastasis (874.0 ± 60.4 d in negative group *vs* 434.9 ± 75.2 d in positive group, $P$ = 0.014) and CRT (811.5 ± 51.2 d in responder group *vs* 459.6 ± 94.0 d in non-responder group, $P$ = 0.00038) and further with an absence of CXCR4 expression or no residual tumor (959.8 ± 51.0 d in null expression or no tumor group *vs* 412.0 ± 57.1 d in positive expression group, $P$ = 0.0001).

**CONCLUSION:** Persistent positive CXCR4 expression is implicated in tumor aggressiveness and poor prognosis in ESCC after CRT, and preoperative CRT may improve the prognosis of ESCC *via* CXCL12-CXCR4 signaling pathway.

**Key words:** CXC chemokine receptor-4; Metastasis; Chemoradiotherapy; Esophageal cancer

## INTRODUCTION

The migration of tumor cells to a secondary site from their primary location is a crucial issue in cancer metastasis. Recently, a novel "homing" signaling mechanism has been proposed, in which target organs produce and release specific chemokines that attract cancer cells bearing corresponding receptors[1,2]. This mechanism was originally characterized for organogenesis, hematopoiesis and inflammation, and draws on the principles of the "seed and soil" hypothesis advocated by Paget more than one century ago[3]. Signaling results in directional, site-specific cancer cell migration leading to implantation in the favorable "soil" of organs. A large number of studies support this "homing" mechanism by demonstrating that malignant cells can target specific organs or tissues using select chemokine receptors, mainly through the CXCL12-CXC chemokine receptor-4 (CXCR4) pathway[4-8].

Chemokines are signaling molecules that function in myriad cell trafficking events. They have been classified into four subgroups (C, CC, CXC, and $CX_3C$) based on the positioning of their cysteine residues[9]. CXCL12, also

known as stromal cell-derived factor-1 (SDF-1), belongs to the CXC chemokine family and CXCR4 is the only known physiological receptor for SDF-1[10]. Chemokine receptor activation can lead to growth, adhesion and, most importantly, directional migration[11]. In hematopoiesis and development, stem cells and progenitor immune cells migrate to and from various organs and tissues under the directional guidance of chemokines[12]. Chemokine migratory activation also plays a role in integrating T-cell migration during immune and inflammatory responses[13]. The discovery that chemokine receptors are expressed on nonhemopoietic cell types, such as endothelial and epithelial cells, will inevitably lead to the receptors being implicated in other biological and disease processes such as angiogenesis, organ development, metastasis and tumorigenesis. Indeed, clinical studies have already revealed that CXCR4 expression is associated with increased metastasis and decreased survival of some cancer patients[14-18].

Esophageal cancer is one of the most aggressive forms of cancer with rapid growth. Common to other cancers, the presence of lymph node metastasis and vascular invasion indicate a highly malignant potential[19]. Surgery is the treatment of choice for patients with locoregionally confined esophageal cancer, but the five-year survival rate is only 10%-30%, even after curative surgery[20]. The reason for this is that esophageal cancer shows extensive local invasion or frequent regional lymph node metastasis, often at the time of initial diagnosis. Since 1996, we have introduced preoperative chemoradiotherapy (CRT) combined with radical surgery for the treatment of esophageal cancers, and have reported that adjuvant preoperative CRT increased resectability, reduced the incidence of both local recurrence and distant metastasis, and achieved better prognosis for CRT responders[21]. However, no data are currently available on the role of CXCR4 expression in esophageal cancer progression, and the prognosis of patients undergoing CRT has not as yet been reliably estimated. In this study, therefore, we retrospectively investigated the expression of CXCR4 protein in human esophageal squamous cell carcinoma (ESCC) tissues and evaluated the clinical implications of these patients who underwent preoperative CRT and radical surgery.

## MATERIALS AND METHODS

### Patients and therapy

Thirty-seven patients, seven women and 30 men with a mean age of 60.32 (range 44-78) years and surgically excised ESCC were studied at the Hyogo College of Medicine, Hyogo, Japan, between April 1996 and June 2003. Preoperative CRT was performed as follows (schedule shown in Figure 1): 5-flurouracil (5-FU) (500 mg/m$^2$ per day) was administered as a 120-h continuous intravenous infusion starting on d 1, and cisplatin (CDDP) (15 mg/m$^2$ per day) as a 2-h iv infusion on d 1-5. Radiation therapy was performed on d 1-5, after CDDP infusion, using a linear accelerator (Mevatron KD2, Siemens, Germany). The radiation method has been previously reported[16]. Chemotherapy was combined with radiation therapy during the first week, and then radiation therapy alone was repeated for the next 3 wk (d 8-12, 15-19, and 22-26). A single dose was 2 Gy/d, with a total dose of 40 Gy.

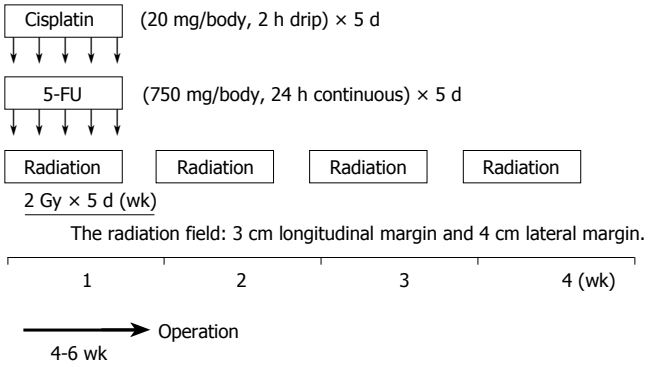

**Figure 1** Schedule of preoperative chemoradiotherapy (CRT).

Surgery was usually performed 4 to 6 wk after the completion of CRT. Resected specimens were cut open longitudinally and fixed with formalin. Follow-up information was obtained from office charts, hospital records, and telephone interviews.

### Immunohistochemistry

ESCC tissue specimens were processed using conventional procedures for paraffin embedding, cut into 4-μm sections, and mounted onto poly-L-lysine-coated slides. Sections were dewaxed in xylene, rehydrated in descending alcohols, and heated twice by microwave oven for 5 min each time in 10 mmol/L sodium citrate (pH 6.0) for antigen retrieval. They were then blocked for endogenous peroxidase with 30 mL/L $H_2O_2$ in methanol, and blocked again for non-specific antibody binding with normal rabbit serum. After then they were incubated for 2 h at room temperature with mouse mAb against human CXCR4 (R&D Systems, Minneapolis, MN, USA), followed by a standard avidin-biotin-peroxidase complex method. The slides were developed with 3, 3'-diaminobenzidine tetrahydrochloride solution containing 1 mL/L $H_2O_2$ and were lightly counterstained with hematoxylin. Normal mouse IgG was substituted for the primary antibody as a negative control. The sections were finally counterstained with Lillie-Mayer's hematoxylin and mounted.

The sections were examined microscopically by three of the authors (R.Y., T.T., and Y.F.) without knowledge of clinicopathologic features. CXCR4 expression was categorized into four grades according to staining intensity in comparison with interstitial infiltrates[18]: score 3 (strong), staining intensity greater than interstitial infiltrates; score 2 (moderate), staining intensity equal to interstitial infiltrates; score 1 (mild), staining intensity less than interstitial infiltrates; and score 0 (negative), no staining. Additional CXCR4 expression scores were also assigned: score 3, CXCR4 high; scores 0-2, CXCR4 null or low.

### Statistical analysis

Overall survival (OS) was defined as the time from the date of initial diagnosis to patient death or the date of the last available information on vital status. In univariate analysis, the difference between the cumulative survival rates of

**Table 1 Patient characteristics**

patient groups was calculated by the log-rank test for comparison using Kaplan-Meier survival curves. Statistical significance was considered at $P < 0.05$. Statistical analyses were carried out using Statistica statistical software, version 06J (Statistica, Tulsa, OK, USA).

## RESULTS

### Patient and tumor characteristics

Patient and tumor characteristics are summarized in Table 1. The patient gender bias was male (M:F, 30:7). Histology of all tumors was shown to be ESCC by histological examination. Thirty-six tumors originated in the thorax. According to the TNM system of the American Joint Committee on Cancer, stage Ⅱ tumors were seen in 17 patients (46%), stage Ⅲ in 13 (35.1%), and stage Ⅳ in seven (18.9%). Thirteen (35.1%) patients had lymph node metastasis ($N_1$ in six, $M_{1a}$ in three, and $M_{1b}$ in four patients) at the time of diagnosis. All lesions before CRT presented with a $T_3$ or $T_4$ extent of invasion. Three-quarters of patients had tumors between 6 and 8 cm in diameter. M+ classification was described in seven tumors. Two patients had distant metastasis of the liver. All patients experienced a disease-free period. During the follow-up period, four (10.8%) patients developed local recurrence or residual tumors, six (16.2%) developed neck or celiac lymph node recurrence, and seven (18.9%) developed distant metastasis. Fifteen (40.5%) patients died during follow-up: 13 (35.1%) died from their tumors and the remaining two (5.4%) were tumor free and died of intercurrent diseases.

### Prognostic value of persistent CXCR4 expression

Eleven tumors were totally eradicated by CRT, resulting in an absence of visible tumor cells: a pathological complete response (CR). CXCR4 expression was absent from 13 tumors (35.1%). Another 13 tumors (35.1%) were positive for CXCR4 expression: 11 scored 1, one scored 2, and the last scored 3. The patient who scored 3 died of multiple lung metastasis two months after surgery. Staining was observed predominantly in the cytoplasm of tumor cells (Figure 2). In the positive CXCR4 expression group ($n$ = 13), recurrences were found in 10 patients: two locally

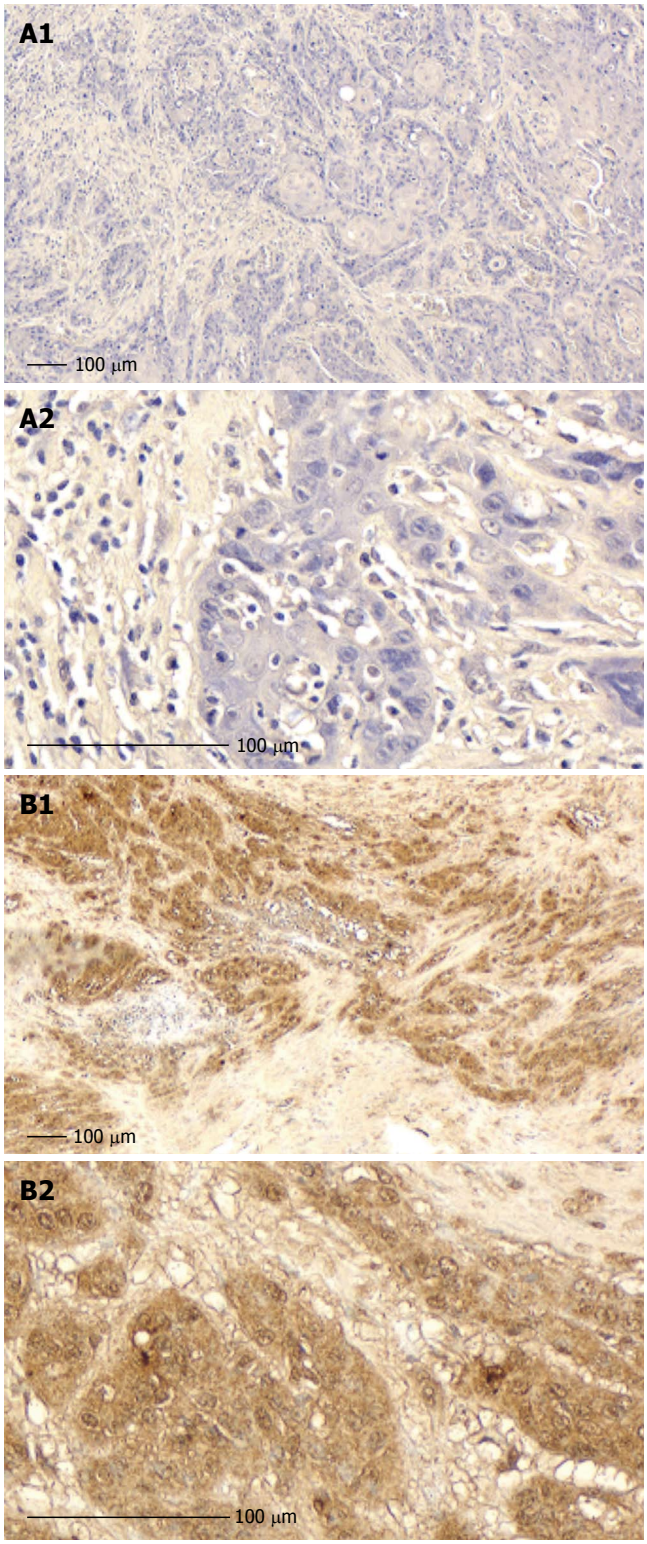

**Figure 2** Immunohistochemical detection of CXCR4 in ESCC specimens. **A**: Null expression (**A1**: × 40; **A2**: × 200); **B**: Strong expression (**B1**: × 40; **B2**: × 200).

and eight distant in the liver, bone, thyroid gland, lung and neck lymph nodes. By contrast, in the null CXCR4 expression group ($n = 11$), recurrences were found in only two patients, in the liver and bone. Statistical analysis showed that distant recurrence was more common in those patients with positive CXCR4 expression ($P = 0.0318$).

After follow-up, disease progression had occurred in 12 of the 13 patients with positive CXCR4 expression, and 11 of them died. Univariate analysis of prognostic factors for OS is summarized in Table 2. Lymph node metastasis and distant metastasis had a significant prognostic value (952.1 ± 53.8 d in lymph node metastasis negative group *vs* 475.1 ± 56.2 d in positive group, $P = 0.023$, and 874.0 ± 60.4 d in distant metastasis negative group *vs* 434.9 ± 75.2 d in positive group, $P = 0.014$, respectively). Furthermore, there was a very significant effect of CRT on OS prognosis (811.5 ± 51.2 d in responder group *vs* 459.6 ± 94.0 d in non-responder group, $P = 0.00038$). Kaplan-Meier analyses (Figures 3 and 4) suggest that prognosis was particularly unfavorable for patients with persistent positive CXCR4 expression in their primary tumors compared with CXCR4 null expression patients or those with no residual tumor (959.8 ± 51.0 d in CXCR4 null expression or no tumor group *vs* 412.0 ± 57.1 d in positive expression group, $P = 0.0001$). In addition, CXCR4 null expression patients showed an improved OS compared with positive expression patients ($P = 0.0005$).

## DISCUSSION

The understanding of the molecular basis of tumor development has progressed dramatically in the last few decades. It is well known that esophageal cancer shows poor prognosis because of its aggressiveness; therefore, it is important to understand the role of molecular factors in the acquisition of malignant potential. The presence and number of metastases in ESCC is important both

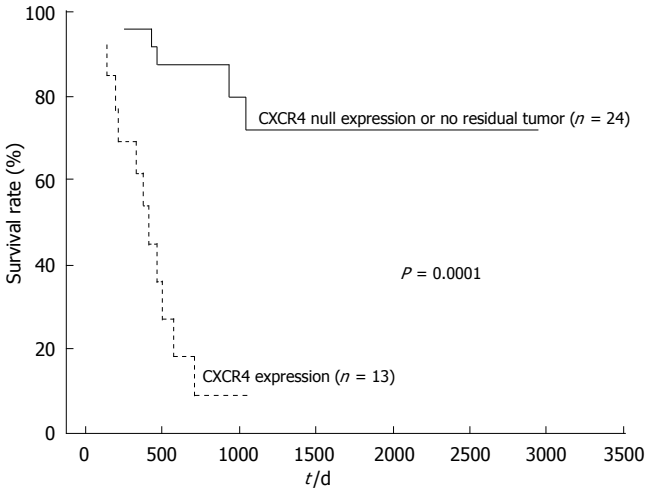

**Figure 3** Overall survival in ESCC patients with no residual tumor or null CXCR4 expression and those with positive CXCR4 expression.

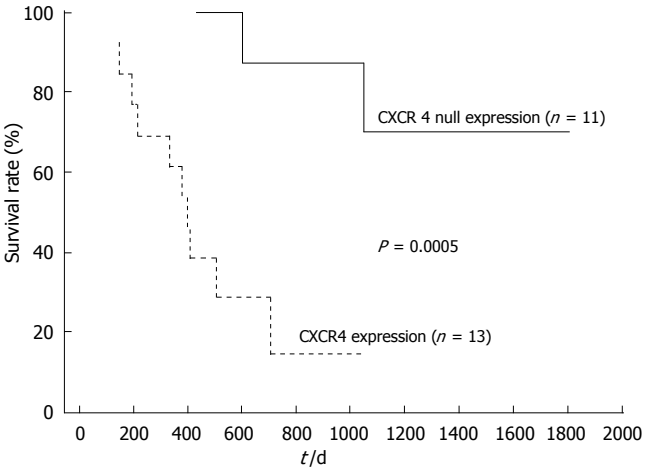

**Figure 4** Overall survival in ESCC patients with null or positive CXCR4 expression.

for staging and prognosis[22]. The metastatic potential of primary ESCC is considerably higher than other primary solid tumors when the size of the primary lesion is compared. Notably, in the present study, univariate analyses demonstrated that persistent CXCR4 expression was the most influential factor for OS in operable ESCC patients who underwent CRT. Patients with advanced ESCC, even in T4 stage, demonstrated improved prognosis when preoperative CRT was successful. Persistent CXCR4 expression after CRT may therefore be a useful biomarker for screening and management of high-risk patients with poor prognosis. To date, this is the first report demonstrating the prognostic role of CXCR4 expression in ESCC patients undergoing CRT.

It is likely that several mechanisms are involved in cancer metastasis including those of the "homing" signaling process described earlier. In ESCC, the signaling mechanism together with a mechanical drainage pattern might facilitate specific metastasis to lymph nodes, liver and lung. After distant metastatic cells have passed through vascular channels and implanted, a favorable "soil" might be responsible for further growth and proliferation.

Frequently, these esophageal metastases occur in multiple foci, but little is known about these patterns. Furthermore, the concept that cancer implantation enacts an immune response, thus accentuating chemoattraction of CXCR4-positive tumor and immune cells, cannot be discounted[23]. It has recently been reported that CXCR4 is highly expressed in malignant but not normal breast tissue, and that CXCL12 is expressed in those organs where breast cancer metastasis is frequently found such as bone marrow, lymph nodes, lung, and liver[1]. Moreover, neutralizing the interactions of CXCL12-CXCR4 by administration of an anti-CXCR4 antibody significantly impairs the metastasis of breast cancer cells to the lung and regional lymph nodes in mice[1]. Taken together with our results, these findings indicate that the CXCL12-CXCR4 interaction is important for the metastasis of solid tumors that fail to respond to CRT. Persistent CXCR4 expression even after CRT appears to have a prognostic value, although the alteration of CXCL12-CXCR4 signaling by CRT was not directly analyzed in our study. CXCR4 antagonists have already been studied in phase I clinical trials in multiple myeloma and non-Hodgkin's lymphoma[24-26]. These preliminary data regarding hematopoiesis suggested that AMD3100, a CXCR4 antagonist, is safe and effective in reversibly inhibiting CXCL12-CXCR4 binding and in mobilizing WBCs, CD34+ cells and hematopoietic progenitor cells (HPCs) into the circulation. Utilization of CXCL12-CXCR4 pathway may be a promising therapeutic approach in the prevention and treatment of metastasis.

In conclusion, we have demonstrated that positive CXCR4 expression after CRT correlates with distant recurrence and provides an independent prognostic factor for ESCC survival. These findings strongly suggest that CXCR4 plays an important role in ESCC progression and could provide a novel molecular target for the treatment of ESCC. Large cohort studies in a multicenter setting will be necessary to validate our findings and explore the potential use of CXCR4 antagonists in the treatment of ESCC patients with a high risk of early relapse following CRT.

## COMMENTS

### Background

The chemokine CXCL12, also known as stromal cell-derived factor-1 (SDF-1), and its receptor CXCR4 have been implicated in organ-specific metastases of several malignancies. Recently, we have reported that adjuvant preoperative chemoradiotherapy (CRT) reduced the incidence of both local recurrence and distant metastasis. However, the impact of CXCR4 expression on disease progression and prognosis in esophageal cancer patients undergoing preoperative CRT remains unknown.

### Research frontiers

It has recently been reported that CXCR4 is highly expressed in malignant but not normal breast tissue, and that CXCL12 is expressed in those organs where breast cancer metastasis is frequently found such as bone marrow, lymph node, lungs, and the liver. Moreover, neutralizing the interactions of CXCL12-CXCR4 by administration of an anti-CXCR4 antibody significantly impairs the metastasis of breast cancer cells to the lungs and regional lymph nodes in mice.

### Innovations and breakthroughs

We have demonstrated that positive CXCR4 expression after CRT correlates with distant recurrence and provides an independent prognostic factor for ESCC survival. These findings strongly suggest that CXCR4 plays an important role in ESCC progression and could provide a novel molecular target for the treatment of ESCC. To date, this is the first report demonstrating the prognostic role of CXCR4 expression in ESCC patients undergoing CRT.

### Applications

Persistent CXCR4 expression after CRT may be a useful biomarker for the screening and management of high risk patients with poor prognosis. CXCR4 antagonists have already been studied in phase I clinical trials in multiple myeloma and non-Hodgkin's lymphoma. Potential use of CXCR4 antagonists should be explored in the treatment of ESCC patients with a high risk of early relapse following CRT.

### Terminology

Chemokines are signaling molecules that function in myriad cell trafficking events. They have been classified into four subgroups (C, CC, CXC, and $CX_3C$) based on the positioning of their cysteine residues. CXCL12, also known as stromal cell-derived factor-1 (SDF-1), belongs to the CXC chemokine family and CXC chemokine receptor-4 (CXCR4) is the only known physiological receptor for SDF-1. Chemokine receptor activation can lead to growth, adhesion and, most importantly, directional migration.

### Peer review

The paper is scientific and innovative contents as well as readability can reflect the advanced levels of the clinical research in gastroenterology both at home and abroad.

## Abstract

**AIM:** To evaluate whether folate levels in mucosal tissue and some common methylenetetrahydrofolate reductase (MTHFR) variants are associated with the risk of gastric cancer through DNA methylation.

**METHODS:** Real-time PCR was used to study the expression of tumor related genes in 76 mucosal tissue samples from 38 patients with gastric cancer. Samples from the gastroscopic biopsy tissues of 34 patients with chronic superficial gastritis (CSG) were used as controls. Folate concentrations in these tissues were detected by the FOL ACS: 180 automated chemiluminescence system. MTHFR polymorphisms were analyzed by PCR-RFLP, and the promoter methylation of tumor-related genes was determined by methylation-specific PCR (MSP).

**RESULTS:** Folate concentrations were significantly higher in CSG than in cancerous tissues. Decreased expression and methylation of c-myc accompanied higher folate concentrations. Promoter hypermethylation and loss of $p16^{INK4A}$ in samples with MTHFR 677CC were more frequent than in samples with the 677TT or 677CT genotype. And the promoter hypermethylation and loss of $p21^{WAF1}$ in samples with MTHFR 677CT were more frequent than when 677CC or 677TT was present. The 677CT genotype showed a non-significant higher risk for gastric cancer as compared with the 677CC genotype.

**CONCLUSION:** Lower folate levels in gastric mucosal tissue may confer a higher risk of gastric carcinogenesis through hypomethylation and overexpression of c-myc.

**Key words**: Folate; Methylenetetrahydrofolate reductase; Polymorphism; DNA methylation; Gastric cancer

## INTRODUCTION

Methylation of gene regulatory elements is a well-documented epigenetic change that can lead to gene inactivation. Human gastric carcinogenesis is suggested to be associated with the decrease of total genomic DNA methylation, hypomethylation of certain specific oncogenes such as c-myc, and hypermethylation of promoter of some tumor suppressor genes containing $p16^{INK4A}$ and *hMLH1* gene[1]. Folate (or folic acid) is essential for normal DNA methylation and synthesis. We have performed a series of studies to investigate the interrelationship between DNA methylation and folate status in plasma of patients with gastric cancer[2,3]. The plasma folic acid concentration in patients who showed hypomethylation of c-myc was lower than that in patients showing normal methylation. Low plasma levels of folate have been associated with an increased risk for gastric cancers[4,5].

Methylenetetrahydrofolate reductase (MTHFR) is a key enzyme in folate metabolism that regulates the intracellular folate pool. Two MTHFR polymorphisms, C677T and A1298C, are known to be risk factors for gastric cancer in Chinese[6], but not in Korean[7]. The MTHFR 677T allele was significantly associated with gastric cancer risk with an odds ratio (OR) of 2.49 [95% confidence interval (CI): 1.48-4.20] in heterozygous MTHFR 677CT carriers and an OR of 2.85 (95% CI: 1.52-5.35) in homozygous MTHFR 677TT carriers in a high risk Italian population[8]. These findings suggest that common variants of MTHFR may play a role in the etiology of gastric cancer, particularly

gastric cardia adenocarcinoma. Future studies using large sample sizes and incorporated detailed data on dietary folate intake and related serological measurements are needed to confirm these findings[9].

The extent to which tissue folate levels and MTHFR 677 (C→T) polymorphism interact to affect DNA methylation in gastric carcinogenesis is uncertain. It is even not clear that there is a relationship between folate concentrations and DNA methylation in gastric mucosal tissue. In the current study, we hypothesized that folate levels and some common MTHFR variants are associated with the risk of gastric cancer through DNA methylation. Our data show that decreased folate in tissues is associated with a higher risk of gastric cancer. However, MTHFR gene polymorphisms are not independent risk factors for initiation and progression of gastric cancer, although the 677CT genotype shows a non-significant higher risk for gastric cancer as compared with the 677CC genotype.

## MATERIALS AND METHODS

### Subjects

Thirty-eight consecutive patients with gastric cancer underwent resection at Shanghai Renji Hospital between May and December 2004. Clinicopathological factors, tumor histologies and disease stages were evaluated according to the General Rules for Clinical and Pathological Studies on gastric cancer. Paired samples (76) of histologically verified primary gastric cancer and corresponding non-cancerous gastric mucosa (> 5 cm away from cancerous margin) of 38 patients were obtained immediately after surgical resection. HE-stained sections were examined for pathological diagnoses, and were categorized according to the WHO histological classifications of gastric cancer. The histological characteristics of non-cancerous tissues were chronic atrophic gastritis, intestinal metaplasia, or dysplasia. All of tumors were located in gastric antrum or corpus, and not in fundus or cardia. There were 23 cases of tubular adenocarcinoma, 4 cases of mucinous adenocarcinoma and 11 cases of tubular-papillary adenocarcinoma. The mean age of the patients at resection was 61 (range 31-81) years and it included 25 men and 13 women. A portion of each tissue (approximately 3-5 g) was snap-frozen on dry ice and kept in liquid nitrogen until use for DNA or RNA extraction. Another 34 patients with chronic superficial gastritis (CSG) were studied as sex, age and *H pylori* infection (by histology, urease test or breath test, as well as alcohol and tobacco intake matched controls to the gastric cancer group). Three endoscopic biopsy tissue samples were obtained from each control. All controls were subjected to clinical assessment, upper gastrointestinal endoscopy, histopathology of antral mucosa. No chronic atrophic gastritis, intestinal metaplasia or dysplasia was detected in any of the controls. Complete written consent was obtained from all patients and controls.

### Determination of folate concentrations in tissues

One milliliter of PBS was added to 10 mg of mucosal tissues. Lysates were sonicated, and the debris was removed from samples by centrifugation for 10 min at 15 000 × *g*, 4℃ in a microcentrifuge. Folate levels in gastric mucosa were measured with an ACS: 180 automated chemiluminescence analyzer (Chiron Diagnostics Corporation, East Walpole, MA). The ACS: 180 Folate assay is a direct chemiluminescence competitive immunoassay. Folates in the patient sample competed with acridinium ester-labeled folates in the Lite Reagent for a limited amount of biotin-labeled folate binding proteins. Biotin-labeled folate binding proteins bind to avidin that is covalently coupled to paramagnetic particles in the Solid Phase. The sample was pretreated to release the folates from endogenous binding proteins.

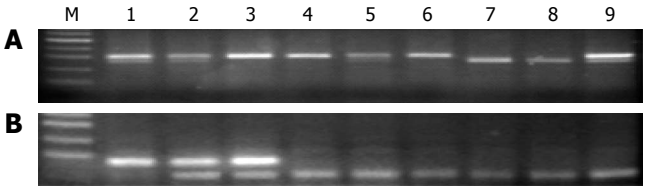

**Figure 1** **A**: *Hinf* I distinguishes MTHFR 677 (C→T) PCR products. M: 50 bp Ladder; L1, 2, 5 and 9: CT genotype; L3, 4 and 6: CC genotype; L7 and 8: TT genotype; **B**: *Mbo* II distinguishes MTHFR (A→C) PCR products. M: 50 bp ladder; L1: CC genotype; L2 and 3: AC genotype; L4-9: AA genotype.

### Analysis of MTHFR polymorphisms using PCR-RFLP

Genomic DNA was isolated from gastric mucosal tissue using QIAamp DNA Mini Kit (Qiagen Inc., Valencia, CA) according to the manufacturer's instructions. MTHFR C677T and A1298C mutations were detected after PCR amplification with the corresponding primers. The restriction enzyme *Hinf* I (New England Biolabs, Beverly, MA) was used to distinguish the 677 (C→T) polymorphism. The variant allele (677TT) gained an *Hinf* I restriction site and resulted in two fragments of 175 bp and 23 bp after digestion. The wild-type allele (677CC) had a single band representing the entire 198 bp fragment (Figure 1A). The restriction enzyme *Mbo* II (New England Biolabs) was used to distinguish the 1298 (A→C) polymorphism. The restriction site was absent in the variant allele (1298CC), and digestion yielded four fragments of 84, 31, 30 and 18 bp, whereas the wild-type allele (1298AA) generated 56, 31, 30, 28 and 18 bp bands (Figure 1B). The restriction products were analyzed by electrophoresis in a 3% agarose gel stained with ethidium bromide. PCR amplifications were run for 35 cycles, with each amplification cycle consisting of 30 s at 94℃, 30 s at 62℃ or 51℃ (for polymorphic sites at positions 677 and 1298, respectively), and 45 s at 72℃. PCR products were visualized on 3% agarose gels[10].

The MTHFR 677 (C→T) allele in gastric cancer and CSG tissues, but not the MTHFR 1298 (A→C) allele in gastric cancer samples, was in Hardy-Weinberg equilibrium ($P > 0.05$).

### Real-time RT-PCR for tumor-related genes

The transcription levels of tumor-suppressor genes, $p16^{INK4A}$ and $p21^{WAF1}$; proto-oncogene, c-myc; and mismatch repair (MMR) genes, *hMLH1* and *hMSH2*; were detected using real-time RT-PCR. Total RNA was isolated using a commercial kit (Trizol) according to the manufacturer's instructions (Invitrogen Gibco BRL, Carlsbad, CA).

M: Methylation PCR primers; U: Unmethylation PCR primers.

Reverse transcription reactions using 5 μg of total RNA in a total reaction volume of 20 μL were performed with Superscript Ⅱ reverse transcriptase (Invitrogen Life Technologies, Inc.). Relative quantitation using the comparative Ct method with data from the ABI PRISM 7700 Sequence Detection System (version 1.6 software) was performed according to the manufacturer's protocol. The primers and fluorogenic probes for these genes were provided by Shenyou Company, Shanghai. The sequences of the probes and forward and reverse primers are shown in Table 1. Real-time PCR was also performed with primers and a probe for *β-actin* to normalize each of the extracts for amplifiable human DNA. The results were expressed as the ratio of copies of target genes to *β-actin*. Ct values were measured, and the average Ct of triplicate samples was calculated. An alteration of mRNA expression was defined as a 3-fold difference in expression level[11].

### Bisulfite modification and methylation-specific PCR of promoters of tumor-related genes

To address whether DNA methylation of tumor-related genes is associated with the folate level in mucosal tissue and MTHFR polymorphisms, methylation-specific PCR (MSP) was performed in CpG-rich regions of $p16^{INK4A}$ and $p21^{WAF1}$, c-myc, and *hMLH1* and *hMSH2*, in order to detect changes in DNA methylation of the genes due to drug treatments. Bisulfite modification protocols were adopted as described by Xiong and Laird[12]. Genomic DNA treated with bisulfite was amplified with promoter specific primers of each gene (Table 1). The primers were designed without CpG dinucleotides to enable the amplification of both methylated and unmethylated alleles.

The 50 μL PCR reactions consisted of 100 ng of bisulfite-treated DNA, 0.1 mmol/L dNTPs, 2.0 mmol/L $MgCl_2$, and 0.5 μmol/L of each primer. PCR products were directly loaded onto 3% agarose gels and electrophoresed. The gel was stained with ethidium bromide and directly visualized under UV illumination. Wild-type $p16^{INK4A}$ and $p21^{WAF1}$ primers were used to verify that complete conversion of the DNA occurred in the bisulfite reaction. A positive control for complete methylation was also amplified.

### Statistical analysis

Data were presented as means ± SD. Comparisons between groups were made using Student's paired *t* test. The differences between cancerous, non-cancerous and CSG tissues, and their relationships were analyzed by Fisher's exact test using SAS v.6.12. All statistical tests were two tailed and considered significant at $P = 0.05$. A case-control study was performed and the allelic frequency of the polymorphism was calculated for both cases and controls. Odds ratios (OR) and 95% CI were calculated to evaluate the association between CSG or cancer and the presence of MTHFR C677T polymorphism. The Mantel Haenszel $\chi^2$ procedure was used to assess the linear trend between lesion severity and magnitude of the association with MTHFR C677T genotype.

**Table 2 Folate level and transcription and methylation of c-myc**

| Methylation status | Transcription | Case number (*n*) | *P*[1] | Average folate concentration (μg/L) | *P*[2] |
|---|---|---|---|---|---|
| Hypomethylated | Up-regulated | 6 | | 2.25 ± 1.23 | |
| | Unchanged | 0 | 0.02 | | 0.06 |
| Methylated | Up-regulated | 13 | | 3.91 ± 2.01 | |
| | Unchanged | 19 | | | |

[1]Transcription and DNA methylation of c-myc; [2]Folate concentration and DNA methylation of c-myc.

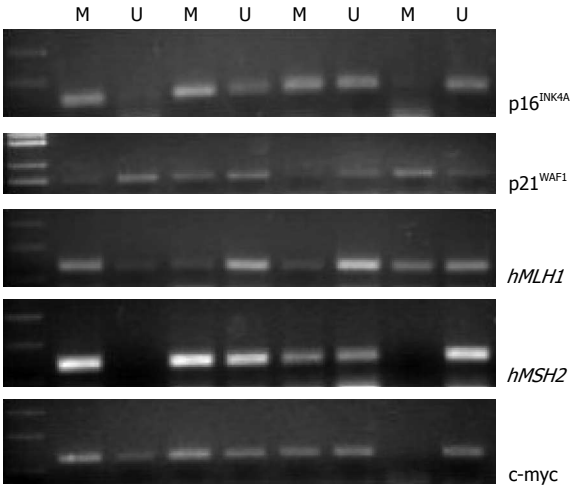

**Figure 2** Methylation-specific PCR (MSP) for tumor-related genes. MSP was performed on DNA from gastric cancerous tissue with primers designed to specifically detect methylated and unmethylated promoter regions. The data shown are representative of three replicate MSP experiments. Marker: 100 bp ladder; U: Unmethylated-MSP; M: Methylated-MSP.

## RESULTS

### *Folate levels were lower in cancerous tissue than in non-cancerous tissue or CSG*

Folate concentrations in CSG tissue (5.48 ± 2.15 ng/mL) were significantly higher ($P < 0.05$) than in the other two groups (gastric cancerous tissue, 3.65 ± 1.97 μg/L and corresponding non-cancerous gastric mucosa, 4.01 ± 2.11 μg/L). There were no significant differences in folate concentrations between different sites of the stomach including antrum and corpus. No correlation was found between folate levels and the degree of infiltration, lymph node metastasis, tumor size, or TNM clinical stage of gastric cancer (data not shown).

### *c-myc expression and methylation were associated with folate concentrations*

As shown in Table 2 and Figure 2, decreased expression of c-myc accompanied higher folate levels. However, there was no definite association between folate levels and different expression levels of tumor suppressor genes including $p16^{INK4A}$, $p21^{WAF1}$, *hMLH1* and *hMSH2* in mucosal tissue (data not shown). Furthermore, hypomethylation of c-myc was found in cancerous tissues, which showed up-regulated expression of c-myc, and folate levels in tissues with a hypomethylated c-myc gene showed a downward trend compared with folates in unmethylated samples in advanced gastric cancer (tubular-, mucinous-, and tubular-papillary adenocarcinoma).

### *MTHFR polymorphisms might affect the methylation status of tumor-suppressor gene promoters*

As indicated in Table 3, the 677CC, CT, CC, CT and CC genotypes of MTHFR were most frequently detected with aberrant methylation of $p16^{INK4A}$, $p21^{WAF1}$, *hMLH1*, *hMSH2* and c-myc, respectively. The 1298AA genotype was found associated with aberrant methylation of all tumor-related genes studied.

Compared to the 677CC genotype, expression of *hMSH2* was significantly down-regulated in cases with the 677CT genotype, and showed a large but non-significant decrease in the presence of 677TT. Cases with the 677CT genotype showed a lower level of $p21^{WAF1}$ expression than did cases with the wild-type 677CC genotype, while *hMLH1* coupled with the 677CC genotype displayed a trend of decreased expression compared with the 677TT genotype. No differences were observed in $p16^{INK4}$ mRNA levels between 677CC, 677CT or 677TT. c-myc transcription in cases with the 677CT genotype was significantly higher than when the 677CC genotype was present.

Compared with the 1298AC genotype, c-myc

transcription showed an increase in cases with the 1298AA genotype. There was no difference in the expression of $p16^{INK4A}$, $p21^{WAF1}$, *hMLH1* or *hMSH2* between the three MTHFR genotypes.

### *MTHFR polymorphisms might not be an independent factor affecting initiation and progression as well as biological characteristics of gastric cancer*

There were no differences in either the genotype distribution or allele frequency for alleles 677T between gastric cancerous tissue and CSG ($P > 0.05$), although the 677CT genotype showed a non-significant higher risk for advanced gastric cancer as compared with the 677CC genotype (Table 4). In addition, due to the limitation of sample size, we failed to find any significant association between MTHFR polymorphisms, 677 (C→T) and 1298 (A→C), and the degree of infiltration, lymph node metastasis, tumor size, or clinical stage of gastric cancer (Table 5).

### *MTHFR polymorphisms were not associated with folate levels in gastric cancerous tissues*

The genotypes of 677 and 1298 sites were not associated with folate concentrations in gastric cancerous tissue and CSG (data not shown).

**Table 4 MTHFR polymorphisms of gastric cancerous tissue and CSG**

## DISCUSSION

Gastric cancer is a common malignant tumor worldwide, with a much higher incidence in Asian than in Western countries. Multiple genetic and epigenetic alterations are involved in gastric carcinogenesis.

Folate is an important constituent of fruits and vegetables and may confer protection against cancer. An important biological function of folate is to provide methyl groups required for intracellular methylation reactions and *de novo* deoxynucleoside triphosphate synthesis; therefore, folate deficiency is thought to be carcinogenic through disruption of DNA methylation and synthesis and impaired DNA repair[13]. However, folate requires metabolic transformations catalyzed by several enzymes including MTHFR, which irreversibly converts 5, 10-methylenetetrahydrofolate to 5-methyltetrahydrofolate. The MTHFR gene is highly polymorphic, of which the two most common variants are located at nucleotides 677 (C→T) and 1298 (A→T). Low MTHFR activity may prevent the shunting of methyl groups from *de novo* dTMP synthesis, a rate-limiting step for DNA synthesis, to methylation pathways.

It has been suggested that the cancer risk associated with MTHFR polymorphisms may be modulated by folate intake[14]. When folate intake is sufficient, individuals carrying the variant MTHFR genotypes may have a decreased risk because under these conditions, while adequate provision of methyl donors is still ensured, enhanced genomic integrity would be achieved *via* conservation of folate within a cyclic intracellular pathway by shunting methyl groups toward nucleotide synthesis due to diminished MTHFR activity. However, when folate intake is low, both DNA methylation and DNA synthesis and repair might be impaired in carriers of variant MTHFR genotypes, which, in turn, results in increased risk of carcinogenesis. This hypothesis of a gene-nutrient interaction may explain the conflicting reports showing either reduced[10,15,16] or elevated[17,18] risk of cancers.

Many previous studies have investigated the relationship between folate status and MTHFR gene polymorphisms in carcinogenesis. However, because they were mainly focused on blood plasma and blood cells, little is known about folate status in mucosal tissues. Gastric cancer originates from epithelial cells; therefore, a study performed in mucosal tissues is more accurate and effective than those performed using blood. In the present study, we examined folate concentrations and MTHFR gene polymorphisms in gastric mucosal tissues, and found that folate levels were significantly lower in cancer cases (including cancerous and corresponding non-cancerous tissues) than that in the CSG controls (no chronic atrophic gastritis, intestinal metaplasia or dysplasia), suggesting that folate deficiency may increase the risk of cancer[4]. However, we failed to find the association between folate levels and the degree of infiltration, lymph node metastasis, tumor size, or clinical stage of gastric cancer. Possibly folate levels in mucosal tissue influence the initiation but not the progression of gastric cancer.

Transcriptional silencing of tumor suppressor genes by DNA hypermethylation and over-expression of proto-oncogenes by DNA hypomethylation play crucial roles in the progression of gastric cancer. Many genes involved in the regulation of cell cycle, tissue invasion, DNA repair and apoptosis have been shown to be inactivated by this type of epigenetic mechanism. The loss of $p16^{INK4A}$ expression, and hypermethylation in the promoter region is the mechanism of loss of $p21^{WAF1}$, and hypermethylation of the *hMLH1* gene promoter has been associated with a transcriptional blockade. The fact that the blockade is reversible with demethylation suggests that an epigenetic mechanism underlies h*MLH1* gene inactivation and MMR genes deficiency[19]. However, the role of DNA methylation in the loss of *hMSH2* expression has been controversial[20,21]. Aberrant methylation of c-myc can induce over-expression of the gene, and participate in the development of tumors. Hypomethylation of c-myc has been detected in gastric carcinogenesis[22], and it has been reported that folate[23] and MTHFR gene polymorphisms[24] are associated with aberrant methylation of some tumor-related genes.

**Table 5 MTHFR polymorphism and biological characters of patients with gastric cancer (*n*)**

| Biological character | | 677CC | 677CT | 677TT | 1298AA | 1298AC |
|---|---|---|---|---|---|---|
| Degree of infiltration | Muscularis mucosae | 2 | 2 | 1 | 3 | 2 |
| | Muscular layer | 1 | 3 | 2 | 5 | 1 |
| | Serosa | 7 | 9 | 1 | 12 | 5 |
| | Out-serosa | 4 | 5 | 1 | 6 | 4 |
| Lymph node metastasis | Yes | 7 | 11 | 2 | 14 | 6 |
| | No | 7 | 8 | 3 | 12 | 6 |
| Tumor size | < 5 cm | 9 | 7 | 2 | 11 | 7 |
| | ⩾ 5 cm | 5 | 12 | 3 | 15 | 5 |
| TNM classification | Ⅰ | 2 | 2 | 1 | 3 | 2 |
| | Ⅱ | 7 | 12 | 2 | 16 | 5 |
| | Ⅲ | 5 | 5 | 2 | 7 | 5 |

Miao *et al*[25] revealed that the 677TT genotype is associated with an increased risk of gastric cardia cancer. However, our data showed that MTHFR polymorphisms may not be an independent factor affecting initiation and progression of gastric cancers, including antrum and corpus cancers. In addition, due to the limit of sample size, we could not find a significant association between the MTHFR polymorphisms [677 (C→T) and 1298 (A→C)] and the degree of infiltration, lymph node metastasis, tumor size, or clinical stage of gastric cancer. Folate levels but not MTHFR polymorphisms affect the methylation and expression of proto-oncogene or tumor suppressor genes related to human gastric carcinogenesis, although it is unclear how low folate levels lead to c-myc hypomethylation and its down-regulated expression.

In summary, a folate level reduction was observed in gastric cancer tissues. This change, but not methylenetetr ahydrofolate reductase polymorphisms, is associated with upregulation of c-myc expression and hypomethylation of its promoter region.

## COMMENTS

### Background

Multiple genetic and epigenetic alterations are involved in gastric carcinogenesis. Folate deficiency is thought to be carcinogenic through disruption of DNA methylation and synthesis and impaired DNA repair. However, folate requires metabolic transformations catalyzed by several enzymes including MTHFR, which is highly polymorphic.

### Research frontiers

The present study discussed the relationship between folate concentrations in mucosal tissues, MTHFR gene polymorphisms and expression of tumor-related genes, as well as DNA methylation in human gastric carcinogenesis.

### Innovations and breakthroughs

Gastric cancer originates from epithelial cells, therefore, a study performed in mucosal tissues is more accurate and effective than those performed in blood. The extent to which folate tissue levels and MTHFR polymorphisms interact to affect DNA methylation in gastric carcinogenesis is uncertain.

### Applications

The present study investigated the etiology of gastric carcinogenesis, which may provide the evidence for prevention and treatment of gastric cancer.

### Terminology

Methylenetetrahydrofolate reductase (MTHFR) is a key enzyme in folate metabolism that regulates the intracellular folate pool. The MTHFR gene is highly polymorphic, of which the two most common variants are located at nucleotides 677 (C→T) and 1298 (A→T).

### Peer review

The authors evaluated whether folate level in mucosal tissue and some common MTHFR variants are associated with the risk of gastric cancer through an effect on DNA methylation. The figures are clear. However, the title and conclusion need to be more concise and exact.

## Abstract

**AIM:** To investigate whether microvessel density (MVD) is related with prognosis in gastric cancer patients, and the expression of cyclooxygenase-2 (COX-2) and vessel endothelial growth factor (VEGF) so as to determine the possible role of COX-2 and VEGF in gastric cancer angiogenesis.

**METHODS:** Forty-seven formalin-fixed paraffin-embedded tissue samples of gastric cancer were evaluated for COX-2, VEGF by immunohistochemical staining. To assess tumor angiogenesis, MVD was determined by immunohistochemical staining of endothelial protein factor Ⅷ-related antigen. The relationship among COX-2 and VEGF expression, MVD, and clinicopathologic parameters was analyzed.

**RESULTS:** Among the 67 samples, high MVD was significantly associated with lymph node metastasis and poor survival. Multivariate survival analysis showed that MVD value and lymph node metastasis were independent prognostic factors. The expression rate of COX-2 and VEGF was significantly higher than that of the adjacent tissues. COX-2 and VEGF expression in gastric cancer was significantly correlated with tumor differentiation and depth of invasion, but not with survival. The mean MVD value of COX-2 or VEGF positive tumors was higher than that of COX-2 or VEGF negative tumors. A significant correlation was found between the expressions of COX-2 and VEGF.

**CONCLUSION:** MVD may be one of the important prognostic factors for gastric cancer patients. COX-2 and VEGF may play an important role in tumor progression by stimulating angiogenesis. VEGF might play a main role in the COX-2 angiogenic pathway. The inhibition of angiogenesis or COX-2, VEGF activity may have an important therapeutic benefit in the control of gastric cancer.

**Key words:** Gastric cancer; Angiogenesis; Microvessel density; Vessel endothelial growth factor; Cyclooxygenase; Prognostic marker; Nonsteroidal anti inflammatory drug

## INTRODUCTION

Gastric cancer is one of the most frequent and lethal malignancies worldwide, especially in Eastern Asia including China, and the 5-year survival rate is only about 20%[1]. A recent research has shown an increasing trend of gastric cancer mortality in China in the past 20 years, especially in rural areas and among aged people[2]. To date, the treatment outcome of this common malignancy is still not satisfactory. One major difficulty in the diagnosis and treatment of gastric cancer is that only a few prognostic indicators can predict its clinical behavior. Recently, angiogenesis has been related to metastasis and poor prognosis in gastric cancer.

Angiogenesis, the process leading to the formation of new blood vessels, plays a central role in cancer cell survival, local tumor growth, and development of distant metastasis[3-5]. The degree of intratumoral microvessel density (MVD) by immunohistochemistry is thought to influence tumor metastasis and consequently prognosis in various human cancers, including gastric cancer[6-10]. The formation of tumor microvessels is dependent on the production of angiogenic growth factors by tumor cells. The formation of tumor microvessels is stimulated

by angiogenic growth factors, including vessel endothelial growth factor (VEGF), platelet derived growth factor (PDGF), and transforming growth factor β1 (TGF-β1). The expression of these factors correlates with tumor angiogenesis, tumor progression and poor prognosis[11-13]. Among the known angiogenic factors, VEGF has emerged as the central regulator of the angiogenic process in cancer. The biological functions of VEGF include selective promotion of mitosis of endothelial cells, stimulation of their proliferation and angiogenesis, an increase in vessel transparency and extra-vasculization of large plasma molecules[14-17].

Cyclooxygenase (COX) is the rate-limiting enzyme in prostaglandin (PG) metabolism. COX has two isoforms: COX-1 and COX-2. COX-1 is constitutively expressed in most normal tissues and is thought to be involved in maintaining physiological function. COX-2 is frequently undetectable in normal tissue, but can be induced in response to growth factors, tumor promoters, hormones and cytokines, thus contributing to the synthesis of prostaglandin in inflamed and malignant tissues[18,19]. Over-expression of COX-2 is detectable in various solid malignancies including gastric cancer, and is thought to be involved in the critical steps in carcinogenesis, as well as a regulator of tumor angiogenesis[20-22]. However, the potential mechanism remains unclear.

To analyze the relationships between MVD, COX-2 and VEGF expression, clinicopathologic parameters and survival time of patients in gastric cancer, 67 specimens were evaluated for COX-2, VEGF and endothelial protein factor Ⅷ-related antigen by immunohistochemical staining of MVD.

## MATERIALS AND METHODS

### *Patients and specimens*

Sixty-seven patients (54 men and 13 women, medium age 56 years) with gastric cancer undergone radical gastrectomy in the Department of Surgery, the First Affiliated Hospital of Anhui Medical University, from October 1997 to October 2000, were enrolled in this study. The eligibility criteria were: histologically proven gastric adenicarcinoma, no previous systemic chemotherapy or radiotherapy before operation, and well documented clinical data. The mean follow-up time was 34 mo (from 16 d to 60 mo).

All tissues were surgically resected. Cancerous tissue and para-cancerous gastric mucosa were all from the same specimens. Each specimen was fixed in 10% phosphate-buffered formalin immediately after resection, embedded in paraffin and cut into 4 μm-thick sections for immunohistochemical study and routine histological examination.

### *Immunohistochemistry*

The sections were dewaxed and rehydrated by sequential immersion in xylene and graded ethanol and water. Endogenous peroxidase activity was blocked by incubation with 3% hydrogen peroxide methanol. Antigen-retrieval treatment was performed in a full pressure cooker for 10-15 min to obtain optimal results. After washed in phosphate-buffered saline (PBS) and exposed to 10% normal horse serum for 10 min to reduce non-specific binding, the sections were incubated with the primary antibody, which reacts specifically with VEGF (polyclonal, L2702, 1:50 dilution, overnight at 4℃; Santa Cruz Biotechnology, Inc.), COX-2 (polyclonal, J1602, 1:50 dilution, overnight at 4℃; Santa Cruz Biotechnology, Inc.), or factor Ⅷ-related antigen (polyclonal, ZA-0111, overnight at 4℃; Santa Cruz Biotechnology, Inc.). All the sections were incubated with biotinylated IgG for 30 min and then with streptoavidin-peroxidase regent for 20 min. Finally, the sections were incubated in PBS containing diaminobenzidine and 1% hydrogen peroxide for 5 min, counterstained with Mayer hematoxylin, and mounted. PBS was substituted for primary antibody as the negative control.

### *Evaluation of immunostaining and microvessel counting*

To evaluate COX-2 and VEGF expression, a score was established corresponding to the sum of a: percentage of positive cells (0 = 0% immunopositive cells, 1 = < 25% positive cells, 2 = 26%-50% positive cells, and 3 = > 50% positive cells), and b: staining intensity (0 = negative, 1 = weak, 2 = moderate, 3 = high). The sum of a + b reached a maximum score at 6. Scores between 0 and 2 were regarded as negative (-), between 3 and 4 as weak (+), and between 5 and 6 as strongly positive (++), respectively.

Intratumoral microvessels were highlighted by immunostaining with anti-factor Ⅷ related antigen polyclonal antibody. Any single brownly stained cells or cluster of endothelial cells clearly separated from adjacent microvessels, tumor cells, and other connective tissue elements were considered as vessels. Branching structures were counted as a single vessel unless there was a discontinuity in the structure. The stained sections were screened at 100-magnification under a light microscope to identify the 5 regions of the section with the highest vascular density. Vessels were counted in the 5 regions at 200-magnification, and the average number of microvessels was recorded. Two observers did the counting, and the mean value was used for analysis.

### *Statistical analysis*

Data were analyzed by SPSS version 10.0 for windows. The correlations between expression of COX-2, VEGF and clinic pathological parameters were assessed by the Chi-square test or the Spearman rank test. The Kaplan-Meier method was used to estimate survival as a function of time, and survival differences were analyzed by the log-rank test. The COX proportional hazard model was used for multivariate analysis of prognostic factors. $P < 0.05$ was considered statistically significant. All $P$ values are represented as two-sided.

## RESULTS

### *Correlation between MVD and clinicopathologic features*

The MVD for 67 tumor specimens ranged from 14 to 58 with a mean MVD of 28.46 ± 8.28. When a mean MVD value of 28 was chosen as the cut-off point

**Table 1 Correlation between MVD, COX-2 and VEGF expression and clinicopathologic parameters of gastric cancer**

| Clinico-pathologic features | *n* | MVD | | | VEGF | | | COX-2 | | |

MVD: Microvessel density; VEGF: Vessel endothelial growth factor; COX-2: Cyclooxygenase-2; -: Negative; +~++: Positive to strong positive.

**Table 2 Multivariate analysis of overall survival in gastric cancer**

| Variable | Regression coefficient | Standard error (SE) | Odds ratio (95% CI) | *P* |
|---|---|---|---|---|
| Microvessel density (MVD) | 1.069 | 0.503 | 0.727-0.893 | 0.033 |
| Lymph node metastasis | 1.168 | 0.457 | 1.312-7.882 | 0.011 |

for discrimination of the 67 patients, 37 patients were categorized as low MVD and 30 as high MVD. The correlation between MVD and clinicopathologic features is shown in Table 1. High MVD was significantly associated with lymph node metastasis ($P = 0.003$).

### Multivariate survival analysis

Multivariate survival analysis showed that MVD value and lymph node metastasis were independent prognostic factors (Table 2). No other variables, including COX-2 and VEGF expression, were retained in the model or affected the magnitude of the hazard ratios of variables in the final model. Kaplan Meier curves for patients' survival are shown in Figure 1. A significant difference in the overall survival rate was found between patients according to the MVD value ($P < 0.001$, comparison between low and high MVD).

### Expression of COX-2 and VEGF in gastric cancer tissues

Immunoreactivity of both COX-2 and VEGF proteins was found in the tumor epithelial cells within cytoplasm (Figure 2). However, occasionally normal epithelial cells in adjacent tissues of cancer showed little staining. Among the 67 gastric cancer samples, the positive rates of COX-2 and VEGF expression were 76.1% and 76.1%, significantly higher than those in the adjacent tissues. The expression of VEGF protein in well-differentiated adenocarcinoma was significantly higher than that in

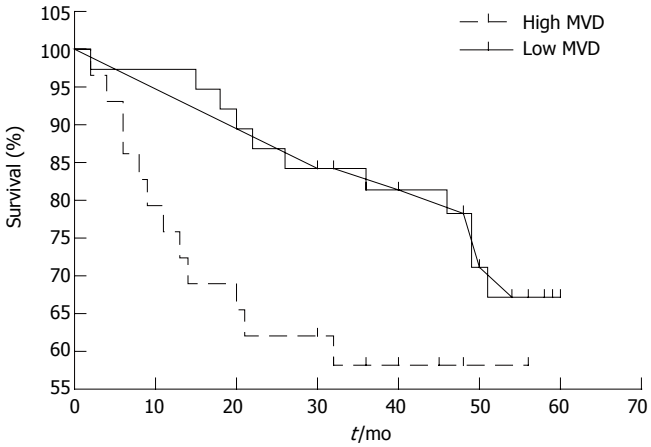

**Figure 1** Kaplan-Meier survival curve correlating disease specific survival with high microvessel density (MVD) or low MVD.

poorly-differentiated adenocarcinoma ($P < 0.05$). There was a statistical difference in the expression of COX-2 protein among well-, moderately- and poorly-differentiated adenocarcinomas ($P < 0.05$).

### Correlation between COX-2 or VEGF expression and MVD

The correlation between COX-2 or VEGF expression and MVD is summarized in Table 3. The mean MVD value of COX-2 or VEGF positive tumors was higher than that of COX-2 or VEGF negative tumors.

### Association between COX-2 and VEGF expression

A significant correlation was found between the expression levels of COX-2 and VEGF (Table 4, $r = 0.425$, $P < 0.001$).

### Correlations of COX-2, VEGF expression with clinicopathologic parameters

The associations between COX-2 and VEGF expressions

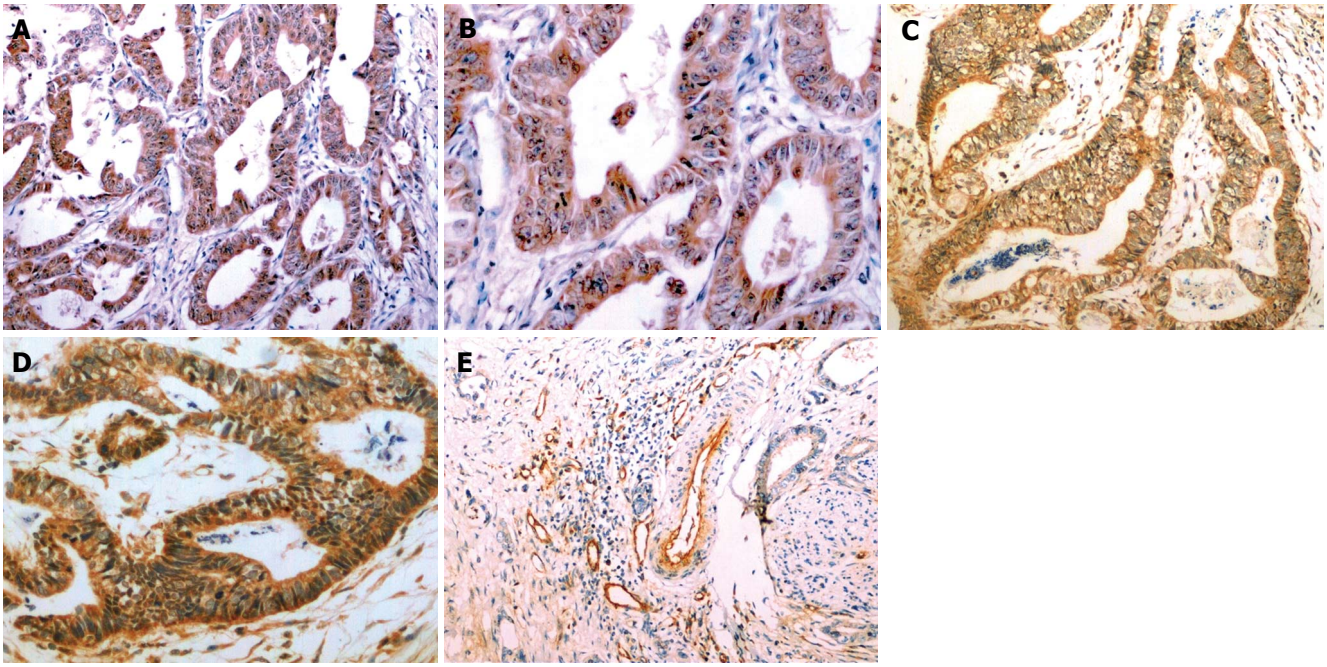

**Figure 2** Immunohistochemical stainings of COX-2 (**A**, **B**), VEGF (**C**, **D**) and microvessels (**E**) in tissue sections obtained from gastric adenocarcinoma. COX-2 was mainly expressed in the cytoplasm of cancer cells (brown staining; **A** × 100, **B** × 200). VEGF expression was restricted to the cytoplasm of cancer cells (brown staining; **C** × 100, **D** × 200). Microvessels were detected in gastric cancer tissues by immunostaining for factor Ⅷ-related antigen (**E** × 100).

**Table 3 Relationship between expressions of VEGF, COX-2 and MVD of gastric cancer (mean ± SD)**

| Group | *n* | MVD | *P* |
|---|---|---|---|
| VEGF | | | 0.008 |
| – | 16 | 20.14 ± 4.52 | |
| +~++ | 51 | 29.46 ± 8.28 | |
| COX-2 | | | 0.005 |
| – | 16 | 22.32 ± 3.80 | |
| +~++ | 51 | 29.88 ± 8.52 | |

VEGF: Vessel endothelial growth factor; COX-2: Cyclooxygenase-2; MVD: Microvessel density; -: Negative; +~++: Positive to strong positive.

**Table 4 Relationship between VEGF and COX-2 expression in gastric cancer**

| VEGF | COX-2 | | *r* | *P* |
|---|---|---|---|---|
| | – | + ~ + + | | |
| – | 9 | 7 | 0.425 | < 0.001 |
| +~++ | 7 | 44 | | |

VEGF: Vessel endothelial growth factor; COX-2: Cyclooxygenase-2; -: Negative; +~++: Positive to strong positive.

and the clinicopathologic parameters are shown in Table 1. The expression of both proteins in gastric cancer was significantly correlated with depth of invasion. There was no significant association between COX-2 and VEGF expression and patient gender, age, tumor size, lymph node metastasis, and TNM stage.

## DISCUSSION

Folkman J and Shing Y[3] initiated a new field of research about tumor angiogenesis in 1971 and found that several factors take part in the process of angiogenesis. Tumor angiogenesis is now believed to be one of the most crucial steps in tumor growth and metastases[3-5]. Moreover, tumor angiogenesis which can be quantified by measurement of MVD is a significant negative prognostic factor[6-10]. In our study, when a mean MVD value was chosen as the cut-off point for discrimination of the study patients, high MVD was significantly associated with lymph node metastasis and poor survival. Multivariate survival analysis showed that MVD value and lymph node metastasis were independent prognostic factors for gastric cancer patients.

Tumor angiogenesis is controlled by a balance between angiogenic and angiostatic regulators involved in multiple pathways that result in endothelial proliferation, differentiation and organization into a functional network of vascular channels[3-5]. Among the reported angiogenic factors[11-14], VEGF (a key factor for induction of tumor angiogenesis) is increased in various human tumors, often correlating with higher MVD[15-17]. In our study, VEGF was over-expressed in gastric cancer tissues. We found that VEGF expression was associated with the histologic types of gastric cancer and depth of invasion. The results suggest that VEGF might be mainly involved in the progression of gastric carcinoma. The mean MVD value of VEGF positive tumors was significantly higher than that of VEGF negative tumors, suggesting that VEGF may facilitate tumor progression by promoting tumor angiogenesis.

Epidemiologic studies indicate that use of aspirin and other non-steroidal anti inflammatory drugs (NSAIDs), with COX being their major target, decreases the incidence

and mortality of colorectal, gastric, and esophageal cancers[23-26]. The expression of COX-2 mRNA and protein is elevated in various human malignancies, which may play a critical role in the development of cancer[27-30]. Our study showed that the positive rate of COX-2 expression in human gastric cancers was significantly higher than that in the matched normal gastric tissue. COX-2 expression was associated with the degree of tumor cell differentiation and depth of invasion, but not with survival. These results suggest that over-expression of COX-2 plays an important role in the development of human gastric cancer, but cannot predicate the outcome in individual cases.

The contributions of COX-2 to tumor angiogenesis include: increasing expression of VEGF, producing of prostaglandin E (PGE) 2 and prostaglandin I (PGI) 2 that can directly stimulate endothelial cell migration and growth factor-induced angiogenesis, and inhibiting endothelial cell apoptosis by stimulation of Bcl-2 or Akt activation[31,32]. In our present study, COX-2 expression was significantly associated with that of VEGF. The mean MVD value of COX-2 or VEGF positive tumors was higher than that of COX-2 or VEGF negative tumors, which is in agreement with previous reports[33,34]. These data strongly suggest that COX-2 and VEGF may be partly responsible for the important process of angiogenesis in the development of human gastric cancer, and VEGF plays the main role in COX-2 stimulated angiogenesis. However, there still exist some other pathways, which also participate in COX-2-induced angiogenesis.

In conclusion, high MVD is significantly associated with lymph node metastasis and poor survival. MVD value and lymph node metastasis are independent prognostic factors for gastric cancer patients. Expression of COX-2 and VEGF is closely correlated to the depth of invasion, and leads to increased angiogenesis, which may be the mechanisms underlying the contribution of COX-2 to the development of gastric cancer. VEGF might play a main role in the COX-2 angiogenic pathway. Inhibition of angiogenesis or COX-2, VEGF activity may have an important therapeutic benefit in the control of gastric cancer.

## COMMENTS

### Background

Gastric cancer is one of the most frequent and lethal malignancies worldwide, especially in Eastern Asia including China, and the 5-year survival rate is only about 20%. To date, the treatment outcome of this common malignancy is still not satisfactory. One major difficulty in the diagnosis and treatment of gastric cancer is that only a few prognostic indicators can predict its clinical behavior.

### Research frontiers

Tumor angiogenesis plays a central role in cancer cell survival, local tumor growth, and development of distant metastasis, which can be assessed by the MVD. The degree of intratumoral MVD is thought to influence tumor metastasis and consequently prognosis in various human cancers, including gastric cancer. Additionally, tumor MVD is associated with COX-2 and VEGF expression.

### Applications

The present work suggests that high MVD is significantly associated with lymph node metastasis and poor survival. MVD value and lymph node metastasis are two independent prognostic factors for gastric cancer patients. Expression of COX-2 and VEGF is closely correlated to the depth of invasion, and leads to increased angiogenesis, which may be the mechanisms underlying the development of gastric cancer. VEGF might play a main role in the COX-2 angiogenic pathway. Inhibition of angiogenesis or COX-2, VEGF activity may have an important therapeutic benefit in the control of gastric cancer.

### Peer review

This is a well-written and carefully performed study. The title, results and discussion are clear. The abstract and introduction are well-organized.

## Abstract

**AIM:** To identify a multi serum protein pattern as well as single protein markers using surface-enhanced laser desorption/ionisation time-of-flight mass spectrometry (SELDI-TOF-MS) for detection and differentiation of liver fibrosis (F1-F2), liver cirrhosis (F4) and hepatocellular carcinoma (HCC) in patients with chronic hepatitis C virus (HCV).

**METHODS:** Serum samples of 39 patients with F1/F2 fibrosis, 44 patients with F4 fibrosis, 34 patients with HCC were applied to CM10 arrays and analyzed using the SELDI-TOF ProteinChip System (PBS-Ⅱc; Ciphergen Biosystems) after anion-exchange fractionation. All patients had chronic hepatitis C and histologically confirmed fibrosis stage/HCC. Data were analyzed for protein patterns by multivariate statistical techniques and artificial neural networks.

**RESULTS:** A 4 peptide/protein multimarker panel (7486, 12843, 44293 and 53598 Da) correctly identified HCCs with a sensitivity of 100% and specificity of 85% in a two way-comparison of HCV-cirrhosis versus HCV-HCC training samples (AUROC 0.943). Sensitivity and specificity for identification of HCC were 68% and 80% for random test samples. Cirrhotic patients could be discriminated against patients with F1 or F2 fibrosis using a 5 peptide/protein multimarker pattern (2873, 6646, 7775, 10525 and 67867 Da) with a specificity of 100% and a sensitivity of 85% in training samples (AUROC 0.976) and a sensitivity and specificity of 80% and 67% for random test samples. Combination of the biomarker classifiers with APRI score and alfa-fetopotein (AFP) improved the diagnostic performance. The 6646 Da marker protein for liver fibrosis was identified as apolipoprotein C-Ⅰ.

**CONCLUSION:** SELDI-TOF-MS technology combined with protein pattern analysis seems a valuable approach for the identification of liver cirrhosis and hepatocellular carcinoma in patients with chronic hepatitis C. Most probably a combination of different serum markers will help to identify liver cirrhosis and early-stage hepatocellular carcinomas in the future.

**Key words:** Hepatocellular carcinoma; Hepatitis C virus; Apolipoprotein C-Ⅰ; Proteomics; Surface-enhanced laser desorption/ionisation

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the most common primary liver cancer and ranks fifth in frequency of all malignancies in the world[1]. In the last decades incidence and mortality rates of HCC have increased significantly in Western countries[2] with hepatitis C virus (HCV) infection being the most important cause[3]. Liver cirrhosis is the most common complication of chronic HCV infection. Once cirrhosis is established, the risk of developing a HCC is 1%-5% a year[4]. In order to reduce HCC mortality, early identification of liver cirrhosis as well as early detection of hepatocellular carcinoma is needed.

However, prediction of liver cirrhosis and small HCC is often difficult in chronic hepatitis C. Several noninvasive tests like transient elastography (FibroScan®, Echosens, Paris, France), Fibrotest™ (Biopredictive, Paris, France; a serologic marker-based algorithm) and the APRI score (relation of AST to thrombocytes)[5] have been set up for discrimination of liver cirrhosis from lower fibrosis stages. In contrast to liver biopsy, these techniques are noninvasive, simple to use but either need further

evaluation or display insufficient predictive value [6].

Screening for HCC is generally recommended in patients with HCV cirrhosis[7]. Determination of alfa-fetopotein (AFP) and ultrasound every 3 to 6 mo has been proposed for early detection of HCC[7]. However, up to 44% of patients with HCC show normal levels of AFP, particularly during early stages[8]. Elevated serum levels of AFP may also be seen in patients with liver cirrhosis, acute and chronic hepatitis[9]. Low sensitivities of 39%-65% and positive predictive values of 9%-50% limit the use of AFP as a single marker for a cut off of 20 ng/mL[10]. Combination of AFP (cut-off level of 20 μg/L) with abdominal ultrasound improves sensitivity and specificity, but results of ultrasound scanning are influenced by the experience of the operator and the quality of the used equipment. Detection of HCC becomes even more difficult in cirrhotic livers since regenerative nodules may mimic tumors. Sensitivities of ultrasound as a screening tool for the detection of HCC vary from 50% up to 78%[11]. Contrast-enhanced ultrasound may improve sensitivity up to 89%, but specificity still remains rather low[12].

Surface-enhanced laser desorption/ionization time-of-flight mass spectrometry (SELDI-TOF MS) is one technology for serum protein profiling and identification of biomarkers. This method uses different chromatographic chip surfaces for binding peptides/proteins of biological samples (i.e. serum, urine, cerebrospinal fluid) and has lead to identification of novel biomarkers in prostate, bladder, ovarian, colorectal, or liver cancer[13-17].

The aim of the study was to identify serum protein patterns and single protein markers by SELDI-TOF mass spectrometry in patients with HCV cirrhosis and HCV associated hepatocellular carcinoma.

## MATERIALS AND METHODS

### Samples

A total number of 117 serum samples were collected from patients with chronic hepatitis C between 2001 and 2004. Three groups were enrolled: (1) patients with low grade fibrosis (F1/2, $n$ = 39), (2) patients with cirrhosis but without hepatocellular carcinoma ($n$ = 44) and (3) patients with cirrhosis and HCC ($n$ = 34). All patients were anti-HCV and HCV RNA (bDNA Assay 3.0, Bayer, Leverkusen) positive. Patients with other liver diseases, HIV co-infections, other malignomas or antiviral treatment were excluded. Liver biopsy was available in all patients. Clinical data of the patients are shown in Table 1. Classification of the fibrosis stage was done according to Scheuer *et al*[18] . Blood samples were stored at -80°. No sample had been thawed more than once.

### Protein profiling

Anion-exchange fractionation was used for serum preprocessing, to increase the number of protein peaks. To separate the serum samples into six different fractions (pH9 + flowthrough, pH7, pH5, pH4, pH3, organic elution), an Expression Difference Mapping Kit (Ciphergen Biosystems, Freemont, USA.) was used. Proteins were separated on the basis of their pI-values. Sample preparation and fractionation was done as described in the manufacturer's protocol. Fractions were stored at 4℃ overnight and analyzed the following day. Protein profiling was done using SELDI-TOF mass spectrometry (Ciphergen Biosystems). After testing several chromatographic chip surfaces and binding conditions the CM10 array were chosen for further experiments as they gave the highest number of discriminative peptide/protein peaks. The best results in terms of number of protein peaks and possibility to separate the three groups was found in fraction 1 (flow through + pH9).

**Table 1 Clinical data of patients**

| | Fibrosis F1/F2 ($n$ = 39) | Cirrhosis F4 ($n$ = 44) | HCC ($n$ = 34) |

The CM10 arrays were equilibrated twice with 150 μL of low stringency binding buffer (0.1 mol/L sodium acetate; pH4.0; Ciphergen Biosystems). Ten microliters of fraction 1 and 90 μL of binding buffer were applied to each spot of the ProteinChip Array and incubated for 30 min at room temperature. Spots were washed three times with binding buffer and rinsed twice with de-ionized water. Arrays were allowed to air dry and 1 μL of sinapinic acid in 50% acetonitrile (ACN) and 0.5% trifluoroacetic acid (TFA) were applied twice to each spot. Afterwards the protein chip arrays were analyzed using the SELDI ProteinChip Reader (PBS-Ⅱc; Ciphergen Biosystems).

### Purification and identification of candidate biomarker

Anion Exchange Fractionation Selected sera (100 μL) containing biomarkers of interest were further fractionated with Q HyperD® F spin columns (Ciphergen Biosystems, Inc.). Each fraction was collected and analyzed again on a CM10 array with low stringency buffer. The candidate biomarkers were seen in the flow through and pH3 fraction. Both fractions were purified first with hydrophobic chromatography resin (BioSepra Q HyperD® F resins (BioSepra, Sergy Saint Christophe, France) then with RPC Poly-Bio beads (BioSepra).

### Hydrophobic chromatography

Fifty microliters of RPC Poly-Bio beads (BioSepra) were equilibrated with 500 μL of 10% ACN/0.1% TFA. The full sample fraction was adjusted to a final concentration of 10% ACN/0.5% TFA and mixed with 50 μL of the

bead-material for 30 min at room temperature. Afterwards, the probe was centrifuged for 1 min at 5000 r/min. The supernatant was removed. Increasing concentrations of ACN (10%-60%) in 0.1% TFA were added in each step, mixed for 5 min and centrifuged for 1 min at 5000 rpm. Proteins in the eluted fractions were detected by profiling 1 μL of each fraction combined with 1 μL of SPA on a NP20 array.

### Gel electrophoresis and passive elution

Fractions containing the candidate biomarkers eluted from the hydrophobic bead material were completely dried in a Speed-Vac, resolubilised in SDS-PAGE sample buffer and loaded onto different SDS-PAGE gels (Invitrogen, Carlsbad, USA). An 18% Tris-Glycine gel was used containing TrisGly SDS running buffer for the 6.6 kDa-marker. The gel was fixed and stained using Invitrogen Staining NuPage® Novex protocols. Bands of interest were excised from the gels and placed in tubes. Destaining was achieved by addition of 150 μL 50% ACN/50 mmol/L ammonium bicarbonate (3 times, 5 min at room temperature) and 200 μL of 50% ACN/100 mmol/L ammonium bicarbonate once. The gel pieces were then covered with 100 μL of 100% ACN for 10 min and dried in a Speed Vac.

For passive elution 100 μL of 45% formic acid, 30% ACN and 10% isopropanol was added. The tubes were sonicated for 30 min in a water bath at room temperature and incubated at room temperature for 4 h. One microliter of each sample was analysed on a NP20 array. Remainder of passive elution was incubated overnight and sonicated the next morning. Each supernatant was transferred to a new tube and dried in a Speed-Vac.

Sequencing grade modified porcine trypsin (Promega, Charbonnières-les-bains, France) with a concentration of 20 ng/μL in 25 mmol/L ammonium bicarbonate was added to each gel piece and incubated at 37℃ for 4 h. One microliter of the peptide digests was analysed on a NP20 array adding 1 μL of 20% CHCA (alpha-cyano-4-hydroxy-cinnamic acid) in 50% ACN/0.5% TFA. External calibration was performed using the All-In-One-Peptide Standard (Ciphergen Biosystems, Inc.). Peptides of the resulting tryptic digest were submitted to a database search with the Mascot search engine (http://www.matrixscience.com) using the Swiss-Prot and NCBI databases.

Additionally sequencing of the most important peptides in the tryptic digest was done using a Micromass Q quattro 2Q-TOF tandem quadruple TOF mass spectrometer equipped with a SELDI-TOF MS ProteinChip Interface PCI1000. The MS/MS data were exported as Sequest files and investigated with the Mascot search engine. Determination of Apo C- Ⅰ was furthermore confirmed by an immunoassay on protein A beads (Biosepra) using a specific rabbit anti-human apolipoprotein C- Ⅰ antibody (Academy Bio-Medical Company, Cambridge, UK) and a non-specific rabbit IgG control antibody. After loading of the beads with the antibody, subsequent washing with PBS (2 ×), followed by an incubation for 1 h with the flow through fraction of one serum sample, the beads were washed again with PBS (3 ×) and deionized water (1 ×). Finally, the captured proteins were eluted with 15 μL 100 mmol/L acetic acid and profiled on NP20 ProteinChip Arrays.

### Statistical analysis

Data were analyzed using the ProteinChip Software package version 3.1 (Ciphergen Biosystems). For acquiring best results, two different protocols were established. The optimization range was set between 2.5 and 50 kDa for the first, 10 and 80 kDa for the second protocol. Mass spectra were generated using laser intensities of 167 and 190, detector sensitivities of 6 and 9, respectively. A total of 130 laser shots for each spot were collected. The protein masses were calibrated externally using the All-In-One Protein Standard (Ciphergen Biosystems.). All mass spectra were normalized to total ion current (TIC normalization), baseline was subtracted.

Protein peaks of all sample spectra were clustered with the Ciphergen Express software, version 3.0.1. The following clustering settings were used: auto-detect peaks to cluster; first pass 5.0 S/N (signal to noise) 3.0 valley depth; minimal peak threshold: 20% of all spectra. Cluster mass window: 0.2 peak width; second pass: 3.0 S/N; 3.0 valley depth; add estimated peaks to complete cluster; mass to charge ratio (M/z) range from 2.5 to 75 kDa. This cluster list was used to perform a decision tree classification with the Biomarker Patterns software, version 5.0.2 (Ciphergen Biosystems.). Initially, a training set of all serum samples was used for generating a decision tree model. The sample set was in addition taken for internal cross-validation (test set). The classification tree split the data into two nodes using one rule at a time in the form of peak intensity. The splitting decisions in this case were based on the normalized intensity levels of peaks from SELDI protein expression profiles. The process of splitting was continued until terminal nodes were created.

## RESULTS

### Biomarker pattern

The comparison between low fibrotic and cirrhotic patients revealed 22 significant peaks. For the differentiation of cirrhotic and HCC-patients 17 significant protein peaks with *P*-values less than 0.05 were found.

For differentiation between low fibrosis and cirrhosis a decision tree using 5 biomarkers with mass values of 2873, 6646, 7775, 10525 and 67867 Da was established (Figure 1). The algorithm correctly assigned 33 of 39 fibrotic (85%) and 44 of 44 (100%) cirrhotic patients in the training set. The ROC analysis gave an AUROC of 0.976. The algorithm for discrimination of cirrhosis versus low fibrosis based on the test data gave a sensitivity of 80%, a specificity of 67%, a positive predictive value (ppv) of 73% and a negative predictive value (npv) of 74% for liver cirrhosis. APRI score (cut-off 1.5) allowed determination of cirrhosis with a sensitivity of 75%, a specificity of 87%, a ppv of 86% and a npv of 76%. The combination of APRI-score with three biomarkers (2873, 6646 and 10525 kDa) resulted in a sensitivity of 93%, a specificity of 95%, a ppv of 95% and a npv of 93%. AUROC increased to 0.955 for the combination of APRI and biomarkers

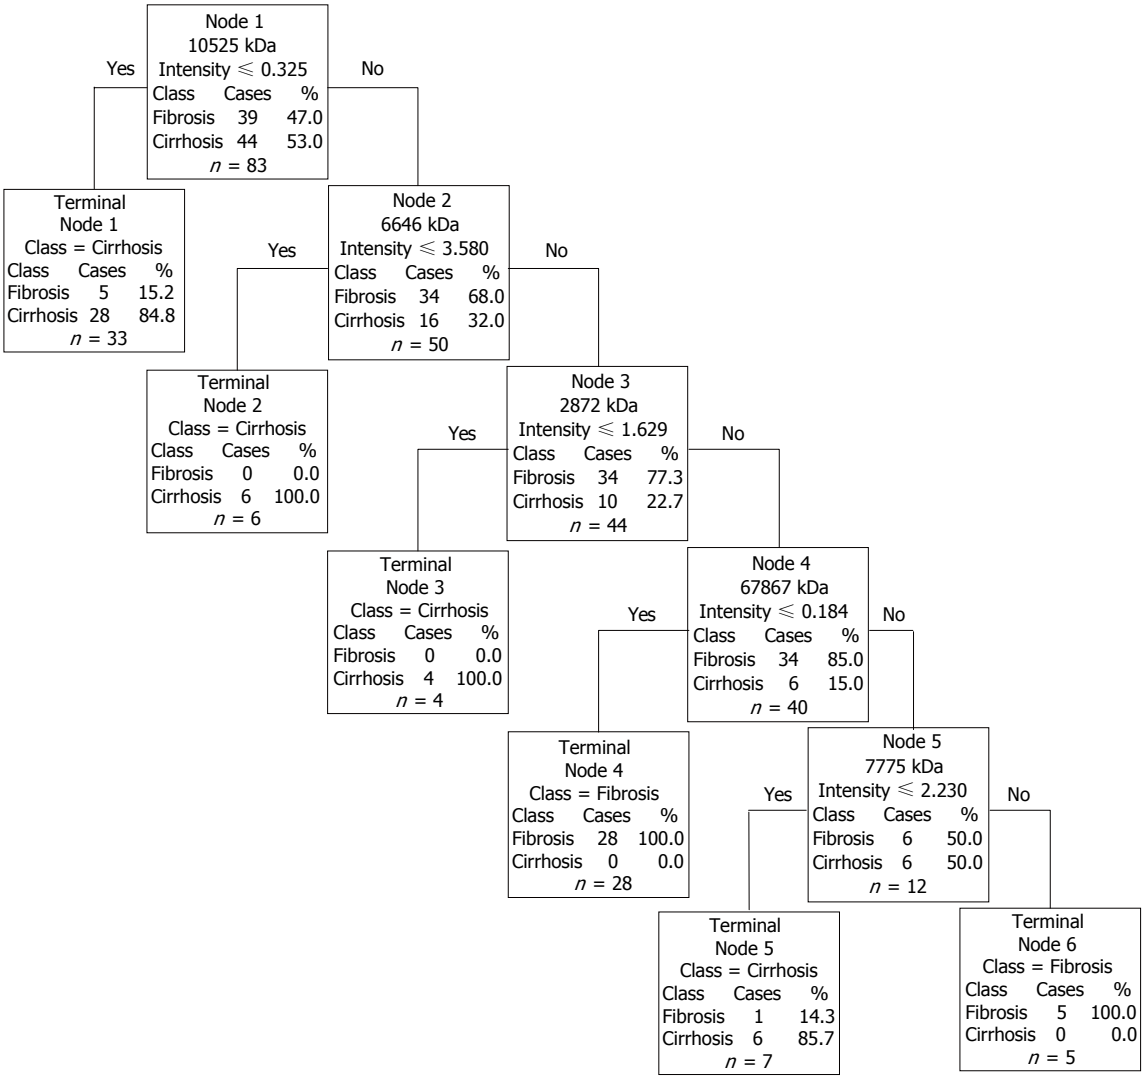

**Figure 1** Decision tree for the differentiation of fibrosis versus cirrhosis**.** The root nodes contain the mass of the selected peak ("node") which is followed by the intensity value. Samples with intensities lower or equal to the intensity value go to the left terminal node, samples with higher intensities go to the next right descendant nodes.

compared APRI alone with an AUROC of 0.811.

Cirrhotic patients could be differentiated from HCC patients by creating a decision tree with 4 biomarkers with mean mass values of 7486, 12843, 44293 and 53598 Da (Figure 2). The training set allowed a correct classification of HCC in 34 of 34 (100%) and cirrhosis in 37 of 44 (84%) patients. The AUROC in the ROC plot was 0.943. The algorithm for discrimination of HCC versus cirrhosis in the test set revealed a sensitivity of 68% for HCC, a specificity of 80%, a ppv of 72% and a npv of 76%. AFP alone (cut-off 18 μg/L) achieved a sensitivity of 76%, a specificity of 82%, ppv of 76% and a npv of 82%. The AUROC was 0.791. Combination of AFP and the 12843 Da biomarker resulted in a sensitivity of 88%, a specificity of 82%, a ppv of 78% and a npv of 90%. The AUROC mounted to 0.861.

### *Identification of novel biomarkers*

A biomarker of 6.6 kDa, used in the first decision tree, could be further characterized. Representative spectra views of the chosen protein are shown in Figure 3. SELDI analysis results of one sample expressing the 6.6 kDa marker after fractionation, purification and overnight passive elution as well as the separation within the stained gel are shown in Figure 4. The peptide mass fingerprinting of the 6.6 kDa biomarker after trypsin digestion is shown in Figure 5. By database search the tryptic digested 6.6 kDa protein was identified as apolipoprotein C-Ⅰ. Apolipoprotein C-Ⅰ was down-regulated in patients with liver cirrhosis (Figure 3) compared to patients with lower stages of liver fibrosis. Confirmation of the apolipoprotein C-Ⅰ identity was performed by an immunoassay using a rabbit apolipoprotein C-Ⅰ polyclonal antibody (Figure 6). The AUROC of apolipoprotein C-Ⅰ for differentiation of fibrosis from cirrhosis was 0.68.

## DISCUSSION

Despite an increasing number of noninvasive tests and imaging techniques, detection of liver cirrhosis and hepatocellular cancer is often difficult in chronic hepatitis C patients. The present study therefore aimed at the identification of serum protein patterns and single protein markers by SELDI-TOF mass spectrometry to predict liver cirrhosis and hepatocellular carcinoma.

Using a weak cationic array (CM10) a 5 biomarker

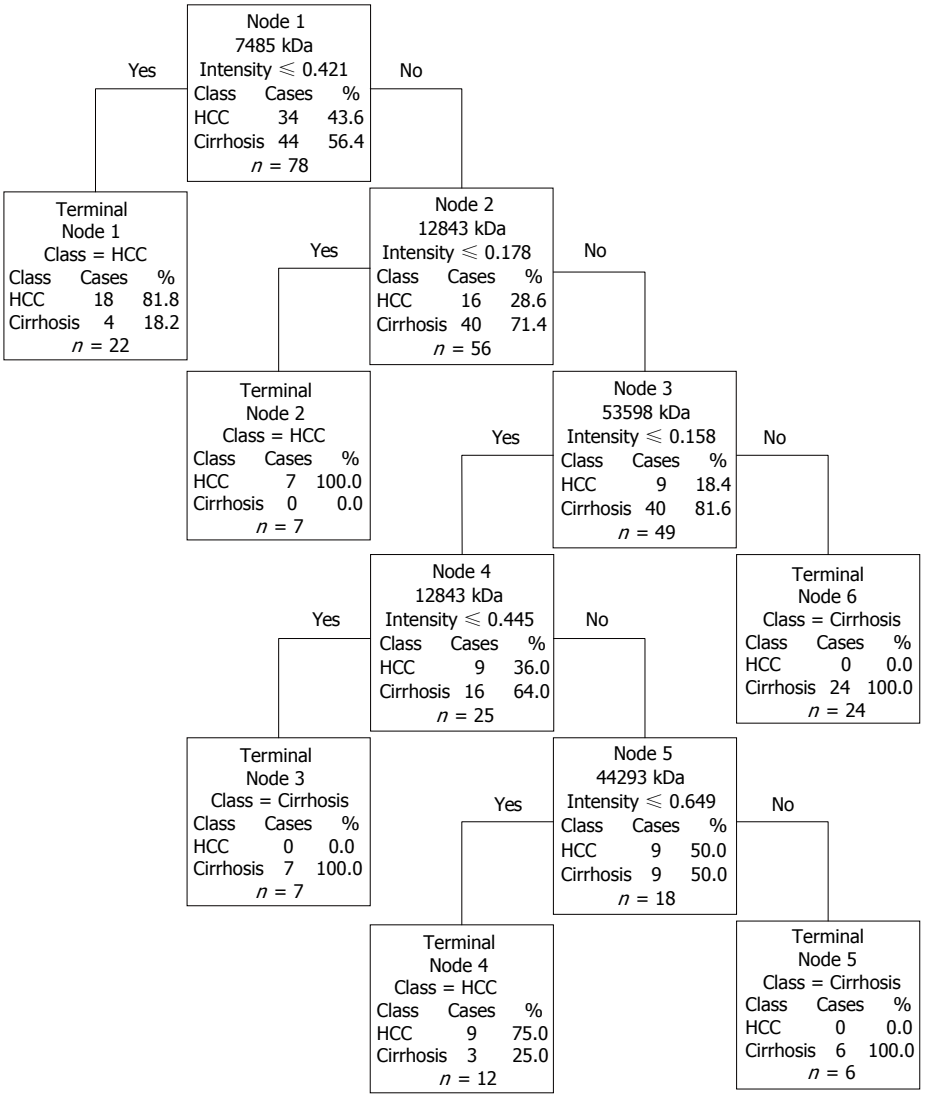

**Figure 2** Decision tree for the differentiation of HCC versus cirrhosis.

pattern was identified, that allowed discrimination of liver cirrhosis from low fibrosis stages with a sensitivity of 80%, a specificity of 67% and a positive predictive value of 73%. APRI score in patients with hepatitis C gave, depending on the chosen cut-off, sensitivities of 57%-89%, specificities of 75%-93% and a ppv of 38%-57% for the identification of patients with cirrhosis compared to non-cirrhotics[5]. FibroTest is another non-invasive test, using a mathematical algorithm of 5 parameters (α2-macroglobulin, haptoglobin, γ-glutamyl transpeptidase, apolipoprotein A-Ⅰ, total bilirubin), to predict liver cirrhosis. Sensitivities and specificities vary significantly dependent on the chosen cut-off[19]. Fibroscan®, which determines liver stiffness by transient elastography, achieves a sensitivity of 87%, a specificity of 91% and a ppv of 77% using 12.5 kPa as the cutoff[6]. Correct prediction of an underlying HCC was possible from the same sample preparation using a 4 biomarker pattern with a sensitivity of 68%, a specificity of 80% and a ppv of 72% in patients with proven liver cirrhosis. Alfa-fetoprotein, which is the most widely used serum marker for diagnosis and surveillance of HCC, achieves sensitivities of 39%-65% and ppv of 9%-50%[7,10,20] according to literature but performed better in the present data set. Although proteomic patterns might not be superior to the mentioned noninvasive tests, they carry the advantage of being operator independent (compared to transient elastography) and allow both the discrimination of liver cirrhosis and hepatocellular carcinoma with one sample preparation.

Previous studies using SELDI-TOF mass spectrometry including only patients with hepatitis C liver cirrhosis have provided evidence that proteomic pattern can be used to discriminate cirrhosis from HCC yielding sensitivities of 85% to 94% and specificities of 86% to 91%[17,21]. The differences to the present study may be explained by the use of a different protein array (CM10 *vs* IMAC) and data analysis with different neuronal networks. A relative complex neuronal network was elaborated by Ward *et al*[21], using a majority vote of six committee models, which included between 4 and 17 protein peaks. Interpretation of the present results with the results of other studies testing proteomic patterns in patients with HCC were hampered by the fact that different HCC etiologies[22] or non-relevant controls like healthy volunteers were included in the other studies[23].

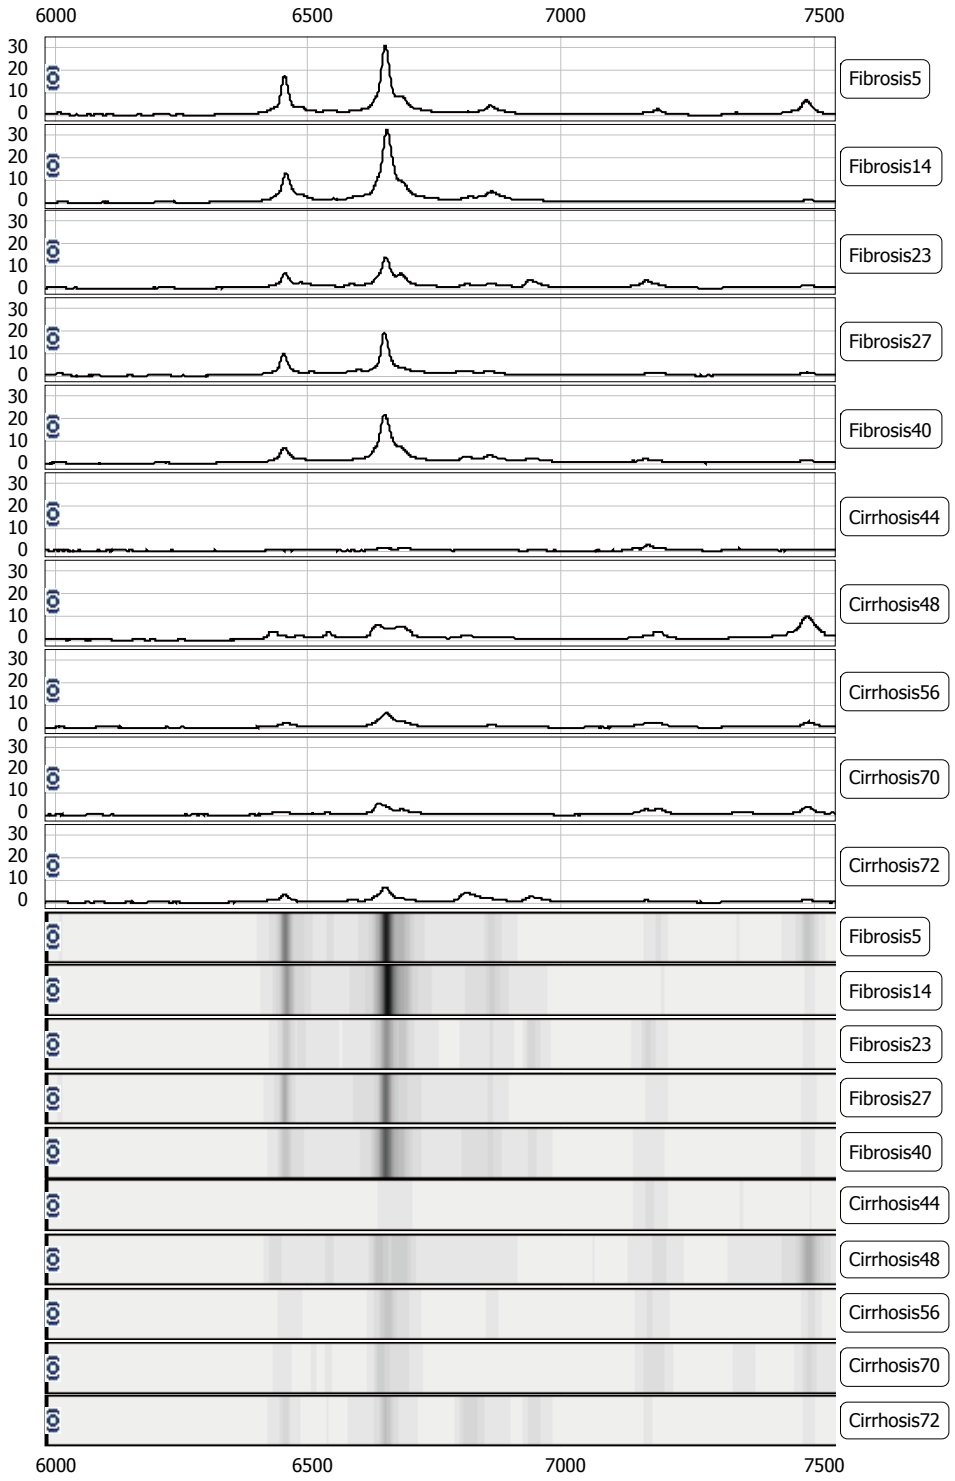

**Figure 3** Representative protein spectra of the 6.6 kDa peak and gel view (below) for the differentiation of fibrosis versus cirrhosis patients. Numbering of patients is according to internally used data.

Apolipoprotein C-Ⅰ was identified as a marker for differentiation of liver fibrosis and cirrhosis. A role for apolipoproteins in liver fibrosis has been recognized earlier. Apolipoprotein A-Ⅰ is one of the parameters used for prediction of liver fibrosis within the Fibrotest-algorithm, in addition an index of prothrombin time γ-glutamyl transpeptidase and apolipoprotein A-Ⅰ has been proposed for identification of severe alcoholic liver disease[24]. However, apolipoproteins have not only been identified as a serum discriminator of fibrosis but also as a marker in different types of cancer[25]. Apolipoprotein C-Ⅰ down-regulation was detected to reliably distinguish colorectal cancer patients from healthy controls[26].

Apolipoprotein C-Ⅰ is primarily synthesized in the liver and only to a lesser degree in the small intestine. It is originally formed as a pro-peptide of 9.3 kDa which generates the mature protein upon cleavage during translation[27]. The observed decrease in serum levels of apolipoprotein C-Ⅰ in cirrhosis and HCC might be due to decreased synthesis rate or due to degradation by activated

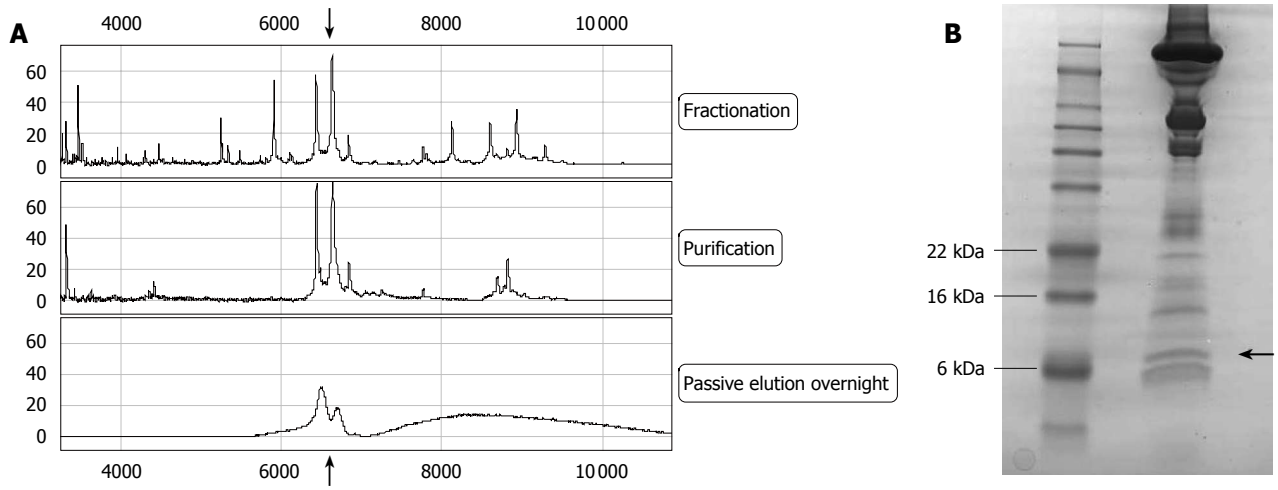

**Figure 4** Isolation of the 6.6 kDa peak. First line shows spectrum after fractionation of the sample with Q Ceramic HyperD®F spin columns, the second line shows the spectra after purification using reverse phase chromatography. The last line spectra represent the purified biomarker on a NP20 array after SDS-gel purification and passive elution. The arrow indicates the 6.6 kDa peak (**A**); One-dimensional SDS polyacrylamide gel electrophoresis after staining of enriched sample (second lane). First lane: molecular marker proteins (See Blue® Plus2, Invitrogen, Carlsbad, USA). The arrow indicates the 6.6 kDa protein (**B**).

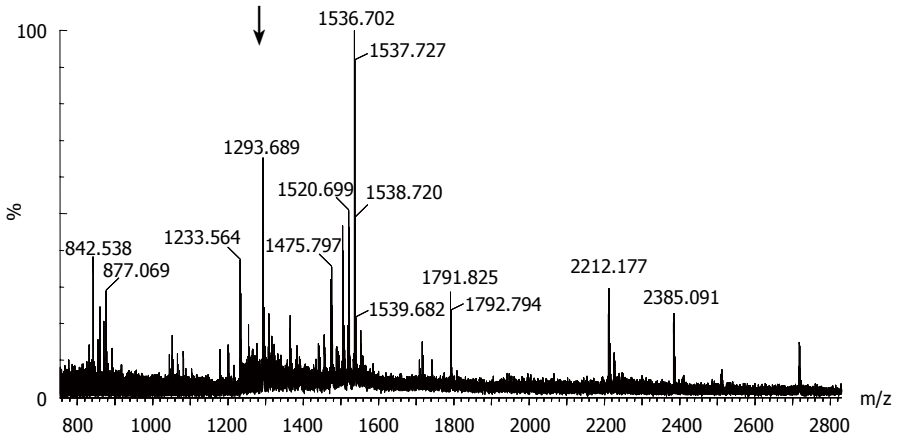

Mascot mapping result of marked peptide: Apolipoprotein C- I

| Start-End | Observed | Mr (expct) | Mr (calc) | Delta | Score | Sequence |
|---|---|---|---|---|---|---|
| 37-47 | 1293.68 | 1292.67 | 1292.66 | 0.01 | 86 | LKEFGNTLEDK |

**Figure 5** Peptide mass fingerprint spectra of the 6.6 kDa biomarker after trypsin digestion using a Micomass Q quattro 2Q-TOF tandem quadruple TOF mass spectrometer equipped with a SELDI-TOF MS ProteinChip Interface PCI1000. The arrow indicates the peptide with the highest score in the database search. Mascot search results of the same peptide are shown below including start and end position of the found peptide sequence, the observed, experimental and calculated mass from the matched peptide sequence, the mass difference (delta), achieved ion score and the peptide sequence.

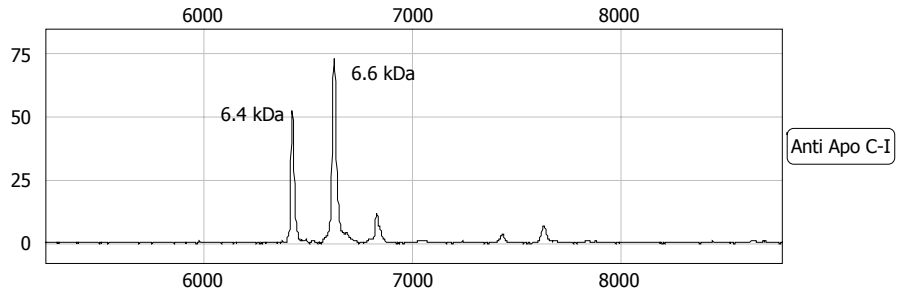

**Figure 6** MS-spectrum of the immunoassay capture using a rabbit anti-human apolipoprotein C-I antibody on a NP20 array. Same peaks as seen in the passive elution are shown. The 6.6 kDa represents Apo C-I, the 6.4 kDa peak is Apolipoprotein C-I missing two N-terminal amino acids.

proteases. However, it has been previously demonstrated that multiple cellular genes involved in lipid metabolism are differentially regulated in chronic hepatitis C[28]. There is considerable evidence that cholesterol and fatty-acid-biosynthesis pathways play a role in HCV replication and infection. Liver steatosis is a typical feature of HCV infection[29], HCV core and NS5A proteins associated with lipid droplets and apolipoproteins A-Ⅰ and A-Ⅱ[30,31]. Interference with lipoprotein metabolism by the use of a HMG-CoA inhibitor pravasin, has been shown to improve survival in patients with hepatitis C associated hepatocellular carcinoma[32] and lovastatin inhibited HCV replication in the replicon model[33]. Thus, besides the function of apolipoprotein C-Ⅰ in lipid metabolism[34] an additional pathogenic role in liver fibrosis and cancerogenesis appears possible.

A number of other protein markers have been identified by mass spectrometry or 2D-gel electrophoresis

in HCV associated hepatocellular carcinoma. Among these are ferritin light chain[35-37], vitronectin[17], apolipoprotein E, chloride intracellular channel 1[37], liver aldolase, tropomyosin β-chain, ketohexokinase, enoyl-CoA hydratase, albumin, smoothelin, arginase-1[36], complement C3a[38] and brain derived neurotrophic factor (BDNF)[39]. Differences to the present study might result from the available samples (e.g. serum *vs* tissue), sample preparation (e.g. fractionation), applied methods (e.g. electrophoresis *vs* SELDI-TOF MS) and patient or control characteristics.

The present study indicates that SELDI-TOF MS is a suitable technique for identification of serum markers in HCV associated liver cirrhosis and hepatocellular carcinoma. Apolipoprotein C- Ⅰ appears to be a valuable marker, however larger studies will be needed to define exactly the role of the biomarker patterns and the single protein markers. Most probably a combination of different serum markers will help to identify liver cirrhosis and early-stage hepatocellular carcinomas in the future.

## ACKNOWLEDGMENTS

The authors thank N Harris for the technical support with MS-MS Q-TOF.

## Abstract

**AIM:** To construct a tumor-selective replication-competent adenovirus (RCAd), SG300, using a modified promoter of human telomerase reverse transcriptase (hTERT).

**METHODS:** The antitumor efficacy of SG300 in hepatocellular carcinoma was assessed *in vitro* and *in vivo*. *In vitro* cell viability by MTT assay was used to assess the tumor-selective oncolysis and safety features of SG300, and *in vivo* antitumor activity of SG300 was assessed in established hepatocellular carcinoma models in nude mice.

**RESULTS:** SG300 could lyse hepatocellular carcinoma cells at a low multiplicity of infection (MOI), but could not affect growth of normal cells even at a high MOI. Both in Hep3B and SMMC-7721 xenograft models of hepatocellular carcinoma, SG300 had an obvious antitumor effect, resulting in a decrease in tumor volume. Its selective oncolysis to tumor cells and safety to normal cells was also superior to that of ONYX-015. Pathological examination of tumor specimens showed that SG300 replicated selectively in cancer cells and resulted in apoptosis and necrosis of cancer cells.

**CONCLUSION:** hTERT promoter-regulated replicative adenovirus SG300 has a better cancer-selective replication-competent ability, and can specifically kill a wide range of cancer cells with positive telomerase activity, and thus has better potential for targeting therapy of hepatocellular carcinoma.

**Key words:** Virotherapy; Oncolytic adenovirus; Human telomerase reverse transcriptase; Hepatocellular carcinoma; Animal tumor model

## INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the malignant diseases with a high incidence and mortality in China. Today, malignant tumors have already become the first death cause in Chinese city residents, and the second in country residents. Among various malignant tumors, HCC is the second cause of cancer death, next only to lung cancer. Based on recent incidence and mortality data available, the International Arctic Research Center (IARC) estimated that there were about 564 000 new cases of HCC in 2000 worldwide, in which 306 000 people were in China. About 300 000 people died of HCC annually in China[1]. The mortality of HCC is more than 40/100 000, especially in the high-risk area of Qidong, Jiangsu Province. HCC severely threatens people's life partially because of lack of effective therapeutic methods in clinics, and most strategies of gene therapy are not quite satisfactory. Therefore, to develop a therapeutic approach mainly targeting at HCC and synchronously at other tumors is an urgent task.

In cancer gene therapy, human adenoviruses have been used extensively[2], because they can infect most types of human cells, carry a large fragment of foreign sequence, and be grown in cultures to high-titered stable stocks[3]. Most adenoviral vectors used in gene transfer are replication-deficient because the adenoviral E1 region is deleted and replaced by antitumor therapeutic genes[4]. The

first generated replication-deficient adenovirus (RDAd) lacks only one (*E1*) or two (*E1* and *E3*) early genes. The second and third ones also contain *E2* and/or *E4* deletions[5,6]. Although the clinical protocols employing RDAd have been large in number[6], all of them have major problems. Since RDAd cannot replicate, they express foreign therapeutic genes at low levels only in cells that are initially infected. As a result, the antitumor effect is easily lost rapidly and the bystander effect on proximal cancer cells is limited. Another problem of RDAd is lack of specificity targeting cancer cells[7], which may further decrease the therapeutic effect on cancer cells and result in toxicity to normal cells. Therefore, development of novel effective tumor-targeting adenoviral vectors to enhance the efficiency and specificity of transgene expression is needed.

Recently, cancer-selective replication-competent adenovirus (RCAd) has attracted more attention in the field of cancer gene therapy. RCAds can specifically replicate in cancer cells, induce cell death and release progeny virions. The progeny virions will continue to infect neighboring cancer cells, thus magnifying the oncolytic effect[8]. In this approach of virotherapy, the specificity of the viral agent to selectively kill cancer cells, while relatively spare non-cancer cells, is achieved by controlling viral replication[9]. Abnormal biological features shared by various cancers have been used to restrict replication of adenoviruses to cancer cells. Recently the promoter of human telomerase reverse transcriptase (hTERT) was used to restrict adenoviral replication to telomerase-positive cancer cells through controlling the adenoviral *E1a* gene or *E4* gene[10,11]. The results suggested that the tight regulation of the adenoviral *E1a* gene is more crucial for replication of viruses. Compared with other promoters, the hTERT promoter is highly active in more than 85% of different human cancers, but inactive in most normal somatic cells, and thus this mechanism can be applied to a wide range of cancers.

We constructed an hTERT promoter-regulated RCAd, designated SG300, in which the adenoviral E1a gene was driven by the hTERT promoter core sequence (-212 bp to +46 bp) with additional 3 E-boxes (CACGTG). It can selectively replicate in a broad array of human cancer cells with positive telomerase activity, but not in normal cells[12]. However, its effect in treating HCC *in vitro* and *in vivo* is unknown. In this study, we further tested the antitumor activity of the tumor-selective RCAd, SG300, and confirmed its highly efficient antitumor activity *in vitro* in several types of cancer cell lines and *in vivo* in xenograft models of HCC.

## MATERIALS AND METHODS

### Cell culture

Human primary HCC cell lines Hep3B and HepG2, and human normal fibroblast cell lines MRC-5 and IMR-90 were purchased from American Type Culture Collection (ATCC, Manassas, VA). Human HCC cell lines BEL-7401 and SMMC-7721, and human normal hepatocellular line L02 were obtained from the Institute of Cell Biology, Chinese Academy of Sciences, Shanghai, China. All cell lines were cultured in media recommended by the providers: MRC-5, and IMR-90 in modified Eagle's medium (Gibco BRL, Gaithersburg, MD), and all other cell lines in Dulbecco's modified Eagle's medium (GibcoBRL) in a 5% $CO_2$ atmosphere at 37℃. All media were supplemented with 10% heat-inactivated fetal bovine serum (FBS) containing 100 U/mL penicillin and 100 μg/mL streptomycin. Telomerase activity of every cell line was measured by the telomeric repeat amplification protocol (TRAP) and ELISA assay with TRAP-PCR-ELISA telomerase detection kit (Chemicon International, Temecula, CA) according to the protocols.

### Construction of SG300

hTERT promoter core sequence (-212 bp to +46 bp) containing three E-box (CACGTG) motifs was synthesized and cloned into plasmid pMD18-T (TaKaRa Biotech. Co., Ltd., Ohtsu, Japan), and plasmid pCAG166TP was generated. After sequencing, the fragment containing hTERT promoter released from pCAG166TP was inserted into upstream of *E1a* gene of the adenoviral vector plasmid pXC1 (Microbix Biosystem Inc.), which has type 5 adenovirus sequence from 22 bp to 5790 bp containing *E1* gene. The obtained novel adenoviral vector plasmid, named pXC20-TP, was co-transfected with pBHGE3 (Microbix Biosystem Inc.), a plasmid of type 5 adenoviral right arm, into HEK293 cells using the Effectene Transfection Reagent (QIAGEN Inc.) to construct the recombinant adenovirus. About 9 to 14 d after transfection, single white plagues emerged in HEK293 cells. After plague purification three times, we obtained a recombinant replicative adenovirus designated SG300, in which *E1a* gene expression was driven by the hTERT core promoter. SG300 was amplified in HEK293 cells, extracted using QIAamp DNA Blood Mini Kit (QIAGEN Inc.), and purified by ultra-centrifugation on cesium chloride (CsCl) gradients.

### Cell viability assay

Cell viability was measured by MTT assay using Cell Proliferation Kit I (Roche Molecular Biochemicals, Indianapolis, IN). Serial concentrations of cells were diluted from $2 \times 10^4$ to $2 \times 10^5$ cells/mL, and seeded in 96-well plates at 100 μL per well. Every concentration was installed in 8 wells. After cultured for 24 h, 100 μL medium per well without FBS was added and cells were continuously cultured for another 7 d. After removal of culture medium from the plates, 100 μL 0.1 mol/L PBS and 10 μL MTT labeling reagent per well were added. The plates were then placed in an incubator for 4 h. After 100 μL solubilization solution was added per well and cultured overnight, the plates were examined with Microplate Reader Model 550 (BIO-RAD Laboratories, Tokyo, Japan) at 570 nm with a reference of 655 nm. Cell viability curves were drawn, on which the most suitable cell concentrations or densities were defined. To test the multiplicity of infection (MOI) of cell viability, every cell line was plated at the density defined above in 96-well plates and infected 24 h later with SG300, ONYX-015 (a control replicative adenovirus, kindly given by Berk AJ, University of California-Los Angeles, Los Angeles, CA), and wild-type

adenovirus 5 (WAd5) at a wide range of MOIs from 0.0001 to 500 pfu/cell. Seven days after infection, MTT assays were performed as described above.

### Virus replication

Cells were plated in 6-well plates at $10^6$ cells per well and infected with the replicative adenovirus SG300 or ONYX-015 at an MOI of 1 pfu/cell synchronously with MTT assay. At 48 h after infection, the cells and supernatants were harvested, and their viral titers were examined with TCID50 method. The titer data were normalized to that at the beginning of infection and expressed as replicative times.

### Animal experiments

BALB/c nude mice aged 6 to 8 wk were purchased from Shanghai Experimental Animal Center, Chinese Academy of Sciences, Shanghai, China. Human HCC cell lines, SMMC-7721 and Hep3B, in log phase ($10^7$ cells in 100 μL medium) were subcutaneously injected into the right flanks of mice. When tumors were induced, mice were divided randomly into four groups as SMMC-7721 models (SG300, ONYX-015, WAd5 and control groups, $n$ = 10 mice/group), and three groups as Hep3B models (SG300, ONYX-015 and control groups, $n$ = 10 mice/group), and given intratumoral injection of $2 \times 10^8$ pfu viruses in a volume of 100 μL viral preservation solution (10 mmol/L Tris-HCl pH 8.0, 2 mmol/L $MgCl_2$, 4% sucrose), once every other day with total injections of five times and total dosage of $10^9$ pfu per mouse in the SG300, ONYX-015 and WAd5 groups, respectively. In the control group, mice received injections of the same volume of viral preservation solution five times. Tumor sizes were measured regularly using calipers. Tumor volumes were estimated with the following formula: $a \times b^2 \times 0.5$, in which $a$ and $b$ represent the maximal and minimal diameters, respectively.

Mice were killed on d 42 after treatment in SMMC-7721 model group and on d 56 in Hep3B model group by cervical dislocation. Specimens from the tumor, liver, and lung were collected, fixed in 10% neutral formaldehyde for 6 h and paraffin-embedded, and 5 μm-thick consecutive sections were sliced for pathological examination. The expression of adenoviral capsid protein, hexon, was located using mouse anti-adenoviral hexon antibody (Biodesign International, MA, USA). To demonstrate apoptotic cell death of tumor tissues on paraffin-embedded sections, terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) assay was performed using In Situ Cell Death Detection Kit (Roche Diagnostics, Basel, Switzerland) according to the manufacturer's instructions. Positive index (PI) was counted from five randomly selected high-power fields under light microscope, and expressed as a percentage of total cells counted.

### Statistical analysis

Experiments were performed three times and the data were presented as mean ± SD. Student's $t$-test was carried out to assess the statistical difference. $P < 0.05$ was considered to be significant.

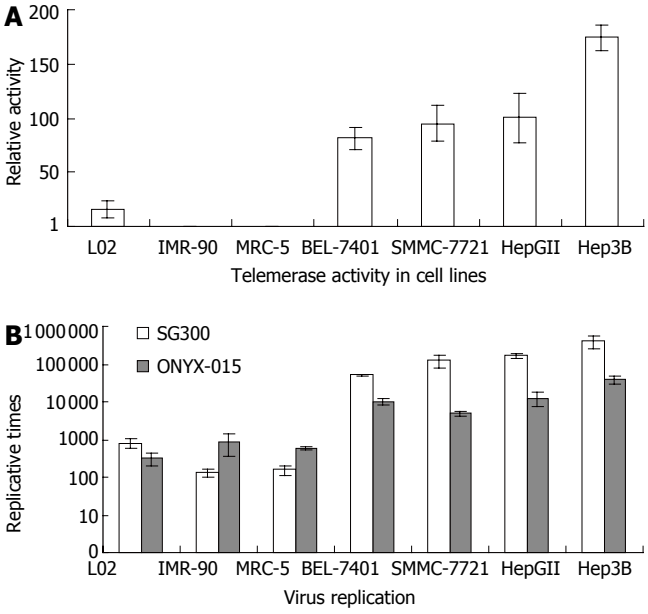

**Figure 1** Relationship between telomerase activity of the cell lines and replicative capability of SG300. By telomeric repeat amplification protocol (TRAP) and ELISA assay (**A**), every cancer cell line was positive for telomerase activity, but the normal fibroblast cell lines were not, whereas the hepatocellular line L02 showed weak telomerase activity. By TCID50 method (**B**), SG300 replicated selectively in cancer cells but rarely in normal cells ($P$ = 0.0453). The replicative capability of SG300 was coincident with the telomerase activity in various cell lines.

## RESULTS

### Telomerase activity of cell lines

By TRAP-ELISA assay, telomerase activity of cultured cell lines was measured. It showed that all cancer cell lines were positive for telomerase activity; however, the two normal fibroblast cell lines were not. The normal hepatocellular line L02 showed weak telomerase activity (Figure 1A).

### In vitro virus selective replication

By TCID50 method, we measured virus titers on d 4 after infected with SG300 and ONYX-015, respectively. The replicative capability of SG300 was markedly enhanced in different cancer cell lines with increases of virus yields by 50 793 to 406 250 times. In normal fibroblast cell lines, however, SG300 had a lower replicative capability. Its replicative times were below 160 ($P$ = 0.0453). It showed a certain replicative activity in human hepatocellular cell line L02, with replicative times of 796 (Figure 1B). ONYX-015 replicated more slowly than SG300 in cancer cells ($P$ = 0.0348).

### In vitro cell viability

To quantify the viability of cells, MTT assay was used. First, a suitable cell concentration or density for each cell line was determined, at which cells were seeded in 96-well plates and would not induce any cytopathic effect (CPE) within 7 d. This was to make sure that the killing effect that might appear in the following experiments was due to adenoviral replication. Second, we investigated the viability of cells, including HCC cell lines and normal cell lines, respectively infected with SG300, ONYX-015 and

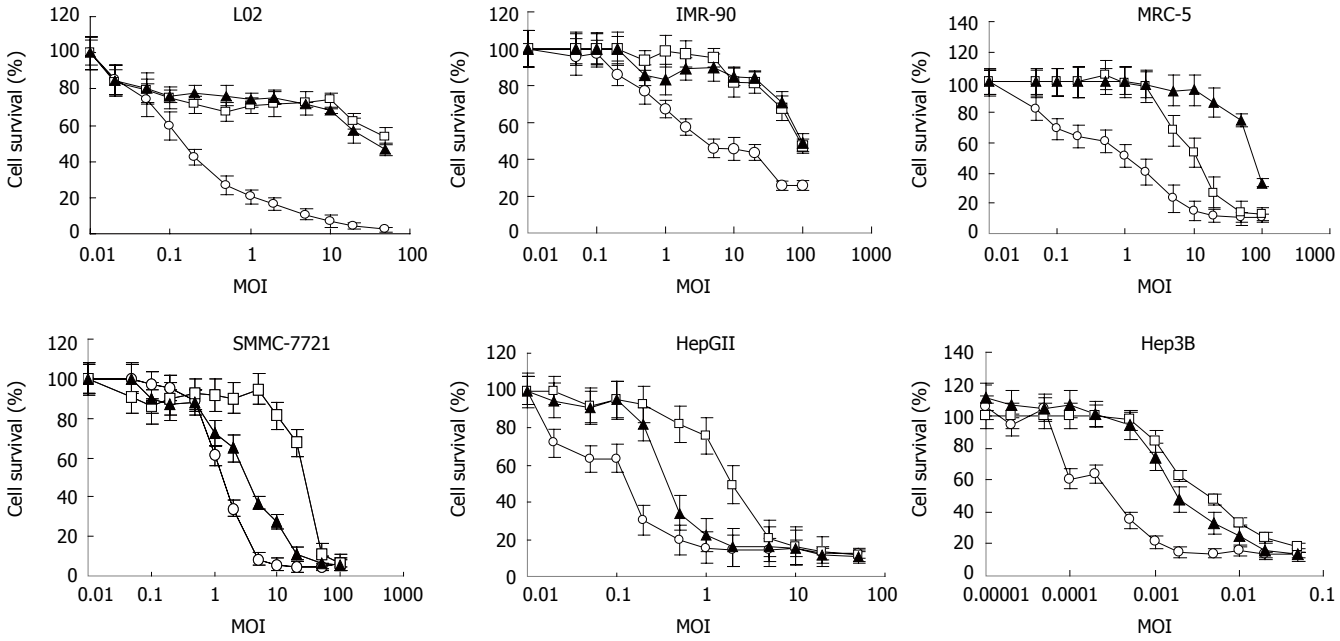

**Figure 2** Selective oncolytic effect of SG300 on HCC cell lines. At MOI = 10, the cell viability was < 30% in HCC cells, but > 68% in normal cells when infected with SG300. The oncolytic effect of SG300 was stronger on HCC cells and weaker on normal cells than that of ONYX-015, being close to that of WAd5. The killing effect of SG300 and ONYX-015 on normal cells became apparent when MOI = 100. —▲—SG300, —□—ONYX-015, —◇—WAd5.

WAd5, which reflected the selectivity and safety of SG300. The results showed that SG300 could lyse HCC cells at a very low MOI (Figure 2). Seven days after infection of SG300 at an MOI of 10 pfu/cell, the viability of each HCC cell line was below 30% (15.3%, 27.6% in HepGII, SMMC-7721, respectively); however, at the same MOI, the viability of each normal cell line was higher (68.0%, 84.8%, 94.0% in L02, IMR-90, MRC-5, respectively). The IC50s (MOI values of 50% viability) of SG300 in cancer cells were markedly lower than that in normal cells ($P$ = 0.0111) (Table 1). Hep3B was very sensitive to SG300, and cells were killed obviously and cell viability decreased to 13.2% at an MOI of 0.05 pfu/cell. ONYX-015 also had a killing effect on cancer cells, but it required a higher MOI than SG300 to reach the same effective level as SG300. The viability of HepGII or SMMC-7721 infected with ONYX-015 was 16.3% or 81.1% at an MOI of 10 pfu/cell, and of Hep3B was 17.8% at an MOI of 0.05 pfu/cell. There was no difference between the IC50s of WAd5 in cancer cells and normal cells ($P$ = 0.4081). MTT assay directly showed that the killing effect of SG300 was several times or even more than that of ONYX-015 on HCC cells, but weaker than that of ONYX-015 on normal cells.

**Table 1 IC50 values of adenoviruses in different cells**

| Cells | SG300 | ONYX-015 | WAd5 |
|---|---|---|---|
| L02 | 41.5658 ± 2.2122 | 58.0351 ± 8.9114 | 0.1520 ± 0.0099 |
| IMR-90 | 94.5783 ± 5.2813 | 90.4534 ± 8.2359 | 2.1342 ± 0.0897 |
| MRC-5 | 82.5674 ± 8.5549 | 14.2622 ± 1.7781 | 1.1525 ± 0.0336 |
| SMMC-7721 | 2.8954 ± 0.0641[a] | 25.5323 ± 6.2351 | 1.3426 ± 0.0625 |
| HepGII | 0.3232 ± 0.0085[a] | 1.9845 ± 0.0046[a] | 0.1123 ± 0.0030 |
| Hep3B | 0.0017 ± 0.0003[a] | 0.0042 ± 0.0005[a] | 0.0013 ± 0.0002 |

[a]$P$ < 0.05 *vs* normal cells in the same group.

### *In vivo antitumor activity of SG300*

Hep3B and SMMC-7721 cells were implanted into BALB/c nude mice to induce subcutaneous tumors. Tumors were seen 20 d later after implantation of SMMC-7721 cells, and about 30 d later after implantation of Hep3B cells. The adenoviruses and the control buffer (viral preservation solution) were injected intralesionally. Forty-two days later, half mice (5/10) died in WAd5 group of SMMC-7721 models. The groups injected with adenoviruses both in these two models of HCC showed antitumor effects to some extent when compared with the control group ($P$ = 0.0001, 0.0364 for SG300 and ONYX-015, respectively, in SMMC-7721 models; $P$ = 0.0005, 0.0019 for SG300 and ONYX-015, respectively, in Hep3B models), and the effects of SG300, being close to that of WAd5, were better than that of ONYX-015 ($P$ = 0.0029, 0.0066 in SMMC-7721 and Hep3B models, respectively) (Figure 3). Mice of the control group in Hep3B models were sacrificed ahead of time on d 42 after treatment by cervical dislocation due to overloading of tumors.

### *Pathological examination*

Pathological examination showed that there were many areas of necrosis in tumor tissues of the SG300-treated group and ONYX-015-treated group. In the control group, however, cancer cells grew luxuriantly with only a few, small focal areas of necrosis (Figure 4A and B). Immunohistochemistry demonstrated that most cancer cells positive for hexon were distributed mainly around the necrotic areas (Figure 4C and D), and that more apoptotic cancer cells were positive for TUNEL labeling in tumor tissues of the SG300-treated group, compared

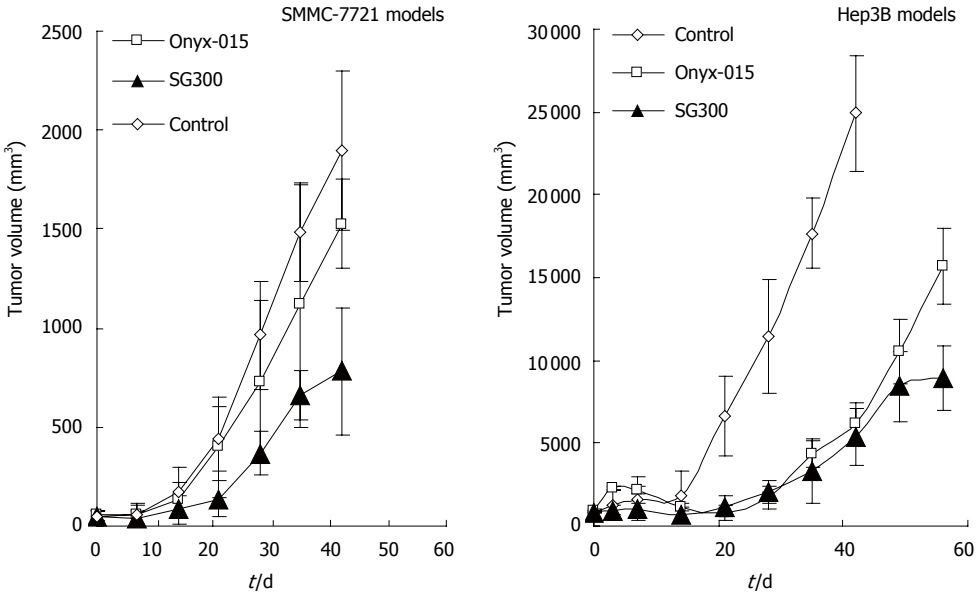

**Figure 3** Antitumor activity of SG300 on HCC xenografts in nude mice. In SMMC-7721 and Hep3B models, efficient antitumor activities were found in groups treated with SG300 when compared with control group on d 42 ($P < 0.05$). The antitumor effect of SG300 was better than that of ONYX-015. WAd5 group in SMMC-7721 models also showed efficient antitumor efficacy, however, 5 of 10 mice died during the period of observation.

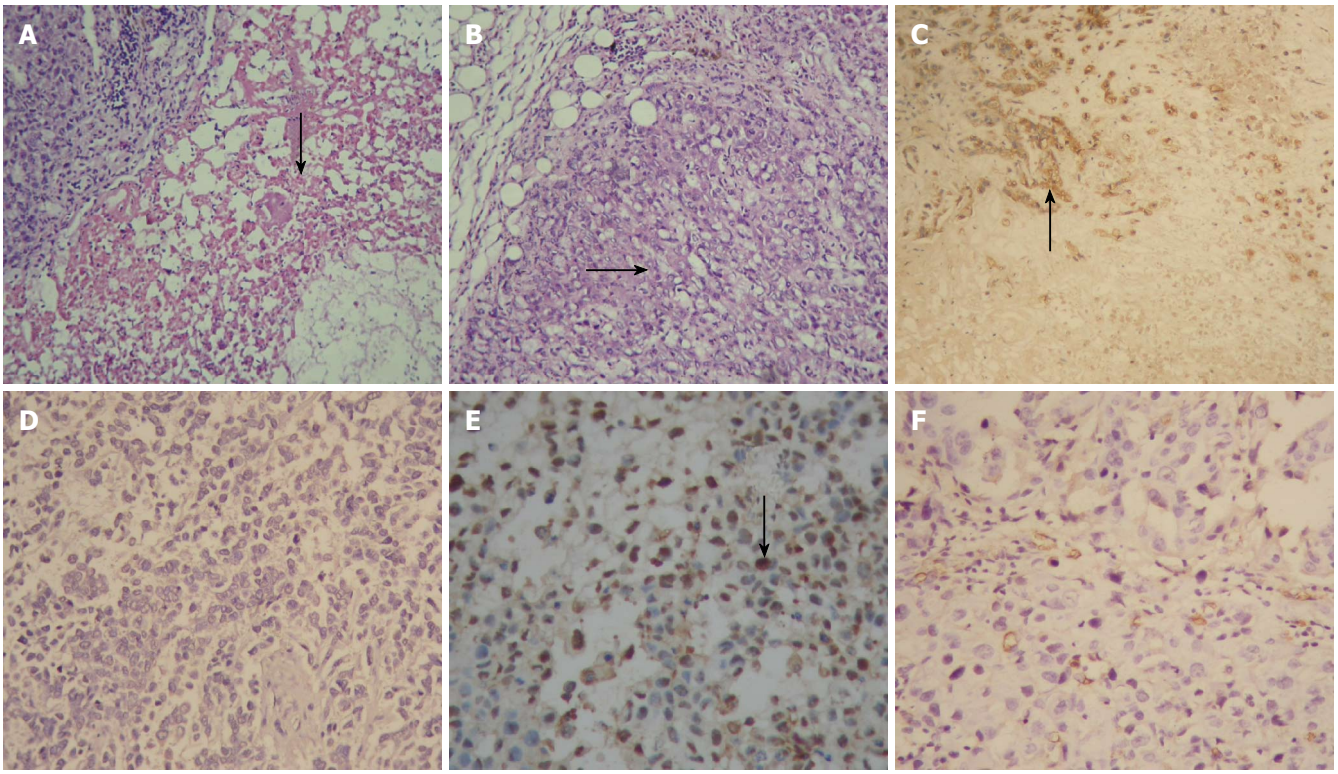

**Figure 4** Pathological examination of tumor specimens (× 200). HE staining showed wide areas of necrosis (arrow) in tumor tissues of the SG300-treated group (**A**), but cancer cells grew luxuriantly (arrow) in the control group (**B**). Immunohistochemistry demonstrated that most cancer cells around the necrotic area were positive for adenoviral capsid protein hexon (arrow) in the SG300-treated group (**C**), but cancer cells were negative for hexon in the control group (**D**). More cancer cells were positive for TUNEL labeling (arrow) in tumor tissues of the SG300-treated group (**E**), whereas only a few cancer cells were positive for TUNEL labeling in the control group (**F**).

with the control group (Figure 4E and F). PIs in SG300, ONYX-015 and control groups were 59.4 ± 21.1, 42.3 ± 18.2, 17.5 ± 8.9 for TUNEL labeling, respectively. There was a difference between TUNEL labeling PI in the control group and in any other replicative adenovirus-treated group ($P = 0.0007$ for SG300, $P = 0.0032$ for ONYX-015). The liver and lung tissues of mice were negative for hexon in SG300-treated group as well as ONYX-015 and control groups.

## DISCUSSION

Virotherapy employing tumor-selective replication-competent adenovirus (RCAd) is a promising strategy in cancer treatment. An alternative approach to restrict adenoviral replication to targeting cancer cells and achieve RCAd is to modify adenovirus by partial deletion of viral genes that are essential for replication in normal cells but not in tumor cells[13-15]. The representative RCAd of

this type is ONYX-015[16]. It has a deletion of *E1b-55K* gene and replicates specifically in cancer cells lacking wide-type *p53*[17,18]. An additional approach to achieve RCAd is to place viral replicative genes under the control of cancer-specific promoters that are activated only in cancer cells[19]. Several cancer-specific promoters that are more active in particular cancer cells but inactive or only weakly active in cancer-originating somatic cells, have been identified and explored to construct RCAds, such as the carcinoembryonic antigen (CEA) promoter targeting colorectal and lung cancer[20], the α-fetoprotein promoter targeting hepatocellular cancer[21,22], the prostate-specific antigen (PSA) promoter targeting prostate cancer[2], the MUC1 antigen promoter targeting breast cancer[7], the E2F transcriptional factor promoter targeting cancers with a defective pRb/E2F/p16 pathway[23-25], the surfactant protein B (SPB) promoter targeting lung cancer[3], and the L-plastin promoter targeting ovarian and bladder cancers[26]. These cancer-specific promoters can provide RCAds, the selective replication in corresponding cancer cells and demonstrate antitumor activity in preclinical models and clinical trials. However, most of them are limited, targeting a narrow range of cancers expressing the corresponding tumor antigen, thus attenuating their efficacy in cancer therapy[27].

