### Laser microdissection and RNA extraction

Before sectioning, tissue blocks were embedded in Tissue Tek OCT compound medium (VWR Scientific Products, San Diego, CA, USA) in a cryostat. Then serial 8-micron thick sections were prepared and mounted onto a foiled slide and stored at -70℃ until use.

Frozen section slides were stained just before laser microdissection on ice. Briefly, the slides were fixed in 70% ethanol for 30 s and stained with 0.1% toluidine blue (TBO) for 15 s, followed by dehydration in 75%, 95% and 100% ethanol respectively for 5 s and dehydration in xylene for 5 min. Once airdried, the sections were laser microdissected with a LMD system (Leica Microsystems, Wetzlar, Germany) and the target cells were selectively collected. Next, total RNA was extracted from the interest cells independently with the RNA-lyase Micro kit (Qiagen, Hilden, Germany), according to the manufacturer's instructions. The integrity of the total RNA was measured by Lab-on-chip (Agilent, Palo Alto, USA).

### cDNA microarray

We carried out cDNA microarray analysis in 58 metastatic gastric cancer tissue samples of lymph node metastatic gastric cancer, 36 tissue samples of primary gastric cancer and 30 tissue samples of normal gastric epithelium, all technical services were provided by Shanghai Biochip Corporation (Shanghai, China). Two hundred ng of total RNA was amplified for array analysis, 100 ng of total RNA was not amplified for later certification. After P27-based RNA amplification, aliquots (2.5-microgram) of aRNA from primary carcinoma tissues and their corresponding metastatic lymph nodes were labeled with Cy3-dCTP and Cy5-dCTP, respectively. The labeled probes were hybridized with Human cDNA Chip version 2.0 (SBC-R-HC-100-20, Shanghai, China) containing 13 824 genes (including 10 positive controls and 6 negative ones), and the signals were detected by the Agilent scanner (Agilent, Palo Alto, USA). We set the cutoff values for signal intensities, i.e., the signal to noise ratios of Cy3 or Cy5

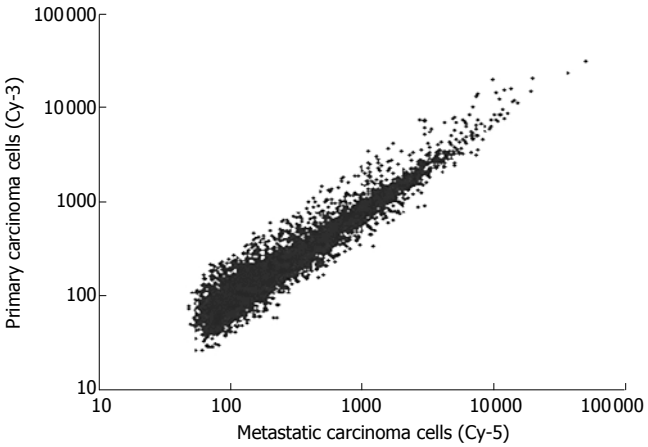

**Figure 1** Scatter plots of cDNA microarray analysis. Primary carcinoma cells and lymph node metastatic cells from 58 patients (TNM stage Ⅲ-Ⅳ) with gastric cancer were labeled by Cy-3 and Cy-5 respectively, and hybridized to the cDNA microarray using laser microdissection in combination with microarray.

must be greater than 2. Genes with Cy3:Cy5 ratios > 4 or < 0.25 in the remaining 22 patients were defined as up- or down-regulated genes.

### *Semiquantitative RT-PCR*

Nonamplified total RNA (100 ng) was reverse transcribed into cDNA using Superscript Ⅱ reverse transcriptase (Invitrogen, USA) at 42℃ for 60 min and at 70℃ for 15 min. Each single-stranded cDNA was diluted for subsequent PCR amplification and the content of cDNA was semiquantitatively normalized by housekeeping gene β-actin. PCR conditions for different genes included an initial denaturation at 94℃ for 3 min, followed by 30-35 cycles of denaturation at 94℃ for 30 s, annealing at 94℃ for 30 s, and elongation at 72℃ for 1 min (The primer sequences, annealing temperatures and cycles of each gene are available on request). Amplified PCR products were visualized by electrophoresis on 1% agarose gel containing ethidium bromide.

### *Immunohistochemical assay*

The slides were incubated with rabbit anti-OPCML antibody (BOSTER, USA) at 1:50 dilution. The sections were then stained with KIT SA1028 (BOSTER, USA) according to the manufacturer's instructions. The tissue was counterstained with hematoxylin.

### *Laser microdissection*

Target cells in each sample were successfully laser microdissected. Consequently, about $6 \times 10^6$-$8 \times 10^6$ cells were collected for total RNA extraction, 200-400 ng total RNA was obtained. The integrity of each sample was proven by Lab-on-chip.

### *Statistical analysis*

All data were expressed as mean ± SD. Statistical significance between the two groups was determined by Student's *t*-test using GraphPad Prism version 3.02 for Windows (GraphPad Software Inc., San Diego, USA). $P < 0.05$ was considered statistically significant.

**Table 2 Differentially expressed genes detected by cDNA microarray**

[1]Up-regulated genes were confirmed by semiquantitative RT-PCR in another group of 15 cases; [2]Down-regulated genes and aRNA from primary carcinoma tissues and their corresponding metastatic lymph nodes were labeled with Cy3-dCTP and Cy5-dCTP, respectively.

## RESULTS

After $P^{27}$-based amplification, we evaluated the expression profiles of tumor cells of primary gastric cancer and their corresponding metastatic lymph nodes in 36 patients. Scatter plots of cDNA microarray analysis are shown in Figure 1. Amplified aRNA from primary gastric carcinoma cells (Cy3) and metastatic carcinoma cells (Cy5) were labeled and hybridized to the cDNA microarray.

Analysis of the cDNA microarray data showed that 49 genes (including 31 with unknown function) were over-expressed (Cy3:Cy5 > 4) in primary carcinoma cells from 36 patients. On the other hand, 37 genes (including 9 with unknown function) were significantly suppressed (Cy3:Cy5 < 0.25) in primary carcinoma cells from 36 patients. The up-regulated genes were related to cell adhesion, cytoskeleton, cell defense and metabolism. Meanwhile, the down-regulated genes included those associated with cell development, cell cycle, signal transduction, adhesion, cell

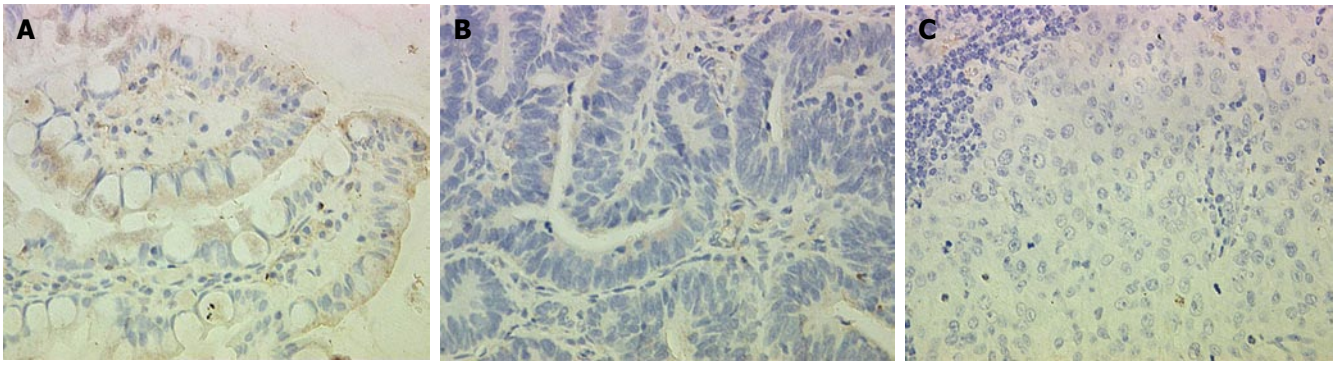

**Figure 2** Immunohistochemical staining of OPCML. **A**: Normal gastric epithelium showing abundant and strong immunoreactivity; **B**: Primary gastric cancer demonstrating weak immunoreactivity; **C**: lymph node metastastasis showing rare immunoreactivity (× 400).

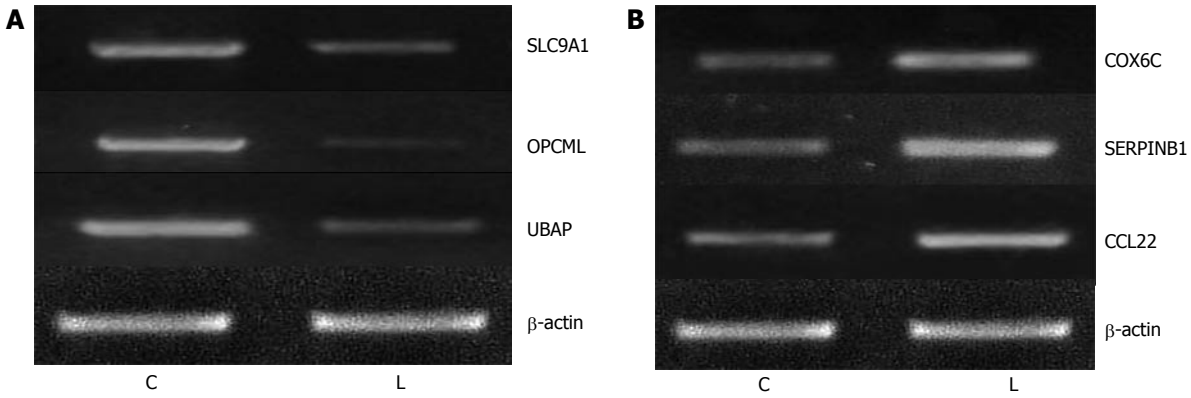

**Figure 3** Validation of microarray data by semiquantitative RT-PCR. **A**: Expression levels of 3 genes (SLC9A1, OPCML and UBAP) was up-regulated in primary carcinoma; **B**: Expression of 3 genes (COX6C, SERPINB1 and CCL22) was down-regulated in primary carcinoma. defense, gene expression and cell metabolism (Table 2).

### *Confirmation of microarray findings*

To examine the reliability of microarray data, we confirmed our data at the level of mRNA and protein. First, we selected 3 up-regulated genes (SLC9A1, OPCML and UBAP) and 3 down-regulated genes (COX6C, SERPINB1 and CCL22) to measure their expression levels by semiquantitative RT-PCR. To obtain truly comparable results, we used the unamplified total RNA (from the same batch used for array hybridizations) as the template. The results were very similar to the microarray data on these genes.

To confirm our data at the protein level, we performed immunohistochemical analysis of OPCML. The results were in parallel with the differential expression pattern detected by cDNA microarray and RT-PCR (Figure 2).

Overall, the above results demonstrated that the samples obtained by P27-based amplification well reflected the status of the original RNA in a proportional manner, and supported the reliability of our expression data (Figure 3).

### *Expression of differential genes in progression of gastric cancer*

By semiquantitative RT-PCR, we further evaluated the expression levels of 25 selected genes, including 10 up-regulated and 15 down-regulated genes, in microdissected normal gastric epithelial cells from 30 healthy individuals, primary gastric cancer cells from 36 patients and lymph node metastatic cells from the remaining 22 patients. First, we investigated the expression levels of these genes in primary gastric cancer and lymph node metastatic cells. The results showed that the expression of 12 genes had the same pattern in > 50% (12/22) patients as revealed by cDNA microarray.

We further measured the expression levels of these 12 genes in paired normal gastric epithelium and primary carcinoma samples from the same 22 patients. We found that the expression pattern of 3 genes (OPCML, RNASE1 and YES1) was similar to that of tumor suppressor genes in > 50% (8/15) patients. For example, the expression level of these genes was the highest in normal gastric epithelium, which was decreased in primary carcinoma and further decreased compared to that in primary gastric cancer patients with lymph node metastasis and normal controls ($P < 0.05$). Meanwhile, the expression level of ACK1 demonstrated the opposite tendency, the pattern of which was similar to that of oncogene in > 50% (12/22) patients (Figure 4). The expression pattern of OPCML was also confirmed at the protein level by immunohistochemical staining (Figure 2).

## DISCUSSION

cDNA microarrays allow an effective investigation of functional genomics. However, the existence of bulky surrounding cells produces much useless noise information because of its high sensitivity[9,10]. Therefore, selection of cancer cells using LMD is of indispensable value in combination with the cDNA microarray. The LMD system used in this study integrates a UV laser of 337 nm wavelength with an upright microscope. The ultraviolet laser microbeam causes dissection by local photolysis of the supporter membrane and tissue section due to the high photon density of the microbeam rather than by local heating or coagulation. The cut sample falls down into PCR tubes placed underneath by gravity without any mechanical contact or further destroying energy and the integrity of the extracted mRNA is maximally kept.

Metastasis of cancer is a highly selective sequential step which favors the survival of a subpopulation of metastatic cells preexisting within the primary tumor mass to produce clinically relevant metastases. The metastatic cells exhibit a complex phenotype that is regulated by transient or permanent changes in different genes at the DNA and/or mRNA level(s). This has also been proved in gastric cancer by other researchers[8,9,11].

Differential expression profiles of laser microdissected primary gastric cancer cells and lymph node metastatic cells were discovered using cDNA microarray consisting of 13824 genes, demonstrating that analysis of gene-expression profiles can be performed using LMD, P27-based RNA amplification and cDNA microarray[1,11]. Although the majority of these genes have been implicated in various aspects of tumor biology, few are associated with gastric cancer.

Among the above genes, some may be differentially expressed because of different living environments[5,12-17]. Therefore, to further confirm and screen the results of cDNA microarray, we measured the expression levels of 25 selected genes in 22 patients by semiquantitative RT-PCR. These target cells were collected by LMD, and the normal gastric epithelium was included. As a result, we identified 4 genes, the expression level of which was different not only between primary carcinoma and metastatic lymph nodes (the same results as cDNA microarray), but also between normal gastric epithelium and primary tumor, suggesting that these four genes play a key role in the tumorigenesis and metastasis of gastric cancer. The expression pattern of 3 genes (OPCML, RNASE1 and YES1) is similar to that of tumor suppressor genes. For example, the expression of these genes is the highest in normal gastric epithelium, which is decreased in primary carcinoma, and further decreased in metastatic lymph nodes. OPCML encodes a member of the IgLON subfamily in the immunoglobulin protein superfamily and acts as a GPI-anchored protein. It was reported that OPCML has tumor-suppressor function in epithelial ovarian cancer[11,18-20], which is in accordance with our findings in gastric cancer. Interestingly, YES1 is the cellular homolog of a virus oncogene associated with esophageal tumorigenesis[12,21-24], which is contrary to our results. The RNAS gene encodes a member of the pancreatic-type of secretory ribonuclease, a subset of the ribonuclease A superfamily, and has no relationship with human cancers.

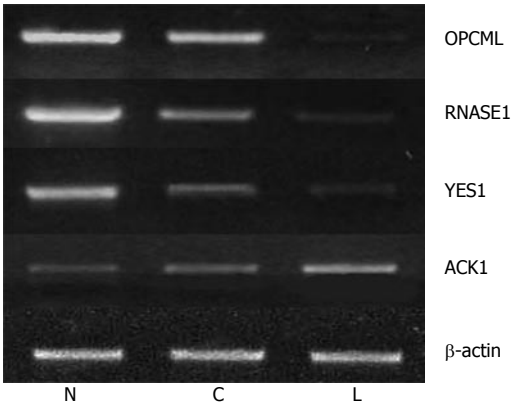

**Figure 4** Identification of differentially expressed genes in progrssive gastric cancer by semiquantitative RT-PCR. N: A sample from normal gastric epithelium; C: Signifies a sample from the primary carcinoma cells; and L: A sample from the metastatic carcinoma cells.

In this study, the expression pattern of gene ACK1 was different from that of the above mentioned genes, but similar to that of oncogenes. ACK1 encodes a tyrosine kinase that binds to Cdc42Hs in its GTP-bound form and inhibits intrinsic and GTPase-activating protein (GAP)-stimulated GTPase activity of Cdc42Hs. It is directly linked to a tyrosine phosphorylation signal transduction pathway, but its effect on tumor progression has not been reported[12-17].

Both tumor suppressor gene and oncogene are important target molecules in clinical diagnosis and treatment of malignant gastric tumors. The different expressions of these four genes have not been reported during the progression of gastric cancer.

In conclusion, analysis of gene expression profiles by LMD, P27-based amplification, and cDNA microarray can provide useful information for clarifying the mechanism underlying the development and metastasis of gastric cancer[25-29], not only revealing the differentially expressed genes in progression of gastric cancer, but also providing information for identifying novel diagnostic and therapeutic targets.

## Abstract

**AIM:** To evaluate which patients with hepatocellular carcinoma (HCC) are most likely to respond to thalidomide treatment.

**METHODS:** From July 2002 to July 2004, patients with HCC who received thalidomide treatment, were enrolled. We extracted relevant data from the patients' medical records, including history and type of hepatitis, comorbidity, serum α-fetoprotein (α-FP) level, volumetric changes in tumor, length of survival, and the dose, duration, side effects of thalidomide treatment. The tumor response was evaluated. On the basis of these data, the patients were divided into two groups: those with either partial response or stable disease (PR + SD group) and those with progressive disease (PD group).

**RESULTS:** Two of 42 (5%) patients had a partial tumor response after treatment with thalidomide, 200 mg/d, and 9 (21%) had stable disease. Patients in the PR + SD group all had cirrhosis. Comparing patients with and without cirrhosis, the former were more likely to respond to thalidomide therapy (PR + SD: 100% *vs* PD: 64.5%, $P = 0.041 < 0.05$). Thalidomide was significantly more likely to be effective in tumors smaller than 5 cm (PR + SD: 63.6% *vs* PD: 25.8%, $P = 0.034 < 0.05$). Compared with patients with progressive disease (PD), patients in the PR + SD group had a higher total dose of thalidomide (13669.4 ± 8446.0 mg *vs* 22022.7 ± 11461.4 mg, $P = 0.023 < 0.05$) and a longer survival (181.0 ± 107.1 d *vs* 304.4 ± 167.1 d, $P = 0.047 < 0.05$). Patients with comorbid disease had a significantly greater incidence of adverse reactions than those without (93.8% *vs* 60.0%, $P = 0.021 < 0.05$). The average number of adverse reactions in each person with a comorbid condition was twice as high as in those without other diseases (2.2 ± 1.3 *vs* 1.1 ± 1.2; $P = 0.022 < 0.05$).

**CONCLUSION:** Thalidomide therapy is most likely to be effective in patients with early stage small HCC, especially in those with other underlying diseases. A low dose (200 mg/d) of thalidomide is recommended to continue the treatment long enough to make it more effective.

**Key words:** Thalidomide; Hepatocellular carcinoma; Antiangiogenic agents; Adverse events

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most prevalent cancer in the world. About one million people die of it each year[1,2]. Particularly in Taiwan, it poses a tremendous threat to citizens' health and lives. HCC has been the leading cause of cancer death in Taiwan for the past two years, leading to about 6000 to 7000 deaths each year.

Potentially curative therapies for HCC include surgical resection, liver transplantation, and percutaneous ablation. However, HCC is often diagnosed at an advanced stage when curative therapy is likely to be of little value. Thus, most patients are candidates for palliative treatment, which includes transarterial embolization (with or without chemotherapy), hormonal therapy, interferon therapy, *etc.* Transarterial embolization has been shown to improve survival[1]. The response rate to systemic chemotherapy is generally less than 30%[1], and patients often tolerate it poorly. A further difficulty is that about 80% of patients with HCC also have cirrhosis, which severely limits the utility of both surgery and chemotherapy. Therefore, we urgently need new therapeutic approaches for HCC.

In 1971, Dr. Judah Folkman suggested using anti-angiogenic agents to inhibit tumors, a proposal which has made a new form of anticancer treatment possible. Cancer cells whose blood supply is disrupted are starved of nutrients and oxygen, leading to atrophy and death. Endothelial cells play a key role in angiogenesis, forming the external theca of new blood vessels and possessing a strong ability to reproduce and migrate. Proteins known to activate endothelial cells include vascular endothelial growth factor (VEGF) and basic fibroblast growth factor

(BFGF), which are regarded as important contributors to the growth of new blood vessels. HCC is a hypervascular tumor, with high concentrations of VEGF and BFGF in tumor cells and blood[3,4]. It is therefore reasonable to infer that anti-angiogenesis may inhibit the growth of HCC.

A number of anti-angiogenic agents have been developed, some of which are in phase Ⅱ or Ⅲ clinical trials. Thalidomide is such a drug. It was widely used in the 1950s as a sedative and anti-emetic agent but was found to be teratogenic. Its use has been therefore prohibited in Europe and America. However, in recent years, thalidomide has been found to have many pharmacological properties, including inhibition of angiogenesis and inflammation and regulation of immunity. Thalidomide apparently blocks factors such as VEGF and BFGF of cancer cells[5,6], thereby inhibiting angiogenesis. In some cancers strongly dependent on angiogenesis, such as Kaposi's sarcoma and metastatic prostate cancer, thalidomide has been used with some success[7,8]. HCC, also strongly dependent on angiogenesis, is treated with thalidomide in Taiwan.

As with any newly proposed therapy, it is important to identify those patients most likely to benefit from the treatment while minimizing the risk of adverse effects. This understanding may also facilitate conservation of medical resources when the drug is unlikely to help. We designed this study to evaluate the efficacy and adverse effects of thalidomide in HCC by retrospectively reviewing the results in a series of patients in order to identify those most likely to benefit from the treatment while avoiding serious adverse effects.

## MATERIALS AND METHODS

### Patients

From July 2002 to July 2004, 159 patients with HCC were treated with thalidomide. All the patients were informed of the necessity of contraception and the benefits and risks of thalidomide treatment. They gave their informed consent to receive it by the Medicine Advisory Committee of Mackay Memorial Medical Center and the Department of Public Health in Taiwan. HCC was diagnosed by histologic examination, imaging findings (abdominal sonography and computed tomography), or a serum α-fetoprotein (α-FP) level greater than 400 ng/mL. The disease was staged by the pathologic tumor-node-metastasis (pTNM) system, the Okuda system for HCC, and the Cancer of the Liver Italian Program (CLIP) scoring system[9-11]. We extracted relevant data from the patients' medical records, including age, gender, history and type of hepatitis, comorbidity, duration of HCC, serum α-FP level, volumetric changes in tumor, length of survival, and the dose, duration, side effects of thalidomide treatment. Patients were excluded from analysis if they took thalidomide for less than one month, had other therapy after thalidomide, or if the data were inadequate in the record to define the stage or treatment response.

### Evaluation of tumor response

The tumor response was evaluated according to the imaging findings one month before and after administration of thalidomide according to the new version of the Response Evaluation Criteria in Solid Tumor (RECIST) Guidelines[12], as well as α-FP levels before and after thalidomide treatment. On the basis of these data, the patients were divided into two groups: those with either partial response or stable disease (PR + SD group) and those with progressive disease (PD group).

### Thalidomide therapy

Thalidomide (50 mg tablet marketed as Thado®, Taiwan Tung Yang Biopharm Co. Ltd., Taipei) in a dose of 50 to 200 mg/d, was give twice daily in the morning and evening. The dose was adjusted according to the clinical response and side effects. Thalidomide-related toxicity was classified by the Common Terminology Criteria for Adverse Events v 3.0 (CTCAE) established by the National Cancer Institute (NCI)[13].

### Statistical analysis

The clinical characteristics, dose of thalidomide, treatment duration, and length of survival of the two groups were compared by using the Mann Whitney *U* test and Fisher's exact test. The relation between comorbidity and adverse reactions was examined by Fisher's exact test. $P < 0.05$ was considered statistically significant. The overall survival was calculated by the Kaplan-Meier method from the time of the first dose of thalidomide to the patient's death or the last follow-up. The statistical software package used was SPSS (version 10).

## RESULTS

### Patients

Of the 159 patients with HCC treated with thalidomide, 57 took thalidomide for less than one month, and 35 were given other treatment in addition to thalidomide. The data for 25 patients were incomplete, leaving records for 42 patients that were available for analysis. The clinical characteristics are shown in Table 1. Thirty-one (74%) patients were older than 60 years. Cirrhosis was present in 31, and 32 (76%) had comorbid conditions. The prevalence of hepatitis B (15/42) and C (11/42) was similar. Twenty-one (50%) of the patients had TNM stage ⅢA, and the majority had their liver function classified as Child-Pugh A or Okuda Ⅱ. The most frequent CLIP score was 3 (15/42).

### Tumor Response

Of the 42 patients, 2 had a partial tumor response to thalidomide at a dose of 200mg/day and a decrease in α-FP level. They both had TNM stage ⅢA disease, Okuda phase Ⅰ or Ⅱ, and a CLIP score of 3 or 4. Another 9 patients had stable disease, 4 of whom also had a fall in serum α-FP level. The remaining 31 patients had disease that continued to progress after thalidomide. These results were comparable to those of other studies[14-19] (Table 2), none of which showed an objective tumor response rate above 10%. The mean time to partial response in our patients was 34 d. The median survival of all 42 patients was 319 d (range, 144 to 494 d), the one-year survival was 14%. The median survival of the PR + SD group was 524 d (range, 218 to 830 d) (Figure 1).

| > 5 cm | 4 | 23 | |

[1]Partial response; [2]Stable disease; [3]Progressive disease; [a]$P < 0.05$ between the two groups.

Table 3 shows that all patients in the PR + SD group had cirrhosis, suggesting that cirrhosis might influence the efficacy of thalidomide. Patients in this group were more likely to have a CLIP score of 0 to 2 (7/11) or an α-FP level of < 400 ng/mL (8/11). Response to thalidomide was significantly more likely when the tumor was < 5 cm (PR + SD: 63.6% *vs* PD: 25.8%, $P = 0.034 < 0.05$). Other clinical characteristics did not differ significantly between the groups.

The duration of thalidomide therapy was longer in the PR + SD group (Table 4). Patients in the PR + SD group had a significantly higher total dose and a significantly longer survival than those in the PD group.

### *Thalidomide therapy*

Twenty patients began their treatment with a dose of 200 mg/d and the remaining 22100-150 mg/d initially. Ten patients had their dose escalated to 200 mg according to treatment response, while three patients had their dose reduced because of thalidomide- induced drowsiness, dizziness and constipation, and 2 discontinued it entirely. Most adverse reactions were slight or moderate, only 6 (14%) events (skin rash in 3, dizziness in 1, and lethargy in 2) were severe. The most common adverse reactions were constipation and skin rash, with an incidence of 57% and 41%, respectively (Table 5).

**Table 6 Thalidomide-related adverse events and comorbidity**

| Adverse drug events per patient | Comorbidity (*n*) | |
|---|---|---|
| | Absent | Present |
| 1 | 3 | 10 |
| 2 | 1 | 7 |
| 3 | 2 | 6 |
| 4 | 0 | 7 |

**Table 7 Correlation between thalidomide-related adverse events and comorbidity**

| | Comorbidity (*n*) | | *P* |
|---|---|---|---|
| | Absent | Present | |
| Without adverse events | 4 | 2 | 0.021 |
| With adverse drug events[a] | 6 | 30 | |
| Adverse events per patient[c] | 1.1 ± 1.2 | 2.2 ± 1.3 | 0.022 |

[a]$P < 0.05$, [c]$P < 0.05$ *vs* without adverse events, between groups of with comorbidity and without comorbidity.

Tables 6 and 7 show the relationship between thalidomide-induced adverse reactions and comorbidity. Adverse reactions were more likely to occur in patients with an other underlying diseases (93.8% *vs* 60.0%, $P = 0.021 < 0.05$). The average number of adverse reactions in each person with a comorbid condition was twice as high as in those without other diseases (2.2 ± 1.3 *vs* 1.1 ± 1.2, $P = 0.022 < 0.05$).

## DISCUSSION

In our series, the partial response rate of HCC to thalidomide at 100 to 200 mg/d was 5%, 21% of patients who had stabilization of their disease after treatment with thalidomide. These results generally agree with those of other researchers. In our study, two thirds of the patients were older than 60 and had cirrhosis or other comorbid conditions. Most of them had TNM stage ⅢA disease or were in Okuda class Ⅱ.

The pharmacological mechanisms of thalidomide include anti-angiogenic, immunomodulatory and anti-inflammatory effects. The drug inhibits angiogenesis in tumors by blocking the activity of VEGF and BFGF[20]. The immunomodulatory effects include induction of TNF-α mRNA degradation, thereby inhibiting the synthesis of TNF-α[21]. It also downregulates lymphocyte surface molecules, lowering the CD4:CD8 peripheral lymphocyte ratio. It can inhibit chemotaxis of neutrophils, interleukin-6 and interleukin-12, and stimulate the synthesis of interleukin-2[22]. In addition, it inhibits the activity of IκB kinase, thus blocking the activity of nuclear factor-κB[23].

Because of its many pharmacological actions, thalidomide is now widely used in the treatment of a number of diseases. In 1999, it was approved by the FDA to treat erythema nodosum leprosum. It has been used for aphthous ulcers in HIV-positive patients, graft versus

host disease after bone marrow grafting, tuberculosis, sarcoidosis, inflammatory bowel disease, rheumatoid arthritis, as well as for some cancers such as multiple myeloma, renal cell carcinoma, brain tumors, prostate cancer, melanoma and Kaposi sarcoma[19,23]. The response of multiple myelomas to thalidomide (600 to 800 mg daily) is about 30%, and increases to 60% when combined with dexamethasone. The therapeutic effect of thalidomide in HCC is thus not as satisfactory as in multiple myeloma. The reported response is 40% in Kaposi sarcoma and 15%-27% in prostate cancer[23].

In our study, the plasma concentrations of VEGF and BFGF in multiple myeloma remained unchanged irrespective of whether the disease responded to thalidomide. It is likely that there are mechanisms other than the inhibition of angiogenesis that are responsible for the drug's efficacy in multiple myeloma. For example, there are decreased adhesion of multiple myeloma cells to stromal cells, reduced secretion of cytokines, and activation of caspase-8, leading to death of multiple myeloma cells[24].

Because of the different structures and functions of blood vessels in different tissues and tumors at different sites and the genetic instability and biologic heterogeneity of tumor cells, new blood vessels in tumors may be quite diverse. There are therefore considerable complexity and unpredictability of tumor microvasculature[25]. This may help explain why thalidomide has different effects on different malignancies. The relatively poor response of HCC compared to multiple myeloma may be related to the differences in angiogenesis.

In our series, only about one fifth of the patients had their disease stabilized after thalidomide therapy, indicating that thalidomide helps only a few patients with advanced HCC, and rarely results in a decrease in tumor size. The median survival in the PR + SD group was 524 d (range, 218-830 d) compared with 319 d (range, 144-494 d) of all 42 patients. The one-year survival was only 14%, suggesting that thalidomide is not very effective in prolonging the life of HCC patients.

Our results did show that patients with cirrhosis tolerated thalidomide well and even had a somewhat better response to treatment. The reason why response in those with tumors smaller than 5 cm is better may be that thalidomide can prominently inhibit formation of new blood vessels rather than disrupt existing mature vessels. Larger tumors with mature vasculature may therefore be relatively resistant to the action of thalidomide. The maximum therapeutic effect may thus be seen in smaller tumors with newer vessels.

In the PR + SD group 64% of patients had a CLIP score of 0 to 2, compared with 42% in the PD group. Similarly more patients in the PR + SD group (73%) had an α-FP level of < 400 ng/mL compared with the PD group (39%). The PR + SD group also took a significantly higher total dose of thalidomide (22022.7 ± 11461.4 mg *vs* 13 669.4 ± 8446.0 mg, $P = 0.023$) and had a significantly longer survival (304.4 ± 167.1 d *vs* 181.0 ± 107.1 d; $P = 0.047$). These results indicate that treatment of earlier stage HCC with thalidomide may leave enough time for the drug to produce a significant therapeutic effect.

A commonly-reported adverse effect in patients treated with thalidomide for multiple myeloma is venous thromboembolism, particularly when combined with doxorubicin or with dexamethasone[27]. None of the patients in our series had thromboembolism, perhaps because we used smaller doses than the commonly-used doses for multiple myeloma. The most common adverse reactions in our series were constipation (57%) and skin rash (41%). Severe reactions were uncommon (14%), and only 5 patients required a dose adjustment or discontinuation of treatment. Three patients developed slight peripheral neuropathy, and one of them had a dose adjustment from 200 mg to 100 mg. Thalidomide-related peripheral neuropathy may occur in patients on long-term treatment and is irreversible. Therefore, if it occurs, the drug should be stopped or the dose is reduced. Generally, the adverse reactions caused by thalidomide are dose- and duration-related[27]. We also found a significant positive correlation between adverse reactions and comorbidity ($P = 0.021$) of diabetes mellitus, hypertension, ischemic heart disease, peptic ulcer, chronic obstructive lung disease and benign prostatic hyperplasia. In considering therapy for patients with HCC, the higher risk of adverse reactions to thalidomide in the presence of other diseases should be taken into account.

Our study is limited by the fact that it was retrospective. It would be difficult to collect enough patients with HCC in similar stages for comparison in a prospective study. We also were only able to analyze the data from a relatively small number of patients, which might skew the results to some extent. However, thalidomide is unlikely to be effective in a large proportion of patients with HCC. This makes it even more important to identify those who are likely to benefit from thalidomide treatment.

## Abstract

**AIM:** To create a new, simple and useful staging system for colorectal liver metastasis analogous to the Tumor Node Metastasis classification system of International Union Against Cancer.

**METHODS:** A retrospective review was undertaken of 81 consecutive patients who underwent partial hepatectomy for colorectal liver metastases (group 1). Clinical and pathological features of both primary and metastatic liver cancers were entered into a multivariate analysis to determine independent variables helpful in accurately predicting long-term prognosis after hepatectomy. Using selected variables, we created a new staging system like TNM classification. The usefulness of the new staging system was examined in a series of 92 patients from another hospital (group 2).

**RESULTS:** Multivariate analysis showed that 81 patients in group 1 had significant multiple hepatic tumors with the largest tumor being more than 5 cm in diameter, resectable extrahepatic distant metastases, and independent prognostic factors for poor survival after hepatectomy. Using these three variables, we created a new staging system to classify patients with colorectal liver metastases. Finally, our new staging system classified the patients both in group 1 and in group 2.

**CONCLUSION:** Our new staging system of colorectal liver metastasis is simple and useful for staging patients.

**Key words:** Colorectal liver metastasis; Staging system; Prognostic factor

## INTRODUCTION

It is well accepted that hepatic resection of colorectal liver metastases is a beneficial clinical procedure in that it reportedly improves 5-year survival rates of affected patients by as high as 30%-50% following curative hepatic resection[1-14]. Although this procedure is performed worldwide by a number of liver surgeons, it is often hazardous to compare results from different studies due to the fact that there is no universally accepted classification system for staging colorectal hepatic metastatic diseases. Several recent papers have offered classification systems based on a variety of variables of colorectal liver metastasis[1-6], including the number of metastatic nodules[1,4-6], the size of metastases[4,6], the sites of unilobar or bilobar involvement[1,4], the extent of liver involvement ($\leqslant$ 25%, and $\leqslant$ 50%)[1,3], the chronology of synchronous or metachronous disease[1,5,6], the invasion to major vessels or bile ducts[2], the presence of extrahepatic metastasis[2-4], the performance status and serum alkaline phosphatase[3]. However, it is uncertain whether these classification systems are accepted and adopted outside the confines of proposing institutions. In the present study, we aimed to create a new, simple and useful classification system for colorectal liver metastases analogous to the Tumor Node Metastasis (TNM) classification system of International Union Against Cancer (UICC).

## MATERIALS AND METHODS

### Patients

**Group 1:** Between January 1, 1981 and March 31, 1997, 83 consecutive patients underwent partial hepatectomy for colorectal liver metastases at the First Department of Surgery (presently the Department of Surgical Oncology), Tokyo University Hospital. During the post-operative period, two patients died in the hospital. One died of secondary aspiration pneumonia and the other died of severe intra-abdominal sepsis (mortality rate: 3.1%). The remaining 81 patients were followed up either until death or their last outpatient visit up to December 31, 2002. The follow-up period ranged from 4 to 197 mo with a median of 53.0 mo. The demographic characteristics and tumor-

related features, which were statistically analyzed later, are summarized in Table 1.

**Group 2:** Between January 1, 1989 and December 31, 2003, 95 consecutive patients underwent partial hepatectomy for colorectal liver metastases at the Second Department of Surgery, Teikyo University Hospital. During the post-operative period, three patients died in the hospital. Two died of hepatic failure due to massive hepatectomy and the other died of severe intra-abdominal sepsis (mortality rate: 3.2%). The remaining 92 patients were followed up either until death or their last outpatient visit up to December 31, 2004. The follow-up period ranged from 4 to 110 mo with a median of 39.0 mo.

Every hepatectomy was considered curative since surgeons were confident of the complete macroscopic resection of hepatic tumors at the time of surgery. Hepatectomy was performed even in the presence of extrahepatic metastases if surgeons were reasonably assured of the complete macroscopic resection of extrahepatic metastases as well. After discharge from the hospital, the patients were closely monitored either at the outpatient clinic or at the affiliated institutions. Measurement of serum carcinoembryonic antigen (CEA) levels and ultrasonography were performed during post-operative visits at least once every two months in an effort to detect early recurrence. In addition, computed tomography was performed approximately twice a year. Almost all cases of cancer recurrence were diagnosed by these investigative tests. If the diagnosis was unclear, angiography and/or needle biopsy was performed, under ultrasonic guidance in an effort to confirm or rule out recurrence of the disease.

### Prognostic factors

Eleven factors that were expected to influence the long-term prognosis were evaluated for statistical significance. These factors could only be determined preoperatively or during surgery (therapeutic factors were excluded and not considered). Factors that were considered included gender, age at hepatectomy (< 60 or ≥ 60 years), chronology of synchronous or metachronous hepatic metastases, and post-operative disease-free interval ≤ 1 year, the number of solitary or multiple metastatic nodule hepatic metastases, the maximum diameter of hepatic metastases (≤ 5 cm), unilobar or bilobar hepatic involvement, resectable extrahepatic metastasis (pulmonary metastases, localized peritoneal metastases, or hepatoduodenal lymph node metastases, each was completely resected), serum CEA levels at hepatectomy (less or higher than 10 times the upper level of normal), serosal exposure to the primary colorectal tumor, and regional lymph node metastases of the primary colorectal tumor.

### Statistical analysis

Survival rates after hepatectomy were calculated using data obtained from patients by the Kaplan-Meier method. Only deaths attributable to recurrent cancer were treated as deaths due to disease. Patients who died of secondary or other causes without recurrence were treated as censored.

Prognostic variables concerned with cancer-related survival rate were entered into multivariate analysis. The Cox stepwise analysis proportional hazard regression model was used to select independent and significant prognostic variables. Stepwise variable selection was performed at a value of $P < 0.20$ level of significance. $P < 0.05$ was considered statistically significant.

**Table 1 Prognostic factors entered into multivariate analysis based on proposed clinical and histopathological features**

| Variable | Patients (*n*) |
|---|---|
| Gender (male/female) | 61/20 |
| Age at hepatectomy (< 60/≥ 60) | 32/49 |
| Chronology of hepatic metastasis (synchronous/metachronous) | 41/40 |
| Disease free interval after colectomy (≤ 1 yr/> 1 yr) | 56/25 |
| Extrahepatic distant metastases (no/yes) | 72/9 |
| CEA (≤ 10 times of normal value/> 10 times of normal value) | 57/24 |
| Primary lesion | |
| Depth of invasion (up to subserosa/more) | 57/24 |
| Lymphnodemetastasi (no/yes) | 39/42 |
| Hepatic metastasis | |
| Number (single/multiple) | 45/36 |
| Maximum diameter (≤ 5 cm/> 5 cm) | 59/22 |
| Lobe involved (unilobar/bilobar) | 64/17 |

## RESULTS

### Group 1

**Significant prognostic factors:** The overall 1-, 2-, 3-, 4-, and 5-year cancer-related survival rates after surgical resection in the 81 patients were 89.6%, 67.7%, 56.0%, 54.2%, and 49.6%, respectively (Figure 1A). The results of the multivariate analysis of the variables expected to influence cancer-related survival rate after surgical resection are provided in Table 1. Only variables selected by the stepwise analysis at a value of $P < 0.20$ level of significance, using the Cox proportional hazard regression model, are also shown in Table 2. Multiple tumors, tumor over 5 cm in diameter, and resectable extrahepatic metastases were significant and independent variables influenced cancer-related survival rate ($P < 0.05$). On the other hand, serosal exposure and regional lymph node metastases of the primary colorectal tumor, and recurrent hepatic metastases within one year after resection of the primary colorectal cancer including synchronous hepatic metastases, were the factors selected by stepwise analysis as the possible indication of poor prognosis, but they were not statistically significant ($P > 0.05$ or $P < 0.20$).

**Classification of patients and survival:** In devising our classification system, we considered three variables selected by the multivariate analysis, including the number and size of hepatic metastases (H-factor), and the presence of extrahepatic metastases (M-factor), which were resected completely. Results were shown as follows: H1: single metastasis with diameter ≤ 5 cm; H2: single metastasis with diameter > 5 cm or multiple metastases with diameter ≤ 5 cm; H3: multiple metastases with diameter > 5 cm; M0: extrahepatic metastasis (-); M1: extrahepatic metastasis (+, resectable). Staging system (A): stage I: H1 and M0; stage Ⅱ: H2 and M0; stage Ⅲ: H3 and M0; stage Ⅳ: H1-3 and M1; staging system (B): stage I: H1&M0; stage Ⅱ: H1 and M1 or H2 and M0; stage Ⅲ: H2 and M1 or H3 and M0; stage Ⅳ: H3 and M1

**Table 2 Regression statistics for the stepwise cox proportional hazard model[1]**

| Variable | Parameter | *P* | Hazard Ratio (95% CI) |
|---|---|---|---|
| Diameter > 5 cm | 1.35657 | 0.0013 | 3.883 (1.703-8.852) |
| Extrahep. Met (+). | 1.19430 | 0.0133 | 3.301 (1.282-8.502) |
| Number ⩾ 2 | 0.85412 | 0.0265 | 2.349 (1.105-4.997) |
| D.F.interval < 1 yr | 0.67838 | 0.1602 | 1.971 (0.765-5.080) |
| *n* (+) of primary | 0.60034 | 0.1352 | 1.823 (0.829-4.007) |
| ⩾ se (+) of primary | 0.54877 | 0.1676 | 1.731 (0.794-3.774) |

[1]Only those variables selected by the stepwise analysis, at the *P*-value of 0.20 level of significance, are shown. *n* = 81 (Tokyo Univ. 1981-1997). Age ⩾ 60, gender, synchronous, bilobar invasion, CEA; *P* > 0.2.

**Staging system (A):** The survival curves of patients in group 1 based on the staging system (A) are shown in Figure 1B. They were statistically significant ($P = 0.0057$). However, the survival curve of patients with stage Ⅳ cancer seemed to be better than that of those with stage Ⅲ cancer. The 5-year survival rates of patients with cancer in stage I ($n = 26$), stage Ⅱ ($n = 38$), stage Ⅲ ($n = 8$), and stage Ⅳ ($n = 9$) were 74.8%, 49.2%, 15.6%, and 25.0%, respectively. Their median survival time was 52, 18 and 19 mo, respectively, with that unsettled in stage I patients.

**Staging system (B):** The survival curves of patients in group 1 based on the staging system (B) are shown in Figure 1C, and the findings were statistically significant ($P = 0.0003$). The 5-year survival rates of patients with cancer in stage I ($n = 26$), stage Ⅱ ($n = 43$), and stage Ⅲ ($n = 12$) were 74.8%, 49.8%, and 9.5%, respectively. Their median survival time was 52, 52, and 18 mo, respectively. By coincidence, there were no patients with stage Ⅳ disease in this group.

### *Group 2*

The overall 1-, 2-, 3-, 4-, and 5-year cancer-related survival rates after surgical resection in the 92 patients were 82.2%, 65.2%, 51.6%, 42.5%, and 40.0%, respectively (Figure 2A).

**Staging system (A):** The survival curves of 92 patients in group 2 based on the staging system (A) are shown in Figure 2B. They were statistically significant ($P < 0.0001$). However, the survival curve of patients with stage Ⅳ cancer seemed to be better than that of those with stage Ⅲ cancer. The 5-year survival rates of patients with cancer in stage I ($n = 24$), stage Ⅱ ($n = 44$), stage Ⅲ ($n = 8$), and stage Ⅳ ($n = 15$) were 75.0%, 44.5%, 0%, and 0%, respectively. Their median survival time was 46, 13.5, and 20 mo, respectively, with that unsettled in stage I patients.

**Staging system (B):** The survival curves of 92 patients in group 2 based on the staging system (B) are shown in Figure 2C, and findings were statistically significant ($P < 0.0001$). The 5-year survival rates of patients with cancer in stage I ($n = 24$), stage Ⅱ ($n = 48$), stage Ⅲ ($n = 16$), and stage Ⅳ ($n = 3$) were 75.0%, 43.0%, 0%, and 0%, respectively. Their median survival time was 41, 12, and 10 mo, respectively, with that unsettled in stage I patients.

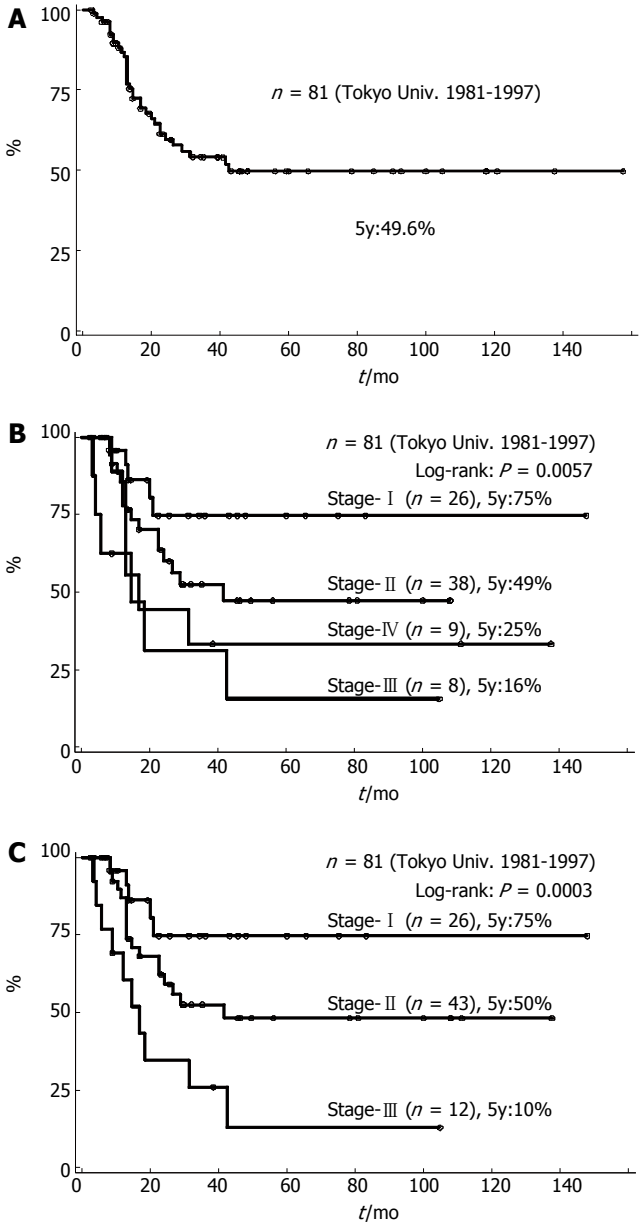

**Figure 1** Kaplan-Meier cancer-related survival curve after hepatic resection for patients with colorectal liver metastases in group 1. **A**: Staging system (A) (log-rank test, $P = 0.0057$); **B**: staging system (B); **C**: stage Ⅰ through sage Ⅲ (log-rank test, $P = 0.0003$ ).

## DISCUSSION

At present, there is no universally accepted classification system for patients with colorectal liver metastasis. Our first step in this investigation was to determine the important clinical and pathological variables that significantly influence prognosis following surgical resection of colorectal liver metastases. Many studies have identified factors which are thought to represent important prognostic determinants, including age at hepatectomy[4,7], sex[23], stage of the primary tumor[2,4,5,7,8,15,20,22,23,28,29] (including regional lymph node metastases and depth of invasion), synchronous or metachronous hepatic metastases[4,7,10,12,14-16,31], the number[4,7,10,11,17,22-25,31] and size[6,7,12,13,15,17,23,26-28] of hepatic metastases, the distribution of hepatic metastases[4,10,20,30], serum carcinoembryonic antigen (CEA) levels[7,11,29,31], extrahepatic metastases[2,8-10,12,14,22,23,26], type of hepatectomy[15], surgical margins[4,9,11,13,15-17,23,24,26], and adjuvant chemotherapy[12,32,33]. Therapeutic factors, such

| [IVb: any H & unresectable extraheptic metastasis (+)] |

as type of hepatectomy, surgical margin, and adjuvant chemotherapy, were excluded in the present statistical analysis, because these therapeutic factors are usually not considered in the classification system. At last three independent and significant determinants, such as multiple tumors, tumor larger than 5 cm in diameter, and macroscopically resected extrahepatic metastasis, were selected in the present study for devising a staging system.

To make a staging system, we considered the number and size of hepatic metastases as hepatic factors (H-factors) while the resected extrahepatic metastases as metastatic factor (M-factor). At first we considered M-factor even if extrahepatic metastases were resected, as an advanced state of disease, e.g. stage Ⅳ in the staging system (A). However, this classification did not seem logical since the prognosis of stage Ⅳ cancer patients was better than that of stage Ⅲ cancer patients. We therefore considered M-factor as one of the risk factors similar to H-factor variable in devising the staging system (B). Following this method, the patients were clearly classified according to their disease stage in group 1 and group 2. This result was reasonable because the risk ratio of M-factor was similar to that of H-factor variables, such as the number and size of hepatic metastases (3.301 *vs* 3.883/2.349) in the present study. Therefore, we propose a new staging system as shown in Table 3. It has not been our policy to perform hepatectomy for patients with unresectable extrahepatic metastases, such as diffuse lung metastases, diffuse peritoneal dissemination, and extensive lymph node metastases. In the present study, we included only the patients with extrahepatic metastases, who underwent hepatectomy as well as complete macroscopic resection of extrahepatic metastases. Therefore, patients with unresectable extrahepatic metastases should be classified as more advanced stages.

In conclusion, we have identified three important and independent prognostic determinants, namely multiple tumors, tumor larger than 5 cm in diameter, and resectable extrahepatic metastasis, using multivariate analysis from a retrospective review of patients who underwent surgical resection for colorectal liver metastases. At last we propose a new and simple staging system with these three determinants to classify the patients according to the long-term outcome after hepatectomy. We hope that it can promote a prospective study on the efficacy of some other therapies such as adjuvant chemotherapy. Although the present study population sample is small, our staging system is simpler and more useful than any other previous classification systems. Further investigation utilizing a larger patient population is necessary.

## Abstract

**AIM:** To study the action of the genes associated with drug-induced liver diseases at the gene transcriptional level during liver regeneration (LR) in rats.

**METHODS:** The genes associated with drug-induced liver diseases were obtained by collecting the data from databases and literature, and the gene expression changes in the regenerating liver were checked by the Rat Genome 230 2.0 array.

**RESULTS:** The initial and total expression numbers of genes occurring in phases of 0.5-4 h after partial hepatectomy (PH), 4-6 h after PH (G0/G1 transition), 6-66 h after PH (cell proliferation), 66-168 h after PH (cell differentiation and structure-function reconstruction) were 21, 3, 9, 2 and 21, 9, 19, 18, respectively. It is illustrated that the associated genes were mainly triggered at the initial stage of LR and worked at different phases. According to their expression similarity, these genes were classified into 5 types: only up-regulated (12 genes), predominantly up-regulated (4 genes), only down-regulated (11 genes), predominantly down-regulated (3 genes), and approximately up-/down-regulated (2 genes). The total times of their up- and down-expression were 130 and 79, respectively, demonstrating that expression of most of the genes was increased during LR, while a few decreased. The cell physiological and biochemical activities during LR were staggered according to the time relevance and were diverse and complicated in gene expression patterns.

**CONCLUSION:** Drug metabolic capacity in regenerating liver was enhanced. Thirty-two genes play important roles during liver regeneration in rats.

## INTRODUCTION

The liver has a very strong capacity to regenerate[1]. Liver cells proliferate rapidly to compensate for lost liver tissues after liver injury or drug stimulus, which is called liver regeneration (LR)[2]. The LR process is usually categorized based on hepatic physiological activities divided into four stages: initiation phase [0.5-4 h after partial hepatectomy (PH)], transition from G0 to G1 (4-6 h after PH), cell proliferation (6-66 h after PH), cell differentiation and reorganization of the structure-function (66-168 h after PH)[3]. The process involves hepatic cell activation, dedifferentiation, proliferation and its regulation, redifferentiation, structure-functional reorganization[4].

Liver is a vital organ of drug metabolism[5]. Disorder of drug metabolism in liver could cause drug-induced liver diseases[6]. It is indicated that 182 genes are associated with drug-induced liver diseases. In addition, there are gene-gene, protein-protein, gene-regulator, and protein-regulator interactions. It is hardly possible to highlight the role of the genes in LR unless gene expression profiles is analyzed with high-throughput[7,8]. Therefore, we used the Rat Genome 230 2.0 array containing 84 genes associated with drug-induced liver diseases to detect gene expression changes after PH, finding that 32 of them were associated with LR, and analyzed these genes expression changes, patterns and actions during LR primarily.

## MATERIALS AND METHODS

### *Regenerating liver preparation*

Healthy SD rats weighing 200-250 g were obtained from the Animal Center of Henan Normal University. The rats were separated into groups at random and each group included 6 rats (male:female = 1:1). PH was performed according to Higgins and Anderson[9], the left and middle

lobes of the liver were removed. Rats were killed by cervical vertebra dislocation at 0.5, 1, 2, 4, 6, 8, 12, 16, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 96, 120, 144 and 168 h after PH and the regenerating livers were observed at corresponding time points. The livers were rinsed three times in PBS at 4℃, then 100-200 mg liver from the middle parts of the right lobe, six samples of each group were collected, wrer mixed with 1-2 g (0.1-0.2 g × 6) total liver tissues, and stored at -80℃. The sham-operation (SO) groups were treated the same with the PH group except that the liver lobes were unremoved. The laws of animal protection of China were enforced strictly.

### RNA isolation and purification

Total RNA was isolated from frozen livers according to the manual of the Trizol kit (Invittrogen)[10] and purified based on the RNeasy mini-kit (Qiagen)[11]. Total RNA samples exhibited a 2:1 ratio of 28S to 18S rRNA intensities by agarose electrophoresis (180V, 0.5h). Total RNA concentration and purity were estimated by optical density measurement at 260/280 nm[12].

### cDNA, cRNA synthesis and purification

As a template, 1-8 μg total RNA was used for cDNA synthesis. cDNA and cRNA synthesis was proceeded by the established method of Affymetrix[13]. cRNA labeled with biotin was synthesized using 12 μL of the above synthesized cDNA as the template, and cDNA and cRNA were purified[13]. Concentration, purity and quality of cDNA and cRNA were measured by the same method mentioned above[12].

### cRNA fragmentation and microarray detection

Fifteen μL (1 μg/μL) cRNA incubated with 5 × fragmentation buffer at 94℃ for 35 min was digested into 35-200 bp fragments. The hybridization buffer was added to the prehybridized Rat Genome 230 2.0 microarray produced by Affymetrix, then hybridization was carried out for 16 h at 45℃ on a rotary mixer at 60 rpm. The microarray was washed and stained by GeneChip fluidics station 450 (Affymetrix Inc., USA). The chips were scanned by GeneChip Scan 3000 (Affymetrix Inc., USA), and the signal values of gene expression were observed[14].

### Microarray data analysis

The normalized signal values, signal detections (P, A, M) and experiment/control (Ri) were obtained by quantifying and normalizing the signal values using GCOS1.2[14].

### Normalization of microarray data

To minimize error in the microarray analysis, each analysis was performed three times by Rat Genome 230 2.0 microarray. Results with a total ratio was maximal ($R^m$) and when the average of three housekeeping genes (β-actin, hexokinase and glyceraldehyde-3-phosphate dehydrogenase) approached 1.0 ($R^h$), it was taken as a reference. The modified data were generated by applying a correction factor ($R^m/R^h$) multiplying the ratio of every gene in $R^h$ at each time point. To remove spurious gene expression changes resulting from errors in the microarray analysis, the gene expression profiles at 0-4 h, 6-12 h and 12-24 h after PH were reorganized by NAP software (normalization analysis program) according to the cell cycle progression of the regenerating hepatocytes. Data statistics and cluster analysis were done using GeneMath, GeneSpring, Microsoft Excel software[14-16].

### Identification of genes associated with liver regeneration

The nomenclature of a liver disease (e.g. drug-induced liver diseases) was adopted from the GENEONTOLOGY database (www.geneontology.org), and input into the databases at NCBI (www. ncbi.nlm.nih.gov) and RGD (rgd. mcw.edu) to identify the rat, mouse and human genes associated with the above liver diseases. Then the genes associated with the drug-induced liver diseases were collated. The results of this analysis were codified, and compared with the results obtained for human and mouse searches in order to identify the difference of human and mouse genes from rats. In comparison to these genes with the analysis output of the Rat Genome 230 2.0 array, the genes, showing a greater than twofold change in expression level as meaningful expression changes[17] , were referred to as rat homologous genes or rat specific genes associated with drug-induced liver diseases. Genes, which displayed reproducible results with three independent analyses with the chip and showed a greater than twofold change in expression level in at least one time point during liver regeneration with significant difference ($0.01 \leqslant P < 0.05$) or extremely significant difference ($P \leqslant 0.01$) between PH and SO, were referred to as associated with liver regeneration.

## RESULTS

### Expression changes of genes associated with drug-induced liver diseases during LR

According to the data from databases at NCBI, GENEMAP, KEGG and BIOCARTA, 182 genes were associated with drug-induced liver diseases. Among them, 84 genes were contained in the Rat Genome 230 2.0 array. Thirty-two of them revealed meaningful changes in expression at least at one time point after PH. There was significant difference or extremely significant difference in expression between PH and SO, and reproducible results were obtained with three analyses with Rat Genome 230 2.0 array, suggesting that the genes were associated with LR (Table 1). The analysis indicated that 12 genes were up-, 11 genes down-, and 9 were up/down-regulated during liver regeneration. Total expression times of up- and down-expressed genes were 130 and 79, respectively (Figure 1A). At the initial stage of liver regeneration (0.5-4 h after PH), 13 genes displayed up-, 7 genes down-, 1 gene up/down-regulation; at the transition phase from $G_0$ and $G_1$ (4-6 h after PH), 10 genes revealed up-, 2 genes down-regulation; at cell proliferation phase (6-66 h after PH), 12 genes showed up-, 8 genes down-, 5 genes up/down-regulation; and at cell differentiation and structure-function reorganization phase (66-168 h after PH), 9 genes displayed up-, 10 genes down-, 5 genes up/down-regulation (Figure 1B).

**Table 1 Expression abundance of 32 genes associated with drug-induced liver diseases during liver regeneration**

| Gene | Recovery time (h) after partial hepatectomy (PH) | | | | | | | | | | | | | | | | | | | | | | |

Italic numbers: Genes are up-regulated more than twofold; Bold numbers: Genes are down-regulated more than twofold.

### *Initial expression time of genes associated with drug-induced liver diseases during LR*

At each time point of LR, the numbers of initial up-, down-regulation and total up-, down-regulation genes were in the sequence: both 6 and 2 at 0.5 h; 3, 3 and 9, 5 at 1 h; 3, 1 and 10, 1 at 2 h; 1, 2 and 10, 2 at 4 h; 0, 0 and 8, 1 at 6 h; 0, 0 and 8, 2 at 8 h; 0, 1 and 6, 2 at 12 h; 2, 1 and 5, 3 at 16 h; 1, 1 and 6, 5 at 18 h; 0, 0 and 4, 4 at 24 h; 1, 1 and 3, 3 at 30 h; 0, 0 and 2, 6 at 36 h; 0, 0 and 4, 3 at 42 h; 0, 1 and 7, 7 at 48 h; 0, 0 and 5, 4 at 54 h; 0, 0 and 8, 3 at 60 h; 0, 0 and 4, 5 at 66 h; 0, 0 and 5, 4 at 72 h; 0, 1 and 4, 4 at 96 h; 1, 0 and 8, 3 at 120 h; 0, 0 and 3, 4 at 144 h , 0, 0 and 5, 6 at 168 h (Figure 2).

### *Expression similarity and time relevance of genes associated with drug-induced liver diseases during LR*

Thirty-two genes mentioned above during LR could be characterized based on their similarity in expression as follows: only up-, predominantly up-, only down-, predominantly down-, and up-/down-regulated, involving 13, 4, 11, 3 and 2 genes, respectively (Figure 3). They could also be classified according to the time relevance into 15 groups, including 0.5 and 1 h, 2 h, 4 and 6 h, 8 h, 12 h, 16 h, 18 and 24 h, 30 h, 36 h, 42 and 96 h, 48 h, 54 h and 60 h, 66 and 72 h, 120 h, 144 and 168 h. Their times of up- and down-regulation genes were respectively 15 and 7, 10 and 1, 18 and 3，8 and 2, 6 and 2，6 and 3, 10 and 9, 3 and 3, 6 and 2, 8 and 7, 7 and 7, 13 and 7, 9 and 9, 8 and 3, 8 and 10 (Figure 3).

### *Expression patterns of genes associated with drug-induced liver diseases during LR*

Thirty-two genes mentioned above during LR might be

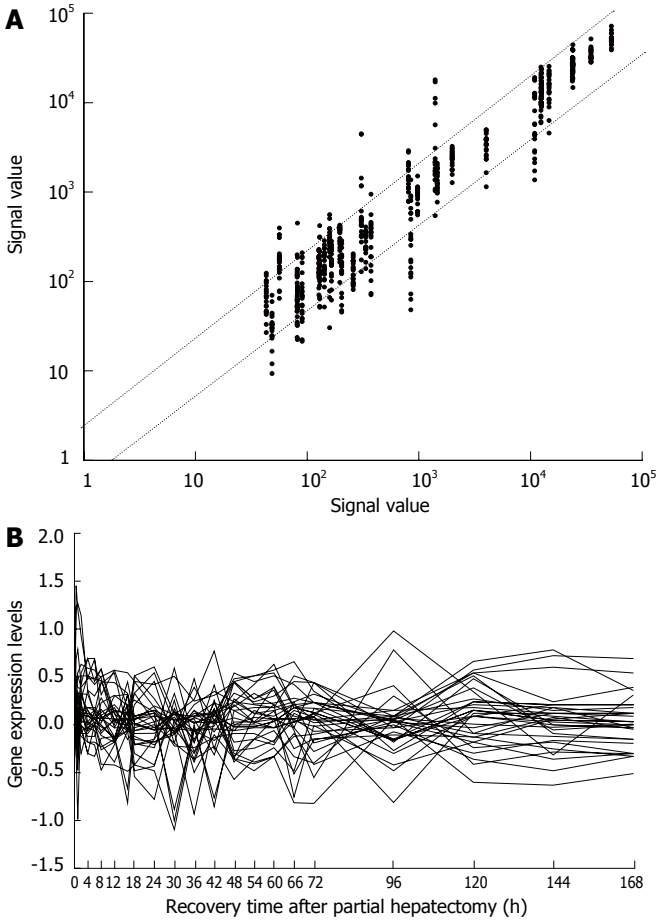

**Figure 1** Expression profiles of 32 genes associated with drug-induced liver diseases during liver regeneration. **A**: The abundance and frequency of gene expression, each point represents the signal value of one gene at corresponding time point. The dots above bias represent the genes up-regulated by more than twofold, those under bias represent the genes down-regulated by more than twofold, and the ones between biases represent the genes meaningless alteration in expression. The farer the genes from the bias, the greater the folds of gene change; **B**: The expression changes of genes associated with LR.

categorized according to the changes in expression into 20 types of patterns: (1) up-regulation at one time point, i.e. at 16, 120 h after PH, (Figure 4A), 2 genes; (2) up- at two time point, i.e. at 1 and 72 h, 30 and 42 h, (Figure 4B), 2 genes; (3) up- at one time point/phase, i.e. at 18 and 48-72 h (Figure 4C), 1 gene; (4) up- at one time point/two phases (Figure 4C), 1 gene; (5) up- at one time point/three phases (Figure 4C), 1 gene; (6) up- at two time points/one phase (Figure 4D), 2 genes; (7) up- at three time points/two phases (Figure 4E), 2 genes; (8) up- at three time points/phases (Figure 4D), 1 gene; (9) down- at one time point, at 0.5, 48 or 96 h (Figure 4F), 3 genes; (10) down- at two time points, i.e. at 1 and 168 h (Figure 4G), 1 gene; (11) down- at three time points(Figure 4G), 1 gene; (12) down- at more time points (Figure 4G), 1 gene; (13) down- at one phase, i.e. at 1-6 h (Figure 4H), 1 gene; (14) down- at one time point/phase, i.e. at 1 and 144-168 h (Figure 4H), 1 gene; (15) down- at two time points/phases (Figure 4H), 1 gene; (16) down- at two time points/four phases (Figure 4H), 1 gene; (17) down- at three time points/one phase (Figure 4H), 1 gene; (18) predominantly up- (Figure 4I), 4 genes; (19) predominantly down- (Figure 4J), 3 genes; (20) up/down- approximately (Figure 4K), 2 genes.

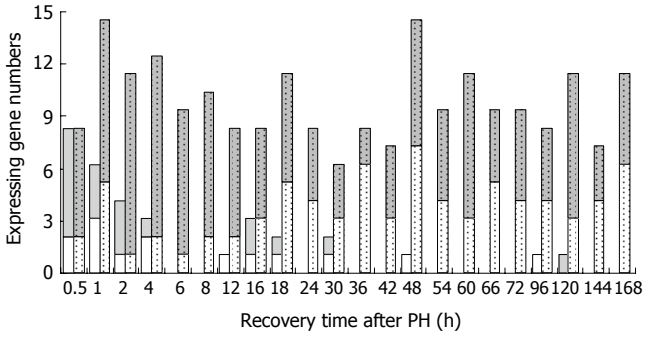

**Figure 2** The initial and total expression profiles of 32 genes associated with drug-induced liver diseases at each time point of liver regeneration. Blank bars: Initial expressing gene number; Dotted bars: Total expressing; Grey bars: Up-regulated; White bars: Down-regulated.

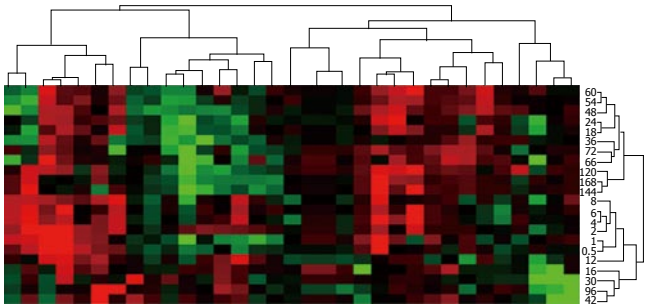

**Figure 3** Expression similarity and time relevance clusters of 32 genes associated with drug-induced liver diseases during liver regeneration. Detection data of Rat Genome 230 2.0 array were analyzed by H-clustering. Red: Up-regulation genes; Green: Down-regulation; Black: No-sense in expression change; The upper and right trees respectively show expression cluster and time series cluster.

## DISCUSSION

In this paper, the roles of 84 genes associated with drug-induced liver diseases during liver regeneration were analyzed. Of the 36 genes associated with drug-induced abnormality of cell proliferation and apoptosis, cocaine addiction-associated cAMP responsive element binding protein 1 (CREB1)[18] and estradiol-induced interleukin 6 (IL6)[19] were related to liver regeneration initiation[20]. Cocaine-induced V-fos FBJ murine osteosarcoma viral oncogene homolog (FOS)[21], troglitazone-induced early growth response 1 (EGR-1)[22], prostaglandin-endoperoxide synthase 2 (PTGS2) repressed by cyclophosphamide[23], estradiol-activated Akt (v–akt) murine thymoma viral oncogene homolog 1 (AKT1)[24] and estradiol-induced brain derived neurotrophic factor (BDNF)[25] all promote cell growth or cell division[26,27]. Valproic acid-restrained estrogen receptor 1 (ESR1)[28] inhibits cell division[29]. Period homolog 1 (Drosophila) (PER1) promotes apoptosis[30]. Cyclophosphamide-induced B-cell leukemia/lymphoma 2 (BCL2) restrains apoptosis[31]. Diethylstilbestrol-restrained transformation related protein 63 (TRP63)[32] is associated with differentiation[33]. Estradiol-induced matrix metallopeptidase 9 (MMP9)[34] is involved in the breakdown of extracellular matrix. Indomethacin-induced phosphatase and tensin homolog (PTEN)[35] blocks tumor cell proliferation and migration[36].

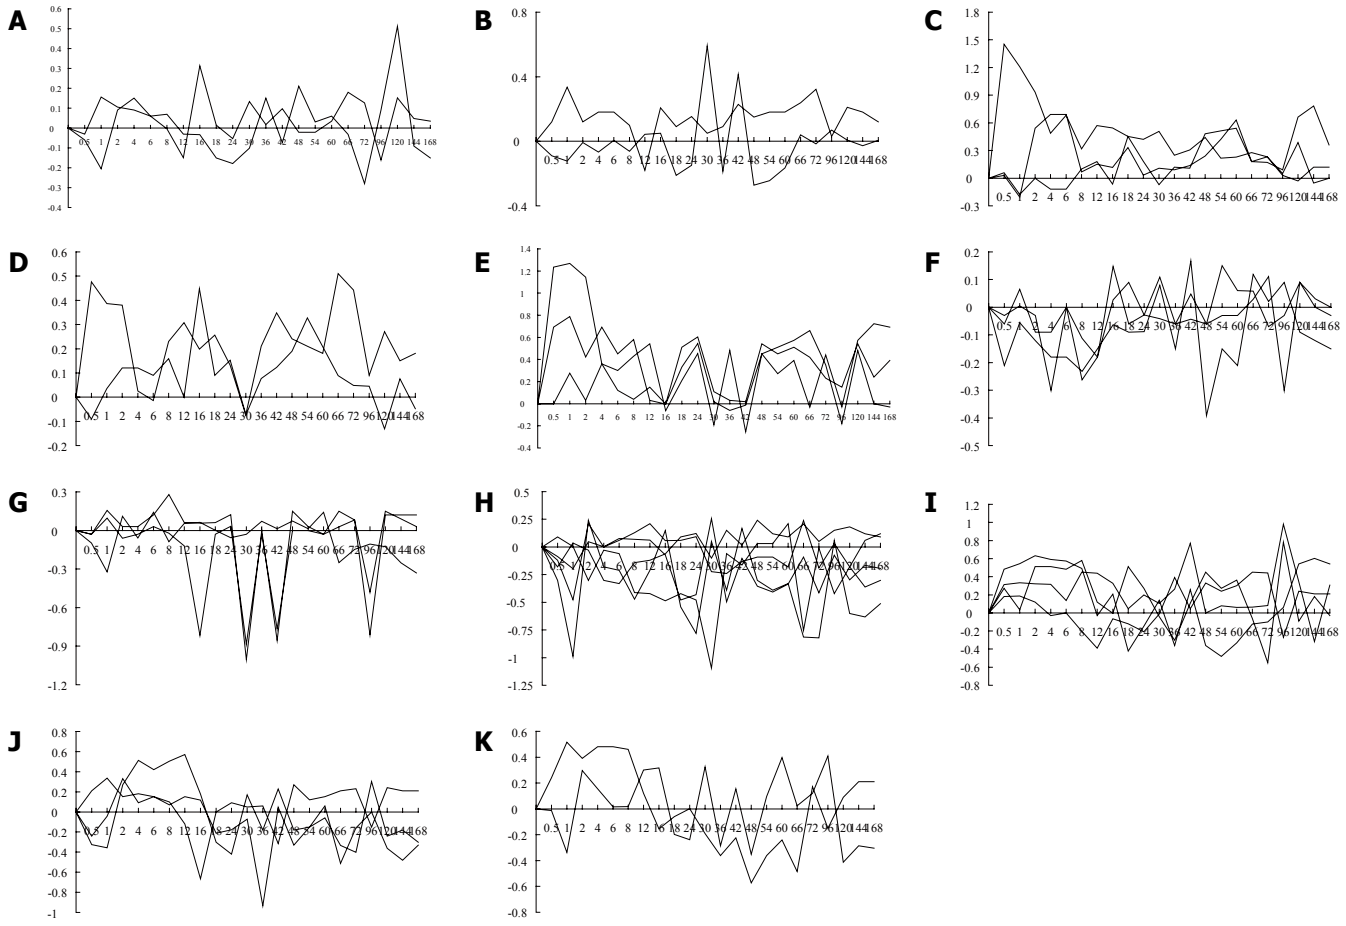

**Figure 4** Expression patterns of 32 genes associated with drug-induced liver diseases during liver regeneration. These genes exhibit 20 types of expression patterns. **A-E**: Up-regulation in expression; **F-H**: Down-regulation; **I-J**: Up/down-regulation mixed. X-axis represents recovery time after PH (h), Y-axis shows logarithm ratio of the signal values of genes at each time point to the control.

Angiotensin I converting enzyme (ACE), whose activity is inhibited by captopril[57], participates in the control of blood pressure. The sameness or similarity in some time points, and the difference in other points of meaningful expression changes of these genes during LR may indicate that they regulate the mass of regenerating liver together.

Of the 21 genes associated with drug-induced disorder of lipid metabolism or amino-acid metabolism, estradiol-induced apolipoprotein E (APOE)[38] and fatty acid binding protein 1, liver (FABP1) play a part in the metabolism and transport of lipid[39,40]. One of the tamoxifens' target proteins: epoxide hydrolase 1, microsomal (EPHX1)[41], and tetracyclin-induced tumor necrosis factor (TNF)[42] participate in lipid metabolism, and 5, 10-methylenetetrahydrofolate reductase (MTHFR)[43] plays a role in methionine biosynthesis. That meaningful expression changes of these genes are the same or similar in some time points, then different in other points during LR perhaps regulate the metabolism of lipid and/or amino-acid together.

Of the 27 genes associated with drug metabolism disorder, six genes including solute carrier family 22 member 1, 2, (SLC22A1, SLC22A2), UDP glucuronosyltransferase 1 family A1 (UGT1A1), glutathione S-transferase M1 (GSTM1), amitriptyline-restrained cytochrome P450 family 2 subfamily D 6 (CYP2D6)[44] and sulfotransferase family cytosolic 1A phenol-preferring member 1 (SULT1A1) are involved in drug metabolism[45-47]. Hippocampus abundant gene transcript 1 (HIAT1) is responsible for transmembrane of tetracyclin[48]. N-acetyltransferase 2 (NAT2) catalyzes decomposition of isoniazid. Hydroxysteroid (11-β) dehydrogenase 1 (HSD11B1) can inactivate cortisol[49]. Carboxylesterase 2, 3 (CES2, CES3) catalyze the hydrolysis of fatty acids and cocaine[50]. Interleukin 5 (IL5) is associated with corticosteroid resistance[51] and inflammation[52]. V-erb-b2 erythroblastic leukemia viral oncogene homolog 2 (ERBB2) can impede the function of tamoxifen[53]. The expression changes of the genes mentioned above were the same or similar at some time points and different at other time points during LR, speculating that they promote drug metabolism together.

In conclusion, some genes associated with drug-induced liver diseases are up-regulated and the others are down-regulated during liver regeneration. In liver regeneration, some drug-induced liver diseases-related genes regulate the liver cell number by adjusting cell proliferation and apoptosis, some control lipid metabolism or amino acid metabolism, and others participate and modulate drug metabolism, demonstrating that they are closely in line with liver regeneration. We will use northern blotting, protein array, RNA interference etc. to further confirm the above results at the cell level in the future.

## Abstract

**AIM:** To compare gemcitabine-based combination therapy and gemcitabine (GEM) alone in patients with advanced pancreatic cancer (APCa) through meta-analysis.

**METHODS:** MEDLINE and EMBASE searches were supplemented by information from trial registers of randomized controlled trials (RCTs) for GEM-based combination therapy and GEM alone for APCa. A quantitative meta-analysis was carried out by two reviewers based on the inclusion criteria from all available RCTs. The meta-analysis involved overall survival (OS), objective remission rate (ORR), clinical benefit rate (CBR), time to progress/progress free survival (TTP/PFS) and toxicity.

**RESULTS:** The meta-analysis included 22 RCTs. There was significant improvement in the GEM combination group with regard to the 6-mo survival rate (RD = 0.04, 95% CI 0.01-0.06, $P$ = 0.008), 1-year survival rate (RD = 0.03, 95% CI 0.01-0.05, $P$ = 0.01), ORR (RD = 0.04, 95% CI 0.01-0.07, $P$ = 0.02), CBR (RD = 0.10, 95% CI 0.02-0.17, $P$ = 0.01) and 6-mo TTP/PFS (RD = 0.07, 95% CI 0.04-0.10, $P$ < 0.00001). However, the Grade 3-4 toxicity set by WHO was higher for the GEM combination group for neutropenia (RD = 0.05, 95% CI 0.01-0.10, $P$ = 0.02), thrombocytopenia (RD = 0.05, 95% CI 0.02-0.08, $P$ = 0.002) and vomiting/nausea (RD = 0.03, 95% CI 0.00-0.05, $P$ = 0.02).

**CONCLUSION:** GEM-based combination therapy may improve the overall survival and palliation in optimal patients with APCa as compared with GEM alone.

**Key words:** Chemotherapy; Pancreatic cancer; Meta-analysis; Gemcitabine

## INTRODUCTION

Gemcitabine (GEM) monotherapy currently is considered as a standard treatment for patients with advanced pancreatic cancer (APCa). However, patients treated with GEM alone have poor prognoses, and their overall median survival (OS) was only 5.65 mo[1]. Attempts have been made to increase the objective remission rate (ORR) and survival of APCa patients, in particular, by exploring the effects of the combined GEM with other drugs. In many phase Ⅱ studies, GEM combinations have improved ORR and OS. Based on these results, many prospective, randomized phase Ⅲ trials comparing GEM used in combination and alone have been carried out. But these trials had different results and the population enrolled is small. Therefore, the NCCN guidelines (National Comprehensive Cancer Network, v.2.2006) indicate that GEM-based combination therapy may be an optimal treatment for APCa patients with a good performance status, including GEM + cisplatin (DDP), GEM + oxaliplatin, GEM + capecitabine, GEM + erlotinib and so on. But these guidelines were based on low level evidence including clinical experience (category 2A). The role of GEM-based combination therapy for the treatment of APCa is still unclear. We therefore, conducted a systematic review and quantitative meta-analysis to evaluate the available evidence from the relevant randomized trials.

## MATERIALS AND METHODS

### *Literature search*

We carried out a comprehensive search of literature

with MEDLINE (1966-2006), EMBASE (1966-2006), CBMdisc (1981-2006), ASCO Abstracts (1995-2005) and EBM Reviews (Cochrane Database of Systematic Reviews 1st Quarter, 2006) ACP Journal Club (1991-2006), (Database of Abstracts of Reviews of Effects 1st Quarter 2006), Cochrane Central Register of Controll ed Trials ( 1st Quarter, 2006 ), using the terms: 'pancreas', 'pancreatic cancer', 'pancreatic carcinoma, 'pancreatic adenocarcinoma', 'pancreatic neoplasms', 'gemzar', ' gemcitabine' (no limit to language). Date of last search: April 26, 2006.

### Selection criteria

**Study design:** Trials should be prospective, properly randomized and well designed, which were matched for age, stage, performance status, *etc*.

**Study population:** Patients with APCa, as well as those with locally advanced, or metastatic disease, were included in the study. Patients eligible for the study were required to have histologically or cytologically proved pancreatic cancer. Furthermore, they should have a baseline Karnofsky performance status of $\geqslant$ 50% (or Eastern Cooperative Oncology Group performance status < 2) and adequate hematological, renal, cardiac and hepatic function. Patients with estimated life expectancy of at least 12 wk, should have received no chemotherapy, radiotherapy and other antitumor therapy in the 6 mo prior to the study entry.

**Intervention:** The treatment group received GEM-based combination therapy, and the control group received GEM alone.

**Outcome:** The primary outcome measurement was OS, followed by ORR and toxicity. The follow-up rate should be above 95%.

**Data collection and analysis:** Two reviewers assessed the abstracts identified from the defined sources. Both reviewers independently selected trials for inclusion according to prior agreement regarding the study population and the intervention. If one of the reviewers concluded an abstract to be eligible, the full text of article was retrieved and reviewed in detail by both reviewers. Missing data from the primary study reports was requested from the investigators. If the same trial appeared on different publications, the final data of the trial was chosen. Methodologic quality of the trials was assessed using a validated scale (range, 0 to 5) applied to items that influence the intervention efficacy. It was reported by Jadad *et al*[2] that the scale consisted of items pertinent to randomization, masking, dropouts, and withdrawals. The following information was obtained from each trial: year of publication, number of patients, performance status, chemotherapy regimen, objective response rate, overall survival, progress free survival, clinical benefit, toxicity, etc. For response assessment, we used trials that included patients with measurable or assessable diseases, and that were analyzed mainly with WHO's criteria. Toxicity profiles were reported according to the WHO's criteria.

### Statistical analysis

The primary end point was a 6-mo survival rate after randomization. The other end points were 1-year survival rate, ORR, CBR, 6-mo TTP/PFS rate and adverse effects. All variables were defined as dichotomous data (e.g., 6-mo survival rate used variables as follows: the alive or dead at 6 mo after randomization). We standardized the therapeutic results by obtaining the risk difference (RD) between the GEM combination group and the GEM alone group. Publication bias was examined using a funnel plot[3]. We looked for heterogeneity among the trials based on Cochran's $\chi^2$ test. All analyses were performed strictly with RevMan software (version 8.2, Cochrane). *P* value less than 0.05 was considered as significant in difference.

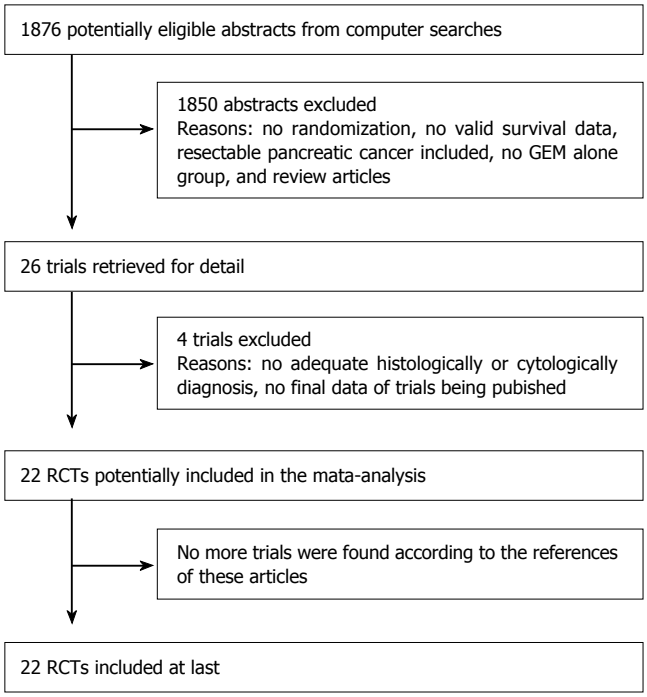

**Figure 1** The flow chart. GEM: gemcitabine; RCTs: randomized controlled trials.

## RESULTS

### Trial flow

The flow chart of our study is shown in Figure 1. Because the trial reported by Degen *et al*[4] involved some patients diagnosed by imageology, we excluded this trial from our analysis. Of the 26 trials, three reported by Ohkawa *et al*[5], Richards *et al*[6], and Shapiro *et al*[7], were excluded because of no final data. Both reviewers finally agreed to include 22 RCTs involving 5473 APCa patients in the meta-analysis.

### Characteristics of selected trials

These prospective randomized controlled studies are summarized in Table 1. All selected trials for inclusion strictly according to prior selection criteria, were prospective, randomized and well designed, and the clinical characteristics were matched for age, stage, performance status, and so on. All studies reviewed were considered high in quality, for they achieved a score of 3 or higher in the assessment scale of Jadad's study design. Patients eligible for these studies had histologically or cytologically

**Table 1 Randomized controlled trials (GEM combination *vs* GEM alone)**

[1]Gemcitabine 1 g/m$^2$ as a 100-min infusion; [2]Gemcitabine 1500 mg/m$^2$ at a fixed dose rate of 10 mg/m$^2$ per minute; [3]RECIST criteria.

proved pancreatic cancer, with same baseline data and without evidence of selection bias. Of the 22 trials, seven were randomized phase Ⅱ trials, and the others were randomized phase Ⅲ trials. The 6-mo survival rate was extracted from each of the 22 trials, and objective remission rates were recorded in most of the trials. Only a few trials provided CBR, PFS, TTP and TTF (time of treatment failure).

### Overall survival

The 5473 randomized patients from 22 RCTs, 2772 in the GEM combination group and 2701 in the GEM alone group, were included in the meta-analysis. The result of the test for heterogeneity of the therapeutic effect was not significant ($P = 0.19$). Therefore, we selected a fixed effect model. There was a significant improvement in 4% of the GEM combination group in 6-mo survival rate (95% CI 0.01-0.06, $P = 0.008$). The results of the meta-analysis in 6-mo survival rate are presented in Figure 2.

With the same technique, 5292 patients from 21 RCTs were analyzed. In the GEM combination group, a 3% improvement was made in 1-year survival rate as compared with the GEM alone group, and this difference being statistically significant (95% CI 0.01-0.05, $P = 0.01$).

The 4912 randomized patients from 21 RCTs, 2461 in the GEM combination group and 2451 in the GEM alone group, were included in the meta-analysis. The result of the test for heterogeneity of the therapeutic effect

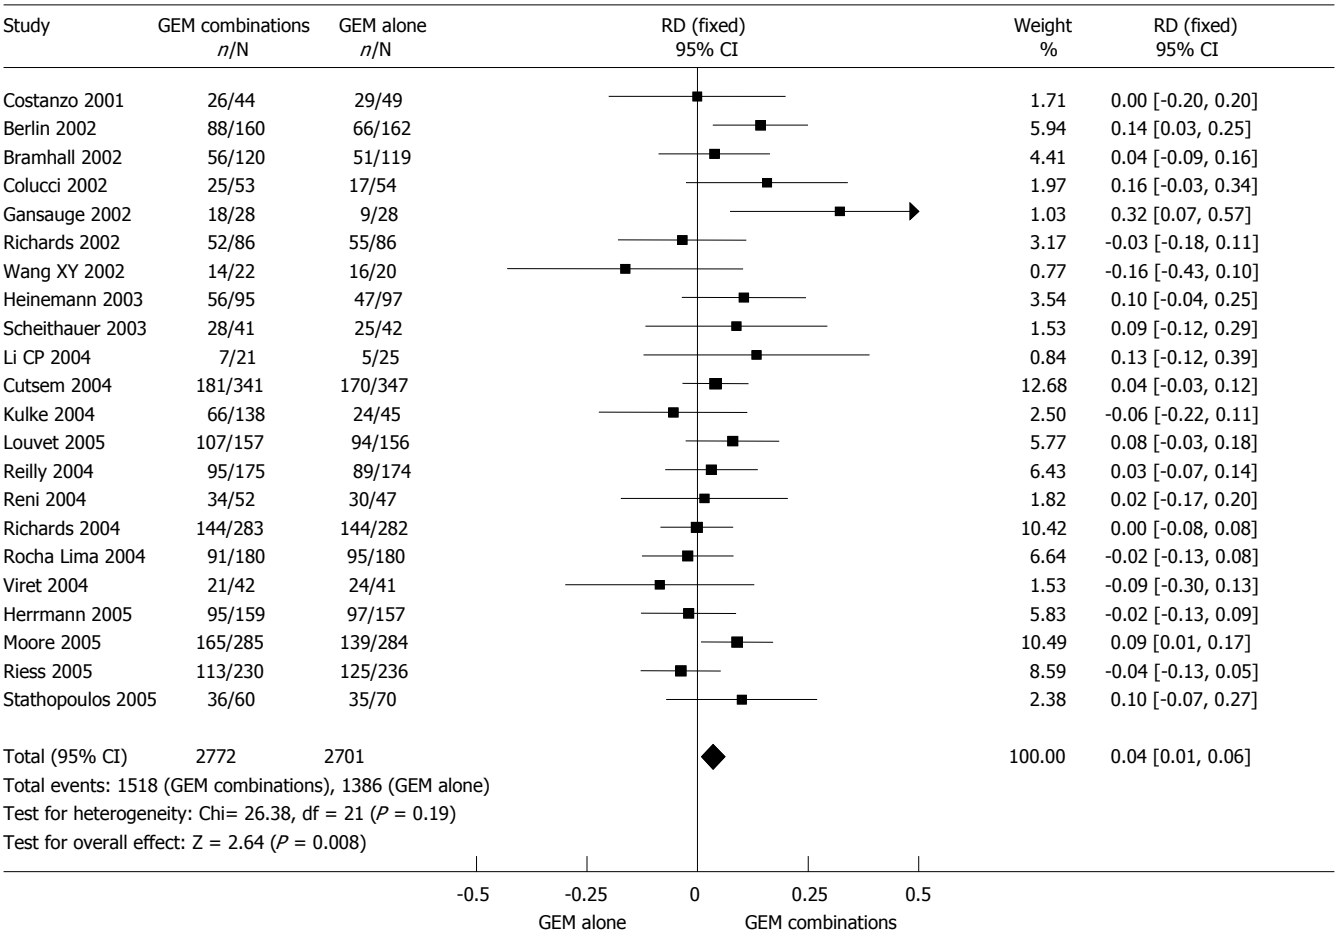

**Figure 2** Fixed effect model on RD of 6-mo survival rate.

was significant ($P < 0.0001$). A random effect model was adopted. There was a significant improvement in 4% of the GEM combination group in ORR (95% CI 0.01-0.07, $P = 0.02$). The outcome of the meta-analysis in ORR is presented in Figure 3.

The 580 randomized patients from 6 RCTs, 290 in the GEM combination group and 290 in the GEM alone group, were included in the meta-analysis. The result of the test for heterogeneity of the therapeutic effect was not significant ($P = 0.05$).

A fixed effect model was used. There was a significant improvement in 10% of the GEM combination group in CBR (95% CI 0.02-0.17, $P = 0.01$). The outcome of the meta-analysis in CBR is shown in Figure 4.

### Six-month TTP/PFS rate

TTP/PFS was defined as the period from randomization to documented disease progression for TTP or to disease progression or death for PFS. In almost all of the trials, patients recruited with good performance status died of disease progression, so TTP was very close to PFS. Therefore, we can analyze TTP and PFS together.

The 3783 randomized patients from 13 RCTs, 1889 in the GEM combination group and 1894 in the GEM alone group, were included in the meta-analysis. The result of the test for heterogeneity of the therapeutic effect was not significant ($P = 0.20$). A fixed effect model was used. Significant improvement was found in 7% of GEM combination group in 6-mo TTP/PFS rate (95% CI 0.04-0.10, $P < 0.00001$). The meta-analysis in TTP/PFS is presented in Figure 5.

### Toxic effects of chemotherapy

Toxic effects of 21 RCTs are summarized in Table 2 (only Grade 3-4 toxic effects were recorded). Main toxic effects were analyzed. Grade 3-4 toxicity was higher in GEM combination group for neutropenia (RD = 5%, 95% CI 0.01-0.10, $P = 0.02$), thrombocytopenia (RD = 5%, 95% CI 0.02-0.08, $P = 0.002$) and vomiting/nausea (RD = 3%, 95% CI 0.00-0.05, $P = 0.02$), all reached significant difference.

### Assessment for publication bias

Figures 6 and 7 represent funnel plots that test for publication bias. Funnel plots for the 6-mo survival rate (Figure 6) and 1-year survival rate (Figure 7) supported the lack of evidence for publication bias.

### Subgroup analysis

Table 3 shows the subgroup analyses in 6-mo survival rate. It revealed that only the combined chemotherapy consisting of GEM plus a new targeted drug yielded a 6% higher survival rate as compared with chemotherapy of GEM alone.

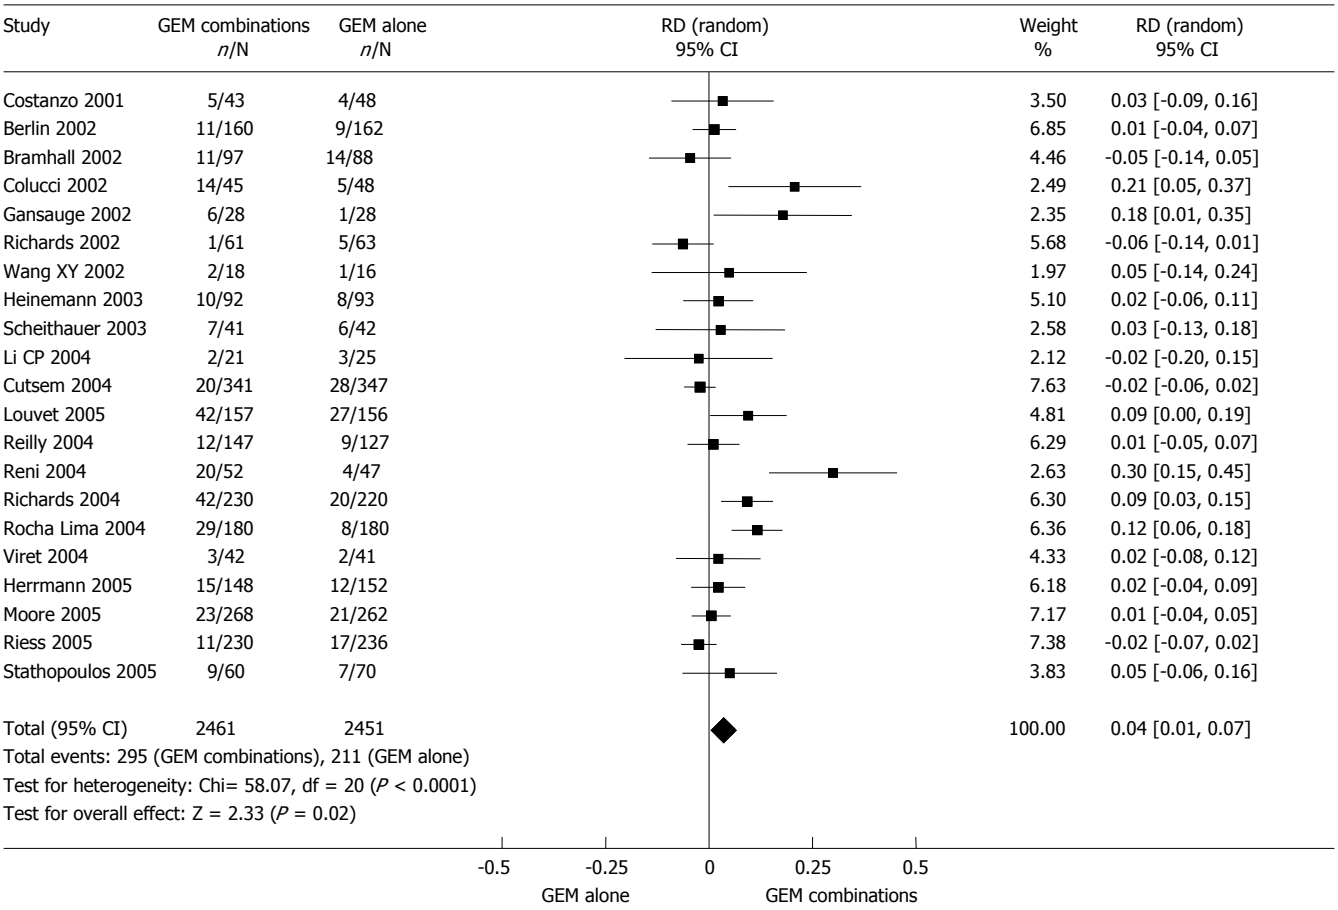

**Figure 3** Random effect model on RD of ORR.

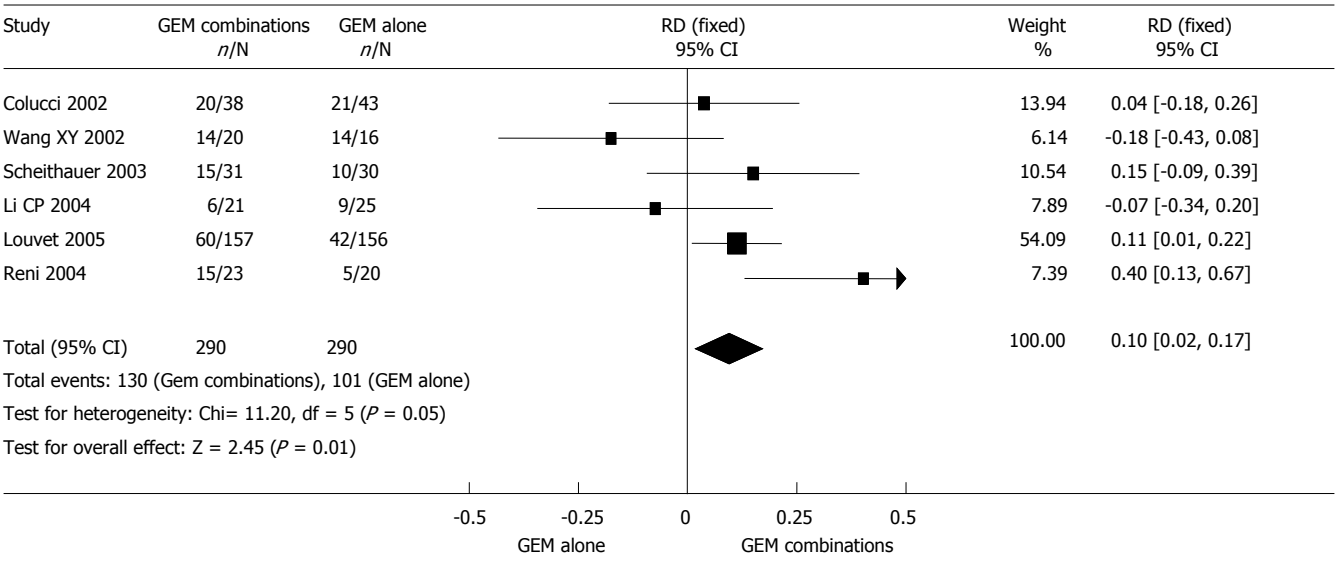

**Figure 4** Fixed effect model on RD of CBR.

## DISCUSSION

To improve the clinical results of GEM, Phase Ⅱ-Ⅲ trials have been made recently to evaluate the efficacy of combination of GEM with other drugs which were shown to be synergistic *in vitro*, such as 5-fluorouracil (5-FU), DDP, topotecan, *etc*[30,31]. Many trials demonstrated that combined GEM chemotherapy improved ORR and PFS compared with GEM alone, and a few trials reported significant OS advantage (Table 1).

The present meta-analysis shows that GEM combination produced a significant survival advantage as compared with GEM alone in patients with APCa. GEM combination was also found superior to GEM alone in

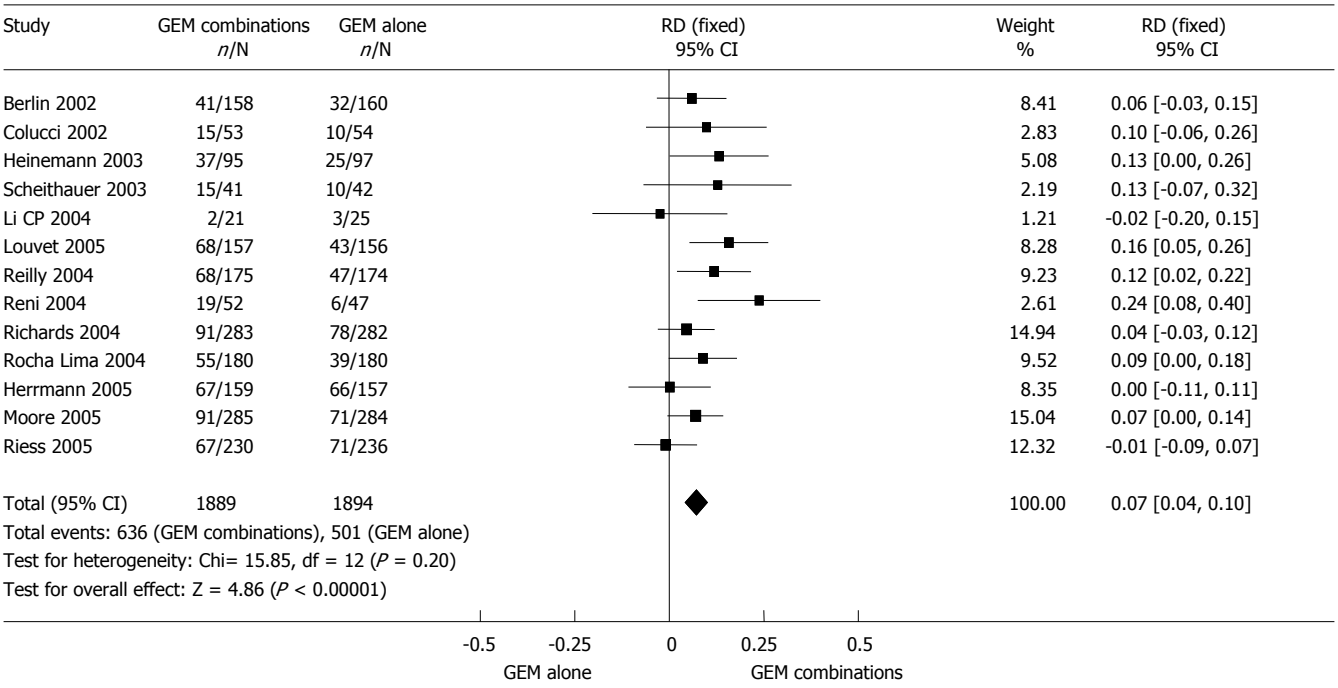

**Figure 5** Fixed effect model on RD of 6-mo TTP/PFS rate.

5-FU: 5-fluororacil; EPI: Epirubicin.

terms of ORR, CBR and 6-mo TTP/PFS. Although most of the selected RCTs showed no significant survival advantage in the GEM combination group, many trials demonstrated slight survival benefit. Physicians should carefully interpret these results when they apply them in clinical practice because GEM combined with other regimens might lead to reversed therapeutic effects.

Straightforward conclusions from the results of this meta-analysis do support the use of GEM combination in patients with APCa, but toxicities from intensive chemotherapy may obliterate the survival benefit of GEM combination. In another meta-analysis, we had reported that the regimens GEM plus DDP were not superior to GEM alone in patients with APCa, which produced more side effects[32]. Furthermore, the subgroup analyses did not show any significant survival advantage in most of GEM combination groups, such as GEM plus 5-FU, GEM plus topoisomerase I inhibitor, and so on. It indicates that not all GEM combined chemotherapy have therapeutic advantage. We suggest that GEM combination, including GEM plus oxaliplatin, and GEM plus erlotinib, should be considered as optimal treatment for patients with APCa. In addition, we found that patients with good perforemance status gained great survival advantage in the sub-group analyses as reported by many other authors[28,29,12]. In our opinion, GEM combination should be applied to patients with good performance status, but carefully to the weak patients.

We found that patients receiving GEM-based combination therapy developed side effects more frequently, including neutropenia, thrombocytopenia and vomiting/nausea , which might lead to a deterioration in

quality of life (QOL). However, the significant advantage of CBR and TTP/PFS in the GEM combination might be converted to the improvement of QOL**.** Because the primary role of chemotherapy in patients with APCa is palliative, the influence on the QOL of the patients is an important issue in determining the true value of the therapy. However, because the methods for QOL assessment from the included trials were quite different, there was no valid meta-analysis of QOL . We also noted that the CBR analysis was made in only six trials, so the result was still unreliable.

The mata-analysis was based on RCTs with high quality. We carried out a comprehensive search of the literature with barely all of cancer database. Publication bias is frequently cited as a reason for lack of validity in meta-analyses. It could occur if studies finding no association between exposure and disease were less likely to be submitted and accepted for publication than studies finding a positive association. In fact, the results of most of the studies in our meta-analyses were negative, as stated by the authors. The funnel plots also showed no evidence of publication bias. Therefore, our meta-analysis provided a valid assessment and creditable results.

Several technical issues have to be mentioned regarding this meta-analysis. One major limitation is the data source extracted from abstracted data and not individual patient data (IPD). In general, an IPD-based meta-analysis would give a more robust estimation for the association, therefore, we should interpret the results with care, especially for a positive result. Clearly, further investigations using IPD should be conducted to examine the main end points. Publication bias is a significant threat to the validity of meta-analysis. Although we detected no evidence of publication bias using the graphical method, it is difficult to completely rule out this possibility. Heterogeneity among trials can be another limitation of our meta-analysis. Although we applied a random-effect model that takes possible heterogeneity into consideration, there were still many factors causing heterogeneity, such as different drug combination, two infusion methods of gemcitabine and so on.

In conclusion, the meta-analysis indicates that GEM-based combination therapy may improve the overall survival and palliation in optimal patients with APCa as compared with GEM alone. Although the application of GEM combination is still controversial, it is a progressive method from the prospective view of point. At the same time, new regimens of drug administration should be explored in future studies.

## Abstract

**AIM:** To investigate in patients with functional dyspepsia (FD) after an every-day meal whether (1) gastrointestinal (GI) and extra-GI symptoms had any relation with the degree of antral volume, (2) the onset of postprandial symptoms was associated with, and may predict, delayed gastric emptying.

**METHODS:** In 94 symptomatic FD patients, antral volume variations and gastric emptying were assessed with ultrasonography after a 1050 kcal meal. Symptoms were evaluated with a standardized questionnaire. The association of GI and extra-GI symptoms with antral volumes and gastric emptying were estimated with logistic regression analysis.

**RESULTS:** Forty percent of patients did not report any symptoms after a meal. Compared to the healthy controls, the antrum was more distended in patients throughout the entire observation period and 37 (39.4%) patients had delayed gastric emptying. Only postprandial drowsiness was associated with antral volume variations (AOR = 1.42; $P < 0.001$) and with delayed gastric emptying (AOR = 3.59; $P < 0.03$).

**CONCLUSION:** In FD patients, GI symptoms are neither associated with antral distension nor with gastric emptying. Drowsiness is associated with antral distension and delayed gastric emptying. The onset of drowsiness is preceded by an increment of antral distension and the duration of the symptom appears to be related to the persistence of antral distension.

**Key words:** Antral distension; Functional dyspepsia; Gastric emptying, Ultrasonography

## INTRODUCTION

Patients with functional dyspepsia (FD)[1] complain of several gastrointestinal (GI) and extra-gastrointestinal (extra-GI) symptoms[2-5] that are usually associated with food ingestion[6]. Several pathophysiological abnormalities have been implicated in the etiology of symptoms, but so far they failed to establish a clear-cut association between symptoms and specific function abnormalities and often similar studies provided contrasting findings[6-13]. Despite symptoms are often related to food ingestion, few studies have assessed the relationship between the occurrence of GI symptoms after meal ingestion and gastric functions[6,10,11,14-19] and reported non-univocal results. In addition, investigations performed while patients are symptom-free may miss their underlying pathophysiological mechanisms because as the symptoms, they may wax and wane over time[20]. Ricci *et al*[14] firstly and others subsequently[15,16,18,21,22] reported a distended fasting antrum and an increased post-prandial antral volume in patients with FD as compared with healthy controls, suggesting that an impaired motor function of the distal stomach is present in a subgroup of patients with FD. However, only two studies[14,15] evaluated the temporal association between the onset of postprandial GI symptoms and antral distension assessed with ultrasonography (US). The first study reported a close association between the onset of the postprandial GI complaints[14] and antral volume increase in the majority (71%) of patients. The second study reported an association between bloating and increased antral area[15]. We have recently shown that a subgroup of patients with FD reported postprandial drowsiness as a bothersome symptom, in addition to the GI dyspeptic ones[5]. Drowsiness is a subjective experience often reported after food ingestion[23]. It has also been shown that solid but not liquid meal results in a decreased sleep onset latency in healthy volunteers[24], suggesting that a post-ingestion mechanism rather than a cephalic stimulus is involved as an initial trigger in mediating the phenomenon.

We aimed to further evaluate the relationship between the onset of postprandial symptoms, both GI and extra-GI symptoms, such as headache and drowsiness, and the modality of the postprandial antral volume increase in FD patients.

The primary aim of the present study was to investigate with regression analysis models, in controlled condition, after an every-day balanced meal, whether upper GI and extra-GI symptoms had any relation with the degree of antral volume assessed with US in FD patients. The secondary aim was to evaluate whether the onset of postprandial symptoms was associated to, and may predict, delayed gastric emptying.

## MATERIALS AND METHODS

### Subjects

Two hundred and seventeen consecutive patients with chronic symptoms of dyspepsia (143 females, 74 males; age, 42.4 ± 12.2 years;) referred to the gastroenterology outpatient clinic were prospectively assessed. Functional dyspepsia (FD) was defined according to the Rome Ⅱ criteria[1]. Organic abnormalities, psychiatric illnesses, eating disorders, history of alcohol and caffeine abuse, use of NSAID, steroids or drugs affecting gastric function, previous GI surgery (except appendectomy and cholecystectomy) and systemic disorders were ruled out by history, clinical examination, biochemical investigations, upper GI endoscopy, and transabdominal US. Dyspeptic patients with Rome diagnostic criteria of irritable bowel syndrome (IBS) and/or referring heartburn and/or regurgitation as predominant or frequent symptoms were excluded from the study.

Severity of epigastric pain and upper abdominal discomfort was graded 0-4 according to its effect on patient's daily activities: 0 = absent; 1 = mild (present but easily bearable if distracted by usual activities); 2 = moderate (bearable but not influencing usual activities); 3 = relevant (influencing usual activities); and 4 = severe (interruption of usual activities)[5]. Patients were symptomatic at the time of, and in the 3 weeks preceding, the investigation. Dyspeptic symptoms had to be present more than 3 days a week, with pain and discomfort scored at least as moderate (≥ 2).

Overall 123 patients (80 females, 43 males; age, 44 ± 13.5 years) were excluded from the study because of the following diagnosis: 59 with gastroesophageal reflux disease; 15 with IBS; 14 with peptic ulcer disease; 16 with migraine; 3 with psychiatric disorders; 2 with celiac disease; and 14 with not properly reporting symptoms during the test.

Ninety-four consecutive patients (63 females, 31 males; age, 42 ± 12 years) fulfilling Rome Ⅱ diagnostic criteria of functional dyspepsia[1] and 21 healthy subjects (13 females, 8 males; age, 30 ± 8.5 years) without GI symptoms participated in the study.

Informed consent was obtained from each subject and the Local Ethics Committee approved the study protocol.

### Assessment of symptoms

An experienced gastroenterologist (EC) interviewed the patients before the study. GI symptoms were enquired by means of the validated Italian version of the Rome Ⅱ modular questionnaire[25]. The validation process and validity of the translated questionnaire have been formally assessed and approved by the Coordinating Committee of the Rome Foundation (on files of the Committee). The questionnaire also includes items inquiring on demography (5 items), daily habits (10 items), meal timing and composition, alcohol consumption, smoking and sleep patterns, past medical history (3 items), somatic extra-GI symptoms (5 items) as previously reported[2].

Frequency and time relationship with meal ingestion were assessed for each of the following dyspeptic symptoms, as defined by the Rome Ⅱ criteria[1]: pain or discomfort centered in the upper abdomen, nausea, vomiting, fullness, bloating, early satiety, epigastric burning and belching. Postprandial drowsiness was defined as a state of impaired awareness associated with a desire or inclination to sleep[26]. Furthermore, patients were requested to refer any other symptom they considered to be bothersome and related to meal ingestion.

### Study protocol

Gastric antral volume was evaluated at US as previously described[27,28] with 3.5-MHz convex probe (Tosbee, Toshiba, Japan). Gastric emptying was evaluated with US according to previously validated and standardized methods[27-32]. All drugs affecting the GI tract were discontinued at least 3 d before the study. Subjects refrained from smoking 12 h before and during the examination. Beverages, including water, coffee and tea were not allowed before and during the examination. The presence of sleep disturbances the night before the test and the quality of sleep in the last month were specifically enquired. After an overnight fast, subjects ate an ordinary standard solid meal of 1050 kcal containing 140 g bread, 70 g cheese, 80 g ham, (50 % carbohydrates, 25% lipids, 25% proteins) and 250 mL of water. The time of meal ingestion did not exceed 30 min (range, 15-30 min). The same proven-skilled operator (NP) performed gastric antral US measurements, with the subjects standing in the upright position. Subjects were studied in fasting condition, soon after the meal ingestion, at 30 and 60 min after the end of the meal ingestion, and at 60 min intervals thereafter for 300 min. In the intervals between measurements subjects could move freely.

Delayed gastric emptying was defined as the final antral volume exceeding the mean value plus 2SDs of the healthy controls[5].

Patients and healthy controls were requested to report every 30 min any symptom occurring after the meal ingestion. The ultrasonographer was blind for the referred historical symptoms.

### Statistical analysis

To compare patients and healthy controls as well as temporal meal-related antral volume variations, arithmetic mean, standard deviation, median values and interquartile ranges were calculated. Continuous variables (age, body mass) were compared using student's t-test. Box-plots[33] were used to provide an immediate graphical evaluation of

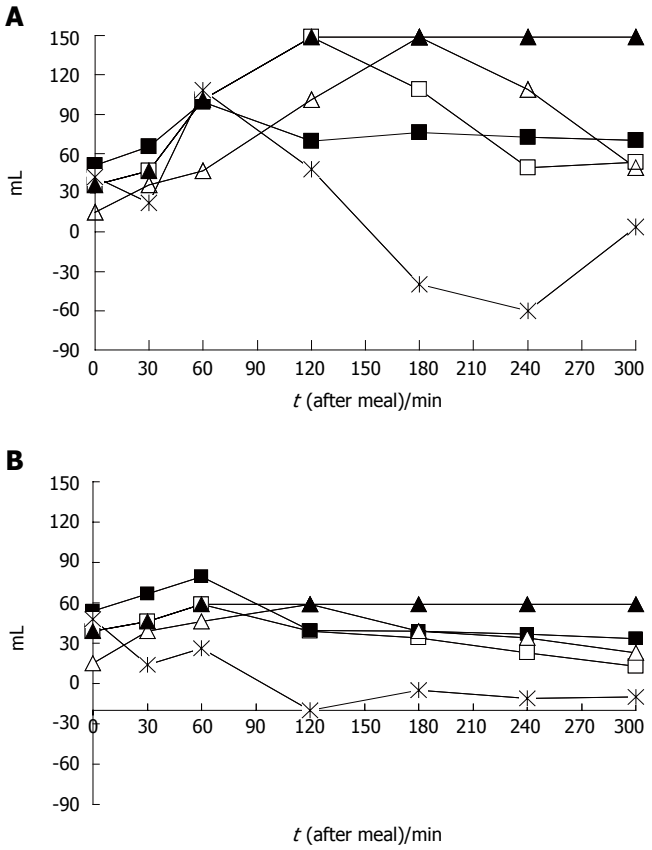

**Figure 1** Antral volume measurements and their transformations. **A**: Patients referring postprandial drowsiness during the study period; **B**: Patients not referring symptoms during the study period. Open quadrangle: current antral volume; asterisk: antral volume delta variation between two consecutive measurements; Closed quadrangle: mean weighted antral volume; Closed triangle: maximal antral volume; Open triangle: antral volume value at the preceding time intervals.

the postprandial gastric antral volume distribution during the study period. Linear regression analysis for repeated measurements was applied to evaluate during the study period whether there were differences in the antral volumes between patients and healthy controls. The cumulative probability of developing symptoms during the 5 h study period was evaluated using the Kaplan-Meier method. Logistic regression models[34] were applied to estimate crude (OR) and adjusted odds ratios (AOR) for age, body mass index (BMI) and gender, and 95% confidence intervals (95%CI) of having an association between antral volume variations and presence/absence of each GI and extra-GI symptom at each time interval evaluated. We also investigated specific transformations of the current gastric antral volume evaluated for a 10 mL unit change as follows (Figure 1 A and B): (1) the antral volume value at the preceding time interval; (2) the antral volume delta variation between two consecutive measurements; (3) the mean weighted antral volume value at each measurement (i.e., at each time when the volume was measured, the value obtained as the arithmetic mean of the current value together with all previous measurements); (4) the maximal antral volume value reached after a meal between the current and the previous measurement.

Logistic regression analysis was also applied to estimate crude and adjusted odds ratios of having delayed gastric emptying for each symptom, fasting antral volume, gender, age, and BMI. We reported results from multiple logistic regression analyses, obtained through a backward selection strategy having excluded factors with a $P$ value >0.20 obtained by a likelihood-ratio test[33]. Two-sided $P$ values were defined statistically significant when $P < 0.05$, and marginally significant when $0.05 < P < 0.2$. All the analyses were performed using STATA release 8.0[35].

**Table 1 Major demographic characteristics of investigated subjects**

| | Healthy controls ($n$ = 21) | FD patients ($n$ = 94) | $P$ |
|---|---|---|---|
| Age median (IQR) yr | 27 (26-29) | 42 (31-52) | < 0.001 |
| BMI median (IQR) kg/m$^2$ | 22.4 (20-23) | 22.0 (19.8-25.0) | 0.47 |
| Female (%) | 13 (61.9%) | 62 (66.0%) | 0.72 |

IQR: Interquartile range.

## RESULTS

### *Study population and GI and extra-GI symptoms profile*

At inclusion, all FD patients reported frequent pain or discomfort (60% of them almost daily) graded at least as moderate. Demographic characteristics of the subjects evaluated are summarized in Table 1. There was no significant difference between the healthy controls and the FD patients for BMI and gender, whereas the controls were younger ($P < 0.001$) than the FD patients. After a meal, none of the healthy subjects reported any symptoms. Of the FD patients, 39 (41.5%) did not refer any symptoms and 55 (58.5%) reported one or more GI and extra-GI symptoms. In this group of 55 symptomatic patients, postprandial drowsiness was reported as a predominantly bothersome symptom in 17 patients, presenting as the only symptom in 3, in association with pain in 3, with fullness in 6, with pain and fullness in 2, with belching in 2 and with bloating in 1. Reported symptoms' severity in the medical history did not significantly differ between the patients with and without postprandial symptoms during the investigation. The cumulative probability to develop at least one of the GI and extra-GI symptoms was 58.5% (Figure 2). None of the patients referred early satiety, vomiting and heartburn (not shown in Figure 2). Despite the patients with history of regurgitation were excluded from the study, 2 patients referred postprandial acid regurgitation (not shown in Figure 2 and Tables 2 and 3). The percentage of patients with symptoms at each evaluated time interval is reported in Table 2. Among the patients who referred at least one symptom, 55.5% had the first symptom within 60 min after meal ingestion. Postprandial drowsiness started later (71.5 ± 64.8 min) than dyspeptic symptoms (38.3 ± 55.4 min, $P < 0.001$).

### *Antral volume assessments and gastric emptying*

Antral volume before, immediately (time 0) and during the 300 min observation period after meal ingestion in

the controls and the FD patients is shown in Figure 3. In the FD patients, the postprandial antral volume was significantly larger compared to the controls ($P < 0.05$) from the end of meal ingestion up to the final observation. The multiple linear regression model showed that in the postprandial period antral volume, adjusted for gender and age, was higher in the dyspeptic patients compared to the controls with a difference in volume value of 11 mL during the entire period ($P < 0.01$). Gastric emptying was delayed in 37 (39.4%) of the FD patients.

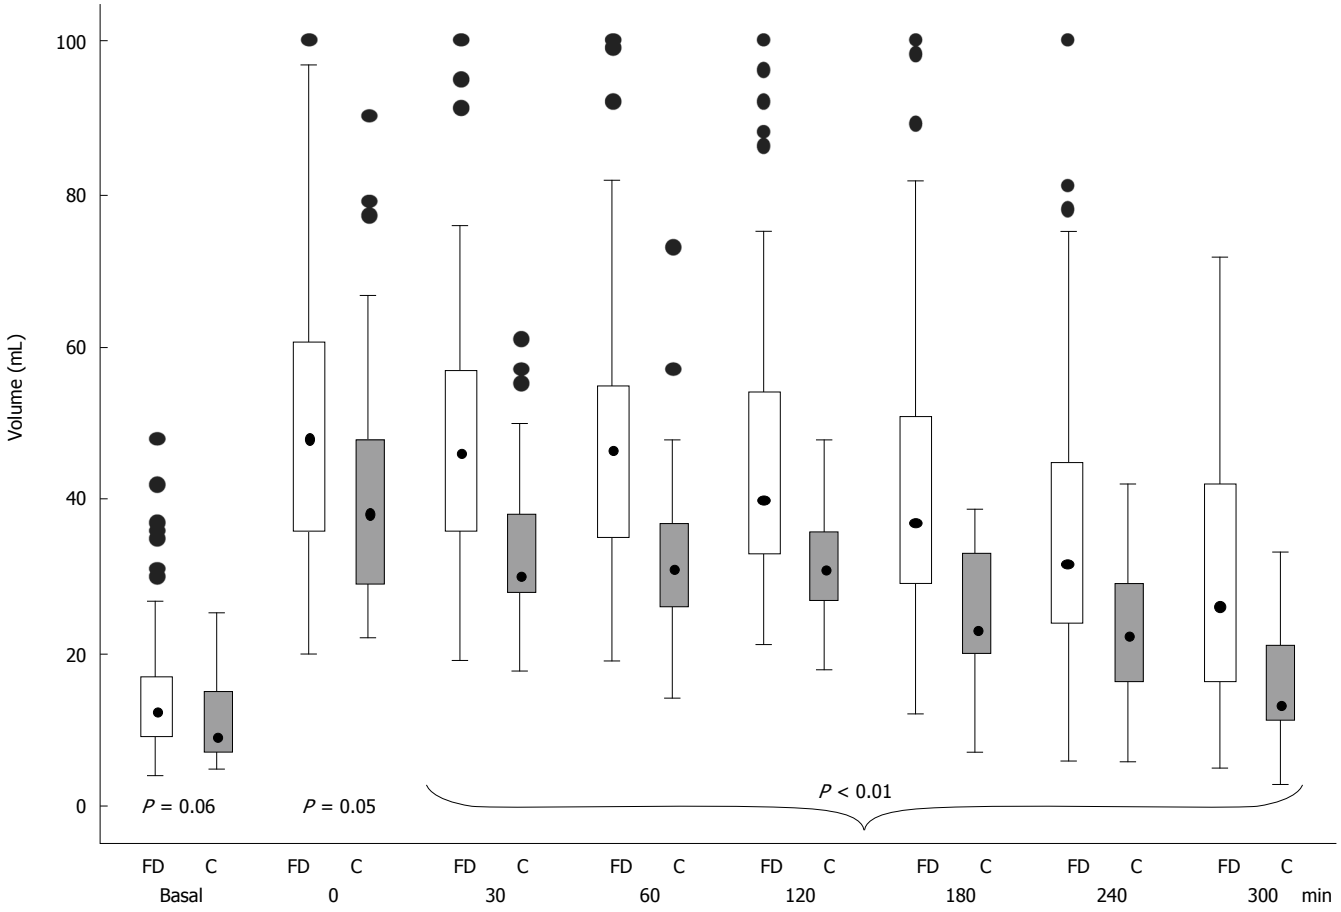

**Figure 3** Box-and-whiskers plots of gastric antral volume before (fasting), immediately (0), at 30 and at 60 min intervals, after the end of the ingestion of a standard meal in controls (gray box) and in dyspeptic (white box). The boxes at each time unit extend from the 25th percentile ($x_{[25]}$) to the 75$^{th}$ percentile ($x_{[75]}$) [i.e., the interquartile range (IQ)]; the lines inside the boxes represent the median values. The lines emerging from the boxes (i.e., the "whiskers") extend to the upper and lower adjacent values. The upper adjacent value is defined as the largest data point $\leqslant x_{[75]} + 1.5 \times IQ$, and the lower adjacent value is defined as the smallest data point $\geqslant x_{[25]} - 1.5 \times IQ$. Observed values more extreme than the adjacent values, if any, are individually plotted (circles).

the antral volume transformations described in Figure 1 are reported in Table 3. The occurrence of postprandial drowsiness was related to (1) the current antral volume value, (2) the antral volume value at the previous time interval, (3) the antral volume delta variation between two consecutive measurements, (4) the mean postprandial weighted antral volume and (5) the maximal antral volume value reached after a meal. The occurrence of nausea and belching was related to the antral volume delta variation between two consecutive measurements. The occurrence of bloating was significantly related to a mean postprandial weighted antral volume, and marginally associated with (1) the current antral volume value, (2) the antral volume value at the previous time interval, and (3) the maximal antral

**Table 4 AOR with 95% CI of having delayed gastric emptying on the basis of symptoms, fasting antral volume (FAV) and BMI**

| | AOR | 95% CI | *P* |
|---|---|---|---|
| Drowsiness | 3.59 | 1.12-11.54 | 0.03 |
| Fasting antral volume[1] | 1.09 | 1.02-1.17 | 0.007 |

AOR: Adjusted odds ratio; [1]AOR estimated per 5 mL increase (e.g. FAV of 20 mL *vs* 15 mL).

volume value reached after a meal.

Age was the only factor associated with the occurrence of some of the GI and extra-GI meal-related symptoms. Particularly, the occurrence of postprandial drowsiness was significantly associated with older age (AOR = 1.05 per 1 year increase, $P < 0.02$), while pain was marginally related to younger age (AOR = 0.96, $P < 0.04$). Epigastric burning was marginally related to older age (AOR = 1.11, $P < 0.03$).

The estimated AORs of having delayed gastric emptying are shown in Table 4. After a backward selection, only fasting antral volume and postprandial drowsiness were significantly associated with delayed gastric emptying, while no statistically significant relationship was found with age, gender and BMI. Fasting antral volume was significantly associated with delayed gastric emptying, increasing the OR of 93% for any additional volume increase of 5 mL.

## DISCUSSION

An unexpected finding of this study was that more than 40% of symptomatic patients at the time of, and in the 3 wk preceding, the investigation did not refer any symptoms when challenged with a normal meal in controlled condition. The lack of any difference in the demography and symptom presentation between symptomatic and symptom-free patients during the investigation excludes a patient selection bias and indicates that the well known long-term variability[20] of dyspeptic symptoms may occur even over a short period of time.

Ultrasonography is a reliable method to estimate in normal physiological conditions gastric antral volume during fasting and after a meal[27-32]. The serial US measurements of the antral volume enable to assess directly the time curve of antral distension, and indirectly the gastric emptying time. Ricci *et al*[14] first reported a close association between the onset of the usual postprandial complaints and an antral volume increase in the majority of FD patients. Hausken *et al*[15] found an association between a wide antral area and bloating. Both studies, however, did not comparatively investigate the antral volume of the FD patients who remained symptom-free after meal ingestion.

Several other studies reporting non-univocal results have attempted to correlate the occurrence of symptoms in FD patients with proximal and distal stomach distension[10,11,17,36,37], gastric volumes[16,19,38-40] or gastric food retention[6,21,22]. These studies were performed at the end[16], 30 min[19] and 1 h[11] after meal ingestion, with either invasive techniques or not physiological ingestion of meals that caused dyspeptic symptoms also in healthy controls[16,17,19, 39,40].

This study assessed, in physiological conditions after a normal meal, the relationship between gastric emptying, antral volume variation and postprandial symptoms in symptomatic compared to asymptomatic dyspeptic patients and healthy subjects. The meal was a normal every day meal. Differing from previous findings at multivariate analysis, gender did not have any relationship with postprandial antral distention or with the modality of gastric emptying[22]. The different results of this study may be explained by the larger number of patients studied.

The antral volume reached its maximal value soon after the end of meal ingestion and subsequently decreased throughout the observation period in both controls and FD patients (Figure 3). However, independently from the concomitant presence of GI dyspeptic symptoms, FD patients showed an antral volume greater than healthy controls, confirming the presence of an altered intragastric meal distribution in FD patients[14-16,21,22]. It has been suggested that impaired accommodation of the proximal stomach to a meal underlies the increased distribution of gastric contents in the distal stomach[21,38].

The antral volume variations and gastric emptying were evaluated for a long postprandial period, i.e. 5 h, thus enabling to detect a subgroup of patients in whom the over distension of the antrum occurred later than, and independently from, an early postprandial altered motor function of the proximal stomach.

The most relevant finding of this study was that postprandial drowsiness was the only of the GI and extra-GI symptoms to be highly significantly associated with antral volume and its transformations.

In patients with postprandial drowsiness, antral volume reached the maximal value 2 h after the meal and did not show a progressive decrement throughout the observation period (Figure 4). The occurrence of postprandial drowsiness was significantly associated with the current and mean weighted antral volume, supporting the time-relationship with antral distension. However, the association with delta antral volume change suggests that its onset is associated with the degree of time-related antral distension rather than the antral volume *per se*. Finally, the finding of an association between drowsiness and the antral volume assessed at the preceding observation period suggests that the antral distension precedes the onset of drowsiness. It could be argued that the fasting and the immediate postprandial antral volumes included in the analysis might have inappropriately contributed to the subsequent antral volume transformation, therefore affecting the results of the present study, but their exclusion from the analyses did not change the results. Furthermore, it has been shown that subtracting the fasting from the final postprandial antral volume, the latter is still greater in dyspeptic patients than in controls, thereby indicating a genuine greater postprandial antral distension in patients compared to healthy controls[5].

At present, whether increased antral volumes may reflect hypotonia of the antral muscular wall or intraluminal distension secondary to gastric retention or to an overload caused by an impaired accommodation of the proximal stomach[21,38], or an increased duodenogastric reflux could

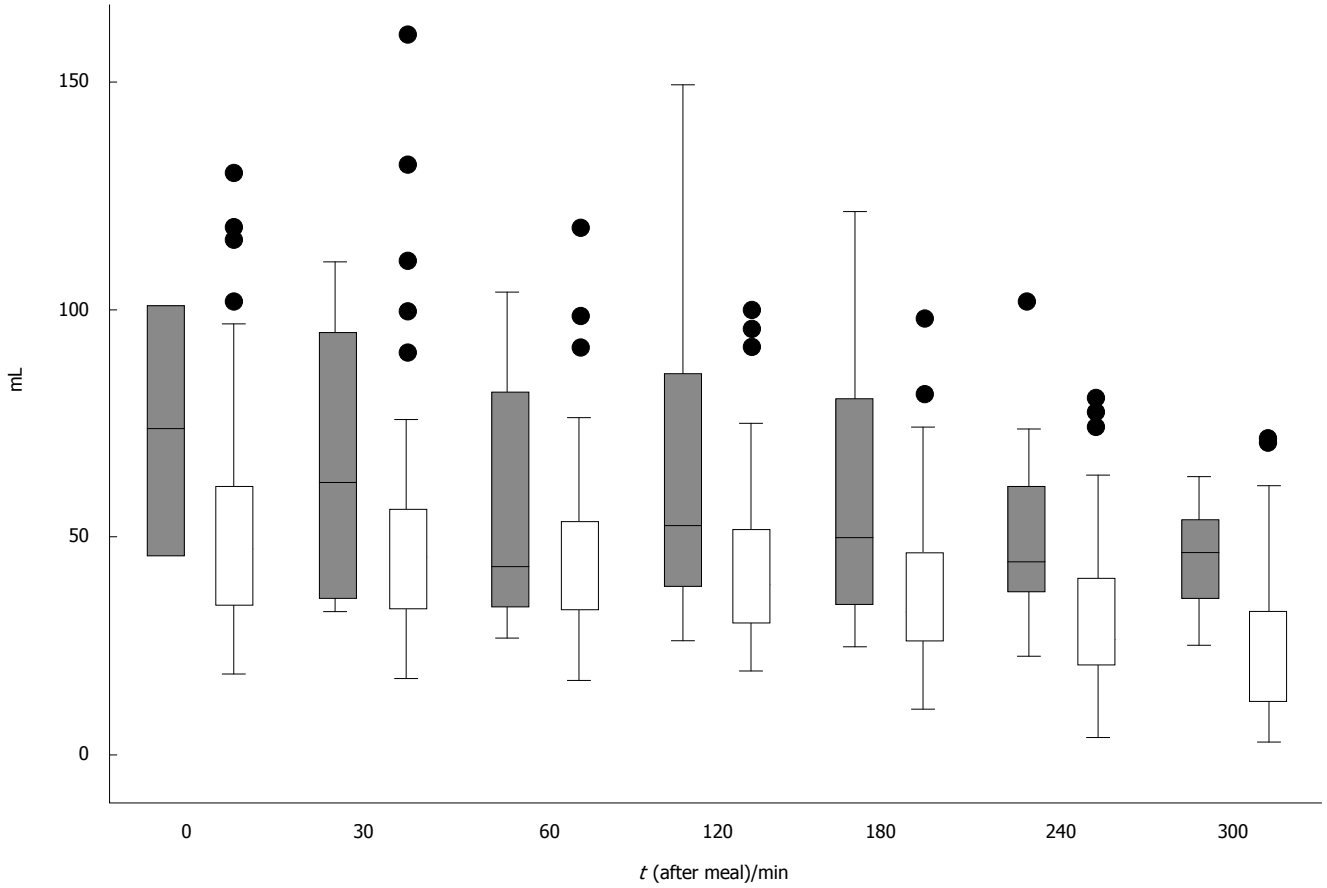

**Figure 4** Box-and-whiskers plots of gastric antral volume immediately (0), at 30 and at 60 min intervals, after the end of the ingestion of a standard meal in FD patients with (gray box) and without (white box) postprandial drowsiness. The boxes at each time unit extend from the 25th percentile ($x_{[25]}$) to the 75th percentile ($x_{[75]}$) [i.e., the interquartile range (IQ)]; the lines inside the boxes represent the median values. The lines emerging from the boxes (i.e., the "whiskers") extend to the upper and lower adjacent values. The upper adjacent value is defined as the largest data point $\leq x_{[75]} + 1.5 \times IQ$, and the lower adjacent value is defined as the smallest data point $\geq x_{[25]} - 1.5 \times IQ$. Observed values more extreme than the adjacent values, if any, are individually plotted (circles).

not be addressed in the present study.

Several studies indicate that a variable degree of sleepiness after a meal is a common sensation[23,24,41-43] in healthy subjects and may also influence food intake[44]. Studies assessing daytime sleepiness with standard tests, in healthy subjects showed that (1) sleep onset latency was significantly shorter after a caloric meal than after water[24] and sham feeding[45], and (2) the occurrence of postprandial sleepiness was neither related to the fat composition of the test meal nor to the circadian variation in sleepiness[23]. Finally, in healthy subjects, it has been shown that in comparison with an equal volume of water and equicaloric liquid meal, a solid meal results in decreased sleep onset latencies[24]. These results, taken together with the observation that drowsiness may occur after intravenous administration[46] of cholecystokinin (CCK), support the hypothesis of a peripherally circulating hormone of GI origin that mediates postprandial sleepiness. It is conceivable that meal ingestion may release CCK and other neuroendocrine substances, such as 5-$HT_3$, that affect the state of consciousness directly or activating vagal nerve afferences or releasing other sleep-promoting substances, such as insulin[47,48]. Several animal studies indicate that CCK sleep-promoting and food intake-reducing effects are closely associated, presumably expressing different, yet related, manifestations of satiety[47].

Postprandial drowsiness reported in this study refers to a sensation regarded to be bothersome enough to interfere with the daily activities. However, the sensation of drowsiness may vary from slight to severe and may be related to sleep disturbances. Sleep disturbances were enquired specifically and patients reporting postprandial drowsiness did not report any sleep disturbances. In the present study, older age in FD patients was an independent factor adjusted for antral volume variables for the occurrence of drowsiness. Control subjects and dyspeptic patients were not balanced for age, however, in the age-adjusted model, the presence of drowsiness in FD patients was associated only with antral volume variations. In addition, it has been shown that in healthy subjects, postprandial drowsiness is related to a younger age and to a greater food intake compared to older subjects[44]. In the present study, healthy controls, although significantly younger than FD patients, did not report any symptom. It would therefore appear that, in contrast with healthy controls, drowsiness reported by older dyspeptic patients was neither related to sleepiness nor to physiological change of postprandial sleep latency. However, we neither evaluated with objective measures postprandial sleep latency or the severity of postprandial drowsiness nor we specifically evaluated physiological adaptive variation or an altered state of the autonomic nervous system that could

justify the occurrence of postprandial drowsiness in our patients[41].

Of the GI symptoms conventionally considered to be a manifestation of dyspepsia, only bloating showed a statistically significant association with the postprandial weighted antral volume and, to a lesser degree, with all the other antral volume variables, confirming previous observations[15,16,37]. Bloating has been frequently reported in healthy subjects in barostat studies, in caloric and even in water drink tests, without any relationship with altered gastric motor function[11,17,44]. In our study, nausea and belching were associated only with antral volume delta change, whereas all the other GI dyspeptic symptoms were not related to any of the assessed antral volume variables. Postprandial fullness is a common sensation even in healthy subjects and it has been reported to be associated with an increase of the antral area[49,50]. In the present study, none of the healthy subjects and about 50% of the study patient population referred fullness that was not associated with any of the antral volume variables evaluated. The frequent occurrence of bloating and postprandial fullness in healthy subjects together with the absence of a constant and univocal association with gastric functions limits the interpretation of the pathophysiological mechanisms of these symptoms in FD patients. Nausea is a non-specific GI symptom that could be elicited by the direct instillation of acid in the duodenum[51], i.e. a condition likely mimicking a physiological condition. Several studies highlighted the potential key role of the duodenum in the symptom generation in functional dyspepsia[51-53]. Hypersensitivity of the duodenum to acid infusion as well as duodenal distension have been reported to elicit upper GI symptoms[51-53]. However, the present study does not allow one to draw any conclusion about the role of the duodenum in the occurrence of symptoms and further investigations are needed.

Early satiety, which is one of the cardinal dyspeptic symptoms and was referred in the medical history by 45% of our patients population, did not occur after a meal in controlled condition in any of the investigated patients. It is conceivable that the sensation referred by the patients was more likely fullness or bloating that had induced the patients to terminate prematurely food ingestion to prevent further discomfort. It has been indeed shown that perception of fullness is a useful predictor of food intake[44,50]. If so, the definition of early satiety as an unpleasant sensation that forces one to stop eating, and the numerous studies in which this symptom has been related to specific function disorder of the stomach, should be reevaluated.

Nevertheless, a relevant limitation of this study is that except for pain and discomfort, severity of postprandial symptoms was not assessed, thus precluding any evaluation of its possible relationship with antral distension.

A significant proportion of FD patients complain of psychological symptoms and the presence of anxiety has been demonstrated in about 70% of these patients[22]. We excluded the patients with eating disorders and clinically evident psychological disorders like major depression from our study; however, we did not fully evaluate the psychological status of the patients.

Despite that it has been widely debated whether a delayed gastric emptying is a relevant factor in causing dyspeptic symptoms, to our knowledge, none of the previous studies evaluated concurrently and in physiological conditions the modality of the gastric emptying and the occurrence of symptoms in FD patients after an ordinary every day meal. In the present study, 39% of FD patients had delayed gastric emptying, but it did not have any relationship with the occurrence of dyspeptic symptoms during the test. A previous study reported a delayed gastric emptying in 41% of the patients and a rapid initial gastric emptying in 43% of them that were associated with higher symptoms score after a challenge meal[19]. Thus, it would appear that a delayed gastric emptying *per se* does not play any role in the origin of the usual dyspeptic symptoms.

The present study confirms our previous finding[5] that patients referring postprandial drowsiness have a greater probability to have delayed gastric emptying than controls and dyspeptic patients without post-prandial drowsiness. Differently from the usual dyspeptic symptoms, drowsiness is a late postprandial complaint occurring significantly later than GI symptoms and is related with antral distension and delayed gastric emptying. It would therefore appear that the two conditions are associated with the onset, and the persistence of postprandial drowsiness in this subgroup of FD patients. We cannot draw any definitive conclusion about the separate role, if any, played by delayed gastric emptying and antral distension, either alone or in combination, in the occurrence of postprandial drowsiness in FD patients.

In conclusion, our study assessed in controlled conditions the relationship between gastrointestinal and extra-gastrointestinal symptoms arising after a normal balanced meal, and antral distension and gastric emptying. Postprandial gastrointestinal symptoms do not have any constant or predictable relationship with antral distension and gastric emptying in functional dyspepsia patients. Of the extra-gastrointestinal symptoms, postprandial drowsiness is associated with antral distension. On the average, drowsiness occurs late after meal ingestion and after the onset of gastrointestinal dyspeptic symptoms. The onset of postprandial drowsiness is usually preceded by an increment of antral distension and the duration of the symptom appears to be related to the persistence of antral distension. Finally, a delayed gastric emptying is significantly associated with postprandial drowsiness and the degree of the fasting antral volume.

## Abstract

**AIM:** To evaluate whether the Milan criteria are useful in patients with hepatocellular carcinoma (HCC) who received transarterial chemoembolization (TACE) before liver transplantation (LT).

**METHODS:** Thirty-six HCC patients who fulfilled the Milan criteria after having received TACE and subsequently underwent LT were included (TACE + LT group) in the study. As controls, 21 patients who also met the Milan criteria and underwent LT without prior treatment were selected (LT group). Post-LT clinical outcomes, such as HCC recurrence, survival rate, and histologic features of explanted livers, were compared between the two groups.

**RESULTS:** Baseline characteristics were not different between the two groups. Pre-LT maximal tumor diameter in TACE + LT group was similar to that of LT group (2.0 ± 0.6 cm *vs* 2.3 ± 0.9 cm; $P = 0.10$). Post-LT histologic findings also revealed similar maximal tumor diameter in the two groups (2.4 ± 1.4 cm *vs* 2.3 ± 0.9 cm; $P = 0.70$). Explanted livers showed similar incidence of unfavorable pathologic features. The morality within 60 d after transplantation was not different between the two groups (8.3% *vs* 9.5%; $P = 0.99$). Post-LT 5-year survival rate (57% *vs* 74%; $P = 0.70$) and cumulative recurrence rate (8.3% *vs* 4.8%; $P = 0.90$) were not significantly different between the two groups.

**CONCLUSION:** The Milan criteria are still a useful selection criteria showing favorable outcomes in HCC patients receiving TACE before LT.

**Key words:** Milan criteria; Hepatocellular carcinoma; Transarterial chemoembolization; Liver transplantation

## INTRODUCTION

Hepatocellular carcinoma (HCC) is a major global health problem involving more than 500 000 new cases a year. Several treatment modalities, such as liver transplantation (LT), surgical resection, radiofrequency ablation (RFA), and percutaneous ethanol injection (PEI), are accepted for curative therapies for HCC. Theoretically, LT remains the only ideal treatment option because LT has been claimed to simultaneously cure the malignant disease and replace the premalignant cirrhotic liver. Early series of LT for HCC yielded poor outcomes[1-4]. In those series, 3- and 5-year survival after LT ranged 15%-67% and 15%-48%, respectively. These inferior results come from inclusion of patients with far advanced HCC. In spite of initial dismal experiences with LT for patients with HCC, patients with confined HCC (solitary lesion $\leqslant$ 5 cm or $\leqslant$ 3 lesions with diameter $\leqslant$ 3 cm, no major vessel invasion, and no extrahepatic involvement; Milan criteria) were reported to show an excellent long-term outcome with a 5-year survival rate of 70% and a recurrence rate below 15%[5]. With pathologic review, modestly expanded selection criteria (solitary lesion $\leqslant$ 6.5 cm or $\leqslant$ 3 lesions with the largest one $\leqslant$ 4.5 cm and total tumor diameter $\leqslant$ 8 cm; UCSF criteria) were suggested to offer an excellent outcomes with a 1- and 5-year survival rate of 90% and 75.2%, respectively[6]. In clinical practice, however, the Milan criteria based on pre-LT radiologic findings could be more useful and a widely accepted selection criteria than

the UCSF criteria based on post-LT pathologic findings.

Because of donor organ shortage or other limits including economic problem in HCC patients waiting for LT, various treatment modalities including resection, RFA, PEI, and transarterial chemoembolization (TACE) were tried to prevent the progression of HCC. Among these, TACE is the most commonly used procedure in patients with unresectable HCC in our country. Up to now, it is not known whether a favorable outcome after LT can also be achieved in HCC patients who have been treated by TACE and meet the Milan criteria, as in treatment-naïve HCC patients.

Hence, we conducted a study to assess the usefulness of the Milan criteria in HCC patients who had been treated with TACE prior to LT.

## MATERIALS AND METHODS

### Subjects

Between September 1996 and April 2004, a total of 105 patients with HCC underwent LT at our institute. Among them, 63 (59.4%) patients met the Milan criteria based on pre-LT imaging. Excluding 27 patients within Milan criteria treated by RFA or surgical resection before LT, 36 patients with one or more sessions of TACE only prior to LT were selected (TACE + LT group). Twenty-one HCC patients who had not been given any treatment before LT were selected as control (LT group) (Figure 1). The Milan criteria was defined as the presence of a tumor 5 cm or less in diameter in patients with single HCC or no more than 3 tumor nodules, each 3 cm or less in diameter, in patients with multiple tumors, and no extrahepatic metastasis, and no major hepatic vessel invasion[5].

### TACE

One to eight sessions of TACE were performed *via* the transfemoral arterial approach under local anesthesia at intervals of 4-12 wk in the TACE + LT group. Selective celiac and superior mesenteric angiography was performed to define the hepatic artery anatomy and to evaluate the portal venous system. The feeding artery to the lesion was catheterized as selectively as possible using a highly flexible coaxial catheter, and the chemotherapeutic agent lipiodol mixture was injected under fluoroscopic guidance. The mixture contained 20-50 mg of doxorubicin, 3-20 mL of lipiodol (Lipiodol Ultrafluide; Guerbet, Aulnay-sous-Bis, France), and 3 mL of water-soluble contrast agent. Embolization was performed with gelatin pellets (Gelfoam; Upjohn, Kalamazoo, Michigan) thereafter in patients with liver function of Child-Pugh class A and tumor confined to single lobe of the liver. This Gelfoam embolization was also performed for patients with Child-Pugh B, if superselection of the feeding vessel was feasible. Abdominal computerized tomography (CT) scan was performed 4 wk after TACE to evaluate the anti-tumor effect of TACE, including lipiodol uptake by the tumor tissue. If viable tumor was still observed in CT, repeated TACE was performed. If lipiodol was compactly uptaken by all tumor nodules and any new lesion was not seen, follow-up CT scan was repeated every 3 mo.

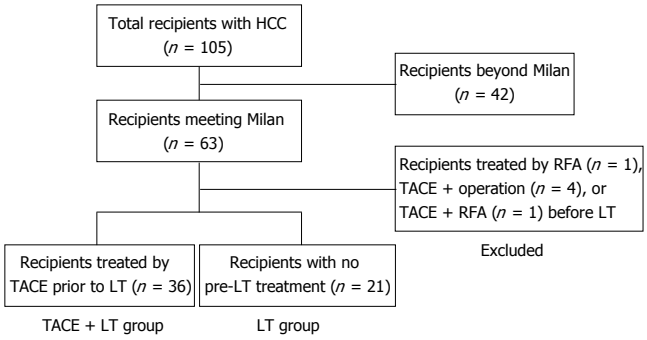

**Figure 1** Selection of patients according to the treatments given prior to LT. Among a total of 105 HCC patients, 63 patients met the Milan criteria at the time of LT. After excluding 6 patients who received treatments other than TACE, there were 36 patients in TACE + LT group and 21 in LT group.

### Pre-LT radiologic measurement of tumor size

As for tumor size in the LT group, any nodular lesion showing arterial enhancement and delayed washout in 3-phase helical CT was regarded as a viable HCC and its largest diameter was considered as a tumor size. In the TACE + LT group, a tumor nodule showing compact lipiodol uptake without arterial enhancement or delayed washout in CT was considered as non-viable tumor and was excluded from the measurement of tumor size or number. For a nodule showing arterial enhancement and delayed washout at the margin, tumor size was defined as the difference from diameter of the entire nodule to diameter of lipiodol-uptaken portion. Representative cases showing how to measure the HCC lesions treated by TACE are illustrated in Figure 2.

### Histopathology

All total hepatectomy specimens were processed by a hepatopathologist using a routine protocol consisting of 1 cm or thinner sections throughout the entire liver. With standard histological staining, the specimens were examined to evaluate tumor characteristics, such as number of nodules, size, pathologic tumor grade (Edmonson grade), percentage of necrosis, and presence of tumor capsule invasion, satellite nodule, or microvascular invasion. By pathologic review of explanted liver, it was evaluated whether the enrolled patients also met the UCSF criteria.

### Post-LT management and follow-up

Post-transplant immunosuppression consisted of corticosteroid plus either tacrolimus or cyclosporin. Corticosteroid was gradually tapered and was discontinued within 1 year. Tacrolimus and cyclosporin were continued after LT unless contraindicated. Acute rejection was treated with steroid pulse therapy. Antithymocyte globulin (ATG) or muromonab (OKT3) antibody infusions were reserved for the patients with acute rejection resistant to intravenous corticosteroids. The interval of the outpatient clinic visits after discharge from the hospital was adjusted according to the patient's condition.

Tumor recurrence was screened by measurement of alpha-fetoprotein and abdominal CT or ultrasonography

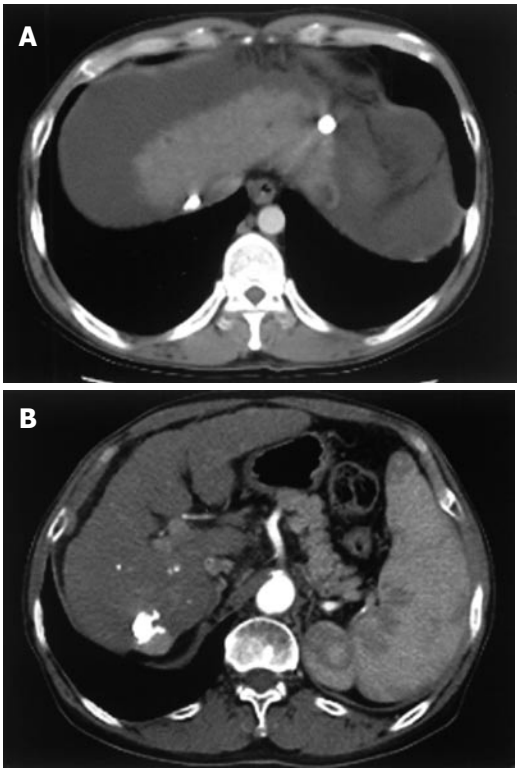

**Figure 2** Representative cases for measurement of viable tumor size treated by TACE prior to LT. **A:** A tumor nodule with compact lipiodol uptake, no enhancement at arterial phase, and no washout at portal or delayed phase was considered as a non-viable tumor and was excluded from the measurement of tumor size or number; **B:** For a nodule showing arterial enhancement and delayed washout at the margin, tumor size was defined as the difference from diameter of the entire nodule to diameter of lipiodol-uptaken portion.

every 3 mo. Additional imaging modalities, such as chest CT and bone scan, were performed if HCC recurrence at lung or bone was suspected. No adjuvant chemotherapy was administered to any patients after LT.

### Comparison of clinical outcomes

In this study, we retrospectively analyzed the medical records, radiologic and pathologic findings of the 36 patients in TACE + LT group and 21 in the LT group. Baseline clinical characteristics of the patients, tumor characteristics, clinical outcomes including recurrence of HCC, and post-LT survival rate were compared between the two groups.

### Statistical analysis

Baseline characteristics of the patients were expressed as mean ± SD. Comparison between the two groups was done by using the independent $t$ test for continuous variables and by chi-square test or Mann-Whitney $U$ test for categorical variables. The overall survival rate and cumulative recurrence rate were calculated by the Kaplan-Meier method. The survival curves were compared by means of the log-rank test. All statistical tests were two-tailed and $P < 0.05$ was considered statistically significant. All statistical analyses were performed with SPSS 11.0 (SPSS Inc., Chicago, IL).

TACE: Transarterial chemoembolization; LT: Liver transplantation; HBV: Hepatitis B virus; HCV: Hepatitis C virus; MELD: Model for end stage liver disease.

## RESULTS

### Patient characteristics

A total of 57 patients (49 men and 8 women; median age 51 years, range 30-68 years) were included in this study. Fifty-three patients (93.0%) had HCC associated with hepatitis B virus (HBV) infection. Other causes consisted of hepatitis C virus (HCV) infection in 2 patients (3.5%), co-infection of HBV/HCV in one (1.8%), and alcohol-related liver disease in one (1.8%). The mean alpha-fetoprotein levels were 494.9 μg/L and model for end stage liver disease (MELD) score was 19.4. One to eight sessions of TACE were performed in TACE + LT group; 1 session in 12 (33.3%) patients, 2 sessions in 16 (44.4%) patients, and 3 or more sessions in 8 (22.2%) patients. Cadaveric grafts were used in 10 (17.5%) and living grafts in 47 (82.5%) cases. As for baseline clinical and demographic characteristics, there was no significant difference between TACE + LT group and LT group (Table 1).

### Tumor characteristics

According to pre-LT radiologic evaluation, 42 (73.7%) patients had single tumor, and 8 (14.0%) and 7 (12.3%) patients had 2 and 3 tumors, respectively. The mean diameter of the largest nodule in all patients was 2.1 cm. In TACE + LT group, 24 (66.7%) patients had single tumor, 6 (16.7%) patients had 2 tumors, and 6 (16.7%)

**Table 2 Histologic finding-based tumor profiles of patients who met the Milan criteria**

| Variable | TACE + LT group ($n$ = 36) | LT group ($n$ = 21) | $P$ |
|---|---|---|---|
| Number of nodules | | | |
| 1/2/3/≥4 | 18/8/3/7 | 13/3/3/2 | 0.79 |
| Diameter of the largest tumor (cm) | | | |
| Mean ± SD | 2.5 ± 1.4 | 2.3 ± 0.9 | 0.70 |
| Range | 0.6-7.5 | 0.5-4.2 | |
| Sum of the tumor diameters (cm) | | | |
| Mean ± SD | 3.8 ± 2.6 | 3.3 ± 1.3 | 0.36 |
| Range | 0.6-14.0 | 0.5-7.0 | |
| Tumor differentiation[1] | | | 0.59 |
| Edmonson grade Ⅰ | 5 (16.7%) | 6 (28.6%) | |
| Ⅱ | 22 (73.3%) | 13 (61.9%) | |
| Ⅲ | 3 (10%) | 2 (9.5%) | |
| Presence of satellite nodule | 5 (13.9%) | 2 (9.5%) | 0.99 |
| Tumor capsule invasion | 11 (30.6%) | 3 (14.3%) | 0.21 |
| Microvascular invasion | 11 (30.6%) | 9 (42.9%) | 0.40 |

[1]Assessment of tumor differentiation was possible in only 30 patients in TACE + LT group due to complete necrosis in 6 patients. TACE: Transarterial chemoembolization; LT: liver transplantation.

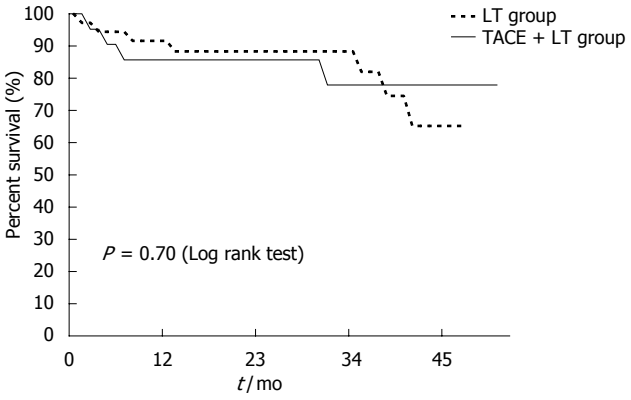

**Figure 3** Comparison of overall survival rate between TACE + LT and LT groups. There was no obvious difference in 5-year survival rate after LT between the two groups (57% *vs* 74%; $P$ = 0.70).

patients had 3 tumors. The distribution of tumor number was similar in the LT group; 1 in 18 (85.7%) patients, 2 in 2 (9.5%) patients, and 3 in 1 (9.5%) patient. No statistical difference was found in the mean diameter of the largest tumor between TACE + LT and LT groups (2.0 cm *vs* 2.3 cm; $P$ = 0.10; Table 1).

According to histopathologic findings of explanted livers, a total of 114 nodules were found from all the patients; 77 in the TACE + LT group and 37 in the LT group. The number of tumor nodule was 1 in 31 (54.4%) patients, 2 in 8 (14.0%) patients, 3 in 3 (5.3%) patients, and 4 or more in 15 (26.3%) patients. The mean diameter of the largest tumor was 2.4 cm and the sum of the tumor diameters was 3.6 cm. There was no significant difference in distribution of tumor number between the two groups. The mean diameter of the largest tumor and the sum of the tumor diameters were also similar between both groups (2.4 cm *vs* 2.3 cm, $P$ = 0.70; 3.8 cm *vs* 3.3 cm, $P$ = 0.36, respectively, Table 2). Twenty-eight (77.8%) patients

**Table 3 Detailed clinical data of the patients in whom HCC recurred after LT**

| Patient | Group | Time to recur (mo) | Site of recur | Treatment after recurrence | Survival (mo) |
|---|---|---|---|---|---|
| 1 | TACE + LT | 9.6 | Liver | None | 10.0 |
| 2 | TACE + LT | 3.3 | Liver, bone | TACE | 7.1 |
| 3 | LT | 15.4 | Lymph node | Excision, TACE | 21.0 |
| 4 | TACE + LT | 0.9 | Lung, liver | TACE | 5.7 |

TACE: Transarterial chemoembolization; LT: Liver transplantation.

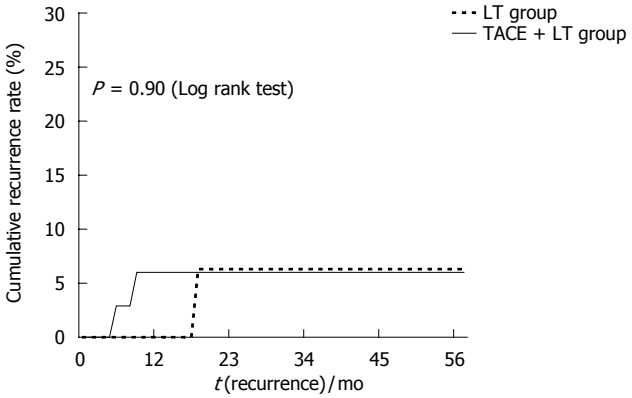

**Figure 4** Comparison of cumulative HCC recurrence rate between TACE + LT and LT groups. Five-year recurrence rate was similar between the two groups (8.3% *vs* 4.8%; $P$ = 0.90).

in the TACE + LT group and 19 (90.5%) in the LT group met the UCSF criteria.

As to the tumor differentiation, Edmonson grade 1 was found in 11 (21.6%), grade 2 in 35 (68.6%), and grade 3 in 5 (9.8%) patients. Of 57 patients, 7 (12.3%) and 14 (28.8%) patients had satellite nodules and tumor capsule invasion, respectively. In addition, 20 (35.1%) patients had microvascular invasion. The incidence of unfavorable pathologic features was similar in the two groups (Table 2). The explanted liver showed TACE-induced complete tumor necrosis without histologic evidence of viable carcinoma in 23 of 77 (29.9%) lesions.

### *Clinical outcomes after LT*

During median follow-up of 24.3 (range: 0.1-99) mo, 14 of 57 (24.6%) patients died. Post-LT early mortality, defined as death within 60 d after transplantation, was not different between TACE + LT and LT groups (8.3% *vs* 9.5%; $P$ = 0.99). The overall survival rates of the patients at 1-, 3-, and 5-year were 86%, 72%, and 67%, respectively. The 1-, 3-, 5-year survival rates between the TACE + LT group and the LT group were not significantly different (89% *vs* 81%, 68% *vs* 74%, and 57% *vs* 74%, respectively; $P$ = 0.70) (Figure 3). The causes of death consisted of graft failure in 3 patients, graft *versus* host disease (GVHD) in 2 cases, hepatic vein problem with hepatic congestion in 1 case, HBV recurrence in 3 cases, HCC recurrence in 4 cases, and intracerebral hemorrhage in 1 case.

During the follow-up period, HCC recurrence was found in 4 (7.0%) patients (Table 3). Five-year cumulative HCC recurrence rate in the TACE + LT group was similar to that in the LT group (8.3% *vs* 4.8%; $P$ = 0.90) (Figure 4).

## DISCUSSION

HCC is one of the serious complications of chronic liver disease associated with high mortality. Although surgical resection is traditionally regarded as treatment of choice for HCC, it is a major problem that resection is feasible in only limited cases due to poor liver function and/or advanced stage of HCC at diagnosis. In addition, many patients suffer from recurrent HCC and aggravation of cirrhosis after operation. In this regard, LT gives patients with HCC an advantage over resection, because it addresses the multifocal potential of HCC in many patients that limits the success and applicability of resection and also treats the underlying liver disease[6].

The criteria developed by Mazzaferro and associates, known as the Milan criteria, have been widely applied around the world in the selection of patients with HCC for LT. However, the Milan criteria were originally made for patients with treatment-naïve HCC. In the clinical setting, a significant number of HCC patients are treated with TACE or RFA prior to LT because of a long waiting list for LT. It remains uncertain whether excellent outcomes can be obtained in HCC patients who previously underwent locoregional treatments and still meet the Milan criteria at the time of LT. In the present study, we retrospectively selected the patients who had received only TACE before they underwent LT since TACE is the most widely used procedure for HCC in our country. Patients undergoing other therapies, such as resection or RFA, were excluded to eliminate confounding effect of those treatments. For validation of usefulness of the Milan criteria in HCC patients treated with TACE before LT, their survival rates following LT were compared with those of HCC patients undergoing LT only.

The current study demonstrates that HCC patients who had undergone one or more sessions of prior TACE showed as good post-LT survival as treatment-naïve HCC patients, if they met the Milan criteria at the time of transplantation. One- and 5-year survival rates of patients in the TACE + LT group and LT group were comparable (89% *vs* 81% and 57% *vs* 74%, respectively; $P = 0.70$). Taniguchi *et al*[7] showed a long-term survival and marked TACE-induced tumor necrosis in patients with unresectable HCC. A recent report on randomized controlled trial showed that TACE with doxorubicin and gelatin sponge, compared with conservative management, provided survival benefits to patients with unresectable HCC[8]. However, as a bridge to transplantation for patients on waiting lists, TACE showed varying results[9,10]. Among these, an European study showed a 5-year survival of 93% in 48 patients receiving TACE, with no dropout over a mean waiting period of 6 mo[10]. Moreover, prospective studies have shown that the probability of preventing tumor progression is significantly higher in patients treated with TACE than those untreated controls[11,12]. In a recent series, pre-LT TACE in 54 predominantly early-stage cases yielded a reasonable 5-year post-LT survival of 74%[13]. However, the benefit of TACE could not be inferred given that waiting list dropout and post-LT recurrence rates were not markedly lower than historical controls. In contrast to previous studies regarding the role of TACE before LT, we elucidated the usefulness of the Milan criteria at the time of LT in patients receiving TACE prior to LT.