A number of gene therapeutic approaches have been proposed to kill cancer cells or inhibit growth of caners by targeting telomerase[28]. Most of them utilize the hTERT promoter to drive antitumor gene expression selectively in cancer cells with positive telomerase activity, without affecting normal cells negative for telomerase[29,30]. It indicates the potential therapeutic application of the strategy targeting telomerase for a wide range of various cancers. Recently the hTERT promoter has been tested for targeting cancer gene therapy with replication-competent viral vectors. It was used to control the adenoviral early gene expression and produce a series of RCAds, but experimental results were inconsistent. Some studies showed that the hTERT promoter provided a sufficient selection for viral replication in cancer cells and did not in normal cells when it was used to construct CRAds by controlling *E1a* gene[10,31,32]. Other studies demonstrated that the hTERT promoter failed to block viral replication in telomerase-negative cells when it was used to control *E4* gene expression[11]. Because the wild-type hTERT promoter is incapable of mediating a high level of RCAd replication in cancer cells, it is necessary to develop a modified form of the promoter with improved transcriptional activity and cancer specificity. Wirth and coworkers reported that the transcriptional activity of the hTERT promoter could be enhanced significantly in a majority of tumor cell lines by inserting the E1a TATA box upstream of the transcription start site of its controlled gene[33]. This modification in an RCAd, named hTERT-Ad, did not alter the tumor-selective specificity of the promoter. Kim *et al*[34] constructed a modified hTERT promoter-controlled RCAd, Ad-mTERT-Δ19, in which a fragment containing one copy of c-Myc binding site and five copies of SP1 binding sites was incorporated into the downstream region of the wild-type hTERT promoter. The experimental results strongly suggested that the transcriptional activity of the modified hTERT promoter was up-regulated in cancer cells but not in normal cells, and the replicative capability and cytolytic effect of Ad-mTERT-Δ19 were enhanced only in cancer cells compared with wild-type hTERT promoter-controlled RCAd, Ad-TERT-Δ19. To further increase the tumor-selective specificity of RCAd controlled by the hTERT promoter and decrease the adenoviral toxicity to normal cells, we previously used a modified hTERT promoter with three additional copies of E-boxes (CACGTG) to construct an RCAd, named SG300. The results suggested that by this modification, the specificity of RCAd targeting cancer cells could be improved and its toxicity to normal cells could be reduced[12].

Our experiments *in vitro* showed that SG300 lysed or destroyed cancer cells at a low MOI, including human HCC cell lines, Hep3B, HepGII, BEL-7401 and SMMC-7721, but did not affect growth of normal cells such as human normal fibroblast cell lines, MRC-5 and IMR-90, even at relative high MOIs. The oncolytic ability of CRAds varied in different types of HCC cells. Both SG300 and ONYX-015 had strong effects on Hep3B. The selective cytolytic ability of SG300 was more powerful than that of ONYX-015 in HCC cells. The effect of SG300 on normal cells was less than that of ONYX-015. ONYX-015 is an oncolytic adenovirus that shows different mechanisms and replicates preferably in p53-deficient tumor cells. Because the positive rate of telomerase activity was higher than the incidence rate of p53-deficiency in human cancers, ONYX-015 targets a narrower range of cancer types than SG300. Furthermore, our previous studies and the current data proved that the replicative capacity of ONYX-015 in tumor cells was weaker than that of SG300 series[12]. Probably that is why the selective cytolytic ability of ONYX-015 was weaker than that of SG300 in HCC cells. All these results, combined with the data of telomerase activity and viral replicative capability in cultured cell lines, demonstrated that SG300 has a better cancer-selective replication-competent ability, and can specifically kill a wide range of cancer cells with positive telomerase activity. The killing effect of SG300 was not only consistent with its replicative capacity in different cell lines but also with the telomerase activity of these cells. L02 cells showed a weak telomerase activity, and SG300 could replicate in this cell line to some extent and resulted in weak cytolysis.

BALB/c nude mice were subcutaneously injected with Hep3B and SMMC-7721 cells, respectively. When the tumors were induced, the replicative adenoviruses were injected intralesionally with a total dosage of $10^9$ pfu per mouse. The results showed that SG300 yielded an obvious antitumor effect on HCC xenografts. Tumor growth was inhibited with a decrease in tumor volume. The antitumor effect of SG300 was better than that of ONYX-015. During the period of observation, half mice of WAd5-infected group in SMMC-7721 models died of virus toxicity, but no mice died in SG300-treated groups either in SMMC-7721 or in Hep3B models, demonstrating that SG300 had no toxicity to normal tissues or organs and therefore, was safe in cancer therapy. Pathological examinations showed that SG300 replicated selectively in

HCC cells and resulted in apoptosis and necrosis of cancer cells. In brief, hTERT promoter-regulated replicative adenovirus SG300 has a selective replicative ability and a specific cytolytic ability targeting HCC cells and other cancer cells that are positive for telomerase activity. It shows superior selective replication and antitumor effect when compared with ONYX-015, and thus has better potential for HCC therapy.

## ACKNOWLEDGMENTS

We thank Lihua Jiang and Yanzhen Qian of our laboratory for their assistance with cell culture; Jianzhong Gu, of Shanghai Experimental Animal Center, Chinese Academy of Sciences, for his help with animal studies. We also thank Berk AJ, University of California-Los Angeles, Los Angeles, for kindly providing the control replicative adenovirus ONYX-015.

## COMMENTS

### Background

Recently, a number of gene therapeutic approaches by cancer-selective replication-competent adenovirus (RCAd) have been proposed in the field of cancer gene therapy, and attracted much attention. However, in vitro experimental results are inconsistent. The objective of this study was to further increase the tumor-selective specificity of RCAd and decrease the adenoviral toxicity to normal cells.

### Research frontiers

In this study we constructed SG300 by use of a modified hTERT promoter. It could lyse hepatocellular carcinoma cells at a low multiplicity of infection (MOI), but did not affect growth of normal cells even at a high MOI. Its selective oncolytic ability was stronger than that of ONYX-015, which is the representative selective replicative adenovirus, and its influence on normal cells was less than that of ONYX-015.

### Innovations and breakthroughs

To further increase the tumor-selective specificity of RCAd controlled by the hTERT promoter and decrease the adenoviral toxicity to normal cells, we constructed an RCAd, SG300, by use of a modified hTERT promoter with three additional copies of E-box (CACGTG). Its antitumor activity in vitro and in vivo was shown to be excellent. Both in Hep3B and SMMC-7721 xenograft models of hepatocellular carcinomas, SG300 had an obvious antitumor effect, resulting in a decrease in tumor volume due to its selective replication in cancer cells and its specific oncolysis.

### Applications

hTERT promoter-regulated replicative adenovirus SG300 has a selective replicative ability and a specific cytolytic ability targeting hepatocellular carcinoma cells and other cancer cells that are positive for telomerase activity. It displays superior selective replication and antitumor effect when compared with ONYX-015, and thus has better potential for HCC therapy.

### Terminology

RCAd: replication-competent adenovirus; hTERT: human telomerase reverse transcriptase

### Peer review

hTERT promoter-regulated replicative adenovirus SG300 has a better cancer-selective replication-competent ability, and can specifically kill a wide range of cancer cells with positive telomerase activity, and thus has better potential for targeting therapy of hepatocellular carcinoma.

## Abstract

**AIM:** To characterize the expression and dynamic changes of bone morphogenetic protein (BMP)-2 in hepatocytes in the regenerating liver in rats after partial hepatectomy (PH), and examine the effects of BMP-2 on proliferation of human Huh7 hepatoma cells.

**METHODS:** Fifty-four adult male Wistar rats were randomly divided into three groups: A normal control (NC) group, a partial hepatectomized (PH) group and a sham operated (SO) group. To study the effect of liver regeneration on BMP-2 expression, rats were sacrificed before and at different time points after PH or the sham intervention (6, 12, 24 and 48 h). For each time point, six rats were used in parallel. Expression and distribution of BMP-2 protein were determined in regenerating liver tissue by Western blot analysis and immunohistochemistry. Effects of BMP-2 on cell proliferation of human Huh7 hepatoma cell line were assessed using an MTT assay.

**RESULTS:** In the normal liver strong BMP-2 expression was observed around the central and portal veins. The expression of BMP-2 decreased rapidly as measured by both immunohistochemistry and Western blot analysis. This decrease was at a maximum of 3.22 fold after 12 h and returned to normal levels at 48 h after PH. No significant changes in BMP-2 immunoreactivity were observed in the SO group. BMP-2 inhibited serum induced Huh7 cell proliferation.

**CONCLUSION:** BMP-2 is expressed in normal adult rat liver and negatively regulates hepatocyte proliferation. The observed down regulation of BMP-2 following partial hepatectomy suggests that such down regulation may be necessary for hepatocyte proliferation.

**Key words:** Bone morphogenetic protein-2; Partial hepatectomy; Liver regeneration; Hepatocellular carcinoma

## INTRODUCTION

Bone morphogenetic proteins (BMPs) were first identified in the 1960s[1]. BMPs are multi-functional growth factors that belong to the transforming growth factor beta (TGF-β) superfamily[2]. Mature BMPs are 30-38 kDa proteins that utilize BMP receptors and intracellular SMADs to transduce their signals to regulate cell proliferation, differentiation, morphogenesis and apoptosis. The role of BMPs in embryonic development and in postnatal and adult animals has been extensively studied in recent years. In addition to their well recognized role in bone physiology, BMPs are known to regulate the development and homeostasis of other organs including the liver[3]. Previous research showed that a receptor for BMP-9 is expressed in the HepG2 liver tumor cells. HepG2 cells bind BMP-9 and undergo a proliferative response[4]. Northern blotting analysis demonstrated the presence of BMP-6 in non-parenchymal liver cells and a role for BMP-6 in the regeneration of liver tissue was proposed[5]. BMP signaling plays a critical role in the regulation of liver development. BMP signaling from the septum transversum mesenchyme is necessary to induce liver genes in the endoderm and the morphogenetic growth of the hepatic endoderm into a liver bud[6,7]. Similar to TGF-β signaling, BMP signaling has been implicated in the development of hepatic fibrosis as BMPs have been shown to stimulate activation of hepatic stellate cells, which results in their

transdifferentiation to an α-smooth muscle antigen positive myofibroblast-like phenotype[8,9].

Among BMPs, BMP-2 has gained more attention because it is the predominant form in natural bone morphogenetic protein extracts[10], and it is widely expressed during mouse development[11]. Researchers find that high affinity receptors for BMP-2 are present not only on osteoblastic cells but also on a large variety of non-hematopoietic cell types[12]. Preclinical and clinical studies have suggested that recombinant BMP-2 may have therapeutic potential in bone repair[13].

A hallmark of developmental biology is that similar pathways are involved in multiple different systems. It is clear that the role of BMP signaling is not restricted to the bone. The liver, just as the bone, has a remarkable regenerative potential, which involves tightly regulated molecular mechanisms that control hepatic proliferation, differentiation and morphogenesis after the loss of hepatic tissue[14]. However, the role of BMP signaling in the regenerating liver remains unclear. Here we focus on the expression and dynamic changes of BMP-2 in hepatocytes in regenerating liver of adult rats.

## MATERIALS AND METHODS

### Experimental animals and grouping

Fifty-four adult and healthy male Wistar rats weighing 180-220 g, obtained from the Animal Center of Shanxi Medical University, were employed in the present study. All rats received humane care during the study under a protocol that was in accordance with institutional guidelines for animal research and was approved by the Ethics and Research Committee of Shanxi Medical University. Experimental rats were randomly divided into three groups: Normal control (NC, $n = 6$) group, partial hepatectomized (PH, $n = 24$) group and sham operation (SO, $n = 24$) group. Rats were sacrificed at 6, 12, 24 and 48 h after partial hepatectomy or sham operation. For each time point indicated, six rats ($n = 6$) were used in parallel.

### Animal model and sample preparation

Rats were maintained on a 12/12 h light-dark cycle. The surgery was performed between 8 and 10 AM. Rats were fasted 12 h before surgery and anesthetized with pentobarbital sodium (30 mg/kg) intra-abdominally, then the abdominal skin was shaved and sterilized with an iodine solution. Two-thirds hepatectomy was performed as described by Higgins and Anderson. In the sham operated rats the liver was manipulated but not resected. Rats were anesthetized with pentobarbital sodium (20 mg/kg) intra-abdominally and killed at 6, 12, 24 or 48 h after partial hepatectomy or the sham procedure. The remnant livers were removed, parts of which were fixed 24 h in 10% buffered neutral formalin. The fixed livers were dehydrated through increasing concentrations of ethanol and in xylene and embedded in paraffin. Liver tissues embedded in paraffin were sectioned at 4 μm for immunohistochemistry. Part of the livers was snap frozen in liquid nitrogen for the preparation of protein lysates for Western blotting.

### Immunohistochemistry

Immunohistochemistry was performed as described in detail below. Paraffin sections (4 μm) were dewaxed and dehydrated in graded alcohols. Endogenous peroxidase activity was quenched with 1.5% $H_2O_2$ in PBS for 30 min at room temperature. Antigen retrieval was performed by heating for 10 min at 95℃ in 0.01 mol/L sodium citrate, and non-specific staining was blocked with TENG-T (10 mmol/L Tris, 5 mmol/L EDTA, 0.15 mol/L NaCl, 0.25% gelatin, 0.05% [vol/vol] Tween-20, pH 8.0) for 30 min at room temperature. Endogenous avidin binding activity due to biotin was overcome by successive 20 min incubations of the tissue sections in 0.1% avidin and 0.01% biotin (DAKO Biotin Blocking System). After a washing with PBS (3 × 5 min), BMP-2 primary antibody (mouse monoclonal BMP-2, MAB355, 1:500, R&D) was applied in PBS containing 1% bovine serum albumin and 0.1% Triton and incubated overnight at 4℃. The following day, for BMP-2 staining, sections were incubated with biotinylated goat-anti-mouse IgG (DAKO 1:200) for 60 min in PBS with 10% human serum, then washed in PBS (3 × 10 min) and incubated for 60 min with streptavidin-biotin-horse-radish peroxidase (DAKO) for 1 h, and washed again 3 × 5 min in PBS. And peroxidase activity was detected with DAB (Sigma), resulting in the formation of a brown reaction product. Finally, sections were briefly counterstained with hematoxylin, then dehydrated, cleared and mounted in neutral gum under cover slips. For controls, the primary and secondary antibodies were substituted and an appropriate IgG control (mouse IgG2b was applied at 1:50) was used to perform negative control staining. A known positive staining specimen (bone tissue of rat) was used as a positive control.

### Immunoblotting

Rat liver tissue was homogenized in lysis buffer. Protein concentrations were measured using the Bradford method. Lysates were diluted as per 300 μL protein sample buffer was added with 600 μg extract in 2 × protein sample buffer and 30 μL of each sample of homogenates was loaded per lane on an SDS-PAGE gel. Equal protein loading was confirmed using β-actin (Santa Cruz) antibodies on the same blots after stripping off the old antibodies in stripping buffer. After protein separation the proteins were blotted onto a PVDF membrane (Millipore, Bedford, MA). The membranes were blocked with 2% protein (Nutricia, The Netherlands) in PBS supplemented with 0.1% Tween-20 for 1 h at room temperature. After a brief wash in washing buffer (0.2% protifar: 0.1% Tween-20), membranes were incubated overnight at 4℃ with primary antibody (mouse monoclonal BMP-2, MAB 355, 1:1000, R&D systems) in 2% blocking buffer. The following day, membranes were washed three times for 5 min, and subsequently incubated with a secondary horseradish peroxidase (HRP)-conjugated antibody in wash buffer (0.2% low fat milk powder) at 1:1000 dilution. After enhanced chemoluminescence using Lumilight + substrate (Roche, Mannheim, Germany), antibody binding was visualized using a Lumi-Image-Pro Plus 5.0.

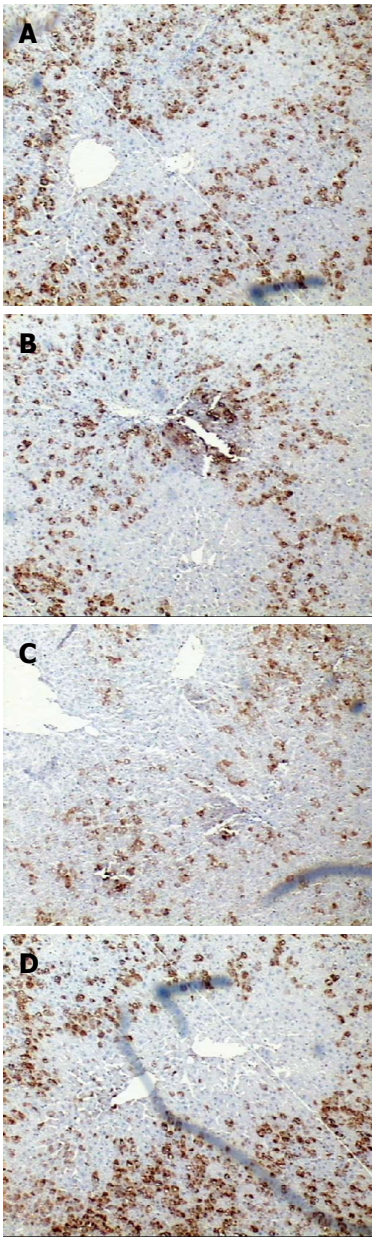

**Figure 1** By immunohistochemistry, BMP-2 is expressed predominantly in hepatocytes around the central vein and portal triad. Strong BMP-2 staining is seen localized to the cytoplasm of NC group (**A**). The strong BMP-2 staining seen in normal tissue is lost at 6,12 h group (**B**,**C**) and resumes at 48 h group (**D**) following PH. There was no significant change in SO group compared with NC group in BMP-2 immunoreactivity (data not shown). Control stainings were performed by omitting the primary antibody and using a control IgG2b that showed no staining. A known positive staining specimen was used as a positive control (data not shown). (**A**, **B**, **C**, and **D** x 200).

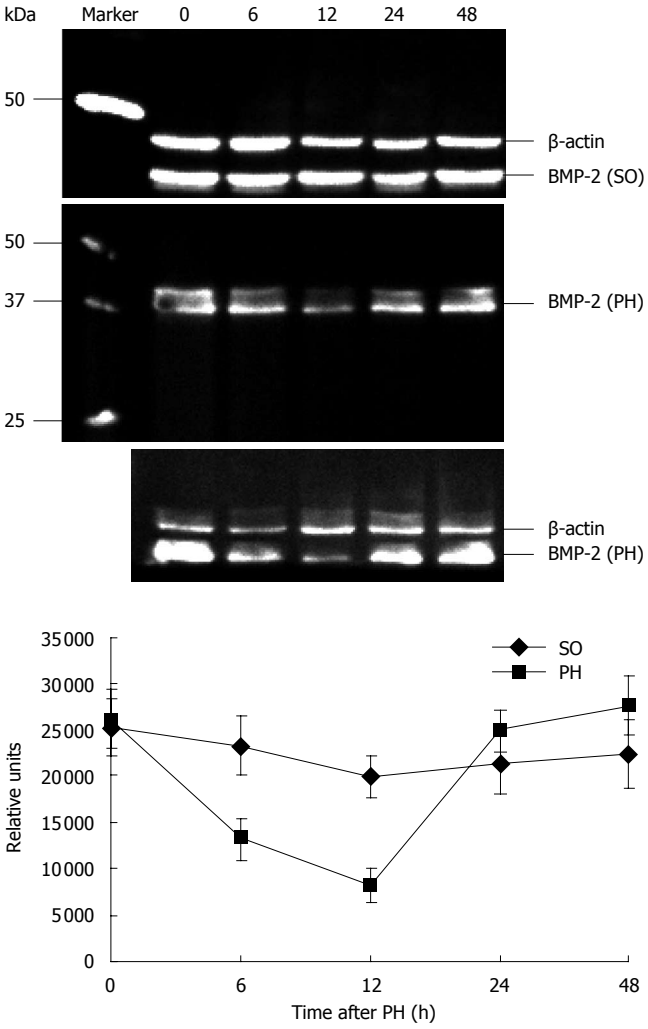

**Figure 2** Immunoblot for BMP-2 in rat liver of NC, SO and PH groups. At all the time points (note: 0 h = NC), rat liver extracts tested showed a band at approximately 37 kDa on the immunoblots. Bio-Rad Precision Protein Standards were used. Equal protein loading was confirmed using β-actin antibodies on the same blots by striping the old antibodies in strip buffer. The calculated molecular weights are shown. Quantification of 12 h immunoblots revealed 3.22 fold lower ($P < 0.01$) BMP-2 protein expression levels in PH group as compared with NC group. BMP-2 protein levels increased progressively to that of NC group at 48 h after PH.

### *Cell culture and proliferation assay*

The Huh7 human hepatoma cell line[15] was obtained from the ATCC (American Type Culture Collection) and cultured in Dulbecco's Modified Eagle's Medium (DMEM)(Gibco, Paisley, Scotland) with 4.5 g/L glucose and 1% L-glutamine. This was supplemented with penicillin (50 U/mL), streptomycin (50 μg/mL) and 10% FBS (Gibco). Cells were grown in monolayers in a humidified atmosphere containing 5% $CO_2$. Eighty to ninety percent confluent monolayers of Huh7 cells were trypsinized and taken up in medium with 10% FBS. Cells at $5 \times 10^4$ per well were seeded in triplicate in flat-bottomed tissue culture of 24 well plates (Falcon) overnight in DMEM medium containing 10% FBS in the absence or presence of recombinant human BMP-2 (rhBMP-2 355-BM, R&D systems) at indicated concentrations for 72 h. MTT [3-(4,5-methylthiazol-2-yl)-2,5-dipheyl-tetrazolium bromide] reagent was added to all wells for 30 min. The medium was removed from the cells, and cells were lysed in acidic isopropanol and absorbance was measured at 550 nm with an enzyme-linked immunosorbent assay plate reader (Molecular Devices, Ther/vio max microplate reader).

### *Statistical analysis*

Values are expressed as mean ± SE. Results were evaluated using analysis of variance and correlated by SPSS11.0 software. $P < 0.05$ was considered significant.

## RESULTS

### *Localization of BMP-2 expression in regenerating rat liver*

To determine the expression and localization of BMP-2 in the regenerating rat liver, immunostaining was carried out using a specific monoclonal anti-BMP-2 antibody. As evident from Figure 1, clear and strong BMP-2 immunoreactivity was present in the cytoplasm of hepatocytes around the central vein (CV) and portal triad (PT) in normal liver. In contrast, immunoreactivity of BMP-2 declined significantly at 12 h after PH. Thereafter

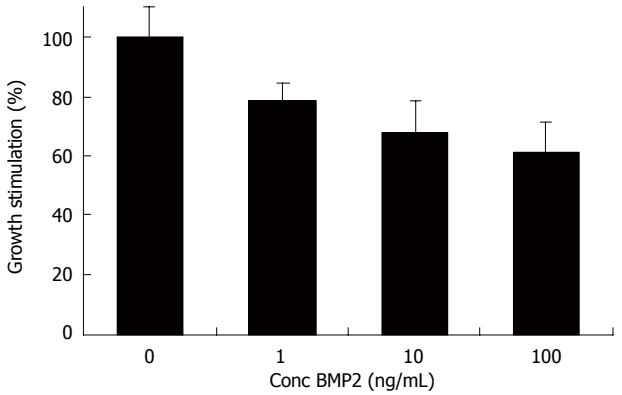

**Figure 3** MTT assay of human hepatoma Huh7 cell line treated for 72 h with various concentrations of BMP2. Values obtained with no BMP2 were set at 100. Error bars represent the standard error of the mean. BMP-2 inhibited the growth of Huh7 cells, maximal effects occurring at 100 ng/mL after 72 h incubation. BMP-2 significantly inhibited the growth of Huh7 cells by 38.8% ± 0.4% ($P < 0.01$).

the immunoreactivity of BMP-2 increased progressively and was back to normal levels at 48 h after PH. No significant change in BMP2 expression in SO group compared to normal controls was observed (data not shown).

### *Levels of BMP-2 in regenerating rat liver*

To confirm the specificity of the observed changes in BMP-2 expression in the regenerating rat liver, levels of BMP-2 expression were determined by Western blot analysis. As shown in Figure 2, using the antibody a band at approximately 37 kDa was detected on the immunoblots, which corresponds to BMP-2 precursor protein. Quantification of BMP-2 expression showed a 3.22 fold reduction ($P < 0.01$) of BMP-2 protein expression compared to controls at 12 h after PH. Similar to the results obtained by immunohistochemistry, BMP-2 protein levels returned to control levels at 48 h after PH. There were no significant changes in BMP-2 expression in the SO group compared to normal controls.

### *Effects of BMP-2 on human hepatoma Huh7 cell line proliferation*

Because BMP-2 expression was down regulated during liver regeneration, we next attempted to determine whether BMP-2 was capable of modulating Huh7 cell proliferation. To this end, Huh7 cells were treated with increasing concentrations of rhBMP-2. MTT assay demonstrated that proliferation of Huh7 cells was dose dependently inhibited by rhBMP-2. A maximal inhibition of 38.8% ± 0.4% ($P < 0.01$) was observed at 100 ng/mL (Figure 3).

## DISCUSSION

Following partial hepatectomy, there is a rapid and highly orchestrated series of biochemical events that regulate hepatic regeneration. This is a complex process, which allows for a short period of rapid cellular proliferation but is subsequently followed by cell cycle arrest and cellular differentiation[14]. It has been shown that BMP signaling plays a critical role in hepatogenesis during endodermal patterning[6]. However, the role of BMPs in hepatic regeneration in the adult has not been studied.

The present study analyzed the expression of BMP-2 in normal rat liver. We studied the changes in BMP-2 expression during liver regeneration in the two-thirds hepatectomy model in rats. Immunohistochemical analysis showed that strong BMP-2 immunoreactivity was present in the cytoplasm of normal rat hepatocytes surrounding CV and PT. Both immunohistochemistry and Western blot analysis showed that BMP-2 declined significantly at 12 h after partial hepatectomy and returned to normal at 48 h. We showed that BMP-2 suppressed growth of Huh7 hepatoma cells *in vitro,* suggesting that BMP signaling negatively regulates hepatocyte proliferation. However, this *in vitro* observation needs further confirmation *in vivo* in a model of hepatocyte regeneration.

Our data remain descriptive but suggest that the role of signaling by BMP-2 may be distinct from that of TGF-$\beta_1$, another TGF-β family member that signals through a different receptor complex. TGF-$\beta_1$ is also an inhibitor of hepatocyte proliferation[16]; however, the normal liver expresses very low levels of TGF-$\beta_1$. Levels of TGF-$\beta_1$ expression increase rapidly after partial hepatectomy and peak at 12 h[17] exactly when the expression of BMP-2 is at its lowest. In mice with a liver specific deletion of TGF-β receptor type II, which is required for TGF-β signaling, increased hepatocyte proliferation and liver mass in response to partial hepatectomy was resulted[18], indicating that TGF-β signaling acts as a negative feedback loop in hepatic regeneration that keeps the mitogenic response in check. The dynamic expression of BMP-2 suggests a distinct role for this pathway. BMP-2 is readily detected in the normal liver and its expression rapidly declines after partial hepatectomy. This may suggest that BMP-2 signaling does not act in a negative feedback loop in hepatocyte regeneration but that instead, its down regulation may be necessary for the initiation of hepatocyte proliferation. Hepatocytes are the first to proliferate after partial hepatectomy. Hepatocyte proliferation started exactly in the area around the CV where BMP-2 expression was lost well before the onset of proliferation which peaked at 24 h[19].

In conclusion, both the localization and timing of expression of BMP-2 suggest that BMP-2 may be a negative regulator of hepatocyte proliferation that needs to be down regulated in order to allow the initiation of hepatocyte proliferation around the CV. Our data remain descriptive and interventional studies need to be performed to test this hypothesis.

## COMMENTS

### *Background*

The role of BMP signaling is not restricted to the bone. The liver, just as the bone, has remarkable regenerative potential which involves tightly regulated molecular mechanisms that control hepatic proliferation, differentiation and morphogenesis after the loss of hepatic tissue.

### *Research frontiers*

A hallmark of developmental biology is that similar pathways are involved in multiple different systems.

### *Innovations and breakthroughs*

We aimed to summarize and emphasize the differences, from other related or similar articles so that readers may catch up the major points of the article easily.

### *Peer review*

This study examines the role of BMP-2 in hepatocyte proliferation following PH and *in vitro* in a human hepatoma cell line. BMP-2 has been shown to play an important role in bone development and may also be important in liver development. The authors proposed that this cytokine may act as a growth inhibitor during liver regeneration. The study is overall well designed and potentially important.

## Abstract

**AIM:** To study the action of hepatitis virus infection-associated genes at transcription level during liver regeneration (LR).

**METHODS:** Hepatitis virus infection-associated genes were obtained by collecting the data from databases and retrieving the correlated articles, and their expression changes in the regenerating rat liver were detected with the rat genome 230 2.0 array.

**RESULTS:** Eighty-eight genes were found to be associated with liver regeneration. The number of genes initially and totally expressed during initial LR [0.5-4 h after partial hepatectomy (PH)], transition from G0 to G1 (4-6 h after PH), cell proliferation (6-66 h after PH), cell differentiation and reorganization of structure-function (66-168 h after PH) was 37, 8, 48, 3 and 37, 26, 80, 57, respectively, indicating that the genes were mainly triggered at the early stage of LR (0.5-4 h after PH), and worked at different phases. These genes were classified into 5 types according to their expression similarity, namely 37 up-regulated, 9 predominantly up-regulated, 34 down-regulated, 6 predominantly down-regulated and 2 up/down-regulated genes. Their total up- and down-regulation frequencies were 359 and 149 during LR, indicating that the expression of most genes was enhanced, while the expression of a small number of genes was attenuated during LR. According to time relevance, they were classified into 12 groups (0.5 and 1 h, 2 and 4 h, 6 h, 8 and 12 h, 16 and 96 h, 18 and 24 h, 30 and 42 h, 36 and 48 h, 54 and 60 h, 66 and 72 h, 120 and 144 h, 168 h), demonstrating that the cellular physiological and biochemical activities during LR were fluctuated. According to expression changes of the genes, their expression patterns were classified into 23 types, suggesting that the cellular physiological and biochemical activities during LR were diverse and complicated.

**CONCLUSION:** The anti-virus infection capacity of regenerating liver can be enhanced and 88 genes play an important role in LR.

**Key words:** Partial hepatectomy; Rat genome 230 2.0 array; Hepatitis virus infection; Genes associated with liver regeneration

## INTRODUCTION

The liver can regenerate and precisely regulate its size. Hepatocytes maintain the ability to proliferate in response to hepatectomy, liver damage caused by viruses or chemicals, liver cell death, *etc*[1,2]. The remaining liver may compensate for the lost hepatic tissue in which the growth situation of regenerating liver can be accurately detected, and liver regeneration (LR) may stop at a proper time point[3,4]. The regeneration process is usually categorized based on hepatic physiological biochemical activities into four stages: initiation [0.5-4 h after partial hepatectomy (PH)], transition from G0 to G1 (0.5-4 h after PH), cell proliferation (6-66 h after PH), cell redifferentiation and reorganization of the architecture-function (66-168 h after PH)[5]. In this process, the cellular physiological and biochemical activities and the gene expression situations have a very sweeping change.

Hepatitis viruses causing hepatic injury and liver diseases[6] include hepatitis A virus (HAV), hepatitis B virus (HBV), hepatitis C virus (HCV), hepatitis D virus (HDV) and hepatitis E virus (HEV)[7]. HAV and HEV do not result in chronic hepatic inflammation because of their self-limited infection, whereas HBV, HCV and HDV cause both acute and chronic hepatic inflammation, and finally

result in chronic hepatitis, cirrhosis or hepatoma[8-10]. In infection, viruses first bind specifically to receptors, then complete their replication cycle by many processes such as adsorbing, penetrating, shelling, biosynthesis, assembling and release. Viruses interact with cells, and alter the gene expression of host cells. The process during which the viruses are cleaned by the host immune system results in changes in physiology and pathology of the host[11,12]. It has been reported that liver tissues with hepatitis may appear inflammation, necrosis or hyperplasia, with which over 200 genes are associated[9,13].

Since hepatitis virus infection-associated genes have a wide variety of kinds and complicated functions, it is almost impossible to give insights into their action during liver regeneration at transcriptional level unless high-throughput gene expression profile analysis is performed[14-16]. Therefore, we used the rat genome 230 2.0 array containing 193 genes associated with hepatitis virus infection to detect the gene expression changes in the regenerating liver after 2/3 hepatectomy. A total of 88 genes were found to be associated with LR, and their expression changes, patterns and actions during liver regeneration were primarily analyzed.

## MATERIALS AND METHODS

### Regenerating liver preparation

Healthy SD rats weighing 200-250 g were obtained from the Animal Center of Henan Normal University. The rats were divided into groups at random, 6 rats in each group (Male: Female = 1:1). Partial hepatectomy (PH) was performed as previously described[17], the left and middle lobes of liver were removed. The rats were killed by cervical vertebra dislocation at 0.5, 1, 2, 4, 6, 8, 12, 16, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 96, 120, 144 and 168 h after PH and the regenerating livers were observed at corresponding time points. The livers were rinsed three times in PBS at 4℃, then 100-200 mg liver tissue was cut from the middle of right lobe. Six samples were taken from each group and mixed into 1-2 g (0.1-0.2 g × 6) liver tissue, then stored at -80℃. The sham-operation (SO) groups underwent the same PH without removal of the liver lobes. The animal protection laws in China were strictly followed.

### RNA isolation and purification

Total RNA was isolated from frozen livers according to the manual of Trizol kit (Invittrogen)[18] and then purified based on the guide of RNeasy mini kit (Qiagen)[19]. Total RNA sample was checked to exhibit a 2:1 ratio of 28S to 18S rRNA intensities by agarose electrophoresis (180V, 0.5 h). Total RNA concentration and purity were estimated by optical density measurements at 260/280 nm[20].

### cDNA, cRNA synthesis and purification

As a template, 1-8 μg total RNA was used for cDNA synthesis. cDNA and cRNA synthesis was carried out as previously described[21]. cRNA labeled with biotin was synthesized using 12 μL synthesized cDNA as a template, cDNA and cRNA were purifid[21]. Measurement of concentration, purity and quality of cDNA and cRNA was performed as previously reported[20].

### RNA fragmentation and microarray detection

Fifteen microliters (1 μg/μL) cRNA incubated with 5 × fragmentation buffer at 94℃ for 35 min was digested into 35-200 bp fragments. Rat genome 230 2.0 microarry produced by Affymetrix was prehybridized, then the hybridization buffer was centrifuged at 60 r/min for 16 h at 45℃. The microarray was washed and stained with GeneChip fluidics station 450 (Affymetrix Inc., USA). The chips were scanned by GeneChip scan 3000 (Affymetrix Inc., USA), and the signal values of gene expression were observed[22].

### Microarray data analysis

The normalized signal values, signal detections (P, A, M) and experiment/control (Ri) were obtained by quantifing and normalizing the signal values using GCOS1.2[22].

### Normalisation of microarray data

To minimize errors in the microarray analysis, each analysis was performed three times by rat genome 230 2.0 microarray. Results with a maximal total ratio ($R^m$) and the average of three housekeeping genes (β-actin, hexokinase and glyseraldehyde-3-phosphate dehydrogenase) approached to 1.0 ($R^h$) were taken as a reference. Modified data were generated by applying a correction factor ($R^m/R^h$) multiplying the ratio of every gene in $R^h$ at each time point. To remove spurious gene expression changes resulting from errors in the microarray analysis, the gene expression profiles at 0-4 h, 6-12 h and 12-24 h after PH were reorganized by normalization analysis program (NAP) software according to the cell cycle progression of regenerating hepatocytes. Data statistics and cluster analysis were done using GeneMath, GeneSpring, Microsoft Excel softwares[22-24].

### Identification of genes associated with liver regeneration

Firstly, the nomenclature of structure and activity of hepatitis virus (e.g. hepatitis B virus) were adopted from the NCBI (http://www.ncbi.nlm.nih.gov/) and GENEONTOLOGY database (www.geneontology.org/), and input into the databases at AmiGO (http://www.godatabase.org/), NCBI (www.ncbi.nlm.nih.gov/), RGD (rgd.mcw.edu/), MGI (http://www.informatics.jax.org/), UniProt (http://www.pir.uniprot.org/) to identify the rat, mouse and human genes associated with hepatitis virus infection. Then the genes associated with hepatitis virus infection were collated. The results of this analysis were codified, and compared with the results obtained for mouse and human searches in order to identify human genes which are different from those of rats. Compared these genes with the analysis output of the Rat Genome 230 2.0 array, those genes which showed a greater than twofold change in expression level, observed as meaningful expression changes[25], were referred to as rat homologous genes or rat specific genes associated with hepatitis virus infection. Genes, which displayed reproducible results with three independent analyses with the chip and showed a greater than twofold change in expression level in at least one time point during liver regeneration with significant difference ($0.01 \leqslant P < 0.05$) or extremely significant difference ($P$

$\leqslant$ 0.01) between PH and SO, were referred to as associated with liver regeneration.

## RESULTS

### *Expression changes of hepatitis virus infection-associated genes during LR*

According to the data from AmiGO, NCBI, RGD, MGI and UniProt databases, 204 genes were associated with hepatitis virus infection, and 193 of the above 204 genes were contained in rat genome 230 2.0 array. Among them, 88 genes revealed meaningful changes in expression at least at one time point after partial hepatectomy (PH), and showed significant or extreme significant differences in expression when compared with sham operation (SO), and were reproducible in three detections by rat genome 230 2.0 array, suggesting that the genes were associated with LR (Table 1). The analysis indicated that 37 genes were up regulated, 34 genes down-regulated, and 17 genes up/down-regulated during LR. Total expression frequencies of up- and down-regulated genes were 359 and 149, respectively (Figure 1A). The expression patterns varied with the phases in regenerating liver. At the initiation stage of LR (0.5-4 h after PH), 20 genes displayed up-regulation, 14 genes down-, 2 genes up/down-regulation; at the transition phase from G0 to G1 (4-6 h after PH), 15 genes revealed up-, 11 genes down-regulation; at cell proliferation phase (6-66 h after PH), 40 genes showed up-, 26 genes down-regulation, 12 genes up/down-regulation; at cell differentiation and structure-function reorganization stage (66-168 h after PH), 35 genes displayed up-, 17 genes down-, 5 genes up/down-regulation (Figure 1B).

### *Initial and total number of hepatitis virus infection-associated genes in expression at each time point of LR*

At each time point of LR, the number of initially up-, down-regulated and totally up-, down-regulated genes was 13 and 5 at 0.5 h; 6, 5 and 15, 7 at 1 h; 3, 2 and 13, 3 at 2 h; 0, 3 and 13, 6 at 4 h; 2, 3 and 13, 7 at 6 h; 0, 0 and 12, 4 at 8 h; 2, 1 and 16, 3 at 12 h; 8, 5 and 21, 7 at 16 h; 5, 9 and 24, 12 at 18 h; 0, 2 and 23, 11 at 24 h; 3, 0 and 13, 7 at 30 h; 0, 0 and 17, 9 at 36 h; 0, 0 and 14, 5 at 42 h; 3, 3 and 23, 11 at 48 h; 1, 1 and 20, 10 at 54 h; 0, 0 and 19, 7 at 60 h; 0, 0 and 21, 4 at 66 h; 0, 0 and 13, 5 at 72 h; 0, 2 and 13, 10 at 96 h; 1, 0 and 15, 3 at 120 h; 0, 0 and 14, 6 at 144 h; 0, 0 and 14, 7 at 168 h (Figure 2).

### *Expression similarity and time relevance of hepatitis virus infection-associated genes during LR*

A total of 88 genes during LR could be divided into as following: 37 up-regulated, 9 predominantly up-regulated, 34 down-regulated, 6 predominantly down-regulated, and 2 up/down-regulated genes based on their similarity in expression (Figure 3). These 88 genes during liver regeneration could also be classified based on time relevance into 12 groups (0.5 and 1 h, 2 and 4 h, 6 h, 8 and 12 h, 16 and 96 h, 18 and 24 h, 30 and 42 h, 36 and 48 h, 54 and 60 h, 66 and 72 h, 120 and 144 h, 168 h) in which the number

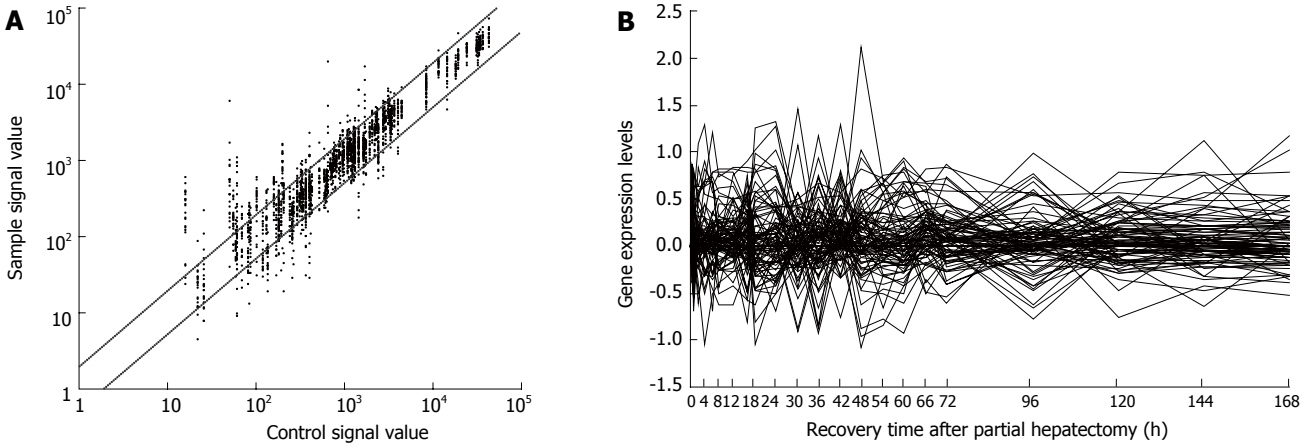

**Figure 1** Expression files of 88 hepatitis virus infection-associated genes in rat liver regeneration. **A**: The abundance and frequency of gene expression, each point represents the signal value of one gene at the corresponding time point. The dots above bias indicate that the genes are more than two-fold up-expressed, the dots under bias indicate that the genes are more than two-fold down-expressed, and the dots between biases indicate that the genes have no alteration in expression. The more far genes are from the bias, the longer the time the greater the gene change; **B**: Expression changes in genes associated with LR.

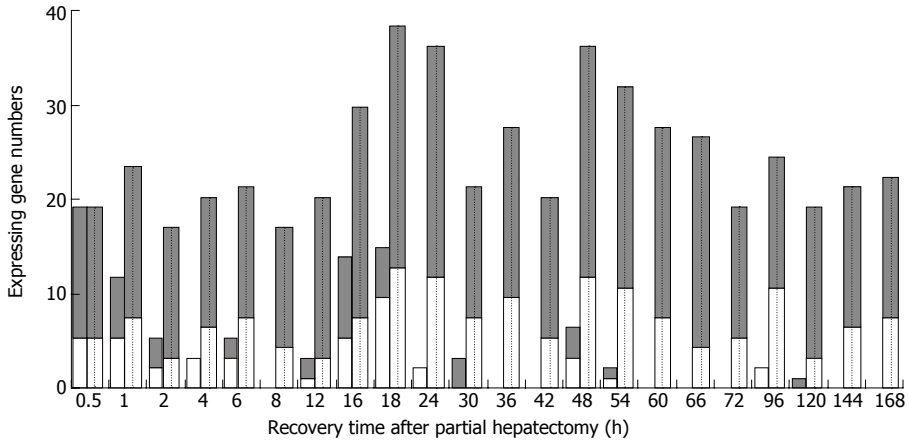

**Figure 2** The initial and total expression profiles of 88 hepatitis virus infection-associated genes at each time point of liver regeneration. Blank bars: the number of initially expressed genes; Dotted bars: the number of totally expressed genes; Grey bars: up-regulated genes; White bars: down-regulated genes.

of up- and down-regulated genes was 28 and 12, 26 and 9, 13 and 7, 28 and 7, 34 and 17, 47 and 23, 27 and 12, 40 and 20, 39 and 17, 34 and 9, 29 and 9, 14 and 7 (Figure 3).

### *Expression patterns of hepatitis virus infection-associated genes during LR*

The expression patterns of 88 genes during liver regeneration might be categorized into 23 types according to the expression changes: (1) up-regulated expression at one time point, i.e. 30, 48, 120 h after PH (Figure 4A-C and E) with 4 genes involved; (2) up-regulated expression at two time points, i.e. 30 and 42 h, 16 and 42 h, 16 and 96 h, 18 and 54 h (Figure 4A and B) with 4 genes involved; (3) up-regulated expression at multiple time points (Figure 4A and B) with 5 genes involved; (4) up-regulated expression at one phase, i.e. 1-168 h, 16-96 h (Figure 4B and E) with 2 genes involved; (5) up-regulation expression at two phases, i.e. 16-24 and 42-48 h (Figure 4B) with 1 gene involved; (6) up-regulated expression at multiple phases (Figure 4E) with 1 gene involved; (7) up-regulated expression at one time point/one phase, i.e. 54 and 144-168 h (Figure 4C) with 1 gene involved; (8) up-regulated expression at one time point/two phases (Figure 4B-D) with 4 genes involved; (9) up-regulated expression at one time point/multiple phases (Figure 4E and J) with 2 genes involved; (10) up-regulated expression at two time points/one phase (Figure 4B, D and E) with 3 genes involved; (11) up-regulated expression at two time points/two phases (Figure 4B and D) with 2 genes involved; (12) up-regulated expression at two time points/multiple phases (Figure 4B, D and E) with 3 genes involved; (13) up-regulated expression at multiple time points/one phase (Figure 4A and C) with 2 genes involved; (14) up-regulated expression at multiple time points/two phases (Figure 4C, D and E) with 3 genes involved; (15) down-regulated expression at one time point, i.e. 2, 4, 6, 16, 18, 24, 48 , 96h (Figure 4F, G and H) with 14 genes involved; (16) down-regulated expression at two time points, i.e. 0.5 and 4 h, 16 and 96 h, 18 and 54 h (Figure 4G, H and I) with 3 genes involved; (17) down-regulated expression at multiple time points (Figure 4G, H and I) with 6 genes involved; (18) down-regulated expression at one phase, i.e. 4-6 h, 18-24 h, 54-60 h (Figure 4G and H) with 3 genes involved; (19) down-regulated expression at one time point and one phase, i.e. 1 and 144-168 h, 48 and 18-24 h, 30 and 2-8 h (Figure 4H, I and J) with 3 genes involved; (20) down-regulated expression at one time point/two phases (Figure 4I) with 1 gene involved; (21) down-regulated expression at two time points/one phase

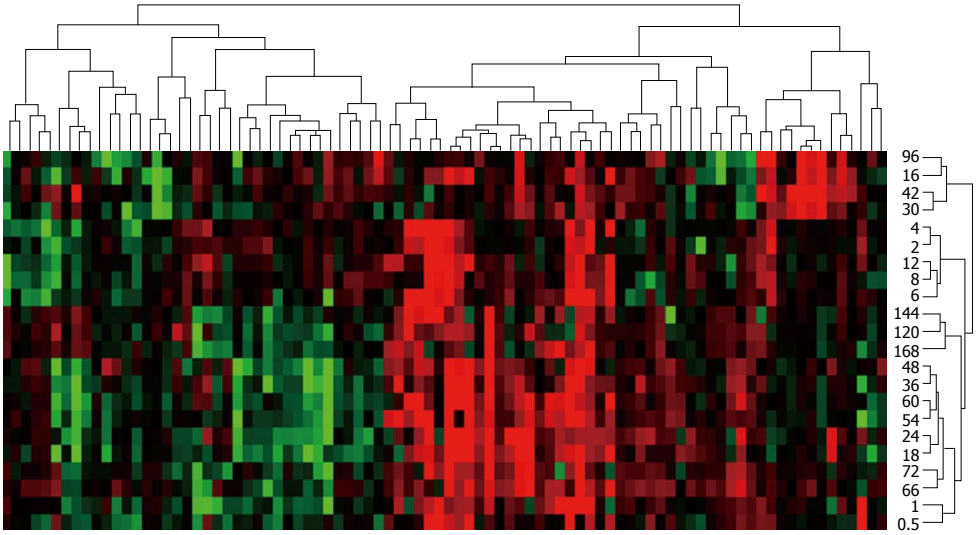

**Figure 3** Expression and time series clusters of 88 hepatitis virus infection-associated genes during liver regeneration. Detection data of rat genome 230 2.0 array were analyzed by H-clustering. (Figure 4I) with 1 gene involved; (22) down-regulated expression at two time points/two phases (Figure 4I) with 3 genes involved; (23) up/down-regulated expression (Figure 4B, H and J) with 17 genes involved.

## DISCUSSION

The role of 193 genes associated with hepatitis virus infection in liver regeneration was studied in this study. Among the 45 genes associated with hepatitis virus life cycle and virion, peptidylprolyl isomerase A (PPIA), nuclear pore associated protein (NPAP60) and opioid receptor kappa 1 (OPRκ1) are involved in viral infection[26]. Eight genes, including chemokine ligand 2 (CCL2), WW domain containing E3 ubiquitin protein ligase 1 (WWP1), chemokine ligand 3 (CCL3), C-terminal binding protein 2 (CTBP2), cathepsin E (CTSE), TNFAIP3 interacting protein 1 (TNIP1), upstream binding protein 1 (UBP1) and heterogeneous nuclear ribonucleoproteins methyltransferase-like 2 (HRMT1L2), participate in the viral genome replication and transcription[27,28]. Hbx interacting protein (HBXIP) suppresses HBV X protein activity[29]. ATP-binding cassette sub-family E member 1 (ABCE1) plays a part in viral capsid assembly[30]. Homeodomain interacting protein kinase 2 (HIPK2) relates to induction of apoptosis[31]. Growth factor independent 1 (GFI1) controls the differentiation of dendritic cells into macrophages[32]. The above genes tend to have a same or similar expression at some time points, but a different expression at other time points which may enhance inflammatory reaction and immunity of regenerating liver.

Of the 65 genes associated with hepatitis B virus infection, forkhead box A2 (FOXA2), interleukin 4 (IL4) and transcription factor 1 (TCF1) may restrain HBV gene replication and RNA transcription[33,34], whereas regulatory factor X 1 (RFX1) promotes RNA transcription by binding to HBV enhancer[35]. Tissue inhibitor of metalloproteinases 1, 3 (TIMP1, TIMP3) exhibits low level expression after HBV transinfection[36], but matrix metallopeptidase 9 (MMP9) displays high activity after HBV transinfection[36]. Interferon gamma (IFNγ) supresses hepatic cell proliferation[37]. CAMP responsive element binding protein 1 (CREB1), nuclear respiratory factor 1 (NRF1) and hepatocyte nuclear factor 4 alpha (HNF4α) activate HBV promoter[34,38,39]. Nine genes, such as early growth response 2 (EGR2), proliferating cell nuclear antigen (PCNA), tumor suppressor p53 (TP53), serpin peptidase inhibitor clade B member 3 (SERPINB3), prostaglandin-endoperoxide synthase 2 (PTGS2), SHC transforming protein 1 (SHC1), interleukin enhancer binding factor 3 (ILF3), nuclear factor of kappa light chain gene enhancer in B-cells 1 (NFκB1) and mitogen-activated protein kinase 8 (MAPK8), accelerate cell proliferation[40-45]. Tumor necrosis factor (TNF) and estrogen receptor 1 (ESR1) increase cell susceptibility to HBV infection[46,47]. 70kDa heat shock protein 5 (HSPA5) plays a role in anti-apoptosis[48]. Protein tyrosine kinase 2 beta (PTK2β) promotes migration and invasion of glioblastoma[49]. Exportin 1 (XPO1) takes part in HBV-induced aberrant centriole replication and abnormal mitotic spindles[50]. Mannose binding lectin 2 (MBL2) participates in HBV infection[51]. Interleukin 1 beta (IL1β) may enhance resistance to chronic diseases[52]. Interleukin 1 receptor type I (IL1R1) elevates blood-brain barrier[53]. Damage specific DNA binding protein 2 (DDB2) promotes turnover of HBV X protein[54]. Nuclear receptor subfamily 4 group A member 1 (NR4A1) enhances role of the HBx-induced Fas/FasL signaling pathway[55]. The above genes may have same or similar expression changes at some time points, but different expression changes at other time points, suggesting that they promote inflammation recovery and strengthen anti-hepatitis B virus infection ability.

Among the 90 genes associated with hepatitis C virus infection, Three genes concluding polypyrimidine-tract binding protein 2 (PTBP2), mitogen-activated protein kinase 1 (MAPK1) and interferon alpha 1 (IFNα1) play a role in suppression of hepatitis C virus replication[56-58]. Nucleolar and coiled-body phosphoprotein 1 (NOLC1), transporter 1 ATP-binding cassette sub-family B (TAP1) and eukaryotic translation initiation factor 4A1 (EIF4A1) promote protein biosynthesis[59]. Six genes including toll-like receptor (TLR2), transforming growth factor beta 1 (TGFβ1), tyrosine 3-monooxygenase/tryptophan 5-monooxygenase activation protein zeta (YWHAζ),

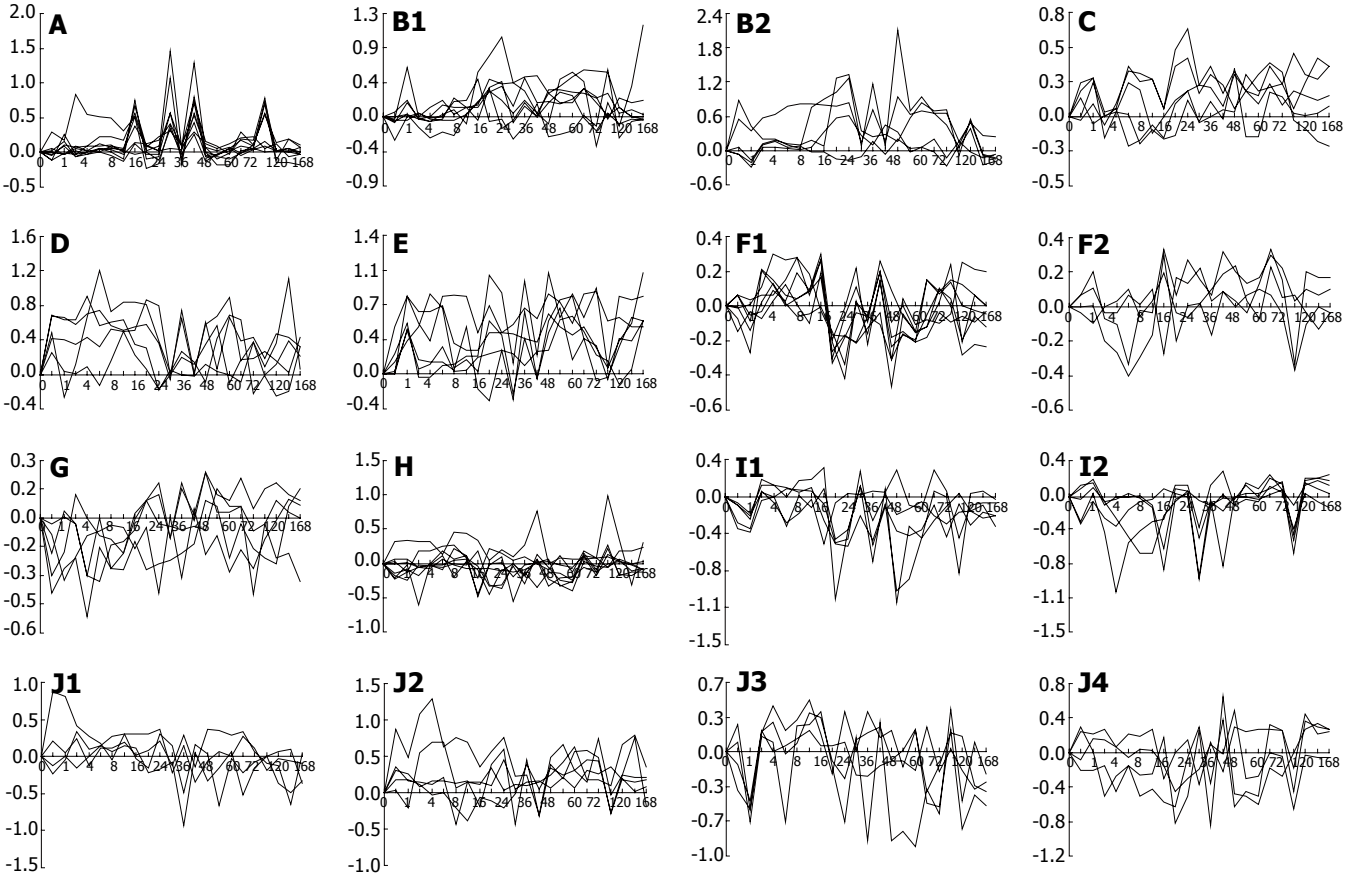

**Figure 4** Expression patterns of 88 hepatitis virus infection-associated genes during liver regeneration. Expression patterns of these genes exhibit 23 types. **A-E**: up-regulated expression; **F-I**: down-regulated expression; **J**: up/down-regulated expression. X-axis represents recovery time after PH (h), Y-axis shows logarithm ratio of the signal values of genes at each time point to control.

vasoactive intestinal peptide receptor 1 (VIPR1), cytochrome P450 family 2 subfamily D polypeptide 6 (CYP2D6) and lymphotoxin B receptor (LTBR), are related to immune reponse[60,61]. VAMP-associated protein A (VAPA) accelerates HCV replication[62]. Nuclear factor of kappa light chain gene enhancer in B-cell inhibitor beta (NFκBIβ) and E2F transcription factor 1 (E2F1) have transcriptional activator activity[63]. Inhibitor of kappaB kinase beta (IKκBKβ) inhibits activation of NFκB. Small nuclear ribonucleoprotein D1 (SNRPD1) and serine peptidase inhibitor clade F member 2 (SERPINF2) can repair liver damage[64,65]. Paired-like homeodomain transcription factor 1 (PITX1) modulates interferon expression[66]. Genetic polymorphisms of cytochrome P450 family 17 subfamily alpha polypeptide 1 (CYP17α1) and epoxide hydrolase 1 (EPHX1) are closely associated with liver disease[67,68]. Four genes containing interferon regulatory factor 1 (IRF1), phosphatase and tensin homolog (PTEN), myelin basic protein (MBP) and DEAD box polypeptide 3 X-linked (DDX3X) are associated with regulation of liver disease[69-72]. Apolipoprotein E (APOE) has a role in liver protection[73]. Retinoblastoma 1 (RB1) and caspase 8 (CASP8) inhibit cell growth[74,75]. Wingless-type MMTV integration site family member 1 (WNT1) can inhibit cell apoptosis[76]. B-cell leukemia/lymphoma 2 (BCL2) is associated with infectious vasculitis[77]. Histocompatibility antigen 13 (HM13) is responsible for immunological recognition[78]. HM13 is highly expressed in human liver HL-7702 cells as HCV NS3-transactivated protein 1 (RGD1306332)[79]. DNA fragmentation factor alpha subunit (DFFα) plays a role in suppressing tumors[80]. The above genes may have the same or similar expression changes at some time points, different expression changes at other time points, thus promoting inflammatory reaction and anti-infection ability of regenerating liver.

In summary, the expression changes of hepatitis virus infection-associated genes after rat partial hepatectomy can be analyzed with high-throughput gene expression profiling. Immunological competence, abilities of anti-inflammation and anti-infection are increased during liver regeneration. Rat genome 230 2.0 array is a useful tool for analyzing hepatitis virus infection and liver disease at transcriptional level. However, DNA→ mRNA→protein is affected by many factors including protein interaction. Further study is needed to confirm the results at cell level.

## Abstract

**AIM:** To study the possible causes of sorbitol (S)-based diarrhea and its mechanism of reduction by rice gruel (RG) in cecectomized rats.

**METHODS:** S was dissolved either in distilled water or in RG (50 g/L) and ingested as a single oral dose (1.2 g/kg body mass, containing 0.5 g/L phenol red as a recovery marker) by S (control) and S + RG groups ($n$ = 7), respectively. This dose is over the laxative dose for humans. Animals were sacrificed exactly 1 h after dose ingestion, without any access to drinking water. The whole gastro-intestinal tract was divided into seven segments and sampled to analyze the S and marker remaining in its contents.

**RESULTS:** Gastric-emptying and intestinal transit were comparatively slower in the S + RG group. Also, the S absorption index in the 3rd and last quarter of the small intestine (24.85 ± 18.88% *vs* 0.0 ± 0.0% and 39.09 ± 32.75% *vs* 0.0 ± 0.0%, respectively, $P < 0.05$) was significantly higher in the S + RG group than in the control group. The S absorption index and the intestinal fluid volume are inversely related to each other.

**CONCLUSION:** The intestinal mal-absorption of S is the main reason for S-based osmotic diarrhea. Where RG enhanced the absorption of S through passive diffusion, the degree of diarrhea was reduced in cecectomized rats.

**Key words:** Cecectomized rat; Sorbitol; Diarrhea; Rice gruel; Phenol red

## INTRODUCTION

Sugar alcohols are widely used as sugar-substitute sweeteners in the food industry, especially in candy, chewing gum, dietetics and diabetic foods, for their lower calorific value and various beneficial effects on health. Among the many sugar alcohols, sorbitol (S) is chosen most often because of its functional, nutritional, and disease-preventative effects impacting positively on health. However, higher dose or over-intake of S causes bloating, flatulence, cramping, abdominal pain and diarrhea both in adults[1] and in children[2]. As the laxative threshold of S varies from person to person, the actual cause of S-based gastrointestinal complications is still unclear. Several possible and dissimilar causes have been previously indicated by a number of investigators[3-7], although most of them reported that diarrhea was caused by increasing colonic osmolality when higher doses were consumed. Soergel reported that indigestible carbohydrate-induced diarrhea occurs when the amount of carbohydrate entering the colon exceeds its fermentation capacity[3]. In another report, it was stated that intestinal mal-absorption is the main reason for diarrhea[4]. Read *et al*[5] reported that the tendency for diarrhea in response to a meal containing un-absorbable carbohydrate depends more on the lack of colonic accommodation than on the small intestinal transit. Short chain fatty acids (SCFAs), the fermentation product of sugar alcohol, were reported to decrease intestinal or colonic water absorption, resulting in diarrhea[6]. Some other investigators found higher lactic and succinic acid levels during diarrhea in the colon of cecectomized rats[7] and in pig feces[8], and thought that the above fermentation products may increase the colonic osmolality to cause diarrhea. Although higher colonic osmolality and lower fluid absorption from the colon are indicated in the above studies as the main reasons for indigestible or fermentable material-based diarrhea, the actual cause of the induction of large gut osmolality is a matter of controversy.

The major difference between the digestive physiology of the rat and humans is that the rat has a large voluminous cecum, whereas humans have no distinct cecum. The cecum in rat acts as an important reservoir and fermentation site especially for indigestible and fermentable materials. Recently, we reported that the digestive physiology of cecectomized rats is more analogous to humans than to normal rats[7]. It was also proposed that the cecectomized rat could be a useful experimental tool to study the physiological effects of indigestible or fermentable materials in humans. In

another study[9], we found that rice gruel (RG), a source of rice starch, significantly reduced the degree of S-based diarrhea in cecectomized rats. In the report of that study, we hypothesized that in the presence of the extra glucose from rice gruel, the influx of S across the luminal membrane increased significantly[10]. This may enhance the small intestinal absorption of S in the presence of the extra glucose released from RG, and only a small amount of S is transported to the colon from the small intestine for fermentation[9]. By the above proposed mechanisms, the colonic organic acid concentration as well as the osmolality was decreased and hard feces were formed in the mid to distal colon of the cecectomized rats. As a result, the degree of diarrhea was reduced in these rats[9].

The present study was undertaken to further examine our above hypothesis that small intestinal mal-absorption, or perhaps rather inadequate fermentation of S or mal-absorption of S fermentation products, is responsible for increasing the colonic osmolality as well as the occurring osmotic diarrhea, and to examine the mechanisms involved in reducing the degree of S-based diarrhea by RG in cecectomized rats.

## MATERIALS AND METHODS

### Animals

Three week-old male juvenile Wistar rats (50.3 ± 3.55 g body mass, Nippon SLC, Hamamatsu, Japan) were housed identically as reported in our previous study[7]. Animals were allowed free access to a diet of commercial pellets (Labo MR Stock, Nihon Nosan Kogyo K.K. Ltd., Tsukuba, Japan) and drinking water for the initial 3 wk, in their acclimatization period. After this period, when the mean body mass of the animals was 184.23 ± 12.85 g, cecectomy of all animals was performed according to our previous report[7]. After a 2 wk recovery period with free access to the commercial pellets and drinking water, animals were randomly divided into two subgroups of 7 animals each as the S (control) and S + RG groups with a similar mean body mass in each group (314.6 ± 8.94 g). They were fasted overnight (16 h) with free access to drinking water only, and then experimental diets were provided as a single bolus by gastric intubations. Animals were maintained according to the rules and regulations of the animal experiments committee of Okayama University.

### Rice gruel preparation

Rice gruel (50 g/L) was prepared according to the procedures described in our previous report[9]. Briefly, 100 g *japonica* rice (*Oryza sativa* L.) was soaked in 200-250 mL of distilled water for about 1 h, and blended until reaching a dense milky appearance. The volume of blended rice was made up to 2.2 L with distilled water and boiled over a gas burner with continuous stirring until the final volume was 2 L.

### Feeding and sampling

For a single oral dose, animals were lightly anesthetized with diethyl ether then S (90 g/L) (Sorbitol, Nacalai Tesque Inc., Kyoto, Japan; Lot no. M3G8055) was dissolved either in distilled water or in RG and ingested as a single oral dose (1.2 g/kg b.w., containing 0.5 g/L phenol red as a recovery marker) to the S (control) and S + RG groups ($n$ = 7) respectively. This dose is over the laxative dose for humans. Animals were sacrificed by diethyl ether anesthesia exactly 1 h after dose administration, without any access to drinking water[11]. The whole gastro-intestinal tract was removed as quickly as possible and frozen in dry-ice-acetone to prevent the movement of gastro-intestinal contents, and immediately preserved at -30℃ for subsequent analysis.

### Analytical methods

The frozen gastrointestinal tract was defrosted over the ice bag, weighed and subdivided into the stomach, small intestine (1st, 2nd, 3rd and last quarter), the proximal half and the distal half of the colon. The contents of each segment were separately collected, homogenized and centrifuged according to the procedures described by Soontornchai *et al*[12]. The mass of the contents of each gastrointestinal segment was calculated from the mass of tissue with and without contents. The collected supernatants were analyzed colorimetrically (UV 1200, Shimadzu Corporation, Kyoto, Japan) for phenol red with bile acid correction[13]. For S analysis, supernatants were deproteinized, derivatized and analyzed by HPLC (Stainless steel column: Inertsil ODS-80A 150 mm × 4.6 mm i.d., Dectector: Shimadzu SPD-10A UV-VIS, Shimadzu Corporation, Kyoto, Japan) methods as described by Miwa *et al*[14]. For maximum recovery of phenol red from gut segments, the tissue of each segment was thoroughly homogenized in 5 mL physiological saline with a rotary stainless steel homogenizer in a centrifuge tube, and centrifuged at 45000 × $g$ at 4℃ for 15 min (Himac-GX series: Himac CS 100GX micro ultra centrifuge, Hitachi Ltd., Tokyo, Japan). The collected supernatants were treated similarly for measurement of phenol red.

### Calculations

The gastric emptying, intestinal transit, and S absorption indexes for each segment of intestine were calculated by the following equations, which were slightly modified from those of Reynell and Spray[11].

Gastric emptying (%) =

$$\frac{\textit{Total phenol red recovered from the int estinal tract}}{\textit{Total phenol red recovered from whole gastro int estinal tract}} \times 100$$

Intestinal transit from the 1st to the last quarter of the small intestine and the proximal colon of the large intestine was calculated by the following formula.

Digesta transit in a certain quarter or part of the intestine (%) = $\frac{a}{b} \times 100$

Where, "a" is the amount of phenol red recovered from the 1st quarter of the small intestine to the distal colon excluding the amount of phenol red recovered from that respective quarter or the part of colon, and "b" is the total amount of recovered phenol red from that respective quarter to distal colon.

The S absorption index in a certain quarter of the small intestine and in the proximal and distal colon was calculated by the following formula.

Sorbitol absorption index (%) = $\left(1 - \frac{a/b}{c/d}\right) \times 100$

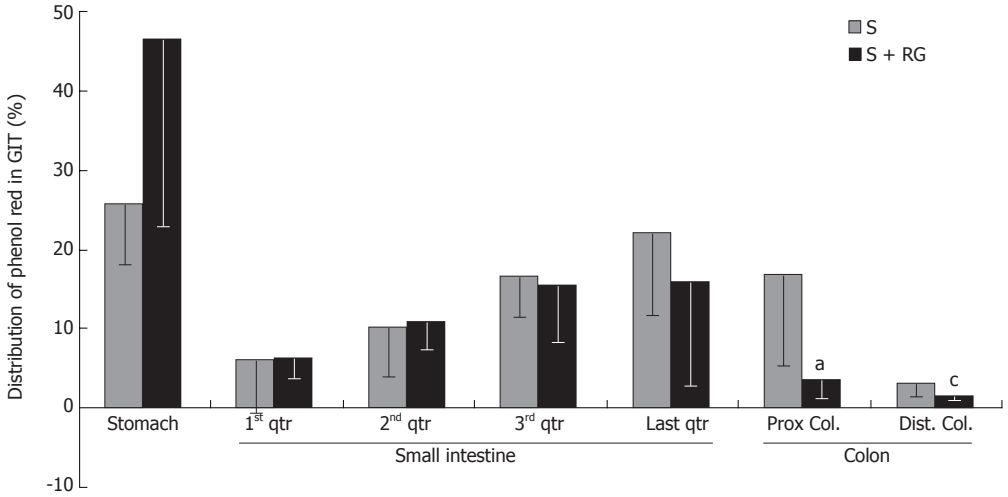

**Figure 1** Distribution of marker (phenol red) in the different segments of the gastrointestinal tract 1 h after the dose ingestion. $^{a}P = 0.035$, $^{c}P = 0.045$ *vs* S group.

**Table 1 Transit of the marker (phenol red) in the different segments of the intestinal tract during 1 h after the dose ingestion (mean ± SD)**

| Group | Small intestine | | | | Colon |
|---|---|---|---|---|---|
| | 1st quarter | 2nd quarter | 3rd quarter | Last quarter | Proximal |
| Sorbitol (%) | 91.94 ± 8.74 | 84.56 ± 10.2 | 69.66 ± 15.42 | 44.22 ± 19.68 | 2.48 ± 2.09 |
| S + RG (%) | 87.40 ± 9.05 | 76.39 ± 10.4 | 56.97 ± 16.04 | 36.48 ± 17.96 | 3.07 ± 2.27 |

Values indicate the amount of marker (phenol red) passing into the following segments, as a percentage of the total marker that entered that particular segment.

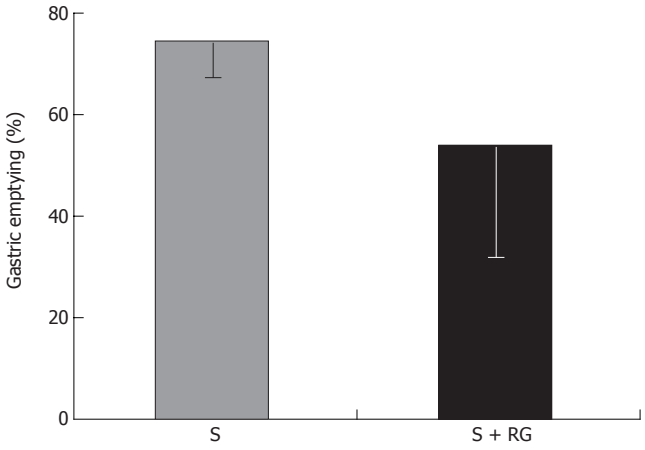

**Figure 2** Gastric emptying 1 h after the dose ingestion.

Where, "a" is the total amount of S recovered from that respective segment and "b" is the total amount of phenol recovered from the same segment of the small intestine; "c" and "d" are the amount of S and phenol red injected into corresponding animal, respectively. Put simply, the value of the S absorption index (%) for a certain segment means the percentage of total S passing through that segment that was absorbed.

### *Statistical analysis*

Data are presented as means and standard deviations for 7 animals. Statistical analyses were performed between control (S) and S + RG groups by the Tukey-Kramer's test using statistical software (Statview, Version 5.0, SAS Institute Inc., USA). Significance of difference was considered to be at $P < 0.05$.

## RESULTS

Phenol red was used as a recovery marker to measure the gastric emptying, intestinal transit, and intestinal S absorption index in this experiment. The mean recovery of the phenol red from the gastrointestinal tract was 93.8% ± 1.56% of the given amount. A very small amount of phenol red was detected in the distal colon (Figure 1) and no feces were defecated in either group during the 1 h period after the dose. Although the marker concentration did not vary significantly (data not shown) between the groups for different volumes of intestinal fluid, the distribution of marker from the stomach to the different segments of the intestine showed that the marker concentration was relatively lower in the distal part of the small intestine, and was significantly lower in the proximal (3.54% ± 2.47% *vs* 16.77% ± 11.48%, $P = 0.035$) and distal (1.38% ± 0.38% *vs* 3.07% ± 1.55%, $P = 0.045$) colon for the S + RG group relative to the S group (Figure 1). The concentration of marker in the stomach of the S + RG group was comparatively higher (46.29% ± 23.33% *vs* 25.69% ± 7.54%, $P = 0.097$) than for the S group (Figure 1) due to slower (53.78% ± 22.02% *vs* 74.3% ± 7.12%, $P = 0.098$) gastric emptying (Figure 2). As a result of the slower gastric emptying, a smaller amount of marker was delivered to the small intestine and onward at a given time in the S + RG fed group compared to the S group. For the same reason, digesta transit in the different segments of the gastrointestinal tract was relatively slower in the S + RG group than in the S-only group (Table 1).

The index for S absorption in the distal part (3rd and last quarters) of the gastrointestinal tract was greatly modified by the addition of RG to the S (Figure 3). Although the S absorption index was relatively lower in the 1st quarter of the small intestine for the S + RG group, it gradually increased from the 3rd to the last quarter of small intestine,

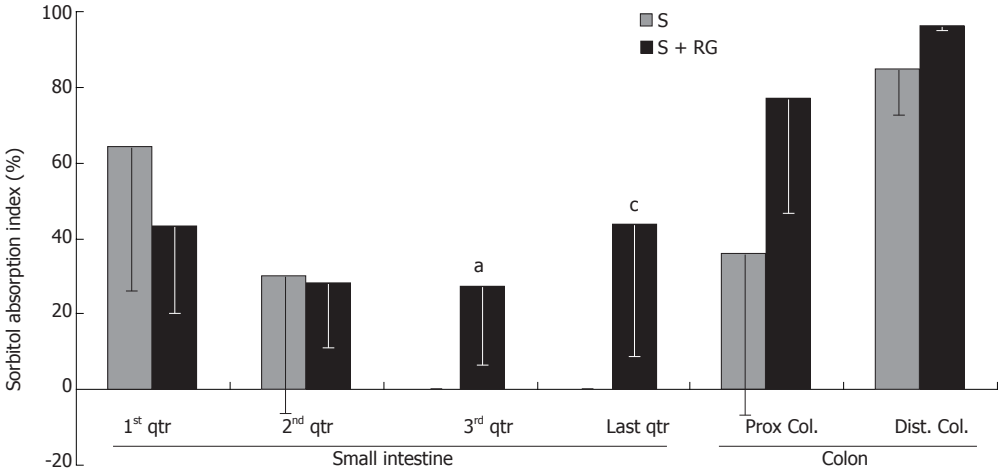

**Figure 3** Sorbitol absorption index in the different segments of the intestinal tract during the 1 h period after dose ingestion. $^{a}P = 0.016$, $^{c}P = 0.023$ *vs* S group.

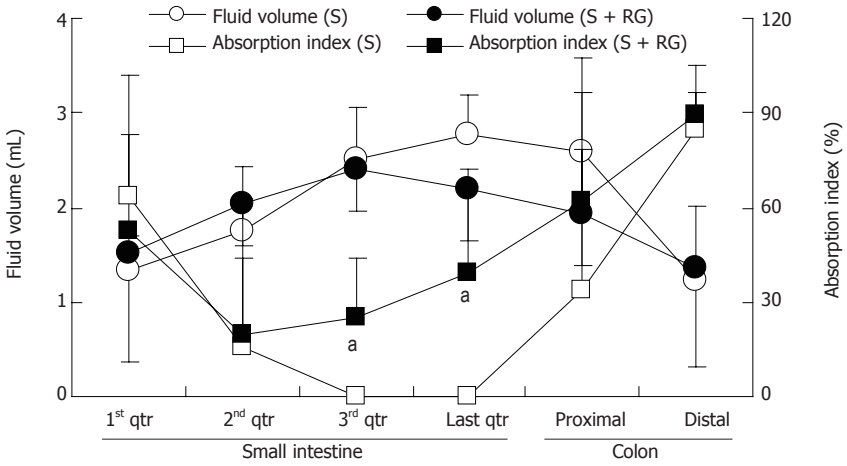

**Figure 4** Relationship between the intestinal fluid volume and sorbitol absorption index of S and S + RG ingestion groups. One gram of intestinal contents was considered as 1 mL for the calculation of the volume of intestinal fluid. $^{a}P < 0.05$ *vs* S group.

and to the distal part of the colon. Significant differences were found at the 3rd and last quarters of the small intestine (24.85% ± 18.88% *vs* 0.0 ± 0.0% and 39.09% ± 32.75% *vs* 0.0 ± 0.0%, respectively, $P < 0.05$) when compared to the S group. It was noted that the absorption index in these two segments for the S group was zero.

The relationship between the intestinal fluid volume and the S absorption index was inversely proportional for both the S and S + RG groups (Figure 4). In other words, the lower the fluid volume, the higher the absorption index of S, in both groups. The linear correlations between the S absorption index and the intestinal fluid volume for the different segments of the small intestine and colon are presented in Figure 5. From these correlations, although the S absorption index was significantly ($P = 0.006$) higher for the S group than the S + RG group in the first quarter of the small intestine, significant but inverse results were observed from the 2nd and last quarters of the small intestine and in the proximal colon of the large intestine ($P = 0.056$, 0.0085, 0.025, respectively). In addition, the overall S absorption index in the whole intestine was significantly ($P < 0.0001$) higher for the S + RG group than for the S group (Figure 5).

## DISCUSSION

When a moderate amount of S (up to 30 g) is taken by a human, a very small amount of it is slowly absorbed in the small intestine through passive diffusion, while most enters into the colon for bacterial fermentation to produce various short chain fatty acids (SCFAs), and less than 10% of the ingested amount is excreted in the feces[15,16]. Higher concentrations of SCFAs, especially succinic and lactic acid, in the colon are responsible for increased colonic osmolality and cause osmotic diarrhea in cecectomized rats[7,9] and pigs[8]. It was reported that ingestion of 30-50 g of S (500-800 mg/kg b.w.) caused diarrhea in adult humans[17,18]. In this study, a non-physiological high and osmotically-active single oral dose of S (1200 mg/kg b.w.) was ingested to study the effects of RG on intestinal absorption of S. This is also more than the laxative threshold dose of S for humans (500-800 mg/kg).

A non-absorbable water-soluble recovery marker (phenol red) was used in this study to precisely measure the gastric emptying, intestinal transit and intestinal absorption indexes of S. It has been reported that there may be some binding of phenol red by the stomach tissue, even if the rat is killed within seconds of intubation[11]. Therefore, the phenol red was extracted from both the gastrointestinal contents and their respective tissues for measurement in this experiment, and a substantial amount of marker was recovered from the gut tissues (13.86% ± 4.62% of the total recovery).

The total recovery of the marker was 93.8% ± 1.56% of the given amount. Urine was not sampled for determination of the concentration of either S or for phenol red,

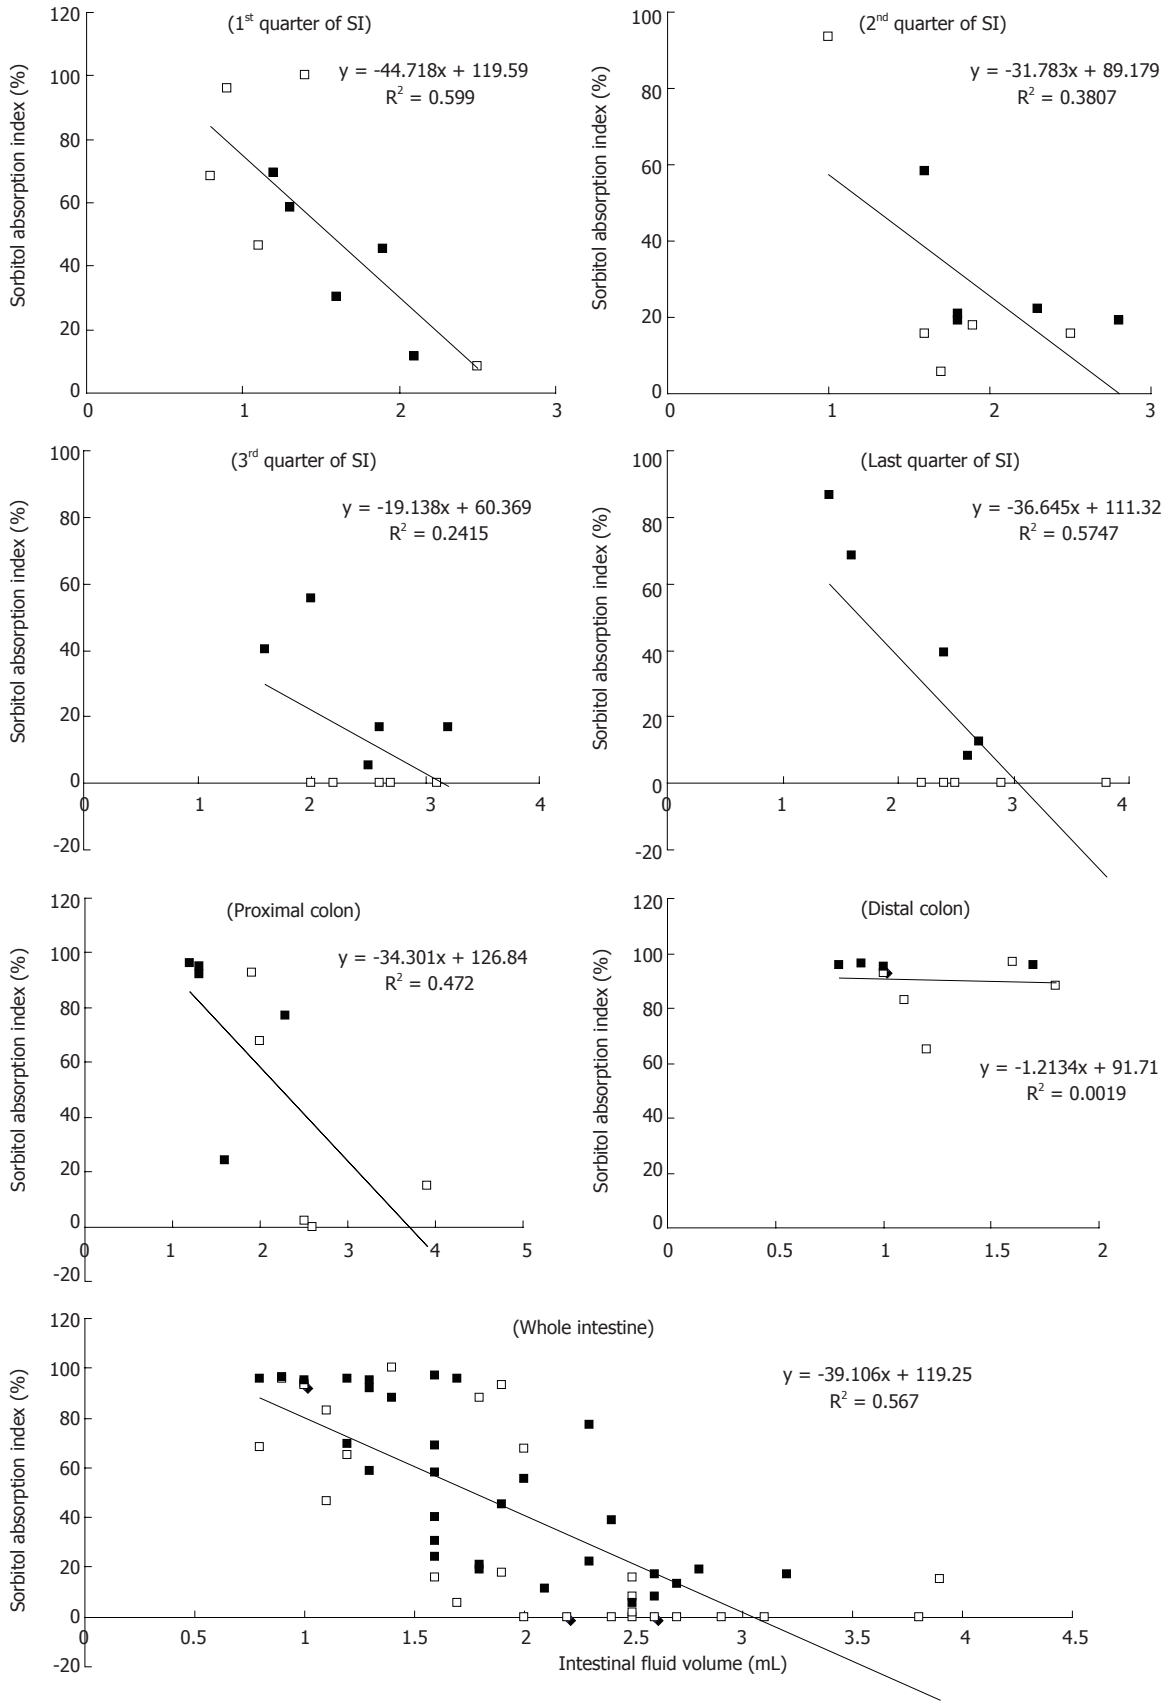

**Figure 5** Correlation between the sorbitol absorption index (Y axis) and intestinal fluid volume (X axis) of S (□) and S + RG (■) groups in the different segments of the small intestine (SI), colon, and whole intestine. The *P* values indicate significant differences in the 1st quarter ($P = 0.0064$), 2nd quarter ($P = 0.056$), last quarter ($P = 0.0085$) of the small intestine; proximal colon of large intestine ($P = 0.0259$); and for the whole intestine ($P < 0.0001$) when S and S + RG groups are compared.

as it is a non-absorbable marker and a very trace amount only can be detected in the urine[11]. The excretion of S in the urine is also only of trace amounts, either with a low or high single oral dose[19].

The determination of the concentration of S along with a non-absorbable marker in the different parts of the digestive tract after a single bolus dose with or without RG is an important investigation that may clarify the effects

of RG on S absorption in the small intestine. In a recent study, Islam *et al*[9] reported that intestinal transit and mean retention time of S are relatively longer when S is fed with RG rather than alone. From the present experiment, it was confirmed that slower gastric emptying (Figure 2) in the S + RG group compared to the S group caused slower digesta transit in the different segments of the gastrointestinal tract.

Rice starch (RS) contained in RG is a bulk aggregation ($n$ = 20-60) of smaller granules (3-8 μm in diameter) than in corn starch (5-15 μm in diameter), and is larger in size (0.99 kg/L) and denser in structure than corn starch (0.63 kg/L)[20]; it was found to be degraded slowly by pancreatic amylase and gradually released oligosaccharides and glucose at a slower rate in the intestinal brush border than corn starch[21]. Therefore, the rate of intestinal transit of S was relatively slower when ingested with RG, rather than alone. After consumption of S, a shorter orocecal transit time has been reported as a cause of S intolerance in a human-based study[22]. The slower gastric emptying and slower intestinal transit may result in maintenance of a constant normal osmotic environment in the inner intestinal lumen and facilitation of S absorption to prevent osmotic diarrhea in cecectomized rats[9]. In addition, slower gastric emptying and slower intestinal transit increases small intestinal mineral absorption in rats[23]. The energy value of sugar alcohols also depends on the extent to which they are absorbed along the small intestine[24]. *In vivo* and *in vitro* studies showed that longer transit times in the large intestine can have profound effects on bacterial physiology and metabolism, leading to breakdown of protein and fermentation of amino acids making an increased contribution to colonic SCFA pools[25-28]. Through this mechanism, RG increases the nutritional value of S not only by increasing the energy value through small intestinal absorption, but also by preventing the possible risk of osmotic diarrhea.

The S absorption index in the 3$^{rd}$ to the last quarter of the small intestine was significantly increased in this experiment when ingested with RG. In contrast, no S was absorbed from the above region during a 1 h period after the ingestion of S only. It was found that the absorption index of S in the small intestine was increased by the addition of RG, but the actual location(s) of increased absorption was not clear from the results of the single oral dose study. However, from the existing data it can be assumed that the highest amount of S was absorbed in the upper half of the small intestine, for both groups. Further study using a continuous feeding method could confirm the quantitative information on S absorption from the small intestinal tract. However, it was previously reported that RG releases an increased amount of glucose at the luminal surface as well as over a large segment of the small intestine[21]. In the presence of extra glucose, the influx of S across the luminal membrane increased significantly[10]. Moreover, slower gastric emptying and slower transit time caused by RG lengthened the contact time between S and intestinal mucosa, and facilitated the absorption of S by passive diffusion[29]. Although RG releases an increased amount of glucose, it avoids creating additional osmolality at the luminal surface, because the release of glucose occurs slowly from the polysaccharide and is over a large segment of the intestine[21]. The higher absorption of S in the presence of extra glucose prevented hyper-osmolality in the intestinal lumen, which prevented osmotic diarrhea in cecectomized rats.

Transit and volume of the intestinal fluid are important determinants of the degree of digestion and absorption in the small intestine. Both parameters, when they are increased excessively, have the potential to reduce degradation and absorption by limiting substrate contact with the mucosal surface[30,31]. The relatively slower transit and lower intestinal fluid volume in the S + RG group than in the S group enhanced the absorption of S from distal parts of the small intestine and colon. A linear correlation between the S absorption index and fluid volume was found in this study (Figure 5).

From the results of our present study it can be summarized that the possible causes of indigestible but fermentable material-based diarrhea are: (1) faster intestinal transit; (2) small intestinal mal-absorption; (3) incomplete colonic fermentation of S, and (4) slower absorption of some organic acids (e.g., lactic, succinic) from the colon.

The above summarized points are interrelated, with a sequential tendency, and are supported by some previously reported proposals of Rambaud *et al*[4], Ammon *et al*[6], and Islam *et al*[7].

In summary, our study shows that RG plays an important role in stimulating the small intestinal absorption of S. As a result, a smaller amount of S entered into the colon for fermentation. Moreover, due to a slower transit time, the S that entered the colon was completely fermented to rapidly absorbable SCFAs and this prevented the possible increment of osmolality by some organic acids (e.g., lactic, succinic). These may be the mechanisms by which hard feces were formed in the mid to distal colon of the cecectomized rats.

## Abstract

**AIM:** To investigate whether manual acupuncture at representative acupoints in different parts of the body can modulate responses of gastric motility in rats and regular effects in different acupoint stimulation.

**METHODS:** The gastric motor activity of rats was recorded by the intrapyloric balloon. The changes of gastric motility induced by the stimulation were compared with the background activity in intragastric pressure and/or waves of gastric contraction recorded before any stimulation. Morphological study was also conducted by observing the Evans dye extravasation in the skin after mustard oil injection into the intragastric mucous membrane to certify cutaneous innervations of blue dots related to gastric segmental innervations.

**RESULTS:** In all six rats that received mustard oil injections into intragastric mucosa, small blue dots appeared in the skin over the whole abdomen, but mainly in peri-midline upper- and middle- abdomen and middle-back, a few in thigh and groin. It may speculate that cutaneous innervations of blue dots have the same distribution as gastric segmental innervations. Acu-stimulation in acupoints of head-neck, four limbs, upper chest-dorsum and lower-dorsum induced markedly augmentation of gastric motility (acupoints on head-neck such as St-2: $n$ = 16, 105.19 ± 1.36 *vs* 112.25 ± 2.02 and St-3: $n$ = 14, 101.5 ± 1.75 *vs* 109.36 ± 1.8; acupoints on limbs such as Sp-6: $n$ = 19, 100.74 ± 1.54 *vs* 110.26 ± 3.88; St-32: $n$ = 17, 103.59 ± 1.64 *vs* 108.24 ± 2.41; St-36: $n$ = 16, 104.81 ± 1.72 *vs* 110.81 ± 2.74 and Li-11: $n$ = 17, 106.47 ± 2.61 *vs* 114.77 ± 3.77, $P$ < 0.05-0.001). Vigorous inhibitory regulations of gastric motility induced by acu-stimulation applied in acupoints on whole abdomen and middle-dorsum were significantly different as compared with the controls before acu-stimulation (abdomen acupoints such as Cv-12: $n$ = 11, 109.36 ± 2.09 *vs* 101 ± 2.21; Cv-6: $n$ = 18, 104.39 ± 1.42 *vs* 91.83 ± 3.22 and St-21: $n$ = 12, 107 ± 2.97 *vs* 98.58 ± 2.81; acupoints on middle-dorsum such as Bl-17: $n$ = 19, 100.63 ± 1.4 *vs* 92.21 ± 2.07 and Bl-21: $n$ = 19, 103.84 ± 1.48 *vs* 97.58 ± 2.16, $P$ < 0.05-0.001).

**CONCLUSION:** Regular regulatory effects of facilitation and inhibition on gastric motility appear to be somatotopically organized in the acupoints of whole body, and the effective regularity of site-special acupoints on gastric motility is involved in segmental innervations between stomach and acupoints.

**Key words:** Gastric motility; Acu-stimulation; Effective regularity; Segmental innervation

## INTRODUCTION

Acupuncture therapy, originated and prospering in China and prevailing in Asia, has been used empirically in clinical practice for several millennia. It has long been accepted that acupuncture at certain points on the body, can have analgesic and therapeutic effects in the treatment of various diseases[1]. This therapy has drawn the attention of many investigators and become a research subject of international interest around the world. Although a large number of previous clinical studies support the efficacy of acupuncture for treating gastrointestinal symptoms and/or diseases[2-4], little is known about the underlying mechanism(s). Motility of the digestive tract encompasses the phenomena of myoelectrical activity, contractile activity, tone, compliance, and transit. In the functional gastrointestinal disorders, various types of dysmotility have been documented repeatedly, and most likely reflect

dysfunction at one or more levels of the brain-gut axis. It has been demonstrated that the somatosensory inputs from the skin and/or muscle are involved in the control of various autonomic functions[5-7]. A series of investigations regarding somato-autonomic reflexes has also been carried out focusing on gastrointestinal function. In some of those investigations, there is good evidence indicating the importance of cutaneo-sensory inputs in the autonomic control of gastrointestinal motility. In anesthetized rats, for instance, it has been shown that the cutaneo-gastric reflexes mediate the inhibition and the stimulation of gastric motility *via* sympathetic and parasympathetic efferents, respectively[7-9]. It was shown that the cutaneo-sensory stimulation induced by pinching abdominal skin of rats inhibits gastric motility by increasing sympathetic activity. On the other hand, cutaneo-sensory stimulation induced by pinching the hindlimb enhances gastric motility by increasing vagal activity[8].

It is generally believed that acupuncture at different acupoints show different effects. Previous studies suggest the site-specific inhibitory or stimulatory effects of acupuncture on gastric motility[8,10,11]. The Pc-6 (neiguan) at wrist and St-36 (zusanli) at hindlimb are the common acupoints used for treating gastric symptoms such as nausea and vomiting[12,13], suggesting that acupuncture at these acupoints may stimulate gastric motility. In contrast, acupuncture on the abdomen has been used for treating abdominal pain[2-4], suggesting that acupuncture at this point may inhibit gastric motility and/or reduce gastrospasm. Acupuncture at St-36 and Pc-6 has been shown to enhance the gastric migrating motor complex in conscious dogs[14] and in anesthetized rats[10]. It has been also shown that manual acupuncture on the abdomen inhibits gastric motility[10] and induced gastric relaxations *via* the somato-sympathetic pathway[15] in anesthetized rats. Meanwhile, it was also existent in inter-contradictive results[16-19]. Recent investigations have suggested that the modulations of acupuncture on visceral functional activities can demonstrate totally different facilitative/inhibitory effects on gastric motility in diverse site-acupoints given. Therefore, the present studies were to investigate whether manual acupuncture at representative meridian-acupoints in different parts of the body can modulate responses of gastric motility, and what are regular effects in different acupoint stimulation given.

## MATERIALS AND METHODS

### *Animal preparation and recording procedures*

All animal experiments were carried out in accordance with the National Institutes of Health Guide for the Care and Use of Laboratory Animals and approved by the Institutional Animal Care and Use Committee of China Academy of Chinese Medical Sciences. Experiments were performed on 48 adult male Sprague-Dawley rats weighing between 250 and 300 g. The animals were maintained on a 12:12-h light-dark cycle (8:00-20:00) with free access to food and water. The rats were fasted overnight with free access to water in proxima luce and anesthetized with an intraperitoneal injection of urethane (1.0-1.2 g/kg). The trachea was cannulated but not immobilized only to keep respiratory tract unobstructed and a catheter was inserted into one of the jugular veins for infusion of the necessary solutions or anesthetics. The abdomen was opened by midline section, and a small longitudinal incision was made in the duodenum about 2-3 cm from the pylorus. A small balloon made of flexible condom rubber was inserted via incision of the duodenum into the pyloric area of rat and kept in position by tying the connecting catheter to the duodenum, and another catheter (inner diameter of 1 mm) was also inserted into the same hole by incision in order to drain digestive juices secreted from stomach. Then the cut skin of the abdomen was closed by suture before experiments. The balloon was filled with warm-water about 0.2-0.5 mL, which gave about 80-150 mm$H_2O$ pressures. Pressure in the balloon was measured by a transducer (TP-400T, Nihon Kohden) for low pressure through a thin polyethylene tube (1.5 mm in outer diameter) and then input on a polygraph (RM-6000, Nihon Kohden) amplifier and led into a data acquisition system (Power-Lab) for further analysis. Demi-fasting gastric motor activity was recorded as a control for at least 1 h before either the acupuncture or somatic stimulation.

The changes of gastric motility induced by the stimulation were compared with the background activity in intragastric pressure and/or waves of gastric contraction recorded before any stimulation. If the changes of gastric motility during stimulation were 20% more or less than the background activity, the response was then considered to have an excitatory or inhibitory regulation, respectively. Systemic blood pressure was continuously monitored from a common carotid artery and heart rate was continuously monitored, rectal temperature kept constantly around 37℃ by means of a feedback-controlled heating blanket.

### *Skin stimulus and acupuncture*

Cutaneous stimulation was obtained by pinching a localized skin area of about 5 $mm^2$ with a forceps, pinching area distributed in forelimb, lateral abdomen, dorsum and hindlimb. And an additional hot water bath (50℃) on the tail was given. Manual acupuncture with a needle of 0.3 mm in diameter was inserted into the skin and underlying muscles at different acupoints of the body, and it was rotated clockwise and anti-clockwise at 2 Hz for 30 s. Based on the comparative anatomical localization in rats as compared with that in human, selected points included 29/45 cephalocaudal acupoints in stomach-Meridian, and Li-11 (quchi) acupoint of Large-intestine-meridian in forelimb, Cv-6 (qihai), Cv-12 (zhongwan) acupoints of conception-vessel in abdomen, Bl-13 (feishu, $T_3$ spinal segment), Bl-17 (geshu, $T_7$), Bl-21 (weishu, $T_{12}$), Bl-27 (xiaochangshu, $S_1$) acupoints of Bladder-meridian in dorsum, Sp-6 (sanyingjiao) of spleen-meridian in hindlimb and the auriculo-concha, non-acupoint in tail (the location of acupoints is shown in Figure 2, Figure 3, Figure 4).

### *Evans blue dye injection and gastric inflammation*

This experiment was performed in ten SD rats including six for mineral oil of injection in intragastric mucous membrane and four for the control of saline injection. Fifteen minutes after the surgery was completed, Evans

blue dye (Sigma) dissolved in sterile water (5 mg per 100 mL) was injected through the arterial catheter. Ten minutes after the dye injection, 0.3-0.5 mL (volume depending on injected points of the stomach) of 10% mustard oil (Sigma, dissolved in mineral oil) was injected into the intragastric mucosa and visceral peritoneum covering the stomach in several areas, in order to induce a chemical inflammation of the gastric mucous membrane. Skin color changes were observed for 1-2 h, and the area of dye extravasation was sketched on the body charts for assessment. Dye extravasation was quantified by counting the number of blue dots in the skin over frontal and dorsal body areas. In control rats, a similar volume of physiological saline was injected into the intragastric mucous membrane. Evans blue dye injection was the same as mustard oil experimental animals.

### Experimental procedures

The rats were kept in supine position; gastric motor activity was first analyzed visually to detect cyclic waves of contractions. When gastric background activity is well recorded, the response of gastric motor to skin stimulation and acupuncture is tested separately. A standard protocol was employed for the determination of effects of acupuncture and somatic stimuli on the gastric motility response. A gastric background activity was recorded for 5-10 min followed by a test of their responses to manual acupuncture at various acupoint or natural stimulation on the skin was applied for 30 s. After the acupuncture or somatic stimulation the gastric motility response was recorded for another 5-10 min. After the series of experiments was finished, rats were sacrificed under an overdose deep anesthesia (urethane, > 2 g/kg ip).

### Statistical analysis

The data obtained before and after intervention in the same group was compared statistically by an independent *t* test. $P < 0.05$ was considered as a statistical significance. All data are expressed as mean ± SE.

## RESULTS

### Number and location of dye extravasation in skin on gastric inflammation

Injection of mustard oil into intragastric mucous membrane resulted in massive mucous inflammation evidenced on histological examination, which showed that the intragastric mucosa had become edematous, dilated blood vessels and ulceration of the endogastric lining. In all six rats that received mustard oil injections into intragastric mucosa (Figure 1), small blue dots appeared in the skin over the whole abdomen, but mainly in peri-midline upper- and middle- abdomen, middle-back, a few in thigh and groin. The number and distribution of blue dots varied considerably among rats. The dots started to appear about 20 min after injection of mustard oil, and the majority of dots were visible within 50 min. The dots were very small, usually ranging from 1-3 mm in diameter. However, several dots appeared in the state of stick-like in length of 3-6 mm (Figure 1). In contrast, two of four control rats that received saline injections into the intragastric mucous membrane showed no skin color changes at all. The remaining two control rats showed only 3-5 small blue dots over the middle-abdomen (Figure 1), perhaps this extravasation restricted to abdominal skin in some of the control rats might be associated with the abdominal surgical incision. It may speculate that cutaneous innervations of blue dots had same distribution as gastric segmental innervations.

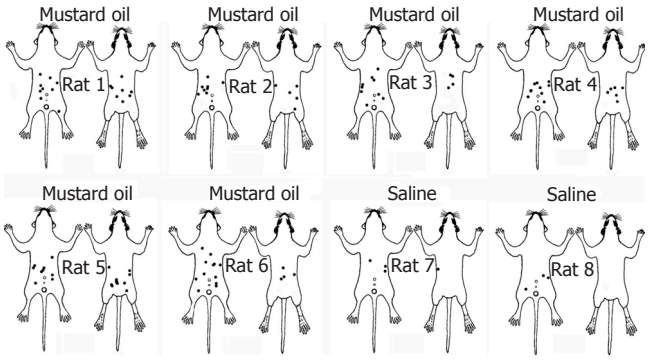

**Figure 1** Schematic drawing of number and location of blue dots in rats. Dye extravasation in skin after inflammation of intragastric mucous membrane and rare small blue dots over abdominal area of control rats.

### Gastric motor characteristics

Gastric motor characteristics were observed in 38 rats under normal anesthetic condition. When the intrapyloric balloon pressure was increased from 0 to about 80-200 mm$H_2O$ levels, the rhythmic wave of contractions in pyloric area were observed in 32 rats, at least in the periodic course during recording. Others showed no cyclic contraction during recording. Among the total, the contractile amplitude of rhythmic wave was about 5-50 mm$H_2O$, whereas strong contractions exceeded to 300 mm$H_2O$. When the pressure in an intragastric balloon was maintained at about 100 mm$H_2O$ by expanding the volume of the balloon with warm-water, rhythmic contractions occurred at a rate of 4-6 per minute. With regard to gastric motor characteristics, it was noteworthy both the changes of intragastric pressure and rhythmic contraction in present study. Generally, the intragastric pressure represents the index of gastric tone motility and rhythmic contraction represents then gastric peristalsis induced by circular muscle contractions, similar to slow-wave of gastric motor activity.

Effects of noxious mechanical or hot cutaneous stimulation of various sites on gastric motility were studied in 14 rats. As illustrated in Figure 2, pinching of the abdominal skin always produced strong inhibition (10/11 rats, 100.09 ± 2.73 *vs* 87.82 ± 3.68, $P < 0.05$) in the pyloric pressure; the maximum response of decrease was obtained about 10-s after the onset of stimulation. Pinching the middle dorsal skin in some, but not all cases, produced slight or moderate inhibition or only post-inhibition ($n$ = 11, 102.3 ± 3.36 *vs* 100 ± 3.33, $P < 0.05$). Interestingly, pinching in fore- or hind-limb induced mainly moderate increase of gastric motility ($n$ = 8, 104.56 ± 1.29 *vs* 113.78

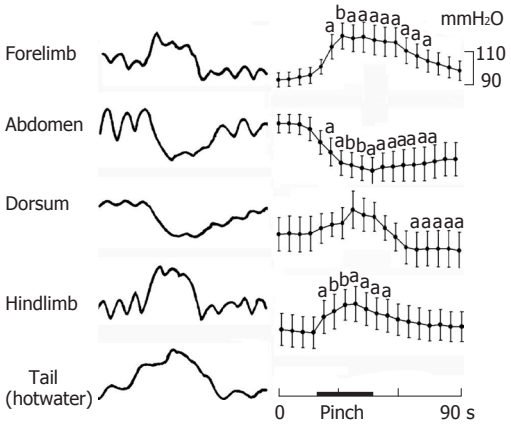

**Figure 2** Gastric motility in response to cutaneous natural stimuli. $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* control gastric motility of pre-stimuli.

± 5.37, $P < 0.05$; $n = 9$, 97.13 ± 4.63 *vs* 104.88 ± 5.03, $P < 0.05$; respectively), meanwhile, hot water bath (50℃) on the tail could produce moderate augmentation of gastric motility.

### *Gastric motility in response to stomach-meridian acupoint stimuli*

Figure 3 shows the gastric motility in response to majority craniocaudal stomach-meridian acupoint stimuli was systemically observed in four rats. Manual acu-stimulation in 9 acupoints of face (St-2, St-3, St-4, St-5 and St-7), neck (St-9) and cephalic-chest (St-12, St-13 and St-15), induced significantly moderate increase of gastric motility. This facilitation could be observed about 2-4 s after application and continued to augment during 30 s acu-stimulation. On seven acupoints of lower-chest (St-18) and whole-abdomen (St-19, St-21, St-23, St-25, St-26 and St-28), acu-stimulation produced moderate-strong suppressive responses on gastric motility, which started to suppress about 2 s delay of onset and lasted throughout the period of application of the acu-stimulation. The inhibitory magnitude on gastric motility was arranged from fadein to fadeout among these cephalocaudal acupoints. Acu-stimulation in hindlimb (St-30, St-31, St-32, St-34, St-35, St-36, St-37, St-39, St-40, St-41 and St-45) evoked moderate augmentation of gastric motility. However, in between acupoints of St-16 (in the 5$^{th}$ intercostal space) and St-30 (slightly above the inguinal groove), acupuncture could not bring about clear response of excitation/inhibition on gastric movement in most cases. It was noteworthy that, from the above observations, manual acu-stimulation applied in the Stomach-meridian acupoints from the lower-breast to the groin suppressed generally the gastric motor activity, whereas acu-stimulation in other acupoints of Stomach-meridian (i.e. face, neck, cephalic-chest and hindlimb) brought about exciting responses in different magnitudes on gastric motility. These results suggested the effective regularity of site-special acupoint on gastric motility. Next study focused at acupoint stimuli in different meridians and different parts of the body, and compared their effects on responses of gastric motility.

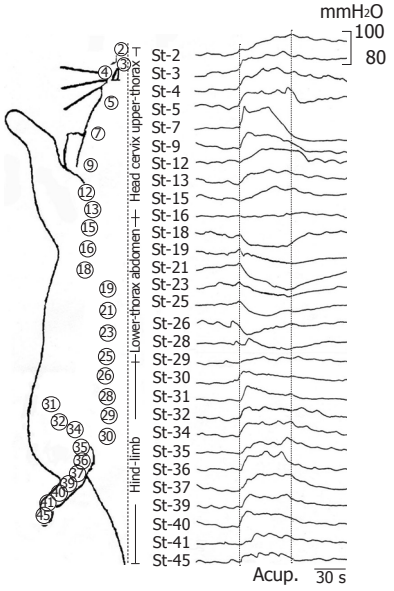

**Figure 3** The gastric motility in response to craniocaudal stomach-meridian acupoints stimuli.

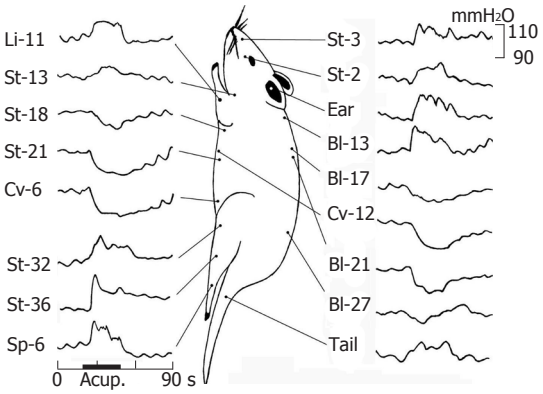

**Figure 4** Gastric motility in response to acu-stimulation.

### *Gastric motility in response to acupoint stimuli in different parts of body*

The acu-stimulation at 16 acupoints in the different parts of the body and one non-acupoint in tail on responses of gastric motility was systemically observed. A total of 27 rats were studied. Most of them (22/27) exhibited the rhythmic wave of contractions in the periodic course, and the pyloric pressure maintained at about 80-200 mmH$_2$O. Gastric motility in the most rats showed various responses to acu-stimulation applied to some representative acupoints in several meridians and different parts of the body. An individual example of various kinds of responses was illustrated in manual acu-stimulation applied to acupoints either St-2 (sibai), St-3 (juliao) of Stomach-meridian and the auriculo-concha in face, Li-11 (quchi) in forelimb, St-13 (qihu) in upper-breast, Bl-13 (feishu) in upper-dorsum, Bl-27 (xiaochangshu) in lower-dorsum, or St-32 (futu), St-36 (zusanli), Sp-6 (sanyinjiao) in hindlimb and non-acupoint in tail, which gave rise to slight-moderate facilitation of gastric motility with a rapid onset, followed by a tonic motor that lasted throughout the period of acu-stimulation. These responses were followed in several cases by after-effects of promotion; this was particularly clear when the auriculo-concha, Li-11, St-36 and Sp-6 acupoints

were acu-stimulated but was also obvious in the other cases (except from Bl-27). However it was interesting to emphasize that, the effects in both abdomen and middle-dorsum on modulation of gastric motility differed basically from those in the head, upper chest/dorsum and fore-/hind-limbs. The same stimulus applied to the acupoints of St-18 (rugen, lower breast) and St-21 (liangmen), Cv-6 (qihai) and Cv-12 (zhongwan) in the abdomen, and Bl-17 (geshu) and Bl-21 (weishu) in the middle dorsum, resulted in high suppression of gastric tonic motility with a rapid onset, followed by a obvious inhibition of rhythmic wave of contractions. These suppressions lasted throughout the period of acu-stimulation and followed in most cases after inhibition.

At a quantitative level, the facilitative/inhibitory responses on the gastric motility were evaluated before 20 s, during 30 s and after 40 s of acu-stimulation. The mean values are shown in Figure 5. Acu-stimulation in acupoints of head-neck, limbs upper chest-dorsum and lower-dorsum induced markedly augmentation of gastric motility (acupoints on head-neck such as St-2: $n = 16$, 105.19 ± 1.36 *vs* 112.25 ± 2.02 and St-3: $n = 14$, 101.5 ± 1.75 *vs* 109.36 ± 1.8; acupoints on limbs such as Sp-6: $n = 19$, 100.74 ± 1.54 *vs* 110.26 ± 3.88; St-32: $n = 17$, 103.59 ± 1.64 *vs* 108.24 ± 2.41; St-36: $n = 16$, 104.81 ± 1.72 *vs* 110.81 ± 2.74 and Li-11: $n = 17$, 106.47 ± 2.61 *vs* 114.77 ± 3.77, $P < 0.05$-0.001 respectively). Notable inhibitory responses of gastric motility induced by acu-stimulation applied in acupoints of whole abdomen and middle-dorsum were significantly different as compared with the control before acu-stimulation (abdomen acupoints such as Cv-12: $n = 11$, 109.36 ± 2.09 *vs* 101 ± 2.21; Cv-6: $n = 18$, 104.39 ± 1.42 *vs* 91.83 ± 3.22 and St-21: $n = 12$, 107 ± 2.97 *vs* 98.58 ± 2.81; acupoints on middle-dorsum such as Bl-17: $n = 19$, 100.63 ± 1.4 *vs* 92.21 ± 2.07 and Bl-21: $n = 19$, 103.84 ± 1.48 *vs* 97.58 ± 2.16, $P < 0.001$ respectively). Acu-atimulation in the tail of non-acupoint could also increase gastric motor. Such regular regulatory effects both of facilitation/inhibition on gastric motility did appear to be somatotopically organized in the acupoints of the whole body and suggested the effective regularity of site-special acupoints on gastric motility.

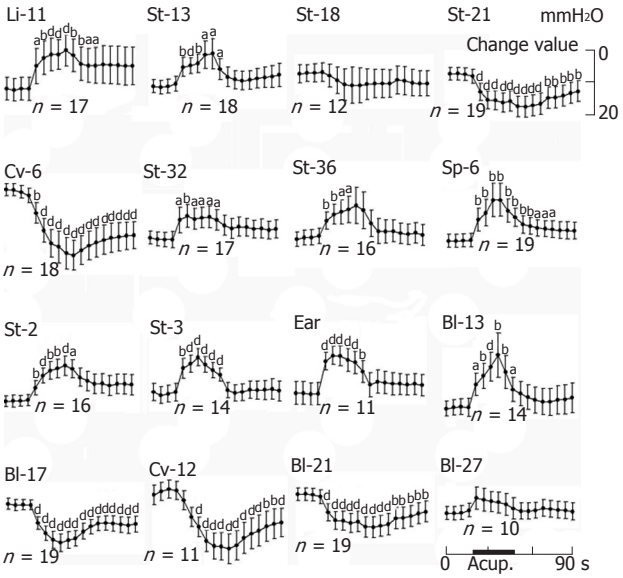

**Figure 5** The quantitative analysis of gastric motility in response to acu-stimulation. $^aP < 0.05$, $^bP < 0.01$, $^dP < 0.001$ *vs* control gastric motility of pre-stimuli.

## DISCUSSION

Recent studies have begun exploring the effects of acupuncture on gastrointestinal physiology and its potential for the treatment of gastrointestinal diseases[2,20-22]. However, despite its well-known effects on nausea and vomiting, relatively little attention has been paid to its potential for the management of disorders of gastrointestinal motility[13,14]. The purpose of this part of the study was to investigate the cutaneous distributions in association with gastric segmental innervations. Discomfort and pain were the sensory experiences most commonly evoked from visceral organs. Many forms of visceral pain were felt in the regions of the body other than the organ whose stimulation caused pain (referred pain, or viscero-somatic reflex).

Stomachal innervation has clear anatomical data, but recent study has further developed. Retrograde axonal transport of horseradish peroxidase (HRP) was applied to the ventral surface of the cat stomach. Hino *et al*[23] investigated the number, size and distribution of HRP-positive cells in spinal ganglia. The unexpected finding was the wide distribution of these cells from $T_3$ down to $L_3$. Spinal ganglion cells innervating the stomach of the rats were demonstrated using the somatopetal HRP transport technique. After injection of the tracer into the anterior wall of the stomach, labelled neurons were observed bilaterally within spinal ganglia $T_4$-$L_1$. They were most numerous in ganglia $T_8$-$T_{10}$[24]. The distribution of sensory neurons innervating the peritoneum was studied using axonal transport of fluoro-gold. The tracer was injected into parietal peritoneum and visceral peritoneum covering the stomach and small intestine. Many neurons in the nodose ganglia in addition to somata in the dorsal root ganglia from $T_4$ to $T_{13}$ were labeled when the tracer was placed on the peritoneum lining the stomach, small intestine or caecum[25].

In agreement with gastric (-intestinal) segmental innervations, chemical gastric inflammation with mustard oil in rats results in neurogenic plasma extravasation in the skin over whole abdomen and middle- and lower-back; neuroanatomically, these somatic territories belong to $T_4$-$L_1$ dermatomes[26]. It may speculate that cutaneous innervations of blue dots distribution were similar to the gastric segmental innervations.

Our results showed that, noxious mechanical (pinch) stimulation applied to limbs or tail as well as noxious heat (hot water bath at 50℃ on the tail) induced gastric excitation. It was remarkable that (electro-) acu-stimulation applied to the acupoints of six in face, two in neck, one in forelimb, five in upper chest-dorsum and one in hindlimb, which were distributed in the remote somite (hetero-segment) with gastric segmental innervation, produced a facilitative response of gastric motility followed by the activities increasing slightly in vagal and/or inhibiting in

sympathetic nerves innervated to stomach.

It is generally believed that acupuncture at different points (acupoints) shows different effects. Previous studies presented the site-specific inhibitory or stimulatory effects of acupuncture on gastric motility[10]. During 2-3 Hz of electroacupuncture on St-36 acupoint, there was a significant increase in the percentage of normal frequency. The percentage of normal frequency in the post-acupuncture period was also increased[16,17]. The pericardium Pc-6 (neiguan) at wrist and stomach St-36 are the common acupoints used for treating gastric symptoms such as nausea and vomiting[12,13]. On the basis of our studies and current results, it is conceivable therefore, that acupuncture at total acupoints, with exception in homo-somite with gastric segmental innervation, may encourage gastric motility and cure some disorders of gastroparesis[27], gastroadynamics or gastroatonia.

In contrast within the remote somite (hetero-segment) with gastric segmental innervations, the present study showed that the mechanical (pinch) stimulation applied at abdomen-dorsum induced gastric inhibition. Interestingly, acu-stimulation applied to the homotopic acupoints in the lower-chest, middle-dorsum and whole abdomen induced an inhibitory response of gastric motility followed by the activities of increasing in sympathetic and/or inhibiting slightly in vagal nerves innervated to stomach. These effects involved in intact preparation of sympathetic (splanchnic) nerves, but did not require intact preparation of bilateral vagal nerves and high spinal cord. Sato *et al*[10] showed that when it was applied to the abdomen and lower chest region, acupuncture-like stimulation elicited suppressive response on gastric motility. The authors proposed that acupuncture provoked a reflex that had cutaneous and muscle nerves as its afferent pathway, and the sympathetic gastric branches as its efferent pathway; and the acu-stimulation in abdomen inhibited gastric motility by increasing the activity of the efferent nerves of sympathetic gastric branches, abdomen acu-stimulation-induced suppression of gastric motility persisted in spinalized rats. The inhibitory duodenal response by electro-acupuncture stimulation in abdomen was a propriospinal reflex response involving splanchnic excitatory nerves, and cutting the vagal nerve branches innervating the duodenum did not affect the suppressed duodenal response[28].

Acupuncture on the abdomen has been used for treating abdominal pain[2-4], suggesting that acupuncture at this point may inhibit gastric motility and/or reduce gastrospasm or gastrohypertonics. It is conceivable that, the inhibition in gastric motility and the increase in sympathetic activity could appear only in electro-acupuncture stimulation applied to the abdomen and middle-dorsum acupoints, e.g., the homo-segmental somatic territory with gastric innervations. The results of this experiment suggest that, regardless of any meridian-acupoints, manual acupuncture at the acupoints of widespread territory except homo-segmental innervations with gastric innervations, induce a facilitative response on gastric motility; it is effective for the treatment of disturbances of gastrointestinal hypomotility such as gastroparesis, gastroptosis, gastroadynamic, enteroparesis, constipation or gastroatonia. However, acu-stimulation at the acupoints of local territory of homo-segmental innervations with gastric innervations, induces inhibitory response on gastric motility and is effective for the treatment of disturbances of gastrointestinal overmotility such as gastralgia, gastrospasm, diarrhea or enterospasm. In conclusion, acu-stimulation applied to the distant acupoints, such as in face, neck, forelimbs, upper chest-dorsum and hindlimbs, produced a facilitative response on gastric motility; whereas acu-stimulation applied to the local acupoints, such as in lower-chest, middle-dorsum and whole abdomen, induced an inhibitory response on gastric motility.

## Abstract

**AIM:** To construct an expression plasmid encoding human wild-type midkine (MK) and enhanced green fluorescence protein (EGFP) fusion protein (MK-EGFP), and to analyze the subcellular localization of MK in different carcinoma cell lines.

**METHODS:** Two kinds of MK coding sequences with or without signal peptide were cloned into plasmid pEGFP-N2, and the recombinant plasmids constructed were introduced into HepG2, MCF7 and DU145 cells, respectively, by transfection. With the help of laser scanning confocal microscopy, the expression and subcellular localization of MK-GFP fusion protein could be detected.

**RESULTS:** Compared with the GFP control, in which fluorescence was detected diffusely over the entire cell body except in the nucleolus, both kinds of fusion protein MK-GFP were localized exclusively to the nucleus and accumulated in the nucleolus in the three kinds of cancer cell lines.

**CONCLUSION:** This study reveals the specific nucleolar translocation independent of signal peptide, which may be involved in the mechanism that MK works. It provides valuable evidence for further study on the functions of MK in nucleus and its possible mechanisms, in which ribosomal RNA transcription and ribosome assembly are involved.

**Key words:** Midkine; Subcellular localization; Laser scanning confocal microscopy

## INTRODUCTION

Midkine (MK) is a 13 kDa protein originally found to be a secretory heparin-binding growth factor that is involved in cell growth, migration and survival. However, a number of subsequent studies showed that it is expressed at high levels in a variety of human carcinomas[1-5], indicating that it may play important roles in carcinogenesis. Recent studies demonstrated that MK can promote the growth of Wilm's tumor cells and fibroblasts[6,7], the transformation of NIH3T3 cells[8], anti-apoptotic activity of Wilm's tumor cells treated with cisplatin[9], and induction of a strong angiogenic response in rabbit corneal assay[10]. All of these suggest the multifunction of MK in carcinogenesis, cell growth, differentiation and apoptosis, and the study of its functional mechanism might lead to a new approach for cancer therapy including gastrointestinal tract cancers, since a number of recent studies have demonstrated that MK is not only highly expressed in gastrointestinal cancers, but also modulates biological phenotypes for gastric cancer growth and metastasis[2,11-13]. Moreover, it has been shown that MK could serve as a marker for the diagnosis and treatment of gastrointestinal cancers[14,15].

In addition, several subcellular localization studies have demonstrated that MK localizes in nucleus[16-18], such as in the nucleolus of PHA-activated peripheral blood lymphocytes[19], indicating that MK may serve as a transcriptional factor, or is involved in nuclear function. Nuclear transcriptional factors have been known to play roles in cell growth, differentiation, apoptosis and carcinogenesis[20-22]; however, whether MK plays roles in these functions is yet to be elucidated. In the present study, we found that MK was localized to the nucleolus of HepG2, MCF7 and DU145 cells by using MK-green fluorescence protein (GFP) fusion proteins as tracking molecules. The results showed that both MKs with or without signal peptide were exclusively localized to the nucleus and accumulated in the nucleolus of all the three carcinoma cells, while the fluorescence of GFP control was detected all over the cell except the nucleolus. Our findings may provide valuable evidence for further studies

on the functions of MK in nucleus and its mechanisms, in which ribosomal RNA transcription and ribosome assembly might be involved.

## MATERIALS AND METHODS

### Cell lines and culture

The following three cell lines were obtained from American Type Culture Collection (ATCC, M anassas, VA): hepatoma cell line (HepG2), prostate carcinoma cell line (DU145) and breast cancer cell line (MCF7). They were cultured in Dulbecco's modified Eagle's medium (DMEM, Hyclone Laboratories, Logan, UT) supplemented with 10% fetal bovine serum (FBS, Hyclone Laboratories, Logan, UT) at 37℃, with 5% humidified $CO_2$ and passaged every 3 d by trypsinization.

### Cloning of MK cDNA by RT-PCR

Total RNA was extracted from the 12-wk abortive fetal liver (provided by our own hospital) with RNeasy mini kit (Qiagen Corp), and full-length human MK gene with or without signal peptide was obtained by reverse transcription polymerase chain reaction (RT-PCR). The upstream primer of MK gene without the signal peptide is 5'-AAAGAAAGATAAGGTGAAGAAGGGCGG-3', which has the *Eco*RI site and the downstream primer is 5'-GGGATCCGGTCCTTTCCCTTCCCTTTCTTG-3', which has the *Bam*HI site. The upstream primer of MK gene with signal peptide is 5'-GGAATTCATGCAGCA CCGAGGCTTCCT-3', which has the *Eco*RI site and the downstream primer is the same with the former. After PCR amplification, the resulting fragments were digested with *Eco*RI and *Bam*HI and identified by electrophoresis and sequenced by ABI 3700 (Sangon Bioengineering Company, Shanghai). Ethical approval for the use of fetal liver tissue was obtained.

### Construction of recombinant plasmids and transfection

Two MK gene fragments with or without signal peptide were separately inserted into pEGFP-N2 plasmids (enhanced green fluorescent protein N-terminal protein fusion vector, Clontech Laboratories, Palo Alto, CA), and the recombinant plasmids were used to transform *E.coli* DH 5α and the product was amplified in LB medium, Qiaprep® Spin Plasmid MINIPREP KIT (Qiagen, Hilden, Germany). After that, two recombinant plasmids pEGFP-MKS (EGFP fused with MK with signal peptide) and pEGFP-MKN (EGFP fused with MK without signal peptide) were obtained. Transient transfections were performed with Effectene Transfection Reagent (Qiagen, Hilden, Germany) according to the manufacturer's instructions. Cells were plated at a density of $1 \times 10^5$ cells per well on a 35 mm dish 24 h before transfection and were transfected with 0.4 μg of pEGFP-MKS, pEGFP-MKN and pEGFP-N2, respectively.

### Western blotting analysis

The cells in microplates were collected into 1.5 mL Eppendorf tubes on ice, centrifuged at 2000 r/min for 5 min at 4℃, resuspended in 100 μL cell lysis buffer, and incubated on ice for 1 h. The lysates were centrifuged at 12000 r/min for 10 min at 4℃; the supernatants were collected and stored at -20℃ for electrophoresis. Proteins in conditioned media were separated by electrophoresis on 13% SDS-PAGE gels and transferred electrophoretically onto nitrocellulose membranes. After being blocked for 2 h with 5% skim milk, blots were incubated with 1:10 diluted rabbit antihuman MK (Biovendor Laboratory Medicine, Inc.) and 1:5000 diluted β-actin (Santa Cruze, CA, USA) at room temperature for 2 h. After being washed three times with TBST, the membrane was separately incubated with donkey anti-rabbit MK (Santa Cruze, USA) at a dilution of 1:5000 and anti-mouse GAPDH (Santa Cruze, CA, USA) at a dilution of 1:5000. Finally, the protein bands were visualized with an ECL kit (Pierce, USA). Quantitative analysis of the blots was performed with an imaging densitometer. Beta-actin was used as a control.

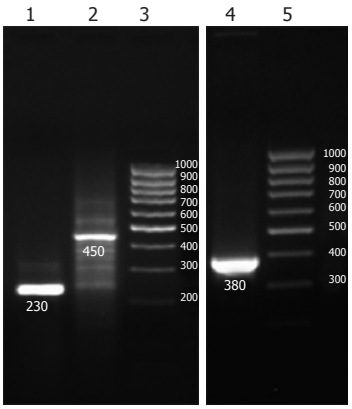

**Figure 1** Electrophoresis analysis of RT-PCR products of MKS and MKN genes. L1: β-actin (positive control); L2: fragment of MKS; L4: fragment of MKN; L3 and 5: 100 bp DNA ladder.

### Subcellular localization analysis

Ten hours after transfection, the cells were observed dynamically with laser scanning confocal microscopy (Leica, Heidelberg, Germany) for live imaging and the live images were obtained using a 40 × 1 NA oil immersion objective.

### Immunostaining assay

To visualize the subcellular localization of MK, HepG2 cells were washed three times with PBS, fixed with 4% paraformaldehyde (PFA) in PBS for 30 min at 4℃ and permeabilized with 0.1% Triton X-100. After blocked with 3% bovine serum albumin (BSA) in PBS at room temperature for 1 h, the cells were stained with 1:100 diluted goat anti-MK antibody (Santa Cruz, CA, USA) at 4℃ overnight. The treated cells were incubated with 1:100 diluted FITC-conjugated mouse anti-goat antibody (Vector Laboratories, Ltd, Peterborough, England) at 20℃ for 45 min. Finally, they were extensively washed with PBS and examined with a fluorescence microscope.

## RESULTS

### Identification of recombinant plasmids

Two expected fragments of 450 bp (MKS) and 380 bp (MKN) were clearly shown in 1.5% agarose gel electrophoresis by RT-PCR and restriction endonucleases (*Eco*RI and *Bam*HI) digestion identification, suggesting that the desired

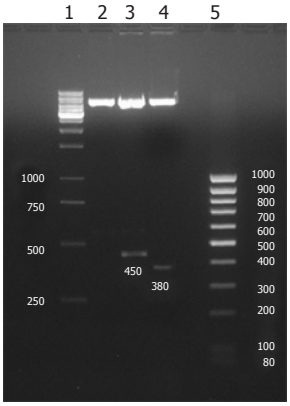

**Figure 2** Identification of constructed plasmids by digestion with restriction endonucleases (*Eco*RI and *Bam*HI). L1: 1000 bp marker; L2: pEGFP-N2; L3: pEGFP-MKS; L4: pEGFP-MKN; L5: 100 bp marker.

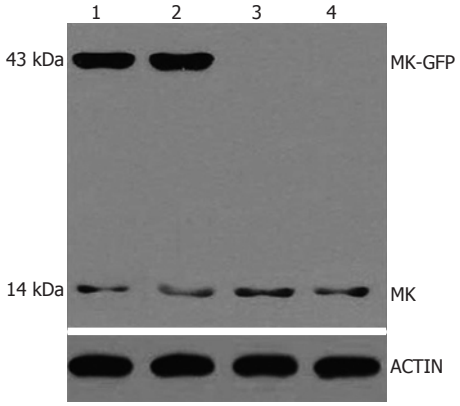

**Figure 3** Western blotting analysis of MK-GFP expressed in HepG2 cells transfected with various plasmids. Cells were transfected with pEGFP-MKS (L1), pEGFP-MKN (L2), pEGFP-N2 (L3) and with no plasmids (L4).

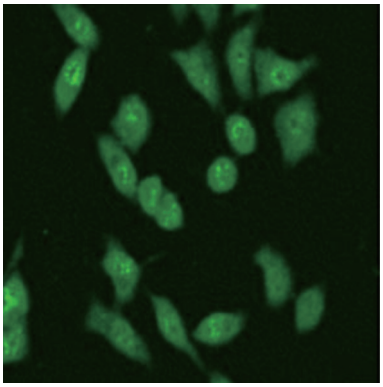

**Figure 4** Presence of MK in the nucleoli of HepG2 cells. The cells were stained with goat anti-MK antibody (1:1000). Cells were fixed with PFA and the secondary antibody FITC-conjugated mouse anti-goat antibody was added. The staining (green for MK) is presented (× 400).

products were obtained (Figures 1 and 2). Subsequent sequence analysis also proved that the obtained fragments were exactly the same as the sequence of MK gene from GenBank.

### *Western blotting and immunostaining assay*

To examine whether the MK-GFP fusion proteins were expressed in the cells transfected with pEGFP-MKN and pEGFP-MKS, 24 h after transfection, Western blotting and immunostaining assay were performed. The results revealed that MK-GFP fusion proteins were highly expressed in all the cells transfected with pEGFP-MKS and pEGFP-MKN in comparison with the low levels of native MK proteins expressed by tumor cells themselves (Figure 3, Lanes 1 and 2), whereas no signals were seen in the cells transfected with pEGFP-N2 (Figure 3, Lane 3) and with no plasmid cell controls (Figure 3, Lane 4). By immunostaining, MK was clearly detectable in the nucleoli in HepG2 cells (Figure 4), thus providing evidence for subcellular localization of MK by laser scanning confocal microscopy.

### *Dynamic subcellular localization analysis by confocal microscopy*

Dynamic subcellular localization process of fusion protein MK-GFP was observed by laser scanning confocal microscopy at different time points using the fusion protein MKN-GFP in HepG2 cells. The results showed that 11 h after transfection, the fusion protein MKN-GFP began to appear in the nucleus where it accumulated in the nucleolus (Figure 5). At 16 h 40 min time point, it was degraded in the nucleolus and finally disappeared.

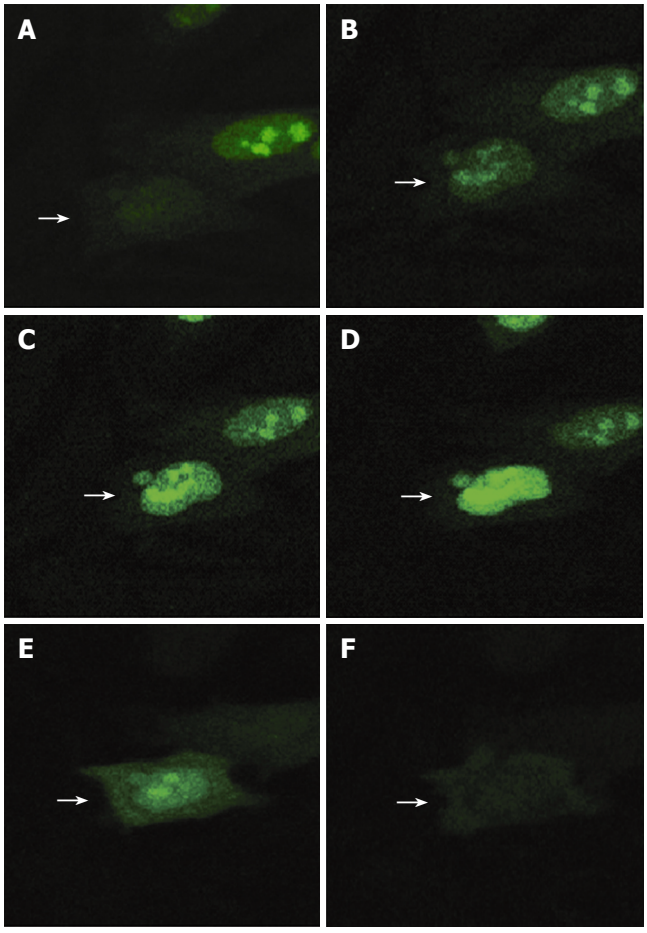

**Figure 5** Dynamic imaging of the subcellular localization of MK-GFP fusion protein in HepG2 cells captured by laser scanning confocal microscopy (marked by an arrow). **A-F**: 11 h 0 min, 11h 30 min, 12 h, 12 h 40 min, 15 h 40 min, 16 h 40 min after transfection, respectively.

### *Subcellular localization of MK in different carcinoma cell lines and the effect of signal peptide on MK*

The effect of signal peptide on MK localization was carefully observed in HepG2, DU145 and MCF7 cell lines, respectively. The results showed that 24 h after transfection, both fusion proteins MKS-GFP and MKN-GFP in the two cell lines, HepG2 and DU145, were localized exclusively to the nucleus and accumulated in the nucleolus, while GFP control was detected diffusely over the entire cell body except in the nucleolus, indicating that

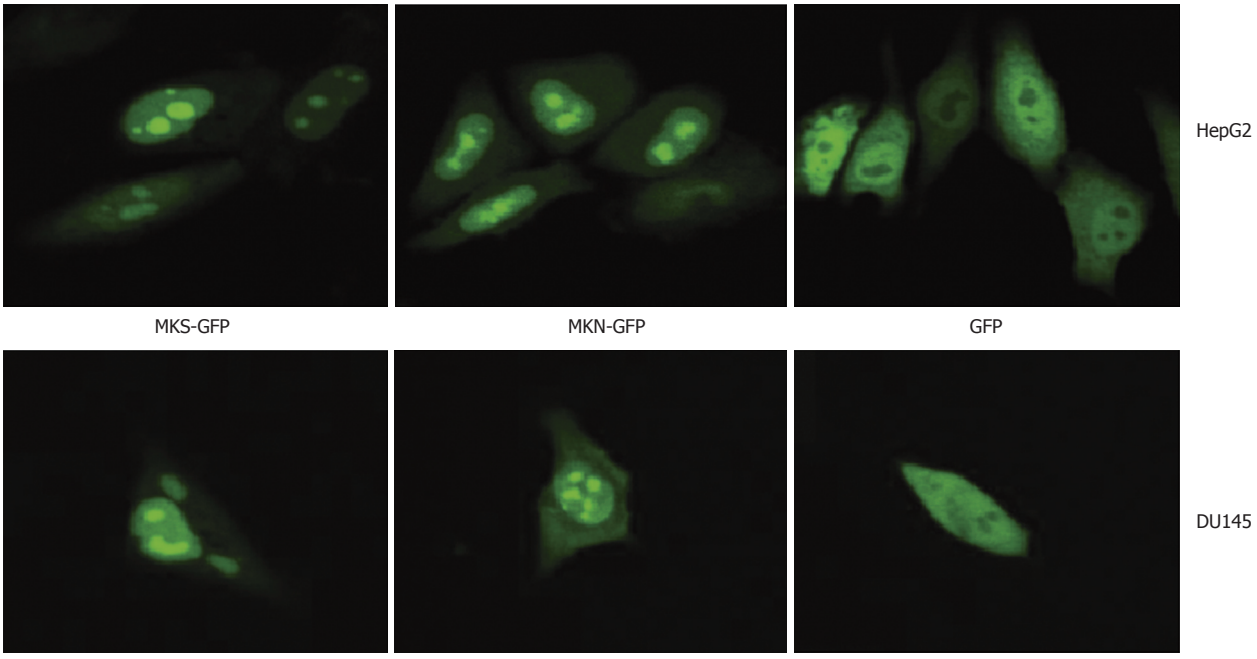

**Figure 6** Subcellular localization analysis of MKS-GFP and MKN-GFP fusion proteins in carcinoma cell lines. Twenty-four hours after transfection HepG2 cells (upper pannel)and DU145 cells (bottom pannel) were separately transfected with EGFP-MKS and EGFP-MKN. MKS-GFP and MKN-GFP fusion proteins were localized to nucleus and accumulated in nucleolus, but rarely localized to cytoplasm. The high light "spots" in the center of nuclei are nucleoli. HepG2 cells (upper panel) and DU145 cells (bottom panel) were also transfected with pEGFP-N2 for control. It seemed that GFP protein could diffuse freely in the whole cell except the nucleoli. The whole cell is light and the low light "spots" are nucleoli.

the signal peptide in pEGFP-MKS did not participate in the nuclear and nucleolar localization (Figure 6). Similar results were obtained in MCF7 cell line (data not shown).

## DISCUSSION

GFP protein is stable *in vivo* and has been fused to the C or N terminus of many cellular and extracellular proteins without a loss of activity, thereby permitting the tagging of proteins for gene regulation analysis, protein localization, or specific organelle labeling[23]. Proteins below 40 kDa, such as GFP, without any specific location signal can diffuse freely through the nuclear pore complex, and thus GFP can be used as a perfect positive control to detect the localization information of MK. In our study, based on the findings that GFP had no effect on the subcellular localization of the fusion protein, we confirmed that it was MK protein that drove the fusion protein into the nucleus, and to be exclusively localized in the nucleolus.

Localization of proteins in subcellular structures is important for the study of their functions. Nuclear located proteins usually act as transcription factors involved in the regulation of cell proliferation, differentiation and apoptosis. The localization of MK to the nucleolus of three carcinoma cell lines suggests that MK may act as a nuclear factor associated with carcinogenesis. In addition, considering the functions of nucleolus, MK may be involved in the transcription of rRNAs and its subsequent manipulation in cellular proliferation and other biological activities.

Nuclear translocation is mainly mediated by signal mechanisms[24], in which nuclear localization signal (NLS) helps extra-nuclear proteins bind with certain carriers to be transported through the nuclear pore complex and enter the nucleolus[25,26]. However, we have revealed similar distributions of both MKN-GFP and MKS-GFP fusion proteins in the HepG2 and DU145 cell lines, indicating that there is no such kind of a "signal" in the peptides of MK. Therefore, further research is needed to detect the possible "NLS" that leads MK to enter the nucleolus and to elucidate the precise translocation mechanism.

## COMMENTS

### Background

MK (Midkine, MK) is a 13 kDa protein originally found to be a secretory heparin-binding growth factor that is involved in cell growth, migration and survival. Subsequent studies have suggested that it may play important roles in carcinogenesis. MK has been shown to be localized in the nucleus or cytosol.

### Research frontiers

Owing to the multifunction of MK in carcinogenesis, cell growth, differentiation and apoptosis, the study of its functional mechanism might lead to a new approach for cancer therapy. Further studies on the functions of MK in carcinoma cells and its possible mechanisms are important for understanding the mechanism by which MK works.

### Innovations and breakthroughs

In this study, we analyzed the subcellular localization of MK in different carcinoma cell lines by using MK-GFP fusion proteins as tracking molecules. The results showed that both MK with or without signal peptide were exclusively localized to the nucleus and accumulated in the nucleolus of all the three carcinoma cell lines, while the fluorescence of GFP control was detected all over the cell except the nucleolus.

### Applications

The results provide valuable evidence for further study on the functions of MK in nucleus and its mechanisms, in which ribosomal RNA transcription and ribosome assembly are involved.

### Terminology

NLS: nuclear localization signal which helps extra-nuclear proteins bind with certain carriers to be transported through the nuclear pore complex and enter the nucleus.

### Peer review

In this manuscript by Dai et al., the authors report the subcellular localization of MK in different carcinoma cell lines. They employed an approach based on the visualization of a fluorescent fusion protein of EGFP with two different variants of MK, with or without signal peptide. The authors observed nuclear localization and nucleolar accumulation of the fusion proteins, regardless of the presence or absence of signal peptide. Their findings may be important for the study of the mechanism(s) of nuclear import of MK, and shed new light on the function of this protein.

## Abstract

**AIM:** To prospectively evaluate the indications, methodology, safety, and clinical impact of double-balloon endoscopy.

**METHODS:** A total of 60 patients with suspected or documented small- or large-bowel diseases were investigated by double balloon endoscopy. A total of 103 procedures were performed (42 from the oral route, 60 from the anal route, and 1 from the stoma route). The main outcome measurements were the time of insertion and the entire examination, complications, diagnostic yields, and the ability to successfully perform treatment.

**RESULTS:** Observation of the entire small intestine was possible in 10 (40%) of 25 patients with total enteroscopy. The median insertion time was 122 min (range, 74-199 min). Observation of the entire colon was possible in 13 (93%) of 14 patients after failure of total colonoscopy using a conventional colonoscope. Small-intestine abnormalities were found in 20 (43%) of 46 patients with indications of suspected or documented small bowel diseases, obscure GI tract bleeding, or a history of ileus. Endoscopic procedures including tattooing ($n$ = 33), bite biopsy ($n$ = 17), radiographic examination ($n$ = 7), EUS ($n$ = 5), hemostasis ($n$ = 1), polypectomy ($n$ = 5), balloon dilatation ($n$ = 1), endoscopic mucosal resection ($n$ = 1) and lithotripsy ($n$ = 1) were all successfully performed. No relevant technical problems or severe complications were encountered.

**CONCLUSION:** Double balloon endoscopy is a feasible technique that allows adequate small and large bowel examination and potentially various endoscopic procedures of small-intestinal lesions. It is safe, useful, and also provides a high clinical impact.

**Key words:** Double-balloon endoscopy; GI tract disease; Endoscopic therapy

## INTRODUCTION

Due to the development of endoscopic instruments and techniques, endoscopy has played an important role in the diagnosis and treatment of disorders in the esophagus, stomach, duodenum, and colon. However, diseases occurring in more hidden areas of the gastrointestinal tract have long remained a gastroenterological problem. Unfortunately, endoscopic small bowel examination has commonly been limited to the proximal jejunum[1,2]. Therefore, more distal lesions have not usually been identified endoscopically. Recently, a new wireless capsule endoscope was introduced. Capsule endoscopy can provide an endoscopic image from the entire GI-tract without requiring a surgical laparotomy. It is undoubtedly an important improvement in diagnostic endoscopy of the small intestine and also offers advances the diagnostic workup of small bowel diseases[2,3]. Nevertheless, this method is limited because it cannot provide for air insufflations, tissue rinsing, biopsies, or therapeutic interventions. Double-balloon endoscopy (DBE), developed by Yamamoto and colleagues in 2001[4], is an exciting new endoscopic technique that allows for complete visualization and therapeutic interventions in the entire small intestine. Preliminary experiences with DBE have illustrated the capability to perform total small-bowel enteroscopy with a good safety profile and patient tolerance for this procedure[4-11]. The aim of this study was to prospectively determine the indications, safety, diagnostic and therapeutic impact of DBE in patients with known or suspected GI-tract disorders.

## MATERIALS AND METHODS

### Patients

Between July 2004 and November 2005, 103 endoscopies, including 42 antegrade and 61 retrograde procedures, were performed on 60 patients in our hospital using the DBE system. The patients were being tested for gastrointestinal bleeding, abdominal pain, diarrhea, inflammatory bowel diseases, suspected small-bowel tumors or polyps, and unsuccessful total colonoscopy using a conventional colonoscope (Table 1). Most patients had undergone at least one esophagogastroduodenoscopy and colonoscopy. DBE was performed when small bowel disease was suspected after negative upper and lower endoscopy and radiographic evaluation of the GI tract, or was previously documented by various imaging investigation [small bowel enema study ($n$ = 20), transabdominal US ($n$ = 10), CT ($n$ = 22), angiography ($n$ = 4), and radionuclide scanning ($n$ = 7)]. In some patients, more than 1 enteroscopy was performed for endoscopic treatment of small-intestinal lesions or patients were reexamined for obscure GI bleeding by DBE previously. The median age of the 60 patients (35 men, 25 women) was 64 years (range, 19 to 83 years). Written informed consent was obtained from all patients. The indications included the following: suspected or documented small intestinal lesions (24 patients), obscure GI bleeding (20 patients), unsuccessful total colonoscopy using a conventional colonoscope (14 patients), and other indications (2 patients). This study was reviewed and approved by our institutional review board.

### Methods

The DBE system (Fujinon-Toshiba ES system Co, Tokyo, Japan) is a high resolution video endoscope with a flexible overtube. The videoendoscope has a working length of 200 cm and a detachable balloon at its tip. It is used with a soft overtube measuring 145 cm in length with another balloon at the distal end. The endoscope and overtube balloons are made from latex that is 0.1 mm thick, very soft, and can be inflated or deflated by a specially designed air pump controller with one-touch controls while monitoring air pressure. The balloons are used at 45 mmHg, which is the lowest possible pressure needed to hold the intestine for endoscope insertion, and the balloon is designed not to cause pain or discomfort to the subjects due to balloon dilation (PB-10, Fujinon-Toshiba ES system Co, Tokyo, Japan)[4]. There are two types of DBE, i.e., one for general use (EN-450P5) and one for treatment (EN-450T5) (Figure 1). The major difference between the EN-450P5 and EN-450T5 is the diameter. EN-450P5 is a thinner endoscope with an external diameter of 8.5 mm and forceps channel diameter of 2.2 mm. It is used with an overtube that has an external diameter of 12.2 mm and an internal diameter of 10 mm. The EN-450T5 has an external diameter of 9.4 mm and forceps channel diameter of 2.8 mm and it is used with an overtube that has an external diameter of 13.2 mm and an internal diameter of 11 mm.

Antegrade DBE was performed transorally after overnight fasting. Retrograde DBE was performed transanally after the patients were prepared with the same oral electrolyte lavage solution as that used for regular colonoscopy. The patients were prepared by continuous intravenous infusion and then were examined by DBE under conscious sedation with intravenous flunitrazepam coupled with 35 mg of petidine chloride. During DBE, blood pressure and oxygen saturation were monitored and, when necessary, intravenous sedatives were added. DBE was carried out under fluoroscopy by experienced endoscopists, and the endoscope was advanced as far as possible in the manner described below. With the endoscope in the intestine

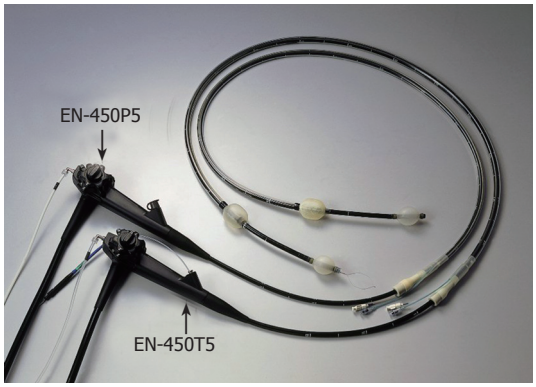

**Figure 1** Two types of double-balloon videoenteroscopes (EN-450P5 and EN-450T5).

**Table 2 Clinical data of patients who underwent DBE**

| Indications | Approach | *n* | Median insertion time (range, min) | Successful insertion |
|---|---|---|---|---|
| Panenteroscopy | Antegrade + Retrograde | 25 | 122 (74-199) | 40% (10/25) |
| Partial enteroscopy for suspected or documented lesion | Antegrade | 9 | 40 (11-99) | 67% (6/9) |
| | Retrograde | 12 | 55 (10-87) | 75% (9/12) |
| | Total | 21 | 46 (10-99) | 71% (15/21) |
| Total colonoscopy | Retrograde | 14 | 47 (15-78) | 93% (13/14) |

and the balloon of the overtube inflated and anchoring the position, the endoscope can thus be advanced. When the endoscope is advanced to its most distal point, the endoscope balloon is inflated to hold the insertion point. The overtube can be advanced after deflating the overtube balloon until the proximal end of the overtube reaches a set mark on the endoscope (150 mm); this corresponds to the distal end striking the rubber ring that holds the balloon onto the endoscope (which acts as a stopper for overtube advancement). The overtube balloon is inflated to maximum pressure and then both the enteroscope and the overtube are slowly withdrawn to reduce the GI-tract loops on the overtube and straighten the lumen for advancement. The endoscope balloon is then deflated, and insertion into the GI tract continues. This process is repeated until advancing the endoscope any further becomes difficult. The insertion route was chosen according to the estimated location of the suspected lesions, e.g., antegrade DBE was chosen when jejunal lesions were suspected and retrograde DBE was chosen when ileal lesions were suspected. A combination of both approaches was used if the indication required inspection of the whole length of the small intestine. However, examination of the entire small intestine is uncertain because there is no landmark in the small intestine. Therefore, an india-ink tattoo is left as a landmark for a subsequent retrograde DBE[4]. Fluoroscopy was used when advancement came to an unexpected halt. Gastrografin (Nihon Schering, Osaka, Japan) was injected via the working channel to allow for a radiographic assessment of the nature of the lesion. Instrumentation with a wide range of instruments is possible; e.g., ultrasound catheter probe, snares, biopsy, clip or injection needle.

## RESULTS

### *Technical aspects*

In our study, endoscopic observation of the entire small intestine was successful in 10 (40%) of the 25 patients with total enteroscopy by a combination of both approaches (anterograde and retrograde) (Table 2). The median insertion time was 122 (range, 74-199) min. Insertion of the endoscope and endoscopic observation of the target lesion was successfully achieved using DBE in 15 (71%) of the 21 patients with partial enteroscopy for suspected or documented lesion. The main reasons for failing to complete total enteroscopy or to reach the region of the target lesion was marked intestinal adhesion caused by previous laparotomy. The median insertion time was 46 (range, 10-99) min. Observation of the entire colon was possible in 13 (93%) of 14 patients in whom total colonoscopy failed using a conventional colonoscope. The median insertion time was 47 (range, 15-78) min.

### *Indications and clinical impacts of DBE*

The indications and clinical impact of DBE are presented in Table 1. Small-intestine abnormalities were found in 20 patients (43%); i.e., 15 (63%) of 24 patients with suspected or documented small bowel diseases, 5 (25%) of 20 patients with obscure GI bleeding and neither (0%) of two patients with a history of ileus. Colonic abnormalities were observed in 11 (79%) of 14 patients who underwent incomplete conventional colonoscopy. DBE resulted in a therapeutic intervention (endoscopic, medical or surgical therapy, excluding symptomatic approaches) in 43% of the patients (26/60) (Table 3). In 9 patients (15%), an endoscopic intervention was carried out during the DBE procedure (polypectomy, $n = 5$; endoscopic injection of hypertonic saline-solution-epinephrine, $n = 1$; endoscopic balloon dilation, $n = 1$; endoscopic lithotoripsy, $n = 1$; endoscopic mucosal resection, $n = 1$). In one patient with Peutz-Jeghers syndrome, it was possible to resect seven small intestinal polyps (without complications in three DBE sessions) by endoscopic polypectomy with clipping, with the sizes of the polyps ranging from 0.7 to 2 cm (Figure 2). In one patient with obstructive symptoms due to a huge enterolith (7 cm), it was possible to crush the enterolith using a large polypectomy snare (Captivator Ⅱ, Boston Scientific Japan, Tokyo, Japan) and remove it (Figure 3). Five patients (8%) underwent surgery for a resection of jejunal cancer (Figure 4), with one patient incurring a resection of a large solitary Peutz-Jeghers type polyp of the jejunum and another incurring a resection of advanced ascending colon cancer.

### *Endoscopic procedures using DBE*

DBE intervention and therapeutics are summarized in Table 4. Thirty-three underwent tattooing, 17 underwent

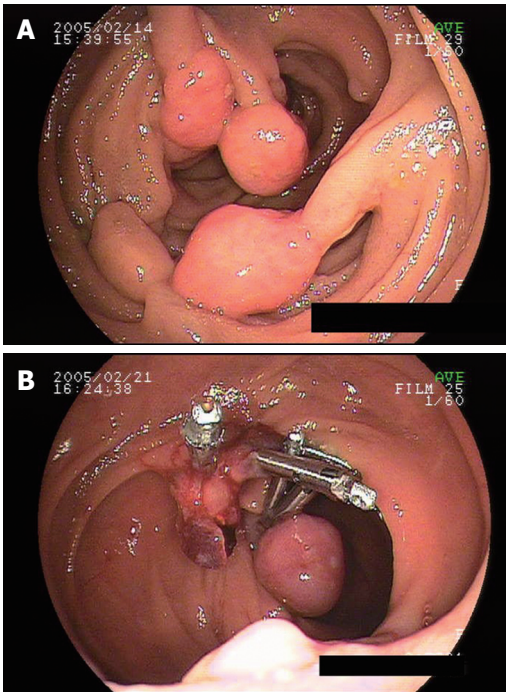

**Figure 2** The successful endoscopic removal of polyps from the mid small bowel in a patient with Peutz-Jeghers syndrome. **A**: Endoscopic view of multiple pedunculated small intestinal polyps; **B**: Endoscopic view of the region after endoscopic polypectomy using clipping.

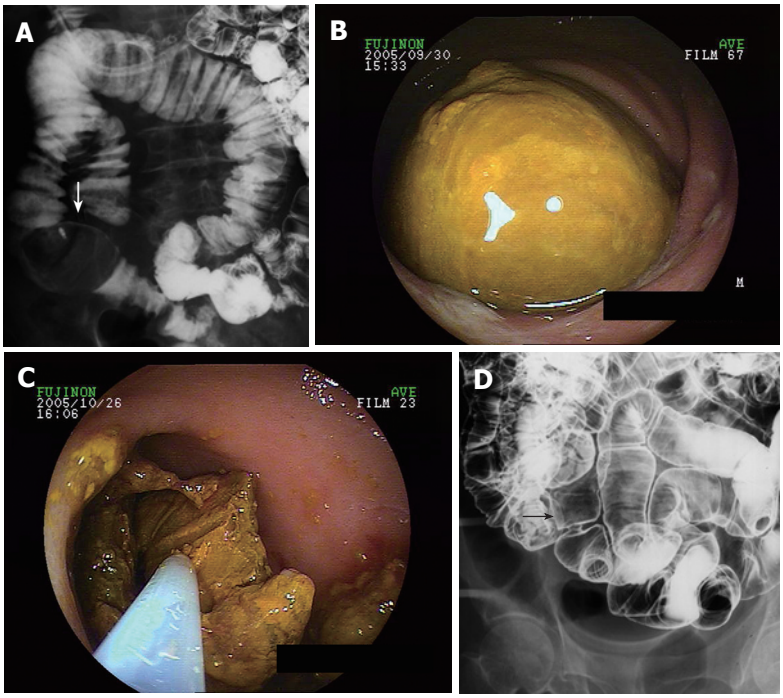

**Figure 3** Successful endoscopic lithotripsy for a huge enterolithiasis. **A**: Radiographic view of the ileum showing a huge enterolith (arrow); **B**: Endoscopic view of a huge enterolith; **C**: Endoscopic view of the lesion during lithotripsy; **D**: Radiographic view of the region after endoscopic lithotripsy showing no enterolith (arrow).

bite biopsy, 7 underwent a selective radiographic examination (Figure 4B), 5 underwent EUS using an ultrasound catheter probe (Figure 4C), 5 underwent endoscopic polypectomy, 1 underwent endoscopic hemostasis (Figure 5), 1 underwent endoscopic balloon dilation, 1 underwent endoscopic lithotripsy using a polypectomy snare, and 1 underwent endoscopic mucosal resection. All endoscopic procedures were successfully performed.

### *Complications*

No severe complications, such as perforation, occurred. DBE was well tolerated by all patients.

## DISCUSSION

Although EGD and total colonoscopy have become unequivocal procedures for the diagnosis and the treatment of GI tract diseases, enteroscopy has not yet been widely accepted by gastroenterologists. This may be partly explained by failures in total enteroscopy and the inconvenience of the procedure in push enteroscopy[1,2,12]. While video capsule endoscopy now permits the direct and painless visualization of small bowel mucosa, it does not provide a histological diagnosis and treatment of small-intestinal pathology at present[4,5,12]. A new insertion method of enteroscopy, i.e., the DBE method, has been reported to enable the endoscopic scrutiny of the entire small bowel with intervention capabilities[4-11].

Total enteroscopy using the antegrade route alone is not usually achieved, but it is possible in rare cases[4,9]. This was not achieve in this study. The strategy of combining antegrade and retrograde approaches with DBE allows total enteroscopy more frequently. To achieve this, the deepest point reached during the antegrade procedure is marked by injecting india ink so that the same point can be reached again using the retrograde approach. When total enteroscopy is intended, previous studies[4-6,8-11] have demonstrated that this mark can be reached in from 0% to 86% of all cases. In our study, this point could only be reached in 40% of the cases. The median insertion time required for panenteroscopy was 122 minutes, which was almost the same as the time reported by Yamamoto *et al* (123 min)[4]. This is certainly longer than with push enteroscopy, in which the examination times are usually approximately 30 min[10,12]. As a result, DBE is certainly a time-consuming procedure that also requires a high level of staffing, with two assistants needed in addition to a well-trained endoscopist (one assistant to help perform the DBE and one to provide patient care). However, we think that, if possible, total enteroscopy is as desirable as total colonoscopy because small bowel diseases sometimes have multiple lesions. To minimize the total effort and costs of this procedure, further technical and mechanical refinements are required.

At present, the main indications for DBE are the investigation of gastrointestinal bleeding and inflammatory bowel disease[4-12]. Other indications for DBE include an evaluation of suspected small-bowel diarrhea, abdominal pain, abnormal radiographic studies, small-bowel intussusception, the removal of small-bowel polyps, treatment for angiodysplasias, the retrieval of tissue samples, accessing Roux-en-Y anastomoses, and most

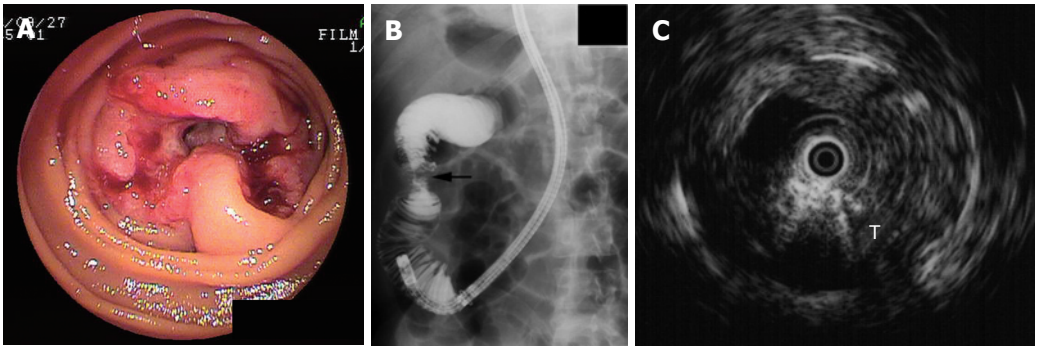

**Figure 4** Primary advanced jejunal cancer. **A**: Endoscopic image; **B**: Selective radiographic image using DBE revealing a stenotic lesion (arrow) suggestive of jejunal cancer; **C**: EUS image using ultrasound catheter probe showing a hypoechoic tumor (T), which extended into the serosal layer (T3).

recently, the evaluation of abnormal capsule endoscopy findings[4-6,8-11]. The indications for the patients examined in our study included suspected or documented small bowel diseases, obscure GI tract bleeding, incomplete conventional colonoscopy, and history of ileus. At present, conventional colonoscopy is the reference standard for evaluating the colon, especially for the screening, diagnosis, and treatment of colorectal tumors. However, the entire colon cannot be visualized during endoscopic colonoscopy in 5%-15% of patients[13,14]. Even an experienced endoscopist may be unable to intubate the colon in its entirety as far as the cecum for a variety of reasons, including a redundant or tortuous colon, marked diverticulosis, angulation or fixation of colonic loops, or spasm[14]. In this study, observation of the entire colon was possible in 93% of the patients for whom total colonoscopy failed using a conventional colonoscope, even though the median insertion time was 47 min. Using the DBE technique, especially *via* the anal route, it is possible to reach deep portions of the terminal ileum. As a result, it is considered to be an effective alternative method for patients who previously underwent incomplete colonoscopy using a standard colonoscope. DBE is much thinner, longer and less stiff than a conventional colonoscope. Therefore, colonoscopy in a "normal"patient appears to be more difficult with the DBE than with the standard colonoscope. We think that the best indication of DBE for total colonoscopy is in difficult cases when using a standard colonoscope.

In the report of Yamamoto *et al* (123 patients)[4], multiple perforations occurred after DBE in a patient with lymphoma who was actively undergoing chemotherapy. A second patient, with Crohn's disease, developed abdominal pain and fever after DBE, but no perforation was found after further investigation. May *et al* (137 patients)[10] demonstrated DBE to be a safe procedure with none of the patients experiencing bleeding or perforation. In the Heine series (275 patients)[9], severe complications were recognized in three patients, all cases involved pancreatitis. In this study, we encountered no complications. Complications have been reported relatively rarely. The reported incidence of severe complications associated with DBE has ranged from 0% to 2.5%[4-12,15].

DBE was clinically useful for making an endoscopic and histologic diagnosis as well as for providing appropriate therapy[4-12,16-21]. DBE was found to be a useful and safe method for obtaining tissue specimens, EUS images using an ultrasound catheter probe, selective

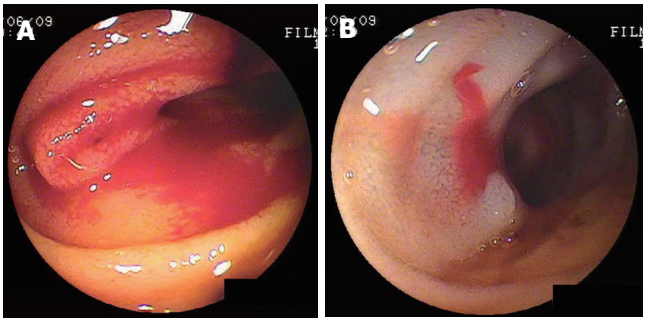

**Figure 5** Endoscopic hemostasis using hypertonic-saline solution epinephrine injection. **A**: Endoscopic image of bleeding angiodysplasia; **B**: Endoscopic image of the region after hemostasis.

radiologic images for making a diagnosis, for perfoming hemostasis, crushing enterolithiasis, performing balloon dilation, and carrying out polypectomies. Furthermore, all patients who underwent these endoscopic therapeutic procedures had an excellent outcome, thereby allowing them to avoid surgical intervention. More importantly, beyond its diagnostic value, the therapeutic value of DBE and its impact on clinical decision-making were favorable in 43% of the patients studied. This technique was also confirmed to have a high diagnostic yield in comparison to previous methods of small-bowel imaging and evaluation[4-12,20,21]. The therapeutic impact of the procedure was evident since the findings associated with this new modality resulted in decisions to start new treatments, change existing ones, and carry out surgical intervention or perform therapeutic endoscopy.

Because DBE is a new diagnostic and therapeutic procedure, it is currently not known when it should be performed during the evaluation of the small bowel. If information from prior tests is available, it is helpful in choosing the type of enteroscope (i.e. thinner type scope, EN-450P5 or therapeutic type scope, EN-450T5) and the type of approach (i.e. from oral route or anal route). Compared with other diagnostic radiologic tests, wireless capsule endoscopy has a significantly higher yield in patients[3,22]. While capsule endoscopy appears to be a reasonable initial diagnostic imaging test, miss rates of up to 36% have been reported with the capsule because of the limited 140° field of view[23]. It is limited in its inability to provide diagnostic sampling and therapeutic intervention for small-bowel lesions. Therefore, if the lesion was suspected or found by capsule endoscopy, the subsequent DBE is vital for confirming the lesion,

including biopsy, and if possible performing endoscopic therapy. Tests prior to DBE are time consuming and increase costs. At present, there are no investigation algorithms for suspected small bowel diseases. From the results of previous studies[4-12, 16-21] and ours, DBE is safe and the most accurate diagnostic modality and is able to deliver endoscopic biopsy and therapy in addition. We believe that DBE should be performed as soon as possible if small bowel disease is suspected after negative upper and lower endoscopy. However, assessing the significance of DBE in small-bowel diseases requires prospective studies comparing DBE with other currently available imaging modalities[24].

In our preliminary study, this new method was found to assist in the diagnosis and treatment of small intestine diseases and any part of the GI tract where conventional endoscopic access is otherwise difficult. It is likely that the indications for this procedure will increase in the future and that novel uses of DBE will be developed for diagnosing, monitoring, and treating entire GI tract diseases.

## Abstract

**AIM:** To assess the sampling variability of computer-aided, fractal-corrected measures of fibrosis in liver biopsies.

**METHODS:** Samples were derived from six to eight different parts of livers removed from 12 patients with clinically and histologically proven cirrhosis undergoing orthotopic liver transplantation. Sirius red-stained sections with a thickness of 2 μm were digitized using a computer-aided image analysis system that automatically measures the surface of fibrosis, as well as its outline perimeter, fractal surface and outline dimensions, wrinkledness, and Hurst coefficient.

**RESULTS:** We found a high degree of inter-sample variability in the measurements of the surface [coefficient of variation (CV) = 43% ± 13%] and wrinkledness (CV = 28% ± 9%) of fibrosis, but the inter-sample variability of Hurst's exponent was low (CV = 14% ± 2%).

**CONCLUSION:** This study suggests that Hurst's exponent might be used in clinical practice as the best histological estimate of fibrosis in the whole organ, and evidences the fact that biopsy sections, which are fundamental for the qualitative diagnosis of chronic hepatitis, play a key role in the quantitative estimate of architectural changes in liver tissue.

**Key words:** Cirrhosis; Hepatitis C virus; Inter-sample variability; Extra-cellular matrix; Image analysis

## INTRODUCTION

The discovery of specific antiviral and antifibrotic treatments and the current debate concerning the possibility of reversing liver fibrosis[1-5] emphasize the need for rigorous quantitative methods capable of detecting small differences in the liver extra-cellular matrix (ECM). Such methods should provide, on the basis of biopsy section analysis, a representative index of the status of the whole organ.

Although the use of a panel of biochemical markers or other non-invasive approaches has been proposed[5-13], liver biopsy remains the "reference standard" for confirming a clinical diagnosis of chronic hepatitis, assessing disease severity, and monitoring the efficacy of therapeutic interventions[14-17].

All of the semi-quantitative systems for defining the histological stage of chronic liver disease[18-21] have been extensively criticized because their scores generate ordinals to label subjective categories of severity that are inevitably influenced by the skill and experience of the observer[22-24]. In addition, these ordinals are not continuous variables because the absolute distances between the labeled categories are unknown, restricting their application to the most widely used methods of mathematical and statistical analyses[25,26].

Available quantitative morphometric methods[27-29] have all the primary defects in their use of the Euclidean geometry, which is inexact to describe irregular objects, and the international system (IS) meter which is unsuitable for measuring highly irregular objects.

To investigate the dynamics underlying chronic hepatitis we have recently developed a computer-aided

method based on the principles of fractal geometry that automatically measures some of the geometric characteristics of the irregularly shaped collagen fragments making up liver fibrosis[30-33]. However, in applying this quantitative method, we reflected upon the patchy (irregularly shaped or considered fractal) deposition of ECM components (Figure 1). Thus, we decided to revisit previous investigations that focused on evaluating whether a biopsy section reflects the fibrotic status of the whole liver[34-41].

We have studied biopsy sections of liver samples derived from patients undergoing orthotopic liver transplantation (OLT) with clinically and histologically proven cirrhosis. We used these samples to assess the degree of sampling variability of the quantitative fractal geometric parameters of liver fibrosis.

We found a high degree of inter-sample variability in the measurements of the surface and wrinkledness of fibrosis, but a low variability of Hurst's exponent, which gives a measure of the heterogeneous distribution of a set of irregularly-shaped objects. With the support of the Euclidean and fractal dimensions, it is capable of evaluating the loss of natural order occurring in the histological picture as a result of the disruption of the natural quantitative relationship between the metric spaces covered by fibrosis and the parenchyma[42]. This gives the alterations in the significance of a physical variable and makes Hurst's exponent the descriptor of the configurational disorder of hepatic tissue.

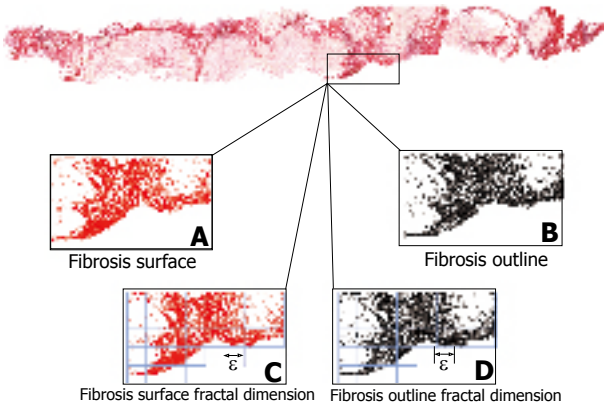

**Figure 1** Fractal morphometry of liver fibrosis in two-dimensional biopsy sections. The software automatically selects the fibrosis surface (**A**) on the basis of RGB colour segmentation, and its outline perimeter (**B**) whose calculated length was subsequently used to estimate the wrinkledness index. The fractal surface (**C**) and outline (**D**) dimensions of fibrosis were estimated using the box-counting algorithm. Covering an irregular surface requires the intersection of contiguous and non-overlapping two-dimensional boxes with a side length of $\varepsilon$: We counted the number of boxes that contain at least one point of the object $N(\varepsilon)$ for different box sizes $\varepsilon$ and then determined the fractal dimension ($D_B$) by using Equation (1).

## MATERIALS AND METHODS

### Biopsy Specimens

The study was conducted in accordance with the guidelines of the Ethics Committee of the Ospedale Maggiore IRCCS (Milan, Italy), where patients were treated.

The study was carried out on livers removed from 12 patients with clinically and histologically proven cirrhosis during OLT in order to define the variability of measured parameters in multiple specimens sampled in different sites of each liver's mass. From each liver, 6 to 8 biopsy specimens (> 10 mm in length) were collected and analyzed. All patients were positive for hepatitis C virus (HCV) infection.

### Histochemistry

Two consecutive 2 μm-thick sections were cut from each formalin-fixed, paraffin-embedded specimen. One was subsequently stained with hematoxylin-eosin solution, and the other was stained with a freshly prepared Sirius red collagen staining solution[43].

### Semi-quantitative analysis

The sections were independently staged by two expert hepatopathologists using Knodell's histology activity index (HAI)[18], and the Sheuer[19], Ishak[20] and METAVIR[21] semi-quantitative scoring systems.

### Image analysis and quantitative evaluations

For image analysis the Sirius red-stained sections were digitized at 20 × objective magnification by using a Leica DMLA microscope (Leica, Italy) equipped with an *x-y* translator table, a digital camera (Leica DC200, Leica, Italy), and an Intel Dual-Pentium Ⅲ, 660 MHz computer with incorporated ad hoc image analysis software. This software automatically selects fibrosis on the basis of RGB color segmentation[32-33]. The same image intensity level was used throughout the study. The surface area and perimeter of the fibrosis, together with its fractal surface and outline dimensions, wrinkledness, and Hurst exponent, were automatically calculated for each digitized histological section as previously described[33]. The entire procedure (patent pending) was very speedy as it digitized and furnished 11 parameters concerning the physical state of fibrosis in 10 s/mm$^2$ of tissue biopsy surface. In brief, we geometrically defined the following:

(a) Fibrosis as a set of irregularly shaped objects (collagen fragments or islets) that could be distinguished from the remaining tissue by their chemical affinity to Sirius red dye (Figure 1A).

(b) Area of fibrosis as the sum of the areas of the collagen islets (Figure 1B), expressed as a percentage of the true liver biopsy section surface area excluding any unfilled natural spaces (vascular and biliary cavities, and sinusoidal spaces) and tissue-free spaces resulting from specimen manipulation. As collagen islets are irregularly shaped, the measures of their surface areas and outline perimeters were automatically corrected by using a fractal-reference meter[32]. The fractal-rectified fibrosis surface area ($A_F$) is given by the formula:

$$A_F \cong A_M + \lambda_A (D - D\gamma) (A_B - A_M) \quad (1)$$

where $A_M$ is the morphometric area of fibrosis, $D$ the fractal surface dimension, $D\gamma$ the Euclidean dimension, $A_B$ the liver biopsy section surface area, $(A_B - A_M)$ the area of the remaining tissue, and $[\lambda_A (\Delta - \Delta\gamma)]$ the probability

factor. $\lambda_A$ was found to be $\cong 0.01$[32,33]. Equation (1) also makes it possible to consider the smallest "probably present" collagen islets (which were invisible at the magnification used in the study)[32,33] in the measurement process.

(c) Fractal-rectified length of the perimeter of fibrosis ($P_F$) as the sum of the lengths of the perimeters of each collagen islet (Figure 1B) given by the formula:

$$P_F \cong P_M [1 + \lambda_P (D - D\gamma)] \quad (2)$$

where $P_M$ is the morphometric perimeter of fibrosis, $\lambda_P$ is the dilation constant for the perimeter of the collagen islets depending only on the scale of observation[32,33], and was found to be $\cong 4.5$[32,33]. The obtained $P_F$ values were subsequently used to determine the wrinkledness of the fibrosis.

(d) Fractal surface and outline dimensions of fibrosis as measures of its space-filling properties (Figure 1C), which were automatically estimated by means of the box-counting method using the formula (Figure 2):

$$D_B = \lim_{\varepsilon \to 0} \frac{Log N(\varepsilon)}{Log(1/\varepsilon)} \quad (3)$$

where $D_B$ is the box-counting fractal dimension, $\varepsilon$ the side length of the box, and $N(\varepsilon)$ the smallest number of boxes of side $\varepsilon$ required to cover the complete surface or the outline of the object (Figure 1D). As the zero limit cannot be applied to biological objects, the dimensions were calculated as D = d, where d is the slope of the graph of log $[N(\varepsilon)]$ against log $1/\varepsilon$. The log-log graphs were plotted, the linear segments were identified using least squares regression, and their gradients were calculated using an iterative resistant line method[30-33,44-46].

(e) Wrinkledness (W) of fibrosis as a form-factor, given by the formula (Figure 3):

$$W = \frac{P_F}{2\sqrt{\pi A_F}} - R \quad (4)$$

where R is the roundness coefficient[32,33].

(f) Hurst exponent of fibrosis as a measure of the heterogeneous distribution of a set of irregularly-shaped objects (in this case, collagen islets), obtained using the relationship:

$$H = D\gamma + 1 - D \quad (5)$$

where $D$ is the fractal dimension of the outline of all of the collagen islets making up the fibrosis[33,47-49].

### Statistical analyses

All data are expressed as mean ± SD and were analyzed using Statistica software (StatSoft Inc., Tulsa, OK, USA).

The sampling variability of the fibrosis surface, wrinkledness, and Hurst exponent was evaluated in each liver by using the coefficient of variation (CV) given by the formula:

$$CV = \left(\frac{SD}{mean}\right) \times 100\% \quad (6)$$

The obtained data were analyzed using the Student $t$-test. $P$ values of less than 0.05 were considered statistically significant.

## RESULTS

### Semi-quantitative evaluations

All histological sections were staged as cirrhosis and classified in the maximum category of each of the 4 systems used in the study (HAI, and the Scheuer, Ishak and METAVIR scoring systems).

### Fractal morphometric evaluations

Table 1 shows the fractal morphometric measures of each investigated liver. The minimum and maximum values of $A_F$ obtained by measuring the 88 biopsy sections were 4.95% and 55.67% of the specimen area, with a mean value of 20.46% ± 10.55%.

The same 88 biopsy sections gave $P_F$ values ranging from 907.6 μm and 16341.1 μm, with a mean value of 6073.6 ± 3299.6 μm.

The values of the fractal surface dimension of fibrosis ranged from 1.47 to 1.84 (mean 1.66 ± 0.07), and those of the fractal outline dimension ranged from 1.41 to 1.77, with a mean of 1.58 ± 0.07.

The mean W value was 1041.6 ± 321.25 (range: 460-1834.8). The H values ranged from 0.23 to 0.59, with a mean of 0.41 ± 0.07.

### Sampling variability

Table 2 shows the inter-sample variability determined in the 6 to 8 biopsy samples that were taken from each of the 12 livers. High CV values were obtained for both the surface (CV = 43% ± 12%, range, 19.79-57.28) and the wrinkledness of fibrosis (CV = 28% ± 9%, range, 14.13-40.22), whereas the variability of Hurst's exponent was low (CV = 14% ± 2%, range, 10.71-17.74). Statistical comparisons of the mean surface, wrinkledness, and Hurst's exponent CVs showed that Hurst exponent was characterized by a smaller range and that Hurst exponent mean CV was statistically different from that of the fibrosis surface ($P < 0.00005$) and wrinkledness ($P < 0.00005$) (Figure 4).

## DISCUSSION

During the course of chronic hepatitis, the net result of the balance between ECM synthesis (fibrogenesis) and degradation (fibrolysis) is the irregular shape and patchy distribution of collagen fragments. Currently, the lack of robust and representative markers of fibrosis is the single greatest factor limiting both the validation of progression or regression of fibrosis, and the testing of antifibrotic therapies in clinical trials. This observation prompted us to investigate whether fractal-rectified measures of fibrosis recognized in two-dimensional liver biopsy sections provide concrete scalars that can represent the state of the whole organ. This aim was reinforced by recent proposals to use methods of analyzing blood stream molecules as a means of scoring liver fibrosis. However, none of these methods has inspired sufficient confidence to displace our reliance on hepatic histology[33,50-57].

To obtain rigorous measures of irregularly shaped collagen islets, a computer-aided method was developed that uses a fractal-corrected meter to provide close-to-reality

**Table 1 Fractal parameters of liver fibrosis measured in biopsies taken at different sites (mean ± SD)**

measurements[30-33]. Such measurements cannot be obtained using the Euclidean meter, which is able to quantify only smooth objects (e.g. geometrical figures) that are practically unknown in Nature[30-33,44-46].

To determine the extent to which a histological section represents the whole liver we compared the scalar number generated by our quantitative method representing the magnitude of the area, wrinkledness and Hurst's exponent of the fibrosis recognized in two-dimensional sections taken from different parts of 12 explanted livers. The present study was restricted to explanted cirrhotic livers as they could make it possible to sample multiple specimens from the same liver, but impossible to obtain from the liver of living patients.

In a previous study, we found a high degree of intra-sample variability in the surface area of fibrosis that revealed the three-dimensional spatial irregularity of fibrosis detectable in the sample that reveals the non-representativity of the sample respect in the whole liver tissue[33]. In line with this finding, our analysis of the surface area (CV = 43% ± 12%) and wrinkledness (CV = 28% ± 9%) of the fibrosis detected in two-dimensional sections (Table 2) taken from multiple biopsies excised in different sites of each liver mass, revealed a high degree of variability and thus a low possibility to predict the state of a sample and that of the whole organ (i.e. liver).

Chronic hepatitis is an irregular dynamical process

complex both in time and in space, and its end stage known as cirrhosis is characterized by a wide distortion of the normal parenchyma configuration and secondary vascular events that might contribute to the heterogeneous distribution of ECM components[58].

The lowest variability (CV = 14% ± 2%) was detected for Hurst exponent in our study. We have introduced this parameter to measure the loss of natural liver tissue harmony[33]. This concept results from the ratio of two quantitative canons normally found in disease-free livers: 2% of ECM belonging to the bearing system of the liver tissue, and 98% of parenchymal tissue.

Hurst's exponent which gives a measure of the heterogeneous distribution of a set of irregularly-shaped objects, is capable of evaluating the loss of natural order that occurs in the histological picture as a result of the disruption of the natural quantitative relationship between the metric spaces covered by fibrosis and the parenchyma[42]. This is because Hurst exponent derives from the interaction between the Euclidean and fractal dimensions, becoming a measure unit. Both Euclidean and fractal dimensions separately express only the position of an object in the Euclidean space.

The present results suggest that this quantitative parameter might be more useful in clinical practice as a means of estimating fibrosis and its progression or reversibility after therapy, than the surface and wrinkledness of fibrosis.

Our results also underscore the key role of biopsy analyses both in diagnosing the histology of chronic hepatitis and in quantifying changes in the geometry of ECM islets. The clinical relevance of any of the parameters issued from morphometry is however not known yet. This incompleteness may be due to the low rigor in the actual detection of the data based on the Euclidean geometry and the use of linear IS meter to measure very irregular objects[30-33].

In summary, our method offers the following theoretical and experimental contributions. Hurst's exponent can be used to provide a good estimate of tissue alterations. Objective and rigorous metric measures of the fibrosis of a section of biopsied tissue do not fully represent the status of the organ as a whole. Hurst's exponent of liver tissue in a histological section is a good descriptor of the architectural condition of the whole liver.

Hurst's exponent therefore gives scientific value to the liver tissue status indicated by the term of architectural change, originally used by Ishak *et al*[20] in their definition of the staging of chronic viral hepatitis.

## Abstract

**AIM:** To examine the effects of anti-high mobility group box 1 (HMGB1) neutralizing antibody in experimental severe acute pancreatitis (SAP).

**METHODS:** SAP was induced by creating closed duodenal loop in C3H/HeN mice. SAP was induced immediately after intraperitoneal injection of anti-HMGB1 neutralizing antibody (200 μg). Severity of pancreatitis, organ injury (liver, kidney and lung), and bacterial translocation to pancreas was examined 12 h after induction of SAP.

**RESULTS:** Anti-HMGB1 neutralizing antibody significantly improved the elevation of the serum amylase level and the histological alterations of pancreas and lung in SAP. Anti-HMGB1 antibody also significantly ameliorated the elevations of serum alanine aminotransferase and creatinine in SAP. However, anti-HMGB1 antibody worsened the bacterial translocation to pancreas.

**CONCLUSION:** Blockade of HMGB1 attenuated the development of SAP and associated organ dysfunction, suggesting that HMGB1 may act as a key mediator for inflammatory response and organ injury in SAP.

**Key words:** Severe acute pancreatitis; High mobility group box-1; Neutralizing antibody; Inflammatory response; Organ dysfunction; Bacterial translocation

## INTRODUCTION

In severe acute pancreatitis (SAP), multiple organ dysfunction syndrome (MODS) in the early phase[1,2] and complications of infection (infected pancreatic necrosis and sepsis) in the late phase are contributors to high mortality in SAP[3,4]. MODS is a consequence of the systemic inflammatory response syndrome, and it is conceivable that release of humoral mediators from the excessive activated macrophages/monocytes and neutrophils may lead to the remote organ injury. Complications of infection are thought to be a result of bacterial translocation from the gastrointestinal tract, and breakdown of intestinal integrity is considered to be implicated in the mechanism[5-7].

High mobility group box 1 (HMGB1) protein, originally discovered 30 years ago as a nuclear DNA binding protein[8-10], was recently identified as a late-acting mediator of endotoxin lethality[11]. Injection of HMGB1 itself was lethal, and serum levels of HMGB1 increased from 8 to 32 h after the administration of endotoxin, when the tumor necrosis factor (TNF) peak had already occurred[11]. Antibodies to HMGB1 attenuated the mortality associated with endotoxemia, even when the antibodies were administered 2 h after the onset of endotoxemia[11]. HMGB1 was also found to have the capacity to induce cytokines and activate inflammatory cells when it was applied extracellularly[11-13]. This implicates HMGB1 as a proinflammatory mediator. Recent investigations reported that serum HMGB1 levels increased in patients with sepsis/endotoxemia[11,14,15], hemorrhagic shock[16], acute lung injury[17,18], rheumatoid arthritis[19] and disseminated intravascular coagulation[20]. It has been demonstrated that HMGB1 is secreted actively by living inflammatory cells such as stimulated macrophages/monocytes, and is released passively from necrotic or damaged cells[21-23]. Therefore, HMGB1 may be related to inflammation and necrosis in SAP, and may be an important mediator for multiple organ failure.

In a recent study, we have first demonstrated that

serum HMGB1 levels were significantly elevated in patients with SAP on admission, and were correlated with the severity[24,25] of the disease. The HMGB1 levels were higher in patients with organ dysfunction and infection during the clinical course. The HMGB1 levels in non-survivors were higher than those in survivors. These results suggest that HMGB1 may play a pivotal role in the pathogenesis of SAP, and that HMGB1 may act as a key mediator for inflammation and organ failure in this disease. In the present study, to clarify the role of HMGB1 in the pathophysiology of SAP, effects of anti-HMGB1 neutralizing antibody were investigated in SAP in mice.

## MATERIALS AND METHODS

### Animals

Female C3H/HeN mice (weighing 20-22 g, 9 weeks old) were purchased from CLEA Japan (Tokyo, Japan). The protocol for this animal experiment was approved by the Institutional Animal Committee of Kobe University Graduate School of Medical Sciences.

### Anti-HMGB1 neutralizing antibody

Anti-HMGB1 neutralizing antibody (chicken anti-HMGB1 polyclonal antibody) was obtained from Shino-Test Corporation (Sagamihara, Japan). This antibody recognizes mouse HMGB1. The specificity and neutralizing activity of this antibody was confirmed by western blot analysis.

### Model for acute necrotizing pancreatitis (closed duodenal loop-induced pancreatitis)

Under general anesthesia with a subcutaneous injection of carbamic acid ethyl ester (urethane) at a dosage of 1.5 g/kg, a midline laparotomy was performed, and a closed loop (2 cm in length) was created by ligating the duodenum at 1 cm proximal and distal sides to the biliopancreatic duct outlet. Only laparotomy was performed in sham-operated mice.

### Experimental design

Saline (0.2 mL) or anti-HMGB1 neutralizing antibody (200 μg, 0.2 mL) was injected intraperitoneally, and immediately closed duodenal loop-induced pancreatitis was made. Mice were divided into three groups as follows. Group A: Sham, laparotomy with saline injection. Group B: SAP, severe acute pancreatitis with saline injection. Group C: HMGB1 Ab + SAP, severe acute pancreatitis with anti-HMGB1 antibody injection. Mice were sacrificed 12 h after induction of SAP. Pancreas and lung tissue was removed, fixed in 10% formalin, and stained with hematoxylin and eosin for light microscopic analysis. Blind analysis was carried out for all histological studies. Blood sample was drawn from heart. Serum amylase, aspartate aminotransferase (AST), alanine aminotransferase (ALT), lactate dehydrogenase (LDH), blood urea nitrogen (BUN), and creatinine (Cr) levels were measured using standard clinical automated analyzer.

### Bacterial culture of pancreas

The skin was cleaned with 10% povidone iodine. Pancreas was obtained 0, 4, 8, and 12 h after induction of SAP under sterile conditions, and processed for culture of aerobic and anaerobic organisms using a standardized method. Specimens were inoculated onto agar plates including BTB agar, sheep blood agar, chocolate agar (Nippon Becton Dickinson Co. Ltd., Tokyo, Japan), brucella HK agar (Kyokuto Pharmaceutical Co. Ltd., Tokyo, Japan), and GAM (Gifu Anaerobic Medium) agar (Nissui Pharmaceutical Co. Ltd., Tokyo, Japan). BTB agar was incubated in the aerobic chamber at 37℃, sheep blood agar and chocolate agar were incubated in the $O_2/CO_2$ incubator, and brucella HK agar was incubated in the anaerobic chamber for 48 h, respectively. GAM agar was incubated in the ambient chamber at 37℃ for 72 h. When the colony forming was detected, it was considered to be positive for bacterial translocation.

**Table 1 Blood biochemical parameters**

| Parameter | Sham ($n$ = 6) | SAP ($n$ = 20) | HMGB1 Ab + SAP ($n$ = 12) |
|---|---|---|---|
| Amylase (IU/L) | 2220 ± 707 | 52155 ± 14449[a] | 8994 ± 1623[c] |
| AST (IU/L) | 1499 ± 335 | 5056 ± 545[a] | 4193 ± 561 |
| ALT (IU/L) | 395 ± 288 | 1215 ± 118[a] | 848 ± 145[c] |
| LDH (IU/L) | 6743 ± 1206 | 16403 ± 1072[a] | 15220 ± 4687 |
| BUN (mg/dL) | 32 ± 3 | 93 ± 6[a] | 94 ± 7 |
| Cr (mg/dL) | 0.10 ± 0.00 | 0.42 ± 0.10[a] | 0.16 ± 0.03[c] |

Blood samples were obtained 12 h after induction of SAP. AST: Aspartate aminotransferase; ALT: Alanine aminotransferase; LDH: Lactate dehydrogenase; BUN: Blood urea nitrogen; Cr: Creatinine. [a]$P < 0.05$ *vs* Sham group; [c]$P < 0.05$ *vs* SAP group.

### Statistical analysis

The results are expressed as mean ± SE. The Mann-Whitney $U$ test and Chi-square test were used to evaluate differences between two groups. A $P$ value < 0.05 was considered statistically significant.

## RESULTS

### Serum amylase level

Twelve hours after induction of SAP, serum amylase levels were significantly elevated in SAP group, and anti-HMGB1 neutralizing antibody significantly reduced its elevation (Table 1).

### Morphology of pancreas and lung

Twelve hours after induction of SAP, HE staining of the pancreas showed edema, hemorrhage, leukocyte infiltration, and necrosis. Anti-HMGB1 neutralizing antibody improved the histological alterations of pancreas (Figure 1A). Twelve hours after induction of SAP, HE staining of the lung showed edema, inflammatory infiltration, hemorrhage and thickening of the alveolar membrane. In contrast, anti-HMGB1 neutralizing antibody ameliorated the histological changes in the lungs (Figure 1B).

### Hepatic and renal dysfunction

Twelve hours after induction of SAP, serum AST, ALT,

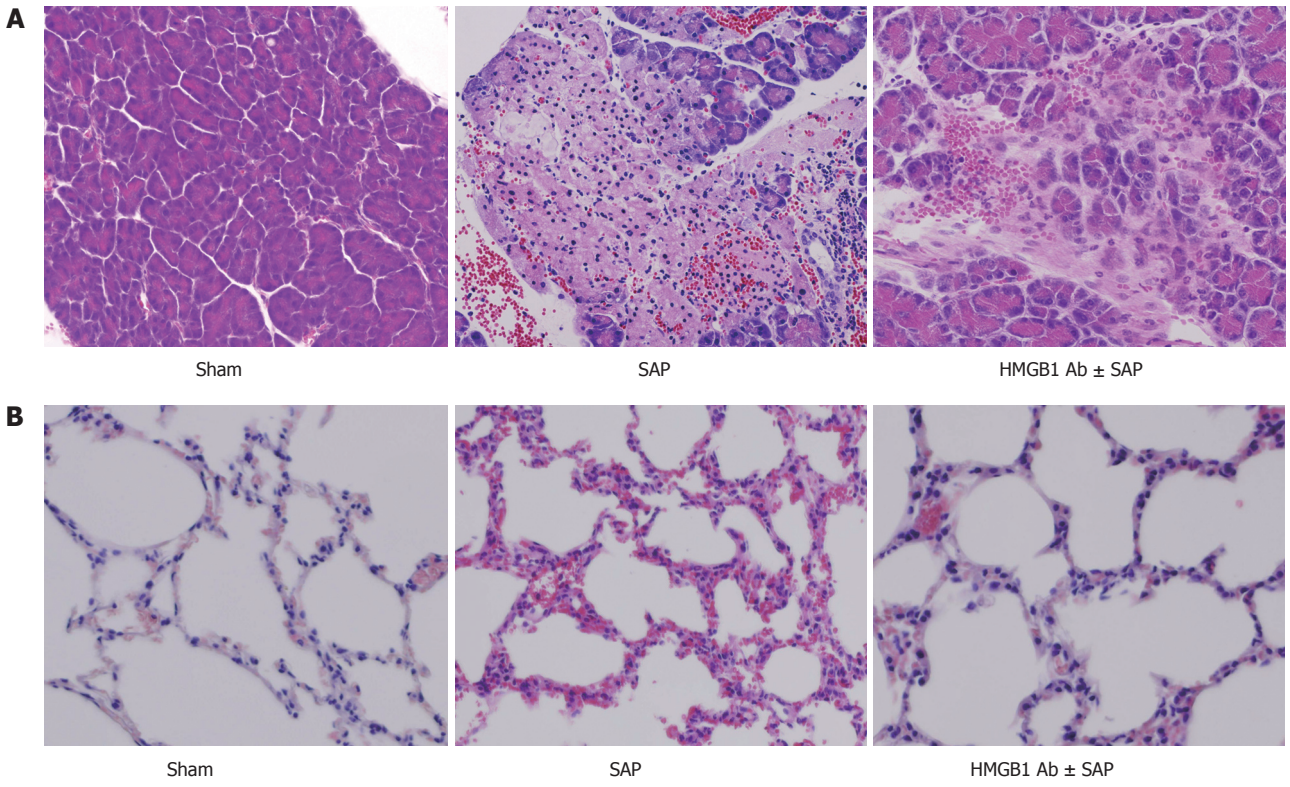

**Figure 1** Effect of anti-HMGB1 antibody on the morphology of pancreas and lung in mouse severe acute pancreatitis (SAP). Tissue samples were obtained 12 h after induction of closed duodenal loop pancreatitis. **A**: HE staining of pancreas (× 200); **B**: HE staining of lung (× 200).

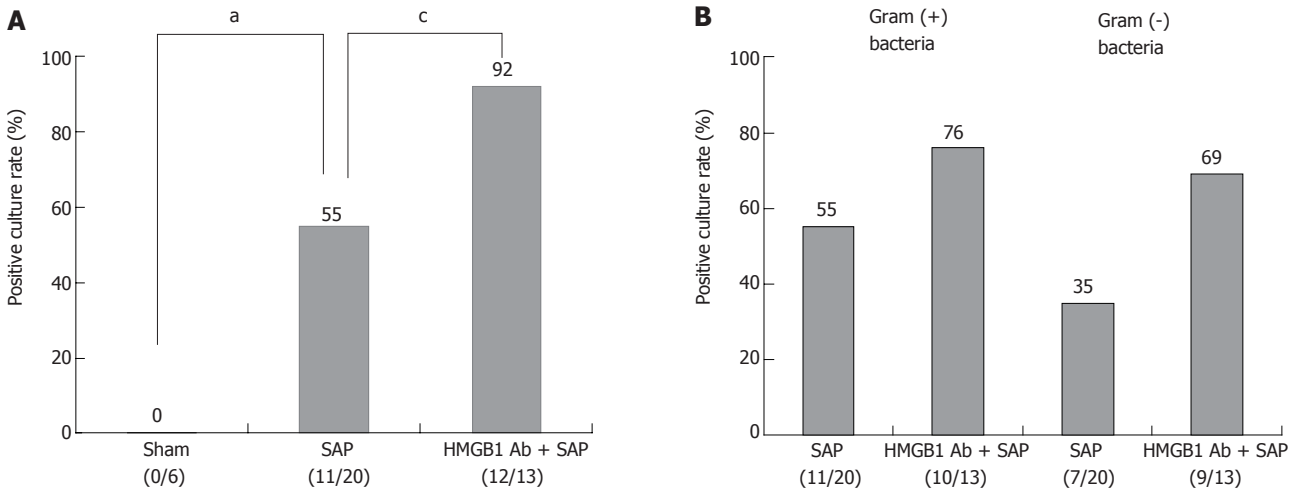

**Figure 2** Effect of anti-HMGB1 antibody on the bacterial translocation to pancreas in mouse severe acute pancreatitis (SAP). Bacterial culture of pancreas was examined 12 h after induction of SAP. **A**: Positive rate of bacterial culture of pancreas (overall). $^{a}P < 0.05$ *vs* Sham group; $^{c}P < 0.05$ *vs* SAP group; **B**: Positive rate of bacterial culture of pancreas (Gram-positive and Gram-negative bacteria).

LDH, BUN, and Cr levels were significantly elevated in SAP group, and anti-HMGB1 neutralizing antibody significantly improved the elevated ALT and Cr (Table 1).

### *Bacterial translocation to pancreas*

Bacterial translocation to pancreas was not observed in Sham group (Figure 2A), but could be detected 12 h after the induction of SAP. In earlier periods (0, 4, and 8 h), it was not detected. In SAP group, 55% of mice (11/20) exhibited positive bacterial culture. Anti-HMGB1 antibody significantly increased the positive culture rate to 92% (12/13) (Figure 2A). Positive rate of gram-positive and gram-negative bacterial culture in SAP group was 55% (11/20) and 35% (7/20), respectively. Anti-HMGB1 antibody increased them to 76% (10/13) and 69% (9/13), respectively, but no significant difference was observed (Figure 2B).

## DISCUSSION

Extracellular HMGB1 was recently identified as a novel proinflammatory cytokine. In a previous study, we dem-

onstrated that serum HMGB1 levels were significantly elevated in patients with SAP, and were correlated with disease severity[24]. In this study, we have for the first time demonstrated that blockade of HMGB1 attenuated the development of SAP and associated organ dysfunction, suggesting that HMGB1 may act as a key mediator for inflammatory response and organ injury in SAP. We think that raised HMGB1 may represent a cause of aggravation of SAP (progression to SAP) and associated organ dysfunction as well as a consequence of SAP. On the other hand, HMGB1 can promote alterations in gut barrier function by increasing the permeability in enterocytic monolayers and increasing bacterial translocation in mice[26]. Similar contributions of HMGB1 to SAP were supposed, but blockade of HMGB1 adversely worsened the bacterial translocation against our expectation.

There have been several reports concerning effects of anti-HMGB1 neutralizing antibody in other pathological conditions. It has been demonstrated that anti-HMGB1 antibody protected against organ injury and improved survival in murine sepsis[14] and rat sepsis[27]. Tsung *et al*[28] clarified that inhibition of HMGB1 with neutralizing antibody significantly decreased liver damage after ischemia/reperfusion, whereas administration of recombinant HMGB1 worsened it. It has been reported that anti-HMGB1 antibody improved lipopolysaccharide (LPS)-induced acute lung injury in mice[18], and ventilator-induced lung injury in rabbits[29]. These observations together with our results in this study indicate that HMGB1 is one of the deteriorating factors in the development of organ injury.

Concerning the elevation of serum HMGB1 levels in SAP, two possible mechanisms can be assumed[24]. First, HMGB1 may be produced and released by macrophages/monocytes in response to inflammatory mediators. In SAP, it is conceivable that release of humoral mediators from the excessive activated macrophages/monocytes may lead to the remote organ injury. Thus, release of HMGB1 from activated macrophages/monocytes may participate in tissue injury and organ failure in SAP. Second, HMGB1 may be produced and released by injured pancreas or other damaged organs. Recent investigations demonstrated that HMGB1 mRNA expression was significantly increased in liver and lung after rat thermal injury[30], that HMGB1 concentration was increased in lung epithelial lining fluid of patients with acute lung injury[18], and that HMGB1 expression was up-regulated in the liver after murine liver ischemia-reperfusion[28]. Therefore, it is likely that HMGB1 is produced and released by damaged organs in SAP. Change of HMGB1 expression in various tissues should be investigated in SAP.

It was recently clarified that extracellular HMGB1 acts as a cytokine by signaling *via* the receptor for advanced glycated end-products (RAGE)[31,32] and/or *via* members of the toll-like receptor (TLR) family (TLR2 and 4)[33]. Activation of RAGE and TLR leads to the induction of inflammatory responses *via* NF-κB. Tsung *et al*[28] demonstrated that anti-HMGB1 antibody failed to provide protection in TLR4-defective mice, but successfully reduced liver damage after ischemia/reperfusion in wild-type mice, suggesting that TLR4 is involved in the process as one of the receptors. As TLR4 recognizes LPS of gram-negative bacilli[34,35], interactions of HMGB1 with TLR4 may provide an explanation for the ability of HMGB1 to generate inflammatory responses that are similar to those initiated by LPS. Moreover, TLR is involved in not only inflammatory response but also host defense mechanism, and it is postulated that TLR may function defensively against infection. In our result, anti-HMGB1 antibody worsened the bacterial translocation (especially gram-negative bacteria) in SAP, suggesting that HMGB1 may function at least partially *via* TLR (especially TLR4).

Results obtained here raise the possibility that blockade of HMGB1 in the early phase is useful as a new therapeutic option against the inflammatory response and MODS in patients with SAP. Further investigations should be performed to elucidate the role of HMGB1 and HMGB1 signaling in the mechanism of inflammatory response, organ injury, and infection in SAP.

## Abstract

**AIM:** To clarify the prevalence of defensive medicine and the specific defensive medicine practices among gastroenterologists in Japan.

**METHODS:** A survey of gastroenterologists in Hiroshima, Japan, was conducted by mail in March 2006. The number of gastroenterologists reporting defensive medicine behaviors or changes in their scope of practice and the reported defensive medicine practices, i.e., assurance and avoidance behaviors, were examined.

**RESULTS:** A total of 131 (77%) out of 171 gastroenterologists completed the survey. Three (2%) respondents were sued, and most respondents (96%) had liability insurance. Nearly all respondents (98%) reported practicing defensive medicine. Avoidance behaviors, such as avoiding certain procedures or interventions and avoiding caring for high-risk patients, were very common (96%). Seventy-five percent of respondents reported often avoiding certain procedures or interventions. However, seasoned gastroenterologists (those in practice for more than 20 years) adopted avoidance behaviors significantly less often than those in practice for less than 10 years. Assurance behaviors, i.e., supplying additional services of marginal or no medical value, were also widespread (91%). Sixty-eight percent of respondents reported that they sometimes or often referred patients to other specialists unnecessarily.

**CONCLUSION:** Defensive medicine may be highly prevalent among gastroenterologists throughout Japan, with potentially serious implications regarding costs, access, and both technical and interpersonal quality of care.

**Key words:** Defensive medicine; Gastroenterologist; Japan; Survey; Clinical practice

## INTRODUCTION

The number of negligence claims against physicians is increasing continuously, not only in Western countries but also in Japan[1-9], where a 10-fold increase in malpractice litigations, from 102 to 1019 cases per year, was observed between 1960 and 2003[7]. Although the number of medical lawsuits in Japan is relatively small in comparison to that in the United States of America (USA), the situation in Japan is gradually becoming more like that in the USA[10,11].

Defensive medicine is a deviation from sound medical practice that is induced primarily by the threat of liability claims[12,13]. Defensive medicine consists of two general behaviors. One is assurance behavior (sometimes called "positive" defensive medicine), which involves supplying additional services of marginal or no medical value with the aim of reducing adverse outcomes, deterring patients from filing malpractice claims, or persuading the legal system that the standard of care is met. The other is avoidance behavior (sometimes called "negative" defensive medicine), which refers to physicians' efforts to distance themselves from sources of legal risk. It was recently reported that nearly all (93%) physicians in the USA practice defensive medicine[12]. Defensive medicine has been reported in other countries[14,15], but the prevalence and specific behaviors of defensive medicine in Japan, particularly among gastroenterologists, remain unclear. Therefore, we studied the prevalence of defensive medicine and specific defensive behaviors in a proportion of gastroenterologists in Japan.

## MATERIALS AND METHODS

### Survey questionnaire and administration

A random sample of 171 Japanese gastroenterologists was drawn from the Hiroshima Medical Association Physician File. A questionnaire with items pertaining to clinical decisions, liability insurance, and malpractice claims, was developed. Respondents were asked to rate on a four-point scale (never, rarely, sometimes, often) how often concerns about malpractice liability claims caused them to engage in each of 4 forms of assurance behavior: (1) order more tests than medically indicated, (2) prescribe more medications than medically indicated, (3) refer patients to specialists unnecessarily, and (4) suggest invasive procedures against their professional judgment. Respondents used the same scale to rate the frequency with which they practiced two forms of avoidance behavior: (1) avoid conducting certain procedures/interventions, and (2) avoid caring for high-risk patients[12]. In addition, respondents were asked in consecutive questions whether they had reduced or eliminated various high-risk aspects of their medical practice in the last 3 years.

The questionnaire was mailed in March 2006 to the 171 randomly selected gastroenterologists in Hiroshima, Japan. One hundred and thirty-one (77%) of these gastroenterologists completed the survey.

### Statistical analysis

Survey responses were analyzed in relation to the number of years respondents had been in practice or to the type of practice. Differences between groups were analyzed by chi-square test or Fisher's exact probability test. $P < 0.05$ was considered statistically significant.

## RESULTS

### Respondent characteristics

The characteristics of respondents are shown in Table 1. Respondents were experienced gastroenterologists (82% with > 9 years in practice). They practiced in hospitals (81%), solo settings (14%), and other contexts (5%). Two percent of respondents had been sued in the past. Most respondents (96%) had obtained liability insurance, either directly from a commercial carrier (93%) or through a hospital (7%). Most respondents perceived their insurance premiums to be financially burdensome, with 33% classifying the burden as major.

**Table 1 Characteristics of gastroenterologists surveyed (*n* = 131)**

| Characteristic | Gastroenterologists *n* (%) |
|---|---|
| Sex | |
| Male | 110 (84) |
| Female | 21 (16) |
| Years in practice | |
| 1-10 | 33 (25) |
| 11-19 | 67 (51) |
| 20-29 | 26 (20) |
| 30 | 5 (4) |
| Practice type | |
| Solo | 18 (14) |
| Hospital clinic | 107 (81) |
| Other | 6 (5) |
| Perceived burden of liability insurance premiums | |
| Not a burden | 14 (11) |
| Minor | 17 (13) |
| Medium | 57 (43) |
| Major | 3 (33) |
| Claims experience | |
| Sued | |
| ≤ 3 yr ago | 1 (1) |
| > 3 yr ago | 2 (1) |
| Never sued | 128 (98) |

**Table 2 Frequency of assurance and avoidance behaviors among gastroenterologists surveyed**

| | Often *n* (%) | Never/rarely *n* (%) |
|---|---|---|
| Assurance behavior | | |
| Order more tests than medically indicated | 7 (5) | 83 (64) |
| Prescribe more medications (e.g., antibiotics) than medically indicated | 0 (0) | 110 (84) |
| Refer patients to other specialists unnecessarily | 36 (27) | 41 (32) |
| Suggest invasive procedures (e.g., biopsy) to confirm diagnosis | 21 (16) | 61 (47) |
| Avoidance behavior | | |
| Avoid certain procedures or interventions | 24 (18) | 32 (24) |
| Avoid caring for high-risk patients | 27 (21) | 32 (24) |

### General findings

Most respondents (98%) reported that they sometimes or often engaged in at least one of the six forms of defensive medicine outlined in the survey.

### Assurance behavior

One-hundred and nineteen (91%) of the 131 respondents reported that they sometimes or often engaged in at least one of the four forms of assurance behavior. Sixty-eight percent of respondents reported that they sometimes or often referred patients to other specialists unnecessarily (Table 2). Fifty-four percent of respondents reported that they sometimes or often suggested invasive procedures that were unwarranted. Thirty-six percent of respondents reported that they sometimes or often ordered more diagnostic tests than medically indicated. Sixteen percent of respondents reported sometimes or often prescribing more medications than were medically indicated.

### Avoidance behavior

One-hundred and twenty-six (96%) of the 131 respondents reported that they sometimes or often engaged in at least one of the two forms of avoidance behavior. Seventy-five percent of respondents reported that they often avoided certain procedures or interventions (Table 2). Fifty-three percent of respondents reported that they sometimes or often avoided caring for high-risk patients.

### Assurance and avoidance behaviors in relation to years in practice

The relation between assurance and avoidance behaviors and years in practice is shown in Table 3. Seasoned

**Table 3 Relation between assurance and avoidance behaviors and years in practice**

| | Number of yearsin practice | Often/sometimes *n* (%) |
|---|---|---|
| Assurance behavior | | |
| Order more tests than medically indicated | 1-9 | 14/33 (42) |
| | 10-19 | 26/67 (39) |
| | 20- | 8/31 (26) |
| Prescribe more medications (e.g., antibiotics) than medically indicated | 1-9 | 7/33 (21)[a] |
| | 10-19 | 13/67 (19)[c] |
| | 20- | 1/31 (3) |
| Refer patients to other specialists unnecessarily | 1-9 | 24/33 (73) |
| | 10-19 | 47/67 (70) |
| | 20- | 19/31 (61) |
| Suggest invasive procedures (e.g., biopsy) to confirm diagnosis | 1-9 | 21/33 (64) |
| | 10-19 | 36/67 (54) |
| | 20- | 13/31 (42) |
| Avoidance behavior | | |
| Avoid certain procedures or interventions | 1-9 | 28/33 (85) |
| | 10-19 | 52/67 (78) |
| | 20- | 19/31 (61)[e] |
| Avoid caring for high-risk patients | 1-9 | 28/33 (85) |
| | 10-19 | 52/67 (78) |
| | 20- | 19/31 (61)[e] |

[a]$P = 0.033$, [c]$P = 0.027$ *vs* 20 yr in practice; [e]$P = 0.032$ *vs* 1-9 yr in practice.

**Table 4 Relation between assurance and avoidance behaviors and practice types**

| | Practicetype | Often/sometimes *n* (%) |
|---|---|---|
| Assurance behavior | | |
| Order more tests than medically indicated | Solo | 2/18 (11)[a] |
| | Hospital clinic | 43/107 (40) |
| | Other | 3/6 (50) |
| Prescribe more medications (e.g., antibiotics) than medically indicated | Solo | 1/18 (6) |
| | Hospital clinic | 19/107 (18) |
| | Other | 1/6 (17) |
| Refer patients to other specialists unnecessarily | Solo | 18/18 (100)[b] |
| | Hospital clinic | 69/107 (64) |
| | Other | 3/6 (50) |
| Suggest invasive procedures (e.g., biopsy) to confirm diagnosis | Solo | 10/18 (56) |
| | Hospital clinic | 57/107 (53) |
| | Other | 3/6 (50) |
| Avoidance behavior | | |
| Avoid certain procedures or interventions | Solo | 12/18 (67) |
| | Hospital clinic | 82/107 (77) |
| | Other | 5/6 (83) |
| Avoid caring for high-risk patients | Solo | 14/18 (78) |
| | Hospital clinic | 80/107 (75) |
| | Other | 5/6 (83) |

[a]$P = 0.013$, [b]$P = 0.0006$ *vs* hospital clinic.

gastroenterologists (20 years in practice or more) prescribed medications that were not medically indicated significantly more often than other gastroenterologists ($P = 0.033$ by Fisher's exact probability test *vs* gastroenterologists in practice for 1-9 years and $P = 0.027$ *vs* gastroenterologists in practice for 10-19 years). Seasoned gastroenterologists were also significantly less likely than those who had been in practice for fewer than 10 years to avoid certain procedures or interventions [19/31 (61%) *vs* 28/33 (85%), $P = 0.032$ by Fisher's exact probability test] and to avoid caring for high-risk patients [19/31 (61%) *vs* 28/33 (85%), $P = 0.032$ by Fisher's exact probability test].

### Assurance and avoidance behaviors in relation to practice type

Adoption of assurance and avoidance behaviors in relation to practice types is shown in Table 4. Gastroenterologists in solo practices ordered significantly less often more tests than medically indicated than gastroenterologists in hospital clinics [2/18 (11%) *vs* 43/107 (40%), $P = 0.013$ by Fisher's exact probability test]. However, they referred patients to other specialists unnecessarily significantly more often than those in hospital clinics [18/18 (100%) *vs* 69/107 (64%), $P = 0.0006$ by Fisher's exact probability test].

### Most recent defensive act

Ninety percent (118 of the 131) of gastroenterologists who reported practicing defensive medicine detailed their most recent defensive act. Specific practices reported by these respondents are summarized in Table 5. The defensive act most frequently reported was recording interactions with a patient in considerable detail (35%). This was followed by unnecessary referral (33%), avoiding certain procedures or interventions, and ordering an unnecessary test (11%).

**Table 5 Specific defensive medicine practices among gastroenterologists ($n = 118$)**

| Most recent act of defensive medicine | Gastroenterologists *n* (%) |
|---|---|
| Recorded interaction with patient in considerable detail | 41 (35) |
| Referred patient to another physician | 39 (33) |
| Avoided certain procedure or intervention | 25 (21) |
| Ordered more tests than medically indicated | 13 (11) |

## DISCUSSION

We found that defensive medicine practices were as widespread among the gastroenterologists we surveyed in Japan as they are among physicians in the USA. In the USA, 88% of physicians have a lawsuit filed against them, reflecting the high rate of litigation in that country[12]. Studdert *et al*[12] reported that 93% of physicians in the USA practice defensive medicine, and that assurance behaviors, such as ordering tests, performing diagnostic procedures, and referring patients for consultation, are very common (92%). In Japan, the number of negligence claims against

gastroenterologists is still very limited. Only 2% of our respondents have been sued, a finding similar to that reported by the Hiroshima Prefectural Medical Association from a survey of all its members[16]. Despite the relatively low frequency of lawsuits, nearly all (98%) gastroenterologists we surveyed reported practicing defensive medicine, and both assurance and avoidance behaviors were very common (91% and 96%, respectively). This may be due to the continuous increase in the number of litigations. With sensational mass media reporting on medical malpractice in Japan, gastroenterologists in Japan have begun to focus on risk management activities, leading them to practice defensive medicine[7,17]. These findings support the idea that individual physicians' propensity to practice defensive medicine is not associated with objective measures of physicians' exposure to and experience with liability claims[18-20]. It has been suggested that the signal to practice defensive medicine may have been broadcasted so widely that individual experience is overshadowed by collective anxiety[18].

Although the prevalence of defensive medicine in Japan is similar to that in the USA, individual components of this trend differ between the two countries. In a USA study of physicians in 6 specialties (not including gastroenterology)[12], almost one-third of respondents reported that they often describe more medications than medically indicated, whereas only 16% of our survey respondents, all gastroenterologists, reported doing so. In addition, 32% of physicians in the USA often suggest invasive procedures to confirm diagnoses, whereas only 16% of gastroenterologists we surveyed did so. Our findings suggest that assurance behavior is less prevalent among gastroenterologists in Japan than among physicians in the USA. In contrast, our findings suggest that the prevalence of avoidance behavior among gastroenterologists in Japan is similar to that among physicians in the USA. This may be due to differences in the structure of the medical economic system between the two countries[21]. In Japan, medical examination fees are considerably lower than those in the USA. Therefore, physicians in Japan may be more apt to suggest invasive procedures to confirm diagnoses.

Avoidance behaviors we surveyed were significantly less common among seasoned gastroenterologists than among those in practice less than 10 years. It is not surprising that less experienced physicians tend to avoid difficult procedures and interventions and caring for high-risk patients. It is reasonable that high-risk patients should be treated by fully experienced doctors.

Respondents who worked in hospital clinics ordered more tests than medically indicated significantly more often than respondents in solo practices. In Japan, patients desiring a thorough examination tend to visit a hospital clinic. To meet patients' expectations, doctors in hospital clinics may order more tests than medically indicated. However, doctors in hospital clinics reported referring patients to other specialists unnecessarily less frequently than doctors in solo practices. Doctors in hospital clinics may refer less frequently because of easy access to specialized examinations or to other specialists, especially in general hospitals.

Our study was limited in several ways. First, measurement and identification of defensive medicine by the physicians themselves are difficult because distinctions between inappropriate and appropriate care are not clear in many clinical situations[22]. Moreover, it can be difficult to disentangle liability-related motivational factors from other factors that influence clinical decision-making, such as physicians' general desire to meet patients' expectations, preserve trust, and avoid conflict[23,24]. To the extent that the responding gastroenterologists attributed their decisions to liability concerns when in fact they were driven primarily by other considerations, our results are exaggerated. Second, the gastroenterologists' self-reports of defensive medicine may have been biased toward giving a socially desirable response or achieving political goals. This may have led respondents to overestimate the frequency of their adoption of forms of defensive medicine.

An increased incidence of defensive medical practices is part of the social cost of a health-care system. The most frequent form of defensive medicine we found is suggestion of invasive procedures to confirm diagnoses, which seems not only wasteful but also likely to increase the risks of medical complications. Efforts to reduce the practice of defensive medicine in Japan should focus both on educating patients and gastroenterologists regarding appropriate care in the gastroenterological context that most commonly prompts defensive medicine, and on developing and disseminating clinical guidelines that target common defensive practices.

## COMMENTS

### *Background*

The prevalence of defensive medicine and the specific defensive medicine practices among gastroenterologists in Japan are unclear.

### *Research frontiers*

Two percentage respondents have been sued, and most respondents (96%) had liability insurance. Nearly all respondents (98%) reported practicing defensive medicine, and avoidance behaviors, such as avoiding certain procedures or interventions and avoiding caring for high-risk patients, were very common (96%). Defensive medicine may be highly prevalent among gastroenterologists throughout Japan, with potentially serious implications regarding costs, access, and both technical and interpersonal quality of care.

### *Applications*

Efforts to reduce the practice of defensive medicine in Japan should focus both on educating patients and gastroenterologists regarding appropriate care in the gastroenterological context that most commonly prompts defensive medicine, and on developing and disseminating clinical guidelines that target common defensive practices.

### *Terminology*

Defensive medicine, a deviation from sound medical practice, is induced primarily by the threat of liability claims.

### *Peer review*

This study is interesting and provides useful information on the characteristics of defensive medicine among gastroeneterologists in Japan.

## Abstract

**AIM:** To elucidate the current status of laparoscopy-assisted distal gastrectomy (LADG) with regard to its short-term outcomes by comparing it with conventional open distal gastrectomy (CODG).

**METHODS:** Original articles published from January 1991 to August 2006 were searched in the MEDLINE, EMBASE, and Cochrane Controlled Trials Register. Clinical appraisal and data extraction were conducted independently by 2 reviewers. A meta-analysis was performed using a random effects model.

**RESULTS:** Outcomes of 1611 procedures from 4 randomized controlled trials and 12 retrospective studies were analyzed. Compared to CODG, LADG was a longer procedure (weighted mean difference [WMD] 54.3; 95% confidence interval [CI] 38.8 to 69.8; $P < 0.001$), but was associated with a lower associated morbidity (odds ratio [OR] 0.54; 95% CI 0.37 to 0.77; $P < 0.001$); this was most significant for postoperative ileus (OR 0.27; 95% CI 0.09 to 0.84; $P = 0.02$). There was no significant difference between the two groups in anastomotic, pulmonary, and wound complications and mortality. Duration from surgery to first passage of flatus was faster (WMD -0.68; 95% CI -0.85 to -0.50; $P < 0.001$) and the frequency of additional analgesic requirement (WMD -1.36; 95% CI -2.44 to -0.28; $P = 0.01$), and duration of hospital stay (WMD -5.51; 95% CI -7.61 to -3.42; $P < 0.001$) were significantly lower after LADG. However, a significantly higher number of lymph nodes were dissected by CODG (WMD -4.35; 95% CI -5.73 to -2.98; $P < 0.001$).

**CONCLUSION:** LADG for early gastric cancer is associated with a lower morbidity, less pain, faster bowel function recovery, and shorter hospital stay.

## INTRODUCTION

Many surgeons are interested in laparoscopic surgery for gastric cancer because it has been proved that laparoscopic surgery has several advantages over conventional open surgery[1-3]. Since 1991, laparoscopy-assisted distal gastrectomy (LADG) has been adopted by Kitano[4] for the treatment of early gastric cancer, and it has been performed worldwide, especially in Japan and Korea. In 1997, Goh *et al*[5] published the early results of 118 LADGs; they sent a questionnaire to 16 surgeons across 12 countries and found that 10 of these surgeons claimed LADG to be superior to conventional open distal gastrectomy (CODG) because of a faster recovery, reduced pain, and better cosmesis[5]. Many studies comparing LADG with CODG with respect to their short-term outcomes have been performed. However, the feasibility and advantages of LADG have not been thoroughly evaluated thus far. Therefore, we performed a meta-analysis by comparing LADG with CODG with regard to their short-term outcomes to elucidate the current status of LADG. Unfortunately, only 4 prospective randomized controlled trials (RCTs) have been published[6-9]. Lack of RCTs may be due to the difficulty encountered in conducting a large RCT in Japan, where LADGs are most frequently performed because the Japanese are disinclined toward enrolling in RCTs and show a strong preference for a specific type of treatment[9]. Therefore, performing a reasonable meta-analysis of only RCTs may not be currently justified. Nevertheless, summarizing all the published data is important because it may help surgeons in choosing a better approach for the management of individual patients with gastric cancer. This meta-analysis is not only limited solely to RCTs but also includes retrospective trials that have compared LADG with CODG. We have also analyzed the RCTs separately in addition to analyzing all the included studies.

## MATERIALS AND METHODS

### *Literature search*

From January 1991 to August 2006, a thorough search of the MEDLINE, EMBASE, and Cochrane Controlled Trials Register databases was performed. The following keywords were used: "laparoscopic," "laparoscopy-assisted/laparoscopic-assisted," and "gastrectomy." The search was limited to studies published in English; all titles and abstracts were scanned and appropriate citations were reviewed.

### *Inclusion and exclusion criteria*

Inclusion criteria were as follows: (1) study type-RCTs and non-randomized prospective and retrospective studies; (2) studies that analyzed both LADG and CODG for the treatment of gastric cancer; (3) studies with any sample size; and (4) when we found several studies reporting the same patients, we included only the most recent study; however, if an older study in this category was an RCT, then it was included in our meta-analysis.

### *Methods of review*

Clinical appraisal and data extraction were conducted independently by 2 authors (S.H. and Y.A.). Discrepancies between the authors were resolved by consensus. The primary outcome measures were operative findings, postoperative complications and operation-related mortality, and postoperative clinical course. The following operative findings were analyzed: operating time, blood loss, and total number of dissected lymph nodes. The following postoperative complications were analyzed: overall complications, anastomotic leakage and stenosis, postoperative ileus, pulmonary complications, and wound infection. Overall complications were evaluated based on the total number of postoperative events. Anastomotic leakage included duodenal stump leakage; postoperative ileus included both mechanical and paralytic ileus; and pulmonary complications included pneumonia, pleural effusion, and atelectasis. Postoperative clinical course was analyzed in terms of bowel function recovery, frequency of additional analgesic requirement, number of days with body temperatures more than 37℃, duration of postoperative hospital stay, and WBC counts and C-reactive protein (CRP) levels on postoperative d 1, 3, and 7. Bowel function recovery was assessed by calculating the time interval between surgery and the first passage of flatus. Data were obtained from individual trials using the most reliable data available. Raw data were considered the most reliable, followed by derivation from the graph. It was assumed that all definitions in the included trials were synonymous, unless specified otherwise.

### *Statistical analysis*

Weighted mean differences with 95% confidence intervals were used for analyzing continuous variables that were presented in the same scale (e.g., operating time, blood loss, and postoperative hospital stay). When the trials had reported medians and ranges instead of means and standard deviations, we assumed that the difference in medians is equal to that in means, and the estimated standard deviation was considered equivalent to a quarter of the reported range. If neither a range nor any other measure of dispersion was available, then the standard deviation was estimated by halving the mean or the median. For dichotomous variables, odds ratios with 95% confidence intervals were calculated using a random effects model. If a particular outcome measure was reported in more than 2 RCTs, we conducted data analyses of these RCTs as well as of the overall studies. All statistical calculations were performed using the computer software Review Manager (RevMan) version 4.2.8 provided by Cochrane Collaboration. A value of $P < 0.05$ was considered significant. Heterogeneity was evaluated by using the $\chi^2$ test; $P < 0.1$ was considered significant for heterogeneity.

## RESULTS

Through our database searches, we found 4 RCTs[6-9] and 12 non-randomized retrospective studies[10-21] that compared LADG with CODG. We performed a meta-analysis of all the 16 studies using the data obtained from 1611 patients (837 and 774 patients who underwent LADG and CODG, respectively). The characteristics of the studies included in our meta-analysis are listed in Table 1.

### *Operative findings*

All studies[6-21] had reported the operating time, and 15 studies[6-17,19-21] had reported blood loss. Most studies claimed that CODG was superior to LADG in terms of operating time; however, some[8,10,12,13,16] did not report such an advantage. Pooled data obtained from the weighted mean difference revealed that an additional 54 min was required to perform LADG ($P < 0.001$), and that the blood loss was decreased ($P < 0.001$) when compared with CODG. The number of dissected lymph nodes had been reported in 14 studies[6-9,11,12,14-21], including 4 RCTs[6-9]. There were different levels of lymphadenectomy (Table 1). Analyses of the pooled data of only the RCTs as well as of all the studies revealed that a significantly higher number of lymph nodes were dissected during CODG ($P < 0.001$) (Figure 1). A significant heterogeneity was observed among all the studies; however, heterogeneity was not detected among the 4 RCTs. A summary of the pooled results with regard to the operative findings is presented in Table 2.

### *Morbidity and mortality*

Thirteen studies[6-14,16,18,19,21], which included 1054 patients, provided data regarding the overall postoperative complications. Overall complications after LADG (58/535) were significantly less than that after CODG (97/519; $P < 0.001$; Figure 2). Seven studies[8,9,11,12,16,18,21], which included 750 patients, provided data regarding anastomotic leakage. The incidence of anastomotic leakage was not different between LADG (2/385; 0.5%) and CODG (10/365; 2.7%) ($P = 0.10$). Similarly, the incidence of anastomotic stenosis was also not different between LADG (6/172; 3.5%) and CODG (5/163; 3.1%) ($P = 0.86$) in 5 studies[7,9,11,12,16]. Six studies[7,10,12,13,16,18] reported that postoperative ileus was significantly less frequent after LADG (2/267; 0.75%) than that after CODG (13/264; 4.9%) ($P = 0.02$) (Figure 3). Wound infection was observed in 9 studies[7,8,11,12,14,16,18,19,21], which included 869 patients. There was no difference

in wound infection rate between LADG (9/448; 2.0%) and CODG (13/421; 3.1%). Only 2 of the 16 studies[8,18] reported on mortality; however, there was no difference between LADG and CODG with regard to mortality. A summary of the pooled results for morbidity and mortality is presented in Table 3.

### Postoperative clinical course

Bowel function recovery was evaluated by counting the number of days from surgery to the first passage of flatus in 12 studies[6,7,9-12,14,15,17-19,21], which included 1296 patients. Our analysis showed that bowel function recovery was achieved 0.7 d earlier by the LADG patients than by the CODG patients ($P < 0.001$) (Figure 4). Postoperative pain was assessed by determining the frequency of additional analgesic requirement for postoperative pain in only 6[6,7,9,10,17,18] of the 16 studies. The requirement of additional analgesics after LADG was 3.3 times less frequent

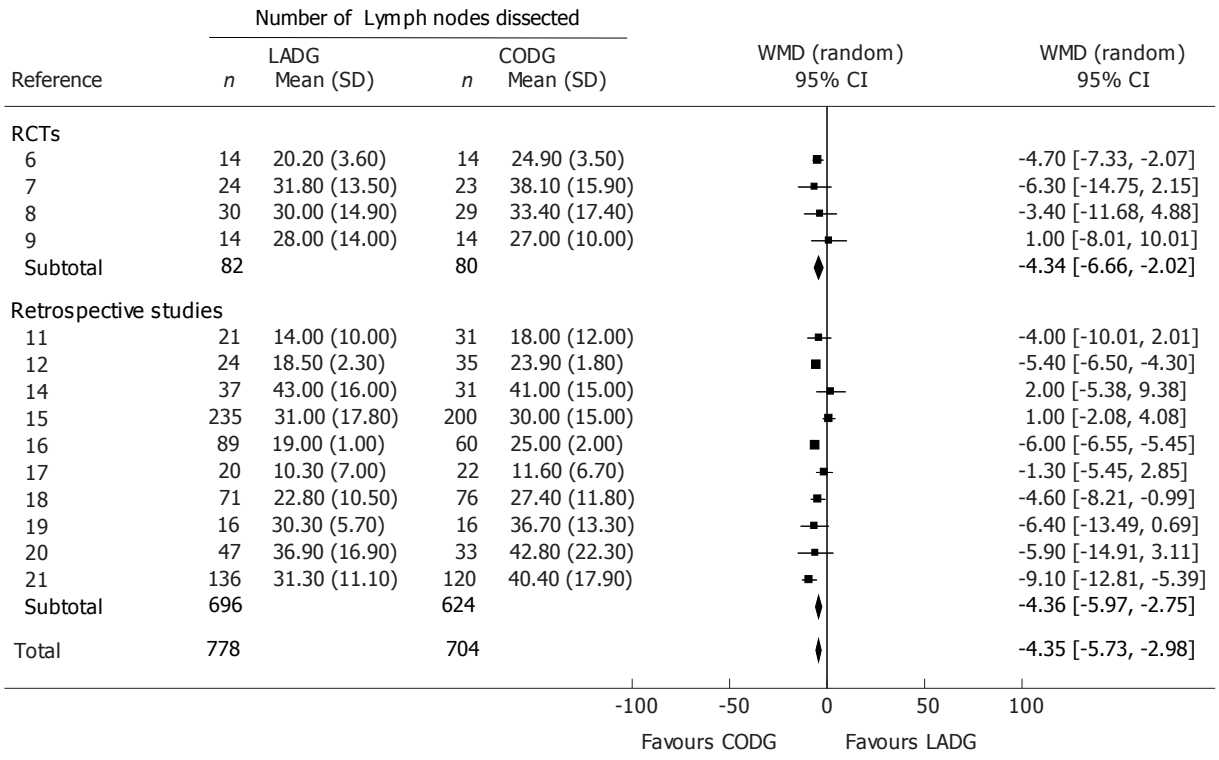

**Figure 1** Analysis of the number of lymph nodes dissected. Weighted mean differences (WMDs) are shown with 95% CI.

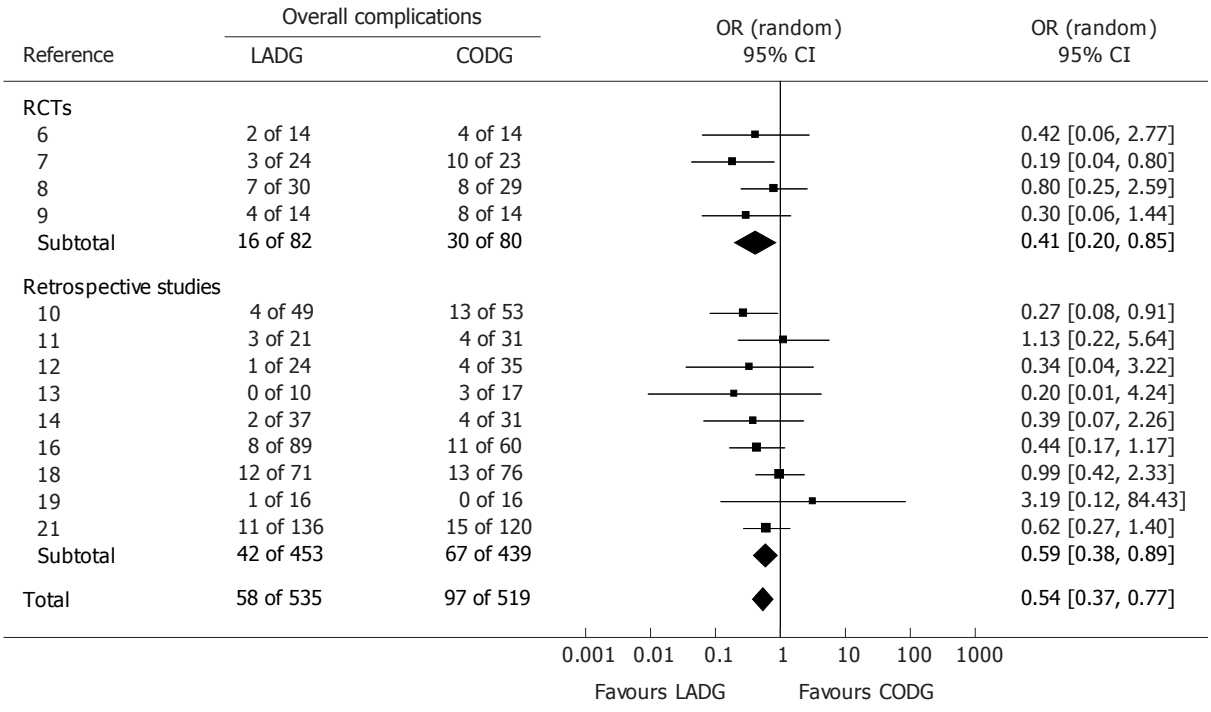

**Figure 2** Analysis of overall complications. Weighted mean differences (WMDs) are shown with 95% CI.

than that after CODG. Data regarding the duration of postoperative hospital stay was provided in 15 studies[6-19,21], which included 1531 patients. From our analysis, this duration was 5.5 d shorter for LADG patients than for CODG patients ($P < 0.001$). Variability of the duration of postoperative hospital stay was extremely high with a mean duration ranging from 7.8 to 29.2 d in LADG and from 11.2 to 40.7 d in CODG. However, most individual studies, except 4 studies[6,7,13,19], reported a significantly shorter hospital stay after LADG than after CODG. The number of days with body temperatures more than 37℃ was reported in 5 studies[9-11,14,17]. Body temperatures normalized 1.3 d earlier in LADG patients than in CODG patients. WBC counts on postoperative d 1, 3, and 7 were

reported in 7[9-11,13,14,17,18], 5[9,10,13,17,18], and 4[9,10,17,18] studies, respectively; serum CRP levels on postoperative d 1, 3, and 7 were reported in 5[9,10,13,14,17], 4[9,10,13,17], and 3[9,10,17] studies, respectively. The increase in both WBC counts and CRP levels on postoperative d 1 and 3 was significantly less in LADG patients than in CODG patients; however, there was no significant difference with regard to WBC counts and CRP levels on postoperative d 7 between these two groups. A summary of the pooled results with regard to the postoperative clinical course is presented in Table 4.

## DISCUSSION

In this meta-analysis, we compared the feasibility and advantages of LADG with those of CODG to elucidate the current status of LADG. Although LADG was found to be a significantly longer procedure, its associated morbidity rate was lower than that of CODG. This observation was most significant with regard to postoperative ileus. There was no significant difference between the two groups with regard to anastomotic, pulmonary, and wound complications and mortality.

Gastrointestinal recovery was faster after LADG. Furthermore, the frequency of additional analgesic requirement, number of d with temperatures more than 37℃, duration of postoperative hospital stay, and acute inflammatory reaction in terms of WBC counts and CRP levels were significantly lower after LADG. However, the

number of lymph nodes dissected in CODG patients was significantly higher than that in LADG patients.

LADG with systematic lymphadenectomy is considered technically more complicated than other laparoscopic procedures such as laparoscopic cholecystectomy and colon resection because in LADG, large vessels have to be identified and extensive lymph node dissection has to be performed. Although the learning curve of LADG has reached a plateau, LADG remains a time-consuming procedure[22]. However, with improvements in instruments and techniques, the operating time for LADG would decrease[10,21]. Furthermore, Kim *et al*[23] claimed that the operating time for LADG is related to the knowledge of and familiarity with the laparoscopic system and instruments and the skill of the operating team. The prevalence of standard techniques and the development of an education and training system would be important in the future.

The Japanese Gastric Cancer Association guideline recommends the following optimal lymph node dissection levels for early gastric cancer: perigastric lymph nodes (D1) and lymph nodes along the left gastric artery for mucosal cancer and for submucosal cancer < 1.5 cm in diameter; D1 and lymph nodes along the left gastric artery and the celiac axis for preoperatively diagnosed submucosal cancer without lymph node metastasis and for early cancer < 2.0 cm in diameter with only perigastric lymph node metastasis; and D2 (D1 and lymph nodes along the left gastric, common hepatic, proper hepatic, celiac, and splenic arteries) for early cancer > 2.0 cm in diameter with lymph node metastasis[24]. On the other hand, many surgeons in the USA and other Western countries rarely perform extensive prophylactic lymphadenectomy because 2 European randomized trials[25,26] showed that there was no survival advantage of D2 over D1 lymphadenectomy, and that operative mortality and morbidity were higher after D2 than after D1 lymphadenectomy. Although there exists some controversy about whether D2 lymphadenectomy is superior to D1 lymphadenectomy in conventional open surgery for gastric cancer, some studies[7,8,14,15,19,27] reported that the mortality and morbidity rates after LADG with D2 lymphadenectomy were acceptable. However, with regard to the number of dissected lymph nodes, which was considered to reflect the quality of lymphadenectomy, our meta-analysis of all the published studies showed that CODG was superior to LADG; meta-analysis of only the RCTs also showed a similar result. Miura *et al*[27] demonstrated that a significantly higher number of lymph nodes were harvested by CODG, and that the difference was significant for the perigastric lymph nodes along the major curvature and the second tier nodes along the celiac and splenic arteries. One of the explainable reasons for these observations is that several studies included in our meta-analysis might have been conducted during the learning phase of LADG. However, Fujiwara *et al*[22] reported that there was no difference between their preliminary study and the study following the learning curve with regard to the number of dissected lymph nodes in LADG. To obtain a definitive answer, a well-designed RCT following the learning curve of LADG would be required. Our meta-analysis may indicate that during the learning phase, LADG should be performed for early gastric cancer with low potential of lymph node metastasis.

The principal advantage of laparoscopic surgery is the reduction in the stress induced by minimal manipulation of the small bowel and the use of a small incision, which accounts for early bowel function recovery and prevention for postoperative ileus. It is noteworthy that all the aforementioned advantages were obtained despite the longer operating time for LADG. Faster bowel function recovery could lead to early resumption of oral intake, and subsequently early hospital discharge. Furthermore, it could result in less postoperative nausea, vomiting, and abdominal discomfort. Mitigating surgical stress reduces the generalized inflammatory reaction; consequently, it might lead to a reduction in the overall complication rate.

The application of LADG for gastric cancer is still controversial because of the lack of clinical evidence regarding its long-term outcomes. Indeed, there is only 1 prospective randomized controlled trial of the long-term outcomes of LADG[8]. Huscher *et al*[8] noted that there was no significant difference in the 5-year overall survival and disease-free survival between LADG and ODG. Several retrospective studies reported comparable results[15,16,28]. However, the lack of statistical significance in the long-term outcomes may be attributable to the small sample size.

Our study demonstrated that all the comparative studies published in the English literature preferred LADG to CODG for the treatment of gastric cancer with regard to short-term outcomes. However, it is uncertain whether there is any need to perform a meta-analysis. The poor methodology of the available trials may be anticipated and their heterogeneity may be statistically proven later although no heterogeneity was observed with regard to the analysis of postoperative complications. The explainable reasons for the heterogeneity were the different levels of laparoscopic expertise; the issue related to the learning curve; different levels of lymphadenectomy; nonblinded assessment of outcomes; lack of randomization, except 4 RCTs; and the assumption regarding the mean and standard deviation. Based on these reasons, we employed the random effects model of DerSimonian and Laird[29] even when statistically significant heterogeneity was not detected. However, in the future, a well-designed RCT with a large sample size would be required to aptly compare the controversial outcome measures, particularly the operating time and quality of lymphadenectomy.

In conclusion, compared to CODG, LADG for early gastric cancer is associated with a lower morbidity, less pain, faster bowel function recovery, and a shorter hospital stay. To establish LADG as the standard treatment for gastric cancer, further studies should be conducted with regard to the following aspects: (1) the prevalence of standard techniques and the development of an education and training system and, (2) well-designed RCTs following the learning curve of LADG to increase the statistical power and elucidate oncological clearance, including the quality of lymphadenectomy and long-term outcomes.

## COMMENTS

### *Background*

Nowadays, laparoscopy-assisted distal gastrectomy (LADG) for the treatment of early gastric cancer is a well-established procedure. However, the feasibility and advantages of LADG have not been thoroughly evaluated thus far. Therefore, we attempted a meta-analysis to elucidate the current status of LADG with regard to its short-term outcomes by comparing it with conventional open distal gastrectomy (CODG).

### *Research frontiers*

The application of LADG for gastric cancer is still controversial because of the lack of clinical evidence regarding its long-term outcomes.

### *Innovations and breakthroughs*

This paper summarizes all the published data comparing LADG with CODG.

### *Peer review*

This paper will provide useful information for the readers of the *World Journal of Gastroenterology* regarding the daily management of patients with gastric cancer.

## Abstract

**AIM:** To analyze the differences of clinical characteristics of colorectal neoplasm including polyps between the elderly and young Thai patients.

**METHODS:** Colonoscopy database from December 2000 to October 2004 was retrospectively analyzed. There were 1822 eligible patients who underwent colonoscopy (with a mean age of 56.6 years). Patients were classified into two groups: the older age group (aged ⩾ 60 years; *n* = 989) and the younger age group (aged < 60 years; *n* = 833). Data were recorded on age, colonoscopic indications, tumor location, colonoscopic findings and their related histological findings.

**RESULTS:** Colorectal malignancy related lesions were more often found in the older age group (21%) than in the younger age group (12%). Left-sided lesions were detected more commonly than right-sided in both age groups in approximately two-thirds of all cases. Hematochezia showed greater association with left-sided lesions in the elderly. No relationship was found between age and neoplasm staging and severity.

**CONCLUSION:** The chance of detecting colorectal neoplasm by colonoscopy was higher in the elderly than in the young Thais. However, both groups had the lesions predominantly located in the left side.

**Key words**: Colon neoplasm; Colonoscopy; Thais; Elderly

## INTRODUCTION

Colorectal cancer is one of the most common cancers worldwide. It is also the most frequent form of cancers among elderly population[1]. In contrast, colorectal cancer is considered to be a rare disease in people younger than 40 years of age[2]. The incidence rate of colorectal cancer is highest in the US, Canada, Japan, and Western Europe, being approximately 40 and 25-30 cases per 100 000 population in male and female, respectively. It is relatively uncommon in many developing countries, particularly those in Africa and Asia, where the average rate among men is 5-10 cases per 100 000 population and even lower in women[3]. In Thailand, data showed that the incidence rates for colorectal cancer among men and women were 7.2 and 5.2 per 100 000 population, respectively[4].

Recently, the Tumor Registry of Thailand reported that colorectal cancer has become the third most common cancer in the country, and the majority of patients were at advanced stages[4]. Our recent study also revealed that more than half of colorectal cancer cases already had lymph nodes invasion, and their prognoses were poor[5]. These reports also showed that most of the patients were older than 60 years of age. However, no data have been reported before regarding the clinical characteristics of this tumor which include adenomatous polyps, cancer staging at diagnosis, site location, pathological cell types, and their relationship to patient symptoms. Furthermore, no previous studies have focused on the older population, that intends to examine the association between age and characteristics of colorectal neoplasm in Thailand.

Therefore, this study was aimed to analyze the relationship between age and clinical characteristics of colorectal neoplasm including polyps in both older and younger Thai patients.

## MATERIALS AND METHODS

### Subjects

This is a retrospective study based on the colonoscopic database information from all colonoscopic examinations performed at King Chulalongkorn Memorial Hospital, Bangkok, Thailand from December 2000 to October 2004.

These data were computerized recordings by attending colonoscopists ($n$ = 8) or by supervised trainees ($n$ = 12). This database consisted of standard information collected for clinical purposes at the Gastroenterology Unit, King Chulalongkorn Memorial Hospital. Patients, who underwent colonoscopy except those who were previously diagnosed with colorectal neoplasms, were included in this study. Exclusion criteria included: cases of colorectal neoplasm followed up, post-colectomy patients and patients who had contraindication for colonoscopy, e.g., bleeding tendency and colonic perforation. Eighty patients were excluded because of the above-mentioned reasons.

There were 1822 patients eligible for the study who underwent colonoscopy during this period (788 men, 1034 women, mean age of 56.6 years). Patients were classified into two age groups: older age group (aged ⩾ 60 years; $n$ = 989) and younger age group (aged < 60 years; $n$ = 833). Colonoscopies were generally performed if the following clinical indications were presented at interview: anemia (hemoglobin below 14 g/dL in male and 13 g/dL in female), abnormal radiography (by computerized tomography, ultrasonography, or barium enema), bowel habit change, family history of colorectal cancer or inherited colorectal cancer syndromes (e.g., familial adenomatous polyposis, hereditary non-polyposis colorectal cancer), positive stool occult blood test, abdominal pain, abnormal abdominal mass, and hematochezia. Additionally, in some cases, colonoscopy was used as a primary modality for investigation in the asymptomatic patients with personal awareness for colon cancer screening.

### Methods

The majority of patients had only one colonoscopic clinical indication but thirty-three patients had more than one clinical indication. In this situation, the most serious indication was put as the first indication on the list. Among the thirty-three patients, only the first indication was used for analysis. In patients who need to repeat colonoscopy in this study period (62 patients), only the information from the first examination was included in this study. The average waiting time for patients who referred to colonoscopy at our hospital was less than 4 wk.

Colonoscopes in the present study were all standard long colonoscopes (CF-140 and CF-160, Olympus, Tokyo, Japan). Some patients required pediatric colonoscopies (PCF-140, Olympus, Tokyo, Japan). No magnified colonoscope was available during this study. Chromoendoscopy was not routinely done in our hospital.

Bowel preparation was selected by attending physicians either using a standard 90 mL of sodium phosphate or at least 3 L of polyethylene glycol. Patients were asked to refrain from fruit and vegetable 2 d prior to the study date. Patients with suboptimal bowel preparation were required to take more of the above agents until the preparation was optimal for colonoscopy, otherwise he or she had to be rescheduled.

Conscious sedation was used for our colonoscopy with a combination of intravenous midazolam and meperidine. The dosage of these agents were titrated by colonoscopists. No other mode of sedation or general anesthesia was used in the present study.

**Table 1 General characteristics of patients**

| Characteristic | Men | Women | Total |
|---|---|---|---|
| $n$ | 788 | 1034 | 1822 |
| Mean age (yr) | 56.4 | 56.7 | 56.6 |
| Age range (yr) | 14-91 | 14-100 | 14-100 |

Data were recorded on age, gender, colonoscopic indications, colonoscopic findings and their related histological findings. Colorectal neoplastic lesions were categorized into colorectal polyp and colorectal cancer. Colorectal polyp is a colonic neoplasm which does not contain tumor cells. They were also classified into 2 types based on their histological findings and potential to become a cancer; 'hyperplastic polyps' contain only hyperplastic cells, with no potential to develop into a cancer. Adenomatous polyps contain tubulous, villous, or tubulovillous cells and have precancerous change. In this study, we termed "colorectal malignancy related lesions" for determining both colorectal adenoma and colorectal cancer.

Both colorectal cancer and polyps were designated as right-sided lesions if they were proximal to the splenic flexure (including cecum, ascending colon, transverse colon) and left-sided lesions if they were distal to splenic flexure (including descending colon, sigmoid colon, and rectum). If polyps or cancers were found in both sides on the same patient, these were classified as pancolonic distribution. Patient with synchronous polyp and cancer was registered as a cancer case. Colorectal cancer was staged based on Modified Dukes classification[6]. They were classified into 4 types based on their histological findings: well differentiated, moderately differentiated, poorly differentiated adenocarcinoma, and other forms of cell types. Incomplete data from computer database were reviewed manually from medical records.

### Statistical analysis

Descriptive statistics are expressed as number (%). Statistical analysis was performed by Chi-square or Fisher exact test. $P < 0.05$ was considered to be statistically significant. Data were analyzed with the Statistic Package for Social Sciences (SPSS 11.5), (Chicago, IL, USA).

## RESULTS

The colonoscopic records of 1822 patients were examined. There were 788 men (mean age 56 years) and 1034 women (mean age 57 years) (Table 1). The overall completion rate for colonoscopy was 96.4% ($n$ = 1756). Sixty-six patients had incomplete colonoscopy and subsequently underwent double contrast barium enema. Only two patients were found to have small polyps in the ascending colon. However, repeated (complete) colonoscopies were unable to detect such polyps.

There was a statistical difference in colonoscopic findings between age groups. Colorectal malignancy related lesions were more often found in the older age group (21%)

**Table 2 Age groups and colonoscopic findings**

| Colonoscopic finding | Younger age group (< 60 yr) (%) | Older age group (≥ 60 yr) (%) | Total | |
|---|---|---|---|---|
| | | | *n* | % |
| Normal | 42.9 | 33.6 | 704 | 38.6 |

| Total (%) | 100 | 100 | | 100 |
| N | 50 | 59 | 109 | |

than in the younger age group (12%), ($\chi^2$ = 22.76, DF = 1, $P$ < 0.05). When we classified colorectal malignancy related lesions into "adenoma" and "cancer", we found that adenoma cases were detected significantly more often in the older age group ($\chi^2$ = 26.45, DF = 1, $P$ < 0.05) as well. In addition, tubulous adenoma was the most common cell type detected in both age groups (45.2% and 47.2%). Although colorectal cancers were more often found in the older patients than in the younger patients, this difference was not statistically significant ($\chi^2$ = 3.67, DF = 1, $P$ < 0.06), (Table 2).

There was no statistical difference in sites of lesions found between younger and older age groups ($P$ < 0.05). Left-sided lesions were detected more commonly than right-sided in approximately two-thirds of all cases in both age groups. Additionally, both colorectal adenoma and cancers were detected more often in the left than in the right. When we analyzed subgroups of "adenoma" and "cancer", we found no statistically significant difference between locations of either "adenoma" or "cancer" and age groups (Table 3). There was no patient with synchronous cancer. However, 3 patients with left-sided cancer had small polyps in the same side. In addition, pancolonic polyps were demonstrated only in 7 patients (not included in the Table). In the elderly patients, bowel habit change was the most common presentation for both left- and right-sided lesions. However, there was no statistical difference among locations of lesions for this symptom. Hematochezia showed greater association with left-sided lesions in elderly group ($\chi^2$ = 8.73, DF = 1, $P$ < 0.05). On the other hand, "check-up" was a common indication to find right-sided lesions in this age group ($\chi^2$ = 10.68, DF = 1, $P$ < 0.05). There was also no statistical correlation between anemia and location of the lesions in elderly group ($\chi^2$ = 1.10, DF = 1, $P$ = 0.29). Patients with colorectal cancer had significantly higher proportion of abdominal pain and abdominal mass than those with adenomatous polyps ($\chi^2$ = 13.48, DF=1, $P$ < 0.05). However, there was no significant difference in other symptoms between patients with colorectal cancer and polyps. Other indications, including abnormal radiography, family history of cancer, positive stool occult blood, and weight loss were presented in only a small number of patients (Table 4).

Moderately differentiated adenocarcinoma was the most common cancer cell type detected in both age groups (51.0% and 59.3%). Duke B (40%) and Duke C (24%) were the most common stages found in elderly group (Table 5). However, there was no statistical difference in cancer staging between age groups.

## DISCUSSION

Evidence supports that the prevalence of colorectal neoplasm increases with age and varies with country and lifestyle[7]. In the United States, autopsy studies have shown an overall prevalence of colorectal neoplasm ranges from 30% to 50%, which is increasing with age: 30% at 50 years; 40%-50% at 60 years, and 50%-65% at 70 years[8]. For

patients undergoing colonoscopies, the detection rate of a neoplasm was significantly higher in the older age group. These findings are supported by reports of neoplasm at colonoscopy of higher yield in the older patients[9-11].

The present series has shown that colorectal neoplasm was more likely to be found in older age Thais. This finding was consistent with previous studies in Western countries[12-14]. The hypothesis "with age advances, alteration or change of tissues in natural process of more accumulation of somatic mutation" may be applicable in this finding[15].

There are several factors that influent prognosis of patients with colorectal cancer, including cell types and staging at presentation. Some reports from many countries suggested that younger patients have cancers with less aggressive cell types and staging than older patients[16-18]. However, the present study did not demonstrate the difference of tumor cell types and staging between the age groups. We speculate that the advanced age may not have a significant effect on the severity of colorectal cancer in Thais. In addition, a subgroup analysis of the extremely aged patients (> 75 years) was not done to determine the impact of extreme age as a factor for colonic neoplasm development.

The completeness of colonoscopy is important to determine the quality of the study. Incomplete colonoscopy may cause a falsely low prevalence of right-sided lesion. Our study demonstrated a high rate of complete colonoscopy (96%) which is comparable to others[19-21]. The present series showed that left-sided cancer and polyp were detected more often than the other side. These findings were consistent in both age groups, whereas the evidences in Western countries were different. They showed a rightward shift of colonic neoplasm in elderly population[22-24]. Although this difference may be the result of a small number of subjects with colorectal polyps and cancer found, the characteristics of this tumor in Thais may actually be different from those in Western countries. Epidemiological studies also describe that this variation in the frequencies of right-sided and left-sided lesions can be explained by differences in some environmental factors including dietary and life style, although the underlying etiology is not clear[13,25]. The pattern of external risk factors in Thai population might be different from those of the Western countries. Moreover, part of our study population was a group of referred patients. In addition, our results represented only patients from a single center. Therefore, we need a multi-center study for the exposure of different risk factors among different age groups in the Thai population in order to identify the reason for the discrepancy between the findings in this study and those from Western countries.

When this study specifically looked at the older age subjects, it showed that bowel habit change, anemia and hematochezia were among the most common presentations associated with "colorectal malignancy related lesions". Additionally, this study found that some clinical indications were associated with the location of lesions. For example, hematochezia showed a greater association with left-sided lesions and "check-up" was the most common indication to find right-sided lesions.

This finding was quite similar to those reported in previous studies from Thailand[26-27]. Information from this study helps predict tumor location based on some clinical presentations, which in turn, may guide the choice of investigation, especially in the settings with limited access to gastroenterologists or colonoscopy, such as the rural area of Thailand. For example, hematochezia suggests that lesions were more likely to be found in left-sided colon. Therefore, physicians may choose to first investigate with flexible sigmoidoscopy, which can clearly examine left-sided colon, and barium enema was only done in cases of tumors which are not detected with sigmoidoscopy.

In our series, bowel habit change was the most common presentation of colorectal malignancy related lesions. In addition, it was also more commonly recorded in right-sided lesions. However, the relationship between this symptom and location was not statistically significant. Furthermore, other major clinical presentations recorded in the older age group, including anemia, abdominal pain and mass did not show significant association between locations of colorectal lesions and these symptoms. Therefore, this study demonstrated that other symptomatic clinical presentations except hematochezia tend to be of no benefit as a diagnostic tool for prediction of location in the older patients.

The present series showed no statistical significance between location of tumor and staging in Thai elderly. While Kawazuma *et al*[28] found that right-sided lesions were more commonly associated with higher degree of staging and severity. The reason why patients with right-sided colon cancer had poorer survival than other anatomical sub-sites may be due to lack of symptoms and delayed detection of cancer[28].

Currently, colonoscopy is widely used for detection of colorectal neoplasm among the older age group because of its high diagnostic yield to detect right-sided lesions[14]. From this study, although we did not find more association with right-sided lesions in advanced age, it showed that right-sided neoplasm represented approximately 40% of all subjects. Therefore, it suggests that colonoscopy continues to be the best screening method for colorectal neoplasm detection for Thai elderly because of its capacity to examine the entire colon and rectum. However, it is practically impossible to have this modality available for the whole nation at this moment due to the lack of colonoscopic resources[29]. In addition, double contrast barium enema plus flexible sigmoidoscopy may be an alternative screening method which could also examine entire colon in the mean time when access to colonoscopic resources is limited.

The major limitation of this study was that many patients underwent colonoscopy in the study had been examined at other institutes and were referred to this department because colorectal cancer was suspected. In addition, we are unable to know whether the subjects in this study were representative of the general population in Thailand. Therefore, the results of this study may overestimate the overall prevalence. Additionally, this study was conducted at only one center, which may limit the generalization. Moreover, data collected in this study only included clinical characteristics of colorectal neoplasm

detected by colonoscopy, but did not include information on risk factors, which are necessary to explain findings in this study. Therefore, further studies regarding risk factors such as diet and life style in Thai population is necessary to explain the similarity and differences in the characteristics of colorectal cancer between Thais and those in Western countries.

In conclusion, colorectal neoplasm was more likely to be found in the elderly Thais. Some clinical presentations in older patients may give a clue to the location of lesions that can help choose appropriate investigations. In contrast to Western population that advanced aged patients had more right-sided lesions, left-sided neoplasm still predominated in the symptomatic Thais elderly.

## COMMENTS

### Background

Colorectal malignancy is one of the major cancers in the West. Recently, there has been a rising incidence of this cancer in Asians. However, data regarding this type of cancer in Asians are still scanty.

### Research frontiers

Elderly Thais had a higher chance of colorectal cancer than the young. The majority of cancers were found to be in the left side of the colon in both elderly and the young.

### Innovations and breakthroughs

This is so far, the largest report of colonoscopic results in Thai elderly. In this report, the location of tumor in elderly Thais was still predominantly in the left side of the colon, whereas there is a rightward shift of tumor location in the western population.

### Applications

The screening for colorectal cancers by colonoscopy is not yet a standard protocol in Thailand. This study shows the benefit of colonoscopy in elderly

Thais. Due to the higher incidence of left-sided tumors, the protocol for screening for Thais may require only a sigmoidoscopy.

### *Peer review*

This study provides the interesting differences in clinical characteristics, presentations and findings of colorectal neoplasm in young and elderly Thais. However, due to the limited data from this retrospective format, there is a need for further prospective studies to address many unanswered questions, especially "what are the most appropriate age and tool for colon cancer screening for Asians?".

## Abstract

**AIM:** To study the prolonged colonic motility under normal conditions with a novel capsule-style micro-system and to assess its clinical significance.

**METHODS:** A single use telemetry capsule (10 mm in diameter, 20 mm in length) embedded with a pressure sensor was ingested by the subjects. The sensor is capable of transmitting colonic pressure wirelessly for more than 130 h. The time of capsule entering the segmental colon was detected by ultrasound. The ultrasonic electrodes were mounted on the surface of the ileocecum and navel and at the junction of the left and rectosigmoid colon of the subjects in sequence, which were identified by abdominal X-rays with radiopaque markers. To verify the accuracy and reliability of ultrasonic detection of telemetry capsules at key points of colon, the segmental colonic transit time was simultaneously recorded by using radiopaque markers.

**RESULTS:** The signal lamp showed that all recorders could receive the radio signal transmitted by the telemetry capsule. The X-rays showed that all telemetry capsules were detected successfully when they were passing through the key points of colon. There was a significant correlation between the transit results obtained by ultrasonic detection or by radiopaque markers. Colorectal recording was obtained from 20 healthy subjects during 613 h (411 h during waking, 202 h during sleep). Compared to waking, the number of pressure contractions and the area under pressure contractions were significantly ($P < 0.05$) decreased during sleep (21 ± 5 $h^{-1}$ *vs* 15 ± 4 $h^{-1}$, 463 ± 54 mmHg·s/min *vs* 342 ± 45 mmHg·s/min). The colonic motility exhibited significant regional variations both in the circadian behavior and in response to waking and meal.

**CONCLUSION:** The capsule-style micro-system is reliable and noninvasive, and may represent a useful tool for the study of physiology and pathology of colonic motor disorders.

**Key words:** Colon; Pan-colonic pressure; Pan-colonic motor activity; Telemetry

Zhang WQ, Yan GZ, Yu LZ, Yang XQ. Non-invasive measurement of pan-colonic pressure over a whole digestive cycle: Clinical applications of a capsule-style manometric system. *World J Gastroenterol* 2006; 12(47): 7690-7694

## INTRODUCTION

Colonic motility disorders are frequently encountered in clinical practice. Intraluminal manometry (*via* perfused and solid-state catheters) allows a direct study of colonic contractile activity over prolonged periods. However, catheter studies have generally been performed in the left and rectosigmoid colon, because of the technical difficulties in accessing the right colon[1].

Hagger *et al*[2] have reported a pan-colonic manometry by combined antegrade/retrograde intubation. However, due to sensor failure and/or catheter displacement, they could not assess the amplitude of pressure activities in the right colon.

Recent technological advances facilitate prolonged pan-colonic investigations. The success of Israeli M2A capsule endoscope has led to the research and development of other capsules aimed at monitoring either functional or organic diseases[3]. The American SmartPill capsule is capable of transmitting pressure, temperature and pH data continuously for 72 h, and suitable for diagnosing small intestine motility or delayed emptying of the stomach[4-6].

To satisfy the need of prolonged and noninvasive monitoring colonic pressures, the authors have developed a novel capsule-style manometric micro-system with its

prototype reported[7]. The system was approved by the Food and Drug Administration of China in 2005. The system is composed of a one-off telemetry capsule, a data recorder, an ultrasonic location detector and a computer with analysis software. The capsule-style manometric system is capable of acquiring and transmitting intraluminal pressure data continuously for more than 130 h.

The aim of this study was to evaluate the pan-colonic motor activity under the physiological conditions with a capsule-style manometric system. A study period of a whole digestive cycle (26-53 h) was used to characterize the infrequent patterns of motor activity of the colorectum.

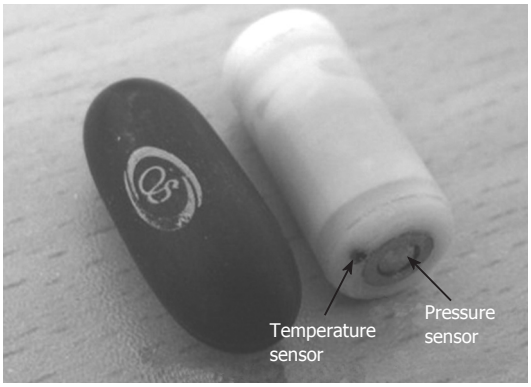

**Figure 1** A vitamin pill (left) and a telemetry capsule (right).

## MATERIALS AND METHODS

### Subjects

Twenty healthy subjects (12 females and 8 males, median age 35 years, range 23-52 years) were studied. The subjects had a normal bowel habit which was defined as a stool frequency of ⩽ 3 stools per day and ⩾ 3 stools per week. The subjects were not on any medication and had no gastrointestinal symptoms and no history of previous gastrointestinal disorder or gastrointestinal surgery. Female subjects had a negative pregnancy test. An informed written consent was obtained from all subjects. The study protocol was approved by the Ethics Committee of Capital Medical University Chaoyang Hospital.

### Capsule-style manometric system

**Telemetry capsule**: The newly-developed telemetry capsule (10 mm in diameter, 20 mm in length, and weighing 2.9 g ) developed by the authors is shown in Figure 1. The effective range could reach 3-5 m between the capsule and the recorder.

The pressure sensor can be used from -60 to 200 mmHg with its error ⩽ ± 1.5 mmHg, and the temperature sensor is sensitive in range of 33-42℃ with its error ⩽ ± 0.25℃. Changes in pressure sensor output due to fluctuations of temperature can be compensated automatically.

**Data recorder:** The data recorder consists of three functional blocks: a wireless receiver module, a microcontroller and an outer pressure transducer. The outer pressure transducer records the pressure changes induced by the surrounding altitude. The timer in the microcontroller records the time of received data. The obtained pressure data, temperature data, ultrasonic location information and relevant time are stored in a flash memory card.

**Ultrasonic detection of capsule location**: When the telemetry capsule passes through the ultrasonic electrodes mounted on the surface of key points of colon, the echo from batteries in the capsule would be much stronger than other echoes. When the amplitude of an echo is higher than the preset threshold, it can be regarded as returning from the capsule. Detailed technical information about the ultrasonic detection of the capsule positions has been reported elsewhere[8].

Colon was divided into three segments by three key points (ileocecum, navel and the junction of the left and rectosigmoid colon), which were identified by an experienced doctor with the help of abdominal X-rays with radiopaque markers.

**Analysis software**: In addition to the novel manometric system, a Matlab-based (The MathWorks, Natick, MA) software program was developed to correct baseline shifts, eliminate artefacts, and calculate the number of pressure contractions, amplitude and area under curve (AUC) in a fully automated way. The software features an intuitive graphical user interface that supports graphical and statistical data analysis. The baseline pressures were determined by identifying the minimum pressure in each 30 min, which was then subtracted from the raw signals. Pressure contractions with an amplitude ⩾ 10 mmHg from the baseline and a duration ⩾ 6 s were included in the analysis.

### Experimental protocol

To verify the accuracy and reliability of ultrasonic detection of telemetry capsules at the key points of colon, the segmental colonic transit time was simultaneously recorded by using radiopaque markers.

After an overnight fast, the subjects ingested 20 radiopaque markers contained in a gelatin capsule (Binhai Hospital, Tianjin, China) at 8:00 AM next morning. A daily abdominal X-ray was taken at the same time on the following consecutive days until the number of remained markers was ⩽ 4. The total and segmental colonic transit time (CTT) was calculated using the following formula: $CTT = 1.2 \times \Sigma n_i$, where 1.2 = time interval (24 h)/number of radiopaque markers (20), i = day of X-rays taken, and $n_i$ = the total number of markers present on a given film sector on day I[9,10].

The subjects took the telemetry capsule an hour after ingestion of the markers. The subjects wore the recorder and checked the signal lamp on the receiver.

To help mounting the ultrasonic electrodes on the surface of the ileocecum of the patients correctly, an abdominal X-ray was taken at 6 h after the telemetry capsule was taken.