Up to now, there is no data on whether pre-LT TACE increases early mortality after transplantation compared to LT without prior therapy. In a previous study, some patients who underwent LT within 30 d of the last TACE developed unexplained severe pneumonia, leading to death very early after transplantation[9]. On the other hand, our results showed that mortality within 60 d after transplantation was not different between TACE + LT and the LT groups. Thus, the issue concerning pre-LT TACE and early mortality after operation still remains controversial.

In our study, 1-year survival rates of LT group were lower than those of TACE + LT group, albeit not statistically significant (89% *vs* 81%). Although the reason for this observation is not clearly understood, it might be due to the poorer liver function of patients in LT group as compared with the TACE + LT group. Urgent transplantations might have been undertaken in patients of the LT group whose liver functions were too poor to perform locoregional therapy. The tendency of higher MELD score (22 *vs* 19; $P = 0.10$) and more frequent living donor transplantation in the LT group compared to the TACE + LT group (90.5% *vs* 77.8%; $P = 0.30$) support the more aggravated liver function and urgent condition of the LT group.

Our data demonstrated that 5-year cumulative recurrence rates of patients in the TACE + LT group were similar to those in the LT group (8.3% *vs* 4.8%; $P = 0.90$). HCC recurred in 3 of 36 patients in the TACE + LT group with a recurrence site of liver in one and distant organs in two patients. In the LT group, the recurrence occurred in one patient at the perihepatic lymph node. Increased incidence of hepatic or extrahepatic recurrence after TACE followed by resection has been an important concern on the grounds that partial necrosis of the tumor favors the shedding of neoplastic cells in a few previous studies[14-17]. However, such a concern was not substantiated in our patients.

There was no significant difference between the TACE + LT group and the LT group in terms of baseline clinical and demographic characteristics, radiologic finding-based or histologic finding-based tumor profiles, and histologic parameters indicating unfavorable prognosis. At this point, we have to comment on the radiologic measurement of HCC lesions previously treated with TACE. In the TACE + LT group, albeit statistically not significant, the radiologically measured diameter of the largest tumor was shorter than the histologically measured one ($2.0 \pm 0.6$ cm *vs* $2.5 \pm 1.4$ cm; $P = 0.06$), and 4 of 36 patients in the TACE + LT group were found to have 4 or more nodules on explanted specimens. In the LT group, the radiologically measured diameter of the largest tumor was similar with the histologically measured one ($2.3 \pm 0.9$ cm for both), and 2 of 21 patients in the LT group had 4 or more nodules on explanted livers. These results imply that pre-LT staging of HCC by the current imaging modalities may be underestimated in terms of number in both groups and in terms of size in the TACE + LT group.

Although the extents of HCCs were estimated by

expert radiologists using a pre-defined method, it was difficult to precisely measure the maximal diameter of lesions in a portion of the TACE + LT group, especially in cases with incomplete or scattered lipiodol uptake in nodules. In a previous study measuring the tumor volume (TV) to improve the selection criteria based on number and diameter of HCC, TV > 28 $cm^3$ was reported to be a predictive factor for HCC recurrence after LT[18]. Other investigators measuring the TV with a region-of-interest CT technique also evaluated the prognostic value of volumetric CT in patients treated with repeated TACE[19]. These alternative methods might better represent the tumor size, but are much more complex and time-consuming.

In conclusion, our data demonstrated that the Milan criteria would be useful selection criteria in HCC patients who underwent the TACE procedure before LT, showing favorable prognosis if they fulfill the criteria at the time of transplantation.

## Abstract

**AIM:** To understand the local pathophysiological alterations and gene ontology-based functional classification of colonic biopsies into inflammatory and neoplastic diseases.

**METHODS:** Total RNA was extracted from frozen biopsies and amplified by T7-method. Expression profile was evaluated by Atlas Glass 1K microarrays. After microarray quality control, applicable data were available from 10 adenomas, 6 colorectal adenocarcinomas (CRCs), and 6 inflammatory bowel diseases (IBDs). Multivariate statistical and cell functional analyses were performed. Real-time RT-PCR and immunohistochemistry were used for validation.

**RESULTS:** Discriminant analysis of selected genes, could correctly reclassify all 22 samples using 4 parameters (heat shock transcription factor-1, bystin-like, calgranulin-A, TRAIL receptor 3). IBD samples were characterized by overregulated chemokine (C-X-C motif) ligand 13, replication protein A1, E74-like factor 2 and downregulated TNF receptor-associated factor 6, BCL2-interacting killer genes. In adenomas upregulation of TNF receptor-associated factor 6, replication protein A1, E74-like factor 2 and underexpression of BCL2-associated X protein, calgranulin-A genes were found. CRC cases had significantly increased epidermal growth factor receptor, topoisomerase-1, v-jun, TNF receptor-associated factor 6 and TRAIL receptor 3, and decreased RAD51 and RAD52 DNA repair gene, protein phosphatase-2A and BCL2-interacting killer mRNA levels. Epidermal growth factor receptor RT-PCR and immunohistochemistry, topoisomerase-1 RT-PCR confirmed the chip results.

**CONCLUSION:** Different histological alterations can be reclassified by functional, multivariate analysis using cDNA microarrays. Further studies with expanded sample number are needed for subclassification of pathological alterations.

**Key words:** Adenoma; Biopsy samples; Colorectal cancer; Gene expression; Inflammatory bowel diseases; Microarray technology

## INTRODUCTION

mRNA expression array analysis is usually performed on high volume surgery or blood samples. However, evaluation of routine biopsy specimens could yield information, as to how the local pathological processes differ from healthy counterparts. In the gastrointestinal tract, biopsy samples are routinely taken. The mRNA expression study of these samples could allow further insight into the development of inflammatory, preneoplastic and neoplastic diseases.

These specimens could not be applied previously for expression array studies, because array technology even today needs significantly more RNA than can be isolated from the tiny biopsy specimen. However, new techniques and commercial kits have recently become available for the reliable mRNA amplification without an effect on the original gene expression pattern[1].

Previous microarray analyses reported in the literature were performed predominantly from surgically resected colon adenocarcinoma samples[2], with gene expression analysis of colonic biopsies done in only two cases[3,4].

In a few studies, local pathological alterations were examined using cDNA microarrays in cells and tissue structures laser-microdissected from surgical material[4,5]. The mRNA expression patterns of tumorous and normal tis-

sues were usually compared by cDNA microarrays[5,7-11] or oligonucleotide microarrays[12,13] containing some hundreds to several thousand fixed target sequences.

Microarray gene expression profiling of adenomas as a precancerous stage of colon adenocarcinoma is less represented in the scientific literature. Oligonucleotide or cDNA microarray-based molecular diagnostics of malignancy in colon adenoma and colorectal cancer samples was described using 10[14], 9[6] and 4[15] adenoma samples compared to adenocarcinoma and normal colonic tissues.

Inflammatory bowel diseases (IBDs) were rarely analyzed by microarrays. Lawrance *et al*[16] published an oligonucleotide microarray comparison between surgically resected human ulcerative colitis (UC), Crohn's disease (CD) and normal colonic tissues. Recently, Langmann *et al*[3] used mucosal biopsy specimens for global gene expression profiling in patients with UC and CD.

cDNA-based mid-sized (1K) commercial arrays have recently appeared, which do not need any special hybridization, washing or scanner apparatus. These open-platform arrays, if of good quality and reproducibility, can contribute to a widespread use of the array technology. Mid-sized so called "overall" microarrays with fixed target cDNAs from the most important cell processes (adhesion, apoptosis, cell cycle, DNA replication and repair, extracellular matrix remodeling, cytoskeleton, immune regulation, metabolism, stress response, oncogenesis and tumor suppression, growth factor-related cell proliferation, neuroendocrine regulation, signal transduction, transcription and transport) give us opportunity for analysis of different cell functions that may be associated with diseases.

Bioinformatical analysis of these types of arrays can then be used to detect the expression pattern differences between limited numbers of diagnostic groups. Multivariate statistical analysis methods can be applied for the development of automated classification methods like image analysis based cervical cancer screening[17,18].

In the present study we aimed to prove that normal, inflammatory, premalignant and malignant colon biopsies that can be used for mRNA expression analysis and the expression differences can be utilized in a multivariate classification system. As colorectal adenocarcinoma (CRC) frequently arises in the setting of various high-risk conditions such as adenomatous polyps and IBD, we looked for gene expression pattern-based connections between these types of diseases.

## MATERIALS AND METHODS

### Patients and samples

Routine biopsy specimens were collected from the pathological and normal part of the colon, placed in RNALater Stabilization Reagent. Total RNA was extracted from frozen biopsy specimens from 11 patients with adenomatous polyps, 12 with CRC and 11 with IBDs (5 UC, 6 CD). After quality control of the microarrays, applicable data were available from 10 patients with adenomatous polyps, 6 with CRC and 6 with IBD (3 UC, 3 CD).

Four male and two female patients of 53-86 years (median, 72.17 years) with CRC were involved in the study. Five patients had left side (2 rectal, 33%; 3 sigmoid , 50%) and 1 had right side (coecal, 17%) involvement. Two patients had localized disease without nodal or distant organic involvement (Dukes B stage, 33%), 1 patient had nodal involvement (17%, Dukes C stage) and 3 had liver metastases (50%, Dukes D stage).

Nine male and one female patient of 17-77 years (median, 61.2 years) with colorectal adenoma were involved in the study. Five of them had left side (1 rectal, 10%; 3 sigmoid, 30%; 1 descendent colonic, 10%), and 5 had right side (2 ascendant colonic, 20%; 1 coecal, 10%; 2 total colonic, 20%) involvement. Six patients had tubular (60%), 2 had tubulovillous (20%) and 2 had villous adenoma (20%). Only one of the villous adenoma patients' biopsy sample contained severe dysplastic alteration.

One male and five female IBD patients of 23-72 years. (42 years. median) were involved in the study. Three of them [50%; 1 UC (33%) and 2 CD (66%)] had total and three [50%; 2 UC (66%) and 1 CD (33%)] had left side colonic disease. The grade of inflammation was severe in 3 cases (50%) and moderate in 3 cases (50%).

### Methods

**Total RNA isolation using Qiagen RNeasy Mini Kit:** Frozen biopsy samples were lysed and homogenized in a mixture of 300 μL GITC-containing lysis buffer and 3 μL β-mercaptoethanol by Polytron homogenizator for 30-40 s. The lysed samples were digested in proteinase K solution at 55℃ for 10 min. After silica membrane cleaning, according to the manufacturer's description and DNase I treatment (in order to absolutely remove genomic DNA), the total RNA was eluted in 50 μL RNase-free water. Quantity and quality of the isolated RNA was tested by measuring the UV absorbance, by using real-time RT-PCR (Light Cycler G6PDH Housekeeping Gene Set, Roche) and by agarose gel electrophoresis. The high quality, intact total RNA samples, which showed regular 18S and 28S ribosomal RNA bend pattern during the agarose gel analysis, and showed positive real-time RT-PCR reaction were used for microarray analysis.

**T7 RNA amplification and labeling:** Because the total RNA content of the biopsy samples was lower than 10 μg, which was not enough for one hybridization reaction-the mRNA fraction was amplified by the T7-method (MessageAmp Ⅰ aRNA Kit, Ambion Inc., US), according to the manufacturer's instructions, fluorescently labeled probes were synthesized using amino allyl UTPs and Cy-3 and Cy-5 monoreactive dyes (Amersham Biosciences Ltd., England).

**Atlas Glass 1.0K microarray analysis:** The mRNA expression profile was evaluated by Atlas Glass microarrays (BD Clontech Inc. US, 1081 genes). Two hundred μL fluorescently labeled probes (mixture of the appropriate Cy3- and Cy5-labelled cDNA) were mixed with the prewarmed hybridization solution and hybridized to the microarray for 16 h at 50℃. Washing steps were done at room temperature in washing solutions (containing 0.75 mmol/L DTT) according to the manufacturer's instructions. The slides were dried by blowing with carbone-dioxyde and were scanned by Axon GenePix4000B reader on 532 nm (Cy3) and 635 nm (Cy5) wavelengths.

**Data analysis:** Scanned arrays were evaluated by the GenePix Pro 4.1 software. Automated spot detection using local background determination was done and feature extraction (ratio of medians, ratio of means, Cy3/Cy5) was performed. Microarrrays with nonhomogeneous background and/or incomplete housekeeping gene spot set were removed from further analysis. Ratios of medians of the detected features were applied in the normalization. Means of the ratio of medians were normalised to be 1. Results were exported into Acquity 3.1 software (Axon Inc.) and datasets were established. Dataset selection into classification categories was performed. Mean, median, SD of each parameter was calculated. Underexpression was defined as ratio of means ± SD < 0.5, overexpression as ratio of means ± SD > 2.0. One-way (group) ANOVA and multivariate exploratory techniques (discriminant analysis, factor analysis and hierarchical cluster analysis) were performed by SAS 6.12 version statistical software. Hierarchical cluster analysis was done using Ward's method (Euclidean distances). The colonic cases were clustered according to their expression pattern based on the filtered ANOVA results. Gene annotation and functional classification were done using Atlas Gene List Version 4.0. Functional analysis and visualization of biological association network were done using Pathway assist 2.53 software.

**Validation:** Real-time RT-PCR was used for validation of expression microarray results (Roche LightCycler). One-step RT-PCR was carried out using the LightCycler h-β2M Housekeeping Gene Set and RNA Master Hybridization Probes kit. For the relative quantification, commercially available β-2-microglobulin (142 bp length fragment) was used as a reference, and newly designed and synthesized epidermal growth factor receptor (EGFR) (227 bp length fragment) or DNA topoisomerase I (Top1) (184 bp length fragment) were used as a target gene. The following primer and hybridization probe sequences were used: EGFR9 S primer: 5'-atcctgccggtggcatt-3', EGFR12 A primer: 5' -gttcaggctgacgactgca-3', EGFR-FL probe: 5'-caggacggac ctccatgcctttga-3', EGFR-LC probe: 5'-LC Red 640-cctag aaatcatacgcggcaggacc-3' in case of EGFR, and Top1-fw primer: 5'-acatcatgcttaaccctagttcac-3', Top1-as primer: 5' -cagagcaagcttgtcgatg-3', TOP1-FL probe: 5'-cggatcttgtcc acacatttttttcagc-3', TOP1-LC probe: 5'-LC Red 640-ccgag cagtctcgtatttctgccag-3' in case of DNA-topoisomerase-I. Evaluation of relative ratios (diseased/normal/same patient) was prepared using RelQuant software.

**EGFR immunohistochemistry:** Formalin fixed paraffin embedded 4 μm thick colonic biopsy tissue sections were dewaxed and rehydrated. Antigen unmasking was carried out by nuclease free Proteinase K digestion for 20 min at room temperature. After washing twice in PBS, endogenous peroxidase activity was blocked by incubation in 3% hydrogen peroxide for 30 min at room temperature. After washing 3 times in PBS for 3 min, a specific blocking was done with 1% BSA-PBS solution for 10 min at room temperature. Then the slides were incubated with diluted EGFR culture supernatant antibody (1 μL EGFR antibody and 40 μL PBS) (Clone: H-11, DAKO) at 37℃ for 60 min in a humidified chamber. After washing 3 times in PBS, signal conversion was carried out with the LSAB2 system (DAKO) according to the manufacturer's instructions. Haematoxylin co-staining was done.

**Ethical consideration:** All routine colonic biopsy specimens from the patients were taken after informed consent and ethical permission was obtained for participation in the study.

## RESULTS

### *Identification of commonly over-and underexpressed genes in colonic diseases*

Genes that were up- and downregulated in at least 2/3 of cases per sample group in colorectal cancer (Supplemental Table 1), in adenoma (Supplemental Table 2) and in IBD (Supplemental Table 3) were considered as a commonly over- and underexpressed genes. CRC cases are characterized by upregulated genes in the DNA replication (such as replication protein A1, DNA topoisomerase Ⅱα, DNA topoisomerase Ⅰ), cell cycle (including cyclin A1, cyclin-dependent kinase 10, protein NIMA-interacting 1), extracellular matrix remodeling (like keratin 5, perlecan, enactin), transcription regulation (such as IRF5, 6, and E74-like factor 2) , oncogenesis (including v-jun, BRCA2) and growth factor related cell proliferation (EGFR, VEGFB, hepatocyte growth factor, transforming growth factor β2) cell function groups; and downregulated genes in the DNA repair (RAD51 and 52 homolog), tumor suppression and apoptosis (like BCL2-interacting killer) cell function groups. Adenoma cases in comparison showed altered gene expression data in apoptosis (such as TNF receptor-associated factor 6, BAX), growth factors, receptors and their signal transduction (like calgranulin A, KIT ligand, Ran GTPase activating protein 1), oncogenesis and tumor suppression (including growth factor receptor-bound protein 10, p53-induced protein and betaglycan) functional groups. IBD cases are featured by the gene expression changes of immune regulation (including GM-CSF2, CXCL13, MMP-3, MMP-12 and interleukin 1 receptor antagonist), transport [like transferring and solute carrier family 25 (mitochondrial carrier; adenine nucleotide translocator), member 5], and growth factor-related cell proliferation (such as B cell growth factor 1, GM-CSF).

### *The most differentially expressed genes between the 3 sample groups in colon-filtered results of ANOVA*

We analyzed the expression differences between all 1081 genes using ANOVA. The results of ANOVA were filtered according to the number of cases. The genes without enough data from all colonic samples were removed from the analysis. 19 genes were found to be significantly differently expressed ($P < 0.05$) between the colonic sample groups using filtered ANOVA method (Table 1).

### *Factor analysis and discriminant analysis*

Factor analysis was prepared on the basis of the results of variance analysis. Factor analysis resulted in two different factor groups. Factor 1 had the most considerable explorative variance value (6.331196), but the factor 2 also showed significant explorative variance values (4.710563). The factor analysis gives information about the functional gene groups which can differentiate the observed diseases

**Table 1 The most differentially expressed genes between the 3 sample groups in the colon**

| Name | GenBank ID | Differences between sample groups | *P* | Number of valid cases/ sample groups | Ratio of means[1] in adenoma | Ratio of means[1] in CRC | Ratio of means[1] in IBD | Cell function |

[1]Cy3/Cy5 (disease/normal).

according to their different expression levels (Table 2).

According to the expression changes of the following genes the three colonic disease groups can be significanty distinguished: HSF1 ($P$ = 0.012537), bystin-like ($P$ = 0.001027), calgranulin A ($P$ = 0.043831), and TNFR superfamily member 10c ($P$ = 0.037888) (Figure 1).

### Cluster analysis

Four different clusters can be identified: two IBD-related clusters containing one CRC case, a carcinoma group containing one adenoma and one ulcerative colitis case, and an adenoma cluster with nine adenoma cases (Figure 2). Tree diagram of 22 colonic cases showed considerable accordance with the conventional histopathological diagnoses. Excluding one case (AD1), all adenoma cases belong to a significantly distinct cluster. The cluster of severely inflammed IBD cases contained one colorectal adenocarcinoma case, as it showed a similar gene expression pattern. This

**Table 2 Results of the factor analysis**

| STAT. factor analysis | Factor loadings (Varimax raw) Extraction: Principal components (Marked loadings > 0.700000) | | Cell function |

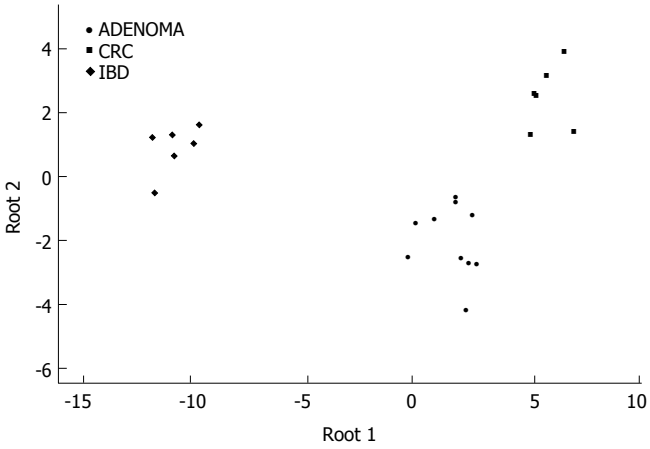

**Figure 1** Discriminant analysis of colonic biopsy specimens. Note the clear separation of the single classification groups based on the discriminatory genes detailed in the results section.

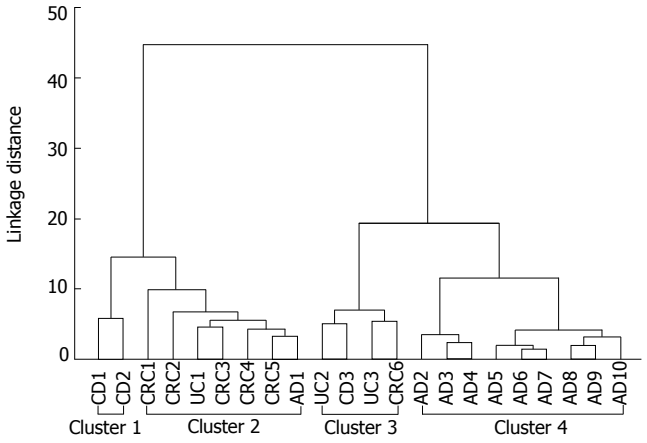

**Figure 2** Tree diagram for 22 colonic diseases (Ward's method euclideandistances). Four different clusters can be identified: 1 and 3 are IBD-related clusters containing one CRC case; 2 is a carcinoma group containing one adenoma and one ulcerative colitis cases; 4 is an adenoma cluster with nine adenoma cases. AD: Adenoma; CD: Crohn's disease; CRC: Colorectal cancer; UC: Ulcerative colitis.

observation could reflect that colorectal cancer can develop from chronic inflammation and some types of adenomas.

### *Validation*

All samples with remaining total RNA (9 CRCs, 2 adenomas and 3 CD samples), were tested using one-step EGFR and TOP1 real-time RT-PCR. Using β-2-microglobulin as a standard control, EGFR- and TOP1 mRNA levels were measured, and ratios of these concentrations to the standard were determined. Ratios for each disease group along with normal samples were compared, and the resulting relative ratios determined (diseased/normal in the same patient). The CRC samples showed higher EGFR mRNA level than the normal paired sample (relative ratio: 3.008, SD: 4.591), while there was no differential expression found in the adenoma samples (relative ratio: 0.772, SD: 0.060). Lower EGFR expression was measured in CD samples (relative ratio: 0.451, SD: 0.173) compared to the normal adjacent mucosa. Increased, 2.802-fold TOP1 mRNA level was evaluated in the CRC samples (SD: 3.884), but TOP1 level of the other sample groups was within the normal range (realtive ratio-adenoma: 0.774, SD: 0.0368; realtive ratio-CD: 0.942, SD: 0.337). The expression differences of EGFR and TOP1, found by microarray analysis, could be confirmed in most, but not in all cases. First, because of the limited total RNA amount in several of the small biopsy samples, the starting isolated total RNA was used in its entirety for probe synthesis. Secondly, differences between the two gene expression analysing method could be due to different gene sequences being amplified and detected during the real-time RT-PCR and the microarray analysis.

### *EGFR-immunohistochemistry*

In colorectal carcinoma samples, EGFR was found to be mildly and moderately expressed in all carcinoma cells. Diffuse cytoplasmatic EGFR staining was found in all carcinoma samples. In normal samples, moderate and high EGFR expression was found in some epithelial cells, but in total amount, EGFR expression was decreased compared to carcinoma samples (Figure 3). EGFR protein expression data were in correlation with EGFR mRNA expression data from both microarray and real-time RT-PCR analysis.

## DISCUSSION

We compared the gene expression pattern of biopsy samples from patients with adenoma, CRC and IBD, on

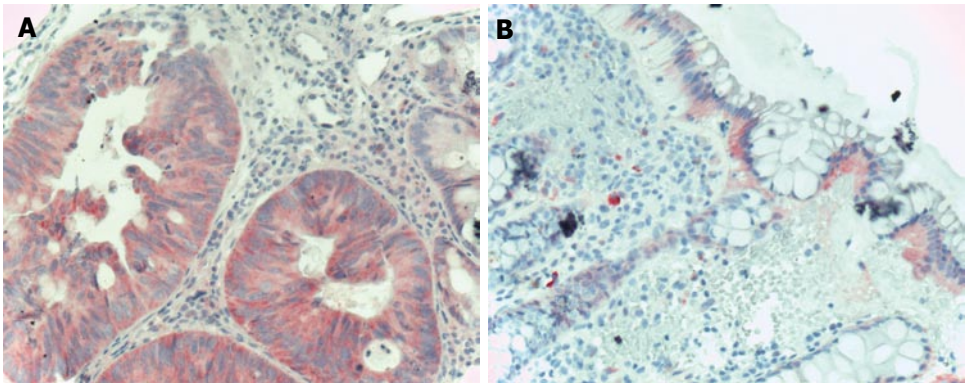

**Figure 3** EGFR immunohistochemistry in CRC. **A**: Carcinomatous glands of the colon showing diffuse cytoplasmatic, moderately intensive EGFR staining (Hematoxylin co-staining × 200); **B**: Normal colonic epithelia showing mildly, moderately intensive basolateral intracytoplasmatic EGFR staining. The lower 2/3 of the crypts do not show EGFR positivity (Hematoxylin co-staining × 100).

Human Atlas Glass 1.0 microarrays containing 1081 target sequences. Biopsies were taken from disease-involved areas of the colon and surrounding disease-free colonic mucosa from the same patient. Multiple filtering methods for reduction of array-array variability origins from the spotted microarray hybridization procedure, and multiple statistical analyses were applied for finding colorectal carcinogenesis-associated genes, which can enhance the conventional histological diagnosis.

The Atlas Glass Human 1.0 microarray platform is a spotted microarray with each probe consisting of a single "long oligo" (80 mer) spotted on a glass slide. On the Atlas Glass microarray, all of the weight of detection rests on a single oligonucleotide. If cross-hybridization with an inappropriate target occurs, then the readout for that gene is incorrect. This could result in an erroneous quantification of mRNA levels[19,20] and relatively high standard deviation values. This main disadvantage of spotted opened system microarrays was apparent in our analyses: several hybridized microarrays (12 from 34) were removed from the further analysis after the quality testing, because of the problems mentioned above. Hence, comparison results from analysis of different microarray types, besides the facts mentioned above, requires due foresight, because of the different signal detection techniques, various sample amounts, sample types, sample processing and storage, and different experimental controls. The results are strongly affected by choice of biopsy samples or surgically resected tissue as a starting material, heterogeneous tissue samples or homogeneous cells such as laser microdissected cells. Our concept was that biopsies taken from patients during endoscopical examination with minimal intervention, are the most suitable samples for identifying early diagnostic target molecules.

CRC cases are characterized by upregulated genes in the DNA replication, cell cycle, extracellular matrix remodeling, transcription regulation, oncogenesis and growth factor related cell proliferation cell function groups; and downregulated genes in the DNA repair, tumor suppression and apoptosis cell function groups, while adenoma cases showed altered gene expression data in apoptosis, growth factors, receptors and their signal transduction, oncogenesis and tumor suppression functional groups. Despite the differences in samples and microarray types, there are genes, which were found differently expressed in our study that were also found commonly with other research groups. This fact emphasizes the importance of these CRC-related genes. Similarly to our findings, overexpression of several oncogenes (v-jun[20], BRCA2[8], growth factor genes (VEGF[22], HGF[23], TGFβ[5,9,24,25]), DNA replication and repair genes (TOP2A[8,26], tankyrase[9]), signal transduction gene (ephrin B2[27]), cell cycle genes (cell growth regulatory with zinc finger domain[8]) and transcription factors (several interferon regulatory factors[8]) was previously found by others using microarray analysis in gastrointestinal cancers.

Over- and underexpression of several apoptosis-, proliferation- and cell survival-related genes were observed in our microarray analysis (Table 1). These cell processes and their balance play a critical role in carcinogenesis and tumor progression. Functional analysis and visualization of biological association networks, especially pathways involved in apoptosis and cell survival were done using Pathway Assist 2.53 software. Figure 4 shows a graphical overview illustrating the role of the most important upregulated apoptosis-related genes. We found differently expressed genes in our study that are involved in or affected by not only one, but four different apoptotic pathways which are known in mammalian cells. These genes include TNFRSF10c (tumor necrosis factor receptor superfamily, member 10c) so called TRAILR3, TRAF6 (TNF receptor-associated factor 6), TNFRSF6 (Fas) and caspase 4 (CASP4) genes, downregulated apoptotic BIK (Bcl-2 interacting killer) and PP2A (protein phosphatase 2A). Two other genes that showed increased mRNA level in CRC, and were verified by real-time RT-PCR and/or immunohistochemistry, DNA topoisomerase I (TOP1) and EGFR (epidermal growth factor receptor), have a possible role in cell processes leading to CRC. Overexpression of EGFR correlates with CRC progression and metastatic potential[28]. EGFR activation can promote proliferation and maintain survival via MAPK (Ras/JNK), Ras/ERK and JAK/STAT signalling pathways. Amplification of receptor signaling by means of overexpression may promote tumor growth and resistance to apoptosis. Human TOP1 associated with intensive cell division and DNA replication occurring in the malignant cells.

We also aimed to find genes that can enhance the molecular classification of CRC and its precancerous stages. Several genes from different functional groups were found to be overexpressed in both adenoma and CRC samples compared to adjacent normal mucosa, and the degree of upregulation of these genes follows the normal-adenoma-

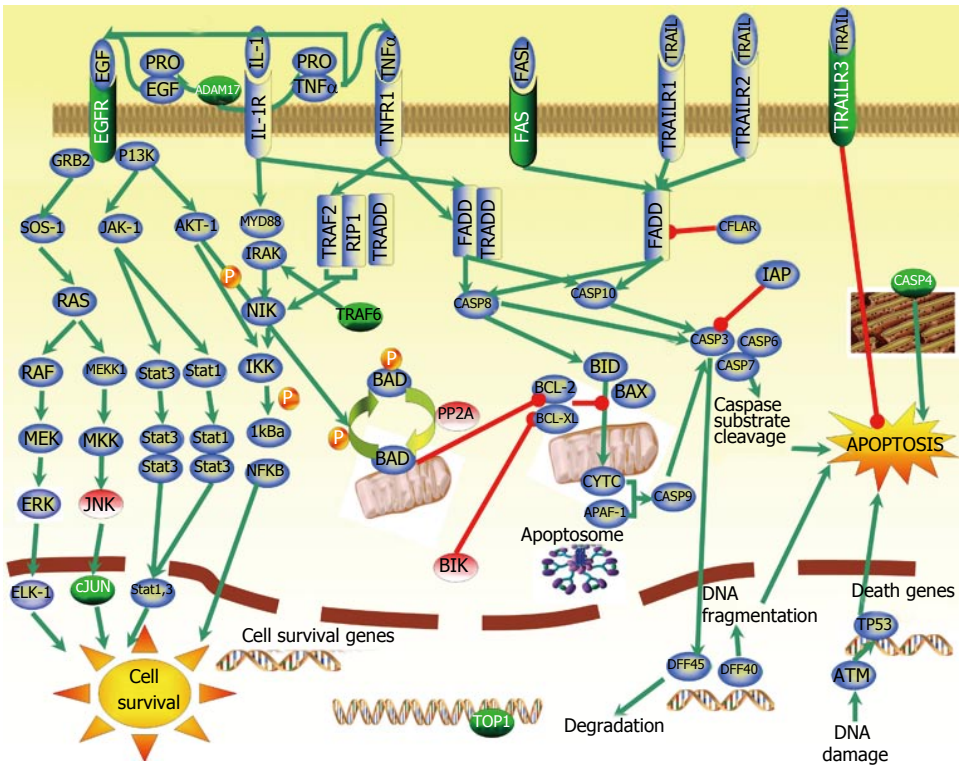

**Figure 4** The main apoptotic and cell survival pathways identified in CRC gene expression study. Genes marked with green were found to be overexpressed, while genes marked with red were found to be underexpressed in our microarray analysis. Genes in blue are previously described as apoptotic and cell survival pathways-related genes. Green arrows refer to the positive regulation, while reds mean negative regulation (inhibition).

CRC sequence. Genes found to be important for this classification include cell survival promoting molecules (TRAF6, Grb10, ELF2, TACE), DNA synthesis and cell cycle involved molecules (RanGAP1, replication protein A1) and CFTR chloride channel. CFTR (cystic fibrosis transmembrane conductance regulator) is the most important chloride channel in the luminal membrane of the colon. A central role has been suggested for CFTR in coordinating electrolyte transport by changing absorption into secretion in colon carcinogenesis[29]. Recent studies demonstrate an enhanced cAMP-activated $Cl^-$ secretion in the hyperproliferative colonic mucosa that is caused by elevated CFTR expression[30].

IBD cases are featured by the gene expression changes of immune regulation, transport and growth factor-related cell proliferation in our study. In correlation with our findings, elevated chemokine (small inducible cytokine A4, interleukin-1 receptor antagonist) and matrix metalloprotease (MMP-3, MMP-12) mRNA levels were detected in IBD compared to normal mucosa by microarray analysis[16]. Small inducible protein A4 is highly expressed in IBD according to the degree of inflammation[31]. IL-1 receptor antagonists inhibit the activity of IL1 and modulate a variety of IL1-related immune and inflammatory responses. Programmed expression of MMPs is involved in tissue remodeling during inflammation, moreover MMP-12 may play a role in macrophage movement and epithelial cell shedding[32]. Several other growth factors and chemo attractants were found overexpressed in our microarray analyses. Secretion of GM-CSF2 (macrophage-granulocyte colony stimulating factor 2) is increased in mucosal lesions in IBD. B cell growth factor 1 released by T cells after antigen stimulation, and supports the clonal proliferation of B cells. CXCL13 B cell chemoattractant is mostly produced by the monocyte/macrophage lineage in UC[33].

### *Discrimination of colonic diseases according to the gene expression markers*

Discriminant analysis shows the genes which can help us to classify an unknown sample into one of the groups of observed diseases, considering their expression levels. According to the expression changes of the following four genes the three colonic disease groups can be significantly distinguished: HSF1, calgranulin A, TNFRSF10c (TRAILR3) and bystin-like.

HSF1 is a heat-shock transcription factor, that was found to be upregulated in CRC compared to normal mucosa in both our and other research groups' gene expression studies[34]. In adenoma and IBD cases it showed lower expression level compared to the CRC samples. Induction of HSF1 gene expression could activate the HSF1 heat shock stress signal pathway in sporadic CRC. The heat shock stress signaling pathway is highly involved in carcinogenesis since heat shock proteins are responsible for maintaining the conformation, stability and function of key oncogenic client proteins involved in signal transduction pathways leading to proliferation, cell cycle progression and apoptosis, as well as other features of the malignant phenotype such as invasion, angiogenesis and metastasis[35-37].

Calgranulin A (S100A8) is a calcium-binding protein that showed higher expression in the IBD sample group, than in CRC and adenoma cases. S100 proteins are involved in the regulation of a number of cellular processes such as cell cycle progression, differentiation and immune response[38].

Significantly increased TRAILR3 level was found in

CRC samples, but not in IBD and adenoma cases. This receptor inhibits the TRAIL-induced apoptosis via binding TRAIL ligand which in this case cannot interact with the pro-apoptotic, death domain containing other TRAIL receptors[39,40].

Interestingly, significant bystin-like 7-fold mRNA overexpression was found in IBD samples in our microarray analysis. Suzuki *et al*[41] identified a cytoplasmic protein, named bystin, that directly binds trophinin and tastin cell adhesion molecules that are involved in the process of the embryo implantation. A role for bystin-like protein in inflammation has not been described.

The factor analysis gives information about the functional gene groups which can differentiate the observed diseases according to their different expression levels. Five of the seven genes (HSF1, TRAILR3, stem cell growth factor, interleukin-7 receptor and pleiotrophin) with the most considerable explorative variance value (belong to Factor 1) were mentioned previously in the scientific literature as cell proliferation and cancer related genes (HSF1[34-37], TRAILR3[39,40], stem cell growth factor[42], interleukin-7 receptor[43] and pleiotrophin[44,45]).

Twenty two colonic biopsy samples were clustered in correlation with the conventional histopathological diagnoses. Excluding one case, all adenoma cases belong to a significantly distinct cluster. The cluster of severely inflammed IBD cases contained one colorectal adenocarcinoma case, as it showed a similar gene expression pattern. This fact can refer that colorectal cancer can develop on the basis of chronic inflammation and some types of adenomas.

In summary, we can say that the overall mid-size glass arrays are suitable for identification of disease-specific genes which are considered as gene expression markers. Detection of the mRNA expression levels of marker gene panels gives an opportunity for classification of colonic samples, even in the case of small biopsy specimens. The limited starting RNA amount arising from the small sample size makes microarray analysis difficult. The standardization of the opened manual microarray systems is more difficult; however, automatization of this technique would further improve the efficacy, reproducibility and quality of microarray analysis.

## Abstract

**AIM:** To evaluate the utility of the innovative fecal tumor M2-Pyruvate kinase (M2-PK) test in our daily clinical routine, as a marker for the pre-selection of patients who should subsequently undergo colonoscopy for the diagnosis or exclusion of colorectal cancer.

**METHODS:** Fecal tumor M2-PK was measured in stool samples of 96 study participants (33 patients with colorectal cancer, 21 patients with rectal carcinoma and 42 controls) who all underwent total colonoscopy.

**RESULTS:** In 39 of 42 individuals in the control group, fecal tumor M2-PK was below 4.0 kU/L (93% specificity). Colorectal tumors were accompanied by a highly significant increase ($P < 0.001$) in fecal tumor M2-PK levels (median: colon carcinoma, 23.1 kU/L; rectal carcinoma, 6.9 kU/L; colorectal carcinoma, 14.7 kU/L), which correlated with Duke's staging and T-classification. The overall sensitivity was 78% for colorectal cancer, increasing from 60% for stage T1 to 100% for stage T4 and from 60% for Duke's A to 90% for Duke's D tumors.

**CONCLUSION:** Fecal tumor M2-PK is an appropriately sensitive tool to pre-select those patients requiring colonoscopy for the further diagnostic confirmation or exclusion of colorectal cancer.

**Key words:** Tumor M2-Pyruvate kinase; Pyruvate kinase type M2; Colon cancer; Rectal cancer; Adenoma; Feces; Cancer screening

## INTRODUCTION

In Germany, about 70 000 people are diagnosed with colorectal cancer each year[1]. This figure is about 1 million worldwide, with approximately 528 000 deaths from colorectal cancer each year[2]. The gold standard for the early detection of colorectal cancer is colonoscopy. However, the acceptance of this costly and invasive method is low. Only 1.7% of people entitled to colonoscopy under the German national colorectal cancer screening program actually undergo the procedure[3].

In order to increase the participation in colorectal cancer screening programs, an easy, fast and economical initial screening method, with good patient compliance, is absolutely necessary. This allows identification of those patients most likely to have colorectal cancer, who require further investigation by colonoscopy.

The guaiac-based fecal occult blood test (FOBT), which is based on the premise that polyps and cancer bleed more than normal mucosa[4], is currently the most commonly used test for colorectal cancer screening. Guaiac-based FOBTs have been investigated in a number of large studies and shown to reduce mortality by about 15%-33% in screened populations[5,6]. However, they have limited sensitivity. For example, Lieberman *et al*[7] and Koss *et al*[8] found their sensitivity was less than 30% for colorectal cancer and less than 15% for advanced adenomas. Newer immunological FOBTs showed higher sensitivities[9,10] with the advantage of no dietary restrictions. In most studies with immunological FOBTs to date, however, colonoscopy has been performed only in FOBT-positive cases. Non-bleeding colorectal tumors and those not consistently discharging sufficient blood into the gut lumen are not detected by either guaiac or immunological FOBTs.

Recently a new screening test for the early detection of adenomas and colorectal tumors has been described. The tumor M2-Pyruvate kinase (M2-PK) stool test is based on the measurement of a key enzyme involved in tumor metabolism[8,11-14].

Tumor M2-PK is the dimeric form of the glycolytic pyruvate kinase isoenzyme type M2[15]. The enzyme catalyzes the last reaction step within the glycolytic

sequence from phosphoenolpyruvate (PEP) to lactate and is responsible for net ATP production within this pathway. Enzymatic characterization of a wide range of different tumors revealed that tumorigenesis is accompanied by an increase in total pyruvate kinase v-max activities. There is also a shift towards the expression of the pyruvate kinase isoenzyme type M2 (M2-PK) and away from the tissue-specific isoenzymes (L-PK in liver and kidney, M1-PK in muscle and brain and R-PK in erythrocytes)[16-18]. The increased expression of M2-PK is under the control of ras, and the transcription factors SP1 and HIF-1. Ras and HIF-1 are both consistently altered in gastrointestinal tumors[19-22]. M2-PK can occur in a tetrameric form which is characterized by a high affinity to its substrate PEP and in a dimeric form with a low PEP affinity. The tetramer: dimer ratio of M2-PK determines the proportion of glucose carbons used for glycolytic energy production (tetrameric form) or channeled into synthetic processes (dimeric form). In tumor cells, M2-PK is mainly found in the dimeric form (tumor M2-PK) due to direct interaction with various oncoproteins, i.e. $pp60^{v\text{-}src}$ kinase and HPV-16 E7[15,21,23]. Tumor M2-PK is released into the blood, and in the case of adenomas and tumors in the lower gastrointestinal tract also into the stool of patients. An increase in tumor M2-PK in EDTA plasma samples is found in gastrointestinal cancers, as well as a wide range of other tumors such as lung, renal, breast and cervical cancer. The EDTA plasma test is highly suitable for patient monitoring[24-30].

The fecal tumor M2-PK test has been described as a promising new screening tool for adenomas and colorectal cancer[8,11-14]. Therefore, the aim of our study was to evaluate the utility of the tumor M2-PK test in our own daily clinical routine as a marker for the pre-selection of patients requiring subsequent diagnostic colonoscopy.

## MATERIALS AND METHODS

### Patients

Our study consisted of 96 participants who underwent complete colonoscopy. The control group consisted of 42 healthy individuals (15 male and 27 female; median age: 58 years; range: 25-79 years) without any findings at colonoscopy, who were participating in the national screening colonoscopy program provided by the German health insurance system. All screening colonoscopies were conducted between September 2005 and April 2006 in a primary care gastroenterology and hepatology medical center. Healthy individuals were included in the control group.

The 54 participants with colorectal cancer underwent diagnostic colonoscopy at the Offenbach Municipal Hospital between January 2003 and April 2006. Rectal carcinomas were diagnosed in 21 patients (15 male and 6 female; median age: 70 years; range: 52-84 years). Colonic adenocarcinomas were diagnosed in 33 patients (24 male and 9 female; median age: 70 years; range: 43-84 years).

All participants received a stool sample collection pot and were instructed to collect a single stool sample (naturally produced, walnut sized) one day prior to the laxative administration in preparation for colonoscopy. No special diet was recommended. Paper collecting devices were used to avoid stool contact with water in the toilet bowl. Stool samples were initially stored at room temperature by the participants until the day of colonoscopy. Thereafter, these pre-colonoscopy stool samples were stored at -20℃ at the medical center or hospital until analyzed for tumor M2-PK.

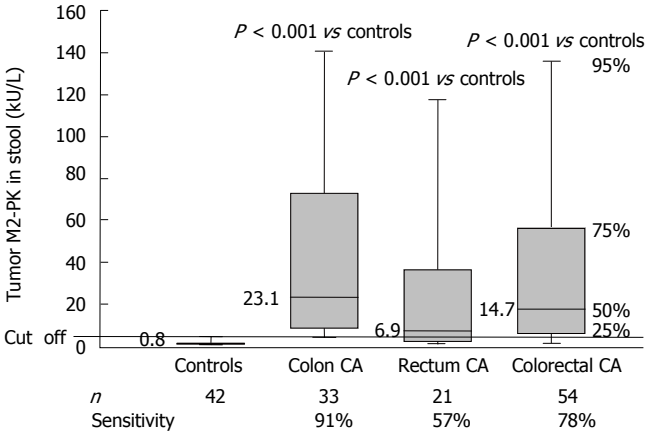

**Figure 1** Tumor M2-PK levels in stool samples of healthy control individuals and patients with colon or rectal cancer.

### Measurement of fecal tumor M2-PK concentrations

Fecal tumor M2-PK concentrations were determined using a commercially available sandwich ELISA based on two different monoclonal antibodies which specifically recognize the dimeric form of M2-PK (ScheBo® · Biotech AG, Giessen, Germany). A positive test result was defined as > 4.0 kU/L, as indicated by the manufacturer.

### Statistical analysis

Since the data were skewed to the right, the statistical analysis was conducted using the Kruskall-Wallis ANOVA test (Statistica, StatSoft® Inc., Tulsa, USA).

## RESULTS

This study evaluated 54 patients with colorectal cancer and 42 healthy controls with no indication of gastrointestinal diseases at colonoscopy. In the control group, fecal tumor M2-PK levels were below 4.0 kU/L in 39 of the 42 subjects (median: 0.8 kU/L), resulting in 93% specificity (Figure 1). In two of the three control samples which were above the cut-off value only a slight increase of tumor M2-PK (4.4 kU/L and 5.3 kU/L) was measured.

Colorectal tumors were accompanied by a highly significant increase in fecal tumor M2-PK levels. The median value was 23.1 kU/L for colon carcinoma ($P < 0.001$), 6.9 kU/L for rectal carcinoma ($P < 0.001$) and 14.7 kU/L ($P < 0.001$) for colorectal carcinoma when both groups were combined.

At a cut-off level of 4.0 kU/L, the sensitivity was 91% for colon carcinoma, 57% for rectal carcinoma and 78% when both groups were combined. Both T classification and Duke's staging of the colorectal tumors revealed a

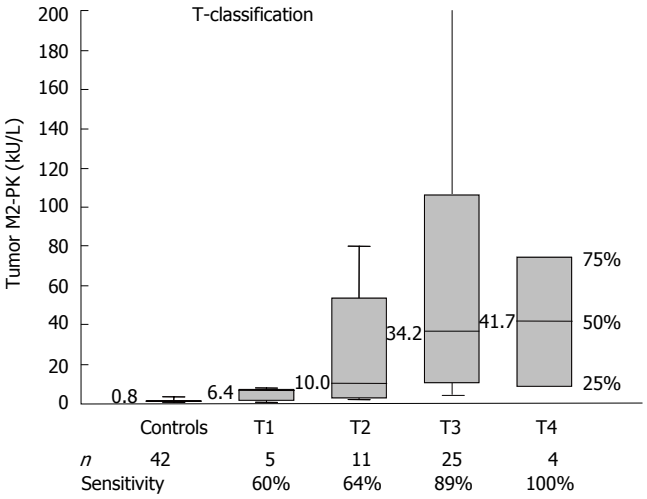

**Figure 2** Correlation between fecal tumor M2-PK levels and TNM staging.

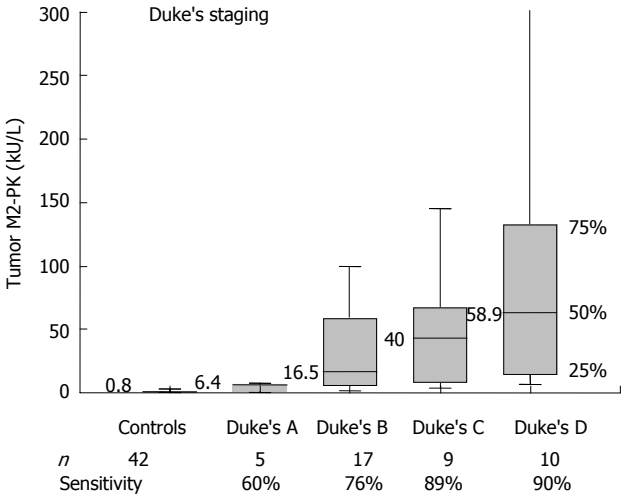

**Figure 3** Correlation between fecal tumor M2-PK and Duke's staging.

**Table 1 Correlation between fecal tumor M2-PK levels and TNM classification or duke's staging**

| Classification | *n* | Median (kU/L) | Mean (kU/L) | SE (kU/L) | Range (kU/L) |
|---|---|---|---|---|---|
| Controls | 42 | 0.8 | 1.5 | 0.4 | 0.1-17.3 |
| T1 | 5 | 6.4 | 4.5 | 1.6 | 0.3-7.7 |
| T2 | 11 | 10.0 | 30.5 | 10.1 | 1.5-100 |
| T3 | 25 | 34.2 | 106.3 | 35.2 | 1.7-620 |
| T4 | 4 | 41.7 | 41.4 | 19.2 | 6.6-76 |
| Duke's A | 5 | 6.4 | 4.5 | 1.6 | 0.3-7.7 |
| Duke's B | 17 | 16.5 | 63.5 | 34.7 | 0.2-604 |
| Duke's C | 9 | 40.0 | 50.0 | 17.8 | 1.9-176 |
| Duke's D | 10 | 58.9 | 138.5 | 65.3 | 4.5-620 |

strong correlation between fecal tumor M2-PK levels and staging. The sensitivities increased from 60% for stage T1 to 100 % for stage T4 and from 60% for Duke´s A to 90% for Duke's D (Figures 2 and 3; Table 1).

## DISCUSSION

Tumor M2-PK is the synonym for the dimeric form of the glycolytic pyruvate kinase isoenzyme type M2[15]. M2-PK is the pyruvate kinase isoenzyme which is characteristic of all proliferating cells and can occur in a tetrameric form as well as a dimeric form. Previous studies describe that tumor M2-PK is released into the stool of patients with adenomas and colorectal tumors and can easily be quantified with a commercially available sandwich ELISA[8,11-14].

In order to evaluate whether tumor M2-PK is a practical tool for the pre-selection of patients with colorectal cancer in our daily routine, we measured fecal tumor M2-PK in a cohort of 96 individuals. All 42 healthy control individuals, 33 patients with colon carcinoma and 21 patients with rectal carcinoma underwent total colonoscopy in order to confirm or exclude colorectal cancer. Our study revealed a highly significant increase ($P < 0.001$) in tumor M2-PK in the stool samples of those patients with colorectal cancer, whereby fecal tumor M2-PK values correlated well with Duke's staging and T-classification (Figures 1-3; Table 1). Even stage T1 or Duke's A showed 60% sensitivity, increasing to 100% in stage T4 and to 90% in Duke's D tumors.

At a cut-off value of 4.0 kU/L, our overall sensitivity for colorectal carcinoma was 78 %. These data correspond well with the results of Hardt *et al*[13] who reported a sensitivity of 78% in 60 colorectal cancer patients, and those of Naumann *et al*[31] who found a sensitivity of 85.2% in a cohort of 27 colorectal cancer patients. A higher sensitivity was reported by McLoughlin *et al*[14] (92% in 25 colorectal cancer patients and 67% in 30 patients with adenomas) and by Koss *et al*[8] (92.3 % in 26 colorectal cancer patients and 60% for adenomas > 1 cm in ten patients).

The most commonly used fecal test in current screening programs is the guaiac-based FOBT[32,33]. Liebermann *et al*[7] and Koss *et al*[8] have reported an overall sensitivity for guaiac-based FOBTs of less than 30% for colorectal cancer and less than 15% for advanced adenomas. Results with newer, immunological FOBTs showed higher sensitivities than guaiac-based FOBTs for colorectal cancers[9,10] but in most studies colonoscopy was performed only in FOBT-positive cases.

The overall sensitivity of tumor M2-PK is increased if a higher proportion of late stage patients are included, but this is also true for FOBTs[10]. Nevertheless, McLoughlin *et al*[14] reported a sensitivity of 67% for adenomas with the fecal tumor M2-PK test. Similarly, Koss *et al*[8] found a sensitivity of 60% for adenomas > 1 cm.

In a head-to-head comparison of fecal tumor M2-PK and the commonly used guaiac-based FOBT, Koss *et al*[8] demonstrated a sensitivity for colorectal cancer of 92.3% for fecal tumor M2-PK and 20% for FOBT. No comparative study of fecal tumor M2-PK and immunochemical FOBTs is currently available.

The high sensitivity of the tumor M2-PK test is due to its ability to detect bleeding and non-bleeding tumors. From a practical viewpoint, the use of a single random formed stool sample for tumor M2-PK analysis, without

requiring dietary restrictions, might be of greater patient convenience compared with the need to collect stool on three consecutive days for the guaiac FOBT.

In our study, the control group consisted of individuals without any signs of gastrointestinal diseases at colonoscopy. The median tumor M2-PK value in this group was 0.8 kU/L. In 39 of 42 subjects, tumor M2-PK levels were below the cut-off value; in two further control samples tumor M2-PK levels were only slightly increased (4.4, 5.3 kU/L). The resulting specificity at a cut off value of 4.0 kU/L is 93%, which is in general accordance with the studies of Hardt *et al*[13], Koss *et al*[8] and McLoughlin *et al*[14] who report specificities between 78% and 98%. Naumann *et al*[31] found increased fecal tumor M2-PK levels in cases of active Crohn's disease and ulcerative colitis in which increased cell proliferation is expected. In addition, patients with inflammatory bowel disease have an increased risk of developing colorectal cancer, probably linked to frequent cycles of damage and regeneration of the colonic mucosa associated with flares of active disease.

Another new approach for pre-selective colorectal cancer screening is the determination of mutated oncogenes and anti-oncogenes[22,34-38]. These tests have the advantage of very high specificities. However, due to high genetic heterogeneity within colorectal cancers, a panel of different targets (k-ras, p53, APC genes, as well as microsatellite instability marker) must be measured in order to reach acceptable sensitivity which makes the test extensive and expensive. Using a 21-target multipanel, sensitivities between 44% and 91% and specificities between 93% and 100% are described[36-38]. Furthermore, to assure the stability of DNA within the stool, samples have to be frozen at -80℃ within 12 h after defecation. Fecal tumor M2-PK is stable for 48 h at room temperature and for up to one year when frozen at -20℃ (manufacturer's data sheet), which makes it practical for routine use. In addition, the tumor M2-PK test could be conducted in virtually all hospital and private diagnostic laboratories because it can either be run manually combined with an ELISA plate reader or automated using existing commercially available equipment.

Overall, our results are in general agreement with previous studies which have demonstrated that fecal tumor M2-PK is an appropriate tool to achieve a sensitive pre-selection by identifying those patients with the greatest need to undergo diagnostic colonoscopy to confirm or exclude colorectal cancer.

## Abstract

**AIM:** To study the effect of oral steroids upon clinical response and rectal mucosa secretion of eosinophil cationic protein (ECP), myeloperoxidase (MPO), basic fibroblast growth factor (bFGF), vascular endothelial growth factor (VEGF) and albumin in patients with collagenous colitis (CC).

**METHODS:** A segmental perfusion technique was used to collect perfusates from rectum of CC patients once before and twice (one and four weeks) after the start of steroid treatment. Clinical data was monitored and ECP, MPO, bFGF, VEGF and albumin concentrations were analyzed by immunochemical methods in perfusates and in serum.

**RESULTS:** Steroids reduced the number of bowel movements by more than five times within one week and all patients reported improved subjective well-being at wk 1 and 4. At the same time, the median concentrations of ECP, bFGF, VEGF and albumin in rectal perfusates decreased significantly. MPO values were above the detection limit in only 3 patients before treatment and in none during treatment. VEGF, bFGF, ECP and albumin concentrations correlated with each other with the exception of ECP and albumin. A decrease of serum ECP and VEGF concentrations was also seen even if the overtime reduction was not significant.

**CONCLUSION:** Oral steroid treatment in CC patients induced a simultaneous reduction of bowel movements and rectal release of ECP, bFGF, VEGF and albumin, suggesting that these polypeptides and increased mucosal permeability are important components of the pathophysiology in collagenous colitis.

**Key words:** Collagenous colitis; Inflammatory mediator; Steroid treatment; Eosinophil cationic protein; Basic fibroblast growth factor; Vascular endothelial growth factor

## INTRODUCTION

Collagenous colitis (CC) is characterized by watery diarrhea and an increased subepithelial collagen layer with infiltration of inflammatory cells in the surface epithelium and lamina propria of the colon[1]. The thickened collagen in CC is an amorphous eosinophilic band located beneath the intercryptal epithelial surface and is best visualized using special collagen staining, such as Masson´s trichrome[1]. The collagen composition of the basal membrane of colonic mucosa in CC patients is identical to that of normal individuals[1]. In contrast, the subepithelial collagen layer differs in CC patients and consists of collagen type I and Ⅲ or Ⅵ[2-4].

Intestinal inflammatory cells present in CC are lymphocytes, plasma cells, often eosinophil and sometimes neutrophil granulocytes. In the epithelium, lymphocytes are most frequent and dominated by $CD8^+$ T-cells[5]. In the lamina propria, the inflammatory cell infiltration includes plasma cells, eosinophils, macrophages and mast cells, but rarely neutrophils. Unlike epithelial lymphocytes, the lymphocytes in the lamina propria are mainly composed of $CD4^+$ T-cells[5].

Eosinophils are one of the main components of the inflammatory cell population in colonic mucosa of CC patients[1]. Eosinophils produce not only cytotoxic granule proteins, such as eosinophil cationic protein (ECP), major

basic protein (MBP) or eosinophil peroxidase (EPO), but also a wide range of polypeptides, such as transforming growth factor-β1 (TGF-β1), vascular endothelial growth factor (VEGF), *etc*[6-10]. Eosinophilopoietic cytokines, such as granulocyte-macrophage colony-stimulating factor (GM-CSF) and interleukin-5 (IL-5), activate eosinophils by inhibiting apoptosis and prolonging the life span of eosinophils[7]. Eosinophils interact with fibroblasts and contribute to fibrosis in inflammatory diseases like asthma and inflammatory bowel disease (IBD). Activated fibroblasts/myofibroblasts are regarded as the major contributors of collagen accumulation in the intestinal wall of IBD[11,12] including CC patients[13].

In asthma, basic fibroblast growth factor (bFGF), separately or in combination with other growth factors, perpetuate chronic inflammation and triggers fibrosis leading to airway tissue remodeling[14] including excessive extra cellular matrix deposition in the subepithelial region. The role of bFGF, as one contributing factor in tissue remodeling, is supported by perfusion studies in ulcerative colitis (UC)[15] and CC[16] patients, where the secretion of bFGF was increased.

VEGF is a pleiotropic polypeptide, which has physiological and pathophysiological actions on the extra cellular matrix and may enhance fibrosis through induction of connective tissue growth factor (CTGF)[17]. A recent study on the pathophysiological role of VEGF in CC showed that VEGF, by changing the local matrix metalloproteinase -1 and tissue inhibitor metalloproteinase-1 (MMP-1/TIMP-1) balance, causes the accumulation of immature subepithelial ECM in CC[18].

Glucocorticosteroids have several anti-inflammatory effects, including the ability to block the recruitment of proinflammatory cells like eosinophils, downregulation of the secretion of proinflammatory cytokines, enhancement of apoptosis in eosinophils[19-21] and engulfment of apoptotic eosinophils by phagocytic cells[7]. In asthma, prolonged treatment with inhaled corticosteroids reverses tissue remodeling by downregulating fibroblast-functions[14,20,22]. In our previous perfusion studies, we found increased colorectal concentrations of ECP[23], bFGF[16], VEGF[24] and the permeability marker albumin in CC patients compared with control patients. We put forward the hypothesis that these mediators enhanced chronic inflammation and fibrosis, leading to pathological accumulation of subepithelial collagen. Oral steroid treatment is effective for inducing remission in CC patients[25,26] but the mechanisms leading to relief of symptoms are not fully known. The aim of this study was to elucidate the relationship between steroid treatment and rectal mucosa secretion of ECP, MPO, bFGF, VEGF and albumin in CC patients.

## MATERIALS AND METHODS

### Patients

Twelve patients (10 women, 2 men; mean age 52 years; range 34-66 years) who fulfilled the diagnostic criteria of CC[1] were recruited between November 2000 and November 2002 at the Department of Medicine, University Hospital, Uppsala, Sweden.

### Ethics

Committee of the Medical faculty at Uppsala University approved the study and informed consent was obtained from all participants. No patient had anti- or pro-inflammatory drug treatment during the investigation period, but one patient (number eight) was taking indomethacin (Indomee$^{R}$, Merck Sharp and Dohme, Stockholm, Sweden) up until one week before the first perfusion. Patient number seven also had celiac disease and lactose intolerance, while patients five and eight suffered from hypothyroidism. Patients eleven and twelve were smokers.

### Design of study

Steroid treatment was initiated after the first perfusion with an oral dose of 40 mg prednisolone daily, which was reduced successively by 5 mg/wk. Three rectal perfusions were fulfilled per patient, one before and two after the start of steroid treatment, at completed weeks one and four respectively. Serum samples were also collected on those occasions. Clinical data were recorded at each perfusion as the patients estimated their average daily number of loose stools and degree of general well-being during the week preceding each perfusion.

### Perfusion technique

A colonoscope-based segmental perfusion technique[23] was used to obtain perfusion fluid from the rectum. Sodium phosphate (Phosphoral$^{R}$, Ferring, Limhamn, Sweden) was used for bowel preparation. The rectal perfusions were carried out with the patients lying in a supine position and started with an endoscopic examination of the rectum and sigmoid colon. The segment, positioned at the end of the flexible endoscope, was established by inflating air into two balloons delimiting the segment in the rectum. The perfusion procedures were carried out for one hour[23] and the perfusates were collected in three portions at 20 min intervals in tubes immersed in ice. Intravenous injections of the sedative diazepam (Stesolid$^{R}$, Alpharma, Stockholm, Sweden) were given at a median dose of 7.5 mg (range: 5-15) and the analgesic meperidine (Petidin$^{R}$, Ipex, Stockholm, Sweden) at a median dose of 25 mg (range: 25-50).

### Perfusion buffer, perfusates and serum samples

A buffer was used, consisting of 120 mmol/L NaCl, 5.4 mmol/L KCl, 2 mmol/L $Na_2HPO_4$, 10 mmol/L glucose, 35 mmol/L mannitol, and 1 g/L polyethylene glycol (PEG; MW 4 kDa) at pH of 8.20-8.48 and osmolarity of 290 mosm/L. The perfusion fluid was kept at 37℃ and then infused at a speed of 3 mL/min for 60 min. By adding ten milliliters of aprotinin (Trasylol$^{R}$ Bayer 1.0 × $10^7$ kIU/L) to every liter of perfusion buffer, proteolytic activity was inhibited. Phenol red solution (50 mg/L in physiological saline) was intermittently infused (5 mL every 20 min) above the proximal balloon to check that the perfusion segment was closed and that there was no contamination of the perfusion fluid by intestinal contents located proximally. All perfusate samples were collected on ice and frozen in aliquots of 2 mL at -70℃. The protease inhibitor, phenylmethylsulphonyl fluoride (PMSF; Sigma

Chemical Co., St Louis, MO, USA), was added to a final concentration of 2 mmol/L immediately before analysis to counteract the effect of even small amounts of proteases in the perfusion fluid. Serum samples were drawn simultaneously with the perfusions being performed and frozen at -70℃ for later analysis.

### Quantification of ECP, MPO and albumin

The concentrations of ECP and MPO in perfusion fluids and serum samples were analyzed by means of a specific RIA (Pharmacia & Upjohn, Diagnostic AB, Uppsala, Sweden). The inter- and intra-assay coefficients of variations were < 10% for both tests. The lower detection limits of ECP and MPO in perfusion fluid were 2 and 8 μg/L, respectively. The reference intervals for ECP and MPO in serum were 2.3-16 μg/L and 170-478 μg/L, respectively. Albumin in perfusion fluid was analyzed by rate nephelometry on a Beckman Array protein system (Beckman Instruments, Brea CA), according to the recommendations of the manufacturer. The lower detection limit in perfusion fluids of albumin was 2.14 mg/L. Analysis of albumin in serum was performed by a photometric assay (Boehringer Manheim, Mannheim, Germany) and the reference intervals were 40-51 g/L (age < 50 years) and 37-48 g/L (age > 50 years). The concentration of phenol red was assessed, after alkalinization of the perfusate samples to pH 11, by a spectrophotometric method at 520 nm.

### Quantification of bFGF and VEGF

ELISA technique was used to measure bFGF (Human bFGF, Quantikine High Sensitivity, R&D Systems, Minneapolis, MN, USA) and VEGF (DVE00, R&D Systems, Minneapolis, MN, USA) as recommended by the manufacturer. The bFGF and VEGF concentrations in the samples were determined by comparing the optical density of the samples with the standard curve. The lowest detectable value for bFGF was 0.25 pg/mL and for VEGF 9 pg/mL in perfusion fluid. Reference intervals of S-bFGF were < 4.0 ng/L (males) and < 10.8 ng/L (females). The reference interval of S-VEGF was < 500 ng/L.

### Statistical analysis

The Wilcoxon signed rank test for two variables was used to compare the differences between wk 0, 1 and 4, while the statistical analysis of changes over time in the perfusate and serum concentrations of ECP, MPO, bFGF, VEGF and albumin, was done by Friedman's ANOVA. Spearman rank correlation test was applied to study co-variation between each mediator and the frequency of bowel movements per day. All statistical calculations were performed on a Macintosh computer by means of a statistical package, Stat View 4.51 (Abacus, Concepta Inc.). If concentrations of the mediator proteins and albumin were below the detection limit of the assay, the value of the detection limit was used in the calculations. $P < 0.05$ was considered significant.

## RESULTS

### Perfusions and clinical outcome

Out of 12 CC patients studied, 11 successfully completed steroid treatment and all three perfusions according to the protocol. The excluded patients stopped taking steroids because of side effects. The number of bowel movements per day declined from median 5 before start of treatment, to 0-1 after one and 0-1 after four weeks, respectively. These differences were significant ($P < 0.0001$) (Table 1). All patients reported that senses of general well-being were better after the start of steroid treatment, compared to the period before it.

### ECP, MPO and albumin

The concentrations of ECP, MPO and albumin in perfusates are shown in Table 1. The median values of ECP concentrations in perfusates were 2.3 μg/L (range: 1.9-6.5) at wk 0, 1.9 μg/L (range: 1.9-7.0) at wk 1 and 1.9 μg/L (range: 1.9-1.9) at wk 4, respectively. A significant

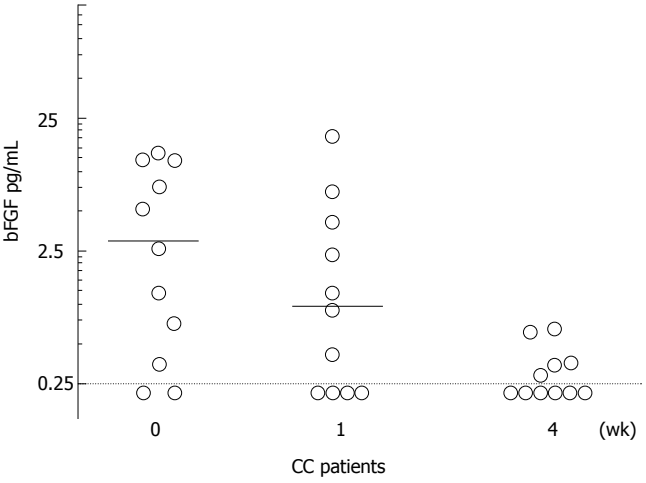

**Figure 1** The individual values of basic fibroblast growth factor (bFGF) concentrations in perfusion fluids from rectum of collagenous colitis (CC) patients before and after one and four weeks of steroid treatment. The bars indicate median values. The dotted line indicates the detection limit for the assay (bFGF: 0.25 pg/mL).

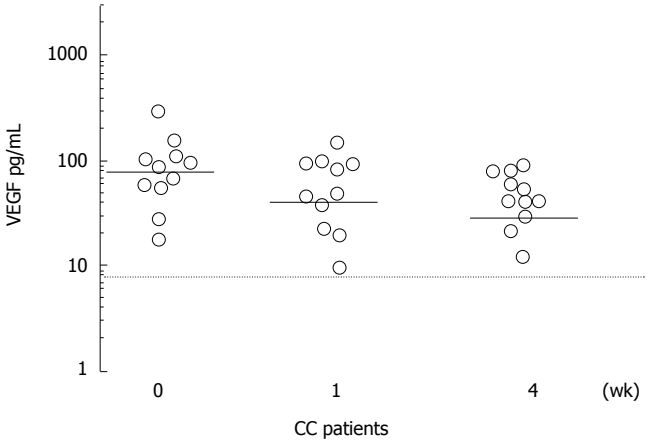

**Figure 2** The individual values of vascular endothelial growth factor (VEGF) concentrations in perfusion fluids from rectum of collagenous colitis (CC) patients before and after one and four weeks of steroid treatment. The bars indicate median values. The dotted line indicates the detection limit for the assay (VEGF: 9 pg/mL).

difference was only found between wk 0 and 4 ($P$ = 0.0277). The corresponding values for ECP in serum at wks 0, 1 and 4 were 11.3 μg/L (range: 1.9-29), 6.6 μg/L (range: 1.9-18.8) and 6.3 μg/L (range: 1.9-18.9), respectively. The decrease between wk 0 and 1 and wk 0 and 4 were significant ($P$ = 0.0076, $P$ = 0.045 respectively), while no difference was found when the decline of ECP concentrations in perfusate and serum over time was analyzed by the Friedman's ANOVA.

Perfusate concentrations of MPO were above the detection level in three out of 11 patients at wk 0, one at wk 1 and none at wk 4 (Table 1). Serum MPO concentrations were 432 μg/L (range: 197-649), 325 μg/L (range: 106-1805), 490 μg/L (range: 144-1190) at wk 0, 1 and 4, respectively. No difference was found between the concentrations during the study period.

The median values of albumin concentrations in perfusates were 20.3 mg/L (range: 2.7-116), 10.7 mg/L (range: 2.13-57.7) and 3.4 mg/L (range: 2.13-17.5) at wk 0, 1 and 4, respectively. The difference was significant only between wk 0 and 4 ($P$ = 0.0329). The decline in albumin concentrations over time was not significant. The corresponding median values of serum albumin at wk 0, 1 and 4 were 42 g/L (range: 38-45), 43 g/L (range: 34-48) and 42 g/L (range: 36-46), respectively ($P$ > 0.05). No correlation was found between the concentrations of ECP and albumin in perfusion fluids.

### *Analysis of bFGF*

The concentrations of bFGF in perfusion fluid are presented in Table 1. The median values of bFGF concentrations in perfusion fluid were at wk 0, 1 and 4, were 2.7 pg/mL (range: 0.2-14.0), 0.9 pg/mL (range: 0.2-18.3) and 0.2 pg/mL (range: 0.2-0.7), respectively. The decline of bFGF perfusate concentrations over time was significant when analyzed by the Friedman's ANOVA ($P$ < 0.01) (Figure 1). A correlation ($P$ < 0.05, $r$ = 0.702) that existed between bFGF and ECP perfusate concentrations at wk 0 disappeared at wk 1 and 4. A correlation between bFGF and albumin in perfusates remained significant throughout the study period ($P$ < 0.05 and $r$ = 0.709, $r$ = 0.805, $r$ = - 0.670 at wk 0, 1 and 4 respectively). The median values of bFGF concentrations in serum were 9.1 ng/L (range: 1.7-44), 2.9 ng/L (range: 0.9-17.6) and 3.6 ng/L (range: 0.3-20.9) at wk 0, 1 and 4, respectively, but the decline over time was not significant.

### *Analysis of VEGF*

Table 1 shows all the individual concentrations of VEGF in perfusion fluid. The median values of VEGF concentrations in perfusates of these individuals at wk 0, 1 and 4 were 86.1 pg/mL (range: 17.6-299.7), 48.2 pg/mL (range: 9.6-146.7), and 41.0 pg/mL (range: 12.3-90.3), respectively. When the Friedman's ANOVA was used to analyze the decline of VEGF concentrations, a significant difference ($P$ < 0.01) was seen (Figure 2). Furthermore, there was a significant correlation between VEGF and ECP at wk 0 and 1 ($P$ < 0.05; $r$ = 0.627 and 0.625 at wk 0 and 1 respectively) but not at wk 4. The correlation between VEGF and albumin in perfusate was significant only at wk 1 ($P$ < 0.05; $r$ = 0.666). Similar significant correlations were present between VEGF and bFGF concentrations at wk 0 and 1 ($P$ < 0.01; $r$ = 0.680 and $P$ < 0.05; $r$ = 0.850) but not at wk 4. The median values of VEGF serum concentrations at wk 0, 1 and 4 were 842 ng/L (range: 622-1517), 775 ng/L (range: 385-1215) and 811 ng/L (range: 574-1114), respectively. The decline in serum concentration of VEGF between wk 0 and 4 was significant ($P$ < 0.05) but the over time change was not significant.

## DISCUSSION

The immediate decrease in frequency of bowel movements and the improvement of the general well-being of these patients under steroid medication were similar to previous reports in IBD, including CC[25,26]. After four

weeks of treatment with the oral steroid prednisolone, the concentrations of ECP, bFGF, and VEGF in rectal perfusion fluids were reduced significantly. There were correlations between ECP, bFGF, VEGF and albumin concentrations initially, but these correlations disappeared at wk 4.

Local infiltration of the colonic mucosa by inflammatory cells is one of the histopathological characteristics of CC, and its composition includes eosinophils. The activation of eosinophils is supported by perfusion studies on UC and CC patients, where significantly increased ECP concentrations were found in these patients compared to controls[23,27,28]. Other studies have confirmed that eosinophils are activated and participate in the inflammatory process of CC[29,30]. The pro-inflammatory and profibrotic actions of eosinophils can be down-regulated by different medications including glucocorticoids[19-21]. In the present study, six, one and none out of 11 patients had ECP concentrations above the detections level at wk 0, 1 and 4, respectively. This decrease of ECP perfusate concentrations, according to Wilcoxon signed rank test between wk 1 and 4, suggests that glucocorticoids significantly reduce the secretion of ECP in the colonic mucosa of CC patients. The absence of significant difference when the over time changes in ECP concentrations according to Friedman's ANOVA did not contradict the finding because ECP median values were equal at wk 1 and 4. This happened because all the perfusate ECP values at wk 1 and 4 were below the detection level, with the exception of one case at wk 1. The anti-inflammatory actions of corticosteroids are numerous, including enhancement of eosinophilic apoptosis, increase of tissue eosinophilic clearance, deactivation of eosinophils and diminished recruitment of eosinophils as mentioned above[19-21]. The reduced perfusate concentrations of ECP found in this study, suggests that corticosteroids diminish the mucosal availability of ECP in CC. Corticosteroid treatment reduces the number of eosinophils in the colonic mucosa of CC, as shown in a small previous study[31]. Furthermore, our observations in CC resemble airway eosinophilia in asthma, which is quickly reduced by steroid treatment[32,33]. In a similarly designed therapeutic intervention study on ulcerative proctitis, the local release of ECP, EPO and MPO dropped significantly under steroid medication[34]. Contrary to CC, the numbers of neutrophils in the inflammatory infiltrate of UC is very high and this is well reflected by the high MPO concentrations found in the perfusion fluids of UC patients[35,36]. The similarity in design and the difference in results between these studies suggest that the role of neutrophils in the pathogenesis of CC is probably of little importance, except in cases where acute exacerbation of the disease cannot be excluded[37].

The bFGF concentrations in the rectal perfusates decreased 3 times from wk 0 to 1 and 11 times from wk 0 to 4. The significant downfall of intraluminal bFGF concentrations and the disappearance of the correlation between bFGF and ECP, imply that steroids markedly decrease mucosal bFGF secretion. Based on our previous findings[16] that local bFGF secretion is increased in CC patients, we suggested that bFGF enhances collagen synthesis in CC by stimulating pericryptal myofibroblasts. Furthermore, *in vitro* experiments showed that bFGF stimulated fibroblasts/myofibroblasts, collected from IBD patients, to produce more collagen, compared to corresponding cells from controls[12]. These observations and the findings in the present study suggest pericryptal myofibroblasts are synthetically active in CC[38,39], are de-activated by corticosteroids and this may be the reason behind the diminished collagen layer observed in corticosteroid-treated CC[30]and asthma patients[31]. The presence of correlations between bFGF and ECP perfusate concentrations in this study, suggests that bFGF, separately or in relation with other proteins, perpetuates chronic inflammation and triggers tissue remodeling in CC.

VEGF concentrations in the perfusion fluid were halved at wk 4 after the start of steroid treatment in CC patients. The amount of VEGF concentrations decreased significantly, as was the case for ECP, bFGF and albumin. Correlations existed between VEGF and ECP, bFGF and albumin. The correlation between VEGF and ECP disappeared at the end of this study, indicating a down-regulating effect of corticosteroids on eosinophils. VEGF and ECP are produced by eosinophils[7,29] and less activated eosinophils entail reduction of released cytokines. There is evidence that the synergetic relationship between VEGF and bFGF depends on the bFGF property to upregulate the expression of VEGF receptors (flt-1 and KDR)[40]. The correlations found between these mediators in this study may have reflected this synergism. The reduction of VEGF secretion may not only depend on steroids and de-activation of eosinophils, but also on deactivation of other VEGF producing cells, such as fibroblasts and other mesenchymal cells. This is in line with previous studies[24], which concluded that VEGF participates not only in the inflammatory process of UC and Crohn´s disease[15,41,42], but also in CC.

The clinical improvement during corticosteroid medication occurred simultaneously with a reduction in mediator concentrations, but no statistically significant correlation was found in relation to the decline in frequency of bowel movements (data not shown). In the present study, the patients themselves were the controls because the first perfusion (control) took place before starting steroid treatment.

The luminal release of albumin decreased, as in the case of ECP, significantly from wk 0 to 4 while the corresponding changes over time analyzed by the Friedman's ANOVA, did not show any significant difference. This may be due to the small number of patients included in this study. This finding, together with the correlation of VEGF and albumin, supports the hypothesis that VEGF enhances mucosal permeability in CC as previously suggested[24]. The disappearance of this correlation at wk 4 suggests that corticosteroids normalize permeability in CC. The correlation between bFGF and albumin indicates that bFGF might play a role in the increased colonic permeability. The appearance of a negative correlation at wk 4 is most probably caused by the numbers of bFGF values under detection level which have the same value, increased between wk 0 and

4 from two to six (Figure 1). Because the bFGF values under the detection levels are in the majority, the relevance of this correlation is questionable. The VEGF and ECP serum concentrations declined after introduction of corticosteroid treatment according to the Wilcoxon signed rank test but not according to Friedman's ANOVA. This may reflect a corticosteroid effect on blood eosinophils, as we did not find any difference in previous studies between the serum concentration of VEGF and ECP in CC patients, compared with controls[23,24]. This finding once again stresses the relevance of methods such as perfusion technique in studying predominantly locally restricted mucosal inflammatory processes, especially in CC.

In summary, our study confirms that the secretion of ECP, bFGF and VEGF is increased in CC and we suggest that corticosteroids relieve symptoms by decreasing the availability, release and functions of these inflammatory mediators in colonic mucosa of CC patients.

## Abstract

**AIM:** To identify the most common hepatitis B virus (HBV) genotype in Saudi Arabia, and correlate the prevailing genotypes with the clinical outcome of patients.

**METHODS:** Patients were consecutively recruited from the hepatology clinics of two tertiary care referral centers. Patients were categorized into 4 different groups: group 1, patients with hepatitis B and normal liver enzymes; group 2, patients with hepatitis B and abnormal liver enzymes but without cirrhosis; group 3, patients with hepatitis B and liver cirrhosis; group 4, patients with hepatitis B and hepatocellular carcinoma. All patients had a positive hepatitis B surface antigen (HBsAg). Genotyping of HBV was performed by nested PCR-mediated amplification of the target sequence and hybridization with sequence-specific oligonucleotides.

**RESULTS:** Seventy patients were enrolled in this study. They were predominantly male (72.9%) in their mid-forty's (mean age 47 years). Forty-nine (70%) patients were hepatitis B envelope antigen (HBeAg) negative. The majority of patients (64%) acquired HBV through unknown risk factors. Hepatitis B genotyping revealed that 57 patients (81.4%) were genotype D, 1 patient (1.4%) had genotype A, 1 patient (1.4%) had genotype C, and 4 patients (5.7%) had genotype E, while 7 patients (10%) had mixed genotype (4 patients ADG, 1 patient DE, 1 patient DF, and 1 patient ADFG). Based on univariate analysis of genotype D patients, significant predictors of advanced liver disease were age, gender, aspartate transaminase, alanine transaminase, albumin, bilirubin, and alkaline phosphatase (all $P < 0.001$). In multivariate analysis decreased hemoglobin ($r = -0.05$; 95% CI: -0.08 to -0.03; $P = 0.001$) and albumin levels ($r = -0.004$; 95% CI: -0.007 to -0.001; $P = 0.002$) were highly significant predictors of advanced liver disease. In patients with HBV genotype D, HBeAg negativity was found to increase across advancing stages of liver disease ($P = 0.024$).

**CONCLUSION:** This study highlights that the vast majority of Saudi patients with chronic hepatitis B have genotype D. No correlation could be observed between the different genotypes and epidemiological or clinical factors. The relationship between genotype D and HBeAg status in terms of disease severity needs to be further elucidated in larger longitudinal studies.

**Key words:** Hepatitis B virus; Genotype D; Cirrhosis; Hepatocellular carcinoma; Saudi Arabia

## INTRODUCTION

Hepatitis B virus (HBV) infection is a global health problem with over 350 million chronic carriers of the virus with the risk of developing chronic hepatitis, cirrhosis or hepatocellular carcinoma (HCC). HBV is a circular, partially double-stranded DNA virus of approximately 3200 nucleotides. This highly compact genome contains four open reading frames encoding the envelope (PreS1, PreS2, S), core (core, precore), polymerase, and X proteins[1]. HBV genotypes represent naturally occurring strains of HBV that have evolved over the years and reflect the geographical distribution of HBV throughout the world. Up to now, eight different HBV genotypes have been identified and shown to cluster in different areas of the world[2,3]. They display an 8% inter-group divergence in the complete nucleotide sequence of HBV and differences

in the nucleotide homology of the surface gene, which result in different hepatitis B surface antigen (HBsAg) serotypes[4-6].

Genotype A is mainly found in Northwestern Europe, North America and Africa[7], whereas genotypes B and C have been described in South-Eastern Asian populations[8,9]. Genotype E and F are seen in East Africa and the New World, respectively. Genotype D is most often found in southern Europe, parts of Central Asia, India, Africa and the Middle East. Genotype G is a recently determined genotype in France, America, and Germany while genotype H has been reported in patients from Central America[10,11].

Recently, a number of publications have examined the impact of HBV genotype on disease pathogenesis and the clinical outcomes in patients with chronic hepatitis B. Most of these natural history studies, in view of the bimodal distribution of HBV genotypes in Asia and Western countries, have compared either genotypes B and C[11,12], or genotypes A and D[13]. The clinical impact of HBV genotypes when studied in Indian patients with a mixed population of both genotypes A and D, has shown that genotype D has a higher likelihood of developing advanced cirrhosis compared to genotype A[13].

Chronic hepatitis B is an important medical problem in Saudi Arabia although, with the implementation of HBV vaccination of children, the prevalence has dramatically reduced from 6.7% in 1989 to 0.3% in 1997[14,15]. However, little is known about the prevalence and distribution of HBV genotypes in Saudi Arabia. Furthermore, the association between the distinct genotypes and the severity of liver disease in the country remains unreported. The epidemiological studies of HBV genotypes arising from the Middle-Eastern region suggest that genotype D is perhaps the most common[16-20]. Accordingly, the objectives of our study were to identify the most common HBV genotype in Saudi Arabia, and to elucidate the relationship between the prevailing genotypes with the clinical outcome of patients.

## MATERIALS AND METHODS

### Enrollment of study cohort

Patients were recruited prospectively from two tertiary-care hepatology clinics at King Khalid University Hospital and the Riyadh Military Hospital in Riyadh, Saudi Arabia. These medical centers serve as referral centers for population groups resident in different geographical regions of the country. The Medical Ethics Committee in both centers approved the study protocol and all patients signed an informed medical consent indicating agreement to participate in this study. Results of all abnormal tests were provided to patients or their immediate relatives, as was deemed appropriate.

Between May 2004 to December 2005, 70 consecutive adult HBsAg positive patients were recruited at the two centers. Patients were interviewed in person by participating investigators (AAA, FMS, NA, KS) at recruitment by using a structured questionnaire. Information on socio-demographic characteristics, alcohol consumption, personal medical and surgical history, time of disease diagnosis, area of birth and upbringing, and family history of liver disease or cancers was collected. Patients who were HBsAg positive for a period exceeding 6 mo and who had not received any antiviral therapy for HBV in the preceding 6 mo were included in the study.

### Serological evaluation

HBV markers [HBsAg and antibody to HBsAg (HBsAb)] were measured using standard commercial assays. In addition, further serological testing for hepatitis B envelope antigen (HBeAg) and anti-HBe antibody was also performed using the same commercial kits. HBV DNA was determined by a sensitive PCR based assay (COBAS Amplicor; Roche Diagnostics) with a lower limit of detection of approximately 200 copies/mL.

### Virologic testing

Genotypic testing was performed in only those with a detectable HBV DNA (qualitative) in serum. HBV genotyping was determined from serum samples by performing nested PCR-mediated amplification of the target sequence and hybridization with sequence-specific oligonucleotides at Bioscientia Laboratory in Germany.

### Study design

The patients were recruited into four groups: group 1, patients with hepatitis B and normal liver enzymes; group 2, patients with hepatitis B and abnormal liver enzymes and no laboratory or radiological features of cirrhosis; group 3, patients with liver cirrhosis secondary to hepatitis B; and group 4, patients with hepatitis B and HCC. General exclusion criteria included: (1) anti-HCV antibody positive; (2) identifiable other causes of chronic liver disease defined as (high serum iron and ferritin, abnormal serum ceruloplasmin, history of significant alcohol consumption, antinuclear antibody > 1:320, antismooth muscle antibody > 1:320, antimitochondrial antibody > 1:40); (3) history of hepatotoxic medications in the preceding three months of presentation; (4) history of antiviral therapy in the last 6 mo.

Group specific inclusion criteria for group 1 (HBV with normal liver enzymes) were: (1) persistently normal alanine transaminase (ALT) and aspartate transaminase (AST) (normal ALT and AST on at least two occasions separated by at least 3 mo), (2) normal serum bilirubin, albumin and International Normalized Ratio (INR), (3) normal complete blood count (CBC), (4) normal abdominal ultrasound (US) without features of liver cirrhosis or portal hypertension. Inclusion criteria for group 2 (HBV with abnormal liver enzymes) included: (1) persistently elevated ALT and AST (more than two times the upper limit of normal on at least two occasions separated by at least 3 mo), (2) normal CBC, (3) normal US without features of cirrhosis or portal hypertension. Patients were excluded from groups A and B if there was any abnormality in the CBC or any signs of cirrhosis or portal hypertension on abdominal US. Inclusion criteria for group 3 (HBV with liver cirrhosis) included: Any four of the following features of cirrhosis (1) platelet count < $100 \times 10^9$/L, (2) evidence of esophageal varices on endoscopy, (3) ultrasonographic features consistent with cirrhosis, (4)

albumin level less than 30 g/L, (5) INR more than 1.4 and (6) bilirubin level more than 30 μmol/L. Patients were also included in this group if there was histological evidence of liver cirrhosis regardless of the above criteria. Inclusion criteria in group 4 (HBV with HCC) included: Evidence of HCC defined as two of the followings: (1) α-fetoprotein > 400 ng/L, (2) liver mass detected by triphasic computed tomography (CT) or magnetic resonance imaging (MRI) of the abdomen, (3) fine needle aspiration (FNA) or liver biopsy showing HCC.

### Ascertainment of cirrhosis and hepatocellular carcinoma

All participants had screening abdominal ultrasonography (US) at the time of recruitment into the study. The US was performed and interpreted by trained radiographers according to a standardized protocol, and the records reviewed by the investigators. Cirrhosis was diagnosed ultrasonographically based on the appearance of the liver surface, liver parenchymal texture, portal vein size, splenic size, presence of ascites and varicose veins in the portal and perisplenic area.

All patients with an α-fetoprotein > 400 ng/L (or a persistently rising α-fetoprotein) or with high clinical suspicion of HCC underwent a CT and/or MRI of the liver. The diagnosis of HCC was based upon the two published European guidelines towards the diagnosis and management of HCC[21,22]. Enhancement of a liver lesion during the arterial phase and contrast washout during the portal phase, in patients with background cirrhosis secondary to HBV was considered diagnostic of HCC. FNA or liver biopsy was obtained only where considerable doubt existed towards HCC diagnosis.

### Statistical analysis

Descriptive statistics are summarized as mean ± SD. For continuous variables, ANOVA was used for comparison of the four groups. Fisher's exact or chi-square test was used for categorical variables. Univariate analysis was performed to identify important baseline characteristics associated with genotype D. Variables examined included age, gender, White blood cells, hemoglobin, platelet count, HBeAg status, albumin, ALT, AST and bilirubin. A multivariate logistic regression model was developed using forward model to assess the effect of baseline variables on disease advancement. All tests were two sided with a 5% level of significance. All analyses were performed using STATS 9.1.

## RESULTS

Seventy patients were enrolled in the period from May 2004 to Dec 2005. Mean age of the patients was 47 years, and 51 patients (72.9%) were male while 19 (27.1%) were female. All geographical regions of the Kingdom were represented, with 51.5% from the central region where the vast majority of the Saudi population reside and also where the study was conducted; 21.4% from the southern region, 8.5% from the eastern region, 13% from the western region and 5.6% from the northern region, vastly representing the population distribution across the country. There were 17 patients included in group 1, 22 patients in group 2, 19 patients in group 3, and 12 patients in group 4. The majority (45 of 70 patients, 64%) had acquired HBV through unknown risk factors, while 11 patients (15.7%) reported blood transfusion, 7 (10%) reported a prior history of surgery or dental procedures and 4 (5.7%) reported a family history of HBV infection.

**Table 1 Biochemical, hematological and virological parameters of all enrolled patients distributed across the four groups**

| Parameter (mean value) | Group 1 (*n* = 17) | Group 2 (*n* = 22) | Group 3 (*n* = 19) | Group 4 (*n* = 12) | *P* |
|---|---|---|---|---|---|
| ALT (U/L) | 41.88 | 177.7 | 52 | 96 | 0.001 |
| AST (U/L) | 22 | 80 | 55.3 | 150 | 0.001 |
| ALP (U/L) | 100 | 111 | 116.4 | 238.8 | 0.001 |
| INR | 1.3 | 1.1 | 1.4 | 1.2 | 0.003 |
| Bilirubin (μmol/L) | 10 | 13.8 | 40.4 | 30 | 0.001 |
| Albumin (g/L) | 40 | 37.6 | 28.9 | 25.4 | 0.005 |
| WBC ($10^9$/L) | 7.1 | 6.1 | 4.9 | 7.2 | 0.160 |
| Hemoglobin (g/L) | 125 | 129.6 | 118.4 | 62 | 0.740 |
| Platelets ($10^9$/L) | 253 | 202 | 121.3 | 213 | 0.230 |
| HBV DNA level | | | | | |
| < 200 copies/mL | 5 | 2 | 3 | 1 | NS |
| 200-$10^5$ copies/mL | 10 | 8 | 8 | 8 | NS |
| > $10^5$ copies/mL | 2 | 12 | 8 | 3 | NS |

ALT: Alanine transaminase; AST: Aspartate transaminase; ALP: Alkaline phosphatase; GGT: Gamma glutamyl transpeptidase; WBC: White blood cells.

Most patients (52 of 70 patients, 74%) did not express HBeAg including 65% (11 of 17 patients) in group 1, 55% (12 of 22 patients) in group 2, 95% (18 of 19 patients) in group 3, and 92% (11 of 12 patients) in group 4. Amongst the patients who were HBeAg positive, only two patients (11.1%) had cirrhosis or HCC. The vast majority of HBeAg positive patients were either carriers with normal ALT (6 of 18 patients, 33.3%), or raised ALT (10 of 18 patients, 55.6%). One patient expressed HBeAg as well as anti-HBe. Two patients were negative for both markers. In group 1, 15 patients (88.2%) had HBV DNA < $10^5$ copies/mL and were also HBeAg negative. Two patients (11.8%) had HBV DNA > $10^5$ copies/mL and were also HBeAg positive. In group 2, 9 patients (41%) had an HBV DNA < $10^5$ copies/mL and were all HBeAg negative. In group 3, 11 patients (58%) had an HBV DNA of < $10^5$ copies/mL and all were also HBeAg negative. In group 4, 9 patients (75%) had an HBV DNA of < $10^5$ copies/mL and all were also HBeAg negative. Although the proportion of patients with a high viral load (> $10^5$ copies/mL) was greater in groups 2 and 3, this did not reach statistical significance (Table 1).

Table 2 shows the genotyping results according to the clinical status of the studied patients. The majority of the patients were genotype D (57 of 70 patients; 81.4%), with 58.8% (10 of 17 patients) in group 1, 95.5% (21 of 22 patients) in group 2, 84.2% (16 of 19 patients) in group 3, and 83.3% (10 of 12 patients) in group 4. One patient (1.4%) had genotype A, and one (1.4%) had genotype C. Four patients (5.7%) were genotype E, and 7 patients (10%) were mixed genotypes (4 patients ADG, 1 patient DE, 1 patient DF, 1 patient ADFG). There were no significant differences between groups in terms of

**Table 2 HBV genotype distribution across different stages of liver disease and in relation to HBeAg status in 70 patients**

| Study cohort (*n*) | HBV genotype % (*n*) | | | | |
|---|---|---|---|---|---|
| | D | E | A | C | Mixed |
| Group 1 (17) | 58.8 (10) | - | 5.9 (1) | - | 35.3 (6) |
| Group 2 (22) | 95.5 (21) | - | - | 4.5 (1) | - |
| Group 3 (19) | 84.2 (16) | 15.8 (3) | - | - | - |
| Group 4 (12) | 83.3 (10) | 8.3 (1) | - | - | 8.3 (1) |
| HBeAg + (18) | 88.9 (16) | - | 5.6 (1) | 5.6 (1) | - |
| HBeAg - (52) | 78.8 (41) | 7.7 (4) | - | - | 13.5 (7) |

genotypes. In addition, we found no difference between different genotypes in terms of patient age, gender, area of upbringing, liver enzyme level, or serum albumin level. HBeAg negative genotype D patients comprised 50%, 57%, 93.8% and 75% across groups 1, 2, 3, and 4 respectively ($P = 0.024$) (Table 3).

The baseline characteristics according to disease severity (groups 1 to 4) are listed in Table 1. Patients in group 4 (HCC) were more likely to have a higher level of alkaline phosphatase (ALP) than those in groups 1, 2 and 3 respectively, (238 *vs* 100, $P = 0.004$; 95% CI 45-230), (238 *vs* 111, $P = 0.003$; 95% CI 45-208), (238 *vs* 116, $P = 0.036$; 95% CI 6.8-201), and also a higher level of AST than those in groups 1, 2 and 3 respectively (150 *vs* 22, $P = 0.001$; 95% CI 52-203), (150 *vs* 80, $P = 0.06$; 95% CI 3-145), (150 *vs* 60, $P = 0.02$; 95% CI 13-65). Furthermore, group 4 (HCC) patients were more likely to have a significantly lower level of albumin. In addition, 83.3% (10 of 12) of the patients in group 4 were genotype D compared to 81.4% (57 of 70) of the recruited patients who expressed the same genotype ($P = 0.30$). However, there was no significant difference in WBC, hemoglobin, and platelet count between the four groups.

Table 3 depicts the patients with genotype D according to disease severity. Patients in group 4 were older (mean age 61.5 years), tended to have higher levels of ALT, AST, and bilirubin, and lower levels of albumin. These differences were significant between the groups (all $P = 0.001$). However, there was no significant difference between the four groups with respect to hemoglobin ($P = 0.70$), platelet count ($P = 0.11$) and WBC ($P = 0.10$). In view of the small sample size in each group we did not perform a head-to-head comparison between the groups.

In univariate analysis of genotype D patients, age, gender, AST, ALT, albumin, bilirubin, and ALP were significant predictors of advanced liver disease (all $P < 0.001$). However, in multivariate analysis decreased hemoglobin ($P = 0.001$) and albumin levels ($P = 0.002$) were highly significant predictors of advanced liver disease (Table 4).

**Table 3 Hepatitis B virus genotype D patients' biochemical, hematological and virological parameters distributed across the four groups (mean ± SD)**

| Parameter | Group 1 (*n* = 10) | Group 2 (*n* = 21) | Group 3 (*n* = 16) | Group 4 (*n* = 10) | *P* |
|---|---|---|---|---|---|
| Age (yr) | 45 ± 18 | 35 ± 9.9 | 52.1 ± 7.7 | 61 ± 12 | 0.015 |
| ALT (U/L) | 40.3 ± 8 | 176.9 ± 100.7 | 54.1 ± 30.4 | 99.3 ± 79.9 | 0.001 |

## DISCUSSION

Chronic hepatitis B is an important medical problem in Saudi Arabia. Al-Faleh *et al* in the late 1980's showed that up to 7% of Saudi children were positive for HBsAg[14]. After the introduction of universal vaccination of all Saudi children in 1989, the incidence of hepatitis B infection has declined to as low as 0.3%[15]. In spite of this dramatic decline, the burden of decompensated liver disease secondary to hepatitis B is expected to increase significantly in the next 40 years as the previously infected children start aging.

Hepatitis B genotyping has received immense attention recently and its clinical implications are being investigated extensively throughout the world. This study is the first to show that genotype D is the most prevalent genotype in Saudi Arabia. In this prospective study all regions of the country are represented as well as the entire spectrum of chronic HBV infection ranging from the carrier state to HCC. Our study concurs with reports from other parts of the Middle East like Egypt, Yemen, Turkey, Iran, and Tunisia[16-20], all showing that genotype D is the most common genotype in this region.

HBV genotypes may contribute in part to the wide variation in prevalence rates of HBV infection in different parts of the world through difference in rates of replication and ability to evade immune clearance. However, studies comparing the replication capacity and immune response of the various HBV genotypes have not been performed. Nevertheless, many studies have shown a strong relationship between HBV genotypes and mutations in the precore and core promoter regions that abolish or

diminish the production of HBeAg[23-26]. In our population which is predominantly HBeAg negative (presumably indicating pre-core or core promoter mutation), the majority of patients had genotype D thereby supporting the above observation.

Hepatitis B genotypes have been correlated with various epidemiological, virological, and clinical variables. It has been recently reported from China that patients with genotype B have a lower prevalence of HBeAg than those with genotype C[12]. Several other studies reported a correlation between HBV genotype and HBeAg clearance. Similarly in our study, we found a lower prevalence of HBeAg among our patients with genotype D (28%), suggesting that HBeAg clearance occurred at higher rates among patients with genotype D.

Correlation between the clinical outcomes of patients with HBV and their genotypes has also been reported. One study found that HBsAg carriers with genotype B had lower histological activity scores[23]. Three other studies involving a total of 939 Chinese patients with chronic HBV infection found that genotype C was more prevalent in patients with cirrhosis[27-29]. In our study, while 58.8% in group 1 (HBV with normal ALT) were genotype D, the number of patients with the same genotype across advancing stages of liver disease, in groups 2, 3, and 4 comprised 95.5%, 84.2%, 83.3% respectively ($P = 0.4$). These findings suggest that genotype D does not correlate with advancing liver disease. However, this could be related to the small sample size of the present study, and probably due to the predominance of genotype D in all clinical forms. Further analysis in large-scale longitudinal studies is required to better delineate this relationship.

In our patients with HBV genotype D, HBeAg negativity was found to increase significantly across more advancing stages of liver disease ($P = 0.024$). Previous studies have revealed that HBeAg positive genotype C[6] or genotype A[30] patients were more likely to have active liver disease. Progress of liver disease in relation to HBeAg status has not been reported as yet in the various studies dealing with genotype D[13,19,20]. Although this observation is significant, the association between HBeAg status and genotype D, in terms of severity of liver disease needs to be studied further before any additional conclusions can be derived.

Since predictors of advanced HBV liver disease were described before as a whole or in relation to individual genotypes other than in genotype D[31], our study describes for the first time these predictors in genotype D. Hemoglobin and albumin levels are independent predictors of advanced liver disease. Furthermore, group 4 patients (HCC) with genotype D showed significantly higher biochemical parameters (AST, ALT, and bilirubin) and lower albumin levels compared to early stage liver disease.

The relation between HBV genotype and HCC is inconclusive. One study found that genotype B was associated with hepatocellular carcinoma at an earlier age[28], but this finding was not confirmed by other studies[11,27,32]. Another study in Indian patients reported that genotype D was commonly found to be associated with HCC in patients < 40 years of age[13]. However, in our study, none of our HCC patients with genotype D (10 patients) were < 40 years of age (mean age 61 ± 12).

In Saudi Arabia HCC is the second most common cancer in men[33], and in a country where hepatitis B is endemic this could imply a correlation between the most prevalent genotype (D) and HCC. In our patients, 83.3% of the patients in group 4 (HCC) were genotype D compared to 81.4% of the overall number of recruited patients who expressed the same genotype. This figure did not reach statistical significance ($P = 0.30$). Moreover, since HBV is thought to be directly carcinogenic because of the integration of HBV DNA into the cellular DNA of the host[34], it may also explain the observed lack of correlation between genotype D and the development of HCC.

There were no significant differences between groups in terms of genotypes. This is likely secondary to the fact that the vast majority of patients had genotype D making comparisons with the other relatively rarer genotypes difficult. Along with the limitations imposed by the small sample size across the different groups, the study was also restricted by the absence of histology in groups 1 and 2, thereby possibly misallocating some of these patients into either more or less active groups.

In conclusion, genotype D is the most common genotype in Saudi Arabia. Because of the fact that the vast majority of the patients have genotype D, no correlation could be observed between different genotypes and epidemiological or clinical factors. A large-scale study is required to obtain further information on the role of genotype D and its impact on the progress of liver disease.

## Abstract

**AIM:** To determine whether hepatitis C virus (HCV) infection of index cases increases intrafamilial transmission (sexual and nonsexual contacts) of HCV.

**METHODS:** In a case-control descriptive study we enrolled 300-household contacts of 60 index cases (40 males and 20 females) of HCV infection and 360 pair-matched controls in Ahwaz JundiShapour University Hospitals from August 1, 1998 to September 1, 2003. The control group consisted of first time blood donors referred to the Regional Blood Transfusion Organization. Serum samples and demographic data and a medical history including the existence of risk factors for HCV (after a questionnaire on the risk factors for parenteral exposure) were obtained from each subject. Antibodies to HCV were detected employing a commercially available second-generation enzyme immunoassay (EIA, Abbott Ⅱ). Positive serum specimens were retested using a second-generation recombinant immunoblot assay (RIBA-2) and a polymerase chain reaction for HCV RNA. Data analysis was carried out for intra-household clustering.

**RESULTS:** Only 4 of 300 (1.33%) cases of household contacts without percutaneous risk factors were positive for HCV Ab while the remaining 296 family contacts were negative for anti-HCV. The mean age of the index cases was 28.4 (Std 15.22) years. The anti-HCV prevalences in parents, spouses, children of the index cases were 0.87% (1/115), 3.39% (2/59)) and 0.79% (1/126), respectively. Among couple partners negative for anti-HCV antibodies, the mean duration of the sexual relationship was 6 years. The two-couple partners positive for anti-HCV antibodies married the index cases for longer than 15 years. The prevalence of positive HCV Ab among household contacts (1.33%) was not significantly higher than that in the controls (1%) ($P > 0.06$).

**CONCLUSION:** Intrafamilial transmission of HCV is not the significant transmission route and sexual transmission does not seem to play a role in the intrafamilial spread of HCV infection. Intrafamilial transmission of HCV is possible but occurs at a low rate.

**Key words:** Intrafamilial transmission; Hepatitis C virus; Khuzestan; South-west of Iran

## INTRODUCTION

One of the most substantial problems in public health is hepatitis C virus (HCV) infection, which affects approximately 1%-5% of the world's population and occurs in all countries. Epidemiological information on HCV is essential for strategic prevention of chronic hepatitis, liver cirrhosis and cancer. The rate of HCV infection differs in particular countries. The prevalence in developed countries amounts to 0.2%-2.2%, while in developing countries it reaches 7%. In some regions or in risk groups the rate of occurrence may be as high as 30%-90%[1,4].

HCV infection is acquired mainly parenterally by transfusion of infected blood, rupture of the continuity of skin or mucous membrane, infected medical equipment despite strict hygienic control, intravenous drug abuse, hemodialysis or organ transplantation. HCV infection is an important cause of post-transfusion hepatitis. Transmission through sexual contacts has been implicated, although this may be a rather inefficient mode of transmission[2,3]. HCV has also been detected in persons in whom no clear risk factor has been defined, and these cases constitute about 40%-45% of HCV infections[4]. According to

**Table 1 Demographic and clinical information on HCV-infected household members**

| Household members | *n* | Age (yr)/sex | Medical history | Clinical liver disease | Transfusion | HCV RNA |
|---|---|---|---|---|---|---|
| Nonsexual household contact (Mother) | 1 | 58/F | None | No | No | Negative |
| Sexual partners of index case | 1 | 43/F | None | No | No | Positive |
| Wife | 1 | 38/F | None | No | | Negative |
| Nonsexual household contact (Daughter) | 1 | 23/F | None | No | No | Positive |

the published data, the prevalence of HCV infection in Iran is 0.59%-0.8%[5]. Mother-to-infant transmission has also been demonstrated[6] but the possibility of other transmission routes has not been thoroughly explored. With the use of RT-PCR or bDNA techniques, HCVRNA has been detected in many systemic fluids other than in blood, including peritoneal effusion, seminal and vaginal secretion, urine, feces and typhoid secretion. At least 20% of hepatitis C patients develop cirrhosis with the associated risk of developing hepatocellular carcinoma (HCC)[7]. Despite primary hepatotropism, HCV can affect tissues and organs such as kidneys, thyroid, salivary glands, eyes, or the hematopoietic and lymphatic systems other than the liver[8]. HCV infection seems to be connected with several autoimmune diseases[9].

To our knowledge little information is available about HCV infection due to contacts of patients infected with HCV in southern Iran: Khuzestan. Because HCV may be transmitted by the non-parenteral routes such as sexual and non-sexual household contacts, this study was undertaken to investigate whether intrafamilial transmission occurs *via* the usual contacts between patients and their household members who are unaware of the potential infectious state of the patients, to determine the prevalence of antibody to HCV in the contacts of HCV positive cases (index patients) and to evaluate the potential risk factors associated with intrafamilial transmission of HCV.

## MATERIALS AND METHODS

### Subjects

During a 5-year period in a case-control descriptive study we enrolled 300 household contacts of 60 index cases (40 males and 20 females) of HCV infection and 360 pair-matched controls in Ahwaz JundiShapour University Hospitals from August 1, 1998 to September 1, 2003. The control group consisted of first time blood donors referred to the Regional Blood Transfusion Organization.

### Methods

Serum samples and demographic data and a medical history including the existence of risk factors for HCV (after a questionnaire on the risk factors for parenteral exposure) were obtained from each subject. The questionnaire consisted of questions regarding demographic variables, household behaviors and extra-familial factors including various potential parenteral exposures to blood or blood products (such as past hospital admission, operation, injuries needing hospital interventions, blood or blood product transfusion), history of parenteral injections and intravenous drips, travel history outside Iran, as well as dental treatment, tattooing and ear piercing. All these factors are known to be associated with HCV infection. All index cases and household contacts and controls answered the questionnaire and had their blood tested for anti-HCV. Antibodies to HCV were detected employing a commercially available second-generation enzyme immunoassay (EIA, Abbott Ⅱ). PCR for HCVRNA and a second-generation recombinant immunoblot assay (RIBA-2) were performed in all index cases and positive serum specimens were obtained from each subject. The Amplicor HCV RNA assay was used to detect HCV RNA in index case serum (Roche Diagnostic Systems). None of our cases (household contacts and index cases) revealed any signs of HBV infection (MEIA, Abbott IMX) or any other causes of acute or chronic liver diseases such as HAV, EBV and CMV infections, autoimmune diseases, alcohol and drug abuse, α1-antitrypsine deficiency, Wilson' s disease, or hemochromatosis. All these index cases were still receiving follow-up at the time of our study.

### Statistical analysis

The data were analyzed statistically using SPSS, version 9. Comparison was made using the Student's *t* test and chi-square test. $P < 0.05$ was considered statistically significant.

## RESULTS

All the 60 index patients gave positive reactions in the second generation anti-HCV EIA. We assumed that most of them were chronically infected with HCV. A total of 300 household contacts of the index patients were subjected to the second generation anti-HCV EIA. Only 4 of 300 (1.33%) cases of household contacts without percutaneous risk factors were positive for HCV Ab while the remaining 296 family contacts were negative for anti-HCV. The mean age of the index cases was 28.4 (Std 15.22) years. The anti-HCV prevalences in parents, spouses, children of the index cases were 0.87% (1/115), 3.39% (2/59)), and 0.79% (1/126), respectively. Among the couple partners negative for anti-HCV antibodies, the mean duration of the sexual relationship was 6 years. The two-couple partners positive for anti-HCV antibodies married the index cases for longer than 15 years. PCR for HCVRNA and second-generation recombinant immunoblot assay (RIBA-2) were performed in household members of two cases, one wife and one daughter (Table 1). The prevalence of positive HCV Ab among household contacts (1.33%) was not significantly higher than that in the controls (1%) ($P > 0.06$).

## DISCUSSION

HCV infection, a world-wide spread liver disease, is most

often asymptomatic in adults. It leads to serious clinical consequences that often occur later. About 50%-70% of mild infections progress to chronic phase and long term observations of natural history of the disease have confirmed that HCV is the risk factor for cirrhosis and primary hepatic carcinoma. However, there is a paucity of data on risk behaviors associated with HCV transmission through household contacts. HCV may be transmitted by the parenteral and other routes similar to that of HIV and HBV. Studies on family members of patients with chronic B hepatitis indicate that this virus can be transmitted both by vertical from mothers positive for hepatitis B surface antigen (HBsAg) and hepatitis B e antigen (HBeAg) and by horizontal (sexual and non-sexual) routes. Spouses and siblings of HBsAg-positive subjects are frequently found to have a high prevalence of serological markers of current or past HBV infection[10,11]. But the epidemiological relevance of intrafamilial transmission of HCV has not been clearly established.

This study estimated (1.33%) HCV seroprevalence among the household contacts of HCV-seropositive index cases, which is lower than the finding of other studies reporting that HCV seroprevalence is 16% and 20% among contacts of HCV-seropositive index patients[12,13]. Our results differ from those in these studies reporting a higher rate of HCV infection in the family members of adult patients with chronic hepatitis C. This difference could be attributed to one or more of the following limitations in studies, i.e. a small-sized study, inadequate duration, intensity of potential contact with adult patients, low infectivity of HCV in blood, genotypes, and unknown sensitivity of the hepatitis C radioimmunoassay used for detecting HCV infection[14]. Although intrafamilial HCV transmission through nonsexual contacts has been recognized as a major route in the Saudi population and elsewhere, the mechanisms underlying such transmissions have not been elucited. Another study has reported an elevated prevalence of 5.7% among household contacts, compared with HCV seroprevalence of 0.5% in the general population[15-17]. There are conflicting data in the literature concerning the role of sexual contacts in the spread of HCV infection. The prevalence of positive anti-HCV in spouses is different and may be a consequence of many factors such as sexual behavior and duration of marriage[18,19].

In this study, we found that spouses of anti-HCV positive patients were more likely to be infected with HCV than other family members and the infection rate increased with duration of marriage. In agreement with other authors[20], we found that positive anti-HCV increased in spouses with their length of marriage. In particular, a significant difference was found in the prevalence of positive anti-HCV between spouses married for more than 15 years and those married for a shorter time. Homology analysis on HCV nucleotide sequence is important in the study of sexual transmission of HCV[21], but we did not perform homology analysis in our studied cases. It is not easy to explain the increased rate of HCV infection in couples married for a longer time. Other authors reported that there is no prevalence in two groups of sexual partners married respectively for 13 and 15 years[3,22]. Marriage usually includes a sexual relationship, but also other kinds of body contact and exposure to the same risk factors (i.e. sharing the same personal tools such as toothbrushes, razors, dental appliances, *etc.*) as suggested by recent findings in Taiwan[20,23]. We did not perform genotyping in our studied cases but in Iran, genotype (1a) has been identified in the majority of chronic HCV patients[24]. HCV genotyping between the index cases and infected family contacts can clarify whether the infection is acquired in or out of the family setting. The HCV seroprevalence among the contacts of HCV-seropositive index patients is lower in our study than in populations elsewhere.

Our data suggest that sexual and nonsexual contacts with HCV-infected hemophilia patients within households are not associated with an increased risk for HCV infection. Further study is needed to assess the extent and the causes of nonparenteral transmission of HCV. Implementation of an education program based on the identified risk factors may reduce the spread of HCV in our area.

## ACKNOWLEDGMENTS

The authors thank the medical and nursing staff of Emam and Golestan Hospitals for their help in the conduct of this study and the faculty of Medicine of Joundishapoor University for its encouragement and support. The authors also thank all those who volunteered for this study and Mrs Shahnaz Shahid zadeh for her excellent assistance.

## Abstract

**AIM:** To elucidate the different serological reactions to *H pylori* using the immunoblotting technique for further understanding of its pathogenic role in gastric cancer.

**METHODS:** A total of 54 patients were divided into two groups after upper gastrointestinal endoscopy: normal control group (25 patients) and gastric cancer group (29 patients). Both groups were further divided into *H pylori* (+) and *H pylori* (-) subgroups based on the results of CLO test, Giemsa staining and culture. Sera were further analyzed with the immunoblotting technique (HelicoBlot 2.0, Genelabs Diagnostics, Singapore).

**RESULTS:** The positive rate of the immunoblotting test was as high as 88.9% in the *H pylori* (-) gastric cancer group and only 14.3% in the *H pylori* (-) normal control group with a statistically significant difference.

**CONCLUSION:** The prevalence of *H pylori* infection is higher in gastric cancer patients than in the normal controls, suggesting that *H pylori* may play a role in the pathogenesis of gastric cancer.

**Key words:** Western blot; Immunoblotting; Gastric cancer; *H pylori*; Enzyme-linked immunosorbent assay

## INTRODUCTION

*H pylori,* a Gram-negative bacterium, is now widely considered as one of the major etiologic factors in the pathogenesis of a great variety of gastrointestinal diseases such as gastritis, peptic ulcers and mucosa-associated lymphoid tissue lymphomas (MALTomas)[1]. There is increasing evidence that cancer of the stomach is also strongly associated with *H pylori* colonization[2-6]. Numerous antibodies against antigens of *H pylori* can be detected by serological analysis using the Western immunoblot technique[7-10]. Among these antibodies to *H pylori*, polypeptides with molecular masses of 116 kDa (against the cytotoxin-associated antigen, CagA), 89 kDa (against the vacuolating toxin antigen, VacA), 35 kDa, 30 kDa, 26.5 kDa and 19.5 kDa are considered as the most specific antibodies used in the diagnosis of *H pylori* infection and their corresponding antigens probably play a pathogenic role in the distinct gastrointestinal diseases. Particularly the antigens CagA and VacA not only seem to have a significant association with peptic ulcer disease but also increase the risk of developing gastric cancer[11-16]. The aim of this study was to elucidate the probable pathogenic role of *H pylori* in gastric cancer and serological stigmata of its remote infection as detected by the immunoblotting technique.

## MATERIALS AND METHODS

### Patients

Between March 1998 and May 2000, 54 consecutive patients (34 women, 20 men; age range: 20-70 years) who had epigastralgia and vague abdominal complaints but no remarkable past medical history of systemic diseases (such as generalized sepsis, uremia or hematologic malignancies) were recruited prospectively in this study. These patients visited the Outpatient Clinic or the Health Management Center of Shin Kong Wu Ho-Su Memorial Hospital for a routine health check-up. During upper GI endoscopy, specimens were taken from the antrum for rapid urease test, Giemsa stain and culture to elucidate the patient's *H pylori* status. When gastric malignancy was suspected, more specimens were taken from the lesion for histological examination. The patients were then divided into a normal control group ($n$ = 25) and a gastric cancer group ($n$ = 29) (Table 1). The normal control group and gastric cancer group were further divided into *H pylori* (+) and *H pylori* (-) subgroups. The *H pylori* (+) subgroup had positive results in at least two of the three tests, while the three tests were

Fisher's exact test was used to test for the different positive rate between CA-*H pylori* (-) and Normal-*H pylori* (-) group.

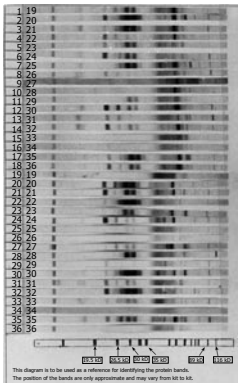

**Figure 1** Example of the immunoblotting reaction bands. A reaction sheet from a group of patients enrolled in the study.

all negative in the *H pylori* (-) subgroup. In the *H pylori* (-) normal subgroup there were 12 female and 2 male patients with a mean age of 34.6 years. In the *H pylori* (+) normal subgroup there were 7 female and 4 male patients with a mean age of 37.2 years. In the *H pylori* (-) cancer subgroup there were 9 female and 9 male patients with a mean age of 58.8 years. In the *H pylori* (+) cancer subgroup there were 6 female and 5 male patients with a mean age of 59 years. In the *H pylori* (-) cancer subgroup, tumors were found in the gastric antrum, angle, corpus and cardia of 6, 3, 5 and 4 patients, respectively. Meanwhile, in the *H pylori* (+) cancer subgroup, tumors were found in the antrum of 5 patients (2 of them had tumor involving antrum and angle), in the antrum and lower corpus of 2 patients, in the angle of one patient, in the corpus of 3 patients, and in the corpus as well as fundus and cardia of one patient. Histopathological studies demonstrated that all the suspicious malignant lesions were adenocarcinoma. In order to analyze the possible link between gastric cancer and remote *H pylori* infection, the sera from patients were analyzed with the immunoblotting technique (HelicoBlot 2.0, Genelabs Diagnostics, Singapore) (Figure 1). Five reaction bands could be recognized with the immunoblot technique: 116 kDa (CagA), 89 kDa (VacA), 35 kDa, 30 kDa, 26.5 kDa and 19.5 kDa. The immunoblotting was considered as positive with the detection of one reaction band of 116 kDa (CagA) and/or 89 kDa (VacA) and/or 35 kDa (major antigens), and/or two other reaction bands (minor antigens, 30 kDa, 26.5 kDa, 19.5 kDa), as recommended by the manufacturer. In addition, sera from the *H pylori* (-) cancer group of patients were further analyzed by enzyme-linked immunosorbent assay (ELISA, Immulite *H pylori* IgG, Diagnostic Products Corporation, Los Angeles, USA), and the two serological methods were compared. The collected data were finally analyzed with the Fisher's exact test.

## RESULTS

The seroprevalence of antibodies to 116 kDa (Cag-A) positive *H pylori* strain was high among the patients enrolled in this study: 100% in the normal *H pylori* (+) control group, 90.9% in the CA-*H pylori* (+) group, and also strikingly high in the CA-*H pylori* (-) group (72.2%). A quite similar finding was observed with the 35 kDa antigen (Table 1). The seroprevalence of antibodies to the third major antigen 89 kDa (VacA) was 44.4% in the normal *H pylori* (+) group, 60% in the CA-*H pylori* (+) group and 35.7% in the CA-*H pylori* (-) group. In the case of minor antigens, the seroprevalence of antibodies to the 30 kDa antigen was 100% in the normal *H pylori* (+) group, 81.8% in the CA-*H pylori* (+) group, and also remarkably high (58.8%) in the CA-*H pylori* (-) group. For the 26.5 kDa antigen, the seroprevalence of antibodies was 90.9% in the normal *H pylori* (+) group, 72.7% in the gastric cancer-*H pylori* (+) group, and 66.7% in the CA-*H pylori* (-) group. For the 19.5 kDa antigen, the seroprevalence of antibodies was 72.7% in the normal *H pylori* (+) group, and 40% in the gastric cancer-*H pylori* (+) group. When the reaction bands were equivocal (neither positive nor negative), they were considered undetermined with a prevalence of 2.2% in the 116 kDa antigen, 10.9% in the 89 kDa antigen, 2.2% in the 35 kDa antigen, 8.7% in the 30 kDa antigen, 3.6% in the 26.5 kDa antigen, and 5.8% in the 19.5 kDa antigen. These equivocal reaction bands might indicate that a low serum concentration of the corresponding antibodies was insufficient to yield a clear-cut reaction with their respective antigens. Analysis of the seroprevalence of antibodies to different antigens yielded the following overall positive rates for immunoblotting test: 100% in the normal *H pylori* (+) subgroup, 14.3% in the normal *H pylori* (-) subgroup, 100% in the gastric cancer-*H pylori* (+) subgroup and 88.9% in the gastric cancer-*H pylori* (-) subgroup, respectively. It should be pointed out that the positive rate for the immunoblotting technique was strikingly higher in the gastric cancer-*H pylori* (-) subgroup than in the normal *H pylori* (-) subgroup and there was a statistically significant difference achieved by Fisher's exact test ($P < 0.05$). This interesting finding denoted that the presence of *H pylori* as a remote infection in both *H pylori* (-) subgroups detected by immunoblotting assay was much more significant in the gastric cancer-*H pylori* (-) subgroup than in the normal *H pylori* (-) subgroup. This important issue might be overlooked if only rapid urease test, Giemsa staining and culture were performed. However, when ELISA was carried out to detect IgG to *H pylori* antigens using sera from these 18 gastric cancer-*H pylori* (-) patients, only 9 of them were positive (50% *vs* 88.9%). Since *H pylori* might not be closely implicated in the development of tumors in the cardiac region, if the four *H pylori* (-)

cancer patients with their tumor localized in the cardia were excluded from statistical analysis, the overall result was identically significant (Table 2).

## DISCUSSION

The role of different *H pylori* antigens in gastrointestinal diseases still remains controversial. In contrast to Western developed countries, different reaction bands in immunoblot assay fail to predict a particular disease in Taiwanese patients[17-21]. Two *H pylori* proteins, VacA and CagA, are virulence factors which may enhance gastric mucosal damage and promote the development of peptic ulcers and gastric mucosa atrophy. By identifying different *H pylori* proteins, immunoblot assay can screen patients at high risk of developing gastrointestinal diseases, such as peptic ulcer and gastric cancer. However, the high seroprevalence of antibodies to CagA-positive *H pylori* strains in Taiwanese patients with various gastrointestinal diseases has rendered the CagA-positive phenotype, an unusable marker for screening patients with a determined disease and immunoblot assay has no predictive and diagnostic value in Taiwanese patients. ELISA may reveal a significant decrease in IgG antibody titers approximately two months after treatment with antimicrobials. In contrast, immunoblot assay may detect IgG antibodies to specific antigens such as CagA and VacA several years after treatment[22-24]. These findings suggest that ELISA is a useful quantitative tool for monitoring eradication of *H pylori* while immunoblot assay is a qualitative method able to demonstrate remote *H pylori* infections which are not detectable by ELISA. The sensitivity and specificity of ELISA may decrease with the decrease in IgG titers. The immunoblotting technique might be recommended as a confirmative test for antibodies detected by ELISA[25,26]. Furthermore, although a high accuracy has been reported in Western countries, commercial ELISA might be unsatisfactory in Asians[27]. Therefore, immunoblot assay may be regarded as a sensitive, non-invasive means for the diagnosis of *H pylori* infection. However, major serological cross-reactions with *Campylobacter jejuni* and bacterial lipopolysaccharide have been found, which might explain the false positive results, while decrease in concentration of antibodies might yield equivocal reaction bands. It is known that *H pylori* colonization causes chronic active inflammation of gastric mucosa which eventually leads to the development of atrophic gastritis, intestinal metaplasia and dysplasia. Eighty-nine percent of *H pylori* (-) patients with gastric adenocarcinoma were proven to have a *positive* immunoblot assay in this study, indicating that these patients might have been infected with *H pylori* in a certain past period of their lifetime. This interesting finding suggests that *H pylori* can be detected in hostile gastric environments such as mucosa atrophy, but its hidden remote infection is still demonstrated in serum by immunoblot assay[28]. Therefore, the role of *H pylori* in the pathogenesis of gastric cancer should be stressed. Further studies are necessary to elucidate the possible link between *H pylori* infection and mechanisms of carcinogenesis.

In conclusion, 88.9% of patients with gastric cancer in *H pylori* (-) subgroup have a positive immunoblot assay for *H pylori* infection. Immunoblot assay can disclose remote *H pylori* infection which might be overlooked if only rapid urease test, Giemsa staining and culture, or ELISA for IgG antibody, is performed.

**Table 2 Positive rate (%) of the different reaction bands in the two groups of patients**

| | Normal | | CA | | |
|---|---|---|---|---|---|
| | *H pylori* (+) | *H pylori* (-) | *H pylori* (+) | *H pylori* (-) | |
| *n* | 11 (%) | 14 (%) | 11 (%) | 14 (%) | *P* |
| Overall | 100.0 | 14.3 | 100.0 | 92.9 | < 0.0001 |
| 116 kDa | 100.0 | 14.3 | 90.9 | 71.4 | 0.006 |
| 89 kDa | 44.4 | 0.0 | 60.0 | 35.7 | 0.04 |
| 35 kDa | 100.0 | 0.0 | 100.0 | 57.1 | 0.002 |
| 30 kDa | 100.0 | 7.14 | 81.8 | 75.1 | 0.01 |
| 26.5 kDa | 90.9 | 14.3 | 72.7 | 71.4 | 0.006 |
| 19.5 kDa | 72.7 | 0.0 | 40.0 | 14.3 | 0.482 |

Four *H pylori* (-) patients with their tumors localized in the cardia were excluded from the analysis. Fisher's exact test was used to test for the different positive rate between CA-*H pylori* (-) and Normal-*H pylori* (-) groups.

## Abstract

**AIM:** To study the proper sites and doses of intraoperative radiotherapy (IORT) for gastric carcinoma and the effects of this treatment.

**METHODS:** A total of 106 patients with stage Ⅰ-Ⅳ gastric carcinoma who received D2 or D3 radical operation combined with IORT were analyzed. Sixty-seven patients with gastric cancer of the antrum and body underwent distal gastrectomy. The sites of irradiation were at the celiac artery and hepatoduodenal ligment area. Another 39 patients with carcinoma of the cardia and upper part of the gastric body and whole stomach underwent proximal gastrectomy or total gastrectomy. The sites of irradiation for this group were the upper margin of the pancreas and the regional para-aorta. The therapeutic effects (including survival and complications) of these 106 cases received operation combined with IORT (IORT group) were compared with 441 cases treated during the same time period by a radical operation alone (operation group).

**RESULTS:** The radiation dose below 30 Gy was safe. The therapeutic method of the operation combined with IORT did not prolong the survival of patients with stage Ⅰ and Ⅳ gastric cancer, but the 5-year survival rates of patients with stage Ⅱ and Ⅲ gastric cancers were significantly improved. The 5-year survival rates of the stages Ⅲ cancer patients receiving D2 resection combined with IORT were markedly improved, while for those receiving D3 radical resection, only the postoperative 3- or 4-year survival rates were improved ($P$ < 0.005-0.001). The 5-year survival rate for those patients was raised only by 4.7% ($P$ > 0.05).

**CONCLUSION:** The 5-year survival rates of patients with stages Ⅱ and Ⅲ gastric carcinoma who received D2 lymphadenectomy combined with IORT were improved, and there was no influence on the postoperative complications and mortality.

## INTRODUCTION

The fate of patients after surgical removal of a gastric carcinoma is determined to a large degree by regional failure of the operation (e.g. tumor recurrence in the tumor bed or in an adjacent structure). This is true for palliative resections with macroscopic tumor residues (D2) as well as for operations with microscopic involvement of resection margins (D1) or no discernible malignant cells (D0). Recurrent tumors may originate from extension of the primary tumor or from regional lymph node metastases not encompassed by the surgical procedure[1]. It is desirable therefore to develop and study additional tumoricidal measures that might eliminate residual malignant tissues, thereby increasing the chance of regional tumor control[2].

Intraoperative radiotherapy (IORT) as an adjunct to surgical excision of solid malignancies has been used, however, clear-cut evidence of its benefit for tumor control is still deficient. In IORT a large single dose of radiation is given to the area with greatest risk of local failure[3-5]. Based on the available oncologic and radiotherapeutic data, radiation thus applied should be able to control tumor growth. The biologic and logistic advantages of radiation applied directly to the tumor bed at a single dose are obvious. For these reasons any information related to the efficacy of IORT is highly desirable and welcome.

Under these considerations, we have used IORT for gastric cancer and report the clinical results in comparison with that of patients treated by operation alone. The clinical results of IORT for gastric cancer were analyzed based on the histologic findings.

## MATERIALS AND METHODS

### *Research subjects*

A total of 106 patients were treated by radical resection and IORT between 1992 and 1998, including 13 cases in

stage Ⅰ, 17 in stage Ⅱ, 48 in stage Ⅲ and 28 in stage Ⅳ. There were 77 men and 29 women, aged from 31-80 years, averaging 52.4 years. Location of the carcinoma was: antrum 58, body 12, cardiac 19, and total stomach 17 cases. Operation method: D2 lymphadenectomy 27, D3 lymphadenectomy 79; distal gastrectomy 17, proximal gastrectomy 67 and total gastrectomy 22 cases. To evaluate the effectiveness of IORT, 441 patients who were treated by operation alone during the same time period were classified histologically, and their survival rates were compared with those of patients treated by IORT. In addition, a comparative study was performed on the survival rates of patients treated by IORT and those treated by operation alone based on the degree of staging (Table 1). Inclusion criteria for IORT[6] were: (a) gastric adenocarcinoma confirmed through preoperative biopsy; (b) age between 25 and 80 years; (c) World Health Organization (WHO) performance status of 0-2; and (d) the availability of IORT facilities.

Patients were excluded if they had serious concurrent illness, active infection, symptomatic ischemic heart disease, congestive heart failure, a recent history of myocardial infarction, or symptomatic arrhythmia. Patients with significant gastrointestinal disturbance that could cloud the interpretation of gastrointestinal toxicity were also excluded. In addition, patients with severe malnutrition or severe nausea, or frequent vomiting were excluded.

Surgery was performed through a median laparotomy and surgeons were allowed to use either total or subtotal gastrectomy (according to the tumor location) combined with D2 and D3 lymphadenectomy. The same two senior surgeons were in charge of the operations during the whole protocol.

### *Radiation location*

After the gastrectomy and lymphadenectomy and before alimentary reconstruction, the local region of the hepatoduodenal ligament and the upper margin of the pancreas or the gastric bed were irradiated in 67 patients who were treated with gastrectomy in the antrum and body of the stomach. The other 39 patients with total gastrectomy underwent removal of the pancreas capsule and extended lymph node dissection including the nodes along the splenic artery. In the patients with body, cardiac and total stomach cancer, the tail and body of the pancreas were moved up to the right side margin of the abdominal aorta and the superior mesenteric vein and the region of the para-aorta received irradiation.

IORT was administered to the tumor bed and celiac axis at the time of gastric resection in those patients whose tumor appeared transmural and who were sufficiently stable to tolerate a transfer to the Radiation Therapy Treatment Room.

A variety of sizes and shapes of the pentagonal treatment cones were prepared so they fit the costal arch adequately and encompassed various anatomic situations of the tumor bed and the high risk lymph node groups noted above.

The field was clearly illuminated by an electric lamp fixed to a telescope attached to the treatment cone. The sterilized cone was inserted into the abdomen inclining degrees so the celiac axis was sufficiently covered.

### *Electronic energy and radiation dose of IORT*

The electronic energy from 6 MeV to 16 MeV was selected. The radiation doses of IORT were selected according to the posibillity of the radicality achieved by surgical operation. A single dose of 10-15 Gy was given to 41 patients who had no clinically undetectable lesions, a single dose of 20 Gy was given to each 27 patients who were suspected to have microscopic residual LN, 25 Gy was given to 37 patients who were suspected to have macroscopic residual LN or direct invasion of adjacent structure, and 30 Gy to one patient who had noncurative surgery because of incomplete excision of metastatic lesions.

## RESULTS

### *Complications*

When IORT is used for gastric cancer, critical organs to which exposure must be avoided, are the pancreas, duodenum and jejunum which must be shielded from radiation. Less than 40% of the pancreas was generally included in the radiation field. Acute and late damage to the pancreas was evaluated by changes in serum amylase and blood glucose levels after IORT. Temporary increases in both serum amylase and blood glucose occurred after IORT, but they returned to preirradiation levels within a week. Neither significant late complications nor deviation

from the usual postoperative course was observed. There was no instance of delayed wound healing. One patient died from cardiac infarction, resulting in a death rate of 0.9% (1/106). Recovery of gut function in all of the patients with IORT was delayed for 24 h.

### *Survival*

Table 2 demonstrates the survival rates based on an analysis of 106 patients treated by IORT and 441 patients treated by operation alone. The survival rate was calculated by the Kaplan-Meier method.

The 5-year survival rate (YSR) for patients treated by operation alone was 92.8% for stage Ⅰ, 80.6% for stage Ⅱ, 45.1% for stage Ⅲ, and 10% for stage Ⅳ. On the other hand, the 5-YSR for patients treated by IORT was 100% for stage Ⅰ and stage Ⅱ, 60.4% for stage Ⅲ, and 14.3% for stage Ⅳ. As shown in Table 2, there was no difference between the 5-YSR of patients in stage Ⅰ, and stage Ⅳ in the two groups. The IORT procedure raised the survival of patients with stages Ⅱ and Ⅲ cancer from 15% to 20%, $P < 0.005$-0.001.

Table 3 demonstrates that the 5-YSR of the stage Ⅲ cancer patients with D2 radical resection combined with IORT was improved as compared with operation alone. The 5-YSR of the stage Ⅲ cancer patients with selective D3 radical resection combined with IORT was not improved as compared to an operation alone. However, the 3- and 4-YSR was significantly improved by IORT combined with operation as compared with operation alone. But the differences of the 3 and 4-YSR between the two groups were statistically significant.

## DISCUSSION

As far as gastric adenocarcinoma is concerned, the prognosis remains poor with a high local failure rate estimated up to 67%[7]. While a lot of trials using systemic chemotherapy are currently being made to decrease the general failure rate in gastric adenocarcinoma, using IORT as a boost to EBRT could be a way to improve local control rate on coeliac area after gastrectomy[2,8]. IORT has been known as a feasible radiation treatment since 1907[9]. Its main advantage is probably to spare normal tissues while delivering a high dose precisely on the tumoral target. Extended lymph node dissection has been used mainly in Japan and the treatment results have improved remarkably as shown in many retrospective studies. But extended lymph node dissection is still controversial in the Western countries because of reported excessive postoperative morbidity and mortality and lack of proof in a recent retrospective study and in randomized controlled trials[1,10]. The Dutch Gastric Cancer Trial and the Medical Research Council (MRC) randomized surgical trial were not able to prove the benefit of extended lymph node dissection.

Due to operating room planning reasons, a great number of patients with gastric adenocarcinoma were not included in the IORT protocol in the reported study, and therefore, no valid comparisons or conclusions can be made. However, it is important to notice that mortality and morbidity rates in patients treated with IORT (1/42 and 3/42) were not excessive when compared with the mortality and morbidity rates reported in the retrospective study of 350 gastric cancer patients treated by surgery alone in the same institution since 1970 (respectively 10.8% and 14%)[11]. Glehen *et al*[12,13] did not detect any acute toxicity of IORT. Concerning the late toxicity of IORT, canine studies provide guidelines for human cancer treatment and the data provided by these canine studies are comparable with the data obtained in an autopsy study which validated the model for clinical use. With a long term follow-up, in the reported study we just detected one case of enteritis, 2 years after irradiation. But this late toxicity was controversial in the literature data because of the reported cases of other enteritis, gastrointestinal bleedings with or without arterioenteric fistulas, vertebral collapses and liver hemangiomas[2,14,15].

Each surgical procedure that does not achieve a complete local excision of the primary tumor in all 3 dimensions (length, width, aboral, and depth of tumor) and of the area of lymphatic drainage is, according to the UICC classification of D1 or D2 resection (i.e. a resection leaving residual microscopic or macroscopic tumor), considered to be a "palliative resection". In addition to procedures that leave the entire tumor *in situ*, any type of operation that leaves residual macroscopic or microscopic tumor at the resection margin, tumor bed, or in the

lymphatic drainage area must also be considered to be a palliative procedure.

The rationale for IORT is to increase the irradiation dose to the tumor without exceeding critical normal tissue tolerance. IORT used as a neoadjuvant therapy, can increase the 5-YSR of patients with advanced gastric carcinoma. Special linear accelerators have been used for the application of high single-dose radiation to the tumor bed[3,4]. Abe *et al*[5] reported 115 gastric cancer patients treated by IORT. The 5-YSR survival of patients in stages Ⅱ through Ⅳ treated by IORT increased by nearly 10%-20%. No difference in the survival of patients was observed between the two groups. IORT did not afford benefit if the lymph node metastases were limited with $n_1$ group or serosal invasion was not found. On the other hand, the 5-YSR for patients treated by IORT increased by nearly 10% when the serosal invasion was observed, and by nearly 18% when $n_2$ and $n_3$ lymph node metastases were found. Ogata *et al*[16] reported that the 5-YSR and 8-YSR for 58 cases treated by IORT were both 100% , and 60% and 48% in control group with stage Ⅱ cancer. The 8-YSR of the stage Ⅲ cancer by IORT was 55%, and 35% in the control group. But these results were controversial. Coquard *et al*[2] reported that the 5-YSR of patients with gastrectomy and local lymph node resection combined with IORT was the same as single expanded lymph node resection. However, the postoperative complications and mortality were lower than that in those who received only gastrectomy. Our results showed that operation combined with IORT is beneficial for patients in stage Ⅱ and stage Ⅲ cancer with a 5-YSR of 14.4%-20%. However, this procedure was ineffective for patients with stage Ⅰ and stage Ⅳ cancer treated with D2 lymphadenectomy combined with IORT, the 5-YSR of stage Ⅱ cancer patients was increased by 60% as compared with D2 lymphadenectomy only by 35.7%. With D3 lymphadenectomy combined with IORT, the 3- and 4-YSR were improved, but it was ineffective for the 1, 2 and 5-YSR. These encouraging results were already reported by Japanese authors[5,17] with a 10%-20% increase in 5-YSR in stages Ⅱ and Ⅲ. However, this has not been reported in Western countries, especially for pN+ patients. But in a shorter follow-up, a local recurrence of under 15% after the use of IORT and EBRT was reported[18,19].

The radiation target area in the region of the upper abdomen includes potential microscopic tumor extensions and known or suspected macroscopic disease[13]. In order to reduce the injury of irradiation to the normal tissues near the stomach, the target area is restricted to the gastric bed. The inferior field border is generally at the level of the L3 to L4 vertebrae, but this depends on the location of the carcinoma and the position of the stomach before treatment. The target area includes the proximal and regional lymphatics, the right and left cardiac nodes, the nodal chains of the lesser and greater curvatures, the suprapyloric and infrapyloric chains, the splenic chains, and the lymph nodes along the hepatic artery. For the cardiac tumors, upper extension of the field to the terminal esophagus and paraesophageal lymph nodes is recommended. If the tumor is unresectable or if, after surgery, macroscopic disease remains, the total irradiation dose can be increased in a coned-down volume, which is restricted to the area of gross disease. With regard to the opitimization of IORT, we developed a new technique that provides a wider irradiation field for patients undergoing total gastrectomy. In these patients, total gastrectomy, splenectomy, removal of the pancreas capsule, and extended lymph node dissection including the nodes along the splenic artery were performed. Then the tail and body of the pancreas were moved up to the right side margin of the abdominal aorta and the superior mesenteric vein. These maneuvers provided a much wider irradiation field, which included the para-aortic lymph nodes. After irradiation, the pancreas was returned to its normal position and an esophagoenterostomy was performed. This method was adopted only in patients without cancer invasion of the pancreas or metastases in the lymph nodes along the splenic artery. The advantage of this method is that it produces a wide irradiation field including para-aortic lymph nodes and does not increase the complications and mortality. Meanwhile, one must be careful to protect the duodenum and jejunum before irradiation as those organs must be shielded from the irradiation field.

With regard to special radiotherapeutic techniques that include the potential of relatively high biologically effective doses, gastric cancer is one of the most convincing indications for intraoperative irradiation. Special linear accelerators have been used for the application of high single doses (15-35 Gy) to the tumor bed. One problem with IORT is to correctly cover tumor sites outside the midline area or under the left hemidiaphgragm. In addition, the maximum tolerable dose administered in one session is limited from 15 to 35 Gy. Abe *et al*[5] reported that doses of irradiation depended on the radicality achieved by the operation. In general, the irradiation doses from 15-30 Gy were applied in curative situations and 30-35 Gy in palliative situations. We selected the doses of IORT according to the residual tumor volume, including clinically undetectable lesions (10-15 Gy), microscopic residual (20 Gy), macroscopic residual (25 Gy), or noncurative surgery (30 Gy). No serious complications occurred in these cases. Our data strongly support the efficacy of IORT for local tumor control.

## Abstract

**AIM:** To investigate the biliary biochemical constituents and cytokines in infantile hepatitis syndrome (IHS).

**METHODS:** From 42 IHS subjects and 21 controls, serum and biliary biochemical constituents, including total bilirubin (TBIL), direct bilirubin (DBIL), alanine aminotransferase (ALT), gamma-glutamyl transpeptidase (γ-GT), total bile acid (TBA), interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) both in bile and serum, were assayed. The subjects with IHS were divided into a cholestasis group ($n$ = 21) and a hepatitis group ($n$ = 21).

**RESULTS:** In the cholestasis group, serum TBIL, DBIL, ALT, γ-GT, TBA, IL-6 and TNF-α levels were higher than those in the control ($P$ < 0.01); and also the biliary TBIL, DBIL, γ-GT and TBA levels were lower than those in the control, whereas biliary IL-6 and TNF-α levels were higher than those in the control ($P$ < 0.01). In the cholestasis group, serum IL-6 and TNF-α levels were lower than those in bile ($P$ < 0.01). In the hepatitis group, serum DBIL, ALT, γ-GT, TBA, IL-6 and TNF-α levels were higher than those in the control ($P$ < 0.01 or 140.57 ± 70.32 *vs* 79.06 ± 35.25, $P$ < 0.05), while biliary TBIL, DBIL, γ-GT and TBA levels were lower than those in the control ($P$ < 0.01), and biliary IL-6 and TNF-α levels were higher than those in the control ($P$ < 0.01). In the hepatitis group, serum IL-6 and TNF-α levels were also lower than those in bile ($P$ < 0.01). Serum TBIL, DBIL, γ-GT, IL-6 and TNF-α levels in the cholestasis group were higher than those in the hepatitis group, while biliary IL-6 and TNF-α levels in the cholestasis group were higher than those in the hepatitis group. Biliary IL-6 and TNF-α were found to be more significantly increased than serum IL-6 and TNF-α in IHS ($P$ < 0.01). The biliary IL-6 and TNF-α levels were positively correlated with serum DBIL, TBA and γ-GT levels in IHS subjects.

**CONCLUSION:** Biliary biochemical constituents alter in coincidence with pathological changes in hepatocellular injury. Cholestasis is more serious in IHS patients of cholestasis subtype. Assay of biliary IL-6 and TNF-α levels can be specific and sensitive to determine the inflammatory status of impaired liver in IHS.

**Key words:** Infantile hepatitis syndrome; Biliary biochemical constituents; Biliary cytokines; Interleukin-6; Tumor necrosis factor-α

## INTRODUCTION

Infantile hepatitis syndrome (IHS), with a morbidity of 1/2500 in live-born infants[1], comprises a series of symptoms, including jaundice, splenohepatomegalia, changes of texture of the liver, hepatic dysfunction in onset mainly in the neonatal period and infancy. It has been reported that the biochemical constituents and cytokines in blood alter when the disorder attacks[2]. However, what changes of those biochemical constituents and cytokines in bile can be, and what relationships between IHS and physiologic jaundice in those constituents can be, remains a puzzle in pediatric practice. In this study, we focused on the alterations of biochemical constituents and cytokines in serum and bile obtained from subjects attacked by IHS.

## MATERIALS AND METHODS

### Subjects

According to the diagnostic criteria[3], IHS was defined as: (1) age < 1 year; (2) jaundice; (3) splenohepatomegalia and changes of texture of the liver; and (4) alteration in hepatic function. Forty-two subjects [29 males and 13

females; average age 56 d (range: 33-120 d)] suffering from IHS, being divided into cholestasis subtype ($n = 21$) and hepatitis subtype ($n = 21$) according to the color of stool[4], were randomly selected from in-patients in Wuhan Children's Hospital. Another 21 subjects [12 males and 9 females; average age 43 d (range: 23-68 d)], being ruled out from IHS and diagnosed as breast-feeding jaundice, were chosen as controls.

### Methods

In fasting condition, next morning after admission to the hospital, non-anticoagulated venous blood was collected from all patients, and the blood specimens were examined instantly. The bile specimens were collected by infant duodenum drainage tube. The procedure of draining was carried out as mentioned below[5]. Before draining, the subjects were instructed to fast for 4 h and given intravenous transfusion for essential nutrition, and given diazapen intravenously or chloral hydrate orally if restless. Then, the infants were placed at right arm reclining and the head was retained by an assistant; after applying a small amount of liquid paraffin and dispelling the tampon at the end of the tube, the operator inserted the tube through right nasal cavity to the stomach at a depth of 30-35 cm and gastric juice was drained out; then through the pylorus, the tube accessed the duodenum at the depth of 40-45 cm and duodenal juice was drained out. The draining was considered successful if yellow draining juice was obtained, or the head of the draining tube was ascertained in the duodenum by X-ray.

The biliary and serum total bilirubin (TBIL), direct bilirubin (DBIL), alanine aminotransferase (ALT), gamma-glutamyl transpeptidase (γ-GT) and total bile acid (TBA) were assayed by CL-7200 Fully-automated Chemistry Analyzer provided by Shimadzu Co. Ltd. The biliary and serum interleukin-6 (IL-6) and tumor necrosis factor-α (TNF-α) were assayed by double antibody Sandwich-ELISA with the apparatus from Micro Reader-3 and the kit from R&D Co. Ltd.

### Statistical analysis

One-way ANOVA (*F*-test, SNK-test) was employed to determine the differences of data among the three groups. Student's *t* test was applied for the differences in same constituent between biliary and serum data. Pearson correlation analysis was adopted to explore the relationships among the data. Statistical analyses were performed using SPSS 12.0 software.

## RESULTS

### Comparison of serum biochemical constituents and cytokines among three groups

Serum TBIL, DBIL, ALT, γ-GT, TBA, IL-6 and TNF-α levels were significantly higher in the cholestasis group than those in controls ($P < 0.01$). Moreover, serum DBIL, ALT, γ-GT, TBA, IL-6 and TNF-α levels were markedly higher in the hepatitis group compared to the controls ($P < 0.01$ or $P < 0.05$); while there was no significant difference in serum TBIL level between the hepatitis and control group. In addition, serum TBIL, DBIL, γ-GT, IL-6 and TNF-α levels in the cholestasis group were markedly higher than those in the hepatitis group ($P < 0.01$), but ALT and TBA levels were not obviously different between these two groups (Tables 1 and 2).

### Comparison of biliary biochemical constituents and cytokines among three groups

Biliary TBIL, DBIL, γ-GT and TBA levels both in cholestasis and hepatitis groups were significantly lower than those in controls ($P < 0.01$), while biliary IL-6 and TNF-α levels in those two groups were notably higher

than those in controls ($P < 0.05$). In contrast to that in the hepatitis group, the value of biliary IL-6 and TNF-α in cholestasis group markedly increased ($P < 0.01$), but TBIL, DBIL, γ-GT and TBA levels in both groups were not significantly different. However, the value of biliary ALT was not obviously different among the three groups (Tables 1 and 2).

### *Comparison between biliary and serum cytokines*

Both in cholestasis and hepatitis groups, the levels of IL-6 and TNF-α in serum were notably lower than those in bile ($P < 0.01$) (Table 2).

### *Relationships between biochemical constituents and cytokines*

Biliary IL-6 was obviously correlated with serum DBIL, ALT and γ-GT with the coefficient of correlation of 0.4621, 0.4152 and 0.5376, respectively ($P < 0.05$). Moreover, the biliary TNF-α was significantly correlated with serum DBIL, ALT and γ-GT with the coefficient of correlation of 0.3972, 0.4309, 0.4713, respectively ($P < 0.05$). However, the serum IL-6 and TNF-α were not correlated with serum TBIL, DBIL, ALT, γ-GT, and TBA.

## DISCUSSION

Serum biochemical constituents, such as TBIL, DBIL, ALT, γ-GT and TBA, are used to monitor liver function in medical practice. Among those constituents, bilirubin is a breakdown product of hemoglobin, and total and direct bilirubin (TBIL and DBIL) are usually measured to screen for or to monitor jaundice caused by liver or gall bladder dysfunction. Alanine aminotransferase (ALT), an enzyme found mainly in the liver, is released into the bloodstream when the liver is damaged or diseased. Gamma-glutamyl transpeptidase (γ-GT), existing in the endochylema of the hepatocyte and epithelium of the intrahepatic bile duct and being mainly synthesized by mitochondria in hepatocytes, is discharged to the duodenum through bile duct. Therefore, rise of γ-GT indicates hepatocytic dysfunction or obstruction of extra-hepatic bile duct. Especially, detection of biliary γ-GT can differentiate extra-hepatic biliary atresia and IHS, for bile not consisting of γ-GT when biliary atresia occurs[5]. Total bile acid (TBA) is an exclusive index reflecting hepatic synthesis, secretion, metabolism and hepatocellular dysfunction, and it has been shown that its specificity, sensitivity and stability tendency in numerical hepatobiliary disorder in liver are all superior to the conventional liver function examinations[6].

Cytokines are small proteins released by cells that have a specific effect on interactions and communications between cells or on behavior of cells, and participate in many pathophysiologic progresses in hepatobiliary disorders. Biliary cytokines are produced by hepatocytes, macrophages and epithelium of bile duct. It has been reported that biliary IL-6 was exclusive for diagnosis of angiocholitis[7] and TNF-α could reflect the extent of angiocholitis[8]. We previously confirmed that under cholestatic condition, biliary IL-6 and TNF-α levels increased and were correlated with hepatocellular impairment and cholestasis in rabbit, thereby indicating that IL-6 and TNF-α could reflect the extent of hepatocellular necrosis and angiocholitis[9].

In this study, we observed that, compared to the controls, almost all biochemical constituents in serum were remarkably increased both in cholestasis and hepatitis groups, while those constituents in bile were mostly decreased, which indicated discharging of those from liver to blood and reduction of those in bile when hepatocyte inflamed and cholangiole was embarrassed. When compared between cholestasis and hepatitis groups, the cholestasis-related indexes TBIL, DBIL and γ-GT in serum increased more obviously in the cholestasis group than those in the hepatitis group, while no significant differences in those biochemical constituents in bile between these two groups were observed. In addition, the ALT and TBA, the indexes related to hepatocellular impairment, were not markedly different between the two groups both in serum and bile, manifesting the feature of cholestasis in IHS.

Following the previous animal experiment, we examined the two related cytokines to explore the role of IL-6 and TNF-α in IHS. We found that the two cytokines notably rose in blood and bile of IHS subjects compared to the controls, thereby indicating the inflammatory status in IHS. Furthermore, IL-6 and TNF-α in the cholestasis group increased more significantly than that in the hepatitis group, elucidating the greater severity in cholestasis. On the other hand, in both cholestasis and hepatitis groups, biliary cytokines were more elevated than serum cytokines, which implied biliary cytokines could be a more sensitive clue for diagnosing hepatic impairment.

From the statistical analysis, it was confirmed that biliary IL-6 and TNF-α had a positive correlation with serum DBIL, ALT and γ-GT, but the serum cytokines had not any correlations with serum biochemical constituents. This result illuminated that as cytokines in blood could be influenced by the state of whole body, assaying biliary inflammatory cytokines might be a specific and sensitive test for monitoring the development of IHS. Thus, the results clearly revealed that biliary biochemical constituents altered in coincidence with pathological changes in hepatocellular injury, which can demonstrate the severity of IHS, especially for cholestasis, and the differences between cholestasis and hepatitis subtype in this disorder. Furthermore, it can be concluded that the test of biliary IL-6 and TNF-α might be a specific and sensitive reference to determine the inflammation status of the impaired liver in IHS.

## Abstract

**AIM:** To construct a live attenuated *Salmonella typhimurium* (*S. typhimurium*) strain harboring the *H pylori* neutrophil activating protein (HP-NAP) gene as an oral recombinant DNA vaccine, and to evaluate its immunogenicity.

**METHODS:** By genetic engineering methods, the genomic DNA of *H pylori* was extracted as a template. The total length of the HP-NAP gene was amplified by polymerase chain reaction (PCR) and cloned into pBT vector for sequencing and BLAST analysis, then subcloned into a eukaryotic expression vector pIRES followed by PCR identification and restriction enzyme digestion. The identified recombinant plasmid pIRES-NAP was transfected into COS-7 cells for target fusion protein expression, and its antigenicity was detected by Western blotting. Then the recombinant plasmid was transformed into a live attenuated *S. typhimurium* strain SL7207 as an oral vaccine strain, and its immunogenicity was evaluated with animal experiments.

**RESULTS:** A 435 bp product was cloned using high homology with HP-NAP gene in GenBank (more than 98%). With identification by PCR and restriction enzyme digestion, a recombinant eukaryotic expression plasmid pIRES-NAP containing the HP-NAP gene of *H pylori* was successfully constructed. The expressed target protein had a specific reaction with *H pylori*i whole cell antibody and showed a single strip result detected by Western blotting. Oral immunization of mice with recombinant DNA vaccine strain SL7207 (pIRES-NAP) also induced a specific immune response.

**CONCLUSION:** The successful construction of HP-NAP oral DNA vaccine with good immunogenicity may help to further investigate its immunoprotection effects and develop vaccine against *H pylori* infection.

## INTRODUCTION

The discovery of *H pylori* has brought about a revolution in the research of etiological factors of gastrointestinal diseases[1]. It has been confirmed that *H pylori* is the main cause of chronic superficial gastritis, chronic active gastritis and peptic ulcer[2-4], and has a close relation to gastric mucosa-associated lymphoid tissue lymphoma and gastric cancer[5,6]. In 1994, the World Health Organization defined it as a class 1 carcinogen. Although significant progress has been made in treating *H pylori* infection with current triple or quadruple therapy based on antibiotics and proton pump inhibitors, the limitations of pharmacological therapy such as side effects, poor compliance, high cost, and most importantly, rapid emergence of antibiotic resistance have set the stage for the development of less costly and more efficient means to prevent and control *H pylori* infection. Ample precedence from previous experiences suggests that vaccination may be an alternative[7].

DNA vaccine has shown a great potential in protecting against and treating many diseases since it was developed. It can induce complete immune responses, provide heterologous cross protection, and can be easily prepared as a polyvalency vaccine[8]. In addition, the live attenuated *Salmonella typhimurium* (*S. typhimurium*) strain expressing foreign antigens may be a very hopeful new-generation for developing *H pylori* vaccine. Experiments on human body indicate that it has very good endurance and immunogenicity, which can be used to transmit foreign antigens[9]. In our present study, we selected a neutrophil activating protein (HP-NAP), a new major virulence factor of *H pylori* identified more recently, which was termed for its ability to induce adhesion of neutrophils to gastric endothelial cells and to produce reactive oxygen radicals[10]. We attempted to construct a live attenuated

*S. typhimurium* strain harbouring the HP-NAP gene as an oral recombinant DNA vaccine, and to explore its immunogenicity to pave the way for biological treatment of *H pylori* infection.

## MATERIALS AND METHODS

### Materials

The *H pylori* standard strain CCUG 17874, kindly presented by the IRIS Research Center of Italy, was cultured on *Campylobacter* selective agar (Merck, Germany) medium supplemented with 10% defibrillated goat blood containing *Campylobacter* selective antibiotic mixture (Merck), and incubated under microaerobic conditions (50 mL $O_2$, 85 mL $N_2$, 10 mL $CO_2$ and 10% relative humidity at 37℃). The *E. coli* strain DH5α, live attenuated *S. typhimurium* strain LB5000 and SL7207, and COS-7 cell lines conserved in our laboratory, were cultured routinely.

Restriction enzymes including *Xho* I and *Mlu* I, T4 DNA ligase, and *EX Taq*™ DNA polymerase were purchased from TaKaRa Biotechnology (Dalian) *Co*., *Ltd*. Mouse anti-HP-NAP antibody was prepared by our laboratory. Alkaline phosphatase anti-mouse IgG made in horse was purchased from Vector Laboratories. Lipofectamine™ 2000 was purchased from Gibco Corporation. T-A cloning vector pBT was purchased from Shanghai Sangon Biological Engineering & Technologies and Services *Co*., *Ltd*. Eukaryotic expression vector pIRES was purchased from Clontech of BD Biosciences. Other reagents were analytically pure reagents produced in China.

Twenty-four specific-pathogen free male C57BL/6 mice aged 4 wk, were purchased from Sino-British Sippr/Bk Laboratory Animal *Ltd*. of Shanghai.

### Construction of recombinant plasmid pIRES-NAP

According to the nucleotide sequence of the HP-NAP gene in GenBank, we designed a pair of oligonucleotide primers P1 (5′-GTC CTC GAG ATG AAA ACA TTT GAA ATT TTA AAA CAT TTG CAA GCG-3', with *Xho* I restriction site) and P2 (5′-GTC ACG CGT TTA AGC CAA ATG GGC TTG CAA CAT CC-3', with *Mlu* I restriction site) synthesized by Sangon with correct ORF. Genomic DNA of CCUG 17874 was extracted as the template. Four mL of template DNA was added to a 100 mL reaction mixture containing 10 mL 10 × PCR buffer, 0.2 mmol/L each deoxynucleoside triphosphate, 2.5 U of *EX Taq*™ polymerase, and 0.2 mmol/L each primer. PCR was performed with Mastercycler® gradient thermocycler (Eppendorf, Germany) as follows. The initial denaturation cycle was at 94℃ for 5 min, followed by 30 cycles of denaturation at 94℃ for 1 min, primer annealing at 60℃ for 1 min, and DNA chain extension at 72℃ for 1 min. The final cycle was at 72℃ for 10 additional minutes, followed by rapid cooling to 4℃. The purified PCR products were T-A cloned into pBT vectors, then transformed into DH5α competent cells using standard methods. Positive clones were screened by blue/white spot and ampicilin resistance. Single-stranded DNA was prepared from selected clones for sequencing with forward M13 universal primer. Homologous analysis between the cloned HP-NAP gene and related genes in GenBank for neucleotide and deduced amino acid sequence was performed by BLAST. The identified recombinant plasmid pBT-NAP was digested with restriction endonucleases *Xho* I, *Mlu* I and subcloned into the corresponding sites of eukaryotic expression vector pIRES. PCR with primers P1, P2 and double enzyme restriction were performed.

### Assay of HP-NAP fusion protein expression

COS-7 cells were cultured routinely and inoculated into 6-well plates one day before transfection, then co-cultured with a mixture of Lipofectamine™ 2000 and recombinant plasmid pIRES-NAP mixed instantly in definite proportion. After incubation at 37℃ for 24-48 h, the culture was centrifuged to collect supernatant. Western blot analysis was performed to evaluate the immunity of HP-NAP antigen expressed in culture supernatant using mouse anti-HP-NAP as primary antibody and horse anti-mouse IgG as secondary antibody.

### Construction of oral DNA vaccine

Recombinant plasmid pIRES-NAP was transformed into *S. typhimurium* strain LB5000 for methylation decoration, then extracted and transformed by electroporation into ending host bacteria *S. typhimurium* strain SL7207. SL7207 (pIRES-NAP) was grown in LB medium containing 100 mg/mL ampicilin at 37℃ for 60 generations. Identification by PCR amplification and double restriction endonuclease digestion was performed every 10 generations.

### Assay of immunology of oral vaccine

Twenty-four mice were divided into 3 groups (8 mice in each group). LB group consisting of non-immunized mice received LB culture fluid and was used as a control group, *Salmonella* group was immunized merely with attenuated The *S. typhimurium* strain SL7207, the vaccine group was immunized with recombinant strain SL7207 (pIRES-NAP). Prior to immunization, all the mice were left overnight without solid food and 6 h without water. A total volume of 100 μL of 30 g/L sodium bicarbonate was given orally using a special catheter to neutralize the stomach pH. Then the mice in the LB group were lavaged immediately with 200 μL LB fluid. Mice in the *Salmonella* group and vaccine group were lavaged with $1.0 \times 10^9$ c.f.u of *S. typhimurium* strain SL7207 and vaccine strain SL7207 (pIRES-NAP), respectively, in a total volume of 200 μL. At 4 wk after immunization, the mice were sacrificed by terminal cardiac puncture under anesthesia and small intestine juices were collected. Indirect ELISA was performed to evaluate HP-NAP-specific IgG or IgA in serum and intestine juice. Purified HP-NAP was used as a coating antigen in ELISA immunoassay.

## RESULTS

### PCR amplification and homology analysis of HP-NAP gene

A 435 bp gene segment was amplified by PCR, which was consistent with the complete sequence of the HP-NAP gene confirmed by sequencing result (Figure 1). BLAST analysis showed that the nucleotide homology between cloned HP-NAP gene and *H pylori* SS1 strain from Genbank reached 98.2% (427/435), including 3 of C-T

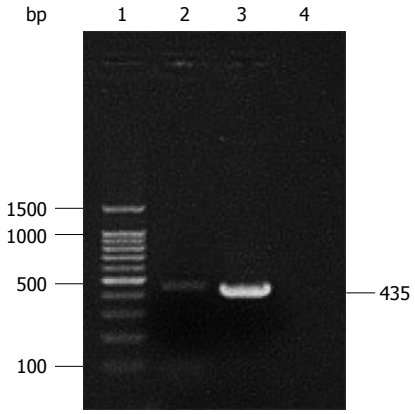

**Figure 1** Electrophoresis of HP-NAP PCR products. Lane 1: 100 bp DNA ladder marker; lanes 2 and 3: PCR products of HP-NAP; lane 4: Blank control.