The ultrasonic electrodes were first mounted on the surface of the ileocecum by an experienced doctor with the help of radiopaque markers and bony landmarks in the X-ray film. The subjects put on the waistcoat containing an ultrasonic signal processor and an alarm buzzer. When

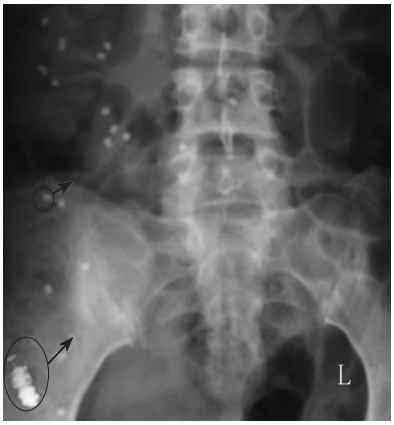

**Figure 2** An X-ray after ultrasonic detection confirming capsule in the ileocecum.

alarming occurred, an abdominal X-ray was taken to confirm the location of telemetry capsules.

After successful detection of the ileocecum, the ultrasonic sensors were then mounted on the surface of the navel and at the junction of the left and rectosigmoid colon in sequence.

The subjects stayed totally ambulatory during inspecting, but drastic sport activities were prohibited. The subjects ate 1000 kcal standard meals. Ingestion of alcohol and caffeine containing drinks was prohibited.

After defecation, the signal lamp on the receiver would indicate whether the capsule was still in body or not. All capsules were recovered to confirm the discharge.

### *Statistical analysis*

The data were expressed as mean ± SD unless otherwise stated**.** High-amplitude contraction (HAC) analysis was made by visual inspection of the pressure trace. The HAC was defined as a pressure contraction with an amplitude ⩾ 50 mmHg from the baseline, a duration ⩾ 20 s and a peak-to-peak time interval ⩾ 40 s.

The diurnal and postprandial differences in AUC and the number of contractions were compared using repeated measures of ANOVA. $P < 0.05$ was considered statistically significant in all analyses.

## RESULTS

The signal lamp on recorders showed that all recorders could receive the radio signal transmitted by the telemetry capsule in the subjects. No discomfort was reported by any volunteers during the experiment.

The telemetry capsules passed through the gastrointestinal (GI) tract without any difficulties. All capsules were recovered with the guidance of the signal lamp.

### *Capsule location and transit results*

All telemetry capsules could be detected successfully when they were passing through the three key points of the colon. Additional X-rays confirmed the capsule location (Figure 2). The location of capsules could be recognized with the help of bony landmarks and radiopaque markers.

The total transit time and segmental colonic transit time obtained by ultrasonic detection and radiopaque markers are shown in Table 1. There was a significant correlation between the two methods for the detection of transit results. It verified the reliability and accuracy of ultrasonic detection for the segmental transit time.

**Table 1 Transit time detected by markers and ultrasound (mean ± SD)**

| Transit time (h) | Total colon | Right colon | Left colon | Rectosigmoid |
|---|---|---|---|---|
| Markers | 31.5 ± 6.8 | 8.6 ± 3.3 | 11.4 ± 3.6 | 11.5 ± 3.3 |
| Ultrasonic | 29.7 ± 5.9 | 9.3 ± 3.5 | 10.8 ± 3.1 | 9.7 ± 2.9 |
| Correlation | 0.92 | 0.91 | 0.93 | 0.86 |

**Table 2 Colonic motility response to waking and meal (mean ± SD)**

| | Waking | | Meal Ingestion | |
|---|---|---|---|---|
| | 1 h before | 1 h after | 2 h before | 2 h after |
| No. of Contrctions ($h^{-1}$) | | | | |
| Right colon | 14 ± 4[a] | 45 ± 6[a] | 21 ± 6 | 44 ± 8[b] |
| Left colon | 13 ± 3[a] | 39 ± 4 | 22 ± 5 | 38 ± 6 |
| Rectosigmoid | 19 ± 5[a] | 29 ± 4[a] | 20 ± 6 | 32 ± 7[b] |
| AUC (mmHg·s·$min^{-1}$) | | | | |
| Right colon | 322 ± 44 | 984 ± 91[a] | 471 ± 59 | 862 ± 79 |
| Left colon | 307 ± 41[b] | 835 ± 82 | 465 ± 52 | 812 ± 74 |
| Rectosigmoid | 431 ± 52[b] | 725 ± 64[a] | 453 ± 52 | 773 ± 71 |

[a]$P < 0.05$, [b]$P < 0.01$ *vs* segmental colons.

### *Colonic motility*

Colorectal recording was obtained from the 20 healthy subjects for a total of 613 h (411 h during waking, 202 h during sleep). In this study, the authors laid more emphasis on the colorectal motility response to meal ingestion and morning waking. During the colorectal pressure recording period, 26 subjects were waking in the morning and 78 had meal ingestions (1.3 and 3.9 per subject respectively).

Compared to waking, the number of pressure contractions and the AUC of pressure contractions during sleep were significantly decreased (21 ± 5 $h^{-1}$ *vs* 15 ± 4 $h^{-1}$, 463 ± 54 mmHg·s·$min^{-1}$ *vs* 342 ± 45 mmHg·s·$min^{-1}$, $P < 0.05$).

After waking and meal ingestion, both the number of pressure contractions and the AUC of pressure contractions were significantly increased. The contractile response to waking was significantly higher in the left/right colon than in the rectosigmoid colon (Figure 3), whereas the waking response was lower in the left colon than in the right colon, but was not significantly different. There were no significant differences in segmental colon motility response to meal ingestion. The details are shown in Table 2.

Regional variations in colonic contractile activity were apparent. During the daytime, the contractile frequency was significantly higher in the right colon than in the left and rectosigmoid colon. However, the contractile frequency was significantly higher in the rectosigmoid colon than in the left/right colon during the night. The HAC was recorded in all of the subjects, with 13.5 ± 6.1

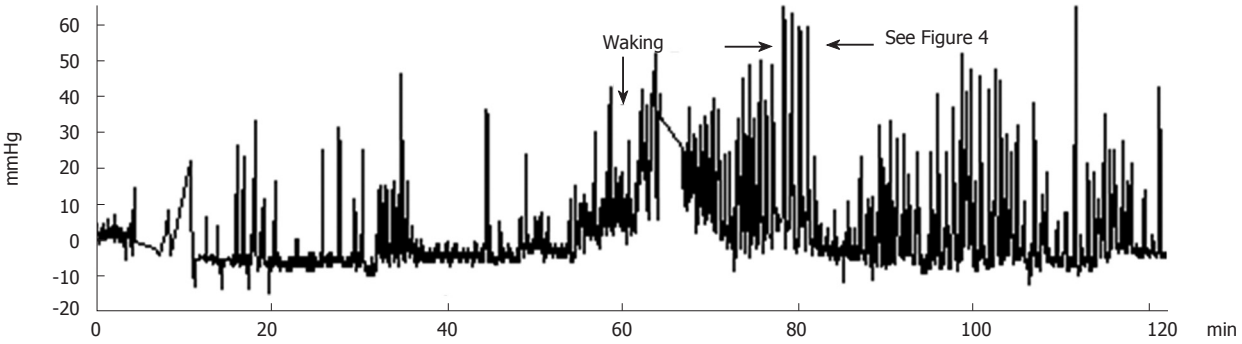

**Figure 3** Pressure curve 1 h before and after waking in the right colon of a healthy subject.

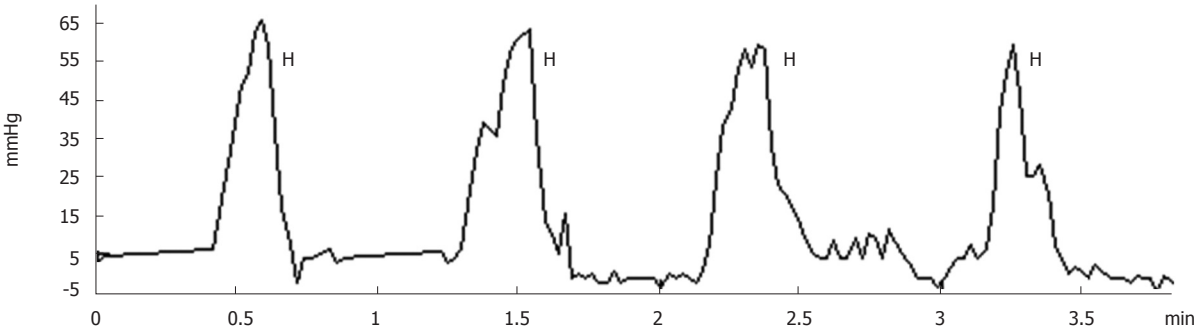

**Figure 4** Occurrence of 4 consecutive HACs 1 h after waking in the right colon.

times per subject (Figure 4). The regional variation was strongly associated with the incidence of HACs. The incidence of HACs was significantly higher in the right and rectosigmoid colon than in the left colon (39%, 44%, and 17%, respectively).

## DISCUSSION

This study introduced a new technique for examining pan-colonic pressures under physiological conditions. Human studies demonstrated that the capsule-style manometric system was safe and easy to handle. The single-use telemetry capsule is encased in inert. The bio-compatible, medical-grade polycarbonate makes it safe for human consumption and easy to swallow. The sensors are surface mounted at the ends of the outer shell. All the other parts are sealed in the shell by medical silicone. The solid-state pressure transducer with a stainless cover is robust and biocompatible.

Location detection of telemetry capsules is a critical issue, since it can move freely through the digestive tract. Some telemetry capsules, such as M2A and Smartpill, can be localize at the capsule's position in the upper digestive tract by detecting the angle and intensity of radio signal[11,12]. Radio signal detection can trace the capsule in real time, yet the precision is limited to 6-10 cm.

In this study, the authors verified that ultrasonic detection of telemetry capsules at the key points of colon was simple and accurate, suggesting that it is suitable for detection of telemetry capsules and segmental transit time in colon. However, it failed to trace the capsule in real time, indicating that a real-time tracing method based on magnetic field mapping should be developed.

The major advantages of telemetry capsule include noninvasiveness, long battery lifespan and low cost. During the process of inspecting, subjects even cannot feel the existence of the telemetry capsule which ensures the examination under physiological conditions. The lifespan of batteries in capsule and a memory capacity of 128 MB of recorder make it feasible to record telemetry capsules and segmental transit time in colon for more than 130 h. The cost of a single-use capsule is also relatively inexpensive.

The major disadvantage of the capsule-style system is hard to judge the propagation and direction of pressure contractions with a single recording point, which will be tested by a multi-capsule method in following studies.

Water-perfused and solid-state catheters are currently available for intraluminal manometry. Water-perfused catheters have the advantages of simplicity, relatively inexpensive components and applicability to the measurement of colon motor activity in several regions. Importantly, they are fully autoclavable, enabling simple sterilization. The major disadvantage of the system is that the catheter is linked to a pneumohydraulic infusion pump and a recording sensor, which almost precludes any ambulatory study.

Solid-state catheters allow measurements over a prolonged period from totally ambulant subjects. However, the transducers in solid state catheters are expensive, rather fragile and hard to be sterilized, and the maximum number of recording sensors available is notably reduced.

Compared to catheter manometry, capsule-style manometry has become a necessary supplement due to its

noninvasiveness and long battery life.

Our results have confirmed in general the circadian behavior of the colonic motility, as well as its response to waking and meals[13-18].

There is no currently accepted gold standard for catheter manometry, because of the differences in catheter type and configurations, and methodology. As a result, the values of some parameters are significantly different. For example, it was reported that the amplitude threshold of HAC in catheter manometry ranges from 50 mmHg to 135 mmHg[19].

It was difficult to compare our results with previous results. However, the average amplitude of pressure contractions in colon obtained with the capsule in this study was lower than that obtained with water-perfused or solid-state catheters[20-25]. This may reflect the stimulation of catheters on colon.

In the present study, the colon also exhibited regional variations in the circadian behavior of the colonic motility, as well as its response to waking and meals, emphasizing the importance of studying the pancolonic motility activities.

In summary, the capsule-style manometric system is reliable and safe for the study of pancolonic motor activity under physiological conditions, representing a useful tool for the study of physiology and pathology of colonic motor disorders.

## Abstract

**AIM:** To analyze expression of ATP7B in gastric cardiac adenocarcinomas, its clinicopathologic significance, in comparison with distal gastric adenocarcinomas.

**METHODS:** Immunohistochemical avidin-biotin peroxidase complex method was applied to detect the expression of ATP7B in 49 cases of cardiac carcinomas, the corresponding adjacent non-neoplastic epithelium and 55 cases of distal gastric carcinomas.

**RESULTS:** The proportion of ATP7B positive samples in gastric cardiac carcinomas (51.0%, 25 of 49) was significantly higher than that in the corresponding adjacent non-neoplastic epithelium (22.4%, 11 of 49) ($P$ = 0.003). ATP7B expression in poorly differentiated gastric cardiac carcinomas was significantly higher than that in well/moderately differentiated gastric cardiac carcinomas ($P$ = 0.030). ATP7B expression in gastric cardiac carcinomas was independent of age, tumor size, nodal stage and metastasis status. ATP7B protein was detected in 30.9% (17/55 cases) of distal gastric carcinomas, markedly lower than that in gastric cardiac carcinomas ($P$ = 0.037).

**CONCLUSION:** ATP7B protein is frequently overexpressed in gastric cardiac carcinomas, and correlated with the differentiation of cardiac carcinoma. ATP7B expression in gastric cardiac carcinomas is significantly higher than that in distal gastric carcinomas, which might partially explain the difference of chemotherapy response and prognosis between these two gastric carcinomas.

**Key words:** ATP7B; Platinum; Distal gastric carcinoma; Gastric cardiac carcinoma; Resistance

## INTRODUCTION

Gastric carcinoma can be subdivided into distal gastric carcinoma and proximal cardiac carcinoma[1]. Recent studies have suggested that distal gastric carcinoma and proximal cardiac carcinoma have distinct epidemiological, biological and clinical characteristics[1]. For instance, the incidence of carcinoma of the gastric cardia was reported to have increased in most countries during the past few decades, while that of carcinoma of the distal stomach has decreased steadily[2-5]. Carcinoma of the cardia has been reported to form a specific category distinct from carcinoma of the rest of the stomach[6,7].

Drug resistance is a major obstacle of cancer chemotherapy[8,9]. The presence of drug resistance may be prior to exposure to chemotherapy (primary resistance), or may be induced after exposure to chemotherapy (secondary resistance)[8,9]. Platinum containing compounds, such as cisplatin, carboplatin, oxaliplatin, satraplatin, are among the most effective chemotherapeutic agents for cancer. However, their clinical efficacy is often limited by primary or secondary resistance[10]. Several mechanisms have been implicated in cisplatin resistance, including reduced drug accumulation, increased cellular thiol/folate levels and increased DNA repair[10,11]. Among them, reduced intracellular accumulation of cisplatin is a determinant of cisplatin resistance[11]. However, it was not until recently that the mechanism of decrease of cisplatin accumulation in cisplatin-resistant tumor cells was elucidated[11,12]. In 2000, Akiyama and co-workers demonstrated that a copper-transporting P-type adenosine triphosphatase (ATP7B) was associated with cisplatin resistance *in vitro*[12]. The ATP7B gene was induced by exposure to cisplatin in human prostate cells and ATP7B-transfected cells showed a dramatic decrease in cisplatin accumulation[12]. The above study was supported by subsequent reports[13,14]. ATP7B protein is a member of a class of heavy metal-transporting P-type ATPases that pump copper, cadmium, zinc, silver or lead[15]. ATP7B has been found to be expressed in

certain breast carcinomas[16], endometrial carcinomas[17], esophageal carcinomas[18], gastric carcinomas[19], oral squamous cell carcinomas[20] and ovarian carcinomas[21]. Moreover, ATP7B expression status in some carcinomas was correlated with prognosis[17,21] and sensitivity of chemotherapy[18,20].

The aim of this study was to investigate the expression of ATP7B in human gastric cardiac carcinomas, and its clinicopathologic significance, in comparison with distal gastric carcinomas.

## MATERIALS AND METHODS

### Patients

It included 49 patients with adenocarcinomas of the gastric cardia, 27 males and 22 females with an average age of 55 ± 12 years, and 55 patients with adenocarcinomas of the distal stomach, 30 males and 25 females with an average age of 58 ± 9.7 years. The 49 patients with adenocarcinomas of the gastric cardia underwent surgery at the Esophageal Carcinoma Hospital of Linzhou in Henan Province, and the 55 patients with distal gastric carcinomas underwent surgery at the First Hospital of Jiaxing in Zhejiang Province. None of the patients had received chemotherapy or radiotherapy before surgery.

### Tissue processing

All specimens were fixed with formalin and embedded in paraffin. Each block was sectioned serially at 5 μm, one of which was stained with hematoxylin and eosin for histopathological analysis by two pathologists and the others were used for immunostaining[22].

### Histopathological analysis

Histopathological diagnoses were made according to previous reports[22].

### Immunohistochemical staining

Anti-ATP7B antibody was a rabbit polyclonal antibody against ATP7B(Boster, China). Avidin-biotin-peroxidase complex (ABC) method was used for ATP7B immunostaining. In brief, after dewaxing of sections, endogenous peroxidase activity was quenched with 3% $H_2O_2$, and cross-reactivity was blocked with normal serum. The tissues were incubated overnight at 4℃ with primary antibodies (1:100 for anti-ATP7B antibody). Localization of the primary antibodies was achieved by subsequent use of a biotinylated anti-primary antibody, an avidin-biotin complex conjugated with horseradish peroxidase, and 3',5'-diaminobenzidine (Vectasitain Elite Kit). Normal serum blocking and omission of the primary antibody were used as negative controls[22].

### Evaluation of immunostaining

The criterion for a positive reaction was clear cytoplasm and cell membrane staining. If more than 10% of the tumor cells were stained, the samples were considered to be ATP7B-positive carcinomas[21].

### Statistical analysis

Pearson Chi-Square and Fisher's exact tests were performed. The statistical analyses were performed using SPSS 12.0 software. Two-sided *P* values were calculated and a difference was considered significant if the *P* value was less than 0.05.

## RESULTS

### ATP7B expression in human cardiac carcinomas and corresponding adjacent non-neoplastic epithelium

To examine the expression of ATP7B at protein level in human gastric cardia carcinomas, we performed immunohistochemical analysis using a polyclonal antibody against ATP7B. As shown in Figure 1, ATP7B expression was observed in the cytoplasm of gastric cardiac adenocarcinoma cells. A negative control did not reveal ATP7B protein. We used 49 primary gastric cardiac carcinoma specimens for the detection of ATP7B by immunohistochemistry and found that various degrees of cytoplasmic staining of tumor cells were observed in 51.0% (25/49) of the analyzed tumors. We also determined ATP7B expression of the corresponding adjacent non-neoplastic epithelium of all the gastric cardiac carcinomas. ATP7B was identified in 11 of 49 (22.4%) of the examined cases, which was markedly lower than that in gastric cardiac carcinomas ($P = 0.003$). ATP7B was localized close to the cell membrane of adjacent non-neoplastic epithelium, mainly concentrated at the pit pole of the gastric epithelium[23].

### Clinicopathologic significance of ATP7B protein expression in human gastric cardiac carcinoma

We examined the relationship between clinicopathologic variables and ATP7B expression in human gastric cardiac carcinomas. No significant association was found between ATP7B expression and age, tumor size, nodal stage and metastasis status. Regarding histopathologic type, ATP7B protein positivity in poorly differentiated carcinomas was significantly higher than that in well/moderately differentiated carcinomas ($P = 0.030$) (Table 1).

### Comparison of expression of ATP7B in human gastric cardiac carcinomas and distal gastric carcinomas

As shown in Figure 2, ATP7B expression was also observed in the cytoplasm of distal gastric carcinoma cells. We used 55 primary distal gastric carcinoma specimens for the detection of ATP7B by immunohistochemistry and found that various degrees of cytoplasmic staining were observed in 30.9% (17/55) of the analyzed tumors, markedly lower than that in gastric cardiac carcinomas ($P = 0.037$).

## DISCUSSION

Recent research has identified that ATP7B, an energy-dependent copper transporter, is a new resistance marker of tumor cells to platinum containing anticancer drugs[12-14]. The present study provides direct evidence of frequent ATP7B expression in gastric cardiac carcinomas, suggesting the importance of ATP7B protein in primary resistance of gastric cardiac carcinoma cells to platinum containing anticancer drugs. Furthermore,

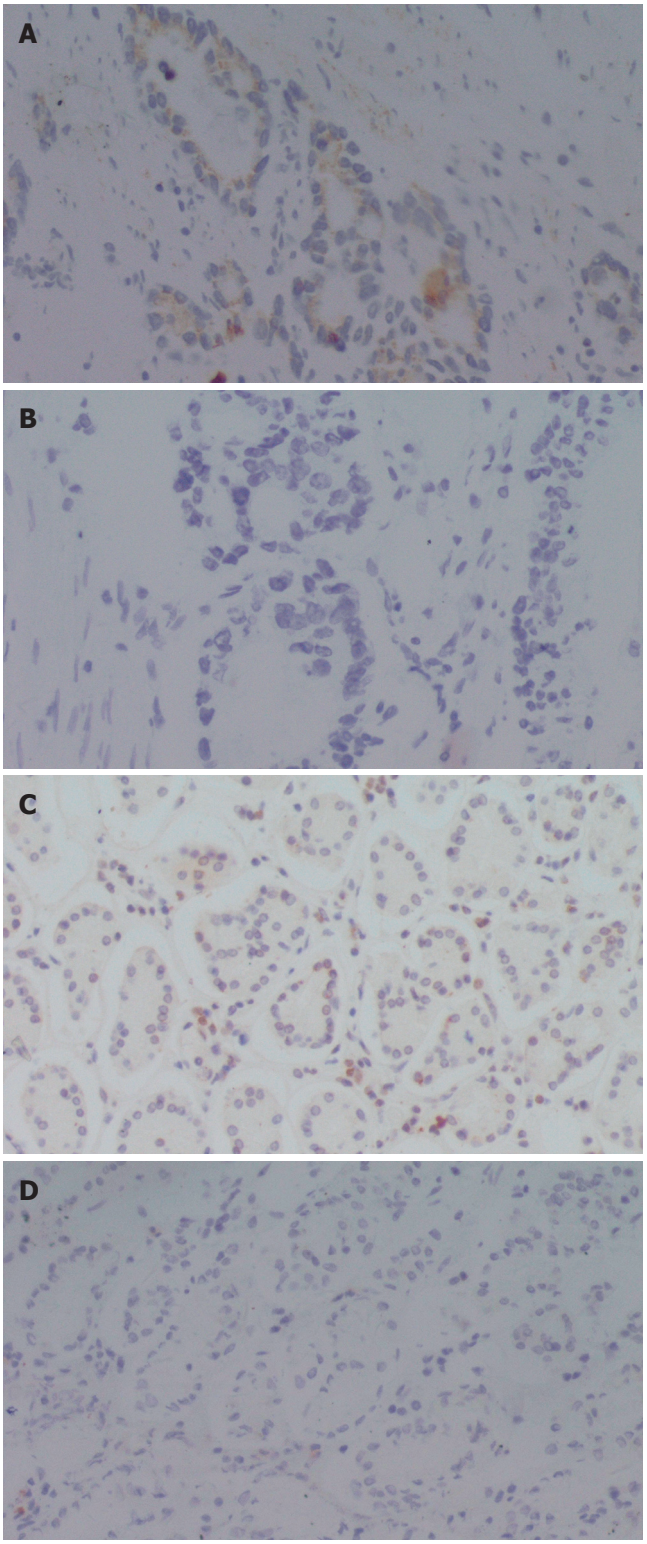

**Figure 1** Immunohistochemical staining of gastric cardiac adenocarcinomas and the corresponding adjacent non-neoplastic epithelium using antibody to ATP7B. **A:** ATP7B-positive gastric cardiac adenocarcinoma; **B:** ATP7B-negative gastric cardiac adenocarcinoma; **C:** ATP7B-positive adjacent non-neoplastic epithelium; **D:** ATP7B-negative adjacent non-neoplastic epithelium.

**Table 1 Relationship between ATP7B expression and clinicopathological variables in gastric cardiac carcinomas**

| Variables | *n* | ATP7B | | Significance[1] |
|---|---|---|---|---|
| | | Negative | Positive | |
| Total | 49 | 24 | 25 (51.0%) | |
| Median age (yr) | | 54 | 56 | NS |
| Degree of differentiation | | | | 0.030 |
| Well/moderately differentiated | | 13 | 6 | |
| Poorly differentiated | | 11 | 19 | |
| Tumor size | | | | NS |
| $T_1 + T_2$ | | 10 | 7 | |
| $T_3 + T_4$ | | 14 | 18 | |
| Nodal stage | | | | NS |
| N (-) | | 3 | 5 | |
| N (+) | | 21 | 20 | |
| Metastasis status | | | | NS |
| $M_0$ | | 21 | 19 | |
| $M_1$ | | 3 | 6 | |

[1]Pearson Chi-Square and Fisher's exact tests were used; NS: Not significant.

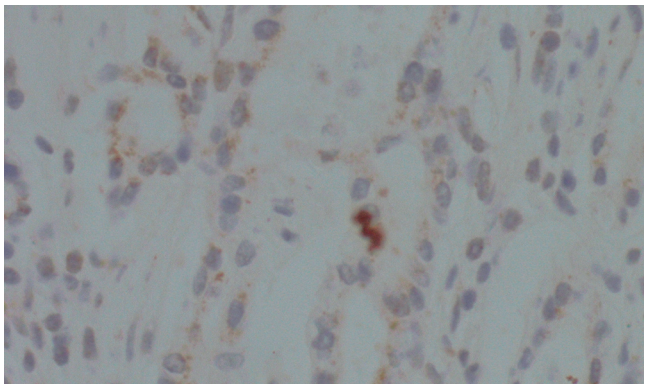

**Figure 2** ATP7B-positive immunohistochemical staining of distal gastric carcinoma using antibody to ATP7B.

ATP7B expression in poorly differentiated gastric cardiac carcinomas was more frequent than in well/moderately differentiated carcinomas, indicating that ATP7B expression might serve as an independent prognostic factor in these patients.

Several study groups detected no ATP7B protein expression in adjacent non-neoplastic epithelium[16-18]. However, our results are somewhat different from the previous reports. We found that ATP7B protein expression was also seen in some of adjacent non-neoplastic epithelium, although it was much lower than in gastric cardiac carcinomas. This suggests that ATP7B protein in gastrointestinal tract may have physiological function. We suppose that ATP7B might protect gastric cardiac epithelium cells from the harmful heavy metals.

It is well known that gastric cardiac carcinoma is more resistant to chemotherapy and has worse prognosis compared with distal gastric carcinoma, although the underlying mechanisms have not been elucidated[1,24]. Our observations demonstrated that ATP7B expression in gastric cardiac carcinomas was significantly higher than that in distal gastric carcinomas. This might partially explain the difference of chemotherapy response and prognosis between gastric cardiac carcinoma and distal gastric carcinoma. Combined determination of ATP7B and other drug-resistant molecular markers[8], such as Pgp, MRP, LRP, BCRP, could be useful for selection of chemotherapy regimens.

## ACKNOWLEDGMENTS

We thank Li-Dong Wang, Professor of Pathology and Oncology, College of Medicine, Zhengzhou University, China for his contribution and help in obtaining esophageal carcinoma specimens.

## Abstract

**AIM:** To explore the mechanisms of uncut Roux-en-Y gastrojejunostomy, which is used to decrease the occurrence of Roux stasis syndrome.

**METHODS:** The changes of myoelectric activity, mechanic motility and interstitial cells of Cajal (ICC) of the Roux limb after cut or uncut Roux-en-Y gastrojejunostomy were observed.

**RESULTS:** When compared with the cut group, the amplitude (1.15 ± 0.15 mV *vs* 0.48 ± 0.06 mV, $P < 0.05$) and frequency (14.4 ± 1.9 cpm *vs* 9.5 ± 1.1 cpm, $P < 0.01$) of slow waves and the incidence (98.2% ± 10.4% *vs* 56.6% ± 6.4%, $P < 0.05$) and amplitude (0.58 ± 0.08 mV *vs* 0.23 ± 0.06 mV, $P < 0.01$) of spike potential of the Roux limb in the uncut group were significantly higher. The migrating myoelectric complexes (MMC) phase Ⅲ duration in the uncut group was significantly prolonged (6.5 ± 1.1 min *vs* 4.4 ± 0.8 min, $P < 0.05$), while the MMC cycle obviously shortened (42.5 ± 6.8 *vs* 55.3 ± 8.2 min, $P < 0.05$). Both gastric emptying rate (65.5% ± 7.9% *vs* 49.3% ± 6.8%, $P < 0.01$) and intestinal impelling ratio (53.4% ± 7.4% *vs* 32.2% ± 5.4%, $P < 0.01$) in the uncut group were significantly increased. The contractile force index of the isolated jejunal segment in the uncut group was significantly higher (36.8 ± 5.1 *vs* 15.3 ± 2.2, $P < 0.01$), and the expression of *c-kit* mRNA was significantly increased in the uncut group (0.82 ± 0.11 *vs* 0.35 ± 0.06, $P < 0.01$).

**CONCLUSION:** Uncut Roux-en-Y gastrojejunostomy may lessen the effects of operation on myoelectric activity such as slow waves, spike potential, and MMC, decrease the impairment of gastrointestinal motility, and remarkably increase the expression of *c-kit* mRNA.

**Key words:** Roux-en-Y anastomosis; Electromyography; Gastrointestinal motility; *c-kit*

## INTRODUCTION

Roux-en-Y anastomosis is a commonly used surgical procedure in gastroenterological surgery; however, more than one third of the patients who experience such an operation suffer Roux stasis syndrome[1,2]. It has been proposed that the occurrence of Roux stasis syndrome is related to the blockage of electro-conduction caused by cut of the jejunum[3]. Therefore, some researchers designed an uncut Roux-en-Y gastrojejunostomy[4], which was based on Billroth Ⅱ subtotal gastrectomy, combined with jejunojejunostomy (Braun's anastomosis) and occluded jejunal-gastric pathway. Theoretically, this surgical procedure can maintain the integrity of the intestinal canal and normal conduction of impulses, as well as make gastric contents to be drained directly into the intestinal tract along the movement direction of the alimentary tract. Due to blockade of gastric pathway, digestive fluids, such as bile, pancreatic juice, are unable to enter the stomach, and can merely be evacuated through the Braun's anastomosis. Clinical practice has proved that this surgical procedure decreases the occurrence of Roux stasis syndrome[5,6]. In order to explore the underlying mechanisms, we observed the changes of myoelectric activity, mechanic motility and interstitial cells of Cajal (ICC) of the Roux limb after cut or uncut Roux-en-Y gastrojejunostomy.

## MATERIALS AND METHODS

### *Experimental protocol*

Male Wistar rats (250 ± 20 g) were provided by the

Animal Research Center of the First Clinical College of Harbin Medical University, Harbin, China. Fourteen rats were divided into two groups randomly. After the rats were anaesthetized with intraperitoneal injection of pentobarbital sodium (40 mg/kg body mass), resection of the distal stomach and reconstruction of the gastrointestinal tract were performed.

For the cut Roux-en-Y gastrojejunostomy, a standard Roux-en-Y gastrojejunostomy was undertaken (Figure 1). In brief, the jejunum was cut 1.0 cm distal to the ligament of Treitz, and the remaining gastric pouch was anastomosed to the aborad portion of the jejunum by an end-to-side procedure. The orad portion of the jejunum was anastomosed to the mid jejunum by an end-to-side procedure 2.0 cm distal to the gastrojejunostomy.

For the uncut Roux-en-Y gastrojejunostomy (Figure 1), an end-to-side gastrojejunostomy was constructed approximately 4.0 cm distal to the ligament of Treitz. The jejunal lumen was occluded 0.5 cm proximal to this anastomosis, and a side-to-side Braun's jejunojejunostomy was made approximately 2.0 cm distal to this anastomosis.

One month after the operation, electric activity of the Roux limb was studied. Then the rats were sacrificed and gastrointestinal motility and levels of *c-kit* mRNA of the Roux limb were detected.

### Myoelectrical studies

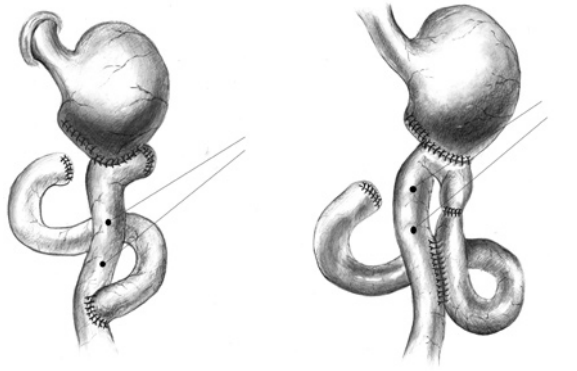
As shown in Figure 1, a couple of monopolar silver-silver chloride electrodes were implanted on the seromuscular layer of the Roux limb, which was spaced evenly 1.0 cm apart. The electrodes were connected by insulated leads to a multipinned socket contained in a plastic cannula, the outer end of which was exteriorizd and the inner end anchored to the left lower quadrant of the abdominal wall. One month after the operation, electric activity was recorded during fasting conditions. The electrodes were connected to a 3802 biological signal amplifier system and the amplified analogue signals were converted to digital signals using NSA4 data acquisition system, sampled at 100 Hz, and displayed in real time on a VGA monitor while simultaneously stored on magnetic media for later analysis using Pclab software (Version 2.2.0).

The amplitude and frequency of slow waves, as well as incidence and amplitude of spike potential of jejunal smooth muscle were recorded. Amplitude of spike potential was represented by the maximum value of spike potential cluster.

Incidence of spike potential (%) = (number of spike potential cluster/number of slow wave) × 100%.

### Determination of gastrointestinal motility in vivo

Each rat took orally 0.3 mL of the mixture of Arabian gel and active charcoal powders. Thirty minutes later, the rats were sacrificed and a laparotomy was performed. Then the stomach from proventriculus to the gastrointestinal stoma was cut and its gross and net mass were weighed. In addition, intact small intestines (from gastrointestinal stoma to ileocecal junction) were took out, and placed on paper without pull strength. Then the lengths from gastrointestinal stoma to the proximal end of charcoal paste reach and to ileocecal junction were measured.



Cut Roux-en-Y gastrojejunostomy Uncut Roux-en-Y gastrojejunostomy

**Figure 1** Distal gastrectomy, cut or uncut Roux-en-Y gastrojejunostomy, placement of electrodes.

Gastric emptying rate (%) = [1- (gastric gross mass-gastric net mass)/mass of charcoal paste] × 100%

Small intestinal impelling ratio (%) = (distance of charcoal paste reach/length of total intestine) × 100%

### Detection of motility of isolated jejunal segment[7]

About 2.0 cm Roux limb was took off and put into 10 mL Tyrode's solution, which had been pre-saturated by a mixed gas (95% $O_2$ + 5% $CO_2$). One end of the jejunal segment was tied on a specimen fixation hook in the water-bath, and the other end was connected with a tonotransducer, then the tonotransducer was linked with the CH1 input interface of BL-New Century bio-signal collecting and processing system. The motility changes of the jejunal segment were recorded. During the experiment, the temperature of Tyrode's solution should be kept at 37.0℃ ± 0.5℃, and continuously ventilated at a constant speed. Contractile force index = contraction amplitude × contraction frequency.

### Measurement of c-kit mRNA by RT-PCR

Total RNA was isolated from one part of the Roux limb using Trizol reagent (Invitrogen, USA) and was reversely transcribed into cDNA according to the instruction of the kit (Promega, USA). The resulting cDNA was used as a template for subsequent polymerase chain reaction (PCR). Samples were then heated to 94℃ for 5 min and cycled 40 times at 94℃ for 15 s, 48℃ for 60 s, and 72℃ for 90 s, and finally extended at 72℃ for 10 min. The primer set designed for PCR amplification of rat *c-kit* mRNA was 5'-AGCAAGAGTTAACGATTCCGGAG-3' and 5'-CCAGAAAGGTGTAAGTGCCTCCT-3', and the predicted size of the PCR product was 344 bp according to the reported sequence of rat *c-kit* mRNA. The primer of housekeeping gene β-actin (348 bp) was 5'CATCAC-CATTGGCAATGAGCG 3' and 5'CTAGAAGCATTT-GCGGTCGGAC 3'. The PCR products were measured using Quantity One software.

### Statistical analysis

Data were expressed as mean ± SD. Comparison between groups was performed with analysis of variance (ANOVA)

**Table 1 Myoelectric activity of the Roux limb in the two groups**

| Group ($n$ = 7) | Frequency of slow wave (cpm) | Amplitude of slow wave (mV) | Incidence of spike potential (%) | Amplitude of spike potential (mV) | MMC phase Ⅲ duration (min) | MMC cycle (min) |
|---|---|---|---|---|---|---|
| Cut group | 9.5 ± 1.1 | 0.48 ± 0.06 | 56.6 ± 6.4 | 0.23 ± 0.06 | 4.4 ± 0.8 | 55.3 ± 8.2 |

and Student-Newman-Keuls test (q test). Statistical significance was assumed at $P < 0.05$.

## RESULTS

### *Myoelectricity of Roux limb smooth muscle*

Slow waves were found in both the uncut group and cut group as shown in Figure 2, which were composed of an initial three phase complex potential and a secondary isopotentiality. When compared with the cut group, the amplitude (1.15 ± 0.15 mV *vs* 0.48 ± 0.06 mV, $P < 0.05$) and frequency (14.4 ± 1.9 cpm *vs* 9.5 ± 1.1 cpm, $P < 0.01$) of slow waves were significantly higher in the uncut group. Spike potential was overlapped with slow wave potential and emerged following the three phase complex potential. The incidence (98.2 ± 10.4% *vs* 56.6 ± 6.4%, $P < 0.05$) and amplitude (0.58 ± 0.08 mV *vs* 0.23 ± 0.06 mV, $P < 0.01$) of spike potential in the uncut group were significantly higher than the cut group (Table 1).

### *Changes of migrating myoelectric complexes (MMC)*

Slow waves were occasionally loaded with spike potential. According to the spike potential loading situation, the periodicity of electric activity could be observed, namely, MMC. At the phase Ⅲ of MMC, large-amplitude and clustered spike potentials almost covered all slow waves, in which the lasting time was defined as MMC phase Ⅲ duration and the interval time between two MMC phase Ⅲ was defined as an MMC cycle. MMC phase Ⅲ duration in the uncut group was significantly prolonged when compared with the cut group (6.5 ± 1.1 min *vs* 4.4 ± 0.8 min, $P < 0.05$), while the MMC cycle obviously shortened (42.5 ± 6.8 *vs* 55.3 ± 8.2 min, $P < 0.05$) (Figure 3 and Table 1).

### *Influence on gastrointestinal motility of rats*

Gastric emptying and food-transmitting rate of rats were reflected by gastric emptying rate and intestinal impelling ratio, respectively. A lower relative charcoal residual rate represents a higher gastric emptying rate, which means a better gastric emptying capacity. On the other hand, the higher the intestinal impelling ratio, the faster the intestinal transmission rate. When compared with the cut group, both gastric emptying rate (65.5 ± 7.9% *vs* 49.3 ± 6.8%, $P < 0.01$) and intestinal impelling ratio (53.4 ± 7.4% *vs* 32.2 ± 5.4%, $P < 0.01$) in the uncut group were significantly increased, suggesting that gastrointestinal motility was impaired more seriously in the cut group (Table 2).

### *Changes of isolated jejunal segment movement*

Spontaneous contraction could be observed in isolated jejunal segment as shown in Figure 4. The contractile force index in the uncut group was significantly higher than that in the cut group (36.8 ± 5.1 *vs* 15.3 ± 2.2, $P < 0.01$) (Table 2).

### Expression of *c-kit* mRNA

To evaluate the quantity and function of ICC, *c-kit* mRNA expression was examined using semi-quantitive RT-PCR.

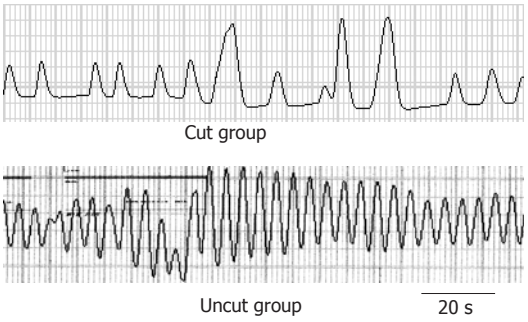

**Figure 4** Motility of isolated jejunal segment.

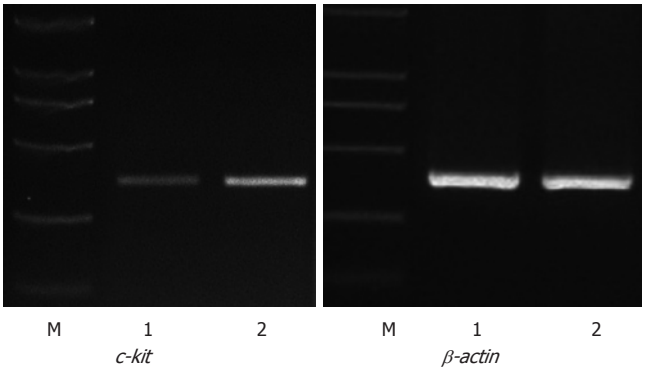

**Figure 5** Expression of *c-kit* mRNA in jejunal segment. L1: Cut group; L2: Uncut group; M: DL-2000 molecular weight markers.

The 348 bp band of β-actin confirmed the integrity of the cDNA obtained from each sample. For *c-kit* a 344 bp band was detectable at variable levels (Figure 5). The expression of *c-kit* mRNA was significantly increased in the uncut group compared with that of the cut group ($0.82 \pm 0.11$ *vs* $0.35 \pm 0.06$, $P < 0.01$) (Table 2).

## DISCUSSION

Patients undergoing Roux-en-Y anastomosis complain of upper abdominal fullness and distension, abdominal pain, nausea or vomiting, and these symptoms are aggravated after meals. Such a syndrome is known as Roux Stasis Syndrome. Van der[8] reported that 26 of 37 (70%) patients experienced such a syndrome. The high incidence has attracted much attention in the research circle. Schippers' findings showed that intestinal movement of patients with Roux stasis syndrome is disordered and lacks regular MMC in interdigestive phase, suggesting that the small intestine may lose the stimulation of pacemaker potential initiated from the duodenum due to destruction of the continuity of the small intestine[9]. Thus, it may be helpful to relieve Roux stasis syndrome by keeping the integrity of the nerves and muscles between duodenal pacemaker potential and the Roux limb. First, back flow of the bile and pancreatic juice through ascending Roux limb should be prevented; second, the integrity of muscular layer of Roux limb should be maintained. Uncut Roux-en-Y gastrojejunostomy could meet these requirements. Chen[10] showed that the reconstitution of the gastrointestinal tract with Roux-en-Y gastrojejunostomy is more effective than with Billroth Ⅱ operation on gastric emptying. Vogel[11] carried out a re-operation to reestablish the continuity of the small intestine for patients with Roux stasis syndrome. As a result, these patients could take food normally post operation without biliary vomiting or burning epigastric pain. In order to explore the underlying mechanisms, we carried out a comparative study between uncut Roux-en-Y gastrojejunostomy and traditional cut Roux-en-Y gastrojejunostomy, and observed the changes of myoelectric activity and motility.

Slow waves, also known as basic or pacemaker potential, are the basis of various electric activities of the gastrointestinal tract, of which the major function is to enhance the excitability of smooth muscles. Cells in each part of the gastrointestinal tract have spontaneous electric activity, and the slow waves attenuate along the gastrointestinal tract; the slow wave of the orad portion with a higher frequency has the inherent effect to drive the lower frequency of the aborad portion, which makes the rhythm of the aborad portion to keep pace with that of the orad portion. After Roux-en-Y gastrojejunostomy, the jejunum is cut off, which causes the frequency of slow waves diminished due to intervention of normal transmission of slow waves. This viewpoint was proved by the current study. Because the intestinal canal was severed in the cut group, the frequency of slow waves was lower compared with the uncut group ($P < 0.05$). It indicated that the excitability of smooth muscles in the uncut group was higher than that in the cut group.

Spike or active potentials are able to trigger contractions of smooth muscles, and the contraction intensity of intestinal smooth muscles has a positive relationship with the incidence of spike potential. This study showed that the incidence of spike potential in the uncut group was higher than that in the cut group ($P < 0.01$). It suggests that the application of uncut Roux-en-Y gastrojejunostomy can decrease the influence on the incidence of spike potential and impairment of the contraction activity of the intestine.

Occurred periodically, MMC is clustered, large-amplitude spike potential activity, which can migrate from the duodenum to terminal ileum. MMC consists of four phases: phase I is characterized by slow waves without spike potential; phase Ⅱ and IV are characterized by a small quantity of spike potential loaded on some slow waves; phase Ⅲ shows large-amplitude, clustered spike potential loaded on all slow waves. Phase Ⅲ electric activity corresponds to a series of propagated contractions, which produce intensive impelling action for small intestinal contents, and periodically scavenge gastrointestinal contents between meals. Deficiency or shortened MMC phase Ⅲ would lead to accumulation of remnant digestive products, cast-off cell, and secretory juice, and facilitate the propagation of bacteria in the small intestine[12]. Le Blanc-Louvry[13] reported that traditional Roux-en-Y operation may shorten MMC phase Ⅲ duration. In the current study, the duration of MMC phase Ⅲ significantly prolonged in the uncut group ($P < 0.01$). Previous findings have shown that uncut Roux-en-Y surgical procedure can relieve Roux stasis syndrome by increasing the frequency of MMC occurrence, prolonging the duration of MMC phase Ⅲ, and

enhancing the clearance of interdigestive remnants. Some studies on gastrointestinal dynamics such as gastric emptying and small intestine impelling ratio also showed that the gastrointestinal motility of experimental animals was significantly improved in the uncut Roux-en-Y group, which is consistent with the studies of Ward[14].

When eliminating the influence of organism adjustment factors such as nerves, and body fluids, we found that there was still some difference in intestinal motility between the two groups. To explore this inner mechanism, we detected the ICC changes of different operations with RT-PCR technique.

ICC is a kind of special interstitial cell in gastrointestinal tract, which has a close relationship with the nervous system. The cell can produce slow waves itself, and thus it has been thought as the pacemaker cell of the gastrointestinal tract[15,16]. It has been shown that ICC plays an important role in the gastrointestinal electrophysiology, dynamo-development and dyskinesis[17,18]. In addition, abnormal expression of ICC has been discovered in some gastrointestinal tract diseases such as gastroparesis[19], chronic idiopathic intestinal pseudo-obstruction[20], slow transit constipation, ulcerative colitis[21] and Crohn's disease[22]. Won[23] observed that the expression of ICC decreased in the animal model of bowel obstruction. *c-kit* is an important marker to identify ICC. It is a kind of transmembrane protein with tyrosine kinase function. During embryonic development period, *c-kit* signal can make ICC precursor develop to myenteric ICC, and finally to be the pacemaker cell of the intestinal tract; whereas those non-connected with *c-kit* signal develop to longitudinal muscle layer[24]. With respect to the long-term maintenance of ICC function, *c-kit* signal is of great importance. Chronic loss or deficiency of this signal transduction may cause blockage or deprivation as well as functional impairment of ICC network[25,26]. Animals with *c-kit* mutant defect have difficulties to produce complete, regular spontaneous slow waves by gastrointestinal tissue[27]. Therefore, *c-kit* reflects the quantity and function of ICC[28]. In this study, *c-kit* mRNA in the uncut group was significantly higher than that in the cut group, which may result from decreased stimulation of the high-frequency electric activity of the orad portion in the cut group.

In summary, compared with traditional cut Roux-en-Y gastrojejunostomy, uncut Roux-en-Y gastrojejunostomy may lessen the effects of operation on myoelectric activity such as slow waves, spike potential, and MMC, decrease the impairment of gastrointestinal motility, and remarkably improve the ICC quantity and function.

## COMMENTS

### Background

Roux-en-Y anastomosis is a commonly used surgical procedure in gastroenterological surgery; however, more than one third of the patients who experience such an operation suffer Roux stasis syndrome. Therefore, it is important to develop a moderate surgical procedure to control these kinds of complications.

### Research frontiers

The etiology and treatment of Roux stasis syndrome are yet to be clarified.

### Innovations and breakthroughs

We studied the myoelectric activity, gastrointestinal motility, and *c-kit*, which represent the ICC quantity and function.

### Applications

Uncut Roux-en-Y gastrojejunostomy has already been used in clinical practice, and this article will provide more rationale for its application.

### Terminology

**Uncut Roux-en-Y gastrojejunostomy** is based on Billroth Ⅱ subtotal gastrectomy, combined with Braun's jejunojejunostomy and occluded jejunal-gastric pathway. Theoretically, this surgical procedure can maintain the integrity of intestinal canal and normal conduction of impulse, as well as make gastric contents to be drained directly into the intestinal tract along the movement direction of the alimentary tract.

### Peer review

The authors performed an experimental study in rats on myoelectric activity and motility of the Roux limb following cut versus uncut Roux-en-Y gastrojejunostomy.

The research background of the study is clearly defined. The presentation of the results and their discussion are adequate. Results provide sufficient evidence for the conclusions drawn. Overall, the content of the manuscript is interesting and could be valuable for a broad readership.

## Abstract

**AIM:** To evaluate the effect of ligustrazine, a traditional Chinese medicine, on renal injury in a rat model of acute necrotizing pancreatitis (ANP).

**METHODS:** A total of 192 rats were randomly divided into three groups: control (C group), ANP without treatment (P group), and ANP treated with ligustrazine (T group). Each group was further divided into 0.5, 2, 6, 12 h subgroups. All rats were anesthetized with an intraperitoneal injection of sodium pentobarbital. Sodium taurocholate was infused through the pancreatic membrane to induce ANP. T group was infused sodium taurocholate as above, and 0.6% ligustrazine was then administered *via* the femoral vein. Serum urea nitrogen (BUN) and creatinine (Cr) concentrations were measured for the evaluation of renal function. The effects of ligustrazine on the severity of renal injury were assessed by renal function, $TXA_2/PGI_2$ and histopathological changes. Renal blood flow was determined by the radioactive microsphere technique (RMT).

**RESULTS:** Compared with control group, the renal blood flow in P group was decreased significantly. Serious renal and pancreatic damages were found in P group, the BUN and Cr levels were elevated significantly, and the ratio of $TXA_2$ to $PGI_2$ was increased at 2, 6 and 12 h. Compared with P group, the blood flow of kidney was elevated significantly at 6 and 12 h after induction of ANP, the renal and pancreatic damages were attenuated, and the BUN and Cr levels were decreased significantly, and the ratio of $TXA_2$ to $PGI_2$ was decreased at 6 and 12 h in T group.

**CONCLUSION:** Microcirculatory disorder (MCD) is an important factor for renal injury in ANP. Ligustrazine can ameliorate the condition of MCD and the damage of pancreas and kidney.

## INTRODUCTION

Acute pancreatitis complicated by multiple organ dysfunctions is still a life-threatening disease[1,2], although the precise mechanism by which such local inflammation in the pancreas progresses to systemic illness is still unclear. Recently, this systemic inflammatory response syndrome (SIRS) has become a widely accepted disease state[3], which could lead to the failure of distant organ systems, such as the lungs, intestine, stomach and kidneys[4-6].

Acute pancreatitis (AP) is often complicated by renal injury. However, its pathogenesis remains unclear. Recent studies indicate that during the pathogenesis of acute necrotizing pancreatitis (ANP), the change of microcirculation plays an important role in the worsening of pancreatitis[7].

Pharmacologic studies have demonstrated that ligustrazine, an intravenous drug made from traditional Chinese herbs, is able to inhibit release of intracellular calcium and to scavenge oxygen free radicals[8,9]. Ligustrazine has been widely applied in the treatment of vascular diseases in China due to its significant efficacy on cerebral ischemia and reperfusion injury. However, its role and mechanism in treatment of renal injury have not been extensively studied. The effect of ligustrazine on renal injury was observed in this study based on the established model of ANP.

## MATERIALS AND METHODS

### *Animals*

One hundred and ninety-two adult Sprague-Dawley rats (250-300 g) were provided by the Laboratory Animal Center of Jiangsu University, China. The animals were kept in rooms at 21 ± 1℃ in a 12 h light/dark cycle for 1 wk to acclimate to the surrounding with free access to water and standard laboratory chow. Prior to experiment, the rats

were fasted overnight with access to water.

### Experimental design

The animals were randomly divided into three groups: control ($n$ = 64, C group), ANP without treatment ($n$ = 64, P group), and ANP treated with ligustrazine ($n$ = 64, T group). Each group was further divided into 0.5, 2, 6, 12 h subgroups. All rats were anesthetized with an intraperitoneal injection of sodium pentobarbital (50 mL/kg). Sodium taurocholate (50 g/L, 4 mL/kg, Ward Blen Kinsop CO., UK) was infused through the pancreatic membrane to induce ANP as previously described[10]. After 5-10 min, pancreatic edema and dotted bleeding occurred. T group was infused sodium taurocholate as above, 6 g/L ligustrazine (Seventh Pharmaceutical Factory, Wuxi, China; batch number: 0008241) was then administered *via* the femoral vein (10 mL/kg) as previously described[11,12]. C group received isovolumetric infusion of 9 g/L physiological saline solution using the same method. The abdominal wounds were closed and all the rats were sent back to their cages. Half of the animals in each subgroup were sacrificed at 0.5, 2, 6 and 12 h after infusion for further examination. Left kindeys were removed immediately and fixed in paraformaldehyde solution for 12-24 h and paraffin-embedded for routine histopathologic analysis. The histopathologist was blinded to routine histopathologic analysis. The blood was obtained from eight rats in each group *via* superior mesenteric vein for determination of serum blood urea nitrogen (BUN), creatinine (Cr), $TXA_2$ and $PGI_2$. The remaining rats in each group were used for kidney blood flow determination by the radioactive microsphere technique (RMT). The left kidney was also removed and weighed at 0.5, 2, 6 and 12 h after infusion for subsequent radioactive measurement.

### Blood flow measurements

At 0.5, 2, 6 and 12 h after the infusion, renal blood perfusion values were determined by RMT as previously described[10]. $^{99}Tc^m$-labeled microspheres ($^{99}Mo$-$^{99}Tc^m$ generator preparation was provided by Chinese Institute of Nuclear Power) with a specific activity of 74 MBq/Ml were used for measurement of blood flow. The right carotid artery was catheterized with placement of the tip of the tubing in the left ventricle for infusion of $^{99}Tc^m$-labeled microspheres. One milliliter $^{99}Tc^m$ radioactive microspheres (approximately 500 000 microspheres) was injected for 10 s *via* the catheter with its tip in the aortic ventricle of the heart. A reference blood sample was obtained from the femoral artery catheter for 60 s at a constant rate of 1 mL/min with a continuous-withdrawal pump. The animals injected microspheres were killed by intra-arterial injection of 2 mL 100 g/L KCL. The whole left kidney was removed, weighed, cut into small pieces and placed in a γ-counter (GC-1200 Gamma Radioimmunoassay Counter, USTC Chuangxin CO. Ltd., China) to determine the radioactivity (cpm).

The blood flow values were calculated according to the following formula:

$$Q_{org}\ [mL/(min \cdot g)] = \frac{Q_{ref}\ (mL/min) \times N_{org}\ (cpm)}{N_{ref}\ (cpm) \times weighing\ (g)}$$

Where $Q_{org}$ denotes organ blood flow (mL/min.g), $Q_{ref}$ is withdrawal rate of the reference sample (mL/min), $N_{org}$ is the number of microspheres in the organ (count/min) and $N_{ref}$ is the number of microspheres in the reference sample.

**Table 1 Grading of histological injury using microscopic injury score**

| Score | Findings |
|---|---|
| O | Normal |
| I | Notable cloudy swelling of tubular epithelial cells |
| II | Swelling denaturation of renal tubular epithelial cells, interstitial congestion, edema and infiltration of inflammatory cells |
| III | Diffuse coagulation necrosis in tubular epithelial cells |

### Detection of serum BUN, Cr, $TXA_2$ and $PGI_2$

The blood from the superior mesenteric vein was collected into a tube. The tube was immediately centrifuged at 3500 r/min for 15 min. Collected plasma was stored at -40℃ until use. BUN and Cr levels were assayed using an automatic biochemistry analyzer (CL-7300; SHIMADZU Corporation, Kyoto, Japan) with assay kits. The level of $TXA_2$ and $PGI_2$ was detected according to the manufacturer's instructions (Science and Technology Development Center, General Hospital of PLA, Beijing, China).

### Histological examination

Renal and pancreas specimens were harvested and fixed in 10 g/L formalin for histological examination. The tissues were dehydrated, embedded in paraffin wax, cut into 5-μm sections, and mounted. After removed from the paraffin, the tissues were stained with hematoxylin and eosin. The severities of renal injury were quantified using a histological scoring system as previously described[13]. Histopathologic analysis of renal specimens was performed and scored as 0-Ⅲ (Table 1). Twenty fields per kidney were examined, a mean of the total score was compared between the groups. The renal sections were also analyzed with a HPIAS-1000 multimedia color analysis system (Huahai Co., Shanghai). Five fields (0.265 mm × 0.2 mm) of each section were read. Average values of neutrophil infiltration were calculated and recorded. All examinations were performed in a blind fashion by an experienced pathologist.

### Statistical analysis

All data were analyzed by the SPSS 11.0 software. The results were expressed as mean ± SD except for data on the grading of renal lesions. Differences in grading of renal lesion were determined using the non-parametric Mann-Whitney test. Statistical analysis was performed with post-hoc test. $P < 0.05$ was considered statistically significant.

## RESULTS

### Renal blood flow

Blood flow in the P group was significantly lower than that in the C group. It began to decrease at 0.5 h and became

|---|---|---|---|---|
| C | 5.5 ± 1.2 | 6.5 ± 1.2 | 6.7 ± 1.3 | 6.9 ± 1.4 |
| P | 13.0 ± 1.6[b] | 15.0 ± 1.9[b] | 18.0 ± 1.7[b] | 21.1 ± 3.0[b] |
| T | 6.9 ± 1.4 | 10.8 ± 1.4[b,d] | 13.0 ± 1.6[b,d] | 15.0 ± 2.0[b,d] |

[b]$P < 0.01$ *vs* C group; [d]$P < 0.01$ *vs* P group.

the lowest at 12 h. However, the blood flow in the T group was significantly higher than that in the P group at 6 and 12 h, showing no significant difference from the C group (Table 2).

### *Serum levels of BUN, Cr, $TXA_2$ and $PGI_2$*

Compared with the control group, the BUN and Cr levels in the P group were elevated significantly ($P < 0.01$ or $P < 0.05$), and the ratio of $TXA_2$ to $PGI_2$ was increased at 2, 6 and 12 h ($P < 0.01$). Compared with the P group, the BUN and Cr levels were decreased significantly ($P < 0.01$ or $P < 0.05$), and the ratio of $TXA_2$ to $PGI_2$ was decreased at 6 and 12 h in the T group ($P < 0.01$ or $P < 0.05$) (Table 3, Table 4, Table 5).

### *Pathological examination*

After induction of ANP model, the pancreas showed mild edema and congestion. At 0.5 h, typical pathological changes of ANP were found, such as a large number of inflammatory cells, necrosis of the adjacent fat tissues, interstitial edema, parenchyma hemorrhage and necrosis, large amount of ascites. The changes became severer with the prolongation of time. The renal pathological changes were aggravated significantly in the P group. Histopathologic scores were higher in the P group than in the C group throughout the experiment ($P < 0.01$) and lower in the T group than in the P group (Table 6). Under the light microscope, different swelling denaturation and necrosis of renal tubular epithelial cells were observed. Simultaneously, interstitial congestion, edema and infiltration of inflammatory cells were also observed. While in the ligustrazine-treated group, the outward appearance of the kidney was normal. The mean number of neutrophils infiltrated in × 400 field increased from 0.5 h in the T group, while decreased significantly from 2 h in the P group (Table 7).

### *Correlated analysis*

Correlated analysis showed that there was a negative correlation between renal blood flow and serum Cr ($r = -0.931$, $P < 0.01$) and $TXA_2/PGI_2$ ($r = -0.977$, $P < 0.05$), as well as between renal blood flow and pathologic score($r = -0.948$, $P < 0.05$).

## DISCUSSION

Acute renal injury is a major cause of morbidity in ANP. Our experimental study in rats demonstrated that microcirculatory disorder (MCD) of rats resulted in a sequence of events that ultimately caused renal injury. Although the renal injury occurring in ANP has been well described, the underlying mechanism remains unclear. The rat model of renal injury in this study resulted in a dramatic decrease in renal blood flow as evidenced by

RMT and renal histological changes.

Microcirculatory disturbances are important early pathophysiological events in various organs during AP[14-18]. Microcirculatory change is an important factor during the development of ANP. It can damage the pancreas and extrapancreatic vital organs[19,20]. The possible contributory mechanisms involved in the development of this disease include increased vascular permeability, reduced blood flow, leukocyte-endothelia interactions and development of intravascular thrombi[21,22]. The radioactive microsphere technique can efficiently estimate blood flow to various organs in the body. With the availability of different radioactive labeled microspheres, it is possible to measure regional blood flow repeatedly[23]. In our study, at the early stage of ANP, the renal blood flow began to decrease significantly at 0.5, 2, 6 and 12 h after infusion as compared with the C group. The renal injury was possibly due to ANP and the release of inflammatory mediators. A series of changes in the nerve endocrine system led to the redistribution of visceral blood flow, thus producing a sharp decrease of renal blood flow, suggesting that microcirculation disturbances may contribute to renal injury under conditions such as ischemia/reperfusion at the early stage of ANP. Therapeutic agents that improve pancreatic blood flow might be valuable in the treatment of acute pancreatitis[24]. In this study, ligustrazine improved microcirculation and reduced acute renal injury in rats with ANP.

In the present study, the protective effect of ligustrazine against renal injury was investigated in rats with ANP. Scrum levels of BUN and Cr were used as indicators of renal protection. $TXA_2$ is both a vasoconstrictor and a potent stimulus for platelet aggregation. Its effect is antagonized by prostacylin, which is released from vascular endothelial cells. Prostacylin exerts a variety of effects on the cardiovascular system, including a decrease in blood pressure associated with a decrease in systemic vascular resistance. Feng *et al*[25] demonstrated that $TXA_2$ may be involved in the pathogenesis of acute pancreatitis at its early stage. The ratio of $TXA_2$ to $PGI_2$ was significantly lower after reperfusion than before reperfusion, indicating that the disorder of $TXA_2$ and $PGI_2$ might also be involved in the circulation disorders during ANP. Although the precise mechanism remains unknown, they may play a role in the pathobiology of ANP.

The second prominent feature in this experimental model is the development of granulocytosis and accumulation of neutrophils in the microvasculature of renal capillaries. Because neutrophils are known to be required for the development of renal injury in ANP, interventional studies were undertaken to assess whether intravenous administration of ligustrazine would result in decreased neutrophil accumulation in renal tissues. Our results showed that neutrophil accumulation was markedly elevated after induction of pancreatitis, which was significantly reduced by ligustrazine.

Ligustrazine is widely used in traditional Chinese medicine, often in combination with other herbs. It was used traditionally to treat a diversity of ailments, particularly cardiac (heart) and vascular disorders such as atherosclerosis or blood clotting abnormalities. Ligustrazine could intervene in hemorheological events, such as blood flow, erythrocyte deformation, leukocyte adhesion, platelet aggregation and thrombolysis[26]. It was reported that ligustrazine could inhibit pulmonary hypertension by decreasing the mRNA expression of endothelin-1, oxygen free radical level, lipid peroxidation and adjusting $TXA_2/PGI_2$ imbalance in pulmonary arterioles[27,28].

To investigate the protective effects of ligustrazine against renal injury, the influence of ligustrazine injection on BUN, Cr and $TXA_2/PGI_2$, as well as changes of morphology of renal tubules, were studied in a rat kidney model during ANP. Ligustrazine improved renal microcirculation, suggesting that the protective effects of ligustrazine against renal injury may be attributable to improving microcirculation and further preventing accumulation of neutrophils.

In conclusion, MCD plays an important role in the development of renal injury. The early use of ligustrazine seems to be effective. This provides further evidence for ligustrazine as a therapeutic strategy against renal injury during ANP.

## COMMENTS

### Background

Acute pancreatitis (AP) is often complicated by renal injury. However, its pathogenesis remains unclear. The significant efficacy of ligustrazine on cerebral ischemia and reperfusion injury was confirmed in this study. However, the role and mechanisms of ligustrazine in treatment of renal injury have not been extensively studied.

### Research frontiers

To investigate the protective effects of ligustrazine against renal injury, the influence of ligustrazine injection on BUN, Cr, and $TXA_2/PGI_2$, as well as changes of morphology of renal tubules, were studied in a rat kidney model during ANP.

### Innovations and breakthroughs

The effect of ligustrazine on renal injury was observed in this study based on the established model of ANP. The radioactive microsphere technique was used to analyze the blood flow. Although it is not commonly used and has major disadvantages, it can analyze the blood flow in the pancreas and extrapancreatic vital organs simultaneously.

### Applications

In the present study, ligustrazine improved renal microcirculation, suggesting that ligustrazine can protect against renal injury by improving microcirculation and further preventing accumulation of neutrophils. The early use of ligustrazine seems to be effective. This provides further evidence for ligustrazine as a therapeutic strategy against renal injury during ANP.

### Terminology

Radioactive microsphere technique (RMT): Microspheres containing radioactive substances are infused into the circulatory system to measure perfusion rates in tumors and normal tissues, cerebral blood flow, tissue oxygenation, cardiovascular function, regional vascular resistance, and the effect of various drugs on these parameters. In the present study, $^{99}Tc^{m}$-labeled microspheres were used for measurement of blood flow.

### Peer review

This is a very interesting study demonstrating the effects of ligustrzineon on the pathophysiology of acute pancreatitis. However, some limitations and additional data should be provided.

## Abstract

The etiology of most cases of idiopathic bile acid malabsorption (IBAM) is unknown. In this study, a Swedish family with bile acid malabsorption in three consecutive generations was screened for mutations in the ileal apical sodium-bile acid cotransporter gene (ASBT; gene symbol, SLC10A2) and in the genes for several of the nuclear receptors known to be important for ASBT expression: the farnesoid X receptor (FXR) and peroxisome proliferator activated receptor alpha (PPARα). The patients presented with a clinical history of idiopathic chronic watery diarrhea, which was responsive to cholestyramine treatment and consistent with IBAM. Bile acid absorption was determined using $^{75}$Se-homocholic acid taurine (SeHCAT); bile acid synthesis was estimated by measuring the plasma levels of 7α-hydroxy-4-cholesten-3-one (C4). The ASBT, FXR, and PPARα genes in the affected and unaffected family members were analyzed using single stranded conformation polymorphism (SSCP), denaturing HPLC, and direct sequencing. No ASBT mutations were identified and the ASBT gene did not segregate with the bile acid malabsorption phenotype. Similarly, no mutations or polymorphisms were identified in the FXR or PPARα genes associated with the bile acid malabsorption phenotype. These studies indicate that the intestinal bile acid malabsorption in these patients cannot be attributed to defects in ASBT. In the absence of apparent ileal disease, alternative explanations such as accelerated transit through the small intestine may be responsible for the IBAM.

**Key words**: Bile acid malabsorption; Diarrhea; Genetics; $^{75}$Se-homocholic acid taurine test; Nuclear receptors

## INTRODUCTION

Bile acids are synthesized from cholesterol in the liver and secreted into the small intestine, where they facilitate absorption of fat, fat-soluble vitamins and cholesterol[1]. The bile acids are then reabsorbed from the intestine and returned to the liver *via* the portal venous circulation. The enterohepatic cycling of bile acids is an extremely efficient process, and less than 5% of the intestinal bile acids escape reabsorption and are eliminated in the feces. The ileal apical sodium/bile acid cotransporter (ASBT)[1] mediates the first step in the active uptake of bile acids from the intestine, and defects in ileal ASBT function may be responsible for bile acid malabsorption associated with watery diarrhea. Impaired ileal uptake of bile acids has been documented in several patients[2] and inherited ASBT mutations were demonstrated in congenital primary bile acid malabsorption (PBAM)[3]. However, ASBT mutations are not found in most patients with adult-onset bile acid malabsorption, chronic diarrhea, and a morphological and

functionally normal ileum[4], a more common condition termed idiopathic bile acid malabsorption (IBAM)[5-7]. In this study we examined the association between IBAM and inherited mutations affecting the ASBT and several of the nuclear receptors known to be important for ASBT expression, the farnesoid X receptor (FXR)[8] and peroxisome proliferator activated receptor A (PPARα)[9], in a Swedish family with three generations of bile acid malabsorption.

## CASE REPORT

Three family members (subjects 1, 10, and 11) reported chronic diarrhea, occurring especially after meals (Figure 1). Fasting blood samples were obtained from each family member. Informed consent to participate in the study was obtained from each subject and the protocol was approved by the Ethics Committee of Karolinska University Hospital Huddinge. Bile acid absorption was determined using $^{75}$Sehomocholic acid taurine (SeHCAT), a synthetic analog of taurocholic acid, as previously described[10]. Briefly, a capsule containing 10 μCi of $^{75}$SeHCAT was given orally and retained activity was measured after 3 h and 7 d using an uncollimated gamma counter. Retention of less than 10% of the administered radiolabeled bile acid was considered abnormal. The plasma level of 7α-hydroxy-4-cholesten-3-one (C4) (normal < 19 ng/mL), an intermediate product in the synthesis of bile acids, was measured as described[11]. C4 is a reliable marker for the activity of hepatic cholesterol 7α-hydroxylase, the rate-determining enzyme in bile acid synthesis[12,13].

Patient 11 had a history of diarrhea since adulthood with 15 to 20 watery bowel movements per day over the past 10 years. Clinical history was unremarkable except for a cholecystectomy at age 24. Patient 10 had a history of frequent watery diarrhea since her teenage years. Patient 1 reported frequent bowel movements following a meal. In all three patients, celiac disease was excluded; lactose tolerance tests, vitamin B12 absorption, and routine laboratory blood tests including hemoglobin, sedimentation rate and liver function tests were normal. Barium contrast gastrointestinal exams and ileocolonoscopy with mucosal biopsies (patients 10 and 11) were normal. SeHCAT tests (patients 10 and 11) and plasma levels of C4 (patients 1, 10 and 11) were markedly abnormal (Figure 1). Treatment of patients 10 and 11 with cholestyramine (Questran, Bristol-Myers) reduced the stool frequency and improved the stool consistency.

Dysfunctional mutations in the ASBT gene were previously identified in a subject with PBAM[3]. To determine if similar mutations in ASBT are associated with bile acid malabsorption in this family, we employed simple sequence length polymorphism (SSLP) analysis using a dinucleotide repeat linked to the ASBT gene and SSCP analysis to screen for mutations in the ASBT coding and proximal promoter regions. The SSCP primers designed for ASBT intron or exon sequences and PCR amplification conditions have been described previously[3,14]. PCR amplification products were resolved using three different gel electrophoresis conditions, gels contained 10% glycerol, 1 × TBE buffer, and 6% acrylamide, 10% acrylamide (acrylamide: N, N'-methylenebisacrylamide ratio 50:1), or 0.4 × MDE (Mutation Detection Enhancement acrylamide; FMC Bioproducts, Rockland, Maine), in order to increase the assay sensitivity[15,16], and the nucleotide sequence changes responsible for the SSCP band shifts were subsequently identified by PCR amplification and sequencing. No ASBT mutations or polymorphisms were found in patients 1 or 10, whereas patient 11 was heterozygous for two common polymorphisms that do not affect ASBT function[14], a G-to-T transversion in exon 3 that causes an alanine to serine substitution at position 171 (A171S) and an intronic A-to-G transition located 20 bp upstream of exon 6 (int 5). Following SSCP analysis, the two ASBT alleles could then be distinguished in the original proband (patient 11) using a combination of the linked dinucleotide repeat marker and the single nucleotide polymorphisms (A171S and int 5). The affected individuals shared only one ASBT allele, and four unaffected individuals (subjects 2, 3, 6 and 8) also inherited this allele.

Since the nuclear receptor, FXR, is an important regulator of ASBT expression and bile acid metabolism, the coding region of the FXR gene, exons 3 to 11[17], was also analyzed in patients 1, 10, and 11 using SSCP conditions described by Lind *et al*[18]. Sequences for SSCP primers designed for FXR intron and exon sequences are shown in Table 1. Briefly, exons 3-11 were amplified by PCR from genomic DNA, generating fragments varying from 200 to 250 bp in length, except exon 10 (315 bp) and exon 11 (385 bp). Due to its larger size, exon 4 was PCR-amplified using two sets of primers that yielded products of 240 and 300 bp. The fragments were separated on precast polyacrylamide gels visualized by silver staining (GenePhor DNA Separation System, Amersham Bioscience, Uppsala, Sweden). This analysis detected no mutations or polymorphisms in the human FXR gene of these patients.

| SeHCAT (% retention) | 1 | 4 | ND |
| C4, times normal | 2.5 | 2.0 | 2.5 |

BMI: Body mass index; ND: Not determined.

Polymorphisms in the intronic and exonic regions of the PPARα gene (PPARA) have been previously described[19,20], and PPARα is a known regulator of ASBT gene expression[21]. We analyzed two well-characterized polymorphic regions of PPARA, exon 5 and intron 7, in the PBAM family in order to determine if a mutation in this gene could be associated with the disease. Specific primers were employed for PCR amplification of exon 5 (forward: 5'-AGTAAAGCAAGTGCGCTGGT-3'; reverse: 5'-AAGGAAGGGGAACTGAGGAA-3') and intron 7 (forward: 5'-CCTCCCGAGTATCTGGGATT-3'; reverse: 5'-TGAGCTGCCTTTAGATATTGTCA-3'). The PCR products were analyzed for polymorphisms or mutations by denaturing HPLC (D-HPLC) (Transgenomic Wave, Transgenomic, Omaha, Nebraska) and automatic sequencing (automatic sequencer CEQ$^{TM}$8000 XL, Beckman Coulter Inc., Fullerton. CA). PPARA gene analysis did not show any new mutations. Analysis of the L162V polymorphism of exon 5 and G > C polymorphism of intron 7 revealed that PPARA alleles did not segregate with the bile acid malabsorption symptoms (Figure 1).

## DISCUSSION

The enterohepatic circulation efficiently conserves bile acids, thereby maintaining bile flow and adequate intraluminal bile acid concentrations for micellular solubilization and absorption of lipids[22]. Defective small intestinal absorption leads to increased concentrations of dihydroxy bile acids reaching the colon, where they alter water and electrolyte movement leading to secretory diarrhea[23,24]. Three types of intestinal bile acid malabsorption are generally recognized[25]. Type Ⅰ bile acid malabsorption is the most common form and is caused by ileal resection, ileal disease such as Crohn's disease, ileal bypass, and radiation enteritis[26,27]. Type Ⅲ bile acid malabsorption is associated with conditions such as cholecystectomy, peptic ulcer surgery, chronic pancreatitis, celiac disease, diabetes mellitus, cystic fibrosis, and the use of various drugs[28].

In contrast to types Ⅰ and Ⅲ, type Ⅱ bile acid malabsorption (also called primary or idiopathic bile acid malabsorption) is not associated with obvious ileal disease. A very rare congenital form of type Ⅱ bile acid malabsorption (primary bile acid malabsorption) exhibiting refractory infantile diarrhea, steatorrhea, and growth failure[2,25] was found to be associated with inherited mutations in the ASBT gene[3]. However, most patients with adult-onset idiopathic bile acid malabsorption appear to have a normal ASBT gene[4] and the etiology is still obscure. The identification of a family with idiopathic bile acid malabsorption in three consecutive generations offered a rare occasion to further evaluate association of this syndrome with inherited mutations affecting

the ASBT. These patients were diagnosed with IBAM on the basis of clinical presentation, low SeHCAT test values, increased bile acid synthesis, and response to cholestyramine treatment. Analysis of these individuals and unaffected family members conclusively demonstrated that the intestinal bile acid malabsorption in these subjects is not due to inherited defects in the ASBT gene. In addition, we also looked for polymorphisms of PPARα and FXR, two nuclear receptors known to be important for the regulation of the ASBT. To our knowledge, polymorphism analysis of the human FXR has not been described previously and no mutations of the FXR gene were found in the present study. Likewise, no association between PPARA and IBAM was found in this family.

There is increasing evidence emerging in support of IBAM etiologies other than defective ileal uptake of bile acids. Earlier studies had provided evidence for an increased ileal uptake of bile acids[29] as well as an expanded bile acid pool in some patients with type Ⅱ bile acid malabsorption[28]. Very recently, Bajor *et al*[30] demonstrated elevated *in vitro* bile acid uptake and ASBT protein expression in ileal biopsies from patients with bile acid malabsorption, abnormal SeHCAT-retention values, and elevated plasma C4 levels. This apparent increase in ASBT activity and expression could be explained by accelerated small bowel transit in IBAM patients, thereby reducing the contact time between the luminal contents and the mucosa. In support of this hypothesis, a more rapid small bowel transit has been reported for patients with IBAM[31]. The etiology of the postulated accelerated small bowel transit in these patients is not clear. However, more rapid small bowel transit has been noted in subjects with elevated BMI[31,32] and in subjects consuming high fat diets[33], suggesting dysregulation of gut motility under these conditions. The rapid small bowel transit is predicted to reduce the opportunity for ileal absorption, leading to decreased levels of bile acids in the ileal enterocytes and increased ASBT expression. Previous *in vitro* studies have shown that the human ASBT promoter is negatively regulated by bile acids through an FXR dependent mechanism[8]. The decreased enterocyte levels of bile acids are also predicted to reduce the FXR-dependent induction of FGF19 expression, thereby increasing hepatic bile acid synthesis and plasma C4 levels. FGF19 is an ileal enterocyte derived factor that mediates repression of the hepatic cholesterol 7α-hydroxylase gene and bile acid synthesis[34,35].

In conclusion, the present findings further argue against defective ileal uptake of bile acids as the direct cause of IBAM and support the exploration of alternative explanations such as reduced contact time with the ileal mucosa due to changes in small intestinal motility.

## Abstract

Alpha-fetoprotein (AFP)-producing colorectal cancer is extremely rarely reported until now. All of the reported cases harboring synchronous hematogenous spread including liver and/or lung metastasis had a poor prognosis and died within 12 mo. We here describe a 71-year old man with AFP-producing colon cancer who presented with an unusual bulky lymph node metastasis instead of hematogenous spread. He underwent adjuvant chemotherapy in addition to curative surgical resection, which prolonged his survival.

**Key words**: Alpha-fetoprotein; Colon cancer; Bulky lymph node metastasis; Computed tomography; Colonoscopy

## INTRODUCTION

Alpha-fetoprotein (AFP)-producing colorectal cancer is extremely rare, and only ten cases have been described in the English literature[1]. All reported cases presented with lung and/or liver metastasis and had a very poor prognosis. We here report the first case of AFP-producing colon cancer with bulky lymph node metastasis. This patient had characteristics such as harboring synchronous bulky nodal involvement but not hematogenous spread. Interestingly, he could be curatively operated and survived a long time after adjuvant chemotherapy in addition to surgical resection.

## CASE REPORT

A 71-year old man visited our hospital for positive fecal occult blood and mild anemia. Physical examination disclosed a painless abdominal mass, approximately 50 mm in diameter, in the right lower quadrant of abdomen. Colonoscopy revealed an ulcerative lesion suggestive of an advanced colon cancer in the cecum (Figure 1). Biopsy specimens revealed a moderately-differentiated adenocarcinoma. Additionally, preoperative computed tomography of the abdomen and pelvis showed a bulky mass around the cecal cancer, which suggested nodal involvement corresponding to the palpated abdominal mass on physical examination (Figure 2). However, no distant hematogenous spread, including liver or lung metastasis, was detected. The serum AFP level was high (318.9 μg/L before operation). Right hemicolectomy including lymph node dissection was performed uneventfully, and histological examination of the surgical specimen revealed a subserosally invasive poorly-differentiated adenocarcinoma with nodal involvement. Immunohistochemically, both the primary tumor and the bulky lymph node metastasis showed strong expression of AFP. The serum AFP level became normal after adjuvant chemotherapy in addition to surgery. The patient was in good condition at the time of our report and had no sign of recurrence in the past 5 years.

## DISCUSSION

Elevated levels of AFP, commonly associated with hepatocellular carcinoma or embryonic cell carcinoma, have been reported in neoplasms of several other organs, such as pancreas, gallbladder and gastrointestinal tract. However, AFP-producing colorectal carcinomas are extremely rare. The reported colorectal carcinomas have generally occurred in middle-aged to older men with the

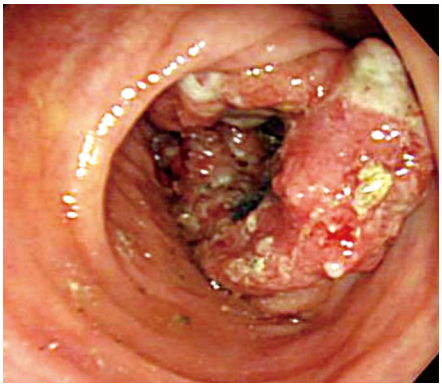

**Figure 1** Colonoscopy showing a circumferentially advanced colon cancer in the cecum.

**Figure 2** Abdominal computed tomography showing a bulky mass approximately 50 mm in diameter, suggestive of nodal involvement around the primary cecal cancer.

rectum most commonly affected, the serum AFP level is usually as high as several-thousand nanograms per milliliter[1-5]. Moreover, AFP appears to be a potential marker for tumor activity, as the serum level of AFP is higher in patients with liver metastasis than in those without liver metastasis[6]. AFP-producing colorectal carcinoma generally has a poor prognosis because of the frequent occurrence of blood-borne metastases. All the reported cases have extensive liver and/or lung metastases at the time of diagnosis and a very poor prognosis[1]. Our patient was unusual in comparison with the reported cases, as his AFP-producing colon cancer was located in the cecum, and showed only synchronous lymphogenous spread but not synchronous or metachronous blood-borne metastasis during a long time of follow-up. Furthermore, he was a long-time survivor, and was able to undergo curative surgical resection in addition to adjuvant chemotherapy. Clinical evaluation of a large number of patients is necessary to clarify whether systemic adjuvant chemotherapy is associated with a favorable prognosis for this kind of patients.

In summary, patients with AFP-producing colon cancer and synchronous bulky lymph node metastasis can survive a long time after adjuvant chemotherapy in addition to surgical resection.

## Abstract

Currently, laparoscopic cholecystectomy is an undoubtfully optimal treatment of cholelithiasis. What about performing this procedure on a patient with situs inversus totalis and what are the difficulties of this operation for a right-handed surgeon? We presented a 35-year-old man with unknown situs inversus totalis who was admitted with epigastric pain and digestive problems. Ultrasonography and computed tomography of the abdomen confirmed the diagnosis of a gallstone. Besides, the liver and gallbladder were on the left side and the spleen was on the right. All systems were left-right reversal as mirror image in all diagnostic studies. Laparoscopic cholecystectomy was safely performed, despite of difficulties of situs inversus. The patient was discharged on postoperative day 1. It should be considered that existence of other anomalies may easily cause uninvited injuries. In the patients with situs inversus, laparoscopic cholecystectomy can be safely managed by an experienced surgeon through laparoscopy, and also hepatobiliary surgery.

**Key words:** Situs inversus totalis; Laparoscopic cholecystectomy; Cholelithiasis

## INTRODUCTION

Situs inversus totalis (SIT) is a very uncommon entity. It was first reported by Fabricius in 1600[1]. The incidence is thought to be in the range of 1:10 000 to 1:20 000[2]. Transposition of the organs may also affect thoracic organs, besides abdominal organs. It can be associated with Kartegener triad or some other cardiac anomalies. There is no evidence for increased incidence of cholelithiasis in SIT[3]. Since Mouret first performed it in 1987, laparoscopic cholecystectomy (LC) has become the standard operative procedure for cholelithiasis[4].

In the present study, the new technique and subsequently possible difficulties of LC in a patient with SIT was reported.

## CASE REPORT

A 35-year-old male was admitted to the Department of General Surgery, Ege University School of Medicine, with a 2-year history of intermittent epigastric pain and concomitant digestive problems. The patient had not been diagnosed as situs inversus totalis before. Apex beat was found in the right hemithorax on physical examination. An electrocardiography showed right axis deviation and right ventricular hypertrophy, in keeping with dextrocardia. Laboratory data showed no abnormality of liver function tests, or white blood cell count. An ultrasonography identified SIT and multiple stones, which were millimetric in size in the gallbladder. The common bile duct was also noted as dilated. A thoracoabdominal computed tomography (CT) revealed the situs inversus totalis abnormality and a suspicious opacity located at the neck of the gallbladder (Figure 1). Endoscopic retrograde cholangiopancreatography was performed and a stone was extracted from the common bile duct (Figure 2). The patient then underwent LC.

### *Operation techniques*

The operation team and the laparoscopic devices were located in the theater as a mirror image configuration of normal LC. Dissection of the Calot's triangle is one of the major problems for a right-handed surgeon in case of situs inversus totalis abnormality. Four ports were used: optical (10 mm), one 5 mm and one 10 mm operating, and one 5 mm assisting port (Figure 3). The optical port was near the umbilicus and a 30° laparoscope was used. Because of previously unoperated abdomen, the closed technique was employed by the insertion of a Veress needle through the subumbilical area. Carbon dioxide ($CO_2$) pneumoperitoneum was then created with a pressure of 12 mmHg. Two 10-mm trocars were inserted into the abdominal cavity, one in the position of the Veress needle for laparoscope and the other one in the sub-xiphoid

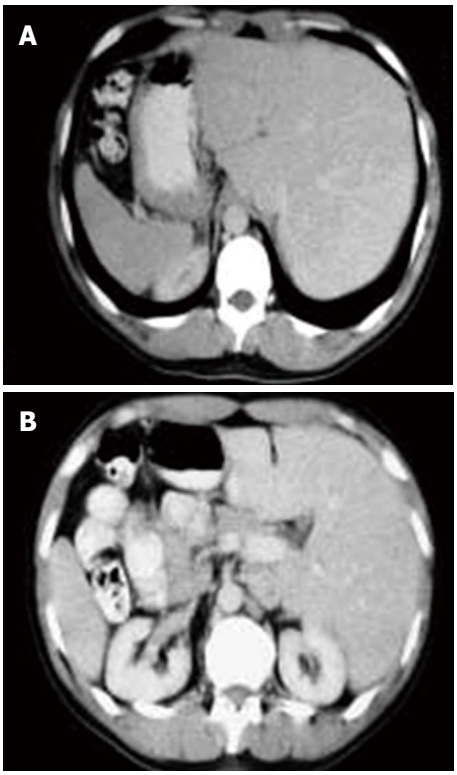

**Figure 1** Computed tomography of the patient. **A**: The liver is on the left side; **B**: The spleen and stomach are on the right side of the patient.

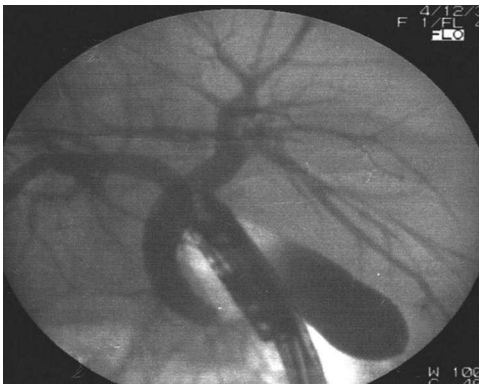

**Figure 2** Endoscopic retrograde cholangiography of the patient. A stone was extracted from the main duct. The gallbladder can be observed on the left side.

location. A 5-mm trocar was inserted midline at the midpoint of xiphoid-umbilicus line and a second 5-mm trocar was inserted into the abdominal cavity in the left mid-axillary line under the view of laparoscope. Fundus of the gallbladder was grasped and retracted by the assistant using a clinch, which was inserted through the 5-mm trocar in the left mid-axillary region. Traction of the Hartmann's pouch was performed by the left hand of the surgeon using a grasper inserted through the trocar located at the subxiphoid region. Dissection of Calot's triangle was carried out with a posterior approach by using a forceps that was inserted through the trocar located in the midline. The cystic duct and cystic artery were first divided by blunt dissection and separated. Dissection was performed above the plane of Rouviere's sulcus to avoid any injury. Both of them were clipped (double proximal, single distal

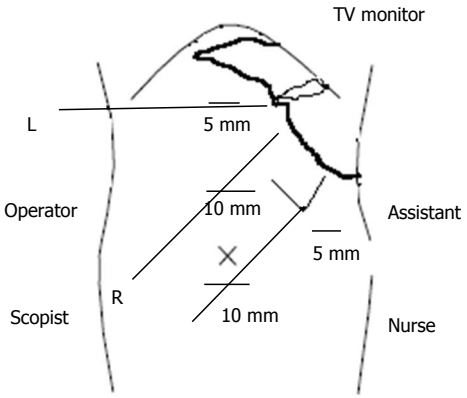

**Figure 3** Port sites in new technique. L: left hand; R: right hand.

10-mm titanium clips) and then divided by hook scissors. After division of all peritoneal reflection on either side, the gallbladder was retrogradely separated from the liver bed by using electrocautery. It was then extracted through the 10-mm operating port. Fascial closure of large ports was sutured with absorbable material (polydiaxonon) to prevent herniation.

## DISCUSSION

Situs inversus viscerum is considered to have a genetic predisposition that is autosomal recessive[5,6] and may be associated with several syndromes[7,8]. Physical examination of the patient with situs inversus can be misleading. As the central nervous system may not share the general transposition, pain may be felt in the epigastrium alone or in the right-upper quadrant and in the mid-scapular region[9-11]. In patients of acute cholecystitis with situs inversus, pain can be felt in the left upper quadrant due to irritation of the peritoneum[11,12]. Intrahepatic biliary tree, arterial and venous systems are in the mirror-image configuration of the normal anatomy. The hepatoduodenal ligament is the same as seen in the orthotopic patient[13]. Arterial system anomalies are in the mirror-image configuration of the orthotopic patients[14]. Although there are many reports of patients with situs inversus and cholelithiasis, there is no evidence that the incidence of cholelithiasis is greater in these patients[15]. In the preoperative period CT may be useful in determining the anomalies[12]. Twenty cases of LC in SIT were reported in the literature[16]. The most challenging factor for performing LC in patients with situs inversus is the mirror image anatomy. This uninvited condition may lead to some problems in orientation and dissection during the procedure since at least two thirds of the surgeons are right handed[16]. To overcome this issue, several alternative modifications were proposed: (1) retraction of Hartmann pouch by the first assistant, (2) surgeon standing between the two abducted lower limbs of the patient[1,16].

We propose that it helps by changing the position of grasper with the dissector and dissecting the Calot's triangle from the lateral side, taking advantage of using the right hand. To use the midclavicular trocar in dissection, which is used only for traction in traditional technique, the view angle should be increased and crossing of the scope and dissector

should be prevented. To achieve this, the midclavicular 5 mm trocar is placed at the midline and a 30º viewing scope is used *via* the subumbilical trocar. By using this technique, an extra 45º is added to the 30º viewing of the scope. Careful dissection of Calot's triangle can be managed by performing it from the lateral side with the help of this totally 75º. Working in two dimensions is the biggest difficulty in laparoscopic surgery. In addition to this, mirror-image that is seen in situs inversus increases the difficulty. As a result, this may lead to high risk of iatrogenic injuries. In those cases as Thomas B Hugh mentioned in his article; in traditional cholecystectomy technique, the start point is fundus of the gallbladder but this is not convenient for laparoscopic method[16]. In laparoscopic cholecystectomy, the sulcus, which is called Rouviere's sulcus that runs to the right of the hilum of the liver can be an alternative reference point. This sulcus is open in 78% of patients and its site is recognizable in more than 90% of the patients[16]. Dissection should be safely carried out close to the gallbladder in the triangle that is described in this article. Reviewing the operative field regularly and releasing the traction of the gallbladder may help you know where you are. Withdrawing the camera will help to obtain a large field of view. With the help of these, overall relationship in the hepatobiliary triangle can be evaluated. The findings during the operation should be checked with other members of the operating team. Care must be taken for the concentration of the operative team and arrangement of the equipment setup in the operation room.

In conclusion, we suggest that LC procedure in these patients with SIT should be performed by surgeons who are experienced in laparoscopy and hepatobiliary surgery as well.

***World Journal of Gastroenterology*** ISSN 1007-9327

# Instructions to authors

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*WJG, World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc*., from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

### *Indexed and abstracted in*

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### *Published by*

The WJG Press

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

### *Online submission*

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

### *Postal submission*

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

### Editorial Office

***World Journal of Gastroenterology***
Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com
Telephone: +86-10-85381901
Fax: +86-10-85381893

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### *Title page*

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

### *Abstract*

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc*. should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

### *Key words*

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

### *Text*

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

### *Illustrations*

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

### *Tables*

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### *Notes in tables and illustrations*

Data that are not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ should be noted ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used. Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under

illustrations should be expressed as $^1F$, $^2F$, $^3F$; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

### *Acknowledgments*

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### *Coding system*

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24 ], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### *PMID requirement*

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (http://www.wjgnet.com/cgi-bin/index.pl), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### *Style for journal references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (http://www.wjgnet.com/cgi-bin/index.pl)

### *Style for book references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

**Patent** (list all authors)

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### *Inappropriate references*

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### *Statistical data*

Present as mean ± SD or mean ± SE.

### *Statistical expression*

Express $t$ test as $t$ (in italics), $F$ test as $F$ (in italics), chi square test as $\chi^2$ (in Greek), related coefficient as $r$ (in italics), degree of freedom as $\gamma$ (in Greek), sample number as $n$ (in italics), and probability as $P$ (in italics).

### *Units*

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, $p$(B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; $CO_2$ volume fraction, 50 mL/L $CO_2$ not 5% $CO_2$; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

### *Abbreviations*

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

### *Italics*

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori, E coli, etc.*

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

### *Language evaluation*

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

### *Copyright assignment form*

Please downloaded CAF from http://www.wjgnet.com/wjg/help/9.doc.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to WJG all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The WJG requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1)direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3)supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The WJG does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to WJG if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

### *Final check list for authors*

The format is at: http://www.wjgnet.com/wjg/help/13.doc

### *Responses to reviewers*

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: http://www.wjgnet.com/wjg/help/10.doc

### *Proof of financial support*

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### *Publication fee*

Authors of accepted articles must pay publication fee.
EDITORIAL and LETTERS TO THE EDITOR are free of change.

## Abstract

The liver is an essential player in the pathway of coagulation in both primary and secondary haemostasis. Only von Willebrand factor is not synthetised by the liver, thus liver failure is associated with impairment of coagulation. However, recently it has been shown that the delicate balance between pro and antithrombotic factors synthetised by the liver might be reset to a lower level in patients with chronic liver disease. Therefore, these patients might not be really anticoagulated in stable condition and bleeding may be caused only when additional factors, such as infections, supervene. Portal hypertension plays an important role in coagulopathy in liver disease, reducing the number of circulating platelets, but platelet function and secretion of thrombopoietin have been also shown to be impaired in patients with liver disease. Vitamin K deficiency may coexist, so that abnormal clotting factors are produced due to lack of gamma carboxylation. Moreover during liver failure, there is a reduced capacity to clear activated haemostatic proteins and protein inhibitor complexes from the circulation. Usually therapy for coagulation disorders in liver disease is needed only during bleeding or before invasive procedures. When end stage liver disease occurs, liver transplantation is the only treatment available, which can restore normal haemostasis, and correct genetic clotting defects, such as haemophilia or factor V Leiden mutation. During liver transplantation haemorrage may occur due to the pre-existing hypocoagulable state, the collateral circulation caused by portal hypertension and increased fibrinolysis which occurs during this surgery.

## INTRODUCTION

The liver plays several key roles in blood coagulation being involved in both primary and secondary hemostasis[1]. It is the site of synthesis of all coagulation factors and their inhibitors except for von Willebrand factor (vWf)[2]. Liver damage is commonly associated with impairment of coagulation, when liver reserve is poor. The hemostatic system is in a delicate balance between prothrombotic and antithrombotic processes, aiming to prevent excessive blood loss from injured vessels and to prevent spontaneous thrombosis. Liver failure is accompanied by multiple changes in the hemostatic system, because of reduced plasma levels of procoagulative and anticoagulative clotting factors synthesised by hepatocytes and sinusoidal cells[3]. Vitamin K deficiency may coexist, so that abnormal clotting factors are produced due to lack of gamma carboxylation. Moreover during liver failure, there is a reduced capacity to clear activated hemostatic proteins and protein inhibitor complexes from the circulation. Thus the global effect of liver disease with regard to hemostasis is complex, so that patients with advanced liver disease can experience severe bleeding or even thrombotic complications (Table 1). Finally, when marked portal hypertension develops with collateral circulation and secondary splenomegaly, thrombocytopenia develops due to splenic sequestration. However, thrombocytopenia may also be due to decreased hepatic thrombopoietin synthesis. There is also impaired platelet function. These hemostatic abnormalities do not always lead to spontaneous bleeding, but the onset of complications of cirrhosis such as variceal bleeding or infection/sepsis may lead to worsening of the coagulation status. The presence of a consumptive coagulopathy other than secondary to sepsis or other predisposing causes is disputed.

Usually therapy for coagulation disorders in liver disease is needed only during bleeding or before invasive procedures. When end stage liver disease occurs, liver

transplantation is the only treatment available, which can restore normal hemostasis, and correct genetic clotting defects, such as hemophilia or factor V Leiden mutation. During liver transplantation hemorrage may occur due to the pre-existing hypocoagulable state, the collateral circulation caused by portal hypertension and increased fibrinolysis which occurs during this surgery.

## HEMOSTATIC FACTORS

### *Procoagulant factors*

The liver is the site of synthesis of fibrinogen and factors Ⅱ, Ⅴ, Ⅶ, Ⅸ, Ⅹ, Ⅺ and Ⅻ[4]. Von Willebrand factor (vWf) is synthetised by the endothelium[5]. Factor Ⅷ is synthetised mainly by the hepatic, but also non hepatic sinusoidal endothelial cells[6-8], thus the plasma concentration of factor Ⅷ is not decreased with liver disease, and may be even increased, as many chronic liver diseases are associated with chronic inflammation[9]. Factor Ⅷ is high in fulminant hepatic failure and low in disseminated intravascular coagulation (DIC)[10] but this differential diagnosis is seldom an issue in clinical practice.

Vitamin K is an essential cofactor for the production of biologically active forms of the coagulation factors Ⅱ, Ⅶ, Ⅸ and Ⅹ. When γ-carboxylation is impaired due to deficiency or antagonism of vitamin K, inert precurcors are synthesised, (known as Proteins Induced by Vitamin K Absence [PIVKA]) and released into the blood stream[11]. The clinical significance of these precursors is not clear. In the case of prothrombin, a specific and sensitive immunoassay for this incomplete PIVKA prothrombin detects changes before conventional coagulation tests[12]. In cholestasis, vitamin K absorption from the small intestine is reduced due to decreased bile salt production. It can be corrected by vitamin K 10 mg daily for 24-48 h, but in parenchymal liver disease as there is a decreased synthesis of coagulation factors, there is no improvement with vitamin K[13]. However, 25% of patients with acute liver injury have a subclinical deficit of vitamin K which improves with parenteral administration of vit K[14].

In acute liver failure, plasma concentration of coagulation factors first those with the shortest half life, factor Ⅴ and Ⅶ (12 h and 4-6 h respectively), and factors Ⅱ, Ⅶ and Ⅹ subsequently[15]. Factor Ⅷ, together with vWf is usually elevated. The differential effects on clotting factor concentrations during acute liver failure occur because high cytokine concentrations increasing tissue factor (TF) which activates factors Ⅱ, Ⅴ, Ⅶ, Ⅹ, whereas any thrombin generated is inhibited by antithrombin Ⅲ, preventing activation of factors Ⅷ, Ⅺ and consequently Ⅺ, thus preserving their plasma levels[9].

Prothrombin gene mutation (G20210A) is the most common thrombophilic cause of portal vein thrombosis without cirrhosis (22% of cases)[16]. In contrast, factor Ⅴ Leiden mutation is common thrombophilic disorder (20%) associated with hepatic vein thrombosis in Western countries[17].

### *vWf*

Plasma concentration of vWf is increased in patients with acute liver failure, due to increased synthesis as an acute phase protein in response to tissue injury[18-20] and also endothelial dysfunction secondary to endotoxemia[5]. In chronic liver disease, endothelial shear stress related to portal hypertension may also contribute to the high plasma levels of vWf *via* a nitric oxide stimulus[21]. A correlation between severity of liver disease and vWf plasma antigen levels has been documented.

### *Fibrinogen*

Plasma fibrinogen is an acute-phase reactant, and remains normal or increased in patients with liver disease[22]. Low concentrations due to decreased synthesis, yet above 100 mg/dL, are only seen with very severe liver disease[23]. However the high fibrinogen concentrations found in patients with chronic hepatitis, cholestatic jaundice and hepatocellular carcinoma, do not result in increased clot formation as most is a non-functional fibrinogen present in 60%-70%: there are abnormal α chains and a higher sialic acid content[24]. This is due to an increased activity of sialil-transferase in immature hepatocytes generated during hepatic injury; this results in an abnormal thrombin time (TT), despite an almost normal PT and PTT, with an apparent normal or raised concentration of fibrinogen.

### *Platelets*

Abnormalities in both number and function of platelets are common in liver disease and contribute to the impaired hemostasis.

About one third of patients with chronic liver disease develop thrombocytopenia, (70.000-90.000 × $10^9$/L), which worsens in parallel with disease progression associated with increased platelet sequestration due to hypersplenism[25-27].

Thrombocytopenia appears not to be associated with an increased risk of bleeding from esophageal varices or other sites, although there are only few studies evaluating this, but it is correlated with blood loss during surgery[28]. A higher spleen diameter/platelet count ratio is highly predictive for the presence of esophageal varices in patients with liver cirrhosis[29].

Splenic sequestration versus other causes of thrombocytopenia in cirrhosis has been recently evaluated by comparing platelet number in extrahepatic portal hypertension, to that of cirrhosis in patients having a similar sized spleen. There is less severe thrombocytopenia in the non-cirrhotic patient[30]. Synthetic function of the liver is essential for platelet production *via* thrombopoietin (TPO), which regulates platelet production in the bone marrow[31]. Although TPO increases in patients with thrombocytopenia due to a homeostatic response[32], this occurs to a lesser degree with severe or chronic liver disease, than in patients with a normal liver[33]. Lower TPO mRNA levels in cirrhotic liver tissue[34] have been shown, confirming impaired TPO synthesis. In addition, a low platelet production from the bone marrow in cirrhotic patients has been shown[35].

Hepatitis C virus (HCV)[36] acute viral infection, alcohol abuse and folate deficiency can all result in some myelosuppression[37] further lowering platelet counts. Thrombocytopenia may also be contributed to by immune mediated mechanisms due to an increase production from B cells of antibodies binding platelet surface antigen GPI-

**Table 1 Hemostatic abnormalities associated with liver disease**

| Favoring hemorrage | Favoring thrombosis |
|---|---|
| Low platelet count | |
| Impaired platelet function and platelet-vessel wall interaction | Elevated levels of factors Ⅷ and vWf |
| Enhanced platelet inhibition by nitric oxide (NO) and prostacyclin | Decreased levels of protein C, protein S, antithrormbin |
| Ⅲ, $\alpha_2$-antiplasmin | |
| Decreased levels coagulation factors (Ⅱ, Ⅴ, Ⅶ, Ⅸ, Ⅹ, Ⅺ) | Macroglobulin |
| Quantitative and qualitative abnormalities of fibrinogen | Heparin cofactor Ⅱ elevated |
| Low level of $\alpha_2$-antiplasmin, TAFI, histidine-rich-glycoprotein | Decreased levels of plasminogen |
| levels of tPA, with small increase of PAI-1 levels | |

Ib-Ⅲa and GPIb/I, shown in viral related cirrhosis B and C[38], primary biliary cirrhosis (PBC) and primary sclerosing cholangitis (PSC)[39].

Platelet aggregation in response to ADP, arachidonic acid, collagen and thrombin is subnormal, probably due to a defective signal transduction mechanism[19]. Intrinsic defects including an abnormal arachidonic acid membrane content[40] and abnormal plasma factors[41] have also been shown to contribute to platelet function abnormalities. In cholestatic liver diseases there often is a normal or hypercoagulable state evaluated by thromboelastography[42] and there can be normal or hyperactive platelet function when assessed by platelet function assay (PFA-100) closure time and flow cytometric study of receptors[43]. When platelet number is too low, both cytometry and aggregation studies may be difficult to interpret. Thromboelastography which is a global test of clot formation and dissolution measures both platelet function and number by the maximum amplitude (ma) parameter[44] which can be used to assess platelet function.

Splenectomy is generally contra-indicated in patients with liver cirrhosis, because of the high mortality rate and a risk of secondary portal vein thrombosis , which leads to bleeding from esophageal-gastric varices and more difficult surgery during subsequent liver transplant[45]. Splenic embolization with 30%-50% reduction in flow can normalize or significantly improve platelet number in some cirrhotics[46] and it is sometimes used before embolisation of hepatocellular carinoma or interferon therapy for viral hepatitis. Insertion of transjugular intrahepatic portosystemic shunt (TIPS) increases, but it does not to normalize platelet number[47,48].

## ANTICOAGULANT FACTORS

### *Antithrombin Ⅲ*

Antithrombin Ⅲ (ATⅢ) is a non-vitamin K-dependent glycoprotein synthesised by the liver and endothelium[49]. In liver diseases, concentration falls due to reduced synthesis and/or increased consumption due to hyperfibrinolysis[50]. Usually the ATⅢ deficit is mild and thrombotic complications are very rare[51]. ATⅢ replacement does not correct hyperfibrinolysis in cirrhotic patients.

### *Protein C and protein S*

Proteins C and S are vitamin K dependent glycoproteins synthesised mainly by hepatocytes[52]. During acute or chronic liver disease, their concentrations decrease concomitantly with the other coagulation factors, but usually not below 20% of normal[53]. Genetic deficiency of protein C is rare in the general population and portal vein thrombosis[54], but is found in 20% patients with Budd-Chiari syndrome (BCS). In patients with liver disease who also have genetic deficiency, plasma concentration is often lower than 20%. When there is severe liver disease, it can be difficult to exclude coexistent genetic deficiency as levels may be very low, due to very depressed synthesis[17]. In this situation a concomitant finding of a normal level of factor Ⅱ and protein C/factor Ⅶ ratio, can help to confirm a coexistent genetic deficit[55]. Genetic deficiency of protein S is extremely rare, but accounts for 7% of patients with BCS or portal vein thrombosis (PVT), especially in series from Asia[56].

## DISORDERS OF THE FIBRINOLYTIC SYSTEM

All the proteins involved in fibrinolysis, except for tPA and PAI-1 are synthesized in the liver. Reduced plasma levels of plasminogen[57], α2-antiplasmin, histidine-rich glycoprotein (HRG)[58], factor XⅢ[59], and thrombin-activable fibrinolysis inhibitor (TAFI)[57] are found in cirrhosis. Conversely tPA levels are increased in liver disease, due to decreased clearance, whereas it's inhibitor PAI-1 is normal or only slightly increased in plasma. The inhibitor concentrations are insufficient to counteract the increase in tPA, accounting for increased fibrinolysis[60]. In contrast, in acute liver failure, there are high levels of the acute phase reactant PAI-1 leading to a shift towards hypofibrinolysis[61].

Hyperfibrinolysis is correlated with the severity of liver dysfunction in cirrhosis as assessed by Child-Pugh score[62]. Ascitic fluid has increased fibrinolytic activity: up to 20 liters are reabsorbed daily, with fibrinolysis being correlated with endotoxin levels[63]. Increased levels of D-dimers, prothrombin fragments 1+2 (F1+2) fibrin degradation products and plasmin-α2-antiplasmin complexes are found[64]. Many studies using different methodologies demonstrate hyperfibrinolysis (thromboelastography[65], diluted whole blood clot lysis assay[66] and euglobin clot lysis time[67]) . TAFI is decreased by an average of 26% in cirrhosis and by 50% in acute liver failure[68,69]. However there is some controversy as regarding hyperfibrinolytic activity in cirrhotics as not all studies have confirmed this.

Interestingly, patients with cholestatic liver diseases, are characterized by a normal or hypercoagulable state: higher PAI-1 concentrations are seen compared to other etiologies, balancing the increased tPA activity. This results in less hyperfibrinolysis in the reperfusion phase during liver transplantation, and antifibrinolytic therapy is not usually administered[70]. Thus the clinical issue is whether cirrhotic patients when under "stress" (e.g. during infection, during surgery or during bleeding) exhibit the increased fibrinolysis, resulting in an increased bleeding tendency, which is not manifest in laboratory terms when patients are stable.

### *Disseminated DIC and accelerated intravascular coagulation (AIC)*

DIC is characterized by intravascular fibrin deposition due to activation of the clotting cascade, which overwhelms the anticoagulation pathway. Secondarily there is consumption of coagulation factors and platelets, associated with secondary fibrinolysis, causing an increased bleeding tendency[71].

Low grade DIC and the hemostatic abnormalities which are present in cirrhotics; they share common laboratory features, ie a prolonged PT and PTT, low fibrinogen level, elevated fibrin-degradation product and D-dimer and thrombocytopenia[72-74]. Thus differential diagnosis by laboratory means alone may be confounding. Early reports linked chronic liver disease to low grade DIC, ascribing the latter to accelerated fibrinolysis. However, the presence of DIC in liver cirrhosis is disputed[75]. Although DIC-like laboratory abnormalities (so called "pseudo-DIC) are observed, autopsy studies in cirrhotics have shown little evidence for fibrin deposition and clinically manifest DIC is very rare[72].

More highly sensitive tests such as quantification of proteolytic cleavage products of the coagulation reaction ie fibrinopeptide A, F1+2, and fibrinolysis reactions (fibrin D-dimer, high molecular weight fibrin/fibrinogen complexes or soluble fibrin), demonstrate an abnormal profile called accelerated intravascular coagulation and fibrinolysis phenomenon (AICF)[75]. The studies to date demonstrate AICF in about 30% of cirrhotics, depending on the severity of liver disease[65].

However, Ben Ari *et al* analyzed 52 patients with stable liver disease for F1+2 thrombin-antithrombin Ⅲ complex (TAT) and D-dimer levels which were no different from controls, yet TEG studies were able to detect hyperfibrinolysis. AICF may be important in the portal venous system, as this phenomenon is more pronounced there than in systemic blood[65]. This could be related to higher levels of endotoxemia in portal blood, which can trigger release of IL6 and TNF-alfa thus activating intravascular coagulation[76].

## PROGNOSTIC VALUE OF COAGULATION FACTORS

In cirrhosis, plasma levels coagulation factors are indicators of hepatic synthesis and thus of liver function. A prolonged PT, which is not corrected by intravenous vitamin K administration 10 mg daily for 2 d, helps differentiate vitamin K deficiency from parenchymal liver diseases[13]. PT is part of the Child-Pugh score, which is the most commonly used prognostic score assessing the severity of liver disease[77]. Recently the MELD score which incorporates INR has been used to allocate priority for liver transplantation in the USA based on estimated probability of death within 3 mo[78].

Determination of individual coagulation factors adds little prognostic information to measuring PT or INR in cirrhosis. A multivariate analysis of prognostic factors in cirrhotic patients showed that the level of factor Ⅶ was an independent predictor factor of survival: factor Ⅶ < 34% was predictive of a mortality in 93%[79].

In acute liver failure, the Clichy criteria indicate poor prognosis and need for liver transplantation, when factor V is below 20% in patients aged ⩽ 30 or below 30% associated with age ⩾ 30[80]. Factor V has less prognostic value in acetaminophen-induced fulminant hepatic failure[81].

In the King's College criteria in acetaminophen-induced liver failure, PT ⩾ 100 s is a prognostic indicator on its own for liver transplantation independent of the grade of coma. In patients with non-acetaminophen induced ALF, PT ⩾ 50 s together with two of the following criteria: age < 10 > 40 years, drug toxicity, interval between jaundice and encephalopathy onset > 7 d and serum biliubin > 300 μmol/L are indications of poor prognosis and for liver transplantation[82].

## ASSESSMENT OF THE RISK OF THROMBOSIS AND ANTICOAGULATION

Thrombotic complications can paradoxically occur in cirrhotic patients even if clinically an increased risk of haemorrhage is considered. Despite prolonged coagulation tests, these patients cannot be viewed as being "anti-coagulated". Wanless *et al* has put forward portal and hepatic vein thrombosis as cause of disease progression in cirrhotic patients. Hepatic and portal vein thrombosis was found in at least 70% of explanted livers, and 36% were associated with regions of confluent fibrosis (focal parenchymal extinction)[83], which is a histological correlate of chronic thrombosis.

Portal vein thrombosis complicates liver cirrhosis between 0.6% to 15% of cases, leading to worsening of liver function, development of ascites and occasionally mesenteric infarction[84]. In these patients early anticoagulation is indicated and has been shown to recanalise the splanchnic veins in about 50% of cases and prevent the extension of the thrombus without causing increased haemorragic complications[85].

In BCS, even if a prothrombotic cause is not identified, anticoagulation should be started immediately after diagnosis, as many genetic prothrombic defects remain yet to be identified and acquired disorders, common in BCS, may be difficult to diagnose, such as polycythaemia rubra vera or paroxysmal nocturnal hemoglobinuria (PNH). Early anticoagulation ameliorates prognosis. Anticoagulation therapy should continue even after liver

transplantation because of the high rate of recurrence and thrombotic complications after OLT, and also because other prothrombotic disorders may exist alongside the diagnosed protein deficiencies[17,86].

The risk of deep vein thrombosis and pulmonary embolism is not well documented in cirrhotics, yet is reported[87]. Patients with cholestatic disease often exhibit a procoagulant state demonstrated by TEG, may be prone thrombosis, but this has not been studied[42]. No guidelines are available for the management of thrombotic complications and neither for prevention of embolic phenomena for example following atrial fibrillation in cirrhotic patients.

## ASSESSMENT OF THE RISK OF BLEEDING

The role played by coagulation defects in the occurrence of bleeding in cirrhosis is still unclear. This is particularly due to the difficulty (and cost) in measuring procoagulant and anticoagulant activities, and assessing the balance between the two (Table 1). In addition there are very few tests which reflect coagulation *in vivo*. Recently generation of thrombin has been explored *in vitro* in cirrhotic patients and found to be normal. In this study, a resetting of the coagulation and anticoagulation system at a lower level was postulated, because during liver disease both procoagulant and anticoagulant pathways are affected in a parallel manner. However, the in vitro technique has some drawbacks, the major one being that platelets are substituted by phospholipids[3].

Minor signs of bleeding tendency are common, such as gum bleeding and epistaxis, but major bleeding can be encountered. The role of hemostatic abnormalities in variceal bleeding is not clear. Hyperfibrinolysis has been shown to be linked but not necessary causal to an increased risk of variceal bleeding, in a cohort of 61 cirrhotics. Higher levels of fibrinogen degradation products were associated with a greater risk of variceal bleeding compared to patients without (odds ratio = 8), but Child-Pugh score and endoscopic characteristics of varices remain the most important prognostic factors[88]. Recently the role of infection and endogenous heparin-like substances demonstrated by TEG has been evaluated in variceal bleeding. Infection may be a trigger factor for bleeding[89] and both infection and heparin-like substances may be mechanisms responsible for the persistence of bleeding in some[90]. TEG, which is a quick and reliable method to assess clot formation and lysis[44], also allows detection of heparin-like substances. Studies from our group have shown worsening coagulation during infection due to low molecular weight heparin-like substances detected by TEG[91].

## INVASIVE PROCEDURES

Historically, PT and platelet count have been used to assess the risk of bleeding prior to invasive procedures. Cirrhotic patients have increased mortality and morbidity during surgery[92], mainly due to increased bleeding in 60% of cases[93,94]. Early studies linked PT to surgical risk (PT prolongation > 1.5 and > 2.5 s associated with 47% and 87% mortality respectively)[95], hence platelet count < 50.000/mm$^3$ and PT > 3 s have been considered relative contraindications to elective surgery[94]. In addition, portal hypertension and collateral veins increase the risk of bleeding during surgical dissection.

Hyperfibrinolysis[96] and clotting activation, due to increase tPA levels have been described in patients undergoing liver resection[97]. However, another study performed in patients undergoing laparoscopic liver biopsy failed to demonstrate any correlation between the risk of bleeding evaluated at the hepatic puncture site and coagulation tests, so that the degree of injury may be the important factor[98].

Liver biopsy is widely used diagnostically and to grade the severity of liver disease or fibrosis. Moreover it is an essential tool after liver transplantation to diagnose rejection and other causes of graft dysfunction. Bleeding complications occur in 0.35%-0.5%, leading to mortality in 0.1%[99]. Despite the evidence that there were no threshold abnormalities of clotting tests associated with risk of bleeding during laparoscopic liver biopsy, INR and platelet count are considered essential to evaluate the bleeding risk for percutaneous liver biopsy[100]. An audit from the British Society of Gastroenterology (BSG) performed in 1991 showed a doubling of bleeding risk in patients with INR $\geqslant$ 1.5, but that only 7.1% of the bleeding occurred with INR greater than 1.5, and 90% occurred with a INR $\leqslant$ 1.3[101]. A cut off for platelet count is difficult to justify from the literature. Most textbooks in the UK and BSG guidelines, require platelet count above 80.000/mm$^3$[13] whereas a survey form the Mayo Clinic suggested 50.000/ mm$^3$ as a cut off[102]. Current recommendations state that a percutaneous liver biopsy can be done safely without support with platelet counts are above 60.000/mm$^3$[100]. Burroughs *et al* advocated evaluating the use of bleeding time to assess the risk of bleeding for percutaneous liver biopsy[103], but this is not routine in clinical practice. If clotting parameters are outside stipulated ranges, a transjugular liver biopsy can be performed more safely, without plasma or platelet therapy[104]. A plugged liver biopsy is also said to be safer, but it may cause greater risk of bleeding in hypocoagulable patients[99].

During minor procedures such as thoracentesis, paracentesis or lumbar puncture performed in patients with liver disease, there are no firm guidelines as to the hemostatic threshold for performing these tests. A contraindication to the procedure is clinically evident DIC or fibrinolysis[105].

## COAGULATION DURING INFECTION AND SEPSIS

The overall cumulative incidence of infection in cirrhotic patients is estimated to be at least 30%[106], and is possibly associated with increased risk of variceal bleeding[89]. Infection is associated with early rebleeding and increased mortality[107,108]. Prophylactic antibiotic therapy has led to less early rebleeding and better control of bleeding, in a randomized study[109].

Using TEG, 20 cirrhotic patients who experienced early

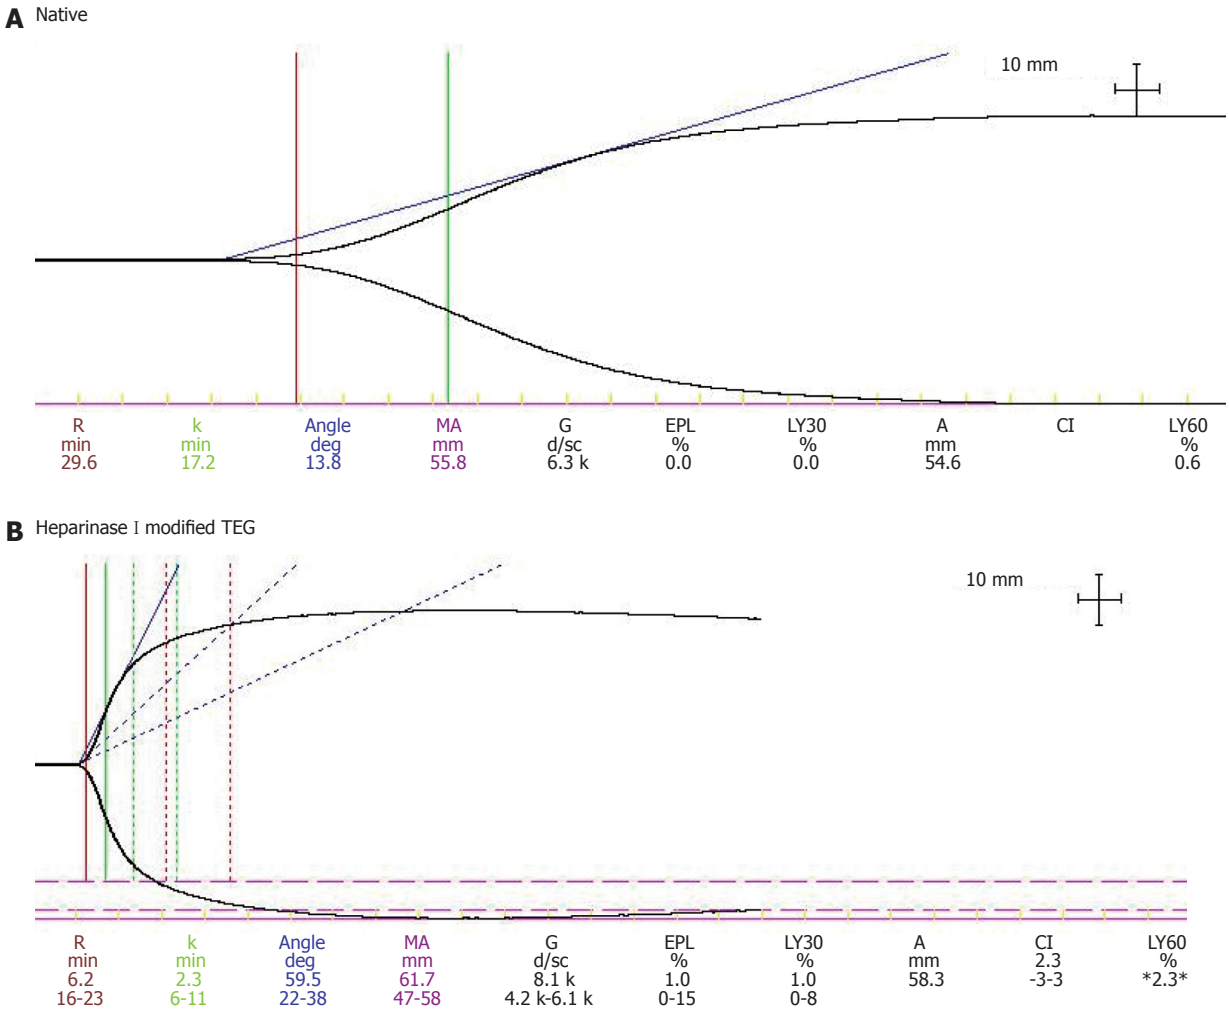

**Figure 1** Native-TEG (**A**) and heparinase I -TEG (**B**) on sample collected at the onset of spontaneous bacterial peritonitis in a patient with liver liver cirrhosis. (**A**) significant heparin-like effect found revealed by the slowed rate of coagulation. (**B**) treatment of the sample with heparinase I increases the rate of coagulation, thus sampling the presence of heparin-like substances.

rebleeding were found to have worsening TEG parameters the day before rebleeding[90], Moreover patients with bacterial infection have worse TEG parameters, which are corrected *in vitro* by heparinase I, which cleaves heparin-like substances[91] (Figure 1A and 1B). The presence of heparin like substances is associated in some with increased antiXa activity[110]. Heparin-like substances have been detected hours after variceal bleeding in cirrhotic patients[111]. Based on this evidence the hypothesis has been postulated that endotoxins and inflammation due to infection can release heparinoids from the endothelium and mast cells[91]. Moreover sepsis can cause impairment of platelet function, decreasing platelet number and aggregability, due to increase NO production[112].

## THERAPY OF HEMOSTATIC ABNORMALITIES IN LIVER DISEASE

Therapy for hemostatic abnormalities of liver disease is needed only during variceal bleeding, surgery or before invasive procedures. Intravenous vitamin K injecton of 10 mg daily for 24-48 h can replace vitamin K deficiency[13].

Fresh frozen plasma (FFP) contains all the clotting factors and can correct the laboratory finding of an elevated PT effectively, but this correction depends on the volume and the baseline abnormality of PT. Whether this correction of the PT results in increasing hemostasis has yet to be proven. In addition, correction is short term (24-48 h), depending on the half-life of the clotting factors (especially factor Ⅶ)[71]. A common indication for FFP infusion is the presence of persistent bleeding in patients with INR $\geqslant$ 2 or PT prolongation greater than 4 s[113]. In surgical or invasive procedures 50% of the normal PT (ie INR of 2) is a target for replacement therapy, and for neurological procedures such as intracranial pressure monitoring during liver failure, 80% of normal PT range (ie an INR of about 1.2-1.3)[113]. During massive blood transfusion, to avoid dilutional decrease of clotting factors for every 2 units of blood, 1 of FFP is typically given[114]. To increase the activity of clotting factor by 1%-2% a dose of 1 mL FFP/kg of body weight is necessary[115]. Because of the high volume required, adequate replacement is difficult both in cirrhotic patients (intravascular plasma volume is already expanded and ascites may be present), and ALF, (increasing plasma volume can lead to increases in intracerebral pressure). Moreover, the short half-life requires infusion every 6-12 h[10]. In patients with INR > 1.5,

FFP is given (12-15 mL/kg) before liver biopsy, but there is no evidence base for this. Transjugular biopsy should be used in patients with coagulopathy not sufficiently corrected with FFP.

Platelet transfusion, one unit every 10 kg is typically administered, and platelet count should be checked 1 h after the infusion[116]. However no correlation between amelioration of bleeding time, increase in platelet count, and enhanced hemostasis has been shown[100].

Cryoprecipitate contains factors Ⅷ, fibrinogen, vWf, fibronectin and XIII. Because of the small volumes (30-50 mL/U/10 kg) required[116], it can be useful in liver cirrhosis and ALF, but it lacks some coagulation factors and may worsen the imbalance already present in patients with liver disease.

Desmopressin (1-deamino-8-D-arginine vasopressin [DDAVP]), an analogue of the antidiuretic hormone, increases plasma level of factor Ⅷ and vWf, probably by increasing the release from endothelial storage sites[117]. It can improve bleeding time, enhancing primary hemostasis at the dose of 0.3 μg/kg in patients with liver failure[118]. However a randomised trial associating terlipressin and DDAVP in patients with variceal bleeding, demonstrated no difference in control of bleeding and maybe a worsening of the terlipressin action in the DDVAP group[119]. In a recent randomized trial, DDVAP failed to decrease blood loss during hepatic resection, despite increase of factor Ⅷ and vWf[120]. ATⅢ infusion is not routinely recommended.

Recombinant activated factor Ⅶ (rFⅦa) was first developed for the treatment of patients with hemophilia A and B who developed inhibitors. It may have promising role in the treatment of coagulation disorders in liver disease[121]. A single dose of recombinant factor Ⅶ a has been shown to correct prolonged PT in a dose-dependent manner in non-bleeding cirrhotic patients[122]. A randomized study using rFⅦa in 71 patients undergoing laparoscopic liver biopsy found no differences in liver bleeding time. Two complications occured in the rFⅦ a group (1 DIC and 1 PVT)[123]. In ALF, rFⅦa may be useful to normalize PT in the setting of intracranial pressure monitoring, as only a small volume of infusion is required. During variceal bleeding in a randomized trial, a modest reduction of early rebleeding rate was observed in a subgroup of Child B and C patients after rFⅦa infusion, although, no difference in control of bleeding or transfusion was shown overall[124]. Another report described initial hemostasis after infusion of rFⅦ a in 10 patients with variceal bleeding, but 6 experienced early rebleeding and all of them died, illustrating the short interval of action of this drug[125]. In a cohort of 8 patients with acute variceal bleeding uncontrolled with endoscopic and medical therapy, rFⅦa administration achieved hemostasis in 25% after a single dose[126].

Safety of rFⅦa, especially about the possible prothrombotic effect or triggering of DIC, still has to be assessed in large studies in patients with liver disease[127].

## LIVER TRANSPLANTATION

Orthotopic liver transplantation (OLT) is the only cure for end stage liver disease. Improvements in operative management, surgical techniques and graft preservation have contributed to a significant reduction in transfusion requirements during the last decade[128]. However, blood losses are highly variable, and correlate in most studies with a higher mortality, poor graft function and risk of infections[129]. In current practice a significant proportion of patients receive no blood during surgery.

Most studies failed to define factors related to bleeding, including preoperative coagulation tests or markers of fibrinolysis during liver transplantation[130-132], with the exception of the collateral circulation due to portal hypertension and previous abdominal surgery [133].

Hemostatic abnormalities during liver transplantation are divided according to the surgical phases which are traditionally: pre-anhepatic phase, anhepatic phase and post reperfusion phase and post operative period.

### *Pre-anhepatic stage*

The first operative stage is characterized by extensive surgical trauma, resulting from dissection of adhesions in the abdominal cavity and transection of many collateral vessels. Usually during this phase, mild coagulation abnormalities occur and the blood losses are mainly correlated with the surgical technique and the baseline hypocoagulable state[133], but etiology of liver disease can also influence the blood product requirement. Hypercoagulability has been demonstrated in patients with hepatocellular carcinoma as well as cholestatic cirrhosis (PBC, PSC). The PBC and PSC patients have a hypercoagulable state by TEG[42] and less fibrinolytic activity during OLT than other aetiologies[134], suggesting that in these patients antifibrinolytic drugs should not be used. Moreover in pediatric liver transplantation for biliary atresia, plasma studies showed less coagulation abnormalities during OLT compared to other etiologies[135]. Enhanced fibrinolytic activity contributes to blood loss in the pre-anhepatic phase in only 10%-20% of patients[136].

### *Anhepatic phase*

During this phase no important surgical blood loss is seen because appropriate vessels are clamped. However, bleeding can occur due to hemostatic changes in this phase. Despite impairment of synthetic and clearance function, early studies failed to show dramatic changes in PT and PTT[129,137]. However, hyperfibrinolysis has been demonstrated in many studies, due to net increase in tPA derived from endothelial cells; this tPA is not cleared due to the absence of the liver at this time[138]. The presence of an active fibrinolytic process has been demonstrated by simultaneous decrease of α2-antiplasmin and plasminogen activity, and a concomitant increase in fibrin and fibrinogen degradation products[139]. Use of rFⅦa has been tried in patients with severe coagulopathy (INR 5.7 and 6.9). Moderate bleeding was still reported during surgery, but 1 patient developed hepatic artery thrombosis after transplant[140]. Studies which evaluated coagulation factors during OLT after rFⅦa infusion showed a sharp increase of thrombin generation, PT and PTT, but no amelioration of fibrinolysis[141,142].

### *Reperfusion and post reperfusion phase*

Reperfusion of the liver is a crucial point of the operation and leads to profound coagulation abnormalities. Within minutes after reperfusion, uncontrollable diffuse bleeding may occur in some patients[143].

Trapping of platelets in the graft may play a role in the bleeding tendency. Experimental studies have shown a 55% gradient in platelet count between arterial and venous blood flow in the new liver. Moreover, some alteration in the bleeding time and platelet function and aggregation have been demonstrated[144]. Signs of DIC after graft reperfusion have been shown by some investigators, mainly correlated with poor quality of the transplanted organ[145].

Increase in fibrinolysis has been implicated as the most important and significant phenomenon responsible for bleeding during liver transplantation. It usually subsides within 60 min after graft reperfusion, but in donor livers with poor function, a sustained increased fibrinolytic response can be seen[146].

After reperfusion, release of heparin or heparin-like substances has been shown in 25%-95% of cases[147]. Protamine sulphate (50 mg) has been used *in vivo* to antagonize this effect. One study has confirmed the presence of heparin-like compounds using heparinase I-modified TEG, which cleaves heparin and heparan sulphate. Increased blood product requirement was correlated with the presence of heparin like effects in TEG traces. However a baseline heparin-like effect has recently been found before reperfusion in patients undergoing liver transplantation not receiving heparin[148].

Antifibrinolytic therapy is used during liver transplantation to reduce blood loss, time of surgery and fibrinolytic activity. Aprotinin is a serine protease inhibitor which antagonizes various proteases[149]. Aprotinin also has anti-inflammatory and anti-oxidant effects which might also be of benefit. Widespread use of aprotinin is not recommended because of the risk of anaphylactic reactions, renal dysfunction and stroke[150], which has been also recently stressed by a multicentre study on 4357 patients undergoing cardiac surgery[151], but this is not been reported nor studied in liver transplantation.

Epsilon aminocaproic acid (EACA) interferes with plasminogen binding to fibrin and thus EACA inhibits the conversion of plasminogen to plasmin[152]. In the only prospective randomized trial, it was shown to reverse TEG fibrinolysis, and reduce blood cell transfusion, without causing thrombotic complications. However this reduction was not statistically significant compared to controls[153]. Similar to EACA, tranexamic acid inhibits fibrinolysis, but it is 6 to 10 times more potent than EACA[154]. Recent trials have shown that at a dose of 2 mg/kg per hour, tranexamic acid reduces fibrinolysis and blood loss. However different doses have been used in other studies without clearcut effects[155-157].

The routine use of coagulation monitoring during liver transplantation is common place. Usually TEG is used, a point of care rapid method to assess the whole coagulation process. It provides the basis of a rational approach to the use of blood component therapy or pharmacologic intervention, but it does not help in addressing blood transfusion per se[44]. Recently TEG was used to monitor postoperative coagulation in patients undergoing hepatic resection for living related liver transplantation. In these patients, a hypercoagulable state correlated with the risk of developing thrombotic complications after surgery[158].

### *Postoperative period*

Thrombocytopenia is common in the early post-operative period, mainly due to platelet activation and consumption following graft reperfusion[159]. Thrombocytopenia is common in the early post-operative period, mainly due to platelet activation and consumption following graft reperfusion[159], and if liver function restores thrombocytopenia subsides a few day after OLT. Following normal synthetic function of the liver, thrombopoietin levels increase significantly on the first day, following by immature bone marrow megakariocites after 3 d and new circulating platelets after 5 d Normalization of platelet count can be seen after 14 d[160]. Peak of TPO level correlates with the pre-OLT platelet count. Levels of bilirubin, cold ischemia time or episodes of rejection do not influence TPO levels[161]. Persistence of thrombocytopenia can be seen in some patients, which can be ascribed to persistent splenomegaly in some[162].

## Abstract

Patients with liver disease may present hepatic encephalopathy (HE), a complex neuropsychiatric syndrome covering a wide range of neurological alterations, including cognitive and motor disturbances. HE reduces the quality of life of the patients and is associated with poor prognosis. In the worse cases HE may lead to coma or death.

The mechanisms leading to HE which are not well known are being studied using animal models. The neurological alterations in HE are a consequence of impaired cerebral function mainly due to alterations in neurotransmission. We review here some studies indicating that alterations in neurotransmission associated to different types of glutamate receptors are responsible for some of the cognitive and motor alterations present in HE.

These studies show that the function of the signal transduction pathway glutamate-nitric oxide-cGMP associated to the NMDA type of glutamate receptors is impaired in brain *in vivo* in HE animal models as well as in brain of patients died of HE. Activation of NMDA receptors in brain activates this pathway and increases cGMP. In animal models of HE this increase in cGMP induced by activation of NMDA receptors is reduced, which is responsible for the impairment in learning ability in these animal models. Increasing cGMP by pharmacological means restores learning ability in rats with HE and may be a new therapeutic approach to improve cognitive function in patients with HE. However, it is necessary to previously assess the possible secondary effects.

Patients with HE may present psychomotor slowing, hypokinesia and bradykinesia. Animal models of HE also show hypolocomotion. It has been shown in rats with HE that hypolocomotion is due to excessive activation of metabotropic glutamate receptors (mGluRs) in substantia nigra pars reticulata. Blocking mGluR1 in this brain area normalizes motor activity in the rats, suggesting that a similar treatment for patients with HE could be useful to treat psychomotor slowing and hypokinesia. However, the possible secondary effects of mGluR1 antagonists should be previously evaluated.

These studies are setting the basis for designing therapeutic procedures to specifically treat the individual neurological alterations in patients with HE.

**Key words**: Hepatic encephalopathy; Glutamate receptors; Neurological alterations; Cognitive function; Motor function; NMDA receptors; Metabotropic glutamate receptors; Nitric oxide; cGMP

## INTRODUCTION

### *Hepatic encephalopathy*

Hepatic encephalopathy (HE) is a complex neuropsychiatric syndrome present in patients with chronic or acute liver disease. HE covers a wide range of neuropsychiatric disturbances ranging from minimal changes in personality or altered circadian rhythms (sleep-waking cycle) to alterations in intellectual function, personality, conscience and neuromuscular coordination. HE is usually reversible, but can lead to coma and death in the worse case.

The neurological alterations in HE are the result of a previous liver failure. Liver failure leads to impaired detoxification of ammonia and other toxic substances that can reach the brain and alter its function. Many studies have been carried out to identify factors responsible for

the neurological alterations in HE. Clinical experience and basic research indicate that ammonia is the main factor responsible for HE. Ammonia is a product of degradation of proteins and other nitrogenated compounds but at high concentrations ammonia is toxic, leading to alteration of cerebral function which can lead to coma and death.

Hyperammonemia is therefore considered the main factor contributing to the neurological alterations found in HE both in acute and in chronic liver disease[1]. Other factors may also contribute to neurological alterations in HE. It has been recently suggested that inflammation exacerbates the neuropsychological effects induced by hyperammonemia in cirrhosis[2].

Classical clinical treatment of HE is mainly directed to reducing ammonia concentration by reducing protein ingestion, lowering ammonia production by the intestinal bacteria as well as by reducing ammonia transport from intestine to the blood flow by acidification of the intestinal lumen.

Overt HE is usually elicited by one of the following precipitating factors (high protein ingestion, gastrointestinal constipation, bleeding, diuretics) usually associated with increased ammonia levels. HE is associated with a poor prognosis[3,4].

Liver cirrhosis patients with normal neurological and mental status may present minimal forms of HE, showing intellectual function impairment which cannot be detected through general clinical examination but can be unveiled using specific neuropsychological or neurophysiological examination[5,6]. Minimal hepatic encephalopathy (MHE) is the first stage in the spectrum of HE[7,8]. Patients suffering from MHE may present psychomotor slowing and cognitive deficits affecting their ability to perform certain activities in daily life. MHE is therefore associated with impaired quality-of-life[9,10]. Patients with MHE and altered oral glutamine challenge have a shortened life-span[7].

Treatment of MHE could prevent or delay the appearance of clinical HE and improve quality of life and life span of patients. In order to detect the presence of MHE and to treat it efficiently, it is necessary to know the mechanisms leading to MHE and subsequently to HE.

The mechanisms leading to HE are mainly studied using animal models of chronic liver failure and chronic hyperammonemia. The neurological alterations in HE are a consequence of impaired cerebral function mainly due to alterations in neurotransmission. Alterations in different neurotransmitter systems (glutamatergic, GABAergic, serotoninergic, *etc*) have been reported in HE[1].

We review here some studies indicating that alterations in neurotransmission associated to different types of glutamate receptors are responsible for some of the cognitive and motor alterations present in HE. Pharmacological manipulation of these receptors or pathways may normalize cognitive and motor function in animal models of HE.

## INTELLECTUAL AND MOTOR FUNCTIONS ARE IMPAIRED IN HE

Cognitive, motor and sleep alterations (impairment of sleep-wake cycle) are commonly observed in patients with HE and their intensities vary with the grade of HE.

Alterations in the regulation of biological rhythms such as sleep, appetite, melatonin production and in sexuality are common in patients with liver disease[11-14].

Patients with HE show alterations in cognition, consciousness, attention, memory, and learning. Cirrhotic patients with minimal HE are "clinically normal" but present cognitive alterations which can be unveiled by a detailed analysis of the patients' history and by neurophysiological and neuropsychological assessment of consciousness and sensory, cognitive and motor functions[5,6]. The prevalence of minimal HE in patients with liver disease ranges from 30% to 84% depending on the kind and number of tests used and the population (etiology and severity of the liver disease) investigated. Even minimal HE is associated with reduced quality of life and ability to work and drive[9,15-17]. Moreover, patients suffering minimal HE have increased probability of suffering later overt HE[7,18,19].

Patients with minimal HE show impaired ability to perform memory tasks, mainly because of deficits in attention and visual perception[20,21]. These patients also perform worse than healthy controls in motor function, visual perception, visual orientation and visual-constructive abilities[22-25].

Sustained attention is also impaired in cirrhotic patients even when memory, language, or motor alterations are absent[21,26,27]. Patients with minimal HE have the tendency to be easily distracted.

Early manifestations of intellectual dysfunction in HE patients include psychomotor slowing and impaired ability to perform tasks that require sustained attention[18,26,28]. As encephalopathy worsens, impairment in speech and inability to copy simple drawings (e.g. a star) appear. Patients in grade Ⅱ HE show temporal and spatial disorientation and reduced vigilance state or delirium. Grade Ⅳ HE is characterized by the appearance of stupor and coma.

Patients with HE show also altered motor function and coordination, including psychomotor slowing and hypokinesia which was attributed to alterations in basal ganglia[29]. Motor alterations include increased muscular tone, reduced speed of rapid alternating movement, ataxia, an increased deep tendon reflexes, abnormal movements such as tremors, particularly asterixis. Also hypomimia, dysarthria, bradykinesia and hypokinesia could be detected on careful neurological examination.

The mechanisms by which liver failure leads to altered intellectual and motor function remain unclear. Identifying these mechanisms would allow designing treatments to improve intellectual and motor function in patients with HE.

Some motor and cognitive alterations present in HE patients are reproduced in animal models of chronic liver failure (e.g. rats with portacaval anastomosis) and chronic hyperammonemia[30-38]. These animal models are being used to study the molecular mechanisms by which liver disease leads to HE and altered intellectual and motor function. Once these mechanisms are identified, new studies begin

to assess whether similar alterations and mechanisms occur in brain of patients with HE.

## GLUTAMATERGIC NEUROTRANSMISSION MODULATES COGNITIVE AND MOTOR FUNCTION AND IS ALTERED IN ANIMAL MODELS OF HE

Glutamate is the main excitatory neurotransmitter in mammals and modulates important cerebral processes including cognitive and motor functions (see below). Glutamatergic neurotransmission involves several steps, beginning with release of glutamate from the presynaptic neuron. Glutamate in the extracellular space activates glutamate receptors present in the synaptic membranes, leading to activation of signal transduction pathways associated to these receptors. To avoid continuous activation of glutamate receptors, glutamate is removed from the synaptic cleft by specific glutamate transporters located mainly in astrocytes. All these steps are tightly modulated under physiological conditions and alterations of any of the above steps may result in impairment of glutamatergic neurotransmission, leading to neurological alterations. Some of the parameters that can be altered under pathological conditions are: (1) the content (expression, synthesis and/or degradation) of the main proteins involved in glutamatergic neurotransmission (e.g. different types of glutamate receptors or transporters); (2) the regulation of the spatial location of the receptors and transporters. Only the receptors or transporters present in the membrane can recognize extracellular glutamate. Many of these proteins are associated to formation of clusters to improve the yield of the neurotransmission process; (3) the function of the receptors and transporters, which is modulated in different ways including phosphorylation-dephosphorylation, binding of co-agonists, *etc*; (4) alterations in the release or uptake of glutamate may result in altered extracellular glutamate, leading to altered neurotransmission; (5) alterations in any of the steps of the signal transduction pathways associated with the different types of glutamate receptors would also result in impaired glutamatergic neurotransmission.

There is therefore a large number of possible sites or molecular targets for interference by hyperammonemia or liver disease of glutamatergic neurotransmission. Hyperammonemia and liver failure alter different steps of glutamatergic neurotransmission including: glutamate concentration in the extracellular fluid in brain, transport and transporters of glutamate, content and function of different types of glutamate receptors and signal transduction pathways associated to these receptors[39].

Glutamatergic neurotransmission plays an important role in modulating intellectual function (learning and memory), motor function and coordination and circadian rhythms. As mentioned above, these processes are altered in patients with liver disease and HE, who show altered sleep-waking patterns, motor function and coordination and decreased intellectual capacity. The alterations in glutamatergic neurotransmission may be responsible for some of these neurological alterations found in HE patients.

We summarize below the alterations in glutamatergic neurotransmission that have been shown to contribute to the cognitive and motor alterations in hepatic encephalopathy.

Glutamate has two main types of receptors: ionotropic and metabotropic. Activation of ionotropic glutamate receptors leads to the opening of ion channels allowing the transport of $Na^+$, $K^+$ through them, and $Ca^{2+}$ in some cases. There are three main types of ionotropic glutamate receptors: NMDA, AMPA and kainate receptors. The NMDA type of glutamate receptors is involved in the control of cerebral processes such as neuronal plasticity, learning and memory. Alterations in signal transduction pathways associated to NMDA receptors are involved in the impairment in cognitive function in HE (see below).

Metabotropic glutamate receptors (mGluRs) are coupled to G proteins. Activation of mGluRs modulates the activity of different enzymes (phospholipase C, adenylate cyclase, *etc*) and ion channels through these G proteins, resulting in modulation of the intracellular levels of second messengers such as diacylglycerol, inositol triphosphates, cAMP, *etc*. These second messengers in turn, modulate the activity of other enzymes (protein kinases C and A, *etc*) that continue the transmission of the signal induced by activation of metabotropic glutamate receptors.

Metabotropic glutamate receptors are involved in modulation of motor function. Alterations in activation of metabotropic glutamate receptors are involved in some motor alterations in HE (see below).

## FUNCTION OF THE GLUTAMATE-NITRIC OXIDE-CGMP PATHWAY ASSOCIATED TO NMDA RECEPTORS IS ALTERED BOTH IN BRAIN *IN VIVO* ANIMAL MODELS OF HE AND IN BRAIN OF PATIENTS DIED FROM HE

Activation of NMDA receptors by glutamate leads to increased intracellular $Ca^{2+}$ in the post-synaptic neurons. $Ca^{2+}$ binds to calmodulin (CM) and activates different enzymes, including neuronal nitric oxide synthase (NOS), leading to increased formation of nitric oxide (NO), which in turn activates soluble guanylate cyclase (GC) and increases cGMP (Figure 1). Part of the cGMP formed is released to the extracellular space. Under appropriate conditions the increase in extracellular cGMP is a good measure of the extent of activation of NMDA receptors in brain *in vivo*.

The function of this glutamate-nitric oxide-cGMP pathway is impaired in brain *in vivo* in animal models of HE (rats with chronic hyperammonemia or with chronic liver failure). The most usual animal model for studying the neurological alterations in HE is the rat with chronic liver failure induced surgically by portacaval anastomosis. This model reproduces some of the neurological alterations found in patients with HE. Liver failure induces, in addition to hyperammonemia, other alterations (decreased muscle mass, altered metabolism of other compounds, *etc*).

To discern the contribution of hyperammonemia to the neurological alterations in HE, we developed an animal model of hyperammonemia without liver failure: rats fed an ammonium-containing diet[40,41]. These rats present a level of hyperammonemia similar to that of patients with liver cirrhosis or of rats with portacaval anastomosis, but do not present other alterations associated to liver failure and may be considered therefore as a model of "pure" hyperammonemia. Comparison of the effects induced by both models can clarify which effects are due to hyperammonemia and which are due to other factors associated to liver failure.

Using this model we found that chronic moderate hyperammonemia without liver failure impairs the function of the glutamate-NO-cGMP pathway in cerebellum *in vivo*, as shown by brain microdialysis in freely moving rats[42]. When microdialysis probes are inserted in the cerebellum of control or hyperammonemic rats without liver failure, administration of NMDA through the microdialysis probe activates the glutamate-NO-cGMP pathway and increases cGMP formation (Figure 1). The NMDA-induced increase in extracellular cGMP in cerebellum is significantly lower in hyperammonemic rats than in control rats[42], indicating that chronic hyperammonemia impairs the function of the glutamate-NO-cGMP pathway in rat cerebellum *in vivo*.

To assess whether the impairment occurs at the level of activation of soluble guanylate cyclase by NO, a NO-generating agent, SNAP (Figure 1) was administered through the microdialysis probe to directly activate guanylate cyclase. The increase in extracellular cGMP induced by SNAP was also significantly reduced in hyperammonemic rats. This indicates that chronic moderate hyperammonemia impairs activation of soluble guanylate cyclase by NO and function of the glutamate-NO-cGMP pathway in cerebellum *in vivo*.

Chronic liver failure induced by portacaval anastomosis, also impairs the glutamate-NO-cGMP pathway in cerebellum *in vivo*, as shown by brain microdialysis in freely moving rats by Monfort *et al*[43]. NMDA-induced increase in extracellular cGMP in cerebellum was significantly lower in rats with portacaval anastomosis than in control rats. These results indicate that the function of the glutamate-NO-cGMP pathway is impaired in cerebellum *in vivo* in animal models of HE. Moreover, one of the steps of the pathway affected is the activation of soluble guanylate cyclase by NO.

To assess whether activation of soluble guanylate cyclase by NO is also altered in cerebellum of cirrhotic patients with HE, we measured the activation of soluble guanylate cyclase by the NO-generating agent SNAP in homogenates of cerebellum from controls and cirrhotic patients who died of hepatic coma. The activation of guanylate cyclase by the NO-generating agent SNAP was significantly lower in cerebellum from cirrhotic patients than in cerebellum from controls[44].

The above results show that animal models of HE reproduce faithfully the alterations in the modulation of guanylate cyclase by NO present in cerebellum of patients died of HE, which supports the idea that hyperammonemia is responsible for these alterations.

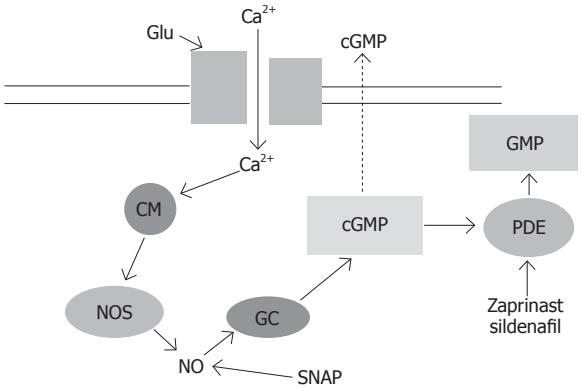

**Figure 1** Glutamate-nitric oxide-cyclic GMP pathway. Activation of ionotropic (mainly NMDA) glutamate receptors leads to increased intracellular calcium ($Ca^{2+}$) which after binding to calmodulin (CM), activates nitric oxide synthase (NOS), leading to increased production of nitric oxide (NO), which in turn activates soluble guanylate cyclase (sGC), resulting in increased formation of cGMP. Part of the cGMP formed is released to the extracellular space. Soluble guanylate cyclase may be also activated by agents that generate NO such as SNAP. cGMP is degraded by phosphodiesterase (PDE) that may be inhibited by zaprinast or sildenafil.

## LEARNING ABILITY IS IMPAIRED IN ANIMAL MODELS OF HE AND RESTORED BY PHARMACOLOGICAL NORMALIZATION OF THE FUNCTION OF THE GLUTAMATE-NITRIC OXIDE-CGMP PATHWAY AND CGMP IN BRAIN

Cognitive function and learning ability are impaired in patients with liver disease (see above) and in animal models of HE[35-37]. The glutamate-nitric oxide-cGMP pathway and cGMP modulate some forms of learning and memory. It is therefore likely that the impairment in the function of the glutamate-nitric oxide-cGMP pathway in brain may contribute to the cognitive impairment in HE patients.

We hypothesize that the alterations in the function of the glutamate-nitric oxide-cGMP pathway and the decrease in extracellular cGMP in brain may be responsible for the impairment in learning ability and intellectual function in HE patients, and that pharmacological modulation of extracellular cGMP concentration may restore learning ability in patients with hyperammonemia and HE.

To assess this possibility we tested whether pharmacological treatments directed to increase extracellular cGMP in brain are able to reverse the impairment in learning ability in rat models of HE. We were able to increase extracellular cGMP and completely restore learning ability of the rats by using three different treatments: continuous intracerebral administration of zaprinast, an inhibitor of the phosphodiesterase that degrades cGMP[36]; chronic oral administration of sildenafil, an inhibitor of the phosphodiesterase that crosses the blood-brain barrier[35], and continuous intracerebral administration of cGMP[36].

The above data indicate that the impairment of learning ability (at least of the ability to learn the Y maze conditional discrimination task) in animal models of HE is due to impairment of the glutamate-nitric oxide-cGMP

pathway. As the function of this pathway is also altered in brain of patients with liver cirrhosis, this alteration should also contribute to the cognitive impairment in these patients.

Increasing extracellular cGMP by pharmacological means may be a new therapeutic approach to improve learning and memory performance both in patients with evident HE and cognitive impairment and in patients with minimal HE who present reduced performance in psychometric tests.

## HYPOLOCOMOTION IN ANIMAL MODELS OF HE IS DUE TO ALTERED ACTIVATION OF METABOTROPIC GLUTAMATE RECEPTORS IN THE CEREBRAL SUBSTANTIA NIGRA PARS RETICULATA

The neurological alterations in patients with HE also include alterations in motor function and coordination. One of the early alterations in patients with liver disease is psychomotor slowing. Jover *et al*[29] reported that 41% of patients with liver cirrhosis show hypokinesia, which is attributed to alterations in basal ganglia. These patients may also present bradykinesia. Rats with chronic liver failure due to portacaval anastomosis also show reduced motor activity which is similar to the motor slowing, hypokinesia and bradykinesia present in patients with HE[38,45-48]. We used this animal model to study the mechanisms involved in motor alterations in HE patients.

The neuronal circuits between basal ganglia and prefrontal cortex are essential in the modulation of motor function. This network includes basal ganglia, motor thalamus and cerebral cortex (Figure 2). The basal ganglia (including nucleus accumbens) produces signals that go to the thalamus which sends signals to the cortex to modulate movement execution. The signals originated in the thalamus are modulated by substantia nigra pars reticulata (SNr), which sends inhibitory projections to the ventromedial thalamus (VMT).

Patients with liver disease show hyperintensities in magnetic resonance imaging in basal ganglia nuclei[49-51], suggesting altered function of these nuclei, which is also supported by PET studies[52]. It has been suggested that the motor symptoms of HE are a consequence of basal ganglia dysfunction and alterations affecting the function of the neuronal circuits between basal ganglia and cerebral cortex[5,49-53].

The motor activity mediated by the basal ganglia-thalamus-cortex circuit is modulated by glutamatergic neurotransmission in nucleus accumbens and SNr (Figure 2). Activating metabotropic glutamate receptors in nucleus accumbens induces motor activity. Activation of glutamate receptors in SNr induces hypolocomotion in normal rats[54-56], while glutamate receptor antagonists administered in SNr induce hyperlocomotion[56,57]. Alterations in glutamatergic neurotransmission in SNr therefore may contribute to the psychomotor slowing and hypokinesia in HE patients.

We analysed the neurochemical alterations in the basal ganglia-thalamus-cortex circuit by *in vivo* brain microdialysis in rats with portacaval anastomosis and correlated the alterations in neurotransmitters (glutamate, GABA) with the alterations in motor function. Moreover we tried to normalize motor function of rats with portacaval anastomosis by pharmacologically modulating glutamatergic neurotransmission.

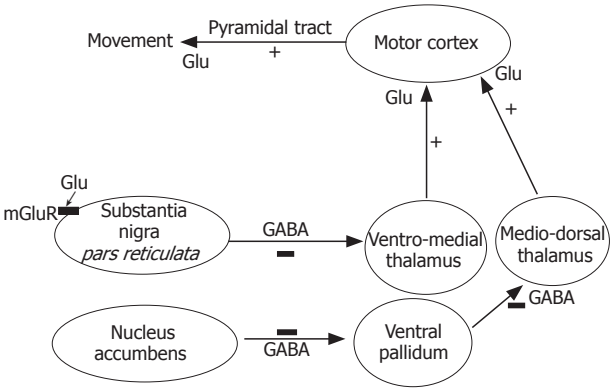

**Figure 2** Hypolocomotion in animal models of HE is due to increased extracellular glutamate and activation of metabotropic glutamate receptors in substantia nigra pars reticulata. Activation of metabotropic glutamate receptors (mGluRs) in nucleus accumbens induces motor activity by activating a neuronal circuit involving ventral pallidum, medio-dorsal thalamus and motor cortex. Activation of mGluRs in substantia nigra pars reticulata (SNr) induces hypolocomotion by activating a neuronal circuit involving ventro-medial thalamus and motor cortex. In rats with HE due to chronic liver failure (portacaval anastomosis), the extracellular concentration of glutamate is significantly increased (15-fold) in SNr, resulting in increased activation of mGluR1 which is responsible for hypolocomotion in these rats. Blocking mGluR1 in SNr with specific antagonists increases motor activity in rats with chronic liver failure up to levels similar to those in normal rats.

Extracellular glutamate is significantly increased (15-fold) in SNr of rats with portacaval shunt (PCS) and its motor activity is reduced by 40%. There is a significant negative correlation between locomotor activity and extracellular glutamate in SNr, indicating that increased glutamate is responsible for hypolocomotion in PCS rats[38].

We hypothesize that hypolocomotion in PCS rats is due to over-activation of metabotropic glutamate receptors (mGluRs) by the increased extracellular glutamate. To assess this possibility, we tested whether blocking mGluR1 with the antagonist CPCCOEt can normalize the motor activity in PCS rats and found that blocking mGluR1 does not affect the motor activity in control rats but increases it in PCS rats to reach the same motor activity than control rats[38]. The above data show that increased activation of the metabotropic glutamate receptor mGluR1 in SNr is responsible for hypolocomotion in rats with chronic liver failure. We studied the possible mechanisms involved in this increased activation. The increased activation of mGluR1 is not due to increased amount of the receptor, which is significantly reduced in SNr of PCS rats[38], indicating that enhanced activation of the metabotropic receptor is due to the increase in the extracellular concentration of glutamate.

The increase in extracellular glutamate could be due to increased release, reduced uptake or both. We analysed the content of the two main transporters that take up glutamate: EAAC-1 and GLT-1. The content of both

transporters is reduced by 23%-27%[38]. The reduced content of glutamate transporters may contribute to increased extracellular glutamate in SNr. Enhanced glutamate release could also contribute to the increased extracellular glutamate.

The increased activation of metabotropic glutamate receptors in SNr results in altered function of the whole basal ganglia-thalamus-cerebral cortex circuit (Figure 2), and therefore in hypolocomotion. Increased mGluR1 activation in SNr leads to increased GABA concentration in ventro-medial thalamus, which mediates hypolocomotion in PCS rats. Blocking mGluR1 in SNr normalizes GABA in ventro-medial thalamus and locomotion. The circuit by which SNr modulates motor activity also involves glutamate in motor cortex. Blockade of mGluR1 in SNr increases glutamate in motor cortex and activity.

There are reports supporting that changes similar to those summarized above in rats with chronic liver failure also may occur in patients with chronic liver disease. Alterations in the function of basal ganglia in liver cirrhosis are supported by the hyperintensities in magnetic resonance images found consistently in these patients[49-51]. Altered function of the thalamus is also supported by PET studies in patients with HE[52]. It is therefore likely that excessive activation of metabotropic glutamate receptors in SNr may be also involved in the psychomotor slowing and hypokinesia in patients with HE.

These studies may have clinical implications. Blocking mGluR1 in SNr normalizes motor activity in a rat model of HE, suggesting that a similar treatment for patients with HE can be used to treat psychomotor slowing and hypokinesia in these patients. However, the possible effects of mGluR1 antagonists on other cerebral functions should be previously evaluated. Each type of glutamate receptors and their associated signal transduction pathways may be expressed in different brain areas where they may modulate different cerebral functions. This implies that, for example, blocking mGluR1 in SNr may restore motor function in patients with liver disease, but blocking it in another brain area may impair some other cerebral functions. Before trying to apply these treatments in humans, careful studies in animal models are therefore required to analyse the possible secondary effects, and ideally, if possible, to develop appropriate delivery procedures allowing to modulate specific receptors or pathways in specific brain areas without affecting its function in other areas.

In summary, the studies reviewed here show that alterations in signal transduction pathways associated to the NMDA type of ionotropic glutamate receptors are involved in cognitive impairment in HE while alterations in activation of metabotropic glutamate receptors are involved in the motor alterations. Moreover, pharmacological manipulation of the altered pathways and receptors can normalize both cognitive and motor functions in animal models of HE. These studies are setting the basis for designing therapeutic procedures to specifically treat individual neurological alterations in patients with HE.

## Abstract

Food allergy is a common and increasing problem worldwide. The newly-found knowledge might provide novel experimental strategies, especially for laboratory diagnosis. Approximately 20% of the population alters their diet for a perceived adverse reaction to food, but the application of double-blind placebo-controlled oral food challenge, the "gold standard" for diagnosis of food allergy, shows that questionnaire-based studies overestimate the prevalence of food allergies. The clinical disorders determined by adverse reactions to food can be classified on the basis of immunologic or nonimmunologic mechanisms and the organ system or systems affected. Diagnosis of food allergy is based on clinical history, skin prick tests, and laboratory tests to detect serum-food specific IgE, elimination diets and challenges. The primary therapy for food allergy is to avoid the responsible food. Antihistamines might partially relieve oral allergy syndrome and IgE-mediated skin symptoms, but they do not block systemic reactions. Systemic corticosteroids are generally effective in treating chronic IgE-mediated disorders. Epinephrine is the mainstay of treatment for anaphylaxis. Experimental therapies for IgE-mediated food allergy have been evaluated, such as humanized IgG anti-IgE antibodies and allergen specific immunotherapy.

**Key words:** Food intolerance; Food allergy; Skin prick test; Serum food-specific IgE; Oral food challenges

## INTRODUCTION

Food allergy is recognized as a common worldwide problem, and, like other atopic disorders, its incidence seems to increase. Moreover, food-related allergic disorders are the leading cause of anaphylactic reactions treated in the emergency departments in a number of countries, accounting for approximately 30 000 emergency department visits, and 150-200 deaths each year, and the public opinion has become increasingly aware of the problem[1,2]. In the past years, investigations of allergic food proteins and related immunological responses have moved to the molecular level, and the newly-found knowledge might provide novel experimental strategies for the laboratory diagnosis and the immuno-modulatory control of food-induced allergic reactions[1,3-5].

Recently, the European Academy of Allergy and Clinical Immunology task force published a revised nomenclature for allergy. Adverse food reactions, defined as "food hypersensitivities", include any abnormal reaction resulting from the ingestion of a food, and it might be the result of food intolerance, defined as "non-allergic food hypersensitivities", excluding immunologic mechanisms, or food allergy, defined as "allergic food hypersensitivities", including clear, or strongly suspected, immunologic mechanisms[6]. Our review focused on the food allergy.

## EPIDEMIOLOGY AND PATHOGENESIS

### *Epidemiology*

Approximately 20% of the population alters their diet for a perceived adverse reaction to food, but the application of double-blind placebo-controlled oral food challenge, considered as the gold standard for diagnosis of food allergy, shows that questionnaire-based studies overestimate the prevalence of food allergies and food intolerance[7-9].

In the United States, approximately 6% of infants and young children and 3.7% of adults have food allergy. In young children, the most common causal foods are cow's milk, egg, peanut, wheat, soy, tree nuts, fish, and shellfish. In adults, the most common causal foods are shellfish, peanut, tree nuts and fish[7,10-12]. Early childhood allergy to milk, egg, soy, and wheat are usually resolved by school age (approximately 80%), whereas peanut, tree nuts and

seafood allergies are generally considered permanent. In Europe, early childhood allergy to cow's milk has an incidence of approximately 2%. The relatively high prevalence of peanut allergy in British children (0.5%) ("Americanised" eating habit) is not reflected in the results from other European countries. Cow's milk, egg and orange seem to be the most common causes of allergy in European infants and children. As the children become adults, allergy to milk and eggs become less frequent. In adults, the allergies appear toward pollen-related food, i.e. *Compositae*-celery, birch-apple and birch-peaches. Adult European population presents a prevalence of food allergy/intolerance of approximately 5%[7,13].

Unfortunately, data from many parts of Asia are still lacking. However, the prevalence of food allergy in Asia seems to be low, but is likely to increase with the global increase of allergy. Asia is unique because of the many different cultures and eating habits, with the existence of unique food allergens. Peanut and tree nuts are rarely the cause of allergic reactions in this area[14]. In a population-based study carried out in the United Kingdom establishing reported food problems and sensitization among 11- and 15-year-old children, the prevalence of food hypersensitivity was 1.4% and 2.1% for the 11- and 15-year-olds, respectively[15] on the basis of a combination of a clear history of previous reactions, a positive skin prick test response, a positive open food challenge result, and a positive double-blind placebo-controlled food challenge.

### *Pathogenesis*

Food allergy represents an abnormal response of the mucosal immune system to antigens delivered through the oral route[6]. The healthy gastrointestinal mucosal immune system encounters enormous quantities of antigen on a daily basis and generally suppresses immune reactivity to harmless foreign antigens (food proteins and commensal bacteria), although it is fully capable of mounting a brisk protective response against dangerous pathogens. The process by which the gastrointestinal immune system avoids attacking harmless antigens is termed "oral tolerance"[16,17]. Food allergy might result from a failure in oral tolerance to food while they are being ingested (class 1 food allergy) or from a sensitization to allergens recognized instead during respiratory exposure (class 2 food allergy). Class 1 food allergy is typically related to food proteins, generally stable to digestion, which is encountered by infants or children at a presumed immunological immaturity. In contrast, class 2 food allergy is the result of a sensitization to protein susceptible to enzymatic degradation, encountered in the respiratory tract, such as pollens, resulting in an IgE antibody production that recognize homologous epitopes on food proteins of plant origin (i.e. pollen-food related syndrome)[10,11,18,19].

**Gut barrier:** The gastrointestinal mucosal barrier is a complex of physical (mucus, acid, enzymes, bile salts, and epithelial cell tight junctions) and immunologic structures-both "innate" (natural killer cells, polymorphonuclear leukocytes, macrophages, epithelial cells, and toll-like receptors), and "adaptive" (intraepithelial and *lamina propria* lymphocytes, Peyer's patches, secretory immunoglobulin type A [sIgA], and cytokines)-which all serve to destroy antigens and to render antigens nonimmunogenic[16,20-22]. Alteration of the gut barrier might lead to food allergy. Developmental immaturity of components of the gut barrier (enzymatic activity and sIgA) might account for the increased prevalence of food allergy in infancy[23]. Despite the evolution of this barrier, about 2% of ingested food antigens, both particulate and soluble, are adsorbed by the follicle associated epithelium (M cells), overlying Peyer's patch and the intestinal epithelial cells, respectively, and transported throughout the normal mature gut, but they infrequently induce clinical symptoms, because tolerance develops in most individuals[24,25].

**Oral tolerance induction:** The immunologic mechanisms involved in oral tolerance induction have not been fully elucidated. Antigen-presenting cells, epithelial and dendritic cells, and regulatory T cells play a central role. Intestinal epithelial cells, as non-professional antigen-presenting cells, process luminal soluble dietary antigen and present it, on an MHC class Ⅱ complex, selectively to $CD8^+$ suppressor T cells, thus playing a role in local control and suppression of immune responses. Dendritic cells, residing within the *lamina propria*, are professional antigen presenting cells that secrete IL-4, a pro-inflammatory $T_H2$ cytokine, and IL-10, an anti-inflammatory cytokine. However, the specific role of these cells in directing the balance between active immunity and food tolerance in the intestine, depends on the cytokine microenvironment and the expression of costimulatory molecules. Five regulatory T cells have been identified in association with intestinal immunity: $T_H3$ cells, a population of $CD4^+$ cells that secrete transforming growth factor β (TGF-β), might play an important role in oral tolerance, inducing T cell suppression and promoting B-cell switching to sIgA production; $T_R1$ cells, $CD4^+$ cells that secrete IL-10 and suppresses the antigen-specific immune responses; $CD4^+CD25^+$ regulatory T cells, together with $CD8^+$ suppressor T cells, that are both capable of suppressing the effector T cells; and γδ T cells, whose role in oral food tolerance is still unclear[26,27]. Dose of dietary antigens, frequency of exposure, and chemophysical properties of food proteins, might also influence the tolerance induction. Particularly in mice, oral food tolerance has been induced after administration of either a single dose or repeated lower doses of antigen. These two forms of tolerance, termed high-dose and low-dose tolerance, respectively, might be mediated by different mechanisms: by the activation of regulatory T cells ($T_H3$, $T_R1$, and $CD4^+CD25^+$), with suppressor function, and by the anergy or delection of effector T cells. Anergy can occur through T-cell receptor activation in the absence of costimulatory signals provided by soluble cytokines or by interactions between costimulatory receptors on T cells and counter-receptors on antigen presenting cells. Delection occurs by means of FAS-mediated apoptosis of lymphocytes[28].

Commensal gut flora might also influence the mucosal immune response. Gut flora is largely established in the first 24 h. after birth and is dependent on maternal flora and local environment. Gut flora might enhance a $T_H1$ cytokine response, with secretion of interferon-γ (IFN-γ) that inhibits $T_H2$ responses. However, in adults, commensal gut flora seems to be less important in the regulation of mucosal immune response[29,30].

**Food allergens:** The regional dietary habits and methods of food preparation clearly play a role in the prevalence of specific food allergies in various countries around the world[31].

The major food allergens identified as class 1 allergens are water-soluble glycoproteins, 10 to 60 kilo-Dalton in size, that are stable to heat, acid, and proteases. Cooking can reduce the allergenicity of certain food proteins; conversely, heating can increase the allergenicity of other food proteins, through the induction of covalent modifications that lead to new antigens or improved stability[11,32]. The class 2 food allergens are presumably comprised of conformational epitopes and therefore are highly heat-labile, susceptible to enzymatic degradation and difficult to isolate. An example of a class 2 allergens is the birch pollen Bet v 1, that can induce sensitization through the respiratory tract and results in oral symptoms of pruritus to homologous class 2 allergens in raw apple (Mal d 1) or carrot (Dau c 1)[19,33].

**Genetic of the host:** Studies examining potential associations of specific HLA antigens with allergies to different food show variable results. No difference was observed when HLA-A, HLA-B, and HLA-C locus antigen were compared between patients with food allergy and control subjects. However, when individuals with peanut allergy and unrelated control subjects were typed for the HLA-class Ⅱ genotypes, DRB1*08, DRB1*08/12tyr16, and DQB1*04 were found at higher frequency in those with peanut allergy than in control subjects. These findings indicate that allergic reactions to peanut are in part under genetic control. Additional genes might be involved in the overall expression of food allergy and are under investigations[34].

## CLINICAL CLASSIFICATION

The clinical disorders determined by adverse reactions to food (or food hypersensitivity) can be classified on the basis of nonimmunologic or immunologic causes (Table 1), and the organ system or systems affected (Table 2)[6]. Food intolerance by toxic and pharmacologic reactions is due to toxic contaminants (histamine in scombroid fish poisoning, and bacterial food poisoning) or pharmacological substances within the food (tyramine in aged cheeses) which can affect most healthy individuals when given at appropriate doses. Food intolerance may also be attributed to some unique physiologic characteristics of the host, such as a metabolic disorder (lactase deficiency), or an idiosyncratic response. Instead, food allergy is defined as an adverse reaction to food that is immunologically mediated, and involves specific IgE or non-IgE (T cell-mediated) mechanisms or both[6].

### *Gastrointestinal food-induced allergic disorders*

Various gastrointestinal food-induced allergic disorders share the same symptoms, such as vomiting, abdominal distension and pain, and diarrhoea, but they can be differentiated by patterns of illness and diagnostic tests.

**Pollen-food allergy syndrome:** Pollen-food allergy syndrome (or oral allergy syndrome): is an IgE-mediated food adverse reaction, elicited by a variety of plant-derived food proteins, especially concentrated in the peel, which cross-react with airborne allergens, including birch, ragweed, and mugwort pollens. It is characterized by mild pruritus, tingling, and/or angioedema of the lips, tongue, palate or oropharynx, occasional sensation of tightness in the throat, and rarely systemic symptoms, because the allergens responsible for these reactions are easily broken down by heat or gastric enzymes, and thus are not absorbed by the gastrointestinal mucosa. Reactions to all related food are rare, but sensitivity to more than one is common. Diagnosis is based on clinical history, positive skin prick test responses to fresh food and relevant airborne proteins, and, if necessary, on an oral challenge, positive with fresh food and negative with cooked food (see above)[35-37].

**Allergic eosinophilic esophagitis:** Allergic eosinophilic esophagitis is an IgE- or non-IgE-mediated, or both, food adverse reactions, seen most frequently during infancy through adolescence, characterized by gastroesophageal reflux, excessive spitting-up or emesis, dysphagia, intermittent abdominal pain, failure to respond to conventional reflux medications, and peripheral blood eosinophilia. Diagnosis is based on clinical history, skin prick tests, endoscopy with biopsy,

elimination diet and challenge. Patients who are not appropriately treated might develop fibrosis, with subsequent esophageal stricture, and Barrett's esophagitis[38,39].

**Allergic eosinophilic gastroenteritis:** Allergic eosinophilic gastroenteritis is an IgE- or non-IgE-mediated, or both, food adverse reactions, being diagnosed more frequently in adults, characterized by early satiety, intermittent vomiting, recurrent abdominal pain, blood loss in the stools, iron-deficiency anemia, and protein-losing enteropathy, with a peripheral blood eosinophilia. Clinical history, skin prick tests, endoscopy with biopsy, and elimination diet and challenge, are required[40,41] for the diagnosis.

**Food protein-induced enterocolitis, proctocolitis, and enteropathy:** Food protein-induced enterocolitis, proctocolitis, and enteropathy is a non-IgE-mediated (T cell-mediated) disorders, most commonly seen in infants before 3 mo of age, provoked by food proteins in maternal breast or cow's milk or soy protein-based formulas, characterized by nausea, protracted projectile vomiting, that begins about 1-3 h. after allergen ingestion, abdominal distension, flatulence, diarrhoea (steatorrhoea), sometimes with dehydratation, acidemia, methemoglobinemia, weight loss and gross or occult blood in stool mixed with mucus. In these patients, skin prick test responses are negative. Endoscopy and biopsy are often required. In patients affected by food protein-induced enteropathy, biopsy reveals a patchy villous atrophy, a prominent mononuclear round cell infiltrate, and few eosinophils. Elimination of food proteins leads to the clearing of symptoms in 24-72 h. Challenge induces recurrent vomiting or bleeding within 72 h.[42-46].

**Celiac disease:** Celiac disease (or gluten-sensitive enteropathy) is a more extensive enteropathy leading to malabsorption, associated with sensitivity to gliadin, found in wheat, rye and barley. Diagnosis is based on celiac IgA, anti-gliadin and anti-transglutaminase antibodies detection, endoscopy and biopsy, elimination diet, with resolution of symptoms and food challenge, if necessary[47,48].

**Infantile colic:** Infantile colic is due to food hypersensitivity in a minority of infants presenting with this disorder characterized by paroxysmal fussiness with inconsolable agonized crying, it generally develops in the first 2-4 wk of life, and persists through the third to fourth month of life. Diagnosis is based on the implementation of several brief trials of hypoallergenic formula[49,50].

**Gastrointestinal anaphylaxis:** Gastrointestinal anaphylaxis is an IgE-mediated reaction, food associated, not exercise-induced, characterized by rapid onset of nausea, vomiting, cramps, abdominal pain, and diarrhoea, often involving other target organs such as skin and respiratory tract. Diagnosis is established according to the clinical history, positive skin prick test or radioallergosorbent test (RAST) responses, and if necessary, based on an oral challenge[11,51].

### *Cutaneous and respiratory food-induced allergic disorders*

IgE-, non-IgE- and mixed IgE- and non-IgE-mediated adverse reactions to food can induce a variety of cutaneous disorders. The most common cutaneous disorder of food-induced allergic reactions is "acute" urticaria and angioedema (symptoms lasting < 6 wk), whereas, food allergy causes infrequently "chronic" urticaria and angioedema (symptoms lasting > 6 wk)[52,53].

**Atopic dermatitis:** Atopic dermatitis is a form of eczema that generally begins in early infancy, characterized by typical distribution, extreme pruritus, and a chronically relapsing course. In about 35% of children with moderate-to-severe disease, food allergens specific serum IgE antibodies against cow's milk, egg, soya and wheat are demonstrable, and the ingestion of specific food might evoke a marked worsening of cutaneous lesions[54,55].

**Dermatitis herpetiformis:** Dermatitis herpetiformis is a rare chronic skin disorder, associated with gluten-sensitive enteropathy, characterized by a chronic, intensely pruritic, papulovesicular rash, symmetrically distributed over the extensor surfaces and buttocks. It can be clearly distinguished from the other subepidermal blistering eruptions by gastrointestinal, immunologic and histologic criteria. Both enteropathy and the dermatologic findings disappear with a gluten-free diet, therefore, dermatitis herpetiformis is thought to be the specific dermatologic finding of celiac disease[56].

Food allergy can also induce a number of disorders in the respiratory tract. Acute respiratory symptoms, caused by food allergy generally represent isolated IgE-mediated reactions, whereas chronic respiratory symptoms represent a mix of IgE- and non-IgE-mediated reactions. Isolated rhinoconjunctivitis and bronchial asthma are rarely the result of food-induced allergic reactions, although they frequently occur in association with other food allergy symptoms. However, food allergy was found to be a major risk factor for severe life-threatening asthma. Food-induced asthmatic symptoms should be suspected in patients with refractory asthma and a history of atopic dermatitis, gastroesophageal reflux, food allergy or a history of positive skin prick test responses to a kind of food[10,57-59].

### *Systemic food-induced allergic disorders*

IgE-, non-IgE- and mixed IgE- and non-IgE-mediated adverse reactions to food can also induce systemic disorders.

**Generalized anaphylaxis:** Generalized anaphylaxis is an IgE-mediated food adverse reaction, accounting for at least one third to one half of anaphylaxis cases seen in hospital emergency departments. In addition to variable expression of cutaneous (itching, flushing and urticaria), respiratory (asthma) and gastrointestinal (nausea, vomiting, abdominal pain, and diarrhea) symptoms, patients might have cardiovascular symptoms, such as hypotension, cyanosis, vascular collapse and cardiac dysrhythmias. Most of fatal food-induced anaphylaxis were adolescents or young adults, with previous histories of reacting to the implicated food (usually not life-threatening), and all were affected by underlying asthma. Peanuts, tree nuts and seafood were responsible for the vast majority of the fatalities in the United States. Aspirin, exercise and alcohol can increase the risk[60-62].

**Food-associated and exercise-induced anaphylaxis:** Food-associated and exercise-induced anaphylaxis is a form of anaphylaxis that occurs only when the patient (generally women aged 15-30 years) exercises within 2-4 h. of ingesting food. Crustaceans and wheat are the two commonest but other food can be implicated. In the absence of exercise, the patient can ingest the food without any apparent reaction. It might account for up to one

half of the cases of exercise-induced anaphylaxis. Diagnosis is based on patient history and the demonstration of food-specific serum IgE antibodies. Food dependent and exercise-induced anaphylaxis should be considered in young children with exercise-induced anaphylaxis of unknown origin[63,64].

## DIAGNOSIS

The evaluation of a patient with a possible allergic food reaction begins through clinical history and a complete physical examination to consider a potentially broad differential diagnosis between food-induced allergic clinical disorders and other gastrointestinal disease, such as food intolerance (toxic and pharmacological effects or metabolic disorders), infections (viral, bacterial and parasitic), celiac disease, inflammatory bowel diseases, bowel ischaemia, gallbladder disease, pancreatic insufficiency, and gastrointestinal neoplasms[7,10,11]. The medical history continues to be a mainstay in the diagnostic process, and might determine the possible causal food, quantity ingested, time course of reaction, ancillary factors (aspirin, exercise and alcohol) and reaction characteristics. However, the identification of suspected food is difficult because food is ingested throughout the day and symptoms that arise soon after an ingestion might be wrongly attributed to food allergy, or attributed to the wrong food. Diet records and symptom diaries can be a useful supplement to a medical history, especially in chronic disorders. From a diagnostic point of view, it is helpful to categorize food hypersensitivity disorders by the mechanism of response and the predominant target organ. IgE-mediated reactions are typically rapid in onset, whereas non-IgE-mediated disorders become evident after allergen ingestion. Some disorders might involve both IgE- and non-IgE-mediated mechanisms and vary in their time of onset. In other words, acute symptoms, such as acute urticaria after ingestion of a food, are likely caused by food allergy, whereas chronic symptoms (chronic urticaria and asthma) are less likely attributable solely to food allergy. Certain disorders are commonly associated with food allergy, such as moderate-to-severe atopic dermatitis. For other disorders such as chronic urticaria, suspicions about particular food are notoriously inaccurate, and are only verified in about 30% of cases. In some cases, confirmation of a diagnosis of allergic food reaction requires invasive tests, such as endoscopy, but usually the diagnosis relies on food-specific IgE determination (or confirmations of its absence), results of elimination diets, and responses to oral food challenges[7,10,11].

### *Skin prick test*

For IgE-mediated disorders, skin prick tests provide a rapid mean to detect sensitization. This almost painless procedure allows the tested protein to interact with food-specific IgE on the surface of skin mast cells. If the antibody is present, mast cells degranulate and release mediators that rapidly cause localised vasodilation, angioedema and wheal and flare. While the patient discontinued antihistamines for an appropriate length of time, a device, such as a lancet, plastic probe or tip of a small gauge needle, is pressed through a commercial extract of food and a positive (histamine) and negative (saline-glycerine) controls into the epidermis. Allergens eliciting within 15 min a wheal at least 3 mm larger than that produced by the negative control are considered positive, indicating the possibility that the patients have symptomatic reactivity to the specific food, with strongly positive results implying a greater likelihood of clinical reactivity. On the other hand, negative skin prick test responses essentially confirm the absence of IgE-mediated allergic reactivity. To maximize the utility of skin prick test results, clinical history and disease pathophysiology are required. For example, a positive skin prick test response may be considered confirmatory for the diagnosis when combined with a recent and clear-cut history of a food-induced allergic reaction to the tested food[65-69].

When evaluating allergy to fruits and vegetables, commercially prepared extracts are often inadequate because they are prone to degradation, and therefore the fresh food might be used for prick-by-prick test[70]. A number of investigators have examined the use of the "atopy patch test" in addition to skin prick test for the diagnosis of non-IgE-mediated food allergy, with delayed reactions to food, but at this time, there are no standardized reagents or methods of application and interpretation. Thus, its diagnostic accuracy remains still controversial, especially in older children[71].

### *Detection of serum food-specific IgE*

Laboratory tests to determine serum food-specific IgE antibodies (RAST or, more recently, the CAP System FEIA, or UniCAP [Pharmacia and Upjohn Diagnostics, Uppsala, Sweden], and others) provide another modality to evaluate IgE-mediated food allergy. Manufactures and substrates vary, and results can be classified into class one to six, or arbitrary units of concentration (kU$_A$/L). Increasingly higher concentrations of food-specific IgE correlate with an increasing likelihood of clinical reaction[72-74]. No conclusive studies indicate that determination of specific IgE-binding epitopes on an allergen might provide increased diagnostic utility. Further analysis revealed that determining epitope-specific binding might correlate with clinical reactivity better than quantitative IgE values to the whole protein. Moreover, evaluating the number of allergenic epitopes bound by the IgE antibodies might be useful for predicting the clinical severity of food-induced allergic reaction[75,76].

### *Other laboratory tests*

When evaluating patients with gastrointestinal symptoms, suspecting a food hypersensitivities, a number of other standard laboratory studies might be useful. Patients with allergic eosinophilic esophagitis and allergic eosinophilic gastroenteritis have peripheral eosinophilia, and patients with severe allergic eosinophilic gastroenteritis might have anemia, blood in the stool, and decreased serum protein, albumin and IgG levels (with preservation of IgM and IgA)[77-79]. Endoscopy and biopsy are the most definitive approaches for diagnosing many of the gastrointestinal food hypersensitivities and might help the differential diagnoses. Greater than 10-20 eosinophils per 40 × high-power field in the esophagus is diagnostic of allergic eosi-

nophilic esophagitis, especially if the pH probe is normal and there is lack of responses to antireflux medication. Eosinophils are normally present in the gastric and intestinal mucosa, and therefore eosinophil number must be greater to make the diagnosis of allergic eosinophilic gastroenteritis. In these cases, diagnosis requires elimination of alternative diagnostic possibilities (parasites, inflammatory bowel disease)[77-79]. No conclusive studies suggest the possible usefulness of analyzing intestinal permeability by determining the 5-h. urinary excretion of [51Cr] EDTA, and inflammation markers, including histamine, eosinophilic cationic protein, tryptase, and calprotectin in gut lavage fluid[80].

### *Oral food challenge*

Skin prick tests with food allergens and determination of serum food-specific IgE can detect "sensitization" (that is the presence of food-specific IgE), but because sensitization can exist without allergic clinical reactions (esophagitis, gastroenteritis, rhinitis and asthma), these tests generally cannot be used alone to diagnose food allergy. In this setting, it is important to consider also the clinical history and the results of oral food challenges. Skin prick tests and RAST are most valuable when they are negative, since their high sensitivity makes them about 95% accurate for discounting IgE-mediated reactions. The double-blind, placebo-controlled oral food challenge (DBPCFC) with gradually increasing amounts of the suspected food under observation over hours or days, is considered the "gold standard" test for the diagnosis of food allergy. The clinical history results, skin prick tests (RASTs) or both, indicate which food should be evaluated by DBPCFCs. Patients with histories of life-threatening anaphylaxis should be challenged only when the history and laboratory tests cannot conclusively determine the causative food. To increase the likelihood of a nonequivocal food challenge result, suspected food should be eliminated for 7-14 d before challenge and longer in some non-IgE-mediated gastrointestinal disorders (non-IgE mediated allergic eosinophilic esophagitis and allergic eosinophilic gastroenteritis). Medications that could interfere with the evaluation of food-induced symptoms (antihistamines and adrenergic bronchodilators) must be discontinued. The length of the observation period depends on the type of reaction suspected. Hypotension might occur in about 15% of these challenges, especially in patients affected by acute IgE-mediated reactions, enterocolitis syndrome, and severe atopic dermatitis, and therefore intravenous hydration therapy and supplies for resuscitation should be immediately available. The false negative rate of DBPCFC is about 3%, so negative challenges should always be followed by a supervised open or a single-blind oral food challenge[8,66,81].

## MANAGEMENT

The primary therapy for food allergy is to avoid the causal food. In most countries, shortcomings on manufacturers and labelling, make it very difficult to identify allergens in commercial food products. Cross contamination, errors in packaged food shop, and restaurants are additional obstacles. Therefore, new food-labelling laws require simple terms to indicate the presence of major food allergens ("milk" instead of "casein"). Patients and care providers should be encouraged to obtain medical identification bracelets, taught to recognize symptoms, and instructed on using self-injectable epinephrine and activating emergency services. Clinical tolerance develops to most food allergens over time, except for peanuts, nuts and seafood. Periodic reintroduction of food allergens under physician supervision is warrant to determine whether clinical tolerance has develop[7,10-12].

There is a relationship between the decrease in serum food-specific IgE concentrations and the likelihood of developing tolerance. A greater decrease in serum food-specific IgE levels over a shorter period of time might be indicative of a greater likelihood of developing tolerance. The confirmation of this model and subsequent application in clinical practice would aid clinicians in the timing of food challenges and in providing prognostic information for patients and their families[82].

### *Medications*

Various medications can provide relief for certain aspect of food-induced disorders[7,10-12].

Antihistamines might partially relieve symptoms of oral allergy syndrome and IgE-mediated skin symptoms, i.e. itching and rash, but do not block systemic reactions. Systemic corticosteroids are generally effective in treating chronic IgE-mediated disorders (atopic dermatitis). A course of corticosteroids can be used to reverse severe inflammatory symptoms, but the side effects of protracted use are unacceptable. Epinephrine is the mainstay of treatment for anaphylaxis. Intramuscolar injection allows more efficient absorption than the subcutaneous route[83].

Novel therapies for IgE-mediated food allergy have been evaluated. Subcutaneous injections of humanized IgG anti-IgE antibodies (TNX-901), that recognize and mask an epitope in the CH3 region of IgE responsible for the binding to the high affinity Fc epsilon receptor I (FCεRI) on basophils and mast cells, for the treatment of patients affected by peanut allergy, showed a long-term increase in the average amount of peanut tolerated, but 25% of subjects showed no improvement[84].

Another anti-IgE preparation (Omalizumab) has been approved for the treatment of persistent allergic asthma in patients who are poorly controlled with inhaled corticosteroids, but has not yet been evaluated for its efficacy in treating patients with peanut allergy. Theoretically, anti-IgE antibody therapy should be protective against multiple food allergens, although it would have to be administered indefinitely to maintain its protective effects[85].

No conclusive studies indicate that standard allergen specific immunotherapy for birch- or ragweed pollen-induced rhinitis might improve pollen-food allergy syndrome. The risk/benefit ratio of traditional immunotherapy for the treatment of peanut allergy was considered unacceptable, because the injection of food protein results in anaphylaxis. To address this problem, engineered proteins are altered to remove IgE-binging epitopes that trigger anaphylaxis, while T-cell epitopes that could induce toler-

ance to specific food allergen, are preserved[86,87]. Other immunotherapeutic strategies include use of engineered proteins lacking IgE-binding sites, immunomodulatory sequences being effective in reversing IgE-mediated sensitization, and engineered chimeric molecules forming complexes with allergen-specific IgE bound to mast cells and basophils, inhibiting their functions.

Some recent studies suggested that probiotics, commonly defined as live microorganisms (bacteria from the genera *Lactobacillus, Bifidobacterium*, *Escherichia*, *Enterococcus*, *Bacillus* and *Saccharomyces*), administered in adequate amounts, which confer a beneficial health effect on the host, might be useful in the treatment and prevention of food allergy. They might provide maturational signals for the gut-associated lymphoid tissue, balance the generation of pro- and anti-inflammatory cytokines, reduce the dietary antigen load by degrading and modifying macromolecules, reverse the increased intestinal permeability, characteristic of children with food allergy, normalization of the gut microecology, and enhance specific sIgA responses frequently defective in children with food allergy[5,88-92].

### *Prevention*

Approaches to delay or prevent allergy through dietary manipulation have been considered. Some studies suggest a beneficial role for exclusive breast-feeding of infants at high risk for atopic diseases in the first 3-12 mo of life and avoidance of supplementation with cow's milk or soy formulas in favour of hypoallergenic formulas if breast-feeding is not possible[93].

Maternally ingested food can pass in immunologically intact form into breast milk and might induce reactions in infants. No conclusive studies indicate that manipulation of mother's diet during pregnancy or breast-feeding or the restriction of allergenic food from the infant's diet will prevent the development of food allergy[94]. The American Academy of Pediatrics recommends that high-risk infants (both parents and siblings atopic) be exclusively breast-fed, that lactating mothers avoid peanuts and nuts to avoid sensitization through breast milk, that the introduction of solid be delayed until 6 mo of age, and major allergens, such as peanuts, nuts and seafood, be introduced after 3 years of age[95].

## Abstract

G-protein-coupled receptor kinases (GRKs) interact with the agonist-activated form of G-protein-coupled receptor (GPCR) to affect receptor phosphorylation and to initiate profound impairment of receptor signaling, or desensitization. GPCR forms the largest family of cell surface receptors, and defects in GRK function have the potential consequence to affect GPCR-stimulated biological responses in many pathological situations.

**Key words:** G-protein-coupled receptor kinases; G-protein-coupled receptor; Signal; Transduction; Phosphorylation

## INTRODUCTION

G-protein-coupled receptor kinases (GRKs) are key modulators of G-protein-coupled receptor (GPCR) signaling. They constitute a family of seven mammalian serine-threonine protein kinases that phosphorylate agonist-bound receptor. GRKs-mediated receptor phosphorylation rapidly initiates profound impairment of receptor signaling and desensitization. Activity of GRKs and subcellular targeting is tightly regulated by interaction with receptor domains, G protein subunits, lipids, anchoring proteins and calcium-sensitive proteins. Moreover, GRK phosphorylation by several other kinases and autophosphorylation have recently been shown to modulate its functionality. This review summarizes our current knowledge of GRKs-regulatory mechanisms and their physiological function.

## GRKs STRUCTURE AND DISTRIBUTION

GRKs comprise a family of seven mammalian serine/threonine protein kinases that phosphorylate and regulate agonist-occupied or constitutively active GPCR[1].There are three sub-groups within the GRK family. GRK1 (rhodopsin kinase) and GRK7 (cone opsin kinase) form one distinct sub-group that is only found in retinal cells. The non-visual GRKs divide into two sub-groups: the GRK2 subfamily, consisting of GRK2 (b-ARK1) and GRK3 (b-ARK2), and the GRK4 subfamily, consisting of GRK4, GRK5 and GRK6. GRK4 is predominantly found in the testes [2], to lesser extent, in some brain regions and the kidney[3,4], whereas GRK2, 3, 5 and 6 are widely expressed. In addition, the different GRKs are highly specific in their receptor preference[5,6].

The basic structure of non-visual GRK family members is similar, with a highly conserved central (263-266 amino acids) catalytic domain. The N-terminal 185-amino acid region displays considerable homology between individual GRKs. The similarity of the N-termini of GRKs has led to speculation that this region might be important in receptor recognition. All non-visual GRKs have a regulator of G-protein signaling (RGS) domain within the N-terminus region, which provides a potential mechanism by which GRKs might regulate GPCR signal transduction *via* phosphorylation-independent mechanisms. Indeed, growing evidence suggests that this could be the case for GRK2 and GRK3[7-9]. GRK4-6 possess a highly conserved binding site (amino acids 22-29 for GRK5) for phosphatidylinositol (4, 5)-bisphosphate [PtdIns (4, 5) P2], which is thought to enhance catalytic activity[8].The C-terminal of GRK2 and GRK3 is longer than that of the GRK4 subfamily, and contains a 125-amino acid pleckstrin homology (PH) domain. This domain glycine-rich β-globulin (Gbg) plays a role in targeting and translocation of these primarily cytosolic GRKs to membranes following GPCR activation[8]. More recently, a second binding site for Gbg-subunits has been identified within the first 53 amino acids of GRK2[9], which suggests that either the N- or the C-terminal regions might be sufficient to allow GRK2 targeting to the membrane. GRK4 and GRK6 are post-translationally palmitoylated at one or more cysteine

residues clustered within the last 15-20 amino acids of the C-terminus, leading to an exclusive membrane-associated localization[8]. GRK5 is also predominantly membrane-associated, and in this case localization is not achieved through lipidation but instead through the PtdIns (4, 5) P2 binding domain of the N-terminus and a polybasic region (amino acids 547-560) close to the C-terminus[11]. Further heterogeneity is possible within the GRK4 subfamily because both GRK4 and 6 are expressed in multiple splice variant forms[10]. Indeed, one splice variant of GRK4 lacks the N-terminal PtdIns (4, 5) P2 binding region, although the physiological significance of isoformic variation is not understood at present. GRK1 and 7 share many structural similarities with the non-visual GRKs, including an N-terminal RGS-like domain and central catalytic domain. Both GRK1 and 7 are membrane-associated; however, unlike GRK4 and 6, this association is via post-translational farnesylation at the C-terminal.

## G-PROTEIN-COUPLED RECEPTOR ENDOCYTOSIS: DESENSITIZATION AND SIGNALING

GPCRs represent the largest family of transmembrane signaling molecules in the human genome. As such, they interact with numerous intracellular molecules, which can act either to propagate or curtail signaling from the receptor. Their primary mode of cellular activation occurs through heterotrimeric G proteins, which in turn can activate a wide spectrum of effector molecules, including phosphodiesterases, phospholipases, adenylyl cyclases and ion channels. In the immune system, triggering of GPCR is important for multiple activities, including cellular differentiation/activation, development of lymphoid tissue, and especially, for control of leukocyte chemotaxis. Active GPCRs are also the target of G-protein-coupled receptor kinases, which phosphorylate the receptors culminating in the binding of the protein arrestin. This results in rapid desensitization through inhibition of G protein binding, as well as novel mechanisms of cellular activation that involve the scaffolding of cellular kinases to GPCR-arrestin complexes. Arrestins can also serve to mediate the internalization of certain GPCR, a process which plays an important role in regulating cellular activity both by mediating long-term desensitization through down-regulation (degradation) of receptors and by recycling desensitized receptors back to the cell surface to initiate additional rounds of signaling. The mechanisms that regulate the subsequent intracellular trafficking of GPCR following internalization are largely unknown. Recently, however, it has become clear that the pattern of receptor phosphorylation and subsequent binding of arrestin play a critical role in the intracellular trafficking of internalized receptors, thereby dictating the ultimate fate of the receptor. In addition, arrestins have now been shown to be GPCRs that are capable of internalizing through arrestin-independent mechanisms[11].

GPCR responsiveness is determined by a tightly regulated balance among receptor signaling, desensitization, and resensitization. Receptor desensitization, the waning of GPCR responsiveness to the agonist with time, is an important, physiological "feedback" mechanism that protects against acute and chronic receptor over-stimulation[6]. The protein families of GRKs and arrestins play a pivotal role in the process of desensitization of agonist-activated GPCR[15-17]. There are seven known GRK subtypes, of which four members are expressed ubiquitously (GRK2, 3, 5 and 6)[15,18]. In the arrestin family, two members are restricted to photoreceptors, whereas β-arrestin1 and β-arrestin2 are expressed ubiquitously[15]. Agonist-induced desensitization of GPCR occurs via a multistep process. First, GRKs phosphorylate the intracellular loops and/or carboxyl terminal tail of the receptor, a process that enhances the affinity of the receptor for binding of cytosolic arrestin proteins. Subsequent binding of phosphorylated receptors by arrestins sterically inhibits interaction of the receptor with the G protein. Thus, agonist-induced phosphorylation of GPCR by a GRK, followed by binding of arrestins, efficiently prevents further coupling of the receptor to its G protein, thereby reducing or preventing receptor signaling[12]. Finally, the GRK-arrestin system promotes clathrin-mediated internalization of inactivated receptors to endosomal compartments for subsequent degradation or resensitization[15-17,19].

It is notable that besides its role in desensitization, β-arrestin-mediated receptor internalization can also regulate signal transduction. The internalized GPCR-β-arrestin complex can form a signalosome that activates signaling proteins, such as ERK1/2, p38 MAPK, and JNK. In addition, arrestins act as scaffolds that connect activated GPCR with tyrosine kinase c-Src and the PI-3K-AKT and NF-κB pathways[13,14].

GRKs display activities well beyond their classical role in receptor phosphorylation as well. For example, GRKs have been shown to interact with PI-3Ks and a guanosinetriphosphatase (GTPase)-activating proteins, GIT1, which are involved in regulating receptor trafficking and signaling[15,16]. In addition, GRK2 interacts with a component of the MAPK pathway, as well as with the PI-3K substrate AKT[17,18]. Furthermore, GRK2 and 3 are well-known to bind the Gβγ subunit complex, a process that induces activation of these GRKs. Direct interaction of GRKs with G proteins is suggested by the presence of regulator of RGS-like domains (RH domains) in GRKs[7,22-24]. RGS proteins act as GTPase-activating proteins (GAPs), which induce hydrolysis of guanosine 5'-triphosphate (GTP) and thereby inactivation of GTP-bound Gβγ subunits[19,20]. Selective binding of activated Gαq (and Gα-11) to RH domains of GRK2 and GRK3 (but not to RH domains of GRK1 and 4) was found to selectively inhibit Gq signaling. However, as GRK2/3 were shown not to act as GAPs for Gq[21,27-29], the main role of RH domains in GRK2/3 appears to prevent activated Gq from interacting with downstream effector molecules (Figure 1).

GRKs and arrestins also interact with non-GPCR. For instance, GRKs and arrestins interact with transforming growth factor -β (TGF-β), epidermal growth factor (EGF), and insulin growth factor receptors[22-28]. In addition, β-arrestin was found to regulate activity of Notch, an important protein in neurogenesis, angiogenesis, and

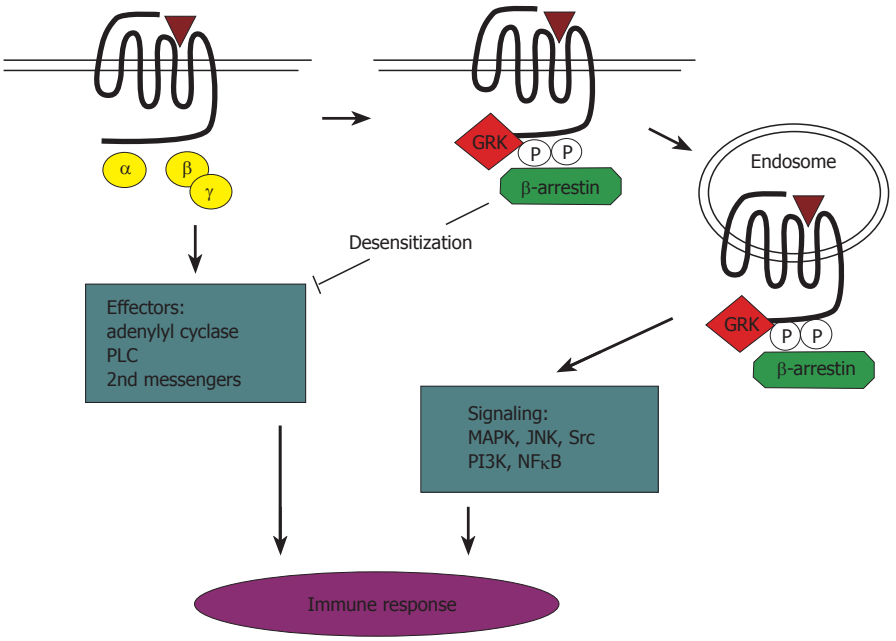

**Figure 1** Schematic summary of the role of GRKs/arrestins in activation, signaling, and desensitization of GPCRs in the immune system. Agonist-activated GPCRs are phosphorylated rapidly by GRKs, leading to recruitment of arrestins. This process, called homologous desensitization, prevents further coupling of the receptor to its G protein, thereby reducing or preventing receptor signaling. In addition, GRKs and arrestins can also act as signal transducers in various signaling pathways. PLC: Phospholipase C.

lymphoid development[23]. GRKs and arrestins may directly affect functioning of these non-GPCR or modulate signaling of these receptors indirectly. Transactivation of growth factor receptors, such as the EGF receptor by GPCR, the β2- adrenergic receptor, CXCR4 chemokine receptor, or PGE2 receptor, has been described extensively[24-30]. Hence, GRK/arrestin-mediated regulation of GPCR signaling may indirectly affect signaling of such growth factor receptors. Interestingly, a recent study shows that formation of a PGE/β-arrestin-1/c-Src signaling complex in colorectal carcinoma cells is a crucial step in PGE2-mediated transactivation of the EGF receptor, indicating that arrestins also directly regulate the transactivation of a growth factor receptor by a GPCR agonist[39].

## G-PROTEIN-COUPLED RECEPTOR INTERNALIZATION

An important aspect of GPCR activity and regulation is the internalization or sequestration of agonist-activated receptors into the intracellular membrane compartments of the cell. GPCR internalization has become the subject of intensive investigation over the past several years[25-34]. Consequently, a large volume of data has accumulated regarding the mechanisms regulating the endocytosis of a wide variety of different GPCRs. These studies have revealed GPCR domains involved in receptor endocytosis, some of the molecular intermediates that regulate GPCR endocytosis, and the potential for GPCR to internalize by multiple endocytic mechanisms. In addition, although the molecular mechanism involved in the initiation of GPCR endocytosis are best characterized for theβ2AR, recent studies using other GPCRs have revealed an important diversity in the patterns of GPCR endocytosis and intracellular trafficking.

The concept that GPCR are lost from the cell surface following agonist activation originated from the observation that β-adrenergic agonist treatment resulted in a loss of β-adrenergic receptor recognition sites on the surface of frog erythrocytes[26]. Subsequently, cell surface *versus* internalized β2AR binding sites were discriminated from one another either by differential sedimentation on a sucrose gradient or by using hydrophobic and hydrophilicβ-adrenergic ligands[26-27]. Internalized receptors were found in a "light vesicular" fraction, whereas cell surface receptors were found in a "heavy vesicular" plasma membrane fraction[26]. Similarly, internalized β2AR was accessible to hydrophobic, but not hydrophilic, adrenergic ligands[27]. More recently, the subcellular redistribution of cell surface β2AR in response to agonist activation was demonstrated by immunocytochemical staining of epitope-tagged receptors[28], as well as in real time microscopy in living cells using a green fluorescent protein (GFP)-taggedβ2AR[29]. Similar experiments have now been performed for several GPCR[30-41]. The rate at which GPCR internalize seems to be receptor-specific. For example, the A1 adenosine receptor internalizes quite slowly (t1/2 = 90 min) when compared with the A3 adenosine receptor (t1/2 = 19 min)[31]. These kinetic differences suggest that GPCR internalization can be mediated by multiple endocytic mechanisms and/or that structural heterogeneity between receptor subtypes modulates their relative affinities to bind endocytic adaptor.

## G-PROTEIN-COUPLED RECEPTOR KINASES AND DISEASES

GPCRs form the largest family of cell surface receptors, and the defects in GRK function have the potential consequence to affect GPCR-stimulated biological responses in many pathological situations. Furthermore, the regulation of GRK levels in opiate addiction, cancers, psychiatric diseases, cystic fibrosis and cardiac diseases is discussed. Both transgenic mice and human pathologies have demonstrated the importance of GRKs in the

signaling pathways of rhodopsin, β-adrenergic and dopamine-1 receptors. The modulation of GRK activity in animal models of cardiac diseases can be effective to restore cardiac function in heart failure and opens a novel therapeutic strategy in diseases with GPCR dysregulation[32].

In human heart failure, impaired βAR signaling compromises cardiac sensitivity to inotropic stimulation[33]. The loss of receptor signaling is associated with an approximate three-fold elevation in myocardial βARK1 expression and GRK activity[34,35]. Myocardial ischemia and hypertension have also been associated with increased expression and activity of βARK1[36,37]. These aspects of human heart disease are similarly evident in animal models, where βARK1 levels are increased in cardiac hypertrophy[38] ischemia[43] and heart failure[39-43]. Given the variety of pathological insults represented in the animal models, βARK1 up-regulation appears to be an early common event in the pathogenesis of heart failure. In fact, βARK1 elevation often precedes the development of clinical heart failure and may represent a novel early marker for cardiac dysfunction. Like βARK1, GRK5 expression and activity are elevated in animal models[40-41], although its role in human heart failure remains unclear. In contrast, GRK3 expression is not increased in human heart failure[42]. At present it seems that for cardiovascular diseases, βAR polymorphisms do not play a role as disease-causing genes; however, they might be risk factors, might modify disease, and/or might influence progression of the disease. Furthermore, βAR polymorphisms might influence drug responses. Thus, evidence has accumulated that a βAR polymorphism (the Arg389GlyβAR) may affect the response to βAR-blocker treatment[42].

GRKs are implicated in the pathophysiology of human diseases, such as arterial hypertension, heart failure and rheumatoid arthritis. While GRK2 and 5 have been shown to be involved in the desensitization of the rat thyrotropin receptor (TSHR), their role in the pathophysiology of hyperfunctioning thyroid nodules (HTNs) is unknown. Therefore, scholars analyzed the expression pattern of the known GRKs in human thyroid tissue and investigated their function in the pathology of HTNs. The expression of different GRKs in human thyroid and HTNs was measured by Western blotting. The influence of GRK expression on TSHR function was analyzed by co-expression experiments in HEK 293 cells. Studies demonstrated that in addition to GRK2, 5 and 6, GRK 3 and 4 were also expressed in the human thyroid. GRK2, 3, 5 and 6 were able to desensitize TSHR *in vitro*. This GRK-induced desensitization is amplified by the additional over-expression of β-arrestin 1 or 2. No any mutation was found in the GRK2, 3 and 5 from 14 HTNs without TSHR mutations and Gsalpha mutations. The expression of GRK3 and 4 was increased in HTNs independently from the existence of TSHR mutations or Gsalpha mutations. In conclusion, the increased expression of GRK3 in HTNs and the ability of GRK3 to desensitize the TSHR *in vitro*, suggest a potential role for GRK3 as a negative feedback regulator for the constitutively activated cAMP pathway in HTNs[43].

## CONCLUDING REMARKS

Much new information regarding the phosphorylation and regulation of GPCR by GRK2 and GRK3 and their role in GPCR signaling has been revealed during the past few years. More recent studies have started to indicate roles for GRK4, GRK5 and GRK6, both in transfected cell lines and in primary cells. However, it remains to be established whether the multiplicity of GRKs is related to the specificity or differential regulation of GPCR signaling or indeed other, yet to be defined, function. The association of particular GRKs within receptor signaling, trafficking and switching is a key area of current and future investigation

## Abstract

**AIM:** To investigate the glutathione-S-transferase M1 (GSTM1) polymorphisms in three Chinese minorities, Kazakh, Uygur, and Tajik; and the pathological significance of GSTM1 polymorphisms in esophageal carcinogenesis in Kazakh.

**METHODS:** A total of 1121 blood samples (442 males and 679 females) were obtained from healthy Kazakh (654), Uygur (412) and Tajik (55). Primary esophageal squamous cell cancer (ESCC) tissues from Kazakh were obtained from 116 patients who underwent surgery. GSTM1 polymorphisms were analyzed by a combined approach of PCR and electrophoresis techniques.

**RESULTS:** GSTM1 null genotype was found in 62.63% Uygur, 50.91% Tajik and 47.40% Kazakh. A significantly higher frequency of GSTM1 null genotype in Uygur was observed compared with Kazakh (OR: 1.859, 95% CI: 1.445 -2.391, $\chi^2$ = 23.71, $P$ = 0.000). In addition, GSTM1 null genotype was found in 23.53% of well-differentiated ESCC in Kazakh, in 49.23% of poorly differentiated ESCC, with a significant difference (OR: 3.152, 95% CI: 1.403-7.080, $\chi^2$ = 8.018, $P$ = 0.007).

**CONCLUSION:** There is a marked difference in the frequency of common GSTM1 null genotype between Uygur and Kazakh. GSTM1 null genotype is associated with differentiation of ESCC in Kazakh.

**Key words:** Glutathione-S-transferase M1; Kazakh; Uygur; Tajik; Esophageal cancer

## INTRODUCTION

Esophageal cancer (EC) is the sixth leading cause of cancer mortality worldwide[1]. The incidence of EC is highly variable in different populations, with more than a 50-fold difference between the high- and low-risk ethic groups[2,3]. For example, Turkomans in northeastern Iran are considered to be a very high-risk group, with age standardized prevalence (ASR) of over 100/100 000 for both men and women; whereas the prevalence of EC in pure Zoroastrian Persians in Iran and India are known to be considerably low, with ASRs of 3-7/100 000.

Epidemiological studies have identified several high EC incidence areas, such as the western and northern parts of China[4], certain areas of France and Brazil[5]. In Xinjiang Uygur Autonomous Region of China, there are thirteen minority ethnical groups (Uygur, Han, Hazakh, Tajik, Hui, Uzbek, Kerkez, Man, Mongolia, Tatar, Darur, Xibo, and Russian), who have lived there since ancient times. Uygur, Hazakh and Tajik are the major residents among those minorities with populations of 8 million, 2 million, and 40 thousand, respectively. Although they are all Muslims and have certain similarities in their life styles, the morbidities of EC among them are quite different. The incidence of EC in Kazakh is highest among all ethnics in Xinjiang, with an age-adjusted mortality of 90.7/100 000, significantly higher than that in Uygur (23.4/100 000) and almost 18-fold higher than that in Tajik (5.13/100 000)[4].

Glutathione S-transferases (GSTs) constitute a superfamily of ubiquitous multifunctional enzymes, which play a key role in cellular detoxification and protection of macromolecules from being attacked by reactive electrophiles[6]. GSTs catalyze the conjugation of tripeptide

glutathione (GSH) to a wide variety of exogenous and endogenous chemicals with electrophilic functional groups (e.g. products of oxidative stress, environmental pollutants, and carcinogens), thereby neutralizing their electrophilic sites, and rendering the products more water-soluble[7]. Based on sequence homology and immunological cross-reactivity, human cytosolic GSTs have been grouped into seven families, designated GST Alpha, Mu, Pi, Sigma, Omega, Theta, and Zeta[8]. The GSTs presumably arise from a single common ancestor and their substrate specificity and diversity have been reshaped by gene duplication, recombination and mutation.

There are marked intra- and inter-ethnic differences in the frequencies of common GST mutations[9,10]. For example, the distribution of GSTM1 genotype frequencies in Indian is significantly different from that in Chinese[11]. GSTM1 polymorphisms have been considered as a risk factor for EC development in a number of studies; however the overall results of such studies are inconsistent[12,13]. Up to date, data on genetic analysis of GSTM1 in Uygur, Tajik are lacking[14], and the correlation between GSTM1 polymorphisms and high incidence of EC in Kazakh has not been clarified.

The present study aimed to investigate the GSTM1 polymorphisms in healthy Kazakh, Uygur, and Tajik; and to explore the pathological significance of GSTM1 polymorphisms in esophageal carcinogenesis.

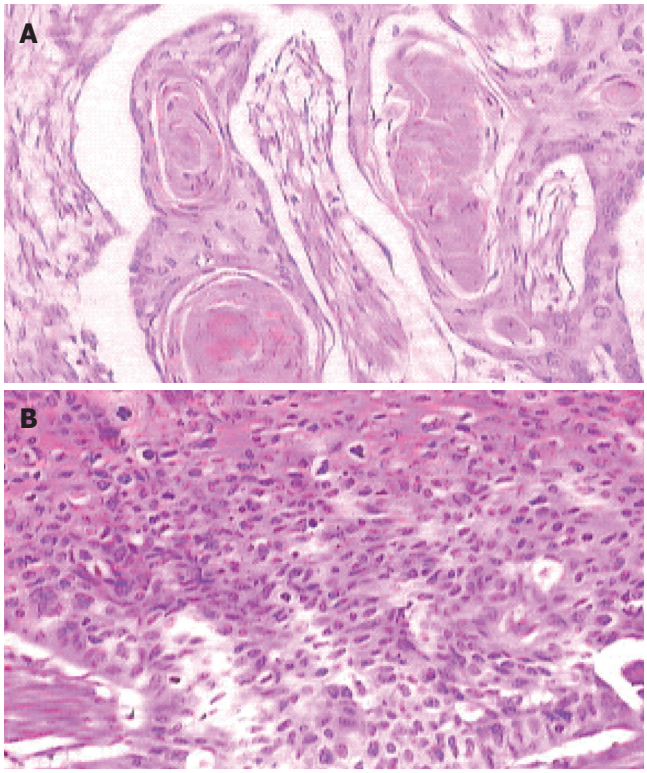

**Figure 1** Histological types of primary ESCC (HE × 400). **A:** Well-differentiated ESCC; **B:** Poorly-differentiated ESCC.

## MATERIALS AND METHODS

### *Blood and tissue*

A total of 1121 blood samples was collected from healthy Kazakh (269 males and 385 females; age 35-65 years, mean 46.5 years), Uygur (146 males and 266 females; age 30-68 years, mean 45.5 years) and Tajik (27 males and 28 females; age 32-70 years, mean 47.5 years). All subjects from north-western of Xinjiang received clinical and biochemical assessments before entering this study and none of them has a clinical or family history of EC. Specimens of 116 primary EC tissues from Kazakh (84 males and 32 females; age 42-76 years, mean 55.5 years), with histological confirmation of primary ESCC, was recruited from two hospitals in Xinjiang from July 1999 to June 2004.

### *DNA extraction and GSTM1 genotyping*

DNAs from healthy controls were extracted from peripheral leukocytes using the classical phenol-chloroform extraction method[15]. Genomic DNA in cancer tissue embedded by paraffin was prepared by proteinase K digestion and phenol/chloroform extraction, followed by ethanol precipitation, as described by Diffenbach[16]. The purity and concentration of DNA was examined by ultraviolet densitometry. GSTM1 genotyping for gene deletion was performed by PCR using primers 5'-GAAC TCCCTGAAAAGCTAAAGC-3' and 5'-GTTGGGCT CAAATATACGGTGG-3'[17], which produced a 219 bp product. At the same time, β-globin gene was amplified, resulting in a 350 bp product as an internal control. PCR was performed in a reaction mixture of 20 μL containing 100 ng sample DNA, 10 mmol/L Tris-HCl, 50 mmol/L KCl, 1.5 mmol/L $MgCl_2$ pH 8.4, 0.1 mmol/L of each dNTP and 1.25 U Taq polymerase. After initial denaturation for 5 min at 94℃, 35 cycles were performed at 94℃ for 30 s (denaturation), at 63℃ for 30 s (annealing) and at 72℃ for 30 s (extension), followed by a final step for 5 min at 72℃. The amplified products were visualized by electrophoresis in ethidium-bromide-stained 1.5% agarose gel in TBE buffer. For genotype of GSTM1 deletion, no amplified product was observed except the band of β-globin gene.

### *Statistical analysis*

Chi-square test was used to examine the correlation between the GSTM1 polymorphism among three healthy ethnics, and association of GSTM1 polymorphisms with differentiation of ESCC in Kazakh with SPSS software (11.0). Odds ratios (ORs) and 95% confidence intervals (CIs) of different variables among groups were calculated.

## RESULTS

### *Histological types of primary ESCC*

Histological confirmation of primary ESCC including well-differentiated and poorly-differentiated are shown in Figure 1.

### *GSTM1 genetic polymorphisms in ESCC of Kazakh*

Figure 2 shows the PCR-amplified fragment of GSTM1. Genotype data for GSTM1 in the three ethnics are summarized in Table 1. The frequency of GSTM1 null mutation in Kazakh was significantly lower than that in Uygur (OR:1.859, 95% CI: 1.445-2.391, $\chi^2 = 23.71$, $P = 0.000$, $P < 0.05$). There was no significant difference

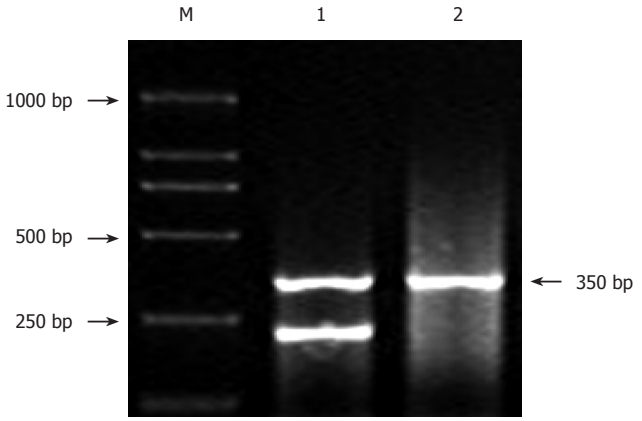

**Figure 2** PCR of the GSTM1 genes. Lane M: DL 2000 DNA molecular weight marker; lane 1: GSTM1 genotype present; lane 2: homozygous deletion of GSTM1.

in the frequency of the GSTM1 null genotype between Uygur (62.63%) and Tajik (50.91%) ($\chi^2 = 2.804$, $P > 0.05$), and there was no significant difference between the Kazakh (47.40%) and Tajikic either ($\chi^2 = 0.250$, $P > 0.05$). In addition, no significant difference of GSTM1 null polymorphisms between the two genders of each ethnical group was observed.

There was a significant difference in the frequency of the GSTM1 null genotype between well-differentiation (high grade) (76.47%) and poor-differentiation (low grade) group (50.77%) of EC of Kazakh (OR 3.152, 95% CI 1.403-7.080, $\chi^2 = 8.018$, $P < 0.05$) (Table 2).

The odds ratio of GSTM1 null genotype of Kazakh people with lowly differentiated ESCC was 3.152-fold higher than those people with highly differentiated ESCC.

**Table 1 Frequencies of GSTM1 polymorphisms in three ethnics**

| Ethnic | GSTM1 | | OR (95% CI) | *P* |
|---|---|---|---|---|
| | Null [*n* (%)] | Present [*n* (%)] | | |
| Kazakh | | | | |
| Male | 130 (48.33) | 139 (51.67) | | |
| Female | 180 (46.75) | 205 (53.25) | | |
| Total | 310 (47.40) | 344 (52.60) | | |
| | | | [1]1.859 (1.445-2.391) | 0.000 |

## DISCUSSION

In this study, we investigated differences in the prevalence of GSTM1 null genotypes in three ethnical groups, Kazakh, Tajik and Uygur, in Xinjiang. As far as we know, we are the first to report the frequency of GSTM1 null genotype in Tajik. GSTM1 null genotype in Uygur in Xinjiang has a similar frequency when compared with Zoroastrians Iranian[18] and Han Chinese[19,20].

The study showed the association of GSTM1 null genotype with ESCC differentiation in Kazakh, suggesting the involvement of GSTM1 null genotype in the development of ESCC. Differences in the risk of EC development between high- and low-risk populations may partly be attributed to the genetic make-up of the populations, reflected by their different susceptibility to EC. GSTM1 encoding metabolic enzymes, the alteration in expression and function of which may increase or decrease carcinogen activation/detoxication, expressed as different phenotypes with different cancer risk[21-23]. Homozygous deletions of such genes, called GSTM1 null genotypes, result in the phenotype of no enzyme activity[24]. Individuals with null genotypes of GSTM1 are reported at high risk for developing several types of cancers, e.g. breast, lung, cervix[25-27] and bladder cancers[28-32]. However, the frequency of GSTM1 null genotype was low in Kazakh with high risk to EC, suggesting that the lack of the null allele or the other genes may play roles in carcinogenesis of ESCC by different mechanisms or via different pathways, from that of the reported breast, lung, cervix and bladder cancers. This large sample study on 654 of healthy Kazakh individuals and our previous genotyping results[14] have confirmed this contradictory finding of low frequency GSTM1 null genotype among Kazakh with a high susceptibility to ESCC.

In conclusion, there are different frequencies of GSTM1 null genotype among Uygur, Tajik and Kazakh, however, a significant difference is only observed between Uygur and Kazakh. The GSTM1 null genotype may play a role in the carcinogenesis and progress of ESCC.

## ACKNOWLEDGMENTS

We thank those people who provided the blood samples of Kazakh, Tajik and Uygur individuals.

## Abstract

**AIM:** To determine the HLA-DQ locus in Mexican patients with Chronic gastritis and gastric adenocarcinoma.

**METHODS:** Oligotyping for HLA-DQ locus was performed in 45 Mexican patients with chronic gastritis and 13 Mexican patients with diffuse-type gastric adenocarcinoma, and was then compared with 99 clinically healthy unrelated individuals. *H pylori* infection and CagA status were assessed in patients by enzyme-linked immunosorbent assay (ELISA) method.

**RESULTS:** We found a significant increased frequency of HLA-DQB1*0401 allele in *H pylori*-positive patients with chronic gastritis when compared with healthy subjects [19 *vs* 0%, $P = 1 \times 10^{-7}$, odds ratio (OR) = 4.96; 95% confidence interval (95% CI), 3.87-6.35]. We also found a significant increased frequency of HLA-DQB1*0501 in patients with diffuse-type gastric carcinoma in comparison with healthy individuals ($P = 1 \times 10^{-6}$, OR = 13.07; 95% CI, 2.82-85.14).

**CONCLUSION:** HLA-DQ locus may play a different role in the development of *H pylori*-related chronic gastritis and diffuse-type gastric adenocarcinoma in the Mexican Mestizo population.

**Key words:** HLA-DQ; HLA-DQ5; HLA-DQB1*0501; *H pylori*; Chronic gastritis; Gastric cancer; Diffuse-type adenocarcinoma

## INTRODUCTION

*H pylori* infection is, in addition to being the main etiologic agent for chronic gastritis, a major cause of peptic ulcer and gastric cancer[1]. In developing countries, prevalence of *H pylori* infection is > 80% among middle-aged adults, whereas in developed countries prevalence ranges from 20%-50%. Approximately 10%-15% of infected individuals will develop peptic disease and 3% a gastric neoplasm[2]. Therefore, *H pylori* infection is a necessary but not a sufficient cause of severe forms of gastric disease. In 1994 the International Agency for Research in Cancer (IARC), a branch of the World Health Organization (WHO), declared *H pylori* to be a Group 1 carcinogen, a definitive cause of cancer in humans[3]. Host genetic constitution is also thought to play a role in gastric carcinogenesis[4]. Among genetic factors, individual differences in inflammatory responses may protect or predispose to malignant transformation of the gastric mucosa. Human leukocyte antigens (HLA) class Ⅱ genes of the Major histocompatibility complex (MHC) are a group of highly polymorphic genes located in the short arm of chromosome 6 and are particularly important in controlling specific immune recognition[5]. HLA class Ⅱ antigens are capable of binding tumor peptides, and T-cell recognition of a combination of HLA class Ⅱ and bound tumor antigen may result in either induction of an effective anti-tumor immune re-

sponse or suppression of such immune response[6,7]. Moreover, adherence of *H pylori* to HLA class Ⅱ molecules expressed in gastric epithelial cells has been demonstrated[8].

Previous investigations have linked specific HLA-DQ alleles to gastric diseases, among others; Azuma *et al*[9] found increased susceptibility for *H pylori* infection in patients carrying the HLA-DQA1*0301 allele, whereas those displaying the HLA-DQA1*0102 allele were resistant to the infection; in other words, in Japan the HLA-DQA1*0102 allele has a lower frequency in *H pylori*-positive patients with atrophic gastritis compared with those with superficial gastritis and normal controls[10]. Conversely, the HLA-DQB1*0401 allele was found to be associated with atrophic gastritis in *H pylori*-infected patients[11]. On the other hand, the HLA-DQB1*0301 allele has been found more commonly in Caucasian patients with gastric adenocarcinoma[12]. The aim of this study was to investigate the relationship between HLA-DQ locus and presence of chronic gastritis and gastric adenocarcinoma in a Mexican population.

## MATERIALS AND METHODS

### Subjects

Forty five patients with chronic gastritis and 13 patients with diffuse-type gastric adenocarcinoma, all of them histologically confirmed, were studied. All patients were attended at the outpatient clinic of the Instituto Nacional de Cancerología (INCan) in Mexico City, because of gastric symptoms. A HLA-DQ database obtained from ninetynine healthy Mexican Mestizo asymptomatic subjects, without clinical evidence of chronic gastritis, peptic ulcer disease, gastric cancer, and personal or familiar history of autoimmune diseases was used for comparative purposes. Mexican Mestizo individuals included in the present study have a proportion of 56% Native American Indian genes, 40% White genes, and 4% Black genes[13]. Informed consent was obtained from all individuals considered in the present study.

### Diagnosis of H pylori infection

*H pylori* status was assessed in patients by serologic analysis. Briefly, immunoglobulin G (IgG) antibodies against *H pylori* were tested in sera from 58 cases employing an enzyme-linked immunoabsorbent assay (ELISA) that was previously validated in Mexican population[14]. A pool of whole antigen preparation was obtained from sonicated preparations of three *H pylori* strains. Serum samples were diluted 1:1000, and 100-μL aliquots were plated. Next, a 1:1000 dilution of antihuman IgG monoclonal antibodies conjugated to alkaline phosphatase (Southern Biotech, Birmingham, AL, USA) was applied. A 1-mg/mL solution of p-nitrophenylphosphate was used as substrate and absorbance was read at 405 nm. All samples were analyzed by duplicate, the final value being the average of the two measurements.

### ELISA for IgG anti-CagA

IgG antibodies for cytotoxin-associated gene A (CagA) protein were tested in patient sera utilizing an ELISA assay previously validated by our group[14]. A total of 0.1 μg/well of recombinant CagA antigen (Acambis, Cambridge, MA, USA) was used and serum at a 1:200 dilution was added. Next, a 1:1000 dilution of antihuman IgG monoclonal antibodies conjugated to alkaline phosphatase (Southern Biotech) was applied. A 1-mg/mL solution of p-nitrophenylphosphate was used as substrate and absorbance was read at 405 nm.

### HLA-DQ typing

Genomic DNA was obtained from peripheral blood leukocytes and extracted by standard techniques[15,16].

### Amplification of genomic DNA

HLA-DQA1 and -DQB1 typing were performed by a polymerase chain reaction (PCR) procedure using Taq DNA polymerase (Promega, Madison, WI, USA) and hybridization with PCR sequence-specific oligonucleotide probes (PCR-SSOP). Primers used for HLA-DQ amplification included DQAAMP-A, -B, DQBAMP-A, and -B. These were synthesized in a DNA-SM automated synthesizer (Beckman, Palo Alto, CA, USA). These typing techniques were approved by the 12th International Histocompatibility Workshop.

### Dot blot hybridization

Five percent of the amplified DNA was denatured in 0.4 mol/L NaOH for 10 min, neutralized in 1 mol/L of ammonium acetate, and transferred to a Hybond-N membrane (Amersham, Bucks, UK). The filters were prehybridized at 42℃ for 30 min in a solution containing 6X SSPE (30X SSPE: 4.5 mol/L NaCl, 0.3 mol/L $NaH_2PO4$, 30 mmol/L EDTA, pH = 7.4), 5X Denhard solution (2% bovine serum albumin, 2% polyvinylpyrrolidone 40, 2% Ficoll 400), 0.1% Lauryl-sarcosine, and 0.02% SDS. Then, the oligonucleotide probes labeled with Digoxygenin dideoxy-Uridine-Triphosphate (Dig-11-ddUTP) were added and hybridized at 42ºC for 3 h. The filters were washed twice in 2X SSPE, 0.1% SDS at room temperature for 10 min, once in TMAC solution [50 mmol/L Tris-HCl (pH = 8.0), 3 mol/L tetramethylammonium chloride, 2 mmol/L EDTA, 0.1% SDS] at room temperature for 10 min, and twice at 60℃ for 10 min. Dots were revealed using the Dig Nucleic Acid Detection Kit (Boehringer Mannheim Biochemical, Mannheim, Germany).

### Oligonucleotide probes

Information on the sequences and specificities of the DQA1 and -B1 oligonucleotides was gathered from the 12th International Histocompatibility Workshop. Oligonucleotide synthesis performed using the cyanoethyl phosphoramidite technique in a Beckman DNA-SM automated DNA synthesizer following the manufacturer's protocol.

### Statistical analysis

Gene frequencies were compared using a 2 × 2 contingency table and $\chi^2$ test. Odd ratios (OR) and 95% confidence intervals (95% CI) have been calculated for the disease in carriers of specific alleles; OR were not adjusted by gender or age. Comparisons of allele frequencies between sub-groups were carried out using the EPIINFO statistical package (Version 5.0, USD Incorporated 1990, Stone Mountain, GA, USA). All *P* values quoted were corrected

by Bonferroni test for multiple comparisons taking into account the number of alleles studied. Statistical significance was considered as $P < 0.05$.

## RESULTS

### Subjects

Among patients with chronic gastritis, there were 35 female and ten male patients with a mean age of 56.3 years (range, 22-87 years). Thirteen patients with diffuse-type adenocarcinoma were also studied; there were eight women and five men with a mean age of 65.5 years (range, 41-90 years). Among patients suffering from chronic gastritis, 24 individuals were serologically positive for *H pylori* (17 females and seven males), while 14 patients were serologically positive for CagA (12 females and two males, respectively); five patients (four woman and one man) were eliminated because they were CagA-seropositive but *H pylori*-seronegative yielding thus a false-positive reaction, as previously stated[17]. Mean age of patients harboring *H pylori* infection was 58.9 years and for CagA-positive individuals, 56.7 years; mean age of *H pylori*-negative individuals was 53.2 years. Conversely, in the group of gastric carcinoma cases there were four patients with serologic evidence of *H pylori* infection (three women and one man), whereas solely one female patient was *H pylori* CagA-positive. Mean age of *H pylori*-positive patients was 74 years, whereas for *H pylori*-negative patients this was 61.7 years. CagA was positive only in one woman 57 years of age. Group of clinically healthy subjects no serologically-tested consisted of 47 women and 52 men, with a mean age of 33 years.

### HLA genotyping in patients with chronic gastritis

HLA-DQA1 allele frequencies were distributed similarly between *H pylori*-positive and -negative patients with a diagnosis of chronic gastritis (data not shown).

In addition, regarding HLA-DQB1 locus a significant increased frequency of HLA-DQB1*0401 was observed in the *H pylori*-positive group compared with the *H pylori*-negative group and clinically healthy individuals (Table 1). A significantly increased frequency of the HLA-DQA1*0501 allele was found in the group of chronic gastritis and CagA-positive patients compared with CagA-negative patients and clinically healthy individuals. Moreover, DQA1*0104 allele frequency was increased in patients with chronic CagA-negative gastritis compared with patients with CagA-positive chronic gastritis and clinically healthy individuals (Table 2).

Table 3 shows an increased frequency of the HLA-DQB1*0501 and DQB1*0401 alleles in the group of patients with CagA-negative chronic gastritis compared with patients with CagA-positive chronic gastritis and clinically healthy subjects.

Haplotype analysis revealed significant increased frequency of HLA DQA1*0401-DQB1*0401 in *H pylori*-positive patients compared with clinically healthy subjects (Table 4).

### HLA genotyping in patients with gastric diffuse-type adenocarcinoma

No significant differences were observed in the allele frequency of DQA1 locus between patients with diffuse-type gastric adenocarcinoma and clinically healthy individuals (data not shown). On the other hand, the HLA-DQB1 locus showed an increased frequency of the HLA DQB1*0501 allele in patients with gastric adenocarcinoma compared with clinically healthy individuals ($P = 1 \times 10^{-6}$, OR = 13.07; 95% CI, 2.82-85.14) but not when *H pylori*-positive and *H pylori*-negative subjects were compared ($P = 0.38$) (Table 5). In addition, HLA-DQB1*0501 allele frequency in *H pylori*-negative patients was also significant when compared with healthy subjects. No significant differences were found in the analysis between patients with gastric adenocarcinoma according to CagA status and clinically healthy individuals (data not shown). In addition, haplotype analysis did not show significant differences between HLA-DQA1-DQB1 haplotypes in patients with gastric diffuse-type adenocarcinoma and clinically healthy individuals (data not shown).

## DISCUSSION

Several previous studies have reported an association between HLA class II molecules and gastric diseases. In this study, we found significant increased frequencies of HLA-DQA1*0501 in patients with *H pylori* CagA-positive serology when compared with *H pylori* CagA-negative individuals as well as clinically healthy subjects, and HLA-DQA1*0104 in *H pylori* CagA-negative patients when compared with *H pylori* CagA-positive patients and clinically healthy individuals. Among patients harboring *H pylori*-associated gastritis, those who were CagA-negative showed a significant increased frequency of HLA-DQB1*0401 and HLA-DQB1*0501 alleles compared with CagA-positive patients and clinically healthy Mexican Mestizo individuals. HLA-DQA1*0401-HLA-DQB1*0401 haplotype showed to be a combination with higher susceptibility for *H pylori*-related gastritis. The finding of a high frequency of the HLA-DQB1*0601 allele in patients with chronic *H pylori*-negative gastritis emphasizes the participation of pathogenic mechanisms other than *H pylori* infection. This association has not been reported previously, and it is important to note that a larger sample size should be studied to maintain such an association.

Regarding patients harboring *H pylori*-associated gastritis, Sakai *et al*[11] also found an association between HLA-DQB1*0401 allele and presence of atrophic gastritis.

On the other hand, the HLA-DQA1*0501 allele was associated in patients with chronic *H pylori*-positive, CagA-positive gastritis. HLA-DQ5 has been also reported in association with atrophy and intestinal metaplasia of the gastric mucosa[18]. Other associations between HLA-DQA locus and gastric diseases have been described: Azuma *et al* found a protective effect of the HLA-DQA1*0102 allele against *H pylori* infection and intestinal-type adenocarcinoma[10], as well as a high susceptibility for *H pylori* gastritis and duodenal ulcer in patients carrying the HLA-DQA1*0301 allele[19].

Separately, Magnuson *et al*[20] found that HLA-DQA1*0102 was inversely associated with *H pylori*-seropositivity with no correspondence with a reduced risk for gastric cancer; this more notorious with diffuse-type carcinoma.

Moreover, Watanabe *et al*[21] have recently shown an increased allele frequency of HLA-DQB1*0401 in patients suffering from intestinal-type adenocarcinoma compared with individuals with *H pylori*-infected non-ulcer dyspepsia. In a Mexican study, Garza-González *et al*[22] concluded that HLA-DQA1*0503 allele could confer resistance to development of carcinoma and high-grade dysplasia of the stomach. Nevertheless, in our study we confirmed no protective effect of HLA-DQ alleles. We also found an association between HLA-DQB1*0501 and diffuse-type gastric adenocarcinoma as compared with clinically healthy individuals.

Interestingly, HLA-DQB1*0501 allele frequency was statistically significant only in patients with gastric carcinoma despite the fact that the majority of patients with gastric carcinoma were *H pylori*-negative and those who were infected, CagA-negative. This association was strong, considering the small number of cases under study; however, it is necessary to increase the sample size in order to confirm such an association. HLA class Ⅱ molecules are closely associated with gastric diseases, particularly the HLA-DQ locus.

Risk for gastric diseases among ethnic groups with different HLA class Ⅱ allele expression reflects several polymorphisms of this and other loci, as genes related

to mucosa protection (i.e. mucins, and trefoil peptides), inflammatory responses (i.e. interleukin-1β; interleukin-1 receptor antagonist, and tumor necrosis factor), and metabolic detoxifying enzymes (phase I enzymes like cytochrome P450 superfamily, and phase II enzymes like glutathione S- and N-acetyl transferases)[4]. The subtle mechanism by which such polymorphisms may drive the immune response and host susceptibility related with a particular stimuli is unclear; nevertheless, in this case, the participation of a unknown and as yet uncharacterized neighboring HLA class Ⅱ antigen could not be ruled out.

Oncogenes and tumor suppressor genes may also participate in several ways; for example, a 13Gly→Asp mutation of the K-ras oncogene has been related with improved prognosis in patients suffering from colorectal carcinoma; this is due to better recognition of partially overlapping epitopes with the 13Asp peptide and presented with HLA-DQ7 molecules by CD4+ T-lymphocyte clones[23].

In Caucasians, HLA-DQB1*0301 has been linked with gastric carcinoma[12], even in the absence of *H pylori* infection; however, this allele is also significantly frequent in patients with carcinoma of the cervix uteri[24] and melanoma[25]. It is noteworthy that the HLA-DQB1*0301 allele is common in healthy Mexican population (G Vargas-Alarcón, personal communication).

Moreover, Wu *et al*[26] reported lower seropositivity of *H pylori* and a higher ratio of diffuse/intestinal-type carcinoma in Taiwanese patients carrying the HLA-DQB1*0301 allele, whereas the HLA-DQB1*0602 allele was associated with susceptibility to proximal gastric cancer. The role of the HLA-DQB1 locus in gastric cancer development was also confirmed by Quintero *et al*[27], who found a significant association between the HLA-DQB1*0602 allele and CagA-positive status with distal gastric cancer in Spanish population. In a Chinese population, Li *et al*[28] found an increased risk for gastric cancer in patients carrying both the CW*03 and DRB1*01 alleles, particularly among those infected with *H pylori*.

Current evidence indicates that the majority of individuals harboring *H pylori* infection remain asymptomatic during their lifetime, with no clinical consequence from their infection. In a community-based seroepidemiologic study in Mexico[29], seropositivity for *H pylori* infection was 66%, and > 80% of adults were infected by age 25 years; seroprevalence remained nearly unchanged after the third decade of life, with an increment in seropositivity of < 0.5% per year in persons between 30 and 69 years. Taken together, these data suggest that risk for gastric diseases depends on factors other than *H pylori* infection and age.

According to histo-epidemiologic classification, gastric adenocarcinoma is divided into intestinal- and diffuse-type adenocarcinomas[30]. In intestinal-type adenocarcinoma, a multi-step process that includes gastritis, atrophy, and intestinal metaplasia of the gastric mucosa has been claimed as the initial event preceding the appearance of gastric carcinoma[31]. Intestinal-type adenocarcinoma, which is more frequent in the distal portion of the stomach, is related to a greater degree with *H pylori* CagA-positive infection[32]. In this case, the mechanism of neoplastic transformation could be mediated by translocation of CagA protein into the gastric cells through a type Ⅳ secretion system[33]. Diffuse-type adenocarcinoma has been also associated with *H pylori* infection, although there are controversial reports on this issue; prevalence of *H pylori* infection in gastric cancer series has been reported from 29% to 100%[3]; allele comparisons between diffuse- and intestinal-type adenocarcinoma are further warranted. Thus, we hypothesize that HLA-DQB1*0501 is associated with genetic susceptibility for developing diffuse-type gastric adenocarcinoma in Mexican Mestizo population regardless of *H pylori* status.

Interestingly, HLA-DQB1*0501 confers protection from malaria anemia and malaria reinfections in Gabonese children[34]. This association appears to be dependent on the cytokine profile, predominantly interferon-γ (INF-γ) production by T-cells and supports the notion that HLA can direct the immune response toward Th1 or Th2 phenotype[35].

In conclusion, our results, together with the body of evidence published in the literature, support that genetic constitution through HLA-DQ locus determines the mechanism of disease as well as clinical and pathologic outcomes, triggered by the interaction between environmental factors and the gastric milieu. In other words, immunogenetic background among different ethnicities is manifested as resistance or susceptibility to the development of chronic gastritis and gastric adenocarcinoma.

## COMMENTS

### Background
Gastric cancer is multifactorial in origin; HLA genes confer susceptibility and resistance to diseases.

### Research frontiers
HLA-DQ alleles are linked to gastric diseases; HLA-DQ locus drives different mechanisms of gastric disease.

### Innovations and breakthroughs
HLA-DQB1*0501 is associated with diffuse type gastric carcinoma; HLA-DQB1*0601 is associated non-*Helicobacter pylori* gastritis.

### Applications
Genotyping of HLA-DQ alleles is useful for determining individual susceptibility and/or resistance to gastric diseases; Knowing individual HLA constitution is useful for prevention, early detection and opportune therapeutics of gastric diseases, particularly, gastric cancer.

### Terminology
Human leukocyte antigens (HLA) class II genes of the Major histocompatibility complex (MHC) are a group of highly polymorphic genes located in the short arm of chromosome 6, and are particularly important in controlling specific immune recognition; HLA class II antigens are capable of binding tumor peptides, and T-cell recognition of a combination of HLA class II and bound tumor antigen may result in either induction of an effective anti-tumor immune response or suppression of such immune response.

### Peer review
The authors reported HLA-DQ locus may play a different role in the development of Helicobacter pylori-related chronic gastritis and diffuse-type gastric adenocarcinoma in the Mexican Mestizo population. Their results together with the body of evidence published in the literature support that genetic constitution through HLA-DQ locus determines the mechanism of disease as well as clinical and pathologic outcomes, triggered by the interaction between environmental factors and the gastric milieu. This is an interesting and important study.

## Abstract

**AIM:** To evaluate the method of noninvasive transient elastography for assessment of histological stage of liver fibrosis in patients with chronic hepatitis C (CHC).

**METHODS:** Two hundred and thirty-seven patients with CHC were included in this study. Liver biopsy was performed under ultrasonography on 217 of the patients, excluding twenty with clear clinical evidence of liver cirrhosis. Fifty subjects without liver disease were enrolled as a control group (stage 0). Twenty-five patients with sustained virological response (SVR) to interferon (IFN) therapy were also enrolled. These patients underwent liver biopsy before IFN therapy. Examination of liver stiffness (LS) was performed by elastography.

**RESULTS:** Medians (50% levels) of LS were 4.1 (3.5-4.9), 6.3 (4.8-8.5), 8.8 (6.8-12.0), 14.6 (10.5-18.6), and 22.2 (15.4-28.0), respectively, in the fibrosis stages 0-4 ($P$ < 0.001). LS was significantly correlated with four serum fibrosis markers. LS values in patients with SVR were 3.8 (3.5-5.6), 5.2 (4.4-6.8), 6.8 (6.1-7.6), and 6.1 (3.6-7.9), respectively, in the fibrosis stages 1-4. In all stages, LS for patients with SVR was significantly lower than that for patients who did not undergo IFN therapy. LS was significantly correlated with serum concentrations of hyaluronic acid, type Ⅳ collagen, type Ⅳ collagen 7S, and type Ⅲ procollagen N peptide.

**CONCLUSION:** LS correlated well with the histological stage of fibrosis. Changes in liver fibrosis stage may thus be estimated noninvasively using transient elastography.

**Key words:** Hepatitis C virus; Echography; Fibrosis; Stiffness; Interferon

## INTRODUCTION

Hepatic fibrosis deeply involves in the advance of stage of chronic hepatitis C (CHC), eventually leading to liver cirrhosis. In addition, the incidence of hepatocellular carcinoma (HCC) increases as the stage of fibrosis associated with CHC progresses[1]. It has been reported that patients with CHC with low-stage fibrosis respond better to interferon (IFN) therapy than those with higher-stage fibrosis[2]. Accordingly, evaluation of the stage of liver fibrosis is important when treating CHC. Although liver biopsy has been considered a gold standard for evaluation of liver fibrosis stage, it is invasive, stressful and is sometimes refused by patients or causes complications. In addition, liver biopsy can have life-threatening complications[3-5]. For these reasons, it is not possible to perform liver biopsy for all patients with CHC. Furthermore, the tissue samples obtained by needle biopsy are sometimes inadequate in quantity for accurate diagnosis[6,7]. Ratings based on examination of the liver tissue specimens may vary even among the specialists in pathology[8]. In addition, staging of fibrosis based on liver tissue specimens allows only step-wise evaluation (rather than as a continuous variable). While several serum markers (hyaluronic acid, type Ⅳ collagen, type Ⅳ collagen 7S, and P-Ⅲ-P) are known to be useful for quantitative evaluation of the liver fibrosis, and are utilized for indirect testing using serum samples[9-12].

In general, liver stiffness (LS) increases as liver fibrosis progresses[13]. The FibroScan 502 (FS, EchoSens, Paris, France) for transient elastography is a new modality

developed for noninvasive evaluation of liver stiffness based on the following principle. Waves including elastic shear waves are emitted from the vibrator attached to the ultrasound transducer probe. Pulse-echo ultrasound acquisitions follow the shear waves, and the velocity of such waves through the liver can be determined. LS is calculated from the shear wave velocity using Young's modulus. Use of transient vibration presents several advantages. First, the transmitted elastic waves can be temporally separated from reflected elastic waves. Second, the acquisition time is short, enabling measurements to be made on moving organs. Transient elastography is thus well adapted to the study of the liver.

We examined the relationships between the liver fibrosis of patients with CHC and LS determined by FS as well as serum markers of fibrosis.

## MATERIALS AND METHODS

### Patients

For initial examination, 237 subjects with CHC managed as patients at the Osaka City University Hospital were enrolled. Of these patients, 214 underwent liver biopsy under ultrasonic guidance. All the 237 patients satisfied the following criteria: (1) they were HCV RNA-positive, (2) free of ascites, and (3) liver disease due to HBV or alcohol could be ruled out for them. The control group ($n$ = 50) was composed of 30 healthy volunteers and 20 patients without hepatic diseases. The mean age was lower in the control group than in any group of patients with CHC (Table 1). The liver biopsy was carried out using a 15-gauge needle biopsy apparatus (Hakko Inc., Tokyo, Japan). The specimens were fixed, paraffin-embedded, and stained with hematoxylin and eosin (H&E). Histological evaluation of the liver specimens was performed by two senior pathologists specialized in liver pathology. Stage of fibrosis and grade of activity in the liver were estimated according to the classification of Desmet *et al*[14]. The interval between the liver biopsy and FS measurement ranged from 0 d (on the same day) to 6 mo. The stage of fibrosis in the control group was rated stage 0. Patients clinically diagnosed with liver cirrhosis on the basis of diagnostic imagings (including computed tomography and ultrasonography) and hematological tests (although liver biopsy had not been performed) were also included in the analysis as stage 4 patients. These patients were included since, if analysis had been confined to the patients who had undergone liver biopsy, results might have been biased, because the liver biopsy is seldom performed in patients with liver cirrhosis (since IFN therapy is not indicated for these patients) and is not possible in cirrhotic patients with thrombocytopenia. Furthermore, 25 patients with CHC exhibiting sustained viral response (both disappearance of serum HCV RNA and normalization of alanine aminotransferase in response to previous IFN therapy) were also included for the next stage of analysis. These 25 patients had undergone liver biopsy and histological evaluation of the liver tissue before IFN therapy (Table 2). The study protocol accorded with the Helsinki Declaration. Patients were enrolled after provision of informed consent.

**Table 1 Characteristics of patients without SVR**

| Stage | 0 | 1 | 2 | 3 | 4 | *P* |
|---|---|---|---|---|---|---|
| *n* | 50 | 113 | 68 | 18 | 38 | |

Results for age are given as mean ± SD. SVR: sustained viral response; ND: not done.

### Liver stiffness measurement

LS was measured by transient elastography using an FS. Briefly, the subject lay on the bed in the horizontally supine position, and a probe was placed on the skin above the right intercostal space. The velocity of shear waves, generated temporarily and passing though the liver, was combined with Young's modulus for automated calculation of elasticity[15]. The median of 10 consecutive measurements was used as the LS for a given subject, and expressed in units of kilopascals (kPa).

### Serum markers of fibrosis

Blood for measurement of serum markers of fibrosis was sampled on the day of LS measurement. Of the markers, serum concentrations of type Ⅳ collagen (Ⅳ collagen) were measured with latex agglutination turbidimetry (PANASSAY Ⅳ C; Daiichi Fine Chemical Co., Ltd., Tokyo, Japan), with a normal range of not more than 150 ng/mL. Serum concentrations of type Ⅳ collagen 7S (Ⅳ collagen 7S) were measured by radioimmunoassay (type Ⅳ collagen-7S kit, Mitsubishi Kagaku Iatron Inc., Tokyo,

**Table 3 Results of biochemical examination of patients**

| Stage | 1 | 2 | 3 | 4 | *P* |
|---|---|---|---|---|---|
| *n* | 113 | 68 | 18 | 38 | |
| Platelet ($\times 10^4$ μL) | 18.0 ± 8.0 | 13.9 ± 6.6 | 12.1 ± 5.7 | 9.9 ± 5.6 | < 0.001 |
| AST (IU) | 47.3 ± 31.9 | 51.6 ± 27.2 | 63.8 ± 33.4 | 95.9 ± 142.2 | 0.001 |
| ALT (IU) | 60.9 ± 59.3 | 61.0 ± 40.5 | 75.8 ± 51.0 | 86.8 ± 135.7 | 0.023 |
| ALB (g/dL) | 3.9 ± 1.0 | 3.6 ± 1.3 | 3.8 ± 1.0 | 3.3 ± 1.1 | 0.036 |
| HA (ng/mL)[1] | 56.7 ± 65.8 | 89.2 ± 112.0 | 113.8 ± 125.8 | 509.3 ± 404.7 | < 0.001 |
| Ⅳ collagen (ng/mL)[2] | 121.0 ± 57.5 | 149.9 ± 67.9 | 176.8 ± 129.2 | 229.7 ± 108.8 | 0.020 |
| Ⅳ collagen 7S (ng/mL)[2] | 5.5 ± 1.8 | 6.0 ± 1.6 | 8.9 ± 2.9 | 8.0 ± 2.1 | 0.001 |
| P-Ⅲ-P (U/mL)[2] | 0.79 ± 0.19 | 0.88 ± 0.30 | 1.23 ± 0.60 | 1.02 ± 0.29 | 0.023 |

Results are given as mean ± SD. [1]HA was measured in 57 patients; [2]Ⅳ collagen, Ⅳcollagen 7S, and P-Ⅲ-P were measured in 52 patients. AST: asparate aminotransferase; ALT: alanine aminotransferase; ALB: albumin; HA: hyaluronic acid.

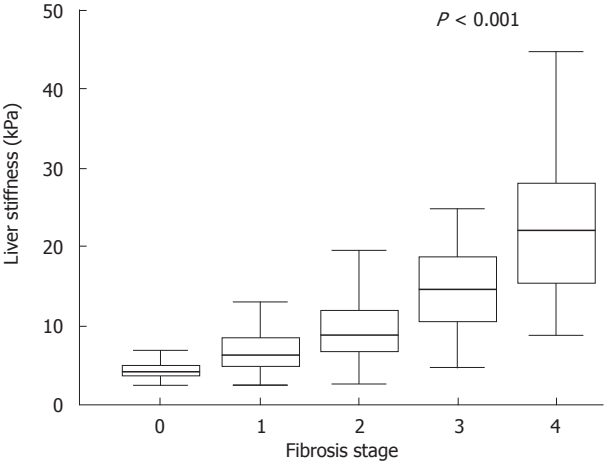

**Figure 1** Liver stiffness measurements for each fibrosis stage. Fibrosis stage 0 is offered to the control group. The top and bottom of the boxes are the 1st and 3rd quartiles. The length of the box thus represents the interquartile range (IQR) within which 50% of values are located. The lines through the middle of the boxes represent the median. The error bars represent the minimum and maximum values (measurement range). Significant correlation was found between stage of fibrosis and liver stiffness ($P < 0.001$, Kruaskal-wallis test).

Japan), with a normal range of not more than 6 ng/mL. Serum concentrations of type Ⅲ procollagen N peptide (P-Ⅲ-P) were measured by radioimmunoassay (RIA-gnost PⅢ P c.t, Nihon Shering K.K., Osaka, Japan), with a normal range of 0.3-0.8 U/mL. Serum hyaluronic acid (HA) concentrations were measured by latex agglutination immunoturbidimetry (LPIA Ace HA, Fujirebio Inc., Tokyo Japan), with a normal range of not more than 50 ng/mL.

### Statistical analysis

Biochemical data were expressed as mean ± SD. Elastography data were expressed as median values. Box plots were used to study the LS value distribution according to the stage of fibrosis. Differences in mean values were tested by one-way analysis of variance (ANOVA), followed by the Kruskal-Wallis test. The Mann-Whitney *U*-test was used to compare the data between the two groups. The $\chi^2$ test was used to compare the distribution of individual variables among the patient groups. Correlations between two variables were examined using Spearman's correlation coefficient. Differences were considered statistically significant when *P* values were less than 0.05. All analyses were performed using SPSS 11.0J (SPSS Japan Inc. Tokyo, Japan).

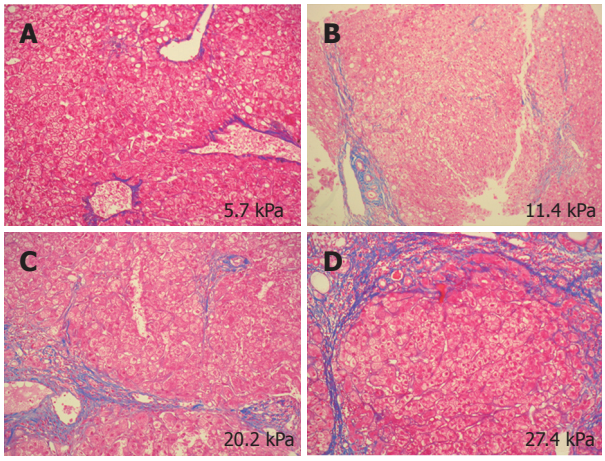

**Figure 2** Azan-Mallory-stained liver tissue and liver stiffness measurement. **A** and **B:** stage 1 liver tissue samples, showing that the grade of fibrosis and elasticity was higher for **B** than for **A; C**: stage 3 liver tissue sample; **D**: stage 4 liver tissue sample. The elasticity thus increased as the fibrosis progressed.

## RESULTS

### Biochemistry

Table 3 shows the results of biochemical tests at each stage of CHC. Platelet count decreased as the stage progressed. Albumin level at stage 4 was significantly lower than at stage 1 ($P = 0.006$). Type Ⅳ collagen 7S level at stage 4 was significantly lower than at stage 1 ($P = 0.032$). However, HA level at stage 4 was significantly higher than at stage 1 ($P = 0.041$).

### Relationship between the histological stage and the liver stiffness

Figure 1 shows LS determined with FS for the control group (stage 0) and serum HCV RNA-positive patients with CHC. Median LS (50% level) was 4.1 (3.5-4.9) at stage 0, 6.3 (4.8-8.5) at stage 1, 8.8 (6.8-12.0) at stage 2, 14.6 (10.5-18.6) at stage 3, and 22.2 (15.4-28.0) at stage 4 (Kruskal-Wallis test, $P < 0.001$). Mean LS differed significantly between each two of the five stages. The differences between the groups were as follows: stage 1 *versus* stages 2 ($P = 0.011$), 3 ($P < 0.001$), and 4 ($P < 0.001$); stage 2 *versus* stages 3 ($P = 0.013$) and 4 ($P < 0.001$); stage 3 *versus* stage 4 ($P = 0.004$). These differences were much superior to those obtained using the biochemical markers. Figure 2 shows the examples of findings for Azan-Mallory-stained liver tissue and LS. Samples A and B were classified as stage 1. However, degrees of fibrosis noted on microscopic examination differed between the two samples.

At each stage of fibrosis, LS was significantly lower in SVR than in HCV RNA-positive patients not treated with interferon (NT) (Figure 3). The median LS of SVR was 3.8

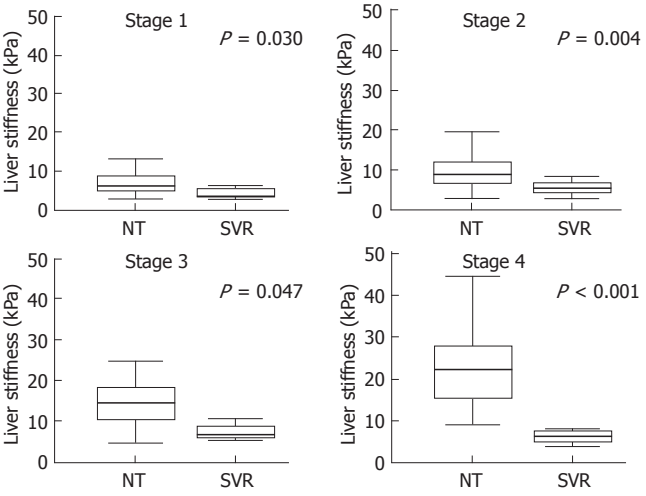

**Figure 3** Liver stiffness measurements for each fibrosis stage in the patients not treated with IFN and the patients with sustained response for IFN therapy. Fibrosis stage 0 indicates the control group. The top and bottom of the boxes are the 1st and 3rd quartiles. The length of the box thus represents the interquartile range (IQR) within which 50% of values are located. The lines through the middle of the boxes represent the median. The error bars represent the minimum and maximum values (measurement range). In each stage, liver stiffness differed between NT and SVR. At each stage of fibrosis, elasticity was significantly lower in SVR than in HCV RNA-positive cases without IFN therapy (NT). NT: Patients without IFN therapy; SVR: Patients with sustained viral response to IFN therapy.

(3.5-5.6) ($P = 0.030$) at stage 1, 5.7 (4.4-6.8) ($P = 0.004$) at stage 2, 6.8 (6.1-7.6) ($P = 0.047$) at stage 3, and 6.1 (3.6-7.9) ($P = 0.001$) at stage 4 (compared with NT patients).

### *Correlations with serum markers of fibrosis*

When correlations between the liver stiffness and serum markers of fibrosis were determined, the coefficient of correlation ($r$) was found to be 0.474 with HA ($n = 70$, $P < 0.001$), 0.581 with type Ⅳ collagen ($n = 70$, $P < 0.001$), 0.581 with type Ⅳ collagen 7S ($n = 69$, $P < 0.001$), and 0.233 with P-Ⅲ-P ($n = 70$, $P = 0.064$), respectively (Figure 4). Each of the four serum markers of fibrosis were significantly correlated with LS measured using FS.

## DISCUSSION

HCC is the most frequent cause of death among patients with CHC. As liver fibrosis associated with CHC advances, HCC develops with high incidence[1]. It has been reported that the rate of viral eradication in response to IFN therapy is high in the patients with low-stage liver fibrosis[2,16]. Evaluation of the liver tissue is thus quite important when selecting a method of treatment and predicting prognosis for the individual patients with CHC. The stage of CHC is usually evaluated based on general assessment of hematological data and findings of diagnostic imagings. However, with these indirect tests, it is difficult to precisely determine the stage of liver fibrosis. Liver biopsy is a gold standard for direct evaluation of liver fibrosis. However, since it is invasive and stressful, and carries certain risks, it cannot be performed for all patients with chronic liver disease[17,18]. Furthermore, it is difficult to perform liver biopsy several times in the same patient. Regev *et al*[19] found that severity of fibrosis differed by

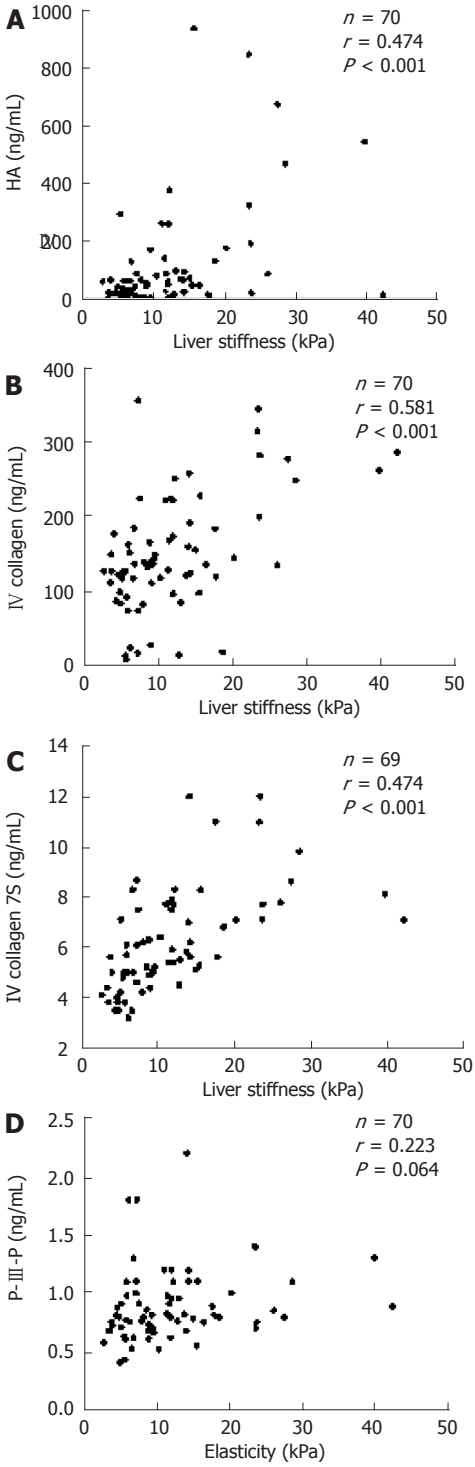

**Figure 4** Correlation between liver stiffness and serum fibrosis markers. Correlations between elasticity measured by the Fibroscan502 and HA (**A**), type Ⅳ collagen (**B**), Ⅳ collagen 7S (**C**), and P-Ⅲ-P (**D**) are indicated. **HA: Hyaluronic acid; P-Ⅲ-P: Type Ⅲ procollagen N peptide.**

at least one stage between the right and left lobes of the liver in 41 of 124 (33%) patients studied. Bedossa *et al*[7] reported that accurate staging by the METAVIR fibrosis staging method was possible in only 75% of cases when liver biopsy specimens of at least 25 mm in length were used for evaluation. Siddique *et al*[20] found that degree of fibrosis differed by at least one stage in 45% of cases when tissue specimens collected from the same puncture site were evaluated. With liver biopsy, precise determination

of the stage of liver fibrosis is sometimes impossible, depending on the amount of tissue sample available. Furthermore, results of evaluation can differ among pathologists[21,22]. Correlations between fibrosis markers and the stage of fibrosis due to liver disease (including liver cirrhosis) have also been reported[9-12]. In the liver, HA is synthesized and secreted by fat-storing cells, which are liver-specific pericytes considered to be major contributors to liver fibrosis[23]. Elevated serum HA concentrations result not only from reduced catabolism of HA in the liver but also from excess hepatic production of HA. Type Ⅳ collagen is one of the major constituents of the basement membrane progressively laid down in fibrotic liver as a continuous subendothelial layer along the space of Disse. Appearance of type Ⅳ collagen 7S in serum is thought to be due primarily to degradation of existing basement membrane rather than newly synthesized type Ⅳ collagen[24]. Serum P-Ⅲ-P concentrations are thought to reflect mainly the degree of fibrosis and fibrogenic activity in chronic liver disease[25]. However, P-Ⅲ-P may also be derived from degradation of tissue type Ⅲ collagen still containing the amino-terminal peptide[26]. In addition, circulating P-Ⅲ-P is metabolized by the liver endothelial cells[24]. These factors may complicate interpretation of changes of serum P-Ⅲ-P, obscuring relationships between serum concentration and fibrogenic activity in the liver. Almost all human studies have used biopsy specimens for histological evaluation. In the present study, positive correlations between measurement with FS and serum markers of fibrosis were found.

Transient elastography using FS permits noninvasive measurement of LS from the body surface with a high degree of reproducibility. According to a recent report, LS determined with FS increased as the stage of liver fibrosis advanced in the patients with CHC. Liver biopsy permits only semi-quantitative evaluation of fibrosis, since degree of fibrosis can be expressed only in steps and not as a continuous variable. FS, on the other hand, may enable more quantitative evaluation of fibrosis. Saito *et al*[27] reported that platelet count correlated well with the stage of fibrosis, and that variation was large for platelet count but small for FS measurement. Measurement of liver stiffness with FS is superior to liver biopsy, in that the former does not cause pain or other adverse events and thus can be repeated. Furthermore, FS measurement features little inter-observer variation and is hence highly reproducible. Since LS determined with FS correlated positively with the stage of liver fibrosis, it should be possible to utilize FS to estimate the degree of liver fibrosis in patients with CHC[28,29]. Data from patients who underwent several liver biopsies indicate that liver fibrosis in the patients with CHC advances at a rate of approximately one stage per 10 years[30]. However, the rate of progression of fibrosis can vary depending on sex, alcohol consumption, and certain other factors[31]. In the present study, degree of liver fibrosis was significantly lower in the patients with CHC who had become SVR in response to IFN therapy than in HCV RNA-positive patients with CHC. This finding indicates that liver fibrosis was alleviated in the patients with CHC who had exhibited viral eradication in response to IFN therapy. A long-term prospective follow-up study of determination of liver stiffness by FS is now needed. The findings of the present study suggest that FS is a promising means of quantitative evaluation of the degree of liver fibrosis associated with CHC.

## Abstract

**AIM:** To develop hepatitis C virus (HCV) vaccine using HBcAg as the immuno-carrier to express HCV T epitope and to investigate its immunogenicity in mice.

**METHODS:** We constructed the plasmid pTrc-core$^{NheI}$ using gene engineering technique, constructed the pcDNA3.1-core$^{NheI}$-GFP plasmid with GFP as the reporter gene, and transfected them into Hela cells. The expression of GFP was observed under confocal microscopy and the feasibility of using HBcAg as an immuno-carrier vaccine was studied. pTrc-core gene with a synthetic T epitope antigen gene of HCV (35-44aa) was fused and expressed in the plasmid pTrc-core-HCV (T). For the fusion of the HBcAg-T protein, sucrose, density gradient centrifugation was used, and its molecular weight and purity were analyzed by SDS-PAGE. Then balb/c mice were immunized by the plasmid with the HBcAg (expressed by pTrc-core) protein as control. The tumor regression potential was investigated in mice and evaluated at appropriate time. After three times of immunization, the peripheral blood and spleen of vaccinated mice were collected. HBcAb was detected by ELISA, and nonspecific T lymphocyte proliferation and response of splenocytes were respectively examined by MTT assay. T cell subset of blood and spleen were detected by FACS.

**RESULTS:** GFP was successfully expressed. Tumor regression trial showed that no tumor formation was found in the group receiving immunization, while tumor xenograft progression was not changed in the control group. Strong nonspecific lymphocyte proliferation response was induced. FACS also showed that the ratio of $CD8^+$ T cells in the experimental group was higher than the controls, but the serum HBcAb in experimental group was similar to the control.

**CONCLUSION:** HBcAg can be used as an immuno-carrier of vaccine, the fusion of HBcAg-T protein could induce stronger cellular immune responses and it might be a candidate for therapeutic vaccines specific for HCV.

**Key words:** Hepatitis C virus; Therapeutic vaccine; T epitope; Cellular immune responses

## INTRODUCTION

Hepatitis C virus (HCV) is a global public health problem, infecting 170 million people now, accounting for approximately 3% of the world population[1]. More than 50 million are infected with HCV in China, and the number has a tendency to rise. Persistent HCV infection has a high risk of progressing to chronic hepatitis, liver cirrhosis, and hepatocellular carcinoma, usually more than a decade after initial infection[2]. Thus, it is important to develop adequate treatment for HCV infection. Polyethylene glycol plus Ribavirin treatment is effective, while new infections are continuously emerging from blood transfusion, needle sharing, close contact of HCV infected patients and other unidentified sources[3]. Thus to control the spread of HCV by developing new methods, such as therapeutic vaccines becomes an urgent task, especially in developing countries including China, where there is a large infected population.