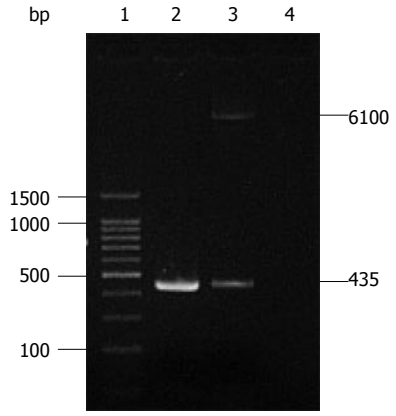

**Figure 2** Identification map of recombinant plasmid pIRES-NAP. Lane 1: 100 bp DNA ladder marker; lane 2: PCR products templated on pIRES-NAP; lane 3: pIRES-NAP digested by endonucleases Xho I and Mlu I; lane 4: Blank control.

and 4 of A-G replacements, and more than 97% (426/435, 425/435) of other common *H pylori* strains such as 5D, 5A, 2B, 2A, RHP901a, DB2 and 1811a. Base replacements of cloned sequence did not significantly affect the translating results. The homology between proteins translated by cloned gene and SS1 strain was 98.6% (142/144).

### *Identification of recombinant plasmid*

A 435 bp target product was cloned as a template on the recombinant plasmid pIRES-NAP using primers P1 and P2. *Xho* I and *Mlu* I enzyme digestion also revealed the target HP-NAP gene in plasmid pIRES-NAP (Figure 2), suggesting that the recombinant plasmid pIRES-NAP and the oral DNA vaccine strain SL7207 (pIRES-NAP) were successfully constructed.

### *Assay of HP-NAP fusion protein*

Western blot analysis results of culture supernatant of COS-7 cells transfected with recombinant plasmid pIRES-NAP are shown in Figure 3. A special simple strip about 17 000 in relative molecular weight was obtained from the supernatant of transfected COS-7 cells, corresponding to the presumed consequence, but no strip was found in the supernatant of non-transfected COS-7 cells as control.

### *Immunology of recombinant strain*

The sera and intestinal juices of the vaccine group immunized with SL7207 (pIRES-NAP) showed positive ELISA results while those of the LB group and *Salmonella* group showed negative ELISA results, indicating that *S. typhimurium* SL7207 (pIRES-NAP) could enable the organism to generate specific mucosal and humoral immunity against the HP-NAP antigen.

## DISCUSSION

Research on the *H pylori* vaccine has been mainly focused on the development of protein vaccines during the past decades, but the preparation and purification of protein antigens is time-consuming and laborious. Since effective immune responses rely on the presence of adjuvants, most of which are toxic to the organism, it is therefore important to develop new *H pylori* vaccines.

Recent advances in immunology and molecular biology have permitted development of DNA vaccines, which have a wide range of applications. Vaccines for such diseases as HIV infection, malaria, and tuberculosis are being developed by using plasmid DNA or viral or bacterial vectors to deliver the genes encoding antigens from pathogens to the host[11]. As live attenuated virus vaccines have come into being for decades, antigenic proteins can be produced *in situ* by the host, engendering cellular and humoral immune responses. But unlike live attenuated vaccines, gene-based vaccines are being designed to deliver only the genes encoding the antigens for the vaccine. The ability of gene-based vaccines to generate cellular as well as humoral responses may be crucial in developing effective vaccines against *H pylori*-induced diseases. Similarly, the ability of gene-based vaccines to generate certain forms of immunogen such as a protein with a particular structure that can be formed only by mammalian cells *in situ*, may be a critical feature of DNA vaccines. It is thought that DNA vaccines can be produced and distributed on a global scale for prevention of diseases such as HIV infection, malaria, and tuberculosis.

*S. typhimurium* can be phagocytized by macrophages and M cells in Peyer node and through mesentery lymph nodes reach the liver and spleen, further stimulating other

organs and tissues to develop mucous membranes, cell and body fluid immunization responses. In the past few years, attenuated *S. typhimurium* as a delivery system has become a new trend to study a new type of oral recombinant live vaccine. Compared with traditional vaccines, live attenuated *S. typhimurium* is used as a new type of vector releasing system for heterologous antigens which does not require antigen purification, and not only protects antigens from degradation and denaturation in the stomach but also expresses adjuvant activity and prevents oral tolerance[12,13].

The development of *H pylori* DNA vaccine is unfolding. Todoroki *et al*[14] have investigated the effect of DNA vaccines encoding *H pylori*-heat shock proteins A and B (pcDNA3.1-hspA and -hspB) on inducing immune responses against *H pylori* in mice. In their study, C57BL/6 mice aged 5 wk were immunized by a single injection of 10 mg of pcDNA3.1-hspA and pcDNA3.1-hspB into intracutaneous tissue. Plasmid DNA lacking the inserted Hsp was injected as a control. Their results demonstrated that DNA vaccines encoding *H pylori*-Hsp could induce a significant immune response against *H pylori* and decrease gastric mucosal inflammation. Miyashita and his colleagues[15] reported that both intranasal and intracutaneous vaccination with pcDNA3.1 encoding *H pylori*-catalase (kat) induces humoral immune responses and suppresses *H pylori* colonization and inflammation of gastric mucosa. Serum IgG and IgA antibodies were induced in mice immunized with intracutaneous pcDNA3.1-kat with suppressed *H pylori* colonization compared to the mice immunized with control DNA, indicating that an effective DNA vaccine can be a new approach against *H pylori* infection in humans with potential foreground.

HP-NAP, a 150 000 dodecameric protein, is released in the medium, most likely after cell lysis, and binds to the bacterial surface, where it acts as an adhesion, mediating its binding to mucin[16] or to polymorphonuclear leukocyte sphingomyelin[17]. Purified recombinant HP-NAP is chemotactic for human neutrophils and monocytes[10] and induces surface expression of $\beta_2$-integrins which are necessary for endothelial trans-migration[18], suggesting that HP-NAP plays a role in the accumulation of these cells at the *H pylori*-infected site. HP-NAP is also a powerful stimulant of the production of reactive oxygen radicals and acts via a cascade of intracellular activation events, including increase in cytosolic calcium ion concentration and phosphorylation of proteins, leading to the assembly of functional NADPH oxidase on neutrophil plasma membrane through a pertussis toxin-sensitive pathway involving extracellular-regulated kinase (ERK) and p38-mitogen-activated protein kinase (MAPK)[19]. The activation of ERK and p38-MAPK is essential for the HP-NAP-induced superoxide anion generation, adhesion and chemotaxis of human neutrophils. Cytokines such as TNF and IFN-$\gamma$ are reported to enhance the production of ROIs induced by HP-NAP and increase the damage of gastric mucosa[20].

HP-NAP has also been shown to increase the synthesis of tissue factor and the secretion of inhibitor-2 of the plasminogen activator in mononuclear cells. By inducing the coordinate expression of cell pro-coagulant and antifibrinolytic activities, HP-NAP might favor fibrin deposition and contribute to the inflammatory reaction of gastric mucosa elicited by *H pylori*[21]. HP-NAP is also capable of crossing epithelial monolayers and inducing activation of the underlying mast cells[22]. These data further support the idea that HP-NAP has an important role in the *in vivo* triggering and maintaining of inflammatory events observed during *H pylori* infection. Once released from the bacterium, HP-NAP would traverse the stomach epithelial layer, reaching the underlying tissue where mast cells reside. The subsequent activation of mast cells by HP-NAP with release of the content of the granules and pro-inflammatory cytokine IL-6, is known to recruit monocytes and neutrophils. Thus, HP-NAP can act at different stages of the inflammatory response by activating mast cells with release of pro-inflammatory molecules able to activate neutrophils and monocytes, and additionally by acting directly on neutrophils and monocytes by promoting their recruitment and activation.

HP-NAP is highly immunogenic in humans. Analysis of serum samples from 35 *H pylori*-infected individuals revealed that 60% of the subjects contain specific antibodies to HP-NAP[2]. Satin and his colleagues[10] immunized 10 mice with purified recombinant HP-NAP by intragastric administration, showing that 80% of them have acquired protective immunity, which is higher than the CagA (70%) group but lower than the supersonic lysate group (90%). These data indicate that this protein is a good vaccine candidate for protecting *H pylori* infection.

In the present study, we successfully amplified and subcloned the HP-NAP gene into the eukaryotic expression vector pIRES, and established the recombinant live attenuated *S. typhimurium* strain SL7207 (pIRES-NAP) as an oral DNA vaccine. BLAST analysis indicated the HP-NAP gene we cloned had a high homology with those in GenBank. The COS-7 cells transfected with recombinant plasmid pIRES-NAP expressing a protein of 17 000 reacted especially with anti-HP-NAP antibody, but no reaction was found in the control group. On the other hand, the serum and intestine fluids from mice immunized with DNA vaccine contained specific antibody to HP-NAP, while those from control groups did not.

In conclusion, HP-NAP DNA vaccine can express target protein with good immunogenicity in eukaryotic hosts, and *S. typhimurium* strain SL7207 (pIRES-NAP) may be a good candidate as a vaccine for prevention and cure of *H pylori* infection. Further study is needed to explore its immunoprotection effects.

## Abstract

**AIM:** Tumor response and normal tissue toxicity of seven-day-per-week continuous accelerated irradiation (CAIR) for patients with esophageal carcinoma were evaluated and compared to conventional irradiation (CR).

**METHODS:** Sixty patients with squamous cell carcinoma of the esophagus were randomized into two groups: the CAIR group (30 patients) and the CR group (30 patients). Patients in the CAIR group received radiotherapy (RT) with 2 Gy/fraction per day at 7 d/wk with a total dose of 50-70 Gy (average dose 64.2 Gy). The overall time of irradiation was 3.6-5.0 wk (average 4.6 wk). RT in the CR group was 2 Gy/fraction per day at 5 d/wk with a total dose of 40-70 Gy (average dose 61.7 Gy). The overall time of irradiation was 4.0-7.0 wk (average 6.4 wk).

**RESULTS:** The data showed that the immediate tumor response to RT was better in the CAIR group than in the CR group. Efficiency rates (CR plus PR) were 82.8% (24/29) and 58.6% (17/29), respectively ($P$ = 0.047). In both groups the incidences of esophagitis and tracheitis were insignificant ($P$ = 0.376, 0.959), and no patient received toxicity that could not be tolerated.

**CONCLUSION:** CAIR shortens overall treatment time and is well tolerated by patients. It may be superior to CR in enhancing the local response of tumor, but its remote effect for esophageal carcinoma awaits further follow-up.

## INTRODUCTION

Esophageal carcinoma, especially in China, is one of the most common cancers. Its treatment results are rather dismal, with 5-year survival rates of about 5%-10% for conventional radiotherapy (CR)[1,2]. The poor prognosis is the result of both, local residual disease and early disease relapse. Thus for esophageal carcinoma, local control is the most important factor in prolonging survival[3]. Several animal experiments and clinical investigations have shown that accelerated repopulation of surviving tumor clonogens during a standard course of RT is one of the major reasons for treatment failure in several cancers[4-6]. Some clinical trials of accelerated hyperfractionated RT have been carried out with the aim of overcoming this problem by shortening the overall treatment time. Some reports have already suggested improvement in local control and survival rates, but at the expense of increasing acute toxicity, particularly with the faster schedule[6-8]. In recent years, another RT schedule has been used to treat head and neck cancer. The idea was simple-to continue radiation during the weekends. In this way, the overall treatment time has shortened for about two weeks, giving one fraction per day, seven days a week (including Saturday and Sunday), without any change of the other parameters as time or dose. This schedule was defined as a continuous accelerated irradiation (CAIR) and has been compared to conventional five days treatment in a randomized prospective study for head and neck cancer[9]. Using this RT schedule, patients with esophageal carcinoma were treated and our study aimed to evaluate tumor response and normal tissue toxicity.

## MATERIALS AND METHODS

### Materials

From October 2003 to December 2005, 60 unresectable or medically inoperable patients with esophageal carcinoma were enrolled and randomized into two groups by the sealed envelope method. The project of clinical randomized trial on seven-days-per-week continuous accelerated irradiation (30 patients) *vs* conventional treatment (30 patients), including the criteria for patient eligibility, the diagnostic procedure, the randomization method, the fractionation schemes of treatment techniques, and patient care was approved by the Ethical Committee of Xuzhou Cancer Hospital. All patients received full information concerning the aim of the study, diagnostic and treatment procedures, medical care, risk of acute and late sequelae before they entered the trial. All patients gave informed consent to this study.

Only patients with histologically proven squamous cells of esophageal carcinoma were included in the trial. Additional criteria for eligibility were age $\leqslant$ 75 years, Karnofsky performance status $\geqslant$ 70, white blood cell and hemoglobin levels within normal range, and no prior treatment. The pretreatment evaluation generally included chest radiography, chest CT scan, esophageal barium film, and ultrasound examination of the abdomen, including liver, kidney, spleen, and retroperitoneal lymph nodes, and liver and renal function tests. Based on examinations mentioned above, tumor staging was performed according to the TNM staging system of the 1997 American Joint Committee on Cancer staging system. Patients' characteristics are presented in Table 1 which shows comparable distribution of biological and clinical factors in both groups of the trial.

**Table 1 Patients' characteristics**

| Characteristic | CAIR group | CR group | $\chi^2$ or $t$ | $P$ |
|---|---|---|---|---|
| $n$ | 30 | 30 | | |
| Gender | | | 0.30 | 0.584 |
| Male | 19 | 21 | | |
| Female | 11 | 9 | | |
| Age (yr) | 66.0 ± 8.0 | 70.9 ± 9.4 | 1.781 | 0.083 |
| Length (cm) | 3-10 | 2-12 | | |
| Average (cm) | 5.5 ± 1.8 | 6.2 ± 3.1 | 0.962 | 0.342 |
| Location | | | 0.018 | 0.985 |
| Upper-thoracic | 4 | 6 | | |
| Middle-thoracic | 23 | 19 | | |
| Lower-thoracic | 3 | 5 | | |
| Stage | | | 1.920 | 0.089 |
| Ⅰ | 0 | 2 | | |
| Ⅱ | 17 | 12 | | |
| Ⅲ | 13 | 16 | | |
| WBC ($\times 10^9$/L) | 6.4 ± 1.9 | 6.1 ± 2.0 | 0.443 | 0.660 |
| HGB (g/L) | 138.4 ± 14.4 | 131.4 ± 17.1 | 1.411 | 0.166 |

### Methods

**Radiation methods:** Radiation source was 6MV-X-ray linear accelerator. For the design of the radiation fields for all patients, a three-field approach was used: one anterior and two posterior oblique portals.The length of the field should cover clinical tumors with 3 cm extended margin at both ends of the lesion. The width of the fields was adjusted to cover gross tumors with 2 cm margins to include the subclinical lesions. RT in CAIR group was 2 Gy/fraction per day for 7 d/wk with a total dose of 50-70 Gy (average dose 64.2 Gy), the overall time of irradiation was 3.6-5.0 wk (average 4.6 wk). RT in CR group was 2 Gy/fraction per day for 5 d/wk with a total dose of 40-70 Gy (average dose 61.7 Gy), the overall time of irradiation was 4.0-7.0 wk (average 6.4 wk).

**Tumor response and acute radiation reactions evaluated:** All patients received esophageal barium examination before, during, and at the end of RT. At the end of RT, the tumor response to RT was evaluated. A complete response (CR) was the disappearance of the mass shadow, no narrowing observed in the esophageal lumen, and no, or slight rigidity of the esophageal wall remains without residual ulceration. A partial response (PR) was a > 50% reduction in tumor bulk but < 100% resolution of the disease and a residual shallow ulcer with a diameter of < 1.5 cm, despite the disappearance of the mass shadow. A minor response (MR) was definite improvement in the barium esophagogram but with < 50% regression, with a large residual ulcer crater and/or narrowing of the esophageal lumen, regardless of the residual state of the mass shadow. No change (NC) was no improvement in the X-ray findings, with a deep and large residual ulcer or complete obstruction of the esophageal lumen, regardless of the residual state of the mass shadow[10]. Acute radiation toxicity was evaluated by the Radiation Therapy Oncology Group (RTOG) toxicity criteria.

### Statistical analysis

Statistical analysis was done by SPSS (Version 10.0). $t$-test, Chi-square test, or Wilcoxon-$W$ test were used to compare the patients' characteristics, tumor response, and normal tissue toxicity to RT of both groups.

## RESULTS

### Early tumor response

One patient in the CAIR group interrupted RT because of multi-metastasis and another patient in CR group died from cardiac muscle infarction in the schedule. Within three months after RT, the patients that completed the schedule planed were evaluated by criteria as described above. In the two groups, efficiency rate (CR plus PR) was 82.8% (24/29) and 58.6% (17/29), respectively and, accordingly, the inefficiency rate (MR plus NC) was 17.2% (5/29) and 41.4% (12/29), respectively. The difference in tumor response to RT was statistically significant, the efficiency rate in the CAIR group was higher than the CR group ($P$ = 0.047). The immediate response of the two groups of patients to RT are listed in Table 2.

### Acute radiation reactions

Table 3 shows the acute radiation reactions during the treatment course and up to three months after RT. We found that acute radiation esophagitis and tracheitis in both groups was mainly grade Ⅰ-Ⅱ and the difference between the two groups was not statistically significant. No patient received treatment resulting in intolerable acute

**Table 2 Tumor response to RT *n* (%)**

| Group | CR | PR | MR | NC | $\chi^2$ | *P* |
|---|---|---|---|---|---|---|
| CAIR | 8 (27.6) | 16 (55.2) | 4 (13.8) | 1 (3.4) | 4.08 | 0.047 |
| CR | 6 (20.7) | 11 (37.9) | 12 (41.4) | 0 | | |

radiation reactions in either group.

### *Impact on blood cell and hemoglobin level*

In the CAIR group, the total number of white cells declined below normal level in 5 patients within two weeks after beginning RT. In three of them, white cell counts normalized by medical intervention. In three patients of the CR group, total number of white cell declined below normal level. In both groups, there were two whose patients, total number of white cells did not increase right up to the end of RT. Furthermore, all patient's hemoglobin level had no statistically significant change during the treatment course.

## DISCUSSION

Esophageal carcinoma is one of most common malignant diseases in China. The prognosis for patients with esophageal carcinoma is extremely poor. The five years survival rate is 5%-10% for CR alone. The poor prognosis is the result of both local treatment failure, seen in up to 80% of cases, and early disease dissemination[3,10]. Thus, for esophageal carcinoma, local control is at present the most important factor in prolonging survival. Accelerated repopulation of tumor cells during conventionally fractionated radiotherapy is a proposed reason of failed local control in head-and-neck tumors. In the clinical setting, one goal of treatment is to limit the extent of tumor cell regeneration that occurs during a course of fractionated RT. There is radiobiological rationale and convincing evidence from a number of clinical studies that a therapeutic gain may be achieved, at least for head and neck cancers, when conventional fractionation is modified by reduction in size of dose per fraction with the increase in total dose, reduction of overall treatment time, or both[9,11]. Rapid repopulation of tumor clonogens is able to compensate about 0.6 Gy/d[5], beginning after a lag period, which on average, in head and neck tumors is about 3-4 wk from the inception of therapy[12]. Thus, shortening overall treatment time should limit the extent of accelerated tumor repopulation, and therefore one may expect an increase in the probability of tumor control for given total dose. Since treatment time is thought to have little or no influence on the response of late reacting normal tissue, a reduction in overall treatment time would not be expected to affect the incidence and severity of late normal tissue injury (provided the size of dose per fraction is not increased and the interfraction interval is sufficient for repair to be completed). These concepts became a basic rationale for the development of various altered fractionation strategies as an alternative to conventional fractionation[13,14]. Simultaneously with reduced treatment time schedules, multiple fraction per day regimens have been used[15-17]. They allow a higher total dose to be given within the tolerance of late responding normal tissues.

**Table 3 Grade of acute reaction (RTOG) of esophagus and bronchus according to fractionation regimen *n* (%)**

| Groups | Ⅰ | Ⅱ | Ⅲ | Ⅳ | *Z* | *P* |
|---|---|---|---|---|---|---|
| Esophagitis | | | | | 0.855 | 0.376 |
| CAIR | 6 (20.7) | 19 (65.5) | 4 (13.8) | 0 | | |
| CR | 11 (37.9) | 13 (44.8) | 5 (17.2) | 0 | | |
| Tracheitis | | | | | 0.051 | 0.959 |
| CAIR | 14 (48.3) | 10 (34.5) | 5 (17.2) | 0 | | |
| CR | 13 (44.8) | 13 (44.8) | 3 (10.4) | 0 | | |

One modality currently in use to achieve this goal is the concomitant boost schedule designed by Maciejewski B *et al*[18] on carcinoma of the head-and-neck. Their data indicated when dose per fraction of 2.0 Gy given once-a-day at 24 h intervals, an analysis of severe mucosal reactions shows significant difference between CAIR group and CR group. Developed severe mucositis was 48% of patients and 5%, respectively. Their conclusion was that the accelerated treatment, using daily fractions of 2.0 Gy, 7 d per week, gives unacceptable toxicity. When dose per fraction was lowered from 2.0 Gy to 1.8 Gy, the overall rate of acute mucosal reactions decreased to 10% as reported by Skladowski K *et al*[9]. Both the 3 years local control rate and the 3 years survival rate was improved.The 3-year local tumor control was 82% in the CAIR group and 37% in the CR group, and 3 years overall survival was 78% and 32%, respectively.

In our trial, dose per fraction was 2.0 Gy in both groups. The data showed that acute radiation esophagitis and tracheitis in both groups was mainly grade I-II, and the difference between the two groups was not statistically significant. No patient received treatment resulting in acute radiation reactions that could not be tolerated in in either group. The immediate response of two group patients to RT was statistically significant. The efficiency rate (CR plus PR) was 82.8% (24/29) and 58.6% (17/29), respectively, the CAIR group was significantly better than the CR group ($P = 0.047$). The overall treatment time has been shortened by two weeks, as given in the result section.

The present trial demonstrates that seven-day-per-week continuous accelerated irradiation provides significant therapeutic benefit for patients with esophageal carcinoma with regard to both response and toxicity to RT. Fractions of 2.0 Gy could keep acute radiation esophagitis and tracheitis on a tolerable level (different from Maciejewski B). The results of our trial suggest that local control in patients with esophageal carcinoma might be improved by CAIR compared to CR methods, when using dose escalation by continuous accelerated irradiation (with sufficiently long interfraction intervals) and a shorter overall treatment time.

## Abstract

**AIM:** To investigate the diagnostic and therapeutic value of laparoscopy in patients with massive small intestinal bleeding.

**METHODS:** Twenty-two patients with massive small intestinal bleeding and hemodynamic alteration underwent laparoscopic laparotomy in our unit from December 2002 to April 2005. Post pathologic sites were found, laparoscopy- or laparoscopy-assisted part small intestinal resection including pathologic intestinal site and enteroanastomosis was performed in all these patients.

**RESULTS:** The bleeding sites were successfully detected by laparoscopy in all these 22 patients. Massive small intestinal bleeding was caused by jejunum benign stromal tumor in 8 cases, by jejunum potential malignant stromal tumor in 5 cases, by jejunum malignant stromal tumor in 1 case, by Mechel's diverticulum in 5 cases, by small intestinal vascular deformity in 2 cases, and by ectopic pancreas in 1 case. A total of 16 patients underwent laparoscopy-assisted enterectomy and enteroanastomosis of small intestine covering the diseased segment and 6 patients received enterectomy of the diseased segment under laparoscope. No surgical complications occurred and the outcome was satisfactory.

**CONCLUSION:** Laparoscopy in diagnosis and treatment of massive small intestinal bleeding is noninvasive with less pain, short recovery time and definite therapeutic efficacy.

**Key words:** Small intestine; Bleeding; Laparoscopy; Meckel's diverticulum; Stromal tumor

## INTRODUCTION

Massive small intestinal bleeding is rare, accounting for 0.4% of all cases of gastrointestinal bleeding. So far there has been no effective method for its definite diagnosis due to its nonspecific clinical symptoms and signs, thus its treatment is a challenge for clinical surgeons[1-3]. From December 2002 to April 2005, 22 patients with suspected massive small intestinal bleeding admitted to our department received laparoscopy for definitive diagnosis and treatment. The outcomes were satisfactory.

## MATERIALS AND METHODS

### *Clinical data*

Twenty-two patients with suspected massive small intestinal bleeding (13 males and 9 females) were included in the present study. Their age ranged from 16 to 61 years with a mean age of 38.6 years. The course of the disease ranged from 20 d to 10 years with a mean of 36.6 mo. The patients had recurrent massive bleeding, ranging from 3 to 15 times prior to admission with a mean of 5 times. The chief complaints were bright red or catsup-like bloody stools with concurrent abdominal pain in 4 cases. On the day of admission, the amount of bleeding was more than 1200 mL with concurrent hemodynamic changes. Hemoglobin ranged from 40.6 g/L to 66 g/L with a mean of 50.6 g/L. Massive small intestinal bleeding was suspected after bleeding from gastric duodenum, colon and rectum was excluded. Double contrast of barium and air examination of the alimentary tract were performed in 6 patients, of them 1 had small intestinal tumor and 1 had Meckel's diverticulum. Small intestine enteroscopy was carried out in 5 patients, of them 2 had small intestinal bleeding due to Mechel's diverticulum and 1 had small intestinal stromal tumor (Figures 1A and B). Emission CT scanning (ECT) of the abdominal cavity was performed in 6 patients, of them 2 had a small intestinal bleeding due to Mechel's diverticulum and small intestinal tumor (Figure 2). Digital subtraction angiography (DSA) was conducted

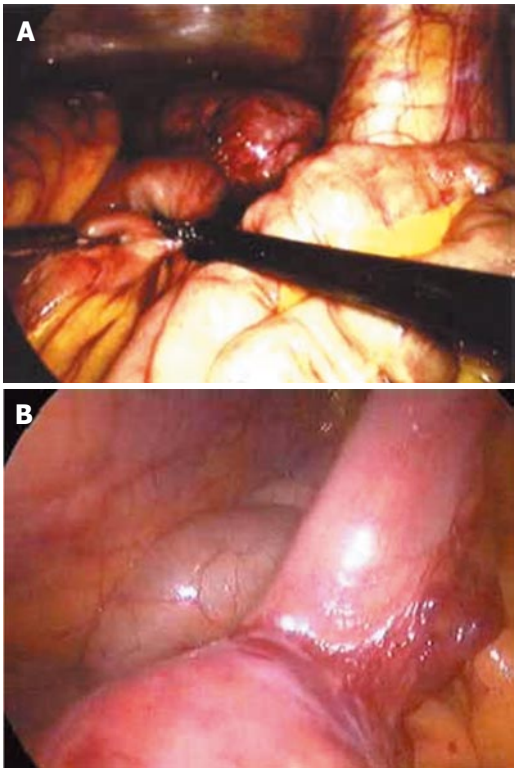

**Figure 1** Laparoscopic laparotomy showing small intestinal bleeding (**A** and **B**).

in 3 patients, of them 1 had a jejunum tumor and 1 had the contrast medium in blood vessels of terminal ileum flowing into the intestinal cavity where pathological changes were not defined.

### *Surgical procedures*

Before operation, shock was treated with blood transfusion until hemoglobin level reached 90 g/L or above. After the blood pressure became normal, emergency laparoscopic laparotomy was performed under general anesthesia with the patients at a head-down position. A transverse incision (1 cm) was made 0.5 cm inferior to the umbilicus to establish pneumoperitoneum with a pressure of 13 mmHg. A hole was made inferior to the umbilicus to insert the laparoscope of 10 mm at 30℃ to examine the abdominal viscera. Under the guidance of a laparoscope, a second and third holes of 5 mm were made at the level of umbilicus on the midlines of right and left clavicles. The second hole was used to check the whole small intestine from the part of the ileum and cecum to Treitz's ligament with a non-impairing laparoscopic bowel clamp, during which the proximal segment of intestinal tract from the boundary of the hematocele was observed and accumulated blood was squeezed out. The recurrent hematocele showed the definite bleeding site. When failing to reach the bleeding site, two alternative methods were used: perioperative small intestine enteroscopy to check the transparency of the intestinal wall with the help of a light source at the top of the enteroscope to localize the bleeding site, thus the small intestine near the hematocele was clamped out of the abdominal wall for incision and perioperative enteroscopy (Figure 3). After the bleeding site was localized, the third hole was dilated to make a 5 cm incision through the left rectus abdominis muscle to clamp the diseased intestinal segment, followed by resection of the diseased intestinal tract according to the laparotomy procedures (Figures 4A and B). In some cases, removal of the diseased small intestine and enteroanastomosis were performed under a laparoscope by transverse dilation of the hole inferior to the the umbilicus.

**Figure 2** An oval stromal tumor causing small intestinal bleeding. Laparoscopic laparotomy found there is an oval stromal tumor on the up segment of jejunum, with clear borderline and smooth surface, having no adhesion with other tissue around it. Expansive abdominal excision was performed to draw out the tumor for resection.

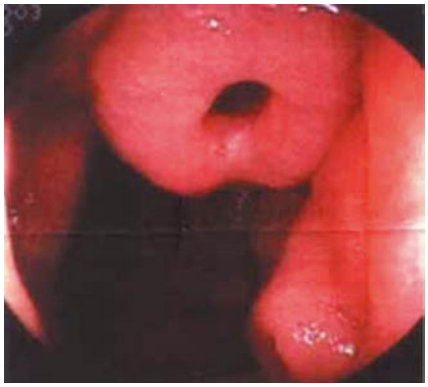

**Figure 3** Electric intestinal endoscopy showing a benign jejunum tumor. A deep ulcer sunken on the top of the tumor could be seen.

## RESULTS

The bleeding sites in these 22 patients were successfully found, of them 2 received laparoscopy combined with perioperative enteroscopy, 4 underwent perioperative incision of the small intestinal tract under laparoscope combined with perioperative enteroscopy under laparoscope. Massive small intestinal bleeding was caused by benign jejunum stromal tumor in 8 cases, by potential jejunum malignant stromal tumor in 5 cases, by malignant jejunum stromal tumor in 1 case, by Mechel's diverticulum in 5 cases, by small intestinal vascular deformity in 2 cases with 1 case having 2 sites of jejunum vascular dysplasia with concurrent intestinal mucous ulcer (the two sites were 10 cm and 40 cm from Treitz's ligament respectively) and by ectopic pancreas in 1 case. A total of 16 patients underwent laparoscopy-assisted enterectomy

and enteroanastomosis of small intestine covering the diseased segment and 6 patients received enterectomy to remove the diseased segment under laparoscope. The operative duration ranged from 45 min to 180 min with a mean of 90 min. After operation, all patients recovered passing flatus through the anus and taking food within 2 d. No surgical complications occurred and the mean postoperative hospitalization time was 6.5 d. Phone call follow-up was conducted for 2-24 mo with no recurrent alimentary tract bleeding. The surgical outcome was satisfactory.

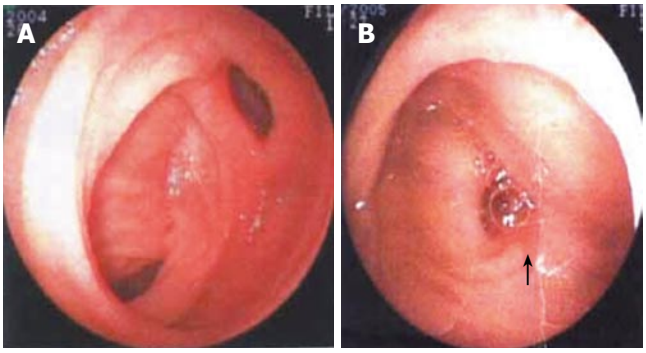

**Figure 4** Double balloon enteroscopy showing the clamped diseased intestinal segment (**A**) and resected diseased intestinal tract (**B**). The double-balloon enteroscope was pushed 200 cm into the ileum through anus. Diverticulum was found in the ileum 90-100 cm away from the ileocecal valve, at the opening of which a 1.2 cm × 1.0 cm ulcer was observed. The ulcer had thin covering of lichenoid substance, but no active bleeding. No other abnormalities were found. Meckel's diverticulum was diagnosed.

## DISCUSSION

The small intestine is about 3-5 m long, occupying three fourths of the whole gastrointestinal tract. The ansa intestinalis is circuitous overlapping active peristalsis and its location varies greatly in the abdominal cavity. Since massive small intestinal bleeding lacks specific clinical symptoms and signs, it is difficult to diagnose and locate it by routine examinations[4-6]. Small intestine enteroscopy is the most specific method for its diagnosis but its application is limited because this examination is time-consuming, extremely unpleasant, and causes bleeding and perforation with a high false positive rate[7-13]. Recently, a capsule endoscope is under clinic experiment, but it cannot perform biopsy and make pathological diagnosis[10-13]. Stromal tumor is the most frequent cause of small intestinal bleeding[1-3,5], Mechel's diverticulum and vascular conditions are the second frequent cause of small intestinal bleeding[1,4,6]. False positive tumor may not be shown on X-ray imaging of the whole alimentary tract because the bleeding foci often grows in exogenesis[14,15]. During the active stage of small intestinal bleeding, DSA can find the contrast medium flowing from the tumor site into the intestinal tract, showing local shadow with a slightly high density and embolism treatment can be conducted during diagnosis[15]. $^{99m}$Tc-sestamibi is sensitive to mild intestinal bleeding , thus marking erythrocytes for gastrointestinal bleeding imaging, while it has no diagnostic value in the resting phase of bleeding or the bleeding being less than 0.05 mL/min[16]. At present, the diagnosis of massive obscure gastro-intestinal bleeding is usually made by exposure laparotomy, which is invasive with a false positive rate of 5%. Besides, patients with massive small intestinal bleeding are often weak with poor conditions and unstable vital signs, which prevent them from undergoing a major surgical operation.

Laparoscopy can clearly, directly and conveniently observe the whole intestinal serosa and mesentery and the small intestinal conditions can be managed with its assistance[11,16-20]. From December 2002, we have tried to use laparoscopy to manage obscure gastrointestinal bleeding in patients with massive small intestinal bleeding. The outcomes showed that laparoscopy could find the bleeding site of massive obscure gastro-intestinal bleeding. It is noninvasive with less pain and short recovery time. We believe that laparoscopy has a promising prospect in diagnosis and treatment of acute massive small intestinal bleeding and can be used as a routine method for the management of massive small intestinal bleeding[11,16,18,20]. Since intestinal stromal tumor and ectopic pancreas that cause small intestinal bleeding are generally small, examination followed by laparotomy cannot find the bleeding foci. Perioperative small intestine enteroscopy in combination with removal of hematocele can avoid the disadvantages of enteroscopy, such as time-consuming, extreme unpleasantness and complications of bleeding and perforation. Laparoscopy can find the bleeding foci, showing the advantages of noninvasive surgery. For those whose bleeding site is not defined by laparoscopy, perioperative enteroscopy of small intestine generally can reach the definite bleeding foci, deserving wide promotion[11,17,19,20].

In the present study, small intestinal bleeding occurred, leading to insufficient blood volume, the average hemoglobin level was 50.6 g/L. Once laparoscopy is accepted by patients, the laparoscope equipment and surgical appliances should be prepared as fast as possible for immediate surgery when shock takes a favorable return. The patient should lie on his/her left side at the head-down position. Firstly, parenchymatous viscera should be generally examined, followed by examination of the whole small intestine. This part of the ileum and cecum has a relatively stable location in the abdominal cavity and thus is easily exposed. Cecum should be used as the landmark during laparoscopic exploration, which starts from the terminal ileum with each 10 cm as one segment to the Treize's ligament. One patient had 2 sites with small intestinal vascular deformity so that exploration of the whole small intestine segment by segment was emphasized to avoid missing any focus. The laparoscopic exploration of small intestinal hemangiomas or vascular deformity should be more careful. The intestinal wall should be carefully explored for local prominence, pitting, overlapping and abnormal mesentery. The suspected bleeding segment should be palpated carefully with clamps to feel its hardness, flexibility, and activity. In case of active massive bleeding, intestinal peristalsis is active and the blood often accumulates in the distal bleeding segment which is dark blue under laparoscope. The suspected foci can be confirmed if emptied, blocked and reformed

hematocele is found. The time-consuming examination is mainly due to repeated enteroscopy. One patient with a history of 3-year bleeding had no positive laparoscopic findings. Repeated examinations had no other positive findings. A slightly hard intestinal wall of this part was touched during exploration, which was ectopic pancreas confirmed by pathological biopsy.

After the bleeding site was found by laparoscopy, laparoscopy-assisted enterectomy and enteroanastomosis were performed, during which an exploratory incision about 5 cm in length was made at the umbilicus level on the midline of the left clavicle to remove the diseased intestinal segment. The resected part of the small intestine should be 5 cm longer than the bleeding site that may result in a fast and reliable excision with light contaminations in the abdominal cavity. Enterectomy and enteroanastomosis can be performed under laparoscope in those whose bleeding sites are adjacent to the Treize's ligament, thus the diseased segment can be conveniently removed[1,2,11,16-20].

In conclusion, laparoscopy in diagnosis and treatment of massive small intestinal bleeding is noninvasive with less pain, short recovery time and definite therapeutic efficacy and has rather good clinical application prospects.

## Abstract

Acute pancreatitis (AP) secondary to drugs is uncommon, with an incidence ranging from 0.3% to 2.0% of AP cases. Drug-induced AP due to statins is rare, and only 12 cases have thus far been reported. In this case report, we report a case of a 50-year-old female on pravastatin therapy for 3 d prior to developing symptoms of AP. The common etiological factors for AP were all excluded. The patient was admitted to the intensive care unit secondary to respiratory distress, though she subsequently improved and was discharged 14 d after admission. Although the incidence of drug-induced AP is low, clinicians should have a high index of suspicion for it in patients with AP due to an unknown etiology. Clinicians should be aware of the association of statins with AP. If a patient taking a statin develops abdominal pain, clinicians should consider the diagnosis of AP and conduct the appropriate laboratory and diagnostic evaluation if indicated.

**Key words:** Drug-induced pancreatitis; Acute pancreatitis; Statins; Pravastatin.

Tsigrelis C, Pitchumoni CS. Pravastatin: A potential cause for acute pancreatitis. *World J Gastroenterol* 2006; 12(43): 7055-7057

## INTRODUCTION

Acute pancreatitis (AP) secondary to drugs is uncommon, with an incidence ranging from 0.3% to 2.0% of AP cases[1]. The literature on drug-induced AP consists mostly of case reports, though there have been reviews analyzing the association of various drugs with AP[1-3]. The following drugs have been definitely associated with AP in many of the reviews: azathioprine, chlorothiazide, hydrochlorothiazide, estrogens, furosemide, sulfonamides, tetracycline, L-asparaginase, sulindac, valproic acid, didanosine, salicylates, aminosalicylates (mesalamine, sulfasalazine), calcium, sodium stibogluconate, pentamidine, vinka alkaloids, and metronidazole. There are many other drugs which have been implicated as having probable or possible associations with AP, including 6-mercaptopurine, methyldopa, ACE inhibitors, clozapine, rifampicin, cyclosporine, and many other drugs.

There have been 12 cases of AP associated with statins described thus far[4-14]. In four of the cases presented, reintroduction of the statin led to a recurrent attack of AP[4-6,12]. In this case report, we report a case of AP associated with pravastatin therapy. In view of the magnitude of use of statins in prevention of coronary artery disease, even an infrequent occurrence is worth reporting.

## CASE REPORT

A 50-year-old female presented to our hospital with right upper quadrant abdominal pain, nausea, and vomiting for 1 d. Four days prior to admission, she was started on 10 mg pravastatin by mouth daily, though the patient stopped this medication the day prior to admission as she attributed her symptoms to the new medication. Her lipid panel one month prior to admission showed a total cholesterol level of 262 mg/dL, triglyceride level of 268 mg/dL, high-density lipoprotein (HDL) level of 52 mg/dL, and low-density lipoprotein (LDL) level of 156 mg/dL. She was also treated for hypertension with 10 mg enalapril by mouth daily for the past 18 mo, and 25 mg hydrochlorothiazide by mouth daily for 6 years. She took 2.5 mg olanzapine by mouth daily for the past year for severe anxiety, and a combination of 500 mg/1 mg metformin and rosiglitazone (Avandamet™) in the past year for type Ⅱ diabetes mellitus. She had osteoarthritis of both knees, and took 325 mg/37.5 mg one to two tablets of acetaminophen/tramadol (Ultracet™) as needed for pain. Of note, she was on atorvastatin 2 years prior to admission for a period of 3 d, though this was discontinued secondary to generalized body pain. Laboratory tests were not performed at that time. She had a cholecystectomy 16 years prior to admission. The common etiological factors for AP such as alcoholism, trauma to the abdomen, HIV disease, hypertriglyceridemia, and hypercalcemia were all excluded.

**Table 1 Laboratory values**

| | Admission | 48 h |
|---|---|---|
| Amylase (U/L) | 914 | 280 |
| Lipase (U/L) | 1613 | 261 |
| WBC ($mm^3$) | 26300 | 21500 |
| HCT (%) | 53.9 | 42.4 |
| LDH (IU/L) | 389 | 645 |
| Glucose (mg/dL) | 495 | |
| AST (IU/L) | 18 | |
| ALT (IU/L) | 28 | |
| Calcium (mg/dL) | 10.2 | 6.5 |
| $PO_2$ (mmHg) | | 76 |
| BUN (mg/dL) | | 17 |
| Base deficit | | -1 |
| Fluid sequestration (L) | | 2.8 |
| Total cholesterol (mg/dL) | 202 | |
| Triglycerides (mg/dL) | 118 | |

On physical examination, her blood pressure was 158/104 mmHg, heart rate was 131 beats per minute, respiratory rate was 30/min, temperature was 98 degrees Fahrenheit, and $SpO_2$ was 93% breathing room air. Her abdominal examination revealed hypoactive bowel sounds, with diffuse tenderness without rebound tenderness or guarding.

Laboratory values are included in Table 1. Three out of five Ranson criteria were fulfilled on admission, and two out of six criteria were fulfilled after forty-eight hours.

She was admitted to the intensive care unit, and given isotonic intravenous fluids and meperidine for pain control. CT scan of the abdomen showed inflammatory changes within the pancreas, though no discrete peripancreatic fluid collections were noted. Abdominal ultrasound did not show biliary ductal dilatation. Magnetic resonance cholangiopancreatography showed a normal pancreatico-biliary system. She developed respiratory distress, though this resolved after support with BIPAP and diuretic therapy. She improved significantly following this, and was discharged 14 d after admission.

Of note, she was restarted on enalapril during the admission and continued to take enalapril without any adverse effects. She was not restarted on pravachol or hydrochlorothiazide. Olanzapine and metformin/rosiglitazone were also restarted without any adverse effects. The patient was last seen 4 mo after discharge, and her hypertension and diabetes were well controlled on enalapril, metformin, rosiglitazone, atenolol, and glipizide. She also continued to take olanzapine without any adverse effects.

## DISCUSSION

Statin-induced AP is rare and only 12 cases have thus far been reported in the literature[4-14]. Although AP is a rare side effect of statin therapy, there seems to be a strong association between statins and AP, as there have been four cases where reintroduction of the statin has led to a recurrence of AP[4-6,12]. In our case report, the patient was on pravastatin for three days prior to symptom onset, and the outcome was favorable. A rechallenge test involving documenting AP development during treatment with a drug, its disappearance after stopping the drug, and recurrence after reintroduction of the drug, was not performed in this patient due to ethical issues. This would be the most reliable evidence that pravastatin caused AP in this patient.

No data about a potential mechanism for statin-induced AP are available at this time. In previously published cases of statin-induced pancreatitis, the duration of statin treatment until the onset of AP varied from 8 h to 7 years, though the vast majority of patients presented within 6 mo of introduction of the statin[4-14]. Generally, the outcome is favorable in statin-induced AP, though there was a fatality in one case after a four-month hospital stay[13].

A number of medications that our patient took are known to be associated with AP. Thiazide diuretics[15], ACE inhibitors[16], atypical antipsychotics[17], biguanides[18], and acetaminophen[19] have been associated with AP. However, continuation of all of the above medications, with the exception of the thiazide diuretic, did not precipitate AP.

In conclusion, though the incidence of drug-induced AP is low, clinicians should have a high index of suspicion for it in patients with AP due to an unknown etiology. A diligent review of medications should be performed, focusing on drugs that have been associated with drug-induced AP[1-3]. Clinicians should be aware of the association of statins with AP. If a patient taking a statin develops abdominal pain, clinicians should consider the diagnosis of AP and conduct the appropriate laboratory and diagnostic evaluation if indicated.

## Abstract

Carcinoids involving the ampulla of Vater are rare lesions that may produce painless jaundice. The published data indicate that these tumors, in contrast to their midgut counterparts, metastasize in approximately half of cases irrespective of primary tumor size. Therefore, radical excision in the form of pancreaticoduodenectomy is recommended regardless of tumor size. As with other gastrointestinal carcinoid tumors, biological treatment with octreotide analogues can be applied to symptomatic patients. Tumor-targeted radioactive therapy is a newly emerging treatment option. We here report case of a carcinoid tumor of the ampulla of Vater presenting as painless jaundice in a 65-year old man and review the relevant literature, giving special attention to the morphologic features, clinical characteristics, and treatment modalities associated with this disease process.

**Key words:** Ampulla of Vater; Histopathologic features; Clinical characteristics; Radical excision

## INTRODUCTION

Carcinoid tumors belong to the family of neuroendocrine tumors, which usually grow slowly with distinct biological and clinical characteristics. The incidence of these tumors is approximately 2.5 in 100 000 people per year. The appendix is the most common location, accounting for roughly 60% of all cases, followed by the ileum, the rectum and the stomach. Approximately 2% of cases involve the duodenum, 1% the biliary tract, and 0.6% the pancreas[1]. Carcinoid tumors that involve the ampulla are an extremely rare clinical entity, with 93 reported cases[2-7]. We report another case of a carcinoid tumor of the ampulla of Vater presenting as painless jaundice. The relevant literature is reviewed, giving special attention to the morphologic features, clinical characteristics, and treatment modalities associated with this disease process.

## CASE REPORT

A 65-year old otherwise healthy man presented with a 2-wk history of intractable pruritus. Review of systems was notable for dark urine. He denied clay-colored stool, diarrhea, flushing or dyspnea. Physical examination was remarkable for mildly icteric sclerae. There were no palpable abdominal masses, adenopathy, or café-au-lait spots. Laboratory studies indicated a markedly elevated level of alkaline phosphatase (712 U/L). Total bilirubin was 29 mg/L. Abdominal computed tomography (CT) scan revealed significant dilatation of both the common bile duct (CBD) and the pancreatic duct, without any obvious periampullary mass, retroperitoneal adenopathy or liver lesions (Figure 1).

Endoscopic retrograde cholangiopancreatography (ERCP) showed a prominent major ampulla with normal overlying mucosa. The CBD measured 17 mm with an abrupt "shoulder" in the region of the ampulla (Figure 2). The ampullary obstruction was relieved with temporary biliary stent placement. Subsequent endoscopic ultrasonography (EUS) identified a 23 mm × 27 mm well circumscribed, round, hypoechoic mass in the region of the ampulla adjacent to the biliary stent, which was distinct from the pancreatic tissue and the duodenal wall (Figure 3). EUS-guided fine needle biopsy was suggestive of a carcinoid tumor. Positron emission tomography (PET) scan confirmed a lesion of increased metabolism in the vicinity of the pancreatic head, and excluded distant metastases. Urinary 5-hydroxyindoleacetic acid (5-HIAA), and serum carcinoembryonic antigen (CEA), CA19-9, serotonin, somatostatin and chromogranin A levels were all within normal limits.

A pylorus-preserving pancreaticoduodenectomy was performed. Pathology revealed a $T_3$, N1 ampullary carcinoid extending into the peripancreatic fat, with 7/13 positive lymphnodes. Immunohistochemically, tumor cells expressed chromogranin A and synaptophysin, and focally serotonin and somatostatin, which were stained negative

**Figure 1** The characteristic "double duct sign" on abdominal CT is indicative of obstruction at the level of the ampulla.

for insulin, glucagon, and gastrin. The patient recovered uneventfully and was discharged to home on the seventh postoperative day. The follow-up plan consists of structural studies and biochemical markers every 3 mo up to 1 year and every 6 mo thereafter. At 9 mo he remained asymptomatic with no radiographically or biochemically detectable disease.

## DISCUSSION

In 1888 the first case of a carcinoid tumor was reported as a lesion of the ileum[8]. Oberndorfer coined the term *karzinoide* ("carcinoma-like") in 1907 to distinguish these presumptively benign neoplasms from the malignant cecal adenocarcinomas[9]. Carcinoids have been detected in the entire gastrointestinal tract, from the esophagus to the rectum, as well as in extra-gastrointestinal locations, such as the bronchus, the testis, the ovary and the larynx. In contrast to the relative rarity of duodenal carcinoids, those of the ampulla of Vater represent a medical curiosity with only 93 cases reported in the world literature.

Indicative of their location, ampullary carcinoids cause jaundice as the leading symptom in approximately two-thirds of cases. Forty percent of patients present with abdominal pain and few with pancreatitis, weight loss, or malaise[2-7]. Every fourth patient has von Recklinghausen's disease[2]. The etiology is not clear, but it is likely that mutation of the NF-1 tumor suppressor gene may predispose to the development of ampullary carcinoids. In contrast to midgut carcinoids, foregut carcinoids are very rarely associated with carcinoid syndrome. In the largest reported series of 73 ampullary carcinoid cases, a history of flushing, diarrhea, or asthma was found in only 2 patients who also had extensive liver metastases[2]. Walton *et al*[4] have described a "variant" form of carcinoid syndrome that may occur in association with gastric or other foregut carcinoid tumors, which may be hidden by the elaboration of other hormonally active substances, such as adrenocorticotropic hormone, parathyroid hormone, calcitonin, gastrin, vasoactive intestinal peptide, growth hormone, or insulin, but responds to treatment with antihistamines.

Immunohistochemistry is of principal importance in accurately diagnosing ampullary carcinoids. Makhlouf *et al*[7] compared the immunohistochemical features of 12 ampullary and 53 duodenal carcinoids and demonstrated that the former group always expresses chromogranin A, but almost never expresses gastrin which has been identified in 56% of cases of duodenal carcinoids. Apart from its role in immunohistochemical diagnosis, chromogranin A has proven particularly useful as a tumor marker for monitoring disease response and progression in patients with gastrointestinal carcinoids. Analyzing data from 301 such patients, Janson *et al*[10] found that serum chromogranin A level > 5000 μg/L (normal value: 0-76 μg/L) is an independent predictor of poor survival.

Surprisingly, in the case of ampullary carcinoids, tumor size does not correlate with metastatic potential. In the case review by Hatzitheoklitos *et al*[2], metastasis is present in 46% of ampullary carcinoids > 2 cm, in 50% of tumors between 1-2 cm, and in 66% of tumors < 1 cm. Makhlouf *et al*[7] have reported two tumors measuring less than 2 cm demonstrating metastases, as well as a 5 cm tumor without any evidence of metastatic disease. These data indicate that carcinoids involving the ampulla of Vater metastasize in approximately half of the cases regardless of tumor size.

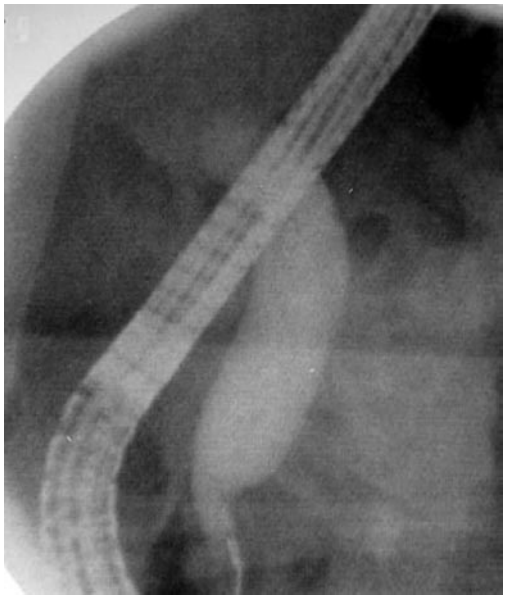

**Figure 2** ERCP showing a markedly dilated CBD with an abrupt "shoulder" in the region of the ampulla, suggestive of a periampullary mass.

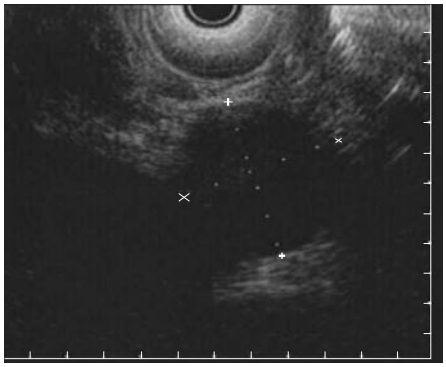

**Figure 3** EUS identifying a 23 mm x 27 mm well circumscribed, round, hypoechoic mass in the region of the ampulla, which is distinct from the duodenal wall.

This is opposed to the classic teaching regarding midgut and hindgut carcinoids, in which the incidence of metastasis is felt to be a function of tumor size and is significantly higher with larger tumors.

Accordingly, the size of ampullary carcinoids cannot predict node-positive status, and therefore cannot determine the extent of operation. Should every patient with this tumor undergo a pancreaticoduodenectomy? The small number of cases and reported follow-up in the literature are not sufficient to answer this question definitively. Instead, each case should be individualized realizing that the goal is complete tumor removal. Given the propensity of ampullary carcinoids smaller than 2 cm to show nodal involvement, and considering the safety of pancreaticoduodenectomy in experienced hands, radical excision should be the treatment of choice to completely extirpate the tumor-bearing tissue. It should be observed that in multiple reported cases, long-term survival has been achieved by local excision of the ampulla[2]. These recommendations, however, were made during a period of surgical history when the operative mortality rate for pancreaticoduodenectomy was high, and therefore are not applied currently.

In cases of liver metastases, surgical resection or other cytoreductive techniques, such as radiofrequency ablation and chemoembolization, have been shown to improve hormone-mediated symptoms, quality of life and survival in certain groups of patients[11]. Patients with slowly growing carcinoid tumors do not generally benefit from cytotoxic chemotherapy. Somatostatin analogues can induce a symptomatic and biochemical response, but more recent studies have also indicated a cytostatic effect[11]. Tumor-targeted radioactive treatment with $^{90}$yttrium and $^{177}$lutetium coupled to a somatostatin analogue is currently under clinical evaluation[12]. Preliminary data indicate interesting clinical potentials.

In summary, carcinoids of the ampulla of Vater are rare tumors. They can cause symptoms mainly secondary to their periampullary location. Up to 25% of patients have von Recklinghausen's disease. Carcinoid syndrome is uncommon, unless hepatic metastasis is present. Chromogranin A is an important tumor marker. Determination of histopathology is of utmost importance and involves specific immunohistochemical staining. Aggressive operative extirpation is the cornerstone of treatment and provides the only chance for cure. Biological treatment with somatostatin analogues can be applied in symptomatic patients with slowly growing neoplasms. Tumor-targeted radiotherapy has been introduced recently with promising results. Future therapy will be based on specific tumor biology and treatment will be customized for each individual patient.

## Abstract

Retroperitoneal fibrosis (RPF) is a rare condition of unclear etiology. It can cause ureteral obstruction. We present the unique case of a 54 years old female, who initially presented with spontaneous perforation of the cecum. Upon exploring the abdomen, the classical glistening white, unyielding retroperitoneal fibrosis was encountered. A right hemicolectomy was performed. Subsequently, the patient presented with bilateral ureteral obstruction, and later on with small bowel obstruction. Ureteral obstruction was treated with stents, and small bowel obstruction was treated with bypass. To our knowledge no case of idiopathic RPF presenting with features of both bilateral ureteral and small bowel obstruction has been reported in the literature.

**Key words:** Retroperitoneal fibrosis; Ureteral obstruction; Small bowel obstruction; Surgery for retroperitoneal fibrosis

Aziz F, Conjeevaram S, Phan T. Retroperitoneal fibrosis: A rare cause of both ureteral and small bowel obstruction. *World J Gastroenterol* 2006; 12(43): 7061-7063

## INTRODUCTION

Retroperitoneal fibrosis (RPF) is a rare condition of unclear etiology. It is believed to be immune-related. About two-thirds of the cases are thought to be idiopathic. We present a case of idiopathic RPF in a 54 years old female who developed bilateral hydronephrosis and then small bowel obstruction due to extrinsic compression from retroperitoneal fibrosis.

To our knowledge no case of idiopathic RPF presenting with features of both bilateral ureteral and small bowel obstruction has been reported in the literature. We recommend early surgical intervention in patients with advanced RPF who are unresponsive to steroids.

## CASE REPORT

A fifty four years old African-American female came to the emergency room with a five-day history of abdominal pain. She described it to be sharp in nature and localized mostly in the middle of the abdomen. She graded pain to be seven on a scale of zero to ten. The pain had no radiation or shifting. The patient also complained of nausea and three episodes of vomiting which was bilious in nature. The patient passed her last bowel movement three days ago and it was normal. She denied fever or shaking chills. Her past medical history was significant for hypertension, type Ⅱ diabetes mellitus and asthma.

Her past surgical history was significant for laparoscopic cholecystectomy done 6 years ago. On physical examination, she was afebrile and her vital signs were stable. She was awake and alert. She had normal heart sounds, and bilateral breath sounds. Her abdomen was soft, and had generalized and reboud tenderness. Her white blood cell count was 18000 cells/mm$^3$; the hemoglobin was 14 mg/dL and platelet count was 253 cells/mm$^3$. Her serum chemistry and coagulation tests were normal. Her flat and upright abdominal radiographs were normal. CT of the abdomen and pelvis showed extravasation of oral contrast and inflammation around the ascending colon (Figure 1). She was brought to the operating room and an exploratory laparotomy was performed via a midline incision. On entering the peritoneal cavity, dense intra-abdominal adhesions were encountered at the hepatic flexure. The classical glistening white, unyielding retroperitoneal fibrosis was encountered. The plaque predominantly encased both kidneys. It extended over the renal pelvis and upper ureters on both sides up to the level of aortic bifurcation and encased the great vessels in the midline. A 1 cm × 2 cm perforation was found in the cecum. A right hemicolectomy was performed. Pathology report showed fibrinous adhesions and inflammatory reaction around the site of perforation. No evidence of any tumor was seen. Patient's post-operative course was uneventful. She started a clear liquid diet on post-operative d 2, and was gradually advanced to a regular diet. The

**Figure 1** CT of Abdomen showing inflammation around right colon and extravasation of oral contrast.

**Figure 2** CT of abdomen showing bilateral hydronephrosis.

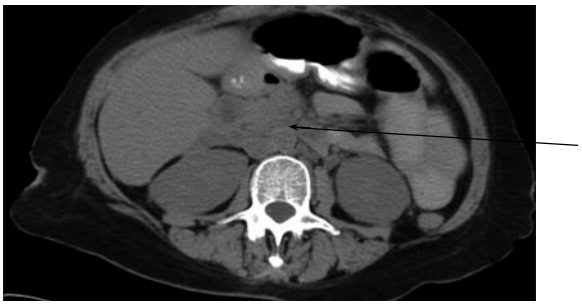

**Figure 3** CT of abdomen showing retroperitoneal fibrosis, encasing aorta and inferior vena cava.

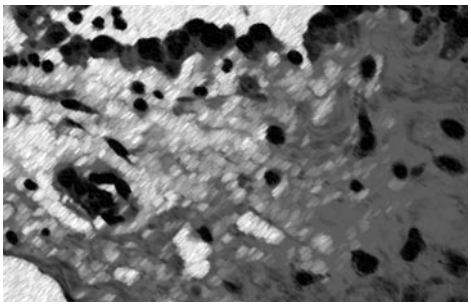

**Figure 4** Hematoxylin and Eosin Staining showing fibrinous adhesions and inflammatory reaction.

patient was diagnosed with retroperitoneal fibrosis and, hence, received oral steroids. The patient was discharged home on post-operative d 6. She was examined in clinic 4 wk after surgery and reported no complaints.

Three months after surgery, the patient presented to the emergency room with complaints of severe back pain. Her examination was normal. Her laboratory tests were normal. CT scan of the abdomen showed marked hydronephrosis of the right kidney. She underwent cystoscopy which showed narrowing of the right proximal ureter. A stent was placed in the right ureter. The stent was removed 3 wk after placement.

She presented to emergency room after 9 mo with complaints of back pain. Her physical examination and laboratory work was normal. CT of abdomen and pelvis showed bilateral hydronephrosis (Figure 2). A cystoscopy was performed which showed a normal bladder. Retrograde pyelogram showed normal ureters until the proximal part of both ureters, where tortuosity and dilation of the renal pelvis on both sides was noted. Bilateral ureteral stents were placed.

Eight months after bilateral stent placement, she presented to the hospital with complaints of severe abdominal pain. The pain was localized to the middle of the abdomen. It was sharp in intensity and had no radiation and no shifting. The pain was associated with repeated bouts of vomiting. On physical examination, she was afebrile and her vital signs were stable. She was awake and alert. Her abdomen was soft and not distended. She had tenderness in the right upper quadrant. Her white blood cell count was 34000 cells/$mm^3$, and the hemoglobin was 13 mg/dL. All other laboratory values were in the normal range. Abdominal radiographs showed multiple air fluid levels. CT of her abdomen showed multiple dilated loops of the small bowel and thickening of the bowel wall. Transition point appeared to be somewhere between the jejunum and the ileum. The colon was normal (Figure 3). An exploratory laparotomy was performed through midline incision. On opening the abdomen, the findings were that of severe fibrotic reaction with almost a frozen abdomen on the right lower aspect. Once again, classical glistening white, unyielding retroperitoneal fibrosis was encountered. Careful lysis of adhesions was done and the left upper quadrant was explored, whereby dilated loops of small bowel were found. Lysis of adhesions was attempted in the right lower quadrant but was encountered with enormous amount of bleeding. It was felt that the obstruction was caused by the external compression from retroperitoneal fibrosis. A decision was made to bypass the dilated segment of the jejunum into the colon without interfering with the frozen abdomen on the right side. The ligament of Treitz was identified and the dilated small segment was seen up to about 200 cm of the jejunum. The last portion of jejunum which entered into the frozen part of the abdomen was identified. A 10 cm long segment was anastomosed with the transverse colon which was free of adhesions. Side-to-side anastomosis was done using a GIA-75 and a TA60. Irrigation of the abdomen was carried out. The abdominal cavity was closed. The postoperative course was uneventful. On postoperative d 2, the patient's nasogastric tube was discontinued. A clear liquid diet was started on postoperative d 3 and was gradually replaced with regular diet. The patient was discharged home on post operative d 9. Pathology report showed fibrinous adhesions and inflammatory reaction (Figure 4).

## DISCUSSION

Classical idiopathic retroperitoneal fibrosis, also known as Ormond's disease, was described in 1948[1]. The typical retroperitoneal fibrosis is a fibrotic process encasing the abdominal vessels and the ureter with an epicenter at the level of L4-5[2]. RPF has an inciting agent in one-third of the cases, while the remaining two-thirds have no known cause[2].

CT scan of the abdomen is the imaging investigation of choice. Cases with ureteric obstruction can be successfully treated with steroids alone[3], and occasionally with tamoxifen[4], but ureterolysis may still be necessary in advanced or unresponsive cases. This case is unusual because the patient did not respond to oral steroids and had symptomatic ureteral and small bowel obstruction due to retroperitoneal fibrosis. We recommend early surgical intervention in patients with advanced RPF who are unresponsive to steroids.

# Meetings

## MAJOR MEETINGS COMING UP

First Biennial Congress of the Asian-Pacific Hepato-Pancreato-Biliary Association
March, 2007
Fukuoka, Japan
http://www.congre.co.jp/1st-aphpba

American College of Gastroenterology
Annual Scientific
20-25 October 2006
Las Vegas, NV

14th United European Gastroenterology Week, UEGW
21-25 October 2006
Berlin, Germany

APDW 2006: Asian Pacific Digestive Week 2006
26-29 November 2006
Lahug Cebu City, Philippines

## EVENTS AND MEETINGS IN THE UPCOMING 6 MONTHS

Falk Symposium 151: Emerging Issues in Inflammatory Bowel Diseases
24-25 March 2006
Sydney - NSW
Falk Foundation e.V.
symposia@falkfoundation.de

10th International Congress of Obesity
3-8 September 2006
Sydney
Event Planners Australia
enquiries@ico2006.com
www.ico2006.com

Easl 2006 - the 41st annual
26-30 April 2006
Vienna, Austria
Kenes International

Prague hepatology 2006
14-16 September 2006
Prague
Foundation of the Czech Society of Hepatology
veronika.revicka@congressprague.cz
www.czech-hepatology.cz/phm2006

12th International Symposium on Viral Hepatitis and Liver Disease
1-5 July 2006
Paris
MCI France
isvhld2006@mci-group.com
www.isvhld2006.com

Falk Symposium 152: Intestinal Disease Part I, Endoscopy 2006 - Update and Live Demonstration
4-5 May 2006
Berlin
Falk Foundation e.V.
symposia@falkfoundation.de

Falk Symposium 153: Intestinal Disease Part II, Immunoregulation in Inflammatory Bowel Disease - Current Understanding and Innovation
6-7 May 2006
Berlin

# Instructions to authors

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*WJG, World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

### *Indexed and abstracted in*

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### *Published by*

The WJG Press

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

### *Online submission*

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

### *Postal submission*

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

### Editorial Office

***World Journal of Gastroenterology***
Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com
Telephone: +86-10-85381901
Fax: +86-10-85381893

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### *Title page*

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

### *Abstract*

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

### *Key words*

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

### *Text*

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

### *Illustrations*

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

### *Tables*

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### *Notes in tables and illustrations*

Data that are not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ should be noted ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used. Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under

illustrations should be expressed as $^1F$, $^2F$, $^3F$; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

### *Acknowledgments*

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### *Coding system*

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24 ], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### *PMID requirement*

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (http://www.wjgnet.com/cgi-bin/index.pl), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### *Style for journal references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (http://www.aushome.cn/cgi-bin/index.pl)

### *Style for book references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### *Inappropriate references*

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### *Statistical data*

Present as mean ± SD or mean ± SE.

### *Statistical expression*

Express $t$ test as $t$ (in italics), $F$ test as $F$ (in italics), chi square test as $\chi^2$ (in Greek), related coefficient as $r$ (in italics), degree of freedom as $\gamma$ (in Greek), sample number as $n$ (in italics), and probability as $P$ (in italics).

### *Units*

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, $p$(B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; $CO_2$ volume fraction, 50 mL/L $CO_2$ not 5% $CO_2$; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

***Abbreviations***

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

***Italics***

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori, E coli, etc.*

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

***Language evaluation***

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

***Copyright assignment form***

Please downloaded CAF from http://www.wjgnet.com/wjg/help/9.doc.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to WJG all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The WJG requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1)direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3)supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The WJG does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to WJG if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

## Abstract

Dyssynergic defecation is one of the most common forms of functional constipation both in children and adults; it is defined by incomplete evacuation of fecal material from the rectum due to paradoxical contraction or failure to relax pelvic floor muscles when straining to defecate. This is believed to be a behavioral disorder because there are no associated morphological or neurological abnormalities, and consequently biofeedback training has been recommended for treatment. Biofeedback involves the use of pressure measurements or averaged electromyographic activity within the anal canal to teach patients how to relax pelvic floor muscles when straining to defecate. This is often combined with teaching the patient more appropriate techniques for straining (increasing intra-abdominal pressure) and having the patient practice defecating a water filled balloon. In adults, randomized controlled trials show that this form of biofeedback is more effective than laxatives, general muscle relaxation exercises (described as sham biofeedback), and drugs to relax skeletal muscles. Moreover, its effectiveness is specific to patients who have dyssynergic defecation and not slow transit constipation. However, in children, no clear superiority for biofeedback compared to laxatives has been demonstrated. Based on three randomized controlled studies in the last two years, biofeedback appears to be the preferred treatment for dyssynergic defecation in adults.

**Key words**: Biofeedback; Constipation; Pelvic floor dyssynergia; Dyssynergic defecation; Functional defecation disorders; Randomized controlled trials

## INTRODUCTION

Chronic constipation is a common self-reported bowel symptom that affects 2%-30% of people in Western countries and has considerable impact on health expenses and quality of life[1]. Most patients respond either to fiber-fluid supplementation or to judicious use of laxatives[1]. Among the non-responders, outlet dysfunction type constipation seems particularly common; it affects up to 50% of referrals to a tertiary care center[2].

Patients with outlet dysfunction can be divided into those with structural causes for obstructed defecation and patients with a functional defecation disorders[3,4]. Possible structural causes for obstructed defecation include stricture, neoplasia, rectocele, enterocele, and Hirschprung's disease. Functional defecation disorders include dyssynergic defecation (i.e., paradoxical contraction or failure to relax the pelvic floor and anal muscles during defecation) and inadequate defecatory propulsion (i.e., insufficient intra-rectal pressure due to inadequate contraction of abdominal wall muscles during defecation); both may lead to inadequate emptying of the rectum[4]. It is unclear whether idiopathic megarectum is associated with dyssynergic defecation. Functional defecation disorders are believed to be more common than obstructed defecation and approximately as common as slow transit constipation; however, the true prevalence of these subtypes of constipation has not been documented. Functional defecation disorders may coexist with slowed transit through the colon. Dyssynergic defecation is commonly considered to be a form of maladaptive behavior because there is no discernable neurological or anatomical defect and because it can be eliminated by behavioral training[4].

Diagnostic criteria for functional defecation disorders[4] include those for functional constipation[5], namely two or more of 6 symptoms present for the last 3 mo with an onset more than 6 mo in the past; the symptoms are straining, lumpy or hard stools, sensation of incomplete evacuation, sensation of anorectal obstruction/blockage, or manual maneuvers to facilitate defecation on more than 1/4 of bowel movements, or less than 3 bowel movements per week. To meet criteria for functional defecation disorders, the patient must also undergo

objective diagnostic testing and demonstrate at least two of three abnormalities: impaired evacuation of the rectum, inappropriate contraction or less than 20% relaxation of the pelvic floor muscles, and inadequate propulsive forces during defecation[4].

An exhaustive explanation of the diagnostic work up of these patients is beyond the scope of this review. However, most normal subjects can easily evacuate a 50 mL water-filled balloon from the rectum. Additional anorectal testing includes anorectal manometry, anal electromyography (EMG) and evacuation proctography (defecography)[4]. Anorectal manometry provides a comprehensive assessment of anal pressures, rectoanal reflexes, rectal pressures, sensation and compliance. Several types of recording devices are available, but perfused catheters and balloon probes are among the most commonly used. A paradoxical increment in anal pressure on straining efforts is a distinctive feature of dyssynergic defecation[4]. An increment in muscle motor activity on straining may be demonstrated by means of EMG either by intra-anal electrodes or by electrodes taped to the peri-anal skin.

Defecography is a radiographic test providing morphological and functional information on the ano-rectum. Several parameters may be assessed, such as pelvic floor descent, anorectal angle, rectocele, and rectal prolapse. Failure of the anorectal angle to become more oblique on straining provides indirect evidence of defective pelvic floor relaxation and impaired evacuation of contrast material is also suggestive of dyssynergia[4]. There must be manometric, EMG, or radiologic evidence for inappropriate contraction or failure to relax the pelvic floor muscles on straining to diagnose dyssynergic defecation according to Rome Ⅲ criteria[4].

Evaluation of colon transit by means of radiopaque markers is not relevant to the diagnosis, but it may be performed to additionally test for slow transit constipation.

Patients with functional defecation disorders are often unresponsive to conservative medical management, and the surgical division of the pubo-rectalis muscle (which has been proposed for the treatment of dyssynergic defecation) has resulted in poor benefit and an unacceptable risk of anal incontinence[1,6]. Treatment with botulinum toxin injection may provide temporary improvement, but it remains an investigational treatment. Therefore, behavioral treatment is a logical choice for these disabled patients[4].

Biofeedback is a conditioning treatment where information about a physiologic process (contraction and relaxation of a muscle) is converted to a simple visual or auditory signal to enable the patient to learn to control the disordered function. Biofeedback is considered appropriate when specific pathophysiological mechanisms are known and the voluntary control of responses can be learned with the aid of systematic information about functions not usually monitored at a conscious level[7]. As early as 1979, Thomas Almy and John Corson, in an enthusiastic editorial about the biofeedback treatment of fecal incontinence, pioneered the extension of behavior therapy to functional defecation disorders[8]. However, the first paper dealing with the subject included only a small number of subjects and was not published until 1987 due to the preference for conservative, drug-oriented therapy[9].

## BIOFEEDBACK TECHNIQUES FOR TREATING DYSSYNERGIC DEFECATION

Paradoxical increases in anal pressure and electromyographic (EMG) activity during straining is easily detected[10,11]. Anal pressure may be measured by means of water-perfused catheters, solid state transducers or balloon catheters[10]. No single technique seems superior to the others, and the choice relies on the researcher's training and experience.

Anal EMG may be recorded either by intra-anal probes or by peri-anal EMG electrodes stuck to the skin[10,11]. The EMG activity used in biofeedback training is the averaged activity of large numbers of muscle cells rather than the activity of small groups of muscle cells innervated by a single axon. This averaged EMG activity is recorded with large electrodes on the skin or the mucosa of the anal canal rather than with needle electrodes. Averaged EMG recorded in this way is proportional to the strength of contraction of the underlying muscles.

Defective expulsion is commonly investigated by asking the patient to defecate a 50-mL water-filled rectal balloon; patients with functional defecation disorders usually fail this test[11]. Some patients also have a higher threshold for perceiving the urge to defecate[10], but the clinical significance of this sensory dysfunction is ill-defined, in contrast to the relevance of rectal sensory impairment in fecal incontinence[12]. Ano-rectal imaging studies (defecography, ultrasonography, and pelvic floor MRI) may also help to characterize the physiological dysfunction responsible for outlet dysfunction, but they do not seem to influence treatment outcome[4,13].

Biofeedback training protocols vary among different centers[10,11]. In the next paragraph, a standard biofeedback protocol is described and differences in biofeedback procedures are outlined. A mainstay of behavior therapy is to first explain the anorectal dysfunction and discuss its relevance with the patient before approaching the treatment[3,11]. Most protocols would then include training the patients on a more effective use of the abdominal muscles to improve pushing effort. Patients are next shown anal manometry or EMG recordings displaying their anal function and are taught through trial and error to relax the pelvic floor and anal muscles during straining[10,13]. This objective is first pursued with the help of visual feedback on pelvic floor muscle contraction, accompanied by continuous encouragement from the therapist. When the patient has learned to relax the pelvic floor muscles during straining, the visual and auditory help are gradually withdrawn[10,13]. Another retraining option is to simulate defecation by means of an air-filled balloon attached to a catheter, which is slowly withdrawn from the rectum while the patient concentrates on the evoked sensation and tries to facilitate its passage[3,11]. In the next phase of training, the patient is taught to defecate the balloon by bearing down, without the assistance of the therapist. Some centers also add a balloon sensory retraining to lower the urge perception threshold[14]. The number of

training sessions is not standardized, but 4 to 6 sessions are frequently provided. Individual training sessions last 30 to 60 min.

Therapeutic sessions are professionally demanding and a highly trained and motivated therapist is essential. No study has addressed the necessary training required for an individual to administer biofeedback therapy. Particularly, it is unclear whether the adequate provider should be either physician, psychologist, or nurse. Experience varies among centers, but the low cost reimbursement provided for behavior therapy is likely to influence future choices.

Controlled studies systematically comparing different biofeedback protocols to each other are lacking. However, a recent meta-analysis showed that in open label studies, the mean success rate with pressure biofeedback was slightly greater than with EMG biofeedback (78% *vs* 70%)[13]. No differences were found between anal *vs* peri-anal EMG recording. In addition, adding balloon feedback did not seem to influence the therapeutic outcome[13]. However, the majority of studies in the last ten years have utilized EMG biofeedback rather than pressure feedback even in the absence of scientific evidence[13]. There are no standardized protocols, and centers use different combinations of laboratory EMG training, home EMG training, and balloon feedback, depending on the researcher's experience.

## EFFICACY OF BIOFEEDBACK TREATMENT FOR DYSSYNERGIC DEFECATION

### *Uncontrolled studies*

In 1987 Bleijenberg and Kuijpers[9] were the first to report the efficacy of EMG biofeedback treatment combined with oatmeal porridge defecation in 10 patients affected by spastic pelvic floor syndrome, later redefined as functional defecation disorder[4]. Treatment was a complete success in 7 patients and a partial success in two others. This open label trial stimulated a number of uncontrolled studies to investigate the efficacy of behavior therapy in functional defecation disorder[7]. Therapeutic outcome varied greatly among centers with success rates ranging from 18% to 100% of patients studied[15,16].

A major drawback to assessing this literature was the huge variance in inclusion criteria, outcome criteria, follow-up intervals, and therapeutic protocols[13,17]. Additional limitations were small sample size (often no more than 30 subjects studied) and lack of any control group[17]. However, the majority of uncontrolled studies in adults reported a favorable outcome in about two thirds of patients, without side effects[7,11,13,17]. Coexisting morphological abnormalities of the pelvic floor, namely rectocele, intussusception and abnormal perineal descent, seemed not to influence behavior treatment outcomes[18]. Researchers were unable to identify any functional variable that could predict treatment outcome, but anxious patients appear to be less likely to succeed[13,17].

Although the majority of published uncontrolled studies reported beneficial effects of treatment, a series of studies from the St. Mark's group cast doubts on whether biofeedback training has specific value in the treatment of functional defecation disorder: these investigators reported similar benefits of biofeedback therapy in patients, irrespective of whether they had slow whole gut transit or functional defecation disorder[19,20] (See below for contrasting views). They also suggested that the autonomic innervation of the colon may influence the outcome of biofeedback treatment[21].

### *Controlled studies*

Randomized, controlled trials were first performed in the pediatric population. In 1987 Wald *et al*[22] compared pressure biofeedback therapy with mineral oil in a group of 55 encopretic children; 16 of whom showed evidence of functional defecation disorder. Although a trend toward greater improvement in the biofeedback group was evident, the difference in success rate did not reach significance. In another controlled study[23], a well-defined pediatric population of 43 children with functional defecation disorder was randomized to receive either biofeedback therapy plus conventional care (laxatives) or conventional treatment only. All children had fecal impaction and encopresis. The biofeedback group did significantly better than the conventional one, with about half of patients showing successful symptoms resolution at one year follow-up compared to 16% in the conventional-care-only group. The clinical benefit was correlated with normalization of defecation dynamics. Similar benefits were reported in another controlled study[24] in the pediatric population, but the follow-up was too short (3 mo) to draw firm conclusions.

In contrast to the successful studies described above, the largest randomized, controlled study in pediatric constipation (192 children), which compared laxatives plus EMG biofeedback therapy to laxatives alone, failed to show any benefit from biofeedback[25]. A criticism of this study was that not all the subjects had functional defecation disorder. However, a similar failure to show superior efficacy with biofeedback was reported in a controlled study considering a smaller sample of children with both functional defecation disorder and encopresis[26]. In both studies, improved defecation dynamics were reported in biofeedback-treated patients, but this did not translate into greater symptom improvement.

In the adult population, four controlled studies were published prior to 2005. Two of these studies compared different biofeedback techniques to each other[27,28] and two studies compared EMG biofeedback to simulated defecation[19,29].

Heymen *et al*[27] compared intra-anal EMG biofeedback to (1) a combination of EMG and intra-rectal balloon distension training, (2) EMG and home trainers, and (3) a combination of all three techniques. All groups showed significant improvement from pretreatment, but no significant differences were found among treatment strategies. Glia *et al*[28] found peri-anal EMG biofeedback to be superior to pressure biofeedback combined with balloon defecation training. However, neither Glia *et al* nor Heymen *et al* had sufficient sample size to provide a meaningful analysis.

Bleijenberg *et al*[29] found an intra-anal EMG biofeedback to be superior to balloon defecation training (90% *vs*

60% improved). Although the sample size was too small to draw reliable conclusions, subjects who failed balloon defecation training were then given biofeedback training, yielding an 80% success rate.

The St. Marks group[19] studied a series of 60 adults with functional constipation unresponsive to conservative management and randomized them either to EMG and rectal balloon biofeedback or to abdomino-pelvic muscular coordination training and balloon feedback. After only two unsatisfactory sessions, patients who were judged unable to respond, were switched to the alternative treatment. At the end of treatment, approximately 50% of patients in both groups rated their symptoms as significantly improved. The outcome did not correlate with colon transit time, the presence of functional defecation disorder, or other functional and clinical variables. In addition, the St. Marks group recently reported biofeedback to be no more effective than bowel training and education for fecal incontinence in a large, controlled, randomized study[30]. These results challenge both the effectiveness of behavior therapy and the claim that retraining makes a specific contribution to the treatment of constipation other than education and/or psychotherapy.

To determine whether biofeedback is equally effective in slow transit constipation and dyssynergic defecation and also whether the benefits are due to education alone, we conducted an open study on 52 patients with slow transit constipation (objectively documented) who were unresponsive to conservative measurements[3]. Thirty-two of them showed evidence of dyssynergic defecation, 6 formed a mixed group who satisfied some but all criteria for dyssynergic defecation, and 12 had slow transit only. All patients received 5 weekly sessions of a biofeedback protocol, including improved use of the abdominal muscles to strain, anal EMG and balloon biofeedback to teach relaxation of the pelvic floor on straining, and simulated defecation.

Functional ano-rectal and clinical parameters were evaluated both before and after behavior therapy. After six months, 71% of patients with functional defecation disorder and slow transit reported satisfaction with treatment *versus* 8% in the slow transit only group. The results were well maintained at follow-up 2 years later[3]. Patients' satisfaction was correlated with improved rectal emptying as demonstrated by successful balloon expulsion and reductions in dyssynergia at manometry. A significant increase in rectal pressure on straining was also evident. Interestingly, biofeedback training resulted in a significant decrement in the threshold volume of balloon distention required to produce a sensation of urge to defecate, although no specific sensory retraining had been provided. Treatment success was predicted by pelvic floor dyssynergia, milder constipation, and less frequent abdominal pain at baseline.

This study allowed us to conclude that biofeedback therapy is specifically indicated for dyssynergic defecation and that retraining works through teaching patients to relax the pelvic floor and anal muscles during straining. Since biofeedback therapy is time- consuming, dedicated trained personnel are not easily found, and drug treatments (laxatives, muscle relaxants) are cheaper and more easily available, we were in strong need of a randomized, controlled study to prove that biofeedback is more effective than laxatives or placebo. This need was reinforced by the recent statement of the American College of Gastroenterology's Chronic Constipation Task Force that osmotic laxatives, namely polyethylene glycol and lactulose, are effective in improving stool frequency and consistency in all patients with chronic constipation[31].

Recently, three randomized, controlled studies coming from different centers have provided satisfactory answers to this question. The first of them[32] compared 5 weekly sessions of biofeedback to a commonly prescribed osmotic laxative (polyethylene glycol [PEG] in incremental dosage (14.6-29.2 g/d) given in combination with 5 weekly counseling sessions. Patients with normal transit constipation secondary to dyssynergic defecation were randomized either to the biofeedback (54 patients) or to the laxative group (55 patients). Follow-up assessment extended up to 12 mo in the laxative group and to 24 mo in the biofeedback group. Satisfaction with treatment, symptoms of constipation, and pelvic floor physiology were assessed at pretreatment, every six months in the first year, and at 24 mo. At six months, major clinical improvement was reported by 80% of patients in the behavior group *versus* only 20% in the PEG group. Biofeedback benefits were well sustained for the whole two-year follow-up interval. Clinical benefits correlated well with objective evidence of a reduction or elimination of paradoxical contractions of the pelvic floor during straining. The only clinical variable that correlated with treatment outcome was digital facilitation of defecation, which predicted failure; anorectal physiology could not predict outcome. Interestingly, laxatives consumption other than PEG was significantly decreased in the biofeedback group compared to the PEG group at 6-12 mo follow-up, while bowel frequency was significantly increased in both group compared to baseline.

Rao *et al*[33] conducted a randomized trial comparing biofeedback to sham feedback (relaxation therapy) and to standard medical care (diet, exercise, and laxatives). A significantly greater proportion of subjects receiving biofeedback (88%) reported more than a 20% improvement in global satisfaction and stool frequency on a visual analog scale compared to subjects receiving sham biofeedback (48%), but not when compared to standard care (70%). The authors also reported a significant improvement in favor of the biofeedback group to normalize the dyssynergic pattern and improve on a defecation index, with trends in favor of biofeedback subjects reducing balloon expulsion time and decreasing colonic marker retention compared to alternative treatment groups.

In a third randomized controlled trial, Heymen *et al*[34] randomly assigned 84 constipated subjects with dyssynergic defecation to receive either biofeedback ($n$ = 30), diazepam ($n$ = 30), or placebo ($n$ = 24). An important feature of this study was that all subjects were trained to do pelvic floor muscle exercises to correct pelvic floor dyssynergia during 6 biweekly 1-h sessions, but only the

biofeedback patients received EMG feedback. All other patients received pills (muscle relaxant or placebo) 1-2 h before attempting defecation. Biofeedback was superior to diazepam by intention-to-treat analysis (70% *vs* 23% reported adequate relief of constipation), and also superior to placebo (38% successful). In addition, biofeedback patients had significantly more unassisted BMs compared to placebo, with a trend favoring biofeedback over diazepam. Biofeedback patients also reduced pelvic floor EMG during straining significantly more than diazepam patients.

### *Limitations of biofeedback training*

The negative outcomes reported in controlled studies have been in the pediatric population. These poorer outcomes may be due to the inclusion of children whose constipation was not due to functional defecation disorder, since it is known that patients with other etiologies for their constipation respond poorly to biofeedback. In addition, biofeedback training requires complex cognitive processing and sustained attention that may be beyond the abilities of younger children. Finally, the quality of the therapist-patient relationship and the skills and experience of the therapist seem to influence the success of behavior therapy, and there is currently a shortage of trained personnel to provide this form of treatment.

In conclusion, a series of controlled studies have now shown that functional defecation disorder, one of the most frequent and disabling subtypes of adult constipation, can be treated effectively with biofeedback training. This form of treatment is more effective than laxatives, and it has no known adverse effects. Although this training is relatively expensive to provide, it produces improvements that are sustained for up to two years. For these reasons, we may conclude that biofeedback training is the treatment of choice for functional defecation disorder.

## Abstract

Insulin resistance is the major feature of the metabolic syndrome and depends on insulin secretion and insulin sensitivity. In chronic hepatitis C, insulin resistance and type 2 diabetes mellitus are more often seen than in healthy controls or chronic hepatitis B patients. Hepatitis C virus (HCV) infection promotes insulin resistance, mainly by increased TNF production together with enhancement of suppressor of cytokine (SOC-3); both events block PI3K and Akt phosphorylation. Two types of insulin resistance could be found in chronic hepatitis C patients: "viral" and "metabolic" insulin resistance. Insulin resistance in chronic hepatitis C is relevant because it promotes steatosis and fibrosis. The mechanisms by which insulin resistance promotes fibrosis progression include: (1) steatosis, (2) hyperleptinemia, (3) increased TNF production, (4) impaired expression of PPARγ receptors. Lastly, insulin resistance has been found as a common denominator in patients difficult-to-treat like cirrhotics, overweight, HIV coinfected and Afro-American. Insulin resistance together with fibrosis and genotype has been found to be independently associated with impaired response rate to peginterferon plus ribavirin. Indeed, in genotype 1, the sustained response rate was twice (60%) in patients with HOMA $\leqslant$ 2 than patients with HOMA > 2. In experiments carried out on Huh-7 cells transfected by full length HCVRNA, interferon alpha blocks HCV replication. However, when insulin (at doses of 128 μU/mL, similar that seen in the hyperinsulinemic state) was added to interferon, the ability to block HCV replication disappeared, and the PKR synthesis was abolished. In summary, hepatitis C promotes insulin resistance and insulin resistance induces interferon resistance, steatosis and fibrosis progression.

## INTRODUCTION

Insulin resistance emerges as a very important host factor in patients with chronic hepatitis C, mainly because it has been related to steatosis development, fibrosis progression and non-response to peginterferon plus ribavirin. IR appears as a consequence of the inability of insulin to induce the effect on glucose metabolism and an abnormally large amount of insulin is secreted to achieve a biological response. The hyperinsulinemic state induces several abnormalities in the liver, endothelium, and kidneys, and is the main feature in the metabolic syndrome. Obesity and metabolic syndrome are frequently found in western countries. In Spain, the prevalence of obesity has been found in around 13% and more than half of the population showed increased body mass index. In chronic hepatitis C, overweight and obesity showed a distribution similar than healthy people. Although insulin resistance has been found to be strongly associated with body mass index, in some circumstances it depends on the virus C. Two types of insulin resistance could be defined in patients with chronic hepatitis C: "metabolic" insulin resistance and "viral" insulin resistance.

## MATERIALS AND METHODS

Insulin, after binding with it's receptor, induces the phosphorylation of receptor substrates in the liver and muscles and induces several steps toward the transactivation of GLUT-4 that increases glucose uptake by cells and the storage as glycogen and inhibits the net production of glucose by the liver, blocking glycogenolysis and neoglycogenesis. Moreover, insulin promotes lipids storage inhibiting lipolysis. When insulin is not able to induce glucose uptake, pancreatic beta-cells increase insulin production and the hyperinsulinemic state avoids hyperglycemia. Insulin secretion increases when insulin sensitivity decreases until a threshold in which insulin secretion did not induce improvement in insulin sensitivity, and diabetic state emerges. Several factors have been proposed as mediators in the islet adaptation: glucose, glucagon-like peptide 1, autonomic nervous system, and

free fatty acids[1].

The best method to measure insulin sensitivity is the hyperinsulinemic euglycemic clamp. This method measures the quantity of glucose required to maintain normal glycemic levels during insulin infusion. Briefly, a perfusion of 60 mU/kg per minute of insulin was started and every 5 minutes glucose levels were measured. To avoid hypoglycaemia, glucose (20%) was infused to maintain levels between 90 mg/dL and 100 mg/dL. The whole-body glucose uptake (M value) depends on the glucose infused in the last 30 min of the test. Lower M value (lower glucose requirements) are associated with insulin resistance. However, the clamp method is expensive, labor-intensive and uncomfortable for practical use in clinical medicine. A simple mathematical model named Homeostasis Model for Assessment [HOMA = fasting insulin (mUI/mL) * fasting glucose (mmol/L)/22.5] has been proved useful in the measurement of insulin sensitivity in euglycemic patients. However, this measurement is not useful once the blood glucose level begins to increase because it lacks accuracy. Normal plasma insulin concentrations are not standardized in healthy controls. Thus, HOMA has not been standardized yet. In previous reports HOMA < 2 has been considered "completely" normal, and higher than 4 as prediabetic state.

## INSULIN RESISTANCE IN CHRONIC HEPATITIS C

The mechanisms by which hepatitis C induces increased insulin resistance and the risk for development of diabetes has not been completely understood. Liver fibrosis progression has been considered for long-time responsible of the appearance of insulin resistance and type 2 diabetes in patients with chronic liver diseases. Taking together available data from several studies about the prevalence of type 2 diabetes mellitus in hepatitis C, we found that in cirrhotic patients ($n$ = 2152 cases) the prevalence of type 2 diabetes was 27.3%, higher than the 17.5% in non-cirrhotic hepatitis C patients ($n$ = 1016 cases). Hyperinsulinemia in liver cirrhosis has been reported to be due to diminished hepatic insulin extraction by liver dysfunction and not to pancreatic hypersecretion. C-peptide and insulin are secreted in equimolar quantities. More than 50% of insulin is degraded in the liver at first pass, whereas C-peptide is degraded in the kidneys[2]. Simultaneous measurements of C-peptide and insulin revealed that both insulin resistance and insulin secretion contribute to glucose intolerance in patients with chronic hepatitis C[3]. In spite of insulin resistance correlated with liver fibrosis, it has been found higher in patients with chronic hepatitis C and mild fibrosis (F0-F1) than in healthy controls matched by age, sex, visceral obesity and body mass index[4]. In a cohort of patients with chronic hepatitis C and chronic hepatitis B matched by age, sex, body mass index and fibrosis stage HOMA index was found statistically higher in hepatitis C[5], this result confirms previous reports showing higher insulin resistance in chronic hepatitis C than in others hepatopathies[6]. Thus, hepatitis C virus induces insulin resistance independently of body mass index or fibrosis stage. Moreover, in a transgenic animal model, HCV core protein has been found able to induce insulin resistance, steatosis and type 2 diabetes mellitus. The main mechanism seems to be the over production of TNF. This cytokine phosphorylates serine residues of insulin-receptor substrates 1 and 2 and enhances the production of suppressor of cytokines (SOC3). The SOC-3 substance inhibits the phosphorylation of Akt and phosphatidyl inositol 3 kinase (PI3K). All these impairments in the intracellular signaling of insulin could block the transactivation of GLUT-4, avoiding the uptake of glucose by cells. Moreover, in transgenic animal models unable to express SOC-3, in spite of core HCV protein expression, insulin resistance does not develop. Indeed, in transgenic mice, TNF correlates with hyperinsulinemic state and the blockade of TNF production by anti-TNF drugs as infliximab also avoid insulin resistance appearance. Therefore, mechanisms inducing insulin resistance by hepatitis C virus include: TNF production, serine phosphorylation of IRS, and over expression of SOCs. Furthermore, over production of TNF in patients with chronic hepatitis C has frequently been seen[7], and correlated with higher fibrosis progression and impaired antiviral response to interferon alpha. Besides, in humans the risk for the development of insulin resistance and further appearance of DM is greater in patients with higher TNF production.

The development of type 2 diabetes mellitus depends on environmental, genetic and diet-related factors. Type 2 diabetes mellitus is more often seen in patients with chronic liver diseases than in general population[8]. Data supporting an association between diabetes mellitus and hepatitis C include: (1) Cross-sectional studies that found increased prevalence of diabetes mellitus in patients with chronic hepatitis C, or higher prevalence of hepatitis C in patients with diabetes mellitus. In a recent meta-analysis taking together available data about the prevalence of DM in patients with chronic liver diseases, the prevalence was higher in chronic hepatitis C than chronic hepatitis B. In non-cirrhotic chronic hepatitis C, DM was found in 17.5% and in chronic hepatitis B in 8.7% while in cirrhotics the prevalence was 27.3% in hepatitis C versus 15.2% in cirrhotics B (Figure 1). Besides, anti-HCV was more often detected in patients with diabetes mellitus (4.9%) than in the general population (0.77%)[9]. (2) case-cohort studies to analyze the development of diabetes mellitus during follow-up in patients with hepatitis C against uninfected patients, including follow-up after orthotopic liver transplantation. In a cross-sectional survey including 9841 persons, Mehta *et al* found that HCV-positive persons who were older than 40 years had an increased risk for type 2 diabetes mellitus higher than 3 times compared with persons without HCV-infection, while no difference was seen in HBV infection[10]. In a cohort of 1084 patients followed-up for 9 years 548 cases developed diabetes mellitus. The presence of hepatitis C was associated with a greater development of diabetes, but solely in high-risk diabetes patients[11]. Besides, in a cohort of 2327 cases, hepatitis C infection increased three times the rate of diabetes mellitus appearance during follow-up in patients aged between 35 and 49 years[12]. Thus, HCV infection could promote type 2 diabetes in high-risk populations.

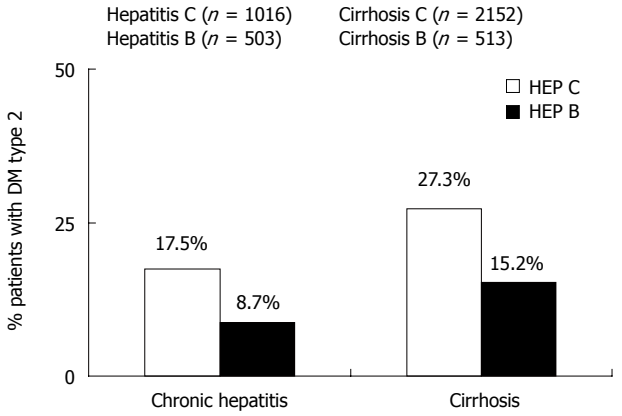

**Figure 1** Prevalence of type 2 diabetes mellitus in patients with chronic hepatitis C and chronic hepatitis B.

Recently, in a Spanish study including 525 chronic hepatitis C patients treated with peginterferon plus ribavirin were followed-up after treatment and the incidence of altered baseline glucose and the appearance of diabetes type 2 was greater in non-responders than in sustained responders even after multivariate analysis including confounding variables as previous diabetes type 2 in relatives, older than 40 years and male sex. Thus, hepatitis C virus clearance induces a decrease in insulin resistance index during a short-time follow-up and decrease the incidence of diabetes type 2 in long-term follow-up[13].

Hepatocyte steatosis is a common feature found in the liver of patients with chronic hepatitis C. The mechanisms implied in steatosis appearance seem to be genotype-dependent. In patients infected by genotype 3, steatosis emerges as a cytopathic effect of the virus while in genotype 1 steatosis seems to be an expression of the metabolic syndrome. In genotype 3, steatosis degree correlated with liver and serum HCV load[14]. In genotype 1, steatosis depends on leptin levels and insulin resistance. Recently, insulin resistance has been found implied in the development of steatosis in 331 non-diabetic genotype 1 patients. Insulin resistance together with gender and gammaglutamyltranspeptidase (a surrogate marker of TNF levels) were independently associated with moderate/severe steatosis in this cohort[15]. Insulin resistance is the main pathogenic factor in the development of steatosis in chronic hepatitis C, both viral insulin resistance and metabolic insulin resistance could be implied in the development of steatosis.

The main deleterious effect of insulin resistance in chronic hepatitis C is the ability to promote fibrosis progression. High serum glucose levels have been found associated with an increased rate of fibrosis progression, greater even than overweight[16]. Mean HOMA index increases with the stage of fibrosis[17] and could help to differentiate stages of fibrosis. Recently, Sud *et al*[18], proposed an index to predict fibrosis containing age, cholesterol, gammaglutamyl transpeptidase and alcohol consumption together with HOMA. The mechanisms by which insulin resistance promotes fibrosis progression include: (a) steatosis, (b) hyperleptinemia, (c) increased TNF production, and (d) impaired expression of PPARγ receptors. (a) hepatocyte steatosis induces fibrosis progression. In a cohort of patients with chronic hepatitis C, the presence of steatosis in the first biopsy was associated with higher fibrosis progression rate, irrespective of genotype[19]. Besides, steatosis is more often seen in patients with advanced fibrosis[20]. (b) Hyperleptinemia has been usually found in patients with insulin resistance, also hepatic stellate cell showed specific leptin receptors, thus leptin could play a role in the activation of HSC and fibrosis progression[21,22]. (c) TNF production is enhanced in hepatitis C and has been implicated in the development of insulin resistance, also, TNF levels were related to fibrosis progression, owing to the ability to activate HSC and promote collagen deposits. Moreover, TNF could inhibit PPARs activity[23]. (d) In patients with hepatitis C an impaired expression of PPARγ receptors has been found[24]. PPARs agonist inhibits inflammation and fibrosis progression by blocking the activation of redox-sensitive transcription factor NFκB and TGFβ1[25].

In HIV-infected patients insulin resistance depends on host, virus and drugs-related factors. Adverse metabolic effects have been found in all antiretroviral drug classes. Protease inhibitors (PI) and nucleoside reverse transcriptase inhibitor (NRTI) therapy induces insulin resistance during treatment[26]. Insulin resistance has been found increased in HIV+/HCV+ co-infected patients. Factors implied in the development of insulin resistance in HIV infected patients include: HCV infection, PI and/or NRTI based-therapy, age, HIV and cytokine dysregulation induced by chronic infection and genetic predisposition[27]. Moreover, the development of type 2 diabetes mellitus was twice in co-infected patients versus HIV non-HCV infected[28]. Duong *et al*[29] reported a higher HOMA in co-infected patients than in HIV-infected cases without hepatitis C. However, in a large study no differences were seen between co-infected or not co-infected patients. In a recent study, including 127 co-infected patients that underwent antiviral therapy (peginterferon plus ribavirin) and 85 hepatitis C, insulin resistance index was higher in co-infected patients, in spite of lower body mass index and lower baseline glucose levels. Besides, in a genotype-dependent manner, insulin resistance was strongly associated with steatosis development and impaired the sustained response rate in genotype 1 co-infected patients. No association between insulin resistance and steatosis or sustained response was seen in genotype 2 or 3 coinfected patients[30]. Lastly, history of diabetes in relatives, increased body mass index and HCV-infection have been found as independent variables associated with diabetes development in HIV patients, supporting the hypothesis that HCV infection promotes diabetes in high-risk patients.

## INSULIN RESISTANCE AND RESPONSE TO PEGINTERFERON PLUS RIBAVIRIN

In healthy volunteers, after the first injection of interferon alpha insulin resistance could be detected[31]. Besides in patients with chronic hepatitis C, interferon alpha induces insulin resistance in the first two weeks, mainly owing to a decrease of hepatic glucose uptake[32]. This effect has been related to the pro-inflammatory repertoire of cytokines induced by interferon. However it's a transitory effect because insulin resistance was not found at month three

of therapy[33] or at the end of therapy[34]. In patients with chronic hepatitis C receiving peginterferon plus ribavirin insulin resistance measured by HOMA, decreased in patient with HCV RNA clearance at mo 6, but not in non-responders. At the end of follow-up sustained responders showed a significantly lower HOMA in comparison with baseline insulin resistance index. However, in relapser patients, the HOMA index increased and the levels at the end of follow-up were not different from the baseline. These data support a connection between HCV replication and insulin resistance, and HOMA decreased when the virus was eradicated. Besides, the incidence of diabetes type 2 is different in cured patients than in non-responders, supporting a better control of insulin resistance after hepatitis C virus clearance[13].

Genotype and viral load have been found as the most important viral factor influencing peginterferon plus ribavirin response. Host factors include genes as HLA, weight, body mass index, hepatocyte steatosis, age, Afro-American ethnicity and fibrosis. Several genes and polymorphisms as HLA-B44 has been found related to the possibility of curing the disease[35]. On the other hand, features of metabolic syndrome as overweight, steatosis and fibrosis have been reported as independently associated with response. The influence of steatosis in the chance of curing hepatitis C has been controversial for long time. Steatosis impairs SVR rate in patients with genotype 1, but not in genotype 3. Thus, the possibility of finding steatosis as independent variable depends on the balance between genotypes included in the cohort. In fact, in a multivariate analyses including steatosis together with fibrosis, body mass index, genotype and insulin resistance, either steatosis or body mass index were not found independently associated with response but insulin resistance, genotype and fibrosis[32]. In genotype 1, sustained response rate was 32% in patients with insulin resistance (HOMA > 2) against 60% in patients with HOMA lower than 2[36]. However, in a recent cohort including 331 non-diabetic genotype 1 chronic hepatitis C patients, steatosis but not insulin resistance was found independently associated with response. Steatosis and insulin resistance showed a great colineality in genotype 1 patients and could be the expression of the same mechanisms. Thus, measure insulin resistance seems to be easier and comfortable than study steatosis in a liver biopsy. Besides, in 52 patients from UK also treated with peginterferon plus ribavirin, HOMA index was significantly higher in non-responders than patients with sustained response[37]. Thus, insulin resistance emerges as the most important host factors in the prediction of response in non-diabetic patients treated with the best available option peginterferon plus ribavirin. Interestingly, insulin resistance has been found as a common denominator to the majority of features associated with difficult-to-treat patients: patients with cirrhosis, obesity, co-infected by HIV and Afro-American. Unresolved question is whether insulin resistance is a marker of very difficult-to-cure or a pathogenic mechanism able to block antiviral activity of the interferon. Peginterferons induce their antiviral activity via extracellular receptor binding. The interferon alpha signalling pathway involves the activation of Janus kinase (Jak1) and tyrosine kinase (Tyk2), initiated by the binding of peginterferon alpha-2 to the interferon heterodimeric receptor complex (IFNAR1/IFNAR2), which leads to activation of their downstream substrates, signal transducers and activators of transcription (STAT 1 and STAT2). Activated STAT then assemble as a multimeric complex and translocate into the nucleus where they bind to interferon alpha-2-stimulated response elements in the promoters of interferon alpha-2-stimulated genes[38]. Recently, in a replicon model using Huh-7 cells transfected by full length HCVRNA, interferon alpha blocks HCV replication. However, when insulin (at doses of 128 μU/mL, similar that seen in the hyperinsulinemic state in patients with metabolic syndrome) was added to interferon, the ability to block HCV replication disappeared, and the PKR synthesis was abolished[39]. In this experiment, a blockage of PI3K by LY294002 avoided the interference of insulin, supporting that interferon resistance induced by insulin is mediated by PI3K (Figure 2). Moreover, in genotype 1 patients obesity has been found able to increase intrahepatic synthesis of SOC-3, inhibiting the interferon signalling and promoting interferon resistance[40]. Thus, hyperinsulinemia and obesity induce interferon resistance blocking intracellular signalling.

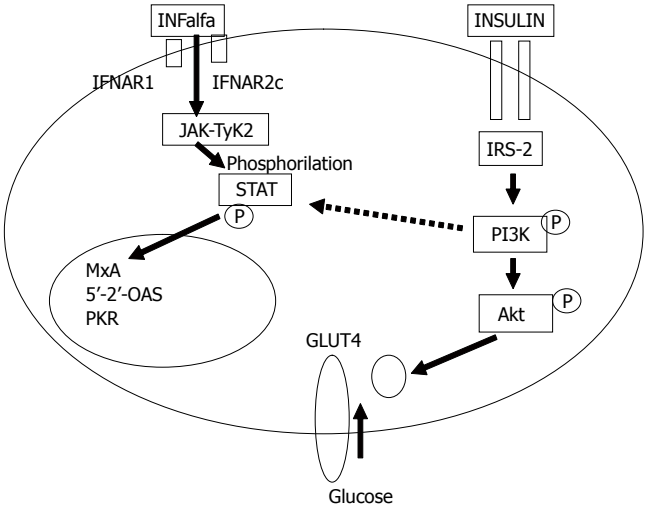

**Figure 2** Interaction between insulin and peginterferon alpha signalling pathway. The phosphatidil-inositol-3-kinase (PI3K) activated by insulin seems to be responsible for the block of STAT 1 translocation avoiding antiviral effect of interferon. Dotted lines represent inhibition, continuous lines represent activation.

## CONCLUSIONS

In summary, hepatitis C promotes insulin resistance and insulin resistance induces interferon resistance, steatosis and fibrosis progression in a genotype-dependent manner. In genotype 1 insulin resistance decreases sustained response rate, and increase the risk for the development of steatosis and fibrosis progression, in both, coinfected HCV+/HIV+ and in hepatitis C. However, the impact of insulin resistance in non-1 genotype seems not achieve enough importance to impair sustained response, probably due to the high sensitivity to peginterferon. The treatment of insulin resistance, decreasing hyperinsulinemia, could improve sustained response rate in genotype 1 patients with chronic hepatitis C when treated with peginterferon

plus ribavirin. A multicenter Spanish trial (TRIC-1) is ongoing to analyze the effect of triple therapy with peginterferon alfa-2a plus ribavirin and metformin versus standard therapy and placebo in patients with chronic hepatitis C infected by genotype 1 and showing insulin resistance.

## ACKNOWLEDGMENTS

The author thanks Drs. ## Abstract

There has been a significant advance in the treatment of chronic Hepatitis B virus (HBV) infection and the following drugs were approved for therapy: Conventional interferon (IFN), pegylated interferon alfa-2a (PEG IFN α2a), lamivudine, adefovir and entecavir. Compared to nucleoside analogues IFN induces higher rates of sustained remission and HBsAg loss. Conventional IFN in lower doses (1, 5-3 MIU) tiw for 4-6 mo has similar efficacy in comparison to "standard IFN therapy". Longer IFN treatment is a significant factor for long-term remission in HBeAg-negative CHB, but the higher actual IFN dose is not such a factor. PEG IFN is superior to conventional IFN. There is no significant difference between PEG IFN α2a at doses 90 mcg/wk and 180 mcg/wk in HBeAg-positive patients. These results provide a rational for further clinical trials with lower doses PEG IFN α2a given in prolonged course as maintenance or intermittent treatment. Serious new problems arose after the introduction of nucleoside/nucleotide analogues in clinical practice. The most important ones are drug-resistance and the high rates of relapse after treatment discontinuation. Therapy should only be recommended if the expected benefit exceeds significantly the abstain from treatment. The choice of therapy should take into account the patient's age, co-morbidity, severity of liver disease and the risk of drug-resistance. New antivirals significantly suppress HBV-replication, but have no effect on cccDNA in hepatocytes, and after the treatment discontinuation viral relapses occurs. At the present level of knowledge it is impossible "to eradicate the virus" The realistic treatment goal is to achieve durable response by clearance of HBeAg, sustained decrease of serum HBV DNA levels, normalization of ALT, improvement of liver histology and stopping of liver fibrogenesis. The competition between IFN based therapy and nucleoside or nucleotide analogues still remains. IFN can cure the liver disease while nucleotide analogues only suppress the viral replication during therapy and can reduce the liver fibrosis. Treatment should be prolonged for 24-mo or longer by using maintenance or intermittent treatment course with the lowest effective IFN and PEG IFN doses. Nucleoside/nucleotide analogues are a promising treatment option, but additional data for treatment duration and long-term post-treatment outcome are necessary.

## INTRODUCTION

Hepatitis B virus (HBV) infection is a global health problem. This infection is especially endemic in Asia, South Pacific Region, sub-Saharan Africa and South America[1]. It is estimated that over 350 million people worldwide are chronically infected with HBV and up to one million die annually due to HBV-related complications, including hepatocellular carcinoma (HCC)[2]. In China and sub-Saharan Africa HCC associated with HBV is one of the leading causes of cancer in men[1].

In the mid-1980s, IFN became the first approved therapy for CHB. In addition effective vaccines against HBV became available and there was a flicker of hope that the problem can be solved. Over the years it became clear that the chronic HBV infection is much more severe and difficult to treat disease than previously supposed. The positive impact of routine infant HBV-immunization programs is beyond doubt, but chronic HBV-infection still remains an important public health issue.

During the last decade much was learned about the HBV genome organization, viral replication cycle, role of host immune response and natural course of chronic HBV infection[3]. The emergence of human immunodeficiency virus (HIV) infection on the other hand facilitated the search for effective and safe antiviral agents. Several new drugs were found to be quite promising candidates for the treatment of CHB. All these findings led to the 'return' of research interest in the treatment of CHB. A large number of clinical trials with new long-acting pegylated interferons (PEG IFN) and antiviral agents were performed. As a result of this intensive clinical research now we have five approved drugs for the treatment of CHB: Conventional IFN, PEG IFN α2a as well as three nucleoside or

**Table 1 Treatment response at the end of 24-wk follow-up after 24-wk therapy with IFN α2a 4.5 MIU tiw, 90 mcg/wk, 180 mcg/wk and 270 mcg/wk PEG IFN α2a (Adapted from W Cooksley *et al*[12])**

| Response at the end of the 24-wk follow-up | 4,5 MU IFN (*n* = 51) | 90 μg PEG IFN α2a (*n* = 49) | 180 μg PEG IFN α2a (*n* = 46) | 270 μg PEG IFN α2a (*n* = 48) |
|---|---|---|---|---|
| HBV DNA < 500 000 cp/mL | 13 (25%) | 21 (43%) | 18 (39%) | 13 (27%) |
| Loss of HBeAg | 13 (25%) | 18 (37%) | 16 (35%) | 14 (29%) |
| HBeAg seroconversion | 13 (25%) | 18 (37%) | 15 (33%) | 13 (27%) |
| Normal ALT | 13 (25%) | 21 (43%) | 16 (35%) | 15 (31%) |
| Combined response[1] | 6 (12%) | 13 (27%) | 13 (28%) | 9 (19%) |

[1]HBeAg-negative, HBV DNA < 500 000 cp/mL, Normal ALT.

nucleotide analogues (lamivudine, adefovir and entecavir). Furthermore, several new drugs are under investigation in phase Ⅱ and Ⅲ clinical trials: emtricitabine, tenofovir, clevudine and telbivudine. Nevertheless, the treatment of chronic HBV infection is still a challenge due to the low rates of durable response with currently available therapies, especially in HBeAg-negative patients. The main problems with current treatments now are associated with suboptimal efficacy, poor tolerability, and/or emergence of resistance.

There are no clinical trials comparing directly the efficacy of all discussed therapies. Furthermore, it is difficult to compare the results of clinical trials in CHB due to the different sensitivity of the assays used for detection of serum HBV DNA over the years. In the early 1980's the virological response was measured only by serological assays (HBeAg and anti-HBe Ab). Later it became clear that the presence and absence of HBeAg is not an accurate indicator of replicative and nonreplicative infection and low-sensitive hybridization assays (detection limit of approximately $10^6$ copies/mL) were developed for the measurement of serum HBV DNA[3]. In the last years the majority of laboratories moved from hybridization techniques, through bDNA, to high-sensitive PCR (Roche Amplicor monitor) and RT PCR assays with lower detection limits of $10^3$ copies/mL and < 100 copies/mL, respectively.

## CURRENTLY APPROVED THERAPIES FOR CHRONIC HEPATITIS B

In spite of the mentioned difficulties, the treatment results of the approved therapies for CHB have been summarized by M Osborn and A Lok[4,5]. Available data suggest that higher rates of sustained remission and HBsAg loss can be achieved with interferon based treatment in comparison to nucleoside analogue therapy.

### *IFN and pegylated interferons in HBeAg-positive CHB: Standard and low-dose treatment schedules*

Conventional IFN has been used in CHB patients for 20 years. IFN has both antiviral and immunomodulatory effects[6], but only 1/3 of HBeAg-positive patients achieve HBV DNA and HBeAg loss after 4-6 mo course of IFN at a dose of 5 MIU daily or 9-10 MIU thrice weekly[7]. Subsequently, 6 to 12 mo post therapy HBsAg loss was found only in 8% of HBeAg-positive patients[7]. These treatment doses and durations have been validated as a "standard IFN therapy" for HBeAg-positive CHB by both EASL and AASLD treatment guidelines[8,9]. However, some studies in HBeAg-positive patients suggested that conventional IFN, given in lower doses (1, 5-3 MIU thrice weekly) for 4-6 mo, is with similar efficacy compared to "standard IFN therapy"[10,11]. This low-dose therapy is much better tolerated than higher IFN doses. Although treatment with low-dose IFN has not been generally accepted, these results are quite interesting especially in the light of new-coming data for the efficacy of PEG IFNs. A phase Ⅱ clinical trail showed that PEG IFN α2a is superior to conventional IFN in HBeAg-positive CHB[12]. In addition no significant difference was found in PEG IFN α2a efficacy given in dose of 90 mcg/wk in comparison to dose of 180 mcg/wk (Table 1)[12].

Having in mind that the majority of the side effects of PEG IFN α2a are dose-related, these results provide a rational for further clinical evaluation of lower dose of PEG IFN α2a as well as for new clinical studies with individualization of treatment schedule by PEG IFN tapering therapy. This might be a possibility to achieve better tolerability and lower treatment costs without losing the treatment efficacy. Further investigations are needed to confirm or reject this hypothesis.

### *IFN and pegylated interferons in HBeAg-negative CHB: standard and low-dose treatment schedules*

Early clinical trials in HBeAg-negative CHB, with 5-10 MIU of conventional IFN for 4-6 mo reported high (60%-90%) end-of-therapy response (ETR), but only 10% sustained response (SR) due to frequent relapses after the therapy[13]. Similarly to HBeAg-positive patients, HBeAg-negative subjects are sensitive to lower doses (1,5-3 MIU) of conventional IFN, but the relapse rate after 6-mo treatment course with low dose was also high[14,15].

Mathematical models of chronic HBV infection indicate that, although the half-life of HBV is short (< 1 d), the half-life of hepatocytes is relatively long (10-100 d) or even higher for the infected hepatocytes[16]. Therefore viral suppressive therapy might be continued for 1-10 years for viral elimination[16]. Subsequently, a longer course with conventional IFN was reported to improve the SR, which was found to be 11% and 22% after 6 and 12 mo of conventional IFN therapy, respectively[17]. Only the longer IFN course was identified as a significant factor of long-term remission, while the higher actual IFN dose was

not[17]. An Italian study showed a 30% SR after a 24-mo maintenance course with 6 MIU IFN tiw[18]. However, this prolonged treatment was associated with poor tolerability of IFN and high incidence of dose-related adverse events. In a recent pilot study we found similar SR by using approximately 2-year cyclic therapy with low-dose (1,5 MIU) conventional IFN therapy[19]. Taken together, this findings suggest that prolonged treatment (24-mo or longer) with conventional IFN in low-dose (1, 5-3 MIU) given as a maintenance or intermittent treatment course is appropriate therapeutic approach for HBeAg-negative CHB.

Recently, the efficacy of IFN-based therapy in CHB was improved by the introduction of PEG IFNs. In HBeAg-negative patients a 36% SR (combined biochemical and virological) was found at 6 mo after the 12-mo therapy with PEG IFN α2a[20]. However, 24-mo after the end of the treatment only 41% of patients with normal ALT levels 6-mo post therapy remained with combined biochemical and virological response[21]. Our results with cyclic (re-induction) treatment[19] provide a rational for further clinical trials with low-dose intermittent PEG INF therapy in responders of 12-mo PEG IFN α2a treatment. We have just initiated such a study aiming to test the potential of this treatment approach for reducing the relapse rate in end-of-treatment PEG IFN responders.

### *Lamivudine*

Lamivudine was the first introduced nucleoside analogue in clinical practice. Twelve-month course with lamivudine induces HBeAg-seroconvertion in 17% to 22% of the patients[22-24]. HBeAg-seroconvertion rates increased to 50% after continuous treatment for 5 years, but this was associated with increasing rates of drug-resistant mutations (up to 70%) after 5-year therapy[25]. One-year lamivudine therapy suppressed viral replication in 65% to 90% of HBeAg-negative patients[26,27]. However more than 90% of HBeAg-negative responders at the end of 12-mo course relapsed after treatment discontinuation[27]. Extended treatment duration was associated with decreased response rate due to drug-resistance[28]. The main concerns with lamivudine treatment are the selection of drug-resistant mutations and the very high relapse rate after treatment discontinuation. Both drug-resistance and relapse are associated with risk of hepatic flare and liver failure. Due to these reasons it is not recommended to use lamivudine as a first line therapy, especially in young patients. It should be also stressed that recent studies show PEG IFN α2a monotherapy to induce higher SR rate in both HBeAg-negative and HBeAg-positive subjects in comparison to 1-year course with lamivudine[20,29]. Combined therapy with lamivudine plus PEG IFN α2a is with efficacy, similar to that of PEG IFN α2a monotherapy[20,29]. According to the current knowledge there is no biological rational for further use of this combination, but the consequent treatment with antivirals and IFN-based treatment is a possible treatment approach.

### *Adefovir*

Recently, adefovir and entecavir were approved in the United States. Adefovir is effective in both HBeAg-positive and HBeAg-negative patients[30,31]. However, only 8% of the patients had a SR one year after treatment discontinuation[32]. Adefovir effectively suppress lamivudine resistant mutants which is a significant advantage of this drug. Because of the high rates of drug-resistance, patients on prolonged lamivudine therapy need to be closely monitored. If virological breakthrough occurs due to drug-resistance, adefovir can be administrated in addition to lamivudine. Resistance to adefovir is uncommon during 2-year therapy, but emerge later in the course of treatment to 30% after 5-year therapy. Thus drug-resistance will be an increasing concern with longer adefovir treatment duration. Nephrotoxicity is another disadvantage of this drug.

### *Entecavir*

Entecavir is more potent than lamivudine in suppressing HBV replication with significantly higher rates of biochemical and histological responses both in HBeAg-negative and HBeAg-positive patients[33,34]. No entecavir-resistance was observed after 2 year therapy among nucleoside analogue naïve patients[35]. However, the presence of lamivudine resistance increases the likelihood of entecavir resistance[35,36]. Long-term data with entecavir still are not available.

## NEW PROMISING ANTI-VIRAL AGENTS

Many new antivirals are under evaluation for the treatment of CHB. Emtricitabine (FTC) and tenofovir are licensed for use in HIV infection.

### *Emtricitabine*

FTC is closely related structurally to lamivudine and therefore they share similar mutational sites[37]. A recent study in HBeAg-positive and HBeAg-negative patients found that 48 wk of treatment with emtricitabine 200 mg daily resulted in significant histological, virological, and biochemical improvement[38]. The results of emtricitabine treatment were quite similar to published data for lamivudine. The incidence of YMDD mutations in patients, receiving emtricitabine 200 mg daily, is 12% and 19% at treatment wk 48 and 96, respectively[37,38]. The role of emtricitabine as a monotherapy may be limited due to its structural similarity to lamivudine and the risk of development of drug resistance.

### *Tenofovir*

Tenofovir is an acyclic nucleotide inhibitor of HBV polymerase and HIV reverse transcriptase with close chemical similarity to adefovir[37]. Antiviral activity of tenofovir against HBV is found to be greater than the one of adefovir 10 mg in lamivudine resistant patients[37,39]. Furthermore, the N236T mutation that confers resistance to adefovir is sensitive to tenofovir[37]. Phase Ⅲ clinical trials are under way to determinate the long-term safety and efficacy of tenofovir.

### *Clevudine*

Clevudine is a nucleoside analog of the unnatural β-L configuration. A recent randomized, double-blind study

found no significant difference between 24-wk therapy with emtricitabine plus clevudine and emtricitabine alone[40]. However, there was a significantly greater virologic and biochemical response at wk 24 after the end of treatment in the emtricitabine plus clevudine arm[40]. Further studies are needed to assess the long-term efficacy and safety of this drug.

### *Telbivudine*

Telbivudine (LdT) is another antiviral agent, which is under clinical investigation in CHB. A phase Ⅱ study in 104 HBeAg-positive patients compared different therapeutic schedules for 52 wk[41]. The telbivudine-treated patients exhibited significantly greater virological and biochemical response in comparison to lamivudine[41]. Results from the combined regimens (LdT plus lamivudine) were similar to those obtained with LdT alone[41]. These data support the ongoing phase Ⅲ evaluation of telbivudine for the treatment of CHB.

## ADVANTAGES, DISADVANTAGES AND TREATMENT LIMITATIONS OF CURRENT THERAPIES

Substantial progress has been made in the treatment of chronic hepatitis B, but quite serious new problems arose after the introduction of nucleoside/nucleotide analogues in clinical practice. The most important of them is the selection of drug-resistant mutations. Drug-resistance usually is accompanied by virologic breakthrough during therapy and increased ALT levels after initial normalization[35]. In some patients this may cause severe hepatic flare with liver failure and death[35]. In addition, resistance to one antiviral drug may confer resistance to other agents and may limit future treatment options[35]. Another important problem is the high rate of relapse after therapy.

With regards to the limited long-term efficacies of the approved therapeutic regimens, therapy should only be recommended if the expected benefit exceeds significantly abstain from treatment[35]. The choice of therapy should take into account the patient's age, co-morbid medical conditions, the severity of the liver disease and the risk of drug-resistance[4].

Interferon based therapy is associated with more durable response and the absence of drug-resistant mutations[42]. However, IFN is effective mainly in a subgroup of young patients with high ALT levels and low viral load[7,37]. At present it is generally accepted that subjects with normal or slightly elevated ALT (< 2x ULN) are not indicated for antiviral therapy[8,9]. These patients should be strictly monitored at 3-mo intervals. Low serum HBV DNA levels (HBV DNA < 30 000 000 copies/mL) are an important predictor of response to both conventional IFN and PEG IFN therapy[37]. With regards to this the initiation of IFN should be avoided in patients with very high viral load and especially if ALT is not markedly elevated. If possible the start of IFN therapy should be postponed for the moment, when serum HBV DNA and ALT levels predict higher likelihood of treatment response. High baseline ALT levels are the most important predictor of response to lamivudine and adefovir as well[42]. However, it should be mentioned that the high levels of ALT also are a predictor of spontaneous remission in HBeAg-positive CHB. So the decision to start nucleoside analogue should balance between the benefits of this treatment and the risk of drug resistance and hepatic flare.

Interferon based treatment is also limited by significant disadvantages in terms of injection-based application, poor tolerability, potentially severe side-effects, contraindications and relatively high cost. Flu-like symptoms, fatigue, bone marrow suppression thyroid disorders, irritability and depression are the most common adverse effects[5]. Patients should be closely monitored with monthly clinical and laboratory examinations. Approximately one-third of subjects may require dose reduction and 5% may discontinue therapy prematurely due to the adverse events.[5] Furthermore, IFN and PEG IFN are contraindicated in decompensated cirrhosis as well as in subjects with autoimmune disorders. They are also ineffective in immunosupressed patients. In fact nucleoside or nucleotide analogues are the only available treatment option in decompensated cirrhosis and in immunosupressed subjects.

## TREATMENT GOALS

Sensitive HBV DNA assays revealed that HBV replication might persist even after HBsAg seroconvertion and this finding changed our treatment concept. Although the new antiviral agents significantly suppress HBV-replication, there is a pool of covalently closed circular DNA (cccDNA), resistant to the available antiviral treatment. This cccDNA serves as a template for viral transcription, so viral relapses occurs once antiviral medications are discontinued[4]. At the present level of knowledge it is impossible "to eradicate the virus" The realistic treatment goal now is to achieve durable response by clearance of HBeAg, sustained decrease in serum HBV DNA levels with normalization of ALT, improvement of liver histology and stopping of liver fibgogenesis[4].

In conclusion the competition between IFN based therapy and nucleoside or nucleotide analogues treatment still remains. IFN can cure the liver disease while nucleotide analogues only suppress the viral replication and can reduce the liver fibrosis. In the future IFN treatment in HBeAg-negative CHB might need to be prolonged for 24-mo or even longer by using maintenance or intermittent treatment course with the lowest effective IFN or PEG IFN doses. Nucleoside/nucleotide analogues are a promising treatment option, but additional data for treatment duration and long-term post-treatment outcome are necessary.

## Abstract

Acute pancreatitis in its severe form is complicated by multiple organ system dysfunction, most importantly by pulmonary complications which include hypoxia, acute respiratory distress syndrome, atelectasis, and pleural effusion. The pathogenesis of some of the above complications is attributed to the production of noxious cytokines. Clinically significant is the early onset of pleural effusion, which heralds a poor outcome of acute pancreatitis. The role of circulating trypsin, phospholipase A2, platelet activating factor, release of free fatty acids, chemoattractants such as tumor necrsosis factor (TNF)-alpha, interleukin (IL)-1, IL-6, IL-8, fMet-leu-phe (a bacterial wall product), nitric oxide, substance P, and macrophage inhibitor factor is currently studied. The hope is that future management of acute pancreatitis with a better understanding of the pathogenesis of lung injury will be directed against the production of noxious cytokines.

**Key words:** Acute pancreatitis; Cytokines; Acute respiratory distress syndrome; Complications of pancreatitis; Pleural effusion; Interleukins

## INTRODUCTION

Acute pancreatitis (AP), an acute inflammatory process of the pancreas in its severe form, is complicated by the development of multi-organ dysfunction syndrome (MODS) with a mortality of 15%-20%. Regardless of etiology, once AP is initiated the inflammatory events within the acinar cells will progress to a generalized systemic inflammatory response syndrome (SIRS). Amongst the systemic complications, pulmonary complications are the most frequent and potentially the most serious. Recognition of these complications and their pathology may lead to more rapid diagnosis and better therapies. The following is a brief summary of the current researches on each of the possible pulmonary complications ranging from hypoxemia to acute respiratory distress syndrome (ARDS). Hypoxemia may occur without radiological abnormalities in 75% of cases. There is a direct correlation between hypoxemia noted early in the course of AP and mortality. Pleural effusion, once thought to be a marker of AP, is now a noted poor prognostic sign. Atelectasis, a frequent radiological complication, is attributed to a decrease in the quantity of pulmonary surfactant. The most dangerous complication of the pulmonary system is ARDS. The pathophysiology of ARDS and most of the other pulmonary complications is multifactorial. Activated trypsin causes damage to pulmonary vasculature and increases endothelial permeability. Active circulating phospholipase $A_2$ ($PLA_2$) is known to remove fatty acids from phospholipids. One of the main components of surfactant is the phospholipid, dipalmitoylphosphatidylcholine. Many recent studies have assessed the role of platelet activating factor (PAF) which stimulates polymorphonuclear cells (PMNs) regulating the interaction between PMNs and endothelial cells facilitating migration of activated WBC into interstitial spaces. Based on the observation a PAF inhibitor Lexipafant has undergone double blind randomized studies. Another major advance in the understanding of the pathophysiology of pulmonary complications is the explosion of knowledge of cytokines. There are pro-inflammatory cytokines released from the pancreas such as tumor necrosis factor-alpha (TNF-$\alpha$), interleukin (IL)-1, IL-6, and IL-8. PMNs also contribute to release of cytokines. Our aim was to help the clinician understand the importance of the many studies looking at the effect of inflammatory modulators in decreasing the severity of AP. Today's experimental medicine is likely to become a therapeutic modality in the near future.

## PATHOPHYSIOLOGY OF PULMONARY COMPLICATIONS OF ACUTE PANCREATITIS

AP is an acute inflammatory process of the pancreas with

variable involvement of peripancreatic organs and/or remote organ systems in different degrees. In 10%-20% of AP, it presents in its severe form, which is frequently complicated by the development of MODS with a mortality rate of 15%-20% or more[1,2]. Recent studies have documented two peaks of mortality in patients with AP, an early mortality due to the effects of SIRS and MODS, and a late mortality caused by the effects of MODS combined with pancreatic sepsis following pancreatic necrosis[3,4]. About 30% of patients with fatal AP have been diagnosed first at autopsy[2,5], indicating how often we miss the diagnosis and how fast the disease can progress after the onset. Regardless of its etiology, the clinical course follows a pattern of interaction between inflammatory events within the pancreas which initiate a generalized systemic inflammatory response. The mortality and severity of the disease appear to be influenced by events occurring subsequently to the pancreatic injury as a result of release of cytokines and other mediators.

Severe AP is associated with MODS and/or local complications such as necrosis, abscess, pseudocyst, or pancreatic ascites. Fortunately, AP is usually mild.

Pulmonary complications of AP occur in almost 75% of cases, ranging from hypoxemia to ARDS[6,7]. The local and systemic complications are listed in Table 1. Of the systemic complications, acute respiratory failure is perhaps the most serious one. In the last two decades, our understanding and management of severe AP have substantially improved. The traditional concept that AP is entirely due to the release of activated proteases from an injured pancreas has been considerably changed. The present view is that the activation of trypsin by intracellular zymogens, trypsin activating chymotrypsinogen, proelastase and prophospholipase A plays an initiating role, but other chains of events predominate in precipitating complications[6-8].

Recent studies using secretagogue-induced models of pancreatitis, caerulein- induced AP in rats, sodium taurocholate- induced AP, choline deficient ethionine-supplemented diet- induced AP in mice and free fatty acid- induced AP in dogs, as well as a number of other models have suggested that pancreatitis is a disease that evolves in 3 phases. The initial phase is characterized by intrapancreatic digestive enzyme activation and acinar cell injury which involves the first few hours of AP. The second phase characterized by an intrapancreatic inflammatory reaction and varying degrees of acinar cell necrosis involves approximately 12-72 h. Finally, the third phase which involves the rest of the progression of AP is characterized by further progression of the pancreatic injury and the appearance of extrapancreatic changes including SIRS and ARDS[9].

It is during phase three that pulmonary insult occurs. In this review, we chiefly focus on the many pulmonary complications of AP, their pathogenesis, and clinical significance. This review is an extension of our previous review and other excellent recent reports on the topic[10-13]. The literature search was done by Medline search using the terms 'pancreatitis', 'pleural effusion', 'hypoxemia', and 'ARDS' in combination searches in the English language.

Pulmonary complications of AP for ease of explanation are divided into three stages. Stage 1 deals with pulmonary manifestations without any noticeable changes radiologically, stage 2 emphasizes radiologic changes observed and stage 3 discusses ARDS. Following these stages is a discussion on the players in the pathophysiology of the pulmonary complications of AP.

**Table 1 Complications of acute pancreatitis**

| | |
|---|---|
| Ⅰ | Pancreatic |
| | 1 Necrosis-sterile *vs* infected |
| | 2 Pseudocyst-infection/rupture/hemorrhage |
| | 3 Abscess |
| Ⅱ | Local-extrapancreatic |
| | 1 Involvement of contiguous organs (intraperitoneal hemorrhage, GI bleeding, thrombosis of splenic vein, bowel infarction) |
| | 2 Pancreatic ascites |
| | 3 Obstructive jaundice |
| Ⅲ | Systemic |
| | 1 Pulmonary |
| | a Early arterial hypoxia |
| | b Atelectasis, pneumonia, pleural effusion, mediastinal abscess |
| | c ARDS |
| | 2 Cardiac: shock, pericardial effusion, EKG changes, arrhythmias |
| | 3 Hematologic: DIC, TTP/HUS |
| | 4 Gastrointestinal: GI bleeding (portal-splenic vein thrombosis, colonic infarction) |
| | 5 Renal: azotemia, oliguria |
| | 6 Metabolic: hypocalcemia, hyperglycemia, hypertriglyceridemia, acidosis, elevation of free fatty acids |
| | 7 CNS: psychosis, pancreatic encephalopathy, Purtscher's retinopathy |
| | 8 Peripheral: fat necrosis (skin and bones), arthritis |
| | 9 Miscelaneous: rhabdomyolysis |

## STAGE 1: HYPOXEMIA WITH NO RADIOLOGICAL ABNORMALITIES

Tachypnea, mild respiratory alkalosis, and hypoxemia are seen in almost two thirds of patients with AP during the first 2 d of admission to the hospital[14]. In these patients, physical examination is essentially normal, chest radiographs rarely demonstrate abnormalities (11%), and clinical signs if present, seldom indicate the severity of the hypoxemia[6]. Ranson and colleagues[15] observed that 52% of patients have arterial oxygen tensions (PaO2) < 71 mmHg. Imrie and co-workers[6] showed that 45% of patients have severe arterial hypoxemia (PaO2 < 60 mmHg) and indicated that a PaO2 of < 52.5 mmHg is associated with a mortality of more than 30%. A study conducted several years ago identified that the incidence of pulmonary insufficiency in acute edematous pancreatitis is < 10%, increasing to 47% for acute sterile necrosis and 74% for infected necrosis[16,17]. Ranson *et al*[18] reported that respiratory insufficiency characterized by an arterial pO2 < 75 mmHg and drawn within 48 h of admission is observed in 58%. Recently Lankisch and associates[19] studied a group of 204 patients with AP and demonstrated that 63% of the patients have an arterial pO2 < 70 mmHg, and 30% have a pO2 < 60 mmHg, showing that hypoxemia is present early in AP patients. The major cause of hypoxia is ventilation and perfusion mismatch,

which results in a right to left intrapulmonary shunting of up to 30% of cardiac output[20] The most important precipitating factor for MODS during the first week of AP is perhaps the failure to promptly recognize and treat hypoxia and hypovolemia[21]. The incidence of respiratory insufficiency is not related to the etiological factors of AP, severity of the disease, age of the patient, admission serum amylase, serum calcium, the amount or the nature of fluid administered (colloid solutions or blood), or the estimated fluid sequestration, but is seen more often in patients experiencing their first attack of AP.

### *Clinical significance*

If pulmonary infiltrates and severe hypoxemia develop concurrently, mortality rate may be as high as 56%[16]. In two studies, Imrie and coworkers[6,22] correlated the overall mortality with the degree of hypoxemia. They found that patients with arterial pO2 below 70 mmHg have a mortality of 3% to 5.9% and when the arterial pO2 decreases below 60 mmHg the mortality rate increases to about 14%. Marked respiratory insufficiency in 22% of the cases of AP is associated with a 60% mortality from uncontrollable hypoxemia[23]. These studies suggest that respiratory insufficiency early in AP represents a risk for future ARDS especially if it is persistent and refractory to oxygen therapy.

## STAGE 2: HYPOXEMIA WITH RADIOLOGICAL ABNORMALITIES

### *Pleural effusion*

In 33% of all patients with AP, respiratory complications are clinically or radiographically detectable[16]. Pulmonary infiltrates or atelectasis (15%), pleural effusions (4%-17%), and pulmonary edema (8%-50%) are the pulmonary manifestations of AP in this category. Mortality and morbidity are significantly higher as compared to Stage 1. Some of these patients require ventilatory assistance. A direct relationship to prognostic factors is observed in this stage.

Presence of pleural effusion is currently considered an indication of severe pancreatitis and not just a marker of the disease[24]. Pancreatic ascites and pleural effusion are rare complications of both chronic and acute pancreatitis, and are associated with a mortality rate of 20% to 30%[25]. Mediastinal pancreatic pseudocysts and acute fluid collections are rare complications of pancreatitis resulting in an increase in morbidity and mortality[26]. Pleural effusions in AP are usually small, occasionally bloody, and are characterized by high amylase (up to 30 times greater than corresponding serum value), protein (> 30 gm/L), and lactic acid dehydrogenase (ratio) (> 0.6 serum value) levels[27]. The majority of pleural effusions (68%) are left-sided, 22% are bilateral and 10% are right-sided only. Two main causes of pleural effusion are transdiaphragmatic lymphatic blockage or pancreaticopleural fistulae secondary to leak and disruption of the pancreatic duct or pseudocyst caused by an episode of acute pancreatitis. The leak or disruption is more likely to lead to a pleural effusion if the duct disruption is posteriorly into the retroperitoneum. The pancreatic enzymes can track up into the mediastinum and then rupture into the pleural cavity either left side or bilaterally and so create a connection between the pancreatic duct and the pleural cavity. Pancreatic pleural effusions may be massive and require treatment[28].

Close to 1/3 of all patients with an internal pancreatic fistula present with pleural effusion[29]. Formation of a posterior mediastinal cyst indicates that a patient is at increased risk of developing pleuropulmonary complications including acute and chronic pleural effusions which can be sympathetic in origin or result from the development of a fistulous tract into the pleural space[30]. Dyspnea and hypoxia, chest pain, atelectasis, cough, and ARDS can develop, worsening the prognosis[26].

Treatment of pleural effusion is usually at first conservative. Pleural effusions which become symptomatic often require thoracentesis, tube thoracotomy, endotracheal intubation, ICU admission, parenteral alimentation, and administration of octreotide. When the intraabdominal etiology is resolved, pleural effusions often resolve as well. Chronic effusions often require drainage of the pseudocyst or abscess or excision of the fistulous tract[27].

### *Atelectasis*

Consolidation of lung tissue and atelectasis are frequent radiological observations. In cerulein-induced experimental pancreatitis-associated lung injury, it has been observed that there is a decrease in the production of pulmonary surfactant[31]. A decrease in the quantity of pulmonary surfactant may be a significant cause of atelectasis formation in dependent lung regions. Cerulein-induced pancreatitis appears to cause a decrease in the strength of the muscles of the diaphragm as well as a decrease in the endurance of these muscles[32]. Because the primary lesion is found at the alveolar interstitial level, it is probable that this decreases lung compliance and increases the work of breathing, leading to fatigue of the diaphragm more quickly[32].

There is mounting evidence that the proinflammatory cytokines are the agents behind the systemic complications of AP[33-35]. Cytokines are low molecular weight proteins, secreted by various cell types, that regulate the intensity and duration of immune responses and mediate cell-to-cell communication[36]. During AP IL-1, IL-6, and TNF-$\alpha$ are formed within the pancreas[32]. There is growing evidence that cytokines, mainly TNF-$\alpha$ and IL-1, could be the orchestrators of skeletal muscle dysfunction during sepsis. An experimental study showed that TNF-$\alpha$ at a lower concentration (50-400 ng/mL) causes no diaphragmatic fatigue in rats[37]. However at a higher concentration (10 $\mu$g/mL) of the cytokine, fatigue occurs in hamsters[38]. It has been noticed that TNF-$\alpha$ and IL-1 have a synergistic negative inotropic effect on the contractility of the diaphragm[39]. According to Matuszczak *et al*[32], cytokine levels need to be at a very high concentration to have a physiologic effect. Since the concentrations of cytokines in muscle during sepsis have not yet been quantified, the higher concentration of cytokines used in the study may be achieved in the natural physiologic setting of sepsis[32]. According to Norman *et al*[35], the intrapancreatic concentration of cytokines achieved in AP is much

higher than the systemic level and this argues in favor of the observation by Matuszczak *et al*[32] who used higher concentrations of cytokines to achieve the end result of diaphragmatic fatigue. According to these studies, it is possible that if IL-1, IL-6, TNF-α are present at high enough concentrations in the pancreatic juice, they could cause diaphragmatic fatigue. Diaphragmatic impairment may be the pathophysiologic cause of atelectasis in the lower regions of the lung via decreased ventilation in these regions[32].

## STAGE 3: ARDS

The most dangerous complication of the pulmonary system is ARDS. ARDS, a syndrome first described in 1967[40], is observed in association with AP[16]. Of the patients who develop AP, 15% to 20% develop ARDS with an associated mortality of 56%[41]. ARDS usually manifests itself between two to seven days following the onset of AP, but may have a much more rapid course. Clinical features include severe dyspnea and extreme hypoxemia refractory to a high inspired oxygen concentration. Multilobar pulmonary infiltrates in patients with previous normal radiographs and a relatively normal pulmonary capillary wedge pressure (< 18 mmHg) are noted[42,43]. Autopsy studies in patients with AP have shown that morphological changes in the lungs are indistinguishable from those in patients with ARDS caused by other conditions, including shock, sepsis, and severe trauma[44]. The lungs are characterized by increased alveolar capillary permeability with interstitial edema. The complication of ARDS parallels the presence of other poor prognostic signs of AP[15]. Although less often than necrotizing pancreatitis, patients with interstitial edematous pancreatitis are also at risk (10%) of developing respiratory failure[45].

There are three clinical features that must be present in ARDS: widespread bilateral radiographic infiltrates, a ratio of the partial pressure of arterial oxygen to the fraction of inspired oxygen (PaO2/FiO2) less than or equal to 200 regardless of the positive end-expiratory pressure (PEEP), and no clinical evidence for an elevated left atrial pressure (less than or equal to 18 mmHg)[21,46]. Hypoxia is worse in ARDS. ARDS accounts for 50%-90% of all deaths from pancreatitis[47]. Improved ventilatory and supportive care, has improved the outcome in ARDS. However the underlying etiology remains unclear, keeping the mortality still unacceptably high.

### *Pathophysiology*

The pathophysiology of ARDS in AP is poorly understood. Actions of pancreatic enzymes as well as inflammatory mediators released as a result of pancreatic injury play a key role in the pulmonary complications. The pathophysiology of ARDS is described as increased pulmonary vasculature leaking protein- rich transudate into the alveolar space and decreased lung compliance manifested clinically as refractory hypoxemia, and radiologically as diffuse infiltration in the lungs.

In the pathogenesis of systemic complications of AP, the role of active enzymes in circulation, liberation of proinflammatory cytokines, leukoagglutination, migration of neutrophils, activation of leukocytes, complement-mediated injury, and platelet activating factor decreasing the normal defense mechanisms and increased production of Nitric oxide (NO) are studied. The agents which are suspected to play a role in the pathogenesis of AP are noted in Table 2. A number of experimental and clinical studies have helped to elucidate the mechanisms involved in the pathogenesis of lung injury secondary to AP.

**Table 2 Pathogenic players in respiratory insufficiency**

| | |
|---|---|
| 1 | Phospholipase A2 |
| 2 | Trypsin inhibitor |
| 3 | FFA/Lipoprotein lipase |
| 4 | Complement activation (C5a) |
| 5 | MIF |
| 6 | IL-6, IL-8, IL-1β |
| 7 | NO |
| 8 | TNF-α |
| 9 | fMet-Leu-Phe (a bacterial wall product) |
| 10 | ICAM-1 |
| 11 | β-2-integrin (CD11b/CD18) |
| 12 | Trypsin |
| 13 | NF-κB |
| 14 | Substance P |

**Activated trypsin:** It is a possible source for the cause of pulmonary insufficiency. Trypsin causes damage to the pulmonary vasculature and increases endothelial permeability[48]. In laboratory experiments trypsin has been shown to cause leukostasis in the pulmonary vasculature and thus activated trypsin could intensify intravascular coagulation in the pulmonary microcirculation[49]. In post mortem studies, patients with acute pancreatitis have been shown to have intravascular fibrin thrombi in different tissues, including the lungs[16]. Trypsin is capable of activating different complement factors directly, which can stimulate cytolysis and chemotactic leukocytes. Complement has been shown to produce ARDS raising the possibility of developing respiratory insufficiency.

**Phospholipase A:** As an incriminating factor in pulmonary complications of AP phospholipase $A_2$ ($PLA_2$) has been investigated by many authors. $PLA_2$, which is activated by trypsin in the duodenum, is known for its ability to remove fatty acids from phospholipids. Pulmonary surfactant lines the surface of the alveoli and prevents the alveoli from collapsing by maintaining the surface tension. One of the main components of surfactant is phospholipid dipalmitoy lphosphatidylcholine, which is a perfect substrate for $PLA_2$. The basic reason for pulmonary insufficiency and ARDS in AP is due to the destruction of the surfactant. Büchler *et al*[45,50] showed that there is a strong correlation between serum-activated $PLA_2$ and pulmonary insufficiency. In their prospective study, patients with pulmonary failure demonstrated a notably higher catalytic $PLA_2$ activity during the first week of AP than patients without arterial hypoxemia. Büchler *et al*[45] and Kortesuo *et al*[51] observed that there are many isoenzymes of $PLA_2$. The source of IR-$PLA_2$ and group I $PLA_2$ is the pancreas, but has no correlation with the severity of pancreatitis or likelihood of development of pulmonary insufficiency. Group II $PLA_2$, which has an extra-pancreatic source, correlates

well with the severity of AP and is probably responsible in part for the pulmonary insufficiency occurring as an extra-pancreatic complication of AP[45,51,52]. The role of other isoenzymes of $PLA_2$ in AP has yet to be elucidated. Inflammatory cells do not seem to be the source of Group II $PLA_2$, but they cause the pulmonary insufficiency and ARDS in AP[53]. The low molecular weight $PLA_2$ inhibitor has been shown to decrease the level of group II $PLA_2$ activity and has no effect on group I $PLA_2$ activity. The inhibitor also decreases tissue destruction and protects pancreatic acinar cells[54]. This is an area which needs further investigation to improve the outcome of AP.

**Platelet activating factor:** PAF is a potent biological mediator whose effect is manifested throughout the body. PAF stimulates PMN white cells and regulates the interaction between PMN cells and endothelial cells, facilitating migration of activated white cells into tissue spaces. PAF is a structural component of membrane lipids and is released upon the action of PLA2[13,55]. In induced experimental pancreatitis (whether induced by immune complex, caerulein, or taurocholate) PAF is released into the pancreas, ascitic fluid, lung and blood[56]. PAF can be controlled via the PAF receptor and PAF antagonists decrease the severity of experimental AP by reducing oxidative injury, morphological changes, white cell infiltration, vascular permeability in pancreas and lungs, pulmonary damage, blood, and peritoneal PAF exudative concentrations[56]. Lexipafant, a computer image analysis generated imidazolyl derivative of $Sp^2$ nitrogen compounds, is a powerful PAF receptor antagonist having an affinity for the receptor seven times more avid than PAF itself[57]. Lexipafant has undergone a randomized double blind phase II clinical trial in human pancreatitis and is very successful in reducing organ failure[58]. However, during phase III clinical trial, Lexipafant is unsuccessful in reducing new organ failure or mortality. In the largest systematic prospective study of severe AP ever undertaken, Johnson *et al*[59] found that 58% of patients in the placebo group and 57% of patients in the Lexipafant group develop one or more organ failures, indicating that there is no difference between these groups. Systemic sepsis affects fewer patients in the Lexipafant group, the development of pseudocysts is 14% in the placebo group and 5% in the Lexipafant group. IL-8, a marker for neutrophil activation and E-selectin, a marker for endothelial damage, decrease more rapidly in the Lexipafant group than in the placebo group. This adequately powered study showed that antagonism of PAF activity on its own is not sufficient to ameliorate SIRS in severe AP or change mortality rates[59].

**Free fatty acid:** Another possible cause of pulmonary insufficiency is the release of free fatty acid (FFA). During the inflammatory process, pulmonary lipoprotein lipase is activated and releases FFA from albumin, to which they are physiologically bound. The free fatty acids released from triglycerides (TG), have been shown to damage capillary alveolar wall membranes[60].

**Digestive enzymes:** In a normal pancreas, potentially harmful digestive enzymes (i.e. protease and phospholipase) are synthesized as inactive proenzyme forms which are only activated after pancreatic secretions reach the duodenum. Enterokinase, a brush border enzyme, cleaves trypsinogen into 2 products, namely N-terminal portion termed trypsinogen-activation peptide (TAP) and active trypsin. Active trypsin then catalyzes the conversion of other proenzymes secreted by the pancreas into their active forms[61]. Gukovskaya *et al*[62] demonstrated that neutrophils infiltrate into the pancreas facilitating intrapancreatic trypsin activation during cerulean (cholecystokinin analogue)-induced experimental pancreatitis. The immunocytochemical localization experiments using specific antibodies to TAP indicate that the trypsin activation mediated by neutrophils occurs within the pancreatic acinar cells[62]. Steer[63], in an excellent hypothesis, suggested that intrapancreatic (i.e., intra-acinar cell) activation of trypsinogen during pancreatitis is itself a 2-phase event. According to this interpretation, the initial phase of trypsinogen activation would be neutrophil-independent and solely dependent on acinar cell events. This initial phase of trypsinogen activation can lead to early acinar cell injury that triggers the pancreatic inflammatory response[63].

Activated neutrophils throughout the body, are attracted to the pulmonary microvascular network by various factors such as complement activation, cytokine production, alveolar macrophages and the upregulation of adhesion molecules[64]. Chemoattractants such as TNF-α, IL-1, IL-6, IL-8, fMet-Leu-Phe (a bacterial wall product) and complement factor C5a upregulate the beta-2-integrin expression on neutrophils and the ICAM-1 receptor on endothelial cells[65,66]. The binding of ICAM-1 to beta-2-integrin (CD11b/CD18) can increase the permeability of the pulmonary vasculature, allowing neutrophils to enter the lung parenchyma. Upon entry into the parenchyma, neutrophils release compounds which have been implicated in the damage caused by ARDS. This theory is supported by studies demonstrating that mice deficient in ICAM-1, develop a much less severe form of pancreatitis, and that ICAM-1 expression is increased in mice with pancreatitis[67,68]. Several compounds released by neutrophils once within the lung parenchyma are discussed in the following paragraphs.

**TNF-α:** High concentrations of TNF-α are found in a variety of locations throughout the body during an episode of AP, and pancreatic parenchyma, ascitic fluid, lymphatic drainage and serum levels can predict disease severity and possible mortality[35,69-72]. TNF-α activates neutrophils and increases lung damage levels at higher concentration in the lung[73,74]. A tetravalent guanylhydrazone compound CNI-1493 has been developed in a research program to prevent the production of macrophage-derived NO. It was then discovered that CNI-1493 blocks the production of inflammatory mediators such as TNF-α, IL-1, IL-6, macroinflammatory peptide (MIP)-1, by preventing the phosphorylation of p38 mitogen- activated (MAP) kinase[75]. If p38 MAP kinase is prevented from being phosphorylated, then TNF-α is not produced or is produced at a significantly lower level[76]. Denham *et al*[77] reported that CNI-1493 significantly attenuates the increase in pulmonary TNF-α resulting in decreased lung injury, confirming that CNI-1493 inhibits its pancreatic and pulmonary TNF-α gene induction in two models

of murine pancreatitis. These results also support that pulmonary congestion is decreased when anti-TNF-α antibody is administered after pancreatitis is induced and overall morbidity and mortality are decreased[78,79]. Several recent studies have suggested that TNF-α is one of the agents orchestrating the early stages of AP, especially in recruitment of inflammatory cells, regulation of cytokine production, and promotion of pancreatic acinar cell death by apoptosis[61,69,79]. TNF-α also plays a protective role in preventing the release of proinflammatory cytokines[76,80]. TNF-α induces concomitantly proapoptotic and antiapoptotic mechanisms[81]. Antiapoptotic mechanisms are controlled by NF-B and MAP kinases. Pancreatitis-associated protein (PAP) prevents apoptosis[81,82]. Apoptosis is possibly a more favorable demise for acinar cells than necrosis because it results in a quick removal of damaged cells without loss of plasma membrane integrity as well as decreased recruitment of leukocytes[81]. According to Kaiser *et al*[81] severe forms of AP demonstrate little apoptosis while edematous pancreatitis shows a higher number of apoptotic cells. There is an interaction between apoptosis and necrosis, with inflammatory cells infiltrating the pancreas and causing necrosis of the apoptotic cells[81,83]. Apoptosis appears to be advantageous over necrosis, but needs to be controlled to prevent excessive tissue loss[81].

**Nitric oxide:** The role of nitric oxide (NO) in vascular collapse during AP is highly controversial[77,84]. CNI-1493 blocks the production of NO by macrophages, subsequently the level of NO decreases lessening the damage to the lungs[84]. However, Tsukahara *et al*[85] demonstrated that alveolar macrophages during experimental pancreatitis mediate endothelial injury as well as increase microvascular permeability resulting in lung injury. In contrast, O'Donovan *et al*[86] showed that administration of sodium nitroprusside, a NO donor, to rats with caerulein-induced pancreatitis decreases lung myeloperoxidase activity, bronchoalveolar lavage protein concentration, and wet-to-dry lung weight, suggesting that NO may be protective against lung injury during pancreatitis. A possible explanation for the contradictory findings between Tsukahara *et al*[85] and O'Donovan *et al*[86] is the different experimental models or is possibly attributable to the paradoxic nature of NO[77].

**Substance P:** Substance P is a neuropeptide which is located in the nerve endings throughout the body and is released into the gap where it acts via the NK1 receptor to mediate pain[12]. It has also been implicated in many inflammatory states, such as immune complex- mediated lung injury, asthma and inflammatory bowel disease[87,88]. Once pancreatitis occurs, there is an increase in substance P levels as well as NK1 receptors on pancreatic acinar cells[12]. Interestingly, mice which have been genetically engineered to be deficient in NK1 receptors are protected from AP[89]. This gives clinical medicine another possibility for preventing AP and thus also for protecting patients against pulmonary complications of AP.

**Chemokines:** Chemokines are a family of cytokines which are distinguished by the fact that they act on the superfamily of G-protein–coupled serpentine receptors[12]. There are two subsets of chemokines based on the orientation of the first two cysteines: CC chemokines and C-x-C chemokines. The CC chemokines stimulate monocytes and C-x-C chemokines stimulate neutrophils. IL-8 is a C-x-C chemokine[90]. There is no direct homologue of IL-8, but there is a homologue of growth-related oncogene-alpha (GRO-α) which is cytokine-induced neutrophil chemoattractant (CINC)[90]. CINC (also a C-x-C chemokine) is a specific neutrophil attractant. A recent study reported that anti-CINC antibody reduces lung damage. During the study, anti-CINC was administered to Caerulein- induced pancreatitis mice prophylactically and during Caerulein administration. The results demonstrate that both the prophylactic group and the therapeutic group have a reduction in lung injury, but not a reduction in AP[90].

**IL-8:** IL-8 is a strong attractant of neutrophils in the lungs and its high concentrations have been observed in the lungs of patients with ARDS[91,92]. Donnelly *et al*[93] showed that bronchoalveolar lavage (BAL) levels of IL-8 are significantly higher in patients who develop ARDS than in those who do not develop ARDS. However they have not found a relationship between blood levels of IL-8 and patients with or without ARDS, but found that IL-8 may be a prognostic factor for ARDS. Kurdowska *et al*[94] took the IL-8 issue one step further to determine if the anti-interleukin 8 and interleukin-8 complex is a marker of patients who are at risk of developing ARDS, and found that anti-interleukin 8 and interleukin-8 complexes may be a marker of patients who may progress to ARDS.

**Macrophage migration inhibitory factor (MIF):** MIF is a cytokine discovered in 1966 and produced by T lymphocytes and plays a role in preventing random migration by macrophages[95,96]. It is now known that MIF is released not only by T lymphocytes but also by monocytes, macrophages, pituitary corticotrophic cells, and epithelial cells. MIF is currently viewed as an important proinflammatory cytokine[97,98]. MIF has a critical role in regulating the immune system by overriding the anti-inflammatory and immunosuppressive effect of glucocorticoids on macrophages and T cells[98,99]. MIF has been shown to be elevated in several inflammatory diseases such as sepsis, rheumatoid arthritis, bronchial asthma and also in the bronchoalveolar lavage samples of adults with ARDS[100-103]. It was reported that MIF levels in the lungs of taurocholate (TCA) pancreatitis rats are significantly higher than those in the lungs of normal rats, whereas MIF levels in the pancreas and liver have no differences between the normal and TCA pancreatitis rats[103,104]. There is a possible connection between TNF-α and MIF[103,105]. Pulmonary TNF-α levels are increased significantly in TCA- induced pancreatitis and the increase can be attenuated by treatment with anti-MIF antibody, but not with the control antibody[103]. Anti-MIF antibody also improves the survival rate in both TCA pancreatitis rats and choline deficient, ethionine-supplemented (CDE) pancreatitis mice[103]. Serum MIF levels are also found to be significantly higher in severe AP than in mild AP or in healthy controls[103]. Combining the increased survivability with anti-MIF antibody, induction of IL-8, stimulus of TNF-α production, ability to override the effects of glucocorticoids and the increased levels of MIF found

**Table 3 Pro-inflammatory cytokines**

| |
|---|
| IL-1β -major inflammatory mediator, major activator of macrophages and enhances B and T cell activation |
| IL-6 -acute phase reactant, stimulates B cell differentiation |
| IL-8 -stimulates the upregulation of adhesion molecules, chemotactic factor for neutrophils and lymphocytes |
| TNF-α -recruitment of inflammatory cells, regulation of cytokine production, and promotion of pancreatic acinar cell death by apoptosis |

IL-10 is an anti-inflammatory cytokine by inhibiting macrophages releasing inflammator mediators.

in severe AP, suggests that MIF plays strongly a vital role in APand lung injury[103]. It also raises the possibility of treatment with anti-MIF antibody to prevent lung injury in AP in the future.

**IL-10:** IL-10 is one of the few known anti-inflammatory cytokines in human body which prevents the production of pro-inflammatory mediators particularly TNF-α by macrophages and T cells[106-109]. IL-10 also inhibits the release of IL-6, and IL-1-beta[12,108,110-112] as well as stimulates the synthesis of IL-1 receptor antagonist (IL-1ra) and the release of soluble p75 TNF receptor which inhibits the action of pro-inflammatory cytokines[113]. (Table 3) In particular IL-10 has been shown to inhibit the release of TNF-α from alveolar macrophages, thus implicating that it can decrease the likelihood of developing ARDS[114]. In another study, IL-10 was administered to one group of mice prior to the development of AP. IL-10 was administered to another group of mice 33 hafter the induction of AP. The study showed that mortality is decreased due to AP in both groups[115]. Two other studies showed that both IL-10 and IL-1ra significantly decrease the severity of AP when given after the induction of AP[113,115]. Several studies have shown that IL-10 when given after AP can decrease the severity of AP, which raises the possibility of IL-10 used in clinical treatment of AP[35,115].

## CONCLUSION

Mortality in AP occurs in two peaks and is usually associated with MODS. Pulmonary dysfunction is perhaps the most critical for all extra-pancreatic manifestations of AP[3,4]. The pathogenesis of pulmonary complications in AP has been the topic of intense research in the past two decades. In this review, we have evaluated the different types of respiratory complications, with their clinical significance assessed and their pathogenesis discussed. Although the data are predominantly from experimental studies, their clinical relevance is of increasing importance. Hypoxemia occurs in nearly 50%-60% of patients with AP[6,18,19]. The major cause of hypoxemia is ventilation/perfusion (V/Q) mismatch which results in right to left intrapulmonary shunting. Failure to promptly recognize hypoxemia and hypovolemia may precipitate MODS. Pleural effusion on the left side, once considered just a marker of AP, is indeed a sign of poor prognosis[24]. Atelectasis is noted to be secondary to a decrease in pulmonary surfactant[31]. The role of cytokines has become quite evident in a number of experimental studies of atelectasis[33-36]. The most dangerous pulmonary complication is ARDS[33-35]. Of the patients who develop ARDS nearly 50% would die[16]. The incidence is much less in edematous pancreatitis. The clinical features of ARDS include widespread bilateral infiltrates in CXR and a ratio of partial pressure of arterial O2 to fraction of inspired oxygen (PaO2/FiO2) $\leqslant$ 200 regardless of PEEP with no evidence of elevated left atrial pressure[21,46]. The pathophysiology of ARDS is complex. The action of enzymes in circulation (trypsin, and phospholipase A2, proinflammatory cytokines, leukoagglutination, migration of neutrophils, activation of leukocytes, complement mediated injury, PAF, NO) is noted to play a different role in the pathogenesis.

The future management of AP that currently carries an overall mortality of 5% and 15%-20% in necrotizing pancreatitis includes measures to counteract the proinflammatory agents[1,2]. With the exception of platelet activating inhibitor agents, such as Lexipafant, nothing seems to be clinically relevant at this time[57]. However, a better understanding of the pathogenesis of lung injury and other organ dysfunction is expected to revolutionize the treatment of AP.

## Abstract

There have been multiple NOD2/CARD15 genotype-phenotype analyses undertaken in patients with Crohn's disease since the gene's discovery in 2001. This review focuses on the major published series based upon their size and on the presence of specific clinical and genetic information provided in the published material from 2001 to 2005. Twelve studies provided raw data to carry out comparisons of disease location while ten studies included analysis of NOD2/CARD15 genotypes. NOD2/CARD15 variant frequency in ileal disease did not differ significantly among studies, whereas a comparison of disease location demonstrated highly significant differences among studies. Meta-analysis confirmed significant associations between NOD2/CARD15 variants and both ileal and ileocolonic disease locations, and with both stricturing and penetrating forms of disease behavior. This review underlines the significant phenotypic differences that exist among populations, including similar ethnic groups, and has demonstrated the need for further studies of patients with long-term "inflammatory" Crohn's disease.

**Key words**: Crohn's disease; Phenotypic heterogeneity; Genotype; Inter-observer agreement; Disease location; Disease behavior

## INTRODUCTION

Chronic idiopathic inflammatory bowel diseases (IBD), made up predominantly of Crohn's disease (CD) and ulcerative colitis, remain fertile ground for both clinical and basic science research. These conditions have been held up as classic examples of complex polygenic disorders with the working hypothesis of a genetically susceptible host manifesting the disease phenotype after exposure to a single or a series of environmental triggers. Study of the genetics of IBD has expanded rapidly over the past 10 years since publication of the first genome-wide scan in 1996[1]. Technical advances have aided this advance with the culmination being the discovery of the NOD2/CARD15 gene within IBD1 on chromosome 16[2,3]. The case for further identification of IBD susceptibility genes has been put forward, specifically regarding the organic cationic transporters, OCTN1 and OCTN2, on chromosome 5 (IBD5) and DLG5 on chromosome 10[4,5]. These genes have not received universal support from independent studies and remain topics for discussion and research, specifically including further functional studies.