In this study, we used HBcAg as immuno-carrier, inserted HCV T epitope into HBcAg el-loop, fused the protein particles of HBcAg-T *via* density gradient centrifugation, and immunized them in Balb/C mice with suitable dosage, then observed the immunogenicity of this fused protein in order to find a candidate for HCV therapeutic vaccine.

## MATERIALS AND METHODS

### Materials

The *E. coli* strain DH5α, JM109 and Hela cell line were conserved in our laboratory; Vector pTrc-core which carries a HBc gene was a kind gift of Dr. Li Jingli (Changchun, China); and Vector pcDNA-GFP was constructed in our laboratory which carries a GFP gene.

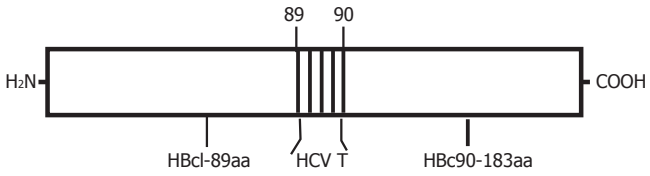

**Figure 1** Hybrid HBcAg-T protein showing HCV T epitope (hatched box) inserted between HBcAg aa 79 and 80, a region located at the tip of core particle surface spikes.

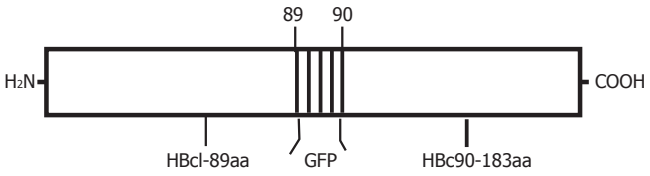

**Figure 3** Hybrid HBcAg-GFP protein showing the GFP protein (hatched box) inserted between HBcAg aa 79 and 80.

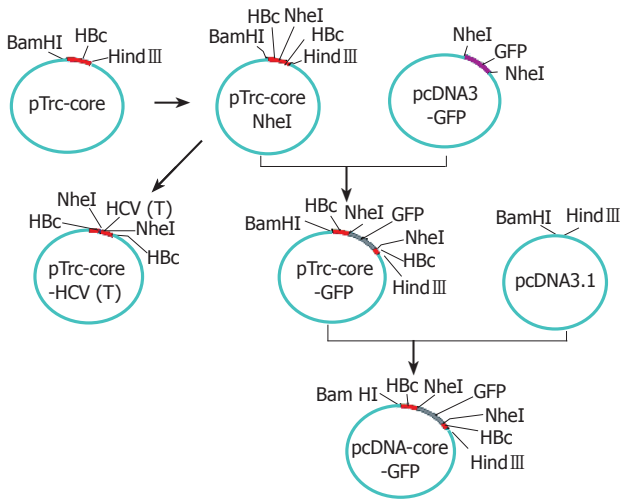

**Figure 2** The construction of plasmids pTrc-core-HCV (T) and pcDNA3.1-core-GFP.

Restriction enzymes including NheI, HindIII and BamHI, T4 DNA ligase, Taq DNA polymerase, CIAP and RNase were purchased from TaKaRa Biotechnology (Dalian, China); Lipofectamine™ 2000 was purchased from Gibco Corporation; and other reagents were analytically pure reagents produced in China.

### Construction of expression vectors

The HBcAg-T recombinant protein (Figure 1) was expressed in *E. coli* JM109 transfected with the expression of plasmid pTrc-core-HCV(T). This plasmid encodes a HBc gene (aa 1 to 183) with the HCV T epitope inserted into the HBcAg loop region between aa 79 and 80.

To construct this hybrid vaccine, a plasmid (pTrc-core$^{NheI}$) containing HBc gene was first digested at the NheI restriction sites, which had been strategically introduced into plasmid pTrc-core by PCR between the codons for $P_{79}$ and $A_{80}$ of the loop region. A synthetic double-stranded DNA fragment CTAGCgccgacctcatggggt acataccgctcgtcG encoding the sequence of HCV T epitope, modified by addition of 5' NheI and 3' NheI overhangs, was then inserted to yield plasmid pTrc-core-HCV(T) (Figure 2). This plasmid was used to direct the expression of a particle containing HCV T epitope. The positive clone of recombinant plasmid pTrc-core-HCV (T) was identified by PCR, restriction endonuclease cleavage and sequencing.

A second plasmid, pcDNA3.1-core-GFP (Figure 2), was used to direct the expression of a particle containing the GFP sequence fused in the 79-80aa loop region of the HBcAg (Figure 3). The plasmid pTrc-coreNheI was first digested with NheI restriction enzyme and dephosphorylated, then, a double stranded DNA fragment encoding the GFP sequence obtained from plasmid pcDNA3-GFP by the NheI restriction enzyme was inserted to produce plasmid pTrc-core -GFP. To yield the final expression vector pcDNA3.1-core-GFP, this plasmid pTrc-core-GFP was cut with BamHI and HindIII and then cloned into the pcDNA3.1 vector, which had been prepared with the same two restriction enzymes, then transfected the plasmid pcDNA3.1-core -GFP into the Hela cell line. Forty-eight hours after transfection, GFP fusion protein expression cells were directly observed under Olympus fluorescence microscope (Japan).

### Expression and purification of recombinant particles

*E. coli* strain JM109 was transformed with either pTrc-core or pTrc-core-HCV (T) and selected on Luria-Bertani plates containing ampicillin (100 μg/mL). After 16-24 h of incubation at 37℃, a single colony was picked, expanded overnight, and used to inoculate a 500 mL culture (tryptone-yeast extract -NaCl [TYN] medium supplemented with 1 g glucose/L and 50 μg/mL ampicillin). After 16-20 h, cells were harvested by centrifugation. The pellets were resuspended in 5 mL of 25% sucrose in 50 mmol/L Tris pH8.0, added with 150 μL freshly prepared lysozyme (50 g/L), 100 μL of RNAse (10 g/L) and 100 μL of DNAse (10 g/L), mixed and incubated in a 37℃ water bath for 30 min. Samples were placed on ice for 5 min, added with 5 mL of lysis solution (10% Triton X-100, 0.4% sodium deoxycholate, 50 mmol/L Tris pH8.0 and 62.5 mmol/L EDTA) and incubated with occasional shaking at 37℃ for 30 min. The solution was incubated for a further 30 min at 37℃ and centrifuged at 4000 r/min for 15 min in a benchtop centrifuge. Supernatant was removed to a new tube. Lysate was vortexed at high speed for 30 s, and added with 2 mL of a 5 mol/L urea stock to create a 1 mol/L concentration. Three mL of this lysate was loaded onto the top of a sucrose gradient (60%, 50%, 40%, 30%, 20%) followed by density gradient centrifugation. After centrifugation at 4℃, 32 000 r/min for 22 h, samples (450 mL/tube) were collected to detect the ELISA response intensity using HBeAg diagnosis kit. Molecular weight and purity were identified by sodium dodecyl sulfate -polyacrylamide gel electrophoresis (SDS-PAGE), and ultraviolet spectrophotometer to measure its concentration. The purified proteins were stored at -20℃ prior to use.

### Immunogenicity

BALB/c mice were obtained from Jilin University. Mice

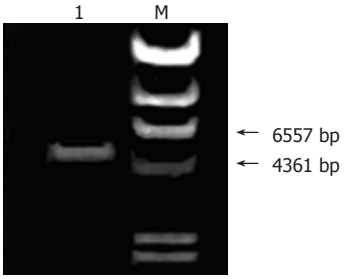

**Figure 4** Plasmid pTrc-core$^{NheI}$ identified by restriction endonuclease NheI cleavage. Land 1: pTrc-core$^{NheI}$ digest; M: λ-Hind Ⅲ digest.

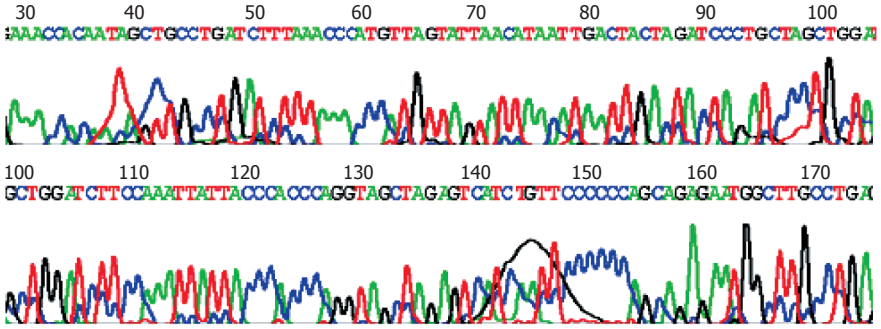

**Figure 5** The sequencing of plasmid pTrc-core$^{NheI}$ PCR product.

were immunized subcutaneouly with 2 μg HBcAg-T or HBcAg in Freund's incomplete adjuvant on d 0, 14, and 28. Fourteen days after the immunizing, half of the mice from each team were simultaneously inoculated with 200 μL ($1 \times 10^9$/L) H22 cell, 10 d after the last protein immunizing, the mice were sacrificed to get the tumor mass. Serum samples were collected 30 d after immunizing. Five days after the booster inoculation, mice were sacrificed and spleen were removed for T-cell analysis. Untreated mice served as controls.

### *Serological assays*

Anti-HBcAg antibody (HBcAb) was measured by ELISA using commercial kit (Rong Sheng, Shanghai, China), the endpoint titer was determined as the dilution of immune sera giving an optical density greater than the mean + 2 standard deviations obtained with normal sera.

### *T lymphocyte subgroup* assays

The $CD3^+$, $CD4^+$ and $CD8^+$ T lymphocyte of blood and spleen were assayed by flow cytometry (Becton Dickson Company, USA).

### *Cellular proliferation assays*

Triplicate wells containing spleen cells of naïve or immunized BALB/c mice were stimulated with HBcAg-T or HBcAg particles (2 g/L). Proliferation in 2-d cultures was measured by MTT to evaluate the cellular immune responses of the vaccinated animals, and results were expressed as stimulation indices (SI).

## RESULTS

### *Identification of plasmid pTrc-core$^{NheI}$*

On agarose gel electrophoresis, the product of pTrc-core$^{NheI}$ digested by NheI formed a band of expected size of 5223 bp (Figure 4), The sequencing of plasmid pTrc-core$^{NheI}$ PCR product was in agreement with expected (Figure 5). These proved that the NheI site was added successfully into the plasmid pTrc-core.

### *GFP expression*

Under confocal microscopy, GFP was expressed successfully after plasmid pcDNA3.1-HBc-GFP was transfected into Hela cells (Figure 6). This suggested that GFP fragment was well exposed on the surface of chimeric VLPs, and the foreign gene inserted could be expressed correctly.

### *Identification of recombinant plasmid pTrc-core-HCV(T)*

A 336 bp specific band was obtained by PCR amplification with pTrc-core-HCV (T) as template (Figure 7), and DNA sequencing confirmed that the sequence was completely concordant with what had been expected. These showed that the construction of plasmid pTrc-core-HCV(T) was successful. Sequencing result: (HCV T epitope underlined, NheI site italic) ctagacaccgcctcagctctgtatcgagaagccttagagtct cctgagcattgctcacctcaccatactgcactcaggcaagccattctctgctggggg gaattgatgacctagctacctgggtgggtaataatttggaagatcca*gctagc*gccga cctcatggggtacataccgctcgtc*gctagc*agggatctagtagtcaattatgttaatac taacatgggtttaaagacaggcaactattgtggtttcatatatcttgccttacttttgga agagagactgtacttgaatatttggtctctttcggagtgtggattcgcactcctcca.

### *Assay of recombination protein*

Protein HBcAg-T and HBcAg were examined by SDS-PAGE. On the gel, a single protein band was displayed at about 2.1 kDa (Figure 8). It was consistent with the molecular weight of the two proteins. It suggested that the HBcAg-T and HBcAg was pure, and we could use them directly to immunize the animals.

### *Results of tumor regression trial*

Four mice in HBcAg immunized group formed tumor masses (Figure 9), while none in the mice in HBcAg-T immunized group, the difference being obvious between the blank and HBcAg immunized groups ($P < 0.05$).

### *Results of HBcAb titer*

ELISA showed that the difference of HBcAb titer between the control and HBcAg-T immunize groups was not significant (1:3880 *vs* 1:3900). This proved that T epitope inserted could not enhance the humoral immunity of mice obviously (Figure 10).

### *Results of $CD3^+$, $CD4^+$ and $CD8^+$ detection*

FACS showed that the ratio of $CD8^+$ T cell in blood and spleen of HBcAg or HBcAg-T immunized mice was higher than the blank, and the ratio of HBcAg-T immunized group was the highest, showing that HBcAg-T could accelerate the proliferation of CTL, and induce stronger cellular immunity (Table 1).

### *Results of MTT*

MTT showed that (Figure 11) HCV T epitope can accelerate unspecific T cell proliferative reaction ($P < 0.05$).

## DISCUSSION

The HCV is a highly variable virus, various attempts have been made to develop a vaccine against HCV infection, such as protein vaccine[4-6], oral vaccine[7] and the new RNAi technique[8]. Although some encouraging results were obtained, no effort on vaccine development has been successful. Recent studies about HCV epitopes showed that epitope vaccines might be a feasible strategy for HCV vaccine designs. Using the epitopes but not the whole HCV protein as the antigen could avoid HCV antigen protein to induce cancer, and its immunosuppressive action at the same time could refrain the patents from promoting HCV immune escape strain formation or aggravating infection degree induced by immune response for unsuitable sites. In this study, we chose a highly conservative T epitope (HLA-$A_2$ type) of HCV core region (35-44aa)[9] to design HCV therapeutic vaccine.

Only one epitope can not induce strong immune response because the immunogenicity is weak, we therefore used HBcAg as the immuno-carrier to develop HCV vaccines. Being a carrier of foreign epitopes, HBcAg has more advantages than other proposed particulate carriers. There are more powerful immunogenic epitopes[10], such as: Th epitopes which lie in 1-20aa, 28-47aa, 50-69aa, 81-105aa, 126-146aa and 141-165aa; HLA-A2,A31,A11 restricted CTL epitopes which lie in 18-27aa, 141-151aa and 88-96aa; and so on. So HBcAg carrier can provide a high level of T cell immunogenicity for the inserted HCV T epitope, its immune response may play an important role in HCV therapy. HBcAg can show exogenous epitopes with multicopy pattern, keep their original conformation, raise the epitope avidity, offer Th signal to exogenous epitopes and strikingly enhance immune responses. Experiments proved that HBC possesses Ti antigen property[11], which can induce immune response without adjuvant. Since Clarke[12] first reported on the virus-like particle (VLP) of HBcAg fusion in 1987, and constructed the first VLPs[13], HBcAg was often used as an immuno-carrier to develop immunogens and vaccines and had been used in many pathogens such as Hantaan virus, malarial parasite and HIV[14-16]. Now some investigators mentioned the features of HBcAg VLPs[17,18], and pointed out that the region between position 78 and 83 of HBcAg (maily immunodominant region, MIR) is surface accessible[19]. It was shown that HBcAg e1loop (78-83aa) was not necessary for assembling, without it HBcAg could auto-assemble into VLPs in vitro itself. In this study, we also showed that after GFP was introduced into this position, the assembly of HBcAg is unaffected and the inserted GFP could be exposed on the surface of VLPs. Thus, the position is an ideal site for HCV epitope inserting[20], and the foreign gene inserted here could be expressed correctly. Based on these findings, we inserted HCV T epitope into HBc e1loop, constructed fusion expression of plasmid

**Table 1 Analysis of T cell subsets in peripheral blood and spleen**

| Group | Peripheral blood | | Spleen | |
|---|---|---|---|---|
| | $CD4^+$ | $CD8^+$ | $CD4^+$ | $CD8^+$ |
| Control | 15.25 ± 2.45 | 3.55 ± 1.65 | 5.02 ± 2.67 | 5.69 ± 1.71 |
| HBcAg | 27.54 ± 2.33 | 9.43 ± 1.56 | 27.71 ± 2.98 | 12.99 ± 1.35 |
| HBcAg-T | 25.14 ± 3.37 | 10.23 ± 1.85[b] | 28.01 ± 2.05 | 15.01 ± 1.45[b] |

[b]$P < 0.01$ *vs* HBcAg group.

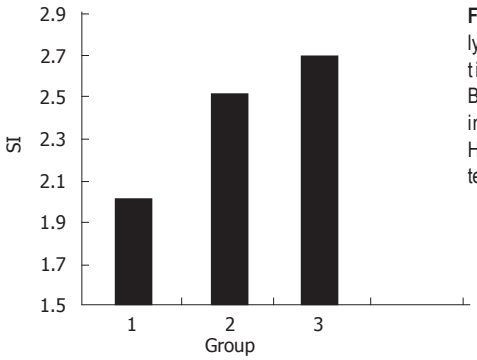

**Figure 11** Nonspecific lymphocytes proliferative response. 1: Blank team; 2: HBcAg immunized team; 3: HBcAg-T immunized team.

pTrc-core-HCV (T), its expression product HBcAg-T was extracted, purified and quantitated, then immunized into Balb/c mice. We investigated its immunogenicity by some tests. Tumor regression trial showed that no tumor from the experimental group was found, being different from the control group. It means that the fusion antigens could stimulate mice to produce high-level CTL, which inhibits the tumor cells to survive; HBcAb was almost similar in the serum of the mice from HBcAg-T or HBcAg injected group, stronger nonspecific lymphocytes proliferation response was induced in experimental group; FACS also showed the ratio of $CD8^+$ T cell in the experimental group was higher than the control. All these findings demonstrated that HBcAg-T had induced stronger cellular immune response.

Since cytotoxic T lymphocytes (CTL) play a critical role in preventing the spread of HCV, and it has been suggested that cell-mediated immune responses played an important role in protection against HCV chronic infection[21], so vaccine-based HCV CTL induction could be a promising strategy to treat HCV-infected patients. In this study, the fused protein has been found to have the capacity to induce CTL in mice, so the success of this experiment undoubtedly could serve as a basis for developing HCV therapeutic vaccine.

## Abstract

**AIM:** To validate the Rockall scoring system for predicting outcomes of rebleeding, and the need for a surgical procedure and death.

**METHODS:** We used data extracted from the Registry of Upper Gastrointestinal Bleeding and Endoscopy including information of 1869 patients with non-variceal upper gastrointestinal bleeding treated in Canadian hospitals. Risk scores were calculated and used to classify patients based on outcomes. For each outcome, we used $\chi^2$ goodness-of-fit tests to assess the degree of calibration, and built receiver operating characteristic curves and calculated the area under the curve (AUC) to evaluate the discriminative ability of the scoring system.

**RESULTS:** For rebleeding, the $\chi^2$ goodness-of-fit test indicated an acceptable fit for the model [$\chi^2$ (8) = 12.83, $P$ = 0.12]. For surgical procedures [$\chi^2$ (8) = 5.3, $P$ = 0.73] and death [$\chi^2$ (8) = 3.78, $P$ = 0.88], the tests showed solid correspondence between observed proportions and predicted probabilities. The AUC was 0.59 (95% CI: 0.55-0.62) for the outcome of rebleeding and 0.60 (95% CI: 0.54-0.67) for surgical procedures, representing a poor discriminative ability of the scoring system. For the outcome of death, the AUC was 0.73 (95% CI: 0.69-0.78), indicating an acceptable discriminative ability.

**CONCLUSION:** The Rockall scoring system provides an acceptable tool to predict death, but performs poorly for endpoints of rebleeding and surgical procedures.

**Key words:** Upper gastrointestinal bleeding; Nonvariceal; Predictors; Rockall; Outcomes

## INTRODUCTION

Upper gastrointestinal (UGI) bleeding is a common disorder affecting over 100 per 100 000 population yearly[1-7]. The most common etiologies include peptic ulcer disease, mucosal erosive disease and variceal bleeding[8-12]. Because there is an increasing concern for cost-containment without sacrificing clinical outcomes[13-15], there is room to implement emergent care for UGI bleeding with appropriate early discharge for subjects at low risk of rebleeding or death[16-20]. Although endoscopic findings can identify individuals at a high risk of rebleeding, overall mortality is often reflective of other factors such as age and comorbid conditions. In an effort to risk-stratify subjects with UGI bleeding, numerous scoring systems have been developed to predict bleeding recurrences, and the need for surgical procedures and death[17,20-28].

One instrument designed for that purpose is the Rockall scoring system[27,28]. The Rockall system has been shown to represent an accurate and valid predictor of rebleeding and death, performing better in the latter than in the former[27-29]. Rockall scores are designed to combine information such as the subject's age, occurrence of

shock assessed from systolic blood pressure readings and pulse rate, presence and severity of comorbid conditions, diagnosis and endoscopic stigmata of recent bleeding. Summing up the different levels of a point grading system assigned to each of the components yields a subject's risk score bounded on a scale of 0 to 11, with 11 representing the highest risk. Results of previous investigations and validations of the scoring system have highlighted that those with a score of $\leqslant 2$ are associated with a very low rate of bleeding recurrences and death and, therefore, can be reasonably managed as outpatients. This has the potential to result in a more appropriate management of subjects' conditions based on their assessed risk of complications following the initial UGI bleeding. Further, managing low risk subjects as outpatients would free up scarce hospital resources for treating more serious cases.

Our objective was to validate the Rockall scoring system in the Canadian setting for the outcomes of rebleeding, the need for a surgical procedure and death, using data of 1869 patients with non-variceal UGI bleeding obtained from the registry of upper gastrointestinal bleeding and endoscopy (RUGBE)[30]. Additionally, we aimed to determine the mean length of hospital stay by levels of the Rockall score to compare current practice for subjects at a low risk of a serious event with an approach of managing their condition on an outpatient basis.

## MATERIALS AND METHODS

### The RUGBE initiative and data collection

A commercially available endoscopic reporting system (GI-Trac™, AD/MediTrac, Las Vegas, NV, USA) was linked to a project-specific patient registry. This software was distributed to 6 community and 12 university-affiliated health institutions across Canada, establishing a network, from which subjects were selected and source data collected. Research staff and monitors were trained at an initiation meeting and standardized definitions for all recorded variables were used. Information on all subjects was collected retrospectively from hospital records, denominalized and entered electronically in the reporting system. Data were then downloaded monthly (09/1999-12/2001) into the central repository and then, reviewed for internal logic and biological plausibility. All queries were resolved within one month of original data entry and 10% of all entries were audited quarterly for quality control.

### Patient population

All subjects presenting with overt UGI bleeding or a history of hematemesis/coffee ground vomiting, melena, hematochezia, or a combination of any of the above within 24 h preceding admission were considered for the study. UGI bleeding was confirmed only if a member of the medical or nursing staff documented the presence of at least one of the following signs: (1) hematemesis; (2) melena; and/or, (3) bloody nasal gastric aspirates or black tarry material on rectal examination. Subjects were selected only if a UGI endoscopy was performed and a non-variceal source of bleeding was confirmed. A sequential time series sampling of eligible subjects was carried out at regular intervals to avoid a possible selection bias. An audit of all subjects presenting over a fixed time period at each institution was performed to further identify and prevent the possibility of a selection bias. The subset sampled constituted the entire dataset used in the study.

### Study variables

Only the data for clinical and endoscopic variables necessary to build the Rockall risk scores and the outcome variables were extracted from the registry. Risk scores for each subject were calculated and used for risk stratification on the outcomes of rebleeding, the need for a surgical procedure and death. Standardized definitions for all outcomes were adopted according to adaptations of established definitions[31,32]. Continued bleeding following initial endoscopy was defined by the persistence of (a) spurting from an artery, (b) a bloody naso-gastric aspirate, (c) shock with a pulse greater than 100 beats per minute, a systolic blood pressure of below 100 mmHg, or both, or (d) the need for substantial replacement of blood and fluid volume (transfusion of greater than 3 units of blood within 4 h). Rebleeding was defined by recurrent vomiting of fresh blood, melena or both with either shock or a decrease in hemoglobin concentration of at least 2 g/L following initial successful treatment (modified from Daneshmend *et al*)[31,32]. Because the distinction is often blurred in practice, continued bleeding and rebleeding were subsequently combined within a single category termed 'rebleeding' for the purpose of this analysis.

### Validation of the Rockall scoring system in the Canadian population

To validate the Rockall scoring system, we used $\chi^2$ goodness-of-fit tests to assess the degree of calibration of each model (i.e. for outcomes of rebleeding, surgical procedures and death), and built receiver operating characteristic (ROC) curves based on a non-parametric technique as implemented in the statistical package STATA® for Window® for each outcome and calculated the area under the curve (AUC) along with 95% confidence intervals[33] to evaluate the discriminative ability of the scoring system. In our setting, a model has internal validity, or is well-calibrated, if it predicts the probability of experiencing an outcome that corresponds closely to the observed proportion of individuals with the outcome at each level of the Rockall risk score (i.e., from 0 to 11). The ROC curves plot the sensitivity of the Rockall score (true positive rate) versus 1-specificity (false positive rate) calculated for a series of different threshold values. The threshold values represent different levels of the Rockall scoring system, for which the rates of true positives (sensitivity) and true negatives (specificity) are calculated. The AUC is used to determine the ability of the scoring system to distinguish between individuals who experienced an outcome versus those who did not, over all possible threshold values. A test or risk scoring system with an AUC of 1 has a 100% sensitivity and 100% specificity, indicating that it would perfectly 'discriminate' between subjects experiencing the health event or not. A test with no better discriminative ability than what would otherwise be obtained by pure chance will have an AUC of 0.5, represented graphically by the

**Table 1 Endoscopic findings in the registry of upper gastrointestinal bleeding and endoscopy (RUGBE)**

| | |
|---|---|
| Peptic ulcer disease | 55.5% |
| Esophagitis | 8.2% |
| Mallory Weiss | 4.4% |
| Dieulafoy | 2.5% |
| Other | 29.4% |

area under a 45 degree line. The accepted statistical rule of thumb is that a test with an AUC of less than 0.7 has a poor discriminative ability; an AUC between 0.7 and 0.8 provides acceptable discrimination and a test with an AUC above 0.8 is considered to have an excellent discriminative ability[34].

Because the ROC curves are plotted over all possible threshold values, it is possible to identify the optimal risk score cut-off value, at which the test is most accurate. For each ROC curve, we identified the optimal threshold of the Rockall score by: (1) determining the pair of sensitivity and specificity associated with the point geometrically closest to the upper left corner of the graph; (2) calculating the Youden index[35] (i.e., J = sensitivity + specificity - 1) for each score level. The cut-off level associated with the highest J coefficient is the one that minimizes the sum of false negatives and false positives.

Mean lengths of hospital stay per level of the Rockall score were also evaluated. To test for significant differences in the distribution of length of hospital stay between risk score levels we used Kruskal-Wallis non-parametric analysis because of the usual skewedness observed in the distribution of that variable.

## RESULTS

The population of 1869 subjects included in RUGBE had a mean age of 66 years [standard deviation (SD): 16.9, range: 7-105], and 62% were males. Fifty-six percent were diagnosed with peptic ulcer disease as the primary etiology for UGI bleeding (Table 1). The mean Rockall score was 4.8 (SD: 1.9, range: 0-10). Overall, 13% of subjects would be considered at a low risk (i.e., Rockall score $\leqslant$ 2) of experiencing rebleeding or death, while 8% of the population was classified as at a high risk (i.e., Rockall score $\geqslant$ 8). The distribution of subjects across levels of the Rockall score is reported in Table 2, as well as the rates of events for the three outcomes of rebleeding, surgical procedures and deaths, and the mean lengths of hospital stay. The results showed that the rates of events typically increased with higher risk levels expressed by the Rockall score. A cutoff score of 8 or greater for high risk persons was based on the same value used in the original analysis by Rockall[35]. Alternatively, in Table 2 we also show the same results for categories with a score of 2 or less for low risk, 3 to 5 for moderate risk and 6 or higher for high risk. The mean length of hospital stay also followed a similar trend with increasing levels of the risk scores. The distribution for the length of hospital stay was quite skewed as shown by the summary statistics on median and interquartile range. Results from the Kruskal-Wallis test confirmed this finding by showing a significant difference in the distribution of length of hospital stay between score levels [$\chi^2$ (7) = 78.7, $P$ = 0.0001]. Figure 1 provides the graphical representation of the trends for the three outcomes and the length of hospital stay.

### *Calibration of the Rockall scoring system*

In Figure 2A we show the comparison of observed proportions and predicted probabilities for the outcome of rebleeding. For most levels of the Rockall score, the predicted probability was slightly lower than the observed proportion of events. The result of the $\chi^2$ goodness-of-fit test indicated an acceptable fit for the model, although calibration could be improved to show better internal validity [$\chi^2$ (8) = 12.83, $P$ = 0.12]. Our findings from the corresponding analyses for the outcomes of surgical procedures and death (Figure 2B and 2C) showed a good fit for the models and thereby, good calibration as the measure of internal validity. For surgical procedures and death, the $\chi^2$ goodness-of-fit test indicated solid correspondence between observed proportions and predicted probabilities [$\chi^2$ (8) = 5.3, $P$ = 0.73 for surgical procedures; $\chi^2$ (8) = 3.78, $P$ = 0.88 for death].

Overall, the predicted probabilities were closer in value to the observed proportions in our subject population for the outcomes of surgical procedures and death. The correspondence for rebleeding was acceptable, but not as strong as that for the two previous outcomes.

### *Discriminative ability of the Rockall scoring system*

The ability of the Rockall scoring system to distinguish between individuals experiencing the events of rebleeding, surgical procedures and death (ROC curve) is illustrated in Figures 3-5, respectively. For rebleeding, the AUC was 0.59 (95% CI: 0.55-0.62) indicating a poor discriminative ability, or external validity of the Rockall scoring system. A similar result was found for the outcome of surgical procedures with an AUC of 0.60 (95% CI: 0.54-0.67). For the outcome of death, the AUC was higher at 0.73 (95% CI: 0.69-0.78), interpreted as an acceptable discriminative ability of the risk scoring system. The optimal cutoff Rockall scores were 6 for surgical procedures and death and 7 for rebleeding. This means that, at these threshold levels, the sum of false negatives and false positives is minimized or that the accuracy of the scoring system is highest.

Overall, the internal and external validity of the Rockall risk scoring system was strongest for the outcome of death. With surgical procedures, the calibration achieved was high, but the scoring system had a poor discriminative ability. The level of calibration and discriminative ability were lowest for the outcome of rebleeding.

## DISCUSSION

Several scoring systems have been developed to predict the clinical outcomes of gastrointestinal bleeding[17,21-25,27,28,35-40]. In 1987, Provenzale *et al*[28] tested various predictors of death from gastrointestinal bleeding and found that comorbid factors (i.e., liver and renal disease) and bleeding (i.e., hematochezia, short duration of bleeding, drop in

hematocrit of 5% and hypotension) were the most valid. Subsequently, several other risk scoring systems have been developed, with some of them validated in different patient populations[30,37,40,41].

Risk scores have been most commonly used as an aid to clinical decision-making to identify subjects who can be efficiently managed as outpatients, rather than being unnecessarily admitted for a prolonged hospital stay. Blatchford[17] and Rockall[27] have developed such scoring systems to forecast: (1) subjects' risk of rebleeding and death; (2) the need for early treatment of upper gastrointestinal bleeding. Although both scoring systems were designed for patients with UGI bleeding, the Blatchford scoring system does not incorporate information on endoscopic findings. This becomes an important limitation in circumstances where early endoscopic assessment is critical to optimal patient management. The Blatchford scoring system is still well-suited to the primary care setting when subjects need to be triaged to admission or outpatient management before an endoscopy is carried out.

When endoscopic information is available, the Rockall risk scoring system has been most widely applied to predict the risk of death and rebleeding. The system was originally

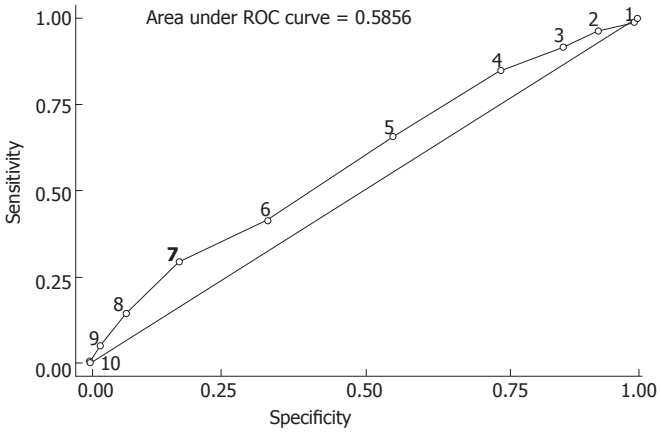

**Figure 3** Receiver operating characteristic (ROC) curve for outcome of rebleeding. Numbers along the curve indicate Rockall risk score cutoff values; The optimal threshold is a Rockall score of 7 (in bold).

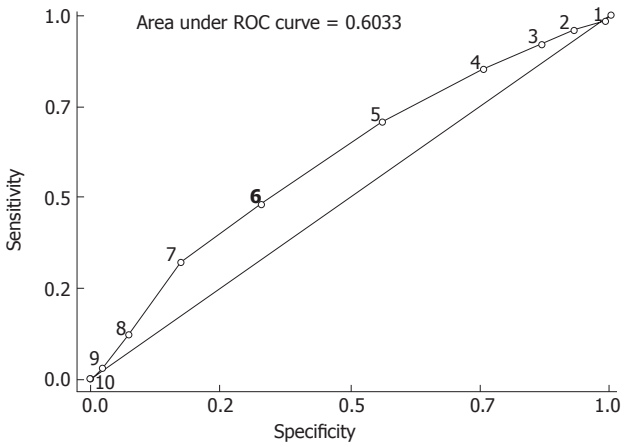

**Figure 4** Receiver operating characteristic (ROC) curve for outcome of surgical procedure. Numbers along the curve indicate Rockall risk score cutoff values; The optimal threshold is a Rockall score of 6 (in bold).

developed to assess the risk of death, and its accuracy to forecast the risk of rebleeding has been shown to be relatively low in some validation studies[29]; however, in other studies the accuracy was relatively high. In two studies that assessed quality of care of a health care utilization[42-43], the risk of rebleeding appeared to correlate well with Rockall scores. In both studies there was considerable concern regarding excessive hospitalization of low risk Rockall patients since resources could be saved by early discharge.

Using data from a Canadian registry of subjects with non-variceal UGI bleeding, our objective was to test for the outcomes of rebleeding, surgical procedures and death: (1) the level of calibration of the Rockall scoring system as a measure of internal validity, and (2) the discriminative ability of the risk score for its generalizability to other populations. For that purpose, $\chi^2$ goodness-of-fit tests for calibration and the area under the ROC curves for discriminative ability were used. Our results showed that the Rockall risk scoring system had acceptable performance for the outcome of death, but external validity and both internal and external validity were poor for surgical procedures and rebleeding, respectively. It is noteworthy that while subjects in the Vreeberg validation study[29] were from a different country (i.e. The Netherlands), the AUCs for the outcomes of death and rebleeding (0.73 and 0.61) resulted in almost identical numbers to ours (0.73 and 0.59). This adds weight to the conclusion that while acceptable to forecast the risk of death, the Rockall risk scoring system does not perform very well for the outcome of rebleeding. This study, performed in a Canadian setting, demonstrates that even with advanced endoscopic techniques, in a 'real-life' setting, the Rockall risk scoring system is acceptable for mortality prediction. Although the internal validity of the scoring system is high for the surgical procedures, its discriminative ability for this outcome is similar to that of rebleeding. We also found that the Rockall scoring system is in close agreement with length of hospital stay. This validation of the Rockall score is the first that has been done in a North American setting.

The Rockall risk scores are not widely used in Canada. However, it is clear that if endoscopic assessment could be expedient, a significant number of subjects (those

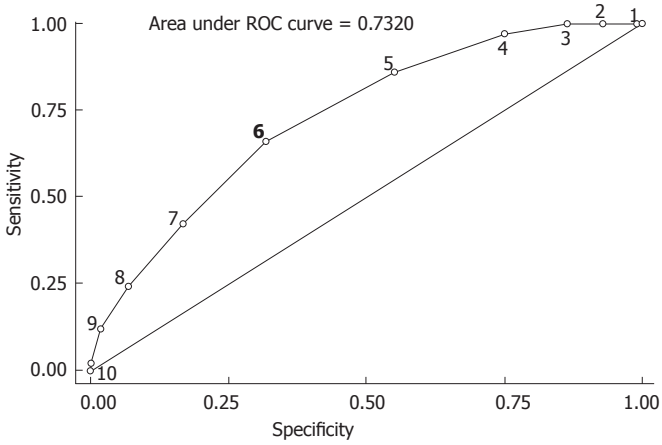

**Figure 5** Receiver operating characteristic (ROC) curve for outcome of death. Numbers along the curve indicate Rockall risk score cutoff values; The optimal threshold is a Rockall score of 6 (in bold).

with Rockall scores of $\leqslant$ 2) at very low risk of death or rebleeding, might be discharged earlier and managed as outpatients since their risk of mortality is low. Although we have not demonstrated validity with rebleeding, in the setting of low Rockall scores it is clear that mortality is low (and in other studies rebleeding as well). Even if rebleeding does not correlate well, the risk of death is extremely low with low Rockall scores and this would likely still support early discharge.

It is unclear why such a low percentage of patients have low Rockall scores. One possible explanation is that in the Canadian medical system, access to rapid hospital admission is relatively difficult and it is conceivable that some low risk patients would be managed as outpatients without coming through a hospital setting and therefore might not be recorded in the RUGBE database.

One the one hand, when these patients are admitted to hospitals, it seems unusual that they are not quickly discharged. One reason why subjects with low Rockall scores are not discharged quickly is that endoscopic assessment is often delayed. In RUGBE, 76% of patients had been investigated at 24 h[30]. The lengthy assessment period may

contribute to the extended length of hospital stay.

On the other hand, subjects identified as high risk of death or rebleeding (Rockall score $\geqslant$ 8) may benefit from more intensive monitoring. This could be performed at an intensive care unit (ICU) or a 'step-down' unit rather than the usual medical/surgical wards. In Canada, the use of ICU beds for subjects with UGI bleeding has been shown to be less common than in some American centers[44]. In RUGBE, 22% of all patients were admitted to the ICU for investigation, therapy and monitoring[30] and even in the 145 patients with a Rockall score $\geqslant$ 8, only 52, or 36%, were sent to ICU. However, a large portion of them would have been classified as average risk and, therefore, unnecessarily monitored in the ICU. Other subjects with a high risk score were sent to medical/surgical wards instead of the ICU.

The strength of this study is in its 'real-life' evaluation of patients presenting to hospitals. The RUGBE database was a thorough one with internal validation that was collected retrospectively. This leads to the major weakness of the study, a retrospective evaluation. Although the RUGBE database was accurate, it was still retrospective with the associated weaknesses of a retrospective database. To device Rockall scores retrospectively will bring about occasional missing data and the inherent patient selection bias. Bias was limited in RUGBE (as best as possible) by having some sites receive virtually all of their non-variceal UGI bleeding patients over the specified time period.

This study has confirmed that the Rockall scoring system provides an acceptable tool to predict the risk of death, but performs poorly for endpoints of rebleeding and surgical procedures. Its cautious use for clinical decision-making purposes could still result in implementing more expedient care for low risk subjects, without sacrificing outcomes, and more efficient monitoring of high risk individuals.

## Abstract

**AIM:** To investigate the factors contributing to health-related quality of life (HRQL) in chronic liver disease (CLD).

**METHODS:** Patients with CLD and age- and sex-matched normal subjects performed the validated Thai versions of the short-form 36 (SF-36) by health survey and chronic liver disease questionnaire (CLDQ). Stepwise multiple regression analysis was used to assess the impact of disease severity, demography, causes of CLD, socioeconomic factors, and self-rating health perception on HRQL.

**RESULTS:** Two-hundred and fifty patients with CLD and fifty normal subjects were enrolled into the study. Mean age and the numbers of low educated, unemployed, blue-collar career and poor health perception increased significantly from chronic hepatitis to Child's Classes A to B to C. Advanced stage of CLD was related to deterioration of HRQL. Increasing age and female reduced physical health area. Low socioeconomic factors and financial burden affected multiple areas of HRQL. In overall, the positive impact of self-rating health perception on HRQL was consistently showed.

**CONCLUSION:** Advanced stages of chronic liver disease, old age, female sex, low socioeconomic status and financial burden are important factors reducing HRQL. Good health perception improves HRQL regardless of stages of liver disease.

**Key words:** Health-related quality of life; Cirrhosis; Chronic hepatitis; Short-form 36; Chronic liver disease questionnaire

## INTRODUCTION

In 1947, the World Health Organization expanded the definition of health to include in addition to the absence of disease, a complete state of physical, mental and social well-being[1]. Health-related quality of life (HRQL) emerges as a tool for measuring outcome from the patient's viewpoint, incorporating social, psychological, physiological and physical functioning[1,2]. Combined using generic and disease-specific instruments can provide more accurate assessment of both the global aspects and the specific features of HRQL of a specific condition[1]. The assessment of HRQL has been done in gastrointestinal diseases and chronic liver disease (CLD)[3-7]. It has been reported that the presence of CLD reduce HRQL and the deterioration of HRQL is apparent while the severity of disease increases[8-13]. Furthermore, demographic factors such as age and gender, alcohol, co-morbid illness, disease awareness and psychological status can affect HRQL in CLD[8-15]. However, a recent study showed that active psychiatric illness and medical co-morbidities, but not severity of liver disease, were determinants of HRQL reduction[16]. Previous researches of HRQL in normal and chronic medical conditions showed that socioeconomic and demographic factors can influence HRQL[17-20]. The contribution of socioeconomic factors and health perception to HRQL was not known in CLD. Self-rating patient health perception is one of the strongest predictors of mortality[21]. HRQL in CLD may be improved by changing patient health perception if there is a relationship between health perception and HRQL. The impact of marital status on HRQL is our interest because its significance had never been studied in CLD[8-13]. Our assumption was that married couple would have more psychosocial and emotional support than single, unmarried

or divorced people. An earlier study revealed that HRQL in Thai patients with CLD was lower than that of normal subjects similar to the reports from Western countries[22]. We aimed to investigate variables that truly affected HRQL, such as disease severity, etiology of liver disease, demographic and socioeconomic factors, and patient health perception in Thai patients with CLD.

## MATERIALS AND METHODS

### Study design and population

A cross-sectional study was carried out at the Gastroenterological Clinic between 1st January 2004 and 30th June 2004. Eligible patients with CLD, age 15-80 years, both men and women, were enrolled consecutively into the study. Exclusion criteria were the concomitant presence of hepatic encephalopathy, active medical co-morbidity, malignancy, current or previous treatment of antiviral agents and those who refused to participate with the study. CLD were classified into chronic hepatitis and cirrhosis. Chronic hepatitis was defined by the elevation of serum transaminase higher than 1.5 times of upper normal limit for 6 mo. The diagnosis of cirrhosis was confirmed from clinical finding, biochemical test, ultrasound or liver histology[23]. The staging of cirrhosis was graded according to Child-Pugh classification: Child's classes A, B and C[24]. Causes of CLD were divided into viral hepatitis, alcohol, viral hepatitis combining with alcohol, non-alcoholic fatty liver disease and miscellaneous causes. Alcohol was the etiology of CLD if daily alcohol drinking was greater than 40 g for at least 10 years. The cause of CLD was viral hepatitis B if hepatitis B surface antigen (Abbott Laboratories, North Chicago, IL) was positive, or viral hepatitis C if antibody to hepatitis C virus (anti-HCV) (Abbott Laboratories, North Chicago, IL) was positive. Data were collected from patient inquiry and medical records. Normal subjects who did not have medical illness were invited into the study. The study protocol was approved by the Hospital Ethical Committee and it was carried out according to the Helsinki Declaration Guidelines[25]. Written informed consent was obtained prior to the study.

### Data collection

**HRQL instruments (dependent variables):** The study patients were asked to self-administer the short-form 36 (SF-36) heath survey and chronic liver disease questionnaire (CLDQ), and the answered questionnaires were checked for completeness by a research assistant who also helped interviewing illiterate patients for the questionnaires. The SF-36 consists of 36 items which are categorized into 8 domains of physical functioning, role-physical, bodily pain, general health, vitality, social functioning, role-emotional and mental health ranging from 0 to 100 with higher scores reflecting better perception of health. Physical functioning, role-physical, bodily pain and general health represent physical health scale, whereas vitality, social functioning, role-emotional and mental health define mental health scale. The domain scores were calculated according to the standard reference[26].

There are 29 items in the CLDQ summarized into 6 domains of abdominal symptoms, fatigue, systemic symptoms, activity, emotional function and worry. Each item consists of 7 linkert scales. Domain score is calculated from the average score of all items of that domain[7]**.** Both questionnaires were formally translated from the original versions and the validation of the questionnaires was reported elsewhere[22,27].

**Definition of study variables (independent variables):** Clinical, demographic and socioeconomic data were collected from each subject. Marital status was dichotomized into single and paired. Single was extended to include unmarried person, divorced or deceased couple. Socioeconomic status was assessed by using the level of education: lower than bachelor's degree and equal to or higher than bachelor's degree; presence and types of career: unemployed, blue-collar and white-collar; presence or absence of financial burden. Subjects were asked to rate their health as "very good", "good", "fair", "poor" or "very poor". Good health perception included "very good", "good" and "fair". Poor health perception consisted of "poor" and "very poor".

### Statistical analysis

Data were entered into Excel spreadsheet (Microsoft Corporation) and analyzed using SPSS (version 11.5; SPSS, Inc., Chicago, IL) Categorical data are described as number and percentage [*n* (%)]. Continuous data were presented as mean ± SD and median (range). Statistical analysis of continuous data was performed with One-way Anova or non-parametric methods as appropriate. $\chi^2$ test was used for analysis of discrete data, which give us the preliminary understanding of the association of the HRQL and studied variables. Stepwise multiple regression analysis was used to study the influence of independent variables on the CLDQ and SF-36 domains while controlling the effect of other variables. *P* value less than 0.05 was considered statistically significant

## RESULTS

### Characteristics of the study population

A total of 364 patients with CLD attended the Gastroenterology Clinic during the 6-mo period. Of these, 114 patients were ineligible for the study: 80 patients were either currently receiving or had received antiviral therapy; 17 patients had hepatocellular carcinoma; 13 patients had active co-morbid illness; two patients were having hepatic encephalopathy and two patients refused to participate in the study. Two-hundred and fifty subjects with CLD, and 50 normal subjects were enrolled into the study. Mean age (range) of the whole group was 48.1 (18-77) years. The number (%) of male to female ratio was 188:112 (62.7%:37.3%). The details of clinical, demographic and socioeconomic data are shown in Table 1. The majority of patients in both groups was male and had education lower than bachelor's degree. Although both groups reported financial problems in equal proportion, the socioeconomic status of CLD group was inferior to that of normal group, which was shown from the higher number of unemployed subjects and blue-collar typed career in the former group ($P < 0.01$). It is not surprising that poor health perception

[1]Incomplete data.

was more frequent in the CLD than the normal group. In this study, there were only 16 (6.4%) patients with Child's class C cirrhosis, and viral hepatitis was the most common cause of CLD (58.8%), followed by chronic alcoholic (17.2%) and non-alcoholic fatty liver disease (10.8%).

### *Association of variables and disease severity*

Similar to previous reports of any chronic liver diseases, male predominated in this study. The greatest number of single was found in chronic hepatitis group ($P < 0.01$). Mean age of this group was the lowest and age increased in advanced stages of CLD ($P < 0.01$). Low socioeconomic status, which was represented by lower education, unemployment and blue-collar typed career, increased in advanced stages of CLD. The reason of this finding is not known. Low socioeconomic status may keep the patients from appropriate treatment; hence the deterioration of liver disease is likely to happen. The proportion of good health perception decreased while the severity of CLD went up (Table 2).

### *The effect of disease severity on HRQL by univariate analysis*

By univariate analysis, higher stages of CLD decreased HRQL in some domains of the SF-36, such as physical function, role-physical, general health and role-emotion ($P < 0.001$), and in all area of the CLDQ ($P < 0.03$). However, we could not make a conclusion that advanced

stages of CLD reduced the HRQL due to the presence of several confounding factors in advanced stages of CLD, such as old age, low socioeconomic status and poor health perception (Figures 1 and 2).

### *Influence of disease stage and variables on HRQL while controlling other variables*

Multiple regression analysis of the association of HRQL domains and multiple variables such as stages of CLD, self-rating health perception, age, sex, financial burden, type of career, education level and viral hepatitis infection as a cause of CLD was performed. The advanced stages of CLD reduced all of the CLDQ domains, the majority of physical health scales of the SF-36 (physical functioning, role-physical and general health) and role-emotional domains. A one-year increase in age was associated with the reduction of 3 domains of physical heath scales of the SF-36 (physical functioning, role-physical and bodily pain), similar to the negative effect of female on physical functioning. While the presence of financial burden decreased multiple domains of the SF-36 and CLDQ, lower levels of education and career reduced predominantly the domains of mental health scales (vitality and role-emotion, respectively). Good health perception increased the SF-36 and CLDQ scores across the board. Viral hepatitis infection was not shown to affect any domains of HRQL (Tables 3 and 4).

## DISCUSSION

Patients with CLD usually have HRQL lower than normal population, and the deterioration of HRQL appears while the severity of CLD increases[8-13]. This study focus not only on liver disease factors but also on other variables, such as age, sex, family support, socioeconomic status (education level, employment and career type), financial burden and self-rating health perception. Multiple regression analysis was performed to confirm the effect of variables on HRQL while controlling the influence of other variables. Advanced stages of CLD reduced all domains of the CLDQ, and the physical function, role-physical, general health and role-emotion domains of the SF-36. The effect of viral hepatitis infection as causes of CLD on HRQL reported from several studies is still inconclusive[15,28]. Recent systematic review revealed that the patients with HCV infection scored lower than the controls across all domains of the SF-36[27]. In our study, we could not find the impact of viral hepatitis infection, especially viral hepatitis C, on HRQL. However, the total cases of HCV infection in the study were quite low. There were only 48 (19.2%) patients with HCV infection distributing in three stages of cirrhosis and chronic hepatitis. In general, the elderly is associated with less favorable appraisal of personal health due to their health concerns, pessimistic health appraisals, social isolation and unemployment[29]. A previous study in CLD revealed that old age had a negative impact on HRQL[11]. Nevertheless, another study reported that cirrhotic patients with younger age had a more impairment in HRQL than the elder[9]. While important factors were controlled, a one-year increase in age reduced the scores of physical function, role-physical, and bodily pain from 0.4 to 0.8. In general, females have more health concerns and are more treatment-seeker than male. One study in CLD reported the minor effect of gender on HRQL in CLD[11]. We found that female gender yielded negative influence on physical functioning. Surprisingly, the marital status did not affect HRQL. This finding may be explained by the close-knit type of Thai society, so CLD patients could get psychosocial support from other family members even when they are single or divorced. Low socioeconomic status was shown to be important factor affecting HRQL in normal population and in patients with medical illnesses, such as prostate cancer, end-stage renal diseases and lung cancer[18-20,30]. Education level and career type were used as markers of socioeconomic status in this study because there is no standard categorization of socioeconomic status in Thailand. In general, education can help people cope their own problems. Low educated people are prone to have psychological problems and have false beliefs. People with lower socioeconomic status have more stress, more depression and interfamilial relationship problems in their life. As far as we know, there is only one study in chronic hepatitis C that reported the effect of education on HRQL[15]. We found that lower education level and type of career reduced vitality and role-emotion. The presence of financial burden can lower HRQL in several areas of the SF-36 and CLDQ. The impact of low socioeconomic status on HRQL supports the proposed conceptual model of HRQL by Wilson IB and Cleary PD in 1995, which states that socioeconomic factors influence multiple domains of functional status[21]. The most important contribution showed from our study is that self-rating patient health perception can affect HRQL in CLD. In the conceptual model, health perception is included in the model together with other factors, such as biological and physiological variables, symptom status, functional status, characteristics of individual and environment[21]. We found that the proportion of good health perception declined while the severity of CLD increased. Good health perception was the only factor shown to be positively associated with the SF-36 and CLDQ domains unanimously. This finding supports the HRQL model that health perception is related to functional status, symptom status, biological and physiological variables. It is possible that HRQL in CLD can be improved by searching strategy to increase patient's health perception. There is some evidence showing that psychological and emotional support can improve patient health perception[31].

In this study, we showed that the important factors that reduced HRQL in CLD included not only advanced stages of CLD but also old age, female sex, low socioeconomic status, financial burden, as well as poor health perception in accordance with the conceptual model of HRQL. We conclude that while medical treatment is a key to improve patient condition and HRQL, additional treatment with psychosocial support to raise patient health perception may improve HRQL, perhaps even better.

## COMMENTS

### *Background*

Health-related quality of life (HRQL) in chronic liver disease patients is lower than normal population. Factors relating to the reduction of HRQL are inconsistently reported. The study of factors affecting HRQL in chronic liver disease in Asians has never been carried out.

### *Research frontiers*

The data of several variables, e.g. disease severity, etiologic factor, demographic and socioeconomic, and patient self-rating health perception were collected. Then, multiple regression analysis was used to identify the factors that independently affect HRQL in chronic liver disease.

### *Innovations and breakthroughs*

The study demonstrated that advanced stages of chronic liver disease, old age and female sex reduced HRQL in Thai patients. Furthermore, socioeconomic factors which hardly receive attention in previous studies of HRQL in chronic liver disease can affect HRQL. Importantly, this is the first time that patient health perception is shown to be strongly associated with HRQL in chronic liver disease.

### *Applications*

While the medical treatment is a key to improve patient condition and HRQL, complementary treatment with psychosocial support aimed to raise patient health perception may improve HRQL. This conclusion needs further study to confirm.

### *Terminology*

HRQL is a concept which reflects the physical, social, and emotional attitudes and behaviors of an individual as they relate to their prior and current health state. HRQL assessment describes health status from patients' perspective and serves as a powerful tool to assess and explain disease outcomes.

### *Peer review*

This study concerns over the understanding of readers for the demonstration of results from multiple regression analysis. The key point of the analysis is to show if the presence of individual relating factor affects HRQL in chronic liver disease. Overall the paper requires grammatical work.

## Abstract

**AIM:** To evaluate disease-specific quality of life (QOL) in liver cirrhosis patients and to compare it with those of a healthy population. Also an important objective was to assess whether QOL in liver cirrhosis patients differs by age and gender, by type and severity of disease.

**METHODS:** The case group of 131 liver cirrhosis patients was selected. The control group of 262 was enrolled from a healthy population according to the scheme of case-control study. Clinical, demographic, laboratory data were collected. QOL was measured with a specific chronic liver disease questionnaire (CLDQ), which was translated and validated in Lithuanian. QOL scores were compared between groups by age, gender, type and severity of disease. Cronbach's alpha statistics calculation was used for evaluation of internal consistency reliability. Student's *t* test or ANOVA were used for evaluation hypothesis about probability equation.

**RESULTS:** QOL was significantly lower in liver cirrhosis patients than in healthy population (59.5 ± 18.3 *vs* 85.3 ± 12.3, $P < 0.001$). The significant QOL differences between case and control groups were observed in domains of worry and abdominal symptoms, the smaller differences-in emotional functions and systematic symptom domains. Significantly worse QOL was in observed patients with increased clinical severity of the disease measured by Child-Pugh class. Age, gender and etiology of disease had an insignificant effect on QOL in cirrhotic patients.

**CONCLUSION:** QOL was significantly impaired in all CLDQ domains in liver cirrhosis patients. Increase in severity of disease was the major factor associated with poorer QOL.

## INTRODUCTION

Measurement of quality of life (QOL) becomes increasingly important in clinical patient management[1-3]. The World Health Organization has expended and codified health definitions to multidimensional adding mental and social well being[4]. This allowed us, in the last decades of the 20th century, to develop quality of life concepts and adopt different instruments for multidimensional evaluation of health[5-9].

The main reason why the rapid development of QOL measures in health care took place was the growing recognition of the importance of understanding the impact of healthcare interventions on the patients' every day life, rather than only treatment of their bodies[10]. Also physicians have always intended to find out and better understand how their patients feel. This is particularly important for patients with chronic, disabling or life threatening diseases, in persons, who live with minor expectation to be cured and with conditions that are likely to impact their physical and social well-being. In such patients it may be more relevant than length of life, because they are frequently more concerned about quality and disability than about longevity[11,12].

Health-related QOL is important in measuring the impact or burden of a chronic disease. Liver cirrhosis is an example of such a disease. Patients with chronic liver disease suffer from: fatigue, pruritus, loss of esteem, depression, and other complications of cirrhosis such as hepatic encephalopathy, ascites, spontaneous bacterial peritonitis and recurrent variceal hemorrhages[13,14]. Some of these conditions have obvious clinical manifestation and could be easily measured by the traditional clinical outcome measures (ascites, spontaneous bacterial peritonitis, varicel hemorrhages). Other important conditions (fatigue, loss of

esteem, inability to function or work, anxiety, depression, emotional problems) are poorly evaluated by the clinical measures. More evidence that measuring QOL provides a better measurement of these latter conditions is presented in the recent literature[15-17].

The general aim of this study was to evaluate QOL in patients with liver cirrhosis and to compare its features with the control group of persons, selected from the population sample. We aimed also to look for associations between QOL scores and demographical characteristics, type of cirrhosis, severity of disease.

## MATERIALS AND METHODS

### Patients

The study was conducted during a one-year period in 2001-2002. In the first stage of the investigation the case group was selected (131 patients with cirrhosis). The control group (262 persons) was selected from randomly selected population according to the scheme of case-control epidemiological study. The group of cases was composed from patients with liver cirrhosis of different etiology. These patients have been admitted, diagnosed and treated at the Clinic of Gastroenterology, Hospital of Kaunas University of Medicine. The diagnosis was verified according to the data of anamnesis, clinical, biochemical and instrumental examinations and the results of percutaneous or transjugular liver biopsy data. Only the persons without hepatic encephalopathy, according to psychomotor tests, were included into the study.

The control group was randomly selected from the list of Kaunas county population. Pair matching method was applied in order to select the control group. The control persons were selected according to gender, age and the education background. Two controls were selected for one case person.

### Methods

The routine clinical examination was carried out for the patients with liver cirrhosis: clinical and biochemical blood sample analysis, ultrasound investigation, esophagogastroscopy, percutaneous or transjugular liver biopsy. These persons were classified according to the etiology of disease. Clinical and biochemical analysis, evaluation of failure of liver function, also commonly manifested complications of cirrhosis were recorded and analyzed. Severity of liver cirrhosis was evaluated according to Child-Pugh score[18].

Clinical and epidemiological investigation methods were used. Investigation data of case groups were registered in the Registration Form for Clinical Data. General data about the cases and controls were collected in the General Questionnaire Form. QOL questionnaires were administered for both respondents of case and control groups.

The chronic liver disease questionnaire (CLDQ) was applied as the instrument for measuring QOL. This QOL investigation instrument was developed at the Department of Gastroenterology, The Cleveland Clinic Foundation by Younossi *et al* in 1999 as the disease specific instrument for evaluating QOL of patients with chronic liver disease[19]. Approval of the authors was received to use this instrument in our study. CLDQ covers 29 items and is designed to measure the six domains of QOL: abdominal symptoms (AB), fatigue (FA), systemic symptoms (SY), activity (AC), emotional functions (EM) and worry (WO). CLDQ has been translated to Lithuanian and passed validation procedures before this study. Evaluation of reliability and validity was carried out. Cronbach's alpha (measure of internal consistency) of overall scores was 0.93, which was above the acceptable level of 0.70. Approval from Biomedical Ethics Committee was obtained and participants signed a written consent prior filing the questionnaires.

SPSS 10.0 for Windows was used for research analysis. Cronbach's alpha statistics calculation was applied for evaluation of internal consistency reliability in QOL questionnaire. Standard means for QOL scores with a 95% confidence interval were calculated. For evaluation of continuous variables the statistical mean (m) and standard deviation (SD) were computed. Student's *t* test or ANOVA were used for proving hypothesis about probability equation. Mann-Whitney or Kruskall-Wallis tests were used for comparison two or more independent variable groups. $P < 0.05$ was considered significant in two-tailed tests.

**Table 1 Clinical and demographical data of liver cirrhosis patients ($n$ = 131)**

| Variable | *n* (%) |
|---|---|
| Age (yr) | |
| < 40 | 23 (17.6) |
| 40-50 | 34 (26.0) |
| 51-60 | 33 (25.1) |
| > 60 | 41 (31.3) |
| Gender | |
| Male | 68 (51.9) |
| Female | 63 (48.1) |
| Etiology of disease | |
| Viral B and/or C cirrhosis | 53 (40.5) |
| Alcoholic cirrhosis | 50 (38.2) |
| Cholestatic cirrhosis | 11 (8.3) |
| Other cirrhosis | 17 (13.0) |
| Child-Pugh class | |
| Class A | 32 (24.6) |
| Class B | 72 (54.6) |
| Class C | 27 (20.8) |

## RESULTS

At the baseline survey 131 patients with liver cirrhosis of different etiology were examined. Table 1 summarizes their demographic and clinical characteristics.

### QOL in liver cirrhosis patients and in the control group

For the researches and clinicians it is important to know, which particular domains of QOL are most affected by liver cirrhosis. Figure 1 presents the distribution of mean scores of six QOL domains measured by CLDQ

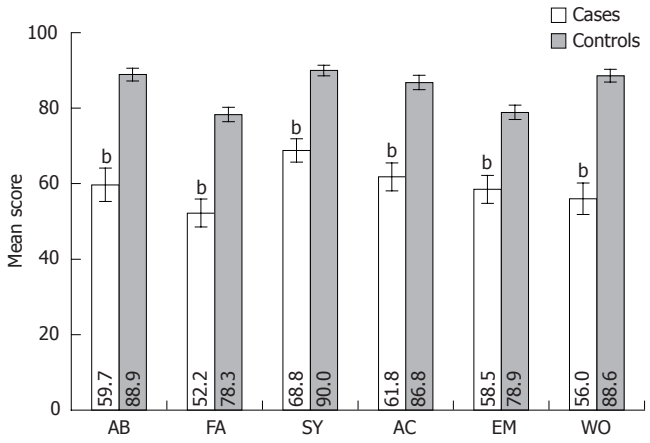

**Figure 1** Chronic liver disease questionnaire (CLDQ) scale score differences in six quality of life (QOL) domains in case and control groups. Error bars indicate 95% confidence interval. AB: Abdominal symptoms; FA: Fatigue; SY: Systemic symptoms; AC: Activity; EM: Emotional function; WO: Worry. NS: Not significant. $^{b}P < 0.001$ *vs* control group.

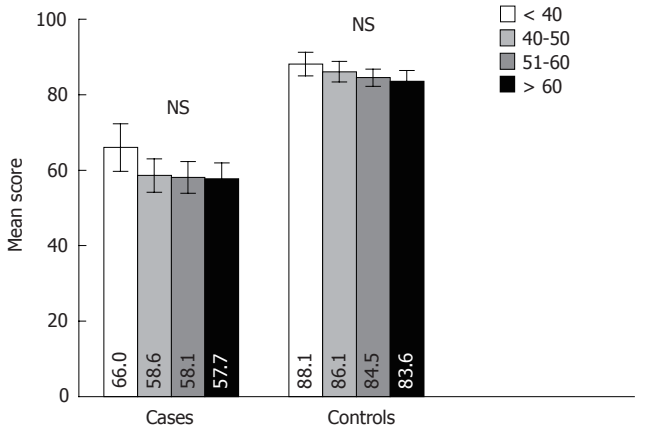

**Figure 2** Chronic liver disease questionnaire (CLDQ) scale score comparison between the age groups in case and control groups. Error bars indicate 95% confidence interval. NS: Not significant.

questionnaire in cases and controls. It was established that in all six domains QOL mean score (SD) were lower in cirrhosis patients than in control group ($P < 0.001$). The most significant difference in QOL was observed in the domain of worry (56.0 ± 24.2 *vs* 88.6 ± 14.4, $P < 0.001$) and in abdominal symptoms (59.7 ± 25.8 *vs* 88.9 ± 14.2, $P < 0.001$). Smaller deterioration of QOL was established in the domain of emotional function (58.5 ± 20.9 *vs* 78.9 ± 16.1, $P < 0.001$) and in the systemic symptoms domain (68.8 ± 18.1 *vs* 90.0 ± 10.9, $P < 0.001$). The overall CLDQ score for patients with liver cirrhosis also was lower than in persons with no cirrhosis (59.5 ± 18.3 *vs* 85.3 ± 12.3, $P < 0.001$).

### *Age and QOL*

The answers of respondents were analyzed in the four age groups. The distribution of patients by age groups was following: age group < 40 years-23 (17.6%), 40-50-year-old group-34 (26.0%), 51-60-year-old group-33 (25.1%) and > 60-years old group-41 (31.3%). The age structure

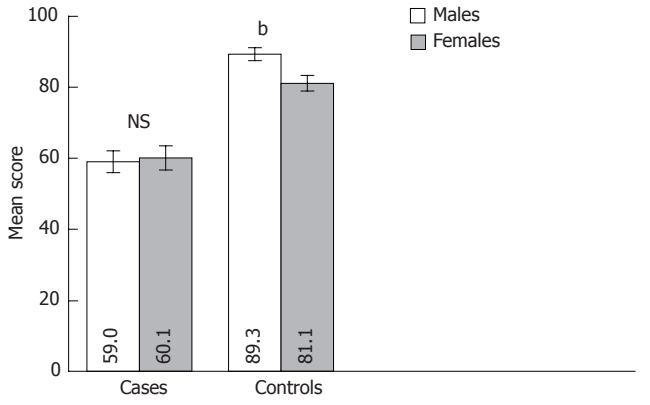

**Figure 3** Chronic liver disease questionnaire (CLDQ) scale score comparison between the genders in case and control groups. Error bars indicate 95% confidence interval. NS: Not significant. $^{b}P < 0.001$ *vs* females in control group.

of the control group was the same according the design of study. Figure 2 presents data on distribution of QOL by age among the respondents in case and control groups. It is evident from this illustration that general QOL was decreasing only insignificantly during period of aging in both case and control groups.

### *Gender and QOL*

The samples of cases and controls were composed of 51.9% of males and 48.1% of females. We have analyzed the effects of gender on QOL. Figure 3 illustrates how gender relates with QOL in both compared groups. It was proved that QOL is higher in control healthy males than in females ($P < 0.001$). However, no significant difference was established in QOL between genders in liver cirrhosis patients.

### *Type of liver cirrhosis and QOL*

Comparison of QOL in patients with different types of liver cirrhosis was carried out in four groups of patients: alcoholic liver cirrhosis, viral liver cirrhosis, cholestatic liver cirrhosis (primary biliary cirrhosis and primary sclerosing cholangitis), and other forms of liver cirrhosis. It was established by our analysis that in all six CLDQ domains QOL was at the similar score level in all four groups of patients analyzed (Figure 4).

### *Severity of the disease according the Child-Pugh scale and QOL*

We have analyzed and compared QOL in patients attributed to A, B and C liver cirrhosis severity classes according to Child-Pugh classification (Figure 5). The CLDQ showed significant worsening of QOL in parallel with increase of the clinical severity of disease measured by Child-Pugh scale (QOL mean score [SD] in A and C classes were respectively 65.9 ± 18.6 and 52.6 ± 17.0, $P < 0.01$).

## DISCUSSION

Despite the fact that QOL investigations cover more and more diseases and population groups, its application in hepatology is still very scarce. Many recent publications

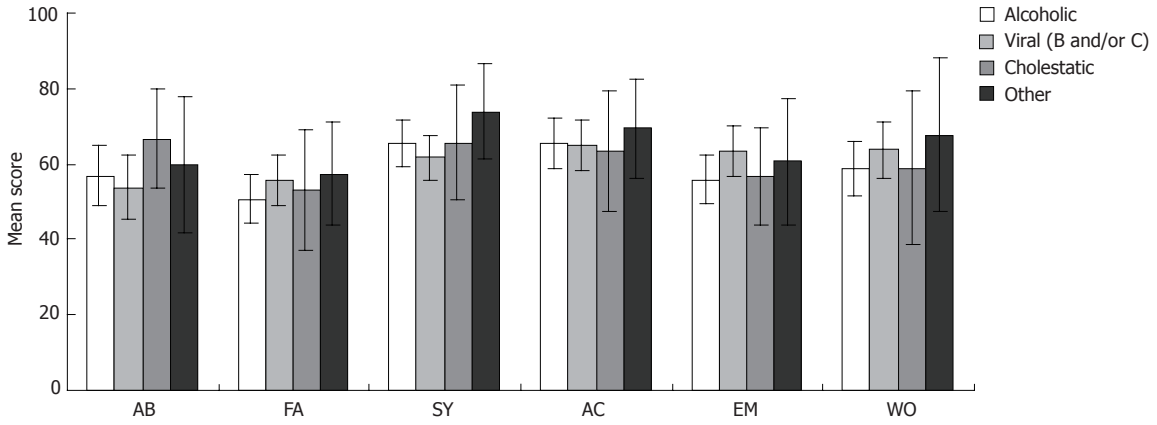

**Figure 4** Chronic liver disease questionnaire (CLDQ) scale score comparison in six quality of life (QOL) domains by the etiology in liver cirrhosis patients. Error bars indicate 95% confidence interval. AB: Abdominal symptoms; FA: Fatigue; SY: Systemic symptoms; AC: Activity; EM: Emotional function; WO: Worry.

still agree that very limited information is available on the impact of liver cirrhosis on QOL and continue investigating different QOL instruments.

This investigation is important as an example where both population based and clinical approaches in research were applied by selecting patients (from hospital) and controls (from population). Also our study was new for our country and for other countries of Central and Eastern Europe because QOL of liver cirrhosis patients was not investigated before in this European region.

By permission of CLDQ authors the specific questionnaire to measure health related QOL in patients with chronic liver disease was translated, adopted and validated in Lithuania. CLDQ previously have been adapted and validated for German speaking countries and also recently was translated into Farsi, Thais[20-22].

In our study QOL of patients with cirrhosis was compared with a randomly selected population group, because CLDQ is not designed exclusively as the liver disease specific instrument and allows us to answer all the questions for healthy persons also. The extent of impaired QOL of cirrhosis patients differed in the various domains. The most significant decrease in QOL was observed in the domain of worry and in abdominal symptoms. Smaller deterioration of QOL was established in the domain of emotional function and in the systemic symptoms domain.

The author of CLDQ, Younossi, also has established negative impact of different chronic liver disease (primary biliary cirrhosis, viral hepatitis B and C, primary sclerosing cholangitis, hepatocellular disease) for QOL and has established that deterioration of QOL is similar as in patients with chronic obstructive pulmonary disease or congestive heart failure[23,24]. Similar findings, which indicate significantly lower QOL in liver cirrhosis patients, were presented by Italian survey, where short form-36 (SF-36) and Nottingham Health Profile (NHP) questionnaires were used and by Croatian authors, who used SF-36 instrument[25,26].

We have calculated how much QOL is affected in cirrhosis patients in relation to age and gender. It is evident from population-based studies that QOL decreases with age in normal population[2,3,25]. However, in our study QOL

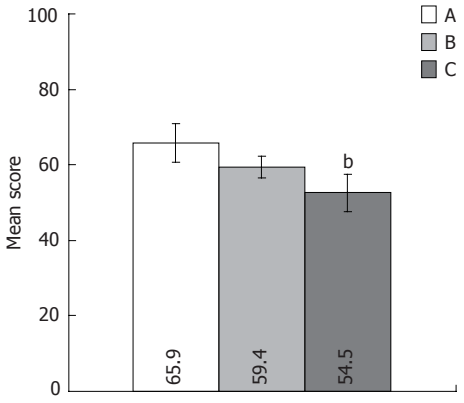

**Figure 5** Chronic liver disease questionnaire (CLDQ) scale score comparison according the disease severity in the case group. Error bars indicate 95% confidence interval. A, B and C represent Child-Pugh class A, B and C, respectively. $^{b}P < 0.01$ *vs* A Child-Pugh class.

both in control and cirrhosis patients groups showed only small and not significant impairment with age ($P > 0.05$). In an Italian study, where SF-36 was used, a minimum deviation from population norms was established in the oldest group[25]. This could be explained, that in our cirrhosis group proportion of patients with more severe disease (higher Child-Pugh class) was higher than in the Italian study. On the other hand "normative" populations in these two studies could have different age structure and levels of QOL.

Our study has demonstrated that QOL is higher in males from random population than in females. However, gender did not show any effect on QOL of liver cirrhosis patients. Majority or researchers, who analyzed QOL data of cirrhosis patients also, have stated that QOL is not determined by gender[27-29].

We have classified cirrhosis patients according to the disease etiology into four groups: viral, alcoholic, cholestatic and other origin. It was established by our analysis that QOL do not differ significantly in all four groups. This fact could indicate that etiology has minor impact for QOL. Our results are in accordance with other surveys, which established the similar patterns[23,24].

However, literature indicates on significant effects of disease severity and worsening of QOL across the disease stages[23-25,30]. In our study chronic liver disease stages were classified into three groups (A, B and C) according to Child-Pugh score. We also established that higher severity of disease (higher Child-Pugh class) was associated with a lower CLDQ score.

Lithuania is a relatively small country and the number of liver cirrhosis patients that could be accessed at the university hospital during one year, is not big. We made an attempt to diminish this possible limitation by selecting two-fold larger control group from randomly selected "healthy" population and by matching case and controls. Groups of patients with liver cirrhosis represents clinical group of cases, which can not be considered as completely representing the whole population of patents with liver cirrhosis in the country. It is evident that in primary stages of disease the patients with liver cirrhosis have less probability to be referred to the hospital. Also severe patients with Child-Pugh class C could have encephalopathy and mental disorders-these were excluded from the study. On the other hand we should take into account the possibility of selection bias in the "healthy" group of controls-non-respondents, who are completely healthy, tend to refuse to fill in questionnaires. This could result in selection of the control group with lower QOL. These circumstances allow extrapolating the research inference for the whole population of cirrhosis patients with caution.

In summary, our data obtained by this survey have shown that general QOL and QOL in all health domains were lower in patients with cirrhosis than in controls selected from the normal population. The most significant QOL differences between case and control groups were observed in domains of worry and abdominal symptoms, the smaller differences-in domains of emotional functions and systematic symptoms. Disease severity (higher Child-Pugh class) was associated with lower Chronic Liver Disease Questionnaire score. Etiological type of liver cirrhosis had minor and insignificant effect on QOL.

## ACKNOWLEDGMENTS

The authors would like to thank the administration of Hospital of Kaunas University of Medicine (head: Professor J Pundzius) for organizational support and input in providing facilities to conduct the study. Research Laboratory for Population-Based Studies (head: Professor S Domarkiene) of Institute for Cardiology of Kaunas University of Medicine has provided possibility to access random samples of normal population.

## Abstract

**AIM:** To explore the efficacy and mechanism of a novel therapeutic method of traditional Chinese medicine in patients with refractory cirrhotic ascites complicated with azotemia.

**METHODS:** Seventy-five cases of refractory cirrhotic ascites complicated with azotemia were randomly divided into 3 groups: comprehensive treatment ($n$ = 29), simple treatment ($n$ = 24), and control ($n$ = 22). The basic treatment methods were the same in all groups, including liver protecting medicines, diuretics and supportive drugs. The control group underwent only the basic treatment. *Shehuang Paste* (SHP) was applied to the navels of the two treatment groups once a day for 30 d. Colon dialysis with Chinese herbs was administered to the comprehensive treatment group once every two days. Before and after treatment, we measured abdominal circumference, BUN, Cr, serum $Na^+$, urine $Na^+/K^+$, liver function, endotoxin content, NO, and ET-1. Color Doppler ultrasonography was conducted to measure the portal vein blood flow.

**RESULTS:** The total effective rate for ascites was 72.4% in the comprehensive treatment group, 45.8% in the simple treatment, contrasting with 18.2% in the controls. Between the two treatment groups and the controls, there were significant differences in the effective rates ($P < 0.01$, and $P < 0.05$). There was also a significant difference ($P < 0.05$) between the two treatment groups. Measurements of Cr and BUN showed higher values for the treatment groups, with the comprehensive better than the simple group ($P < 0.05$). Sera Na, urine Na/K were different, $P < 0.01$ between pre- and post-treatment in the comprehensive group, and $P < 0.05$ in the simple group. The treatment groups' endotoxin content was also significantly reduced ($P < 0.01$, and $P < 0.05$), with the comprehensive group better than the simple group ($P < 0.05$). Portal vein blood flow and NO content significantly reduced ($P < 0.05$), as did ET-1 content ($P < 0.01$). There were no significant changes in the control group ($P > 0.05$). The comprehensive treatment group's pre- and post-treatment portal vein and splenic vein blood flows showed a positive correlation to NO, ET-1 and endotoxin contents.

**CONCLUSION:** When treating refractory cirrhotic ascites complicated with azotemia, *Shehuang Paste* combined with Chinese herbal dialysis is better than Shehuang Paste alone for ascites resolution, azotemia, and endotoxin elimination. However, both methods on their own were also effective for reducing portal and splenic vein blood flow, and lowering the contents of NO, ET-1 in the two treatment groups.

**Key words:** Cirrhotic; Refractory ascites; Azotemia; Vasoactive substance

## INTRODUCTION

Cirrhotic ascites is one of a triad related to portal hypertension, which is not difficult to be cured if patients receive early treatment. Only about 10% of patients proceed to develop 'refractory ascites'. The International Ascites Club[1] definition of refractory cirrhotic ascites is that ascites is not obviously reduced after treatment (mainly by diuretics administration) or that early ascites recurrence can not be prevented by medicines after discharging liquid administration, which was defined by the Chinese experts based on the simple fact that patients' abundant ascites

lasts more than 3 mo[2]. Approximately 20% of the patients will go on to develop hepatorenal syndrome (HRS) within 1 year[3]. Once HRS develops, the mortality rate is almost 100%. In their development, hepatopathy and nephropathy interact with each other. Hepatocirrhosis and fluid and sodium retention, easily complicate any dysfunction of the renal blood stream. If treated with diuretics, azotemia may be induced. However, anuria induced by renal dysfunction can aggravate ascites. Thus it is very important that clinical research should be aimed to prevent, to treat early or to stop the development of hepatorenal syndrome[4].

The pathogenesis of refractory cirrhotic ascites is not well understood. There are many theories, but portal hypertension is generally accepted as the basis of ascetic formation. Neural-tumour reaction is induced by portal hypertension, and an endogenesic vessel activity abnormality in which endotoxin, NO and ET-1 play important roles. These factors lead to hyperdynamic circulation and an effective blood capacity deficiency. Renal blood stream kinetic and functional abnormalities are important in the pathogenesis[5].

The major medicinal treatments are an abundant discharge of liquid, supplemented by a large volume of protein or self-liquid retransfusion. However, it cannot sustain for a long time and a circulatory functional disorder can easily happen after massive liquid discharging. To date, a medicine to completely reverse low perfusion of nephridium has not been determined[6]. Thus, it is difficult to treat refractory cirrhotic ascites by the normal methods of internal medicine.

There are reports of herbs being applied to the navel for the treatment of cirrhotic ascites[7], indicating that the application of herbs to the navel for the treatment of cirrhotic ascites is possible. Such treatment can act fast, significantly reduce ascites, improve symptoms while it neither injures patient's right Qi ("life energy" according to the principle of traditional Chinese medicine) nor disturbs the water-electrolyte balance. But there are few reports about the application of herbs to the navel for the treatment of refractory cirrhotic ascites. Chinese herbal colon dialysis has for many years been applied for treating renal failure. The mechanism for this treatment is that the human colon has functions of absorption and secretion. The mucosa of the colon, a semi-dialytic membrane, can selectively absorb or secrete, using the ion grads in dialytic water, discharge poisonous metabolic productions as endotoxins, carbamide, ammonia, and absorb substances useful for human life from herbs. *Da huang* is the herb usually used. Chen HL[8] added *Fu zi, chuan xiong, Hua Q*[9] conjugated *Fu zi, Shui zhi,* and *Sheng mu li,* Chen HC[10] *Jin yin hua*, *Huai hua*, *Pu gong ying*, and *Duan mu li*. These treatments are mostly used to treat chronic renal failure or hemorrhagic fevers of nephritic syndrome complicated with acute renal failure. However, we have found no reports about these treatments being used for cirrhotic ascites complicated with azotemia.

This study used SHP applied to the navel in combination with Chinese herbal colon dialysis. It aimed to observe the clinical effect on 'refractory cirrhotic ascites', measure the levels of endotoxins, NO, ET-1 and portal vein blood flow. We sought to prevent or postpone the process of hepatorenal syndrome during azotemia.

## MATERIALS AND METHODS

### *Clinical material*

All 75 patients enrolled with refractory cirrhotic ascites were inpatients hospitalized in the authors' hospital from July 2002 to June 2005. They were randomly assigned to 3 groups by SAS software: 29 cases to the comprehensive treatment group; 23 male, 6 female; average age 43 ± 10 years; and average disease duration 6.1 ± 3.0 mo. There were 19 cases of hepatitis B-related cirrhosis, 2 of alcohol-related cirrhosis, 1 of blood fluke related cirrhosis, and 1 of autoimmune related cirrhosis; 24 to the simple treatment group, 17 male, 7 female, average age 43 ± 13 years, average disease duration 7.7 ± 3.5 mo. There were 20 cases of hepatitis B-related cirrhosis, 1 of alcohol-related cirrhosis, and 1 of blood fluke related cirrhosis. The level of ascites, Cr, BUN, age, duration of disease, and disease condition between the two treatment groups were comparable, without significant differences ($P > 0.05$).

### *Diagnostic criteria for refractory cirrhotic ascites*

The diagnosis of refractory cirrhotic ascites was made with reference to guidelines contained in the literature. Inclusion criteria[1]: (1) Patients with a confirmed diagnosis of cirrhotic ascites; (2) Cases of refractory ascites, that is, previous treatments were either not satisfactory in dispelling ascites or there was an unavoidable early recurrence of ascites after discharge and the ascites had lasted more than 3 mo; (3) The patients' serum Na < 130 mmol/L, urine Na < 10 mmol/24 h, urine Na/K < 1, and glomerular filtrating rate (GRE) were below normal ranges. The level of Cr is 141-211 μmol/L[11].

### *Exclusion criteria*

Patients were excluded if one of the following conditions was present: (1) Ascites originating from cirrhosis complicated with a malignant tumor; (2) Complications with acute digestive tract bleeding or hepatic encephalopathy; (3) Complications with primary diseases of cardiovascular, renal and hematopoietic systems, or with mental disease; (4) Anal stricture, internal or external hemorrhoids with active bleeding; and (5) Patients who did not meet the inclusion criteria, did not follow directions about taking medication, medical records were missed, or the effects and safety of the treatment were difficult to be determined.

### *Therapeutic methods*

**SHP Ingredients:** Each piece of SHP consisted of snail flesh (approximately 30 g), *Moschus* 1 g , artificial *Calculus Bovis* 1 g, *Radix Euphorbiae Kansui* 10 g and *Bulbus Allii Fistulosi* 10 g.

**Preparation:** *Bulbus Allii Fistulosi* was pressed juice. *Radix Euphorbiae Kansui* was decocted with water twice, at each 2 h, and mixed with *Bulbus Allii Fistulosi* juice that had been filtrated. The mixture of the juice of the 2 herbs was concentrated to a dense paste with a relative density of 1.20. Moschus and artificial *Calculus Bovis* were extracted after being recirculated three times in 95% ethanol. Snail

flesh was minced, the dregs removed and then stewed. The extract of *Moschus* and artificial *Calculus Bovis*, the stewed snail product and the dense paste were mixed and then formed into a medicated patch of 3 cm × 3 cm in size (undertaken by the Pharmaceutical Department of Shenzhen Hospital, affiliated to Guangzhou University of TCM, batch No: 030113)[12]. The patch was placed into a bag and stored at 4℃.

**Quality control:** Quality control for the SHP was by detecting the content of Kotone musk and Bilirubin, the main ingredients of *Moschus* and artificial *Calculus Bovis*. *Moschus* (Batch No: 030912) and artificial *Calculus Bovis* (Batch No: 031221) were purchased from Shenzhen Branch of the Medicinal Material Company of China. The amount of medicinal paste on each patch was 1.2 g/100 $cm^2$. Bilirubin content in *Calculus Bovis* was above 41% (Bilirubin content is noted as being 35% in the 2005 edition of Pharmacopeia of China ). Ketone musk in each piece of SHP was 2.73 mg/g[13] measured by high performance liquid chromatograph (Gillson, France). The method is reliable and stable.

**Colon dialysis ingredients:** The formula used for colon dialysis consisted of *Rheum Palmatum L*, Sophorage Japonica L, Lonicera Japonica Thunb, Taraxcum mongolicum, Herba-Mazz, and Ostrea telienwhanensis Crosse; 30 g of each.

**Preparation:** All ingredients in the colon dialysis formula were decocted together twice in a routine way. The 2 juices were mixed, filtrated to 200 mL, and stored at -70℃ until use. For use, the mixture was warmed to 38℃(carried out by the Preparation Room, Guangzhou University of Traditional Chinese Medicine affiliated Shenzhen Hospital, No. 030113).

### Group treatment

The basic treatment was given to all three groups. Included in this were liver protecting medicines such as Wuzhi Jiaonang (mainly deoxyschizandrin, two tablets given each time, three times a day) and Silybin Meglumine (two tablets each time, three times a day); diuretics furosemide and antisterone at a ratio of 1:2 (80 mg: 160 mg); and supportive drugs such as 20% human albumin at a dosage of 100 mL per day. Ascites were discharged from 1000 mL to 1500 mL the first time and then from 2000 mL to 3000 mL each time for 3 times once every 2 d. Antibiotics (fortum 2.0 g/d) were administered to patients who complicated with peritonitis.

For the simple treatment group, the treatment method was the basic treatment plus SHP applied to the navel. For the comprehensive treatment group, the basic treatment plus SHP on the navel and the herbal colon dialysis. For the control group, only basic treatment .

### Treatment procedures

**Navel application:** One piece of paste was compressed on the navel (Shenque acupoint) every day.

**Colon dialysis:** The following were the procedures carried out by patients; first, defecate and urinate. Incline on the right while lying down and prop the buttocks up by about 10 cm. Before dialysis, insert a SaveMedical double-cavity tube into the anus, insert the entering end about 50 cm into the inner anus and the exiting end would then be about 20 cm into the inner anus. Apply 1200 mL mannitol and 1200 mL dialytic fluid as an enema for 2 h. Clear the intestinal tube to maintain the high penetrability to intestinal mucosa. Later, insert 200 mL of the colon dialysis fluid for 30-60 min until an unforced defecation occurs. For the control group, a placebo of flour was applied to the navel, and the colon dialysis fluid was replaced with Sodium Chloride.

**Period of treatment:** One month made up one course of therapy. The following items were measured before treatment and at the end of treatment: abdominal circumference, BUN, Cr, serum $Na^+$, urine $Na^+/K^+$, liver function, endotoxin content, NO, and ET-1 nephritic syndrome. All items were then rechecked every month over a follow-up period of 3 mo.

### Observational methods

**General condition:** Body weight, abdominal circumference, tongue and coating, pulse rate, volume of urine in 24 h, levels of urinary $Na^+$ and $K^+$, and $Na^+/K^+$ ratio in urine were measured every morning.

**Blood $Na^+$ and liver function indexes:** Blood $Na^+$, and indexes of liver functions including alanine transaminase (ALT), and aspartate aminotransferase (AST) were measured. Gamma glutamyl transferase (r-GT), total bilirubin (TB), albumin (ALB) and albumin/globulin ratio (A/G) and indexes of renal function, including serum Cr: liver function, serum Cr and BUN were checked using an Olympus 27000 (Japan) for routine automatic biochemical analysis once a week.

**Levels of endotoxin, NO and ET-1:** Levels of endotoxin, NO and ET-I were measured before and after treatment using 5 mL of fasting (8 h) cubital venous blood drawn in the morning. Plasma was separated and stored at -20℃. Plasma endotoxin was determined by limulus lysate chromogenic test, and NO by indirect colorimetry. The reagents used were provided by the Beijing Bangding Corporation of Biological Medical Science. ET-1 was determined by radio-immunoassay using a testing kit was provided by the East Asia Technological Institute, of the General Hospital of the People's Liberation Army. All tests were conducted by a trained technician using the same device and kits from the same batch.

**Blood dynamics:** Examination was conducted early in the morning on the day of blood collection. Patients were required to lie supinely and breathe calmly; a dual-function Color Doppler, Fynergy by GE, DIASONICS Corporation of America , with a 35 MHz frequency detector was used to measure the peak velocity of the blood flow (Vp) in the inner diameter(D) of the portal vein trunk and the splenic vein of the hilum . Examinations were carried out by a trained technician with the volume of the sampling as close as possible to that of the diameter of the blood vessel, and the angle between the sound beam and the blood flow as small as possible (less than 60º). All variables were measured twice and averaged. The volume of blood flow (Q) of portal and splenic veins were calculated by the formula [Vmean × $(D/2)^2\pi$ × 60] (D means diameter of blood vessel, Vmean means average velocity of blood flow)[14].

### *Efficacy evaluation standards*

Using the "Standards for Efficacy Evaluation of TCM on Liver Cirrhosis Ascites" formulated at the Dalian Conference in 1993 by the special committee of Internal Heptatology, the China Association of Chinese Medicine (draft)[15], the efficacy on ascites was classified into 3 grades. Grade I: complete resolution of ascites, with no abdominal fluid found in ultrasound B examination, and condition stabilized for more than 3 mo; Grade Ⅱ: most of the ascites disappeared with only slight shifting dull sound upon percussion in a physical examination and ultrasound B shows little ascites; and Grade Ⅲ: ascites are somewhat diminished and the abdominal circumference at the level of the naval has decreased by more than 30 cm.

### *Statistic analysis*

Variance analysis and $\chi^2$ test were used to analyze all measurement and enumeration data, respectively. Linear correlation regression analysis was used for the relationship among PVQ and SVQ with levels of endotoxin, NO, and ET-1.

## RESULTS

### *General efficacy for ascites in all groups*

In most patients symptoms and physical signs improved to various degrees after treatment. Especially, abdominal distension, reduced urine, and abdominal circumference, lower limb swelling apparently improved, and body weight loss. However, fatigue, liver palm, and spider telangiectasia did not show any change.

In Table 1, the total effective rate on ascites in the treatment group is 72.4% (21/29), the simple treatment group 45.8% (11/24), and the control group 18.2% (4/22). There is no grade I resolution of ascites in the control group. By $\chi^2$ test, there is a significant difference between the control and comprehensive treatment groups ($P < 0.01$), and the control and the simple treatment groups ($P < 0.05$). There is also difference between the two treatment groups ($P < 0.05$).

### *Changes of azotemia*

Table 2 shows statistically significant differences between pre- and post-treatment changes of azotemia in the comprehensive treatment ($P < 0.01$) and simple treatment ($P < 0.05$) groups. The control group has no obvious change ($P > 0.05$). There are distinct differences between each treatment group and the controls ($P < 0.01$, $P < 0.05$). However, there is no difference between the two treatment groups ($P > 0.05$).

### *Changes of liver function, blood $Na^+$ and urine $Na^+/K^+$*

Changes of liver function are shown in Table 3. Liver function ALT, TB, ALB, A/G are significant different between pre- and post- treatment stages in all three groups ($P < 0.05$), but there is no significant difference between the treatment and control groups. Changes of serum $Na^+$, and $Na^+/K^+$ are shown in Table 4. The serum $Na^+$, and $Na^+/K^+$ rates of the control group were increased after treatment, but there was no significant difference ($P > 0.05$). However, there are significant differences between before and after treatment in the comprehensive treatment ($P < 0.01$) and simple treatment ($P < 0.05$) groups. Though there is no statistical difference between the two treatment groups ($P > 0.05$).

### *Levels of endotoxin, NO, and ET*

Endotoxin content decreased in the comprehensive

**Table 4 Pre- and post-treatment serum $Na^+$ and urine $Na^+/K^+$ changes (mean ± SD)**

| Groups | *n* | | Serum $Na^+$ | Urine $Na^+/K^+$ |
|---|---|---|---|---|
| Comprehensive | 29 | Before | 126.32 ± 5.13 | 0.86 ± 0.23 |

[a]$P < 0.05$, comparison of pre- and post-treatment; [c]$P < 0.05$, *vs* control group.

treatment ($P < 0.01$) and simple treatment ($P < 0.05$) groups. NO ($P < 0.05$) and ET-1 ($P < 0.01$) also decreased after treatment. There was no significant difference between the two treatment groups ($P > 0.05$). Endotoxin, NO and ET-1 contents of the control group also showed no statistical difference ($P > 0.05$) (Table 5).

### *Comparison of blood flow in portal and splenic veins*

For both treatment groups, the diameter (D value) and quantity of blood flow (Q value) of the portal and splenic veins decreased significantly after treatment ($P < 0.05$). In the control group, no great change was found after treatment ($P > 0.05$). Comparison of D and Q among the treatment and control groups after treatment found significant differences ($P < 0.05$). But there were no significant difference between the two treatment groups ($P > 0.05$). No significant changes were shown in Vp in all three groups before and after treatment ($P > 0.05$) (Table 6).

### *Pre- and post-treatment correlations between splenic and portal vein blood flows and endotoxin, NO and ET-1*

As shown in Table 7, the PVQ and SVQ show a positive correlation to the pre- and post-treatment endotoxin levels in the 29 cases of the comprehensive treatment group with a pretreatment r (PVQ) = 0.67, $r$ (SVQ)= 0.73 for $P < 0.01$; and post-treatment $r$ (PVQ) = 0.75, $r$ (SVQ) = 0.69 for $P < 0.01$. They have a positive correlation to the NO level with a pretreatment $r$ (PVQ) = 0.68, $r$ (SVQ) = 0.68 for a $P < 0.01$; and a post-treatment $r$ (PVQ) = 0. 45, $r$ (SVQ) = 0.51 for $P < 0.05$. They also have a positive correlation to ET with a pre-treatment $r$ (PVQ) = 0.79, $r$ (SVQ) = 0.78 for $P < 0.01$; and a post-treatment $r$ (PVQ) = 0.73, $r$ (SVQ) = 0.74 for $P < 0.01$.

### *Adverse reactions and follow-up*

Five patients in the treatment groups showed papilla, reddening, swelling or itching skin where paste was applied to the naval area. The symptoms were endurable after treatment with dexamethasone acetate, ointment and there was no need to discontinue the paste application. No other kinds of allergic or adverse reactions were seen. Colon dialysis was implemented every two days and all 53 patients completed the treatment.

During the 3 mo follow-up, 7 cases control dropped out (3 cases effectively, 4 ineffectively treated). In 4 effectively treated patients, the ascites returned to the same level as pre-treatment; 2 ineffectively treated cases died because of HSR. In the treatment groups, 13 cases dropped out (8 effectively, 5 ineffectively treated). In 11 effectively treated patients, the ascites returned to the same level as pre-treatment; 20 cases remained in a stable condition; and in 9 cases the ascites increased but was were less than before treatment. No patient in the treatment groups was found to suffer from HSR.

## DISCUSSION

For a long time, we have been using SHP applied to the navel area to treat refractory cirrhotic ascites, and have achieved good efficacy[16]. SHP is useful to treat refractory cirrhotic ascites; however, if complicated with azotemia the efficacy is not so good. Therefore, we have combined this with a herbal colon dialysis treatment; in accord with the theory of colon dialysis for treating uremia. The *Moschus* in the SHP aromatically opens orifices, unblocks network vessels and disperses stasis. Modern research shows that it dilates the blood vessels and has the same curative effect as

nitroglycerin[17]. The Snail ingredient clears heat, disinhibits fluids, and treats jaundice. The artificial *Calculus Bovis* clears the heart and disinhibits the gallbladder; likewise, modern research shows that it safeguards the liver and disinhibits the gallbladder[17]. Bulbous Allii Fistulosi frees Yang (the bright positive masculine principle in Chinese dualistic cosmology), unbinds toxins, and can guide medicinals to the affected site; likewise, modern research shows it has bacteriostatic capabilities[17]. *Radix Euphorbiae Kansui* drastically precipitates and expels water. The *Rheum Palmatum L* in the colon dialysis formula removes residues in the stomach intestine, reduces the reabsorbing of azotic, restrains decomposition of BUN and Cr, and has bacteriostatic capabilities[17]. *Lonicera Japonica Thunb, Taraxcum Mongolicum Herba-Mazz* have heat-clearing and detoxification effects; again, modern research shows they have broad-spectrum bacteriostatic capabilities[17]. Sophorage Japonica L clears heat and cools the blood; it can improve filtering capabilities of kidneys[17]. *Ostrea Teliennhanensis Crosse* retains Yin (the dark negative feminine principle in Chinese dualistic cosmology) and suppresses yang; it can also absorb toxic substances in the intestines. Both SPH and the colon dialysis formula dissipated blood stasis and disinhibited the gallbladder, clearing away heat and toxins, and eliminating fluid by purging.

In our 75 cases presented here, after the basic treatment that included liver pretecting, diuretics, human albumin, and antibiotics, liver function ALT, TB, ALB, A/G in all treatment and control groups had obvious improvements. There was no significant difference between each of the treatment and control groups. However applying herbs on the navel plus herbal colon dialysis was found to not improve the liver function compared with the basic treatment.

After the 3 groups underwent treatment, some improvements in some symptoms were seen. Taking the resolution of ascites as the major efficacy standard, the general rate of the effectiveness of the comprehensive treatment was 72.4%, the simple treatment group was 45.8% (11/24), while that of the control group was 18.2% (4/22). No patient reached Grade I for resolution of ascites in the control group. The effective rate of the comprehensive treatment group was higher than that of the simple treatment group ($P < 0.05$). From this we can infer that only using the basic treatment to treat refractory ascites cannot reach the therapeutic goal, putting herbs on the navel as a treatment has some effect on refractory ascites complicating with azotemia, but combining this with herbal colon dialysis can elevate the efficacy. The three-month follow-up here showed the lasting effects. From an assessment of the indexes having relationships with clinical azotemia, such as Cr, BUN, serum Na, and urine $Na^+/K^+$, there was no efficacy pre- and post-treatment in the control group. However, there was a significant difference between the simply treatment group and the comprehensive treatment group, which is better than using just SHP in addition to the basic treatment.

The main pathogenesis of refractory cirrhotic ascites is due to portal vein hypertension (PVH). Therefore, this study sought to show the way to lower PVH. PVH forms as a result of mechanical and functional factors.

**Table 7 Pre- and post-treatment correlation between splenic and portal vein blood flows and endotoxin, NO and ET-1 (mean ± SD)**

| Indexes | *n* | | *r* | |
|---|---|---|---|---|
| | | | PVQ | SVQ |
| Endotoxin | 29 | Before | 0.67[b] | 0.73[b] |
| | | After | 0.75[b] | 0.69[b] |
| NO | 29 | Before | 0.68[b] | 0.68[b] |
| | | After | 0.45[a] | 0.51[a] |
| ET-1 | 29 | Before | 0.79[b] | 0.78[b] |
| | | After | 0.73[b] | 0.74[b] |

[a]$P < 0.05$, [b]$P < 0.01$.

First, patients present increased blood flow resistance and blood volume in the portal vein. Then they exhibit PVH. We observed portal vein trunk hemodynamic changes by color Doppler ultrasonography; showing that the portal vein blood flow was reduced (mainly by decreasing the diameter of the portal vein) in the two treatment groups after treatment; there was no difference between the two treatment groups. We highlighted that the improvements in PVH came mainly because of SHP. SHP possibly activates blood circulation to dissipate blood stasis, and has the effect of reducing platelet coagulation, improving circulation in the liver and decreasing portal vein resistance. Also, SHP can decrease vasoactive substances, slow down hypertension in the mesentery, and work toward decreasing PVH. Thus it appears a real way to reduce ascites.

PVH is also the initiating factor for the release of vasoactive substances. An increase of endotoxin during cirrhosis stimulates iNOS synthesis, which releases a significant quantity of NO[18]. The increased amount of NO released in the body leads to dilation of the peripheral vascular system, decreased arterial pressure and effective blood capacity. The decrease in arterial pressure then stimulates the sympathetic nervous system and activates the rennin-angiotonin-aldosterone system to alter the compensatory balancing of hemodynamics. As the illness continues, there is further compensation, even excessive compensation that can ultimately cause a decrease in the amount of blood circulating in the body, retention of both fluid and sodium, a redistribution of the renal blood flow, and the appearance of ascites, edema and azotemia[19]. The peripheral vascular dilation caused by NO inevitably stimulates the body to compensate by synthesizing and releasing large quantities of ET-1. The increase of ET-1 leads to the contraction of blood vessels in the liver and kidneys, aggravating them to ischemia and portal shunting causing increased endotoxins to enter into the circulatory system; thus initiating a vicious cycle[20]. A reason why refractory ascites is difficult to treat is that as it appears, the amounts of NO, ET-1, and endotoxin also gradually increase[21]. Our research results also show that ascites have a positive correlation to the amount of portal vein blood flow and vasoactive substances. In refractory ascites patients, NO, ET and endotoxin are at an elevated level, together with the ongoing ascites. With ascites eliminated after treatment, the levels of endotoxin, NO and ET-1 correspondingly decreased.

Refractory cirrhotic ascites easily reduces azotemia, which also has an early role in hepatorenal syndrome. For treatment, it is effective for ascites to improve intrahepatic circulation and decrease portal vein blood flow, but this is not sufficient for ascites associated with azotemia. Thus, along with the application of Shehuang Paste to the navel area, we combined a Chinese herbal colon dialysis. The crucial procedure in the method is that patients undergo dialysis 2 h daily using mannitol and peritoneal dialysis liquid, and then a colon-enema for 30 min with a Chinese herb decoction. The mechanism utilizes the high diosmosis of the colonic semi-permeable membrane caused by a high diosmosis dialysis liquid to absorb other liquids, and Chinese herbs to reduce the release of harmful and vasoactive substances, especially ammonia and endotoxin. All the cases here were refractory cirrhotic ascites complicated with azotemia. The results presented here demonstrated that applications of Shehuang Paste to the navel area in combination with Chinese herbal colon dialysis is superior to Shehuang Paste alone for eliminating ascites, lessening azotemia, and for reducing vasoactive substances such as endotoxin.

## Abstract

**AIM:** To assess the level of undiagnosed coeliac disease (CD) in relatives of patients affected by the condition.

**METHODS:** We collected blood from 914 relatives of probands. We screened these individuals by ELISA for IgA and IgG tTG antibodies, confirming any positive IgA tTG results with an IgA EMA and looked for evidence of IgA deficiency in those who were IgG tTG positive alone, and performed IgG1 EMA in these individuals. We undertook HLA typing where positive screening was found, and this confirmed a strong prevalence of HLA-DQ2 in the coeliac population. Follow-up small intestinal biopsy was undertaken in cases with positive serological screening, wherever possible.

**RESULTS:** Use of this serological screening algorithm revealed a prevalence of undiagnosed CD in 5%-6% of first degree relatives of probands.

**CONCLUSION:** Our data suggests that first degree relatives of individuals with CD should be screened for this condition.

**Key words**: Coeliac disease; Screening; Endomysial antibody; Familial study; IgA deficiency; Prevalence; Tissue transglutaminase

## INTRODUCTION

Coeliac disease (CD) is a disorder in which genetically predisposed individuals develop a small intestinal enteropathy on exposure to dietary gluten. The small bowel abnormalities are reversed on withdrawal of gluten from the diet. Recent population studies and serological testing of at-risk groups reveal a much higher prevalence of CD than previous studies. Whereas the previous prevalence was thought to be in the order of 1 in 1500 in Europeans, it is now thought to be in the order of 1 in 100 to 1 in 250. In the largest population screening study[1], 17 000 Italian school children, aged 6-15 years, were screened using a stepwise protocol with anti-gliadin antibodies (AGA), anti-endomysial antibodies (EMA), and finally duodenal biopsies in those who screened positive for these two serological tests. A prevalence rate of 1 in 184 was found. A Swedish study involving healthy blood donors found a prevalence of 1 in 256, confirmed by small bowel biopsy[2], and an American study[3] using EMA in blood donors found a rate of 1 in 250, although this was not confirmed by biopsy. In Ireland, the rates are even higher, with a reported prevalence rate of 1 in 122 determined in a screening study [4].

The incidence and prevalence of CD are therefore similar in populations with a similar genetic background. CD is thought to occur rarely in people from an Afro-Caribbean background, though there are reports of the condition in Asians from the Indian sub-continent[5]. CD is a familial condition, and the main risk factor for development of the condition is the presence of HLA DQ2 or DQ8. Most Northern European patients express the DQ2 heterodimer HLA-DQA1*0501 and DQB1*0201. Those who do not express this heterodimer, most commonly, have the HLA-DR4, DQ8 haplotype. In Italian and Tunisian patients there is also a significant association with DR53 heterodimers[6,7]. Further susceptibility genes, such as the CTLA-4 gene on chromosome 2q33[8], are thought to reside both inside and outside the HLA region and are currently being evaluated, although the disease is not expressed in the absence of the HLA genes. CD is thought to occur in 10%-15% of first degree relatives of probands[9], with 40% of HLA identical siblings being affected, and a concordance of 75% in monozygotic twins[10]. In some countries, such as Italy, first-degree relatives of patients with CD are screened routinely.

There are various serological screening tests available, which have different sensitivity and specificities. Circulating antibodies to gliadin were previously used for screening, but have largely been superseded due to their low specificity. Anti-endomysial antibodies (EMA) of the IgA class are considered highly specific markers of coeliac disease. Using human umbilical cord (HUC), the reported sensitivity is 90%, with a specificity of 99% in adults with

untreated coeliac disease (Table 1)[11]. However, this test is labour intensive and somewhat subjective, relying on the interpretation of a staining pattern on connective tissue, using a fluorescent microscope. The discovery of tissue transglutaminase (tTG) as the antigen for EMA[12], allowed the development of a simple ELISA to detect this antibody, the sensitivity and specificity of IgA tTG test are reported to be 94.5% and 93.7% respectively[13]. However, there are pitfalls in serological screening for CD. Selective IgA deficiency occurs in 2.6% of patients with CD[14], which is a 10-15 fold increase in prevalence of IgA deficiency over that in the general population. Testing for IgA antibodies only would cause false negative results and missed diagnoses. Additionally, a new sub-group of CD patients has recently been described, who develop only IgG class antibodies (specifically IgG1) to endomysium, in the absence of IgA class antibodies, and with normal quantities of total serum IgA[15].

We wished to establish an accurate screening protocol to assess the prevalence of undiagnosed coeliac disease in relatives of probands.

**Table 1 Sensitivity, specificity and reproducibility of screening coeliac serology**

| | IgA-AGA | IgG-AGA | IgA-EMA |
|---|---|---|---|
| Sensitivity | 83 | 86 | 90 |
| Specificity | 82 | 76 | 99 |

## MATERIALS AND METHODS

### Study subjects

We collected details of families where either one or more individuals were affected by CD. The families were identified either in the Gastroenterology Outpatient Clinic at St Thomas' Hospital, or by consultant colleagues at other hospitals. A further recruitment drive involved a short article and request for volunteers printed in the 'Crossed Grain' magazine, published by Coeliac UK for its members. In this way we were able to recruit a total of 151 families into the study. Of these 73 families had only one affected member and were referred to as single affected families, 78 families had more than one affected family member (range 2-7) and were referred to as multiply affected families. Full ethical approval was obtained from the Local Research Ethics Committee of St Thomas' Hospital (Ref. No.EC00/233). We recorded family relationships and collected blood for serology from as many relatives as were willing to consent. Serum was stored at -20℃. DNA was extracted from heparinized blood using the Nucleon BACC3 kit and stored at -20℃.

### Controls

In order to set up the parameters for serological testing we first took a group of normal controls. These comprised laboratory staff and their relatives who were healthy and symptom-free. The age range was 24-60 years. Volunteers were questioned about the health of other family members. Those with any family history of gastrointestinal problems, diabetes and auto-immune thyroid disease were excluded from the study.

### ELISA for anti-tissue transglutaminase antibodies

Two individuals with biopsy-confirmed CD and high titre for IgA and IgG-tTG antibody respectively were selected as positive controls. Sera of these individuals were made at 1:100 dilution, aliquoted and sterilised by gamma irradiation. ELISA was performed according to the method of Sulkanen[13]. Microtitre plates were coated with guinea pig liver tTG (Sigma T 5398), 1 μg per well in 100 μL of 0.05 mol/L tris buffered saline, with 5 mmol/L calcium chloride. The plates were left over night at 4℃, then washed three times with 0.05 mol/L TBS, 0.01 mol/L EDTA and 0.1% Tween 20 (TTBS). Test sera were diluted to 1:100 in TTBS, 100 μL of the test and positive control sera was added in duplicate to two plates. The plates were covered and incubated for 1 h at room temperature, then washed three times. Peroxidase-conjugated rabbit anti-human IgA (Dako P-0216) or anti-human IgG (Dako P-0214) was diluted to 1:2000 in TTBS, and added to the plates at 100 μL per well. This was incubated for 1 h at room temperature, and washed three times. The reaction was developed by adding OPD as substrate (Dako S2045), prepared according to the manufacturer's instructions. One hundred microlitres was placed in each well, and the plates were incubated in the dark at room temperature for 30 min. The plates were read on a Titertek Multiskan MCC/340 ELISA plate reader at 450 nm. The end point was reached when the IgA and IgG positive controls reached optical density of 1.2-1.3. The cut off value for a positive result was established as 0.3 for IgA and 0.325 for IgG. These values were calculated from the mean plus 2 standard deviations for our normal population. Individuals whose IgA-tTG was above the cut-off value were further investigated by IgA-EMA. Those without IgA-tTG antibodies, but with IgG-tTG antibodies went on to have total IgA quantification and IgG1-EMA. Those with negative results for both antibodies were considered negative for screening, and no further action was taken.

### Indirect immunofluorescence for anti-endomysial antibody

The method used was described by Ladinser *et al*[16]. Human umbilical cord (HUC) was cut into 5-μm cryostat sections on 4 well coated slides. Each section was blocked with 100 μL of 1% BSA in PBS for 30 min. Test sera were diluted to a concentration of 1:5, and added to each well. Each experiment also contained a positive and a negative control. The sections were incubated for 30 min, and washed twice in a PBS bath. FITC-conjugated rabbit anti-human IgA (specific for alpha chains) immunofluorescent antibody (DAKO F0204) or FITC-conjugated mouse anti-human IgG1 (Sigma Monoclonal anti-human IgG1 clone 8c/6-39, product number F0767) was diluted to 1:40 using PBS. Fifty microlitres was added to each well and the sections were incubated at room temperature for 30 min in a humid chamber, and immersed in a PBS bath as before. Fluorescent mounting medium (DAKO, S3023) was added and the sections were examined immediately under a fluorescent microscope. The test was considered positive

**Table 2 Overall results of coeliac screening for singly and multiply affected families**

| Type of family | Coeliacs (*n*) | Relatives (*n*) | Positive screenings | 1st degree relatives | 2nd degree relatives | Not related |
|---|---|---|---|---|---|---|
| Singly affected family | 73 | 223 | 11 | 11 | 0 | 0 |
| Multiply affected family | 232 | 691 | 28 | 22 | 2 | 4 |

if the antibody stained the endomysium of umbilical arteries in a defined reticular pattern at a dilution of 1:5.

### Total IgA quantification

This was performed by a competitive ELISA assay. Microtitre plates were coated with 100 μL of 2 μL/mL whole molecule human IgA (Harlan Sera-Lab PP-17-01) in PBS, and left overnight at 4℃. The plates were then washed three times in PBS with 0.05% Tween 20, blocked with 100 μL of 1% BSA, incubated at 37℃ for 1 h, and then drained.

The serum samples were diluted in peroxidase-conjugated rabbit anti-human IgA at a concentration of 1:4000. A standard curve was produced by diluting known amounts of human IgA in peroxidase-conjugated rabbit anti-human IgA. Dilutions and sera were pre-incubated for 30 min at room temperature, then added to the plates and incubated for a further 30 min. The plates were washed three times in PBS/Tween, the reaction was developed by adding OPD as a substrate (Dako S2045), prepared according to the manufacturer's instructions. One hundred microlitres was placed in each well. The plates were incubated in the dark at room temperature for 30 min and read on a Titertek Multiskan MCC/340 ELISA plate reader at 450 nm. The concentrations of IgA in the serum were calculated from the standard curve.

### HLA-DQ typing

DNA was extracted from whole blood by the following protocol, using the Nucleon BACC kit (SL-8512). In brief, primer sequences were chosen to detect the presence of HLA-DR3, -DR7, -DR5 and -DR4, which are the most common haplotypes in patients with coeliac disease, being present in > 98% of European individuals with the condition. The products were loaded onto 1% agarose gel containing ethidium bromide. The gels were run for 22 min at 300 V, and visualised under UV light.

## RESULTS

Nine hundred and thirteen serum samples were tested for anti-tTG antibodies, which were from first, second and third degree relatives, as well as some individuals who were not blood relatives of coeliac disease probands, including individuals with coeliac disease such as husbands or wives and their relatives.

IgA-tTG antibodies were found to be present in 60 individuals. When these were followed up with IgA-EMA, 36 were found to have IgA-EMA antibodies, and 24 individuals were deemed to be false positives. The individuals who were positive for IgA-EMA had IgA-tTG levels of 0.31 to 2.34, whilst those who were negative for IgA-EMA had IgA-tTG levels of 0.31-1.1. IgG-tTG antibodies in the absence of IgA-tTG antibodies were found in 194 individuals. Samples from all of these individuals were tested for IgG1-EMA. Of these, only 3 were found to be positive for IgG1 EMA. In total, 194 individuals had IgA quantification. Of these, only 2 out of the 3 IgG1 positive individuals were IgA deficient (Table 2).

**Table 3 Single affected families-relationships of individuals to probands**

| Relationship | Number tested (*n*) | Number affected (*n*) | Percentage affected (%) |
|---|---|---|---|
| Mother | 73 | 5 | 6.85 |
| Father | 73 | 4 | 5.48 |
| Sibling | 37 | 2 | 5.41 |
| Child | 18 | 0 | 0 |
| Uncle/Aunt | 5 | 0 | 0 |
| Grandparent | 6 | 0 | 0 |
| Grandchild | 2 | 0 | 0 |
| Nephew/Niece | 3 | 0 | 0 |
| Husband/Wife | 6 | 0 | 0 |

Of all the relatives in the single affected families, those newly diagnosed with coeliac disease are shown in Table 3. Five point four seven percent of first-degree relatives were found to have positive anti-endomysial antibodies, no second-degree relatives were found to have positive anti-endomysial antibodies. These data were analysed to give a percentage factor of those affected in each category of relative. There were not many children of individuals with CD in this group, as the proband was a child in the majority of volunteer families.

Of all the relatives in the multiply affected families, those newly diagnosed with coeliac disease are shown in Table 4. Five point forty-one percent of first degree relatives were found to have anti-endomysial antibodies, and 1.62% of second degree relatives we found to have positive coeliac antibodies. These data were analysed to give a percentage factor of those affected in each category of relative.

Four (2.52%) of the 159 individuals who were related only by marriage to the person with coeliac disease were found to have positive coeliac antibodies. This rate was significantly higher than would be expected for the general population (1%).

### HLA-typing

The 39 individuals with positive anti-endomysial antibodies were further investigated by HLA-typing. Twenty-nine of these were successfully typed. Reasons for failure in the other 10 individuals included: inability to locate EDTA blood for extraction, poor DNA extraction and poor PCR or uninterpretable gels. Our HLA-typing revealed the same distribution of HLA-types, as would be expected in a population of patients with coeliac disease. The HLA types are shown in Table 5.

**Table 4 Mutliply affected Families-Relationships of Individuals to probands**

| Relationship | Number tested (*n*) | Number affected (*n*) | Percentage affected (%) |
|---|---|---|---|
| Mother | 51 | 3 | 5.88 |
| Father | 31 | 3 | 9.68 |
| Sibling | 165 | 9 | 5.4 |
| Child | 137 | 7 | 5.11 |
| Uncle/Aunt | 6 | 1 | 16.67 |
| Grandparent | 11 | 0 | 0 |
| Grandchild | 39 | 0 | 0 |
| Nephew/Niece | 67 | 1 | 1.49 |
| 3rd degree or more | 24 | 0 | 0 |
| Husband/Wife | 159 | 4 | 2.52 |

### *Follow-up*

We attempted to contact all those individuals with a positive screening result, to arrange a small intestinal biopsy. Thirty-five underwent a small intestinal biopsy. Of these, 32 were positive, having increased intra-epithelial lymphocytes with partial or sub-total villous atrophy. Three biopsies were reported as normal.

## DISCUSSION

We used a two-tier screening system for coeliac disease. The initial anti-tTG ELISA test was used as a highly sensitive, cheap and simple initial screening test, rather than as a specific diagnostic test. The limits for a positive result were deliberately set low in order to avoid missing any cases, but this did have a major impact on the specificity, hence the number of positives were subsequently found to be EMA negative. While we would not propose this two-tier method for use in a diagnostic laboratory, we found it useful for rapid large scale screening, avoiding EMA testing on a great number of samples.

Our prevalence rates in relatives of probands with coeliac disease were significantly lower than those previously estimated by other groups (10%-15% for first degree relatives). This is perhaps surprising, since our families were recruited through voluntary self-referral. Thus, one may have expected increased rates, as suspicious symptoms may have encouraged some families to be volunteers. However, one would expect these lower rates in the multiply affected families since by definition, relatives of probands have already been diagnosed, and our figures only indicate the existence of undiagnosed cases. We used guinea-pig liver tissue transglutaminase as our detection antigen, on a cost basis. However, human recombinant tTg is now available, and might have given a higher rate of positive detection.

In the two IgA deficient individuals, one had a normal duodenal biopsy, while the other had an increase in intra-epithelial lymphocytes (IEL) only. The patient with increased IELs was investigated for ataxia when she joined our screening study. After having a gluten free diet (GFD) for 24 mo, her symptoms improved slightly.

It could be argued that volunteers in the study may be more likely to have been symptomatic, although we have no evidence for this. Our study raises the question whether we should screen first-degree relatives of patients with CD, since they carry a high-risk of being similarly affected. The screening method we proposed is sensitive, specific and non-invasive. The general well being of individuals with sub-clinical coeliac disease appears to improve on a GFD. It has been shown that there is a long-term health benefit to these people if a GFD is instituted with a reduction in the otherwise significantly increased mortality.

In conclusion, we propose the algorithm shown in Figure 1 for screening family members for coeliac disease, as we believe it is important that these individuals should be picked up, diagnosed and offered appropriate treatment.

**Table 5 Results of HLA-typing for individuals with positive screening tests**

| HLA-type | DR3/DRx | DR3/DR7 | DR5/DR7 | DR4 | DR3/DR4 | DR4/DR7 |
|---|---|---|---|---|---|---|

## Abstract

**AIM:** To investigate the conformity of management practices of gastrointestinal hemorrhage in cirrhotic patients with relevant guidelines.

**METHODS:** A questionnaire on the management of digestive bleeding was completed for all consecutive cirrhotic patients admitted to 31 French hospitals.

**RESULTS:** One hundred and twenty-six bleeding events were recorded. It was the first bleeding episode in 79 patients (63%), of whom 40 (51%) had a prior diagnosis of cirrhosis and 25 (32%) had previously undergone an endoscopy. The bleeding episode was a recurrence in 46 patients (37%). The median time between onset and admission was 4 h, but exceeded 12 h in 42% of cases. There was an agreement between centers for early vasoactive drug administration (87% of cases), association with ligation (42%) more often than sclerosis (21%) at initial endoscopy, and antibiotic prophylaxis (64%). By contrast, prescription of beta-blockade alone or in combination (0 to 100%, $P = 0.003$) for secondary prophylaxis and lactulose (26% to 86%, $P = 0.04$), differed among centers.

**CONCLUSION:** In French hospitals, management of bleeding related to portal hypertension in cirrhotic patients is generally in keeping with the consensus. Broad variability still remains concerning beta-blockade use for secondary prophylaxis. Screening for esophageal varices, the use of antibiotic prophylaxis and patients information need to be improved.

**Key words:** Digestive bleeding; Portal hypertension; Cirrhosis; Evaluation studies

## INTRODUCTION

Gastrointestinal hemorrhage is a major complication of cirrhosis, and several consensus conferences[1,2] have attempted to standardize its management. All the recommendations are based on results of meta analysis of randomized trials, which are designed to assess the efficacy of treatment modalities on survival. In fact, several recent reports suggest that better management has improved the prognosis of patients with variceal bleeding over the past four decades[3-6].

By contrast, the conformity of management practices with relevant guidelines in the field of portal hypertension has rarely been addressed. The few available studies[7-10]

have shown broad variability among centers and under-use of treatments designed to prevent bleeding. None of these surveys took into account the interval from bleeding onset to initial management, despite its prognostic significance[11].

The aim of this cross-sectional survey was to analyze French management practices for digestive bleeding linked to portal hypertension in patients with cirrhosis, and to evaluate their conformity with European guidelines[2].

## MATERIALS AND METHODS

### Patients and methods

This prospective questionnaire-based survey was conducted from 1 September to 30 November 2003 by gastroenterologists in 31 general and teaching hospitals located in five French regions (Aquitaine, Champagne-Ardennes, Pays de Loire, Picardie and Poitou-Charentes) and two counties (Oise and Val d'Oise). These seven sectors were non-randomly selected according to the following criteria: in each sector an investigator, member of the "Club Francophone d'Hypertension Portale", accepted to participate in the study and recruited all the hospitals covering the geographic area, including university and non-university hospitals. Patients were eligible if they had clinically or histologically documented cirrhosis of any cause, and if they had overt digestive bleeding related to portal hypertension presenting with hematemesis or melena. Patients were not eligible if bleeding was unrelated to portal hypertension, or if portal hypertension was not related to cirrhosis. The anonymous questionnaire included the patient's date of birth and home town, the mode of hospital admission, the interval between bleeding onset and initial management, the cause of bleeding, treatment, outcome 42 d after admission, the cause of cirrhosis, preventive measures started before and after the bleeding episode, transfer to a referral center, re-bleeding and its treatment, and complications of cirrhosis during the study period. Cirrhosis was graded on admission using the Child-Pugh score[12]. A single questionnaire was analyzed per patient, corresponding to the first bleeding event during the study period. Subsequent bleeding events were recorded but their management was not taken into account in this analysis. The study protocol was approved by the French Ethics Committee for the Treatment of Computerized Information concerning Research in Health Domain.

### Statistics analysis

Data were recorded with the Microsoft Access database. All responses to the questionnaire were controlled and validated. Statistical analyses used SAS software version 8.2. Management practices were compared with the recommendations of the last consensus conference held before the survey, namely Baveno Ⅲ[2] and 95% confidence limits were calculated using the normal approximation or exact computation if not applicable. Differences in practices among the six geographic sectors (five regions and two combined counties) were analyzed with the generalized Fisher's exact test for qualitative variables, with a significance level of $P < 0.05$. Nonparametric Mann-Whitney test was used for quantitative variables. Bleeding control was defined as hemodynamic stability, without transfusion, 48 h after admission[2]. Hemorrhagic relapse was defined as any bleeding event occurring between 48 h and 42 d after admission. Mortality was evaluated 42 d after admission. In European studies published from 1993 to 1996, the estimated incidence of upper digestive bleeding was between $45/10^5$ and $143/10^5$ inhabitants, depending on the country, and esogastric varice rupture accounted for 5.0% to 13.7% of cases (incidence rate $4.0/10^5$ to $19.6/10^5$ inhabitants)[13-15]. Thus, it was predicted that a maximum of three months would be necessary to recruit at least 100 cases in the geographic area covered by the survey.

**Table 1 Main characteristics of the patients**

| Characteristics | *n* = 126 |
|---|---|
| Age (yr, median and range) | 56 (32 to 83) |
| Sex (M/F) | 103/23 |
| Causes of cirrhosis [*n* (%)] | |
| - Alcoholism | 101 (80%) |
| - Hepatitis virus (B, C) | 11 (9%) |
| - Alcoholism plus another cause | 4 (3%) |
| - Other causes | 5 (4%) |
| - Unknown | 5 (4%) |
| Child-Pugh class A/B/C (*n*)[1] | 27/42/53 |

[1]Missing data: two incomplete files and two early deaths.

## RESULTS

During the three-month study period, 135 patients were consecutively admitted in 31 hospitals. Nine patients were excluded from the analysis because the bleeding event was not linked to portal hypertension in 7 cases (gastric or duodenal ulcer in 5 cases, peptic esophagitis and hemorrhoidal bleeding in one case each). In the other two cases the portal hypertension was linked to hepatic metastases of breast and pancreatic primary tumors. The following analysis thus involved 126 patients.

The patients' main characteristics are shown in Table 1. Prophylaxes before admission are detailed in Table 2. Bleeding occurred at home in 100 cases (79%), and in hospitals in the other 26 cases. Forty-six patients (37%) arrived by mobile intensive care unit (MICU), either from home ($n = 37$) or from another hospital unit ($n = 9$). This mode of admission was evenly distributed among the participating centers ($P = 0.18$). Among the 100 patients who arrived from home, the median interval between onset and hospital admission was 4 h (1 to 80 h). This interval was significantly shorter among patients transported by MICU (median 3.4 h *vs* 5.2 h; $P = 0.049$). The interval was < 2 h in 18 cases, 2-6 h in 27, 6-12 h in 11, 12-24 h in 19 and > 24 h in 25. It did not differ between patients with first and subsequent bleeding events ($P = 0.14$), or between patients with and without documented cirrhosis ($P = 0.16$).

Table 3 shows the conformity to the Baveno Ⅲ consensus of management practices, and their variability among the participating centers. Ninety-five of the 100

**Table 2 Previous bleeding and prophylaxis given before the index bleeding**

[1]Missing data: one death shortly after admission; [2]Cirrhosis had not been diagnosed at the time of the previous hemorrhage in three patients.

patients who were admitted from home, underwent an endoscopy. The median interval between admission and endoscopy was 5 h (< 1-139 h), and was less than 12 h in 60% of cases. This interval was not influenced by blood transfusion ($P = 0.09$), the bleeding history ($P = 0.78$), or previously documented cirrhosis ($P = 0.29$). The median interval was 10 h when admission occurred between 10 PM and 7 AM, 4 h between 7 AM and 5 PM, and 13 h between 5 PM and 10 PM. Bleeding was due to esophageal varices in 89 cases (72%), gastric or ectopic varices in 13 cases (11%), and gastropathy linked to portal hypertension in 6 cases (5%); in 15 cases (12%) the endoscopy revealed mixed lesions combining occasionally erosive gastritis and signs of a possible variceal origin. Five of the 6 patients in whom bleeding was due to gastropathy alone received a vasoactive drug. Vasoactive drug therapy consisted mainly of octreotide (93% of cases); terlipressine was used alone in 6 cases and somatostatin in 2 cases. The use of vasoactive drugs did not differ among the geographic sectors ($P = 0.08$). The drugs were administered within a median of 2 h after admission (< 6 h in 66% of cases), for a mean of three days (1 to 6 d). None of the patients received emergency transjugular intrahepatic portosystemic shunting (TIPS), and a balloon tamponade was inserted in 8 (6%) patients. Tracheal intubation was performed in only 21 cases (17%), usually to facilitate an endoscopy ($n = 11$); this practice differed significantly among the geographic sectors (0 to 54%, $P < 0.0001$). Nasogastric tube was used in 57 patients (46%), usually for gastric lavage before an endoscopy (significant difference among geographic sectors; 25% to 86%, $P = 0.0002$). Data concerning antibiotics and lactulose prescription are given in Table 3.

Bleeding was controlled within 48 h after admission in 99 patients (80%). Twenty-one patients re-bled, a median of 16 d (d 3 to 40) after admission; they usually received a combination of endoscopic treatment and vasoactive drugs. TIPS was used in four patients, and one patient had a surgical portocaval anastomosis. Five patients were transferred to a referral center. In 94 patients evaluable, after exclusion of deaths, the main prophylactic treatments were a combination of beta-blockade and ligation in 31 patients, beta-blockade alone in 29 patients, ligation alone in 18 patients, endoscopic sclerosis in 4 patients and 3 patients received no prophylaxis. Prescription of beta-blockade, alone or in combination, was significantly different among geographic sectors ($P = 0.003$).

Outcome on d 42 was unavailable in 9 cases. Ninety-one (78%) were alive on d 42. Six of the 26 deaths occurred in the first 48 h. The main causes of death were hemorrhage, liver failure, multiorgan failure, shock, and hepatorenal syndrome. Fifteen patients had hepatocellular carcinoma, and three of them died before d 42. The main in-hospital complications were hepatic encephalopathy ($n = 14$), hepatorenal syndrome ($n = 6$), and bacterial infections ($n = 7$).

## DISCUSSION

This survey shows that the management of digestive bleeding in cirrhotic patients in France generally complies with the Baveno Ⅲ international consensus statement issued three years ago. However, certain practices differed among the participating centers, and some recommendations should be applied more systematically. This is not surprising since many practitioners are involved in the management of cirrhotic patients and most of them are not hepatology experts. Our study was not designed to compare the outcomes of patients according to the physician's compliance with the recommendations. In our study, the outcome was as favorable as in recent publications[4,5]. However, improvement in mortality has rarely been observed in randomized trials, and this benefit was demonstrated only in meta analysis, suggesting that many confounding factors are involved.

First bleeding events revealed the presence of cirrhosis in half the patients. One-third of the patients with a prior diagnosis of cirrhosis had not had endoscopic screening for large esophageal varices and did not therefore receive preventive therapy. Esophageal varices are of a recognized prognostic value in this setting[16,17], and both beta-blockade[18] and endoscopic ligation[19] are known to reduce the bleeding risk. Our results are similar to those of US practice surveys. Arguedas *et al*[7] reported that only one-half of cirrhotic patients referred for liver transplantation had endoscopic screening for varices. Sorbi *et al*[8], in a survey undertaken in 1997 in the United States, also noted that primary prophylaxis was under-used, as only 20% to 30% of patients received beta-blockade before the index bleeding event. Following the publication of the 1997 guidelines of the American Board of Gastroenterology, Zaman *et al*[10] found that 54% of gastroenterologists claimed they followed recommendations to screen for and treat large varices in patients with no history of bleeding, representing a three-fold increase compared to the same survey prior to the publication of the recommendations.

Admission to clinical centers remains too late in many cases (> 12 h in nearly 40% of patients), even though the general French population is no more than one hour from a hospital. The interval between onset and initial

ND: variability not assessed. [a]Generalized Fisher's exact test of the homogeneity in practices among the six geographic sectors (five regions and two combined counties).

management is not shorter in patients with a history of bleeding or with known cirrhosis, suggesting that they are poorly informed of the risk of variceal bleeding and the need for early hospital admission. Although overall survival in this survey was better than previous, and similar to that in recent publications[5,6], fatal outcome is still closely related to failed bleeding control or to early rebleeding[11]. Early resuscitation is firmly recommended[20]. We recently showed that about one-quarter of deaths occur very early after bleeding onset, mainly before hospital admission[21]. Levacher *et al*[22] also reported that early terlipressin administration (en route to hospital) significantly improved the prognosis. This should be taken into account at the forthcoming consensus conferences.

Contrary to recommendations, an endoscopy was performed more than 12 h after admission in one-third of patients admitted from home in this survey. However, early use of vasoactive drug therapy in nearly all the patients, as recommended, suggests that initial bleeding control allowed an endoscopy to be deferred, particularly among patients admitted in the evenings. Conversely, one-third of patients did not receive antibiotics, which should have been routinely considered[2]. Indeed, antibiotics can prevent infections and rebleeding, and thereby improve survival[23]. In our survey, lactulose was only prescribed to about 40% of patients, and there were significant differences among the participating centers with respect to this practice. This is not surprising since the efficacy of lactulose in preventing encephalopathy has not been clearly demonstrated.

Regarding prophylactic measures, beta-blockade was extensively used for primary prevention in patients with large varices, in keeping with the consensus, however, secondary prevention in one third of patients consisted of a combination of beta-blockade and endoscopic ligation, even though this treatment had not been shown at the time of Baveno Ⅲ to be more effective than ligation or beta-blockade alone[2]. Practices differed significantly between centers regarding secondary prophylaxis, and the combined treatment was finally accepted in 2005 consensus[1]. This study was not designed to investigate the cause and origins of lack of adherence to guidelines, which is a worldwide problem. Many factors may be involved, including patient information and behavior, local organization of health care, formation of practitioners especially in non-specialized emergency units. This question needs to be addressed in the future.

In conclusion, while French practices are generally in line with the consensus statement, there is significant room for improvement in the diagnosis of cirrhosis and in primary bleeding prevention. However, these results show that cirrhotic patients are poorly informed of the clinical signs and gravity of bleeding, and of the need for rapid treatment by a specialized team. Antibiotics are under-used, and this calls for better information of physicians who manage such patients in intensive care units.

## COMMENTS

### Background

Gastrointestinal hemorrhage is a major complication of cirrhosis. Prognosis improved over the past four decades in relation with a better management of patients with variceal bleeding. Variability and conformity of practices with relevant guidelines have rarely been addressed. Previous US practice surveys reported underuse of esophageal varices screening and primary prophylaxis with beta-blockers.

### Research frontiers

This article deals with evaluative epidemiology of medical practices. The lack of adherence to guidelines is a worldwide problem.

### Innovations and breakthroughs

Major concerns for improvement: improving the endoscopic screening of esophageal varices, patient information about the clinical signs and gravity of bleeding, shortening the delay from bleeding to admission and endoscopy, and generalizing antibiotic prophylaxis. Lactulose administration and prophylaxis of rebleeding were highly variable practices among sectors.

### Applications

These results support the need for active promotion of international guidelines focused on information of physicians who manage such patients and encouraging them to criticize their own practice.

### Peer review

This is an interesting cross-sectional, descriptive study of treatment related to adherence to international guidelines in a French mixture of academic and non-academic hospitals. However, this work did not analyse possible causes to explain such behavior.

## Abstract

**AIM:** To determine the overall prevalence of *H pylori* and CagA positive *H pylori* infection and the prevalence of other bacterial and viral causes of chronic infection in patients with coronary heart disease (CHD), and the potential role of anti-heat-shock protein 60 (Hsp60) antibody response to these proteins in increasing the risk of CHD development.

**METHODS:** Eighty patients with CHD and 160 controls were employed. We also compared the levels of anti-heat-shock protein 60 (Hsp60) antibodies in the two groups. The *H pylori* infection and the CagA status were determined serologically, using commercially available enzyme-linked immunosorbent assays (ELISA), and a Western blotting method developed in our laboratory. Systemic antibodies to Hsp60 were determined by a sandwich ELISA, using a polyclonal antibody to Hsp60 to sensitise polystyrene plates and a commercially available human Hsp60 as an antigen.

**RESULTS:** The overall prevalence of *H pylori* infection was 78.7% ($n$ = 63) in patients and 76.2% ($n$ = 122) in controls ($P$ = 0.07). Patients infected by CagA-positive (CagA$^+$) *H pylori* strains were 71.4% ($n$ = 45) *vs* 52.4% of infected controls ($P$ = 0.030, OR = 2.27). Systemic levels of IgG to Hsp60 were increased in *H pylori*-negative patients compared with uninfected controls ($P$ < 0.001) and CagA-positive infected patients compared with CagA-positive infected controls ($P$ = 0.007).

**CONCLUSION:** CagA positive *H pylori* infection may concur to the development of CHD; high levels of anti-Hsp60 antibodies may constitute a marker and/or a concomitant pathogenic factor of the disease.

**Key words:** *H pylori*; Coronary heart disease; CagA protein; Heat shock protein 60; Antibody response

## INTRODUCTION

Atherosclerosis-related diseases -particularly coronary heart disease (CHD)- are a leading cause of death and disability in most developed countries. Many epidemiological studies have shown a strong relationship between CHD and chronic bacterial and viral infections, suggesting a primary role of inflammatory diseases in the pathogenesis of vascular cardiac disorders[1,2]. Infectious agents may cause a spectrum of systemic effects and induce atherosclerosis in several different ways. For instance, by increasing the production of circulating cytokines (interleukin-1 [IL-1] and interleukin-6 [IL-6]), through the generation of acute-phase reactants (white blood cells and C reactive protein) and the stimulation of immune-mediated responses, such as the production of antibodies targeted to the invading pathogens, *etc*[3]. Several authors[4] have also reported that infections might stimulate smooth muscle cell proliferation and migration and lipid accumulation; apoptosis of endothelial cells can be inhibited and many procoagulant effects could be produced[4].

*H pylori* infection is one of the most widely spread in-

fectious diseases in human[5]. This microorganism infects half the world population and causes chronic gastritis. The disease usually lasts for the entire host's life and constitutes a main risk determinant of peptic ulcer and gastric neoplasia[6,7]. The infection elicits a chronic humoral and cellular inflammatory response, stimulates an increase of polymorphs and basophils[8] and elevates the local and systemic concentrations of vasoactive cytokines[9], whose effects may not be confined to the digestive tract[10].

Recent epidemiological surveys have indicated that *H pylori* infection may be associated with atherosclerotic vascular diseases[11], although it is still disputed whether this infection increases the risk of CHD[12-14]. Some studies have shown an increased risk of CHD in patients with a systemic immune response to heat shock proteins (Hsps)[15]. Hsps are families of highly conserved proteins that share wide homologies of sequence among different species, ranging from bacteria to human beings[16,17]. They are induced or up-regulated in cells exposed to sudden elevations in temperature, but are also synthesized in large numbers when cells are exposed to stressful stimuli such as inflammation, infections, mechanical stress, hypoxia and oxidizing agents[16,17]. They play a fundamental role in the growth of bacteria at all temperatures and their production could represent an essential mechanism of cell protection against different noxae[17,18]. *H pylori* produces two main Hsps, a groEs-like HspA with a mass of 13 kDa, and a groEL-like HspB with a mass of 54-60 kDa[19,20]. Both proteins stimulate a specific systemic antibody response and, due to the high sequence homology of Hsps, it is highly possible that they can trigger an autoimmune response directed against the bacterial proteins and also to human tissues expressing Hsps, including vascular endothelial cells[20,21]. The aim of the present study was to determine the prevalence of anti-Hsp antibodies in patients with CHD and controls and to identify the potential role of an antibody response to these proteins in increasing the risk of CHD development. We tested serum samples for the overall prevalence of *H pylori* and CagA positive *H pylori* infection, and for antibodies to the other bacterial and viral causes of chronic infection that are recognised determinants of CHD risk development. Our results suggest that CagA positive *H pylori* infection may concur to the development of CHD and that high levels of anti-Hsp antibodies may constitute a marker and/or a pathogenic factor of the disease.

## MATERIALS AND METHODS

### Patients and controls

We studied 80 consecutive patients with stable angina; their mean age was 65 years (range 45 to 75 years). Patients were admitted to this Institute for evaluation by clinical history, physical examinations, heart echography, and basal and exercise ECGs. Patients were enrolled if they showed signs or symptoms of angina at exercise ECG; an ST segment depression more than 2 mm was considered positive. As control, we enrolled 160 age- and gender-matched patients, who came from the same socio-economic background and were hospitalised in the same Institute for diseases other than CHD, vascular diseases, dyspeptic and liver disorders, hematological diseases, and thyroid abnormalities. Their mean age was 64.5 years (range 43 to 75 years). Patients and controls had not taken antibiotics potentially active against *H pylori* in the last three months. Both patients and controls gave their written informed consent.

### Determination of H pylori infection and CagA status

The *H pylori* infectious status was determined serologically using a commercially available enzyme-linked immunosorbent assay with a sensitivity and specificity of 96% *ca.* (*Helicobacter pylori* IgG, Diesse, Monteriggioni, Siena, Italy). *H pylori* infectious status was confirmed by Western blotting (WB). WB was also used to detect antibodies to *H pylori* CagA. Briefly, a whole cell suspension of *H pylori* CCUG 17874 (a CagA-positive and cytotoxic strain) was denatured in Laemmli's buffer at 100℃ for 5 min and electrophoresed in a 10% polyacrylamide gel with sodium dodecylsulphate. The resolved proteins were transferred electrophoretically onto nitrocellulose membranes, and the free sites were saturated with 3% skim milk in phosphate buffered saline (PBS) pH 7.4 containing 0.1% Triton X (PMT). Afterward, strips were cut and immunoblotted with serum samples diluted 1:100 in PMT for immunoglobulin G (IgG). After overnight incubation at room temperatures, strips were washed three times with PMT, and a peroxidase labelled antibody to human IgG, diluted in PMT 1:2000 (Sigma Che. Co., Milan), was added and incubated at room temperatures for 90 min. Strips were washed three times with PMT, once with PBS-Triton X, and twice with Tris buffer 0.05 mol/L pH 6.8. The reaction was visualised by addition of the substrate ($H_2O_2$ in a solution of 4-chloro-1-naphthol in Tris buffer 0.05 M pH 6.8). The reaction was stopped with water. The presence of more than six bands of reaction indicated an infection. As positive controls, anti-CagA and anti-Hsp rabbit polyclonal antibodies (kindly given by R. Rappuoli, Novartis, Siena) were used.

### Determination of anti-Hsp60 antibodies

Antibodies to Hsp60 were determined by an ELISA, using a commercially available human Hsp60 (Sigma Che. Co., Milan, Italy). In preliminary tests, we determined the working concentrations of Hsp60 with the aid of a pool of human serum samples, which contained antibodies to *H pylori* HspB (54-60 kDa), as detected on WB. Briefly, we sensitised each well of polystyrene microtiter plates with 150 μL of an anti-polyclonal *H pylori* HspB antibody raised in rabbits, diluted 1:50 in PBS pH 7.4. After one hour of incubation at 37℃, we washed the plates three times with PBS containing 0.05% Tween 20 (PBST) and 2% bovine serum albumin (BSA). Then, we added to each well 2.5 μg of Hsp contained in 100 μL of PBS-BSA (this amount of Hsp was determined in preliminary tests). After one hour of incubation at 37℃ and three washes with PBS-T-BSA, we added 100 μL of each serum samples, both from patients and controls, diluted 1:50 in PBS-BSA. Plates were incubated at 37℃ for one hour, then they were washed

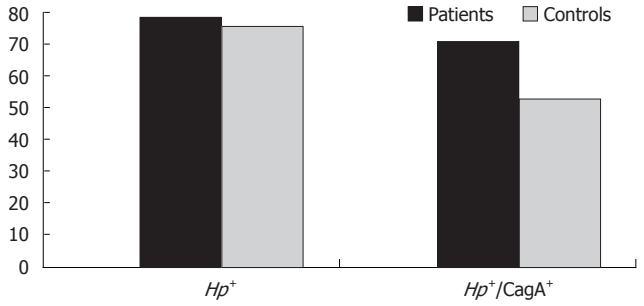

**Figure 1** Prevalence of overall *H pylori* and CagA+ *H pylori* infection in patients and controls.

three times and 100 μL of an anti-human immunoglobulin G (IgG) (Sigma Che. Co., Milan, Italy), labelled with peroxidase, diluted 1:2000, was added to each well. After incubation, we added to each well 50 μL of the substrate (a solution of tetramethylbenzidine dihydrochloride in 0.1 mol/L phosphate-citrate buffer pH 5.0, containing 0.03% sodium perborate and 0.01% of 30% hydrogen peroxide). Incubation was carried out at room temperatures in the dark for 30 min. The reaction was stopped by the addition of 50 μL of 2 mol/L sulphuric acid and read spectrophotometrically at 450 nm. All tests were performed in triplicate and levels of antibodies were expressed in optical density (OD). As a control, we used an anti-Hsp60 polyclonal serum raised in rabbits tested at several dilutions. The intra-tests and inter-tests deviations were lower than or equal to 10%, and lower than or equal to 15%, respectively.

### Determination of other pathogens

Antibodies against other putative causes of chronic infections were determined by the following commercially available kits: *Chlamydia pneumoniae* (CFT-MAT Chlamydia, Diesse, Monteriggioni, Italy); *Mycoplasma pneumoniae* (CFF-MAT Mycoplasma, Diesse, Monteriggioni, Italy); cytomegalovirus (ENZIGNOST CMV IgG, Behering, Milan, Italy); *herpes simplex* virus (ENZIGNOST HSV IgG, Behering, Milan, Italy); E-B virus (ENZIGNOST HSV IgG, Behering, Milan, Italy).

### Statistical analysis

The differences in the prevalence of infection by the various pathogens were compared using the chi-square test with the Yates's correction. The mean levels of anti-urease antibodies were compared using the *t*-test for independent samples, utilising the software Primit.Exe, version 3.0.1. *P* values < 0.05 were considered significant.

## RESULTS

### Overall prevalence of H pylori infection

We determined the prevalence of *H pylori* infection between patients and controls to verify the hypothesis that such an infection could increase the risk of CHD. The mean age of patients was 65 years (range 45 to 75 years); controls had a similar mean age of 64.5 years (range 43 to 75 years). The overall prevalence of *H pylori* infection was 78.7% ($n = 63$) in patients and 76.2% ($n = 122$) in controls ($P = 0.07$).

**Table 1 Prevalence of infection by pathogens other than *H pylori* in patients and controls *n* (%)**

| Group | *C. pneumoniae* | CMV | HSV-1 | EBV | *M. pneumoniae* |
|---|---|---|---|---|---|
| Patients (80) | 63 (78.7) | 75 (93.5) | 77 (96.2) | 74 (92.5) | 37 (46.2) |
| Controls (160) | 110 (68.7) | 145 (90.6) | 140 (87.5) | 148 (92.5) | 62 (38.7) |

### Determination of CagA status in infected patients and controls

Recent studies have shown that infection by strains that express CagA protein induces increased levels of local and systemic cytokines that could contribute to the damage of the cardiovascular system. We therefore determined the seroprevalence of CagA seropositivity in patients and controls. Patients infected by CagA-positive (CagA+) *H pylori* strains were 71.4% ($n = 45$) *vs* 52.4% of infected controls ($P = 0.030$, OR = 2.27; 95% CI 1.0-5.1) (Figure 1).

### Prevalence of infections by pathogens other than H pylori

Since it is well-known that many pathogens could contribute to the genesis of a chronic systemic inflammatory status, we determined the seroprevalence of the most common infectious agents that might increase the risk of CHD. We found that the majority of both patients and controls were seropositive for *C. pneumoniae,* cytomegalovirus*, herpes simplex* virus and Epstein-Barr virus, while 46.2% of patients and 38.7% of controls had anti-*M. pneumoniae* antibodies (Table 1). No statistically significant difference was found in the prevalence of infections by the different pathogens in patients and controls (data not shown).

### Determination of anti-Hsp60 antibodies in patients and controls

Hsps are a family of well-conserved proteins and Hsp60, in particular, is widely shared by *H pylori* and eukaryotic cells. As antibodies to Hsps are found at high titers in cardiovascular disorders, we compared the levels of anti-Hsp60 antibodies in patients and controls. Levels of antibodies to Hsp60 were significantly increased in *H pylori*-negative (*Hp*-) patients, compared with those in *H pylori*-negative controls (341.5 ± 159.6 *vs* 197.6 ± 44.4; $P < 0.001$, 95% CI 66.4-221.3) (Figure 2); levels of antibodies to Hsp60 in CagA+ patients were higher than in CagA+ controls (418.8 ± 144.2 *vs* 317.2 ± 175.6; $P = 0.007$, 95% CI 28.8-174.3), but were not significantly higher than in *Hp*+/CagA- patients (350.2 ± 169.1; $P = 0.110$) and in *Hp*- patients (341.5 ± 159.6; $P = 0.072$) (Figure 2). Levels of antibodies to Hsp60 in CagA+ controls (317.2 ± 175.6)

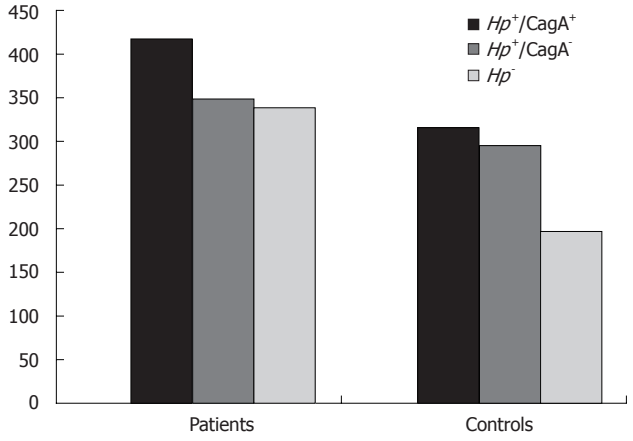

**Figure 2** Mean levels (in optical density) of anti-Hsp60 systemic antibodies in patients and controls.

and $Hp^+$/CagA$^-$ controls (297.1 ± 80.82) were higher than in $Hp^-$ controls (197.6 ± 44.42) ($P = 0.006$, and $P < 0.001$, respectively) (Figure 2).

## DISCUSSION

In the present study we have observed an increased prevalence of CagA$^+$ *H pylori* infection, as well as increased levels of antibodies to Hsp60 in patients with CHD, compared with controls. Because of the notion that atherosclerosis may be regarded as an inflammatory process and that the presence of a chronic systemic inflammatory status is a strong risk factor for the development of coronary artery disease and ischemic stroke, we need to identify the cause of inflammation. In our study, almost all patients and controls were seropositive for pathogens other than *H pylori*, suggesting that these agents of chronic infection have a minor role (if any), at least in our area, in the development of cardiovascular disorders. *H pylori* is the logical and most important candidate for this role as a cause of the low-grade, persistent inflammatory stimulation induced by the infection, i.e. the vascular damage could be an indirect effect of systemic inflammatory mediators stimulated by the local mucosal inflammation, which may affect homeostasis. Recent epidemiological surveys have indicated that *H pylori* infection may be associated with atherosclerosis in different districts, but it is still disputed whether this infection increases the risk of CHD[11,12,14,21]. The increased levels of cytokines induced by infections can lead to changes in endothelial cell function by recruiting monocytes and T cell lymphocytes into the vessel walls; as a consequence, the local inflammatory responses may be exacerbated, even in the absence of resident pathogens. In addition to promoting atherosclerosis, infections can also trigger acute coronary events, such as plaque rupture[12]. Mendall *et al*[11] reported an association between *H pylori* infection and CHD, however, such an observation is still questioned[12-14,22]. A possible reason for contradictory results may include the variable circulation in different areas of *H pylori* strains endowed with an increased inflammatory potential, i.e. those possessing a genomic insertion called *cag*[23]. Patients infected by highly virulent *H pylori* strains can be easily identified, because CagA, the protein encoded by *cagA*, one of the *cag* genes, is always expressed[23,24]. CagA is strongly immunogenic and specific systemic antibodies can be determined by simple methods. *H pylori* is not a clonal pathogen. Although strains from unrelated cases of infection are all genomically diverse, most clinical isolates can be grouped into two types, according to whether they possess or not the pathogenicity island *cag*, a genomic region that encodes proteins involved in virulence such as *cagA*[23]. The importance of the infection by *H pylori* carrying the *cag* insertion has recently been confirmed by the observation that patients with CHD are more likely infected by CagA positive strains and have a more severe clinical picture of the disease[1,2,25]. The increased risk of CHD, to which patients infected by CagA-positive *H pylori* are exposed, may be attributed to the intensified inflammatory potential of such organisms[23]. Thus, the infectious status could determine elevated systemic levels of tumour necrosis factor-alfa, IL-1 beta, IL-6 and interleukin-8 and these cytokines may exert a deleterious activity against vascular endothelial cells. The chronic local inflammatory response to *H pylori* infection may also have repercussions for the whole organism[8,9]. Systemic indices of inflammation, such as levels of polymorphs and basophils, can be increased in individuals infected by *H pylori* and many vasoactive substances like cytokines, produced locally to fight the bacteria, may reach the blood stream and promote a chronic systemic inflammatory status of low degree, which may contribute to injury of other organs, different and far from the stomach[8-11].

Another explanation for contradictory results in experimental and clinical studies, pointing to find out a real association between *Hp* and CHD, may reside in the different inclusion criteria of patients and controls employed in different studies and the strong association of *H pylori* infection with confounding factors, such as age and social class. In order to avoid these variables we have enrolled both patients and controls of the same gender, age and coming from the same social background. The infection by CagA-positive *H pylori* cannot directly induce coronary atherosclerosis and need, most probably, the presence of other co-factors capable of inducing the onset and evolution of ischaemic heart disease. Hsps are highly conserved, immunogenic molecules whose cellular levels are raised by heat, inflammatory mediators and other forms of physiological stress[16,17]. Their most important function is to enhance cellular survival under physiologically stressful conditions, since they have been recognized as molecular chaperones and helpful in correct protein folding and oligomeric assembly[16-18]. Although Hsps are normally intracellular proteins, marked stress-induced overexpression may lead to their presentation on the cell surface, stimulating an autoimmune reaction, and thereby representing an important marker of inflammation. The observation that almost all patients with gastric carcinoma have systemic antibodies to *H pylori* HspB may support such observations[26]. According to the hypothesis of Wick *et al*[27], the association between high levels of anti-Hsp antibodies and

atherosclerotic vascular disease is due to an autoimmune reaction to endothelial cells that express high levels of Hsp in response to stressful stimuli, like oxyded LDL, free radicals, local infections, cytokines or hemodynamic stress. In the present study, we confirmed that the increased anti-Hsp60 immune response observed in patients cannot be attributed to chronic infections by pathogens other than *H pylori*, since their prevalence in patients was similar to that in controls. On the contrary, the infection by $CagA^+$ *H pylori* strains increased the levels of anti-Hsp60 antibodies both in patients and controls; however, although in patients the difference was not statistically significant, in controls such a difference was significant, suggesting that a relationship between chronic *H pylori* infection and development of antibodies to Hsp60 cannot be excluded. Another explanation could consist in the possibility that the inflammatory response triggered by the infection, together with putative toxic substances secreted by bacteria, alters the epithelial Hsp to such a degree that the patient' s immune system loses the immune tolerance to self chaperon and starts producing autoantibodies that cross-react with *H pylori* Hsps. Latif *et al*[28] have identified a strong homology between cardiac myosin heavy chain and Hsp60, suggesting that a cross-reactivity between similar epitope motifs may contribute to autoimmunity; circulating anti-Hsp antibodies may be involved in an autoimmune reaction to myocytes or endothelial cells, respectively, that have expressed Hsps due to stress.

Considering the importance of CHD in the industrialized world as a main cause of illness and since *H pylori* infection (even by CagA-positive strains) can be easily eradicated by specific treatments, the accurate definition of this new risk factor may lead to novel strategies for the prevention of ischemic heart disease.

## Abstract

**AIM:** To identify the independent predictors of hepatic fibrosis in 69 children with nonalcoholic steatohepatitis (NASH) due to nonalcoholic fatty liver disease (NAFLD).

**METHODS:** All patients with clinically suspected NASH underwent liver biopsy as a confirmatory test. The following clinical and biochemical variables at baseline were examined as likely predictors of fibrosis at histology: age, body mass index (BMI), systolic blood pressure (SBP), dyastolic blood pressure (DBP), fasting glucose, fasting insulin, homeostatic model assessment for insulin resistence (HOMA-IR), cholesterol, tryglicerides, alanine aminotransferase (ALT), aspartate aminotransferase (AST), AST/ALT ratio, gamma glutamil transferase (GT), platelet count, prothrombin time (PT).

**RESULTS:** At histology 28 (40.6%) patients had no fibrosis and 41 (59.4%) had mild to bridging fibrosis. At multivariate analysis, BMI > 26.3 was the only independent predictor of fibrosis (OR = 5.85, 95% CI = 1.6-21).

**CONCLUSION:** BMI helps identify children with NASH who might have fibrotic deposition in the liver.

**Key words:** Nonalcoholic steatohepatitis; Obesity; Body mass index; Liver fibrosis; Non invasive diagnosis

## INTRODUCTION

With the current epidemic prevalence of obesity and diabetes mellitus in the general population[1], nonalcoholic fatty liver disease (NAFLD) has become the most common cause of chronic liver disease in many countries[2,3]. The characteristic histological features of NAFLD may range from a bland hepatic steatosis to hepatocellular damage plus inflammation with or without fibrosis known as nonalcoholic steatohepatitis (NASH)[4,5]. Paralleling the increasing prevalence of obesity and type 2 diabetes in the pediatric population, NAFLD especially its more severe histological form-NASH, is expected to become one of the most common causes of end-stage liver disease in both children and young adults. In this population, histological confirmation remains controversial due to the cost of liver biopsy and the complications directly related to the procedure or to the sedation, reported to be higher (up to 18%) in infants than in adults[6]. Furthermore, there is no proven therapy for NASH that could justify paired biopsies to compare histology with baseline features.

A first step for the clinician is to select children at risk of progressive liver disease from those with steatosis alone, and the secondary step is to identify in the former possibly by non invasive diagnosis of those with liver fibrosis. Raised alanine aminotransferase levels (ALT) have been shown to correlate best with a diagnosis of steatohepatitis (95% CI = 3.1-23.5, $P < 0.001$), but the other two factors, namely insuline resistence index (IR > 5.0, 95% CI = 3.4 -26, $P < 0.001$) and hypertension (> 140/90, 95% CI = 2.0-13.5, $P = 0.001$), are also found to have significant independent predictive effects[7]. The presence of at least two of the three factors provides the best combination of sensitivity (0.8) and specificity (0.89) for predicting NASH[7].

Non invasive diagnosis of liver fibrosis has been extensively evaluated in adult population with NAFLD[8-11]. Obesity, hypertension, male gender, hyperdyslipemia, and insulin resistance have been reported to be independent predictors of advanced fibrosis. In contrast, in paediatric population data are lacking and liver biopsy is still considered the only reliable tool for diagnosing histological

features.

The aim of this study was to identify the independent predictors of fibrosis in children with NAFLD by selecting groups of children at a higher risk of progressive liver damage (NASH population). Clinical and/or biochemical parameters routinely performed in clinical practice that can predict abnormal liver histology were tested.

## MATERIALS AND METHODS

The study protocol was conformed to the ethical guidelines of the 1975 Declaration of Helsinki and performed according to the recommendations of the Ethics Committee of Children's Hospital and Research Institute Bambino Gesù in Rome, Italy. Informed consent was directly obtained from each parent or responsible guardian.

### Patients

Sixty-nine untreated consecutive children (49 males and 20 females) seen at our institution from June 2001 to April 2003 were included in this study. All patients underwent evaluation for persistently elevated serum aminotransferase levels associated with diffusely echogenic liver on imaging studies suggestive of fatty infiltration. The diagnosis of NAFLD was confirmed by a percutaneous liver biopsy in all cases. Secondary causes of steatosis including alcohol abuse ($\geqslant$ 140 g/wk), total parenteral nutrition, and the use of drugs known to precipitate steatosis were excluded in all cases. Hepatitis A-G, cytomegalovirus and Epstein-Barr virus infections were ruled out by appropriate tests. In all cases, autoimmune liver disease, metabolic liver disease, Wilson's disease, and $\alpha$-1-antitrypsin deficiency were ruled out using standard clinical and laboratory evaluation as well as liver biopsy features. Body mass index (BMI), the weight in kilograms divided by the square of the height in meters, was calculated. To compare BMI across different ages and in both boys and girls, BMI Z score was calculated. The Z score represents the number of standard deviations above or below the considered population mean value, based on standardized tables for children[12].

### Evaluation of glucose metabolism and insulin sensitivity

All patients underwent a 2-h oral glucose tolerance test (OGTT) with the standard 1.75 g of glucose per kg, or a maximum of 75 g. Glucose tolerance status was determined according to the recently revised American Diabetes Association classification[14] in which a fasting plasma glucose (FPG) level up to 99 mg/dL is considered normal, impaired fasting glucose (IFG) is defined by a FPG of 100-125 mg/dL, impaired glucose tolerance (IGT) is defined by a 2-h plasma glucose of 140-199 mg/dL, diabetes mellitus is defined by a FPG $\geqslant$ 126 mg/dL, or a 2-h plasma glucose $\geqslant$ 200 mg/dL. IFG and IGT are officially termed "pre-diabetes'.

The degree of insulin sensitivity/resistance was determined by the homeostatic model assessment insulin resistence (HOMA-IR) using the formula: IR = (insulin* glucose)/22.5[13], and by the insulin sensitivity index (ISI-comp) derived from OGTT using the formula: ISI = (10 000/square root of [fasting glucose × fasting insulin] × [mean glucose × mean insulin during OGTT])[13]. Both HOMA-IR and the OGTT-derived ISI have a significant correlation with the 'gold standard' euglycemic hyperinsulinemic glucose clamp technique. A HOMA-IR value > 2 and/or ISI-comp value < 6 were considered an indication of insulin resistance.

### Liver histology

Biopsies were performed in all children using an automatic core biopsy device (Biopince, Amedic, Sweden) with an 18-G needle (150 mm long), which is able to cut tissue with lengths up to 33 mm with extreme precision[6]. Liver biopsies were at least 15 mm in length and read by a single liver pathologist who was unaware of the patient's clinical and laboratory data. Biopsies were routinely processed (formalin-fixed, paraffin-embedded) and analysed in sections stained with (1) hematoxilin and eosin for overall assessment of parenchymal architecture, hepatocyte abnormalities and inflammatory infiltrates; (2) Van Gieson for assessment of fibrosis and architectural changes; (3) PAS-D after diastase predigestion to highlight debris in portal macrophages and Kupffer cells as well as eosinophilic globules in periportal hepatocytes (characteristic of endoplasmic reticulum storage disease, namely $\alpha$-1 antitrypsin); and (4) Perl's (Prussian blue) stain for estimation of iron storage in hepatocytes and sinusoidal lining cells. Additionally, immunoistochemical staining with $\alpha$-1 antitrypsin was used to exclude $\alpha$-1 antitrypsin-associated liver disease.

The main histological features commonly described in NALFD/NASH including steatosis, inflammation (portal and lobular), hepatocyte ballooning, and fibrosis, were scored according to the scoring system for NAFLD, recently developed and validated by the NIH-sponsored NASH Clinical Research Network[14]. Briefly, steatosis was graded on a 4-point scale: grade 0 = steatosis involving < 5% of hepatocytes; grade 1 = steatosis involving up to 33%of hepatocytes; grade 2 = steatosis involving 33%%-66% of hepatocytes; and grade 3 = steatosis involving > 66% of hepatocytes. Lobular inflammation was graded on a 4-point scale: grade 0 = no foci; grade 1 = less than 2 foci per 200 × field; grade 2 = 2-4 foci per 200 × field; grade 3 = more than 4 foci per 200 × field. Hepatocyte ballooning was graded from 0 to 2: 0 = none, 1 = few balloon cells, 2 = many/prominent balloon cells. Stage of fibrosis was quantified in a 4-point scale: stage 0 = no fibrosis; stage1 = perisinusoidal or periportal fibrosis (1a = mild, zone 3, perisinusoidal; 1b = moderate, zone 3, perisinusoidal; 1c = portal/periportal); stage 2 = perisinusoidal and portal/periportal fibrosis; stage 3 = bridging fibrosis; and stage 4 = cirrhosis. Other features, such as zonal distribution of steatosis, presence of microvesicular steatosis, glicogenated nuclei, lipogranulomas, PAS-D cells, acidophil bodies and Mallory bodies, also were recorded. Portal tract inflammation was graded from 0 to 3 (0 = s none, 1 = mild, 2 = moderate and 3 = severe).

### Statistical analysis

Continuous variables were expressed as mean ± SD, while categorical variables were expressed as absolute and percentage frequency. Mann-Whitney rank-sum test and Yates

**Table 1 Anthropometric, clinical and biochemical characteristics of patients ($n$ = 69)**

| Variables characteristics | mean ± SD | Range |
|---|---|---|
| Age (mo) | 145.7 ± 39.5 | 44-226 |
| BMI (kg/m$^2$) | 26.3 ± 4.1 | 15.2-38.3 |
| BMI Z score | 2.0 ± 0.79 | 0.8-5.0 |
| Type II diabetes $n$ (%) | 2 (2.3) | |
| Hypertension $n$ (%) | 2 (2.3) | |
| AST (IU/L) | 42 ± 16 | 19-90 |
| ALT (IU/L) | 60 ± 31 | 10-192 |
| GT (IU/L) | 23 ± 20 | 10-130 |
| Cholesterol (mg/dL) | 152 ± 32 | 75-222 |
| Triglyceride (mg/dL) | 86 ± 44.5 | 28-348 |
| Fasting glucose (mg/dL) | 82 ± 11 | 60-138 |
| Fasting insulin (mU/L) | 12.5 ± 6.4 | 3.5-30.7 |
| HOMA-IR | 2.55 ± 1.39 | 0.67-6.29 |
| ISI-comp | 4.4 ± 2.0 | 1.26-9.16 |

BMI: body mass index; AST: aspartate aminotransferase; ALT: alanine Aminotransferase; γGT: gamma-glutamyl transpeptidase; HOMA-IR: homeostatic model assessment-insulin resistence; ISI: insulin sensitivity index.

corrected $\chi^2$ were used when appropriate, at the univariate analysis in which several proposed indices for the assessment of fibrosis were assessed with consideration of the following clinical and biochemical parameters, such as glycemia, BMI, body mass index standard deviation score (BMI-SDS), cholesterol, thriglicerides, systolic blood pressure (SBP), dyastolic blood pressure (DBP), ALT, alanine aminotransferase (ALT), AST/ALT ratio, GT, PLT, PT, HOMA, ISI, insulin. The independent role of variables selected by univariate analysis was tested by stepwise logistic regression. Maximal likelihood method was used for entering and removing variables. For all calculations, the biomedical data processing system (BMDP dynamic version 7, University of California, Los Angeles, CA) was used.

## RESULTS

### Patient characteristics

Clinical details of the 69 children with NAFLD are summarized in Table 1. The median age was 147.5 ± 39.5 (range, 44-226) mo with a male predominance (71%). The mean ALT and AST levels were 60 IU/L (normal values < 36 IU/L) and 42 IU/L (normal values < 32 IU/L) respectively. Insulin resistance, as indicated by a HOMA-IR > 2 or ISI-comp < 6, was present in 37 (53.6%) and 54 (78.2%) children, respectively. There was no significant correlation between BMI Z-score and HOMA-IR ($r$ = 0.15, $P$ = 0.21) or BMI Z-score and ISI-comp ($r$ = 0.13, $P$ = 0.27). The mean total cholesterol and triglyceride levels were 152 mg/dL and 86 mg/dL, respectively. Only 3 children had elevated triglyceride levels (i.e. > 160 mg/dL), and 7 children had hypercholesterolemia (i.e. > 200 mg/dL).

### Glucose metabolism

Overall, 67 (97.1%) patients showed normal glucose metabolism on OGTT, whereas the remaining 2 patients (2.9%) showed impaired glucose metabolism, including 1 patient classified as IFG, and 1 patient as IGT. These 2 patients were significantly older (18.4 ± 0.4 *vs* 10.8 ± 4.5 years; $P$ < 0.05) than those with normal glucose metabolism. The BMI Z-score (1.5 ± 1.32 *vs* 1.94 ± 0.67, $P$ = NS) and HOMA-IR (2.35 ± 1.75 *vs* 2.5 ± 1.34, $P$ = NS) were not statistically different between the two groups (no fibrosis *vs* fibrosis).

**Table 2 Histological findings in the patients population (Biopsies scored according to Kleiner *et al*), $n$ (%)**

| Grade/Stage | Steatosis | Necroinflammation | Fibrosis |
|---|---|---|---|
| 0 | - | 12 (17.4) | 28 (40.6) |
| 1 | 25 (36.2) | 52 (75.3) | 36 (52.2) |
| 2 | 27 (39.2) | 5 (7.2) | 1 (1.4) |
| 3 | 17 (24.6) | - | 4 (5.8) |
| 4 | - | - | - |

### Liver histology

The histological findings are summarized in Table 2. All biopsies showed steatosis, mostly macrovesicular. The pattern of steatosis was diffuse or scattered lobular, and only showed zonal distribution in ten cases. Inflammation was present in 57 (82.6%) biopsies. The inflammatory infiltrate was mainly composed of lymphocytes and neutrophils, and when granulomas were present, mononuclear histiocytic cells and eosinophils were also present. Hepatocyte ballooning was present in 34 (49%) of the 69 biopsies, whereas apoptotic cells were noted occasionally. Glycogenated nuclei of variable dimension were present in 35 (50.7%) of the 69 cases, and this nuclear change was noted mostly in zone 1 of the hepatic lobule. No Mallory hyaline was noted in any case, and mild iron deposition was present in 3 cases.

Increased fibrosis was noted in 41 patients (59.4%), mostly of mild (stage 1) severity, one patient in stage 2, and 4 children (5.8%) were showing septal fibrosis (stage 3). Among the 36 patients with stage 1 fibrosis, 3 were 1a, 5 were 1b, and 28 were 1c. No patient showed liver cirrhosis at histology.

Table 3 shows the comparison between children with and without liver fibrosis. Children with liver fibrosis were slightly older, and had significantly higher BMI than those without fibrosis. Those with fibrosis also showed higher serum levels of cholesterol and triglycerides, although the mean values were still within the normal range, and the prevalence of hypercholesterolemia and hypertriglyceridemia was not different between the two groups. Liver enzymes or AST/ALT ratio was not different between those with and without fibrosis.

At multivariate analysis of baseline clinical and biochemical parameters in 28 patients with stage 0 fibrosis in comparison to the 41 patients with stage higher than or equal to 1, only BMI was independently associated with fibrosis (OR = 5.85, 95% IC = 1.6-21). At ROC analysis the cut off value for BMI was 26.3 (sensibility 66%, specificity 71%). Among the 35 patients with BMI ⩾ 26.3, 27 (77.1%) had fibrosis stage ⩾ 1, whereas fibrosis stage ⩾ 1 was present in 14 (41.2%) out of 34 children with BMI < 26.3.

**Table 3 Comparison of clinical and biochemical features according to stage of fibrosis (mean ± SD)**

| Features *n* (%) | No fibrosis 28 (40.6) | Fibrosis ⩾ 1 41 (59.4) | *P* |
|---|---|---|---|
| Age (mo) | 140.3 ± 34 | 151.4 ± 41 | 0.2 |
| Fasting glucose (mg/dL) | 82.4 ± 9.9 | 81.5 ± 11.7 | 0.7 |
| BMI (kg/m$^2$) | 25.2 ± 3.3 | 27.5 ± 4.5 | 0.01 |
| BMI-SDS | 1.84 ± 0.5 | 2.0 ± 0.7 | 0.05 |
| Cholesterol (mg/dL) | 148.8 ± 34.4 | 160.2 ± 36.2 | 0.2 |
| Triglycerides (mg/dL) | 82.4 ± 59.5 | 97.9 ± 39.4 | 0.2 |
| Systolic pressure (mmHg) | 110.2 ± 11.6 | 116 ± 15 | 0.07 |
| Diastolic pressure (mmHg) | 67.0 ± 8.2 | 67.1 ± 8.3 | 0.9 |
| AST (U/L) | 41.6 ± 14.6 | 49.3 ± 32.2 | 0.18 |
| ALT (U/L) | 65.6 ± 26 | 76.2 ± 82.6 | 0.4 |
| AST/ALT | 0.7 ± 0.3 | 0.9 ± 0.5 | 0.05 |
| GT (U/L) | 25.2 ± 25 | 23.7 ± 16.6 | 0.7 |
| PLT (10$^3$/L) | 285 ± 66 | 295 ± 59 | 0.5 |
| PT | 87.9 ± 9.3 | 90.2 ± 7.6 | 0.3 |
| HOMA-IR | 2.7 ± 1.5 | 2.4 ± 1.1 | 0.4 |
| ISI | 4.0 ± 1.7 | 4.5 ± 1.9 | 0.4 |
| Fasting insulin (mU/L) | 13.5 ± 6.7 | 11.6 ± 5.8 | 0.2 |

BMI-SDS: body mass index standard deviation score; AST: aspartate aminotransferase; ALT: alanine aminotransferase; PLT: platelets count; PT: prothrombin time; HOMA-IR: homeostatic model assessment-insulin resistence; ISI: insulin sensitivity index.

## DISCUSSION

Over the last decades, the prevalence of overweight and obesity among children has increased dramatically, becoming an important public health problem. The negative consequences of paediatric overweight can occur during childhood or adulthood and may result in metabolic, physical, psychosocial and economic consequences. Among these, non alcoholic fatty liver disease has become a growing clinical problem and a major cause of liver-related morbidity.

The accurate means to distinguish between simple fatty liver and steatohepatitis is a liver biopsy as NASH is diagnosed when tissue histology shows fat along with inflammation and damage to liver cells. This distinction has a prognostic relevance because whereas NAFLD is a benign nonprogressive condition, NASH can progress to cirrhosis, liver failure and hepatocellular carcinoma[15]. However, the need for histological evaluation of NAFLD remains controversial as no efficacious treatment strategies have been yet designed. Persistent hypertransaminasemia of non-alcoholic steatohepatitis in obese children may resolve after weight reduction and high doses of vitamin E treatment, but the impact on the natural history needs to be validated by large-cohort controlled studies[16-19]. Thereby, the search for non invasive diagnostic tests of liver fibrotic deposition should be preferred to the expensive and invasive procedure of liver biopsy, whereas the latter should be limited to those cases with uncertain diagnosis[7].

Our previous validation study regarding non invasive diagnosis of liver fibrosis in adults with chronic hepatitis C to cirrhosis showed a significant inverse correlation between stage of fibrosis and platelet count with the highest platelets count in patients with fibrosis 0-2, lower in those with grade 3 and lowest in those with grade 4[20]. Also, an inverse correlation between spleen size and platelets count has been observed ($r$ = - 0.54, $P < 0.0001$) and thrombocytopenia presents in 71% and 23% of patients with or without splenomegaly respectively[21]. The accuracy of platelet count was not significant in children ($P$ = 0.5) as most of the children with NAFLD had stage 1 of fibrosis (52.2%), and less than 8% had a fibrotic score ⩾ 2. The amount of scar deposition that characterizes these stages of fibrosis is too low to favour hemodynamic changes with portal hypertension, altered production of thrombopoietin and enlarged spleen sequestration.

At multivariate analysis of baseline clinical and biochemical parameters in the present study, BMI was an independent predictor of fibrosis (OR = 5.85, 95% CI = 1.6-21); at the cut off value of 26.3 kg/m$^2$, the BMI evaluation showed a sensibility and specificity of 66% and 71%, respectively, in ascertaining the presence of fibrosis in children. Conceivably, the BMI evaluation may be useful in picking up those children at higher risk of disease progression. Future studies investigating the natural history and the long-term sequelae of our histological findings in children are warranted to corroborate our claim.

In conclusion, increased BMI appears to correlate with long term progression to fibrosis and cirrhosis. Reversal of obesity with a gradual weight reduction can improve laboratory abnormalities, histologic changes and liver size in children with NAFLD. BMI may be considered a good non invasive indicator of the underlying disease. Although little controversy exists about the role of liver biopsy as the best accurate method available to assess the stage of the disease, the decision to perform it should be weighed against the risk of the procedure and the impact of the information obtained. In particular, in paediatric population, the timing of biopsy should be individualized and postponed to non-invasive diagnostic tools.

## COMMENTS

### Background
Interest is growing regarding the nonalcoholic steatohepatitis (NASH) in pediatric age and in the usefulness of liver biopsy for its detection.

### Research frontiers
Non invasive detection of liver fibrosis may help better define new therapeutical approaches in a larger number of pediatric NASHs.

### Innovations and breakthroughs
Still new diagnostic parameters for non invasive detection of liver fibrosis need to be searched and validated in paedriatic population. This work proves that BMI helps identify children with NASH who might have fibrotic deposition in the liver.

### Applications
BMI as one of the future criteria can be used for detection of pedriatic patients with NASH-fibrosis.

### Peer review
This study tested the accuracy of various clinical and biochemical parameters for the diagnosis of NASH in 69 children. The results show that only increased BMI is significantly associated with fibrosis, whereas other parameters have not been identified as predictive. This study is accurate and is of importance due to the absence of any non invasive method for the diagnosis of liver fibrosis in the paediatric population. While being interesting, this observation should be further confirmed.

## Abstract

**AIM:** To summarize the evidence available for the clinical effectiveness of insulin sensitizers in the treatment of nonalcoholic fatty liver disease (NAFLD) systematically.

**METHODS:** Relevant articles were located using computer-assisted searches of Medline (1966-March 2006), EMBASE (1988-March 2006), CINAHL (1982-March 2003), Educational Resource Information Center (1966-March 2006), Library, Information Science & Technology Abstracts (1967-March 2006), Cochrane Database of Systematic Reviews, Database of Abstracts of Reviews of Effects (1994-2006), dissertations in ProQuest and FirstSearch databases. Manual searches were made in the abstracts from meetings of the American Gastroenterological Association (1999-2006), and the American Association for the Study of Liver Diseases (2003-2005). Studies were retrieved using the following selection criteria: (1) clinical trials using insulin sensitizers in subjects with NAFLD, (2) adult patients, (3) published as full manuscripts or abstracts, and (4) English, Spanish, German, and French languages only. Data were abstracted independently by two reviewers following standardized procedures. A face-to-face comparison of data was conducted to ensure the completeness and reliability of the abstraction process.

**RESULTS:** Nine studies were included, six using metformin and three using thiazolidinediones. Only two studies were placebo-controlled trials. The median sample size for all studies was 18 subjects. In the placebo-controlled trials, metformin improved insulin resistance markers and liver function tests, but not histological scores. In the single-arm trials, metformin and thiazolidinediones improved insulin resistance markers and liver function tests, and beneficial histological changes were reported. There is limited high-quality information available from which to draw categorical conclusions about the clinical use of insulin sensitizers in NAFLD.

**CONCLUSION:** Current information indicates that the use of insulin sensitizers in NAFLD improves insulin resistance and liver function. Histological changes must be corroborated in randomized controlled trials.

**Key words**: Diet; Metformin; Rosiglitazone; Pioglitazone; Fatty liver; Steatohepatitis; Evidence based medicine; Systematic review

## INTRODUCTION

Nonalcoholic fatty liver disease (NAFLD) is an increasingly recognized condition that may progress to end-stage liver disease, ranging from simple steatosis to steatohepatitis, advanced fibrosis, and cirrhosis (in 1.6% of patients with NAFLD). The pathological picture resembles that of alcohol-induced liver injury, but it occurs in patients who do not abuse alcohol[1]. The true prevalence of NAFLD in the USA is unknown. Based on the percentage of people in the Third National Health and Nutrition Examination Survey (NHANES-Ⅲ) with unexplained elevated levels of serum aminotransferase, up to 7.3% of the USA population could be suffering from NAFLD[2]. When the diagnostic criteria are modified, the estimated prevalence of NAFLD reaches 24%[3]. According to

Byron *et al*[4], NAFLD is the third most common diagnosis in gastroenterological referrals, accounting for 11% of patients. NAFLD is expected to become one of the most important liver diseases in the near future as a result of the obesity epidemic[5].

NAFLD was first described more than 20 years ago[1] and many advances in our understanding of its pathophysiological mechanisms have been made. Diet and exercise constitute the central strategies in NAFLD treatment[6]. Considering the pathogenic mechanisms that may be involved, several pharmacological strategies for NAFLD have been tested that focus on correcting the risk factors for insulin resistance and decreasing hyperinsulinemia, as hepatoprotective effects, using diverse drugs: gemfibrozil, metformin, betaine, *N*-acetylcysteine, and vitamin E[7]. However, no consensus regarding an effective therapy for NAFLD has been reached[8].

Over the last five years, clinical trials evaluating the use of insulin sensitizers in the treatment of NAFLD, such as metformin and thiazolidinediones, have been conducted. Mixed results, heterogeneous therapeutic approaches, and the small numbers of subjects have limited their application as clinical guidelines. We performed a comprehensive systematic review to summarize the evidence available for the clinical effectiveness of insulin sensitizers in the treatment of NAFLD.

## MATERIALS AND METHODS

### Search strategy

Relevant articles were located using computer-assisted searches of Medline (1966-March 2006), EMBASE (1988-March 2006), Cumulative Index to Nursing & Allied Health Literature (CINAHL) (1982-March 2003), Educational Resource Information Center (ERIC) (1966-March 2006), Library, Information Science & Technology Abstracts (LISTA) (1967-March 2006), Cochrane Database of Systematic Reviews (CDSR), Cochrane Controlled Trials Register (CCTR), Database of Abstracts of Reviews of Effects (DARE) (1994-2006), dissertations in ProQuest and FirstSearch databases, and Literatura Latinoamericana y del Caribe en Ciencias de la Salud (LILACS). Manual searches were conducted in the abstracts from the Digestive Disease Week of the American Gastroenterological Association (1999-2006), the American Association for the Study of Liver Diseases Meetings (2003-2005), and the reference lists included in the retrieved articles. Searching terms included: nonalcoholic fatty liver disease, nonalcoholic steatohepatitis, hepatic steatosis, treatment, clinical trial, metformin, thiazolidinediones, rosiglitazone, troglitazone, pioglitazone, englitazone, PPAR-gamma, peroxisomal proliferator activated receptor.

### Study selection criteria

Two investigators (ChN, BT) independently reviewed the titles and abstracts of all the citations identified. Potentially relevant studies were retrieved based on the following selection criteria: (1) clinical trials using one or a combination of insulin sensitizers (metformin and thiazolidinediones: rosiglitazone, troglitazone, pioglitazone, englitazone) in subjects with NAFLD, (2) adult patients, (3) data published in full manuscript form or abstract form, and (4) English, Spanish, German, and French languages only.

### Eligibility and data abstraction

After retrieval, the articles were subject to evaluation to ensure their compliance with the inclusion and exclusion criteria considered for data abstraction. The exclusion criteria for data abstraction from the selected studies were: (1) use of a concomitant therapeutic approach (ursodeoxycholic acid, antioxidants, *etc*.) with insulin sensitizers, and (2) less than 10 participants at the beginning of the study. Inclusion criteria were: (1) controlled trials of insulin sensitizers versus placebo or diet, (2) single-arm studies of rosiglitazone, troglitazone, pioglitazone, or englitazone, and (3) NAFLD or nonalcoholic steatohepatitis (NASH) based on histological diagnosis or imaging studies (computed tomography, abdominal ultrasound, or magnetic resonance imaging) and/or aberrant liver function tests in the absence of alcohol consumption. Unblinded evaluation of the inclusion/exclusion criteria was conducted separately by all authors. Discrepancies in selection were resolved by consensus. Checks for repeated references were conducted based on the authors' names, publication dates, and reported population characteristics. Data abstraction was conducted independently by ChN and BT following the standardized procedures developed by the research team. The criteria included: publication and study characteristics, study population, diagnostic criteria, intervention description, and baseline and postintervention clinical characteristics. In cases where the information to be abstracted was not presented in the published reports, the authors attempted to contact the corresponding authors (Blaszyk, Azuma, and Duseja), and the responses (Duseja) were included in the abstraction formats. After all studies were abstracted, a face-to-face comparison of data retrieved by ChN and BT was conducted to ensure the completeness and reliability of the abstraction process. Minor discrepancies were recorded and resolved by referring to the original paper.

## RESULTS

A total of 94 studies were retrieved from the broad search terms used (Figure 1). After elimination of editorials, reviews, and repeated reports, 10 studies[9-18] remained candidates for evaluation. One study was excluded because of concomitant use of vitamin E[18] (Table 1). Heterogeneity of treatments, methodologies, and reporting quality in the studies precluded any attempt to estimate summary measures, forcing a narrative presentation of our findings. All studies were classified into one of three groups based on the characteristics of the pharmacological interventions: metformin *vs* diet trials, metformin single-arm trials, and thiazolidinedione single-arm trials.

Most (77%) studies were designed as single-arm trials, one was designed as a randomized controlled trial, and one as a nonrandomized controlled trial. Sample sizes ranged

**Table 1 Details of trials eligible for this systematic review**

| Ref. | Design | Participants | Intervention | Outcomes | | |
|---|---|---|---|---|---|---|
| | | | | IR | Biochemical | Histological |
| [9] | Nonrandomized open-label controlled | Italy. 20 consecutive subjects. No diabetic or severely obese subjects. | Treatment: metformin 500 mg/d for 4 mo Control: diet | + | + | NE |

| [15] | Nonrandomized open-label single-arm trial | USA. 25 subjects. | Rosiglitazone 8 mg/d for 48 wk plus diet and physical activity | + | + | + |
| [16] | Nonrandomized open-label single-arm trial | USA. 18 nondiabetic subjects. | Pioglitazone 30 mg/d for 48 wk | + | + | + |
| [17] | Nonrandomized open-label single-arm trial | Japan. 12 subjects. | Pioglitazone 30 mg/d for 12 wk | + | + | NE |

IR: Insulin resistance; NE: Not evaluated. [1]In this study, metformin was compared with vitamin E. We have included only the metformin-treated group, with biopsies at baseline and at the end of the study; [2]Hypothesis test was not provided.

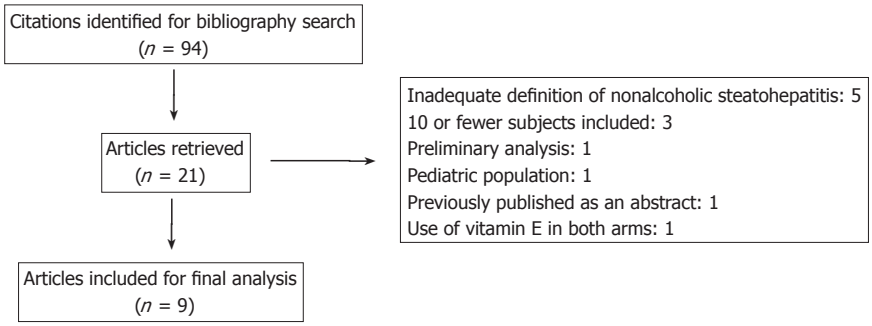

**Figure 1** Literature search and selection.

from 10 to 36 subjects, with a median of 18 subjects. All studies used a histological diagnosis of NASH as the inclusion criterion, and posttreatment biopsies were available in only six studies.

### *Description of the studies*

**Metformin versus diet trials**: Two studies compared the efficacy of metformin versus diet in the treatment of NAFLD. Marchesini *et al*[9] studied 20 consecutive patients (no diabetic or severely obese subjects were included) with liver function tests, and tests for insulin and insulin resistance (by euglycemia and a hyperinsulinemic glucose clamp). Liver biopsies were conducted in 14 subjects who received metformin (500 mg tid) and six were treated with diet alone for four months. The only significant difference between the two groups was in their alanine aminotransferase values. Histological improvement was not evaluated. The diet group did not differ from the drug group in weight reduction, which could reflect the effect of metformin. The most common adverse effect was gastrointestinal. Although subjects undergoing active treatment showed increased levels of lactic acid (by 30% in actively treated patients), just one patient was above the normal range of 2 mmol/L (2.2 mmol/L).

Uygun *et al*[10] studied 36 patients with NAFLD. The treatment group received metformin (850 mg bid) plus dietary treatment. The control group received only a restricted diet (1600-1800 calories per day). Compared with the controls, the treatment group showed improvements in: alanine aminotransferase (37.1 *vs* 17.4 U/L, respectively, $P = 0.003$), aspartate aminotransferase (22.1 *vs* 6.8 U/L, respectively, $P = 0.0001$), body mass

[1]Only seven patients in the treatment group. Information about the control group is not available; [2]This study reported anemia as an adverse effect, but numerical data are not available. NR: not reported; NA: not applied; HOMA: homeostatic model assessment.

index (2.4 *vs* 1.9 kg/m$^2$, respectively, $P = 0.01$), and index of insulin resistance (1.15% *vs* 0.02%, respectively, $P = 0.001$). In fact, a comparison of the treatment group at baseline and at six months showed improvements in alanine aminotransferase (83.5 ± 24.6 *vs* 46.4 ± 23.3 U/L, respectively, $P = 0.0001$) and aspartate aminotransferase (57.9 ± 17.3 *vs* 35.8 ± 10.5 U/L, respectively, $P = 0.0001$). However, this was also seen in the control group: alanine aminotransferase (72.8 ± 31.2 *vs* 55.4 ± 16.3 U/L, respectively, $P = 0.001$) and aspartate aminotransferase (48.1 ± 26.3 *vs* 41.3 ± 13.5 U/L, respectively, $P = 0.06$). No differences were observed in the liver biopsies of subjects after treatment. No patient discontinued metformin because of a lack of tolerance for the treatment. No patient reported symptoms of hypoglycemia. Four patients complained of gas and bloating and two patients complained of mild to moderate abdominal pain in the first month. However, these complaints did not require cessation of the drug.

**Metformin single-arm trials**: Four single-arm trials evaluated the use of metformin in NAFLD (Table 2)[11-14]. The mean age of the study participants ranged from 36 to 51 years in all but one study[14]. Males were predominant (ranging from 53% to 83%). The doses used in the different series ranged from 20 mg/kg per day (approximately 1.4 g per day in a subject of 70 kg) to 2 g/d. Treatment duration varied from six months[14] to 48 wk. Insulin resistance was assessed by the QUICKI, HOMA, or KITT methods.

All trials reported an improvement in the indices of insulin resistance, three studies[12-14] reported a reduction in liver function test values, and one study reported a nonsignificant increase in these values[11].

In terms of histological improvement, only one report[13] showed statistical differences in inflammation, steatosis, fibrosis, and global evaluations of NASH after treatment. The most common adverse effects were associated with poor gastrointestinal tolerance. One patient had an increase in serum lactate levels that required the patient to withdraw from the study.

**Thiazolidinediones single-arm trials**: The use of thiazolidinediones (pioglitazone, rosiglitazone, and

troglitazone) was evaluated in three studies (Table 3)[15-17]. The mean age in each study was 40-46 years. In one study, men were in the majority[17], and in two studies, diabetic subjects were included[15,16]. Of these studies, two used pioglitazone and one used rosiglitazone, at varying doses (pioglitazone 15-30 mg/d and rosiglitazone 4 mg, bid). The durations of the studies ranged from 12 wk[17] (pioglitazone 15 mg/d) to 48 wk. Two studies assessed insulin resistance with HOMA-IR[15,16] and the other with serum insulin levels[17]. Posttreatment hepatic biopsies were reported in two studies[15,16].

All studies showed significant improvement in insulin resistance. Alanine aminotransferase and aspartate aminotransferase showed significant decreases in all studies. Posttreatment biopsies showed statistically significant improvements with respect to baseline biopsies[15,16]. The adverse effects reported were weight gain, serum lactate increases, bad dreams, and heavy legs. The pooled dropout rate was high, at 11 of 60 subjects. No cases of liver failure were reported.

## DISCUSSION

This systematic review analyzes the clinical use of insulin sensitizers in the treatment of NAFLD. Although it has been more than 20 years since the first description of NAFLD[1], and much progress has been made in understanding its epidemiology and pathophysiology, few advances have been made in its treatment.

In this review, only two clinical studies compared pharmacological treatments with diet treatments. The methodological limitations are clear: the small numbers of subjects, nonrandomization and the lack of blinded measures, and the limited use of histological outcomes.

The fact that limited high-quality information available is interesting, especially because (1) NAFLD is a very common disease, with incidences between 3% in the low-risk population[19] and 93% in high-risk subjects[20,21], (2) subjects have some degree of histologically evident chronic liver damage, and at least 30% have fibrosis at diagnosis[22], (3) it is an important cause of chronic liver failure and adversely affects survival rates, with 7-10-year liver-related mortality rates of 12% to 25%[23], and (4) it is an important factor in cardiovascular-related mortality; in a 10-year prospective study of subjects with NASH or hepatitis C viral infection, the mortality rates were 5.2% *vs* 0.6%, respectively ($P < 0.03$)[24].

Analyzing the usefulness of insulin sensitizers by comparing metformin with thiazolidinediones in single-arm trials suggests that thiazolidinediones are the better option. However, when diet-controlled studies are considered, this conclusion is less clear because, contrary to the single-arm trials, these studies indicate that the use of metformin clearly benefits liver enzymes. Unfortunately, no data from a well-designed head-to-head comparative clinical trial are available to answer this question. In all the studies analyzed, a heterogeneity of drugs and doses was observed, which made it more difficult to evaluate the efficacy of insulin sensitizers in clinical practice.

The evidence presented in this systematic review indicates that the treatment of NAFLD with insulin sensitizers has been, until now, a nebulous field. However, new well-designed trials have been in progress during the preparation of this paper. Four trials using metformin and three studies on thiazolidinediones are in the recruitment phase[25]. Information derived from these studies should help in the clinical management of this disease.

Despite this (and future) information, many issues are not answered: (1) cost-analysis comparing diet and exercise with pharmacological treatment, (2) safety of insulin sensitizers in large samples, and perhaps one of the most important questions that (3) insulin sensitizers only treat one face of the metabolic syndrome and pharmacological approaches to treat all components of the metabolic syndrome sounds too simplistic[26]. This indicates that more creative prevention policy is mandatory.

In conclusion, current information indicates that the use of insulin sensitizers in the treatment of NAFLD improves insulin resistance and liver function. Single-arm studies have shown positive histological changes. However, placebo-controlled trials do not support this histological response. Future information derived from well-designed running trials will be useful in defining the clinical implications of insulin sensitizers in the treatment of NAFLD.

## Abstract

**AIM:** To present our clinical experience with gallbladder perforation cases.

**METHODS:** Records of 332 patients who received medical and/or surgical treatment with the diagnosis of acute cholecystitis in our clinic between 1997 and 2006 were reviewed retrospectively. Sixteen (4.8%) of those patients had gallbladder perforation. The parameters including age, gender, time from the onset of symptoms to the time of surgery, diagnostic procedures, surgical treatment, morbidity, and mortality were evaluated.

**RESULTS:** Seven patients had type Ⅰ gallbladder perforation, 7 type Ⅱ gallbladder perforation, and 2 type Ⅲ gallbladder perforation according to Niemeier's classification. The patients underwent surgery after administration of intravenous electrolyte solutions, and were treated with analgesics and antibiotics within the first 36 h (mean 9 h) after admission. Two patients died of sepsis and multiple organ failure in the early postoperative period. Subhepatic abscess, pelvic abscess, pneumonia, pancreatitis, and acute renal failure were found in 6 patients.

**CONCLUSION:** Early diagnosis and emergency surgical treatment of gallbladder perforation are of crucial importance. Upper abdominal computerized tomography for acute cholecystitis patients may contribute to the preoperative diagnosis of gallbladder perforation.

**Key words**: Acute cholecystitis; Gallbladder perforation; Early diagnosis; Computed tomography; Emergency surgery

## INTRODUCTION

Gallbladder perforation (GBP) is a rare but life threatening complication of acute cholecystitis. Sometimes GBP may not be different from uncomplicated acute cholecystitis with high morbidity and mortality rates because of delay in diagnosis[1-3]. Thus GBP still continues to be an important problem for the surgeons. Most cases can only be diagnosed during surgery[1,4]. Male acute cholecystitis cases with high fever, high white blood cell (WBC) count, and associated systemic diseases should be meticulously investigated[1,5,6].

Niemeier[7] in 1934, classified free gallbladder perforation and generalized biliary peritonitis as acute or type Ⅰ GBP, pericholecystic abscess and localized peritonitis as subacute or type Ⅱ GBP, and cholecystoenteric fistula as chronic or type Ⅲ GBP. This classification is still in use. We aimed to present our clinical experience with GBP in this study.

## MATERIALS AND METHODS

### *Subjects*

Records of 332 patients who received medical and/or surgical treatment with the diagnosis acute cholecystitis in our clinic between January 1997 and February 2006 were reviewed retrospectively. Sixteen (4.8%) of those patients were found to have gallbladder perforation. Perforations due to trauma, iatrogenic causes, and gallbladder (GB) carcinoma were excluded.

### *Methods*

The original classification of Niemeier[7] was used to identify the patients. The parameters including age, gender, time from the onset of symptoms to the time of surgery, diagnostic procedures, surgical treatment, postoperative morbidity and mortality were evaluated. Direct abdominal X-ray series, abdominal ultrasound scanning (US), abdominal contrast-enhanced computerized tomography (CT), routine blood cell count, and blood chemistry tests were performed. Peritoneal spaces were lavaged thoroughly with isotonic saline and drains were placed for postoperative drainage in all of the patients.

## RESULTS

There were 10 male and 6 female patients. Their mean age was 69 (range, 54-85) years. Their complaints were abdominal pain, poor general condition, high fever, nausea, and vomiting on admission. Cholelithiasis was unknown prior to perforation in 5 patients. The patients

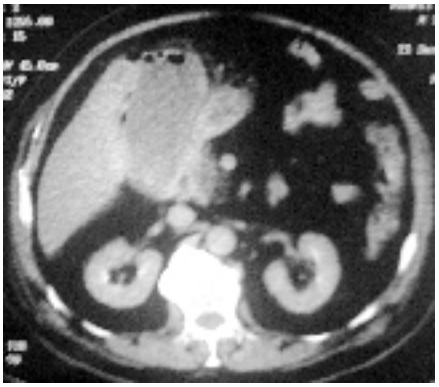

**Figure 1** Contrast-enhanced CT image at the level of gallbladder.

**Figure 2** Contrast-enhanced CT image of hepatic abscess adjacent to the superior part of gallbladder.

had several associated diseases, of which atherosclerotic heart disease (AHD) was the most common. One patient with type I gallbladder perforation was on long term steroid treatment for systemic lupus erythematosus. White blood cell (WBC) count was high in 14 patients, and 10 patients had high fever. Patients with type I gallbladder perforation had signs of peritoneal irritation such as extensive abdominal tenderness, guarding and rebound tenderness. Patients with type Ⅱ gallbladder perforation had local tenderness, guarding, positive Murphy's sign and 4 of them had palpable right subcostal mass while one patient had jaundice with a total bilirubin level of 28 mg/dL. Two patients with type Ⅲ gallbladder perforation had epigastric tenderness and one of them also had abdominal distension. Four patients had systemic inflammatory response syndrome, of them two patients with type I gallbladder perforation and two with type Ⅱ and type Ⅲ gallbladder perforations. The number of patients and their clinical features in each type of gallbladder perforation are shown in Table 1.

Abdominal X-ray series and abdominal US were performed for all of the patients and abdominal CT scanning for 14 patients. Only one patient with type Ⅲ gallbladder perforation had air-fluid levels on direct abdominal radiograms. Abdominal US showed gall stones in all of the patients with type I and type Ⅱ gallbladder perforations, extensive intraperitoneal free fluid in 7 patients with type I gallbladder perforation, and a small amount of pericholecystic free fluid in 6 patients with type Ⅱ gallbladder perforation. Abdominal US did not show GB wall defect in any of the patients. CT revealed GB wall thickening in all of the patients, gall stones in 10 patients, extensive intraperitoneal free fluid in 5 patients, a small amount of pericholecystic free fluid in 7 patients, and GB perforation sites in 5 patients. Abdominal CT and US detected liver abscesses in 2 patients, dilated extra and intrahepatic bile ducts in 1 patient. Abdominal CT showed dilated intestinal loops suggesting mechanical obstruction in one patient with type Ⅲ gallbladder perforation. Abdominal CT showed dilated stomach suggesting gastric outlet syndrome in another patient. The stomach was dilated with a normal mucosa, but the gall stone could not be seen during upper gastrointestinal endoscopy of this patient.

**Table 1 Clinical features of the patients, *n* (%)**

| Feature | Type Ⅰ | Type Ⅱ | Type Ⅲ |
|---|---|---|---|
| *n* (%) | 7 (43.7) | 7 (43.7) | 2 (12.6) |
| Mean age (yr) | 67.5 | 68.4 | 76.5 |
| Gender (Male/Female) | 5/2 | 5/2 | 0/2 |
| Fever (more than 38℃), *n* (%) | 5 (71.4) | 5 (71.4) | - |
| White blood cell count (mean) | 23966 | 17314 | 13200 |
| Mean duration of symptoms (d) | 5 | 8.6 | 15 |
| Systemic disorders[1], *n* (%) | | | |
| Atherosclerotic heart disease | 4 (14.3) | 4 (57.1) | 1 (50) |
| Diabetes mellitus | 2 (28.6) | 1 (14.3) | 1 (50) |
| Hypertansion | 1 (14.3) | 1 (14.3) | 1 (50) |
| Systemic lupus erythematosus | 1 (14.3) | - | - |
| Chronic obstructive pulmonary disease | 1 (14.3) | 2 (28.6) | 1 (50) |
| Systemic inflammatory response syndrome | 2 (28.6) | 1 (14.3) | 1 (50) |
| Preoperative diagnoses, *n* (%) | | | |
| Gallbladder perforation | 4 (14.3) | 1 (14.3) | - |
| Acute cholecystitis | 2 (28.6) | 4 (14.3) | - |
| Cholangitis | - | 1 (14.3) | - |
| Peptic ulcus perforation | 1 (14.3) | - | - |
| Perforated appendicitis | - | 1 (14.3) | - |
| Mechanical bowel obstruction | - | - | 1 (50) |
| Gastric outlet syndrome | - | - | 1 (50) |
| Sites of perforation, *n* (%) | | | |
| Fundus | 6 (85.7) | 3 (42.9) | - |
| Corpus | 1 (14.3) | 2 (28.6) | - |
| Infundibulum | - | 1 (14.3) | 2 (100) |
| Cystic duct | - | 1 (14.3) | - |

[1]Some patients had more than one sytemic disorder.

Enlarged gallbladder, irregularity of the gallbladder walls at the fundic region, air density lateral to the fundus and corpus, and increased density of the mesentery anterior to the fundus suggesting free fluid on CT image of a patient with type Ⅱ gallbladder perforation are shown in Figure 1. The abdominal CT image of a patient with hepatic abscess adjacent to the superior part of GB is shown in Figure 2.

The patients underwent surgery after administration of intravenous crystalloid solutions, and were treated with analgesics and antibiotic (third generation cephalo-

sporins) within the first 36 h (mean 9 h) after admission. The patients who had associated diseases such as diabetes, chronic obstructive pulmonary disease (COPD), and AHD underwent surgery after specific medical treatment was started. Antibiotic treatment was changed when required, according to the results of microbiological assessment of the infected bile specimens obtained from the gall bladder. The most common preoperative diagnoses were perforated cholecystitis in patients with type I gallbladder perforations, and acute cholecystitis in patients with type Ⅱ gallbladder perforations. Laparoscopic cholecystectomy was performed in 6 patients, two of them had type I gallbladder perforation, and four type Ⅱ gallbladder perforation. Conversion was required in 2 of them due to unclear anatomy. Laparotomy was performed in the remaining 10 patients. Perforations were recognized intraoperatively in 11 patients. The perforated site of the GB was the fundus in 9 patients, the corpus in 3 patients, the infundibulum in 3 patients, and the cystic duct in 1 patient. Two patients with type Ⅱ gallbladder perforation also had hepatic abscesses, which were covered by the omentum. Hepatic abscesses were also drained in these patients. All of the patients received a cholecystectomy. Common bile duct exploration was performed, gall stones were extracted, and a T-tube was placed into the common bile duct in addition to cholecystectomy in 1 patient with obstructive jaundice. One of the 2 patients had a cholecystoduodenal fistula (type Ⅲ gallbladder perforations) underwent surgery for gastrointestinal tract obstruction due to bile stones in the jejunum, which were removed through an enterotomy. Gall stones were also found in the duodenum of the other patient with type Ⅲ gallbladder perforation and removed through a duodenotomy.

The median hospital stay was 15 d (4-26 d). Two patients (12.5%) died of sepsis and multiple organ failure in the early postoperative period. One was a female patient at the age of 79 with type Ⅲ gallbladder perforation and COPD. The other was a 84 year-old male patient with delayed type Ⅱ gallbladder perforation and pericholecystic abscess associated with AHD and diabetes. Subhepatic abscess, pelvic abscess, pneumonia, pancreatitis and acute renal failure were found in 6 patients (Table 2). Subhepatic and pelvic abscesses were drained percutaneously under ultrasound guidance. The other diseases were treated conservatively.

**Table 2 Surgical procedures and morbidities of the patients *n* (%)**

| | Type Ⅰ | Type Ⅱ | Type Ⅲ |
|---|---|---|---|
| Surgery | | | |
| Laparoscopic cholecystectomy | 2 (12.5) | 4 (25) | - |
| Laparotomy and cholecystectomy | 5 (31.2) | 3 (18.7) | 2 (12.5) |
| Morbidity[1] | | | |
| Subhepatic abscess | | 1 (11.1) | 1 (11.1) |
| Pelvic abscess | | 1 (11.1) | 1 (11.1) |

| Pancreatitis | | 1 (11.1) | |
| Acute renal failure | 1 (11.1) | | |

[1]Some patients had more than one morbidity.

## DISCUSSION

Inflammation may progress and cause ischemia and necrosis, thus resulting GBP in 2% to 11% of acute cholecystitis patients[6,8,9]. GBP also develops following acalculous cholecystitis, although rare[10,11]. GB fundus, the most distal part with regard to blood supply, is the most common site of perforation[8,12]. The incidence of GBP was 4.5% and the most frequent site of perforation was the fundus (60%) in our study. Six of the 7 type I gallbladder perforations and 3 of 7 type Ⅱ gallbladder perforations were at the fundus. When GB is perforated at the fundus, it is less possibly covered by the omentum, thus the bile drains into the peritoneal space. If the perforation site is not at the fundus, it is easily sealed by the omentum or the intestines and the condition remains limited in the right upper quadrant with formation of a plastrone and pericholecystic fluid. This observation suggests that if the perforation site is at the fundus, it is more likely to end up with a type I perforation. The relation between the site and the type of GBP has not been defined. Although statistical analysis was not possible because of the insufficient number of patients in this series, this observation may be supported by larger series.

Acute uncomplicated cholecystitis is more common among females with a female to male ratio of 2:1[13]. However, GBP is more frequent in male gender[1,6]. In our study, male patients made up of 60% and the two patients with type Ⅲ gallbladder perforation were females. GBP is usually seen over 60 years of age[4,14]. Roslyn *et al*[1] reported that type I and Ⅱ GBP tend to occur in younger patients, especially more or less at the age of 50 years, whereas type Ⅲ gallbladder perforations are more common in the elderly. The patients with type I gallbladder perforation were relatively younger than those with type Ⅱ and Ⅲ gallbladder perforations in our study.

Type I gallbladder perforations are usually seen in patients with AHD, diabetes, malignancy, cirrhosis, and immunosupressive diseases, or during immunosupressive treatment, without a history of chronic cholecystitis. On the other hand, type Ⅲ gallbladder perforations most often occur in patients with a previous long time history of gall stones[1,9,12]. Severe AHD has been reported in 21% of patients with type I and Ⅱ gallbladder perforations, and diabetes, in 25% of patients with type I gallbladder perforation[8,14]. Such high rates are related to vascular disorders caused by these systemic diseases. It has been reported that type Ⅱ GBP occurs more frequently[1,3,9,12]. The incidence of type I and Ⅱ gallbladder perforations was equal and the most frequent associated systemic disease was AHD in the present study. Type Ⅲ gallbladder perforations usually occur in chronic cholecystitis patients with obstructive gastrointestinal symptoms[9,12,15]. Since the symptoms of type Ⅰ-Ⅱ GBP and uncomplicated cholecystitis are similar, differential diagnosis may be difficult based on physical examination, laboratory tests, and radiological methods and the diagnosis may not be established

preoperatively[6,12]. Delay in diagnosis is the major cause of its high morbidity and mortality[1,4,9,16]. Tanaka *et al*[17] reported that only one patient had a concrete diagnosis preoperatively in their series of 9 patients. The majority of GBP patients include those who undergo early surgery with the diagnosis of acute cholecystitis. The main complaint of the patients is abdominal pain accompanied with nausea and vomiting during the last 7 d[12,18]. The duration of symptoms was shorter in patients with type Ⅰ gallbladder perforation than in patients with type Ⅱ and Ⅲ gallbladder perforation in our study. High fever and elevated WBC count are not the diagnostic indications for gallbladder perforation. Parker *et al*[19] reported that high fever and high WBC count could be observed in 56% and 59% of patients with acute cholecystitis, respectively. The majority of type Ⅰ and Ⅱ gallbladder perforation cases had fever whereas type Ⅲ gallbladder perforation cases did not in our study. The patients with type Ⅰ and Ⅱ gallbladder perforation had elevated WBC count, but those with type Ⅲ gallbladder perforation had only a mild increase in WBC count.

US findings in acute cholecystitis, such as the GB wall thickening, GB distension, pericholecystic free fluid, and positive sonographic Murphy sign, may also be present in gallbladder perforation cases[2,9,20]. Sood *et al*[2] noted that the sonographic hole sign, in which the defect in GB wall is visualized, is the only reliable sign of gallbladder perforation. They reported that GB wall defect could be shown with a high resolution ultrasound scanner device in 70% of patients[2]. However, Kim *et al*[21] reported that the site of defect could not be visualized on US in any patients, which is similar to our study. On the other hand, CT can show more accurate signs of free intraperitoneal fluid, pericholecystic fluid, and abscess[1,2,22]. CT can also show GB wall thickness and the defect on the wall due to perforation[2,20]. In our study, all of the 5 patients who had the diagnosis of gallbladder perforation preoperatively were diagnosed by CT. Since the patients were admitted for acute abdominal pain, standard pelvic CT rather than upper abdominal CT was applied. Kim *et al*[21] reported that the defect could not be visualized on CT in 54% of patients. Doppler ultrasound, magnetic resonance imaging and radionuclide methods have been used in the diagnosis of gallbladder perforation[23-25]. The majority of our patients with type Ⅱ gallbladder perforation were initially treated conservatively and then underwent surgery as no improvement was observed during the first 3 d.

Cholecystectomy, drainage of abscess if present, and abdominal lavage are usually sufficient to treat gallbladder perforation[1,4]. Cholecystectomy may be difficult in type Ⅲ gallbladder perforations. If a cholesystectomy is performed, additional surgical procedures such as repair of the fistula may be required[15,16]. Cholecystectomy can be performed after the infection is relived by US guided percutaneus drainage in type Ⅱ gallbladder perforations[22]. Laparoscopic cholecystectomy can be performed for acute, gangrenous, and/or perforated cholecystitis as well as uncomplicated cholecystitis, but a conversion may be necessary in case of difficulties like an unclear anatomy[9,16]. In our study, laparoscopic procedure was initiated in 6 patients but conversion was required in two.

Since the difficulties in diagnosis cause delay in treatment, higher morbidity and mortality rates are often encountered[1,2,9]. Glenn and Moore[26] have reported that the mortality rate of gallbladder perforation patients is 42%, while other studies reported that the mortality rates are decreased to 12%-16% owing to the developments in anesthesiology and intensive care conditions[1,3]. The morbidity and mortality rates were 37.5% and 12.5%, respectively in the present study.

In conclusion, early diagnosis of gallbladder perforation and immediate surgical intervention are of crucial importance. Although standard abdominal CT has an important role in diagnosing gallbladder perforation, upper abdominal CT for acute cholecystitis in which pericholecystic fluid is found by US may increase the rate of preoperative diagnosis of gallbladder perforation.

## Abstract

**AIM:** To compare the effect of intravenous and oral omeprazole in patients with bleeding peptic ulcers without high-risk stigmata.

**METHODS:** This randomized study included 211 patients [112 receiving *iv* omeprazole protocol (Group 1), 99 receiving *po* omeprazole 40 mg every 12 h (Group 2)] with a mean age of 52.7. In 144 patients the ulcers showed a clean base, and in 46 the ulcers showed flat spots and in 21 old adherent clots. The endpoints were re-bleeding, surgery, hospital stay, blood transfusion and death. After discharge, re-bleeding and death were re-evaluated within 30 d.

**RESULTS:** The study groups were similar with respect to baseline characteristics. Re-bleeding was recorded in 5 patients of Group 1 and in 4 patients of Group 2 ($P$ = 0.879). Three patients in Group 1 and 2 in Group 2 underwent surgery ($P$ = 0.773). The mean length of hospital stay was 4.6 ± 1.6 d in Group 1 *vs* 4.5 ± 2.6 d in Group 2 ($P$ = 0.710); the mean amounts of blood transfusion were 1.9 ± 1.1 units in Group 1 *vs* 2.1 ± 1.7 units in Group 2 ($P$ = 0.350). Four patients, two in each group died ($P$ = 0.981). After discharge, a new bleeding occurred in 2 patients of Group 1 and in 1 patient of Group 2, and one patient from Group 1 died.

**CONCLUSION:** We demonstrate that the effect of oral omeprazole is as effective as intravenous therapy in terms of re-bleeding, surgery, transfusion requirements, hospitalization and mortality in patients with bleeding ulcers with low risk stigmata. These patients can be treated effectively with oral omeprazole.

**Key words:** Oral omeprazole; Peptic ulcer; Bleeding

## INTRODUCTION

Acute upper gastrointestinal (UGI) bleeding remains the most common reason for emergency hospital admission managed by gastroenterologists. It is reported that it has an annual incidence ranging from approximately 50 to 150 per 100 000 of the population[1], and it is still rising steadily in the aspirin/nonsteroidal antiinflammatory drugs (NSAIDs) era. The most common cause of UGI bleeding in adult patients is peptic ulcer disease, which accounts for about 50% of the cases[2]. Patients with peptic ulcer bleeding account for an overall mortality rate that has remained around 5%-10% for the past five decades, despite improved therapy options and the availability of intensive care units[3].

Previous consensus guidelines and several studies have demonstrated that the risk for re-bleeding or continued bleeding from an ulcer is strongly associated with the stigmata seen at endoscopic examinations[4-7]. These hemorrhagic stigmata consist of a clean ulcer base, flat spots, adherent clots, nonbleeding visible vessels and active bleeding (oozing and spurting). Major stigmata of recent hemorrhage include spurting, oozing vessels, nonbleeding visible vessels or fresh adherent clots, while an old adherent clot was considered as minor stigmata[8]. There are also several studies that classified the high-risk stigmata as spurting, oozing, or nonbleeding visible vessels, excluding all adherent clots[9,10]. Currently, endoscopic hemostatic therapy is strongly recommended in patients with arterial spurting, oozing ulcers and nonbleeding visible vessels[11,12]. The optimum management of adherent clots has long been controversial. Although there are studies with opposite conclusions in this field[13,14], a cited meta-analysis showed that endoscopic therapy is of significant benefit in patients with active bleeding or a visible vessel but not in patients with adherent clots[15].

The overuse of parenteral proton pump inhibitors (PPI) in UGI bleeding is a common practice all over the world.

A recent meta-analysis pointed out that both intravenous (*iv*) and oral (*po*) PPIs are effective in UGI bleeding. However, the mortality is increased with *iv* PPI in the same report[16]. Moreover, it is reported that most patients who present with ulcer bleeding have low-risk stigmata and do not require *iv* PPI treatment but can be appropriately and adequately treated with oral PPIs in clinical practice[17]. In case intravenous treatment is particularly expensive, oral treatment would be appropriate.

Most previous studies on omeprazole have been performed with *iv* administration and not with *po* form. It is known that most physicians do not prefer *iv* PPI in patients with low-risk ulcers. In spite of this view, the issue needs a better confirmation. In the literature there are an abundant number of studies that compare oral PPI *vs* placebo, with[18] or without[19] endoscopic therapy, *iv* PPI *vs* placebo[20] or oral PPI *vs* endoscopic injection[11]. At the same time, to the best of our knowledge, there is no study in the literature that has been designed to allow head-to-head comparison of oral *vs* intravenous PPI treatment in UGI bleeding. We therefore designed this study to make a comparison of oral and intravenous omeprazole in patients with bleeding peptic ulcers without high-risk stigmata, in terms of re-bleeding, surgery, hospital stay, blood transfusion and mortality. We believe that it is important to add stronger study-supported evidence to the literature in this population.

## MATERIALS AND METHODS

### *Patients, definitions and study design*

Patients were enrolled in the study if they had any symptoms of upper gastrointestinal bleeding, such as hematemesis, melena or the presence of blood in a patient' s nasogastric tube lavage. They were all older than 18 years. Informed consent to participate in the study was obtained from all patients and the study was performed in accordance with the principles stated in the Declaration of Helsinki. Exclusion criteria were as follows: (1) a history of chronic liver disease and portal hypertension, (2) gastroduodenal malignancy, (3) gastric surgery, (4) known adverse drug reactions to the trial drugs, (5) current use of antisecretory drugs, $H_2$-receptor antagonists or PPIs, (6) a history of endoscopic therapy for bleeding ulcer within the past four weeks, (7) pregnancy or lactation, (8) had endoscopic findings of active bleeding (spurting, oozing vessels or nonbleeding visible vessels), (9) refusal to provide written informed consent. Moreover, patients found to have malignant ulcers after initial enrolment were also excluded.

Gender, age, current smoking, alcohol consumption, comorbid medical illnesses, use of aspirin/NSAIDs (any dose within last week), prior epigastric pain, history of previous upper gastrointestinal bleeding, prior major surgery, concomitant use of anticoagulants, antithrombocytic agents other than aspirin, and steroids and previous eradication treatment for *H pylori,* were investigated. The spectra of the comorbid illnesses included chronic obstructive pulmonary disease, pneumonia, end-stage renal disease with hemodialysis, chronic renal insufficiency or acute renal failure, congestive heart failure, coronary artery disease and cerebrovascular accident. Besides, we recorded the duration of hospitalization, number of re-bleeding episodes, initial hemoglobin level, coagulation parameters, need for blood transfusion, the endoscopic data and addresses/phone numbers of all patients.

Endoscopic examinations were performed using a videoendoscope (Olympus GIF-V70, Tokyo, Japan) within the first 24 h of admission. At endoscopy all primary and secondary lesions were recorded. The coagulation factors (prothrombin time, partial thromboplastin time, platelet count) were checked and corrected prior to any endoscopic intervention, if needed. Patients with an underlying anatomic cardiac abnormality were considered at a high risk for endocarditis, and recommended antibiotic regimens were given. An ulcer was defined as a circumscribed mucosal break at least 5 mm in diameter and with a perceptible depth. The ulcer size was measured using biopsy forceps, of which the fully opened cup was 5 mm in diameter. Besides, stigmata of recent hemorrhage were recorded. A 'fresh' adherent clot was defined as the presence of an adherent clot over the ulcer that could not be dislodged by vigorous washing with a jet of water delivered through the channel of the endoscope[21]. An 'old' clot was defined, on the contrary, as a clot dislodged easily by washing. These lesions were also excluded from the study due to their needs for an endoscopic therapy. All patients with benign gastroduodenal ulcers showing a clean ulcer base, flat spots or old adherent clots at endoscopy were included in the study. During the emergency admission, oral anticoagulant therapy was stopped in users and coagulation was corrected when applicable. The criteria for blood transfusion were as follows: hemoglobin levels of lower than 9 g/dL in older than 65 years, hemoglobin levels of lower than 8 g/dL in younger patients, or if the patient had a new episode of hematemesis in both age groups. Besides, if a state of shock existed, blood was transfused independent of haemoglobin levels. All patients with upper gastrointestinal bleeding were examined for *H pylori* in biopsy specimens taken from the antrum by hematoxylin and eosin (HE) staining.

We performed a single-center randomized clinical trial, comparing the effect of high dose intravenous omeprazole (Group 1) and oral omeprazole (Group 2) on bleeding peptic ulcer. The study was conducted between January 2004 and August 2006 at Gastroenterology Clinic of Dicle University Research Hospital in Turkey. After a stabilization period, patients were randomly divided into two groups in the endoscopy laboratory. A person outside from the study staff placed the two drug formulations into sealed non-transparent envelops and coded them based on random table numbers. Only this person knew the codes. The research assistant, other medical personnel, the endoscopists, and patients were blind to this information. The study was conducted in a double-blind manner as all treatment assignments were revealed at the end of the study. The high dose intravenous group received a bolus injection of omeprazole (Losec®, AstraZeneca, Molndal, Sweden), 80 mg, given at admission, followed immediately by a continuous infusion of 8 mg/h for 72 h, then 40

mg orally daily for 6 wk. The other group received oral omeprazole (Omeprol®, Ilsan-Hexal (Sandoz), Gebze, Turkey) 80 mg a day (20 mg capsule, two in the morning and two in the evening) for 72 h, then 40 mg orally daily for 6 wk. It is well-known that PPI treatment is an essential option in bleeding peptic ulcers and we did not include a placebo group for each treatment due to ethical problems.

The primary endpoints of the study were recurrent bleeding (early re-bleeding), surgery requirement, and death rates before discharge. Re-bleeding was defined as new hematemesis, melaena, or hypotension (< 100 mm Hg systolic blood pressure) associated with a drop in haemoglobin and/or endoscopic evidence of fresh re-bleeding. Patients with recurrent bleeding underwent urgent second endoscopy for confirmation and the lesion was classified as in previous description. Surgical intervention was considered if the bleeding could not be controlled by endoscopic therapy. Shock was defined as a pulse rate > 100 beats/min, systolic blood pressure < 100 mmHg accompanied by cold sweats, pallor, and oliguria. Secondary endpoints were duration of hospital stay, blood transfusion requirement, and re-bleeding or death within 1 mo after index bleeding (late re-bleeding). All patients were also evaluated in terms of risk analysis by Rockall scoring system, which is based on five variables (age, presence of shock, comorbidity, endoscopic diagnosis, and endoscopic stigmata)[22].

### Follow-up

Each patient was visited in the ward daily by a clinical research assistant who recorded information about their condition, their management, and results. After the treatment procedures, we observed the patients for complications such as recurrent bleeding, perforation or death in the hospital. Blood pressure and pulse rate were monitored hourly during the first 24 h and every 4 h, hemoglobin levels every 4 h during the first day and daily thereafter until discharge. Those who had no evidence of recurrent bleeding were discharged as soon as possible. After a treatment protocol of 72 h, patients with histologically proven *H pylori* were prescribed a 2-wk course of full dose omeprazole, twice daily, amoxicillin 1 g twice daily and clarithromycin 500 mg twice daily, irrespective of the treatment protocol. In addition, we recommended them not to use aspirin/NSAIDs if not needed anymore or use them in combination with PPIs. After discharge, all of the patients were informed about our contact phone number and the patients or their relatives were asked to report to us if any re-bleeding or death occurred within 30 d.

### Statistical analysis

Data were entered into a personal computer and analysed using the Epi-INFO 2000 software package (version 2000, CDC, Atlanta). Continuous variables were presented as mean (standard deviation). The results of the two treatment groups were compared by $\chi^2$ test, Student's *t* test and Fisher's exact tests in the analysis as appropriate. To test the association between outcomes and clinical covariables, we estimated risk ratios and 95% CI. In all analyses, statistical significance was defined as $P < 0.05$.

## RESULTS

During the study period, a total of 278 patients with bleeding gastroduodenal ulcers were admitted to our clinic. Of these ulcers, 21 were actively bleeding, 17 had nonbleeding visible vessels and 17 had a fresh adherent clot. At the beginning, all these 55 patients, together with 5 patients with malignant ulcer presentation, 4 patients currently known to take antisecretory drugs, $H_2$-RAs or PPIs and 3 patients with gastric surgery were excluded from the study.

Thus, a total of 211 eligible patients were included in the study and all of them completed the treatment protocols. The mean age of the patients was 52.7 (range, 18-93 years). The total number of patients with duodenal ulcer was 160 (75.8%) and gastric ulcer 51 (24.2%). Of the ulcers, 144 (68.2%) had a clean base, 46 (21.8%) had flat spots and 21 (10.0%) had old adherent clots. There were 112 patients in Group 1 (taking *iv* omeprazole) and 99 patients in Group2 (taking *po* omeprazole). The study groups were similar with respect to gender, age, stigmata of ulcer hemorrhage, use of aspirin/NSAIDs, *H pylori* status and previous eradication treatment, co-existing illnesses, previous abdominal surgery, alcohol consumption, smoking habit, previous epigastric pain, previous UGI bleeding, hematemesis, coagulopathy, shock, hematocrit, ulcer site (gastric-duodenal) and size. The characteristics of patients in both groups are summarized in Table 1. Multiple ulcers were found to be more common in Group 2 compared to Group 1 (6 and 17, respectively, $P = 0.007$). Besides, gastric antral and corporal ulcers were more common in Group 2 compared to Group 1 (33 *vs* 18, respectively, $P = 0.007$), while the number of duodenal anterior and posterior ulcers was similar in both groups. *H pylori* infection was present in 61.2% patients with duodenal ulcer and 41.2% patients with gastric ulcer ($P = 0.012$). Aspirin/NSAID use was recorded in 82% of gastric ulcers, while in 62% of duodenal ulcers ($P = 0.007$).

### Clinical outcomes during hospital stay (inpatient basis)

Recovery without major complications was seen in 107 (95.5%) patients of Group 1 and in 95 (96.0%) patients of Group 2 ($P = 0.945$). Recurrent bleeding was recorded in 5 (4.5%) patients assigned to Group 1 and 4 (4.0%) patients assigned to Group 2 ($P = 0.879$, Fisher's exact test). Re-bleeding rates were similar between duodenal and gastric ulcers, and posterior duodenal and gastric corporal ulcers ($P = 0.511$ and 0.673, respectively. Fisher's exact test). Only one ulcer with a clean base (11.1%), while 3 ulcers with old clots (33.3%) and 5 with flat spots (55.5%) showed rebleeding.

Three patients (2.7%) in Group 1 and 2 (2.0%) in Group 2 underwent surgery to control re-bleeding after a failure in second endoscopic intervention ($P = 0.773$, Fisher's exact test). Surgery requirement was mostly seen in patients taking aspirin/NSAIDs in both groups (2, for each). Four patients (1.9%), two in each group died ($P = 0.981$, Fisher's exact test). Three were older than 65 years. The Rockall score higher than 8 was present in 18.1% of Group 1 and 19.1% of Group 2. The causes of death were pneumonia in 2, myocardial infarction in 1 and pneumonia

plus adrenal insufficiency in 1. Total hospital stay was 3 d at minimum and 20 d at maximum. The mean duration of hospital stay was 4.6 ± 1.6 d in Group 1 and 4.5 ± 2.6 d in Group 2. Length of hospital stay did not differ significantly between two groups ($P = 0.710$, Student's *t* test). Hospital stay more than 5 d was also similar between the groups ($P = 0.093$). The median number of units of blood transfused was approximately 2 in each group ($P = 0.350$, Student's *t* test). Blood transfusion requirement was more than 3 units in 27 (24.1%) patients of Group 1 and 25 (25.3%) patients of Group 2 ($P = 0.610$). Details about clinical outcomes are summarized in Table 2.

Bleeding from posterior duodenal (44.4%) and gastric corporal (33.3%) sites was more common compared to other sites [$P = 0.041$, OR 7 (1.5-18.2) and $P = 0.049$, OR 5 (1.0-14.3), 95% CI], respectively]. Of ulcers with re-bleeding, a diameter greater than 1 cm had a higher risk [$P = 0.001$, OR 11.0 (2.6-46.3), 95% CI]. Ulcers with flat spots and old clots had also higher risks for re-bleeding. Co-existing illnesses, hematemesis, smoking habit, aspirin/NSAIDs use and age older than 65 years did not have any effect on re-bleeding rates. The risk estimates of cofactors and their powers are summarized in Table 3.

### *Clinical outcomes after discharge in 30 d (outpatient basis)*

We strictly informed patients or their relatives that it was very important to report to us any problems (new bleeding attack or death) immediately that occurred during the discharge period. None of the patients took aspirin or NSAIDs during the 30 d follow-up period. Four patients (or a relative) re-contacted us within 30 d. A new bleeding occurred in 2 patients of Group 1 and in 1 patient of

Group 2 after the index bleeding episode. The overall re-bleeding was seen in 12 (5.6%) patients [7 (6.2%) in Group 1 and 5 (5.0%) in Group 2]. Additionally, one patient died from Group 1 due to a new cerebrovascular event. Hence, the overall death was seen in 5 (2.3%) patients.

## DISCUSSION

In the present study, we demonstrated that oral omeprazole was as effective as intravenous omeprazole in controlling bleeding peptic ulcers without high-risk stigmata. Importantly, the study implies that treatment with the oral agent is indicated for the bleeding instead of the *iv* approach when in reality, PPI use in this situation is simply to heal the ulcer. Although most of bleeding episodes from peptic ulcers resolve spontaneously and are not detrimental, recurrence of bleeding adversely affects prognosis. The overall re-bleeding rate in the oral treatment group (5.0%) was similar to that in the intravenous treatment group (6.2%) within 30 d, and both groups were also similar with respect to the need for surgery, duration of hospitalization, total amounts of blood transfusion, and mortality. Although clean base ulcers form the largest portion of the study population, the calculated Rockall scores were higher than 8 in approximately one fifth of the patients. As well-known, a score of higher than 8 is associated with a high risk of death[22]. Comorbidity and age were the predominant contributors to these high scores in our population.

Although the Federal Drug Administration has not approved intravenous proton pump inhibitors for the treatment of UGI bleeding, these agents are being used widely all around the world. A meta-analysis pointed out that PPI therapy in UGI bleeding was effective only in patients with UGI bleeding caused by peptic ulcers and with high-risk stigmata for re-bleeding[16]. Moreover, it has been reported that patients with endoscopy results showing a low risk of re-bleeding should not be treated endoscopically as their prognosis is excellent when treated conservatively[1].

What about oral versus intravenous drug administration? Most of the previous studies on omeprazole have been conducted with intravenous omeprazole and not with the oral drug. The oral absorption of omeprazole is 50%; however, as gastric pH rises, as much as 75% may be absorbed. It is highly protein-bound in plasma and is rapidly metabolized in the liver, and the metabolites are excreted in urine. The onset of antisecretory effect occurs within 1 h, with peak effects occurring in 2 h, depending on the dose[23]. Demonstration of effectiveness of oral treatment would be particularly attractive as it would allow treatment to be initiated outside, prior to hospital admission. However, it was concluded that pharmacotherapy alone could not replace endoscopic hemostasis for patients with actively bleeding ulcers or ulcers with nonbleeding visible vessels[12]. On the other hand, it was reported that oral omeprazole therapy can be a valid alternative to endoscopic therapy, especially when injection therapy is not readily available[11]. Replacement of endoscopy in bleeding may be more possible in ulcers with low risk stigmata. Interestingly, one meta-analysis warned readers that those patients with UGI bleeding with significant comorbid diseases (such as diabetes mellitus, collagen vascular disease and hypercoagulable states) need careful monitoring, as intravenous PPI therapy in such patients may be harmful. Besides, all-cause deaths and non-ulcer deaths in trials using intravenous PPI were higher in the treatment group and not in trials using oral PPI[16].

The role of oral omeprazole in bleeding peptic ulcers was studied, especially in ulcers with high-risk stigmata by some authors and they found the rebleeding rates of omeprazole groups to be 7%, 10.9%, 15%, 22.9% and 26%, respectively[11,18,19,24,25]. Bour *et al*[25], Khuroo *et al*[19] and Jung *et al*[11] did not perform endoscopic therapy in omeprazole groups, while Javid *et al*[24] and Kaviani *et al*[18] did so. Jung *et al*[11] reported that oral omeprazole administration was comparable to endoscopic ethanol injection therapy for prevention of re-bleeding in patients with nonbleeding visible vessels or adherent clots. Moreover, Kaviani *et al*[18] showed that oral omeprazole reduced the re-bleeding rate, hospital stay and need for blood transfusion even in high-risk ulcers after endoscopic therapy. Khuroo *et al* reported a lower re-bleeding rate with oral omeprazole alone compared to placebo[19], which is comparable to the re-bleeding rates achieved by endoscopic therapy alone[13,14]. Bour *et al* also reported that oral omeprazole was comparable to endoscopic injection therapy[25], but they administered a smaller dose of omeprazole (40 mg every 24 h) than we did. This dosage may not be sufficient to maintain intragastric pH > 4. Detailed studies *in vitro* have shown that at a pH of < 6, the extrinsic and intrinsic coagulation cascades are impaired, and platelet aggregation is virtually abolished[26]. In our study, omeprazole at a dose of 40 mg every 12 h was administered because the gastric pH was reported to be > 6 during 85% of the first 24 h period at that dose[19].

Although it was declared four years ago by the British Society of Gastroenterology Endoscopy Committee[1] that patients who have active bleeding from the ulcer, a non-bleeding visible vessel, or have adherent clots should be recommended to receive endoscopic therapy (grade A), it was subjected to strong objections[27] and the disapproval was supported by a meta-analysis[15]. After a clot has been diagnosed, approaches to its management are quite different. Removal of blood clots is probably more hazardous in centers where clinicians are less experienced in handling peptic ulcer bleeding. However, targeted irrigation has been shown repeatedly to be safe and should be widely adopted in managing ulcers with adherent clots[28]. Randomized, controlled trials of endoscopic therapy versus non endoscopic therapy for ulcers with adherent clots have yielded conflicting results[13,29], and a meta-analysis does not support routine use of endoscopic therapy[15]. Our study groups had a low count (10 *vs* 11) of adherent clots and they had a lower risk for re-bleeding. The risk for re-bleeding with clots that remained adherent after washing has been reported to be only 8%[30]. We repeated the analysis excluding clots and found out that re-bleeding rates were also similar in both groups. On the other hand, the rebleeding rate of 10.8% (5/46) in the flat spot group is higher compared with other studies[4]. Interobserver variability of stigmata classification could be

a major limitation in this condition.

*H pylori* infection and chronic aspirin/NSAID use are the two major risk factors among patients hospitalized for ulcer bleeding[17]. Eradication of *H pylori* has been demonstrated in many randomized, controlled trials[31,32], to reduce the rate of ulcer recurrences and rebleeding in complicated ulcer diseases. In a recent study, duodenal ulcers were more likely to be associated with *H pylori* infection than gastric ulcers. In contrast, gastric ulcers were more likely associated with aspirin/NSAID use than were duodenal ulcers[17]. In patients with upper gastrointestinal bleeding, the sensitivity of the rapid urease test is relatively low in detecting *H pylori*. It was reported that this was best accomplished by histologic examination with a sensitivity above 90%[33], and therefore we did so. In our study, *H pylori* infection was present in 98 (61.2%) patients with duodenal ulcer, and in 21 (41.2%) patients with gastric ulcer ($P = 0.012$). Aspirin/NSAID use was seen in 82% of gastric ulcers, while in 62% of duodenal ulcers ($P = 0.007$). It was also reported that prior use of aspirin/NSAIDs increases the risk of re-bleeding in bleeding ulcer patients, and leads to a higher need for urgent surgery[34]. In parallel with this conclusion, surgery requirement was mostly seen in patients taking aspirin/NSAIDs in both groups (2, for each) in our study. On the other hand, endoscopic features of high-risk included ulcer size (> 1 or 2 cm)[34,35] and the site of bleeding (the posterior lesser gastric curvature and posterior duodenal wall)[36-38]. Bleeding from posterior duodenal (44.4%) and gastric corporal (33.3%) ulcers was more common compared to other sites in our study (Table 3). The mean age of our study population was 52 years, and more than one third had co-existing illnesses.

In conclusion, our results suggest that the effectiveness of oral omeprazole administration is comparable to intravenous therapy in terms of re-bleeding, need for emergency surgery, transfusion requirements, length of hospital stay and mortality in patients with bleeding peptic ulcers without high risk stigmata. In most of the countries, most patients with bleeding ulcers have low risk stigmata, and thus, can be treated with oral omeprazole. These patients do not explicitly require expensive omeprazole infusions.

## ACKNOWLEDGMENTS

The authors are thankful to Sandoz Pharmaceutical Company for their contribution in providing capsules for patients who could not obtain the drug. The authors would also like to thank the nursing staff (Şehnaz Cingöz and Yılmaz Beyaztaş) of the Endoscopy Center of Dicle University Hospital for their generous support.

## COMMENTS

### *Background*

As yet, there is no study in the literature that had a head-to-head comparison of oral *vs* intravenous proton pump inhibitor treatment in bleeding peptic ulcers. We designed a study to compare the effect of *iv* and *po* omeprazole in patients with bleeding peptic ulcers without high-risk stigmata.

### *Research frontiers*

We demonstrate that the effect of oral omeprazole is as effective as intravenous therapy in terms of re-bleeding, surgery, transfusion requirements, hospitalization and mortality in patients with bleeding ulcers with low risk stigmata. These patients can be treated effectively with oral omeprazole.

### *Innovations and breakthroughs*

Our results suggest that the effectiveness of oral omeprazole administration is comparable to intravenous therapy in terms of re-bleeding, need for emergency surgery, transfusion requirements, length of hospital stay and mortality in patients with bleeding peptic ulcers without high risk stigmata. Generally speaking, most patients with ulcer bleeding have low-risk stigmata, and thus, can be treated with oral omeprazole. These patients do not explicitly require expensive omeprazole infusions.

### *Peer review*

It is a practical research to compare the effectiveness of oral omeprazole *vs iv* omeprazole in peptic bleeding cases without high risk stigmata. The results showed that oral treatment is as effective as the iv treatment but less expensive. The study was well designed with enough material as well as statistical analysis.

## Abstract

**AIM:** To study the brain-gut interaction and the effect of behavioral or psychiatric conditions on irritable bowel syndrome (IBS) in an African population.

**METHODS:** IBS was diagnosed using the Rome Ⅱ diagnostic criteria. The entry of each patient was confirmed following detailed explanations of the questions. Four hundred and eighteen patients were studied. Subjects satisfying the Rome Ⅱ criteria for IBS were physically examined and stool microscopy was done to identify the presence of "alarm factors". Depression was diagnosed using the symptom-check list adapted from the Research Diagnostic Criteria (DSM-Ⅳ) of the American Psychiatric Association.

**RESULTS:** Seventy-five (56.8%) of the 132 IBS patients were depressed whereas only 54 (20.1%) of the 268 non-IBS patients were depressed. There was a significant relationship between IBS and depression ($\chi^2$ = 54.29, Odds ratio = 5.21, 56.8 ± 8.4 *vs* 20.1 ± 5.2, *P* = 0.001). Even though constipation predominant IBS patients were more likely to be depressed, no significant relationship was found between the subtype of IBS and depression ($\chi^2$ = 0.02, OR = 0.95, *P* = 0.68).

**CONCLUSION:** IBS is significantly associated with major depression but not gender and bowel subtypes of the patients. Patients with IBS need to be evaluated for depression due to the highly significant relationship between the two conditions.

**Key words:** Irritable bowel syndrome; Depression; Nigeria; Africa

## INTRODUCTION

Irritable bowel syndrome (IBS) has been widely studied in the western world and pathophysiologic mechanisms have been available to explain the constellation of symptoms[1]. IBS is a chronic disorder of unknown etiology clinically consisting of altered bowel habits, abdominal pain and the absence of any detectable organic pathologic process[1]. Along with the putative pathophysiologic mechanisms of post-infectious inflammatory disorder, disordered intestinal motility and visceral hypersensitivity, there has been much discussion regarding the brain-gut interaction and the influence of behavioral or psychiatric conditions on these symptoms[2].

IBS is recognized widely as one of the most commonly encountered gastrointestinal disorders[1-4]. Locally, there is paucity of data concerning IBS in Africa. Of the studies available however, IBS was reported in 30 percent of an African population at the University College Hospital, Ibadan[5] and 8% in Kenya[6]. Peak prevalence of IBS was reported in the third decade of life in the study in Kenya. A more recent report from our centre demonstrated a prevalence of 26.1% among a healthy student population[7]. In addition, patients with IBS are at increased risk for other non-gastrointestinal functional disorders such as fibromyalgia[8-11] and interstitial cystitis[12]. IBS is known to co-exist with some psychiatric disorders such as depression, anxiety disorders, somatoform disorders[9,13] and sexual dysfunction (e.g., dyspareunia)[14]. The situation is however, not known in African population. This study aims at determining the prevalence of depression among African IBS patients.

## MATERIALS AND METHODS

### *Patients*

This is a descriptive cross-sectional study. The principal investigator administered the questionnaire after obtaining informed consent to randomly selected subjects attending the General Outpatient (GOP) Clinics of the three hospitals in Jos. These hospitals were: Jos University Teaching Hospital (JUTH), Evangel Hospital (EEH) and

Plateau State Specialist Hospital (PSSH). The GOP clinics of these hospitals are where primary care physicians attend to patients prior to referrals for specialist care. On selected days of the week, the investigators went to the various clinics until the proposed study sample size was achieved.

The number of patients visiting each of the GOP clinics in the previous year was used to divide the total sample to be studied proportionately. This was obtained from the records of the hospitals. Individual patients were randomly selected in each GOP clinic. Every fifth patient at EEH, every fourth patient at JUTH and alternate patient at PSSH were selected, subject to satisfying the inclusion criteria.

The study was approved by the Ethics Committee of the three hospitals prior to the commencement of the study. The study at EEH was conducted between July 2003 and September 2003, PSSH between October and November 2003, and JUTH between December 2003 and February 2004. Each patient's entry was confirmed following detailed explanations of the questions. Subjects satisfying the Rome Ⅱ criteria for IBS were physically examined to identify the presence of "alarm factors." Major depression was diagnosed using the symptom-check list adapted from the Research Diagnostic Criteria (DSM-Ⅳ) of the American Psychiatric Association[15].

### Sample size

The minimum sample size was determined based on the prevalence reported in the literature using the following formula:

$$N = \frac{(Zi\text{-}a)^2 (P) (1\text{-}P)}{d^2}$$

N = minimum sample size; P = best estimate of prevalence of IBS from the literature review expressed as a fraction of 100 (in this case, 30% = 0.3)[5]; Zi-a = a constant at 95% confidence interval for a two-tailed descriptive study (= 1.96); d = absolute precision, i.e. value required (in percentage) which in actual terms describes the maximum difference between the population rate and the sample rate that can be tolerated. Five percent (0.05) was adapted for this study. Thus:

$$N = \frac{1.96^2 (0.3) (0.7)}{(0.05)^2} = 323$$

However, 400 subjects were recruited for the study. Systematically selected adult patients aged 18 to 50 years attending the GOP clinics of the three hospitals were included and the pregnant women and subjects using laxatives for any reason, those with memory problems and the presence of alarm symptoms, including a positive stool test for helminthes were excluded from the study.

The 400 patients who attended the three selected hospitals and who satisfied the inclusion criteria were studied with the questionnaires by the principal investigator. Four hundred and eighteen patients were initially evaluated, but 18 were excluded for various reasons. Six were above 50 years of age, 4 had significant weight loss, 5 could not give a coherent history, 2 declined to participate in the study and 1 had recurrent bloody stools. Of the 400 subjects, 174 were from ECWA Evangel Hospital, 148 from Jos University Teaching Hospital, and 78 from Plateau State Specialist Hospital.

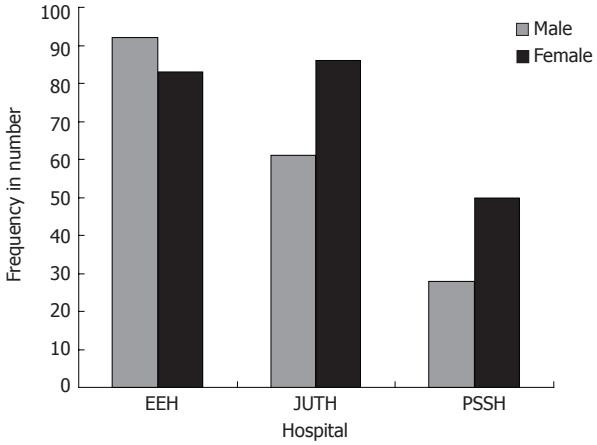

**Figure 1** Distribution of study population by gender in the three GOP clinics.

### Statistical analysis

Data were analysed using the Epi Info 2000 Statistical Program[16]. Means and standard deviations were used to describe continuous variables and proportions for categorical data. Two-tailed Student's *t* test and analysis of variance (ANOVA), a parametric test for inequality of population means, were used for comparison of group means while the significance of observed differences (proportions) was determined by Chi-square test. $P < 0.05$ was considered statistically significant.

## RESULTS

The mean age of the study population at EEH, JUTH and PSSH were 32.5 ± 9.3, 32.0 ± 10.0 and 31.1 ± 8.8 years, respectively and with an age range of 18-50 years at each hospital. There was no statistically significant difference in the mean age among the three study populations (f = 0.62, $P = 0.54$). Figure 1 shows the gender distribution of the study population in the three GOP clinics. Eighty-three (47.4%) females and 92 (52.6%) males were recruited at the EEH, while 86 (58.5%) females and 61 (41.5%) males were recruited at JUTH. Fifty (64.1%) females and 28 (35.9%) males were selected at PSSH.

### Age and gender distribution of study subjects

The mean age of this population was 32.0 ± 9.4 years with a range of 18-50 years. The mean age for females was 31.9 ± 9.5 years and males 32.1 ± 9.3 years, showing no statistically significant difference ($t = 0.2$, $P = 0.8$). Subjects in the third decade of life predominated over the other age groups, and the number of females was higher than their male counterparts.

### Irritable bowel syndrome and depression

Table 1 gives a summary of this relationship. Seventy-five (56.8%) of the 132 IBS patients were depressed whereas only 54 (20.1%) of the 268 non-IBS patients were depressed. There was a significant relationship between IBS and depression (Odds ratio = 5.21, $\chi^2 = 54.29$, $P = 0.001$). There was no significant relationship between the gender of the IBS patients and depression (Odds ratio = 0.95, $\chi^2 = 0.02$, $P = 0.89$) (Table 2). Even though

**Table 1 Relationship between IBS and depression**

| IBS | Depressed *n* (%) | Not depressed *n* (%) | Total (*n*) |
|---|---|---|---|
| Yes | 75 (56.8) | 57 (43.2) | 132 |
| No | 54 (20.1) | 214 (79.9) | 268 |
| Total | 129 (32.3) | 271 (67.7) | 400 |

OR = 5.21, 95% CI = 3.22-8.45, $\chi^2$ = 54.29, $P$ < 0.001.

**Table 2 Relationship between depression and gender among the IBS patients**

| Depression | Male *n* (%) | Female *n* (%) | Total (*n*) |
|---|---|---|---|
| Yes | 32 (42.7) | 43 (57.3) | 75 |
| No | 25 (43.9) | 32 (56.1) | 57 |
| Total | 57 (43.2) | 75 (56.8) | 132 |

OR = 0.95, 95% CI = 0.45-2.03, $\chi^2$ = 0.02, $P$ = 0.89.

**Table 3 Relationship between subtype of irritable bowel syndrome and depression**

| Subtype | Depression *n* (%) | No depression *n* (%) | Total (*n*) |
|---|---|---|---|
| Constipation | 36 (61.0) | 23 (39.0) | 59 |
| Diarrhoea | 31 (53.4) | 27 (46.6) | 58 |
| Alternator | 8 (53.3) | 7 (46.7) | 15 |
| Total | 75 (56.8) | 57 (43.2) | 132 |

$\chi^2$ = 0.77, df = 2, $P$ = 0.68.

constipation predominant IBS patients were more likely to be depressed, Table 3 shows that no significant relationship exists between the subtype of IBS and depression ($\chi^2$ = 0.77, $P$ = 0.68). No significant difference was observed between the gender of the population and the subtypes of IBS.

## DISCUSSION

Seventy-five (56.8%) IBS patients were depressed compared with 54 (20.1%) of the 268 non-IBS patients fulfilled the DSM Ⅳ criteria for depression. There was a highly significant relationship between IBS and depression ($\chi^2$ = 54.29, Odds ratio = 5.21, $P$ < 0.001). This compares well with western studies that reported 60% psychiatric co-morbidity among their IBS patients who have sought healthcare[17,18]. Abnormal psychologic features have been recorded in a large percentage of patients with IBS. In a study by McDonald and others[19] involving 35 patients with IBS and 32 patients with non-IBS disease, 20% of the non-IBS group had diagnosable psychiatric disorders when compared with 53% of the IBS group. This high prevalence of depression among our cohort is most likely due to the fact that it was a study among a patient population. Most western community-based studies and a recent study done by us among stable students showed that the rate of depression was comparable to that among the non-IBS group[7,17]. Indeed, co-morbidities such as psychological symptoms are recognized factors that affect healthcare seeking of IBS patients[20].

Most investigators have found that psychiatric features predate the onset of bowel symptoms or occur concurrently, suggesting that it is not the bowel symptoms of IBS that induce psychiatric diseases[4]. Many theories have implicated the role of depression in IBS[9,14]. In addition, serotonin and catecholeamines (neurotransmitters that play some role in depression), have been shown to be in excess in patients with IBS[21-23]. Emotional stress can trigger bowel hypermotility both in normal subjects and in patients with IBS[24]. These events are associated with development of both organic and functional abdominal illness[25]. Moreover, the existing evidence suggests that treating depression and anxiety can improve the patient's gastrointestinal distress.

There was no significant difference between the gender of the IBS patients and depression, implying that both men and women are equally prone to depression. Even though, a trend was observed in constipation-predominant IBS and depression, there was no statistically significant relationship ($P$ = 0.68). This finding agrees with that by Whitehead *et al*[26].

IBS is significantly associated with major depression, but not with gender and bowel subtypes of the patients. Patients with IBS need to be evaluated for depression due to the highly significant relationship that exists between the two conditions.

The Rome Ⅱ criteria has been widely validated in the western world and found to have a positive predictive value of 98%[27]. In our setting however, where a lot of helminthic and protozoa infestations exist, it is unclear whether the subjects fulfilling these criteria truly have IBS or not. A subset of the patients who had their stools evaluated for these infestations did not change the pre-examination diagnosis of IBS. This is a subject for further evaluations.

## ACKNOWLEDGMENTS

We are grateful to the chief executives of the three hospitals, heads of departments of the GOP clinics of the three hospitals for using their patients.

## COMMENTS

### Background

Irritable bowel syndrome (IBS) has been widely studied in the western world and many pathophysiologic mechanisms have been provided to explain the constellation of symptoms. Along with the putative pathophysiologic mechanisms of post-infectious inflammatory disorder, disordered intestinal motility and visceral hypersensitivity, there has been much discussion regarding the brain-gut interaction and the influence of behavioral or psychiatric conditions on these symptoms.

### Innovations and breakthroughs

IBS is known to co-exist with some psychiatric disorders such as depression, anxiety disorders, somatoform disorders and sexual dysfunction (e.g., dyspareunia). The situation is however, not known in African populations. This study aimed at determining the prevalence of depression among African IBS patients.

### Applications

IBS is significantly associated with major depression. Patients with IBS need to be evaluated for depression due to the highly significant relationship between the two conditions. The Rome criteria has been widely validated in the Western world and found to have positive predictive value of 98%. It is necessary to validate this criteria in the African setting, where a lot of helminthic and protozoa infestations exist that may be confused with IBS.

### Terminology

IBS is a chronic disorder of unknown etiology clinically consisting of altered bowel habits, abdominal pain and the absence of any detectable organic pathologic process. Depression is a state of low mood, loss of interest and energy that may result in suicidal ideation or act.

### Peer review

This is a well-done and interesting study on co-expression of depression and IBS in an African population.

## Abstract

**AIM:** To present novel frameshift mutation c.31delC [p.L11X] in the *MLH1* gene identified in an extended Bulgarian hereditary non-polyposis colorectal cancer (HNPCC) family and to analyze the molecular and clinical findings within the pedigree concerning the proposal of adequate individual prophylactic strategy for all mutation carriers.

**METHODS:** The pedigree of the family consists of 42 members in four generations. Search for mutations in the *MLH1* and *hMSH2* genes was performed in the proband. After PCR amplification of all exons including flanking intronic regions, amplicons were directly sequenced.

**RESULTS:** The mutation was found in nine from the thirteen pedigree members who signed informed consent to participate in the study. In three adenocarcinomas, microsatellite instability and lack of the MLH1 protein expression were detected. The only one tubulovillous adenoma analyzed was microsatellite stable and the MLH1 protein showed an intact staining.

**CONCLUSION:** The newly described mutation c.31delC is HNPCC causative. Besides the typical clinical features of the syndrome, we found a specific pathologic manifestation such as moderate to high differentiated adenocarcinomas of the colon. One of the mutation carriers developed a benign giant cell soft tissue tumor. The primary tumor localizations were frequently extracolonic and detailed yearly gastrointestinal and gynecological examinations have been proposed to the mutation carriers. We emphasize the importance of including the HNPCC genetic counseling and testing as well in the following surveillance of all patients at risk in the services covered by the health insurance in Bulgaria.

**Key words:** Colon cancer; Hereditary non-polyposis colorectal cancer; *MLH1*; Microsatellite instability

## INTRODUCTION

Hereditary non-polyposis colorectal cancer (HNPCC) or Lynch syndrome is the most common type of hereditary colorectal cancer (CRC), which accounts for about 1% to 3% of all cases with CRC[1] and may be caused by germline mutations in DNA mismatch repair (MMR) genes. Mutations in the *MLH1*[2,3] and *hMSH2*[4,5] genes are responsible for the disease in the majority of HNPCC families. Some mutations have been found to be common in many population studies, whereas others are rare or unique[6] (http://www.insight-group.org/). When a predisposing mutation is found in the proband, the carrier status of the first degree relatives might be clarified after genetic counseling and signing of informed consent[7]. This process is hard and delicate. One of the most frequently observed problems is the anxiety from the result. For all mutation carriers, a prophylactic program is proposed[8]. In Bulgaria, the genetic counseling and testing in hereditary cancer syndromes and the following surveillance for the individuals at risk are not defined or covered by the health insurance. In the period of 1998-2006 the genetic counseling and testing have been financially supported by the National Science Fund

research grants. Our team analyzes individually the pedigrees with heterogenic localizations and particular clinical features, together with the official result from the DNA analysis. Mutation carriers receive information about the exact prophylactic exams to take and the recommended frequency.

In this paper we report a novel frameshift (c.31delC [p.L11X]) mutation in the *MLH1* gene due to a deletion of a cytosine at nucleotide position c.31 in the first exon of the gene in a proband of an extended Bulgarian HNPCC family, fulfilling the Amsterdam criteria. The aim of this study was to analyze the molecular and clinical findings within the pedigree concerning the proposal of adequate individual prophylactic strategy for all mutation carriers.

## MATERIALS AND METHODS

The pedigree of the family consists of 42 members in four generations (Figure 1). The proband, a 39 year old man (Ⅲ-7) was operated because of cancer of the cecum. In the family, 15 members were operated on 21 malignant tumors (15 colorectal and 6 extracolonic). The mean age of the first malignant localization was 55 years for the first generation, 63 years for the second generation, 38 years for the third generation and 25 years for the last generation.

A set of five polymorphic markers-BAT26, D2S123, D5S346, D18S35 and FGA, previously found as the most informative in our group of HNPCC patients, have been selected for analysis of microsatellite instability (MSI). Both normal and tumor tissue DNA samples were amplified for the five markers and electrophoresis was performed on an automated fluorescence sequencer (ALF Express, Pharmacia). MSI analysis was possible in four patients (Table 1).

Search for mutations in the *MLH1* and *hMSH2* genes was performed in the proband Ⅲ-7. After PCR amplification of all exons including flanking intronic regions, amplicons were sequenced in both directions using the ABI PRISM Dye terminator cycle sequencing reaction kit (Applied Biosystems Foster City, CA) and ABI-310 Genetic Analyzer. The additional pedigree members were tested only for the presence of the identified mutation in the *MLH1* gene.

In order to investigate the effect of this mutation on the MLH1 protein expression, we chose the immunohistochemistry (IHC) assay. This analysis was performed in four patients with available paraffin-embedded specimens (Table 1). The rabbit polyclonal antibody against the C-terminus of the MLH1 protein (Santa Cruz Biotechnology, Santa Cruz, CA) at 1:100 dilutions was used, following the manufacturer's protocol, with minor modifications. Two investigators assessed the slides for MLH1 staining independently. Informed consent for DNA analysis was obtained from individuals included in the study.

## RESULTS

We identified a novel frameshift mutation in the *MLH1* gene, due to a deletion of a cytosine (c.31delC [p.L11X]) leading to a stop codon 16 (TGA), 18 bases downstream (Figure 2). The mutation was found in nine out of the thirteen pedigree members who signed informed consent to participate in the study (Table 1). Individual Ⅱ-1 developed a colorectal cancer at the age of 80 years. Now he is 96 years old and none of his descendents developed cancer. The *MLH1* mutation c.31delC was excluded in this family member.

**Table 1 Diagnosis, microsatellite instability, c.31delC mutation and immunohistochemical analysis of ten affected and six healthy at risk relatives in the hereditary non-polyposis colorectal cancer (HNPCC) family**

| Family member | Diagnosis | Histological data | MSI Analysis | c.31delC mutation | MLH1 expression |
|---|---|---|---|---|---|
| Ⅱ-1 | Colon carcinoma | NT | NT | No | NT |
| Ⅱ-3 | Colon carcinoma | + | NT | NT | NT |
| Ⅲ-6 | Colon carcinoma | + | NT | NT | NT |
| Ⅲ-7 | Colon carcinoma | + | MSI | Yes | NS |
| Ⅲ-8 | Endometrial carcinoma | + | NT | Yes | NT |
| Ⅲ-12 | Healthy, at risk | NT | NT | Yes | NT |
| Ⅳ-13 | Healthy, at risk | NT | NT | Yes | NT |
| Ⅳ-14 | Colon carcinoma | + | MSI | Yes | NS |
| Ⅳ-15 | Tubulovillous Adenoma | + | MSS | Yes | PS |
| Ⅳ-16 | Healthy, at risk | NT | NT | No | NT |
| Ⅳ-17 | Healthy, at risk | NT | NT | Yes | NT |
| Ⅳ-18 | Colon carcinoma | + | NT | Yes | NT |
| Ⅳ-19 | Healthy, at risk | NT | NT | No | NT |
| Ⅳ-20 | Healthy, at risk | NT | NT | No | NT |
| Ⅳ-21 | Mixed germ cell tumor | + | NT | NT | NT |
| Ⅳ-22 | Colon carcinoma | + | MSI | Yes | NS |

NT: not tested; +: available; MSI: microsatellite instability of the tumor; MSS: microsatellite stability of the tumor; Yes: mutation was present; No: mutation was absent; PS: positive staining; NS: negative staining.

All three adenocarcinomas available from CRC patients for MSI analysis showed high instability. The IHC assay showed lack of expression of the MLH1 protein in these tumors. In contrast, microsatellite stability was characteristic of the tubulovillous adenoma and ICH of the tumor showed an intact nuclear staining.

From the remaining 23 members of this branch of the family, fourteen were operated on 20 different malignant tumors, four adenomas and one benign giant cell tumor of soft tissues. Synchronous tumors were found in three individuals, and metachronous in five. Eight colorectal cancers were right sided, three were left sided and no information on the exact tumor localization of the remaining three was available. Only one of the left sided colorectal tumors was the primary localization. The histomorphological study showed that all malignant colorectal tumors were adenocarcinomas, two lowly and nine moderately to highly differentiated. Mucinous production (predominantly extracellular type) was detected in all cases.

## DISCUSSION

In the present study we describe a novel *MLH1* mutation c.31delC in relation to the HNPCC phenotype and

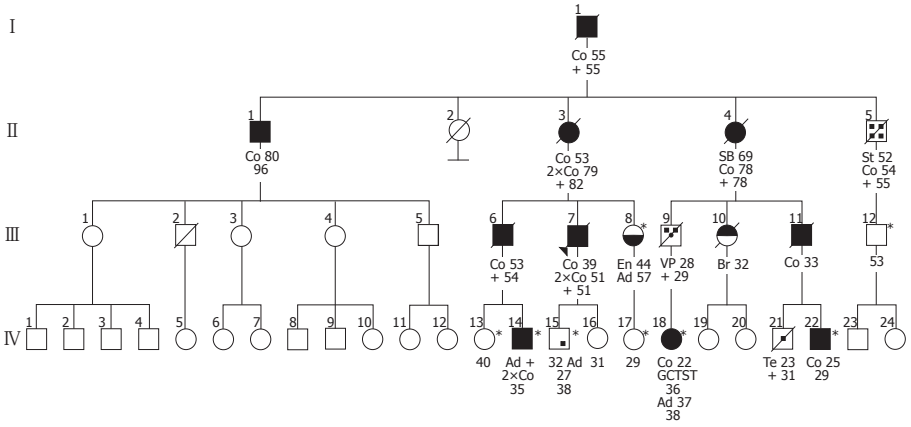

**Figure 1** Pedigree tree of the investigated family. Spouses, some of the unaffected and clinically undefined individuals are not presented in the figure. Co: colorectal cancer; VP: vater's Papilla cancer; SB: small bowel cancer; En: endometrial cancer; St: stomach cancer; Br: breast cancer; Te: testicular GCT; Ad: adenoma; GCTST: germ cell tumor of the soft tissue; *healthy mutation carriers.

MLH1 protein expression in colon tumors. Frameshift mutations are frequently found in both *MLH1* and *hMSH2* genes. Bisgaard *et al*[9] identified a mutation in the *MLH1* gene, c.9delC, resulting in a premature stop at the same location (codon 16) as in our study. In the family a skipped generation was present. However the authors conclude that stop codon and exon deletion mutations can be implemented for predictive testing without further analysis. In our study ICH and MSI analyses were used additionally to evaluate the role of this mutation in three adenocarcinomas and one adenoma.

Our genetic analysis showed that the CRC in Ⅱ-1 was not due to the mutation c.31delC. The late age of cancer development (80 years) in this patient, lack of metachronous carcinomas 15 years later and the lack of affected descendents support the sporadic origin of the malignant tumor in this case. Thanks to our study, this branch of the family was relieved of the excessive fear of inherited cancer. Patient Ⅳ-18 developed mixed germ cell tumor (GCT). He provided detailed clinical and genealogical information before his death but refused DNA analysis. The relation between c.31delC/*MLH1* and the risk of breast cancer could not be confirmed, since both daughters of Ⅲ-10 were not carriers of the mutation.

We found the typical features for HNPCC as early age of cancer development, dominant inheritance, high MSI and lack of detectable protein expression in the adenocarcinomas. The colorectal cancers were the most frequent lesions in the family, predominantly right sided, with extracellular mucinous production, presence of synchronous and metachronous tumors. All these observations support the data published by others[10-12]. Interesting findings were the anticipation in the last three generations and the moderate to high colorectal tumor differentiation. High differentiation has been described as specific for Chinese HNPCC families only[13].

The MLH1 protein expression in patient Ⅳ-15 was retained and the tumor showed microsatellite stability (MSS). Protein expression in a mutation carrier with adenoma was described by Stormorken *et al*[14]. The authors speculated that this event might be due to the sporadic origin of the adenoma or that the tumor did not reach the stage of protein loss. The early stage of the tumor diagnosis in our case might explain the presence of intact MLH1 protein, due to the proper functioning of the second, unaffected *MLH1* copy.

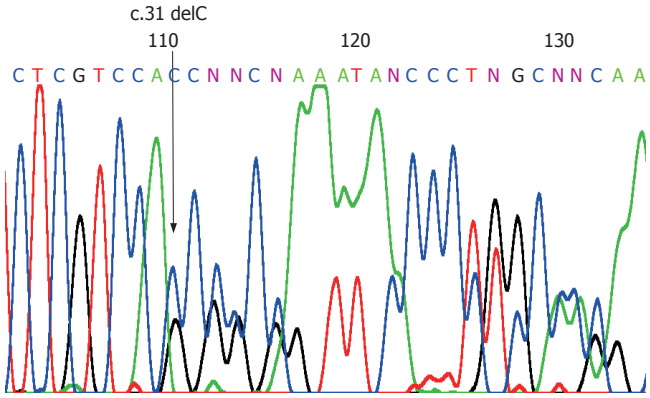

**Figure 2** Direct sequencing of the *MLH1* exon 1, demonstrating the mutation c.31delC. The arrow indicates the position of the C deletion.

The observed extracolonic malignant tumor localizations related to this mutation were in endometrium, stomach, Vater's papilla and small bowel. The last two are relatively rarely associated with HNPCC[15] and may be missed by the routine endoscopy.

Besides the tumors involved in the HNPCC spectrum, one of the family members (Ⅳ-23) developed a benign giant cell soft tissue tumor of the third finger, fourteen years after the primary colon localization. We have no data about the finding of such a metachronous tumor in other HNPCC families.

We conclude that the newly described mutation c.31delC is HNPCC causative. Besides the typical clinical features of the syndrome, we have found a specific pathologic manifestation as moderately to highly differentiated adenocarcinomas of the colon. The primary tumor localizations are frequently extracolonic and detailed yearly gastrointestinal and gynecological examinations have been proposed to the mutation carriers. We emphasize the importance of including the HNPCC genetic counseling and testing as well in the following surveillance of all patients at risk in the services covered by the health insurance in Bulgaria.

## ACKNOWLEDGMENTS

We thank all family members who agreed to attend our

study. We also thank Dr. Traykova who kindly provided us with paraffin-embedded tissues and medical records.

## Abstract

**AIM:** To study the relationship between innate immune response and liver regeneration (LR) at transcriptional level.

**METHODS:** Genes associated with innate immunity response were obtained by collecting the data from databases and retrieving articles. Gene expression changes in rat regenerating liver were detected by rat genome 230 2.0 array.

**RESULTS:** A total of 85 genes were found to be associated with LR. The initially and totally expressed number of genes at the phases of initiation [0.5-4 h after partial hepatectomy (PH)], transition from G0 to G1 (4-6 h after PH), cell proliferation (6-66 h after PH), cell differentiation and structure-function reconstruction (66-168 h after PH) was 36, 9, 47, 4 and 36, 26, 78, 50, respectively, illustrating that the associated genes were mainly triggered at the initial phase of LR and worked at different phases. According to their expression similarity, these genes were classified into 5 types: 41 up-regulated, 4 predominantly up-regulated, 26 down-regulated, 6 predominantly down-regulated, and 8 approximately up/down-regulated genes, respectively. The expression of these genes was up-regulated 350 times and down-regulated 129 times respectively, demonstrating that the expression of most genes was enhanced while the expression of a small number of genes was decreased during LR. Their time relevance was classified into 14 groups, showing that the cellular physiological and biochemical activities during LR were staggered. According to the gene expression patterns, they were classified into 28 types, indicating that the cellular physiological and biochemical activities were diverse and complicated during LR.

**CONCLUSION:** Congenital cellular immunity is enhanced mainly in the forepart, prophase and anaphase of LR while congenital molecular immunity is increased dominantly in the forepart and anaphase of LR. A total of 85 genes associated with LR play an important role in innate immunity.

**Key words:** Partial hepatectomy; Rat genome 230 2.0 array; Innate immune response; Genes associated with liver regeneration

## INTRODUCTION

Organisms can resist and remove endogenous and exogenous poisons *via* their innate immune cells and other factors. This process is known as innate immune response[1], a self-protection mechanism of living organisms which is absolutely indispensable to their survival[2]. Innate immune responses consist of three parts, namely barrier of self-tissue, innate cellular immunity and innate molecular immunity. Tissue barrier can excrete antibacterial and bactericidal matters to kill pathogens, innate cellular immunity can not only remove pathogens invading body *via* immune cells but also clear the broken, dead and abnormal cells, while innate molecular immunity can demolish and dissolve injurious substances *via* active molecules and cytokines[3]. Liver containing NK cells, T lymphocytes, macrophages, *etc*, is an important organ where innate immune response takes place[4]. After partial hepatectomy (PH), liver undergoes severe injury. How the remnant liver cells are protected by the innate immune system deserves intensive study[5].

In addition, PH[6] can activate the remaining hepatocytes to rapidly proliferate and compensate for the

loss of liver mass, which is known as liver regeneration (LR)[7,8]. Based on the cellular physiological activities, the regeneration proceeding is usually categorized into four stages: initiation (0.5-4 h after PH), transition from G0 to G1 (4-6 h after PH), cell proliferation (6-66 h after PH), cell differentiation and reorganization of the structure-function (66-168 h after PH)[8]. According to the time course, it can be classified into four phases: forepart (0.5-4 h after PH), prophase (6-12 h after PH), metaphase (16-66 h after PH), and anaphase (72-168 h after PH)[9], involving many physiological and biochemical events, such as cell activation, cell de-differentiation, cell proliferation and its regulation, cell re-differentiation, reorganization of structure-function[10], which are regulated by many factors including innate immune response. The action of genes associated with liver diseases caused by hepatitis virus infection and pathogen infection during LR, has been analyzed[11-13]. In the present study, rat genome 230 2.0 array containing 151 genes involved in innate immune response was used to detect the gene expression changes in regenerating liver after 2/3 hepatectomy as previously described[14-17] in order to investigate the relevance between LR and innate immune response at transcriptional level. The expression changes, patterns and action of these genes during LR were primarily analyzed. Our results indicate that 85 out of the 151 genes are associated with LR[18].