These rapid advances in IBD genetics, fuelled by the interest and enthusiasm of both clinicians and geneticists, has set the pace of IBD research over the past 8-10 years, which has succeeded the "IBD immunology" era of the 1990's. While the latter gave us a plethora of cytokine data, including the important role of TNF-α leading to anti-TNF strategies in CD, the discovery of NOD2 highlighted the significance of the gut's innate immune system including pathogen-associated molecular patterns (PAMPs)[6]. This progress has been particularly challenging for clinician researchers as they are expected to translate these critical discoveries into meaningful changes and advances in clinical practice, including assessment and treatment of IBD patients. In this review, we will assess the clinical interpretations of major breakthroughs in CD genetics focusing on the NOD2/CARD15 gene, including both the strengths and limitations of such studies and an analysis of significant differences in phenotypes and genotypes, and we will offer suggestions for future studies[7,8].

## CLASSIFICATION OF PHENOTYPE

Clinical classifications of CD seem to be used synonymously with terms for phenotypes, and a number of papers have described "genotype-phenotype

correlations". However, genotypes and phenotypes are derived in fundamentally different ways. While genotype is based upon a limited number of options that can be determined mechanically and thus objectively, derivation of phenotype is subjective and influenced by potentially multiple variables, with many yet to be identified. A number of variables may not be included in multivariate analysis when genotype-phenotype analyses are performed.

The clinical classification systems that have been put forward have been purposefully kept simple. This may have been done to encourage individuals and groups to adopt them and hence maximize opportunities to compare and combine datasets[9-11]. However, given this intention, it does not appear to have been successful for genotype-phenotype studies in CD. The updated Vienna classification for Crohn's disease, now known as the Montreal classification, has maintained a simple approach including age at diagnosis, location, and behavior as the major parameters, with perianal disease as a subgroup of behavior[11]. It has appropriately split age at diagnosis and perianal penetrating from internal penetrating, but has not clarified the issue of stricturing disease working independently of penetrating disease[12]. There is no mention of the need to demonstrate the presence of transmural inflammation, assuming that this is a prerequisite for the diagnosis of CD. This is relevant to subsequent study of those patients with inflammatory CD who do not evolve into a stricturing and/or penetrating pattern. Do these patients fit into the definition of CD, given that they do not appear to show any association with NOD2/CARD15 after correction for disease duration?[13] Other variables that may well influence natural history, including smoking, prior appendectomy, and body mass index, have thus far not been included in this classification[14-16]. The latter may influence development of penetrating disease, the level of inflammation and hence CRP and the risk of metabolic bone disease[17,18].

Clinical classification systems for ulcerative colitis are few. There was no such system included in the Vienna initiative. The Montreal paper presented a simple classification based upon distribution and activity, but both of these parameters are subjective, particularly when the former is based upon macroscopic and not microscopic observations. There is again no inclusion of smoking or prior appendectomy despite strong evidence supporting a role for appendectomy in (re)shaping the natural history of ulcerative colitis.

No classification system or phenotypic approach has attempted to embrace the microscopic pattern of inflammation, damage and repair seen in both CD and ulcerative colitis. Limited work has been done on granulomata and their association with both clinical outcomes and with some genetic polymorphisms[19-21]. This is in contrast to several other fields of research, including liver disease, where histological appearances are used as important aids in determining the risk of fibrosis, and colorectal cancer, in which significant heterogeneity has been identified among cancers based both upon histological appearances and molecular markers[22,23].

## STRENGTHS AND LIMITATIONS OF STUDIES TO DATE

Disease susceptibility and phenotype-genotype analyses have arrived in two "waves" since the seminal publications on NOD2/CARD15 and CD in 2001. The first wave of papers identified the key CD-causing variants in this gene and went on to establish an association with ileal location[12,24-29]. Some studies in this group supported a stronger association with stricturing disease behavior and not ileal location, after multivariate analysis[12,24,29]. Two studies carried out haplotype analysis[27,28]. The second wave included studies from smaller centers, predominantly across Europe, focusing on phenotype-genotype correlations[30,40]. There have been a limited number of studies that have investigated response to therapy[41,42].

The limitations of these studies center around two points: case-control ascertainment and phenotypic classification. Thus far, all of these studies have been sourced from specialist-based cohorts and often from large, tertiary referral centers[12,24-29]. Ascertainment of cases has also been influenced by earlier genetic studies where the primary aim has been "gene discovery" and hence there have been an exaggerated number of CD multiplex families[12,24]. Many of the studies combine the resources of multiple sites, which have contributed to collection of these multiplex families[12,24,25]. The method of ascertainment of controls is not always clear, and in the majority of cases they do not represent true population controls. Specifically, some studies have excluded controls with a family history of IBD thus biasing the population even further.

Since the majority of studies lack power to carry out detailed phenotype-genotype analyses, it is tempting to combine datasets in a meta-analysis. However, this has been hampered by a plethora of different approaches to clinical classification of the case population. Disease location is variously described as "any ileal" and "any colonic", or "ileal and right colon" with "left colon and rectum", without prior validation of these systems[24,26,28]. Similarly, disease behavior, which clearly evolves with time, was modified from the Vienna classification in several studies, again making it difficult to combine datasets. Disease duration has often been omitted. There have been inconsistencies in defining disease location, including the inclusion or exclusion of perianal abscess, combining ileal and ileocolonic locations without giving raw data on these locations individually and providing data on very specific subgroups, such as UC-like CD, where the number in this group ($n$ = 56) is greater than the "colon-only" location as a whole ($n$ = 29). More recent studies have concentrated on using the Vienna classification despite its known limitations, but have in some cases tried to address these limitations by carrying out supplemental analyses including investigation of an association between NOD2/CARD15 and stricturing disease independent of penetrating disease and internal penetrating disease independent of perianal disease.

In summary, studies thus far have provided us with

some important information on the strength of the NOD2/CARD15 association with CD as a susceptibility gene but these have not been based on population-based cohorts. Population-based studies are awaited and may be best coordinated through an international effort using agreed upon methods of case-control ascertainment, genotyping and clinical classification. Associations with ileal location have provided us with important clues to disease pathogenesis, including the role of Paneth cells and defensins. However, extensive further work is required using much larger datasets that include other key variables, such as treatment received, to determine the mechanisms by which NOD2/CARD15 variants may increase the risk of stricturing disease, and whether these variants are also implicated in the development of internal penetrating disease.

## RESULTS OF STUDIES ON NOD2/CARD15 TO DATE

Multiple studies have now investigated the contribution of variants in the LRR domain of the NOD2/CARD15 gene to development of CD. This has been summarized in a recent meta-analysis. Individuals carrying only one high-risk allele had 2.39-fold (95% CI: 2.00-2.86) increased risk of the disease, while those with 2 or more high risk alleles carried a 17.1-fold (10.7-27.2) increased risk of CD compared to individuals without any high-risk alleles. The greatest relative risk was identified for the SNP13 variant (OR 3.76, 95% CI: 3.22-4.38 for one variant) but significant heterogeneity existed among studies ($P = 0.01$)[40].

For the purposes of the rest of this paper, we have selected 15 studies that each provide both genotype and (some) phenotype data on a minimum dataset of 200 CD cases[12,24-36,38]. We will discuss the evidence for associations between NOD2/CARD15 and key clinical variables including age at diagnosis, disease location and behavior, need for surgery and the presence of granulomata. We have carried out further analyses on these studies as a combined dataset and as individual series, where sufficient clinical and genetic data are available in the original publication. We focus specifically on differences in phenotype and genotype among studies, and have carried out meta-analysis for NOD2 associations with disease location and behavior.

## DISEASE LOCATION

Of the 15 studies selected, 13 provide clearly interpretable data on disease location. Of these, 10/13 support a significant association with ileal disease (L1)[12,25-27,31-34,36,38], while some also demonstrate an association with absence of colonic location (L2)[24]. As indicated above, some studies have combined ileal (L1) with ileocolonic (L3) patients to investigate this association. This may be due to a lack of power in subgroup analysis. Clinically, this may be inappropriate. There are limited data on the natural history of ileocolonic disease compared with ileal disease but associations have been made between L3 and younger age at diagnosis and an increased risk of surgical recurrence compared to other disease locations[43,44]. In addition, some patients with L3 may have their major disease burden in the colon, thus weakening the association with NOD2/CARD15 compared to pure ileal disease or L1. Once again, the interpretation of results depends heavily on the clarity of describing phenotypes, and in this case how the presence or absence of ileal disease was determined, whether by endoscopy, histology, radiology or a combination of these.

## DISEASE BEHAVIOUR

Of 13 studies that provided data for the variable disease behaviour, 7 showed a significant association with stricturing behaviour[12,24,29,30,34,36,38]. Two studies show significant positive associations with both stricturing and penetrating disease behaviour[12,34], but one of these excluded perianal penetrating disease from the analysis. If included, this association with NOD2 variants is lost[12]. One study described a negative association with penetrating behaviour[26]. Penetrating disease is defined according to the Vienna classification in 8/13 studies and in another study it is defined as "internal penetrating" behaviour, separating it from perianal penetrating disease[12]. The rest of the studies describe their own "in house" definition of penetrating disease. Given the overlap between these forms of disease behaviour and the length of time some patients may take to develop "complex" CD, supplementary analyses seem necessary to clarify these observations. Specifically, stricturing CD will often occur in combination with penetrating disease, both being hallmarks of transmural inflammation. One may therefore predict that NOD2/CARD15 should be associated with both complications. If this is not the case, it may relate to a lack of association of NOD2/CARD15 with perianal penetrating disease that influences the relationship with penetrating disease overall, as suggested by Brant *et al*[12]. Alternatively, NOD2/CARD15 variants may promote the development of fibrosis over fissuring ulceration. These questions clearly need to be addressed in future studies.

## AGE AT DIAGNOSIS

Five of thirteen studies that looked for an association between NOD2/CARD15 and age of diagnosis found a significant association with early onset of the disease[12,24,26,32,38]. Of these, 4 found association only for NOD2/CARD15 homozygotes and compound heterozygotes and 1 found association with these groups as well as with the frameshift variant alone. Importantly, these findings remained significant after multivariate analysis when important confounders such as disease location and stricturing behaviour were included. These data support the results of previous linkage studies that demonstrated an association between IBD1 and earlier age at diagnosis[45]. They also support the concept of pediatric CD being a "more genetic" disease, consistent with other polygenic disease models.

## OTHER CLINICAL ASSOCIATIONS

Eleven studies provided data on surgery for CD and 8 of

these provided NOD2/CARD15 genotype data on the "surgical" cohort. Two groups have identified an association between NOD2/CARD15 and increased risk of surgery. Lakatos *et al* demonstrated this to have an independent effect on need for surgery after logistic regression (OR 1.71, 95% CI: 1.13-2.62, $P = 0.01$) together with presence of stricturing disease behaviour. This cohort had the largest complete dataset of 527 patients and provided the most comprehensive analysis of NOD2/CARD15 genotype-phenotype relation[38]. The second study showing this association also carried out similar statistical analysis, finding a higher risk for surgery with those carrying two variant alleles (OR 17.8, 95% CI: 4.9-64.3)[36].

## FURTHER ANALYSIS OF CLINICAL CHARACTERISTICS AND GENETIC ASSOCIATIONS

### *Statistical methods*

Differences in proportions among different studies were tested using simple $\chi^2$ distribution obtained as the sum of [(Observed – Expected)$^2$/Expected] with (R-1)*(C-1) degrees of freedom where R is the number of rows (studies) and C is the number of columns (locations, genotypes). The higher contribution to the $\chi^2$ from different studies suggested a higher degree of variation in the distribution of reported location.

Meta-analysis was performed by calculating the odds ratio and confidence interval using the frequency distribution of NOD2 variants and the variable of interest presented by studies involved in the analysis. Fixed analysis used an inverse variance method to calculate weight, and weighted average was calculated as a pooled estimate. Heterogeneity among studies was calculated using Cochran's Q (sum of squared difference between individual study effect and pooled effect across studies). Analysis was performed using Meta command in STATA 9[46].

### *Differences among studies*

Ten studies gave clear data on numbers of patients with pure ileal CD and their NOD2 variant frequencies. The majority of studies had small numbers in this important subgroup of CD (mean, 85 patients, range 23-136) with an overall NOD2 variant frequency of 41.1% (23.4%-53.6%). Comparisons between studies just failed to show a significant difference ($P = 0.06$). However, exclusion of one study from Finland, which is known to have lower NOD2 variant frequencies compared to the majority of other European populations, demonstrated similar proportions in the majority of these studies ($P = 0.53$).

In contrast, a comparison of disease location among 12 studies that provided data on this variable as per the Vienna and Montreal systems, demonstrated highly significant differences ($P < 0.0001$). Unlike the genotype data for NOD2, exclusion of any one study from this analysis did not influence heterogeneity. Proportions among studies did not appear to correlate with geographical region, but two groups emerged from the data; i.e., those with high rates of ileal CD (40%-50%), and those with lower rates of ileal disease (20%-30%). Does disease location for CD vary substantially among Caucasian populations? There are no population-based data to answer this question. Clearly, other factors may play a role, including rate of familial disease, smoking, type of center (medical or surgical bias), and methods of ascertainment. Interestingly, of the four studies with high rates of ileal disease, two had a high rate of familial CD (0.47, 0.86), one had a relatively low rate (0.11), and the fourth did not include data on familiality. Similarly, figures for surgery did not show consistency within this subgroup, ranging from 0.33 to 0.67, and rate of stricturing disease was surprisingly low (0.17-0.23). Alternatively, are there major differences in clinical assessment of patients and a corresponding reduction in interobserver agreement among centers? Studies have recently indicated that this may be so for both CD behavior and location[47,48]. The NOD2 analysis given above indicates that, at least for NOD2 variant ileal CD, there are limited differences among populations. As indicated above at the outset of this review, clinical characterization of CD, and IBD in general, remains a significant challenge.

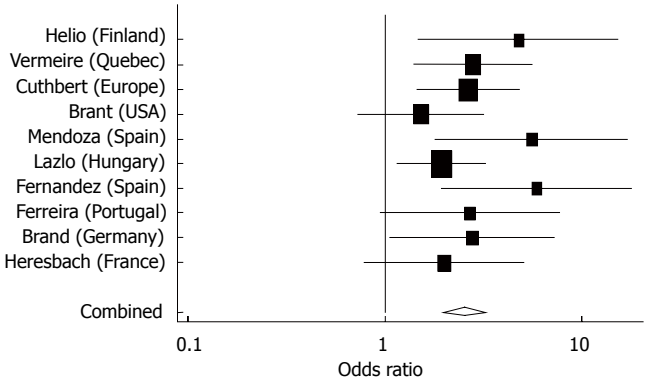

**Figure 1** Meta-analysis comparing odds of having a NOD2 variant (SNPs 8,12 and/or 13) among Ileal versus Colonic CD patients in 10 studies. Pooled estimate = 2.50 (95% CI 1.97-3.25), $P < 0.0001$), test of heterogeneity among studies, $P = 0.49$.

## META-ANALYSIS OF NOD2 ASSOCIATIONS WITH DISEASE LOCATION AND BEHAVIOUR

### *Location*

These analyses confirmed the strong association between NOD2 variants and pure ileal CD compared to pure colonic disease, which was used as the reference group (Figure 1). Similar results were obtained in comparing patients with ileocolonic disease and the reference group (Figure 2). Both meta analyses achieved significance ($P < 0.0001$), while there was no significant heterogeneity demonstrated between studies.

### *Behaviour*

Nine studies provided adequate data for inclusion in these meta analyses, of which four provided data on disease duration (range, 8.2-17.6 years). A strong association was confirmed between NOD2 variants and stricturing CD

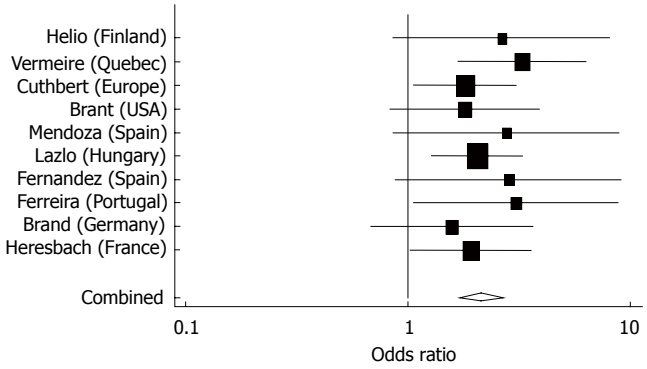

**Figure 2** Meta-analysis comparing odds of having a NOD2 variant among Ileocolonic *versus* Colonic CD patients in 10 studies. Pooled estimate = 2.13 (95% CI 1.7-2.7), $P < 0.0001$, test of heterogeneity among studies, $P = 0.927$.

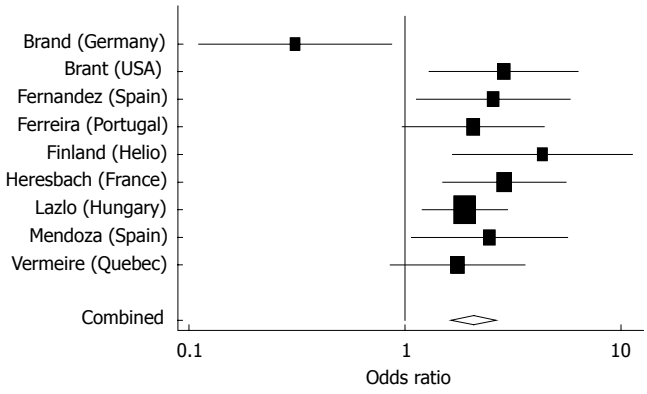

**Figure 3** Meta-analysis comparing odds of having a NOD2 variant among Stricturing *versus* Inflammatory CD patients in nine studies. Pooled estimate = 2.06 (95% CI 1.42-2.98), $P < 0.0001$, test of heterogeneity among studies, $P = 0.02$.

(Figure 3) with inflammatory disease (non-stricturing, non-penetrating) as the reference group. Significant heterogeneity was detected among studies ($P = 0.02$) related to one "outlier". Importantly, and not surprisingly, the other form of complex disease behavior also showed significant association with NOD2 variants (Figure 4). This association is likely to be strengthened if data were available for internal penetrating disease independent of perianal penetrating disease for all studies.

## CONCLUSION

The discovery of NOD2 as the first susceptibility gene for CD has resulted in a leap forward in our understanding of disease pathogenesis. It has also highlighted the heterogeneity of the disease. NOD2 represents the "low-lying fruit" of CD genetics-other susceptibility genes for this disease and for ulcerative colitis may not carry the same relative risk. The phenotype-genotype studies carried out to date have provided us with the critical observations that link NOD2 variants to ileal location, and this has highlighted the role of Paneth cells and antimicrobial peptides. However, there remain a number of questions. All these studies have been drawn from specialist cohorts leaving no accurate figure for NOD2 population attributable risk. There is significant heterogeneity in

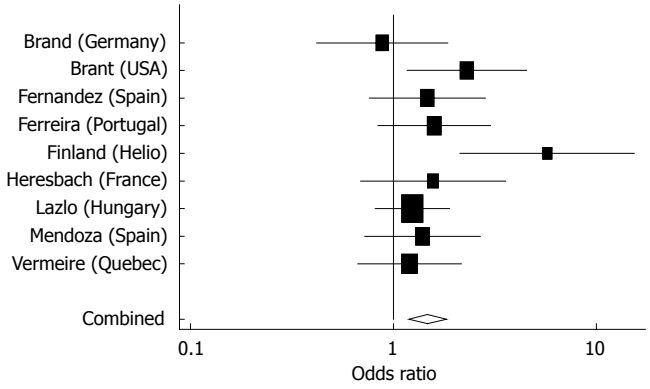

**Figure 4** Meta-analysis comparing odds of having a NOD2 variant among Penetrating versus Inflammatory CD patients in nine studies. Pooled estimate = 1.47 (95% CI 1.19-1.82), $P < 0.0001$, test of heterogeneity among studies, $P = 0.15$.

phenotype among studies, raising concerns with respect to clinical characterization of patients at different centers and thus the utility of current classification systems and interobserver agreement in this field. Our meta-analysis has demonstrated a highly significant association between penetrating CD and NOD2 variants, and confirms the associations with stricturing behaviour and with both pure ileal and ileocolonic locations. These observations highlight the need for further clinical and genetic characterization of phenotypes not associated with NOD2, including inflammatory CD, perianal (penetrating) disease, and pure colonic disease.

## Abstract

**AIM:** To assess the proteome of normal versus tumor tissue in squamous cell carcinoma of the esophagus (SCCE) in Iranian patients and compare our results with former reports by using proteomics.

**METHODS:** Protein was extracted from normal and tumor tissues. Two dimensional electrophoresis was carried out and spots with differential expression were identified with mass spectrometry. RNA extraction and RT-PCR along with immunodetection were performed.

**RESULTS:** Fourteen proteins were found whose expression levels differed in tumor compared to normal tissues. Mass spectrometric analysis resulted in the identification of β-tropomyosin (TMβ), myosin light chain 2 (and its isoform), myosin regulatory light chain 2, peroxyredoxin 2, annexin I and an unknown polypeptide as the down regulated polypeptides in tumor tissue. Heat shock protein 70 (HSP70), TPM4-ALK fusion oncoprotein 2, myosin light polypeptide 6, keratin I , GH16431p and calreticulin were the up-regulated polypeptides found in tumor tissue. Several of these proteins, such as TMβ, HSP70, annexin I , calreticulin, TPM4-ALK and isoforms of myosins, have been well recognized in tumorigenesis of esophageal or other types of cancers.

**CONCLUSION:** Our study not only supports the involvement of some of the formerly reported proteins in SCCE but also introduces additional proteins found to be lost in SCCE, including TMβ.

**Key words:** Squamous Cell Carcinoma; Esophagus; Esophageal; Proteomics; Two dimensional electrophoresis; Polypeptide marker

## INTRODUCTION

As a complex disease, cancer arises from a range of genetic alterations that result in both structural and functional cellular changes. Such alterations, including up and down regulation of certain genes, mutations, chromosomal alterations, and suppression or activation of specific genes, confer cells with growth advantage and clonal expansion[1,2]. As a result, cells may acquire the ability to produce new proteins and other proteins that normally are present may be modified, reduced, augmented or even eliminated[3,4]. Quantitative variations in protein abundance represent alteration in functional gene expression, which demands analysis. Proteomics has provided simultaneous analysis of a large number of cellular protein constituents and is the most powerful direct analytical method for protein detection and evaluation[5,6].

Squamous cell carcinoma of the esophagus (SCCE) is the sixth most common cancer in the world. However, in developing countries it ranks fourth and occurs with higher frequencies in certain regions of the world, such as Iran, China, South Africa and France. The last epidemiologic

report indicated the highest incidence rate of this cancer from Iran[8]. So far, many molecular studies have been carried out on this cancer and the role of oncogenes, tumor suppressors, chromosomal abnormalities and other molecular events have been investigated. Noteworthy among these molecular alterations is the down regulation of important tumor suppressor genes and consequently their protein products, such as P53, Retinoblastoma (RB), Mutated in Colon Carcinoma (MCC), and Deleted in Colon Carcinoma (DCC)[9], which further indicates the importance of Tumor Suppressors (TSs) in the carcinogenesis of this type of cancer.

The present report represents further extension of our earlier work on esophageal cancer[10]. Here we applied proteomics as a method of comprehensive analysis of differential protein abundances present in esophageal cancer. Among the fourteen differentially expressed proteins identified in this study, we observed loss of ß-tropomyosin (TMβ) in all tumor samples, a protein that has been suggested to function as a tumor suppressor. Furthermore, this study additionally supports the involvement of TSs in the etiology of SCCE.

## MATERIALS AND METHODS

### Chemicals

All chemicals were purchased from Sigma unless otherwise specified.

### Patients and tissue sampling

Cancerous and normal tissue specimens were collected from 45 patients with SCCE whom underwent surgery. Tissue samples were collected immediately after surgery, wrapped in aluminum foil, snap frozen in liquid nitrogen and maintained at -70℃. The age of the patients at the time of diagnosis ranged from 27 to 86 years (63% males, 37% females) with a mean of 55 years.

### Protein preparation

100-150 mg of tissue was sliced on ice and pulverized under liquid nitrogen using a microdismemberator (Braun, Germany). Subsequently 600 μL homogenization buffer (10 mmol/L Tris-HCL (BioRad), 5 mmol/L $MgCl_2$ PH 7.4) was added to the pulverized tissues, mixed and 10 μL of the following protease inhibitors were added: Pepestatin (1 mg/mL in isopropanol), benzamidine (16 mg/mL in $H_2O$), phenylmethylsulphonyl fluoride (PMSF at 25 mg/mL in isopropanol). To this homogenate, 10 μL of RNaseA (10 mg/mL in homogenization buffer) and DNase Ⅰ (1 mg/mL in homogenization buffer**)** were added and incubated on ice for 20 min. Subsequently, urea at 7 mol/L, thiourea at 2 mol/L, 5% ß-mercaptoethanol and 0.5% SDS were gradually added and the volume of solution was adjusted to 1.5 mL with the homogenization buffer. Samples were centrifuged at high speed for removal of insoluble particles and five μL of each was used for protein concentration assessment using the Bradford assay.

### Two-dimensional electrophoresis

Samples were subjected to isoelectrofocusing (IEF) following to adaptations and slight modification[11]. The first dimension gel was composed of 4.2% acrylamide, 0.22% N, N'methylenebisacrylamide, 8.5 mol/L urea, 0.27% (V/V) Nonidet P-40 (NP-40), 5% sucrose, and 6% ampholytes (pH 4-6, 5-7 and 6-8 at a ratio of 2:1:2, respectively) and 0.05% TEMED (N, N, N', N'-Tetamethylethylene diamine). The solution was degassed and 0.04% ammonium persulfate was added, mixed and poured to a height of 130 mm in cylindrical glass tubes with a 1.5 mm internal diameter. A volume of sample equal to 75 μg total protein was mixed with 0.33 volume of neutralizing buffer (9 mol/L urea, 8% NP-40 and 5% ampholytes pH 3.5-10), loaded on IEF gel, overlaid with 10 μL sample buffer (4 mol/L urea, 1% ampholytes pH 3.5-10) and filled with catholyte. The upper chamber buffer or catholyte was composed of extensively degassed 0.02 mol/L NaOH and the lower chamber buffer or anolyte; 0.01 mol/L phosphoric acid. Isoelectric focusing was applied, without prefocusing, at 300 V for 1 h, afterward at 600 V for 10 h and 800 V for 1 h in order to final focusing. Gels were removed and equilibrated for 20 min at room temperature in equilibration solution (60 mmol/L Tris-HCl, pH 6.8, 2% SDS, 5% β- mercaptoethanol (V/V), 10% glycerol (V/V), and 0.002% bromophenol blue). The second dimension gel consisted of 33.3 mL of 30% stock acrylamide solution and N, N'-methylene bisacrylamide (29.2% and 0.8% W/V respectively), 41.7 mL deionized water and 25 mL separation gel buffer (1.5 mol/L Tris-HCl, pH 8.8, 0.4% SDS [Sodium Dodecyl Sulfate]), 0.034% (W/V) ammonium persulfate and 0.05% TEMED. The equilibrated first dimension gel was layered on the second dimension gel and fixed in place with 1% agarose and electrophoresis was carried out at 30 mA/plate at 10℃ constant temperature by applying a cooling system.

### Protein detection

Proteins were detected using a slight modification of the previously reported method[11]. The gel was fixed (methanol, water, acetic acid and formaldehyde: 50/38/12/0.05 per volume) for at least 1h with constant shaking followed by 3 times 20 min washes with 50% ethanol, pretreated with sodium thiosulfate ($Na_2S_2O_3.5H_2O$; 0.2 g/L) for 1 min, and washed three times each for 20 s with $ddH_2O$. Impregnation of the gel with $AgNO_3$ (1.9 g/L and 0.075% (V/V) of 37% formaldehyde) was carried out and the residual $AgNO_3$ was removed by 3 × 20 s successive washes with de-ionized water. Successively the gel was developed by soaking in developing solution containing $Na_2CO_3$ (60 g/L), 0.05% (V/V) of 37% formaldehyde and 4 mg/L of $Na_2S_2O_3 \cdot 5H_2O$ for 10 min up to the appearance of yellowish brown spots. The gel was then rinsed twice, each for 2 min, with $ddH_2O$. Further development was stopped by immersing the gel in stop solution (50% methanol and 12% acetic acid) and stored in 30% ethanol at 4℃ until scanning.

### Isoelectric point determination

The isoelectric point (pI) of polypeptides was determined by either application of protein PI markers (Sigma) or by determining PI change along the entire length of the first dimension gel[12]. Gels were cut into 0.5 cm long pieces. Each piece was placed in a separate tube containing 0.5

mL of distilled $H_2O$, crushed and incubated at room temperature for 2 h. The pH of each tube was then measured.

### Image analysis

Silver-stained gels were scanned using a calibrated GS-800 densitometer (Bio-Rad) at resolution of 600 dots and 12-bits per inch. Spot detection and gel matching were done according to Melanie-4 default settings and spot pairs were investigated visually (GeneBio, Geneva, Switzerland). Pairs of Two dimensional electrophoresis (2DE) gels composed of tumor and normal gels from each patient were used and the percent volume of each spot was estimated and analyzed for image analysis. The polypeptide variants of each pair of gels (tumor versus normal) were recorded and the most common changes in the polypeptide expression pattern (70% or higher) in all 2DE gels were used as a reference for comparison between tumor and normal gels.

### Immunological detection and localization of actin

Following to the 2DE, gels were equilibrated for 30 min in transfer buffer (25 mmol/L Tris-base, 192 mmol/L glycine, 20% methanol and 0.1% SDS) and polypeptides were electrophoretically transferred to nitrocellulose membranes at 14 V overnight. Membranes were blocked for 2 h in blocking solution (TBST; 100 mmol/L Tris-base or HCl, pH7.5, 0.9% NaCl and 0.05% Tween 20) and exposed to biotinylated anti-actin antibody at 1/3000 dilution for 1 h with constant shaking. Membranes were subsequently washed 3X with TBST, incubated with strptavidin conjugated alkaline phosphatase in TBST at 1/4000 dilution and further incubated (1 h) with constant shaking. Membranes were washed two times with TBST, once with TBS and exposed to color solution (33 μL NBT from 50 mg/mL stock solution in 70% dimethylformamide and 17 μL BCIP from 50 mg/mL stock solution in 100% dimethylformamide). To stop excess color formation, membranes were washed with distilled water[13].

### RNA extraction and RT-PCR of TMβ and beta actin

Total RNA was extracted by acid phenol method and the first strand cDNA was synthesized applying oligo dT 18 (Roche). Subsequently amplification was carried out using the forward primer 5'-GGC TGA TGA GAG CGA GAG AG-3' and the reverse primer 5'-GCA CTG GCC AAG GTC TCT TC-3' for amplification of TMβ and 5'-TGA CGG GGT CAC CCA CAC TGT GCC CAT CTA-3' as forward and 5'-CTA GAA GCA TTT GCG GTG GAC GAT GGA GGG-3' as reverse primers for amplification of beta actin. The PCR condition was composed of primary denaturation at 95℃ 1 min followed by 30 cycles of amplification according to the subsequent scheme; denaturation 1 min at 95℃, annealing at 56℃ 1 min and extension at 72℃ 1 min and final extension at 72℃ for 10 min. Subsequently 4 μL of the PCR product was used for agarose gel electrophoresis.

### Mass spectrometry

Silver stained protein spots containing the proteins of interest were destained thoroughly with 1% $H_2O_2$ (typically 1 min) and lyophilized to dryness[14]. Silver stain removal using $H_2O_2$ was performed to enhance peptide adsorption by matrix-assisted laser desorption/ionization time-of-flight mass spectrometry (MALDI)[14]. The dehydrated gel bands were hydrated with 15 μg/L (Promega, Madison, WI) of porcine trypsin in 25 mmol/L $NH_4HCO_3$, pH8.2 on ice for 45 min. Excess trypsin was removed; gel bands were covered with 25 mmol/L $NH_4HCO_3$, pH8.2 and incubated at 37℃ overnight. Tryptic peptides were extracted from the gel bands with 70% acetonitrile and 0.1% trifluoroacetic acid. Samples were desalted with C18 Zip Tips (Millipore, Bedford, MA) as per manufacturer's protocols. 0.5 μL of sample was co-crystallized with 0.5 μL of α-cyano-4-hydroxycinnamic acid in 50% acetonitrile, 1% trifluoroacetic acid and spotted directly on a stainless steel MALDI target plate. Mass spectra were acquired using a MALDI-TOF/TOF mass spectrometer (Voyager 4700, Applied Biosystems, Foster City, CA). MALDI-TOF/TOF spectra were internally calibrated (< 20 ppm) using trypsin autolysis products. Post-acquisition baseline correction and smoothing was carried out using software provided with the TOF/TOF instrument. Spectra were submitted to Mascot (http://matrixscience.com) for peptide mass fingerprinting.

## RESULTS

### Protein extraction, 2DE and image analysis

Before doing 2DE, the concentrations of extracted proteins from tissue samples were determined. The protein extraction efficiencies were similar for tumor tissues and their adjacent normal nonmalignant tissues. The yields of extractions were approximately 80 μg/mg for both tumor and normal tissues. Subsequently seventy five micrograms of proteins from either tissue type were used in the first dimension. Because of the epithelial origin of squamous cell carcinoma, the mucosa of the normal non malignant tissues were separated from the rest of the esophageal tract for protein extraction and proteome comparison with corresponding tumors. For further verification that an equal amount of protein from either type of tissue was applied, immunological detection of actin was carried out following to 2DE. Following electrophoresis, the resolved proteins were recorded for each of the 2DE gel pairs. The densitometry map contained almost 800 features ranging in the molecular masses from 10 to 220 kDa and pIs from 4.8 to 8.0. For deciphering tumor-associated polypeptides, 2DE gels of tumor tissues were compared with their corresponding matched normal tissues. Compared with the matched normal tissues, 92 definite proteins (spots) in 2DE gels from 45 tumor tissues belonging to 45 patients were found indicating lower levels of expression. In contrast, 88 spots were identified in tumors that indicated higher levels of expression with respect to the 2DE gels of their corresponding matched normal tissues. To eliminate the possibility of artifacts, pairs of 2DE gels (tumor versus normal for each patient) were matched and compared and spot variants that occurred most often, or at least in 70% or higher of all 2DE patterns, were considered to be significant and were used for further comparisons. There were 7 out of 92 spots that indicated lower levels

**Table 1** Mass spectrometric identification and characteristics of the 14 proteins whose expression were subjected to change in SCCE

| Polypeptide | Tissue specification | Protein name | Accession number based on NCBI | Chromosome | PI/MW | Expression profiling or level |
|---|---|---|---|---|---|---|
| A | Normal | Beta tropomyosin | NM-003289 | 9p13.2-p13.1 | 5.5/40.3 | Disappearance |
| B | Normal | Myosin regulatory light chain 2 | XM-027060 | 18p11.31 | 5.45/17.6 | Down Regulation |
| C | Normal | Myosin light chain 2 | NM-000432 | 16p11.2 | 5.6/17.6 | Down Regulation |
| D | Normal | Unknown | NC-000963 | Map No | 5.8/17.6 | Down Regulation |
| E | Normal | Myosin light chain 2 | NM-000432 | 16p11.2 | 6/17.6 | Down Regulation |
| F | Normal | Peroxiredoxin 2 | NM-005809 | 19p13/2 | 6.6/26 | Down Regulation |
| G | Normal | Annexin 1 | NM-000700 | 9 | 7.3/35.5 | Down Regulation |
| 1 | Tumor | Heat shock protein 70 kD | XM-044201 | Unpublish | 6/64 | Up Regulation |
| 2 | Tumor | TPM4-ALK fusion oncoprotein 2 | A186109 | 19p13/1 | 5.5/32.5 | Up Regulation |
| 3 | Tumor | Myosin light polypeptide 6 | NM-0211019 | 12p13/3 | 5.4/20.1 | Up Regulation |
| 4 | Tumor | Keratin 1 | AF304164 | 12q13 | 6.9/42.5 | Up Regulation |
| 5 | Tumor | DNA directed RNA polymerase B (ropB) | NC-000915 | | 6.1/27.2 | Up Regulation |
| 6 | Tumor | GH16431P | Ay051511 | | 6.6/30.1 | Up Regulation |
| 7 | Tumor | Calreticulin | NM-004343 | 19p13/3 | 5.2/50 | Up Regulation |

of expression and 7 out of 88 spots that indicated higher levels of expression respectively. Figures 1A and 2A represent the resulting 2DE gels of the normal and the corresponding tumor tissues of one patient.

To identify whether an equal amount of protein was applied in 2DE, immunodetection of actin was carried out as an internal control of loading (Figures 1B and 2B). As Figures 1B and 2B show, equal amount of proteins were applied in the first dimension. The 14 observed differentially abundant proteins are indicated by arrows (Figures 1A and 2A). The proteins that were observed with decreased abundance in tumors, compared with their corresponding normal tissues, are labeled alphabetically as A, B, C, D, E, F and G. Spots B, C and E are observed in a chain of spots and likely indicate that they are isoforms or modified forms of a specific protein. On the other hand, those proteins that were observed to have an increased abundance in tumors were numbered as 1, 2, 3, 4, 5, 6 and 7. The apparent molecular weight of polypeptides, approximate isoelectric points and changes in expression level, is presented in Table 1. It was found that spot A was absent in tumor samples whereas, spots B, C, D and E were considerably down regulated and spots F and G were shown to be more than two-fold down regulated. It suggests that down regulated proteins were involved in the maintenance of normal phenotype whereas the other up-regulated polypeptides were involved in the development of malignancy.

### *Mass spectrometric analysis, identification of polypeptides and RT-PCR*

Following to 2DE, spots of interest were excised, in-gel

digested and analyzed with a MALDI/TOF/TOF (Matrix-assisted laser desorption/Ionization/ Time of Flight/ Time of Flight) mass spectrometer. The observed peptide mass spectra were analyzed for protein identification by peptide mass fingerprinting that resulted in the identification of the 14 proteins that are listed in Table 1. The identified protein corresponding to spot A was found to be β-tropomyosin as shown in Table 2. As mentioned above, this protein was found to be lost in tumors thus, for further validation of results achieved regarding with TMβ, RT-PCR was conducted by applying TMβ specific primers. As Figure 3A indicates, the 431 bp amplification product is only limited to the cDNA synthesized from RNA extracted from normal tissue. Applying beta actin as an internal control of RT-PCR, which gives rise to a 670 bp amplification product (Figure 3B), and running the extracted RNA (Figure 3C) indicate that lack of amplification in tumor tissues should be due to the loss of expression of TMβ. These observations further point out that down regulation of TMβ occurs at transcriptional level in SCCE. As discussed later in the Discussion section, TMβ is a down stream target for several oncogenes and functions as a tumor suppressor gene.

## DISCUSSION

Former studies on SCCE have led to the identification of Annexin I [15,16], tumor rejection antigen (gp96)[16], clustrin[17], tropomyosin 3, retinoblastoma binding like protein and K506 binding protein[18] as potential markers of esophageal and other types of cancers, some of which were also identified in the present study for instance loss of TMβ in breast cancer[19], myosin light chain 2 isoforms in transformed osteosarcoma[20], peroxiredoxin Ⅱ in pancreatic adenocarcinoma[21], calreticulin in bladder[22] and colon cancers[23], HSP70 in hepatocellular[4] and keratin 1 in gastric carcinoma cell lines[24]. In addition to those proteins previously introduced for esophageal cancer, we identified new proteins, among which TMβ was found to be completely absent in all tumor samples. Therefore we suggest this protein as a potential marker for SCCE. Loss or down regulation of TMβ in cancer is not restricted to our study. Studies on other types of cancers such as oral tongue squamous carcinoma[25] and carcinomatous breast lesions[26] have also led to this observation.

Different studies have indicated that TMβ functions as a tumor suppressor. For example, reversion of neoplastic phenotype, anti-angiogenic activity[27,28], induction of slow growth rate, anchorage, cytoskeleton organization in breast cancer MCF7 cell lines[29] and anoikis[19] are all the consequence of TMβ expression. TMβ is required for cytoskeleton establishment and mediation of TGF-β mediated stress fiber formation. Alternatively, the Ras-ERK pathway antagonizes with TGF-β induced stress fiber formation by suppressing TMβ expression[30]. Indeed TMβ is a down stream target for the ras oncogene[31]. To the best of our knowledge, no strong evidence has been documented regarding with the involvement of the

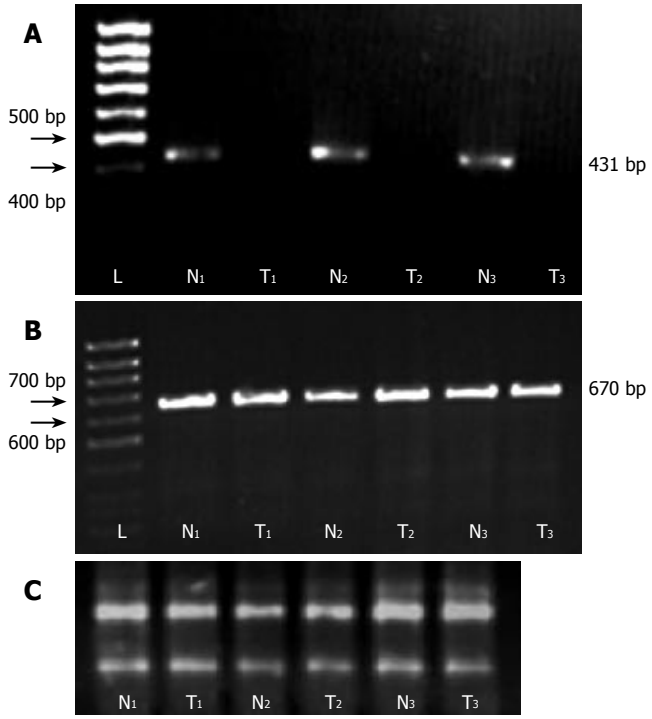

**Figure 3** **A**: Verifying differential expression pattern of ß tropomyosin by RT-PCR in three separate experiments as indicated by numbers (1 to 3), normal versus tumor tissues. The amplification product (431bp) is limited to normal tissue which indicates loss or strong down regulation of this protein as observed by 2DE; **B**: RT-PCR amplification of ß-actin as an internal control of RT-PCR; **C**: Electrophoresis of the total RNA from normal and tumor tissues used for cDNA synthesis and RT-PCR. L: DNA marker; N: normal tissue; T: tumor tissue.

ras family of oncogenes in esophageal carcinogenesis, therefore it is likely that other oncogenes may be involved in the down regulation of TMβ, such as TGF-α and activation of EGFR, both of which participate in the down regulation of TMα and β[32]. Interestingly high levels of TGF-α were reported in all gastrointestinal cancers, including the late stages of esophageal cancer[33], along with amplification of EGFR in esophageal cancer[34]. Loss of TMβ in tumors suggests that this protein may play an important role in tumor suppression of esophageal carcinogenesis.

In addition to TMβ, down regulation of several other proteins was also observed in this study, including annexin Ⅰ. As we mentioned above, reports on the loss of annexins Ⅰ or its isoforms was not limited to our study but other research groups[15,16,37] have also observed this event. It was suggested that such a loss of expression in esophageal and prostate tumors is an early event[15] of carcinogenesis. Hypermethylation of annexin Ⅰ was suggested as another mechanism leading to inactivation and loss of expression in cell lines such as B cell non-Hodgkin's lymphoma[35]. Annexin Ⅰ induces both spontaneous and caspase-3 activated apoptosis[36]. Furthermore, mutations in p53 were also found to result to the down regulation of annexin 10, another member of the annexins family in hepatocellular carcinoma, along with vascular invasion, early recurrence and poor prognosis[38]. We formerly showed mutations in the p53 tumor suppressor gene in SCCE[10], thus it is possible that such mutations correlate with down regulation of annexin 10 as well as annexin Ⅰ. It is well-demonstrated that EGFR amplification occurs in SCCE[34]. On the other hand, annexin Ⅰ undergoes phosphorylation and inactivation by EGFR[39]. Thus our result additionally supports former report[16] regarding with loss of annexin Ⅰ in SCCE.

To our knowledge this is the first report introducing down regulation of peroxyredoxin Ⅱ in SCCE. Peroxiredoxins are members of the phase Ⅱ detoxifying enzymes involved in cytoprotection and cellular defense against oxidants by detoxifying xenobiotics and oxidants, especially $H_2O_2$. By reducing $H_2O_2$, peroxyredoxins protect cells from oxidative stress induced apoptosis and proapoptotic signals. Peroxyredoxins inhibit $H_2O_2$ induced signal cascade in response to PDGF and EGF. They also inhibit NFκB and tumor necrosis factor α in response to external $H_2O_2$ and $H_2O_2$ induced expression of proapoptotic protein; BAX[40,41]. Thus, it is possible that loss or down regulation of this protein or other members of detoxifying enzymes in esophageal epithelium, which normally could be exposed to stresses, contribute to the carcinogenesis by cellular failure in detoxification of oxidative agents affecting this tissue.

Loss of muscle forming proteins is an important cause of body weight loss or cachexia in cancers primarily due to loss of the myosin heavy chain[42]. Myosin light chain 2 is an indispensable component of cytoskeleton, migration and apoptosis[43]. Down regulation of myosin light chain 1 and myosin regulatory light chain 2 proteins was shown in oral tongue squamous cell carcinoma[25]. Due to a common embryonic origin of oral and esophagus tissues, strong down regulation of myosin regulatory chain 2 indicates an important role for this protein in both organs. Formerly Kumar and Chang have shown that transformation of osteosarcoma cells is associated with complete loss of myosin light chain 2 isoforms, which indicates myosin light chain 2 as a target for cellular transformation and malignancy[20]. Our report is the first demonstrating down regulation of myosin light chain isoforms in esophageal cancer. Alternatively, up regulation of myosin light polypeptide 6 in tumors could possibly be due to the selective down regulation of myosin heavy chain and other isoforms of myosin light chain. Supporting our results is the report of Samoszuk *et al* that have shown up regulation of this protein in clonogenic human breast cancer[44].

We also found several up regulated proteins in tumors, among which is heat shock protein 70. Investigations on gastric, hepatocellular and colonic adenocarcinoma cancers have indicated higher levels of expression of HSP70 along with other stress associated proteins[4,45]. HSP70 exerts antiapoptotic activity by suppressing tumor necrosis factor induced apoptosis and caspase 3 down stream events[46], interfering with SAPK/JNK and ceramide induced apoptosis and cleavage of caspase 3 substrate enzyme PARP, which is involved in DNA repair[47]. Theses findings have raised the idea that HSP70 not only should be considered as a tumor marker for HCV-caused hepatocellular carcinoma[48] but also as a target for cancer treatment[49]. Thus, as an organ of the digestive system, esophagus carcinogenesis might follow the same molecular path as other organs of this system.

Calreticulin and keratin 1 were among other up

regulated proteins in tumors. The involvement of calreticulin in tumors has been reported by several groups. Rendon Huerta *et al*[50] have shown that protein kinase C isoforms bind and phosphorylate calreticulin. This would suggest a possible role for calreticulin in signal transduction and involvement in cell division. It was also found that calreticulin regulates p53 function by affecting its rate of degradation and nuclear localization[51]. Thus, association of p53 mutations with esophageal carcinogenesis[10] as well as p53 degradation could explain the role of calreticulin in the development of esophageal tumor. In addition to calreticulin we also found overexpression of Keratin 1, a member of keratin family in SCCE. Formerly Trask and colleagues have shown different expression patterns of keratin isoforms in normal versus tumor tissues[52]. They proposed the expression pattern of keratin isoforms as biomarkers for differentiating normal from malignant cells. Furthermore, Kinjo and coworkers have shown overexpression of keratin 1 in colonic adenocarcinoma cells[53] and Nishikawa *et al*[24] have found up to 17 folds of truncated keratin 1 in Epstein-Barr virus transfected gastric carcinoma cell lines. In esophageal cancer, several groups have reported an increased level of cytokeratin 19 (keratin 19) in serum and secretion by cell lines[54]. The later groups have proposed cytokeratin 19 to have the best specificity and sensitivity as a prognostic marker for evaluating esophageal cancer. Thus involvement of another member of the keratin family in SCCE not only supports former results but also introduces a new marker from this family.

Activation of anaplastic leukemia kinase (ALK) is an example of chromosomal abnormalities, such as translocations, that lead to fusion proteins. ALK was first identified in anaplastic large cell lymphomas (ALCL) and subsequently in inflammatory myofibroblastic tumors (ITM). The aberrantly expressed protein activates several protein kinases, such as IP3 kinase, STAT5 and transcription factors, which end up to mitogenic effects[55]. The fusion of ALK with nucleoplasmin is frequently observed in ALCL. Walking on chromosome 2, Lamant *et al* have shown the fusion of tropomyosin 3 and ALK as a result of t (1; 2) (q25; p23)[56]. They suggested that such a fusion provides an active promoter for ALK, because nucleoplasmin is a housekeeping gene and TM3 is constitutively expressed. Further studies led to the identification of not only TM3-ALK but also TM4-AKL fusion proteins in patients with inflammatory myofibroblastic tumors[57] and as a result perturbation of normal tumor suppressor activity of TM isoforms. It was also suggested that the extent of such rearrangements and fusions could possibly engage other proteins. Here we demonstrated that expression of ALK is not restricted only to the neural but also to other tumors. TPM4-ALK fusion protein is also among proteins being introduced for the first time in SCCE.

There were also three other proteins found in SCCE as homologues of formerly identified proteins in other organisms. Thus, we interpret them to be newly found proteins in SCCE. Among these proteins, two were up regulated in tumors that were identified to be DNA-directed RNA polymerase Beta subunit (ropβ) with almost 100% (99.998) homology with that of *H pylori*. The other protein, spot 6 had a mass spectrum that matched with a high score (99.925) with GH16431P of Drosophila melanogaster (NCBI ACCESSION; AAK92935). Looking into patients pathology files indicated that almost all were *H Pylori* positive, thus we think that up regulation of this protein in tumors, to some extent, may be due to contamination with this bacterium. However, the question that remains unanswered is why such contamination was not observed in normal tissues. A possible explanation could be a preferentially higher growth of bacteria in tumors than in normal tissues. The other protein was the spot D in normal tissue whose mass spectrum matched with high score (99.963) to an unknown protein (NCBI Accession; NC 000963). This protein is highly expressed in normal tissue while loss of it was observed in tumor specimens. Being an unknown protein, further studies are required to reveal its true biological activity in tumor suppression.

In conclusion, this is the first report on the proteomics of SCCE from Iran, a country with the highest incidence rate of SCCE[8]. We were able to identify fourteen differentially expressed proteins in esophageal tumors. Our study further showed that several proteins, which are commonly affected in other digestive organs such as liver, are also affected in SCCE, which may indicate a common molecular mechanism for digestive system tumorigenesis and putative candidate biomarkers. It should also be mentioned that our study brings further evidence for the importance and requirement of a deeper investigation of the molecular events down stream to the EGFR activation in SCCE. The expression levels of several proteins identified in our study is affected by the activation of this receptor. To our knowledge a general molecular marker has not been introduced for cancers, however, finding the disappearance of TMβ in SCCE could introduce a useful tumor marker for SCCE diagnosis, evaluation and follow up.

## Abstract

**AIM:** To investigate the functions of promoter hypermethylation of secreted frizzled-related proteins (sFRPs) genes in colorectal tumorigenesis and progression.

**METHODS:** The promoter hypermethylation and expression of *sFRP* genes in 72 sporadic colorectal carcinomas, 33 adenomas, 18 aberrant crypt foci (ACF) and colorectal cancer cell lines RKO, HCT116 and SW480 were detected by methylation-specific PCR and reverse transcription PCR, respectively.

**RESULTS:** None of the normal colorectal mucosa tissues showed methylated bands of any of four *sFRP* genes. *sFRP1*, *2*, *4* and *5* were frequently methylated in colorectal carcinoma, adenoma and ACF (*sFRP1* > 85%, *sFRP2* >75%, *sFRP5* > 50%), and the differences between three colorectal tissues were not significant ($P > 0.05$). Methylation in colorectal tumors was more frequent than in normal mucosa and adjacent normal mucosa. The mRNA of *sFRP1-5* genes was expressed in all normal colorectal mucosa samples. Expression of *sFRP1, 2, 4* and *5* and *sFRP1*, *2* and *5* was downregulated in carcinoma and adenoma, respectively. The downregulation of sFRP2, 4 and 5 was more frequent in carcinoma than in adenoma. Expression of *sFRP3* which promoter has no CpG island was downregulated in only a few of colorectal tumor samples (7/105). The downregulation of *sFRP1*, *2*, *4* and *5* expression was significantly associated with promoter hypermethylation in colorectal tumor. After cells were treated by DAC/TSA combination, the silenced *sFRP* mRNA expression could be effectively re-expressed in colorectal cancer cell lines.

**CONCLUSION:** Hypermethylation of *sFRP* genes is a common early event in the evolution of colorectal tumor, occurring frequently in ACF, which is regarded as the earliest lesion of multistage colorectal carcinogenesis. It appears to functionally silence *sFRP* genes expression. Methylation of *sFRP1*, *2* and *5* genes might serve as indicators for colorectal tumor.

**Key words:** Colorectal tumor; *Secreted frizzled-related protein* genes; Methylation; Indicator; Re-expression

## INTRODUCTION

Secreted frizzled-related proteins (sFRPs) comprise a family of five secreted glycoproteins that antagonize Wnt canonical and noncanonical signaling by different mechanisms directly or indirectly[1]. Wnt signaling regulates cell growth, motility and differentiation in animal development and has increasingly been implicated in tissue homeostasis in adult organisms. Aberrant Wnt signaling pathway is an early progression event in 90% of colorectal cancers, contributing to the growth, proliferation and loss of apoptosis of tumor cells[2]. Thus, role of sFRP as a negative regulator of Wnt signaling may have important implications in tumorigenesis, and its downregulation has been correlated with human cancers. To date, no mutation in *sFRP* genes has been associated with their dysregulation in tumors. Aberrant hypermethylation of CpG islands in gene promoter has been found to be a primary mechanism in the inactivation of several tumor suppressor genes. As we know, colorectal tumor is one of the tumors with high frequencies of gene methylation[3,4]. Epigenetic gene silencing plays an extremely important role in the early stage of colorectal tumorigenesis. In this study, we examined hypermethylation and expression of *sFRP* genes in different stages of colorectal tumor and colorectal cancer cell lines in order to investigate the functions of promoter hypermethylation of *sFRP* genes in colorectal tumorigenesis and progression, and whether it can serve as an indicator for colorectal tumor.

## MATERIALS AND METHODS

### Materials

**Tissue samples:** Tissue samples, including 72 sporadic colorectal carcinomas, 33 sporadic colorectal adenomas (male 56, female 49, age 27-76 years), 38 adjacent normal mucosa from 28 colorectal carcinomas and 15 colorectal adenomas, and 20 normal colorectal mucosa tissues (male 11, female 9, age 20-54 years) were obtained from surgical resection of patients receiving endoscopy examination at the clinic of Zhongnan Hospital of Wuhan University and The Tumor Hospital of Hubei Province between October 2003 and April 2006. Eighteen ACFs from 15 colorectal carcinomas were also collected[5]. Samples were stored at -70℃ until processing. None of the patients had received chemotherapy or radiation therapy prior to surgery. All patients gave informed consent for their participation in the study which had been approved by the Ethical Committee of our university.

**Cell culture and treatment:** Three colorectal carcinoma cell lines, including RKO, HCT116, and SW480 (cell lines were purchased from China Center for Type Culture Collection) were used in this study. Cell lines were cultured in RPMI 1640 medium (GIBCO BRL) supplemented with 10% fetal bovine serum and treated with 5-aza-2' -deoxycytidine (DAC), a DNA methyltransferase (DNMT) inhibitor, and trichostatin A (TSA), a histone deacetylase (HDAC) inhibitor. Three cell lines all received four different treatments: low-dose DAC (200 nmol/L, 48 h), high-dose DAC (5 μmol/L, 72 h), TSA (300 nmol/L from a 1.5 mmol/L ethanol-dissolved stock, 24 h), and DAC (200 nmol/L, 48 h) followed by addition of TSA (300 nmol/L, 24 h), the drugs and medium being replaced every 24 h.

### Methods

**Methylation analysis:** Methylation-specific PCR (MSP) was used to examine the promoter hypermethylation of *sFRP1, 2, 4* and *5* genes. Genomic DNA was extracted by the phenol-chloroform standard methods. Bisulfite genomic DNA modification and purification was performed as previously reported[6]. The modified DNA was amplified by methylated and unmethylated primers (exact primers are available upon request). Products were visualized by 12% polyacrylamide gel electrophoresis. MSP was not performed for *sFRP3*, which has no CpG island in promoter region.

**Reverse transcription PCR (RT-PCR) analysis:** RT-PCR was employed to detect *sFRP1-5* genes mRNA expression. TRIZOL Reagent (Invitrogen) was used to extract total RNA from tissues and cells. The integrity of RNA was identified by methanal denatured agarose electrophoresis. Ultraviolet-visible light spectrophotometer (Beckman Coulter DU530) was used to determine $A_{260/280}$ of total RNA. Reverse transcription was performed on 1 μg of total RNA in a reaction volume of 20 μL. PCR assays were performed in 50 μL volume using 100 ng cDNA. Glyceraldehyde phosphate dehydrogenase (*GAPDH*) was employed as an internal reference gene to ensure cDNA quality and loading accuracy. Products were visualized by 2.5% agarose electrophoresis, and then analyzed by gel imaging system (SynGene GGM) and GeneTools software. RT-PCR was performed three times for the tumor samples with detectable mRNA, and then the gene expression index (density Lum of samples mRNA/density Lum of *GAPDH* mRNA) of these samples was compared with the normal samples (*t* test). Those with reduced mRNA expression and $P < 0.01$ were considered as significantly downregulated.

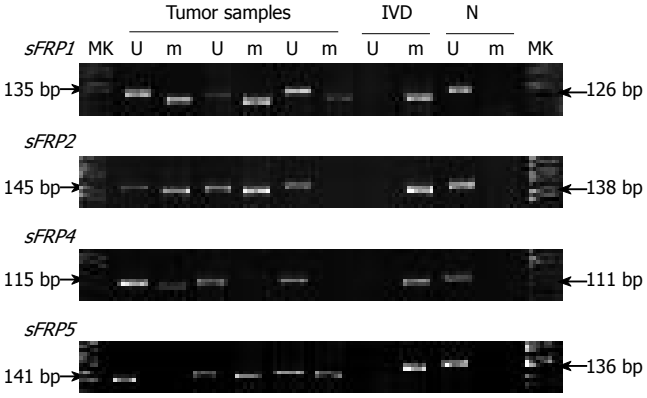

**Figure 1** Hypermethylation of *sFRP* genes in colorectal tissues. Tumor samples showed unmethylated (U) and methylted (m) bands, but normal tissues (N) showed only unmethylated bands. The *in vitro* methylated DNA (IVD) serves as a positive control of methylated *sFRP* genes.

### Statistical analysis

Statistical analysis was performed using SPSS 11.5 software. Associations between the discrete variables were assessed using the two-sided Fisher's exact test or Pearson's chi square tests. *P* value less than 0.05 was regarded as statistically significant.

## RESULTS

### Methylation of sFRP genes

None of normal mucosa showed methylated bands. *SFRP1, 2, 4* and *5* were methylated in 93.1% (67/72), 83.3% (60/72), 36.1% (26/72) and 52.8% (38/72) of colorectal carcinoma; 87.9% (29/33), 81.8% (27/33), 24.2% (8/33) and 57.6% (19/33) of colorectal adenoma (Figure 1); 52.6% (20/38), 28.9% (11/38), 2.6% (1/38) and 18.4% (7/38) of adjacent normal mucosa to colorectal carcinomas and adenomas, respectively. Most of *sFRP* genes were methylated in tumor samples when methylation was presented in the adjacent normal mucosa from the same sample, *sFRP1* (20/20), *sFRP2* (9/11), *sFRP4* (1/1) and *sFRP5* (6/7). The tumors showed stronger methylation signals than the adjacent normal tissues (Figure 2).

The methylation of each of the *sFRP1, 2, 4* and *5* genes was significantly different between carcinoma and normal mucosa ($P < 0.001$ for *sFRP1, 2* and *5*, $P = 0.002$ for *sFRP4*), between carcinoma and adjacent normal mucosa ($P < 0.001$ for *sFRP1, 2, 4* and *5*), between adenoma and normal mucosa ($P < 0.001$ for *sFRP1, 2* and *5*, $P = 0.0462$ for *sFRP4*), and between adenoma and adjacent normal mucosa ($P = 0.001$ for *sFRP1*, $P < 0.001$ for *sFRP2* and *5*, $P = 0.018$ for *sFRP4*). While no significant difference was found between carcinoma and adenoma ($P = 0.614$ for

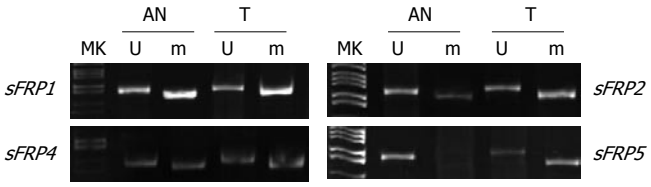

**Figure 2** Hypermethylation of *sFRP* genes in colorectal tumor samples (T) and the corresponding normal tissues adjacent to them (AN). The tumors showed stronger methylation signals than the adjacent normal tissues.

**Table 1 Correlation of sFRP expression with methylation status**

| Gene | | Colorectal tumor | | |
|---|---|---|---|---|
| | | Unmethylated | Methylated | $\chi^2$, *P* |
| *sFRP1* | + | 6 | 9 | $\chi^2 = 17.627$ |
| | - | 3 | 87 | $P < 0.001$ |
| *sFRP2* | + | 11 | 28 | $\chi^2 = 5.345$ |
| | - | 7 | 59 | $P = 0.021$ |
| *sFRP4* | + | 68 | 15 | $\chi^2 = 37.041$ |
| | - | 3 | 19 | $P < 0.001$ |
| *sFRP5* | + | 38 | 10 | $\chi^2 = 39.872$ |
| | - | 10 | 47 | $P < 0.001$ |

Expression (+) and reduced expression (-).

*sFRP1*, $P = 0.848$ for *sFRP2*, $P = 0.228$ for *sFRP4* and $P = 0.647$ for *sFRP5*).

*SFRP1, 2, 4* and *5* were methylated in 94.4% (17/18), 77.8% (14/18), 27.8% (5/18) and 55.6% (10/18) of 18 ACF samples. *SFRP1, 2, 4* and *5* methylation differed significantly between ACF and normal mucosa ($P < 0.001$ for *sFRP1*, *2* and *5* and $P = 0.017$ for *sFRP4, Fisher's* exact test). While no significant difference was found between ACF and carcinoma ($P = 1.000$ for *sFRP1*, $P = 0.836$ for *sFRP2*, $P = 0.506$ for *sFRP4* and $P = 0.833$ for *sFRP5*), and between ACF and adenoma ($P = 0.794$ for *sFRP1*, $P = 1.000$ for *sFRP2*, $P = 1.000$ for *sFRP4* and $P = 0.059$ for *sFRP5*). At least one of the four *sFRP* genes was methylated in 18 ACF samples.

### Expression of sFRP genes

The 20 normal colorectal mucosa specimens expressed considerable levels of sFRP1-5. Compared with the normal mucosa, *sFRP1, 2, 4* and *5* expression was silenced or significantly reduced in 90.3% (65/72), 70.8% (51/72), 26.4% (19/72) and 61.1% (44/72) of colorectal carcinomas, respectively ($P < 0.001$ for *sFRP1*, *2* and *5* and $P = 0.023$ for *sFRP4*); *sFRP1, 2,* and *5* were markedly downregulated or silenced in 75.8% (25/33), 45.5% (15/33) and 39.4% (13/33) of colorectal adenomas ($P < 0.001$ for *sFRP1, 2* and *5*). *SFRP4* was downregulated or silenced in 9.1% (3/33) of colorectal adenomas relative to the normal mucosa ($P = 0.438$). The downregulation of *sFRP 2, 4* and *5* expression was more frequent in carcinoma than in adenoma ($P = 0.012$, $P = 0.043$ and $P = 0.038$). *SFRP1* expression had no significant difference between carcinoma and adenoma ($P = 0.094$). A minority of adjacent normal mucosa samples had reduced expression

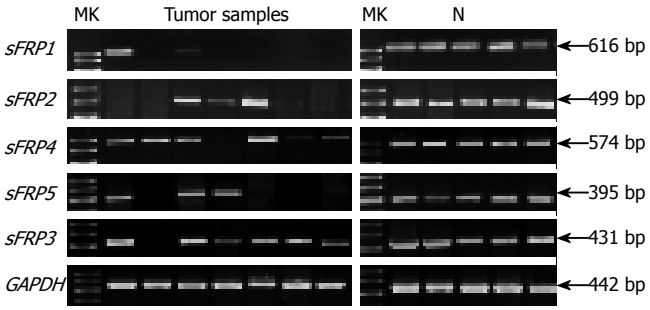

**Figure 3** Expression of *sFRP* gene family in colorectal tumor and normal tissues (N). The gene *GAPDH* serves as a positive indicator for RNA quality and loading.

of *sFRP1-5* genes, and the ratio was 13.2% (5/38), 5.3% (2/38), 0% (0/38), 7.9% (3/38) and 7.9% (3/38), respectively. *SFRP3* that has no CpG island in promoter region was downregulated in only 7 of 105 colorectal tumor samples (Figure 3). Reduced expression of *sFRP1, 2, 4* and *5* genes was significantly associated with aberrant hypermethylation of these genes (Table 1).

### Re-expression of silenced sFRP genes in colorectal carcinoma cell lines

*SFRP1*, *2*, *4* and *5* genes were methylated in RKO and HCT116 cell lines. *SFRP1* and *2* but not *sFRP 4* and *5* were also methylated in SW480 cell line (Figure 4A). When *sFRP* genes were methylated, their corresponding mRNA expression was absent in three colorectal carcinoma cell lines. SW480 cell line expressed *sFRP 4* and *5* mRNA, in which methylation was not detected in *sFRP 4* and *5* promoter. *SFRP3* was expressed in three colorectal carcinoma cell lines.

However, after cells were treated by low-dose DAC, the silenced *sFRP1, 2* and *5* mRNA expression could be re-expressed in RKO and HCT116 cell lines; and *sFRP1* expression could be re-expressed in SW480 cell line. High-dose DAC treatment could strengthen the effects of low-dose DAC treatment, and result in reexpression of *sFRP 4* (RKO and HCT116) and *2* (SW480) mRNA, which could not be induced by low-dose DAC. The addition of TSA to DAC rendered the silenced *sFRP* genes mRNA to be re-expressed effectively, and markedly elevated the mRNA expression level that had been re-expressed or increased by high-dose DAC. A single application of TSA could not induce re-expression of *sFRP* genes mRNA. The influence of demethylation treatment on *sFRP3* expression was minimal (Figure 4B and 4C).

## DISCUSSION

Aberrant activation of the Wnt canonical signaling pathway is associated with a variety of human cancers, such as head and neck carcinoma, lung cancer, melanoma, and mesothelioma, and particularly colorectal cancer, as well as the growth, proliferation and loss of apoptosis of tumor cells. The tumor suppressor adenomatous polyposis coli (APC) mutates in a high proportion of colorectal carcinomas; meanwhile it is an important member of Wnt canonical pathway involved in the degradation of

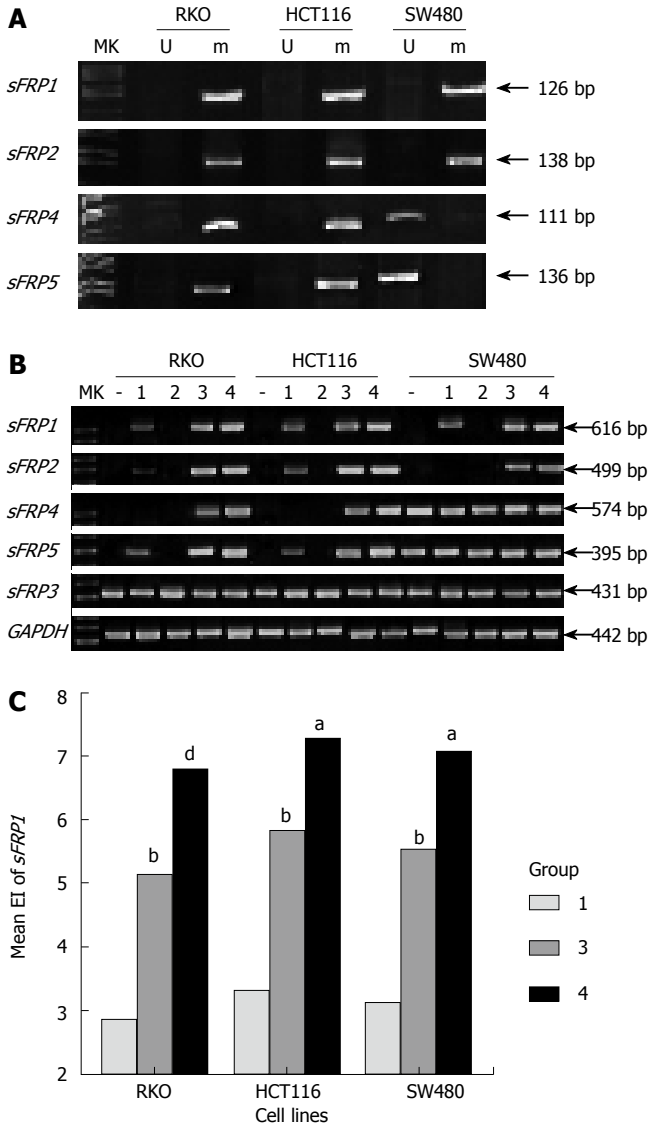

**Figure 4** **A**: Hypermethylation of *sFRP* genes in colorectal cancer cell lines; **B**: The mRNA expression level of *sFRP* genes in colorectal cancer cell lines before and after demethylation treatment. Three cell lines all received 4 different treatments: never treated (-), low-dose DAC (1), TSA (2), high-dose DAC (3), DAC + TSA (4); **C**: The *sFRP1* gene expression index (EI) in three cell lines after demethylation treatment, low-dose DAC (1), high-dose DAC (3), DAC+TSA (4). $^{b}P < 0.01$ *vs* 1, $^{d}P < 0.01$ *vs* 3, $^{a}P < 0.05$ *vs* 3.

β-catenin. Wnt signaling has been identified as one of the key signaling pathways in cancer, regulating cell growth, motility and differentiation. It has been reported that the noncanonical pathway is also involved in tumorigenesis, being associated with inhibition of apoptosis[7].

SFRPs contain a characteristic cysteine-rich domain (CRD) that shares homology with the CRD of frizzled (Fz) receptor of Wnt in the N-terminal half of the proteins. Thus, sFRPs may block Wnt signaling either by interacting with Wnt proteins to prevent them from binding to Fz proteins or by forming nonfunctional complexes with Fz[1]. It has been reported that sFRPs can potentially inhibit the entire canonical Wnt pathway even in the presence of activating mutations of *APC* or β-*catenin* downstream of the Fz receptor in colon cancer cell[8]. Therefore, silence of *sFRP* genes may be essential for the aberrant activation of the Wnt canonical pathway in colorectal tumorigenesis.

To date, no mutation in *sFRP* genes has been associated with their dysregulation in tumors. Aberrant hypermethylation of CpG islands in gene promoters has been found to be a primary mechanism in the inactivation of several tumor suppressor genes. However, the presence of gene silencing by hypermethylation is an important character of colorectal tumor[3,4]. This study demonstrated that genes of the sFRP family were methylated in most cases of colorectal carcinoma, adenoma and ACF, especially *sFRP1* and *2*. The proportion of *sFRP1* and *2* methylation was more than 85% and 75%, respectively. However, *sFRP* genes methylation was much less common in normal-appearing epithelia adjacent to colorectal tumor and never detected in normal mucosa. These data suggest that methylation of *sFRP* genes occurs as an early event in the evolution of ACF-adenoma-carcinoma sequence and is increased through carcinogenic transformation. Notably, 80.6% of colorectal carcinomas showed methylation of both *sFRP1* and *2*, and at least one of the four *sFRP* genes with CpG islands was methylated in 97.2% of the colorectal carcinomas and all ACF samples. *SFRP1*, *2 and 5* appeared to be more specific for colorectal carcinoma, adenoma and ACF, and may be more suitable candidate markers for these lesions.

Based on our study, methylation represents a likely mechanism of *sFRP* gene silencing in colorectal tumor: (1) *sFRP* expression is absent or markedly decreased in colorectal carcinoma and adenoma but generally high in normal mucosa, which is associated with *sFRP* gene methylation; (2) mRNA expression of *sFRP* genes is absent in cancer cell lines with corresponding *sFRP* gene methylation but high in cell lines with unmethylated *sFRP* genes; and (3) *sFRP* gene expression is reactivated in methylated cancer cell lines treated by demethylation; (4) s*FRP3* that has no CpG island in promoter region is expressed in cancer cell lines and a majority of tumor and normal samples. These data suggest *sFRP* gene silencing induced by promoter hypermethylation plays a key role in colorectal tumorigenesis by permitting aberrant activation of Wnt canonical signaling. Furthermore, we propose that the inhibiting effect of s*FRP3* on Wnt signaling is weak. Although sFRP3 is still expressed in tumor cells, it is not sufficient to block Wnt signaling. To confirm that, further studies are needed on the action of Wnt signaling in colorectal tumor cells.

We also found promoter hypermethylation of *sFRP* genes was present at equal frequency in colorectal carcinoma and adenoma, but the downregulation of *sFRP 2*, *4* and *5* expression was more frequent in carcinoma than in adenoma. These suggest that *sFRP* genes are not completely silenced by promoter hypermethylation in the stage of adenoma, although methylation has been presented in adenoma and even early stage ACF. The silence of *sFRP* genes tends to increase with the colorectal tumor progression. Thus, the downregulation of *sFRP* genes may be associated with the progression and malignant potential of colorectal tumor. Our data showed *sFRP1* methylation and downregulation were both extremely frequent in colorectal carcinomas and adenomas. It suggests the methylation and downregulation of *sFRP1* occur more frequently and earlier than other *sFRP* genes

in colorectal tumor, and perhaps play more important role in the progression of colorectal tumorigenesis. However, the methylation and downregulation of *sFRP4* were less common than *sFRP1, 2* and *5* genes in colorectal tumor, though they were both high in mesothelioma and esophageal adenocarcinoma as previously reported[9,10]. It has been reported *sFRP4* has the least homology with other family members[11]. These suggest the Wnt signaling is regulated by different sFRP molecules in different histiocytes. In colorectal tumor cells, the role of sFRP1, 2 and 5, especially the sFRP1, is more important than sFRP3 and 4.

Two key epigenetic pathways are involved in gene transcription regulation: DNA methylation and histone acetylation. DNA methylation is carried out by three DNA methyltransferases (DNMT), DNMT1, DNMT3A, and DNMT3B. DNA methylation represses transcription directly, by inhibiting the binding of specific transcription factors, and indirectly, by recruiting methyl-CpG-binding proteins and their associated repressive chromatin remodeling activities[12]. Deacetylation catalyzed by histone deacetylases is important for turning off genes and maintaining some genes in a repressed state[13]. DAC is a DNMT inhibitor that induces DNA demethylation by metabolic incorporation into genomic DNA, thereby covalently arresting DNMT. TSA is an HDAC inhibitor that causes hyperacetylation on histones H3 and H4. Our data showed *sFRP* genes were effectively demethylated by the high-dose DAC or combination of DAC and TSA treatment and re-expressed in colorectal cancer cell lines. The effect of combination of DAC and TSA treatment was better than high-dose DAC, even though the DAC concentration was low in the combination. A single application of TSA could not induce re-expression of *sFRP* genes mRNA, although some genes were upregulated in expression by TSA alone in the previous report[14]. These data indicate DNA methylation and histone deacetylation are synergetic in the inhibition of gene transcription, and in terms of *sFRP* genes, DNA methylation plays the dominant role.

Our study shows that hypermethylation of *sFRP* genes is a common early event in the evolution of colorectal tumor, and hypermethylation patterns of *sFRP* genes may provide a potentially useful marker system for predicting the risk of colonic neoplasia.

Silence of *sFRP* genes induced by promoter hypermethylation plays a key role in colorectal tumorigenesis. As DNA sequence is not altered by epigenetic modification, and gene silenced by promoter hypermethylation could normally transcript after demethylation, modulation of Wnt protein-driven cell growth, through reversal of *sFRP* genes silencing, may represent potential targets for colorectal cancer prevention and treatment.

## ACKNOWLEDGMENTS

We thank Dr. Bing Xiong, Qun Qian and Liao-Bing Chen for providing and storing CRC and normal samples, and Jun-Zhu Wu for helpful comments on the manuscript.

## Abstract

**AIM:** To investigate whether transfection of plasmid DNA encoding these cytokines enhances both humoral and cellular immune responses to hepatitis C virus (HCV) in a murine model.

**METHODS:** We established a tumor model of HCV infection using syngenic mouse myeloma cells stably transfected with NS5. Co-vaccination of DNA encoding granulocyte macrophage colony-stimulating factor (GM-CSF) and Flt-3 ligand together with a plasmid encoding for the HCV NS5 protein was carried out. Mice were sacrificed 14 d after the last immunization event with collection of spleen cells and serum to determine humoral and cellular immune responses.

**RESULTS:** Co-vaccination of DNA encoding GM-CSF and Flt-3 ligand together with a plasmid encoding for the HCV NS5 protein induced increased antibody responses and CD4+ T cell proliferation to this protein. Vaccination with DNA encoding GM-CSF and Flt-3L promoted protection against tumor formation and/or reduction in mice co-immunized with cytokine-encoding DNA constructs. This suggests this strategy is capable of generating cytotoxic T lymphocyte activity *in vivo*. Following inoculation with plasmid DNA encoding Flt-3L, no increase in spleen size or in dendritic cell (DC) and natural killer cell numbers was observed. This was in contrast to a dramatic increase of both cell types after administration of recombinant Flt3-L *in vivo*. This suggests that vaccination with plasmid DNA encoding cytokines that regulate DC generation and mobilization may not promote unwanted side effects, such as autoimmunity, splenic fibrosis or hematopoietic malignancies that may occur with administration of recombinant forms of these proteins.

**CONCLUSION:** Our data support the view that plasmid DNA vaccination is a promising approach for HCV immunization, and may provide a general adjuvant vaccination strategy against malignancies and other pathogens.

**Key words:** DNA-vaccination; Dendritic cells; Flt3-L; granulocyte macrophage colony-stimulating factor; Hepatitis C virus

## INTRODUCTION

Dendritic cells (DCs) play a pivotal role in the initiation of immune responses and are considered as important targets for effective immunotherapeutic strategies against cancer and infectious diseases[1,2]. DCs acquire antigen in peripheral tissues, migrate to peripheral lymphoid tissue and subsequently present MHC-peptide complexes to naive T cells for the induction of immune responses. In this scheme, DCs are also believed to control the type of immune response that is generated through the secretion of cytokines such IFN-γ or IL-4 which regulate Th1 or Th2 responses, respectively. The development of DC

and their activation state is dependent upon growth factors, such as fms-like tyrosine kinase 3 ligand (Flt-3L) and granulocyte macrophage colony-stimulating factor (GM-CSF). When administered *in vivo* in the form of recombinant proteins, these cytokines can dramatically alter the absolute number of DC and the subset composition of lymphoid tissue and blood-borne DC[3,4]. This has important implications for the use of these cytokines as adjuvants, since recent evidence suggests that distinct DC subsets are responsible for the generation of different classes of immune responses. Monocyte-derived CD11c+ DCs induce T cells to produce Th1 cytokines *in vitro*, whereas the CD11c- plasmacytoid T cell-derived DCs elicit the production of Th2 cytokines. Flt-3L can increase the number of cells in both subsets of DC, but GM-CSF only increases the CD11c- precursors[3,4]. A number of studies have shown that recombinant Flt-3L protein can augment *in vivo* immune responses and that this cytokine has immunotherapeutic potential[5-7]. It is important to establish if the adjuvant effects of Flt-3L can be achieved by plasmid DNA immunization, which would provide a more versatile delivery system for antigen delivery in vaccination protocols that involve this cytokine[8].

Direct intramuscular or intradermal injection of plasmid DNA generates potent cell-mediated and humoral immune responses against a variety of pathogens, such as human immunodeficiency virus (HIV), hepatitis B virus (HBV), ebola virus, influenza virus, mycobacteria and malaria in animal models of these diseases[9-11]. Genetic vaccines induce antigenic expression that resembles a response to native viral epitopes more closely than do other conventional vaccines. Live attenuated or killed vaccines are often altered in protein structure and antigenicity and may be rendered less efficient at stimulating protective immunity. An important feature of DNA-based immunization is the induction of cytotoxic T cells (CTL) that recognize and lyse virus-infected cells, thereby limiting viral spread. Recent DNA-based immunization studies have reported the induction of anti-HIV CTL activity and anti-plasmodium T cell responses in chronically infected individuals who were immunological naïve for these pathogens[12,13]. Several lines of evidence implicate DC as the principal antigen-presenting cell (APC) in mediating effective immune responses that involve plasmid DNA vaccination. Firstly, bone marrow-chimeric mice have shown that bone marrow-derived APCs are responsible for the induction of the immune response after DNA vaccination[14,15]. Secondly, DCs but not B cells or keratinocytes, isolated from DNA-vaccinated mice were able to present the immunizing antigen to T cells *in vitro*[17]. Thirdly, injection of DNA leads to the direct transfection of DCs *in vivo*[1]. Finally, direct *in vivo* visualization of antigen-expressing DCs from draining lymph nodes after gene-gun vaccination has been demonstrated[18]. Collectively, these reports indicate plasmid DNA immunization with a DC-specific adjuvant is likely to lead to a potent immune response.

Hepatitis C virus (HCV) infection is the major causative agent of transfusion-associated and community-acquired non-A or non-B hepatitis. An estimated 170 million individuals are infected with HCV worldwide and this represents a viral pandemic[19]. Infection with HCV is associated with high morbidity and mortality, since 75%-85% of individuals infected with HCV develop chronic infection and hepatitis whilst approximately one third progress to cirrhosis and eventual liver failure[20]. Moreover, HCV-infected individuals are at increased risk for hepatocellular carcinoma (HCC) within 10-20 years of infection[21]. An effective therapeutic and/or prophylactic anti-HCV vaccine is, therefore, of considerable clinical importance[22]. We have previously identified various HCV structural and non-structural proteins that may be used for vaccination studies designed to limit HCV pathogenesis[23-25]. Here we have shown that co-immunization of DNA encoding GM-CSF and Flt-3L, together with DNA encoding HCV viral antigen leads to enhanced humoral and cellular immune responses that collectively provide protective immunity against HCV-induced pathogenesis in mice.

## MATERIALS AND METHODS

### Construction of DNA expression vectors

A plasmid coding for HCV NS5 was cloned as described in detail previously[25]. pcDNA3-Flt3-L was cloned from a plasmid PCRblunt-mFlt3-L encoding the leader sequence and the extracellular domain of mouse Flt3-L. PCR amplification was performed with the following primer pair: in sense direction 5´-CGG*GGTACC***ATG**ACAGTGCTGGCGCCAGCCTGG-3´ (*Kpn* I *site* and **engineered start codon** ) and in antisense direction 5´-GC*TCTAGAAAGCTT***TTATTA**ATGGTGATGATGGTGATGCTGCCTGGGCCGAGGCTC-3´ (*Xba* Ⅰ *and Hind* Ⅲ *site*, **engineered stop codons** and 6xHis Tag) with a proof reading high fidelity system (Roche, Germany) and a standard PCR protocol as follows: Pre-denaturation at 95℃ for 2 min; 30 amplification cycles, each cycle consisting of denaturation at 95℃ for 1 min, primers annealing at 57℃ for i min and extension at 72℃ for 1 min; and finally an extra incubation at 72℃ for 7 min to ensure full extension of the products. After restriction enzyme digest with *Kpn* Ⅰ and *Xba* Ⅰ for 20 h, the insert was cloned into a standard mammalian transfection vector with a CMV promoter and a given number of CpG motifs (pcDNA3; Invitrogen, Groningen, Netherlands)). Standard sequencing was performed to verify correct nucleotide sequence (Sequence Laboratories, Göttingen, Germany). Cloning and characterization of pGM-CSF was described elsewhere[25]. Plasmids were grown in DH5α cells, and plasmid DNA was subsequently purified by Qiagen Giga Kit using the endofree buffer system (Hilden, Germany).

### HCV infection model

In the absence of a small animal model for HCV infection, we used a tumor model expressing a target HCV antigen (HCV-NS5). A stable HCV NS5-expressing mouse myeloma cell line SP2-NS5-21 (H-$2^d$ background) syngenic to BALB/c mice was established by electroporation and limiting dilution, followed by Western blot analysis for HCV NS5 expression. BALB/c mice inoculated with $2 \times 10^6$ syngenic myeloma cells (SP2-NS5-21) into the flank

develop visible tumors within 7 d and succumb to terminal tumor burden within 15-25 d. The tumors constitutively express HCV NS5 protein and are an established model of HCV viral challenge that has been characterized previously[25].

### *In vitro expression*

A human hepatoma cell line (HuH-7) was transiently transfected with the various plasmids pcDNA-Flt3-L, pcDNA3-NS5 and pcGM-CSF to verify protein and antigen expression as determined by Western blot and ELISA. Detail protocols for immunoblot for NS5 and for Western blot and ELISA for GM-CSF are described previously[23,25]. Flt3-L expression was confirmed by Western blot technique with an anti-His-Tag antibody and a mouse Flt3-L-specific ELISA (R&D, Minneapolis, MN). Cell supernatants were collected 48 h after standard calcium phosphate transfection and cell lysates were prepared in a RIPA buffer (50 mmol/L Tris, 150 mmol/L NaCl, 10 mL/L Nonidet P-40, 5 g/L sodium deoxycholate, 10 g/L SDS). Proteins were lysed and supernatants were loaded onto a 150 g/L-SDS-PAGE gel and blotted onto nitrocellulose membranes. After blocking with 30 g/L BSA in TBS for 2 h, membranes were incubated for 1 h with an anti-His-Tag antibody (Quiagen, Hilden, Germany) in TBS at room temperature (dilution 1:1000), followed by an incubation with sheep-anti-mouse Ig horseradish peroxidase antibody (Amersham Pharmacia, Freiburg, Germany) at 1:1000 dilution. Chemiluminescence detection was performed with the ECL system following the manufacturer's protocol (Amersham Pharmacia). Flt3-L ELISA was performed with a commercially available ELISA kit (R&D, Minneapolis, MN). Lysates and supernatants were used undiluted. To analyze Flt3-L serum levels of immunized mice, a 1:50 dilution of serum collected through tail vein bleeding was used as first antibody in this assay.

### *Plasmid DNA Immunization*

BALB/c (H-$2^d$) and C57/BL6 (H-$2^b$) mice were purchased from Charles River Laboratories and maintained under standard pathogen-free conditions in the animal facility (Zentrales Tierlabor) at our institution (University of Heidelberg). Five days prior to plasmid immunization, 100 μL of 50 μg/mL Flt3-L or mock plasmid DNA was injected into the quadriceps muscle over five different sites. Plasmid immunization was performed three times thereafter (100 μg plasmid DNA in 100 μL 9 g/L NaCl) at bi-weekly intervals (administration into the opposite leg). Empty plasmid vector (mock) immunization was employed as a negative control. Animals ($n$ = 5) were injected with pcDNA3-NS5 (50 μg) alone or in combination with an Flt3-L (50 μg) or GM-CSF (50 μg) plasmid. Furthermore, one group was immunized with 50 μg of HCV NS5 and Flt3-L combined with GM-CSF (both 25 μg) to study the combined effect of both cytokines. One group was immunized subcutaneously into the footpad. Mice were sacrificed 14 d after the last immunization event with collection of spleen cells and serum to determine humoral and cellular immune responses. The immunization experiments were once repeated; each immunization group contained at least 5 animals.

### *Measurement of humoral immune responses*

Anti-HCV NS5 antibody level in the serum of each immunized animal was determined by ELISA. In brief, microtiter plates (Nunc Maxisorp) were coated with 0.5 μg/well recombinant HCV NS5-4 protein (Mikrogen, Munich, Germany), incubated overnight at 4℃ and blocked with foetal bovine serum (FBS) for 2 h at 20℃. A 1:50 dilution of mouse serum was added to the plates, incubated for an additional 1 h at 20℃, and washed 4 times with phosphate buffered saline (PBS) containing 5 mL/L Tween-20. A peroxidase-conjugated AffinePure goat anti-mouse IgG (Dianova, Hamburg, Germany) was applied to the plates at a 1:2000 dilution, incubated for 1 h, washed, and substrate (OPD) was added for color development (Abbott).

### *Lymphoproliferation and cytokine release assays*

Mice were anesthetized with diethylether for harvesting of spleen cells. Erythrocytes were removed by incubation in 8.3 g/L $NH_4Cl$ / 0.17 mol/L Tris (pH 7.4) for 5 min at 25℃. Spleen cells were washed 2 times and cultured in triplicate using 96-well round bottom plates at $5 \times 10^5$ cells/well in 200 μL DMEM (Cellgro Mediatech, Washington, DC) containing 100 mL/L FBS and 2-mercaptoethanol ($5 \times 10^{-5}$ mol/L). Cells were stimulated for 3 d with recombinant HCV NS5-4 protein (aa 2622–2868) (Mikrogen, Munich, Germany) at various concentrations (0, 0.01, 0.1 and 1 μg/mL). Following the addition of radioactive $^3$H-thymidine (1 μCi/well), cells were incubated for an additional 18 h, and $^3$H-thymidine uptake into DNA was measured after harvesting; incorporation of radioactivity was corrected for background activity (Δ cpm). To determine cytokine secretion levels of lymphoproliferative cells stimulated with recombinant HCV NS5-4 protein, cells were cultured as described, and mIFN-γ and mIL-4 levels were measured by commercial kits according to manufacturer's instructions (Pharmingen, San Diego, CA).

### *ELISPOT assay*

To assess the number of IFN-γ-secreting cells at the individual cell level, single cell suspensions from spleens harvested from immunized mice mouse were analyzed in an IFN-γ ELISPOT assay. Cells were directly assessed in this assay without prior *in vitro* expansion in the presence of 1 μg/mL recombinant NS5-4 protein at 37℃ (50 mL/L $CO_2$) in IFN-γ-bound microtiter plates to measure IFN-γ cytokine secretion as means of CD8+-T-cell function (AID, Straßberg, Germany). After washing with PBS-Tween buffer, cells were incubated with a secondary antibody suspended in DMEM supplemented with 100 mL/l FCS and 2-mercaptoethanol.

### *Assessment of CTL activity in vivo*

BALB/c mice were immunized im three times with either mock DNA or NS5 vector and co-immunized with Flt3-L or Flt3-L and GM-CSF. One week after the last immunization event with $2 \times 10^6$ syngenic SP2/0-derived cells stably expressing NS5 were washed (Sp2-NS5-21), resuspended in 200 μL of PBS, and inoculated sc into

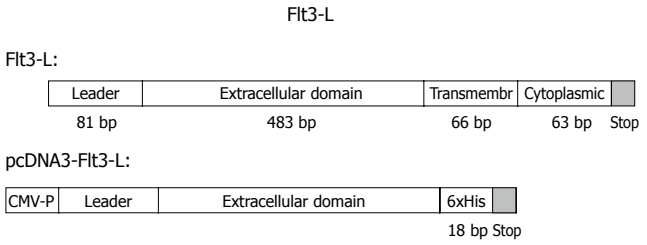

**Figure 1** Cloning of the soluble form of mouse Flt3-L containing the leader and the extracellular domain into a mammalian expression vector with CMV-promoter and RSV-enhancer. The C-terminus was tagged with a 6xHis. The soluble form of mFlt3-L is fully active.

the right flank. SP2/0 cells that stably expressed HCV core protein (SP2/19) were used as a control in selected animals. Tumor formation, tumor size, mouse weight and mouse survival was assessed at distinct intervals post inoculation.

## RESULTS

### *In vitro expression of Flt-3L from Flt-3L-pcDNA3*

Flt-3L is type I transmembrane, non-disulphide linked, homodimer glycoprotein of approximately 30 ku. This cytokine may also be found as a soluble form in serum that comprises only the extracellular domain of approximately 160 amino acids that retains full biological activity[26,27]. We, using PCR, have cloned Flt-3L DNA encoding the leader sequence and extracellular domain, together with a hexahistidine C-terminal tag, into the eukaryotic expression vector pcDNA-3 for use as a Flt-3L delivery system. Figure 1 shows a schematic representation of the major domains of full-length and truncated forms of Flt-3L. DNA encoding the leader and extracellular domains of Flt-3L was generated by PCR and ligated into the eukaryotic expression vector pcDNA3 to generate Flt-3L-pcDNA3. Restriction digest and DNA sequence analysis confirmed the presence of the predicted insert size and its correct orientation (data not shown).

Figure 2 shows that Flt-3L-pcDNA3 was authentically expressed after transient transfection into HuH-7 cells. Figure 2A shows a Western blot of Flt-3L-pcDNA3-transfected HuH-7 cell lysate and culture supernatant probed with an anti-His monoclonal antibody. Anti-His reactive protein bands of 20 – 30 ku were present in both cell lysate and supernatant of cells transfected with Flt-3L-pcDNA3. This protein band pattern most likely represents the different glycosylation forms of Flt-3L which have been described previously[27]. Additional bands of 40 – 42 ku were detected in the cell culture supernatants that may represent the dimeric form of Flt-3L. No reactivity with the anti-His monoclonal antibody was seen in either cell lysate or culture supernatants from HuH-7 cells transfected with control vector. Further confirmation that Flt-3L was expressed from Flt-3L-pcDNA3 was provided by ELISA using an anti-Flt-3L specific monoclonal antibody with samples from Flt-3L-pcDNA3-transfected HuH-7 cells as substrate. Figure 2B shows that Flt-3L could be detected in cell lysate and culture supernatant from Flt-3L-pcDNA3-transfected cells, whereas no reactivity was detected in equivalent samples from control transfected cells. This

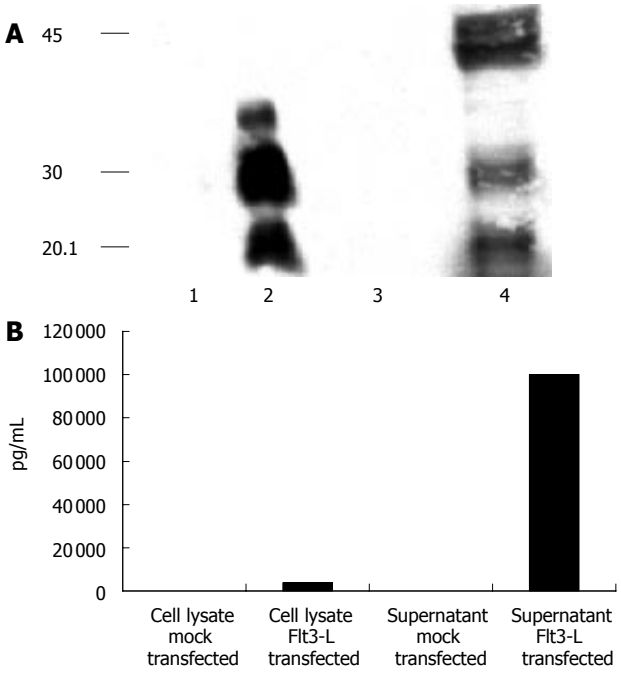

**Figure 2** Expression of Flt3-L in transiently transfected HuH-7 cells: (**A**) Detection of mouse Flt3-L on a 150 g/L SDS-PAGE using an anti-His-Tag antibody. Different glycosylation forms of Flt3-L in cell were detected in cell lysates and supernatants. Lane 1 and 3: mock-transfected cells; lane 2 and 4: Flt3-L-transfected cells; lane 1 and 2: supernatants after transient transfection; lane 3 and 4: cell lysates. (**B**) To confirm these results, supernatants and cell lysates were incubated by an Flt3-L-specific ELISA. Again, secretion levels into the supernatant were more than 20-fold higher compared to levels seen in the cell compartment.

data demonstrates that Flt-3L protein could be generated from Flt-3L-pcDNA3.

### *Flt-3L- or GM-CSF-pcDNA3 enhances anti-HCV immune responses*

Immune responses in mice to the HVC structural protein NS5 in the presence or absence cytokines that regulate dendritic cells were examined. Mice were immunized intramuscularly three times, at bi-weekly intervals, with pcDNA3-NS5 in combination with either Flt-3L-pcDNA3 or GM-CSF-pcDNA3. Serum samples from vaccinated mice were investigated for the presence of anti-HCV antibodies by ELISA using as substrate, the peptide NS5-4 which comprises amino acids 2622-2868 of the protein NS5. The data in Figure 3 shows that co-immunization of pcDNA3-NS5 with Flt-3L-pcDNA3 led to elevated levels of anti-HCV antibody compared to that found when pcDNA3-NS5 was administered alone. The level of anti-HCV antibody was further increased when pcDNA3-NS5 was co-immunized with GM-CSF-pcDNA3. Similar results were obtained using either BALB/c or C57/BL6 mice (data not shown). These experiments showed that administration of plasmid DNA encoding cytokines that regulate the development and maturation of dendritic cells, at the same time as inoculation with DNA encoding HCV protein, can produce elevated anti-HCV humoral immune responses. The adjuvant effect of Flt-3L or GM-CSF did not appear to affect the level of anti-HCV-specific T cell proliferation not readily evident at the level of T cell activation and proliferation. Spleen T cells from NS5 plasmid DNA-immunized mice were stimulated *in vitro* with recombinant

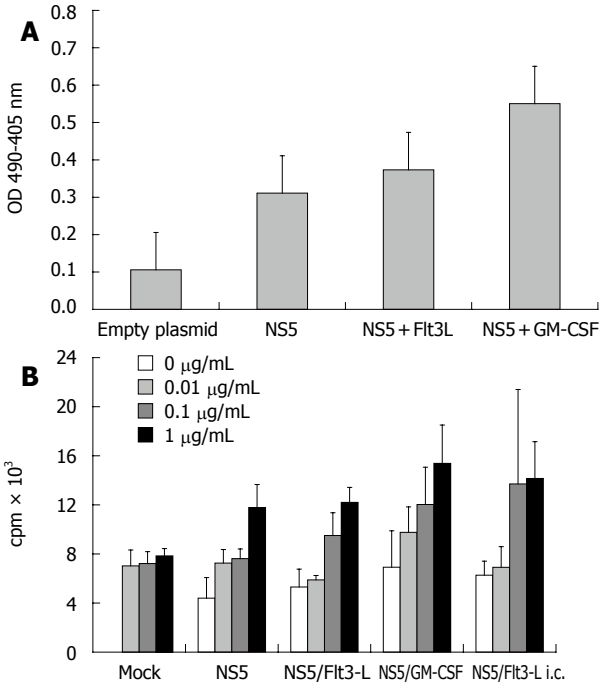

**Figure 3** **A:** Anti-HCV NS5 ELISA showing mean levels of specific antibodies after genetic immunization with HCV-NS5-expressing plasmid. Controls included wells coated with BSA and sera derived from mock-immunized mice. Each group comprised 10 BALB/c mice and mice sera were pooled before the assay. ELISA plates were coated with HCV-NS5-4, therefore, antibody levels may be underestimated; **B:** T-cell proliferation assay ($n$ = 10 mice/group) with different amounts of stimulating recombinant HCV NS5-4 protein (0.01-1 μg/mL). An increase of thymidine incorporation was seen after stimulation with 0.1 and 1 μg/mL recombinant protein. However, levels of T-cell proliferation after co-immunization with Flt3-L were only slightly higher than in NS5-immunized mice. Note that stimulation with a non-relevant protein (HBsAg) induced only background activity, demonstrating the antigen specificity (data not shown).

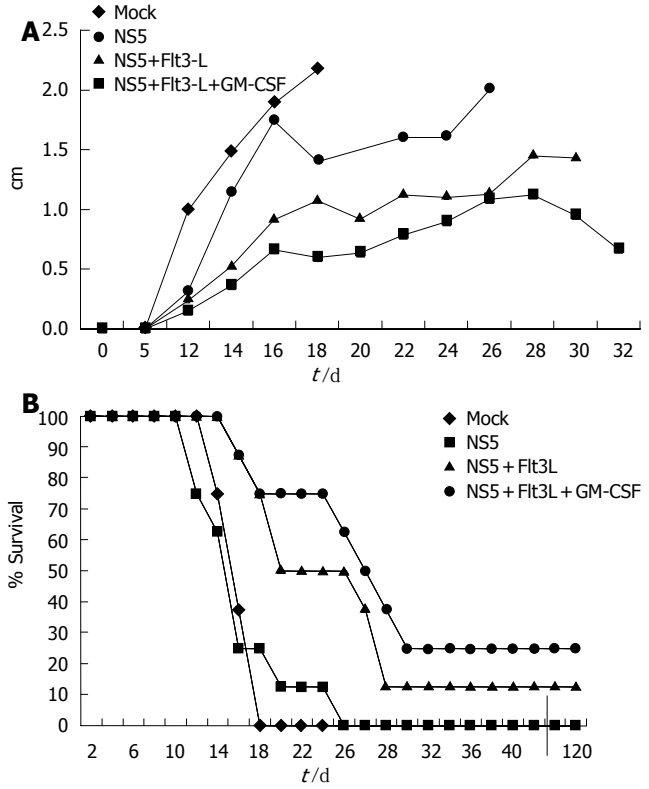

**Figure 4** Tumor model to assess CTL activity generated *in vivo* after genetic vaccination. Mice were immunized three times with a total of 100 μg of plasmid DNA. Each vaccination group ($n$ = 8) was challenged with 2 × $10^6$ syngenic mouse myeloma cells stably expressing HCV-NS5 protein in the right flank. Mice developed notable tumors around d 8-10. (**A**) Tumor size in different immunization groups. Note that mice had to be sacrificed at maximum tumor diameter size of 2 cm. Sacrificed mice were then taken out from the measurement. (**B**) Mouse survival after genetic vaccination in each group. Three mice were long-term survivor and never developed significant tumor burden.

HCV NS5-4 peptide and the subsequent proliferative response measured by 3-H-thymidine uptake. The data in Figure 3 shows that there was no significant difference in anti-NS5 HCV T lymphocyte proliferation between cells isolated from mice immunized with NS5-pcDNA3 alone or in combination with either Flt-3L pcDN3 or GM-CSF-pcDNA3. In addition, when IFN-γ and IL-4 levels in the supernatant of stimulated T cells were measured by ELISA, there were no significant differences between any of the immunization groups (data not shown).

### *Protective immunity generated by Flt-3L and GM-CSF*

*In vivo* CTL activity was assessed by a tumor model. Ten days after the last immunization event, animals were challenged in the right flank with a HCV-NS5 mouse myeloma cell line. Eighteen days after challenge, all mock plasmid-immunized animals were dead. Animals immunized with 50 μg of HCV-NS5 plasmid lived slightly longer, but all animals died by d 26. Co-vaccination with Flt3-L or Flt3-L and GM-CSF lead to survival and complete protection in some animals: 25% and 10%, respectively. Tumor size was also significantly reduced in co-immunized animals (Flt3-L and combination of Flt3-L and GM-CSF). Mice immunized with the same syngenic SP2/0 cell line expressing a different HCV structural protein (HCV core) as a control died as well by d 17, like mock-immunized animals. Indeed, 100% of mice immunized with mock DNA or challenged with SP2/19 cells demonstrated tumor formation, confirming the specificity of the cytotoxic activity in this tumor model (Figure 4).

### *In vitro and in vivo CTL activity: ELISPOT and tumor model*

We used IFN-γ-bound microtiter plates to measure IFN-γ cytokine secretion as means of CD8+-T cell function in an ELISPOT on an individual cell level. Spleen cells were harvested and cultured overnight in the presence or absence of 1 mg/L recombinant NS5-4 protein. Flt3-L, GM-CSF, the combination of both cytokines injected each with smaller amounts of DNA (25 μg per vaccination) and the subcutaneous injection with Flt3-L resulted in comparable levels of NS5-4-specific IFN-γ-producing T cells. The number of cells was significantly higher compared to NS5-immunized animals alone and the mock-injected animals (Figure 5).

### *In vivo expression of Flt3-L from Flt3-L- pcDNA3*

In studies by He *et al* where Flt-3L DNA has been administered by hypodynamic needle, levels of serum Flt-3L have been raised 10-fold compared to control values. To determine whether Flt3-L-pcDNA3 administration *in vivo* also led to elevated levels of serum Flt-3L, mice were inoculated with this vector by intramuscular injection and serum samples harvested at 3, 6, 12, 24 h and at 3 d and 7

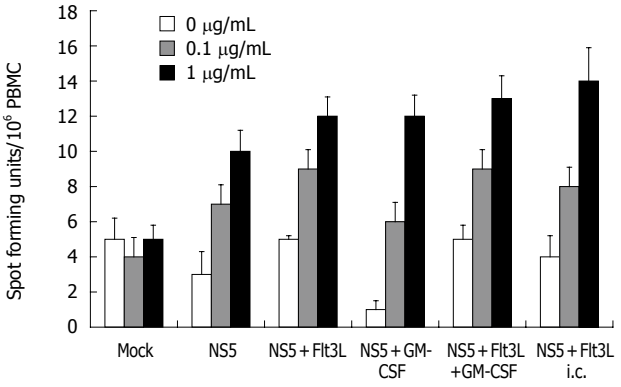

**Figure 5** ELISPOT assay: Assessment at the individual single cell level of the number of mIFN-γ-secreting cells as means of CD8 T cell function. Spleen cells were stimulated with recombinant HCV-NS5 protein at 0.1 and 1 μg/mL, and the number of spot forming units/$10^6$ PBMC was counted after 24 h incubation period ($n$ = 10 mice/group). Note that lymphocytes were not restimulated in NS5-expressing cells.

d post-inoculation. Serum samples were assessed for Flt-3 L by Flt-3L-specific ELISA. On no occasion, using either BALB/c or C57/BL6 mice, were the levels of serum Flt-3L significantly increased compared to control mice (data not shown). In addition, there was no increase in the size of lymphoid tissue, such as the spleen (data not shown), as has been reported following administration of recombinant Flt-3L protein or Flt-3L DNA by hypodynamic needle.

## DISCUSSION

DNA vaccination is an efficient and versatile mechanism for the delivery of antigen to the immune system. The mechanism of antigen delivery is believed to operate by direct transfection of dendritic cells with the inoculated DNA construct; plasmid expression within these cells and the subsequent processing and presentation of antigen to T cells[17]. Dendritic cells are potent antigen-presenting cells for naïve antigen-specific T cells and, therefore, have the capacity to initiate humoral and cellular immune responses, which is an essential requisite of any vaccination strategy[28,29]. A feature of plasmid DNA vaccination has been the reported longevity of expression of the DNA construct which may lead to evidence of immunity for periods greater than 12 mo[14]. This may represent continuous expression of the plasmid DNA construct within lymphoid tissue where antigen-presenting cells, such as dendritic cells and antigen-specific T cells, interact in the appropriate environment to allow the necessary cellular interactions that lead to an effective immune response[30]. Because of these features, plasmid DNA vaccination has been considered as an effective means to provide prophylactic or therapeutic immune responses against HCV infection[31]. However, several studies to date that have investigated plasmid DNA vaccination in animal models of human HCV infection have so far only demonstrated low antibody titers against the immunizing HCV proteins[23-25]. It is clear if plasmid DNA vaccination is to provide effective immunization against HCV infection that enhanced immune responses will need to be generated. In order to address this issue, we considered it appropriate to target dendritic cells in an attempt to promote enhanced plasmid DNA-induced anti-HCV immunity in mice.

In this study, we have successfully generated an enhanced immune response against a structural HCV protein by co-immunization with plasmid DNA-encoding cytokines that regulate development and maturation of dendritic cells. When HCV plasmid and Flt-3L DNA were co-injected, the resultant anti-viral antibody titer was significantly increased, and was further enhanced by co-immunization with GM-CSF plasmid DNA. These phenomena parallel what has been seen upon administration of recombinant Flt-3L and GM-CSF protein during immunization with protein antigens. Importantly, we have demonstrated that this enhanced plasmid DNA-based immunization is effective at providing protective immunity against HCV-based tumor formation. We used an *in vivo* tumor model that expressed a HCV non-structural protein. Control mice died after 18 d, whereas co-immunized mice survived to some extend, especially after co-administration of an Flt3-L and a GM-CSF plasmid underlining synergistic effects of both cytokines seen in *in vitro* studies[8]. This underlines the local and antigen-specific immune induction, because models of recombinant administration (up to 500 μg/kg per day) or virally transduction with Flt3-L DNA have also demonstrated inhibition of the growth of B16 melanoma, EL-4 lymphoma, murine leukemia, and C3L5 breast tumors in mice[32-35]. However, these models used large amounts of recombinant FLT3-L and repeated injections are required to induce these effects, unlike the relatively small amounts of plasmid DNA injection used in this study.

A feature of our study is that protective immunity against HCV-induced tumor formation was achieved in the apparent absence of any detectable increase in serum cytokine level from the inoculated plasmids. In humans, serum levels of Flt3-L are relatively low (< 100 pg/mL). In mice we measured serum levels around 300 pg/mL and did not find an increase after genetic vaccination with Flt3-L plasmid. These results are in contrast to data that have reported an initial increase in serum Flt3-L levels after a single injection of hydrodynamic human Flt3-L gene delivery when serum levels up to 40 μg/mL were observed and remained above 1 μg/mL for 6 d in mice[36]. In addition, elevated levels of serum Flt-3L, such as those following *in vivo* administration, resulted in an increase in the size of peripheral lymphoid tissues like spleen and lymph nodes. Furthermore, these elevated levels of Flt3-L were associated with significant increases in the number of DCs and NK-cells in various tissues, such as spleen and liver[36]. Our observations on the absence of any change in serum Flt3-L following plasmid DNA vaccination with this cytokine are in agreement with reports by others using other cytokines, such as IL-2, GM-CSF or IL-12, for plasmid DNA co-vaccination studies[23,37,38]. High levels of DC in a number of different organs may, under certain conditions, be associated with adverse side effects, including induction of haematopoietic malignant disease and the induction of autoimmunity[39]. Interestingly, a very recent study demonstrated the successful local recruitment of DC to the side of injection and the induction of CD4+ proliferative

responses in a large animal model of a veterinary disease (calves) after co-vaccination with Flt3-L and GM-CSF plasmids, which has important implications of translating results from the small animal model mouse to men[40]. In this regard, a local increase in DC numbers with an accompanied enhancement of the immune response would be distinct clinical advantage and is demonstrated against HCV in our study. This approach of co-immunization with Flt3-L and GM-CSF has, therefore, important implications for the development of an effective antiviral HCV vaccine.

## ACKNOWLEDGMENTS

We are most grateful to Jack R Wands, Brown University Medical School for providing the pcDNA3-NS5 plasmid and the syngenic mouse myeloma cell line for this study established by JE in his laboratory.

## Abstract

**AIM:** To characterize the immunogenicity of a hepatitis C virus (HCV) E2 DNA vaccine alone or with a protein vaccine boost in murine and porcine animal models.

**METHODS:** A DNA vaccine expressing a secreted form of HCV E2 protein was constructed and used to vaccinate mice and piglets with or without boosting with a recombinant E2 protein vaccine formulated with CpG ODN and 10% Emulsigen. The immunogenicity of HCV E2 vaccines was analyzed by ELISA for antibody responses, MTT assay for lymphocyte proliferation, ELISPOT for the number of interferon-γ secreting cells, and cytotoxic T lymphocyte assays.

**RESULTS:** Intradermal injection of E2 DNA vaccine induced strong Th1-like immune responses in mice. In piglets, E2 DNA vaccine elicited moderate and more balanced immune responses. A DNA vaccine prime and protein boost vaccination strategy induced significantly higher E2-specific antibody levels and shifted the immune response towards Th2-like ones in piglets.

**CONCLUSION:** A DNA vaccine expressing a secreted form of HCV E2 protein elicited E2-specific immune responses in mice and piglets. Recombinant E2 protein vaccination following DNA immunization significantly increased the antibody response in piglets. These HCV E2 vaccines may represent promising hepatitis C vaccine candidates for further investigations.

**Key words:** Hepatitis C virus E2; DNA vaccine; DNA vaccine prime-protein boost

## INTRODUCTION

Hepatitis C continues to be a severe health threat to a large population with about 123 million people being affected globally[1]. The etiologic agent, hepatitis C virus (HCV)[2] is able to establish persistent infections in up to 85% of infected individuals with severe clinical consequences[3]. Current therapy with pegylated interferon and ribavirin is only effective in about 50% of the patients[4]. Although vaccines represent one of the most effective means to combat infectious diseases, there is no vaccine available for hepatitis C[5]. Hence, evaluating different vaccination strategies that can induce HCV-specific immunity is critical for the development of effective vaccines to reduce HCV-related mortality and morbidity.

HCV is the only member of the *Hepacivirus* genus in the *Flaviviridae* family[6]. The positive-sense, single-stranded RNA genome encodes a polyprotein of about 3100 amino acids in length[7]. Processing of the polyprotein by cellular or viral proteases generates up to 11 viral proteins, including three structural proteins (core, envelope proteins E1 and E2) and six non-structural proteins (NS-2, -3, -4A, -4B, -5A, and -5B). As the major envelope protein in HCV particles[8,9], the E2 protein is likely to be critical for inducing antibody responses against HCV infections. In line with this notion, anti-E2 antibodies have been consistently detected in hepatitis C patients[10-13]. Furthermore, there is evidence to suggest that anti-E2 antibodies can inhibit HCV infections in both *in vivo* and *in vitro* settings[14-17]. However, generation of E2-specific antibodies in hepatitis C patients is usually delayed and of low magnitude, which may be one of the reasons for such a high rate of persistent HCV infections[12,13]. These findings indicate that E2-specific antibodies are beneficial and induction of these antibodies should be taken into

consideration when designing a vaccine against hepatitis C.

Although the correlations for a successful immune response that can resolve HCV infections have not been well characterized, previous studies suggest a rapid, vigorous, and broadly targeted cell-mediated immune response tends to be associated with HCV clearance[18-22]. In line with this notion, E2-specific cellular immune responses have been detected in hepatitis C patients as demonstrated by E2-specific lymphocyte proliferation, cytotoxic T lymphocyte, and ELISPOT assays[23-25]. More importantly, it has been demonstrated that a stronger E2-specific cell-mediated response is associated with better response to interferon therapy and viral clearance[25]. These findings indicate that it is desirable for a candidate HCV E2 vaccine to induce cell-mediated immune responses.

Delivery of transgenes by plasmid DNA is a novel platform technology for vaccine development. DNA vaccines tend to induce a Th1-biased response in the host[26-30]. Manipulation of protein subcellular localization may enhance antibody responses to the antigen. For instance, directing antigenic expression to secretion pathways by adding a signal peptide sequence may increase B-cell mediated responses[31]. In addition, boosting with a protein subunit vaccine following DNA vaccination is another feasible means for inducing strong antigen-specific humoral responses[32-36].

In this study, a DNA vaccine was designed to induce expression of a secreted form of HCV E2 protein. Immunogenicity studies using inbred mice showed that this HCV E2 DNA vaccine elicited strong Th1-like immune responses. In piglets, the E2 DNA vaccine elicited a moderate and more Th1-Th2 balanced response. E2 protein vaccination after DNA immunization had a more pronounced boosting effect in piglets than in mice by significantly increasing E2-specific antibody response, causing a shift of the immune response towards a Th2-type.

## MATERIALS AND METHODS

### *HCV E2 DNA vaccine construction*

To generate a DNA vaccine encoding a secreted form of HCV E2 protein, a portion of the E2 coding sequence (amino acid residues 412-661 of HCV polyprotein) without the hypervariable region 1 (HVR1) and the hydrophobic region was amplified by polymerase chain reaction (PCR). The template was plasmid pDM22, a cDNA clone of the BK isolate (genotype 1b; kindly provided by Dr. A. Takamizawa)[37]. The primers were E2-412-Nhe-Sense (5'-AATTGCTAGCCAGCTTATAAACACCAATGGG-3', *Nhe*I site is underlined) and E2-661-Bgl-AS (5'-AATTAGATCTTCACTCCGGCCTATCCCTGTC-3', a stop codon TGA was added followed by a *Bgl*Ⅱ site which is underlined). The PCR product was cloned into a plasmid vector pSLIA-tPAs[38] with *Nhe*I and *Bgl*Ⅱ (New England Biolabs), allowing the addition of the signal peptide sequence of the tissue plasminogen activator (tPA) to the amino-terminus of the truncated E2 protein. The identity of PCR amplified E2 gene was confirmed by DNA sequencing experiments. Subsequently, the *Hin*dⅢ-*Bgl*Ⅱ fragment containing the tPAs-tE2 fusion gene was cloned into a CpG enriched DNA vaccine vector pBISIA24[39], which contains 24 copies of a Th1-promoting CpG motif (GTCGTT). An unexpected extension of the open reading frame resulted from the *Nde*I recognition sequence in the multiple cloning site of plasmid pBISIA24 was removed by deleting the small fragment after *Pst*I digestion and subsequent ligation of the large fragment. The final DNA vaccine construct was designated pBISIA24-tPAs-tE2 (Figure 1). Plasmid prepared by endotoxin-free plasmid purification reagents (Qiagen) was used for immunization.

### *Transfection and immunoblotting analysis*

To determine whether the constructed DNA vaccine plasmid expressed the E2 protein, TE671 cells, a human rhabdomyosarcoma cell line, were transfected with plasmids pBISIA24-tPAs-tE2 and pBISIA24 using the calcium phosphate method[40]. At 24 h after transfection, culture medium was collected and cells were lyzed in a lysis buffer (1% SDS, 10 mmol/L Tris-HCl, pH8.0). The protein concentration was determined by the Bradford assay (Bio-Rad) using bovine serum albumin (BSA) (Sigma) as a standard. Twenty-five micrograms of protein were loaded on a 10% SDS protein gel and transferred to a PVDF membrane (GE Healthcare). The membrane was incubated with a monoclonal antibody against HCV E2 protein (H52, kindly provided by Dr. J. Dubuisson). After incubation with an HRP-conjugated secondary antibody, immuno-reactive protein bands were visualized by the enhanced chemiluminescence system (ECL$^{Plus}$, GE Healthcare).

### *Recombinant E2 protein expression and purification*

To generate a recombinant E2 protein vaccine, HCV E2 protein was expressed and purified as a fusion protein with a poly-histidine tag. For this purpose, the coding sequence of HCV E2 was amplified by PCR using plasmid pDM22 as the template. The primers for the PCR reaction were E2-Bam-Nhe-Sense (5'-GGGGGGGGATCCGCTAGCGATACCCACGTGACAGGGG-3', *Bam*HI and *Nhe*I sites are underlined) and E2-746-Bgl-AS (5'-GGGGGGAGATCTCAGGCCTCGGCCTGGGCTA-3', a stop codon TGA was added followed by a *Bgl*Ⅱ site which is underlined). The PCR fragment was cloned into an expression vector pRSETA (Invitrogen) using restriction enzymes *Bam*HI and *Bgl*Ⅱ, allowing the addition of a poly-histidine tag at the amino-terminus of the E2 protein. The resultant plasmid, designated pRSET-E2, was confirmed by restriction analysis and DNA sequencing. The *Not*I-*Bgl*Ⅱ fragment of plasmid pRSET-E2 was substituted by the *Not*I-*Bgl*Ⅱ fragment of pBISIA24-tPAs-tE2, generating plasmid pRSET-tE2 encoding a poly-histidine-tagged E2 protein without the carboxyl hydrophobic region. Plasmid pRSET-tE2 was then transformed into *E. coli* BL21 (pLysS) and expression of E2 protein was induced by isopropylthio-β-galactoside (IPTG, Invitrogen). The induced poly-histidine-tagged tE2 protein was purified under denaturing conditions in the presence of 8 mol/L urea using Ni-NTA agarose (Qiagen) *as per* manufacturer's instructions. The urea was removed from the protein preparation after dialysis against phosphate buffered saline (PBS). The level of endotoxin was determined by the

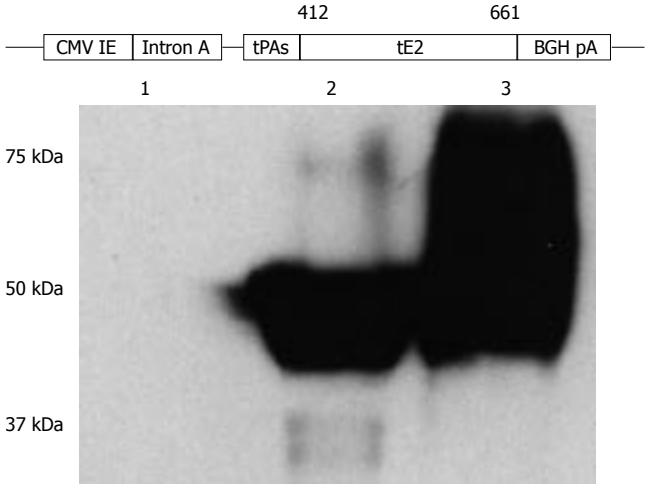

**Figure 1** Construction and characterization of HCV E2 DNA vaccine. A secreted form of HCV E2 protein generated by removing the carboxyl-terminal hydrophobic region and replacing the hypervariable region 1 with the signal peptide sequence of the tissue plasminogen activator (tPAs) was cloned into a DNA vaccine vector pBISIA24. The construction of E2 DNA vaccine, pBISIA24-tPAs-tE2, is schematically presented. TE 671 cells were transfected with pBISIA24 (lane 1) or pBISIA24-tPAs-tE2 (lanes 2 and 3). Cell lysates (lanes 1 and 2) and culture medium (lane 3) were analyzed in immunoblotting using an E2-specific antibody.

*Limulus* amoebocyte test (QCL-1000 Chromogenic *Limulus* amebocyte lysate kit, Cambrex).

### Mouse and piglet immunization

The experimental protocols were approved by the Committee of Animal Care and Supply, University of Saskatchewan. In the mouse trial, 24 six-week old B6C3F1 (H-2$^d$) female mice were randomly divided into three groups. Groups of mice were immunized either three times with 40 μL saline subcutaneously (s.c.), three times with 50 μg of DNA vaccine pBISIA24-tPAs-tE2 intradermally (i.d.), or twice with 50 μg of DNA vaccine pBISIA24-tPAs-tE2 i.d. followed by one subcutaneous vaccination with 5 μg of recombinant tE2 protein. The recombinant truncated E2 protein vaccine was formulated with 10 μg of CpG oligonucleotide (ODN) 1826 (5' -TCCATGACGTTCCTGACGTT-3', CpG motifs are underlined; kindly provided by Merial Limited) and 10% Emulsigen (MVP Laboratories) per dose. This formulation has been shown to elicit strong immune responses with a superior safety profile[41]. The vaccines were given three weeks apart. Blood was sampled two weeks after each immunization and spleens were collected two weeks after final immunization for analyzing immune responses.

In the piglet trial, 24 out-bred piglets (Landrace cross, 4-5 wk old, Prairie Swine Center) were randomly allocated into three groups with eight piglets in each group. The vaccination schedule was the same as that in the mouse trial but the doses were 10-fold of those used for mice. In addition, CpG ODN 2007 (5'-TCGTCGTTGTCGTTTTGGTCGTT-3', kindly provided by Merial Limited), which can stimulate porcine peripheral blood mononuclear cells (PBMCs)[42], was used for protein vaccine formulation.

### Enzyme-linked immunosorbent assay (ELISA)

To analyze antibody levels in murine or porcine sera after immunization, 96-well polystyrene plates (Immulon 2, Dynatech Laboratories) were coated with purified E2 protein at 100 ng/well in a carbonate buffer (pH9.6) overnight at 4℃. Serially diluted murine or porcine sera were added to each well and incubated for 2 h at room temperature (RT). To determine the total IgG levels, biotinylated goat anti-mouse IgG antibody (Caltag Laboratories) at a dilution of 1:10000 or alkaline phosphatase labeled goat anti-porcine IgG (KPL) at a dilution of 1:2500 was applied to detect bound IgG. To determine E2-specific IgG1 and IgG2a antibody levels in murine sera, bound antibodies were incubated with biotinylated goat anti-mouse IgG1 or IgG2a antibodies (Caltag Laboratories) at a dilution of 1:10000, respectively, followed by streptavidin-AP (Jackson ImmunoResearch Laboratories) at a dilution of 1:5000. To determine E2-specific IgG1 and IgG2 antibody levels in porcine sera, bound antibodies were incubated with mouse anti-porcine IgG1 or IgG2 antibodies (Serotec) at a dilution of 1:100, respectively, followed by biotinylated goat anti-mouse IgG antibody (Caltag Laboratories) at a dilution of 1:10000. The reactions were developed by adding *p*-nitrophenyl phosphate (PNPP) (Sigma) at 100 ng/well and the optical density was recorded at 405 nm.

### Enzyme-linked immunospot (ELISPOT) assay

ELISPOT assay was performed to determine the frequency of interferon-γ (IFN-γ) secreting cells in mouse splenocytes or porcine PBMCs after vaccination. Microplate Devices Unifilter 96-well plates (Waterman) were coated with anti-mouse IFN-γ antibody (125 ng/well) (BioSource International) or anti-porcine IFN-γ monoclonal antibody (500 ng/well) (Endogen) overnight at 4℃. After washing and blocking, $1 \times 10^6$ murine splenocytes or porcine PBMCs were added along with 200 ng of purified E2 protein into each well. The plates were incubated at 37℃ and 5% $CO_2$ for 40 h. For mouse sera, biotinylated anti-mouse IFN-γ antibody (125 ng/well) was added and incubated at 37℃ and 5% $CO_2$ for 3 h. For porcine sera, rabbit anti-porcine IFN-γ antibody (200 ng/well) (Endogen) was added and incubated at RT for 4 h followed by the addition of biotinylated goat rabbit IgG (Zymed) at a dilution of 1:5000 for 2 h at RT. All the plates were then incubated for 1.5 h at RT with streptavidin-AP (Jackson ImmunoResearch Laboratories) at a dilution of 1:500 and developed with 5-bromo-4-chloro-3-indolylphospohate and nitroblue tetrazolium substrate tablets (Sigma). The plates were dried and the spots were recorded.

### Lymphocyte proliferation-MTT assay

Splenocytes ($3 \times 10^5$ cells) isolated from each group of mice were seeded into each well of round bottom tissue culture 96-well plates (Nunc). Purified E2 protein (100 ng) was added to each well and incubated at 37℃ and 5% $CO_2$ for 72 h. Eighty ng of 3-(4, 5-dimethylthiazol-2-yl)-2, 5-diphenyl tetrazolium bromide (MTT, Sigma) was added to each well and incubated at 37℃ and 5% $CO_2$ for 3 h. The plates were centrifuged at 1000 × g for 10 min. One hundred μL of the supernatant was mixed with 100 μL of acidified isopropanol (0.375% HCl in isopropanol) and the optical density was recorded at 590 nm.

### *Cytotoxic T lymphocyte (CTL) assay*

**Effector cell preparation and stimulation:** To prepare effector cells, splenocytes were isolated from each group of mice and pooled 14 d after vaccination. To generate stimulating cells, splenocytes isolated from naïve, syngenic mice were infected with a recombinant vaccinia virus expressing HCV BK E2 protein (VP1478, kindly provided by Sanofi Pasteur MSD) at an m.o.i. of 10 for 1 h at 37℃ followed by an irradiation at 3000 rads. The splenocytes from experimental groups were cultured with irradiated stimulating cells for four days at 37℃ and 5% $CO_2$ before they were used as effector cells in CTL assays.

**Target cell preparation:** To generate target cells, a syngeneic mastocytoma cell line P1-HTR-TK$^+$[43] (H-2$^d$, a highly transfectable variant of P815 cells, kindly provided by Dr. T. Boon) was transfected with a plasmid expressing HCV BK E2. Stable transfectants, designated P1-E2 cells, were selected with 800 μg/mL of Geneticin (Invitrogen). The expression of HCV E2 protein was confirmed by immunohistochemical staining using an E2-specific polyclonal antibody as previously described[44]. In brief, after fixation and blocking, P1-E2 cells or plasmid vector-transfected P1 cells were incubated with an anti-E2 antibody at a dilution of 1:1000 in PBS for 30 min. Cells were then washed and incubated with a biotinylated secondary antibody for 30 min. The reaction was developed with 3, 3'-diaminobenzidine tetrahydrochloride (DAB) (Vector Laboratories).

**CTL assay:** CTL assays were performed based on the evaluation of the cytoplasmic lactate dehydrogenase (LDH) after cell lysis as described previously[45]. In brief, effector cells were harvested by centrifugation at 800 × g for 10 min and washed twice with medium. The cells were then adjusted to $2.0 \times 10^7$ cells/mL in AIM-V medium and incubated with target cells at standard effector:target (E:T) ratios in triplicates in a 96-well round bottom plate. After 4 h incubation, the plate was centrifuged at 250 × g for 4 min. Fifty μL of the supernatant was transferred to a 96-well flat bottom plate and mixed with the Substrate mix provided in the Cytotox 96 Non-radioactive Cytotoxicity Assay kit (Promega). After 30 min, the reaction was terminated by adding 50 μL of the Stop Solution into each well and the optical density was determined at 490 nm. Spontaneous and maximal LDH release by target cells was determined by incubating the target cells with medium alone or with medium plus the lysis buffer containing 0.9% Triton X-100 (Promega). HCV E2-specific lysis was calculated as [(experimental release-spontaneous release)/(maximal release-spontaneous release)] × 100.

### *Statistical analysis*

The experimental data were analyzed by software programs Prism 4 (GraphPad) or Excel (Microsoft) and were expressed as mean ± SE. A $P$ value of ≤ 0.05 determined by Student's $t$ test was considered statistically significant.

## RESULTS

### *Construction and characterization of a DNA vaccine expressing a secreted form of HCV E2 protein*

We designed a DNA vaccine encoding a secreted form of HCV E2 protein by removing the transmembrane domain and replacing the hypervariable region 1 (HVR1) of the E2 protein with the tissue plasminogen activator signal peptide sequence (tPAs). The corresponding coding sequence was amplified by PCR and cloned into a DNA vaccine vector pBISIA24[39], resulting in the plasmid pBISIA24-tPAs-tE2 (Figure 1). To determine the expression of E2 protein, TE671 cells were transfected with pBISIA24 (vector control) and pBISIS24-tPAs-tE2. The presence of E2 protein in cell lysates and culture medium was analyzed by immunoblotting. As shown in Figure 1, an E2-specific antibody recognized proteins of about 50 kDa in cell lysates and of 50-75 kDa in culture medium after pBISIA24-tPAs-tE2 transfection, whereas these proteins were not detected after pBISIA24 vector transfection, indicating the expression and secretion of the E2 protein by pBISIA24-tPAs-tE2. The apparent molecular masses (50-75 kDa) of tE2 protein are larger than the calculated one (31 kDa) and the extracellular form contained larger protein species than the intracellular form, suggesting that E2 protein may have been modified post-translationally by glycosylation.

### *Recombinant tE2 protein expression and purification*

The E2 protein used in immunization was produced in *E. coli*. The expression of poly-histidine tagged tE2 was induced by IPTG and purified by affinity chromatography (not shown). The purified poly-histidine tagged tE2 protein was dialyzed into phosphate-buffered saline before it was used in mouse and piglet immunization. The protein vaccine contained endotoxin at a concentration of 80 ng/mg of protein as determined by the *Limulus* amoebocyte test.

### *Antibody responses to HCV E2 DNA vaccine in mice*

To determine whether the DNA vaccine expressing a secreted E2 protein elicited antibody responses in mice, mouse sera collected after vaccination were analyzed for E2-specific IgG titers by ELISA assays. As shown in Figure 2A, vaccinated-mice all developed E2-specific IgG antibody after intradermal DNA vaccination with the average IgG titer being $1.6 \times 10^5$. To test whether a protein vaccine could enhance the IgG response, mice were injected twice with the DNA vaccine followed by recombinant E2 protein boosting. Mice that received the protein boosting vaccination had about two-fold higher titers of E2-specific IgG ($3.0 \times 10^5$) (Figure 2A). These results indicate that the DNA vaccine expressing a secreted form of HCV E2 protein induced strong antibody responses in mice, which were further increased by a protein vaccine.

Since the relative levels of IgG subclasses are an indicator for evaluating the quality of the immune response[46,47], the titers of IgG1 and IgG2a were determined. E2 DNA vaccine induced higher IgG2a titers than IgG1 (Figure 2), indicating a Th1-biased response. Boosting with E2 protein formulated with CpG ODN and 10% Emulsigen did not change this pattern, although the IgG1 and IgG2a levels were elevated (Figure 2).

### *Cell-mediated responses to HCV E2 DNA vaccine in mice*

To determine whether the HCV E2 vaccine induced cell-mediated immune responses in mice, we analyzed the

responses of mouse splenocytes after vaccination by measuring cell proliferation and interferon-γ secretion upon antigen re-stimulation *in vitro*.

In lymphocyte proliferation assay, splenocytes from saline vaccine group showed detectable proliferation after antigen stimulation (Figure 3A). Splenocytes isolated from mice after DNA vaccination expanded to a significantly higher degree after E2 antigen re-stimulation than medium control ($P < 0.001$, Figure 3A). Protein boost immunization did not change E2-specific lymphocyte proliferation (DNA *vs* DNA/Protein, $P = 0.47$, Figure 3A). The results of IFN-γ ELISPOT assay demonstrated that DNA vaccination elicited a strong IFN-γ response (DNA *vs* saline, $P < 0.001$, Figure 3B), whereas a protein boost immunization induced fewer IFN-γ secreting spots (DNA *vs* DNA/Protein, $P = 0.03$, Figure 3B). These results indicate that stronger E2-specific Th1-type immune responses were induced in mice that received the DNA vaccine three times than in mice that received twice DNA vaccination followed by a protein boosting injection.

Since cytotoxic T lymphocytes are one of the major effectors in cell-mediated immune responses, we also determined the presence of E2-specific cytotoxic T lymphocytes after vaccination. For this purpose, a syngeneic cell line expressing HCV E2 protein was generated. Immunohistochemistry staining using an anti-E2 antibody detected specific signal in P1-HTR cells stably transfected by the E2-expressing plasmid, but not in vector-transfected cells, demonstrating the expression of the E2 protein by the stable transfectant (not shown). When the E2-expressing cell line was used as target cells in the CTL assay, effector cells from DNA vaccine- or DNA and protein vaccine-immunized mice showed 36% or 31% specific lysis at an effector to target ratio of 100:1, respectively (Figure 4). No CTL activity was detected after saline immunization (Figure 4). These results demonstrate the elicitation of E2-specific cytotoxic T lymphocytes in mice immunized with E2 DNA vaccine or DNA vaccine followed by a protein boost.

### *Immune responses to HCV E2 vaccines in piglets*

Since vaccine efficacy can be different in various test species[31] and pigs represent a promising model for human biology because of its body size and physiology[48], we evaluated our E2 vaccines in piglets. As shown in Figure 5A, all the piglets receiving the E2 DNA vaccine three times intradermally developed E2-specific IgG titers with the average titer being $1 \times 10^3$. Vaccination with the E2 protein after two DNA vaccine priming injections significantly boosted the E2-specific IgG titers (DNA vaccine *vs* DNA/Protein, $P = 0.0156$, Figure 5A). These results indicate that E2 DNA vaccine was also effective in inducing antigen-specific antibody response in piglets, which was boosted significantly by a protein vaccine.

To analyze the type of the immune responses, we determined the ratios of E2-specific IgG1 to IgG2 levels in the porcine serum samples after vaccination. As illustrated in Figure 5B, DNA vaccination induced a slightly Th1-biased immune response with the IgG2 to IgG1 ratio being 1.4, whereas protein boosting after DNA vaccination shifted the immune response towards Th2 direction as demonstrated by a reduced IgG2/IgG1 ratio (0.58).

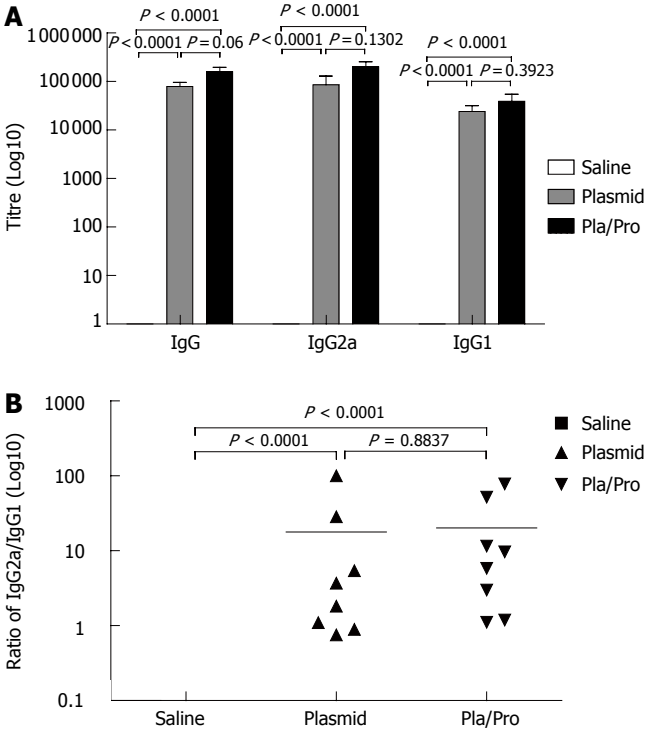

**Figure 2** Antibody responses to HCV E2 vaccines in mice. B6C3F1 mice were intradermally injected with pBISIA24-tPAs-tE2 three times or pBISIA24-tPAs-tE2 twice followed by subcutaneous vaccination with E2 protein formulated with CpG ODN 1826 and 10% Emulsigen at 3-wk intervals. E2-specific IgG, IgG1, and IgG2a levels were determined by ELISA assays (**A**). The ratios of IgG2a to IgG1 were determined (**B**) ($P < 0.0001$, *vs* saline).

To further characterize the immune responses of piglets to E2 vaccines, the number of IFN-γ secreting cells in porcine PBMCs was determined after vaccination. As shown in Figure 6, PBMCs from E2 vaccinated piglets contained significantly higher number of IFN-γ secreting cells than saline treated piglets after *in vitro* antigen re-stimulation in ELISPOT assay (DNA *vs* saline, $P < 0.0001$, DNA/Protein *vs* saline, $P < 0.0001$). No difference was detected between the DNA vaccine alone group and the DNA prime and protein boost group (Figure 6, DNA *vs* DNA/Protein, $P = 0.4531$).

## DISCUSSION

Numerous research groups have evaluated the potential of using E2 protein as a hepatitis C vaccine candidate through different strategies[5,36,49-74]. These studies have demonstrated E2-specific immune responses, mostly in mouse trials, when E2 alone or as part of the entire HCV structural region was delivered as a DNA vaccine, viral vectored vaccine, or subunit protein vaccine. The most important finding of these studies is that the vaccine-induced E2-specific immune responses were able to delay HCV infections in chimpanzees or humans[55,61,62,64]. While these studies have demonstrated the feasibility of inducing E2-specific immune responses through vaccination, the efficacy of E2 vaccines is less satisfactory in inducing sterilizing immunity. It is thus obvious that further

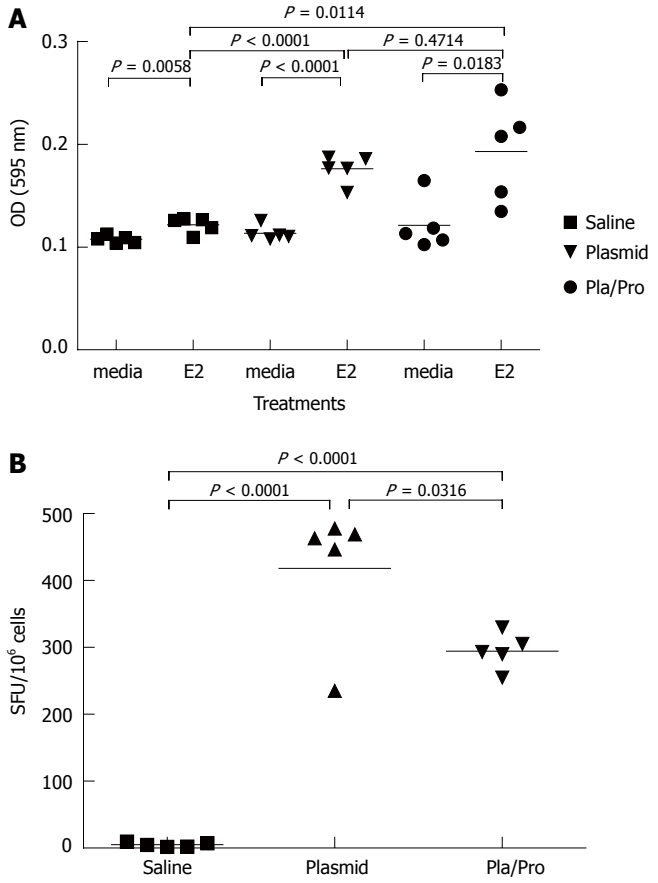

**Figure 3** Cell-mediated immune responses to HCV E2 vaccines in mice. Murine splenocytes were isolated 2 wk after last immunization and were re-stimulated with E2 protein. Cell proliferation was analyzed by MTT assay (**A**). ($P < 0.0001$ *vs* saline; $P < 0.05$, $P < 0.01$ *vs* media). The number of interferon-γ secreting cells was determined by ELISPOT assay (**B**). ($P < 0.05$ *vs* plasmid; $P < 0.0001$ *vs* saline).

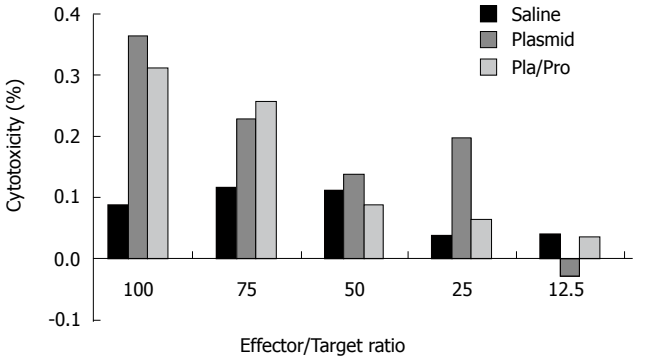

**Figure 4** Cytotoxic T lymphocyte (CTL) response to HCV E2 vaccines in mice. Murine splenocytes isolated from groups of mice two weeks after final immunization were pooled and stimulated with feeder cells infected with recombinant vaccinia virus expressing HCV E2 protein. The cytotoxic activity was determined by measuring the released lactate dehydrogenase (LDH) by the target cells after incubation with the effectors at different ratios.

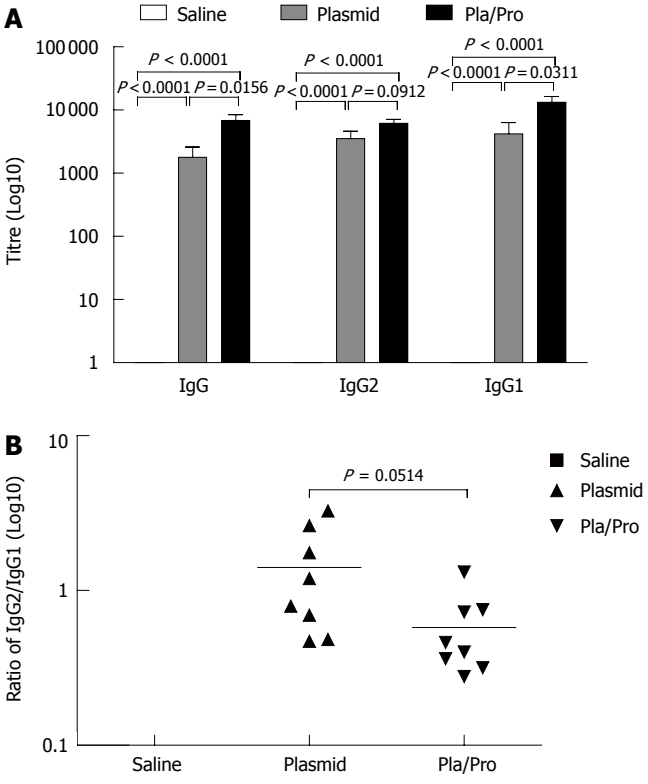

**Figure 5** Antibody responses of piglets to HCV E2 vaccines. Piglets were immunized by saline, E2 DNA vaccine three times, or E2 DNA vaccine twice followed by subcutaneous vaccination with E2 protein formulated with CpG ODN 2007 and 10% Emulsigen at three-week intervals. ELISA assays were performed to determine E2-specific IgG, IgG1, and IgG2 levels (**A**), as well as the ratios of IgG2 to IgG1 (**B**) ($P < 0.05$ *vs* plasmid; $P < 0.0001$ *vs* saline).

improvement of E2 vaccines is required by evaluating additional vaccination strategies.

Given the importance of E2 protein in inducing host immune responses, we have chosen E2 as a vaccine candidate against hepatitis C. It has been established that HCV E2 expressed by a number of systems is an intracellular protein modified by high-mannose type oligosaccharides[75-78]. However, the envelope proteins on the hepatitis C virions have been shown to be modified by complex type oligosaccharides[79], suggesting secretion of E2 protein has occurred in HCV life cycle. In agreement with this notion, the secreted, complex form E2 protein possesses greater immunoreactivity against hepatitis C patient sera than the intracellular E2 protein when it is expressed in cell culture[78]. The retention of the expressed E2 protein is due to the presence of a membrane anchor domain (amino acids 718-746) at its carboxyl-terminus[80-82] and deletion of the transmembrane domain leads to E2 protein secretion[83]. However, a comparative study of a series of carboxyl-terminally truncated E2 proteins has demonstrated that truncation to amino acid residue 661 is necessary to achieve proper folding of the secreted E2 protein[83]. Hepatitis C virus is known to be able to quickly develop multiple sequence variants after infection within the host due to the lack of proof-reading activity of RNA-dependent RNA polymerase[84]. A short stretch of coding sequence (amino acids 384-411, the hypervariable region 1) at the very amino-terminus of E2 has shown extremely high variability[85,86] and may contribute to the generation of immune escape HCV variants. Although E2 HVR-1 may contain antigenic epitopes[15,16], rapid appearance of variable mutants and their interference with the development of cellular immunity in the host[87] make it a less favorable component in an E2 DNA vaccine. Based on

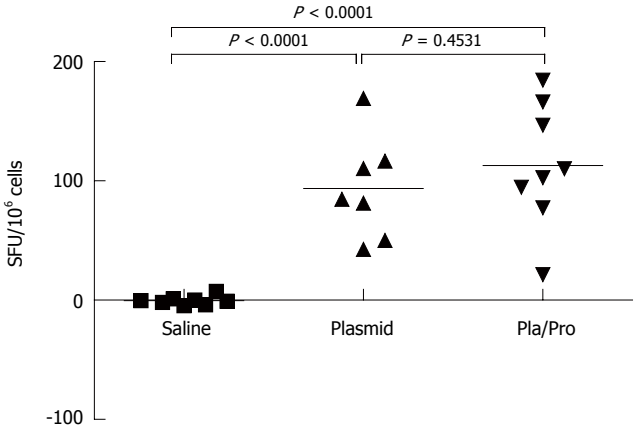

**Figure 6** Cell-mediated immune response of piglets to HCV E2 vaccines. Porcine peripheral blood mononuclear cells (PBMCs) were isolated three weeks after final immunization. After re-stimulation with E2 antigen, the number of interferon-γ secreting cells was determined by ELISPOT assay ($P < 0.0001$ *vs* saline).

the above findings and analysis, we designed an E2 DNA vaccine by deleting the carboxyl-terminal hydrophobic region after amino acid residue 661 and replacing HVR1 by a strong signal peptide sequence derived from tissue plasminogen activator[88]. Indeed, we showed that the engineered E2 protein was efficiently secreted into the culture medium (Figure 1). In addition, in agreement with previous studies[83], the apparent molecular masses of the intracellular as well as secreted tE2 proteins are larger than that calculated from the amino acid sequence and the secreted tE2 proteins contain species of even higher molecular mass than the intracellular tE2 protein, suggesting that intracellular and extracellular E2 proteins may have been modified by different glycosylation.

Intradermal injection of this E2 DNA vaccine elicited strong E2-specific antibody responses in mice as demonstrated by high IgG levels (Figure 2). IgG isotyping, IFN-γ ELISPOT, lymphocyte proliferation, and CTL assays (Figures 2-4) indicated that both Th1 lymphocyte and cytotoxic T lymphocyte responses were induced by E2 DNA vaccine. Interestingly, DNA vaccine alone or DNA vaccine followed by an E2 protein formulated with CpG ODN and 10% Emulsigen induced comparable E2-specific IgG2a to IgG1 ratios (Figure 2B) and CTL responses (Figure 4). This is in agreement with the proven roles of immuno-stimulatory CpG ODN in promoting Th1 immune responses[41,89-91]. However, although DNA prime and protein boost strategy induced a relatively strong IFN-γ response, the number of IFN-γ secreting cells in the splenocytes derived from mice immunized with DNA prime and protein boost was significantly lower than that of DNA vaccine group (Figure 3B).

DNA vaccines are often less effective in large model animals and in humans than in mice[31,92]. Therefore, it is critical to test the vaccine efficacy in an out-bred, large animal model. Our piglet trial indicated that E2 DNA vaccine induced E2-specific IgG titers (Figure 5A) that were about 100-fold lower than those detected in mice (Figure 2A). As for the type of vaccine-induced immune response, E2 DNA vaccine induced a more balanced response in piglets (Figure 5B), in contrast to a strongly Th1-biased response in mice (Figure 2B). The effect of protein boost injection in modulating the type of the immune response was also different: while protein boost had little effect in mice (Figure 2B), a shift towards Th2 direction was detected in piglets (Figure 5B). Taken together, while these results demonstrate that E2 vaccines were also effective in inducing antigen-specific immune responses in piglets, inter-species difference in immune responses to different vaccine strategies requires further investigation.

In conclusion, our results demonstrate that a DNA vaccine expressing the secreted form of HCV E2 protein induces E2-specific immune responses in mice and piglets. An E2 protein vaccine formulated with CpG ODN and 10% Emulsigen further increases the antibody responses. In addition, our results highlight the importance of testing the magnitude and type of vaccine-induced immune responses in multiple model species before primate or human trials are initiated.

## ACKNOWLEDGMENTS

We would like to thank Sylvia van Drunen Littel-van den Hurk, Philip Griebel, and Lou Qualtiere for providing reagents and/or helpful discussions. We thank Lucy Liu, Shirley Lam, Candice Jackel, Marlene Snider, Laura Latimer, Ponn Benjamin, and Satya Viswanathan for their contributions to this work. We thank VIDO Animal Care staff for doing the animal trials. This work is published as VIDO Journal series #427. LAB is a recipient of a Canada research chair in vaccinology.

## COMMENTS

### Background
Hepatitis C is a devastating liver disease worldwide. Current interferon and ribavirin therapy is far from satisfactory. An effective vaccine for hepatitis C is urgently needed.

### Research frontiers
To develop an effective vaccine for hepatitis C, a rational design based on the understanding of the magnitude and the quality of the immune responses is critical for a success. The application of appropriate adjuvants and vaccine delivery means also play a major role.

### Innovations and breakthroughs
The novelty of this article lies in the design of the HCV E2 vaccine, namely the hypervariable region-1 was replaced by the signal peptide sequence of the tissue plasminogen activator and the hydrophobic region at the carboxyl-terminus was removed.

### Applications
The HCV E2 DNA vaccine developed in this study should be further tested in primate models with hepatitis C virus challenge to demonstrate protective activity of the vaccine.

### Peer review
HCV infection is a big burden worldwide. Numerous studies have evaluated the potential of using E2 protein as a hepatitis C vaccine candidate through different strategies, but the efficacy of E2 vaccines is less satisfactory in inducing sterilizing immunity. It is interesting to investigate further improvement of E2 vaccines by evaluating additional vaccination strategies. The authors characterized the immunogenicity of a HCV E2 DNA vaccine alone or with a protein vaccine boost in murine and porcine animal models. They found that this E2 DNA vaccine elicited E2-specific immune responses in mice and piglets and recombinant E2 protein vaccination boosting significantly increased the antibody response in piglets. The study is well designed and results are convincing. The presentation and readability of the manuscript is satisfactory.

## Abstract

**AIM:** To evaluate the antibacterial activity of *Sapindus mukorossi* (*S. mukorossi*) and *Rheum emodi* (*R. emodi*).

**METHODS:** Powders of *S. mukorossi* and *R. emodi* were extracted successively with petroleum ether, benzene, chloroform and ethanol and were concentrated in vacuum. The disk diffusion method was used for *in vitro* studies and *in vivo* studies were performed on male Wister rats. Thirty resistant clinical isolates of *H pylori*, as determined by their antibiotic sensitivity patterns by *E*-test, along with two Gram +ve (*S. aureus*, *B. subtilis*) and two Gram -ve (*E. coli*, *P. vugaris*) organisms were screened for their susceptibility patterns against these extracts.

**RESULTS:** In our screening, all 30 resistant isolates and the other four organisms (two Gram +ve *S. aureus*, *B. subtilis* and two Gram -ve, *E. coli*, *P. vugaris*) were sensitive to the test compounds. It was found that ethanol and chloroform extracts of *S. mukorossi* and ethanol and benzene extracts of *R. emodi* inhibited *H pylori* at very low concentrations. In the *in vitro* study, the isolates showed a considerable zone of inhibition at very low concentrations (10 μg/mL) for both the extracts. In the *in vivo* study, the *H pylori* infection was cleared with minimal doses of extracts of *S. mukorossi* (2.5 mg/mL) and *R. emodi* (3.0 mg/mL) given orally for seven days.

**CONCLUSION:** We can conclude from this study that the extracts of *S. mukorossi* and *R. emodi* inhibited the growth of *pylori in vitro* and, in *in vivo* studies, the *H pylori* infection cleared within seven days at very low concentrations. We also found that *H pylori* did not acquire resistance against these herbal extracts even after 10 consecutive passages.

## INTRODUCTION

*H pylori* has infected more than half the population of the world. Most people are unaware that they are infected because they remain asymptomatic throughout life and survive without any harmful infection-related clinical sequelae. However, some develop duodenal or gastric ulcers and a small proportion are diagnosed with MALT lymphoma or gastric malignancy[1]. Others suffer from non-specific dyspeptic symptoms with no obvious cause other than *H pylori* infection and its associated gastritis.

Global elimination of *H pylori* is a noble goal that would have a major impact on present and future world health. During the past decade effective treatment therapies have been developed to cure *H pylori* infection, following the work of Bazzoli *et al*[2] and Lamouliatte *et al*[3]. Current treatment is based on a combination of a proton pump inhibitor (PPI) with either amoxycillin or metronidazole. Large multicentric studies, especially MACH 1[4] and MACH 2[5], have confirmed the excellent results of pilot studies leading to eradication rates higher than 90%. Unfortunately, in subsequent years such good results have not been achieved, especially in South East Asia and Southern Europe, where resistance to antibiotics has become more prevalent. Complete eradication of *H pylori* is still in the initial stage. Resistance to amoxycillin, clarithromycin and metronidazole is widespread, and probably increasing as a result of the constant use of these drugs against *H pylori* infection. In our recent multicentric study, undertaken by the Indian *H pylori* study group, we assessed the Indian scenario of resistance[6]. The study showed higher resistance to antibiotics than in developed countries[7]. In this study, 100% resistance of *H pylori* towards metronidazole was reported in Hyderabad, which was much higher compared to other regions of India. If this trend continues the treatment with clarithromycin and metronidazole may become ineffective.

In view of the incomplete cure achieved with the

triple therapy described above and its possible side effects, alternative medicine cures are gaining much prominence and are found to be safe and effective eliminators of *H pylori* infection. Thus, in an endeavor to overcome increasing resistance, we continued to look for some selected herbal extracts that are capable of inhibiting the growth of *H pylori* with minimal or no side effects. In the present study, we selected two plants, namely *Sapindus mukorossi* and *Rheum emodi,* and investigated the inhibitory effect of these plant extracts against *H pylori in vitro* and *in vivo*.

*S. mukorossi* Gaerten (Sapindaceae), commonly known as Ritha or Aritha is found throughout India. The major constituents of its fruit are saponins (10%-11.5%), sugars (10%) and mucilage[8]. The fruit of the plant is reported to have expectorant, emetic, alexipharmic and abortificiant effects. It is also used for excessive salivation, epilepsy and chlorosis[9,10]. Saponins from this plant are known to be spermicidal *in vitro*[11]. This spermicidal property has been used in contraceptive cream[12]. The alcoholic extract of (*Sapindus trifoliatus Linn*) is reported to possess anti-implantation activity[11].

*R. emodi* (Polygonaceae), commonly known as Indian or Himalayan Rhubarb, is found in India. The major constituents of rhubarb rhizomes are anthraquinones. Rhubarb is used as a laxative and diuretic to treat kidney stones and it is used for gout and liver diseases characterized by jaundice. Externally, it is used to heal skin sores and scabs. Paradoxically, larger doses are used as a laxative, although small doses are used to treat dysenteric diarrhea[13]. The Chinese use rhubarb as an ulcer remedy, anti-helminthic and to treat cancer, upper intestinal bleeding (ulcers), fever, and headache. They consider it to be a bitter, cold dry herb used to "clear heat" from the liver, stomach and blood[14,15]. It is also used to treat toothache[16]. In Europe, rhubarb is a component of spring tonics or blood cleansing cures, including Swedish bitter[17]. Turkish or medicinal rhubarb is also one of the four major ingredients in the herbal cancer remedy.

We isolated extracts from both plants and carried out antimicrobial screening for various micro-organisms. Based on the above results, a study was designed using the obtained products of *S. mukorossi* and *R. emodi* to assess the antibacterial activity against *H pylori in vitro* and *in vivo*.

## MATERIALS AND METHODS

### Plant Materials

Authentic samples of *S. mukorossi* and *R. emodi* were obtained from an authorized supplier (M/s Munnalal Dawasas and Co. Hyderabad, Andhra Pradesh, India). The plants were identified and authenticated by experts in the Post Graduate and Research Department of Botany, Anwar-ul-loom College, Hyderabad, Andhra Pradesh, India.

### Bacterial strains

Thirty *H pylori* strains along with two gram +ve (*Staphylococcus aureus, Bacillus subtilis*) and two gram -ve (*Escerichia coli*, *Proteus vulgaris*) pathogenic bacteria were used in the study. The *H pylori* strains were isolated from gastric biopsy specimens [15 from duodenal ulcer (DU), 8 from gastric ulcer (GU), 4 from non-ulcer dyspepsia (NUD), 3 from gastric carcinoma (GC)], after informed consents were obtained from patients who underwent upper gastrointestinal endoscopy at Deccan College of Medical Sciences, Hyderabad, India. The other four pathogens were obtained in pure culture form from the Department of Microbiology, Deccan College of Medical Sciences, Hyderabad, A. P, India.

### E-test strips

E test strips were obtained from AB Biodisk, Solna, Sweden.

### Animals

Male Wister rats (175-200 g) were acclimated to the housing facilities for 5 d before initiation of the study. Free access to standard pellet chow was allowed throughout the experimental protocol, with the exception of overnight fasting before induction of the ulcer. All protocols were approved by the Animal Care and Use Committee of the Deccan College of Medical Sciences and Research Centre, Hyderabad, India where the study was conducted.

### Extraction, separation and purification of the compounds

For phytochemical analysis, approximately 100 g of fruit pericarp of *S. mukorossi* and rhizomes of *R. emodi* were collected and the materials were chopped, air dried at 35-40℃ and pulverized in an electric grinder. The powder obtained was successively extracted in petroleum ether (60-80℃), benzene, chloroform and ethanol.

The extracts were then powdered by using a rotary evaporator under reduced pressure. Fruit pericarp of *S. mukorossi* yielded 38g, 28g, 34g and 35g of powdered extracts with petroleum ether, benzene, chloroform and ethanol respectively. Rhizomes of *R. emodi* yielded 19 g, 17 g, 21 g and 22 g of powdered extracts. Extracts obtained by percolation using 70% of ethanol as a solvent at room temperature were processed according to process A of Farmacopeia dos Eastados Unidos do Brasil (1959) (AOAC 1990).

The extracts were evaporated at 40℃ under vacuum and the residue was freeze-dried. The dry extracts of the fruit pericarp of *S. mukorossi* and rhizomes of *R. emodi* were tested for the presence of saponins and anthraquinones. Each extract of the fruit pericarp of *S. mukorossi* (SM) and rhizomes of *R. emodi* (RE) were column chromatographed over a silica gel (200 mesh), eluted with $CHCl_3$-MeOH (70:30, 60:40, 50:50, 25:75) and compound fractions of (250 mL each) were collected and monitored by TLC. These column chromatographed compound fractions were further filtered to yield saponins and anthraquinones, which were separated by paper chromatography and preparative TLC to yield saponins [(SM-A (petroleum ether), SM-B (benzene), SM-C (chloroform) and SM-D (ethanol)] and anthraquinones [(RE-A (petroleum ether), RE-B (benzene), RE-C (chloroform) and RE-D (ethanol)] respectively.