## MATERIALS AND METHODS

### *Regenerating liver preparation*

Healthy SD rats weighing 200-250 g were obtained from the Animal Center of Henan Normal University. The rats were divided into groups at random, 6 rats in each group (male: female = 1:1). PH was performed as previously described[6], the left and middle lobes of liver were removed. The rats were killed by cervical vertebra dislocation at 0.5, 1, 2, 4, 6, 8, 12, 16, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 96, 120, 144 and 168 h after PH and the regenerating livers were observed at corresponding time points. The livers were rinsed three times in PBS at 4℃, then 100-200 mg liver tissue was taken from middle part of the right lobe. Six samples were collected from each group and mixed into 1-2 g (0.1-0.2 g × 6) liver tissue, then stored at -80℃. The sham-operation (SO) groups underwent the same PH without removal of the liver lobes. The animal protection laws of China were strictly followed.

### *RNA isolation and purification*

Total RNA was isolated from frozen livers according to the manual of Trizol kit (Invittrogen)[19] and then purified based on the guide of RNeasy mini kit (Qiagen)[20]. Agarose electrophoresis (180V, 0.5h) showed that total RNA sample exhibited a 2:1 ratio of 28S to 18S rRNA intensities. Total RNA concentration and purity were estimated by optical density measurements at 260/280 nm[21].

### *cDNA, cRNA synthesis and purification*

Total RNA (1-8 μg) was used as a template for cDNA synthesis. cDNA and cRNA synthesis was proceeded as previously described[16]. cRNA labeled with biotin was synthesized using 12 μL synthesized cDNA as a template, cDNA and cRNA were purified[16]. Measurement of concentration, purity and quality of cDNA and cRNA was performed as previously reported[21].

### *cRNA fragmentation and microarray detection*

Fifteen μL (1 μg/μL) cRNA incubated with 5 × fragmentation buffer at 94℃ for 35 min was digested into 35-200 bp fragments. The hybridization buffer was added to the prehybridized Rat Genome 230 2.0 microarry produced by Affymetrix, and then hybridization was carried out for 16 h at 45℃ on a rotary mixer at 60 rpm. The microarray was washed and stained by GeneChip fluidics station 450 (Affymetrix Inc., USA). The chips were scanned by GeneChip scan 3000 (Affymetrix Inc., USA), and the signal values of gene expression were observed[17].

### *Microarray data analysis*

The normalized signal values, signal detections (P, A, M) and experiment/control (Ri) were obtained by quantifying and normalizing the signal values using GCOS1.2[17].

### *Normalisation of microarray data*

To minimize the errors in microarray analysis, each analysis was performed three times by rat genome 230 2.0 microarray. Results with a maximal total ratio ($R^m$) and an average of three housekeeping genes β-actin, hexokinase and glyseraldehyde-3-phosphate dehydrogenase approaching 1.0 ($R^h$) were taken as a reference. Modified data were generated by applying a correction factor ($R^m/R^h$) multiplying the ratio of every gene in Rh at each time point. To remove spurious gene expression changes resulting from errors in the microarray analysis, the gene expression profiles at 0-4 h, 6-12 h and 12-24 h after PH were reorganized by normalization analysis program (NAP) software according to the cell cycle progression of regenerating hepatocytes. Data statistics and cluster analysis were done using the GeneMath, GeneSpring, Microsoft Excel softwares[17,22,23].

### *Identification of genes associated with liver regeneration*

First, the nomenclature of innate immune response was adopted from the GENEONTOLOGY database (www.geneontology.org) and input into NCBI (www.ncbi.nlm.nih.gov) and RGD (rgd.mcw.edu) to identify the rat, mouse and human genes associated with the biological process. According to the maps of biological pathways embodied by GENMAPP (www.genmapp.org), KEGG (www.genome.jp /kegg/pathway.html#amino) and BIOCARTA (www.biocarta.com/genes/index.asp), genes associated with innate immune response were collated. The results of this analysis were codified and compared with those obtained for humans and mice in order to identify human and mouse genes which are different from those of rats. Comparing these genes with the analysis output of rat genome 230 2.0 array, genes showing more than twofold change in expression level as meaningful expression changes[18], were referred to as rat homologous or rat specific genes associated with innate immune response

[1]Reported genes associated with liver regeneration; associated to others: genes are involved in another kind of the responses besides one kind of innate immune responses; others: other genes associated with innate immune response, but cannot be clearly categorized.

under evaluation. Genes displaying reproducible results in three independent analyses with the chip and more than twofold change in expression level at least at one time point during LR with a significant difference ($P \leqslant 0.01 < 0.05$) or an extremely significant difference ($P \leqslant 0.01$) between PH and SO, were referred to as genes associated with liver regeneration.

## RESULTS

### *Expression changes of innate immune response-associated genes during liver regeneration*

According to the data from databases at NCBI, GENEMAP, KEGG and BIOCARTA, a total of 275 genes are involved in innate immune response, of which 151 are contained in the rat genome 230 2.0 array. In the resent study, 85 out of these 151 genes revealed meaningful expression changes at least at one time point after PH, showing a significant difference or an extremely significant difference in expression when PH was compared with SO and reproducible results checked by three detects with rat genome 230 2.0 array, suggesting that the genes were associated with LR. Their expression was up-regulated 2 to 128 times and down-regulated 2 to 10 times of the control (Table 1). The expression was up-regulated in 41, down-regulated in 26, and up/down-regulated in 18 genes, respectively, during LR. The expression of these 85 genes was up-regulated 350 times and down-regulated 129 times (Figure 1A). At the initiation stage of LR (0.5-4 h after PH), the expression was up-regulated in 28 and down-regulated in 8 genes. At the transition phase from G0 to G1 (4-6 h after PH), 21 was up-regulated in 21 and down-regulated in 5 genes. At cell proliferation period (6-66 h after PH), the expression was up-regulated in 42, down-regulated in 29, and up/down-regulated in 8 genes, respectively. At cell differentiation and reorganization of the structure-function stage (66-168 h after PH), the expression was up-regulated in 32, down-regulated in 14, and up/down-regulated in 4 genes, respectively (Figure 1B).

### *Initiation expression time of innate immune response-associated genes during liver regeneration*

At each time point of LR, the number of initially and totally up-regulated, down-regulated genes respectively was both 10 and 2 at 0.5 h; 7,6 and 15, 6 at 1 h; 7, 0 and 18, 1 at 2 h; 4, 0 and 20, 1 at 4 h; 1, 4 and 14, 5 at 6 h; 0, 0 and 16, 3 at 8 h ; 1, 0 and 19, 3 at 12 h ; 7, 4 and 19, 4 at 16 h ; 3, 9 and 19, 14 at 18 h ; 1, 0 and 17, 14 at 24 h ; 0, 3 and 12, 8 at 30 h ; 1, 3 and 19, 9 at 36 h ; 1, 1 and 15, 5 at 42 h ; 2, 1 and 26, 12 at 48 h; 0, 2 and 15, 11 at 54 h ; 0, 1 and 16, 7 at 60 h ; 0, 0 and 12, 4 at 66 h ; 0, 0 and 10, 4 at 72 h ; 1, 0 and 14, 7 at 96 h ; 3, 0 and 18, 6 at 120 h ; 0, 0 and 12, 5 at 144 h ; 0, 0 and 14, 6 at 166 h (Figure 2). Generally, gene expression changes occurred during the

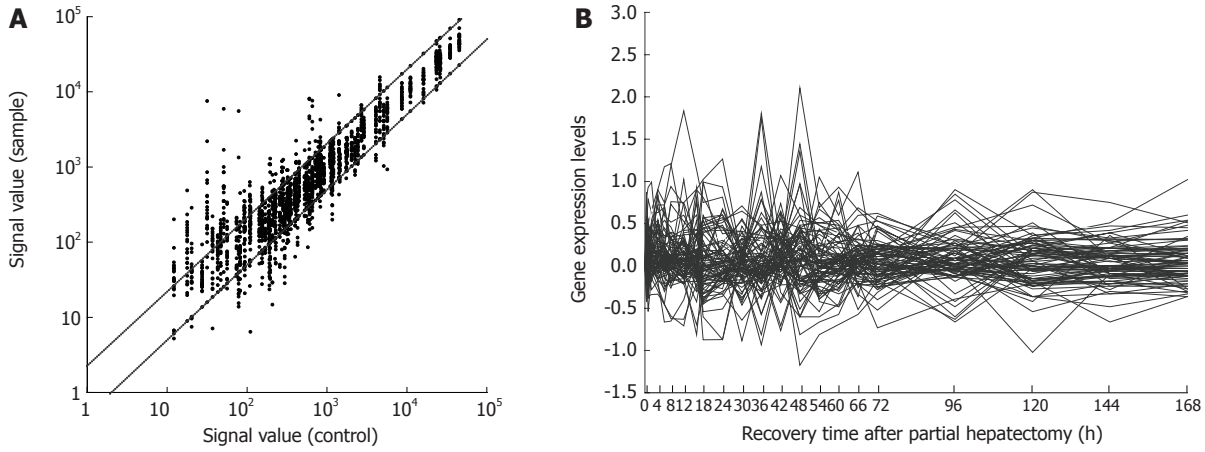

**Figure 1** Expression frequency (**A**) and changes (**B**) of 85 innate immune response-associated genes during rat liver regeneration. Data detected by rat genome 230 2.0 array were analyzed and graphed by Microsoft Excel. The dots above bias indicate that the expression of genes was increased more than two folds and up-regulated 350 times, the dots under bias indicate that the expression of genes was decreased more than two folds and down-regulated 129 times, the dots between biases indicate that the expression of genes has no alteration. The expression of 59 genes was increased 2-128 folds, while the expression of 44 genes was increased 2-10 folds.

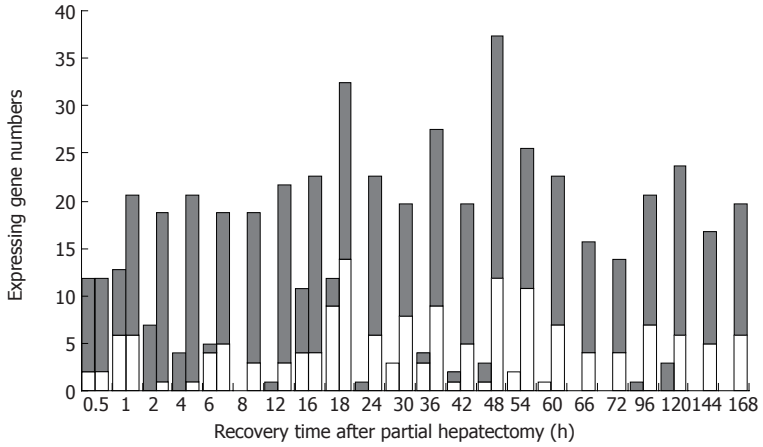

**Figure 2** Initial and total expression profiles of 85 innate immune response-associated genes at each time point of liver regeneration. Grey bars: up-regulated expression gene; white bars: down-regulated expression gene; blank bars: initially expressed genes in which up-regulated genes are predominant in the forepart, and down-regulated genes in the prophase and metaphase, whereas very few in the anaphase; dotted bars: the total number of expressed genes, in which the expression of some genes is up-regulated and the expression of others is down-regulated during LR.

whole LR. The expression of these genes was up-regulated 350 times and down-regulated 129 times. The expression of the genes was predominantly initially up-regulated in the forepart, and initially down-regulated in the prophase and metaphase, whereas the initial expression of very few genes was observed in the anaphase.

### *Expression similarity and time relevance of innate immune response-associated genes during liver regeneration*

Based on their similar expression, the 85 genes during LR could be divided into 41 up-regulated, 4 predominantly up-regulated, 26 down-regulated, 6 predominantly down-regulated, and 8 up/down-regulated genes, respectively (Figure 3). Based on their time relevance, they could also be classified into 14 groups (0.5 h, 1 and 66 h, 2 h, 4 and 8 h, 12 and 36 h, 16 and 96 h, 18 and 24 h, 30 and 42 h, 48 h, 54 and 60 h, 72 h, 120 h, 144 and 168 h), in which their expression was up- and down-regulated at 10 and 2 h, 27 and 10 h, 18 and 1 h, 20 and 1 h, 30 and 8 h, 38 and 12 h, 33 and 11 h, 36 and 20 h, 26 and 12 h, 31 and 18 h, 10 and 4 h, 18 and 6 h, 26 and 11 h (Figure 3). The up-regulated expression of genes was mainly associated with cellular immunity. The down-regulated expression of genes was significantly associated with molecular immunity.

### *Expression patterns of innate immune response-associated genes during liver regeneration*

According to their expression changes during LR, the patterns of the above 85 genes might be categorized into 28 types: 5 up-regulated genes at one time point, i.e. at 4, 48, 96, 120 h after PH (Figure 4A); 4 up-regulated genes at two time points, i.e. at 12 and 60 h, 42 and 120 h, 16 and 42 h (Figure 4B); 1 up-regulated gene at three time points (Figure 4B); 5 up-regulated genes at more time points (Figure 4B); 3 up-regulated genes at one phase, i.e. at 0.5-8 h, 4-8 h, 120-168 h (Figure 4C); 1 up-regulated gene at two phases, i.e. at 16-36 h, 42-48 h (Figure 4C); 1 up-regulated gene at three phases (Figure 4C); 1 up-regulated gene at more phases (Figure 4C); 1 up-regulated gene at one time point/one phase, i.e. at 120 and 2-72 h, 48 and 2-24 h, 18 and 48-60 h, 42 and 120-168 h (Figure 4D); 1 up-regulated gene at two time points/three phases (Figure 4E); 1 up-regulated gene at two time points/one phase (Figure 4E); 1 up-regulated at one time point/ three phases (Figure 4E); 1 up-regulated gene at two time points/three phases (Figure 4E); 3 up-regulated genes at two time points/two phases (Figure 4E); 1 up-regulated gene at three time points/ one phase (Figure 4F); 1 up-regulated gene at three time points/two phases (Figure 4F); 3 up-regulated genes at

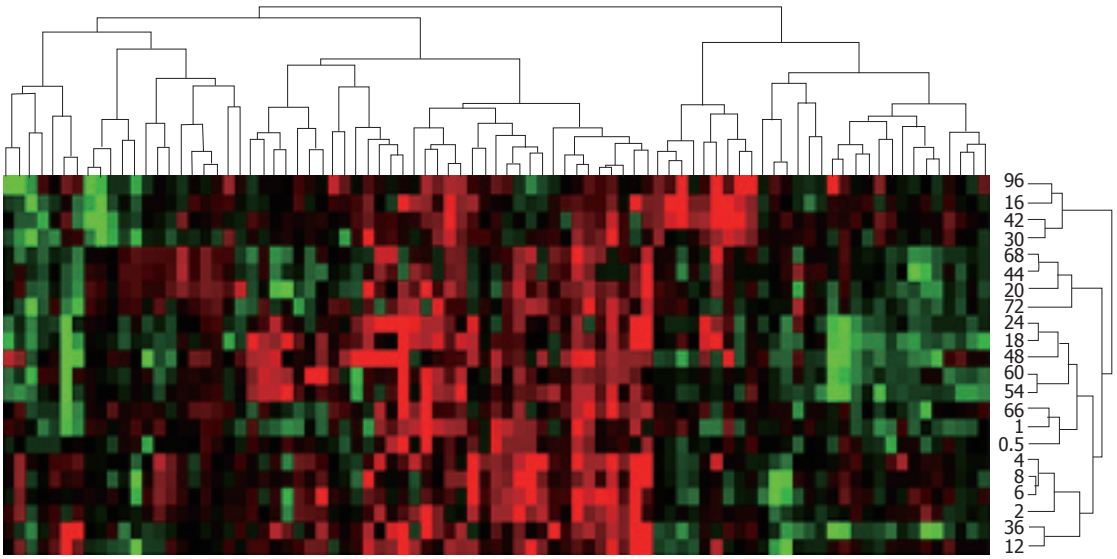

**Figure 3** Expression similarity and time relevance clusters of 85 innate immune response-associated genes during liver regeneration. Data detected by rat genome 230 2.0 array were analyzed by H-clustering. Red indicates up-regulated gene expression chiefly associated with cellular immunity; green indicates down-regulated gene expression mainly associated with molecular immunity; black indicates meaningless change in gene expression. The upper and right trees show the expression similarity and time series clusters, by which the above genes were classified into 5 and 14 groups respectively.

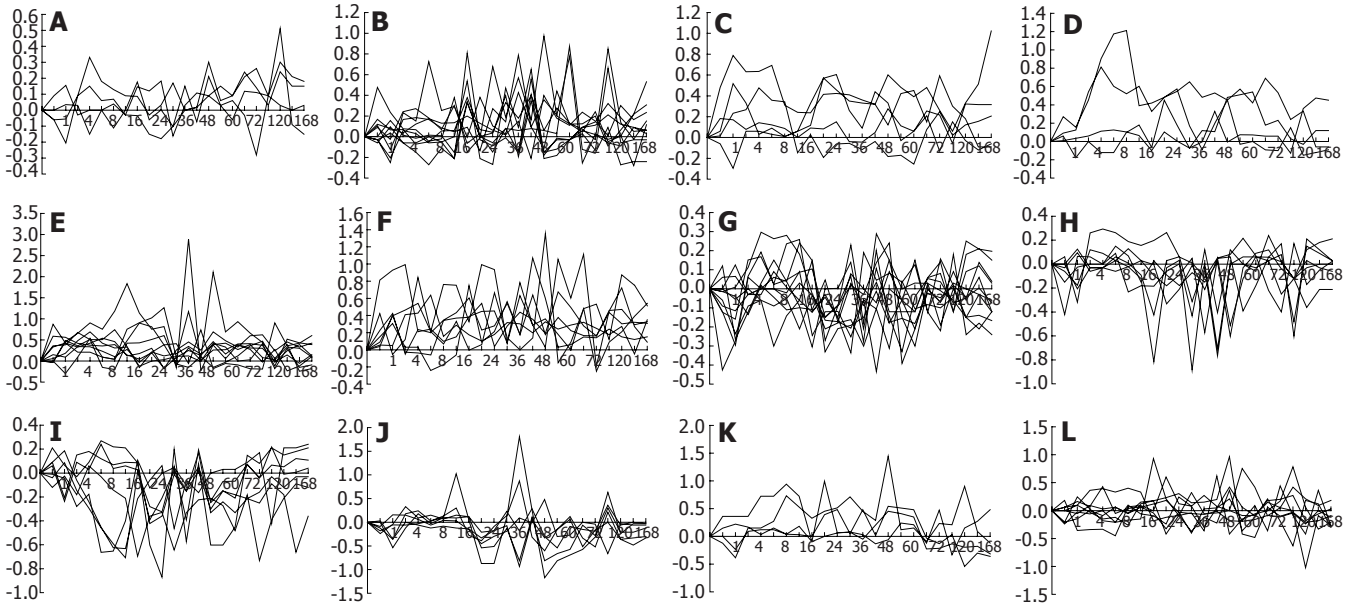

**Figure 4** Expression patterns of 85 innate immune response-associated genes during liver regeneration. Twenty-eight expression patterns were obtained by the analysis of data detected by rat genome 230 2.0 array with Microsoft Excel. **A**-**F**: 41 up-regulated genes; **G**-**I**: 26 down-regulated genes; **J**-**L**: 18 up/down-regulated genes. X-axis represents recovery time after PH (h); Y-axis shows logarithm ratio of the signal values of genes at each time point to control.

more phases (Figure 4F); 11 down-regulated genes at one time point, i.e. 0.5, 6, 16, 18, 30, 36, 42, 48, 54, 60 h (Figure 4G); 5 down-regulated genes at two time points, i.e. at 0.5 and 48, 1 and 72, 18 and 54, 30 and 42h (Figure 4H); 1 down-regulated gene at three time points (Figure 4H); 2 down-regulated genes at more time points (Figure 4H); 2 down-regulated genes at two time points/one phase (Figure 4I); 1 down-regulated gene at one phase, i.e. 6-12h (Figure 4I); 2 down-regulated genes at one time point/two phases (Figure 4I); 2 down-regulated genes at two time points/one phase (Figure 4I); 6 first down- and then up-regulated genes (Figure 4J); 4 first up- and then down-regulated genes (Figure 4K); 8 up/down-regulated genes (Figure 4L).

## DISCUSSION

Innate immune response, which is a self-protection mechanism formed during the long-term evolutionary process, includes tissue barrier, innate cellular immunity and innate molecular immunity, being closely linked to existence of high animal[2]. Of the proteins associated with innate cellular immunity, seven proteins including toll-like receptor 2 (TLR2) have a role in recognition of pathogens, interferon excretion of NK cells and activation of congenital immune system[24,25]; four proteins including attractin (ATRN) positively regulate antigen representation[26,27]; fifteen proteins including CCAAT/

enhancer binding protein beta (CEBPB) and S100 calcium binding protein A8 (S100A8) promote macrophage phagocytosis[28-32]; macrophage migration inhibitory factor (MIF), also called glycosylation-inhibiting factor, inhibits the function of macrophages[33]; glucocorticoid receptor (NR3C1) inhibits action of dendritic cells[34]. In the present study, the expression of the above genes was identical or similar at some time points, while different at other time points, indicating that they co-regulate cellular immune response. Among them, *cebpb* expression was up-regulated at 0.5-8 h after PH and reached its peak at 1 h, which was 3.1 folds of the control. *s100a8* expression was up-regulated at 2-72 h and 120 h after PH, and reached its peak at 4 h, which was 6.5 folds of the control. *nr3c1* and *tlr2* expression was up-regulated at multiple phases during LR and reached their peak at 168 h and 42 h respectively, which was 4.7 folds and 10.6 folds of the control. *atrn* expression was up-regulated mainly at the metaphase, showing that the highest expression at 42 h was 4.4 folds that of the control. These findings suggest that the genes are the key to innate cellular immunity in regenerating liver.

Of the proteins associated with innate molecular immunity, eleven proteins, such as chemokine C-C motif ligand 2, 4 (CCL2, CCL4), are associated with recognition of pathogens and immune enhancement[35-38]. Two proteins, such as annan-binding lectin serine peptidase 1 (MASP1), activate the complement system[39]. Five proteins including complement component 2 (C2) enhance inflammation[40,41]. Four proteins including interferon regulatory factor 3 (IRF3) interfere with the multiplication of virus[42]. Two proteins including complement component 1 q subcomponent receptor 1 (C1QR1) are responsible for removal of apoptotic cells[43,44]. Ten proteins including interleukin 1 family member 5 delta (IL1F5) have a role in elimination of the pathogens in inflammatory response[45-47]. Three proteins including tumor necrosis factor (TNF) have the function of sterilization by promoting NK cell proliferation[48]. In the present study, the expression changes of the genes encoding these proteins were identical or similar at some time points and different at other time points, suggesting that they can co-modulate innate molecular immunity. *ccl4* expression was up-regulated only at 48 h after PH, which was 3-fold of the control. However, Masson *et al*[38] reported that it is down-regulated at 3 and 12 h. *ccl2* expression was up-regulated at 0.5-1, 12-24, 36, 48-72 and 120 h, and reached its peak at 48 h, which was 128-folds of the control. *c1qr1* expression was up-regulated at multiple time points post PH and reached its peak at 8 h, which was 5.6 folds of the control. *masp1* expression was up-regulated at 42 and 120-168 h and reached its peak at 144 h, which was 3 folds that of the control. These findings indicate that the genes are important in molecular immunity during LR.

In conclusion, the expression changes of congenital immune response-associated genes after rat PH can be analyzed with high-throughput gene expression assay. The congenital immunity is enhanced during LR. Rat Genome 230 2.0 array was a useful tool analyzing the above response at transcriptional level. Nevertheless, DNA→ mRNA→ protein is influenced by various factors including protein interaction. Therefore, such techniques as Northern blotting, protein chip, RNA interference, protein-interaction *etc*, are needed to further test the above results.

## Abstract

**AIM:** To study the expression pattern of Ets-like protein 1 (Elk-1) in human esophageal squamous cell carcinoma (ESCC) and to analyze its relationship with clinicopathologic parameters.

**METHODS:** The expression of Elk-1 in fresh esophageal cancer tissues and their corresponding normal mucosae was detected immunohistochemically (IHC) by means of tissue microarray (TMA). Its correlation with clinical characteristics was evaluated and analyzed by univariate analysis. All statistical analyses were performed by SPSS version 13.0.

**RESULTS:** Expression level of transcription factor Elk-1 increased in 78.5% (84/107) ESCC tissues compared with their matched normal esophageal epithelium. However, the expression of Elk-1 did not show any obvious correlation with degree of differentiation of esophageal carcinoma (in well-differentiated, moderately-differentiated and poorly-differentiated tumors, the increased expression was 7/8, 60/74, and 19/25, respectively, $P > 0.05$). Moreover, no obvious correlation was found with lymph node metastasis and depth of invasion.

**CONCLUSION:** Increased expression of transcription factor Elk-1 may play an important role in esophageal carcinogenesis.

**Key words:** Ets-like protein 1; Esophageal squamous cell carcinoma; Immunohistochemistry; Tissue microarray

## INTRODUCTION

Esophageal cancer ranks among the 10 most frequent cancers in the world, with a predominant distribution in developing countries. It is one of the most common malignant tumors in China[1,2]. Our previous study showed that genetic susceptibility to esophageal cancer is one of the important causes for the high prevalence and familial aggregation of this disease in some areas of northern China[3]. Ets-like protein 1 (Elk-1) is a member of the ternary complex factor (TCF) subfamily of E twenty-six (ETS)-domain transcription factors[4,5]. The three ternary complex factors (TCFs) Elk-1, Net and Sap-1 form a subfamily of the ETS domain transcription factors. Their characteristic property is the ability to form a ternary nucleoprotein complex with the serum response factor (SRF) over the serum response element (SRE) of the c-*fos* promoter. The molecular mechanisms underlying the function and regulation of these factors have been extensively studied and the TCFs are a paradigm for the study of transcriptional regulation in response to extracellular signalling through the mitogen-activated protein (MAP) kinase pathway. As final effectors of multiple signalling pathways and components of protein complexes on immediate early promoters, they represent key elements in the complex and dynamic regulation of gene expression[6].

Tissue microarray (TMA) was first introduced in 1998[7]. It is a high throughput technique that can significantly accelerate the processing of a large number of tissue specimens with excellent quality, good reliability and the preservation of original tissue. TMA studies can demonstrate their accuracy and reliability compared to those of standard histological techniques and correlate with clinicopathologic information to determine disease progression and prediction of the clinical outcome[8]. It allows simultaneous analysis of many tumors using small diameter cores sampled from larger blocks of tissue, but may be limited by tumor heterogeneity[9]. In this study, we used TMA to investigate the transcription factor Elk-1 in esophageal squamous cell carcinoma (ESCC), including

method for assessing immunohistochemical scoring of microarrays. TMA blocks were constructed from 107 cases of ESCC with corresponding normal tissues, taking two cores from different areas of each tumor and two cores from adjacent esophageal epithelia. Immunohistochemical labelling was performed for Elk-1. The extent and intensity of scoring were determined for each core and the degree of agreement was determined for results from the assessment of two, three or four cores for each case. The results show that TMA is a reliable tool to demonstrate cellular and molecular alterations in ESCC.

In this study, we investigated the protein expression of transcription factor Elk-1 in ESCC. The expression levels of Elk-1 increased in ESCC tissues compared with their normal counterparts. Therefore, Elk-1 might be related to human ESCC and further study on Elk-1 may provide insight into the mechanisms of carcinogenesis of esophagus.

## MATERIALS AND METHODS

### Materials

Specimens of cancer tissues and matched adjacent normal mucosa were taken from 107 consecutive patients with squamous cell carcinoma of the thoracic esophagus who underwent esophagectomy with regional lymph nodes dissected from July 2005 to April 2006 at the Department of Thoracic Surgery, the First Affiliated Hospital of Anhui Medical University. None of the patients received radiotherapy or chemotherapy before surgery. The patients included 79 men and 28 women with a median age of 60 (range 40-79) years. Fourteen tumors were located in the upper thorax, 60 in the middle thorax and 33 in the lower thorax (Table 1). The removed specimens were stained with hematoxylin and eosin, examined histologically, and then the clinicopathologic stage was determined according to TNM classification.

**Table 1 Clinical and histopathological characteristics of patients**

| Characteristic | *n* (%) |
|---|---|
| Sex | |
| Male | 79 (73.8) |
| Female | 28 (26.2) |
| Location of tumor | |
| Upper thoracic | 14 (13.1) |
| Middle thoracic | 60 (56.1) |
| Lower thoracic | 33 (30.8) |
| Degree of differentiation | |
| Well-differentiated | 8 (7.5) |
| Moderately-differentiated | 74 (69.2) |
| Poorly-differentiated | 25 (23.3) |
| Depth of invasion | |
| T1 | 6 (5.6) |
| T2 | 39 (36.4) |
| T3 | 62 (58.0) |
| T4 | 0 (0) |
| Lymph node metastasis | |
| Positive | 35 (32.7) |
| Negative | 72 (67.2) |

### Construction of tissue microarray

The collected samples were fixed with formalin and embedded with paraffin, and then tissue microarray was performed. Two pathologists selected representative areas from each donor tumor block, and then punched cores 1.0 mm in diameter, from the donor blocks, and then transferred these tissue cores to a recipient block using a tissue microarrayer (Beecher Instrument, Silver Spring, Maryland, USA). The resultant tissue microarray was cut into sections and transferred to glass slides for processing of Elk-1 by immunohistochemistry.

### Immunohistochemical staining

Immunohistochemical analysis was done retrospectively. Resected esophageal specimens, including both tumor and normal mucosae, were fixed in a 40 g/L formaldehyde solution and embedded in paraffin. Rabbit polyclonal IgG Elk-1 antibody (Santa Cruz Biotech Co, USA) was used in this study (diluted 1:100). Formalin-fixed and paraffin embedded tissue blocks of esophageal tumors were cut into 4-μm thick sections. TMAs were deparaffinized in xylene, rehydrated in ethanol and treated with 30 mL/L $H_2O_2$ for 30 min to block the endogenous peroxidase activity. Antigen retrieval was achieved by microwaving in 0.01 mol/L citrate buffer (pH 6.0) at 96℃ for 15 min. After incubation with 10% normal goat serum to block non-specific binding, they were then incubated with anti-Elk-1 antibody at 1:100 dilution overnight at 4℃. After antibody was washed in PBS, TMAs were incubated with the secondary antibody and the third antibody (Streptavidin/HRP) according to the manufacturer's instructions. Finally DAB was used as a chromogen and hematoxylin as a counterstain. Negative control was designed by using PBS instead of primary antibody.

### Assessment of staining

The percentage of Elk-1-positive tumor cells was determined semiquantitatively by assessing the entire tumor section and scored as: a = 0, < 5% of epithelial cells in the respective lesions; b = 1, 5%-25% of epithelial cells in the respective lesions; c = 2, 26%-50% of epithelial cells in the respective lesions; d = 3, 51%-75% of epithelial cells in the respective lesions; e = 4, > 75% of epithelial cells in the respective lesions. The intensity was graded as: a = 0, negative; b = 1 +, weak; c = 2 +, moderate; d = 3 +, strong. A final score between 0 and 12 was achieved by multiplication of the extent of positivity and intensity[10,11]. Positive staining of more than 5% in cell cytoplasm was defined as positive staining, less than 50% in cell cytoplasm as preserved expression, more than 50% in cell cytoplasm as increased expression[12].

### Statistical analysis

Paired-samples T test, chi square test or Fisher's exact probability test was used to assess the association between immunohistochemical features and clinicopathologic characteristics. A $P$ value less than 0.05 was considered statistically significant. All the statistical analyses were performed using the SPSS 13.0 V for Windows.

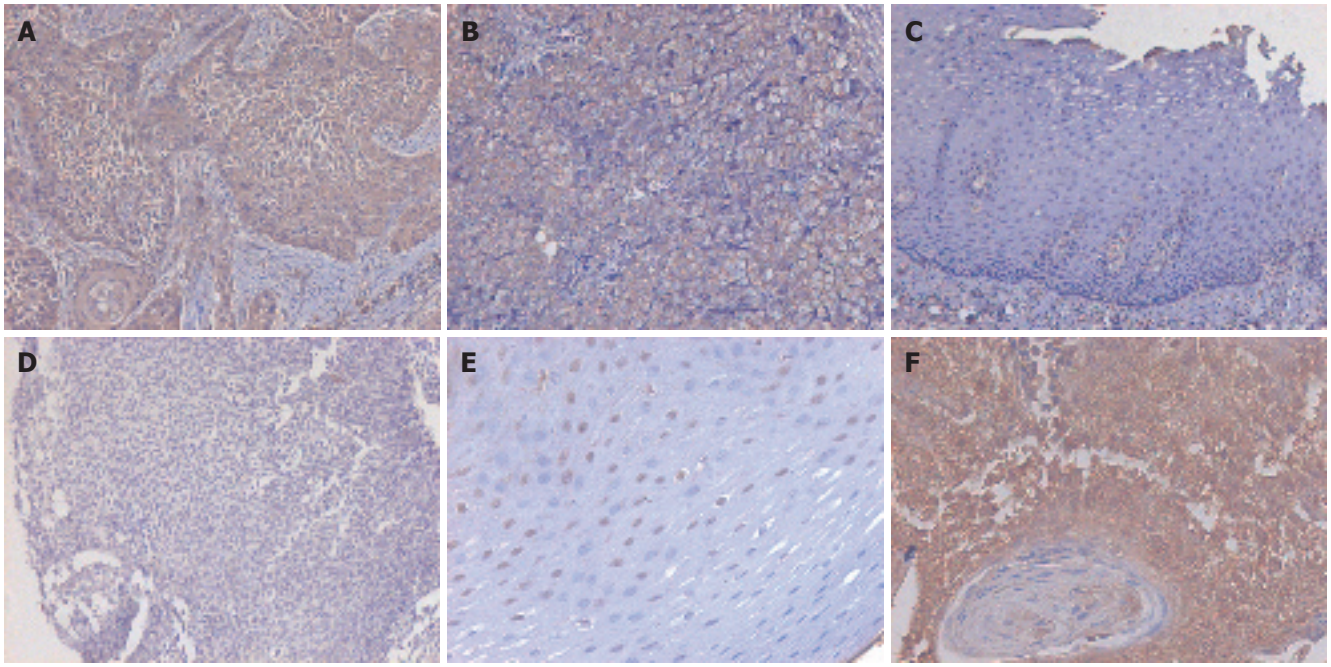

**Figure 1** Immunohistochemical analysis of Elk-1 in paired ESCC samples using anti-Elk-1 antibody (1:100) showing diffuse and strong staining in cytoplasm of esophageal cancer epithelial cells well-differentiated tumor (**A**), moderately-differentiated tumor (**B**), sporadic and weak staining in the cytoplasm of normal epithelial cells (**C**), negative control designed using PBS instead of primary antibody (**D**), strong staining in nuclei of normal epithelial cells (**E**) (**A-E** × 100), and in cytoplasm of well-differentiated esophageal cancer epithelial cells (**F**) (× 200).

## RESULTS

### *Expression of Elk-1 in esophageal squamous cell carcinoma*

Positive Elk-1 expression showed brown staining signals in ESCC cytoplasm and nuclei, reduced or negative expression of Elk-1 was found in normal squamous epithelium, with only a small number of expressions in cell membranes. The increased expression rate of Elk-1 in 107 esophageal cancer patients was 78.5% (84/107) compared to that in the matched normal tissue. A significant positive correlation was found in Elk-1 expression between esophageal carcinoma tissue and paired normal squamous epithelium ($P < 0.01$). The increased expression rate of Elk-1 was 80.4% (86/107) (Figure 1).

### *Relationship between Elk-1 expression and clinicopathologic variables in esophageal squamous cell carcinoma*

The expression of Elk-1 had no obvious correlation with the degree of differentiation of esophageal squamous cell carcinoma. The increased expression was found in 7/8 well-differentiated, 60/74 moderately-differentiated and 19/25 poorly-differentiated tumors, respectively, ($P > 0.05$). In addition, no significant correlation was found among Elk-1 expression, lymph node metastasis and depth of invasion (Table 2).

**Table 2 Relationship between clinicopathologic parameters and expression of Elk-1**

| Type | Case | Elk-1 | | *P* |
|---|---|---|---|---|
| | | Preserved | Increased | |
| Degree of differentiation | | | | |
| Well-differentiated | 8 | 1 | 7 | > 0.05 |
| Moderately-differentiated | 74 | 14 | 60 | |
| Poorly-differentiated | 25 | 6 | 19 | |
| Depth of invasion | | | | |
| Mucous layer (T1) | 6 | 1 | 5 | > 0.05 |
| Muscular layer (T2) | 39 | 6 | 33 | |
| Full-thickness (T3) | 62 | 14 | 48 | |
| Lymph node metastases | | | | |
| Positive | 35 | 5 | 30 | > 0.05 |
| Negative | 72 | 16 | 56 | |

## DISCUSSION

Regulations of cell growth are dependent on a number of gene families including proto-oncogene, growth factor, growth factor receptor and immediate early transcription factor gene. The first member of Ets gene family was discovered a decade ago by studying avian erythroblastosis virus, E twenty six (E26). Subsequently, a series of cellular Ets genes were isolated (Ets-1, Ets-2, Erg, Elk-1, Sap-1, PEA-3, PU.1, Fli-1 *etc.*)[13]. The Elk-1 gene is localized on human chromosomes Xp11.2-p11.1 and 14q32[14,15]. Elk-1 was first discovered in a fraction of HeLa cell nuclear extract that forms ternary complexes with SRF on the c-*fos* SRE. This novel component is called p62 due to its 62 kDa molecular mass[16]. Elk-1, Sap-1 and Sap-2/Net comprise the TCF subfamily of Ets-domain transcription factors. The TCF transcription factors play an important role in transducing extracellular signals into a nuclear response by acting as targets for the mitogen-activated protein kinase signaling pathways[4,5,17]. In addition to a N-terminal DNA-binding domain, Elk-1 contains a "B box" mediating its interaction with SRF, a "C domain" acting as a transcriptional activation domain, two repression domains,

and two domains that act as docking sites for multiple mitogen-activated protein kinases, including extracellular signal-regulated kinase (ERK), c-Jun N-terminal kinase (JNK) and p38[4,18,19]. The ERK cascade responds to growth factors and mitogens, whereas the JNK and p38 cascades are triggered by cytokines and stress.

The understanding of the molecular basis of tumor development has progressed dramatically in the last two decades. Since tumor is essentially a genetic disease, it is important to demonstrate what these oncogenes are and how they work in carcinogenesis. Identifying the genetic differences between normal and tumor cells or tissues will help discover the genes that directly cause tumor or are associated with tumorigenesis and provide novel markers for early detection and appropriate therapy.

Elk-1 is thought to impact neuronal differentiation[20], cell proliferation[4], tumorigenesis[21], and apoptosis[22]. Elk-1 plays a role in the neuronal expression of immediate-early genes like c-*fos* in the brain[23]. Elk-1 functions as a nuclear transcriptional activator via its association with SRF on serum response elements present in the promoters of many immediate-early genes, such as c-*fos*, *egr-1*, *egr-2*, *pip92*, and *nurr77*[17]. In addition to its regulation of growth-responsive genes, Elk-1 has been shown to play a role in regulating differentiation of smooth muscle, skeletal muscle, and neuronal cells[24-26]. Recently the SRF gene has also been identified as a target for Elk-1, thereby providing a positive-feedback loop where Elk-1 activation leads to enhanced expression of its partner protein, SRF[27]. Although the role of Elk-1 has been extensively studied, little information is available concerning its involvement in esophageal epithelia. In our study, we first investigated immunohistochemically the expression of Elk-1 protein in paired ESCC by TMA. The results of IHC revealed that the expression of Elk-1 was increased 78.5% (84/107) in tumor tissue compared to that in corresponding normal tissue. A significant positive correlation was found between esophageal carcinoma tissue and paired normal squamous epithelium ($P < 0.01$). Among the 107 histologically-examined esophageal squamous cell carcinomas, eight tumors were well-differentiated, 74 moderately-differentiated and 25 poorly-differentiated, suggesting that up-regulated Elk-1 expression has no difference in degree of tumor differentiation. No significant correlation was found among expression of Elk-1, degree of differentiation, lymph node metastasis and depth of invasion. Overexpression of two target genes of Elk-1 (c-*fos*, *egr*-1 mRNAs and their proteins) were found in dysplasia and esophageal squamous carcinomas, suggesting that these genes are involved in the development of esophageal carcinoma[28]. In addition to its nuclear location, Elk-1 is found throughout the cytoplasm of tumor and normal epithelial cells (Figure 1). This is in agreement with previous studies on nuclear transcription factor Elk-1 in neuronal cells[29,30].

In conclusion, Elk-1 may have alternative extranuclear functions in esophageal carcinogenesis. The mechanism of the involvement of Elk-1 in the development and progress of esophageal carcinoma remains to be further investigated.

## ACKNOWLEDGMENTS

We thank Hao Li in Anhui Medical University for providing the paraffin-embedded, formalin-fixed tissues used in this work. We are grateful to Drs. Xiao-Hui Tan and You-Yong Lu in Beijing Institute for Cancer Research, School of Oncology, Peking University, for construction of TMA.

## COMMENTS

### Background

Esophageal squamous cell carcinoma (ESCC) has one of the highest malignant potentials of any tumor, and is characterized by poor survival and wide geographical variation in incidence. The molecular pathology underlying the development and progression of ESCC is poorly understood. In this study, the expression of Elk-1 was immunohistochemically examined in 107 ESCCs and its relationship with clinicopathologic parameters was analyzed.

### Research frontiers

The molecular mechanisms underlying the function and regulation of the three ternary complex factors (TCFs) Elk-1, Net and Sap-1 have been extensively studied and the TCFs are a paradigm for the study of transcriptional regulation in response to extracellular signalling through the mitogen-activated protein (MAP) kinase pathway. As final effectors of multiple signalling pathways and components of protein complexes play a role in immediate early promoters, they represent key elements in the complex and dynamic regulation of gene expression.

### Terminology

Tissue microarrays (TMAs) are means of combining tens to hundreds of specimens of tissues onto a single slide, using all types of *in-situ* analyses including immunohistochemistry (IHC), fluorescence *in situ* hybridization (FISH), and RNA *in situ* hybridization (RNA-ISH). Potential applications include the establishment of associations between molecular changes and clinical endpoints, testing of potential therapeutic targets using tissue samples from specific cancer patients, standardization of molecular detection of targets, and rapid translation of results from cell lines and animal models to human cancer.

### Peer review

The paper contributes to the mechanisms of carcinogenesis in the squamous epithelium of esophagus. The molecular study is focused on the Elk-1 transcription factor which is overexpressed in esophageal cancer. This fact is well demonstrated, showing that increased expression of transcription factor Elk-1 may play an important role in esophageal carcinogenesis.

## Abstract

**AIM:** To investigate the therapeutic effectiveness of colonic exclusion and combined therapy for refractory constipation.

**METHODS:** Thirty-two patients with refractory constipation were randomly divided into treatment group ($n$ = 14) and control group ($n$ = 18). Fourteen patients in treatment group underwent colonic exclusion and end-to-side colorectal anastomosis. Eighteen patients in control group received subtotal colectomy and end-to-end colorectal anastomosis. The therapeutic effects of the operations were assessed by comparing the surgical time, incision length, volume of blood losses, hospital stay, recovery rate and complication incidence. All patients received long-term follow-up.

**RESULTS:** All operations were successful and patients recovered fully after the operations. In comparison of treatment group and control group, the surgical time (h), incision length (cm), volume of blood losses (mL), hospital stay (d) were 87 ± 16 min *vs* 194 ± 23 min ($t$ = 9.85), 10.4 ± 0.5 cm *vs* 21.2 ± 1.8 cm ($t$ = 14.26), 79.5 ± 31.3 mL *vs* 286.3 ± 49.2 mL ($t$ = 17.24), and 11.8 ± 2.4 d *vs* 18.6 ± 2.6 d ($t$ = 6.91), respectively ($P$ < 0.001 for all). The recovery rate and complication incidence were 85.7% *vs* 88.9% ($P$ = 0.14 > 0.05), 21.4% *vs* 33.3% ($P$ = 0.73 > 0.05), respectively.

**CONCLUSION:** Colonic exclusion has better therapeutic efficacy on refractory constipation. It has many advantages such as shorter surgical time, smaller incision, fewer blood losses and shorter hospital stay.

**Key words:** Constipation; Colonic exclusion; Subtotal colectomy; Quality of life; Follow-up

## INTRODUCTION

Refractory constipation is a common clinical symptom. Because it is very obstinate and its etiological factors are unclear, it is difficult for medical workers to treat the patients. The problem of difficult defecation usually cannot be solved with drug treatment. According to our experience, surgical treatment is suggested for the patients who are unresponsive to cathartics or who need to ingest exceeding cathartics to evacuate their bowels. There are many conventional surgical methods, such as total colectomy, subtotal colectomy, hemicolectomy, *etc*. However, the operation time of these surgical methods is too long. Besides, these surgical methods with big trauma will give rise to many postoperative complications and negatively affect the quality of the patients' lives. Moreover, the very aged patients cannot bear these operations and their treatment is far from satisfactory[1]. Since 1998 we have adopted colonic exclusion with colorectal anastomosis and treated 14 patients of refractory constipation. All of them were satisfied with the therapeutic effects. The quality of patients' lives had been improved significantly after operations. Our clinical practice demonstrates that colonic exclusion is a safe and feasible operation. It has good therapeutic effects, shorter surgical time, and lower complication incidences.

## MATERIALS AND METHODS

### General data

Thirty-two patients were diagnosed as refractory constipation between January 1998 and April 2006. These patients received surgical intervention after ineffective medical treatment. They were divided into two groups randomly. There were two males and twelve females in treatment group ($n$ = 14). Their ages ranged from 31 to 77 years with a mean age of 45. Their courses of disease ranged from three to thirty years with 12 years on average. Among them, ten patients had rectocele, and eight patients had rectal prolapse. Five males and thirteen females entered control group ($n$ = 18). Their ages ranged from 28 to 75 years with a mean age of 51. Their courses of

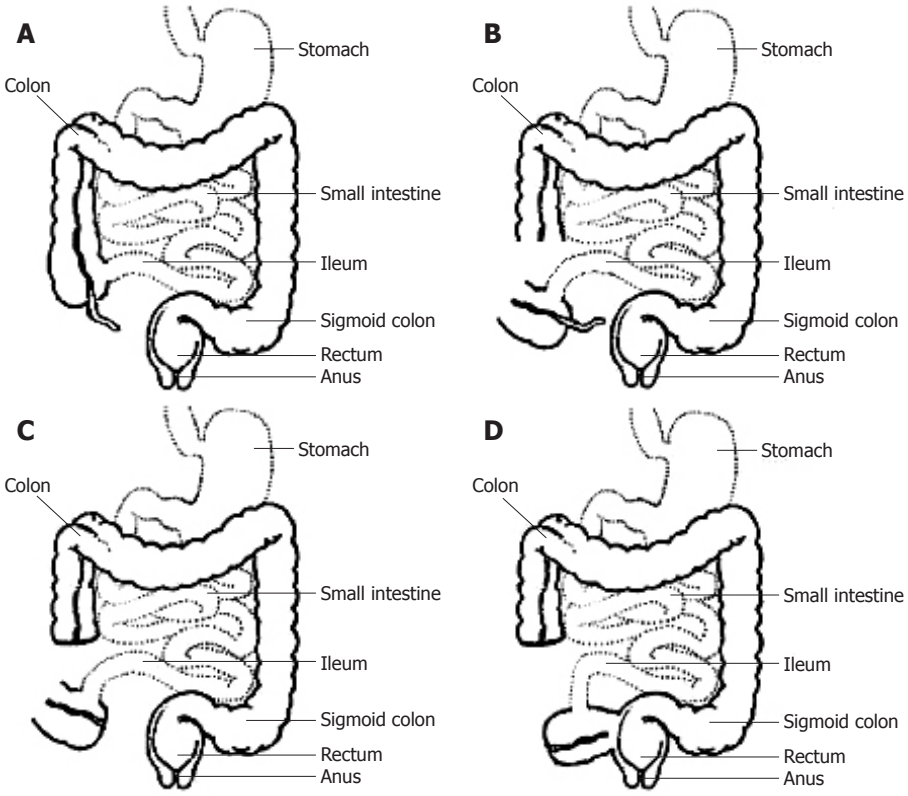

**Figure 1** Surgical procedures of colonic exclusion. **A**: Normal gastrointestinal structure in human body; **B**: Transect the ascending colon at the chosen level with good blood supply; **C**: Close the distal colon by U-shape sutures and sever the vermiform appendix; **D**: Lay the distal colon in abdominal cavity. The proximal ascending is made end-to-side anastomosis with rectum.

disease ranged from four to thirty-five years with 13 on average. Eleven patients had rectocele among them. There were no statistical differences in age and courses of disease between the two groups.

### *Clinical symptoms*

All patients had difficult defecation for three or more than three years. Some serious cases had difficult defecation beyond thirty years. They had been ingesting cathartics or other medicine for a long time. Patients usually complained of headache, general malaise, decreased appetite, abdominal pain, abdominal distension, straining at stooling, incomplete evacuation, or a need for digital manipulation to defecate. The frequency of defecation was about once four to eight days.

### *Diagnostic criteria*

Diagnostic criteria included (1) The time of difficult defecation exceeded one year; (2) The stool frequency was below three times per week for at least three months in one year. Patients had difficult defecation accompanied by abdominal pain and abdominal distension. Stools hardened gradually to form hard feces; (3) Digital rectal examination suggested that the patient had fecal impaction accompanied by anal stenosis, hemorrhoid, and rectal prolapse; (4) Gastrointestinal transit test showed that colonic transit became slower. Rectocele and long-winded sigmoid colon were confirmed with defecography; (5) Gastrointestinal organic diseases were excluded by electronic colonoscopy.

### *Surgical methods*

Patients in treatment group were in a lithotomy position after general anesthesia. We adopted median abdominal incision around the umbilicus. After entering the abdominal cavity, the peritoneal reflexion was severed, and the anterior wall of the rectum was dissected until the rectocele was exposed. We sewed three or four needles with 3-0 absorbable suture perpendicular to the longitudinal axis of the rectum, and subsequently sewed two needles along the longitudinal axis of the rectum. The needles should penetrate the serous membrane and muscular layer so as to restore the anterior wall of the rectum. Cautions must be taken not to penetrate the mucous membrane at the same time. Freeing of distal ileum, ileocecal junction and partial ascending colon allowed us to obtain enough slack proximal colon, which guaranteed a tension-free anastomosis. Colonic blood supply was carefully examined about 4 to 6 cm away from the ileocecal junction, and the ascending colon was transected at the chosen level with good blood supply. The distal colon was closed by U-shaped sutures to lay the indwelling colon in the abdominal cavity. Vermiform appendix was severed from the cecum by a conventional method. The proximal ascending colon and cecum were moved to the pelvic cavity in anticlockwise, and then end-to-side colorectal anastomosis was performed with stapler under peritoneal reflexion. Long-winded sigmoid colon was resected simultaneously. The rectum was raised and fixed with the lateral side of pelvic peritoneum in order to suspend the rectum. The basement of pelvic cavity was reestablished and the posterior peritoneal space was closed. Finally the abdominal cavity was closed after checking surgical instruments and gauzes. It was unnecessary to place drainage tubes in the abdominal cavity to prevent postoperative adhesion (Figure 1).

The patients in control group had median abdominal incision. After entering the abdominal cavity, peritoneal

**Table 1 Surgical therapeutic efficacy for 32 refractory constipation patients**

| Group | Cases (*n*) | Surgical time (min) | Incision length (cm) | Blood loss (mL) | Hospital stay (d) | Recovery (%) | Improvement (%) | Complication (%) |
|---|---|---|---|---|---|---|---|---|
| Treatment group | 14 | 87 ± 16 | 10.4 ± 0.5 | 79.5 ± 31.3 | 11.8 ± 2.4 | 12 (85.7) | 2 (14.3) | 3 (21.4) |
| Control group | 18 | 194 ± 23 | 21.2 ± 1.8 | 286.3 ± 49.2 | 18.6 ± 2.6 | 16 (88.9) | 2 (11.1) | 6 (33.3) |
| *t* | | 9.85 | 14.26 | 17.24 | 6.91 | *P* = 0.14 | *P* = 0.14 | *P* = 0.73 |
| *P* | | < 0.001 | < 0.001 | < 0.001 | < 0.001 | > 0.05 | > 0.05 | > 0.05 |

reflexion was severed. The anterior wall of the rectum was dissected until the rectocele was exposed. Then the rectocele was restored as above. The whole colon was freed. Vermiform appendix was severed. Subsequently the colon from the ascending colon, which was about 4 to 6 cm away from ileocecal valve, to sigmoid colon was resected subtotally. The proximal ascending colon and cecum were moved to the pelvic cavity in anticlockwise, and then the proximal ascending colon was end-to-end anastomosed with the rectum. The abdominal cavity was closed after closure of the posterior peritoneal space. We also did not place drainage tubes in the abdominal cavity.

### *Statistical analysis*

All data are expressed as mean ± SD. They were entered into SPSS 12.0 statistical package. Statistical comparison was done with group *t*-test and Fisher exact probabilities in 2 × 2 table. A *P* value less than 0.05 was considered statistically significant.

## RESULTS

### *Surgical results*

The surgical time (h), incision length (cm), volume of blood losses (ml), hospital stay (d) were 87 ± 16 min, 10.4 ± 0.5 cm, 79.5 ± 31.3 mL, 11.8 ± 2.4 d in treatment group, and 194 ± 23 min, 21.2 ± 1.8 cm, 286.3 ± 49.2 mL, 18.6 ± 2.6 d in control group, respectively ($P < 0.001$) (Table 1). The treatment group had several advantages such as shorter surgical time, smaller incision, less blood losses and shorter hospital stay. Compared with the control group, colonic exclusion could reduce local trauma for many patients.

### *Criteria for therapeutic effect*

(1) Recovery: Constipation and relevant symptoms disappeared. Auxiliary examinations showed that associated manifestations disappeared; (2) Improvement: Constipation and relevant symptoms were relieved. Auxiliary examinations showed that major relevant symptoms disappeared; (3) Inefficacy: Constipation and relevant symptoms were not obviously improved. Auxiliary examinations showed that constipation still existed.

### *Postoperative effects*

According to the above criteria, twelve patients recovered (12/14, 85.7%) and two patients improved (2/14, 14.3%) in treatment group. In control group sixteen patients recovered (16/18, 88.9%) and two patients improved (2/18, 11.1%).

### *Postoperative complications*

In treatment group, adhesive ileus occurred in one patient (relieved after expectant treatment later). Another patient developed grease liquefaction of incision. Acute pancreatitis occurred in one patient. Complication incidence was 21.4%. In control group, adhesive ileus occurred in three patients. The infection of incisional wound occurred in two patients. One patient developed adhesive stenosis of the ureter. Complication incidence was 33.3%. There were no death case, no postoperative stomal leak or anastomotic stricture in either groups.

### *Long-term follow-up*

All patients were followed for six to thirty-eight months. The follow-up rate was 100%. Most patients recovered very well after operations. Their constipation disappeared and the quality of their lives improved. One patient in treatment group still had abdominal distention. She was diagnosed as endometriosis later. And the indwelling colon was resected in another hospital. The other patients did not have any abdominal pain or abdominal distention. They evacuated their bowels one to three times every day. Their stools were almost forming. Three patients in control group still had slight abdominal distention. They evacuated their bowels one to four times every day. The shape of their stools was pasty.

## DISCUSSION

Over the recent years in China, along with the improvement of the economy, quickening up of the life pace, change of the structure of foods and drinks, as well as aging of the population, the incidence of refractory constipation rises year by year. It has become one of the common diseases that affect the quality of people's lives. Refractory constipation is usually classified into three types: slow transit constipation (STC), outlet obstructive constipation (OOC), mixed constipation (MC). Among them, mixed constipation is the most commonly seen in clinics.

### *Etiological factors*

The etiological factors of refractory constipation are very complicated and largely unclear; however, some of the etiological factors have been certain[2,3]. (1) Abnormalities in the enteric nervous system; (2) Abnormalities of extrinsic nerves; (3) Smooth muscle abnormalities; (4) Interstitial cell of Cajal dysfunction; (5) Structural abnormalities of the rectum and anus: such as rectal prolapse, rectocele, hemorrhoid; (6) Endocrine and metabolic conditions;

**Figure 2** The indwelling colon didn't inflate and anastomotic stoma transmitted normally.

**Figure 3** After twenty-four hours barium in the indwelling colon was evacuated completely.

(7) Drugs; (8) Psychogenic conditions. Understanding of the etiological factors will help us make correct treatment plans for the disease. Effective combined therapy can lead to better therapeutic efficacy.

### *Surgical indications*

Refractory constipation is not a fatal disease. We suggest expectant treatment for the constipated patients with a short course of disease and light pathogenetic condition. Constipated patients who have serious clinical symptoms, poor quality of life and a strong desire for surgery, however, should be considered to take colonic exclusion, except for the aged patients. According to our clinical observation and experience over the years, there are the following surgical indications for colonic exclusion: (1) Patients have serious difficult defecation for at least three years. The stool frequency is below three times every week. (2) Drug treatment for at least half a year is confirmed ineffective or patients have to ingest exceeding cathartics for a long time. (3) Gastrointestinal transit test shows that colonic transit becomes slower, while the stomach and small bowel transit are normal. Accompanying outlet obstructive diseases are confirmed by preoperative defecography. (4) Constipation-predominant irritable bowel syndrome and constipations which are caused by drugs must be excluded. (5) The patient has no serious mental disorder and she (he) has a strong desire for operation. Surgeons should be cautious of surgical treatment for refractory constipation and handle surgical indications strictly. Patients should undergo preoperative psychological tests and clinical examinations of colorectal function. After that, individualized therapeutic strategies and surgical schema are made.

### *Variations of colonic propagated activity before and after colon exclusion*

The phenomenon of slow colonic transit more or less exists in patients with refractory constipation. We used gastrointestinal transit test to detect gastrointestinal function of 14 patients in treatment group before operation. Forty-eight hours later the photographs showed that baric markers were still stagnated in transverse colon or sigmoid colon in 12 patients. Seventy-two hours later the photographs displayed retention of baric markers in sigmoid colon or rectum in nine patients. Bassotti *et al*[4] studied colonic propulsive activity in constipated patients and found colonic dysfunction. Both colonic contraction amplitude and high-amplitude propagated contractions were significantly decreased, which might be the immediate cause of colonic inertia. We examined nine patients in treatment group with barium enema after colon exclusion a month later. The intestine did not inflate and the anastomotic stoma transmitted normally (Figure 2). Three patients had barium reflux into the indwelling colon, but it was evacuated completely 24 h later (Figure 3). Hereby it demonstrated that the indwelling colon still had itself movement. It did not lose its peristalsis under the condition of disuse. However, it is uncertain whether it has any practical clinical significance to lay the colon with neuromuscular diseases in the abdominal cavity. By now, there is no definite conclusion about the long-term influence of the indwelling colon on human bodies.

### *Characteristics and clinical application perspectives of colon exclusion*

Arbuthnot first adopted total colectomy with ileorectal anastomosis to treat slow transit constipation in 1908. Afterwards people gradually adopted total colectomy with caecorectal anastomosis. These surgical methods could relieve constipation symptoms in most patients with chronic idiopathic constipation; however, they were associated with a considerable morbidity and were less effective in resolving symptoms of abdominal pain and bloating[5]. Based on the result of gastrointestinal transit test, people adopted hemicolectomy to treat constipated patients. They only resected some segmental long-winded colon. Hemicolectomy could lead to fewer postoperative complications and a faster recovery[6], but the postoperative recurrence rate was very high[7]. This is because the excisional range of the pathological colon is not large enough. After operation the residual colon transmits slower, which will lead to recurrence of constipation. On the other hand, subtotal colectomy is a popular operation to treat refractory constipation. It seldom leads to serious diarrhea for the remaining of ileocecal valve. However, it still has some disadvantages, such as big trauma, long surgical time, delayed recovery, many complications. Besides, patients' postoperative quality of life is not so ideal[8]. We adopted colonic exclusion with colorectal anastomosis and neoplasty for symptomatic rectocele to treat constipated patients. The clinical results were satisfactory. Patients recovered excellently after operations. And there were no serious postoperative complications among them. Compared with the control group, it had

smaller incision, fewer blood losses, shorter operational time and shorter hospital stay.

In conclusion, colonic exclusion has such advantages as: (1) less trauma, fast recovery; (2) simplified operation, shorter surgical process; (3) preservation of some bowels with normal function; (4) higher clinical cure rate; (5) avoidance of serious postoperative complications. For most constipated patients, colonic exclusion is the best surgical method because it is convenient, economical, less trauma, and less painful. It is especially indicated for aged constipated patients whose surgical endurances are not so good. We assume that it has wide application value.

## COMMENTS

### *Background*

The incidence of refractory constipation is very high in modern people, especially in aged people and middle-aged females. Some constipated patients have to be treated by surgery, while conventional surgical methods have big trauma. We recommend a new surgical method to treat refractory constipation. It is convenient, economical, less trauma, and less painful.

### *Research frontiers*

Surgical methods to treat refractory constipation are improving. Recently people pay more attention to microinvasive operation. Laparoscopic operations instead of conventional surgical methods are used to treat refractory constipation.

### *Innovations and breakthroughs*

Colonic exclusion is a technical innovation in treating refractory constipation. Compared with conventional surgical methods, it doesn't need to sever or resect too much colon and it retains some bowels with normal function. Rectocele is restored and the basement of pelvic cavity is reestablished. Therefore, it has less trauma and patients recover faster after operation.

### *Applications*

Colonic exclusion has better therapeutic efficacy for refractory constipation. It has many advantages such as smaller incision, fewer blood losses, less adhesive ileus, shorter surgical time and shorter hospital stay. It is especially indicated for aged constipated patients, whose surgical endurances are not so good. It has wide application prospect in clinical practice.

### *Terminology*

Colonic exclusion: It is a surgical method that needn't to resect the colon. The ascending colon is transected. Then the distal colon is closed and the proximal colon is end-to-side anastomosed with the rectum. An indwelling colon is laid in the abdominal cavity.

## Abstract

**AIM:** To assess CT manifestations and its diagnostic value for lymphoma in the abdominal lymph nodes (LALN).

**METHODS:** CT findings in 52 cases of LALN proved by surgery or biopsy, including Hodgkin's disease (HD) in 16 cases and non-Hodgkin's lymphoma (NHL) in 36 cases, were retrospectively analyzed.

**RESULTS:** (1) CT manifestations based on distribution of the lesions of LALN: Solitary mass type was found in 10 cases, including solitary, round, uniform-density, enlarged lymph nodes in 3 cases; and multiple, enlarged lymph nodes fusing into singular lobular mass in 7 cases. Thirty-four cases of multiple-nodular type showed multiple, round, enlarged lymph nodes with uniform density and clear margins. Vessels-embedded signs, including mesenteric vessels, renal vessels, abdominal aorta or inferior vena cava, were seen in 6 cases, and duodenum-embedded signs were seen in 2 cases. Eight cases of diffuse type showed characteristic "cobblestone signs". (2) CT manifestations correlated with pathological type: CT manifestations of 12 cases of HD were different from those of 40 cases of NHL in distribution, size, quantity and fused lesion of enlarged lymph nodes. (3) Twenty-eight cases of 52 patients were accompanied with extra-nodal lymphoma in the abdomen, especially gastrointestinal lymphoma, which had characteristic CT findings. (4) In follow-up examinations, CT images showed uniform, heterogeneous or rim enhancement in 15 cases, and occasional calcifications accompanied with reduction of the lesion size and quantity in 12 cases, whereas the lesions disappeared in 3 cases after treatment.

**CONCLUSION:** CT images show many characteristic manifestations valuable for qualitative diagnosis of LALN, and it is also helpful for pathological classification of LALN and therapeutic evaluation in follow-up of patients.

**Key words:** Lymphoma; Lymph nodes; Computed tomography; Diagnosis; Classification

## INTRODUCTION

Abdominal lymphoma is clinically not uncommon and lymphoma in the abdominal lymph nodes (LALN) is most frequently encountered[1]. Though it may be part of a systemic lymphoma, single onset of LALN is not rare. LALN can be divided into Hodgkin's disease (HD) and non-Hodgkin's lymphoma (NHL). HD is seldom seen in China[2-3] and mostly occurs in middle-aged and young people. The number of NHL patients is larger than that of HD with a diffuse distribution in age. In addition, AIDS patients are more susceptible to NHL[4].

CT is useful for diagnosis[1-2,5-14] and staging[15-21] of abdominal lymphomas. For evaluation of lymph node involvement, the sensitivity of contrast-enhanced CT is 88%, and specificity is 86%. For evaluation of organ involvement, the sensitivity of contrast-enhanced CT is 50%, and specificity is 90%[15]. To our knowledge, however, CT classification of LALN has not been reported in previous documents. We reviewed retrospectively CT findings of 52 patients with LALN confirmed by pathology and histology from 2000 to 2005 in our hospital, and analyzed its value in diagnosis, pathological classification and therapeutic assessment of LALN.

## MATERIALS AND METHODS

### *Subjects*

Of the 52 LALN patients, 29 were males and 23 females, with age ranging from 18 to 77 years (mean, 43.4 years), including Hodgkin's disease (HD, age range 18-59 years, mean 34.6 years) in 12 cases and non-Hodgkin's lymphoma (NHL, age range 20-77 years, mean 47.3 years) in 40 cases. The diagnosis was confirmed by surgery (20 cases) and lymph node biopsy (32 cases) including peripheral

lymph nodes (19 cases) and abdominal lymph nodes (13 cases). The duration of symptoms ranged from 1 to 18 mo. All the patients had evident improvement in clinical symptoms and signs, and reduction in size of the lesions or disappearance of the lesions after chemotherapy and radiotherapy.

### CT scanning

Twenty patients were performed with a Somatom HiQ CT machine (Siemens Medical Systems, Forchheim, Germany) and 32 patients were performed with a 4-detector row CT machine (Volume Zoom, Siemens Medical Systems, Forchheim, Germany). All patients were in routine fasting states. Some patients were given 1000-1500 mL of diluted iodinated contrast medium (10 g/L meglumine diatrizoate) orally 60-90 min before scanning. Scan scope ranged from the dome of diaphragm to symphysis pubica. All patients were examined with plain scanning at first and then examined using Ultravist (Schering, Berlin, Germany) 80 mL for enhanced scanning, with a section thickness of 10 mm and internal of 10 mm (Somatom HiQ CT machine) or 1.5 mm section thickness, a pitch of 1.25, 5 mm reconstruction interval (4-detector row CT machine).

## RESULTS

### CT manifestations based on distribution of the lesions of LALN

**Solitary mass type:** Ten cases of solitary mass type of LALN were located in the retroperitoneum, mesenterium and lesser omentum. Of them, 3 cases on CT plain scanning showed solitary, round, enlarged lymph nodes of uniform-density with diameters of 3.2-5.8 cm. The lesions had rim enhancement in one case and slight homogeneous enhancement in 2 cases on enhanced CT. The other 7 cases showed multiple enlarged lymph nodes fusing into lobular masses with diameters of 7.8-18 cm and clear margins, of which 5 cases showed uniform density and 2 cases showed heterogeneous density on plain CT. Enhanced CT showed slight uniform enhancement in 4 cases, and heterogeneous enhancement in 3 cases. Of the all cases, the mesenteric vessels, abdominal aorta and inferior vena cava were embedded (vessels-embedded signs) in 3 cases (Figure 1).

**Multiple nodular type:** Thirty-four cases were of multiple nodular type of LALN, which referred to regional distribution of lymph nodes. CT showed multiple, round, enlarged lymph nodes with clear margins and uniform density in the abdomen (Figure 2). Most enlarged lymph nodes were over 1.0 cm in diameter with exception of 2 cases of less than 1.0 cm, which located in the mesenterium. Among the 34 cases, 29 showed slight uniform enhancement, and 5 appeared slight uniform enhancement accompanied with rim enhancement after contrast administration. Nineteen cases revealed a fusion of lesions of different degrees and 6 cases showed embedding of vessels (vessels-embedded signs), including the mesenteric vessels (3 cases) (Figure 3), renal vessels (3 cases), abdominal aorta (2 cases) and inferior vena cava (1 case), and 2 cases showed embedding of the horizontal segment of the duodenum (duodenum-embedded signs).

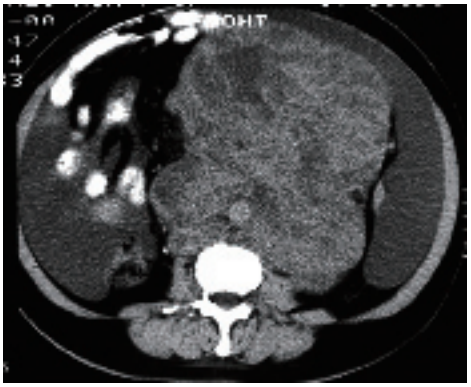

**Figure 1** Solitary mass type: Enhanced CT showing multiple enlarged lymph nodes fused into uneven density, huge lobular tumors with abdominal aorta and inferior vena cava encased and ascites.

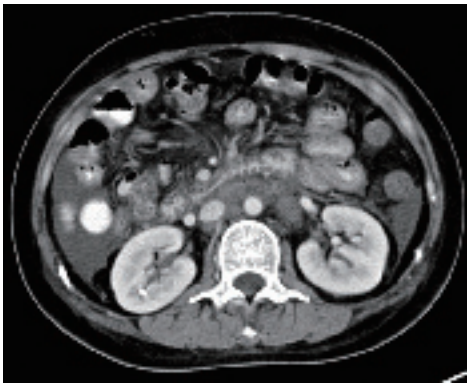

**Figure 2** Multiple-nodular type: Enhanced CT showing multiple, homogeneous density, enlarged lymph nodes in retroperitoneal region with ascites.

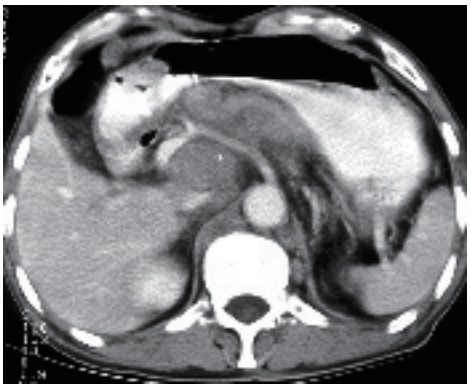

**Figure 3** Multiple-nodular type: CT of portal venous phase showing mesenteric multiple enlarged lymph nodes with superior mesenteric artery encased.

**Diffuse type:** The diffuse type of LALN involved the whole distribution areas of abdominal lymph nodes, mainly in the mesenteric and retroperitoneal regions in eight cases. CT revealed diffuse, round, non-confluent, enlarged lymph nodes with homogeneous density and clear margins, forming the characteristic "cobblestone signs" named by us. All the enlarged lymph nodes were slightly homogeneously enhanced after contrast administration (Figure 4).

### CT manifestations correlated with pathological types

**HD:** Twelve cases of HD included solitary mass type and diffuse type in one case each (8.3%, respectively), and multiple nodular type in 10 cases (83.4%). The enlarged lymph nodes were mainly distributed in the lesser omentum and retroperitoneal region adjacent to the abdominal aorta (Figures 2 and 5) and inferior vena cava. All the enlarged lymph nodes showed homogeneous

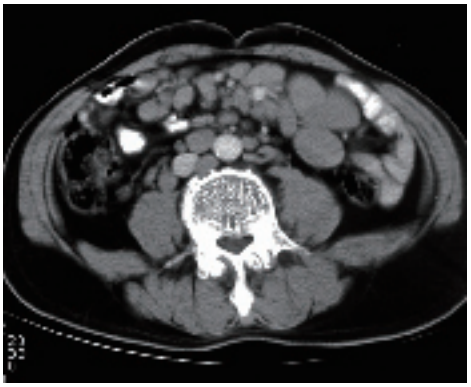

**Figure 4** Diff-use type: Enhanced CT showing diffuse, clear margins, homogeneous density enlar-ged lymph nodes in the mesenteric and retroperitoneal region.

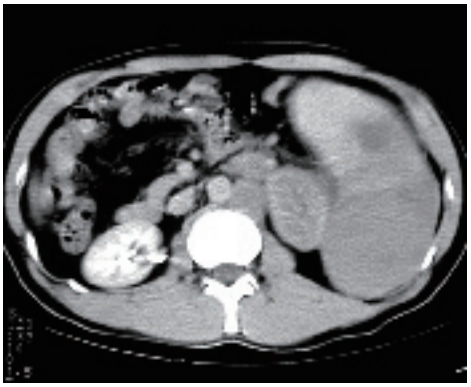

**Figure 5** Enhanced CT showing multiple, homogeneous density, enlarged lymph nodes in para-abdominal aorta and multiple, low-density lesions in the spleen (splenic lymphoma).

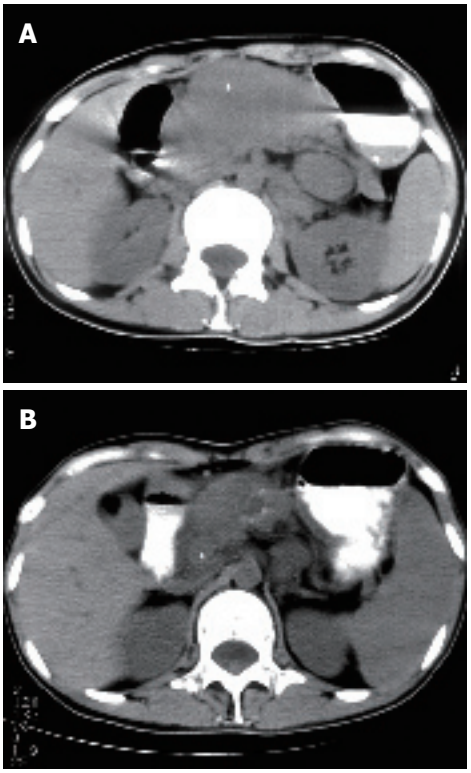

**Figure 6** **A**: Plain CT showing a uniform density, slightly lobular tumor (formed by multiple enlarged lymph nodes) in the lesser omentum; **B**: The tumor having a notable shrinkage in size and flecked calcifications found within the tumor after treatment on plain CT.

**Figure 7** Enhanced CT showing notable circular thickening of intestinal wall with homogeneous density.

enhancement except one rim enhancement after contrast administration. Among the 12 cases, only one case (8.3%) involved the mesenteric lymph nodes, which showed scattered distribution of lesions and a small number of lymph node involvement with less than 2.0 cm in size. Two cases (16.7%) had confluence of lesions and 7 cases (58.3%) showed involvement of other abdominal organs (Figure 5). **NHL:** Forty cases of NHL included solitary mass type (9 cases, 22.5%), multiple-nodular type (24 cases, 60%) and diffuse type (7 cases, 17.5%) (Figure 4). All the abdominal lymph nodes were involved, including 18 cases (45%) of mesenteric involvement. Among the 40 cases, 24 (60%) showed a fusion of the enlarged lymph nodes of different degrees, appearing as lobular masses (Figures 1 and 6); 4 exhibited embedding of vessels (Figures 1 and 3) and 2 had involvement of the intestine. Twenty-one cases (52.5%) were accompanied with involvement of other abdominal organs.

### *CT manifestations of LALN after chemo-radiotherapy*

In follow-up, CT was performed in 15 cases of LALN after chemo-radiotherapy, of which abdominal enlarged lymph nodes completely disappeared in 3 cases. The lesion size was reduced by different degrees in 12 cases, including 9 cases with homogeneous density and 3 cases with heterogeneous density, and one case with flecked calcification (Figure 6).

### *CT manifestations of the involvement of other abdominal organs with lymphoma*

Of the 52 cases of LALN, 28 involved other abdominal organs. Among the 28 cases, intestinal tract lymphomas (13 cases) showed notable circular thickening of the intestinal wall (25-38 mm, Figure 7) in 9 cases, including 2 cases with distinct dilation of intestinal cavity and one case with coexistence of narrowing and dilation of intestinal cavity, resulting in incomplete intestinal obstruction. The other 4 cases of intestinal lymphomas developed lobular masses with uneven margins in intestinal cavity. The CT manifestations of hepatic (7 cases) and splenic (6 cases) lymphomas were solitary or multiple nodular, low-density lesions (Figure 5). Ten cases of gastric lymphomas appeared notable circular thickening of gastric wall (22-33 mm). Renal lymphomas and adrenal gland lymphomas (2 cases each) were characterized by bilateral masses of both kidneys and adrenal glands. Involvement of the peritoneum and omentum (2 cases) resulted in a large amount of ascites (Figures 1 and 2) and omental cakes.

## DISCUSSION

### *Diagnostic value of CT for LALN*

CT plays an important role in the diagnosis and staging

of abdominal lymphomas. Based on the CT features of LALN, we classified LALN into solitary mass type, multiple-nodular type and diffuse type.

Solitary mass type of LALN included singular enlarged lymph nodes and fusion of multiple enlarged lymph nodes (most cases). CT featured a huge round mass or a lobular homogeneous density mass with uniform enhancement.

Multiple-nodular type of LALN, the most frequently seen, was characterized by enlarged lymph nodes with regional distribution. Parts of enlarged lymph nodes were fused together and formed a huge mass. CT showed uniform density lesions with mild homogenous enhancement. Sometimes coexistence of mild homogenous enhancement and rim enhancement was also observed, but fully rim enhancement of all lesions was rarely seen.

All the lesions of solitary mass or multiple-nodular type had clear margins. The vessels such as mesenteric vessels, renal vessels, abdominal aorta, and inferior vena cava could be imbedded by the fused multiple enlarged lymph nodes forming the unique "vascular-imbedded signs"[5,6], which were commonly seen in multiple-nodular type. The "duodenal-imbedded signs", named by us and found in multiple-nodular type, could be induced by LALN due to rich lymphoid tissues in the horizontal segment of the duodenum, which was different from intestinal lymphomas in CT manifestations. The former was marked by narrowing of the intestinal cavity surrounded by the fusion of multiple small nodular lesions with a streak appearance and the latter was manifested as circular thickening of intestinal wall and sometimes complicated with intestinal distension. Therefore, "intestinal-imbedded signs" have an important value for the diagnosis of LALN, although this was not reported in previous documents.

The CT features of diffuse type were diffuse but non-confluent enlarged lymph nodes in the mesenteric and retroperitoneal region with uniform density and cobblestone appearance, named as "cobblestone signs". It has an important value for the diagnosis of diffuse type of LALN because it has not been seen in other diseases. Moreover, the retroperitoneal lymph nodes below the level of lumbar 2-3 vertebrae were frequently involved (HD 94%, NHL 89%, respectively), which is of great importance in the differential diagnosis with tuberculous lymph nodes [1,6].

The above classification of CT manifestations into 3 types in LALN can not only help in the radiographic diagnosis of LALN but also guide the clinical management of LALN, e.g. the scope of radiotherapy.

LALN is frequently associated with abdominal extra-nodular lymphomas, and about 54% patients had gastrointestinal tract involvement[4]. This is of significance in the diagnosis of LALN, particularly lymphomas of the gastrointestinal tract, which have a high morbidity and show characteristic circular thickening of gastrointestinal wall with notable distension of intestinal cavity on CT. More than half of the patients in this series were associated with gastrointestinal lymphomas. In addition, the association with other solid organ lymphomas such as the liver and spleen is also helpful for the diagnosis. The peritoneum and omentum are seldom involved by LALN[7-11]. There were 2 cases in this series and CT showed a large amount of ascites and omental cakes.

CT findings of HD are different from those of NHL. According to the literature and this report[6,14], we summarize the differences as follows: The enlarged lymph nodes of HD are rarely seen in the mesentery, less than 5%[14], 8.3% in this paper, with a small number of small lesions distributed dispersedly. The confluence of enlarged lymph nodes of HD is seldom seen (16.7%), which mainly occurs in multiple-nodular type (60%). NHL has a wide distribution including all sites of abdominal lymph nodes, and the mesentery is frequently involved (45%). The fusion of enlarged lymph nodes is common (60%), showing vessel-imbedded signs, intestinal-imbedded signs and cobblestone signs. NHL is seen not only in the multiple-nodular type (60%), but also in nearly all of the diffuse type and solitary type (22.5%, 17.5%, respectively).

The CT manifestations of LALN before radio-chemotherapy are different from those of LALN after treatment[22], including reductions in extent of lesions and changes in internal nodal characteristics. The CT features of LALN after treatment are characterized by the reduction in the number of enlarged lymph nodes and the shrinkage of lesions. Though most enlarged lymph nodes remain uniform density on CT, an evident increase in heterogeneous or rim enhancement of lesions may occur due to intra-nodular necrosis after treatment and calcifications of lesions may occur in individual cases[5]. The results of this series revealed that 20% lesions disappeared after radio-chemotherapy and most of these occurred in multiple-nodular type with relative concentration of enlarged lymph nodes. Therefore, CT is valuable for the evaluation of therapeutic efficacy of radio-chemotherapy and helps guide the following treatment.

### *Differential diagnosis of LALN*

**Lymph node tuberculosis:** Lymph node tuberculosis may be easily confused with lymphomas and should be considered emphatically. Lesions of lymph node tuberculosis are relatively concentrated (non-hematogenous disseminated type) and the mesenteric lymph nodes are commonly involved. CT shows rim or multilocular enhancement of enlarged lymph nodes, and sometimes with intra-nodular calcifications. This disease is often associated with tuberculous peritonitis, which has characteristic signs of omental cakes, smudged mesentery signs and high-density ascites. LALN is relatively disperse and the mesenteric lymph nodes are not commonly involved in HD. CT shows homogenous enhancement of lymph node enlargement with fewer calcifications (only 0.84%) in untreated cases[12-13] and peritoneal and omental lymphomatosis is not often seen. In addition, rim enhancement of enlarged lymph nodes of LALN (including before and after radio-chemotherapy) on CT is different from that of lymph node tuberculosis. The lesions of LALN with clear margins and multilocular enhancement are not often found.

**Metastatic tumor:** The occurrence of abdominal lymph node metastasis usually follows the development of a

primary tumor. The enlarged lymph nodes are located near the primary lesion, showing heterogeneous or rim enhancement due to necrosis of lymph nodes, with frequent occurrence of ascites. Neither tuberculous lymph nodes nor metastatic lymphadenopathy has blood vessel-imbedded signs, intestinal-imbedded signs, or cobblestone signs.

In summary, LALN has three kinds of CT manifestations and each kind has some unique features valuable for qualitative diagnosis of LALN. CT is also helpful for the pathological classification of LALN and the therapeutic evaluation in follow-up.

## Abstract

A 58-year-old female with a recurrent history of upper abdominal pain and intermittent dysphagia underwent endoscopic evaluation that demonstrated an irregular and nodular esophago-gastric (EG) junction and grade Ⅰ erosive esophagitis. Biopsies showed prominent intestinal metaplasia of Barrett's type without dysplasia, chronic inflammation and multiple aggregates of large cells within the mucosal lamina propria, some with spindle shaped nuclei. Immunohistochemistry stains for keratins AE-1/AE-3 were negative, while S-100 and NSE were positive. This, together with routine stains, was diagnostic for mucosal ganglioneuromatosis. The background of chronic inflammation with intestinal type metaplasia was consistent with long-term reflux esophagitis. No evidence of achalasia was seen. Biopsies of gastric antrum and fundus were unremarkable, without ganglioneural proliferation. Colonoscopy was unremarkable. No genetic syndromes were identified in the patient including familial adenomatous polyposis and multiple endocrine neoplasia type Ⅱb (MEN Ⅱb). Iansoprazole (Prevacid) was started by oral administration each day with partial relief of symptoms. Subsequent esophagogastroscopy repeated at 4 mo showed normal appearing EG junction. Esophageal manometry revealed a mild non-specific lower esophageal motility disorder. Mild motor dysfunction is seen with gastro-esophageal reflux disease (GERD) and we feel that the demonstration of localized ganglioneuromatosis was not likely related etiologically. In the absence of findings that might suggest neural hypertrophy, such as achalasia, the nodular mucosal irregularity seen with this instance of ganglioneuromatosis may, however, have exacerbated the patient's reflux.

## INTRODUCTION

This paper presents a solitary ganglioneuroma of the esophago-gastric junction in a 58-year old woman with a chief complaint of recurrent bouts of abdominal pain and mild dysphagia over several years and a recent onset of diarrhea. There are several primary esophageal tumors, which show neuroid differentiation, most arising from innate innervations of the esophagus.

These may be solitary or disseminated with Schwann cell and ganglion cell components involving any portion of the gastrointestinal tract. Cases may demonstrate either an exophytic polypoid or endophytic configuration and tend to arise from the neural plexus in the bowel wall. Non-neoplastic neural proliferations involving the esophagus include achalasia with inflammation and localized neural proliferation, which closely mimics ganglioneuromatosis. Neoplastic neural tumors that can involve the esophagus include ganglioneuroma, gastrointestinal autonomic nerve tumor (GAN), schwannoma, neurofibroma, granular cell tumor; and gangliocytic paraganglioma. Ganglioneuroma is a benign tumo, and the solitary variant may be cured by excision. Lesions in syndromic ganglioneuromatosis may require more extensive surgery.

## CASE REPORT

### *Clinical presentation*

The patient is a 58-year old Caucasian woman who presented with a complaint of recurrent bouts of abdominal pain, mild dysphagia over several years and recent onset of diarrhea. Previous medical history was significant for hyperlipidemia, insulin dependent diabetes mellitus, coronary artery disease, pancreatitis and diagnosed meningioma. Previous surgical history included cholecystectomy, appendectomy, cervical spine

fusion and celiac axis stenting. Medicactions prior to endoscopic biopsy of esophagogastric EG junction included the following: Atorvastatin, pioglitazone HCl, diphenhydramine, Glipizide, Pyridoxine, isosobide and dihydrocodeinone.

### *Endoscopic and microscopic findings*

Endoscopy showed a somewhat nodular and irregular appearing EG junction with non-erosive mucosa (Figure 1). The antrum showed mild non-erosive gastritis. The pylorus and duodenum were unremarkable. Biopsies of the EG junction, antrum and duodenum were obtained. Hematoxylin and Eosin stained histologic sections from the EG junction showed aggregates of tangled fascicles of large cells mixed with Schwann like spindle cells expanding lamina propria (Figure 2). At low magnification this gave a pseudo granuloma appearance with distortion of the adjacent gland architecture. Higher magnification revealed a fibrillar cytoplasmic matrix with monomorphic bland nuclei without mitotic activity. Differential diagnosis for these features included ganglioneuroma, neurofibroma and schwannoma[1]. Immunohistochemical staining for S100 demonstrated a nerve sheath component. Focal positivity for Synaptophysin confirmed the presence of a ganglioneuronal tissue (Figure 3). The glandular epithelial component showed frequent goblet cells with no evidence of dysplasia. Chronic inflammatory cells were scattered in mucosal stroma. The biopsy diagnosis based on both HE and immunophenotypic characterization was of localized ganglioneuromatosis of EG junction within a background of mild chronic inflammation and prominent intestinal metaplasia without dysplasia.

### *Treatment and follow-up*

Clinical correlation excluded the presence of achalasia or MEN-ⅡB. Treatment following this diagnosis of localized ganglioneuroma associated with esophagitis included prevacid 30 mg daily. Neurontin had been considered if symptoms would have progressed; however, this was not the case. A follow-up observation with repeat endoscopic evaluation at 4 mo was performed and showed mild gastritis with mild chronic inflammation in an unremarkable EG junction without ulceration or nodularity. Early recognition of symptomatology that might suggest either lower esophageal sphincter (LES) dysfunction or esophageal dysmotility was reviewed with the patient. No other family members were symptomatic or presented a history that might suggest hereditary or familial factors. Colonoscopy showed no discrete lesions.

Except for occasional bouts of mild non-specific abdominal pain and mild dysphagia, the patient remained well for a year. There was no complaint, odynophagia or nausea. Esophageal manometry was performed for persistent dysphagia at one year following the initial biopsy. This demonstrated a distal esophageal amplitude of 106 mm mercury with a duration of 3.5 s, peristaltic contraction 90% with 10% simultaneous contractions. Detailed review of the manometric data suggested a mild non-specific lower esophageal motility disorder.

In the absence of changes that might suggest neural hypertrophy, occasionally seen with achalasia, the mild motor dysfunction in this patient may be related to GERD. The demonstration of localized ganglioneuromatosis was most likely fortuitous and not etiologically related to the gastroesophageal reflux. However, the patient's insulin dependant diabetes might have affected esophageal motility possibly associated with an increased incidence of reflux.

It is most likely that the generous biopsy sampling of the nodular EG may have removed a significant portion of the lesion; therefore, it was not overtly visible on the subsequent endoscopy.

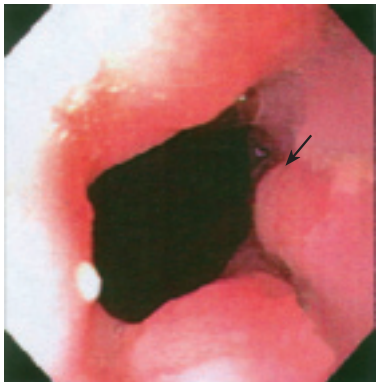

**Figure 1** Initial endoscopic image of localized nodularity in esophageal mucosal surface with irregular Z-line.

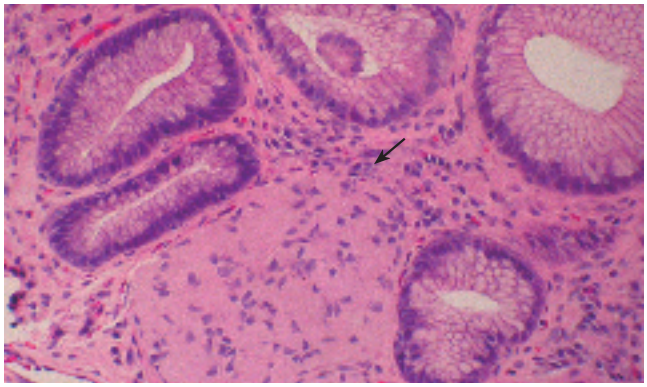

**Figure 2** Hematoxylin and eosin stained tissue section of biopsy from irregular EG-Junction showing neuroid proliferation within lamina propria (× 10).

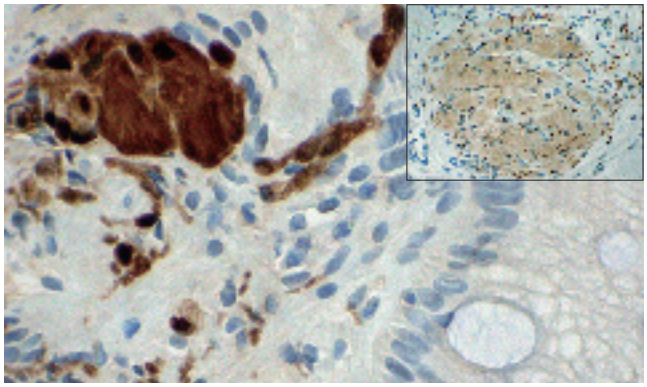

**Figure 3** Focal positivity for synaptophysin (insert × 10) confirms the presence of a neuronal (ganglio) component. S100 (× 20) confirms nerve sheath-neuromatous/ neuromatosis component.

## DISCUSSION

Primary esophageal tumors that show neuroid differentiation in addition to ganglioneuromata, include gastro-intestinal autonomic nerve tumor (GAN)[2,3], schwannoma[4,5] (some occasionally showing melanocytic differentiation)[6], and neurofibromas[7]. The innervation of the lower esophagus includes parasympathetic supply from the vagi and sympathetic innervation from the greater splanchnic and thoraci ganglia[8]. Histologically the neural components are seen within the muscle layer as myenteric plexus and in the submucosal neural plexus with branches entering the lamina propria[9].

Solitary or disseminated Schwann cell and ganglion cell proliferation anywhere in the gastrointestinal tract may appear as small intramucosal nodular lesions[10], exophytic polypoid lesions, or poorly demarcated transmural proliferations[11]. Ganglioneuroma, a fully differentiated tumor with no immature components[12], may occur as a solitary lesion (sporadic) or as multiple lesions called ganglioneuromatosis and may be associated with other diseases (syndromic).

Sporadic ganglioneuroma has been unknown to be associated with genetic syndromes and has been detected in patients of all ages with a mean age of 50 years. The majority of the solitary lesions are asymptomatic and, therefore, found incidentally, most frequently in the left colon[13].

Among the cases of multiple lesions, ganglioneuromatosis of an exophytic polypoid type (ganglioneuromatous polyposis) is characterized by interposition of neural proliferations with glandular components and is usually associated with familial adenomatous polyposis and multiple cutaneous lipomas. Ganglioneuromatosis of transmural proliferation type arising from the neural plexus in the bowel wall is frequently associated with other tumors, including MEN Ⅱb (medullary carcinoma thyroid, pheochromocytoma, oral-mucosal neuromas and skeletal deformities)[14], multiple ganglioneuromas and neurofibromas of the gastrointestinal tract, von Recklinghausen's disease, and neurogenic sarcoma[15]. Florid hyperplasia of submucosal or myenteric plexus is distinct for intramural ganglioneuromatosis and occurs with type Ⅰ neurofibromatosis[16]. Patients with syndromic ganglioneuromatosis present with symptoms, and the lesions are found much earlier in life, with a mean age approximately 35 years. There is no gender predominance in the incidence of this disease.

Non neoplastic neural proliferations involving the esophagus include achalasia, which is an esophageal motor disorder associated with a loss of myenteric ganglion cells with inflammation and secondary changes including neural proliferation, which closely mimics ganglioneuromatosis[17]. Neoplastic neural tumors that can involve the esophagus include ganglioneuroma, GAN, schwannoma, neurofibroma and other less prevalent forms like granular cell tumor with large eosinophilic cells[18]; gangliocytic paraganglioma showing predominantly spindle shaped cells with both ganglion and neuroendocrine features (more often seen in duodenum)[19]. Ganglioneuromatosis is visibly present throughout the gut showing predominantly spindle shaped neural proliferations with frequent ganglion type cells.

Ganglioneuroma is a benign tumor and the solitary variant may be cured by excision of the nodular lesion or complete polypectomy. Lesions in syndromic ganglioneuromatosis may require surgery, but the patient may die from the associated syndromes.

In summary, this case illustrates an instance of sporadic ganglioneuromatosis involving EG junction in a 58-year old female with a recurrent history of upper abdominal pain. Background of chronic inflammation and intestinal type metaplasia suggested that the symptoms were related to reflux esophagitis, possibly exacerbated by the nodular growth of the ganglioneuromatosis, which involved the gastro-esophageal junction. The attendant mild lower esophageal motility disorder (demonstrated by manometry) may reflect nonspecific reflux disorder. The patient was initially treated with Iansoprazole (Prevacid), which resulted in a partial relief of symptoms. This was followed by esomeprazole (Nexium) with additional relief of symptoms. The patient continued to experience mild intermittent dysphagia without odynophagia or nausea. Repeat EG endoscopy at 4 mo showed unremarkable GE junction. The importance of recognizing symptomatology indicative of lower esophageal sphincter dysfunction was reviewed with this patient with a discussion of follow-up studies over time[20]. It appears that the initial generous biopsy sampling removed the EG tumor nodularity, and this, together with the anti-acid treatment, decreased the intensity of the reflux esophagitis. Following the manometric study the patient was advised to swallow slowly with at least 30 s intervals, avoid beverages with extreme temperatures and was maintained on her current medications. We believe that although not etiologically associated, localized esophageal ganglioneuromatosis may exacerbate aspects of gastro-esophageal reflux disorder.

## Abstract

Osteoclast-like giant cell tumors (OGCT) are rare abdominal tumors, which mainly occur in the pancreas. The neoplasms are composed of two distinct cell populations and frequently show an inhomogenous appearance with cystic structures. However, due to the rarity of these tumors, only very limited clinical data are available. Imaging features and sonographic appearance have hardly been characterized. Here we report on two cases of osteoclast-like giant cell tumors, one located within the pancreas, the other within the liver, in which OGCTs are extremely rare. Both patients were investigated by contrast sonography, which demonstrated a complex, partly cystic and strongly vascularized tumor within the head of the pancreas in the first patient and a large, hypervascularized neoplasm with calcifications within the liver in the second patient. The liver OGCT responded well to a combination of carboplatin, etoposide and paclitaxel. With a combination of surgical resection, radiofrequency ablation and chemotherapy, the patient's survival is currently more than 15 mo, making him the longest survivor with an OGCT of the liver to date.

**Key words:** Osteoclast-like giant cell tumor; Liver cancer; Pancreatic cancer; Contrast sonography

## INTRODUCTION

Osteoclast-like giant cell tumors (OGCTs) have been described in several extraskeletal sites. Within the alimentary tract, these rare neoplasms mainly occur within the pancreas. Since the first description by Rosai in 1968[1] and further classification by Alguacil-Garcia and Weiland in 1977[2], there have been at least 38 publications describing approximately 60 occurrences of OGCTs in the pancreas[1-15], whereas only 12 liver tumors have been reported[16-27].

## CASE REPORTS

### *Case 1*

A 54-year-old man regularly visited his urologist because of prostate hyperplasia. After a renal ultrasound was suspicious of a tumor within the left kidney, computed tomography (CT) of the abdomen was performed. CT only showed a parenchyma bridge within the left kidney but surprisingly demonstrated a 7 cm large inhomogenous solid liver tumor involving segments Ⅱ and Ⅲ. The patient was then referred to our clinic. He had no clinical symptoms, no history of liver diseases and denied alcohol and tobacco consumption. His further medical history was remarkable for peripheral arterial disease, hypertension, esophageal reflux, hiatal hernia and sleep apnea.

Physical examinations revealed an obese male (173 cm, 92 kg, BMI: 31) with normal vital signs. His abdomen was soft and nontender. Serum chemistries were within the normal range except for a gamma-glutamyl transferase level of 69 IU/L (normal range < 55 IU/L) and normocytic, normochromatous anemia [hematocrit 0.38% (0.4%-0.52%)]. Serum alpha-fetoprotein, carcinoembryonic cancer antigen and cancer antigen 19-9 were normal. Serology for hepatitis A, B, and C was negative.

B-mode sonography (HDI 5000, Philips) demonstrated a well-defined, inhomogenous, cauliflower-like tumor with multiple small calcifications, causing retraction of the liver contour. Within the center of the tumor, a focal nodular hyperplasia (FNH)-like stellar scar was present (Figure 1A). Contrast-enhanced sonography by use of an Acuson Sequoia 512 (Siemens, Germany) with Sonovue® (2 mL; Bracco, Italy) using coded pulse sequences (CPS) and a low mechanic index (MI) demonstrated an inhomogenous perfused tumor with a large feeding artery heading towards the center of the tumor, radially branching to the periphery. During the capillary and arterial perfusion phase, non-perfused tumor areas indicative of necrotic areas were observed, making a focal nodular hyperplasia highly unlikely (Figure 1B). Diagnosis of haemangioma or adenoma was excluded by the spoke-like architecture of tumor arteries with centrifugal filling (Figure 1B). The portal perfusion phase was characterized by a rapid decrease of perfusion

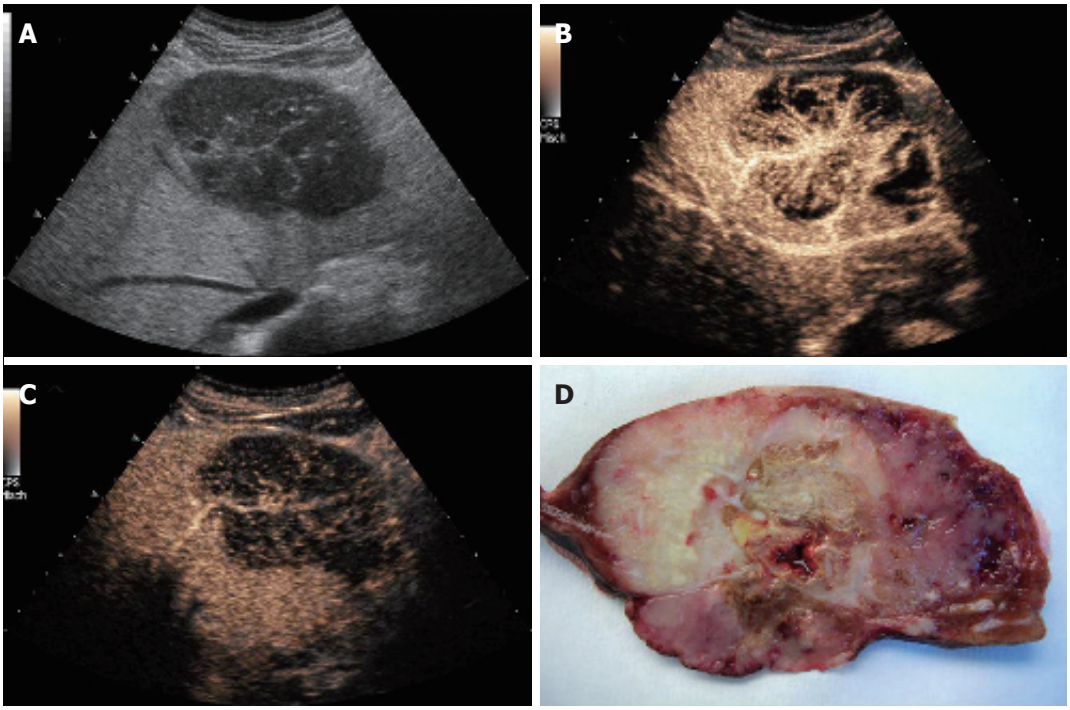

**Figure 1** Patient 1: Osteoclastic giant cell tumor of the liver: **A**: B-mode sonography (HDI 5000, Philips), contrast sonography during the **B**: arterial and **C**: portal phase (Siemens); **D**: resected tumor: cut surface shows distinct tumor areas with necrotic and hemorrhagic regions.

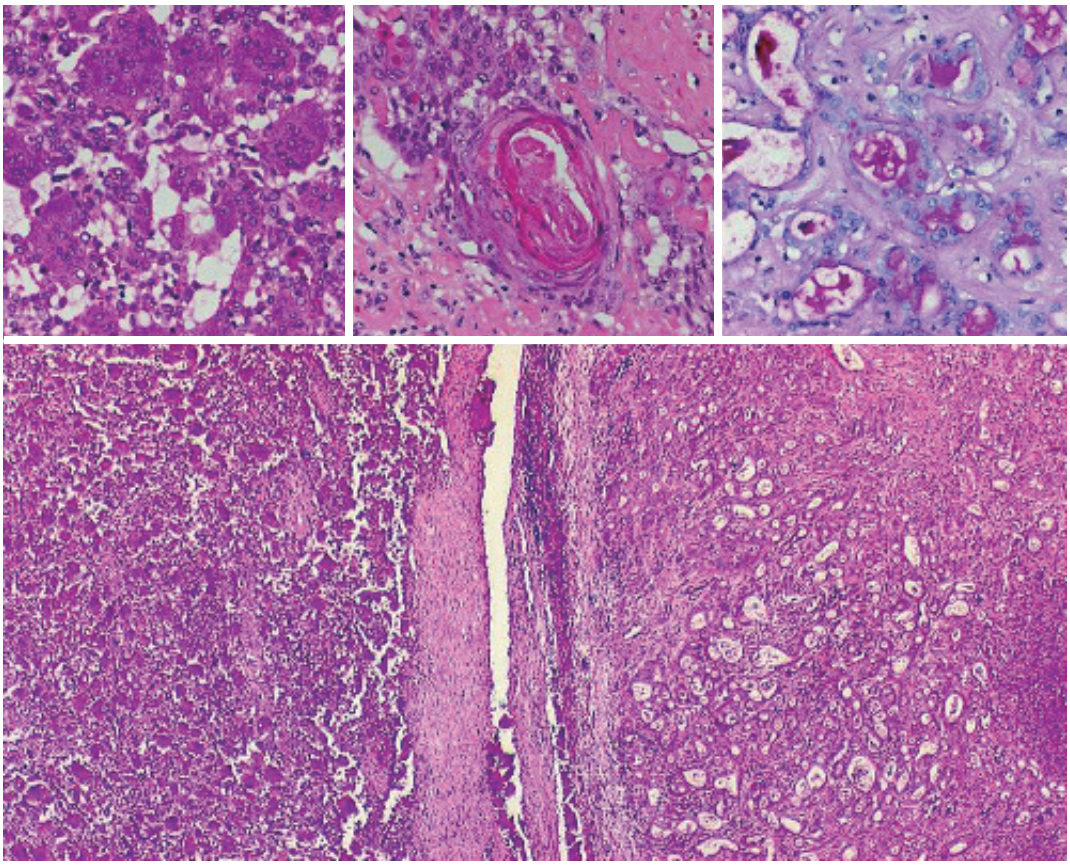

**Figure 2** Histology (HE, x 20-40) of OGCT of the liver with a mixed cell population of osteoclastic giant cells and pleomorphic mononuclear cells (left), adenocarcinomatous component with mucinous inclusions (PAS, upper right) and squamous cell differentiation (middle).

within the tumor (Figure 1C), indicating absence of portal vessels and thereby, together with the finding of a strong perfusion within the arterial phase, proving a malignant neoplasm.

Biopsy of the tumor was performed, demonstrating that the neoplasm was composed of pleomorphic mononuclear cells and scattered non-neoplastic osteoclast-like giant cells (OCGCs) with usually 10-20 uniformly small nuclei. Small mononuclear cells were differently characterized by cytological atypias and showed an increased number of mitoses with a proliferation rate of 70%. Focally there was an adenocarcinomatous component with mucinous inclusions and also areas of squamous cell differentiation (Figure 2). Immunofluorescence

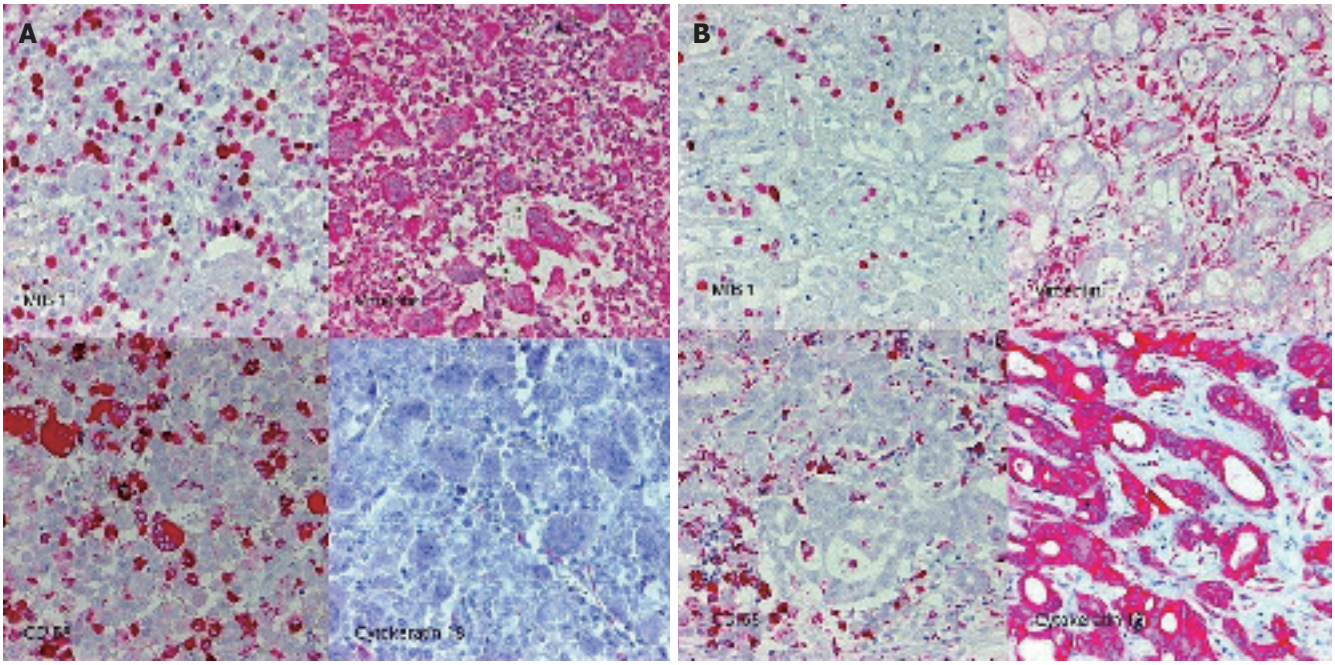

**Figure 3** Immunohistology of the OGCT of the liver. Panel **A**: mixed cell population of osteoclastic giant cells and pleomorphic mononuclear cells. demonstrated expression of vimentin within both OCGCs and mononuclear cells, expression of macrophage marker CD 68 within OCGC and negative staining for CK18 (Figure 3). The adenocarcinomatous tumor components demonstrated expression of CK18 but negative staining for CD 68 and vimentin (Figure 3). In conclusion, the histopathological diagnosis revealed an osteoclast-like giant cell tumor of the liver.

As extensive further diagnostic procedures including gastroscopy, colonoscopy, endoscopic ultrasound and bone scintigraphy showed no evidence of another tumor or metastases, surgical resection of liver segments Ⅱ and Ⅲ with excision of regional lymph nodes was performed. Macroscopic examination of the resected specimen revealed an irregular shaped firm mass measuring 8.5 cm with hemorrhage and necrosis (Figure 1D). All surgical margins were free of tumors. However, two lymph nodes (retroduodenal and at the hepatic artery) showed metastases of an adenocarcinoma.

As OGCT's are typically aggressive tumors with a short life-expectancy, adjuvant chemotherapy consisting of carboplatin 250 mg/m$^2$ (d 1), etoposide (alternating doses of 50 and 100 mg, d 1-10) and paclitaxel (175 mg/m$^2$, d 1) was initiated. However, 6 wk after resection, as the first chemotherapy had just been completed, a single metastasis in the right lobe of the liver was diagnosed. The metastasis was successfully treated by radiofrequency ablation. Chemotherapy was proceeded for 6 mo. After restaging revealed no evidence of active tumor disease, chemotherapy was stopped. However, 3 mo after cessation of chemotherapy, tumor recurrence (liver and peritoneal metastases) was observed and chemotherapy (carboplatin, etoposide, paclitaxel) restarted. Restaging after 6 wk revealed partial remission with size reduction of metastases of 50%. Chemotherapy is currently proceeded. The patient's survival since diagnosis has been 15 mo.

### *Case 2*

A 49-year-old man suffered from pain in the upper abdomen since 4 mo ago, which was independent of food intake. During this time, his appetite and body weight were unchanged, however, his physical performance was reduced. Abdominal ultrasound revealed a 3 cm cystic mass in the region of the body and tail of the pancreas. The patient was then referred to our clinic for further diagnosis.

At admission he presented in fairly well condition with normal body weight (186 cm, 82 kg, BMI: 21). His abdomen was soft and nontender without evidence of ascites or signs of liver disease. Laboratory work-up showed no pathologic results except for moderate normocytic and normochromatous anemia (Hct 0.36% [0.4%-0.52%]). Neuron-specific enolase was slightly elevated (19.2 μg/L [< 15.2]), carcinoembryogenic antigen (CEA) and cancer antigen (CA) 19-9 were normal. He had stopped smoking 2 years ago and reported only moderate alcohol consumption. His past medical history was unremarkable. His family history revealed prostate carcinoma of his father.

B-mode sonography in our clinic (HDI 5000, Philips) indicated rapid enlargement of the pancreatic neoplasia, which presented as a well-defined complex lesion with several cysts and solid parts and had grown from 3 to 5 cm within 5 wk (Figure 4A). Contrast sonography by use of an Acuson Sequoia 512 with Sonovue® and CPS/low-MI technique demonstrated an intensively perfused tumor with strong vascularized margins and septs (Figure 4B), excluding a ductal pancreatic carcinoma. Strong vascularised pancreatic neoplasms have primarily to be differentiated

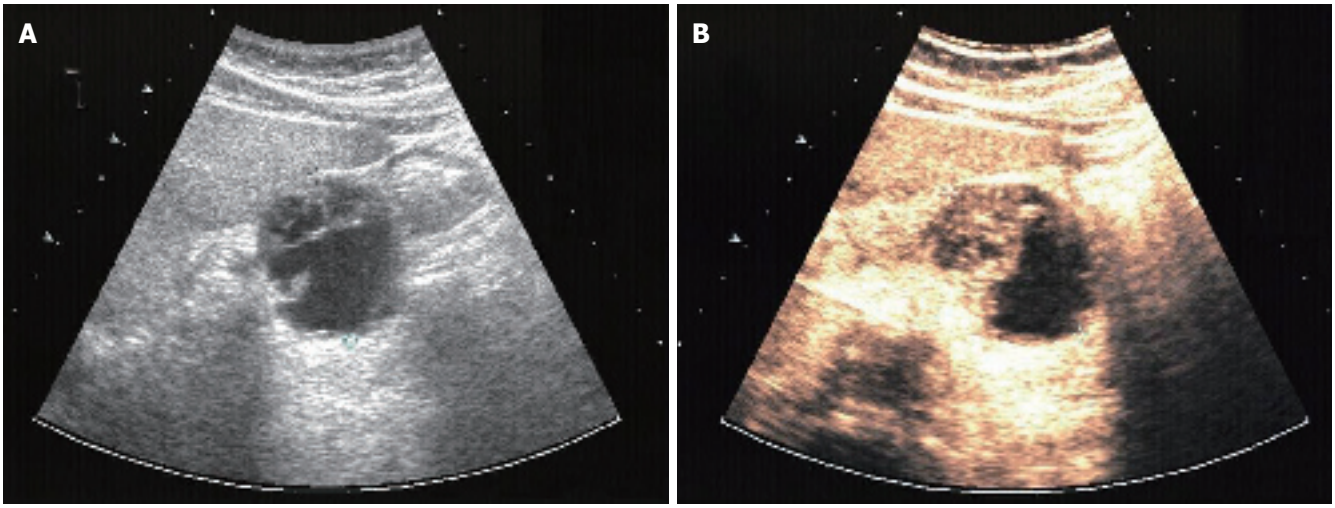

**Figure 4** Patient 2: osteoclastic giant cell tumor of the pancreas. **A**: B-mode (HDI 5000, Philips) and **B**: contrast sonography (Sonovue®, low MI/CPS, Acuson Sequoia 512).

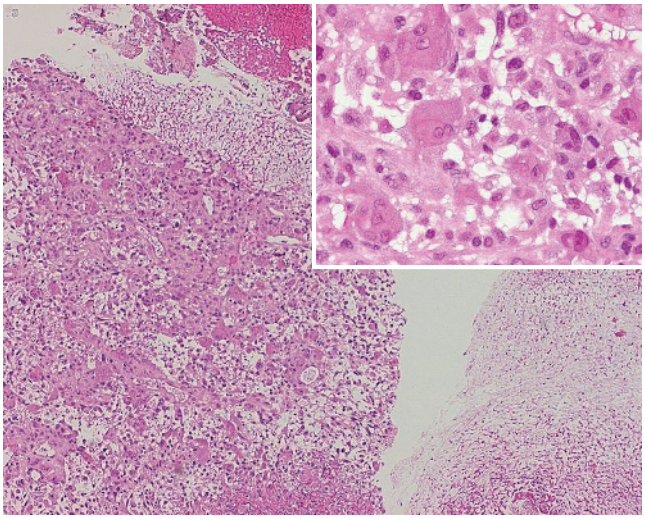

**Figure 5** Histology (HE, x 20-40) of OGCT of the pancreas with a mixed cell population of osteoclastic giant cells and pleomorphic mononuclear cells (left) and myxoid tumor areas (right).

from neuroendocrine tumors of the pancreas and from cystadenomas, which may also demonstrate strong vascularisation. However, malignant diseases become apparent after liver sonography. B-mode sonography demonstrated two complex nodular structures of 1 and 3 cm. Contrast sonography showed intensively perfused lesions with necrotic areas without portal perfusion, indicating metastases.

Biopsy revealed that the neoplasm was composed of pleomorphic mononuclear cells and scattered non-neoplastic osteoclast-like giant cells (OCGCs) with multiple uniformly small nuclei. OCGC's occasionally contained phagocytosed mononuclear cells. Immunohistochemically, the OCGC's were negative for cytokeratin but positive for vimentin and CD 68. Immunohistology of the pleomorphic cells demonstrated expression of vimentin, negative staining for cytokeratin and a proliferation rate of 30% (MIB-1). In conclusion, the histopathological diagnosis indicated osteoclast-like giant cell tumor of the pancreas (Figure 5).

As surgical resection was not possible, the patient received palliative chemotherapy with cisplatin 80 mg/m$^2$ (d 1), etoposide (100 mg/m$^2$, d 1, 3, 5) and ifosfamide (2 g/m$^2$, d 1-3) (PEI). After completion of three cycles of PEI, partial remission with significant size reduction of liver metastases was achieved. Thirteen mo after diagnosis chemotherapy is currently proceeded.

## DISCUSSION

Osteoclast-like giant cell tumors typically display an inhomogenous macroscopic appearance with cystic-liquid and necrotic areas and parenchymatous and calcified parts. Histologically, this mixed macroscopic structure corresponds to heterogeneous tissue structures of epithelial or undifferentiated tumor cells, which may contain foci of conventional adenocarcinoma, focal cartilagenous differentiation and bone formation[2,6,7,9]. The tumors are composed of two distinct cell types: a mononuclear cell population and in addition, osteoclastic tumor giant cells of uncertain lineage. The exceptional morphology and origin of the different cell types has been a matter of controversy since its first description in 1968. Recent evidence indicates that only the mononuclear cells constitute neoplastic tumor cells and that osteoclastic giant cells develop from secondary infiltrating cells.

Formation of osteoclast-like giant cells (OCGC) is speculated to result from fusion of bone-marrow derived mononuclear histiocytes/macrophages attracted to the tumor by chemotactic factors produced by the neoplastic cells[7,9,12,13]. Indeed, the CD-68/lysozyme reactivity of OCGCs suggests a histiocytic origin. Lack of mitoses and MIB-1 reactivity indicates a terminal stage of differentiation and non-neoplastic nature of the osteoclast-like giant cells, which are also K-ras negative[11]. Moderate staining of OCGCs with epithelial markers[20,25] is now explained by immunoreactivity of phagocytosed epithelial tumor cells[11,27]. The infiltrating mononuclear cells display

pleomorphism and neoplastic features and sometimes show features of epithelial tumors. However, other OGCTs lack epithelial differentiation[9,27]. Consequently, the term undifferentiated carcinoma with osteoclast-like giant cells has been proposed to more precisely describe these aggressive tumors.

Probably due to rapid tumor growth, osteoclast-like giant cell tumors of the pancreas only rarely present as small neoplasms. In more than 50 cases, in which tumor size was documented, only three neoplasias measured less than 3 cm. Typically OGCTs present as large tumors with cystic structures and necroses. The cystic component can become predominant, so that lesions may be misdiagnosed as pancreatic pseudocysts[3,4]. At time of diagnosis, more than 80% of tumors were already greater than 5 cm, 50% even greater than 10 cm. Most tumors arise in the head or body of the pancreas[1-15].

The differential diagnosis of pancreatic OGCTs includes cystic lesions like pancreatic cystadenomas, cystadenocarcinomas, serous and mucinous cystic tumors, pancreatic pseudocysts and also solid pancreatic tumors like ductal pancreatic carcinomas or neuroendocrine tumors. Solid tumors may be homogenous on computed tomographic imaging; however, they can also be very inhomogenous, as focal hemorrhage or necrosis is frequently found[9,12,15]. Vascularisation of these neoplasias has been described only in single cases. In one well-characterized patient, the tumor wall was slightly enhanced on contrast-enhanced CT[13]. Selective angiography demonstrated slight tumor staining[13].

In our patient with a pancreatic OGCT, contrast-enhanced sonography demonstrated a strong vascularisation within both the tumor and the liver metastases, making a pancreatic ductal carcinoma, which is typically only poorly vascularised, highly unlikely. A strong vascularised pancreatic neoplasm has to be differentiated from neuroendocrine tumors of the pancreas and from cystadenomas, which may also demonstrate strong vascularisation. In contrast, cystadenocarcinomas are generally poorly vascularised[28]. However, further studies are necessary to evaluate whether intense perfusion is a characteristic feature of OGCTs.

Osteoclast-like giant cell tumors of the liver are also generally large and inhomogenous neoplasias, ranging from 5 to 12 cm in size. Tumors typically feature necrotic or hemorrhagic regions and may also show cystic structures[16-27]. As published reports mainly focused on histopathology, radiological findings have only been documented in single cases. Magnetic resonance imaging in one case demonstrated a 10 cm large, fairly well circumscribed heterogenous solid mass with multiple fluid-like regions representing cystic components or necrosis on T1-weighted images[25]. Positron emission tomography scan in the same patient showed fluorine-18 fluorodeoxyglucose-uptake within the tumor[25]. In another patient, computed tomography described a 6 cm homogenous and hypervascularised tumor, which after resection presented as an inhomogenous tumor with hemorrhagic and necrotic areas[26].

In our patient, the liver tumor presented as an inhomogenous, cauliflower-like tumor with multiple small calcifications and a central stellar scar. However, contrast sonography revealed non-perfused tumor areas during the capillary and arterial perfusion phase, indicating necroses, thereby making a focal nodular hyperplasia highly unlikely[29,30]. Diagnosis of hemangioma or adenoma could be excluded by the spoke-like architecture of tumor arteries with centrifugal filling. The portal perfusion phase was characterized by a rapid decrease of perfusion within the tumor, indicating absence of portal vessels and thereby, together with the finding of a strong perfusion within the arterial phase, proving a malignant neoplasm[29,30].

A hepatocellular carcinoma was very unlikely, as the tumor demonstrated a very unusual vascular architecture and because there were no signs of cirrhosis. According to sonographic morphology and vascularisation pattern, the differential diagnosis included malignant primary liver tumors like peripheral cholangiocarcinoma (which, however, typically are poorly vascularized and do not show cysts or necroses), fibrolamellar carcinoma, epithelial hemangioendothelioma (which generally shows a multinodular structure) and a metastasis. However, a definitive sonographic diagnosis was impossible.

The average age of patients with osteoclast-like giant cell tumors of both pancreas and liver is around 60 years, ranging from 28 to 88 years. In pancreatic OGCTs, males and females appear to be affected in a fairly equal ratio[9,13]. The main symptoms are abdominal pain or discomfort and weight loss. Jaundice also frequently occurs if the tumor is located in the head. In cases of great cystic tumors, a palpable mass may be found. Invasion into adjacent structures is common. Nodal or intra-abdominal metastases are found in approximately 50% of patients at the time of diagnosis[1-15]. Overall, the prognosis of pancreatic OGCTs is unfavorable. As patients usually present with advanced diseases, complete resection can only rarely be performed. Leighton and Shiozawa reviewed 20 and 32 cases of pancreatic tumors, respectively, and determined the median survival rates to be less than 1 year. Interval to death or disease progression ranged from 4 mo to 5 years in these series[12,13]. In one patient, long-term survival of 15 years was documented; however, tumor recurrence within the pancreas after 10 years has also been reported[8]. Overall, the prognosis of pancreatic OGCTs is comparable to that of common ductal pancreatic carcinomas[12].

In contrast to pancreatic manifestations, OGCTs of the liver have been mostly described in male patients. Ten of 12 tumors (in one publication no data on patient's age and sex were reported)[27] occurred in men. The overall prognosis of OGCTs of the liver seems to be even worse than for pancreatic cases. Previous reports have demonstrated that these tumors are uniformly very aggressive and that survival ranges from 1 to 10 mo[16-26]. To date, there is only one report of chemotherapy and radiotherapy in the management of osteoclast-like giant cell tumors. Hood *et al* treated a patient with recurrent liver tumor with a combination of chemotherapy (5-fluorouracil and adriamycin), external beam radiation and radioimmunotherapy ($I^{131}$-labeled antiferritin immunoglobulin [IgG]), but could only achieve a partial response for several months[20]. In our case, the liver OGCT responded well to a combination

of carboplatin, etoposide and paclitaxel. With a combination of surgery, local ablative therapy and chemotherapy, our patient is currently the longest survivor reported. Due to epithelial features of the mononuclear neoplastic cells in some patients, agents like gemcitabine have been suggested as adjuvant or palliative therapy. As histology in our patients demonstrated undifferentiated tumors in both cases, we chose a polychemotherapy with cisplatin, etoposide and ifosfamide (PEI) and carboplatin, etoposide and paclitaxel, respectively. After three cycles of PEI, partial remission was observed in the patient with pancreatic OGCT. In the other patient with an OGCT of the liver, early tumor recurrence within the right lobe of the liver was observed 6 wk after surgical resection.

In conclusion, the histopathological features of these rare tumors have been precisely described in recent years, providing the basis for correct histological classification. OGCTs should also be included in the sonographic differential diagnosis of tumors of the pancreas and liver. B-mode sonography, as well as arterial perfusion of a liver OGCT resembles those of an FNH, reflecting its hepatic origin. However, demarcation of hemorrhagic necroses during the arterial and capillary phase together with a missing increase of signal intensity in comparison to the surrounding liver tissue during the portal and late phases allows exclusion of an FNH and diagnosis of a malignant neoplasm. For optimization of chemotherapy and other treatment strategies of osteoclast-like giant cell tumors, future studies should not only focus on histopathologic features, but also on diagnostic and therapeutic approaches.

*ACKNOWLEDGMENTS*

# Acknowledgments to Reviewers of *World Journal of Gastroenterology*

Many reviewers have contributed their expertise and time to the peer review, a critical process to ensure the quality of *World Journal of Gastroenterology*. The editors and authors of the articles submitted to the journal are grateful to the following reviewers for evaluating the articles (including those were published and those were rejected in this issue) during the last editing period of time.

**Fernando Alvarez, Professor**
Service de gastroentérologie, hépatologie et nutrition, Hôpital Sainte-Justine, 3175 Côte Ste-Catherine, Montréal, Québec, Canada H3T 1C5, Canada

# Meetings

## MAJOR MEETINGS COMING UP

First Biennial Congress of the Asian-Pacific Hepato-Pancreato-Biliary Association
March, 2007
Fukuoka, Japan
http://www.congre.co.jp/1st-aphpba

American College of Gastroenterology Annual Scientific
20-25 October 2006
Las Vegas, NV

14th United European Gastroenterology Week, UEGW
21-25 October 2006
Berlin, Germany

APDW 2006: Asian Pacific Digestive Week 2006
26-29 November 2006
Lahug Cebu City, Philippines

## EVENTS AND MEETINGS IN THE UPCOMING 6 MONTHS

Falk Symposium 151: Emerging Issues in Inflammatory Bowel Diseases
24-25 March 2006
Sydney - NSW
Falk Foundation e.V.
symposia@falkfoundation.de

10th International Congress of Obesity
3-8 September 2006
Sydney
Event Planners Australia
enquiries@ico2006.com
www.ico2006.com

Easl 2006 - the 41st annual
26-30 April 2006
Vienna, Austria
Kenes International

Prague hepatology 2006
14-16 September 2006
Prague
Foundation of the Czech Society of Hepatology
veronika.revicka@congressprague.cz
www.czech-hepatology.cz/phm2006

12th International Symposium on Viral Hepatitis and Liver Disease
1-5 July 2006
Paris
MCI France
isvhld2006@mci-group.com
www.isvhld2006.com

Falk Symposium 152: Intestinal Disease Part I, Endoscopy 2006 - Update and Live Demonstration
4-5 May 2006
Berlin
Falk Foundation e.V.
symposia@falkfoundation.de

Falk Symposium 153: Intestinal Disease Part II, Immunoregulation in Inflammatory Bowel Disease - Current Understanding and Innovation
6-7 May 2006
Berlin
Falk Foundation e.V.
symposia@falkfoundation.de

ILTS 12th Annual International Congress
3-6 May 2006
Milan
ILTS
www.ilts.org

Internal Medicine: Gastroenterology
22 July 2006-1 August 2006
Amsterdam
Continuing Education Inc
jbarnhart@continuingeducation.net

6th Annual Gastroenterology And Hepatology
15-18 March 2006
Rio Grande
Office of Continuing Medical Education

# Instructions to authors

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*WJG, World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

### *Indexed and abstracted in*

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### *Published by*

The WJG Press

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

### *Online submission*

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

### *Postal submission*

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

### Editorial Office

***World Journal of Gastroenterology***
Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com
Telephone: +86-10-85381901
Fax: +86-10-85381893

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### *Title page*

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

### *Abstract*

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

### *Key words*

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

### *Text*

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

### *Illustrations*

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

### *Tables*

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### *Notes in tables and illustrations*

Data that are not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ should be noted ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used. Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under

illustrations should be expressed as $^1F$, $^2F$, $^3F$; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

### *Acknowledgments*

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### *Coding system*

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24 ], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### *PMID requirement*

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (http://www.wjgnet.com/cgi-bin/index.pl), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### *Style for journal references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (http://www.aushome.cn/cgi-bin/index.pl)

### *Style for book references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### *Format*

**Journals**

*English journal article (list all authors and include the PMID where applicable)*

1 **Grover VP**, Dresner MA, Forton DM, Counsell S, Larkman DJ, Patel N, Thomas HC, Taylor-Robinson SD. Current and future applications of magnetic resonance imaging and spectroscopy of the brain in hepatic encephalopathy. *World J Gastroenterol* 2006; **12**: 2969-2978 [PMID: 16718775]

*Chinese journal article (list all authors and include the PMID where applicable)*

2 **Lin GZ**, Wang XZ, Wang P, Lin J, Yang FD. Immunologic effect of Jianpi Yishen decoction in treatment of Pixu-diarrhoea. *Shijie Huaren Xiaohua Zazhi* 1999; **7**: 285-287

*In press*

3 **Tian D**, Araki H, Stahl E, Bergelson J, Kreitman M. Signature of balancing selection in Arabidopsis. *Proc Natl Acad Sci U S A* 2006; In press

*Organization as author*

4 **Diabetes Prevention Program Research Group**. Hypertension, insulin, and proinsulin in participants with impaired glucose tolerance. *Hypertension* 2002; **40**: 679-686 [ PMID: 12411462 ]

*Both personal authors and an organization as author*

5 **Vallancien G**, Emberton M, Harving N, van Moorselaar RJ; Alf-One Study Group. Sexual dysfunction in 1, 274 European men suffering from lower urinary tract symptoms. *J Urol* 2003; **169**: 2257-2261 [PMID: 12771764]

*No author given*

6 21st century heart solution may have a sting in the tail. *BMJ* 2002; **325**: 184 [PMID: 12142303]

*Volume with supplement*

7 **Geraud G**, Spierings EL, Keywood C. Tolerability and safety of frovatriptan with short- and long-term use for treatment of migraine and in comparison with sumatriptan. *Headache* 2002; **42** Suppl 2: S93-99 [PMID: 12028325]

*Issue with no volume*

8 **Banit DM**, Kaufer H, Hartford JM. Intraoperative frozen section analysis in revision total joint arthroplasty. *Clin Orthop Relat Res* 2002; (**401**): 230-238 [ PMID: 12151900 ]

*No volume or issue*

9 Outreach: bringing HIV-positive individuals into care. *HRSA Careaction* 2002; 1-6 [PMID: 12154804 ]

**Books**

*Personal author(s)*

10 **Sherlock S**, Dooley J. Diseases of the liver and billiary system. 9th ed. Oxford: Blackwell Sci Pub, 1993: 258-296

*Chapter in a book (list all authors)*

11 **Lam SK**. Academic investigator's perspectives of medical treatment for peptic ulcer. In: Swabb EA, Azabo S. Ulcer disease: investigation and basis for therapy. New York: Marcel Dekker, 1991: 431-450

*Author(s) and editor(s)*

12 **Breedlove GK**, Schorfheide AM. Adolescent pregnancy. 2nd ed. Wieczorek RR, editor. White Plains (NY): March of Dimes Education Services, 2001: 20-34

*Conference proceedings*

13 **Harnden P**, Joffe JK, Jones WG, editors. Germ cell tumours V. Proceedings of the 5th Germ Cell Tumour Conference; 2001 Sep 13-15; Leeds, UK. New York: Springer, 2002: 30-56

*Conference paper*

14 **Christensen S**, Oppacher F. An analysis of Koza's computational effort statistic for genetic programming. In: Foster JA, Lutton E, Miller J, Ryan C, Tettamanzi AG, editors. Genetic programming. EuroGP 2002: Proceedings of the 5th European Conference on Genetic Programming; 2002 Apr 3-5; Kinsdale, Ireland. Berlin: Springer, 2002: 182-191

**Electronic journal** (list all authors)

**Morse SS**. Factors in the emergence of infectious diseases. Emerg Infect Dis serial online, 1995-01-03, cited 1996-06-05; 1(1): 24 screens. Available from: URL: http//www.cdc.gov/ncidod/EID/eid.htm

**Patent** (list all authors)

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### *Inappropriate references*

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### *Statistical data*

Present as mean ± SD or mean ± SE.

### *Statistical expression*

Express $t$ test as $t$ (in italics), $F$ test as $F$ (in italics), chi square test as $\chi^2$ (in Greek), related coefficient as $r$ (in italics), degree of freedom as $\gamma$ (in Greek), sample number as $n$ (in italics), and probability as $P$ (in italics).

### *Units*

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, $p$(B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; $CO_2$ volume fraction, 50 mL/L $CO_2$ not 5% $CO_2$; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

### *Abbreviations*

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

### *Italics*

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori, E coli, etc.*

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

### *Language evaluation*

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

### *Copyright assignment form*

Please downloaded CAF from http://www.wjgnet.com/wjg/help/9.doc.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to WJG all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The WJG requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1)direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3)supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The WJG does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to WJG if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

### *Final check list for authors*

The format is at: http://www.wjgnet.com/wjg/help/13.doc

### *Responses to reviewers*

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: http://www.wjgnet.com/wjg/help/10.doc

### *Proof of financial support*

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### *Publication fee*

Authors of accepted articles must pay publication fee.
EDITORIAL and LETTERS TO THE EDITOR are free of change.