All the filtrates obtained were dried by evaporation

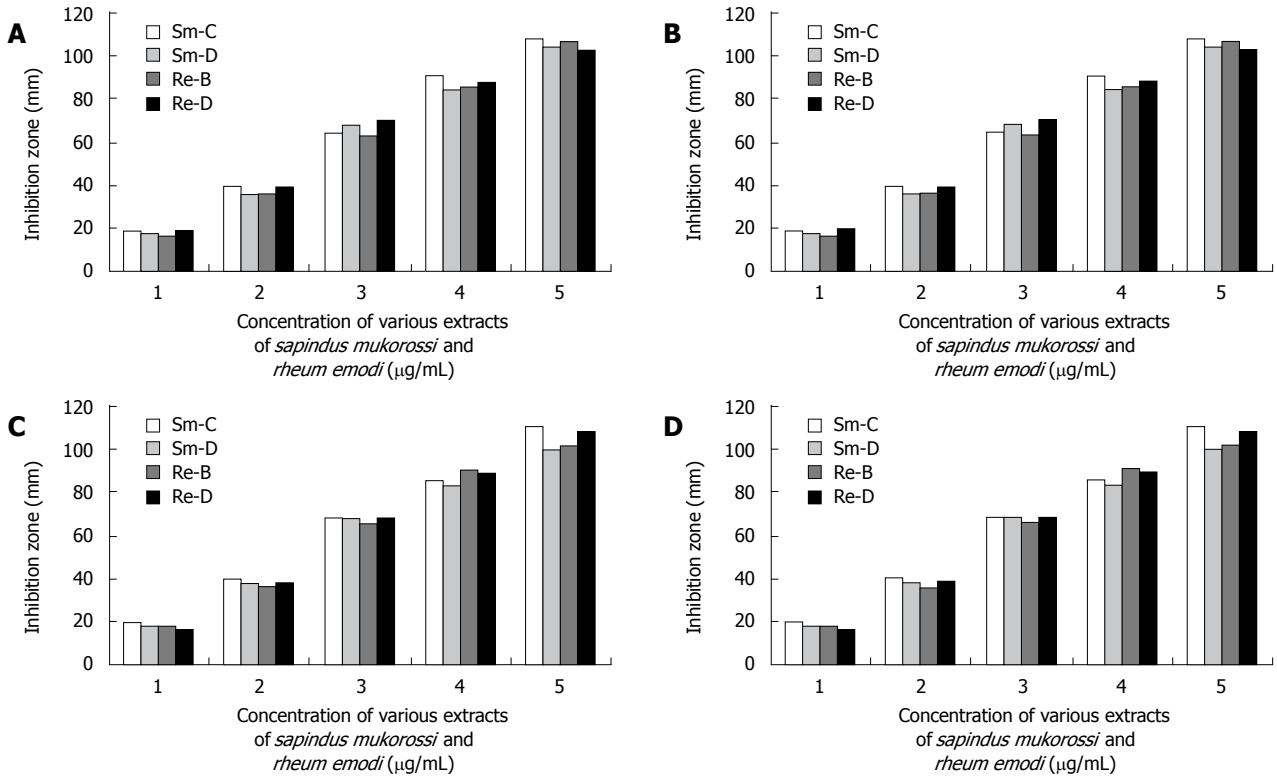

**Figure 1** Antibacterial activity of various extracts *Sapindus mukorossi* and *Rheum emodi* against *S. Aureus* (**A**), *B. Subtilis* (**B**),*E.Coli* (**C**), *P vulgaris* (**D**).

(Rotometer, 40℃) and the dried extracts were individually once again dissolved in 10 mL ethanol (95%). Then subjected to a complete drying process and weighed according to the AOAC (1990) method[18]. The products obtained were tested initially for antimicrobial activity against different gram +ve organisms (*S.aureus, B.subtilis*) and gram -ve organisms (*E.coli*, *P.vulgaris*). Effective antibacterial activity was noted (Figure 1A-1D).

### *Isolation of H pylori*

From every patient a total of three-biopsy specimens were collected, 1 in urea solution and two biopsies (1 from the antrum and the other from the corpus) were collected in Brucella broth supplemented with 2% fetal calf serum [FCS] (Gibco BRL, Germany) and 10% glycerol. The biopsy specimens were smeared directly onto Brucella agar (Difco Chemicals, Detroit, USA) supplemented with 7% (v/v) sheep blood, Vancomycin- 6 mg/mL, Amphoteracin B- 2mg/mL and Polymixin B- 2500 IU/mL (Sigma Chemicals Inc, Bangalore).

The agar plates were incubated at 37℃ for 3-5 d under microaerobic conditions (4% Oxygen, 5% Hydrogen, 5% Carbon-di-oxide, and 86% Nitrogen) in a candle jar dessicator. *H pylori* were identified based on the culture characteristics, such as small translucent colonies (2-4 mm) under a dissected microscope, gram -ve spiral organisms, positive for catalase, cytochrome oxidase and urease tests. Stocks of pure culture were preserved in Brucella broth (Difco Chemicals, Detroit, USA) supplemented with 10% FCS and 15% glycerol and stored in -80℃ and revived when required.

### *Antibiotic sensitivity tests*

The antibiotic sensitivity patterns of all the 30 *H pylori* strains towards commonly used antibiotics such as metronidazole, amoxycillin, tetracycline and clarithromycin were evaluated by the *E*-test method. All the strains were seeded on Brucella agar supplemented with 7% sheep blood and grown for 48 h under microaerobic conditions. Bacterial growth was scraped from the plates and resuspended in sterile saline. The inoculum was prepared to contain $10^8$ CFU/mL by adjusting the suspension to match the McFarland No-0.5 turbidity standard for MIC studies[19] and $2 \times 10^8$ CFU/mL of Mc Farland no- 1 standard for antibiotic sensitivity studies[20,21] (Table 1).

### *Determination of MIC of the herbal extracts on H pylori by disc diffusion method*

Growth inhibition was performed by the filter paper disc diffusion method[22] on brucella agar plates supplemented with 7% sheep blood under micro-aerobic conditions at 37℃. To check the antimicrobial activity of the extracts and to read the antibiotic sensitivity of the isolates, inoculum was prepared as described above and the culture was spread over the plates with the help of a sterile cotton swab.

Various concentration disks (10-200 μg/mL) of the plant extracts were prepared and the latter were placed on brucella agar plates with 7% sheep blood earlier inoculated with 50 μL bacterial suspension in brucella broth with 5% FCS ($10^8$-$10^9$ CFU/mL). This was done to evaluate the minimum concentration of the extracts at which *H pylori* growth was inhibited effectively. The MIC was determined

**Table 1 Antibiotic sensitivity patterns of *H pylori* strains as determined by *E*-test (*n* = 30)**

| Antibiotic | Sensitive *n* (%) | Resistance *n* (%) | Range (μg/mL) | MIC[1] (μg/mL) |
|---|---|---|---|---|
| Metronidazole | 7 (23.4) | 23 (76.6) | 0.0125 - > 256 | > 8 |
| Clarithromycin | 28 (93.3) | 2 (6.7) | < 0.016 - > 256 | > 2 |
| Amoxicillin | 28 (93.3) | 2 (6.7) | < 0.016 - > 256 | > 0.5 |
| Tetracycline | 28 (93.3) | 2 (6.7) | < 0.016 - 2 | > 4 |

[1]MIC- Minimum Inhibitory Concentration. (Values in parentheses are percentages).

by measuring the zone of inhibition at each concentration after incubation at 37℃ for 3-5 d (Figure 2).

### *Determination of antimicrobial activity of the herbal extracts in an in vivo model*

**Induction of ulcers:** Ulcers were induced using a model modified from that described by Okabe and Pfeiffer[23]. Briefly, rats were given acetic acid (0.5 mL of 80% vol/vol) with a syringe instilled into the stomach and allowed to remain in contact with the stomach for 1 min, then it was aspirated and the area rinsed with sterile saline. The area exposed to acetic acid was 60 $mm^2$. The rats were killed by cervical dislocation and the stomach was removed and pinned out on a wax block. A paper grid with an area of 25 $mm^2$ was placed alongside the ulcer, which was then photographed (Figure 3). We then determined the ulcer area by planimetry, using × 5 enlargements of the photographs.

The area of ulceration in pixels was converted to square millimeters using the paper grid as a reference. Previous work using this ulcer model has revealed that ulcers induced by acetic acid are characterized by a thick layer of granulation tissue at the base and glandular disorganization at the ulcer margins. The ulcers involved the full thickness of the mucosa and penetrated into the muscularis mucosa. Perforation was not observed with this model. The rats were infected by giving the *H pylori* inoculum orally every alternate day for seven days.

**Bacterial content of ulcers:** To determine the bacterial content in gastric ulcers, animals were killed under aseptic

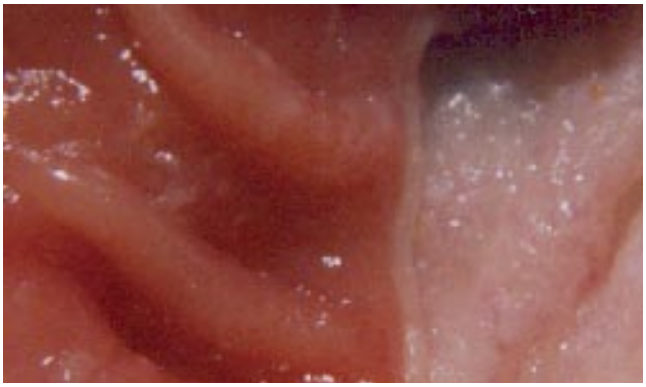

**Figure 3** Control Ulcer.

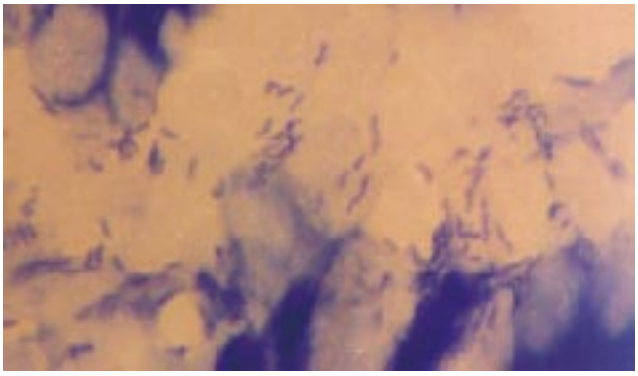

**Figure 4** Typical photograph showing gastric biopsy stained with Giemsa Stain showing tufts of spiral shaped *H pylori*.

conditions. Tissue (150 mg) was washed in sterile PBS and transferred to sterile, pre-weighed containers (to determine sample weight), sterile PBS was added, and then the sample was homogenized. Serial dilutions were then plated on Mc-Conkey agar and tryptic soy agar plates and incubated for 18-24 h under aerobic conditions. The colony-forming units (CFU) were determined using a Leica colony counter. Results are expressed as CFU per gram of tissue. Tissue samples of the ulcers and healthy tissues were embedded in plastic using a commercially available kit (JB-4 embedding kit; Polysciences, Warrington, PA). Thin sections (1-1.5 μm) were stained with methylene blue-fuchsin (basic) and examined under a light microscope (Figures 4 and 5).

Further, the stomach tissue was collected for determination of ulcer size, histopathology and molecular confirmation of *H pylori* using Polymerase Chain Reaction (PCR) (Figure 6).

The rats were then divided into two treatment groups, Group Ⅰ of 6 rats who orally received methanolic extract of *S. mukorossi* (Figure 7) and Group Ⅱ of 6 rats who orally received ethanolic extract of *R. emodi* (Figure 8). Group Ⅲ of 6 rats received saline or dextrose. The total daily intake of dried *Smukorossi* and *Remodi* was 2.5 mg/d and 3.0 mg/d respectively for seven days.

### *Effect of treatment*

The effect of treatment with the extracts of *S. mukorossi* and *R. emodi* was assessed. Ulcers were induced in the rats

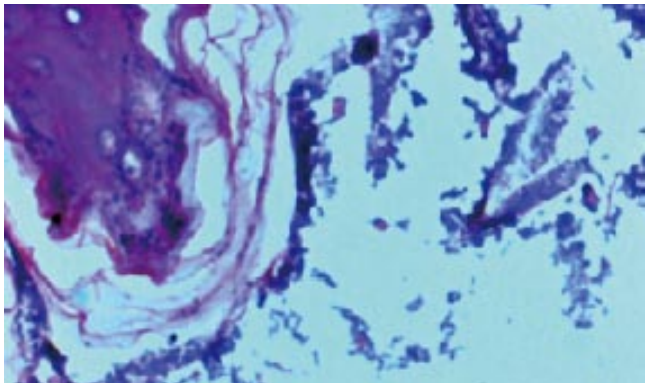

**Figure 5** Photograph showing colonization of *H pylori* in the upper gastric and esophageal region.

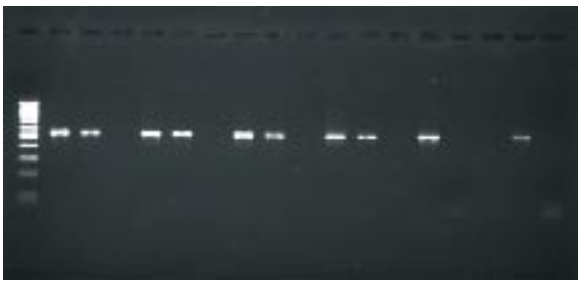

**Figure 6** Typical gel image showing 16S rRNA amplification of *H pylori*. Lane 17 represents positive control of band at 534 bp. (ATCC26695), Lane 18 represents negative control.

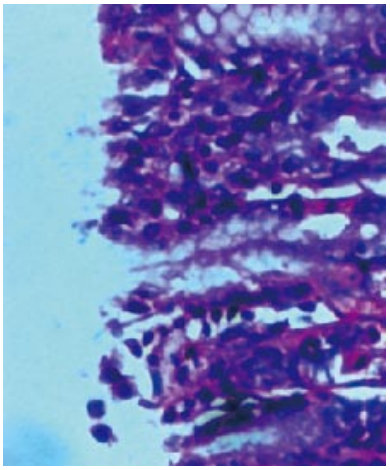

**Figure 7** Photograph of gastric mucosal section showing surface erosion and mucous depletion, *H pylori* can not be seen. Photograph of Post-infection treatment with the extract of *Sapindus mukorossi.*

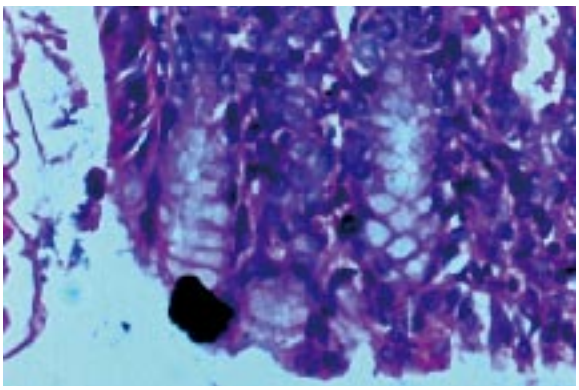

**Figure 8** Photograph of gastric mucosal section showing small foci surface erosion mucin secreting cells in pits are seen, No *H pylori* detected. Photograph of Post-infection treatment with the extract of *Rheum emodi.*

as described above. Seven days after ulcer induction and *H pylori* infection, both groups of rats were orally given the prescribed dose of both the extracts of 2.5 mg/mL and 3.0 mg/mL for seven days. The effect of treatment was checked by sacrificing the rats by cervical dislocation, removing the stomach and photographing it for ulcer determination, and taking tissue samples for bacterial culturing.

### *Statistical analysis*

The data were analyzed with a chi-square ($\chi^2$) test.

## RESULTS

In the *in vitro* study, we found that *S. mukorossi* and *R. emodi* extracts exert an inhibitory effect on *H pylori* (Figure 9). Ethanol and chloroform extracts of *S. mukorossi* and benzene and ethanol extracts of *R. emodi* with various concentrations ranging from 10-200 μg/mL were tested for their effect on *H pylori* growth by the disk diffusion method. In the *in vivo* study, we found that the extracts of *S. mukorossi and R. emodi* were able to clear *H pylori* infections in the rat models at concentrations of 2.5 mg/mL and 3.0 mg/mL post-infection (Figures 7 and 8).

### *MIC of the extracts as determined by Kirby Bauer's disc diffusion method*

It was found that, in the 30 isolates tested, the strains showed approximately 20 mm and 19 mm zones of inhibition with very low (10 μg/mL) concentrations of the ethanol extract of *S. mukorossi* and the benzene extract of *R. emodi*. The chloroform extract of *S. mukorossi* and the ethanol extract of *R. emodi* showed approximately 18 mm and 15 mm zones of inhibition at 10 μg/mL concentration. Maximum inhibition zones of approximately 98 mm and 94 mm were attained with the extracts of *S. mukorossi,* and maximum inhibitions zones of 92 mm and 90 mm were attained with the extracts of *R. emodi* at a concentration of 200 μg/mL. The details of the MIC of both the extracts against *H pylori* are listed in (Figure 9). *In vivo,* we found that the extracts of *S. mukorossi and R. emodi* were able to clear *H pylori* infections at the concentrations of 2.5 mg/mL and 3.0 mg/mL post-infection (Figures 7 and 8).

## DISCUSSION

Elimination of *H pylori* has been a major objective of treatment strategies worldwide. Unfortunately, none of them have been able to achieve 100% eradication rates[24]. The main reason underlying this failure could be the rapidly emerging resistance among many strains of *H pylori* towards various antibiotics. In addition to increased acquired resistance with the majority of

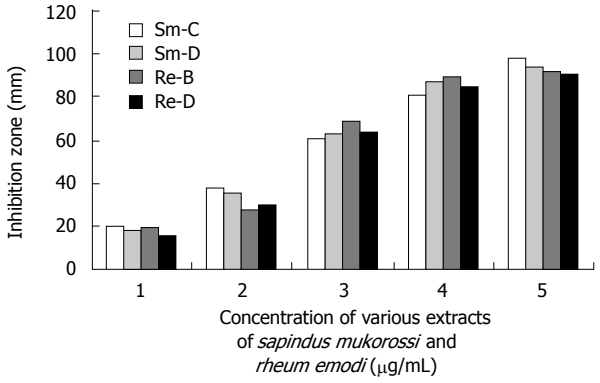

**Figure 9** Antibacterial activity of various extracts *Sapindus mukorossi* and *Rheum emodi* against *H pylori*.

antibiotic therapies, which are considered highly efficient for long-term treatment, studies have shown non-compliance among patients.

Apparently related to the incomplete cures achieved with the triple therapies and their possible side effects, herbal systems of medicine have become increasingly popular in recent years. According to one estimate, nearly 70% of synthetic drugs are derived from medicinal herbs and medicinal herbs have figured high in pharmaceutical industry research because of their high therapeutic activity. Herbal therapies have shown better efficiency and efficacy in inhibiting *H pylori* at both *in vitro* and *in vivo* levels[25,26]. Based on the above, we decided to look for plant extracts capable of inhibiting the growth of *H pylori*. The reason for selecting *S. mukorossi* and *R. emodi* to assess antibiotic activity against *H pylori* is their chemical nature. The chemistry of these herbs is very complex and involves large amounts of physiologically active compounds. Not all the constituents present in the plant have therapeutic activity. Physiological activity is largely dependent on the complete structure, including the glycosidic moiety[27]. This activity is enhanced several-fold due to the presence of sugars in these compounds[28]. *S. mukorossi* and *R. emodi* are saponins and anthraquinones in nature and it is because of this that these plants exhibit antibacterial activity.

Among various extracts of both these plants, we found chloroform and ethanolic extracts of *S. mukorossi* exerted strong antibacterial effects on all the gram +ve and gram -ve organisms, including *H pylori,* while the petroleum ether and benzene extracts did not show any effect. Similarly, benzene and ethanolic extracts of *R. emodi* were found to exhibit a strong inhibitory effect on *H pylori* and other organisms while the petroleum ether and chloroform extracts showed no potential affect either on *H pylori* or other gram +ve and -ve microbes. Our study is the first to report the antibacterial effect of these plant extracts on *H pylori*. In our screening, we found that all 30 *H pylori* isolates were sensitive to the test compounds. As evident from the results, the compounds tested were found to possess antibacterial activities on *H pylori* and were not affected by the resistance of the organism to antibiotics.

The sensitivity of *H pylori* to commonly used antibiotics by (*E*-test) was carried out to assess susceptibility patterns and the sensitivity of the compounds was studied to evaluate the anti-*H pylori* activity of our extracted compounds (10-200 μg/mL by disk diffusion method). We assessed the minimum inhibitory dose of the compounds at which the survival of *H pylori* was in jeopardy. As evident from Figure 9, the extracts of *S. mukorossi* and *R. emodi* are highly effective even at a very minimal dose of 10 μg/disk.

Further, we found that none of the isolates acquired resistance even after 10 passages at sub-inhibitory concentrations. We found that *S. mukorossi* extracts and *R. emodi* extracts of 10 μg/mL concentration proved to be the MIC for almost all the isolates (except MS-24 and MS-28, which were found to be completely inhibited at 8 μg/mL). The reason behind this could be strain variation (data not shown).

*S mukorossi and R. emodi* extracts were found to inhibit all strains of *H pylori* (both sensitive and resistant) at a concentration of 10 μg/mL. This inhibitory concentration is comparable with the previously reported allicins 6-12 μg/mL, garlic oil 8-32 μg/mL[29] and ajoenes 10-25 μg/mL of oil macerated garlic extract. Our compounds proved to be more potent than thiosulfinate 40 μg/mL, vinyldithiins < 100 μg/mL, epigallocatechin gallate in Chinese lung chen tea 50-100 μg/mL and garlic powder 250 μg/mL[29]. Further more, the organism did not develop any resistance to the test compound even after 10 subsequent passages, grown at sub-inhibitory concentrations, whereas *H pylori* strains acquired resistance to amoxycillin and clarithromycin after 10 sequential passages[30,31]. In addition, we found that our extract had almost equivalent bacterial activities against both antibiotic susceptible and resistant *H pylori* strains. Animal studies suggest that an extract of *S. mukorossi and R. emodi* taken orally may help prevent stomach ulcers and it is of interest to note that *S. mukorossi and R. emodi* appear to be both anti-inflammatory and anti-ulcerogenic. However, future studies concerning these properties must be carried out to justify their anti-ulcerogenic properties.

In conclusion, the results presented here indicate that the extracts of *S. mukorossi and R. emodi*, which were screened for their anti-bacterial activity against *H pylori,* are active both *in vitro* and *in vivo.* In addition, the *in vivo* studies also proved to be highly efficient in terms of dosage, tolerability and curing active *H pylori* infection. Future studies will assess the mechanism by which these extracts effect the survival of *H pylori.*

## Abstract

**AIM:** To study the effects of elenoside, an arylnaphthalene lignan from *Justicia hyssopifolia*, on gastrointestinal motility *in vivo* and *in vitro* in rats.

**METHODS:** Routine *in vivo* experimental assessments were catharsis index, water percentage of boluses, intestinal transit, and codeine antagonism. The groups included were vehicle control (propylene glycol-ethanol-plant oil-tween 80), elenoside (i.p. 25 and 50 mg/kg), cisapride (i.p. 10 mg/kg), and codeine phosphate (intragastric route, 50 mg/kg). *In vitro* approaches used isolated rat intestinal tissues (duodenum, jejunum, and ileum). The effects of elenoside at concentrations of 3.2 x $10^{-4}$, 6.4 x $10^{-4}$ and 1.2 x $10^{-3}$ mol/L, and cisapride at $10^{-6}$ mol/L were investigated.

**RESULTS:** Elenoside *in vivo* produced an increase in the catharsis index and water percentage of boluses and in the percentage of distance traveled by a suspension of activated charcoal. Codeine phosphate antagonized the effect of 25 mg/kg of elenoside. *In vitro*, elenoside in duodenum, jejunum and ileum produced an initial decrease in the contraction force followed by an increase. Elenoside resulted in decreased intestinal frequency in duodenum, jejunum, and ileum. The *in vitro* and *in vivo* effects of elenoside were similar to those produced by cisapride.

**CONCLUSION:** Elenoside is a lignan with an action similar to that of purgative and prokinetics drugs. Elenoside, could be an alternative to cisapride in treatment of gastrointestinal diseases as well as a preventive therapy for the undesirable gastrointestinal effects produced by opioids used for mild to moderate pain.

**Key words:** Elenoside; Gastrointestinal motility; Small intestine preparation

## INTRODUCTION

A great number of arylnaphthalene lignans have been isolated from different species of *Justicia*, many of them exhibiting diverse biological activities including antitumoral[1-4], antiviral[5-7], insecticidal[8], cardiotonic[9,10], antiulcerogenic[11] and anti-inflammatory properties[12,13], and an ability to inhibit lipid peroxidation[14]. Interesting activities also include platelet activating factor antagonism and central nervous system action[15]. Recently it has been observed that magnolol and honokinol, two neolignans, obtained from *Magnolia officinalis* Rehd. et Wils, inhibited the contractility of isolated gastric fundus strips from rats treated with Ach or 5-HT and of isolated ileum from guinea pigs treated with Ach or $CaCl_2$; in each case, the neolignans behaved as non-competitive muscarinic antagonists[16]. However, clinical or experimental studies on the effects of the gastrointestinal activity of lignans obtained from *Justicia* species have not, to our knowledge, been performed.

In a previous paper[17] we reported the isolation from *Justicia hyssopifolia L.* of an arylnaphthalene lignan and its aglycone, now called elenoside and elenin respectively, the former being a β-D-glucoside. Elenoside is a cytotoxic arylnapthalene lignan (NSC 644013-W/1) that displayed cytotoxic activity in the human tumor cell line panel of the US National Cancer Institute[18]. Preliminary screening results suggest that elenoside exerts a sedative, hypnotic barbiturate-type effect[18,19]. In addition, we have found that elenoside has digitalis-like activity similar to that of mammalian lignans[20]. Recently we have also observed that elenoside has central sedative effects and a possible application in anxiety conditions[21]. The current study was designed to investigate the effects of elenoside on gastrointestinal motility.

## MATERIALS AND METHODS

### Plant material and chemicals

*Justicia hyssopifolia L.* belongs to the family *Acanthaceae* and is an endemic species in the Canary Islands. Leaves of *J. hyssopifolia* were collected in April 2002 at Punta Cangrejo,

Adeje, Tenerife. A voucher specimen was deposited at the Herbarium of the Department of Botany, Faculty of Biology, University of La Laguna (TFC-28938). The elenoside was extracted and identified in *Centro de Productos Naturales y Agrobiologia, CSIC,* of Tenerife. It was suspended in a mixture of propylene glycol-ethanol-plant oil-Tween80 (40:10:50:2) and administered intraperitoneally in a total volume of 0.5 mL. The control group received vehicle only. An activated charcoal suspension indicator was prepared with 10 g activated charcoal (Panreac, Barcelona, Spain) and 2.5 g Arabic gum dissolved in 100 mL of distilled water. Cisapride was also used (Janssen-Cilag, S.A. Madrid, Spain).

### Animals and treatment

Male Sprague Dawley rats weighing 200-250 g were used. The rats were housed under normal laboratory conditions at 22℃ on a standard light-dark schedule (12:12; lighted from 8 am-8 pm) and had free access to standard laboratory chow and water. Animal care complied with the Guide for the Care and Use of Laboratory Animals in accordance with the Guiding Principles in the Use of Animals in Pharmacology. The study protocol was approved by the Local Ethical Committee for animal experimentation at the University of La Laguna.

The standard dosage treatment protocol for each set of experiments described is as follows: rats assigned to randomized groups of 10 each receiving intraperitoneally (i.p.) a solution of propylene glycol-ethanol-plant oil-Tween 80 (40:10:50:2) (vehicle control group), 25 or 50 mg/kg of elenoside in vehicle, or 10 mg/kg cisapride.

### Catharsis index

The established index of catharsis is the number of humid boluses produced in 24 h. Masri *et al* found that the majority of humid boluses are produced in the first hours following administration of the substance[22]. Thus, we used their method to study the effect of elenoside. Rats were fasted for 24 h prior to the experiment. Following this period, the rats received the standard dosage treatment protocol ($n$ = 10 per dosage group). Rats were then individually placed in metabolism cages, and the boluses were collected for a 6 h period above blotting paper to facilitate counting.

### Water percentage of boluses

Using the standard dosage protocol described above, we tested the water percentage of the boluses. Rats ($n$ = 10 per dosage group) were individually placed in metabolism cages, and the boluses were collected in a methacrylate container for a period of 6 h and deposited in a watch glass. Afterward, the samples were weighed and placed in a heater at 100℃ for 3 h, followed by another weighing to establish the percentage of water in each.

### Intestinal transit

This experimental method allows the evaluation of drug action on intestinal transit speed, by measuring the distance travelled by a suspension of activated charcoal when it has been administered intragastrically (po). Rats ($n$ = 10 per dosage group) were fasted for 24 h prior to the experiment. At 15 min following treatment with the standard dosage protocol, the rats received 2 mL of a suspension of activated charcoal po. After 20 min, the rats were anesthetized and sacrificed; their intestines were removed from the pylorus through the ileocecal junction. The migration of activated charcoal from the pylorus to the most distal point of migration was expressed as distance (cm) migration using the stain. The percentage of distance travelled by the activated charcoal suspension established the intestinal transit. This percentage was expressed as % = 100 × l/L, in which *"l"* is the migration distance of the activated charcoal and *"L"* is the distance between the pylorus and the ileocecal junction.

### Intestinal transit and codeine antagonism

Using the standard treatment protocol, we studied the effect of elenoside in the presence of codeine phosphate, an opioid with inhibitory activity on intestinal motility. Following administration of the standard dosage treatment, the rats immediately received 50 mg/kg of codeine phosphate po. The method used for the measurement of intestinal transit was the same as that described in the preceding section.

### Isolated rat intestine

Rats were anesthetized and sacrificed. The abdomen was opened and a length of duodenum, jejunum and ileum was removed and placed in Tyrode´s solution. Pieces of smooth muscle (1-2 cm) were dissected free from surrounding tissues and mounted in an organ bath with Tyrode´s solution at 37℃, pH 7.4, through which a mixture of 50 mL/L $CO_2$ and 950 mL/L $O_2$ bubbled continuously[23]. The isotonic contractions of the preparation were recorded on a Grass Model 7D Polygraph through a Statham force displacement transducer. The load applied to the lever was 1 g. After stabilization, the effect of elenoside was studied for 5 min at the following concentrations: $3.2 \times 10^{-4}$, $6.4 \times 10^{-4}$ and $1.2 \times 10^{-3}$ mol/L, and cisapride at $10^{-6}$ mol/L. Ten samples each of duodenum, jejunum, and ileum were used for each concentration.

### Statistical analysis

Statistical analysis was performed using the Prism program with two-way analysis of variance (ANOVA) (between group-factor: dose repeated measures factor: time), followed by Tukey´s Multiple Comparison *post-hoc* test. For nonparametric analysis, the Kruskal-Wallis test, was followed by the Mann-Whitney test for catharsis index, water of boluses, intestinal transit, and intestinal transit and codeine antagonism. A probability of 5% or less was considered to indicate a significant difference.

## RESULTS

### Catharsis index

Table 1 shows the results of cathartic activity for the vehicle control group and groups receiving elenoside at doses of 25 or 50 mg/kg or cisapride at dose of 10 mg/kg. Elenoside produced an increase in the catharsis index compared to the control group. The results of 50 mg/kg group and controls ($P < 0.01$) and of the 50 mg/kg and 25

**Table 1 Effect of vehicle control, elenoside (E) and cisapride (C) on catharsis index in rats ($n$ = 10) per treatment group**

| | Rat weight | Catharsis index |
|---|---|---|
| Control | 239 ± 4 | 0.1 |
| E-25 mg/kg | 240 ± 3 | 1.5 |
| E-50 mg/kg | 238 ± 3 | 2.16[a] |
| C-10 mg/kg | 236 ± 2 | 2.04[a] |

Values are mean ± SE for 10 rats. [a]$P < 0.05$ *vs* control.

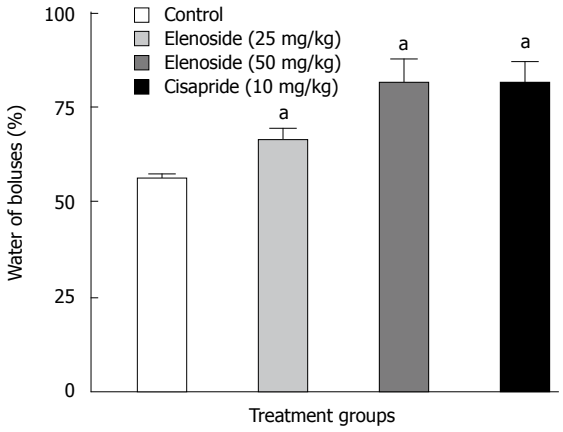

**Figure 1** Percentage increase in water of boluses in vehicle control, elenoside, and cisapride. Values are mean ± SE for 10 rats/group. [a]$P < 0.05$ *vs* control.

mg/kg elenoside treatments, respectively, were significantly different from one another. Cisapride produced an increase in the catharsis index compared to the control group ($P < 0.05$), but it did not differ significantly from 50 mg/kg of elenoside in its effects.

### Water percentage of boluses

Figure 1 shows the results of the water percentage of boluses analysis for control group, elenoside at doses of 25 and 50 mg/kg, and cisapride at 10 mg/kg. Both concentrations of elenoside produced an increase in water percentage *vs* vehicle control (*vs* 25 mg/kg elenoside, $P < 0.01$; *vs* 50 mg/kg elenoside, $P < 0.01$). Cisapride caused a significant increase in the water percentage versus the control group ($P < 0.01$), an effect similar to that produced by 50 mg/kg elenoside.

### Intestinal transit

Figure 2 shows the results of the analysis of the effects of elenoside and cisapride on small intestinal transit (SIT) speed. Both concentrations of elenoside produced an increase in the percentage of distance the suspension of activated charcoal travelled *vs* the vehicle control (*vs* 25 mg/kg elenoside, $P < 0.01$; *vs* 50 mg/kg elenoside, $P < 0.01$). Cisapride produced a significant increase in SIT (control *vs* cisapride 10 mg/kg, $P < 0.05$). There was no difference between cisapride and the 50 mg/kg of elenoside.

### Intestinal transit and codeine antagonism

Figure 3 shows the results of SIT analysis for elenoside with codeine phosphate. Codeine phosphate antagonized

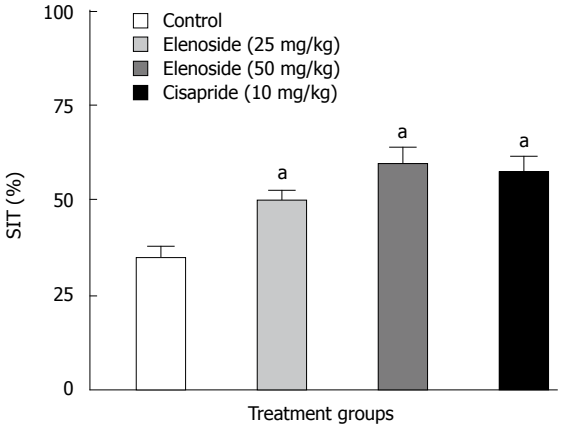

**Figure 2** Small intestinal transit (SIT) in vehicle control and elenoside-treated and cisapride-treated animals. Values are mean ± SE for 10 rats/group. [a]$P < 0.05$ *vs* control.

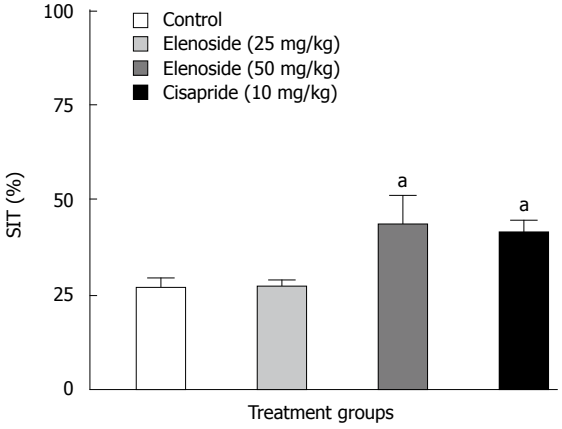

**Figure 3** Codeine phosphate induced delay in small intestinal transit (SIT) in vehicle control, elenoside, and cisapride groups. Values are mean ± SE for 10 rats/group. [a]$P < 0.05$ *vs* control.

the effect of 25 mg/kg of elenoside. Moreover, codeine phosphate at 50 mg/kg produced an antagonistic effect on 50 mg/kg of elenoside and 10 mg/kg of cisapride, although this effect was not complete (control *vs* 50 mg/kg elenoside, $P < 0.05$; control *vs* 10 mg/kg cisapride, $P < 0.05$)

### Isolated rat intestine

Figure 4 A-C show the results of the concentration force analysis; effects of elenoside and cisapride on duodenum, jejunum and ileum are depicted in Figures 4A, 4B and 4C, respectively. There was a clear dose-effect relationship over the three concentrations of elenoside.

At one minute, elenoside produced a decrease in the contraction force, which continued with increasing concentration from $3.2 \times 10^{-4}$ mol/L ($P < 0.01$) to $6.4 \times 10^{-4}$ mol/L ($P < 0.01$) to $1.2 \times 10^{-3}$ mol/L ($P < 0.01$) during a five-minute assessment. Cisapride produced an effect similar to that of the $6.4 \times 10^{-4}$ mol/L of elenoside. Elenoside at a concentration of $1.2 \times 10^{-3}$ mol/L produced a significant increase in contraction force *vs* $3.2 \times 10^{-4}$ mol/L at 2 ($P < 0.01$), 4 ($P < 0.01$) and 5 ($P < 0.01$) min respectively (Figure 4A).

Elenoside applied to jejunum produced a decrease in the contraction force at one minute, followed by an

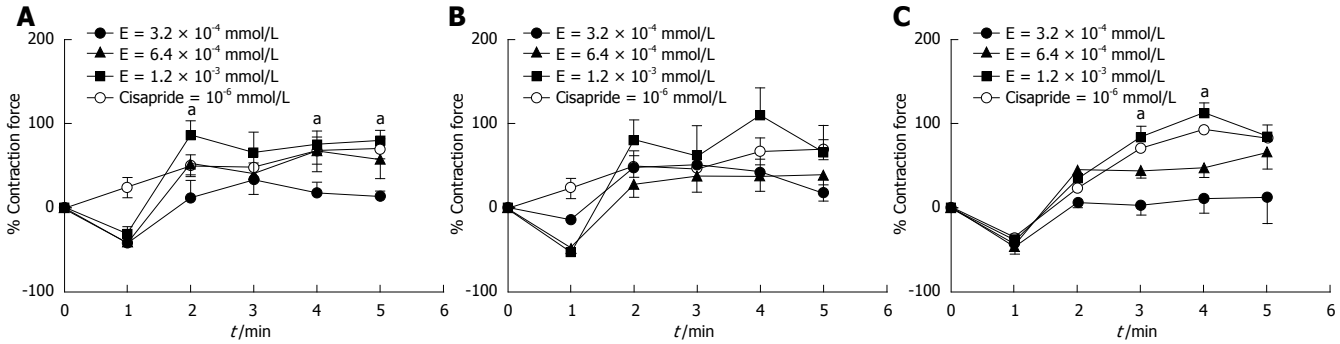

**Figure 4** **A**: Time-course of the effects of elenoside and cisapride on contraction force in rat duodenum vs baseline. Values are mean ± SE for 10 duodenum samples during 6 min; $^aP < 0.05$. **B**: Time-course of the effects of elenoside and cisapride on contraction force in rat jejunum vs baseline. Values are mean ± SE for 10 jejunum samples during 6 min; $^aP < 0.05$. **C**: Time-course of the effects of elenoside and cisapride on contraction force in rat ileum vs baseline. Values are mean ± SE for 10 ileum samples during 6 min; $^aP < 0.05$.

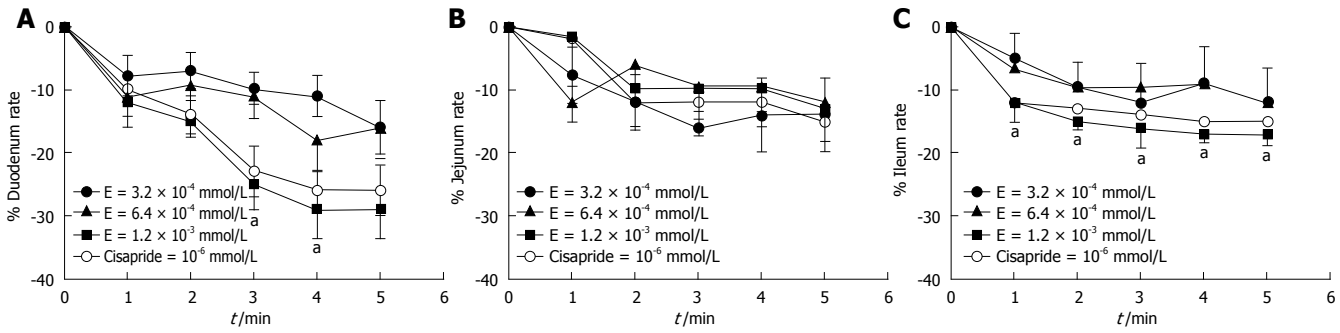

**Figure 5** **A**: Time-course of the effects of elenoside and cisapride on intestinal frequency in the rat duodenum vs baseline. Values are mean ± SE for 10 duodenum samples during 6 min; $^aP < 0.05$. **B**: Time-course of the effects of elenoside and cisapride on intestinal frequency in the rat jejunum vs baseline. Values are mean ± SE for 10 jejunum samples during 6 min; $^aP < 0.05$. **C**: Time-course of the effects of elenoside and cisapride on intestinal frequency in the rat ileum vs baseline. Values are mean ± SE for 10 ileum samples during 6 min; $^aP < 0.05$.

increase at concentrations of $3.2 \times 10^{-4}$ mol/L ($P < 0.01$), $6.4 \times 10^{-4}$ mol/L ($P < 0.05$), and $1.2 \times 10^{-3}$ mol/L ($P < 0.01$) at 5 min. Cisapride produced an effect similar to that obtained with elenoside at a concentration of $3.2 \times 10^{-4}$ mmol/L (Figure 4B).

When elenoside was applied to ileum, a decrease in the contraction force was produced a minute later. In the next minute, the contraction force increased and continued to do so up to five minutes with elenoside concentrations of $6.4 \times 10^{-4}$ mol/L ($P < 0.01$) and $1.2 \times 10^{-3}$ mol/L ($P < 0.01$). There was no effect on contraction force with the mid-range concentration of elenoside. Cisapride induced an effect similar to that of elenoside at a concentration of $1.2 \times 10^{-3}$ mol/L. Elenoside at a concentration of $3.2 \times 10^{-4}$ mol/L produced a significant increase in the contraction force *vs* $1.2 \times 10^{-3}$ mol/L elenoside at 3 ($P < 0.05$) and 4 ($P < 0.05$) min, respectively (Figure 4C).

Figure 5A-5C depicts results from the time-course analysis of the effects of elenoside on intestinal frequency of duodenum, jejunum, and ileum respectively. Elenoside produced a decrease in the intestinal frequency of duodenum at concentrations of $6.4 \times 10^{-4}$ mo/L ($P < 0.05$) and $1.2 \times 10^{-3}$ mo/L ($P < 0.01$) during the time-course. Cisapride produced an effect similar to that of elenoside at a concentration of $1.2 \times 10^{-3}$ mo/L. Elenoside at a concentration of $1.2 \times 10^{-3}$ mo/L produced a significant decrease in the intestinal frequency *vs* $3.2 \times 10^{-4}$ mo/L at 3 ($P < 0.01$) and 4 ($P < 0.01$) min, respectively (Figure 5A).

Elenoside decreased intestinal frequency in jejunum at all concentrations used during the time-course. No statistical differences among the concentrations of elenoside were observed (Figure 5B).

Elenoside produced a decrease in intestinal frequency in ileum at all concentrations, but only the concentration of $1.2 \times 10^{-3}$ mo/L ($P < 0.01$) produced a statistically significant decrease (Figure 5C).

## DISCUSSION

In this study, elenoside, has been shown to act as a stimulant of gastrointestinal motility. It produced an increase in the catharsis index and in the number of humid boluses at a dose of 50 mg/kg. The water volume of the boluses was also enhanced after treatment with elenoside at the two doses used. These effects of elenoside on the gastrointestinal tract suggest its actions similar to that of purgative drugs.

Another effect of elenoside was the increase in the distance traveled by the charcoal suspension at doses of 25 and 50 mg/kg. The distance traveled by the charcoal suspension has been used in the evaluation of drugs to determine their effects on gastrointestinal motility[24-26]. Elenoside elicited gastrointestinal activity similar to that effected by cisapride at a dose of 10 mg/kg. This effect exerted by elenoside suggested an action similar to that of cisapride, a commonly used prokinetic drug

that acts *via* a mechanism that facilitates cholinergic neurotransmission[27], and of other prokinetic drugs, such as metoclopramide, domperidone, erythromycin, and mosapride[28,29], ghrelin and GHRP-6[30], betanecol[31], and magnolol and honokiol[16]. Other lignans can exert similar effects: Podophyllotoxin and picropodophyllotoxin, lignans isolated from *Podophyllum* species, and produce diarrhea when administered to animals[32]. Herbal remedies with prokinetic activity similar to elenoside are peppermint oil[33], *Cocculus hirsutus*[34], *Zingiber officinale*[35], *Indigofera dendroides*[25], Shundao granules[36], and Banxia-houpo-tang HKT[37].

Codeine phosphate totally antagonized this prokinetic action at the lowest dose of elenoside and partially antagonized it at the higher elenoside dose. In addition, it antagonized the prokinetic action of cisapride. Codeine phosphate is an opium alkaloid with an activity similar to but weaker than that of morphine. It is given mainly orally in the treatment of mild to moderate pain[38]. However, although opioids are given to relieve pain, they exert undesirable gastrointestinal side effects such as nausea, vomiting, and a decreased gastrointestinal transit[39].

Elenoside could be an alternative together with cisapride in the treatment of the undesirable gastrointestinal effects produced by opioid drugs. Increased peristaltic and cathartic activity are parameters of irritant cathartics, according to Fling classification[40].

In isolated rat duodenum, jejunum, and ileum, elenoside produced a decrease in the contraction force followed by an increase. Elenoside applied to duodenum and ileum decreased intestinal frequency, but no significant changes in jejunum were found. Other lignans have been shown to affect contraction force and intestinal frequency[41-43]. Lignans obtained from *Podophylum* species caused a decrease in the initial rate and amplitude of contractions of isolated intestinal preparations followed by an increase in the force of contraction[32]. 2, 3-dibenzil-butirolactone, a lignan obtained from *Carthamus tinctorus* L. (Compositae), was responsible for the cathartic activity of this plant[44]. *Curcuma longa* relaxed spontaneous contractions in isolated rabbit jejunum[45]. On the other hand, some lignans used in the treatment of diarrhea, produced an inhibition in the normal intestine propellant movement[46]. Magnolol and honokiol obtained from *M. officinalis* induced a decrease in contractility of guinea pig ileum[16].

Traditional herbal remedies are used because they can improve the symptoms of gastrointestinal diseases, such as dyspepsia, nausea, vomiting, and abdominal distension. Elenoside obtained from *J. hyssopifolia* could be used to treat these symptoms of gastrointestinal diseases. It produced an increase in the catharsis index or number of humid boluses; an enhancement of the water volume of boluses; and an increase in the distance traveled by the charcoal suspension. In addition, codeine phosphate totally antagonized its prokinetic action; in isolated rat duodenum, jejunum, and ileum, elenoside elicited a decrease in contraction force followed by an increase; and elenoside caused a decrease in intestinal frequency in duodenum and ileum, but not in jejunum.

In conclusion, elenoside in the gastrointestinal tract exhibits activities similar to that of purgative and prokinetics drugs. Elenoside could be an alternative to cisapride in the treatment of gastrointestinal diseases as well as a preventive of the undesirable gastrointestinal effects produced by opioids used for mild to moderate pain.

## Abstract

**AIM:** To investigate the effect of a Chinese medicine, Kaiyu Qingwei Jianji (KYQWJJ) used for diabetic treatment, on the morphometry and residual strain distribution of the small intestine in streptozotocin (STZ) -induced diabetic rats. Correlation analysis was also performed between the opening angle and residual strain with the blood glucose level.

**METHODS:** Forty-two male Wistar rats weighing 220-240 g were included in this study. Thirty-two STZ-induced diabetic rats were subdivided into four groups ($n$ = 8 in each group), i.e. diabetic control group (DM); high dose of KYQWJJ (T1, 36g/kg per day); low dose of KYQWJJ (T2, 17 g/kg per day) and Gliclazide (T3, 50 mg/kg per day). Another ten rats were used as non-diabetic control (CON). The medicines were poured directly into stomach lumen by gastric lavage twice daily. The rats of CON and DM groups were only poured the physiological saline. Blood glucose and plasma insulin levels were measured. Experimental period was 35 d. At the end of experiment, three 5-cm long segments were harvested from the duodenum, jejunum and ileum. Three rings of 1-2 mm in length for no-load and zero-stress state tests were cut from the middle of different segments. The morphometric data, such as the circumferential length, the wall thickness and the opening angle were measured from the digitized images of intestinal segments in the no-load state and zero-stress state. The residual strain was computed from the morphometry data. Furthermore, the linear regression analysis was performed between blood glucose level with morphometric and biomechanical data in the different intestinal segments.

**RESULTS:** The blood glucose level of DM group was consistent 4-fold to 5-fold higher than those in CON group during the experiment (16.89 ± 1.11 *vs* 3.44 ± 0.15 mmol/L, $P < 0.001$). The blood glucose level in the T1 (16.89 ± 1.11 *vs* 11.08 ± 2.67 mmol/L, $P < 0.01$) and T3 groups (16.89 ± 1.11 *vs* 13.54 ± 1.73 mmol/L, $P < 0.05$), but not in T2 group ($P > 0.05$) was significantly lower than those in DM group. The plasma insulin levels of DM, T1, T2 and T3 groups were significantly lower than those in CON group (10.98 ± 1.02, 12.52 ± 1.42,13.54 ± 1.56,10.96 ± 0.96 vs 17.84 ± 2.34 pmol/L respectively, $P < 0.05$), but no significantly difference among the groups with exception of CON group. The wet weight/cm and total wall thickness of duodenum, jejunum and ileum in DM group were significantly higher than those in CON group (wet weight (g/cm): duodenum 0.209 ± 0.012 *vs* 0.166 ± 0.010, jejunum 0.149 ± 0.008 *vs* 0.121 ± 0.004, ileum 0.134 ± 0.013 *vs* 0.112 ± 0.007; Wall thickness (mm): duodenum 0.849 ± 0.027 *vs* 0.710 ± 0.026, jejunum 0.7259 ± 0.034 *vs* 0.627 ± 0.025, ileum 0.532 ± 0.023 *vs* 0.470 ± 0.010, all $P < 0.05$), T1 and T3 treatment could partly restore change of wall thickness, but T2 could not. The opening angle and absolute value of inner and outer residual stain were significantly smaller in duodenal segment (188 ± 11 degrees, -0.31 ± 0.02 and 0.35 ± 0.03 *vs* 259 ± 15 degrees, -0.40 ± 0.02 and 0.43 ± 0.05) and larger in jejunal (215 ± 20 degrees, -0.30 ± 0.03 and 0.36 ± 0.06 *vs* 172 ± 19 degrees, -0.25 ± 0.02 and 0.27 ± 0.02) and ileal segments (183 ± 20 degrees, -0.28 ± 0.01 and 0.34 ± 0.05 *vs* 153 ± 14 degrees, -0.23 ± 0.03 and 0.29 ± 0.04) in DM group than in CON group ($P < 0.01$). T1 and T3 treatment could partly restore this biomechanical alteration, but strong effect was found in T1 treatment (duodenum 243 ± 14 degrees, -0.36 ± 0.02 and 0.42 ± 0.06, jejunum 180 ± 15 degrees, -0.26 ± 0.03 and 0.30 ± 0.06 and ileum 163 ± 17 degrees, -0.23 ± 0.03 and 0.30 ± 0.05, compared with DM, $P < 0.05$). The linear association was found between the glucose level with most morphometric and biomechanical data.

**CONCLUSION:** KYQWJJ (high dose) treatment could partly restore the changes of blood glucose level and the remodeling of morphometry and residual strain of small intestine in diabetic rats. The linear regression analysis

demonstrated that the effect of KYQWJJ on intestinal opening angle and residual strain is partially through its effect on the blood glucose level.

## INTRODUCTION

Dysfunction of upper gastrointestinal tract (GI) is common among diabetic patients[1]. As many as 75% of patients visiting diabetes clinics report significant GI Symptoms[2,3]. Common complaints include dysphagia, early satiety, reflux, abdominal pain, nausea, vomiting, and diarrhea[2,3]. As with other complications of diabetes, the duration of the disorder and poor glycemic control seem to be associated with more severe GI problems[2,3]. Histologically, many experiments have demonstrated prominent proliferation of GI wall layers, especially mucosa in the small intestine and esophagus of diabetes[4-9]. Many studies have shown that DM causes morphological changes and biomechanical remodeling in the esophagus[10,11], stomach[12] and small intestine[13,14]. Recently, Frøkjær et al in a human study found an increase in esophageal wall thickness and altered deformation to the distension with reduced longitudinal shortening and the radial stretch in insulin dependent diabetes mellitus (IDDM) patients (unpublished data). The biomechanical remodeling of the GI tract likely plays an important role in the GI disorder of diabetic patients[1]. Therefore, it is important to study the biomechanical properties of the small intestine in diabetic animals. Remodeling of the structural and biomechanical properties can be measured as changes in the residual strain and stress-strain distributions. Residual strain is defined as the strain in the no-load state (where external forces are zero) in reference to the zero-stress state.

To the best of our knowledge, only few studies related to the residual strain in diabetic small intestine have been studied[13,15]. Previously we have demonstrated that gliclazide treatment could partially restore the changes of biomechanical parameters of small intestine in the diabetic rats[15]. Regarding the Kaiyu Qingwei Jianji (KYQWJJ), several previous studies have demonstrated that it could decrease blood glucose level, decrease blood lipid level, increase sensitivity of insulin and decrease resistance of insulin[16-18]. However, no study has been performed about the effect of KYQWJJ on the morphometric and biomechanical properties of small intestine in diabetes. Therefore, the goal of the present study was to investigate the effect of KYQWJJ on the remodeling of the zero-stress state of the small intestine. The gliclazide is serving as positive control in the present study.

## MATERIALS AND METHODS

### Animal model and groups

Fifty male Wistar rats weighing 220-240 g were included in this study. Forty rats were made diabetic by a single intraperitoneal injection of 60 mg/kg streptozotocin (STZ, Sigma Company). This dose resulted in a fasting serum glucose level greater than 11.1 mmoL/L in 80% of rats after 4 d of injection; the remaining 20% were finally not used in this study. Another 10 rats of similar age and body weight from the same vendor were used as non-diabetic control (CON). Thirty-two diabetic rats were subdivided into four groups ($n$ = 8 in each group), i.e. diabetes mellitus control group (DM); high dose of KYQWJJ (T1); low dose of KYQWJJ (T2) and Gliclazide (T3).

### Drugs and administration methods

KYQWJJ was composed of Radix Bupleuri, Radix et Rhizoma Rhei, Rhizoma Pinelliae and Rhizoma Coptidis, and provided by China-Japan Friendship Hospital. Gliclazide was purchased from Hua Ju pharmaceutical factory (Tanjun, China). The medicines were injected directly into stomach lumen by gastric lavage twice daily and the dosage was 36 g/kg for T1, 17 g/kg for T2 and 50 mg/kg for T3 respectively. The rats of CON and DM groups were only poured the physiological saline.

### Experimental procedures

Weight and blood glucose levels were measured 5 d, three weeks and five weeks after initiating the experiment. The plasma insulin level was measured when the experiment finished. Experimental period was 35 d.

After 35 d, the animals were anesthetized with sodium pentobarbital (50 mg/kg ip). Following laparatomy, the calcium antagonist, papaverine (60 mg/kg) was injected into the lower thoracic aorta through a cannula (22 G/25 mm) in order to abolish contractile activity in the GI tract. After obtaining smooth muscle relaxation, the whole small intestine was harvested. The most proximal segment was close to the pylorus whereas the most distal segment was close to the ileo-cacal valve. The length of duodenum and whole jejunum and ileum in vitro was measured. Within a short time, the residual contents in the lumen were gently cleared using saline and the wet weight of duodenum, jejunum and ileum was measured. Three 6 cm-long segments from duodenum, jejunum and ileum were harvested. The duodenum was taken from the descending part, 1 cm down the pylorus; the jejunum from 5 cm distal to the ligament of Treitz, and the ileum from 5 cm proximal to the ileo-cecal valve. Then the segments were placed immediately into cold aerated Krebs solution containing 6% dextran. Three rings, 1-2 mm in length, were cut from the middle part of each segment for no-load and zero-stress state tests. The rings were photographed in the no-load state using a video camera (SONY CCD Camera, Japan) and then cut radially on the anti-mesenteric side to obtain their zero-stress state. A 60-min-period

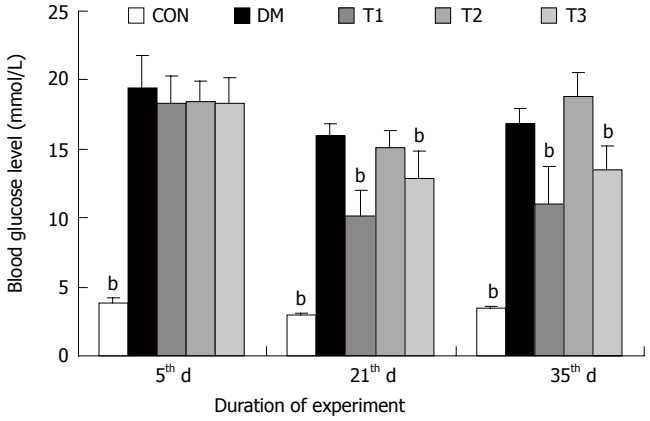

**Figure 1** The blood glucose levels in different groups, compared with DM group ($^bP < 0.01$).

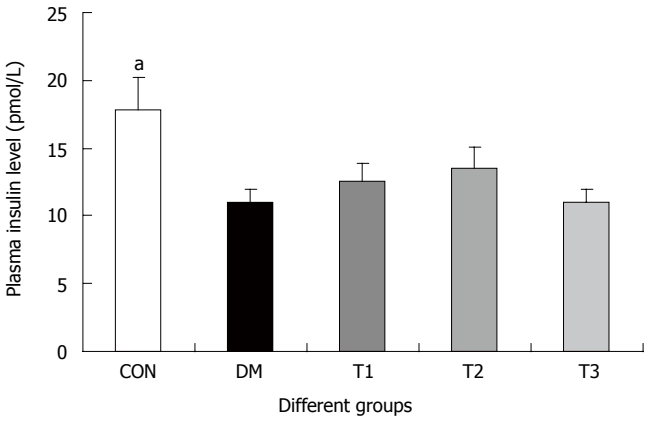

**Figure 2** The serum insulin levels in different groups, compared with DM group ($^aP < 0.05$).

was allowed for equilibration and the specimens were photographed again. The selection of this time period was based on pilot experiments.

### Data analysis

The morphometric data were obtained from the digitalized images of the photographs of the segments in the zero-stress and no-load states. Measurements were done using SigmaScan software (Jandel Scientific, Germany). The following data were measured from each specimen: the circumferential length (C), the wall thickness (h), and the opening angle at the zero-stress state. The subscripts i, o, n, and z refer to the inner (mucosal) surface, outer (serosal) surface, no-load state and zero-stress state condition. The data from triplet of rings were averaged before further analysis.

The measured data was used for computation of residual strains defined as:

Residual Green's strain at the mucosal surface:

$$e_i = \frac{(\frac{C_{i-n}}{C_{i-z}})^2 - 1}{2} \quad (1)$$

Residual Green's strain at the serosal surface:

$$e_o = \frac{(\frac{C_{o-n}}{C_{o-z}})^2 - 1}{2} \quad (2)$$

Thus, from the circumferential lengths at the no-load and zero-stress state, we can compute the circumferential residual strain, at the mucosal and serosal surfaces in the sense of Green strain. Green strain is used when large deformations are encountered as in this study. Negative strain implies that the tissue is in compression whereas positive strain implies extension.

The association between the glucose level with opening angle and residual strain in different groups with referenced to the DM group were performed using the linear regression analysis.

### Statistical analysis

The data were representative of a normal distribution and accordingly the results were expressed as mean ± SD unless otherwise stated. Analysis of variance was used to detect difference among the different groups (Sigmastat 2.0TM). Linear regression analysis was used to demonstrate possible association between the blood glucose levels and opening angle and residual strain (Sigmastat 2.0TM). The results were regarded as significant when $P < 0.05$.

## RESULTS

### The blood glucose and plasma insulin level

The changes of the blood glucose level during the development of diabetes are shown in Figure 1. The blood glucose level of DM group was consistent 4-fold to 5-fold higher than those in CON group during the experiment ($F = 19.4$, $P < 0.001$). Compared with DM group, significant lower of blood glucose level was found in the T1 and T3 groups ($F = 16.1$, $P < 0.01$ and $F = 5.8$, $P < 0.05$), but not in T2 group ($F = 0.8$, $P > 0.05$). The plasma insulin level was shown in Figure 2. The plasma insulin levels of DM, T1, T2 and T3 groups were significantly lower than those in CON group ($P < 0.05$), but no significantly difference was found among the groups with exception of CON group ($P > 0.05$).

### The intestinal weight and wall thickness (Figures 3 and 4)

The wet weight per centimeter and the wall thickness were increased during diabetes in the duodenum, jejunum and ileum ($P < 0.01$). After treatment with T1, T2 and T3, the wet weight per centimeter of different segments did not change significantly. However, T1 and T3 partly inhibited the wall thickness increase, in which the effect of T1 was stronger ($P < 0.05$).

### Biomechanical data

The opening angles and residual strains of the different intestinal segments were shown in Figures 5 and 6. In brief, the opening angles and absolute value of residual strain were smaller in duodenum and larger in jejunum and ileum in the DM group when compared to those in CON group ($P < 0.01$). T1 and T3 treatment could partly restore this biomechanical alteration, in which the effect of T1 was stronger ($P < 0.05$). No significant effect in T2 treatment was found.

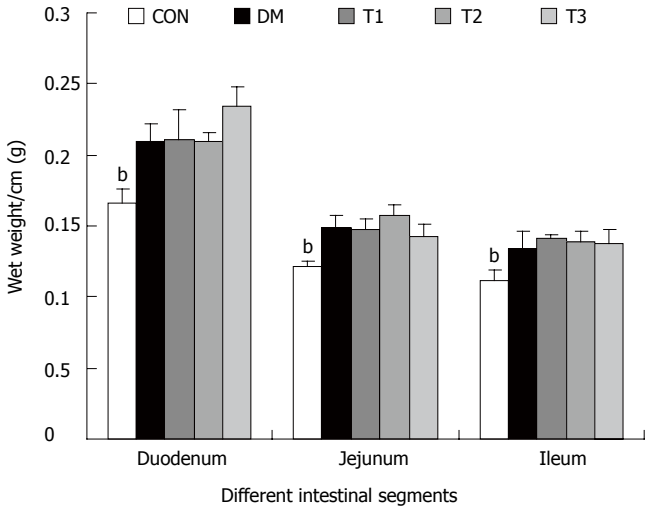

**Figure 3** The intestinal wet weight of different segments per centimeter long in different groups, compared with DM group ($^bP < 0.01$).

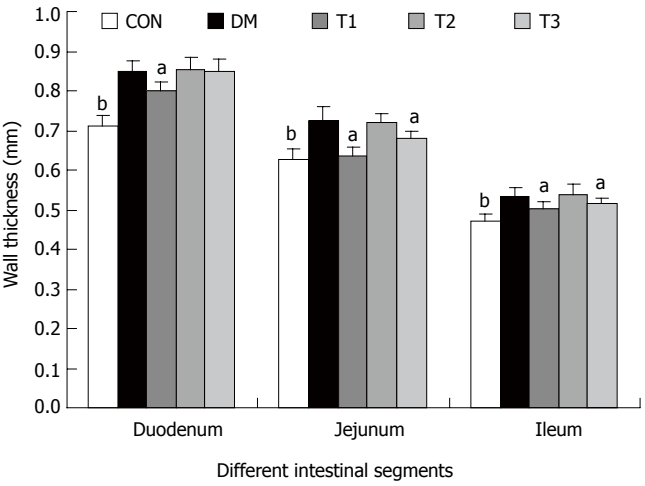

**Figure 4** The intestinal wall thickness of different segments in different groups, compared with DM group ($^aP < 0.05$; $^bP < 0.01$).

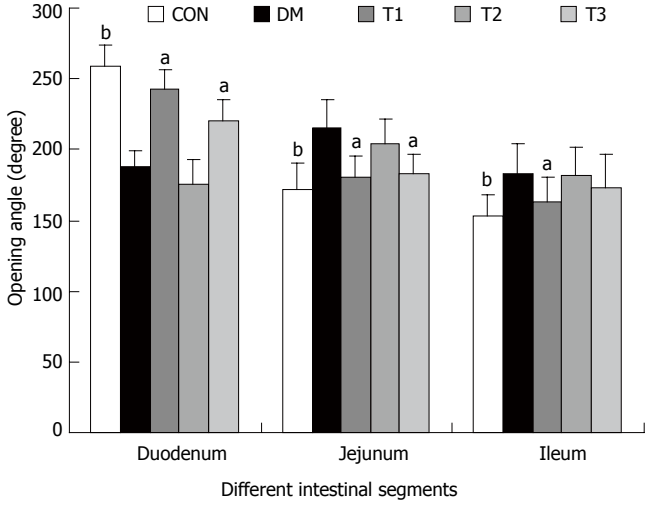

**Figure 5** The opening angles of different intestinal segments in different groups, compared with DM group ($^aP < 0.05$; $^bP < 0.01$).

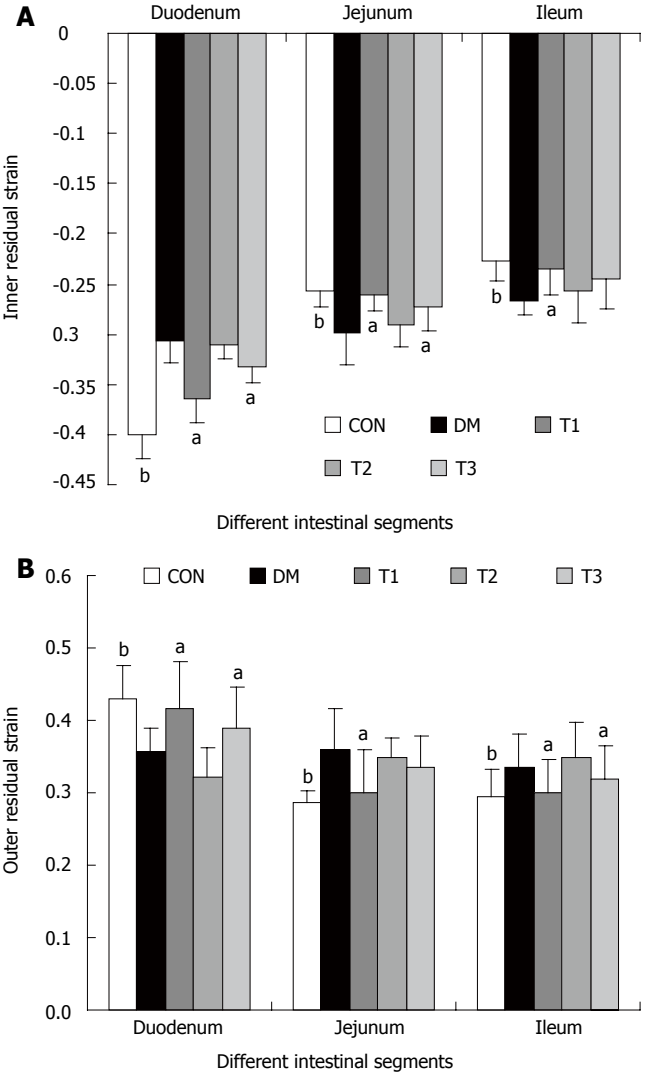

**Figure 6** The inner (**A**) and outer (**B**) residual strain distribution of different intestinal segments in different groups, compared with DM group ($^aP < 0.05$; $^bP < 0.01$).

### *Association between blood glucose level with morphometric and biomechanical data*

Linear regression analysis indicated that the linear association existed between blood glucose level with most morphometric and biomechanical data (Table 1). The examples of association between the glucose with opening angle and inner residual strain in duodenal segment were shown in the Figure 7. The high linear association existed between blood glucose level with opening angle ($r = 0.657$, $P < 0.001$, Figure 7A) and inner residual strain ($r = 0.653$, $P < 0.001$, Figure 7B).

## DISCUSSION

Studies of the gut in the streptozotocin model of diabetes have almost entirely involved use of the rat. The form of diabetes mellitus induced by parenteral streptozotocin administration in rats is insulin-dependent (type I). Without treatment with insulin, STZ-induced diabetic rats become hyperglycaemic, polyphagic, polidipsic, poliuric and undernourished. In our studies, the blood glucose level was 4-5 times higher in diabetic rats than in non-

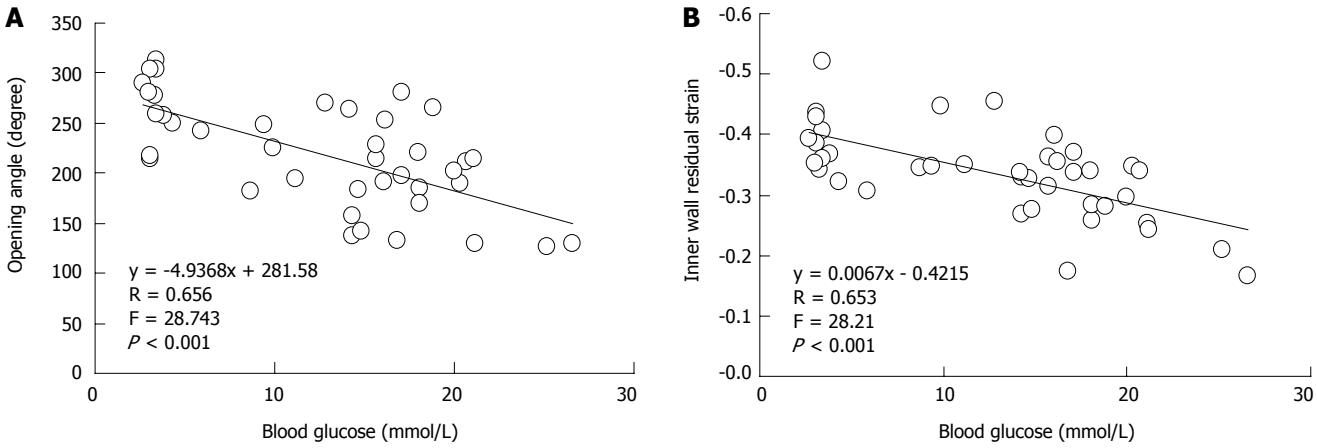

**Figure 7** The examples of association between the glucose with opening angle (**A**) and inner residual strain (**B**) in duodenal segment.

diabetic rats. The major findings in our studies were that the opening angle and residual strain were smaller in the duodenum and larger in the jejunum and ileum in diabetic rats compared to normal rats. After gliclazide and high dose KYQWJJ treatment, these biomechanical parameters trend to back to normal state. Furthermore, we confirmed previous data that the intestinal weight per-unit length prominently increased in the diabetic rats[9,12-14], gliclazide and high dose KYQWJJ treatment can partly reverse the remodeling of intestine. High dose KYQWJJ seems better than gliclazide to reverse the morphometric and biomechanical remodeling of intestine in STZ -induced diabetic rats.

The small intestine is the longest section of the digestive tract and consists of three segments, namely the duodenum, jejunum and ileum, forming a passage from the pylorus to the large intestine. The main functions of the small intestine can be roughly divided into transport, absorption and secretion. The movement of luminal contents is facilitated by changes in the geometry of the wall and lumen due to the motility. It is well known that a bolus propelled in front of a peristaltic contraction distends the gut wall[19]. Therefore, it is important to know the passive mechanical wall properties devoid of any neurohumoral regulatory mechanisms. The biomechanical properties of the small intestine depend on its structure. Because significant structural remodeling of the intestine is occurred in the diabetes[3-9,12], therefore, the biomechanical properties of the small intestine may be also changed. To our understanding of knowledge, we consider the zero-stress state and residual strain as the most relevant quantitative aspect of remodeling because it is a measure of the non-uniformity of growth or resorption in different parts of the intestinal wall. Furthermore, the structural components of the intestinal wall must be measured at the zero-stress state because in this state the morphology and sizes of the cells and extracellular matrix are not distorted by stress and strain. In our present experiment, during the development of diabetes, the opening angles and absolute value of residual strains were decreased in the duodenum and increased in the jejunum and ileum when compared to those in the controls. High dose KYQWJJ and Gliclazide treatment partly restored this biomechanical alteration, the effect of the former is stronger. In the previous study we have discussed the possible mechanism of effect of Gliclazide on the diabetic intestinal remodeling[15]. Regarding the KYQWJJ, several previous studies have demonstrated that it could decrease blood glucose level, decrease blood lipid level, increase sensitivity of insulin and decrease resistance of insulin[16-18]. We confirmed in the present study that KYQWJJ could decrease blood glucose level in the diabetic rats. The linear regression analysis demonstrated that the linear association existed between blood glucose level with most morphometric and biomechanical data. Therefore, the effect of KYQWJJ on intestinal opening angle and residual strain is partially through its effect on the blood glucose level. These seem to be the part mechanism for the effect of KYQWJJ on the diabetic intestinal remodeling. However, regarding more detail mechanisms of effect of KYQWJJ on the diabetic intestinal remodeling, further studies should be done.

The changes in the opening angle of intestine during the development of diabetes shown in this study suggest that the morphological and biomechanical remodeling of different layers are an important determinant of growth and remodeling of the zero-stress state. Fung's hypothesis of non-uniform remodeling suggested that if the inner wall grows more than the outer wall, the opening angle will increase; whereas if the outer wall grows more than the inner wall, the opening angle will decrease[20]. In this experiment, since the changes in jejunum and ileum primarily are in the mucosa layers, the inner wall grows more than the outer wall and hence the opening angle increased. Correspondingly, the outer residual strain became more tensile whereas the inner residual strain became more compressive in these two segments. But in the duodenal segment, the opening angle and absolute value of residual strain were decreased during the diabetes. We have demonstrated that the all layers of duodenum increased after experimental diabetes and the wall became stiffer[13], at this condition the biomechanical properties of layers may determine the remodeling of the zero-stress state. Because the wall becomes stiffer, the opening angle may become smaller.

The GI wall structure or deformation changes in the diabetes may alter the relative positions of the mechanosensitive afferents (zero setting of the mechanosensitive afferents)[21]. The biomechanical remo-deling in the diabetes such as alterations of residual strain and stress distribution[15] and increase the wall stiffness[13,14] will alter the tension and stress distribution of the mechanosensitive afferents[22,23]. As results, the perception and motility of the GI tract will change as well. Hence, the morphological changes and biomechanical remodeling of GI tract in the diabetes is likely to affect the function of mechanosensitive afferents in the GI wall and further affect the motor and sensory function. After KYQWJJ treatment, the structural remodeling of different segments was partly improved, accordingly the biomechanical remodeling of these segments was partly reversed. Therefore, the KYQWJJ should have the effect to improve motor and sensory dysfunction of diabetic small intestine.

In conclusion, Chinese medicine of KYQWJJ treatment could partly restore the changes of blood glucose and insulin levels and remodeling of morphometry and residual strain of small intestine in STZ-induced diabetic rats. The linear regression analysis demonstrated that the effect of KYQWJJ on intestinal opening angle and residual strain is partially through its effect on the blood glucose level. Therefore, it is possible to develop some Chinese herbs, such as KYQWJJ, to improve the intestinal dysfunction and further may be applicable in the clinics.

## Abstract

**AIM:** To elucidate the impact of hemodynamic parameters on ultrasonography and serum fibrosis markers for the assessment of liver fibrosis in the children with infant hepatitis syndrome (IHS).

**METHODS:** Forty-one children with IHS and 46 healthy infants were examined by ultrasonography, and several hemodynamic indices such as peak systolic velocity (PSV) and resistant index (RI) of proper hepatic artery (PHA) were measured. Serum fibrosis markers including hyaluronic acid (HA), pre-collagen type-Ⅲ (PC-Ⅲ), collagen type Ⅳ (C-Ⅳ), and laminin (LN) were assayed by radioimmunoassays. In children with IHS, liver tissues were obtained either by ultrasound-guided liver biopsy ($n$ = 35) or in the course of operation ($n$ = 6). The stages of hepatic fibrosis were scored as mild ($S_1$ and $S_2$), moderate ($S_3$), or severe ($S_4$) according to liver histological diagnosis. Multiple groups comparative and Spearman correlative analyses were carried out.

**RESULTS:** Histopathologically, 39 children (95.1%) were found to have hepatic fibrosis, 12 of them stage S1 or S2, 12 stage S3, and 15 stage S4. PSV, RI of the PHA, and serum HA showed a consecutive increase from mild to severe hepatic fibrosis and a close positive correlation with hepatic fibrosis in IHS group ($r$ = 0.717, 0.745 and 0.712, respectively, $P$ = 0.001). The Doppler waveform of HV was also positively correlated with the degree of hepatic fibrosis in IHS group ($r$ = 0.783, $P$ < 0.001).

**CONCLUSION:** Combination of ultrasonic studies on the hepatic hemodynamics with the evaluation of serum HA may provide an indicator for hepatic fibrosis in patients with IHS. This may be a useful noninvasive method for the diagnosis and evaluation of the prognosis of IHS.

**Key words:** Infant hepatitis syndrome; Hepatic fibrosis; Doppler ultrasonography; Hemodynamics; Hyaluronic acid

## INTRODUCTION

Infant hepatitis syndrome (IHS)[1] is defined as elevation of serum levels of conjugated bilirubin in the first 12 mo of life, may be due to infectious, genetic, metabolic, or undefined abnormalities, giving rise either to mechanical obstruction of bile flow or to functional impairment of hepatic excretory function and bile secretion. Main symptoms are prolonged jaundice, hepatomegaly or hepatosplenomegaly, and impairment of the liver focused. Although IHS has multiple etiologies, hepatic fibrosis is one of the main pathologic features. Histology is the gold standard for assessing the degree of hepatic fibrosis and for estimating prognosis[2-6]; however, there are several limitations in the usage of liver biopsy in general clinical practice due to the invasive nature of the examination, especially in infant age group. So there is a need for a non-invasive examination, which is clinically useful and accurately reproducible.

In adults, two-dimensional ultrasonography (2DUS)[2-5,7,8], Doppler blood stream[7-10,11-14,26], and determination of serum fibrosis markers[15-19,21-23,25,26] have been performed widely for the noninvasive diagnosis of hepatic fibrosis and therapeutic surveillance[20,24], and they were also useful in the assessment of cirrhosis in the pediatric age group[27-30]. But until recently, only a few studies[31,32] focussed on infants, especially on infants with IHS.

This prospective study investigated the association

between the hepatic fibrosis in infants with IHS and hepatic hemodynamic parameters and serum fibrosis markers, correlated the results with the histological findings, and evaluated the clinical relevance of the noninvasive methods.

## MATERIALS AND METHODS

### Patients

Forty-one infants (27 boys and 14 girls; mean age 5.2 ± 3.6 mo) who were admitted in the Department of pediatrics in our hospital from January 2000 to December 2003 were included. The patients were diagnosed as infant hepatitis syndrome (IHS) according to the diagnosis criteria of the national infant virus hepatitis prevention and cure symposium[1]. Infants presented with jaundice, hepatomegaly or hepatosplenomegaly, and impairment of the liver function. They didn't have any contraindication for liver biopsy. Those with clinically overt heart failure were excluded. Etiologies included viral infection, metabolic disorders, familial cholestasis, or idiopathic neonatal hepatitis. Etiologies were categorized on the basis of their clinic and pathologic diagnosis (Table 1). Forty-six infants (34 boys and 12 girls; mean age 4.6 ± 3.6 mo) who presented with normal liver size and function, negative HBV status, and without any history of clinical signs of liver disease served as healthy controls.

### Ultrasonography

Ultrasonography was performed on all children (healthy and those with IHS) by two physicians, who were unaware of the results of the liver biopsy and any laboratory finding at the time of the examinations. All children were held in the arms of their mothers and studied after a fasting period of 2-4 h. Some of them were examined during normal sleep, some were helped by use of a sugar nipple, if necessary, and some were given a sedative drug before the examination. GE-LOGIQ9 ultrasound scanner (GE, Milwaukee, and American) equipped with an 8-MHz electric curved scanning transducer or HP 8500 ultrasound scanner (HP, Andover, American) with a 7.5-MHz electric curved scanning transducer were used for the examination. Evaluation of liver parenchyma includes the assessment of the size, configuration, homogeneity, contour, and the vascular structure. Spleen and visibility of the gallbladder were also evaluated and compared with normal data. Color Flow Mapping(CFM) was used to determine the direction of flow of the hepatic blood vessels, and Pulse Wave Doppler (PW) was used to measure the Doppler waveforms of the PHA, portal vein (PV), and hepatic vein (HV). During the PW examination, the angle between the Doppler beam and longitudinal axis of the blood vessels was kept at 30°, and Doppler sample volume was smaller than the inner diameter of vessels. In each individual, the Doppler waveforms of the PHA, PV, and HV were measured. Doppler waveform analysis was calculated from 3-5 consecutive waveforms on the Doppler tracing in each subject. Flow in the middle hepatic vein (MHV) was evaluated at subcostal or intercostals, a distance of at least 2 cm from the inferior vena cava (IVC). This distance was important to rule out the possibility that the MHV flow pattern was influenced more by the flow pattern of the IVC than by the surrounding liver parenchyma.The waveforms of the MHV were classified into 3 types[11,14]: Type 1 (HV0), regular triphasic waveforms (with a short phase of reversed flow) which were considered to be normal flow, whereas type 2 (HV1), biphasic waveforms (without reversed flow) and type 3 (HV2), flat waveforms (with continuous blood flow) were considered to be abnormal.

**Table 1 Etiology of IHS**

| Etiology | *n* | % |
|---|---|---|
| Cytomegalovirus hepatitis (CMVH) | 18 | 43.90 |
| CMVH + Glucose-6-phosphate dehydrogenase | 3 | 7.32 |
| CMVH + congenital choledochocele | 2 | 4.88 |
| CMVH + intrahepatic biliary atresia | 1 | 2.44 |
| CMVH + hemangioma | 1 | 2.44 |
| Glycogen storage disease | 5 | 12.20 |
| Infant Hepatitis Syndrome (undefined) | 8 | 19.51 |
| Congenital deformity of biliary tract (Extrahepatic biliary atresia) | 1 | 2.44 |
| Congenital choledochocele | 1 | 2.44 |
| Drug-induced hepatitis | 1 | 2.44 |
| Total | 41 | 100.00 |

### Laboratory tests

Serum total bilirubin (T-Bil), indirect bilirubin (I-Bil), direct bilirubin (D-Bil), aspartate aminotransferase (AST), alanine aminotransferase (ALT), γ-glutamyl transpeptidase (γ-GTP), alkaline phosphatase (AKP), total protein, albumin, globulin, the ratio of albumin to globulin (A/G), and prothrombin time were measured by routine methods. The etiologic differential diagnosis was made according to the presence of serological markers for viral hepatitis type B, toxoplasma, rubella, cytomegalovirus, herpes simplex, and syphilis (TORCHS) (positive IgM or more than a fourfold rise in IgG titer), and urine cytomegalovirus (CMV) culture. The serum specimens for fibrosis indices, including HA, PC-Ⅲ, C-Ⅳ and LN, were determined by commercially available radioimmunoassays (RIA kits; Shanghai Navy Medical Institution, Shanghai, China). Samples of peripheral venous blood of the subjects were collected, immediately separated, and preserved at -40℃ until they could be assayed.

### Liver biopsy and histological analysis

Liver biopsy was performed in 41 children with IHS, 35 cases underwent US-guidance liver biopsies and 6 cases underwent operation biopsies. Intercostals or subcostal ultrasound-guided liver biopsies were performed during the scanning with an 18G biopsy-cut (CR Bard, Inc., Covington, GA, USA) needle driven by the spring-loaded automatic biopsy gun (CR Bard, Inc., MAGNER, USA). The Bard biopsy gun consists of a hand-held device that triggers rapid firing of an 18G cutting needle. When the gun is fired, an inner trocar with its 1.9 cm sample notch thrusts forward, followed by its outer cannula which shears a core of tissue with minimum crushing of the specimen. For a satisfactory sampling, an average of two specimens

was obtained in each ultrasound-guided core-needle biopsy case. All biopsy specimens were 0.8-1.9 cm in length and were fixed in 10% buffered formalin. Sections were stained with hematoxylin-eosin; Masson's trichrome stain was used specially for staining of fibrous tissue components.

The stage of hepatic fibrosis was scored according to the diagnostic criteria of viral hepatitis in Xian, China, 2000[33]. S0 corresponds to the absence of fibrosis, S1 to fibrosis within portal tract areas, S2 to fibrosis around the portal tract areas with formation of fibrosis segregation while maintain lobular structure, S3 to the formation of fibrosis segregation and disorder of lobular structure without hepatic cirrhosis, and S4 to early or late stage cirrhosis. Then these patients were divided into three groups: mild (S1-S2 grade), moderate (S3 grade) and severe (S4 grade).

### Statistical analysis

The one-way ANOVA was used to compare numerical variables between multiple groups. The chi-square test and Fisher exact test were used to compare categorical variables. Association between the ranked values was evaluated using Spearman rank correlation. $P < 0.05$ was considered statistically significant. All statistical analyses were done with SPSS for windows, version 10.0 (SPSS Inc. American).

## RESULTS

In the IHS group, there was an increase in T-Bil which reached up to 810 μmol/L. D-Bil increased in almost all except for 5 children (I-Bil was higher than D-Bil). There was an increase in serum ALT activity in all cases, the highest value was 598 U/L, mean 126.9 U/L. Serum AST activity increased in all except for 3 cases, and the highest value was 2816 U/L, mean 282.4 U/L. The AST/ALT ratio was 3.5 (normal 1.15), the ratio of albumin to globulin (A/G) decreased in 29 cases, and inversed in 5 cases. Pathology showed liver fibrosis in 39 cases (95.1%), 12 cases with S1 or S2, 12 cases with S3, and 15 cases with S4. Further findings were ballooning change ($n$ = 35, 85.4%), hepatocyte necrosis ($n$ = 30, 73.2%), cholestasis in liver cells ($n$ = 26, 63.4%), cholestasis in the hepatic lobules ($n$ = 21, 51.2%), cholestasis in portal area ($n$ = 7, 17.1%), and cytomorphosis of giant corpuscle ($n$ = 20, 48.8%).

### 2DUS findings

In the 39 cases of liver fibrosis, 15 cases with S4 stage liver fibrosis (confirmed by histological diagnosis) showed that the liver parenchyma was more echogenic and coarse than normal, among which 6 severe cases with obvious echogenic changes showed nodularity of the liver edge and ascites by two-dimensional ultrasonography (2DUS). The other 24 cases with S1-S3 stage liver fibrosis (confirmed by histological diagnosis) were all hepatomegaly but the liver parenchyma was normal, except for 5 cases of Glycogen Storage Disease (1 case in S0 stage, 2 in S2 stage and 2 in S3 stage) presented with significant hepatomegaly, increased echogenicity, and slightly increased attenuation. Additionally, we found that proper hepatic arteries (PHA) in the IHS group were enlarged and even were easy to display on the 2DUS.

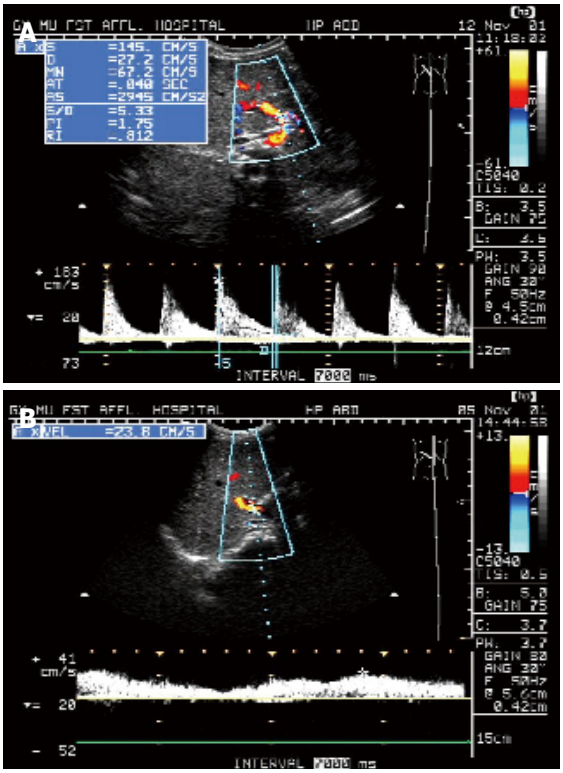

**Figure 1** **A**: Duplex Doppler Sonogram of case with IHS showed the PHA was easy to see as well as PSV and RI of the PHA increased significantly; **B**: Duplex Doppler Sonogram of the normal subject showed normal waveform of PV, and PHA cannot display clearly.

### CDUS findings

We found that PHA in the IHS group can be displayed easily on the B-Mode, as well as on the Color Flow Mappings and even better (Figure 1A). PHA can be seen in 100% of patients in IHS group but only in 58.7% of the control subjects, there was significant difference between IHS group and control group ($P < 0.001$). And then, PW parameters showed an increase in PSV, EDV, and RI (Figure 1A). PSV and RI in IHS group were significantly higher than in the control group ($P < 0.05$), as well as, with development of hepatic fibrosis from mild to severe, PSV and RI of the PHA increase gradually (Figure 2A and 2C), and EDV of the PHA decreased gradually (Figure 2B), there was a significant difference between groups ($P < 0.05$). Furthermore, PW waveform of the MHV developed from HV1 (damped biphasic waveform without reversed flow) to HV2 (flat waveform) with the severity of the hepatic fibrosis (Table 2).

### Serum fibrosis index

Serum concentration of fibrosis markers was higher in the IHS than in the control group ($P < 0.05$). Especially serum HA increased gradually from the mild to the severe group along with the severity of the hepatic fibrosis (Figure 2D), and it was significantly higher in IHS group than in the control group ($P < 0.05$). For PC-Ⅲ, C-Ⅳ and LN, there were also significant differences between infants with severe hepatic fibrosis and the control group ($P < 0.05$). When infants of the IHS group with mild or moderate

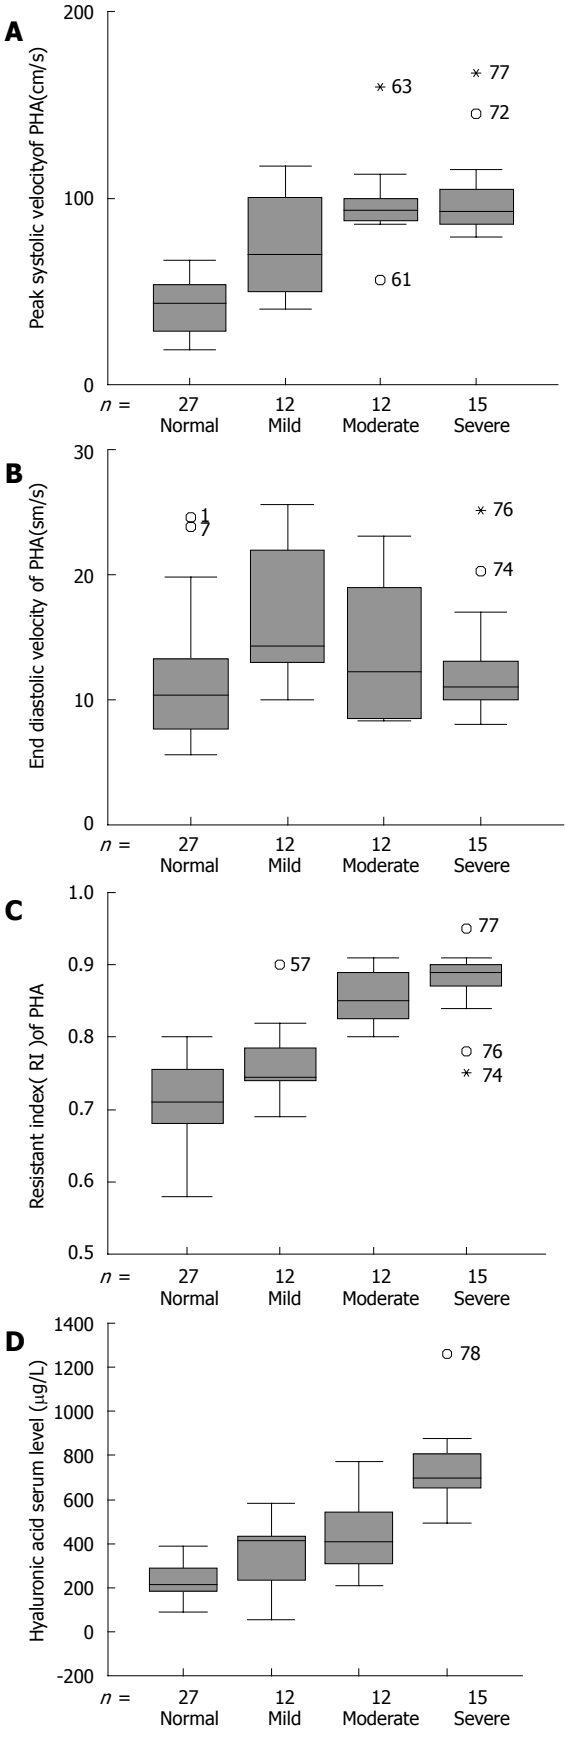

**Figure 2** Boxplots showing **A**: Significantly higher PSV of PHA in patients with advanced liver fibrosis; **B**: Decreased gradually EDV of PHA in patients with advanced liver fibrosis; **C**: Significantly higher RI of PHA in patients with advanced liver fibrosis; **D**: Significantly higher serum HA level in patients with advanced liver fibrosis.

**Table 2 Doppler sonograms in hepatic veins in patients with different fibrosis stage of IHS *n* (%)**

| Group | Patients (*n*) | HV0 | HV1 | HV2 | Total |
|---|---|---|---|---|---|
| Control group | 46 | 43 (93.50) | 3 (6.50) | 0 (0.00) | 46 (100) |
| Mild group | 12 | 2 (16.67) | 10 (83.33) | 0 (0.00) | 12 (100) |
| Moderate group | 12 | 1 (8.33) | 10 (83.4) | 1 (8.33) | 12 (100) |
| Severe group | 15 | 1 (6.67) | 10 (66.67) | 4 (26.67) | 15 (100) |

Chi-square test, $\chi^2 = 37.67$, $P < 0.001$.

fibrosis were compared to the healthy group, differences did not reach statistical significance (Table 3).

### *Correlative analyses*

We found close positive correlations between the serum HA and hepatic fibrosis ($r = 0.712$, $P < 0.001$), between PSV of PHA and hepatic fibrosis ($r = 0.717$, $P = 0.001$), and between RI of PHA and hepatic fibrosis ($r = 0.745$, $P = 0.001$). The changes of hepatic vein waveforms were also positively related to liver fibrosis ($r = 0.783$, $P < 0.001$). In contrast, liver size, the size of the spleen and hepatic capsule, the echogenicity of the liver parenchyma, the inner diameter of the PV, nor the velocity of the PV were found to be useful for the diagnosis of hepatic fibrosis in IHS patients.

## DISCUSSION

The basic pathological changes of chronic liver disease in the adults have been recognized more accurately and profoundly[33-36]. According to a new pathological classification method which was carried out in the adults in our country[33], staging of hepatic fibrosis can help us to recognize the development of the hepatic fibrosis in infants with IHS in our study. In the IHS group, 39 cases (95.1%) showed to have hepatic fibrosis by pathology. Further findings were ballooning change ($n = 35$, 85.4%), hepatocyte necrosis ($n = 30$, 73.2%), cholestasis in liver cells ($n = 26$, 63.4%), cholestasis in the hepatic lobules ($n = 21$, 51.2%), cholestasis in portal area ($n = 7$, 17.1%), and cytomorphosis of giant corpuscle ($n = 20$, 48.8%) of. Our findings showed that hepatic fibrosis was also one of the main pathologic features in the patients of this age group. We found no significant changes between the mild and the moderate hepatic fibrosis in 2DUS examination, it is compatible with other reports in the literature about adults[2,3,5-8].

PSV and RI of the PHA were significantly higher in infants with IHS than in the control group ($P < 0.05$). This phenomenon might be due to shrunken intrahepatic blood vessel space and the correspondingly increased peripheral resistance of the artery microvasscular bed, which increased the PSV and RI. This might also be the result of the severity of diffuse liver parenchyma impairment, hepatocellular degeneration and necrosis, inflammatory cell infiltration and fibrous connective tissue development[9,10]. Our findings also showed that PSV, RI of

the PHA increased gradually and EDV decreased gradually with advanced liver fibrosis, and there were significant differences between their groups ($P < 0.05$). PSV and RI of the PHA were positively correlated with the severity of liver fibrosis ($r = 0.717$ and 0.745, respectively $P = 0.001$). Hemodynamic changes of chronic liver disease in adults[7, 9,10] and in the pediatric age group[29] have been described by other researchers. Some results of our study were inconsistent with the findings of Xue *et al*[10] whose work was focused on chronic liver disease and confirmed cirrhosis in adults. One point was EDV of PHA elevating in IHS group instead of declining, another was velocity of PHA increasing without deficiency of PV. These may be concerned with a relatively short course of disease, abundant hepatic blood flow, active liver fibrosis and inflammation, or vasodilatation induced by inflammatory substances in patients with IHS.

In our findings, the changes in the waveforms of the hepatic vein were positively correlated with the severity of liver fibrosis ($r = 0.783$, $P < 0.001$). Other groups described a damped waveform in the hepatic veins of patients with liver cirrhosis, and our results were consistent with the studies of Bolondi *et al*[14]. This may be due to increased parenchyma stiffness, which impaired the compliance of the hepatic veins and caused the waveforms to change from HV0 to HV1. With the development of the hepatic fibrosis, diffuse fibrosis can cause disorganization of lobular architecture. Therefore, the hepatic veins were stenosis by pressure of the fibrosis tissues, pseudo lobule and the hepatic capsule. Furthermore, a damped waveform (HV2) in the hepatic veins was associated with focal hepatic vein stenosis[11-14].

Many groups addressed serum indexes such as HA, PC-Ⅲ, LN and C-Ⅳ, which reflected the stage of hepatic fibrosis. There is agreement that the four serum fibrosis indexes are relevant for the serodiagnosis of hepatic fibrosis, either alone[2,5,12,15,17-19,21,24,31,32] or in combination[4,16, 20,22,23,25-28]. In our study, although we found some cases were inconsistent with pathological diagnosis, even with a high stage of hepatic fibrosis, the four serum fibrosis indexes were still around normal range, but statistical results indicated that the serum fibrosis index HA increased gradually from the mild to severe group as severity of liver fibrosis increased, and was significantly higher in each of fibrosis groups than in the control group. And then, the serum fibrosis index HA has a high positive correlation with the severity of hepatic fibrosis in IHS group. For the other serum fibrosis indices, PC-Ⅲ, C-Ⅳ and LN, there was only a significant difference between the severe hepatic fibrosis group and control group. And PC-Ⅲ, C-Ⅳ had a low positive correlation with the severity of hepatic fibrosis in IHS group. There was no correlation between LN and the severity of hepatic fibrosis in IHS group. One researcher's result showed the rate of inconsistency between the four serum fibrosis indexes and stage of hepatic fibrosis: HA was 29.2%, C-Ⅳ 31.9%, PC-Ⅲ 34.5% and LN 38.1%, the rate of consistency between serum HA and stage of hepatic fibrosis was the highest one, which was followed by C-Ⅳ. This suggested that among the four serum fibrosis indexes, HA was the most ideal index for the diagnosis of hepatic fibrosis[15]. Our results were also consistent with other reports in the literature[5,15-17,22]. Furthermore, infants less than one year old belong to a special group in the mostly active developing phase, the concentration of serum fibrosis indices was affected by many factors. In particular, serum PC-Ⅲ is very high in neonates, but quickly decreases by one year of age showing a marked negative correlation with age[30].

Liver biopsy guided by ultrasound in infants in 35 cases were performed during the scanning with an 18 G biopsy-cut needle driven by spring-loaded automatic biopsy gun, satisfactory sampling were get in all cases without any complication. A level of serum total bilirubin ⩽ 200 μmol/L( former 136 μmol/ L) was indicated for liver biopsy in IHS group. According to our results, we consider that in clinical application, ultrasound-guided liver biopsy is also a valuable technology, secure, rapid, with high achievement ratio and no complication in the infant age group.

Our findings showed that young age, short course of disease, incompatibility with age and degree of liver fibrosis were the features of IHS group, parameters such as serum HA, PSV, and RI of PHA as well as the changes in the waveforms of the hepatic veins were more sensitive and reliable indicators in evaluating hepatic fibrosis in patients with IHS. Combination of ultrasonic studies on the hepatic hemodynamics with the evaluation of serum HA may provide an indicator for revealing hepatic fibrosis in children with IHS. This may be a useful noninvasive method for the diagnosis and estimation of the prognosis of IHS.

## Abstract

**AIM:** To study the association between Crohn's disease (CD), *Mycobacterium avium* subspecies *paratuberculosis* (MAP), and genetic factors by examining the role of natural resistance-associated macrophage protein 1 (*NRAMP1*) gene polymorphisms (now *SLC11A1*) in Sardinian patients with CD and controls.

**METHODS:** Thirty-seven CD patients and 34 controls with no inflammatory bowel disease (IBD) were recruited at the University of Sassari after giving written consent. Six *SCL11A1* polymorphisms previously reported to be the most significantly associated with IBD were searched. *M. paratuberculosis* was identified by IS900 PCR and sequencing. Logistic regression was used to calculate odds ratios (OR) for the associations among CD, presence of MAP, and 6 loci described above.

**RESULTS:** For the first time, a strong association was observed between polymorphisms at *NRAMP1* locus 823C/T and CD. While CD was strongly associated with both *NRAMP1* and MAP, *NRAMP1* polymorphisms and MAP themselves were not correlated.

**CONCLUSION:** Combined with previous work on the *NOD2/CARD15* gene, it is clear that the interplay of genetic, infectious, and immunologic factors in the etiology of CD is complex.

**Key words:** *Mycobacterium avium* subspecies *paratuberculosis*; Crohn's disease; *SCL11A1* polymorphisms

## INTRODUCTION

Natural resistance-associated macrophage protein 1 (NRAMP1), now strictly referred to as SLC11A1 (Solute carrier 11a1) and the gene which encodes for it is recognized as having a role in the susceptibility of men and animals to a number of mycobacterial infections. In human beings, the *NRAMP1* gene is located on human chromosome region 2q35. It is composed of 15 exons and covers at least 16 kb of DNA. It encodes an integral membrane protein of 550 amino acids that is expressed exclusively in the lysosomal compartment of monocytes and macrophages[1]. The promoter region of the *NRAMP1* gene possesses a polymorphism within a possible enhancer element containing a Z-DNA-forming dinucleotide repeat[2,3].

It has been proposed that *NRAMP1* polymorphisms play a role in susceptibility to mycobacterial infections[4,5]. To date, studies have yielded contradictory results[2]. In a West African population, NRAMP1 variants have been associated with susceptibility to *Mycobacterium tuberculosis*[6]. Malik *et al*[7] reported that variants of NRAMP1 are associated with tuberculosis (TB) in children. *NRAMP1*

gene polymorphisms have been linked with genetic susceptibility to infection with *M. tuberculosis* and progression of TB into severe clinical forms in eastern China[8]. Abe *et al*[9] reported that genetic variation in the *NRAMP1* gene is associated with tuberculous cavitation of the lungs in Japanese patients. Kim *et al*[10] found that *NRAMP1* polymorphisms are associated with tuberculous pleurisy.

Various studies have been carried out to establish a connection between *NRAMP1* variants and diseases caused by mycobacteria other than the TB bacilli, such as *Mycobacterium ulcerans* causing Buruli ulcers[11] and *Mycobacterium leprae*[12]. A recent study[5] showed that the *NRAMP1* promoter region polymorphism are positively associated with leprosy but not with the Mitsuda reaction (intradermal injection of lepromin), and that variants of the *NRAMP1* gene favour microbial survival inside the macrophages by blocking the efficient transport of iron. It was reported that the *NRAMP1* gene may have a role in some autoimmune diseases, including rheumatoid arthritis (RA)[13]. It was also reported that *NRAMP1* 823 C/C prevents the development of rheumatoid nodules in RA patients[14], type 1 diabetes[15] and multiple sclerosis[16]. Variants of the *NRAMP1* gene have been associated with improved response to Bacillus Calmette-Guerin immunotherapy for superficial bladder cancer[17]. Hofmeister *et al* showed that *NRAMP1* variants are specifically associated with Crohn's disease (CD)[18].

In a previous study, we found that CD is associated with polymorphisms of the *NOD2* gene and the pathogen MAP in Sardinian patients[19]. NOD2 protein is an intracellular protein that activates NFkB upon binding to microbial peptidoglycan. MAP is the etiological agent of Johne's disease, a granulomatous enteritis of ruminants and other monogastric animals[20]. Although the association between MAP and CD (a human equivalent of paratuberculosis) has been postulated for a long time, only recent studies have made improvements in isolation and genomic techniques have allowed this link to be firmly established in a number of different populations[21-24].

As a part of our ongoing studies with *NOD2/CARD15*, we also looked at the role of other genes, especially *NRAMP1*, which may be associated with the survival of intracellular pathogens such as MAP. The role of NRAMP1 in regulating microbial survival inside phagosomes is related to iron transport, although the mechanism has not yet been completely elucidated[5,25].

## MATERIALS AND METHODS

Patients were recruited at the University of Sassari after giving written consent. Using a case-control design, we analyzed 37 CD patients and 34 controls with no inflammatory bowel disease (IBD).

We searched for polymorphisms in 6 loci previously reported to be the most significantly associated with IBD[13]. The *SCL11A1* polymorphisms that we analyzed included a (GT)n microsatellite in the promoter region, (-)237 C/T; 469 + 14G/C, INT4; a non-conservative base substitution at codon 543 (D543N); 823 C/T; and a 4-bp TGTG deletion locating 55 nucleotides downstream of the last codon in exon 15 (1729 + del55del4).

Amplification was performed as previously reported[13] using 100 ng of template genomic DNA previously extracted from intestinal tissues. The primer sequences that we used were previously reported[13]. Detection of MAP also was performed as previously reported[24].

Logistic regression was used to calculate odds ratios (OR) for the associations among CD, presence of MAP, and the 6 loci described above. Saturated and reduced models were computed and their comparability was assessed using the likelihood ratio test. The reduced model was assessed for goodness of fit using the covariate patterns as groups. In addition, the actual and model-predicted probabilities of CD according to levels of the independent variables in the final model were calculated.

[1]Reference category; [2]Model statistics: Likelihood ratio test for equivalence with full model: $P = 0.436$; Pearson goodness-of-fit test: $P = 0.407$; Area under Receiver-Operating Characteristic curve: 0.886.

## RESULTS

Table 1 shows the full and reduced logistic regression models computed for this study. The full model showed significant associations between CD and the presence of MAP, the 1729 + 55del4 deletion polymorphism and the 823 C/T CT polymorphism. No significant associations were found between CD and the INT4, D534R, GT (n) and (-) 237 C/T loci. These non-significant loci were dropped in the reduced model and likelihood ratio testing showed no difference between the full and reduced models (likelihood ratio test: $P = 0.436$). Furthermore, the reduced model showed good fit (Pearson goodness-of-fit test: $P = 0.407$) and predictive power. We tested for significant interactions between MAP infection and each of the genetic loci, none of which was statistically significant. We therefore selected the reduced main effect model as our final model. No association was found between MAP and the 823 C/T or 1729 + 55del4 polymorphisms.

Figure 1 shows the actual and final model-predicted probabilities of CD by MAP infection and the two statistically significant loci, 823 C/T and 1729 + 55del4. The close similarity between the actual and predicted probabilities reflected the good fit of our final model to the data. Strong independent effects of MAP infection and each of the loci on the probability of CD were observed (Figure 1). Even with no mutant polymorphism, MAP infection was highly predictive of CD. Having the CT polymorphism at the 823 locus, the probability of CD was greatly increased both among patients infected with MAP and among patients not infected with MAP. The effect of deletions at the 1729 locus was more moderate. It should be noted that these probabilities were sensitive to the ratio of cases to controls in the study, which were shown here to illustrate the particularly strong association among CD, MAP infection and the 823 C/T locus as well as the close fit between the experimental data and our chosen statistical model.

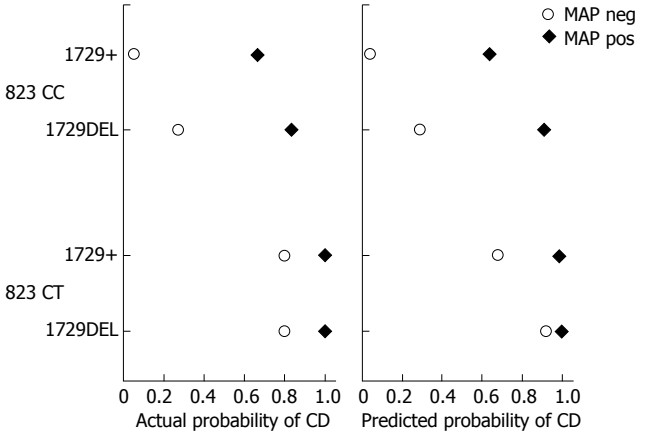

**Figure 1** Actual probability of CD and predicted probability of CD showing strong independent effects of MAP infection and each of the loci on the probability of CD.

## DISCUSSION

For the first time, a strong association has been observed between CD and polymorphisms at the 823C/T and 1729 + 55del4 loci in the *NRAMP1* gene in Sardinians.

Although the combination of MAP infection and 823 CT mutation could perfectly predict CD, generalizations were limited by the small sample size in our study. Only 8 patients in this study simultaneously had MAP infection, 823 CT mutation, and CD. It would be worthwhile to follow up this finding in a larger study to determine if these two factors are a useful prognostic index for the development of CD.

It was reported that polymorphisms in the *NOD2* gene and the presence of MAP are strongly associated with CD[19]. Both *NOD2* polymorphisms and MAP infection had a strong independent association with CD, and are also associated with one another, suggesting that susceptibility to MAP infection may be influenced by *NOD2* polymorphisms[26]. NOD2 protein is involved in the activation of NFkB factor and failure of its priming signal causes failure of pathogen clearance, possibly explaining the abnormal adaptive immune response to pathogens[27].

Our findings agree and disagree with some previous genetic studies of various *NRAMP1* loci and CD. Our finding which is lacking of association between GT (*n*) alleles and CD is consistent with the failure to find an association between any of these alleles and IBD in Americans[28]. Stokkers *et al*[29] found that mutations at the 823C/T or (-) 274C/T loci mutations are not associated with CD, which is in agreement with our findings at (-) 274C/T locus in this study. However, we have found a very strong association between CD and the 823CT polymorphism.

Although previous studies have suggested that NRAMP1 mutations may favour microbial survival, the fact that this study failed to find any association between *NRAMP1* polymorphisms and MAP infection does not support that viewpoint. Interestingly, although a previous study[6] showed allele 2 of this polymorphism is associated with mycobacterial infections, we did not find such an association between this allele and MAP infection.

The lack of association between *NRAMP1* polymorphisms and MAP infection is particularly curious because NRAMP1 is thought to directly impact microbial survival inside of macrophages. NRAMP1 is thought to either deny needed iron in intraphagosomal microbes, or to increase transphagosomal iron needed to create bactericidal hydroxyl radicals via the Haber-Weiss/Fenton reaction[25].

The 823CT and 1729 + 55del4 polymorphisms have been associated with autoimmune disease[14], but not with another mycobacterial disease, tuberculosis[30], which probably does not have an autoimmune etiology. In the present study, these polymorphisms were found to be associated with CD which probably does have an autoimmune component, but not associated with MAP infection. These findings, combined with the strong association between MAP infection and CD, suggest that *NRAMP1* polymorphisms may not cause CD by affecting the survival of MAP in intestinal tissue, but rather work together with MAP infection to cause CD *via* an autoimmune mechanism. In other words, one possible interpretation may be that these data support the aetiology of CD with both infectious and autoimmune components. At least, one study has elucidated a mechanism by which NRAMP1 affects the survival of intracellular pathogens and is simultaneously involved in autoimmune responses[25].

A further step of the study is to test the derived model on a large cohort of patients and controls.

In conclusion, CD may be strongly influenced by both NRAMP1 and MAP, although *NRAMP1* polymorphisms and MAP infection are not themselves correlated. Combined with previous work on the *NOD2/CARD15* gene, a complex interplay of genetic, immunologic and infectious factors may play a role in the aetiology of CD.

## ACKNOWLEDGMENTS

The authors are thankful to Professor Giovanni Fadda for his guidance and support. The authors are also thankful to the International Society for Genomic and Evolutionary Microbiology (ISOGEM) for supporting and endorsing the study.

## Abstract

**AIM:** To determine the complications and incidence of the first and second access-related vascular injuries induced by videolaparoscopic cholecistectomy.

**METHODS:** We retrospectively reviewed vascular injuries in 200 consecutive patients who underwent videolaparoscopic cholecistectomy from 2003 to 2005. One hundred and one patients with placement of radial expanding trocars were assigned into group A and 99 patients with placement of pyramidal tipped trocars into group B. All the patients were submitted to open access according to Hasson for the first trocar.

**RESULTS:** Bleeding did not occur at the intraoperative cannula-site in group A. However, it occurred at the intraoperative cannula-site of 7 patients (7.1%) in group B, with a statistically significant difference ($P < 0.01$). No mortality was registered. More vascular lesions were found in group B.

**CONCLUSION:** The advantage of Hasson technique is that peritoneal cavity access is gained under direct vision, preventing most severe injuries. The open technique with radial expanding trocars is recommended for secure access to the abdominal cavity in videolaparoscopy. Great care should be taken to avoid major complications and understanding the abdominal wall anatomy is important for reducing bleeding during or after s placement of trocars.

**Key words:** Videolaparoscopy; Minor vascular complications; Trocars; Prevention

## INTRODUCTION

As minimally invasive techniques become more popular in modern surgery, laparoscope is now an instrument used by almost all surgical disciplines[1].

Primary and secondary accesses to the peritoneal cavity are the most crucial phases of laparoscopy. In fact vascular and visceral injuries (0.003%-6%) have been reported secondary to incisions made for positioning the laparoscopic cannulae or ports[1-3].

These injuries usually occur during the initial phase of operation or during placement of secondary cannulae, which should be placed under direct vision and with prior transillumination of the abdominal wall[4]. The technique of open laparoscopy developed by Harrith M. Hasson in 1970[4] combines safety of minilaparotomy with versatility of laparoscopy. This open access technique has also been introduced with the aim of reducing such injuries[3].

The aim of this study was to evaluate our laparoscopic experience with a focus on access-related vascular injuries and compare the effectiveness of two different types of trocar.

## MATERIALS AND METHODS

We retrospectively reviewed the vascular injuries in 200 consecutive patients who underwent videolaparoscopic cholecystectomy in our university hospital from 2003 to 2005, with the approval of the ethics committee of our hospital.

One hundred and one patients with placement of radial expanding trocars (Ethicon Endo-Path Excel Endo-Surgery©) were assigned into group A and 99 patients with placement of pyramidal tipped trocars (Ethicon Endo-Path Tristar Endo-Surgery©) into group B. All the patients were submitted to open access according to Hasson for the first trocar, and then the following trocars were introduced under direct vision, after abdominal wall puncture and transillumination. We even used "open access" as previously described[4].

Carbon dioxide was insufflated into the intra-abdominal cavity with a pressure of 10-12 mmHg. We did not formally evaluate the time needed to achieve

abdominal entry and distension during open laparoscopy, but we noted that it generally varied from 3 to 10 min. Time variations depended on patient weight, abdominal wall strength, a well-developed Richet's fascia and post-operative fibrosis.

The diameter of Hasson, subxyphoid, and hypocondriac trocars was 10, 5, and 10 mm, respectively. The "primary access-related complications" were defined as those caused by the introduction of the first trocar and the "secondary access-related complications" as those caused by the introduction of the second or following trocars in the open access using Hasson's technique.

## RESULTS

The age, gender, clinical history, comorbidity and American Society of Anesthesiology (ASA) classification of the patients were similar in both groups (Table 1).

Primary access-related complications occurred in 7 cases (3.5%), all in group B. No first-trocar lesions (Hasson-related) were registered in the two groups. Secondary access-related complications occurred in 6 cases of epigastric vessels injuries, all of which were treated with direct suture by the end of general anaesthesia (in all cases the bleeding started at the disinflation of pneumoperitoneum). One case (0.5%) of large abdominal wall haematomas was managed conservatively. No bleeding occurred at the intra-operative cannula-site in group A. However, bleeding occurred in 7 patients (7.1%) of group B, with a statistically significant difference ($P < 0.01$). Statistical analysis was performed by $\chi^2$ test and $P < 0.01$ was considered statistically significant. No intraoperative morbidity or mortality was registered in our study.

**Table 1 Personal experience**

| | Group A | Group B | *P* |
|---|---|---|---|
| Equipe position | French | French | - |
| ASA class Ⅰ / Ⅱ / Ⅲ | 10/64/27 | 8/72/19 | NS |
| Bleeding comorbidities | 4% | 1% | NS |

| Patients | 101 | 99 | NS |
| M:F ratio | 0.6:1 | 0.6:1 | NS |
| Age (mean) | 62 | 64 | NS |
| Body weight (mean, Kg) | 72.7 | 70.8 | NS |
| Bleeding (7 cases = 3.5%) | 0 | 7 (7.1%) | < 0.01 |
| Relaparotomy | 0 | 0 | 0 |
| Mortality | 0 | 0 | - |

## DISCUSSION

Between 1997 and mid-2002, FDA received more than 1300 trocar-associated injury reports, including 30 deaths. Hemorrhage due to vessel injury and infection secondary to bowel injury, especially when diagnosis is delayed, are the most serious complications which most likely result in death. Most data suggest that the rate of trocar-related complications is about 0.003%-6% and the average incidence of trocar-related vascular injuries is approximately 0.1%[5,6].

Minor vascular injuries are referred to the injuries to vessels of lesser importance than the aorta, inferior vena cava and iliac vessels. By far, the most common minor vascular injury of the inferior epigastric vessels occurs in up to 2.5% of laparoscopic cholecystectomies[3,7].

The major advantage of the open access technique using a step-by-step entrance to all layers of the abdominal wall is that peritoneal cavity access is gained under direct vision, preventing severe injuries[5].

The "11 secured steps" for the safe insertion of trocars using conical disposable trocars are recommended[8]. A randomized study comparing the conventional cutting with radial expanding trocars at all port sites reported that there is a significant difference in cannula-site bleeding and post-operative wound complications, which is in favour of using radial expanding trocars[9].

In a rabbit model, the relative risk of vessel injury induced by pyramidal tipped trocars is significantly increased compared with that induced by conical tipped trocars, especially if larger diameter trocars are used. The smooth contour of the conical tip stretches and separates the tissue layers with little damage, whereas the sharp-edged pyramidal tip lacerates any tissue it encounters, including vessels, even if the trocar is inserted directly over (in 88% of cases, partial interruption of vessel) or at 1-2 mm from the vessel (no injuries)[10,11].

In 1999, Balzer KM *et al*[11] dissected the abdominal walls of 21 cadavers transversally and measured the morphometric distances as well as determined the distances of the epigastric arteries and the ascending branch of the deep circumflex iliac artery from the midline and lateral edge of rectus muscle. The results showed that In order to minimize the danger of lesions of abdominal vessels, trocars should be placed in the ventral midline or in a 5 cm wide zone to the lateral border of the rectus sheath.

If prevention fails, it is possible to try to tamponade by applying pressure to the abdominal wall with a balloon trocar or a Foley catheter pulled against the abdominal wall and attached to a clamp (the temporary pressure usually stops bleeding from small vessels or veins), which should not be used to stop the bleeding at the trocar site.

If significant bleeding occurs, ligation is needed using Keith or Reverdin needle and large suture that can be removed in the recovery room when the patient awakens. Occasionally, in catastrophic bleeding from the abdominal wall, an incision should be made to dissect down the bleeding vessels and control the bleeding by ligation[12].

In conclusion, the risk of vessel injury varies markedly with the different trocars used. The open technique with radial expanding trocars is recommended for access to the abdominal cavity during videolaparoscopy. However, open laparoscopy cannot prevent small bowel injury or post-operative herniation, but can eliminate failed laparoscopy attempts, inappropriate insufflation, gas embolism, peritoneal, stomach, colon and vessel injury.

## Abstract

**AIM:** To study the effects of amphetamine, an indirect-acting adrenomimetic compound on the indomethacin-induced gastric ulcerations in rats.

**METHODS:** Male Wistar-Bratislava rats were randomly divided into four groups: Group 1 (control), received an ulcerogenic dose of indomethacin (50 μmol/kg) and Groups 2, 3 and 4, treated with amphetamine (10, 25 and 50 μmol/kg). The drug was administered simultaneously with indomethacin and once again 4 h later. The animals were sacrificed 8 h after indomethacin treatment. The stomachs were opened and the incidence, the number of lesions and their severity were evaluated. The results were expressed as percentage and as mean ± standard error (mean ± SE).

**RESULTS:** The incidence of ulceration in the control group was 100%. Amphetamine, at doses of 10, 25 and 50 μmol/kg, lowered the incidence to 88.89%, 77.78% and 37.5% respectively. The protection ratio was positive: 24.14%, 55.17% and 80.6% respectively. The total number of ulcerations/rat was 12.44 ± 3.69 in the control group. It decreased to 7.33 ± 1.89, 5.33 ± 2.38 and 2.25 ± 1.97 under the effects of the above-mentioned doses of amphetamine.

**CONCLUSION:** Amphetamine affords a significant dose-dependent protection against the indomethacin-induced gastric ulcerations in rats. It is suggested that the adrenergic system is involved in the gastric mucosa protection.

**Key words:** Amphetamine; Gastric ulceration; Indomethacin; Rats

Sandor V, Cuparencu B, Dumitrascu DL, Birt MA, Krausz TL. Protective effects of amphetamine on gastric ulcerations induced by indomethacin in rats. *World J Gastroenterol* 2006; 12(44): 7168-7171

## INTRODUCTION

The involvement of the adrenergic system in some models of gastric ulcerations is well documented[1-4]. Our previous investigations have shown that amphetamine, an indirectly acting sympathomimetic amine has a protective activity on gastric ulcerations induced by reserpine and immobilization in rats[5]. These findings were interpreted as an evidence of a protective activity of the adrenergic mechanisms on the integrity of the gastric mucosa[3,4,6].

Other models of gastric ulcers imply the administration of some nonsteroidal anti-inflammatory agents such as acetylsalicylic acid[7], phenylbutazone[8] or indomethacin[9]. The genesis of these ulcerations arises from both the local depression of prostanoid biosynthesis[10-12] and a local injury[13]. However, the participation of the adrenergic system in this experimental setting is not excluded[14,15].

In this paper, we studied the effect of amphetamine on the indomethacin-induced gastric ulcerations in albino rats.

## MATERIALS AND METHODS

### *Animals and ulcer model*

The experiments were carried out on male Wistar albino rats, weighing 144-255 g (from the Animal Center of University of Medicine and Pharmacy Iuliu Haţieganu, Cluj-Napoca). The animals were kept in a room with a constant temperature (20-22℃) and humidity, under a natural light-dark regime. They were fed common rat chow and received water ad libitum. The food was withdrawn 12 h prior to administration of the ulcerogenic agent. The rats were randomly divided in four groups.

Control group (Group Ⅰ) was administered intraperitoneally (ip) with indomethacin 50 μmol/kg. Groups Ⅱ, Ⅲ and Ⅳ were simultaneously ip injected with

**Table 1 Effect of amphetamine on incidence and severity of indomethacin-induced gastric ulcerations (%)**

| Groups | | TU | LU | PR |
|---|---|---|---|---|
| I | $I_{50}$ | 100 | 100 | |
| II | $I_{50} + A_{10}$ | 88.89 | 77.778 | (+) 24.138 |
| III | $I_{50} + A_{25}$ | 77.78 | 66.667 | (+) 55.172[1] |
| V | $I_{50} + A_{50}$ | 37.5[a] | 12.5[a] | (+) 80.603[1] |

The subscript indices represent the doses expressed as μmol/kg. I : Indomethacin; A: Amphetamine; TU: Total number of ulcerations; LU: Large ulcerations (> 1 mm); PR: Protection ratio. [a]$P < 0.05$ *vs* group I (Fischer's exact probability and median's test); [1]Significant at PR > (+) 33.33%.

**Table 2 Effect of amphetamine on number and severity of indomethacin-induced gastric ulcerations (mean ± SE)**

| Groups | | Number of ulcerations/stomach | | Severity |
|---|---|---|---|---|
| | | TU | LU | UI |
| I (9) | $I_{50}$ | 12.44 ± 3.69 | 10.11 ± 3.74 | 1.61 ± 0.31 |
| II (9) | $I_{50} + A_{10}$ | 7.33 ± 1.89 | 5.44 ± 1.52 | 1.22 ± 0.25 |
| III (9) | $I_{50} + A_{25}$ | 5.33 ± 2.38 | 3.11 ± 1.9 | 0.72 ± 0.21[a] |
| IV (8) | $I_{50} + A_{50}$ | 2.25 ± 1.91[c] | 1.0 ± 1.0[c] | 0.31 ± 0.19[b] |

The subscript indices represent the doses expressed as μmol/kg. I: Indomethacin; A: Amphetamine. TU: Total number of ulcerations; LU: Large ulcerations (> 1 mm); UI: Ulcer index. [a]$P < 0.05$, [b]$P < 0.01$, [c]$P < 0.05$ *vs* group I .

indomethacin and amphetamine sulphate, and 4 h later, only with amphetamine. The doses of amphetamine were 10, 25 and 50 μmol/kg , respectively.

During the ulcerogenesis period, the rats were fasted, but water was allowed ad libitum. Eight hours after indomethacin administration, the animals were sacrificed; the stomachs were removed, opened along the curvatura maior and rinsed with saline. They were examined immediately, with a magnifying glass. The following parameters were recorded: the body weight (g), the incidence of ulcerations/group, the total number of ulcerations (TU), the number of large ulcerations (LU) i.e. ulcerations larger than 1 mm and the severity of ulcerations estimated according to a scale between 0 and 4 (ulcer index-UI)[3].

### Drugs

**Indomethacin:** Powder supplied by Terapia SA, Cluj-Napoca, Romania, was suspended in a mixture of 2% methylcellulose and 1% glycerin, ten times diluted with saline. The concentration was 0.025 mol/L (8.945 g/L) and the dose, 50 μmol (17.89 mg)/kg.

**Amphetamine sulphate (racemate):** It was prepared as an aqueous solution 0.025 mol/L (9.21 g/L) for the dose of 50 μmol (18.425 mg)/kg. Doses of 10 μmol (3.685 mg)/kg and 25 μmol (9.2105 mg)/kg were adapted after dilution. All drugs were ip administered in a volume of 2 mL/kg.

### Ethical issues

The study was conducted in accordance with the Helsinki's Declaration on Animal's Studies and approved by the local ethics committee.

### Statistical analysis

All values are expressed as means and standard errors (mean ± SE). The indicators of ulcerogenesis were analyzed initially by a one-way ANOVA test. The significance of differences between groups was observed by the bilateral Student's *t* test and by multiple comparison tests of Newman-Keuls and Scheffé. This last test allows comparisons between blocks of groups. These procedures were followed by non-parametric Kruskal-Wallis, Mann-Whitney, median's and Fischer's exact probability tests[16,17]. The statistical significance of the differences was admitted if $P < 0.05$.

The protection ratio (PR) was calculated according to the formula:

$$PR\% = (UI_{control} - UI_{treated}) / UI_{control} \times 100$$

Statistical significance for PR was considered for values outside (-) 33% → (+) 33% range[3].

## RESULTS

The body weight of the rats was a homogenous parameter, i.e. there were no significant differences between groups (data not included in Tables). The doses of 25 and 50 μmol/kg of amphetamine induced a stereotyped behavior. It was not affected by indomethacin.

Indomethacin induced ulcerations in 100% of the rats. The total number of ulcerations was 12.4 ± 3.69, most of them (10.1 ± 3.74) were larger than 1 mm. The UI was 1.61. When amphetamine was administered, all the parameters diminished in a dose-dependent manner (Tables 1 and 2). In addition, a dose-dependent increase of the PR was found (Table 1).

Significant differences between the control group and the groups treated with 25.0 μmol/kg and 50.0 μmol/kg of amphetamine were found in most tests. Some tests showed significant differences between the 10.0 μmol/kg amphetamine administered group and the group that received 50.0 μmol/kg (Tables 1 and 2). For the parameters of ulcerogenesis (TU, LU, and UI), an increase of significance was found in the order: total ulcerations (TU) < ulcerations larger than 1 mm (LU) < ulcer index (UI).

## DISCUSSION

These results seem at first glance rather surprising, since, according to most authors, the ulcerations produced by nonsteroidal anti-inflammatory agents are due to an impaired prostanoids biosynthesis in the gastric mucosa[10,18,19], and to a local injury as well[13].

It is possible that other mechanisms are involved in the ulcerogenesis caused by indomethacin: the direct cytotoxic effect[20], the promotion of apoptosis of gastric mucosal cells[21-23] as well as the induction of interactions between polymorphonuclear leukocytes and endothelium of gastric mucosa vessels[24-28]. The effects of amphetamine may be related to any of these mechanisms. However, only the links between prostaglandins and adrenergic system are firmly established[29]. Prostaglandins, particularly those

from E series inhibit catecholamines release[30,31]. On the other hand, adrenergic stimulation evokes an increase of prostaglandin release[32,33].

It is well known that amphetamine acts mainly via the release of dopamine and noradrenaline from both central and peripheral sites[34,35]. The question arises whether dopamine or noradrenaline or both are involved in the protection of gastric ulcerations afforded by amphetamine. Our previous results have shown that dopaminergic mechanisms were not involved in the protective activity of amphetamine and catecholamines in restraint and reserpine-induced gastric ulcerations[3,5,7]. We did not investigate the involvement of dopamine receptors in indomethacin-ulcerations.

On the other hand, there are data in the literature indicating that the dopaminergic system may be also involved in the genesis of the ulcerations induced by nonsteroidal anti-inflammatory agents[36,37]. So, dopaminergic agonists, such as apomorphine and bromocriptine, diminished significantly the incidence and the severity of the ulcerations evoked by indomethacin in albino rats. The protective activity of apomorphine was antagonized by haloperidol[36]. This agent and other dopaminergic antagonists aggravated gastric ulcerations induced by indomethacin[36], reserpine[37] and stress[38,39]. These findings suggest that dopamine would have a protective activity in various models of experimental ulcers[37,40-42]. It was also shown that gastric pentadecapeptide BPC 157 markedly affects the central and peripheral dopaminergic system. It blocks the acute stereotype??? elicited by amphetamine[43]. At the same time, it completely prevents the gastric ulcerations induced by haloperidol[37,44].

More recently, a cocaine- and amphetamine-regulated transcript (CART) messenger RNA was isolated from the brain[45,46], peripheral nerves[47] and tissues[48,49]. Its corresponding polypeptide inhibits after central injection, food intake, the gastric emptying and gastric acid secretion in 24 h fasted rats. However, CART polypeptide, ip injection does not have the same effect. It was also shown that the intracisternal injection of CART greatly reduces the gastric acid output elevated by subcutaneous indomethacin administration[50]. These data are consonant with the view that the adrenergic system has a protective action on gastric mucosa.

In conclusion, amphetamine protects gastric mucosa against the damaging effect of indomethacin. The mechanism of action is still obscure, it might involve both the central and peripheral segments of the adrenergic system.

## Abstract

**AIM:** To validate a non-invasive method to detect gastric mucosal atrophy in a Chilean population with high prevalence of gastric cancer and a poor survival rate.

**METHODS:** We first determined the optimal cut-off level of serum pepsinogen (PG)-1, PG-1/PG-2 ratio and 17-gastrin in 31 voluntary symptomatic patients (mean age: 66.1 years), of them 61% had histologically confirmed gastric atrophy. Then, in a population-based sample of 536 healthy individuals (209 residents in counties with higher relative risk and 327 residents in counties with lower relative risk for gastric cancer), we measured serum anti-*H pylori* antibodies, PG and 17-gastrin and estimated their risk of gastric cancer.

**RESULTS:** We found that serum PG-1 < 61.5 μg/L, PG-1/PG-2 ratio < 2.2 and 17-gastrin > 13.3 pmol/L had a high specificity (91%-100%) and a fair sensitivity (56%-78%) to detect corpus-predominant atrophy. Based on low serum PG-1 and PG-1/PG-2 ratio together as diagnostic criteria, 12.5% of the asymptomatic subjects had corpus-predominant atrophy (0% of those under 25 years and 20.2% over 65 years old). The frequency of gastric atrophy was similar (12% *vs* 13%) but *H pylori* infection rate was slightly higher (77% *vs* 71%) in the high-risk compared to the low-risk counties. Based on their estimated gastric cancer risk, individuals were classified as: low-risk group (no *H pylori* infection and no atrophy; *n* = 115; 21.4%); moderate-risk group (*H pylori* infection but no atrophy; *n* = 354, 66.0%); and high-risk group (gastric atrophy, with or without *H pylori* infection; *n* = 67, 12.5%). The high-risk group was significantly older (mean age: 61.9 ± 13.3 years), more frequently men and less educated as compared with the low-risk group.

**CONCLUSION:** We propose to concentrate on an upper gastrointestinal endoscopy for detection of early gastric cancer in the high-risk group. This intervention model could improve the poor prognosis of gastric cancer in Chile.

**Key words:** Gastric cancer; *H pylori*; Gastric atrophy; Non-invasive diagnosis; Pepsinogen; Gastrin

## INTRODUCTION

Gastric cancer (GC) is still highly prevalent in Chile and the world[1]. With the exception of Japan, which has implemented early detection strategies through the population screening, the diagnosis of GC is usually late and its prognosis is very poor. In Chile, a study showed that a global survival rate at 5 years after diagnosis was less than 15%, although it surpassed 90% when early stage tumors were treated with curative resection[2].

In spite of the identification of *H pylori* infection as a relevant etiological factor, this has not yet led to significant changes in the diagnostic or therapeutic strategy. The initial pathogenic role of *H pylori* infection is currently undisputed, explaining between 70% and 90% of GC risk in a given population[3,4]. As first postulated by Correa[5], *H pylori* produces an inflammation of the gastric mucosa (gastritis) that, evolving asymptomatically through many years, progresses in a decreasing proportion to gastric atrophy (GA), intestinal metaplasia, dysplasia, and finally to well differentiated adenocarcinoma. Other diverse environmental and genetic factors modulate this chain of

events. Atrophy and intestinal metaplasia of the gastric mucosa are doubtfully reversible lesions that determine a significant increase in the risk of developing GC[5,6].

The "gold standard" for the diagnosis of gastric atrophy is the histological study of biopsies obtained during an upper gastrointestinal (GI) endoscopy, an invasive method hardly suitable for population screening. Non-invasive strategies, applicable to an asymptomatic population, would allow having better knowledge of the frequency and natural history of gastric mucosal atrophy, testing prevention strategies and diagnosing more effectively the progression to (early) gastric cancer.

The possibility to detect gastric atrophy by means of some serum markers, such as pepsinogen (PG)-1, PG-1/PG-2 ratio and 17-gastrin, has recently been described[7-9]. However, the apparent geographic or even racial variability in the diagnostic performance of these tests precludes its simple extrapolation to our milieu.

The general objective of this study was to validate a non-invasive diagnostic tool for gastric mucosal atrophy and then to apply it to an asymptomatic population in order to identify the population groups at greater risk for developing GC. The specific objectives were: (1) to determine the diagnostic performance of PG-1, PG-1/PG-2 and 17-gastrin in serum for the diagnosis of gastric atrophy in a sample of symptomatic patients, compared to the histology as a gold standard; (2) to determine serologically the frequency of gastric atrophy in a sample of asymptomatic subjects residing in counties with different risks of developing GC; and (3) to non-invasively categorize the estimated risk of developing GC in the same sample.

## MATERIALS AND METHODS

### Subjects

For the diagnostic validation study, we included voluntary patients older than 40 years old, with clinical indications for upper GI endoscopy. Exclusion criteria were: use of proton pump inhibitors within the last month, gastric cancer, active peptic ulcer or previous gastric resection. The Ethics Committee of our institution approved the study.

For the population study, we used the sera of 536 subjects selected from the 3600 subjects that constituted a random Chilean population sample in which a National Health Survey was performed[10]. This sub-sample was obtained by ordering the subjects from the original sample according to mortality risk for GC in their county of residence (described below) and then selecting subjects from the extreme counties on the list (those with greater and lower relative risk of GC, respectively) until reaching the number of available determinations.

### Diagnostic validation study

After obtaining informed consent from the patients, an upper GI endoscopy was performed. Two sets of biopsies from the gastric corpus and the antrum (both the gastric wall and greater curve) were sent separately for histological analysis. An additional antral biopsy was destined to a rapid urease test (ProntoDry®, Medical Instrument Corp, Brignais, France). Serum from a 10-mL blood sample was separated and stored at -20℃ until processing.

### Population study

Blood samples were obtained from all over the country during the 2003 National Health Survey, sent to regional hospitals and then to our center, where the sera were stored at -80℃ until processing. The categorization of relative risk (RR) of GC for each subject was calculated according to the mortality rates for GC registered in his/her county of residence during 1985-2002, corrected for age, sex and population size, and adjusted through a hierarchical Poisson regression model, considering the extra-Poisson structural variability, estimated by Bayesian analysis[11,12]. The counties with a RR of mortality for GC > 1 were considered high-risk counties.

### Analytical determinations

For anti-*H pylori* serology, the commercial bioelisa assay HELICOBACTER IgG (BioKit®, Barcelona, Spain) was used. In previous studies, we determined that the most appropriate cut-off level for the diagnosis of *H pylori* infection in the Chilean adult population was 72.8 arbitrary units (AU)/mL.

Determination of serum levels of PG-1, PG-2 and 17-gastrin was performed using a commercial ELISA assay (Gastropanel®; (BioKit®, Helsinki, Finland), following the manufacturer's instructions.

### Histological study

The formalin-fixed and paraffin-embedded samples were cut into thin sections and stained with hematoxylin-eosin (H&E). The modified Sydney classification[13] was used to classify the histological findings in the gastric corpus and the antrum separately. We used previously described criteria for histological categorization[14]. Non-atrophic chronic gastritis was defined as the presence of chronic inflammation (score $\geqslant$ 1), with or without acute inflammation, with no atrophy (score = 0) in the corpus or the antrum. Chronic atrophic gastritis was diagnosed in the presence of atrophy (Sydney score $\geqslant$ 1), with or without intestinal metaplasia, associated with chronic inflammation (score $\geqslant$ 1). The patients with atrophic gastritis were classified as antrum predominant when the atrophy score was greater in the antrum than in the corpus, corpus predominant when the score was greater in the corpus and multifocal when the score was the same in the both sites.

### Statistical analysis

The Student's *t* test, ANOVA or Kruskal-Wallis test were used for univariate analysis of the discrete variables (age and serum levels of PG-1, PG-1/PG-2, 17-gastrin) and the chi-square test or the Fisher exact test for categorical variables (sex, endoscopy variables and levels of PG-1, PG-1/PG-2 and 17-gastrin above or below the respective cut-off levels) associated with the presence of histological atrophy. Through ROC (receiving operator characteristic) curves, the best cut-off levels were determined for the serum levels of PG-1, PG-1/PG-2 and 17-gastrin for the detection of the antrum and corpus atrophy (Table 1). To evaluate the diagnostic performance of the serologic

[1]Suggested by the manufacturer; [2]Determined by ROC curves; [3]To detect corpus-predominant atrophic gastritis; [4]To detect antrum-predominant atrophic gastritis; [5]LR = likelihood ratio.

determinations, we used the likelihood ratio (LR) and Youden's J index[15] (Table 2). Nominal logistic regression was used to perform a multivariate analysis of variables associated to the groups with different estimated risks of GC (Table 3). A $P$ value less than 0.05 was considered statistically significant. The statistical analyses were performed using Epi Info version 3.2 (Epidemiology Program Office, CDC, Atlanta, GA, USA) and SPSS version 14 (SPSS Inc, Chicago, Illinois, USA) computer programs.

## RESULTS

### Diagnostic validation of the serologic methods

Thirty-one patients (21 women, 68%) with an average age of 66.1 (range: 42-90) years were included. Endoscopy was normal in 12 (39%) patients, compatible with gastric atrophy in 8 (26%) patients, showed erosive esophagitis in 2 (6.45%) patients and erosive antropathy in 1 (3.22%) patient. Using histology, serology and rapid urease test, *H pylori* infection was found in 13/31 (42%) patients. The serum level of PG-1 was significantly greater in the *H pylori*-infected patients (136.7 ± 60.8 μg/L) as compared with the non-infected patients (78 ± 68.2 μg/L) ($P < 0.05$). The serum levels of PG-2 and 17-gastrin and the PG-1/PG-2 ratio were similar in the both groups.

### Histological features of the gastric specimens

According to the Sydney classification[13], chronic gastritis was found in 29 (94%) patients, 19 (61%) of them were atrophic. The atrophy was antrum-predominant in 10 (53%) patients, corpus-predominant in 8 (42%) and multifocal in 1 (5%) patient. Glandular atrophy was scored as moderate or severe (score ⩾ 2) in 47% of the cases. The frequency of *H pylori* infection was higher in the patients with chronic non-atrophic or antrum-predominant atrophic gastritis compared to the patients with corpus-predominant atrophic gastritis (60% and 11%, respectively; $P = 0.054$).

### Correlation between histology and serum levels of pepsinogen and gastrin

The results are summarized in Table 1. The serum level of PG-1 was significantly lower in the group with the corpus atrophy, and the PG-1/PG-2 ratio was also lower in this group, although without attaining statistical significance. In comparison with non-atrophic gastritis, the average serum level of 17-gastrin was significantly lower in the patients with the antrum atrophy and significantly higher in those with the corpus atrophy. Table 2 shows the diagnostic performance of the different determinations for the detection of the corpus or antrum gastric atrophy, using the cut-off levels recommended by the manufacturer and those determined through ROC curves. The latter slightly improves sensitivity for the diagnosis of the corpus atrophy, conserving high levels of specificity, which determines LR+ in ranges close to those considered clinically useful (> 10)[16] and a slight improvement in the Youden's J index. The diagnosis of the antrum atrophy through the 17-gastrin level was not reliable. In contrast, the 17-gastrin level over 13.3 pmol/L had a diagnostic performance comparable to PG-1 and the PG-1/PG-2 ratio to diagnose the corpus atrophy.

### Population study

Of the 536 subjects, 209 resided in counties at high risk for GC (mean RR = 1.25) and 327 in counties at low risk for GC (mean RR = 0.8). The frequency of *H pylori* infection was 72.9% (95% CI: 70%-76%). The frequency

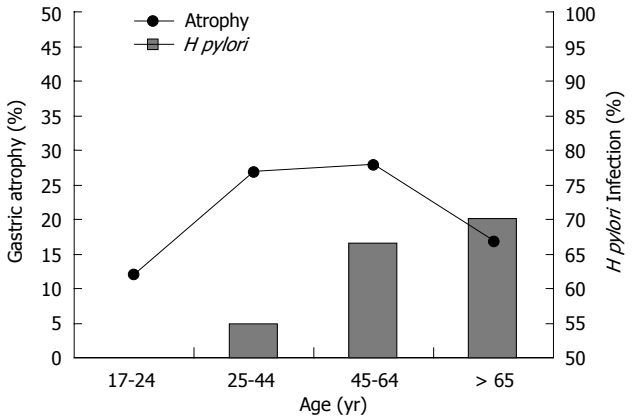

**Figure 1** Frequency of gastric atrophy and *H pylori* infection in 536 asymptomatic subjects by age.

of the corpus atrophy was 26.5% when using serum level of PG-1 ⩽ 61.5 μg/L as a diagnostic criterion, and 12.5% when using the more restrictive combination of PG-1 ⩽ 61.5 μg/L and PG-1/PG-2 ⩽ 2.2[17], which was used for the following analyses.

The frequency of *H pylori* infection was higher in the counties with high RR for GC (76.6%) compared to those with low RR (70.6%), although did not reach a statistical significance. The frequency of gastric atrophy was similar between the both groups (11.5% and 13.1%, respectively). The gastric atrophy was significantly correlated with age (Figure 1). No atrophy was detected in the subjects younger than 25 years, while 20.2% of those older than 65 years had PG-1 level and PG-1/PG-2 ratio compatible with the corpus atrophy, which probably explained the reduction in the serological evidence of *H pylori* infection observed in this group.

Using serological data, we divided the samples into three groups: Group A = no *H pylori* infection and no gastric atrophy (low GC risk); Group B = *H pylori* infection but no gastric atrophy (moderate GC risk); and Group C = serological evidence of gastric atrophy, with or without *H pylori* infection (high GC risk). The demographic characteristics and relevant comparisons among the three groups are shown in Table 3. There were significant differences in the distribution of some variables classically related with GC risk, such as age and educational level. Similar to the samples of the symptomatic patients, *H pylori* infection was associated with a significant elevation of PG-1 (87.4 ± 53.2 in non-infected group *vs* 116.6 ± 51.2 μg/L infected group; $P < 0.05$). Similarly, the corpus atrophy was associated with a significant elevation in the serum level of 17-gastrin (Table 3). The proportion of the subjects residing in counties with a high RR of GC was not significantly different among the three groups, although due to the relatively low frequency of gastric atrophy, dispersion of this parameter was wide (95% CI: 25.3%-43.3% for Group A; 36.1%-46.6% for Group B; and 24.5%-48.5% for Group C). In a multivariate analysis, using Group A as a reference, the only variable associated with *H pylori* infection (Group B) was 17-gastrin (OR: 1.05 (95% CI: 1.005-1.10), $P < 0.05$). For the gastric atrophy, the most significant variable was 17-gastrin (OR: 1.13 (95% CI: 1.07-1.18), $P < 0.001$), and also male (OR: 2.08 (95% CI: 1.07-4.04), $P < 0.05$) and older age [OR: 1.02 (95% CI: 1.004-1.05), $P < 0.05$] were significant risk factors, while educational level was a protective factor [OR: 0.9 (95% CI: 0.84-0.99), $P < 0.05$].

**Table 3 Characteristics of the asymptomatic population samples according to the estimated gastric cancer risk**

| Characteristics | Estimated gastric cancer risk | | | Total ($n$ = 536) |
|---|---|---|---|---|
| | Low (A) ($n$ = 115) | Medium (B) ($n$ = 354) | High (C) ($n$ = 67) | |
| Corpus atrophy[1] | Absent | Absent | Present | |
| *H pylori* infection[2] | Absent | Present | Present or absent | |
| Men, *n* (%) | 46 (40.0) | 168 (47.5) | 35 (52.2) | 249 (46.5) |
| Age (yr)[a], (mean ± SD) | 49.6 ± 22.2 | 48.6 ± 18.0 | 61.9 ± 13.3 | 50.5 ± 19.0 |
| Educational level (yr)[a], (mean ± SD) | 8.8 ± 5.2 | 8.2 ± 4.3 | 5.8 ± 4.2 | 8.0 ± 4.6 |
| Rurality, *n* (%) | 27 (23.5) | 99 (28.0) | 22 (32.8) | 148 (27.6) |
| Living in high-risk counties, *n* (%) | 39 (33.9) | 146 (41.2) | 24 (35.8) | 209 (39.0) |
| 17-Gastrin[a] (pmol/L), (mean ± SD) | 4.1 ± 6.8 | 5.6 ± 7.1 | 14 ± 14.3 | 6.3 ± 8.8 |

[1]As determined by serum level of PG-1 ⩽ 61.5 μg/L and PG-1/PG-2 ratio ⩽ 2.2. [2]Serology (+) for *H pylori* (ELISA). [a]Significant variables in the multivariate analysis ($P < 0.05$): B *vs* A: 17-gastrin (OR 1.05); C *vs* A: sex (OR 2.08); age (OR 1.02); education years (OR 0.9); 17-gastrin (OR 1.13).

## DISCUSSION

In spite of the advances in the knowledge of gastric carcinogenesis, including the role of *H pylori* infection, early diagnosis and opportune time for surgical intervention will continue to be the basis of effective treatment. Digestive symptoms are late and non-specific events[18] such that in order to diagnose early stage tumors, it is necessary to identify high-risk asymptomatic subjects. This work intends to validate a non-invasive method to advance in this direction.

Even though the detection of *H pylori* infection identifies a group that concentrates virtually all the subjects at risk to develop GC in a population[4], the low incidence of GC in the infected and the generally high frequency of infection in countries with high GC frequency, such as Chile and other Andean countries of South America, determine a limited localizing effect. Additionally, the loss in serological evidence of infection detected in the old-aged group in this population, probably as a consequence of gastric atrophy, would imply missing the group with the highest GC risk. Moreover, the eradication of *H pylori* infection does not seem to prevent the development of GC in subjects that have already developed gastric atrophy or intestinal metaplasia[19].

Gastric atrophy is generally accepted the major risk factor for GC development. A prospective study by Uemura *et al*[4] showed that the patients with severe atrophy had 5 times greater RR than those without atrophy. Other Japanese studies have shown that in *H pylori*- infected subjects, gastric atrophy is associated with up to 90 times greater risk for GC[6,20,21].

The serological diagnosis of gastric atrophy by means of serum PG is based on the fact that a small proportion of the diverse isoforms of this digestive enzyme, produced in the mucosa of the upper digestive tract, enters the blood. The isoforms corresponding to PG-1 are synthesized only in the gastric corpus, while PG-2 isoforms are synthesized in the whole gastric mucosa and even in the proximal duodenum. In the presence of corpus atrophy, the serum level of PG-1 diminishes, while PG-2 is stable or diminishes very slightly. However, published studies are relatively heterogeneous. While most studies seem to validate the diagnostic performance of the method[22-27], other studies show a much less reliable performance[28,29] and even suggest the influence of racial factors[30]. A recent meta-analysis suggested that additional studies are required in diverse populations to determine its real value[17].

Our results showed that in this population, low level of serum PG-1 or low PG-1/PG-2 ratio were able to detect the presence of the corpus atrophy with moderate sensitivity (56%-78%) and high specificity (91%-100%). The latter minimizes the risk of false positives and makes the method especially appropriate to be used in a low prevalence setting, such as expected in an asymptomatic population. The diagnostic performance of low levels of 17-gastrin to detect the antrum atrophy was clearly unsatisfactory in these samples, probably due to the antagonistic effect of concurrent corpus atrophy, which determines a significant elevation of the gastrin level. In contrast, an elevated level of 17-gastrin was highly reliable for the diagnosis of corpus atrophy in the group with confirmed histological diagnosis (Table 1) and also showed a significant correlation with the gastric atrophy in the group with serological diagnosis (Table 3), which supports the validity of this finding. A recent multi-ethnic non-European study, including subjects from Japan, China, Tanzania and the Dominican Republic, and using diagnostic criteria very similar to ours, showed wide variation in serum 17-gastrin levels, related to sex, age and the country of origin, and also demonstrated a significant positive correlation between the level of 17-gastrin and the presence of gastric atrophy[31]. If these results are confirmed through correlation with histology, 17-gastrin may be as useful as PG-1 level to diagnose corpus-predominant gastric atrophy in some populations.

The serum level of PG-1 is also affected by antagonistic influences. Our study and other previous studies[32] confirm that *H pylori* infection, and also the use of proton pump inhibitors[33], raise the level of serum PG-1, which could mask the diminishment determined by gastric atrophy and thereby explain the limited sensitivity of the method.

It is pertinent to ask whether the diagnostic performance demonstrated in the initial sample, constituted of selected, symptomatic, old-aged patients with a high frequency of gastric atrophy (60%) and therefore a relatively low frequency of *H pylori* infection, can be extrapolated to an asymptomatic population sample. To dispel this doubt, it would be necessary to certify histologically the frequency of gastric atrophy in a representative sub-sample of the latter group, which we expect to do soon. In the meantime, we restricted the diagnosis of gastric atrophy only to those subjects who simultaneously had PG-1 levels and PG-1/PG-2 ratios below the previously determined cut-off levels, a more demanding and restrictive diagnostic criterion that has been suggested to minimize the risk of false positive[17]. There is no reliable data with respect to the frequency of gastric atrophy in the Chilean population. A recent study from Japan, a country with which we share an elevated risk for GC, using the same methodology, demonstrated the frequencies of *H pylori* infection and gastric atrophy for the age groups very similar to ours[34].

The demographic analysis of the three proposed risk groups, that were determined serologically, showed that they differed significantly in some variables recognized as associated with GC risk, such as age[35], gender and educational level[36], which indirectly supports the validity of this categorization. Our suggestion is that the group with evidence of gastric atrophy should be followed up and studied preferentially through upper GI endoscopy and biopsies. This non-invasive assessment of GC risk has been evaluated in a recent Japanese study[37], showing that the subjects with serologically detected gastric atrophy, either with or without *H pylori* infection, had annual incidence of gastric cancer significantly higher than those subjects without atrophy. As has been recommended[38], focusing invasive and more expensive diagnostic methods on high-risk groups significantly increases the chance of detecting early GC, that in our country comprised less than 10% of the diagnosed cases[2,39] and merely increased to 15% in the only population-based study performed by Llorens[40] between 1978 and 1986 in non-selected volunteers. As long as the precocity of the diagnosis is not modified, it will not be possible to change the disappointing prognosis of GC in Chile, with a 5-year survival rate after diagnosis, ranging between 3% and 12%[2,39]. In contrast, a recent Japanese population screening study, using serum PG and radiology as diagnostic the methods, detected 88% of early GC with a much lower cost than the conventional screening and concluded that this type of program would be very beneficial for high-risk populations[41].

It is known that Chile has one of the highest mortality rates for GC in the world[42]. Nevertheless, the RR is markedly heterogeneous at the regional and county level, ranging between 0.26 and 2.25. Apparently, the greater part of this difference is explained by the higher frequency of *H pylori* infection, mainly in young people, in high-risk counties (Ferreccio *et al* submitted). The eradication of *H pylori* in this stage, before the development of gastric atrophy, would probably reduce the incidence of GC, as has been demonstrated in a Chinese population[19], although it is a strategy of doubtful practical feasibility given the Chilean population's high frequency of infection (73%). The frequency of gastric atrophy, a late consequence of infection, was expected to be greater in the high-risk counties which could not be confirmed in this study, probably due to an insufficient sample size.

In summary, our results confirmed the diagnostic usefulness of the serum levels of pepsinogen and gastrin for the non-invasive detection of corpus-predominant gastric atrophy in the symptomatic patients, showed its

feasibility in an asymptomatic population and suggested that the method could be useful to identify the groups with higher risks of developing GC, in which preventive and control measures can be focused. It is probable that successive PG and/or 17-gastrin determinations (annually or biannually), confirming low levels or showing a decreasing tendency, would lead to even better diagnostic performance. The incorporation of this method to preventive health examination in a selected population (i.e., men, older than 50, residents in high-risk counties) could probably increase the proportion of GC diagnosed in the early or incipient phase, the only method to improve the prognosis of this serious and frequent disease.

## Abstract

**AIM:** To assess the efficacy and safety of ultrasound guided percutaneous cholecystostomy (PC) in the treatment of acute cholecystitis in a well-defined high risk patients under general anesthesia.

**METHODS:** The data of 27 consecutive patients who underwent percutaneous transhepatic cholecystostomy for the management of acute cholecystitis from January 1999 to June 2003 was retrospectively evaluated. All of the patients had both clinical and sonographic signs of acute cholecystitis and had comorbid diseases.

**RESULTS:** Ultrasound revealed gallbladder stones in 25 patients and acalculous cholecystitis in two patients. Cholecystostomy catheters were removed 14-32 d (mean 23 d) after the procedure in cases where complete regression of all symptoms was achieved. There were statistically significant reductions in leukocytosis, ($13.7 \times 10^3 \pm 1.3 \times 10^3$ μg/L *vs* $13 \times 10^3 \pm 1 \times 10^3$ μg/L, $P < 0.05$ for 24 h after PC; $13.7 \times 10^3 \pm 1.3 \times 10^3$ μg/L *vs* $8.3 \times 10^3 \pm 1.2 \times 10^3$ μg/L, $P < 0.0001$ for 72 h after PC), C -reactive protein (51.2 ± 18.5 mg/L *vs* 27.3 ± 10.4 mg/L, $P < 0.05$ for 24 h after PC; 51.2 ± 18.5 mg/L *vs* 5.4 ± 1.5 mg/L, $P < 0.0001$ for 72 h after PC), and fever (38 ± 0.35℃ *vs* 37.3 ± 0.32℃, P < 0.05 for 24 h after PC; 38 ± 0.35℃ vs 36.9 ± 0.15℃, $P < 0.0001$ for 72 h after PC). Sphincterotomy and stone extraction was performed successfully with endoscopic retrograde cholangio-pancreatography (ERCP) in three patients. After cholecystostomy, 5 (18%) patients underwent delayed cholecystectomy without any complications. Three out of 22 patients were admitted with recurrent acute cholecystitis during the follow-up and recovered with medical treatment. Catheter dislodgement occurred in three patients spontaneously, and two of them were managed by reinsertion of the catheter.

**CONCLUSION:** As an alternative to surgery, percutaneous cholecystostomy seems to be a safe method in critically ill patients with acute cholecystitis and can be performed with low mortality and morbidity. Delayed cholecystectomy and ERCP, if needed, can be performed after the acute period has been resolved by percutaneous cholecystostomy.

## INTRODUCTION

Cholecystectomy is the appropriate treatment of acute calculous and acalculous cholecystitis, and it has a mortality rate of 0%-0.8%[1,2]. However, the mortality rate of surgical treatment may be as high as 14%-30% in elderly or critically ill patients with comorbid diseases[3,4].

Percutaneous cholecystostomy (PC) has been introduced as an alternative method to treat acute cholecystitis in patients with significant comorbid diseases[5-8]. PC can be achieved with the guidance of either computed tomography (CT) or ultrasonography (USG). PC, which was initially described by Radder in 1980, has proved to be an effective treatment for acute cholecystitis in critically ill patients, and it has low morbidity and mortality rates[9].

In this study, we have retrospectively evaluated the clinical data of patients treated with PC for acute cholecystitis. The aims of the study were to investigate the efficiency of PC in the treatment of acute cholecystitis in critically ill patients, the ratio of delayed cholecystectomy, and the clinical outcome of patients who had no further interventions following PC.

## MATERIALS AND METHODS

Between January 1999 and June 2003, percutaneous transhepatic cholecystostomy was performed on 27 elderly patients with acute cholecystitis and comorbid diseases. All patients received physical examination, whole blood count, biochemical analysis, and ultrasonography. Age, gender, comorbid diseases, etiology of cholecystitis, clinical and laboratory findings, morbidity associated with PC, and the clinical outcome were recorded. The diagnostic criteria of acute cholecystitis included clinical signs and symptoms (right upper quadrant pain or tenderness), leukocytosis or positive C - reactive protein (CRP) (> 5 mg/L) value, and at least one of the ultrasonographic criteria including gallbladder stones (for calculous cholecystitis), ultrasonographic Murphy's sign, gallbladder wall thickening (> 3 mm), pericholecystic fluid, and gallbladder distension. All patients were given empiric intravenous Ampicillin-sulbactam (1 g/d four times) treatment starting immediately after the diagnosis, and subsequently antibiotic therapy was managed according to the culture results of bile samples. All of the procedures were performed in the Department of Radiology. None of the patients were premedicated and the procedure was performed under local anesthesia.

### Risk classification

The American Society of Anesthesiologists (ASA) physical status classification was used to define the risk for cholecystectomy. Twenty (74.1%) patients were classified as ASA Ⅲ and 7 (25.9%) as ASA Ⅳ.

### Procedure

Under aseptic conditions, a USG guided transhepatic approach through the right lobe was used to access the gallbladder in all patients. After puncture of the bile duct with an 18 GA Seldinger needle, a guide-wire (Amplatz, 0.035 inch, 75 mm) was inserted into the gallbladder via the lumen of the Seldinger needle. The route was then dilated using 8F and 10F dilatators. Finally a 10F locking pigtail catheter was inserted into and locked within the gallbladder. Catheter localization was controlled by fluoroscopy (by injecting a small amount of contrast) and USG. Bile samples were obtained for cultures. The catheter was flushed with 10 mL of a saline-gentamycin (40 mg) mixture every 6-8 h to avoid obstruction, and the catheter was left for gravity drainage.

On the second day of the PC, USG was performed to check the site of the catheter, look for bile or blood leakage, and to observe the ultrasonographic findings following PC. Positive clinical response was defined as the normalization of at least two of the three clinical parameters of acute cholecystitis (abdominal pain, fever, and leukocytosis) and a decrease in CRP value within 72 h.

### Statistical analysis

Demographic data are given as medians (range), whereas the other data are expressed as means ± SE. Differences were evaluated using the Wilcoxon signed ranks test. $P < 0.05$ was accepted as significant. Data were analyzed using statistical software (SPSS for windows 10.0; SPSS, Chicago, IL, USA).

**Table 1 Comorbid diseases of the patients**

| Comorbid diseases | *n* |
|---|---|
| Cardiac disorders[1] | 19 |
| Haematological diseases[2] | 2 |
| Chronic obstructive pulmonary failure | 1 |
| Polytrauma | 1 |
| Diabetes mellitus and chronic renal failure | 4 |
| Total | 27 |

[1]Congestive heart failure, hypertension, ischemic heart diseases, valve replacement; [2]Chronic myeloid leukemia, thrombotic thrombocytopenic purpura.

**Table 2 White blood cell (WBC), C-reactive protein (CRP), and axillary temperature of the patients before and after PC**

| | Before PC | 24 h after PC | 72 h after PC |
|---|---|---|---|
| WBC × $10^3/\mu L$ | 13.7 ± 1.3 | 13 ± 1 | 8.3 ± 1.2 |
| CRP mg/L | 51.2 ± 18.5 | 27.3 ± 10.4 | 5.4 ± 1.5 |
| Body temp. (℃) | 38 ± 0.35 | 37.3 ± 0.32 | 36.9 ± 0.15 |
| | | $P < 0.05$ | $P < 0.0001$ |

## RESULTS

The median age of the patients was 71.4 years (range 64-93 years) and the female/male ratio was 4.4/1 (22/5). Two (7.4%) patients had acalculous and 25 (92.5%) had calculous cholecystitis. Comorbid diseases included congestive heart failure or severe ischemic heart disease in 19 (70.3%) patients, haematologic diseases [chronic myeloid leukemia (CML) and thrombotic thrombocytopenic purpura (TTP)] in 2 (7.4%) patients, renal failure in 4 (14.8%), chronic obstructive respiratory failure in one (3.7%), and polytrauma in one (3.7%) patient (Table 1). The majority (96.3%, $n = 26/27$) of the patients had pain and tenderness in the right upper quadrant.

The mean white blood cell counts (WBC) upon admission ($13.7 \times 10^3 \pm 1.3 \times 10^3/\mu L$), axillary temperatures (38 ± 0.35℃), and CRP (51.2 ± 18.5 mg/L) values were significantly decreased in the 72 h following PC [$8.3 \times 10^3 \pm 1.2 \times 10^3/\mu L$ ($P < 0.0001$), 36.9 ± 0.15℃ ($P < 0.0001$), 5.4 ± 1.5 mg/L ($P < 0.0001$), respectively ] (Table 2).

The clinical and ultrasonographic findings of acute cholecystitis decreased in all patients. Bile cultures were negative in 5 (18.5%) patients. *E.coli* was the only bacteria in 17 (63%) patients and *E.coli, Enterobacter,* and *Enterococci* were identified in the remaining 5 (18.5%) patients.

The median hospitalization time was 8 d (1-20 d) and the median catheterization period was 23 d (14-32 d). Catheter dislodgement occurred in three patients on the $6^{th}$, $8^{th}$, and $14^{th}$ d. Catheters were reinserted in two patients due to prompt recurrent cholecystitis but the other patient did not need recatheterization. Unexpected bleeding from the liver parenchyma occurred in only one (3.7%) patient following catheter removal. USG guided percutaneous drainage of a hematoma in the subhepatic region was performed in this patient and no further complications occurred.

Cholecystocholangiography was performed prior to the removal of the catheter to visualize the bile tree and gallbladder in 24 (88.8%) patients. This procedure could not be performed in 2 patients due to noncompliance and difficult mobilization (polytrauma) in one patient with acalculous cholecystitis. The cystic duct was patent in 16 (66.7%) and occluded in 8 (33.3%) patients. Common bile duct stones were detected in 3 (11.1%) patients.

These 3 patients underwent sphincterotomy and stone extraction from the common bile duct with ERCP. Delayed cholecystectomy was performed in 5 (18.5%) patients within a mean period of 2 mo following PC. The postoperative outcome was uneventful in these patients. The remaining 22 patients were followed up by physical examination and USG monthly for a median of 11 (6-18) mo after the removal of the catheter. Three of these 22 patients experienced recurrent cholecystitis and recovered with medical therapy (Table 3).

The morbidity rate of PC was 25.9% [catheter dislodgement ($n$ = 3), recurrent cholecystitis ($n$ = 3), and bleeding ($n$ = 1)] and there was no mortality associated with PC.

**Table 3 Follow-up of the patients after PC**

| | Calculous cholecystitis ($n$ = 25) | Acalculous cholecystitis ($n$ = 2) |
|---|---|---|
| No further treatment | 18 (72%) | 2 |
| Recurrence | 3 (12%) | 0 |
| Reinsertion of the catheter | 2 (8%) | 0 |
| Medical treatment | 1 (4%) | 0 |
| ERCP | 3 (12%) | 0 |
| Delayed surgery | 5 (20%) | 0 |

## DISCUSSION

PC was defined as an alternative treatment method in patients with acute cholecystitis who were at high risk during surgery due to comorbid diseases. The morbidity and mortality associated with emergent cholecystectomy is considerably higher in such patients, 55%-66% and 14%-30% respectively[3,4]. The morbidity and mortality rates of PC were found to be much lower, less than 10% and 2% respectively[10,11]. PC resulted in successful treatment in 56%-100% of patients with acute cholecystitis and significant comorbid diseases[12-17]. The therapeutic rate of PC was significantly higher in patients with clinical signs and symptoms referred to the right upper abdomen compared to patients without clinical signs and symptoms (intensive care patients)[12]. Although unexplained sepsis regressed dramatically after PC in approximately 60% of intensive care patients, the therapeutic response to PC is lower in patients with symptoms and signs in the right upper abdomen who received open cholecystectomy[11,12]. In this study, morbidities were seen in 7 (25.9%) patients, but 3 of these complications were due to catheter squeezing as a result of patient carelessness. There was no procedure-related mortality.

PC can be easily performed under local anesthesia with USG or CT guidance. Two ways of accessing the gall bladder were defined for the procedure. Either a transhepatic or transperitoneal approach can be used. The complications related to the procedure include bile duct injury, bile leakage and peritonitis, portal or parenchymal vessel injury and bleeding, catheter dislodgement, colon injury, and vagal reactions. The transhepatic approach decreases the risk of bile leak, portal vessel injury, and colon injury but it carries a risk of pneumothorax and bleeding from the liver parenchyma[18-20]. Although the transperitoneal approach decreases the risk of bleeding and secondary liver contamination by infected bile, it increases the risk of bile peritonitis, colon perforation, portal vessel injury, and displacement of the catheter after decompression of the gall bladder[21-23]. In addition to other complications, van Sonnenberg *et al* also reported vagal reactions in the transperitoneal approach due to vagal innervation of the gall bladder wall[24]. Therefore, the transhepatic approach seems to be the best approach for PC except in the presence of severe liver disease and coagulopathy[25-27]. In this study the transhepatic approach was preferred to access the gall bladder. All procedures were completed under local anesthesia without any complications related to the procedure.

We performed cholecystocholangiography in 24 patients. The cystic duct was patent in 16 (66.7%) patients. Common bile duct stones which could not be visualized by USG, were detected in three (11.1%) of these 16 patients. These three patients underwent sphincterotomy and stone extraction with ERCP. Bleeding from the liver parenchyma was detected unexpectedly in only one (3.7%) patient following removal of the catheter. No bile leakage was detected in any patient.

The management of patients after the acute cholecystitis period is still controversial. Lebigot *et al* followed up 90% of patients for 12 mo after PC and reported only one (6.25%) endoscopic sphincterotomy and one (6.25%) delayed cholecystectomy[28]. No additional therapy was needed in the remaining 87.5% of the patients. The risk of recurrent cholecystitis was reported as 12% at 1 year in a study by Welch *et al*, and the authors mentioned PC as a possible definitive treatment in patients with acalculous cholecystitis[29]. In a recent study, the authors were able to apply delayed surgery in 56.4% of patients after the acute period[6]. In this study, we reevaluated the patients after regular medical treatment of the comorbid diseases. Five (18.5%) patients were then selected for delayed elective surgery and the remaining 22 were followed. Nineteen (86.4%) of these 22 patients required no additional therapy. Recurrent cholecystitis was detected in 3 (13.6%) patients and the symptoms regressed with medical therapy.

In conclusion, PC is a fast, easy, effective, and safe treatment method for the acute phase of cholecystitis in elderly and critically ill patients. Procedure-related morbidity and mortality is very low compared to surgery. Patient management after the acute phase of cholecystitis is still controversial. Conservative treatment for patients who are not suitable for surgery is acceptable. Delayed elective cholecystectomy is another option in patients who respond well to medical treatment of comorbid diseases.

## Abstract

**AIM:** To evaluate the efficacy of dipstick test in diagnosis of spontaneous bacterial peritonitis (SBP) in cirrhotic patients who underwent abdominal paracentesis based on the locally available dipstick test.

**METHODS:** There were 200 consecutive samples from cirrhotic patients who underwent abdominal paracentesis. Urine dipstick (Combur$^{10}$ Test®M, Roche, Mannheim, Germany) was used as a screening test. A manual cell count with differential study was done in all samples by experienced technicians. The polymorphonuclear (PMN) cell count more than 250 cells/mm$^3$ was used as a diagnostic cut off level. One to three plus dipstick results were used as cut off levels for a positive result. The dipstick test results had to be agreed by three experienced readers. The sensitivity, specificity, positive and negative predictive values and accuracy of two different colorimetric cut off scales (1+ and 2+) were calculated and compared.

**RESULTS:** The prevalence of SBP diagnosed by manual cell count was 21.0%. There were 128 specimens that had a true negative result by dipstick. The sensitivity, specificity, positive and negative predictive values and accuracy of 1+ and 2+ cut off scale to diagnose SBP were 88%, 81%, 55%, 96% and 83% respectively, and 63%, 96%, 82%, 81% and 89% respectively.

**CONCLUSION:** Dipstick test can be used as a rapid test for screening of SBP. The higher cut off colorimetric scale has a better specificity and positive predictive value but a lower sensitivity.

**Key words:** Spontaneous bacterial peritonitis; Diagnosis; Dipstick; Screening

## INTRODUCTION

Apart from variceal bleeding, spontaneous bacterial peritonitis (SBP) is another serious complication that can develop in cirrhotic patients. Prompt diagnosis and treatment are essential for the survival of patients with SBP[1,2]. Unfortunately, symptoms of SBP including fever, abdominal pain, nausea, and vomiting are not presented in all cirrhotic patients who develop SBP[3,4]. In addition, many hospitalized cirrhotic patients develop SBP during their non-SBP related admissions especially those with gastrointestinal bleeding[5]. Therefore, routine diagnostic paracentesis is the recommended practice for patients with ascites who develop signs or risk factors for SBP. The standard criteria for diagnosis of SBP are an ascitic fluid polymorphoneuclear (PMN) cell count of $\geqslant$ 250/mm$^3$ and/or a positive ascitic fluid bacterial culture[6-8]. Due to the nature of bacterial culture, the result is not available within a day. Therefore, decision making for SBP treatment is mainly based on PMN cell count. However, manual ascitic fluid PMN cell count is not always available in some small patient care units especially in the out patient offices and sometimes it cannot be done as in emergency basis.

Recently, leukocyte esterase activity testing by dipstick has been used for a rapid diagnosis of infection in many body fluids such as urine, pleural fluid, and cerebrospinal fluid[9-11]. The leukocyte esterase released from PMN cells reacts with an esterified chemical compound in the reagent strip yielding a violet azo dye, the intensity of which correlates to leukocyte count[12]. Recently, many studies have shown the efficacy of dipstick in diagnosing SBP[13-19]. However, strip tests used in these studies are not the same and have different colorimetric scales. Therefore, the sensitivity and accuracy of different dipsticks may vary. To date, there has been no recommended calorimetric scale for each dipstick to diagnose SBP.

The aim of this study was to evaluate the usefulness of dipstick in rapid diagnosis of SBP in cirrhotic patients who underwent abdominal paracentesis based on the locally available dipstick test and to define the validity scores from 2 different thresholds of colorimetric scales.

## MATERIALS AND METHODS

During the period between July 2004 and November 2005 at King Chulalongkorn Memorial Hospital, 200 consecutive ascitic fluid specimens (including 21 from out patient unit) were collected from 127 cirrhotic patients (Table 1). The clinical indications for paracentesis were routine paracentesis ($n$ = 95), relief of patient's discomfort ($n$ = 54), suspected SBP ($n$ = 13), miscellaneous ($n$ = 38). The diagnosis of cirrhosis was established according to the histologic criteria or analytical, clinical, and ultrasonographic findings of the liver. Informed consent was obtained from all patients, and the study was approved by the Ethics Committee of the University.

Immediately after paracentesis, fresh ascitic fluid specimen was collected in a clean dry container and tested using a dipstick (Combur$^{10}$ Test®M, Roche, Mannheim, Germany) for granulocyte esterase designed for urine analysis. The strip has a colorimetric 4-grade scale (negative, 1+ to 3+) and is read at 90 s for granulocyte esterase activity. The procedure was the same as what the manufacturer described for urine.

Each of the colorimetric scale readings was graded by 2 well trained on-duty internists (the reading processes were scored separately). All the readings were confirmed by WR who is a house staff covering for this project. WR made the final decision for all discrepancy results. A correlation between PMN cell count and the 4-grade scale was suggested by the manufacturer as follows: negative, 0 PMN cell/mm$^3$; 1+, 10-25 PMN cells/mm$^3$; 2+, 75 PMN cells/mm$^3$; 3+, 500 PMN cells/mm$^3$.

Ascitic fluid was conventionally processed including cytology, PMN cell count and lymphocyte count, and appropriate biochemical tests (glucose, protein, albumin, lactic dehydrogenase, and sugar). The sample for PMN and total leukocyte count was collected into a heparin anticoagulant tube and analyzed within 4 h of extraction. Differential cell count and cytology were examined with a conventional optical microscope. A manual cell count with differential study was done in all samples by experienced technicians.

Ascitic fluid cultures were performed by inoculation of at least 10 mL fluid in VersaTrek® REDOX 1® (TREK Diagnostic Systems, Cleveland, OH). All bottles were processed in a standard fashion according to the manufacturer's guideline.

SBP was defined as PMN cell count in ascitic fluid $\geqslant$ 250/mm$^3$. The 1+ or 2+ result of the leukocyte esterase from dipstick was considered as a positive test. The negative result from dipstick was considered as a negative test. We also defined bacterascites as the combination of a positive ascitic fluid culture, PMN cell count in ascitic fluid < 250/mm$^3$, and no evident intra-abdominal surgically treatable source of infection. In patients with hemorrhagic ascites (i.e. ascites red blood cell count > 10000/mm$^3$), a subtraction of one PMN leukocyte per 250 red blood cells was made[6]. Secondary peritonitis was suspected when there was an abdominal source of infection, acute pancreatitis, or more than one organism in the ascitic fluid culture.

**Table 1 Characteristics of 127 patients and 200 ascitic fluid specimens**

| Characteristics | $n$ (%) |
|---|---|
| Male/Female | 75/52 |
| Age (mean + SD) | 57.4 ± 13.3 |
| Child-Pugh classification A/B/C | 3/34/90 |
| **Etiology of cirrhosis** | |
| Hepatitis B | 34 (26.8) |
| Hepatitis C | 8 (6.3) |
| Alcohol | 25 (19.7) |
| Alcohol and hepatitis B | 9 (7.1) |
| Alcohol and hepatitis C | 9 (7.1) |
| Hepatitis B and hepatitis C | 1 (0.8) |
| Autoimmune | 2 (1.6) |
| Hemochromatosis | 2 (1.6) |
| Cryptogenic | 10 (7.9) |
| Others | 27 (21.3) |

### *Statistical analyses*

Results of dipstick test were compared to PMN cell count, ascitic fluid culture and clinical data in all patients. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of dipstick in the diagnosis of SBP from two different colorimetric scales (1+ and 2+) were calculated and compared (Figure 1).

## RESULTS

We diagnosed 42 episodes of SBP by PMN cell count, of which 37 (88.1%) was diagnosed using 1+ cut off scale and 27 (64.3%) 2+ cut off scale. Of the 158 specimens with PMN cell count < 250/mm$^3$, 128 had a true negative result by dipstick test (Table 2). Five patients were diagnosed as SBP by manual cell count but had a negative dipstick test result.

Sixteen specimens had a positive culture for bacteria, of which four were compatible with bacterascites. The dipstick test results in these bacterascites specimens were all negative. No secondary bacterial peritonitis was diagnosed in this series. The most common organism growing from these specimens was *E. coli* (Table 3).

The sensitivity, specificity, PPV, NPV and accuracy of 1+ and 2+ cut off scales to diagnose SBP were 88%, 81%, 55%, 96% and 83% respectively, and 63%, 96%, 82%, 91% and 89% respectively (Table 4).

## DISCUSSION

Due to the high rates of morbidity and mortality from delayed treatment in cirrhotic patients who suffered from SBP, diagnostic tests for early diagnosis are very important[20,21]. Currently, ascitic fluid PMN count is the standard tool for SBP treatment decision making. However, several-hour delay in reporting the result may arise from the laboratory department. In addition, this test may not be available in a small out patient setting.

Leukocyte esterase has been shown as an important marker for PMN cell activity[22]. Originally, the purpose

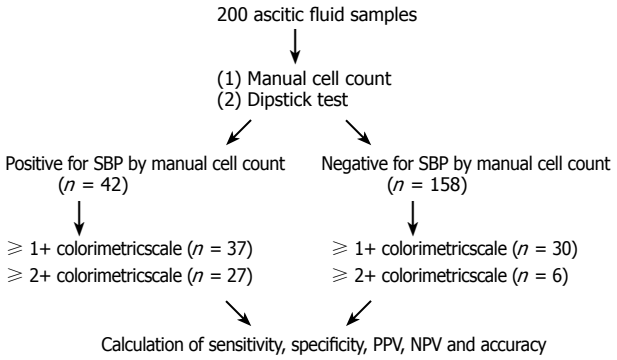

**Figure 1** Flow diagram for SBP evaluation.

**Table 2 Dipstick test results in SBP and non-SBP groups**

| Colorimetric scales | PMN cell count ⩾ 250/mm$^3$ | PMN cell count < 250/mm$^3$ | Total |
|---|---|---|---|
| 1+ | 10 | 24 | 34 |
| 2+ | 19 | 6 | 25 |
| 3+ | 8 | 0 | 8 |
| 0 | 5 | 128 | 133 |
| Total | 42 | 158 | 200 |

of leukocyte esterase test was limited to urine analysis[23]. Recently, it has been found to be useful across the wide range of body fluid infections[9-11]. The efficacy of this test in detecting infection in the ascitic fluid has been confirmed from many centers[14-19]. The overall sensitivity, specificity, PPV and NPV of this test are approaching 90% (Table 5)[14-19]. However, the different commercial dipsticks used in previous studies had different colorimetric scales for PMN cell count. In addition, the cut off colorimetric scale for each dipstick has not been standardized yet.

To date, there has been no dipstick that was specifically designed to use in ascitic fluid. Moreover, many dipsticks do not have a precise colorimetric scale for 250 PMN cells/mm$^3$. In our study, we used the Combur$^{10}$ Test®M that is widely available in Thailand as a screening test for SBP. According to the manufacturer's guideline, the 1+, 2+ and 3+ scales are equivalent to 10-25 PMN cells/mm$^3$, 75 PMN cells/mm$^3$ and ⩾ 500 PMN cells/mm$^3$ respectively. We chose the lower scales (1+ and 2+) as cut off levels for SBP diagnosis. The limitation of the Combur$^{10}$ Test®M is an absence of precise calorimetric scale for the cut off level of PMN cell count at ⩾ 250/mm$^3$. Because of this limitation, we speculated that our specificity might be lower than others[17-19]. Although our sensitivity (88%) from 1+ cut off level was comparable to others, the specificity and PPV were lower (81% and 55% respectively) compared to other studies[17-19]. By using 2+ scale as a cut off level for SBP, our specificity and PPV increased (96% and 82% respectively), unfortunately the sensitivity decreased to only 63%. Anyhow, NPV and accuracy from these two cut off levels were comparable to other series[17-19].

Aution stick (A. Menarini Diagnostics, Firenze, Italy) is another dipstick that can be read at 90 s. The benefit of the Aution stick over the Combur$^{10}$ Test®M is the precise colorimetric scale that correlates with ⩾ 250 PMN cells/mm$^3$. The correlation between PMN cell count and colorimetric scale suggested by the manufacturer are as follow: grade 0, 0 PMN cell/ mm$^3$; grade 1, 25 PMN cells/ mm$^3$; grade 2, 75 PMN cells/ mm$^3$; grade 3, 250 PMN cells/mm$^3$; and grade 4, 500 PMN cells/mm$^3$. Catellote *et al*[15] studied the use of Aution sticks for diagnosis of SBP in cirrhotic patients with ascites who underwent abdominal paracentesis at a university based hospital, and found that the sensitivity, specificity and PPV are 89%, 99% and 98%, respectively[15].

**Table 3 Results of dipstick tests and PMN cell counts in positive culture specimens**

| 16 | 3398 | 3 | *E. coli* |

**Table 4 Validity scores of the Combur$^{10}$ Test®M to diagnose SBP considering a positive test > 1 or > 2 in the 4-grade colorimetric scale**

| Variables | ⩾ 1 grade, % | ⩾ 2 grade, % |
|---|---|---|
| Sensitivity | 88 | 63 |
| Specificity | 81 | 96 |
| Positive predictive value | 55 | 82 |
| Negative predictive value | 96 | 91 |
| Accuracy | 83 | 89 |

Multistix®10SG (Bayer Diagnostics Corporation, Puteaux, France) has colorimetric scales as follow: grade 0, 0 PMN cell/ mm$^3$; grade 1, 15 PMN cells/mm$^3$; grade 2, 70 PMN cells/ mm$^3$; grade 3, 125 PMN cells/ mm$^3$; and grade 4, 500 PMN cells/mm$^3$. Butani *et al*[24] used the Multistix®10SG to diagnose SBP in 136 specimens by using grade 2 as a cut off scale, and found the sensitivity, specificity, PPV and NPV of the Multistix®10SG are 83%, 99%, 91% and 98% respectively. Although, the Multistix®10SG has no precise colorimetric scale for 250 PMN cells/ mm$^3$, its specificity was still better than that of the Combur$^{10}$ Test®M in our series. This may be due to a closer 250 PMN/mm$^3$ colorimetric scale of Multistix® 10SG (grade 3+ ⩾ 125 PMN cells/mm$^3$).

There are many factors that influence the accuracy of the dipsticks. False positive result can result from alteration of pH, osmolality and temperature of the specimens[25].

**Table 5 Validity scores reported in previous studies**

| Authors | Castellote *et al* | Kim *et al* | Butani *et al* | Sapey *et al* | Thévenot *et al* |
|---|---|---|---|---|---|
| Dipsticks | Aution sticks | UriSCAN/Mutistix10SG | Multistix®10SG | Nephur test/ Multistix10SG | Multistix 8SG/Combur²test LN (combined result) |
| Inclusion scale | $\geqslant$ 3 (PMN $\geqslant$ 250/mm$^3$) | $\geqslant$ 3 (PMN $\geqslant$ 500/mm$^3$) /$\geqslant$ 3 (PMN $\geqslant$ 75/mm$^3$) | $\geqslant$ 2 (PMN $\geqslant$ 70/mL mm$^3$) | N/A | $\geqslant$ 3 (PMN $\geqslant$ 125/mm$^3$) /$\geqslant$ 2 (PMN $\geqslant$ 75/mm$^3$) |
| Sensitivity (%) | 89 | 67/50 | 89 | 88/65 | 89 |
| Specificity( %) | 99 | 100/100 | 99 | 100/100 | 100 |
| PPV (%) | 98 | 100/100 | 89 | 94/92 | 100 |
| NPV (%) | 97 | 89/87 | 99 | 99/97 | 99 |

In addition, non-leukocyte cells can release esterase and produce a false positive result[26]. Moreover, antibiotics can produce both false positive and negative results[27]. The false negative result in the present series was found in 5 patients (12%), which is similar to the series presented by Sapey *et al*[19] None of our patients with false negative result received antibiotics prior to abdominal paracentesis. Interestingly, 3 specimens had a manual PMN cell count between 250/mm$^3$ and 300/mm$^3$ (data not presented), suggesting that the smaller number of PMN cells in these specimens may lead to a false negative result. Campillo *et al*[28] demonstrated that the sensitivity of dipsticks remains low with PMN cell count $\leqslant$ 1000/mm$^3$ when they used Multistix 8 SG and Combur 2 LN as dipstick tests.The false positive rate in our series was 19% which is higher than that of Sapey *et al*[19], who found that only one patient form each test (Nephur-test® and MutistixSG®) had a false positive result. The possible explanation for a better result from their series is a much closer 250 PMN cells/mm$^3$ of their dipstick scales. Again this information helps to confirm that a precise colorimetric scale for 250 PMN/mm$^3$ is essential for an ideal dipstick to detect SBP.

Currently, there is no specific dipstick test for bacterial count in the ascitic fluid. In our series, it is not surprised that the correlation between the culture and dipstick results was very poor. There were 4 specimens that were compatible with a condition generally called "monomicrobial non-neutrocytic bacterascites (MNB)". All the MNB specimens had a negative dipstick result. Generally, the clinical outcome of asymptomatic MNB is much better than that of classic SBP[29]. Our 4 patients with MNB did not receive any treatment and were asymptomatic during 3-6 mo follow-up. In addition, repeat ascitic fluid analysis and culture were performed and reported unremarkable results in these 3 patients.

Patients with $\geqslant$ 250 PMN cells/mm$^3$ in the absence of bacterial growth from the culture are classified as culture-negative neutrocytic ascites (CNNA). In the present series, only 12 patients (28.6%) had a classic SBP (positive culture and cell count $\geqslant$ 250 PMN cells/mm$^3$). Of these culture negative SBP patients, at least 25 (83.3%) had CNNA (no history of prior antibiotics use), demonstrating that CNNA has the same clinical course as classic SBP[6]. Therefore, dipstick that determines mainly for PMN cell activity can be used for SBP screening.

In conclusion, dipstick test in ascitic fluid from cirrhotic patients is a good screening tool for SBP. However, not all dipsticks have a precise colorimetric scale for a measurement of $\geqslant$ 250 PMN cells/mm$^3$, therefore the sensitivity of different dipsticks may not be similar. With a good NPV the decision making not to treat SBP based on the results of Combur$^{10}$ Test®M can be made in the majority of cases. Further study is needed to improve the efficacy of the test in detecting PMN cells and bacteria in ascitic fluid.

## COMMENTS

### Background

The decision making for SBP treatment is mainly based on PMN count. However, manual ascitic fluid PMN count is not always available in every patient care unit.

### Research frontiers

Leukocyte esterase activity testing by dipstick has been used for a rapid diagnosis of infection in a variety of body fluids such as urine, pleural fluid, and cerebrospinal fluid. The efficacy of this test in detecting infection in the ascitic fluid has been confirmed from many centers. The overall sensitivity, specificity, PPV and NPV of these tests are approaching 90%.

### Innovations and breakthroughs

The sensitivity and NPV of dipstick test is excellent in all different types of stick. However, some have a slightly better value due to their approximity to the 250 cell/mm$^3$ cut-off level.

### Applications

The dipstick may be used as a screening tool for SBP. A better designed test is awaited.

### Peer review

The study used Combur as a screening test. The sensitivity of this test is slightly poorer than others. However, the other validity scores are comparable. The author may need to continue to explore other dipsticks and compare their results using manual cell count as a gold standard.

## Abstract

**AIM:** To investigate the clinical and pathological significance of altered retinoblastoma (Rb) encoding protein (pRb) in gastric carcinoma.

**METHODS:** Expression of altered pRb was analyzed in 91 patients with gastric adenocarcinoma by immunohistochemistry.

**RESULTS:** Sixty-five percent (59/91) of the tumors were positively stained and the staining in tumor nuclei of gastric carcinoma ranged 0%-90%. Moreover, strong expression of altered pRb was found in 35% (6/17), 24% (5/21), 17% (8/46) and 0% (0/7) of T1, T2, T3 and T4 gastric carcinomas, respectively. Altered pRb expression was inversely correlated with the depth of tumor invasion ($P$ = 0.047). Degree of immunoreactivity had no significant correlation with tumor grade, node metastasis and distant metastasis. In terms of prognostic significance, univariate analysis showed that poor differentiation [41 (66.1%) *vs* 34 (42.5%) $P$ = 0.051], advanced tumor stage ($P$ < 0.001) and weakly altered pRb expression [17 (80.5%) *vs* 58 (49.6%) $P$ = 0.044] were associated with worse prognosis in these patients. However, multivariate analysis revealed that advanced tumor stage was the only independent poor prognostic factor ($P$ < 0.001).

**CONCLUSION:** The mutation of Rb gene is frequent in gastric carcinoma. The expression of altered pRb inversely correlates with tumor invasion and is not an independent prognostic marker in gastric adenocarcinoma.

**Key words:** Gastric adenocarcinoma; Altered retinoblastoma protein; Immunohistochemistry

## INTRODUCTION

Cellular proliferation normally follows an orderly progression through the cell cycle, which is governed by protein complexes encoding various genes. Malignant transformation results from a series of genetic alterations that lead to aberrant regulation of cell division (cell-cycle control), cell death (apoptosis), and maintenance of genomic integrity (DNA repair).

The retinoblastoma gene (Rb) encoding the 105kd nuclear phosphoprotein, maps to chromosome 13, band 13q14, and is a prototypical tumor-suppressor gene[1,2]. The retinoblastoma protein plays an important role in regulating the ability of cells to enter S phase, during which DNA is synthesized[3]. Although the alteration of the Rb gene has been shown to be critical for the development of retinoblastoma[4-6], dysregulation of the Rb gene is important in a wide array of human cancers, such as sarcoma[7], hepatoma[8], leukemia[9], and esophagus[10], breast[11], bladder[12], prostate[13] and lung cancers[14]. But studies concerning Rb gene change in gastric carcinoma are limited.

This study was to examine the correlation of altered pRb expression with the clinicopathological status and prognostic value of altered protein expression in patients with gastric carcinoma.

## MATERIALS AND METHODS

### Patients

The study population consisted of 91 patients (80 men, 11 women; mean age: 68 years; range: 32-86 years) who underwent surgery for primary gastric adenocarcinoma at our institute between 1992 and 2000. Eighteen (19.8%) tumors were located in the upper third, 19 (20.9%) in the middle third, and 54 (59.3%) in the lower third of the stomach, respectively. Following the international tumor node metastasis (TNM) staging system, 23 (25.3%)

tumors were considered stage Ⅰ, 20 (22.0%) stage Ⅱ, 28 (30.8%) stage Ⅲ, and 20 (22.0%) stage Ⅳ, respectively. Histological grade was assessed following the World Health Organization (WHO) criteria. Forty-nine (53.8%) tumors were well- or moderately- differentiated, and forty-two (46.2%) poorly- or undifferentiated.

Sixteen of the 20 stage Ⅳ patients had distant metastasis (5 peritoneal, 5 hepatic, 1 lung, 3 peritoneal and T4 lesion, 1 peritoneal and hepatic, 1 peritoneal and N3 lymph node status), while the other cases were classified as stage Ⅳ because of N3 lymph node status ($n$ = 3) and/or T4 lesions ($n$ = 1). Sixteen patients underwent palliative surgery (16 distant metastases). The other 75 patients underwent radical D2 resection. Of the patients 12 were treated with postoperative systemic chemotherapy (5 for 6 cycles of FEM, and 7 for 6 cycles of 5-FU). To rule out any confounding effect of adjuvant chemotherapy, this variable was entered in the multivariate analysis of survival. Follow-up evaluation consisted of physical examination, chest radiography, and tumor marker (CEA, and CA19.9) assay every 6 mo for the first 3 years and once a year thereafter, abdominal computed tomography (CT), and endoscopy once a year.

### *Immunohistochemistry*

Formalin-fixed and paraffin-embedded tumor samples taken during surgery were used for the study. pRb expression was detected immunochemically using the monoclonal antibody (M7131, DAKO, Denmark) generated from mouse anti-human Rb product. The 4-μm thick sections from their original histology blocks were eparaffinized in xylene and treated with 3% hydrogen peroxide in methanol to block endogenous peroxidase. For immunohistochemical detection of the pRb protein, the sections were boiled for 30 min in 10 mmol/L citrate buffer solution (pH6.0) using a microwave heater for antigen retrieval. Mouse monoclonal anti-Rb (Clone Rb1, DAKO, Glostrup, Denmark) was used as primary antibody. The clone Rb1, which can be used on (archival) paraffin-embedded material, is a mouse monoclonal antibody against recombinant human retinoblastoma gene product representing amino acid 330-612 and reacts with the retinoblastoma gene product as indicated by immunoblotting SV40 transformed human tumor cell lines[15]. The sections were first incubated for 60 min at room temperature with the primary antibody. Biotinylated anti-mouse IgG was then applied as secondary antibody, followed by peroxidase-cojugated streptavidin. Demonstration of binding sites with the peroxidase reaction was achieved with 3, 3'-diaminobenzidine tetrahydrochloride (0.25 mg dissolved in 1 mL 0.02% hydrogen peroxide). Phosphate-buffered saline was used for rinsing between each step. Faint nuclear staining, sufficient to aid in orientation but not to influence the judgement of positivity, was performed with Mayer hematoxylin solution.

### *Evaluation of pRb protein expression*

For each section, 10 high-power fields were chosen randomly, and a total of 1000 cells were evaluated by a pathologist (Tseng HH), who had no prior knowledge of the patients' outcomes or tumor characteristics. The pattern of immunoreactivity was scored on the basis of the percentage of tumor cell nuclei with positive staining. The parameter obtained was the mean relative nuclear positive area evaluated on at least 10 fields observed at a magnification of × 40.

Immunoreactivity was semiquantitatively graded. The grade scheme was: 0+ (no immunoreactive cells present), 1+ (1%-24%), 2+ (25%-49%), 3+ (50%-74%), 4+ (75%-100%) immunoreactivity cells, respectively.

In evaluation of the clinical significance of pRb expression in gastric carcinoma, tumors with grade "0+ - 2+" immunostaining were grouped as weak staining, and tumors with grade "3+ and 4+" immunostaining as strong staining.

### *Statistical analysis*

Associations between categorical variables were analyzed using Fisher's exact test, $\chi^2$ test, or Mann-Whitney $U$ test. Univariate analysis of survival was carried out with a Kaplan-Meier estimator, and the difference between curves of subgroups was determined using the log-rank test. Survival curves were calculated by the Kaplan-Meier method and compared by the log-rank test. Independent survival variables were studied by Cox regression analysis. All data were calculated with SPSS for windows with $P < 0.05$ as the level of significance.

## RESULTS

A total of 59 out of 91 (65%) tumors were positive for altered pRb, with 16 cases graded as "1+", 24 as "2+", 11 as "3+" and 8 as 4+". In 91 unselected primary gastric carcinomas, we compared the common prognostic markers, such as age, sex, tumor location, Lauren type, tumor grading, TNM system, and altered pRb expression. On examining the distribution of tumors with strong or weak altered pRb expressions (Table 1), no significant differences were found in sex, age, tumor site, Lauren type, and histologic grading. However, statistical analysis demonstrated a significant association between altered pRb status and tumor stage. The altered pRb protein-high tumors were more in earlier stage (stages Ⅰ and Ⅱ) than in more advanced stage (stages Ⅲ and Ⅳ) ($P$ = 0.010). Moreover, the altered pRb status significantly correlated with depth of invasion (T status), but not with lymph node metastasis (N status), and distant metastasis (M status). The altered pRb expression was weak in 11 of the 17 (65%) T1 tumors, 16 of the 21 (76%) T2 tumors, 38 of the 46 (83%) T3 tumors, and 7 of the 7 (100%) T4 tumors. The altered pRb was inversely correlated with the depth of tumor invasion ($P$ = 0.047).

Analysis of survival was carried out in 75 patients undergoing curative resection. The results of univariate analysis of survival in relation to clinicopathological findings are reported in Table 2. Tumor staging and altered pRb expression were correlated with 5-year survival. Kaplan-Meier curves showed that the 5-year survival was 80.5% in patients with strong altered pRb expression ($n$ = 17) compared with 49.6% in patients with weak altered pRb expression ($n$ = 58) ($P$ = 0.0436). Only TNM

stage was found to be an independent prognostic factor for survival (Table 3) on multivariate analysis by Cox regression.

## DISCUSSION

The half-life of mutant Rb protein is even longer than that of the wild Rb protein. This feature results in immunohistochemically detectable expression of the mutant Rb protein. It has been established that altered Rb protein expression pattern gives a fairly good estimate of the mutation frequency in the Rb gene[16,17].

In this study, 65% (59/91) of the tumors were positively stained and the staining in tumor nuclei of gastric carcinoma ranged 0%-90%. Constancia *et al*[18] reported that alterations affecting the Rb gene are rather infrequent in human gastric carcinomas, but our data indicate the altered pRb protein expression is frequent and widely variable in gastric carcinoma. We directly detected the altered Rb protein in tumor cells, which is different from the Constancia's study detecting the normal Rb protein[18]. The Rb gene mutation is frequent in various human malignancies including sarcoma[7], hepatoma[8], leukemia[9], and esophagus[10], breast[11], bladder[12], prostate[13] and lung cancers[14], being similar with that in gastric carcinoma in our study.

Rb mutations resulting in the loss of Rb function play a role in the initiation of retinoblastoma and other tumors that develop as second malignancies in individuals with the hereditary form of retinoblastoma[19]. The functional loss of the Rb gene has been implicated in a diverse group of human malignancies, including carcinoma of the breast, urinary bladder, liver, esophagus, prostate, and colon[8,10-12,20,21]. The significance of these mutations in other tumors is a potentially critical issue. A key issue is whether the changes reported within the Rb gene in other various cancers are causally related to the initiation of tumors or whether they are involved in tumor progression. Phillips *et al*[20] reported that loss of Rb gene function is an early event in prostatic tumorigenesis. Our findings demonstrate that the altered pRb protein expression is more frequent in gastric carcinomas with superficial invasion than in those with advanced invasion. This feature means that the Rb gene mutation is also an early event in the development of gastric carcinoma and then gradually gets lost during its progression. However, only 35% (6/17) of T1 lesions had strong staining in our study. The T1 lesions occurred earlier than T2, T3, and T4 lesions and might be a "late" event in the development of gastric carcinoma. Therefore, in-depth studies should be undertaken to clarify whether the Rb gene mutation is causally related to the initiation of gastric adenocarcinoma

as in the hereditary retinoblastoma.

The prognostic value of pRb protein expression in various carcinomas has been investigated. Some studies found that pRb protein expression is an important prognostic indicator of cancers, such as bladder cancer[22] and non-small-cell lung cancer[23]. Low pRb protein expression is associated with significantly poorer survival among them. In contrast, in colorectal cancer no prognostic significance of pRb protein expression has been reported[14]. Our findings demonstrate that there is a negative correlation between pRb protein expression and survival in gastric carcinoma at univariate analysis, but not significantly correlated between them at multivariate analysis. In the present study, however, the pRb protein-high tumors were more frequent in earlier stage (stages Ⅰ and Ⅱ) than in advanced stage (stages Ⅲ and Ⅳ), suggesting that the pRb protein expression is not an independent prognostic marker of gastric adenocarcinoma.

In conclusion, our data indicate that the mutation of Rb gene is frequent in gastric carcinoma. The expression of altered pRb protein inversely correlates with tumor invasion and is not an independent prognostic marker in gastric adenocarcinoma

## Abstract

**AIM:** To compare the sequencing of PCR products, pyrosequencing, and real-time PCR for detection of Tyrosine-methionine-aspartate-aspartate (YMDD) mutants in patients with chronic hepatitis B.

**METHODS:** Mixtures of plasmids and serum samples from 69 chronic hepatitis B patients treated with lamivudine were tested for YMDD mutations by sequencing of PCR products, pyrosequencing, and real-time PCR, respectively. Time required and reagent costs of the three assays were evaluated.

**RESULTS:** Real-time PCR detected 100%, 50%, 10%, 1% and 0.1% of YVDD plasmid in mixtures with $10^6$ copies/mL of YMDD plasmid, whereas sequencing and pyrosequencing only detected 100% and 50% of YVDD plasmid in aliquots of the corresponding mixtures. Completely concordant results were obtained from 60 (87%) out of the 69 clinical serum samples by the three assays. Mutants were detected by real-time PCR in less than 20% of the total virus population, but no mutant was detected by sequencing and pyrosequencing. In addition, real-time PCR required less time and was more cost-effective than the other two assays. However, throughput of pyrosequencing was the highest.

**CONCLUSION:** Among the three assays compared, real-time PCR is the most sensitive, cost-effective, and time saving for monitoring YMDD mutants in patients with chronic hepatitis B on lamivudine therapy.

**Key words:** Tyrosine-methionine-aspartate-aspartate mutant; Hepatitis B virus; Real-time PCR; Sequencing; Pyrosequencing

## INTRODUCTION

It is estimated that 350 million individuals are chronically infected with hepatitis B virus (HBV) and that more than 1 million will die of liver cirrhosis and hepatocellular carcinoma (HCC) each year[1-3]. Lamivudine is an effective antiviral agent for patients with chronic hepatitis B and advanced liver diseases[4]. However, long-term lamivudine monotherapy induces emergence of lamivudine-resistant HBV mutants in some patients chronically infected with HBV[4,5]. Resistance is associated with mutations in the highly conserved tyrosine-methionine-aspartate-aspartate (YMDD) motif of the reverse transcriptase, which is part of the catalytic site of HBV polymerase[6]. Virological breakthrough and alanine transaminase (ALT) flare have been observed in 2 and 3 mo after the emergence of YMDD mutants, respectively[7]. Several technologies developed can detect lamivudine-resistant mutants[8], but the number of studies actually comparing these assays is limited.

Nucleotide sequencing of PCR products is routinely used to detect lamivudine resistance. However, this method is expensive and laborious and only can detect mutant virus when it comprises at least 25% of the total virus population[9]. Pyrosequencing has a high throughput and can detect minor sequence variants[10]. Real-time PCR is a rapid and highly sensitive method for detection of mutant HBV[11-14].

In the present study, we compared the sequencing of PCR products, pyrosequencing, and real-time PCR for detection of YMDD mutants in mixed plasmids and clinical samples from chronic hepatitis B patients treated with lamivudine. Time required and reagent costs were also analyzed to enable a comparison among these assays for their cost-effectiveness.

## MATERIALS AND METHODS

### Plasmids and controls

Plasmids and controls were prepared as previously described[14]. Briefly, three previously identified serum samples containing YMDD, YVDD and YIDD respectively were used as a template and amplified by PCR. PCR products were cloned using pGEM-T systems (Promega, Madison, WI, USA), and clones were sequenced using ABI 3100 sequencer (Applied Biosystems, Foster, CA, USA).

### Patients, samples and extraction of HBV DNA

Serum samples were collected from 69 patients with chronic HBV infection. Real-time PCR showed that all the patients after treatment with lamivudine for three months to three years were HBV-DNA positive. HBV DNA was extracted from serum samples using the QIAamp blood kit (Qiagen, Chatsworth, CA, USA) according to the manufacturer's instructions. HBV DNA was measured on Mx3000P real-time PCR system (Stratagene, La Jolla, CA, USA) with quantitative real-time PCR reagents (Fosun Diagnostics, Shanghai, China) approved by the State Food and Drug Administration of China for *in vitro* diagnostic use.

### Sequencing of PCR products

HBV DNA samples were prepared for sequencing by PCR amplification as described by Allen *et al*[6]. HBV DNA extracted from serum samples was amplified by PCR. PCR products were purified with QIAquick PCR purification kits (Qiagen, Chatsworth, CA, USA) and eluted from the column with 80 μL of distilled deionized water. The DNA quality and concentration of DNA were determined by absorbance measurements at 260 and 280 nm and by gel electrophoresis on 2.5% agarose gel. All sequencing reactions were performed on ABI 3130 DNA sequencer (Applied Biosystems, Foster, CA, USA).

### Pyrosequencing

Pyrosequencing was carried out as described by Lindstrom *et al*[10]. In brief, the primer (5'-AGT GGG CCT CAG TCC GTT TC-3') was designed to anneal the adjacent YMDD motif. HBV DNA was extracted from serum samples and amplified by nested-PCR. One of the inner PCR primers was biotinylated to prepare single-stranded DNA with PCR products on the streptavidin-coated beads for pyrosequencing. Pyrosequencing was performed on the automated 96-well PSQ pyrosequencer (Pyrosequencing AB, Uppsala, Sweden) with the PSQ SNP 96 reagent kit (Pyrosequencing AB, Uppsala, Sweden). The nucleotide dispensation order was ATGTATGATG, which was designed on sequences of the interested YMDD motif of the wild-type and mutant HBV.

### Real-time PCR

Real-time PCR for detection of YMDD mutants was performed as previously described[14]. In brief, parallel reactions C, V and I were used to detect total HBV, YVDD, and YIDD, respectively. The reactions differed only in the reverse primer they contained. The amplification was performed on Mx3000P PCR system (Stratagene, La Jolla, CA, USA) by incubating the reaction mixture (50 μL) at 50℃ for 2 min, at 95℃ for 5 min, followed by 40 cycles of PCR amplification at 94℃ for 20 s and at 53℃ for 30 s. The reaction system was provided and optimized by Fosun Diagnostics (Fosun Diagnostics, Shanghai, China). The threshold cycle (Ct) is the cycle at which a significant increase in fluorescence occurs. The percentage of mutants in total viruses was calculated by the equations of Bernard (ΔCt = Ct of control-Ct of mutants)[15] and Shi (ratio of mutants to total viruses = $2^{\Delta Ct}$)[14].

### Mixing experiments

Mixing experiments were used to evaluate the abilities of the sequencing, pyrosequencing and real-time PCR to accurately detect and quantify minor sequence variants. Mutant plasmid containing YVDD sequence and wild-type plasmid were mixed at a final concentration of $10^6$ copies/mL, and the percentage of YVDD plasmid in the mixture was 100%, 50%, 10%, 1%, 0.1% and 0.01% respectively. The mixtures were analyzed by the three methods, respectively. For real-time PCR, each mixture was analyzed five times, and the mean of the five runs was calculated.

### Time study

Time analysis was carried out as described by Krafft and Lichy[16]. Three skilled technologists were selected to perform the assays. Time required for each assay was calculated by direct observation during the procedures.

### Cost analysis

Costs for each assay were estimated based on the prices of reagents in China. The costs of instruments and labors were not included.

## RESULTS

### Detection of YVDD and YMDD mutants in plasmid mixture

YVDD and YMDD mutants in the plasmid mixture were detected at different ratios by sequencing, pyrosequencing and real-time PCR, respectively. YVDD, YVDD/YMDD mutants in the mixture containing 100% and 50% of YVDD plasmid and only YMDD in the mixture containing 10%, 1%, 0.1% and 0.01% YVDD plasmid were detected by sequencing and pyrosequencing. YVDD mutants in the mixture containing 100% YVDD plasmid, YVDD/YMDD mutants in the mixture containing 50%, 10%, 1% and 0.1% YVDD plasmid and only YMDD mutants in the mixture containing 0.01% YVDD plasmid were detected by real-time PCR. The ratio of YVDD to YMDD mutants in the real-time PCR assay was almost identical to the true ratio in the mixtures (Table 1).

### Comparison of sequencing, pyrosequencing and real-time PCR for detection of YMDD and YVDD mutants in clinical samples

We detected YMDD and YVDD mutants in clinical serum samples from 69 chronic hepatitis B patients treated with lamivudine. The results obtained by sequencing, pyrosequencing and real-time PCR were compared (Table 2). Completely concordant results were obtained from 60

**Table 1 Results of sequencing, pyrosequencing and real-time PCR for detection of mixed plasmids containing YVDD and YMDD at a final concentration of $10^6$ copies/mL**

| YVDD plasmid in the mixture | Sequencing | Pyrosequencing | Real-time PCR | ΔCt (mean ± SD) | Calculated percentage (mean ± SD) (%) |
|---|---|---|---|---|---|
| 100% | YVDD | YVDD | YVDD | -0.024 ± 0.06 | 98 ± 4.0 |
| 50% | YVDD | YVDD | YVDD | -0.98 ± 0.07 | 51 ± 2.5 |
| 10% | YMDD | YMDD | YVDD | -3.12 ± 0.09 | 11 ± 0.7 |
| 1% | YMDD | YMDD | YVDD | -6.60 ± 0.14 | 1 ± 0.1 |
| 0.1% | YMDD | YMDD | YVDD | -10.12 ± 0.20 | 0.09 ± 0.01 |
| 0.01% | YMDD | YMDD | YMDD | ND | 0 |

ND: Not detected.

(87%) samples by the three assays. YMDD mutants in 24 samples and YVDD mutants in one sample were detected by pyrosequencing, while YMDD mutants in 22 samples and YVDD mutants in three samples were detected by real-time PCR. The percentage of mutants in the virus population obtained by real-time PCR in the three YVDD samples was 20%, 7% and 6% respectively. Twenty-four types of YIDD mutant and two mixed types of YIDD and YVDD mutants were detected by pyrosequencing, while 21 types of YIDD mutants and 5 mixed types of YIDD and YVDD mutants were detected by real-time PCR. The results were identical in 18 YVDD samples obtained by pyrosequencing, but YVDD mutants were detected in one sample by sequencing and pyrosequencing while YMDD mutants were detected in one sample by real-time PCR.

Among the five samples containing mixed types of YIDD and YVDD mutants by real-time PCR, mixed mutants were detected by pyrosequencing whereas only dominant mutants were detected by sequencing in two samples.

### *Time required*

The time required for each assay of a certain number of samples was dependent on the throughput of the instruments used for detection. We measured the time required for each assay based on a 4-sample run because the highest throughput of ABI 3130 sequencer used in this study was 4 samples per run. The total assay time for sequencing, porysequencing and real-time PCR was 5, 4.5 and 2 h, respectively.

### *Costs*

The cost for each assay was calculated based on the prices of the reagents in China. The sequencing reagents were from Applied Biosystems (Applied System, Foster, CA, USA). Pyrosequencing reagents were from Pyrosequencing AB (Pyrosequencing AB, Uppsala, Sweden). Primers and probes were synthesized in TaKaRa Biotech (TaKaRa, Dalian, China). Real-time PCR mixtures were from Fosun Diagnostics (Fosun Diagnostics, Shanghai, China). The total reagent cost for each sequencing, pyrosequencing and real-time PCR was 120, 150 and 80 Yuan RMB, respectively.

## DISCUSSION

Lamivudine is one of the first-line medicines for chronic hepatitis B. Mutations in the YMDD motif of polymerase gene have been detected in patients with chronic hepatitis B treated or untreated with lamivudine[14,17-19]. Clinical breakthrough can be observed 2 wk to 7 mo after the emergence of YMDD mutations[7,9,19-20]. Acute and severe exacerbation due to YMDD mutations can cause considerable morbidity and mortality[21-24]. Lamivudine therapy after the emergence of YMDD mutations has no effect on chronic hepatitis B patients[25]. Antiviral agents, such as adefovir and entecavir, are effective against lamivudine-resistant HBV[26-28]. Pegylated interferon is also one of the first-line therapeutic options for hepatitis B virus infection and can induce sustained responses in some of lamivudine-resistant patients[29-31]. Monitoring YMDD mutation during lamivudine therapy contributes to the clinical decision of treatment of chronic hepatitis B patients.

Many assays have been used for detection of lamivudine-resistant mutants in patients with hepatitis B[8]. However, they are different in sensitivity, specificity, cost, and time required. Sequencing of PCR products is a conventional assay and pyrosequencing is a high throughput method that can detect minor sequence variants. In the present study, we compared sequencing of PCR products, pyrosequencing, and real-time PCR for detection of YMDD mutations in chronic hepatitis B patients treated with lamivudine. The results obtained by sequencing, pyrosequencing and real-time PCR were completely concordant in 60 (87%) patients. YVDD mutants were detected by real-time PCR in three samples. The percentage of the mutants in total viruses in the three samples was 20%, 7%, and 6%, respectively, all of which were below the detection limit of sequencing[9]. YVDD mutants were detected by pyrosequencing in the sample with 20% of mutants. These results suggest that real-time PCR is more sensitive, cost-effective and time saving than sequencing and pyrosequencing. In one sample, YVDD mutants were detected by sequencing and pyrosequencing and YMDD mutants were detected by real-time PCR. Further study of the clinical data of the sample revealed that it contained 620 copies/mL of HBV DNA, which was below the limit of real-time PCR assay[14].

Pyrosequencing is a high throughput, non-gel-based DNA sequencing technique based on real-time detection of the released pyroghosphate during DNA synthesis[10]. Pyrosequencing is widely used in detection of single nucleotide polymorphisms (SNP) in the human genome[32].

However, pyrosequencing only can detect DNA sequence with a length of no more than 40 base-pair, while sequencing of PCR products can detect much longer DNA sequences. Real-time PCR detects specific point mutations recognized by the primers or probes.

The time required for each assay is dependent on the throughput of instruments used. In the present study, ABI 3130 was used for sequencing of PCR products. Its highest throughput was 4 samples per run. The instruments used for pyrosequencing and real-time PCR were 96-well plates and had the highest throughput of 96 samples and 32 samples, respectively. Although pyrosequencing has the highest throughput, relatively few laboratories have used pyrosequencing equipments[10]. Real-time PCR assay is well suited for routine screening of YMDD mutants because real-time PCR systems are routinely used in many laboratories.

For detection of mutants in virus population, real-time PCR can calculate the ratio of mutants to total viruses[14], while sequencing and pyrosequencing only can estimate the ratio by the signal intensity. The background noises affect the results. When serum HBV-DNA is below $10^8$ copies/mL, no false positive results have been observed[14]. However, the accuracy of the ratios calculated in real-time PCR can be affected by variations in the ΔCt value, especially in cases where mutants are above 50% in the virus population.

In conclusion, among the three assays studied, real-time PCR is the most sensitive, cost-effective, and time saving method for monitoring YMDD mutations in patients with chronic hepatitis B on lamivudine therapy.

## Abstract

Hypertriglyceridemia is an established cause of pancreatitis. In a case-based approach, we present a review of hypertriglyceridemia and how it can cause pancreatitis. We outline how to investigate and manage such patients. A 35 year old man presented to the emergency department with abdominal pain and biochemical evidence of acute pancreatitis. There was no history of alcohol consumption and biliary imaging was normal. The only relevant past medical history was that of mild hyperlipidemia, treated with diet alone. Physical exam revealed epigastric tenderness, right lateral rectus palsy, lipemia retinalis, bitemporal hemianopsia and a delay in the relaxation phase of his ankle reflexes. Subsequent laboratory investigation revealed marked hypertriglyceridemia and panhypopituarism. An enhanced CT scan of the head revealed a large suprasellar mass impinging on the optic chiasm and hypothalamus. The patient was treated supportively; thyroid replacement and lipid lowering agents were started. He underwent a successful resection of a craniopharyngioma. Post-operatively, the patient did well on hormone replacement therapy. He has had no further attacks of pancreatitis. This case highlights many of the factors involved in the regulation of triglyceride metabolism. We review the common causes of hypertriglyceridemia and the proposed mechanisms resulting in pancreatitis. The incidence and management of hypertriglyceridemia-induced pancreatitis are also discussed.

**Key words:** Hypertriglyceridemia; Pancreatitis; Hyperlipidemia

## INTRODUCTION

Acute pancreatitis is a common condition with several possible etiologies. The mortality rate may be up to 20%. While alcohol and gallstones are the most common etiologies, metabolic, structural and iatrogenic causes are responsible for 20%-25% of cases in the United States. Although hyperlipidemia can be associated with acute pancreatitis as an epiphenomenon, hypertriglyceridemia or chylomicronemia is the underlying cause in up to 7% of all cases of pancreatitis. It is the most common cause of acute pancreatitis not due to gallstones or alcohol[1-4]. Hypertriglyceridemia-induced pancreatitis rarely occurs unless triglyceride levels exceed 20 mmol/L[3,5]. For triglyceride levels to exceed 20 mmol/L, most patients will have some form of primary or genetic defect in lipid metabolism. Genetic factors determine over 60% of the variability in serum lipids. As most patients can be effectively treated with existing drug therapy, it is critical that the gastroenterologist recognize these patients and manage them appropriately. Since not all hyperlipidemia is familial in nature, an awareness of the secondary causes of hypertriglyceridemia and factors that can alter triglyceride metabolism is imperative.

In a case-based approach, we present a review of the common causes of hypertriglyceridemia, the proposed mechanisms resulting in pancreatitis as well as further details on the incidence and management of hypertriglyceridemia-induced pancreatitis (Table 1). Although the case presented is an uncommon scenario, it clearly demonstrates how a sequence of metabolic and endocrine abnormalities can lead to a common disease process- acute pancreatitis. The key to investigating, diagnosing and managing this patient was taking a detailed history and performing a thorough physical exam.

## CASE PRPORT

A 35-year-old man presented to the emergency department with a 36-h history of severe epigastric pain and vomiting. He also complained of a four-month history of headaches, fatigue, cold intolerance, constipation, reduced libido, and erectile dysfunction. One year prior to presentation, he was

Modified from Fung and Frohlich[44].

told that he had mildly elevated "cholesterol" and was told to modify his diet. His past medical history was otherwise negative. He did not smoke, rarely consumed alcohol (none in the last 14 d) and was not taking any medications. Physical exam found a somnolent but easily rousable male with marked epigastric tenderness. No masses or organomegaly was noted on examination of his abdomen. A right lateral rectus palsy, lipemia retinalis and bitemporal hemianopsia were also noted on exam but there were no signs of increased intracranial pressure. The thyroid exam was normal but the relaxation phase of his ankle reflexes was delayed.

Electrolytes and complete blood count were normal. Serum lipase was 754 U/L (normal 20-190 U/L) and his liver transaminases, alkaline phosphatase and lactate dehydrogenase were normal. Ultrasound detected inflammatory changes in the pancreas but the gallbladder and biliary tree were normal. Serum triglyceride was 38.5 mmol/L (normal 0-2), cholesterol; 12.4 mmol/L (normal 0-5.2), thyroid stimulating hormone; 0.17 (normal 0.4-4.0), free T4; 3.8 pmol/L (normal 10.8-23.8), random cortisol; 62 mmol/L (normal 138-690), serum testosterone < 0.7 nmol/L (normal 10-33), and luteinizing hormone; 0.1 IU/L (normal 1.3-6.3). An enhanced CT scan of the head revealed a large suprasellar mass impinging on the hypothalamus and optic chiasm.

**Figure 1** Enhanced CT scan showing a large suprasellar craniopharyngioma (arrow).

A diagnosis of acute pancreatitis was made. Chylomicronemia caused by central hypothyroidism was the most likely etiology. The patient was treated with intravenous fluids and narcotics for pain control. His epigastric pain resolved over three days. He was given dexamethasone 4 mg three times daily preoperatively and L-thyroxine 50 micrograms daily. The fibric acid derivative gemfibrozil was started at 600 mg twice daily. At craniotomy, a suprasellar craniopharyngioma displacing the optic chiasm and encasing the pituitary stalk was completely removed (Figure 1). He was started on glucocorticoid replacement therapy, L-thyroxine, DDAVP and testosterone for panhypopituitarism. His postoperative course was uncomplicated; he has subsequently remained asymptomatic over a three-year follow-up period.

## DISCUSSION

### *Hypertriglyceridemia-induced pancreatitis*

**Epidemiology:** It is well known that hyperlipidemia is associated with acute pancreatitis, both as a precipitant and as an associated epiphenomenon[1,2]. Hypertriglyceridemia or chylomicronemia may be responsible for 1%-7% of all cases of pancreatitis[3,4]. Failure to consider and investigate chylomicronemia as a cause of pancreatitis may lead to an underestimate of the incidence. Pregnancy or medical conditions such as diabetes (both known to precipitate marked hypertriglyceridemia) should prompt further work-up[6,7]. Chylomicronemia may be the cause of 20% of episodes of acute pancreatitis in non-drinkers free of biliary tract disease. Chang *et al* found that hypertriglyceridemia was the cause of 56% cases of gestational pancreatitis[7]. In many settings, determining the exact etiology of pancreatitis may be complicated by the role of ethanol in precipitating severe hypertriglyceridemia. The proportion of "alcoholic pancreatitis" caused by direct as opposed to secondary hyperlipidemic effects is unknown.

Hypertriglyceridemia-induced pancreatitis rarely occurs unless triglyceride levels exceed 20 mmol/L[3,5]. In contrast, mild to moderate elevations in triglycerides (2-10 mmol/L) are extremely common in the early phase of acute pancreatitis of any etiology. One study noted such elevations in 47% of randomly selected patients presenting with acute pancreatitis[2]. In the same study, mild to moderate elevations of triglycerides were felt more

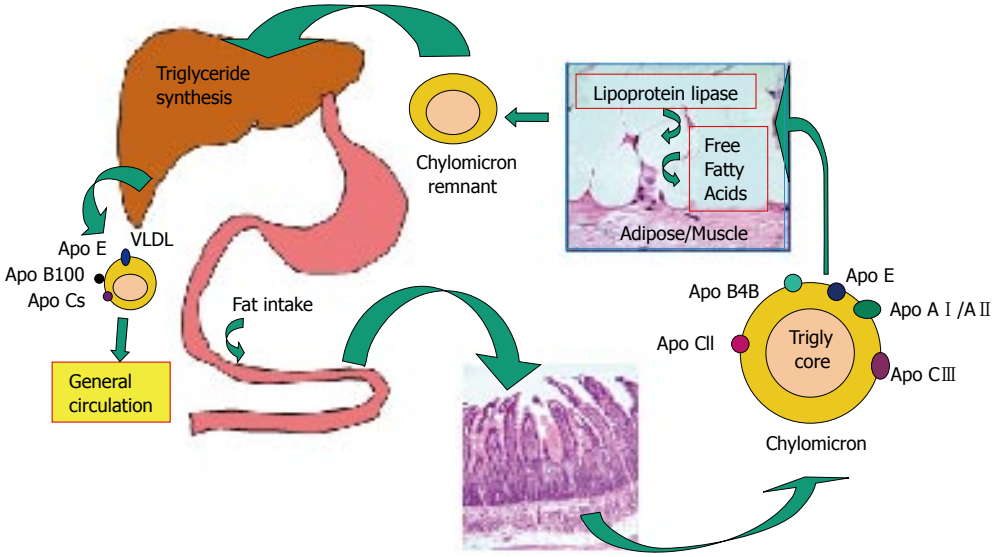

**Figure 2** Triglyceride metabolism.

likely to be an epiphenomenon of the acute pancreatitis rather than a true causal precipitant[2]. It is important to remember that chylomicrons are the product of dietary fat absorption. Enforced abstinence from eating after a diagnosis of pancreatitis may allow rapid metabolism of the triglyceride-rich chylomicrons. Dominguez-Munoz *et al* found severe elevations (> 20 mmol/L) in 10% of patients but levels rapidly fell in the majority of patients within 72 h of presentation; therefore, a delay in the presentation or consideration of diagnosis can lead to false conclusions about etiology. Triglyceride levels remained mildly elevated for up to 15 d, probably reflecting an underlying lipid disorder[2].

### *Pathogenesis of hypertriglyceride-induced pancreatitis*

The exact mechanisms involved in hypertriglyceridemia-induced pancreatitis are unclear. Chylomicrons are triglyceride-rich lipoprotein particles believed to be responsible for pancreatic inflammation. They usually present in the circulation when serum triglyceride levels exceed 10 mmol/L. These largest of lipoproteins might impair circulatory flow in capillary beds; if this occurs in the pancreas, the resulting ischemia might disturb the acinar structure and expose these triglyceride-rich particles to pancreatic lipase. The pro-inflammatory non-esterified free fatty acids generated from the enzymatic degradation of chylomicron-triglycerides may lead to further damage of pancreatic acinar cells and microvasculature. Subsequent amplification of the release of inflammatory mediators and free radicals may ultimately lead to necrosis, edema, and inflammation[8,9]. This hypothesized sequence of events was substantiated by studies showing both triglycerides and free fatty acids caused edema, hemorrhage and elevated amylase levels[9]. Hypertriglyceridemia has also been shown to exacerbate other experimental models of pancreatitis[10].

Studies using oral lipid-loading tolerance tests have documented elevated post-load plasma triglyceride levels in patients with previous pancreatitis as compared with controls[11,12]. To address whether hyperlipidemia is a pre-existing metabolic disorder or a consequence of acute pancreatitis, Dominguez-Munoz and co-workers addressed the hypothesis that mild to moderate elevation of serum triglyceride levels are likely to be an epiphenomenon of the pancreatic disease whereas the severe hyperchylomicronemia and hypertrygliceridemia required to trigger acute pancreatitis would require a relevant defect in the lipid catabolism and clearance[13]. They looked at a group of ten patients with a history of acute pancreatitis associated with severe elevations of serum triglycerides (> 20 mmol/L) and ten patients with acute pancreatitis and normal lipid values. Four to six months after recovery from the pancreatitis, they administered an infusion of intralipid of 20% and calculated the fractional removal rate (K2) and the maximal clearance capacity (K1) of exogenous triglycerides. All patients with a previous attack of "normo-lipidemic" acute pancreatitis had normal K2 and K1 values. However, five patients (50%) with previous hyperlipidemic acute pancreatitis had an abnormally low clearance capacity of exogenous triglycerides while the remaining five had normal removal values. They concluded that, even in the setting of a marked elevation of serum lipid levels, there may be other etiological factors involved[13]. These findings were supported by a similar earlier study[14].

Interestingly, mutations in the lipoprotein lipase (LPL) gene have been identified in patients with hypertriglyceridemia-induced pancreatitis[15-20]. Specifically, mutations in the LPL gene are thought to be a common cause of pregnancy-induced chylomicronemia. One group described 5 such patients all of whom had different mutations in the LPL gene leading to dramatic reductions in LPL activity[21]. Dysregulation or deficiency of key enzymes and substrates involved in triglyceride metabolism has also been described in patients with recurrent hypertriglyceridemia-induced pancreatitis (Figure 2). Lecithin-cholesterol acyltransferase (LCAT) deficiency is one example[22].

### *Hyperchylomicronemia and hypothyroidism*

All patients that develop significant chylomicronemia are thought to have an underlying genetic disorder of lipoprotein metabolism. A disturbance in lipoprotein

lipase activity, the rate-limiting enzyme of triglyceride-rich particle metabolism, is often the culprit. Clinical problems rarely develop unless there is another precipitating condition affecting metabolism such as diabetes, ethanol excess, pregnancy, certain drugs (estrogen[23-26], furosemide[27], isotretinoin[28,29], tamoxifen[30], beta-blockers[31]) or, as in this case, hypothyroidism. Physical findings can include eruptive xanthomas produced by macrophage uptake of chylomicrons which accumulate in the skin over extensor surfaces and lipemia retinalis that is a result of high concentrations of circulating chylomicrons in retinal vessels[32].

Hypothyroidism has a well-established association with hyperlipidemia. Elevations of triglyceride levels are observed in up to 35% of hypothyroid patients[33]. Impaired low-density lipoprotein (LDL) receptor activity may result in decreased clearance and thus an accumulation of LDL particles. A low circulating free thyroid hormone level may also impair lipoprotein lipase activity in adipose tissue. Replacement therapy with L-thyroxine treatment may reverse both of these defects.

### *Treatment*

In the acute setting, pancreatitis due to hyperlipidemia should be treated in much the same manner as other causes of pancreatitis. Currently there is no clear evidence that hyperlipidemia-induced pancreatitis differs from other types of pancreatitis in terms of frequency of necrosis[2], complications or outcomes[3]. A similar approach to medical and diagnostic management is thus indicated. Although chylomicron and triglyceride levels fall rapidly after oral fat intake ceases, efforts to accelerate the removal of the precipitating lipoproteins have been considered.

Direct removal of chylomicrons in the acute setting can be readily achieved by plasmapheresis and there are numerous documented reports[34-37]. Chronic plasmapheresis as prophylaxis has also been reported in patients with recurrent pancreatitis due to severe primary hypertriglyceridemia that was unresponsive to drug and dietary interventions[38]. Recognizing that decreased lipoprotein lipase (LPL) activity is a prominent cause of hypertriglyceridemia has fuelled attempts to enhance LPL activity. Although this is an interesting concept only one small study in the literature has addressed this in which intravenous insulin and heparin, both of which enhance LPL activity, were used to treat a small number of patients with hypertriglyceridemia-induced pancreatitis[39]. They found that the therapy reduced triglyceride levels and appeared to improve the pancreatitis[39]. Diabetic patients should be treated aggressively with intravenous insulin infusions to obtain and maintain euglycemia rapidly.

Patients with known rare defects in lipid metabolism have been treated with replacement therapies with some success. Purified apoC-Ⅱ infusion has yielded transient normalization of triglyceride levels and clinical improvement in pancreatitis patients with apoC-Ⅱ deficiency[40].

Therapeutic efforts following recovery from pancreatitis need to be directed at preventing recurrence by controlling triglyceride levels. As most cases of hyperlipidemia occur when a genetically-predisposed individual is exposed to a secondary condition, therapy should be targeted towards the concomitant disorder. Alcohol should be discontinued as should oral estrogen therapy or selective estrogen receptor modulators such as tamoxifen or raloxifene. Diabetes should be treated with oral hypoglycemics and/or insulin aiming for tight glycemic control. Obviously, as in our case, hypothyroidism should be treated with L-thyroxine.

Persistence of hyperlipidemia on a fat-reduced diet should prompt the institution of lipid-lowering agents. The fibric acid derivatives (fibrates), such as gemfibrozil, fenofibrate or bezafibrate, are the drugs of first choice. These agents are generally well tolerated and highly effective if taken regularly and diet restrictions are continued. Niacin is inexpensive and often effective alone or in combination with a fibrate. Side effects such as flushing, hyperuricemia and hepatic transaminasemia may limit the use of niacin as a first line agent. Controversy exists as to whether niacin may exacerbate glucose intolerance in patients with diabetes mellitus. Omega-3 fatty-acid products show promise as adjunctive agents in refractory cases. Medium-chain triglycerides have also been used to prevent acute hyperlipidemic pancreatitis during pregnancy[41] as their absorption doesn't require chylomicron formation.

Interestingly, in a study of 21 such patients with primary hypertriglyceridemia and a history of recurrent attacks of pancreatitis, lipid lowering toward normal was achieved in all patients with a program of combined dietary and drug therapy[42]. Five patients had recurrent episodes of pancreatitis during the treatment program all of whom were diagnosed subsequently with bulimia[42]. Anti-oxidant therapy (selenium, beta-carotene, vitamin C and $\alpha$-tocopherol) has been used with success in the reduction of recurrent pancreatitis episodes in patients with familial lipoprotein lipase deficiency who remained markedly hypertriglyceridemic after medical therapy[43]. It is postulated that the antioxidants might protect the pancreatic acinar cells from free radical damage brought on by the ischemia of chylomicron-induced changes in pancreatic capillary circulation[43].

## CONCLUSIONS

This case illustrates a sequence of clinical events, due to a combination of genetic and acquired disorders, which resulted in a common medical problem. The main clues to diagnosing this complex chain of events leading to pancreatitis became evident from a thorough history and physical exam. Identifying features of a possible intracranial lesion, hypothyroidism, hypogonadism and hypertriglyceridemia in the context of an understanding of triglyceride metabolism facilitated the diagnosis.

Hypertriglyceridemia is a common clinical problem that can be exacerbated by numerous medications and medical conditions. Markedly elevated triglyceride levels can lead to pancreatitis, a serious and potentially fatal complication. General and specific therapy is available to reduce triglyceride levels during the acute phase of pancreatitis, which may improve the outcome. Nutrition, pharmacologic therapy and avoiding agents that can

elevate triglycerides may be essential in preventing further attacks. There are numerous causes of pancreatitis. Various diagnostic tools can be very helpful in determining the cause of pancreatic inflammation; however, the most valuable approach remains a thorough history and physical exam.

## Abstract

In benign or low-grade malignant pancreatic tumors, complete removal of the lesion is sufficient for a cure, and thus minimal resection techniques with preservation of the pancreatic functional reserve have advantages over more extended pancreatic resections. However, a high incidence of postoperative pancreatic fistula in such procedures has been reported. Moreover, branch-type intraductal papillary mucinous neoplasms of the pancreas tend to locate in the head of the pancreas, and show less malignant potential. We describe an endoscopic naso-pancreatic stent-guided single-branch resection of the pancreas for branch-type multiple intraductal papillary mucinous adenomas, along with a gastric wall-covering method for the prevention of pancreatic leakage.

**Key words:** Intraductal papillary mucinous neoplasm; Single-branch resection; Gastric wall-covering method

## INTRODUCTION

Intraductal papillary mucinous neoplasm (IPMN) of the pancreas is characterized by dilatation of the main and/or branch pancreatic ducts, mucin-secretion, and intraductal papillary growth. IPMNs are classified into three types, a main pancreatic duct type, branch type, and mixed type. The branch type IPMN is more frequently located in the head of the pancreas, and shows less malignant potential[1,2]. Therefore, several new surgical procedures for minimal resection of the pancreas with pancreatic functional reserve have been proposed, including duodenum-preserving pancreatic head resection, segmental pancreatectomy and single-branch resection of the pancreas[3-5]. Single-branch resection is a minimally invasive surgical procedure for the resection of the pancreas because it requires no reconstruction for the main pancreatic duct or the common bile duct. In addition, single-branch resection should avoid injury to the main pancreatic duct which could cause a postoperative pancreatic fistula. Although several surgical techniques and devices have been advocated to avoid breaking the main pancreatic duct, the incidence of pancreatic fistula is still relatively high[6]. We report herein a case of successful single-branch resection for two IPMNs within the head of the pancreas under the guidance of intraoperative pancreatography by using an endoscopic naso-pancreatic drainage (ENPD) tube along with a gastric wall-covering technique for the prevention of pancreatic leakage.

## CASE REPORT

A 59-year-old man was referred to our hospital for further evaluation of two cystic tumors in the head of the pancreas which were detected by routine ultrasonography (US). Upon admission, there were no abnormal findings in the laboratory data. The endocrine pancreatic function by a 75 g oral glucose tolerance test and the exocrine function by a pancreatic function diagnostic (PFD) test were within normal range. Abdominal US and computed tomography (CT) showed two multilobular cystic lesions, 15 mm and 40 mm in diameter, respectively, in the head of the pancreas. Endoscopic retrograde pancreatography (ERP) showed two cystic lesions communicating with the main pancreatic duct. Although mucous secretion was detected from the duodenal papilla, the main pancreatic duct showed no abnormality. Magnetic resonance cholangiopancreatography (MRCP) and ERP revealed a communicating branch to these two cystic lesions (Figure 1). No mural nodules were noted in the cysts. The cytology of

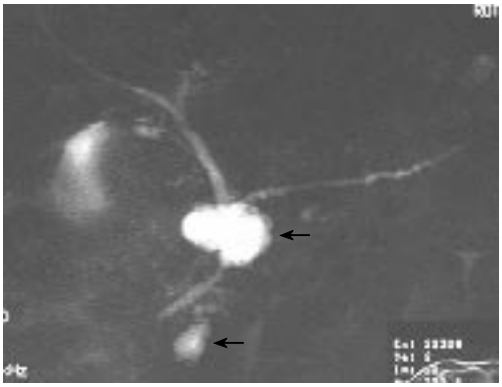

**Figure 1** MRCP showing two cystic lesions in the head of the pancreas (arrows).

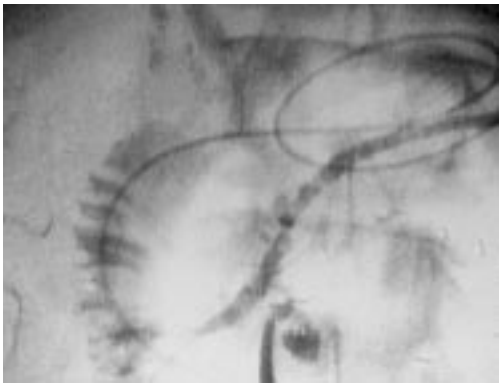

**Figure 2** Intraoperative pancreatography using an ENPD tube demonstrates a communicating duct between the main pancreatic duct and cystic lesion.

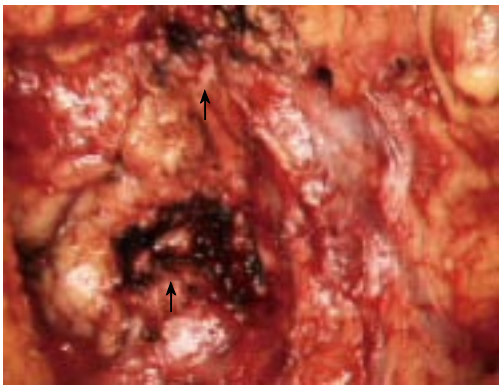

**Figure 3** Operative photograph shows the pancreas after completion of the single-duct resection of the pancreas for multiple IPMNs. Arrows indicate the cut surface after pancreatic resection.

the pancreatic juice was negative for malignant cells. K-ras point mutation at codon12 was detected in the pancreatic juice. Consequently, the cystic lesions were diagnosed as a branch-type intraductal papillary mucinous neoplasm (IPMN) and the patient was considered a candidate for surgery.

Under general anesthesia, we placed a 5F-size ENPD tube (Olympus, Tokyo Japan) for intraoperative pancreatography prior to laparotomy. The ENPD tube was inserted deep into the main pancreatic duct for approximately 10 cm through the orifice. After an upper abdominal midline incision, the gastrocolic ligament was divided and the pancreas exposed. The duodenum was mobilized to facilitate access to the head of the pancreas. The communicating branches between the cystic lesions and main pancreatic duct were carefully evaluated by using intraoperative US and pancreatography (Figure 2), and a single-branch resection for both cystic tumors was then performed. During the resectioning of the cystic tumors, the ENPD tube in the main pancreatic duct was clearly and easily detected by intraoperative US, and thus both the direction and position of the main pancreatic duct and the correlation between the cystic tumors and main pancreatic duct were correctly identified. The two cystic tumors were dissected along the border of the tumor and the surrounding normal pancreatic parenchyma, and then the confluences of the pancreatic branch ducts and main pancreatic duct were ligated using a 4-0 non-absorbable monofilament suture. Intraoperative frozen section histological examination of the dissected pancreatic ducts revealed a disease-free margin. After removal of the tumors, pancreatography through the ENPD tube was performed and revealed no injury to the main pancreatic duct or leakage from the transected pancreatic branch ducts. Because a mixture of indigocarmine and contrast material was used for the pancreatography, we were able to detect any minor pancreatic leakage as a blue spot at the cut surface of the pancreas and close the leaking points appropriately with 4-0 absorbable monofilament sutures. After pancreatic resection, the ENPD tube was used for the drainage of the pancreatic duct. It was not necessary to perform any reconstruction of the digestive tract (Figure 3). To prevent pancreatic leakage from the small pancreatic branches at the cut surface of the pancreas, the "gastric wall-covering method [7]" was performed as follows: each cut surface after resection of the two cystic tumors was fixed to the posterior wall of the gastric body by suturing between the pancreatic parenchyma and the seromuscular layer of the stomach with 4-0 absorbable monofilament. The operating time was 225 min, and blood loss was 240 mL. Histological diagnosis was intraductal papillary mucinous adenoma of the pancreas. The ENPD tube was removed on the 14th postoperative day. The postoperative course was uneventful, and the patient was discharged home on the 25th postoperative day with no endocrine or exocrine pancreatic insufficiency.

## DISCUSSION

The branch type of IPMN of the pancreas shows a more favorable prognosis than invasive ductal adenocarcinoma of the pancreas. In the benign or low-grade malignant IPMN, complete tumor resection is sufficient for a cure[1,2]. Therefore, several organ-preserving techniques, including duodenum-preserving pancreatic head resection, have been advocated in the surgical treatment for IPMN in the head of the pancreas[3]. The advantage of duodenum-preserving pancreatic head resection is the complete preservation of the duodenum, including the duodenal papilla sphincter function, compared with a pylorus-preserving pancreaticoduodenectomy. However, the

duodenum-preserving pancreatic head resection requires a reconstruction of the main pancreatic duct and/or common bile duct. In addition, another challenge when performing the duodenum-preserving pancreatic head resection is preserving the blood supply to the duodenum. Therefore, single-branch resection of the pancreas for multiple IPMNs has been performed as an ultimate organ-preserving surgery[5]. In the present case, we developed single-branch resection of the pancreas using an ENPD tube for multiple branch-type IPMNs as an ideal pancreas-preserving surgery. The most important advantage of the single-branch resection is both the complete preservation of the main pancreatic duct and the complete removal of the lesions. The insertion of an ENPD tube was useful for identifying the pancreatic duct in order to prevent injury to the main pancreatic duct. The ENPD tube in the main pancreatic duct is easily detectable using intraoperative US, and it can demonstrate a repeated intraoperative pancreatography. The first benefit of intraoperative pancreatography using an ENPD tube is that the identification of the anatomical relationship between the cystic lesions and main pancreatic duct can be confirmed not only by a radiological image, but also by a direct palpation. In addition, we used a mixture of a dye and contrast medium for the intraoperative pancreatography, which allowed us to identify the pancreatic leakage directly as a visible blue point by detecting the dye leakage. Pancreatic leakage is the most frequent complication and is still responsible for most mortality after pancreatic surgery[6]. In particular, the incidence of pancreatic leakage following partial resection of the pancreas is high. In the present case, a novel surgical procedure, a "gastric wall-covering method," was performed to prevent pancreatic leakage[7]. The concept of the gastric wall-covering method is that the opening small pancreatic ducts at the cut surface as a cause of pancreatic leakage were covered completely with the gastric wall. As shown in our patient, the multiple partial resections of the pancreas had a wide cut surface. Therefore, the gastric wall-covering method is useful for the prevention of pancreatic leakage from the opening of the small pancreatic branch ducts at the cut surface.

In conclusion, single-branch resection of the pancreas, without reconstruction of the pancreatobiliary tract, is the most ideal, least invasive pancreatic resection for a low-grade malignant neoplasm, including multiple IPMNs. ENPD tube-guided pancreatectomy is an improved technique that allows the surgeon to more accurately determine the precise location and correlation of tumors and pancreatic ducts.

## Abstract

Gallbladder disease is no more common in patients with systemic lupus erythematosus (SLE) than in the general population. We describe a 17-year-old patient with SLE, who developed nephritis that was well controlled with medications. Initial treatment consisted of azathioprine, aspirin and prednisone with stable control of her symptoms. Two years later she developed a right quadrant abdominal pain, and an abdominal ultrasound revealed microlithiasic cholecystitis. Open cholecystectomy was performed and the histopathological findings revealed vasculitis with thrombotic microangiopathy in the gallbladder. This case presentation illustrates that calculous or acalculous cholecystitis should be considered as a manifestation of active SLE and APS.

**Key words:** Gallbladder; Cholecystitis; Systemic lupus erythematosus; Antiphospholipid syndrome

## INTRODUCTION

Gallbladder disease is no more common in patients with systemic lupus erythematosus (SLE) than in the general population[1]. Scarce reports on acalculous cholecystitis (ACC) in SLE or in antiphospholipid syndrome (APS) have been described in the literature[2-12]. We describe a patient with SLE, nephritis, pancreatitis and microlithiatic cholecystitis. Open cholecystectomy was performed and the histopathological findings revealed vasculitis and thrombotic microangiopathy in the gallbladder. She was diagnosed with secondary APS and started on anticoagulation therapy. Coincidentally, her lupus nephritis also improved. This case illustrates that calculous or acalculous cholecystitis should be considered as a manifestation of SLE and APS.

## CASE REPORT

In 2002, a 17-year-old female with arthritis and oral ulcers was referred to the Instituto Nacional de Pediatría in Mexico City. Laboratory results showed autoimmune hemolytic anemia, leucopenia, lymphopenia, hypocomplementemia. She also had positive anti-nuclear antibodies (ANA), anti-dsDNA, anti-$\beta_2$-glicoprotein-I, and anti-cardiolipin antibodies. Based on her clinical presentation and laboratory studies, she was diagnosed with SLE. Initial treatment consisted of azathioprine, aspirin and prednisone with stabilization of symptoms. In 2003 she presented with renal complication including proteinuria and hematuria. Oral cyclophosphamide was started with improvement in her renal function. In 2004 she developed right quadrant abdominal pain, and an abdominal ultrasound revealed microlithiasic cholecystitis. The abdominal pain spontaneously resolved and dietary modifications were initiated. She was clinically well until July 2005 when she presented with a flare consisting of hypertension, autoimmune hemolytic anemia and marked proteinuria.

On admission the physical examination was unremarkable. Laboratory tests showed proteinuria: 7.2

g/d, serum Cr: 1.6 g/dL, Coombs: +, Hb: 9.3 g/dL, leucocyte count: 3300/mm$^3$, total lymphocyte count: 369, platelets: 218000/mm$^3$. Immunological tests were positive for anti-dsDNA, anti-β2-glicoprotein- Ⅰ, and anti-cardiolipin antibodies, CH50: 49 IU/mL (normal 150-250 IU/mL), C3: 21 mg/dL (normal 86-184 mg/dL), C4: 5.3 mg/dL (normal 19-58 mg/dL). She was started on methylprednisolone and cyclophosphamide.

A renal biopsy showed a global, diffuse, proliferative and membranous glomerulonephritis (class Ⅳ-Ⅴ) without thrombosis. During her admission she developed acute abdominal pain, including a positive Murphy sign on exam. Liver and pancreatic function tests were elevated: gamma-glutamyltranspeptidase was 210 mU/mL (30-60 mU/mL), AST 339 mU/mL (11-33 mU/mL) ALT 154 mU/mL (4-30 mU/mL), total bilirubin 1.1 mg/dL (0.2-1.0 mg/dL) with direct bilirubin, 0.6 mg/dL,amylase 932 mU/mL (68-215 mU/mL) and lipase 649. Abdominal ultrasound revealed lithiasic cholecystitis and pancreatitis. The patient underwent open cholecystectomy and histopathological findings of the gallbladder showed segmental necrotizing vasculitis and vascular occlusion with fragmented erythrocytes (Figures 1A and 1B). Anticoagulation therapy was started with subsequent resolution of the proteinuria and normalization of the laboratory values including the creatinine level.

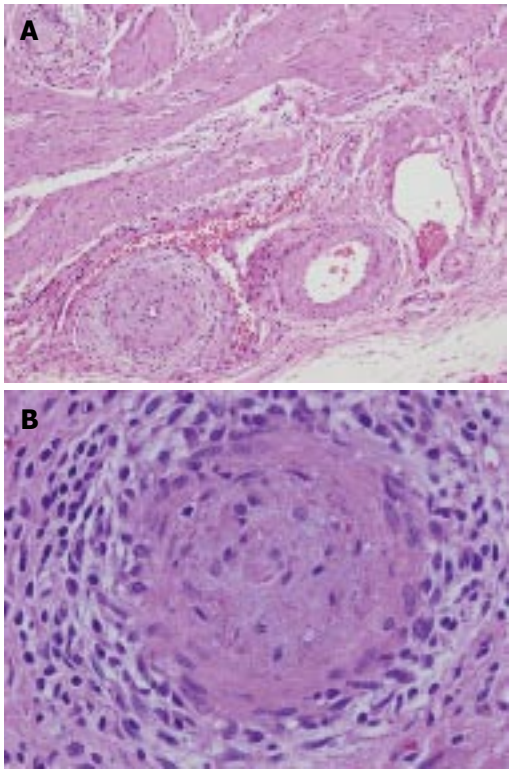

**Figure 1** Occlusion with fibrosis in a gallbladder artery (HE x 1) (**A**); Total artery occlusion, fragmented erythrocytes and perivascular inflammation with mononuclear infiltration (**B**).

## DISCUSSION

A variety of gastrointestinal complications have been reported in association with systemic lupus erythe-matosus (SLE), including mesenteric arteritis, intestinal perforation, and peritonitis[9]. Gallbladder disease is no more common in patients with systemic lupus erythematosus than in the general population[1]. Gallstone disease is a common condition in Western populations, and its etiology is multifactorial, including genetic and environmental factors. Hemolysis, obesity, aging, estrogen treatment, pregnancy and diabetes are consistently associated with a higher risk of developing gallstones[10].

Symptomatic gallbladder vasculitis requiring treatment by cholecystectomy is rare. Chen[13] has divided the gallbladder vasculitis into three groups: gallbladder vasculitis as a manifestation of polyarteritis nodosa (group 1), gallbladder vasculitis occurring in diseases known to be associated with vasculitis as in our SLE case (group 2) and isolated gallbladder vasculitis (group 3). In 1983, Swanepoel *et al*[5] described the first case of acute acalculous cholecystitis (ACC) in SLE. Since then, only a few SLE cases have been reported in the literature. Newbold *et al*[9] have reported two cases of gallbladder involvement in patients with SLE; histologically there was acute arteritis with periarterial fibrosis, changes similar to those found in polyarteritis nodosa. In fact, the development of gallbladder disease appears to be more common in polyarteritis nodosa than in SLE. Recently, Bando *et al*[12] have reported a case of acalculous cholecystitis induced by mesenteric inflammatory veno-oclusive disease in SLE. Although surgical removal of the gallbladder is the generally accepted treatment for SLE patients who develop acute cholecystitis successful treatment with corticosteroids alone has also been reported[11]. It is of note that, rarely, the symptoms of serositis can mimic those of acute cholecystitis[13,14].

Antiphospholipid syndrome (APS) was first described in patients who suffered from recurrent fetal loss and thromboses. Since then the spectrum of associated symptoms in APS has broadened considerably. The clinical criteria for diagnosis of APS include arterial, venous, or small vessel thrombosis in any tissue or organ. Thrombosis has to be confirmed by imaging, Doppler studies or histopathology. For laboratory diagnosis of APS, affected patients have antibodies to β2-glicoprotein- Ⅰ, cardiolipins or positive lupus anticoagulant in two separate occasions at least 6 wk apart. Gallbladder involvement secondary to APS has rarely been described in the literature. Dessailloud *et al*[2] reported a fatal case of a 29-year-old woman with acalculous cholecystitis secondary to catastrophic APS. The patient developed mesenteric ischemia, left limb ischemia and acute renal failure. In another report, Nolen *et al*[3] have described a 26-year-old female with primary APS who was treated successfully with medical management. Rhoton *et al*[8] described a 22-year-old woman with SLE who developed hemobilia, and also had high titers of anticardiolipin antibodies.

Our case presented with thrombotic and inflammatory complications involving the gallbladder, likely secondary to both SLE and APS. The vasculopathy showed thrombotic microangiopathy (TMA) and perivasculitis. Although microlithiasis could have contributed to the inflammatory process located in the gallbladder and pancreas, the presence of vasculitis reflects an autoimmune process.

Eventually the histopathological findings helped us diagnose the APS and initiate anticoagulation therapy, which led to improvement of our patient's renal disease. Although presence of small gallstones is associated with increased risk of acute pancreatitis, our patient's pancreatitis could also be a manifestation of APS[15]. All the SLE and APS cases reported in the literature with gallbladder involvement are summarized in Table 1. Of note is that our patient is the youngest patient described to date, reflecting the rarity of this complication in the pediatric age group.

Renal thrombotic manifestations have been reported since the initial description of APS. TMA is the best known characteristic lesion of APS nephropathy, leading to hypertension, proteinuria and renal impairment. Recently, consideration of the APS nephropathy in every SLE case has been emphasized because successful treatment requires both anticoagulation in addition to immunosuppresion[16].

In summary, although rare, gallbladder involvement in patients with SLE should raise the suspicion of vasculitis or APS. We believe that both gallbladder vasculitis and thrombosis contributed in the clinical picture of our patients. Sometimes surgical cholecystectomy is needed for both therapeutic and diagnostic purposes. If thrombotic manifestations of APS are documented, anticoagulation therapy should be started.

## Abstract

A 53-year-old male patient with a large hydatid cyst of the left hemidiaphragm and smaller secondary cysts located in the left thoracic cavity and upper left abdominal quadrant presented with two progressively enlarging lipoma-like masses in the left hypochondrium and under the left scapulae respectively. Total excision of all the cysts was performed through a bilateral subcostal incision, with the left hemidiaphragm near totally excised and replaced by a synthetic bilayer mesh.

**Key words:** Hydatid cyst; Diaphragm; Mesh reconstruction; Intrathoracic cavity; Subcutaneous extension

## INTRODUCTION

Hydatid disease is a parasitosis, known as hydatidosis or echinococcosis caused by the larval stage of the Echinococcus granulosus tapeworm. The disease was first described by Hippocrates as "cysts full of water" in a man's liver and by Aristotle in human lungs and liver[1]. The disease remains a considerable public health problem in endemic countries, including the Mediterranean and Middle East countries, New Zealand, Australia, South Africa and South American countries. The primary hosts are members of the Canidae family (dogs, wolves and coyotes); the intermediate hosts are sheep, cattle and deer[2]. Humans are accidental intermediates in the biologic cycle of taenia echinococcus granulosus, more frequently by direct contact with dogs than by ingestion of food or water contaminated with their feces[3]. The most commonly involved organs are the liver and lungs. Extrapulmonary intrathoracic location of a cyst involving the mediastinum, pleura, pericardium, chest wall and diaphragm is rare[4] and even rarer is the subcutaneous extension of echinococcus. Herein, we report a 53-year-old man with a primary large hydatid cyst of the diaphragm and smaller secondary hydatid cysts of the abdomen and thorax protruding subcutaneously.

## CASE REPORT

A 53-year-old farmer with a past medical history of two car accidents at 16 and 18 years of age, which resulted in a left hemothorax evacuated with a chest tube in the first one and a fracture of the left femur internally fixated in the second one, was admitted to our surgical department. The patient's main complaint was the presence of a small soft lump in the left hypochondrium 15 years ago that was gradually increasing in size. A similar lump protruding under the left scapulae 1 mo before his admission presented without any symptoms indicating absence of compression of adjacent organs. Diminished breath sounds in the lower left hemithorax, the presence of a small (3-5 cm) subcutaneous lump between the posterior segments of the 7th and 8th ribs and a larger (13-15 cm) soft-tissue subcutaneous mass in the left hypochondrium were the clinical findings. Chest radiograph showed a left-sided opacity with scarce microcalcifications (Figure 1A). Pulmonary functional tests were normal. Thoraco-abdominal CT scan (Figure 2) revealed a hydatid cyst (14 cm in diameter) located in the left hemidiaphragm extending simultaneously to the thoracic cavity and the upper abdomen (cyst a), a cystic lesion (6 cm in diameter) in contact with the left side of the pericardium and the anterior surface of pleura anteriorly to the previous cyst (cyst b), a cystic lesion (9 cm in diameter) in the postero-lateral thoracic wall (cyst c) protruding intercostally to a small subcutaneous cyst under the scapulae (solid arrow) and an abdominal cystic lesion (13 cm in diameter, cyst d) protruding through the left costal cartilage to the left hypochondrium subcutaneously (broken arrow). CT scan showed a sand-glass appearance of the last two cysts. Laboratory tests were normal and serologic tests were

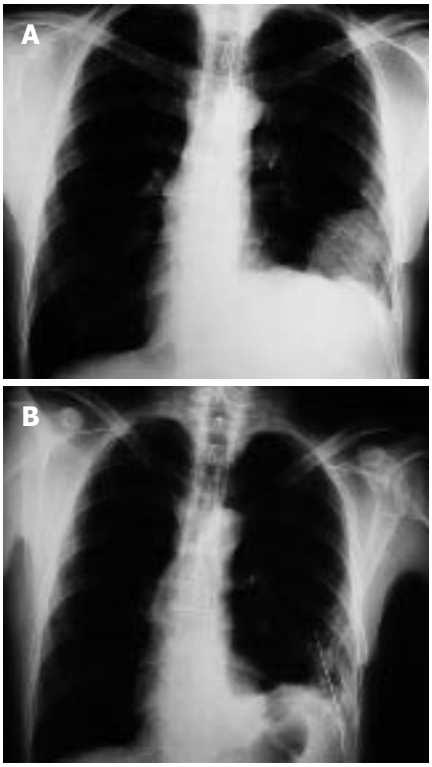

**Figure 1** (**A**) Preoperative chest radiograph showing the left-sided opacity and (**B**) postoperative chest radiograph showing the chest tube placed in the left thoracic cavity.

positive for echinococcus granulosus (1/2048 antibodies, using enzyme-linked immunosorbent assay).

A bilateral subcostal incision was performed. Precautions were taken in order to avoid any spillage of cyst contents in the operation field including intact excision of all hydatid cysts and placement of sponges impregnated with hypertonic saline surrounding the involved organs. The subcutaneous hydatid cyst of the left hypochondrium was removed with its intra-abdominal portion and a partial resection of the left costal cartilage. The large hydatid cyst of the left hemidiaphragm embedded in the muscular layer was free of adhesions to the adjacent abdominal and thoracic organs. A total excision of this cyst with a nearly total excision of the left hemidiaphragm was performed. The hydatid cyst adjacent to the pericardium was completely removed. The hydatid cyst on the posterolateral thoracic wall was removed with concomitant resection of the subscapular protrusion and the eroded posterior segment of the 9th rib. The left hemidiaphragm was replaced by a bilayer synthetic mesh (Bard Composix ® Mesh 15.2 cm × 20.3 cm) and a chest tube was placed in the left thoracic cavity (Figure 1B). The patient was discharged on the 7th postoperative day and albendazole therapy was started at a dose of 400 mg bid. The postoperative course of our patient during the follow-up period (14 mo) was uneventful, with a good respiratory function.

## DISCUSSION

Hydatid disease most frequently involves the liver (50%-70%) and lungs (20%-30%), which can be explained by a hypothesized novel dissemination theory via diaphragmatic lymphatic drainage proposed by Isitmangil *et al*[5]. However, other organs may be involved as well,

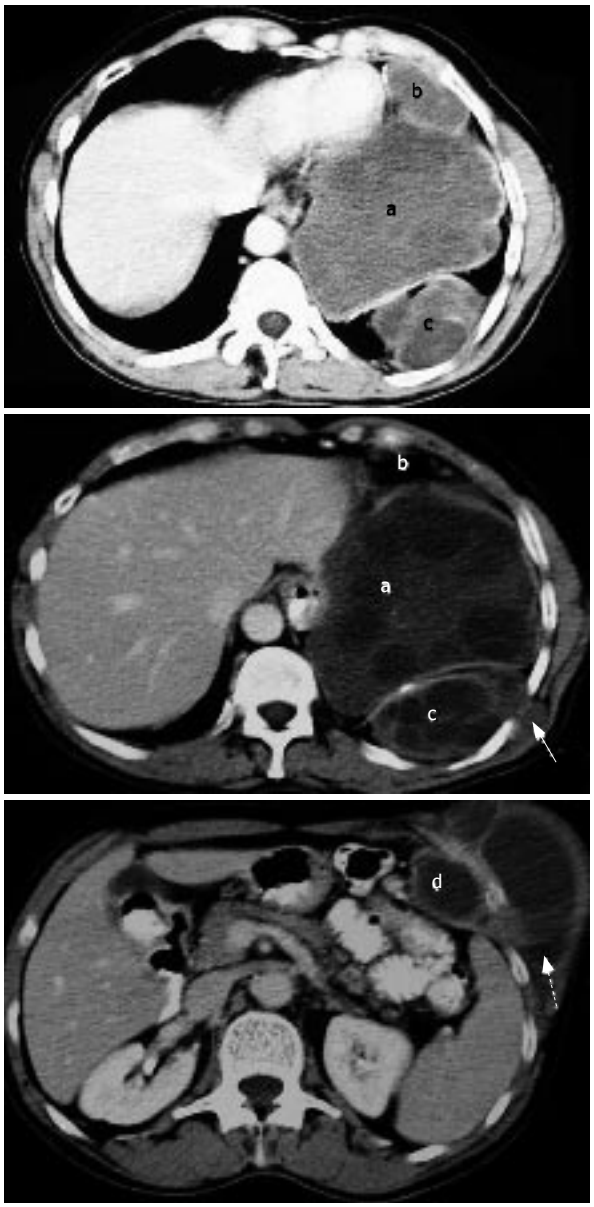

**Figure 2** Thoraco-abdominal CT scan showing four separate hydatid cysts located in the left hemidiaphragm (a), anteriorly in contact with the left side of the pericardium (b) and the posterolateral wall of the left hemithorax (c) and intra-abdominally in contact with the left hypochondrium (d). Subcutaneous extension of hydatid cyst c protruding intercostally to a small subcutaneous cyst under the scapulae (solid arrow) and abdominal cyst d protruding through the left costal cartilage to the left hypochondrium subcutaneously (broken arrow) are demonstrated.

such as the brain, heart, bone and muscle (10%)[6]. Subcutaneous location or extension of a hydatid cyst is even more rare[7-9]. This rare localization of echinococcosis presents as painless soft tissue tumors or lipomas and the patient usually does not seek surgical advice.

Total excision of hydatid cysts is the definitive therapy. A thorough preoperative study of the involved organs combining the findings of chest radiograph, ultrasonography, computed tomography and magnetic resonance imaging is necessary. The bilateral subcostal incision performed in this case has the advantage of a better approach to both the abdominal and thoracic lesions, without necessitating the use of standard thoracotomy which is preferred to treat intrathoracic extrapleural

hydatid disease. However, repair or reconstruction of the diaphragm poses a technical challenge. If a synthetic mesh is used to close the defect, it must be properly applied and sutured under tension to avoid paradoxical movement and respiratory distress postoperatively. Moreover, septic complications related to mesh reconstruction during these procedures are rare and have not been reported in the literature.

## Abstract

A seven-month-old infant was admitted to our hospital with a 1-wk history of shortness of breath, dysphagia, and fever. Diagnosis of esophageal perforation following fish vertebra ingestion was made by history review, pneumomediastinum and an irregular hyperdense lesion noted in initial chest radiogram. Neck computed tomography (CT) confirmed that the foreign body located at the cricopharyngeal level and a small esophageal tracheal fistula was shown by esophagogram. The initial response to treatment of fish bone removal guided by panendoscopy and antibiotics administration was poor since pneumothorax plus empyema developed. Fortunately, the patient's condition finally improved after decortication, mediastinotomy and perforated esophagus repair. To our knowledge, this is the first case report of esophageal perforation due to fish bone ingestion in infancy. In addition to particular caution that has to be taken when feeding the innocent, young victim, it may indicate the importance of surgical intervention for complicated esophageal perforation in infancy.

## INTRODUCTION

In East Asia (China, Japan, Korea), fish bone ingestion is a common cause of emergency room visits and usually needs no invasive management other than prompt removal of the fish bone[1,2]. However, fish bone impaction complicated with esophageal perforation and pneumomediastinum is life-threatening and needs emergency surgical management. Most of the patients are above one year old since self-feeding has not begun at infancy. The mortality is extremely high if diagnosis is delayed and the sequelae might exhaust the patient and cause a catastrophic result. The outcome depends on the size of the rupture, the time elapsed between rupture, and diagnosis, as well as the underlying health of the patient[1]. Successful treatment is very difficult. Here, we report such a case of 7-mo-old infant of fish bone ingestion, and review the related literature.

## CASE REPORT

A seven-mo -old male infant weighing 7.8 kg was brought to our pediatric emergency room for progressive shortness of breath and fever over the previous 1 wk. Associated symptoms included progressive irritability, poor sleep quality, fever off and on, drooling, and dysphagia. On review of his history, he was previously healthy and had no admission record. The patient's development and growth were within the normal range. He had been fed fish-rice soup as a nutrition supplement since the age of 5 mo. The initial chest radiogram showed pneumomediastinum (Figure 1A), and an irregular hyperdense lesion in the cricopharyngeal area was seen in the lateral view of the neck (Figure 1B). He was admitted to our pediatric Intensive Care Unit with unstable vital signs. Due to his feeding history, fish bone ingestion was strongly suspected. Emergency neck computed tomography (CT) and an esophagogram were arranged to confirm the diagnosis. The neck CT showed a hyperdense material at the cricopharyngeal level (Figure 2) and a small fistula tract at C3–C4 was noted on the esophagogram (Figure 3).

The day following admission, he was intubated via a bronchoscope to establish an accurate tube position. Panendoscopy was then performed after sufficient sedation

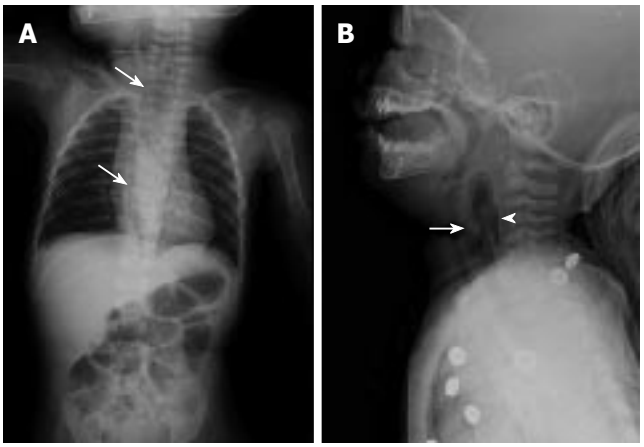

**Figure 1** **A**: Extensive pneumomediastinum and air collections in retropharyngeal area (arrows), **B**: Irregular hyperdense lesion (arrow head) around cricopharyngeal area, and intra-esophageal opacification (arrow) was noted at C3 - C4 level.

**Figure 3** Much air collection (arrow) was in the retropharyngeal space and mediastinum, contrast leakage (arrow head) into the retropharyngeal space with opacification of a small fistulous tract at C3-4 level (cricopharyngeal level), suggestive of esophageal perforation.

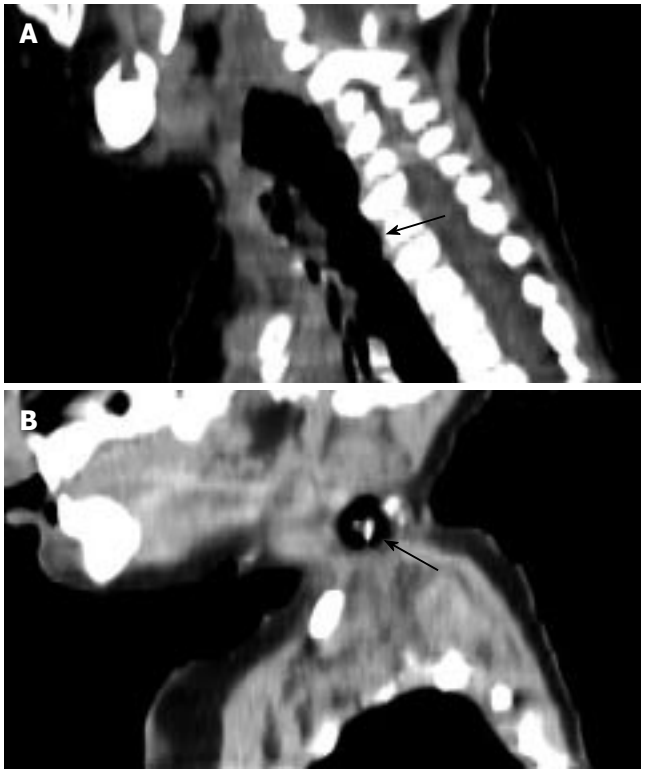

**Figure 2** **A**: Esophageal rupture with retropharyngeal air collection (arrow), and **B**: Irregular foreign body impacted at upper esophagus (arrow).

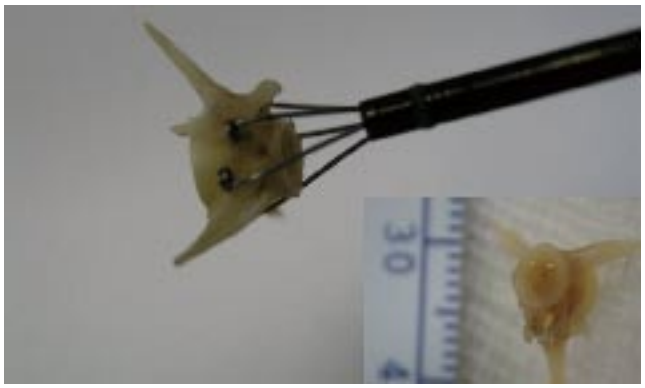

**Figure 4** The fish vertebra with three sharp spines, which is about 1 cm x 1 cm in size, was removed by grasping forceps.

of the patient. A fish bone (part of a vertebra) measuring 1 cm × 1 cm was found near the esophageal inlet, which was removed smoothly with grasping forceps (Figure 4).

Although the fish bone was removed, antibiotics (ceftriaxone + amikin + metronidazole) were administrated empirically to prevent esophageal wound infection. The patient continued to drool and suffer from dyspnea on the third day of admission, and a subsequent chest radiogram showed persistent retropharyngeal air collection. Bronchoscopy and panendoscopy were repeated, but did not improve the dyspnea. CT-guided retropharyngeal aspiration was performed on the fifth day of admission and 200 mL of air was aspirated. A pneumothorax with desaturation developed on the seventh day of admission, and empyema was detected after a chest tube was inserted. A pediatric surgeon was consulted, and surgery was performed. At surgery, the findings included multilocular empyema with trapped lung, mediastinitis (abscess formation), and esophageal perforation in the cervical region. Decortication and mediastinotomy were performed to remove the inflamed tissues, and the perforated esophagus was repaired with Dexon sutures. After surgical management, the medical treatment became more effective. Coagulase-negative Staphylococcus aureus was cultured in the pus, and the fever disappeared after combination treatment with antibiotics (vancomycin + ceftriaxone + metronidazole). Total parenteral nutrition was instituted, and a nasogastric (NG) tube was inserted via panendoscopy for decompression and to prevent esophageal stricture or synechia. The right Horner's syndrome that occurred postoperatively resolved within 6 mo. Although the patient's weight had decreased to 5.8 kg, he regained body weight steadily after beginning NG feeding (15 d after the operation). Complete oral feeding was achieved after 1 mo of NG feeding. The patient was discharged from our hospital after 4 mo, without developing the obvious symptoms of esophageal stricture. On follow-up, he weighed 7.7 kg at 8 mo ($20^{th}$ percentile),

9.4 kg at 13 mo (25th percentile), and 11.3 kg at 21 mo (30th percentile). No serious respiratory complications were noted.

## DISCUSSION

Foreign body ingestion is common in children and can be underestimated because there are no witnesses and 50% of cases are asymptomatic[3,4]. Less than 1% of foreign body ingestions result in serious morbidity; most cases need observation only. The peak age in children is from 6 mo to 3 years[5]. Based on previous experience with the pediatric population, fish bones are the second most commonly ingested foreign body (coins are the most common). In East Asia, fish bones are the most commonly ingested foreign body[2]. Nevertheless, fish bone ingestion is quite rare in infancy since self-feeding has not begun, and the caretaker screens the food before feeding.

The symptoms of foreign body ingestion are variable and depend on the size, shape, and material of the foreign body. Usually, large sharp objects cause greater morbidity[1]. The common signs and symptoms[6] in patients with a foreign body that has been retained for less than 24 h tend to be gastrointestinal and include dysphagia, drooling, vomiting, gagging, and anorexia. Major respiratory symptoms are more common weeks or months after ingestion, such as coughing, stridor, fever, chest pain, wheezing, chronic upper respiratory tract infections, pneumonia, and hemoptysis. Patients may also develop acute respiratory distress with choking and cyanosis. In our case, the patient's symptoms were compatible with typical foreign ingestion, and a lack of awareness delayed the diagnosis.

Only 32% of ingested fish bones can be identified radiographically[7], and most part of fish skeletons that cause impaction in esophagus is fish rib. Fish vertebra was seldom reported. Due to its prolonged course, pneumomediastinum was seen on the plain chest radiograph in our patient. The esophagogram confirmed the diagnosis of foreign body impaction and located the esophageal perforation. In fact, instrumental perforation and spontaneous perforation are the two major causes of esophageal injury in infants and children. Esophageal perforation due to fish bone ingestion in infancy has not been reported. Furthermore, the complications of mediastinitis, pneumothorax, and empyema were life-threatening in our patient. The following guidelines are suggested for selecting nonoperative treatment[8]: clinically stable patients; instrumental perforations detected before major mediastinal contamination has occurred, or perforations with such a long delay in diagnosis that the patient has already demonstrated tolerance for the perforation without the need for surgery; and esophageal disruptions well contained within the mediastinum or a pleural loculus. In a series of 12 children (3-7 years old) with esophageal perforation, Demirbag *et al*[9] reported that esophageal perforation could be treated safely by nonoperative means. Rivas *et al*[10] recommended conservative treatment as the best option for esophageal perforation in children. In contrast to adults, children have some important advantages in esophageal perforation with regard to complication severity, wound-healing rate, and mediastinal tissue resistance. In our case, however, the patient was younger (7 mo old), and the diagnosis delayed (about 1 wk). Although the fish bone was removed via panendoscopy soon after admission, the conservative management was ineffective, and surgery was required.

Total parenteral nutrition supplement played an important role in the postoperative therapy. It provided sufficient nutrition for the patient and allowed complete rest of the gastrointestinal tract. Treatment with broad-spectrum intravenous antibiotics was also essential for reversing the potentially fatal infection secondary to esophageal perforation. In this case, coagulase-negative S. aureus was identified on culturing of the pus. This organism is the predominant pathogen causing empyema in developing countries[5].

Two special techniques were applied in this case: bronchoscopy for intubation and CT-guided aspiration to reduce the retropharyngeal air collection. Both of these measures prevented deterioration in the patient's respiratory status. The excellent outcome in this patient was beyond our expectations. No major complications were noted one year later. We believe that the great support of his family contributed equally to the medical management.

To our knowledge, this is the first case report of esophageal perforation complicated by fish bone ingestion in infancy. Although current guidelines of therapy for fish bone ingestion in children remains conservative, this case illustrates the possibility of unpredictable and severe complications which demand surgical intervention.

## Abstract

We presented an unusual case with coexistence of carcinoid, signet-ring cell carcinoma (SRC) and heterotopic pancreatic tissue in stomach. Gastroscopic examination of this 63-year-old male patient showed multiple protrusions in gastric corpus near the greater curvature, identified by subsequent biopsy as carcinoid. Distal subtotal gastrectomy was performed. Histological and immunohistochemical examinations showed a carcinoid tumor in gastric corpus near the greater curvature, an intramucosal SRC at the lesser curvature of corpus and heterotopic pancreatic tissue in muscularis propria of the antrum at the lesser curvature with hyperplasia of peripheral endocrine cells producing multiple pancreatic hormones. We reviewed the literatures on clinicopathological characteristics and the differential diagnosis of the above three abnormalities, and concluded that the carcinoid in corpus near the greater curvature and SRC in the lesser curvature are independent lesions; the foci of endocrine cells in the muscularis propria and serosa are hyperplastic lesions from the heterotopic pancreatic tissue, rather than dissemination of carcinoid in corpus.

**Key words:** Heterotopic pancreas; Carcinoid; Signet-ring cell carcinoma; Gastric tumour; Endocrine cell hyperplasia

## INTRODUCTION

Gastric carcinoid is rare, accounting for 0.4%-1.8% in tumors of the gastrointestinal tract[1], while signet-ring cell carcinoma (SRC) is frequent[2]. Both of them occur often in an occult way, with different behavior and prognosis. Pancreatic heterotopia in stomach is often incidentally encountered during surgery or autopsy, with its incidence ranging from 0.6% to 13.7%[3]. We presented a case with synchronous occurrence of these three lesions in stomach, and reviewed related literatures.

## CASE REPORT

A 63-year-old male patient visited this hospital with the complaint of "cauterized discomfort in the upper abdomen for more than 2 years, and aggravated for 2 mo". By gastroscopy, multiple flat nodules (Lesion 1) were found in the front wall near the greater curvature, ranging from 0.2-0.8 cm in diameter. Mucosal biopsy was taken, and the lesions were considered a malignant neuroendocrine cell tumor with the help of immunohistochemistry. Findings from physical examination were unremarkable except for deep tenderness under xiphoid. Chest X-ray, upper alimentary canal contrast, abdominal ultrasonography failed to detect any abnormalities, while a slight increase in thickness of the antrum wall was observed by computed tomography (CT) scanning. Levels of circulating CA199, CEA, CA724 and CA242 were in normal ranges. Serum antibody against parietal cell was positive, and serum gastrin was 93.2 mg/L. No family history of cancer was recorded. Distal subtotal gastrectomy specimen was routinely resected. The samples were fixed in 4% buffered formaldehyde, and embedded in paraffin. Sections of 5 μm in thickness were prepared and stained with hematoxylin and eosin (HE) and Alcin blue/periodic acid Schiff reaction (AB/PAS). Immunohistochemical staining was conducted using a polymer-peroxidase detection kit (PV-9000) following the instructions of the manufacturer. Polyclonal antibodies were used to detect glucagon, gastrin, somatostatin, vasoactive intestinal peptide (VIP), pancreatic polypeptide (PP), and monoclonal antibodies were used for demonstration of CK18, insulin, ACTH, synaptophysin (SY), chromogranin A (CgA), NSE, vimentin, p53 protein (DO-7) and Ki-67 antigen. All of the reagents were supplied by Zhongshan Golden Bridge Biotech Co. Ltd., Beijing. Samples of a gastric SRC and a

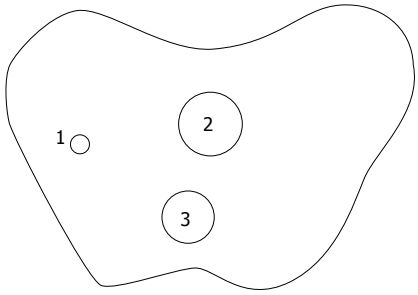

**Figure 1** Diagrammatic representation of three lesions. 1: Carcinoid nodule of 0.7 cm in diameter near the greater curvature of gastric corpus; 2: SRC sizing 3.0 cm × 2.0 cm within mucosa at the lesser curvature of gastric corpus; 3: Ectopic pancreas nodule of 2.5 cm in diameter between submucosa and serosa in gastric corpus-antrum.

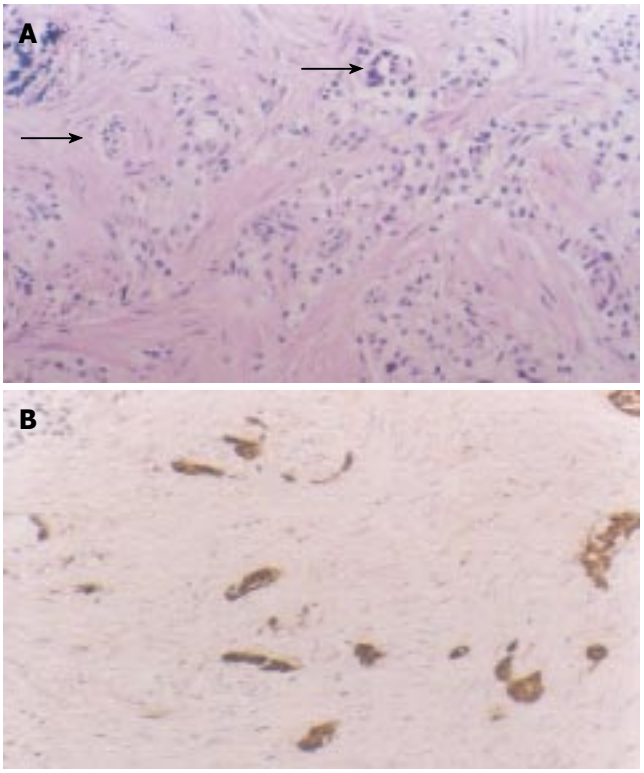

**Figure 2** Lesion 1, intramucosal carcinoid with the muscularis mucosa infiltrated (**A**) (arrows, HE × 20), positively expresses CgA (**B**) (S-P method, conterstained with hematoxylin, × 20).

pancreatic endocrine tumor were used as positive controls, and the immunoglobins from a preimmune rabbit and mouse were used to substitute for the primary antibodies as negative controls. Slides were scored semi-quantitatively according to the percentage of positive cells in all counted cells from 5 randomly selected representative fields based on staining distribution and intensity as below: positive rate < 5% was defined as negative (-); weakly positive (+): 5%-25%; moderately positive (++): 25%-50%; strongly positive (+++): > 50%.

Three non-continuous lesions (Figure 1) with distinct histochemical phenotypes (Table 1) were identified: Lesion 1 (Figure 2), multiple nodules of 0.2-0.8 cm in diameter was seen in the anterior wall near the greater curvature of

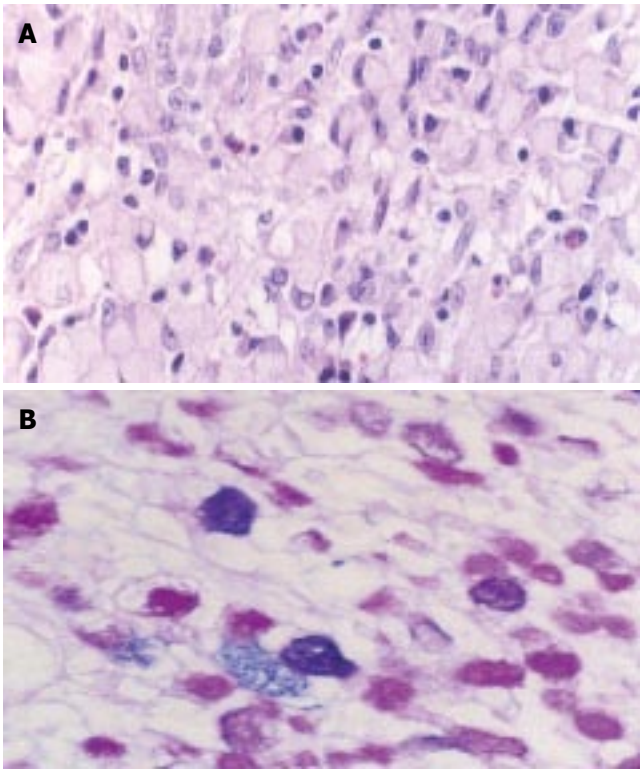

**Figure 3** Lesion 2, intramucosal signet-ring cell carcinoma (**A**) (HE × 40) with cytoplasmic mixed mucin (**B**) (AB/PAS reaction, × 40).

gastric corpus, and multiple foci of hyperplastic endocrine cells were seen in the deeper part of lamina propria, infiltrating the muscularis mucosa. Immunoreactivities were seen in the cells for CK18, NSE, SY and CgA. Therefore, Lesion 1 was regarded as intramucosal endocrine cell hyperplasia and formation of a type I carcinoid, with muscularis mucosae involved. Lesion 2 was identified beside the lesser curvature of corpus and sized 3.0 cm × 2.0 cm. The cancer cells contained mixed mucin, positive for both Alcin blue and PAS, but were negative for the neuroendocrine markers (Figure 3). Therefore, Lesion 2 was diagnosed as an intramucosal SRC (superficially flat type), rather than a signet-ring-like carcinoid. Lesion 3 (Figure 4) was a yellowish mural mass sizing 3.0 cm × 2.0 cm on cut surfaces, located between the submucosa and lamina muscularis of the antrum. Histologically, the mass was composed of well developed pancreatic acini and ducts, intermingled with hyperplastic smooth muscle tissue, giving rise to the pattern of an adenomyoma. At the peripheral area, multiple nodules of 0.1-0.4 mm in diameter were found. They were composed of well circumscribed small, bland epithelial cells which arranged in solid nests. The nodules resembled normal pancreatic islets in shape, scattered within the muscularis propria and serosa of the gastric wall. No stromal reaction was observed. The epithelial cells were shown to be diffusely positive for CK18, CgA, SY, insulin, glucagons, somatostatin and gastrin, the pattern being similar to that of pancreatic islets. Neither mitosis nor necrosis was identified. Therefore, the mass was diagnosed as pancreatic heterotopia and those peripheral nodules were hyperplastic

ACTH: adrenocorticotropin; CK18: cytokeratin 18; CgA: chromogranin A; Ki-67-LI: Ki-67-lebelling index; PP: pancreatic peptide; NE: neuroendocrine; NSE: neuron-specific enolase; SRC: signet-ring cell carcinoma; VIP: vasoactive intestinal peptide.

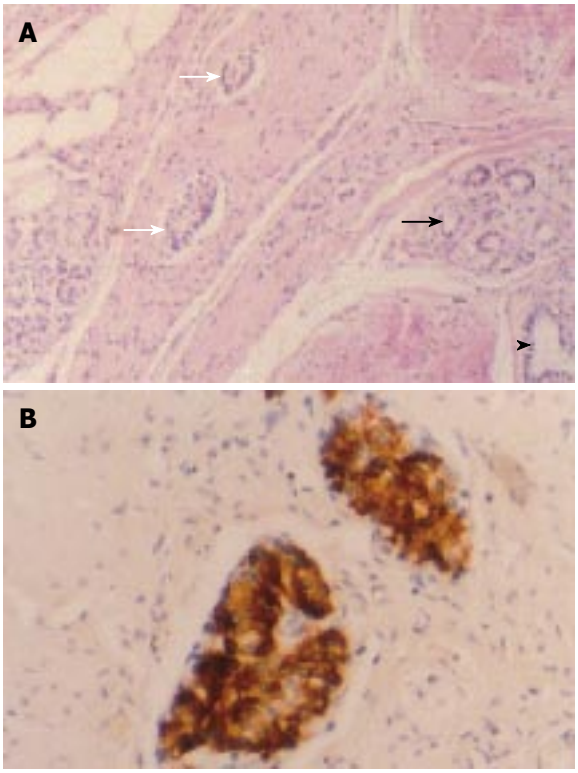

**Figure 4** Lesion 3, heterotopic pancreatic tissue in gastric wall, which was composed of well developed pancreatic acini (darker arrow), ducts (arrowhead), and islets (lighter arrow) intermingled with the hyperplastic smooth muscle tissue, giving rise to the pattern of an adenomyoma (**A**) (HE × 20); Small-cell nodules of 0.1-0.4 mm in diameter scattered within the muscularis propria and serosa of the gastric wall and strongly positive for insulin (**B**) (S-P method, conterstained with hematoxylin).

tissues from endocrine pancreatic heterotopia rather than dissemination of Lesion 1.

Standard lymph node dissection was conducted and no metastasis was found in all of the twelve dissected lymph nodes.

The patient remains well 17 mo after surgery.

## DISCUSSION

Gastric endocrine neoplasms are classified into carcinoid (well differentiated endocrine neoplasm), small cell carcinoma (poorly differentiated endocrine neoplasm) and tumor-like lesions (including hyperplasia and dysplasia of endocrine cells)[4]. Most endocrine tumors of the stomach are well differentiated, nonfunctioning enterochromaffin-like (ECL) cell carcinoids arising from lamina propria in the corpus or fundus[5]. Three distinct types have been recognized. Type I carcinoids are associated with autoimmune chronic atrophic gastritis. Type Ⅱ carcinoids are linked to multiple endocrine neoplasia type 1(MEN-I)) and Zollinger-Ellison syndrome (ZES). Type Ⅲ carcinoids are sporadic, without hypergastrinemia or autoimmune atrophic gastritis[6]. Types I and Ⅱ carcinoids develop through a sequence of "hyperplasia-dysplasia-neoplasia", and ECL-cell hyperplasia and dysplasia are identified as the precancerous lesions of ECL-cell carcinoid[7]. Lesions up to 0.5 cm in diameter or infiltrating submucosa are recognized as carcinoids[8]. In this case, mild to moderate atrophic gastritis was noted, coexisted with intestinal metaplasia and a high level of serum gastrin. A carcinoid of 0.7 cm in diameter was identified. All of the lesions listed above were in line with Type I carcinoid associated with endocrine cell hyperplasia.

In this case, superficial SRC (Lesion 2) was identified in corpus mucosa of the lesser curvature, which was failed to be detected by gastroscopy and biopsy before surgery. An unusual type of signet-ring-like carcinoid[9-11] was reported in literature, but the following three points in this case ruled out the possibility. First, cells in Lesions 1 and 2 were different from each other in morphology. Second, they occurred in two different sites, without anatomical continuity. Third, their histochemical and immunohistochemical phenotypes were different. Lesion 1 was negative for mucin, while positive for neuroendocrine markers (Table 1). Lesion 2, however, showed positive staining of mucin, while negative for neuroendocrine

markers. Therefore, the carcinoid and SRC in this case were two independent lesions. Up to date, 5 cases of gastric carcinoid coexisting with adenocarcinoma have been reported[12-16], and only one of them with SRC[16].

The incidence of gastric ectopic pancreas ranges from 0.6% to 13.7%, frequently in the antrum and prepyloric region on the greater curvature or posterior wall. It often locates in submucosa, lamina muscularis or subserosa. Histologically, heterotopic pancreas can be divided into 4 types: type 1, composed of all cell types, namely complete heterotopia; type 2, composed of ductal components only, the canalicular heterotopia; type 3, composed of acinar cells only, the exocrine heterotopia; and type 4, composed of islet cells only; the endocrine heterotopia[17]. In this case, the heterotopic pancreas belongs to the first type. Most of the patients with gastric ectopic pancreas are asymptomatic. When mucosa is involved, however, patients may complain of an upper abdominal pain, bleeding, and obstruction may occur. Malignant transformation has been encountered, albeit rarely, giving rise to an adenocarcinoma[18-25] or a neuroendocrine neoplasm[26]. Caution should be paid to establishing a diagnosis of a carcinoma from heterotopic pancreas. For this, 3 points were considered necessary. First, the carcinoma should be found within or close to the heterotopic pancreas. Second, the transitional area between pancreatic structures and carcinoma should be observed and a metastatic carcinoma or dissemination of carcinoma from the adjacent gastrointestinal tract must be excluded. In addition, the non-neoplastic heterotopic pancreatic tissue should contain at least fully developed acinar or ductal structures[3]. It is evident that SRC in this case is independent from Lesion 3. Besides, a functional pancreatic endocrine tumor is composed of neoplastic cells secreting the same hormone (insulin, glucagon or somatostatin), differing from the endocrine cell hyperplasia whose constituent cells produce multiple hormones. In this case, Lesion 3 belonged to the complete heterotopic pancreas, with endocrine cell proliferation, which scattered preferentially among bundles of smooth muscle fibers or along vascular structures, mimicking intramural infiltration or metastasis of the carcinoid. It is important to know whether the endocrine tissue is hyperplastic or neoplastic, in consideration of the presence of a carcinoid (Lesion 1) at the corpus of the stomach and their structural and morphologic similarities. The following data revealed that endocrine component in Lesion 3 is non-neoplastic. The endocrine tissue was accompanied by the exocrine components in most parts of the lesion. Functionally, the endocrine tissue was composed of cells separately producing insulin, glucagon or somatostatin, reflecting its polyclonal nature, the phenotypes being similar to that of islets and different from Lesion 1 (Table 1).

In summary, we presented a case with coexistence of carcinoid, SRC and heterotopic pancreas in stomach. Differential diagnosis of the three abnormalities was of great importance for prognosis evaluation of the patient.

## Abstract

In neonates, persistent hyperinsulinemic hypoglycemia (PHH) is associated with nesidioblastosis. In adults, PHH is usually caused by solitary benign insulinomas. We report on an adult patient who suffered from insulin-dependent diabetes mellitus, and subsequently developed PHH caused by diffuse nesidioblastosis. Mutations of the MEN1 and Mody 2/3 genes were ruled out. Preoperative diagnostic procedures, the histopathological criteria and the surgical treatment options of adult nesidioblastosis are discussed. So far only one similar case of adult nesidioblastosis subsequent to diabetes mellitus Ⅱ has been reported in the literature. In case of conversion of diabetes into hyperinsulinemic hypoglycemia syndrome, nesidioblastosis in addition to insulinoma should be considered.

## INTRODUCTION

Persistent hyperinsulinemic hypoglycemia (PHH) caused by functionally defectice β-cells in the setting of a nesidioblastosis is the most common pathological substrate in newborns, whereas in adults, PHH is usually caused by solitary insulinomas[1-3]. Several genetic abnormalities were identified as the causes of PHH in infancy. The most important mutations are in the β-cell sulfonylurea receptor (SUR1) gene and encoding proteins composing the ATP-sensitive potassium channel in the cell membrane of the β-cell (Kir6.2)[4,5]. Loss of function due to mutations of the glucokinase (GCK) and glutamat dehydrogenase (GLUD1) genes were also identified as possible causes of PHH of infancy[6-8]. The morphologic substrate of these molecular changes are either diffuse β-cell hypertrophy (diffuse nesidioblastosis) or focal β-cell hypertrophy and β-cell hyperplasia (focal nesidioblastosis)[4,9]. The term nesidioblastosis for describing the lesions of the endocrine pancreas in neonates was first used by Yakovac[10] in 1971, when he described 12 infants with PHH.

Establishing the diagnosis of nesidioblastosis in an adult is a great challenge in endocrinology. To date, it is not possible to diagnose diffuse nesidioblastosis in adults on clinical grounds, since imaging techniques or detection of a specific causative mutation are of no help. The fasten test for the diagnosis of nesidioblastosis has been controversially discussed. Up to now, the diagnosis is based on (1) exclusion of an insulinoma by all means of clinical diagnostic procedures and (2) pathological analysis of the pancreatic tissue specimens. A combination of various histopathological criteria, marked as major and minor criteria, has recently been published to establish the diagnosis of a diffuse adult nesidioblastosis[11].

Since the first reported case of an adult nesidioblastosis in 1975, less than 100 patients have been described in the literature. Most of them were reported in individual case studies. Reports of PHH with known diabetes mellitus are extremely rare[12-15]. In our hospital, diffuse nesidioblastosis has been diagnosed in 4 out of 137 patients suffering from PHH. A coincidence of PHH with diabetes was diagnosed in only one patient. The aim of our report is to describe this patient in detail concerning (1) clinical presentation, (2) mutational analysis of the MEN1 and Mody 2/3 genes, (3) pathology of the pancreatic specimens. The diagnostic procedures and the surgical treatment strategies are discussed on the basis of the presented case.

## CASE REPORT

### *Clinical presentation*

A 40-year-old man (170 cm in height; BMI: 24.9) diagnosed with organic hyperinsulinism was admitted to our

hospital. The previous medical history was marked by a primarily insulin-independent diabetes (type Ⅱ). Insulin treatment has been required over the past 6 years. At the age of 35, he developed an idiopathic facial nerve pareses and brainstem encepahlitis of unknown etiology. Family history showed no pathologic findings, except diabetes of a grandmother. On the onset of diabetes, his blood sugar rose to 3800 mg/L with elevated HbA1c (8.0%). The patient was started on insulin treatment. During three hospital admissions for hyperglycemia over a 5-year period, blood sugar levels were often higher than 4000 mg/L and he was treated with insulin. Starting in 2005, the insulin treatment began to reduce and two months later discontinued, because of normalized serum glucose levels. He was admitted to hospital for symptoms of hyperadrenergic reactions and neuroglycopenic symptoms of confusion and somnolence due to hypoglycemia with blood sugar levels of 250 mg/L.

Diagnosis with a pathological fasting test indicated hypoglycemia. Blood sugar levels were repeatedly reduced to 300 mg/L with typical neuroglycopenic symptoms. The insulin level was up to 93.3 mU/L with a raised insulin index of 2-3. Exogenous insulin intake could be excluded by C-peptide levels. Unfortunately, the real C-peptide level could not be specified because of insufficient terms of transport (external laboratory). Insulin antibodies were negative. Attempts to localize an insulinoma with computed tomography (CT), ultrasound (US) of the abdomen and endoscopic ultrasound (EUS) were unsuccessful.

Laparotomy was performed and the pancreas was completely exposed and investigated by bimanual palpation and intraoperative ultrasound. A spleen preserving pancreatic-tail resection was performed because of a suspected small tumor in the tail of the pancreas. The patient's postoperative course was uneventful. Postoperatively, he displayed no signs of recurrent hypoglycemia. The blood sugar levels measured rose up to 1660-2430 mg/L, therefore low dose insulin application was necessary. The patient was discharged on the seventh postoperative day.

The patient and his family doctor reported recurrent diabetes metabolism over the previous 5 mo during a nine month follow-up after surgery (blood sugar levels: 300-2420 mg/L depending on insulin intake). Unfortunately, a reassessment of the diabetes was declined by the patient at the time.

### *Mutational analysis*

Genetic sequence analysis of the exons 2-10 of the MEN1 gene on chromosome 11q13 as previously described[16,17], was performed for differential diagnosis. The genetic make-up ruled out a molecular germline mutation in the MEN1 gene. Additional genetic sequence analyses of the glukokinase-gene of exon 1A-10 on chromosome 7p15-p13 were performed. Mutations pointing to maturity diabetes of the young Typ 2 were excluded. In addition, genetic sequence analyses of exons 1-10 of the hepatic nuclear factor 1 alpha gene for MODY Typ 3 were negative.

### *Histopathological analysis*

Pathological examinations were done using serial sections from different regions of the specimens which were immunohistochemically stained, by the avidin-biotin-complex (ABC) method with a monoclonal antibody against insulin (BioGenex, San Ramon, Canada, primary dilution 1:40) and polyclonal antibodies against glucagon (BioGenex, dilution: 1:60), somatostatin (Dako, Glostrup, Denmark, dilution: 1:200) and pancreatic polypeptide (DAKO, dilution: 1:5000). Appropriate controls were performed in order to ascertain the staining specificity. Histological and immunostained pancreatic sections were analyzed by three different pathologists in a double-blind fashion. Histological criteria for nesidioblastosis in adults were used to evaluate the sections[11]. Age- and sex-matched control pancreatic specimens were used as references.

Gross examination and step sectioning of the pancreatic samples excluded the presence of an endocrine tumor. The lobular architecture of the exocrine parenchyma was preserved. The pancreatic duct was patent and of normal size. There was no evidence of amyloid deposits or a quantitative disturbance of beta-cells. A consistent finding was the presence of multiple enlarged islet cells, whose arrangement often produced a lobulated islet pattern. Cytologically, a considerable subpopulation of endocrine cells showed enlarged and hyperchromatic nuclei (Figure 1A). These cytological changes were seen in more than 2/3 of the islets. Using immunohistochemistry and subsequent staining with hematoxylin, the cytologically conspicuous endocrine cells were identified as beta-cells (Figure 1B). In contrast, glucagon, somatostatin and pancreatic polypeptide cells did not reveal any cytologic abnormalities (Figure 1C). The subcellular distribution of insulin was regular and apparently equal amounts of C-Peptide were seen. There was no evidence of an expression of the nuclear proliferation antigen ki-67 within the islets. According to this histopathological analysis the patient fulfilled the recently described "major criteria" of a diffuse nesidioblastosis in adults[11].

## DISCUSSION

Nesidioblastosis was detected and diagnosed in 4 patients out of a series of 137 patients treated for organic hyperinsulinism at our hospital. One of them was diagnosed by clinically reversing a highly insulin-dependant diabetes. Diagnosis of nesidioblastosis was established by (1) exclusion of an insulinoma by all means of clinical diagnostic procedures and (2) by pathological examination revealing the characteristic signs of a diffuse nesidioblastosis.

Preoperative localization by CT-scan, abdominal ultrasound and endoscopic ultrasound (EUS) failed to detect an endocrine tumor. An indication for surgery was based on hypoglycemia in the presence of elevated insulin levels and excluding exogene insulin intake by C-peptide levels and screening for sulfonylureas.

After completely exposing the pancreas and investigation by bimanual palpation and intraoperative

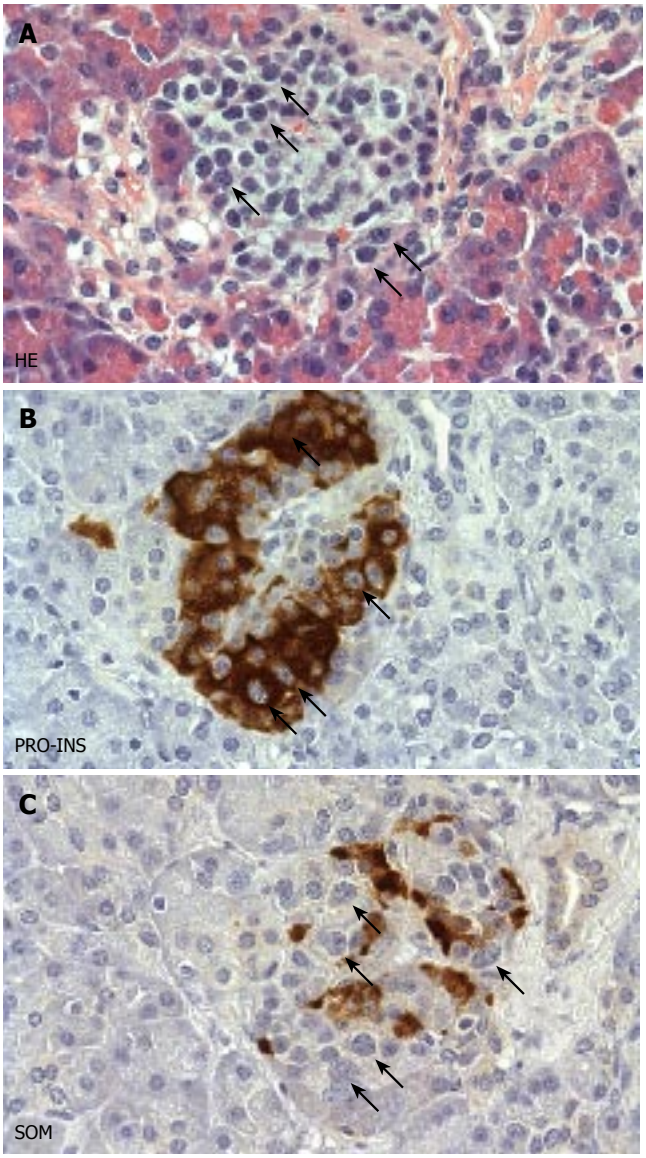

**Figure 1** Histopathological features of diffuse nesidioblastosis. **A:** HE stained sections demonstrating a prominent lobulation of an islet. Some of the endocrine cells showing hyperchromatic and enlarged nuclei are labelled with arrows. **B**, **C**: Adjacent section analysis demonstrating cytoplasmic positivity for proinsulin (PRO-INS) in those endocrine cells with hyperchromatic nuclei (arrows in **B**). In contrast, these cells are negative for somatostatin (SOM) (arrows in **C**).

ultrasound, a small tumor in the tail of the pancreas was suspected and a spleen preserving pancreatic-tail resection was performed. Nesidioblastosis was diagnosed postoperatively by the pathologist according to the recently published major and minor criteria for nesidioblastosis in adults[11].

Our knowledge of the pathogenesis of PHH in infants has expanded in recent years. Some genetic abnormalities underlie the disease. The most important genetic defects are inactivating mutations on chromosome 11 (SUR1 and Kir6.2)[4,5]. Gain-of-function mutations of the glucokinase gene (GCK) and glutamate dehydrogenase genes are infrequent (GLUD1)[11]. Because of the patient's young age, a subgroup of diabetes mellitus, a maturity onset diabetes of the youth (MODY), should be discussed for differential diagnosis. So far 6 different types of MODY have been diagnosed. Glucokinase plays a critical role in the insulin secretion in β-cells. Heterozygous mutations in the glucokinase-encoding gene (GCK) results in the reduction of encymatic activity (MODY 2)[18,19]. Loss of function mutations in GCK could be ruled out as a possible reason for hyperglycemia in our patient.

The diagnosis and treatment of an adult nesidioblastosis still remain an open issue. There are no imaging techniques to differentiate focal from nonfocal (diffuse) organic hyperinsulinism. Frequently, insulin-producing tumors are less than 10 mm in diameter and may therefore escape preoperative detection. Additionally, preoperative imaging as EUS can yield misleading findings in the pancreas[20]. An intra-arterial calcium stimulation test may be able to differentiate focal hyperactive β-cells from diffuse hypertophic β-cells[21-23]. Due to the failure of the modern imaging techniques in these patients, the localization of pathologic increased insulin secretion would be a diagnostic tool for the surgeon to help avoid blind pancreatic resection. The treatment of adult nesidioblastosis is surgical resection. However, the line between 'too much' and 'too less' resection, with the risk of endocrine and exocrine pancreatic insufficiency and recurrent hypoglycemia is very narrow. Nesiodioblastosis has to be considered in all cases without localized insulinoma because it has been recently shown that this disease can be present in up to 4% of patients with PHH[11]. In the case of recurrence, a secondary surgical intervention with further pancreatic resection is necessary. In our case, hypoglycemia may be life threatening, but the risk of lifetime diabetes should be considered as well. Nowadays, recurrent pancreatic resections can be performed with low risk in specialized centers.

The present case illustrates a very rare coincidence of diabetes and adult nesidioblastosis. Up to now, only four cases with organic hyperinsulinism and diabetes have been reported[12-15]. Our case is the second description of a concomitant adult nesidioblastosis and diabetes type Ⅱ. In summary, diabetes can be reversed by functionally defective hypertrophic β-cells. In the case of reversing diabetes, an organic hyperinsulinemic hypoglycemia should be considered as a differential diagnosis.

## TO THE EDITOR

In their recent review article[1], Andoh and Fujiyama examined the various therapeutic approaches targeting intestinal microflora in patients with inflammatory bowel disease (IBD). I would like to provide some additional data to complete and update their comments. First of all, when considering the role of probiotics in IBD treatment it must be emphasized that, in addition to *Bifidobacteria*, the *Nissle 1917 E. coli* strain and cocktails of microorganisms such as *VSL # 3* mentioned in the article, other probiotic agents have been tested in the short- and long-term treatment of either ulcerative colitis and Crohn's disease, the results of those studies being reported in major international scientific journals.

For instance, *Saccharomyces boulardii*, a non-pathogenic yeast, which is widely used in the treatment of diarrhea and is effective in preventing relapse of *Clostridium difficile* infection[2], has been employed in the maintenance treatment of patients with inactive Crohn's disease[3]. Thirty-two patients were randomly allocated to a six-month maintenance therapy either with mesalazine alone (500 mg of sustained-release microgranules, 3 times daily) or with the same mesalazine preparation 500 mg twice daily plus *Saccharomyces boulardii* 500 mg once daily. Clinical relapse, defined as CDAI > 150 with an increase of 100 points over the baseline values for more than 2 wk, was observed in 37.5% of patients receiving mesalazine alone and in only 6.25% of subjects in the group treated with mesalazine plus *Saccharomyces boulardii* ( $P = 0.04$ by Fisher's exact test).

Furthermore, in 25 patients with a history of poor tolerance to corticosteroids, who had a clinical flare-up of mild to moderate left-sided ulcerative colitis while on maintenance with mesalazine, *Saccharomyces boulardii* (250 mg, 3 times daily) was added to the ongoing mesalazine treatment for 4 wk[4]. Clinical evaluation was performed before and after the treatment with Rachmilewitz's activity index. Clinical remission, -Endoscopically confirmed clinical emission was achieved in 68% of cases on an intention-to-treat basis.

Although the effect of each probiotic agent is different, placebo-controlled clinical trials employing *Lactobacillus GG* in the maintenance treatment of Crohn's disease have failed to show any significant effect in preventing recurrences at 6-24 mo[5,6]. However, the probiotic is able to maintain clinical remission of ulcerative colitis[7].

Finally, when considering the possible role of antibiotics in IBD, the recent data on rifaximin, a poorly absorbable antibacterial agent, must be quoted. A double-blind, placebo-controlled trial showed that addition of 800 mg rifaximin twice a day for 12 wk is effective in inducing clinical remission of active Crohn's disease[8]. It was reported that 400 mg rifaximin twice daily for 4 wk can achieve clinical remission in 76% of ulcerative colitis patients who had relapse while on mesalazine maintenance[9].

The virtual absence of systemic side-effects and the encouraging results reported so far suggest rifaximin can effectively inhibit the intestinal flora in IBD patients without severe side effects.

Dear Editior-in-Chief,

I am grateful to the renowned World Journal of Gastroenterology for publishing our manuscript about hepatoma radiosensitivity in volume 11 issue 26, page 4098-4101[1]. Since this paper appeared online first, it was widely considered. Up to date, it has been cited four times in various journals covered by Science Citation Index[2-4], and the click count and download count added up to 459 and 163[1], respectively. Some scientists from Australia and Germany frequently sent me letters to ask for original data to be cited, but a fatal mistake made them arduous. The correspondence author's e-mail address should be yangjs@impcas.ac.cn, but not tuyangjs@impcas.ac.cnit. I sincerely expected your editors could rephrase and upload it to your online data base.

*World J Gastroenterol* 2006 November 28; 12(44): 7230-7232
***World Journal of Gastroenterology*** ISSN 1007-9327

# Instructions to authors

## GENERAL INFORMATION

*World Journal of Gastroenterology* (*WJG, World J Gastroenterol* ISSN 1007-9327 CN 14-1219/R) is a weekly journal of more than 48 000 circulation, published on the 7th, 14th, 21st and 28th of every month.

Original Research, Clinical Trials, Reviews, Comments, and Case Reports in esophageal cancer, gastric cancer, colon cancer, liver cancer, viral liver diseases, *etc.*, from all over the world are welcome on the condition that they have not been published previously and have not been submitted simultaneously elsewhere.

### *Indexed and abstracted in*

Current Contents®/Clinical Medicine, Science Citation Index Expanded (also known as SciSearch®) and Journal Citation Reports/Science Edition, *Index Medicus*, MEDLINE and PubMed, Chemical Abstracts, EMBASE/Excerpta Medica, Abstracts Journals, *Nature Clinical Practice Gastroenterology and Hepatology*, CAB Abstracts and Global Health. ISI JCR 2003-2000 IF: 3.318, 2.532, 1.445 and 0.993.

### *Published by*

The WJG Press

## SUBMISSION OF MANUSCRIPTS

Manuscripts should be typed double-spaced on A4 (297 mm × 210 mm) white paper with outer margins of 2.5 cm. Number all pages consecutively, and start each of the following sections on a new page: Title Page , Abstract, Introduction, Materials and Methods, Results, Discussion, acknowledgements, References, Tables, Figures and Figure Legends. Neither the editors nor the Publisher is responsible for the opinions expressed by contributors. Manuscripts formally accepted for publication become the permanent property of The WJG Press, and may not be reproduced by any means, in whole or in part without the written permission of both the authors and the Publisher. We reserve the right to put onto our website and copy-edit accepted manuscripts. Authors should also follow the guidelines for the care and use of laboratory animals of their institution or national animal welfare committee.

Authors should retain one copy of the text, tables, photographs and illustrations, as rejected manuscripts will not be returned to the author(s) and the editors will not be responsible for the loss or damage to photographs and illustrations in mailing process.

### *Online submission*

Online submission is strongly advised. Manuscripts should be submitted through the Online Submission System at: http://www.wjgnet.com/index.jsp. Authors are highly recommended to consult the ONLINE INSTRUCTIONS TO AUTHORS (http://www.wjgnet.com/wjg/help/instructions.jsp) before attempting to submit online. Authors encountering problems with the Online Submission System may send an email you describing the problem to wjg@wjgnet.com for assistance. If you submit your manuscript online, do not make a postal contribution. A repeated online submission for the same manuscript is strictly prohibited.

### *Postal submission*

Send 3 duplicate hard copies of the full-text manuscript typed double-spaced on A4 (297 mm × 210 mm) white paper together with any original photographs or illustrations and a 3.5 inch computer diskette or CD-ROM containing an electronic copy of the manuscript including all the figures, graphs and tables in native Microsoft Word format or *.rtf format to:

### Editorial Office

***World Journal of Gastroenterology***
Editorial Department: Apartment 1066, Yishou Garden,
58 North Langxinzhuang Road,
PO Box 2345, Beijing 100023, China
E-mail: wjg@wjgnet.com
http: //www.wjgnet.com
Telephone: +86-10-85381901
Fax: +86-10-85381893

## MANUSCRIPT PREPARATION

All contributions should be written in English. All articles must be submitted using a word-processing software. All submissions must be typed in 1.5 line spacing and in word size 12 with ample margins. The letter font is Tahoma. For authors from China, one copy of the Chinese translation of the manuscript is also required (excluding references). Style should conform to our house format. Required information for each of the manuscript sections is as follows:

### *Title page*

Full manuscript title, running title, all author(s) name(s), affiliations, institution(s) and/or department(s) where the work was accomplished, disclosure of any financial support for the research, and the name, full address, telephone and fax numbers and email address of the corresponding author should be included. Titles should be concise and informative (removing all unnecessary words), emphasize what is new, and avoid abbreviations. A short running title of less than 40 letters should be provided. List the author(s)' name(s) as follows: initial and/or first name, middle name or initial(s) and full family name.

### *Abstract*

An informative, structured abstract of no more than 250 words should accompany each manuscript. Abstracts for original contributions should be structured into the following sections: AIM: Only the purpose should be included. METHODS: The materials, techniques, instruments and equipments, and the experimental procedures should be included. RESULTS: The observatory and experimental results, including data, effects, outcome, *etc.* should be included. Authors should present *P* value where necessary, and the significant data should accompany. CONCLUSION: Accurate view and the value of the results should be included.

The format of structured abstracts is at: http://www.wjgnet.com/wjg/help/11.doc

### *Key words*

Please list 6-10 key words that could reflect content of the study mainly from *Index Medicus*.

### *Text*

For most article types, the main text should be structured into the following sections: INTRODUCTION, MATERIALS AND METHODS, RESULTS and DISCUSSION, and should include in appropriate Figures and Tables. Data should be presented in the body text or in Figures and Tables, but not in both.

### *Illustrations*

Figures should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each figure on a separate page. No detailed legend should be involved under the figures. This part should be added into the text where the figures are applicable. Digital images: black and white photographs should be scanned and saved in TIFF format at a resolution of 300 dpi; color images should be saved as CMYK (print files) but not as RGB (screen-viewing files). Place each photograph in a separate file. Print images: supply images of size no smaller than 126 mm × 85 mm printed on smooth surface paper; label the image by writing the Figure number and orientation using an arrow. Photomicrographs: indicate the original magnification and stain in the legend. Digital Drawings: supply files in EPS if created by freehand and illustrator, or TIFF from photoshops. EPS files must be accompanied by a version in native file format for editing purposes. Existing line drawings should be scanned at a resolution of 1200 dpi and as close as possible to the size where they will appear when printed. Please use uniform legends for the same subjects. For example: Figure 1 Pathological changes of atrophic gastritis after treatment. A: ...; B: ...; C: ...; D: ...; E: ...; F: ...; G: ...

### *Tables*

Three-line tables should be numbered as 1, 2, 3 and so on, and mentioned clearly in the main text. Provide a brief title for each table. No detailed legend should be included under the tables. This part should be added into the text where the tables are applicable. The information should complement but not duplicate that contained in the text. Use one horizontal line under the title, a second under the column heads, and a third below the Table, above any footnotes. Vertical and italic lines should be omitted.

### *Notes in tables and illustrations*

Data that are not statistically significant should not be noted. $^{a}P<0.05$, $^{b}P<0.01$ should be noted ($P>0.05$ should not be noted). If there are other series of *P* values, $^{c}P<0.05$ and $^{d}P<0.01$ are used. Third series of *P* values can be expressed as $^{e}P<0.05$ and $^{f}P<0.01$. Other notes in tables or under

illustrations should be expressed as $^1F$, $^2F$, $^3F$; or some other symbols with a superscript (Arabic numerals) in the upper left corner. In a multi-curve illustration, each curve should be labeled with ●, ○, ■, □, ▲, △, *etc.* in a certain sequence.

### *Acknowledgments*

Brief acknowledgments of persons who have made genuine contributions to the manuscripts and who endorse the data and conclusions are included. Authors are responsible for obtaining written permission to use any copyrighted text and/or illustrations.

## REFERENCES

### *Coding system*

The author should code the references according the citation order in text in Arabic numerals, put references codes in square brackets, superscript it at the end of citation content or the author name of the citation. For those citation content as the narrate part, the coding number and square brackets should be typeset normally. For example, Crohn's disease (CD) is associated with increased intestinal permeability[1,2]. If references are directly cited in the text, they would be put together with the text, for example, from references [19,22-24 ], we know that...

When the authors code the references, please ensure that the order in text is the same as in reference part and also insure the spelling accuracy of the first author's name. Do not code the same citation twice.

### *PMID requirement*

PMID roots in the abstract serial number indexed by PubMed (http://www.ncbi.nlm.nih.gov/entrez/query.fcgi?db=PubMed). The author should supply the PMID for journal citation. For those references that have not been indexed by PubMed, a printed copy of the first page of the full reference should be submitted.

The accuracy of the information of the journal citations is very important. Through reference testing system (http://www.wjgnet.com/cgi-bin/index.pl), the authors and editor could check the authors name, title, journal title, publication date, volume number, start page, and end page. We will interlink all references with PubMed in ASP file so that the readers can read the abstract of the citations online immediately.

### *Style for journal references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR). Title of the cited article and italicized journal title (Journal title should be in its abbreviation form as shown in PubMed), publication date, volume number (in black), start page, and end page [PMID: 11819634]

Note: The author should test the references through reference testing system (http://www.aushome.cn/cgi-bin/index.pl)

### *Style for book references*

Authors: the first author should be typed in bold-faced letter. The surname of all authors should be typed with the initial letter capitalized and followed by their name in abbreviation (For example, Lian-Sheng Ma is abbreviated as Ma LS, Bo-Rong Pan as Pan BR) Book title. Publication number. Publication place: Publication press, Year: start page and end page.

### *Format*

**Journals**

*English journal article (list all authors and include the PMID where applicable)*

16 **Pagedas AC**, inventor; Ancel Surgical R&D Inc., assignee. Flexible endoscopic grasping and cutting device and positioning tool assembly. United States patent US 20020103498. 2002 Aug 1

### *Inappropriate references*

Authors should always cite references that are relevant to their article, and avoid any inappropriate references. Inappropriate references include those that are linked with a hyphen and the difference between the two numbers at two sides of the hyphen is more than 5. For example, [1-6], [2-14] and [1, 3, 4-10, 22] are all considered as inappropriate references. Authors should not cite their own unrelated published articles.

### *Statistical data*

Present as mean ± SD or mean ± SE.

### *Statistical expression*

Express $t$ test as $t$ (in italics), $F$ test as $F$ (in italics), chi square test as $\chi^2$ (in Greek), related coefficient as $r$ (in italics), degree of freedom as $\gamma$ (in Greek), sample number as $n$ (in italics), and probability as $P$ (in italics).

### *Units*

Use SI units. For example: body mass, m (B) = 78 kg; blood pressure, $p$(B) = 16.2/12.3 kPa; incubation time, t (incubation) = 96 h, blood glucose concentration, c (glucose) 6.4 ± 2.1 mmol/L; blood CEA mass concentration, p (CEA) = 8.6 24.5 μg/L; $CO_2$ volume fraction, 50 mL/L $CO_2$ not 5% $CO_2$; likewise for 40 g/L formaldehyde, not 10% formalin; and mass fraction, 8 ng/g, *etc.* Arabic numerals such as 23, 243, 641 should be read 23 243 641.

The format about how to accurately write common units and quantum is at: http://www.wjgnet.com/wjg/help/15.doc

### *Abbreviations*

Standard abbreviations should be defined in the abstract and on first mention in the text. In general, terms should not be abbreviated unless they are used repeatedly and the abbreviation is helpful to the reader. Permissible abbreviations are listed in Units, Symbols and Abbreviations: A Guide for Biological and Medical Editors and Authors (Ed. Baron DN, 1988) published by The Royal Society of Medicine, London. Certain commonly used abbreviations, such as DNA, RNA, HIV, LD50, PCR, HBV, ECG, WBC, RBC, CT, ESR, CSF, IgG, ELISA, PBS, ATP, EDTA, mAb, can be used directly without further mention.

### *Italics*

Quantities: *t* time or temperature, *c* concentration, *A* area, *l* length, *m* mass, *V* volume.
Genotypes: *gyr*A, *arg* 1, *c myc*, *c fos*, *etc.*
Restriction enzymes: *Eco*RI, *Hin*dI, *Bam*HI, *Kbo* I, *Kpn* I, *etc.*
Biology: *H pylori, E coli, etc.*

## SUBMISSION OF THE REVISED MANUSCRIPTS AFTER ACCEPTED

Please revise your article according to the revision policies of *WJG*. The revised version including manuscript and high-resolution image figures (if any) should be copied on a floppy or compact disk. Author should send the revised manuscript, along with printed high-resolution color or black and white photos, copyright transfer letter, the final check list for authors, and responses to reviewers by a courier (such as EMS) (submission of revised manuscript by e-mail or on the *WJG* Editorial Office Online System is NOT available at present).

### *Language evaluation*

The language of a manuscript will be graded before sending for revision. (1) Grade A: priority publishing; (2) Grade B: minor language polishing; (3) Grade C: a great deal of language polishing; (4) Grade D: rejected. The revised articles should be in grade B or grade A.

### *Copyright assignment form*

Please downloaded CAF from http://www.wjgnet.com/wjg/help/9.doc.

We certify that the material contained in this manuscript:

**Ms:**

**Title:**

is original, except when appropriately referenced to other sources, and that written permission has been granted by any existing copyright holders. We agree to transfer to WJG all rights of our manuscript, including: (1) all copyright ownership in all print and electronic formats; (2) the right to grant permission to republish or reprint the stated material in whole or in part, with or without a fee; (3) the right to print copies for free distribution or sale; (4) the right to republish the stated material in a collection of articles or in any other format. We also agree that our article be put on the Internet.

**Criteria for authorship:** The WJG requests and publishes information about contributions of each author named to the submitted study. Authorship credit should be based on (1)direct participation in the study, including substantial contributions to conception and design of study, or acquisition of data, or analysis and interpretation of data; (2) manuscript writing, including drafting the article, or revising it critically for important intellectual content; (3)supportive work, including statistical analysis of data, or acquisition of funding, or administration, technology and materials support, or supervision, or supportive contributions. Authors should meet at least one of the three conditions. The WJG does not publish co-first authors and co-corresponding authors.

We hereby assign copyright transfer to WJG if this paper is accepted.

Author Name in full (Full names should be provided, with first name first, followed by middle names and family name at the last, eg, Eamonn MM Quigley). Handwritten names are not accepted.

Author Name in abbreviation (Family name is put first in full, followed by middle names and first name in abbreviation with first letter in capital, eg, Quigley EMM). Handwritten names are not accepted.

### *Final check list for authors*

The format is at: http://www.wjgnet.com/wjg/help/13.doc

### *Responses to reviewers*

Please revise your article according to the comments/suggestions of reviewers. The format for responses to the reviewers' comments is at: http://www.wjgnet.com/wjg/help/10.doc

### *Proof of financial support*

For paper supported by a foundation, authors should provide a copy of the document and serial number of the foundation.

### *Publication fee*

Authors of accepted articles must pay publication fee.
EDITORIAL and LETTERS TO THE EDITOR are free of change.

## Abstract

Colon cancer is still one of the leading causes of cancer death worldwide. Although the host immune system has been shown to react against tumor cells, mainly through tumor infiltrating lymphocytes and NK cells, tumor cells may utilize different ways to escape anti-tumor immune response. Tumor infiltration of CD8+ and CD4+ (T-bet+) effector T cells has been attributed to a beneficial outcome, and the enhancement of T cell activation through T cell receptor stimulation and co-stimulatory signals provides promising strategies for immunotherapy of colon cancer. Growing evidence supports a role for the Fas/FasL system in tumor immunology, although the mechanisms and consequences of FasL activation in colon cancer are not completely understood. In animal models, depletion of regulatory T cells (CD4+ CD25+ T cells) can enhance the anti-tumor immune response under certain conditions. Taken together, recent insights in the immune reaction against colon carcinoma have provided new approaches to immunotherapy, although much remains to be learned about the exact mechanisms.

## INTRODUCTION

Colon cancer is still one of the leading causes of cancer death worldwide. In the United States approximately 145 290 new cases of colorectal cancer are diagnosed every year. With more than 56 000 deaths in the United States in 2005, colorectal cancer is responsible for more than 10 percent of all cancer deaths[1]. However, the molecular pathogenesis of colorectal cancer is still poorly understood. Recent studies suggested that different mechanisms such as mutations in cell cycle-[2] and apoptotic-pathways[3], signal transduction[4-6], angiogenesis[7,8], invasion and metastasis[9] significantly contribute to cancer progression (Table 1). Another important mechanism consists of the ability of tumor cells to escape the host immune reaction, as outlined below.

Sir Macfarlane Burnet and Lewis Thomas first proposed the existence of an immunological response to tumors in the cancer immunosurveillance hypothesis in the 1950s[10,11]. However, strong evidence supporting this concept was lacking and the hypothesis was abandoned for many years[12]. In the past two decades, however, the identification of tumor specific antigens and immune modulation leading to tumor regression suggested the existence of cancer immunosurveillance[13-17]. The activation of the host immune system through tumor cells is a complex cascade involving both the innate and adaptive immune systems (Figure 1)[11]. The presence of tumor specific T cells has been correlated with improved clinical outcome in different human cancers[18-21], but does not necessarily result in anti-tumor immunity, since T cells can also promote the progression of tumors through different growth factors[22]. It has been shown that CD8+ T cells and CD4+ effector T cells may have anti-tumor properties, whereas regulatory T cells (CD4+ CD25+ Tregs) may be responsible for immunological hypo-responsiveness observed in cancer[23-26].

The human gastrointestinal tract contains several phenotypically and functionally distinct populations of T cells, which may play a role in anti-tumor immunity[27-29]. Interestingly, T cell activation has been shown in colorectal cancer and proposed as a prognostic factor[30]. The following editorial will discuss recent advantages in our understanding of T cell activation in colorectal cancer and possible therapeutic strategies.

## EVIDENCE FOR T LYMPHOCYTE ACTIVATION IN COLON CANCER

Tumor-infiltrating lymphocytes (TILs) have been isolated from a variety of solid human cancers. It has been widely accepted that one of the most promising T cell subsets

for an effective anti-tumor response consists of CD8+ T cells[26]. In a study on 131 patients with colorectal cancer, Naito *et al* showed a positive correlation between CD8+ T-cells within cancer cell nests and patient survival[30]. Another study using 959 specimens of resected colorectal cancer analyzed the correlation between tumor metastasis and T cell activation[31]. Elevated expression of genes, specific for cytotoxic T lymphocytes (CTLs), such as CD8α, granzyme B, or granulysin as well as Th1-associated genes as T-bet, or interferon-γ was significantly higher in patients without signs of early metastatic invasion as compared to those with early invasion (VELIPI+). In addition, the authors proposed the presence of CD45RO+ CCR7- memory cells as an independent, positive prognostic factor in colorectal cancer. The detected cells represented all subpopulations in the differentiation pathway and are characterized by long-term persistence *in vivo* and the ability to rapidly expand upon reencounter with antigen[32].

Interestingly, microsatellite instability in colon cancer results in significantly increased infiltration of tumors with larger numbers of CD8+ T cells and is associated with a favorable prognosis[33,34]. Microsatellite instability is characterized by defective DNA mismatch repair mechanisms, which result in higher rates of mutations and cell-to-cell variability in the length of DNA microsatellites. Tumors revealing extensive microsatellite instability, such as Hereditary Nonpolyposis Colorectal Carcinoma (HNPCC), which is associated with germ-line mutations of DNA mismatch repair genes, are designated as microsatellite instability (MSI)-high. In contrast, sporadic colorectal cancers display MSI-H in only 15%[35]. The better prognosis of MSI-H carcinomas is explained by frequent mutations in oncogenic genes and mutation-dependent abnormal peptides resulting in a cytotoxic immune response against cancer cells and hence increased infiltration by CTLs[36]. Several immunogenic antigens, such as mutated CDX2, TGFβIIR, or Caspase-5, have been identified for MSI-H associated colon cancers[37-39]. In MSI-H negative sporadic colorectal carcinoma, the identification of different tumor associated antigens (TAAs) has also been correlated with the activation of the host immune system to tumor cells[34,40-44].

In some patients, recurrent or persistent inflammation may promote carcinogenesis and trigger cancer growth. For instance, the risk of colorectal cancer in patients with chronic inflammatory bowel disease (ulcerative colitis and Crohn's disease) increases with longer duration of disease[45,46]. In particular, patients with ulcerative colitis have a significant risk for development of colitis associated colon cancer dependent on the extension of the disease, the presence of backwash ileitis and the number of flares suggesting that inflammation drives carcinogenesis. Whereas defined molecular changes in progression of sporadic colon cancer lead to stepwise changes in histology according to the adenoma-carcinoma sequence, carcinogenesis in ulcerative colitis starts with a hyperplastic lesion in the inflamed mucosa and develops through dysplasia into adenocarcinoma, ("inflammation-dysplasia-carcinoma" sequence)[47]. Different molecular mechanisms such as oxidative stress and NF-κB-activation have been attributed to inflammation dependent carcinogenesis[47-49]. Even T cell activation can lead to tumor growth through cytokine secretion. For instance Becker *et al* showed that IL-6 signaling through TILs results in tumor progression, as IL-6 serves as a growth and proliferation factor for tumor cells. This signaling was dependent on tumor derived soluble IL-6 receptor and could be inhibited through TGF-β[50,51].

**Table 1 Different pathways of colon cancer progression and possible therapeutic targets**

| Pathway | Targets |
|---|---|
| Cell cylce | p53, pRb, p16, p21, D-type cyclins |
| Apoptosis and survival | Bcl-2, Cox-2 |
| Signal transduction | EGF-R, Akt, AP-1, Her2/neu, NFκB |
| Angiogenesis, invasion, and metastasis | VEGF, TSP-1, CXCR-4 |
| Immunity | IL-6, TGF-β |

Taken together, the immune system may promote progression of colorectal cancer in cases of chronic inflammation, but can also lead to tumor regression through the innate immune system with tumor specific activation of CTLs and effector CD4+ T cells (Figure 2). However, the high incidence and death rate of colorectal cancer suggest an ineffective immune response in many cases. Although it has been shown that CTLs can recognize specific TAAs, many mechanisms of suppression or failure of such recognition do exist[18,21,52].

## ESCAPE MECHANISMS IN COLON CANCER

It has been proposed that tumor progression is a result of the natural selection of rapidly growing tumor cell variants leading to a growth advantage of such cells over other cells. This concept has also been applied to the immune escape of tumor cells. The loss or down-regulation of HLA class I antigens, the lack of co-stimulation, defective death receptor signaling, apoptosis of activated T cells, immunosuppressive cytokines, and activation of suppressor T cells are important examples for this phenomenon[53].

Norazmi *et al* described decreased HLA class I antigen in malignant colonic tissues as compared to non-malignant tissues from the same individuals[54], thereby enabling tumor cells to escape CTL-mediated lysis due to circumvention of MHC-restricted, antigen-specific triggering of the T-cell receptor (TCR) complex. On the other hand cross-priming of CTLs through antigen presenting cells (APCs) is ineffective, as powerful APC-activating stimuli are usually absent in tumors[53,55].

Antibody-guided targeting of antigenic MHC class I -peptide tetramers on colon cancer cells results in a destruction of tumor cells by cytotoxic T lymphocytes *in vitro* and *in vivo* and has been proposed as a new form of immunotherapy[56,57]. Otherwise, data from Luo *et al* show a protection of colon carcinoma cells from apoptosis and cytolysis induced by hepatic NK cells through higher MHC

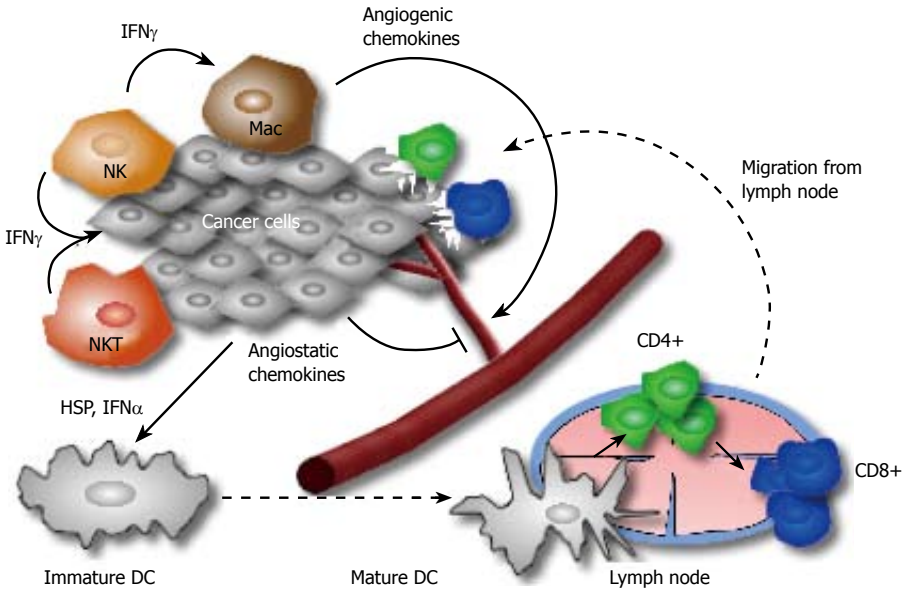

**Figure 1** A proposed model for the host immune reaction to cancer cells. At the initiation of the immune reaction lymphocytes and other cells participating in innate immunity (e.g. APCs, NK, NKT cells) recognize transformed tumor cells and produce IFN-γ. This starts a cascade of reactions with production of chemokines (for instance angiogenic or angiostatic chemokines like MIG, IP10 and I-TAC), IFN-γ (antiproliferative mediator for the developing tumor) and direct cytotoxicity of NK cells and macrophages on tumor cells. This cascade may result in partial tumor cell death and tumor cell debris is ingested by dendritic cells, which move to draining lymph nodes and activate CD4+ and CD8+ T cells. Activated and tumor specific T cells move to the tumor along a chemokine gradient and destroy tumor cells expressing a distinctive tumor antigen.

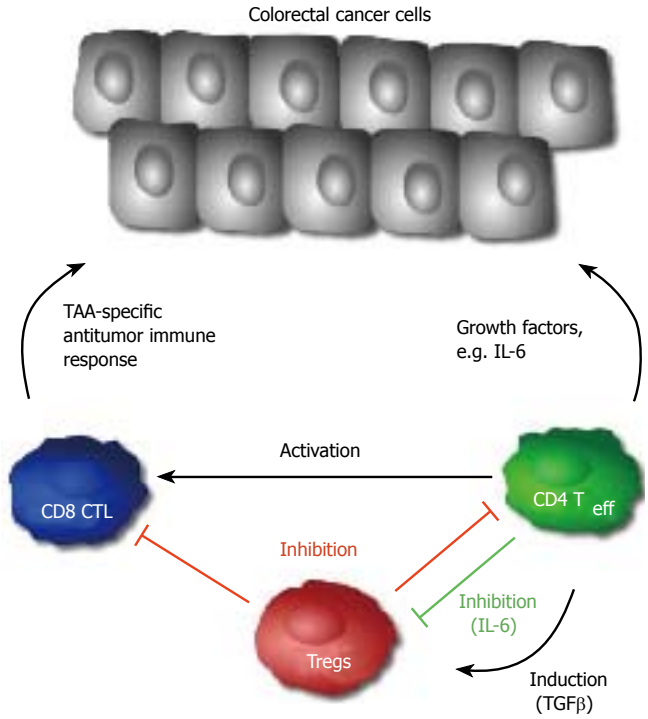

**Figure 2** The role of different T cell subsets in colorectal cancer. Activated CD4+ T cells can release growth factors and thereby lead to tumor progression or activate tumor specific CD8+ T cells. Secretion of TGFβ can induce adaptive Tregs, which may suppress the anti-tumor immune response. Once activated, Tregs can be suppressed by IL-6 derived from CD4+ T cells.

class I expression, most likely by blocking the perforin/granzyme pathway[58].

T cell activation is mediated not only by triggering of the T cell receptor complex, but also by antigen-independent mechanisms such as co-stimulation. Co-stimulation induces cytolysis, cytokine secretion, proliferation and protection from apoptosis in CTLs. The poor immunogenicity of tumor cells has been partly ascribed to the lack of expression of co-stimulatory ligands (see Abken *et al*[59] for review). In the past few years, the increasing knowledge about the mechanisms of T cell activation led to new approaches for immunotherapy. Concerning colon carcinoma, the therapeutic amplification of the expression of co-stimulatory molecules as B7.1[60] and CD40L[61], the induction of co-stimulatory molecules as OX40 and 4-1BB[62] on T cells, and the administration of soluble co-stimulator proteins as B7.1-Fc[63], a B7.1 fusion protein consisting of the extracellular domains of human B7.1 and the Fc portion of human IgG1, or Ig-4-1BBL[64], a soluble fusion protein of 4-1BB Ligand and IgG2a, have shown promising results in experimental settings.

Growing evidence supports a relevant role of Fas/Fas Ligand (FasL) interactions in the immune escape of tumors. Fas and FasL belong to the tumor necrosis factor receptor and ligand families and activation of Fas by anti-Fas antibodies results in apoptosis of Fas expressing cells. It has been shown that tumors may provide resistance to Fas-mediated cytotoxicity, and that FasL expression on tumor cells could counterattack the immune system by inducing apoptosis of immune effector cells[65,66].

Several studies gave evidence for a role of the Fas tumor counterattack in colon carcinoma[67-69]. However, in a study with two different Fas-expressing target cell lines and seven different human colon cancer lines Favre-Felix *et al* failed to detect an induction of apoptosis in Fas-expressing target cell lines, namely Jurkat T cells and murine leukemia cells[70]. Recent studies suggest different functions of FasL in the immune response, since it has been shown that FasL is also delivering costimulatory signals to T cells, inducing motility of tumor cells, contributing to liver regeneration and yielding growth stimulatory signals to neurons[65]. The role of FasL in tumor escape is far from being understood and further studies are mandatory to elucidate the mechanisms and consequences of FasL activation.

## CD25+CD4+ T CELLS IN COLON CANCER: REGULATORS OF IMMUNE ESCAPE?

While it is generally accepted that CD4+ T cells may

contribute to the host anti-tumor immune response, a small subset of CD4+ T cells, the CD4+ CD25+ regulatory T cells (Treg) have been shown to accumulate in the tumor environment and induce immune escape mechanisms[26,71]. Elevated expression of FOXP3, a transcription factor crucial in the development and function of Tregs, has been associated with a poor prognosis in different types of cancer[72,73].

Depletion of Tregs by specific antibodies has enhanced vaccine-induced anti-tumor immunity in colon cancer and other cancer subsets such as leukemia, plasmocytoma, melanoma, fibrosarcoma, or renal cell carcinoma[24,25,74-80]. On the other hand the addition of Tregs resulted in growth regression of inflammation associated intestinal tumors in two studies provided by Erdman *et al*[81,82]. This is also in agreement with the above-mentioned data about tumor progression through IL-6 signaling, since Tregs can suppress cytokine release. Interestingly enough, TGF-β seems to have a central role in these mechanisms, since the cytokine itself can inhibit IL-6 signaling and lead to FOXP3 expression in tumor infiltrating CD4+ T cells[83]. Accordingly, the role of Tregs in colon carcinoma may also depend on tumor pathogenesis, but the exact mechanisms of Tregs in the regulation of tumor immunology remain undefined.

## CONCLUSION

Colon cancer is still one of the leading causes of cancer death worldwide. Although the host immune system can initiate an immune response against colon cancer cells, tumor cells may utilize different ways to escape those defense mechanisms. Detection of tumor associated antigens, stimulation of the T cell receptor, enhancement of costimulatory signals and depletion of regulatory T cells have shown promising results to overcome tumor escape and provide new strategies for immunotherapy of colon cancer.

## Abstract

Hepatocellular carcinoma (HCC) is the fifth most common neoplasm, the major cause of death in patients with liver cirrhosis, and the third most common cause of cancer-related death in the world. The geographic distribution of HCC varies significantly and 80% of cases occur in developing countries (Far East and South Asia) where the prevalence of viral hepatitis is higher. The treatment of HCC is difficult because most patients are diagnosed when the tumour is in an advanced stage and is not amenable to potential curative therapy, thus prevention is the key to reducing HCC and its related morbidity and mortality. HCC is unique among cancers, occurring mostly in patients with a known risk factor. Ninety percent of HCCs develop in the context of chronic liver diseases and mainly in patients with cirrhosis. Viral hepatitis is the most common cause of HCC worldwide, followed by alcoholic liver disease (ALD) and other causes such as non-alcoholic fatty liver disease (NAFLD), genetic haemocromatosis (GH) and primary biliary cirrhosis in an advanced stage (Ⅲ-Ⅴ). In certain areas of the People's Republic of China, exposure to aflatoxin and HBV infection are thought to be responsible for the extraordinary high risk of HCC. Substantial progresses in the prevention of virusl-related hepatitis (screening of blood units, use of disposable sanitary tools, HBV vaccination) have been achieved in developed countries, but in the same areas, alcohol- and dysmetabolism-related HCCs are emerging problems which require specific interventions in terms of public health measures. In developing countries, economic constraints limit the development of any program for the prevention of viral hepatitis transmission (including health education campaigns, healthcare politics, primary prevention and the improvement of hygienic and sanitary conditions). When viral liver disease is established, only a minority of patients are treated worldwide and benefit a possible preventive effect of medical treatment on HCC development. Thus the real contribution of medical treatment to HCC prevention in patients with chronic viral hepatitis is small. Great efforts are needed to identify more effective medical measures for primary and secondary prevention of HCC.

**Key words:** Hepatocellular carcinoma; Viral hepatitis; Cirrhosis; Treatment; Prevention programs

## INTRODUCTION

Hepatocellular carcinoma (HCC) is the fifth most common neoplasm, the major cause of death in patients with liver cirrhosis, and the third most common cause of cancer-related death in the world[1,2]. Every year, 560000 people in the world develop HCC and about the same number die of liver cancer. It is reported to be the leading cause of death in patients with cirrhosis in Europe[3] and Asia[4]. In Italy, its incidence varies from 2% to 4% each year in patients with cirrhosis[5-7].

The geographic distribution of HCC varies significantly and 80% of cases occur in developing countries (Far East and South Asia) where the prevalence of viral hepatitis is higher[8]. Epidemiological data show that its incidence is changing around the world according to the etiology since it is increasing in many developed countries, whereas HCC is declining in developing countries[9]. Studies on the epidemiology and natural history of chronic hepatitis C virus (HCV) infection suggest that HCC frequency has been increasing over the past 20-30 years in USA[10,11] and Europe[12]. HCC is one of the few types of cancer increasing in frequency and mortality in USA[11]. In Japan there has been a three-fold increase in HCC incidence since 1970[13]. Moreover, it has been shown that 80% of newly diagnosed HCCs in Japan are HCV-positive patients[14]. It has been hypothesized that HCC incidence and mortality will indeed increase over the next 10-20 years because

of the increased incidence of HCV-related cirrhosis[10]. With regard to the decline of hepatocellular cancer in developing countries, the introduction of mass hepatitis B virus (HBV) vaccination programs seems to play an important role. In Taiwan the carrier rate of HBsAg in children and adolescents has been significantly reduced[15], as has the incidence of childhood HCC[16]. Nevertheless, the decrease in the incidence of HCC among adults is still a long way off and is not expected for another 3 or 4 decades later[17]. Thus, the role of HBV vaccination in the current decline of HCC incidence, at least in Taiwan, is still to be clarified. In addition, other factors may have a role in changing the epidemiology of HCC incidence around the world: the migration of people from endemic areas and better detection of HCC in Western countries.

The treatment of HCC is difficult because most patients are diagnosed when the tumour is in an advanced stage and is not amenable to potential curative therapy[18], thus prevention is the key to reducing HCC and its related morbidity and mortality.

Notably, HCC is unique among cancers, occurring mostly in patients with a known risk factor. Ninety percent of HCCs develop in the context of chronic liver diseases and mainly in patients with cirrhosis[19,20]. Viral hepatitis is the most common cause of HCC worldwide, accounting for more than 80% of cases, followed by alcoholic liver disease (ALD) and other causes such as non-alcoholic fatty liver disease (NAFLD), genetic haemocromatosis (GH) and primary biliary cirrhosis in an advanced stage (Ⅲ-Ⅳ)[20-23]. In certain areas of the People's Republic of China where HCC is the leading cause of cancer death, exposure to aflatoxin, a potent hepatocarcinogen produced by food contaminant, and HBV infection are thought to be responsible for the extraordinary high risk of HCC[24].

Therefore, a prevention strategy should be addressed to each single risk factor ranging from food conservation to alcohol abuse, metabolic disease (NAFLD) and viral infection. Then, HCC prevention can focus on different levels: prevention of the underlying disease (primary prevention), prevention of liver disease progression to cirrhosis and cancer (secondary prevention), prevention of cancer relapse in successfully treated HCC (tertiary prevention).

## HCC RELATED TO VIRUSES AND OTHER FACTORS

### *HBV*

HBV-related chronic hepatitis is the most common cause of HCC in the world[25]. The incidence and ways of transmission of this virus vary substantially in different endemic areas throughout the world. HBV is usually acquired in adulthood and its incidence is low in Western countries, while its incidence is high in Asia and in most African countries and its transmission is vertical from mother to child[26].

The relationship between HBV and HCC development is not completely understood. Nevertheless, it seems that two main mechanisms play a role in the induction of liver cancer: one involves repeated liver damage causing necroinflammation and consequent regeneration of hepatocytes, the other is the direct oncogenic property of HBV which integrates itself into the hepatocyte DNA, producing cis- or transactivation of the cellular oncogenes[27,28]. It is important to note that HBV and HCV have been classified among human carcinogens by the International Agency for Research on Cancer[1].

There is a relationship between viral replication (defined as the presence of detectable HBV-DNA by non-PCR assay or HBeAg positivity) and HCC development. A recent study showed that the cumulative risk of HCC development is higher (87%) in patients at the age of 30-70 years persistently positive for HBsAg and HBeAg than in those (12%) who are positive for HBsAg only and in those (1%) who are HBsAg-negative[29]. HBeAg prevalence, a marker of infectivity and viral proliferation, decreases with increasing age. HBeAg seroconversion (both spontaneous and IFN-induced) usually confers a favourable outcome. However, the selection of the e minus mutant (HBV-DNA positive) leads to the development of cirrhosis (not only in the Mediterranean area but also worldwide) which is the prerequisite for HCC development[30].

Therefore, two strategies can be used to prevent HBV-related HCC: one is the prevention of HBV infection, the other which is more questionable is the treatment of HBV-related liver disease and cirrhosis. Only a minority of patients treated with interferon-α (IFN-α) achieve HBs clearance while the majority of HBsAg-positive and HBeAg-negative patients have a persistent viral replication. These patients are still at risk of developing cancer. About 35% of patients[31] who respond to IFN-α treatment achieve HBs clearance and therefore can be considered cured. In the remaining HBsAg-positive patients who can clear HBeAg, a persistent viral replication is still detectable[31]. These patients, especially those with liver cirrhosis remain at risk of developing cancer. On the other hand, the occult HBV infection (HBsAg-negative patients) is related to an increasing or a persistant risk of HCC development in both anti-HCV-related and unrelated cirrhosis[32].

Therefore, occult HBV infection should be investigated specially in patients with chronic HCV infection and considered as an additional factor related to HCC development.

### *HCV*

HCV-related carcinogenesis is still not clearly understood. Hepatitis C virus infection increases the risk of developing HCC and its prevalence among patients with liver cancer varies between different geographic areas from 20% to 90%[10,33]. HCC occurs mostly in patients with end stage liver disease and advanced fibrosis[34]. In this population, the risk of developing liver cancer is 2%-8% per year[35-37] based on clinical studies. The only prospective study evaluating HCC risk in HCV-positive patients, has attributed a 20-fold increased risk to viral infection, but the presence of cirrhosis in the study population was not evaluated[38]. Other studies have not evaluated the presence of co-factors, such as alcohol intake or HBV co-infection and the eventual role of antiviral therapy. Therefore, a bias may exist in the literature, which may explain the variation in the incidence estimates of HCC among patients with HCV infection[11].

HCV itself probably has a direct role in the induction of HCC. Some studies showed that the HCV replicon and both non-structural and core viral proteins are capable of inducing a complex series of intracellular events leading to apoptosis suppression and cellular growth through the down-regulation of PKR and the up-regulation of transcription factors including NF-κB, STAT-3 and ATF-6[39-41].

### *Other causes of HCC*

Alcohol consumption is a risk factor for the development of HCC[42,43]. HCC develops mostly in patients with cirrhosis although a direct carcinogenetic role of alcohol has been documented and is a known risk factor also for cancers other than HCC[44]. Ethanol is mainly metabolized in the liver, producing acetaldehyde and free radicals which produce liver injury and DNA damage through the increase of oxidant stress[45]. Moreover, alcohol abuse produces an accumulation of iron which in turn, contributes to oxidative stress[46] with an additive and possibly synergistic mechanism causing hepatocellular damage.

Hereditary hemochromatosis is a common genetic defect in the Caucasian population causing iron accumulation in different organs as well as in the liver[47]. As has already been stated, iron itself may have a direct role in the development of HCC. The risk of developing HCC in these patients is reported to be 20-200 times greater than that in healthy controls[48-51]. Male sex, older age, cirrhosis and the presence of co-factors such as alcohol, viral hepatitis and tobacco smoking are known risk factors[52,53].

Non-alcoholic fatty liver disease (NAFLD) has recently been described in cohorts of patients as a cause of HCC[54-56], but larger prospective studies are needed to define the real incidence and risk factors for HCC development in this setting of patients

Aflatoxins are hepatocarcinogens produced by *Aspergillus Flavus* and contaminate the food supply in South-east Asia and Africa[57,58], increasing the risk of HCC development, especially in patients with HBV infection, by causing a mutation of the p53 gene[59]. This kind of contamination occurs mostly in developing countries with a hot-humid climate where a variety of oilseeds and cereal crops are produced[60].

## PUBLIC HEALTH MEASURES FOR PRIMARY PREVENTION OF LIVER DISEASE

As already mentioned, HCC occurs in the context of known risk factors and its treatment is disappointing. Therefore the best way to prevent its development is preventing the onset of acquired liver diseases and applying surveillance programs for patients with estabilished liver diseases.

In developed countries, viral hepatitis infection has decreased since the mid-1980s when blood donor screening for viral hepatitis became available. Moreover, the use of medical disposables has contributed to this phenomenon[61] and nowadays, the risk of HBV infection is limited to sexual risk relations, intravenous drug users and in a few cases of patients undergoing dental therapy, acupuncture, piercing and tattooing[62-64]. In developing countries, this field is still a matter of public health because almost half of the blood units are not screened for viral hepatitis[65], sanitary conditions are poor and disposable sanitary tools are often not available.

**Table 1 Recommended doses and schedules for HBV vaccine**

| Vaccine | Patients | Dose (mcg) | Volume (mL) | Schedule (mo) |
|---|---|---|---|---|
| Engerix-B | < 11 yr | 10 | 0.5 | 0, 1, 6 |
| (GlaxoSmithKline, Research Triangle Park, NC) | 11-19 yr | 10 | 0.5 | 0, 1, 6 |
| | > 20 yr | 20 | 1.0 | 0, 1, 6 |
| | Dialysis | 40 | 2.0 | 0, 1, 2, 6 |
| Recombivax HB (Merk & Co. Inc., Whitehouse Station, NJ) | < 11 yr | 5 | 0.5 | 0, 1, 6 |
| | 11-19 yr | 5 | 0.5 | 0, 1, 6 |
| | > 20 yr | 10 | 1.0 | 0, 1, 6 |
| | Predialysis/ dialysis | 40 | 1.0 | 0, 1, 6 |

With regard to HBV, the development of a specific vaccine has dramatically changed the virus epidemiology. This is very important in developing countries where HBV transmission is mostly vertical. HBV vaccination has been shown to be able to prevent cancer[16]. Effective vaccines have been available since 1982 and the World Health Organization has recommended the implementation of mass immunization programs since 1991. This has led to a significant decrease in HCC incidence among children and adolescents in Taiwan and it is expected to occur in the next few decades, also in those countries where the vaccination program was started later[16,66-68]. Different HBV vaccines are available, with recombinant HBs antigen (Table 1). HBV vaccination is one of the fundamental and effective forms of public health prevention measures. Unfortunately, immunization programs have a cost and a large proportion of children do not receive basic vaccines because of economic problems in many developing countries[65]. A plant-derived HBV vaccination could be a cheaper approach, this vaccine is under study with the aim of incorporating the vaccine into the alimentary chain[69].

Especially in developing countries where HBV transmission is mainly vertical with a high prevalence of infection, the screening for HBV is advisable at least in late pregnancy. Mothers positive for HBV-DNA should be given lamivudine or continue lamivudine treatment in order to reduce the viral load and the risk of vertical transmission[70]. Passive immune prophylaxis and immediate vaccination of newborns are required immediately within the perinatal period[70].

Unfortunately, an effective vaccine against HCV is still unavailable. The lack of a small animal model, genomic HCV diversity and the difficulties in establishing an *in vitro* culture of large quantities of HCV are some of the problems encountered by researchers in this field[71]. Therefore, the uncertainty of obtaining an effective vaccine imposes the call for the hygienic strategies already applied in the Western countries in order to reduce the incidence of new cases from about $50 \times 10^5$[72,73] to $< 1 \times 10^5$ inhabitants[74].

The first step in the prevention of alcohol and

NAFLD-related HCC is the fight against chronic abuse and the education for a healthier lifestyle in the general population. Similarly, warnings against alcohol abuse or unsuitable diets and a campaign for the control of body weight through moderate physical activity could play a major role. These concepts are also good for the primary prevention of colon, breast and pancreatic cancer which recognizes a risky lifestyle as their primum movements.

Iron depletion is reported to have a protective effect[75] against the development of hepatocellular carcinoma in genetic hemochromatosis, therefore phlebotomy should be performed when indicated in patients with iron accumulation.

With regard to aflatoxin, the best preventive approach would be pre-harvesting crop management, avoiding infection of the crop with *Aspergillus*[60]. Irrigation and use of fungicides or pesticides may be helpful, but this approach is expensive, especially in poor countries. Post-harvesting technologies are available to limit fungus growth and crop contamination. There are drugs capable of modulating the aflatoxin metabolism once ingested. Oltipraz, an antischistosomal drug, has been shown to be effective in detoxifying patients with serum aflatoxin-albumin adducts[76]. Chlorophyllin is a cheaper drug which has been tested in a perspective, randomised study in China with good results[77].

## PATIENTS WITH ESTABLISHED LIVER DISEASE

### *HBV*

Although it varies according to different geographic areas, HCC incidence among subjects chronically infected with HBV is higher in cirrhotics than in patients with chronic viral hepatitis[6,7,18,30,78-100] (Table 2, adapted from[101]), suggesting that other factors play a relevant role in cancerogenesis. In general, endemic East Asian countries as compared to Western countries where HBV prevalence is low or intermediate have a higher incidence of HCC among all groups considered: asymptomatic carriers, inactive carriers, chronic hepatitis and cirrhosis. It was reported that the five-year cumulative incidence in cirrhotic patients is 15% in East Asian studies and 10% in European studies with a 3-fold higher risk of developing liver cancer in endemic areas than in those with a lower prevalence[101].

This phenomenon is due to several factors associated with an increased risk of HCC development such as patient's age at onset of infection, core promoter variants, the presence of HBe antigen, and probably HBV genotypes. However, the role of HBe antigen and HBV DNA replication in the development of HCC is still being debated. A large study from Taiwan on 11 893 men with chronic hepatitis B, found that the risk of developing HCC is 10-fold higher in patients with HBsAg alone at diagnosis and 60-fold higher in those with both HBs and HBeAg than in HBsAg negative patients[102]. The EUROHEP cohort, with a smaller sample size and a low incidence of HCC showed different results, suggesting that probably in different geographical areas, the same co-factors may produce different results[78]. However, two additional European cohort studies showed that cirrhotic patients, who cleared HBeAg and HBV-DNA (and eventually HBsAg), and achieved ALT normalization, are at low risk of developing HCC[3,103]. Therefore, suppressing HBV replication which represents "per se" a major risk factor may prevent HCC development. Only one randomised controlled trial has reported a decreased incidence of HCC in 67 Taiwanese men treated with interferon as compared to 34 untreated men followed up for 1-12 years. HCC occurred in 1.5% of patients in the treated group as compared to 12% in the untreated group ($P = 0.04$). It is important to note that the only patient who developed HCC in the treated group initially cleared HBeAg, but relapsed later, again becoming HBeAg-positive with elevated transaminases[96]. A meta-analysis of 7 studies comparing treated patients *versus* untreated controls with HBV-related compensated cirrhosis has shown a very weak protective effect of interferon with a 6.4% difference in risk (95% CI: 2.8% to 10%)[104].

In conclusion, interferon treatment may have a beneficial effect on the development of HCC in HBV-infected patients, particularly when a virological response is achieved.

Nowadays, different nucleotide and nucleoside analogues are available for the treatment of HBV. The oldest in this family is lamivudine, a cytidine analogue, which is able to inhibit HBV replication, improve liver enzymes and inflammatory score and arrest progression to fibrosis[105]. A retrospective study evaluated the efficacy of lamivudine in terms of HCC prevention in 377 Japanese patients, compared to the same number of untreated HBV infected controls. HCC occurred in 1.1% of patients with an annual incidence of 0.4% (patient/year) in the treated group and in 13.3% of patients with an annual incidence of 2.5% (patient/year) in the untreated group ($P < 0.001$)[106]. Only one prospective randomized controlled

**Table 2 HCC incidence rates according to clinical setting and geographic areas**

| Clinical setting | Geographic area | Studies (*n*) | Patients (*n*) | Mean follow-up (yr) | HCC incidence | 95% CI |
|---|---|---|---|---|---|---|
| Asymptomatic carrier | North America | 2 | 1804 | 16 | 0.1 | 0.07-0.14 |
| | Taiwan and China | 4 | 18869 | 8 | 0.7 | 0.61-0.70 |
| | Japan | 1 | 513 | 7.3 | 0.2 | 0.08-0.39 |
| Inactive carrier | Europe | 3 | 410 | 16 | 0.02 | 0-0.04 |
| | Taiwan | 1 | 189 | 8 | 0.2 | 0-0.42 |
| Chronic hepatitis | Europe | 6 | 471 | 5.9 | 0.1 | 0-0.27 |
| | Taiwan | 2 | 461 | 4.0 | 1.0 | 0.36-1.56 |
| | Japan | 2 | 737 | 5.1 | 0.8 | 0.46-1.06 |
| Compensated cirrhosis | Europe | 6 | 401 | 5.8 | 2.2 | 1.62-2.80 |
| | Taiwan/ Singapore | 3 | 278 | 4.3 | 3.2 | 1.94-4.55 |
| | Japan | 2 | 306 | 5.8 | 4.3 | 3.40-5.25 |

study has been conducted using HCC development as an endpoint. In this study 651 patients with HBV-related cirrhosis or advanced fibrosis were randomly assigned with a 2:1 ratio, to receive lamivudine or a placebo. The study was stopped after a median duration of treatment of 32.4 mo based on the recommendations of an independent data and safety monitoring board because of a significant difference between the treated groups in the number of endpoints reached. HCC occurred in 3.9% in the lamivudine group and 7.4% in the placebo group (hazard ratio, 0.49; $P = 0.047$)[25]. This study showed that lamivudine plays a role in preventing HCC but a longer follow-up is needed to confirm this result in consideration of the high rate of lamivudine resistance which could reactivate HBV DNA replication.

A large Italian retrospective analysis of 656 patients with chronic HBV infection, with or without cirrhosis, showed that the likelihood of developing HCC is significantly less in cirrhotic patients having a virological response than in those having a virological breakthrough[84]. Further studies are also needed to evaluate the effect of the newest antiviral drugs (adefovir, entecavir, tenofovir, emtricitabine, *etc*) in terms of HCC prevention.

In conclusion, different factors contribute to the risk of HCC development in patients with HBV infection: HBV replication, HBV direct oncogenetic effect through the integration in host genoma and cirrhosis itself. Until now, the only mechanism we could control pharmacologically is viral replication and consequently liver disease evolution to cirrhosis. Therefore, a strict imaging follow-up is recommended in all patients even those responding to therapy.

### HCV

HCC incidence is higher in patients with cirrhosis due to chronic hepatitis C infection with a variable incidence in cirrhotics of 2%-8% per year[35-37,107]. As for HBV its incidence varies between geographic areas. Studies from Japan [79,108-112] have documented a summary HCC incidence of 1.8 per 100 subjects per year in patients with chronic hepatitis as compared to 7.1 in patients with cirrhosis. Therefore there is a 4-fold risk of developing HCC when cirrhosis is present[101]. In Europe and the United States[5-7,23,36,37,78,80,113-117], the summary incidence is 3.7 in cirrhotic patients whereas it is impossible to calculate it in non-cirrhotic patients due to the lack of HCC in the only study available[36]. Analyzing these data showed that the 5-year cumulative risk of HCC development in cirrhotics is 17% in Europe and 30% in Japan[101]. Thus the best way of preventing HCC development in HCV-infected patients is preventing cirrhosis itself. This is a challenging issue but difficult to carry out, as a large proportion of patients are unaware of their status and the disease is mostly asymptomatic. Therapy is offered to a small proportion of patients worldwide, and moreover, the infection can be eradicated in only about half of the treatable patients[118-120].

IFN may prevent HCC by preventing liver damage evolution by the eradication of viral hepatitis, this is generally the case of sustained responders[121]. Eradicating HCV infection may prevent HCC development, at least in patients without cirrhosis. With regard to cirrhosis, a different incidence of HCC between treated and untreated cirrhotics (Table 3) and a decline in HCC incidence in patients achieving a sustained virological response have been reported[104,108]. The residual risk is related to the cirrhosis itself. Moreover, if some dysplastic or neoplastic cells are present, IFN alone is not capable of eradicating them. As a consequence, we should follow up patients by ultrasonography even after eradication of the infection. In fact, the cirrhotic background probably persists and HCC may develop years after clearance of the virus[122]. A study recently published by our group has shown the best results in terms of HCC prevention in cirrhotic patients treated with IFN plus ribavirin as compared to those treated with IFN alone, and the reduction in HCC incidence after re-treatment of non-responders[122]. The tight relationship between a high Ag-NOR proliferative index [silver stained (Ag)-nucleolar organizing region (NOR)] and HCC development in this study confirms that clinical utility of cellular proliferation markers can predict HCC development as reported in previous studies[5,122]. Since IFN is an anti-proliferative cytokine, it may have a beneficial role in preventing HCC development in cirrhotic paptiens through the reduction of hepatocyte proliferation,

**Table 3 Effect of IFN on HCC incidence among HCV cirrhotic patients**

even when a virological response is not achieved[122]. Moreover, a recent retrospective study has shown a lower incidence of HCC in patients with HCV chronic hepatitis who were non-responders to long-term IFN treatment as compared to those treated for less than 24 mo[123].

Data on non-cirrhotic patients derive from retrospective analysis. The largest from Japan, included 2890 patients, 490 of whom were untreated. HCC incidence was higher in the untreated group (3.1% per year) than in the treated group (1.1% per year), but the difference reached a statistical significance only among patients with stage 2 or 3 fibrosis. Patients were also stratified according to virological response showing the greater benefit in responder patients with fibrosis F2-F3[108]. These data have been confirmed by a recent update of the study[124].

This study has also confirmed that HCC development seems related to the transaminase level, which is basically the rationale of treatment, the aim of which is to reduce liver inflammation. The long term use of glycyrrhizin, an aqueous extract from licorice root capable of reducing transaminases when administered for a short period of time, can significantly reduce HCC incidence in HCV patients[125]. Long-term glycyrrhizin injections have recently been shown to reduce the incidence of HCC in patients with HCV-related chronic hepatitis C with or without cirrhosis and in non-responders to IFN-based treatment[126]. Similarly, ursodeoxycholic acid (UDCA) administration has been shown to reduce transaminases in patients with HCV-related chronic hepatitis although the data are insufficient to support this effect on viral markers, mortality, incidence of cirrhosis, or liver histology[127,128]. The mechanisms involved in ALT normalisation are unknown. However, the reduction of HLA antigen expression and cholestasis, changes in membrane plasticity and bile acid pool hydrophobicity may reduce liver inflammation[129]. All these mechanisms are probably involved in the ability of UDCA to lower the incidence of HCC both in rats and in humans[130,131]. Vitamin $K_2$ may also have a protective effect against HCC development in women with cirrhosis[132].

The preventive role of these drugs needs to be further investigated and their use in the treatment of HCV is not recommended as the only effective drug is interferon.

Finally, epidemiological studies have shown that coffee consumption lowers the incidence of HCC in patients with HCV-, HBV- or alcohol-related cirrhosis[133-136], and that the preventive effect is cup-dependent (3 cups decrease the risk of HCC by 75%).

## HCC RECURRENCE PREVENTION (TERTIARY PREVENTION)

HCC recurrence is about 80% after 5 years of curative treatment[137,138] with a local tumour progression of 10% after 5 years of radiofrequency ablation[138]. Recurrence may originate in intrahepatic metastasis from the treated tumour or from multicentric occurrence.

Several approaches to the prevention of HCC recurrence have been attempted. The most convincing seems to be polyprenoic acid administration. Polyprenoic acid is an acyclic derivate of retinoic acid which has been shown to have chemopreventive activity[139-142] by interfering with cellular regulation and differentiation. It was reported that oral administration of polyprenoic acid could significantly reduce the incidence of new HCCs after a median follow-up of 38 mo[143,144]. Its effect does not seem to be mediated by the reduction of liver inflammation (the transaminase level did not differ between the treatment and control groups)[145], but is related to the clearance of dysplastic/HCC clones by apoptotic mechanisms. The mechanism of polyprenoic acid seems to be different from that of interferon which seems to be related to multiple mechanisms such as increased immune-surveillance, S0 arrest of the cell cycle and restoration of apoptosis. A randomised controlled study on patients with HCV-related HCC showed that administration of IFN-$\alpha$ for 48 wk after the effective ethanol injection treatment of HCC, could improve the prognosis by reduction of the second and third recurrence with an improvement of survival in treated patients[146]. Thus, IFN seems to play a more significant role in cirrhosis as a pre-cancer condition than in liver cancer itself. IFN-$\alpha$ lymphoblastoids also seem to be capable of reducing HCC recurrence and improving survival in HBsAg-positive patients with their HCC resected[147]. Another small randomised controlled study showed that the recurrence rate is lower in patients treated with IFN-$\beta$ after surgery or curative alcohol injection than in untreated patients[148]. The problem in these studies is that they included a small number of patients who were treated with different kinds of IFN and different treatment schedules.

Another approach is irradiation of the liver using intra-arterial iodine$^{131}$-labeled lipiodol after HCC resection with the aim of eradicating neoplastic foci. This strategy has been used in a small randomised controlled trial, showing a reduction in the recurrence rate and an increase in disease-free survival when compared to controls[149].

There is evidence that IFN and polyprenoic acid have a modest effects at least in small studies. In practice, when HCC develops in a cirrhotic liver, medical treatment has a very limited efficacy on the prevention of recurrence.

## CONCLUSION

HCC prevention is a public health challenge. Since HCC mostly develops in a sick liver and the secondary prevention is of little effect, the best strategy is to prevent the onset of liver diseases.

Substantial progresses have been achieved in developed countries in the prevention of virusl-related hepatitis (screening of blood units, use of disposable sanitary tools, HBV vaccination) , but alcohol- and dysmetabolism-related HCCs are emerging problems in the same areas, which require specific interventions in terms of public health measures.

In developing countries, there is still a long way to go. In fact, economic constraints limit the development of any program for the prevention of viral hepatitis transmission (including health education campaigns, healthcare politicies, primary prevention and improvement of hygienic and sanitary conditions). In this setting, the

first step should be a political approach aimed to increase people awareness, extensive vaccination programs, blood units screening, sanitary conditions and use of disposables in poor countries. It is obvious that pharmacological approach should follow. In Western countries our efforts should be directed towards educational approach and counceling activities in order to reduce alcohol abuse and obesity.

As a rule, when the diagnosis of viral liver disease is established, only a minority of patients are treated worldwide and benefit from a possible preventive effect of medical treatment for HCC. Once again economic support in developed countries should be given to treat those patients who could benefit from antiviral treatment.

With regard to HCC recurrence, the real contribution of medical treatment to prevention of chronic viral hepatitis is small. However, more effective medical measures against secondary and tertiary prevention of HCC should be taken.

Finally, the role of co-factors in the development of HCC is still unknown and should be further investigated. Co-factors may also clarify the large differences in the geographic incidence of HCC and give further targets of intervention.

## Abstract

Primary biliary cirrhosis (PBC) is an organ-specific autoimmune disease that predominantly affects women and is characterized by chronic, progressive destruction of small intrahepatic bile ducts with portal inflammation and ultimately fibrosis, leading to liver failure in the absence of treatment. Little is known about the etiology of PBC. PBC is characterized by anti-mitochondrial antibodies and destruction of intrahepatic bile ducts. The serologic hallmark of PBC is the presence of auto-antibodies to mitochondria, especially to the E2 component of the pyruvate dehydrogenase complex (PDC). Current theories on the pathogenesis of PBC favor the hypothesis that the disease develops as a result of an inappropriate immune response following stimulation by an environmental or infectious agent. Some reports suggest that xenobiotics and viral infections may induce PBC. The pathogenetic mechanism is believed to be caused by a defect in immunologic tolerance, resulting in the activation and expansion of self-antigen specific T and B lymphocyte clones and the production of circulating autoantibodies in addition to a myriad of cytokines and other inflammatory mediators. This leads to ductulopenia and persistent cholestasis, by developing end-stage hepatic-cell failure. In this review are given our own and literary data about mechanisms of development of intrahepatic cholestasis and possible ways of its correction.

## ETIOLOGY OF PRIMARY BILIARY CIRRHOSIS

Primary biliary cirrhosis (PBC) is a chronic cholestatic, granulomatous, and destructive inflammatory lesion of the interlobular and septal bile ducts, which is likely to be caused by an autoimmune mechanism with a potential tendency to progress to cirrhosis[1,2].

Primary biliary cirrhosis is characterized by a T-cell-mediated destruction of bile duct epithelial cells that line the small intrahepatic bile ducts. This leads to ductulopenia and persistent cholestasis, by developing end-stage hepatic-cell failure.

The etiology of the disease is still unknown[3]. Many authors regard the disease as impaired immunoregulation with a loss of tolerance of histocompatibility antigen-enriched tissues. How and why the bile ducts are involved in this process remains unknown. Viruses[4,5], bacteria, xenobiotics, and human immunoregulatory defect may be possible PBC triggers that initiate the immunopathological cascade[6-8].

The development of PBC is preceded by a long asymptomatic period[9-11]. The wide use of computer-aided screening biochemical and immunological studies has significantly increased the detection of asymptomatic patients. In this period, there are generally no physical signs of PBC, at the same time anti-mitochondrial autoantibodies (AMA) are detectable in the serum of virtually all patients (95%)[12-15]. The fact that AMA are detectable many years before PBC manifests itself is indicative of their primary immunopathological role rather than a secondary phenomenon that occurs in the presence of cholestasis. The production of AMA is not an epiphenomenon, and an understanding of the mechanism of AMA induction will shed light on the etiology of PBC[3].

The activity of antibodies to antigens of various specificity (exogenous and autologous genesis) is associated with different classes of immunoglobulins. In PBC, there is an elevated concentration of the immunoglobulin M class (IgM)[16]. The increase in serum IgM is the result of chronic B-cell activation induced *via* the toll-like receptor (TLR) signaling pathway[17]. The activity of tissue, bacterial, and viral antibodies are assumed to be associated with the biological properties of IgM. Testing for AMA and IgM are the most useful laboratory procedure in the diagnosis of PBC[18].

Active searches are recently under way for autoantigens

whose expression induces an immune response that results in destruction of the biliary epithelium. The antigens reacting with AMA are located on the internal mitochondrial membrane. The targets of activated T-lymphocytes are the dihydrolipoamide acetyltransferase components of the 2-oxoacid dehydrogenase, enzyme complexes that are important in oxidative energy metabolism. Pyruvate dehydrogenase complex (PDC) is the best known of these. Among the events demonstrated to induce an antibody response cross-reactive with PDC are exposures to bacterial PDC or retroviral proteins or xenobiotics or microchimerism[2]. Its dihydrolipoamide acetyltransferase component is referred to as PDC-E2[6]. PDC-E1 and PDC-E2 antigens are sensitive (98%) and specific (96%) for the diagnosis of PBC[19,20]. A major question in understanding the pathogenesis of PBC is why PBC patients lose their tolerance to antigens that are found in virtually every cell in the body. The identification of anti-PDC responses (present in over 95% of PBC patients) has given rise to important questions pertinent to our understanding of the pathogenesis of PBC. How and why does immune tolerance break down to as highly conserved and ubiquitously expressed self-antigen as PDC? Why does the body stop recognizing individual components of the pyruvate dehydrogenase complex as proper proteins? Why does breakdown in tolerance to an antigen present in all nucleated cells result in damage restricted to the intra-hepatic bile ducts? How does the internal mitochondrial membrane antigen initiate the production of autoantibodies?

Noteworthy is the assumption that infectious agents are involved in the etiopathogenesis of PBC. Based on the proposed role of microorganisms in the pathogenesis of the disease, Mao TK *et al* and Amano K *et al* hypothesize that patients with PBC possess a hyperresponsive innate immune system to pathogen-associated stimuli that may facilitate the loss of tolerance[21,22]. In PBC patients, AMA shows a cross-reaction with the subcellular components of gram-negative and gram-positive microorganisms[23].

Recent studies have suggested that the induction of PBC is multifactorial, in which the primary player involves the xenobiotics modification of mitochondrial proteins or exposure to xenobiotics-modified bacterial mitochondrial protein homologs, leading to breaking of tolerance to the human mitochondrial autoantigens and eventually liver pathology in genetic susceptible individuals[3,24,25]. A possible cause is molecular mimicry between microbial agents and self-antigens[26-28]. Infection with or exposure to a microorganism whose PDC-E2 bears a close homology with human PDC-E2 could act as an immunological trigger that initiates the development of PBC. It is suggested that the mutant forms of *E. coli*[26,29,30] and mycobacteria[31-33] trigger an immunopathological process in PBC. Anti-PDC-E2 antibodies cross-react specifically with mycobacterial hsp65[34]. Immunization of rabbits with *E. coli* rough (R) mutants gives rise to PBC-specific AMA. The PBC patients' feces contain more or less counts of *E. coli* R-forms that specifically react with AMA[29]. Whether the intestinal R-forms are etiologically important for the development of PBC remains still unclear.

There has been recent evidence for the etiological role of *Novosphingobium aromaticivorans* in the development of PBC[35-37]. *N. aromaticivorans* is a gram negative strictly aerobic bacterium that is found worldwide in soil, water, and coastal plain sediments. Its PDC-E2-like proteins have a higher degree of homology with the immunodominant region of human PDC-E2 than any microorganism thus far studied (100-1000 times greater than that of *Escherichia coli*)[35,37]. *N. aromaticivorans* can metabolize xenobiotics that are similar to the chemical compounds that react with sera from PBC patients. Some of these xenobiotics are immunologically related to lipoic acid, the cofactor that is at the active center of PDC-E2. Thus, *N. aromaticivorans* can theoretically break down self-tolerance in two ways: by molecular mimicry due to subclinical infection and by the metabolism of xenobiotics that are present in the environment.

## PATHOGENESIS OF PRIMARY BILIARY CIRRHOSIS

It was deduced that antibodies against *N. aromaticivorans* were found in 77 of 77 PBC patients from Milan, Italy, who had antibodies to PDC-E2 and that the titers to *N. aromaticivorans* proteins were similar to those to human PDC-E2[35,37]. Thirteen of 14 Icelandic PBC patients who were AMA positive reacted against at least one of the 2-oxoacid dehydrogenase-E2 complexes[36]. These observations provide additional evidence that exposure to *N. aromaticivorans* may trigger the development of PBC.

The epithelium of the bile ducts whose cell surface expresses antigens of the histocompatibility complex is considered to be the major target for AMA. The cross-interaction of AMA with the epitheliocytic antigens of bile cholangioles may damage the epithelium of ductules, by resulting in their obliteration. This leads to cholestasis in the minor canaliculi and bile capillaries with impaired bile excretion processes.

A morphologic study of liver biopsy specimens from asymptomatic patients with anti-mitochondrial autoantibodies detected during a screening makes it possible to diagnose one of the early stages of PBC. In stages Ⅰ-Ⅱ PBC, the biopsy specimens show different phases of lesion of bile canaliculi. Early disorders develop in the interlobular ducts, 45-75 μm in diameter[38]. Dystrophy of ductal epitheliocytes should be considered to be the earliest disorder. Their cytoplasm becomes granular or homogeneous eosinophilic, swollen, and vacuolized, the nuclei get pycnotic. Later on, there is necrosis of a small segment of a canaliculus, but its outlines still remain and, finally, the wall is destroyed, that is a pattern of destructive cholangitis forms[39].

The generation of immune responsiveness to self-antigen can result in pathogenic autoimmune damage of the intrahepatic biliary epithelial cells mediated by both humoral and cellular immune responses[2,40]. In PBC osteopontin is an important immune molecule in portal tracts, and contributes to the recruitment of mononuclear cells into epithelioid granuloma and also participates in bile duct injury *via* B-cell differentiation and plasma cell expansion[41]. PBC is characterized by chronic destructive cholangitis with a Th1-predominant cytokine milieu[42-44].

CD8+ and CD69+ T cells were predominant in inflammatory infiltrates around damaged cholangiocytes; $\beta_2$-microglobulin conformational epitope and intercellular adhesion molecule-1 expression were enhanced in bile ducts and hepatocytes[45,46]. Toll-like receptor-3 and type I interferon signaling pathways are active in both the portal tract and liver parenchyma of early-stage PBC, and form the basis for hypothesis that these signaling pathways are involved in the pathophysiology of PBC[47]. Oxidative stress- and nitric oxide-mediated cellular senescence may be involved in bile duct lesions, which are followed by progressive bile duct loss in primary biliary cirrhosis[48-51].

The canals of Hering (CoH) are destroyed in PBC in concert with the destruction of small bile ducts. This destruction appears to be an early event, because CoH numbers are lowest around stage 0 portal tracts, which still contain normal bile ducts[52]. The canals of Hering (CoH), converging from the hepatic lobule onto the portal tract, connect bile canaliculi to the interlobular bile ducts, and represent the most proximal portion of the bile drainage pathway with a cholangiocyte lining. *De novo* expression of intercellular adhesion molecule-1 (ICAM-1) both on mature cholangiocytes in CoH and epithelial cells in bile ductules in PBC implies that lymphocyte-induced destruction through adhesion by ICAM-1 and binding of lymphocyte function-associated antigen-1 expressing activated lymphocytes takes place not only in the bile ductules, but also in the CoH[53,54].

## PATHOGENESIS OF INTRAHEPATIC CHOLESTASIS

Thus, autoimmune pathological processes gradually leading to ductulopenia develop in asymptomatic PBC[55-57]. The increased number of desolating bile ductules gradually result in impairment of bile excretion and in deficient entry of bile acids into the duodenum. In response to this, the hepatocyte increases the synthesis of bile acids. But ductulopenia does not diminish and bile secretion fails to restore. The reduction in the intestinal level of bile acids through the feedback system induces a compensatory hepatocytic increase in the biosynthesis of bile acids and cholesterol, the major substrate for their biosynthesis. The progressively increased bile acid biosynthesis occurring with the participation of cytochrome $P_{450}$ of the smooth endoplasmic reticulum and mitochondria leads, on the one hand, to hypertrophy of the endoplasmic reticulum and then to its hyperplasia and vacuolization, and, on the other, to the biosynthetic involvement of primary bile acids, other than specific $P_{450}$-dependent monooxygenase and non-specific $P_{450}$-dependent monooxygenase[58] that can oxidize cholesterol by the peroxide mechanism[59] to "atypical" metabolites. The latter may be further oxidized to "nonphysiological", "atypical" bile acids in the mitochondria. Moreover, the hepatocytic concentration of bile acids gradually elevates and their entry into the intestinal lumen remains insufficient, giving rise to a closed vicious circle that results in the accumulation of bile acids in the liver cell. Due to the elevated hepatocytic level of bile acids, their reabsorption from the portal venous bed decreases, leading to the entry and progressive accumulation of bile acids in systemic circulation. This triggers the development of intrahepatic cholestasis that shows up as immunological, morphological, and biochemical signs when the disease is asymptomatic.

## MECHANISMS OF DEVELOPMENT OF BIOCHEMICAL AND MORPHOLOGICAL SIGNS

To inactivate the detergent effect of excess bile acids on the cell membrane apparatus, their sulfation and glucuronidization occur and the hepatocytic biosynthesis of cholesterol and phospholipids that are able to generate micellar-lamellar structures wherein bile acids are inserted diminishes. The biosynthesis of phospholipids occurs with the use of orthophosphate formed by hydrolysis of organic phosphorus compounds under the action of phosphatases: alkaline phosphatase (AP), and 5'-nucleotidase. The activity of these enzymes increases in patients with PBC just in the asymptomatic stage of the disease[16,60,61]. The increased activity of AP and 5'-nucleotidase is presumed to be due to their accelerated biosynthesis in the hepatocytes[62-64]. To enhance the synthesis of these enzymes, it is necessary to increase delivery of amino acids to the cells with the participation of γ-glutamyltransferase (GTP). A.S. Loginov[60] has noted that the change in blood γ-glutamyltransferase activity in patients with PBC outstrips the enhancement of the activities of AP and 5'-nucleotidase.

It is theorized that AP and 5'-nucleotidase give rise to orthophosphate where the latter is required[65]. Based on this theory, the enhanced activity of AP and 5'-nucleotidase in PBC is indicative of the higher hepatocytic need for orthophosphate.

High-resolution $^{31}$P NMR spectroscopy has established the level of phosphate-containing compounds in the native bile of healthy individuals and PBC patients. There are lower levels of lecithin and orthophosphate in the patients' hepatic bile portion (Table 1).

The data given in the table show the average statistical integral intensity of the corresponding $^{31}$P NMR spectral signals in conditional units.

The change in the concentration of one of the native bile components-phosphatidylcholine (lecithin) suggests its altered acid-dependent (dependent on the secretion of bile acids) secretion by hepatocytes[66]. Biochemical studies have revealed that hepatic bile portions from PBC patients contain lower levels of not only lecithin, but also bile acids and cholesterol (Table 1). These findings suggest that hepatocytic bile secretion of the study components is decreased and that the relationship is retained between the secretion of bile lipid components (lecithin and cholesterol) and bile acids. At the same time there is an irregular reduction of bile acids and lipid components in the hepatic bile portion from patients with PBC. Thus, the levels of bile acids, lecithin, and cholesterol are decreased by 6, almost 5, and only 2.4 times, respectively, which is indicative of higher bile lithogenicity in these patients (Table 1).

The decreased quantity of orthophosphate in the hepatic bile portion from PBC patients points to its

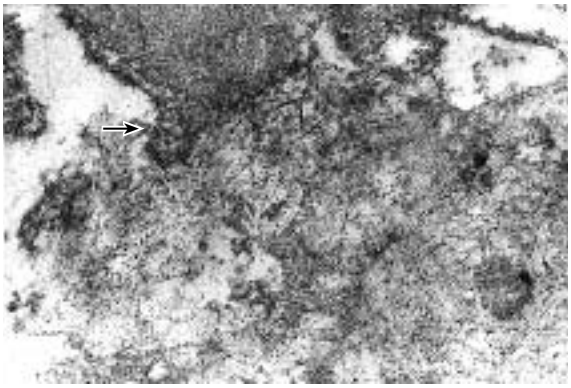

**Figure 1** Hepatocytic ultrastructure. Digitonin-treated biopsy specimen. The specimen is contrasted with aqueous uranyl acetate and lead citrate. Deposits of cholesterol-digitonin complexes (the view of "tender spoondrift clouds") are seen in the cytoplasm close to the mitochondria. The mitochondrial membrane forms pseudopodia here and there (indicated by arrow).

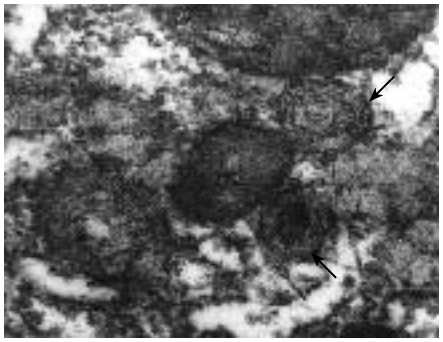

**Figure 2** Hepatocytic ultrastructure in PBC. Biopsy specimen. The specimen is contrasted with aqueous uranyl acetate and lead citrate. Arrows indicate myelin-like and multilamellar structures with increased osmiophilia.

hepatocytic secretion in bile excretion and its simultaneous reduction in its liver cell content since the secretion of orthophosphate, as other inorganic ions, is passively effected by the concentration gradient and does not depend on that of bile acids. The reduced hepatocytic concentration of orthophosphate (despite the enhanced activities of AP and 5'-nucleotidase) indicates the intensive uptake of a phosphorus group in the metabolic processes taking part in the liver cell in PBC.

Biosynthesis of phospholipids is one of the possible ways of using orthophosphate[67]. The hepatic biopsy specimens of PBC show a 1.5-fold increase in the total amount of phospholipids[68]. This increase occurs, by elevating the content of lecithin in the cell membranes. Moreover, the same membranes contain the lower levels of lysophosphatidylcholine, sphyngomyelin, phosphatidylserine, phosphatidylinositol, and phosphatidylethanolamine[68]. There is a 2-fold decrease in the ratio of free cholesterol to phospholipids in the cell membranes. Major alterations in protein status and lipid composition occur in the erythrocyte membrane of patients with PBC[69].

Along with this, segments of membrane cholesterolization and those of free cholesterol deposition in the cytoplasm (Figure 1) and Disse's space are detectable by electron histochemical studies of liver biopsy specimens from PBC patients, by using digitonin. All cholesterol-digitonin complexes show a more or less significant osmiophilia, which points to the presence of phospholipids and proteins in these complexes.

Yokomori H *et al* demonstrate the increased expression of caveolins in proliferating bile ductules in PBC, which may be related to the homeostasis of cholesterol transport in regenerating bile ductules in PBC liver[70]. Caveolins are cholesterol-binding proteins involved in the regulation of several intracellular processes including cholesterol transport.

Electron microscopic studies of liver biopsy specimens from patients with PBC, including those with its early stage, have revealed ultrastructural alterations: hypertrophy and vacuolization of the smooth and rough endoplasmic reticulum, formation of lipid drops and myelin-like structures (Figure 2); the mitochondrial shape and structural changes characterized by the reduced number of internal membrane cristae, the appearance of external membrane "pseudopodia" (Figure 1), as well as local discrepancies of hepatocytes due to their intercellular space.

In the PBC biopsies, the enzymatic activity is increased in the bile canaliculi and is also present in the lateral membranes of the hepatocyte. Transmission electron microscopy of the lateral surface of the hepatocyte in normal livers showed a smooth surface without microvilli but in PBC livers a large number of microvilli were seen in the lateral membranes[71]. The localization of the enzymatic reaction, microvilli and Golgi apparatus at the PBC hepatocyte lateral membranes may represent a compensatory mechanism for derivation of bile flow and other components from the hepatocyte to the intercellular space.

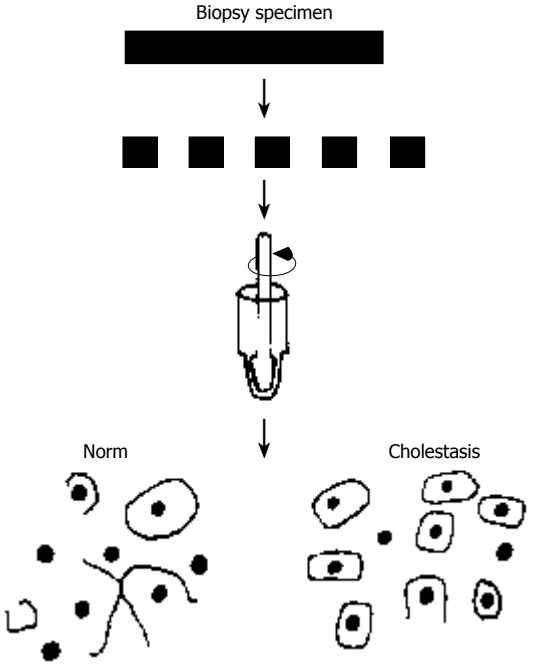

**Figure 3** The scheme of liver biopsy specimen homogenization for quantitative adhesiometric study.

The results of electron microscopic studies of intercellular contact impairments in cholestasis agree well with the estimates of cell adhesion, by using the quantitative method developed by the authors to evaluate adhesive interactions in hepatocytes[72]. The essence of the method is as follows: tight junction (TJ) ensures a mechanical strength of interhepatocytic interactions and when liver tissue disperses with strong intercellular contacts, the plasma membrane breaks and the cell nuclei release. Decreased intercellular contacts lead to that in mechanical dispersion of liver tissue, the hepatocytes move away from each other, without rupturing the plasma membrane. A great number of single cells and much fewer cell nuclei are detectable (Figure 3).

After homogenization of a liver tissue biopsy specimen, single hepatocytes and free cell nuclei are detectable by light microscopy. Then the dissociation coefficient ($C_d$) is the ratio of the number of single cells ($N_c$) to the amount of single cells and the cell nuclei ($N_n$) isolated after liver tissue dispersion is calculated by the formula: $C_d = N_c/(N_c + N_n)$.

A study of liver biopsy specimens indicated a statistically significant increase in $C_d$ in patients with PBC as compared with those with chronic liver diseases, which were similar (Table 2). There is a 1.5-2-fold decrease in the size of hepatocytes. In PBC, the increase in $C_d$ is associated with decreased intercellular contacts, particularly at the site of tight junction, probably due to cholestasis and its related elevated pressure in the bile capillaries. Substantial alteration in the TJ protein occurs predominantly in bile ducts and in hepatocytes in PBC, suggesting increased paracellular permeability along different paracellular routes for bile regurgitation in these chronic cholestatic liver diseases[73]. Melero S *et al* provide functional evidence that PBC cholangiocytes exhibit a widespread failure in the regulation of carriers involved in transepithelial $H^+/HCO^{3-}$ transport, thus, providing a molecular basis for the impaired bicarbonate secretion in this cholestatic disease[74].

**Table 2 Arithmetic means of the dissociation coefficient in different nosological forms of chronic diffuse hepatic lesions**

| Liver lesion | $C_d$ (mean ± SD) | $C_d$ ranges |
|---|---|---|
| PBC ($n$ = 11) | 0.61 ± 0.03[b] | 0.41 ± 0.84 |
| CH ($n$ = 20) | 0.14 ± 0.04 | 0.02-0.24 |
| LC ($n$ = 3) | 0.18 ± 0.03 | 0.14-0.24 |

| Controls ($n$ = 16) | 0.09 ± 0.02 | 0.00-0.18 |

CH: Chronic hepatitis of various etiology; PBC: Primary biliary cirrhosis; UH: Gilbert's unconjugated hyperbilirubinemia; FH: Fatty hepatosis; LC: Liver cirrhosis; [b]$P < 0.001$ *vs* both the controls and other groups of the disease.

There is no direct evidence for elevated hepatocytic levels of bile acids since methods for their determination within the liver cell are lacking. However, many indirect experimental data lead to the conclusion that liver cell lesion observed in chronic cholestasis is at least partially caused by the hepatocytic accumulation of excessive cellular toxic bile acids[75-77].

Osmiophilic myelin-like and cholesterol-digitonin structures detectable in the liver biopsy specimens by electron microscopic study appear to be intracellular located complexes of cholesterol, phospholipids, and bile acids.

The blood of patients with early-stage PBC contains higher levels of phospholipids, cholesterol[78,79], and bile acids[80-82] (Table 1). The change in the content of cholesterol, phospholipids, and bile acids in the blood of patients with PBC is associated with their increased formation in the liver and regurgitation into blood flow. Down-regulation of basolateral uptake systems and maintenance/up-regulation of canalicular and basolateral efflux pumps may represent adaptive mechanisms limiting the accumulation of toxic biliary constituents[83]. The elevated levels of phospholipids and cholesterol in the serum of patients with PBC seem to be determined by the necessity of neutralizing the detergent effect of excess bile acids entering the systemic circulation. Cholesterol and phospholipids are able to bind bile acids, by inactivating their solubilizing effect. This gives rise to the so-called micellar-lamellar structures that are water soluble.

## MECHANISM OF CLINICAL SIGN DEVELOPMENT

Protracted and steady-state elevations in the concentration of cholesterol in the blood of patients with PBC give rise to xanthelasmas. There is a relationship between the development of cutaneous xanthelasmas and the elevated serum levels of cholesterol. According to the data obtained by HG Kunkel & EH Ahrens[84], cutaneous xanthelasmas appear when the blood concentration of cholesterol is more than 450 mg/dL. Moreover, this cholesterol level should persist for at least 3 mo. Hyperlipidemia in PBC does not seem to be associated with an increased risk of atherogenesis[85].

The normal (or slightly enhanced) activity of aminotransferases for several years[86] suggests the preserved integrity and normal permeability of the cytoplasmic membrane of hepatocytes in most patients with PBC.

Skin hyperpigmentation is due to the excessive biosynthesis of melanin, as shown by S Sherlock[87]. The initial reaction of melanin biosynthesis is catalyzed by tyrosinase, the copper-containing enzyme. The liver is known to play an important role in the metabolism and regulation of copper homeostasis due to the formation of hepatocytic complexes of protein and copper and its bile excretion[39]. In normalcy, about 80% of the dietary copper is excreted into bile and eliminated with feces. Disturbance bile formation processes in PBC lead to the accumulation of copper in the body. Excess serum copper levels in patients with PBC may cause increases in the activity of tyrosinase and in the biosynthesis of melatonins that deposit in the skin, inducing hyperpigmentation. Simultaneous deposition of copper in the skin imparts a bronzed tint. Since copper is in ceruplasmin-bound state, its elevated content exerts no toxic effect on the body, as in the Wilson-Konovalov disease.

Further progression of intrahepatic cholestasis results in the occurrence other of clinical signs of the disease.

Local or diffuse, moderate or severe skin itching is the earliest and permanent, and, occasionally for several months, sole symptom of the disease[88]. Epidermal deposition of bile acids resulting from cholestasis with PBC patients is a cause of skin itch[89].

At the same time, all fractions of conjugated bile acids increase in the blood[90] while in the skin 50%-85% of bile acids are not conjugated with glycine or taurine[91] and less than 20% of bile acids are in the form of sulfoesters[92]. Sulfation and glucuronization of bile acids diminish their toxic properties and increase their urinary and fecal excretion. The processes of acid bile sulfation and glucuronization, which occur in PBC, seem to be a response to the toxic effect of excess bile acids and to aim at enhancing their elimination through the skin, kidney, and intestine and at lowering their detergent and irritant effect on cells, tissues, and organs. On entering the skin, bile acids induce skin itch. The latter's intensity depends on the ratio of sulfated (glucuronized) and nonsulfated (nonglucuronized) bile acids accumulating in the skin.

The sera of patients with PBC show a higher ratio of trihydroxy-/dihydroxycholanic acids and a lower glycine/taurine coefficient[90]. Garcia-Marin JJ *et al*[93] have indicated that taurine salts of bile acids stimulate the production of micelles with cholesterol and lecithin, promoting the inactivation of cholanic acids. Greim *et al*[94,95] have shown that cholic (trihydroxy-) bile acid has smaller detergent properties than dihydroxy- (deoxycholic, chenodeoxycholic) bile acids. The higher ratio of trihydroxy-/dihydroxy- bile acids in PBC as a compensatory detoxifying mechanism becomes apparent.

"Atypical", "nonphysiological" bile acids appear in the blood and urine of patients with PBC[96]. The appearance of "atypical" bile acids suggests that bile acid biosynthesis accomplished by the participation of 7-α and 12-α hydroxylases is impaired[80]. This may be due to the involvement into the process of biosynthesis of primary bile acids, apart from specific and nonspecific $P_{450}$-dependent monooxygenases[58].

"Atypical" bile acids have a more potent irritant effect on the nerve receptors located in the skin. The intensity of skin itch also depends on the amount of "nonphysiological" ("atypical") bile acids in the skin of patients with PBC.

PBC affects mainly middle-aged, able-bodied females[97]. What is associated with is still unknown so far. Alterations in the content of sex hormones referring to as steroid ones are one of the possible causes of PBC in females[98]. There may be a change in the number or sensitivity of sex hormone receptors. The low expression of estrogen receptors-alpha in PBC and their disappearance in the advanced histological stages suggests that an estrogenic deficiency could favor the evolution of this disease toward ductopenia[99].

A study of steroids hormones in the plasma of patients with PBC has demonstrated a statistically significant reduction in the levels of progesterone and cortisol[100]. The found changes seem to be associated with the delayed biosynthesis of steroid hormones in late-stage PBC. This may be due to the competitive inhibitions of monooxygenases (by enhancing the biosynthesis of bile acids from cholesterol) that participate in the biosynthesis of progesterone and cortisol. Changes in sex hormone profile are secondary to hepatic dysfunction in PBC[98]. Lower cortisol concentrations in the blood of patients with PBC may cause a change in the fluidity of membranes[101,102], including hepatocytic cytoplasmic membranes. The changed fluidity of hepatocytic membranes leads to impaired bile excretion through the canalicular portion of a hepatocytic cytoplasmic membrane, which aggravates and enhances intrahepatic cholestasis.

Deficient entry of bile acids into the intestinal lumen substantially diminishes the absorption of fats and fat-soluble vitamins (A, D, and K)[103]. Along with insufficient vitamin D absorption, there is a lower formation of 1,25-dihydroxyvitamin $D_3$ on cytochrome $P_{450}$ (competitive inhibition of monooxygenases due to the enhanced biosynthesis of bile acids). This all brings about the inadequate calcium ion absorption in the small bowel and impaired phosphorus-calcium metabolism. Impaired hepatocytic calcium metabolism may affect the contractility of intracellular microtubules and microfilaments, which may cause a decrease in the contractility of bile capillaries and enhance cholestasis[77].

Impaired phosphorus-calcium metabolism gradually results in osteodystrophy[104]. Signs of osteoporosis are most commonly detected in patients with end-stage PBC by bone X-ray studies[105,106] and morphological studies of bone biopsy specimens[87,107,108].

The pathogenesis of osteoporosis in cholestatic lesions of the liver appears to be multifactorial[109] and involves impairments of vitamin $D_3$ absorption and metabolism[85], decreased intestinal calcium ion absorption[108,110], genetic predisposition[111], and impact of corticosteroid therapy[112].

Recent data suggest that serum leptin is associated with bone mineral density (BMD). F Szalay *et al* found a lower

serum leptin level and a higher soluble leptin receptor in patients with PBC, which could not be explained by the difference in body mass index. As leptin was associated with BMD, it may be hypothesized that leptin is involved in the complex regulation of bone metabolism in PBC[113]. There was a clear increase in serum leptin levels according to the histological stage of PBC[114].

Glucocorticosteroids (GCSs) diminish intestinal calcium absorption, by reducing the production of 1, 25$(OH)_2$-$D_3$, increasing urinary calcium excretion, and depressing canalicular reabsorption. As a result, there is a compensatory increase in the production of parathyroid hormone (PTH) and bone resorption. In addition, GCSs directly increase PTH release and enhance its sensitivity. Furthermore, GCSs inhibit bone formation indirectly, by suppressing the synthesis of testosterone in gonads and by decreasing the production of growth hormone, insulin-like growth factor, and accordingly type 1 collagen, as well as directly by suppressing the function of osteoblasts[115,116]. Impaired fat absorption brings about steatorrhea - a daily fecal fat loss of more than 7 gram.

The altered composition of bile acids secreted into bile in patients with PBC leads to the impaired ratio of cholesterol, bile acids, and lecithin (in favor of cholesterol), which changes bile viscosity, and increases the bile lithogenicity index. This enhances evolving cholestasis in the bile capillaries and cholangioles. Blood bile reflux occurs. Another clinical sign of PBC, such as jaundice, develops. The development of jaundice is favored by attenuated interhepatocytic interactions and membrane fluidity changes leading to the impaired transport of bilirubin and copper through the canalicular portion of the hepatocytic cytoplasmic membrane. There is accumulation of copper in the body, activation of the copper-containing enzyme tyrosinase, an increase in the synthesis of melanins and in their skin deposition. Skin hyperpigmentation develops.

The serum concentration of bile acids increases and skin itch occurs in patients with PBC long before hyperbilirubinemia and jaundice develop in them. In end-stage PBC, an increase in the level of bilirubin occurs mainly due to its conjugated fraction. These data suggest that the development of hyperbilirubinemia in PBC is most likely to be associated with bile reflux from the bile capillary lumen or hepatocyte into blood and due to its impaired secretion through the apical portion of the hepatocytic cytoplasmic membrane. The altered fluidity of the liver cell membrane in PBC may promote impaired bilirubin transport and enhanced hyperbilirubinemia. Down-regulation of uptake transporters may contribute to the impaired hepatobiliary elimination in advanced PBC, and partially altered localization of MRP2 may reflect the onset of changes leading to icteric PBC[117]. It is clear to say that the glycosylating function of liver cells is retained at early stages of the disease.

At the late stage of the disease, hyperbilirubinemia may also develop due to erythrocytic hyperhemolysis caused by excess serum bile acids in patients with PBC. As potent detergents, bile acids (they are absent in systemic circulation in the normal state) can solubilize the cytoplasmic membranes of erythrocytes and other blood formed elements, by causing their hemolysis. This in turn leads to the development of erythrocytopenia, thrombocytopenia, hypochromic anemia, and other hematological symptoms occurring in advanced stages of the disease with the significant increase in the serum bile acid levels[118]. The degree of hyperbilirubinemia is characterized by not only the conjugated fraction of bilirubin, but also by its unconjugated fraction.

Thus, an autoimmune pathological process occurring for unknown reasons triggers the development of intrahepatic cholestasis in PBC. A gradual progression of the latter contributes to the occurrence of immunological, biochemical, morphological, and clinical signs of the disease. The mechanisms responsible for triggering and developing the major signs of PBC are given in the scheme (Figure 4).

## TREATMENT OF PBC PATIENTS

The presented diagram is far from perfection. The diagram contains many debatable representations, but it gives an insight into the mechanism of development of major clinical signs in PBC and into their sequence and into that it is necessary to break a "closed vicious circle" in order to prevent the progression of the disease. This can be done by externally administering the missing content of bile acids into the intestinal lumen. The given scheme shows that use of ursodeoxycholic acid (UDCA) is a pathogenetically justified treatment for PBC, which promotes the stabilization of the disease process.

UDCA is a 7-beta-epimer of chenodeoxycholic acid (CDCA) (Figure 5). The OH group at carbonic atom 7 is at the alpha-position in CDCA, one of the primary bile acids, and that is at the beta-position in UDCA. It is precisely these structural differences that are at first glance minor, inducing essential dissimilarities of their chemical properties: UDCA is more hydrophilic and less hepatotoxic. With administration of UDCA agents, there is systemic improvement, diminished weakness, and reduced skin itch intensity. Moreover, it should be noted that some patients report greater itching in the first month of an agent's administration and when temperature drastically drops in the transition fall-winter period. Intensified skin itching at the beginning of a drug's administration seems to be associated with the incorporation of UDCA into enterohepatic circulation of bile acids and with their blood concentrations. However, then there is a gradual substitution of endogenous bile acids for administered UDCA and alleviation of skin itch.

The use of UDCA drugs in cholestatic liver lesions results in stabilization of clinical and biochemical signs of the disease. The stabilizing effect of UDCA in patients with PBC is associated with the delivery of missing bile acids into the small bowel (replacement therapy). The drug also inhibits the hepatocytic biosynthesis of endogenous bile acids from cholesterol. The "closed vicious circle" is discontinued. UDCA is particularly effective in early-stage[119,120] and asymptomatic PBC[121]. The early use of the drug prevents these histologic features of PBC[122]. In 30% of patients with PBC, UDCA causes full biochemical normalization, while 70% are incomplete responders[123]. In

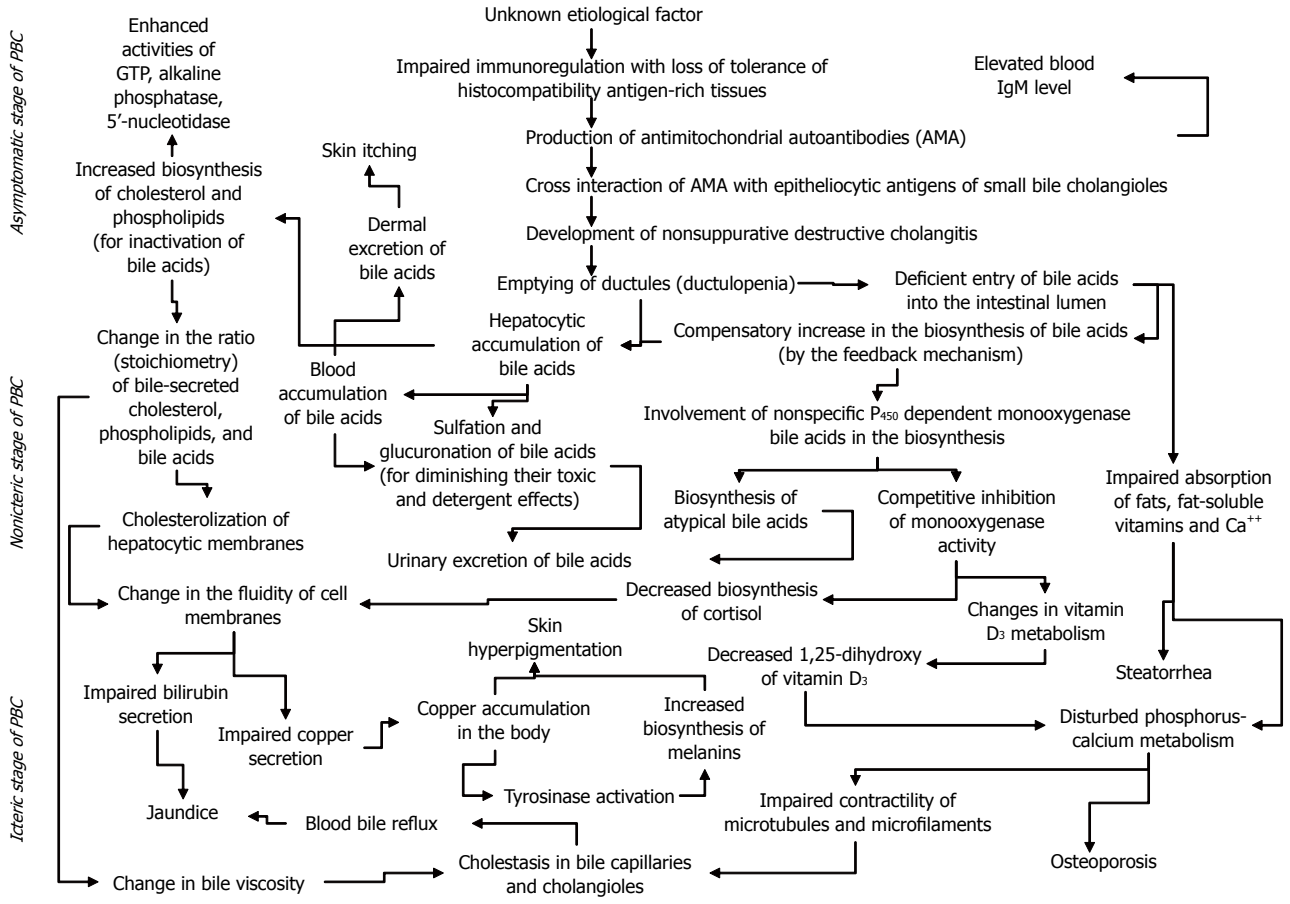

**Figure 4** The scheme of mechanisms responsible for triggering and developing the major signs of PBC.

early PBC, higher dose ursodeoxycholic acid appears to be more effective than the currently recommended doses[124].

UDCA has a positive effect on the prognosis of PBC and can slow down the progression to end- stage liver disease[125]. Treatment with UDCA prevents the deposition of perisinusoidal collagen and reduces the apoptotic activity in PBC patients after 2 years of therapy[126]. Increased endothelin-2 is an early defect in PBC that is significantly reduced by UDCA treatment[127]. Budesonide combined with UDCA improves liver histology, whereas the effect of UDCA alone is mainly on laboratory values[128]. UDCA is not a relevant inducer of CYP3A enzymes in humans[129].

More significant UDCA-induced changes are observed at early stages of the disease. The use of UDCA in patients with PBC is pathogenetically substantiated. However, this treatment modality does not eliminate the cause of the disease and patients with PBC have to take UDCA agents continuously at short intervals.

There are available reports wherein the authors state that UDCA agents show a low efficacy[130,131].

Excess of endogenous blood bile acids can be eliminated by plasmapheresis, followed by a mandatory transfusion of fresh-frozen plasma of the analogous blood group and/or albumin. Plasmapheresis enhances and accelerates the positive therapeutic effect of UDCA agents.

Ion-exchange resins [cholestyramine (vasosan, quantalan), bilignin, questran] are used to control skin itching in patients with PBC. These drugs are not absorbed by enterocytes. By binding to bile acids in the intestinal lumen, ion-exchange resins clear them from the body by transit, by excluding from enterohepatic circulation. This causes a decrease in bile acid levels in blood and, accordingly, in the skin, which lowers the intensity of skin itching.

Ion-exchange resins may not be co-administered with UDCA agents since the latter will combine and be cleared from the body by transit, without achieving a therapeutic effect.

The given diagram also allows an understanding of the pathogenetic mechanisms of the efficiency of use of S-adenosyl-L-methionine in patients with PBC. S-adenosyl-L-methionine is a product of metabolism of the essential sulfur-containing aminoacid methionine (Figure 6). The latter is an officinal drug recommended for the treatment of chronic liver disease. Moreover, methionine is either built into new-synthesized proteins or metabolized to form an active form of S-adenosyl-L-methionine.

The use of S-adenosyl-L-methionine results in relieved skin itching and slightly stabilized clinical and biochemical signs of the disease. The beneficial effect of the drug on the intensity of skin itch is more pronounced when it is parenterally administered.

The mechanism of action of S-adenosyl-L-methionine in chronic cholestatic liver diseases is not completely elucidated so far. This compound is known to play an important role in the body's cells as a source of methyl and sulfonate groups. Therefore it may be suggested that S-adenosyl-L-methionine participates in the formation of

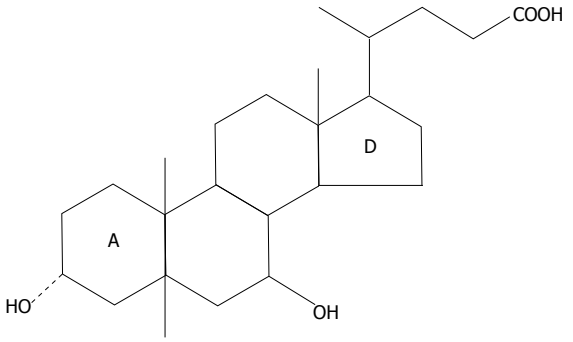

**Figure 5** Ursodeoxycholic acid.

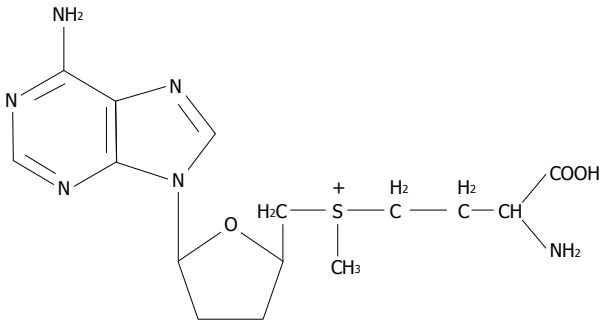

**Figure 6** S-adenosyl-L-methionine.

sulfated bile acids that, unlike nonsulfated ones, may be renally cleared from the body. Moreover, their content in the blood and tissues of the body may decrease, which should yield a positive therapeutic effect. S-adenosyl-L-methionine may also participate in the cellular biosynthesis of phospholipids. This may contribute to the formation of micellar-lamellar structures composed of phospholipids and bile acids. The formation of such structures enables the toxic effect of excess bile acids to be neutralized. Reasoning from these assumptions and the mechanism of development of intrahepatic cholestasis in PBC (see the scheme), the use of S-adenosyl-L-methionine in chronic liver diseases accompanied by intrahepatic cholestasis is pathogenetically justified. Its use is perhaps long and conceivably continuous, as the administration of UDCA agents.

It is advisable to co-administer UDCA and S-adenosyl-L-methionine[132]. This should lead to the potentiation of a therapeutic effect of each of the drugs individually.

Since the etiology and pathogenesis of cholestatic liver lesions remain unknown so far, their treatment is generally symptomatic and aimed at eliminating skin itching[133-137] and jaundice, diminishing steatorrhea, and simultaneously affecting osteoporosis[83,138-140]. The assumed autoimmune nature of PBC has served as the basis for using prednisolone[141] and other immunomodulators[142-144]. However, a rapid rise in bone changes, a great deal of side effects, and a low therapeutic efficacy of these agents have not permitted these drugs to be commonly used for the treatment of PBC[141].

Liver transplantation currently remains to be the most radical treatment for PBC[145,146]. However, selection of patients for surgery is a difficult task. The patient generally gives his/her consent to surgery when his/her condition causes a drastic reduction in the quality of life. Severe weakness, intolerable skin itch, and persistent severe jaundice make the patient be at home and complicate his/her relations with his/her peoples and relatives. This condition is aggravated by the occurrence of ascitis, bleedings from the varicose veins of the esophagus and stomach, or encephalopathy[147]. Liver transplantation may be expected to show the best prognosis in this condition[148,149]. As a rule, the postoperative rehabilitative period is fair[150].

After liver transplantation, there is a change in the titer of anti-mitochondrial autoantibodies: the AMA titers generally drop in the first postoperative months then tend to return to their original values[9].

Whether the disease recurs remains to be solved[151]. Histological changes typical of PBC are detectable in the needle liver biopsy specimens in 9 of 10 patients a year after surgery; of them, 4 patients are then observed to have skin itch and/or other clinical signs[152]. On the contrary, Demetris AJ *et al*[153] detected no histological data of a recurrence in patients with PBC after liver transplantation. Changes in the bile ducts may be induced by other causes: hepatitis C or G viruses; cytomegalovirus; a gradual rejection of the organ or problems associated with biliary anastomotic changes.

With this, 25% of patients needed liver retransplantation due to the development of "bile duct loss" syndrome.

In conclusion, a great body of new data on primary biliary cirrhosis has been recently accumulated. However, inadequate efficiency of its therapy has given impetus to further studies of the pathogenetic mechanisms of the disease[154] and on their basis to searches for new treatment options[155]. No specific therapy that effectively stops or reverses disease progression has been identified, thus it behooves investigators to aggressively pursue identification of the etiology of PBC[156].

## ACKNOWLEDGMENTS

Author thanks Professor TM Tzharegorodtzheva, Professor LU Ilchenko and Dr. TI Sharafanova for their collaboration in the field of PBC research.

## Abstract

**AIM:** To investigate the effect of troglitazone on peroxisome proliferator-activated receptor γ (PPARγ) expression and cellular growth in human colon cancer HCT-116 and HCT-15 cells and to explore the related molecular mechanism.

**METHODS:** Human colon cancer HCT-116 and HCT-15 cells cultured *in vitro* were treated with troglitazone. Reverse transcription-polymerase chain reaction (RT-PCR) and Western blot were employed to detect the effect of troglitazone on PPARγ expression. The proliferative activity was determined by MTT assay, cell cycle and apoptosis were detected by flow cytometry. Apoptosis-related genes, cell cycle regulatory genes and p53 were examined by RT-PCR and Western blot respectively.

**RESULTS:** The expression of PPARγ in colon cancer HCT-116 and HCT-15 cells was up-regulated by troglitazone. Troglitazone inhibited proliferation, induced apoptosis and cell cycle G1 arrest in colon cancer cells. Troglitazone induced p53 expression in HCT-116 cells, but not in HCT-15 cells. The down-regulation of survivin and bcl-2 was found in both cell lines and up-regulation of bax was found only in HCT-116 cells, being consistent with growth inhibition in HCT-116 cells but not in HCT-15 cells. Troglitazone increased expression of $p21^{WAF1/CIP1}$ (p21), $p27^{KIP1}$ (p27) and reduced cyclin D1 in HCT-116 cells while only a minor decrease of cyclin D1 was found in HCT-15 cells.

**CONCLUSION:** Troglitazone is an inductor of PPARγ in colon cancer cells and inhibits PPARγ-dependently proliferation, which may attribute to cell cycle G1 arrest and apoptosis in colon cancer cells. Troglitazone may induce p53-independent apoptosis and p53-dependent expression of p21 and p27. Depending on cell background, different activation pathways may exist in colon cancer cells.

**Key words:** Peroxisome proliferator-activated receptor γ; Colon cancer; Troglitazone; Cellular growth; Cell cycle; Apoptosis

## INTRODUCTION

Nowadays, there is increasing interest in the use of specific agonists of peroxisome proliferator-activated receptor γ (PPARγ) as a new antineoplastic approach. PPARγ is a member of the nuclear receptor superfamily of ligand-dependent transcriptional factors[1-3]. It has been shown that PPARγ plays an important role in the differentiation of adipocytes and monocytes/macrophages, as well as in cell proliferation, apoptosis and carcinoma cell arrest[4-6]. Many investigators have focused on the role of PPARγ in colon cancer because PPARγ is highly expressed in human colon and colorectal cancer[4,5].

PPARγ is an excellent target for cancer chemotherapy because it expresses highly in tumors and its activation results in decreased cell proliferation and progression from G0-G1 to S phase, increased differentiation and apoptosis. However, within each cancer type, individual cell lines have been found to respond differently to distinct PPARγ ligands according to ligand structure and cell context. For example, PPARγ-activated C-DIMs could induce p21 expression in Panc-28 but not in other pancreatic cell lines[7]. Rosglitazone, ciglitazone and PGJ2 are all potent agonists of PPARγ transactivation in lung adenocarcinoma cell lines but have no effect on squamous cell or large

cell carcinomas of the lung[8]. It is somewhat paradoxical about the induction of these responses by PPARγ agonists and the relative contributions of these pathways are often not well-defined. The PPARγ ligand, troglitazone, one of the thiazolidinediones which are used in the treatment of type II diabetes, is a potent and selective activator of PPARγ. The role of troglitazone in growth of cancer cells has been elucidated in some studies[3,9]. It has been shown that troglitazone has negative effects on the proliferation of malignant tumor cells, including colon cancer cells[3]. However, Lucarelli *et al*[9] found that troglitazone could stimulate growth of osteosarcoma cells. Up to now, whether troglitazone inhibits or stimulates the growth of cancer cells is still unclear. Whether troglitazone activates PPARγ-dependent and/or –independent pathways, which may be beneficial for cancer chemotherapy, has not been elucidated.

This study was to detect the effect of troglitazone on PPARγ expression and colon cancer cell growth and to explore its molecular mechanism. In order to elucidate the effect of troglitazone on colon cancer cells, we chose colon cancer HCT-116 and HCT-15 cells, because these two cell lines are wild-type (WT) and mutant-type p53 respectively[10].

## MATERIALS AND METHODS

### Materials

Two established human colon cancer cell lines, HCT-116 and HCT-15 (Central Chinese Type Culture Collection, Wuhan, China) were used in this study. All standard culture reagents were obtained from Gibco BRL Inc., USA. Troglitazone was obtained from Alexis Corporation (Switzerland) and dissolved in dimethyl sulfoxide (DMSO) at a final concentration of 0.1% DMSO in the culture medium. 3, [4, 4-dimethylthiazol-2-yl] 2, 5 diphenyltetrazolium bromide (MTT) was purchased from Serva (Germany). Annexin V-FITC and TRIzol were obtained from Pharmingen and Invitrogen (USA). Anti-PPARγ, anti-p53, anti-p21, anti-p27, anti-cyclin D1, anti-survivin, anti-bcl-2, anti-bax and anti-β-actin were purchased from Santa Cruz Biotechnology (USA). All primers were obtained from Shanghai Sangon Biotechnology (China).

### Cell culture

HCT-116 and HCT-15 cells were maintained in Dulbecco modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum (FBS) and 0.238% N-2-hydroxy-ethlpiperazine-N-2-ethanesulfonic acids (HEPES), 100 U/mL penicillin G and 0.1 mg/mL streptomycin. Cells were incubated at 37℃ in the 5% $CO_2$ incubator. Before the experiment, the cells were incubated in a serum-free medium for 12 h and treated with experimental reagents.

### MTT assay for cell proliferation

Cell proliferation was evaluated by MTT assay. Briefly, cells were seeded at a density of 5000 cells/well in 96-well plates with or without troglitazone. DMSO was used as vehicle control. MTT solution in phosphate-buffered saline (PBS) was added to reach a final concentration of 0.5 mg/mL and incubated for 4 h at 37℃. Medium was removed and cells were resuspended in 100 μL DMSO, and then the absorbance was measured at 570 nm using a microplate reader. The ratios of the absorbance of treated cells relative to those of control wells were calculated and expressed as proliferation percentage.

### Flow cytometric detection for cell cycle and apoptosis

The cells were collected by centrifugation and washed with PBS. The pellets were resuspended in ice cold 70% ethanol and fixed at 4℃ for 24 h. The cells were centrifuged and washed repeatedly with PBS for removal of ethanol. The cell pellets were resuspended in 1 mL DNA staining reagent and kept at 4℃ for 30 min. DNA contents were analyzed using a FACS 440 flow cytometer (Becton Dickinson). Apoptosis was evaluated by Annexin V-FITC and flow cytometer. Cells were harvested and washed with PBS, and then stained with Annexin V-FITC and 2 μg/mL PI in binding buffer for 15 min at 37℃ in the dark. Finally, the samples were analyzed by using a FACS 440 flow cytometer.

### Semi-quantitative reverse-transcription polymerase chain reaction (RT-PCR)

Total RNA was isolated from human colon cancer cells with TRIzol reagent following the manufacturer's instructions. Concentration of the RNA was detected by the absorbance at 260 nm, and the integrity was verified by electrophoresis on formaldehyde gels. RT-PCR was carried out as described previously[11]. Total RNA was reverse-transcribed into complementary deoxyribonucleic acid (cDNA) which was subjected to PCR for measurement of messenger RNA (mRNA). The product of PCR was checked by 2% agarose gel electrophoresis for a single band of the expected size. The abundance of each mRNA was detected and normalized to that of GAPDH mRNA. The sequences of all primers used in this project are shown in Table 1.

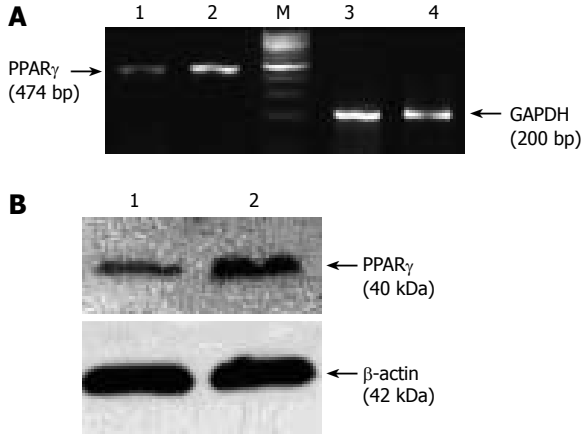

**Figure 1** PPARγ expression in HCT-116 and HCT-15 cells detected by RT-PCR (**A**) and Western blot (**B**). Lane 1: HCT-15 cells; lane 2: HCT-116 cells; M: marker; lanes 3 and 4: GAPDH.

### *Cell protein extraction and Western blot analysis*

Nuclear and cytoplasmic extractions were carried out as previously described[12]. Protein concentrations were measured with a Micro BCA protein assay reagent kit. After being boiled in electrophoresis SDS sample buffer, 40 μg proteins were separated on 10% polyacrylamide gel and transferred onto nitrocellulose membranes. Nonspecific binding sites were blocked with blocking buffer (5% fat-free skimmer milk with 0.1% Tween 20) for 2 h. Subsequently, the membranes were washed with TBST buffer and incubated with the particular primary antibodies diluted in the blocking buffer overnight at 4℃. Then the membranes were washed with TBST buffer and incubated with secondary antibodies. The proteins were detected by enhanced chemiluminescence reagent according to its manufacturer's instructions. The abundance of each protein was detected and normalized to that of β-actin.

### *Statistical analysis*

All experiments were performed in triplicate and the data were expressed as mean ± SD. Statistical analysis was performed by one-way analysis of variance (ANOVA) using SPSS11.0 for windows and $P < 0.05$ was considered statistically significant.

## RESULTS

### *Effect of troglitazone on PPARγ expression in colon cancer cells*

The expression of PPARγ in colon cancer cells was detected by RT-PCR and Western blot. Before exposure to troglitazone, PPARγ was expressed in both HCT-116 and HCT-15 cells, while the mRNA and protein levels of PPARγ in the former were higher than those in the latter (Figure 1A and 1B). After cells were treated with 10 μmol/L troglitazone, the mRNA level of PPARγ increased by 3.03-fold (3.12 ± 0.55 *vs* 1.03 ± 0.31, $P < 0.01$) and 1.52-fold (1.02 ± 0.35 *vs* 0.67 ± 0.25, $P < 0.05$) (Figure 2A) and the protein level increased by 1.86-fold (2.33 ± 0.53 *vs* 1.25 ± 0.42, $P < 0.05$) and 1.48-fold (1.95 ± 0.48 *vs* 1.32 ± 0.38, $P < 0.05$) respectively (Figure 2B).

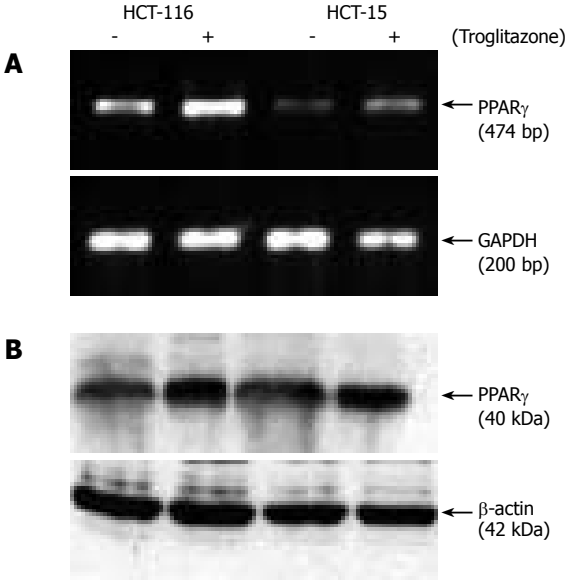

**Figure 2** Effect of troglitazone on PPARγ expression in HCT-116 and HCT-15 cells detected by RT-PCR (**A**) and Western blot (**B**).

### *Effect of troglitazone on proliferation of colon cancer cells*

MTT assay was used to determine the effect of troglitazone on growth of colon cancer. Two cell lines were treated with different concentrations (1, 10 and 30 μmol/L) of troglitazone for different periods of time (12, 24 or 48 h). The results illustrated that troglitazone inhibited significantly proliferation of both HCT-116 and HCT-15 cells in a concentration- and time-dependent manner, which were observed as early as 12 h in HCT-116 cells and 48 h in HCT-15 cells after treatment with 10 μmol/L troglitazone. Significant proliferation inhibition of HCT-15 cells could be only found at 24 h with 30 μmol/L troglitazone (Figure 3).

### *Effect of troglitazone on cell cycle and apoptosis in colon cancer cells*

To determine whether the decrease in cell proliferation was associated with cell cycle arrest or apoptosis, cells were treated with 10 μmol/L troglitazone for 12, 24 or 48 h, then cell cycle and apoptosis were analyzed by using a flow cytometer. Ten μmol/L troglitazone led to increase in percentage of cells in G1 phase and decrease in S phase at 12 h in HCT-116 cells (Figure 4A) and at 48 h in HCT-15 cells (Figure 4B), and there was no significant change in the proportion of cells in $G_2$/M phase. Moreover, the apoptosis rate for HCT-116 cells increased at 12 h (2.52-fold) while that for HCT-15 cells increased at 48 h (2.09-fold), albeit the apoptosis rate gradually increased time-dependently in both cell lines (Figure 4). These results were consistent with the growth inhibition of HCT-116 and HCT-15 cells (Figure 3), suggesting that the anti-proliferation effect of troglitazone should be associated with cell cycle G1 arrest and apoptosis in colon cancer cells.

### *Effect of troglitazone on p53 and apoptosis-related genes*

It is well-known that p53 plays an important role in the induction of apoptosis and growth inhibition, so we

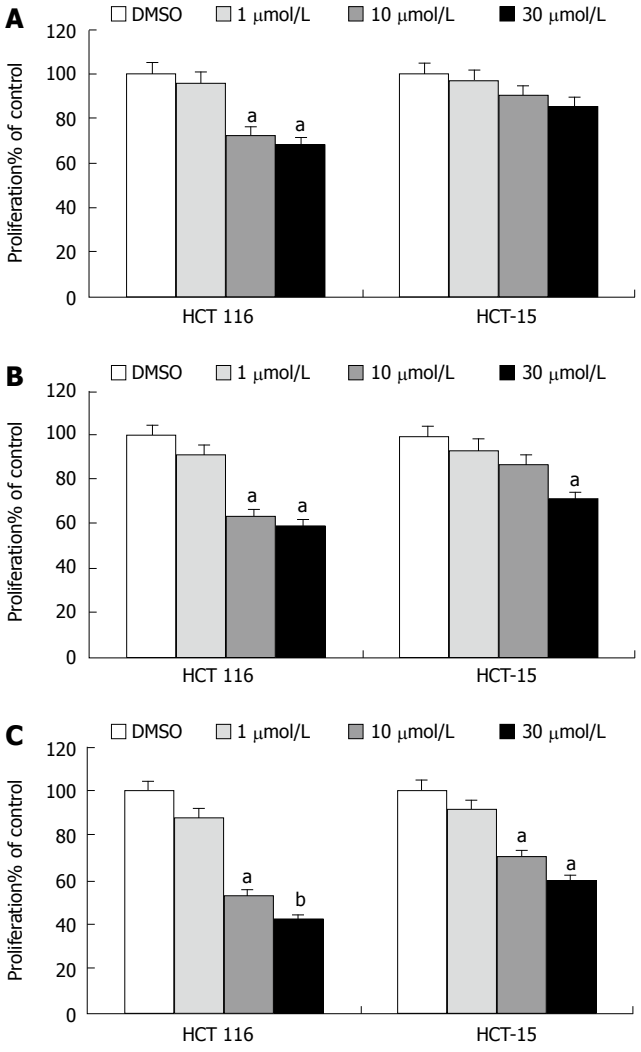

**Figure 3** Effect of troglitazone on proliferation of colon cancer cells at 12 h (**A**), 24 h (**B**), 48 h (**C**). The percentages of cell growth were compared with DMSO (solvent control was set at 100%). $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* corresponding control group respectively.

| 48 | 69.87 ± 3.67[a] | 18.62 ± 2.50[a] | 11.51 ± 2.05 |

**Figure 4** Effect of troglitazone on cell cycle and apoptosis in HCT-116 (**A**) and HCT-15 (**B**) cells and p53 expression in HCT-116 cells (**C**). $^{a}P < 0.05$, $^{b}P < 0.01$ *vs* corresponding control group respectively.

tried to investigate the potential mechanism by which troglitazone causes apoptosis and to clarify whether p53 is related with troglitazone-induced apoptosis in colon cancer cells. After cells were treated with 10 μmol/L troglitazone for 12, 24 or 48 h, mRNA and protein levels of p53 and apoptosis-related genes, such as survivin, bcl-2 and bax, were analyzed by RT-PCR and Western blot. P53 expression was found to be affected by troglitazone in a time-dependent manner in HCT-116 cells (Figure 4C) but not in HCT-15 cells. As shown in Figure 5A, the mRNA levels of survivin and bcl-2 in HCT-116 and HCT-15 cells were down-regulated at 12 h and 24h, respectively. Moreover, the up-regulation of bax was found only in HCT-116 cells, but not in HCT-15 cells. The protein levels detected by Western blot were consistent with the mRNA levels in the three genes (Figure 5B). After exposure to troglitazone for 24 h, the decreased survivin and bcl-2 expression and the unchanged bax expression in HCT-15 cells without corresponding apoptosis suggested that neither survivin or bcl-2 nor bax might be the key regulators for troglitazone-induced apoptosis in HCT-15 cells.

### *Effect of troglitazone on cell cycle regulatory genes*

After cells were treated with 10 μmol/L troglitazone, various markers of cell cycle progression, such as $p21^{WAF1/CIP1}$ (p21), $p27^{KIP1}$ (p27) and cyclin D1 were measured at different time points for verifying the effect of troglitazone on cell cycle regulatory genes. It was observed that the effect of troglitazone on the induction of p21 at mRNA and protein levels in HCT-116 cells was time-dependent. The transcriptional up-regulation of p27, another type of cyclin-dependent kinase inhibitor, was also observed. In addition, cyclin D1 expression was also down-regulated in a time-dependent manner (Figure 6). These results were

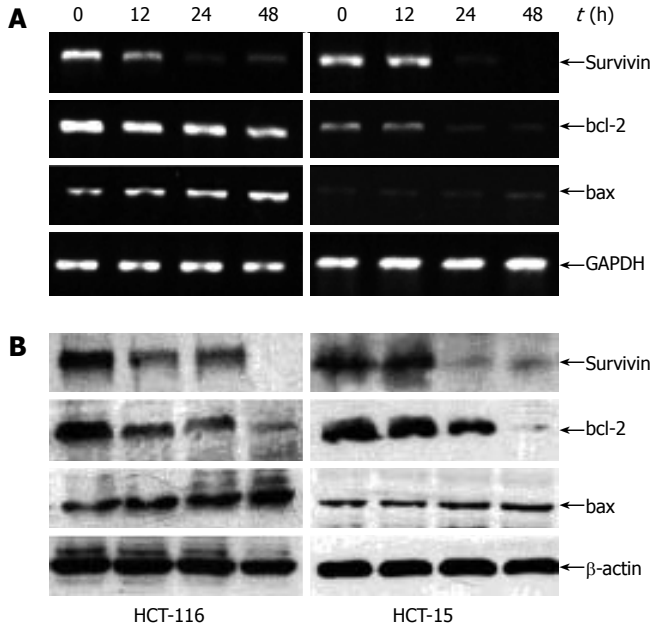

**Figure 5** Effect of troglitazone on survivin, bcl-2 and bax expression by RT-PCR (**A**) and Western blot (**B**) in HCT-116 and HCT-15 cells.

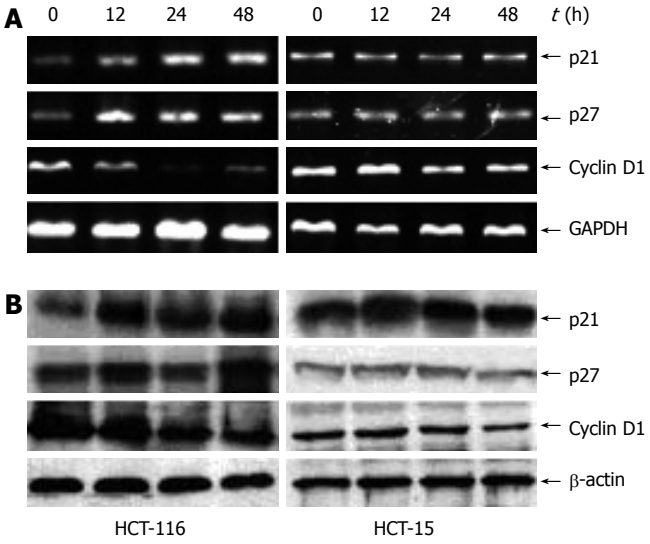

**Figure 6** Effect of troglitazone on p21, p27, and cyclin D1 expression by RT-PCR (**A**) and Western blot (**B**) in HCT-116 and HCT-15 cells.

consistent with cell cycle G1 arrest in HCT-116 cells (Figure 4A). Neither p21 nor p27 was found to be significantly altered in HCT-15 cells, but a minor down-regulation of cyclin D1 was observed (Figure 6). The reasons why p21 and p27 in the two cell lines reacted to troglitazone differently were unclear. Troglitazone could not induce p21 or p27 in HCT-15 cells but could induce p21 and/or p27 expression in a p53-dependent manner.

## DISCUSSION

PPARγ ligands have been shown to regulate gene networks involved in control of cell growth, differentiation, apoptosis and cell cycle[1-3]. Structurally diverse PPARγ agonists inhibit the growth of multiple cancer cell lines[7,13-15], including colon cancer cells. However, the mechanism of growth inhibition is dependent on ligand structure and cell context.

This study was therefore undertaken in an effort to provide additional support for the hypothesis that PPARγ is a negative growth regulator of colon cancer cells. The results showed that PPARγ was expressed in colon cancer HCT-116 and HCT-15 cells, which is consistent with previous report that PPARγ was expressed highly in colon cancer cells[15]. The fact that troglitazone treatment resulted in increased PPARγ mRNA and protein levels in both cell lines suggests that PPARγ signaling is functional. Furthermore, the enhancement of PPARγ in HCT-116 cells was higher, indicating that HCT-116 cells may be more sensitive to troglitazone treatment than HCT-15 cells.

The effect of troglitazone on growth of colon cancer cells was determined by MTT assay. Although troglitazone inhibited growth of both cell lines in a concentration- and time-dependent manner, there were significant differences in the responsiveness of colon cancer cells to the treatment with troglitazone. The growth of HCT-116 cells was inhibited significantly at 12 h (Figure 3) by 10 μmol/L troglitazone, which is consistent with that by 5 μmol/L troglitazone reported by Baek *et al*[16]. In contrast, the growth of HCT-15 cells could be only inhibited by high concentrations of troglitazone (30 μmol/L) at 24 h (Figure 3). A recent study in HCT-15 cells found that only 50 μmol/L troglitazone could induce the same responses, indicating that activation of some (K422Q) PPARγ-dependent mutant responses in HCT-15 cells may be observed with higher concentrations of thiazolidinediones[17]. In our study, troglitazone decreased cell growth in both cell lines, but only high concentration could inhibit growth of HCT-15 cells, suggesting that HCT-15 cells are less responsive to the growth inhibition effect of troglitazone than HCT-116 cells.

There is growing evidence that cell cycle arrest and apoptosis play a key role in the development of human cancer. Troglitazone and other PPARγ-modulating drugs are known to induce cell cycle G1 arrest and apoptosis in some cell types[18]. Our results showed that troglitazone resulted in a remarkable increase of cells in G1 phase and induced apoptosis at 12 h in HCT-116 cells (Figure 4A), but significant increase in G1 phase and induction of the fraction apoptosis were found at 48 h in HCT-15 cells (Figure 4B). This phenomenon was coincident with the growth inhibition in both cell lines. Therefore, the inhibitory effect of troglitazone on cell growth of both colon cancer cell lines may be partly due to cell cycle G1 arrest and apoptosis. Similar effects of troglitazone on other colon cancer cells, liver cancer cells and bladder cancer cells have been reported[3,19,20].

Since troglitazone could inhibit growth and induce G1 arrest and apoptosis in HCT-116 and HCT-15 cells, more attention has been paid to its potential mechanism. Wild type p53 is a potential mediator of apoptosis and more sensitive to DNA-damaging treatment than mutant p53[21]. It is also demonstrated that wild type p53 in human colon epithelial cells is functionally dominant over mutant p53 and restoration of wild type p53 expression is insufficient

to trigger apoptosis of transformed colonic cells[22]. The fact that troglitazone induced p53 in HCT-116 cells (wild type p53) but not in HCT-15 cells (mutant p53), along with induction of apoptosis in both cell lines, suggests that troglitazone-induced apoptosis in both cell lines *in vitro* may be p53-independent. Different results in human gastric cancer MKN-74 cells suggest that p53 might be involved in troglitazone-induced apoptosis[23], which may lie in the different cell context.

Survivin, a member of inhibitors of apoptosis family, plays an important role in cell proliferation and cell death. Down-regulation of survivin may cause a cell-cycle defect that leads to programmed cell death[24]. It has been reported that troglitazone can cause a marked decrease of survivin in glioblastoma cell lines[25]. Other critical regulators of apoptosis, such as bcl-2, bcl-xL (which promotes survival) and bax (which promotes apoptosis), also play a different role in programmed cell death[26-28]. Some researches on PPARγ ligand-induced apoptosis in human myeloid leukemia K562 and HL-60 cell lines showed that up-regulation of bax as well as down-regulation of survivin and bcl-2 may be the important mechanism underlying the induction of apoptosis[26]. However, other reports have shown different mechanisms, depending on the target cell type, PPARγ agonists, duration of treatment, dosage, and the presence of other mitogenic factors[27,28]. In our study, troglitazone decreased survivin and bcl-2 expression and increased bax expression at 12 h in HCT-116 cells, which were consistent with corresponding apoptosis, further suggesting that these apoptosis-associated genes may participate in troglitazone-induced apoptosis in HCT-116 cells. Similar results have also found in breast cancer cells[29] and hepatic cancer HepG2 cells[30]. Troglitazone decreased survivin and bcl-2 expression in HCT-15 cells at 24 h and had no impact on bax expression, which did not correlate with any alteration in troglitazone-induced apoptosis. These data indicate that survivin, bcl-2 and bax do not play a major role in the regulation of troglitazone-induced apoptosis of HCT-15 cells. Chintharlapalli *et al*[27] have reported that the cell context-dependent differential induction of caveolins 1 and 2 may be connected with this process, which is under further investigation.

Inhibition of cell cycle has been considered a target for the management of cancer. We detected the effect of troglitazone on modulation of p53 and its natural target genes p21, p27 and studied the role of two types of p53 in colon cancer cells by examining their effect on cell cycle regulatory genes. P21 and p27 are the downstream effectors of p53. Generally, p21 regulates CDK2-cyclin complexes at the G1 phase of cell cycle following DNA damage or nucleotide pool perturbation, while p27 is a key regulator of the G1/S phase entry and involves the response of cells to environmental mitogen stimulation[31-33]. Once activated by cellular signals, p53 brings about transcription of several cell-cycle regulatory genes, including p21 and p27[34]. P21 expression can be up-regulated by p53-independent or p53-dependent mechanisms, and mutant type p53 induces lower expression of p21 than non-mutant p53[35,36]. Increased p53 expression and transcription-induced p21 and p27 in response to troglitazone treatment at 12 h in HCT-116 cells were found in our study. However, troglitazone had no significant influence on HCT-15 cells, indicating that p21 and p27 play an important role in cell cycle arrest by suppressing HCT-116 cell proliferation. It might be reasonable to consider that troglitazone-induced p21 and p27 may function in a p53-dependent manner. In addition, cyclin D1 is another major positive regulator of G1-S transition by binding to and activating cyclin-dependent kinase 4 or 6, which then phosphorylates and thereby inactivates the tumor suppressor protein pRB[37]. In our study, troglitazone decreased cyclin D1 expression at mRNA and protein levels in HCT-116 cells but only slightly decreased cyclin D1 expression in HCT-15 cells (Figure 6), demonstrating that p21, p27 and cyclin D1 may play a role in the regulation of troglitazone-induced G1 arrest in HCT-116 cells, which are different from some studies on the other type of PPARγ ligands, such as ciglitazone[38]. Meantime, the difference in activation of specific cell cycle regulatory genes by troglitazone was observed between HCT-116 and HCT-15 cells, indicating that different activation pathways may exist in different cell responses to troglitazone-induced G1 arrest, further investigations are underway to clarify the mechanism.

In conclusion, troglitazone is an inductor of PPARγ, a member of nuclear receptor superfamily of ligand-dependent transcriptional factors that has pro-apoptotic and antitumorigenic properties in colon cancer cells. PPARγ-dependent proliferation inhibited by troglitazone is predominant and the growth inhibition attributes partly to cell cycle G1 arrest and apoptosis. Troglitazone may induce p53-independently apoptosis but p53-dependently expression of p21 and p27. Different activation pathways may exist in colon cancer cells.

## COMMENTS

### Backgrounds

Peroxisome proliferator-activated receptor γ (PPARγ) is a member of the nuclear receptor superfamily of ligand-dependent transcriptional factors. There is increasing interest in the use of specific agonists of PPARγ as a new antineoplastic approach.

### Research frontiers

PPARγ is an excellent target for cancer chemotherapy because it expresses highly in tumors and its activation results in decreased cell proliferation, decreased G0-G1 to S phases progression, increased differentiation and apoptosis. However, within each cancer type, individual cell lines were found to respond differently to distinct PPARγ ligands according to ligand structure and cell context.

### Innovations and breakthroughs

Troglitazone is an inductor of PPARγ in colon cancer cells and it inhibits PPARγ-dependently proliferation, which may attribute to cell cycle G1 arrest and apoptosis in colon cancer cells. Troglitazone may induce p53-independently apoptosis and p53-dependently expression of p21 and p27. Depending on cell background, different activation pathways may exist in colon cancer cells.

### Applications

To conclude, this results in this article qualify PPARγ ligands as promising antineoplastic agents and form the basis for future PPARγ ligands-mediated therapeutic approaches.

### Terminology

PPARγ: peroxisome proliferator-activated receptor gamma. PPARγ is a member of the nuclear receptor superfamily of ligand-dependent transcriptional factors, It has been showed that PPARγ plays an important role in the differentiation of adipocytes and monocytes/macrophages, as well as in cell proliferation, apoptosis and carcinoma cell arrest.

### Peer review

The main objectives of the study were to determine the exression of PPAR gamma in colon cancer HCT-116 and HCT-15 cells and to focus on the proliferation and apoptosis under the influence of troglitazone. Expression of PPAR gamma was demonstrated by RT-PCR and immunoblotting. Proliferation was evaluated by MTT assay. Cell cycle arrest and apoptosis were measured by immunoblotting and FACS analysis. Involvement of p53 was determined by RT-PCR and genes associated with p53 activation were also measured by immunoblotting (p21, p27 and cyclin D1). Overall this is a complete story providing strong evidences that PPARgamma agonist may be useful in colon cancer therapy. The authors point out that not all cancer cell lines react to these agonists in the same fashion and thus each cell line should be taken under examination.

## Abstract

**AIM:** To evaluate the impact of hepatitis C virus (HCV) infection with genotype 1 or 3 and the presence or absence of liver cirrhosis (LC) in the early viral kinetics response to treatment.

**METHODS:** Naive patients ($n$ = 46) treated with interferon-α (IFN-α) and ribavirin and followed up with frequent early HCV-RNA determinations were analysed. Patients were infected with genotype 1 ($n$ = 28, 7 with LC) or 3 ($n$ = 18, 5 with LC).

**RESULTS:** The first phase decline was larger in genotype 3 patients than in genotype 1 patients (1.72 *vs* 0.95 log IU/mL, $P < 0.001$). The second phase slope decline was also larger in genotype 3 patients than in genotype 1 patients (0.87 *vs* 0.15 log/wk, $P < 0.001$). Differences were found in both cirrhotic and non-cirrhotic patients. Genotype 1 cirrhotic patients had a slower 2nd phase slope than non-cirrhotic patients (0.06 *vs* 0.18 log/wk, $P < 0.02$). None of genotype 1 cirrhotic patients had a 1st phase decline larger than 1 log (non-cirrhotic patients: 55%, $P < 0.02$). A similar trend toward a slower 2nd phase slope was observed in genotype 3 cirrhotic patients but the 1st phase slope decline was not different. Sustained viral response was higher in genotype 3 patients than in genotype 1 patients (72% *vs* 14%, $P < 0.001$) and in genotype 1 non-cirrhotic patients than in genotype 1 cirrhotic patients (19% *vs* 0%). A second phase decline slower than 0.3 log/wk was predictive of non-response in all groups.

**CONCLUSION:** Genotype 3 has faster early viral decline than genotype 1. Cirrhosis correlates with a slower 2nd phase decline and possibly with a lower 1st phase slope decline in genotype 1 patients.

## INTRODUCTION

Chronic hepatitis C virus (HCV) infection is a major health problem with about 170 million infected subjects worldwide[1]. It is the most common cause of liver cirrhosis (LC), hepatocellular carcinoma, end-stage liver failure, and liver transplantation around the world. Achieving a sustained viral response (SVR), which is defined as undetectable HCV-RNA in serum 24 wk after the end of treatment, is the most effective way to prevent disease progression. Interferon-alpha (IFN-α) plus ribavirin (RBV) therapy (combined therapy) achieves an overall response rate ranging from 42% to 82% in naïve patients[2]. Treatment outcome is highly influenced by dosage and IFN-α presentation, use of RBV, and HCV genotype. For HCV genotype 1-infected patients, optimal SVR rates are achieved with pegylated IFN-α plus RBV for 48 wk (a SVR rate of 40%-55%)[3]. For patients infected with HCV genotypes 2 and 3, a high SVR rate (65%-80%) is observed with standard IFN-α and RBV treatment for 24 wk[4]. Various baseline factors, including histological status and the presence of cirrhosis also affect the outcome of treatment[5].

Hepatitis C viral kinetics has provided an explanation

for the differential response among the different genotypes and allows to evaluate the response rates early during therapy with conventional or pegylated interferons[6]. The effects of treatment on the replication of HCV genotype 1 and the clearance of free virions and infected cells have been investigated in previous studies of viral kinetics[7-9]. Blocking virion production from infected cells with daily IFN-α treatment results in a biphasic viral decline pattern[8] which can predict the treatment outcome[10,11]. Studies of viral kinetics in patients infected with HCV genotype 2 showed that IFN-α treatment is more effective in blocking viral production, and results in faster clearance of virions and infected cells[12,13]. Genotype 4 viral dynamics parameters appear similar to HCV-1 and are slower than those of HCV-2 and HCV-3 infected patients, who should be grouped with those with HCV-1 infection when therapeutic schemes are considered in relation to genotype[14]. Other baseline parameters, such as viral load before treatment, race, gender, and age, have been studied for their effect on HCV viral kinetics[11,15].

However, viral kinetics and the effect of cirrhotic status on viral kinetics in patients infected with HCV genotype 3 have not been extensively studied yet. In a previous report analysing the viral kinetics response to standard or pegylated interferon α2a, HCV-3 patients were grouped as "HCV non-1" with HCV-2, -4 and -5 patients and compared to HCV-1 infected patients[16]. Genotype 3 deserves special attention as it is particularly common in some regions of the world, such as South and South East Asia[17], Australia[18] and Brazil[19], as well as in intravenous drug users in Europe[20].

In this study, considering the frequency of HCV-3 infection in our country, we compared the viral kinetics of early response to treatment by taking frequent samples from naïve patients infected with HCV genotypes 1 and 3. Furthermore, we assessed the effects of LC in the early viral kinetics.

## MATERIALS AND METHODS

### Patients

Forty-six naïve chronic hepatitis C patients from the Hepatology Branch, Department of Gastroenterology, University of São Paulo School of Medicine, São Paulo, Brazil were enrolled. Inclusion criteria were patients infected with HCV genotype 1 or 3 who did not undergo previous treatment, with an age of 18 to 70 years, those with their viraemia detectable by reverse transcriptase-polymerase chain reaction (RT-PCR) and their alanine aminotransferase (ALT) serum levels being 1.5 times the upper normal limit, and those having no other significant pathological findings. Histological activity grade and fibrosis stage were evaluated according to the METAVIR scoring system[21]. In particular, cirrhosis was considered when stage F4 was detected. Normal hepatic function and a liver biopsy within six months before treatment demonstrating necroinflammatory stage A2 or A3 were required. Standard inclusion and exclusion criteria for chronic hepatitis C treatment with IFN and ribavirin were applied. Written informed consent was obtained from all patients. The study protocol conforms to the ethical guidelines of the 1975 Declaration of Helsinki as reflected in a *priori* approval by the Ethical Committee of the University of São Paulo School of Medicine and the Instituto Adolfo Lutz.

### Therapy groups

Patients were randomised into different IFN-α treatment schedule groups (Table 1). All patients received conventional IFN-α (Roferon®, F. Hoffmann-La Roche Ltd., Basel, Switzerland) to allow a better comparison among the kinetic parameters, but the treatment was continued for 48 wk to allow a better response in all the studied groups. All patients received a first dose of 9 Mega units (MU) of IFN-α. Group "3 TIW" (11 patients) received additional 3 MU doses of IFN-α three times a week until wk 48, while group "3 Q2D" (10 patients) received the same dose every other day. Group "3 QD" (13 patients) received 3 MU daily after the first dose until d 4, followed by 3 MU every other day until wk 48. Finally, group "9 QD" (12 patients) received 9 MU daily after the first dose until d 14, followed by 3 MU every other day until the end of treatment (48 wk). All groups received two doses of 500 mg ribavirin daily for 48 wk.

### Sampling

Serum samples were collected just before IFN-α injections (with a tolerance of 15 min) in the first 2 wk and then every other day until d 28. Samples were processed within 2 h after collection and stored at -80℃.

### Viral load quantitation

HCV viral loads were determined using a commercially available quantitative assay (COBAS AMPLICOR MONITOR™ 2.0, lower limit of detection 600 IU/mL, upper limit of linear quantitation 850 000 IU/mL, Roche Molecular Systems, CA, USA). Samples below the limit of detection were subjected to a qualitative PCR assay (AMPLICOR™, limit of detection 50 IU/mL, Roche Molecular Systems, CA, USA) while samples above the upper limit of detection were retested at 10 or 100 fold dilution in normal serum. Viral load determinations were performed at the same time using the same lot of the kit for all patients. Viral load results were transformed to log10.

### HCV genotyping

Viral RNA was extracted from 100 μL of serum using guanidine isothiocyanate-phenol-chloroform as previously described[22]. The 5' untranslated region (5' UTR) of HCV genome was amplified, PCR products were subjected to cycle sequencing reactions using dideoxynucleotides (ddNTPs) with fluorescent markers (Kit ABI Prism® BigDye™ terminator cycle sequencing ready reaction, Applied Biosystems, Foster City, CA, USA). Genotyping was carried by aligning both sequenced strands (sense and antisense), obtaining a consensus sequence and comparing this consensus sequence to a database[19].

### Mathematical analysis

Kinetic data were analysed using a previously published mathematical model[8], which assumes that there is a pre-

**Table 1 Interferon administration schedule (interferon dosage in MU)**

| Group | d 0 | d 1 | d 2 | d 3 | d 4 | d 5 | d 6 | d 7 | d 8 | d 9 | d 10 | d 11 | d 12 | d 13 | d 14 | d 15 | d 16 | |
|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|---|
| 3 TIW | 9 | - | 3 | - | 3 | - | - | 3 | - | 3 | - | 3 | - | - | 3 | - | 3 | 3 TIW until wk 48 |
| 3 Q2D | 9 | - | 3 | - | 3 | - | 3 | - | 3 | - | 3 | - | 3 | - | 3 | - | 3 | 3 Q2D until wk 48 |
| 3 QD | 9 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | 3 | - | 3 | |
| 9 QD | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | 9 | - | 3 | |

All patients received a first dose of 9 Mega units (MU) of IFN-α. Group "3 TIW" received 3 MU doses of IFN-α three times a week until wk 48; group "3 Q2D" received 3 MU doses of IFN-α every other day; group "3 QD" received 3 MU daily after the first dose until d 14, followed by 3 MU every other day until wk 48; group "9 QD" received 9 MU daily after the first dose until d 14, followed by 3 MU every other day until wk 48. All groups received two doses of 500 mg ribavirin daily for 48 wk. -:Interferon was not administered that day.

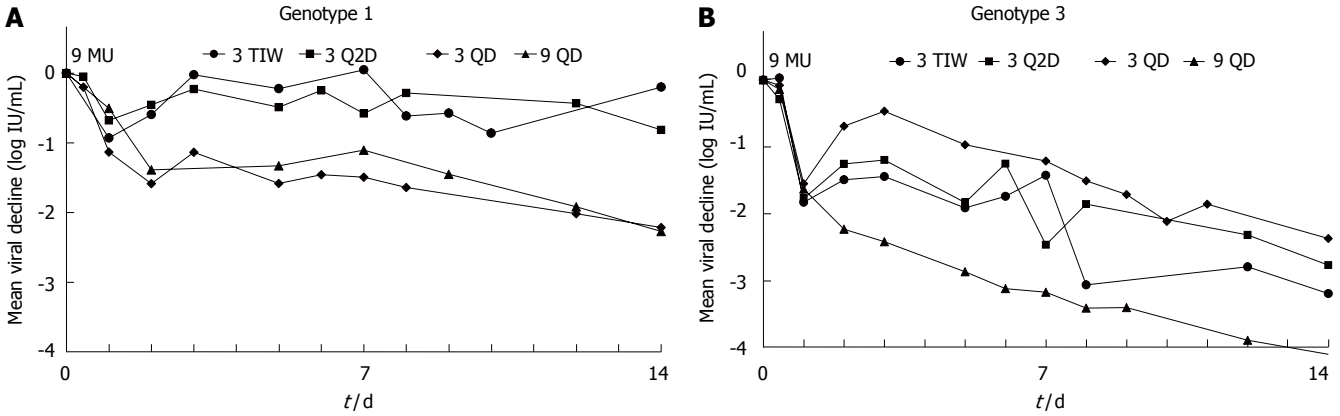

**Figure 1** Mean viral decline over time in each IFN dosing schedule group for HCV genotype 1 (**A**) and genotype 3 (**B**) non-cirrhotic patients. Note that on the first day (vertical line) all groups received 9 MU IFN and had a similar 1st phase decline. A transient rebound was then observed until d 3 in patients who switched to a lower 3 MU IFN dose. Furthermore, patients on a dosing schedule of 3 TIW or 3 Q2D showed viral rebounds on the days they did not receive IFN (d 5-7 for the 3 TIW group and d 5-6 and 7-8 for the 3 Q2D group) in both genotype 1 and 3 patients. However, patients with genotype 3 continued a rapid 2nd phase decline albeit the dosing related transient viral rebounds.

treatment steady state and that the primary effect of IFN-α is to block viral production from infected cells. The first phase decline was defined as the log decline in viral load in the first 24 h, which was equal for all dosing schedule groups. The second phase slope decline was calculated from d 4 (96 h after the first injection) to d 14 to avoid effects of the transient rebound observed after switching from the 9 MU dose to the 3 MU dose on d 2 and differences between the study arms.

### *Statistical analysis*

The statistical significance of differences between groups was assessed with the Mann-Withney non-parametric U-test for the distribution of quantitative variables and the Fisher's exact test for the categorical variables. Multivariable analysis was not performed since the small number of patients per sub-group did not allow any statistical power. $P < 0.05$ was considered statistically significant.

## RESULTS

Forty-six HCV infected patients were included in this study. Twenty-eight of the patients were infected with genotype 1 virus, 7 of them (24%) were cirrhotic. Eighteen patients were infected with genotype 3 virus, 5 of them (27.7%) were cirrhotic. Four different IFN dosing schedules were tested (Table 1). There was no difference in baseline viral load (mean 5.9 log IU/mL) between the genotypes.

### *Effect of genotype and interferon treatment schedule on viral kinetic parameters in patients without cirrhosis*

For non-cirrhotic patients, the kinetics of viral decline for each HCV genotype and treatment schedule is shown in Figure 1. As seen in this figure, oscillations in the viral load were found in patients of groups 3 TIW and 3 Q2D. Each treatment group had particular viral kinetic patterns in accordance with the IFN-α schedule. However, the decline was faster in genotype 3 patients than in genotype 1 patients (Table 2, Figures 2A and 2B). In patients without cirrhosis, the first phase decline after the first 9 MU dose which was given for all groups together, was significantly ($P < 0.001$) larger in genotype 3 patients (1.65 log) than in genotype 1 patients (1.03 log). Only 2 (15%) out of the 13 patients with genotype 3 had a 1$^{st}$ phase decline less than 1 log, compared with 9 (43%) out of the 21 patients with genotype 1. Also the decline of the second phase slope was significantly ($P < 0.001$) faster in genotype 3 patients (0.99 log per week) than in genotype 1 patients (0.18 log per week). None of the genotype 3 patients had a slope slower than 0.3 log per week compared with 16 out of the 21 (76%) genotype 1 patients.

The effect of different treatment schedules on viral kinetics was also compared separately between the two

**Table 2 Mean viral kinetic parameters of each HCV genotype and treatment schedule group in non-cirrhotic patients**

| | IFN dose and schedule | *n* | 1st phase decline[1] (log IU/mL) | 2nd phase slope[2] (log/wk) |
|---|---|---|---|---|
| HCV genotype 1 | 3 TIW | 5 | | 0.09 |
| | 3 Q2D | 4 | | 0.12 |
| | 3 QD | 7 | | 0.15 |
| | 9 QD | 5 | | 0.27 |
| Total non-cirrhotic | | 21 | 1.03 | 0.18 |
| HCV genotype 3 | 3 TIW | 3 | | 0.9 |
| | 3 Q2D | 3 | | 0.78 |
| | 3 QD | 2 | | 0.96 |
| | 9 QD | 5 | | 1.11[b] |
| Total non-cirrhotic | | 13 | 1.65[b] | 0.99[b] |

[1]Treatment during the 1st phase decline was equal in all dosing groups and thus was not given separately. [2]There was no significant difference in the 2nd phase decline slope between dosing groups per genotype. [b]$P < 0.001$ *vs* genotype 1.

**Table 3 Mean viral kinetic parameters for each HCV genotype and histological status**

| HCV genotype | Histology status | *n* | Baseline viral load (log IU/mL) | 1st phase decline[1] (log IU/mL) | 2nd phase slope[1] (log/wk) |
|---|---|---|---|---|---|
| 1 | cirrhotics | 7 | 5.9 | 0.69 | 0.06 |
| | non-cirrhotics | 21 | 6 | 1.03[a] | 0.18[a] |
| Total | | 28 | 5.9 | 0.95 | 0.15 |
| 3 | cirrhotics | 5 | 6.4[c] | 1.89[b] | 0.57[b] |
| | non-cirrhotics | 13 | 5.7 | 1.65[b] | 0.99[b] |
| Total | | 18 | 5.9 | 1.72[d] | 0.87[d] |

[1]Treatment during the 1st phase decline was equal in all dosing groups and no significant difference was found in the 2nd phase decline slope between the dosing groups (Table 2), thus the effect of histological status was studied in all dosing groups together. [a]$P < 0.02$ *vs* cirrhotic genotype 1 patients; [c]$P < 0.03$ *vs* all other patients; [b]$P < 0.01$, [d]$P < 0.001$ *vs* genotype 1 patients.

genotypes (Table 2, Figures 2A and 2B). As expected there was no difference in the 1st phase decline between the treatment groups since the treatment on the 1st day was the same for all patients. Also for the 2nd phase slope, no significant difference was found in the treatment groups, although there was a trend toward faster decline with the daily dose schedules (3 QD and 9 QD) in genotype 1 patients. Indeed, among non-cirrhotic genotype 1 patients receiving daily IFN-α (3 QD and 9 QD), 4 (36%) out of 11 patients had a slope faster than 0.3 log/wk as compared with 1 out of 10 (10%) in the 3 TIW or 3 Q2D group. In each treatment group, genotype 3 patients had a faster second phase slope than genotype 1 patients, with a statistical significance for the 9 QD group even with a small number of patients (Table 2).

Lastly, a lower viral load at the end of the first phase was strongly correlated with a faster second phase slope in all patients ($P < 0.001$; $r = 0.6$).

### *Effect of liver histology on viral kinetic parameters*

The impact of cirrhosis status on cirrhotic and non-cirrhotic patients was addressed by comparing parameters of viral kinetics for each HCV genotype. Patients of all treatment groups were analysed together since there

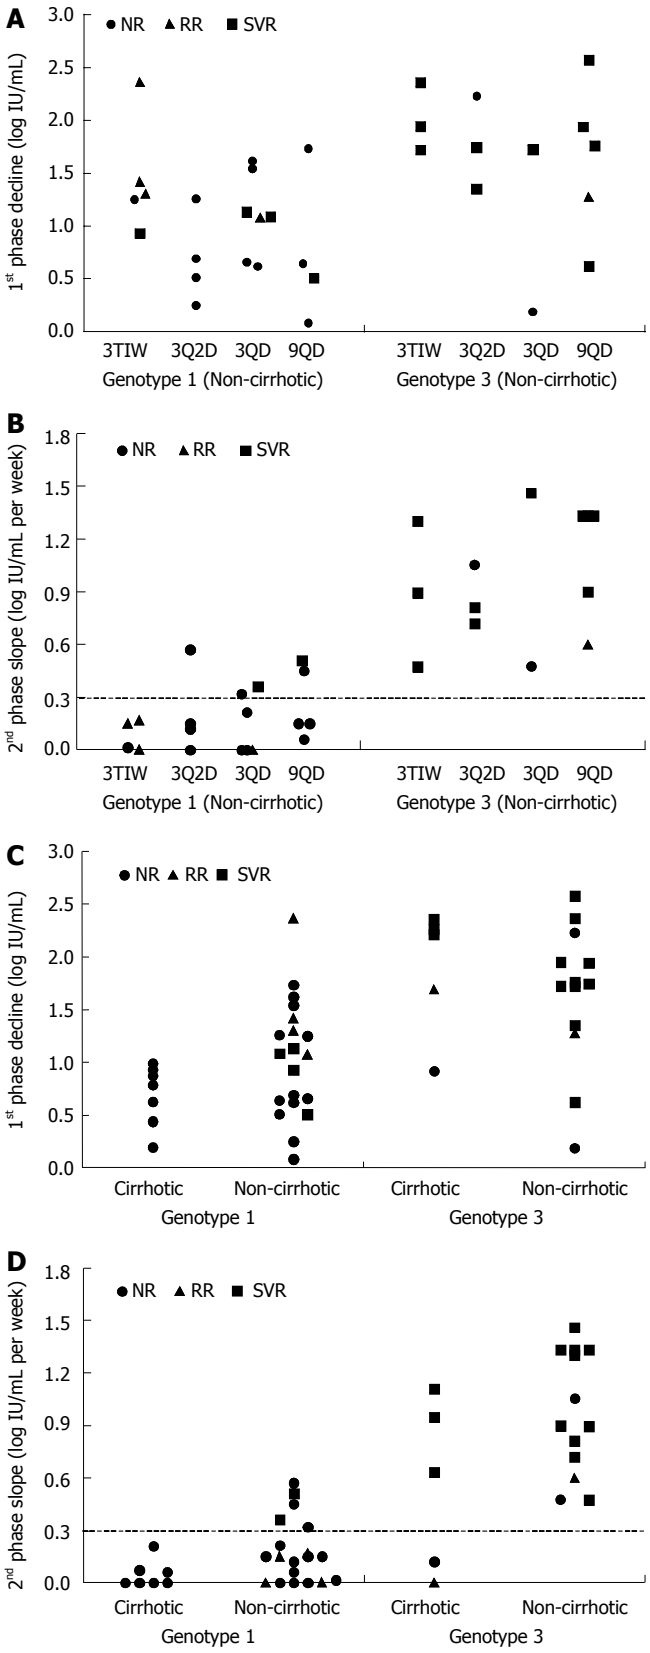

**Figure 2** Distributions of the 1st phase decline (**A** and **C**) and the 2nd phase slope (**B** and **D**) and their correlation with virological end-points given per HCV genotype and dosing schedule for non-cirrhotic patients (**A** and **B**) and each HCV genotype and histological status (**C** and **D**). As in previous studies a 2nd phase decline slope slower than 0.3 log IU/mL per week is predictive of non-SVR (horizontal dashed line in **B** and **D**).

**Table 4 Virological end-points per HCV genotype and histological status *n* (%)**

| HCV genotype | Histology status | *n* | No response | Relapse | Sustained virological response |
|---|---|---|---|---|---|
| 1 | cirrhotics | 7 | 7 (100) | 0 (0) | 0 (0) |
| | non-cirrhotics | 21 | 13 (62) | 4 (19) | 4 (19) |
| Total | | 28 | 20 (72) | 4 (14) | 4 (14) |
| 3 | cirrhotics | 5 | 1 (20) | 1 (20) | 3 (60)[a] |
| | non-cirrhotics | 13 | 2 (15) | 1 (8) | 10 (77)[b] |
| Total | | 18 | 3 (17) | 2 (11) | 13 (72)[b] |

[a]$P < 0.05$, [b]$P < 0.001$ *vs* genotype 1.

was no significant difference in viral kinetic parameters between the interferon treatment schedules. There was no difference in baseline viral load between cirrhotic (5.9 log) and non-cirrhotic (6.0 log) genotype 1 patients (Table 3). Interestingly, genotype 3 cirrhotic patients had a significantly ($P < 0.03$) higher baseline viral load (6.4 log) than non-cirrhotic (5.7 log) genotype 3 patients and genotype 1 patients (Table 3).

A lower first phase decline was observed in genotype 1 cirrhotic patients (0.69 log) than in non-cirrhotic patients (1.03 log), but the difference was not statistically significant (Table 3). Nevertheless, as shown in Figure 2C, none (0%) of genotype 1 cirrhotic patients had a first-phase decline larger than 1 log IU/mL, compared with 55% of the non-cirrhotic genotype 1 patients ($P < 0.02$). Furthermore, a significantly ($P < 0.02$) slower second-phase decline was observed in genotype 1 cirrhotic patients (0.06 log IU/mL per week) when compared with non-cirrhotic patients (0.18 log per week) (Table 3). None of the cirrhotic genotype 1 patients had a slope faster than 0.3 log per week compared with 5 (24%) of 21 non-cirrhotic genotype 1 patients (Figure 2D).

As shown in Table 3, no difference in first phase decline was observed in genotype 3 patients as a function of cirrhosis status (1.89 *vs* 1.65 log IU/mL, $P < 0.05$). However, cirrhotic patients with the genotype 3 virus did have a trend towards a slower second-phase decline (0.57 log IU/mL per week) compared with non-cirrhotic patients (0.99 log per week), and notably the only 2 genotype 3 patients with a flat second phase were cirrhotic patients (Figure 2D).

Cirrhotic patients (Table 3) infected with genotype 1 virus had a less intense first phase ($P < 0.01$) and a slower second phase slope ($P < 0.01$) when compared with genotype 3 infected patients. When cirrhotic and non-cirrhotic patients were pooled together the differences in the genotypes became even more significant (Table 3).

### *Effect of liver histology and HCV genotype on virological end-points*

Only 4 (14%) of 28 genotype 1 patients achieved a SVR. In contrast, 13 (72%) of 18 genotype 3 patients ($P < 0.001$) achieved a SVR (Table 4 and Figure 2). The difference in the genotypes was also seen between cirrhotic and non-cirrhotic patients.

The 4 (19%) of 21 genotype 1-infected patients who achieved a SVR were non-cirrhotic. In contrast, none (0%) of cirrhotic patients achieved a SVR. Interestingly, all the patients who relapsed were also non-cirrhotic (none of the cirrhotic patients achieved a SVR). On the other hand, 3 (60%) out of 5 cirrhotic genotype 3 patients achieved a SVR, which was comparable with 77% of non-cirrhotic genotype 3 patients. Only 1 genotype 3 patient was a true non-responder. A cirrhotic patient and 2 non-cirrhotic non-responders discontinued their treatment early (Table 4 and Figure 2).

Lastly, none of the patients with a second phase slope slower than 0.3 log IU/mL per week, irrespective of genotype, histology status or treatment group, achieved a sustained virological response (negative predictive value = 100%, Figure 2).

## DISCUSSION

Hepatitis C viral kinetics has become an important tool both for investigating the effects of drugs on HCV viral replication[7-10,23,24] and for making clinical decisions about HCV treatment with interferon plus ribavirin therapy[2]. Previous studies have addressed the kinetics of HCV genotypes[7-10,12-16,23-25]. To our knowledge, only one study has addressed the viral kinetics of the early response in patients infected with genotype 3[25] and in that study, HCV-3 patients were grouped together with HCV-2, -4 and –5 patients and viral kinetic data were shown for the "HCV non-1" patients. Our results clearly showed that the 1st and 2nd phase declines were faster in genotype 3 patients than in genotype 1 patients, which were independent of the treatment schedule used or the cirrhosis status when compared to HCV-1. The data relavant to geographic areas were genotypes 1 and 3 which are the most frequent in Brazil, Australia, South and South East Asia, *etc*. To our knowledge, this is the first study to evaluate the effect of LC on viral kinetic parameters.

As conventional IFN-α is still used in many regions of the world particularly in developing countries due to its lower cost, we consider that these data are always valuable for understanding the viral response to conventional IFN-α as the response to treatment of genotype 3 patients is similar to the response to pegylated IFN-α. To ensure a better comparison to genotype 1-infected patients, they were also treated with standard IFN-α, but a 48 wk course was chosen to ensure a better response among all the studied patients in our study.

These results agree with clinical trials of IFN-α (standard or pegylated) and ribavirin treated patients, demonstrating that SVR rates are significantly higher in genotype 3 HCV-infected patients than in genotype 1-infected patients[2,4,5,12]. These results are also consistent with the differences found in viral kinetics between genotype 1 and 2 patients[12,13], as it is known that genotypes 2 and 3 have a similar response rate. We found that the effectiveness in blocking viral production was higher in genotype 3 and the rate of loss of infected cells was faster. Unfortunately, the frequency of sampling in the first 2 d in our study was not enough to study the clearance of free viruses. A detailed comparison between viral kinetics of genotypes 2 and 3 is still of interest.

We observed in this study an intriguing higher baseline viral load in genotype 3 cirrhotic patients than in genotype 3 non-cirrhotic patients or in genotype 1 patients in general. This result was not demonstrated in genotype 1 cirrhotic patients and non-cirrhotic patients, or in genotype 1 or 3 non-cirrhotic patients. The difference observed in genotype 3 cirrhotic patients may be related to the higher steatosis found in these patients[26].

One of the most important results of this study is the observed effect of liver histology on viral kinetics. We have clearly demonstrated that LC adversely impacts early viral kinetics, especially the slope of the second phase viral decline. This is the first viral kinetics study demonstrating a significant difference in the second phase, which is related to the rate of loss of infected cells and is predictive of SVR as a function of the histological status of the liver. The slower decline in cirrhotic patients, which is statistically significant in genotype 1 and genotype 3, can explain the sub-optimal results obtained with interferon and ribavirin in this difficult-to-treat subgroup, even with pegylated interferons[5]. The mechanism behind this effect may be due to a lower immune infiltration to all parts of the liver and/or a lower potency of the immune response to clear infected cells in the cirrhotic environment. Further experimental studies are needed to clarify the mechanism.

On the other hand, our observation that the first phase decline was limited in genotype 1 patients with cirrhosis, but not in genotype 3 patients, was unexpected. The mechanism behind this observation is not understood. Since resistance to IFN-$\alpha$ can be viral or cellular, a possible hypothesis is that hepatocytes in a cirrhotic liver of HCV genotype 1 patients are more resistant to IFN-$\alpha$, which is different from cirrhosis due to genotype 3 that is strongly related to steatosis[25-28]. Steatosis among genotype 3-infected patients does not appear to be related to the presence of HCV antigens within single hepatocytes but to indirect mechanisms, possibly mediated by cytokine[29]. Two HCV proteins, core and NS5A seem to be sufficient to induce lipid accumulation in hepatocytes[30,31], especially in genotype 3[32]. Steatosis is associated with the development of fibrosis[29], which is related to genotype 3[26] and may accelerate fibrosis progression. In genotype 3 patients, steatosis can regress when HCV replication is inhibited supporting a cytophatic effect of genotype 3[33], but the mechanisms underlying the influence of steatosis in response remain to be determined.

In summary, infection with genotype 3 or genotype 1 virus is a more important factor in determining viral kinetics than cirrhosis status or IFN-$\alpha$ treatment schedule. However, within genotypes 1 and 3, patients with cirrhosis have a slower 2$^{nd}$ phase decline, and among genotype 1 patients the 1$^{st}$ phase has a trend toward a lower decline. Thus, advanced histological status although multi-factorial, has a significant adverse effect on viral kinetics, especially in genotype 1 cirrhotic patients. Our results suggest that both genotype 1 and 3 patients with cirrhosis may need more aggressive treatment than the current standard treatment for each genotype. In our study, early prediction of sustained viral response using a second phase slope slower than 0.3 log per week had a negative predictive value of 100%, which is in accordance with previous studies [6]. Thus early viral kinetic prediction can work for cirrhotic patients, since the net effects of all factors are summarized into the first and second phases of viral kinetics.

## Abstract

**AIM:** To determine the presence of *Helicobacter* species DNA in the liver of chronic hepatitis C (CHC) patients with and without cirrhosis as compared to controls, and to identify the bacterial species involved.

**METHODS:** Seventy-nine consecutive patients (HBV and HIV negative) with a liver sample obtained after liver biopsy or hepatic resection were studied: 41 with CHC without cirrhosis, 12 with CHC and cirrhosis, and 26 controls (HCV negative). Polymerase chain reactions (PCRs) targeting *Helicobacter* 16S rDNA and species-specific were performed on DNA extracted from the liver. A gastric infection with *H pylori* was determined by serology and confirmed by $^{13}$C-urea breath test.

**RESULTS:** Overall, *Helicobacter* 16S rDNA was found in 16 patients (20.2%). Although positive cases tended to be higher in CHC patients with cirrhosis (41.6%) than in those without cirrhosis (17.0%) or in controls (15.4%), the difference was not statistically significant ($P$ = 0.08). *H pylori*-like DNA was identified in 12 cases and *H. pullorum* DNA in 2, while 2 cases remained unidentified. Gastric infection with *H pylori* was found in only 2 of these patients.

**CONCLUSION:** Our results do not confirm the association of *Helicobacter* species DNA in the liver of CHC patients with advanced liver disease. The lack of correlation between positive *H pylori* serology and the presence of *H pylori*-like DNA in the liver may indicate the presence of a variant of this species.

**Key words**: Hepatitis C virus; Hepatitis; Cirrhosis; *Helicobacter*

## INTRODUCTION

Chronic hepatitis C virus (HCV) infection is a major public health problem with over 170 million people infected worldwide. It is the leading cause of chronic liver disease and the main indication for liver transplantation in the Western world[1]. Approximately 80% of patients with acute infection develop chronic hepatitis. Chronic hepatitis C is associated with a wide spectrum of liver histological lesions ranging from mild chronic hepatitis to cirrhosis and hepatocellular carcinoma (HCC)[2]. The course of HCV-related hepatic disease varies markedly from one patient to another. Several factors including age at exposure, duration of infection, alcohol intake, male gender and more recently steatosis have been shown to be associated with fibrosis progression[3-6]. However, even in the absence of these factors, disease progression may be observed in some

patients, suggesting the role of other factors which remain to be identified. Host genetic factors or environmental factors, such as a bacterial coinfection, could be involved.

Several *Helicobacter* species colonize the liver of animals and induce hepatitis[7]. In the past few years, the emergence of new *Helicobacter* species associated with the pathogenesis of human enterohepatic diseases has been observed[8-10]. *H pylori* and *Helicobacter pullorum* (*H. pullorum*) DNA have been detected in the liver tissue of patients with chronic hepatitis C and HCC, suggesting that these bacteria could be implicated in the progression of chronic hepatitis C to cirrhosis and HCC[11]. In addition, we have shown recently in a cross-sectional retrospective study, a significant association between the presence of *Helicobacter* species DNA in the liver and HCV-related cirrhosis with and without HCC[12]. Given the limitation of retrospective studies, the aim of this new study was to prospectively determine the prevalence of *Helicobacter* infection of the liver in HCV-infected patients with and without cirrhosis as compared to controls.

## MATERIALS AND METHODS

### Study population

All patients with chronic hepatitis C undergoing a percutaneous liver biopsy at the Hepatology Clinics of Bordeaux University between March 2002 and December 2003 were eligible. Chronic hepatitis C was defined by detection of HCV antibodies using a third generation test (Ortho HCV 3.0 ELISA Monolisa anti-HCV, BioRad, Marne la Coquette, France), detectable HCV RNA (Cobas amplicor HCV 2.0, Roche Diagnostics, Neuilly sur Seine, France) in serum, and elevated alanine aminotransferase (ALT) levels for more than 6 mo. Exclusion criteria were age under 18 years, co-infection with hepatitis B virus (HBV) or human immunodeficiency virus (HIV).

The following data were collected at the time of enrolment of patients with chronic HCV infection: age, gender, route of HCV transmission, duration of HCV infection, alcohol intake, aspartate aminotransferase (AST), ALT, gamma-glutamyl transpeptidase (GGT), HCV genotype and viral load.

All patients seronegative for HCV and undergoing hepatic resection for benign tumors or metastatic tumors during the study period, were eligible and served as controls. All patients gave their informed consent and the study protocol conformed to the 1975 declaration of Helsinki and was approved by the Ethics Committee of our institution.

### Processing of liver tissues

Fresh liver tissues obtained either from needle biopsies or from surgical specimens during usual diagnostic or therapeutic procedures, were immediately cut into three parts with three different conditionning protocols: formalin fixation for routine histology (at least 1 cm for needle biospies), freezing in liquid nitrogen-cooled isopentane followed by storage at -80℃ before molecular biology, and immersion in a specific culture medium for culture characterization of the bacterium.

### Pathological study

For all patients, conventional liver histology was performed on formalin-fixed liver tissues. Sections were stained with hematein-eosin-safran, Masson's trichromic stain and reticulin stain. In patients with chronic hepatitis C, liver fibrosis and necroinflammatory activity were evaluated semi-quantitatively according to the METAVIR scoring system[13]. Fibrosis was staged on a 0-4 scale as follows: F0 = no fibrosis; F1 = portal fibrosis without septa; F2 = portal fibrosis and few septa; F3 = numerous septa without cirrhosis; F4 = cirrhosis. Activity was graded as follows: A0 = none; A1 = mild; A2 = moderate; A3 = severe. The diagnosis of hepatocellular carcinoma was based on usual criteria[14].

### H pylori infection diagnosis

Serum samples from all patients were tested for anti *H pylori* IgG antibodies, using the commercially available kit Pyloriset EIA-G Ⅲ (Orion Diagnostica, Espoo, Finland) and the Western blot assay HELICO BLOT 2.1 (Genelabs Diagnostics®, Singapore). When antibodies were present, gastric infection with *H pylori* was searched by $^{13}$C-urea breath test (UBT) or by culture on gastric biopsy specimens obtained during upper gastrointestinal endoscopy when indicated for diagnosis of esophageal varices in patients with cirrhosis. UBT was performed after overnight fasting, 75 mg of urea was ingested after citric acid. Air samples were obtained before and 30 min after urea ingestion and analyzed by isotope ratio mass spectrometry. Serology and UBT have 95% sensitivity and specificity[15].

### Helicobacter culture from liver tissue

Standard *Helicobacter* culture methods were used including Wilkins Chalgren agar with antibiotics[16] and chocolate agar without antibiotics. The plates with fresh liver tissues were incubated at 37℃ for 4 d, one set in a microaerobic atmosphere and another in an anaerobic atmosphere.

To maximize the culture of *Helicobacter* from the biopsies, a flask of confluent murine hepatic (CCl 9.1) cells was systematically inoculated with liver samples and observed during a week for a color change or opacification of the medium, or for a cytopathic effect. The medium was also observed microscopically before discarded.

### DNA extraction from liver tissues

DNA from frozen liver material (20 to 25 mg/specimen) was extracted by using the QIAamp kit (Qiagen Inc., Chatsworth, CA) as previously described[12].

### PCR conditions

Standard PCR amplifications were carried out as previously reported and PCR products were analyzed on a 1%-4% agarose gel, depending on the amplicon size, and stained with ethidium bromide[12].

Two real time PCRs were performed using the TaqMan® or SYBR® Green chemistries. The TaqMan real time PCR amplification and hybridization reactions were carried out in a final volume of 10 μL containing 5 μL of TaqMan® Universal PCR Master Mix, 0.3 μmol/L of each primer, 0.2 μmol/L of the labeled probe Helico-spp-16S and 1 μL

of purified DNA in a ABI PRISM® 7000 thermocycler (Applied Biosystems, Foster City, CA). DNA was amplified using the following cycling parameters: heating at 95℃ for 10 min followed by 40 cycles of a two-stage temperature profile of 95℃ for 15 s and 60℃ for 1 min. The SYBR® Green real time PCR amplification and melting curve analysis were carried out in a final volume of 10 μL containing 5 μL of SYBR® Green PCR Master Mix, 0.3 μmol/L of each primer and 1 μL of purified DNA in a ABI PRISM® 7000 thermocycler (Applied Biosystems). DNA was amplified using the following cycling parameters: heating at 50℃ for 2 min, then at 95℃ for 10 min followed by 40 cycles of a two-stage temperature profile of 95℃ for 15 s and 60℃ for 1 min. Then a dissociation of the amplicon from 60℃ to 95℃ was followed during 20 min.

### *Escherichia coli* PCR amplification

A PCR targeting a 130-bp sequence of the malate deshydrogenase (mdh) gene of *E. coli* was applied to the liver tissue as previously described[12].

### *Helicobacter* genus- and species-specific PCR amplification

*Helicobacter* genus-specific primer pairs C97/C98[17] and HS1/HS2[8,18] were used to generate 16S rDNA amplicons of approximately 400 bp. Moreover, a new PCR targeting the *Helicobacter* genus 16S rRNA gene was developed using the TaqMan chemistry. Sequences of different *Helicobacter* species such as *H pylori*, *Helicobacter heilmannii*, *Helicobacter fennelliae*, *Flexispira rappini*, *Helicobacter bilis*, *Helicobacter cinaedi*, *Helicobacter winghamensis*, *Helicobacter pullorum*, and *Helicobacter bizzozeronii* were aligned. Closely related 16S rRNA genes from various bacteria, such as *Campylobacter coli*, *Campylobacter jejuni*, C*ampylobacter fetus*, *Wolinella succinogenes,* were also included and a search was carried out to identify conserved regions specific to the *Helicobacter* genus. As a result, a set of primers (AS2-Helico-TQM: 5'-CCGTGTCTCAGTTCCAGTGTGT-3' and S1-Helico-TQM: 5'-GATCAGCCTATGTCCTATCAGCTTGT-3') were designed to amplify a 106-bp sequence in *Helicobacter* species. After the specificity of the PCR was ensured, a probe was also designed (Helico-spp-16S FAM-TCACCCTCTCAGGCCGGATACCC-TAMRA). TaqMan probes were synthesized with the FAM reporter dye covalently linked to the 5'P ends and the TAMRA quencher dye at the 3'P ends which were phosphorylated to prevent probe extension. Primers and probes used for the TaqMan assays synthesized by Proligo (Paris, France) were designed using a Primer Express software package PE-ABI (Applied Biosystems).

Samples generating a positive result with the *Helicobacter* genus-specific PCR were subsequently analyzed with seven different sets of primers for the detection of four species previously found in human liver, i.e. *H. sbilis*, *H. spullorum*, *H pylori* and *F. rappini*[12]. For *H. sbilis* and *H. spullorum* primers amplifying a 151-bp product and a 140-bp product on the *cdt*B gene were used, respectively[12]. For *F. rappini*, primers amplifying a 101-bp product on the *ure*B gene were used[12]. For *H pylori*, four real time PCRs were performed for detecting a 267-bp product on the 23S rRNA gene[19], a 146-bp product on the *glm*M (*ure*C) gene[20], a 231-bp product on the *ure*A gene[21], and a 303-bp product on the 26 kDa specific antigen gene[22].

### Purification and cloning of PCR products for 16S rDNA sequencing

Given the possibility of the presence of different strains in the same sample, PCR products were cloned prior to sequencing. *Helicobacter* species 16S rDNA samples were amplified, cloned and sequenced as previously reported[12]. *Helicobacter* genus-specific and species-specific amplified primer-less sequences were compared to the GenBank database with the Blast program at the National Center for Biotechnology Information Computer server[23].

### Statistical analysis

Descriptive statistics are provided as means ± SD. One way analysis of variance (ANOVA) or the Mann-Whitney test was used when necessary for statistical comparison of quantitative data, and the chi-square test or Fisher's exact test for qualitative data. $P < 0.05$ was considered statistically significant.

## RESULTS

### Characteristics of the study population

A total of 79 patients with a liver sample obtained after percutaneous liver biopsy or hepatic resection were included. The median length of the needle biopsy specimens was 1.4 cm (mean 1.35 cm). The characteristics of the patients are shown in Table 1.

Fifty-three patients who had chronic hepatitis C were divided into two groups: group 1 consisting of patients without cirrhosis ($n = 41$), group 2 consisting of patients with cirrhosis ($n = 12$). One patient in group 2 also had HCC. As expected, patients with cirrhosis (group 2) were significantly older than those without cirrhosis (group 1) (60 ± 11 years *vs* 50 ± 13 years, respectively; $P < 0.03$) and had significantly higher AST levels (3.7 ± 2.4 upper limit of normal value *vs* 1.5 ± 1.1 upper limit of normal value, respectively; $P = 0.001$) and ALT levels (3.7 ± 2.8 ULN *vs* 1.7 ± 1.3 ULN, respectively; $P < 0.003$). Conversely, they did not differ in gender distribution, route of HCV transmission, duration of infection, alcohol intake, GGT levels, HCV genotype and viral load.

Group 3 consisted of HCV negative control patients ($n = 26$) in whom liver tissues were taken from the non-tumoral part of hepatectomy specimens after resection for hepatic benign tumors ($n = 11$; i.e. 4 focal nodular hyperplasias, 2 hydatic cysts, 1 cavernous hemangioma, 1 liver cell adenoma, 1 biliary cyst, 1 cystadenoma, 1 abcess) or metastatic tumors ($n = 15$; i.e. all 15 of colorectal origin).

### *Helicobacter* culture

Despite our efforts, it was impossible to grow any *Helicobacter* strain from the liver, either on the plate media or in the tissue culture flasks.

### *Helicobacter* genus detection by PCR

Overall, *Helicobacter* genus DNA was detected in the liver of 16 patients (20.2%). These positive cases were found in

**Table 1 Characteristics of the 79 patients at the time of inclusion**

IVDU: Intravenous drug use; ULN: Upper limit of normal value; NS: Not significant.

7/41 (17.0%) patients of group 1, 5/12 (41.6%) patients of group 2, and 4/26 (15.4%) patients of group 3 (Figure 1). Although positive cases tended to be more frequent in patients with cirrhosis than in those without cirrhosis or in controls, the difference did not reach statistical significance ($P = 0.08$). Among the 79 liver specimens studied, none was positive by PCR for *E. coli*, a frequent colonizer of the gut.

A number of factors were tested for their association with the presence of *Helicobacter* DNA in the liver of 53 patients with chronic hepatitis C (with or without cirrhosis). None of these factors was associated with the presence of *Helicobacter* (Table 2). Positive patients were significantly younger than negative patients (46 ± 13 years *vs* 54 ± 13 years, respectively; $P = 0.05$).

### *Helicobacter pylori* serology and urea breath test

Overall, anti *H pylori* IgG antibodies were detected in 20/76 (26.3%) cases. These positive cases were found in 12/41 (29.2%) patients of group 1, 3/11 (27.0%) patients of group 2 and 5/24 (20.8%) patients of group 3. As shown in Table 3, among the 16 patients positive for *Helicobacter* DNA in the liver, anti *H pylori* IgG antibodies were detected in 2/7 (28.5%) patients of group 1, 1/4 (25.0%) patients of group 2 and 1/4 (25.0%) patients of group 3. Serology was not performed in one positive patient. All the results obtained by ELISA were also confirmed using an immunoblot specific for *H pylori*. Gastric infection was confirmed by UBT in the 2 positive patients of group 1 but not in the positive patient of group 2. UBT was not performed in one positive control patient.

### Identification of Helicobacter species

Material from 16 *Helicobacter* genus positive patients was tested with species-specific primers (Table 3). Neither *H. bilis* nor *H. rappini* was found (data not shown). *H pylori*-like organisms were identified in 12 (75%) cases and H. spullorum-like organisms were identified in 2 cases (12.5%), 2 samples remained unidentified. *H pylori*-like organisms were present in 4/7 (57%) patients of group 1, 4/5 (80.0%) patients of group 2, and 4/4 (100%) patients of group 3. These results were confirmed by sequencing the 16S rRNA gene in the 7 cases where it was carried out. Among the positive samples by sequencing or by *H pylori* specific PCR, none of them reacted with the highly conserved primer designed to amplify the specific *vac*A gene of *H pylori* and variable results were obtained with other *H pylori* specific targets, such as *ure*A, *glm*M. Among the 7 samples for which the near complete 16S rRNA gene was sequenced, the 2 nucleotide polymorphisms in position 92 and 130 which were found to be associated with *Helicobacter* 16S rDNA sequences from the liver described by Verhoef *et al*[29] were detected in 5 instances: 3 sequences harboured the 2 polymorphisms simultaneously, 2 sequences

[1]Also confirmed by 16S rDNA sequence; ND: Not determined. The 16S rRNA amplified primer-less sequences of approximate 1370 bp for biopsies 2, 3, 5, 7, 8, 9 and 14 were submitted to GenBank and assigned accession numbers DQ062210 to DQ062216, respectively.

harboured one of these 2 polymorphisms and 2 sequences did not present these polymorphisms.

## DISCUSSION

In a previous retrospective cross-sectional study[12], we showed that DNA from *H pylori*- and *H. spullorum*-like organisms was present in the liver of patients with hepatitis C cirrhosis with or without HCC, suggesting that *Helicobacter* species could be a co-risk factor for progression of HCV chronic liver diseases. However, a limitation of this preliminary study was its retrospective nature which did not allow us to determine whether *H pylori* was present in the stomach of these patients and to gather all of the clinical and biological information on HCV genotype and duration of infection, *etc*, which is needed for a more accurate analysis.

In this prospective study, we were able to better characterize the presence of *Helicobacter* species in the liver of a group of consecutive patients with HCV infection with or without cirrhosis, using both the tools which were developed in the retrospective study as well as new tools.

The results of the present study only partially confirm those obtained previously. Although the prevalence of *Helicobacter* DNA tended to be higher in the liver samples from patients with hepatitis C cirrhosis than in those from HCV-infected patients without cirrhosis or from controls, the difference did not reach statistical significance ($P = 0.09$ and $P = 0.08$, respectively). However, we cannot exclude the fact that given the limited number of patients with HCV- induced cirrhosis, this result may be due to a lack of statistical power. The negative results obtained with regard to the detection of *E. coli* DNA in liver material confirm that *H pylori* DNA detected is not the result of a non specific transport or failure in elimination by a non functional liver. Indeed, since *E. coli* is constantly present in the human intestine, if a non specific bacterial translocation occurred, we could find *E. coli* DNA in the liver.

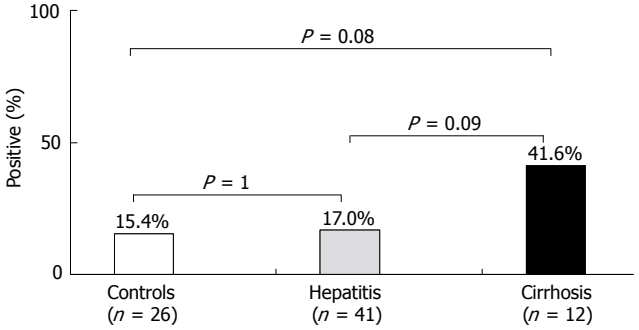

**Figure 1** Percentage of positive biopsies for *Helicobacter* genus by DNA detection. Group 1 corresponds to hepatitis ($n = 41$), group 2 corresponds to cirrhosis ($n = 12$), and group 3 corresponds to controls ($n = 26$). *Helicobacter* genus positivity and negativity was compared using Fisher's exact test.

This study did not enable us to solve the issue of identifying specific *Helicobacter* species involved since no positive culture occurred on the media usually used for *Helicobacter* culture. Indeed, in another study bacteria closely related to *H pylori* morphologically were visualized in the liver of 6 out of 20 patients with HCC[24]. Furthermore, Oliveira *et al* only found *H pylori* in two studies on ulcerative colitis[25] and Crohn's disease patients[26]. For the latter, *H pylori* was more frequent than in the intestinal mucosa of the control group. These two studies were however carried out in a country of high *H pylori* prevalence, Brazil.

In the current study, we also had the possibility to perform *H pylori* serology on most patients. Interestingly, among the 15 patients (out of 16) positive for *Helicobacter* DNA in the liver, only 4 (26.6%) had *H pylori* antibodies.

Given this surprising result, immunoblot was performed and the results were confirmed.

Unfortunately, the protocol did not include a UBT when *Helicobacter* DNA was present in the liver, but only when *H pylori* serology was positive. Indeed, 2 out of 3 positive serology cases were confirmed by UBT. As the sensitivity of our serological kit is 95%[15,27], it is surprising that such a high number of patients (11/15) did not produce *H pylori* antibodies, which casts a doubt on the identification of the species present. Two potential explanations can be given: (1) *H pylori* is truly present in the liver, but not in the stomach, and at an insufficient load to stimulate an immune response; and (2) another *Helicobacter* species which is closely related to *H pylori* but does not cross-react with *H pylori* antigens, is present in the liver. These patients did not receive *H pylori* eradication therapy, which could explain the eradication of the bacteria. The possibility of immunodeficiency in HCV positive patients, especially with cirrhosis can also be considered as an explanation of the lack of serological response but we have not found arguments for this hypothesis.

The 1370 bp sequence of the 16S rRNA gene of six patients with *H pylori* DNA shows 99% homology with *H pylori*, but it is known that 16S rDNA sequences do not have a good discriminatory power in the *Helicobacter* genus. A recent taxonomic analysis showed for example that *H. felis, H. salomonis* and *H. bizzozeronii* could not be differentiated on the basis of the 16S rRNA gene sequence[28].

There are a number of genes which are theoretically specific for *H pylori*, eg *ure*A, *glm*M, and *vac*A. Although they were looked for in this study, they were not uniformly present. The absence of the *H pylori* specific *vac*A detected by a PCR targeting a short sequence is particularly surprising. Furthermore, a striking feature in the 16S rDNA sequences obtained from liver material is the presence of 2 nucleotide polymorphisms at the positions 92 and 130 as described by Verhoef *et al*[29]. Indeed, this polymorphism was already present in the sequences first described by Avenaud *et al*[8] and Ponzetto *et al*[11], and was present in most of our cases (5/7). It is important to note that in the study of Verhoef *et al*[29], *H pylori* was grown from the stomach of 3 out of 9 (33%) patients with this *Helicobacter* 16S rDNA polymorphism in the liver, and the corresponding gastric strains also had this polymorphism and were confirmed to be *H pylori*. It is therefore most likely that this species corresponds to a variant of *H pylori* with different properties including bile resistance and the ability to colonize the liver. This polymorphism is also present in the only strain grown from liver material[10]. The study of strains obtained from the same patients several years apart has shown a greater diversity than in other bacterial species studied due to high rates of mutations and recombinations[30]. This observation has led to the concept of quasi species which could correspond to the situation found in the liver.

Despite the doubt concerning the reality of the presence of *H pylori* in the liver (absence of culture and negative-*H pylori* specific PCR), the presence of *H. spullorum*-like organisms in the liver is much more likely as has been confirmed by *H. spullorum* specific *cdt*B PCR and by sequencing of the 16S rRNA gene. The identification of *H. pullorum* is easy, given that this bacterium has been designated as a separate species on the basis of 16S rRNA gene sequencing[31]. *H. pullorum* isolates were initially recovered from the cecal content of broiler chickens and from the liver and intestinal content of laying hens with vibrionic hepatitis, suggesting that this bacterium can infect the liver and that poultry may serve as the source of human infection[31]. *H. pullorum* has also been cultured from immunocompetent patients with gastroenteritis and one HIV-infected patient[31]. One individual, in addition to having diarrhea, developed elevated liver enzyme levels and hepatomegaly which, although not proven, may have been induced by *H. pullorum* invasion of the liver in a manner similar to the organism's ability to cause hepatitis in chickens[32]. There is clearly a potential for zoonotic foodborne transmission of *H. pullorum* to humans, as is known to occur with *Campylobacter* species.

In conclusion, *Helicobacter* DNA can be present in the liver of patients with liver disease, with a tendency to have a higher prevalence in those with cirrhosis. Although *H. pullorum* appears to be regularly found at a low rate, the exact nature of the main *Helicobacter* species present is still uncertain. It is most likely a variant of *H pylori* which has acquired specific properties. Further studies exploring both the liver and stomach of patients with liver diseases need to be carried out to unravel the mystery of this intriguing association.

## Abstract

**AIM:** To study the genes associated with the responses to chemokines, nutrients, inorganic substances, organic substances and xenobiotics after rat partial hepatectomy (PH) at transcriptional level.

**METHODS:** The associated genes involved in the five kinds of responses were obtained from database and literature, and the gene expression changes during liver regeneration in rats were checked by the Rat Genome 230 2.0 array.

**RESULTS:** It was found that 60, 10, 9, 6, 26 genes respectively participating in the above five kinds of responses were associated with liver regeneration. The numbers of initially and totally expressed genes occurring in the initial phase of liver regeneration (0.5-4 h after PH), $G_0/G_1$ transition (4-6 h after PH), cell proliferation (6-66 h after PH), cell differentiation and structure-functional reconstruction (66-168 h after PH) were 51, 19, 52, 6 and 51, 43, 98, 68 respectively, illustrating that the associated genes were mainly triggered in the initiation and transition stages, and functioned at different phases. According to their expression similarity, these genes were classified into 5 groups: only up-regulated (47), predominantly up-regulated (18), only down-regulated (24), predominantly down-regulated (10), and up- and down-regulated (8). The total times of their up-regulated and down-regulated expression were 441 and 221, demonstrating that the number of up-regulated genes is more than that of the down-regulated genes. Their time relevance and gene expression patterns were classified into 14 and 26 groups, showing that the cell physiological and biochemical activities were staggered, diversified and complicated during liver regeneration in rats.

**CONCLUSION:** The chemotaxis was enhanced mainly in the forepart and metaphase of LR. The response of regenerating liver to nutrients and chemical substances was increased, whereas that to xenobiotics was not strong. One hundred and seven genes associated with LR play important roles in the responses to chemical substances.

## INTRODUCTION

The liver has tremendous capacity to regenerate itself[1,2]. Liver cells proliferate rapidly to compensate the lost liver tissues after liver injury or chemical stimulus, which is called liver regeneration (LR)[1,3]. Generally, based on the cell physiological activities, the regeneration process is classified into 4 phases: the initiation (0.5-4 h after hepatectomy, PH), the transition from $G_0$ to $G_1$ (4-6 h after PH), the cell proliferation (6-66 h after PH), the cell differentiation and structure-functional reorganization (66-168 h after PH)[2]. According to the time course, it is divided into 4 phases: forepart (0.5-4 h after PH), prophase (6-12 h after PH), metaphase (16-66 h after PH), and anaphase (72-168 h after PH)[4], involving hepatic cell activity, dedifferentiation, proliferation and its regulation, redifferentiation, structure-functional reorganization[5], which are regulated by many factors including chemical substances[6].

Liver is a vital organ where chemical substances undergo transformation[7-9], it also can respond rapidly to chemical stimulus[10]. This process involves more than 400

genes, so high-throughput biological analysis is needed[11,12]. The pathogenesis of drug-induced liver disease, toxic liver injury and the characteristics of responses of regenerating liver to drug, toxin, oxidation and unfolded protein have been studied at transcriptional level[13]. In this paper, the expression changes of the genes in rat regenerating liver after PH were detected by Rat Genome 230 2.0 array[14]. Two hundred genes were related to the response to chemical substances, in which, 107 genes were observed to be associated with liver regeneration[11]. Expression changes, patterns and action of the genes were primarily analyzed.

## MATERIALS AND METHODS

### Regenerating liver preparation

Healthy SD rats weighing 200-250 g were obtained from the Animal Center of Henan Normal University. The rats were separated into groups randomly, each group consisting of 6 rats (male: female = 1:1). PH was performed according to Higgins and Anderson[15], the left and middle lobes of liver were removed. Rats were killed by cervical vertebra dislocation at 0.5, 1, 2, 4, 6, 8, 12, 16, 18, 24, 30, 36, 42, 48, 54, 60, 66, 72, 96, 120, 144 and 168 h after PH and the regenerating livers were observed at corresponding time point. The livers were rinsed three times in PBS at 4℃, then 100-200 mg livers from middle parts of right lobe (total 0.1-0.2 × 6 g liver tissues, six samples for each group) were collected and stored at -80℃. The sham-operation (SO) groups were the same with PH groups except that the liver lobes were not removed. The laws of animal protection of China were enforced strictly.

### RNA isolation and purification

Total RNA was isolated from frozen livers according to the manual of Trizol kit (Invittrogen)[16] and then purified based on the instructions of RNeasy mini-kit (Qiagen)[17]. Total RNA samples were found to exhibit a 2:1 ratio of 28S to 18S rRNA intensities by agarose electrophoresis (180 V, 0.5 h). Total RNA concentration and purity were estimated by optical density measurement at 260/280 nm[18].

### cDNA, cRNA synthesis and purification

As template, 1-8 μg total RNA was used for cDNA synthesis. cDNA and cRNA synthesis was carried out based on method of Affymetrix[19]. cRNA labeled with biotin was synthesized using 12 μL of the above synthesized cDNA as the template, and cDNA and cRNA were purified according to the sample purification procedure of GeneChip Analysis[19]. Measurement of the concentration, purity and quality of cDNA and cRNA were the same as above[18].

### cRNA fragmentation and microarray detection

Fifteen μL (1 μg/μL) cRNA incubated with 5 × fragmentation buffer at 94℃ for 35 min was digested into 35-200 bp fragments. The hybridization buffer was added to the prehybridized Rat Genome 230 2.0 microarray produced by Affymetrix, then hybridization was carried out for 16 h at 45℃ on a rotary mixer at 60 rpm. The microarray was washed and stained by GeneChip fluidics station 450 (Affymetrix Inc., USA). The chips were scanned by GeneChip Scan 3000 (Affymetrix Inc., USA), and the signal values of gene expression were observed[14].

### Microarray data analysis

The normalized signal values, signal detections (P, A, M) and experiment/control (Ri) were obtained by quantifying and normalizing the signal values using GCOS1.2[14].

### Normalization of microarray data

To minimize error in the microarray analysis, each analysis was performed three times by Rat Genome 230 2.0 microarray. The results in which the total ratio($R^m$) was maximal and the average of the three housekeeping genes β-actin, hexokinase and glyseraldehyde-3-phosphate dehydrogenase approached 1.0 ($R^h$), were taken as a reference. The modified data were generated by applying a correction factor ($R^m/R^h$) multiplying the ratio of every gene in $R^h$ at each time point. To remove spurious gene expression changes resulting from errors in the microarray analysis, the gene expression profiles at 0-4 h, 6-12 h and 12-24 h after PH were reorganized by NAP software (normalization analysis program) according to the cell cycle progression of the regenerating hepatocytes. Data statistics and cluster analysis were done using GeneMath, GeneSpring, Microsoft Excel software[14,20,21].

### Identification of genes associated with liver regeneration

The nomenclature of the responses to chemical substances was adopted from the GENEONTOLOGY database (www.geneontology.org), and input into the database at NCBI (www. ncbi.nlm.nih.gov) and RGD (rgd.mcw.edu) to identify the rat, mouse and human genes associated with the responses to chemical substances. According to KEGG (www.genome.jp/kegg/pathway.html#amino) and BIOCARTA (www.biocarta.com/genes/index.asp), the genes associated with the biological process were collated. The results of this analysis were codified, and compared with the results obtained for mouse and human searches in order to identify human and mouse genes which are different from those of rat. Comparing these genes with the analysis output of the Rat Genome 230 2.0 array, those genes which showed a greater than twofold changes in expression level, and observed as meaningful expression changes[22], were referred to as rat homologous or rat specific genes associated with the responses to chemical substances under evaluation. Genes, displaying reproducible results with three independent analyses with the chip and showing a more than twofold change in expression level in at least one time point during liver regeneration with significant difference ($0.01 \leqslant P < 0.05$) or extremely significant difference ($P \leqslant 0.01$) between PH and SO, were considered as associated with liver regeneration.

## RESULTS

### Expression changes of genes associated with responses to chemical substances during liver regeneration

According to the data from databases at NCBI, GENEMAP, KEGG, BIOCARTA and RGD, 403 genes

**Table 1 Expression abundance of 107 genes associated with responses to chemical substances during rat liver regeneration**

| Gene Abbr. | Associated to others | Fold difference | Gene Abbr. | Associated to others | Fold difference | Gene Abbr. | Associated to others | Fold difference | Gene Abbr. | Associated to others | Fold difference |

[1]Reported genes associated with liver regeneration; Associated to others: involved in the other kind of responses to chemical substances.

were involved in the responses to chemical substances, 200 of them were contained in the Rat Genome 230 2.0 array. Among the 200 genes, 107 displayed meaningful changes at least at one time point after PH, there was significant difference or extremely significant difference in expression between PH and SO groups, and results were reproducible from the three checks with Rat Genome 230 2.0 array, suggesting that the genes were associated with liver regeneration. The up-regulation was 2-128 folds, and the down-regulation was 2-10 folds that of controls (Table 1). The analysis indicated that 47 genes were up-regulated, 24 down-regulated, and 36 up/down-regulated during liver regeneration. The total up- and down-regulated times were 441 and 221, respectively (Figure 1A). At the initial phase, 34 genes were up-regulated and 16 down-regulated; at the transition phase from $G_0$ to $G_1$, 24 genes were up-regulated and 14 down-; at the cell proliferation phase, 47 genes were up-, 26 down- and 24 up/down-regulated; at cell differentiation and structure-function reorganization phase (66-168 h after PH), 44 genes were up-, 17 down- and 6 up/down-regulated (Figure 1B).

### *Initial expression time of genes associated with responses to chemical substances during liver regeneration*

At each time point of liver regeneration, the numbers of initially up-, down-regulated and totally up-, down-regulated genes were in the following sequence: both 10 and 3 at 0.5 h; 11, 6 and 21, 8 at 1 h; 6, 1 and 18, 4 at 2 h; 8, 6 and 25, 8 at 4 h; 3, 2 and 19, 11 at 6 h; 1, 1 and 14, 9 at 8 h; 2, 3 and 20, 11 at 12 h; 10, 4 and 28, 7 at 16 h; 2, 10 and 26, 22 at 18 h; 2, 0 and 24, 12 at 24 h; 5, 1 and 19, 7 at 30 h; 0, 0 and 20, 15 at 36 h; 1, 0 and 17, 4 at 42 h; 0, 0 and 26, 18 at 48 h; 1, 1 and 22, 18 at 54 h; 1, 0 and 24, 11 at 60 h; 2, 0 and 22, 9 at 66 h; 1, 0 and 19, 10 at 72 h; 2, 0 and 25, 10 at 96 h; 0, 1 and 14, 10 at 120 h; 0, 0 and 15, 7 at 144 h; 0, 0 and 13, 7 at 168 h (Figure 2). Generally, gene expression changes occurred during the whole liver regeneration, and the up- and down-regulated times were 441 and 221, respectively. The initially up-regulated genes were predominantly expressed in the forepart, prophase and pre-metaphase, and only few genes were initially expressed in the metaphase, pre-anaphase and mid-anaphase, whereas no initial expression in the late anaphase.

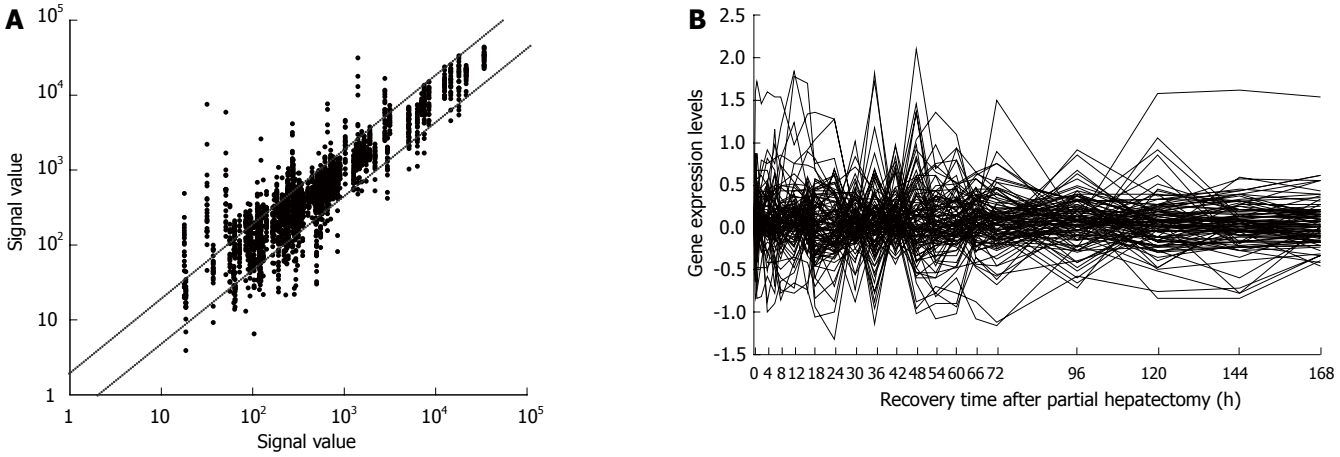

**Figure 1** Expression frequency, abundance and changes of 107 genes associated with responses to chemical substances during rat liver regeneration. Detection data of Rat Genome 230 2.0 array were analyzed and graphed by Microsoft Excel. **A**: Gene expression frequency. The dots above bias represent the genes up-regulated more than 2-fold, those under bias represent the ones down- more than 2-fold, and total times of up- and down-regulation were 441 and 221; the ones between two diagonal lines represent the genes without alteration in expression; **B**: Gene expression abundance and changes. Eighty-three genes were 2-128 folds up-regulated, and sixty genes 2-10 folds down-regulated.

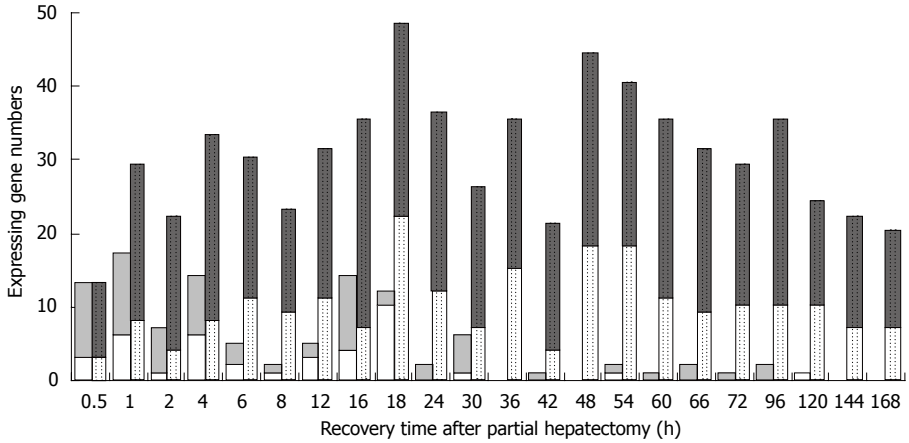

**Figure 2** The initial and total expression profiles of 107 genes associated with responses to chemical substances at each time point of liver regeneration. Grey bars: up-regulated genes; White bars: down-regulated genes. Blank bars represent initially expressing genes, in which up-regulation genes are predominantly in the forepart, prophase and early metaphase, and few genes initially expressed in the metaphase, early anaphase and middle anaphase, whereas no initial expression in the late anaphase. Dotted bars represent the total expressing genes, in which some genes are up-expressed, and the others down-expressed during LR.

### *Expression similarity and time relevance of the genes associated with the responses to chemical substances during liver regeneration*

Among the 107 genes characterized, 47 were up-regulated, 18 predominantly up-, 24 only down-, 10 predominantly down-, 8 up/down-, based on their similarity in expression (Figure 3). According to the time relevance, they were classified into 14 groups: 0.5 and 1 h, 2 and 4 h, 6 h, 8 and 12 h, 16 h, 18 and 24 h, 30 and 42 h, 36 h, 48 h, 54 and 60 h, 66 h, 72 and 120 h, 96 h, 144 and 168 h. The up- and down-regulated times were 31 and 11, 43 and 12, 19 and 11, 34 and 20, 28 and 7, 50 and 34, 36 and 11, 20 and 15, 26 and 18, 46 and 29, 22 and 9, 36 and 20, 25 and 10, 28 and 14 (Figure 3). The up-expressed genes were mainly associated with chemotaxis, xenobiotics metabolism, protein transport and apoptosis development, and the down-expressed genes were mostly the ones associated with transportation and mucosal defense.

### *Expression patterns of genes associated with responses to chemical substances during liver regeneration*

The expressions of 107 genes were categorized into 26 patterns according to the expression trends. Figure 4A-4G shows the up-regulated trends of gene expression profiles after PH, involving 14 patterns (47 genes); Figure 4H-4K shows the opposite expression trends, involving 9 patterns (24 genes); Figure 4L,4M,4N respectively displays that 18 genes were predominantly up-regulated, 10 genes predominantly down-regulated and 8 genes similarly up/down-regulated, involving 3 patterns.

## DISCUSSION

Liver is an important site of substance transformation, and it can also rapidly respond to chemical stimuli. During the process, the proteins associated with chemotaxis are as following: nine receptors bind with corresponding chemokine ligand to activate chemotaxis[23]; eighteen chemokine factors and chemokine-like factors, such as chemokine CC ligand 2 (CCL2), bind to corresponding chemokine receptors to activate chemotaxis[24]; eleven proteins including protein kinase C alpha (PRKCA) participate in chemotaxis[25,26]; five proteins such as plasminogen activator urokinase receptor (PLAUR), accelerate cell migration[27]; three proteins including integrin alpha 1 (ITGA1), contribute to cell adhesion[28].

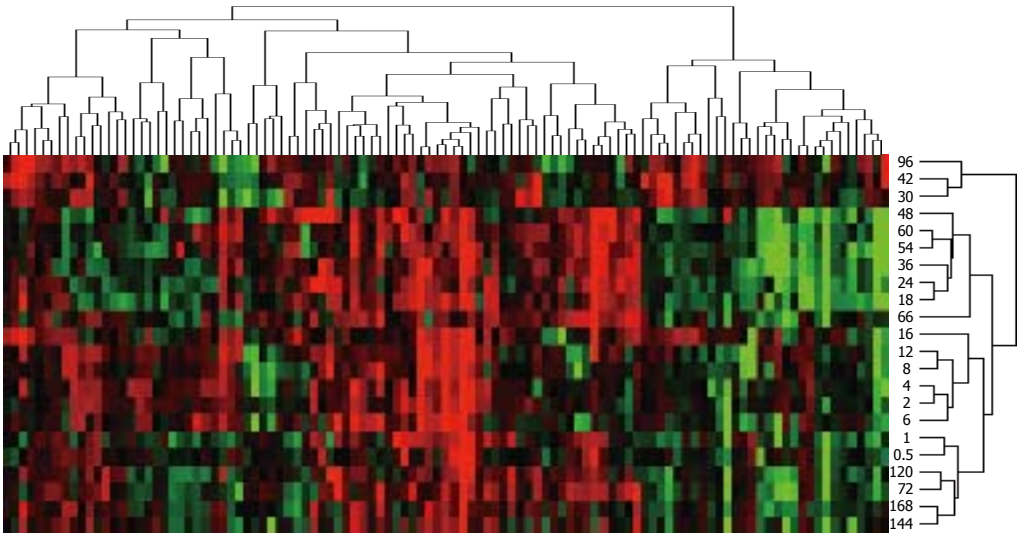

**Figure 3** Expression similarity and time relevance clusters of 107 genes associated with responses to chemical substances during LR. Detection data of Rat Genome 230 2.0 array were analyzed by H-clustering. Red represents up-regulated genes mainly associated with chemotaxis, xenobiotics metabolism, protein transport and apoptosis development; Green represents down- ones mainly associated with transportation and mucosal defense; Black: the genes having insignificant expression changes. The upper and right trees respectively show expression similarity and time series clusters, by which the above genes were classified into 5 and 14 groups.

The genes encoding the above proteins showed similar expression profiles at some points while different at other points, indicating that they may co-regulate chemotaxis. Among them, *prkca* was up-regulated at 16, 30, 42 and 96 h after PH, and reached a peak at 96 h that is 4.6 times higher than the control; *itga1* was up-regulated at 6-24 and 54 h, reaching a peak at 8 h, 2.9 times higher than the control. The two genes are generally consistent with the result reported by Dransfeld *et al*[11]. *ccr1* was up-regulated at 8-36, 48 and 120 h, and peaked at 48 h, 27.9 times that of control. *ccl2* was up-regulated at 0.5-1, 12-24, 36, 48-72 and 96 h, and reached a peak at 48 h, 128 times that control. *plaur* was up-regulated at 1, 6, 18-24, 48, 72 and 120 h, and peaked at 6 h, 13.9 times higher than the control, presuming that they play a key role in inflammation during liver regeneration.

Karyopherin alpha 2 (KPNA2) involved in glucose response, transports karyophilic proteins into the nucleus[29,30]. Cholecystokinin A receptor (CCKAR) promotes pancreatic enzyme secretion and smooth muscle contraction of stomach and gallbladder[31]. Three proteins including somatostatin (SST) inhibit gastrointestinal hormone release[32]. The meaningful expression profiles of the genes encoding the above-mentioned proteins show the identity or similarity at some points, whereas difference at others, presuming that they may co-regulate absorption and consumption of nutrients. Especially, *kpna2* displayed up-regulation at 16-24, 36 and 48-96 h, and had the highest abundance at 60 h, 4.3 times that of control. This result was basically in line with Dransfelds' result[11]. *cckar* appeared at 0.5-24, 36 and 48-54 h, and had peak expression at 8 h, 46.2 times that of control. *sst* was up-regulated at 4-24, 36, 48-60 and 120 h, and peaked at 12 h, 4.3 times that of control, presuming that they play a crucial role in nutrients assimilation and utilization in regenerating liver.

Aquaporin 9 (AQP9) influenced by inorganic substances, which could be inactivated by $Hg^{2+}$, stimulates transmembrane transportation of water and a variety of noncharged solutes, including urea[33]. It was up-regulated at 0.5-1, 24 and 54-72 h, and reached a peak at 66 h, being 3.7 times higher than the control, but the result was not consistent with Dransfelds' at 6 h[11], and need to be further analyzed with Northern blotting. Zinc responsive protein beta (ZD10B) stimulated by $Zn^{+}$ plays a role in apoptosis[34], and was up-regulated at 16-24, 36, 48-72 and 144-168 h, and reached a peak at 72 h, 5.6 times higher than control, indicating that the two play crucial roles in inorganic substances transport and removal in regenerating liver.

Amiloride-sensitive cation channel 1 (ACCN1) affected by organic substances, plays a part in neurotransmission and $Na^{+}$ transport[35], and is up-regulated at 30 and 42 h with the highest abundance of 10 folds at 30 h. Protein phosphatase 2a catalytic subunit beta (PPP2CB) stimulated by ceramide is implicated in the negative control of cell growth and division by dephosphorylation[36,37]. It was up-regulated at 16, 30, 42 and 120 h, and had abundance peak at 42 h, 4.5 folds of control, presuming that the two genes play a crucial part in response to organic substances in regenerating liver.

In response to xenobiotics, fourteen enzymes including cytochrome P450 family 1 subfamily a 1 (CYP1A1), metabolize xenobiotics[38]. Aryl hydrocarbon receptor nuclear translocator 2 (ARNT2) enhances expression of oxygen-responsive genes[39]. Alpha-fetoprotein (AFP) is involved in transportation of copper and nickel[40]. The meaningful expression profiles of the genes encoding the above proteins are the same or similar at some points while different at others, indicating that they may co-regulate the response to xenobiotics. Notably, *cyp1a1* was up-regulated at 0.5-24, 36, 48-72 and 120 h, and reached a peak at 12 h, 59.7 times higher than the control. *arnt2* was up-regulated at 30-42, 60, 72 and 120 h, and reached a peak at 30 h, 6.8 times higher than the control. *afp* was up-regulated at 1 and 54-72 h, and reached a peak at 66 h, 3.7 times higher than the control, showing that they play a critical role in xenobiotics biotransformation in regenerating liver.

In conclusion, the expression changes of the genes associated with chemotaxis, the responses to nutrients, inorganic substances, organic substances and xenobiotics during liver regeneration in rats were investigated by high-throughput gene expression analysis. It was primarily proved that chemotaxis and the responses to the chemical substances are enhanced during LR, that Rat Genome 230

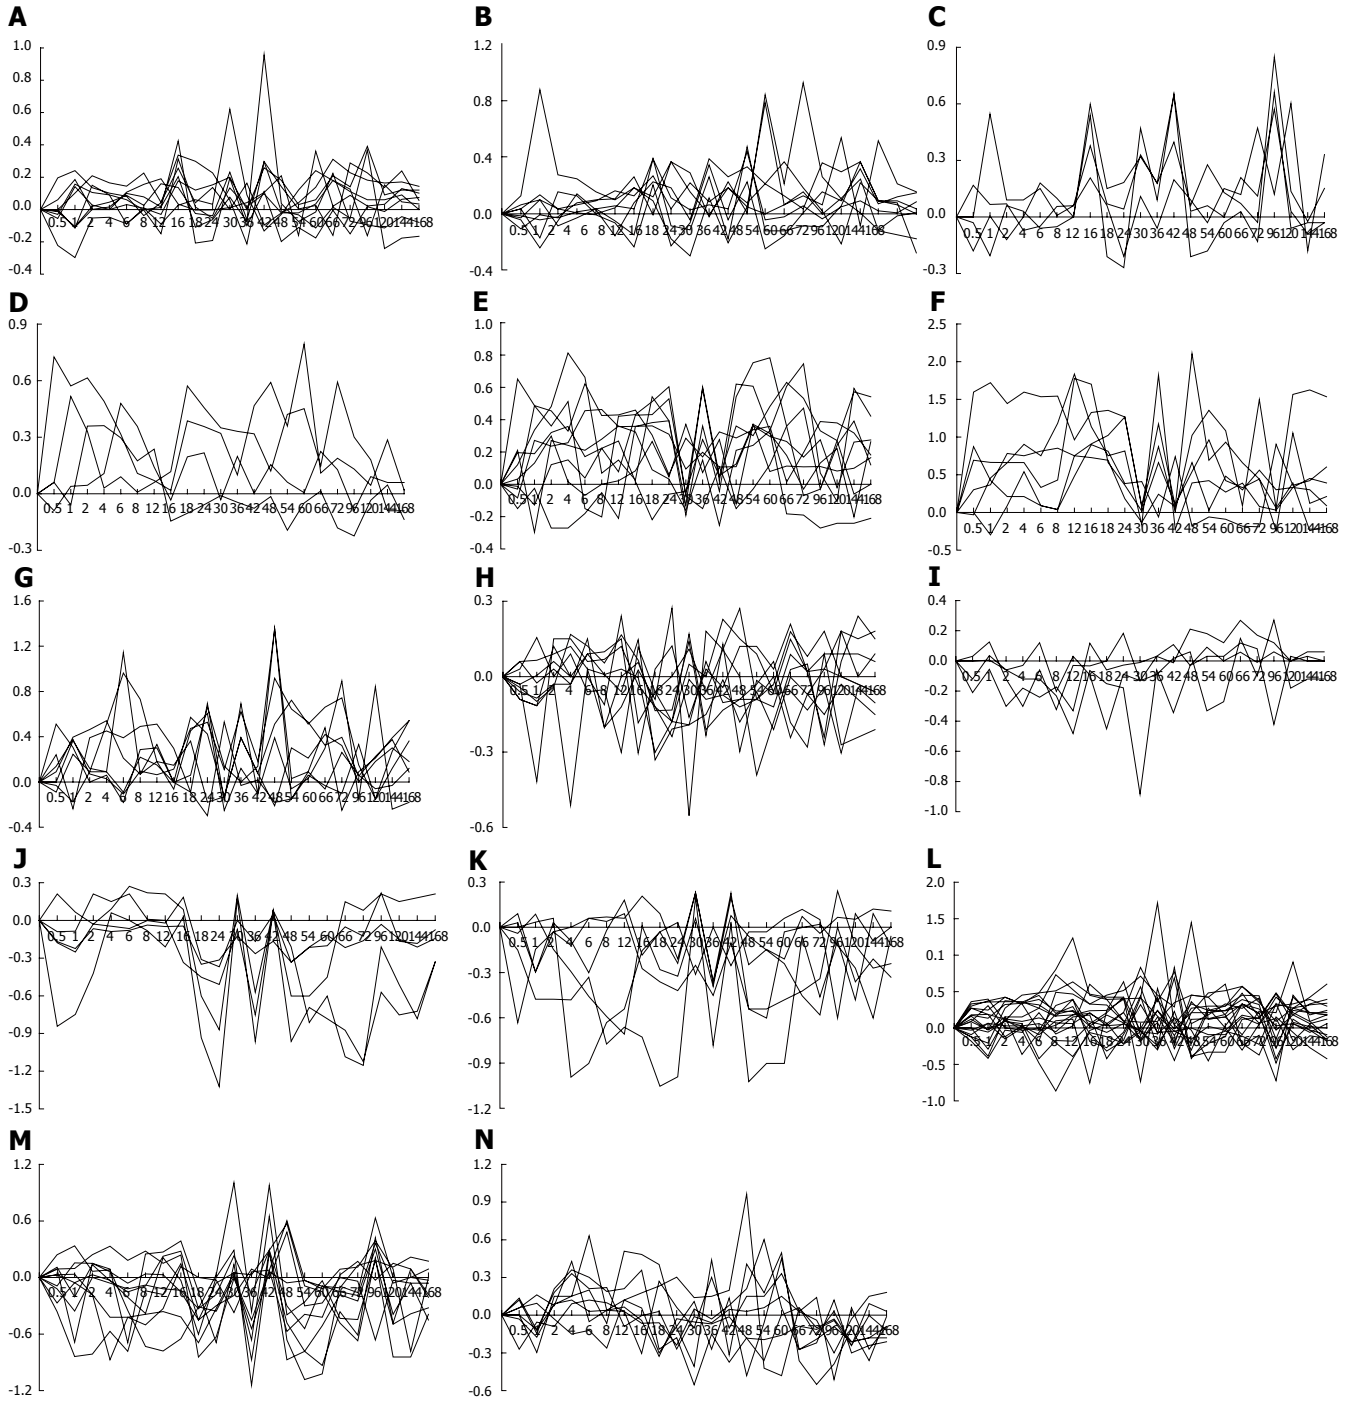

**Figure 4** Gene expression patterns of 107 genes associated with responses to chemical substances during LR. Twenty-six expression patterns were obtained by analysis of data detection of Rat Genome 230 2.0 array with Microsoft Excel. **A**-**G**: 47 up-regulated genes; **H**-**K**: 24 down-regulated genes; **L**-**N**: 36 up/down-regulated genes. X-axis represents recovery time after PH (h); Y-axis shows logarithm ratio of signal values of genes at each time point *vs* control.

2.0 array is a useful tool analyzing the above responses at the transcriptional level. However, the process DNA → mRNA→ protein was influenced by many factors including protein interaction. Therefore, the above results need to be further analyzed by the techniques, such as Northern blotting, protein chip, RNA interference, protein-interaction, *etc*.

## Abstract

**AIM:** To investigate the effect of transplanted fetal liver epithelial progenitor (FLEP) cells on liver fibrosis in mice.

**METHODS:** FLEP cells were isolated from embryonal day (ED) 14 BALB/c mice and transplanted into female syngenic BALB/c mice ($n$ = 60). After partial hepatectomy (PH), diethylnitrosamine (DEN) was administered to induce liver fibrosis. Controls received FLEP cells and non-supplemented drinking water, the model group received DEN-spiked water, and the experimental group received FLEP cells and DEN. Mice were killed after 1, 2, and 3 mo, and alanine aminotransferase (ALT), aspartate aminotransferase (AST), hyaluronic acid (HA), and laminin (LN) in serum, and hydroxyproline (Hyp) content in liver were assessed. Alpha-smooth muscle actin (α-SMA) of liver was tested by immunohistochemistry. Transplanted male mice FLEP cells were identified by immunocytochemistry for sry (sex determination region for Y chromosome) protein.

**RESULTS:** Serum ALT, AST, HA, and LN were markedly reduced by transplanted FLEP cells. Liver Hyp content and α-SMA staining in mice receiving FLEP cells were lower than that of the model group, which was consistent with altered liver pathology. Transplanted cells proliferated and differentiated into hepatocytes and bile duct epithelial cells with 30%-50% repopulation in the liver fibrosis induced by DEN after 3 mo.

**CONCLUSION:** Transplanted FLEP cells proliferate and differentiate into hepatocytes and bile duct epithelial cells with high repopulation capacity in the fiberized liver induced by DEN, which restores liver function and reduces liver fibrosis.

**Key words:** Fetal liver; Epithelial progenitor cells; Cell therapy; Proliferation; Liver fibrosis

## INTRODUCTION

The incidence of hepatic injury and end-stage liver fibrosis is high in China. Cirrhosis represents a serious health care problem worldwide. The prognosis of patients with the disease is poor, although liver transplantation is a successful treatment for end-stage cirrhosis[1]. Counteracting the success of liver transplantation are problems such as lack of donors, operative damage, rejection, and high costs[2]. As a result, novel effective therapies are needed urgently.

Hepatocyte transplantation has been proposed as an alternative to whole organ transplantation[3]. It not only provides temporary liver function in patients waiting for liver transplantation but has also shown to be curative in certain metabolic conditions[4,5]. However, hepatocyte transplantation has very rarely produced therapeutic effects in human clinical trials, mainly because the number of transplanted hepatocytes is too small to achieve a biological effect[6]. Moreover, hepatocytes are quiescent cells that are difficult to maintain in culture and to cryopreserve.

Progenitor or facultative stem cells reside within or adjacent to the canals of Hering and comprise a quiescent compartment of dormant cells in adult livers. They can be activated to proliferate and differentiate into hepatocytes or bile duct epithelial cells when hepatocytes are impaired persistently[7]. Attempts have been made to identify their counterpart in fetal liver, and it has been suggested that the dormant stem-like cells originate most probably from bipotential fetal liver epithelial progenitor (FLEP) cells[8,9]. It was reported that embryonal day (ED) 14 rat liver

contains a subpopulation of bipotent epithelial cells that can differentiate into hepatocytes or bile duct epithelial cells[10-12]. These cells have characteristics of hepatic stem cell, self-renewal potential, and multiple differentiation capability to selectively repopulate the liver. FLEP cell transplantation could offer prospects of novel therapeutic strategies for patients with chronic liver disease or cirrhosis. However, there have been very few reports on the ability of these cells to reduce liver fibrosis after their transplantation.

This study aims to isolate and transplant FLEP cells into the liver of syngenic mice to explore the ability of FLEP cells to proliferate and differentiate into hepatocytes and bile duct epithelial cells and restore impaired liver function and liver fibrosis.

## MATERIALS AND METHODS

### Animals

Six to eight week old BALB/c mice were purchased from the Animal Breeding Center of Sun Yat-Sen University (Guangzhou, China). Mice were bred and maintained in an air-conditioned animal house with specific pathogen-free conditions, using an alternate 12 h cycle of daylight and darkness, and unlimited access to chow and water. All animal handling and experimental procedures were all in accordance with the Guidelines of the Animal Care and Use Committee at Sun Yat-Sen University.

### Isolation and transplantation of FLEP cells

FLEP cells were isolated on ED 14 from normal pregnant mice as described previously[8]. The cells were suspended at a concentration of $10^7$ cells/ml and cell viability (> 95%) was measured by trypan blue dye exclusion. The isolated FLEP cells were considered to be composed of 50% male cells and 50% female cells.

Anesthesia was performed with ether and partial hepatectomy (PH) was undertaken using the standard method for two-third resection[11]. Briefly, after ligation of the pedicule and resection of the two largest lobes (median and left), the remaining liver was composed of the caudate and epiploic lobes. Freshly isolated ED 14 FLEP cells were injected into the female liver via the superior mesenteric vein using insulin syringes after hepatectomy[13]. A total of $1 \times 10^6$ cells were injected per mouse.

### Flow cytometry

Approximately $2 \times 10^5$ FLEP cells were harvested and resuspended in 1 ml phosphate buffered saline (PBS) containing 1% bovine serum albumin (BSA). The cell suspension was incubated with goat anti-CK-19 monoclonal antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA), rabbit anti-AFP polyclonal antibody (Santa Cruz Biotechnology), or rabbit anti-albumin polyclonal antibody (Dako; Glostrup, Denmark), for 40 min at 4℃, then washed three times, and fixed in 2% paraformaldehyde. FITC-conjugated secondary antibody or PE-conjugated secondary antibody was used. FACScan was used for flow cytometry analysis (Becton-Dickinson, San Jose, CA) as previously reported[14].

### Diethylnitrosamine-induced liver injury

After partial hepatectomy and FLEP cells injection, mice were allowed to recover for one week. Thereafter, DEN (Sigma-Aldrich, St. Louis, MO) was continuously administered in drinking water at a final concentration of 100 μg/L for 12 wk[15]. The weight of the animals was carefully monitored during DEN administration.

Sixty female BALB/c mice were randomly divided into three groups (20 in each group). Mice in the normal control group were given FLEP cells and non-supplemented drinking water. The mice in the model group were continuously administered DEN in drinking water for liver injury induction. The experimental group received FLEP cells and DEN. Mice were killed under anesthesia and the livers were removed 1, 2, and 3 mo after cell transplantation. In most experiments, five animals were used at each time point. Blood was collected for evaluation of liver function and hepatic fibrosis at mo 3. Liver tissue was harvested for examination of hydroxyproline (Hyp) content and for histological evaluation.

### Serum parameters for liver function and fibrosis and hepatic Hyp content

Alanine aminotransferase (ALT), aspartate aminotransferase (AST), and total bilirubin in serum were assessed using routine laboratory methods. Hyaluronic acid (HA) and laminin (LN) in serum were also measured with a radioimmunoassay kit (Navy Medical Institute, Shanghai, China).

Hyp determination followed a method designed by Thirunavukkarasu *et al*[16]. Dried liver tissue after hydrolysis was oxidized by $H_2O_2$ and colored by p-dimethylaminobenzaldehyde and absorbance was determined at 540 nm. The amount of Hyp was expressed in mg/g liver.

### Liver histopathology and immunohistochemistry

To identify hepatocytes in fetal mouse liver sections, we immunostained AFP, albumin, and CK-19 with diaminobenzidine using standard techniques[17]. Liver sections were blocked with 1% BSA and 0.1% normal goat or rabbit sera at room temperature for 1 h, followed by incubation with rabbit anti-AFP polyclonal antibody (dilution 1:100; Santa Cruz Biotechnology), rabbit anti-albumin polyclonal antibody (1:200 dilution, Dako), or goat anti-CK-19 monoclonal antibody (dilution 1:100; Santa Cruz Biotechnology) at 4℃ overnight.

HE staining and immunohistochemistry for alpha-smooth muscle actin (α-SMA) were performed to determine the extent of liver inflammation and liver fibrosis development. Liver sections were tested with the antibody against α-SMA (dilution 1:200; NeoMarkers, Fremont, CA, USA) and immunoreactive materials were visualized with diaminobenzidine using a streptavidin-biotin staining kit (UltraSensitive SP kit; Maixin-Bio, Fujian, China).

To identify the origin of cells in the liver, immunohistochemistry was performed for sry (sex-determining region for Y chromosome) protein as described previously[18]. It was expected that transplanted cells (originating from fetal liver) would be approximately 50% male and 50% female.

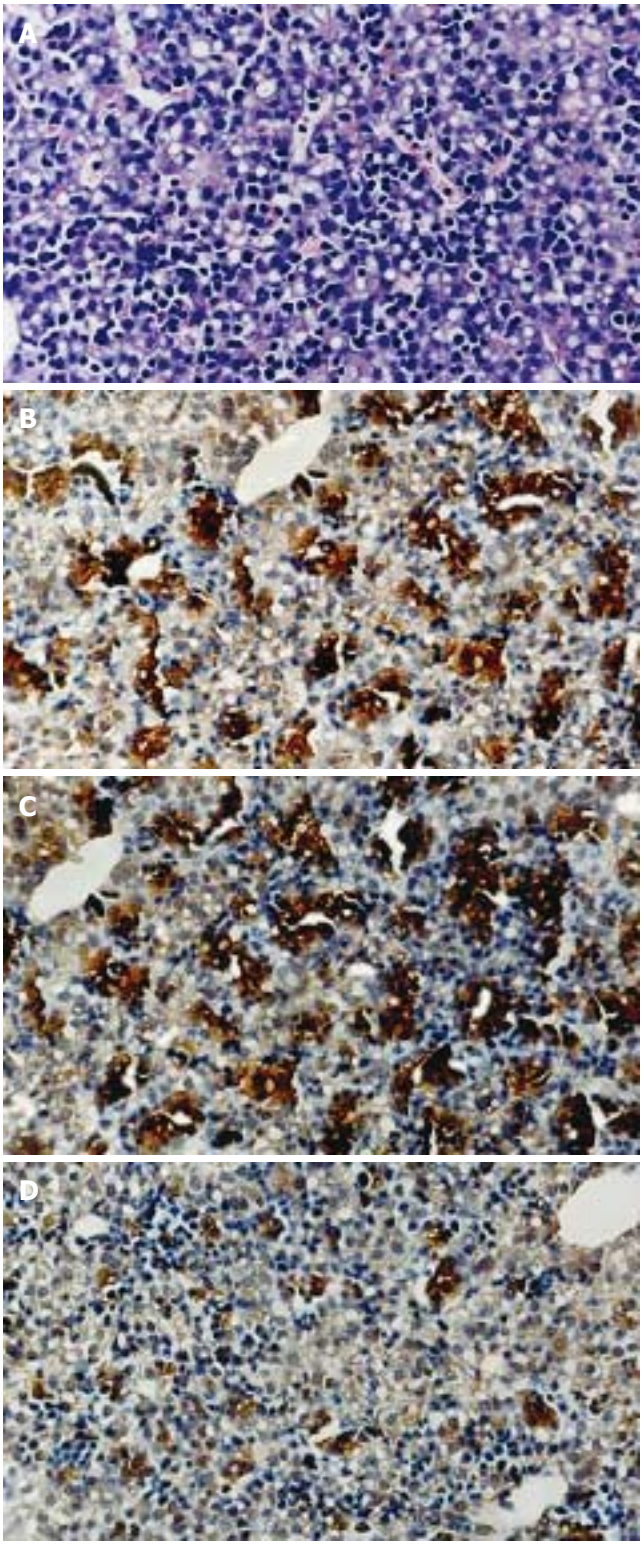

**Figure 1** Characteristics of ED 14 mouse FLEP cells. **A**: Fetal liver tissue, HE staining; **B**: AFP, immunohistochemical staining for FLEP cells; **C**: Albumin, immunohistochemical staining for FLEP cells; **D**: CK-19, immunohistochemical staining for FLEP cells. (Original magnification, x 200).

For histologic examination, several fields in each slide were randomly selected.

### *Statistical analysis*

Data were expressed as mean ± SD. Significant differences were determined using ANOVA in SPSS10.0. Results were considered significant when $P < 0.05$.

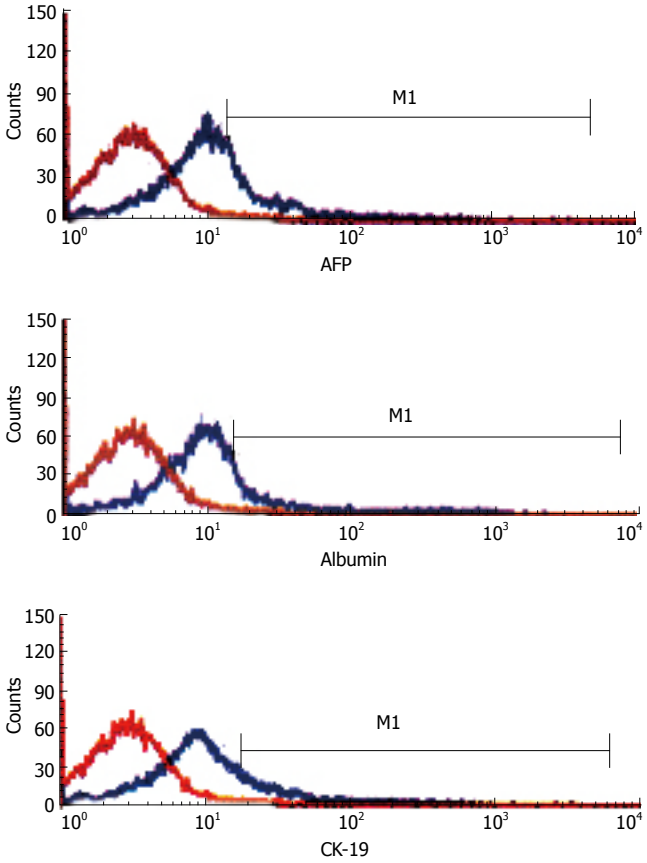

**Figure 2** Flow cytometric analysis performed on freshly isolated fetal mouse hepatocytes. Analysis of total cells after additional labeling for AFP, albumin, and CK-19. Fetal liver contained cell populations staining positive for AFP (15.5%), Albumin (13.9%), or CK-19 (6.4%).

## RESULTS

### *Characteristics of isolated FLEP cells*

Mouse liver at ED 14 contained immature epithelial cells and hematopoietic cells at different stages of differentiation (Figure 1A). Cells from ED 14 fetal liver were analyzed for expression of AFP, albumin, and CK-19. The percentage of FLEP cells was approximately 20% in the ED 14 fetal liver, determined as the number of cells expressing AFP (Figure 1B), albumin (Figure 1C), or CK19 (Figure 1D).

### *Flow cytometric analysis*

To further characterize the phenotype of immature liver epithelial cells, we tested for expression of AFP, albumin, and CK-19 in isolated ED 14 FLEP cells by flow cytometry. Results demonstrated the existence of at least three distinct subpopulations of epithelial cells in 14-d fetal mouse liver. The percentage of FLEP cells expressing AFP, albumin, and CK-19 was 15.5%, 13.9% and 6.4%, respectively (Figure 2).

### *Effects of FLEP cell transplantation on liver function and biochemical markers of liver fibrosis*

The survival rates were not different at the end of the 3-mo experiment in the two groups of DEN-treated mice ($P > 0.05$), with 90% of DEN-treated mice in the cell transplantation group and 80% of DEN-treated mice in

**Table 1 Liver function and biochemical markers of liver fibrosis (mean ± SD)**

| Groups | *n* | ALT (U/L) | AST (U/L) | TBIL (mg/L) | HA (μg/L) | LN (μg/L) | Hyp (mg/g) |
|---|---|---|---|---|---|---|---|
| Control | 8 | 42 ± 12 | 105 ± 35 | 8.8 ± 4.2 | 54 ± 19 | 58 ± 16 | 313 ± 118 |
| DEN | 8 | 341 ± 66[b] | 506 ± 81[b] | 12.9 ± 6.1 | 362 ± 83[b] | 232 ± 63[b] | 1255 ± 205[b] |
| DEN/FLEP cell | 8 | 176 ± 21[b,d] | 332 ± 83[b,d] | 14.0 ± 5.3 | 276 ± 65[b,c] | 176 ± 31[b,c] | 650 ± 173[b,d] |

[a]$P < 0.05$, [b]$P < 0.01$ *vs* control group; [c]$P < 0.05$, [d]$P < 0.01$ *vs* model group.

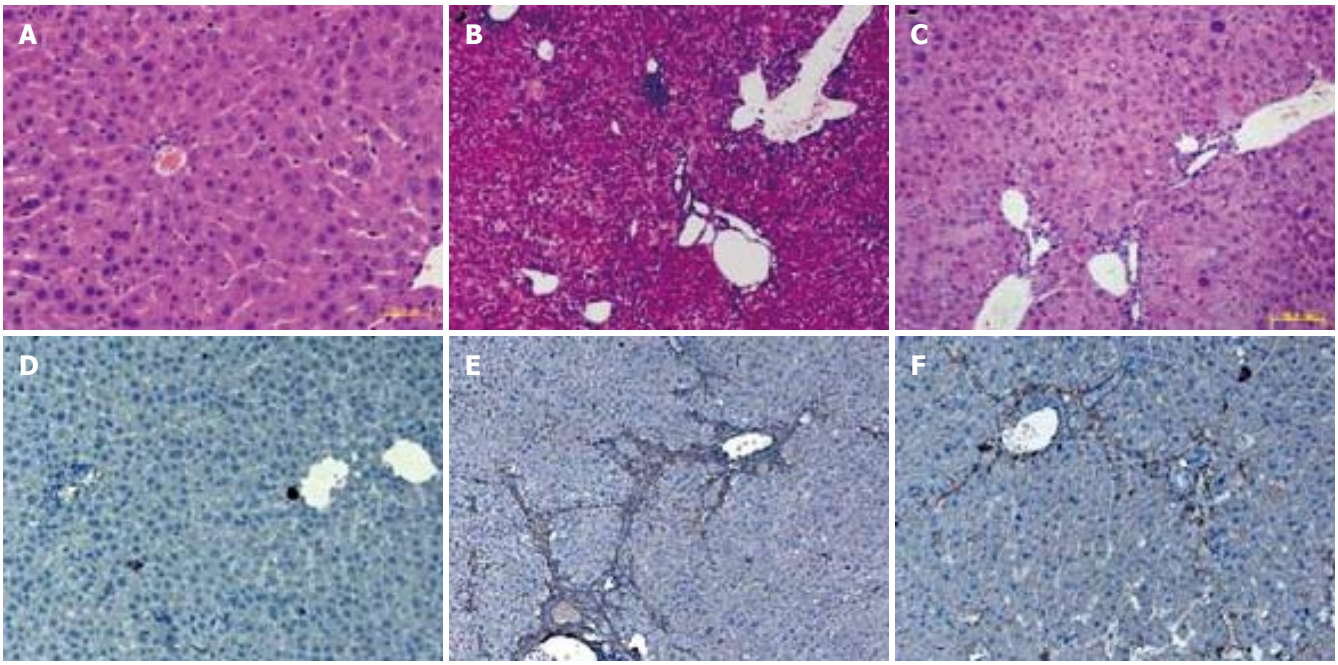

**Figure 3** Effect of FLEP cell transplantation on liver fibrosis by HE staining and immunohistochemistry of α-SMA. **A**: Normal liver tissue in control group (HE staining); **B**: Liver fibrosis in model group, fibrous tissue was formed with inflammatory cell infiltration in liver (HE staining); **C**: Liver fibrosis in FLEP cell transplantation group. The pathological change of liver was rather lighter compared with the model group (HE staining). **D**: Normal liver tissue, only α-SMA expression of vascular smooth muscle cell (immunohistochemical staining); **E**: Liver tissue in model group, displaying an increased amount of α-SMA expression with a dense network (immunohistochemical staining); **F**: Liver tissue in FLEP cell transplantation group, α-SMA expression was reduced compared with the model group (immunohistochemical staining). (original magnification, × 200).

the group without cell transplantation. Table 1 shows the values for the activities of the serum indicator enzymes and the markers of hepatic fibrosis.

DEN administration produced a marked increase in the activities of serum ALT and AST in mice ($P < 0.01$), compared with those of control group. The DEN plus FLEP cell transplantation group showed a significant decrease in the enzyme levels ($P < 0.01$), but the levels were still higher than those of control group ($P < 0.01$). Serum total bilirubin levels were similar among mice in all groups ($P > 0.05$) (Table 1).

We also examined levels of HA and LN in serum and Hyp contents in liver, which are biochemical markers of liver fibrosis. The serum levels of HA and LN in FLEP cell transplantation group was significantly decreased compared with the model group ($P < 0.05$), but the levels were still higher than those of control group ($P < 0.01$). Hyp contents of liver were significantly lower in FLEP cell transplantation group than in the model group ($P < 0.01$). However, the contents of liver in FLEP cell transplantation group were still higher than those of control group ($P < 0.01$) (Table 1).

### *Effects of FLEP cell transplantation on liver pathology*

We analyzed liver histology in mice with FLEP cell treatment using HE staining and immunohistochemistry. HE staining for sections of normal control group showed structural integrity without inflammation or fibrosis development (Figure 3A). However, DEN-induced liver injury in the model group showed fibrosis and inflammatory cell infiltration with the loss of structural integrity (Figure 3B). Nevertheless, results from DEN plus FLEP cell transplantation in the experimental group showed that FLEP cells could significantly alleviate DEN-induced fibrosis and inflammation compared with the model group (Figure 3C).

To further verify fibrosis, we analyzed α-SMA, an activating marker of mouse hepatic stellate cells by immunohistochemical staining of liver sections. Only α-SMA expression of vascular smooth muscle cell was observed in normal control group (Figure 3D). An increased amount of α-SMA expression with a dense network by activated HSC was observed in the model group (Figure 3E). However, the expression was reduced significantly in the FLEP cell transplantation group (Figure 3F).

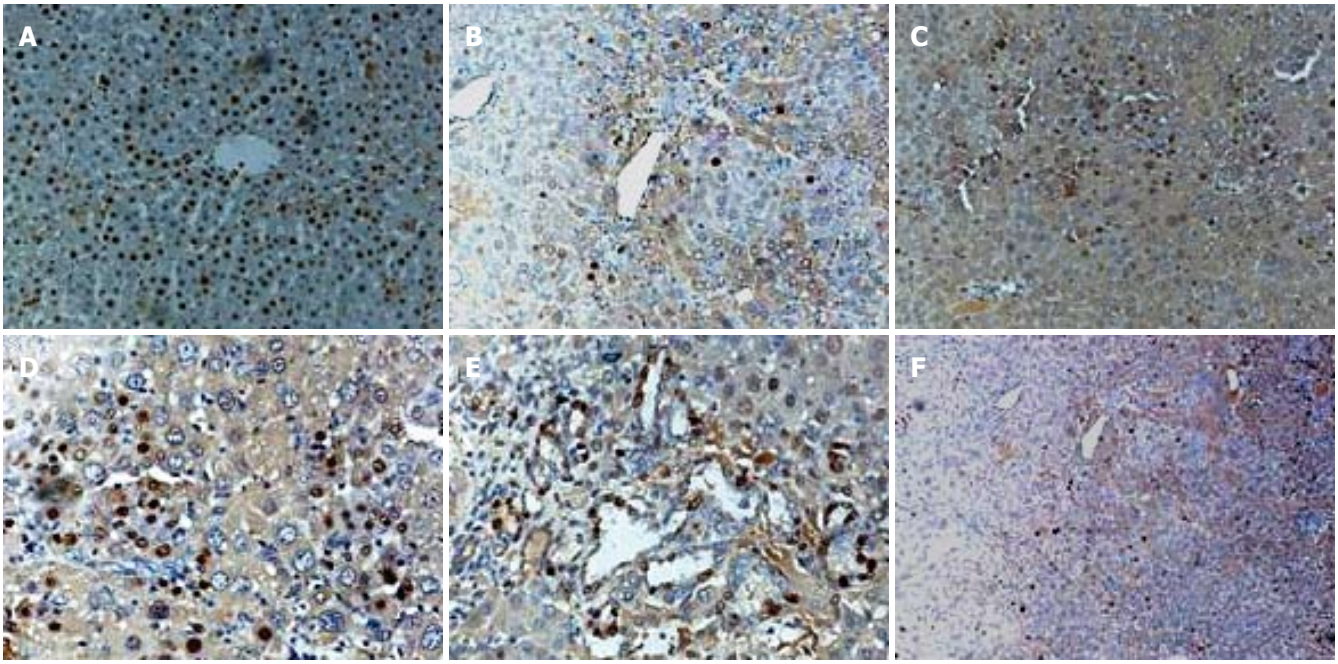

**Figure 4** Proliferation and differentiation of FLEP cells in DEN-treated mice and normal mice. **A**: Immunohistochemical positive control staining for sry protein; normal male mouse liver with nuclear positivity in the majority of hepatocytes (brown nuclei); **B**: One month after FLEP cell transplantation and DEN treatment, some cells stained for sry. **C**: Two months after FLEP cell transplantation and DEN treatment, sry$^+$ cells were present in liver parenchyma. **D** and **E**: Three months after FLEP cell transplantation and DEN treatment, sry$^+$ cells formed numerous mature hepatocytes showed canalicular structures (**D**), or bile duct epithelial cells in bile duct region, as evidenced by diffusely stained sry+ small epithelial cells in bile duct-like structures (**E**); **F**: Three months after FLEP cell transplantation without DEN treatment, scattered sry$^+$ cells were observed. Original magnifications, x 200 (**A-E**) and x100 (**D**).

### *Repopulation of liver by FLEP cells in DEN-treated mice and normal mice*

To follow the proliferation and differentiation of FLEP cells, we transplanted FLEP cells into the liver of normal and DEN-treated female mice subject to two-thirds PH. Detection of sry protein served as a marker for proliferation of transplanted FLEP cells. The sry$^+$ cells represented 50% of transplanted cells (originating from fetal liver).

In DEN-treated mice, sry$^+$ cells were distributed in the periportal regions of the liver after cell transplantation. One mo after FLEP cell transplantation into DEN-treated mice, some sry$^+$ cells were observed (Figure 4B). Two months after transplantation, sry$^+$ hepatocytes increased and were already present in the liver parenchyma (Figure 4C). Three months after transplantation, numerous sry$^+$ mature hepatocytes were observed, representing a substantial portion of the liver parenchyma (Figure 4D). We also found sry$^+$ cholangiocytes that formed mature sry positive bile ducts; sry$^+$ bile duct structures became evident as early as 1 mo after ED 14 FLEP cell transplantation, but became more numerous and fully developed in the portal regions at 3 mo (Figure 4E). The number of transplanted cells increased over time and repopulation ranged from 5%-10% at 1 mo, 15%-20% at 2 mo, and 30%-50% at 3 mo.

In the absence of DEN, sry$^+$ cells were still observed 3 mo after FLEP cell transplantation, but were less numerous and contained fewer cells (5%-10% of the total number of cells) than in DEN-treated mice (Figure 4F). In normal mice, PH was required for proliferation of transplanted FLEP cells.

## DISCUSSION

To determine whether ED 14 FLEP cells represent hepatic precursor cells, the characteristics of markers for various liver cell types have been explored, including AFP and albumin for fetal hepatocytes and CK19 for cholangiocytes. Three subpopulations of ED 14 FLEP epithelial progenitor cells have been detected. The first group of cells expressed AFP or albumin but not CK-19, comprising roughly 88% of FLEP cells. The second group (9% of total) expressed CK-19, but not AFP and albumin. The third and smallest group of cells (3% of total) expressed both AFP and albumin and CK-19[19]. Our immunohistochemical and flow cytometric analyses confirmed the existence of three distinct subpopulations of epithelial cells in 14-d fetal mouse liver. Furthermore, the present results demonstrate that immunostaining and flow cytometric analyses for the hepatic epithelial-specific markers AFP, ALB and CK-19 provided a definitive approach to characterize epithelial cell populations in the fetal liver.

We evaluated the anti-fibrosis effects of FLEP cells using a DEN-induced liver fibrosis model. DEN is a hepatotoxin, carcinogen, and mutagen, which can cause liver fibrosis. It provides a suitable experimental fibrosis model to examine human liver fibrosis[20,21]. Our results show that the transplantation of FLEP cells significantly restores the liver function and improves liver fibrosis index in DEN-injured mice. Transplanted FLEP cells can reduce necrosis collagen accumulation of liver and clearly inhibit the fibrosis formation. Moreover, levels of α-SMA positive staining of liver sections decrease significantly after FLEP cells administration in this model. This is exciting because

the expression of α-SMA in liver is an indicator of hepatic stellate cell activation, which is recognized as being critical in liver fibrogenesis[22,23]. FLEP cell transplantation thus appears to be effective for the suppression of liver inflammation and fibrosis formation.

We also investigated the underlying mechanisms regarding the repair mechanisms of transplanted FLEP cells to liver recovery after liver injury. We evaluated the stem cell properties and repopulation capacity of ED 14 FLEP cells after their transplantation into normal and chronically damaged livers. The effect of FLEP cell transplantation on reduction of liver fibrosis was studied using immunohistochemistry for sry (sex-determining region for Y chromosome) protein after sex-mismatched transplantation. Immunohistochemical staining for the sry protein offers the advantages of convenience and rapidity to enable the reliable detection and quantification of mixed chimerism in paraffin tissues[18]. We also provided evidence of sry detection in male cells, because the vast majority of cells in all male untreated control livers were positive for sry.

Stem cells are generally considered to exhibit self replication or renewal, differentiation into two or more specific cell phenotypes, and long-term repopulation of the host under appropriate circumstances. Hepatic stem cells include oval cells in canals of Hering of the adult liver and fetal liver hepatoblasts[24,25].

Our results show that FLEP cells selectively proliferate in the normal liver in response to a regenerative stimulus, such as partial hepatectomy. They differentiate into mature hepatocytes and incorporate into the host liver lobule as part of normal hepatocytic cords. Transplanted FLEP cells repopulate to comprise 5%-10% of the liver cells after 3 mo.

In this model, stimulation of the regeneration is amplified by two-thirds hepatectomy in addition to DEN administration. One month after administration of DEN, sry-positive cells were observed around the portal areas. At 2 mo, positive cells were detected in the liver lobes, indicative of FLEP cell migration into the hepatic parenchyma. At 3 mo, there was extensive proliferation and liver repopulation with FLEP cells in DEN-treated mice. The persistent liver damage made by DEN administration is important for the proliferation and differentiation of FLEP cells, and the number of cells migrating into the damaged liver is related to improvement of the liver function and suppression of liver fibrosis. These results suggest that FLEP cells themselves can functionally rescue the recipients by directly substituting the damaged cells.

More interestingly, we demonstrate that transplanted FLEP cells also can differentiate into mature bile duct epithelial cells. Our studies provide direct evidence for differentiation of FLEP cells with dual markers into hepatocytes and bile duct epithelial cells after transplantation into the regenerating liver of DEN-treated mice. This is consistent with other reports that bipotential cells of FLEP cells can proliferate and differentiate into hepatocytes and bile ducts[19,26].

In conclusion, we report that transplanted FLEP cells engraft, proliferate, and differentiate into hepatocytes and bile duct epithelial cells with high repopulation capacity in the liver fibrosis induced by DEN. FLEP cell transplantation restores liver function and reduces liver fibrosis effectively, which rescues the damaged liver by substituting the damaged cells directly. These results suggest that FLEP cell transplantation is an attractive method for chronic liver diseases.

## Abstract

**AIM:** To assess optimum endoscopic biliary drainage (EBD) in cases with unresectable pancreatic cancer in the era of gemcitabine (GEM).

**METHODS:** Thirty patients with unresectable pancreatic cancer, who presented with jaundice and underwent chemotherapy using GEM after EBD were included in this study (GEM group). Fifteen cases with the same clinical manifestation and stage of pancreatic cancer treated with EBD alone were also included as controls. A covered metallic stent (CMS) or a plastic stent (PS) was used for EBD. The mean survival time (MST) in each group, risk factors of survival time, type of stent used and associated survival time, occlusion rate of stent, patency period of stent, and risk factors of stent occlusion were evaluated.

**RESULTS:** MST in the GEM group was longer than that in the control (9.9 mo *vs* 6.2 mo). In the GEM group, the survival time was not different between those who underwent metallic stenting and those who underwent plastic stenting. Stent occlusion occurred in 60% of the PS group and 7% of the CMS group. The median stent patency in the PS-GEM group and the CMS-GEM group was 5 mo and 7.5 mo, respectively. Use of a PS was the only risk factor of stent occlusion.

**CONCLUSION:** A CMS is recommended in cases presenting with jaundice due to unresectable pancreatic cancer, since the use of a CMS makes it possible to continue chemotherapy using GEM without repetition of stent replacement.

**Key words:** Gemcitabine chemotherapy; Endoscopic biliary drainage; Covered metallic stent; Pancreatic cancer; Unresectable pancreatic cancer; Obstructive jaundice

## INTRODUCTION

Pancreatic cancer is one of the most intractable malignancies of the digestive tract and has a dismal prognosis. Such cancer in most patients is in an advanced stage when they first visit medical facilities, and management of obstructive jaundice caused by the tumor is of great concern in the treatment. Endoscopic biliary drainage (EBD) is the mainstay in the control of jaundice[1-5]. Due to a relatively short survival time after establishment of the diagnosis, placement of a plastic stent is considered to be reasonable from the viewpoint of cost-effectiveness[2,3,6-8]. The development of anticancer agents, however, has necessitated reassessment of the optimal choice of stents in this patient group. We evaluated the optimum EBD in cases with unresectable pancreatic cancer in the era of gemcitabine (GEM) chemotherapy.

## MATERIALS AND METHODS

### *Subjects*

One hundred and twelve patients with unresectable pancreatic cancer presented with obstructive jaundice at our medical center during the period from May 2001 to March 2005. Of those, 30 patients (age, 80 years or less; Karnofsky performance status, 60% or greater; stage Ⅳ or greater) who achieved successful decompression of the biliary tree by EBD and underwent chemotherapy with GEM were included in this study (GEM group). Fifteen cases that fulfilled the same criteria and were treated by EBD and the best possible supportive care without chemotherapy during an earlier period (May 1997 to November 2000) were selected as a control. The demographics of the two groups are shown in Table 1.

**Table 1 Patients characteristics**

| | GEM group $n$ = 30 | Control group $n$ = 15 | $P$ |
|---|---|---|---|
| Age (yr) | 61 ± 10 | 67 ± 8 | 0.06 |
| Male/Female | 21/9 | 7/8 | 0.13 |
| Stage (Ⅳa/Ⅳb) | 22/8 | 7/8 | 0.08 |
| PS/CMS | [1]15/15 | 11/4 | 0.32 |

GEM: gemcitabine; PS: plastic stent; CMS: covered expandable metallic stent. [1]The PS was exchanged to CMS after occulusion in 4 patients.

**Table 2 Prognostic factors of survival by univariate analysis**

| | OR | 95% CI | $P$ |
|---|---|---|---|
| Age | 1.03 | 1.00-1.06 | 0.08 |
| Gender (Female) | 1.56 | 0.81-2.99 | 0.18 |
| Stage (Ⅳb) | 2.36 | 1.15-4.84 | 0.02 |
| Liver metastasis (+) | 2.55 | 1.24-5.22 | 0.01 |
| Gemcitabine (-) | 2.72 | 1.35-5.48 | 0.01 |

### Methods

GEM was administered in a standard manner, i.e., a drip infusion of 1000 mg/m$^2$ at a stable speed was given once per week for three consecutive weeks with an interval of one week between courses. After confirming a decrease in the serum total bilirubin level of 20 mg/L or less, administration of GEM was started. When some adverse events occurred, administration of GEM was postponed or its dose was reduced. Adverse effects were evaluated following National Cancer Institute Common Terminology Criteria for Adverse Events ver.3.0 (CTCAE)[9]. The stents used were covered expandable metallic stents 10 mm in caliber (covered biliary Wallstent, Boston Scientific Co.) (CMS) and plastic stents 10 Fr in diameter (Double Layer Biliary Stent, Olympus Co.) (PS). In the GEM group, CMS was placed in 15 patients (CMS-GEM group) and PS was applied in the remaining 15 (PS-GEM group). In the control group, CMS was deployed in 4 patients (CMS-alone group), while PS was applied in the remaining 11 (PS-alone group). The period of stent patency was measured from the day of stenting to the day when the initial occlusion was diagnosed. Stent occlusion was defined as development of cholangitis or jaundice with abnormalities in laboratory tests indicating bile stasis. When a PS has clogged and was replaced with a CMS, the duration from placement of PS to its occlusion was regarded as the patency period of PS. As for survival time, the total period was counted as PS in such cases. In the CMS group, when the stent was occluded and was replaced with a PS, the duration between the initial stenting and the second stenting was measured as the patency period of CMS, and the total time until death was regarded as the survival time for this group. The median survival time (MST) was calculated based on the definition of survival time as the time from the day of hospitalization to that of death or the last date of confirmed survival. The following were evaluated: (1) MST of the GEM group and the control, (2) prognostic factors, (3) correlation between the stent applied and survival time, (4) occlusion rate and patency of stents, (5) risk factors of stent occlusion, and (6) complications of stenting and adverse events of GEM.

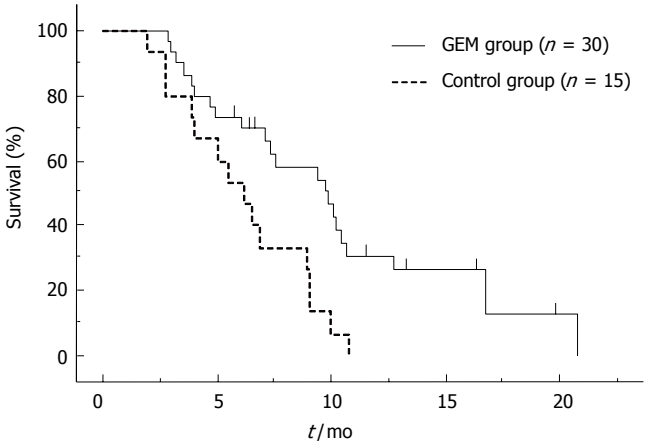

**Figure 1** Survival time in GEM and control groups (9.87 ± 0.33 *vs* 6.23 ± 0.93, $P$ = 0.004).

### Statistical analysis

Stat View v5.0 was used for statistical analysis. Comparison of the two groups was carried out using the Chi-square test, the unpaired $t$ test (Student's $t$- test), or the Mann-Whitney $U$ test, MST and the median patency time of stents were evaluated by the Mantel-Cox log rank test of the Kaplan-Meier curves. For the analysis of the risk factors of stent patency and survival, univariate analysis by Cox's proportional hazard model followed by multivariate analysis was performed.

## RESULTS

The mean survival time in the GEM group and the control was 9.9 mo and 6.2 mo, respectively (9.87 ± 0.33 *vs* 6.23 ± 0.93, $P$ = 0.004, Figure 1). The following were listed as prognostic factors of survival by univariate analysis: clinical stage of pancreatic cancer (Ⅳa *vs* Ⅳb, $P$ = 0.02; OR = 2.36; 95% CI, 1.15-4.84), liver metastasis (+ *vs* -, $P$ = 0.01; OR = 2.55; 95% CI, 1.24-5.22), and GEM treatment (+ *vs* -, $P$ = 0.01, OR = 2.72; 95% CI, 1.35-5.48) (Table 2). Multivariate analysis, however, revealed that none of these prognostic factors had reached the level of significance. The survival curves of the PS group and the CMS group with/without GEM are shown in Figures 2 and 3. There were significant difference between the PS-alone group and the PS-GEM group (5.53 ± 0.94 *vs* 10.1 ± 2.70, $P$ = 0.02), as well as between the PS alone group and the CMS-GEM group (5.53 ± 0.94 *vs* 9.87 ± 0.43, $P$ = 0.001). The difference between the CMS-GEM group and the PS-GEM group was not significant (9.87 ± 0.43 *vs* 10.1 ± 2.70, $P$ = 0.26, Figure 4). Stent obstruction was observed more frequently in the PS group than in the CMS group (PS *vs* CMS, $P$ = 0.0002; OR = 26.4; 95% CI, 11.4-14.6). Only one patient developed stent occlusion (1/15, 7%), which was due to overgrowth of the tumor in the CMS-GEM group; this was treated by additional PS stenting. The stent patency in the PS-GEM group and PS-alone group was 5.0 mo and

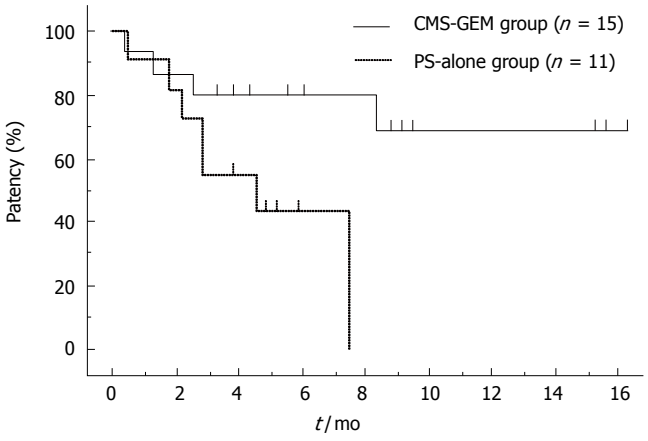

**Figure 7** Stent patency in CMS-GEM and PS-alone groups (7.49 ± 0.82 *vs* 4.53 ± 1.31, *P* = 0.01).

4.5 mo, respectively (5.00 ± 2.26 *vs* 4.53 ± 1.31, *P* = 0.59, Figure 5). Compared with these two groups, the CMS-GEM group showed a patency of 7.5 mo (not reached) (5.00 ± 2.26 *vs* 7.49 ± 0.82, *P* = 0.03 and 5.00 ± 4.53 *vs* 1.31 ± 0.82, *P* = 0.01, respectively, Figures 6 and 7). Univariate analysis revealed use of a plastic stent to be the only risk factor of stent occlusion (*P* = 0.01; OR = 4.7; 95% CI, 1.48-15.4, Table 3). One patient each in the CMS-GEM and the CMS-alone groups developed acute cholecystitis. Either dislodgement of a stent or development of acute

Administration of gemcitabine (GEM) was abandoned due to adverse effects in 4 patients.

pancreatitis after stent placement was observed. In the GEM group, 24 patients (89%) showed adverse effects of GEM on the bone marrow system, these effects benign grade 3 or greater in 4 patients. Reduction of the dose of GEM was necessary in 3 patients due to bone marrow suppression and in 7 due to digestive symptoms such as nausea and anorexia. Finally, administration of GEM was abandoned due to adverse effects in 4 patients (Table 4).

## DISCUSSION

Before starting chemotherapy, biliary drainage is mandatory in patients with unresectable pancreatic cancer who present with obstructive jaundice. Endoscopic biliary drainage (EBD) is now widely used for such purpose. Many studies have been published on the selection of stents in EBD[1-5]. With regard to PS, development of Teflon stents[4,10] has not been able to prolong the patency period much longer than that of polyethylene stents[5,11-13]. Many a study has revealed the patency of metallic stents to be longer than that of PS[1-3]. The reported patency is 3-5 mo for PS[1-3,5,7,14] and nearly 9 mo for metallic stents[1-3,14]. In current clinical practice, stent selection is based on the stage of malignancy and expected prognosis. Distant metastasis, tumor size, and local extension are considered to be prognostic factors[15-17]. In cases with short life expectancy (4-6 mo or less), such as in advanced pancreatic cancer, occlusion of PS usually does not occur before death, and application of PS is considered to be adequate from the viewpoint of cost-effectiveness as well[2,3,6-8]. Thus far, chemotherapy, radiation and chemoradiotherapy have been performed for patients with unresectable pancreatic cancer, which necessitates hospitalization. However, the results have been quite unsatisfactory. Development of GEM has had an impact on the treatment. Rothenburg *et al*[18] reported significant prolongation of survival with GEM in their phase Ⅱ study of patients in whom 5-FU was not effective. Burris *et al*[19] carried out a randomized controlled trial on the comparison of GEM with 5-FU in cases without previous chemotherapy, and reported that although mass reduction was observed in only 5.4% of the cases, alleviation of symptoms was achieved in 23.8% with a significant difference. The survival time was also significantly prolonged in the patient group treated with GEM compared with that in the 5-FU group. GEM is given to patient by drip infusion at a stable speed that requires a relatively short time without critical side effects, enabling its administration on an outpatient basis. Shortening of the period of hospitalization is quite meaningful for patients with poor prognoses. In this study, prolongation of MST by GEM in patients with stage Ⅳ pancreatic cancer was confirmed. With respect to MST, there was no difference between the CMS-GEM group and the PS-GEM group. However, stent occlusion developed more frequently in the PS-GEM group than in the CMS-GEM group (60% *vs* 7%). Stent occlusion may necessitate postponement of administration of GEM and requires additional intervention or hospitalization, which leads to deterioration of the patient's QOL. Possible influences of GEM on the patency of stents are prolongation of patency by controlling the tumor mass and shortening of patency by clogging subsequent to biliary infection induced by bone marrow suppression. As the comparison of stent patency in the PS-GEM group and that in the PS-alone group showed no difference, GEM may have no or only a subtle effect on the stent patency. Acute cholecystitis, which was managed conservatively, was the only complication relevant to stenting. Discontinuance of GEM due to adverse effects was necessary in only 16% of the patients. When compared to that of the PS group, the stent patency of the CMS-GEM group was longer. It is expected that those patients who are to undergo GEM will have a longer survival than that before GEM was available. The significance of the maintenance of stent patency is much greater than before as it can eliminate readmission due to stent occlusion and postponement of GEM. Development of effective chemotherapy, including a combination of some agents, will further extend the significance of longer stent patency further. The selection of stents should be reassessed from this point of view. Based on the data shown here, we suggest that the use of CMS should be considered in patients with unresectable pancreatic cancer presenting with jaundice that are to undergo GEM. Further studies including cost-benefit assessment and a randomized, prospective comparison trial with metallic and plastic stents are necessary.

## Abstract

**AIM:** To relate the endoscopic findings in patients with hematochezia with regard to age in "low and average risk" for colorectal cancer (CRC) and to localize significant lesions in order to identify patients who need sigmoidoscopy or total colonoscopy.

**METHODS:** This prospective study was performed in an open access GI endoscopy unit. Out of 4322 consecutive patients undergoing colonoscopy, 918 reported hematochezia. The final study group comprized 180 patients aged below 45 and 237 over 45. Main exclusion criteria were a 1st-degree family history of colorectal carcinoma, patients reporting blood mixed with stools and/or progressive colonic symptoms, or patients who had undergone colon surgery for neoplastic lesions.

**RESULTS:** Total colonoscopy could be performed in 96% of patients. Abnormal findings were observed in 34.3% of the younger and in 65.7% of the older ones. Findings were the presence of polyps in the distal colon ($n$ = 2) and IBD in the proximal colon ($n$ = 29) in the group of the younger patients, and polyps ($n$ = 15), IBD ($n$ = 13), and carcinoma ($n$ = 6, 4 of the lesions were located proximal to the splenic flexure) in the elderly. Our findings suggest that the diagnostic potential of total colonoscopy in patients younger than 45 referring scant hematochezia, is not mandatory. By exploring only the distal tract of the colon we have misdiagnosed two cases of IBD located in the ascending colon. In this group of patients additional risk factors must be identified before performing a total colonoscopy. Regarding the patients older than 45 yr, the exploration of the distal colon would have led to our overlooking a carcinoma, two neoplastic polyps and one IBD located in the proximal colon.

**CONCLUSION:** Young patients with scant hematochezia but without risk factors for neoplasia do not need a total colonoscopy, whereas is mandatory performing a total colonoscopy in older patients even in the presence of anal pathology.

**Key words:** Hematochezia; Colonoscopy; Neoplasia; Colonic neoplasia

## INTRODUCTION

Hematochezia defined as a chronic intermittent passage of a small amount of bright red blood from the rectum is a clinical problem frequently found in adults of all ages. Its prevalence in the apparently healthy general population is between 9% and 19%[1-5] and in general practice this means 6 consultations every 1000 over 45-year-olds a month[6]. Almost 20% of colonoscopies are prompted by rectal bleeding[7,8].

In addition to its high prevalence, hematochezia is a symptom to be considered carefully, since it is known to be associated also with neoplastic diseases (adenoma, cancer). Studies showed that 7%-10% of patients with chronic overt rectal bleeding did in fact have a colorectal cancer[5-7].

Since neoplastic and non neoplastic diseases may also coexist, a complete diagnostic work-up is indicated including clinical evaluation (clinical history, physical examination of the anal region, digital anorectal exploration), anoscopy, and endoscopic evaluation of the colon. It is a source of controversy as to whether scant hematochezia necessitates total colonoscopy as a first-line procedure or a 60 cm flexible sigmoidoscopy[9-18].

The aims of this study were: (1) to identify the type and prevalence of endoscopic findings in two groups of patients with hematochezia alone aged under *vs* over 45 years old; (2) to ascertain the distal (rectum, sigmoid, descending colon) or proximal (transverse and ascending colon) location of "significant lesions" in order to establish which patients need total colonoscopy.

## MATERIALS AND METHODS

The study was performed prospectively on 4322 consecutive out-patients undergoing colonoscopy during a two-year period (November 2004-October 2005) at the "open access" Unit of Gastroenterology and Digestive Endoscopy at University of Catania, in eastern Sicily-Italy (Figure 1).

Before colonoscopy all patients were asked about the colour of the expelled blood, the frequency and duration of the bleeding episode, and how the blood appeared (on stools, on toilet paper, on the toilet, or mixed with stools).

Exclusion criteria were age below 18 years, positive 1$^{st}$-degree family history of CRC, patients reporting blood mixed with stools, and those whose bleeding was severe enough to require transfusion or hospitalization, patients who reported progressive colonic symptoms, those who had undergone colon surgery for neoplastic lesions, and those who had already had a colonoscopy within the previous year.

After clinical evaluation, all patients underwent anal inspection and anoscopy. Regardless of any anal pathologies detected, all patients underwent total colonoscopy. Endoscopy was performed by 5 expert endoscopists (> 5000 colonoscopies) in patients after the ingestion of 4 litres of polyethylene glycol solution.

The endoscopic evaluation was considered complete when the entire colonic mucosa was visualized. Patients whose colon had been inadequately cleansed and cases in which anatomical or technical problems had prevented a complete exploration of the colon were excluded. Endoscopic findings were classified as normal, inflammatory bowel disease (IBD), neoplastic disease (adenoma and carcinoma), diverticulosis, or angiodysplasia.

Neoplastic polyps > 10 mm, colorectal carcinoma, and colitis were defined as "significant lesions". The pathologies identified were classified as proximal (situated in the transverse and/or ascending colon) and distal (between the rectum and the splenic flexure). The numerical values obtained are expressed as a percentage and the two groups of values were compared using the chi-square test and the Fisher's exact test; a value of $P < 0.05$ was considered statistically significant.

## RESULTS

### *Endoscopic diagnosis*

From 4322 patients who underwent colonoscopy over a two-year period, the indication was hematochezia in 918 cases (21.2%), and other lower digestive tract symptoms in 3404 cases (78.8%).

From 918 patients with hematochezia, 417 (45.4%) met the inclusion criteria (Figure 1). This study group was composed of 244 males (mean age 50.5 ± 14.6 years, range 19-93) and 173 females (mean age 51 ± 14.6 years, range 18-96) yielding a male/female ratio of 1.4:1. 43.2% of these patients (180/417) were between 18 and 45 years old, while 56.8% (237/417) were older than 45 (Table 1).

Proctological examination revealed anal lesions potentially responsible for the bleeding in 265 cases (63.5%). Endoscopy was performed up to the cecum in 96.0% of the patients (417/430) with no complications worthy of note. The 13 incomplete explorations were due to poor colon cleaning ($n$ = 7), abnormal sigmoid-descending colon length ($n$ = 4), and low patient compliance ($n$ = 2). The most common pathologies detected were polyps ($n$ = 77, 18.5%), diverticular disease ($n$ = 44, 10.5%), IBD ($n$ = 42, 10%), and carcinoma ($n$ = 6, 1.4%) (Table 2).

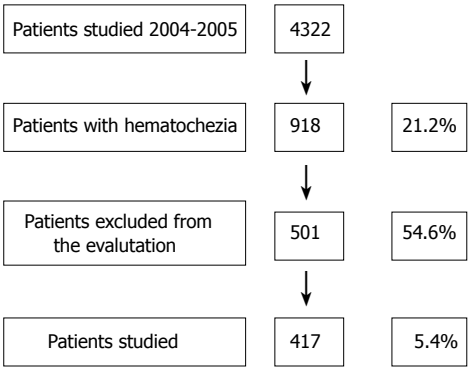

**Figure 1** Study profile.

**Table 1 Demographic data of patients with hematochezia**

| | |
|---|---|
| Patients ($n$) | 417 |
| Men/women | 244/173 |
| Mean age (yr) | 50.5 ± 14.6 |
| Range | 18-96 |
| < 45 years old | 180 (43.2%) |
| > 45 years old | 237 (56.8%) |

**Table 2 Diagnosis ($n$ = 493) in patients with hematochezia ($n$ = 417)**

| Diagnosis | $n$ | % |
|---|---|---|
| Anal pathology | 265 | 63.54 |
| Polyps | 77 | 18.46 |
| (< 10 mm) | 60 | 14.38 |
| (> 10 mm) | 17 | 4.07 |
| Diverticular diseases | 44 | 10.55 |
| IBD | 42 | 10.07 |
| Normal finding | 55 | 13.18 |
| Carcinomas | 6 | 1.43 |
| Angiodysplasia | 4 | 0.95 |
| Total | 493 | |

### *Endoscopic diagnosis with regard to age*

Table 3 shows the endoscopic diagnoses with regard to the patients' age. Anal lesions potentially responsible for hematochezia were seen in 57.2% of the patients (103/180) younger than 45 and in 68.4% (162/237) of the patients older than 45. This difference did not reach statistical significance ($P < 0.84$).

Total colonoscopy revealed pathologies in 45.6% (82/180) of the younger, and in 61.6% (146/237) of the older patients.

None of the younger patients had diverticular disease,

**Table 3 Endoscopic diagnoses in patients with hematochezia**

| Diagnosis | Age group (yr) | | | | *P* |
|---|---|---|---|---|---|
| | < 45 (*n* = 180) | | > 45 (*n* = 237) | | |
| | *n* | % | *n* | % | |
| Anal pathology | 103 | 57.2 | 162 | 68.4 | < 0.05 |
| Polyps | 15 | 8.3 | 62 | 26.2 | < 0.0001 |
| Diverticular diseases | 0 | - | 44 | 18.6 | < 0.0001 |
| IBD | 29 | 6.1 | 13 | 5.5 | < 0.001 |
| Normal finding | 35 | 19.4 | 20 | 8.4 | < 0.01 |
| Carcinomas | 0 | - | 6 | 2.5 | < 0.05 |
| Angiodysplasia | 3 | 1.6 | 1 | 0.4 | NS |

**Table 4 Significant lesions in relationship to age and proximal or distal location of lesions in patients with hematochezia**

| Significant lesions | Age group (yr) | | | | *P* | Location | | Tot. |
|---|---|---|---|---|---|---|---|---|
| | < 45 (*n* = 180) | | > 45 (*n* = 237) | | | Proximal | Distal | |
| | *n* | % | *n* | % | | *n* | *n* | |
| Polyps | 2 | 1.1 | 15 | 6.3 | < 0.05 | 1 | 16 | 17 |
| IBD | 29 | 16.1 | 13 | 5.5 | < 0.001 | 5 | 37 | 42 |
| Carcinomas | 0 | - | 6 | 2.5 | < 0.05 | 1 | 5 | 6 |
| Total | 31 | | 34 | | | 7 | 58 | |

while this was found in 18.6% (44/237) of the older patients. The presence of neoplastic polyps and carcinomas was also much greater in the latter, with a statistically significant difference, particularly for carcinoma ($P < 0.0002$). Rectal bleeding (which has predictive value for the diagnosis of CRC) increased with age: it was 1.0 (95% CI 0.12-3.64) among patients younger than 45 *vs* 6.2 (95% CI 1.30-17.19) for those over 45. No carcinoma was diagnosed among the younger patients, but they had a higher prevalence of IBD (29/180, 16.1%) than the older younger ones (13/237, 5.5%)

Among the 417 patients considered, 65 "significant lesions" were diagnosed in 64 patients (15.3%) (one patient had 2 lesions) including IBD ($n = 42$), polyps with a diameter > 10 mm ($n = 17$), and carcinoma ($n = 6$). Six of these lesions (3 cases of IBD, 2 polyps and 1 carcinoma) were located in the proximal tract of the colon and 59 (39 IBD, 15 polyps and 5 carcinomas) in the distal tract.

As for the age-related prevalence of significant lesions, the patients younger than 45 had 2 polyps > 10 mm and 29 cases (16.1%) of IBD, while the patients over 45 had 15 polyps, 13 cases (5.5%) of IBD, and 6 carcinomas (Table 4).

### *Age-related distribution of "significant lesions" on the colon mucosa*

Figure 2 correlates the patients' ages with the prevalence of "significant lesions" in the proximal and distal colon.

Thirty-one of the 64 patients (48.4%) with "significant lesions" were up to 45 years old and none had carcinoma. Two patients were diagnosed with polyps > 10 mm, both located in the distal colon. Twenty-nine were cases of IBD, two in the proximal colon and 27 in the left colon. Two (non neoplastic) significant lesions would have gone undiagnosed in this younger group if only flexible sigmoidoscopy had been carried out.

Thirty-four of the 64 patients (53.1%) with significant lesions were over 45 years old and included all 6 cases of carcinoma, 15 polyps > 10 mm and 13 cases of IBD. Four of these lesions (1 carcinoma, 2 polyps > 10 mm and 1 IBD) were located proximal to the left flexure and were consequently beyond the reach of flexible sigmoidoscopy (Table 4).

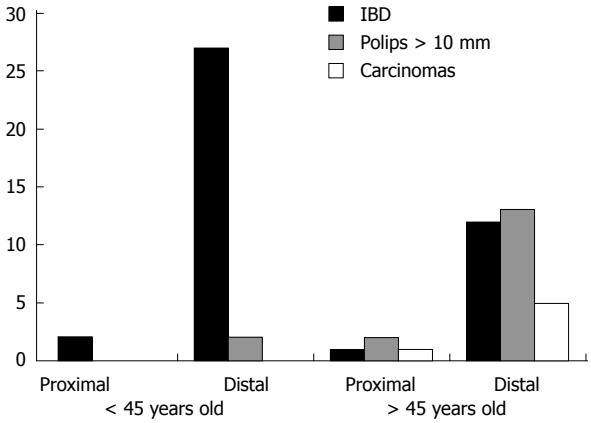

**Figure 2** Age-related location of "significant lesions" on the colonic mucosa.

## DISCUSSION

The passage of blood through the anus is a common symptom in adults and coincides with anal pathologies in 27%-74% of cases[16,19]. In our sample, the prevalence of anal lesions was 63.5%, with no statistically significant difference between the two age groups considered (under/over 45 years old: 57.2% *vs* 68.4%).

Since a large proportion of these patients only bleed from the anus, performing colonoscopy in all cases would only burden the endoscopy unit with an unjustified increase in costs. That is why numerous studies have been performed in an attempt to stratify patients at low and high risk of severe proximal colon according to their bleeding symptoms, but such analyses have produced contradictory results.

In 3 studies[16,20,21], haemorrhoid-type blood loss has rarely been associated with significant pathologies at proximal colon level, so the authors concluded that anal inspection with the rectosigmoidoscope suffices in such situations. Different conclusions were reached in three other papers finding no correlation between anal bleeding symptoms and the severity or location of colonic lesions[14,22].

Similar results were reported in a large prospective assessment that found no correlation between anal bleeding and colonic lesions: the authors concluded that total colonoscopy with a rectosigmoidoscope is always a safe, effective choice, and is also less expensive. This paper also stressed that 3 carcinomas were diagnosed in proximal colon segments among 45 patients under 45 years old[18].

Contrasting opinions are also expressed in the guidelines prepared by the American Society for Gastrointestinal Endoscopy (ASGE) and the European Panel for Appropriateness of Gastrointestinal Endoscopy (EPAGE): while the former specify that middle-aged or older individuals must always undergo a total colonoscopy, even in the presence of an anal lesion that could justify

the hematochezia[23], the latter consider total colonoscopy inappropriate when the source of bleeding has been ascertained by ano- or sigmoido-scopy[24].

When anal lesions causing bleeding are detected, the choice of investigation method should be based on the evaluation of two variables: the bleeding symptoms and the patient's age. For hematochezia patients up to 45 years old, we believe that exploring the colon up to the left flexure is sufficient, whereas it is best to examine all of the mucosal surface in older patients[19,25-30]

It is important to remember, however, that this approach is valid for diagnosing carcinoma, but could overbook up to 7% of other, equally significant pathologies[27]. Our findings suggest that the diagnostic potential of total colonoscopy is low in population up to 45-year-old referring scant hematochezia. By exploring only the distal tract of the colon, we have misdiagnosed two case of IBD located in the ascending colon. In patients under 40 years old, additional risk factors must be identified before performing a total colonoscopy i.e. chronicity (even if it is an intermittent bleeding), the discharge of blood mixed with stools, and a 1st-degree family history of colorectal cancer. Concerning this last point, the *American Cancer Society* (ACS) guidelines suggest that individuals with a positive 1st-degree family history of colorectal carcinoma must undergo total colonoscopy if they are 45 or older, irrespective of any presence or absence of lower digestive tract symptoms[31]. As regard as patients over 45 years endoscopic exploration of the whole colon is indicated even is a distal cause of the bleeding was ascertained.

In the older group of patients, the exploration of the distal colon alone would have led to our overlooking a carcinoma and a neoplastic polyp (> 10 mm) both located in the hepatic flexure. In conclusion, the diagnostic algorithm to adopt in the case of hematochezia can be as follows:

- total colonoscopy is always warranted for patients older than 45 years;

- for patients younger than 45 with no risk factors (e.g. discharge of blood mixed with stools, positive 1st-degree family history of colorectal carcinoma, or clinical history of progressive colorectal disease), rectosigmoidoscopy is initially sufficient. The work-up should be completed with a total colonoscopy in cases of haemorrhage during follow-up despite the site of bleeding having been identified and a suitable therapy implemented.

Such guidelines are justified by the fact that significant lesions can occur, albeit rarely, even in the proximal colon of young adults with a negative family history for colorectal cancer. Failing to consider such a hypothesis has devastating clinical consequences for the patient and also exposes the family physician and specialist to medico-legal consequences.

In the USA, the majority of lawsuits for malpractice have to do with the misdiagnosis of colorectal carcinomas[5,9].

## Abstract

**AIM:** To evaluate the effect of relaxing music during colonoscopy under low-dose conscious sedation, on patient satisfaction, scope insertion time and procedure duration, medication doses, and the perceived adequacy of sedation and scope insertion difficulty on the part of the endoscopist.

**METHODS:** One hundred and sixty-seven consecutive adult outpatients presenting for routine colonoscopy under low-dose conscious sedation were randomized to undergo their procedures either with music played during the procedure or no music played.

**RESULTS:** There were no statistical differences between the two groups in terms of meperidine dose, midazolam dose, time to reach the cecum, total procedure time, endoscopist assessment of scope insertion difficulty, endoscopist assessment of adequacy of sedation, or the pain experience of the patients during their procedure. The music group did report significantly better overall procedure satisfaction as compared to the non music group on two of our three different scales.

**CONCLUSION:** While music does not result in shortened procedure times, lower doses of sedative medications or perceived patient pain, the patients who have music playing during their procedures report modestly greater satisfaction with their procedures.

**Key words:** Colonoscopy; Gastrointestinal endoscopy; Music; Music therapy; Relaxation music

## INTRODUCTION

Colonoscopy plays an important role in the prevention of colon cancer through the diagnosis and removal of premalignant polyps. It is also the most accurate diagnostic tool for the detection of inflammatory bowel disease and many other structural lesions of the colon. Patient satisfaction with a particular medical procedure, including colonoscopy, reflects a number of variables, including the amount of anxiety prior to the procedure and the amount of anxiety and discomfort during it[1]. Anxiety about a procedure and fear of pain are also the reasons why some patients refuse endoscopic procedures for colon cancer screening[2].

The therapeutic uses of music have involved a number of disciplines of medicine, including cardiology, radiology and pulmonary medicine. For instance, studies have shown that music may decrease the anxiety of patients admitted to coronary intensive care units following cardiac surgery, and of patients undergoing stressful procedures like magnetic resonance imaging and bronchoscopy[3-6]. Studies of patients undergoing gastrointestinal endoscopic procedures have also shown that music tends to decrease patient anxiety[7-9]. However, the effects of music have been much more inconsistent when one looks at other outcomes such as pain, procedure time, doses of sedative medications, and patient vital signs. Some studies have reported shorter procedure times[10] and a reduced need for sedative medications[10-12] in colonoscopy patients who listen to music.

We conducted a randomized controlled trial of the use of relaxing music during outpatient colonoscopy done under low-dose conscious sedation, to examine its effects on patient satisfaction and pain, and to see if music has any beneficial effects on endoscopic parameters including colonoscope insertion time, medication doses, and insertion difficulty and adequacy of sedation from the standpoint of the endoscopist.

## MATERIALS AND METHODS

The study was approved by the Institutional Review Board of the University of Missouri-Columbia. One-hundred and sixty-seven consecutive patients presenting for elective outpatient colonoscopy were offered entry into this prospective study. Patients were only told that we were collecting information to assess their attitudes regarding colonoscopy before and after the procedure. They were not told that they were participating in a study to assess the beneficial effects of music. Exclusion criteria were: patients

with a history of prior colon resection, patients scheduled to undergo same-day esophagogastroduodenoscopy (EGD) and colonoscopy, and inability to give informed consent. One patient declined to participate in the study.

The study was single-blinded (from the standpoint of patients). Patients agreeing to participate in the study were randomized to either a music group or a non music group. Randomization was carried out by the use of opaque envelopes, half of which containing a piece of paper that said "music," and the other half containing a piece of paper that said "no music." In the music group, a CD player was playing relaxing music upon the entrance of the patient into the procedure room. We played the same music for all patients in the music group: "Watermark" by Enya (Reprise Records, a Time Warner Company, 1988), which contains 12 tracks (ranging from 1:59 to 4:25 in length). The CD was set on repeat.

Before starting any procedures, patients were given a written questionnaire, administered by one of the investigators (RAP). Patients rated their anxiety about having the colonoscopy on a visual linear analog (VLA) scale[13], in which the patient was asked to place a mark, representing anxiety, on a 100-mm long line, that was scored from 0 to 100, with 0 representing "not anxious at all" and 100 representing "extremely anxious".

All procedures were performed by one of the four experienced gastroenterologists utilizing Olympus colonoscopes (Olympus America Inc, Melville, NY). Trainees were not involved in any of the procedures. Patients were sedated with meperidine and midazolam. Procedures were started after the patient received 50 mg of meperidine and 1 or 2 mg of midazolam. Additional medication was given at the discretion of the endoscopist.

Procedures were timed by one of the investigators (RAP) who observed all the procedures quietly in the room. This investigator recorded the time required to reach the cecal base (insertion time) and the total procedure time.

After each procedure, the endoscopist graded the procedure difficulty on two scales. The "insertion difficulty Ⅰ scale" is a 100-mm VLA scale where 0 represents "very easy" and 100 represents "very difficult". The "insertion difficulty Ⅱ scale" is a five-point scale: 1 = very easy; 2 = relatively easy; 3 = average; 4 = somewhat difficult; and 5 = very difficult. The endoscopist also graded the adequacy of sedation on a four-point scale: 1 = satisfactory; 2 = anxious; 3 = agitated; and 4 = combative.

Following all procedures and just prior to discharge, the patients were given a written post-procedure questionnaire by the same investigator to assess their experience/satisfaction. The "experience Ⅰ scale" is a four-point scale which includes the following responses: 1 = pleasant; 2 = tolerable; 3 = difficult; and 4 = unacceptable. The "experience Ⅱ scale" is a five-point scale which includes the following responses: 1 = much better than I expected; 2 = somewhat better than I expected; 3 = about what I expected; 4 = somewhat worse than I expected; and 5 = much worse than I expected. The "experience Ⅲ scale" is a 100-mm VLA scale where 0 represents "pleasant", and 100 represents "worst experience I ever have". The "pain experience scale" is a 100-mm VLA scale where 0 represents "not painful at all" and 100 represents "unbearable". Patients were also asked if they would like to have "relaxing music" played at their next colonoscopy.

**Table 1 Population demographics and results of pre-procedure patient questionnaires**

| | Music ($n$ = 85) | No music ($n$ = 81) | $P$ |
|---|---|---|---|
| Age (yr) | 58.5 | 54.1 | 0.036 |
| Gender (% females) | 51.8 | 48.1 | 0.64 |
| Prior colonoscopy (%) | 36.5 | 30.9 | 0.45 |
| Pre-procedure anxiety (mm) | 36.3 | 45.1 | 0.053 |

The sample size of our study was estimated based on the data obtained during previous trials we performed on colonoscopy, so that we could detect a difference in the mean procedure time of 3 min between the two groups. Descriptive statistics were used to summarize baseline and outcome variables of the two groups. Mean was used to summarize normally or approximately normally distributed continuous variables. Median was used to summarize non-normally distributed ordinal variables. Proportion was used to summarize nominal variables. Chi-square test and Fisher's exact test were used to compare categorical variables. Both parametric ($t$-test) and non-parametric (Wilcoxon rank-sum test) tests were used to compare continuous variables. $P < 0.05$ was considered statistically significant.

## RESULTS

Table 1 summarizes the population demographics and results of the pre-procedure patient questionnaires for the music and non-music groups. They were similar in terms of gender (51.8% females for the music group *vs* 48.1% for the non-music group, $P = 0.64$) and history of prior colonoscopy (36.5% *vs* 30.9%, $P = 0.45$). The music group was slightly older (58.5 years *vs* 54.1 years, $P = 0.036$), and reported less pre-procedural anxiety (36.3-mm *vs* 45.1-mm, borderline significance at $P = 0.053$).

The indications for colonoscopy were colorectal cancer screening in 24, rectal bleeding in 67, positive fecal occult blood test in 13, anemia in 8, polyp follow-up in 24, chronic diarrhea in 15, change in bowel habits in 9, abdominal pain in 4, and ulcerative colitis surveillance in 2. The distribution of indications in the two groups was similar.

The results of various colonoscopy outcomes and the results of post-procedure questionnaires given to endoscopists are given in Table 2. There was no difference between the two groups in terms of doses of sedative medications, time to reach the cecum, total procedure time, perceived colonoscope insertion difficulty, or perceived adequacy of sedation.

The results of post-procedure patient questionnaires are given in Table 3. Patients reported a better overall experience on the three experience scales, though the difference only attained a statistical significance on the experience Ⅰ and Ⅲ scales ($P = 0.045$ and $P = 0.037$ respectively, compared to $P = 0.080$ for the experience

**Table 2 Procedure outcomes and results of the questionnaire given to endoscopists**

| Outcome | Music ($n$ = 85) | No music ($n$ = 81) | $P$ |
|---|---|---|---|
| Meperidine dose (mg)[1] | 57.0 | 54.6 | 0.68 |
| Midazolam dose (mg)[1] | 1.92 | 1.85 | 0.46 |
| Time to reach cecum (min)[1] | 10.4 | 9.2 | 0.46 |
| Total procedure time (min)[1] | 20.7 | 21.0 | 0.84 |
| Insertion difficulty Ⅰ scale (mm)[1] | 40.9 | 36.5 | 0.47 |
| Insertion difficulty Ⅱ scale (1-5)[2] | 3 | 3 | 0.31 |
| Adequacy of sedation scale (1-4)[2] | 1 | 1 | 0.093 |

[1] Mean value; [2] Median value.

**Table 3 Post-procedure patient questionnaire results**

| Outcome | Music ($n$ = 85) | No music ($n$ = 81) | $P$ |
|---|---|---|---|
| Experience Ⅰ scale (1-4)[2] | 2 | 2 | 0.045 |
| Experience Ⅱ scale (1-5)[2] | 1 | 2 | 0.080 |
| Experience Ⅲ scale (mm)[1] | 22.5 | 28.1 | 0.037 |
| Pain experience (mm)[1] | 25.3 | 25.4 | 0.8 |
| Want music at next colonoscopy (%) | 96.3 | 56.1 | < 0.0001 |

[1] Mean value; [2] Median value.

Ⅱ scale). The perception of pain in the two groups was similar when compared using unpaired $t$-test ($P$ = 0.8). More patients in the music group requested music at the next colonoscopy ($P$ < 0.0001).

## DISCUSSION

Music has been proposed as a useful adjunct for patients undergoing a variety of medical experiences and procedures, including gastrointestinal endoscopy. Music trials relating to gastrointestinal (GI) endoscopic procedures, can be categorized as those that have examined flexible proctosigmoidoscopy[7,8], colonoscopy[9-12], and a mix of upper endoscopy and colonoscopy[14-16]. The one consistent effect that therapeutic music seems to have beneficial effects in the setting of GI endoscopy is to decrease procedure-related anxiety[7-9,16]. Consistent with the anxiolytic effects of music is the observation that music may also decrease heart rates and blood pressure values in patients undergoing lower GI endoscopic procedures[7,12].

However, the effects of music on other outcomes besides anxiety have been much less consistent. Two small studies, one involving 50 flexible sigmoidoscopy patients[7] and the other involving 32 colonoscopy patients[12], showed that the reduction of heart rate and blood pressure values is associated with music. However, no difference has been seen in music-associated vital signs in a trial of 198 patients undergoing upper endoscopy and colonoscopy[16]. Three music trials in colonoscopy patients found that the need for sedative medications is reduced in patients listening to music[10-12], while a trial of music in upper endoscopy and colonoscopy patients has found no difference[5]. A small trial of patients undergoing flexible proctosigmoidoscopy[8] reported that abdominal pain is less severe in patients listening to music. However, other GI endoscopic trials have not found any difference in pain scores[11,15].

Our randomized controlled trial examined the use of music in the outpatient colonoscopy setting in adult patients receiving relatively light conscious sedation (the mean dose of meperidine and midazolam in our patient population was approximately 50 mg and 2 mg respectively). We observed a modest improvement in the overall satisfaction with the colonoscopy experience in patients who listened to music. The music group also expressed a strong preference for having music played again if they would undergo another colonoscopy in the future. However, we found no difference in patients' perception of pain, colonoscope insertion time, total procedure time, doses of sedative medications, or endoscopists' ratings of the difficulty of scope insertion and adequacy of sedation.

Our study has several limitations and weaknesses. First, our results are only applicable to colonoscopy patients who receive light conscious sedation. In many, even most practice settings in America at the present time, patients undergoing colonoscopy are sedated substantially heavier than our patients were sedated in this study.

Second, the benefits of music we observed are modest. We employed just one selection of music for all patients. It is possible that giving patients many more selections and letting them select the music they want would result in greater benefits. This would also be made easier by letting patients use headphones.

Third, the baseline characteristics of the two groups are different. The music group was somewhat older and expressed less pre-procedure anxiety as compared to the non music group. However, since the music group was older and less anxious than the non music group, one might have anticipated that medication administration should have been much less for the music group, assuming that music decreases medication administration. To the contrary, sedative medication doses were not statistically different between the two groups. Therefore, the amount of sedative medication was not benefited from the use of music during colonoscopy.

In conclusion, our study demonstrates that the use of relaxing music during colonoscopy performed under light conscious sedation can modestly improve the overall patient satisfaction. However, in contrast to some other published trials, we did not find a benefit in terms of shortening scope insertion or procedure times, reducing sedative medication doses, or decreasing patients' perceptions of pain. Nonetheless, the observation that music can improve patient satisfaction provides a rationale for its use as a safe adjunct during colonoscopy procedures when light conscious sedation is used. Specific areas in need of further investigation include the role of patient-selected music, the best way to deliver music, the role of music before and during recovery from procedures, and the use of combined audio-visual stimulation in the improvement of patient satisfaction at colonoscopy.

## COMMENTS

### *Background*

Over the years, music has been used as a therapeutic modality in numerous disciplines of medicine to help reduce anxiety. Though studies of the use of music as an adjunct to GI endoscopic procedures are limited, it has been suggested that relaxing music might reduce anxiety, shorten procedure time, and reduce the doses of sedative medications needed.

### *Research frontiers*

Further research is needed to better define how music can be used to improve patient satisfaction and other outcomes associated with GI endoscopy. Specific areas in need of further investigation include the role of patient selected music, the best way to deliver music, the role of music before and during recovery from procedures, and the use of combined audio-visual stimulation.

### *Innovations and breakthroughs*

Our study demonstrates that the use of relaxing music during colonoscopy performed under light conscious sedation can modestly improve the overall patient satisfaction. However, in contrast to some other published trials, we did not find a benefit in terms of shortening scope insertion or procedure time, reducing sedative medication doses, or decreasing patients' perceptions of pain. Nonetheless, the observation that music can improve patient satisfaction provides a rationale for its use as a safe adjunct during colonoscopy procedures, particularly when light conscious sedation is used.

### *Applications*

The results of our study and others published in the field support the use of relaxing music during colonoscopy done under light conscious sedation as a way of improving patient satisfaction and possibly decreasing patient anxiety. The results also provide impetus for the study of relaxing music in patients being prepared for and awaiting their procedures, and during their post-procedure recovery.

### *Peer review*

The paper provides support for the practice of using relaxing music during colonoscopy procedures done under light conscious sedation.

## Abstract

**AIM:** To assess the extent and reasons of non-compliance in surveillance for patients undergoing polypectomy of large (≥ 1 cm) colorectal adenomas.

**METHODS:** Between 1995 and 2002, colorectal adenomas ≥ 1 cm were diagnosed in 210 patients and subsequently documented at the Erlangen Registry of Colorectal Polyps. One hundred and fifty-eight patients (75.2%) could be contacted by telephone and agreed to be interviewed. Additionally, records were obtained from the treating physicians.

**RESULTS:** Fifty-four out of 158 patients (34.2%) neglected any surveillance. Reasons for non-compliance included lack of knowledge concerning surveillance intervals (45.8%), no symptoms (29.2%), fear of examination (18.8%) or old age/severe illness (6.3%). In a multivariate analysis, the factors including female gender ($P$ = 0.036) and age > 62 years ($P$ = 0.016) proved to be significantly associated with non-compliance in surveillance.

**CONCLUSION:** Efforts to increase compliance in surveillance are of utmost importance. This applies particularly to women's compliance. Effective strategies for avoiding metachronous colorectal adenoma and cancer should focus on both the improvement in awareness and knowledge of patients and information about physicians for surveillance.

**Key words:** Colorectal adenoma; Colorectal cancer; Surveillance colonoscopy; Non-compliance

## INTRODUCTION

Regular surveillance is strongly recommended for patients who have undergone an intestinal polypectomy due to the high adenoma recurrence rate and elevated risk of subsequent colorectal cancer (CRC)[1-4]. In particular, according to the guidelines of the Germany Society of Digestion and Metabolism [Deutsche Gesellschaft für Verdauung und Stoffwechsel (DGVS)], a surveillance colonoscopy should be performed in Germany not longer than 3 years after the initial polypectomy, regardless whether a single or multiple adenoma is resected[4]. When no metachronous adenoma is found at the 3-year surveillance colonoscopy, the next surveillance colonoscopy should be performed no later than 5 years. Clinically important colorectal adenomas include large (≥ 1 cm) lesions, those with a high degree of dysplasia, and those with villous histology. In particular, adenoma diameter is considered an important marker of malignant potential due to the fact that a larger adenoma at baseline is associated with a higher risk of CRC[5,6]. In persons who have been found to have a large colorectal adenoma, the colon cancer incidence rate is approximately 4 times higher than the normally expected incidence rate[7-10]. In a study by Gandhi *et al*[11], the 5-year recurrence rate after polypectomy of a colorectal adenoma was 40.93% (1651/4046) while the malignancy rate was 2.17% (88/4046). Although the length and schedules of surveillance programs are not clarified, a follow-up interval of no longer than 3 years in high-risk patients seems justified[4,12].

However, only 11%-51% of all participants with a resected polyp (≥ 1 cm in diameter) have ever returned for a follow-up colonoscopy[2,3,13,14]. Little is known about the reasons of non-compliance in those high-risk patients. However, awareness of the underlying reasons is the cornerstone for changing the prevailing attitude towards colonoscopy surveillance. Therefore, the purpose of

this retrospective study was to evaluate the surveillance behavior in patients undergone resection of a clinically relevant (≥ 1 cm) colorectal adenoma.

## MATERIALS AND METHODS

### Patients and survey methods

The Erlangen Registry of Colorectal Polyps (ERCRP) was established in 1978. Since then all clinico-pathological features concerning resected colorectal carcinomas have been prospectively recorded in this database. In addition, all colorectal polyps removed by endoscopy in the Department of Medicine or in the Department of Surgery of Erlangen University Hospital were prospectively documented and histologically categorized by the Department of Pathology in accordance with the WHO classification[15]. The size of all removed adenomas was accurately measured in the Department of Pathology. Patients whose adenomas were proved to contain invasive carcinomas at the initial examination and patients with inflammatory bowel disease were excluded from this survey. According to the guidelines of the DGVS, a surveillance colonoscopy should be performed after polypectomy at a time interval no longer than three years[4]. These recommendations were part of the discharge letter after initial polypectomy. However, automatic reminders for surveillance colonoscopies were usually not sent to the patients. The present study comprised the period from 1995 to 2002, because prior to these period follow-up recommendations have not been specified and a follow-up no longer than 3 years seemed to be adequate.

### Study variables and analysis

From 1995 to 2002, colorectal adenomas (≥ 1 cm in diameter) were diagnosed in 210 patients by complete colonoscopy. These adenomas were subsequently resected by endoscopic polypectomy or by surgery. Whether the death of 47 patients was due to CRC was evaluated according to the data obtained from the corresponding treating physician.

A total of 163 patients were still alive at the time of our study and could be contacted by telephone. Verbal consent was obtained about their willingness to take part in this survey and to obtain additional information from the treating physician before starting the interview. After the exclusion of 5 patients who refused to take part in this survey, 158 patients were interviewed by a trained research assistant.

Our standardized interview consisted of 10 questions. In the case of non-attendance to the follow-up colonoscopy, some items were skipped and the reasons of non-compliance were asked as shown in Appendix 1.

Additionally, the treating physician of the respective patient was addressed by an official letter from our department, in which he/she was asked to answer a standardized interview of 4 questions shown in Appendix 2.

In the case of not answering our survey for six weeks after having posted the letter, the corresponding physician was called by telephone and the interview based on the interview items, was orally performed.

Information on age, gender, localization of the initial adenoma and indication for initial polypectomy were obtained from the Erlangen Registry of Colorectal Polyps (ERCRP). An overview about the study setup is shown in Figure 1.

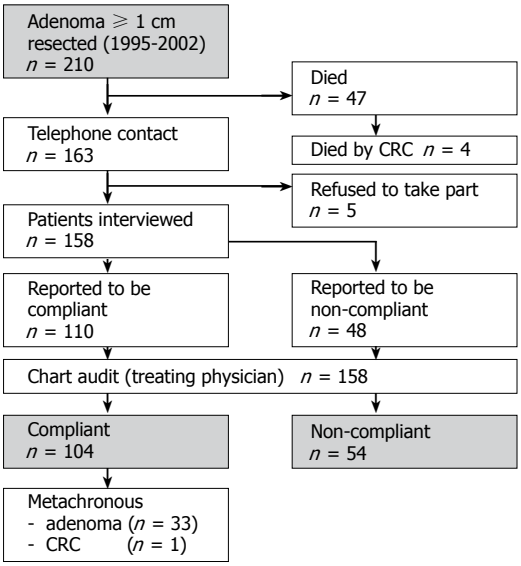

**Figure 1** Flow chart about the study setup.

### Statistical analysis

The significance of differences between the specific proportions was tested by the Fisher's exact test and differences between average values by the non-parametric Mann-Whitney test. Two-sided *P* value less than 0.05 was considered statistically significant. The relative importance of risk factors was assessed by the Cox's stepwise proportional hazard model. Statistical analyses were performed with SPSS version 13 ( SPSS Inc, Chicago, USA).

## RESULTS

A total of 210 patients with a colorectal adenoma (≥ 1 cm in diameter) were diagnosed at Erlangen University Hospital and tested for surveillance. No interview could be carried out with 52 patients, either because they refused to take part in the survey ($n = 5$) or because they died ($n = 47$). According to the corresponding records or to the information given by the treating physician and the civil registry office records, death occurred in 4 (8.5%) of 47 patients at a median period of 9. 2 years after initial colonoscopy due to CRC.

One hundred and fifty-eight patients could be interviewed. The clinico-pathological characteristics of the patients are shown in Table 1. One hundred and four (65.8%) out of the 158 patients underwent regular surveillance colonoscopies. In 33 out of the 104 patients (31.7%) at least one metachronous adenoma was discovered in at least one of the surveillance colonoscopies. The median size of the metachronous adenoma was 1.3 cm (range 0.3 cm to 2.2 cm). A colonic cancer [transverse colon, pT2pN0M0 (UICC I)] was diagnosed in one out of 104 surveillance participants and

| No | 78 (62.9) | 46 (37.1) | 0.140 |

[1]Fisher's exact 2-sided test.

could resected in a curative (R0) manner. An incongruence between the statements of the patients and treating physician concerning the existence of metachronous adenomas was found in 7 (6.7%) out of the 104 patients. Of the 7 patients, 3 wrongly assumed that they had a metachronous colorectal adenoma, and 4 assumed that they had no metachronous adenoma in contrast to the records. The size ($P$ = 0.318), localization ($P$ = 0.213) and histology ($P$ = 0.268) of adenoma as well as the grade of dysplasia ($P$ = 0.135) were not significantly associated with compliance. Furthermore, education ($P$ = 0.979), daily intake of nonsteroidal anti-inflammatory drugs (NSAID) ($P$ = 0.140) and a family history of CRC ($P$ = 0.441) were not significantly related to compliance.

Fifty-four (34.2%) out of 158 patients did not participate in a current surveillance program. Forty-eight (88.9%) out of 54 patients communicated this fact during the telephone interview, and discrepancies between the statements of the patients and the treating physician were found in 6 patients. The main reasons why the 48 patients did not report compliance included no knowledge about the surveillance intervals ($n$ = 22, 45.8%), no symptoms ($n$ = 14, 29.2%), fear of examination ($n$ = 9, 18.8%) or old age/severe illness ($n$ = 3, 6.3%). Difference in gender was also the reason for non-compliance. Male participants reported mainly that they had no symptoms while female patients explained that they had no knowledge about the surveillance intervals. However, there was a trend towards significance in this gender specific difference ($P$ = 0.071) (Figure 2).

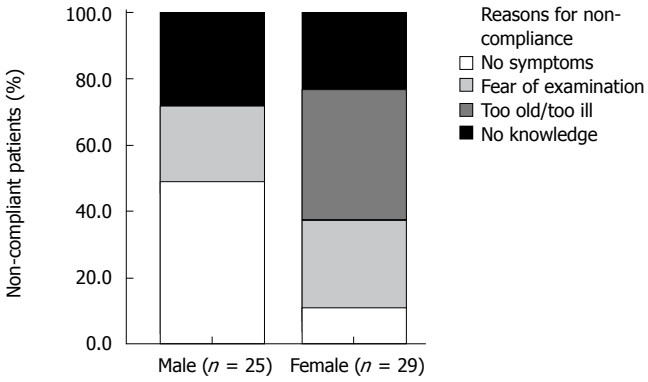

**Figure 2** Gender specific reasons for incompliance in 48 patients with large colorectal adenomas ($P$ = 0.071).

[1]Cox's stepwise proportional hazard model.

Stratifying various clinico-pathological features between compliance and non-compliance showed that the factors including age > 62 years ($P$ = 0.011) and female gender ($P$ = 0.021) were significantly associated with non-compliance. A multivariate analysis revealed that both were proved to be independent factors for non-compliance (Table 2).

## DISCUSSION

Our findings show that more attention must be paid to the evaluation of CRC screening and the improvement of screening compliance. More than one third (34.1%) of the patients undergone a polypectomy are still alive, and never have any of the recommended controls. Taking into account that most of the patients who died did not attend any follow-up colonoscopy, up to 48% had non-compliance, which is in concordance with several studies reporting that only 11%-51% of all participants with resected polyp have returned for a follow-up colonoscopy[2,3,13,14]. However, a recently study reported that 91% patients underwent follow-up colonoscopy[6], indicating that accurate recall data of testing are required, especially by the treating physician who is responsible for the follow-up of patients. Indeed, most patients in our study with current surveillance were regularly informed by their treating physician and 93.3% of them had knowledge

about the results of the follow-up colonoscopies.

Who are the patients with non-compliance and what is their motivation? Unexpectedly, a significantly higher rate of compliance was found in men than in women during surveillance colonoscopies in our study. In particular, female sex was independently associated with non-compliance. This is *prima facie* surprising and in contrast to data on cancer screening for breast or cervical cancer, according to which 77% of women reported that they have undergone a mammogram and a papanicolaou smear within the past 2 years[16]. However, the participation rates seem to be different in CRC screening where procedures are involved, which may be perceived as disgusting or embarrassing[17]. In particular, only 27% of women undergoing regular breast and cervical cancer screening reported that they have undergone sigmoidoscopy in the preceding 5 years[16]. Furthermore, numerous studies indicate that the participation rates for prophylactic CRC screening are significantly higher in men than in women[18-21]. Although the risk of CRC is similar in men and women, CRC is considered a man's disease[22].

To our knowledge, no data on gender effects are available so far concerning surveillance colonoscopies after resection of a relevant colorectal adenoma. Therefore, in order to understand and improve the compliance rate, it is most important to know the reasons for refusing follow-up strategies. Furthermore, identifying the reasons for the failure to obtain surveillance is an important public health issue, as early detection of recurrences decreases CRC occurrence and societal cost[23,24].

Not having knowledge about surveillance intervals is the reason for non-compliance most frequently mentioned. In particular, 45% of the non-compliant patients and 50% of the female patients considered that they were not informed of the screening procedures by their physicians. These data show the essential importance of the primary care doctors in colorectal surveillance and are somewhat comparable with data from a study by Mandelson *et al*[25], who reported that lack of recommendation by their primary care doctor as a reason for not undergoing initial colorectal cancer screening in older women. However, in contrast to our data, probably all patients undergoing polypectomy in their study were told by the endoscopist to return for a surveillance examination. In contrast to USA, automatic reminders are not usually sent out by the specialists in Germany. Therefore, until now, it is the responsibility of patients and their primary care doctors to arrange surveillance colonoscopies.

Interestingly, the non-compliant patients in our study were not more interested in further information on colorectal adenomas and screening recommendations than patients under current surveillance. In particular, only 9 (16.7%) out of 54 patients without any follow-up coloncoscopy were interested in further information. One explanation might be the fact that most of the non-compliant patients were not aware of the importance of follow-up and that they were not sufficiently informed about running an increased risk of recurrent adenomas and CRC in contrast to the whole population. Another possible explanation might be the fact that these persons wished to avoid unfavorable health information[26]. In addition, flexible sigmoidoscopy trial from the United Kingdom showed that interest in information on colorectal screening is significantly associated with attendance at colorectal screening[20], which is in accordance with our data. Having no symptoms is a reason for incompliance. In our study, 45% of the male patients and only 15% of the female patients brought forward this argument. Furthermore, it is a widespread misbelief, especially in male patients, that bowel cancer development is associated with pain and gastrointestinal symptoms at an early stage.

Some limitations should be considered in interpreting our results. Since the study population pertains to a single university hospital, it remains unclear whether our findings are applicable to other populations in other medical settings. Future studies are obviously needed to corroborate our findings and address this potential limitation. Other considerations in generalizing our findings are the limited number of incompliant patients, the amount and reasons of non-compliance. This assumption is supported by the fact that most of the patients had no interest in further information although they were incompliant.

Of the 210 patients in the present study, 5 (2.4%) developed CRC during the follow-up, 4 died of it, and 33 had a diagnosed metachronous adenoma. This is in accordance with data recently published by us and others, showing that patients with clinically relevant adenomas ($\geqslant$ 1 cm) run an increased risk of recurrence and CRC[3,6,27]. Therefore, careful and frequent total colonoscopies (at intervals not longer than 3 years as long as metachronous adenomas are detected) for patients have to be warranted. Special recommendations have been proposed for patients with a family history of colorectal adenoma or CRC, who ran an increased risk of developing CRC[12].

Family history of CRC was stated by 19 (12.0%) of 158 patients in our study. However, only 14 (73.7%) of the 19 (73.7%) patients with a burden of familial CRC underwent follow-up colonoscopies after a relevant colorectal adenoma was removed. This lack of compliance is consistent with a study by Pho *et al*[28], who evaluated the communication about familial CRC risk in patients with newly diagnosed colorectal adenomas, and demonstrated evidence of poor communication, as only 41% of the patients were aware of the fact that their first-degree relatives run an increased risk of CRC, and stated the need for novel strategies to promote awareness and facilitate screening.

In conclusion, efforts have to be made to further increase CRC surveillance, especially in patients who have undergone resection of a clinically relevant adenoma. Particularly in women and patients with a family history of CRC or adenoma, effective strategies improving the awareness of recurrence and increased CRC risks are needed. Additionally, a thoughtful design of data management systems that document the available data and inform the treating physicians of screening and surveying patients, is necessary to reduce CRC morbidity and mortality.

## ACKNOWLEDGMENTS

The authors thank Dr. Corinna Koebnick, oec. troph.,

statistics at the German Institute for Nutrition, Potsdam-Rehbruecke, Germany, for statistical supervision.

## APPENDIX 1

The standardized interview with the patients contained the following questions and information.

(1) The currently treating physician (name and address);

(2) The question of whether a surveillance colonoscopy was performed not longer than three years after the initial polypectomy (yes/no);

(3) The surveillance intervals and the issue of whether the patient was informed of the pending surveillance colonoscopy;

(4) The main reason for a follow-up colonoscopy (What was the main reason for you to have a follow-up?"

□ Routine

□ Having symptoms

(5) The recurrence of metachronous colorectal adenoma ("Has an additional adenoma been discovered at follow-up?" (Yes/no).

In the case of non-attendance to the follow-up colonoscopy, items 3-5 were skipped and the patients were asked for

(6) The reasons of non-compliance ("What was the main reason for you not having a follow-up colonoscopy to date?". The possible answers were:

□ Not knowing about follow-up intervals

□ Having no symptoms

□ Having fear about the endoscopic examination

□ Old age / severe illness for surveillance.

All patients were asked for

(7) Known cases of colorectal cancer in the family history (yes/no)

(8) A daily intake of non-steroidal anti-inflammatory drugs (e.g. aspirin®) (yes/no)

(9) The attendance to the last grade of high school (which approximately corresponds to the German term "Abitur") (yes/no)

(10) Their interest in additional information on surveillance after polypectomy (yes/no).

## APPENDIX 2

The standardized interview with the treating physicians contained the following questions.

(1) Whether the named patient was under his/her treatment (yes/no)

(2) Whether a family history of previous colorectal cancer incidents was known in the patient concerned (yes/no)

(3) Whether a follow-up colonoscopy was performed

□ Yes

□ No

□ No information

(4) In case of a follow-up colonoscopy, whether a metachronous colorectal adenoma or a carcinoma was ever found (yes/no).

## Abstract

**AIM:** To assess pre-orthotopic liver transplantation (OLT) factors that could be evaluated pre-operatively or controlled post-operatively associated with hepatocellular carcinoma (HCC) recurrence and disease-free survival after liver transplantation (LT).

**METHODS:** Four hundred and twelve patients transplanted for HCC between 1988 and 1998 in 14 French centers, who survived the postoperative period were studied. Kaplan Meier estimates were calculated for 24 variables potentially associated with recurrence of HCC. Uni- and multivariate analyses were conducted to identify independent predictors of recurrence.

**RESULTS:** Overall 5-year disease-free survival was 57.1%. By univariate analysis, variables associated with disease-free survival were: presence of cirrhosis ($P$ = 0.001), etiology of liver disease ($P$ = 0.03), $\alpha$ fetoprotein level (< 200, 200 to 2000, or > 2000; $P$ < 0.0001), $\gamma$-GT activity (N, N to 2N or > 2N; $P$ = 0.02), the number of nodules (1, 2-3 or $\geqslant$ 4; $P$ = 0.02), maximal diameter of the largest nodule (< 3 cm, 3 to 5 cm or > 5 cm; $P$ < 0.0001), the sum of the diameter of the nodules (< 3 cm, 3 to 5 cm, 5 to 10 cm or >10 cm; $P$ < 0.0001), bilobar location ($P$ = 0.01), preoperative portal thrombosis ($P$ < 0.0001), peri-operative treatment of the tumor ($P$ = 0.002) and chemoembolization ($P$ = 0.03), tumor differentiation ($P$ = 0.01), initial type of calcineurin inhibitor ($P$ = 0.003), the use of antilymphocyte antibodies ($P$ = 0.02), rejection episodes ($P$ = 0.003) and period of LT ($P$ < 0.0001). By multivariate analysis, 6 variables were independently associated with HCC recurrence: maximal diameter of the largest nodule ($P$ < 0.0001), time of LT ($P$ < 0.0001), tumor differentiation ($P$ < 0.0001), use of anti-lymphocyte antibody (ATG) or anti-CD3 antibody (OKT3) ($P$ = 0.005), preoperative portal thrombosis ($P$ = 0.06) and the number of nodules ($P$ = 0.06).

**CONCLUSION:** This study identifies immunosuppression, through the use of ATG or OKT3, as a predictive factor of tumor recurrence, and confirms the prognostic value of tumor differentiation.

**Key words:** Immunosuppression; Hepatocellular carcinoma; Tumor differentiation; Liver transplantation

## INTRODUCTION

Hepatocellular carcinoma (HCC) is one of the most common neoplasms and its incidence is currently rising worldwide[1-3]. HCC usually occurs in cirrhotic livers and less than 30% of patients presenting with HCC are considered candidates for resection[4]. When liver transplantation (LT) was first developed, it was hoped that it would provide a cure for patients with unresectable HCC. However, it became apparent that both intra- and extra-hepatic post-transplant recurrence were frequent, accounting for poor mid-term survival[5-9]. Subsequently, some predictors of recurrence were identified[10-13] in order to select those who may benefit from LT, among patients with HCC.

During the past decade, liver transplantation criteria for HCC were refined and are currently based on the number and size of tumors[10,13]. Other predictors of recurrence have been more recently proposed[14-20]. Some of them, such as micro-vascular involvement[14-18] cannot be assessed prior to LT. Others, such as bi-lobar distribution of HCC[14,18] the sum of diameters of all tumors[19] or tumor differentiation[15-17,19-20] could be evaluated preoperatively and used in clinical practice. In addition, the impact of post transplant factors on HCC recurrence, such as the intensity and type of immunosuppression, have been little studied[21].

The aim of this study was, therefore, to assess in a large series of patients transplanted for HCC, the prognostic value of recurrence criteria, including those more recently proposed, as well as variables that could be evaluated pre-operatively or controlled post-operatively.

## MATERIALS AND METHODS

### Patients

Patients transplanted for HCC between 1988 and 1998 in 14 French liver transplant centers were studied. Patients with incidental HCC, which were defined as tumors diagnosed on the explanted liver but not prior to transplant, were excluded.

Based on these criteria, a cohort of 467 patients was identified. Fifty-five (11.8%) patients who died postoperatively and were not exposed to the risk of recurrence were excluded from the analysis of factors associated with recurrence. Therefore, the final study population consisted of 412 patients who had been transplanted for HCC and were suitable for analysis of recurrence and tumor-free survival. The features of these 412 patients are shown in Table 1.

**Table 1 Clinical features of the study population**

| | |
|---|---|
| Age (yr) | 52.7 ± 9.2 |
| Sex (M/F), *n* (%) | 339 (82.3)/73( 17.7) |
| Etiology: Alc./Vir./Metab./Miscel[1], *n* (%) | 136 (33.2)/236 (57.3)/ 8(2.0)/32 (7.5) |
| Cirrhosis (yes/no), *n* (%) | 377 (91.5)/35 (8.5) |
| AFP (μg/L) | 26.9 (ext: 0.5-245.240) |
| Number of nodules | 1.8 ± 1.3 (median: 1, range: 1-11) |
| Maximum diameter (cm) | 4.1 ± 3.1 (median: 3.4, range: 0.6-25) |
| Bilobar location (yes/no), *n* (%) | 105 (25.5)/307 (74.5) |
| Portal or hepatic vein obstruction (yes/no) (*n*) | 33 (8.1)/379 (91.9) |

### Methods

Charts of the 412 patients were individually reviewed and the following data were collected.

**Pretransplant data:** Demographics, etiology and severity of liver disease, liver biochemical tests and prothrombin time, α fetoprotein level, Karnofsky index[22], pretransplant treatments of HCC during the waiting time and time from evaluation to LT (months) were noted. Cirrhotic patients were classified according to Child-Pugh classification[23].

Morphological features and preoperative staging of HCC were evaluated from medical reports of abdominal imaging including ultrasonography, angiography, dynamic computed tomography, and contrast-enhanced magnetic resonance imaging, when available. The number, size, and locations of the tumors as well as the presence of a vascular obstruction were assessed. When the number and size of the nodules differed between the different imaging techniques, the technique that showed the largest number of nodules and the largest nodule was taken into account. From their preoperative characteristics, HCCs were classified according to the modified TNM staging classification for liver transplantation[24] (Figure 1) and according to the Milan Criteria[13] (Table 1).

Treatments of HCC during the waiting time were also assessed [pre-operative treatment: surgery, transarterial chemoembolization (TACE) or percutaneous ethanol injection (PEI)], as well as the immediate post-operative treatments (Table 1).

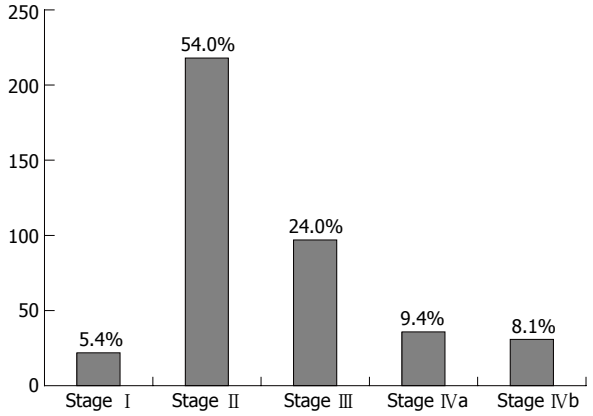

**Figure 1** Staging of tumors according to the modified TNM classification for liver transplantation[24]. T0: Tumor not found; T1: 1 nodule < 1.9 cm; T2: 1 nodule 2.0-5 cm; 2 or 3 nodules, all <3 cm; T3: 1 nodule > 5.0 cm; 2 or 3 nodules, at least 1 > 3.0 cm; T4a: 4 or more nodules, any size; T4b: T2, T3, T4a plus gross intrahepatic portal or hepatic vein involvement as indicated by US, CT or MRI; N1: Involvement of regional (porta hepatitis) nodes; N2: Metastatic disease, including extrahepatic portal or hepatic vein involvement.

**Pathological study of the tumors:** Results of pretransplant tumor biopsies were available in 79 patients. Tumor differentiation was therefore determined by reviewing the pathological reports of the explanted livers, to obtain a larger set of data. Tumor differentiation was graded in 3 stages (grade 1: well-differentiated tumors, grade 2: moderately differentiated tumors and grade 3: poorly differentiated tumors) according to the modified Edmondson Criteria[25]. In case of several tumors showing different stages of differentiation on the explanted liver, the worst grade of differentiation was arbitrarily chosen. Tumor differentiation was obtained in 358 patients (85.4%). It could not be obtained in 40 patients because of total necrosis of tumor nodules due to pre-LT treatment (transarterial chemoembolization or percutaneous ethanol injection), and was not available in 14 patients. Other pathological features which could not be assessed pre-operatively, such as microvascular invasion, number and size of tumor nodules on the explanted liver were also available but were deliberately not taken into account in the present study.

**Posttransplant data:** The type of immunosuppressive drugs (calcineurin inhibitors *vs* antilymphocyte antibodies) (Table 1) and the presence of a histologically proven acute rejection and its treatment were noted (methyl-prednisone pulses, antilymphocyte antibodies). Postoperative death was defined as death occurring during the first 3 mo post-LT. Causes of death (deaths due to HCC recurrence and other late causes of deaths), HCC recurrence, length of follow-up from listing on the waiting list to transplantation and from transplantation to death, HCC recurrence or the most recent information, were determined. Data on immunosuppression and adjuvant postoperative treatment of HCC were also collected. As previously described, patients were screened for tumor recurrence by AFP assay and thoracic and abdominal CT every 3 mo for the first two years and/or when clinically indicated. Additional imaging techniques (bone scan, MRI) were used if necessary.

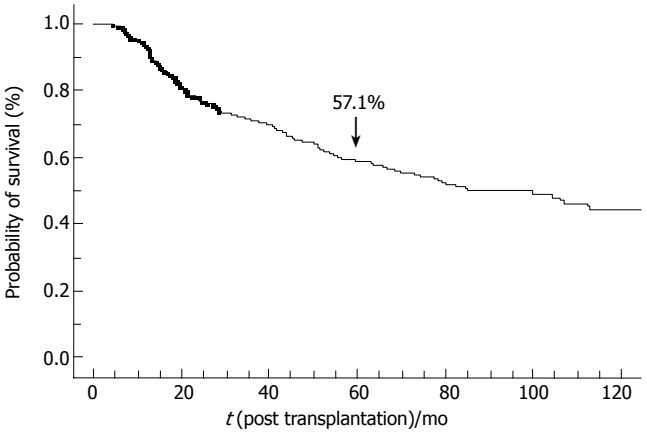

**Figure 2** Overall 5-year disease-free survivals.

### *Statistical analysis*

The proportion of missed data ranged from 0.0% to 14.6%, from one variable to another. In the case of missing data, no extrapolation of the missed values was done for the purpose of statistical analysis. Baseline patient characteristics and other continuous variables were reported as means ± SD or median and range when appropriate. Distributions of categorical variables are expressed as percentages. The Kaplan-Meier method was used to evaluate the probability of survival. Kaplan Meier estimates were calculated for 24 variables with potential prognostic significance and compared by the Logrank test. Factors associated with tumor-free survival at a P level of 0.1 in univariate analysis were entered in a multivariate analysis, using a Cox proportional hazards model to identify independent predictors of recurrence.

## RESULTS

The median waiting time from evaluation to LT was 3.3 mo (range: 0.1-32.3 mo). Median post-operative follow-up period was 52.0 mo (range: 3.2-186.3 mo). Tumor recurrence occurred in 131 cases (31.8%), after a median of 11.8 mo (1-125 mo). Recurrence involved a single site in 55.1% of the cases and multiple locations in 44.9% of the cases. Recurrence involved the liver graft, lungs, bones, brain, skin and other sites in 49.1%, 44.9%, 34.7%, 6.7%, 5.9% and 14.4% of the cases, respectively. The median time from recurrence to death was 5.6 mo (0.2-62.7 mo). One hundred and ninety-seven patients died (47.8%) during follow-up beyond the postoperative phase. Causes of death were HCC recurrence in 121 cases (61.4%), infections in 14 cases (7.1%), cardiovascular events in 11 cases (5.6%), recurrence of underlying liver disease in 8 cases (4.1%), and *de novo* cancers in 9 cases (4.5%). By the end of follow-up, only 10 patients with recurrence were alive.

Overall 5-year tumor-free survival was 57.1% (Figure 2). Five-year overall survival was 57.9% ± 2.5% since the vast majority of patients with recurrence died within 6 mo following recurrence. When restricted to the 330 patients transplanted after 1991, 5-year overall survival was 65%

± 2.7%. However, if the database was restricted to these 330 patients, statistical analysis of factors associated with recurrence-free survival did not change.

Among the 24 variables that were tested, 16 variables were associated with tumor-free survival by univariate analysis (Table 2): (1) period of LT (< 1991, 1991 to 1993, 1994 to 1996 and >1996; $P < 0.0001$). (2) pre-operatively: presence of cirrhosis ($P = 0.001$), etiology of liver disease ($P = 0.03$), α fetoprotein level (< 200, 200 to 2000 or > 2000; $P < 0.0001$), G-GT activity (N, N to 2N or > 2N; $P = 0.02$), the number of nodules (1, 2-3 or ⩾ 4; $P = 0.02$), maximal diameter of the largest nodule (< 3 cm, 3 to 5 cm or > 5 cm; $P < 0.0001$), the sum of the diameter of the nodules (< 3 cm, 3 to 5 cm, 5 to 10 cm or > 10 cm; $P < 0.0001$), bi-lobar location ($P = 0.01$), preoperative portal or hepatic vein obstruction ($P < 0.0001$), use of a peri-operative adjuvant treatment ($P = 0.002$), use of pre-operative transarterial chemoembolization ($P = 0.03$), (3) pathological data: tumor differentiation (well, moderate or poorly; $P = 0.01$), (4) post-operatively: the initial type of calcineurin inhibitor (cyclosporine A *vs* tacrolimus, $P = 0.003$), the use of antilymphocyte antibodies (mono- and polyclonal) ($P = 0.02$) and rejection episodes requiring steroid pulses ($P = 0.003$). It is noteworthy that calcineurin tacrolimus was more recently used in recent cases and that ATG-OKT3 was not routinely used recently.

**Table 3 Factors associated with recurrence-free survival (Multivariate analysis)**

| | Relative risk | 95% CI | *P* |
|---|---|---|---|
| Use of anti-lymphocyte antibodies | 1.8 | 1.2-2.6 | 0.005 |
| Tumor differentiation | 1.6 | 1.24-2.06 | 0.0006 |
| Maximum diameter of the largest nodule | 1.12 | 1.08-1.17 | < 0.0001 |
| Portal/hepatic vein obstruction | 1.6 | 1.01-2.72 | 0.06 |
| Number of nodules | 1.13 | 1-1.28 | 0.06 |
| Recent period of transplantation | 0.66 | 0.54-0.82 | 0.0001 |

By multivariate analysis (Table 3), 6 variables were independently associated with HCC recurrence: maximal diameter of the largest nodule ($P < 0.0001$; RR = 1.12), period of LT ($P < 0.0001$; RR = 0.66), tumor differentiation ($P < 0.0001$; RR = 1.6), the use of anti-lymphocyte antibody (ATG) or anti-CD3 antibody(OKT3) ($P = 0.005$; RR = 1.8), preoperative portal or hepatic vein thrombosis ($P = 0.06$; RR = 1.65) and the number of nodules ($P = 0.06$; RR = 1.13). Figure 3 shows the influence of the use of anti-lymphocyte antibodies, tumor size and number of nodules on tumor-free survival.

## DISCUSSION

This multicenter retrospective study reports one of the largest numbers of patients transplanted for HCC. In this work, we chose to focus on data that could be assessed preoperatively or monitored postoperatively, because such parameters are the only one of clinical relevance in predicting recurrence. On this basis, first, we show that the immunosuppressive regimen, through the use of anti-lymphocyte antibodies, have an independent negative impact on HCC recurrence. Secondly, we confirm that tumor differentiation, a feature that could be assessed preoperatively, has an independent prognostic value. Thirdly, we show that, among the more recently proposed prognostic factors, bi-lobar distribution of the tumor and

the sum of diameter of the tumors are not independent predictors or recurrence. Lastly, we obviously re-identify the prognostic value of the number and size of the nodules as well as that of tumorous macrovascular invasion.

The negative impact of anti-lymphocyte antibodies on tumor recurrence has not been reported previously. A negative role of immunosuppression on recurrence had been suggested by Pittsburgh's group by comparing the doubling time of tumor recurrence after LT or surgical resection[26]. This negative effect was also suggested in a model of tumor recurrence in immunosuppressed, liver transplanted rats[27] and in a model of liver tumor in cyclosporine A-treated rats[28]. More recently it has also been proposed in a clinical study that tumor recurrence could be favored by the intensity of immunosuppression[21]. In this study, the risk of recurrence was proportional to cyclosporine A blood levels. Anti-lymphocyte antibodies are currently the most powerful immunosuppressive agents and could further impair the anti-tumoral mechanisms required to control tumor cell spreading after LT for HCC. This was suggested by the faster recurrence observed during the first 2 years postoperatively in anti-lymphocyte antibodies-treated patients (Figure 3). Caution is therefore mandatory in using anti-lymphocyte antibodies after LT for HCC. This finding also suggests that the clinical studies carried out in the early 1990s, when the criteria for transplantation of hepatocellular carcinoma were introduced, may have been influenced by the immunosuppressive regimens adopted at that time. Since the current trend is to use less powerful immunosuppressive regimens than a decade ago, it raises the possibility that the impact of the current selection criteria on recurrence, based on tumor staging, might have changed over time and should be re-evaluated on a prospective basis[21].

In our study, tumor differentiation had a strong independent value in predicting recurrence: the poorer the differentiation, the higher (Table 3) and faster (Figure 3) the recurrence. This result is in agreement with the results of 3 other groups[15-17,19], which have found an association between tumor differentiation and the risk of recurrence. The negative impact of dedifferentiation could be explained by the relationship between poorly differentiated tumor cells and microvascular invasion, especially in large tumors[17]. In the present study, tumor differentiation was assessed on the explanted liver in order to make use of a larger set of data since the result of preoperative tumor biopsies were available in only 79 cases, and concerned mainly with well-differentiated tumors. These results suggest, however, that grading tumor differentiation could be useful in improving the selection of liver transplant candidates for HCC, provided there is a relationship between tumor grading on preoperative needle biopsy and postoperative grading on the explanted liver. This could be particularly important in the case of large tumors, exceeding 5 cm[17], for which an expansion of the classical criteria of LT has been recently proposed[19]. The presence of poorly differentiated tumor cells in preoperative biopsy samples would argue against LT in such patients, but LT could be considered in a group of patients suffering from

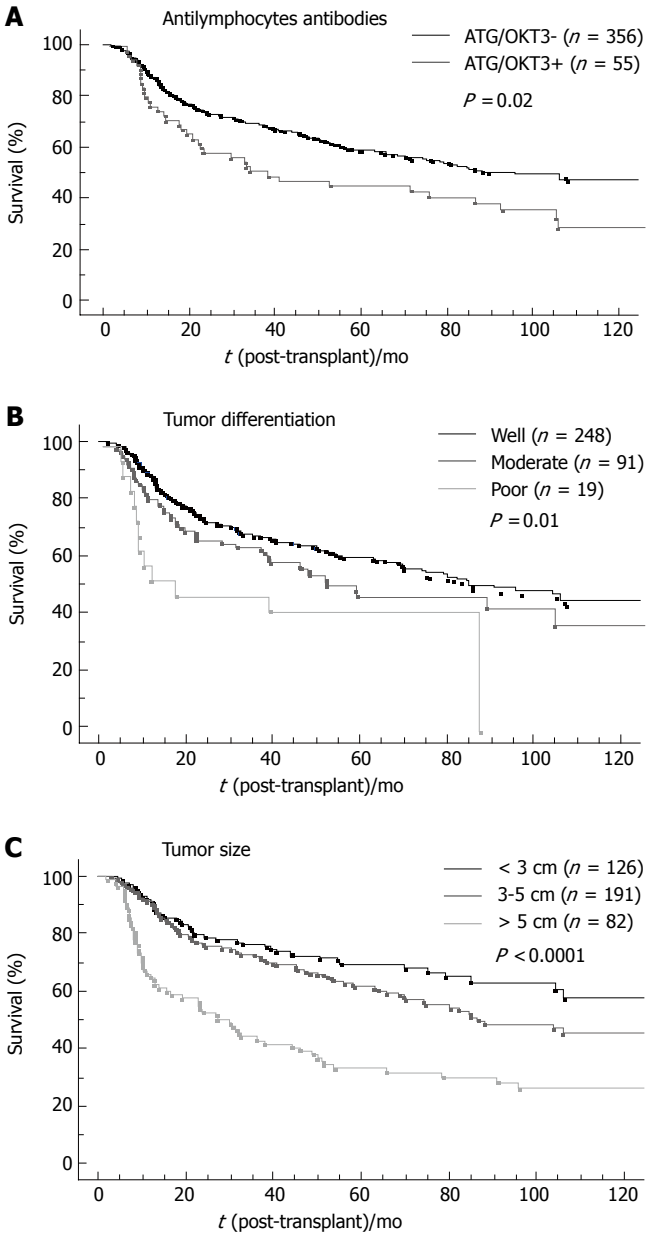

**Figure 3** Influence of immunosuppession (**A**), tumor differentiation (**B**) and size (**C**) on tumor-recurrence free survival.

well-differentiated tumors. Such an approach is supported by the results of a recent Italian study[29] reporting a 6% rate of recurrence after LT for HCC in patients selected on the basis of a preoperative tumor biopsy showing no poorly differentiated cells and including 38% patients who did not meet the Milan Criteria. Such a strategy would mean a change of current protocols, because pre-transplantation biopsies are generally not obtained as a result of the lack of an obvious benefit and the occasional report of needle-tract seeding[30,31].

The number and size of HCC have been identified a decade ago as 2 major predictors of recurrence. Based on this finding, Mazzafero *et al*[13] proposed to restrict LT indications to patients with a single nodule < 5 cm in diameter or with < 3 nodules with a maximum diameter of 3 cm to minimize post-LT recurrence. More recently, bi-lobar distribution of the tumor and the sum of diameter of the tumors, 2 factors that take into account

size and number, have been proposed as predictors of recurrence[14,18,19]. In the present series, we found that these two last factors had no independent predictive value. With respect to this point, we must point out that in our multivariate analysis, the number of tumors was the factor that had the lowest power in predicting recurrence with a *P* value at 0.06; the lack of independent value of bi-lobar distribution, which can be considered a peculiar form of multifocal HCC, is therefore not unexpected. In addition, our results indicate that the size of the largest nodule is more closely related with recurrence than the sum of diameters of all tumors, suggesting that the sum of diameters of the nodules is mainly determined by the size of the largest nodule in a majority of cases. According to the poor recurrence-free survival of patients with a maximal diameter of the largest nodule exceeding 5 cm, we actually consider that liver transplantation should be avoided in such cases.

Finally, we found that a recent period of LT was independently associated with tumor-free survival. This suggests that other factors than those identified in the present study that may have varied over time, such as maintenance immunosuppression levels[21], or improvements in surgical techniques, limiting the peri-operative risk of tumor cell spreading, might also influence recurrence.

In conclusion, we have identified the use of anti-lymphocyte antibodies as a new predictive factor of tumor recurrence after LT for HCC. We also confirmed the independent prognostic value of tumor differentiation and did not confirm the independent prognostic value of either bi-lobar distribution of the tumor or the sum of diameters of the tumors. Based on these results we propose to avoid the use of anti-lymphocyte antibodies after transplantation for HCC, a finding that also raises the issue of a change in the impact of tumor staging over time on recurrence, due to parallel changes in immunosuppression policies. We also propose to test prospectively the usefulness of a pre-transplant tumor biopsy in order to evaluate the importance of tumor differentiation in the decision-making algorithm of candidates for transplantation in HCC.

## Abstract

**AIM:** To evaluate the clinical and endoscopic patterns in a large series of patients with metastatic tumors in the stomach.
